There is no explicit communication between cores and the host, although the host can "preview" the data at any time. In addition, cores do not exchange data in any other way than using the external memory, as previously mentioned.

The role of the host is only limited to initializing the population, copying data to the external memory and, after all iterations, copying the final population and fitness values back.

D. Implementation solutions used in test programs

In order to improve the efficiency of the implementation, we have implemented and tested technical optimizations such as removing the need for reloading the Epiphany code and using better communication facilities.

1) Removing need for reset–load before each computation: By default Epiphany does not provide a simple way to "restart" the same computation as before. The programmer needs to reset a device group and load the device code again when needed. Although such an approach generally works, it could have a noticeable impact on performance. We have measured the reload time and presented the results in Section IV.

The solution to this issue is to make the computation execute in an infinite loop and signal new data available for processing by using the same interrupt that is used for starting the computation (`E_SYNC`). At the beginning of the computation we register and enable an empty handler for this interrupt. Then, when waiting, we execute `idle` opcode in a loop effectively putting the core to sleep. When it receives the interrupt, it wakes up and retests the loop condition which can be, for example, checking for new data. The waiting loop is shown in the Listing 2.

```
while (1) {
  // Perform computation
  while (/* Test status/flag */){
    // Go into idle mode
    __asm__ __volatile__ ("idle");
  }
}
```

Listing 2. Waiting loop

On the host side we simply execute `e_start_group` on the whole workgroup each time we want to signal new data. Internally, it sends the correct interrupt.

2) Communication: In most cases there is no need for communication between cores, as data can be cleanly split among them. On the other hand, communication with the host is performed at least two times for every step of the computation (for versions executing on Epiphany only partially). Epiphany does not provide any way to synchronize its cores with the external host.

We solved this issue by using a simple status variable that eCores use to share their statuses with the host and the host signals that there is new work to do. We store statuses in a 16-element array of `uint8_t` (8-bit unsigned integer) elements. This gives us enough flexibility to use multiple different statuses and is still small enough not to waste the memory.

To wait for a specific status on the host side we make a tight loop for reading the whole array and check all values after every read.

On the Epiphany side if the core needs to wait for a particular status, it is done by a simple `while` loop checking a dedicated array index.

3) DMA: We have also decided to test the difference the DMA engine makes to memory operations. Epiphany offers two DMA channels per core. They can be used in a linear (copying continuous blocks of memory) or non-linear (copying regularly spread fragments of memory) fashion. In most cases we used the former method, but for the porting of the whole algorithm, we used the latter. This allowed us to efficiently shuffle populations without involving cores.

TABLE I
MEASURED MEMORY BANDWIDTH ON PARALLELLA.

Initiator	Target	Type	Bandwidth (MB/s)
ARM Host	eCore (0,0)	write	45.82
ARM Host	eCore (0,0)	read	5.20
ARM Host	DRAM	write	88.25
ARM Host	DRAM	read	131.96
ARM Host	DRAM	memcpy	353.01
eCore (0,0)	eCore (1,0)	write (DMA)	1242.38
eCore (0,0)	eCore (1,0)	read (DMA)	401.46
eCore (0,0)	DRAM	write (DMA)	233.94
eCore (0,0)	DRAM	read (DMA)	87.45
eCore (0,0)	eCore (1,0)	write	534.37
eCore (0,0)	eCore (1,0)	read	115.70
eCore (0,0)	DRAM	write	71.61
eCore (0,0)	DRAM	read	4.29

IV. RESULTS

Our tests focused mainly on execution time and memory performance. We performed two micro-benchmarks in order to determine:

- memory bandwidths,
- Epiphany initialization penalty.

Then, we measured times related to the execution of the test case presented in the previous section.

A. Microbenchmarks

1) Memory bandwidth: The memory bandwidth results shown in Table I were obtained using a micro-benchmark provided with the Parallella SDK. It is easily observable that writes involving the Epiphany processor perform significantly (several times) better than corresponding reads. This is related to the way the reads are executed (see Section II) – they consist of two transactions. The DMA engine also provides a large speed boost.

Moreover, these operations are significantly slower than the theoretical limits which would be 1.6 GB/s [15] for the bidirectional off-chip traffic and 8 GB/s for on-chip DMA [16]. However, for the former the cMesh implementation limits it to around 4.8 GB/s. There are also two errata items reporting issues with DMA engine limiting its bandwidth to around 25% of this value.

These speeds and significant differences to the theoretical values are similar to other results [17].

2) Loading the code on Epiphany: To load and start the code on the Epiphany processor we need to call the following functions:

1) `e_reset_group`
2) `e_load_group`
3) `e_start_group` (this can be implicitly called by previous function).

There is no means provided to "restart" the same code on Epiphany and it is necessary to handle it manually using interrupts (see Section III). Thus, we decided to perform a microbenchmark measuring the time it takes to execute a full reload operation on all 16 cores.

The results are as follows: for the code and data filling the whole 32 kB of core memory: 314.613 ms. For the

minimal example (writing a single integer to the well-known memory buffer): 117.620 ms. These values are not high, but considering possible multiple iterations of the algorithm they can accumulate to significant delays.

B. Genetic algorithm

We implemented several different optimization scenarios and measured execution times for each of them. These scenarios were:

- naive — no Epiphany-specific optimizations: we put the data in the external (DRAM) memory and restarted Epiphany in each iteration, cores use data directly from DRAM,
- no reload — as above but without code reloading and Epiphany restart (see Section III-D1),
- local — as "naive" but each core copied fragments of data to local memory before processing,
- no reload, local — as "no reload" but each core copies fragments of data to the local memory before processing (using standard `memcpy`),
- no reload, local, dma — as "no reload, local" but cores used DMA engine to perform copying of data,
- no reload, push — as "no reload" but the host (ARM) pushed data directly to the local memory of each core; it is the host's responsibility to split the data into sizes fitting the local Epiphany memory.

Additionally, we executed the basic one-thread computation on the Parallella's ARM CPU as a reference for other measurements.

For every scenario we executed 100 (one hundred) iterations over various selected population sizes: 16, 32, 128, 256, 1024, 2048, 8192, 10240, 51200. These numbers needed to be divisible by 16, as each core should have the same population to work on. The results for 51200 are presented in Table II.

Our time measurements included three, increasing in size, portions of the code:

- code execution on the Epiphany coprocessor in a single iteration and the same code on the host (in the CPU version),
- a single iteration — both ARM host and Epiphany code including code upload in some of the above scenarios but without the generation of a new population,
- a whole algorithm — from the Epiphany initialization to closing the device.

For measuring the execution time we used the `clock_gettime()` function with the `CLOCK_MONOTONIC` clock.

We tested the three scenarios described in Section III: fitness offloading, population evaluation and a whole algorithm. For the whole algorithm we measured only the full computation time, as the measurement of a single iteration would not be efficient or useful.

It is worth noting that in the largest measured population (51200 organisms) each Epiphany core has only 3200 organisms to evaluate.

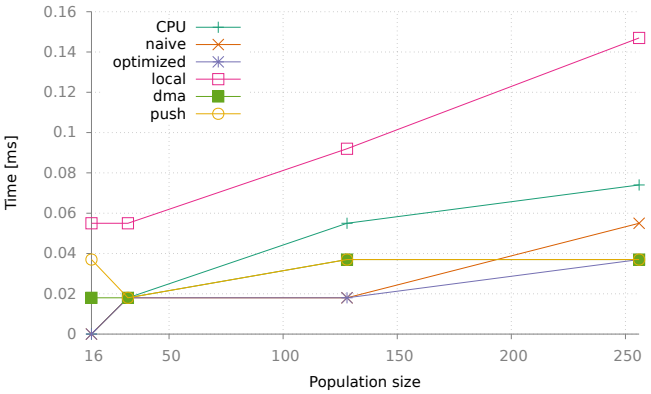

Fig. 3. Time of a single iteration execution of the "fitness offloading" version on the Epiphany processor for population sizes 16, 32, 128, 256.

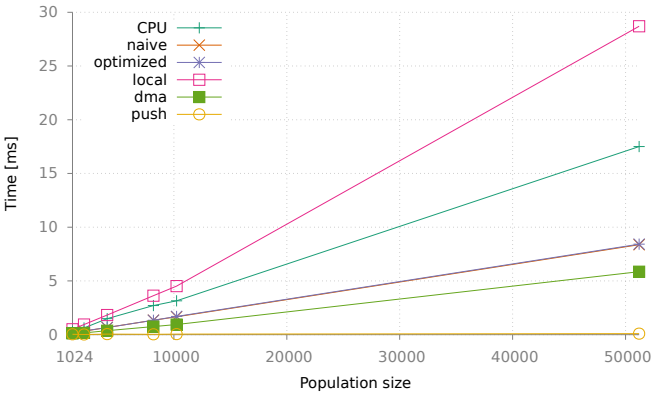

Fig. 4. Time of a single iteration execution of the "fitness offloading" version on the Epiphany processor for population sizes 1024, 2048, 8192, 10240, 51200.

Figures 3 and 4 show times for the Epiphany-offloaded code and the equivalent code on the CPU. Firstly, we can observe, that the "push" version performs the best. This is a direct result of the fact that there are no external memory operations on the Epiphany side in this version. All memory handling is done on the host. Secondly, the "local" version that uses `memcpy` performs more than two times worse than the CPU version. This is caused by very slow (around 4.3 MB/s, as shown in Table I) read rates for non-DMA copies between cores and DRAM. After changing the copy method to DMA the measured time was significantly reduced, performing even better than no-copy versions ("naive" and "no reload"). Finally, there are no significant differences between versions with and without code reloading so more complicated iteration logic on the Epiphany side has no penalties (as expected).

For smaller population sizes some of these observations differ (DMA and "push" versions are slower), but this is due to the initialization of these memory access paths [16].

Figures 5 and 6 show times for the whole iteration – host and device sides – without generation of the new population. They do not include lines for the "naive" version for readability.

TABLE II
MEASURED EXECUTION TIMES FOR 51200 ORGANISMS.

Version	Version	Epiphany [ms]	Iteration [ms]	Full [s]
CPU	—	13.769	16.533	545.53
fitness offloading	none	8.368	223.764	546.83
	no reload	8.423	22.303	546.24
	no reload, local	28.699	42.559	546.03
	no reload, local, dma	5.806	19.593	545.89
	local, dma	5.861	232.556	546.93
	no reload, push	0.276	51.702	546.11
full	none	8.645	215.802	546.68
	no reload	8.737	18.248	545.90
	no reload, local, dma	5.714	15.280	545.87
whole	local memory	—	—	2.42
	external memory	—	—	38.73

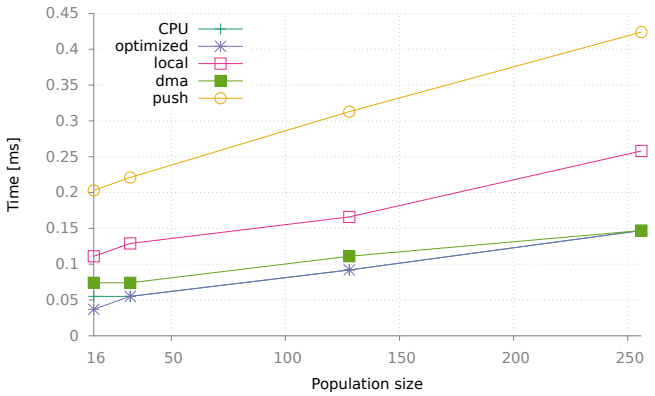

Fig. 5. Time of a single iteration execution of the "fitness offloading" version (Epiphany + host) for population sizes 16, 32, 128, 256. The "naive" version is not included due to the scale.

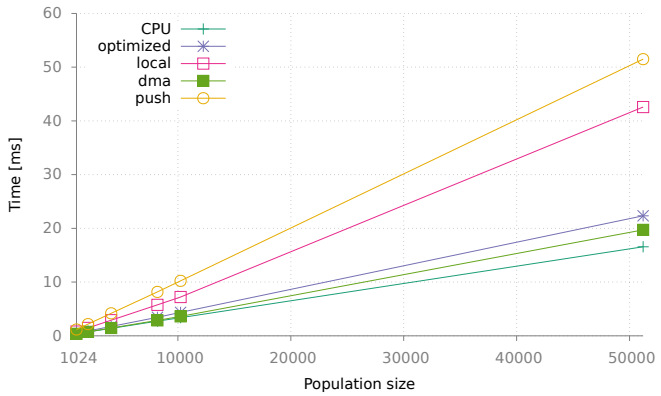

Fig. 6. Time of a single iteration execution of the "fitness offloading" version (Epiphany + host) for population sizes 1024, 2048, 8192, 10240, 51200. The "naive" version is not included due to the scale.

The first thing to observe is the very poor performance (as much as ten times worse) of the versions that reset the Epiphany during the iteration. As we noted in Section IV-A2, such an operation takes at least 110 ms (for the smallest possible binary).

In these results, we see that the "push" version performs poorly. This is due to the fact, that all of the memory operations are executed on the host side and, firstly, host-to-core transfers are slower (as seen in Table I), secondly, the host needs to perform sixteen separate copies instead of one to the external memory. The CPU version has the best performance, but it is important to note, that there are no additional memory copies in this version. In all Epiphany implementations we need to perform at least one additional copy of the population per iteration.

We also measured the execution time of the whole program (for a smaller number of iterations), however, as the most time-consuming task for large populations is the generation of the new population, the results are similar in each implementation.

The "full evaluation" version, which also included finding the best organism on Epiphany, did not make any significant difference to the previous one. We can observe, that iteration times are several milliseconds shorter than the corresponding "offload" version. This follows from the fact, that we split the lookup on all cores.

The final version we tested — the whole algorithm ported to Epiphany — was implemented in two versions: one which copied the data to the local memory of cores (using DMA), and another which operated fully on the external memory.

The latter performed nearly 15 times better than the single CPU version, which is very good considering the memory bandwidths shown in the Table I. However, the former, using the local memory, presented the best computation time: below 3 s.

C. Memory limits of Parallella

As mentioned in Section II, the Epiphany cores in Parallella board can address only 32 kB of the internal and 32 MB of the external memory. These limits have significant impact on the size of program and data size.

This 32 kB of internal memory is divided in four banks, of which only two are usable for the user data without limitations, because the first one contains the code and the last one – the stack (starting at the end of the block). It is safe to assume that, for user data, 16 kB is fully available on each core, plus the remaining memory from the fourth bank. We have limited the local memory used in test scenarios to these sizes. As we use 24 bytes for a single organism, we can store a maximum

of 1024 organisms (if we ignore the stack). However, in cases where we do not need to remember the population between iterations we can safely reuse the same memory for delivering results to the host, giving us 1536 organisms for a single core.

As previously mentioned, one has to consider the stack, so the final numbers have to be smaller and the real code size must be taken into account.

D. Observed issues

During development we observed several issues with the board and SDK.

First, the board has a tendency to overheat. When the temperature measured by sensors reached 65°C we observed unstable behavior: missing writes (the host did not see updates from Epiphany) and hangups. To counteract these issues we kept the board cooled to around 50°C.

Second, the default linker configuration places standard C library and math functions in the external memory (DRAM). For example, we tested the code with the two-dimensional Ackley test function:

$$f(x,y) = -20\exp\left(-0.2\sqrt{0.5\left(x^2+y^2\right)}\right) - \exp\left(0.5\left(\cos\left(2\pi x\right)+\cos\left(2\pi y\right)\right)\right) + e + 20$$

In this case, the Epiphany version was several times slower than the plain CPU implementation. This is due to the execution of the math functions from the external memory. One of the solutions for this issue is to change linker configuration to place them in the local memory of the Epiphany.

V. Conclusions and future work

Our main concern in this paper was to review the Parallella board in order to follow later with more advanced plans touching on simulations and multi-agent systems. We have reviewed the board internals and its programming model. We then performed some microbenchmarks and tested a genetic algorithm in various versions from a naive implementation to more advanced optimizations.

Our benchmark results show that the Parallella can be fast and offers quite large benefits, but these are destroyed by slow memory transfers and the large number of manual optimizations required to get to them. Comparing only the results for a single-core CPU version and Epiphany "push" versions (as described in Section IV) we can notice that actual computation is nearly 50 times faster on Parallella. However, the work required for memory copying between the device and the host causes the Epiphany version to perform worse in a single iteration than the single-core ARM one. To gain really better results, we need to port the whole algorithm to the Epiphany in order to avoid Epiphany–ARM memory copying. However, porting the code, especially with a very small local memory, requires significant work.

Nevertheless, in the case of offloading only the most costly part of algorithms (for example, fitness computation), the local copying by Epiphany cores using the DMA engine has the best performance among all implementations and would be recommended for simple scenarios.

It is clear from our and others' results that Parallella is not mature enough to replace more advanced and well-established manycore platforms. However, it is an interesting board that can be used to accelerate parallel workloads in a very simple and cheap way. There is nearly no effort required to port programs written in C to the Epiphany compiler in a naive way. Optimization of such programs requires more work, but it is still simple considering the relatively poor feature set of the Software Development Kit and the processor.

Our next steps regarding Parallella will focus on the usage of multiple boards in a single cluster and Java–Epiphany interaction. We see possibilities for deploying island and agent-based models of evolutionary algorithms [4] on such clusters, as they usually can be organized in a way that requires little communication between islands. Separate populations could be computed on different boards with rare synchronization events between them.

The last model, namely Evolutionary Multi-Agent Systems (EMAS) [18], [19], which uses the agent paradigm for decentralizing the process of evolution, is of special interest to us, since it allows achieving a fine-grained parallelism with its implementation of agents [7]. This opens the way for another possible approach, even without using multiple boards – the implementation of multi-agent systems with lightweight agents (or groups of agents) executing on separate cores [20]. The MIMD nature of the Epiphany processor should be a matching architecture for these systems.

Acknowledgment

The research reported in the paper was supported by the grant "Hybrid model of the early detection of internal diseases based on the paradigm of interacting particles and multi-agent system" (No. DEC-2013/09/N/ST6/01011) from the Polish National Science Centre.

***Abstract*—Unlike the network TCP/IP's and OSI's layered structure of protocols, which allows the independence of protocols of different layers, as well as defining the upper layer protocols through the protocols of the lower layers, the cloud service layers are tightly dependent on each other. For example, an application of the SaaS layer can neither communicate nor exchange data with another application found on the same layer. The goal of this paper is to overview the cloud interoperability and to analyze it as a service model perspective. Several aspects and categories of cloud interoperability are analyzed in this paper.**

***Index Terms*—Migration, interoperability, portability.**

I. Introduction

ADOPTION of cloud rests largely on interoperability and standardization as they define the new age IT industry [1].

The main stakeholders (cloud providers and clients) have opposite motivations for cloud interoperability. The providers prefer vendor lock-in situations to keep the clients and ensure higher profits enabling more and more cloud features. On contrary, the clients would like freedom, and the ability to choose the provider that offers the highest quality of services they want. Therefore, the need for cloud interoperability is more initiated by the clients than the providers.

Cloud interoperability is closely linked with cloud portability [2]. Whenever one analyzes the process of porting data and applications from one cloud provider to another, then the cloud interoperability is the essential problem to be solved. An easy way to port data, application and platform is through transferring an image of the virtual machine (VM) between the providers that use the same cloud environment.

There are a lot of surveys about ongoing initiatives that address the cloud computing interoperability. Petcu [3] discusses the classical problem of too many different approaches by various vendors in the way they realize the interface to the cloud and offer cloud features.

The interoperability problems in cloud computing arise when the clients are trying to exchange data, applications and services between different cloud providers. The identified problems can be classified into the following categories: a) system, initiated by incompatible implementations of cloud virtualization; b) applications, including incompatible application programs and code, c) service, defined by the ability to use various services hosted on different clouds; d) data, initiated by different standards of data presentation. Data interoperability is mainly addressed by other computing areas, whereas, the cloud interoperability addresses mainly the system, application and service interoperability.

This paper observes the cloud interoperability on IaaS, PaaS and SaaS levels analyzing its context from the management, platform or application levels. An approach is introduced to analyze the cloud interoperability *as a service model*.

II. Background

The concept of *interoperability* is not a new one. In the fields of information technology or systems engineering, it has been defined as the ability of two or more heterogeneous elements to not only exchange, but also use the exchanged information (interoperate). However, in the field of Cloud computing, the concept of interoperability is rather new and has recently been an active field of research. In this section we will define and explain all related concepts.

The interoperability can not be uniformly defined - there are very many different definitions which vary in technological aspects, and development frameworks, which can be more general or address only some standard details. Generally, the definition of *interoperability* depends on the context of its application.

IEEE describes the interoperability as a system or product feature to work with other systems or products without additional intervention of the client [4]. According to NIST [5], the cloud interoperability allows seamless exchange and use of data and services among various cloud infrastructure offerings and to use the data and services exchanged to enable them to operate effectively together.

Interoperability can be regarded as the ongoing process of ensuring that the systems, procedures and culture of an organization are managed in such a way as to maximize opportunities for exchange and reuse of information. It includes many areas with its characteristics [6]:

- *Technical interoperability* - development of standards of communication, transport and representation
- *Semantic interoperability* - the use of various different terms to describe similar concepts may cause problems in communication, execution of programmes and data transfers.
- *Political/Human interoperability* - the decision to make resources widely available has implications for organizations, their employees and end-users

978-83-60810-90-3/$25.00

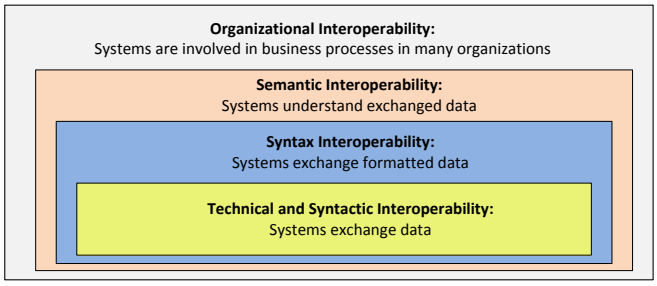

Fig. 1. Interoperability types and their correlation

- *Interoperability of communities or societies* - there is an increasing need to require access to information from a wide range of sources and communities.
- *International interoperability* - in international matters, there are variations in standard, communication problems, language barriers, differences in communication styles, and a lack of common basis.

In most known interoperability frameworks, this term is considered in three levels [7], as follows:

- *Technical interoperability* which includes standards and protocols. This aspect of interoperability covers the technical issues of linking computer systems and services.It includes key aspects such as open interfaces, interconnection services, data integration and middleware, data presentation and exchange, accessibility and security services [8]. Technical interoperability is usually associated with hardware/software components, systems and platforms that enable machine-to-machine communication to take place. This kind of interoperability is often centred on (communication) protocols and the infrastructure needed for those protocols to operate [9].
- *Syntax interoperability* is usually associated with data formats when they are exchanged among systems. Certainly, the messages transferred by communication protocols need to have a well-defined syntax and encoding, even if it is only in the form of bit-tables [9].
- *Semantic interoperability* is concerned with ensuring that the precise meaning of exchanged information is understandable by any other application that was not initially developed for this purpose. Semantic interoperability enables systems to combine received information with other information resources and to process it in a meaningful manner. Semantic interoperability is therefore a prerequisite for the front-end multilingual delivery of services to the client [8].

Additionally, *organizational interoperability* is also discussed, which allows systems to be involved in business processes of multiple organizations [8].

An overview of all interoperability types is given in Fig. 1. The application of interoperability in any domain is usually realized by defining and applying standards. Generally, the goal of interoperability and the standards is the same - to allow exchange and cooperation of computer services. Standards define protocol by which all service suppliers that implement the standards offer structured data and information exchange no matter the inner architectural design or implementation is used for the service.

III. Cloud interoperability

Interoperability in cloud can be considered and defined as a service model, and therefore, we will discuss interoperability of applications, platforms, and management.

Cloud application interoperability addresses the application components, whether they are deployed as IaaS, PaaS, or SaaS. An application component may be a complete monolithic application, or a service as a part of a distributed application. These components invoke respective platforms that implement various communications protocols and data presentation standards; and therefore, can not be used without cloud platform interoperability.

Cloud platform interoperability concerns the platform components, usually deployed as PaaS or IaaS. Information exchange and service discovery requires standard protocols to realize interoperable platforms.

Cloud management interoperability targets the management aspects between various cloud services deployed on SaaS, PaaS, or IaaS levels. Each provider realizes different cloud features and interfaces to manage them, so the clients would prefer to have a unique approach and generic off-the-shelf system management, offered via standard interfaces.

A. IaaS level interoperability

Interoperability on the IaaS level of cloud management implies simple and standardized management of infrastructures of different cloud systems. The management includes instantiating and control of virtual machines, enabling and discovering network characteristics, setting and editing security rules, etc.

This type of interoperability is the best defined when compared to other types. Fig. 2 shows a taxonomy of its basic concepts [10], [11], [12]:

- *Access Mechanism* - defines how a service in cloud may be accessed by users and/or software developers,
- *Virtual Resources* - service delivery as a complete software stack of installing a virtual machine,
- *Network* - addressing and API,
- *Storage* - management and organization of storage,
- *Security* - authentication, authorization, user accounts and encryption,
- *Service-Level Agreement* - architecture format, monitoring, and
- *Other*.

B. PaaS level interoperability

Interoperability on the PaaS level implies simple exchange of data and services among different platforms hosted on different infrastructures on cloud, and their effective reuse without extra effort on part of the user.

When analyzing the data exchange, one can consider data compatibility among different platforms, such as if numbers

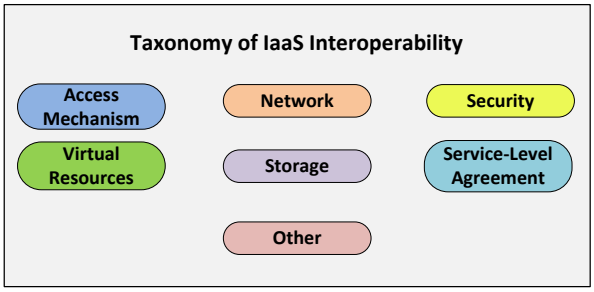

Fig. 2. Taxonomy of IaaS interoperability [10]

are to be transferred, then Little or Big Endian mode should be preserved, or a special function enabled to realize an easy transformation between the formats prior to transfer.

Analysis of the interoperability of services to be hosted in different cloud platforms rises the question of portability. For example, to transfer a service from one cloud to another that uses a different platform, initiates a lot of portability problems. If the origin and target clouds use the same environment, then a simple packing and copying procedure can be used to realize the porting process.

In case of different platforms on the origin and target clouds, one has to start a different transfer procedure that consists of packing, copying, instantiating, installing, deployment and customization to enable an interoperability. Still, there are open issues that address the way services interact with others, if there are additional cloud services invoked by the origin cloud that are not supported by the target cloud, or any dependence on a specific operating system hosted in the origin cloud.

C. SaaS level interoperability

Interoperability on the SaaS level of cloud applications implies simple exchange of data and services among different applications hosted on different platforms and infrastructures on cloud, and their effective reuse without extra effort on part of the user. Additionally, this type of interoperability can be considered from different application domains.

Interoperability on the level of applications is first defined by Kumar et al. [13] in 2010. According to their definition, interoperability can be considered in four categories (Fig. 3):

- Interoperability among applications in the same cloud,
- Data exchange and operation calls in applications on different cloud-computing environments
- Software programs that are distributed in different cloud environments and integrate data and applications in cloud in a unified way, and
- Migration of applications from one cloud environment to another.

When a client switches between two cloud providers on the SaaS level does not involve porting the applications and services, rather it involves exchange of structured data.

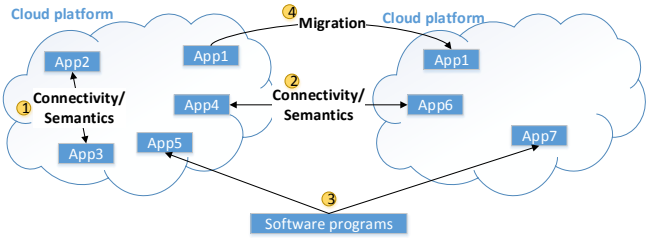

Fig. 3. Interoperability types in cloud applications [13]

TABLE I
DEVELOPMENT STATUS OF EACH ASPECT OF INTEROPERABILITY OF CLOUD COMPUTING

Context	Layer	Developing standards
Management	IaaS	OCCI, CIMI, UCI
Platform	PaaS	Stub
Application	SaaS	mOSAIC

The cloud interoperability is probably the most significant to address the compatibility of exchanged data on the functional level, it means not just to transfer the structured data, but also all relations between them. So far, no interface has been developed to allow such an interoperability. The problem is mainly manifested on the definition on functional level of realization the interface to the application.

Most of the research in the area of SaaS level, and even on the PaaS level is limited by the support of the vendors. Usually, the vendors prefer to lock-in the customer to its cloud and do not cooperate in the efforts to support the interoperability on this level.

IV. DISCUSSION

Table I presents the current development stage for each of the perspectives (i.e. categories), as well as, mapping of the use cases to the perspectives.

One can notice in Table I that certain aspects are more developed than other (i.e. interoperable management of virtual machines and application portability). We can also notice that the Platform context is least developed.

Large number of developing standards has arisen during the past few years:

- OCCI - The Open Cloud Computing Interface standard represents protocol and API for all kinds of IaaS management tasks [14]
- CIMI - Cloud Infrastructure Management Interface standard represents an interface for management of cloud services and the operations and attributes [15]
- UCI - Unified Cloud Interface concept aim to provide a unified interface for entire infrastructure stack using semantic technology [16]
- mOSAIC - The mOSAIC platform and engine enables deployment, configuration and management of applications using semantic technology [17]

- OVF - Open Virtualization Format standard provides open and platform-independent packaging format for software solutions based on virtual systems [18]
- CAMP - Cloud Application Management for Platforms aims to standardizing cloud PaaS management API [19]
- TOSCA - The Topology and Orchestration Specification for Cloud Applications aims to standardize application description in order to provide portability and management [20]. We introduced the extension - P-TOSCA, which handles several TOSCA weaknesses and ambiguities [21]. The demo applications for automated portability with P-TOSCA are developed for porting a SOA application [22] and an N-tier application [23].
- OData - The Open Data Protocol enables service creation to publish, share and edit resources via HTTP [24]
- CDMI - The Cloud Data Management Interface standard defines interface for creation, retrieval, update and deletion of data elements from the Cloud [25]

V. Conclusion

This paper gives an overview of the cloud interoperability on different service layers analyzed from cloud management, platform and application aspects *as a service* model. The cloud interoperability should be considered as cloud management on IaaS layer, exchange of data and services among different platforms (on PaaS layer) hosted on different infrastructures and exchange of structured data (on SaaS layer) among different applications deployed on platforms hosted on different infrastructures.

Although there are several standards and solutions on the data presentation level (data formats and communication protocols), still there are open issues on interoperability on systems and applications and there are no solutions when one wants to exchange structured data between providers. One can conclude that cloud interoperability on IaaS and PaaS levels has been addressed and several partial solutions exist, while the cloud interoperability on the SaaS level is still in an infant development.

***Abstract*—The massive amounts of data processed by information systems raise the importance of detailed database performance analysis. Column-oriented data stores are becoming increasingly popular in big data appliances. This paper identifies database performance factors on the basis of empirical studies on a custom implementation. To summarize the research, a simple performance mathematical model has been created.**

I. Introduction

THIS article is the result of experiments performed on a custom column-oriented database management system. Performance studies presented in this paper are a part of a broader research initiative about an optimization of columnar data store sharding with the use of a natural computing algorithms. The research has been overviewed in the previous FedCSIS conference paper. [1] Performance modeling and discovering what determines a single database's behaviour is considered as the first step towards creating a more sophisticated partitioned database model. Such a model will be a subject of optimization by metaheuristic algorithms. Columnar data store performance studies are considered important because non-relational data stores are gaining popularity and more and more applications. However, the goal of this research is not a comparative study of the column-oriented database model versus other data models, nor CODB custom implementation versus other columnar data stores. It aims to discover which factors determine performance and the relationships between these factors' impact. Absolute values are considered less important in this study since it is intended to be a foundation of the weights (importance) estimation of the specific factors.

The paper is structured as follows. Section II contains a general description of a column-oriented database model relatively to the relational model for the sake of better understanding, and the custom implementation of columnar data store is introduced. The next section III presents how the performance of a Java application (specifically a database) can be measured and expressed. The second half of the article comprises of sections IV, V and VI, which include assumptions and conclusions brought on the basis of the experiments' results.

Because the research and benchmarking is performed on a custom database management system, the article has relatively unique character. However, available literature offers examples of research initiatives driven by similar ideas, such as [2] or [3]. Since this is a short paper, it presents a general overview and the most important facts of the research.

II. Column-oriented DBMS

The column-oriented database model has been around for almost as many years as the most popular, row-oriented relational model by E.F. Codd [4]. One of the first concepts regarding column-oriented storage are transposed files databases from late 1970s [5].

After an initial rush, columnar databases remained in their own, narrow niche for more than 20 years, while the relational model dominated a majority of applications. Relational model's strength came from the strong mathematical foundation based on the set algebra and focus on the data consistency and reliability. Despite this, in the recent decade, alternative models have gained more interest in the commercial world with the rise of the non-relational database trend. Databases that focus on other aspects than traditional Relational Database Management Systems (RDBMS) started gaining more attention. This trend has been called the *not only SQL* or *NoSQL* and was one of the outcomes of a rise of interactive, especially social, web services within the *web 2.0* movement. [6] The most significant developments in the area of columnar data stores are the C-Store [2] [7] and MonetDB [7].

Viewed from some angles, it can be said the column-oriented model is essentially only a physical-tier modification of the relational model. [3] However, experiments prove that implementing adequate modifications to the row-oriented Database Management System (DBMS) storage tier is not enough to rival the columnar store in some applications [8]. Nevertheless, some column database management systems offer roughly the same interface as the relational ones, hiding all the internal differences [9]. Certainly, there are analogies between fundamental terms of both domains. Keyspace parallels a database from the RDBMS domain. Relational table (or

978-83-60810-90-3/$25.00

relation) is roughly the same as a column family in columnar stores. Correlation of values with the same key from different columns in columnar store leads to construction of a tuple, which is comparative to a record in the relational database.

Despite obvious analogies, there is a fundamental difference in the storage structure. In row-oriented stores there is a single data file for the whole table and data is stored in a tuple-by-tuple manner where tuples are stored column-by-column. Thanks to this, it is cheap to iterate over records and read all the values in order to construct a complete tuple. Moreover, it is cheap to write the whole record at once by just appending or replacing another entry. However, this architecture has significant disadvantages too. Firstly, the table schema is effectively immutable - changing the column set in a table requires rebuilding the whole data file and all of the indices. Secondly, iterating through values in a single column from all the records requires long jumps within a data file, which involves huge I/O overhead.

These issues are addressed by column-oriented architecture. In a classical approach with explicit record ID storage [7], each column is a sequence of id-value pairs stored in a separate file. Database schema is flexible, columns can be freely added or removed and if a given record does not have value in a given column, it does not take any space to record such an information. Iteration over every value in a column is simple, so that columnar stores are effective in terms of generating aggregations, summaries and other read-intensive applications [3] [9]. But this schema also has a significant drawback. It is expensive to collect all the distinctive elements of a record altogether. Such an operation requires searching of all the data types (columns).

Taking this into consideration, in a domain of columnar data stores, a concept of the record does not actually exists. At the lower tiers of the system, there is no such concept and a specific values in a *record* can be associated to others only by matching the row id. This is the most fundamental conceptual difference between the two models. The columnar model storage is organized around pieces of information of the same type, not of the same entity.

This paper relies solely on the CODB database management system. The implementation has been partially reviewed in [1]. Database logic is comprised of execution of a set of processes touching a physical storage tier. A given part of an algorithm is considered as a significant in terms of performance when its execution time or resource consumption depends on any external factor. For example, looking for a value in the value storage file depends on a number of currently stored values in the set, whereas appending new value in some cases does not, in case when it is performed at EOF (end of file - the very last possible offset in a file), given that the EOF can be obtained instantly from the filesystem. In order to decrease space waste and speedup operations, a concept of storage maps has been implemented. Storage maps are responsible for keeping track of free space chunks. When any operation needs to allocate a bit of space, it asks the storage map first, and jumps to EOF only if free space does not offer an adequate fragment. For the same reason, a key storage data file operates on value hashes instead of actual values. Hashing overhead is orders of magnitude lesser than the potential overhead caused by moving around bigger pieces of data.

III. Performance analysis

A very important aspect of a performance measurement is an overhead. In conformity with common sense and intuition, it must be predictable and have a minimal possible impact on the measurement's result.

Another critical concern, when it comes to software performance measurement, is concurrency and parallelism. In a classical, single-threaded sequential program execution, the matter is trivial. The execution time is proportional to a cycle per instruction (CPI) value, whereas CPI is an inversion of the instructions per cycle (IPC) value with constant, known cycle time. [10] In multi-threaded or parallel conditions none of these assumptions are true. At the time of writing this paper, the test CODB system operates in a single thread for the most of the time. The only multi-threaded parts are Java parallel streams used for processing some of the internal collections. This does not affect database logic, which is discussed in this paper. Taking this into consideration, sequential processing measurement techniques were used.

There are many execution parameters which can be measured. For the sake of the research, the following parameters were chosen: execution time, CPU workload and a heap size. Such a selection lets us to take two important perspectives of the system's performance: the user view (time-oriented) and the system view (resource-oriented). The user perspective is connected to considering system as efficient, it determines system's capacity as well. The faster requests are processed, the more of them can be handled in a unit of time. This aspect is particularly important in interactive applications, requiring fast responses for a massive amount of requests. A fundamental time metric is the execution time. The other perspective, a system one, is resource-oriented. Resource is a part of a system, which serves for the other elements of the same system. [11]

Metric is defined as a way to determine whether a system has given property or not and to what extent. Specifically, in the performance engineering domain, metrics provide information about performance parameters with regards to time and amount of computational work. Application context is crucial for interpretation of a metric's result. For time-sensitive applications, like real-time systems, time domain is fundamental, whereas applications processing huge volumes of data will put a pressure on throughput, regardless of resource usage.

In the literature of the subject there is no generally-adopted standard on performance metrics. They are rather ad hoc, defined for each application or class of applications. However, there are common types of metrics used, compliant with two major perspectives mentioned earlier. In this research, the following metrics have been used: Response time [ms] - the total time of a request execution; Throughput (capacity) - the number of requests completed in a given time unit; Resource

consumption [MB] - the highest JVM heap size during the test execution. In terms of scalability, the most important metric is the capacity.

A custom, configurable workload generator has been used. It enabled the configuration of the following aspects of the generated requests:

- read/write requests ratio;
- data granularity: defined or random size of entries;
- data entropy: a number of generated values or a unlimited randomness;
- whether the generated requests should touch many columns or not;

CODB Benchmark application configures a dedicated loggers for the sake of collecting execution time, throughput and heap measurements. Measurement data is written in CSV (comma-separated values). Execution time is calculated as a difference between two consecutive `System.nanoTime()` invocations, one just before measured method invocation and one just after. JVM heap consumption is measured using the `java.lang.Runtime` class.

IV. Performance factors

This section presents a set of factors which are suspected to impact on database performance. They were chosen based on expertise, but do not necessarily have a real, significant influence. Verification of these suspicions is the key objective of benchmarking.

First category of performance factors are the universal factors, related to data processed by a database, but unrelated to specific technology concerns.

Read and write operations ratio can determine a lot of performance-impacting elements. Firstly, write operations require synchronization effort. For obvious reasons, insert, update or delete requests imply I/O operations, which need to be enqueued and buffered on many tiers of the system down to the physical layer, where they are really executed.

Assuming a constant amount of data to be written; fewer, big portions are expected to be processed faster than a larger number of small portions. With the use of a benchmark, it needs to be measured to what extent such a prediction is true.

Due to CODB storage file structure, which is essentially a RLE-like-compressed structure, entropy is predicted to have a significant influence on performance of the system. RLE, or run-length encoding, is a simple way of data compression based on substitution of numerous occurrences of a term with a single instance and a number value which represents the number of occurrences. The lesser the entropy is, the better performance should be, because as stated before, when a single column is discussed, appending a new entry with an already existing value may require as little as increasing a single 8B counter and writing a 16B key.

Requests are issued by multiple threads, but the threshold on which synchronization and context switching between threads becomes bigger than concurrency performance gain is unknown. Benchmarking may provide a reasonable empirical information regarding how many threads is too many and, specifically, how that number is related to the CPU's core number and the CPU's hyper threading capabilities.

Besides the technology-independent factors, performance can be affected by technology-specific components. From the wide variety of candidates, two were chosen for the research as potentially having the biggest impact on results.

The Java Virtual Machine platform, and thus the Java programming language, memory model is based on indirect memory management. The application does not allocate and release the memory occupied by the objects on its own, but it is done implicitly by the JVM within a part of the memory called the heap. A critical component of the memory management facility in Java is the garbage collector, a module responsible for removing unused objects from heap. According to the official documentation [12], the HotSpot JVM v.1.8 provides four garbage collector implementations: serial, parallel, concurrent mark-sweep (CMS) and G1.

As CODB is executed on the JVM, it's state may (or may not) have an impact on performance. For example, some internal data collections or buffers are expanded exponentially, so that at the beginning (*cold* state) it will happen more frequently than later (*hot* VM). Hot tests are performed by issuing 1000 write/read requests before starting measurement. After the warm-up all the database internal structures are cleared in order to avoid performance impact by having prefilled collections or buffers.

V. Results and discussion

Each test was performed 4 times and consisted of issuing 50 000 requests. Tables I, II and III present the measurement results. In all the tables, extreme values which are to be discussed further are highlighted. Every table header contains information about what values are desired (low or high).

Each section in result tables contains results with different values of a single factor. Unless a given factor is tested, the following values were stated as defaults for each test: parallel garbage collector, hot JVM, r/w ratio = 0.5, low entropy and two columns in use.

Testing environment was: Intel Core i7-4600U CPU with 12GB DDR3-1600 RAM and SSD drive with the ext4 filesystem. The operating system was a 64-bit GNU/Linux 4.2.0 with Oracle HotSpot 64-bit JVM v1.8.0-74. Benchmark was started using Maven Exec Plugin.

Garbage collector implementation has very low impact on request execution time. Results for all the implementations are similar and of similar stability (almost the same standard deviation). Serial GC performed the best, probably because of relatively low data volume and single threaded testing. Stopping a single thread is less harmful in terms of performance than stopping multiple threads. For heap usage levels GC has an obviously fundamental impact, although some patterns are visible here. Parallel GC achieved the lowest minimum heap size of as little as 15MB. This result probably is an outlier, because of distance from all the other implementations and needs a deeper investigation. The highest standard deviation also may be skewed by one or more outliers. Differences in terms of

maximum and average recorded usage are much more stable. Execution with the serial GC consumed the highest amount of memory, which seems to be a trade-off of its simplicity and speed. In terms of request processing throughput, Serial GC has the best minimum recorded throughput, but the true winner is the G1 GC, which offered the highest maximum result and the highest average throughput. Results are similar and the impact is relatively low, though.

The JVM state variable shows a little impact on performance in both time-oriented metrics. It has much higher impact on the heap usage levels, but that would probably make sense - the longer the program is running, the higher is heap usage. In connection with similarly low standard deviation, it brings a conclusion that the JVM state is not very important for the performance. In general, technology-specific factors turned out to have much less impact on a database performance.

When it comes to the data oriented metrics, their impact is much more visible in performance results. Read-write ratio, according to intuition, showed that read operations are performed much faster than write operations. A clearly visible pattern is present in both time-oriented metrics. Starting from the 50% share of write operations, results are stable. This may represent the logarithmic dependency. In terms of heap usage, 100% read pattern showed surprisingly high minimum recorded usage, which may be an outlier. The highest maximum usage was registered for 50-50 pattern. Probably the pattern here is the higher diversity of objects, the higher memory usage is. This requires a further investigation, but is not very important in the research context. Relatively low standard deviation in time-oriented metrics shows that results

are quite stable.

Data entropy presents very interesting case in the request execution time results. The request processed in 0.001ms may be a previously discussed corner case with the insertion of a new instance of already existing value that requires to only append 16B and increment a single long variable. Enriching the execution time log with additional information about request type would help to verify this prediction. High entropy resulted also in a very good maximum request processing time. The reason is probably again an appending at EOF. High entropy tests also proved to have much more stable result than low entropy tests. In terms of heap usage, pattern is similar, high entropy has much better and much more stable results. Throughput metric repeats discoveries from request execution time, as these metrics are related to each other, in a sense. The entropy results are surprising, and require a deeper data mining in order to bring more specific conclusions on its impact.

The last analyzed variable was a multi-column vs. single-column mode. Single column mode showed better results in all of the metrics, although the impact on request execution time results is relatively low. Influence on throughput is moderate, whereas the highest impact is put on the heap usage levels. Standard deviations are similar, but relatively high.

In the context of a horizontal scalability, especially important for this research, data-oriented observations are viable. An optimum case of a single-column with a high entropy and a relatively low share of write operations emerges from the results.

VI. Performance model

In order to produce the mathematical model, chosen factors presented in sections IV and V needs to be converted to a mathematical value. The model is necessary to estimate a performance of a database instance with the specific parameters. This is the first approach to a simplified model and it is to be refined in subsequent work. Weights are determined on the basis of impact displayed in tables I and III. Weights sum must be equal to 1. Other variables were considered immaterial and thus are not present in the formula. Garbage collector implementation also was skipped, as its impact on time-oriented metrics is much lower than data-oriented factors. P metric estimates database instance performance, the higher is the better.

$$P = 0.2 * MC + 0.4 * E + 0.4 * \frac{1}{ln(RW + 1.1)} \quad (1)$$

MC represents a single- or multi-columnar mode. At the moment it is defined as a binary factor with values of 0 for a multicolumn, and 1 for a single column mode. In future research the MC factor may need to be refined to a functional form, depending on the number of columns involved. E takes a values from range $[0, 1]$ where 0 is using the same value all the time and 1 means a total randomness. RW is a ratio between the read and write operations, in range $[0, 1]$ where 0 is the read only and 1 write only. Taking everything into consideration, P metric can take values from range approx $[1.35, 4.80]$. The lowest value is a write-only, multi-column instance with a low entropy, whereas the highest is achieved for a single-column read-only instance with a high entropy. This model will be validated and enhanced during the further work.

VII. Summary

This paper is the very first phase of a performance analysis of column-oriented database management system. Column-oriented databases were described in details, in relation to the popular relational model. Some of the CODB implementation details were presented, putting special emphasis on the data layout. Then, performance engineering concerns were reviewed along with performance metrics. Consecutively, different components, both technological and data-originated, with potential influence on performance results were discussed and verified. Finally, a first approach to a database mathematical performance model was created and discussed, on the basis of the results.

***Abstract*—Big data is a broad term with numerous dimensions, most notably: big data characteristics, techniques, software systems, application domains, computing platforms, and big data milieu (industry, government, and academia). In this paper we briefly introduce fundamental big data characteristics and then present seven case studies of big data techniques, systems, applications, and platforms, as seen from academic perspective (industry and government perspectives are not subject of this publication). While we feel that it is difficult, if at all possible, to encapsulate all of the important big data dimensions in a strict and uniform, yet comprehendible language, we believe that a set of diverse case studies – like the one that is offered in this paper – a set that spreads over the principal big data dimensions can indeed be beneficial to the broad big data community by helping experts in one realm to better understand currents trends in the other realms.**

***Index Terms*—Metadata, semantic annotations, Spark, NoSQL, data-intensive applications.**

I. Introduction

The principle dimensions of big data include its defining characteristics (such as volume, velocity, variety, and veracity), techniques (such as data mining, machine learning, natural language processing, neural networks, clustering, pattern recognition, sentiment analysis, predictive modeling, supervised learning, time series analysis, to mention a few), software systems (such as Hadoop, Spark, NoSQL DBMSs), applications (such as business analytics, marketing, healthcare, research, performance optimization, security, law enforcement, transportation, and many others), computing platforms (such as clusters, NUMA in-memory database servers, and cloud computing platforms), and big data milieu (such as industry, government, academia).

The big data dimensions are not only broad but also in perpetual change. This is why the task of compiling and maintaining a specification that is rigorous yet comprehensible seems impractical. Instead, we believe that reports like this one, presenting case studies with broad coverage of the big data realm can be beneficial for the broad big data community. Our broad collection of case studies can potentially help experts in one big data dimension expand their understanding of other dimensions.

The technical core of this paper comprises seven case studies. In section II, Techniques, we illustrate the potential of ontologies to semantically enhance data (subsection II.A) and metadata to facilitate image data mining (subsection II.B). In section III, Software Systems, we focus on some of the forces behind the transition from relational to NoSQL DBMS (subsection III.A) and from Hadoop MapReduce to Spark. In section IV, Application Domains, we discuss applications in astronomy and earth science (subsection IV.A) and in biomedical research (subsection IV.B). Finally, section V, Platforms, highlight the convergence of HPC and big data, as seen in the Avitohol computers system (subsection V.B).

All case studies are based on the authors' own research projects.

II. Techniques

A. Semantic Enhancement of Data with Ontologies

The characteristics of big data discussed above create a number of challenges to the methods and tools for their utilization. For example, the volume of data to be processed requires an ability to abstract the data in a form that summarizes the situation and is actionable from the point of view of humans and

978-83-60810-90-3/$25.00

decision-making software systems [16]. This requirement for *semantic scalability* is also important in the context of variety of data formats. The latter implies an additional requirement for an ability to integrate and interoperate with heterogeneous data – "to bridge syntactic diversity, local vocabularies and models, and multimodality" [19]. The velocity, i.e. the rapid appearance and change of data, requires the ability to focus on the relevant data and to process it quickly. Data veracity requires the capability of finding anomalies in it and making some types of reasoning based on proper domain knowledge. Extracting value using data analytics methods on various kinds of data creates the need of ability to extract knowledge from data and integrate it with existing knowledge bases.

Such challenges need be overcome to permit big data's full-scale potential for the user. Most traditional utilization approaches do not work in a satisfactory way for big data, so more agile utilization paradigms are needed in this case.

The main idea of the so-called *semantic utilization of big data* is to provide a kind of *semantic enhancement of data* that can be realized with the help of proper ontologies used to annotate data.

An *annotation* is a form of metadata attached to a specific dataset, to a particular database field or to a particular section of a document content. An annotation provides additional information (metadata) about an existing piece of data. Compared to tagging, which speeds up searching and helps one to find relevant and precise information, *a semantic annotation* goes one level deeper: It enriches the unstructured or semi-structured data with a context that is further linked to the available structured domain knowledge and makes it possible to process complex filter and search operations expecting results that are not explicitly related to the original search queries.

Ontologies [6] are the only widely accepted paradigm for the representation and management of open, sharable, and reusable knowledge in a way that allows automatic interpretation and inference. They provide semantic enhancement of data suggesting controlled vocabulary for annotations and thus permitting agile integration and semantic interoperability.

This kind of semantic enhancement of data may be characterized as an "arm's length approach" [15] – it presumes no change of data but association of each database field with an entire knowledge base. Data should be leaved as they are but incrementally tagged with terms from a consistent and non-redundant set of ontologies.

The successful implementation of the discussed approach depends on the creation of a shared resource (for example, a shared repository) of ontologies that could be used for annotation purposes. Moreover, it will be necessary to build an agile methodology for dynamic creation, application and extension of ontologies to annotate new sources of streaming data [15]. Such methodology should define a simple, repeatable process for ontology development and change management as well as an unambiguous process for data annotation using available ontologies.

B. Metadata in Image Data Mining

A most commonly accepted definition of "data mining" is the discovery of "models" for data. A "model", however, can be one of several things [12]. There are different approaches to modeling data. For thousands of years science was empirical. It was only in the last few hundred years that the theoretical paradigm emerged. The data-driven scientific inquiry came with data mining. The typical feature-based model looks for the most extreme examples of a phenomenon and represents the data by these examples. Some of the important kinds of feature extraction from large-scale data are:

1) *Frequent Itemsets* – a model makes sense for data that consists of "baskets" of small sets of items;
2) *Similar Items* – data looks like a collection of sets, and the objective is to find pairs of sets that have a relatively large fraction of their elements in common.

Data mining can be viewed as a result of the natural evolution of information technology. Data mining has incorporated many techniques from other domains such as statistics, machine learning, pattern recognition, database and data warehouse systems, information retrieval, visualization, algorithms, high-performance computing, and many application domains. In the field of image data mining, we developed an approach for extending the learning set of a classification algorithm with additional metadata. It is used as a base for the assignment of appropriate names to found regularities. The analysis of the correspondence between connections established in the attribute space and existing links between concepts can be used as a test for the creation of an adequate model of the observed world. Meta-PGN classifier is suggested as a possible tool for establishing these connections. We applied this approach to the field of content-based image retrieval of art paintings by designing system architecture for the extraction of specific feature combinations, which represent different sides of artists' styles, periods and movements [8]. Technically, we provide the system with a description of the real world and the systems then follows our mental model to generate appropriate names of detected concepts. The system interacts with the user, displaying those parts of the mental model that are utilized in the name generation process. This interaction is used to further improve and extend the mental model.

III. Software Systems

A. NoSQL versus RDBMS

The huge amounts of data that needs to be stored and processed on multiple servers is a recognized challenge of big data.

To manage the integrity of data, the classical database decisions (mostly relational databases) are based on transactions and support the main transactional characteristics – **A**tomicity, **C**onsistency, **I**solation, **D**urability, also known as ACID property.

But relational databases are difficult to scale, and they cannot guarantee increasing expectations for the performance

and availability when it comes to managing huge volumes of data on different servers.

Published by Eric Brewer in 2000, the CAP Theorem sets the basic requirements for a distributed system – Consistency, Availability, and Partition Tolerance [5]:

- Consistency – all the servers in the system have the same data;
- Availability – the system always responds to a request;
- Partition Tolerance – the system continues to operate as a whole even if an individual server fails.

The CAP Theorem postulates that only two of the three different aspects of scaling out can be fully achieved at the same time.

Traditional relational databases (Oracle, MS SQL, IBM DB2, etc.) are architected to run on a single machine and use strong, schema-based approach to modeling data that rely on consistency. So they represent the first group – Consistent, Available (CA) systems. Some column stores like Vertica, etc., also belong in that group.

NoSQL database decisions, on the other hand, are considered as an alternative to relational databases at times when organizations like Google and Amazon recognize that operating at scale is more effective using clusters of servers, and a schema-less data models are a feasible alternative in case of variety of data.

When distributed data stores are used, at the time of network partition, it is not possible to have both Consistency and Availability. So while traditional data-bases focus on Consistency, the NoSQL systems try to focus on Availability. In that case Consistency could be replaced by Eventual Consistency – data is not consistent at all time, but will be at given time or Local Consistency (the consistency is assured only within one single node and not throughout the cluster). Thus most NoSQL databases rely on properties less strict than the ACID ones, which are called BASE – Basic Availability, Soft state and Eventual consistency [13].

Consistent and Partition-Tolerant (CP) systems like HBase, MongoDB, and Big Table have difficulty to achieve data consistency over partitioned nodes, while Cassandra, Couch DB and Dynamo that support AP (Availability, Partition-Tolerance) achieve ”eventual consistency” through replication and verification.

Furthermore, the first group contains systems that support even ACID properties – like Dynamo, but most systems conform to BASE properties.

In the majority of cases non-traditional systems yield a better performance when ordinary data operations are measured. Our experiments on Oracle, Vertica, and Mongo DB platforms present particular results that confirm this thesis [10], [11].

B. From Hadoop MapReduce to Spark

Spark, initiated at the University of California, Berkley in 2009, was donated in 2013 to Apache. As an Apache project, Spark has gained popularity as a flexible and efficient in-memory implementation of the map-reduce distributed computing model and has already emerged as a faster substitute for the original Hadoop MR in-disk engine. Early Apache projects, such as Hive and Mahout, which originally compiled into Hadoop MR [27], have now been implemented to run on Apache Spark. Besides speed, Apache Spark's advantages to Hadoop MR include capabilities for interactive computing, stream processing, and sensor data processing (which are all lacking from the rigid two-stage Hadoop MR engine). While Apache Spark can be used within Apache Hadoop, it can also run independently, together with its own libraries, such as Spark SQL, Spark Streaming, Spark GraphX, and MLib (machine learning).

It has been broadly acknowledged that Spark has a pronounced efficiency edge over MR, but strict performance comparisons and analysis were scarce before 2014. In late 2014, Databricks, the company founded by the creators of the original Spark, released big data benchmark results that illustrate the speed advantages of Spark over Hadoop MR [26]. Spark was reported to perform three times faster than Hadoop MR on a 100 TB sort workload, and four times faster on a 1 PB workload, using – in both cases – significantly less hardware.

In early 2015, [14] reported performance experiments with codon count algorithms on nucleotide sequence data on AWS (the Amazon cloud computing platform). To do so, the authors measured the performance of a basic Spark codon count algorithm and compared it to a couple of Hadoop MR algorithms: a basic Hadoop MR codon count algorithm and an optimized ”local aggregation” Hadoop MR algorithm. The experiments confirmed that basic codon count with Spark is 15 times faster than basic codon count with MapReduce, a result that is unsurprising. Unexpectedly, however, basic codon-count with Spark remains about two times slower than optimized ”local aggregation” codon count with Hadoop MR. This result hints that properly optimized Hadoop MR code can be faster than the same analysis with Spark. The authors therefore suggest that available optimization techniques, such as local aggregation, be considered for speeding-up of legacy Hadoop MR applications in place of their eventual re-implementation in Spark for performance gains.

IV. Application Domains

A. Astronomy and Earth Science

With the current emergence of terabyte– and very soon petabyte-scale astronomical and Earth observation systems, the traditional approach to basic functions such as data searching, analytics and visualization are becoming increasingly difficult to handle. Simple database queries can result now in data subsets so large that they are incomprehensible, slow to handle, and impossible to visualize with commodity visualization tools. Astronomy and remote sensing complement each other, as they are on the quest for new big data interpretation capabilities: both disciplines have peculiar data, typical data processing and analysis chains, and specific models to be fed with data. However, both disciplines lack the capabilities for easily accessible semantics-oriented browsing in large data archives. Therefore, joint efforts to design and develop

innovative big data tools should help users in many different fields and set new standards for many communities. Several broad challenges to this line of reasoning that demand a multidisciplinary approach through international networking of experts and professionals have been identified. These challenges would then be channeled into COST Action TD1403 Objectives [1]:

- Digital curation and data access;
- New frontiers in visualization;
- Adaptation to new high performance computing technologies;
- New generation of interdisciplinary scientists.

The COST Action TD1403 was launched in April 2015 and will last for two years with a possible extension of 2 more. Now it involves 26 European countries. BigSkyEarth COST Action is organizing meetings, workshops, training schools and conferences. Also it supports Short Term Scientific Missions – exchange visits for individual mobility, strengthening existing networks and fostering collaboration between researchers.

The Bulgarian participation in the Action is in connection with a group of experts in astro-informatics – astronomers, mathematicians and computer science specialists [9]. Our fields are digitization of widefield (larger than or equal to 1 square degree) astronomical photographic plates, image processing and image compression.

The Wide-Field Plate Database [24], established in 1991, is the basic source of data for the wide-field plates obtained with professional telescopes world-wide [22]. It consists of four parts:

- Catalogue of Wide-Field Plate Archives with data for over 500 instruments (telescopes, cameras, etc.);
- Catalogue of Wide-Field Plate Indexes with descriptions of about 600 000 plates;
- Data Bank of digitized plate images (at low resolution for quick plate visualization and easy on-line access, and at high resolution intended for photometric and astrometric measurements);
- Links to online services and cross-correlation with other existing catalogues and journals.

We have identified more than 2 400 000 wide-field plates [21]. They allow one to obtain information of celestial objects over the past 133 years (1872-2005). At present over 300 000 wide-field plates have been digitized with total data about 30 TB.

Digitized photographic plates are irreplaceable sources for:

- Studies of the stellar long term brightness changes, as a result of observations conducted in different observatories;
- Studies of the long term variability of active galaxies;
- Searching and identification of potentially hazardous asteroids and comets which might cause catastrophic events by their collision with Earth.

B. Biomedical Research

Stimulated by the progress in computer technology and electronics data acquisition, recent decades have seen the growth of huge databases in biomedical sciences. For instance, Next generation sequencing (NGS) is a significant technological advance in biomedical sciences. It generates massive genomic datasets that play a key role in the big data phenomenon that surrounds us today. Advancing machine learning, data mining and statistical techniques for processing of big data are the key to transforming big data into actionable knowledge. One major problem with big data is that the standard methods of applied statistics are not really relevant for big data analysis. To extract information from high-dimensional data sets and make valid statistical inferences and predictions, novel data analytic and statistical techniques are needed. Here are some modern issues that we focus on.

Current advances in biomedical research technology, expression and SNP microarrays yield big data sets for many thousands of transcripts, genes or SNPs. Researchers are often interested in finding differences among these features between two separate groups, e.g. patients and controls, treatment and control groups; different strands; different tissues etc. Due to the differences of the underlying technologies and their biophysical and biochemical processes, scientists need to use statistical data analysis methods designed specifically for the particular technology. These tests often employ multiple comparison designs, where each gene, transcript or SNP is separately tested for significance and in many situations these tests are conservative. In complex multiple testing hypotheses, the classic statistical tests overestimate the p-values, leading to both loss of statistical power and increased experimental costs. One really common choice for correcting for multiple testing is to use the false discovery rate to control the rate at which things you call significant are false discoveries. There has been recent interest in developing efficient algorithms for multiple comparison to increase the statistical power and reduces the experimental costs. A computationally efficient technique has been proposed recently [4] that increases the statistical power, while controlling the False Discovery Rate of the statistical tests. This technique is applied to DESeq – a popular method for finding differentially expressed genes using RNA-sequence data. The statistical power increase is particularly high in small sample size experiments, often used in preliminary experiments and funding applications.

Some other issues arise from the method for finding differentially expressed gene. Apart from the DESeq method there are a few more like edgeR and limma frequently used by biomedical researchers [17]. These methods often produce similar, but not identical results. At the same time, due to randomness, even the same method can produce slightly different results on a data simulated from the same model. Therefore we are interested whether the slightly different results produced by different models can be attributed to randomness or to an underlying difference in the methods. Since the gene sequence is very long, we might not be interested in the full ranking

of the p-values but in some incomplete or partial orderings of them. Consequently, we want to compare such partial orderings. For example we can split the genes into several groups according to the size of their p-values lying in the sub-intervals $[0, 0.001]$, $[0.001, 0.01]$, $[0.01, 0.05]$, $[0.05, 0.1]$, $[0.1, 1]$. Then we construct a distance measure to compare how similar/dissimilar two incomplete rankings are based on the number of items present in the same ordered groups in both rankings [18]. Based on simulated large number of rankings and computed distance between any two of them, we can make inferences about the significance of a particular distance. That is to estimate the similarity between the corresponding incomplete rankings. Scientific computing is involved in all of these steps: simulating incomplete rankings, applying the method for finding differentially ex-pressed genes, computing all distances and estimating the distribution of the distance. We use the advanced computing resources at the Institute of Information and Communication Technologies (IICT) [7].

V. Platforms

Academic organizations are already moving towards unifying their HPC and big data processes within integrated HPC/big-data platforms, as observed in the development of the Avitohol platform at the Institute of Information and Communication Technologies at the Bulgarian Academy of Sciences.

As owner and manager of the Advanced Computing and Data Centre [7], IICT provides advanced computing resources and expertise thus helping Bulgarian science to come at the forefront of development worldwide.

The new multifunctional High Performance Computing system – Avitohol, forms the core of the computing infrastructure in the Institute. It consists of 150 computational servers HP SL250s Gen8, equipped with two Intel Xeon E5-2650v2 CPUs and two Intel Xeon Phi 7120P coprocessors, 64 GB RAM, two 500 GB hard drives, interconnected with non-blocking FDR InfiniBand running at 56 Gbp/s line speed. The total number of cores is 20700 and the total RAM is 9600 GB, respectively. The servers are deployed in 4 dual racks HP MCS 200, which have water cooling and can deliver up to 50 kW of power per rack. A central rack contains most of the storage, management servers and the central communication switches.

The system is controlled by two management (head) nodes and 4 I/O nodes. All those nodes are of the type HP ProLiant DL380p Gen8 with 2 Intel Xeon E5 2650v2 CPUs and 64 GB RAM. The I/O nodes provide access to 96 TB of raw storage capacity (24 disks of 4 TB each), which is provided by a SAN system.

The theoretical peak performance of the system is estimated at 412.3 TFlop/s in double precision while the RMAX Performance according the LINPACK benchmark is 264.2 TFlop/s. The Avitohol HPC system has been operational since June 2015 and it is ranked on 388th place according the 46th T0P500 list [20].

The second advanced computing system at IICT is the heterogeneous High Performance Computing Grid (HPCG)

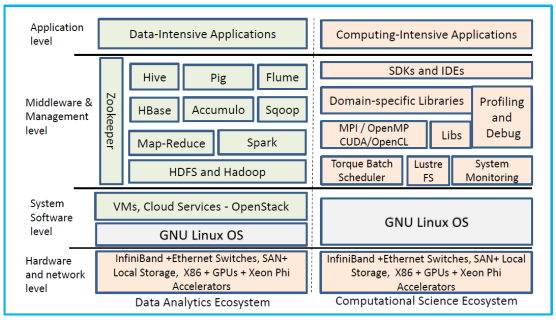

Fig. 1. Data analytics and computational ecosystems.

cluster [7]. It has been operational since 2010 and consists of HP Cluster Platform Express 7000 enclosures with 36 blades BL 280c (Total 576 CPU cores), 24 GB RAM per blade; 8 controlling nodes HP DL 380 G6 with dual Intel X5560 2.8 GHz, 32 GB RAM (total 128 CPU cores); 2 HP ProLiant SL390s G7 4U servers with 16 NVIDIA Tesla M2090 graphic cards (total 8192 GPU cores); 2 HP SL270s Gen8 4U servers with 8 Intel Xeon Phi 5110P Coprocessors each (total 480 cores, 1920 threads); 3 SAN storage systems with 132 TB total storage. All servers are interconnected with FDR InfiniBand running at 56 Gbps line speed. The theoretical peak performance of the system is estimated at 21.92 TFlops/s in double precision.

A dedicated optical network link has been established between the two systems, as well as between the Avitohol system and the main node of the Bulgarian Research and Educational Network (BREN) [2].

The existing computing facilities at IICT are involved in two computational infrastructures: the European Grid Infrastructure [3] and regional VI-SEEM infrastructure [23].

Based on their experiences in the last 10 years, the scientific and support staff in the center for HPC and Data computing at IICT [7] is dedicated to providing full support for the development and deployment of innovative scientific and industrial applications with substantial needs for computing power and data storage and transfer. The system can be considered to have two equally important sides. On the one hand it allows for state-of-the-art high performance computations, providing a full stack from base operating system software and libraries up to specially configured and deployed applications that make full use of the special capabilities of the systems, e.g. the Xeon Phi accelerators and CUDA GPGPU devices and the InfiniBand network. On the other hand, the storage systems provide access to data using various base protocols. The Lustre file system is the most frequently used for HPC workloads, while protocols like iSCSI are used for Cloud provisioning and other types of data processing. The data processing capabilities of the new Avitohol system are currently under configuration and testing, with the aim to build-up the full ecosystem with Hadoop and HDFS as the base layer and the components like Hive, Spark, Pig, etc., working on top of it. We plan to allow these components access to the Xeon Phi coprocessors

for advanced deep learning and related algorithms. Such new data processing capabilities will foster the development of integrated scientific applications that are based on realtime data, coming from local and international sources. Fig. 1 shows a schematic representation of the hardware and software components that are available or planned for deployment. System architects and engineers are developing a mixed HPC/Big data cluster, to provide for the convergence of HPC and Big data computing into a "single" environment.

The current goal of IICT is to achieve petaflop and petabyte-level of computing and storage capability, coupled with a developed software and middleware stack and services, opening the way to new forms of scientific research, more directly connected with the national industry and the societal challenges.

VI. Conclusion

This paper offers seven case studies that span several dimensions of big data: techniques, systems, applications, and platforms. All case studies are extracted from current research projects of the authors themselves. The case studies cover various aspects of big data and can, hopefully, be beneficial to the broad big data community by helping experts in one realm get acquainted with current cases in other realms.

The main contributions of the individual authors can be described as follows. M. Nisheva presented the potential of ontologies to semantically enhance data (section II.A). P. Stanchev discussed the use of metadata in image data mining (section II.B). K. Kaloyanova reviewed the capabilities of NoSQL databases as opposed to RDBMS (section III.A). N. Kirov described utilization of big data in Astronomy and Earth Science (section IV.A), while E. Stoimenova highlighted the specifics of statistical applications in biomedical research (section IV.B). T. Gurov focused on the convergence of HPC and big data, as realized with the Avitohol platform (section V.B). A. Radenski discussed the transition from Hadoop MapReduce to Spark (section III.B). A. Radenski also planned the overall structure of this publication and drafted the abstract, the introductory section I (minus the specification of the big data characteristics), the background section V.A, and the concluding section VI.

***Abstract*—The speedup is usually limited by two main laws in high-performance computing, that is, the Amdahl's and Gustafson's laws. However, the speedup sometimes can reach far beyond the limited linear speedup, known as superlinear speedup, which means that the speedup is greater than the number of processors that are used. Although the superlinear speedup is not a new concept and many authors have already reported its existence, most of them reported it as a side effect, without explaining why and how it is happening.**

In this paper, we analyze several different superlinear speedup types and define a taxonomy for them. Additionally, we present several explanations and cases of superlinearity existence for different types of *granular* algorithms (tasks), which means that they can be divided into many sub-tasks and scattered to the processors for execution. Apart from frequent explanation that having more cache memory in parallel execution is the main reason, we summarize other different effects that cause the superlinearity, including the superlinear speedup in cloud virtual environment for both vertical and horizontal scaling.

***Index Terms*—Cache memory, load, parallel and distributed processing, performance.**

I. Introduction

THE goal of today's world of parallel and distributed systems is to achieve the greatest speedup, represented either as the lowest time for execution of a single task (High Performance Computing), or to execute as many tasks as possible for a given time (High Throughput Computing), when the task(s) are executed on scaled resources. Many new algorithms and computing paradigms appeared in the last decade, and new challenges have emerged to solve more complex problems faster, or to achieve greater speedup, as much as possible [1].

The speedup is usually defined as a ratio of the wall times of sequential and parallel execution of an algorithm. The target of the parallelization is to achieve the lowest execution time in order to maximize the speedup against the best sequential algorithm. Increasing the number of computing resources will increase the intra-resource's communication and requires additional operations, such as reduction operations.

Most of the authors analyze the computer only as a processing unit, focusing on the processing power, without analyzing the details of the computer as a complex system with memory and I/O devices as resources. Actually, these resources limit the speedup, or can boost its performance.

According to the Gustafson's Law [2], the speedup is limited with the number of processors, when the linear speedup is achieved. However, beyond the limits, the superlinear speedup happens in reality for plenty of reasons and it allows an increased utilization of parallel systems [3].

Many authors reported the existence of a superlinear speedup, but most of them only mentioned it as a side effect [4]. Besides reporting a superlinearity, other researchers briefly presented that the reason for achieving a superlinear speedup is because of the greater amount of cache memory in the parallel execution compared to the sequential [5]. However, these explanations are insufficient. For example, all currently produced multiprocessors contain a multi-level cache, but a superlinear speedup is not reported always. Also, it is not reported for all algorithms. Sometimes it is limited to the problem size or the number of used multiprocessors.

In this paper, we present a systematic overview of the reasons why the superlinear speedup appears. The analysis approach is to focus on granular algorithms, in both traditional and cloud virtual environments. Tthe superlinearity is reported in both environment types, explaining the reasons summarized in this paper. Data- or code-parallelism divides a single task into threads or processes and sends them for execution on different processors, thus aspiring to become a high-performance computing system with a goal to finish the task as fast as possible. On the other hand, today's service oriented architectures offer scalable web services to their customers using elastic cloud resources. The latter approach tends toward a high throughput computing system aiming at serving as many possible customers for a certain time, without reducing the service performance.

Due to its elasticity and the linear pay-as-you-go model, the cloud is preferred platform both for high performance algorithms, especially if they are low communication-intensive, such as scientific applications [6], [7]. Many scientific applications are moving from computation-intensive to data-intensive, that is, they require high throughput computing, rather than high-performance computing. This is a huge challenge in the cloud because the data transfer between the cloud compute nodes and storage is a bottleneck [8]. Despite the additional virtualization layer, a superlinear speedup is also reported for granular algorithms [9].

978-83-60810-90-3/$25.00

The rest of the paper is organized as follows. The speedup limits in parallel executions are described in Section II. Section III elaborates when and how a superlinear speedup can be achieved for a parallel implementation of some algorithm. Examples of obtained superlinear speedup for high performance algorithms are presented in Section IV. Despite the virtualization layer, the cloud environment can also achieve a superlinear speedup, as discussed in Section V. Section VI discusses several paradoxes, as well as further challenges. Finally, we conclude the paper and present the plans for future work in Section VII.

II. Speedup Limitations

This section briefly explains the two main laws in the computer architecture about the limit of the maximal speedup that can be achieved when an algorithm is executed parallel with more computing resources, that is, Amdahl's [10] and Gustafson's laws. The former targets the speedup for problems with fixed problem size while the latter the algorithms that require intensive parallel processing.

Speedup $S(p)$ is defined as a ratio of the execution times of the best sequential algorithm $T(1)$ and the parallel implementation on p processors $T(p)$, as presented in (1). However, this definition holds only for fixed-time algorithms. When analyzed more broadly, the speedup should be defined as a ratio of speeds, and not of times, as defined in (2). Note, that for fixed-time algorithms, the amount of work is constant, which results in (1).

$$S(p) = \frac{T(1)}{T(p)} \tag{1}$$

$$S(p) = \frac{(\frac{ParallelWork}{ParallelTime})}{(\frac{SerialWork}{SerialTime})} \tag{2}$$

Fig. 1 presents the theoretical or ideal speedup for both laws, depending on the number of processors used in the parallel execution. The Amdahl's Law limits the speedup to the value $1/s$, as defined in (3), where s is the portion of the serial part for the fixed size program. The conclusion is that the speedup is limited regardless of the number of processors, when the problem is fixed.

$$S^{max}_{Amdahls}(p) = 1/s \tag{3}$$

The Gustafson's Law, on the other side, shows that if the problem is executed within a fixed time, the maximum value of the speedup is *linear* limited by the number of processors, as defined in (4), assuming that the problem size increases and the serial portion becomes negligible. However, in real executions, due to communication, synchronization, and resource sharing, the speedup is *sublinear*, or $S(p) < p$.

$$S^{max}_{Gustafson}(p) = p \tag{4}$$

Both the Amdahl's and Gustafson's laws calculate the maximum speedup, that is, the speedup limit of a parallel algorithm or program; they both consider that the serial part of the algorithm does not depend on the number of processors. However, this is in the ideal condition, while in a real situation, each processor does not start and finish in the same time, and the communication overhead and synchronization can harm the parallel execution when the number of processors increases.

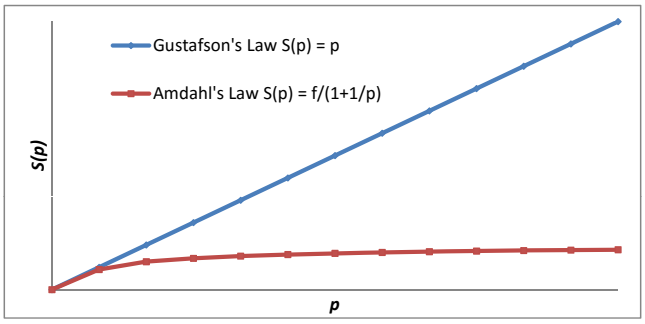

Fig. 1. Speedup for Amdahl's and Gustafson's laws

Karp and Flatt [11] introduced the *scaled serial fraction* f_k of an algorithm as defined in (6), where p is the number of processors, and s_k is the speedup that calculates the overhead (5) as a number of the executed additional arithmetic operations for parallel execution. Parameter k represents the scaling factor for the overhead in a parallel implementation using p processors.

$$s_k = \frac{k \cdot T(1,1)}{T(p,k)} \tag{5}$$

$$f_k = \frac{1/s_k - 1/p}{1 - 1/p} \tag{6}$$

Let's discuss the relation for the scaled serial fraction. If s_k = p, then $f_k = 0$, which yields to the Gustafson's Law. The results of the parallelization will still be good even if the parallel implementation achieves a small speedup, while f_k retains to a some constant value, because the algorithm has limited parallelization.

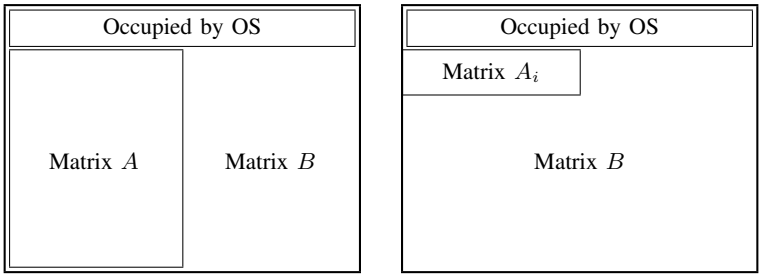
Let's rewrite (6) as (7) in order to determine the speedup that calculates the overhead s_k and yield special cases, that is, the Amdahl's and Gustafson's law.

$$s_k = \frac{1}{f_k \cdot (1 - 1/p) + 1/p} \tag{7}$$

If the scaled serial fraction $f_k = 0$, then $s_k = p$, which yields toward Gustafson's Law, while if $p \to \infty$, then $s_k = 1/f_k$, as Amdahl's Law states. For each scaled system with $f_k > 0$, the scaled speedup that calculates the overhead is sublinear, i.e. $s_k < p$.

III. Beyond the Speedup Limits. Why and When?

Although the limits are given by the Gustafson's Law, the speedup achieved by executing some algorithms on parallel configurations goes beyond it, achieving a superlinear speedup. This section presents several such cases, along with detailed



a) sequential version b) parallel version

Fig. 2. Cache occupancy in sequential and parallel execution

explanation about the reason for various superlinear speedup appearances.

Let's analyze when a superlinear speedup can be achieved while parallelizing a sequential problem. The CPU execution times for sequential algorithm T_s and parallel algorithm T_p are respectively defined in (8) and (9), where CC and MC represent the clock cycles required by the processor for execution of operations and memory accesses, correspondingly, and CT the time period of a single clock cycle. In a homogeneous environment, CT will be the same for both implementations.

$$T_s = (CC_s + MC_s) \cdot CT \tag{8}$$

$$T_p = (CC_p + MC_p) \cdot CT \tag{9}$$

Shi [12] classified the parallel versions of algorithms to be either structure persistent or non-persistent. The former means that the number of total operations that the algorithm executes is same both for the sequential and parallel implementation, for the same input. The latter's parallel implementation does not execute all operations, that the compatriot sequential algorithm would. A formal notation of (7) means that the scaled serial fraction $f_k < 0$, which yields toward a superlinear speedup $s_k > p$.

Gusev and Ristov [13] defined the condition when a superlinear speedup can be obtained for a shared memory multiprocessor, which is presented in (10), where a positive number ϵ exists, such that $0 \leq \epsilon \leq p$ and $CC_s = CC_p \cdot (p - \epsilon)$. The parameter ϵ represents the effect of parallelization overhead and synchronization and p the number of scaled computing resources.

$$MC_s > p \cdot MC_p + \epsilon \cdot CC_p \tag{10}$$

The superlinearity was defined for cache-intensive algorithms only (algorithms where the cache-intensive complexity represented by the average reuse of an element c is greater than 1 [14]). For example, the dense matrix-matrix multiplication algorithm has cache-intensive complexity $c = O(N)$ because each element of matrices is accessed N times for different computations. On the other hand, the cache-intensive complexity of the scalar product is $c = 1$, which yields that a superlinear speedup cannot be achieved. We must note that the cache-intensive complexity defines the level of superlinearity, that is, an algorithm with greater cache-intensive complexity ($c \gg 1$) will achieve a greater superlinear speedup.

A. Superlinear speedup for non-persistent algorithms

Typical examples of non-persistent algorithms are searching algorithms, which finish when one of the processors finds the solution, and together with all the other processors stop the execution, without finishing all operations. In this case, a superlinear speedup usually appears because CC_p is smaller than CC_s, thus compensating the overhead of parallelization. This case can be better presented if the total number of clocks are presented through the number of instructions I and CPI (clocks per instruction), as presented in (11) and (12) [15]. I_p will be smaller than I_s, which will cause a spurious superlinear speedup.

$$CC_s = I_s \cdot CPI_{CC}; \tag{11}$$

$$CC_p = I_p \cdot CPI_{CC} \tag{12}$$

Many examples can be found in the literature for superlinear speedup of the non-persistent algorithms. For example, parallel shortest path planning [16].

B. Superlinear speedup for persistent algorithms

The total number of instructions of the sequential and parallel implementations of structure persistent algorithms is the same, that is, $I_p = I_s$, which means that superlinear speedup appears due of the memory clock cycles, that is, by reducing the number of clocks per instruction for memory access CPI_{MC} in the parallel implementation. There are several different cases when CPI_{MC} in parallel implementation will be smaller than its serial compatriot. Let us explain all these cases.

1) More cache for parallel execution: The case when the parallel execution of a structure persistent algorithm can obtain a superlinear speedup due to utilizing more cache memory is the mostly reported by the researchers [17].

Since more cache memory is used in parallel execution, for some region of problem size, it can store the whole problem

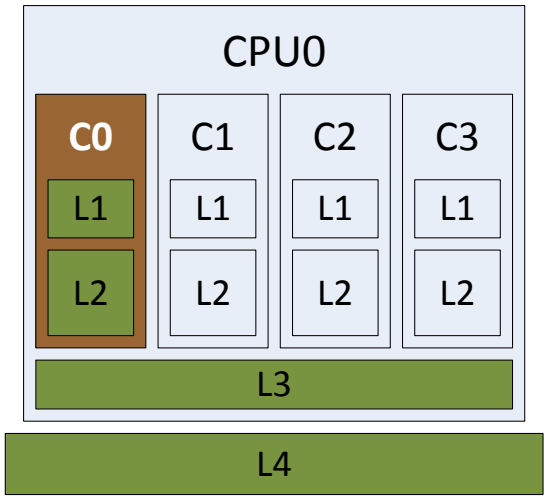


Fig. 3. Utilized memory for sequential execution

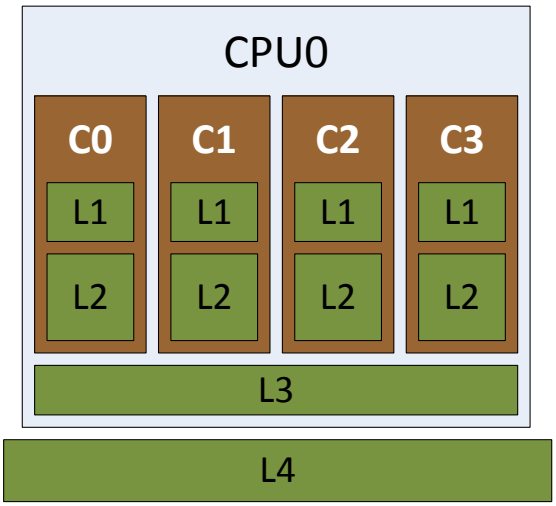

Fig. 4. Utilized multi tiered memory for loosely coupled processors for parallel execution

size, while the sequential execution cannot, as presented for storing matrices in Fig. 2 [13].

Fig. 3 [18] presents an example for utilized memory tiers of a typical multiprocessor with four cores, each with private L1 and L2 cache memory, shared L3 cache memory, and main memory represented by L4.

Velkoski et al. [18] went beyond this analysis. They have analyzed the impact of loosely and tightly coupled cores for parallel implementation and concluded that the former is superior for naive dense matrix-vector multiplication. The utilization of memory tiers of a typical multiprocessor for loosely and tightly coupled cores in parallel execution is presented in figures 4 and 5 [18]. The tightly coupled case uses all four cores on one chip, while the loosely coupled case uses one CPU core of four chips on a shared memory multiprocessor. The results show that a superlinear speedup region appears for both loosely and tightly coupled processors, which starts for the same matrix size, but the former's region is wider, as well as it achieves a greater superlinear speedup. These results clearly present that the use of more L2 cache memories for parallel execution yields a superlinear speedup in the tightly coupled processors, while more L3 cache memory generates even a greater superlinear speedup and region, despite the increased overhead of the inter-chip communication, compared to the intra-chip for tightly-coupled systems.

Another interesting example was reported by Djinevski et al. [19] achieving a superlinear speedup region on GPU, when they used one loosely coupled processing unit of all streaming multiprocessors (SMs) for parallel execution, and a single processing unit of one SM for sequential execution. The superlinear speedup regions are achieved regardless of the used number of SMs.

2) Shared cache for parallel execution: Although most of the reported superlinear speedups are obtained because of the increased cache memory in a parallel execution, a superlinear speedup is achieved in those some algorithms addressing a common shared cache. That is, a superlinear speedup can be achieved even in the tightly coupled processors.

For example, this is the case for an algorithm where the same variables (data) are used by several or all shared memory multiprocessors. If these variables are defined as shared, then fetching a variable by one processor will load it in the upper memory tier (for example, from RAM to the shared L3 cache), thus reducing the access time for the same variable by other processors.

Next, let's explain the difference when multiprocessors, which use private per core cache or shared cache, access the data from the memory. Without loosing generality, assume that the multiprocessor has one cache level and the accessed memory location is not present in the cache.

Fig. 6 presents how two multiprocessors, each with a private cache, access the same memory location. Let's assume that the instruction $Read(X)$ is executed by the processor A earlier. It will generate a cache miss, and pay the penalty for that. After fetching the variable X from the memory into its private cache, the processor B will do a similar sequence. This means that in this case, two cache misses and two memory accesses will happen.

Accessing the data in the memory by two multiprocessors that use a shared cache is presented in Fig. 7. In this environment, when the processor A accesses the variable X, a cache miss will be generated and one memory access. Now, when the processor B will require the same variable X in the near future without replacing it from the cache, a cache hit will be generated without a cache miss penalty and an additional memory access.

We can conclude that a tightly coupled multiprocessor (that uses a shared cache) can benefit when shared variables are used by reducing the cache misses and memory accesses.

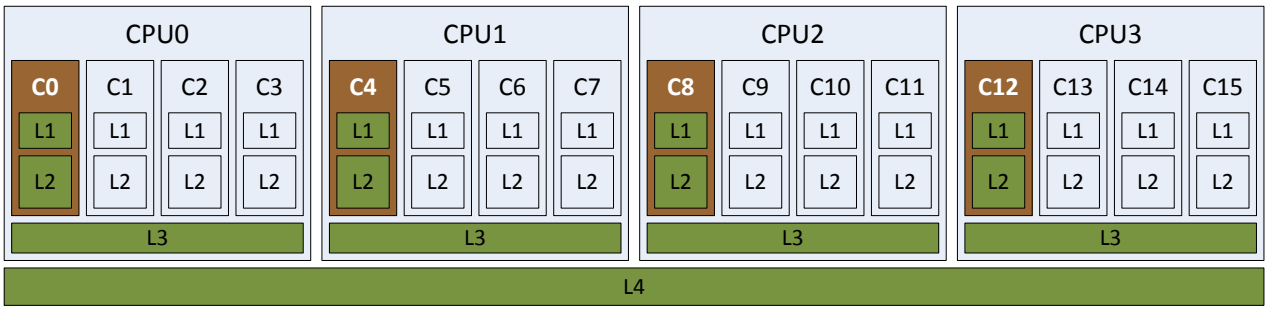

Fig. 5. Utilized multi tiered memory for loosely coupled processors for parallel execution

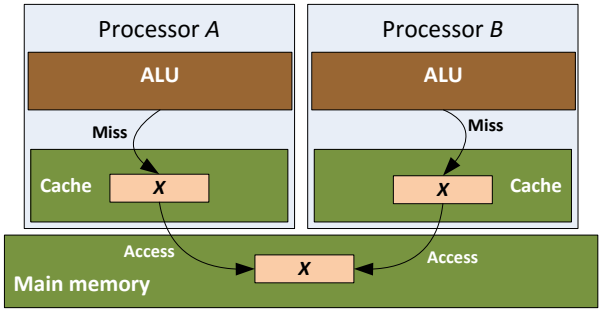

Fig. 6. Accessing the data from the memory by two multiprocessors that use private cache. Two cache misses and two memory access will happen.

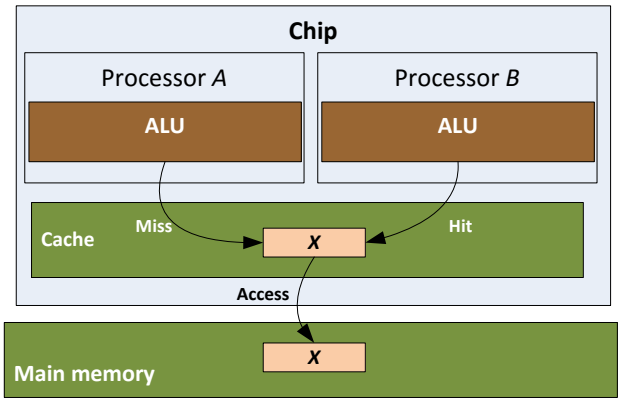

Fig. 7. Accessing the data from the memory by two multiprocessors that use shared cache. Only one cache miss, one cache hit and only one memory access will happen.

The precondition is that the time and space locality should be utilized by all processors.

Anchev et al. [20] reported a superlinear speedup for dense matrix-matrix multiplication. The reason for superlinearity is the use of a shared L3 cache, or, as we explained earlier, the implicit prefetch of the data (matrix elements).

However, we must note that the superlinear speedup was reported only for AMD Opteron, while Intel's i7 obtained a sublinear speedup only. We believe that the reason for this is due to the fact that the frequency gap between L3 and main memory is much bigger for AMD Opteron, and thus reducing the cache miss ratio and penalties, which compensates the parallelization overhead, and generates a superlinear speedup.

3) Superlinear speedup in a heterogeneous environment: Superlinear speedup is reported in a heterogeneous environment that consists of three Intel Xeon CPU + one GPU NVIDIA FX Quadro, because the heterogeneous environment schedules the tasks better than the homogenous environment and thus reduces the impact of Amdahl's Law with a limited overhead in parallel execution [21].

IV. Superlinear Speedup Regions

This section overviews several examples of granular algorithms, where the existence of a superlinear speedup is reported. We define two different region types of a superlinear speedup: 1) for some range of the number of processors, usual

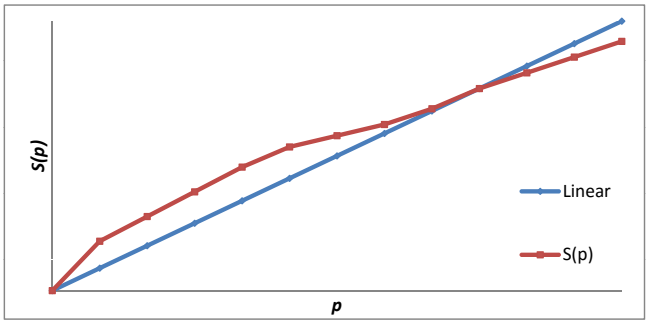

Fig. 8. Example of superlinear speedup for a particular range of number of processors (fixed problem size)

for fixed problem size, and 2) for a particular range of problem size, but fixed number of processors.

Fig. 8 presents a superlinear speedup for some range of the number of processors, usual for fixed problem size. The superlinearity usually starts even when two processors are used. However, it is lost as the scaling factor increases [22] due to the communication and synchronization overhead.

Another situation is to fix the number of processors, but

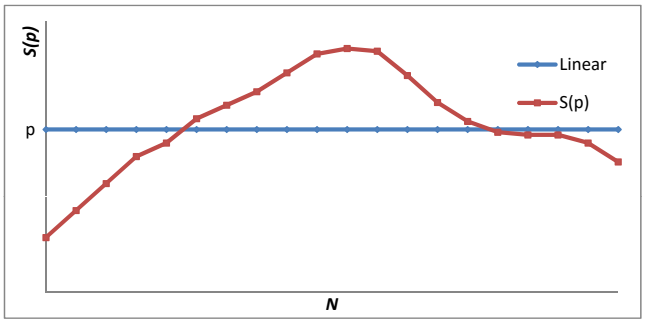

Fig. 9. Example of superlinear speedup for a particular range of problem size, but fixed number of processors

change the problem size, which can also impact the speedup, as presented in Fig. 9. We observe that there is a superlinear region for a specific range of problem size N where the speedup $S(p) > p$, while in other regions, it is sublinear.

We must note that sometimes, the speedup could be $S(p) < 1$, (sublinear speedup), which means that it is not speedup, but a slowdown. This could happen for several reasons. For example, for small problem size, which is negligible for good performance comparison, sequential execution will be faster than the time for forking threads. Another example is the case when the number of threads or processes is greater than the number of existing processors. Or more generally, a slowdown may happen due to the communication and synchronization time, or the overload of instruction in parallel execution. Further on, using the cache line for time and space locality in sequential execution can overcome the problem of the limited number of processors. Let's define it more formal, that is, the condition $MC_s < p \cdot MC_p$ will compensate $CC_p \leq p \cdot CC_s$, which will lead to a slowdown. In this case, the speedup could be achieved if problem size is divided into huge data chunks that will be scattered to the processing resources that will execute them sequentially.

Without losing generality, many authors use the *Efficiency* indicator calculated by $E(p) = \frac{S(p)}{p}$, which maps the limited speedup into the range [0, 1]. This parameter helps a lot to compare parallel executions with a different number of processors among each other. However, the value of $E(p)$ for superlinear speedup is $E(p) > 1$.

Gustafson [23] presented two cases of non-spurious superlinear speedup. Superlinear speedup can be obtained in distributed memory ensembles because of various memory speed. He also reported a superlinear speedup in cases when algorithms and tasks are with different speed.

Sometimes, parallel execution achieves a superlinear speedup because it partitions and reduces the data chunks, which can be placed in the cache memory, thus reducing the cache misses [24], [25], [26], [27], [28].

Many authors reported a superlinear speedup for parallel execution of some algorithms. However, most of them presented a likely explanation only for the superlinear speedup appearance. For example, one explanation is that the reason for achieving a superlinear speedup is because of having more cache in parallel execution. Still, in most cases the superlinear speedup is achieved for some range of the used number of processors, or for a specific problem size, or in a combination of both cases. For example, Monagan and Pearce [29] achieved a superlinear speedup for the parallel sparse polynomial division. However, they did not explain why a superlinear speedup has not appeared for extremely sparse problems, although a parallel execution uses the same amount of cache. Also, the same experiments have not reported a superlinear speedup on the Core 2 processor, although the level 3 cache has more cache than the sequential one.

Phillips et al. [30] reported a superlinear speedup, even when comparing parallel executions up to 26 processors with the one that uses two processors for continuous iterative guided spectral class rejection (CIGSCR). Peschlow et al. [31] achieved a superlinear speedup while simulating wireless networks, but only in a single range of a number of processors and for a specific number of nodes.

V. Analysis of a Superlinear Speedup in Cloud Environment

This section presents several cases where a superlinear speedup is achieved in cloud virtual environment for various types of scaling the resources.

Nowadays, cloud computing is being increasingly used for high-performance and high throughput applications. Its elastic on demand resources allow the customers to rent, for example, 1000 processors and execute a certain task, instead of building their own underutilized data center. Since the cloud's pricing strategy is linear, and expected speedup is also linear, it seems that customers will be charged fairly. In reality, the reported performance for communication-intensive high-performance algorithms shows that customers might feel that they are cheated. However, there are several cases where the superlinear speedup is achieved, despite the virtualization layer.

Customers can scale their rented resources horizontally, vertically or diagonally in the cloud. If the original configuration maps one process to a virtual machine (VM) instance hosted on a processor with one CPU core, as presented in Fig. 10 a), then Fig. 10 b), c) and d) present the three possible cloud scalings. The horizontal scaling presented in Fig. 10 d) increases the number of same VM instances and maps separate process (with a single thread) to a different VM instance. The vertical scaling presented in Fig. 10 b) increases the number of CPU cores per VM (resized VM) and maps separate threads of a single process to a different core on the same VM instance. A combination of the both scaling types yields a diagonal scaling presented in Fig. 10 c). To realize the vertical and diagonal scaling, the customer should use some API for parallelization, such as OpenMP, which will create parallel threads.

There are published papers that present a superlinear speedup in both the horizontal and vertical scaling. A superlinear speedup is reported and elaborated for cache-intensive algorithms [9] in the case of vertical scaling. Although sequential execution utilizes cache more, the superlinear speedup

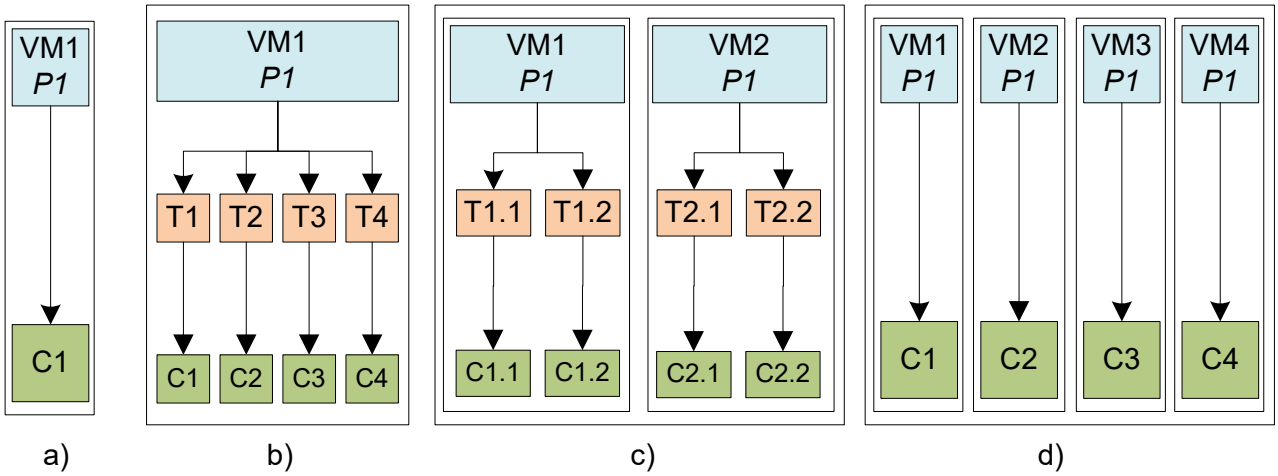

Fig. 10. Example of b) Vertical, c) Diagonal, and d) Horizontal scaling of nominal resources a)

is achieved also for horizontal scaling in the cloud, as well [14]. The authors have determined that the cloud environment handles the cases when the problem size can be fitted in the last level cache memory better, which is the reason why a superlinear speedup is achieved [32].

VI. Discussion

The superlinear speedup is achieved by many researchers, usually as a side effect without elaborating the theoretical background and explaining the details. In this paper, we have analyzed several aspects how to achieve a superlinear speedup, explaining why and when it can happen when various algorithms are executed on different platforms.

A. Superlinearity versus algorithm type

Mainly, the multi-tiered memory organization is the main reason to obtain a superlinear speedup for granular algorithms. We have classified two paradoxical cases; in the first case, the superlinearity appears because of the increased capacity of L2 and L3 cache memory, while in the second case, it is achieved because of the shared last level cache memory. A superlinear speedup is achieved in the first case, when the algorithm is executed on a loosely coupled system, while in the other case, the algorithm executed on a tightly coupled system.

The main reason is the difference of the algorithms. The loosely coupled parallel execution outperforms the tightly coupled for dense matrix-vector multiplication, in which, the matrix $A_{N \cdot N}$ is divided horizontally among processors for row-major memory, and implicit fetching is not used, while it is used only for the vector $B_{N\ cdot1}$, as presented in Fig. 11 a). However, its dimension is $O(N)$, while the matrix dimension is $O(N^2/p) \rightarrow O(N^2)$ is dominant, because the number of processors $p << N$.

On the other side, Fig. 11 b) presents the data that is accessed by the processor P_i for parallel execution of dense matrix-matrix algorithm, which shows that each processor uses the whole matrix B and therefore, implicit fetching yields a superlinear speedup. In this case, the size of shared data among all processors is bigger than the private chunks of matrix A, as well as compared to the vector's size in dense matrix-vector multiplication.

Another issue is the way of storing the matrices. Without loosing generality, we will assume that a row-major storing is used. Accessing the data of the matrix A is linearly, which utilizes the cache lines and thus reduces the cache misses regardless of the cache size. For example, when accessing the element $a_{i,j}$, the elements $a_{i+1,j}, a_{i+2,j}, \ldots a_{i+k,j}$ are also fetched in the cache. The size of k depends on the cache line and matrix element sizes. Therefore, cache misses are generated for the element $a_{i,j}$ only. Accessing the elements of the matrix B does not utilize the cache line, because a column of the matrix B is accessed linearly. In this case, the cache size is very important in order to store as much as possible a part of the matrix B.

We must note that although very naive examples of dense matrix-matrix and matrix-vector multiplications were presented, the generality is not lost. Our goal is not to prefer this algorithm for parallel execution, but just to show how and when a superlinear speedup can be obtained, paradoxically, for various algorithm - totally different reasons.

Using a multi-tiered memory is not the sine qua non for superlinearity. As we presented an example in Section III-B2, Intel i7 processor has not obtained a superlinear speedup for the same algorithm, as AMD Opteron. For example, a superlinear speedup is obtained on Cray XMT [33]. Intel Xeon achieved a superlinear speedup for two processors using the data-parallelism benchmarking (Black-Scholes), but only a sublinear speedup with dense matrix-vector multiplication [34]. Therefore, having cache memory is only one of the conditions for the existence of a superlinear speedup. An important observation is to return to the speedup definition,

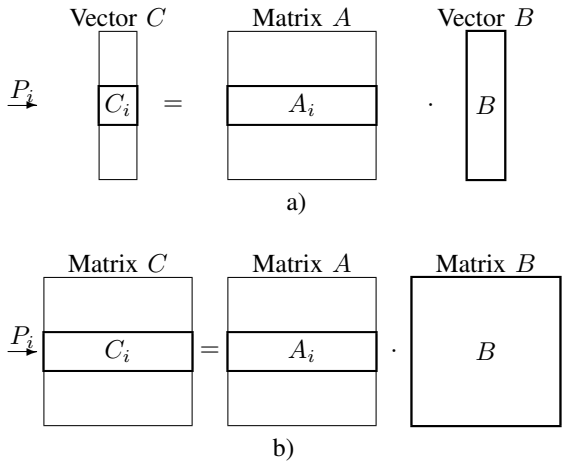

Fig. 11. Example of parallel implementations of matrix-vector and matrix-matrix multiplication.
a) Processor P_i uses chunk block A_i of matrix $A_{N \cdot N}$ and the whole shared vector $B_{N \cdot 1}$
b) Processor P_i uses chunk block A_i of matrix $A_{N \cdot N}$ and the whole shared matrix $B_{N \cdot N}$

i.e. to the benefits of parallelization that should compensate its overhead.

Also, another condition is to use cache-intensive algorithms, or to reuse of data; otherwise, having cache memory could be useless since, in both executions, each access will generate a cache miss. Even more, the superlinearity appears for some range of the number of processors, or for some problem size, or for both.

B. A new challenge: How to scale?

Cache-intensive granular algorithms, whose data reuse complexity is proportional to the problem size, will benefit from bigger cache. Many Intel's multiprocessors use a marketing trick with a huge L3 smart cache. However, one can easily check that it is not shared among all cores, but only among part of them. For example, 6MB of total 12MB cache is shared between each group of two cores. In this case, vertical scaling will utilize more the last level cache. AMD multiprocessors usually have smaller L3 cache, but it is shared among all cores of the multiprocessor. Therefore, depending on the algorithm, appropriate processor and scaling type should be chosen in order to achieve the best speedup, potentially superlinear.

On the other hand, today's cloud elastic resources can also be scaled in different ways: horizontally, vertically or diagonally, each of which can offer various performance and possibility for achieving superlinear speedup [35]. Vertical scaling provides a better speedup, but horizontal offers more flexible scaling of resources, which can minimize the cost.

C. Is the superlinear speedup always our target?

Achieving superlinear speedup does not necessarily mean that customers will obtain the maximum achievement. For example, the cache associativity in CPUs and GPUs [36] can provide a huge performance drawbacks for a specific memory pattern reading, and achieving the superlinear speedup for those inputs is not enough, but other techniques, such as padding, should be used. In the workflow executions in parallel and distributed systems, customers usually use bi-objective optimizations to minimize the makespan and cost. These two parameters are opposite one to another. Minimizing the makespan produces greater cost and vice verse.

Cloud computing customers can set a deadline for the execution requiring minimal cost, rather than minimal makespan [37]. In these cases, budget constraints and reducing the race for the speedup can yield the reduced cost for the execution. For example, although superlinear speedup is achieved in Windows Azure cloud for matrix multiplication when virtual machine instances with Windows operating system are used, Linux virtual machine instances achieved better performance cost trade-off because they are cheaper.

On the other side, there is a risk of cloud resources performance variation and instance failure during the time. Increasing the budget by duplicating the tasks on more than one instance could mitigate those risks, in order to meet the deadline [38]. Sometimes, using a bigger instance executes the task faster, rather than waiting several minutes for the deployment time to start another smaller, but an appropriate instance, which reduces the turnaround time of an activity [39].

VII. Conclusion and Future Work

Since the race in processor's frequency (Gigahertz) was abandoned a decade ago, which in the meantime has been migrated into the TOP500 race [40] for hunting ExaFLOPS, this overview of superlinearity could have an impact in the supercomputers' architecture and design, since the goal of each parallelization is to achieve the maximal speedup, which is superlinear.

The defined taxonomy for various scalings and definitions of superlinearity can open new ways for parallel and distributed systems. Defining how much to scale the resources is insufficient. One needs to define how to scale. Algorithms that can benefit from greater cache memory should scale vertically, while those that need to finish more work in a given time, should scale horizontally.

This paper overviews many reasons and presents practical cases to achieve a superlinear speedup when an algorithm is executed using various scaling. The analysis can help to maximize the utilization of the parallel and distributed hardware [41].

This work summarizes and discusses several cases for the appearance of superlinearity. Superlinear speedup in non-persistent algorithms appears due to a smaller number of executed operations. Mainly the superlinear speedup performance in persistent algorithms occurs due to the increased cache resources in the parallel computer architectures, the prefetching of shared variables in shared memory organization, or better scheduling in heterogeneous environments. The effects of the shared memory architectures also impact the performance behavior of the granular and scalable algorithms. All these analyses will guide the developers of parallel implementation

not only how to parallelize a given problem, but to choose the most appropriate environment and scaling type in order to achieve the maximal speedup.

Additionally, this analysis opens many challenges, such as finding a correlation among parallel hardware's architecture and organization, a certain form of a parallelized algorithm, a parallelization technique, the server load and input problem size, and other possible factors that impact the existence of a superlinear speedup.

Further focus will be towards modeling the speedup by considering all these factors, as well as to determine an analytical relation of a complex computer system that will enable the conditions for superlinearity. Additionally, our challenge is to model the multidimensional space of superlinearity, which will determine the value of superlinearity by considering the problem size region and the region of the number of processors. Since this paper focuses on granular high performance algorithms, we would analyze and define the taxonomy for *scalable* algorithms, in which many tasks that are coming, are scattered among parallel processing units.

ACKNOWLEDGMENT

Education, Curricula & Research Methods

ECRM is a FedCSIS conference area aiming at interchange of information, ideas, new viewpoints and research undertakings related to university education and curricula as well as recommended methods of doing research in all computing disciplines, i.e. computer science, computer engineering, software engineering, information technology, and information systems. This area spans typical FedCSIS events (conferences, workshops, etc.) with rigorous paper submissions and review processes as well as panels, PhD and research consortia, summer schools, etc. Events that constitute ECRM are:

- IEES'16 - 1st International E-education Symposium—Education of the Future
- DS-RAIT'16—3rd Doctoral Symposium on Recent Advances in Information Technology

1st International E-education Symposium—Education of the Future

THE idea of the conference is a meeting of scientists, researchers and business sector in order to determine the development of the changes which are taking place in modern education. Solutions like cloud computing, virtualization or high performance computing are changing the nature and extent of education. Disappearance of barriers and boundaries between regions and sectors mean that education must adapt to the modern world. The conference participants will be able to discuss existing solutions, focus on the problems of their implementation and the risks and benefits that may involve.

***Abstract*—We describe an education model that was developed and put in place to improve student engagement and attainment in a first year undergraduate programming course.**

The work is founded in a checkpoint-based formative assessment experiment undertaken for two years, the success of which is analysed in this document. The results provide evidence leading to a move towards a blended model of education, which requires the design of a software application to support the system. We present the main features of that application, covering aspects that range from traditional approaches and established delivery methods, to e-learning and MOOCs with, for instance, gamification.

This blended model of education fosters the development of a teaching practice that adapts to student diversity through informed teaching.

I. Introduction

FIRST year higher education undergraduate teaching is normally challenging for most areas: students face issues when transitioning from the school system; the class as a whole presents an inhomogeneous skill diversity. This is certainly the case in computer science, an area that attracts candidates with many different backgrounds. A particularly challenging topic within the discipline is the induction of students to programming [1], [2]: students taking a first year undergraduate course in that subject range from those who have never seen a line of code, to those who have completed software projects at school.

This document describes and evaluates a formative assessment experiment undertaken for two years in such a first-year course: the practical sessions were radically transformed by the introduction of a *checkpoint system*. The main goal of this new approach was to improve student engagement and attainment, but other objectives were also taken into consideration when designing the system.

Lab sheets with strategically placed low granularity checkpoints drive the practical sessions, which are supported by teaching assistants (TAs). Their role is to validate the checkpoints, provide help and feedback to the students, and gather data. Updated on a weekly basis, a checkpoints map measures how students progress through the course, and is used to inform teaching: early failure triggers quick remedial actions; high achievers are provided with challenging material; the contents of the sessions are adapted weekly to the overall pace and performance of the class. The experience of running this model for two years proved successful, with high student engagement and very positive feedback both from academic staff and students.

The analysis of the experiment has led to the development of a blended learning model to support practical sessions. Blended learning [3], [4], [5] uses both paradigms of traditional brick-and-mortar teaching, and online digital technologies, taking stock of techniques proven successful in e-learning and MOOCs, for example in the context of primary school mathematics education [6].

The course already uses Moodle to publish all its material, namely the weekly lab sheets used in practical sessions. The approach we propose includes extensions based on gamification [7] and a semi-automation of the checkpoint validating process. This is achieved through a software application, which design is described in this document.

The remainder of this paper is organised as follows: Section II provides context to both model and experiment, which are described in Section III. Section IV details the qualitative analysis of the experiment, and leads into a discussion on moving towards a blended model of education, presented in Section V. The checkpoint system is supported by an application described in Section VI. Section VII discusses related work, and Section VIII presents the conclusions.

II. Context

A. Teaching first year students

Formative assessment plays a major role in teaching computer science at our department, in particular when it comes to programming. Students start the degree with a great diversity of individual skills, which adds to the challenge of getting all of them to the end of first year with a similar body of knowledge. Treating that range of ability as an homogeneous body raises lack of engagement at both ends of the spectrum, which has been observed during many years of teaching experience in the department. As such, we need tools that help us both address failure at a very early stage, and encourage students who have a high level of familiarity with the subject to move on to more challenging material.

Each course delivery takes that diversity into account, to some extent. However, when it comes to first-year practical sessions, this aspect plays a major role: those sessions are, for many students, the first contact with written computer code. Students with different backgrounds proceed at different paces,

and a one-size-fits-all approach will inevitably fail to engage at least two kinds of students:

- those that are further dragging behind after each session, skipping most practical exercises and writing very little code;
- those that already know how to write some code and would appreciate a higher degree of complexity in the presented material.

An example of a first-year course with a strong practical component is CS1801 – Object-oriented programming. It spans over the two teaching terms and is taken by all single and joint-honours undergraduate computer science degrees. During the course, students learn the concepts of object-oriented programming that will be used through the entire degree and in their future profession. Acquiring those essential skills is critical to their success during the following years.

B. The CS1801 course

The course structure follows a traditional approach. Every week, there are two one-hour lectures, delivered to all the cohort in one go, and one three-hour practical session, organised in groups of approximately 30 students each. The uneven level of the students prevents the lecturer, during a practical session, from addressing the attendants as a whole. That problem is addressed by the presence of TAs for one-to-one interactions with students that have questions or are lost.

Each practical session is attended by three TAs, one per 10 students, which amounts to an interaction average time of 18 minutes per student per session. This can seem a lot of time, but in a three-hour session it corresponds to 6 minutes per hour – too short a time for detailed feedback.

Students are given a lab sheet that they are supposed to complete by the end of the session, but can carry from one session to the following ones, proceeding at their own pace. The lab sheets consist of several programming exercises, which the students have to code, compile and run. The exercises cover material from the lectures, and also include revisions from previous practical sessions. Completing the lab sheets plays an essential role in acquiring the skills of a proficient programmer: any developer knows that going from the pseudo-code written in a piece of paper to the real thing running on a computer requires a great deal of craftsmanship [2]. This learn-by-doing process of trial and error is regarded as one of the central aspects of education, and is not specific to computer science. For instance, In his 1984 book on *experiential learning* [8], Kolb emphasises the role of discovery and experience as sources of learning and development.

What we observe, however, is that many students fail to engage with the lab sheets: they do not tackle most of the exercises, leaving the sessions with important gaps in essential skills. This leads to a gradual block in their progress (most tasks require material from previous checkpoints). Furthermore, given that the acquisition of craftsmanship is a slow process requiring repetition, the more they drag behind, the less a chance they have to recover: it becomes a slow road to failing the course and, most probably, the first year.

The lack of engagement of some other students happens for different reasons: the presented material is trivial for their level; attending practical sessions is viewed as a mandatory boring activity. To address that issue, there are exercises, towards the end of the lab sheet, specifically aimed at highly-skilled students. They present interesting challenges requiring both problem solving and code proficiency. These are exercises that benefit from fruitful one-to-one interactions, which would need to be longer that the 18 minutes allocated to each student.

Overall, regardless of the motives, we observe a general tendency among students: even if the TAs are available and willing to help, most students will choose skipping exercises over calling the TAs.

III. An experiment in the practical sessions

A. Checkpoint system

During the last two academic years, with the main goal of overcoming the lack of engagement, but also in response to feedback provided by student and staff on the teaching of programming, we have conducted a formative assessment experiment in the CS1801 practical sessions: in each session, students have several checkpoints that help us (and them) keep track of their progress.

The process is coordinated by a lecturer, and follows the steps detailed below. We would like to note, as an early motivation of a blended model, that all these steps were conducted without any tool support, being therefore onerous in terms of time and dedication.

1) Lab sheet: A highly structured lab sheet is published on Moodle at the start of each practical session – this contains not only exercises, which are separated by well-identified (and strategically placed) checkpoints, but also examples and hints on how to approach the different tasks.

2) Practical session: During the session, each TA has a list with the checkpoints that every student has completed so far. When a student reaches a checkpoint and calls a TA, the checkpoint is verified – which consists in checking if the tasks were correctly completed, and the checkpoints list is updated accordingly.

3) Processing the information: Before the next practical session, the lecturer merges the information from the individual sheets, and publishes the updated list on Moodle. The history of those weekly updates is kept for reference – it shows the individual learning curves.

4) Publishing the results: At strategic points during the term, the lecturer produces a report with every student's achievements. This is used for internal monitoring of progression, and for deciding on any remedial actions.

B. Verifying the checkpoints

Every student has a different way of approaching checkpoints: some will regularly call the TAs at each checkpoint, others will prefer to have them verified in bulk. Nonetheless, whatever the approach, we have identified three stages at which students choose to have their checkpoints verified.

1) Complete solutions: Some students make sure that they have gone as far as they can, and present a program that not only works, but often will have different solutions for the same task. They expect the TA to give them advice on which solution is better, to comment on the code, and to encourage them to dig deeper.

2) Good attempts at a solution: Most students will consider a checkpoint ready to be verified as soon as they have written a snippet of code that compiles and presents a reasonable behaviour. Those programs will often miss particular cases and clever solutions, and the role of the TA is to inform the student about those alternatives.

3) Insufficient work: There are a few students that call the helper as soon as they have something that resembles the desired outcome. They expect to get major help from the TA in order to complete the task.

C. Acting on the results

One of the main aspects of using the checkpoint system is the ability to act on the gathered information. This is done at two levels: the information concerning a student allows for quick remedial actions; the information about the progression of the class as a whole provides a measure of the overall pace, informing the design of the lab sheets from session to session. If the entire class is lagging behind on a specific lab sheet, the following session can be lighter, allowing the students to catch up and relieve a possible frustration.

IV. Analysis of the experiment

A. Student engagement

The results of the experiment are presented in Table I, which only covers the first term of each year. There are significant differences in the approach to course delivery within both terms, which led us to focus mainly on the first term.

1) Differences between the two terms: In general, the level of student engagement drops during the second term, which is partially due to an increase in the number of checkpoints from one term to the other. Both terms have eleven practical sessions, but the last four sessions of term one are dedicated to the students that still have checkpoints to verify. All the other students no longer have to attend the sessions, dedicating this extra free time to other courses where their new skills will thrive in concrete applications (like, for example, games or robotics). For the students that are required to attend the remaining CS1801 sessions, there is no introduction of new material, and given the reduced number of students, the average support time from TAs is much higher.

We have observed that, during the second term of both years, the increase of 50% in the number of checkpoints (from 26 to 44 in 2014/15, and from 28 to 40 in 2015/15) leads to a decrease of approximately 75% in the overall rate of completion, when compared to the corresponding first term. The material studied in the practical sessions is also more complex during the second term, and the number of exercises is higher. All these contribute to the lack of engagement during the second term, and one of the reasons we went for the design of a blended model is to achieve, during the entire year, the success rate of term one.

TABLE I
Student engagement during the first term

	2014/15	**2015/16**
Number of checkpoints	24	28
Number of students	83	113
Students with more than 50% of the tasks verified	93%	88%
Students with more than 75% of the tasks verified	87%	77%

TABLE II
CS1801 results for non-repeating students

	2012/13 – 2013/14	**2014/15 – 2015/16**
Grade average	59.4%	66.2%
Failing students	19.6%	13.6%

2) The success of term one: In term one, as Table I shows, approximately 90% of the students complete more than half of the tasks. Given that this corresponds to the least amount of work expected from an average student, the percentage shows a very good level of overall engagement. Moreover, approximately 80% of the students complete more than three quarters of the tasks, which shows a high level of participation.

These numbers are not directly comparable to any measures from previous years (no control was done during practical sessions), but a measurable outcome is the level of success in the mid-year CS1801 test, which is a piece of formative assessment conducted on a weekly basis, from weeks 7 to 11 of term one. The students that achieve a grade above 85% are released from the lectures for the rest of the term. Usually, by the end of term one, most students will have succeeded in passing the test, but we have observed that, with the introduction of the checkpoint system, students are reaching the passing grade earlier.

3) Summative assessment outcomes: Summative assessment for CS1801 consists of several small pieces of coursework (10% of the final grade) and an exam (90% of the final grade).

The checkpoint system was introduced in 2014/15 and has been running for the last two academic years. Table II presents the outcomes of those two years, comparing them to the two previous years. In order to better measure the effect of the experiment, we have only considered students taking the exam for the first time – repeating students may have undertaken more programming courses, which gives them a clear advantage. The results indicate a significant increase in the success of summative assessment: higher grades and fewer failing students. However, these first observations still need to validated by a proper statistical analysis, for which we are gathering further data.

B. Further improvements

When looking at the numbers, and whilst the experiment can be considered successful, there are still 20% of the students

that are missing one quarter of the checkpoints, which is a significant number. To identify these students, we need a closer analysis of the process. The students have different levels of interaction with the TAs; the nature of those fundamental and time-consuming interactions reflects the level of the student, and raises different types of frustration.

1) Skilled students: Students with a prior knowledge of programming are very confident of their skills, and fail to realise that, although they have some programming abilities, there are specific requirements (for instance the style of the code and its readability by other programmers), which they are not familiar with. They regard the checkpoint system as a boring formality, and will skip it altogether. However, most of those students, when forced to check their work by an engaging TA, come to the conclusion that having skilled programmers reviewing the code is always a fruitful source of knowledge.

Skilled students tend to persist on recurrent mistakes and, in general, overestimate their abilities. It is not rare to find, in solutions presented by those more experienced students, many fragments of *bad code* that reveal misunderstanding and confusion. One such example is the following Java snippet (while being fully functional, it certainly leaves a bad impression on any trained programmer):

```
public static boolean negate(boolean a) {
  if (a == true) return false;
  else return true;
}
```

The student that produces such a piece of code is certain of having reached the goal of the task, but is missing important notions of programming. Those gaps in the acquired knowledge are mended by the interaction with TAs.

2) Struggling students: Students that are having a great deal of difficulty with programming feel uncomfortable asking for help, in particular when they look around and observe colleagues progressing at a faster pace than they are. When talking to those students, the variety of entry requirements becomes apparent: since neither mathematics nor programming are required, students that have taken those courses during their undergraduate studies are at an advantage. We also insist regularly on the fact that the learning outcomes should be measured by the end of the year, and that they should keep on trying. However, this does not prevent their frustration and/or impression of underachievement.

3) Limited resources: There is also the overhead of checking the exercises. The resources are limited, and sometimes students have to wait a considerable amount of time before getting checked. As they have to call a TA as soon one becomes free, this may end up being tiresome. Some students simply abandon the process midway.

C. Student satisfaction

There are several factors that affect the way students perceive the effectiveness of a course delivery. In the context of our experiment, we could identify two main perceptions among students: checkpoints are viewed either as a reward system, or as a remedial plan to address failure. Those different perceptions entail different ways of interacting with the system, leading to variable outcomes.

1) Feedback from students: Every term, students fill in a feedback questionnaire provided by Royal Holloway. Those questionnaires are highly detailed and present an overall picture of the course status. In the feedback forms for 2013/14 – term 1, 10 comments (in a total of 18) complain about the practical sessions. In the corresponding feedback forms from 2014/15, when the checkpoint system was introduced, 29 comments (in a total of 56) specifically mention good points about the practical sessions. The same tendencies were observed for the second term, although with less significant numbers. Anonymous comments included:

> "Compared to last year, the new format of the lab is much better."
>
> "The checkpoints in the labs were a good way of tracking progress."
>
> "Tasks on the lab sessions were chosen very well."

Besides those standard course feedback questionnaires, we foster further discussion with both staff and students to identify possible improvement opportunities. The yearly feedback provided by the students' committee for 2013/14 (the year preceding the introduction of checkpoints) mentioned that the practical sessions were delivered at a "too fast pace for people with little experience". During the next academic year, in the mid-term one-to-one meetings with their advisors, students were directly asked about the impact of checkpoints on their learning experience. The response was unanimous in acknowledging the system as extremely helpful. This impression was reiterated in the general feedback from the students' committee for 2014/15.

2) A rewarding system: The checkpoint system is perceived by students as a reward for their effort. Most students view this as an incentive, others as a way of monitoring their learning, and some even view the system as a competition. In general, they agree that the checkpoints really help them progress.

The responsible for the Student Experience in our Department has provided feedback about the system [9]: "The checkpoint system provides immediate formative feedback to the students. Students can identify problems and then in the lab discuss with the TAs what their problems are."

Given that a satisfied student is a better student, the positive feedback from students partially validates the effectiveness of the process. Furthermore, it also informs the approach, enabling a continuous fine-tuning of details in response to input from students.

3) Personal development: There is a growing awareness of the need to develop personal skills such as the ability to communicate, to present oneself with confidence, and to tackle unfamiliar problems. More generally, students' personal development should be understood to cover aspects of educational development (for example, the ability to use feedback to improve performance or to make use of educational resources such as Moodle or the library) and of career development

(for example, understand professional issues associated with careers in IT or the ability to work effectively in teams).

Questionnaires give evidence of students' perception of the quality of support that they received. However, to act on such responses and improve our support, one also needs to:

- understand the expectations that students have in relation to their personal development;
- ensure that students understand how, through the received feedback, they are given the opportunity to develop those personal skills.

That is, students need to take ownership of their development, and they cannot do so on a vague understanding of what support they are provided with.

Our Head of Department has provided feedback about the system in this context [9]: "The checkpoint system is an excellent contribution to allowing students take more ownership of their personal development. It allows them to progress at their own pace by getting quick feedback on their performance and understand what they need to improve."

D. Informed teaching

At first, the system was introduced to promote students' engagement, by having them asking for help and interacting with the TAs. However, it ended up covering many other aspects of the student's learning process that deserve more attention and development. The system can, namely:

- maximise success and minimise failure in practical courses by continuously giving feedback to students on their progression;
- measure the pace at which each student progresses, allowing for early actions to be taken on the learning difficulties that are detected.

1) Acting on failure: The weekly feedback provided by checkpoints allows academics to take action early on.

A co-responsible for the CS1801 lectures has provided feedback about the system in this regard [9]: "The checkpoint system provides me with much needed timely feedback on student performance in the weekly labs. I can quickly grasp how well students keep up with the course material and can spot particularly challenging topics. This is invaluable especially in the first year, where many students do not easily come forward after lectures or during office hours to ask for clarification or help. In addition, it allows to spot students who seem to not be engaging with the course; their personal advisors can then focus their attention on these students during the tutorial sessions for the course."

Together with his feedback mentioned in Section IV-C2, the system has been deemed by the responsible for Student Experience, with respect to providing a continuous overall picture of students' progression, to provide staff members with feedback that is "immensely useful for the department particularly with respect to quickly identifying progress in CS1801 for the progressions committee."

2) Promoting success: During the first year of the experiment, we have regularly provided optional exercises in the lab sheets, aimed at the students that welcome harder challenges. However, we have observed that most students would simply ignore those extra tasks. We were even surprised by students complaining about not feeling challenged in the practical sessions, and confessing at the same time that they had never attempted to solve any of those extra tasks.

Under the hypothesis that this phenomenon was mainly due to the fact that those extra tasks did not correspond to an extra checkpoint, we have made small change to the lab sheets published during the second year of the experiment: for each practical session, we have moved those optional exercises into a *platinum* checkpoint. And, in every weekly status update, we have published the results of the platinum checkpoints along all the other ones. The result was surprising: this simple alteration has triggered a much higher student participation in those extra tasks.

Observing the success of platinum checkpoints, we are led to consider the system as a tool enabling a fine analysis of the students' behaviour, both when addressing failure and when promoting a higher level of engagement for highly skilled students.

V. Towards a blended model of education

The success of the experiment lies in both the achieved results and, more importantly, the room for improvement that the process seems to present with respect to automation. Indeed, there are several aspects of the checkpoint system that would greatly benefit from automated or semi-automated mechanisms involving online techniques.

A. Assessment and feedback

The checkpoint system provides continuous feedback on each student's progress. With an average of four checkpoints per practical session, students reach the end of term with more than 40 checkpoints.

Since the results are made available every week, both students and academics have a detailed perception of individual learning curves throughout the term. We aim to combine those qualitative appreciations with a score (1-3 stars) and a badge-reward system (similar to the ones implemented in games and other scenarios [10]). Platinum checkpoints are a first simple example of what special badges can achieve, namely when it comes to encouraging students to complete the most challenging exercises.

B. Bringing the MOOCs to the classroom

MOOCs have been, in the past two years, gaining traction as a model for massively teaching students off campus. Although the results are mixed and debatable, some of their characteristics are remarkable: active learning (self-pacing and instant feedback) and gamification (with, for instance, badge-awarding systems).

What we intend is to bring those successful aspects of MOOCs to the classroom. According to Anant Agarwal, CEO

of edX, this process is about "taking ... the technologies we are developing in the large and applying them in the small to create a blended model of education" [11].

We propose to bring teaching, assessment and gamification techniques from MOOCs to the classroom, namely:

- students are able to follow the sessions at their own pace;
- progression to the next level only occurs when the previous levels have been completed, understood and verified;
- badges encourage students to perform better in the achievement of specific goals;
- the visualisation of progress bars and learning curves provides students with an overall perception of their performance.

C. Advantages of an automated system

We have identified the following possible improvements.

1) A first response line: If the code written by students is submitted to an IT system instead of being directly present to a TA, a few automatic tests will provide feedback to students on how to correct common mistakes. Several systems for automatic assessment of programming assignments exist, with different levels of support and feedback, as discussed in [12]. In our case the complexity of the tests can vary, but they constitute an automated line of action that will rely on human assistance only when necessary: the TAs will be called fewer times and their overall availability will increase. Furthermore, the automation trivially orders TA requests by submission time, which frees the student to start working on the next checkpoint after the submission of the code, instead of recurrently looking for an available TA.

2) Speeding up feedback: The automated submission also provides different levels of feedback, going beyond the typical interaction with the TAs. After passing the code through several tests, the student may get specific feedback on particular mistakes without interacting with a TA. Nonetheless, the TAs will always be available to provide further detail, if necessary. When the system is not able to provide automated feedback, a TA is called. Whatever the reason to call for human help, the responding TA will have a device with available information about the student's checkpoint history, the current checkpoint, and the code issues. This will speed up the process of interaction, during which the TAs can spend a considerable amount of time going through the checkpoints and looking for problems in the code before being able to help the student.

3) Increased promotion of different paces: The lab sheets are published on a weekly basis, rather then in bulk. The rationale behind this procedure is to allow the progressive unfold of a story during the term, for which the sessions sequence is essential. However, this approach has two main drawbacks:

- the faster students will finish the lab session in less than two hours, even when completing some optional harder tasks, which leaves out an hour that could be used to progress to the next tasks;
- some students will get stuck on a particular task and, although we insist that students may move on and come back later to that particular problem, some future tasks may depend on the left-behind task, and students get sometimes confused about what they know, and what they still have to acquire.

An automated system would overcome these issues by using a graph of task precedences that would allow all the tasks to be published at the same time, disabling those that require previous tasks to be completed. As soon as a student completes one checkpoint, the system will display any new available checkpoints. Also, any disabled checkpoint will display the tasks that are required for its unlocking. This also doubles as a knowledge map, where students can easily find paths leading to the acquisition of a specific skill.

D. Further aspects of an automated system

Beyond the advantages described in Section V, the checkpoint system automation would also provide a realtime source of information about the students' progress, both individually and as a whole. Different ways of looking at the data provide different insights. An automated system could easily provide charts with realtime statistical analysis, that can include the progression curve of one student or of the class, a classification of students according to several filter options (number of completed checkpoints, total score, ranking), comparison between several years and sessions, etc.

VI. Designing the application

In order to fulfil the mentioned goals and provide a better service to both students and academics, we have designed a web-based application that automates the checkpoints process. Running on the browser of any computer (desktop, laptop, tablet or phone), the application may be used by lecturers and students alike. The basic functionality of the checkpoints mechanism will be supported by a core module, and an API will provide the ability to extend the application with additional useful features that can enhance the learning experience of students, individually and as a whole. A proof-of-concept prototype has been developed and is functional, covering some of the essential features. The final application is under development since early 2016.

The outcome of this development is a software system that will not be specific to computer science, and that can be used by any discipline to provide formative assessment in practical sessions. The overall goals of the system are to:

- monitor student achievement and performance;
- reward the student with a score corresponding to those achievements and performances;
- measure the difficulty of exercises by looking at the overall performance of the class;
- adapt at runtime the delivery of the practical sessions to the level of the class, and propose course revisions for the next years;
- give tailored content to students that have specific difficulties or a higher level of achievement;
- provide a methodology for exercise-based sessions that can be used in a systematic way.

A. Overall description

During a typical session, students are working on computers where they can submit their checkpoints. TAs will have portable devices (tablets) that they use to identify students in need of help, and to verify the checkpoints.

When the users log into the system they have access to a general view of their account where they can either edit personal information, or select a course. Inside the course, each type of user has different options, as described below.

1) Students: Students are able to view rankings, individual achievements, and an overall picture of the checkpoints. In that view, students access the graph of checkpoints for the course, as well as the checkpoints that are completed and those that are unlocked, given the current score. There is also a graph with the learning curve of the student with respect to that course.

2) Academics: Academics are able to edit the graph of checkpoints, add new checkpoints, and monitor all the students' activities. They are also able to create rewards awarded to students when they reach certain points of the graph, or certain scores.

3) Administrators: Administrators have a different kind of access, allowing them to create courses and to perform functionalities such as management, monitoring and maintenance.

B. Definition of checkpoint

A checkpoint is a set of tasks that students have to perform. Usually that set is small, as fragmentation is an essential aspect of checkpoints: overcoming several small challenges is more rewarding than dealing with a complex task that will take long to complete [13].

The contents of a checkpoint can have several declinations: tutorial with simple tasks, complex tasks requiring problem solving, quizzes, etc.

The students' general view of all the checkpoints in the application highlights those that are accessible. Regardless of accessibility, each checkpoint displays a description of its content. This allows the student to understand, with the help of the graph, which checkpoints need to be completed before acquiring a specific knowledge.

The students' work on a checkpoint is independent of the software application, which only manages checkpoints and deals with the submitted material. This allows different kinds of disciplines to use the system. In the case of CS1801, for example, students work on a Linux server using an editor of their choice, and a Java compiler. Once the student considers that the tasks are completed, they upload the relevant files to the application and wait for the verification process.

C. Verifying a checkpoint

The solutions to the checkpoint tasks are verified by an automated system and/or a TA. The verification by an automated system requires the solution of the tasks to be submittable to an electronic system. In the absence of that feature, the system will always rely on a TA to verify a checkpoint. In this document, we will consider that the students are able to submit a file to get the checkpoint verified by an automated testing mechanism.

The verification process may have several outcomes, including the need to go back to the tasks in order to correct critical mistakes. One crucial aspect of a checkpoint is that is can be attempted several times: each attempt can result in a better outcome, which may also be awarded a higher score. This characteristic is aligned with literature on gamification [14], and with the article by Karpicke and Blunt [15] where they conclude:

> "Research on retrieval practice suggests a view of how the human mind works that differs from everyday intuition. Retrieval is not merely a readout of the knowledge stored in one's mind; the act of reconstructing knowledge itself enhances learning."

Hence, the students overcome mistakes by trial and error, which is a procedure they are familiar with [8].

Figure 1 shows the flow involved in the verification of a checkpoint. Each step of the process is detailed below.

1) Working on a checkpoint: The student is working on the tasks of the checkpoint. Some help from the TAs may be required, but students are encouraged to work on their own and submit solutions they deem adequate.

2) Submitting the tasks: When a student finishes a set of tasks, they upload the relevant files to the application, or fill in a form with the outcomes of the task (depending on the nature of the task). In the specific case of CS1801, the student submits a Java source file. As soon as the submission is done, the checkpoint becomes unavailable until either the verification is completed, or the process is cancelled by the student.

While waiting for the verification, the student may start working on any other unlocked checkpoint. The student may also choose not to submit the solutions to the tasks, but this means that no new checkpoints will ever be unlocked, and the student will eventually get stuck.

3) Testing the submission: A series of automated tests are performed. This first line of action looks for common mistakes that are easily detectable, and for which some feedback can be provided without any human intervention. Sophisticated tests can also be performed, if such a test suite is available for the discipline that is using the system. In the case of CS1801, a series of automated tests allow a complete verification of the checkpoint (see Section VI-D).

4) Getting feedback: If the tests are not passed, the system will try to provide some automated feedback to the student. If that feedback cannot be produced, the application puts the submission in the TAs' queue: a TA will be notified and the student will eventually be approached to get some oral feedback, or to have the checkpoint validated. This may happen when, for instance, the student has an easy-to-fix error in the code.

5) Validating a checkpoint: The validation of a checkpoint can be automatically completed by the application, or require the intervention of a TA. In the latter case, the TAs use their tablets to capture a QR code on the computer of the student (uniquely identifying the student-checkpoint pair).

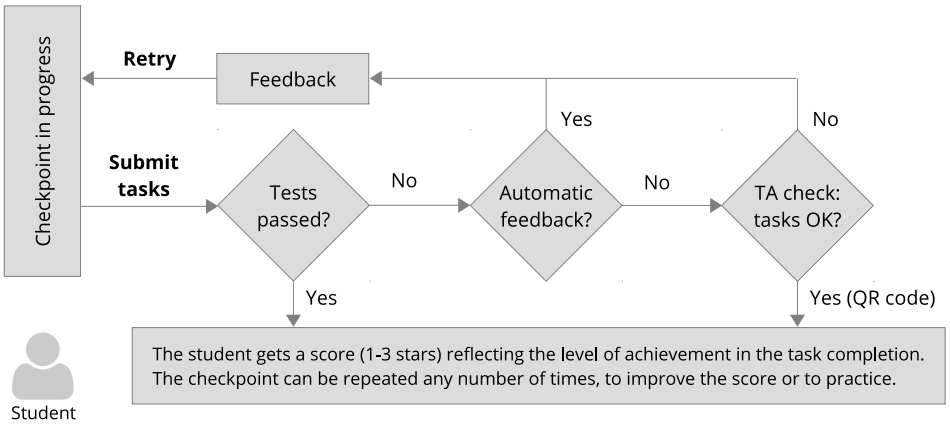

Fig. 1. Verifying a checkpoint with the application

This will bring up an interface that allows the TA to score the checkpoint. When the checkpoint gets validated, some new checkpoints may become unlocked.

6) Score: When the checkpoint is validated, the student gets a score (1-3 stars) based on several criteria. This score can be automatically provided by the system, according to the outcomes of the test suite, or it can be attributed by the TA.

D. The submission assessment for CS1801

The submission of a checkpoint consists of uploading the file with the code to the server. The file is then submitted to a series of tests that check if the code corresponds to what was asked in the set of tasks. The tests are sequential and follow the steps described below, shown in Figure 2.

1) Compilation: The first requirement to complete a checkpoint is that the submitted code compiles. If the compilation issues warnings, the student may be given some automated feedback that will suggest improvements on the code.

2) Unit testing: The exercises have specific outcomes that allow unit testing. For example, a program that defines a class can be tested by creating an object of that class and calling its methods. There are several tests for each exercise; those tests can be weighted in order to assess the student accordingly. The number of stars the student is awarded for the checkpoint will increase with the number of passed tests.

3) Checking the style: Students often write code that does the required job, but presents stylistics flaws that, even if they are optimised by the compiler, show some gaps in the acquired knowledge. One of the goals of CS1801 is to get students to write programs that are readable and free from *bad code*.

E. Prototype

We have developed an early prototype that covers the following functionality:

- log in with testing accounts;
- set different groups of checkpoints (emulating a course);
- organise, in each group, a linear sequence of checkpoints;
- view the stages of completion of each group of checkpoints;
- view the unlocked checkpoints;
- view the locked checkpoints, and the precedences that unlock them;
- verify a checkpoint using a QR code.

F. Extensions to the prototype

The application extends the prototype with the following additional features, most of them via an API.

1) Remote authentication: The users can use their usual credentials, which are securely fetched from a remote server.

2) Timed checkpoints: When a student starts a set of tasks, a timer is activated to measure the time spent on that checkpoint.

3) Graphical representations of data: Several views of the students' progress, individual and by groups, will help both students and teachers have snapshots of the students' status and the learning curves.

4) Graph of checkpoints: Students can progress according to their actual skills, in a non-linear fashion, instead of having to follow a sequence of checkpoints that may not be the most adequate to their learning curve.

5) Automated verification process: The submissions are subjected to an automated suite of tests.

6) Enhanced gamification: Student's achievements will be awarded trophies, rewarding effort – not just success; those trophies are viewed by other students and establish peer motivation.

7) Students' feedback on the exercises: Academic staff will receive a constant measurement of how students perceive the exercises, allowing them take early action and adapt the exercises to the needs of the students.

8) Look and feel: The new features will require a revision of the application user interface.

VII. Related Work

A. Checkpoints

The notion of checkpoints applied to support teaching of programming has been used for some time. The concrete goals have ranged from formal assessment [16] to testing the rate of student progress and improve the process [17]. The

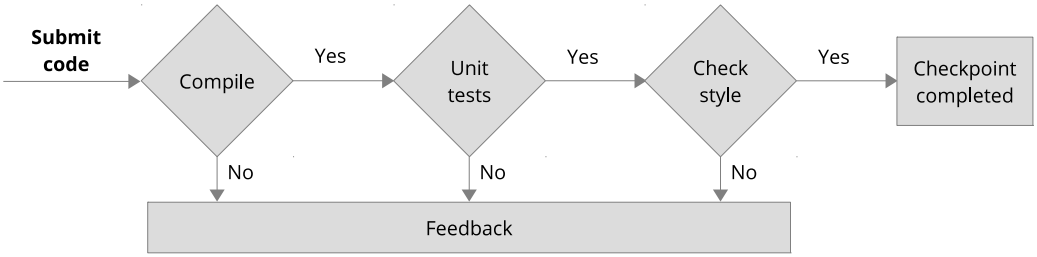

Fig. 2. Automated test sequence for CS1801

granularity at which these are used also varies significantly. In some models, checkpoints are set after small exercises are completed [18], whilst others set these only when more considerable tasks are finalised [19]. In the case of our approach, the checkpoints are designed at a low level of granularity to allow both a detailed view of student progress, and a good understanding of the difficulty in each set of tasks. However, the application is also suited to different approaches, like for instance long sessions focusing on one single difficult task.

The way the completion of these checkpoints is taken into account also varies. The results are logged in various fashions, ranging from simple manual accounting to free [20] and commercial tool support [21], [22]. The model we present includes the design of a toolchain that takes into account the required granularity of the specific checkpoints, fosters a good user experience for both assessors and students (e.g. the use of QR code recognition so that manual input is minimised), allows for a graph of dependencies, and is integrated with some gamification concepts.

Checkpoints are also used either as a means to assist in supporting students in traditional programming laboratory settings [21] or as part of automated assessment [20]. Our approach still includes traditional sessions, where students are presented with exercises and benefit from the support of teaching assistants. But it also takes advantage of modern techniques, such as those widely used in Continuous Integration, to reduce the amount of required intervention and to give immediate feedback to students.

B. Serious games and gamification

Serious games were introduced in order to facilitate purposes other than simply entertainment. These ranged from games in a general sense as described by Abt in 1970 [23], to digital games as presented more recently by Sawyer and Rejeski [24] and Michael and Chen [25]. Whilst sharing some concepts with serious games, *gamification* [7] focuses on using game elements to enhance several activities, rather than having users specifically play a game. These activies include learning [26], [27], business [28], and even self-help [29]. The model we describe uses the concept of gamification to improve student engagement in practical sessions (and with the goal of improving attainment), whilst resulting in better learner analytics.

C. Blended learning

Blended learning [3], [4], corresponds to models where the Internet and digital media are combined with traditional classroom settings. In his 2012 report [30], Friesen presents the following definition:

> "Blended learning" designates the range of possibilities presented by combining Internet and digital media with established classroom forms that require the physical co-presence of teacher and students.

This technique was used in the context of our approach as a means to reap benefits from both worlds. Traditional practical sessions allow close support and quick and helpful feedback, whilst the digital content and automatic checks accelerate the administrative process and allow students to focus in learning how to think computationally.

D. Automatic checks

Automatically checking student programming work has been researched for many years [31], [32], and is still an active area [12], [33]. Whilst it is possible to use these techniques to address, for instance, issues of scale, the level of feedback and assistance still lags behind what can be achieved with direct support from experienced teaching assistants. Notwithstanding this gap, it is a useful approach that can be integrated with the traditional one. In the model we describe, this has been achieved by including automated checks to address a first line of issues, followed by human support when required.

VIII. Conclusion

We have presented a blended model of education motivated by a successful formative assessment experiment conducted in the practical sessions of a first-year undergraduate programming course. That model will benefit from the support of an application, which design was informed by building and testing a functional prototype. The application is currently under development, and will be deployed in 2016/17.

One of the main improvements in the final application, compared to the prototype, is the strong gamification component. We have observed how the introduction of platinum checkpoints has motivated some students to engage with harder tasks. We expect, similarly, the star-based scores and the

achievement badges to stimulate a higher level of overall engagement. Moreover, given the current trends in gamification research, this is an aspect with much room for improvement: the API will easily accommodate third-party awards like, for instance, Mozilla Open Badges [10].

We will evaluate and monitor the initiative mainly through: student feedback (advisor tutorials, one-to-one meetings and student feedback questionnaires); results of further formative and summative tests, including the final CS1801 examination.

This will allow us to consider any necessary improvements and evolve the model accordingly, before moving to a wider dissemination of the application that, by design, is not specifically targeted at teaching programming. Nonetheless, the system has the potential of creating a baseline of tools and techniques for other courses in our department that include exercise-based practical sessions, providing a clear added value: it allows the identification of students needing additional support, and measures the effectiveness/difficulty of particular tasks. By increasingly adopting this technique, the Department of Computer Science, as a whole, can have a better and up-to-date perception of student achievement and, hence, proactively make changes as necessary.

We also plan, in the future, to introduce a mechanism through which students can give a simple quantitative feedback on the quality and perceived difficulty of each set of tasks. Based on those pieces of information – as measured through performance and as perceived by students – academics will move yet another step towards taking more informed pedagogical decisions.

Pitfalls of E-education: from multimedia to digital dementia?

R. Robert Gajewski
Warsaw University of Technology
Al. Armii Ludowej 16, 00-637
Warszawa, Poland
Email: rg@il.pw.edu.pl

***Abstract*—This paper presents lessons learned from nearly 25 years long experiences with different forms of E-education. All experiences are definitely positive but during conducted research many pitfalls and traps were recognized and observed. Widely used multimedia materials do not motivate weak students to learn. Instead of learning they do prefer to watch materials in a passive way. Mobile learning in which all materials are available also for smartphones increased this attitude to learning. All quizzes and tests even very sophisticated cannot replace a real exam. Knowledge of the answers on hundreds of questions is not equal to the real knowledge of a certain field. Flipped classroom paradigm forcing to learn at home was not accepted by students. Moreover, E-education creates chances for e-cheating. All these pitfalls and traps lead to the conclusion that E-education is not a straightforward remedy for all current education problems.**

I. Introduction

IN 450 B.C Confucius aid: "tell me and I will forget, show me and I may remember, involve me and I will understand." As outlined by many researchers individuals remember much more details and information as well as for longer if they are more involved in the learning process. In 1946 Dale published his famous Cone of Experience [1]. Dale stated that the cone device can be a visual metaphor of learning experiences, where the different kinds of audio-visual materials are arranged in the order of increasing abstractness as one proceeds from direct experiences (see Fig. 1). One of the later extensions of this idea is a common opinion that individuals generally remember: 10% of what they read, 20% of what they see, 50% of what they see and hear, 70% of what they say and write and 90% of what they say as they perform a task. Moreover, the entire process of learning is split into two parts: passive learning and active learning.

Blooms Taxonomy proposed in 1956 [2] by a panel of educators chaired by Benjamin Bloom is a categorization of learning objectives as well as activities split up into three areas: cognitive (mental skills, knowledge), affective (feelings, emotional areas and attitude) and psychomotor (manual and physical skills). The cognitive domain most significant in higher education requires mental abilities and also knowledge. Within this domain one can find six major categories outlined from the most straightforward: knowledge, comprehension, application, analysis, synthesis and finally evaluation.

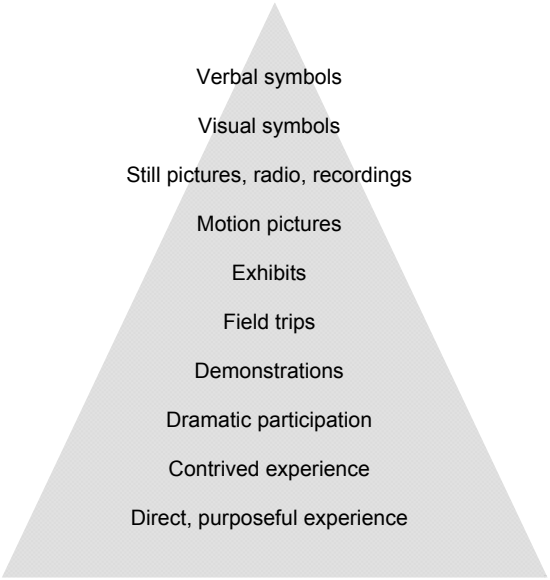

Fig. 1. Dale Cone of Experience

In the middle of 1990's the cognitive domain has been modified. Titles associated with different types have been transformed from nouns to verbs. Moreover, their order has been somewhat changed. Bloom's Revised Taxonomy [3] demonstrates to a greater extent the active way of thinking and also consists of six different categories: remembering, understanding, applying, analyzing, evaluating and finally creating. This taxonomy much better accounts for completely new behaviors and multimedia technology innovations (see Fig. 2).

E-education enables to take into account different learning styles [4]. Such approach increases costs of education but also increases its efficiency. In the class "one type of delivery" should satisfy all participants. E-education enables addressing different materials for different learning styles [5], [6] even for Computer Science and Informatics Courses.

This work was supported by 504/01921/1088/40 grant.

II. MULTIMEDIA

Multimedia materials were prepared for all subjects taught by the Division of Information Technologies (DoIT), namely Information Technologies, Fundamentals of Computing and Computational Methods in Civil Engineering in the form of podcasts – personal on demand broadcasts. First podcasts prepared by DoIT had the form of screencasts – "digital recordings of computer screen output often containing audio narration". Screencasts contain software animations helping students to learn how to use software. The second kind of podcasts are slidecasts – "audio podcasts combined with slideshow". Slidecasts have the form of knowledge clips – short explanatory presentations of a particular problem and its solution. The last kind of multimedia materials prepared by DoIT are webcasts – "media presentations distributed over the Internet using streaming media technology to many simultaneous viewers". In fact webcasts were lecture captures which were recorded and later distributed as podcasts. Tenths of hours of podcasts stored on an educational portal helped a lot during classes but did not have an expected impact on quality of learning process measured in terms of grades obtained by students.

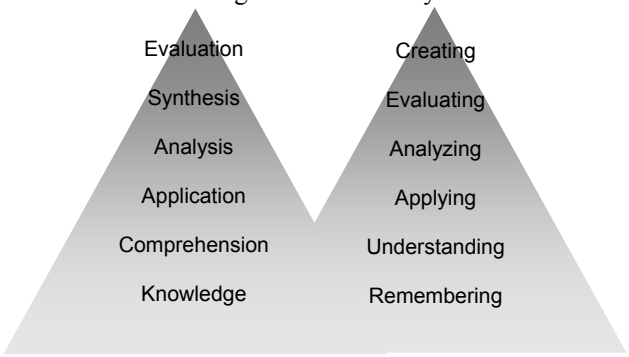

Fig. 2. Bloom's Revised Taxonomy

First podcasts were prepared in a Flash format. Nowadays this format is not available for iOS and the newest version of Android so for current mobile devices. All Flash podcasts were converted to the MP4 format or created from scratch. Now on the YouTube channel there are more than 200 clips. Their total length exceeds 50 hours.

Questionnaires performed in the academic year 2011/12 showed that having a full range of podcasts not all of students were fully satisfied by them. They were pleased by the quality and ease of use as well as by their availability in the mode 24/7. Moreover, they stressed positively that such an approach addressed different learning styles. However, in additional field of questionnaire reserved for remarks some of the students complained that the part of computer laboratories was boring for them because they repeated what was recorded in screencasts. All podcasts were designed as an additional, supplementary and auxiliary tool and all teaching and learning activities were conducted in a traditional way. Students were "taught" at the university how to use software and they were supposed to solve individual problems at home. In many cases solving problems was too difficult for them.

Starting from the academic year 2012-2013 in some of the groups podcasts were used in a different way. Students were asked to watch podcasts at home. During classes they should be prepared to use software without any problems and to solve particular problems using it. First results of this experiment were to some extend promising - students gained better scores in this mode, but they were not very keen to spend time at home watching podcasts. Students do prefer to "be taught" during classes. This problem can be easily solved by adding a simple point to subject regulations – students should be prepared to computer laboratories and this fact is checked by means of a test before the class. In fact, according to European Credit Transfer System (ECTS) an average student should spend learning at home the same amount of time as at the university. It is much more effective to watch passive by nature screencasts at home and solve problems with a tutor in the class than the other way round.

III. FLIPPED CLASSROOM

Idea of inverting education is already nearly fifteen years old. One of the first papers in that field was published in 2000 [7]. This paper describes two parts of subject taught at Miami University while using the inverted classroom concept and analyzes the outcomes. Numerous technologies offered completely new possibilities for students to learn away from the classroom, while a school period was used to perform collaborative experiments and worksheets. Authors of the paper concluded that the idea of inverted classroom offers alternatives for various learning styles and report that students favor that strategy. A different outline and evaluation of flipped education within a huge, primarily based on lectures, computer science course was published in 2002 in [8]. In this project new multimedia and video streaming application eTech was employed to change a course. In-class lectures were substituted by recorded lectures and auxiliary materials which could be viewed by students in the Internet independently. This make it possible to utilize the live period in the class for team problem solving facilitated by tutors. Another interesting paper in that field was published one year later in 2003 [9]. Within a series of five experiments hundreds of students from two different universities supervised by three different professors and six different teaching assistants took one semester long course in the field of casual and statistical reasoning in both traditional or online format. Within the frame of this project pre and post test results were compared. Features of the online experience which were helpful and which were not helpful were identified as well as most and least effective student learning strategies. Three years later a paper evaluating a web lecture intervention in a human–computer interaction course was published [10]. By utilizing lectures available in the Web before class more in-class period was used engaging students with hands-on

tasks. Class time was spent on learning by doing rather than learning by listening. In 2007 Gannod presented his work in progress on how to use podcasts in an inverted classroom [11]. One year later Helmick presented integrated online courseware for computer science courses [12]. Last but not least in 2008 a paper describing how to use the inverted classroom to teach software engineering was published [13]. Idea of flipped classroom was fully described in three books recently published by Bergmann and Sams [14], Bretzmann [15] and Walsh [16].

The research concerning students' satisfaction with flipped classroom was conducted in academic year 2013/2014 on a group of 222 students studying in Polish (PL) and a group of 51 students studying in English (EN). Out of 222 PL students the questionnaire was filled by 211 students which makes 95%. Similar data are for students studying in English. Questionnaire was filled by 49 out of 51 students. One third of students studying in English were foreigners.

Questionnaire used in this survey consists of fifteen closed form questions and 6 opened form questions. Due to the nature of answers all questions were divided into three groups. In order to compare the results of survey with other outcomes some of the questions were based on similar surveys: first one conducted in Canada [17] and second one described in blog Flipping with Kirch conducted by Mary Kirch from United States.

Scale of answers for all first five questions is from "strongly agree" to "strongly disagree". Results for Polish language and English language students were compared with surveys from Canada. The first of the asked questions was about the level of engagement in traditional classroom instructions and flipped classroom (see Fig. 3). The second question from that group was about potential recommendation of a flipped classroom to a friend (see Fig. 4).

40% of students studying in Polish language strongly disagree or disagree with the statement what is in accordance with the observation, that nearly half of the students was not interested in traditional classes. Answers of students studying in English language are closer to the answers from survey conducted in Canada.

For this question answers of students studying in Polish and English languages are similar but they definitely differ from the results of survey conducted in Canada. Nearly six times more students studying in Polish language in comparison to Canadian agree or strongly agree with the statement that they would not recommend flipped classroom to a friend.

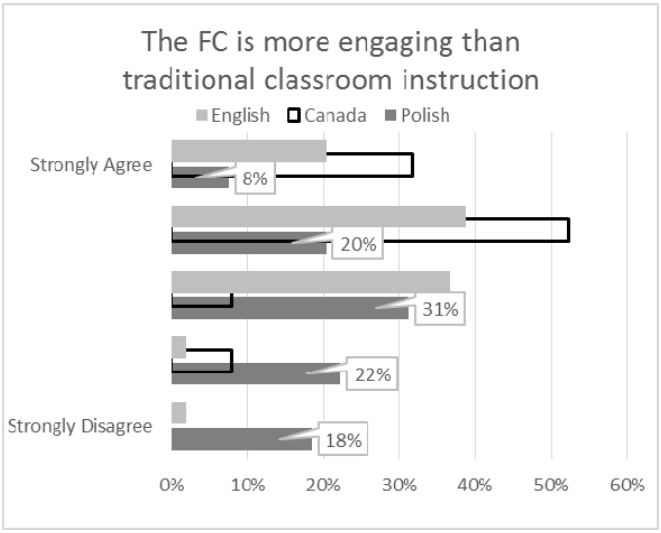

Fig. 3. Answers on question 1.1

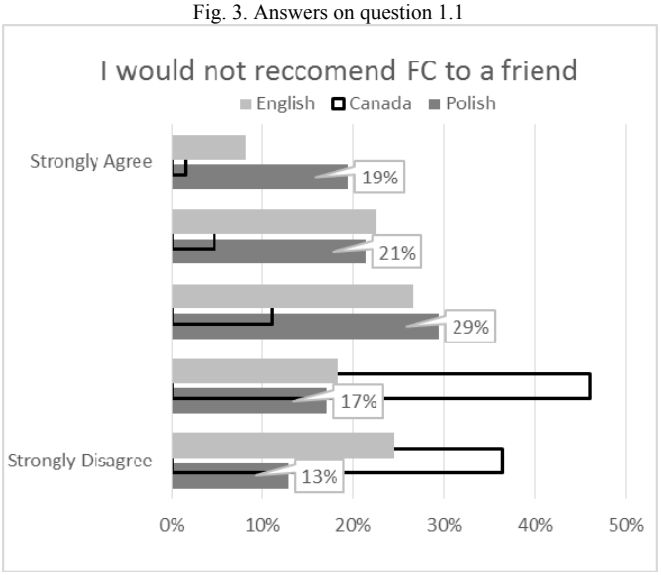

Fig. 4. Answers on question 1.2

Next question (statement) was very simple – I like watching lessons on video (see Fig. 5). In this case answers for all three groups were very similar.

Fourth question in this group of questions was about better motivation to learn in the flipped classroom mode (see Fig. 6). In the case of this question answers of students studying in Polish language differ from the answers of two other groups. Nearly 40% of them strongly disagree or disagree with that statement that they are more motivated to learn in a flipped classroom mode.

The last question in this group is about improvement of learning in the flipped classroom mode (see Fig. 7).

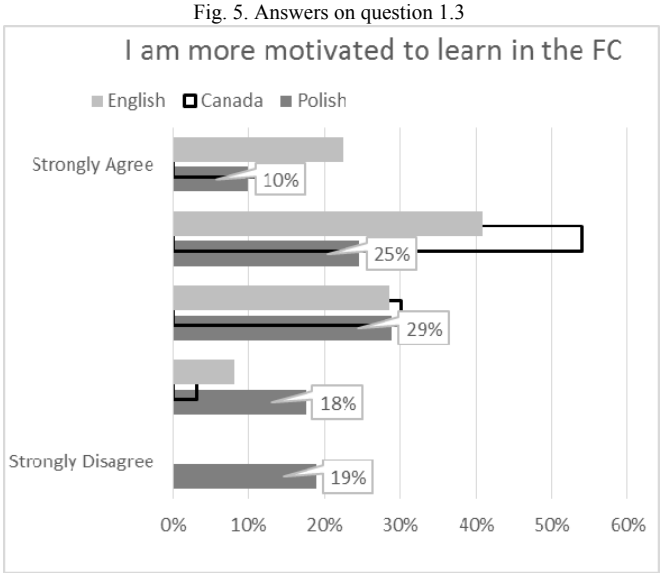

Fig. 6. Answers on question 1.4

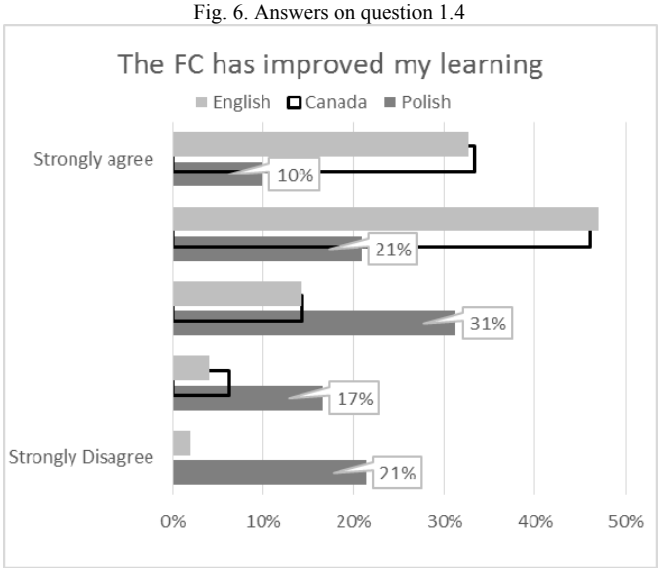

Fig. 7. Answers on question 1.5

IV. Tests and Quizzes

From the very beginning different forms of tests and quizzes were used mainly due to increasing number of students. It was not possible to check their knowledge in a classical way. Databases for subjects taught by DoIT consist of hundreds of different types of questions available on the Moodle platform like: calculated, simple calculated, calculated multi choice, description, matching, multiple choice, short-answer, numerical and True/False. After twenty years' experiences are rather sad. Students are trying to memorize answers on the questions rather than to understand the appropriate part of material. Quizzes were also used in a flipped classroom experiment. There were quick tests consisting of up to ten questions checking knowledge gained before the class at home from podcasts. Nowadays quick tests are placed at the end of classes and they force students to make notes during the class.

In order to help students to prepare for tests flashcards were used (see Fig. 8). This tool invented by Sebastian Leitner [18] can support learning treated as memorizing but rather not as understanding.

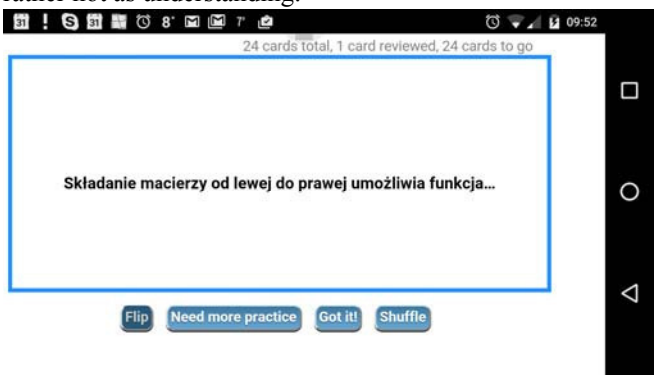

Fig. 8. Sample flashcard for mobile device

During the present academic year for traditional lectures conducted in a lecture theater at the university clickers were used. Instead of special hardware devices specialized software and smartphones were utilized (see Fig. 9).

V. Mobile Learning

Shift from instructional design to e-Learning [19] was the first step of educational revolution. The next step will be devoted to transforming the system of delivery of education and training [20]. The best historical overview of m-Leaning [21] can be found in Handbook of m-Learning [22]. In the last decades there were many shifts in learning and learner-centered pedagogies and theories. Mobile courses from the field of Computer Sciences or Engineering require the usage of new and effective design strategies [23] and implementation of appropriate learning theories [24]. From a technical point of view instead of producing different applications for different mobile operating systems used on various mobile devices it is more efficient to create courses available through web browsers also on mobile devices (see Fig. 10).

Fig. 9. Sample Poll Everywhere question

Changes in the course of engineering calculations and their programming which took place in the last few years show differences and similarities between traditional learning, e-Learning and m-Learning [25]. Regarding time traditional learning is frequently constrained by school hours, e-Learning by a time of access to computer while in the case of m-Learning in fact there are no time constraints. Learning can occur anywhere where access to the network is possible. Traditional learning is rather not personalized which contrasts with personalized e- and m-Learning. Traditional learning is definitely formal while m-Learning is rather informal – e-Learning can be formal and informal. Last but not least traditional learning is not spontaneous while m-Learning is highly spontaneous.

VI. Cheating

Cheating is perhaps as old as education. Mavis [26] wrote about college cheating as a function of subject and situational variables in 1962 and Haines [27] about college cheating as effect of immaturity, lack of commitment, and the neutralizing attitude in 1986 and also ten years later [28]. But nowadays due to the information and communication technology it is much easier to cheat so it starts to be a crucial problem. One can say that e-Learning caused e-Cheating as presented by Jones in [29] and in [30]. Cyber cheating is a crucial problem in an information technology age [31]. There were tenths of papers written on this subject. Their review can be found in [32]. The answer on the important philosophical question why cheating is so wrong is given in [33]. More information about this subject can also be found in [34].

In order to learn what is the attitude towards cheating among students two surveys were conducted. In order to learn what are the cultural differences between different countries first survey was based on survey from Gettysburg in USA and second was based on survey conducted in Monash University in Australia. Similar comparative analysis on students' perception and attitudes towards academic dishonesty between the students in China and United Stated was done by Zhou and Lan in [35]. Research on cheating was also conducted in Dubai [36] and in Philippines [37], [38].

The first survey was conducted during the first week of classes in October 2015 and was based on the test from Gettysburg. Total number of responses was 203. Number of students registered for the subject was 221. Total number of the questions in this survey was 24. Answers on the question "have you ever reported another student you suspected of cheating" are rather similar (see Fig. 11).

Answers for two next questions ("have you ever interrupted a student who was cheating" and "did you ever cheat during high school") show definitely bigger differences in attitude to cheating (see Fig.12 and Fig. 13.).

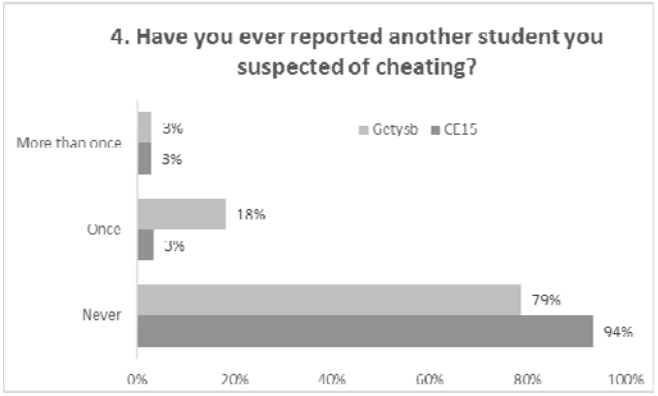

Fig. 11 Comparison of the answers on question 4 from Gettysburg survey

The second survey was conducted during the last week of classes in January 2016. Total number of responses was 179. Number of students attending classes was 201. Questionnaire of this survey is fully based on the questionnaire used in 2000 during the survey conducted in Australia at Monash University and at Swanbourne University which results were published in [39]. The same survey was conducted ten years later and results were compared in [40]. The most important part of both surveys

consists of 18 scenarios. For each of them answers are given using Likert's scale [41] with the answers ranging from 1 – acceptable to 5 – not acceptable.

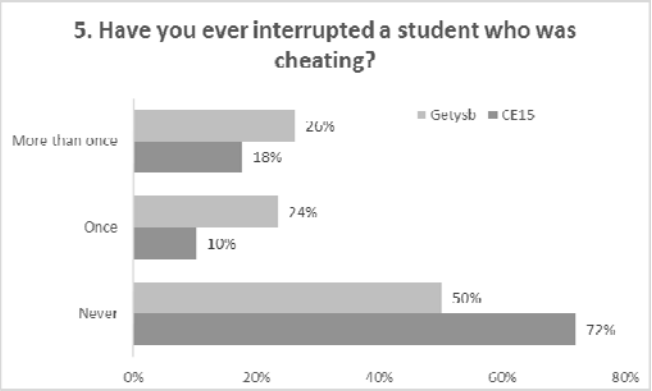

Fig. 12. Comparison of the answers on question 5 from Gettysburg survey

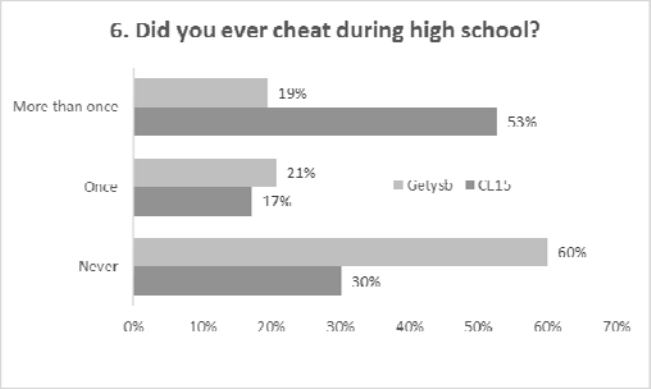

Fig. 13. Comparison of the answers on question 5 from Gettysburg survey

What can be easily learned from Table 1 is that in Australia a positive change has occurred among students over the decade with regard to cheating awareness, acceptability and practice. Results of survey conducted in Poland are much worse than Australian from the year 2000. Especially big differences are in the case of the three following scenarios:

- Copying material from the book or from the Internet,
- Swapping assignments with another person,
- Using a hidden sheet of paper with important facts during an exam.

The first problem can be generally solved by means of plagiarism checkers on the university level. The second one should be mainly solved by instructor manually. The third one which can be generally called as using unauthorized materials during exams can be solved by means of specialized IT tools. For the last mentioned scenario – using unauthorized materials – worth mentioning is a relatively small difference in mean values of acceptability (4.59, 4.64 and 4.32) and a very big difference in practice (4%, 2% and 53%).

Perhaps cheating is as old as education, and the only change is in methods (see Fig. 14).

Fig. 14. No cheating

VII. Discussion

"Digital Dementia", a term coined by the top German neuroscientist Manfred Spitzer in his 2012 book with the same title [42], is a term used to describe how overuse of digital technology is resulting in the breakdown of cognitive abilities in a way that is more commonly seen in people who have suffered a head injury or psychiatric illness. Spitzer proposes that short-term memory pathways will start to deteriorate from underuse if we overuse technology.

Nowadays it is getting more and more important to know how does the brain work [43]. In many situations treating Internet as a natural source of information is replaced by FoMO – Fear of Missing Out [44]. Multimedia which ten years ago were a very promising educational tool nowadays make students unwilling to learn. They do prefer to watch video in a passive way rather than to learn in an active way.

Tests widely used in E-education to control knowledge are also a kind of pitfall. What is really controlled by tests this is an art of passing tests and knowledge of the answers on numerous questions. The best databases updated continuously cannot replace the teacher asking questions. Knowledge and understanding of a certain field is not equal to the knowledge how to answer on numerous questions.

Last but not least E-cheating seems to be the biggest problem in E-education. Different IT tools can make cheating more difficult but will not fully stop it.

Lessons learned from twenty five years long research in the field of e-Learning show that cultural differences should be taken into account while introducing new solutions like in the case of flipped classroom. Fifteen years after the question "how to change the unchanging" [45] was raised many things has changed. Despite all pitfalls and traps there is the only one answer on the question to be e- or not to be in the field of education. But we should be e- in a more rational way. There is still need for deep look into all three dimensions of learning [46] or how professionals learn in practice [47].

Acknowledgment

The author wishes to thank Marcin Jaczewski for his support during flipped classroom experiment and all surveys. Thanks are also due to Tomasz Dubilis and Tomasz

TABLE I.
COMPARISON OF RESULTS OF SURVEYS

Scenario	Acceptability			Practice		
	2000 mean	2010 mean	2015 mean	2000 %	2010 %	2015 %
Showing assignment work to a lecturer for guidance	2.07	2.21	1.68	37	42	67
Posting to an Internet newsgroup for assistance	2.07	2.28	1.77	27	34	68
Two students collaborating on an assignment meant to be completed individually	2.54	3.20	2.65	44	36	54
Resubmitting an assignment from a previous subject in a new subject	2.82	2.99	2.49	27	17	41
Submitting a friend's assignment from a past running of the subject	2.86	3.46	3.03	34	20	32
Copying the majority of an assignment from a friend's assignment, but doing a fair bit of work yourself	2.98	3.37	2.98	31	21	39
Not informing the tutor that an assignment has been given too high a mark	3.08	3.29	2.82	17	16	39
Being given the answer to a tutorial exercise worth 5% by a class mate if the computer you used has problems	3.76	4.29	3.03	7	3	9
Copying material for an essay from a text book	3.81	4.19	3.71	22	10	34
Copying material for an essay from the Internet	3.85	4.28	4.29	23	10	33
Obtaining a medical certificate from a doctor to get an extension when you are not sick	3.94	4.02	3.35	12	3	9
Swapping assignments with a friend, so that each does one assignment, instead of doing both	3.96	4.45	3.37	9	3	37
Copying another student's assignment from their computer without their knowledge and submitting	4.18	4.62	3.94	7	3	7
Copying all of an assignment given to you by a friend	4.30	4.62	3.92	10	3	10
Hiring a person to write your assignment for you	4.51	4.62	3.97	3	1	6
Using a hidden sheet of paper with important facts during an exam	4.59	4.64	4.32	4	2	53
Hiring someone to sit an exam for you	4.65	4.69	4.32	3	0	5
Taking a student's assignment from a lecturer's pigeonhole and copying it	4.72	4.72	4.29	4	2	3

Warda from for their IT assistance. Last but not least the author wishes to thank all students who filled many very long questionnaires in the beginning and at the end of semester.

***Abstract*—With time education becomes more personified. New categories of learners join in educational processes and new areas of education appear. Brain-computer interfaces have good perspective to contribute to these tendencies. This technology may allow disabled people to participate in social life, including education, and may let healthy people to develop the skill of controlling brain waves. Training the skill is the object of investigation and researchers recommend taking into account human factors: general principles of learning, motivations, personal patterns and abilities (among them, spatial). Education may be a source of highly motivated training tasks. The paper treats brain-computer interface as a type of communication and argues for semiotic training that is a variant of training spatial abilities. Semiotic training have proved effectiveness in other areas of education. Theoretical background and preliminary empirical comments of the approach are considered.**

I. Introduction

THE aim of the paper consists in attracting attention to educational perspectives connected with future development of brain-computer interfaces (BCI) and proposing theoretical rationale for semiotic training as a possible way of developing the skill of controlling brain waves. BCI is considered as a sort of communication.

I. Structure of the Paper

Consequent reasoning characterizes the trends in education and introduces the aspects of BCI that are important for the issue under consideration (Section II). Section III presents general information about BCI. Section IV proposes semiotic view on BCI, argues for methodology of field linguistics as the perspective way of learning BCI skill; discusses basic lines of semiotic training and its benefits. Section V proposes the illustrative model by considering semiotic regularities of human pictorial imagination appearing in comics, the other products of human intentional imagination. The model analysis provides data that may be useful for strategies of semiotic training. Section VI resumes the considered issue.

II. Trends in Education

Three trends of contemporary education are especially important for the current consideration: individualization of educational trajectories, widening the scope of educational activity, and involving new categories of learners.

The scope of educational activity have substantially widened when its virtual forms appeared and allowed new categories of learners to participate in e-learning. Besides, education tends to become more individually fitted and polyvariant. Strategies of education come closer to self-education. Subjectively estimated, elaborated and regulated ways of developing knowledge and experience gain their significance for the subjects of education. Not only general solutions concerning perspectives of education in whole are significant, specific educational technologies designed for concrete category of learners are also valuable.

Developing BCI seems to have a strong potential of contributing to these trends. Communication in whole is basic for education, thus training BCI as the specific means of communicating with external world for mastering internal skills can involve certain categories of people (disabled or healthy) into educational processes [1]–[4]. Besides, according to [5], reproducing physical actions (with the help of movement interactive devices) trains memory and motor abilities. This result supports the hypothesis that implementing physical actions by the force of imagination may give the same benefits. The proposed semiotic training procedure may give double benefit by affecting both semiotic and brain control skills. The former is valuable for dealing with semiotic systems (for instance, natural languages), the latter – for mastering BCI.

III. Brain-Computer Interfaces

I. General Characteristics

BCI allows a person to perform physical actions (on the screen or really) by the force of intended imagination, or more precisely, by the force of another side of imagination – brain waves – that are fixed and translated into characteristics of the physical action. The intentions often are not fully arbitrary, and should follow a task that is given to a BCI user. The tasks may differ in complexity and content. Some BCI designs presuppose a free training session. During this session, a BCI user chooses imagery tasks by his / her own decision [6].

Among the current discussions about BCI, two items are especially crucial for prospective education.

I am very grateful to *Sobolev Institute of Mathematics* and *Novosibirsk State University* for supporting my research

First, training procedures for mastering this sort of interaction, particularly mental tasks and feedbacks. Currently used training protocols are discussed, for instance, in [6]. Feedback provides perceivable data for accessing effectiveness of brain control. There are different variants of feedback, for instance, neurofeedback [7], the motor imagery training system proposed in [8]. The present paper discusses only the variant of training BCI skill and does not concern the details of designing feedbacks.

Second, perspectives of BCI that go beyond solely medical purposes and cover other sorts of activities intended for disabled or healthy people [1]–[2].

BCI is substantially interdisciplinary undertaking and, as the authors of [9] notice, cooperation across disciplines has good potential to improve situation. The present paper proposes linguistic view on the situation.

This view rests on considering BCI as a sort of communication subject to semiotic interpretation. The stance suggests the idea of semiotic training based on the methodology of field linguistics. In case of BCI, the semiotic training will develop spatial abilities. This is important because according to the hypothesis [10]–[11] spatial abilities may efficiently contribute to the development of BCI skill.

II. Training Procedures

Efficiency of BCI may depend on ability of a human to control brain activity, and this skill is not inherent by nature, many people (between 15 and 30 % [10]) cannot use it at all. It is crucial for certain types of BCI, particularly for spontaneous BCI [6]. Lack of the capacity to control brain waves is called “BCI illiteracy” or “BCI deficiency” [10].

Thus, thinking over strategies of preliminary training and perfecting the capacity is often marked as actual. Two approaches are noteworthy in the context of the present paper. The first [6] recommends to generalize the key features of efficient training in different areas of knowledge and to infer relatively skill-independent recommendations. The second [10] suggests personifying the process by using individually designed strategies of mastering the skill. Since we consider BCI as a sort of communication, the former approach gives reason for generalizing linguistic experience of learning unknown languages by reconstructing the semiotic structure of a language on the base of the speech data. According to the latter approach individual semiotic training (as a skill of reconstructing semiotic structures from communicative data) seems to be promising.

IV. Semiotic View on Brain-Computer Interface

I. Brain-Computer Interface as a Semiotic System

BCI is interpretable as a sort of translation that transforms information along the following line: intention – (visual or kinesthetic) image of a desired physical action – brain waves – specification of the action (recognized by special equipment and appropriate algorithms) – physical action. A user of BCI cannot monitor directly brain waves; nevertheless, (due to perceivable feedback) he / she may regulate it indirectly, through modifying intentions and therefore images. Thus for a user of BCI the aforementioned line of translation is shorter: intention – image – physical action. The shortened line admits semiotic representation.

The notion of sign varies in different semiotic theories. “Dyadic” [12] and “triadic” [13] models of sign are the most common. The visual form of the latter is “semiotic triangle”. There is no full agreement about the terms marking the interrelated angles of the triangle. We will use the following terms: sign (signifier, a linguistic form) – meaning (mental entity, concept) – reference (physical or abstract entity indicated by the sign in a real act of communication). A language user can directly control the usage of a sign and voluntary modify it if necessary.

In BCI, image plays the role of a signifier. A BCI user can intentionally modify it. Resulting physical action plays the role of the referent Meaning is individual intrinsic skill of building appropriate images, i.e. images that effectively initiate desired actions.

An image may be a simple sign or a compound sign. The components of a compound sign correlate with the features of a referent. Compound signs appear on rather developed level of communicative skill.

In linguistics, natural language signs are usually considered as linear, one-dimensional. In BCI, signs are non-linear. BCI as communication is closer to sign languages, (used by deaf people): sign languages localize in space, not in line.

II. Extractability of Semiotic System

Semiotic systems can vary in their substance broadly. They are not limited in modalities of realization, in number of dimensions, or nature of elementary and complex signs. At the same time, there are general rules governing their internal structure and functioning, and these two aspects are closely connected: a structure becomes apparent during functioning and thus is extractable from the instances of functioning. Validity of the result depends on quantity and quality of communicative data.

Sign languages give the appropriate illustration. These languages are spatial: a “speaker” creates signs by different sorts of gestures, including body movements and mimics. Thus, competence in a sign language requires sufficiently developed spatial abilities.

The history of sign languages is rather instructive. Many years had passed before linguists recognized semiotic nature of sign languages and began to consider them not as a mere pantomime. This happened due to the pioneer work of William Stokoe [14]; in 1960th sign languages became the objects of contemporary linguistics. Possibility of the crucial turn was stipulated by semiotic analysis fulfilled by Stokoe: he extracted constituents of semiotic system (“cheremes”) from continuum of raw communicative data. This process is similar to deciphering a language. Corresponding linguistic methodology is typical for field linguistics.

Viewing the gesture space as a medium obeying semiotic regularities permits to segment gestures into elementary features of signs and to imitate (to a certain extent) communication based on a sign language automatically in the systems of machine translation [15].

Theoretically, an intended image in BCI can also be semiotically complex and consist of several more simple parts

of signs. Presumably, these constituents of the intended image correspond to certain constituents of the desired resulting movement; and a set of such constituents is individual and specific for each person.

Special area of linguistics develops methodology for extracting semiotic systems from raw communicative data. This is "field linguistics" [16].

III. Field Linguistics

Field linguists are learning and studying the languages (usually exotic) that are unwritten, familiar only to their native speakers who do not know any other language besides their own. Moreover, the circumstances of life and phonetic features of the target language are also exotic thus limiting linguists in using analogies.

Field linguist works in specific investigational situation when the researcher has no linguistic competence in the target language, and the native speaker constitutes the only source of information about the language [16]. Similarly, a BCI user fulfills the role of a "linguist", which is analyzing perceptive data in order to extract the underlying semiotic patterns.

Both types of communicators, intentionally and experimentally, by trial and error, are trying to detect (rationally or only perceptually) the proper abstract knowledge. Difference is in the nature of this knowledge: a BCI speaker develops visual or kinesthetic skill, a linguist – articulatory skill that also can be auditory or kinesthetic. In both cases kinesthetic skill is said to be more basic ([6], [16]).

At the very beginning of a scientific research (within so called "zero cycle"), a field linguist knows nothing about semiotic structure of the target language, he / she should discover the signs and meanings of the language on the base of analyzing language use.

Undoubtedly, BCI speaker usually is not a linguist; these two types of people have different interests and goals. Nevertheless, the linguistic character of BCI training is substantially similar to that of a zero cycle in field linguistics. Both are akin to deciphering.

IV. Semiotic Training

If a BCI user wants to develop the skill of controlling brain waves, he / she tries to discover why the image of desirable movement appeared to be insufficiently strong. Actually, the process means that the BCI user tries to change hypothesis about the proper constituents of the images (signs) and to elaborate the more effective ones. Developing BCI skill actually means the process of refining the hypothesis. In fact, a BCI user intentionally trains his / her linguistic competence in BCI communication. The field linguist fulfills the similar task.

The learning procedures for developing semiotic skill should train general subject independent schemas of semiotic analysis; at the same time, the object of the analysis is individual (individual perceptive data). In contrast, a foreign language learner usually learn the concrete semiotic system with previously stated signs.

Semiotic training involves series of iterative semiotic analysis. The latter consists in searching for combinatorial regularities in perceptive data. General regularities are common and sufficiently strict; [17] presents basic variant of the procedures used in field linguistics. The whole scope of investigation in field linguistics embraces all language levels and thus may seem not easy for a BCI user if he / she is not a linguist. Nevertheless, semiotic analysis is flexible and does not require building a multilevel structure (as for natural languages); the analysis may not go beyond one level thus becoming well understandable.

The proposed procedure of semiotic analysis is a sort of mental experiment. A user of BCI, or an "experimenter", may realize it by fulfilling the following types of operations: 1) to fix some part of an image of the desired physical action; 2) to vary the remained part / parts and simultaneously trace the results (check if the resulting physical action is appropriate); 3) to repeat (if necessary) the experiment with different variants of the division; 4) to search for interchangeable parts that may replace each other without changing the context (the sets of such parts hypothetically correspond to abstract entities).

The experimenter may repeat these operations cyclically and then summarize the results of several experiments. The obtained system of signs will be individual and specific for each person.

It is worth noting that each semiotic cycle exercises spatial abilities of the person.

Semiotic training may give double benefit by affecting both brain control skill and semiotic skill.

The latter is substantial for dealing with other semiotic systems, particularly with natural languages, and this idea has the empirical confirmation. The Traditional Linguistics Olympiads successfully use the linguistic variant of supposed semiotic tasks (in the spirit of field linguistics) for searching and training linguistically gifted children. For solving the tasks of the Olympiad, no prior knowledge of linguistics or languages is required: logical ability and the will are sufficient. Information about the Olympiads and the collections of tasks are available at http://www.ioling.org/, http://www.lingling.ru/olymps/mos_olymp/. Several decades (46 years) of fruitful practicing this type of semiotic tasks give empirical support for efficiency of training procedures based on the methods of field linguistics.

V. Semiotic Analysis

I. Parameters of Images

Semiotic analysis briefly depicted in the previous section does not provide deterministic procedure. The analysis has no less than four degrees of freedom: 1) the way of segmentation and granularity of the static perceived data, 2) the way of segmentation and granularity of the dynamic perceived data, 3) the set of simple / elementary actions, and 4) the goals of actions. For instance, a BCI user fulfilling the task of grasping an apple may imagine only a rather undetermined and undivided movement beginning from the initial location of the hand and ending at the location of the apple. In other case, the user may imagine the same process in details including, for instance, the images of tensed muscles, trajectory of hand movements, positions of fingers on the apple, rotation of the apple. The whole task may correspond to one goal or to the

set of interconnected goals, for instance: to bring the hand nearer to an apple, to open the fingers, to touch the apple by the palm, to clasp the fingers around the apple.

Thus, semiotic analysis may be characterized by certain numeric parameters, among them: number of discrete parts detected in the visual continuum; number of modified parts; number of steps implementing the modifications; power of the set of elementary static / dynamic constituents. A person may determine these parameters of imagination by his / her own choice.

Nevertheless, semiotic analysis depend not only on individual decisions; it may reflect some general regularities: limitations, peculiarities and habits of people. Semiotic analysis made by linguists cannot give an appropriate example for learning these regularities because linguists usually have overtrained semiotic skill; a BCI user, on the contrary, may have a minimal experience in semiotic analysis. Besides, linguists as a rule do not analyze dynamic imagination. According to the survey of linguistic approaches to comics [18], the works in this area usually use comics for supporting the already existing linguistic theories elaborated for ordinary human languages. For our aims, we need to understand how the mind transfers meanings from imaginary to visual modality.

It would be useful to have some preliminary considerations about the parameters. These considerations may help to specify initial point for launching a semiotic cycle and to propose some guidelines for its developing.

It is not easy to undertake wide-ranging semiotic investigation of BCI data. Contemporary BCI is still barely used outside laboratories [10]–[11] and thus does not allow to observe diversified and complex physical movements implemented by brain force. Therefore, it is productive to make preliminary observations concerning the abovementioned substantial features of human intentional imagination on the base of other data that are more easily acceptable and do not need sophisticated or expensive equipment. We suppose to consider pictorial imagination for illustrative model analysis.

II. Model Analysis

The main question for consideration: How do a person split imaginary actions into parts when he / she reproduces the copies of the actions in the physical world?

The purposes of model analysis are: 1) to refine the list of parameters substantial for visualizing imaginary actions; 2) to provide data useful for operating with the parameters. Primarily we should choose a type of pictorial imagination appropriate for the purposes of model analysis.

As [19] shows, the way of performing a spatial task depends on the medium where it is performed. If one performs the task in virtual world, on the screen, the operations should be precise, discrete, well planned, governed by the goal in mind. The details of performing operations should be rather explicit than implicit. On the contrary, in the real world, one performs the same task intuitively, operations are continuous, and do not require high degree of specification. The image of a future action often appears in consciousness only vaguely. The authors of [19] suggest that spatial thinking skills required for creating representations in virtual and real worlds may be different. Actions performed due to BCI, like actions in virtual world, require higher degree of refinement.

In this respect, painting gives a similar example because for depicting an imagined scene, a painter should refine the image (initially viewed as integral and continuous) and may divide it into discernible well-defined parts. A picture alone is static, yet a sequence of pictures may depict dynamic stages of an action. This is typical for comics, thus comics give appropriate illustrative model for considering regularities in visual representations of imagined actions.

A person implementing a complex action by the force of imagination divides the action into parts. The painter of a comics also transforms a continuous action into discrete parts, i.e. determines, among other things, the static and dynamic components of the image, the elementary movements, the goals and sub-goals of actions; the abstract characteristics like speed, chronological order, importance, intensity. In other words, the painter makes decisions similar to these that are crucial for implementation of a physical action within BCI.

Comics may vary broadly in their genres. For our purposes, we need an example with a realistic plot, which depicts coherent realizable situations and processes. Logicomix [20] is the suitable variant for our model analysis.

The analysis showed that the way of splitting actions into parts depends rather on distribution of attention than on type of action. Attention may focus on the stages of an action and / or on its characteristics (particularly, abstract). For instance, intention to attract attention to quickness of an action often results in dividing the action into stages, i.e. fixing the successive phases of the action. This mode of emphasizing the speed / intensity may be used with reference to physical or to internal actions (for instance, mental).

Thus, the main recommendation for developing semiotic abilities may consist in training the skill of distributing degrees of attention between actions, their stages and characteristics. The skill presupposes elaborating the subjective patterns of simple actions (stages of actions) typical for essential behavior and training these patterns separately, as the isolated signs; stages are especially actual for intensive / high-speed actions. It may be useful to ask a person who wants to develop semiotic skill to make a drawing of the stages of a desired action. However, for disabled people this variant may be impossible. Concrete material for preliminary designing patterns and splitting actions is extractable from the typology of actions.

The analyzed material induces the ternary typology of actions that include active states, detailed actions, and undetailed actions.

Active states include: a) monotonic repeated movements, b) random movements specific for a situation under consideration, c) panoramic view of co-located motions. One active state usually corresponds to one panel.

For instance, several elementary movements on one panel may correspond to a continuous monotonous process like walking round and round a flowerbed during a course of cogitation. The panel in this case shows several positions of the person located on the garden path around the flowerbed. Monotonous repeated processes like dangling a foot give

another example of elementary movements representable on one panel; in this case, the panel shows several positions of the foot simultaneously. Both cases give evidences for relatively small importance of elementary movements; the movements from one panel have common purpose.

The detailed action has refinements that may indicate stages, chronological order, highlighted constituent parts, speed, and degree of importance or intensity. Indicators of these characteristics include assortment of colors (the past is less colored), focus distance (may reflect degree of importance, intensity, speed); rotations (may serve as a means of highlighting the actual constituents). Little difference between successive panels may indicate intensity of an action (predominantly for mental actions). Visual indicators of changing attention may include; moving away from a depicted scene or closer to it (making an image, not frame, smaller / larger); modifying the angle of the field of vision; modifying the environment, elimination of the background (thus emphasizing the focus of attention).

In addition to the parameters listed above the annotation of the panels includes information about the hierarchy and the types of physical actions.

The whole slot of the comics breaks up to sub-slots (scenes); a sub-slot depicts a sequence of collocated actions. In Logicomix, the volume a sub-slot may reach several dozens of panels.

Realization of a complex action may include several simple actions (the stages). A simple action may include several elementary movements; a panel presents all of them simultaneously. Thus, we have the following hierarchy: slot – sub-slots – complex actions – simple actions – elementary movements. The hierarchy of actions corresponds to the hierarchy of goals.

The database provides characteristics actual for semiotic training (calibration, launching and developing semiotic analysis); proposes the ways of visualizing complex actions and their characteristics (particularly, abstract) for designing BCI and other types of visualized human-computer interfaces.

VI. Conclusion

BCI and the skill of controlling brain waves are prospective areas of future education. This position, expressed, for instance, in [3] and [4], is the starting point of the paper.

BCI is a sort of communication and allows semiotic analysis. The proposed semiotic training procedure bases on the linguistic experience elaborated for dealing with unknown semiotic systems. Semiotic training (in its linguistic version) has already proved its effectiveness in linguistic education.

The realized model analysis considers pictorial intentional imagination as a source of preliminary data useful for developing semiotic analysis.

The proposed variant of semiotic training is consistent with general recommendations that the specialists in BCI suggest: it takes into account human factors, individual capacities, and trains spatial abilities of a person.

Semiotic training may have different implementations; its potential seems to be promising and going beyond the area of BCI or training the skill of controlling brain waves.

***Abstract*— This study develops a unified pedagogy for the design and evaluation of e-learning software for high-school Computer Science. In accordance with the pedagogy, prototype e-learning software was developed for use in student instruction and independent learning. The pedagogy was iteratively refined based on the evaluation of teachers and education experts and the resulting e-learning software was developed considering student feedback. The problem domain focuses on the UK's recent shift in educational emphasis towards Computer Science GCSEs; however, the findings are broadly transferable to other developed nations. The pedagogy synthesizes the following learning theories: Constructivism, Social Constructivism, Connectivism, Cognitive Load, ARCS and VARK learning styles, these were in turn distilled into 31 heuristics. The research is broken into three phases, the first two phases are discussed in this paper; Phase 1 is the Initial Pedagogical Strategy and Prototype, Phase 2 is the Elaboration via Action Research.**

I. Introduction

THERE is a well-publicized body of inquiry, consisting of various reports, analysis and political rhetoric that assert that computing education in the UK has been struggling [9], [11], [22]. This concern led to the programme of study for Information and Communication Technology (ICT) being temporarily dis-applied while new initiatives introduced an arguably more academically rigorous Computer Science GCSE [8].

The prevalence and ubiquitous nature of ICT in developed countries and its impact on recent generations is well documented [13]. Digital technology is shown to be a fundamental part of the fabric of society in developed countries such as the UK [9], [15], [18]. These findings arguably make the need for computing education all the more important, and in support of computing education it is postulated that e-learning software can offer learning benefits in the form of a media rich interactive environment that is engaging and can promote active learning [7].

The objective of the research presented in this paper is to study and synthesize leading learning theories into a single unified e-learning pedagogy that will support high school computing, and in particular, the new Computer Science GCSEs. This pedagogy will be embodied in an e-learning software prototype and both will be evaluated to identify their impact on student learning and engagement.

This work was not supported by any organization

II. Quality E-Learning Software

Although e-learning software has become mainstream, one of the main concerns still remains that what is delivered often falls short [1], [6]. Content quality, pedagogical usability, instructional design and a lack of alignment with education needs and standards remain a concern in existing e-learning software [6], [12], [20].

This research aims to support increased use of e-learning in high-school Computer Science, and to safeguard the pedagogical quality of the e-learning software, by defining a comprehensive set of pedagogical heuristics to guide teachers in designing and/or evaluating e-learning software for use in teaching. Therefore, in the context of this research, quality focuses on the standard and degree of excellence of the pedagogy underpinning the learning process.

III. Learning Theories

One approach to ensure the pedagogical quality of e-learning software is to ground it in established learning theories. There is a significant body of research into learning theories, e-learning and Science, Technology, Engineering and Mathematics (STEM) education, but this is somewhat overwhelming; there are complementary and competing learning theories and varied perspectives on how to best implement these theories in technology [14], [25].

Illeris [14] proposes that since learning is so complicated, any "*analyses, programmes and discussions of learning must consider the whole field if they are to be adequate and reliable*"(p.18). It is for this reason that this research synthesizes this overwhelming body of knowledge into an accessible set of pedagogical heuristics. The learning theories considered include Constructivism [4], Social Constructivism [19], [24], Connectivism [3], Cognitive Load [7], [23], ARCS [16], [17] and VARK learning styles classification [10]. These theories were selected primarily

due to their maturity and the availability of research that discusses them, their effective implementation, and the evidence of their positive affect on learning and motivation. A final consideration was to include theories that relate to technology and our current digital society.

IV. Research Methodology

The research study that is presented in part in this paper is divided into three phases (Refer to Fig. 1) and each phase uses a mixed methods approach, but with a different qualitative-quantitative mix. Overall, the phased approach utilizes an exploratory mixed methods design in which Phase 1 and 2 use primarily qualitative data from students, teachers and education experts to synthesize a set of pedagogical heuristics. The rationale for this research design is to initially work in depth using significant literature review and iterative Action Research cycles to gradually refine the heuristics and e-learning test tool.

Phase 3, although not discussed in this paper, will have a quantitative priority and a larger student sample in order to generalize the findings to the wider student population. The aim will be to measure whether there are improved assessment results using e-learning software that adheres to the pedagogical heuristics synthesized in this research.

A. Phase 1: Initial Pedagogical Strategy and Prototype

The primary objective of Phase 1 was to set a strong foundation for the research study; this was achieved in terms of:

1. Piloting the research methods and protocol,
2. Developing the first draft of the e-learning pedagogical heuristics,
3. Developing a working e-learning software prototype for the topics of Algorithms and Computational Thinking that was in turn used for evaluation purposes.

This supported the early identification of shortcomings in the research methods and protocol, and in the design and development processes; but most importantly, it allowed early feedback on the pedagogy and e-learning software.

The first step was to undertake a comprehensive literature review resulting in the first draft of the e-learning pedagogical heuristics for GCSE Computing.

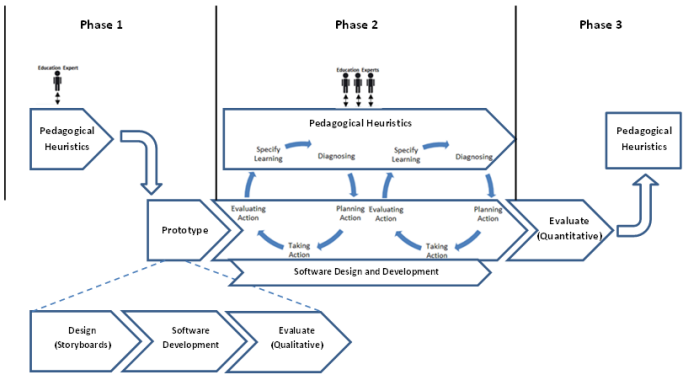

Fig. 1 The three phases of research.

An experienced GCSE teacher and five education experts then evaluated the pedagogy and provided constructive feedback and validation of the appropriateness of the heuristics for Computer Science for the GCSE age group. This feedback was analyzed and incorporated into the research prior to Phase 2-Cycle 1.

As a proof of concept, a prototype e-learning software was developed according to the e-learning pedagogical heuristics. Eight GCSE ICT students were recruited from a local high school and observed using the e-learning software. Prior to the observation study, an online VARK questionnaire was administered to participants to collect their learning style preferences. Additionally, after the observation study an online survey was administered to collect participants' feedback on their experience of using the e-learning software. This survey also included John Keller's Instructional Materials Motivation Survey (IMMS), which measures student motivation according to the ARCS motivation model [16]. Subsequently, a focus group was held in which the participants had a facilitated discussion where they elaborated on the key themes identified in the observation study and the survey results.

The findings from the observation study, VARK questionnaire, student survey and focus group were examined holistically to understand whether the different research strands converged or diverged, to identify areas requiring further investigation, and to inform the development of the pedagogical heuristics and the e-learning software for Phase 2-Cycle 1. The findings are predominantly qualitative in nature; have a small sample size and are a collection of open and ordinal data (Likert and Ranking). Descriptive statistics gave basic quantification of results and are followed by textual descriptions that link to open responses from either the questionnaire or focus group and interpret the result findings.

B. Phase 2: Elaboration via Action Research

The purpose of Phase 2 was to further refine and elaborate the e-learning pedagogical heuristics and software via an Action Research methodology. An Action Research approach was chosen since it links theory and practice, achieving both practical and research objectives. The practical focus lies in the iterative development of the e-learning software and the research focus on the elaboration, evaluation and validation of the e-learning pedagogical heuristics. Susman and Evered [21] detail a five phase cyclical process, which forms the basis of the action research cycle used in this research. The five phases are diagnosing, action planning, action taking, evaluating and specify learning; these are outlined in Fig. 2.

Two cycles of evaluation and update were included in Phase 2. Phase 2-Cycle 1 study participants were six year 5 high school students (2nd year of the GCSE) and three year 4 high school students (1st year of the GCSE). The year 5 students also participated in Phase 1 and have worked with

the previous version of the e-learning software. With each cycle of Action Research, the e-learning pedagogical heuristics were updated based on the evaluation of teachers, education experts and ongoing literature review. Then, aspects of the pedagogy were represented in the e-learning software for evaluation purposes.

As with Phase 1, the student feedback on the e-learning software was collected via a combination of direct observation of software usage, online questionnaire and associated focus groups. Again, aligned with Phase 1, these findings were represented with descriptive statistics and contextualized with text description and links to open responses. These findings are examined holistically and merged with the feedback from education experts in order to inform the next cycle of action research.

V. Development of Pedagogical Heuristics

The pedagogical heuristics originally developed in Phase 1 have been iteratively refined and evaluated by two teachers and five education experts in Phase 1 and Phase 2-Cycle 1. Both teachers teach GCSE Computer Science or ICT; one teacher had five years of experience at the time of the study, the other less than one year of experience. The education experts were university academics in the fields of Child Computing Interaction, Computer Science, Education and Educational Media.

In Phase 1-Cycle 1 there were 31 e-learning heuristics defined. The evaluation findings in Phase 2-Cycle 1 indicate that the heuristics have a comprehensive pedagogical coverage, are appropriate for Computer Science, and are overall appropriate for the GCSE age group (15 and 16 year olds).Whilst the heuristics themselves have received positive feedback, the pedagogy document requires further work in Phase 2-Cycle 2 to reduce the document size, rationalize the heuristics and make the pedagogy more appropriate for its intended usage and audience.

VI. Results

Research findings from Phase 1 and Phase 2-Cycle 1 have informed the e-learning pedagogical heuristics and the e-learning prototype; however, this section discusses only the most significant findings, such as multimodal learning, active learning, authenticity vs. cognitive load, moderation in the heuristics, collaborative learning and learner motivation. Phase 2-Cycle 1 gave some initial encouraging findings since all nine participants agreed or strongly agreed that the e-learning software was easy to use. All participants either agreed or strongly agreed that the learning content in the e-learning software was represented in a clear and understandable way. Furthermore, none of the eight respondents reported that they supplemented, or needed to supplement, the learning material in the e-learning software with further textbook reading. This is self-reported feedback and does not equate with learning, but it does give a positive indicator of the value of the pedagogical heuristics.

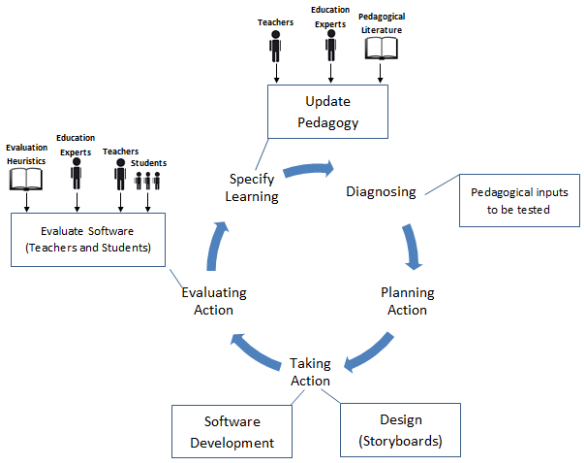

Fig. 2 Action Research Cycle

A. Multimodal Learning

Multi-modal learning was implemented in the software by representing educational material through combinations of text, audio, video, diagrams, pictures, animations and activities. The findings from Phase 1 and Phase 2-Cycle 1 support the multi-modal strategy outlined in the pedagogy. The combined VARK modal preferences of the student participants in both phases show a relative balance across the four modalities. This is further supported by the feedback in Phase 2, where four students agreed and four students strongly agreed with the statement "*The approach of using varying methods to represent the same educational concepts helped my understanding.*" Speaking on this point one student summarized that: "*I really liked the short videos, I think the pictures were actually really good, the text was also decent…"* [Student 19]

The multimodal approach is also given additional credibility since in Phase 1 the instructional designer for the e-learning software had a dominant Read/Write modal preference, which was left unmanaged and resulted in e-learning software with a heavy text bias. This led to a clear negative reaction in the Phase 1 student feedback. In Phase 2-Cycle 1, knowing this bias, the instructional designer took appropriate mitigation steps. This led to an improved response from the student participants in Phase 2-Cycle 1.

B. Active Learning

In support of the constructivist principle of active learning, the pedagogy proposes a significant focus on activities, problem solving and kinesthetic learning. This form of learning was well received by students; all nine students agreed or strongly agreed that the activity-based parts (problem solving, games, simulations, assessments and quizzes) of the e-learning software helped them to understand the subject matter. In addition, all nine students agreed or strongly agreed that the activity-based parts of the e-learning software were engaging.

C. Authentic learning vs reducing cognitive load

In schools, there is a tension between preparing students for assessments and the responsibility to develop well-rounded individuals who can think beyond exams. This pedagogical tension is also reflected in the e-learning pedagogy. For example, in order to reduce cognitive load, all learning material that does not directly contribute to learning outcomes should be reduced or removed; but this in turn, can weaken the authentic learning also proposed in the pedagogy. The tension between authenticity and cognitive load was discussed in both focus groups; the majority of students felt that authentic learning material that may not be directly examinable should not be sacrificed in favor of reducing cognitive load. Speaking on this point one student summarized that: "*It might not be in the exam but it really broadens your perspective, especially in giving you examples of real life applications. "* [Student 23]

The important factor was that each student needed to use their judgment to decide whether they would focus on such supplementary learning content. In the focus groups, it was agreed that in order to support this decision making process, such learning material would be clearly marked with a visual marker to reflect that it is supplementary information.

D. Moderation and balance in Heuristics

Taken at their extremes, learning theories such as Constructivism and Connectivism postulate some radical positions; these include learners being free to identify their own learning needs as they materialize, being free to support those learning needs by choosing their own learning (nodes) from the learning network and being free to construct their own understanding. In contrast, the preliminary findings of this research support a moderate balanced set of heuristics. The findings from Phase 1 and Phase 2-Cycle 1 show that the students value a degree of freedom, especially in learning activities, but that freedom needs to be bounded within a structured environment.

In Phase 2 Cycle 1, five students agreed and four students strongly agreed with the statement "*It is easy to use the navigation and program controls of the e-learning software.*" This strengthened the Phase 1 results and gave positive support for heuristics related to restricted navigational control. During both focus groups, the students clearly voiced support for the restricted navigation approach.

Furthermore, the results of the survey instrument suggest that the students are fully aware of the value of using the Web to support their subject learning, but the majority still prefer the guidance of the e-learning software to support their learning. This aligns with the moderate Connectivist approach suggested in the pedagogy in which the e-learning software becomes the hub that suggests (links to) other learning resources that are known to be reliable. As in Phase 1, the e-learning software was perceived to be comprehensive and the students preferred the structure of having one place to learn from, avoiding the wasted time in searching the Web and evaluating whether the information they find is correct. Almost all student feedback was aligned with the following comment: "*The E-Learning software has activities and features that are much more engaging than looking up information on the Web. The Web sometimes contains sites with wrong information, so the E-Learning software would be a much more reliable and easy source of information.*" [Student 14]

The Phase 2-Cycle 1 focus groups also revealed some unexpected feedback. Although, the e-learning software had an implicit structure and grouping of learning content, a significant portion of the students expressed the opinion that they would like explicit sections to be introduced. These sections were suggested to mimic a traditional chapter format, with the chapter learning objectives, learning material, review questions and finally a learning summary.

E. Collaboration

The research study has shown conflicting findings in relation to collaborative learning. Based on a student ranking of ten learning object types collaborative learning is ranked lowly in eighth place. Furthermore, only three from eight students agreed or strongly agreed that collaborative activities helped them understand the subject matter. However, a follow up question in the survey instrument and further discussion in the focus groups offered a different context. The students were asked to describe briefly, whether the collaborative activities gave them any learning or motivational benefits and what those benefits were. "*The collaborative activities gave me and my partner the opportunity to help each other understand the questions we had. One could answer the questions of the other, which was really helpful in order to complete our task.*"[Student 14]

The positive responses where reiterated and elaborated during the focus groups; however, one critical factor was also expressed. The respondents clarified that technology enhanced collaborative activities are artificial in a classroom context and much more suited for homework. In the context of this study, the majority of time spent using the e-learning software and the collaborative learning environment (CLE) was in class hence did not feel natural to the students. What was tentatively postulated in Phase 1 was more clearly established in Phase 2-Cycle 1; the experiment design had influenced the research findings. To naturally reflect a collaborative learning context requires a longer duration in which the students have weeks to review, respond and interact. However, the abiding conclusion from Phase 2-Cycle 1 was that despite the mixed feedback, overall, the students saw good potential for collaborative learning in spite of an initial learning curve.

F. Motivation

One of the key objectives of the e-learning pedagogy is to improve learning motivation; a number of heuristics specifically focus on student motivation and others offer supplementary motivational benefits. Phase 2-Cycle 1

findings are therefore broadly positive that six from nine respondents reported that the e-learning software increased their overall enthusiasm and interest in computing.

In relation to the ARCS motivation model, which focuses on Attention, Relevance, Confidence and Satisfaction, the results from the IMMS survey gave further positive indicators for student motivation. The results range between 3.52 and 3.76 on a continuum between Moderately True (3) to Mostly True (4), the maximum on this scale being Very True (5).

VII. Conclusion and Further Work

In this paper we have presented early research that suggests that e-learning can offer educational benefit to high school Computer Science. This educational benefit is realized and maximized by ensuring that the e-learning is underpinned by an appropriate set of e-learning pedagogical heuristics. The qualitative research described here offers support for a number of the heuristics developed in the pedagogy and offer further direction on areas to further refine in Phase 2-Cycle 2.

Although the focus of this research is primarily the UK there are various international comparisons [2], [5], [22] that show that the concerns and challenges outlined in the UK are common to a number of countries. The US, New Zealand, Israel, Germany and India are all in varying stage of similar initiatives to give greater prominence to the high-school computing curriculum. It follows that the findings of this research will be broadly transferable to such initiative in other nations.

The progress so far in Phase 1 and Phase 2 of the presented research, give a sound indication that the developed heuristics positively affect the pedagogical quality of e-learning software. The planned final research phase (Phase 3) of this study is to establish whether the pedagogy influences learning performance and motivation as theorized, it will further validate the findings of the first two phases by confirming them using quantitative methods and attempting to generalize them to a wider population.

3rd Doctoral Symposium on Recent Advances in Information Technology

THE third international Doctoral Symposium on Recent Advances in Information Technology (DS-RAIT 2016) will be held as a satellite event of the Federated Conference on Computer Science and Information Systems (FedCSIS 2016) and Education, Curricula & Research Methods (ECRM 2016) conference.

The aim of this meeting is to provide a platform for exchange of ideas between early-stage researchers, in Computer Science, PhD students in particular. Furthermore, the symposium will provide all participants an opportunity to get feedback on their studies from experienced members of the IT research community invited to chair all DS-RAIT thematic sessions. Therefore, submission of research proposals with limited preliminary results is strongly encouraged.

Besides receiving specific advice for their contributions all participants will be invited to attend plenary lectures on conducting high-quality research studies, excellence in scientific writing and issues related to intellectual property in IT research. Authors of the two most outstanding submissions will have a possibility to present their papers in a form of short plenary lecture.

Abstract— The *b*-matrix spatial distribution (BSD) is an effective method of improving accuracy of diffusion tensor imaging (DTI) measurements. It is based on a calibration with an anisotropic phantom measured in six positions inside an MRI scanner. However, if the contribution of non-diffusion gradients to the *b*-matrix can be neglected, simplified form of calibration with only 3 positions of the phantom could be sufficient. We called this approach simplified BSD-DTI (sBSD-DTI).

In this paper we introduce the above-mentioned technique and present the results of the computer simulations of BSD-DTI experiments and compare them with standard DTI. The complete BSD method, sBSD as well as BSD with assumption of phantom uniformity (uBSD) were simulated.

The simulations revealed that both simplified methods are less accurate than the complete BSD-DTI. Nevertheless, the calibration procedures and the algorithms are streamlined.

I. Introduction

Diffusion tensor imaging (DTI) is a powerful MRI technique with multiple clinical applications, including presurgical planning and intraoperative guidance in regions adjacent to critical neural tracts, evaluation and treatment of neurodegenerative diseases like epilepsy, multiple sclerosis, Alzheimer's or ischemic stroke [1]. Its accuracy depends strictly on correct identification of the *b*-matrix for a given imaging sequence [2][3]. Due to the complex character of the *b*-matrix and the fact that it is not constant across the volume [2], its analytical derivation is a very tedious and imprecise process [4][5]. Therefore, in the majority of MRI systems, the *b*-matrix is calculated relying only on the diffusion gradient vectors.

Several ways of improving the precision of derivation of the correct form of the *b*-matrix have been reported. Some of them take into account the cross-terms between the diffusion and imaging gradients. That includes refocusing each imaging gradient before turning on the diffusion gradient and refocusing each diffusion gradient before the imaging gradient is applied [6] or acquiring data twice; once with the given diffusion gradient and once with the opposite polarity [7][8]. However, these methods involve a prolonged acquisition time. The cross-terms effect can be also minimized by numerical calculations of the *b*-matrix [9][3], using calibration scans of an isotropic phantom [10] or by establishing the optimal diffusion gradient scheme [11].

In all of the above-mentioned techniques only diffusion, imaging and other known gradients are taken into account, while the background noises and further unknown factors, which may have an impact on the *b*-matrix, are neglected. Moreover, all of these practices assume the same form of the b-matrix throughout the imaging space, what is not true in general.

The *b*-matrix Spatial Distribution in Diffusion Tensor Imaging (BSD-DTI) is a method which enables one to discover the real form of the *b*-matrix for every voxel using a precisely defined anisotropic phantom [2]. It allows to maintain the accuracy and precision of the measurement even if the diffusion properties of the phantom are not spatially constant [12].

In this paper the simplified form of the BSD calibration is introduced. It requires measurement of the phantom in only three positions instead of six. Moreover, we present the results of the computer simulations which depict the effectiveness of this method.

II. Theory

A. Diffusion Tensor Calculation

The elements of a diffusion tensor can be calculated from the formula: [13]

$$\ln\left(\frac{S_n(b)}{S(b_0)}\right) = -\sum_{i,j=1}^{3}(b_{ij} - b_{0ij})D_{ij} \qquad (1)$$

which is the form of the Stejskal-Tanner equation, where $S_n(b)$ is a signal intensity for the nth diffusion gradient, $S(b_0)$ is a signal intensity without any diffusion gradient.
D_{ij} and b_{ij} are the components of the diffusion tensor and the *b*-matrix, respectively.

B. B matrix calculation

The *b*-matrix used in eq. (1) is given by [9]

Research financed by the National Centre of Research and Development, contract. No. PBS2/A2/16/2013 and contract No. STRATEGMED2/265761/10/NCBR/2015.

$$b = \int_0^{2\tau} \left[k(t) - 2H(t-\tau)k(\tau)\right]\left[k(t) - 2H(t-\tau)k(\tau)\right]^T dt \,, \quad (2a)$$

where

$$k(t) = \gamma \int_0^t G(t')dt' \,. \quad (2b)$$

G(t) is a column vector which represents the particular gradient in the imaging sequence. γ is the gyromagnetic ratio, 2τ is the echo time, *H(t)* is the Heaviside unit-step function.

If the imaging and other background gradients can be ignored, the *b*-matrix can be calculated from the dyadic product of the adequate gradients [14]; for example

$$b_n = G_n G_n^T = \begin{bmatrix} g_x \\ g_y \\ g_z \end{bmatrix} \begin{bmatrix} g_x & g_y & g_z \end{bmatrix} = \begin{bmatrix} g_x^2 & g_x g_y & g_x g_z \\ g_x g_y & g_y^2 & g_y g_z \\ g_x g_z & g_y g_z & g_z^2 \end{bmatrix} \quad (3)$$

Otherwise, the expressions for components of the *b*-matrix, due to the cross-terms between diffusion and other gradients, has more complex form:

$$b_{ii} = aG_i^2 + bG_i + c \quad (4a)$$

for the diagonal components and

$$b_{ij} = aG_iG_j + bG_i + cG_j + d \quad (4b)$$

for the off-diagonal.

C. Calibration with anisotropic phantom in three positions

To perform the simplified BSD-DTI (sBSD) calibration the phantom is situated inside an MRI scanner in such a way, that its diffusion tensor is diagonal in the laboratory coordinate system and then the diffusion tensor is measured. Subsequently, the phantom is rotated twice about 90° around the two orthogonal axes of the coordinate system respectively and each time the measurement is repeated. In this situation, according to the Stejskal-Tanner equation, the signal attenuation in voxel (*k, l, m*) in laboratory coordinate frame for a particular diffusion gradient is given by

$$\ln\left(\frac{S(b_{klm})}{S(0)}\right) = -b_{klm} : \begin{bmatrix} D1_{klm} & 0 & 0 \\ 0 & D2_{klm} & 0 \\ 0 & 0 & D3_{klm} \end{bmatrix} = b_{xx,klm}D1_{klm} + b_{yy,klm}D2_{klm} + b_{zz,klm}D3_{klm} \,, \quad (5)$$

Providing that diffusion properties of the phantom are well known in a coordinate system associated with the phantom *(r, s, t),* in laboratory coordinate frame (*k, l, m*) they can be found in two steps [15]. First, the (*k, l, m*) coordinates are found by

$$\begin{bmatrix} k \\ l \\ m \end{bmatrix} = R(\alpha,\beta,\gamma) \cdot \begin{bmatrix} r \\ s \\ t \end{bmatrix}, \quad (6)$$

where $R(\alpha,\beta,\gamma)$ is a rotation matrix.

In the next step the diffusion tensor D_{klm} is derived by rotation transformation

$$= R(\alpha,\beta,\gamma) \cdot D_{rst} \cdot R^T(\alpha,\beta,\gamma) \,. \quad (7)$$

In order to calculate the diagonal components of the *b*-matrix, one must solve the system of three equations for every diffusion gradient direction. Assuming that *b*-matrix has a form given by Eq. (3), off-diagonal components are equal to:

$$b_{ij} = \mathrm{sgn}(g_i g_j)\sqrt{b_{ii}b_{jj}} \,. \quad (8)$$

where $sgn(g_ig_j)$ is a sign of the product g_ig_j, where g_i and g_j are the diffusion gradient strengths in *i* and *j* direction, respectively.

If the diffusion properties of a phantom are assumed to be constant in its whole volume, the *k, l* and *m* indexes of the tensor *D* can be removed. BSD calibration under such assumption has been called uniform BSD-DTI (uBSD-DTI) [7].

III. Materials and Methods

In order to examine the effectiveness of simplified BSD-DTI method in comparison to BSD-DTI, uniform BSD-DTI (uBSD-DTI) and standard DTI (S-DTI), the computer simulations were conducted. First of all, the expressions given by Eq. (4a) and (4b) were derived for an exemplary imaging protocol for Bruker BioSpin 9.7 T imaging system. Components of *b*-matrices are given by

$b_{xx} = 598.5\ G_x^2 + 73.5\ G_x + 12.5,$ (9a)
$b_{yy} = 600\ G_y^2 + 72\ G_y + 12.5,$ (9b)
$b_{zz} = 596\ G_z^2 + 76\ G_z + 13,$ (9c)
$b_{xy} = 597\ G_xG_y + 37\ G_x + 37\ G_y + 12.5,$ (9d)
$b_{xz} = 597.5\ G_xG_z + 38\ G_x + 37\ G_z + 13,$ (9e)
$b_{yz} = 598.5\ G_yG_z + 37.5\ G_y + 36\ G_z + 13.$ (9f)

Diffusion gradient directions were chosen as follows

$G_1 = [0.666, 0.333, 0.666],$
$G_2 = [0.666, -0.333, 0.666],$
$G_3 = [0.333, 0.666, 0.666],$

$G_4 = [-0.333, 0.666, 0.666]$,
$G_5 = [0.666, 0.666, 0.333]$,
$G_6 = [0.666, 0.666, -0.333]$.

Then, the *b*-matrix spatial distribution was established by distorting the diffusion gradients and calculating b matrices for every voxel separately using Eqs. (9a)-(9f). The gradients were distorted systematically in following way

$$G'_{n,xyz} = G_n \sigma (x + y + z - 36) / 12.4904,$$

where $G'_{n,xyz}$ is a distorted diffusion gradients for a voxel (x, y, z) in the laboratory coordinate system. G_n is a diffusion gradient in nth direction. σ is the relative standard deviation of the spatial gradient distribution. In described simulations this parameter was set equal to 5%.

Subsequently, simulations of the BSD-DTI calibrations were performed for a virtual anisotropic phantom. The phantom was a cube with a side equal to 41 voxels. This size is required to indicate the *b*-matrix spatial distribution in the 25x25x25 voxels field of view (FOV). Diffusion properties of the phantom were similar to the diffusion properties of the anisotropic plate phantom [16]. The mean eigenvalues of its diffusion tensor were 0.002, 0.002 and 0.0005 mm^2/s. In order to imitate the properties of a real phantoms the tensor was spatially distorted by Gaussian noise with relative standard deviation equal to 1% and mean value equal to 0. The distribution of the *b*-matrix was calculated in four ways. Using the complete BSD-DTI method, uniform BSD, simplified BSD and simplified uniform BSD (uniform BSD with three phantom's positions - usBSD). Finally, diffusion tensor experiment were simulated for other two virtual homogeneous phantoms P1 and P2. The former was characterized by diffusion tensor with eigenvalues equal to 0.001, 0.002 and 0.003 mm^2/s. The latter was isotropic with diffusion coefficient equal to 0.002 mm^2/s. The first phantom was orientated in such a way that in the laboratory coordinate system its edges were inclined at 45^o angle from the axes of the laboratory coordinate system. The tensor was calculated using each of the aforementioned *b*-matrix spatial distributions, spatially constant *b*-matrix (S-DTI) and distribution calculated with approximation given by Eq. (3).

IV. Results

Tables 1 and 2 report the *b*-matrix elements calculated according to expressions (3) and (9a)-(9f), while table 3 reports the relative difference between them.

Mean values and relative standard deviations of diffusion tensor eigenvalues obtained in the simulations are reported in table 4.

In the case of isotropic phantom P2 as well as the phantom P1 orientated in such a way that its diffusion tensor was diagonal and in the case of *b*-matrix calculated with dyadic approximation, obtained results were similar for the simplified BSD and the BSD-DTI approaches.

Computing time of the *b*-matrix spatial distribution calculations performed on a personal computer was 331s, 227s, 72s and 44s for BSD-DTI, uBSD, sBSD and usBSD, respectively.

I. Discussion

The calculations of the *b*-matrix for the exemplary imaging sequence show that neglecting the cross-terms leads to a systematic error in the off-diagonal elements up to 5.47%.

As expected the BSD-DTI method ensures the highest accuracy and precision of DTI experiments, but also takes the longest period of computing time. However, in the case of post hoc image analysis it may be irrelevant.

Accuracy of the uBSD-DTI is almost as good as in the case of BSD-DTI. Nevertheless, due to not taking into account the imperfections of the phantom the precision is lower.

In the simplified BSD-DTI, due to the differences in *b*-matrix elements reported in tab. 3, precision is slightly lower. Nevertheless, in comparison with S-DTI the accuracy is significantly improved. It also allows to reduce the computing time.

When one combines the uniform and simplified BSD approaches, in comparison to complete BSD-DTI method, the accuracy and the precision definitely decrease but also the calculations time is drastically reduced.

If the diffusion tensor of imaged object is diagonal in laboratory coordinate system (like in the cases of isotropic media) the off-diagonal components of the *b*-matrix can be neglected, therefore the quality of sBSD-DTI is the same that of BSD-DTI.

II. Conclusion

BSD-DTI is a robust and effective method of improving precision and accuracy of DTI experiment. Nevertheless, sBSD approach can be an expedient trade-off between quality and simplicity, especially when non-diffusion gradient presents during the imaging sequence are negligible.

***Abstract*—In the article a new insight into an optimal control problem of the multistage processes has been given. The multistage descriptor processes with differential-algebraic constraints are under considerations. The new representation of the descriptor model has been presented. Moreover, the new structures to represent the differential state variables, algebraic state variables, control function, as well the global parameters have been introduced. The generalized description enables the unified representation of a broad group of the multistage processes with differential-algebraic relations and indicates on the physical interpretation of the process variables.**

***Index Terms*—optimal control, descriptor systems, DAE systems, generalized description approach.**

I. Introduction

IN THE article some new aspects of the multistage descriptor control systems and their unified representation have been discussed. The control and optimization of the technological processes with the differential-algebraic constraints have nowadays a great importance [12], [18], [19]. Therefore, one of main aims of the presented considerations is to emphasize the applicability of the obtained theoretical results.

The multistage technological processes are often designed in technology, especially in biotechnology [1], [9], [10], [11], chemical engineering [4], [8], as well as in environmental engineering [13], [14], [15].

The presence of a large number of successive stages is a characteristic feature of the modern technological processes. This reflects a complexity, as well as an arrangement of the designed processes. Therefore, the large number of the state variables, control functions and other process parameters needs a generalized description of the multistage systems. The generalized process description can enable us to unify the new control algorithms design.

The large-scale technological systems should be flexible to change their configurations, as well as to be open for necessary modifications. These requirements indicate a one of the new, unified process description approach, which can enable the process to develop.

To design the methodology, which allows us the integration of the additional stages within the process, is a task that requires the specific theoretical basis preparation. The generalized description methodology is the main result of the carried out considerations.

The rest of the paper has been organized in the following way. In Section II the general optimal control problem with the multistage differential-algebraic constraints has been formulated. In Section III the generalized description approach for the multistage DAE system has been proposed. Then, in Section IV, the generalized description approach has been illustrated with the three-stage chemical process. In Section V the presented considerations have been concluded.

II. Statement of the optimal control problem

The origin of the considerations about the multistage descriptor processes analysis are connected with two articles [16] and [17]. The assumptions and algorithms proposed in these articles are treated as the mile stones in control and optimization of the multistage technological processes. The observed progress in the control algorithms has been presented in details in three monographs [2], [3], [5].

In this section the most important features of the optimal control problem with the multistage differential-algebraic constraints have been given.

Assumption 2.1: The multistage process are consisted on the N successive stages, where N is the known number and $N \in \mathcal{N}$.

Assumption 2.2: [6] Each stage can be described by the system of the differential-algebraic equations. The index of the DAEs system is not greater than 1.

Moreover, to simulate, optimize and control a process, the time range has to be known.

Assumption 2.3: The range of the process time duration is known *a priori* and

$$t \in [t_0 \quad t_F]. \tag{1}$$

According to the Assumptions 2.1 and 2.3, the time domain of the each considered stage can be defined separately.

Definition 2.1: The time domain of the stage number $i = 1, \cdots, N$ can be defined as

$$t^i \in [t_0^i \quad t_F^i]. \tag{2}$$

978-83-60810-90-3/$25.00

In the stage number i and during the time domain t^i the process is governed by the set of the differential-algebraic equations.

Assumption 2.4: [7] At the stage number i, the process is governed by the set of the differential-algebraic relations

$$\begin{array}{rcl} \dot{\mathbf{y}}^i(t) & = & F^i(\mathbf{y}^i(t), \mathbf{z}^i(t), \mathbf{u}^i(t), \mathbf{p}, t^i) \\ 0 & = & G^i(\mathbf{y}^i(t), \mathbf{z}^i(t), \mathbf{u}^i(t), \mathbf{p}, t^i) \end{array} \tag{3}$$

where $i = 1, \cdots, N$ is the number of the stage considered, $\mathbf{y}^i(t) \in \mathcal{R}^{n_{\mathbf{y}^i}}$ is a differential state variable, $\mathbf{z}^i(t) \in \mathcal{R}^{n_{\mathbf{z}^i}}$ is an algebraic state variable and $\mathbf{u}^i(t) \in \mathcal{R}^{n_{\mathbf{u}^i}}$ denotes the unknown control function. The independent variable (e.g. time or length of the chemical reactor) is denoted as $t \in \mathcal{R}$.

Definition 2.2: The relations in (3) are defined as follows

$$F^i : \mathcal{R}^{\mathbf{y}^i} \times \mathcal{R}^{\mathbf{z}^i} \times \mathcal{R}^{\mathbf{u}^i} \times \mathcal{R}^{\mathbf{P}} \times \mathcal{R} \to \mathcal{R}^{\mathbf{y}^i} \tag{4}$$

and

$$G^i : \mathcal{R}^{\mathbf{y}^i} \times \mathcal{R}^{\mathbf{z}^i} \times \mathcal{R}^{\mathbf{u}^i} \times \mathcal{R}^{\mathbf{P}} \times \mathcal{R} \to \mathcal{R}^{\mathbf{z}^i}. \tag{5}$$

The minimized process performance index, which can be treated as the measure of the control quality, is defined as follows

$$\begin{array}{l} \min_{\mathbf{u}^i(t), i=1,\cdots,N} Q \\ = \sum_{i=1}^{N} \int_{t_0^i}^{t_F^i} \mathcal{L}(\mathbf{y}^i(t^i), \mathbf{z}^i(t^i), \mathbf{u}^i(t^i), \mathbf{p}, t^i) dt \\ + \mathcal{E}(\mathbf{y}^N(t_F^N), \mathbf{z}^N(t_F^N), t_F^N). \end{array} \tag{6}$$

III. The generalized description approach

In this section we would like to propose the new generalized description approach for the multistage differential-algebraic processes. The presented methodology extends the proposition from the article [16].

Definition 3.1: **The particular differential state vector** for the i-th stage $\mathbf{y}^i$ is consisted from all the differential state variables in the whole process. The differential state variables, which are constant during the i-th stage, are equal to their initial values.

The particular differential state vector is characteristic for the each stage and for the i-th takes the form

$$\mathbf{y}^i(t) = \begin{bmatrix} y_1^i(t) \\ \vdots \\ y_{n_{\mathbf{y}^i}}^i(t) \end{bmatrix} \in \mathcal{R}^{n_{\mathbf{y}^i}}. \tag{7}$$

Therefore, the particular differential state vector for the each stage has the same size. Moreover, the particular differential state vectors can be combined together to form the differential state matrix.

Definition 3.2: **The differential state matrix** is formed by the particular differential state vectors is the following way

$$\mathbf{Y}(t) = [\mathbf{y}^1(t) \quad \cdots \quad \mathbf{y}^N(t)], \tag{8}$$

where $\mathbf{y}^i(t)$, $i = 1, \cdots, N$ denotes the particular differential state vectors.

The properties of the differential state matrix:

1) The number of the differential state matrix rows is equal to the size of the particular differential state vector. Therefore, the number of the differential state variables can be identified.
2) The number of the differential state matrix columns is equal to the number of the process stages.
3) The differential state matrix indicates the stages, in which the chosen differential state variable has the same physical interpretation.

In the same way like the differential state matrix, **the algebraic state matrix** can be formed

$$\mathbf{Z}(t) = [\mathbf{z}^1(t) \quad \cdots \quad \mathbf{z}^N(t)], \tag{9}$$

the control matrix

$$\mathbf{U}(t) = [\mathbf{u}^1(t) \quad \cdots \quad \mathbf{u}^N(t)], \tag{10}$$

as well as **the matrix of the parameters constant in the time**

$$\mathbf{P} \equiv \mathbf{p}. \tag{11}$$

The differential state matrix, the algebraic state matrix, the control matrix, as well as the matrix of the parameters constant in the time can be used to define the multistage descriptor process

$$\begin{array}{rcl} \dot{\mathbf{Y}}(t) & = & \mathbf{F}(\mathbf{Y}(t), \mathbf{Z}(t), \mathbf{U}(t), \mathbf{P}, t) \\ 0 & = & \mathbf{G}(\mathbf{Y}(t), \mathbf{Z}(t), \mathbf{U}(t), \mathbf{P}, t) \end{array} \tag{12}$$

where

$$\mathbf{F} : \mathcal{R}^{n_{\mathbf{Y}}} \times \mathcal{R}^{n_{\mathbf{Z}}} \times \mathcal{R}^{n_{\mathbf{U}}} \times \mathcal{R}^{n_{\mathbf{P}}} \times \mathcal{R} \to \mathcal{R}^{n_{\mathbf{Y}}} = \mathcal{R}^{n_{\mathbf{Y}}} \times \mathcal{R}^{N}, \tag{13}$$

$$\mathbf{G} : \mathcal{R}^{n_{\mathbf{Y}}} \times \mathcal{R}^{n_{\mathbf{Z}}} \times \mathcal{R}^{n_{\mathbf{U}}} \times \mathcal{R}^{n_{\mathbf{P}}} \times \mathcal{R} \to \mathcal{R}^{n_{\mathbf{Z}}} = \mathcal{R}^{n_{\mathbf{Z}}} \times \mathcal{R}^{N}, \tag{14}$$

and t denotes the duration time of the whole considered process

$$t \in [t_0 \quad t_F]. \tag{15}$$

The generalized system description has been used to obtain the new form of the optimal control problem of three-stage chemical process .

IV. Application in the multistage process

The matrix-based approach for the multistage DAE systems description has been applied to model of the three-reactor process (Fig. 1). The considered system is consisted of two chemical reactors and a mixing stage between them [16].

At the beginning, the first reactor is loaded with the substrate A with the volume 0.1 m^3 and concentration 2000 mol/m^3.

Due to reactions, which take a place in the system, the products B and C are obtained according to the scheme

$$2A \rightarrow B \rightarrow C. \tag{16}$$

Additionally, the first reactor was equipment with a heating exchanger, which can be used to control the process temperature and in this way - to influence the trajectories of the process variables. The concentrations of the substrate and products are changing in the following way

$$\dot{C}_A = -2k_1(T)C_A^2 \tag{17}$$

$$\dot{C}_B = 2k_1(T)C_A^2 - k_2(T)C_B \tag{18}$$

$$\dot{C}_C = k_2(T)C_B \tag{19}$$

with the kinetics constraints

$$k_1(T) = 0.0444\exp(-2500/T) \tag{20}$$

and

$$k_2(T) = 6889.0\exp(-5000/T). \tag{21}$$

Then, in the mixing stage at the time t_2^0, the component B of concentrations C_B^0 = 600mol/m^3 and some volume S is added. Therefore, the volume and concentrations of the substrates are changing, so the following relations are satisfied

$$V_2C_A(t_0^2) = V_1C_A(t_F^1) \tag{22}$$

$$V_2C_B(t_0^2) = V_1C_B(t_F^1) + SC_B^0 \tag{23}$$

$$V_2C_C(t_0^2) = V_1C_C(t_F^1) \tag{24}$$

where V_1 is the volume of substrates loaded at the beginning of the first reactor. Therefore, the volume V_2 in the second reactor is given by

$$V_2 = V_1 + S \tag{25}$$

The volume S is a decision parameter with

$$0 \leq S \leq 0.1(m^3) \tag{26}$$

After the mixing stage, the substrates are loaded into the last reactor, where three reactions are taking a place

$$B \rightarrow D \tag{27}$$

$$B \rightarrow E \tag{28}$$

$$2B \rightarrow F \tag{29}$$

In the 2*nd* reactor, the reactions take place under isothermal conditions. The state variables are changing in the following way

$$\dot{C}_A = 0 \tag{30}$$

$$\dot{C}_B = -0.02C_B - 0.05C_B - 2 \times 4.0 \times 10^{-5}C_B^2 \tag{31}$$

$$\dot{C}_C = 0 \tag{32}$$

$$\dot{C}_D = 0.02C_B \tag{33}$$

$$\dot{C}_E = 0.05C_B \tag{34}$$

$$\dot{C}_F = 4.0 \times 10^{-5}C_B^2 \tag{35}$$

The decision variables are the profile of the temperature $T(t)$, the duration time of the reactions in each stage, and the amount S of component B, which is added at the mixing step.

The process is aimed to maximize the amount of the product D at the output of the 2*nd* reactor

$$\max_{t_1,t_2,S,T(t)} V_2C_D(t_2) \tag{36}$$

subject to the constraints on the temperature profile

$$298 \leq T(t) \leq 398(K), \qquad t^1 \in [t_0^1 \quad t_F^1]. \tag{37}$$

According to the presented methodology, the three-stage technological process can be rewritten in the generalized matrix form. There are six state variables, which indicate the appropriate concentrations

$$\mathbf{y}(t) = \begin{bmatrix} y_A(t) \\ y_B(t) \\ y_C(t) \\ y_D(t) \\ y_E(t) \\ y_F(t) \end{bmatrix}. \tag{38}$$

The particular vector of the state variables takes the form

$$\mathbf{y}^1(t^1) = \begin{bmatrix} y_A^1(t^1) \\ y_B^1(t^1) \\ y_C^1(t^1) \\ y_D^1(t_0^1) \\ y_E^1(t_0^1) \\ y_F^1(t_0^1) \end{bmatrix}, \tag{39}$$

$$\mathbf{y}^2(t^2) = \begin{bmatrix} y_A^2(t_0^2) \\ y_B^2(t_0^2) \\ y_C^2(t_0^2) \\ y_D^2(t_0^2) \\ y_E^2(t_0^2) \\ y_F^2(t_0^2) \end{bmatrix}, \tag{40}$$

$$\mathbf{y}^3(t^3) = \begin{bmatrix} y_A^3(t_0^3) \\ y_B^3(t^3) \\ y_C^3(t_0^3) \\ y_D^3(t^3) \\ y_E^3(t^3) \\ y_F^3(t^3) \end{bmatrix}. \tag{41}$$

Therefore, the matrix of the state variables for the considered process takes the form

$$\mathbf{Y}(t) = [\mathbf{y}^1(t^1) \quad \mathbf{y}^2(t^2) \quad \mathbf{y}^3(t^3)]. \tag{42}$$

The control function is constructed in a similar way

$$\mathbf{u}(t) = \begin{bmatrix} T(t) \\ S \\ C_0 \end{bmatrix}. \tag{43}$$

$$\mathbf{u}^1(t^1) = \begin{bmatrix} T(t) \\ 0 \\ 0 \end{bmatrix}. \tag{44}$$

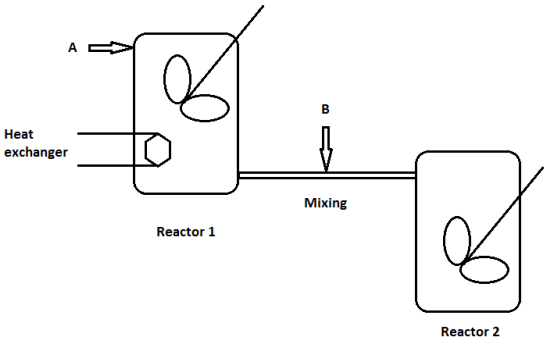

Fig. 1. The three-stage chemical process.

$$\mathbf{u}^2(t^2) = \begin{bmatrix} 0 \\ S \\ C_0 \end{bmatrix}. \tag{45}$$

$$\mathbf{u}^3(t^3) = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}. \tag{46}$$

and finally

$$\mathbf{U}(t) = [\mathbf{u}^1(t^1) \quad \mathbf{u}^2(t^2) \quad \mathbf{u}^3(t^3)]. \tag{47}$$

V. Conclusion

In the presented article the considerations about the new generalized description approach for the multistage technological processes with the differential-algebraic constraints were discussed. Therefore, the proposed approach was characterized by some important features:

a) the general and simple schematic multistage processes description,

b) the physical interpretation of the process variables,

c) easy modification of the process by addition of new elements to the model,

d) integration of processes developed according to different standards,

e) indication the successive stage of the process by the matrix-based structure of the process variables.

From the presented reasons, the carried out theoretical considerations possess a significant practical application. Thus, the generalized description approach has been used to obtain the new form of the three-stage chemical process model.

***Abstract*—The aim of this work was to find an analytical expression describing the b-matrix spatial distribution (BSD) in diffusion tensor imaging, obtained by means of simple calibration to a water isotropic phantom.**

The bivariate second degree polynomial function was fitted for the complete set of spatially distributed b-matrix elements derived through measurements on a 3 Tesla clinical scanner.

Smooth, noise free b-matrices were obtained with clear patterns of systematic errors. Diffusion tensor eigenvalues were derived with much better accuracy than for previous BSD calibration. The proposed approach does not require many averages during the acquisition of the phantom and thus can shorten the BSD calibration.

I. Introduction

DIFFUSION Magnetic Resonance Imaging (dMRI) which appeared in the eighties and quickly developed towards Diffusion Tensor Imaging (DTI) [1] [2], has found number of clinical applications. It became very successful tool for neurological structural and functional imaging [3]. However, DTI is intrinsically prone to the numerous artifacts [4], which makes any quantitative comparison of the images obtained by different scanners questionable.

In order to calculate a diffusion tensor one has to acquire series of images, each with a different diffusion sensitizing gradient applied. The gradients can differ in both magnitude and orientation. Information about diffusion gradient schemes is stored in a b-matrix. The most common way of deriving the b-matrix is an approximated analytical calculation of each element. However, the applied diffusion gradients interact with other magnetic field gradients applied during the imaging sequence and thus the resultant gradients differ from what was expected. Variations of the magnetic susceptibility across the sample volume can also affect the b-matrix [5].

Several methods to partially solve such problems were proposed. Some of them introduced bipolar gradients which cancel out the cross-terms between the applied gradients [6], [7]. The other focused on choosing the best gradient encoding scheme [8], [9], [10]. There were also post processing methods [11] and phantom calibration techniques [12] suggested.

Research financed by the National Centre of Research and Development (contract No. PBS2/A2/16/2013)

A recent report revealed that for particular imaging sequence parameters the errors superimposed on the b-matrix have a systematic character and can be reduced through a calibration procedure [13]. The solution is based on the derivation of the b-matrix spatial distribution (BSD) which substitutes the standard b-matrix, constant for an entire volume. The BSD method improves the accuracy of diffusion measurements, but since the calibration is based on a real data, the derived distribution of the b-matrix is always biased with noise.

In this paper we present a procedure of deriving the noise free approximation of the actual spatial distribution of the b-matrices. The results are compared with both standard DTI and hitherto BSD-DTI.

II. Materials and methods

Standard diffusion tensor imaging of a water isotropic phantom was performed on a 3 Tesla clinical scanner. Six diffusion gradient directions were applied and the b-value was set to $1000\,\mathrm{s/mm^2}$. The imaging was done in axial orientation, 25 interleaved slices with voxel size 1x1x3 mm were taken, with number of averages set to 4. The acquisition was repeated then for the BSD calibration purposes.

The spatial distribution of the b-matrices was obtained through simple calibration to water phantom. The experiments were carried out in stable thermal conditions in temperature of $21\,^{\circ}\mathrm{C}$. The diffusion tensor eigenvalues for an isotropic water phantom in constant temperature are all equal and can be derived theoretically from the Einstein-Smoluchowski equation [14]:

$$\left\langle r^2 \right\rangle = 6Dt, \tag{1}$$

where: $\left\langle r^2 \right\rangle$ – is a mean square displacement, D – is a diffusion coefficient, and t – is a diffusion time. The off-diagonal elements of the tensor can be assumed equal to zero, since they describe the rotations of the diffusion ellipsoid being in this case spherically symmetrical. With the above assumptions

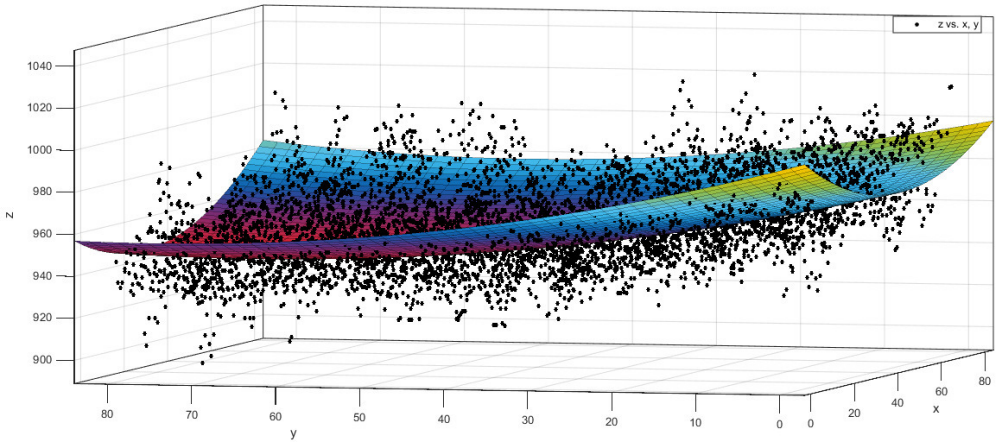

Fig. 1. Plot of bivariate polynomial fitted to data. In this case the diffusion gradient was applied solely along the x axis. The expression of the fitted function is the following: $f(x, y) = 992.5 - 1.021x - 1.043y + 0.013x^2 + 0.004xy + 0.007y^2$.

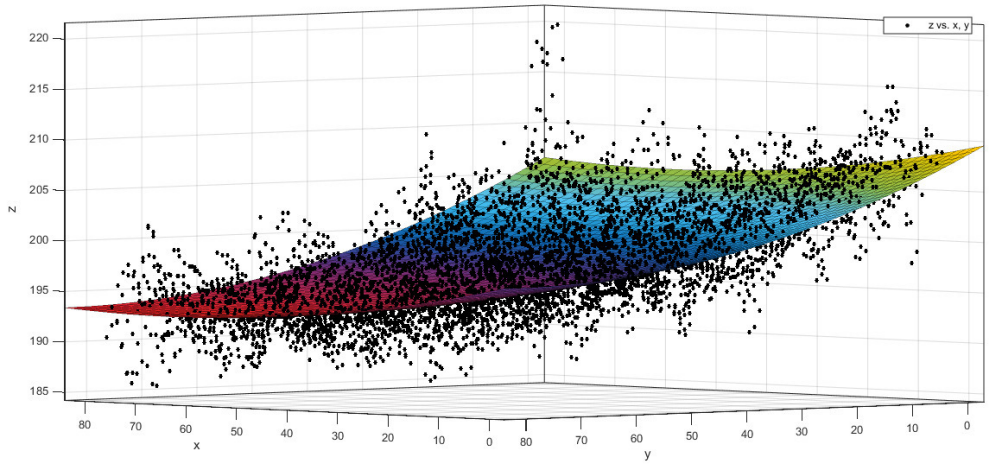

Fig. 2. Plot of bivariate polynomial fitted to data. In this case the dominating diffusion gradient was applied along the y axis with a nonzero x component. The expression of the fitted function is the following: $f(x, y) = 208.4 - 0.1145x - 0.2833y + 0.0009x^2 - 0.0001xy + 0.0017y^2$.

the spatial distribution of the b-matrix elements for each voxel can be derived from Stejskal-Tanner equation [15].

$$\ln\left(\frac{S_x}{S_0}\right) = -\mathbf{b} : \mathbf{D}, \tag{2}$$

where: S_x – is a signal intensity in particular voxel measured with x diffusion gradient applied, S_0 – is a signal intensity in particular voxel measured without diffusion gradient applied, $\mathbf{b}$ – is a b-matrix in particular voxel, $\mathbf{D}$ – is a diffusion tensor in particular voxel. The colon indicates a generalized dot product defined as:

$$\mathbf{b} : \mathbf{D} = \sum_{i,j} b_{ij} D_{ij}, \tag{3}$$

where b_{ij} and D_{ij} are particular b-matrix and diffusion tensor elements, respectively.

The complete set of b-matrices derived from the above formulas consisted of 900 b-maps (25 slices times 6 b-matrix elements times 6 diffusion gradients).

An 80 x 80 pixel square region of interest (ROI) R1 inscribed in the circle of the phantom's axial projection was chosen for the analysis.

Theoretically each element of the b-matrix should be a scalar value derived from the sum of various quadratic gradient terms. The number of terms depends on what is really taken into account in calculating the b-matrix, but the diffusion gradients are always dominating, because of their relatively big strength. The influence of the imaging gradients is of secondary importance. Cross-terms between various types of gradients may also appear. Due to imperfections of the gradients, their nonlinearity and interactions between them the actual b-matrix should be described by a superposition of quadratic functions instead of a single constant value.

The actual character of the b-matrix may be expected to be

TABLE I
COMPARISON OF THE MEAN EIGENVALUES AND THEIR STANDARD DEVIATIONS OBTAINED BY MEANS OF THE THREE APPROACHES. THE IMPROVEMENT FACTOR K_{SD} IS EQUAL TO THE RATIO OF STANDARD DEVIATION OF STANDARD DTI TO THE SD OF A PARTICULAR APPROACH.

Experiment	D [mm^2/s]	sd [mm^2/s]	K_{sd}
DTI	1.9822×10^{-3}	5.73×10^{-5}	1.00
BSD	1.9984×10^{-3}	5.42×10^{-5}	1.05
A-BSD	1.9973×10^{-3}	3.92×10^{-5}	1.46

described by a superposition of quadratic functions instead of a single constant value.

In order to fit a second order bivariate polynomial function:

$$f(x, y) = a_0 + a_1 x + a_2 y + a_3 x^2 + a_4 xy + a_5 y^2, \qquad (4)$$

to all the 900 ROIs, a python script using least-squares fitting procedure was written.

The initial b-matrix values within the ROIs were substituted with values derived from the fitted functions. Eventually, diffusion tensors were calculated in three ways:

1) Standard DTI - using single b-matrix, constant in the entire ROI.
2) BSD - incorporating spatial distribution of the b-matrix, derived directly from the calibration procedure.
3) Actual BSD (A-BSD) - with usage of b-matrix spatial distribution derived from the fitted polynomial. The tensors were calculated for a circle ROI R2 inscribed in the R1 used for the fitting.

III. RESULTS

The calculated diffusion tensors were diagonalized with LU decomposition method in order to obtain the eigenvalues. For each of the 25 slices mean eigenvalue in R2 and its standard deviation were calculated. The results for selected slices together with the improvement factors K_{sd} are presented in table I. Mean eigenvalues are quite similar for all the three approaches, however, standard deviations differ. The lowest value of sd, which indicates the best accuracy, was obtained for the A-BSD approach using the fitting procedure.

Plots of exemplary bivariate polynomial fits obtained for two different gradient directions are depicted in figures 1 and 2, respectively. The first corresponds to the diffusion gradient applied solely in x direction, whereas the latter, to the stronger component in y direction and weaker, nonzero component in x.

Two dimensional maps of the fitted b-matrices for selected slices are depicted in figures 3 and 4.

IV. DISCUSSION AND CONCLUSIONS

The described procedure resulted in a noticeable improvement of the diffusion tensor eigenvalues homogeneity for the isotropic water phantom. The analysis was done in axial direction in which distortions in b-matrices are the smallest, accordingly to the previous studies [13] [16]. Thus also the K_{sd} improvement factor is relatively small. However, fitting the b-matrix data to the bivariate polynomial function decreases the

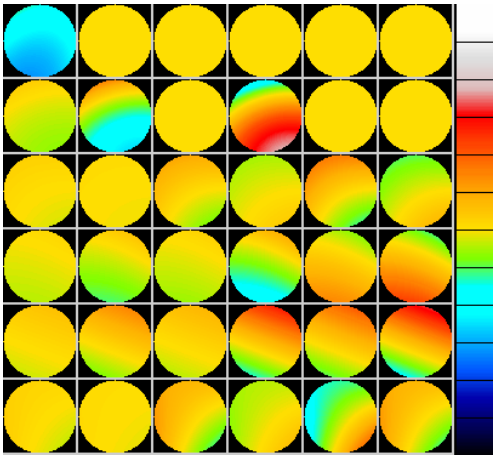

Fig. 3. Two dimensional map of b-matrix elements corrected with fitted bivariate polynomials. Each row represents one of the diffusion gradient directions, and each column is a b-matrix element in order: b_{xx}, b_{yy}, b_{zz}, b_{xy}, b_{xz}, b_{yz}. The maps correspond to the middle slice, positioned in the isocenter of the scanner. The scale ranges from $-50\,s/mm^2$ to $50\,s/mm^2$. The map is differential, i.e. from each element standard, constant b_{ij}-value was subtracted.

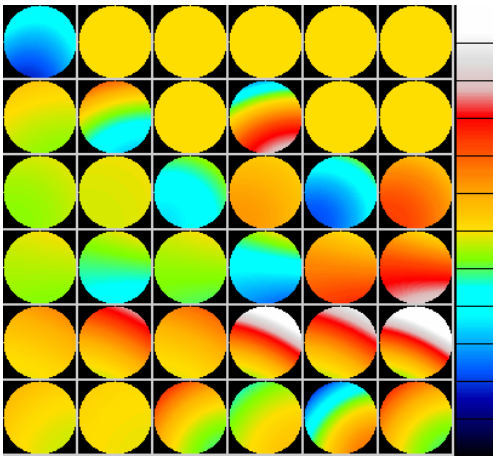

Fig. 4. Two dimensional map of b-matrix elements corrected with fitted bivariate polynomials. Each row represents one of the diffusion gradient directions, and each column is a b-matrix element in order: b_{xx}, b_{yy}, b_{zz}, b_{xy}, b_{xz}, b_{yz}. The maps correspond to the 25 slice, the farthest from the isocenter of the scanner. The scale ranges from $-50\,s/mm^2$ to $50\,s/mm^2$. The map is differential, i.e. from each element standard, constant b_{ij}-value was subtracted.

mean eigenvalue standard deviation to the approximately one third of the sd obtained through hitherto BSD calibration.

The analyzed dataset is characterized by a relatively high noise level, due to only 4 averages. Application of the fitting procedure visibly smooths the b-matrix spatial distribution and emphasizes the shape of the systematic errors. Figures and the equations of the fitted functions show that a_3 coefficient is an order of magnitude bigger than a_5 when the gradient direction was set along x axis and on the contrary the a_5 coefficient is an order of magnitude bigger than a_3 when the gradient is directed mostly along the y axis. The linear coefficients of the fits are also not negligible. It corresponds to the already

discussed in this paper theoretical underpinning of the b-matrix. Complicated, by number of terms which are difficult to take into account in the analytical derivations (including cross-terms), the structure of the b-matrix in the presented approach is revealed in its final shape through an experiment.

The two dimensional maps of the b-matrix elements depict the shape and intensity of the systematic errors. Comparison of figures 3 and 4 confirms the best homogeneity of the b-matrices in the isocenter of the scanner (most of the terms in figure 3 are close to yellow color corresponding to the assumed standard value of b_{ij} element), and intensification of the distortions while moving towards the edges of the scanner (fig 4.).

In conclusion the presented method improves the BSD approach to DTI further. It enables one to derive noise-free spatial maps of b-matrices even from a dataset with relatively high noise level. This gives hope for shortening the BSD calibration time. Second degree bivariate polynomials turn out to define well the b-matrix elements according to the theory.

The presented approach successfully excludes the systematic errors affecting the accuracy of diffusion tensor derivation and opens the path for truly quantitative diffusion tensor measurements independent of a chosen scanner and imaging sequence.

Multilayer perceptron for gait type classification based on inertial sensors data

Damian Szczepański
Rzeszów University of Technology al. Powstancow Warszawy 12, 35-959 Rzeszów, Poland
Email: dszczepanski@prz.edu.pl

***Abstract*—In this study, the gait type classification process is considered. Input data are obtained by using the inertial sensors tracking system. Three types of gait are recorded: normal walk, tiptoeing and walk retaining long stance phase. Two data set types, describing the registered motion, are prepared. The most significant input features are selected by means of the sensitivity analysis (SA) procedure. The classification process is conducted using multilayer perceptron (MLP) with various structures. The classification accuracy of the network is computed with the use of a cross validation procedure. The obtained results show that the successful classification of presented gait types can be achieved using relatively simple MLP architecture.**

I. Introduction

NOWADAYS, as the society is getting older, the illnesses typical for the elderly age, are becoming more and more meaningful part of modern medicine. In turn, the doctors need immediate and accurate methods in everyday diagnosing. The analysis of human gait from the very beginning has been a basic method in rehabilitation and early locomotive disease detection. Nowadays, Parkinson's disease (PD) is most common and onerous dysfunction of medicine [1]. At the early stage, PD does not show any significant symptoms, except for small gait and posture changes. Typical gait modification relies on the increasing foot contact in stance phase (shuffling steps), forward-flexed posture and limbs tremor. In order to treat PD effectively, the rehabilitation and exercises should be employed at the very early stage of disease detection. The technology progress in human body motion capture provides new solutions which could be used in human gait and posture analyses.

Since the beginning, the optical systems have been the basic tool in human motion capture. However, due to its complicity, their usage can be very complicated on a daily basis. One of the most promising approaches is the inertial sensors technology, which is simpler in usage and comparable in accuracy with the optical systems . Inertial systems have been used in many fields of medical diagnose assistance[2], i.e.: cerebral palsy [3], [4], determining gait defects, sport medicine [5]. Flexibility advantage of such system is very useful in rehabilitation [6], exercise motivation [7] and automatic exercise advising [8].

The main purpose of this article is to explore the classification problem of gait which is registered on the basis of the motion parameters such as joint angles, segments velocity and accelerations values. The motion acquisition is conducted by using Xsens MVN Biomech suit (MVN) [9] which is based on inertial measure units (IMU) wirelessly connected to the computer. In the classification process, the MLP classifier is used and the best architecture with highest accuracy is chosen. In current study, one also considers the problem of input features' selection. Therefore, the SA procedure is utilized to determine the most significant gait attributes. MLP classification performance is assessed with reduced number of inputs.

All simulations, the classification process and the IMU synthesis are conducted by using Matlab [10], DTReg [11] and MVN Studio [12] software.

The paper is composed of the following sections. Section II presents the input data used in this work. In Section III, the problem statement is formulated and the approaches utilized in the classification process are shortly described. Sections IV and V outline the experiments' settings and the obtained results, respectively. Section VI concludes the paper.

II. Input data

A. Data acquisition

The registration process is conducted by using MVN which utilizes 17 inertial sensors attached to each body segment (see Fig. 1).

Two subjects (M: 90kg, 180 cm, 29 years, M: 75 kg 181 cm, 26 years) take part in the experiment. They are asked to walk in three different gait manners: (a) – normal walk with natural speed, (b) – tiptoeing and (c) – walk retaining long stance phase and very small distance between foot and ground in swing phase. The (c) type of gait is similar to PD walk. Registration is repeated 20 times per gait type by each person, which gives 120 data series for all gait types.

One gait cycle, which is one step, is defined as a time between heel ground contacts. Fig. 2 presents a joint angle registered within a single gait cycle.

B. Data type

Raw data (accelerometer, gyroscope, magnetometer values), which are acquired directly from IMU sensors during registration process, are synthesized by MVN Studio Software. All joint angles, segment accelerations, segment velocity, angular segment accelerations and angular segment velocity are calculated. Each parameter has three values in each dimension what, in turn, gives 612 values per one time frame data. Sample screen-shot from MVN Studio with rendered subject avatar and plotted joint angles are presented in Fig. 3.

978-83-60810-90-3/$25.00

Fig. 1. Inertial sensors attached to body segments.

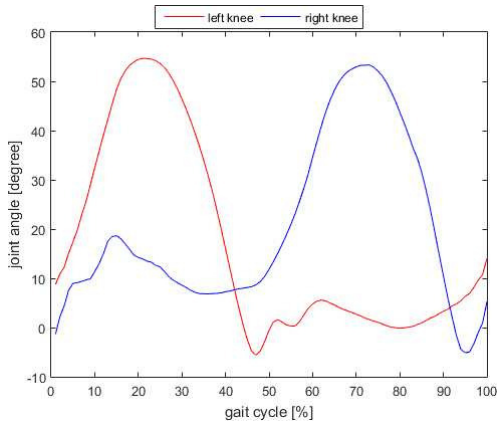

Fig. 2. Flexion - extension knee angle in one gait cycle: left knee (red), right knee (blue).

C. Input vectors

For the purpose of the comparison, two data sets are prepared from the gait recordings. The first data set is represented by statistical values (SV): maximum value, minimum value, mean and standard deviation, which are calculated from acceleration values of 17 body segments. Every IMU accelerometer measure signal in *x, y, z* axis what in result gives 204 values (4 statistical values of 17 segments in 3 axis). These are: pelvis, thoracic spine, head, right shoulder, right upper arm, right forearm, right hand, left shoulder, left upper arm, left forearm, left hand, right upper leg, right lower leg, right foot, left upper leg, left lower leg, and left foot. An exemplary single body segment, i.e. left upper leg, is illustrated in Fig. 3 (red curve).

The second data set is represented by the normalcy index (NI) parameters commonly used in gait analyses [13]. The 15 values proposed in [14] are determined: time of toe off, walking speed, mean pelvic tilt, range of pelvic tilt, mean pelvic rotation, minimum hip flexion, range of hip flexion, peak abduction in swing, mean hip rotation in stance, knee flexion at initial contact, time of peak knee flexion, range of knee flexion, peak dorsiflexion in stance phase, peak dorsiflexion in swing, and mean foot progression angle. All calculations are conducted in Matlab software.

Three types of gait described in subsection II-A impose three class classification problem.

III. Application of MLP network to gait classification problem

A. Problem statement

For the input data set described in Section II, the task is to find the optimal MLP architecture with respect to the highest prediction accuracy (*Acc*) of the model. The accuracy is calculated as a sum of true positives and true negatives divided by number of all input vectors. The experiment is repeated 10 times and after all tests, the average value and the standard deviation (*Std*) of *Acc* are calculated. The accuracy in each test trial is computed using a 10-fold cross validation procedure. Furthermore, an optimal subset of input features is found with the use of the SA procedure. As in the case of all input attributes, the highest *Acc* of MLP is determined for reduced data set.

B. Multilayer perceptron

MLP is the feedforward neural network [15], [16], i.e. the model where the input signal is fed forward through a number of layers [17]. There are three types of layers in MLP: an input layer, one or more hidden layers and an output layer. The input layer consists of the nodes which are the features of an input vector. Each of $i = 1, \ldots, n$ input features is connected to a hidden layer neuron activated as follows

$$y_j^{(1)} = f\left(\sum_{i=1}^{n} w_{ji}^{(1)} x_i + b_j^{(1)}\right), \tag{1}$$

where $f(\cdot)$ is the activation function, $\mathbf{w}_j^{(1)} = [w_{j1}^{(1)}, \ldots, w_{jn}^{(1)}]$ is the weight vector of the jh hidden neuron, $\mathbf{x} = [x_1, \ldots, x_n]$ is an input vector and $b_j^{(1)}$ denotes the bias of the jh hidden neuron. The outputs $y_j^{(1)}$ of the hidden neurons are linearly combined with the second layer weights $w_{kj}^{(2)}$ and the bias $b_k^{(2)}$ and, after activation, create an output of the kth neuron in the second layer

$$y_k^{(2)} = f\left(\sum_{j=1}^{m} w_{kj}^{(2)} y_j^{(1)} + b_k^{(2)}\right). \tag{2}$$

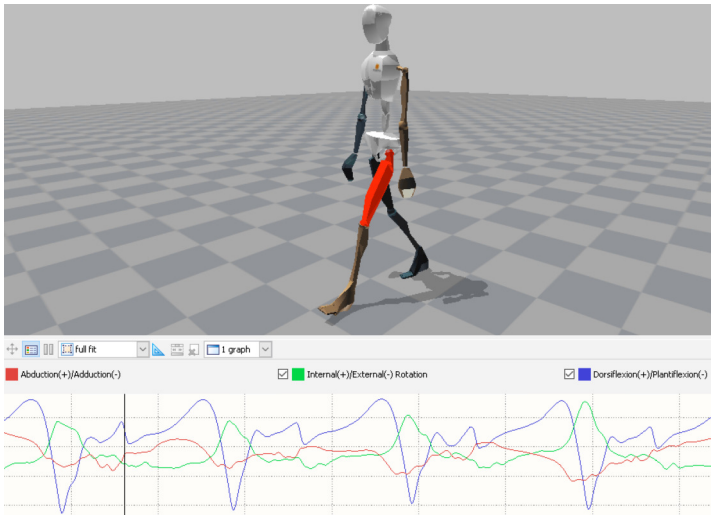

Fig. 3. MVN Studio screen-shot presenting rendered avatar with selected upper leg segment and plotted knee angles.

In (1) and (2), $f(\cdot)$ should be selected in the way it is continuous, differentiable and monotonically increasing. $f(a) = \frac{1}{1+e^{-\lambda a}}$ is the most commonly used activation function. The number of hidden layers and the number of neurons in each hidden layer must be optimized in order to maximize MLP's prediction accuracy. In this study, scaled conjugate gradient algorithm is used for MLP training.

C. Sensitivity analysis procedure

SA procedure steps separately through a single feature in each iteration. It randomly permutes its values across the rows of the data set. The values of this feature remain the same but they are randomly moved to different rows. Then the accuracy the network is evaluated on the modified data set. If the feature is important, randomizing the order of its values greatly degrades the accuracy of the predictions. If the feature is not valuable in prediction, the order of its values has little or no influence on the accuracy of the network. Last step is to determine the rank of the importance of features based on the amount of degradation that occurred by randomizing their values and to scale the scores so the most important feature has a relative importance of 100.

IV. Experiments

MLP used in experiment has 3 outputs (one for each gait type). The number of neurons in the hidden layer is taken from the set $\{2, \ldots, 10\}$. The linear, logistic and tangent activation functions are utilized for MLP training. In the first part of the experiment, MLP is trained by using all input variables both for SV and NI data. As a result, the best network architectures for both data sets are chosen. The second part of the experiments relies on applying the SA procedure to select features for input neurons' representation. Table I and II present the importance of features for NI and SV data set, respectively. Due to the fact that SV data vector is composed of 204 attributes, only 7 significant features are presented. For the second part of the experiment, only 3 most significant features of SV and NI dataset are selected. The classification process is repeated using reduced MLP and best network architectures are chosen.

TABLE I
First 7 most important NI data set features.

Parameter	Importance
peak body dorsiflexion in stance phase	100.00
knee range flexion	61.90
peak body dorsiflexion in swing phase	48.87
range of hip flexion	9.61
mean foot progression angle	7,28
walking speed	5,45
mean hip rotation in stance	3,21

TABLE II
First 7 most important SV data set features.

Parameter	Importance
mean right foot acceleration in Z axis	100.00
mean acceleration of right thigh in Y axis	69,79
mean left foot acceleration in Z axis	69,75
mean right foot acceleration in X axis	48,72
mean left foot acceleration in Y axis	38,11
mean left foot acceleration in X axis	35,08
standard deviation of pelvis tilt acceleration in Z axis	18,75

V. Results

A. Result for SV dataset

For MLP with 204 inputs, the highest accuracy (99.18%) is achieved for the network with 2 hidden neurons. Using only mean right foot acceleration in Z axis (importance 100), mean acceleration of right thigh in Y axis (importance 69.79), mean acceleration of left foot in Z axis (importance 69.74),

TABLE III
RESULTS OF SV DATASET CLASSIFICATION.

Used parameter	Neurons	*Acc*	*Std*
all parameters	2	99.18%	0.11%
mean right foot acceler. in Z axis, mean acceler. of right thigh in Y axis, mean left foot acceler. in Z axis	2	100.00%	0.00%
mean right foot acceler. in Z axis	2	100.00%	0.00%
mean acceler. of right thigh in Y axis	3	91.14%	0.93%
mean left foot acceler. in Z axis	9	94.59%	1.51%

TABLE IV
RESULTS OF NI DATASET CLASSIFICATION.

Used parameter	Neurons	*Acc*	*Std*
all parameters	2	100.00%	0.00%
peak body dorsiflexion in stance phase, knee range flexion, peak body dorsiflexion in swing phase	2	99.92%	0.26%
peak body dorsiflexion in stance phase	9	81.91%	3.25%
peak body dorsiflexion in swing phase	4	88.71%	0.72%
knee range flexion	3	91.40%	1.16%

$Acc = 100\%$ for the model with 2 hidden neurons. Having run the classifications process with a single parameter (mean right foot acceleration in Z axis) for single layer MLP, 100% accuracy is also obtained. Interestingly, $Acc = 91.14\%$ when using only mean acceleration right thigh in Y axis parameter with 3 neurons in hidden layer. Utilizing only the mean acceleration left foot in Z axis parameter, 94.59% accuracy is achieved for MLP with 9 hidden neurons.

B. Result for NI dataset

The classification with all 15 features allows MLP with 2 hidden neurons to achieve 100% accuracy. When using 3 most important features selected by the SA procedure, i.e.: peak body dorsiflexion in stance phase (100 importance), knee range flexion (61.90 importance), peak body dorsiflexion in swing phase (48.87 importance), $Acc = 99.92\%$ for MLP with 2 neurons in hidden layer. By employing only one parameter (peak body dorsiflexion in stance phase), 9 hidden neurons' MLP yields 81.91% of accuracy. Application of the knee flexion parameter allows MLP with 3 hidden neurons to reach $Acc = 91.40\%$. Consequently, the use of 4 neurons in hidden layer of the network with a single input parameter (peak body dorsiflexion in swing phase) provides the accuracy of 88.71%.

VI. CONCLUSION

In this article, the gait classification problem was studied. Three types of gait were registered: normal walk, tiptoeing and walk retaining long stance phase. For the purpose of the comparison, two data sets were created from the gait recordings. The first data set represented the statistical values calculated from 17 body segments. The second data set was composed of the NI parameters, which are commonly used in gait analyses. Furthermore, the SA procedure was applied to select the most important features in the data sets. The classification tasks were performed by MLP for both original, and reduced data. In all cases, the prediction accuracy achieved very high values at relatively simple architecture of MLP. Moreover, in some cases, decreasing the number of neurons in the hidden layer contributed to the increase of the accuracy.

The results presented in this work encourage the author to explore gait classification problem deeper. For this purpose, real gait recordings will registered from the patients in near future.

***Abstract*—This paper present identification algorithms of the VAG gas valve and a comparison between them. One of the mathematical models is based on the differential-integral cal-culus of fractional order. This mathematical tool can be used for modeling devices serving to closed-loop systems synthesis. Admitting fractional orders in difference equations improves the performance of proportional-integral-derivative controller action.**

Index Terms—gas valve, differential-integral cal-culus of fractional order, identification.

I. Introduction

THE AUTOMATION determines a comfort of use and operating costs of the heating system, which is responsible for controlling its operation [1, 2, 3]. In discussed case the VC200 control unit is responsible for it, which along with the VAG gas valve constitutes a set to control the operation of heating boilers. This control unit is designed to maintain the degree of the valve opening based on measured temperature parameters and set temperature by the user. The valve offers linear and constant characteristics of operation of a gas burner to heating boiler with standby position. This solution causes a measurable reduction in gas consumption in older type of systems, elimination of incomplete burning and condensation of the exhaust fumes in emittors.

Many unpredictable factors must be taken into account in design of control systems. Application of coil and steel core in the VAG valve causes non-linear dependence of the degree of opening to current amplitude and hysteresis of valve motion up and down. In case of control with using information about the model, there is a possibility to remove uncontrolled disruptions. In PID type of control units the signal that controls the device is a sum of three functional blocks: multiplication, integration and differentiation. Difference, which appears between the set and currently measured value, is a result of specified operations. It is possible in more accurate way to describe real objects using differential equations of fractional order, and therefore application of fractional order control units in such cases is more beneficial [1, 2, 3].

II. Identification algorithms

In a room was placed the test bench in order to study static and dynamic characteristics of the control system temperature. Setting parameters of the control unit operation is carried out by RS232 communication channel connected to the computer. The computer has installed the Windows operating system that is required to run the DIAG200 program. The test bench

Fig. 1. The test bench for measuring the VAG gas valve.

consists of: 1. the VAG gas valve, 2.the VC200 controller, 3. a computer with the Windows OS, 4. a injector air nozzles, 5. a gas cylinder LPG.

Description of the black box which is a linear system having one input and output is described by a differential equations [3, 4]. In this case, time is a independent variable and binding input values and the observed response. Measured system is described by the following differential equation:

$$\frac{dx(t)}{dt} + a_0 x(t) = b_0 \frac{du(t)}{d(t)} \tag{1}$$

978-83-60810-90-3/$25.00

the solution of the Equation (1) is:

$$x(t) = ae^{-bt} \tag{2}$$

The difference backward v-th row is defined as:

$$_{k_0}\Delta_k^{(v)} x(k) = \sum_{i=k_0}^{k} a_{i-k_0}^{v} f(k + k_0 - i) \tag{3}$$

another form of the difference backward:

$$_{k_0}\Delta_k^{(v)} x(k) = \begin{bmatrix} a_0^v & a_1^v & \cdots & a_{k-k_0}^v \end{bmatrix} \begin{bmatrix} x(k) \\ x(k-1) \\ \vdots \\ x(k) \end{bmatrix} \tag{4}$$

To create the differential equation is applied the backward difference of first order $x(k)$ function:

$$_0\Delta_k^{(1)} x(k) + a_0 x(k) = b_0 u(k) \tag{5}$$

$$x(k) - x[(k-1)h] + a_0 x(k) = b_0 \tag{6}$$

$$x(k) = \frac{1}{1+a_0}[x(k-1)] + \frac{1}{1+a_0} \tag{7}$$

A. Static model

Static model can be described in a form of graph that presents static characteristics of studied object. The graph of this type is not dependent on the time. Static characteristics constitute a material for system identification; it is a relation between the input and output signal.

The controller uploads current temperature in the room from a sensor and according to parameters set by the program is controlled by a needle in the valve. This type of regulation enables to supply of planned quantity of gas to the injector air nozzles, and depending on demand to increase or reduce the temperature in examination room.

Study consisted on leading into the control system, unchanging in time, subsequent values of the input signal, and on measurement of corresponding values of the output signal. As a result of conducted experiment related to determination of the static characteristics, discreet values were obtained and they were marked on a graph (Fig. 2). Obtained graph of static characteristics shows the position of valve in relation to output voltage of the control unit.

The second basic aim in determination of static characteristics is to appoint characteristics equation from the graph (Fig. 2). Using computer synthesis methods and analyses there was a few methods to resolve the task. For the valve an approximation was used with method of the smallest squares. In order to obtain the static characterization of object, an approximation of received extortion values was conducted and corresponding responses on the graph (red line in Fig. 2). Below is presented third degree polynomial that approximates results of conducted measurement:

$$w(x) = -x^3 + 0,0005x^2 + 0,0322x + 15,579 \tag{8}$$

In order to describe appearing phenomena and processes there are used mathematical models. Complexity result of identification depends on its destination. It is possible to describe its correct construction by mapped accuracy of the process flow with reference to applied model. On the one hand, too high complexity of the model structure may require a lot of calculation by which the model may turn out to be useless. However, on the other hand, the simplified model may have large variations in relation to mapped reality [5].

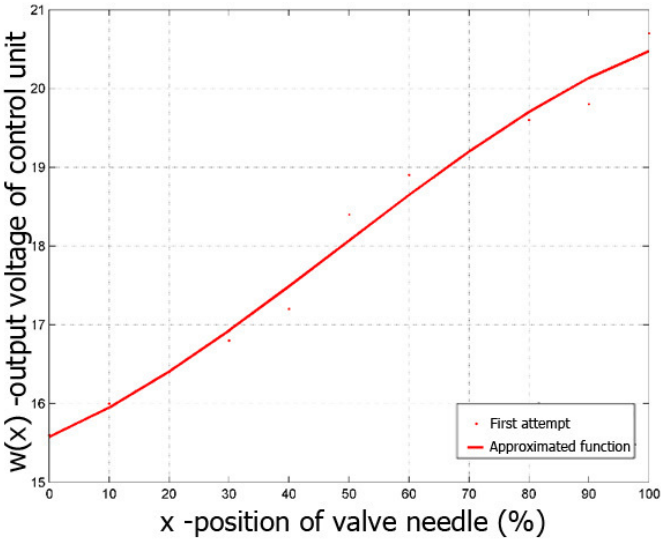

Fig. 2. Graph of static characteristics shows the position of valve in relation to output voltage of the control unit.

B. Dynamic models

An important aspect is identification of dynamic properties of the object. Observation of the process response to stimulation enables to obtain information about its description in the field of variable time. Time line of the output rate triggered by extortion is called dynamic characterization of the object. Dynamic characterization is a transmittance between two established states. Method of dynamic model identification in case of valve consists in evaluation of the object transmittance based on variable characterization. The object of regulation is a movable control needle fixed on the electromagnet core in the VAG valve. As the variable characterization of valve a percentage relation of needle fall was accepted, when set temperature and measured temperature starts to reach standby position.

Temperature in the room, which is the object of regulation, at the time of measurement was 17°C. On the controller was set temperature 23.5°C. After reaching required temperature the valve began to limit supply of gas to the burner by linear needle fall. Figure shows the moment of needle fall to full opening to a minimal position. Duration of a single experiment was 33s, results of sampling every 1s. were presented in points. Figure presents three selected sample measurements, differences between individual measurements result from carrying out examining within the entire day. As the variable characterization of valve a percentage relation of needle fall was accepted.

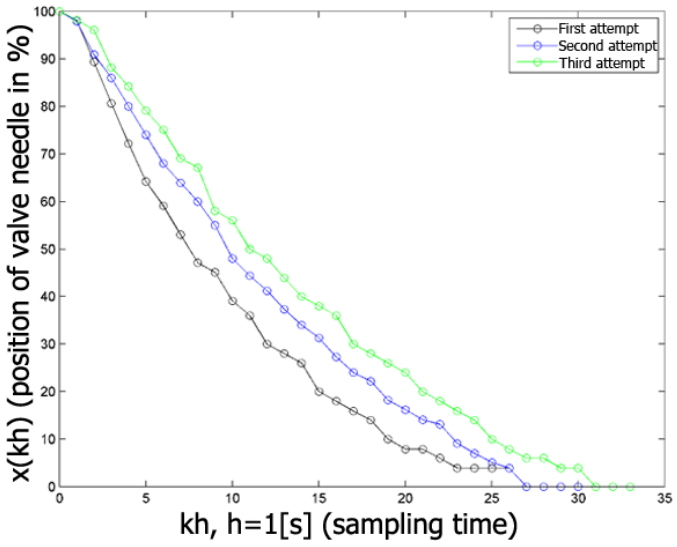

Fig. 3. Measurement of the valve responses to reduce the temperature.

Based on the Fig. 3 it is possible to state that it is the inert object of first order. Inert response type of regulation object to irregular extortion results from the process occurring during the study. Extortion in reductions of opening degree of the valve causes a change of gas supply flow. Reduced power of injector air nozzles resulting for this reason proceeds with certain delay. Other processes are also delayed: heat transfer between the burner and examination room via air and heat transport from surrounding to the temperature sensor. After leveling of new heat loss value in the room with the amount of heat provided by the burner arise a new steady-state and air temperature, and a level of the needle position remains unchanged.

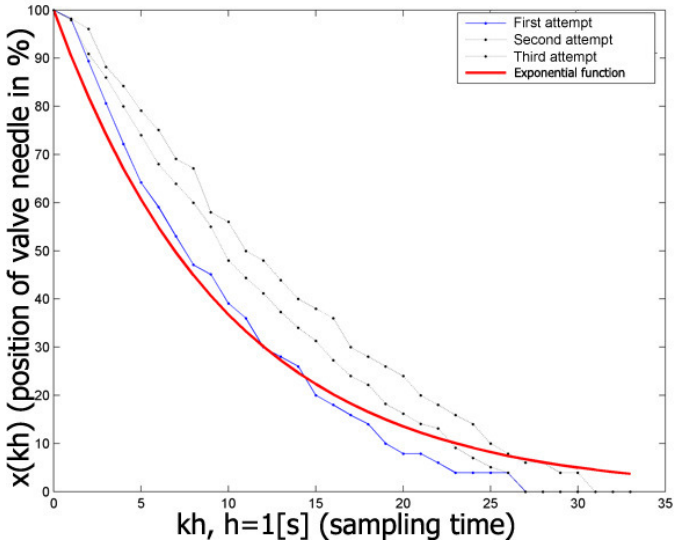

Fig. 4. Exponential function approximate results of the first measurement.

In the measured discreet system described by Equation (2) where continuous time t must be replaced by the value k which is next step, the h value is a sampling time and equal 1 second. On obtained values was approximated exponential function:

$$x(kh) = ae^{-bkh} \tag{9}$$

To the subsequent measurements was matched functions. For the first attempt of response was approximated and illustrated in Fig. 4 exponential function: $x(k) = ae^{\frac{-k}{10}}$, the second attempt of response: $x(k) = ae^{\frac{-k}{12}}$, the third attempt of response: $x(k) = ae^{\frac{-k}{14}}$.

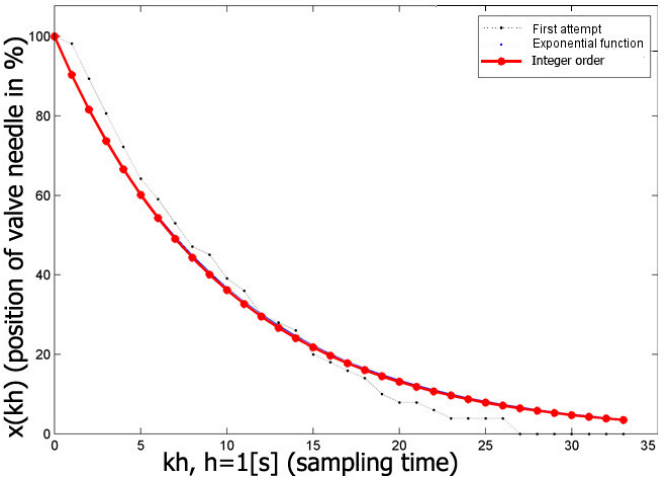

Fig. 5. Function is based on differential equation of the integer order which aproximate the results of the first test measurements.

The second dynamic model is described by a discrete transfer function and the state-space equations [3]. Equation (1) is approximated by the backward difference of first order:

$$\frac{\Delta x(kh)}{h} + a_0 x(kh) = b_0 \frac{\Delta u(kh)}{h} \tag{10}$$

$$\Delta x(kh) + a_0 h x(kh) = b_0 \Delta u(kh) \tag{11}$$

the difference of function $f(kh)$ is:

$$\Delta f(kh) = f(kh) - f[(k-1)h] \tag{12}$$

the difference of function (12) is substituted to the backward difference of first order (11). Based on fact that the measured object got the Dirac delta function extortion it follows $\Delta u(kh)$ is replaced by $\delta(kh)$:

$$x(kh) - x[(k-1)h]a_0 h x(kh) = b_0 \delta(kh) \tag{13}$$

$$(1 + a_0)x(kh) = x[(k-1)h] + b_0 \delta(kh) \tag{14}$$

The solution of the approximation which is based on the backward difference of first order is:

$$x(kh) = \frac{1}{1+a_0} x[(k-1)h] + \frac{b_0}{1+a_0} \delta(kh) \tag{15}$$

The next step is to adjust the parameters a_0, b_0 in order to reproduce the response. The approximate function is based

on the differential equation of integer order (Fig. 6) where: order of differential equation for all attempts $v = 1$ and rate b_0 of differential equation is equal v . Rates of differential equation for the first attempt: $a_0 = 0,107$; for the second attempt $a_0 = 0,085$; for the third attempt $a_0 = 0,073$.

The third dynamic model is also described by a discrete transfer function and the state-space equations. The differ-integral of fractional order is a generalization of the calculus[3]. Equation (1) is approximated by the backward difference of fractional order:

$$\frac{\Delta^v x(kh)}{h} + a_0 x(kh) = b_0 \frac{\Delta u(kh)}{h} \tag{16}$$

The solution of the approximation which is based on the backward difference of fractional order is:

$$\begin{bmatrix} 1 & a_1^v & \cdots & a_k^v \end{bmatrix} \begin{bmatrix} x(kh) \\ x(k-1)h \\ \vdots \\ x(h) \end{bmatrix} + a_0 x(kh) = b_0 \delta(kh) \tag{17}$$

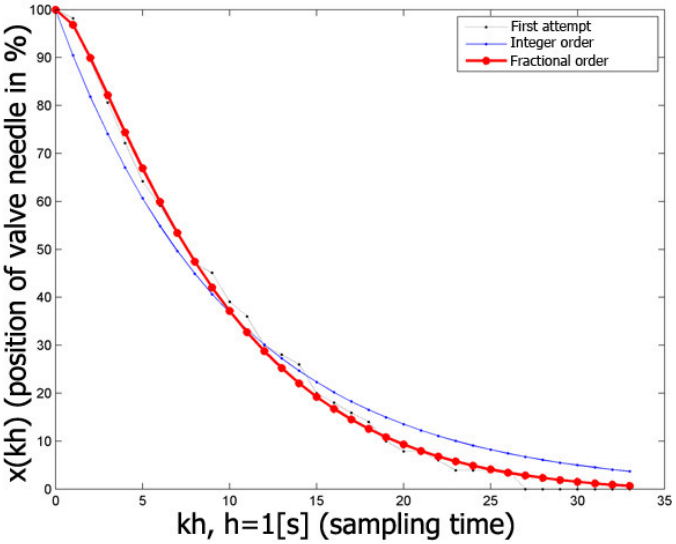

Fig. 6. Function based on the differential equation of fractional order.

The next step is to adjust the parameters a_0, b_0, v in order to reproduce the response. Function based on differential equation of fractional order (Fig. 6), where: rate b_0 of differential equation for all attempts is equal v . Order of differential equation for the first attempt $v = 1,08$, rates of differential equation: $a_0 = 0,115$; Order of differential equation for the second attempt $v = 1,08$, rates of differential equation: $a_0 = 0,092$; Order of differential equation for the third attempt $v = 1,08$, rates of differential equation: $a_0 = 0,073$.

In order to exclude the role of subjective factors in assessing the accuracy of model, as a basis it is necessary to adopt measurable criterion. It is possible to evaluate the level value of control system using integral rates of the course of regulated size. In case of conducted study of valve response, the model accuracy consists on comparison to what extend modeled functions correspond to real measurements. As the correctness criterion of model selection a value of the integral was chosen from the Integral Square Error between measured values and mathematical model [5].

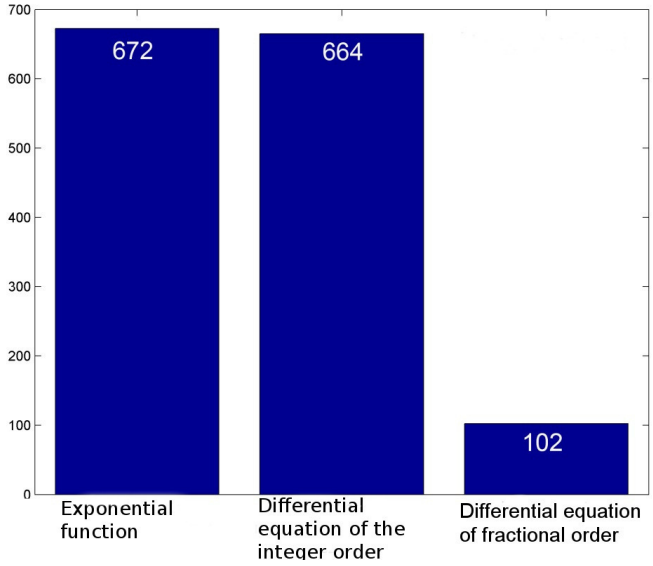

Fig. 7. Comparision a quality of the identification models.

Based on above graphs it is possible to conclude that in any case the best response of device reflects a model based on differential equation of fractional order. The model that reaches the best results in each comparison is several times better than other. Models based on exponential function and differential equation of first order reaches similar degree of approximation.

***Abstract*—This article describes the determination of the quality of results obtained by various numerical methods for BSD (B-matrix Spatial Distribution). In order to verify the influence of the numerical error on the real data, two datasets acquired using two types of phantoms (isotropic and anisotropic) and the reference random data were analyzed. Additionally examined aspect was the duration of the calculations. The research were carried out on six of numerical methods for solving systems of equations (Gauss, Gauss Jordan, LU, Gauss with partial pivoting, LU (numerical recipes), Gauss-Jordan (numerical recipes)).**

I. Introduction

DIFFUSION Tensor Imaging (DTI) is one the of the most widely used methods of imaging the anisotropic biological structures such as white and grey matter andskeletal muscles. DTI is an imaging technique basing on the phenomenon of nuclear magnetic resonance (NMR), which allows for measurement of diffusion coefficient and its direction, expressed in the form of diffusion tensor. Scientific reports present a broad range of clinical applications of the described method e.g. nerve fibers (tractography), diagnosis of cerebral ischemia, multiple sclerosis, epilepsy, metabolic disorders, tumors of the brain [1-3], and studies on the brain function [4].

Diffusion tensor is a symmetrical 3x3 matrix containing six independent elements. To derive all elements of the diffusion tensor one reference and 6 diffusion weighted images (obtained with various non collinear orientations of a diffusion gradient vector) are required. The relations between the signal and diffusion tensor is described by Stejskal-Tanner equation [6]:

$$\ln\left(\frac{S_n}{S_0}\right) = -\mathbf{b}:\mathbf{D} = -\sum_{i,j=1}^{3} b_{ij} D_{ij} \qquad (1)$$

where $S_n(b)$ and $S(b_0)$ are the signal intensities with and without nth diffusion sensitizing gradient, respectively; b_{ij} is a component of the diffusion gradient b matrix; D_{ij} is a component of the diffusion tensor D. The colon designates the generalized dot product. Each direction of a diffusion sensitizing gradient is described by individual matrix [5].

Computations on floating-point numbers are biased with an error resulting from numerical representation of the numbers. Only a finite length string of binary words can be used for representation of a number, what in the case of irrational values (i.e. with infinite binary expansion) such as π or Euler's number, leads to a necessary rounding and loss of the precision.

Another type of an error is the cut-off error. It occurs during computing as a result of decreasing the number of operations, e.g. during computing an infinite Taylor series while calculating the value of ln, extremely important fact is that a minor numerical error can grow during further calculations (e.g. multiplication of small values by larger ones) and cause a major error in the result. The aim of this work is to test the influence of the numerical error on the result of the DTI method. The errors stemming from the fact that the measurements of physical quantities can be done only with the limited accuracy are neglected here.

Several numerical methods for calculating a system of linear equations such as the method of Gauss elimination and its variations (Gauss-Jordan, Gauss with partial pivoting), LU method and Cramer's rule, were implemented. Additionally the implementations of Gauss elimination method and LU decomposition from the Numerical Recipes were added. The following experimental equipment specification were used: Processor Intel Core Intel Core i7-4700MQ @ 2.4 GHz, 8 GB RAM.

II. Verification of the Methods

The first stage of the work was checking the correctness of the implemented methods on random data. For this purpose, each independent value of bn matrix and D tensor were drawn from the range -1 to 1. By transforming the equation (1) one obtains the formula expressing Sn value:

$$S_n = \mathrm{e}^{-\mathrm{b_n}:\mathbf{D}} S_0 \qquad (2)$$

For final determination of S_n one needs a value of S_0 which is also drawn from the range [-1;1].

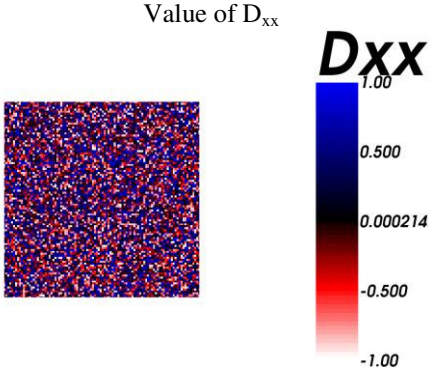
Equation (1) has the following form in the matrix representation:

$$\begin{bmatrix} -b_{xx1} & -b_{yy1} & -b_{zz1} & -2b_{xy1} & -2b_{xz1} & -2b_{yz1} \\ -b_{xx2} & -b_{yy2} & -b_{zz2} & -2b_{xy2} & -2b_{xz2} & -2b_{yz2} \\ -b_{xx3} & -b_{yy3} & -b_{zz3} & -2b_{xy3} & -2b_{xz3} & -2b_{yz3} \\ -b_{xx4} & -b_{yy4} & -b_{zz4} & -2b_{xy4} & -b2_{xz4} & -2b_{yz4} \\ -b_{xx5} & -b_{yy5} & -b_{zz5} & -2b_{xy5} & -2b_{xz5} & -2b_{yz5} \\ -b_{xx6} & -b_{yy6} & -b_{zz6} & -2b_{xy6} & -2b_{xz6} & -2b_{yz6} \end{bmatrix} \begin{bmatrix} D_{xx} \\ D_{yy} \\ D_{zz} \\ D_{xy} \\ D_{xz} \\ D_{yz} \end{bmatrix} = \begin{bmatrix} ln\left(S_1/S_0\right) \\ ln\left(S_2/S_0\right) \\ ln\left(S_3/S_0\right) \\ ln\left(S_4/S_0\right) \\ ln\left(S_5/S_0\right) \\ ln\left(S_6/S_0\right) \end{bmatrix} \quad (3)$$

In the case of the presented test, all values in the above equation are known. In DTI, the problem lies in determination of unknown values of the diffusion tensor D. To do that, a system of equations containing six unknown variables has to be solved. By solving the system of equations for randomly generated b and S_n (3), new values of diffusion tensor D' were determined. Comparing the values of initially determined tensor D with calculated D' one obtains the numerical error ε.

$$\varepsilon = \sum_{i,j=1}^{3} \left| D_{ij} - D'_{ij} \right| \quad (4)$$

Value of D_{xx}



Distribution of the error ε

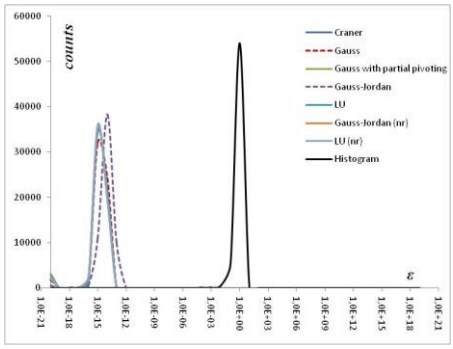


Fig. 1 Distribution of the numerical error ε for all elements of tensor D and value of the xx element of randomly generated diffusion tensor.

On the basis of Fig. 1 one can conclude that the numerical error independently from the method chosen, is 15 orders of magnitude smaller than values of components of the drawn Tensor D, what confirms correctness of the implementation of the methods.

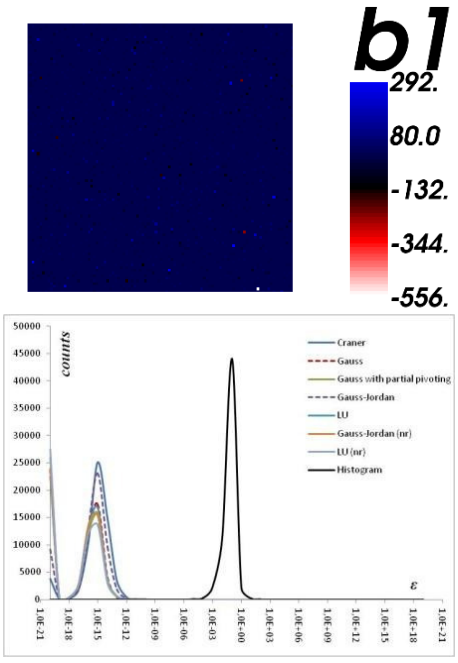
III. Comparison of the Methods

In the case of DTI data, the exact value of tensor D is unknown, what makes the direct determination of the numerical error impossible. However, the error can be estimated alternatively. In DTI one measures values of S_n for the assumed gradient b_n. Solving the system of equations (3) for S_n and b_n data the values of Tensor D (with a certain numerical error) are obtained. Then, using the formula (2) S'_n values were determined. Comparing the input values S_n with re-calculated S'_n, one obtains indirect numerical error ξ:

$$\xi = \sum_{n=1}^{6} \left| S_n - S'_n \right| \quad (5)$$

In order to verify the influence of the numerical error on the real data, two datasets acquired using two types of phantoms (isotropic and anisotropic) and the reference random data were analyzed. It is important that real data belong to distributions which are far from the uniform distribution (-1.0, 1.0).

On the basis of Fig. 2 it can be stated that, for the randomly generated data, the indirect error for all numerical methods is 15 orders of magnitude smaller than the average value of the input data. But on the other hand, in the case of real measurements, the results for the Gauss elimination- and Gauss-Jordan method are different from the others. In theory, the difference between these methods is: If, using elementary row operations, the augmented matrix is reduced to row echelon form (REF), then the process is called Gaussian elimination. If the matrix is reduced to reduced row echelon form (RREF), the process is called Gauss-Jordan elimination. For these methods, a large part of the error is of the same order as the input values.



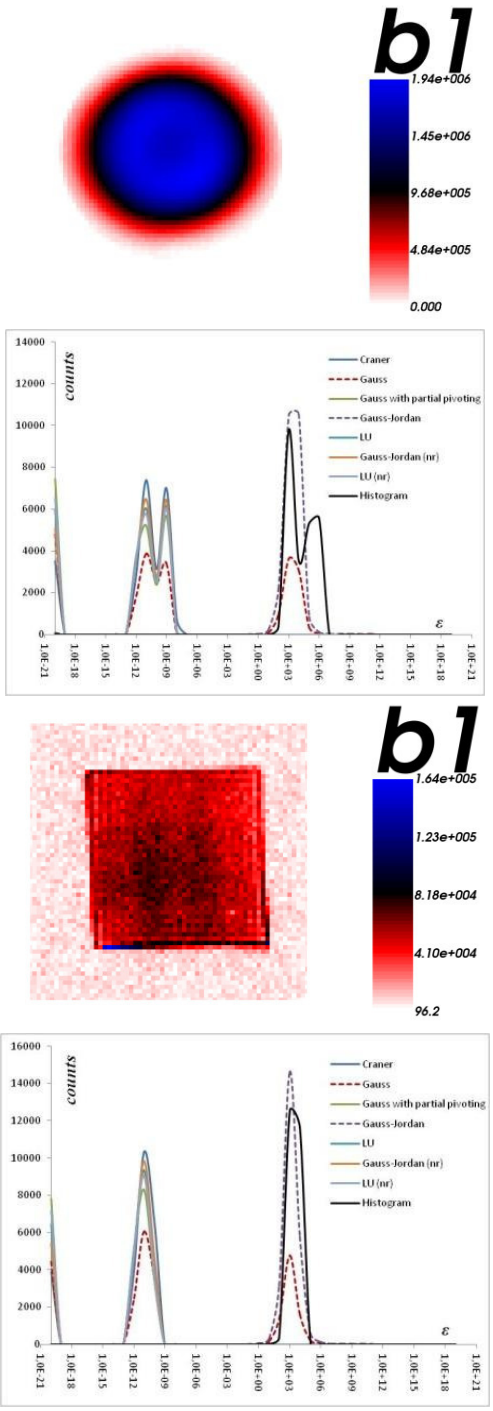


Fig. 2 Distribution of the indirect numerical error for various methods a) random data, b) isotropic phantom, c) anisotropic phantom.

Subsequently the difference between the results obtained with LU method (numerical recipes) and the results obtained in the remaining methods and (Fig.3) were compared. On this basis it can be concluded that the biggest numerical error appears in the noise area. In the case of Gauss and Gauss-Jordan those errors are significantly larger than in the phantom region. In the other methods the errors in both phantom and noise regions are of the same order as the errors in the noise area in Gauss and Gauss-Jordan methods.

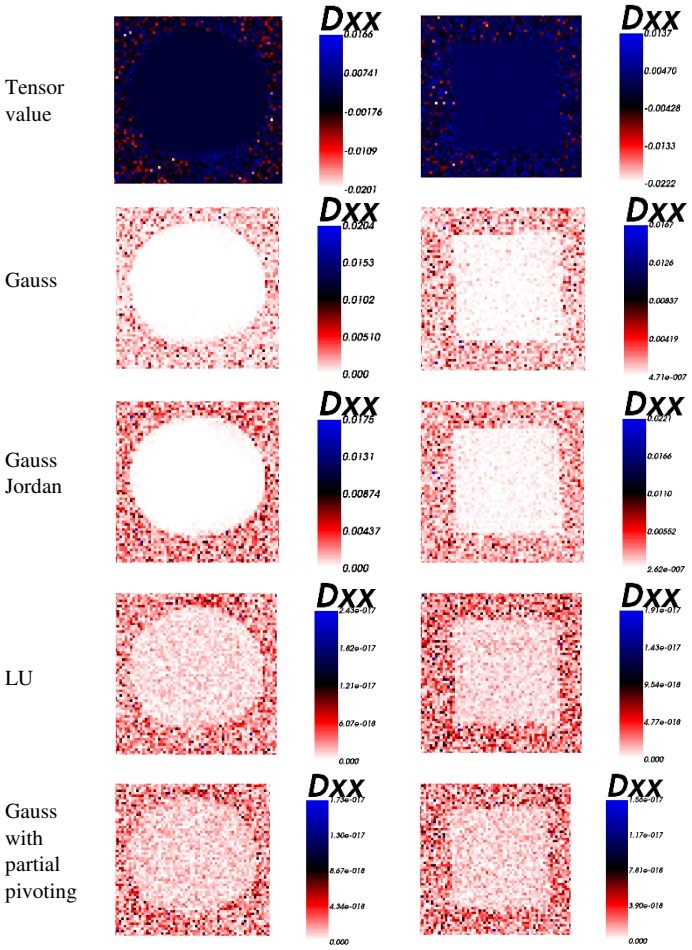

Fig. 3 Distribution of the indirect numerical error for various methods

The last examined aspect was the duration of the calculations. For this purpose, the averaged computing time was determined by repeating the calculations 1000 times for anisotropic phantom (64x64 image) for each of the implemented methods. The fastest method was the Gauss elimination method, the rest were 15-70% slower. From the previous tests it is known that Gauss method is very prone to numerical errors. The fastest method out of ones giving correct results was the LU, which was 15% slower than Gauss. if one takes into account the total duration of computing for DTI, i.e. the memory allocation, calculation of own values etc., then the percent difference between Gauss and LU decreases to 8%.

TABLE I.
DEFINING CHARACTERISTICS OF FIVE EARLY DIGITAL COMPUTERS

	Time of computing tensor D		Time of computing BSD	
Method	**Time [ms]**	**Ratio to Gauss[%]**	**Time [ms]**	**Ratio to Gauss[%]**
Gauss	2.05	100.00	5.49	100.00
Gauss-Jordan	2.88	140.48	6.38	116.21
LU	2.36	115.12	5.95	108.37
Gauss with partial pivoting	3.49	170.24	7.04	128.23
LU (nr)	2.54	123.90	5.92	107.83
Gauss-Jordan(nr)	3.33	162.43	6.72	122.40

IV. Conclusion

Calculating the diffusion tensor D in DTI one has to take into account the impact of the numerical errors, occurring especially in the noise area. Computing time, if all aspects such as the time taken for the allocation of the memory and determining own values and vectors are taken into account, is of minor importance. The methods less affected by the numerical errors, differs in the execution time about 10%. The optimized algorithms will be implement in the B-matrix Spatial Distribution DTI(BSD-DTI) method using a spatial distribution of b-matrix.

4th International Conference on Innovative Network Systems and Applications

MODERN network systems encompass a wide range of solutions and technologies, including wireless and wired networks, network systems, services and applications. This results in numerous active research areas oriented towards various technical, scientific and social aspects of network systems and applications. The primary objective of Innovative Network Systems and Applications (iNetSApp) conference is to group network-related events and promote synergy between different fields of network-related research. To stimulate the cooperation between commercial research community and academia, the conference is co-organised by Research and Development Centre Orange Labs Poland and leading universities from Poland, Slovak Republic and United Arab Emirates.

The conference continues the experience of Frontiers in Network Applications and Network Systems (FINANS), International Conference on Wireless Sensor Networks (WSN), and International Symposium on Web Services (WSS). As in the previous years, not only research papers, but also papers summarising the development of innovative network systems and applications are welcome.

- EAIS'16—3rd Workshop on Emerging Aspects in Information Security
- SoFast-WS'16—5th International Symposium on Frontiers in Network Applications, Network Systems and Web Services
- WSN'16 - 5th International Conference on Wireless Sensor Networks
- main iNetSApp'16 track includes remaining topics, related to network systems and addressed not only to one of the tracks listed above

TOPICS

- Architecture, scalability and security of network systems,
- Web services – standards and applications,
- Service delivery platforms—architecture and applications,
- The applications of intelligent techniques in network systems,
- Innovative network applications,
- Network-based computing systems,
- Network-based data storage systems,
- Technical and social aspects of Open API and open data,
- Computer forensic and network security,
- Social, organizational and other aspects of information security,
- Network, cloud and data security,
- Misuse and intrusion detection,
- Traffic classification algorithms and techniques,
- Network protocols and standards,

***Abstract*—Recent years can be characterized by the rapid increase of mobile device usage in people's lives. Contemporary mobile devices are equipped with many sensors and have high computational and processing capabilities. In a crowdsourcing systems, mobile users participate constructively in specific information handling. Data collected by crowd of mobile devices and stored in a database may help offering new services such as operator's radio quality evaluation and tracking of users. In this paper, we focus on mobile positioning by clustering and interpolating data to match fingerprints to positions. Our method is trained during the offline phase and parameters are periodically updated to track possible changes in propagation environment.**

I. Introduction

IN RECENT years a new field of research in radio communication technologies was born taking benefit from wisdom of mobile crowds [1]. In crowdsourcing a large group of users or crowd participate in service gathering, enhancement or evaluation, information sharing and passing in a professional or a social network. Many crowdsourcing applications have been designed so far, and some of them require provision of location information, with different level of accuracy. The traditional way to retrieve mobile location is GPS positioning but its drawback is activating GPS on mobile phone which is power consuming and it does not work well in indoor environment. The actual challenge for crowdsourcing location based techniques, is how to estimate mobile position using only collected statistics and network parameters.

Our paper deals with mobile user location based on crowdsourcing data collected with the use of smartphones. Various techniques exist in literature, the most common is fingerprinting based positioning. Another positioning method is lateration technique, lateration technique depends mainly on propagation model which changes from one area to another, network parameters may also change: transmitted power, antenna parameters, the environment also may changes when there is a new buildings and new trees, some special events may also change model parameters.

Techniques that use mapping between fingerprints and mobile location were also studied and such methods as: $k-$nearest neighbors $k-$NN, neural network and support vector machine (SVM) were applied in order to approximate the location of mobile user [4].

In this work, we investigate the possibility of mobile position determination based on information collected from cellular networks and WLANs. The main idea is based on data clustering and multidimensional interpolation, the use of clustering is justified by the fact that similar fingerprints could exist in different locations, mobile devices sense and retrieve network information periodically, collected data are sent to a database, where received information is organized in tables and columns.

User's position are sparse in outdoor environment and estimation of mobile position is a challenge. The proposed method takes into account the fact that equal fingerprints may occurs in different positions.

The remainder of the paper is organized as follows: in section II we described structure and pre-processing of collected data, in section III we presented the propagation model, related works are discussed in section IV. In section V we propose our method of crowdsourcing based terminal positioning. Performance evaluation and results are presented in section VI we finish by a conclusion and future works.

II. Crowdsourcing data

A. System architecture and data structure

In crowdsourcing context, mobile applications data are collected by user devices and sent to a database. The overall architecture of the application is depicted in Fig. 1. Various data are collected related to the network parameters and also fingerprints, timestamps are also recorded. To summarize, the collected information covers:

1) Received signal strength (RSS) collected from 2G, 3G, 4G serving cells and WLAN access points (AP).
2) Cell and BS identifier (CID or BSID).
3) Primary scrambling code (PSC) or physical cell identity (PCI) for LTE.
4) Timestamp.
5) GPS coordinates.
6) RSS from neighboring cells and access points.

The reference static database contains information about cellular network parameters in the region of interest:

978-83-60810-90-3/$25.00

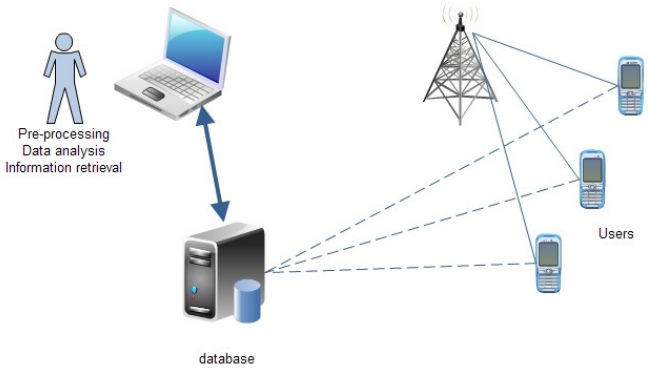

Fig. 1. General overview of a crowdsourcing system

1) Cells in the region of interest.
2) Tilt and Azimuth angle of each cell for cellular technologies.
3) Antenna height and maximum gain.
4) GPS coordinates of a base station.
5) Frequencies.
6) Cell identifier.

B. Data pre-processing

Collected data are periodically sent by mobile phone to the database, user should activate the selected technology for measurement, sometimes there are missing or wrong information. The preprocessing phase is necessary to organize data into tables, each table contain measurements relative to a wireless technology (GSM, UMTS, LTE, WLAN).

Pre-processing phase is compulsory to delete rows with non-significant or missed measurements and to match measurement with the reference database. GPS information is needed in the training phase only. To solve the problem of UTM coordinates, we can refer to conversion method in [3] to use Cartesian coordinate system. For example lateration technique based on fingerprints data uses Euclidean distance.

III. Propagation model

We assume the log-distance shadowing model [5], [9] in most cases of outdoor scenario, spatial received power correlation is also considered [6]. Vector of received power P from K transmitters at a specific position (x, y) is given by:

$$P = \bar{P} + \alpha S(x, y) + \Gamma U \tag{1}$$

Where, P is $K \times 1$ vector of received power at user side, $\bar{P} = P_{TX} + G_{TX}(\theta, \phi) - L_{feeder} - L_c - 20log_{10}(f)$ is the received power at one meter from the transmitter. G_{TX}, P_{TX} and L are: antenna gain, transmitted power and feeder attenuation respectively, and:

$$S(x, y) = \begin{bmatrix} -10\log_{10}(d_1) \\ -10\log_{10}(d_2) \\ \cdots \\ -10\log_{10}(d_K) \end{bmatrix} \tag{2}$$

is the vector of log of distance between location X and each transmitter's location, each element of the vector is given by: $d_i = \sqrt{(x-\alpha_i)^2 + (y-\beta_i)^2}$ for $i = 1 \ldots K$, where (α_i, β_i) is the position of transmitter i. Γ is the result of Cholesky decomposition of the covariance matrix R of the shadowing channel, R is given by:

$$R = \Gamma^T \Gamma \tag{3}$$

U is a vector of normal distribution with mean zero and identity covariance matrix. Elements of U are statistically independent. Many others models based on environment characteristics are reported in the literature. In our work, collected RSS at each user position are assumed to be the mean value of power in equation 1, $RSS = \bar{P} + \alpha S(x, y)$. Statistical properties of the shadowing model are not covered by this paper.

IV. Related works

In outdoor scenario, received power depends on several parameters such as: network configuration, propagation environment, mobile orientation and user's velocity, complexity of exploiting fingerprints information from crowdsourcing data increases when one or more parameters are missing or erroneous. lateration and radio map techniques assume knowledge of network parameters and also radio models. Many propagation models exist in literature, and choice of the right model depends on the environment. In many research works we assume shadowing model with known parameters such as propagation exponent and shadowing variance.

Geolocalization methods of mobile users range from geometrical approaches such as lateration techniques using Cartesian coordinates [8], time and angle of arrival at a given position, to data analysis approach using matching methods between fingerprints and associated positions:

1) Lateration based: In lateration technique, we assume the shadowing propagation model with known parameters, hence, we estimate the distance between current position and transmitter position, the number of received signals should be at least 3, by solving a set of K linear equations, mobile position $X = (x, y)^T$ is estimated as:

$$\hat{X} = (A^T A)^{-1} A^T b \tag{4}$$

Where, A and b are defined as:

$$\begin{cases} A_{i,1} = 2(\alpha_i - \sum_{j=1}^{K} w_{i,j}\alpha_j) \\ A_{i,2} = 2(\beta_i - \sum_{j=1}^{K} w_{i,j}\beta_j) \\ b_i^{(1)} = (\alpha_i^2 + \beta_i^2) - \sum_{j=1}^{K} w_{i,j}(\alpha_j^2 + \beta_j^2) \\ b_i^{(2)} = \hat{d_i}^2 - \sum_{j=1}^{K} w_{i,j}\hat{d_j}^2 \\ b_i = b_i^{(1)} - b_i^{(2)} \\ \sum_{j=1}^{K} w_{i,j} = 1 \\ \hat{d_i}^2 = 10^{-\frac{P_i(d) - P(d_0)}{5\alpha}} \end{cases} \quad (5)$$

This method is known as linear least square (LLS) [7], weighting coefficients $w_{i,j}$ are set to $\frac{1}{K}$. Other techniques based on distance estimation such as nonlinear least square (NLS) and Differential RSS techniques are applied when information on transmitted power and antenna parameters is missing [9].

Geometrical method has some limitations because propagation channel is subject of fast and slow fluctuations that vary from location to another, hence affects positioning accuracy. It is possible to exploit the lateration method in the future in crowdsourcing concept.

2) Neural network based: Neural network is commonly used in pattern recognition in signal processing, in mobile positioning it is used to map received RSS P and associated positions X in a given region [10], during training phase, layer's parameters are tuned in order to minimize the global mean square error MSE. Neural network techniques used in literature are MLP (multilayer perception) and ANN (artificial neural network). Simulation results obtained for indoor environment are good in terms of accuracy. The disadvantage is the computational complexity of the method.
3) Radio coverage map based: During planning phase of radio network, coverage and quality maps should be traced and stored in a database. Strength of the signal received by a mobile phone from nearby base stations is compared to reference points in the radio map. The reference points are usually organized into rectangular or hexagonal grids. This technique is not adapted to the variation of radio propagation channel and parameters changes.

Localization methods are evaluated based on accuracy and algorithmic complexity. When collected data are sparse in space, previous methods seem to be less accurate because there is not enough points to determine model parameters in each area and we may face the problem of appearance of the same fingerprints (SF) in different positions.

V. Proposed Method

In our proposed method we start by subdividing data into two sets, the first one used to perform data clustering using collected information and built up functions that fit well each cluster in order to overcome spatial data sparsity problem, the second set is used to perform tests. Fig. 2 summarizes our approach.

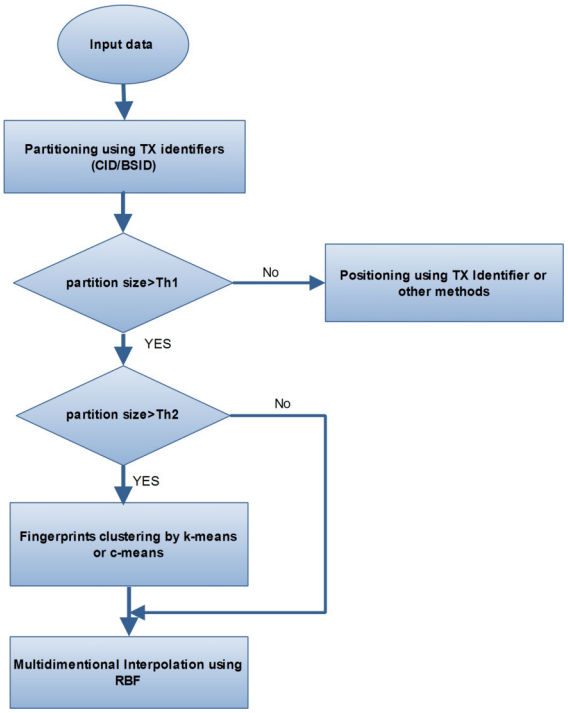

Fig. 2. proposed method

Many clustering techniques are used in literature, such as $k-$means, $c-$means, multimodal classification. First, we cluster collected data based on their CID or BSID, to guarantee that samples belong to one geographical area. Let P_i be the vector of received power in a given position $X = (x, y)^T$, number of element in P_i may change from position to another, depends on sensitivity of the mobile terminal. Clustering using cell identifier or base station identifier is an alternative to determine location area of mobile user, if we consider identifier of more than one cell, we can enhance precision.

After classification of user positions into small regions of interest, we will focus on data interpolation assuming compactness of input data in each cluster, clustering using both transmitter identifier and RSS may reduce the similar fingerprint problem and enhance then positioning accuracy. We look for function f that fits well all points inside a specific class. For example in [7] interpolation using polynomial regression was applied. Our method assumes the use of radial basis function (RBF) with Gaussian kernel.

A. Data clustering

Clustering or data partitioning, is the way of grouping data based on some parameters or criteria, for example, received power, CID or BSID, frequency.

1) Network parameters based:

- Frequency: frequency of the received signal can give information about location of serving cell, if we know frequency plan of region of interest each cell is characterized by its frequencies, but frequency plan may change when needed, hence this method is not good from crowdsourcing point of view.
- Cell identifier or base station identifier: knowledge of CID/BSID increase location accuracy of mobile user, if we consider more than one signal we can approximate better the mobile position, generally, values of CID and BSID are fixed, CID/BSID is considered also as spatial clustering.
- The strongest signals: The number of received signal K in a given position may change from area to another, the RSS vector contains the power of the serving cell/transmitter and the candidate cells or the neighboring cell.

2) Fingerprint based clustering:

$k-$Means: $k-$Means is an unsupervised clustering algorithm taking as input multidimensional data and as input N centroids. Each input fingerprint P_i, power vector of received signal strength, is assigned to the cluster with center C_j as:

$$C_j = \arg\min_{C_l} ||P_i - C_l||^2 \tag{6}$$

Cluster centers C_j are computed by iterative process, the new center of each cluster is the centroid of the old cluster.

Fuzzy $C-$Means: Is a modified version of $K-$means, was proposed by James Bezdek [11], where each sample may belong to a cluster with some membership degree, the mathematical formulation of FCM is given by:

$$\begin{cases} \arg\min_{C_j,U} \sum_{i=1}^{M}\sum_{j=1}^{K} u_{i,j}^m ||P_i - C_j||^2 \\ \sum_{j=1}^{K} u_{i,j} = 1 \\ m > 1 \end{cases} \tag{7}$$

Optimization is performed using the differentiation with respect to U, C and λ_i of:

$$\xi(U,C) = \sum_{i=1}^{M}\sum_{j=1}^{K} u_{i,j}^m ||P_i - C_j||^2 - \sum_{i=1}^{M} \lambda_i (\sum_{j=1}^{K} u_{i,j} - 1) \tag{8}$$

λ_i are the Lagrangian multipliers relative to each condition, cluster centers and weights are computed using iterative algorithm.

B. Class definition

Each data class is represented by a vector V containing: the number of sensed signals K, cell identifier CID/BSID and fingerprint centroid C_j.

$$V = \{CID, K, C_j\}$$

CID may contain two or three identifiers of transmitters. From cellular network point of view, we know that location area with one CID vector, where more than two signals co-exists, are unique, but we can not generalize this assumption in cell's borders. If we increase the number of identifiers that characterize one area, it is possible to reduce the cluster and hence enhance positioning accuracy. Before using interpolation, each measurement is assigned to its corresponding class V, for more accuracy we can use more than one cell for CID clustering.

C. Multidimensional data interpolation

Multidimensional interpolation is a mathematical tool that fit some input data with dimension $N \times K$ to output data with dimension $N \times 2$, Interpolation problem is equivalent to solving set of linear equations in order to determine parameters of interpolating function [12]. In positioning radial basis function was used for indoor localization in [13] where RSS fingerprints are fitted with corresponding positions, mathematical formulation of interpolation is given by:

$$\begin{array}{cccc} X: & \mathbb{R}^K & \longrightarrow & \mathbb{R}^2 \\ & P & \longmapsto & f_K(P) \end{array} \tag{9}$$

Where K is the number of detected signals by the receiver at a given position. P is the input vector and X the associated position. Interpolation by radial basis function (RBF) is given by:

$$X = \sum_{i=1}^{N} W_i \phi_h(||P - P_i||) \tag{10}$$

Where ϕ_h is a radial function, h a shape parameter, and W_i are 2×1 weighting coefficients. To compute weight coefficients, it is necessary to train the network using fingerprints and associated locations.

We assume N input and output data (X_i, P_i), Equation 10 became:

$$X_j = \sum_{i=1}^{N} W_i q_{i,j} \tag{11}$$

Where $q_{i,j} = \phi_h(||P_j - P_i||)$, T_h is $N \times N-$symmetric matrix, and X is $N \times 2$ matrix. Equation 11 is equivalent to:

$$W = Q_h^{-1} X \tag{12}$$

In the case where Q_h is singular matrix, we can modify the solution by introducing small value ϵ as:

$$W_h = (Q_h + \epsilon I)^{-1} X \tag{13}$$

This case occurs when there are the same fingerprints in one cluster. If we want to fix the number of basis functions in each cluster, the weight vector is given as:

$$W = (Q_h^T Q_h)^{-1} Q_h^T X \tag{14}$$

Gaussian kernel function is used for data interpolation.

$$\phi_h(r) = \exp(-(hr)^2) \tag{15}$$

Performance of RBF interpolation depends mainly on choice of h, number of radial basis functions and also the choice of the radial norm.

D. Advantages and limitations of the proposed method

In the test phase, first we assign mobile to its cluster using one clustering technique, then, we estimate its position based on interpolation function.

In order to evaluate the accuracy of our method, we use two approaches: in the first one we compute the distance between from the estimated value of the position and a reference point, with nearest RSS vector. Let start by first order Taylor expansion of $\phi_h(||P - P_i||)$ around P_j:

$$\phi_h(r_i) = \phi_h(r_{i,j}) - 2h^2(P - P_j)^T(P_j - P_i)\phi_h(r_{i,j}) \quad (16)$$

Where P_j is the nearest neighbor to P, $r_i = ||P - P_i||$ and $r_{i,j} = ||P_j - P_i||$. The distance between the nearest point with position X_j and test point with position X, and using function interpolation of user's position, is expressed as:

$$d_{RBF} = 2h^2||\sum_{i=1}^{N} W_i(P - P_j)^T(P_j - P_i)\phi_h(r_{i,j})|| \quad (17)$$

The second level of evaluation is to check if CID cluster of the test point and the reference point are overlapping or not. If the two clusters are not overlapping, the estimation using RBF is wrong and we have to assign a position from the training set that have similar CIDs.

If the value of the distance d_{RBF} is low, and the test cluster overlap with the reference one, the RBF interpolation approximates well the position.

When receiving low numbers of signals from transmitters, the probability of getting SF increases. We conclude that interpolation is more efficient when the number of received signals is high in one hand, in the other hand, we need more sample data to get good approximation by interpolation when the dimension of the received signal is high. The number of collected identifiers may reduce the size of the cluster. Then in the training phase, when the number of samples is high within the cluster region, accuracy increases, otherwise, we cluster the data with lower number of cell identifiers.

Differences between global interpolation and interpolation within cluster are:

- Lower complexity for interpolation within a cluster and matrix inversion do not consume memory.
- Lower number of SF for cluster based interpolation, hence good fitting properties.
- Higher error in positioning for global interpolation with some probability different from zero.

Limitations of the proposed method are:

- Samples are sparse, to overcome this problem we need more measurements and more memory to store data.
- This method should be upgraded in order to track fluctuations of propagation channel, transmitted power and network's parameters changes.

VI. Performance Evaluation

A. Measurement setup

The crowdsourcing system used for evaluation of the proposed approach consisted of application and database servers responsible for data storage and pre-processing, and a group of Android-based mobile devices. The test devices were equipped with dedicated mobile application running in the background and responsible for collecting of the measurement data during normal device operation. The background service is also responsible for communication with the application servers and periodic uploading of the measured data to the system database. The data were collected in the opportunistic manner, i.e. during everyday device usage by a group of test users, and using different devices. The range of data reported to the system covered strengths of the signals received by the device from surrounding radio access network transmitters (the set of parameters depends on the radio access technology as described in Section II) and from nearby Wi-Fi access points, as well as actual GPS-based position of the user.

B. Experimental results

During the initial tests of the system, the measured data were collected in the surroundings of Lodz University of Technology campus area using number of terminals. The locations of reference measurement points are shown in Fig. 3 and 4, measurements could be performed dependently or separately.

Fig. 3. ROI and part of experimental data positions (GSM measurements)

Fig. 4. ROI and part of experimental data positions (LTE measurements)

A selection of 80% of measurements are dedicated to find clusters and interpolate data in each cluster using radial

basis functions, the remaining 20% of RSS measurements are reserved to the test phase.

Fig. 5 shows cell identity pairs from collected data, in y-axis the identifier of the strongest cell or server and in x-axis the best neighbor cell, hence each point describe a set of fingerprints, more the number of fingerprints is more the accuracy we get. In cellular network, theoritically two CIDs are sufficient to characterize a compact location area because antenna are directive, in WLAN technology antennas are generally omni-directional and at least three received signals are required for area identification. It is possible also to cluster data using three or more best cells in order to identify a location area with some serving cells. Fingerprints associated

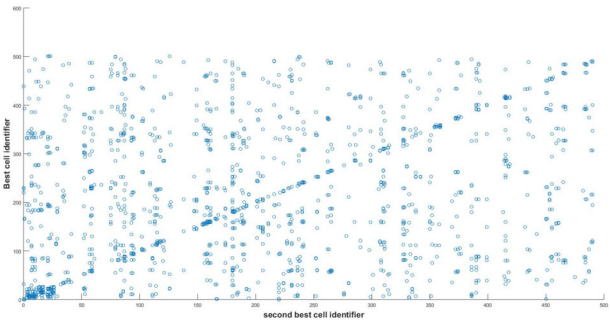

Fig. 5. CID based clustering

to unique CID pair are collected together. Then RSS vectors are clustered based on their dimensionality, dimension K of received RSS vary from 2 to 7.

Clustering using k-means or FCM will be applied only when the number of fingerprints in each fixed (CID, K) set is huge, the splitting of data into smaller clusters may reduce the complexity in the interpolation phase.

Table I shows the number of samples for each signal dimension. The fitting error increase with the number of

TABLE I
DISTRIBUTION BASED ON K

K	Total samples
7	87296
6	55294
5	17813
4	3982
3	225
2	35

existing SF pairs in the training sequence, it is obvious that for global fitting method the error is higher than for clustered method.

In total we have 416 pairs of cell identifiers (CID), retrieved from the collected data, an average number of fingerprints in a CID cluster equal to 348.4. In order to increase accuracy of location area, we can also use triplets of CIDs, in this case the size of the area will be further reduced.

When the number of fingerprints is between $Th2 = 50$ and $Th2 = 10$ for given pairs we use interpolation technique after CID clustering. When the number of fingerprints is higher than $Th2$, we create new sub-clusters using c-means or FCM, then we use interpolation. Table II show the distribution of cluster's size Fig. 6 shows three GSM clusters of size 52, 55

TABLE II
DISTRIBUTION BY CLUSTER SIZE

cluster size ≥ 51	$10 \leq$ cluster size ≤ 50	cluster size ≤ 9
201	143	72

and 171 respectively: Clusters with sample size higher than

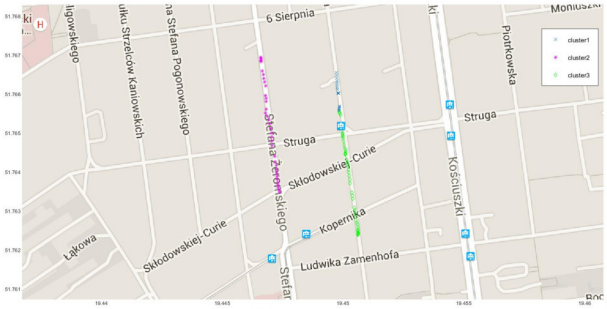

Fig. 6. GSM clusters

$Th2$ are subdivided into subsets using $k-$means or FCM, furthers studies will be focused on how to tune thresholds and also in which case we should use one or the other of the clustering algorithm in order to get more accurate results.

After the clustering phase, we determine the interpolation function assigned to each cluster using RBF. We compare in the table III the fitting error between the proposed method and interpolation only method.

TABLE III
ERROR OF FITTING

cluster based RBF	Global RBF
$8.9357.10^{-10}$	$9.03111.10^{-10}$

Increasing the number of cell identifiers per each cluster may adds more accuracy comparing to the case when using only a pair of CI, but number of samples will be low and interpolation error will increase too.

From measurements we can notice that, a test point could be assigned a position in a different cluster while using global interpolation technique, as we discussed in the limits and advantages paragraph, we can detect this error and assign a new position to the test point based on CID only, in this case we may gain in terms of accuracy. Our method requires many measurements to train and extract associated parameters for each cluster, as we introduce the SF problem, we may also define the same position problem SP and how to solve it. In future we plan to consider such issues as network parameters

tackling as a result of tilts modification, transmitted power and azimuth changes using correlation between measured information with its corresponding cluster. Crowdsourcing adds more consistency to positioning, In our method we add clustering using transmitter identifier with comparison to lateration techniques which based on propagation model, our approach is more realistic and can track possibles changes that occurs in propagation channel. Lateration technique assumes knowledge of APs positions and also transmitter's parameters. Our method can outperform also radio map based technique as many changes may happen in the network after the initial deployment.

Disadvantages of our method is the updating policy of the database. Any change of radio network parameters induces possible changes in received power, and old value of saved RSS will be useless.

VII. Conclusion and future works

This paper deals with crowdsourcing data analysis with special emphasis on localization. Statistical information from data collected by smartphone can be exploited for user localization, approach using techniques like lateration depends on propagation model and the model vary in space and time. We start our work by data partitioning into small or compact area using cell identifier of received signals, if the cardinality of partition is higher than a given threshold, associated RSS fingerprints are clustered into each region using $k-$means or $c-$means methods. Adding clustering may reduce the same fingerprint problem SF that can occur in radio propagation scenario. The second step of the training process was multidimensional interpolation using RBF with Gaussian kernel to estimate the user's position. Clustering and interpolation increase positioning accuracy, in global interpolation method, the probability of similar measurement in two different locations increase with collected data, hence it is possible to get a bad estimate of the position, due to the channel fluctuation it is possible also to get two different fingerprints for the same position. The proposed method, can be updated each time we have new training data, it is possible also to store new sub area and update parameters of interpolation function. As future works, we focus to exploit more correlation techniques between fingerprints and transmitter's identifiers and tracking techniques.

***Abstract*—The article presents an innovative method for assessing performance of modular SDN controllers, focusing on test customization. The method was validated by construction of a testing framework that gives its users the opportunity to emulate various network traffic patterns by using arbitrarily chosen applications, rather than simulating workloads. The presented solution is more comprehensive than others available in contemporary SDN environments also because it that takes into account specific features of modular SDN controllers.**

I. Introduction

Software Defined Networking (SDN) is a promising concept for computer networking. The main idea behind it is the separation of control and data planes. The control plane is moved to a logically centralized, software-based controller. However, as the scale of the application grows, the performance of a controller can become a bottleneck and appropriate techniques for controller scaling need to be employed. For example consider using hierarchical controllers [1], increasing the autonomy of data plane components [2], [3], distributing controllers [4] or elastic scaling [5]. It is also possible to use adaptation mechanisms utilized in SOA systems [6]. Another method - which is of focus for the article - is increasing controller's performance by building upon the modularity offered by modern programming and runtime environments, such as Erlang.

Although there are works related to measuring the performance of monolithic SDN controllers, there is little research regarding modular ones. Therefore, this paper is focused on the development of a method and framework for assessing performance of modular SDN controllers. The framework also provides its users with means required to emulate various network traffic patterns. It was implemented upon open technologies, such as the *LOOM Controller Framework* [7], *Mininet Cluster Edition*[1], and *Open vSwitch (OVS)*[2].

The paper organization is as follows. Sections II and III overview the domain of the presented research, including research in the area of measuring performance of SDN controllers. The survey forms a base for choosing a testing approach and designing the framework architecture - both are presented in Section IV. Section V presents a proof-of-concept implementation of a testing environment and in this way demonstrates the options for customizing the framework to a practical use case. Moreover, it presents results gathered from a series of experiments and the conclusions that were drawn from them. The article ends with concluding remarks and acknowledgments, which form Sections VI and VII, respectively.

II. Background

In *SDN*, forwarding logic no longer has to run on specific hardware built into the switches, routers or other networking devices. The *control plane* functions, implemented by a *SDN controller*, can be achieved in general purpose programming languages and run on regular servers. Thanks to that, *control plane* development is much more flexible, cheaper and faster.

To make user traffic reach its destinations, the control plane needs to communicate with data plane devices. Currently, the most popular protocol for control to data plane communication is *OpenFlow*, created and maintained by *Open Networking Foundation*[3]. The *OpenFlow* protocol allows to define simple actions (e.g. drop packets or send packets specific ports), but it is also possible to build more complex policies [8]. *SDN* and *OpenFlow* concepts can also be applied to PON networks [9] , vehicular networks [10] or multimedia transmission over *HTTP* [11].

The research in the area of SDN results in many new concepts and technologies being developed. Traffic patterns for new applications can be highly distributed and can require extremely short response times [12], [13]. As the result, various solutions regarding network topologies have been proposed [14], [2]. However, there is no consistent framework that would facilitate early stage performance evaluation of SDN environments designed to host new applications. The framework presented in this article aims to fill the gap.

Because new control plane developments are typically implemented using open controllers and new data plane developments use virtual switches, this section overviews the respective categories.

Controllers. As *SDN* and *OpenFlow* gain popularity, many *controllers* appear on the market. In most cases, they are distributed as open source projects. Table I lists some of the

[3]https://www.opennetworking.org/

controllers along with their core technologies, the number of contributors and popularity indicators. The latter are expressed by the number of cloned repositories (table column *Forks*) and the number of people which found the project interesting (table column *Stars*). Based on this information (and on the last activity times) one can estimate the potential and size of a particular developing community.

Name	Language	Devs	Stars	Forks	Last activity
Ryu	Python	60	457	339	recently

LOOM	Erlang	22	26	8	7 months ago

TABLE I: Popularity of OpenFlow controllers (based on *GitHub* data).

In many cases *controllers* are in fact entire *SDN platforms* (they are often referred to as *monolithic controllers*). They consist of many components which deliver rich functionalities to users, such as topology discovery or security analysis tools. *OpenDaylight*[4], the leading production controller, is a representative of this group. On top of the controller developers write single, monolithic network applications. They use supported languages, APIs, and libraries provided by the framework, compile the entire platform and run the created application as a single process. Note however that an error in any part of the application can have adverse effects on the entire system.

Erlang community promises to deliver extensible, robust *OpenFlow* controllers based on the *LOOM* [7] framework. The main goal is to make the controller scalable and distributed (that is the main rationale for using *Erlang* virtual machine). *LOOM* has a modular and layered design. In control plane it consists of *Network Execution* and *Application* layers. LOOM-based controllers share core libraries, such as low-level library for encoding and decoding *OpenFlow* messages, an abstract interface to *OpenFlow* switches and a driver with a common base for *OpenFlow* controllers. LOOM developer creates a controller (specific to his needs) that can be later orchestrated by the network execution layer. Such approach clearly differs from monolithic controllers.

Virtual switches. When it comes to switches supporting *OpenFlow*, there are many hardware and software products on the market. However, from the perspective of early stage testing, software ones are the most important, because it is much easier to build test environment based on software switches (and larger environments can be prepared more easily). Moreover, because software switches often implement the latest version of the *OpenFlow* standard, new features can be used as soon as a reference implementation is available. Software switches are also widely used in production environment (e.g., *VMware NSX* [3]), so their evaluation is also valuable.

Erlang community (together with *Infoblox* and *Erlang Solutions*) is currently working on *LINC-Switch*[5]. It is run in operating system user space to facilitate usage flexibility and quick development. *LINC-Switch* is used as a simulator of an optical network, in one of *Open Network Operating System (ONOS)*[6] controller use cases. *LINCX*[7], which alse comes from Erlang community, is a new, faster version of *LINC-Switch*.

In the presented framework we use *Open vSwitch* because of its popularity and implementation quality. The switch supports multiple protocols and network standards. Moreover, because *OVS* is integrated with *Mininet*[8], it is easier to build test environment based on the switches distributed among multiple physical servers.

III. Related work

There are a few noteworthy research efforts in the area of measuring SDN controllers performance that can be leveraged by new ones, especially to identify the metrics to be measured and key test environment parameters. Shalimov et al. [15] measured latency, and throughput of controllers based on (1) the number of cores the controller uses, (2) the number of switches connected to the controller, and (3) the number of hosts in the network. For their tests, they created their own *Haskell* emulator of *OpenFlow* switches - *hcprobe*[9].

Similar work [16], evaluates performance of two Java-based controllers: *OpenDaylight* and *Floodlight*. The authors used a cluster of hosts running *Cbench*[10]. The tool directly stresses a controller by sending OpenFlow Packet-In messages. Another study [17], describes metrics of *ONOS*, including *Flow installation throughput*. The metric shows a number of flow mods, which can be sent by the SDN control plane in response to requests coming from applications or network events.

While all the mentioned characteristics were studied using network emulators, authors of the [18] proposed a methodology that utilizes network virtualization. To interconnect virtualized hosts, *Mininet* was used. They evaluated performance, as the number of Packet-In messages (requesting installation of new flows), a controller can handle per second.

As an example of more structured and holistic approaches, consider *IETF* draft describing the methodology for reporting SDN controller performance [19]. The document touches three aspects, namely: the number of switch sessions a controller can handle, the network size (number of nodes, links, and hosts) a controller can discover, and forwarding table capacity.

[4]https://www.opendaylight.org/

[5]http://flowforwarding.github.io/LINC-Switch/

[7]https://github.com/FlowForwarding/lincx
[8]http://mininet.org/
[9]https://github.com/ARCCN/hcprobe
[10]https://goo.gl/CEgQ68

No performance tests are covering modular controllers (especially written in Erlang), although the authors of [15] mentioned that they examined *FlowER*, and it was not ready for evaluation under heavy workloads. Nonetheless, Erlang is designed to be used in the telecommunication industry and seems to be well suited for SDN use cases. Therefore, we decided to focus on controllers developed upon *LOOM* framework. To our best knowledge, this article is the first to present any results on Erlang SDN/OpenFlow controller performance testing.

Additionally, the presented framework aims to facilitate profiling of network topologies in context of specific applications (which generate specific traffic) by enabling the developer to define the virtual network topology to be constructed by the framework, and to deploy the applications in the network.

IV. Architecture of solution

Before starting to test performance of a *SDN* controller, it should be decided what to measure, and how to perform the measurements, i.e., what kind of environment to use to generate load against the controller, how to collect the data, and how to interpret it. This article proposes a method that follows a generic methodology consisting of the following steps:

1) Deciding upon testing objectives.
2) Building the test environment.
3) Configuring the test system.
4) Running tests and collecting data.
5) Interpreting the test results.

The following subsections refer to the steps in more detail.

A. Testing objectives

For measuring controllers performance two characteristics seem to be most important: *latency* and *throughput*. Latency describes an average amount of time that is needed to process a request. Although *OpenFlow* controllers have to be able to process various requests, those related to topology changes and new traffic flows are crucial. Regarding networking devices configuration, when a new traffic flow occurs, a controller has to handle *Packet-In* requests. Handling them, from a controller perspective, usually boils down to installing flow entries in the data plane device that originated the Packet-In, in order to instruct it what to do with packets belonging to the new flow. Note that latency in processing a Packet-In depends on the kind and context of a particular request, so the values measured can be different for particular application, network topology, etc.

Throughput is a metric describing how many requests a controller can handle, on average, in a given period. The requests related to receiving an unrecognized traffic flow may be sent simultaneously from multiple data plane devices to a single controller. Thus, this metric is sensitive to the characteristics of the network, i.e., its topology, number of switches and hosts, etc.

Regarding the controller itself, the following parameters affect its performance (i.e., both latency and throughput): number of cores used by the controller, the amount of memory used by the controller, the number of instances of the controller (if it can operate as a distributed system), and workload distribution strategy.

The framework presented in the article provides means for building test environments that enable the user to manipulate all the mentioned variables and measure metrics including, but not limited to, latency and throughput.

B. Building the Test Environment

There are three generic approaches to building an environment that mimics a real network generating Packet-In messages:

- *Building an SDN network from hardware.* Testing a controller with a real network can provide most accurate results. On the other hand, the approach is expensive, not flexible, and not scaling well. Additionally, it is not easy to gather statistics from all the devices on the network.
- *Emulating an SDN network by using specialized software.* There are switch emulators designed for testing SDN networks, e.g., *Cbench* and *Hcprobe*, which offer easy configuration and automation of test scenarios. It is relatively easy to scale the environments based on emulators – it usually involves adding new servers/virtual machines with emulator instances. This approach has been used in evaluation of *Network Management Systems* [20]. Note however, that emulators are hard to synchronize across instances, making it more difficult to coordinate test scenarios, and to gather and analyze the results.
- *Using network virtualization to simulate an SDN network.* In this approach, a tool such as *Mininet* can be used to virtualize a complex network on hardware hosts by using Linux containers interconnected with software switches. Such a tool allows for easy automation, controlling traffic generation and gathering statistics.

The presented list is not exhaustive. It is easy to imagine an approach that combines all of the above. It is also possible to test scalability using discrete-event network simulator such as *NS-3*[11].

For the implementation of our framework, We chose virtualization-based approach because of the ease of test automation and low cost.we chose virtualization-based approach. Figure 1 presents essential components of a test environment that could be developed with the proposed test framework. It outlines three main modules, as well as the data channels between them.

The core elements of the *Network Module* are those related to network simulation: *OpenFlow switches*, *hosts*, and *topology*. To enable the user to reproduce arbitrarily designed topologies, the framework uses *Mininet Cluster Edition*, and *Open vSwitch*. The emulated network characteristics can be very close to what would be observed in production networks also because the *Mininet* hosts come with a full implementa-

[11] https://www.nsnam.org/

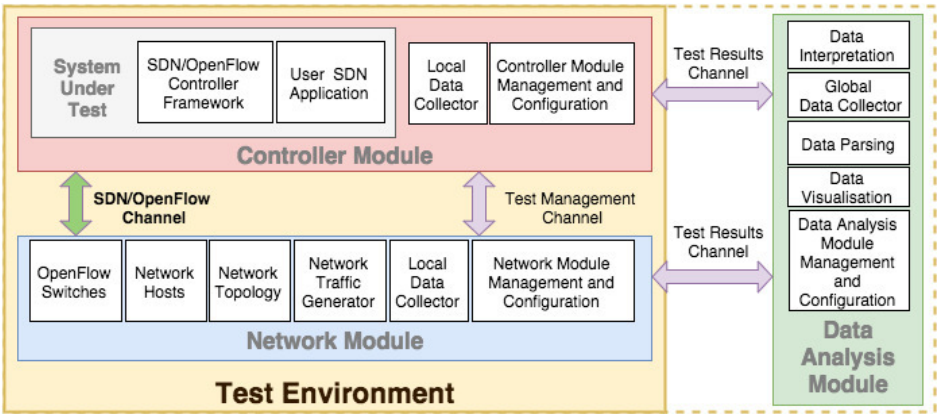

Fig. 1: Test Environment Components

tion of OSI protocol stack, so arbitrarily chosen applications can be used for testing, and act as *traffic generators*.

Local Data Collector is a component responsible for collecting and persisting tests-related data, like traffic metrics or counters of OpenFlow messages sent by the switches (i.e., the load metrics). The *Test Results Channel* indicates the likely transfer of collected data to the *Data Analysis Module*. The *Network Module Management and Configuration* component's task to facilitate automatization of *Network Module* set up and its coordination with the *Controller Module* via the *Test Management Channel*.

The *Controller Module* module encapsulates the *SDN/OpenFlow Framework* and *User SDN Application* components, that together form a fully capable SDN controller, which is the *System Under Test*(SUT). Because the framework is intended to be used mainly with modular, Erlang-based SDN controllers, a natural choice was to leverage the LOOM framework as the basis for SUT implementations, so that custom controllers can be easily built into the framework. The *Local Data Collector* and *Management and Configuration* components have similar responsibilities as their counterparts from the *Network Module*. Similarly to the *Network Module* case, the *Test Results Channel* indicates the likely transfer of collected data to the *Data Analysis Module*.

The *Data Analysis Module* is related to data produced during the tests: gathering, parsing, presenting and interpreting information. Depending on a particular test scenario, this component could be placed either inside the environment (in the case of runtime analysis) or outside (in the case of offline analysis). *Global Data Collector* is a component that gathers all the metrics from other modules so that they can be processed further in a consistent way. *Data Parsing* and *Data Visualization* components are designed for presenting the data in readable formats. *Data Interpretation* denotes additional tools that facilitate interpretation processes. *Data Analysis Module Management and Configuration* component is intended for management and configuration of the data analysis process.

C. Configuring the Test System

The configuration of a test environment can result in changes of traffic patterns. The key network configuration parameters include number of switches, number of hosts per switch, topology, and deployed applications.

Regarding the controller, there are usually less parameters to change. However, changing the hardware specification (e.g., memory, CPU), setting some options at the controller level (e.g., the number of cores it can use) or choosing the controller system structure option (centralized, distributed) have to be considered.

D. Data Collection and Interpretation of Results

Metric probes (i.e., values read from a given metric) can be taken at different intervals, cover different time spans, and have various aggregation rules. For example, when measuring load as the number of Packet-In requests, one needs to decide on how often the value will be measured, what time it will cover (e.g., last 10 minutes), and how it will be aggregated (e.g., maximum, average). Those decisions have to be taken keeping in mind the planned test scenarios.

In the presented framework, the core of the component responsible for collecting test data is implemented by using the *exometer*[12] package - it is run as a user application dependency in the same Erlang Virtual Machine. The package allows for instrumentation of Erlang code, so that data reflecting system performance can be exported to a variety of monitoring systems.

The following *exometer* metrics are implemented:

Application Packet-In Handle Time: histogram metric that captures elapsed time it takes for the SDN application (part of the SUT) to handle a single Packet-In request.

LOOM Packet-In Handle Time: similar as above, but time for the whole SUT (i.e., *LOOM* framework and SDN application) is captured.

Packet-In Count: counts Packet-In messages that are processed by the SDN application.

[12]https://github.com/Feuerlabs/exometer

Packet-Out Count: counts Packet-Out messages that are sent out by the SDN application.

Flow-Mod Count: counts Flow-Mod messages sent out of the SDN application.

In order to make updates to the **LOOM Packet-In Handle Time** metric, the *LOOM* framework code had to be instrumented. In the proof of concept implementation it is assumed that **each Packet-In message has a corresponding Packet-Out message**. Based on that, each Packet-In message that arrives to the controller framework is marked with a timestamp just after being decoded. Then, the mark is copied into the corresponding Packet-Out message. When the message is about to be encoded before sending, the mark is retrieved and the metric value is computed. Note that such instrumentation would not be possible with closed controller code.

The value of **Application Packet-In Handle Time** is based on the same assumption. The first timestamp is made when a Packet-In message enters the application process, and the second when Packet-Out and possibly Flow-Mod messages are sent.

The presented set of metrics is not closed and can be extended by metrics specific for a particular controller. To make use of the metrics collected during a test run, appropriate subscriptions and reporters need to be configured. Each reporter reads values from a metric at given interval and writes them to a file. The values are then processed by the *Data Analysis Module*. Depending on test scenarios' specifics, data can be analyzed (and, e.g., visualized) at run time or saved for later reference.

V. Framework Evaluation

In order to prove the framework usability and test whether it fulfills the requirements, a learning switch application was developed. The switch (called later *LOOM Switch*), was built upon the *LOOM Framework*. Together with the framework it formed a simple, but fully functional, SDN controller. The basic design decisions regarding the *LOOM Switch* were as follows:

1) There is no topology detection service: *LOOM Switch* fills in the forwarding tables based on the standard MAC addresses learning algorithm.
2) There is exactly one forwarding table (FT) for each data plane switch connected to the controller.
3) A packet that does not match any of the flow table entries is buffered in the data plane switch and its portion is sent to the controller using a Packet-In message.
4) At most one flow table entry is installed in the data plane switch that sent a Packet-In message.
5) Flow tables of other data plane switches are not changed.

Figure 2 depicts an example test setup. It demonstrates how the most important parts of the test environment are related to each other. Thick solid lines represent network links. Arrows show OpenFlow channels, connecting each of the switches to the *LOOM Switch* controller. Test management and data collection components were omitted for clarity.

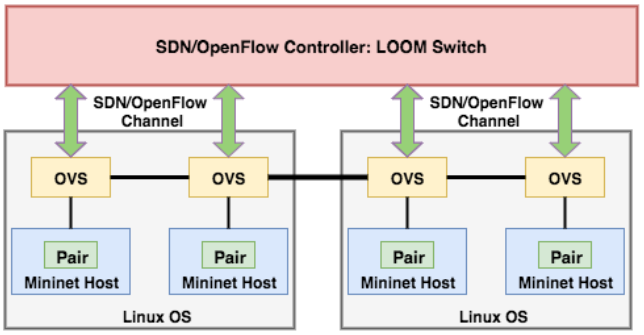

Fig. 2: An example test setup

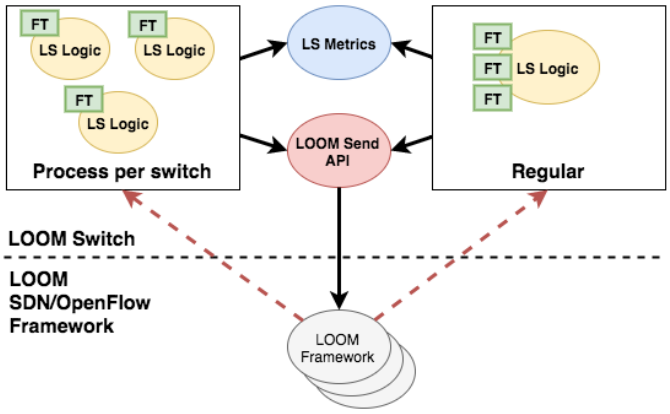

Fig. 3: Options of LOOM Switch Deployment

The network used for proof-of-concept testing was built from a number of switches that formed a linear topology, each of which had an even number of hosts attached. Network traffic was generated by a simple application called *Pair*, that was deployed on *Mininet hosts*. The application was sending out a UDP datagram to a random counterpart, receiving a reply, changing its configuration (including MAC address) and flushing its *ARP* table. Such an application provided an evenly distributed, constant load during the test runs.

A. Testing scenarios

Because Erlang is a highly concurrent functional language, and the presented framework supports the specifics of Erlang LOOM, it was a natural choice to evaluate two options of *LOOM Switch* deployment. In the first, called later *regular*, a single Erlang process handled requests coming from all the switches. In the second, called later *process per switch*, each switch had its dedicated process. The intention was to compare performance offered by the deployment options.

Figure 3 shows the *LOOM Switch* deployment architectures from the perspective of Erlang processes, for *LOOM Switch* application instance that serves 3 switches. The dashed arrows in the figure represent invocations of *LOOM Switch* callbacks from the LOOM framework.

In the case of *process per switch* deployment, each forwarding table (implemented as a hash map) is associated with

a separate Erlang process. In the *regular* deployment case, all the tables are accessed from one process. Regardless of the deployment option, *LOOM Switch* uses a single process for asynchronously handling metrics (**LS Metrics**) and for sending messages to the switches via *LOOM Send API*.

B. Experimental results

We conducted framework proof-of-concept tests for configurations in which the controller (i.e., *LOOM Switch*) used 2, 4 or 8 cores. As a representative test case, we chose the results gathered for 4 cores serving the *LOOM Switch*, run in the *process per switch* deployment option.

Figures 4a, 4b, 4c and 4d contain plots with metrics obtained during respective test runs. Each graph is labeled with *(X, Y)*, where X is a number of switches in the (linear) topology and Y is a number of hosts per switch. The overall number of hosts (240) was constant across all the test runs, and the same number of traffic generator (i.e., *Pair*) instances was used, so the performance was expected to be dependent only on the deployment option and the number of switches used. Note that the same number of hosts and conversations resulted in different loads in terms of Packet-In requests due to the assumptions regarding LOOM Switch and the varying number of data plane switches in the topology.

The following metrics are presented:

- **Application Packet-In Handle Time**, i.e., SDN application (part of the controller) latency, called later **LS Time**,
- **LOOM Packet-In Handle Time**, i.e., SDN controller latency, called later **LOOM Time**.

The collected values correspond to a 20 minute period of a stable load. To get a time frame in which the load is stable, the measurement was started after 15 minutes of test execution. The values were sampled every minute.

The difference in values of **LS Time** and **LOOM Time** is quite impressive. Average **LS Time** values, indicating the time it takes *LOOM Switch* to handle a request are becoming lower and less significant in relation to **LOOM Time**, which represents the overall time needed to serve a request by the controller (which consists of the *LOOM Switch* and the LOOM framework). In percentages, they take $38.7\,\%$, $9.8\,\%$, $1.7\,\%$, and $0.6\,\%$ of **LOOM Time**, respectively.

The phenomenon of decreasing values of **LS Time** metric can be explained as follows. In the *process per switch* deployment option, computations related to switching decisions are spread across the available cores, because each switch is served by a separate process. Along with the increase of Packet-In messages rate the *LOOM* framework gets overloaded and slower in serving requests, in comparison to the *LOOM Switch* application. As a result, as the framework needs more time to process the messages, and they are delivered at a lower pace to the *LOOM Switch*. Consequently, a message spends less time being processed by *LOOM Switch*, because it is able to process it instantly, since a major part of the messages is buffered (and stuck) in the framework.

C. Comparison of deployment options

In the presented test case of *process per switch*, four cores deployment scenario, the LOOM framework was observed to be a bottleneck. As presented in section V-B, the **LS Time** constituted only a few precent of the whole **LOOM Time**, which clearly denotes that the Packet-In messages were stuck in the framework. The highest load measured was about $228\,000$ Packet-Ins per minute with average times of $3\ \mathrm{ms}$ and $572\ \mathrm{ms}$ for **LS Time** and **LOOM Time** metrics, respectively.

Similar values of **LOOM Time** ($580\ \mathrm{ms}$) were observed in case of the *regular* deployment for the load of 73000 Packet-Ins per minute. In that case, the values of **LS Time** and **LOOM Time** metrics were almost equal, indicating that most of the processing time was consumed by the *LOOM Switch* application. Its pace of serving requests was significantly slower than the pace of request delivery performed by the *LOOM* framework.

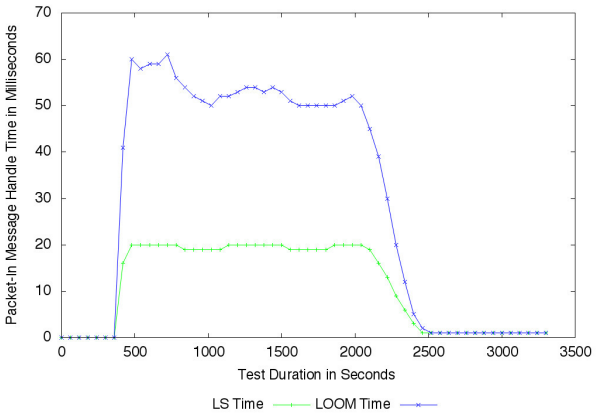
From the results gathered from two test sets for the two *LOOM Switch* deployment options, it is clear that the way of deploying a modular SDN controller has a tremendous impact on its performance. The same hardware configuration, 4 cores per controller, yielded about three times better processing capability in the *process per switch* case than in the *regular* one while offering the same processing time. Note that the processing time values cannot be directly compared with results presented in other articles, because it was measured for the maximum number of Packet-In messages that the controller was able to process. As shown in [5], the processing time grows rapidly after excessing a certain threshold, mainly due to request queuing.

In the following section, we present an experiment that was conducted to check whether adding more cores to the LOOM controller improved the situation, i.e., lowered the processing time for the maximum load identified for 4 cores.

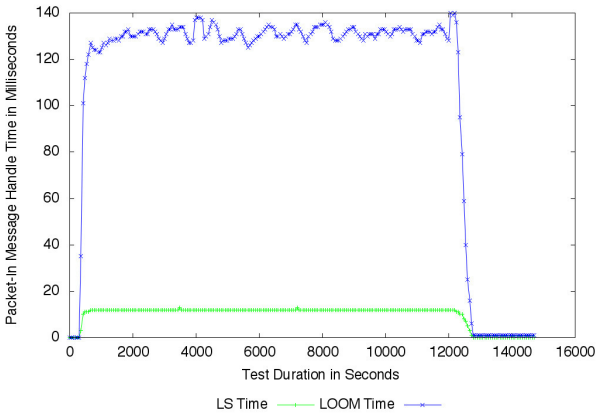
D. Scalability Test for Process Per Switch Deployment

Figure 5 presents a plot for the tested controller running in the *process per switch* mode, that depicts the relation between controller performance and the number of cores available for the schedulers. The plot was created based on experiments conducted on the same topologies that were used for comparing deployment options. Each test scenario (denoted (X,Y) on the X axis) has three values for three corresponding controller configurations that vary only in the number of used cores. Each point represents an average value of the **LOOM Time** metric measured in a given test scenario and controller configuration. Note that the experiment was conducted under heavy load (228000 Packet-In messages per minute processed), which proved to be the limit of processing capability of the tested controller running on 4 cores.

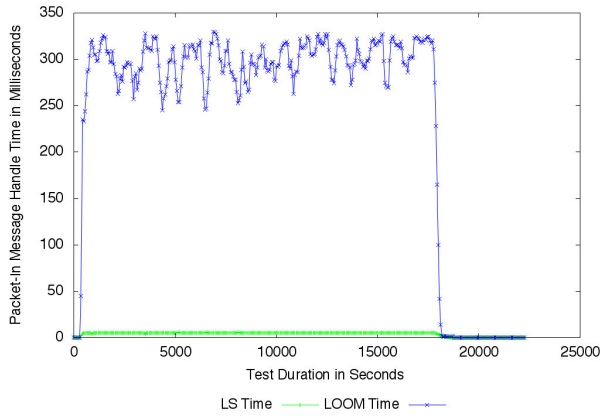
The most important conclusion from comparing the results depicted in figure 5, is that while switching from 2 cores to 4 gives a significant increase in performance in all test scenarios, such situation does not happen when doubling the number of cores again, from 4 to 8. In the case of 5 schedulers the controller performed even a bit worse. As a consequence, it



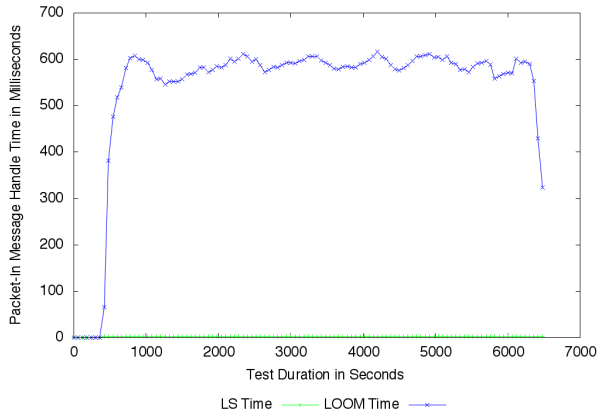
(a) Test Scenario (5, 48);
61000 Packet-Ins/minute



(b) Test Scenario (10, 24);
117000 Packet-Ins/minute



(c) Test Scenario (15, 16);
172000 Packet-Ins/minute



(d) Test Scenario (20, 12);
228000 Packet-Ins/minute

Fig. 4: Handle Request Time in Function of Time for Different Test Scenarios

should be stated that the bottleneck (for 8 cores) does not result from insufficient computing power, but rather from the LOOM framework implementation.

The reason that *LOOM* running *LOOM Switch* in the discussed deployment option scales well only up to the certain point (to 4 cores given the presented results), may be related to *locks*. Some processes in *LOOM* may be acquiring the same *lock*. The more cores available to the system, the more processes can execute simultaneously. As a result, there could be more failed attempts to acquire a particular *lock*. Of course, there could be other potential reasons but checking the locks seems to be a good starting point in searching for an explanation.

VI. Conclusions

In the article, we presented our research on the development of an innovative framework for measuring the performance of SDN controllers. As a part of the presented research, we built a test environment to evaluate the framework practically by testing specific features of modular SDN controllers. The presented results are promising, and form a good base for further development and analysis. We plan to extend our environment with different traffic generators to emulate various application workloads (e.g. multimedia sessions, big data processing). It will allow measuring performance of SDN controllers in real scenarios, with real applications and with different traffic conditions.

The framework presented in this article is designed for assessing various network topologies, and controller deployments, with arbitrarily chosen applications generating network traffic. Such a tool is needed, e.g., for early stage testing of a new network-intensive application that creates network traffic with certain characteristics. Using the framework presented in the article one can define both the network topology and traffic patterns that run on top of it as well and observe the effects of modifying multiple attributes on the performance of the controller.

3rd Workshop on Emerging Aspects in Information Security

ADMITTEDLY, information security works as a backbone for protecting both user data and electronic transactions. Protecting the communication and data infrastructure of an increasingly inter-connected world has become vital nowadays. Security has emerged as an important scientific discipline whose many multifaceted complexities deserve the attention and synergy of the computer science, engineering, and information systems communities. Information security has some well-founded technical research directions which encompass access level (user authentication and authorization), protocol security, software security, and data cryptography. Moreover, some other emerging topics related to organizational security aspects have appeared beyond the long-standing research directions.

The Emerging Aspects in Information Security (EAIS'16) workshop focuses on the diversity of the information security developments and deployments in order to highlight the most recent challenges and report the most recent researches. The workshop is an umbrella for all information security technical aspects. In addition, it goes beyond the technicalities and covers some emerging topics like social and organizational security research directions. EAIS'16 is intended to attract researchers and practitioners from academia and industry, and provides an international discussion forum in order to share their experiences and their ideas concerning emerging aspects in information security met in different application domains. This opens doors for highlighting unknown research directions and tackling modern research challenges. The objectives of the EAIS'16 workshop can be summarized as follows:

- To review and conclude researches in information security and other security domains, focused on the protection of different kinds of assets and processes, and to identify approaches that may be useful in the application domains of information security
- To find synergy between different approaches, allowing to elaborate integrated security solutions, e.g. integrate different risk-based management systems
- To exchange security-related knowledge and experience between experts to improve existing methods and tools and adopt them to new application areas
- To present latest security challenges, especially with respect to EC Horizon 2020

TOPICS

Topics of interest include but are not limited to:

- Biometric technologies
- Human factor in security
- Cryptography and cryptanalysis
- Critical infrastructure protection
- Hardware-oriented information security
- Social theories in information security
- Organization- related information security
- Pedagogical approaches for information security
- Individual identification and privacy protection
- Information security and business continuity management
- Decision support systems for information security
- Digital right management and data protection
- Cyber and physical security infrastructures
- Risk assessment and risk management in different application domains
- Tools supporting security management and development
- Emerging technologies and applications
- Digital forensics and crime science
- Misuse and intrusion detection
- Security knowledge management
- Data hide and watermarking
- Cloud and big data security
- Computer network security
- Security and safety
- Assurance methods
- Security statistics

***Abstract*—Malware evaluation is a key factor in security. It supposed to be safe and accurate. The contemporary malware is very sophisticated. Usually it uses complex distributed infrastructure an investigation of which is a very challenging task. In the paper, the development of the testbeds toward malware and its infrastructure evaluation is presented. Based on the real-life experience with the subsequent CryptoWall generations analysis, the MESS evaluation system is introduced. A rich set of analytical results is discussed. A new methods of visualization for malware artefacts analysis are given.**

I. Introduction

In the last decade the main motive of attackers' actions was associated with money. In the previous years the most precious treasures were credit cards numbers or data used for accessing to e-banking systems. However, it is worth mentioning that reaction to these threats from financial organizations made such attacks harder. From the last few years, more and more popular are attacks that lock victim's computers and demand some ransom for enabling access to the infected machines. Due to a ransom request, any malware used during these attacks is called ransomware. Reports prepared by antivirus companies show a huge increase in this kind of attacks in the last two years. For example, McAfee shows that only in the first quarter of the 2015 year, the number of observed ransmoware samples rose by 165% [1]. Symantec shows even more horrifying data - accordingly to its report number of ransomware which encrypts files in the hard drive rise almost 45 times, from 8274 samples observed in 2013 to the 373342 in 2014 [2].

At the end of March 2015 our security group had to clean-up an infected machine in the Institute of Computer Science. That malware sample (CryptoWall 3.0) was then examined using dynamic analysis. Performed analysis revealed very interesting behavior concerning the network activity of the ransomware. After the infection the sample contacts attacker's Command and Control server using a list of prior infected Web servers. We called this kind of a Web server a *CryptoWall proxy*. What should be emphasized, these servers are innocent victims, too. Analysis of few more CryptoWall samples showed that these lists of proxies contain many infected servers, and these lists are centrally managed by attackers. Detailed description of this network activity and results from its initial analysis can be found in [4].

During continuation of research many samples of CryptoWall family were soon gathered. Manual analysis of all samples soon became almost impossible. So, the ARTA system (Automatic Ransomware Traffic Analyzer) was develop and deployed. It consists of several modules. The ARTA has a dedicated subnet with a set of HoneyPots and a DNS redirecting the whole traffic to these HoneyPots. The malware sample is executed within the dynamic evaluation system Maltester (see [4]). Moreover, the whole system is remotely controlled with dedicated the Web application. Results and practical experience gathered with ARTA is presented in [9].

The advantages of using ARTA are really great. However, two things are missing (even if the lack of their presence should not be considered as drawbacks). First of all, in ARTA, the whole network traffic was enclosed within the HoneyPots. It is a safe solution and allows to identify the basic (i.e. initial) communication made by the malware. However, there is no further knowledge about the liveness of external parts of malware infrastructure (i.e. nodes it tries to communicate with). Also subsequent communication of the sample is not known (due to limitations of HoneyPots). Secondly, the Maltester is not designed to provide information about detailed actions taken by the sample within the target system. Maltester allows sample execution and comparison of system state only after the sample evaluation is finished. It is an environment for evaluation of malware in a Xen-based virtualized host by state comparison (only network traffic is monitored on-line from the outside).

There are some ready-to-go solutions, like Cuckoo Sandbox [10] - due to its popularity and availability it is common to meet malware samples that detect being executed in environment like this. Another popular system, Anubis (exposed as a service in web application) is no longer available as its developers has created their own company with malware analysis services. That is why it is important to build own solutions. Moreover, as the malware dynamically evolve, the evaluation infrastructure must be open for fast developing. So, we decided to develop and implement our own solutions.

In this paper we present the Malware Evaluation Support System - MESS - an environment based on Hyper-V virtualization that uses on-line, on-site monitoring of the malware activity. Comparing to Maltester, it delivers not only information about changes made by the malware but also how the execution proceeds. One of the main advantage on

978-83-60810-90-3/$25.00

MESS is the ability to remotely control the analysis process including the security settings of the network traffic. This capability was used in long-term experiment with the rich set of Cryptowall ransomware samples. One of the goals was to identify and observe the life-cycle of the so-called *proxy servers* being a vital part of the Cryptowall infrastructure. For the analysis we also propose a graph-based method that, in our opinion, facilitates identification of the most interesting artefacts of malware infrastructure. In the paper the MESS test-bed, methodology and results of different kinds of analysis are presented.

In the next section the basic differences between different kids of malware analysis are discussed. Section III generally presents the most contemporary malware type - ransomware. In more detail the behavior of a CryptoWall family ransomware is described. Then, the insights into the MESS test-bed are given in section IV followed by the description of experiments automation (section V). The paper presents the obtained results in section VI.

II. Malware analysis problems

Analysis of malware can be conducted in several ways. First of all, statically - with the analysis of the de-assembled/decompiled code. Generally, such analysis can be very effective. However, in the case of malicious software it can be challenging or even impossible: to cheat anti-virus scanners and to obstruct such analysis, the malware usually implements several obfuscating techniques [5], [6], [7]. For example, some techniques introduce dynamic code modifications (upon execution - decryption using XOR or ROT13 on some code blocks, garbage instructions overwritten with NOPs, return statements without previous calls).

In dynamic analysis, the black-box model is assumed - the examined application is analyzed through its behavior. Such analysis requires malware execution along with some dedicated monitoring utilities [6]. Gathered logs are then used to investigate actions taken by the malicious code on the host. Here, two main problems arise: how to safely execute malicious software and how to identify malicious behavior. Virtualization may address the problem of maltware sand-boxing. Another advantage is scalability - different malware samples can be examined in parallel and the guest system can be efficiently prepared for the evaluation using snapshot for state recovery. On the other hand, there is a risk of virtualization hypervisor disclosure [7]. One of the simplest way to identify virtualization is to check if the hard disk contains any user activity related files (e.g. changed desktop background, web browser temporary files). More sophisticated one is checking in the system registry for CPU information and verification of the number of threads with the declared by the CPU manufacture.

Creating an environment for malware evaluation a key issue is to assure security of other IT resources in the neighborhood. As the contemporary malware often requires Internet connection to be fully operable, the connectivity limitations may also significantly limit the analysis (e.g. unavailability of command-and-control servers, downloading of other malware). At the same time it is obvious that during our experiments we would like to protect our infrastructure as well as limit possible attacks made by the executed malware. So, in particular, the ports 25 and 587 should be blocked to not allow spamming over the Internet.

Dynamic analysis can be made on-line - the malware execution is monitored while its execution - or off-line - the analysis is based on the comparison of the system state before and after the execution.

In the second case, the analysis is mainly focused on changes in the file-system and system registry (i.e. new, deleted, renamed files and directories, registry entries). The main advantage is low probability of analysis disclosure but the temporal analysis is very limited. In fact, only the network traffic can be analyzed in details as it can be gathered from the outside of the host.

The most detailed information can be collected with the real-time monitoring of malware execution on the host itself. In this case the probability of monitoring disclosure by the malware is very high. Especially using debuggers can be easily identified - it interfere with the execution much more than other monitoring utilities [5], [7], [8].

III. CryptoWall Family Ransomware

The first generation of ransomware only locks access to the computer, preventing logging to the machine. For many skilled users these threats can be easily overcome. In the most severe cases full system reinstallation is needed. However, all user's data stored in the infected machine can be restored. Due to this fact, shortly, a second generation of ransomware become popular which works in more hostile fashion.

In its second generation the malware encrypts various types of files associated with user precious data generated by, for example, word processors, spreadsheets or games - yes, some ransomware encrypts games' saves files. As in most cases the ransomware uses modern encryption algorithms, like AES (Advance Encryption System), the decryption without the key is almost impossible. The first malwares of this generation utilized symmetric-key algorithms, which use the same key for encryption as well as for decryption. In effect, this key could be extracted from its poor implementation (key was not deleted after encryption of the whole data) or during its transfer from the victim's machine to the attacker.

The one of the most sophisticated ransomware family is called CryptoWall which uses an asymmetric-key encryption algorithm. Such algorithm uses two separate keys: public - used for encryption and private - used for decryption. In this situation both keys are generated somewhere in the Internet and only the public key used for encryption of users' data is transferred to the infected machine. Private key used for decryption never appears in the victims' machine. Considering that this malware uses 2048 bit RSA asymmetric-key algorithm, decryption of victim's data without the private key is unfortunately impossible. Detailed analysis of various ransomware families can be found in [3].

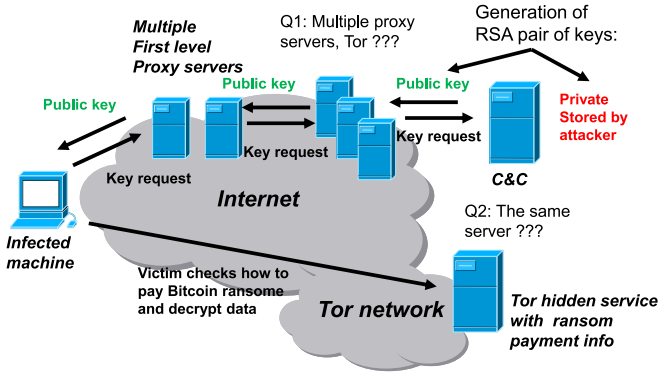

Fig. 1. CryptoWall infrastructure overview

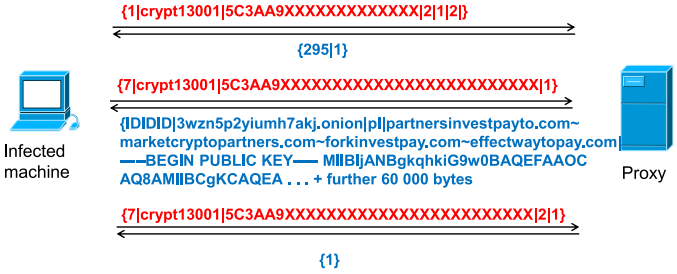

Fig. 2. CryptoWall 4.0 communication overview

The CryptoWall family, due to utilization of asymmetric cryptography, was one of the most sophisticated ransomware in the 2015 year. Usage of this type of cipher has big advantage in contrast to previous ransomware families that utilize symmetric cryptography - the key required for decryption is not present in infected machine at any moment of ransomware activity. However, the one disadvantage of this approach is a need of contact between a victim and an attacker's command and control server, which generates asymmetric key pair and provides a public key used for data encryption.

At the end of January 2015 a new version was observed - CryptoWall 3.0. This version uses infected web servers for hosting proxy script that hinder the location of attackers' command and control server. Detailed description of used communication protocol was presented in [4]. Fig. 1 presents CryptoWall infrastructure.

At the beginning of November 2015, the CryptoWall 4.0 came out. Despite the similar protocol (at first glance), we failed to decrypt its communication for more than a month. Fortunately, due to attackers' mistake, at 6th of December, one of the proxy servers, instead of the execution of the malicious proxy script, was sending its copy. Analysis of the script source code revealed that (in comparison to the previous versions) it has new four lines of code. This part of the code removes some random bytes added by the attacker at the beginning of the encrypted data (within the communication protocol). Probably, this change is introduced for hindering CryptoWall 4.0 activity from detection by Intrusion Detection System. The previous version uses messages that have almost the same length in particular communication phase during communication with proxy. Analysis of decrypted messages revealed a second change in comparison to the CryptoWall 3.0 - the protocol used is simplified. Instead of five transmissions, CryptoWall 4.0 exchanges only three. Decrypted communication of this CryptoWall version is presented in the Fig. 2.

The first transmission (message exchange) informs the attacker that a new machine is infected. This message contains the message of type one (see the first number in sent request - red color), the name of the used campaign (e.g. crypt13001 - see Fig. 2, the machine unique identifier and the encoded description of Windows operating system version. The next transmission (message with the type of 7) is responsible for downloading the public key and the personalized image presented to the victim. The last transmission confirms reception of all the data needed for the encryption process.

IV. Malware Evaluation Support System

Malware Evaluation Support System (called MESS later on) is a system toward dynamic monitoring in real-time of malware sample execution. Contrary to Maltester, the data collection is made on-the-target machine during the runtime.

A. MESS architecture

It consists of several components, as depicted in Fig. 3:

- Executor - responsible for malware sample execution and on-site monitoring tools. It resides on a target system on which the malware sample is executed - a virtual machine VMx
- NAT/Firewall - responsible for recording and filtering the network traffic to and from the Executor systems from/to the Internet
- Controller - responsible for coordinating the whole MESS infrastructure and interaction with the user
- Supervisor - responsible for controlling the Executors through the hypervisor management API.

All these components can be located on a single physical machine or on multiple virtualization servers. In the first, simplest scenario, the Controller and the NAT/Firewall can be located on a single virtual machine along with a set of Executor - separated virtual machines.

The Supervisor (in order to manage the virtual machines) has to be located within the physical host system. In more complex infrastructure (as in Fig. 3) MESS scales-up with the number of physical virtualizators (each requires its own Supervisor) and their virtualization capabilities (on each physical virtualization host a set of virtual machines VM1-VMx with the Executors can be used in parallel). Theoretically, MESS can utilize several different hypervisors (if a proper Supervisor component is available), however, at the moment only Microsoft Hyper-V is supported.

Within the MESS three networks are defined. The NAT/-Firewall machine has to have three network interfaces. The first one is connected to the Internet. The second one serves as a communication channel with the Controller. The third one

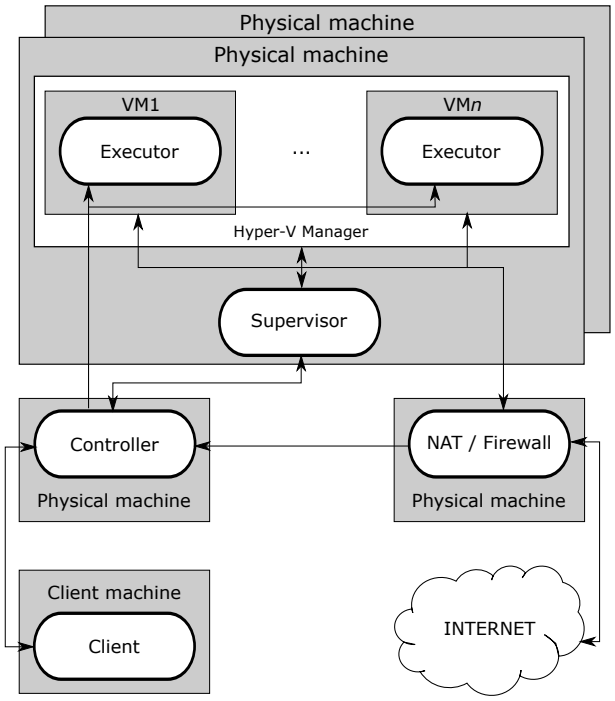

Fig. 3. MESS Architecture

serves the Internet connectivity for the target virtual machines with the Executors. However, due to security restrictions, that network is filtered. Executor's machine is not allowed to communicate with local network as well as with physical LAN (university network in our case). As some ports are commonly used to spread malware (e.g. through automatically sent spam) these ports are also disabled (e.g. 25, 587). During the analysis the settings of the firewall can be changed.

B. Usage scenarios

Typical usage scenario consists of several steps. First of all, a malware sample has to be executed within specially crafted virtual machine. That means, that a set of user-level applications with typical vulnerabilities and a desired set of operating system updates should be installed. A set of system services should be running as well as some user-level emulators (to emulate users' activity). After preparation of such environment, the virtual machine should be frozen in the snapshot. Later on, it will be rolled back to this state before each sample analysis.

A user has to choose at which target system snapshot he wants to conduct the analysis, as well as the malware sample and its filename at which it should be saved in the target machine. He can also pass a set of tools and scripts (in PowerShell) to be executed upon:

- before actual sample execution - some additional preparation tasks
- before restart of the virtual machine - sometimes an analysis might require to restart the machine
- before the end of the analysis - before the gathered results of monitoring utilities are prepared for sending to the user

If the chosen virtual machine is ready, the Supervisor rolls its state to the one saved in the chosen snapshot and runs it. Then, all the informations (scripts, additional monitoring tools are the malware sample) are transferred to the Executor component on the target machine. The monitoring tools are started and finally, the sample is executed - the actual analysis begins. During the analysis any user actions are not required, however, the user may request target machine restart, can interact with the target system (e.g. with remote desktop or console) or preview the network activity. The option to restart the machine is MESS unique feature. Some malware samples, do not start the main activity during the first execution - they just setup itself within the system. In such case, the system has to be restarted to observe the malware. In MESS, the target system will continue the analysis after such restart.

The sample analysis can end in several ways. In normal scenario the MESS is requested to stop the analysis. Then, the Executor on the target system stops the monitoring tools, executed proper user-defined scripts and the results (from embedded monitoring tools as well as the user's) are provided to the MESS as a ZIP file. That file is downloaded by the MESS and sent to the user. After this step, the target virtual machine is stopped and rolled back to its initial state, and ready for the next analysis. Sometimes the user may be not interesting in the results or some unusual circumstances occur (e.g. the sample become a part of DDoS attack or do other unpredicted actions). Then, the analysis is interrupted without result preparation and downloading.

By default, MESS uses Process Monitor tool from the Windows Sysinternals suite to register all the actions made by the sample [11]. It can trace events like system registry accesses (reads, writes of keys and values), filesystem operations and thread/process management. Moreover, the tool provides a rich GUI functionality for further data analysis in off-line. For dumping the network traffic, the Wireshark is used directly on the target system. However, the whole traffic can also be registered on the NAT/Firewall machine.

C. Component integration

Communication between MESS components is implemented with REST approach and XMLRPC protocols (both using HTTP beneath). The REST (Representational State Transfer) is used between the Supervisor(s) and the Controller. It was chosen because of its simplicity, very simple implementation on both, the client and the server side. Moreover it is independent to the implementation technology. It is very important aspect, as the Supervisors (as mentioned earlier) can be located on different kind of operating systems and environments.

Communication between the Controller and the Executors is implemented with XMLRPC (XML Remote Procedure Call). Functionally, it allows to implement remote-like procedure calls. All the parameters and results (even collections or binary files) are passed between the client and server sides very

convenient way. The external interface Controller (from the user side) is also implemented with XMLRPC. Thanks to that, the MESS can be easily integrated with external management systems or scripts.

In order to implement these quite complex tasks, the MESS components consists of subcomponents. For example, the Executor consists of a dedicated system service for keeping the analysis context between system restarts, HTTP service to provide convenient way of analysis result downloading and user-level application for sample startup.

D. Remarks

After several months we gained a lot of experience in using MESS. One of the biggest challenge is to properly prepare the target system environment and trim the monitoring tools. From the one side, the one is interesting in many details of the actions taking place but most of them are not anyhow related to the analysed malware activity. The target system or user-related applications may generate a lot of actions, because, for instance, automatic update services, background tasks etc. It has to be stressed that the Process Monitor can provide very rich set of data. That is great, but the result file might be huge. The proper filter may significantly limit the size of gathered data. We faced these problems as we missed (by oversight) that the Opera browser within the target system was left in the snapshot in the state just before the update. In effect, soon after each analysis, the Opera was starting update downloading and installation. That introduced additional traffic (ca. 40MB) and a lot of system actions (registry and filesystem related).

To properly conduct an analysis the target system should be evaluated in different configurations. Using only updated system might be "too good" for the analysed malware. On the other side, using "too old" version of the system (like WindowsXP, or very outdated version) might be useless (unusual configuration) or suspicious for the malware sample (see section II.

As the MESS utilize Hyper-V technology, there is a risk that the malware sample will detect the presence of the hypervisor. Typically, such sample simply terminates the execution without any malicious actions. Generally, we have met such situation only for a few samples. Only one sample has detected Hyper-V. It was stressfully analyzed in Maltester then. The other sample has detected the Xen hypervisor of Maltester. In this particular case, the sample executed in MESS, after some operations suggesting hypervisor detection procedure, failed to detect Hyper-V and was successfully analysed. These cases proves that both solutions are complementary.

V. Experiment Automation

Manual analysis of each available sample in attempt to retrieve all active servers utilized by it proves to be tiresome and time consuming process. Fortunately preliminary results of manual analysis helped developing tools which used available experiment environment capabilities to automate the process.

Algorithm 1 briefly presents automated experiment procedure. For clarity timeouts calculation and detection in lines 5 and 9 are not shown. Algorithm contains single procedure, repeated for each malware sample. Each sample is analyzed as long as it tries to connect to new servers. During preliminary analysis of malware it was detected that CryptoWall communicates with its servers in semi-random order. It starts to repeat that order after three attempts to connect to each server. That lead to condition used to detect completeness of the sample analysis (line 5). To mitigate potential transient communication problems, configurable timeouts where also applied in that condition, forcing the timed out experiment to be repeated for the given sample. To ensure high quality of gathered data, each active server was detected using separate execution of the sample in the controlled environment (line 6). After executing sample, experiment controller was monitoring network communication for occurrence of incoming malware server response or until some timeout passed (line 9). If response from server was received, it was added to the experiment results, and communication with IP address of that server was blocked for future experiments with the same sample, forcing that sample to try to stimulate another server (lines 10-13). Nevertheless reason for stopping sample run (line 9), all malware requests sent by this sample were gathered (lines 14-18) and used for experiment completeness condition (line 9). For next sample run, all network traffic blocks were lifted (line 4). Procedures used for detection of malware requests and responses were prepared during manual analysis.

Algorithm 1 Acquiring list of active malware servers.

```
1:  for all Sample ∈ MalwareSamples do
2:    Sample.Servers ← ∅
3:    Sample.ActiveServers ← ∅
4:    Unblock all network traffic
5:    while ∃ S ∈ Sample.Servers : S.Retries < 3 do

19:     end for
20:   end while
21: end for
```

VI. Cryptowall infrastructure analysis

As was described in the section III, communication to hinder detection infected machine connects to the command and control server via so called proxy servers. These servers are

hacked by the attacker and special proxy script was installed into web server. To raise the chance that an infected machine successfully download public key, each sample of CryptoWall malware contains hard-coded list of multiple proxy servers. The sample tries to connect in a sequence at the beginning of the infection. Our initial analysis reveals that various samples have the same list of proxy servers. Due to this fact we decided to cluster analyzed samples using proxy list as unique group identifier. Our analysis concerns almost 360 samples taken from openly available sources:

- blog `malware-traffic-analysis.net`
- `malwr.com`
- `reverse.it` services

To manage the collected samples during our research, they can be additionally tagged (beside a number) to be easily identified (*cw3-Feb* - for a sample of CryptoWall 3.0 obtained in February, *cw3-Mar*, etc.).

The samples use 59 unique proxy lists; average proxy list contains almost 40 unique URL, however maximal observed number of URL was 70. During our research we detect more than 2000 unique URLs, hosted in 1945 domains. Detailed analysis concerning domains and addresses is presented later in this chapter. Initial analysis of gathered data was performed with the help of graph theory. Data is used for generation of graphs, which represent connections between proxy lists and used domains. In the constructed graph two types of vertexes are introduced - blue and green. The blue vertexes represent name of proxy list. The green vertexes represent domains. Connection between vertexes indicates that this particular proxy list contains URL which is provided by server in this domain. Analysis of constructed graphs can reveal interesting patterns rapidly and help the person, who is performing analysis of gathered data. Analysis of samples from the beginning of the 2015 shows, that each new proxy list uses completely independent set of domains. Plotted graphs from this period are rather simple, especially in comparison to more complex plots from the end of the year. Fig. 4 presents sample graph of this type, in our security team called "flower".

However, from the middle of the 2015 year we started to observe more connections between various proxy lists. Sample graph of this type is presented in the Fig. 5.

As can be seen in the presented image there are many domains which are associated with two or even with three distinct proxy lists. What is interesting, some domains are used both for samples of CryptoWall version 3.0 and 4.0. This is an evidence that this malware is operated by one group of attackers. Moreover, in our opinion this reuse of domains can be sign that attackers have some problems with hacking or buying new machines, which hosts proxy script for various complains. Additionally, due to vast amount of data, rapid finding of interesting domains which should be investigated in the first row is very important. For this purpose graphs constructed in this fashion, can be beneficial, too. The most interesting domains are those, which connects two or more proxy lists. Shouting down such proxies we can eliminate the broadest spectrum of malware. These domains can be easily

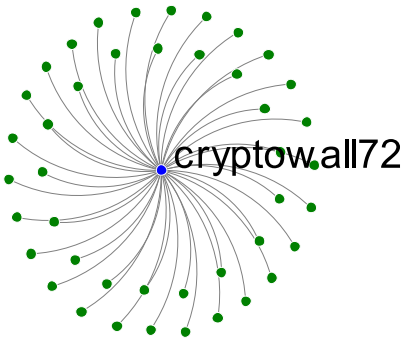

Fig. 4. Simple graph of member domains (green vertexes) associated with given proxy list (blue vertex)

automatically found, they are a green vertexes which degree value is greater than one. Additionally to the static analysis of all domain contained in each malware sample, we performed analysis which reveals information how many proxy servers in given instant provides access to the command and control servers. Accordingly to generally published information infected servers are easily detected and rapidly shut down by administrators. Our research confirms the first part of this statement. Unfortunately, we cannot agree with its second part. The most long lived proxy server observed during our research, allows access for victims to the C&C server for 11 weeks and 1 day. What is alarming, such servers are common. Fig. 6 presents how many servers in given proxy servers list associated with for CryptoWall 3.0 still allows access to the attackers C&C.

We executed samples in controlled environment, provided by the Maltester and MESS dynamic analysis systems. After successful reception of the public key form the C&C server we marked this server as alive, block its IP address in firewall and execute another analysis. Due to manual method we could perform no more than one check of given proxy list in a week. Because achieved in such way data was very valuable we decided to develop and deploy automatic system which could perform analysis more frequent. Details of the system were presented in the section IV. In the plot two instants are very interesting: the one in the middle of the September and the second just before the end of the December (both are marked in the figure with red arrows). In these two instants almost at the same time all proxy servers stopped forwarding the traffic to the command and control server. Due to the fact that these servers are placed in various countries such simultaneous actions with high probability was performed by the attackers. The first situation confirms our assumptions, because almost immediately many new samples of CryptoWall 3.0 come out with completely new proxy servers list. The second event marks the end of the CryptoWall 3.0 activity. After this we

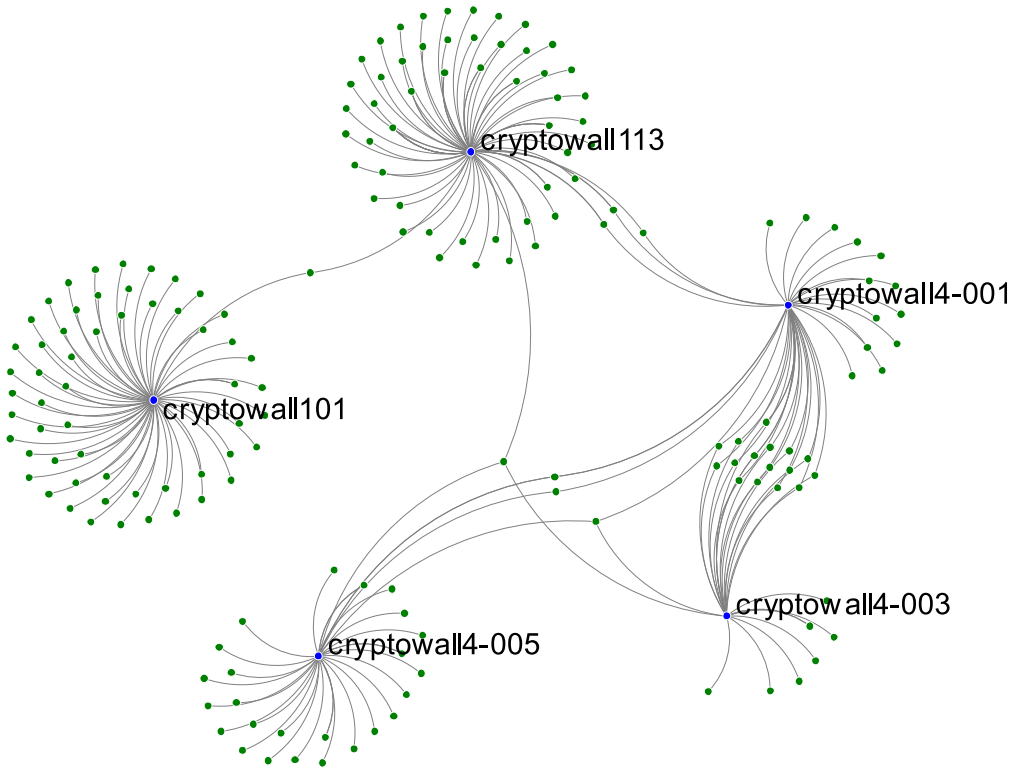

Fig. 5. Complex graph of member domains of proxy lists and its associations, observed at the end of 2015

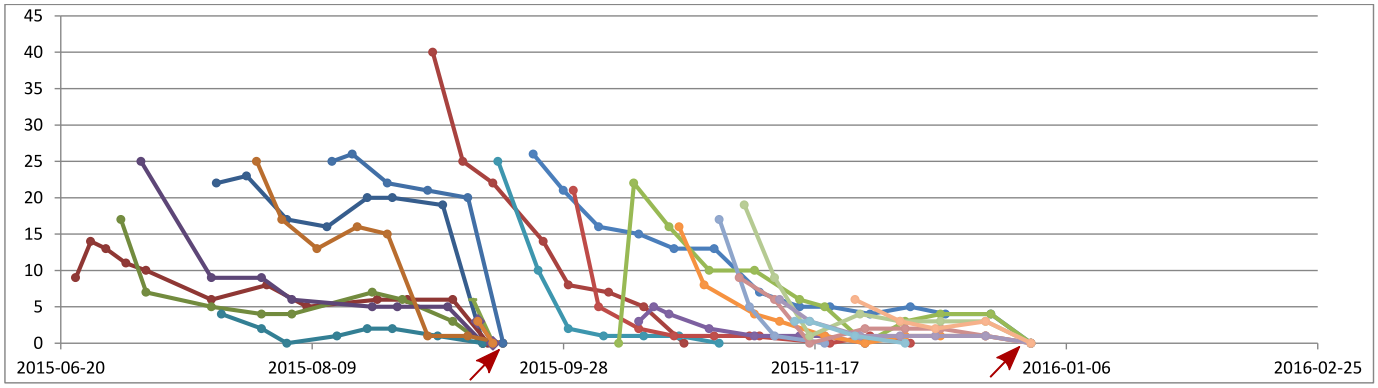

Fig. 6. Number of active CryptoWall proxy servers during 2015

have never observed responding proxy servers for CryptoWall 3.0 samples. However, the new threat came out - CryptoWall 4.0.

In addition we investigated the domain IP addresses and countries of origin of the infected proxy servers. The second aspect is very important, because it specifies to which national CERT or law enforcement agency (LEA) report concerning detected hostile activity should be provided. At the beginning, this aspect of analysis seems to be very simple. We have at least two source of such information: top level domain or geolocalization information associated with IP address. However, our research shows that this information can be inconsistent. We observed numerous examples, when country associated with DNS top level domain was other than country provided by the geolocalization database. To eliminate errors in gelocalization database, we investigated real localization of a server using `traceroute` utility program. In all such situations, information provided by the geolocalization database was accurate - the last few routers observed in the output have country top level domain associated returned country.

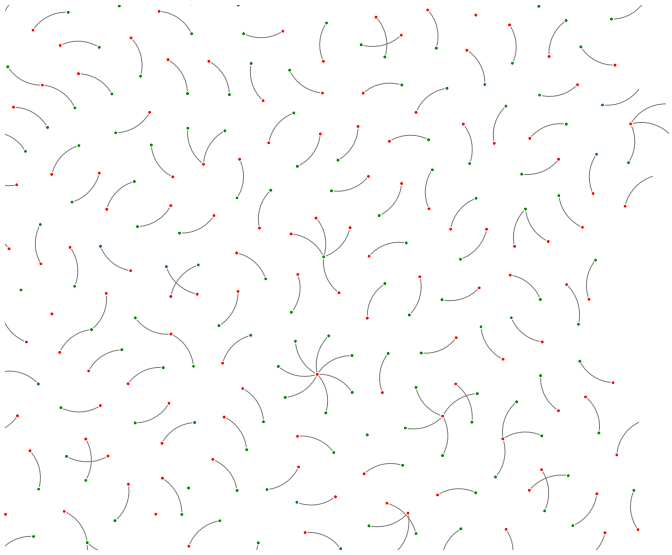

Fig. 7. Examples of graphs presenting associations between domains (green vertexes) and used IP address (red vertexes)

The good thing from this situation is that we could provide information concerning infection, both: to country of top level domain as well as to country where physically server is located. The vast amount of detected domains and IP addresses cannot be investigated all in short time. Due to this fact we introduces method which shows the most interesting data, which should be investigated in the first place. For this purpose we construct custom graph which have two types of vertexes - red and green. The green vertex represents detected domain. The red vertex represents associated with detected domain IP address. Connection between green and red vertexes determines that this domain is resolved to this particular IP address. Fig. 7 presents sample visualization of graphs, constructed in described manner.

Presented plot at first look is completely illegible. The most of presented graphs have only two vertexes, and these simple irrelevant ones hinder interesting knowledge. The first step in analysis of such data is removal of all irrelevant graphs. In data recorded during analysis of CryptoWall there are 1286 such graphs. Remaining ones consist of more than two vertexes. What is interesting, in remaining graphs only three have all vertexes which degree is greater than one. They are presented in the Fig. 8 (left). In remaining graphs there is always one vertex with degree greater than one and all other vertexes have degree equal to one. These graphs can be divided into two categories, depending on the type of vertex, which have degree greater than one. Two types of such graphs are presented in the Fig. 8 (right).

The first type of graph, with green vertex with degree greater then one, represent domains that have multiple IP addresses. The second one in contrast have multiple domains which are hosted in one IP address. The latter one is very promising from security perspective. In such situation, disabling this one address, can stop all domains hosted on it. Our research

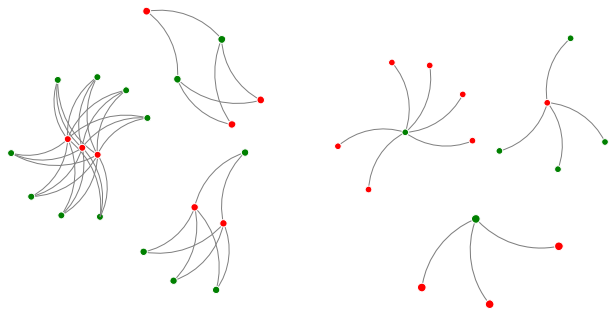

Fig. 8. Some of the most interesting graphs: with all vertexes of degree greater than one (left). Graphs with only one vertex of degree grater than one (right)

shows that attackers from the middle of the 2015 start reusing this same domains. In effect shutting down such domain can protect not only this one analyzed complain, but some before unknown, too. The first type of graphs can be useful, too. Because this same domain is hosted on various IP addresses, they are managed by on organization. In effect one contact with responsible person, can deactivate all of them. Results of our research lead to methodology which can be used for automatic prioritization of received date. In the first step graphs concerning domains and used IP addresses are constructed. In the second step degrees of all vertexes are calculated. These, which all vertexes have degree one, are removed from data presented to the person performing analysis. In effect, the most interesting from the security perspective domains or IP addresses can be easily detected and presented to the security officer in the first row, which can speed up whole process of finding and disabling hostile machines in the Internet.

VII. Conclusion

Starting on March 2015 the CryptoWall ransomware become a point of the authors interest. In order to evaluate its behaviour a rich set of experimental runs were conducted. To make these analysis safe and effective a special toolset and methods are needed.

Based on previous experience with malware analysis, the new, dynamic on-line analysis system, called MESS, was proposed. It proved to be an effective solution toward automated analysis, in particular, in data collection upon the malware behaviour within the operating system. The Hyper-V virtualization is quite effective approach in our case. There is a need to operate on different platforms in order to avoid hypervisor detection. In this sense, the MESS is complimentary to other similar systems.

Analysing the nowadays malware it has to done in two domains: actions within the target system and actions (i.e. communication) over the Internet. In the second domain, it is important to discover and investigate the infrastructure associated with the malware. Sometimes, to restrain the spread and side effects of malware, the easiest way is to identify and limit connectivity to its proxies or Command&Control servers.

In the paper we present the methodology of identification of CryptoWall proxies as well as propose new graph-based method for more effective analysis. The sad true is that the proxy servers, even when identified, are very hard to be turned off or cleaned. In several cases the authors successfully contacted proxy administrators (7 in Poland). However, the obtained life-time of the set of CryptoWall proxies is not optimistic. Further work will concentrate on the analysis of new malware families, like Locky or TeslaCrypt.

ACKNOWLEDGMENT

We would like to thank Wojciech Mazurczyk PhD., Dsc. for his assistance with finding and labeling samples of CryptoWall ransomware provided in the malwr.com service.

***Abstract*—In this paper, the randomness of binary sequences generated from elliptic curves over a finite field of characteristic 2 is studied. A scheme of construction based on the Chaos-Driven Elliptic Curve Pseudo-random Number Generator (C-D ECPRNG) is proposed. The generators based of this scheme are verified by using tests from the NIST Statistical Test Suite to analyze their statistical properties. An elliptic curve used in the numerical example is defined over $\mathbb{F}_{2^8}$. The investigations which made for the generated series of two output sequences of the lengths of 2^{10} and 2^{20} bits shown that 14 generators working according to our general scheme exhibit good randomness properties. Next, the binary sequences generated by these 14 schemes were used for encrypting a 256×256 grayscale Lena image as an application example and the security analysis of the ciphered images was carried out.**

I. Introduction

IN 1985, Neil Koblitz [1] and Victor Miller [2] independently proposed one of the most important public-key cryptosystems named the elliptic curve cryptosystem, whose security rests on the discrete logarithm problem over points on an elliptic curve (EC) [3]. Elliptic curve public-key cryptosystems over finite fields ($\mathbb{F}_{2^m}$ or $\mathbb{F}_p$) have become widely used in applications such as smart cards which provide limited space for implementation of modular computations. Recently, the operations (Add, Double, Multiply) of points on elliptic curves over $\mathbb{F}_{2^m}$ or $\mathbb{F}_p$ have a well-developed technology in both hardware and software implementations.

Elliptic curves applications in, both, cryptography and communications are currently the subject of extensive investigation, as means for increasing security in transmission and reception of data over an insecure communication channel. The advantage is that elliptic curves over finite fields ($\mathbb{F}_{2^m}$ and $\mathbb{F}_p$) provide an inexhaustible supply of finite abelian groups. It is found that different elliptic curves defined over the same field have a different structure as finite fields of the same order are isomorphic to each other. With the increase in available computation power, it is found for a given key size that an EC public-key cryptosystem has higher security compared to RSA cryptosystem [4]. EC operations which used in the generation of pseudo-random sequences with strong cryptographic properties have been studied in the literature, such as [5], [6], [7].

In this paper, new constructions for the generation of pseudo-random sequences based on the properties of random numbers and elliptic curves over a finite field of characteristic 2 ($\mathbb{F}_{2^m}$) are proposed. These constructions are based on the C-D ECPRNG which takes benefits from a chaotic generator to reinforce the quality of an Elliptic Curve Pseudo-random Number Generator (ECPRNG). The addition of chaos will define a family of ECPRNGs that are chaotic while being fast, statistically perfect and cryptographically secure as discussed in [8], [9]. The randomness properties of the new constructions are also tested and found to pass tests in the NIST randomness test suite [26]. Such sequences can be used for generating random numbers in the EC digital signature algorithm and a session key in their encryption phases.

The paper is organized as follows. In Section II, the preliminaries of EC are discussed. An overview of various EC based pseudo-random sequence generators are given in Section III. In Section IV, we present several construction methods of binary sequences obtained from the C-D ECPRNG. An illustrative example is presented in Section V. In Section VI, randomness properties of the proposed sequences are discussed. A simple application of the proposed sequences for image encryption is executed in Section VII while conclusions are given in Section VIII.

II. Preliminaries

The definition of elliptic curves over a finite field of characteristic 2 and their arithmetic are given here to provide the general background for our exposition.

A. Elliptic Curve over a Binary Finite Field

The field $\mathbb{F}_{2^m}$ called a *characteristic-two* finite field or a *binary* finite field, can be viewed as a vector space of dimension m over the field $\mathbb{F}_2$ which consists of the two elements $\{0,1\}$. A non-supersingular elliptic curve E over the binary field $\mathbb{F}_{2^m}$ is defined by an equation of the form

$$y^2 + xy = x^3 + ax^2 + b \tag{1}$$

where the parameters $a, b \in \mathbb{F}_{2^m}$ with $b \neq 0$. The set $E(\mathbb{F}_{2^m})$ consists of all points $(x,y), x \in \mathbb{F}_{2^m}, y \in \mathbb{F}_{2^m}$, which satisfy the defining equation (1), together with a special point O called the point at infinity. These set of points form an abelian group with respect to the addition rules given in the following section.

978-83-60810-90-3/$25.00

B. Arithmetic of Elliptic Curve Group over $E(\mathbb{F}_{2^m})$

As mentioned in the previous section, when $b \neq 0$, the set of all points on the elliptic curve E along with a point at infinity constitute an abelian group under addition operation with O serving as its identity element [10]. It is to be noted here that this addition operation $(+)$ is not the "conventional addition" operation as it is based on the arithmetic of elliptic curves [11].

The algebraic formula for the sum of two points and the double of a point are the following:

1) $P+O=O+P \quad$ for all $P \in E(\mathbb{F}_{2^m})$.
2) If $P=(x,y) \in E(\mathbb{F}_{2^m})$, then $(x,y)+(x,x+y)=O$, note that the point $(x,x+y)$ is denoted by $-P$, and it is called the negative of P; observe that $-P$ is indeed a point on the curve E.
3) Point addition: Let $P=(x_1,y_1) \in E(\mathbb{F}_{2^m})$ and $Q=(x_2,y_2) \in E(\mathbb{F}_{2^m})$, where $P \neq \pm Q$. Then $P+Q=(x_3,y_3)$ where
$$x_3 = \left(\frac{y_1+y_2}{x_1+x_2}\right)^2 + \left(\frac{y_1+y_2}{x_1+x_2}\right) + x_1 + x_2 + a \tag{2}$$
and
$$y_3 \quad = \left(\frac{y_1+y_2}{x_1+x_2}\right)(x_1+x_3) + x_3 + y_1. \tag{3}$$
4) Point doubling: Let $P=(x_1,y_1) \in E(\mathbb{F}_{2^m})$, where $P \neq -P$. Then $2P=(x_3,y_3)$ where
$$x_3 = x_1^2 + \left(\frac{b}{x_1^2}\right) \ . \tag{4}$$
and
$$y_3 = x_1^2 + \left(x_1 + \frac{y_1}{x_1}\right)x_3 + x_3 \ . \tag{5}$$

III. Literature Review

A pseudo-random number generator (PRNG) is a deterministic algorithm which takes a random binary sequence of length k and outputs a binary sequence of length $n \gg k$ which "appears" to be random [12]. The input to the PRNG is called the seed, while the output is called a pseudo-random sequence. Different EC-based PRNG schemes suggested in literature use different ways to proceed from seed value for ith iteration to that for $(i+1)$th iteration and different predicates the output sequences, while the used one-way function is the EC point addition operation. Various suggestions for PRNG which based on ECs and their brief analysis are presented below.

A. The EC Power Generator

The Power Generator on EC (EC-PG) is introduced in [13], [14]. The definition of EC-PG for a given point $G(x,y) \in E(\mathbb{F}_p)$ of high order ℓ and an initial secret key $e \geq 2$ provided that the greatest common divisor (gcd) of $(gcd(e,\ell)=1)$ is generated by:

$$U_i = [e]U_{i-1} = [e^i]G \quad ,i=1,2,\ldots, \tag{6}$$

where $U_0(x,y) \in E(\mathbb{F}_p)$ is the "initial value". The output point sequence is the truncated x-coordinate of the resulted points $U_i(x,y)$.

B. The EC Linear Congruential Generator

The Linear Congruential Generator on EC (EC-LCG) has been suggested in [15] and then studied in a number of papers such as [16], [17], [18]. For a given point $G(x,y) \in E(\mathbb{F}_p)$ of high order ℓ, the EC-LCG is defined as the following sequence:

$$U_i = G + U_{i-1} = [i]G + U_0 \quad ,i=1,2,\ldots, \tag{7}$$

where $U_0(x,y) \in E(\mathbb{F}_p)$ is the "initial value". The output point sequence is generated as the resulted points $U_i(x,y)$ and passes through the complete cyclic subgroup of the point $G(x,y)$.

C. The Pseudo-random Bit Sequence Generator-B

The Pseudo-random Bit Sequence Generator (PBSG-B) which presented in [19] is a modification of the EC-LCG such that the periodicity is independent of the order of point $G(x,y)$ and the output sequence does not have any symmetric properties which makes the cryptanalysis easier. For security, the authors of [19] assume that both point $G(x,y)$ and the seed value of the Linear Feedback Shift Register (LFSR) are kept secret.

D. The Chaos-Driven Elliptic Curve Pseudo-random Number Generator

The Chaos-Driven Elliptic Curve Pseudo-random Number Generator (C-D ECPRNG) which presented in [20] for the finite field $\mathbb{F}_p$ is considered to be the EC-LCG driven by a chaotic map. Such a modification improves randomness of the sequence generated and increases it's periodicity. The C-D ECPRNG for a given seed point $G(x,y) \in E(\mathbb{F}_{2^m})$ as the secret key, is defined as the following sequences generated by additive EC-points operation:

$$\begin{aligned} U_i &= [i(1+b_i)]G + U_0 \\ &= \begin{cases} [i]G+U_0 & if \quad b_i=0 \\ [2i]G+U_0 & if \quad b_i=1 \end{cases} \quad ,i=1,2,\ldots \end{aligned} \tag{8}$$

where $U_0(x,y) \in E(\mathbb{F}_{2^m})$ is the "initial value" and b_i is the random bits generated by a chaotic map Φ

$$b_i = \begin{cases} 0 & if \quad \Phi^i(s) \in S_0 \\ 1 & if \quad \Phi^i(s) \in S_1 \end{cases} \quad ,i=1,2,\ldots \tag{9}$$

where the state space $S=[0,1]$ is the interval and $S_0=[0,0.5]$, $S_1=(0.5,1]$ are two subsets of the interval equal to 0.5. (For more details see [21]).

E. The EC Based Random Number Generator

The random number generator proposed in [22] has reduced latency and increased periodicity with a single point multiplication operation in each iteration. The output point sequence is $U_i=[k_i]G$ and $k_i=(i-1)+x_{i-1}$ where x_{i-1} is the x-coordinate of the point $U_{i-1}(x,y)$. The random number generator has good statistical properties and high periodicity.

F. The Dual-EC Generator

The Dual-EC generator has appeared in NIST recommendations [23]. It makes use of two points $G(x,y)$ and $Q(x,y)$ on a non-super singular elliptic curve $E(\mathbb{F}_p)$ for generation of random numbers. One point for generating the iterating key k as $k_i = x([k_{i-1}]G)$ and the other point for generating the output bit sequence as $t_i = x([k_i]Q)$ where t is the truncation function. The Dual-EC generator mechanism represents an EC scalar multiplication operation, followed by the extraction of the $x-$coordinate for the resulting points followed by truncation to produce the output sequence. We mention here that this recommendation is now withdrawn.

G. The Pseudo-random Bit Sequence Generator-A

A modification of the Dual-EC generator with increased periodicity named Pseudo-random Bit Sequence Generator-A (PBSG-A) is published in [19]. In PBSG-A, the iteration key k is modified as $k_{i+1} = [k_i]G + [i]C$ where $C = x([e]G)$ and "e" is the seed value. In addition to two point multiplication operations the modified algorithm requires a finite field multiplication of iteration number "i" and the value "C" to be carried out in each iteration. This increases both the hardware complexity and the time complexity of the system.

IV. Proposed constructions for EC Binary Sequences

In this section, we propose 22 different schemes resulted from different construction methods based on the C-D ECPRNG discussed in Section III-D.

The points resulted $U_i(x,y)$ with $x-$ and $y-$coordinates of each point are used to obtain the binary sequences. We will shortcut the word sequence to (Seq) throughout this paper and mention that an Initialization Vector (IV) is a fixed initialization vector that should be specified with the scheme. The exclusive or (XOR) logical operation with the symbol $\oplus$ is used here and one can show that it can be replaced by any operation that is an *easy-to-invert* permutation of one of its inputs when the second input is fixed.

After applying the C-D ECPRNG, we get the resulted points $U_i(x,y)$ and the $x-$ and $y-$coordinates of these points are used according to the construction methods listed in table I. These construction methods result in 22 different schemes by applying the ith iteration function R_i. For example, R_i for the first scheme is given by:

$$R_i = [R_{i-1} \oplus X_i], \quad , i \geq 1 \tag{10}$$

where $R_0 = IV$ and X is the $x-$coordinate of the first point U_1. The output R_i is the pseudo-random bit sequence. We will use the notion of a permutation operation (appear in table I as *Perm*) of the results from XOR operation for mapping the bit elements then considering them into the output sequence R for the next iteration process in some schemes. In other schemes, the substitution-box operation ($S-box$) which considers the heart of some ciphers because they are highly nonlinear is also used. $S-box$ takes the results from XOR operation and transforms them into the corresponding output then considering them into the output sequence R. $S-box$ is a basic component of symmetric key algorithms which performs substitution. In our calculations we used the Advanced Encryption Standard (AES) block cipher $S-box$ which discussed in [24].

V. Implementation Example

For experimental results we consider the EC defined over $\mathbb{F}_{2^8}$ given by:

$$E : y^2 + xy = x^3 + \alpha x^2 + 1 \tag{11}$$

where the parameters $a = \alpha, b = 1 \in \mathbb{F}_{2^8}$ with $b \neq 0$ and the EC is based on the irreducible polynomial $x^8 + x^4 + x^3 + x^2 + 1$ over $\mathbb{F}_2$. The total number of EC points is found to be 288 including O (point at infinity) and the element α is a generator of $\mathbb{F}_{2^8}$. The EC point $G = (\alpha^{186}, \alpha^{225})$ is chosen as the base point, which has the order $\ell = 288$ and the initial point is $U_0 = (\alpha^{34}, \alpha^{99})$. Also, $\{G, [2]G, \ldots, [288]G\}$ generates all the elements of EC over $\mathbb{F}_{2^8}$, hence the given elliptic curve group is cyclic. In the case of C-D ECPRNG, we use the Logistic map [25] as our chaotic map to generate the random bits b_i defined in (9).

VI. Randomness Properties

The purpose of this section is to check experimentally the randomness properties of the sequences generated in Section IV. The whole sequences generated by Section IV should have good statistical properties, we also decided to check the statistical properties and test the randomness using six basic statistical tests from [26], [27]. These tests are:

1) **Frequency (Monobit) Test**, it verifies if the number of "1" bits in the sequence lies within specified limits.
2) **8-bit Poker test**, it verifies whether bytes of each possible value appear approximate the same number of times.
3) **Runs Test**, it checks whether the number of runs (the test is carried out for runs of zeros and runs of ones) of length 1, 2, 3, 4 and 5 as well as the number of runs which are longer than 5, each lies within specified limits.
4) **Discrete Fourier Transform (Spectral) Test**, it detects the periodic features in the tested sequence that would indicate a deviation from the assumption of randomness.
5) **Linear Complexity Test**, it determines whether or not the sequence is complex enough to be considered random. Random sequences are characterized by longer LFSRs. An LFSR that is too short implies non-randomness.
6) **Cumulative Sums (Cusums) Test**, it determines whether the cumulative sum of the partial sequences occurring in the tested sequence is too large or too small relative to the expected behavior of that cumulative sum for random sequences. The test has two modes, which are either forward through the sequence or backward through the sequence, named in the Tables *Cusums (forward)* and *Cusums (reverse)*, respectively.

All the generated sequences from $Seq-1$ to $Seq-22$ is tested using the six basic tests discussed above. The test

results are shown that 14 schemes of the proposed 22 schemes exhibits good randomness properties. The other 8 schemes are found to have non-random properties especially with long binary sequences (2^{20} bits) and fail to pass most of the six tests. We presented in Tables II and III the test results for four schemes as examples to discuss. In Table II are presented results for the sequence $Seq-1$ and $Seq-5$. As it is noted, the generator works correctly for short and long binary sequences (2^{10} and 2^{20}bits). In Table III, results for the sequence $Seq-12$ and $Seq-16$ are presented. Also it is clear that the C-D ECPRNG enables generating correctly short and long sequences and the generator passes all the presented tests. For the rest of the paper, we will consider only the 14 schemes (namely $Seq-1$, $Seq-2$, $Seq-3$, $Seq-5$, $Seq-8$, $Seq-9$, $Seq-11$,$Seq-12$, $Seq-13$, $Seq-14$, $Seq-16$, $Seq-19$, $Seq-20$, $Seq-22$) that had good randomness properties.

VII. IMAGE ENCRYPTION APPLICATION EXAMPLE

Image encryption is a potential application where stream cipher is highly preferred over block cipher due to the bulky nature of the data and high correlation between the adjacent pixels. The pseudo-random sequence used for image encryption must have good randomness properties and high periodicity so that the encrypted image is secure. Recently, several attempts for using ECs in image encryption has been proposed in literature such as [28],[29],[30]. In this section, the pseudo-random sequences generated by the considered 14 schemes are used for encrypting a 256×256 grayscale Lena image in which each pixel has a 8-bit value of between 0 and 255 and the security analysis of the ciphered images are carried out.

A. Entropy Analysis

Entropy is defined to express the degree of uncertainties in the system. It is well known that the entropy $H(m)$ of a message source m can be calculated as:

$$H(m) = -\sum_{i=0}^{255} P(m_i) log_2 P(m_i) \tag{12}$$

where $P(m_i)$ represents the probability of symbol m_i. For all the considered cipherimages shown in Figs. 3(a – n), the number of occurrence of each gray level is recorded and the probability of occurrence is computed. Table IV indicates the various values of the entropies for the plain and encrypted images by the considered 14 schemes. It can be noted that the entropy of the encrypted images are very near to the theoretical value of 8 indicating that all the pixels in the encrypted images occur with almost equal probability. Therefore, the information leakage in the considered cipher schemes is negligible, and it is secure against the entropy-based attack. Also it is comparable

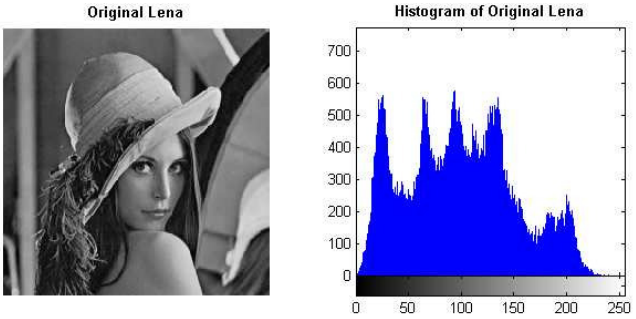

Fig. 1. Lena image and it's Histogram

to the entropy values presented by references [30], [31] and [32].

TABLE IV

Ref.[31]	7.9885	0.0132	0.0017	0.0034
Ref.[32]	7.9968	0.0025	0.0037	0.0011

B. Correlation Analysis

It is known that two adjacent pixels in a plainimage are strongly correlated vertically, horizontally and diagonally. This is the property of any ordinary image. The maximum value of correlation coefficient is 1 and the minimum is 0. A robust encrypted image to statistical attack should have a correlation coefficient value of ˜0 as discussed in [33]. Results of horizontal, vertical and diagonal directions are obtained as shown in Table IV for Lena plainimage and the ciphered images by the considered 14 schemes respectively. These results demonstrate that there is negligible correlation between the two adjacent pixels in the encrypted images, even when the two adjacent pixels in the plainimage are highly correlated.

C. Sensitivity Analysis

In order to avoid the known-plaintext attack, the changes in the cipherimage should be significant even with a small change in the plainimage. If one small change in the plainimage can cause a significant change in the cipherimage, with respect to diffusion and confusion, then the differential attack actually loses its efficiency and becomes practically useless. To quantify this requirement, two common measures are used: Number of Pixels Change Rate (NPCR) and Unified Average Changing Intensity (UACI) [34]. We have tested the NPCR and UACI with the considered 14 sequence schemes to assess the influence of changing a single pixel in the plainimages on the encrypted images. From the results, we have found that the average values of the percentage of pixels changed in encrypted image is greater than 99.60% for NPCR and 30.50% for UACI for all the 14 generated sequences. This implies that the considered 14 schemes are very sensitive with respect to small changes in the plainimage.

D. Histogram Analysis

To prevent the leakage of information to an adversary, it is important to ensure that cipherimage does not have any statistical resemblance to the plainimage. A good image encryption scheme should always generate a cipherimage of the uniform histogram for any plainimage. In this work, the histograms are plotted for Lena plain and encrypted images. The histogram of Lena plainimage contains large spikes as shown in Fig. 1 while the histograms of it's cipherimages are almost flat and uniform which indicates equal probability of occurrence of each pixel as shown in Figs. 2(a – n). They are significantly different from the respective histogram of the Lena plainimage and hence does not provide any clue to employ any statistical attack on the considered 14 image encryption schemes.

VIII. CONCLUSION

In this paper, we have presented several construction methods based on a common general scheme for generating binary sequences from EC over a binary finite field ($\mathbb{F}_{2^m}$). The proposed scheme is based on the C-D ECPRNG with simple arithmetic transformations (XOR and permutation or $S-box$) to produce long size binary sequences with good randomness properties. The generated sequences are tested using tests from the NIST randomness test suite to analyze their statistical properties. It is found that 14 schemes of the 22 proposed specific schemes have passed the selected six complementary tests and the sequences generated by these 14 schemes work correctly

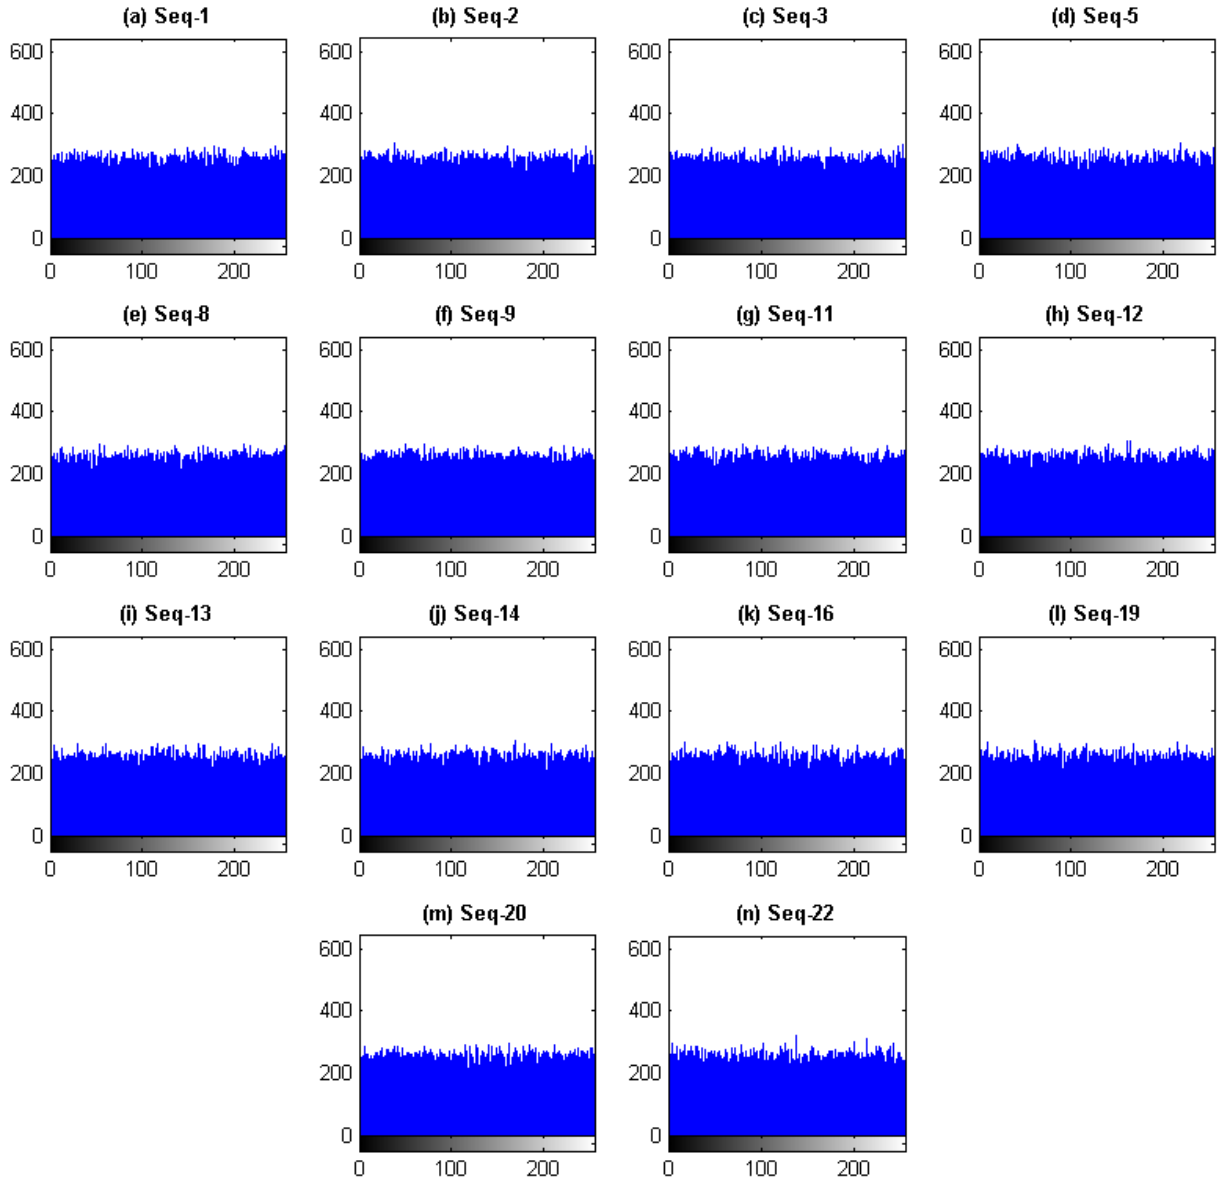

Fig. 2. Histogram of encrypted Lena image with the considered 14 sequences

with short (2^{10} bits) and long (2^{20} bits) size sequences. The pseudo-random sequences generated by these 14 schemes are applied to image encryption as an application example and the security analysis of the ciphered images are carried out. It is found also that the sequences generated using the C-D ECPRNG had high periodicity so that the encrypted images are secure. In addition, it has large key space, which is by far very safe for image encryption applications, and outperforms the competitive image encryption algorithms in terms of efficiency comparing to other encryption schemes.

ACKNOWLEDGMENT

This work has been supported financially by the Ministry of Higher Education of Egypt. Calculations in this paper were performed at the Interdisciplinary Center for Mathematical and Computational Modeling (ICM) of the University of Warsaw part of the grant calculation No. G63-2.

***Abstract*—Much of the debate surrounding risk management in information security (InfoSec) has been at the academic level, where the question of how practitioners view predominant issues is an essential element often left unexplored. Thus, this article represents an initial insight into how the InfoSec risk professionals see the InfoSec risk assessment (ISRA) field. We present the results of a 46-participant study where have gathered data regarding known issues in ISRA. The survey design was such that we collected both qualitative and quantitative data for analysis. One of the key contributions from the study is knowledge regarding how to handle risks at different organizational tiers, together with an insight into key roles and knowledge needed to conduct risk assessments. Also, we document several issues concerning the application of qualitative and quantitative methods, together with drawbacks and advantages. The findings of the analysis provides incentives to strengthen the research and scientific work for future research in InfoSec management.**

I. Introduction

THE PRIMARY goal of InfoSec is to secure the business against threats and ensure success in daily operations by ensuring confidentiality, integrity, availability, and non-repudiation [1]. Best practice InfoSec is highly dependent on well-functioning InfoSec risk management (ISRM) processes[2]. While ISRM is the practice of continuously identifying, reviewing, treating and monitoring risks to achieve acceptance[3].

This paper investigates the practitioners view of research problems within information security (InfoSec) risk assessment (ISRA). While there is plenty of available material regarding what ISRA frameworks contain and how they compare with each other [4], the literature is scarce regarding the current ISRA industry practices. There are several known theoretical problems in ISRA[4], [5], however, we do not know if the risk practitioners agree that these problems are either relevant or representative. Thus, there is the possibility that existing literature is incomplete and that academia is missing the important issues. This paper contains the results and analysis from a combined quantitative and qualitative study of the practitioners view, and represents a step towards a more holistic picture of industry ISRA practices.

Part one of this study [6] researched practices in InfoSec (ISRM) with emphasis on the risk management part and issues, while this study emphasizes the risk assessment and analysis parts. We provide new knowledge regarding where the research in ISRA should be focusing the efforts, making the ISRA community and researchers the primary beneficiaries of this study. Improving ISRA is essential in making progress in the InfoSec research field as it is this process that helps organizations determine what and how to protect. Thus, the intended audience of this paper is InfoSec professionals and academics, together with other ISRA practitioners and stakeholders.

The main research problem investigated in this article is "How do the ISRA problems outlined in previous work ([4]) reflect problems experienced in the industry?". The scope of this article covers the ISRA process, including risk identification, estimation, evaluation, and risk treatment practices [3], and is limited to the practitioner point-of-view. We separate between risk assessment (ISRA) and analysis (ISRAn), where the assessment is defined as the overall process of risk identification, estimation, and evaluation. While risk analysis is the practical hands-on parts of risk identification and estimation, for example, a practitioner may choose ISO/IEC 27005:2011 as the overall approach to ISRM/ISRA, while prioritizing *Fault tree analysis* for ISRAn.

The remainder of this article has the following structure: First, we briefly describe the related work, before presenting the research method in the form of data collection approach, demographics, and analysis. Following this is a combined analysis and discussion of the results, where we start with findings on the high-level risk assessment practices, before diving into the deeper aspects of InfoSec risk analysis (ISRAn) and risk treatment. Lastly, we summarize our findings, including limitations of this study, and conclude the paper.

A. Related work

This work primarily builds on previous work conducted on the topic of research problems in ISRM/ISRA. Both Wangen and Snekkenes [4] and Fenz et al. [5] have published articles on current challenges in ISRM; The former is a literature review that categorizes research problems into a taxonomy. The latter discusses current challenges in ISRM, pre-defines a set of research challenges, and compares how the existing ISRM methods support them. The primary purpose of the Fenz et al. study was to categorize and present known research problems at different stages in the ISRM/RA areas and activities. These two articles provide the primary literature foundation for this study. The data for this study was gathered in one comprehensive questionnaire, where the first part concerning ISRM was published in [6].

II. Research Method

This study was conducted to investigate ISRM industry practices and the respondents' views of several known challenges within the research field. 46 respondents participated in

Fig. 1. How respondents ranked themselves (x-axis) and how they were rated in the survey (Y-axis)

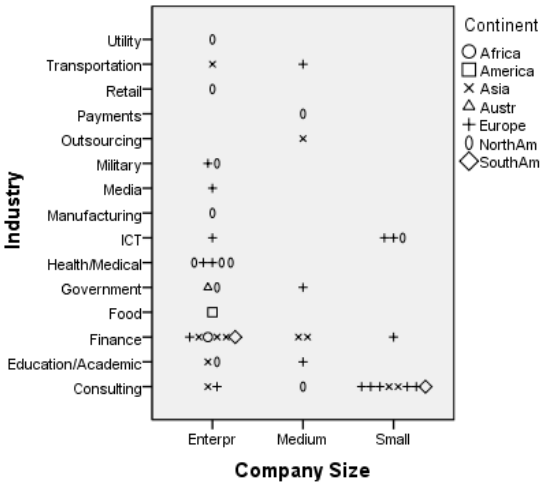

Fig. 2. Respondent demographics, based on company size (x-axis), industry (Y-axis) and Continent.

our online survey. The first sub-section addresses the choice of data collection method and measurement, followed by the demographics, and a brief overview of the statistical methods used for data analysis.

A. Data Collection, Sample, and Measurement

In their study, Kotulic and Clark [7] highlights that one of the most prominent problems in InfoSec studies is getting in touch with the target group and acquiring respondents. They propose several potential explanation for this: Where one is that InfoSec research is one of the most intrusive types of organizational studies. Also, that there is a general mistrust of any ”outsider” attempting to gain data about the actions of the security practitioner community [7]. Thus, we consider non-intrusiveness an essential requirement when designing the data collection tool. The narrow target group, industry professionals, made obtaining respondents a challenge as the study was subject to geographical limitations. To overcome said limitations we attempted to recruit participants from InfoSec risk specialized online forums. We considered this approach as non-intrusive, and it exposed the survey to many within the target group. However, it presents several problems; with this strategy the researcher has little control of participants except that they are members of particular forums, Table I. We, therefore, included self-rating questions in the questionnaire for the respondents to rate their knowledge, expertise and experience, together with our knowledge-based control questions. We designed a classification scheme based on this information, see Fig. 1.

We designed the questionnaire in Google Forms according to the procedure for developing better measures [8]. As for the level of measurement, the questionnaire had category, ordinal, and continuous type questions. Category type questions mainly for demographics and categorical analysis, while the main bulk of questions were designed using several mandatory scale- and ranking questions. The main categories applied for analysis is seen in Fig. 1, together with company size, and work type. The questionnaire also included several non-mandatory fields for commenting on previous questions or just for sharing knowledge about a subject. It had four pages of questions in total; the first page was demographics and self-rating questions. The questionnaire consisted of 37 questions in total, with an estimated completion time of 15-40 minutes depending on how much information the respondent shared. This paper consists of the results from questions regarding risk assessment and analysis.

TABLE I. GROUPS AND FORUMS WHERE THE QUESTIONNAIRE WAS POSTED

LinkedIN Forum name	**Members (at release time)**
IT Risk Management	3 443
CRISC (Official) *(Certified in Risk and Information Systems Control)*	1 400
Information Security Risk Assessment	441
ISO27000 for Information Security Management	22 620
Information Security Expert Center	8 906
Risk Management & Information Security *(Google+)*	521

B. Demographics

We received 46 accepted answers, See Table II for the classification of respondent expertise and work type (technical or administrative). While Fig. 2 displays respondent demographics categorized on company size, industry, and geographical affiliation. For the analysis, we applied the following definitions of company size: Small equals 1-249 employees, Medium 250 -1000, and Enterprise more than 1000.

TABLE II. CLASSIFICATION OF RESPONDENTS, TOTAL 46.

	Expert	Proficient	Competent
Administrative Work	13	10	6
Technical Work	7	7	3

C. Analysis

We applied a variety of statistical data analysis methods specified in the results, and the IBM SPSS software for the statistical analysis. A summary of the statistical tests used in this research is as follows:

For *Descriptive analysis* we have considered distributions including range and standard deviation. On continuous type

questions, we applied measures of central tendency mean, median and mode. We also conducted *Univariate* analysis of individual issues, and *Bivariate* analysis for pairs of questions, such as a category and a continuous question, to see how they compare and interact. However, we have restricted the use of mean and standard deviation for Likert-type questions and ordinal data where there was not defined a clear scale of measurement between the alternatives, as the collected data will seldom satisfy the requirements of normality. We have, therefore, analyzed the median together with an analysis of range, minimum and maximum values, and variance. This study also analyses the distributions of the answers, for example, if they are normal, uniform, binomial, or similar. *Crosstabulation* was applied to analyze the association between two category type questions, such as "Company Size" and "Expertise." We have used Pearson two-tailed *Correlation test* to reveal relationships between pairs of variables as this test does not assume normality in the sample.

The questionnaire also had several open-ended questions. We have treated these by listing and categorizing the responses. Further, we counted the occurrence of each theme and summarized the responses. Also, each continuous question had the possibility for the respondent to write a comment and offer further qualitative insight on an issue, where the most valuable comments are a part of this paper.

III. InfoSec Risk Assessment practices

This section contains the results and discussion of the statistical analysis regarding the ISRA practices. We start at a high-level; with the ISRA practices in organizational tiers, who should attend the ISRA, and what knowledge is important to have included in the process.

A. ISRA and Organizational Tiers

It is common to differentiate between risks at different tiers of abstraction when assessing an organization, such as Operational/Information Systems (low level), Tactical (mid-level), and Strategic (high level) information risks (for example [9]). The strategic and tactical type-risks can provide the risk analyst more time to estimate, risks in the operational environment often has to be handled ad-hoc or within a limited period. As these tiers are quite different and come with different types of risk, we asked if the practitioners distinguish between ISRA methods for them. 28% answered that they do, while the remainder answered no or other. There was no significant difference between groups in this question, Fig. 3. There were three detailed technical insights offered by the participants to shed light on practices, one technical (tech) expert responded: *"We apply the same methodology but are far less formal with tactical solutions. While a strategic solution would require formal sign off, tactical solutions need only require an email approval."*

While an administrative (admin) expert answered:*"High or Very High risks require detailed documented analysis (eg Bowtie diagrams) At each organisational level the risks are assessed against consequences at that level and mitigation applied at that level - if mitigation are insufficient at that level, the risk is escalated to the next higher level and re-assessed."*

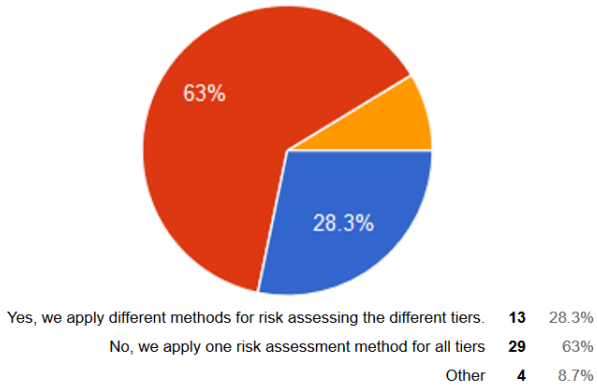

Fig. 3. ISRA practices on different organizational tiers

A tech proficient respondent answered: *"We use different methods for financial risk, IT (security) risk and business strategic risk. method for financial risk is "FOCUS" (successor of "FIRM"), as prescribed in regulations; method for IT security risk based on ISO 27005/31000, method for strategic risk is not formalised."*

The three answers show that there are several nuances to this problem that has not yet been highlighted in academia. The lower organizational tiers may be handled less informally, as it is likely these need faster decision-making. Our results show that some organizations have implemented different approaches to dealing with this problem, while others stick to one approach for all risk types. Awareness around this issue is also something that can be further researched in academia.

B. Who attends and conducts InfoSec risk assessments?

Having people with the right expertise and knowledge about the target system attending the risk assessment is one crucial success factor. Our results should provide a pointer on how to organize thee risk assessment and who should attend.

To get a generic overview of who attends and conducts ISRA in the practitioners organizations, we asked the participants who attends risk assessments in their organization. As two respondents pointed out, this picture depends on the type of risk assessment being conducted, yet, frequencies of attendance can still be estimated. Table III holds an overview of who attends ISRAs in the respondents organizations. The alternatives was "Never attends" (1), Sometimes attends (2), Always attends (3), Leads assessments (4), and we removed the respondents opting *Not present* for the statistical analysis, Table IV.

The results show that the CSO/CISO (Chief InfoSec Officer) most frequently leads risk assessments, while ICT security personnel most frequently attends. With the Head of ICT department and Operations personnel also attending with a high frequency. IT architects and software developers also attend the ISRA process frequently.

We found that in smaller companies, the CEO and CTO is much more likely to attend/lead risk assessments than in medium and enterprise sized companies, Table IV. Although, in some organizations, especially small ones, employees will have overlapping roles. One admin expert provided a caveat

about having high management involved: *"Having C[EO] or high management inside Information Security assessment will not allow the participants to be open when providing input for risk identification."*[1]

Comments on the results in table III, were from six admin experts and one admin proficient. Out of the seven written comments, five of them specified that the composition of the risk assessment team is dependent on the scope of the assessment; *"If business processes or systems are included in the scope, system owners or users with good knowledge of the processes attend."*

TABLE III. ROLES ATTENDING IN RISK ASSESSMENTS.

Attends/ Roles	Never present	Sometimes	Always	Leads	Not present in Organiza.
CEO	34.8%	28.3%	15.2%	13 %	8.7%
CSO/CISO	4.3%	15.2%	34.8%	32.6%	13 %
CTO	15.2%	17.4%	30.4%	8.7%	28.3%
CIO	19.6%	19.6%	28.3%	13 %	19.6%
Head of IT Dep	10.9%	26.1%	32.6%	21.7%	8.7%
ICT sec. personnel	4.3%	8.7%	50 %	30.4%	6.5%
IT architects	8.7%	34.8%	30.4%	13%	13%
Softw. dev	8.7%	39.1%	30.4%	10.9%	10.9%
Operations Personnel	8.7%	32.6%	37 %	15.2%	6.5%
External Consultants	21.7%	43.5%	15.2%	6.5%	13 %

TABLE IV. NOTICEABLE DIFFERENCES BETWEEN ATTENDS, SCALE FROM 1 (NEVER ATTENDS) - 4 (ALWAYS ATTENDS). (NOTE: THE RESPONDENTS CHOOSING "NOT PRESENT IN ORG." HAS BEEN REMOVED FROM THE SAMPLE)

		N	Minimum	Maximum	Range	Median	Grouped Median
@CEO	Small	12	0	4	4	3,00	2,67
	Medium	8	1	4	3	2,00	1,71
	Enterpr	26	0	4	4	1,00	1,53
CTO	Small	12	0	4	4	3,00	2,10
	Medium	8	0	4	4	2,00	2,00
	Enterpr	26	0	4	4	2,00	1,69

C. Critical knowledge areas in ISRA

Conducting an ISRA is a complex task with several different variables to consider, having discussed who attends risk assessments we look into critical knowledge areas to succeed with a risk assessment. So, we asked the participants to rank the importance of having knowledge about a set of items for the results of the ISRA (scale: 1 equals "not important" - 6 "very important"), Table V. For the comparison of knowledge areas the median is 5 for all but the *Organizational Structure* option, meaning that all were ranked highly by the respondents. Knowledge of *information assets* as the most important according to the mean score. Second, knowledge about *Laws & regulations* and *Information systems* were ranked equally, knowledge about *ISRA methods* was ranked the lowest. The diversity of the alternatives and the density of the results, supports that InfoSec is a very diverse field which demands a broad range of knowledge form its practitioners.

There was three noticeable differences between the expertise categories, the difference in view between experts and the two other groups on the importance of software, threat intelligence, and ISRA methods, Table VI. Whereas the experts valued threat intelligence less (grouped median = 4.75) than the proficient and the competent (grouped median = 5.13 and 5.47). There was also a slight difference in views between administrative (median=5, grouped median = 4.71) and technical workers (median=4, grouped median=4.71) on having knowledge of the organizational structure.

Two experts commented on the criticality of experience, *"The assessors experience is critical to a effective and accurate risk assessment"*, and *"Any method in use is only as good as the person(s) executing it and overall understanding of the business (or the part of business to evaluate) is critical to get results that are business beneficiary and useful to work with"*. Both comments highlights the need for experience, while the latter also highlights business understanding as key knowledge items. Our results also support this, as the top three ranked knowledge items relate to business understanding.

TABLE V. VIEWS ON IMPORTANCE OF KNOWLEDGE AREAS FOR ISRA. (*1 - Not Important* TO *6 - Very Important*

	Expert	20	3	6	3	5,00	4,50

IV. RISK ANALYSIS PRACTICES

Risk analysis (ISRAn) is the hands-on tasks performed during the assessment, primarily risk identification and estimation related tasks. This section starts with addressing some common issues regarding information assets, before investigating common risk analysis issues. We then survey the views of ISRAn methods and concepts.

We started the inquiry by asking an optional question on what the respondents thought to be working well in ISRAn. We got sixteen valid answers (eighteen total) with few common denominators, notably six respondents rated the risk assessment process to be working well, where two specified the risk identification phases to be well-developed. Two tech experts and one admin expert mentioned quantitative (numerical) ISRAn methods to be working well. While one tech and one admin expert answered that risk assessment on an overall works well, while *"implementation of risk mitigation and measurement follow up lags in many organizations."*

[1]Edited by author for readability, original answer *"having C or high management inside Information Security assessment not allow the participants to be open when providing input for risk identification."*

A. Views on Information Assets

Asset evaluation is one of the key challenges in ISRA [4], [10]. Due to being intangible, information assets can be particularly elusive to monetize and quantify. Which makes it hard to estimate, evaluate, and predict consequences of asset breaches in ISRA. To investigate issues regarding assets, we asked the participants to rate five statements regarding known issues on information assets [4]. Figure 4 shows the distribution of answers and Table VII displays descriptive statistics, typical of these results is a high variability in the answers.

With regards to Statement 1 (Table VII), the descriptives show that most practitioners agree that assigning monetary value is difficult, with the highest reported median 5 and mean 4.7, with no noticeable difference between groups. The results support the claims regarding information assets in Wangen & Snekkenes (2013) [4]).

The result from ranking Statement 2 regarding risk assessment method adequacy for asset evaluation, shows the sample mean being divided almost in the middle with a median of 3.67. The distribution for statement 2 is also close to normal but being negatively skewed (-0.299), Figure 4, and, therefore, ran significance tests. Our results showed that there was a statistically significant difference (P=0.031%) between expertise groups regarding Statement 2, regarding ISRA method adequacy, Table VIII, showing the Experts being less satisfied with the available asset value estimation methods. Three admin experts also commented on assigning the monetary value to assets, where two commented regarding asset evaluation not always being necessary: (i) *"The value doesn't necessarily be expressed in monetary terms."* (ii)*"... Knowing the value of personal information is not required to be able to protect it from unauthorized collection use of disclosure. The law says to do it."* These two insights show that asset evaluation is not always necessary, especially when the existing security legislation applies then a security classification is sufficient. While the third comment is on the importance of asset evaluation, (iii) *" Asset value can be assigned in various ways, and monetary value is in most cases the hardest one and most often wrongly set. Erroneously set values may in the worst case result in a totally erroneous assessment result. Asset value may have monetary value as one parameter but should be defined by much more than just a monetary number. E.g. if assets protected by law governed requirements are lost in the worst possible way, that may be "end of business," but that most often only relate to a small percentage of the total information assets of the business."*

Zhiwei [11] critiques the asset-based approach, and claims that protection of assets is not a primary goal of organizations, while priority number one should be the protection of the reliability and security of the organizations business processes. Statements 3 and 4 (Table VII addresses Zhiwei's view:

Regarding statement 3, most agreed that Asset protection is the primary goal of the InfoSec program, median = 5 and a mean = 4.37. However, there is a large variability in the results; nine respondents answered three or less showing that a minority disagrees with this statement. Out of this minority, six qualify as experts. The answer to statement 4 regarding the importance of asset security compared to ensuring stable

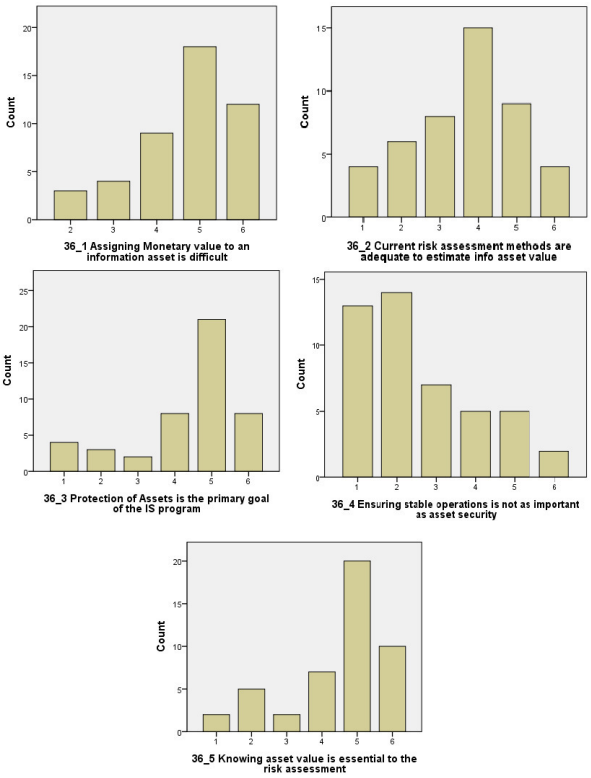

Fig. 4. Statements and rankings regarding Assets (Scale *1 - Strongly disagree* to *6 - Strongly agree*)

operations: The scores was on the low side (median = 2), showing that most of the respondents thought that stable operations are just as (or more) important than asset security. There was a notable difference between expertise groups for both Statement 3 and 4: The competent group consistently valued asset security higher than the proficient and expert group, indicating that protection priorities may be altered with experience in support of Zhiwei, Table VIII.

TABLE VII. PRACTITIONER VIEW ON ISSUES RELATED TO ASSETS. (SCALE 1 - STRONGLY DISAGREE, 6 - STRONGLY AGREE)

	N	Min	Max	Median	Range	Mean	Variance
1. Assigning Monetary value to an information asset is difficult	46	2	6	5	4	4,7	1,328
2. Current risk assessment methods are adequate to estimate info asset value	46	1	6	4	5	3,67	1,958
3. Protection of Assets is the primary goal of the IS program	46	1	6	5	5	4,37	2,149
4. Ensuring stable operations is not as important as asset security	46	1	6	2	5	2,59	2,248
5. Knowing asset value is essential to the risk assessment	46	1	6	5	5	4,48	1,988

S10.Consequences of occurred incidents tend to be outliers (extreme)	46	1	6	2,91	1,548	3	,316	5
S11.Causes for severe incidents/ disasters tend to not be thought of in our assessments	46	1	6	2,85	2,043	3	,518	5

TABLE X. DISTRIBUTION OF ANSWERS (X-AXIS) REGARDING ISRA STATEMENTS (Y-AXIS). STATEMENT NUMBERS CORRELATE WITH DESCRIPTIONS IN TABLE IX. (1 - STRONGLY DISAGREE, 6 - STRONGLY AGREE)

Statement nr	1	2	3	4	5	6
S1	0 (0%)	4 (8.7%)	7 (15.2%)	11 (23.9%)	14 (30.4%)	10 (21.7%)
S2	7 (15.2%)	10 (21.7%)	11 (23.9%)	5 (10.9%)	8 (17,4%)	5 (10.9%)
S3	8 (17.4%)	10 (21.7%)	10 (21.7%)	6 (13%)	10 (21.7%)	2 (4.3%)
S4	2 (4.3%)	3 (6.5%)	13 (28.3%)	10 (21.7%)	17 (37%)	1 (2.2%)
S5	2 (4.3%)	10 (21.7%)	18 (39.1%)	6 (13%)	7 (15.2%)	3 (6.5%)
S6	1 (2.2%)	3 (6.5%)	11 (23.9%)	10 (21.7%)	14 (30.4%)	7 (15.2%)
S7	2 (4.3%)	8 (17.4%)	14 (30.4%)	5 (10.9%)	10 (21.7%)	7 (15.2%)
S8	7 (15.2%)	12 (26.1%)	13 (28.3%)	4 (8.7%)	7 (15.2%)	3 (6.5%)
S9	4 (8.7%)	8 (17.4%)	18 (39.1%)	7 (15.2%)	7 (15.2%)	2 (4.3%)
S10	7 (15.2%)	8 (17.4%)	20 (43.5%)	5 (10.9%)	5 (10.9%)	1 (2.2%)
S11	9 (19.6%)	11 (23.9%)	14 (30.4%)	4 (8.7%)	6 (13%)	2 (4.3%)

The qualitative versus quantitative risk assessment is a well-known debate in ISRA [4], the former is mostly subjective knowledge-based and often describes risk using qualitative expressions, such as high, medium, and low. While the quantitative approach is mainly numerical and often based on statistical methods. There are arguments both for and against both approaches [4]. With the described issue at its core, we asked the participants to rank several statements regarding ISRAn practices, Table IX holds the statements with results and the distributions are in Table X. The results were diverse regarding all the statements, with the lowest median at 3 and highest at 5. In the following text, we analyze each statement with regards to descriptive statistics and correlation analysis. There are multiple differences between the three analyzed categories regarding nine of the statements, Table XI, and we analyze these differences together with the statement in question.

The results from Statement (S) 1, shows, with about 75% answering 4 or more, that most respondents consider their approach to be mainly qualitative. Worth noting is the minimum value of 2 in the results documenting that all of the participants consider their ISRAn methods to at least have some level subjectivity. S1 also has the highest median of 5 and lowest variability in the results. Regarding S2, less than half of the respondents consider their approaches to be more quantitative than qualitative, with 28% answering 5 or 6 indicating a mainly quantitative approach. Table XI shows that there is a notable difference between work types in this matter, whereas technical/hands-on practitioners view their approach as more quantitative. S2 regarding quantitative methods is also negatively correlated to S1 at the 0.05 level, Table XII.

In S3, regarding prediction of monetary costs, the median is 3 with a large variability in responses indicating that it is hard to predict the monetary cost of an incident based on ISRAn results. Also, the Expert group rated S3 lower than the other two groups, with the proficient group agreeing most with S3. Meaning that the experts in our sample find it harder to use the ISRAn results to predict the monetary cost of an incident.

The risks of being too reliant on expert predictions are that results can become too opinion-based, vulnerable to several external human factors, for example, emotional state and feelings [12], the Narrative Fallacy [13]), and involve a high degree of guesswork (see [4]). S4, regarding ISRAn reliance on expert predictions, the median is 4, with 87% of the responses being in the 3-5 range. There is notable difference between company sizes (Table XI), where small and medium companies seem more reliant on expert predictions than the enterprise-sized organizations.

Regarding S5, asks if spending resources on quantitative ISRAn are worth the results. The results show that majority (65%) answered 3 or less, while a minority (22%) answered 5 or more. However, there is a notable difference between technical and administrative work type (Table XI). Where the admin respondents consider quantitative risk assessments as a bigger waste of time than the tech respondents, which also corresponds to differences between these groups in S1 and S2.

Lack of historical data is claimed to be a consistent problem in InfoSec [4] and S6 addresses this issue. The median of 4 provides some evidence to support this assertion, there was also a notable difference between expert groups here, whereas the experts ranked this issue higher than the competent and proficient group.

Mathematical probability calculations is an issue with many opinions in the ISRA community [4], S7 and S8 connects to this issue. S7 addresses views on the adequacy of mathematical ISRAn methodology for probability calculations, with the results showing a difference of opinion on existing methods, the median of 3. There was a notable difference between the respondents from Small and Medium companies, ranking this issue higher than those from the Enterprises. The results are similar for S8, regarding Annual loss expectancy (ALE), although the difference is smaller for both total results and between the companies.

S9 addresses risk forecasting accuracy, and the results show that the respondents' general confidence in their predictions is on the low side. There was no notable difference between the expert groups indicating that confidence in precision has not improved with increased experience and expertise. However, there was a difference between company sizes, where the small and medium companies perceive a higher accuracy in their estimates. There is more complexity in larger organizations, which is one of the key challenges for prediction [14] and may be one of the causes.

Both S10 and S11 are connected to unforeseen incidents and causes, both related to Black Swan Risks [13] which are rare outlier risks that carry an extreme impact. Our results indicate that consequences of occurred incidents tend not be outliers and that causes for severe events/disasters are more often known than not. The analysis displays a difference between expert groups, with Experts being confident in their

knowledge about causes of incidents and disasters. From our results we see that most causes are believed to be known, and that Black and Grey Swan-type incident are very seldom. However, rare events and how they drive the InfoSec program is a path for future research.

This section has touched on one of the key challenges in ISRA, which is obtaining quantitative estimates of the probability of occurrence for security incidents, together with a reliable estimate of the consequence in a methodologically sound way. Which is difficult because of several reasons [14], [4], [10], where the factors that limit the forecasting are, for example, complexity, interconnectivity, and active adversaries. These factors do not apply for all InfoSec risks [14] and there is utility in obtaining statistical distributions of InfoSec risks [14]. As our results have shown, there are degrees of subjectivity to every risk assessment and one area to strengthen research is in risk quantification by working on obtaining probability distributions. In addition to combining both the quantitative and qualitative estimates in the risk model.

TABLE XI. NOTABLE DIFFERENCE BETWEEN CATEGORIES (FULL STATEMENTS CORRESPOND TO NUMBERS IN TABLE IX)

Statement	**Expertise**	N	Min	Max	Range	Median	Grouped Median
S3	Comp	9	2	5	3	3,00	3

S5	Technical	17	1	5	4	3,00	2,73
	Admin	29	2	6	4	3,00	3,44

C. Correlations between statements

Several of the statements have strongly correlating results, Table XII. There is an interesting correlation regarding S2 on quantitative and statistical ISRAn methods: S2, is strongly correlated with S3 and S8, and weakly correlated with S9 and S11. The former correlations indicate that applying quantitative methods makes it easier to convert ISRAn results into monetary costs of incidents. The weak correlation to S9 indicates that working with risk quantification can improve precision and confidence in risk estimates. S3 is also strongly correlated with S8 and S9 further indicating that there are benefits from working with quantification and monetizing risk estimates. S3 is also negatively correlated with statement 1 in Table VII; *Assigning Monetary value to an information asset is difficult*. Further, the correlations test between the two sets of statements also indicates that gathering precise knowledge regarding asset value (36_5) correlates with confidence in consequence estimate precision. Another finding from this table is that prioritizing assets security as more important than stable operations (36_4) correlates with less insight into causes for severe incidents (S11).

Being reliant on expert predictions (S4) correlates strongly with the lack of historical data problem (S6) and lack of mathematical approach (S7) to ISRAn probability calculations. However, expert predictions also correlate with precision (S9), it seems a combination of mathematical models and expertise is then optimal. Lack of historical data (S6) also correlates with S10 and S11, indicating that historical data is necessary to prevent outliers and discover causes.

One Admin expert commented that *"Mathematical probability calculations are not worth anything if the organization does not believe in the probability of an incident occurring. Math alone is not the issue here. It is about the human ability to not just identify risk but accept risk presence (for real and react before the consequence of a corresponding issue hits)"*. Another Admin expert commented that *"There is still a lack of understanding of threat assessment as an input to identifying an actual risk."* The latter statement touches on the intersection between qualitative and quantitative methods since threat assessments are mainly subjective and can be more comprehensive than a purely quantitative approach being limited to observed data.

Consider the complexity and many aspects of loss calculations; one admin proficient commented: *"We consider the impact to business of loss of business (future) / customer impact, loss of reputation / brand impact, legal or regulatory breach and loss of money / financial impact."* Which highlights the many variables that must be considered in such calculations.

TABLE XII. CORRELATIONS BETWEEN ISRAN STATEMENTS. (FULL STATEMENTS CORRESPOND TO NUMBERS IN TABLE IX)

*. Correlation is significant at the 0.05 level (2-tailed).
**. Correlation is significant at the 0.01 level (2-tailed).

D. Application of ISRAn methods and concepts

To obtain an insight into industry practice and adaptation of methods and concepts we compiled a non-exhaustive list of popular risk assessment tools and concepts, and asked how often they applied them in their ISRAn practice. Table XIII displays how the concepts were ranked by the participants. The three most frequently used methods are Business Impact Analysis, Penetration tests, and Security scanners, all with a median of 5. Cascading/correlating risks are the most

frequently applied concept for risk analysis. The items from *Component Testing* down to *Common Mode Failure* have medians between 3-2. The results show that methods for different genres of risk assessment (collected from [15], [13], [16]), such as Fault and Event tree analysis, HAZID, and HAZOP, are not common in ISRAn, where practitioners prefer methods developed specifically for InfoSec. Common concepts such as Black Swan Risks [13] and ALARP (As Low As Reasonably Practicable) [15] are also not widely known and applied by the surveyed practitioners. One admin expert commented on this particular issue: *Fault Tree Analysis, FMEA [Failure Mode and Effect Analysis], Hazop etc. are usually methods used by safety professionals, not information security professionals (I have however used them both but for slightly different purposes) and MTF or MTBF (Mean Time Before Failure) is typically also used in these safety oriented methods. I see the ability to merge methodologies between these areas of expertise for mutual benefit, but as far as I know, the industry does not do that in current operation.*

The same expert also commented on the three of the item's role of tools in reducing uncertainty: - *Different tools are in use for different purposes. I do not see penetration testing/security scanner/component testing as part of risk analysis. It is additional tools relevant to use if the risk evaluators are unable to be certain about probability - such testing can document probability and it also provides low-level insights to mitigation means.*

TABLE XIII. APPLICATION OF TOOLS, METHODS, AND CONCEPTS IN ISRA. (SCALE: 1 - UNFAMILIAR, 2 - VERY SELDOM, 3 - SELDOM, 4 - SOMETIMES, 5 - OFTEN, 6 - VERY OFTEN)

		N	Min	Max	Median	Range	Mean	Variance	Category

18	ALARP	46	1	6	1	5	1,7	1,416	Concept
19	CORAS	46	1	5	1	4	1,7	1.372	Method
20	HAZOP	46	1	5	1	4	1,65	1,032	Method
21	HAZID	46	1	5	1	4	1,61	1,088	Method

E. Cost-effectiveness of ISRA methods

As a follow up, we asked the participants which ISRAn method they considered to be most cost-effective, in which we received ten answers. There were no clear answer to this inquiry: Two Admin experts argued for Business Impact Analysis (BIA), as *"at the end of the day the systems that our business use are our main reason to have an IT area"*, and it *"can be done without bringing in external resources"*. BIA contains several tools and methods for reducing uncertainty related to consequences of risks.

Two argued (Admin expert and proficient) for security scanners and penetration tests (pentests), as *"they provide undeniable evidence of vulnerabilities. It is hard for someone to argue with them."* While two respondents (Admin expert and proficient) argued for the use of *Bowtie*-diagrams based on cause, threat, and risk analysis. We do not find Bowtie diagrams extensively described in the ISRA literature, although they are found in the more generic safety-related risk assessment literature, such as [15]. Bowtie are used for both risk analysis, visualization and communication.

F. What is the most important task of the ISRA?

There several tasks that are common when conducting an ISRAn [17], we gathered the common denominators and asked the participants to rate them according to their importance, 1 - Not important to 6 - Very important. Table XIV displays the results, with no notable difference between any groups. The participants ranked all the items highly, with lowest median being 4. The low end of the scale contains importance of knowledge about Stakeholders, Attacker capability, and Uncertainty. Whereas the remainder of the items are rated 5 or higher, meaning they are essential to the process. The respondents ranked Impact/consequences and threat as the most important tasks for the ISRA work.

TABLE XIV. VIEWS ON IMPORTANCE OF TASKS AND ITEMS FOR RISK ANALYSIS. (SCALE: 1 - NOT IMPORTANT, 6 - VERY IMPORTANT)

	N	Min	Max	Median	Range	Mean	Variance
1. Asset	46	1	6	5.5	5	5,15	1.287
2. Threat	46	3	6	6	3	5,33	0,936
3. Guardian/Control	46	3	6	5	3	5,02	1,133
4. Uncertainty	46	1	6	4	5	4,24	1,742
5. Probability/Likelihood	46	3	6	5	3	5,2	0,828
6. Impact/Consequences	46	3	6	6	3	5,37	0,638
7. Stakeholders	46	1	6	5	5	4,5	1,9
8. Attacker Capability	46	2	6	4	4	4,11	1,432
9. Vulnerability	46	3	6	5	3	5,24	0,586
10. Expert Knowledge	46	3	6	5	3	4,96	0,665

V. CHOOSING RISK TREATMENT STRATEGIES

Jaquith [18] claims that for most people, risk management really means risk identification, although these phases are clearly defined in the ISO/IEC vocabulary [1]. Applying ISO/IEC 27005:2011 [3] as a yard stick, the risk identification-phase clearly contains the majority of data collection and analysis. So, we asked the participants to rank the three different ISRA phases on importance. Table XV shows that the phases are almost equally ranked by our sample, with the risk identification scoring highest with a 6 median, otherwise, the difference between the phases are negligible.

TABLE XV. RANK THE PHASES OF THE ISRA PROCESS ACCORDING TO YOUR PERCEIVED IMPORTANCE, SCALE 1 (NOT IMPORTANT) - 6 (VERY HIGH IMPORTANCE)

	N	Min	Max	Median	Range	Mean	Variance
Risk Identification	46	4	6	6	2	5,57	,340
Risk Estimation	46	4	6	5	2	5,15	,532
Risk Evaluation	46	4	6	5	2	5,26	,464

Blakley et.al.[2] claims that the risk treatment strategies applied in IS focus primarily on risk mitigation, while transference, acceptance and avoidance as alternatives are seldom considered. The authors explain that the reason for this is the general approach to ISRM, where the practitioners are geared to imagining and then confirming technical vulnerabilities in information systems, so that steps can be taken to mitigate them. InfoSec activities rarely include any discussion of indemnity or liability transfer, although some organizations do address these issues in an "operational risk" organization

separate from the information security organization. Table XVI displays how the survey participants replied when we asked them how often they recommend the different risk treatment strategies for ISRA (scale 1 - Never, 2 - Very Seldom, 3 - Seldom, 4 - Sometimes, 5 - Often, and 6 - Very Often). Risk mitigation is the option ranked highest with 87% of respondents answering often or very often. This result supports Blakley et.al.'s claims about this strategy. However, the results also show that other strategies are frequently considered. The Blakley et.al. paper was written over a decade ago and the ISRA community may have matured in this area, although this is a field for future research. The *Transference* option is almost normally distributed, while the *Avoidance* option is bimodal with one top at *Sometimes* (39,1%) and one at *Very seldom* (19,6%). The *Acceptance/Retention* option is described by the median with 71% opting for *Sometimes* and *Often* alternatives. A clarification is provided by an admin expert with regards to type of industry: *"When it comes to health information, where regulatory requirements are very clear at placing the responsibility within the business, and a risk could lead to loss of life or health or patient confidentiality, transference is seldom an option."* Whereas another admin expert comment: *"Avoidance is seldom an option. Acceptance is most often already defined at some certain level in the business and is therefore most often not an option for any identified risks above defined threshold of acceptance. Optimisation is most often not prioritized until a result shows all risks identified to be below defined level of risk acceptance or as something to "think about" when all identified risks beyond acceptance threshold is reduced to a level within acceptable threshold."*

TABLE XVI. RESPONDENTS' RECOMMENDATION OF RISK TREATMENT OPTIONS IN ISRA. SCALE 1 (NEVER) TO 6 (VERY OFTEN)

	Valid	Min	Max	Median	Range	Mean	Variance
Transference	46	1	6	4,00	5	3,46	1,631
Mitigation	46	2	6	5,00	4	5,20	,872
Avoidance	46	1	6	4,00	5	3,76	1,608
Acceptance/Retention	46	2	6	4,00	4	4,15	1,065
Optimisation	46	2	6	4,00	4	4,30	1,150

Blakley et.al. also claims that InfoSec as a discipline focus more on reducing the probability of an event than on reducing its consequences. And where the focus is on reducing consequence, it tends to focus much more strongly on quick recovery (for example, by using aggressive auditing to identify the last known good state of the system) than on minimizing the magnitude of a loss through measures to prevent damage from spreading. We asked the participants which they thought more important, reducing the probability or consequence of the risk. Fig. 5 shows that the results are almost 50/50 distributed, no better than random. According our sample, there is no clear preference towards one or the other. With that said, this is often a two part process, where one can treat both probability and consequence of the risk to obtain a reasonable risk level. This issue was also highlighted to some extent by six of the twelve written comments to this question. The type of risk was also highlighted in four answers as a determining factor. One admin expert wrote: *"Proactive approach to risk reduction (i.e. probability) is most often chosen prior to reactive approaches (i.e. impact/consequence) as long as that is a feasible approach compared to cost of reactive approaches. The risk assessment result however, includes recommendations of both types for the business to conclude."* Also highlighting the need for cost/benefit analysis of the proposed risk treatment.

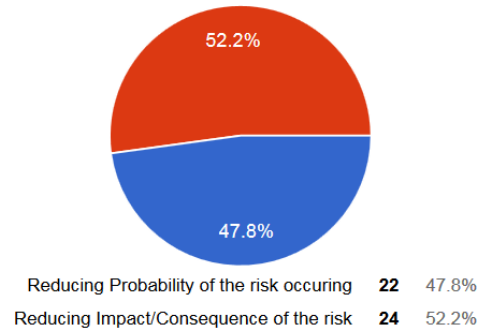

Fig. 5. Results from opting to reduce either probability or consequence

VI. SUMMARY & CONCLUSION

In this section, we first discuss the limitations of this study. Then, we conclude our findings, together with research implications and directions for future work.

A. Limitations

While our choice of online survey allowed us to recruit participants from our target group through specialized web-forums, this approach has some limitations. First of all, our data are self-reported values based on participants perceptions, while not a substitute for behavioral and observational data from real-world scenarios, this self-reported data can still provide valuable insight into day-to-day practices and how practitioners view the research problems. Furthermore, the study design and recruitment process gave us less control of the research participants; the control questions somewhat mitigated this problem, but these were not fool-proof, and circumvention was possible. The sample size was also small, although the online groups and forums exposed the survey to many potential respondents we only managed to recruit forty-six in one month. Based on the many members of these groups, the recruitment strategy was not a success. Many restricting factors could have caused this outcome, for example, activity in the forums, exposure of the survey, and questionnaire length. Although the sample had a good geographical spread and diverse background from the participants, this small sample is sensitive to outliers. The written responses and comments are more anecdotal evidence.

Another limitation of this study is concerning what is not asked for, issues we are not aware of or not present in the questionnaire can not be answered. We partially addressed this issue by adding with comment sections in the questionnaire, but this issue is likely better addressed in open interviews.

B. Conclusion & Future Work

InfoSec risk management and assessment are essential to well-functioning InfoSec program as it determines what to protect and how. In this paper, we have addressed three major areas of practice in ISRM and provided incentives to strengthen

research within them; on the ISRA level, we found that the majority did not differentiate between ISRA methods for different organizational tiers. However, several respondents did distinguish, for example through formality, and handled risks at the higher abstraction levels more formally. As a future direction, we propose to research handling and assessing risk between the organizational tiers, together with risk escalation issues.

Gathering the ISRA team and securing the right knowledge is essential to the assessment; Our results showed that the CISO/CSO and InfoSec personnel most frequently leads and attends risk assessments while various roles in IT department attends based on the scope of the assessment. Knowledge about information assets and business understanding was highlighted as essential, together with knowledge about laws & legislation stressing the importance of legal counsel in the ISRA. Composition and optimization of the ISRA team from the knowledge perspective is a potential path for future research.

Throughout the results, several respondents highlighted the significance of the risk assessors experience for the results, as *any method is only as good as the person executing it.* On qualitative and quantitative approaches, we found that the majority of ISRAn approaches are qualitative. While those who described their work as more technical were more likely to describe their ISRAn approach as quantitative. Our analysis shows that confidence in impact estimates precision tends to be low, however, working with risk quantification is likely to improve accuracy and trust in risk estimates. Which highlights the importance of both the expert and the benefits working with quantification. A path for future work is to research the intersection between these two approaches to optimize the ISRA results.

Related to the precision in impact estimation, we found that Black Swan theory is very seldom applied in ISRA. Possible paths for future work is an analysis of InfoSec risks and how they relate to Black Swans, together with research on rare events and how they drive the InfoSec program. We have provided incentives for strengthening research within obtaining probability distributions for frequencies and consequences for InfoSec, as this is an area that has a potential for producing useful knowledge for decision-makers.

Worth noting is that experts ranked the importance of threat intelligence for ISRA lower than the less experienced groups. On the risk analysis practices, this study documented that asset evaluation is a challenge, with experts considering the existing risk assessment methods as not sufficient to handle this problem. The participants also ranked knowledge about assets as important in multiple instances in the results which make asset evaluation stand out as an issue for future research.

From our list of suggested tools and concepts Business impact analysis, penetration tests, and security scanners are the most frequently applied tools for ISRA. Together with Bowtie-diagrams, these methods and tools are deemed the most cost-effective.

ACKNOWLEDGMENT

The Author thanks professors Einar Snekkenes for discussion, and my colleagues Andrii Shalaginov, Ambika Shrestha Chitrakar, Yi-Ching Lao and Goitom Weldehawaryat for quality assurance. Professor Stewart Kowalski for his knowledge on Likert-scales and analysis. We extend a thanks to all who answered the questionnaire, the anonymous reviewers for their comments, and the support from the COINS Research School for InfoSec.

5th International Symposium on Frontiers in Network Applications, Network Systems and Web Services

SYMPOSIUM SoFAST-WS focuses on modern challenges and solutions in network systems, applications and service computing. The Symposium builds upon the success of Frontiers in Network Applications and Network Systems (FINANS'2012) and 4th International Symposium on Web Services (WSS' 2012) held in 2012 in Wroclaw, Poland. These two events are now integrated into one event to fully exploit the synergy of topics and cooperation of research groups.

The topics discussed during the symposium include different aspects of network systems, applications and service computing. The primary objective of the symposium is to bring together researchers and practitioners analyzing, developing and administering network systems, with particular emphasis on Internet systems. Authors are invited to submit their papers in English, presenting the results of original research or innovative practical applications in the field.

TOPICS

- Architecture, scalability and security of Open API solutions,
- Technical and social aspects of Open API and open data,
- Service delivery platforms—architecture and applications,
- Telecommunication operators API exposition in Telco 2.0 model,
- The applications of intelligent techniques in network systems,
- Mobile applications,
- Network-based computing systems,
- Network and mobile GIS platforms and applications,
- Computer forensic,
- Network security,
- Anomaly and intrusion detection,
- Traffic classification algorithms and techniques,
- Network traffic engineering,
- High-speed network traffic processing,
- Heterogeneous cellular networks,
- Wireless communications,
- Security issues in Cloud Computing,
- Network aspects of Cloud Computing,
- Control of networks,
- Standards for Web services,
- Semantic Web services,
- Context-aware Web services,
- Composition approaches for Web services,
- Security of Web services,
- Software agents for Web services composition,
- Supporting SWS Deployment,
- Architectures for SWS Deployment,
- Applications of SWS to E-business and E-government,
- Supporting Enterprise Application Integration with SWS,
- SWS Conversational Protocols and Choreography,
- Ontologies and Languages for Service Description,
- Ontologies and Languages for Process Modeling,
- Foundations of Reasoning about Services and/or Processes,
- Composition of Semantic Web Services,
- Innovative network applications, systems and services.

Abstract — The paper presents proposal of practical implementation simple IoT gateway based on Arduino microcontroller, dedicated to use in home IoT environment. Authors are concentrated on research of performance and security aspects of created system. By performed load tests and denial of service attack were investigated performance and capacity limits of implemented gateway.

I. Introduction

IoT gateway concept is one of the most important aspect in Internet of Things idea. This network element is presented as a proxy between sensing network and application layers. Many small and autonomous devices and sensors urgently needs this component for communication with higher layers of the network.

In contemporary world of digital communication one of the major aspects is data transmission protection. The ways of implemented protection mechanisms depends on infrastructure details and characteristics of services dedicated to end users. IoT Gateway is a very interesting approach from this point of view and very often a single point of failure for IoT infrastructure. IoT gateway installed in single instance can be observed as Single Point of Failure [2] and is really vulnerable to all threats which are based on network traffic volumetric attack.

II. Existing Solutions

There can be defined two types of IoT gateway implementations. The first one: gateway installed in form of dedicated software located e.g. in typical wireless router or in smartphone as an application [2]. The second implementation is based on a gateway which is using a dedicated hardware. IoT gateway must meet requirements such as: hardware low cost, easy extensibility and application-layer support. The fact is that standardized to different network platforms IoT gateway doesn't exist. Each type of IoT device and each vendor uses own IoT gateway implementation e.g. on smartwatches market each supplier can offer client buying his own IoT gateway application which is installed in smartphone device. This approach is generally different than presented in Wifi segment where each computer, tablet or smartphone can use one common Wifi gateway.

Because of low hardware cost, availability and possibility of modifying the hardware and software in very easy way, the authors of this paper created a prototype of IoT gateway based on Arduino platform. Arduino is an open-source electronics single board microcomputer based on easy implementable hardware and software. In the literature we could find many examples of using Arduino (mostly used as sensor node) and different most advanced platform such as Raspberry Pi which were used to build the IoT Gateway: [4],[5],[6], [7]. In the literature is presented only one similar IoT gateway implementation based on Arduino. In [3] authors presents the concept of Arduino board based IoT gateway dedicated specially to the medical purposes. This gateway implemented on Arduino Yun is dedicated for monitoring vital parameters of human body using different sensors such as: heart rate sensor, blood pressure, pulse oximetry or body temperature.

III. IoT home gateway concept

IoT Gateway is a single place where a lot of sensors and other components can communicate with applications using standard protocols included in wireless technology like mobile networks or WiFi. Sensing domain elements are connected to one root component which is a point of communication with rest part of devices [1]. IoT home gateway [2] can be defined as an element connecting simple sensors installed in dedicated network often connected wireless e.g. using BLE (Bluetooth Low Energy) technology with home network layer.

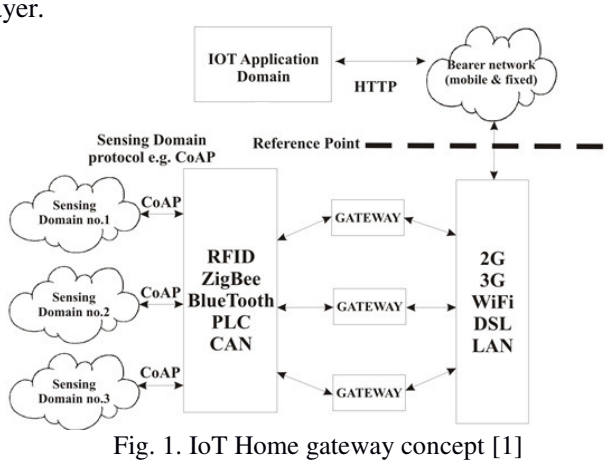

Fig. 1. IoT Home gateway concept [1]

As it was presented on Figure 1. IoT gateway fulfils a role of point between sensors and network domain, where tiny sensors can communicate with other subnetworks. For IoT networks it is recommended to use protocols which packets have low overhead and stateless communication method e.g. Constrained Application Protocol (CoAP). CoAP is an application part protocol to present readings from sensors in unreliable transmission. It uses only UDP datagrams to send information very fast and with low latency. It is great protocol for reading sensor data and controlling actuators to drive motors.

IV. SYSTEM ARCHITECTURE

On Figure 2. high level system architecture was presented. Arduino based on IoT gateway (2) collects an information from different sensors from sensing domain (1). In tested environment: Passive Infra Red sensor, sound sensor, pressure and smoke sensors were used.

Web Application (3) hosted on board presents information from sensors and exposes them for third party systems. In implemented gateway two different Ethernet Modules (4) (Ethernet ENC28j60 and Wiznet550 with tcp offload capability) were used to provide connection to network domain. As IoT gateway system core element three boards: Arduino UnoR3, Mega2560 and Leonardo (2) were tested. As third party application http client (6) e.g. web browser was connected to network domain (5).

Moreover, the IoT Gateway designed architecture provides a connection to web service which presents in browser the information returned by each sensor.

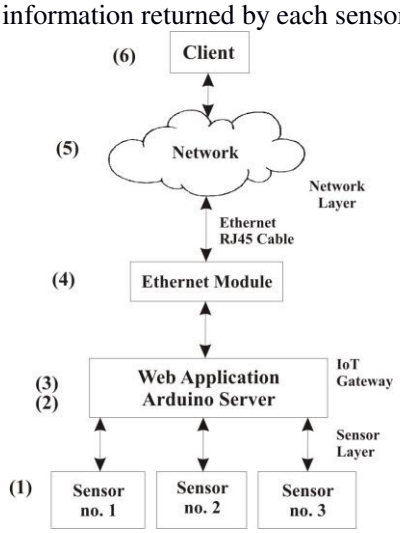

Fig. 2. Iot Gateway System Architecture

However, it should be emphasized that presented architecture is designed to perform IoT Gateway tests according to performance and security aspects. Two main most probably issues are Flash Crowd and (D)DoS (eng. Distributed Denial of Service) attacks. The first one occurs when too many legitimate users want to get access to the service in the same moment. IoT Gateway is vulnerable due to the fact that Arduino has low capacity of RAM and CPU parameters. The second one is a malicious attack using thousands of network machines to block a service.

A) *Arduino environment*

Two web applications which fulfil a crucial role of plugin for sensing domains, have been developed and installed on Arduino Leonardo, Mega2560 and UnoR3 supported by different Ethernet Modules (hardware Wiznet550 and software ENC28j60). Configuration of Ethernet Network Module which is presented on Fig. 3. was provided by ICSP pin with settings and configuration on board side. User can send and read information from sensors by using http client and dedicated web application

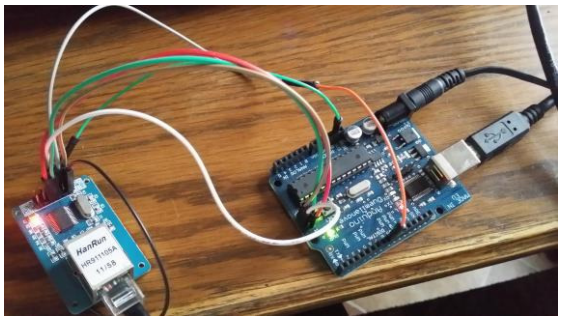

Fig. 3. IoT gateway prototype with ENC28j60 card.

B) *Web Application*

Web application was hosted on Arduino board. It was a standard web server which exposed information from connected sensors. It displayed a single html page with presented a few changing values of sensor readings after refreshing the web page content from web browser.

V. MEASUREMENTS

A) *Test environment*

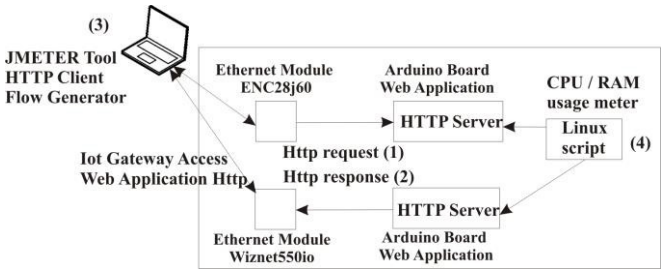

Fig. 4. Load test concept

Fig. 4. presents test environment used for IoT gateway performance tests. Based on Apache JMeter tool (3) http traffic to Arduino Gateway was generated (1). IoT gateway returned web page (2) with information from sensors (with http 200 message). In other cases no response or http 404 message was generated. CPU/RAM meter (4) based on Linux script running on dedicated Laptop was used to measure Arduino device performance.

Moreover, the second part of the research was performed with usage of Hping3 security tool. It gives a lot of possibilities to generate a huge traffic simulating Distributed Denial of Service. TCP SYN Flood and Http Slowloris attacks were used to block an access to a web service. Unfortunately, it could be observed that service is very sensitive to receiving big part of http traffic. It was unresponsive to next requests sent by clients. It had to be restarted to provide access after web logic failure.

B) Load test – error rate

Based on test scenario described in details in point A of this paper load tests for three Arduino boards and two Ethernet cards were performed. Figures 5-10 presents results of load tests (observed packet error rate in network traffic).

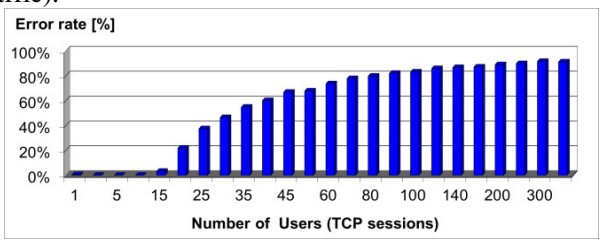

Fig. 5. Error rate (Arduino Leonardo + Wiznet550)

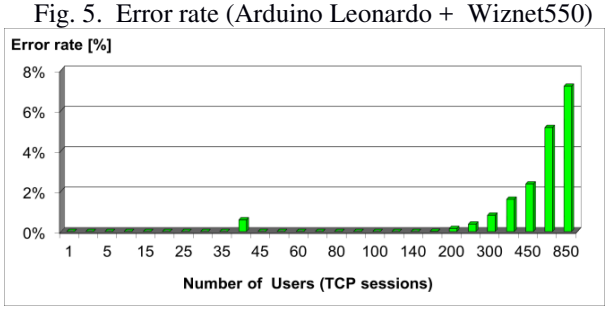

Fig. 6. Error rate (Arduino Leonardo + Enc28j60)

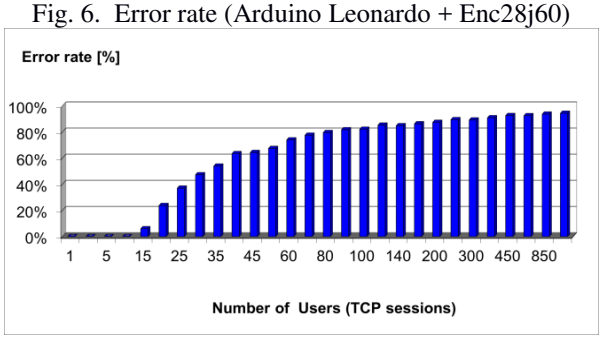

Fig. 7. Load Error rate (Arduino Mega2560 + Wiznet550)

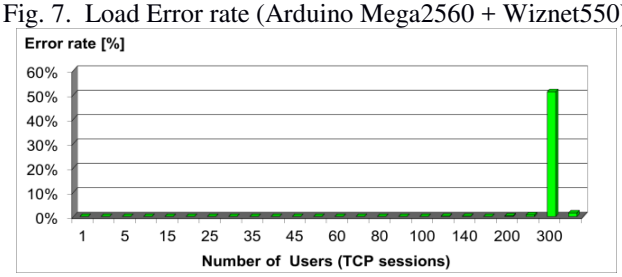

Fig. 8. Error rate (Arduino Mega2560 + Enc28j60)

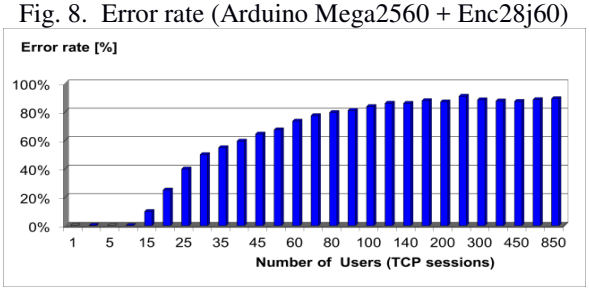

Fig. 9. Error rate (Arduino UnoR3 + Wiznet550)

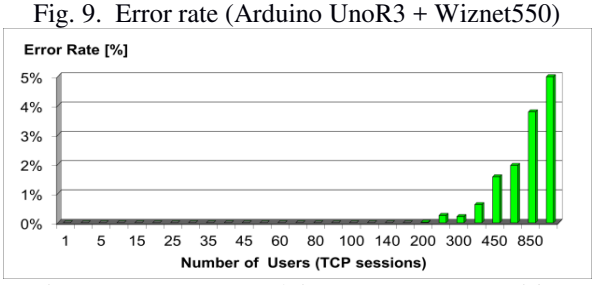

Fig. 10. Error rate (Arduino UnoR3 + Enc28j60)

Moreover, based on the result of load test for Wiznet550 network adapter module maximal number of 15 simultaneous sessions was defined. Large number of sessions results in showing high error rate of receiving packets. The better result was observed for ENC28J60 Ethernet card and for this component the lower error rate about 5-8% for 300-800 TCP sessions was detected.

A) Load test – average response time

Besides the error rate during the load tests average response time was measured.

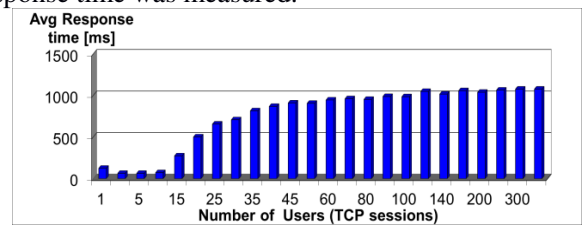

Fig. 11. Avg. response time (Arduino Leonardo+Wiznet550)

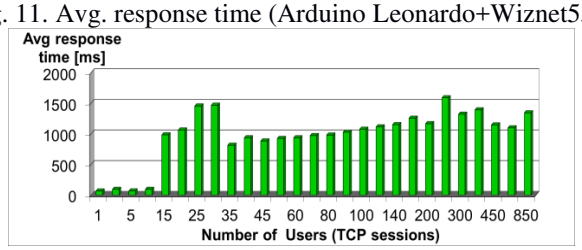

Fig. 12. Avg response time (Arduino Leonardo + Enc28j60)

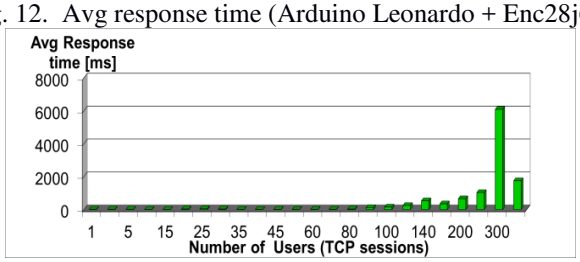

Fig. 13. Avg response time (Arduino Mega2560+Enc28j60)

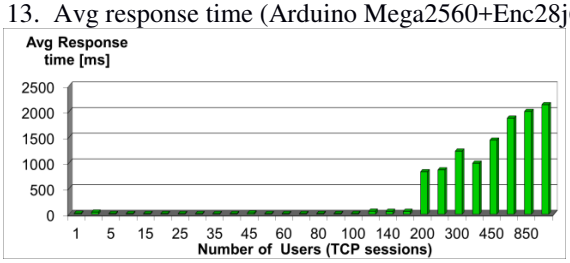

Fig. 14. Avg response time (Arduino UnoR3 + Enc28j60)

Based on requirements it should be emphasized that for the real time communication systems maximum acceptable response time should not exceed 100 ms and this value were reached for 10 simultaneous TCP sessions for Arduino Leonardo with Wiznet550 card (Fig 11). For others Arduino boards and Wiznet550 adapter we can observe similar values. For Enc28j60 network card we can observe better performance (avg response time 94 ms for 10 TCP sessions for Arduino Leonardo, time 125 ms for 140 TCP sessions for Arduino Mega2560 and 56 ms for 160 TCP sessions for UnoR3).

Table 1 and 2 presents observed CPU and RAM usage. It can be observed that percentage usage of CPU for Arduino board is higher about 10% when Enc28j60 Ethernet module was connected to device. It is a result of receiving and parsing packets on core of application web server. When Wiznet550 tcp off load connector is used a

big part of packet processing is handled by this element. It protects presented gateway against change of web server logic into block state.

300	38,733	14,800	39,191	38,900	19,669	-

RAM percentage usage results presented for Arduino boards don't depend on kind of Ethernet module.

Sometimes the usage WIZnet550io module resulted in the error XML Parse Exception. It is a result of blocking a part of data on the same link which is used by legitimate user and by attackers. Service doesn't have to be suspended in case of receiving too many requests to web application. Packet error rate (PER) has always been the biggest value for Ethernet module WIZnet550io. In contrast to Wiznet550io Ethernet ENC28J60 requires a large number of users to return permanent failure. It leads to rejection of the packets due to insufficient capacity of Arduino board resources at very high network traffic.

VI. FUTURE WORK

In the future, the authors of this publication are planning to focus on improving security aspects. The most important is implementation of encryption for data transmission between the IoT gateway and http client [8]. Nowadays a lot of Man in The Middle attacks can be performed successfully because of sending data via plain text. Implementation of SSL protocol and certificate on web server side should prevent against this situation.

Due to the fact that only limited resources are available such as: CPU, memory and number of I/O ports the implementation of similar IoT environment based on more advanced hardware platform should be performed. For example the usage of Intel Galileo should allow to implement some additional features such as Web application or firewall features inside the board because of better hardware capabilities in comparison with Arduino board. The use of Intel Galileo allows to keep compatibility of sensors layer with the platform Arduino and allows to focus on the software development.

VII. SUMMARY

Presented in this paper Arduino boards are offered as a standalone device without network adapter. For load tests Arduino boards were equipped with Wiznet550io module and ENC28j60 network adapter. Better results of performance were observed for ENC28j60 from 10 TCP sessions for Arduino Leonardo to 160 TCP sessions for Arduino UnoR3.

As a device with very limited hardware Arduino can host services which can't be stable if too many users want to get access to the resources in the same time. Arduino board can be used as the IoT gateway only in very small IoT environment. ENC28j60 Ethernet module could better cope with Http request avalanche when in the same time Wiznet550io module was really poor to protect IoT gateway. However, it should be emphasized that there is a need to build new solution for Iot gateway protection.

Prototype of IoT Gateway was made as part of the Open Middleware 2.0 Community by Orange Labs program [9].

***Abstract*—Transient queue-size distribution in a finite-buffer system with Poisson arrivals and generally distributed processing times is investigated. In the evolution of the system the server needs randomly distributed setup times preceding the service initialization in each new busy period. Applying the paradigm of embedded Markov chain and the formula of total probability, a Volterra-type system of integral equations for the transient queue-size distribution, conditioned by the number of packets being accumulated in the buffer before the opening of the system, is built. The solution of the corresponding system written for Laplace transforms is obtained algebraically in the compact explicit form. Numerical examples are attached as well.**

I. Introduction

FINITE-BUFFER queues are widely used in modelling real-life processing systems, in which the phenomena like buffering of waiting packets (jobs, customers, calls, etc.), delays of different nature, and packet losses caused by buffer overflows or temporary suspensions of the service process occur. In particular, e.g. the incoming/outcoming stream of packets in a node of computer network (like, e.g. IP router in the Internet) can be efficiently modelled by using one of finite queueing systems. One of the most important challenges of wireless communication (e.g., based on Wi-Fi IEEE.802.11 standard or wireless sensor networks), is the problem of energy saving. In practice, a mechanism for temporary switching off the radio transmitting/receiving, e.g. at a time at which the stream of packets directed to this node becomes less intensive or when the accumulating buffer is empty, is being implemented. After such a time of unavailability, to start the processing normally, a node needs some period of time (called a setup time, usually random) to achieve full readiness to work. During the setup time the service process is blocked and the arriving packets accumulate in the buffer queue. Such a mechanism can be observed, e.g. in manufacturing systems or in the GSM standard transmission in which the node is being switched on just before sending the identification frame by a BS (=Base Station).

In [10] a steady-state threshold strategy for jobs behavior in a model with setup times is obtained. One can find the study of a Markovian system with server setups preceding the first processing in each busy period in [6]. Different results on queueing models with setup times applied in the analysis of WSNs' operation are derived, e.g. in [11] and [12]. In [12] the model of a sleep/wakeup protocol in the IEEE 802.15.4 can be found (see also [7], [9] and [13] for some other results concerning the energy saving problem in WSNs). The IMS session re-setup delay in WiMAX/LTE heterogeneous networks is modelled by an appropriate queueing system in [1]. The $M/G/1$-type queue with vacation policy and server setup times is used in [8] for modelling the BS sleeping mode in cellular networks. In [2] a model of data center with servers leaving their idle periods "via" setup times is investigated.

The non-stationary study of the queue-size distribution in the $M/G/1$-type queueing system with random batch arrivals, N-policy and server setup times can be found in [3] (see also [4], where departure process is investigated).

In the paper we investigate the finite-buffer $M/G/1$-type queueing system in which the first service beginning each new busy period is preceded by a generally-distributed setup time, during which the processing is still blocked and the server acquires full readiness for the service process. Applying the approach based on the idea of embedded Markov chain and the total probability law, a system of integral equations for the transient queue-size distribution, conditioned by the initial buffer state, is built. The solution of the corresponding system written for Laplace transforms is obtained by using the linear algebraic approach and given in a closed form, utilizing a certain functional sequence defined recursively.

II. Model Description and Auxiliary Results

In the article we deal with a single-server finite-buffer queueing model, in which packets occur according to a Poisson process with intensity λ and are being processed individually with a general-type CDF (=cumulative distribution function) $F(\cdot)$ of the service time, according to the FIFO discipline. The total number of packets present in the system simultaneously is bounded by a non-random value K, i.e. we have $K-1$ places in the buffer queue and one place "in processing". As it is usually assumed, packets arriving during the buffer overflow period, i.e. when the server is busy with processing and the buffer is saturated, are being lost. In general, it is allowed for

978-83-60810-90-3/$25.00

the buffer to contain a number of packets being waiting before the opening of the system at time $t = 0$. Each busy period, which starts together with the first arrival after the idle time, is preceded by a random setup time with a CDF $G(\cdot)$ of a general type. The setup time is a period during which the processing is blocked and the server "acquires" full readiness for processing. It is assumed that the system being empty before the start also initializes a setup time at the first arrival epoch. We assume, moreover, that all interarrival, processing and setup times in the evolution of the system are independent.

Let us denote by $X(t)$ the number of packets present in the system at time t, including a packet being processed at this time (if any). Define the transient distribution function of $X(t)$, conditioned by the initial level of buffer saturation, in the following way:

$$Q_n(t,m) \stackrel{def}{=} \mathbf{P}\{X(t) = m \,|\, X(0) = n\}dt, \tag{1}$$

where $t > 0$, $0 \le n \le K$ and $m \ge 0$. We are interested in finding the closed-form representation for the LT (=Laplace transform) of $Q_n(t,m)$, i.e. for the functional

$$\widetilde{q}_n(s,m) \stackrel{def}{=} \int_0^\infty e^{-st} Q_n(t,m)dt, \quad \mathrm{Re}(s) > 0. \tag{2}$$

In the analytical approach we use the following result from linear algebra which can be found in [5]:

Lemma 1. *Let (α_k), $k \ge 0$, and (ϕ_k), $k \ge 1$, with the assumption $\alpha_0 \ne 0$, be two given number sequences. Each solution of the following system of linear equations:*

$$\sum_{k=-1}^{n} \alpha_{k+1} x_{n-k} - x_n = \phi_n, \quad n \ge 0, \tag{3}$$

can be written in the form

$$x_n = CR_{n+1} + \sum_{k=0}^{n} R_{n-k}\phi_k, \quad n \ge 0, \tag{4}$$

where C is a constant independent on n, and (R_k) is the sequence (which is called in [5] a potential) associated with the sequence (α_k) as in the following relationships:

$$R_0 = 0, \quad R_1 = \alpha_0^{-1},$$
$$R_{k+1} = \alpha_0^{-1}\big(R_k - \sum_{i=0}^{k} \alpha_{i+1} R_{k-i}\big), \quad k \ge 1. \tag{5}$$

We end this section with stating some additional notations. We use the abbreviation $\overline{G}(x) \stackrel{def}{=} 1 - G(x)$ and the nomenclature $I\{\mathbb{A}\}$ for the indicator of the random event $\mathbb{A}$. Besides, let us denote by $f(\cdot)$ and $g(\cdot)$ the Laplace-Stieltjes transforms of CDFs $F(\cdot)$ and $G(\cdot)$, respecively.

III. System of Equations for Conditional Queue-Size Distribution

Let us start with the case of the system being empty at time $t = 0$. Thus, the evolution of the system begins with an idle period during which the service station "waits" for packets. Simultaneously with the arrival occurrence a setup time begins. Let us note that we can distinguish three mutually excluding situations (random events):

(1) the first packet arrives before time t and the setup time also ends before t (we denote this event by $A_1(t)$);
(2) the first packet enters before t but the setup time completes after t ($A_2(t)$);
(3) the first packet arrives after time t ($A_3(t)$).

Introduce the following notation:

$$Q_0^{(i)}(t,m) = \mathbf{P}\{\big(X(t) = m\big) \cap A_i(t) \,|\, X(0) = 0\}, \tag{6}$$

where $t > 0$, $m \ge 0$ and $i = 1, 2, 3$. It is obvious that the formula of total probability leads to the following relationship:

$$Q_0(t,m) = \mathbf{P}\{X(t) = m \,|\, X(0) = 0\} = \sum_{i=1}^{3} Q_0^{(i)}(t,m) \tag{7}$$

and, moreover,

$$\widetilde{q}_0(s,z) = \sum_{i=1}^{3} \int_0^\infty e^{-st} Q_0^{(i)}(t,m)dt. \tag{8}$$

Considering the random event $A_1(t)$, we get the following equation:

$$Q_0^{(1)}(t,m) = \int_{x=0}^{t} \lambda e^{-\lambda x}dx$$
$$\times \int_{y=0}^{t-x} \Bigg[\sum_{i=0}^{K-2} \frac{(\lambda y)^i}{i!} e^{-\lambda y} Q_{i+1}(t-x-y,m)$$
$$+ Q_K(t-x-y,m) \sum_{i=K-1}^{\infty} \frac{(\lambda y)^i}{i!} e^{-\lambda y}\Bigg] dG(y). \tag{9}$$

Let us note that the first summand on the right side of (9) corresponds to the situation in which there is at least one free place in the buffer at the completion epoch of the setup time. The second summand presents the case in that the buffer becomes saturated during the setup time.

Similarly, for $A_2(t)$, we obtain

$$Q_0^{(2)}(t,m) = \int_0^t \lambda e^{-\lambda x}\overline{G}(t-x)$$
$$\times \Bigg\{ I\{1 \le m \le K-1\} \frac{\big[\lambda(t-x)\big]^{m-1}}{(m-1)!} e^{-\lambda(t-x)}$$
$$+ I\{m = K\} \sum_{i=K-1}^{\infty} \frac{\big[\lambda(t-x)\big]^i}{i!} e^{-\lambda(t-x)}\Bigg\} dx. \tag{10}$$

Let us comment (10) briefly. The first summand under the integral on the right side of (10) relates to the case when the number of packets, measured at time t, is less than the maximal value K. The second one concerns the situation $m = K$, so during the time $(t-x)$ (the time between the first arrival epoch and t) at least $K-1$ packets must occur. However, $K-1$ packets only are physically buffered. The remaining ones will be lost due to the buffer saturation.

Finally we have, obviously,

$$Q_0^{(3)}(t,m) = I\{m = 0\}e^{-\lambda t}. \tag{11}$$

From (9)–(11), referring to (7), we get

$$Q_0(t,m) = \int_{x=0}^{t} \lambda e^{-\lambda x} dx \times \int_{y=0}^{t-x} \Bigg[\sum_{i=0}^{K-2} \frac{(\lambda y)^i}{i!} e^{-\lambda y} Q_{i+1}(t-x-y,m) + Q_K(t-x-y,m) \sum_{i=K-1}^{\infty} \frac{(\lambda y)^i}{i!} e^{-\lambda y} \Bigg] dG(y) + \int_0^t \lambda e^{-\lambda x} \overline{G}(t-x) \Bigg\{ I\{1 \le m \le K-1\} \times \frac{\big[\lambda(t-x)\big]^{m-1}}{(m-1)!} e^{-\lambda(t-x)} + I\{m=K\} \sum_{i=K-1}^{\infty} \frac{\big[\lambda(t-x)\big]^i}{i!} \times e^{-\lambda(t-x)} \Bigg\} dx + I\{m=0\} e^{-\lambda t}. \tag{12}$$

Investigate now the case of the system being non-empty at the start moment (i.e. $1 \le n \le K$). Due to the fact that successive departure epochs are Markov (renewal) moments during the operation of the $M/G/1$-type system, then, by virtue of the continuous version of the total probability law, applied with respect to the first departure moment after $t = 0$, we obtain the following system of integral equations for $1 \le n \le K$:

$$Q_n(t,m) = \int_0^t \Bigg[\sum_{i=0}^{K-n-1} \frac{(\lambda x)^i}{i!} e^{-\lambda x} Q_{n+i-1}(t-x,m) + Q_{K-1}(t-x,m) \sum_{i=K-n}^{\infty} \frac{(\lambda x)^i}{i!} e^{-\lambda x} \Bigg] dF(x) + \overline{F}(t) \Bigg[I\{n \le m \le K-1\} \frac{(\lambda t)^{m-n}}{(m-n)!} e^{-\lambda t} + I\{m=K\} \sum_{i=K-n}^{\infty} \frac{(\lambda t)^i}{i!} e^{-\lambda t} \Bigg], \tag{13}$$

It is easy to note that the first summand under the integral on the right side of (13) describes the case in which the buffer does not become saturated before the first departure time $0 < x < t$, while the second one relates to the opposite situation. In the last summand the first service completes after t.

Observe that the following identity is true (compare (9)):

$$\int_{t=0}^{\infty} e^{-st} dt \int_{x=0}^{t} \lambda e^{-\lambda x} dx \int_{y=0}^{t-x} \frac{(\lambda y)^i}{i!} e^{-\lambda y} \times Q_j(t-x-y,m) dG(y) = a_i(s) \widetilde{q}_j(s,m), \tag{14}$$

where

$$a_i(s) \stackrel{def}{=} \frac{\lambda}{\lambda+s} \int_0^{\infty} \frac{(\lambda y)^i}{i!} e^{-(\lambda+s)y} dG(y). \tag{15}$$

Similarly, defining (see (10))

$$\overline{a}_i(s) \stackrel{def}{=} \frac{\lambda}{\lambda+s} \int_0^{\infty} \frac{(\lambda u)^i}{i!} e^{-(\lambda+s)u} \overline{G}(u) du, \tag{16}$$

and taking into consideration (14)–(15), we rewrite the equation (12) in the following form:

$$\widetilde{q}_0(s,m) = \sum_{i=0}^{K-2} a_i(s) \widetilde{q}_{i+1}(s,m) + \widetilde{q}_K(s,m) \sum_{i=K-1}^{\infty} a_i(s) + \beta(s,m), \tag{17}$$

where

$$\beta(s,m) \stackrel{def}{=} I\{1 \le m \le K-1\} \overline{a}_{m-1}(s) + I\{m=K\} \sum_{i=K-1}^{\infty} \overline{a}_i(s) + I\{m=0\} \frac{1}{\lambda+s}. \tag{18}$$

Similarly, denoting

$$\alpha_i(s) \stackrel{def}{=} \int_0^{\infty} e^{-(\lambda+s)x} \frac{(\lambda x)^i}{i!} dF(x); \tag{19}$$

$$\gamma_n(s,m) \stackrel{def}{=} \int_0^{\infty} e^{-(\lambda+s)t} \overline{F}(t) \Big[I\{n \le m \le K-1\} \times \frac{(\lambda t)^{m-n}}{(m-n)!} + I\{m=K\} \sum_{i=K-n}^{\infty} \frac{(\lambda t)^i}{i!} \Big] dt, \tag{20}$$

where $\mathrm{Re}(s) > 0$, we transform (13) as follows:

$$\widetilde{q}_n(s,m) = \sum_{i=0}^{K-n-1} \alpha_i(s) \widetilde{q}_{n+i-1}(s,m) + \widetilde{q}_{K-1}(s,m) \sum_{i=K-n}^{\infty} \alpha_i(s) + \gamma_n(s,m). \tag{21}$$

Let us apply to (17) and (21) the following substitution:

$$\widetilde{u}_n(s,m) \stackrel{def}{=} \widetilde{q}_{K-n}(s,m), \quad 0 \le n \le K. \tag{22}$$

After this operation, we get from (21) the following system:

$$\sum_{i=-1}^{n} \alpha_{i+1}(s) \widetilde{u}_{n-i}(s,m) - \widetilde{u}_n(s,m) = \phi_n(s,m), \tag{23}$$

where $0 \le n \le K-1$, and

$$\phi_n(s,m) \stackrel{def}{=} \alpha_{n+1}(s) \widetilde{u}_0(s,m) - \widetilde{u}_1(s,m) \sum_{i=n+1}^{\infty} \alpha_i(s) - \gamma_{K-n}(s,m). \tag{24}$$

In the same manner, inserting (22) into (17), we obtain

$$\widetilde{u}_K(s,m) = \sum_{i=0}^{K-2} a_i(s) \widetilde{u}_{K-i-1}(s,m) + \widetilde{u}_0(s,m) \sum_{i=K-1}^{\infty} a_i(s) + \beta(s,m). \tag{25}$$

IV. Main Results for Transforms

Let us note that (23) has the same form as (3), but with coefficients $\alpha_i(\cdot)$ and $\phi_i(\cdot,\cdot)$, $i \geq 0$, depending on s and (s,m), respectively. So, there is possible to solve (23) by utilizing the result (4). Moreover, due to the fact that the number of equations in (23) is finite comparing to (3), the representation for $C = C(s,m)$ can be found explicitly, considering the last equation (25) as a special-type boundary condition. According to (4), we obtain for $n \geq 0$

$$\widetilde{u}_n(s,m) = C(s,m)R_{n+1}(s) + \sum_{i=0}^{n} R_{n-i}(s)\phi_i(s,m), \quad (26)$$

where the sequence $\big(R_k(s)\big)$ is defined in (5) (with $\alpha_k(s)$ instead of α_k). Substituting $n=0$ into (26), we get

$$\widetilde{u}_0(s,m) = C(s,m)R_1(s). \quad (27)$$

Taking $n=1$ in (26) and referring to (24) and (27), we obtain

$$\widetilde{u}_1(s,m) = C(s,m)R_2(s) + R_1(s)\Big(\alpha_1(s)R_1(s)C(s,m) - \widetilde{u}_1(s,m)\sum_{i=1}^{\infty}\alpha_i(s) - \gamma_K(s,m)\Big) \quad (28)$$

that leads to

$$\widetilde{u}_1(s,m) = \eta(s)\Big[C(s,m)\big(R_2(s) + \alpha_1(s)R_1^2(s)\big) - R_1(s)\gamma_K(s,m)\Big], \quad (29)$$

where $\eta(s) \stackrel{def}{=} \frac{f(\lambda+s)}{f(s)}$. Since using (27) and (29) the functionals $\phi_i(s,m)$, $i \geq 0$, can be found, if only the formula for $C(s,m)$ is known, the key problem is in finding the explicit representation for $C(s,m)$. By using the representations (24) and (26), we can present (25) in the following form:

$$\widetilde{u}_K(s,m) = \Delta_1(s)C(s,m) + \kappa_1(s,m), \quad (30)$$

where we denote

$$\Delta_1(s) \stackrel{def}{=} \sum_{i=1}^{K-1} a_{K-i-1}(s)\Big[R_{i+1}(s) + \sum_{j=0}^{i} R_{i-j}(s) \times \Big(R_1(s)\alpha_{j+1}(s) - \eta(s)\big(R_2(s) + \alpha_1(s)R_1^2(s)\big)\sum_{r=j+1}^{\infty}\alpha_r(s)\Big] + R_1(s)\sum_{i=K-1}^{\infty} a_i(s) \quad (31)$$

and

$$\kappa_1(s,m) \stackrel{def}{=} \sum_{i=1}^{K-1} a_{K-i-1}\sum_{j=0}^{i} R_{i-j}(s)\Big[R_1(s)\gamma_K(s,m)\eta(s) \sum_{r=j+1}^{\infty}\alpha_r(s) - \gamma_{K-j}(s,m)\Big] + \beta(s,m). \quad (32)$$

Similarly, let us take $n=K$ in (26) and apply the formulae (24), (27) and (29). In consequence we obtain

$$\widetilde{u}_K(s,m) = \Delta_2(s)C(s,m) + \kappa_2(s,m), \quad (33)$$

where

$$\Delta_2(s) \stackrel{def}{=} R_{K+1}(s) + \sum_{i=0}^{K} R_{K-i}(s)\Big[\alpha_{i+1}(s)R_1(s) - \eta(s)\big(R_2(s) + \alpha_1(s)R_1^2(s)\big)\sum_{j=i+1}^{\infty}\alpha_j(s)\Big] \quad (34)$$

and

$$\kappa_2(s,m) \stackrel{def}{=} \sum_{i=0}^{K} R_{K-i}(s)\Big(\eta(s)R_1(s)\gamma_K(s,m) \times \sum_{j=i+1}^{\infty}\alpha_j(s) - \gamma_{K-i}(s,m)\Big). \quad (35)$$

Comparing the right sides of (30) and (33), we express $C(s,m)$ as follows:

$$C(s,m) = \frac{\kappa_2(s,m) - \kappa_1(s,m)}{\Delta_1(s) - \Delta_2(s)}. \quad (36)$$

Now the formulae (24), (26), (27), (29) and (36) lead to the following main theorem:

Theorem 1. *The representation for the LT of the conditional transient queue-size distribution in the $M/G/1/K$-type model with generally distributed setup times is following:*

$$\widetilde{q}_n(s,m) = \int_0^{\infty} e^{-st}\mathbf{P}\{X(t) = m \,|\, X(0) = n\}dt = \frac{\kappa_2(s,m) - \kappa_1(s,m)}{\Delta_1(s) - \Delta_2(s)}\Bigg\{R_{K-n+1}(s) + \sum_{i=0}^{K-n} R_{K-n-i}(s) \times \Big[\alpha_{i+1}(s)R_1(s) - \eta(s)\Big(R_2(s) + \alpha_1(s)R_1^2(s)\Big) \times \sum_{j=i+1}^{\infty}\alpha_j(s)\Big]\Bigg\} + \sum_{i=0}^{K-n} R_{K-n-i}(s)\Big(\eta(s)R_1(s)\gamma_K(s,m) \times \sum_{j=i+1}^{\infty}\alpha_j(s) - \gamma_{K-i}(s,m)\Big), \quad (37)$$

where the formulae for $\alpha_i(s)$, $\gamma_i(s,m)$, $R_i(s)$, $\Delta_1(s)$, $\kappa_1(s,m)$, $\Delta_2(s)$ and $\kappa_2(s,m)$ are given in (19), (20), (5), (31), (32), (34) and (35), respectively.

Remark IV.1. *Let us note that from the formula (37) the stationary queue-size distribution π_m, $m = 0,...,K$, can be found by using the Tauberian theorem, namely for any $n \in \{0,...,K\}$*

$$\pi_m = \lim_{t\to\infty}\mathbf{P}\{X(t) = m\} = \lim_{s\downarrow 0} s\cdot\widetilde{q}_n(s,m). \quad (38)$$

V. Numerical examples

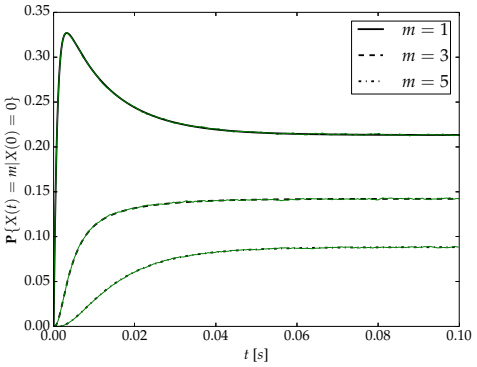
Let us take into consideration a node of the wireless network with buffer of size 6 packets, with the arrival stream of packets of average sizes 200 B, entering with intensity 600 Kb/s. Adjusting the Poisson arrival process, we have the rate $\lambda = 375$ packets per second. Assume that packets are being transmitted with speed 720 Kb/s, where the processing times have 2-Erlang distribution, that gives the intensity 450 packets

per second and the value $\mu = 900$ of the parameter of this distribution. Hence, the load of the node is at the high level ($\rho = 0.833$). Moreover, we consider the mechanism of exponentially distributed setup with three different means: 0 (without setup - "pure" system), 5 and 50 [ms].

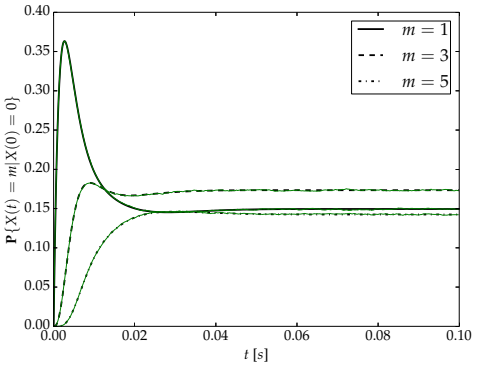
The evolution of the transient probabilities $\mathbf{P}\{X(t) = m \,|\, X(0) = 0\}$ for $m = 1, 3, 5$ are presented in Fig. 1. Evidently, due to different durations of setup times, the transient evolutions and stationary values of the proper probabilities are different in cases (a)–(c). As one can observe, a short setup time with mean 5 [ms] allows the system to stabilize faster than in the absence of such a period (compare cases (a) and (b)). From the other side, if the setup time is relatively long in comparison to the arrival/service rates (case (c)), the time of stabilization elongates in comparison to the system without setup time. It is worth mentioning that all analytical results are confirmed by process-based discrete-event simulations (DES).

VI. Summary

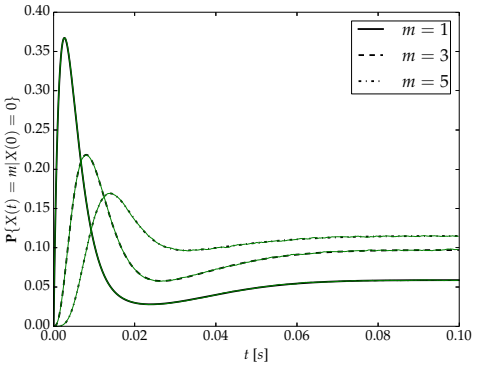
In the article a finite-buffer queueing model with Poisson arrivals and generally distributed processing times and server setup times is considered. The closed-form representation for the LT of the transient queue-size distribution conditioned by the initial buffer state is found, from which the stationary distribution can be obtained directly by using the Tauberian theorem. Numerical examples are attached as well.



(a) no setup time



(b) setup time mean 5 ms



(c) setup time mean 50 ms

Fig. 1. Subfigures (a), (b) i (c) present the probabilities $\mathbf{P}\{X(t) = m|X(0) = 0\}$ for $m = 1$ (solid line), $m = 3$ (dashed line) and $m = 5$ (dot dashed line), for the case of no setup time (subfigure (a)), a setup time with mean 5 [ms] (subfigure (b)) and with mean 50 [ms] (subfigure (c)). Bold black lines and thin green lines correspond with analytical and DES results, respectively

***Abstract*— Authenticating users connecting to online services, social networks or m-banking became an indispensable element of our everyday life. Reliable authentication is a foundation of security of Internet services but, on the other hand, also a source of users' frustration due to possible account blocking in case of three fails. In this paper we propose a model of authentication service management which helps in keeping a balance between the authentication security level and positive users' perception of this procedure. The proposed procedure allows a user more than three attempts of authentication by switching after two failures to a more secure authentication protocol keeping a balance between QoP and QoE measures. Finally, the procedure determines an optimal path of authentication using a decision tree algorithm.**

***Index Terms*— authentication, Quality of Experience, Quality of Protection.**

I. INTRODUCTION

Diversity of Internet services at the present time grows faster and faster. In particular, the variety of manners in which the services are provided, from a wired environment (e.g., LAN) to a wireless environment (e.g. WiFi, mobile environment), is observed. Many users become more and more demanding about services' usability. Thus, any services, especially newly designed, should be developed taking into account users' satisfaction factor.

One of the main issues in all Internet services is security protection. Nowadays, there are few user- friendly and at the same time secure services. It is well known that for most services the high level of protection makes their usability is declined. So, it is important to find a balance between security and usability of a service. Of course, that idea depends on kind of a protection mechanism which is considered. Examples of such security mechanisms are authentication solutions. The authentication is an act of reliable entity identification. Within this process two problems can be considered: a choice of the specific authentication solution and its influence on user's behavior. The choice of the proper identification mechanism isnot a simple problem, because many factors can have a significant impact on it. Even if such a mechanism is selected, in most cases it is not considered how a person feels using it. Therefore, an appropriate authentication solution should provide both an adequate security level and sufficient users' satisfaction.

In this paper we propose a service model which can be used to proper management of the authentication mechanisms based on users' satisfaction.

The rest of the paper is organized as follows: Section 2 presents a connection between QoP and QoE measures characterizing Internet services. Section 3 briefly discuses an impact of security context and contextual data on security management while Section 4 presents basic known results on contextual security and user-friendly authentication mechanisms. .Section 5 contains main theoretical result of the paper which is an authentication management model oriented on user's experience. Finally, Section 6 presents results of a simulation which confirms correctness of a created model and Section 7 concludes the paper and outlines the future work.

II. RELATION BETWEEN QOS, QOE AND QOP

In Internet services, to measure Quality of Service (QoS) [1] many parameters like jitter, network latency, throughput, etc. are used. Based on their value a service and a network parameters should be correctly modify to ensure the best quality. However, not always changing a QoS parameter is enough to provide a good quality service. Sometimes to provide high quality of a service not all parameters should have the best values. In most cases it is expensive to set the best values of QoS parameters. Thus, investigations concerning users' experience were conducted. As a result of the research a Quality of Experience (QoE) factor was designed [2, 3]. This implies that QoS parameters should be set based on a users' QoE value [4, 5].

In the area of security the Quality of Protection (QoP) measure is a counterpart of QoS [6, 7]. The term defines a minimum protection level that should be provided to a secure Internet service. For example, it is obvious that different level of protection ensures an authentication mechanism which used a hash function SHA-1 than those with a hash function SHA-2/256 [8]. So, it is natural to measure a level of protection which is required. But, as it is for QoS, not always a security mechanism applied meets users' requirements. Sometimes the mechanism is too

978-83-60810-90-3/$25.00

difficult to use (e.g., a multi-factor authentication can be a barrier for elder people), sometimes it is too annoying (e.g., a continuous request for fingerprinting due to a device read/scan problems).

To summarize above considerations, the relationship between QoS, QoP and QoE can be presented in a form of the graph (see Fig 1). The QoS parameter has an impact on security services (a security level) and at the same time on users' satisfaction. Once again, a proper security mechanism should be provided with respect to a user's expectations.

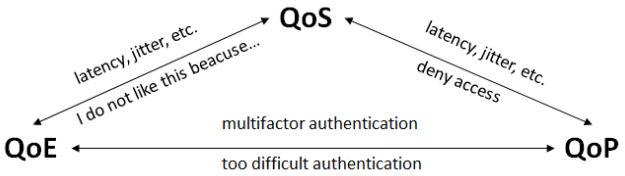

Figure 1. Relationship between QoS, QoP and QoE

An open problem is to answer a question which mechanism should be provided in particular conditions. For this issue the solution can be the idea of context-based systems in which a state of the system is dynamically changed with respect of environmental conditions.

III. Security context

The term "context" concerns all data which can be used to adapt state of a system to particular conditions. They come from many sources [9].There are many descriptions about context. In [10] Schilit et. al. show context-aware systems as systems able to adapt to dynamically and continuously changing GPS coordinates , type of devices, people relations and time. The author describes three features of context data: where you are?, with whom you are?, what is your neighborhood? Furthermore, he emphases that contextual information is not only a localization, but also other useful information. Recently this definition had been used by many authors. In general they claim that contextual data are data which are answers on a question that starts with: Who?, Where?, What?, When?. Beside context-aware system, description of the context-aware application can be found in [11]. More universal definition was proposed by Wrona and Gomez [12]. According to them the contextual data are information which can describe a state of an entity. This definition is better than the previous one because it includes all data which can be contextual information.

Some contextual data have common features. For example, day, part of a year and day of birth apply to determine the time while GPS coordinates, the UK and the Earth describe a localization. For this reason it is naturally to divide contextual data into categories. Two context categories were are already defined: time and position. Beside these, many more exist like: access device, operating systems, environment, neighborhood, etc.

All contextual information can be divided in three classification groups: storage of context, retrieval of context and its dynamism. First group includes all aspects of store data (in database, in Hidden Markov Model, in file, etc.). Second group describe different aspects of data retrieval like its history, presentation, the way in which was gathered, etc. The last third group consists data connected with a specific environment- some environment could be dynamically changed over time and some could be more static- every information changed very rarely or not changed at all.

As it was shown in the literature (see e.g., [13, 14, 15]) contextual information can be used to improve Internet systems work. Using contextual data, QoP and QoE measures combination cause that a model of providing the best authentication mechanism adequate for specific requirements can be created.

IV. User authentication and Quality of Experience: related works

As mentioned earlier, not many works apply to problem of providing an appropriate authentication mechanism based on user's context and respecting the user's QoE. Security solutions which include contextual data aspects are more common. Several approaches for the context security have been described in [16, 17, 18, 19]. The authors in their papers present an idea how contextual information can be used in an authentication mechanism, but they do not consider user's Quality of Experience. Another example of using contextual data in security is access control approach. Based on sensitivity or importance of data (e.g. patient health history, personal data, etc.), proper access to them should be provided to avoid information leakage. This idea is shown in [20, 21, 22, 23]. However, the aspects of security should be considered as well as user's satisfaction. In most cases it is difficult to obtain an answer to the question which security features have impact on user's experience. In [24] the authors present the results of a survey of over 300 users to determine their understanding of the security feature in selected applications. The experiment includes some areas of difficulty with many security features showing usability challenges for users. Similar considerations includes the paper [25]. Based on conclusions from [24, 25] was created a few papers which apply to experiments of balancing QoE and QoP. In [26, 27] is described provisioning of QoE and QoP in Mobile Networks and Wireless Networks. Authors focus on ensuring an appropriate level of QoE and QoE of cryptographic algorithms used in a mobile environment. The paper [28] shows long – term QoP in mobile networks with QoE aspects, too. More experimental results can be found in [29]. The paper contains research about impact of an authentications mechanism on users perceive logins. Computed exponential QoE-QoP relationship can be served to assessing used identification mechanism in the domain of user acceptability. The extension of these research and more detailed description can be found in [30, 31]. Based on [29] was created an experiment shown in [32]. The author tries to find QoE – QoP dependence in popular SaaS cloud products. A similar approach, but with mobile devices, is shown in [33], where security barriers survey was described.

Other, more holistic idea of connection security and user experience can be found in [34]. The paper shows a framework of

criteria for the evaluation of authentication schemes in IMS, focus on security, user-friendliness and simplicity. Very interesting description contains [35] where authors explain how contextual information can be used to provide secure and user oriented mechanisms. The paper [36] is an example of using the framework from the paper [35] for constructing an adaptable authentication protocol.

V. Authentication Model Using User's Context and QoE

A described solution is an example of a model which helps in authentication mechanisms management. The model was created to provide a correct authentication mechanism based on user's context (e.g. position, time, neighborhood, etc.) and on the knowledge about user's experience in using a particular authentication service. One of the most important elements of the model is a table which contains a list of authentication mechanisms (A_1,A_2,…,A_n) and their QoP (QoP_1,QoP_2,…,QoP_n) and QoE (QoE_1,QoE_2,…,QoE_n) measures (see TABLE I). The values of such parameters (measures) are usually based on experts' knowledge and data obtained from experiments. The table is used to select the best authentication mechanism from many possible choices.

TABLE I
ASSIGNMENT OF AUTHENTICATION MECHANISMS AND THEIR QOP AND QOE VALUES

LP	Kind of mechanism	QoP	QoE
1	A_1	QoP_1	QoE_1
2	A_2	QoP_2	QoE_2
3	A_3	QoP_3	QoE_3
…	…	…	…
n	A_n	QoP_n	QoE_n

A user who wants to use a service at first must authenticate himself. Based on current user's context the required minimal value of Quality of Protection level is calculated according to formula (1):

$$f(c_1, c_2, c_3, \ldots, c_m) = QoP_c \tag{1}$$

where c_1,c_2,…,c_m are context factors.

Having the boundary QoP_c value it is possible to select some authentication mechanisms for which the QoP value is greater than or equal to QoP_c. The best authentication mechanism can be chosen using a decision tree structure (see Fig. 2). The tree is spanned on j states. Each state represents a situation in which a user tries to authenticate himself with a particular authentication protocol. In every state the user has two trials to identify himself with a selected protocol (of course, twice means that first trial was failed and now is a second trial). In the third trial, when the first and second trials were incorrect, he or she can still use the same protocol or, if it is possible, change an authentication protocol to some more convenient in a specific situation. If he or she decides to change the protocol, the new one is with a higher value of OoP. The required higher value of QoP implicates less probability of a successful attack in three trials of the new protocol than in a case of a single try in the previous one. A user can choose a new authentication protocol option until the cumulative value of QoP in a current state does not achieve the boundary value QoP_c.

The main goal of created model is to choose the best path of the tree. The best path means a scenario where a user uses the last authentication protocol in the state j and he finally authenticates correctly with the highest probability. Moreover, the path should contain the authentication protocols which are relatively simple, secure and at the same time with the high value of the QoE measure. A choice of this path could be made by calculations based on a decision tree algorithm. In the next paragraph we will describe the probability of a successful authentication in every branch of the decision tree.

As it shown in Figure2, in an authentication decision tree there are two types of states: state 1 without changing an authentication protocol (but with three possible trials of the same protocol) and the states from 2 to n where a user changes this protocol (after two trials of the same protocol he or she tries with a new one in the third trial). Furthermore, every trial of an authentication protocol can be successful; the event R_{ij} means that in state i (i=2…n), in its step j (j=1,2,3) an authentication is right or successful , the event F_{ij} means that in state i, in its step j the authentication fails. Moreover, the event B_i was defined as correct authentication in state i after using all options of a path. So, for state 1 the probability of correct authentication according to (2) is equal:

$$\begin{aligned} P(B_1) &= P(R_{11}) + P(R_{12} \mid F_{11})P(F_{11}) + \\ &P(R_{13} \mid F_{11} \cap F_{12})P(F_{11} \cap F_{12}) \end{aligned} \tag{2}$$

The state 2 and next states are different from state 1, thus, for state 2 the probability of correct authentication according to (3) is equal:

$$\begin{aligned} P(B_2) &= P(R_{21} \mid F_{11} \cap F_{12})P(F_{11} \cap F_{12}) + \\ &P(R_{22} \mid F_{11} \cap F_{12} \cap F_{21})P(F_{11} \cap F_{12} \cap F_{21}) + \\ &P(R_{23} \mid F_{11} \cap F_{12} \cap F_{21} \cap F_{22})P(F_{11} \cap F_{12} \cap F_{21} \cap F_{22}) \end{aligned} \tag{3}$$

Analogously, it is possible to calculate the probability of correct authentication formula for each states from 2 to n. A general formula for the states from 2 to n is equal:

$$\begin{aligned} P(B_n) &= P\left(R_{n1} \mid \left(\bigcap_{j=1}^{n-1} F_{j1} \cap F_{j2}\right)\right) P\left(\bigcap_{j=1}^{n-1} F_{j1} \cap F_{j2}\right) + \\ &P\left(R_{n2} \mid \left(\bigcap_{j=1}^{n-1} F_{j1} \cap F_{j2}\right) \cap F_{n1}\right) P\left(\left(\bigcap_{j=1}^{n-1} F_{j1} \cap F_{j2}\right) \cap F_{n1}\right) + \\ &P\left(R_{n2} \mid \left(\bigcap_{j=1}^{n-1} F_{j1} \cap F_{j2}\right) \cap F_{n1} \cap F_{n2}\right) P\left(\left(\bigcap_{j=1}^{n-1} F_{j1} \cap F_{j2}\right) \cap F_{n1} \cap F_{n2}\right) \end{aligned} \tag{4}$$

Finally, a formula for the probability of correct authentication in a decision tree is equal according to (5):

$$P(B_n)=\begin{cases} P(R_{11})+P(R_{12}\mid F_{11})P(F_{11})+P(R_{13}\mid F_{11}\cap F_{12})P(F_{11}\cap F_{12}) & ,for \quad n=1 \\ P\left(R_{n1}\mid\left(\bigcap_{j=1}^{n-1}F_{j1}\cap F_{j2}\right)\right)P\left(\bigcap_{j=1}^{n-1}F_{j1}\cap F_{j2}\right)+P\left(R_{n2}\mid\left(\bigcap_{j=1}^{n-1}F_{j1}\cap F_{j2}\right)\cap F_{n1}\right)\cdot & \\ P\left(\left(\bigcap_{j=1}^{n-1}F_{j1}\cap F_{j2}\right)\cap F_{n1}\right)+P\left(R_{n3}\mid\left(\bigcap_{j=1}^{n-1}F_{j1}\cap F_{j2}\right)\cap F_{n1}\cap F_{n2}\right)P\left(\left(\bigcap_{j=1}^{n-1}F_{j1}\cap F_{j2}\right)\cap F_{n1}\cap F_{n2}\right) & ,for \quad n=2,\ldots,n \end{cases} \tag{5}$$

TABLE II
EVENTS AND THEIR IMPACT ON QOE AND QOP MEASURES

	QoE			QoP	
	Description	Parameter	Value	Description	Parameter
Increase	A user has still possibility of authentication using the same or a new mechanism	α	≈0,15	An authentication mechanism was changed	QoP_j
Increase	A user finally authenticate himself	β	≈0,25		
Decrease	With every user try his or her satisfaction is lower	γ	≈0,1	First or second trial was failed	$\frac{1}{\lvert t_j\rvert}$

To obtain the best authentication path it is necessary to calculate the probability of correct authentication for every branch of the tree in a state number n (we denote it as $P(B_{nm})$ where m means a number of the branch). From the set of received probabilities the maximal value is selected ($\max\{P(B_{n1}), P(B_{n2}), P(B_{n3}),\ldots, P(B_{nm})\}$) and this value indicates a path with authentication mechanisms which should be used to deliver proper levels of protection (QoP) and user's satisfaction (QoE).

Beside the probability of a successful authentication, the level of QoP and QoE measures for every branch of the tree should be calculated. These two values define together a new parameter called Quality of User Security Service (QoUSS). Usually in literature information about parameter QoSS (Quality of Security Services) can be found. This factor describes security based on QoS of an Internet service [37, 38]. The QoUSS measure includes information about both the security level and, what is important, the satisfaction level of a used service; it is defined by a function:

$$f(QoP, QoE) = QoUSS \tag{6}$$

The argument QoE in that formula means final user satisfaction after correct authentication in a last state and QoP means the resultant level of protection in the final state.

Before we define the expressions for calculating QoE and QoP measures suitable in our model, let us describe example cases which can have impact on these two values. The TABLE II includes events which affect increase or decrease of the QoUSS arguments.

We postulate that the values of parameters moderating QoP and QoE included in TABLE II should be small, because they must not impact a resultant value of the measures. They are considered as correction parameters, so we assume $\alpha, \beta, \gamma \in (0,1)$. In TABLE II we proposed some intuitively assumed values of these parameters to reflect users' emotions connected with successes and fails of their authentication. More realistic parameters should be dedicated to specific authentication mechanisms and they must be obtained from gathering experimental data. Moreover, the value QoP_j is a minimal protection level of a new authentication protocol and $|t_j|$ is the number of all possible trials of the authentication protocol in step number j.
Thus, we propose the QoP formula as:

$$QoP_{jFIN} = QoP\left(1-\frac{1}{|t_j|-1}\right). \tag{7}$$

The proposed formula for QoE is more complicated, so it will be briefly described.
Again, like in the case of calculating the probability of a successful authentication, all states can be divided on two QoE types:

- The first state when an user authenticates himself,
- The second and next states when an user authenticates himself.

We propose a general formula of MOS dependency in an exponential form:

$$QoE = A\cdot\exp\{Z\} \tag{8}$$

where A is a constant value allowing tune the model to users' behavior, e.g., $A\in(0{,}01;1)$.

Such a shape of this function is to provide adequate sensitivity of the measure in critical areas of minimal and maximal scorings. The argument Z depends on a state in a decision tree, and the scaling constant A is determined by the MOS scale (which is from 1 to 5). Each authentication protocol has a particular QoE value. For the first failed try a user can be a little confused that he does not authenticate himself (the QoE decreases with γ_1) and at the same time the user feels good that he or she can still try with next attempt (the QoE value increases with α_1). For the second failed try user is more confused (decrease with

γ_2) but still can try authenticate himself (increase with α_2). Finally, a user authenticates himself so his satisfaction increases with the value (β).
In most cases MOS dependency has an exponential distribution, so in the first state final QoE value is equal:

$$QoE_{jFIN=1} = \begin{cases} 1 & ,if\ A \cdot \exp\{Z\} \le 1 \\ A \cdot \exp\{Z\} & ,if\ 1 < A \cdot \exp\{Z\} < 5 \\ 5 & ,if\ A \cdot \exp\{Z\} \ge 5 \end{cases} \quad (9)$$

where $Z = QoE_1 - \gamma_1 - \gamma_2 + \alpha_1 + \alpha_2 + \beta$

For the second state (and each next one) the value of QoE depends on QoE value from the previous state. QoE value on the beginning of a new state, which is connected with the previous is equal:

$$QoE_{j-1FIN} = \begin{cases} 1 & ,if\ A \cdot \exp\{Z\} \le 1 \\ A \cdot \exp\{Z\} & ,if\ 1 < A \cdot \exp\{Z\} < 5 \\ 5 & ,if\ A \cdot \exp\{Z\} \ge 5 \end{cases} \quad (10)$$

where $Z = QoE_1 - \gamma_1 - \gamma_2 + \alpha_1 + \alpha_2 + \alpha_3$

The value of α_3 is reflects the result of changing the authentication protocol. Basically founding connection between two values of QoE and calculation one average value is a difficult issue. Thus, reasonable is to assume the worst case in which choosing value is lesser. In presented case the lesser value is chosen between a value from the previous state and the QoE value for the present authentication protocol (for the present state):

$$QoE_j = \min\{QoE_{j-1FIN}, QoE_{jFIN}\} \quad (11)$$

For such a value of QoE calculations are performed based on formula (8) in case of an authentication. When the user finally do not authenticate correctly, his/her QoE decrees to 0 (but with flow of time this value can grow because the user thinks about this situation and agrees that this mechanism is secure and protects him against crackers).

Finally, for each branch of the tree the following 3-tuple was calculated: **$(P(B_n), QoE_{FINpath}, QoP_{FINpath})$**. Probability of choosing particular path includes QoE and QoP values. But it may be that paths have values like in TABLE II.

TABLE III
EXAMPLE OF RESULTS OF THE DECISION TREE ALGORITHM

Path number	1	2	3	4
QoE	3	3,5	4,5	3
QoP	3	4,5	3,5	4
Probability	0,5	0.9	0,7	0,6

It would seem that the path number 2 is the best one when considering the probability. However it is not so obvious. The path number 3 has a higher value of QoE, but a lesser value of QoP. Due to this fact there is need to use multi-objective optimization to choose the best path.
Let us assume that all results from the decision tree algorithm are in TABLE IV.

TABLE IV
ALL RESULTS FROM THE DECISION TREE ALGORITHM

Path number	1	2	3	4	…	n	**Weight**
QoE	qoe_1	qoe_2	qoe_3	qoe_4	…	qoe_n	$\mathbf{w_1}$
QoP	qop_1	qop_2	qop_3	qop_4	…	qop_n	$\mathbf{w_2}$
Probability	p_1	p_2	p_3	p_4	…	p_n	$\mathbf{w_3}$

To choose which path is the best weight sum method should be used. In general below conditions must met:

Maximize: $f(u) = \sum_{i=1}^{n} w_j \cdot K_i(u)$

Subject to: $u \in U$,
where the weights w_i, i=1,…,n corresponding to objective function satisfy the following conditions:

$$\sum_{i=1}^{n} w_1 = 1, \quad w_i \ge 0, \quad i = 1,\ldots,n,$$

and $K_i(u)$ is the objective function and U is feasible design space.
In general the maximized formula must be satisfied:

$$u_k \succ u_l \Leftrightarrow \sum_{i=1}^{n} w_i \cdot K_i(u_k) > \sum_{i=1}^{n} w_i \cdot K_i(u_l)$$

It means that decision u_k is better than decision u_l when sum of multiplications of weight and objective function of decision u_k is greater than for the decision u_l.

In presented case the function f(u) for each path is presented in TABLE V

TABLE V
VALUE OF FUNCTION F(U) IN MULTI –OBJECTIVE OPTIMIZATION

Path number	1	2	3	4	…	n	**Weight**
QoE	qoe_1	qoe_2	qoe_3	qoe_4	…	qoe_n	$\mathbf{w_1}$
QoP	qop_1	qop_2	qop_3	qop_4	…	qop_n	$\mathbf{w_2}$
Probability	p_1	p_2	p_3	p_4	…	p_n	$\mathbf{w_3}$
f(u)	$qoe_1 \cdot w_1 + qop_1 \cdot w_2 + p_1 \cdot w_3$	$qoe_2 \cdot w_2 + qop_2 \cdot w_2 + p_2 \cdot w_3$	$qoe_3 \cdot w_1 + qop_3 \cdot w_2 + p_3 \cdot w_3$	$qoe_4 \cdot w_1 + qop_4 \cdot w_2 + p_4 \cdot w_3$		$qoe_n \cdot w_1 + qop_n \cdot w_2 + p_n \cdot w_3$	

Of course to perform optimization values of should be normalized. What is also important that calculation are made with assumption that the most important should be path with the highest QoE value than path with QoP value and a finally probability of path. It means that $w_1 > w_2 > w_3$.
In considered example f(u) has the following values (see TABLE VI):

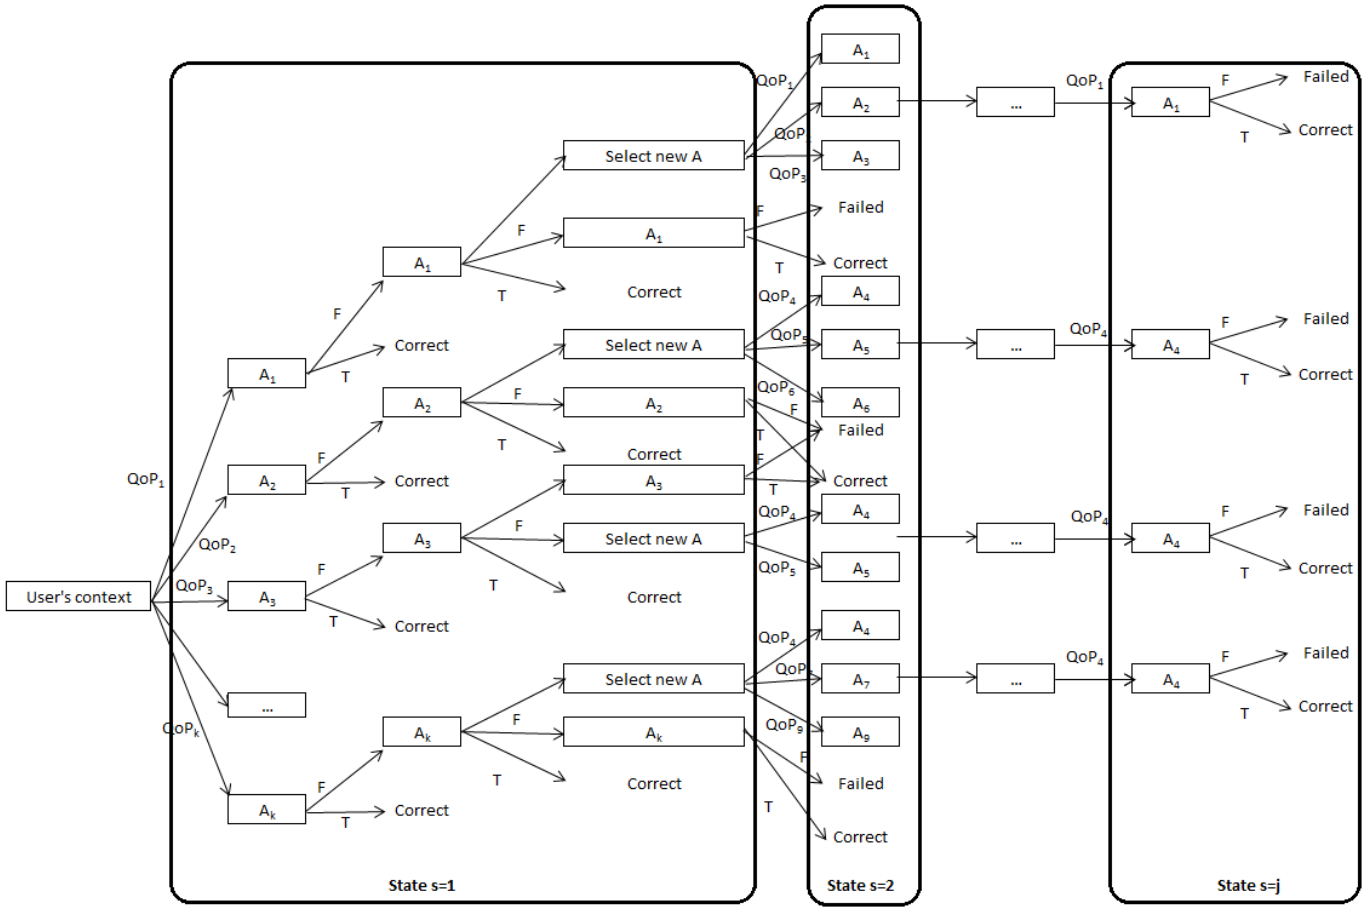

Figure 2. A decision tree for the authentication mechanism

TABLE VI
THE VALUE OF FUNCTION F(U) IN THE CONSIDERED EXAMPLE

Path number	1	**2**	**3**	4	**Weight**
QoE	0,6	**0,7**	0,9	0,6	**0,45**
QoP	0,6	**0,9**	0,7	0,8	**0,35**
Probability	0,5	**0,9**	0,7	0,6	**0,2**
f(u)	0,58	**0,81**	0,79	0,67	

Based on TABLE VI, the best path with authentication mechanism is the second one, but a few more than third path.

VI. Discussion

Now some facts about α, β, γ impact on the formula (7) will be considered. The discussion assumes two scenarios:

- A user correctly authenticates himself in the third step in stage number 1 (Scenario 1),
- A user correctly authenticates himself in the third step in stage number 2 (Scenario 2).

For these scenarios TABLES VIA, VIB, VIC (Scenario 1), VIIA, VIIB, VIIIA, VIIIB, VIIIC (Scenario 2) and corresponding to them charts were created. In Scenario 1 and Scenario 2 we assume the factor A=0,075. Moreover, if the value of QoE_{FIN} after calculations is greater than 5, automatically it is corrected to 5.

TABLE VIA
PARAMETERS FOR SCENARIO 1 – INCREASE OF Γ

QoE_1	α_1	α_2	β	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,25	0,1	0,1	3,56
3,5	0,15	0,16	0,25	0,2	0,25	2,77
3,5	0,15	0,16	0,25	0,25	0,3	2,51
3,5	0,15	0,16	0,25	0,3	0,33	2,32
3,5	0,15	0,16	0,25	0,35	0,4	2,05

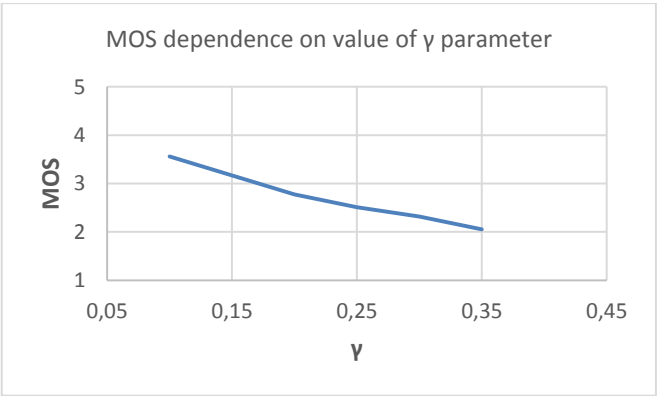

Figure 3. MOS dependence on value of γ factor in Scenario 1

TABLE VIB
PARAMETERS FOR SCENARIO 1 – INCREASE OF A

QoE_1	α_1	α_2	β	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,25	0,1	0,15	3,39
3,5	0,2	0,22	0,25	0,1	0,15	3,78
3,5	0,25	0,3	0,25	0,1	0,15	4,30
3,5	0,31	0,35	0,25	0,1	0,15	4,81
3,5	0,35	0,4	0,25	0,1	0,15	5,00

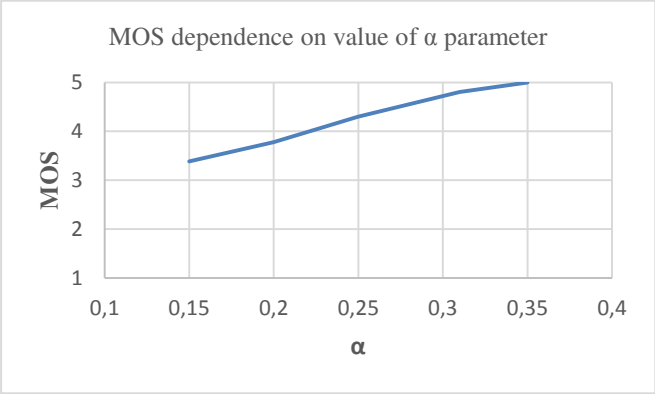

Figure 4. MOS dependence on value of α factor in Scenario 1

TABLE VIC
PARAMETERS FOR SCENARIO 1 – INCREASE OF B

QoE_1	α_1	α_2	β	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,25	0,1	0,15	3,39
3,5	0,15	0,16	0,3	0,1	0,15	3,56
3,5	0,15	0,16	0,35	0,1	0,15	3,74
3,5	0,15	0,16	0,4	0,1	0,15	3,93
3,5	0,15	0,16	0,45	0,1	0,15	4,14

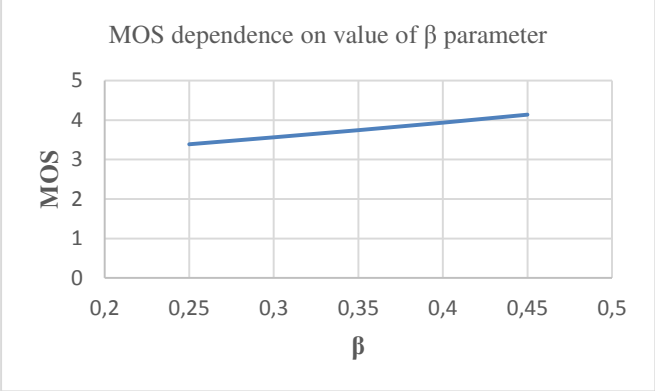

Figure 5. MOS dependence on value of β factor in Scenario 1

Based on Scenario 1 with a correct authentication in third step increase of α, β, γ parameters will be considered with their impact on a final QoE value. Figure 3 shows a situation in which γ increases and QoE value decreases. According to formula (7) it is a proper behavior. The γ factor is a parameter of QoE, which informs about decreeing of user's satisfaction. The greater factor is, the worse final QoE value is. Figure 4 shows the case in which α parameter increases. As it was shown in Figure 4, the greater α values are, the greater final QoE value is. But, wrong choice of α parameters results in a too high final value of QoE: for greater α the value of QoE is greater than 5 (but of course in MOS scale it will be corrected to maximum 5).Thus, α parameter should be determined on a proper, not too high level. Finally, Figure 5 presents β parameter impact on the final QoE value. As it was shown, QoE value increases with β increasing. And it is a proper situation, because β is a factor which value describes user's satisfaction when he/she correctly authenticates him/herself. Moreover, Figure 5 shows that β has not got such an impact on QoE as α has.

Comparing all these three factors we can notice that a significant influence has the α parameter. As a result the final QoE value can be overestimated.

TABLE VIIA
PARAMETERS FOR SCENARIO 2 – PART 1

QoE_1	α_1	α_2	α_3	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,17	0,1	0,15	3,13
3,5	0,15	0,16	0,17	0,2	0,25	2,56
3,5	0,15	0,16	0,17	0,25	0,3	2,32
3,5	0,15	0,16	0,17	0,3	0,33	2,14
3,5	0,15	0,16	0,17	0,35	0,4	1,90

3,5	0,25	0,3	0,33	0,1	0,15	4,66
3,5	0,31	0,35	0,37	0,1	0,15	5,00
3,5	0,35	0,4	0,43	0,1	0,15	5,00

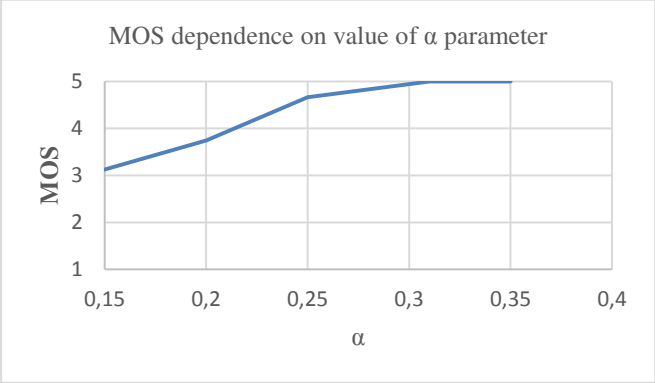

Figure 7. MOS dependence on value of α factor in Scenario 2 - part 1

Considering part 1 of Scenario 2 it can be noticed that α and β factors have similar tendency like in the Scenario 1 – an increase of γ results in decrease of QoE and an increase of α results in too fast QoE increase.

TABLE VIIIA
PARAMETERS FOR SCENARIO 1 – PART 2: INCREASE OF Γ

QoE_1	α_1	α_2	β	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,25	0,1	0,15	3,39
3,5	0,15	0,16	0,25	0,2	0,25	2,77
3,5	0,15	0,16	0,25	0,25	0,3	2,51
3,5	0,15	0,16	0,25	0,3	0,33	2,32
3,5	0,15	0,16	0,25	0,35	0,4	2,05

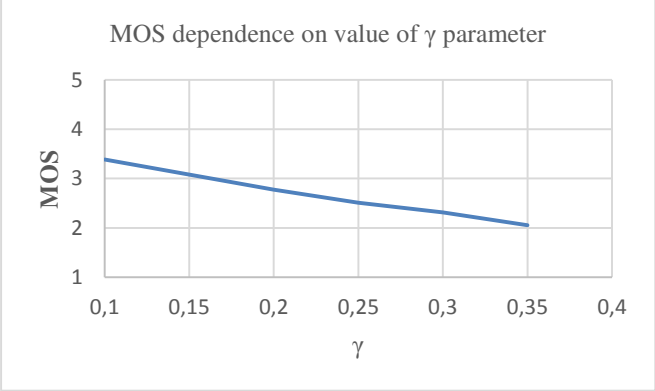

Figure 8. MOS dependence on value of γ factor in Scenario 2 - part 2

TABLE VIIIB
PARAMETERS FOR SCENARIO 1 – PART 2: INCREASE OF A

QoE_1	α_1	α_2	β	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,25	0,1	0,15	3,39
3,5	0,2	0,22	0,25	0,1	0,15	3,78
3,5	0,25	0,3	0,25	0,1	0,15	4,30
3,5	0,31	0,35	0,25	0,1	0,15	4,81
3,5	0,35	0,4	0,25	0,1	0,15	5,00

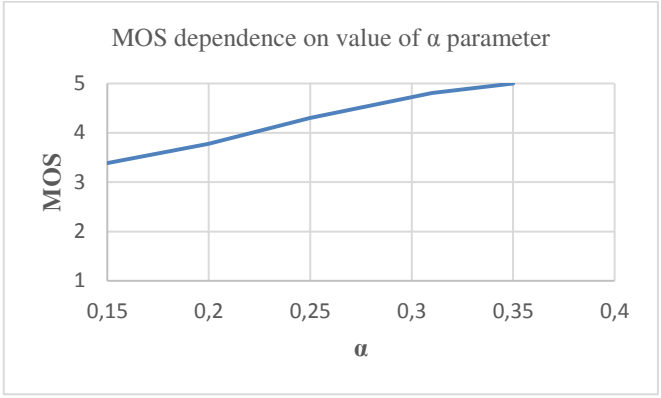

Figure 9. MOS dependence on value of α factor in Scenario 2- part 2

TABLE VIIIC
PARAMETERS FOR SCENARIO 1 – PART 2: INCREASE OF B

QoE_1	α_1	α_2	β	γ_1	γ_2	QoE_{1FIN}
3,5	0,15	0,16	0,25	0,1	0,15	2,89
3,5	0,15	0,16	0,3	0,1	0,15	3,03
3,5	0,15	0,16	0,35	0,1	0,15	3,19
3,5	0,15	0,16	0,4	0,1	0,15	3,35
3,5	0,15	0,16	0,45	0,1	0,15	3,52

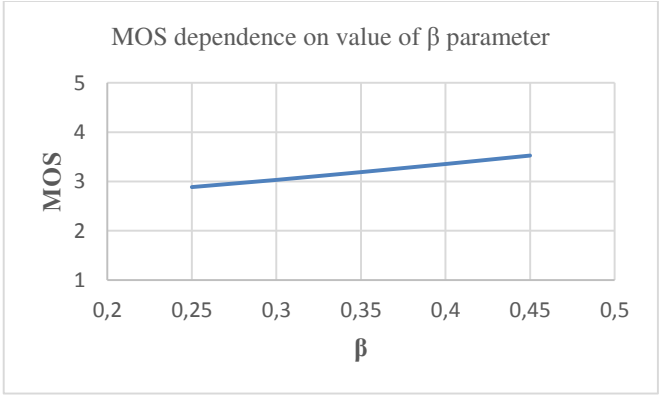

Figure 10. MOS dependence on value of β factor in Scenario 2 - part 2

Considering part 2 of Scenario 2 we can notice that it is similar to Scenario 1 – α parameter has a meaningful impact on the final QoE value.

VI. Conclusions and Future Work

In this paper a model of selecting the best authentication mechanism has been proposed. The model consists of two stages. The first stage constructs a decision tree algorithm, which is used to calculate three parameters characterizing the authentication: a probability of choosing particular path describing the steps of authentication, a final QoP value and a final QoE value. The second stage concerns multi-objective optimization of the measures established in the first stage. Based on a weighted sum method applied to QoP and QoE measures for the authentication mechanism the best path is chosen. Moreover, a discussion about an impact of QoE parameters on a final value of QoE was

conducted. The assumptive final QoP and QoE formulas fulfill requirements applied to acceptable values. In spite of all, experiments which verify created formulas should be performed.

To illustrate the results a simple numerical example has been presented. In our future work the research will be concentrated on conducting a real-world experiment of a reasonable scale authentication mechanism based on the created model. This will make possible to compare theoretical and experimental results to verify the model and tune its numerical parameters.

***Abstract*—Persistent Identifiers (PID) are the foundation referencing digital assets in scientific publications, books, and digital repositories. In its realization, PIDs contain metadata and resolving targets in form of URLs that point to data sets located on the network. In contrast to PIDs, the target URLs are typically changing over time; thus, PIDs need continuous maintenance – an effort that is increasing tremendously with the advancement of e-Science and the advent of the Internet-of-Things (IoT). Nowadays, billions of sensors and data sets are subject of PID assignment. This paper presents a new approach of embedding location independent targets into PIDs that allows the creation of maintenance-free PIDs using content-centric network technology and overlay networks. For proving the validity of the presented approach, the Handle PID System is used in conjunction with Magnet Link access information encoding, state-of-the-art decentralized data distribution with BitTorrent, and Named Data Networking (NDN) as location-independent data access technology for networks. Contrasting existing approaches, no green-field implementation of PID or major modifications of the Handle System is required to enable location-independent data dissemination with maintenance-free PIDs.**

***Index Terms*—Persistent Identifier; Information Centric Networks; Named Data Networking; Magnet Link; URN; Handle System; Digital Object Identifier; Overlay Network**

I. Introduction

The concept of *Persistent Identifier (PID)* is essential for referencing, citing and linking (digital) resources using a durable and reliable identifier. PIDs are used to ensure the long-term valid access to possibly moving digital resources that suffer from changing URLs and storage locations in networks. PIDs contain an adjustable target Uniform Resource Locator (URL). To reflect changing and volatile data locations, the target URL of a PID must be updated to the currently valid storage location. By employing organizational and technical measurements, different PID systems allow building, using and maintaining a long-term existing (digital) identifier that is backed by distributed systems, replication schemes, and policies. With these measurements in place, PID infrastructure operating organizations are able to offer PID systems that are resilient against failure, and even catastrophic scenarios. Ideally, the range of PID infrastructure resilience includes scheduled downtimes of server and networks, major infrastructure problems caused by power failures, and hardware and software problems, as well as ultra critical events of complete data center losses caused by fires, explosions or natural disasters.

Besides the measurements that protect PIDs on infrastructure level, PIDs have to be protected on the content-side as well. The content of the PID has to be intact and readable with given encoding schemes. Furthermore, the metadata have to be addressed with a given metadata scheme that explains the semantics of the metadata. Then, the content has to reflect the current state of the data object the PID is linking to. This includes the *up-to-dateness* of metadata sets stored in PIDs, which are often encoded as *key-value* pairs. Particularly important is the correctness of the PID metadata field `target URL`, which points to the digital object addressed by the PID for long-term access (c.f. Figure 1). Contrasting the infrastructure protection of PID, this content validation is not done by the PID infrastructure operating organization. It is a task of the data owners that registered the PID for their data or the subsequent organization that has the task of curating the data and its associated PIDs. Only those organizations have the necessary understanding on the data and its metadata to check and update PIDs for assuring long-term access. Moreover, they are aware of the current location of the data linked by PID. Thus, with regular control and adjustment of the target URLs to the current data location, well-established PID systems can guarantee persistency of identifiers physically, while data owner organizations have to accept the burden of regularly checking and updating metadata and target URLs. Only with collaboration PIDs are able to provide long-term access [1].

While PIDs solve the problem of changing data locations by constant efforts from PID infrastructure providers and data hosting organizations, the network research community has come up with numerous concepts for creating location-independent data access. In these concepts that access information for data attached to a network is not based on the data location, but it is based on the content of the data [2]. Hence, in the case of changing data location the access information remain stable. Two efforts that realize location-independent access is the state-of-the-art decentralized data distribution technology *BitTorrent* and *Named Data Networking (NDN)* as next-generation Internet technology. Although both technologies allow stable location-independent access to data, they do not provide persistent access like PID.

Our approach presented in this paper combines the very stable concept of the *Handle* PID system with the advantages of

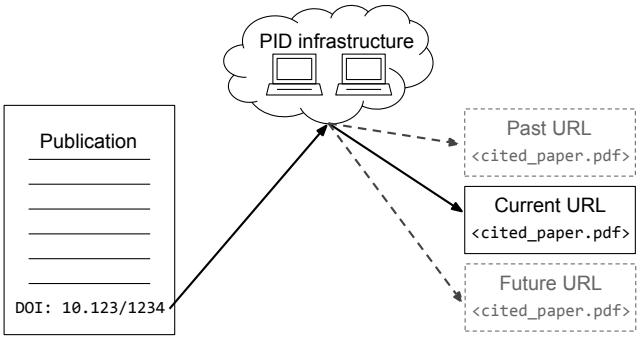

Figure 1: Adjustment of PID target URLs to reflect current data location.

location-independent access with its stable access information scheme. By this, we significantly lower the efforts of PID maintenance, as regular checks for data hosting organizations concerning locations and data availability will become obsolete. PIDs that are enabled for location-independent access remain valid as long as data is available online in BitTorrent or Named Data Networking (NDN) networks. To store the location-independent access information in existing Handle PID data structures, we extend the – yet not standardized – approach of *Magnet Link Schemes*, which is very successful in peer-to-peer communities [3]. In detail, our novel approach has the benefits of using an unmodified version of the Handle PID system that allows a practical implementation of our approach in existing Handle PID systems. Besides the advantages of interoperability, it does not come with a significant impact on PID resolution. For the location-independent access with BitTorrent and NDN only the small overhead of PID resolution is added.

Furthermore, we extend the Magnet Link scheme into the domain of NDN and provide a transport container format that includes besides the NDN data name also the necessary cryptographic access information for verifying data access authenticity. Thus, we can also improve Web browser-based NDN applications that use HTML-links for interconnecting NDN Web resources by the Magnet Link scheme. The latter has been originally designed for interconnecting non HTTP-resources in hypertext document contexts.

This paper is structured as follows. First, we present existing efforts in Section II. Second, we summarize the existing approaches of location-based data access through PID in Section III. Then, we line out state-of-the-art techniques for location-independent access in Section IV. In Section V, we introduce the Magnet Uniform Resource Identifier (URI) scheme format as container for storing location-independent access information. After that, we extend the Magnet URI scheme for the usage in the domain of content-centric networks and PID in Section VI. A proof-of-concept implementation is illustrated in Section VII together with an evaluation of performance in Section VIII that is combined with a discussion of the results. Finally, we draw a conclusion in Section X.

II. Related Work

To our knowledge, the concept of building care-free persistent identifier targets using content-centric technology has not been subject of extensive study. In the literature several related concepts can be identified.

The concept of bridging different content-centric network systems through a centralized Uniform Resource Name (URN) system has been initially drafted by Sollins in 2012 [4]. Her concept utilizes foundations of PID principles for creating an identification system for different Information Centric Networks (ICN) families and their related data objects that meets the requirements of scalability, longevity, evolvability, and security. Sollins's identification system abstracts different object naming schemes from ICN families such as Data Oriented Network Architecture (DONA) [5], Network of Information (NETINF) [6] and Publish-Subscribe Architecture (PURSUIT) [7]. Although, PID principles are used for location-independent data access, the publication by Sollins does not suggest access through an existing well-introduced PID system that is provided in our work, but rather uses a greed-field approach for location-independent data access.

The realization of complex secure naming schemes for content-centric data has been covered by Dannewitz et al. in 2010 [8]. They demand name persistency without incorporating the concept of PIDs. In their publication, Dannewitz et al. clarify that basic security functionality must be attached directly to the data and its naming scheme, because the identity of network locations cannot be used as a trust base for data authenticity. Our approach follows this principle for secure location-independent data access and facilitates directly attached PID security mechanisms. By this, location-independent access through PID is shifted into the requirements formulated by Dannewitz et al., and our approach enables authentic data access through PIDs.

In the context of semantic digital archives for archiving data of Personal Information Manager (PIM) applications, Haun and Nürnberger proposed a PID schema for accessing objects in file systems using an URN-like Magnet Links scheme [9]. They link the congruent attributes of the Magnet Link scheme to the attributes provided by some PID systems such as global uniqueness, persistence and scalability for the application in offline data archives serving data from archive medium such as file systems on Write Once Read Multiple (WORM) medium. In contrast, our approach relies on currently employed PID systems and incorporates location-independent data access in a distributed online environment using the full-featured Handle PID system.

III. Location-based PID Targets

Today's data dissemination is dominated by end-to-end connections, URLs, and DNS-backed domain names. When data is moved from one host to the other, it results in broken URLs and inaccessible content. To ease these problems, PIDs are used for long-term data access by providing a long-living identifier. When using a PID, the identifier is embedded into a

medium such as scientific publications, books, or Web sites. To access the digital resources, *behind* the PID a resolution service is employed that uses the PID to provide a currently valid network location (target URL). Figure 1 illustrates how the target URL is adjusted to the current location when the data behind the PID is moved from one host to the other. Thus, PIDs reflect the current location of data and the identifier on the medium can remain unchanged.

The location-dependent data access through target URLs stored in PIDs also forms the chain of PID resolution. For this we have a look at the resolution chain presented in Figure 2. It depicts the fact that data access through PID with Hypertext Transport Protocol (HTTP) relies on different infrastructures and involves five levels from the PID resolution up to the data download. Even if the chain is shortened, e.g. by directly linking PID targets to IP-addresses instead of DNS-based host names, the problem remains identical: If PID-tagged data is moved from one host to the other, the PID access chain needs to be adjusted on one or even on multiple levels to provide valid PID resolution. If the adjustment is not done or partially incorrect, location-depended data access is impossible through PID. Defects can occur on every level. On level ❶ the PID HTTP resolution service can be temporary out of order. The target URL does not reflect the current location of the data in stage ❷. On level ❸ the Domain Name System (DNS) resolution can fail if a domain has been expired or DNS resolution fails due to misconfiguration. Level ❹ and ❺ are related to the network, but their functionality is also required for successful data access through PID. To detect broken PID resolution a check of every PID target and, thus, a successful resolution is necessary for judging the integrity. The check is done in many cases by evaluating the HTTP status codes like `404 - not found` that are provided by the data repositories software [10]. This can only be achieved by regularly checking *all* PIDs of an organization. This is very time consuming since typically robot or spider programs crawl all PIDs of a data owner. The crawling programs are programmed and operated by repository owners and not PID infrastructure providers. They provide an optional data quality assurance service.

The adjustment of target URLs has impact on different dimensions and is shared unevenly between the users – the PID operators and data repository owners. The costs and efforts behind URL adjustments have been accepted as part of the PID operation. They are considered *inevitable*, such as energy leaks in today's electrical grid infrastructure. The adjustment of target URLs is a shared effort on the side of data owners and dependent on the number of PIDs a data owner has registered.

It can be questioned whether the proliferation of e-Science already increases the effort necessary for PID maintenance. We thus have visualized statistics from DataCite (one of the largest PID infrastructure providers) in Figure 3. The assignment of new PIDs (*line*) massively increased, following a super-linear pattern [11]. An aggregation of the DataCite Statistics for successful DOI PID resolutions shows also a massive increase in PID-tagged data sets (*bar*) [12] [13]. With a massive increase of PID numbers, the efforts for maintaining PID targets will

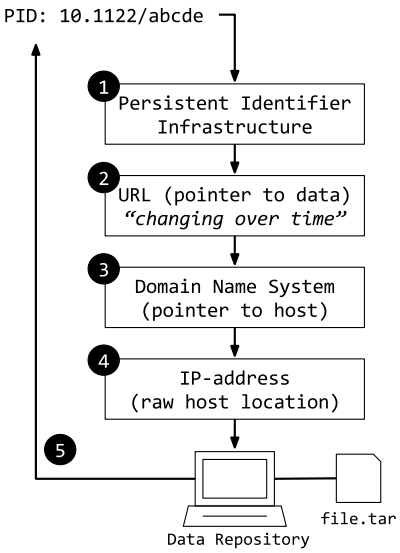

Figure 2: Data access through PID requires a working chain of services relying on unstable URLs.

increase identically, as every assigned PID needs to be checked for validity to comply with PID infrastructure policy. It is not a question, whether the PID systems are scaling out sufficiently, but rather the data hosters are able to verify their location-dependent PIDs with a reasonable effort regularly. PIDs with location-independent targets decouple the growing number of PIDs from the efforts of maintaining PID target URLs.

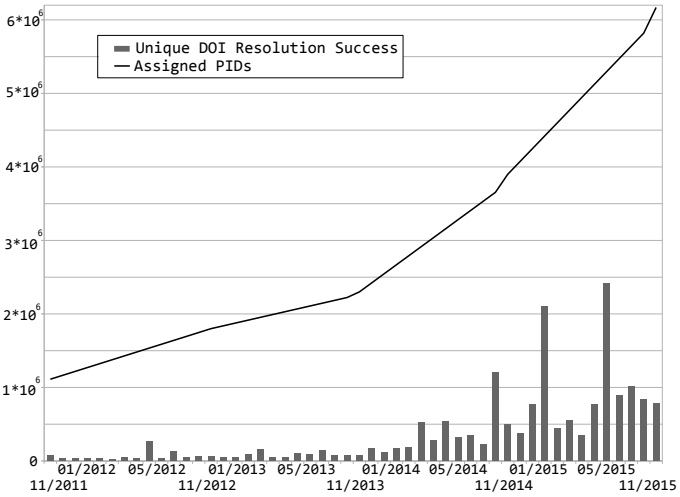

Figure 3: PID assignment and unique successful resolution for the DataCite DOI infrastructure between 11/2011 and 11/2015 based on data from [11] [12].

IV. Location-Independent Access

For location-independent data access, we propose two different techniques that allow access based on the content and not on the network location. We can thus show that our approach of location-independent persistent PID resolution targets works with various location-independent access technologies.

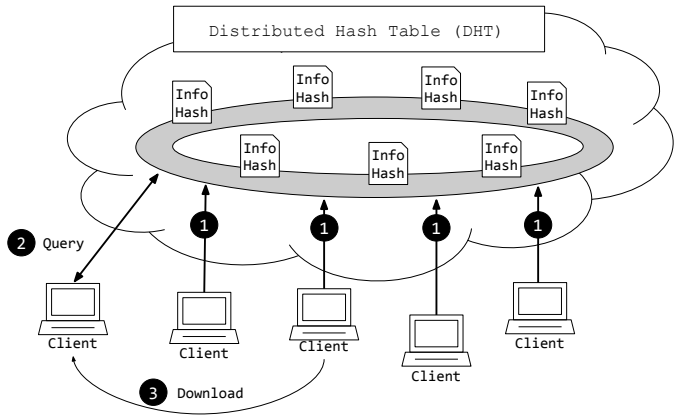

Figure 4: Accessing data from a DHT-controlled swarm using an infohash in BitTorrent.

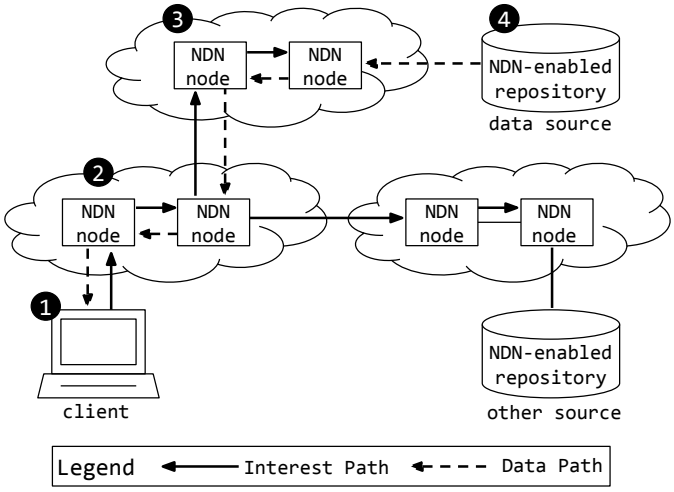

Figure 5: Accessing data using data names in NDN networks.

We propose BitTorrent, a well-established location-independent access technology. It works on top of today's location-based networks with Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) [14]. In contrast to existing location-based data repositories that are subject of PID target resolution, BitTorrent technology uses a peer-to-peer approach supporting parallel downloads. With its latest features of Distributed Hash Table (DHT) and Peer Exchange (PEX), BitTorrent does not require central infrastructure to discover other network peers and localize files [15] [16]. Thus, data can be accessed with BitTorrent from every connected peer, as long as data is available online. For addressing data sets, BitTorrent uses *infohashes* that are computed as SHA-1 checksums on the content of the file. Every peer that possesses the infohash can download the data set from the BitTorrent *swarm* that consists of the peers offering the data set for download. The swarm arrangement and the *overlay network* for the specific file is computed for every download. In Figure 4, the BitTorrent file access is depicted. In step ❶, every node is sending its network address and the infohashes of the files ready for upload to the DHT. Then, a client can look up the infohash in the DHT (step ❷) to locate other peers that are able to serve the file that belongs to the infohash (or at least parts of the file). Through connecting to the peers in step ❸, the client is retrieving the file. This can be done simultaneously by parallel peer connection.

In contrast to BitTorrent, Named Data Networking (NDN) is a current research topic of location-independent data access using information-centric principles [17]. NDN is also featured in the location-independent PID approach presented in this paper to support a next-generation Internet technology. In NDN, data sets are enumerated through *Data Names* that form a hierarchical name space [17]. The working principle of NDN is shown in Figure 5. To access data from a client (step ❶) in the *Named Data* space, an interest data package is sent through the network. Based on the data name driven routing principles, the NDN network directs the interest through the network (step ❷ and ❸). If a NDN node is found that owns a named data set (step ❹), a data package is sent back along the interest path to reach the node, which stated the data request. Hence, NDN abstract from the network location and the data source remains opaque [17].

V. Magnet URI Scheme

For embedding location access information into PID, the Magnet URI scheme is used as transport container, which is a work-in-progress specification for *Magnet Links* [18]. Magnet Links can store extensive information on accessing resources in networks, like HTTP download URLs, mirror server information, or peer-to-peer access data. By applying this principle, Magnet Links are usable for describing digital resources and its content. But as a descriptive access format, Magnet Links need a storage medium to be present on. This could be a Web site with HTML content, an E-Mail message content, or – like in our use case – a Persistent Identifier. To provide persistent access to digital data encoded in Magnet Links for a time of years, or possibly decades, a medium is needed that provides these properties. Hence, persistency is not archived by the Magnet Links but provided by the PID System that ensures long living existence of access information through its infrastructure, policies and replication partnerships. If Magnet Links are stored on *perishable* media like Web sites, they do not provide any advantage over common URL access information. The conjunction with PID provides the additional benefit of long-term access from data hosted at suddenly moving data. Besides the encoding of access information, one design goal of Magnet Links is to integrate features made available by local utility programs seamlessly into the storage medium like a Web site, by following best practices among the Internet Engineering Task Force (IETF) specifications for URN [19]. Although its lack of specification, Magnet Links are supported by numerous peer-to-peer tools and are the de facto standard in large file sharing communities, such as BitTorrent [20]. In BitTorrent-enabled Magnet Links, access information for downloading

files from a decentralized peer-to-peer infrastructure are stored together with optional metadata and suggested file names (c.f. Tab. I). To initiate a download with a Magnet Link from a Web browser, a pseudo-protocol handler for the Magnet Link URL format `magnet:?xt=urn:<System>:<Access Information>` is registered. It passes the information to a location independent download client.

Table I: Magnet URI scheme keys

Key	Name	Purpose
as	Acceptable Source	location dependent download URL
dn	Display Name	file name
kt	Keyword Topic	search key word
tr	Address Tracker	optional tracker information for BitTorrent
xl	Exact Length	size in bytes
xt	Exact Topic	location independent access information in URN-format

VI. Location-Independent Data Access through PID

For creating a persistent resolution target in a Handle PID that is based on the content of linked data set and not the network location like the target URL, we leverage the principles of location-independent data access with Magnet URI-encoded access information. In the first step in Subsection VI-A, we extend the Magnet URI scheme into the domain of NDN applications to support this cutting-edge data access technology. By this, we can encode all access information for BitTorrent and NDN as well as all systems listed in Table II into one uniform scheme.

Then, in the second step in Subsection VI-C, we propose an approach of embedding the Magnet Link URI scheme into PIDs of an unmodified Handle System. Starting from Subsection VI-E onward, we examine the PID resolution of PIDs with enabled location-independent access data.

A. Magnet URI Scheme Extension for NDN

Besides the already established usage of the Magnet URI scheme in peer-to-peer overlay networks that particularly allow BitTorrent location-independent data access, a next-generation access technology for supporting location-independent data access is integrated in our approach. We extend the Magnet URI schema into the domain of content-centric networks, enabling support for Named Data Network data access through Magnet Links. Thus, the Magnet URI schema is extended to store a NDN data name that identifies a digital object within a NDN network. With the data name, the NDN network can transport data from a source node holding the data back to the client node requesting the information through an interest [17]. The location of the data is not important, as long as it is attached to the network through a reachable NDN node. The data name is encoded through an extended `xt` key that holds besides the data name also a checksum of the data name to detect data corruption. The schema is `uid:ndn<DATANAME>.<CHECKSUM>`. Unlike current host-based networks that use a Public Key Infrastructure (PKI) to verify host identities through SSL certificates, NDN data cannot verified through a trustful data location. As a result, the Magnet Link also has to include the verification information needed to assure that the received content *is* the requested content. This is done by adding a cryptographic signature of the NDN content in a separate `<SIGNATURE>` field, which is part of the second `xt` key extension. Thus, verification needs to be done on content level using a public PKI, which is in the scope of current NDN research. To get the certificate needed to verify the data, the NDN access information for the certificate need to be added to the Magnet Link, too. To obtain the certificate with the public key, we propose the `xt` key `uid:ndnsec<SIGNATURE>.<CERT_DATANAME>` that allows the download of information for content verification. By this, access NDN access information can be encoded into a Magnet Link and also the genuineness of the obtained data can be verified through security information embedded into the Magnet Link. The extension we provide for the Magnet URI scheme supporting NDN is depicted in bold letters in Table II.

B. Embedding Magnet Links in Handle PIDs

For this integration of Magnet Links into the Handle PID System maximum compatibility is paramount, as data dissemination has a very slow change momentum, owed to billions of PID-tagged data sets. Hence, the usage of Magnet Links for location independent data access and its impact on the adaption in the Handle System is investigated. By design, Handle supports hierarchical data types, identified by UTF-8 named fields. The data itself is organized as indexed, typed key-value pairs that store sequences of octets, which are preceded by its length in a 4-byte unsigned integer. Like other PID systems, the Handle System provides a URL data type `0.TYPE/URL` [21]. Supplemental services such as PID HTTP resolvers, also known as Handle proxies, use the URL semantic to resolve PIDs into target URLs by using HTTP-forwarding with HTTP status code `303`.

Table II: Magnet Links Scheme Adopters (proposed schemes for Named Data Networking in bold font)

System	URN	Value
Gnutella2	sha1	file hash (SHA-1)
BitTorrent	btih	unique file identifier
Gnutella2	tiger	file hash (Tiger Tree Hash)
Kazaa	kzhash	file hash (proprietary)
NDN Access	**ndn**	**DataName and Checksum (SHA256)**
NDN Verification	**ndnsec**	**content signature & public key data name (NDN specs.)**

Unlike URLs, Magnet Links do not specify the data location but can be considered as URN-like data classification. Hence, the Handle PID data type `0.TYPE/URL` does not fit semantically for Magnet Links, because URL is a subset of URI [22]. As a result, an own data type `MAGNET` needs to be registered at a Handle PID server that should be capable of holding Magnet Links. To retrieve data from the PID via location-independent technology, a Magnet Link can be placed into the Handle. As Magnet Links fit into the UTF-8 encoding of Handle values, they can be placed without any further encoding.

For Instance, a valid DHT-enabled Magnet Link containing BitTorrent information for retrieving a file can be generated and stored in the MAGNET field of a Handle PID. Additionally, a Magnet Link-wrapped NDN Data Name can be placed into the MAGNET using URL escaping according to NDN name specifications [23].

C. Data Access Through PID with Persistent Resolution Targets

Handle PIDs that are equipped with a Magnet Link can be resolved like any other PIDs using the native Handle protocol. This can be done either by using that protocol on top of TCP or UDP, or via a HTTP-based proxy that answers resolution requests as a Web service. The *resolving* process for PIDs with persistent resolution targets works similar to the resolution process of location-based PIDs regarding the initial steps done within the Handle infrastructure. Hence, Figures 2 and 6 share the first initial step ❶, where the PID is resolved by the Handle infrastructure. In this step the Global Handle Registry (GHR) determines the Local Handle System (LHS), which is responsible for a specific local sub-namespace (Handle prefix). Then, the LHS looks up the requested PID in its database and returns the requested values to the client. For resolving using location-based data access, the value with the type 0.TYPE/URL is returned from the database and for resolving a with a persistent target location independent data access information in form of MAGNET is returned.

The new data access chain depicted in Figure 6 is different from the location-based data access using the target URL shown in Figure 2. With the Magnet Link of the PID acquired through the resolution process in step ❷ the data access is now handled by the overlay network in BitTorrent, or by the NDN network (step ❸). The PID resolving process is then a single redirection that leads to a starting download right after resolving, instead of multiple redirections using an entire chain of services for data access. These connections rely on peer connections based on IP-addresses for BitTorrent and node connections for NDN. Thus, the number of steps is reduced to three; also fewer layers and infrastructure are required for accessing the data. No central infrastructure is involved and the entire chain of location-based infrastructure is not needed anymore. The only requirements for data access is a running PID infrastructure and employing BitTorrent or NDN software for sharing the data online.

D. Creating and Resolving PIDs with Persistent Resolution Targets in Web Environments

For a convenient and smooth resolution of PIDs in the context of the World Wide Web, querying and resolving of Handle PIDs is realized by using a proxy service that accepts requests in HTTP(S) and resolves and maintains PID with the native protocol [21]. The Handle System maintainer, the Corporation for National Research Initiatives (CNRI), provides a Handle Proxy Servlet that offers HTTP-based resolving. The official Handle Proxy needs a small extension to resolve PIDs smoothly with HTTP into location-independent access information. This is done by changing the resolving mechanism

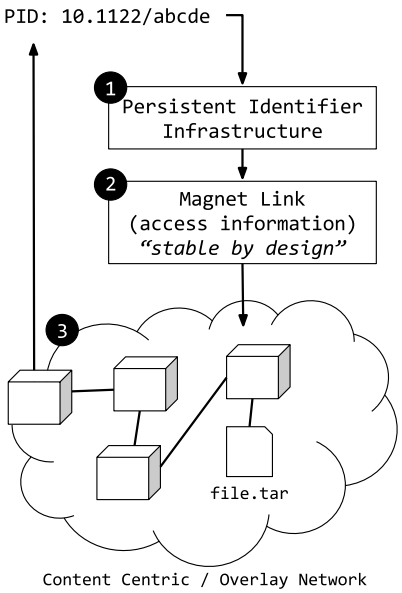

Figure 6: Location independent access through PID relies on stable content-based access information.

from 0.TYPE/URL to MAGNET for the default value. However, non-modified Handle Proxies also work, when explicitly querying for MAGNET or using URL rewriting appending query parameters on the HTTP request.

For offering a Web-based creation of PIDs that features a Magnet Link as persistent resolution target, a Web service is a reasonable choice. For every system that is offered for location-independent access technology, the Web service consumes either the native access information and encodes them into a Magnet Link or directly Magnet Links. Then, the Web service is registering a Handle PID at the LHS using the native Handle protocol and updates the Handle with a MAGNET containing the Magnet Link. In case of BitTorrent, the Web service consumes torrent files that contain along with the checksum and the name of the torrent also the infohash. These information are parsed and embedded into the Magnet Links as persistent PID resolution target using the current Magnet URI scheme description. For NDN data access, the Web service consumes the data name and the SHA-256 checksum of the data set. Furthermore, the Web service allows attaching NDN verification information to PID by extending the Magnet Link in the PID containing the cryptographic signature, as well as the data name to obtain the public certificate of the owner. The NDN access information are encoded into Magnet Link using our proposed Magnet URI scheme (c.f Subsection VI-A) in order to be embedded into the PID.

E. Data Access Through PID with Persistent Resolution Targets using a Web browser

Although, the Handle System can remain unmodified and the Handle proxy is only subject of optional minor modifications, the automatic resolution on HTTP clients provides solvable challenges. To provide a smooth resolution, a HTTP client like

a Web browser needs to support multiple protocols through asking a protocol handler that determines the behaviour for resources outside HTTP sphere, like `mailto:` resources that are forwarded to the E-Mail program. For `magnet:` resources, the Magnet Link protocol handler is invoked [24]. Based on information stored in the Magnet Link value `Exact Topic (xt)`, the Magnet Link Handler selects the appropriate application and passes all information necessary for the download. Then the application is doing the heavy data download via the suggested access technology stored in the Magnet Link.

For invoking the process automatically in the Web browser, following steps are applied. When resolving HTTP-related URLs, the proxy-based resolver responds with HTTP status "`303 – See Other`". According to the HTTP standard RFC 7231, a `303` response to a `GET` request indicates that the server does have a representation of the target resource which can be transferred over HTTP [25]. In the case of normal location-based forwarding, the target `URL` field of the PID is resolved into a target server target URL, as the proxy server does not possess the data. In the case of PID holding location-independent access information, the `MAGNET` field is resolved into a forwarding to the overlay network of NDN name space. This HTTP-forwarding indicates that the Handle proxy server does not posses the data and it is not reachable via HTTP. Hence, the use of Magnet URIs in PID for HTTP-based resolution is in line with the HTTP standard and especially supports it with embedding additional information into the Magnet Link for a self descriptive data access.

VII. Implementation

A. Server Side

For verifying our approach, we set up an entire stack of software component for verification. On the server side, the stack consists of an unmodified Handle System (c.f. VII-A1) and a custom Web service called *PID-Burner* (c.f. VII-A2), which is able to create, update and resolve Magnet Link enabled PIDs based on our approach.

1) Local Handle System: The LHS that hosts the Handle PIDs under a specific prefix does not require any modifications in the source code to run our approach for storing and serving PIDs with Magnet Links. By default, the Handle System supports a list of preconfigured data types that are available as standard type set in every Handle System of a specific version. The list of pre-configures data types contains types for realizing typical PID scenarios with `EMAIL` and `URL` for location-based access. But also special scenarios like target URL forwarding based on users' geolocations. It should also contain a `URN` data type according to the Handle System documentation [26], but it – unfortunately – is not part of the preconfigured data types in the most recent version 8.1.0 [27].

As none of these preconfigured data types are suitable or working for storing Magnet Links, we use the well-designed extensible type system of the Handle System architecture to register a new data type `MAGNET`. By this, we only add a configuration item to the LHS that has no impact on the existing type system and runs on Handle legacy systems, too.

2) PID-Burner - Creating, Maintaining and Resolving of PIDs with Persistent Resolution Targets: The PID-Burner Web service allows creating, updating and resolving PIDs with Magnet Links embedded as persistent resolution targets. It is implemented from scratch, but incorporates libraries and frameworks for PID management, as well as BitTorrent libraries and initially created libraries for Handling NDN access information and processing Magnet Links with the extensions proposed. The PID-Burner engine is implemented in Python using the *Bottle Web framework* from creating a Representational State Transfer (REST) interface [28]. Besides the REST interface it offers a JavaScript-based user interface for the Web browser. As back-end for interacting with the Handle PID service the EPIC-API v2 Web service from European Persistent Identifier Consortium (EPIC) is incorporated to create and update PIDs [29]. For processing BitTorrent access information contained in torrent files, *libtorrent* Python bindings are used for extracting the necessary access information like the infohash, the file name and checksum [30]. NDN access information processing is done with a custom library, as well as the generation of Magnet Links.

For creating and updating PIDs with Magnet Links, the user can upload a torrent file that contains the BitTorrent access information. These torrent files can be created from original files in BitTorrent programs like Transmission [31]. NDN access information are uploaded as Java Script Object Notation (JSON) data structures and can store the data name and the checksum. The NDN data names has to be determined by the user depending on its NDN network topology. The checksum can be computed using any checksumming tool like OpenSSL. JSON is used for NDN access information encoding due to the lack of standardized access container formats in NDN that are comparable to torrent container files. The optional cryptographic verification information are attachable to the PID using NDN access information containing the cryptographic signature of the data and the NDN data name to retrieve the X.509 certificate of the data signer.

For resolving Magnet Links enabled PIDs with HTTP, the Web service implements a resolution functionality that is almost identical to the original Handle HTTP proxy by CNRI [32]. As described in Subsection VI-C, the resolution process does not depend on target URLs, but rather uses the PID value stored in the `MAGENT` data field of the PID. Hence, if a Web client asks the PID-Burner service for resolving, the Magnet Link with the access information is returned as HTTP status `303 – See Other` for existing PIDs. If the PID does not contain a Magnet Link, the resolution is done against the URL value of the PID and PID-Burner behaves identical to the Handle HTTP proxy service. The behaviour allows a maximum on compatibility towards the original Handle System also on HTTP resolution.

B. Client Side

End-users who are interested in using Magnet Link-enabled PIDs for data access need client software that is able to

process access information for location-independent access. For BitTorrent-based access a client software is needed that is able to process Magnet Links. To simulate end-user environment we are using a Gnome 3.16.2 Desktop on Fedora 22 together with Chromium 47.0.2526.106 as Web browser running on Intel i5-2400 with 8GB RAM. As BitTorrent Software, we use an unmodified version of Transmission 2.92 [31] and use public BitTorrent infrastructure available to every Internet user (DHT bootstrap servers) for file download.

For NDN access, we provide an own Magnet Link adapter that process the NDN access information and passes them to the NDN download tools. This NDN Magnet Link adapter has been implemented in Python and is necessary to parse NDN Magnet Links the based on our proposes schema extension. For NDN data hosting and downloading, we use the experimental NDN Repo NG tool set that consists of NDN server and download applications for exchanging data over a NDN network [33]. The Repo NG tool set is running in a private testbed at Gesellschaft für wissenschaftliche Datenverarbeitung Göttingen mbH (GWDG) that consists of six NDN nodes.

VIII. Evaluation and Discussion

All approaches related to PID systems have to provide interoperability at its highest degree to comply with the slow changing momentum of the Handle Infrastructure.

First, the Handle System is a very large distributed infrastructure with shared responsibilities. The services consist of 1 000 servers in 75 countries, which are operated by hundreds of organisations. It currently holds over >100 million PIDs, owned by over 12 thousand registrants in 2015 [34] [35]. Hence, approaches that demand a fundamental change in the system have the challenges of convincing a large community. In contrast, our approach presented in the paper operates on-top of the infrastructure and has no impact on existing PID infrastructure. If LHS operators are interested in implementing PIDs with persistent resolution targets they just have to add a service that is able to resolve, maintain and update `Magnet` Links within PIDs as described in VII-A2.

Second, for data repository owners that use PID for registering their data and HTTP-based file distribution, our approach opens up new perspectives on data dissemination. With our approach they can combine the advantages of location-independent access, peer-to-peer networks and PID into a single concept. For this, they have to create access information for their existing files and provide a location-independent upload point such as a BitTorrent Upload server.

Although our concept offers many advantages, we have to investigate its performance. The evaluation has to be split into two parts; the first is the evaluation of the PID access. This is done by comparing the distribution of string lengths in PID target URLs against existing Magnet Link resources, checking whether Magnet Links will increase the size of PIDs. If Magnet Links increase the size, resolution performance will decrease. This can be explained with higher data transmission volumes and larger data sets that are to be handled by software stacks.

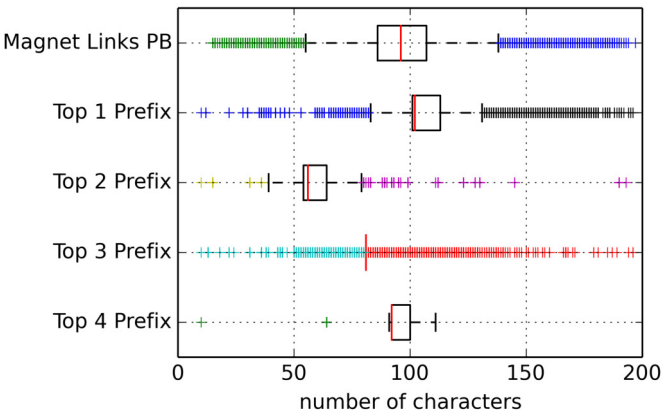

Figure 7: Distribution of string length for Pirate Bay Magnet Links and PID target URLs for frequently resolved Handle prefixes (95% data shown in plot, x-axis limited at 200 chars)

In Figure 7, the string length distribution for BitTorrent Magnet URLs aggregated from the *Pirate Bay* Web site is plotted as box-plot in row one. The Pirate Bay data set (row one) is chosen as a benchmark data set, as it forms one of the largest data accumulation for heterogeneous files exchanged by BitTorrent. For the string length analysis of the Pirate Bay data sets the tracker information have to be removed in order to provide clean analysis; furthermore, the tracker information are not necessary to perform a download using DHT techniques in BitTorrent. It consists of 1 643 194 Magnet Links in total that consist of BitTorrent access information in the form of infohashes and file names [20].

In comparison to the access information in Magnet Links, we now compare the string lengths of PIDs (row two to five). For this we use real-world data from network users who resolved PIDs at Handle Servers hosted at GWDG. The data set for PID resolving data consists of 1.294.668 target URLs in total for a time span between June 2014 and August 2014. The five Handle prefixes with the top-most resolution at the time span have been selected.

The box plots in Figure 7 show that real-world Magnet Link collections share a comparable string length distribution with Handle PID target URLs. To investigate the relation between PID size and the PID resolution performance, we measured the resolutions performance with PIDs of a defined size (c.f. Figure 8). The measurements were done at the LHS, hosting the Handle Prefix 11022 at GWDG with suppressed caching support to measure raw resolution times. It can be observed that the resolution time is slightly increasing for a number of milliseconds for extreme PID sizes with 32 768 characters. With the average PID size derived from the Pirate Bay data set of 97 characters (c.f. with the 2^7 bar in Figure 8), the impact of Magnet Link usage in PID is not perceivable to users. As a result, the PID replication and resolution can be expected similar to the existing target URL-based approach. Embedding Magnet Links in PIDs has no significant impact on the size

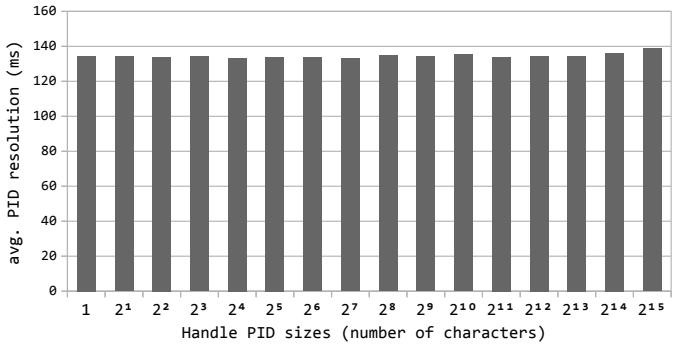

Figure 8: Average resolution time of Handle PIDs with different target URL lengths measured at the GWDG LHS for the Handle Prefix 11022.

of PIDs and underlines the practical usability of the concepts presented in this paper. Hence, Magnet Link enabled PIDs will not resolved into location-independent targets slower than current state-of-the-art Handle PIDs. The PID resolution time t_r can be assumed to be identical.

The second part of the evaluation is the data download speed provided from the location-independent data access. For BitTorrent and NDN the time for bootstrapping t_b the node and initiate a data download from the swarm is time intensive. Bootstrapping includes in the case of BitTorrent joining the DHT. The latter is very fast, although state-of-the-art DHT joining is accelerated through hard-coded bootstrapping servers. For NDN bootstrapping includes learning the node environments and the name routes. Different NDN bootstrapping algorithms are subject of current research [36].

After successful bootstrapping the advantages can speed up data transfer. If a peer is found that offer data access the download speed is at least comparable to existing location-based access that uses HTTP for download. If more than one peer is found, the bandwidth can be utilized to provide simultaneous data transfers, too. In this case the data volume v is split into n parts and the longest transfer $max()$ time of chunk is setting the overall transmission time as most time consuming partial transfer. Hence, the transfer duration d_{tr} of the first transfer through PID can be estimated as

$$d_{tr} = t_r + t_b + max\left(\frac{v_n}{v/sec}\right) \quad (1)$$

This parallelization results in higher download bandwidth and short transmission duration. Thus, for large download volumes the data access starting from PID resolution to download completion is faster. For small download volumes the completion time is longer in comparison to traditional data access through PID. Traditional location-based approaches using HTTP with no multi-source download capabilities have a transfer duration of

$$d_{tr} = t_r + \sum_{n=0}^{N} \frac{v_n}{v/sec} \quad (2)$$

where the duration is the sum of all partial volumes that are downloaded in serial.

Besides the performance aspects, it is observable that the PID usage of the PID infrastructure usage has an impact on the string length distribution of the target URLs. The top 4 prefix has a dense character distribution that is caused by the fixed pattern of the target URL, where only parts of the URL are varying. This is caused by the repository software that is managing the PIDs and uses IDs with similar length for ever data set. In contrast, the top four prefix shows a sparse distribution of target URL string length caused by almost non-systematic target PIDs. This distribution can be found by PID System operator that offer PID services to a large group of institutions like EPIC [29].

IX. Future Work

Despite our contribution to the PID efforts in the Handle System challenges provide open research questions for future work. The support for non-URL targets in HTTP-based Handle PID resolution could be moved into the existing Handle stack. By this, resources can be directly linked in the typical workflows that end-user facilitate in their Web browsers. Thus, location-independent access through PIDs in the Handle system could work with click, as simple as opening a PDF file. Fortunately, the Handle PID is very well designed and implemented by CNRI, and the source code is available.

A number of challenges arises from the usage of Magnet Links. The Magnet URI scheme originates in the file sharing community and has evolved in the past decade. Despite being a community effort, it is widely used by the most frequented file sharing search engines. For usage in the research data community, Magnet URI community contributions and drafts have to be collected and a standardisation effort needs to be started, e.g., as an initial IETF draft. The relation between Magnet URI and URN will facilitate the standardisation efforts and help to improve the reputation of Magnet Links.

Moreover, we propose using Magnet Links in the NDN community for encoding of full access information. Magnet Links could be one appropriate container format for transmitting NDN access information, which is closer to the original idea of object identification, based on URN, rather than location identification done with current NDN concepts based on URL. Similar approaches have been provided for other content-centric network like Open NetINF and proposed at IETF [37].

X. Conclusion

The integration of location independent data access in persistent identifiers is feasible without major modification of PID infrastructure. The Magnet URI scheme is suitable container for storing application independent access information inside Handle PIDs although it currently lacks IETF standardisation. As illustrated in our evaluation, their usage has no major implication on PID System operation and usage. Employing Magnet Link enables the creation of maintenance free PIDs, which do not require target URL adjustments and thus reduce the residual efforts on data repository owner sides. With the

support of overlay network usage and NDN data access, *better* data dissemination is achievable with augmented resilience through multi-peer data hosting.

ACKNOWLEDGMENTS

We like to thank Sven Bingert from the European Persistent Identifier Consortium for his support on the Handle evaluation infrastructure used for this paper. 5th International Conference on Wireless Sensor Networks

TOPICS

DEVELOPMENT of sensor nodes and networks
Sensor Circuits and Sensor devices – HW

- Applications and Programming of Sensor Network – SW
- Architectures, Protocols and Algorithms of Sensor Network
- Modeling and Simulation of WSN behavior
- Operating systems

Problems dealt in the process of WSN development

- Distributed data processing
- Communication/Standardization of communication protocols
- Time synchronization of sensor network components
- Distribution and auto-localization of sensor network components
- WSN life-time/energy requirements/energy harvesting
- Reliability, Services, QoS and Fault Tolerance in Sensor Networks
- Security and Monitoring of Sensor Networks
- Legal and ethical aspects related to the integration of sensor networks

Applications of WSN

- Military
- Health-care
- Environment monitoring
- Transportation & Infrastructure
- Precision agriculture
- Industry application
- Security systems and Surveillance
- Home automation
- Entertainment – integration of WSN into the social networks
- Other interesting applications

EVENT CHAIRS

***Abstract*—Speed measurement is an important issue for some types of Wireless Sensor Networks (WSN), especially for Vehicular Ad-hoc Networks (VANETs). However, calculating this value is error-prone and costly. This report intends to demonstrate the calculation of speed of an object without the use of any additional devices or sensor boards, only using Received Signal Strength Indication (RSSI) for localization of the vehicles and time calculation using synchronization. We implemented these methods in actual IRIS motes, and tested them. The results show that, while not perfectly accurate, our method proved to be reliable and close to the real speed. In addition, the results do not have any linear correlation in divergence of real speed and calculated speed, which means the system avoids systematic errors.**

I. Introduction

NOWADAYS, Wireless Sensor Networks form a big part of our networks and their utilization has seen a rapid increase. This growth is effected due to newly developed wireless multimedia services and attributions such as data, voice and video [1]. In this way, WSN have started to play a significant role in our everyday life. They have a wide range of applications, from monitoring the environment and the human body to industrial and military applications which are slowly becoming ubiquitous [2].

Mobility is a major issue for several WSN applications. An example of a useful application is in the branch of VANETs, a subclass of Mobile Ad-hoc Networks (MANETs), which relies on vehicles to provide functionality. Their approach is of great importance to Intelligent Transportation Systems (ITS). The main differences between normal MANETs and VANETs are the mobility constraints, high mobility, and the driver's behaviour all of which are found in the latter [3]. VANETs provide a variety of applications that ranging from safety solutions, collision detection and crash avoidance to Internet access and multimedia [4]. These applications are expected to be deployed on a larger scale in the future due to their usefulness, for example in providing safety to drivers or enhancing inter-vehicle communication [1].

VANETs make use of several traffic flow parameters to perform the monitoring, such as speed of the vehicle. Several methods have been implemented to calculate this parameter, for example: Global Positioning System (GPS)localization[5], the Laser Doppler Techniques[6], or Received-Signal-Strength(RSS)[5]. Most of these methods need additional devices for their calculation such as directional antenna [7] or GPS module that can increase the cost of deployment.

In this report, a simple method using RSSI according to characteristics and attributes of VANETs mobility model was implemented. We are modelling a street by using some IRIS motes as fixed nodes for gathering data as the infrastructure of the network, and send information of cars to our base station. The base station calculates the velocity of cars by means of this data.

The paper is organized in seven sections: Section 2 discusses related works. Section 3 explains the methodology. In section 4, various advantages and disadvantages of the chosen approach are discussed. Section 5 explains further challenges. Results of experimental measurements are provided in section 6. In section 7 conclusions are drawn.

II. Related works

There exist several ways to measure the speed of a moving object. This is of particular interest to law-enforcement for speed limits of vehicles on the roads. The most popular and widespread method is through the use of radio signals.

In this section previous approaches and works on this topic are highlighted.

A. Doppler Effect

Doppler radar speed measuring unit: Radar guns or speed guns are commonly used in the enforcement of speed limits on highways. They employ the doppler effect to measure the speed of moving objects by detecting a change in frequency of the returned radar signal. From the difference in frequency, the speed of the object can be calculated.

There are two types of speed guns[6]: Stationary and moving radar. For the stationary radar, a signal with a frequency equal to this difference is created by mixing the received radio signal with a little of the transmitted signal. These two radio signals are mixed to create a "beat" signal (called a heterodyne) and an electrical circuit that measures this frequency using a digital counter and displays the number on a digital display as the object's speed. In moving radars, a gun receives reflected signals from both the target vehicle and stationary background objects such as the road surface, nearby road signs, guard rails and street light poles.

978-83-60810-90-3/$25.00

Although very useful, this method has several drawbacks. In order to function correctly, radio waves must leave the gun in a narrow beam that do not spread out much to avoid receiving a false return from nearby objects or vehicles. Another disadvantage, is that user training and certification are required so that a radar operator can use the equipment effectively. They also do not work very well in traffic and significant vehicle separation is needed to ensure an accurate measurement.

B. GPS

GPS tracking units: The Global Positioning System is another technology that can be utilized to obtain the speed of a vehicle. It provides time and location information, regardless of the weather, or the location on Earth. A GPS tracking unit is a device that uses the Global Positioning System to determine the precise location of a vehicle, person, or other objects; to which it is attached and to record the position of the asset at regular intervals. The recorded location data can be stored within the tracking unit, or it may be transmitted to a central location data base, or internet-connected computer, using a cellular (GPRS or SMS), radio, or satellite modem embedded in the unit.

One type of GPS tracking unit is the data pusher; that is used for asset tracking, personal tracking and Vehicle tracking systems. Also known as a GPS beacon, this kind of device sends the position of the device as well as other information to a determined server to be stored and analysed. By knowing the exact location of a moving object, its speed can be easily calculated, thus making GPS a tool for obtaining the said value.

C. Other methods

LiDAR speed gun: LiDAR is a remote sensing technology that measures distance by illuminating a target with a laser and analysing the reflected light. The term is a portmanteau of ”light” and ”radar.” The police uses LiDAR[6] speed guns for speed limit enforcement, which in turn use LiDAR technology to detect the speed of a vehicle. Unlike radar speed guns, which rely on doppler shifts to measure the speed of a vehicle, these devices allow a police officer to measure the speed of an individual vehicle within a stream of traffic.

RSSI: RSS is defined as the voltage measured by a receiver's received signal strength indicator (RSSI) circuit. Often, RSS is equivalently reported as measured power, i.e., the squared magnitude of the signal strength. We can consider the RSS of acoustic, RF, or other signals. Wireless sensors communicate with neighbouring sensors, so the RSS of RF signals can be measured by each receiver during normal data communication without presenting additional bandwidth or energy requirements. RSS measurements are relatively inexpensive and simple to implement in hardware. Some approaches used for localization are Time of Arrival (ToA) [5] , Angle of Arrival (AoA) [7] and Triangulation Method [8].

The Infra-Red Traffic Logger: The Infra-Red Traffic Logger, more commonly known simply by the acronym TIRTL, is a multi-purpose traffic sensor that can be used as a traffic counter, speed sensor, red light camera sensor, heavy vehicle tracker, over-height vehicle sensor, rail crossing sensor and network management system.

The system consists of a receiver unit and transmitter unit placed on opposite sides of the road perpendicular to the direction of travel. The transmitter sends two cones of infra-red light across the roadway, and the receiver records vehicles as they break and remake these cones [9].

D. Chosen approach

This project aims at demonstrating how to calculate the speed of an object, particularly a vehicle, which moves from one point to another by using only traditional wireless sensor motes without the aid of any specialized sensor boards. In order to obtain said speed, two measures are required: distance and time elapsed. For our project, the distance is a set value, which is given by the distance between two fixed nodes. The time elapsed however, is the main concern. It is calculated by using the RSSI approach to obtain the approximate point in time and space in which the vehicle passes through a fixed point. The higher the received signal, the closer the vehicle is to the fixed point. This allows calculating the difference in times between the nodes, and thus, obtain also the total time elapsed while the vehicle stayed between these fixed points. Implementing other procedures such as GPS to obtain the location of the moving nodes results in high costs and is not energy efficient. Therefore it is intended to demonstrate that a simpler and cheaper approach can be applied with approximately equal effectiveness, rather than a costly and complex one such as GPS or radar based systems.

III. Methodology

In this section, the methodology and experimental setup will be described in details.

A. Lab setup

Sending nodes: These are the main target of the project. A wireless mote is attached to the vehicles or moving objects. It will be constantly sending dummy packets, which also contain the nodes ID to be processed by the fixed nodes. The

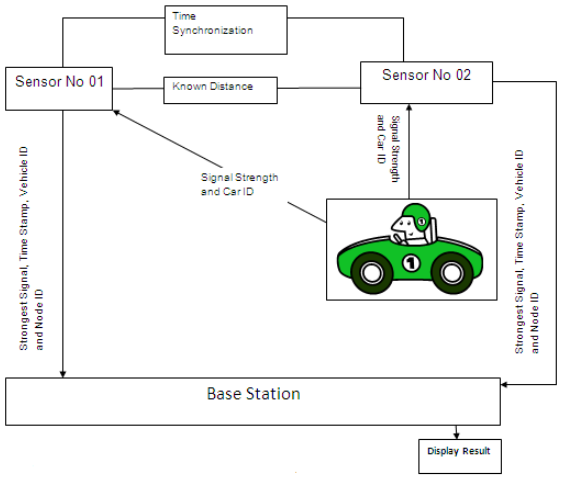

Fig. 1: Overview diagram.

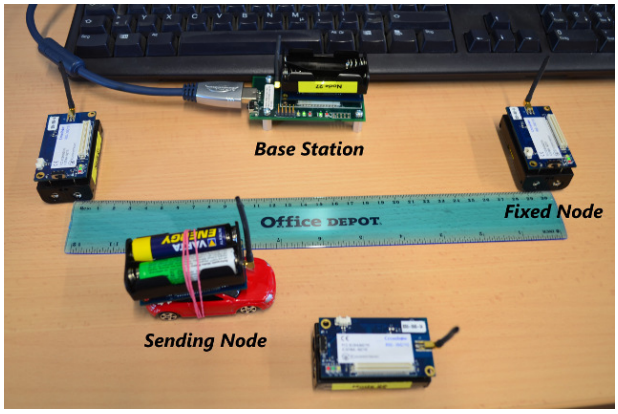

Fig. 2: Lab setup.

ID distinguishes all the different moving nodes. The speed measurement obtained at the end of the process is calculated based on the linear speed of this node assuming it has a constant speed and moves in a linear path. It then sends the packets at a high speed in order to achieve a higher accuracy.

Fixed node: Its function is to receive data, i.e. sense the moving motes and receive their ID and send it to the Base Station. In these motes, the RSSI for the packets sent by vehicular nodes is obtained, as well as the time-stamp of the moment in which the packets are received from the moving mote. Only the strongest signals are chosen to be sent to the Base Station together with the ID and time of receipt. These motes are scattered across the lane and have a fixed distance between them. This allows for the calculation of the speed of the vehicle in a portion of the road, between two fixed nodes.

Base station: The base station gathers the data from the fixed points and makes decisions based on the first packet having the signal strength of the moving mote. Using this information, a graphical interface is deployed to calculate the speed of the vehicle by filtering the data received and finally displaying the results.

B. Process

1. Sending packets: The mobile sending motes are the representation of the vehicles in a highway. These nodes are flashed with a program that executes the following functions: First, when the node is booted, the radio capability is enabled. This will allow communication between the node and the fixed points. Afterwards, packets are assembled by obtaining the nodes ID which will be used to identify the vehicle or object among all the different nodes. These packets are then continuously broadcast.

2. Receiving packets: Fixed motes are scattered across the lane or path which the mobile nodes pass by. They represent the second stage of the process and are flashed with a program called RssiBase that performs the following actions:

When a fixed node receives a packet from a sending node, the fixed node starts preparing a new packet with the information obtained from the sending node, that is the nodes ID, and two new values: the time-stamp and the Received Signal Strength Indication (RSSI) from said mote, which are calculated at the time of reciept. This time is synchronized by applying the Flooding Time Synchronization Protocol(FTSP).

The RSSI value of the sending nodes is used to determine when a mobile node gets to the closest point to the fixed node. When this happens, a time-stamp will allow for the calculation of the total time elapsed between fixed nodes, which is one of the values required in the formula of speed. Therefore, only the values with maximum RSSI received must be used. The fixed node calculates this from a set number of packets, which are received and compared to the previous RSSI value to determine if it is higher or not. If the new value received is higher, then it is stored along with its node ID. After a maximum amount of packets received is reached, the values are encapsulated into a packet and broadcast in order to be received by the base station.

3. Gathering data: The base station receives the packets which contain the highest RSSI received at each fixed node, along with the associated ID and timestamp. The base station mote additionally participates in time synchronization by means of the FTSP protocol.

4. Calculating and displaying the results: After gathering the information needed from all the fixed notes, the results are displayed. This is achieved by a Java application running on a PC, to which the base station is attached. It obtains the data collected from the base station and displays it in a graphical user interface. The actions executed by this program are described in the following steps:

A packet is received at the base station. First, any packets that are useless to the application are filtered out. This avoids cases like getting a second reading from the same car and same fixed node, to preserve the order of events, which could confuse calculation.

There is also another filter that checks if all the packets from the participant fixed nodes have been sent and received by the base station. Calculations can only be done when the condition is met.

After passing both filters, the elapsed time is calculated. This value is obtained by subtracting the time-stamp of the last fixed node's packet from the previous fixed node's packet, and so forth. This will result in the total time between the first and last fixed node.

The elapsed time, along with the vehicle's ID are then passed down to another function within the program, which finally calculates the vehicle's speed.

The common formula to calculate velocity is applied inside that function:

$$v = \frac{d}{t}$$

Here, "d" is the distance travelled, and "t" elapsed time. For the distance value, since the locations of fixed nodes are known, the travelled distance is simply found as shown in figure 4. A fixed distance is set before running and compiling the Java program, and is dependent on the distance between fixed nodes.

After obtaining the speed value, the speed and node ID are displayed in the GUI. (Results are given in m/s.) This process

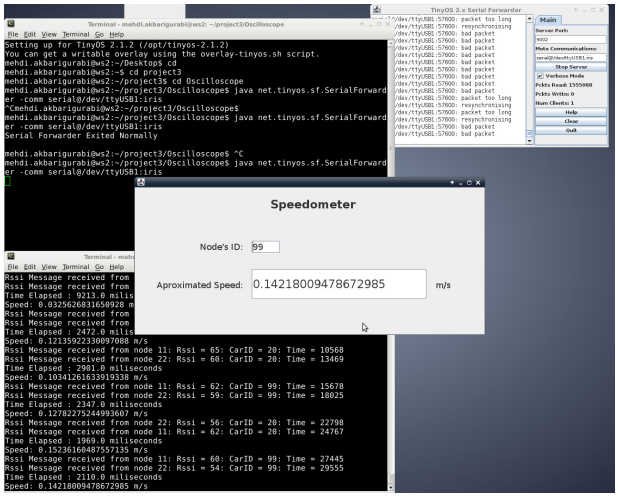

Fig. 3: Results screen.

will repeat indefinitely every time a vehicle passes by the fixed nodes from start to end.

IV. Evaluation of the approach and challenges

In the following, advantages and disadvantages of the described approach are explained.

A. Advantages

Cheaper and easier deployment compared to other approaches that require expensive or complicated tools. By using only the RSSI of the moving nodes, the time elapsed from a fixed point to another can be calculated without the need of special sensor boards or complex schemes to determine the exact moment when the node passes by a point.

By avoiding the use of additional devices, battery consumption is reduced, as opposed to cases where more power-demanding sensors are required. This also translates to lower costs spent in energy and maintenance.

According to our measurements, this approach has reasonably good accuracy.

B. Disadvantages

The approach also has some disadvantages and drawbacks, as explained in the following:

The vehicle or moving object requires a wireless sensor mote. This is the biggest drawback of the project since it will only calculate the speed of an object that has a wireless sensor mote attached to it. If it were to be implemented in a real scenario, vehicle manufacturers would have to be required to implement a similar device which can transmit similar packets. Alternatively, wireless devices of this type could be distributed to vehicle owners. Another possibility that could be investigated would be the use of ubiquitous smart phones as a packet source.

In free space, signal power decays proportional to d^2, where d is the distance between the transmitter and receiver. In real-world channels, multipath signals and shadowing are two major sources of environmental influence on the measured RSS.

Multiple signals with different amplitudes and phases arrive at the receiver, and these signals add constructively or destructively as a function of the frequency, causing frequency-selective fading [5].

These factors may lead to lower accuracy in real world scenarios.

C. Challenges

As of now, this project is very limited due to the magnitude of implementing a real life system where actual cars and fixed points are used. It can be considered a proof of concept to be built upon in future works. As explained in the previous section, several physical constraints appear.

One of the problems with this approach is that the speed of cars could surpass that which our current motes can send at. Packets can get lost easily, not arrive at the correct time or not arrive at all at the fixed nodes, which would lead to incorrect calculations. A solution to this would be deploying more powerful devices with a better transmitting power range.

Another challenge to be tackled is the scalability of the project. For simplicity reasons, we have only implemented a two-component system where one or several moving nodes pass by only two fixed nodes. Real world implementation would require several fixed nodes to have a practical use. This is because the distance between motes has to be within their transmitting range, which limits the distance for a given measurement. Therefore several fixed motes should be employed to be within the range of the network and measure a much greater distance in a highway or path for the purpose of increasing accuracy.

V. Results and discussion

In the following, the testbed is described and experimental measurements are given.

A. Test setup

To prove the effectiveness and accuracy of our project, several tests were performed. A ruler was used to set the exact distance between the fixed nodes. The ground truth is measured using a stop watch. Two IRIS nodes are used as fixed nodes, one IRIS node is attached to a toy car and one acts as a base station.

B. Steps

The system was tested by flashing all the motes with their respective programs, so they could perform their respective duties. The sending mote was attached to a toy car, and proceeded to place both of the fixed nodes at a fixed distance. We tested with four different distances. First, a distance of 30cm, then 60cm, 100cm, and finally 200cm were tested. We tried the system with different random paces: slow (around 0.2 m/s), medium (around 0.5 m/s) and fast (around 1 m/s). We test the system 10 times for each distance and speed. The measurement of time was done with a stopwatch, starting and

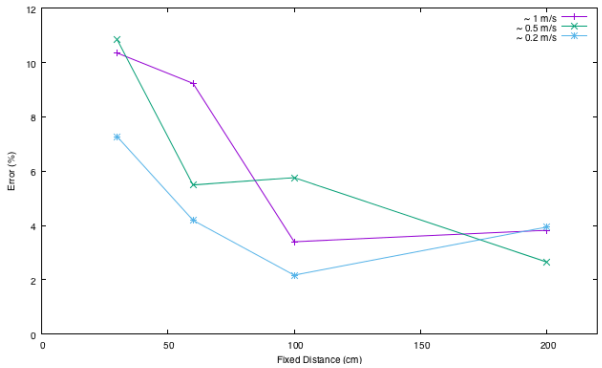

Fig. 4: Accuracy of speed calculations, Error percentage $= 100 * \left| \frac{v_{\text{real}} - v_{\text{calc}}}{v_{\text{real}}} \right|$

ending the timer whenever the sending mote passed next to one fixed node. This allowed us to obtain the total time elapsed. At the end of each test, the manual results obtained from our calculations (The real, accurate speed) with the results displayed on screen given as output from our program.

C. Results

Our results are shown in figure 4. From these results, it is observed that the error percentage between the manually measured values and the values obtained with our application is very small. The most accurate result obtained had an error of 0.94%, whereas the least accurate result had an error of 14.86%. This is out of 120 tests performed which is averaged from 10 tests per each pair of distance and speed.

Another observation is that the set of tests with the shortest distance between fixed nodes (0.30m) has the least accurate results, whereas the set of tests with the longer distances (1m or 2m) has the most accuracy. This can indicate that the closer the fixed nodes are, the less accurate calculations are obtained, possibly due to the packet's arrival times at the Base Station. Shorter paths mean that packets may arrive at close or same time. Additionally, over longer distances, small errors in measurement time will have less influence than equal errors over short distances, because the total amount of time is higher and, overall, outweighs it.

VI. Conclusion

The approach used in this project to calculate the speed of a vehicle using wireless sensor networks proved to be effective and reasonably reliable as shown in the results of the testing. Calculating the time elapsed without the aid of any extra devices or sensor boards is a big advantage, compared to the higher costs of deploying a network of several more power-consuming and expensive devices, as the RSSI of a wireless mote can be obtained without specialized sensor boards. The results show that our method proved to be reliable and close to the real velocity, and no linear correlation in difference of real and measured velocity shows that the speed measurement is free of systematic errors.

In the future, the approach can be extended in various ways, such as including more fixed nodes, using commonly available devices such as smartphones for the mobile node role and scaling everything up to a real world scenarios outside of a controlled testbed.

Abstract—**An LED-ID system works like an electronic "tag" transmitting a short digital broadcasted message. Low complexity LED-ID installations, being a subset of an emerging class of visible light communication (VLC) systems, may be considered as a replacement of popular RFID tags, Bluetooth tags and Wi-Fi beacons. In this work, we focus on multi LED-ID environments with "dense" tag placement. The problems that we focus on are estimating the level of cross-tag interference and the issue of tag proximity: how closely can we place the tags without making the system unusable? We present a theoretical model with a numerical simulation of sample arrangements. We also describe the results of experiments we conducted in a real-world test environment under different external lighting conditions.**

I. Introduction

Visible light communication (VLC) is wireless optical communication technology through which baseband signals are modulated on the light emitted by an LED [1] – [3]. The decreasing cost and hence rapid adaptation of LED-based light make VLC a promising communication technique and an excellent alternative to radio-based wireless communication. A unique feature of a VLC system is that it performs two functions simultaneously: illumination and communication. This results in a reduction of costs because a separate system for data transmission is not needed any more – existing illumination infrastructure is used instead.

VLC systems have been proposed and implemented both for indoor and outdoor applications (see [2] and [4]). Indoor applications include a range of communication facilities provided today by WLAN and personal area networks (PAN) such as office communication [5], multimedia conferencing [6], peer-to-peer data exchange, data broadcasting (especially multimedia such as home-audio and video streams – see [7] – [10]). A relatively simple VLC system is able to achieve data rates of up to 100 Mbit/s over a distance of 1 – 3 m with a single light source and a simple equalized receiver [11]. Data rates of over 1 Gbit/s have been recently obtained for more complex transmitter-receiver configurations.

One application of VLC are LED-ID platforms, which can be used in numerous environments including shops and supermarkets, museums, plenum spaces, etc. An LED-ID system works as an electronic "tag" transmitting a short digital broadcasted message. LED-ID systems, with their low complexity, may be considered as replacements of popular RFID and Bluetooth tags. An example of LED-ID systems in use are "smart" supermarket carts, which via illumination infrastructure record a shoppers' path for subsequent analysis. LED-ID systems may also be used to "tag" particular shop shelves and areas to enable fast product localization. Digital signage systems used in museums, exhibitions, etc. are another example of LED-ID technology. These signage systems may be used with specialized applications for mobile platforms to provide information about objects in proximity. Yet another LED-ID field of application arises in environments where the usage of radio-based technology, such as Bluetooth, ZigBee or RFID, is hazardous or limited by regulations, for example in mines, petrochemical plants, aeronautics and hospitals.

In comparison to more complex VLC systems, LED-ID tags are simple: their functionality is limited to broadcasting digital information. LED-ID tags typically do not provide duplex communication; tag "programming" is done via wired or wireless connections and in some cases the ID is simply hardcoded into the tag's microcontroller unit. In many cases, the tag is simple enough that it does not support cooperation in a multi-transmitter environment – it simply broadcasts its information with no regard for other tags competing for the same medium. As was explained in [12] and [13], an optical communication link can be modelled as a Poisson channel. In the general case of multiple transmitters, it was shown that the maximum total throughput of the Poisson MAC monotonically increases with the number of transmitters and is bounded from above. Therefore, adding more inputs to a Poisson

This work was supported by the Statutory Grant of the Polish Ministry of Science and Higher Education to the Institute of Computer Science, Warsaw University of Technology.

MAC eventually saturates the entropy rate (and hence the information content) of the output. Given the channel capacity limitation, a signal source with sufficient transmitting power will be able to saturate the channel, obscuring the data source. The same result may also be obtained by a larger number of low-power transmitters.

In this work, we will focus on multi LED-ID environments with "dense" VLC tag placement. Examples of such environments include article tagging on shop shelves, the tagging of individual items in museum exhibitions, and other cases where light-tagged items are placed closely together. In such environments with dense arrangements of tags, the cones of light emitted by different luminaires overlap. The problems that we focus on in this work are as follows: what measures may we use to evaluate such an environment? What is the level of cross-tag interference? How closely can we place the tags without making the system unusable?

The structure of this paper is as follows: in section II we present the architecture of LED-ID systems, which leads us to the theoretical system model then described in section III. We use the model for the numerical simulation presented in section IV. In section V, we show the results of an experiment that we conducted on a sample installation built from commercially available LED-ID components. Our work is summarized in section VI.

II. Architecture of an LED-ID system

An LED-ID system consists of a transmitter ("tag") and a receiver ("reader"). The transmitter must be able to modulate the emitted light to transmit the digital tag. It consists of a luminaire which may use one or more LEDs (typically a high power white-light LED in blue-LED / yellow phosphorous technology), an LED-driver IC and a microcontroller unit driving the amplifier.

The critical difference between VLC and radio-based communication is that in VLC, data can not be encoded in the phaseof the light signal. The information has to be encoded in the varying intensity of the emitted light. The demodulation depends on direct detection at the receiver - hence IM/DD (Intensity Modulated/Direct Detection) modulation techniques are used in VLC. Modulation in VLC must also take into account the requirements of dimming and flicker mitigation. Various modulation schemes have been proposed for VLC systems, including:

- On-Off Keying (OOK) - the data bits 1 and 0 are transmitted by turning the LED on and off respectively. In the "0" state, the LED is not completely turned off but rather the light intensity is reduced. The advantages of OOK include its simplicity and ease of implementation.
- Pulse Width Modulation (PWM) - the widths of the pulses are adjusted based on the desired level of light dimming while the pulses themselves carry the modulated signal in the form of a square wave.
- Pulse Position Modulation (PPM) - the position of the pulse in a series of pre-defined time-slots identifies the transmitted symbol.
- Orthogonal Frequency Division Multiplexing (OFDM) - the channel is divided into multiple orthogonal subcarriers and data is sent in parallel sub-streams modulated over the subcarriers. Standard "radio-based" OFDM techniques need to be adapted for application in IM/DD techniques because OFDM generates complex-valued bipolar signals which need to be converted to real values.
- Frequency Shift Keying (FSK) – the instantaneous frequency of a constant-amplitude carrier signal is changed between two (for BFSK) or more (for MFSK) values by the baseband digital message signal.

The modulation methods described above have numerous pros and cons [14]. OFDM is very effective in high speed transmission, when inter-symbol interference and multipath fading start to dominate the channel capacity. However, it is difficult to implement OFDM with the LED-driving analogue hardware that is currently used. PWM, PPM and their numerous variants provide light dimming and a simple way to eliminate flicker while maintaining good channel bandwidth. In some cases, the dominant factor in choosing a modulation method is the hardware available and its limitations. For example, with customer mobile devices, a plug-in photodetector is the simplest and the cheapest choice (see the receiver section below), and a compatible modulation method therefore must be used – FSK in this case. In this study, we assume that FSK modulation is used, as it is currently the dominant modulation method for mobile platforms.

In general, VLC systems may use two types of receivers: (1) a photodetector – typically a photodiode (a non-imaging receiver); (2) an imaging sensor (a camera). In LED-ID systems, where low cost is an important factor, simple photodetector receivers are used. Even with no or with very simple analog equalization they provide bandwidth that is more than adequate for LED-ID applications. In customer-grade VLC, a smart-phone or a similar device is used as a reader. In this case, the phone's built-in camera could be considered as the receiving device.

However, this type of imaging sensor is very slow and inadequate for data transmission applications[1], hence plug-in photodetector modules compatible with a standard audio-in/out port are used instead.

III. System model

The components of an LED-ID system include an LED transmitter consisting of one light source and a photodiode receiver. The received signal depends on the physical characteristics of the transmitting LED, the receiver, and channel characteristics. We use ray optics theory to calculate signal and noise levels and derive adequate metrics. We assume the Multiple Input Single Output (MISO) model, with multiple transmitting LEDs and one photodiode detector. A single transmitting LED is characterized by a half-power semi-angle and central luminous intensity (measured in candelas). The receiver is a simple non-imaging photodetector with an optical filter, optical concentrator and a single photodiode element with a field of view (FOV) angle, gain, a photodetector area and conversion efficiency (measured in A/W).

The metric that we use to measure the impact of the interference is bit error rate (BER), which depends on the signal to noise ratio (SNR) and modulation scheme. The relationship between BER and SNR depends on the modulation type and modulation parameters. For binary frequency shift keying (BFSK) with non-coherent detection [15]:

$$BER_{BFSK}(SNR) = \frac{1}{2} exp\left(-\frac{SNR}{2}\right) \quad (1)$$

we calculate SNR as follows:

$$SNR_s = \frac{\overline{s_{data}^2}}{\left(N + \overline{s_{interf}^2}\right)} \quad (2)$$

where s_{data} is the data signal, s_{interf} is the signal transmitted by other luminaires, and N is noise.

The problem of noise in VLC environments has been studied in detail [16]. In general, the following noise sources should be considered:background and transmitter LED shot noise, thermal noise in the detector and the influence of inter symbol interference (ISI). The background or ambient noise comes from the sun and artificial light sources:

$$N = \sigma_{shot}^2 + \sigma_{thermal}^2 + \sigma_{ISI}^2 \quad (3)$$

where N is the total noise variance and $\sigma_{shot}, \sigma_{thermal}, \sigma_{ISI}$ is the standard variance of shot noise, thermal noise and ISI respectively. The proper estimation of noise in VLC environments is crucial in studying the maximum attainable transfer rates under various conditions and modulation schemes. The input referred noise variance depends on the signal data rate. For low data rates in the range of 10^2 – 10^4 bits/s, the major noise factor is shot noise:

$$\sigma_{shot}^2 = 2qRPB + 2qI_{bg}I_2B \quad (4)$$

Where q is the electronic charge, R is the responsivity of the photodiode, B is the equivalent noise bandwidth, P is the received power, I_{bg} is the background current, and for a p-i-n/FET receiver we assume $I_2 = 0.56$. In the multi-luminaire study that we conduct in this paper, the dominant noise factor is the interfering signal from neighboring luminaires and not physical noise itself.

Now we will present the analytical model of the optical wireless channel which will let us derive SNR and BER measures for different physical scenarios. Our analysis is based on the fundamental paper by Komine and Nakagawa [17].

A single LED is a Lambertian emitter – its radiation intensity is a cosine function of the viewing angle and is given by

$$I(\theta) = P_t \frac{(m+1)}{2\pi} cos^m(\theta) \quad (5)$$

where θ is the irradiance angle, P_t is the transmitted power and m is the order of Lambertian emission given by irradiance semi-angle $\theta_{1/2}$ (half power angle)

$$m = -\frac{\ln 2}{\ln(\cos(\theta_{1/2}))} \quad (5)$$

Light propagates from the LED to the receiver via a channel which is modeled by direct channel transfer function h_d:

[1]It is possible to use a more complex multi-light source transmitter which takes advantage of the "imaging" properties of the sensor, however this is much more expensive than a simple single luminaire solution.

$$h_d = \begin{cases} \frac{(m+1)A\cos^m(\theta)}{2\pi d^2}\cos(\psi)\,R(\psi) & 0 \le \theta \le \theta_{FOV} \\ 0 & \theta > \theta_{FOV} \end{cases} \quad (7)$$

whereθ is the irradiance angle, ψ is the angle of incidence, A is the receiver area, $R(\psi)$ is receiver gain, d is the distance from the LED to the receiver and $\theta_{FOV}$is the receiver's FOV semi-angle. The geometric model of this simple line of sight (LOS) case is shown in Fig. 1.

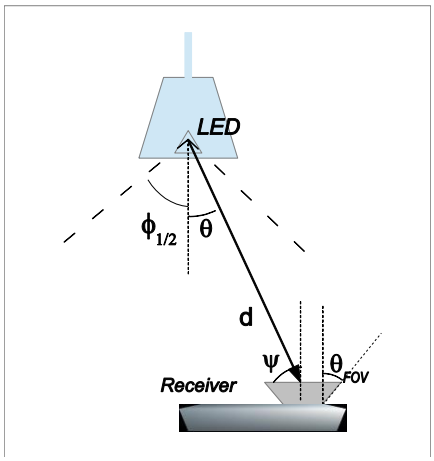

Fig. 1. Geometric model of LOS communication

For a single source, the output signal of the LED transmitter is given by the following general formula:

$$p_0(t) = P_t[1 + \mu\, x(t)] \quad (8)$$

where$P_t$is the power transmittedfrom a single LED, μ is the modulation index and *x(t)* is the modulating signal. Assuming that the receiver is DC blocked, we get the following general formula for the received signal:

$$s(t) = h_d P_t\, \mu\, x(t) \quad (9)$$

Considering the "legitimate" and "interfering" sets of transmitters, we obtain the following:

$$s_{data}(t) = \sum_{data\_LEDs} \{P_{LED}\, \mu\, x(t) h_d\} \quad (10)$$

$$s_{interf}(t) = \sum_{interf\_LEDs} \{P_{LED}\, \mu\, x(t) h_d\} \quad (11)$$

We use (10) and (11) in a numerical model to calculate BER as given in (1) for our study.

IV. Simulation results

For our numerical simulations, we designed sample scenarios with 3 and 9 luminaires. The scenarios' dimensions are 2m x 2 m x 2m. We assume that the detector's photodiode is parallel to the luminaire plane. We simulated two luminaire placement scenarios: L1 - with 3 luminaires arranged in a line as shown in Fig. 2,and scenario G1 - with 9 luminaires arranged in a 3x3 square gridas shown in Fig. 3. The first scenario relates to a "shop shelf" arrangement and the second to an exhibition cabinet or stand. The physical parameters are summarized in Table I.

TABLE I
PHYSICAL PARAMETERS OF THE SIMULATED SCENARIOS

Photodetector parameters	
FOV (field of view)	60^o
Detector area	1 cm^2
Detector gain	1.3
Scenario parameters	
Dimensions	2m x 2 m x 2 m
Luminaire spacingΔx, Δy	L1: 16 cm G1: 16 cm, 16 cm
# of luminaires, scenario L1, G2	3, 9
Luminaire parameters	
Optical power	1 W
Radiation semi-angle	20^o

In both scenarios we show the logarithmic plots of the computed BER for data transmission. We assume that the BER level of maximum 10^{-2} is required for effective transmission of the LED-ID tag.

In scenario L1 we calculated BER for outer lamps, while the inner lamp is the interfering transmitter. BER is calculated on a plane at a distance of 30, 40 and 50 cm from the luminaire plane – Fig. 4. BER decreases as we move the receiver away from the luminaires and achieves values in the range of 10^{-6}, 10^{-2} and 10^{-1} respectively. We can conclude that BER becomes intolerably high when the light cones (as limited by the radiation semi-angle) start to fully overlap each other, i.e. when the radius of the luminaire light cones is equal to the distance of their centers.

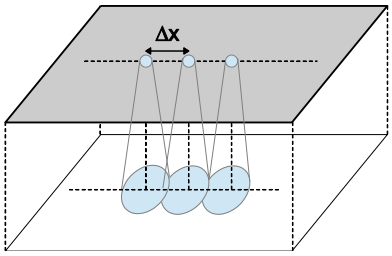

Fig. 2. Simulated scenario arrangement L1.

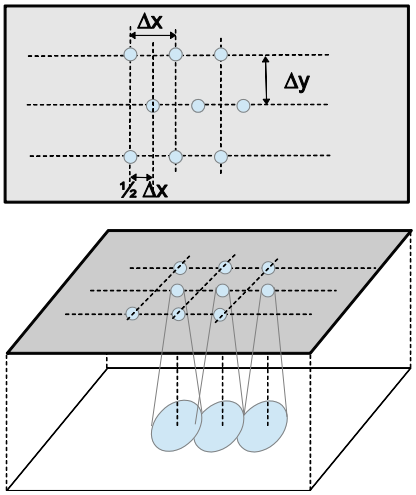

Fig. 3. Simulated scenario arrangement G1.

In scenario G1 we also calculated BER on a plane at a distance of 30, 40 and 50 cm from the luminaire plane – Fig. 5. BER decreases as we move the receiver away from the luminaires and achieves values in the range of 10^{-6} 10^{-2} and 10^{-1} respectively. The LED-ID tag under respective luminaires can be properly resolved, as was in the case of a single luminaire line.

The scenarios prove that the resolution of LED-ID tagging is quite satisfactory – even with dense luminaire placement, we are still able to obtain a reliable tag readout.

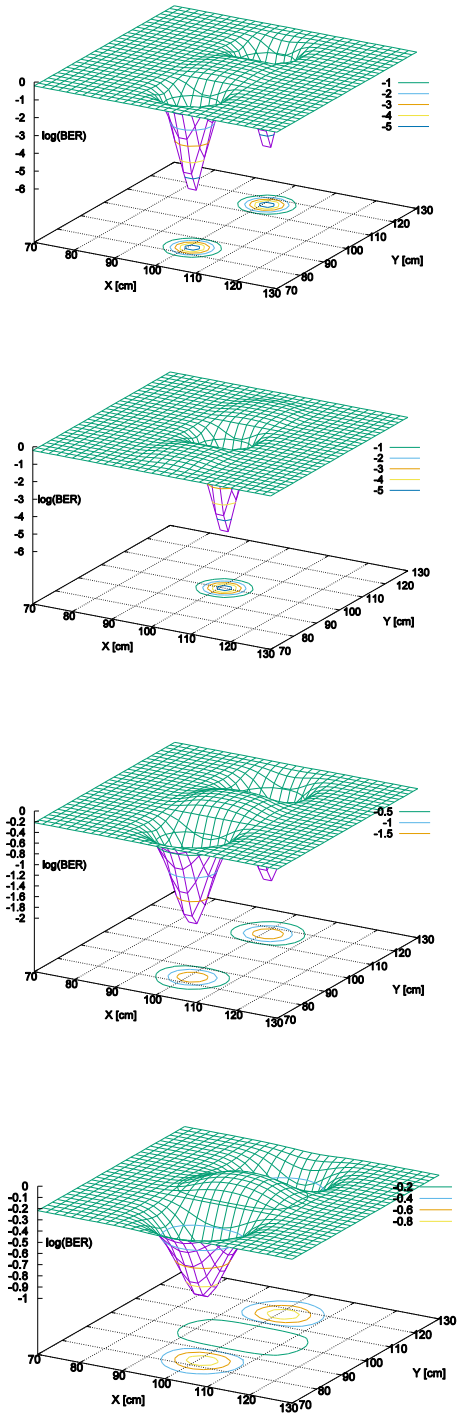

Fig.4.BER - simulation results for scenario L1. From top: (1) outer luminaires, distance 30 cm; (2) inner luminaire, distance 30 cm; (3) outer luminaires, distance 40cm; (4) outer luminaires, distance 50cm.

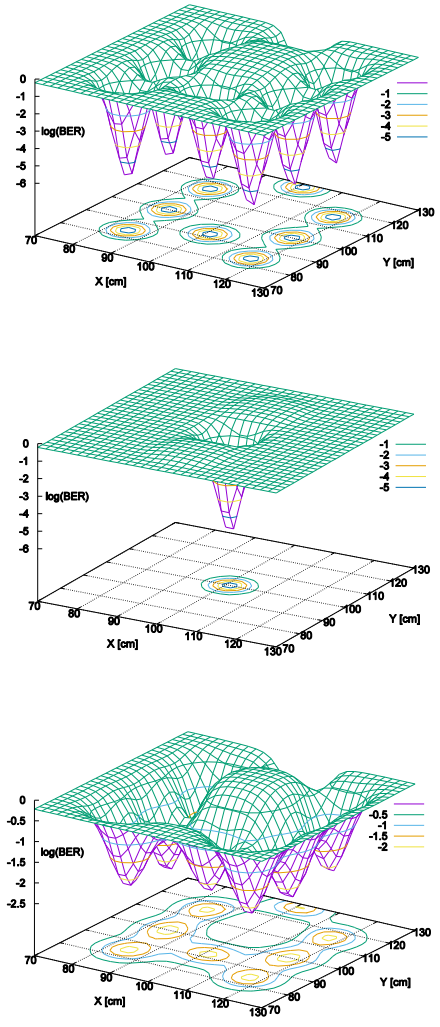

Fig. 5.BER - simulation results for scenario G1. From top: (1) outer luminaires, distance 30 cm; (2) inner luminaire, distance 30 cm; (3) outer luminaires, distance 40cm.

V. SAMPLE SYSTEM EVALUATION RESULTS

For our experiments, we used LED-ID devices manufactured by OLEDCOMM as shown in Fig.6. These luminaires came in the form of a desktop lamp with a 1W single LED light source, with a ~15^{o} radiation semi-angle (as declared by the manufacturer, this parameter varies from unit to unit, and in most cases is a few degrees larger than declared). The luminous flux when measured 50 cm from the light source is ~ 900 lx (it varies by 5% between different luminaires). The OLEDCOMM kit also contained an audio-port plugin receiver compatible with most Android devices and an SDK library. The receiver uses a simple PIN photodiode with no optical concentrator or filter.

Fig.6. LED-ID equipment used in experiments

For the tests, we implemented a client-server test suite consisting of an Android client program written in Java which gathers information regarding light intensity and lamp-ID numeric tags as reported by the library and sends it to the data-collecting server. The client has provisions for recording semi-automatic LED-sensor distance and is also able to buffer the data if the server is not accessible. Collected data may be manually tagged in the application to record various field conditions such as test series name, external illumination conditions, etc. The server stores data received for the client for further analysis. The server was implemented with the Django Rest Framework [18].

A. Testing under various field conditions

To establish the baselines, we tested three sets of communication kits under the following external light conditions: (1) minimal external light source (< 10 lx); (2) ambient dispersed light (50-200lx); (3) unmodulated direct light from an external LED source (up to 3000 lx); (4) direct sunlight (3000 – 5000 lx). The ambient light intensity levels were measured with a certified lux meter.

In each case we measured the maximum distance that guaranteed reliable ID transmission (5 tags correctly received in sequence). Measurements were collected with 1 - 5 cm intervals for d and x values – see Fig. 7, for 3 different luminaires and repeated 2-3 times.The results were averaged. As expected, we can conclude that as interfering conditions vary, so does the maximum reliable distance and to the lesser extent the maximum reliable angle. Table II summarizes the obtained data.

TABLE II
MAXIMUM DISTANCE AND MAXIMUM ANGLE FOR RELIABLE TRANSMISSION UNDER DIFFERENT CONDITIONS

Condition	Maximum reliable distance [cm]	Maximum reliable angle [deg]
Declared	370	30
Measured w/o and with interfering light sources		
No external light	250	38
Ambientlight	230-240	34
Unmodulated LED	100-220	36
Direct sunlight	60-180	26

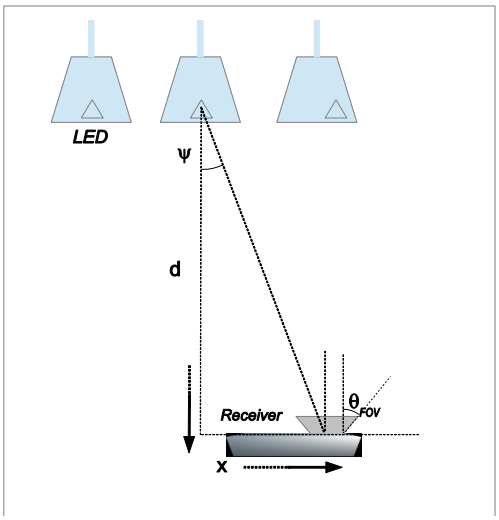

Fig.7. Single and multiple transmitter experiment setup.

B. Testing with multiple luminaires

The experiment was set up to verify simulation results. We used three lamps, placed at a distance of 16 cm from each other. We collected tag read-outs with the receiver moving directly under the lamps on a parallel plane distanced 30 cm from the luminaires(*d*). The horizontal distance corresponds to *x* from Fig. 7. Fig.8 shows the obtained results – the resolution of tag readouts is compatible with the results of the simulation, and the error rate (number of bad or inconclusive tag readouts) was ~ 5%, with errors occurring in the transition area.

VI. CONCLUSION

We tested a multi-tag LED-ID system both via numeric simulations and by means of an experiment. We have concluded that in a dense transmitter setup, i.e. with overlapping light cones, it is still possible to resolve transmitted digitaltags, up to the point where light cones start to totally overlap. The methodology that we have presented should be useful for planning more complex LED-ID scenarios.It should also be helpful to the vendors of LED-ID hardware.

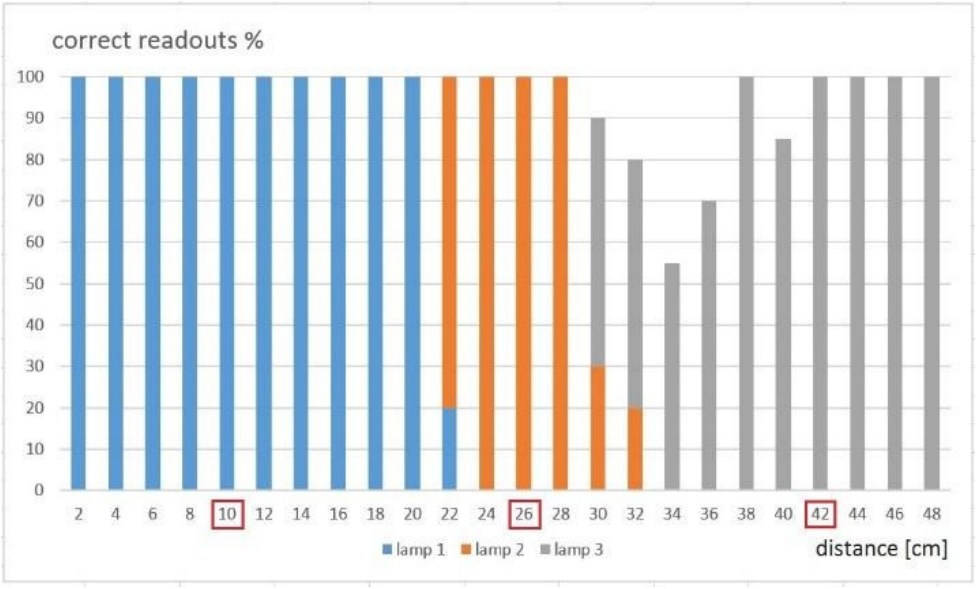

Fig.8. Summary of tag readouts from experiment. Transmitters were placed at positions: 10, 26, 42 cm (marked as squares on the axis).

***Abstract*—Radio signals can be used to detect the presence of a person (target) in an environment by analysing the fluctuations in the Received Signal Strength Indicator (RSSI). The velocity of the target can be estimated by examining the sequence of disturbances in consecutive radio links over a period of time. This requires knowledge of the deployment of the radio transceivers and the time when the target crosses the Line of Sight (LoS) of each radio link. However, it is not trivial to precisely estimate the exact time of the link crossing due to the broad range of RSSI fluctuations generated as the target approaches the link. In this paper, we evaluate and compare 15 techniques for estimating the velocity of the target and propose enhancements to some of the techniques. In our experiments the techniques perform with an average accuracy in the range between 13.02% and 96.18%, which corresponds to an average error of 0.05m/s for a moving target.**

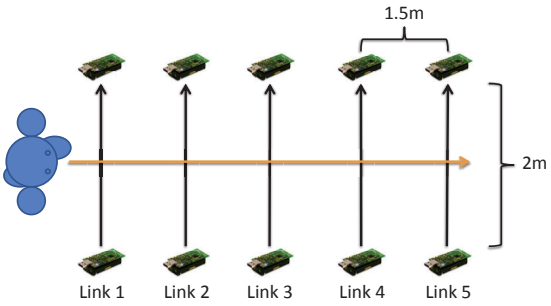

Fig. 1. Concept diagram of experiment set-up

I. Introduction

WIRELESS sensor networks (WSN) have been the interest of the research community for many years. They consist of a number of small, affordable devices (*motes*), typically equipped with a microprocessor, some sensors, for example a light or humidity sensor, and a transceiver chip for radio transmissions. Traditionally, WSNs are used to monitor environments for long-term changes in attributes like temperature, but recent studies have shown, that they can also be used to detect the presence of persons by analysing disturbances in the radio links between the motes [1], [2], [3], [4], [5].

Generally, if a person (the target) enters a radio link, the human body causes multipath fading of the radio signal [2]. This is detected by analysing for example the *Received Signal Strength Indicator* (RSSI) of the transmission. The resulting characteristic of the RSSI values will show the presence of a target, but can take different shapes. A highly sensitive link will react early to the presence of a human. The collected RSSI samples will have strongly varying values in a relatively large time interval, even when the target is still some distance away. On the other hand human presence might only create a few higher or lower spikes than the average RSSI signal on an insensitive link. Furthermore, if the target is not just standing still, but moving through the link, this will cause additional fluctuations in the RSSI values [6].

In addition to simply detecting a target it is also possible to estimate the targets' position. One approach would be employing a grid of motes, creating a mesh of multiple radio links [3]. If events are simultaneously detected on several intersecting links, the targets' position can be estimated at this intersection. To track a target through such a system, the detection can be repeated periodically, each time updating the targets' position. Using multiple position estimates it is also possible to derive further information about the targets' behaviour, for example the targets' trajectory or velocity.

There are various reasons why determining the velocity of a target can be useful. For example in a system tracking not one but multiple targets, like in [7], [8], [9], it is beneficial to not only know the position of every target, but also to predict future positions. This information can be used to differentiate between two targets crossing their paths in close vicinity [9]. Knowing the direction and speed is also interesting when monitoring an area where only a limited amount of sensors is available. Since the coverage might be too sparse to allow continuous tracking, a general idea about the movement could be helpful, especially when monitoring an area with movement restrictions. For example, if monitored targets are moving towards a dangerous location, like a broken elevator shaft or the site of a fire, then an alarm sound could be triggered to prevent possible harm.

In any case, the challenge of deducing additional information from the pure detection of a target lies in pinpointing a precise moment within the detection event. This moment should be identifiable, even when the radio link behaviour is different. For our experiments we use the point of the detection event when the target has the greatest influence on the RSSI, which we define as the peak. Since humans are three

978-83-60810-90-3/$25.00

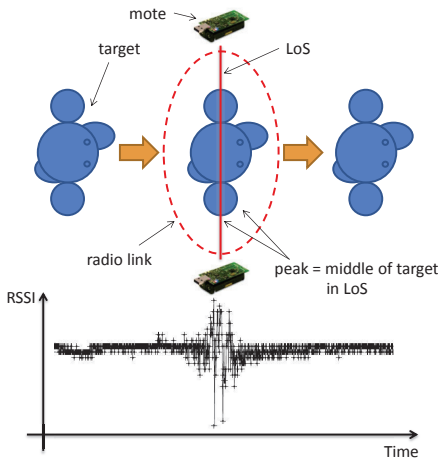

Fig. 2. Target passing the Line of Sight of a radio link

dimensional, it takes a certain time for a target to pass a radio link, as seen in Fig. 2. The peak can be seen as the point in time, when the middle of the target is in the Line of Sight of the link [4]. The goal of this paper is to evaluate 15 different techniques on how to best detect the velocity of a target with the highest possible accuracy. For this we estimate the peak of the radio link crossing event and use the generated results in the velocity estimation of a target moving at different speeds.

Consider the velocity estimation following the simple formula $v = \frac{s}{t}$ as an example. To compute the speed of a target, the locations of at least two radio links are required, and the RSSI values and their respective timestamps are taken from the links. If a target consecutively moves through the radio links, as for example seen in Fig. 1, the actual crossing of a link is recorded as an interval of collected RSSI samples while the link was disturbed. The detection events on both links need to be identified to estimate the time it took the target to cross the distance between the links. Because of the unsteady nature of the RSSI it is not possible to simply use the earliest distorted sample, since its occurrence can be different for dissimilar links. For accurate velocity estimation we have to identify the targets position in the link, respectively for each link. However, the best samples to indicate the actual crossing do not necessarily need to be the samples with the highest RSSI attenuation or the middle sample of the collected interval. The different link states and general fluctuation in the RSSI distort the collected data and make accurate predictions difficult.

The remainder of this paper is structured as follows: Section II gives an overview of research similar to our approach. Section III describes the different techniques used, followed by an evaluation which details the results of our experiments in Section IV. The paper is concluded in Section V with a summary and a short outlook.

II. Related Work

Traditionally, instead of using the RSSI to record an event, a system detecting the presence of a target can be based on using a laser range finder. A range finder emits a laser beam that is reflected off of any object it hits. The reflection is caught by the light sensor of the device, the Time of Flight is measured, and the distance to the object computed. If the distance suddenly decreases, the laser beam is reflected at a shorter distance. This is the case, if a target is in the LoS between the laser emitter and the light sensor. However, using a range finder is unfavourable in scenarios, where a larger region needs to be covered, since the laser beam only stretches over a relatively narrow area. Furthermore, the sensor measuring the light intensity needs to be shielded from direct sunlight, to avoid false negatives. Also, these systems can easily be fooled, when a target is avoiding the beam by stepping over it, without interrupting it. Depending on the scenario, a RSSI-based device-free localisation system might be more suitable. Since the RSSI is already disturbed when a target moves near the radio link, avoiding it is not easily possible.

Multiple systems employing the RSSI to detect the presence of a target have been developed [2], [10], [11]. In these systems sensor nodes are deployed at all edges of the monitored area and a grid of radio links is created. A target standing or walking through the grid will cause a characteristic disturbance which can be detected [2].

However, the link characteristic is not specific to a target. In [7] multiple targets are tracked by dividing the monitored area into voxels. A target entering the area will cause disturbances in a set of voxel simultaneously, which are then clustered. Each cluster in the area symbolises a target and is tracked while in the system. But intersecting trajectories create the difficulty of continuously keeping track which target is matched to a specific cluster.

To cope with RSSI irregularities, alternatives to the use of the absolute RSSI or its average have been explored. In [8] the time of flight of radio messages is used in an antenna set-up with five transmit antennas and five receive antennas. The signals reflecting off of the human body are analysed, which allows for the tracking of up to five people. While no longer based on the absolute RSSI, like in [7] still no clear identification of the tracked target out of a group is possible.

The behaviour of the radio links is further analysed in [12]. In general, RSSI values are unstable and always slightly fluctuating because of minimal changes in the environment. Slight variations in the area, for example moving a chair or opening a window, can have a huge impact on the radio propagation. Despite that, [12] defines two classes of observed link behaviour when a target enters the link. Both are based on the different qualities of a link. An *anti-fade* link has very high RSSI values and will experience a strong attenuation and a significant drop in the RSSI values when a target enters the area of the link. A *deep-fade* link on the other hand already has a very weak signal quality. For such links it is possible that the quality increases when a target enters the link, due

to refraction and scattering of the signal. Thus, the resulting RSSI characteristic is generally an inverted version of the anti-fade one. For this reason and other environmental influences, a detection event can have a very dissimilar RSSI characteristic compared to the characteristic of an event on a different link.

The authors of [4] suggest focusing on the changes in the variance of the RSSI, instead of looking at the absolute value. Regardless whether the absolute RSSI average in- or decreases after a target enters the area of the link, the RSSI variance will always be higher, because the link gets disturbed. Fundamentally, a long-term and a short term variance are computed, compared, and incorporated to the *alert magnitude*. The larger the alert magnitude is, the more likely a target is present in the detection area. This method simultaneously reduces the influence of different link qualities but also of changes in the environment on the RSSI in long-term measurements. By adapting the long-term variance in phases of tranquillity, in which the variance of the RSSI is low, small changes in the radio propagation model caused by the environment are handled.

Using the RSSI to detect the speed of driving vehicles, [13] collects samples of the signal strength of four links covering a road section. The resulting measurements are analysed using a statistical and a curve fitting technique. In the statistical approach, the time between the entering and exiting event of the monitored area is used to estimate the speed. The curve fitting technique exploits the relation of the height of the variance and the speed of a car. The faster the car passes the monitored area, the higher is the influence on the recorded RSSI variance. However, this technique is applied to fast moving cars made of metal [14], not to humans.

III. Analysed Techniques

In this paper we analyse 15 different techniques for estimating the velocity of a target. The techniques are divided into three classes based on their input data. The techniques of the first class are working with the RSSI. They either use all available samples or search for the samples with the minimum value, as introduced in [15]. The techniques of the second class use the *alert magnitude*, the result of the RSSI variance based algorithm introduced in [4]. The techniques either select the maximum alert magnitude values or again use all available samples. We propose enhancements to the second class to form the third class of techniques. Instead of only using samples with the maximum value, more samples with high values are included into the input data. We evaluate the different methods for estimating the targets' speed in an experiment.

To accurately compute the targets' speed two things are needed: The distance travelled and the time it takes the target to do so. This can be measured for example in a system, where the crossing of the *Line of Sight* (LoS) between two sensor nodes creates a disturbance in the RSSI values of periodically sent messages. Two measures of the targets' position at two different times can be subtracted from each other to determine the distance. Since the motes in our experiments are set at fixed positions, in the evaluation we consider the distance between them as known. To determine the time, the presence of the target at each position needs to be detected and the detection event analysed. The event itself stretches over an interval consisting of several recorded RSSI samples. Each sample includes a RSSI value and a timestamp. During the recording interval, the target approaches the link, enters it, passes the Line of Sight, and leaves it again. Disturbances in the stream of RSSI values are caused during the time the target stays in the area of the radio link.

Would at this point a sensor producing a boolean result be deployed to record the disturbances, the outcome would be binary: Either a body part of the target is perceived by the sensor and the target is detected, or the sensor is not triggered and no detection is registered. However, the human movement also incorporates the swinging of arms and legs. Therefore, an event can be triggered prematurely, when for example an arm is detected before the rest of the body enters the monitored area, artificially prolonging the event. The targets' distance to the LoS of the radio link will be shifted during the whole event, when compared to the event of a different link. Also, it cannot be assumed that the LoS crossing of the target is in-line with the middle of the detection event. This reduces the accuracy of the velocity estimation.

Fortunately, in the case of detecting an event using RSSI values, the attenuation following the disturbance of the radio link is the highest when the target is closest to the LoS [16]. However, this does not necessarily make the lowest RSSI value the best point describing the event. There might be more than one recorded RSSI sample with the lowest value. Additionally, the RSSI values of a disturbed link are fluctuating. Another sample could time-wise better describe the link crossing, but may not match the lowest RSSI recorded.

The following sections illustrate the techniques to cope with these restrictions and estimate the velocity of a target moving through a group of radio links. For a better overview, all introduced techniques are listed in Table I. Afterwards, the methods are experimentally evaluated.

A. RSSI-based Techniques

The RSSI-based techniques use the unaltered data stream of RSSI values as input to estimate the events' peak and the targets' velocity. They can be found in the first column of Table I.

1) minRSSI: The first approach to identify the best RSSI sample indicating the peak is the naïve approach, abbreviated minRSSI. This appraoch was also used in [15]. The RSSI data stream of the monitored link is searched for the sample with the minimum value. If multiple samples with the same lowest value are found, all of them are collected. After the time interval of the event has been analysed, the timestamp of the first occurring sample with the lowest RSSI value is selected for the velocity estimation. This approach is easy to implement and low on computational and space complexity, since the samples can be discarded once analysed.

2) medianRSSI: The next approach, medianRSSI, does not simply collect all samples with the minimum value to select

TABLE I
APPLIED TECHNIQUES ORDERED BY INPUT DATA

Technique	Based on Value		
	Minimum RSSI	**Maximum Alert Magnitude**	**Maximum Alert Magnitude Set**
Raw	minRSSI [15]	maxAlertM [4], [13]	topMaxAlertM
Median	medianRSSI	medianAlertM	topMedianAlertM
Average	avgRSSI	avgAlertM	topAvgAlertM
Linear Regression	linRegRSSI	linRegAlertM	topLinRegAlertM
Curve Fitting	CurveFittingRSSI	CurveFitting [13]	-
Cross Correlation	CrossCorrelationRSSI	CrossCorrelation	-

the first one, but uses the timestamp of the middle sample. This change is introduced as a precaution against outliers and incorporates additional information about the order in which the samples arrive, the data stream. However, this approach ignores the timestamps of the other collected samples, which might have a beneficial influence on the peak estimation, especially when only two samples with the minimum value exist.

3) avgRSSI: Simply selecting the first sample or selecting the median sample is not always the best choice, given the fact, that an event can have a non-symmetrical characteristic. The avgRSSI approach is addressing this issue by removing the dependency on the precise timestamp of the RSSI sample. Again, all samples with the minimum RSSI value are collected, but then the average of all available timestamps is computed. The new value does not necessarily need to match the timestamp of any sample, but can take an arbitrary point in the event interval. Since the peak does not need to match the sample with the minimum value, or more precisely any single sample, this technique avoids the very limiting dependency of selecting a timestamp from a predefined set.

4) LinRegRSSI: An alternative method, which is also not bound to the exact timestamp of a sample, is the LinRegRSSI approach. LinRegRSSI models the relationship between the detected events on different links by computing a linear regression, based on the RSSI values. The input data set for this approach is the distance between the links and the timestamps of the selected samples. To obtain the necessary data, first all samples with the minimum RSSI value as well as their timestamps are collected for each link. With the distance between the links known in our scenario, the parameters of the linear regression are then estimated from the input.

The simple equation $y = m \cdot x + b$ is the equation of a linear function, where m describes the slope, b the y-intercept.The result of the linear regression is the linear function with the minimum squared error towards all input data points.

In order to estimate the velocity, data from at least two links is needed, but can be extended onto more. In our case, values from all available links are used. The slope of the resulting linear regression line equals the speed of the moving target. To get the time of the peak, the position of a link can be set as y and the equation then solved for x.

Ignoring the restrictions of having to choose a precise timestamp, this approach additionally uses information from multiple links.

5) CurveFittingRSSI: A technique introduced in [13] is the fitting of a curve to the data stream of the RSSI variance. The highest point of the curve would indicate the time of the peak. To analyse how well this performs based on the unaltered RSSI stream, we use the CurveFittingRSSI approach. A Gaussian function is fit as continuous curve to the stream of all RSSI values per link. The maximum of the resulting curve is defined by the characteristic of the detection event and will be shifted towards the highest disturbance of the link. Unfortunately this approach is rather computationally expensive, since all samples of the event interval have to be collected and incorporated into the Gaussian function.

6) CrossCorrelationRSSI: Another approach using all available RSSI samples per link is the Sliding Dot Product, also known as cross correlation. The cross correlation originates in the field of signal processing. Two signals are shifted towards each other along the x-axis, while in each step their data points are multiplied with each other. The resulting product is called the correlation coefficient coef_{cc}. The higher the correlation coefficient is, the more similar are the data streams. This method is often used to measure how far the signals need to be shifted in order for them to reach their point of highest similarity.

In this paper we use the cross correlation to sample-wise compare the data streams of two links by computing their coef_{cc}. Given the characteristic of the input data, the highest similarity is obtained when the events of both links are overlapping.

The approach works in detail as follows: The first sample of the first link is multiplied with the last sample of the second link. The resulting cross correlation coefficient is stored. Next the links are shifted towards each other by increasing the number of samples that are compared. The first two samples of the first link are compared with the last two of the other and again the correlation coefficient is stored. This is repeated until the last sample of the first link has been compared with the first sample of the last link. Afterwards, the highest correlation coefficient between the links is selected and the number of shifts to reach this coefficient is counted.

Since the frequency with which the samples are sent, is known, the number of shifts indicates how many samples have

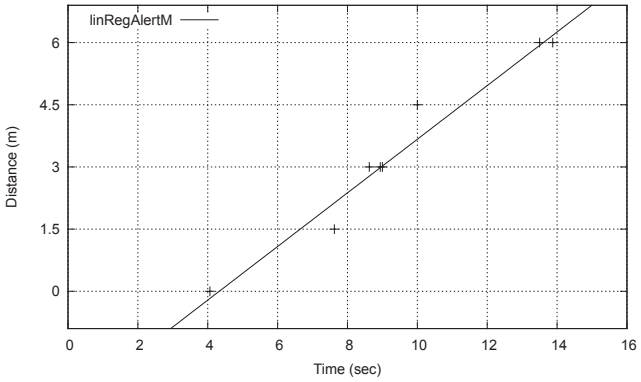

Fig. 3. Linear regression using alert magnitude values of five links

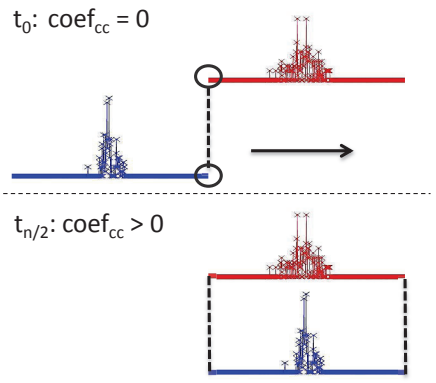

Fig. 4. General mechanism behind the cross correlation

been sent in the time it took the target to cross the space between first and second link. Analysing the sample rate we deduce the time between the LoS crossings. Strictly speaking, the cross correlation is not searching for the best sample to describe the event, but computes the velocity directly.

B. Alert Magnitude based Techniques

All unaltered RSSI-based techniques work best with anti-fading links, since they use the minimum RSSI value and on these links the maximum drop in the RSSI level is characterizing the crossing event. In the case of deep-fading links, where the signal improves after a target enters the link, a different method is needed. On those links the RSSI values near the peak are higher, even though fluctuations cause some RSSI samples to have a very low value.

To handle both cases, a RSSI variance based technique is used. Contrary to the absolute value, the variation of the RSSI always increases when a target is in the link [16]. In this paper the algorithm from [4] is applied. While the better handling of the issue of anti- and deep-fading links is addressed by changing the input data, the general issue of selecting a sample still remains the same. This being the case, the aforementioned methods of finding the peak of the LoS crossing event can also be applied on the alert magnitude.

All techniques using the alert magnitude are summarized in the second column of Table I.

1) maxAlertM: Following the given nomenclature in [4], the technique searching for the maximum alert magnitude is called maxAlertM. After all samples with the highest alert magnitude are found, the first occurring sample, which is the sample with the minimum timestamp, is selected.

2) medianAlertM: Like the medianRSSI approach, the medianAlertM approach selects the middle one of all samples with the highest alert magnitude. If an even number of samples with the same highest alert magnitude is encountered, the first occurring of the two middle samples is selected as a tie-breaker.

3) avgAlertM: The avgAlertM approach computes the average time from the timestamps of the collected samples with the highest alert magnitude. Again, this is analogous to the RSSI-based approach, in this case avgRSSI.

4) linRegAlertM: The approach to compute the linear regression, based on the alert magnitude, is LinRegAlertM. It is computed from all samples with the maximum alert magnitude of each link, using data from all available links. The resulting regression line is visualized as an example in Fig. 3. The displayed data is taken from the first run of the first measurement of our experiment. The y-axis value represents the distance of a radio link to the first link of the experiment set-up, the x-axis value represents the arrival time of the samples. For this example the distance between the links was set to 1.5 m and samples from five different links are used.

5) CurveFitting: While RSSI values are always unsteady and slightly fluctuating, the alert magnitude takes the form of a steady line, except during an event. All values are zero, as long as the link is not disturbed. However, they become greater than zero when indicating a target in the area of the radio link. This behaviour is beneficial to the CurveFitting approach, which fits a Gaussion function to all available alert magnitude values. Again, the precise time of the peak is not restricted by the timestamp of the samples.

Since the alert magnitude is based on the RSSI variance, this more closely resembles the curve fitting used in [13], then CurveFittingRSSI does.

6) CrossCorrelation: Computing the cross correlation from the alert magnitude values is the CrossCorrelation approach. The mechanism behind this approach is visualized in Fig. 4. In the beginning of the correlation process $coef_{cc}$ equals 0, but is gradually increased, when the data streams of the alert magnitude are shifted towards each other.

C. Alert Magnitude Set based Techniques

To enhance the performance of the methods using the alert magnitude and to take precautions against outliers, we introduce a new group of techniques. Instead of only searching for the samples with the maximum alert magnitude, the set

Fig. 5. Gird of motes in an lab environment

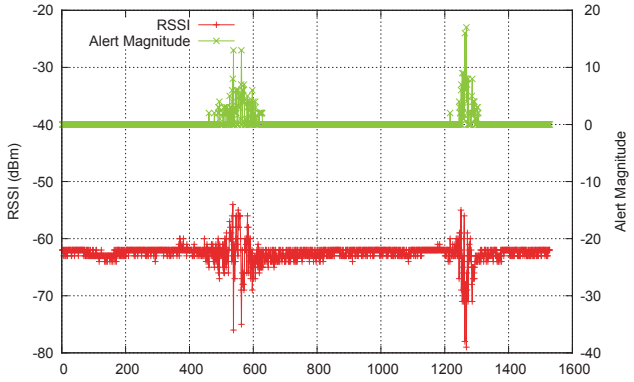

Fig. 6. Example of recorded RSSI and alert magnitude

of n samples with the highest values is collected. The value of n is analysed further in section IV. The set includes a guaranteed minimum number of n sample, but can include an even greater number, when more samples with the same high alert magnitude exist. In this case all samples are added to the set. Using a set of samples reduces the effect of the sample with the maximum alert magnitude being an outlier and thus unfavourable influencing the result.

Since the input data has been reduced to a selective subset of the complete data stream, the curve fitting and cross correlation techniques cannot be used. However, most methods estimating the velocity from the highest alert magnitude value can also be applied to this slightly enlarged set of samples.

1) topMaxAlertM: The topMaxAlertM approach uses the first occurring sample of the set with the n highest values. This could be realized by either selecting the first occurring sample with the highest alert magnitude, or the first occurring sample of the complete sample set. However, the first case is identical to the maxAlertM approach, in the second case a timestamp from the border of the event is selected, not representative for the peak.

Because of the above mentioned issues, the topMaxAlertM approach is not further considered in the evaluation.

2) topMedianAlertM: The topMedianAlertM approach selects the middle sample of collected set. This sample does not necessarily have to be the one with the highest value.

3) topAvgAlertM: The topAvgAlertM technique uses the timestamps of all samples in the collected set to estimate the time of the peak by computing the average time, again loosening the restriction of the precise timestamp.

4) topLinRegAlertM: topLinRegAlertM models the linear regression using the slightly larger data set, again with input from multiple links.

IV. Evaluation

For the evaluation of the different techniques we perform an experiment with a test set-up, as seen in Fig. 5. The set-up consists of ten Crossbow telosB sensor nodes, five on each side of a 2m wide and 6m long detection area. The motes are set in an interval of 1.5m on the same side. Radio links are formed between the motes directly opposite of each other in a way, that five consecutive links are generated across the space. During the experiment the links exhibited a mean RSSI of -62.5, -57.9, -58.3, -64.5 and -60.26 respectively from link one to link five. The motes use the TI MSP430 microcontroller and the CC2420 transceiver chip. They are sending on a frequency of 2.4 GHz and use a TDMA scheme with a 62.5 millisecond cycle time to avoid collisions. This value is chosen as a trade-off between energy consumption and detection accuracy. For our analysis all sent messages are recorded as samples using the IRIS tool introduced in [17]. IRIS is an experiment management tool, that allows for simultaneous data collection and visualisation. Samples collected can be analysed using provided or self-written functions and can be saved for further processing.

To evaluate the accuracy of the velocity estimation of a moving target, we compute the average error respective to the actual velocity. Two measurements with 12 runs each are performed in an lab environment. The error values are calculated as an average of the 12 runs for each measurement. During one experiment run, the target is entering the lab, walking crossing the links through the detection area once and then leaves the room. For the purpose of this evaluation, we assume that the target is walking with constant speed, does not suddenly change direction and walks directly in the middle of the detection area in a straight line. In the first measurement the target is walking with a speed of 0.6m/s, in the second measurement with 1.35m/s. The behaviour of the RSSI and the corresponding alert magnitude can exemplary be seen in Fig. 6. The figure shows a target crossing a link first with the slower, then with the faster speed. Markings on the floor indicating the step interval and a metronome to time the steps are used to help the target maintain constant speed, while still walking normally. Also, to not be reliant on the human perception of time, the precise moment of the LoS crossing is recorded as ground truth, using a laser based system.

The results of the measurements are summarized in Table II and Table III. Table II contains the average error in % and its Sample Standard Deviation. Column one and two list the values for the measurements with the slower speed of

TABLE II
AVERAGE ERROR AND SAMPLE STANDARD DEVIATION OF THE VELOCITY ESTIMATION

	Technique	Measurement Velocity 0.6m/s		Measurement Velocity 1.35m/s

15	topLinRegAlertM$_5$	21.73	13.32	22.76	23.45

0.6m/s, column three and four the values for the faster speed of 1.35m/s. Each row shows the results for a different technique. Table III contains the results of the measurement runs with the maximum error for each approach and the Squared Mean Error, also for both measurements and velocities.

A. RSSI

The results of the measurements using the minimum RSSI data stream, minRSSI, can be found in the first row of Table II, for both slower and faster speed. Estimating the velocity from the first found sample selected by the minRSSI has an average error of 16.8% with a sample standard deviation of 13.4 for the slow velocity measurement and 11.2% error with a deviation of 6.8 for the faster velocity. This corresponds to an absolute error in the estimation of 0.1m/s for a speed of 0.6m/s and an absolute error of 0.15m/s for a speed of 1.35m/s.

Achieving a high accuracy using this technique turns out to be easier when detecting a target walking in a faster pace. The duration of the LoS crossing event is shorter, involving fewer samples and a narrower time interval, as seen in Fig. 6.

Using the median of all samples with the minimum RSSI (medianRSSI) or the average of those (avgRSSI) does not improve the performance significantly. The deep-fade link behaviour is ignored, which leads to a less accurate event detection and higher error values.

The most accurate approach according to our results, when working with pure RSSI values, is computing a linear regression. linRegRSSI shows a slightly better performance in the measurement with slower speed, and average performance, when the target is moving faster. Since multiple links are used in this approach, irregularities of one link can be evened out by the others.

Modelling the stream of RSSI values with a Gaussian function in the CurveFittingRSSI approach is unfavourable compared to the other techniques. Since the RSSI varies around a baseline, creating both positive and negative spikes in the case of an event, CurveFittingRSSI has a very high sample standard deviation. This causes very inaccurate behaviour.

Comparing two RSSI data streams using a cross correlation is possible, but since the similarity of two links is compared, the original input data needs to be similar. The unsteady and fluctuating nature of the RSSI with a high variance during the crossing event prevents this. Also, the deep-fading and anti-fading behaviour of the RSSI creates completely different characteristics, that cannot directly be compared. The resulting error values are constantly above 80% in both our measurements and have a very small Sample Standard Deviation, achieving in the worst performance of all tested RSSI-based methods.

B. Alert Magnitude

1) maxAlertM, medianAlertM and averageAlertLevel: Using the alert magnitude as a basis for the detection achieves better results for the slow velocity measurement and similar results to the RSSI-based techniques for faster speeds. Exploitation of the RSSI variance, and by doing so coping with the deep-fade qualities of the links, is the cause of this improvement. The average estimation error of maxAlertM can be seen in row seven of Table II, the results for medianAlertM and averageAlertLevel are in row eight and nine. All three techniques perform similar to each other, with error values around 11.5% $\pm$ 1%, which is an improvement of about 4% towards the RSSI-based techniques in the 0.6m/s measurement.

2) linRegAlertM: Using the linear regression has an improvement of 5% when applied to the data of the slow velocity measurement. However, linRegAlertM shows worse performance with the data of the faster velocity measurement. The average error is 13.2%, which is 2% worse than when based on the RSSI.

TABLE III
MAXIMUM AND SQUARED MEAN ERROR OF THE VELOCITY ESTIMATION

	Technique	Measurement Velocity 0.6m/s		Measurement Velocity 1.35m/s	
		Maximum Error (%)	Squared Mean Error	Maximum Error (%)	Squared Mean Error
1	minRSSI	51.89	460.85	28.07	170.74
2	medianRSSI	51.89	492.89	28.07	179.94
3	avgRSSI	51.89	455.93	28.07	175.09
4	linRegRSSI	39.45	283.59	26.85	181.98
5	CurveFittingRSSI	85.23	828.11	69.77	1144.93
6	CrossCorrelationRSSI	87.15	7057.48	91.27	7567.14
7	maxAlertM	46.85	292.43	32.73	203.99
8	medianAlertM	46.856	288.19	32.73	214.34
9	avgAlertM	46.85	289.73	32.73	208.78
10	linRegAlertM	22.71	87.58	59.34	427.44
11	CruveFitting	46.85	292.43	32.73	203.99
12	CrossCorrelation	11.36	36.88	14.71	67.68
13	topMedianAlertM$_5$	12.77	31.61	17.74	63.30
14	topAvgAlertM$_5$	18.12	35.53	15.87	31.94
15	topLinRegAlertM$_5$	49.03	649.73	71.50	1067.68

Since the target is moving with a higher speed, the time between the LoS crossing of the links is shorter. This has an impact on the slope of the linear regression line. It is more steep and outliers have a higher influence since fewer samples are sent, explaining the behaviour in the faster velocity measurement.

3) Curve Fitting: Curve fitting is performed using all values of the respective data streams, without previous filtering for minimum RSSI or maximum alert magnitude values. Fitting a curve through the alert magnitude values achieves similar results to maxAlertM, medianAlertM and avgAlertM, as seen in row 11 of Table II. The average error is at 12% for the first measurement and at 11,6% for the second.

The results of the alert magnitude based CurveFitting achieve a higher accuracy than fitting a curve to the RSSI data stream. The steady nature of the alert magnitude, which is only interrupted in the case of a detection event, positions the maximum of the Gaussian function close to the peak of the LoS crossing. Still, the results are on the same accuracy level as maxAlertM, medianAlertM and averageAlertLevel.

4) Cross Correlation: The cross correlation computes the correlation coefficient coef$_{cc}$ between two links. To utilize the approach and estimate the velocity of a target, all possible link combinations for both measurements are analysed first. The results of this test are shown in Fig. 7. There, the average error is plotted over the distance of the links towards each other. A clear trend is visible, showing that the estimation becomes more accurate, the further the links are apart. The overall error is being reducing and the minimum and maximum error values are closer to the average. The messages for the experiment are being sent with a frequency of 62.5 milliseconds and it takes the target a certain time to cross the distance between two links. The larger the distance, the longer is the time needed to cross it and the more samples can be sent in the duration,

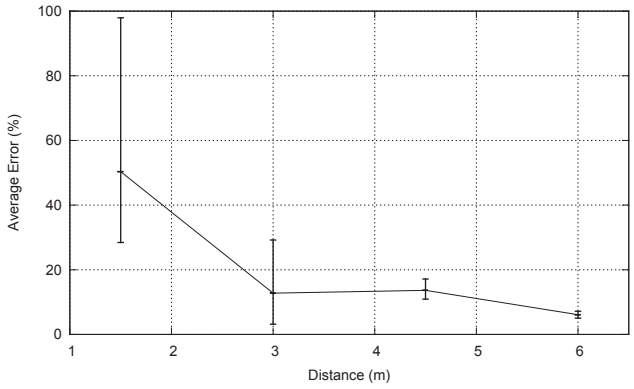

Fig. 7. Average of the velocity estimation error over the link distance

explaining the increase in the accuracy. For this reason the cross correlation between the two links farthest apart is used for the comparison with the other techniques.

As mentioned in Section IV-A, estimating the velocity using the cross correlation of the RSSI values has a very low accuracy, because of the RSSI fluctuations. However, applying it on the alert magnitude is very promising. The average error is shown in row 12 of Table II. It is at 5.0% with a sample standard deviation of 3.4 for the slow velocity measurement. For the fast velocity measurement these values are at 7.2% average error with 4.0 sample standard deviation.

These results surpass the previous techniques using the maximum alert magnitude. Since the alert magnitude values are zero except during an event, as seen in Fig. 6, the correlation coefficient reaches its maximum when the events on two different links are directly overlapping. This achieves a precise approximation of the time between the LoS crossing events on two compared links used in the velocity estimation.

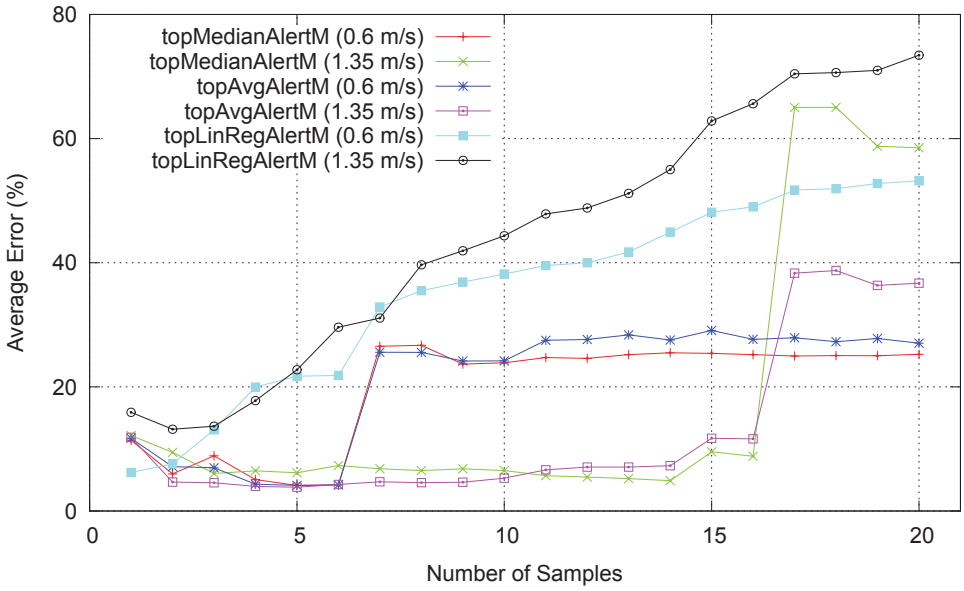

Fig. 8. Average velocity estimation errors with different sizes of alert magnitude sets

C. Alert Magnitude Set

Instead of using the sample(s) with the maximum alert magnitude, using the set of the n highest alert magnitude values can achieve a very different result. The set provides a more balanced picture of the event, since it includes all of the most interesting samples and not just the highest, reducing the influence of outliers. Unfortunately, this is not beneficial to all methods. The CurveFitting and CrossCorrelation techniques use all the samples from the complete measurement and cannot be applied on a subset. Furthermore, since the sample with the maximum alert magnitude is still in the set of the highest n samples, using the topMaxAlertM approach will not have a different outcome than maxAlertM, as explained in section III-C1. However, for the techniques of topMedianAlertM, topAvgAlertM and topLinRegAlertM the improved sample set is applicable.

The influence of the size of the sample set is analysed in Fig. 8, showing the average error over the number of samples. For each of the remaining three techniques all sample set sizes from 1 to 20 were examined. The set size of 1 equals the respective approach based on the maximum alert magnitude value. The figure displays six graphs, two for each technique, split by the velocity of the measurement. To further differentiate between the techniques an index i is introduced, indicating the size of the sample set. topMedianAlertM$_3$, for example, would describe the topMedianAlertM approach with a sample set size of 3 samples.

The analysis shows a high improvement of the topMedianAlertM and the topAvgAlertM approach for the measurement with a velocity of 0.6m/s, when increasing the sample size to up to 6 samples in the set. The lowest error is achieved by topMedianAlertM$_5$ with an average error of 4.12%, directly followed by topAvgAlertM$_5$ with an average error of 4.124% for the slower velocity. This is an accuracy of around 95.8%, estimating the velocity of the target. These improvements are due to the fact that both techniques benefit from the larger selection of possible samples describing the peak of the crossing event.

For the fast velocity measurement of 1.35m/s the topAvgAlertM$_5$ approach achieves the lowest average error of 3.82%, giving it an estimation accuracy of 96.1%. For the topMedianAlertM techniques topMedianAlertM$_1$4 has the lowest error with 4.88%.

Additionally, Fig. 8 indicates a trade-off between too few or too many samples in the sample set. While the performance of the topMedianAlertM and topAvgAlertM techniques initially improves when adding samples to the set, the average error abruptly increases after a certain threshold. For the slow velocity measurement this happens in our experiment at sample set size 7, for the fast velocity measurement at sample set size 17.

The reason for this is the inclusion of samples in the set which are not representative for the peak. These sample cause a reduction in precision. The effect occurs, when the number of samples with unique values is not very large. If only a few samples with high alert magnitude values exist, all of them will be included into the sample set. However, when raising the set size, more samples will need to be added. Eventually, some samples with only moderate alert magnitude values will be in the sample set. Those are less likely to describe the detection event. As soon as that happens, the accuracy of the alert magnitude set based techniques diminishes.

Table II summarizes the results for topMedianAlertM$_5$ in row 13, and topAvgAlertM$_5$ in row 14.

Since more samples are guaranteed to be in the sample set, the linear regression loses much of its accuracy. Fig. 8

shows: The more samples are added to the set, the worse the topLinRegAlertM technique performs. This deterioration occurs, because the values of all samples are included in the computation. The average error drops from 7% (linRegAlertM) to 21,7% (linRegAlertM$_5$) in the slow velocity measurement and from 13,2% to 22,8% in the fast velocity measurement. The results for linRegAlertM$_5$ are listed in Table II, row 15.

The evaluation shows that the topMedianAlertM$_5$ and the topAvgAlertM$_5$ techniques are the best choices for accurately detecting the peak of an event and estimating the velocity of a target. Furthermore, they are also less computational expensive then a linear regression, the curve fitting technique or the cross correlation.

V. Conclusion & Future Work

In this paper we experimentally evaluated 15 techniques in order to estimate the velocity of a target moving through a set of radio links. The precise moment of the Line of Sight crossing is determined based on the collection of RSSI samples. The techniques are separated into groups, based on their input values. Analysing the average of the minimum RSSI attains less accurate results than focusing on the maximum alert magnitude or the set of the *n*-highest alert magnitude samples. This is caused by the RSSIs unstable character.

Three techniques were found delivering unsuitable results below 80% accuracy, nine techniques performed moderately, three techniques achieved a performance above 90% estimation accuracy. Performing a cross correlation of the links with the highest distance from each other achieves good results in estimating the velocity. The accuracy for slow moving targets is around 95.0%, for fast moving targets it is around 92.9%. Furthermore, not focusing on the samples with the highest absolute value, but on the set of highest values offers a layer of protection against outliers and improves simple median or average computing techniques. Selecting the median timestamp of the set of samples with the highest detection value achieves 95.8% accuracy for slow moving targets and 95.1% for fast moving ones. Computing the average of those samples also achieves 95.8% accuracy for slow moving targets and 96.1% accuracy for fast ones.

In the future we want to extend our research by using the velocity estimation to differentiate between multiple targets in the same radio environment.

***Abstract*—In this paper, we propose a new protocol for sensors Frequency Shift Keying data transmission named RF-Tania protocol framework. This protocol focuses on Energy Efficiency and it is based on an existent open source protocol stack. Tania protocol framework includes a set of three protocols: The Sensors Data Transmission Protocol (Tania-SDTP), the Ad-Hoc On Demand Protocol (Tania-AHOD) and the Ad-hoc Alerts Protocol (Tania-AHA), each one servicing different user functionalities.**

Tania protocol is used on a specific system architecture of a crowded sensors network. Such network is composed of two different types of equipment: The measuring sensor transponders and the Ad-hoc receivers. Sensor transponders are battery operated systems with installed sensors. Ad-hoc receivers are mobile phones equipped with transponders that operate as both sensor output devices as well as sensor data re-transmitters.

In the case study, a test bed system architecture for monitoring CO_2 and temperature levels has been used. In this study, tests of energy endurance, RF coverage and energy performance have been performed. From the evaluation results, it is proven that RF-Tania protocol outperforms in terms of energy existing RF protocols that use periodic broadcast data transmissions.

Keywords—Wireless Sensor Networks, RF communication, Energy Efficient Operation

I. Introduction

ENERGY efficiency is a fundamental issue concerning the design of communication protocols for wireless sensor networks (WSNs). Hence, the proposed protocol focuses on that key objective.

Another important attribute of an RF sensor network is the relaxed mobility of sensors' monitoring clients. While the term mobility is a well-defined term that signifies the communication means and interoperability between clients and wireless sensors, we define the term "*relaxed*" as a new term. The term "relaxed" determines a wireless communication state where sensors exchange information with one another; intermediate gateways traverse sensor information to allotted servers and clients act both as sensors' data repeaters and as actual monitoring devices.

Based on these concepts a new RF protocols suite for data transmissions has been implemented. This set of protocols tries to maintain both Energy efficiency by reducing utilization of the sensors' RF transponders and MCU, while pertaining the characteristics of a relaxed mobility network architecture.

RF-Tania protocol is divided into three sub-protocols: The WSN sensor protocol for the broadcasting of sensor data, the WSN client protocol, for the reception and acknowledgement of sensor protocol messages and the WSN alerts protocol for the transmission of sensor critical information. The major function of RF-Tania is to save energy by putting the sensor transmitter into sleep-mode, when the sensors measurements remain constant between two or more consecutive periods. As far as the transmitted measurements are concerned, the RF-Tania protocol forces the receivers to handle frame re-transmission, whenever the sensor measurement remains at a constant level (Sensors Data Transmission Protocol, Tania-SDTP).

The mobile user requests a sensor's measurement through a mobile phone client application. If the sensor is in sleep mode, the nearby clients will inform the client that issued the request about the last sensor measurement (Ad-Hoc On Demand Protocol, Tania-AHOD).

Ultimately, Tania-RF protocol is capable of informing all WSN nodes whenever sensor measurement or measurements correlation function is higher or equal to a threshold value. In such alert cases the transmitter will immediately send an alert-message to all connected receivers in the network (Ad-Hoc Alerts Protocol, Tania-AHA).

RF-Tania protocol is comprised of 3-layer according to the OSI model. The physical layer includes a Frequency-Shift Keying (FSK) data transmission. The Data link layer is consisted of a MAC layer of node broadcast frames called Jeelab frames [1]. The network layer includes the RF-Tania protocols.

This paper structure is organized as follows: In section II we discuss the related work, in section III we present the proposed protocols suite, in section IV we provide the implementation of protocol and in section V we conclude to

our contribution and present a future system and protocol modifications.

II. Related Work

There is a wide number of WSN energy efficient protocols seen in the literature. A comprehensive classification and survey on this topic presented in [2]. These protocols work on the assumption that energy is limited and exhaustible. Consequently, the effort is primarily shifted towards prolonging the network lifetime. However, with energy harvesting capability [28], there is a need of fresh perspective on protocols and network design. Specifically, in the scenario of RF energy transfer, the protocol proposed in [6], and its subsequent analytical model in [7], adopts a duty-cycle based on the proportion of harvested energy.

The authors in [3] proposed a Medium Access Control (MAC) protocol, called RF-MAC, which ensures optimal energy delivery to the requesting node. In RF-MAC, a node broadcasts its request for energy harvesting (RFE) frames containing its ID, and then waits to hear for the Energy feeding Transmitters (ETs) in the neighborhood.

In [4], the authors proposed a network architecture which consists of two types of RF sensors. One class of sensors harvests RF energy on the DTV band (614MHz), while another uses the 915MHz ISM band. The energy transfer stage begins when the ET sends out the Request to Charge (RTC) packet, at 915MHz (operating frequency of Mica2 mote), offering to transfer wireless energy to the sensors in the network. Consequently, both types of devices can hear the RTC packet sent by the ET. The sensors that received the RTC then acknowledge this packet by sending back a response, called energy pulses. Once the ET receives the energy pulses from the responding sensors, it estimates the average power that sensors will receive during the charging process.

In [7] the authors implemented the WirelessHart (Highway Addressable Remote Transducer), which is a digital protocol for two-way communication between a host application and smart field instruments, providing access to diagnostics, configuration and process data. It specified a physical layer which used FSK to superimpose digital communication signals at a low level of 4-20mA. It supports two types of networks: Point to point and multi-hop network. WirelessHart is an RF protocol used by industrial vendors such as ABB and OMRON (PLC). It prevents message collisions using a TDMA use of the radio channel on predefined time slots instead of sensing the medium to transmit (CSMA/CA-CSMA/CD). However, its adoption to industrial application limits the feasibility for use in commercial and residential application due to its increased deployment cost [10].

Synkro RF network specification was developed by Freescale [11]. Synkro is mainly implemented for ad-hoc and low cost sensors. It offers a maximum transmission rate of 250kbit/s, three independent channels in the 2.4GHz band and two network node types: a controller and controlled nodes. The main weakness over its PAN alternatives is the maximum number of 32 controlled nodes per controller (similar to Jeelab implementation). Moreover, the SMAC protocol [6] is used for developing proprietary RF transceiver applications using a Freescale 802.15.4 transceiver. It supports point to point communications by having a very-low power, proprietary, bi-directional RF communication link between nodes. Freescale is porting its protocol and network specification into home appliances such as DVDs and TVs offering a two-way communication alternative, in order to replace existing infrared technologies.

Bluetooth Low Energy is a 2MHz BW protocol at 2.4 GHz and uses TDMA as a medium access mechanism (IEEE 802.15). It uses a low to medium power transmission of -20 up to 10 dBm in comparison with Bluetooth Class 1/2/3 accordingly [12, 13, 16]. ZigBee [15] is a Bluetooth alternative protocol created for industrial applications. It uses a variety of IEEE 802.15.4 [14] standard and the same frequency band with Bluetooth and BLE. ZigBee is more of a mesh wireless protocol rather than a P2P protocol such as BLE [16].

The RF4CE [5, 8] is a convenient, low-cost, low-power wireless transmission protocol used both by the ZigBee company and the RF4CE association. It is built from the standard specs of the networking layer and the application layer is implemented by the IEEE 802.15.4. It differs from ZigBee, as it does not have a complicated Internet routing protocol or multiple transmission communication mechanisms. It operates in the 2.4GHz frequency band utilizing three RF channels with a total BW of 2MHz [8].

WiMedia Ultra-WideBand (UWB) radio platform uses frequencies from 3.1 GHz - 4.85GHz, or at 6.2GHz - 9.7GHz [18]. WiMedia frames may be sent in either unicast or broadcast fashion. Unicast frames are directed to their destination based on a 16-bit device address; certain addresses are also reserved for broadcast groups. WiMedia Ultra Wide Band (UWB) is a short range high throughput technology using Tx Power of (12-20dBm) covering a maximum range of 10-20m with speeds up to 500Mbit/s. It is commonly used for multimedia applications.

Aside from the WiMedia implementation, an extension of IEEE 802.15.4, IEEE 802.15.4a-2007 uses the unlicensed Gigahertz bands. The standard provides two physical protocols the UWB PHY and Crisp Spread Spectrum – CSS PHY. UWB provides high data rate channels in three distinct unlicensed GHz bands, providing speeds of 110Kb/s up to 26Mb/s and maximum range of 100m, with the optional feature of precision ranging(used for indoor positioning) [19]. CSS PHY on the other hand, is a low power consumption, low range and low data rate alternative used at the 2.4GHz band for sensor data transmissions up to 1Mb/s [19, 20, 22].

III. PROTOCOLS SUITE FOR SENSORS DATA TRANSMISSION

The main purpose of the RF-Tania protocols suite is to save energy by reducing the utilization of the sensors' RF transponders and MCU, while maintaining relaxed mobility network architecture.

Our protocols suite has been implemented on the RF12 driver, used for the RFM12B JeeNode module [1]. The RF12 driver operates as follows:

- Nodes can only communicate with each other if they are in the same "net group" (1-250)
- Nodes in the same net-group have a unique ID(0..31)
- Frames (Jeelab frames) are 0-66 bytes long
- Frames utilize extra 9 bytes of overhead, including the preamble
- Data is sent at a maximum rate of 45-50Kbit/s

The RF-Tania protocol stack consists of 3-layers, according to the OSI model: Physical layer, Data link layer, Network layer. Each one of these layers is explained below.

A. Network Architecture

Network architecture consists of two entities, the transmitter and the receiver, as we can see in Fig 1. Specifically, the transmitter or sensor entity contains RF-transponder and microcontroller equipped with sensors. The receiver or mobile client entity contains mobile phones equipped with RF-transponders.

The transmitter, called sensor entity, is placed on a stable position transmitting the sensors measurements to the mobile receivers. The mobile receivers, called client receivers, are moving around. The sensor entity transmits data every period T_p to all mobile receivers, located in the coverage area.

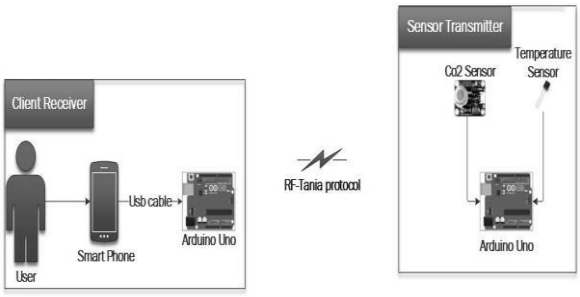

Fig.1: WSN receiver and sensor entities

In the WSN network we use a series of RFM12B transponders. Technical characteristics of RFM12B chip are outlined at [23] and [24] for the long-range transceivers.

B. Physical Layer

The RFM12B initialization includes the communication transponder used for our WSN network. The physical layer includes the following configuration fields: Configuration Settings, Power Management, Frequency Settings, Data Rate and the Receiver Control.

As far as the configurations settings are concerned we used the band of 433MHz, in order to minimize interference with other transmissions in the area (GSM frequencies, Wi-Fi, Bluetooth and GPRS data transmissions). Furthermore, we can activate the RX Register and TX FIFO Buffer. These chip configuration settings parameters are set from the Arduino microcontroller (sender or receiver entity) via the SPI (Serial Peripheral Interface), sending 16bit commands to the RFM12B chip.

The parameters control the power to the RFM12 submodules and allow the selection of circuits, until the RFM12 is turned on or turned off accordingly. So by disabling these circuits, when it is not required, we can control the amount power consumption of the device.

The RFM12B chip has the ability of frequency hopping-shifting to nearby frequencies. The default carrier frequency shifting is 90 KHz. If there is an interference on one frequency, another frequency can be selected manually and interference problems can be avoided.

The RF12B incorporates a fully integrated Power Amplifier (PA) with antenna tuning and a Low Noise Amplifier (LNA) with switchable gain. The Power Amplifier (PA) has an open-collector differential output and can directly drive a loop antenna with a programmable output power level of maximum of 0dBm transmission power.

An automatic antenna tuning circuit is built in to avoid costly trimming procedures and the so-called "hand effect". The Low Noise Amplifier (LNA) has approximately 250Ohm input impedance, which functions well with the proposed $\lambda/4$ monopole antennas (of 17.3cm length). If the RF input of the chip is connected to 50Ohm devices, an external matching circuit will be required to provide the correct matching and to minimize the noise figure of the receiver. The LNA gain can be selected in four steps (between 0 and -20dBm) according to RF signal strength required.

The Data Rate command sets the bitrate of the transmitted data or the expected bitrate of the received data. The actual bit rate in transmit mode and the expected bit rate of the received data stream in receive mode are determined by the 7-bit parameter R (bits r6 to r0) and bit cs. The highest data rate is set at 57.4Kbit/s. This gives 17usec per bit transmission and 139usec per byte (7192Kbyte/s or 57,553Kbit/s).

The Receiver Control command contains a series of various bits, according to [25]:

Bit 10 (P20): sets the function of INT/VDI pin on the RFM12 module. It configures the module as input (Interrupt from MCU) or output (VDI Valid Data Indicator).

Bits 9-8 (d1 to d0): VDI (valid data indicator) signal response time setting

Bits 7-5 (i2 to i0): Receiver baseband bandwidth (BW). The receiver bandwidth is selectable by programming the bandwidth (BW) of the baseband filters. The bandwidth settings are linked to both data rate, and Tx modulation

commands. When data rate is fast a higher receiver bandwidth is required. The default baseband BW of the RF12B is set to 134 KHz. The highest receiver BW is set to 450 KHz [24].

Bits 4-3 (g1 to g0): LNA (Low Noise Amplifier) gain (dBm). Typically, 0dBm is the LNA output of the RFM12B chip. Consequently, the maximum transmission power of the transponder is 0dBm.

Bits 2-0 (r2 to r0): bits that set the RSSI detector threshold. The RSSI threshold is based on the 433MHz beacon carrier and expresses how strong or weak the transmitter beacon signal is (as spotted at the receiver end). If it is below a certain threshold (set by bits) the receiver will ignore the incoming transmitted frame.

C. Data Link Layer

The Data link layer includes the MAC layer, which is responsible for controlling how and when network devices gain access to medium and permission to transmit data. The nodes broadcast frames, called Jeelab frames constructed in this layer.

The Carrier Sense Multiple Access with Collision Avoidance (CSMA/CA) is a network multiple access method in which carrier sensing is performed. The nodes attempt to avoid collisions by transmitting data only when the channel is sensed to be idle. Moreover, a rule of 1% channel utilization applies at the data link layer. This means that each transmitting node in our network should send up to 1% of the time, on average. The 1% rule is a very simple collision avoidance mechanism. There is also a random back off collision avoidance mechanism included in Jeelabs library whenever a collision occurs in cases of frames retransmission. Both of these mechanisms are implemented on the rf12_easy transmit Jeelab's library function [1].

The original frame header, implemented by Jeelabs [1] is shown in Fig. 2 (Preamble, SYN, Head and CRC).The proposed protocol suite header field is encapsulated in a Jeelab frame, shown in Fig. 3 (Packet_ID, Node_Id Measurements and Send_time).

The Preamble and SYN fields are used for data transmission synchronization and group selection (Each group can contain up to 32 nodes with unique node ids). The Head field includes Jeelab protocol options and source or destination node id. The frame Payload is 0-56bytes. The CRC (Cyclic Redundancy Check) is the error-detecting code field.

In order to transmit frames, RF-Tania protocol uses the Head field of the original Jeelabs frame. There are three bits: C = CTL, D = DST, A = ACK and a 5-bit node ID. (Fig. 2 – Head field). Node id values can be 0-31. The A bit (ACK) indicates whether this frame wants to get an ACK back. The C bit needs to be zero in this case. The D bit (DST) indicates whether the node ID specifies the destination node or the source node. For frames sent to a specific node, DST = 1 (The destination node id is included in the Head field).

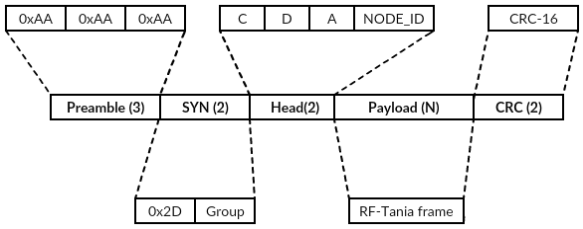

Fig 2: The Jeelab frame header [1]

For broadcasts, DST = 0, in which case the node ID field refers to the originating node. The C bit (CTL) is used to signify ACK request and should be combined with the A bit set to zero. The node receiving an ACK can check the originator of the ACK reply.

As for the Payload field of the Jeelab frame, we propose the format shown at Fig. 3. The first field of RF-Tania payload contains an auto incremented number of frame ID. The second field carries the ID of the sending node and it is 5 bits (3 bits left for future use possibly QoS or Collision experience provisions). The Measurements field includes 4 bytes sensor measurements and the Send_time field includes a 4 bytes timestamp of the frame. In case of sensor entity measurement, Send_time is represented by the MCU millis time.

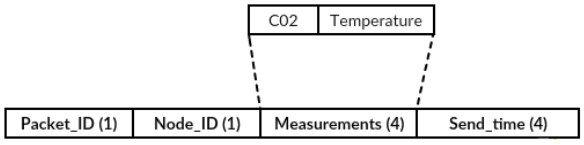

Fig. 3: RF-Tania frame

RF-Tania frame can include simultaneously 24 measurements of 2bytes each one (48 bytes overall) or 12 measurements of 4 bytes each one. In our case study we use 2 measurements of 4 bytes from a CO_2 and Temp sensor accordingly.

D. Network Layer

The network layer includes the RF-Tania protocol, which is categorized into 3 sub-protocols:

Tania-SDTP: According to SDTP protocol the receiver entity periodically collects sensor measurements from the sensor entities (Fig. 4). Each sensor entity collects measurements from a number of sensors connected to the entity. The sensor entity device has two periods: the sensor device data collection period (T_{sc}≈2s) and the sensor device network data transmission period T_p (initially T_p=30s). For a period T_p, all sensors measurements retrieved from a sensor entity, are stored in the sensor entity SRAM. At the end of each period T_p, the sensor entity calculates the mean sensor values using equation (1) and checks whether equation (2) is satisfied:

$$x_p = \frac{1}{n}\sum_{i=1}^{n} x_{Ci} \quad (1)$$

$$\left(\left|\frac{xc_i - xc_{i-1}}{dt}\right|\right)_{Tc} \geq 4\min\left(\left|\frac{dxp}{dt}\right|\right)_{Tp} \quad (2)$$

In the above functions, xc_i is one sensor measurement at time T_{sc} (i=1..n sensor measurements collected in a time interval T_p), x_{pi} (x_p)is the mean calculated sensor measurement ready for transmission, $xp_{i-1}$is the previously transmitted sensor measurement. If equation (2) is satisfied, the current sensor mean measurement will be considered of high variance and an alert will be set by the sensor entity using Tania AHA protocol. A sensor entity alert forces the sensor entity to perform a multiplicative decrease of its transmission period ($T_p=T_p/2$, $T_p>2s$).Transmission period value multiplicative decrease is performed in each transmission interval until equation (2) is satisfied. If equation (2) does not apply, the sensor entity will perform an increase of the transmission period T_p using the following equation: $T_p=T_p+1\times f_p$ (sec), where f_p is the sensor data transmission frequency coefficient.

In a previous data transmission interval T_p, a sensor entity collected n number of measurements (M) from a CO_2 sensor in period $T_{sc}<<T_p$. For the T_p period interval the maximum measured CO_2 sensor value is M_{max} and the minimum measured value is M_{min} (Equation (3)). For each transmission period, a frequency coefficient parameter f_p is calculated based on equations (3) and (4) and used for the determination of the next period T_p value.

$$cp = \frac{M_{max}^{Tp} - M_{min}^{Tp}}{\frac{1}{n}\sum_{i=1}^{n-1}[M_{Tsc}^{i} - M_{Tsc}^{i-1}]} \quad (3)$$

$$f_p = \frac{1}{cp} \quad (4)$$

M_{TSC} values are the sensor measurements per time intervals called ticks (T_{sc}).The denominator of equation (3) expresses the average M_{TSC} value for a period T_p. If $f_p<1$, f_p will be set to 1. Coefficient (c_p) is called energy efficient parameter. When its value decreased, the sensor will become less sensitive to measurement variations or sensor variations are minimum. Moreover, when the energy efficient parameter value decreased, the sensor values variations will be significant and at the same time the sensor entity will spend more energy for data transmission.

If equation (2) is satisfied, the sensor entity will send alerts to the receiver entities using Tania AHA alerts protocol. As soon as a frame is sent to the receiver, it should send back an ACK frame to the sensor entity (see Fig. 6).

Tania-AHOD: This is the on demand measurements request protocol. Specifically the client-receiver, which is connected to the users' mobile-phone, requests measurements from a sensor entity. In that case, either the sensor entity (if it is in listen mode-Fig. 4, Tania on demand request listen period) might respond to the request or another nearby receiver entity might respond. In case of reception of multiple responses by the receiver entity, the receiver will choose the sensor entity responses first. If nobody response, the receiver entity will response with the most current timestamp field in its Tania header frame.

Once the receiver makes a decision about the best frame to keep, then it will forward it to the mobile phone application layer. The requested measurement will appear on user mobile display (see Fig. 5).

Tania-AHA: This protocol is responsible for informing all receiver nodes for critical measurement values. Sensor alerts occur whenever sensor measurements satisfy the equation (2) or the sensor measurements are higher or equal to a threshold value.

For example, in a sensor network that monitors environmental CO_2 values, the sensor entity collects CO_2 sensor data. Furthermore, it is checking once for every period T_p whether equation (2) is satisfied or the mean sensor value for that period is above threshold value of 1000ppm for CO_2 (see Fig.6). If equation (2) is satisfied or mean sensor value is above threshold value then the sensor entity will immediately send an alert-message to all connected receiver entities in the WSN network using unicast transmissions (Alert frames will be sent to all sensor nodes that acknowledged last periodic sensor entity transmission using Tania-SDTP protocol). As soon as the alert-messages are sent, the receiver entities will open a serial connection with mobile phone, in order to inform the user (Fig. 6).

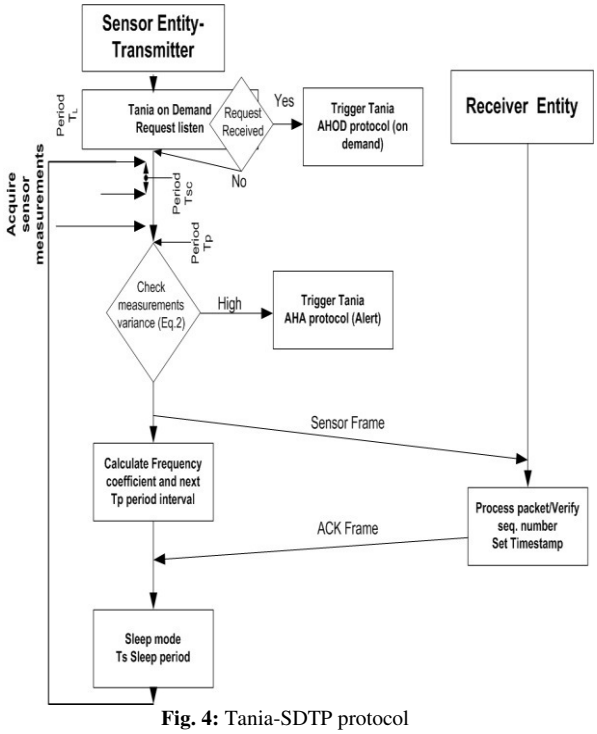

Fig. 4: Tania-SDTP protocol

The Tania AHA alerts transmission phase is persistent and energy consuming. If a receiver entity does not acknowledge the reception of the alert frame, the alert message transmission will be broadcasted and the alert broadcast will be repeated every 1sec for a period T_p equal to the period of 30sec (30 alerts back to back). This step is per-

formed until at least one receiver entity acknowledges the alert reception to the sensor entity.

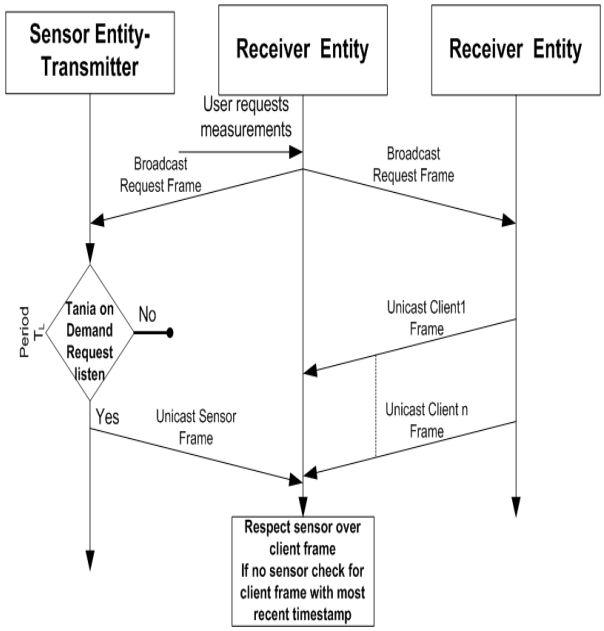

Fig. 5: Tania-AHOD protocol

The sensor entity timeout value for all unicast acknowledgements reception is set to 2sec (RTO=2s). If RTO is reached, a frame alert retransmission for non-acknowledged nodes will be performed at least three times for each node. As soon as the alert frame transmission is completed, a multiplicative decrease in transmission period will be performed.

IV. CASE STUDY AND PERFORMANCE MEASUREMENTS

The case study includes one sensor entity (see Fig. 1 – MCU transmitter with temperature and CO_2 sensors). The sensor entity equipment uses a 3.3V Arduino pro mini microcontroller connected to an MG-811 C02 analog sensor and a DS18B20 digital temperature one-wire sensor. On the Arduino SPI pins the RF12B transponder is connected in order to transmit periodically measurements to the WSN network. The WSN network consists of two receiver entities nodes. These nodes include an Arduino UNO 5V microcontroller with an SPI RFM12B transceiver. The Arduino is back to back connected via OTG cable to Android mobile phones where the measurements monitoring application resides. The application measurements real time is set by the mobile phones as soon a measurement is received.

The Arduino board used at sensor entities operates at 3.3V DC, since there is a CO_2 sensor requirement to operate at 5V DC the sensor is powered directly from the battery unit. The typical power consumption of an Arduino UNO 5V board in idle mode is 282-300mW. However, the same board Arduino pro mini, operated at 3.3V provides power requirements at idle mode of 27-35mW, including the voltage regulator 5V-3.3V chip power consumption (10 times less than an Arduino5V UNO board used at primer experimentation).

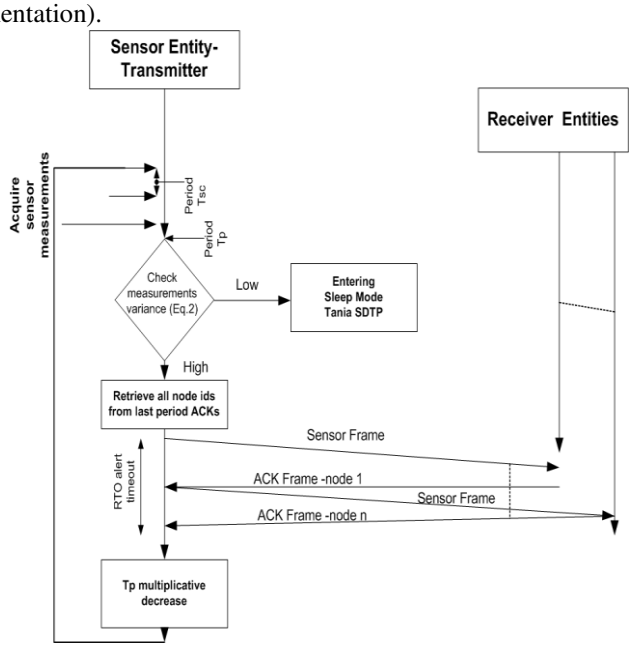

Fig. 6: Tania-AHA protocol

We are using an MG-811 CO_2 sensor [25], which includes a signal conditioning circuit along with a LNA amplifier. Its power consumption is rated from 15-18mA, thus giving a power consumption outcome for 5V sensor required voltage of max 90mW. This is still 3 to 4 times less than Arduino UNO idle power consumption. On the other hand, both digital thermometer DS18B20 and RF12B transponder operate at 3.3V, with transmission RF12B power consumption of 76mW and thermometer consumption of 6mW.Moreover, more power-enhanced improvements have been performed by providing a low power consumption algorithm for the sensor entity. The algorithm's description follows.

Arduino board has six different sleep mode states: idle, ADC noise reduction, power-down, power-save, standby and extended standby [26]. Power save and power down modes power off all Arduino peripheral chips such as SPI, TWI and ADC, contrary to idle mode that still consumes power. Both power save and power down can be triggered by external Interrupts (INT0 and INT1). However, power save mode still feeds power to Arduino timers (0/1/2), while power down mode disables their functionality completely. This of course leads us to Arduino timing problems (millis function connected to timer0) [26].

Arduino includes a watchdog timer (WDT). This timer has a separate on chip RC clock operating at 128 KHz and has 9 prescaler modes of operation starting from 30ms up to 8s. From these modes authors selected the following sleep interval modes to be configured at their algorithm's initialization step: 1s, 2s, 4s and 8s. WDT timer is functional on all Arduino power modes (including power down).

The Brown out detector (BOD) [26] is another functionality of the Arduino board that consumes power and is not required for the sensor entity. The BOD detector checks for voltage anomalies or dips in the voltage of the board and resets the Arduino chip by calling the watchdog timer. This BOD functionality is set by the Arduino fuse bits (extended fuse bit 0x05 to 0x07) and is programmatically pushed to the sensors using in circuit programmers. This BOD functionality reduces the board energy consumption from 0.1 to 0.3mW of continuous power. Moreover, removing the Arduino power led also contributes to less power consumption of 10-12mW.

We propose the following low power reduction steps for our sensor entity measurements:

Step 1a– Setup step: Arduino disables the watchdog timer and initializes timer0 and RFM12B transmission parameters. The CO_2 board is powered directly from 6V battery pack as well as the Arduino Pro mini. RFM12B is powered from Arduino Pro mini Digital pin 5 set to HIGH (3.3V), DS18B20 is powered from Digital pin 6 set to HIGH (3.3V). T_{sc} period counter is set to zero, millis() value is at 5000ms (5s).

Step 1b – Sensor main loop: This is the initiation of the MCU sensors measurement process of sensor probing and it is repeated every T_{sc} time interval set at 2sec.

Step 2a – Check for Ad-hoc requests: Arduino opens the RFM12B transponder for 100ms and checks for any Ad-hoc on demand requests. If a request is sensed it transmits data to the request node.

Step 2b – T_p period reached: Arduino checks whether the periodic counter value of sensor measurements initially set at T_p=30sec has elapsed. If it has elapsed, it will initialize the SPI interface and transmits sensor data via the RFM12B transponder. Afterwards, it opens an I2C communication with the EEPROM chip, an Atmel AT24C128 I2C EEPROM chip [27], reading past period measurements and performs calculation (period increase or decrease) of the next period interval based on the algorithm described at section III.D.

Step 2c – Sensors probing Loop: If T_p<30 or $T_{pcalculated}$, Arduino enters a probing Loop, sets its ADC frequency to 125KHz and performs sequentially 96 measurements of CO_2 and 96 measurements of temperature (around 2ms of time). The time completion and averaging result is produced and saved to an external EEPROM memory I2C communications chip [27].

Step 3 – Sensor MCU Sleep mode: Watchdog timer is set for time of 1s with interrupt1 enabled. The Arduino goes to power down mode and the digital pins 5,6 are set to low. The WDT timer is set as the main millis timer (128 times slower counting – for time period of 1s WDT increases millis value by a value of 8 instead of 1000).

Step 4 – Sensor MCU wake up: Interrupt service routine of Interrupt 1 is entered disabling the watchdog timer and setting the Arduino chip out of the power down mode.

Step 5 – MCU clock calibration: End of Microcontroller loop, set millis counter to millis()+1000-8. T_{sc} period counter calculation equal to (millis()-5000)/1000 and loop re-start from step 2a.

TABLE 1:

PROPOSED SENSOR ENTITY ARCHITECTURE COMPONENTS AND POWER CONSUMPTION

Equipment	Power Consumption-idle mode
Arduino UNO 5V	282mW
Arduino Pro mini 3.3V –idle state	33mW
MG-811 sensor 5V	90mW
DS18B20	6mW
RFM12B transmission	76mW
RFM12B data reception, ad-hoc sensing	39.6mW
AT24C128 EEPROM	17mW (100,000 writes)

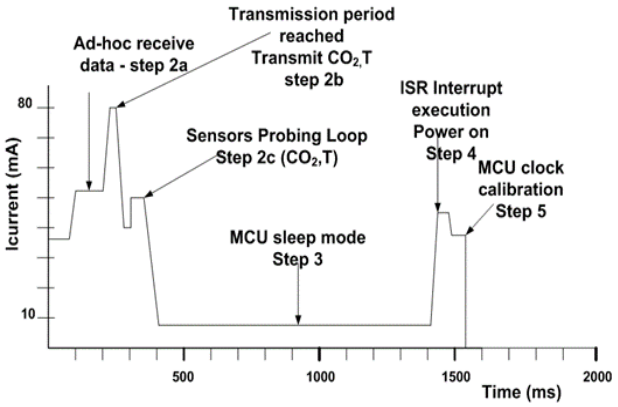

Fig. 7: Sensor entity energy footprint for a Tp=2sec.

TABLE 2:

WSN COVERAGE AREA FRAME LOSS AND MAXIMUM CHANNEL CAPACITY

Coverage Distance (meters)	Frame loss	Mean delay (sec)	Throughput (bits/sec)
10	0%	0.08	2373.5
20	0%	0.1	2362.3
30	3%	0,15	2286.2
40	7%	0,19	2187,6
50	15%	0,22	1996,5

From the sensor entity and WSN experimentation the maximum energy footprint for a minimum sensor entity period of T_p=2s is presented at Figure 7. In addition, the WSN sensor pin powered RFM12B transponder-receiver RFM12B transponder maximum coverage distance and

maximum channel throughput capacity are shown at Table 1.

The WSN sensor pin powered RFM12B transponder-receiver RFM12B transponder maximum coverage distance and maximum channel throughput capacity are shown at Table 2.

V. CONCLUSIONS

This paper presents a new WSN architecture comprised of sensor entities and mobile receiver entities, for the transmission of sensory data to mobile roaming clients with medium to small transmission ranges coverage. Our approach is based on existing cheap and open source hardware and software solutions. On the proposed WSN architecture, a set of three network layer protocols is presented, called RF-Tania protocol framework, for the transmission of relaxed sensory data, ad-hoc on demand transmission of sensory data and alert transmissions in cases of sensors' threshold events.

It is set as a future work, a further detailed experimentation of proposed architecture and protocols, as well as comparison results of the sensor entity energy consumption and coverage with similar transponder devices energy consumption and coverage results.

***Abstract*—Mobile wireless ad hoc network (MANET) becomes increasingly popular in responding to emergency situation. In this paper a possibility to support rescue team in monitoring heavy gas cloud with MANET comprised of mobile sensing devices is investigated. In the view of the current state of research, two methods for controlling mobile sensing devices during MANET self-organization are presented. The first one is based on a greedy approach whereas the second on a repulsion from the estimated centroid of a cloud and other nodes. Various variants of both methods are considered and their efficiency in terms of detection quality and energy saving is evaluated with MobASim simulation software. The results are discussed and one variant is chosen as the basis for the future research.**

I. Introduction

ALL over the world great amount of toxic substances is transported and stored. Some of these substances after release form clouds of gas heavier than air [1]. Despite high safety standards severe accidents, in which dangerous substance is released to the atmosphere, occur. Examples of accidents involving heavy gas release include those with chlorine [2], nitrogen dioxide [3] and sulfur dioxide [4]. Heavy gas cloud can be created by natural reasons as well — in 1986 a massive, sudden release of carbon dioxide occured from Lake Nyos, a volcanic crater lake, and as a result around 1700 people were killed [5]. Another source of the toxic gas cloud can be military or terrorist attack [6], [7].

As heavy gas cloud is formed a rescue team has two goals: evacuate endangered area and neutralize the cloud. In both knowledge of position, boundary and direction of the cloud is substantial as it supports rescue team in surrounding and then suppressing the cloud, making decision which area to evacuate first and identifying safe evacuation routes. Usually there is no need for modeling exact concentration level of gas inside the cloud.

Because of the negative buoyancy behavior of the heavy gas cloud is different than the one showed by positively or neutrally buoyant clouds. The main difference is gravitational velocity field (gravitational slumping) which influences the way cloud moves and changes its shape with time. Hence, special group of mathematical models was developed to describe the dispersion of heavy gas in the atmospheric air [8]. However, usage of these models to define boundary and position of the cloud demands specifying values of many parameters as direction and speed of wind, quantity of released gas, type of release (instantaneous or continuous), etc., which are often unknown and/or variable. Most of the described models assume obstacle-free, flat terrain; Even if obstacles or topography of terrain is considered only simple scenarios can be modeled. These issues create need for more universal, environment independent methods for the cloud boundary tracking in an unknown terrain.

In this work implementation of Mobile Ad Hoc Networks (MANET) for supporting rescue team in emergency action is proposed. MANET is comprised of wireless mobile devices, which can dynamically and autonomously self-organize into temporal networks to provide a discovering and tracking boundaries of dynamic heavy gas cloud. The network adapts to current conditions in deployment area by forming adequate topology. Nodes communicate wirelessly to exchange their knowledge about the environment.

The article is organized as follows. First, state of the current research on applying MANET in emergency situations and methods for boundary detection/tracking is presented. Then in the section III problem is formulated. Next two simple distributed methods for boundary of heavy gas cloud discovering and tracking are proposed. In the section V different variants of these methods are evaluated and compared in terms of both quality and energy efficiency. Finally, results are discussed and future directions of work are briefly outlined.

II. Related work

Contemporary lots of research focus on both using sensor networks to support detection and response to emergency situations and on detecting boundary of phenomena. Below the most interesting works in these two fields are briefly presented.

MANET can be used in emergency situation to address various issues. Usually as the result of natural disaster communication systems are down [9]. Thus MANET can be used to establish new communication layer for rescue team [9], [10]. In [11] system for firefighters that provides possibility to conduct audio and video conference during action is described. Another communication network architecture is presented and assessed for existing Telemedicine Service in [12]. In [13] MANET is created to establish communication with single robot that searches building in emergency scenario. The comparison of the MANET based solution with the static network in terms of throughput shows improvement

978-83-60810-90-3/$25.00

if network's topology does not change often, but decrease otherwise. The influence of relay nodes placement on network reliability, stability and availability is discussed in [14].

Another purpose of MANET can be supporting decision making process of emergency team by providing important data. In [15], network is created to serve as a communication layer and collect medical data from remote sources about mass casualty incidents, thus supports decision making. Similar scenario of MANET application is presented in [16] — locations and current state of victims are monitored and provided to rescue team. Another application of MANET is to support evacuation of people from endangered area by providing an appropriate evacuation route in real time [17], [18].

MANET can be also used in disaster detecting — methods based on analyzing people behavior are proposed in [17], [19], whereas distributed control system for maximizing the joint detection probability of events in a given area is presented in [20].

In the same time much effort has been spent on research on detecting and tracking *phenomena clouds* — events characterized by nondeterministic, dynamic temporal variations of cloud shape, size, speed, and direction of motion along multiple axes [21]. The examples of phenomena cloud are oil spills, movement of group of people and gas clouds. Most interesting approaches are presented below, divided according to the type of used devices — stationary and mobile (can move autonomously).

A number of works on phenomena cloud detection with stationary nodes exists. In [22] authors focus on meeting time and accuracy constraints in a task of tracking phenomena. In [23], scenario with nodes sparsely deployed in the area is considered. In such situation collected data can be ambiguous in terms of number and shape of detected phenomena clouds. To reconstruct contours method based on gradients of concentration is designed.

Important issue in WSN networks is energy saving. In [24], method for limiting power usage by selecting subset of WSN nodes that are localized on the boundary of phenomena (representative nodes) and reducing size of messages is proposed. Distributed boundary estimation strategy with mechanisms for decreasing number of messages sent between nodes, and adaptive turning off sensors, is described in [25]. In [21] authors propose several distributed methods and focus on minimizing resource utilization by both reducing number of active sensors and optimization of centralized query processor, which gather information about cloud in real time. Energy efficient algorithm for phenomena tracking for the case of void area (area not covered by nodes) existence is presented in [26]. Interesting scenario is considered in [27] — sensors are carried by people, thus nodes have no influence on their location, but are mobile. Authors address their method for scenarios with dense network, where lowering traffic is crucial aspect in terms of energy efficiency.

As concluded in work on target tracking [28] use of mobile devices can increase tracking performance significantly in comparison with stationary network of the same number of devices. Hence, much research on applying mobile devices has been conducted. Comprehensive survey on boundary estimation, covering and tracking with collaborative sensors can be found in [29]. In the next few paragraphs the most important approaches (including the newest research, not included in the survey) are discussed. In some works instead of detecting boundary more general task is considered – detection of perimeter defined as curve of the given constant concentration. Boundary can be seen as perimeter given by concentration close to zero.

Tracking and exploring phenomena cloud with one device is important issue in the first phase of detection, when phenomena cloud is sensed by one node only and other nodes did not arrived yet to the area of interest. The decision about the direction of movement can be based on trigonometric reasoning [30] or gradient of concentration [31]. Additionally, in [31] use of artificial neural networks for the nonholonomic mobile robot to move in the designed direction is described.

In [32] multiple autonomous vehicles are used to estimate boundary, however, with no cooperation between them. Authors focus on tracking algorithm, that enables each vehicle to go along boundary based on it's concentration measurements. Measurement noise is addressed. Data gathered from all vehicles is used to estimate boundary. The tracking algorithm was validated in static environment using testbed in [33]. The same algorithm was used in [34] to estimate phenomena cloud boundary with single mobile node. Additional support by WSN was introduced to correct mobile node's movement by predicting future center of the cloud.

Cooperation between robots can increase quality of cloud boundary detection. In [35], algorithm for even robots placement on the boundary was proposed. The algorithm was proved to converge in case of static boundaries and to be efficient for slowly-moving boundaries. However, assumptions that initial estimation of boundary is known to agents and each agent is able to locally estimate the tangent and the curvature of the boundary are needed. These assumptions are not valid in the case of heavy gas cloud, because robot can measure gas existence in one point only at the same time.

Another cooperation based method for placing evenly on the boundary was introduced in [36]. Additionally, group of mobile robots track perimeter of certain substance counterclockwise using camera. However, to uniformly distribute around perimeter the desired separation distance need to be set a priori.

An interesting method for the stationary environment, inspired by the active contour model used in the image segmentation field, was proposed in [37]. The approach is strictly dependent on the concentration of substance — it is assumed that lowest concentration is on the boundary and a gradient of concentration points to that boundary. Algorithm for scattering devices evenly, based on pairwise repulsion force, was additionally proposed. However, node needs to choose between tracking boundary or scattering in every step. Similar idea is presented in [38], where non-stationary environment is considered. Again, assumption on concentration is needed.

Another method based on concentration value is described in [39]. Every sensor knows concentration in its location and in its close neighbourhood. To reach the location with the given concentration (concentration on the boundary) the sensor decides in every step which neighbouring location move to. Various strategies of taking decision were proposed and examined in scenarios with linear and non-linear variations of concentration.

In [40], group of unmanned underwater vehicles is used to find and patrol underwater perimeter. Two methods for controlling movement of vehicles were proposed and compared. The first one is based on aforementioned snake algorithm (concentration based). The second models vehicles as a gas of particles, which affects each other speed, similarly to the one of the approaches presented in this paper. The authors conclude that free-concentration methods are better for tracking underwater perimeter in real world scenarios.

Some research was conducted on using UAVs (unmanned aerial vehicles) to detect and track the shape of an environmental boundary. In [41], authors propose the method for calculating path of UAV that allows recognition of the contaminant cloud's shape. The approach was extended with methods for predicting contaminant cloud's shape [42] and avoiding obstacles [43]. UAVs can also be used to track forest fire boundary [44].

Interesting issue of the boundary detection is discussed in [45]. Authors propose some algorithms for deciding when to start spreading sensors (how far in advance before reaching the boundary) to speed up converge. The algorithm is based on a rate of concentration change, thus is not proper for situation in which boundary is defined with small concentration value (whole area where any gas exists should be classified as cloud interior). However, the idea of early sensor spreading should be addressed in our work in the future. Other drawbacks of proposed spreading algorithm is its centralized nature and assumption on obstacles free environment.

In the view of this brief review, MANET can be successfully used in emergency situation. At the same time there is lack of proper mobility control method for nodes for case of detecting boundary of dense gas cloud. Most of above methods base on concentration distribution, which is inadequate for scenarios with dense gas dispersion, because of various reasons. Firstly, heavy gas cloud has very dynamic internal changes. Secondly, gas sensors sense gas in single point only at a time and the sensory readings can be inaccurate. Additionally, even slightly pleated area influences distribution of gas in the area - lower concentration can be caused by existence of both cloud boundary and hill. Hence, we propose two new methods for real time estimation of area covered by heavy gas cloud with MANET, based on binary information from sensors about gas existence.

III. Problem Description

The aim of the paper is to create a sensing network for a heavy gas cloud detection in a two-dimensional workspace W, and boundary tracking to estimate a size of this. In our investigation, a network is a physical system modeled as a set of n unmanned vehicles or mobile robots D_i, $i = 1, \ldots, n$. All these vehicles are equipped with radio transceivers and gas sensors. All network nodes are solid bodies with an arbitrary shape. In order to simplify the description of the system we model each network node by a polygon with its reference point $\mathbf{c}^i = [x^i, y^i]$, which is the location of the device (exactly its antena). All vehicles are forced to move in advisable direction with the speed $v \in [v_{min}, v_{max}]$.

In this work it is assumed that each pair of nodes D_i and D_j can communicate independently on the Euclidean distance between these nodes (d_{ij}), with use of external communication system. In the future, local multi-hop communication between each pair of nodes should be considered to enable deploying the network in area with no external connectivity system.

The goal of both methods is to control direction and speed of each node in such way, that would increase quality of estimation of area covered by gas and decrease total distance traveled by all nodes. The proposed methods are based on PFM (*Potential Function Mobility*) model described in details in [46]. In this model each node has single goal g defined with target point in the workspace $\mathbf{c}_g^i = [x_g^i, y_g^i]$ and its movement is influenced by positions of other nodes and obstacles. The PFM model combines concepts of an artificial potential fields and particle-based mobility schemes. Each node is treated as a self-driven particle moving from a high-value state to low-value state of artificial potential field. The artificial potential function is constructed as a sum of repulsive and attractive potentials. Its value depends on Euclidean distance between a given node and all other nodes in the network, and the distance to target position and obstacles in W. As in this work obstacles-free environment is assumed each device D_i has to calculate its new position solving problem of minimizing an artificial potential function U^i (influence of obstacles is omitted):

$$\min_{\mathbf{c}^i} \left[U^i(\mathbf{c}^i) = U_g^i(\mathbf{c}^i) + \sum_{j=1, j\neq i}^{n} U_j^i(\mathbf{c}^i) = \epsilon_g^i \left(\frac{\overline{d}_g^i}{d_g^i} - 1 \right)^2 + \sum_{j=1, j\neq i}^{n} \epsilon_j^i \left(\frac{\overline{d}_j^i}{d_j^i} - 1 \right)^2 \right], \tag{1}$$

where U_g^i and U_j^i are potentials derived from g and D_j, respectively. $\epsilon_g^i \geq 0$ and $\epsilon_j^i \geq 0$ are weighting factors determining the importance of, respectively, the goal g and the device D_j. d_g^i and d_i^i are real Euclidean distances between $\mathbf{c}^i$ and respectively, $\mathbf{c}_g^i$ and $\mathbf{c}_j^i$ after a network transformation, and $\overline{d}_g^i$ and $\overline{d}_j^i$ the reference distances between $\mathbf{c}^i$ and respectively, $\mathbf{c}_g^i$ and $\mathbf{c}_j^i$. The reference distance is understood as the expected distance between node and target or other node, accordingly.

The final network topology depends on choice of target location ($\mathbf{c}_g^i$), the values of the reference distances ($\overline{d}_g^i$, $\overline{d}_j^i$) and weighting factors (ϵ_g^i, ϵ_j^i). Hence, in the next section two distinct methods for calculating these values in task of estimating boundary of area covered by gas are presented.

IV. METHODS

The detection of area covered by gas is divided into two phases. In the first one, when only one node detects heavy gas with sensor, the node has to track the cloud and broadcast information about its position to others. All nodes that do not sense gas are attracted by the point defined by the position of the node that senses gas. Tracking phase last to the moment in which at least one more node arrives to the area covered by gas. Then, the boundary detection phase starts.

The algorithm for controlling node that senses gas in the tracking phase is presented in Algorithm 1. The algorithm is executed as only the node starts to sense gas. The idea of the algorithm is to move inside the cloud as long as gas is sensed (k steps), then when the cloud is lost return to the cloud by taking opposite direction ($k/2$ steps) and choose new direction randomly. In this phase $\epsilon^i_j = 0$ (thus $U^i = U^i_g$). Moving in the given direction is achieved by adding attracting goal g in an appropriate location $\mathbf{c}^i_g$ with $d^i_g = 1$. The advantage of this algorithm is simplicity and power efficiency thanks to little computation needed. More advanced approach, that does not base on gas concentration as well, was presented in [30].

Algorithm 1 Algorithm for controlling node in tracking phase

```
if moving then
    continue moving in that direction
else
    start moving in random direction
end if
while ( nodesSensingGas.length == 1 ) do
    k := 0
    while ( sensingGas ) do
        continue moving in that direction
        k = k + 1
    end while
    start moving in the opposite direction
    while ( not sensingGas ) do
        continue moving in that direction
    end while
    k = k / 2
    while ( k >0 and sensingGas ) do
        continue moving in that direction
        k = k - 1
    end while
    choose new direction randomly
end while
```

As at least two nodes sense gas the estimation area covered by gas phase begins. Below two different approaches for implementation of this phase are proposed. Before the approaches are described in details few remarks have to be made:

Remark 1. Binary sensory reading causes that all sensors that do not sense gas in a given moment are treated the same way, independently on how many steps have passed after last positive sensory reading. Such simplification causes that much of important information can be lost from the perspective of rescue team. Hence, three different states of node are introduced:

(a) sensing gas at time t
(b) not sensing gas at time t, but did sense gas at least once in last h steps
(c) not sensing gas at time t, and did not sense gas in any of last h steps

The boundary of the covered area is estimated as convex hull of the set C^+ defined as the set of locations of all nodes in state (a) or (b) with $h = 2$.

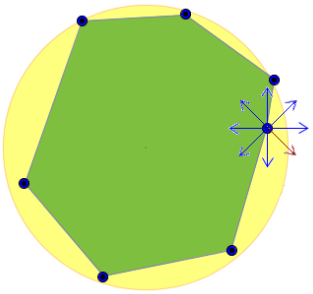

Fig. 1: Directions of movement considered by a node in the greedy approach ($k_d = 8$).

Remark 2. The term *centroid* will refer to the center of the cloud $\mathbf{c}_c$, which is calculated as an arithmetic average of positions of all nodes that sense gas:

$$\mathbf{c}_c = \frac{\sum_{\mathbf{c}^i \in C^+} \mathbf{c}^i}{|C^+|}. \tag{2}$$

Remark 3. In both approaches the nodes that do not sense gas are attracted by single goal located in centroid ($\mathbf{c}^i_g = \mathbf{c}_c$) with reference distance $d^i_g = 1$ and influence of other nodes is omitted ($\epsilon^i_j = 0$).

A. Greedy approach

In greedy approach every node in every time step chooses one of k_d directions to move. The decision is based on localization of all other nodes that sense gas (C^+). The node calculates the area of current cloud's shape estimation (convex hull of C^+), simulates the move in each of k_d directions and calculates the change of area after each move. In accordance to greedy approach the direction that increases the area most is chosen as a new direction of the node's movement. However, as decision is independent on the simultaneous decisions of other nodes, it may occur that the chosen direction is not optimal in the given situation. As in the exploration phase moving in the chosen direction is achieved by adding attracting goal g in an appropriate location $\mathbf{c}^i_g$ with $d^i_g = 1$. The example of possible directions for $k_d = 8$ is presented in Figure 1.

The above decision making process should be applied only to the node D_i which location c^i is one of the vertices of convex hull created by C^+ (lies on the estimated boundary). The node that is inside the estimated boundary should move towards one of the edges of approximated cloud's shape. To

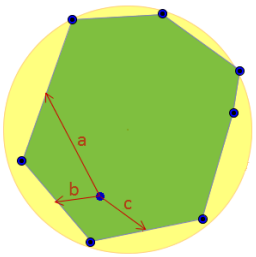

Fig. 2: The target edges chosen by the node inside estimated boundary according to the strategy: (a) — the longest, (b) — the closest, (c) — the greatest relation of the length of the edge to the distance to the edge.

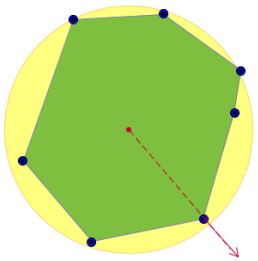

Fig. 3: The force acting on the node in the centroid approach. Red dot is the estimated centroid of the cloud, red arrow represents the force.

improve uniform distribution of nodes on the boundary the target g is located in the middle of the chosen edge. Three strategies for choosing an edge were proposed (Fig. 2):

(a) the longest (to distribute nodes uniformly on the boundary);
(b) the closest (to limit energy consumption);
(c) with the greatest value of ratio *length of the edge* to *distance of the node to the middle of the edge* (trade off between energy consumption and uniform distribution).

When the node is on the boundary of the real cloud its greedy decision to increase area of convex hull causes that it escapes from the area covered by gas. Then it is attracted by centroid and returns to the position on the boundary. Such repeated behaviour causes that node pass considerable distance within small area but do not improve quality of cloud detection significantly. Hence, simple stabilization mechanism to limit energy consumption is proposed. If the node senses gas in the given time and was outside the cloud (did not sense gas) in one of the last k_s steps then it freezes ($\epsilon_g^i = 0$[1]). The higher value of k_s is the greater network stability is expected.

B. Centroid repulsion

The second, as well decentralized, method is based on idea to repeal nodes that sense gas from the center of cloud to keep track of changing cloud's shape. To repel the node to the boundary of cloud the goal g is localized in $\mathbf{c}_c$. The reference distance of that goal $\hat{d}_g^i$ is slightly greater than the greatest distance between any of points from C^+ and $\mathbf{c}_c$:

$$\hat{d}_g^i = \max_{\mathbf{c}^i \in C^+} d(\mathbf{c}^i, \mathbf{c}_c) + \epsilon \tag{3}$$

where ϵ is slightly greater than zero and $d(\mathbf{c}^i, c_c)$ is Euclidean distance between two points $\mathbf{c}^i$ and $\mathbf{c}_c$. The result of the repulsion from the centroid is the node movement in direction shown on Fig. 3.

Similarly to greedy approach, when the node is on the boundary it is frequently being pushed out and drag into the cloud. Hence, the aforementioned stabilization mechanism is added also in this case.

[1]It is assumed that if $U^i = 0$ than the node D_i freezes.

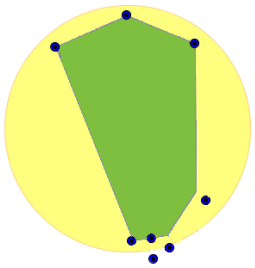

Fig. 4: Distribution of nodes after 40 steps of exemplary simulation if only goal localized in centroid is considered and other nodes' locations are ignored (i.e. $\epsilon_j^i = 0$).

If the node location is not influenced by locations of other nodes (i.e. $\epsilon_j^i = 0$) then estimated area covered by gas is strictly dependant on initial location of nodes. If the location of nodes is similar, which is a frequent situation in real life scenarios, the nodes are not uniformly distributed on the boundary, thus much of dangerous area is not discovered (Fig. 4). To uniformly distribute nodes on the boundary in decentralized manner each node should repel from each node that senses gas. Hence, ϵ_j^i should be greater than zero if node D_j senses gas and the expected distance between node D_i and D_j (d_i^j) should be greater than current distance between these nodes ($\hat{d}_j^i$). As long $\hat{d}_j^i - d_i^j = \Delta d = const$ ($\Delta d > 0$) for each node D_j it can be observed that according to (1) the closer the nodes are the bigger influence on each other they have. Fig. 5 depicts forces acting on exemplary node from all other nodes and the goal located in centroid, as all are treated as potential sources.

Due to the introduction of stabilization mechanism the question when $\epsilon_j^i > 0$ arises. Four variants exist:

(i) only when repelling from centroid is considered ($\epsilon_g^i > 0$);
(ii) only in stabilization phase — when repelling from centroid is deactivated ($\epsilon_g^i = 0$);
(iii) always (independently on value of ϵ_g^i);
(iv) never.

It can be expected that the more often interaction between nodes is taken into account the better shape of cloud will be estimated. However, the consequence of often interaction

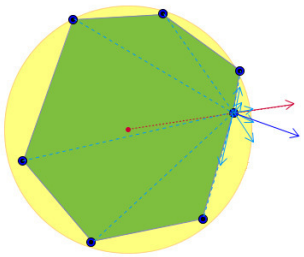

Fig. 5: Forces acting on the node if repelling from other nodes is considered. Red dot is the centroid of estimated cloud area, red arrow is force resulting from repelling from the centroid and blue arrows are forces resulting from repelling from other nodes. Dark blue arrow is resultant force acting on the node.

between nodes will be increased energy consumption due to longer distance traveled by nodes and more communication. All variants, as well as other ideas presented in this section for both greedy and centroid approach, were examined and the results are presented below.

V. Experiments

The experiments were conducted with MobASim platform [47], which contains both PFM model and simple model of heavy gas dispersion. The aim of the experiments was to verify the quality of the proposed approaches and to adjust their parameters according to the following criteria:

1) percent C_{cov} of the gas cloud covered by a MANET

$$C_{cov} = \frac{cov_{\mathcal{G}}}{cov_{GC}} \cdot 100\%, \tag{4}$$

where C_{cov} is the percent of a surface of a gas cloud detected by MANET, cov_{GC} denotes a surface of the whole gas cloud, $cov_{\mathcal{G}}$ an area of a polygon with boundary discovered by all sensing devices.

2) total distance traveled by all nodes, which is the major factor of the energy consumption.

Each experiment was composed of nine different (in terms of wind velocity and cloud initial position) simulations in which the MANET was used to detect area covered with gas (Fig. 6). The variety of scenarios allowed for gathering results independent on initial position of network relative to the cloud. In each simulation the same configuration of environment and gas (chlorine) are taken (Table I). In every experiment each of the nodes used the same configuration of the method in the process of network self-organization. The network is composed of $n = 10$ nodes.

The result of each experiment are graphs of the above criteria versus time (in each simulation $t = 0$ is the moment of detecting the gas by at least one node).

A. Greedy approach

Firstly, the strategies for choosing target edge by node inside the detected area were examined. The other parameters of this method were set as follows: k_d = 8 and k_s = 4. The results are

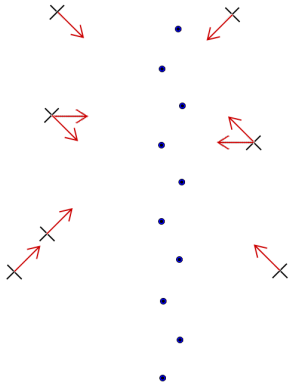

Fig. 6: Initial topology of MANET and configurations of clouds — initial position of cloud is marked with a black cross and the velocity of wind with a red arrow. If one cross is associated with two different arrows then it is two different configurations (with the same initial position of the cloud).

TABLE I: Values of parameters of the chlorine gas cloud simulation model [47].

Symbol	Value	Units
$\mathbf{c}_c$	[200, 200]	$[m,m]$
$\|v_c\|$	1	$\frac{m}{s}$
r	10	m
m_0	2000	kg
m_a	0	kg
g	9.81	$\frac{m}{s^2}$

T_{air}	293.15	K
α	0.9	-

presented in Figure 7. As expected the quality of gas cloud detection is directly proportional to the distance traveled by nodes. Hence the choice of strategy depends on priorities in concrete application — if the priority is quality of detection than (a) strategy should be chosen and this strategy is chosen for further considerations. Otherwise, if the energy efficiency is critical aspect the (b) strategy is the most efficient choice.

The second parameter to adjust was the number of directions considered by a node localized on the estimated boundary of cloud, k_d. The length of stabilization phase was set as before to k_s = 4. The obtained results (Fig. 8) for $k_d \in \{4, 8, 16\}$ shows that influence of this parameter on the traveled distance is minimal. However, greater number of considered directions (8 and 16) increases quality of detection. Because of no difference between results for $k_d = 8$ and $k_d = 16$, the $k_d = 8$ is deemed as better as less computation is needed to take single decision.

Finally length of stabilization phase (parameter k_s) was

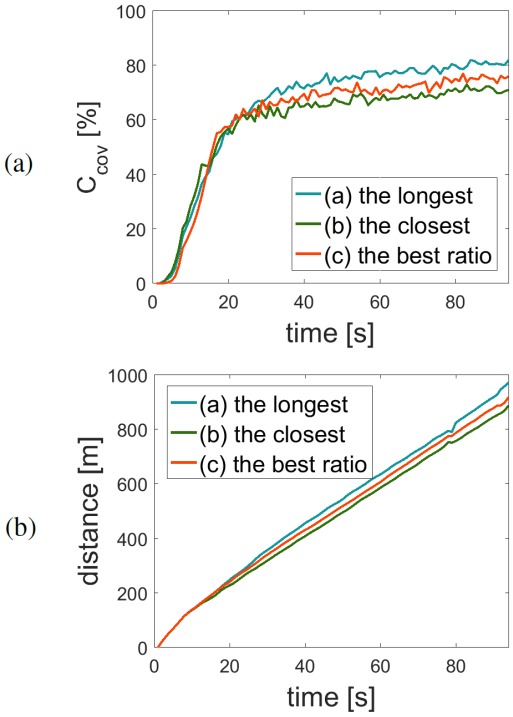

Fig. 7: Cloud detection quality and distance traveled if nodes take decision with greedy approach configured with $k_d = 8$ and $k_s = 4$ and different strategies for choosing edge.

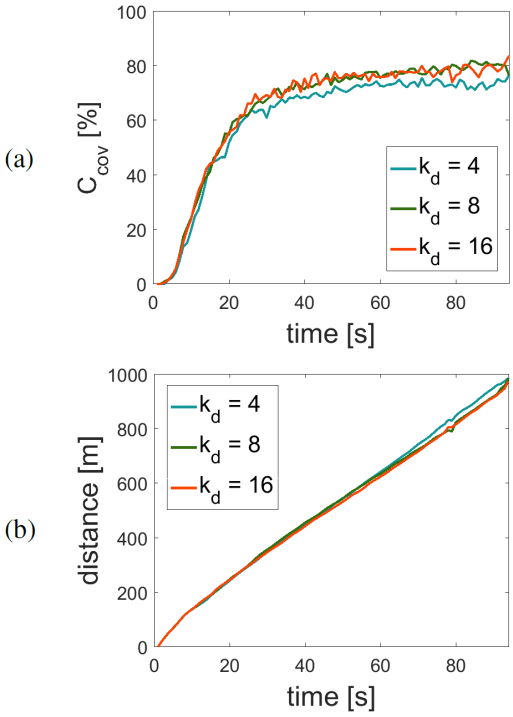

Fig. 8: Cloud detection quality and distance traveled if nodes take decision with greedy approach configured with $k_s = 4$, choosing the longest edge and different values of k_d.

considered. As Figure 9 depicts, the stabilization mechanism has great influence on distance traveled — for $k_s = 4$ the increase of traveled distance is about 45%, whereas decrease in quality of finally detected area covered by cloud is minimal. This value is assumed to be the best in further considerations. According to the results disabling stabilization mechanism can be justified for cases when faster detection of covered area is critical.

The result of deploying MANET composed of nodes taking decision with greedy approach ($k_s = 4$, $k_d = 8$ and choosing the middle of the longest edge) at the end of simulation is presented on Figure 10.

B. Centroid repulsion

Then centroid repulsion approach was examined. In the first experiment the influence of stabilization mechanism and its length (parameter k_s) was tested (Fig. 11), with $\epsilon_j^i = 0$. Significant influence of the stabilization mechanism on the quality of cloud shape detection can be observed only in a very beginning of simulation, when the cloud grows rapidly — as expected the longer stabilization period is the smaller area covered by gas is detected. Comparing the distance traveled for different configurations it appears that $k_s > 4$ does not reduce the energy consumption enough to justify weaker cloud detection. For $k_s = 4$ the reduce of distance traveled is around 50% and this value is used in further considerations.

The second experiment was conducted to examine the influence of repelling nodes from each other. The results of implementing aforementioned strategies (Fig. 12) indicate significant improvement in cloud detection quality if repelling is turned on ($\epsilon_j^i > 0$). However, activating repelling from other nodes in stabilization phase (strategies (ii) and (iii)) causes serious increases of distance traveled by nodes. Hence strategy (i) — repelling from other nodes only when repelling from centroid is active ($\epsilon_g^i > 0$) — can be deemed as conciliation between energy and quality aspects. In the future the possibility of changing strategy during the network deployment to increase quality of detection without significant increase of the distance traveled should be examined.

In Figure 13 the topology of network created by nodes that takes decisions according to centroid approach ($k_s = 4$ and repelling from others nodes only when repelling from centroid is active - strategy (i)) is presented.

C. Comparison

The detection of the exact boundary of the cloud is impossible due to the limited number of nodes. Hence, it can be assumed that both methods detects the area covered by gas satisfactorily — the nodes are placed uniformly on the boundary, thus detected area is close to the maximum. The greedy approach performs slightly better in the middle phase of the cloud detection (steps 15-60) in terms of detection

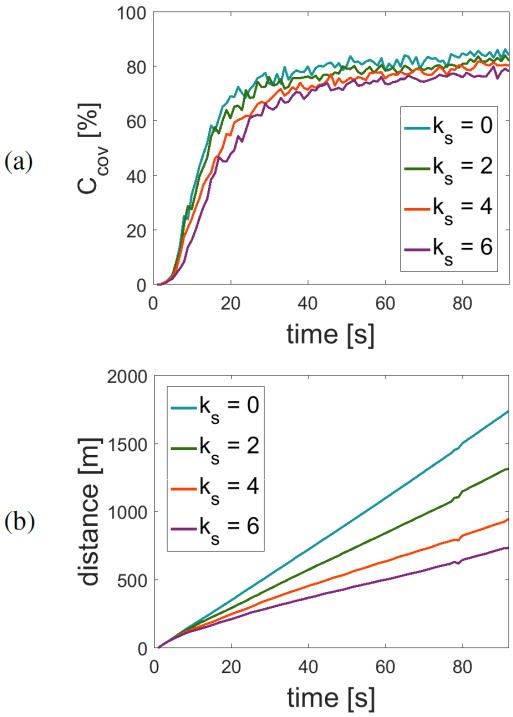

Fig. 9: Cloud detection quality and distance traveled if nodes take decision with greedy approach configured with $k_d = 8$, choosing the longest edge and different values of k_s.

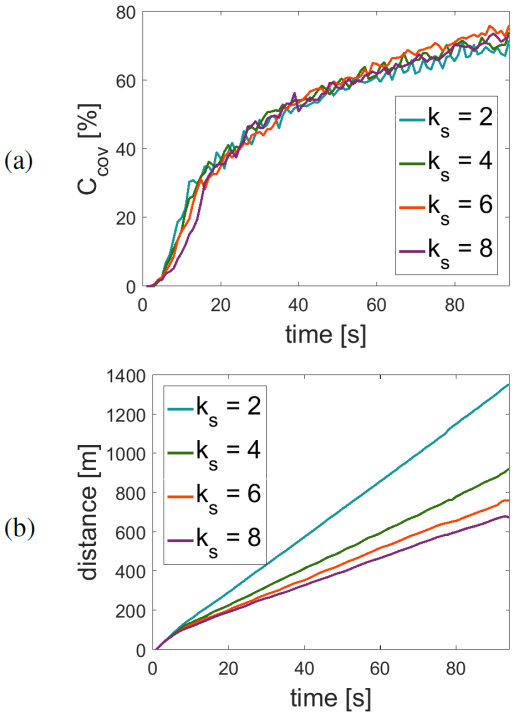

Fig. 11: Cloud detection quality and distance traveled if nodes take decision with centroid approach configured with no repelling from other nodes and different values of k_s.

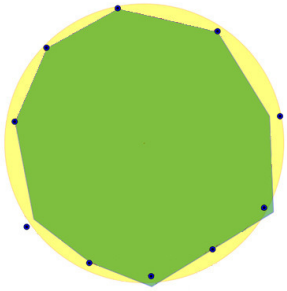

Fig. 10: Topology of MANET in the end of simulation — greedy approach with $k_d = 8$, choosing the longest edge strategy and $k_s = 4$.

quality (Fig. 14). In respect of energy saving there is no significant difference between both methods.

VI. Conclusions

The application of MANET for detecting and tracking cloud of heavy gas was proposed. Two decision-making methods, based on greedy approach and centroid repulsion, were proposed. Both methods proved to be satisfactory in detecting and tracking gas cloud in a simple scenario. Different configurations of methods where tested and compared to adjust parameters values in order to decrease energy consumption and increase quality of cloud's shape detection.

We believe that method based on repulsion from centroid should be used as the basis for future research as this method allow straightforward integration with other decision modules (e.g. module to avoid collisions or tracking the boundary), especially if they are based on PFM model as well.

The future research should concentrate on few areas. Firstly, more complex environment should be considered, e.g. with obstacles, slopes and changing wind direction, to examine method in the case of irregular cloud shape. The possibility to dynamically adjust values of discussed parameters during MANET deployment is also worth considering.

Secondly, scenarios without external communication system should be considered. Thus, the method should be extended with connectivity maintenance mechanism which would allow multi-hop communication between each pair of nodes. As presented approaches create ring topology, which can be ineffective and error prune in terms of communication, creating some internal-cloud communication layer or network clusterization should be investigated.

Mobile sensor elements based on robotic platform YROBOT

***Abstract*—During the years 2014-2015 a kit called Yrobot was developed at the Department of technical cybernetics. The kit is a mobile robotic platform designed mainly to support technical education at high schools and universities. Since the kit was presented at conferences RAAD 2014 and EDERC 2014 for the first time, several expansion modules and interesting applications were developed. One application is presented in this paper. The application uses the mobility of wireless sensors to map the chosen area. As an example, we realized RSSI measurements and visualized them as a function of sensor position. Obviously, one can find many similar tasks: mapping of temperature or gas concentration in given space and the like. Our ultimate goal is to analyze the possibilities of using RSSI measurements for indoor localization. However, at this stage of research, we were focused just on acquiring the data and their subsequent visualization.**

I. Introduction

IN PREVIOUS years, simple mobile system Yrobot was developed at the Department of technical cybernetics. This system was designed especially for teaching IT subjects in the high schools. The concept of the system, its features and functions, as well as first experience of deployment of the system in teaching, were presented at the conference RAAD in 2014 [2, 3]. Original author's intent was as following: "By using a simple technical device to increase the motivation of high school students in studying technical fields, particularly in information technologies." Thanks to the long-term support of the Volkswagen Slovakia Foundation, Yrobot kits were delivered to the high schools. Our team prepared detailed textbooks also [1]. Based on the Yrobot platform, competition for high school students "Program the robot - Yrobot Cup" was organized and other supporting activities were carried out. Note that the robotic platform has the nature of open source hardware and thus, we suppose the development of other applications (hardware and software modules) directly by high schools and universities students. In addition to the typical educational mission, the platform allows verification of various methods of information processing. The data can be obtained from the real environment using different sensor modules.

Many modules were developed to sense:

- temperature and humidity,
- parameters of magnetic fields,
- acceleration,
- illumination,
- sound (20 Hz to 4 kHz),
- concentrations of CO2, CO, NOx,
- distance (using ultrasound),
- optical reflectivity of the surface.

Connection of sensors with mobile platform brings many solutions that often go beyond the simple application tasks.

The mobile platform is formed by a simple MCU ATmega 16, a pair of DC motors and supporting electronics. The block structure of the platform is shown in Fig.1.

Wireless connectivity of mobile robots can further expand set of tasks that can be successfully solved by Yrobot platform. Therefore, we developed a communication module providing wireless communication between the mobile platforms.

II. RF Communication Modules

We assume that wireless connectivity of mobile robots extend significantly the application potential of the platform. Recall that Yrobot was originally developed as an autonomous device capable of solving simple tasks based on the status of its sensors (line following, obstacles avoiding, area browsing). Wireless communication changes the autonomous Yrobot platform to the cooperative system of multiple robots for solving problems using data fusion. Providing connectivity allows transition from autonomous to multi-robotic system and the robust solutions of complex challenges. To allow effective communication between elements of the system a variety of communication technologies (protocols and network topologies) can be used. First, we have decided to implement three separate communication modules operating in the ISM 2.4 GHz band.

In table I. are shown main parameters of selected communication technologies.

All developed modules are connected via connectors of the motherboard to the microcontroller on Yrobot. The motherboard provides power supply to the communication modules. Communication with modules is serial, either asynchronous (UART) or synchronous (SPI). The module contains circuitry to ensure power supply, logic signals level shift and selection of communication line UART/SPI. LEDs are used to signalize status of communication module. The buttons on the module allow restarting of the module, firmware change or change of the operation mode.

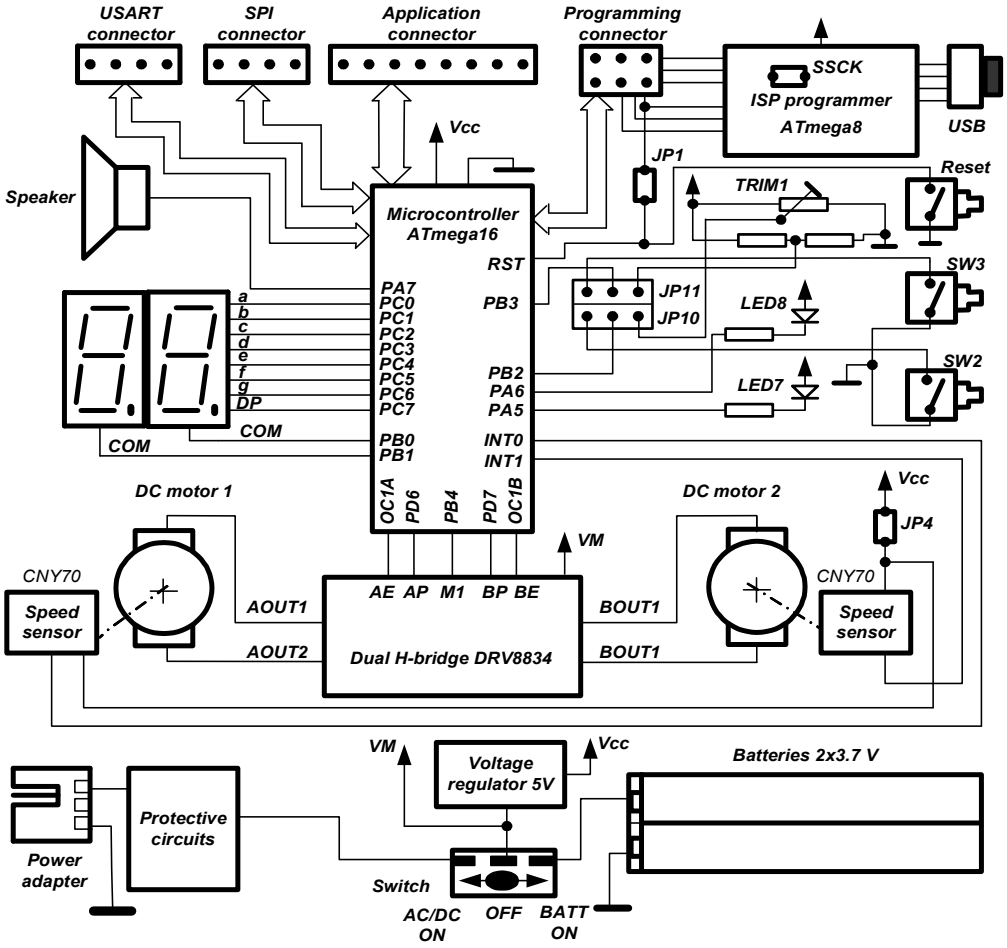

Fig 1. Block structure of Yrobot mobile platform

III. Communication Module Y-WiFi

As a first module, we developed communication module Y-WiFi. The essential element of this system is WizFi250 communication module. The WizFi250 module has an integrated LNA, printed antenna, and connector for external antenna. It offers secure communication based on protocols WEP, WPA, and WPA2. It is controlled by a set of AT commands.

Module Y-WiFi includes all other components that allow easy connection to the mobile Yrobot platform or to a personal computer. The module Y-WiFi can be connected to the PC via the USB port. FT323RL circuit was used to convert UART to USB. Block diagram of the module is shown in Fig. 2.

The module contains two buttons S1 and S2 that allow selection of basic operation mode and restarting of the module. Status of the WizFi250 module is displayed using two LEDs – LED1 is on when the connection is established and LED 2 is on in data mode. Status of the FT323RL circuit is likewise indicated by LED3 (pulsing when data are transmitted) and LED4 (pulsing when data are received). LED5 is used to indicate the power-supply.

Jumper JMP1 allows selection between application or BOOT mode in which can be updated module firmware.

Table I.
Communication technologies

Network technology	Standard	Frequency band	Embedded module	Max bit rate
WiFi	802.11 b/g/n	2.4 GHz	WizFi250	65 Mbps
Zigbee	802.15.4	2.4 GHz	JN5168M0	1Mbps
			MRF24J40	250 kbs
Bluetooth v. 2.0 EDR	802.15.1	2.4 GHz	BTM182	3 Mbps

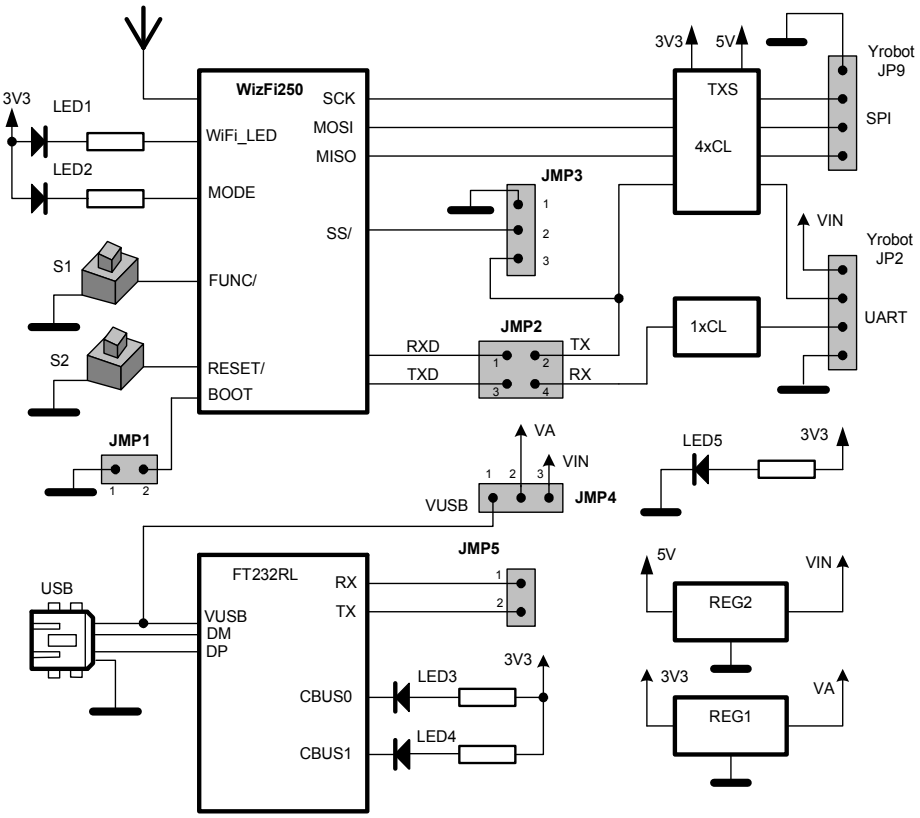

Fig 2. Block structure of Yrobot mobile platform

Jumpers JMP2 and JMP5 select connection of communication module WizFi250 to a PC (via USB) or to the Yrobot platform. It is also possible to connect a PC to the Yrobot. Jumper JMP3 is used when communicating with the module using SPI interface. Finally, with a jumper JMP4 we choose source of power supply for the module – PC USB or Yrobot batteries.

IV. Experiment

Using the described technical means, we conducted an experiment to determine the signal strength map in the 2.4 GHz band. The experiment was carried out in the hallway of our workplace. WiFi internet connection in the hallway and in adjacent rooms is provided by Access Point Planet WAP-4000 with the following parameters: standard 802.11g, channel 7, authentication: WPA-PSK, transmitter power set to a minimum (-12 dB). Transmitter power during the measurement was set to a minimum in order to magnify the signal attenuation in places distant from the AP. The measurement was carried out at the time when the hallway was empty, as the presence of people could influence the results.

Yrobot was programmed so that it can be controlled via a notebook. The Y-WiFi module was configured in Station Mode with a fixed IP address. The Y-WiFi module had an activated TCP server that listens on port 5000. Yrobot movement was based on orders received by the server. The speed of rotation of the robot's wheels was set at about 1 revolution per second. This corresponds to a speed of 0.2 m/s. After each half turn of the wheel (e.g. every 0.1 m), the strength of the signal (RSSI) was measured and sent to the client (notebook).

Control notebook was also connected to a WiFi network and using the Realterm application it was connected to the Y-WiFi module. Realterm application was used for the reason that it allows to send pressed buttons to the server and record the received data to a file simultaneously. Fig. 3 shows the robotic platform Yrobot with Y-WiFi module used in the experiment.

Fig. 4 depicts a plan view of the hallway and the route of the robot during the experiment. The distance of adjacent tracks was 0.3 m. The whole experiment was divided into three parts – the two short passages and a larger central hall were measured independently. After measurements, the three sets of data were combined into one. RSSI was measured about 1900 times during the experiment. The data were interpolated using Matlab in order to obtain values with a spatial resolution of 0.1 m. The measured values are shown in Fig. 5. The map is consistent with our assumptions that the weakest signal is in the areas that are shaded by walls.

Note that during the measurement the antenna of Y-WiFi module was only about 7 cm above the ground. The situation in different height may be different.

The acquired map can be partially used for determining the position of the robot based on RSSI measurements. Obviously, the estimation of the position of the robot based on a single measurement is not possible. Significantly more

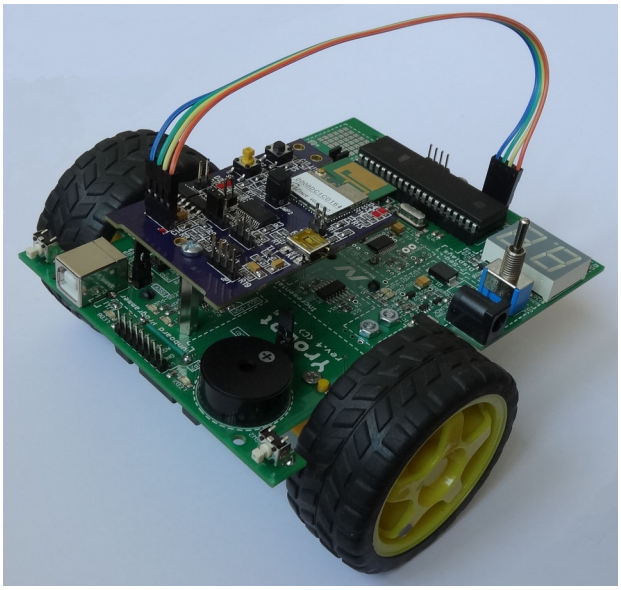

Fig 3. Mobile platform Yrobot with Y-WiFi module

precise localization should be possible with a map obtained by a directional antenna that can be rotated in different directions. Such a system is currently under development.

V. Conclusion

Extension of the Yrobot platform with network modules significantly expands the variety of applications that can be realized with it. Based on the experiment with indoor RSSI measurements it can be stated that the Yrobot system enhanced by communication modules with wireless connectivity provides more functionality and allows development of many interesting applications such as precise localization of mobile systems using signal strength measurements.

In the next step we want to integrate the mobile platform into IoT environment using ThingWorx suite. We would like to expand the possibilities of the Yrobot platform further by developing of the additional modules for technologies such as RFID, NFC, Z-Wave and a chosen proprietary communication systems in the ISM bands (eg. RFM70).

***Abstract*—Greedy routing in VANETs requires some geographical informations, such as the source location and the destination location. The first one could be obtained using some localization devices like GPS receiver. However, the second one is provided by a location service. This later has a high overhead especially if it is implemented over V2V (vehicle to vehicle) communications. Many location services are well known as HLS, RLS, GLS.**

This paper is interested in reducing this overhead by using some Road Side Units (RSU) already deployed along the roads. We propose here a location service called "improved Reactive Location Service (iRLS)", which is an extension of the RLS service. The major difference is that RLS assumes only V2V communications and iRLS takes profit of a wireless backbone based on RSUs to catch the destination's position. This allows to reduce the overhead instead of flooding requests and also makes the communication faster since we will not have to wait to the request to reach the destination before receiving the response and then starting sending data. In our proposal, the closest RSU will reply with the actual location.

In order to show the contribution of our approach, we have conducted some simulations that prove that iRLS outperforms any geographic protocol by using the V2I communications in terms of end-to-end delay which is one of the most important parameter. We considered also the ratio of packet received correctly by the destination vehicle (PDR), our protocol improves significantly this second parameter, and ensures more than 20% of packets received correctly

***Index Terms*—VANETs; Location-based Services; Geographic Routing Protocols, .**

I. Introduction

VANETs (Vehicular Ad-hoc NETworks) are a special case of MANETs (Mobile Ad-hoc NETworks). Therefore, the routing protocols used for MANETs could be adapted for MANETs. However, the topology-based protocols in MANETs are not useful for VANETs because of the high mobility rate. Then, geographic routing protocols are more suitable for such networks since they are more scalable.

The geographic routing protocols need as an input the node's location as well as the destination's location. The node's position is easy to obtain. However the destination's position is obtained from a location service. This service is responsible to reply to requests like : "Where is the node X?". "Reactive Location Service" (RLS) is a well known location service. When a node needs to find the position of another node, it floods a request. When this request reaches the destination, this latter replies with its current position using the same path for the request delivery. Therefore, RLS uses only V2V communication without considering the V2I (vehicle to infrastructure) ones. For this purpose, we propose a new location service denoted "improved Reactive Location Service" (iRLS). This service uses mainly the RSU network to reply directly to the location request in order to avoid previous flooding. This allows to gain in term of overhead and delay as demonstrated by the simulations that have been conducted using the well known NS-3 simulator.

The paper is organized as follows. The section II presents some works related to the location-based service and the geographic routing protocols. Section III described our iRLS proposal. Section IV introduces the simulations conducted with our proposal. Finally, section V concludes the paper and presents some future works.

II. Related works

In this section, we will describe some related works, published these last two decades. All these works focused on routing in VANET environments where most of solutions used V2V communications and/or V2I communications. They do not consider position changes during the dissemination process. Both the source node and the destination node are vehicles in general case. To deal with the high moving speed and dynamic changes of the topology, RSUs can provide a lot of benefits in order to achieve efficient routing of messages over the network. In order to propose a realistic solution,, we do not need to deploy an RSU at each road intersection. An overview on routing for mobile and vehicular ad hoc networks is well detailed in [1].

In [2], authors propose an improved version of DGRP (Directional Greedy Routing Protocol). In addition to the information used by DGRP (position, speed, direction) provided by a GPS sensor, they consider and evaluate link stability. As a result, they reduce links breakage, enhance reliability of a used path and ensure a high packet delivery ratio.

Another proposed work which assists routing in VANETs using base station was presented in [3]. Roads are composed of segments, each of them is governed by a base station. This later sends a response to a route request packet by choosing the shortest path using RSUs. But if we do not

have any available path, the RSU checks if there is enough free bandwidth to grant the request. They have used two mechanisms, using Fast Learning Neural Networks, to prevent link failure and to predict bandwidth consumption during handoffs. An alternative path will be established, before that a broken link occurs.

Authors in [4] have proposed an infrastructure-assisted routing protocol. The main benefits behind this approach is to reduce the routing overhead and improve the end-to-end performance. A backbone network ensures connectivity by using RSUs, an enhancing search of the shortest path to reach the destination is done by this infrastructure. Authors present an extended protocol to the topology-aware GRS routing protocol. At any intersection, anchor nodes in the GRS system compute the shortest path to reach the destination using the Djikstra algorithm without considering the road density or any other parameter which can ensure connectivity of roads.

Roadside-Aided Routing (RAR) has been proposed in [5]. It is another study which prefers V2I communication to improve the search for a stable routes over VANETs networks.

A. Location-based services

Location-based services can be classified into two classes : "Flooding-based" and "Rendez-vous-based". The first class is composed of reactive and proactive services. In the proactive flooding-based location-based service, every node floods its geographic information through all the network periodically. Thus, all the nodes are able to update their location tables. Since this approach uses flooding and may surcharge the network by location update messages, several techniques to reduce the congestion were used. One of them is to tune the update frequency with the node mobility (the more node is moving fast, the higher update location frequency is used).

Therefore, the update frequency decreases with the distance to the node. The second idea is, a node with high mobility sends more update location packets. As a result, there are less packets than a simple flooding scheme without affecting the network performances. For the second group (i.e the reactive flooding-based location-based service), the location response is sent when receiving a location request. This avoids the overhead of useless location information of some nodes updated and never used. But, it adds high latencies not suitable in VANETs. One of these known services is Reactive Location Service (RLS) [6].

In the second class (rendez-vous-based location service), all the nodes agree on a unique mapping of a node to other specific nodes. The geographic information are disseminated through the elected nodes called the "location servers".

Thus, the location-based services consists of two components :

1) Location Update : A node has to recruit location servers (chosen from other nodes) and needs to update its location through theses servers. The location servers are responsible of storing the geographic data of the relating nodes.
2) Location Request : When a node needs to know the location of another node, it broadcasts a location request. The location server will replay as soon as it receives this request.

B. Geographic Routing Protocols

Routing protocols algorithms must choose some criteria to make routing decisions, for instance the number of hops, latency, transmission power, bandwidth, etc. The topology-based routing protocols suffer from heavy discovery and maintenance phases, lack of scalability and high mobility effects (short links). Although, geographic routing are suitable for large scale dynamic networks. The first routing protocol using the geographic information is the *Location-Aided Routing (LAR)* [7]. This protocol used the geographic information in the route discovery. This latter is initiated in a *Request Zone*. If the request doesn't succeed, it initiates another request with a larger *Request Zone* and the decision is made on a routing table. The first real geographic routing protocol is the *Greedy Perimeter Stateless Routing (GPSR)* [8]. It is a reactive protocol which forwards the packet to the target's nearest neighbor (Greedy Forwarding approach) until reaching the destination. Therefore, it scales better than the topology-based protocols, but it does still not consider the urban streets topology and the existence of obstacles to radio transmissions. Another geographic routing protocol is the *Geographic Source Routing (GSR)* [9]. It combines geographical information and urban topology (street awareness). The sender calculates the shorter path (using Djikstra algorithm) to the destination from a map location information. Then, it selects a sequence of intersections (anchor-based) by which the data packet has to travel, thus forming the shortest path routing. To send messages from one intersection to another, it uses the greedy forwarding approach. The choice of intersections is fixed and does not consider the spatial and temporal traffic variations. Therefore, it increases the risk of choosing streets where the connectivity is not guaranteed and losing packets.

In [10], authors propose an improved version of DGRP (Directional Greedy Routing Protocol). In addition to the information used by DGPR (position, speed, direction) provided by GPS, they consider and evaluate link stability. As a result, they reduce links breakage, enhance reliability of a used path and ensure a high packet delivery ratio.

III. Improved Location-based Service

To better understand our proposal, we present a simple scenario in the Figure 1. We suppose that the vehicle V1 has data to send to the vehicle V6, which is not in its direct neighborhood. If V1 has a valid and fresh route in its routing table, it sends immediately the data without any routing service requirement, otherwise it broadcast a request to find a suitable route to use. Since V1 is in the RSU4's range, V1 sends a request to RSU4 asking for the new V6's location. RSUs are connected together and exchange vehicles' positions when needed. After receiving the response from RSU4, V1 starts sending data using the greedy approach, where it selects

the closest neighbor to the destination V6 (here V8). Then, data packets travel through V8, V7 and finally to reach V6. Therefore, destination's location could be found more rapidly than using V2V communications when a destination node is far away from the source node;

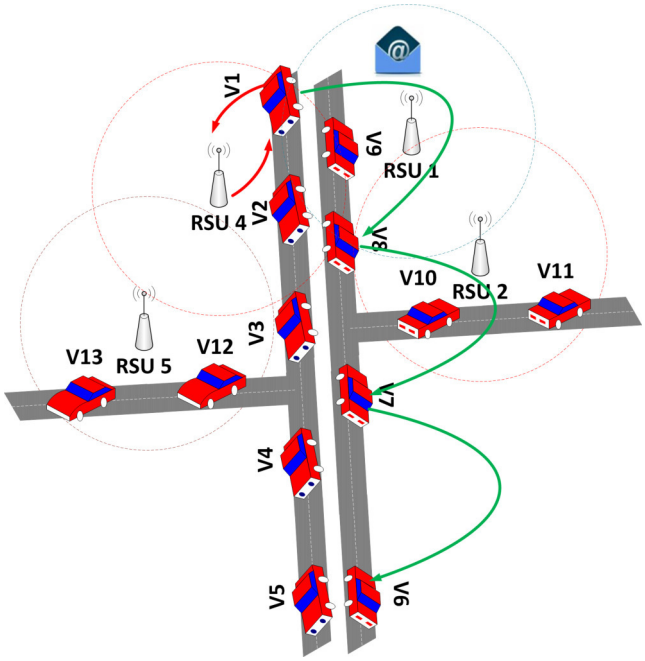

Figure 1. An example of a scenario with iRLS

The algorithm 1 presents more details how the iRLS service works. When starting, the source s looks if it is not in the range of a RSU, then it works like RLS. It floods a request to find the location of the destination d. When the request reaches the node Z that has this information, the latter replies directly to s with d's new position. Otherwise, the node s sends the request in unicast way to this RSU (RSUX). RSUX forwards this request to all connected RSUs. When RSUY receives the request and it has already this information, it replies to RSUX. RSUX then transmits the d's position to node s. Therefore, s has all required information to start sending data. These data are forwarded using the greedy approach until reaching the destination. By reducing the V2V search phase, the available limited bandwidth of our links will be used to transmit the effective data rather than the transmission of control packets. Indeed, our protocol ensures a higher PDR than the standard protocol (see Figure 3).

In the case where a node S has no RSU in its neighborhood, it first sends a request to find the closest RSU. This request is run in a setup step before starting the routing process.

But in some cases, there is not enough vehicle density and the initial request could not be sent (caused by a lack of connectivity). We suggest to resend the packet after a defined time (timeout) until a reply is received from a close RSU.

Algorithm 1 iRLS Location Service

```
1:  function iRLS(s, d, Data)
2:      Initialization : s source, d destination
3:      if (source ∉ RSUX's range) then
4:          s broadcasts requests to find d's position
5:          neighbors floods the request
6:          node Z has d's location and replies directly to s
7:          s sends location request to RSU to find d's position
8:      else
9:          RSU sends request to other RSUs
10:         RSUY has d's location and replies to RSUX
11:         RSU forwards response to s
12:     end if
13:     next ← s
14:     while (next != d) do
15:         choose n the best next hop using greedy approach
16:         s sends data to n
17:         next ← n
18:     end while
19:     Data reaches destination d
20: end function
```

IV. Simulations

A. Working Environment

The simulations were performed using the Ns-2 simulator 2.33 [11]. The geographic routing protocol used is the Greedy Perimeter Stateless Routing (GPSR) [8]. The chosen area is a 2x2 km^2 of a real map representing part of the French city *Reims*. This area is extracted from Open Street Map [12]. The MAC layer used is 802.11p [13]. The parameters used in the simulation are summarized in the Tab. I.

At each simulation, every node initiates 4 CBR traffics of 100 packets with a size of 128 KB to 4 random destination nodes with a second of interval between each sent message. The CBR traffic simulates for example an audio or a video streaming. It may be used in security applications, such as viewing the video stream from a camera located on a bus by the police car or the security agent vehicle. Also, this traffic could be used in entertainment applications to connect to the Internet or to play online video games.

B. Experimentation Results

Our experimentations have provided the following figures. On each figure, we show the network behavior with usual RLS (denoted RLS curve) and the behavior of our proposed solution (denoted iRLS curve for improved RLS). Figure 2 shows the delay to send a message depending on the size of the network from 10 nodes to 100 nodes. we observe that the delay to send a message from a node s to d decreases with iRLS even if the number of nodes is higher. The gain is around 10 per cent. In Figure 3, the results highlight that our protocol can achieve a higher PDR than the RLS one. In the density 100 vehicles, it is clear that taking the same scenario of simulation, our protocol guarantee the same ratio but when using RLS this ratio decreases.

Table I
THE SIMULATION PARAMETERS

Parameters	Value
Channel type	Channel/WirelessChannel
Propagation model	Propagation/TwoRayGround
Network interface	Phy/WirelessPhyExt
MAC layer	802.11p [13]
Interface queue type	Queue/DropTail/PriQueue
Link layer	LL
Antenna model	Antenna/OmniAntenna
Interface queue length	512 packets
Ad-hoc routing protocol	GPSR
Location-based service	RLS
Location cache maximum age	4, 8, 12, 16, and 22 s
Area	2x2 km^2
Number of nodes	10-150
Simulation time	150 s
GPRS beacon interval	0,5 s
CBR traffic	4 x 100 packets / node
CBR packet size	128 KB
CBR sent interval	1 s

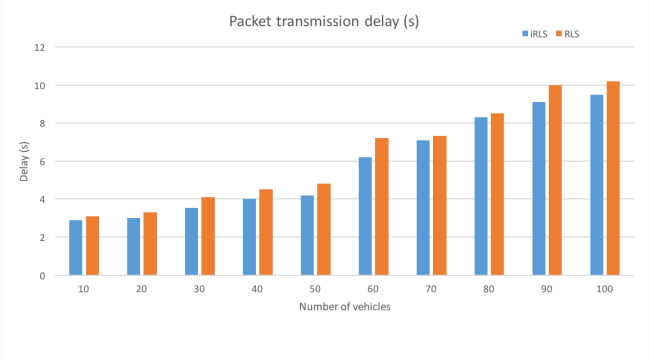

Figure 2. The average delay for packet transmission

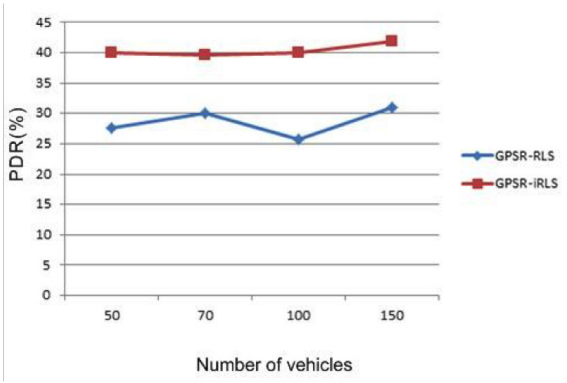

Figure 3. Impact of the number of vehicles on the achieved PDR average

These results show that our protocol outperform by more than 10% in general case the use of RLS. All these result can be explained by the best consumption of the network resources like bandwidth. This observed result is quite predictable since the RLS process uses the V2V communications (a RSU is considered as a vehicle also) then the request is sent through the whole network without any efficiency. Contrary to RLS, iRLS takes advantage of the RSU backbone which provide a fast connection between the initial RSU and the closest to the destination one.

V. Conclusion & Future Works

This paper presents the iRLS location service. This location service takes advantage of deployed RSUs on roads in order to ensure fast replies of destination lookup . RSUs are already wirelessly connected. Therefore, they can exchange data of the nodes position. This enhances the network routing performances. As a consequence, network performances such as the end-to-end delay are better than in the original RLS service. The presented work is realistic since it is applicable in any deployed C-ITS (cooperative Intelligent Transport System) and offers the ability to route packet from a node to another with interesting performances.

As future works, we intend to use the RSUs backbone to send real data. We intend also to study the scalability of such a mechanism. It could be interesting also to evaluate our protocol with another kind of protocols (Topology based protocol), with bandwidth metrics.

***Abstract*—Distributed compressed sensing task can be parallelized into several nodes that is highly suitable for using in Wireless Sensor Networks. Localization is one of the critical tasks solved in wireless systems. This paper investigates the possibilities of localization using compressed sensing implemented on wireless nodes and aggregation node. The presented case study simulates the application scenario of a target deployed in the field. This target is being localized by the wireless sensor network based on the emitted acoustic signal. Several types of the emitted signals have been used during the simulation runs. The emphasis was put on the properties of the reconstruction process such as compression ratio and minimization of the reconstruction error.**

I. Introduction

THE PROBLEM of target localization, in general, can be defined as finding an object in the space. Localization process in wireless sensor networks aims to localize a target based on the sensor data from the spatially distributed wireless nodes. For a single target and/or source localization in wireless sensor networks, there are various methods. For outdoor localization, this can include localization in traffic monitoring (vehicles, aircraft, bicycles, etc.). In indoor environment persons as well as animals and object can be tracked. Scientific literature refers to two core ways for estimation of the target location:

- Angle of Arrival (AOA) [1];
- Time Difference of Arrival (TDOA) [2-5].

In this paper, we are focused on the algorithms for single-source localization. The literature recognizes two basic groups of these algorithms:

- Energy Decay Model-based Localization Algorithms (EDMLA);
- Model Independent Localization Algorithms (MILA).

A. Decay Model-Based Method

The following formula shows the decay model which is in detail described in [6-8]. The received signal strength at i-th wireless node in time instant t can be expressed as follows:

$$y_i(t) = g_i \frac{E(t)}{d_{ik}^2(t)} + n_i(t), \tag{1}$$

where g_i means *gain factor* of i-th sensor. $E(t)$ is the *energy of the received signal in 1 meter distance from the wireless node*, and d_{ik} is the *Euclidean distance between i-th sensor and the target*. Moreover, n_i represents *measurement noise with zero mean value and Gaussian probability distribution* with variance σ_i^2, i.e.$N(0, \sigma_i^2)$.

B. Model-Independent Method

Authors in [9] describe a kernel averaging approach which does not need information about energy decay model. On the other hand in [10], the authors propose novel model-independent localization method and employed a distributed sorting algorithm. The research relies on the fact that the nodes closer to the target can measure higher RSSI (received signal strength indicator). Assuming that the wireless nodes know their rank, the distance estimates can be calculated from the respective probability density functions. RSSI indicator at i-th sensor in time instant t is as follows:

$$y_i(t) = g_i \sum_{k=1}^{K} \frac{E_k(t)}{d_{ik}^{\alpha}(t)} + \epsilon_i(t), \tag{2}$$

where $d_{ik}(t)$ is the *distance between the i-th sensor and k-th target*. K is the *number of targets*. g_i is *gain of i-th sensor*. $\epsilon_i(t)$ is random variable with mean value equal to μ_i and variance given as σ_i^2. $E_k(t)$ is the *energy of the received signal in 1 meter distance from k-th target*. α represents *attenuation exponent*.

The target localization task can be performed by the distributed nodes of a wireless network. An interesting approach arises from combination of compressed sensing and wireless sensor networks using distributed compressed sensing.

II. Distributed Compressed Sensing

A wireless sensor network (WSN) is formed by numerous spatially distributed devices (nodes) that process sensor data. Each node has a power source e.g. in form of battery thus having a limited lifetime. Since the energy consumption is a critical point, low power and efficient signal processing units are used in wireless nodes. Thus, wireless sensor nodes have limited computing and communication capabilities. Although, these nodes have low individual computing power, they can cooperate so that the computational power of the whole network allows performing advanced signal processing tasks [11]. Having the ability of advanced processing tasks leads to higher degree of robustness and greater versatility in low-lost scenario. This represents one of the most attractive reasons

978-83-60810-90-3/$25.00

why WSNs are used for wide range of remote sensing and environmental monitoring applications [12].

From the point of signal processing theory, a major challenge in WSNs is effective design of set of sensor-local signal processing operations and strategies suitable for inter-sensor communication and networking in order to address the desired trade-off among energy consumption, simple design, and overall system performance [13]. This trade-off shows, for example, in sensor lifetime maximization and effective battery utilization when reducing communication bandwidth. This can be achieved by each sensor by locally compressing the observed data and thus low rate inter-sensor communication is required. Such techniques can be represented by distributed compressed sensing (DCS).

Typical DCS scenario comprises numerous sensors measuring individually sparse signals, which are correlated among each other [14]. It should be noted that the signals are sparse in a certain basis. Each sensor individually encodes its signal by transforming it into another, incoherent basis (for example a random one). Then the sensor broadcasts only a few of the resulting coefficients to the aggregation node [14]. One of the advantages of DCS is that it does not require collaboration among the sensors when obtaining and processing the signal. Moreover, random projections in DCS are universal [15]. This means that any sparse basis can be used, which allows the same encoding strategy to be applied in different scenarios. This contributes to the robustness of the solutions based on DCS, i.e. the measurement stream from each sensor has equal priority. This is different from Fourier or wavelet transforms. It should be also mentioned that random measurements allow a progressively better recovery of the data, that means single measurement or more can be lost without the effect on the entire recovery process.

The problem of DCS illustrates the described example that follows. Let's have a network of n nodes, where each node has a piece of information given by x_j where $j = 1, \ldots, n$. Let's assume that each piece of information x_j is a scalar quantity. Together, the scalar quantities form a data vector $\boldsymbol{x} = [x_1, \ldots, x_n]^T$, which is called *networked data*. This underlines the fact that the data is distributed across the network and that the data may be shared over the network [17].

In wireless sensor networks, n can be a large number, thus having the networked data large as well. Therefore, the process of data acquisition at a single point is daunting. However, let's imagine that it is possible to create highly compressed version of vector $\boldsymbol{x}$ in a decentralized fashion. Scientific literature states several decentralized compressed sensing strategies. One strategy relies on the correlations among the a priori known data at different nodes [21]. In such case, a technique called *distributed source coding* known as Slepian-Wolf coding can be utilized as a compression scheme that allows none or little collaboration among the nodes. However, in lots of application scenarios the prior knowledge of the data correlations is not known. This situation supports research in collaborative signal processing within the sensor networks as well as data compression techniques [20]. It can be quite challenging to propose and implement an effective algorithm of distributed and collaborative processing for wireless sensor network [22]. Such algorithms rely to a great extend on specific prior knowledge and the relation of the expected signal correlations. The success of the implementation of such algorithms lies in sophisticated communication pattern and good processing capabilities of a sensor node.

The mentioned projections in standard multi-hop wireless networks utilizing compressed sensing can be expressed as vector $\boldsymbol{y}$, which components y_i can be calculated as follows:

$$y_i = \sum_{j=1}^{n} A_{i,j} x_j. \tag{3}$$

The components y_i are able to be computed in a decentralized fashion and efficiently because each value of the compressed data is represented as a simple linear combination of the values obtained at each node [23].

Basically, there are two simple steps in the computation and transmission of each compressed data sample y_i, where $i = 1, \ldots, k$ [23]:

1) Let's consider n sensor nodes in the wireless sensor network. Each of the sensors as its index $j = 1, \ldots, n$. Each node n_j computes locally properties $A_{i,j}$ and x_j so that the measured data are being multiplied with the corresponding element of the measurement matrix. The measurement matrix can be distributively created as local (at node) realization of $A_{i,j}$ using a pseudo-random number generator initialized by the node identifier, e.g. integers $j = 1, \ldots, n$. Having these node identifiers, particular node can simply calculate the vectors $\{A_{i,j}\}_{i=1}^{k}$, where sensors are indexed as $j = 1, \ldots, n$.
2) The local sensor node variables $A_{i,j}x_j$ are being continuously combined and transmitted over the sensor network using so called *randomized gossip*. The *randomized gossip* represent a decentralized algorithm, which computes linear functions such as:

$$y_i = \sum_{j=1}^{n} A_{i,j} x_j. \tag{4}$$

To summarize compressed sensing, one could say that it is a technique for signal processing and signal representation, where the signal can be sensed only by such number of samples, which corresponds to the signal sparsity in some base. The overall nature of compressed sensing matches the nature of event-driven control presented in the previous sections. Event-driven signal representation and reconstruction mechanism also leads to signal sampling and its reconstruction by as many (little) samples as are truly needed.

III. Case Study and Numerical Results

The idea of the localization system is to identify the position of the target by multiple WSN nodes deployed in the area. To decrease the consumption of the nodes the compressed sensing algorithms are supposed to be used. In order to use DCS the transmitted signal by the target has to follow special

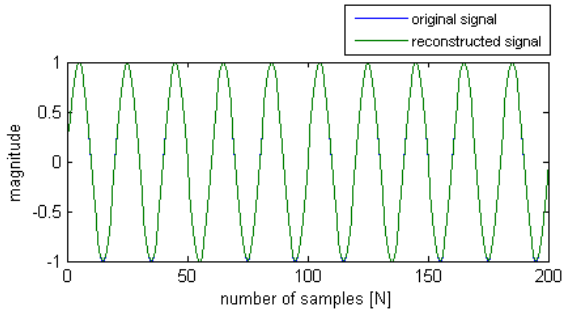

Figure 1. Continuous signal before and after reconstruction

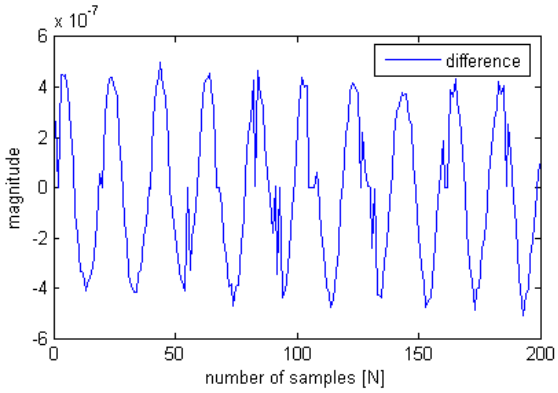

Figure 2. Difference of original and reconstructed continuous signal, cr=100

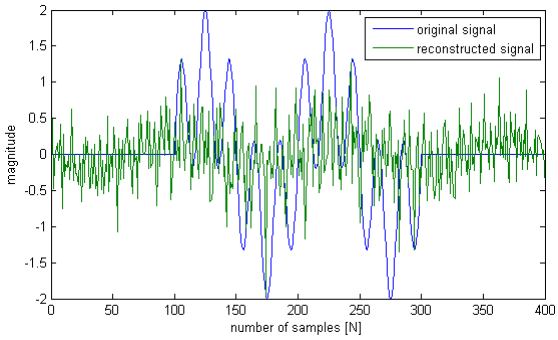

Figure 3. Burst signal (BURST01) before and after reconstruction

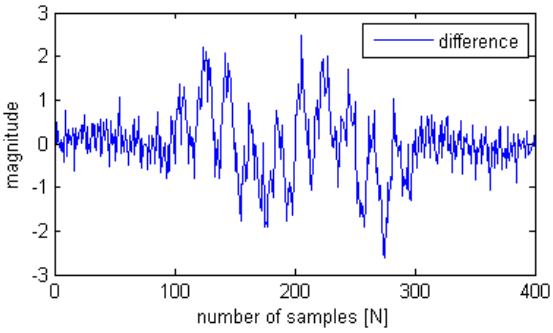

Figure 4. Difference of original and reconstructed burst signal, cr=100

requirements, e.g. certain sparsity in the frequency domain. This paper investigates signals in acoustic domain, i.e. in rage 20Hz up to 20kHz.

For the simulation purposes, the Matlab version 2013b was used. Reconstruction of original signal was performed by using the L1-magic library. The main goal of this article was to inspect the properties of different signals which could be used in the localization tasks. These signals should have suitable parameters for the reconstruction in order to use compressed sensing. All used signals are sparse in the frequency domain.

In the first simulation case, the signal was continuously transmitted. The signal has the sinusoid shape with the frequency of 100 Hz. The reconstruction using the distributed compressed sensing performs well with compression ratio (cr - see equation (5)) up to 200. The compression ratio is expressed by the following formula:

$$cr = \frac{s_a}{\chi}, \tag{5}$$

where cr is the compression ratio, s_a represents the number of all samples in the original signal and χ is the number of randomly selected compressed sensing coefficients. The following Fig. 1 shows the reconstruction of harmonic signal 100 Hz. Despite the fact that in the reconstruction of such a signal the compression ratio can be relatively high, this class of signals are not suitable for localization purposes. The reason is that we are not able to identify the same particular part of the received signal, e.g. the start of the same period.

The second simulation scenario is based on the transmitting the signal in bursts. By modification of the above-mentioned continuous signal, we are able to detect the start of the burst, thus, all nodes are able to determine the time of arrival of the received signal.

The Fig. 3 depicts the reconstruction of the burst signal with the same compression ratio as in the Fig. 1. The burst signal is compounded of the carrier signal and a secondary frequency. Carrier signal has a frequency of the 100Hz and secondary modulated signal has a frequency of 500Hz. The burst contains two periods of the carrier and ten periods of the secondary signal. Having this compression ratio the reconstruction results are insufficient for localization purposes.

Proper change of the parameters of the compression ratio leads to reconstruction improvement. This is demonstrated on the Fig. 5, along with difference between the original and the reconstructed signal on the Fig. 6. Compression ratio was decreased from 100 to 20.

Sumarization of the parameters used in the simulation is shown in Table I. It is obvious that continuous signals are very suitable for compressed sensing and can be reconstructed using high compression ratio, however, it is difficult to use them for localization purposes. The reconstruction error was calculated as a mean value based on differences between the original and reconstructed signals (see Fig. 2, 4, 6).

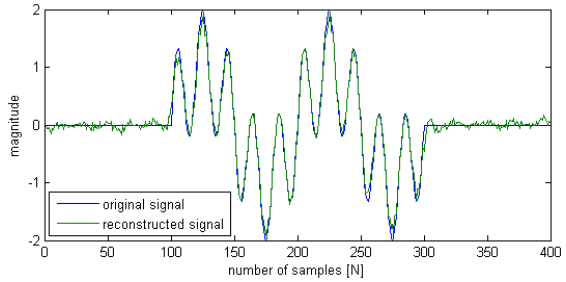

Figure 5. Burst (BURST02) signal before and after reconstruction

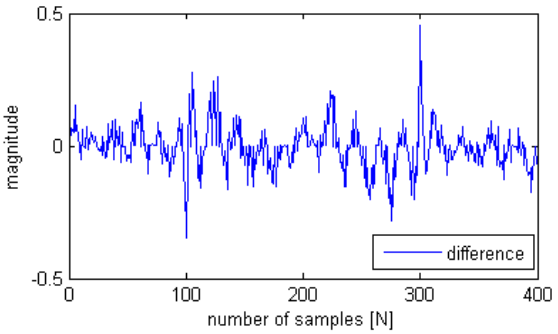

Figure 6. Difference of the original and reconstructed burst signal, cr = 20

Table I
PARAMETERS AND THE RESULTS OF THE SIMULATIONS

Type of the signal	Frequency	Number of periods	cr	Error
CONTINUOUS	100Hz	10	100	$9.52 \cdot 10^{-8}$
BURST01	100Hz	10	100	0.5638
BURST02	100Hz	10	20	0.0536

IV. CONCLUSION

This contribution investigates suitable signals for target localization using WSN and DCS. The results show, that continuous periodic signals can be reconstructed easily with high compression ratio using DCS. However, these signals are not target-identifiable. Changing the form of the transmitted signal broadcast from the target enables the sensor network to detect it. The changed signal has the form of burst, which enables to detect the start of the beacon signal. Based on the time of the arrival and the ability to detect the start of the beacon signal, the network is able to localize the target.

Uniform Inbuilt Wireless Sensor Node for Working Conditions Monitoring

Denis Spirjakin, Alexander M. Baranov
Moscow Aviation Institute
(National Research University),
Moscow, Russia
Email: denis.spirjakin@gmail.com

***Abstract*—All companies strive to eliminate work accidents. But still a lot of professions are exposed to different hazardous conditions and many work injuries and even deaths occur everyday. Monitoring of working conditions is a very important part of labor protection. Combining wireless sensor networks with wearable technology is possible to significantly improve safety delivery capability of such systems and add new functionality to them. In this work we present the design results of the uniforms inbuilt wireless sensor node for working conditions monitoring. The node is able to signalize about employee presence in relation to working facilities, and to monitor the atmosphere for temperature and combustible gases concentration. It consists of light-weighted distributed pieces which are built in to clothes and has low power consumption. The average power consumption of the node is low enough for several weeks autonomous lifetime.**

I. Introduction

While safety standards for industrial plants become tougher, the demand for continuous monitoring of employee state and working conditions including environmental conditions is rising. At the same time modern wearable technology tends to build electronics in to clothes [1] providing new quality in healthcare [2], [3], military [4] and other spheres.

Variety of wireless sensor networks were developed recently. These networks consist of small nodes and are equiped with transceivers, microprocessors and sensors [5], [6]. They can be used in different areas of life (security, military, home automation, etc.). But the most frequent area is environmental [7] and human [8] monitoring.

Incorporating wireless sensor networks with wearable technology is possible to significantly improve safety delivery capability of monitoring systems and add new functionality to them. Such “smart” uniforms can provide in-situ monitoring of people, facilities and environmental conditions and in case of an emergency situation assist special services and employees.

It is expected that in the nearest future wireless sensor networks will connect computer networks and physical world. That will lead to tight integration of real and virtual worlds [9] where communication will go between people and devices – Internet of Things [10].

In this work we present the design results of the uniform inbuilt wireless sensor node for working conditions monitoring. The node is able to control employee presence in relation to working facilities, and to monitor the atmosphere for temperature and combustible gases concentration. It consists of light-weighted distributed pieces which are built in to clothes and has low power consumption. The average power consumption of the node is low enough for several weeks autonomous lifetime.

The paper is organized as follows: at first we overview the node in Section II. In Section III we describe the sensing circuit of the node. Section IV is dedicated to data transmission and presence detection principles which are used in this work. The power consumption of the node is discussed in Section V. Finally, we provide concluding remarks in Section VI.

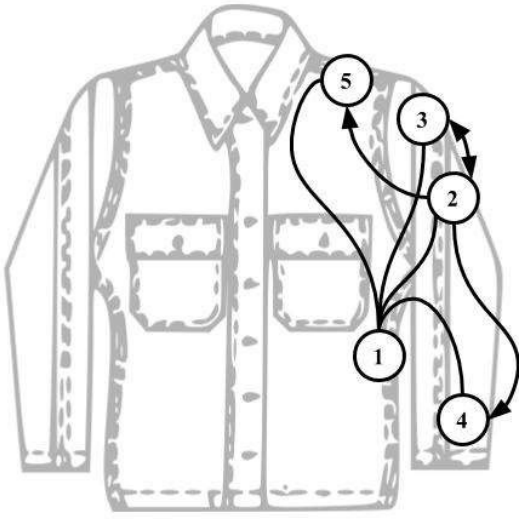

Fig. 1. Block diagram of the node: a power source (1), a sensor module (2), a trasceiver (3), a light indicator (4) and a buzzer (5).

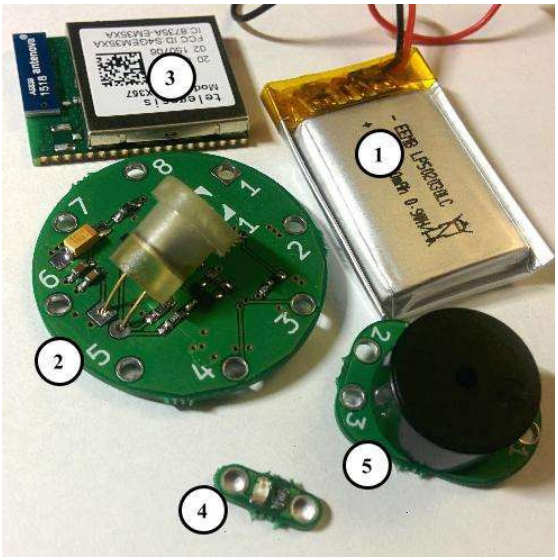

Fig. 2. The node pieces: a power source (1), a sensor module (2), a trasceiver (3), a light indicator (4) and a buzzer (5).

Fig. 3. The assembled node: the light indicator (1), the sensor module (2) and the buzzer (3).

II. Node Overview

The diagram of the uniform inbuilt wireless sensor network node is presented in Fig. 1. The node consists of several distributed pieces wich are built in to a jacket: a power source (1), a sensor module (2), a trasceiver (3), a light indicator (4) and a buzzer (5). The node pieces are presented in Fig. 2.

Since the node is wearable and built in to clothes, all its pieces are light and small. At the same time, the pieces are placed according to their functions and distributed around the clothes to make wearing comfortable.

The power source of the node is a lithium-polymer battery. Its nominal voltage is 3.6 V and the capacity is 250 mAh. The weight of the battery is about 5 g and the dimensions are 30×20×5 mm. The battery is placed in the bottom of the jacket and connected to a ribbon cable to provide power to other pieces.

The sensor module provides sensing of the atmosphere temperature and combustible gases concentration. It also controls the light indicator and the buzzer to maintain alarm signals and send and receive data using the transceiver.

This module is based on ATxmega16E5 microcontroller. It uses built-in temperature sensor to measure the atmosphere temperature and the commercial catalytic gas sensor for combustible gases concentration measuring. The gas sensor is manufactured by NTC IGD (Russia) and its power consumption is 200 mW in continuous measurement mode. Therefore, the catalytic gas sensor is very power hungry. To decrease its power consumption, the special measuring algorithm is used. More details about the measuring circuit and the algorithm are presented in Section III.

The sensor module is placed on the left shoulder and connected to the power supply ribbon cable and cables to the light indicator, the buzzer and the transceiver. The light indicator consists of light emitting diode and current limiting resistor. It placed on the left arm to be on the line of sight of the wearer. The buzzer is placed on the left shoulder near the neck. The task of light indicator and the buzzer is to perform visual and audial alarm signals to wearer when dangerous condition occurs.

Except visual and audial signals, information about dangerous conditions is transmitted to other devices in a wireless sensor network. For this purpose the transceiver module Telegesis ETRX3 is used. The module provides IEEE 802.15.4/Zigbee standards compatible protocol and is controlled by UART interface using AT-style commands set.

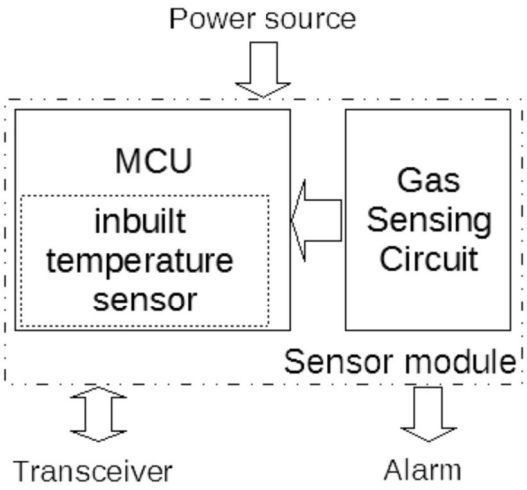

Fig. 4. Block diagram of the sensor module.

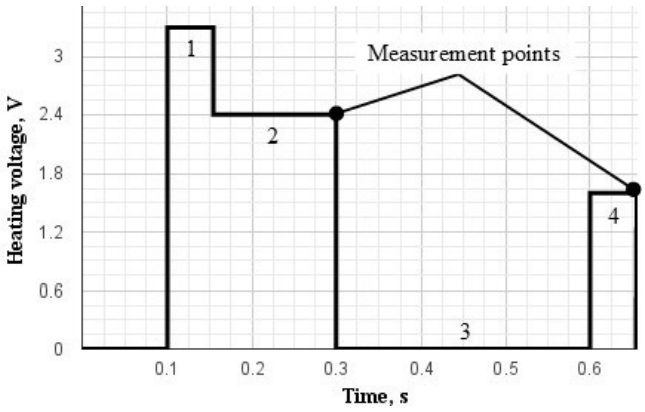

Fig. 5. Gas sensor heating profile.

The transceiver is also used to perform employee's presence tracking. The algorithm to detect wearer presence is described in Section IV.

The node which is assembled on the jacket is presented in Fig. 3.

III. Sensor Module

Sensor module consists of the MCU with inbuilt temperature sensor and the gas sensing circuit. To measure gas concentration the catalytic sensor is used. The block diagram of the sensor module is presented in Fig. 4.

Catalytic gas sensor circuits are usually based on the Wheatstone bridge circuit. That circuit consists of two resistors and two sensors, one active and one reference. Measurement process includes heating of the sensors (up to 450C for methane) which is the main part of sensor's power consumption. The power consumption value of the Wheatstone bridge circuit is about 200 mW. That's too much and not appropriate for autonomous operation of the node.

Excluding the reference sensor decreases the power consumption. The compensation of the atmosphere humidity and temperature which is usually performed by the reference sensor in this case is fulfilled by using the specific multistage heating pulse. This method was offered and discussed in [11]-[13].

In this work we use four stages for every multistage pulse (1-4 regions in the diagram, Fig. 5).

In the first and the second stages the sensor is heated up to the catalysis external diffusion region (about 450C) and the partial evaporation of surface water is performed. During the third stage heating is not applied. In the final fourth stage the sensor is heated up to the beginning of the catalysis kinetic region (about 200C). After this pulse, the element cools down to ambient temperature. Heating voltages for the stages are 3.3 V, 2.4 V, 0 V and 1.6 V respectively.

The measurement result is the difference between sensor voltages at two different temperatures (measurement points in the diagram).

The gas sensor measuring circuit for the multistage pulse method is presented in Fig. 6. The circuit is controlled by the microcontroller and consists of a sensor R5, a MOSFET key VT1 which controls heating, two range switching MOSFET keys VT2 and VT3 which scale up output signal based on sensor resistance, and an output low pass filter R7-C1 which is connected to microcontroller's inbuilt ADC.

Different voltage levels of the multistage heating pulse are generated by applying pulse-width modulated signal to the heating key. As it was shown in [14] PWM heating allows to significantly decrease sensor power consumption and therefore use a catalytic gas sensor in battery powered autonomous devices.

Range switching keys maintain the scale of circuit output signal inside the input range of ADC converter. Two ranges are used since two measurements per cycle are performed.

To match safety standards [15], [16] the measuring pulses are performed once per 20 seconds. Between pulses to spare the power the node is switched to sleep mode.

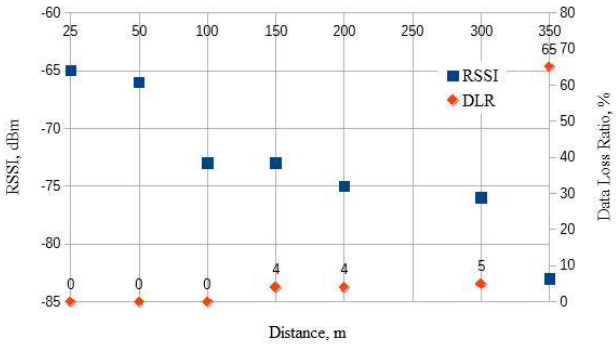

Fig. 7. Relative signal strength versus transmission distance and related data loss ratio.

The node is configured to activate alarm based on two threshold values of methane concentration which are 0.5 and 1 % vol. If the concentration is less than first threshold, there is no relation from the node. If the concentration is going higher than 0.5 % vol. methane, the node provides the light and short sound alarm. When the concentration is more than 1 % vol. the sound alarm becomes longer. In both cases the alarm signal is also sent over the wireless network to the data sink node.

IV. Data Transmission and Presence Detection

Data transmission is performed by using the transceiver module Telegesis ETRX3. The module is IEEE 802.15.4/Zigbee compatible. The communication with module is performed by UART interface using AT-style command set.

To communicate by wireless network the node should join it before. After it is joined, it has parent node where the data will be sent to later routing. If the connection with parent node is lost, the node should rejoin the network to be able to send any messages.

The transmission distance depends on the signal power. The transceiver module is able to change its output power. Therefore, the signal transmission distance can be regulated. This feature is used to implement the node presence detection.

Since the node is connected to the network its presence is already detected by parent node. If the connection is lost the node is trying to rejoin the network every work cycle which is 20 seconds. Attempts are continued till the node is joined the network and at that moment the presence will be detected by new parent node.

The detection radius is based on the transmission power of the node. Reliable service distances versus transceiver output power are shown in Table I. The service area is considered as

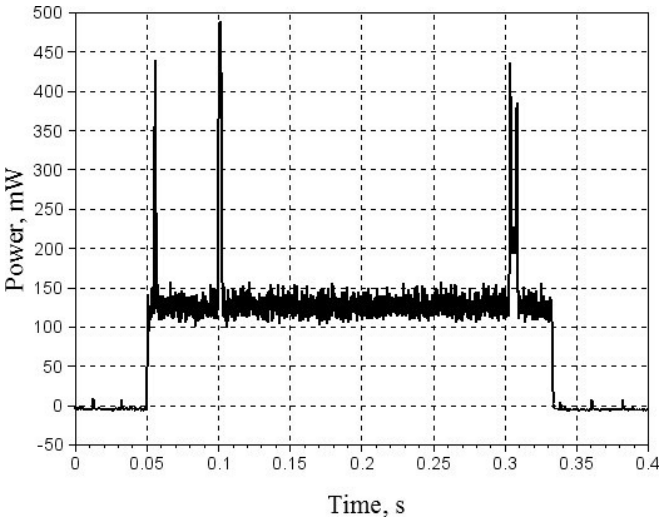

Fig. 9. The node power consumption during data transmission.

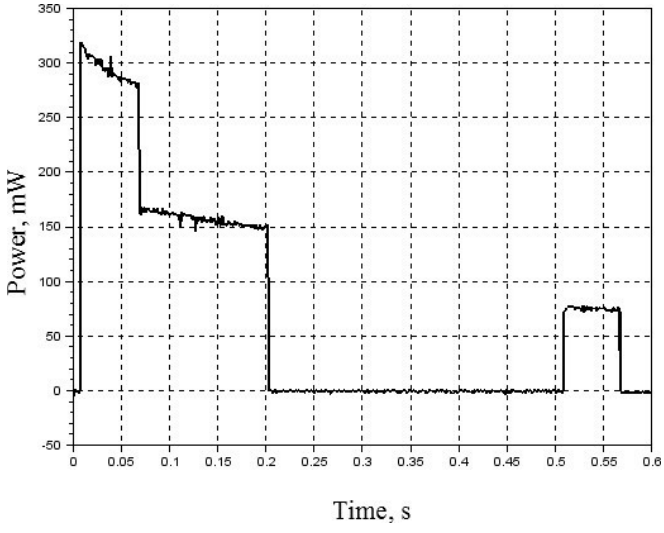

Fig. 8. The node power consumption during measurements.

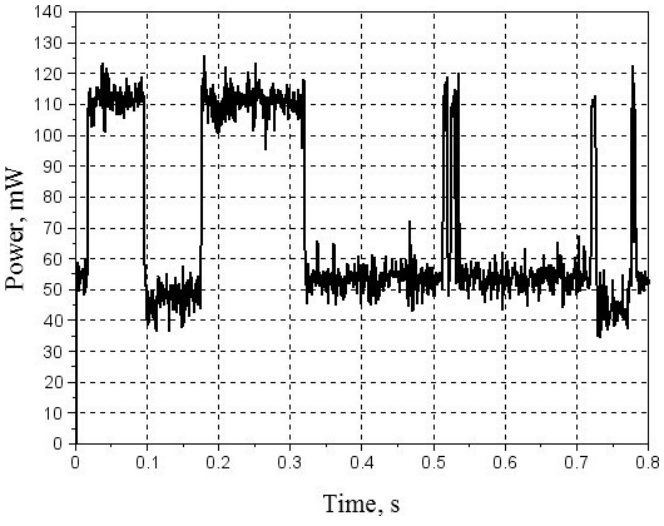

Fig. 10. The node power consumption during joining the network.

reliable if the RSSI value is more than -70 dBm which corresponds to zero data loss ratio (Fig. 7). In this work, for more precise detection, the transceiver output power is reduced to -26 dBm.

At the same time, when the node is going to alarm state it's necessary to ensure that the message have the best chances to be delivered. Relative signal strength versus transmission distance and related data loss ratio are presented in Fig. 7. The transceiver output power in that case is +8 dBm. As it's shown in the figure the reliable service area of the transceiver is 100 meters since in this distance there are no data losses. At this distance the RSSI value is -70 dBm.

Therefore, during alarm data transmission the output power of the transceiver is setted to +8 dBm which is the maximum output power of the transceiver in its boost mode.

V. Power Consumption

As it was said before, the work cycle of the node is 20 seconds. During the cycle the node goes through following stages: the multistage measurement pulse, the data transmission and presence detection and the power saving mode.

The power consumption of the node during the multistage pulse is presented in Fig. 8.

As it's shown in the figure the power consumption value during first stage of the multistage pulse is 320-280 mW. For second stage the value is 170-150 mW. And during fourth stage it's less than 80 mW. The average power consumption for whole multistage pulse is 77 mW and it's legth is about 0.6 s.

The multistage pulse is followed by data transmission to assure that the wireless connection is established in common situation or to deliver data during alarm mode. The average power consumption in this stage is about 125 mW for alarm mode (when transceiver output power is +8 dBm) and about 70 mW otherwise. The node power consumption during data transmission is shown in Fig. 9.

The data transmission takes no more than 0.5 s. But if the wireless connection isn't established it takes about 1s to rejoin the network. The node power consumption during joining the network is presented in Fig. 10. The average power consumption of the node in this mode is about 70.5 mW.

Since the cycle length is 20 s, the average power consumption for whole cycle is about 8.56 mW in worst case of an alarm situation while the connection to the network was lost. And the average power consumptions is about 2.66 mW in general situation when the connection is established.

Providing 900 mWh power supply the autonomous lifetime of the node will be about 105 hours in worst case and about 338 hours in general situation. Assuming that a work day has 8 hours, that's more than 13 work days long autonomous lifetime. Therefore, the average power consumption of the node is low enough for more than two weeks autonomous lifetime.

VI. Conclusion

In this work the uniform inbuilt wireless sensor node for working conditions monitoring is presented. The node consists of the sensor module (with the catalytic methane sensor, the temperature sensor and the MCU), the ZigBee transceiver, the light indicator and the buzzer. All these pieces are low power, light-weighted and built in to the clothes. The node is able to signalize about employee presence in relation to working facilities, and to monitor the atmosphere for temperature and combustible gases concentration. Due to the average power consumption optimization, the autonomous lifetime of the node is more than two weeks. The reliable service area of data transmission is 100 meters.

***Abstract*—In practical applications, we often encounter problems controlling weakly damped resonant systems. These are devices which often include inertia masses and flexible connecting elements. These devices are mainly gantry cranes, mechatronic systems, elevators, filling lines for the food industry and many others. One approach to improving the transition process in the control of these weakly damped systems is a method of shaping control signals. This method starts to be used in the control of systems with flexible elements in the 90s of the twentieth century. Over the next twenty years, we meet with successful applications, especially in the control of positioning systems. When we are talking about the theoretical description of input shaping today, we meet mainly with two basic approaches. The first is based on the selection of a proper sequence of pulses in the time domain. The second is based on the design of such discrete shaper, which compensates the effect of the complex poles of a controlled system causing residual vibration. Irrespective of the shaper design method, we must know either the systems oscillations and controlled system damping, or the location of the complex poles causing the vibration.**

I. Introduction

THE AIM of the input shaper is to adjust the control signals of the weakly damped system in order to eliminate residual vibrations of the system. With its proposal, we try to minimize transition time simultaneously. To illustrate this, let us have oscillatory system with the transfer function:

$$F(s) = \frac{1}{T^2 s^2 + 2bTs + 1}, b \in < 0, 1), \tag{1}$$

where b is the damping of the system and T is the time constant.

The task is to propose such methods of the control signal adjustment, that the transition process fits stated requirements. The possible system arrangement is shown in figure 1. It is evident that the shaper acts as a serial correction element that is known from the classical theory of automated control.

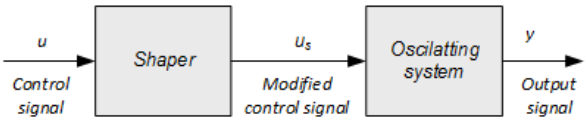

Fig. 1. The input shaping process

For the shaping of the control signal, two approaches can be used:

1) Signal shaping in the time domain, e.g. direct generation of the control signals with suitable properties [1], [2].
2) Using discrete shaping members [6], [9].

Appropriately chosen shaper suppress residual vibrations of the system. Note that the suppression ratio of residual vibrations is often expressed as the ratio of the amplitude of the output signal with the shapers input signal to the amplitude of the output signal without the shaper [4], [7], [8].

II. Proposal of an input shaper in the time domain

The rate of suppression of residual vibrations can be expressed as a function of the angular velocity ω and the proportional damping factor b of the system as:

$$V(\omega, b) = e^{-b\omega t_n} \sqrt{(C(\omega, b))^2 + (S(\omega, b))^2}, \tag{2}$$

while:

$$\begin{aligned} C(\omega, b) &= \sum_{i=1}^{n} A_i \cdot e^{b\omega t_i} \cdot cos(\omega \cdot t_i \sqrt{1 - b^2}), \\ S(\omega, b) &= \sum_{i=1}^{n} A_i \cdot e^{b\omega t_i} \cdot sin(\omega \cdot t_i \sqrt{1 - b^2}), \end{aligned} \tag{3}$$

where A_i is the amplitude, t_i is the time of occurrence of the ith pulse and n is the number of input shapers pulses. Ideally, with complete suppression of the vibrations, the relation (2) has to be equal to zero for its own circular speed and relative system damping. It is obvious that for $\omega = \omega_0$ is given:

$$C(\omega_0) = 0, S(\omega_0) = 0, \tag{4}$$

If the shaped output is to have the same final value as the unshaped (normalized shaper), then it is given that the sum of the amplitudes of all pulses has to be equal to one:

$$\sum_{i=1}^{n} A_i = 1. \tag{5}$$

Note that if the pulse amplitudes A_i are not limited, then in terms of minimizing the total time of transition t_n, it will acquire an infinitely large value. When practical solutions, we most often encounter with two restrictive conditions:

978-83-60810-90-3/$25.00

3) The pulse amplitudes can take values from the range of $\pm A_{max}$,
4) The pulse amplitudes can take only non-negative values $A_i \geq 0$.

It is obvious that if amplitudes of all the pulses are non-negative, then respecting conditions (5), it must belong to the interval $0 \leq Ai \leq 1$. With respect to those limitations, by solving the equations (2) we get for $min(t_n)$ the solution describing positive ZV shaper whose design is often stated in matrix form [3], [5], [6], [7]:

$$\begin{bmatrix} A_i \\ t_i \end{bmatrix} = \begin{bmatrix} \frac{1}{1+K} & \frac{K}{1+K} \\ 0 & 0.5 \cdot T_D \end{bmatrix}, \tag{6}$$

where:

$$T_D = \frac{2 \cdot \pi \cdot T}{\sqrt{1-b^2}}, K = e^{-\frac{b\pi}{\sqrt{1-b^2}}}. \tag{7}$$

ZV shaper (zero-vibration) (6) may be described in the time domain by a relation:

$$y(t) = A_1 \cdot \delta(t) + A_2 \cdot \delta(t - t_2). \tag{8}$$

ZV shaper described, however, is quite sensitive to changes in the parameters of the controlled system, in particular, to the changes in its own circular speed. For this reason, more robust input shapers have been developed. The most famous is ZVD (zero vibration derivate) shaper. In deriving the ZVD shaper, it is assumed that the derivative of the function $V(\omega, b)$ is equal to zero.

$$\begin{bmatrix} A_i \\ t_i \end{bmatrix} = \begin{bmatrix} \frac{1}{(1+K)^2} & \frac{2K}{(1+K)^2} & \frac{K^2}{(1+K)^2} \\ 0 & 0.5 \cdot T_D & T_D \end{bmatrix} \tag{9}$$

From (9) it is clear that the increase of robustness is penalized by the increase of the transition time. Transition time rose from $0.5 \cdot T_D$ to T_D.

III. Proposal of discrete input shaper

The problem of suppression of residual vibrations in the control of weakly damped systems can be successfully resolved with the appropriate design of discrete systems (correction elements) regulating the spectrum of the control signal to suppress residual vibration of the system. It is clear that the task can be solved by the appropriate placing the zeros of the z-transfer function characteristic element to the z-plane points corresponding to the field effect system. As the controlled system is characterized by a continuous transfer function, it is necessary to find a suitable transformation of the continuous system to a discrete equivalent. The discrete shaper will then be the inverse of the discrete equivalent of the continuous system. If the designed shaper compensates only selected complex transfer poles, then it is sufficient to place zeroes to the appropriate poles of the shaper. To find the discrete equivalent of the continuous system $F(s)$ defined by poles which cause oscillation of the system, it is suitable to use the transform between s and z plane by using the relation:

$$z = e^{sT_v}, \tag{10}$$

where T_v is the sampling period.

Recall that we want to compensate only complex poles, therefore we consider the transfer in the form:

$$F(s) = \frac{1}{\prod_{i=1}^{N}(T_i^2 s^2 + 2b_i T_i s + 1)}, \tag{11}$$

where N represents the number of pairs of complex conjugate poles to be compensated, T_i stands for the time constant and b_i is the damping coefficient of the ith subsystem. The poles of the system with transfer (11) are:

$$p_{i,1,2} = -\frac{b_i}{T_i} \pm j\frac{\sqrt{1-b^2}}{T}, i = 1, 2, 3, ..., N \tag{12}$$

In applying the transformation equation (10), for the poles of discrete equivalent of continuous system (11) will apply:

$$p_{di,1,2} = r_i e^{\pm j\phi_i} = e^{-\frac{T_v b_i}{T_i}} e^{\pm j\frac{T_v\sqrt{1-b_i^2}}{T_i}}, i = 1, 2, ..., N \tag{13}$$

To compensate for the effect of selected poles of the continuous system, the discrete shaper has to contain zeroes in such points in the z-plane that correspond to poles of the discrete equivalent ($p_{i1,2}$) (Fig. 2).

If we place the zeroes of the shapers z-transfer function into the points corresponding to the position of poles, then transfer function shaper will be in the form:

$$F(z) = \prod_{i=1}^{N}(z - z_{i1})(z - z_{i2}), \tag{14}$$

alternatively, when considering a 2N-multiple pole at the origin of the plane:

$$\begin{aligned} F(z) &= \textstyle\prod_{i=1}^{N} C_i(1 - z_{i1}z^{-1})(1 - z_{i2}z^{-1}), \\ F(z) &= \textstyle\prod_{i=1}^{N} C_i(a_{i2}z^{-2} + a_{i1}z^{-1} + a_{i0}), \end{aligned} \tag{15}$$

where

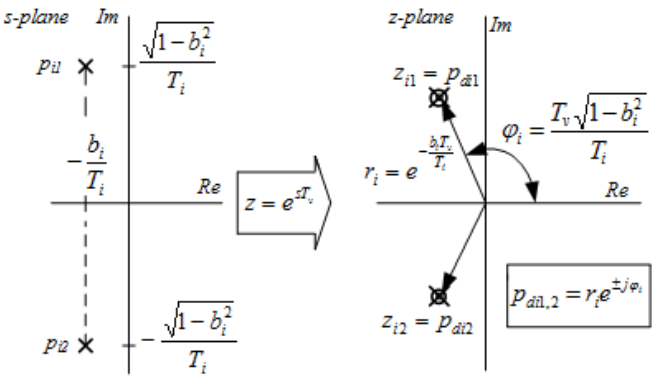

Fig. 2. Poles representation in the s-plane and z-plane

$$\begin{aligned} C_i &= \prod_{i=1}^{N} \frac{1}{a_{i0}+a_{i1}+a_{i2}}, \\ a_{i0} &= 1, a_{i1} = -(z_1+z_2), a_{i2} = z_1 \cdot z_2, \end{aligned} \tag{16}$$

alternatively:

$$\begin{aligned} a_{i0} = 1, a_{i1} = -2r_i cos(\phi i), a_{i2} = r_i^2, \\ r_i = e^{-\frac{T_{vi} b_i}{T_i}}, \phi_i = \frac{T_{vi}\sqrt{1-b_i^2}}{T_i}. \end{aligned} \tag{17}$$

When defining the gain C_i, we assume that consistentely with the continuous system transfer(11) is the shaper normalized (shaper gain is equal to one). From (13) it is clear that the position of poles of the discrete equivalent of the continuous system (11) $p_{di,1,2}$ can be changed in the z-plane by selecting the sampling period T_v. This is illustrated in figure 3.

The curves on the right side of figure 3 illustrate a possible $p_{d1,2}$ poles location of the discrete equivalent of a continuous system, depending on the selection of sampling period T_v. The left side of figure 3 shows the poles of the original continuous oscillating system with the transfer function (1). It is clear that the value T_v can be theoretically chosen in the range of 0 to ∞. Recall that the settling time of system output is proportional to the sampling period T_v. It follows that if we focus on achieving good system dynamics shaper-system, we are trying to make T_v minimal during the design of the shaper. Obviously, the choice of T_v minimum value is related to the energy options of the actuator and the constraints of system input. More specifically, the input shaper synthesis and the problem of choice of sampling frequency was discussed in the paper [10].

IV. The Problem of Oscillating Subsystem Identification

As already indicated, the basic assumption of the successful suppression of residual vibrations of a transition process by input shaper is the knowledge of the controlled oscillating subsystem parameters. Due to the rapid adaptation, it is advisable to devote to the identification of only that part of the system, which causes vibration. The proposed solution is illustrated in figure 4. This example does not discuss the identification of the drive of subsystem M, but only analyze the dependence of the pivot position $x(t)$ and the load position $y(t)$.

In order to verify the proposed comprehensive solutions, wireless acceleration sensors have been developed in our department. The sensors were used to measure the displacement $x(t)$ and the load movement $y(t)$. Based on the input to the oscillating system section $x(t)$ and the corresponding output $y(t)$, parameters T and b of the oscillating section were identified with the transfer function:

$$F(s) = \frac{1}{T^2 s^2 + 2bTs + 1} \tag{18}$$

V. Case Study

In general, it is common to face to the problem of identification in control applications. In order to be able to appropriately modify the control signal and thus the system response to this signal, it is important to know the transfer function of the system. For this purpose, the modules providing collection and data transfer were designed.

A. Description of used nodes

When designing the node, microcontroller ATmega168 was chosen as an element controlling the data collection and transfer. Considering that the system frequency and damping have to be known in the identification, we decided to retrieve data through LSM303DLHC module that includes a 3D digital linear acceleration sensor and a 3D digital magnetic sensor. Data obtained from the accelerometer is sent via I2C serial bus interface to the microcontroller. The microcontroller uses a timer/counter for timing each data collection process, and it ensures equidistance sampling ($fs = 400Hz$). The output of the accelerometer is represented by three 16-bit words, where each represents one of the axes x, y, and z. Gathered data is further sent through the wireless module RFM70. The proprietary module operates at a 2.4GHz frequency, and can be configured as a transmitter and as a receiver. Communication with RFM70 is ensured via the SPI interface. The data from the nodes is sent at each subsequent reading of the accelerometer, which means that we have a real-time data.

In order to get the data to the PC for processing, the node consisting of a microcontroller ATmega8 was proposed. Its role is to ensure the data reception from two transmitters via wireless module RFM70 and subsequently to send the data to

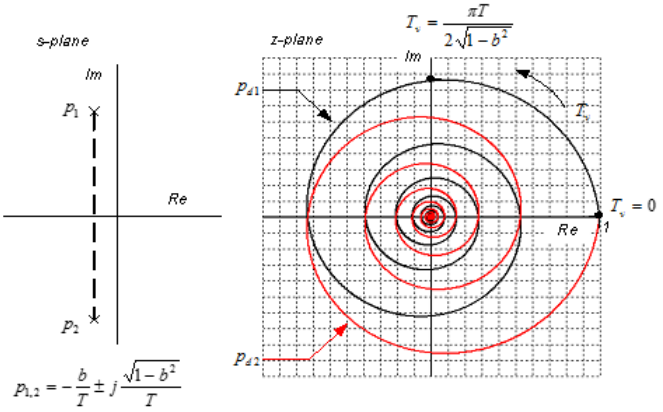

Fig. 3. Locus of the poles of discrete equivalent of the continuous system

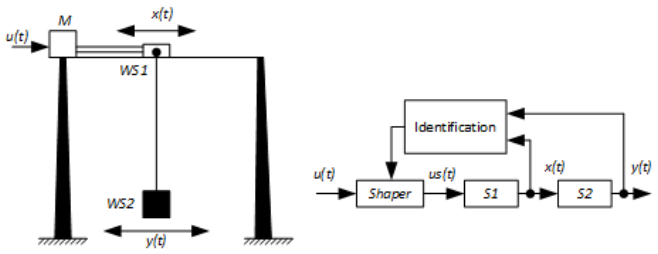

Fig. 4. Oscillating subsystem identification

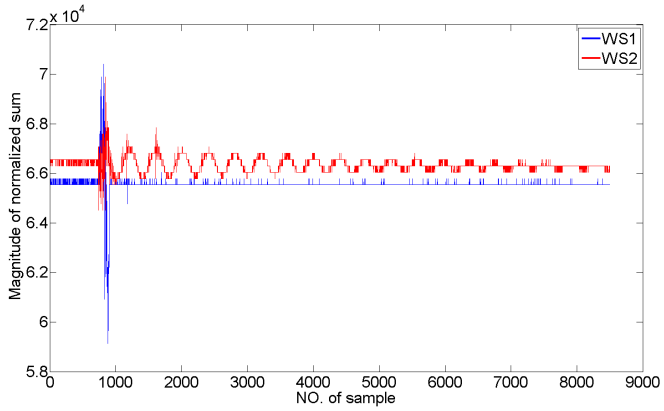

Fig. 5. Step response of weakly damped system

the PC via the UART interface. Here the data is visualized and further processed.

B. The measured results

Data obtained from the 3D accelerometers is sent via the RS232 interface to the PC where it is rendered over Matlab environment in the graph in real-time. In addition to displaying operation, the received data is recorded to the file, which forms the basis for further processing. Considering the change of the sensor position is not recorded only in one accelerometer axis, the data measured at the same time is summed. The data obtained through sensors $WS1$ and $WS2$ is represented in figure 5.

C. System identification

In order to identify the system, it is important to describe the output signal. As can be seen in figure 5, the output signal has damped oscillatory character after excitation (Fig. 6) [11]. As the input signal, the output signal is stabilized at the original level.

From the data obtained, it is approximated (determined) the system equation. After the system excitation, we get the local minimum $K-y_2$ and the local maximum y_1-K. These values are in equation 19 represented as x_1 and x_2.

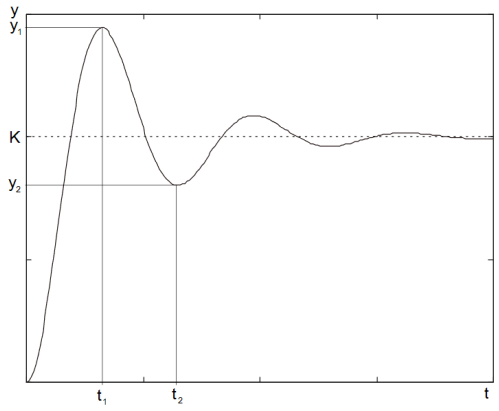

Fig. 6. Step response of weakly damped system

$$b = ln(\frac{x_1}{x_2}) \cdot \frac{2}{T}, \tag{19}$$

where b represents the damping of the system output. Period T, and thus the natural frequency of the system is defined by a difference between the times when there was a local minimum t_2 and the local maximum t_1. Substituting the obtained parameters in equation 18, we get the system step response (Eq. 20).

$$F(s) = \frac{1}{0.98^2 s^2 + 2 \cdot 0.1702 \cdot 0.98 s + 1} \tag{20}$$

VI. Conclusion

In this paper, conventional methods of input shaping techniques were reviewed. To propose suitable input shaper the controlled system should be identified. For this reason, nodes providing data from the accelerometer and wireless communication were constructed. These devices are small so they can be used also in other applications (e. g. to identify weaknesses of construction proposal and getting its mathematical model).

As the results show, the identification of second order system is not computationally demanding but captured data suffer from unwanted noise. To improve the process of identification data gathered from the accelerometer should be appropriately filtered.

There is a need to propose new nodes involving the gyroscope coming to the fore. This fact will result in the future work that will be focused on data fusion, particularly combining data from accelerometer and gyroscope.

***Abstract*—In this paper, we propose voltage converter with high efficiency over wide input voltage. This converter is suitable for the solar panel for WSN applications where the only power source is a solar cell that outputs highly variable voltage. The aim is to achieve this by using multiple converter topologies in parallel. Use of such converter has a meaning in renewable resources that in the long term operation significantly change their output voltage. The efficiency of particular topologies is estimated in simplified loss model, which is later experimentally tested.**

I. Introduction

EFFICIENT ENERGY production from alternative sources is one of the main problems that must be solved to make the use of solar or wind power came to the fore. The greatest weakness of renewable energy sources is their fluctuating power availability [1]. Existing power converters are tuned for operation at peak power of the particular source. The task of this paper is to design a converter that can efficiently take power from renewable source even while their energy potential is lower. To do this we need to examine the efficiency of commonly used topologies to determine their suitable operating point. This would allow creating control unit able to operate multiple topologies in parallel while maintaining better total efficiency than single topology converter.

II. The model of topologies

There are multiple topology designs for DC-to-DC converters. This paper will consider topologies with potentially lowest power loss, disregarding their other properties (output noise, transient response, etc.). Favorable candidates are elementary step-up and step-down converters (Fig. 1 and 2). They contain least components and offer relatively high efficiency while V_{in}/V_{out} ratio is close to one [2]. Harvestable power sources, however, offer a wide range of operating voltage. In such cases, other topologies may be preferable. Effective conversion with high V_{in}/V_{out} difference is a convenient property of transformers. Integrating transformer into mentioned topologies will result in fly-back transformer converter (Fig. 3) [3].

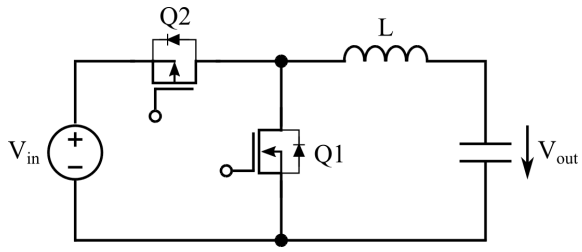

Fig. 1. Step-down converter basic topology

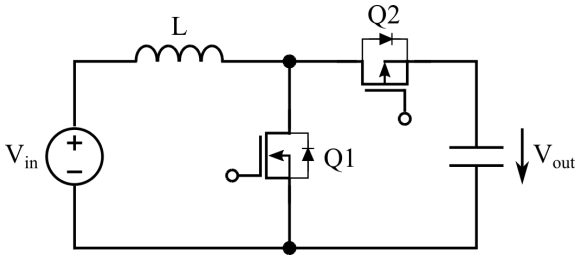

Fig. 2. Step-up converter basic topology

Our application for sensor nodes assumes solar cell as a power source. This means an available voltage will heavily fluctuate from low during dawn and dusk to high during midday. To find out which topology is most effective for given input voltage we need a model of losses for each of them. Simplified loss model of buck and boost converters can be described as shown in equation 1. Loss of the two topologies differentiate by RMS current calculation of particular branches. Table I contains the list of squared currents with their respective duty cycle D, where I_{RMS_L}, $I_{RMS_{Q2}}$ and $I_{RMS_{Q1}}$ represent effective current through inductor and transistors respectively [4].

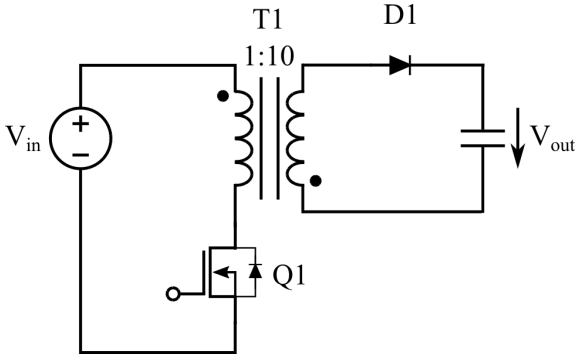

Fig. 3. Fly-back transformer topology

TABLE I
COMPUTATIONS OF CURRENTS WITH RESPECT TO THE DUTY CYCLE

	I_{RMS_L}	$I_{RMS_{Q2}}$	$I_{RMS_{Q1}}$
Buck	I_{out}^2	$I_{out}^2 \cdot D$	$I_{out}^2 \cdot (1-D)$
Boost	$(\frac{I_{out}}{1-D})^2$	$(\frac{I_{out}}{1-D})^2 \cdot (1-D)$	$(\frac{I_{out}}{1-D})^2 \cdot D$

$$\begin{aligned} P_{loss} = {} & R_{DS(ON_{Q1})} \cdot I_{RMS_{Q1}} + Q_G \cdot V_{G_{Q1}} \cdot f + \\ & \frac{1}{2} V_{IN} \cdot I_{RMS_{Q1}} \cdot (\frac{Q_G}{I_G} + \frac{Q_G}{I_G}) \cdot f + \\ & R_{DS(ON_{Q2})} \cdot I_{RMS_{Q2}} + Q_G \cdot V_{G_{Q2}} \cdot f + \\ & R_L \cdot I_{RMS_L} \end{aligned} \quad (1)$$

where:

- $R_{DS(ON_{Q1})}$ - drain-source resistance of transistor Q_1
- Q_G - total gate charge
- V_G - gate voltage (same as output voltage)
- I_G - gate charge current
- R_L - inductor resistance at switching frequency
- f - switching frequency

Power loss in the fly-back circuit can be approximated as stated in equation 2 [5]. This loss model simplifies transformer loss only to its wiring loss. Core loss is omitted due to the anticipation of low power provided by solar cell during operation of this topology.

$$\begin{aligned} P_{loss} = {} & R_{DS(ON_{Q1})} \cdot I_{RMS_{Q1}} + Q_G \cdot V_{G_{Q1}} \cdot f + \\ & \frac{1}{2} V_{IN} \cdot I_{RMS_{Q1}} \cdot (\frac{Q_G}{I_G} + \frac{Q_G}{I_G}) \cdot f + \\ & R_{L1} \cdot I_{RMS_{L1}} + R_{L2} \cdot I_{RMS_{L2}} + \\ & V_{D1} \cdot I_{RMS_{D1}} \end{aligned} \quad (2)$$

where:

- R_{L1} - primary winding at f
- R_{L2} - secondary winding at f
- V_{D1} - diode forward voltage drop

Duty cycle computation for boost and fly-back topologies is described in equation 3 and 4 respectively [6].

$$D = 1 - \frac{V_{in}}{V_{out}} \quad (3)$$

$$D = \frac{\frac{V_{out}}{V_{in}}}{\frac{N_s}{N_p} + \frac{V_{out}}{V_{in}}} \quad (4)$$

A. Optimal operating point

Next step is to fill described models with parameters of real-world equipment measured at switching frequency (Tab. II). We have chosen components that will later be used for testing. However, these components are by no means ideal for the power converter, which will be reflected in converter's efficiency [7].

We will simulate load at 3.3V drawing 10mA constant current. To minimize unaccounted parasitic losses, we have chosen lowest operating frequency that allows continuous conduction mode of operation. Transistors will, therefore, operate at 100kHz. Figure 4 shows the efficiency of step-up topologies relative to the input voltage. The simulation shows ranges of input voltage where respective topologies achieve better efficiency than the others.

TABLE II
LIST OF COMPONENTS USED FOR THE TESTING

	Component
N-channel MOSFET	TN0604N3
P-channel MOSFET	LP0701N3
Inductor	Generic toroid coil
	L = 203uH R=5.35 OHM
Diode	IN5817
Transformer	Rp=1.16 OHM, Lp = 51.9uH
	Rs= 33.6 OHM, Ls = 5.116mH
	Turn ratio 1:20

III. DESIGN OF MULTI-TOPOLOGY CONVERTER

Utilizing optimal operating point given by particular topology can be achieved by power management system with multiple parallel topologies and suitable control algorithm. The parallel conjunction of buck and boost topologies require some modifications [8]. Main reason is body diode of switching transistors. In the case of boost topology (Fig. 2), body diode

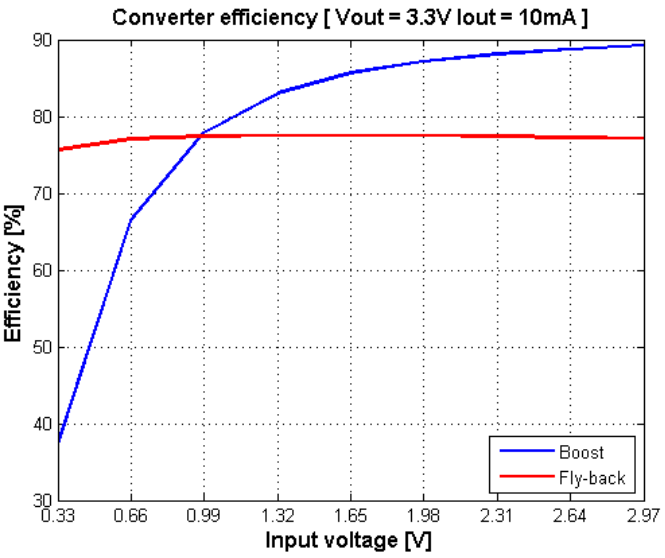

Fig. 4. Converter efficiency

of $Q2$ restricts the use of input voltage to value lower than the output voltage. If this restriction is not respected, body diode will conduct current making it impossible to maintain regulation on the output voltage. The similar limitation can also be observed on buck topology when the output voltage is greater than the input. This raises a need to add an extra transistor, which would be controlled to restrict current in cases where body diode is conductive. The more convenient solution is to add not one, but two transistors resulting a buck-boost topology where input and output voltages are separated by two transistors (Fig. 5). This modification will increase overall power loss due to extra resistance of constantly opened transistor - $R_{DS(ON)}$ of P-channel transistor.

This way, the properly designed control algorithm can step-up or step-down input voltage regardless of V_{in}/V_{out} ratio. Control signals needed for operation are described in Tab. III.

Choice of topologies and their total number depends on the used power source. For WSN node with a low power solar cell, we have chosen one fly-back and one buck-boost topology. For more power demanding appliances and sources it may be beneficial to have multiple buck-boost topologies due to the decrease of conductive losses [9]. Schematic of resulting converter for a solar cell is shown in figure 6.

IV. Experimental testing of the model

Verification of loss model will be performed on designed converter in boost operating mode. The converter will be tested for efficiency at the constant output voltage and current with a variable input voltage. Measured results are compared with loss model in Tab. IV.

Measurement confirms modeled data within an acceptable margin of error. As model estimated, this converter performs poorly while there is large difference between the input and the output voltage. This is due to high conduction losses that contribute about 90% of the total loss. Main reason is properties of used testing components. Better overall efficiency can be achieved by balancing conduction losses with switching losses (i.e. using transistors with lower drain-source resistance at cost of higher gate charge).

TABLE III
Control signals description

	Inactive	Boost	Buck
Q1	High / closed	Low / open	Switching at D
Q2	High / closed	Switching at (1-D)	Low / open
Q3	Low / closed	Low / closed	Switching at (1-D)
Q4	Low / closed	Switching at D	Low / closed

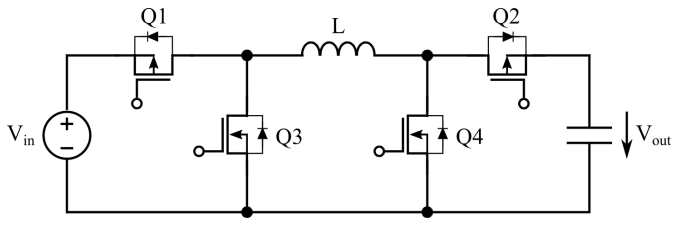

Fig. 5. Buck-boost topology

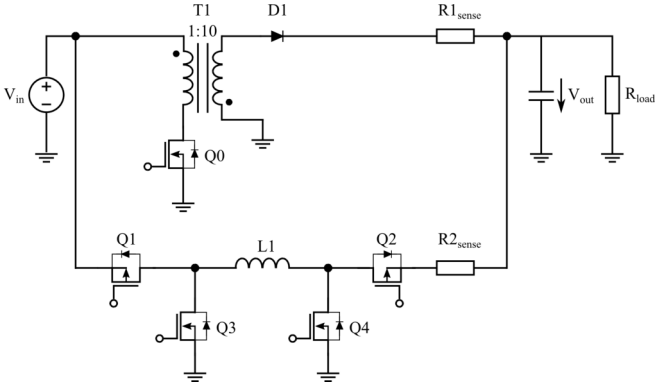

Fig. 6. Schematic of resulting converter for a solar cell

TABLE IV
Modelled and measured efficiency comparison

Input/output voltage ratio [%]	Modeled efficiency [%]	Measured efficiency [%]
10	37.32	34.81
20	66.44	65.10
30	77.90	75.94
40	82.99	81.73
50	85.63	84.33
60	87.16	85.64
70	88.12	87.60
80	88.77	88.05
90	89.22	88.67

This paper, however, shows relative efficiency between two voltage increasing topologies. The efficiency of both, boost and fly-back topologies can be improved with technologically advanced components. The elementary shape of their efficiency to input voltage function should, however, remain similar, which is given by topology operation. With boost topology, a high difference between input and output affects duty cycle. High duty cycle means a long time to charge inductor and a short time to discharge it. This creates high current peaks and therefore a significant loss. The fly-back converter may use transformer ratio to cope with high voltage difference and keep duty cycle in balance. This can also be seen from the computation of their respective duty cycle (Eq. 3 and 4).

V. Conclusion

We have evaluated voltage converter which utilizes multiple parallel topologies. Modeled data shows convenience of parallel operation of different topologies. As a result, fly-back and boost topologies are well suited for complementary operation where fly-back will be active at the lower input voltage and boost at higher. We also develop control algorithm selecting best available topology for devices with low computational power.

Implementation of modeled data into converter control may have a form of the lookup table where the device would measure all relevant parameters (input and output voltage, output current and current passing each active topology) and decide which topology (or their combination) to use. Experimental measurement confirmed our expectations about the efficiency of single topology derived from the model. To perfect efficiency for wider operating conditions, more topologies need to be examined.

Information Technology for Management, Business & Society

IT4MBS is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the disciplines of information technology and information systems. The IT4BMS area emphasizes the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This area takes a sociotechnical view on information systems and relates also to ethical, social and political issues raised by information systems. Events that constitute IT4BMS are:

- ABICT'16—7th International Workshop on Advances in Business ICT
- AITM'16—14th Conference on Advanced Information Technologies for Management
- ISM'16 - 11th Conference on Information Systems Management
- KAM'16—22nd Conference on Knowledge Acquisition and Management
- UHH'16 - 2nd International Workshop on Ubiquitous Home Healthcare

7th International Workshop on Advances in Business ICT

ABICT focuses on Advances in Business ICT approached from a multidisciplinary perspective. It will provide an international forum for scientists/experts from academia and industry to discuss and exchange current results, applications, new ideas of ongoing research and experience on all aspects of Business Intelligence. ABICT will be also an opportunity to demonstrate different ideas and tools for developing and supporting organizational creativity, as well as advances in decision support systems.

We kindly invite contributions originating from any area of computer science, information technology and computational solutions for different applications areas, data integration and organizational implementation of ABICT, as well as practical ABICT solutions.

TOPICS

Topics include (but are not limited to):

- Advanced technologies of data processing, content processing and information indexing
- Analytics as a service
- Big Data: benefits and challenges
- Business Analytics
- Business applications of social networks
- Business data mining and knowledge discovery
- Business Intelligence
- Business Rules
- Business-oriented time series data mining, analysis, and processing
- Cloud based Business Intelligence
- Creativity Support Tools
- Customer Relationship Management, social Customer Relationship Management
- Data driven marketing
- Data Warehousing
- Decision support
- Digital Business Strategy
- Enterprise Device Management
- ICT technologies in enterprise management
- Information forensics and security, information management, risk assessment and analysis
- Information Systems Design
- Internet of Things

***Abstract*—Process models can specify various aspects of business processes. In this paper, we present an overview of the existing solutions for describing time aspects of such models. We focus on Business Process Model and Notation and provide examples of representing time patterns in this notation. As temporal issues can be specified using temporal logics, we provide a short overview of selected temporal logics which can be used to specify the time patterns in business process models.**

***Index Terms*—BPMN, Business Processes, Temporal Logics, Temporal Issues, Time Patterns**

I. Introduction

BUSINESS Process Management (BPM) [1] is a modern approach to improving organization's workflow, which focuses on reengineering of processes to obtain optimization of procedures, increase efficiency and effectiveness by constant process improvement.

The key aspect of BPM is a Business Process (BP). A BP is usually described as a collection of related activities which transform different kinds of clearly specified inputs to produce a customer value, mainly considered as products or services and organizational goals, as output [2]. Such a process can be represented as a BP model [3]. However, there can be many representation methods for modeling processes. We give an overview of the existing representation methods for business processes, such as Petri nets, EPC, IDEF3, UML AD, YAWL and BPMN diagrams.

As temporal logics can have various applications related to knowledge management [4]–[6] and business process models [7], it is important to consider process representation from the perspective of time issues. Thus, we analyze the presented process representations in terms of time-related elements. The main focus is on the BPMN notation and time issues in this notation. We present how to represent the Allen's algebra relations using BPMN notation. As it was proven empirically in [8], representing relations using the 2D models is efficient in terms of understanding temporal aspects of time intervals.

Moreover, based on the existing time patterns from the literature, we describe how they can be used in BPMN as well as we provide a short overview of temporal logics which can support these time patterns.

The rest of this paper is organized as follows: Section II presents an overview of process modeling notations with with an emphasis on time or temporal aspects.. The most popular BPMN representation is analyzed in details in this context in Section III. In Section IV, we give an overview of temporal logics which can be used to support time patterns for process models. The paper is summarized in Section V.

The paper is supported by the AGH UST grant.

II. Business Process Representation

As process modeling is an essential part of BPM, in the following subsections, we present the most popular business process representations.

Although there are many process modeling languages, we focus here on the six visual and most successful ones: EPC, IDEF3, UML AD, Petri net, YAWL and BPMN. Processes in these languages consist of activities, which may be decomposed to subactivities. The order of activities defines the sequence of work. In the lower level, each activity transforms some inputs into outputs.

Table I presents a simple yet illustrative example of a car rental process [9] in the above mentioned notations. The process starts with a registering request, and then extra insurance can be added. When check-in is initiated, the customer can select a car; at the same time the driver's license is checked and the customer's credit card is charged. The process ends when the chosen car is supplied to the customer. This exemplary process contains only basic control flow elements, which can be represented in all of these languages. However, it is important to mention that the expressiveness of each of these languages is much higher than the required for this example.

A. Process Modeling Languages

1) Event-driven Process Chain (EPC): Event-Driven Process Chain (EPC) is a simple graphical modeling language for modeling processes introduced by August-Wilhelm Scheer [10]. The EPC models are directed graphs visualizing the control flow [11]. Each EPC consists of events, functions and connectors, starts with at least one event and ends with at least one event, In EPC, each event triggers a function that leads to a new event. The notation supports three types of connectors (AND, XOR, OR) which can be used to model splits and joins.

As events in EPC are rather passive elements which specify under what circumstances a process works or what is a result state of a process, such constructs are rather not suitable for time-related extensions.

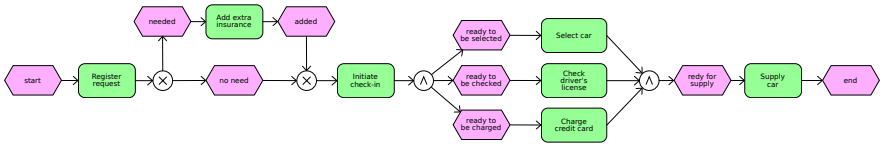
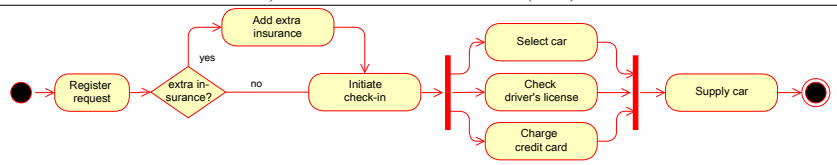
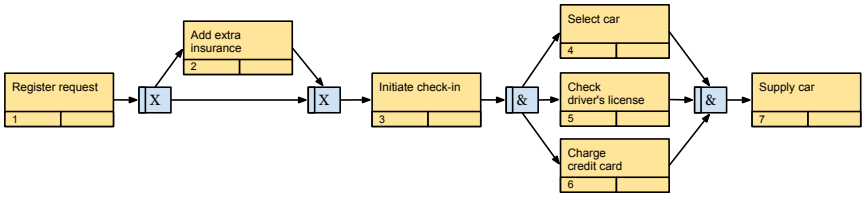
Table I
AN EXAMPLE OF CAR RENTAL PROCESS IN VARIOUS PROCESS MODELING NOTATIONS



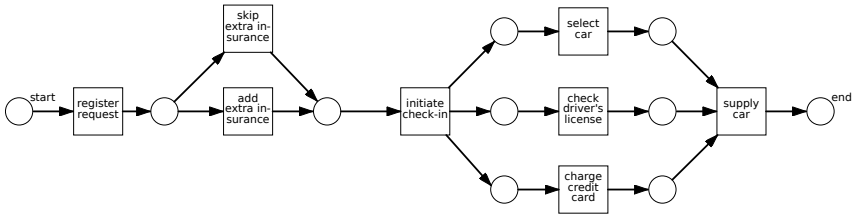
1) Event-driven Process Chain (EPC)



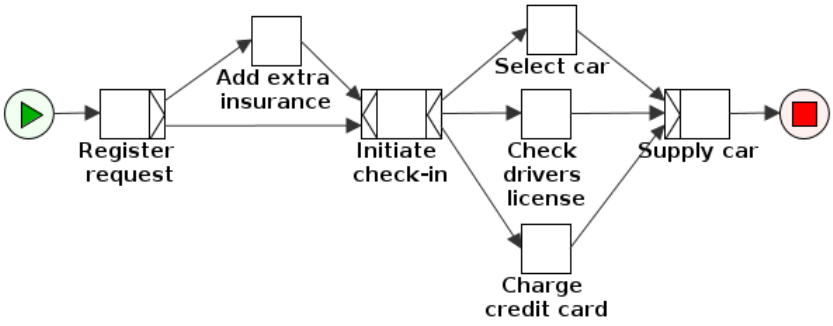
2) UML Activiti Diagram (UML AD)



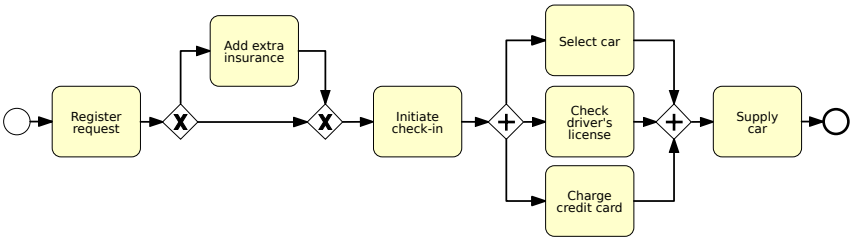
3) Integrated DEFinition Method 3 (IDEF3)



4) Petri net



5) Yet Another Workflow Language (YAWL)



6) Business Process Model and Notation (BPMN)

2) Integrated DEFinition Method 3 (IDEF3): Integrated Definition (IDEF) is a family of modeling languages that arose in the 1979s out of the U.S. Air Force in order to increase manufacturing productivity [12], [13]. The IDEF suite contains sixteen types of modeling languages in the field of systems and software engineering; however, the majority is still under development and only IDEF0-4 are commonly used in practice. IDEF3 is concerned with modeling the processes of a business or its systems [14], [15]. IDEF3 Process Flow diagram consists of such elements as Unit of Behavior (UOB) boxes, precedence links, junctions (AND, XOR, OR), referents, and notes. An IDEF3 process description organizes the network of relations between situations in a specified scenario from the process-centered perspective.

As in IDEF3, events are not modeled directly, there are no time events. However, IDEF3 specifies constraint precedence links which express simple temporal precedence relations between instances of one UOB and another UOB. They add constraints over and above the activation semantics of simple precedence and can indicate that an instance of the source UOB must be followed or preceded by an instance of the destination UOB [16].

3) UML Activiti Diagram (UML AD): The Unified Modeling Language (UML) [17] from the Object Management Group (OMG) constitutes a standardized notation for modeling software applications [18]. This multipurpose modeling language offers a variety of notations to capture different aspects of software [19], [20]. UML has become the dominant notation among software engineers and attempts to be a universal visual notation for software design. Activity diagram (AD) is a kind of the UML behavior diagrams for modeling dynamic aspects of the system, which focuses on the flow of activities involved in a single process and shows the dependencies among them. Although UML AD can be used for process modeling purposes, its complex nature makes it a barrier for non-technicians and it is not suitable for all aspects of this type of modelling. A simple process consists of a sequence of nodes modeled using control-flow and object-flow. The control-flow comprises two types of nodes: action nodes (activities to be performed or signals to be received/sent by the process) and control nodes, which model sequencing and parallel or alternative branching. The flow of data between nodes can be represented by associations of object nodes with activities.

In the case of UML AD, a time event trigger is supported (notated with an hour glass symbol). On the other hand, UML semantics do not dictate the amount of time between actions or events. However, additional timing constraint elements can be defined using customized stereotypes or specified in OCL (Object Constraint Language), especially as pre- and post-conditions for actions.

4) Petri net: Petri nets [21] offer a graphical notation for modeling processes that include choice, iteration, and concurrent execution. A classical Petri net is a directed graph composed of two types of nodes: places and transitions. An arc in the net may connect a place to a transition or vice versa, but no arc may connect two nodes of the same type. A transition can have a number of input and output places. As Petri nets have an exact mathematical definition of their execution semantics and a well-developed mathematical theory for process analysis, they are suitable for modeling, analysis and simulation of dynamic systems. As generally the execution of Petri nets is nondeterministic, they are well suited for modeling the concurrent behavior of distributed systems [22].

Although the original Petri nets do not model time issues explicitly, there are extensions, such as time Petri nets, which were used in analysis of concurrent systems where behavior was dependent on explicit values of time [23]. A detailed overview of the algorithms that allow for analysing time-dependent Petri nets can be found in the book [24].

5) Yet Another Workflow Language (YAWL): YAWL is a Petri Net based workflow language [25], [26]. Having formal semantics, it supports specification of the control flow and the data perspective of business processes. The language encompasses workflow patterns to guarantee language expressibility [27]. The YAWL language extends the class of workflow nets with multiple instances, OR-joins and cancelations. Workflow net (WF-net) [28] is a subset of Petri net used to model workflows. In a WF-net, there is a unique input place and a unique output place and every other place and transition are on a directed path from input to output place, and WF-nets introduce additional notations for joins and splits (AND and XOR). In the case of YAWL, in contrast to Petri nets and WF-nets, its syntax allows tasks to be directly connected, which helps compress the visual representation of a YAWL model.

Although in YAWL there are no separate time elements, any atomic task can be assigned a timer behaviour using a timer property. Such timer can be activated either when a task is enabled (i.e. is offered or allocated) or when it starts. What is more, there are also additional timer predicate expressions which can be used as flow predicates.

6) Business Process Model and Notation (BPMN): BPMN [29], adopted by the OMG group, is the most widely used notation for modeling BPs. The BPMN notation uses a set of models with predefined graphical elements to depict a process and how it is performed. Although the current BPMN 2.0 specification [29] defines three models to cover various aspects of Business Processes, in most cases, using only the Process Model is sufficient. Thus, in this paper we analyze the internal Business Process Model of BPMN, which can be compared to the previously presented approaches.

Table II presents an evaluative analysis of the described Business Process modeling languages (the summary prepared on the basis of [30]–[35]). The symbols in the tables have the following meaning: ❍ – not supported, ● – supported. ◗ – partially supported (not standardized or possible to present but not directly).

As one can see from the Table II, BPMN 2.0, a de facto industry standard for modeling processes, supports most of the listed elements. Thus, in the following sections we will focus on this notation and present time issues related to BPMN.

III. TIME ISSUES IN BUSINESS PROCESS MODELS

A. Time Representation in BPMN

If it comes to the time-related issues in BPMN, some of them can be represented directly in the following way:

- Timers are supported as Timer start and Timer intermediate events (see Figure 1) For such an element, one of the following properties can be specified:
  - time date – specifies a fixed date when trigger will be fired,
  - time duration – specifies how long the timer should run before it is fired, or
  - time cycle – specifies repeating interval, which can be useful for starting process periodically, or for sending multiple reminders for overdue user task.
- Event-based Subprocess are subprocesses which are started by an event, such as a timer (see Figure 2).
- Timer boundary events allow for following additional or alternative control flow when the timer is fired. This can either interrupt or not the associated task or subprocess (see Figure 3).
- Event-based gateway with timers works like an exclusive gateway (XOR) as both involve one path in the flow (see Figure 4). In the case of an event-based gateway, however, it is evaluated which event has occurred, not which condition is being met.

Apart from the time issues which are basically supported by the existing BPMN elements, some issues can be modeled indirectly using more complex combination of elements. In Table III, we presented the classic Allen's algebra relations [36] applied to BPMN models. On the left hand side there is a simple model with additional artefacts depicting time relations. On the right hand side, we present a refined model, compliant with the BPMN 2.0 specification [29] which should fulfil the presented relation (this can be also interpreted as a method of imposing some constraints related to Allen's algebra relations). As there are many equivalences in BPMN [37], the presented models are not the only one that are possible. One can also noticed that in some cases, the model is quite complex and requires additional BPMN elements.

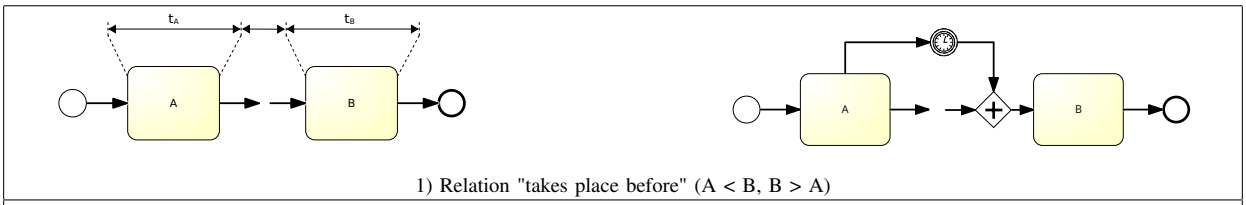
Simpler models for these relations can be found in [38] and [39]. However, they require additional non-standardized elements. Thus, they extend the BPMN notation.

A survey of some time-related aspects of process models conducted by Cheikhrouhou et al. can be found in [40], [41]. Their survey focused on the existing approaches to specifying and verifying temporal aspects of processes, not focusing on processes represented using the BPMN notation, but rather temporal constraints specification methods.

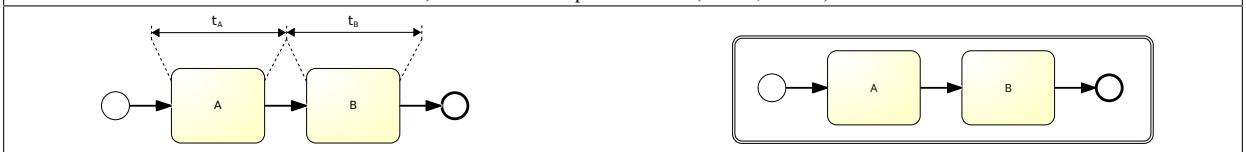
B. Time Patterns in Process Models

The objective of time patterns is to facilitate the analysis and comparison of Process-Aware Information Systems (PAIS). Their classification and selection criteria were presented in [42] and further developed in [38]. In [43], a dedicated tool for PAIS management and support was demonstrated. Time constraints related to specific patterns can be

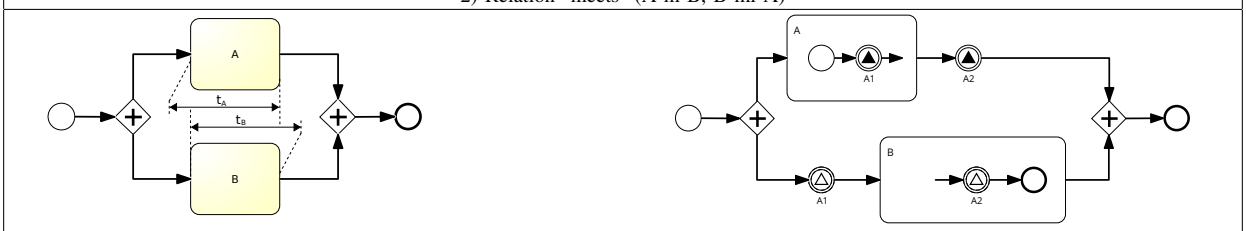
Table III
ALLEN'S RELATIONS IN BPMN: LEFT: STANDARD MODEL WITH TWO TASK (WITHOUT IMPOSED RESTRICTIONS), RIGHT: REFINED MODEL FULFILLING THE RELATION



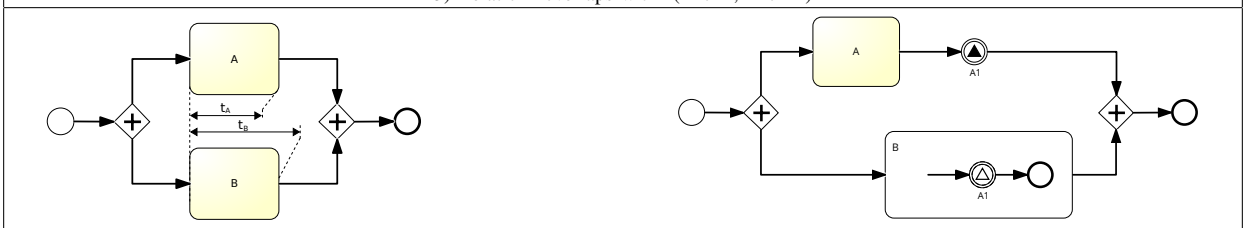
1) Relation "takes place before" (A < B, B > A)



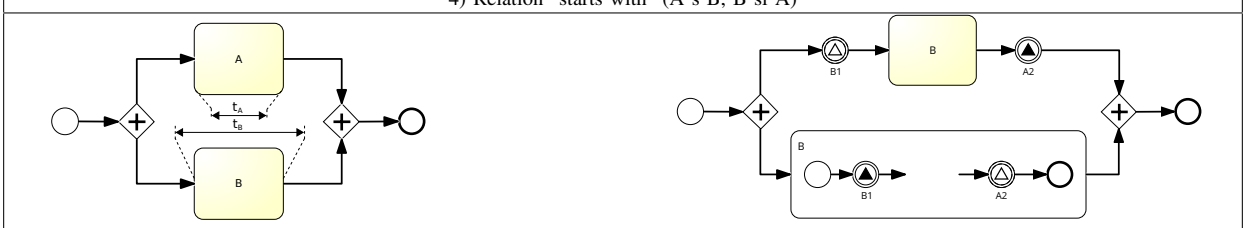
2) Relation "meets" (A m B, B mi A)



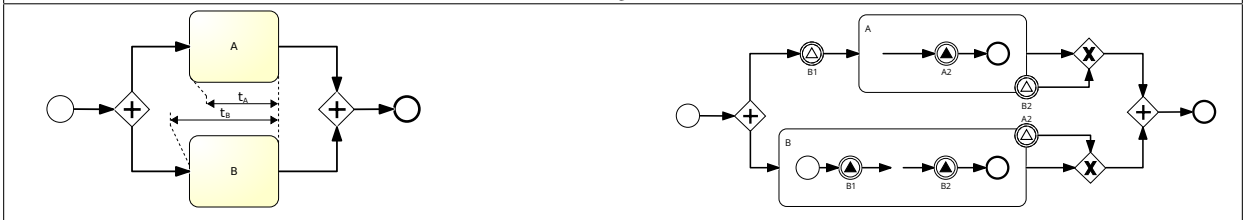
3) Relation "overlaps with" (A o B, B oi A)



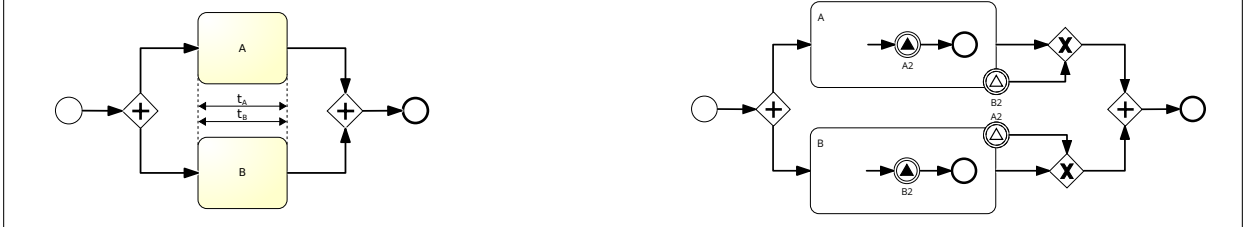
4) Relation "starts with" (A s B, B si A)



5) Relation "during" (A d B, B di A)



6) Relation "finishes" (A f B, B fi A)



7) Relation "is equal to" (A = B)

used in generating optimized plans for declarative process models [44], where a user determines the final purpose instead of an explicit task sequence. Another approach is to present temporal information along with resources using a modified Petri Net [45], where validity periods as well as maximal processing times are determined.

Thus, in [38], based on the representative set of business process models from different domains, 10 time patterns (divided to four categories) were identified and described:

I Duration and Time Lags
- TP1 Time Lags between two Activities
- TP2 Durations
- TP3 Time Lags between Arbitrary Events

II Restricting Execution Times
- TP4 Fixed Date Elements
- TP5 Schedule Restricted Elements
- TP6 Time-based Restrictions
- TP7 Validity Period

III Variability
- TP8 Time-dependent variability

IV Recurrent Process Elements
- TP9 Cyclic Elements
- TP10 Periodicity

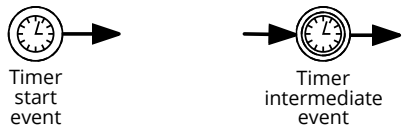


Figure 1. BPMN Timers

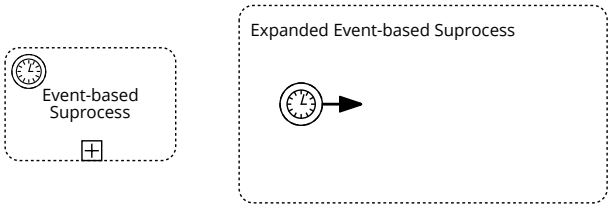

Figure 2. BPMN Event-based Subprocess

Each of these patterns can be used in various forms and applied to different elements (design choices). Thus, some of such choices of the patterns TP 1-4, 8 and 9 are supported by BPMN constructs as well:

- TP1 – supported by timers or combination of signals, as in diagrams in Table III,
- TP2 – supported by boundary timer events, as in Figure 3,
- TP3 – supported by timer intermediate event, as presented in Figure 1,
- TP4 – supported by timer start event, as in Figure 1 and 2,
- TP8 – supported by event-based gateway with timers, as in Figure 4,

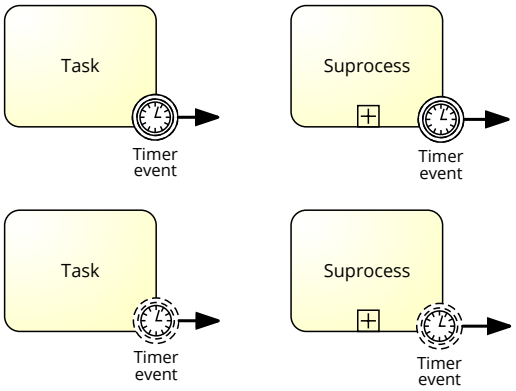

Figure 3. BPMN Timer boundary events

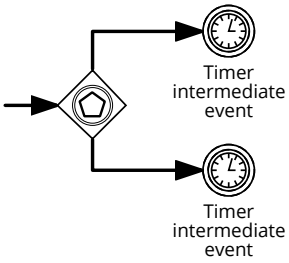

Figure 4. BPMN Event-based gateway with timers

- TP9 – supported either by a loop modeled using control flow with a timer intermediate event or by multi instance loop task or subprocess.

C. Analysis and Verification of Time Related Process Models

An important issue in process modeling is verification process models [46]–[48]. Among the existing papers concerning time issues in business processes, there are also papers related to analysis and verification of process and workflow models. There are several methods that can be used for validation of time related processes [49]–[56]. One of the existing methods concerns dynamic detection of temporal violations and providing possible solutions to a specific problem [49]. An analysis of time compatibility of web services with respect to time constraints, correlated with data and caused by message interaction between services, was conducted in [51]. As an extension to this solution a technique of analyzing and validating a set of processes was presented in [52]. It includes checking if a process choreography fulfils the declared time requirements and is based on Business Process Execution Language models which are then interpreted in the Fiacre formal verification language. Another method used to verify temporal constrains is based on new formal language, XTUS-Automata, which can be used to specify both relative and absolute time properties and also include deadlock verification [53]. This solution use temporal specification patterns, which are provided for different types of properties. In [54], a solution where an extended BPMN model is mapped onto timed automata and then verified using UPPAAL model checker is proposed. Temporal requirements

represented by deadline constraints within inter-organizational workflows, where certain private processes remain unexposed for other users, can be verified using modified Petri Nets [55]. Another approach is base on building a semantic model of a business process, including the occurring delays, and its verification using CSP process algebra [56]. Table IV presents a summary of selected process validation techniques.

IV. TEMPORAL LOGICS FOR TIME PATTERNS IN PROCESS MODELS

Based on the presented time patters [38], we analyzed selected temporal logics [57], [58] in order to assess their suitability to represent these patterns.

A. Linear Temporal Logic

Linear Temporal Logic (LTL) [59] is a temporal logic system for representing of time linearity. Its language is obtained from standard propositional language (with the Boolean constant $\top$) by adding temporal-modal operators such as: *always in a past* (H), *always in a future* (G), *eventually in the past* (P), *eventually in the future* (F), *next and until* ($\mathcal{U}$) and *since* ($\mathcal{S}$) – co-definable with "until".

B. Computation Tree Logic

LTL is traditionally interpreted in models based on the point-wise time-flow frames $\mathcal{F} = \langle T, < \rangle$, so in a poit-wise semantics. If we also admit two additional quantifiers: A ('along all paths)' and E (read: 'there exists at least one path such that'), we obtain a new system – commonly called *Computation Tree Logic* (CTL) [59] as a branching-time logic.

The construction way of these systems demonstrates that these systems are rather suitable for describing situations, somehow, temporally 'open' in a past or in a future.

C. Halpern-Shoham logic

The logic of Halpern-Shoham (HS) – introduced in [60] forms a multi-modal system suitable to represent the 13 well-known Allen's relations between intervals [36], and constitutes a concurrent approach to temporal reasoning w. r. t. the Computational Tree Logic (CTL) or the Linear Temporal Logic LTL – the more traditional and pointwise approaches. More, precisely, HS forms a modal representation of temporal relations: **a**fter (or **m**eets, **l**ater), **b**egins (or **s**tart), **d**uring, **e**nd and **o**verlap and they are rendered in HS by corresponding modal operators: $\langle A \rangle$ for **a**fter, $\langle B \rangle$ for **b**egins, $\langle D \rangle$ for **d**uring, etc. The full syntax of HS-entities ϕ is defined by:

$$\phi := p | \neg\phi | \phi \wedge \phi | \langle X \rangle | \langle \bar{X} \rangle \,, \tag{1}$$

where p is a propositional variable and $\langle \bar{X} \rangle$ denotes a modal operator for the inverse relation. Such logic is more suitable for representing some temporally 'closed' events, actions and processes, their mutual temporal relations or time lags.

Table V presents the overview of these logics in terms of time pattern representation for process models.

V. SUMMARY

Process models can specify various aspects of business processes, among them the temporal ones. In this paper, we present the existing solutions for describing time aspects of process models. Although there are many notations for modeling processes, the main focus is on the BPMN notation. We provide several examples of representing time patterns in BPMN as well as discuss temporal issues with temporal logics for such specifications. Thus, the original contribution of this paper is threefold – we present:

1) the overview of business process modeling notations focusing on time-related elements,
2) the process models in BPMN notation which fulfil the Allen's relations,
3) the assessment of temporal logics in terms of using them for representing time patterns in process models.

The research presented in this paper is a proposal for further studies related to time issues in BPMN process models. Our future work will focus on practical assessment of process models with the time related logic specification and the possibility of validation and verification of such models [61] or compliance checking [62], especially with the existing tools which uses temporal knowledge [63], [64]. One of the possible directions is related to integration of timed process models with timed rules models for complex reasoning on contex data [65], [66]. Important issue is also practical design of timed models of processes and rules [67]. As we focus on analysis of a single process model, additional research for analyzing process models of processes changing over time can be an important issue [68].

***Abstract*—Creating new software or software-intensive systems is still a challenge and far removed from a traditional engineering domain. The increasing size of software deployed in typical systems and the emergence of very large highly distributed systems necessitates additional techniques to assure the systems quality. Using the example of the German automatic toll system we briefly outline a simulation driven development approach: Using simulation models starting with the very early design stages to verify and validate the overall dynamic system behavior throughout the whole development process. In practice the approach depends particularly on the performance of the simulation model: Many simulation runs are necessary while exploring the solution space of a proposed change or while calibrating and optimizing parameters of the simulation models. Starting with an existing model of the German automatic toll system we look at two different possibilities for parallelization – parallelized optimization and the partial transformation of the simulation model to a parallelized implementation.**

I. Introduction

MOST of the critical system design problems occur in the early design stages while specialists are specifying the system under a high degree of uncertainty. Many studies show that the probability of critical problems due to poor design decisions is very high in the specification phase [1]. The root cause is that either text-based or non-executable, model-based specifications are utilized: We build models of complex systems because we cannot comprehend any such system in its entirety [2]. Such specifications cannot be validated at the system level where the architecture and performance is determined as an emergent property.

The typical system development process will of course try to mitigate the consequences e.g. by shortening the step from the design to the deployment stage. But in distributed systems – "one in which the failure of a computer you didn't even know existed can render your own computer unusable" [3] – the properties of the whole system emerge only when all subsystems are integrated into a complete system.

Hence we propose to accompany the system development process with an executable specification of the whole system: At any stage during the system development process we implement the current level of detail as a simulation model. In that way the specification becomes executable (i.e. has sufficient detail to be executable).

In this article we briefly touch upon the concept of simulation driven development (SDD) – the starting point of an investigation into the performance of simulation models. When the intention is to base the system development process on simulation models the simulation results should be valid and readily available at any time. At least for complex systems both apsects necessitate a high simulation performance.

In particular the article applies two different ways of parallelizing simulations: The trivial parallelization of a genetic algorithm is of use when the simulation model is used either to explore the solution space in search of an optimal configuration or when parameters need to be fitted to data observed in the real world, e.g. modeling the user interaction. The non-trivial parallelization concerns the simulation model itself where – depending on the specific application – parts might be run independently. Starting with a simple benchmark model we apply the parallelization to an existing simulation model of the German automatic toll system.

The article is split into three parts: The first section explains the concept of simulation driven development in more detail (see section II) whereas the second and third section cover the simulation performance as one prerequisite for basing the software development process on simulation models: Parameter optimization using a genetic algorithm and the partial parallelization of a simulation model (sections III and IV). All parts have the same use case in common (section III): Applying the approach in the context of the German automatic toll system – a large scale liability-critical distributed system and a typical example of an electronic tolling system based on global navigation satellite systems (GNSS) [4].

II. Simulation Driven Development

SDD is characterized by applying modeling and simulation technologies during the whole product lifecycle: An executable model exists at any time encapsulating the current knowledge of the system. The benefit of SDD lies both in the early design stages (when most of the important design decisions are made) and the ability to verify and validate the system at any time through executable models.

A. Design approach

In general a system specification defines the functional and non-functional properties of a system in a formal, consistent, and self-contained manner to enable processing. Functional properties define the tasks of the system including information

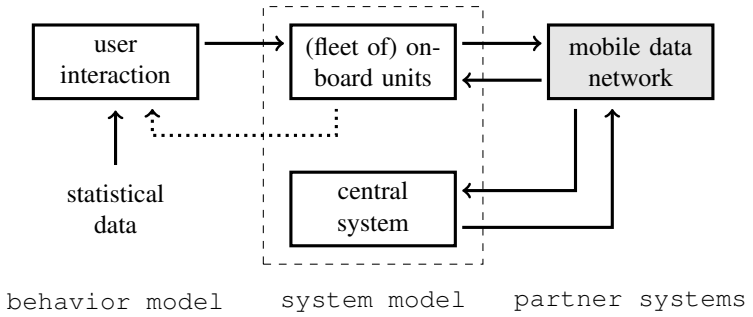

Figure 1. The simulation model of the German automatic toll system encompasses the the user interaction (left), the operators' technical systems (center) and systems under the responsibility of partners (right).

processing in relation to data, operation and the systems behavior.

Non-functional properties are more difficult to pin down there is not even a consensus on the term and its use [5]. They are used to describe the circumstances necessary to render the required functionality, e.g. the performance requirements, quality properties and constraints. In a sense the non-functional requirements become either constraints (to the system development or the system operations) or emergent properties (in the worst case emerging only at the system level when the user interaction is taken into account). SDD allows modeling both the constraints and the whole system including the user interaction and feedback loops.

Unfortunately, the specification phase is far removed from the final acceptance testing and the transition to operations. Many process models exist to close the gap, either by introducing more tests and documentation along the way or by shortening the development cycle (e.g. shifting requirements to the next cycle). To illustrate the system engineering process we take the "V-model" [6], a highly adaptable meta-model commissioned by the German federal government. At the core of this model is the well-known waterfall model dating back to 1970 with the design and development phases placed on the left and the test phases on the right – forming the letter "V". While it proceeds through the typical phases it differentiates the testing phase so that every design or development phase also sets up its own test phase.

Executable system specifications allow the validation, analysis, evaluation, and optimization of complex distributed systems even before the first line of source code is written – including dynamic interactions. Bottlenecks and resource shortages owing to dynamic coupling effects can be captured and resolved without running or implementing the real system. On a meta-level the executable model can include the system development process as well.

B. Applying SDD

In its current implementation we used SDD in the specification phase of two upcoming changes to the application-level protocols governing the interaction between the on-board-unit (OBU) and the central systems of the German automatic toll system in essence switching from an open-loop controller (the OBU decides in large parts independently if and when to connect to the central system) to a closed-loop controller (where the control resides at any time with the central system). The impact of SDD on the specification phase was twofold: Performing simulations of the whole integrated system at a scale of 1:1 allows predicting the system load for the chosen system architecture (and in combination with a cost model the estimation of operational costs) in effect operational risks become visible in the very first step of the system development process.

So far, researching the impact of architectural choices (or the systems parametrization) is a manual task: The simulation model needs to be altered (or at least re-configured) and the simulation run performed and analyzed. Using a fitness-function to grade the simulation results (e.g. the correlation with the real-world update rates observed for a fleet-wide update) is the first step to automate the design process: An additional optimization algorithm is able to change the parametrization or even the systems architecture automatically and to search for the overall optimal solution.

An intangible benefit of SDD in our example is the emphasis on the operational performance of any change already during the specification phase: Using the simulation model the consequences to the day-to-day performance is quantified and easily comparable to todays (or the intended future) performance.

III. Simulation model of the German toll system

In practice we introduced SDD to the system development process of Toll Collect GmbH (e.g. [7] and references therein) the operator of the German toll system for heavy goods vehicles (HGVs).

The automatic toll system consists of four major parts (figure 1): It uses OBUs to automatically collect the toll charges due. Most of the time the OBU is running independently and rarely connects to the central system via a mobile data network connection to upload the tolls collected and possibly download updates to its software, geo and tariff data. Using this architecture the reliability of the system depends heavily on the OBU its hardware, software and operational data as well as the user interaction.

In principle the system behavior could affect the user behavior (dotted line in figure 1): E.g. when the OBU signals 'out-of-order' the user could be tempted to quickly power-cycle the OBU. Particularly in the case of outages, e.g. when the central system cannot be reached by the OBU, the OBU will reach a point where it needs to signal the user a technical problem. It is therefore conceivable that the user behavior changes – either as intended by the system design (the user switches to the manual toll system, e.g. via internet booking) or by power cycling the OBU and thereby potentially triggering additional system load.

Looking at figure 1 it is interesting to note the first indications of a software-intensive system-of-systems: The system depends not only on the user interaction – it also includes partner systems that are operated independently (e.g. the mobile data network) and whose inner working is not accessible.

The model of the toll system depends on the external stimulus of the user interaction. With an emphasis on the fleet-wide propagation of updates we include only the temporal behavior: The points in time when an HGV is powered on (or off) and when a toll event is created.

Regarding the fleet-wide updates we use a genetic algorithm to adapt the simulation results to the data observed in the real-world system (for details and results see [8]). Parameter optimization requires the ability to compute a large number of results for different sets of parameters. In our case we used two sets of 16 probabilities (i.e. the probability for a given HGV of being active N out of 16 weeks, once for German HGVs and again for foreign HGVs). Even using a running at a scale of less than 1:1000 a single simulation run takes almost one minute to complete.

IV. Parallel DES models

For many purposes scaling is the appropriate solution – yet close to the specification limit of a system or once processes become non-linear, scaling is no longer an option. Simulation performance becomes important.

A. Domain independent parallel DES models

Many approaches exist to parallelize existing serial mode simulation models [9]. In our case, the space-parallel domain decomposition accelerates a simulation run by executing parts of the model in parallel. This approach is applicable to any model and shows the greatest potential in offering scalable performance for complex models [10], [11].

An optimistic approach to parallelization is to execute components even if – at a later time – it becomes known, that the execution was unnecessary or violated a causality constraint ("time warp", [12]). As long as excess computing power is available the consequence is only that causality errors need to be rolled back, i.e. each component has to be enhanced by an additional rollback block and from time to time rollbacks will occur. In a real-world application the expected speed-up is limited by those parts of a domain-specific simulation model that are intrinsically serial.

B. Domain specific parallel DES models

"Time warp" or optimistic parallelization has the advantage of being domain-independent – it is a feature offered by the simulation toolset as well as a programming paradigm. However, "artifical" rollback and commit steps need to be implemented and verified by additional testing. This effort could also be spent on an explicit, domain-specific parallelization of the simulation model itself.

In the example of the German automatic toll system (see figure 1) parallelism is inherent in many parts of the model (e.g. in the user behavior, the OBU fleet). Since most of the processing occurring in the simulation model is connected to the OBU fleet a sizable degree of parallelism could be achieved.

Simulation performance quickly becomes a bottleneck when the DES model is coupled to a real-world system, i.e. in a software-in-the-loop scenario. An example could be a server of the central system being subjected to the TCP/IP traffic generated by the OBU fleet.

Here the artificial concept of time – time is expressed in terms of events occurring and jumps immediately to the next event present in the "future event list" – needs to be coupled to the time passing in the real-world (system). Figure 2 depicts both concepts of time: In the real-world system time progresses continuously (indicated by the thick arrow from left to right) – aptly summarized as the wall-clock time. In contrast the DES tool considers time only in the presence of events: Each event generated in the simulation run carries a (future) time of execution and is accordingly put into the future vents list (FEL) for later processing. The current time in the DES model is therefore given by the pointer to the next event up for processing. Whenever multiple events occur at the same time a serial-mode simulation takes the events for processing from the future event list as if it were a queue. I. e. simultaneous events are processed sequentially while the clock is stopped.

When a real-world system is interfaced to the simulation model both possibilities break down: Even during times without events time passes at the same rate and sequential processing of simultaneous events will insert artificial delays, potentially disturbing the simulation results with two noteworthy consequences:

- Any speed-up of a DES simulation is negated once the real-world system is interfaced, the simulation will proceed (at most) at wall-clock time.
- The DES simulation model introduces artificial delays, when taking outgoing events from the FEL or inserting incoming events into the FEL – possibly to the degree of invalidating the simulation resuls by violating the 'real-time' constraint.

V. Summary

As in the test-driven development (TDD) case, testing is not the aim of the SDD rather the "driven [...] focuses on how TDD leads analysis, design, and programming decisions" [13]. In that sense, SDD tries to put the design to

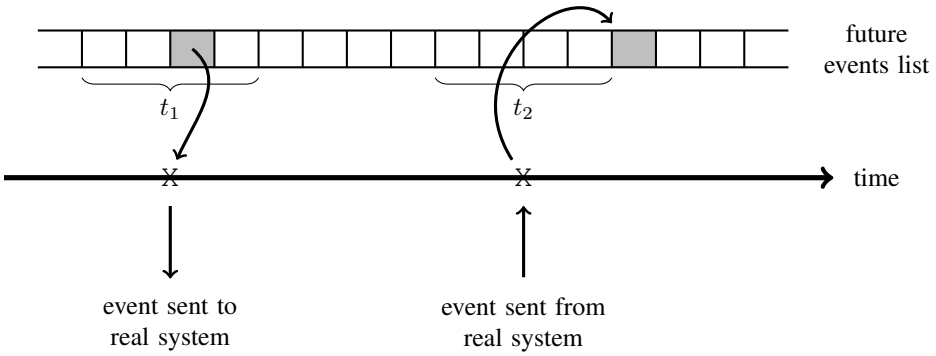

Figure 2. The concepts of time differ between the continuous time line in the real world and the list of (future) events at discrete points in time. Interfacing a real-world system will couple the two concepts.

the ultimate test-case – the real-world operational context. The simulation model – an executable specification of the existing real-world system – is the starting point to focus any software development on the operational consequences. These consequences might be of a purely technical nature, e.g. the system architecture and performance, or include non-functional requirements and business or financial aspects. In particular these challenges dominate environments that are rich in legacy systems, where the on-going development is largely faced with integration issues. SDD addresses integration of systems as a cross-cutting concern by providing the software developer (or requirements engineer) with an executable copy of the real-world system.

A prerequisite for applying SDD is the performance of the simulation model. We summarized two areas where performance matters: Exploring the solution space needs many simulation runs, albeit possibly at a small scale. Interfacing a simulation model with a real-world system is the final challenge – mingling simulated discrete and continuous real time.

***Abstract*— paper deals with the transition of companies to information systems operated using cloud computing services. The influence on the competitiveness of company and its organizational support is analysed. The developmental trends and their impact on company management are also described. The benefits and drawbacks from the transition to flexible ICT architecture are emphasized. Theoretical framework and literature support the fact that exploitation of cloud computing services is an inevitable component of the information strategy of European countries in the support of companies' competitiveness. Based on the collected information and own experiences with using the cloud computing, the recommendations for the effective transition to the application of cloud computing services in a company are proposed.**

I. Introduction

Managers keep looking for new means to improve management efficiency. Intensive use of modern IT technologies has become an essential part of the management process. Managers are aware of that and want to exploit the potential of new ICTs in the management of companies and their environment.

Thanks to today's modern communication technologies and social networks, each day we create huge amounts of data, both in the corporate environment and beyond.

The impressive boom in information technology, which started in the late 1990s, brought about a rapid acceleration of our lifestyles as well as of the overall approach to entrepreneurship and its support by ICTs.

The current trends in ICT having an impact on the efficiency and the type of organizational structure include, in particular:
the development of dynamic network services,
increase in the performance and capacity of data centres,
business through mobile technologies,
increasing demands on IS security,
processing increasing volumes of data
the development of Cloud Computing (CC). [1]

The economic crisis, development of new technologies and rapid globalization, the growth of the importance of access to relevant information and desire for mobility, act as catalysts for the global population.

II. Transition to the use of ICT as a shared service – Cloud Computing

Managers require a comprehensive information system containing the necessary functions, at different times and in the necessary scope. The aim is to ensure the necessary flexibility in management. This is made possible by Cloud Computing services. The CC services increase company flexibility and have a positive impact on its production and competitiveness.

CC has no uniform definition; each definition depends on the perspective of its author.

„A cloud is defined as the combination of the infrastructure of a data centre with the ability to provision hardware and software.“, says Sosinsky. [2]

Gartner defines cloud computing as "a style of computing in which scalable and elastic IT-enabled capabilities are delivered as a service using Internet technologies".

Another definition of CC from a different perspective says that "*Cloud Computing is essentially a concept that allows you to access applications that are actually located elsewhere than on a local computer or device connected to the Internet, most commonly in a remote data centre.*" [3]

In summary, CC is simply the "*approach to the use of computer technology, which is based on providing shared computing resources and their use in the form of a service.*"

The author of this paper relies on the definition of the US National Institute of Standards and Technology, which defines the CC as a "*model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction.*" [4]

III. Definition of the problem

This article aims to identify possible pitfalls of the transition of the company IS to a flexible ICT architecture

This work was not supported by any organization

and operation of IS in the form of CC services and to draft procedures and recommendations to successfully manage this transition.

Due to the long experience of the author with CC services, the paper discusses benefits and risks of operating the IS in the form of CC services. In the recommended transformation of the company IS into the CC, the author also draws on her personal experience.

Innovative, so far untested information and communication technologies can significantly improve the performance of a company IS on the one hand, but if incorrectly implemented, they can cause fatal damage in situations beyond the control of the company. [5]

IV. Transformation of a company's information system into Cloud Computing

It needs gradually and conceptually change the overall IT architecture. The investment in building the concept of a flexible IT architecture have no direct financial return, but they lead to a significantly faster and cheaper integration of new components and implementation of changes.

- Demands on the suppliers of CC services:
  Today, managers emphasize the requirements for shortening the delivery times, budget reductions and complexity of mutually integrated systems.
  Customers also increasingly demand the mobility of solutions. Applications can run anywhere; therefore, their mutual integration should be defined by standard interfaces.
  There is an increased pressure on the use of innovative approaches, such as agile development, prototyping or extreme programming.
  Analyses of a new generation of ICT infrastructure. Analytical tools based on big data become critical and their real-time analysis then facilitates the development of applications for business intelligence and control of transmission networks. [6]
  Analytical tools based on big data and their real-time analysis then facilitate the development of applications for business intelligence and control of transmission networks.

The decisions on the transformation of part or the entire company IT to CC is part of the information strategy of a company or institution. The supplier cannot deal with the transition to CC without coordination with company managers, who are informed about the possibilities of current ICT in relation to the entire business strategy of the company, availability of human and financial resources, know-how, etc.

The decision to transform the entire company IT (or its part) to CC is part of the information strategy of a company or institution. The supplier cannot deal with the transition to CC without coordination with company managers. [7]

- Impacts on user companies and organizations:
  As a result of operating applications in CC, companies will reduce the number of technology-oriented specialists (there will be less need for programmers, administrators, and other professionals).
  However, the number of employees ensuring the links between business and ICT services is set to grow. Nevertheless, the total number of workers involved in the use of ICT in the company will not decrease, although their qualification structure will change. [8]
  Companies will need to develop key skills supporting the use of ICT – how to use ICTs to gain a competitive advantage, create new products or services, find new customers, speed up the company's response to external events and reduce the costs of business processes. [9]
- In other words, how to support business processes by an appropriate selection of ICT services:
  - how to determine the content, volume, quality and price of ICT services,
  - how to design the overall architecture of ICT services,
  - how to find and implement the selection of the optimal supplier of ICT services,
  - how to systematically monitor the delivery of ICT services,
  - how to develop rules for the controlling of IT services and measure the impact of ICTs on the quality of company processes. [10]

This will require changes in skill required from managers. Managers who will understand how to use ICT to create a new product or service and how to get new customers will become indispensable members of senior management.

V. Approach to cloud computing services in Europe

Europe pays close attention to CC services because their use can significantly affect performance and competitiveness, particularly of small and medium-sized enterprises, which in many countries have a considerable impact on their economic stability.

A significant role played in these initiatives EuroCloud Europe. EuroCloud agrees that in a world Cloud Computing will become the main tool for collecting, processing, storing and selecting information and knowledge.

EuroCloud Europe is a cloud-based organization with its headquarters in Luxembourg. It builds strong relationships with local governments and the European Commission and supports the environment for the development and growth of cloud computing as a tool to support the growth of business and competitiveness. It sees cloud computing as one of the most important impulses for the creation of a knowledge

society in which physical resources are optimized and shared resources are universally accessible.

Currently, members of EuroCloud include 22 European countries that are very different both in terms of the rate of utilisation and provision of cloud services and the willingness to participate in the observance of standards and legal and security conditions which are crucial for an effective Europe-wide application. The activities of individual members can be found on the EuroCloud Europe website. [11]

VI. How to Maximize the Effect of Shared Services

This chapter provides a summary of the measures that should be implemented to support the strategy of transition to CC services in order to get the greatest possible benefit from its implementation.

Individual steps (phases) in the transition to the CC:

- The initial step when trying to maximize the effects of the transition to CC is the preparation of a schedule of a gradual conceptual transformation of the entire IT architecture. In terms of management, this document is a strategic document (see Chapter 4).
- It is followed by the specification of requirements which will be crucial in the choice of the supplier. Fundamental aspects include:
  - time of delivery,
  - amount of cost,
  - functionality,
  - performance of the information system,
  - complexity of the information system.
- In the third step, it is necessary to specify the progressivity rate of the IS. If the IS is to be progressive, the specification should also include demands on the rate of mobility and alternatives of the required access to its implementation. At this stage, it is also necessary to specify possible requirements for means allowing real-time analyses and the management of computer networks.

  Managers must be trained in these steps so that they can propose how to use ICT to improve the course and management of business processes, thus promoting the development of their own business.

  The possible focus of training:
  - how to use ICT to gain a competitive advantage,
  - create new products or services, find new customers,
  - speed up the company's response to external events,
  - reduce the costs of business processes. [12]
- The next step is adapting the qualification structure of employees as needed. This is due to the increase in the demand for employees ensuring the link between business and ICT services.

  Managers who have been trained and proved their worth among the members of senior management will then participate in all senior discussions on company strategy, changes in marketing and sales.
- Now, attention is paid to the financial aspects of the transition.

  It is necessary to:
  - prepare the budget in consideration of the changes in the cost structure – linearization of costs (elimination of the investment component),
  - prepare the employees for the measurement of consumption – gaining control over their work.

It needs to use of the scalability of shared services. [13]

Also:

Prepare the employees for the measurement of consumption – gain control over their work. The manager gets a good overview of what his/her employees are doing and how they are doing it.

- Thanks to fees for shared services, it is easy to get a detailed overview of the operating costs of individual agendas and identify these agendas.
- The final step is the preparation of a document on contractual relations with the service provider.

  It contains:
  - specific requirements
  - specific responsibilities to be delegated to the provider, under what conditions,
  - with what guarantees and also with what sanctions in case of non-compliance.

Likewise, agreements are to be prepared.

- The specification of the contractual relationship is to be focused on:
  - the provision of services
  - subject, functionality
  - objectives
  - expectations.

  Service scaling:
  - change of scope,
  - quality,
  - time of provision).

  Ensuring connectivity:
  - connectivity provider,
  - connectivity downtime,
  - the protection of personal and other sensitive data,
  - the division of responsibilities between the company and the supplier,
  - the legal status of physical equipment used to provide services,
  - software licensing terms,
  - conditions of system migration,
  - required customization.

Specific impacts will also become evident on the side of interested users of shared services, whether users from among companies or private owners, because they change to shared services so that they could benefit from a profit and be able to operate more efficiently, faster, and with better

planning. They can concentrate more on their core business, their mission or the entrusted tasks and do not have to be distracted by operational or other secondary activities.

VII. Conclusion

Current demands on the pace of life require the appropriate form of management. Management puts demands on the flexibility and information resources to support decision making. In order to maintain the quality of management at the highest level, it is necessary to use all the features of the existing information and communication technologies. The use of CC is one way to achieve this. Based on the findings in the available literature and the author's own experience of working with CC technologies, the paper provides recommendations for the transition to CC in companies and institutions. Recommendations are made with regard to the current situation in each company. These recommendations include a set of activities that need to be done to maximize the benefit from this change. Due to the variability of current conditions, this paper encourages further research into this area to ensure increasing flexibility and quality of the management of companies and institutions.

***Abstract*—Social media constitute a challenging new source of information for intelligence gathering and decision making. Twitter is one of the most popular social media sites and often becomes the primary source of information. Twitter messages are short and well suited for knowledge discovery. Twitter provides both researchers and practitioners a free Application Programming Interface (API) which allows them to gather and analyse large data sets of tweets. Twitter data are not only tweet texts, as Twitter's API provides more information to perform interesting research studies. The paper briefly describes process of data gathering and the main areas of data mining, knowledge discovery and data visualisation from Twitter data.**

I. Introduction

TWITTER is a social networking site directed towards short-form, fast communication. Launched in 2006, Twitter rapidly gained global popularity and has become one of the ten most visited websites in the world. As of March 2016, Twitter boasts 302 million active users who collectively produce 500 million tweets per day, and these numbers are continually growing. These characteristics have made it a primary source of real-time information.

Given this enormous volume of data, analysts have come to recognise Twitter as a virtual treasure trove of information for data mining, social network analysis and information for sensing public opinion trends. For companies, Twitter can be used to build business intelligence tools focused on Twitter data acquisition and processing. It can be used in many ways to collect raw Twitter data and to transform it into valuable business intelligence data.

Twitter is an exceptional tool for knowledge discovery due to six key features:

- Twitter's API is clean and well-documented, with rich developer tools.
- Twitter data are rich in information and have a data format that is convenient for analysis
- Twitter's terms of use for data are relatively liberal. Tweets are public and reachable to anyone. Twitter is based on the asymmetric following model that allows access to any account without request for approval.

However, analysis of Twitter messages (tweets) is regarded as a challenging problem due to some difficulties:

- large amounds of data that cannot be easily handled.
- tweets are short,
- over 40% [1] of tweets are of an informal type of discourse that does not cover any functional topics,

Despite these difficulties discovering knowledge can be simple and bring significant value.

II. Twitter data terminology

The Twitter messages are called tweets. Twitter users post messages that show up in the streams of all of the people who have subscribed to them. Unlike traditional blogs, microblogs are typically limited in the amount of text that can be posted. Twitter's limit is 140 characters.

Tweets often contain links to on-line resources, such as web pages, images, or videos, and more often than not, they refer to other users (called mentions). As is the case with most microblogging, when a message is posted, updates are seen by all users who have chosen to "follow" the author who posted the message (submitter).

In Twitter, all the posts are public. Most people may not receive them if they do not follow the submitter, but messages can be searched for with a keyword or topic and found by someone who is talking about a specific subject.

Twitter has its own conventions that renders it distinct from other textual data. Understanding the language and terminology that is used is important for effective knowledge acquisition.

There are some particular features used in Twitter:

1) Tweet — is a message posted on Twitter, consisting of 140 characters or fewer. It can contain text, photos, links and videos.
2) Twitter name — Twitter usernames appear with an at sign "@" before the name.
3) Hashtags — The # symbol, called a hashtag, is used to mark keywords or topics in a Tweet. It was created organically by Twitter users as a way to categorize messages.
4) Mention — Users of Twitter use the "@" symbol to refer to other users. Referring in this manner automatically alerts them.
5) "Reply" — is used to respond to a tweet. Replying to a tweet is a way of building relationships with followers and friends and joining in conversations.
6) A Retweet — is where one chooses to take a tweet from someone else and tweet it to one's own followers. It can either be done directly with the retweet button or by adding one's own message and including the letters "RT" ahead of the content that is being retweeted.

Twitter names, hashtags and mentions provide an easy way of identifying people and topics, and thus allow to search for and filter information on any subject of interest. Twitter messages have also many unique attributes connected with a tweet which are available with the Twitter API or other tools.

III. Gathering Twitter data

Any social media investigation is only as good as the data used for its analysis. The process of social media analysis involves essentially four steps: data identification, data analysis, data interpretation and, finally, information presentation.

The main problem is how to extract the information that is available on Twitter and how it can be used to draw meaningful insight. To achieve this, first there is a need to build a data analyser for tweets. Tweets are available to researchers and practitioners through public Twitter APIs. Twitter allows developers to collect data via Twitter REST API (https://dev.twitter.com/rest/public/) and the Streaming API (https://dev.twitter.com/streaming/overview).

APIs to access Twitter data can be classified into two types based on their design and access method [4]:

- REST APIs are based on the REST architecture that is now popularly used for designing web APIs. These APIs use the pull strategy for data retrieval, i.e. a user must explicitly request information in order to collect it.
- Streaming APIs provides a continuous stream of public information from Twitter. These APIs use the push strategy for data retrieval. Once a request for information is made, the Streaming APIs provide a continuous stream of updates with no further input from the user.

The response from Twitter APIs is in JavaScript Object Notation (JSON) format. JSON data can be converted to CSV and imported to databases. NoSQL databases, such as MongoDB, allows to store and access JSON data directly, without conversion.

Since gathering of data have particular target, further preprocessing and filtering of collected data can be done using @twitter_names and #hashtags as a search arguments for Twitter API. This method is more precise and provides better results in narrowing data than other text mining approaches.

IV. Storage of data

Explosion in the size of data generated on social media calls for a new data storage paradigm. Commonly used relational databases are insufficiently effective in storing very large datasets. Also the JSON-based data format, used in social media, requires additional conversion to a relational form. At the forefront of this movement is NoSQL, which promises to store large amounts of data in a more accessible way than the traditional, relational model.

There are several NoSQL implementations. One of the most popular ones is MongoDB (https://www.mongodb.org). MongoDB is a proper solution for storing Twitter data due to its adherence to the following principles:

- MongoDB is an open–source document database that provides high performance, high availability and automatic scaling.
- A record in MongoDB is a document, which is a data structure composed of field and value pairs.
- MongoDB documents are similar to JSON objects. This makes it very easy to store raw documents from Twitter's APIs.

In addition to these abilities, it also works well in a single-instance environment.

V. Data structure

Twitter APIs, besides basic information such as the tweet text and the author of the tweet, returns data structure contains additional information which can be used to provide further analysis. For each maximum 140 character tweet, API returns a JSON document containing over 160 items of metadata presented as key and value pairs.

Some the most useful keys for knowledge acquisition are:

- 'coordinates', 'geo' and 'place' — determine the location of the tweet's author;
- 'lang' — allows to easily specify the language of the tweet without text analysis;
- 'created_at' — the date and time of the tweet
- 'entities' — "symbols", "hashtags", "user_mentions" and "urls" included in the tweet;
- 'retweeted_status' — information about retweets;
- 'source' — application or website uses to create a tweet;
- 'text" — text of the tweet;
- "id" — unique identification of the tweet;
- "user" — contains 38 fields about the user. The most useful may be:
  - 'name' — user name;
  - 'time_zone' — time zone of computer or mobile;
  - 'created_at' — date and time of account creation;
  - 'description' — additional information about the user;
  - 'friends_count' — number of friends;
  - 'followers_count' — number of followers;
  - 'location' — actual location.

The above-mentioned keys can make it easier to analyse the text data, but also to perform various specific analyses of users, users nets, time and geolocation information.

VI. Methods of Twitter Data Analysis

Analysing Twitter data is searching through massive amounts of unstructured data. Filtering the data by Twitter names, topic or hashtags may reduce the data size, but it can still be enormous. Also, most Tweets contain no useful information.

Many different types of analysis can be performed with obtained Twitter data. The first can be simple text mining of posts, yet information provided within a tweet's text allows to conduct more Twitter-specific analysis, e.g. user information, connections between users, and localisation at the level of country even any place on the map of the world.

A. Text Mining

Text Mining refers to the process of deriving information from a text. A typical approach in Tweeter analysis is a document-level approach to scan a set of tweets written in a natural language and either to model the document set for predictive classification purposes or to populate a database or search index with the information that is extracted.

Most NLP-based text mining methods perform without particular success in social media. The informal and specialised language that is used in tweets as well as the nature of the microblogging domain make Twitter text mining analysis a very different task. Almost all forms of social media are very noisy and full of all kinds of spelling, grammatical, and punctuation errors. Text mining of tweets can be easier because Twitter API provides information about the language that is used, hashtags and usernames, hence there is no need for its detection.

B. Collecting a User's information

On Twitter, users create profiles to describe themselves to other users on Twitter. When a user creates or reconfigures an account, he/she provides some personal information, such as his/her name, username, password, email address, or phone number. The user may also provide with profile information, such as a short biography, location, website, date of birth, or a picture. On the Twitter Services, the name and username are listed publicly, including on the user profile page and in the search results. A user's profile is a rich source of information about him or her.

The Twitter REST API function users show (https://dev.twitter.com/rest/reference/get/users/show) is an easy way to obtain valuable information about a user, including:

- Real name,
- Description - which typically contains additional information about user,
- Entities such as hashtags, links and media, which can point to further sources of data,
- Followers_count,
- Friends_count,
- Location,
- Language.

An even more valuable function is the followers list (https://dev.twitter.com/rest/reference/get/followers/list). As the name suggest, it allows to access a whole list of followers in one query. The returned data may contain the same information for all followers as the function users/show. Using this function for Twitter's most followed users allows to collect information about millions of users without exceeding twitter API limits.

Information about the friends list is provided by function friends list (https://dev.twitter.com/rest/reference/get/friends/list).

Crawling using the above functions can be used to recognise networks of users.

C. Network Information

A Twitter user network refers to connected user accounts based on various types of relatedness. Structured content, in the form of friends and followers, @replies and @mentions, #hashtags and retweets, makes the Twitter user population networked in multiple ways. Each of these features can be considered as a kind of connection that can exist between two Twitter users. Kumar, Morstatter and Liu [4] categorised two main types of networks:

- Information Flow Networks.
- Friend-Follower networks,

A first kind of network shows who was mentioned or replied-to in the users' Tweets. Second kind of network is based on list of friends and followers of user.

Another type of network is one associated with time-bounded events, such as conferences. Many events like conferences now communicate a common "hashtag" or keyword to identify messages related to the event. Hansen, Smith and Shneiderman [5] [6] created EventGraps. EventGraphs help make sense of the collections of connections that form when people follow, reply or mention one another and a keyword.

To analyse and visualise social media network data from Twitter, the most popular software to use is NodeXL, a free and open add-in for Excel 2007/2010/2013. NodeXL is a project from the Social Media Research Foundation (http://www.smrfoundation.org/). NodeXL is a general purpose network analysis application that supports network overview, discovery and exploration.

D. Sentiment Analysis

The nature of microblogs is that people post real-time messages about their opinions on a variety of topics, discuss current issues, and complain and express either positive or negative sentiment for products they use in daily life. Data from these sources can be used in opinion mining and sentiment analysis tasks, e.g. manufacturing companies may be interested in the following questions:

- What do people think about their product (service, company, etc.)?
- How positive (or negative) are people about our product?
- What would people prefer our product to be like?

All of this information can be obtained from social networks. Opinions and related concepts such as sentiments and emotions are the subjects of study of sentiment analysis and opinion mining.

Sentiment analysis is a growing area of the Natural Language Processing. With the growing population of blogs and social networks, sentiment analysis have become a field of interest for many researches. A very broad overview of the existing studies was presented in [7].

E. Geolocated information

Twitter is also characterised by the diversity of its users, in terms of location. Harvesting this geospatial information provides a unique opportunity to gain valuable insight into information flow and social networking within society.

An important aspect of Twitter data is that some data are geotagged, which means that the posting user has attached a GPS coordinates to the tweet when uploading the information. Such information can be particularly important in order to understand where the user is and what he/she is referring to.

Fischer [8] tracked geo-tagged tweets from Twitter's public API for the last three and a half years. He claimed that there are about 10 million public geotagged tweets every day, which is about 120 per second. This is still a small portion of all tweets, and it is often necessary to use all sources of location information to determine the Tweet's location.

VII. Visualisation of Twitter data

Textual information is generated when users publish on Twitter. Analysing Twitter users and conversations is more than tabulating counts and trends — it is about connections and interactions between people. Twitter enables the collective creation and sharing of digital artifacts. The use of these tools inherently creates network data. These networks represent the connections between content creators as they view, reply, annotate or explicitly link to one another's content.

Twitter provides other embedded information, such as location data. All kinds of gathered data can also be analysed in the time dimension. Visualisation techniques can help to efficiently analyse and understand how and why users interact on Twitter. The display data task requires a remarkable collection of tools and skills.

A. Text visualisation

Text visualisations provide visual representations of documents or small corpora with the primary aim of supporting language analysis. The most popular method of text visualisation are tag or word clouds. Tag clouds are a simple but effective way of representing the distribution of words in a document or corpus, such as a tweet. They are widely employed for both casual use and serious analysis [9]. Clouds give greater prominence to words that appear more frequently in the source text. Clouds can be tweaked with different fonts, layouts, and color schemes.

Another method of text visualisation is the word tree, which is a technique that transforms text into a hierarchical representation based on a selected word or phrase [10].

B. Network visualization

By using network analysis, one can visualise complex sets of relationships such as graphs or sociograms of connected symbols and calculate precise measures of the size, shape, and density of the network as a whole and the positions of each element within it [11]. Structured content, in the form of friends and followers, @replies and @mentions, #hashtags and retweets, makes the Twitter user population networked in multiple ways. Each of these features can be considered as a kind of connection that can exist between two Twitter users.

There are at least as many kind of networks as there are features listed here. All networks can be categorised into network of friends, network of followers and information flow networks — retweet propagation. These and many other kinds of networks are identified and described in depth in [12] and [4].

C. Geolocation visualization

Location information is typically used to gain insight into the prominent locations that are discussing an event. Maps are an obvious choice to visualise location information. A basic method of creating map identifying tweet locations is to simply highlight the individual tweet locations. Each tweet is identified by a dot on the map, and such dots are referred to as markers. Another way is drawing circles of size representing an number of tweets aggregated.

The second kind of map is a trends map. A trends map allows to make real-time mapping of Twitter trends on map. These are displayed as hashtags, @mentions or keywords superimposed over a world map. The map of course can be zoomed in for more detail, and trends from various cities can be selected.

Another kind of map is a heat map of tweets. It allows to quickly identify regions of interest or regions with a high density of Twitter users. A heat map of twitter data can be generated using the https://worldmap.harvard.edu/tweetmap/ website.

14^{th} Conference on Advanced Information Technologies for Management

WE are pleased to invite you to participate in the 14^{th} edition of Conference on "Advanced Information Technologies for Management AITM'16". The main purpose of the conference is to provide a forum for researchers and practitioners to present and discuss the current issues of IT in business applications. There will be also the opportunity to demonstrate by the software houses and firms their solutions as well as achievements in management information systems.

TOPICS

- Concepts and methods of business informatics
- Business Process Management and Management Systems (BPM and BPMS)
- Management Information Systems (MIS)
- Enterprise information systems (ERP, CRM, SCM, etc.)
- Business Intelligence methods and tools
- Strategies and methodologies of IT implementation
- IT projects & IT projects management
- IT governance, efficiency and effectiveness
- Decision Support Systems and data mining
- Intelligence and mobile IT
- Cloud computing, SOA, Web services
- Agent-based systems
- Business-oriented ontologies, topic maps
- Knowledge-based and intelligent systems in management

EVENT CHAIRS

- **Dudycz, Helena,** Wrocław University of Economics, Poland
- **Dyczkowski, Mirosław,** Wrocław University of Economics, Poland
- **Korczak, Jerzy,** Wrocław University of Economics, Poland

PROGRAM COMMITTEE

- **Abramowicz, Witold,** Poznan University of Economics, Poland
- **Ahlemann, Frederik,** University of Duisburg-Essen, Germany
- **Andres, Frederic,** National Institute of Informatics, Tokyo, Japan
- **Atemezing, Ghislain,** Mondeca, Paris, France
- **Banaszak, Zbigniew,** Warsaw University of Technology, Poland

***Abstract*—The main aim of this article is to show the characteristics of individuals playing computer games and their styles of play. In order to present the relevant data, the authors limited the study sample to a selected group of individual users. In the current paper the authors presented the commonalities of gamers, their approach towards participation in games, and the awareness of potential changes and improvements in the area. They also held discussions concerning the obtained solutions and drew conclusions based on the present stage of research.**

I. Introduction

The main aim of this work is to analyze the use of computer games as one of the alternative forms of entertainment in the selected group of users under the circumstances of a dynamic development of devices and mobile applications running on them. The aim of this article is to analyze the situation where computer games are used by people who treat them not only as a form of entertainment but also as a kind of sport. The popularity and specific universal nature of the access to computer games facilitates a fast development of information technologies. A broadly defined concept of mobility also impacts the use of computer games, moving the focus from using PCs to the use of smartphones and tablets.

According to the statistics of Newzoo [12] service, in Poland in 2013 the number of gamers amounted to 13.4 million, out of which 98% used their PCs to play computer games (together with other platforms). We take the second position in Europe among the examined countries. The market of computer games in Poland is growing every year – in the end of 2014 it was worth about 280 million dollars and it will be growing by 3.8% a year, thus increasing the value of the entire market to 437 million dollars at the end of 2016 [9]. Hence, undoubtedly the subject matter is worthy of attention.

Unfortunately, the phenomenon itself is difficult to define and examine taking into account the formalized scientific analyses. Firstly, there is no clear definition of computer games [8, 10, 11, 13, 15, 20, 24]. In its narrow sense, this concept is treated literally as games in the form of software running only on traditional hardware such as (desktop, microcomputers, laptops or palmtops). In its broad, historical approach, the group encompasses also games running on devices such as a console, TV, gaming machines, smartphones and tablets (which are in fact communication and application computers). As the games running on all kinds of devices were being developed in parallel, and, in fact, there are PC equivalents of all kinds of games, we sometimes use this term in its broad meaning. Thus, for the needs of this study, the authors assumed that computer games are a generic term (hypernym) encapsulating the whole class of all kinds of games presented as a homogenous phenomenon. Secondly, there is no one generally accepted definition of a person playing computer games (e-gamer). Thus, in the narrow sense of the word, an e-gamer is a person who plays computer games every day or a few times a week, individually or taking part in a multi-player game. Sometimes, the scope of this term is limited to include only those players who treat MMO (Massively Multiplayer Online games) class games as a sport, and they try to play them professionally. However, we observe a more and more common tendency to expand the term to include also any individuals who play any kind of game from time to time, perceiving it as just one more alternative kind of entertainment. This article treats the concept of e-gamers in such a way. Thirdly, there is no (specific or clear) classification of computer games: there are a number of typologies based on various criteria, most frequently taking into account the type of activity required from the e-gamer playing games (e.g. logic, strategic, arcade, RPG (role-playing games), MMO (Massively Multiplayer Online games) etc., with a number of varying kinds and versions.

The phenomenon of computer games has been examined in numerous studies, in numerous countries and social groups [e.q. 4, 6, 7, 22, 25], including large-scale studies [e.g. 5, 21, 26]; nevertheless, they were carried out before the recent period of extreme popularity and growth in the number of applications running on smartphones and tablets. And the second point is – that they are concentrated on statistics of the players (with their features) or social field of problem rather then on IT development. The authors hoped to establish certain implications of the new phenomena with regard to the direction of computer games development. Therefore, the authors have undertaken the studies whose main aim is to analyze the use of such applications among users. The findings presented in this article constitute a brief report on the first stage of the research conducted among the gamers in Poland in 2015.

II. The assumptions of research methodology and population sample

Due to limited and fragmentary research concerning the area of internet computer games and e-gamers, both from the point of view of an individual client and a group of customers, in Polish and foreign literature, the studies have been based on the authors' own approach [1], quite different from surveys in Poland [25,26] and some different from research in the other countries [18, 19], consisting of the following steps:

- analysis of a selected group of players on the basis of a quantitative and qualitative survey, divided into the following parts:
  - characteristics of a computer player and identifying his or her preferences in computer games,
  - identification of potential effects and consequences of playing computer games for e-gamers.
- placing an internet version of a survey on the servers of the Faculty of Management of the University of Warsaw, conducting functionality test and its verification,
- carrying out the survey among the users, analysis and discussion of the findings,
- drawing conclusions from the obtained results concerning the current situation and possible directions of the future development of internet computer games on the basis of the users' opinions.

The article presents the results of the analysis of the first part of the completed survey. It allowed for identifying a particular group of people who play various kinds of games, using different kind of hardware and software, with a varying level of skills and expectations concerning the organizational and technical aspects of playing games. Only after the selecting the group of best, "professional" players, we may proceed to specify the implications and psychophysical effects of their involvement in individual and multi-player games. The latter aspect was examined in the second, sequentially conducted, stage of the survey, whose results and conclusions will be presented in subsequent publications [3].

The questionnaire surveys were conducted near the end of December 2015. The selection of the study sample was not accidental: it belonged to the category of convenience sampling, the respondents were mainly students of selected universities in Warsaw (University of Warsaw and Vistula University (Akademia Finansów i Biznesu Vistula)), of full-time and part-time BA, BSc and MA studies. The survey was also completed by two members of university staff who declared playing computer games. The surveys were circulated electronically, and the response rate did not exceed 70%. Students are particularly open to all kinds of innovation, especially if it concerns their private life or entertainment [23].

A specific limitation concerning this particular sample was an anticipated high percentage of smartphone, tablet, laptop and mobile phone users, devices of lower quality but with a longer durability. An additional argument for conducting research in this social group was the demand from company cooperating with us on the design and construction of specific game platforms. The company depended on the wide market recognition of students as the main customer of such a platform.

The survey was completed by 274 people, out of which 254 participants submitted correctly completed questionnaires (which constitutes 92.70% of the sample). Among the respondents there were 59.45% of women and 40.16% of men; 0.39% respondents did not answer this question. An average age of the respondent was 20.62 years, and the medium value was 19 years. The age is typical of students of the first years of BA and BSc students and the first years of the studies of the second cycle – the group asked to complete the questionnaires. The oldest person taking part in the survey (member of the university staff) was 37. Among the survey participants there were 63.39% of students, 35.83% working students and 0.79% employees. 70.87% indicated secondary level education and 20.08% post-secondary education – the survey was primarily conducted among the students of BA studies. 8.66% declared holding a BA degree or a certificate of completion of studies, only one person indicated having a PhD degree.

Over 45% of survey participants indicated that they are inhabitants of cities with over 500,000 residents, over 14% came from cities with 100,000-500,000 of inhabitants, over 21% from towns with 10,000-100,000 residents, almost 5% from towns up to 10,000 residents, and 12.6% declared that they come from rural areas. The simplicity of the survey did not cause many distortions during its completion; few respondents (17) completed also additional sections of the survey.

III. Analysis of the findings and discussion

Respondents provided answers to forty-one substantive questions, out of which responses to first twenty-one questions concerned the issues which are the aim of this article. The first group of questions concerned the characteristics of e-gamers and their use of computer games.

Nearly 40% of respondents provided positive answers to the question concerning frequent use of computer games, i.e. every day (20%) and a few times a week (over 19%). This is the score which is 10 percentage points lower than rare use of e-games, which amounts to more than 49%. After preliminary interviews with respondents it seemed that the interest in computer games will be higher. The high score of a reasonable way of playing computer games (a few times a month) - 22% showed that the games are just one of many alternative kinds of entertainment available today. Fig. 1 illustrates the findings of the research.

Taking into account the technical aspects concerning platforms which e-gamers use, in the last 12 months we observe a specific shift towards mobile devices, smartphones in particular. Thus, over 35 % of e-gamers (80.75% including other platforms) used mobile platforms (mainly Android) last year. The second place was taken by PC platform – 28.31% (65.24% including other devices), and the third position was occupied by the console (e.g. Xbox, PS) with the

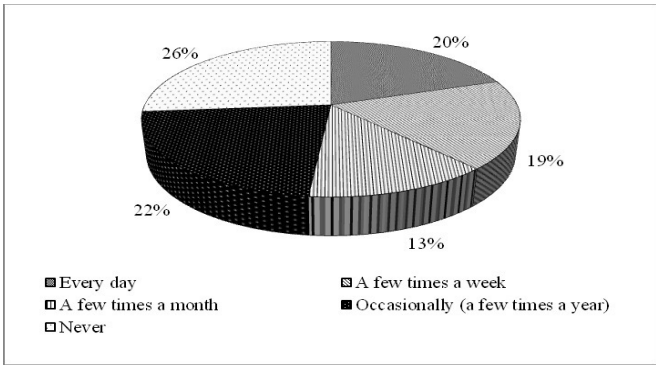

Fig 1. The frequency of playing computer games

score of 27.38 (63.10% - respectively). Smart TV platform received the lowest scores in this ranking – 2.09% (4.81).

In the perception of particular platforms among the e-gamers, we notice considerable discrepancies, amounting to 33 percentage points. The greatest number of respondents simultaneously use smartphones and PCs as platforms for games. Here, the dispersion of the results reaches almost 76 percentage points. The observed tendencies are presented in Fig. 2.

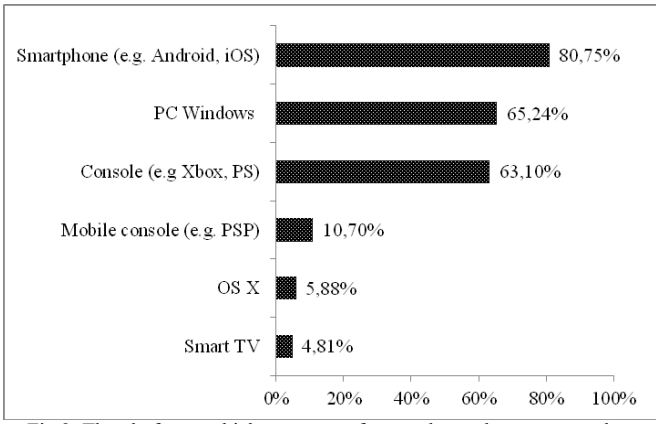

Fig 2. The platforms which were most frequently used as e-games platforms in the last year

On the other hand, it probably stems from the fact that the majority of e-gamers 59.87% (including other kinds of game access – 97.33%) use the games installed on a device (a PC or a smartphone). The second position of Steam, Origin etc. platforms amounting to 26.32% (respectively 42.78%) is a rather interesting phenomenon. The two main sources of games together constitute over 86% of "places" where e-gamers used the possibility of playing games in the last year. The remaining places where games were downloaded e.g. Facebook (6.25%) and low score of browsers (e.g. Quake Live) -7.57% seem to be of marginal importance in this relation. The Fig. 3 illustrates the scores.

The responses to the question concerning the age of e-gamers at the moment when they started to play games brought about very interesting results. The age which was most frequently indicated by respondents (almost 50% of responses) was within the range of 6-9 years (median of 6-7 years). If we add a group of people aged 10-11, we have

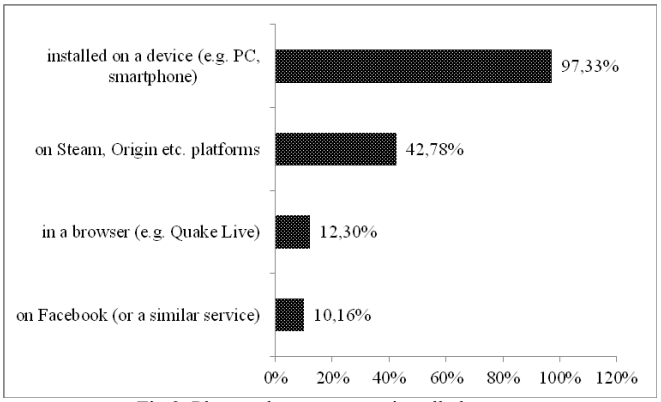

Fig 3. Places where e-gamers installed games

more than two thirds of all gamers! It is also significant that 17.11% of e-gamers declare that they started being interested in games at the age of 5. A marginal number (1.07%) admits starting playing games at the age of 20-25 (and the group that indicated the age of 16-25 amounted to 2.76%). This indicates the very early age when people become interested in computer games and treating the games as an alternative kind of entertainment in relation to films, TV, games or outdoor activities. Unfortunately, the limitation of the research was the fact that the authors did not examine children and young people from this age group. Nevertheless, the obtained results explain where – among others – the interest in computer games later in life comes from. The responses of survey participants were presented in Fig. 4.

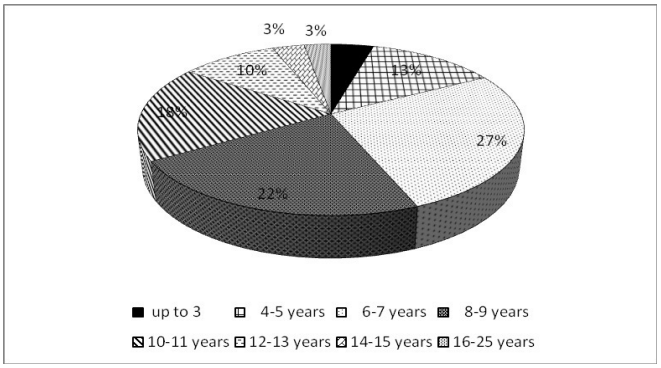

Fig 4. The age when respondents started playing computer games

Subsequently, the authors examined also the amounts of money which e-gamers spend monthly at playing computer games. The vast majority of them – 79.14% - use free applications installed on smartphones or free (or, as some people claim, illegally downloaded from the Internet) PC games. The remaining 18.18% of respondents are willing to pay up to PLN 80 monthly, and only 2.67% from PLN 81-300. From the commercial point of view, the last group (in particular 2.14% of survey participants who are willing to pay between PLN 151-300) is most interesting to examine because it includes mainly hobbyists, enthusiasts and fanatics – as it seems – professional e-gamers. The representatives of this group are interested in sport, which in this case is realized by means of various electronic tools (PC, smartphone or

tablet, console, etc.). The study results are presented in Fig.5.

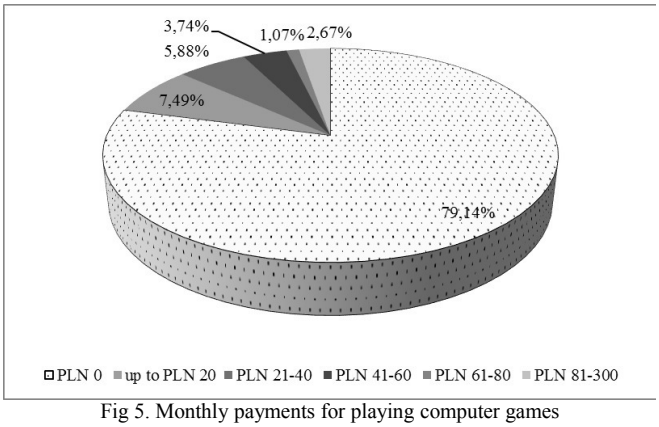

Fig 5. Monthly payments for playing computer games

The subsequent questions were used to evaluate the situation. Their goal was to indicate what kind of games the e-gamers played most frequently in the last year. The games were divided according to the typology indicated by the most frequent e-gamers:

- arcade games (shooting, fighting) (e.g. Counter Strike, Tom Clancy's Rainbow Six, Super Mario),
- action-adventure games (e.g. Assassin's Creed, Half-Life),
- adventure games (e.g. The Walking Dead, Wallace & Gromit),
- RPG (role-playing games) games (e.g. Diablo, Fallout),
- simulation games (e.g. The Sims, FIFA 16, Need for Speed),
- strategic games (e.g. StarCraft II, Civilisation, Warhammer, Heroes of Might and Magic),
- survival horror games – (e.g. Resident Evil),
- Massively Multiplayer Online games –MMO and their variants (e.g. World of Warcraft, Lord of the Rings Online).

Subsequently, the respondents answered the questions related to whether they played a particular kind of game in the period of last year. The questions formulated in such a way seemed to allow for more accurate responses that the ones which referred to the type of games they played most frequently. The authors worried that the responses concerning the last few months would dominate in the survey. They did not examine the recent trends in the market, the influence of newly published books and films related to particular themes, etc. The greatest number of positive responses, 80.75%, was indicated in the case of the simplest type of games – e.g. simulation games. The group of simple games also includes arcade games (57.75%) and action-adventure games (50.27%), where the number of positive responses exceeded 50%. In general, the greater complexity, the more complex relations, or the duration and additional limitations, the smaller the percentage of e-gamers admitting that they play a particular kind of game. The external factors, such as the history (the game was on the market "since I remember"), the popularity of a hero or a heroine or a plot constructed and popularized in films, books, board games, etc. contribute to the preeminence of the game. The games where the gamer needs to be more involved and stay in one place are less popular. The results of this part of the study are presented in Fig. 6.

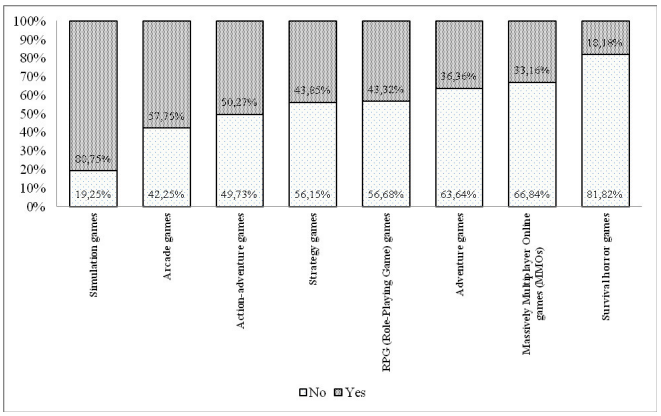

Fig 6. The most popular and most frequently played kinds of games

A good indication of the level of the engagement of the player is his or her willingness to choose to spend time in a game over other kinds of entertainment. The respondents were asked two questions if they 1) ever or 2) within the period of last year have chosen to spend time in a game over other, alternative forms of entertainment, such as:

- going to the cinema,
- meeting friends,
- going on a date,
- going for a trip with friends,
- going to a party,
- no such case.

It turned out that computer games are not enjoyable enough for players to give up anything in the past (61.78%) or in the last year (77.40%). If the respondents are willing to resign from something, it is mainly a meeting with friends 15.11% and a party 9.78%. In case of giving up anything in the last year in favor of a computer game, the results were similar. The respondents indicated a social meeting - 8.17% and a party – 6.73%. In reality, the difference indicated in the percentage of people who are willing to give up other forms of entertainment amounts to 17.32 percentage points, and decreases the actual numbers of indications in particular categories – the greatest with regard to social meetings – nearly 7 percentage points and parties – over 3 percentage points. The detailed scores are illustrated in Fig. 7.

In the respondents' views, the quality of computer games meets all or most expectations of players in 70% (Fig 8). The response that the game fulfills e-gamers' expectations to a moderate and limited degree is indicated only by 28% of respondents. A fraction of the sample evaluated the games as not enjoyable enough to consider giving up other activities

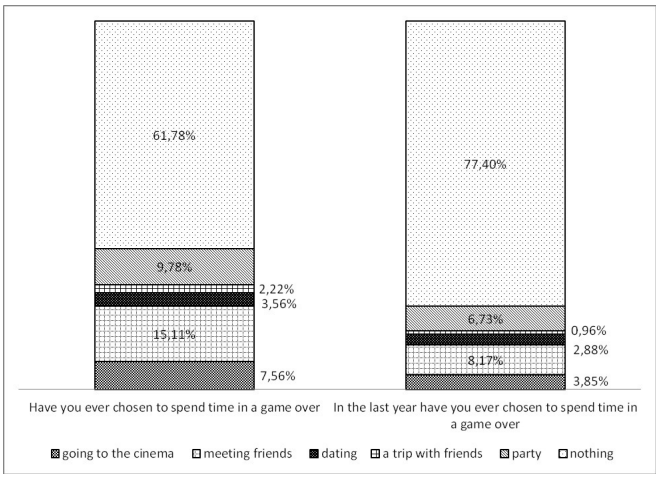

Fig 7. The willingness to give up other forms of entertainment among e-gamers

in favor of spending time in the game. Probably, it is one of the reasons why games are still so popular.

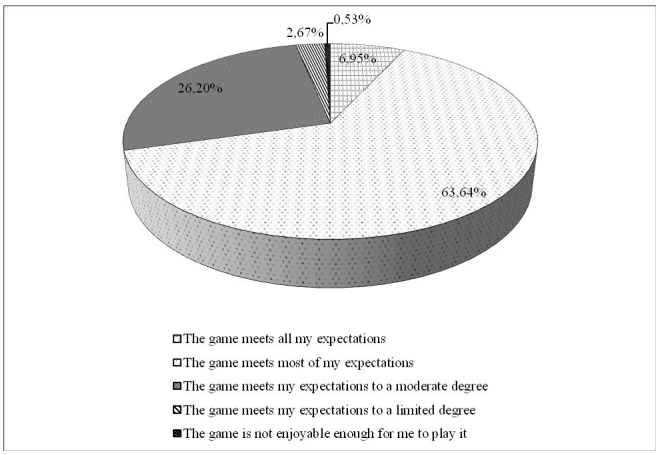

Fig 8. The quality of computer games in e-gamers' opinions

The vast majority of interviewed e-gamers (64%) are not interested in being leaders in games (provided that games offer such an opportunity). The remaining options are rather evenly distributed: 11% - clan leader, 7% - officer, 6% - advisor, 4% - higher-ranked officer and 8% - playing other roles (Fig. 9).

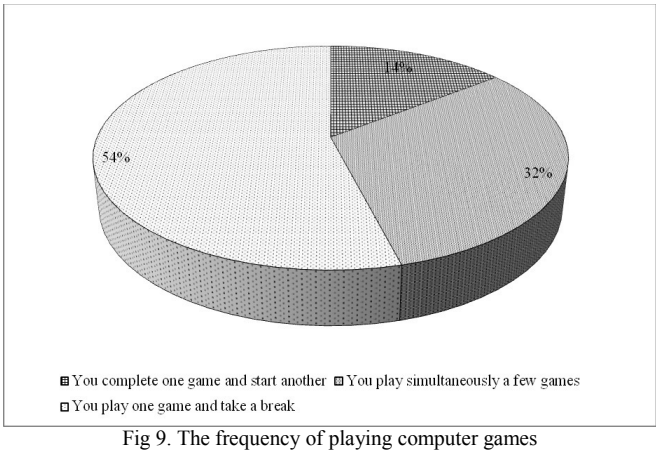

Fig 9. The frequency of playing computer games

Most e-gamers (54%) complete one game, take a break and only later start to play another computer game. Nearly 32% play a few games simultaneously. Only 14% finish playing one game and immediately start playing another. The frequency of playing games among respondents is shown in Fig. 10.

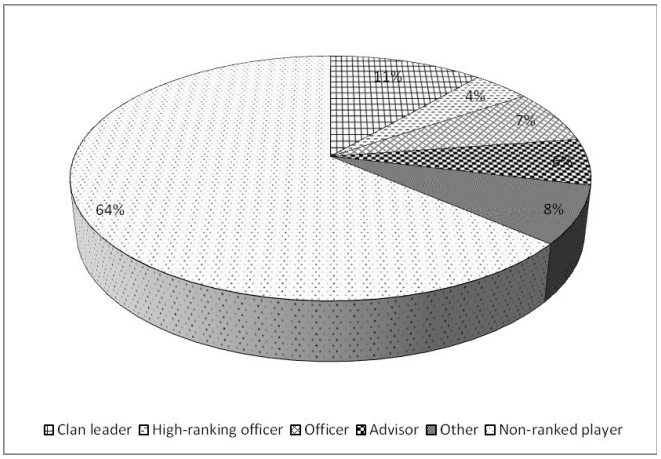

Fig 10. The willingness to be a leader among e-gamers

e-Gamers have a high opinion of their own skills as players (over 60%): they describe their skills as master level (18.72%) or advanced (42.72%). The number of gamers who see their skills as intermediate amounts to 33%, and less than 6% claim that they possess gaming skills at beginner level. Of course, due to the fact that gamers play games for a number of years, and general rules stay the same, e-gamers usually perceive themselves as specialists at using such opportunities, even if, thanks to new technologies these possibilities are constantly being developed. The structure of the e-gamers' skills is presented in Fig. 11.

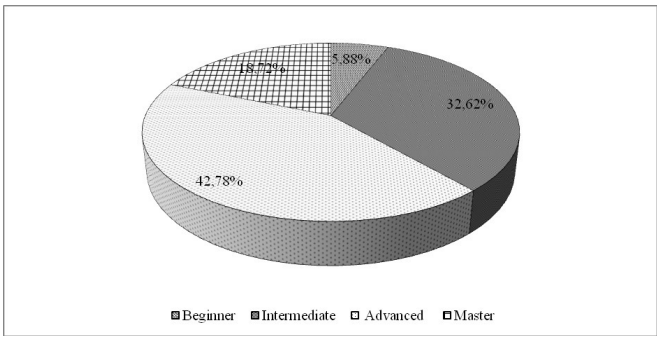

Fig 11. The structure of e-gamers' skills

The two remaining questions concerned the possible hardware conveniences and software advantages. In the first case, the respondents were given the following options to select from:

- obtaining mentor's help,
- using video and text tutorials (from game publishers),
- using in-game help,
- getting help from other gamers (e.g. forum),

- getting virtual or real payment,
- other advantages,
- no other advantages.

Almost 30% of gamers do not expect any advantages in this regard. They focus on the game they are currently playing, and they are satisfied with the game itself (passive players). Undoubtedly, the other e-gamers would be more satisfied if they could get help from other game users e.g. forum (22.14%), use text and video tutorials (12.55%) or in-game help (12.18%). Their satisfaction (18.08% of respondents) would increase if they received bonuses (additional options, game paths, etc.) or even actual reward (payment); yet, they have unrealistic or vague expectations concerning the latter. They do not pay attention to other conveniences or advantages of such kind. The results of this query are presented in Fig. 12.

With regard to the technical conveniences, e-gamers were

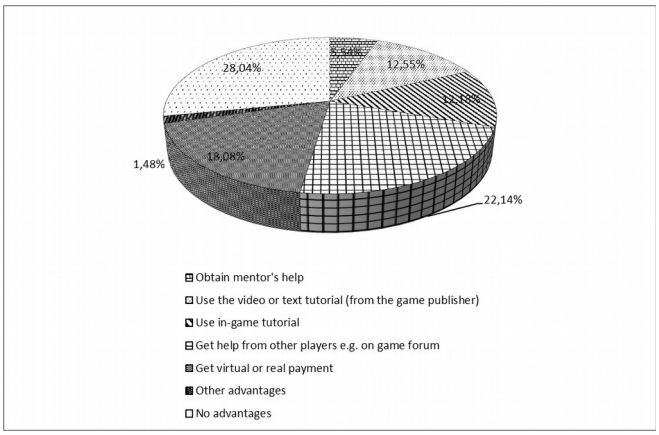

Fig 12. Non-technical conveniences for e-gamers

asked about the following, potential possibilities of changes concerning:

- computer hardware (e.g. graphic card) or a better tablet,
- armchair/seat,
- accessories (e.g. professional mouse, keyboard, earphones),
- better monitor/ VR goggles,
- other,
- I don't want to change anything.

In this case the responses were completely different than in the previous rankings. First of all, the structure of their responses was not evenly distributed. Nevertheless, almost one fourth (23.53%) of respondents are not satisfied with the hardware they own that they use to play a game, and they would like to change it. The distribution of the potential changes or lack thereof, was actually similar in relation to the remaining elements: better monitor or goggles – 18.53%, better armchair/seat – 21.76%, better accessories – 16.76% or no change at all – 16.47%.

Similarly to the previous case, basically e-gamers do not notice any potential for changes – less than 3% provided positive responses to this question, and there were no significant indications which we could relate to (e.g. additional lighting, additional monitors, etc.). The results are presented in Fig. 13.

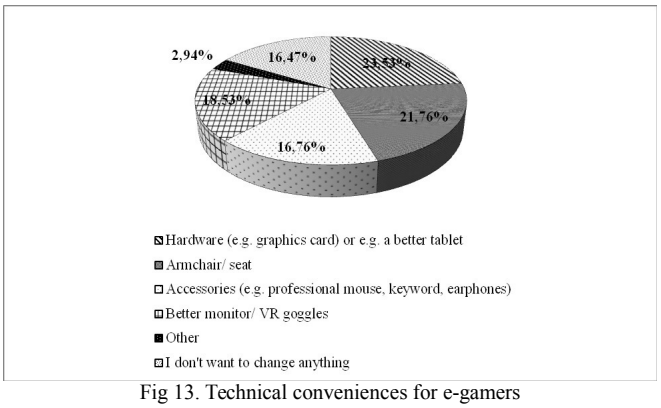

Fig 13. Technical conveniences for e-gamers

IV. Conclusions

The research conducted and presented so far points to the following conclusions:

- almost all respondents (over 99% of the sample) in the current study were students, which was reflected in the obtained scores. The older the students, the weaker interest in completing the questionnaire or its findings. It is caused by the increasing number of tasks connected with studies as well as the heavy workload connected with regular or temporary work (nearly 36% of working students). The latter is confirmed in the scores of other surveys [14, 16, 17, 26], despite the fact that, in total, fewer than 25-16% students participated in the study (even though it was always the largest group of players),
- among people who completed questionnaires there were markedly more women (almost 60%) than in other survey studies (around 43-48%) [25], conducted two or three years ago. Thus, we may conclude that there occurs a specific change with regard to the number of women playing computer games. Naturally, we should also be aware of the fact that the present study examined mainly the responses of students of economic faculties, and in this case the general number of female students in these faculties is greater than men. Still, the survey included also the option I don't play computer games, which the women could indicate,
- the frequency of playing the game (every day, up to a few times a week) in the examined sample was 20 percentage points smaller than in the case of other studies (39%, as compared to 62-63%). We should also consider the fact that in the other studies we took into consideration also another large group of potential gamers - pupils the group which ranks second with regard to the number of individuals spending time in the game –. The pupils have more free time than students, especially senior students.

All in all, majority of players – 54% of the interviewees, after completing one game, take a break before they start playing another game, and only 14% immediately start to play another game,

- the vast majority of players use their smartphone to play computer games (over 80%, mainly Android system – a large number of free games), which does not exclude also simultaneous use of other devices, mainly PC (over 65%) and a console, a regular (63%) or mobile one (11%). Smartphones and tablets started to take a role of a PC. Two or three years ago the proportions were more or less reversed; approximately 90% of respondents [9, 16, 17] used mainly personal computer, and only half of them a smartphone or a tablet. The devices allow for occasional use of many kinds of generally simple games at any place or time (not just during a break at work using your PC), killing the time while waiting for something else to take place,
- 97% of gamers use the games installed on a smartphone or a PC, with a surprisingly low percentage (10%) of people using Facebook games,
- due to the dynamic development of the use of smartphones and tablets in the last two years it occurred that the greatest number of people play simple simulation games (over 80%) and arcade games (58%) and action-adventure games (50%) which are becoming popular again. When we compare the present research with the earlier studies related to this area [9, 16, 17], the RPG games lost its popularity due to the increasing importance of mobile devices use (here: 44%, 65% - in other studies),
- notably, however, the early age when children start playing computer games, a shift towards younger and younger children (3-4 years younger since 2013) contributes to further development of computer games. More and more frequently it is caused by the fact that the first device with access to games is a smartphone, not a PC, and the fact that smartphones offer a greater number of free game applications,
- in general, the respondents (almost 80%) are not willing to pay for this kind of entertainment, and, as a vast majority, they use free smartphone applications and computer games which they received for their PC free of charge. It is reflected in the studies concerning the use of smartphones [1, 2] and a low tendency among students to spend their earnings on this purpose,
- it also explains the unwillingness to give up other kinds of entertainment, social life or rest to spend one's time in a game: almost 62% are not interested in choosing a game over any other kind of entertainment, and over 77% declared that they did not give up any activity in favor of a game last year,
- it appears that the fact that over 70% respondents claim that the level and quality of computer games fulfill all or almost all their expectations does not impact the situation,
- they have no expectations concerning taking leadership in a game (64%), they treat the games as a simple, not overly complex, form of entertainment. In general, they play games individually, and they are not interested – at least to a considerable degree – in multiplayer games,
- e-gamers have high opinions about their gaming skills – over 60% of participants claim that their skills are at least at an advanced level, and only 6% that they are beginners. On the one hand, it may be caused by the length of time of playing computer games (experience); on the other, it may result from the simplicity of most games that they play,
- the above said phenomenon is the reason why they do not expect too many advantages (none - 28%). If they were to choose, they would get help from other users (22%) or they would try harder to succeed in the game (18%) if they had a chance to obtain a reward or virtual bonus for winning the game,
- the case of technical conveniences is somewhat different. 23% would like to change their hardware hoping that this way they would have better chances to participate in the existing games and a greater possibility to participate in games of higher technical requirements. They pay attention to better accessories. Less than 3% would not improve anything as far as technical conditions of gaming are concerned.

The conclusions from the first stage of the research constitute good basis for further studies and expanding their offer, their consequences and impact of using games from the point of view of players. However, the present results already show interesting implications for the development of mobile information technologies towards new development trends of the use of this kind of software as a source of entertainment.

The further research – after preparing discussion and conclusions about sociological and psychological aspects of the gaming (include discussion of perceived positive and negative aspects of being a gamer or attempt to identify of the subcultures of players (the first attempt see [3]) - will focus on the market for suppliers of computer games and video games, in particular delivered to for mobile devices.

Results of a survey may be used not only by researchers in the field of computer games but by computer firms which want to make one step ahead in the development of this phenomenon.

***Abstract*—The use of Information and Communication Technology (ICT) has touched various aspects in the domain of transport engineering and logistics (TEL). As the development of TEL tends to be more complex in operation and large in scale, recent practices start to pay more attentions on improving system robustness and reliability. In addition, current ICT innovations (such as WSN and IOT) could record and deliver system descriptors (physical measurements, virtual resources, operational configurations) in real time. Such large-stream and heterogeneous data requires an integrated framework to process and management. To address such challenges, in this paper, a novel concept of context-aware supervision is proposed. An intelligent system with integration of semantic web and agent technology is proposed to support the concept realization, which aims at providing condition-monitoring and maintenance service to relevant user. A generic ontology-agent based framework will be illustrated. Finally, it will be applied for the supervision of a large-scale material handling system- belt conveying system as a proof-of-concept.**

***Index Terms*—Context-awareness, ontology-agent integration, system supervision, material handling system**

I. Introduction

THE USE of information communication technology (ICT) in TEL domain can be traced back to 1960s. It is chosen as a primary enabler to deal with increasing complexity of TEL development and enhance its competitive position with cost reduction and service promotion. Several conceptual ideas have been proposed that support the process of logistics and ICT technologies integration. The concept of *Integrated Logistics* is proposed to integrate IT with logistics management system to achieve synergy [1]. Afterwards, the concept of *E-Logistics* emerges that integrates Internet and mobile technology with logistics for providing one-stop value-added services to end-users [2], [3]. Recently, the concept of *Prognostics Logistics* has been put forward which utilizes wireless sensors (particularly RFID) together with decision making tools to enhance traceability and reliability of the logistics system [4].

Since the scale and complexity of TEL system has tremendously expanded, the attention of researchers and engineers have been shifted from enhancing operational efficiency towards improving system reliability and sustainability. Fact has been revealed by [5] who give a statement that the ultimate goal for a manufacturing system is guaranteeing an efficient production while providing functions needed by society in a sustainable and reliable way. It provides a new perspective regards the future development of TEL system. However, challenges still remain which can be categorized as follows:

- Heterogeneity: The heterogeneity is defined as system entities have different types of data model, properties, operation mechanisms and even different hardware and operating system [6]. As for TEL management especially for asset management and supervision, different data resources, operational information, past experiences and knowledges are characterized as heterogeneous resource and thus impose difficulties in integration.
- Interoperability: When it comes to interoperability, three perspectives can be identified [7], (1) organizational level: generic approaches and shared understanding of concepts, process, beliefs and terms [8]. (2) system level: interconnection between independent systems. (3) data level: consider the data properties include data format, data availability, data representation and semantic meanings. With respect to asset supervision, the interoperability challenges are inevitably presented at all three levels.
- Integrated decision making: Logistics asset is considered as large-scale and complex equipment. If a malfunction of single component or process has not been detected and corrected timely, it could lead to an expensive downtime and furthermore impose a great impact on the entire logistic activities. Consequently, a system with decision support becomes an essential element to provide relevant users a consistent understanding regards the system status and enabling an effective planning and execution of maintenance, such functionality could be referred as integrated decision making.

To cope with above mentioned challenges, in this paper, a context-aware supervision system is proposed which is used for information integration and supervision of large-scale asset service in TEL domain. The key ICT enablers are semantic web and autonomous agent. The ontology is used to model the semantic connections for heterogeneous data and various entities in supervision domain , thus enable information integration, data filtering and problem decomposition for specific supervision tasks. The usage of agent system intends to provide intelligent diagnosis and decision making functionalities through agent intelligence and cooperation. The integration of ontology-MAS delivers a context-aware intelligent system

978-83-60810-90-3/$25.00

and its practical usage will be considered with a case study of intelligent belt conveying system supervision.

The remaining part of the paper is organized as follows: Section II will introduce the concept of context-aware supervision system (CASS) and the motivations behind it. Section III will provide key technological enablers that could support the implementation of a CASS system. Section IV will first present the system design from an abstract structure perspective and the design of each functional block is discussed. Section V will presents a case study of applying CASS for intelligent supervising of a large-scale belt conveying system. The conclusion and future work will be addressed in section VI.

II. Context-aware supervision system

A widely recognized definition of context is given by [9] as *Context is any information that can be used to characterize the situation of an entity. An entity is a person, place or object that is considered relevant to the interaction between a user and an application, including the user and the application themselves.* And a system can be termed as context-aware if *it uses context to provide relevant information and/or services to the user, where relevancy depends on the user's task* [9]. A context-aware system (CAS) adapts and provides relevant information and the most appropriate service to users in an active and autonomous manner while requires little interactions [10].

In this paper, we focused on investigating the potential of applying CAS for asset supervision service. In essence, the supervision service includes system monitoring, failure/abnormality diagnosis/prognosis and maintenance planning. Apart of being context-aware of delivering meaningful information to user, it also requires a transparent flow from data to supervision method. To achieve that, the objective of a supervision system is to deliver accurate and timely information regards system conditions and propose effective maintenance actions to ensure reliability and availability of the system. Its success relies on integrating different diagnosis/prognosis methods. However, such methods often have certain scope of applicability and input context. As such, it put additional requirements on CAS to systematically integrate and manage system supervision processes. To integrate CAS for system supervision and fulfill additional requirements, a novel concept of *Context-aware supervision* is defined:

A context-aware supervision system (CASS) should include a series of functionalities include monitoring, supporting and advising in relation to system events. It not only focuses on diagnosing and prognosis failures, but also responsible for managing and organizing system knowledge, reasoning facts, integrating resources and analyzing problems. As such, the failure context can be given in a more meaningful manner that delivers information include: the specification of fault condition, recorded data linked to it, maintenance or operating actions linked to it, users that responsible for it and method that been used to determine it.

The characteristics of *context-awareness* are presented at two levels in CASS: (1) the supervision method should be aware of the context information it operates upon; (2) the end user should comprehend the created supervision context. In literature, several works have been established which attempt to consolidate the concept of context-aware with asset management such as context-awareness predictive maintenance [11], context-aware e-maintenance [12] and context-aware condition monitoring [10]. Two limitations are drawn from previous works: (1) the scope of applicability of proposed concept is limited given the fact that it only concerns partial aspect of the supervision process, For instance, the work of [11] concerns predictive maintenance, it lacks details regards how context been modeled and processed. (2) most works stay on a conceptual level which lacks sufficient technical details on how to put the concept into practice. Our work contributes to the literature by first introducing the concept of CASS, then we will discuss the technology been selected for putting such concept into action. Finally, a case study would demonstrate how the system works.

III. Key technological enabler for CASS

A. Context-modeling methodology

Intuitively, large amounts of context information are either acquired or derived from sensor devices. Normally, there exist gaps between raw data and the level of information which is useful to applications [13]. The context-modeling is used to bridge this gap by processing and transforming raw data before passed to context-aware services. Krummenacher et.al [14] have proposed several criteria for context model selection which include applicability, comparability, traceability, quality and so on. Meanwhile Hoareau et.al [13] conducted an extensive review for existing modeling choices such as key value models, makeup scheme, logic based models, object oriented models, ontology and so on. According to their in-depth discussion, the use of ontology is proposed to be the most expressive models to fulfill our requirements [15]. A formal definition of ontology is given by [16] as *an explicit specification of a conceptualization* which was used to describe a specific domain knowledge where concepts and relationships are unambiguously defined and checked. Recent works extensively applied ontology to facilitate the context modeling, its applicability covers domain include risk management of cold chain logistics [17], enterprise application [18], process supervision [19] and so on.

B. System supervision

A system supervision process considers providing users with decision support before/during/after the occurrence of system failure or abnormal situations. A typical supervision process consists of data acquisition, condition diagnosing/prognosis and maintenance planning. In this paper, rather than considering specific method or algorithm, we focus on how to provide a generic and adaptive environment to incorporate and integrate different methodologies and mechanisms operate together with flexibility and scalability.

Agent, as a tool in artificial intelligence domain, provides a way of dealing with complex engineering problem and

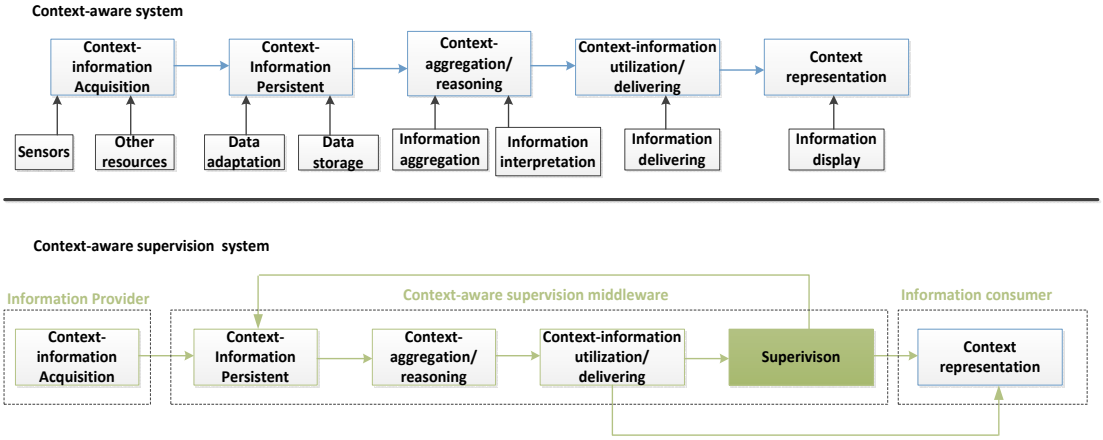

Fig. 1. System abstract architecture: a comparison between CAS and CASS

establishing adaptive system for decision making and information management through agent intelligence and collaborations [20]. State-of-arts demonstrate that agent system are largely applied to support system supervision functions, which include condition monitoring [21], risk management [22], e-maintenance [23] and so on. As such, agent technology is chosen as the key enabler for supervision system design, reasons are given as: (1) agent could cooperate and deploy on top of existing software. (2) In a multi-agent-system, agents could collaborate with each other to communicate and exchange information. (3) agent system could be deployed in distributed environment where new agent could easily join the system or leave the system as needed.

C. Ontology-agent integration

Key technological enablers have been chosen in previous section. We select ontology as the context-modeling method and agent system as the environment to support system supervision integration. In order to implement CASS, a next step is to consider the integration issues. In literature, several works have been established that concerns the integration of ontology and agent system. Dibley et.al [24] presented a work of building monitoring system where three ontologies are developed to capture the major semantics of a building environment and agent system is deployed to facilitate the monitoring tasks. For most of existing works, attentions are paid on using ontology to assist agent communication and knowledge retrieving. To implement CASS, potentials include information analysis, problem decomposition, agent status control are needed. To achieve this, a novel ontology-agent integrated framework is proposed, it will be elaborated in next section.

IV. System Framework

Fig 1 presents a comparison between a context-aware system and the proposed context-aware supervision system from an abstract structure perspective. A classical context-aware system follows five key processes [10]: (1) context information acquisition: gather information from virtual resources and physical sensors; (2) context-information persistent: data filtering and storing ;(3) context-aggregation/reasoning: interpretation and transfer low-order data to high-level applicable information via aggregation and reasoning; (4) context information utilization/delivering: apply context information to implement application-specific service; (5) context representation.

All of the functional blocks from CAS are inherited and implemented in CASS. The major difference is distinguished from two aspects. **The supervision block**: The key objective of CASS is to assist system supervision with aspects include equipment monitoring, condition diagnosis and maintenance planning. Such tasks are unable to perform well by only using context-modeling(e.g. ontology reasoning). In most cases, it requires advanced platform/engine for decision making. As such, the supervision block is introduced. **The information flow**: The information flow is also adjusted. In CAS, the information flow follows an open loop style where data is gathered from ground layer, processed through each functional block and becomes context-aware. For CASS, a partial closed-loop is formed. In essence, the aggregated and processed context information will be the input source for supervision module. The output of supervision module will be feedback for further processing. It will be first stored in data base and then processed by context model. By doing so, not only the measured data from ground layer would be context-aware but also the supervised result will be aggregated with other relevant information together to make result meaningful to end user. Moreover, it would be helpful to use the returned supervision information to infer new knowledge and propose further actions.

A. Context Model Design

We design an ontology termed *ontoSupervision* to capture major concepts and relationships in the domain of system supervision. The schematic of ontoSupervision is given in Fig 2 and explanation of each taxonomy is given below:

(1) *System taxonomy* is the core concept that presents a description of the system. It includes notions of system

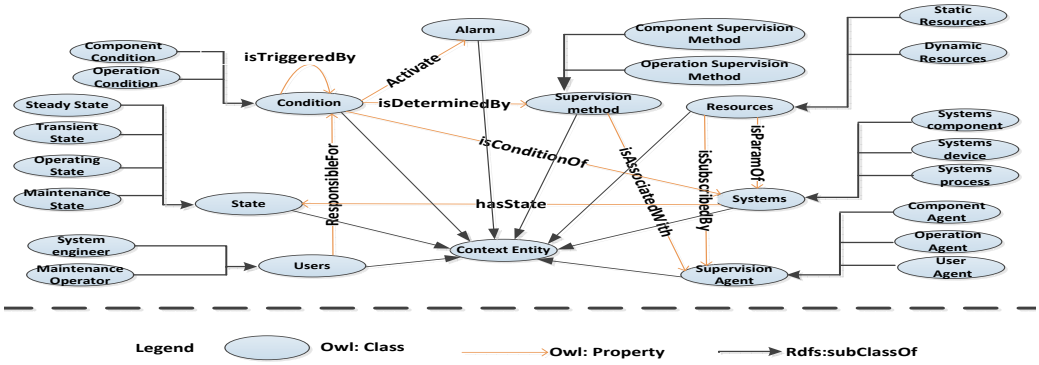

Fig. 2. Upper ontology taxonomy: definition of classes and object properties

fundamental components and operations that needs to be supervised. In addition, the subclass *system devices* contains peripheral devices. Other taxonomies either directly or indirectly connect with system through well defined relationships. (2) *Condition taxonomy* incorporates the notion of condition in the system. Two subclasses are included, namely operation condition and component condition. The former one concerns the system abnormal condition during operations and the latter one addresses the physical condition of system at different levels (component,instrument and equipment). (3) *Resources taxonomy* represents all relevant information resources that need to be accessed by supervision method. It is composed of two subclasses, namely static resources and dynamic resources. The former one can be thought as the resource that does not change over time such as system specification, historical information and system configurations. The latter one represents the notion of resources that change in real time, such as data acquired from sensor devices and any updated supervision results. (4) *Supervision agent & method* represents all available agents been deployed in current system and its associated supervision method. In essence, it serves as a bridge that connects context model with agent system. (5) *State taxonomy* represents possible state of the system. In current model, four states are considered namely maintenance state, transient state and operation state and steady state. (6) *Alarm taxonomy* represents the notion of possible alarm level that been activated by supervised conditions in the system. (7) *User* represents the information consumers in the system. It specifies the responsibilities and point of interests of respective user.

B. Agent system design

Regardless of the models, scopes and design tools, all supervision methods require system measurements as input and generate results which transform system conditions (operation and component condition) as supervision result. Such common structure allows the supervision methods be represented as supervision agent. The multi agent system can be perceived as a wrapper which provides environment for different supervision intelligence to perform supervision tasks. It also enable integrated decision making by taking the advantages of agent communication and collaboration. In the proposed framework, three kinds of agent are developed:

(1) **Supervision Agent**: Two categories of agent groups are considered as supervision agent. The first one is termed healthiness agent (HA) which is responsible for fault diagnosis at different level of system granularity. Single HA could be used to assess the condition of piece of equipment while multi HAs could work together for evaluating the overall healthiness of the whole system by consolidating different conditions. Another one is termed operation agent (OA) which is used to capture the abnormality during system operation. Typically, it is used to identify the abnormal deviation from normal operations or improper configurations. The agent intelligence, scope of interest, input information and responsibility are determined by its associated methods. (2) **Information Mediator Agent**: The information mediator is used to manage and control the agent execution and interactions. Its necessities are given as: It serves as an information portal for supervision agents; It keeps an active connection between agent system and ontology knowledge model. (3) **User Agent**: It contains the information consumer of the system. Any on-going supervision conditions will be relayed to it via IMA. Sophisticated GUI will connect with it to provide end user a friendly interface.

C. Agent-Ontology integration

The key of agent-ontology integration is achieved via the interaction between information mediator agent and ontology knowledge base. Such interactions aim at manipulating ontology to acquire information and knowledges where actions include create, read, update and delete entities in ontology. We identified three major processes:

- *Information acquisition*: In this case, ontology is treated as a hybrid database which is used to locate and retrieve information. A typical scenario can be that when a new sensor measurement is available in ontology, the IMA could retrieve it by executing well defined query template. An example of a query template is shown in Fig 3.
- *Knowledge acquisition*: It fully utilizes the reasoning capability of an ontology model. When certain information is available, the ontology could infer new knowledge

```
SELECT ?par ?agent ?system ?method ?timeStamp
?state ?measurement
WHERE {
        ?par onto:isSubscribedBy ?agent.
        ?par onto:isParametersOf ?system.
        ?agent rdf:type onto:AgentName.
        ?method onto:isAssociatedWith ?agent.
        ?system onto:hasState ?state.
        ?par onto:hasTimeStamp ?timeStamp.
        ?par onto:isMeasuredBy ?measurement.}
```

Fig. 3. Example of information acquisition template

by executing context-rules. For instance, if a belt idler temperature is over 70 degree, the ontology could use rules to determine that such context indicates a idler is in fault condition.

- *Knowledge reasoning and agent control*: As discussed previously, a partial closed loop is formed in the structure of CASS. The key motivation is given that any returned supervised information could be further processed by ontology. And the inferred knowledge could be useful in coordinating agent activities. For instance, a misalignment condition often occurs during the running of a belt conveyor and such condition could be induced by multiple reasons(improper power supply, overloading and so on) and such casualty relationships could be predefined in the ontology via proper object properties. By doing so, when a misalignment condition is supervised and returned, the ontology could running context rules to find the relevant condition relate with it. Consequently, the associated agent will be activated to allow a depth investigation of the root cause.

V. Implement CASS for large scale material handling system

A. case demonstration

Belt conveying system is widely accepted as a major equipment in continues material handling domain. Its usages are well developed in various logistics domains, such as container/dry bulk terminals, airport and mine industry. Normally, the BCS is deployed in an open and harsh environment, as such, major components could suffer severe damage as system ages. Consequently, a monitoring and supervision system with decision support is essential to help users(from operations, maintenance, reliability and other departments) gain a consistent understanding about the system status and enabling effective planning and execution of maintenance. Due to the limit space of the paper, we demonstrate a typical fault supervision process- belt tear condition supervision which is made up for 85% among all system component damages for a BCS [25].

B. Scenarios

This scenario demonstrates the CASS capability of the system. Specifically, when inspection of tear shape is available, the system should analyze the damage level and propagation pace of the damage by intelligent supervision method, and create decisions in the form of possible maintenance activities and/or warning/alarm message if needed. We identify three key processes of implementing the context-aware supervision service for belt tear condition:

- Context modeling: It concerns extending the upper ontology (ontoSupervision) with definition of new entities for application purpose. Such extension is termed domain-specific ontology and partial illustration for BCS supervision (ontoBeltCon) is depicted in Fig 4. The semantic meaning is given as: a tear shape (TS) *isMeasuredBy* a human inspection tool(HIT), which *isParameterOf* belt (belt section01). To supervise the tear condition, a belt tear supervision agent (BTSA) is designed. The BTSA *hasAssociatedMethod* belt tear supervision method (BTSM1). For supervision purpose, TS and a belt tear condition log (BTCL) *isSubscribedBy* BTSA. Upon successful decision making, a belt tear condition (BTC) is supervised which *isDeterminedBy* BTSM1 and *activate* alarm (alarm level 1). Finally the BTC *isResponisbleFor* user (maintenance operator 01).
  Besides newly added entities and its individuals, the data properties for a belt tear shape and belt tear condition is also available in Fig 4.
- Context supervision: After context information are collected and pre-processed by ontology, the agent intelligence should be invoked. For a belt tear condition supervision, a fuzzy logic based approach is applied [25]. Decisions are made based on the current tear shape measurement and history inspection log for the same shape. Two indicators (belt wear index and inspection frequency index) are provided to deliver a consistent understanding and interpretation of the supervision result and give straight forward suggestions for possible maintenance actions.
- Response actions: The supervised condition will be send back to ontology model for further processing before finally delivered to end users. In essence, it will use the supervision indicators to quantify the alarm level by running defined rules. For the given scenario, the rules can be given as:
  BeltTearCondition(?condition), greaterThan(?level, 0), hasWearIndex(?condition, ?level), lessThanOrEqual (?level, 0.7) $->$ AntiHealthCondition(?condition)

VI. Conclusion and future work

In this paper, a novel concept of *context-aware supervision* and its associated implementation techniques are proposed. The motivation behind the concept is to enable an efficient and transparent information flow for asset supervision tasks. We implement such system for supervision of a large-scale material handling system to demonstrate its major functionalities and potential usage in the domain of logistics. Future works include further extending the ontology model to incorporate more generic entities and concept in the system supervision domain. Moreover, to cope with more complex diagnosis/prognosis problem and enable more sophisticated decision making engine, the agent intelligence should be future investigated.

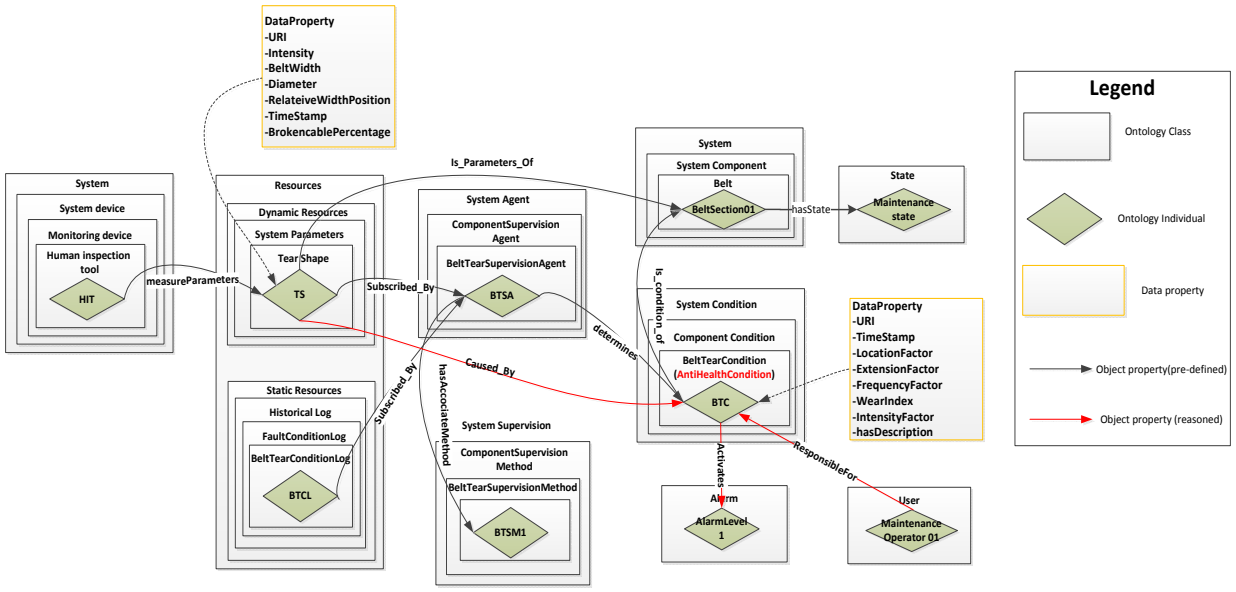

Fig. 4. OntoBeltCon configuration for belt tear condition supervision: include class, subclasses, data properties and object properties

***Abstract*—Paired transactions or paired transfers have their origin in accountancy systems. The Resource-Event-Agent (REA) ontology uses paired transactions as a basic building block for business process modeling. A business process (REA model) is composed of two sets of paired transactions. REA itself originates from accountancy systems and has gradually developed into a full-fledged information system framework. REA model used to be depicted by ER diagrams and later by UML class diagrams. However, both these diagrams were not designed to capture conceptual models which are more precise, comprehensible for domain experts and easily to modify. ORM (Object Role Modeling) represents approach to conceptual modeling which fulfils above mentioned requirements. The main goal of the paper is to derive and describe the ORM model of paired transactions which corresponds to REA exchange model and assess this approach.**

I. Introduction

The REA ontology can be classified as a domain specific ontology that is focused on value modeling of business processes. The three core REA concepts are *resource*, *event* and *agent* from which the name of the modeling approach was derived. The aim of the REA modeling approach is to record any changes in property rights to resources, register resource usage, resource consumption or resource production, see [1,4,7].

Resource entities can be exchanged for other resource entities in REA exchange processes and can be converted to other resources in REA conversion processes as well. A REA application keeps track of which resources were exchanged for which ones or which resources were converted for which others.

The REA model records information based on the coherence between data of one or more business events. The REA process is defined by related REA events and has at least two composite economic events: a *decrement event* that outflows, consumes or uses the outgoing resource(s) and an *increment event* that inflows or produces the incoming resource(s). The REA process is called the REA model and represents the notion of a business process.

The main benefit of the REA modeling approach is the possibility of keeping track of primary and raw data about economic resources, by [5]. All accounting artifacts such as debit, credit, journals, ledgers, receivables and account balances are derived from the data describing exchange and conversion REA processes [4,8]. For example, the data describing the sale event is used in the warehouse management, payroll, distribution, finance and other application areas, without transformations or adjustments.

The quality of a database application depends crucially on its design, see [13]. To ensure correctness, clarity, adaptability and productivity, information systems should be specified at the conceptual level first, using concepts and the language that both designers and customers can easily understand [6]. Object-Role-Modeling (ORM) is a fact oriented approach for modeling information at the conceptual level. A fact is a particular arrangement of one or more objects. Depending on the number of objects that are involved in a fact, we speak about unary, binary, ternary, etc., facts. An example of unary fact is that *Vendor is a Person*. Another example of binary fact is that a *Customer receives a Pizza*. Unlike traditional approaches, ORM make no use of attributes as a base constructs, instead expressing all facts types as relationships [6]. This attributes free-approach leads to greater semantic stability in conceptual models and enables ORM fact structure to be directly verbalized and populated using natural language sentences.

The ORM method provides a more precise way to capture and validate data concepts and business rules with domain experts. ORM diagrams simply capture the world in terms of objects (entities or values) that play roles (parts in relationships) which forms a fact. ER notation as well as UML notation allows relationships to be modeled as attributes. ORM models the world in terms of objects and roles, and hence has only one data structure – the relationship type. As a consequence, ORM diagrams take up more room than corresponding UML or ER diagrams. The aim of the paper is to find out a "semantic" connection between REA business process model and fact-based model utilizing ORM approach.

The structure of the paper is as follows. Section Two describes REA modeling approach. Concise possibilities of the ORM modeling method are mentioned in Section Three.

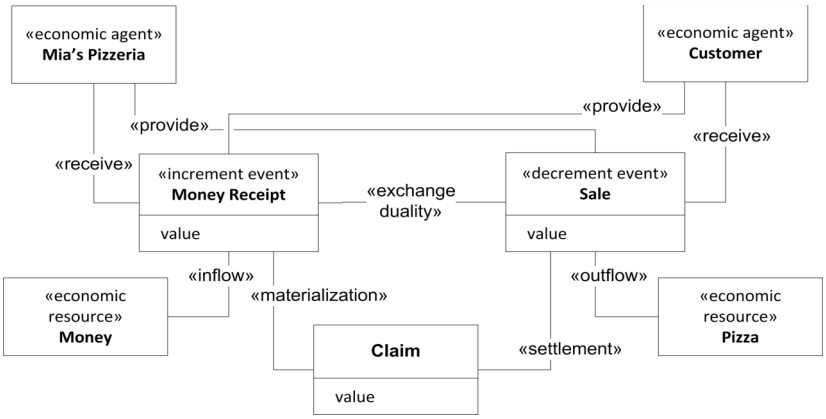

Fig. 1 REA core pattern example

ORM model of paired transactions is described and illustrated in Section Four. Discussion of the results is mentioned in Section Five and conclusion is contained in Section Six.

II. REA MODELING APPROACH

The REA ontology is based on the REA core pattern that expresses the basic principle [2,4]. The fundamental entities of the pattern are different events that are involved in various transactions which have something in common; there has always been a *decrement economic event* (one in which something is provided) and an *increment economic event* (one in which something is received). Apart from economic events, the economic agents that represent human beings partake in the exchange process. Resources are entities which are kept track because their property rights can be exchanged or they can be converted to create new resources. As the mutually bound events cannot happen at the same time, the claim entity is utilized for deferred revenue, prepaid expenses, accounts payable and so on. The REA core pattern is illustrated as a Pizzeria shop in Fig. 1. The economic events in REA models usually encapsulate properties for *date, time* and *location* in space.

The REA model is an extension of the REA core pattern. The principal feature of the REA modeling approach is that it explicitly distinguishes between past and current events and events performed in the future for which it introduces the commitment entity. The relationships of *committed provide* and *committed receive* mean that some agreement about the future exchange has to be achieved between economic agents. The commitment entity addresses the issue of modeling promises of future economic events and the issue of reservation of resources. Commitment entities and their relationships with other entities are shown in Fig. 2. To a considerable extent, the commitment entity copies the structure of the event entity, by which we mean the existence of an increment and decrement commitment and the exchange reciprocity relationship. The exchange reciprocity relationship between the increment and decrement commitments identifies which resources are promised to be exchanged for which other resources.

Each commitment is related to an economic resource by a reservation relationship which specifies which resources will be needed or expected by future economic events. The reservation relationship between the resource and commitment represents obligation of economic agents to provide or receive rights to economic resources in exchange processes and represents scheduled usage, consumption or production of economic resources in conversion processes.

The most important relationships of the REA model are the *exchange reciprocity* and *exchange duality* relationships, by [5,9,10,11]. The exchange reciprocity relates a pair of an increment and decrement commitment entities. The exchange reciprocity relationship identifies which resources are promised to be exchanged for which others.

The exchange duality relationship which relates corresponding increment and decrement economic events keeps track of which resources were exchanged for which ones.

III. ORM CONCEPTUAL MODELING METHOD

Object-Role Modeling is a conceptual modeling method that views the world as a set of objects that play roles (parts in relationships) according to [6]. For example, you may play a role of walking in the country (a unary relationship involving just you) or you may play a role reading this paper (a binary relationship between you and the paper). Thus a role in ORM corresponds to an association-end in UML, except that ORM also allows unary relationships. Object-Role Modeling is a conceptual modeling method that views the world as a set of objects that play roles (parts in relationships) according to [6].

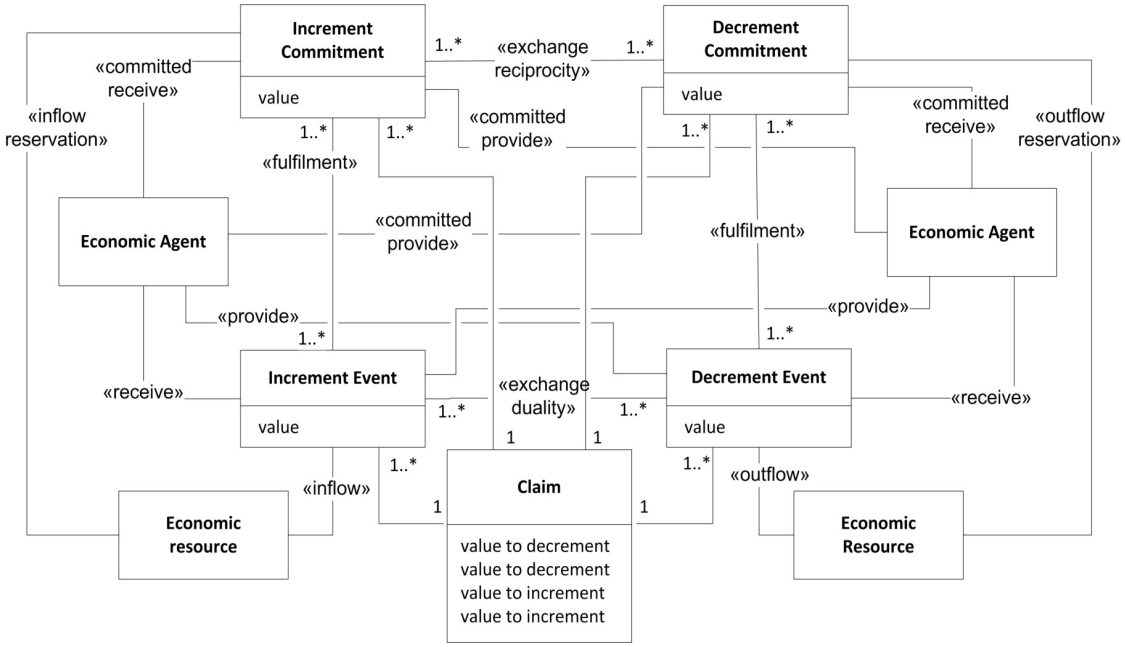

Fig. 2 REA model. Adapted from [1]

The main structural difference between ORM and UML is that ORM excludes attributes as a base construct and treats them instead as a derived concept. The conceptual schema using ORM specifies the information structure of the application in the forms of: *fact types* that are of interest; *constraints* on these; and *derivation rules* for deriving some other facts.

A fact is a proposition that is taken to be true by the relevant business community. A fact type is a kind of fact that may be represented in the database [3]. The constraints represent constraints or restrictions on populations of the fact types. The derivation rules include rules that may be used to derive new facts from other facts, see [6,12].

The ORM model (left part of Fig. 3) indicates that employees are identified by their employee numbers. The top three roles (*EmpName*, *Title* and *Sex*) are mandatory roles. This is indicated by the black dots at the *Employee* box. The other black dot where two roles are connected (at the bottom of *Employee*) is a disjunctive mandatory role constraint indicates that an employee must have a social security number or a passport number or both. The uniqueness of constraints (cardinalities in UML) indicates vertical lines over roles. In Fig. 3 it means that *empNr*, *EmpName*, *Sex*,

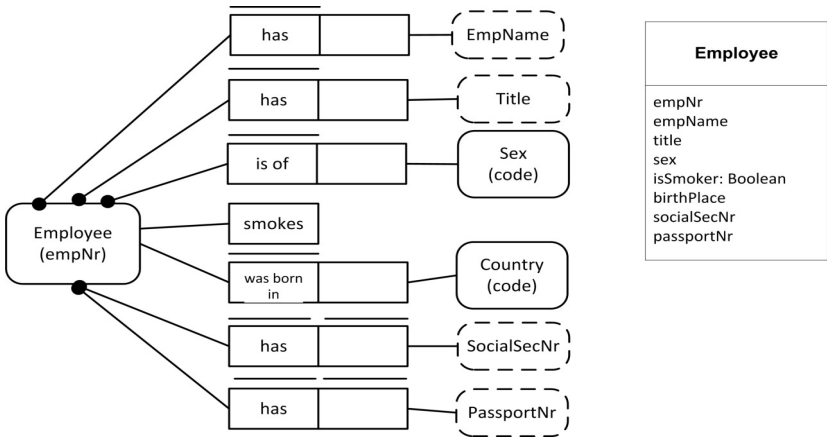

Fig 3. ORM and UML models of Employee

and *Country* is unique for each employee. Two vertical lines over each roles (*SocialSecNr*, *PassportNr*) indicating that each employee number, social security number and passport number refers to the one employee at most. The dashed line over e.g. *PassportNr* indicates that this is a value not an object.

Graphically, object types are depicted as named boxes (solid for entity types, and dotted for value types). As in logic, a predicate is a proposition with object-holes in it. In ORM, a predicate is treated as an ordered set of one or more roles, each of which is depicted as a box, which may optionally be named. A fact type is formed by applying a predicate to the object types that play its roles.

IV. ORM Model of Paired Transactions

The ORM model of paired transactions is composed of two kinds of transactions (left hand side, right hand side). These paired transactions actually represent result of an exchange process in which some resources were exchanged for other resources. The cardinality between exchanged resources is in general many-to-many as was stated in the REA model, see Fig. 2. Despite the REA model, the ORM model of paired transactions contains only one relationship that joins both kinds of transactions which is called the duality relationship. The name *duality* expresses the final state of an exchange process. The duality has mandatory relationships to both kinds of transactions. The left-hand side transactions represent a transfer of goods and the right-hand transactions stand for a transfer of money. We consider the common case of transfer in which resources or services are exchanged for money. These two transfers are depicted by object classes with the same name. The object class *Goods Transfer* is related to two kinds of actor roles the *vendor* and the *customer* who both belong to the object class *Person*. There is a relationship *exclusive or* between two actor's roles which means that these actor roles have to be different persons. The *customer* is an actor role who receives goods in *Goods Transfer*. The *vendor* is an actor role who provides the goods for the transfer. The corresponding object class *Money Transfer* is related to the *payer* and the *cashier* actor's roles. Between both actor roles there is a relationship *exclusive or* with the same meaning as in the previous case. Both *payer* and *cashier* belong to the object class *Person*. It is important to use a proper actor role. The *customer* can be e.g. wife and the *payer* can be her husband.

The object class *Goods Transfer Contracted* is a subclass of the object class *Goods Transfer*. This relationship between these object classes means that there must exists at first *Goods Transfer* object class and subsequently it may happen that the object class *Goods Transfer Contracted* becomes existent. Conversely, *Goods Transfer Contracted* cannot exist without the object class *Good Transfer*. This point is very important and differs from the REA model. The object class *Goods Transfer Contracted* means that the *customer* promised that he would receive the goods and the *vendor* promised that he would deliver the goods. But as we are talking about paired transactions there must be the other transaction(s) because paired transactions mean that some resources are transferred in consideration of the other resource transfers.

The other transaction(s) of the paired transactions is represented by the object class *Money Transfer Contracted*. In this case, the *payer* promised that he would pay for the goods and the *cashier* promised that he would accept the amount of money (resource). At this point it is essential that the state *promise* is reached on both object classes *Goods Transfer Contracted* and *Money Transfer Contracted*.

Each object class (*Goods Transfer Contracted*, *Money Transfer Contracted*) contains property types of contracted goods kind and contracted location. The object class *Money Transfer Contracted* has the same kinds of property attributes and scale attributes. These property attributes and scale attributes represent facts that were contracted. The construction of this model enables that the resource kind can occur more times. For instance a *customer* would like to buy the given number of a specific pizza types, a certain number of cola kinds and a certain number of chocolate kinds. In general, *Money Transfer Contracted* may represent some kind of payment before the purchase, payment after delivery and possibly payment in installments.

Goods Transfer Completed is the next object class that is a subclass of *Goods Transfer Contracted* object class. The meaning of the subclass relationship is as follows: a transfer have to be contracted at first and then it can be completed. The property attributes and the scale attributes are the same as in *Goods Transfer Contracted* but in this case the property attributes express the real values. In the detail insight, the proposed solution enables differences between the individual number of *Goods Transfer Completed* and the number of *Goods Transfer Contracted*.

Goods Transfer Contracted represents planned transactions. The delivery, which is performed in *Goods Transfer Completed* is usually performed in several shipments. The corresponding object class to *Goods Transfer Completed* is the object class *Money Transfer Completed*. This object class property attributes deal with real payment transactions which means that they deal with the real installments. The business rules are stated in the contract which comes into existence when the transactions are contracted. The structure of the property attributes is the same as the structure of *Money Transfer Contracted* but the real values may be different. All this recorded information is required in database solutions.

V. Discussion

Designing an information system involves building a formal model of the application domain which requires a good understanding of the application domain and utiliziation of the proper tools for modeling specifications in a clear and unambiguous way. ORM simplifies the design

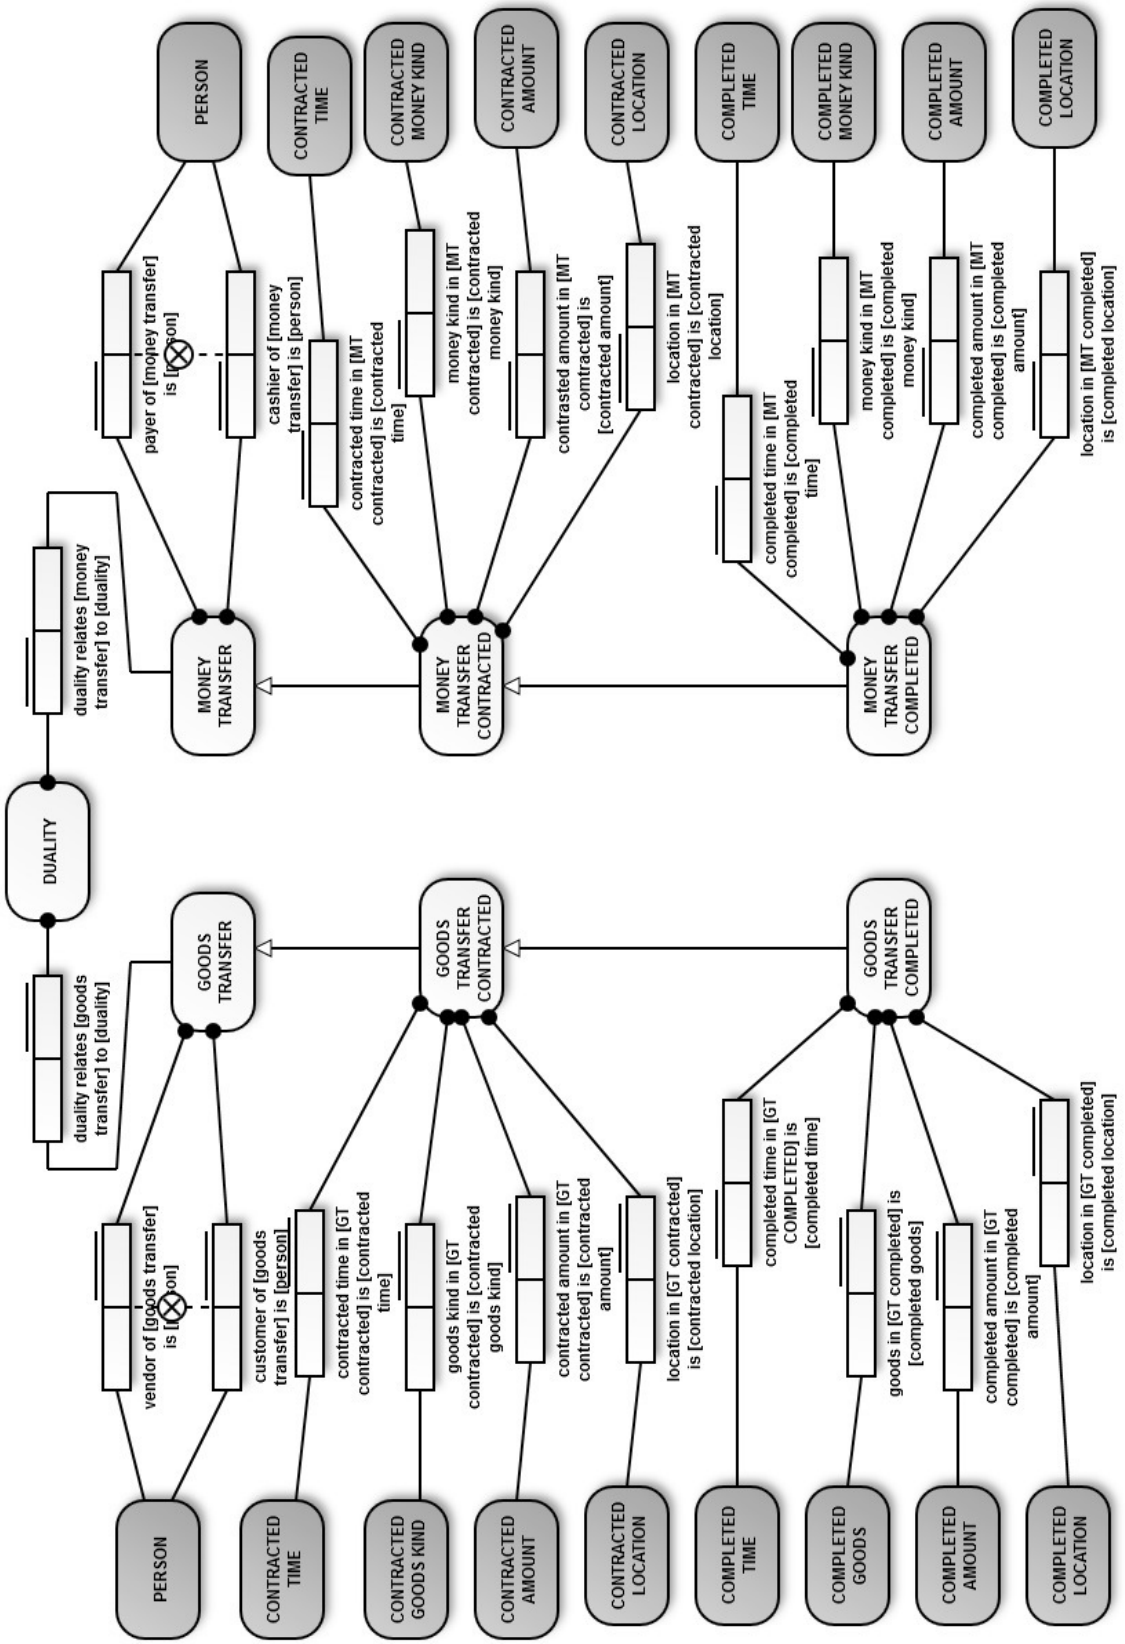

Fig. 4 ORM model of paired transactions

process by using natural language, and by examining the information in terms of simple and elementary facts. By expressing the model in terms of natural concepts, like objects and roles, it provides a conceptual approach to modeling.

The REA modeling approach addresses the paired transactions model in the REA core pattern and in the REA model. The REA core pattern corresponds to accounting model and captures events which were completed. The REA model is more general than the REA core pattern and provides possibilities to address future events. However, connection between the commitment entity and the event entity in the REA model is insufficiently consistent. This is done by the fact that both commitment and event entities represent production and that the REA model doesn't have a proper state machine, see [9]. For these reasons it is difficult to distinguish the phases in which the paired transactions were *contracted* (promised) and *completed*. When comparing the REA core pattern with the REA model it is evident that the REA model covers all operations of the REA core pattern despite the fact that the commitment actions are only formal.

The ORM model of the paired transactions enables clear distinguishing between the *contracted phase* and the *completed phase*. This is done by utilization a sub-classing mechanism of the ORM modeling approach. The corresponding object classes *Goods Transfer Contracted* and *Money Transfer Contracted* express the *contracted* (planned) property types and attributes types which are essential to be stored in the database solution. In the same way, *Goods Transfer Completed* and *Money Transfer Completed* capture the real value of property types and attribute types of finished paired transactions.

The object classes *Goods Transfer* and *Money Transfer* form the beginning of the paired transactions process which means that they identify partaking actor roles which will be involved in the process. They have to be created first. After that, the object classes *Good Transfer Contracted* and *Money Transfer Contracted* can be created. Similarly, existence of *Goods Transfer Completed* and *Money Transfer Completed* is dependent on the existence of contracted transfers.

VI. Conclusion

The paper deals with paired transactions modeling utilizing the ORM conceptual modeling method. The benefits of this mathod can be sumarized as follows. This method and modeling approach enables to explicitly distinguish the contracted phase from the completed phase of the paired transactions model. It also ensures unified transaction processing which means utilizing only contracted and completed phases. The proposed solution also eliminates usage of the claim temporal entity. Future research will cover implementation, verification and validation of the proposed ORM model.

***Abstract*—Project management is one of the main areas of contemporary organization management. This article is aimed at analysis of existing tools of project assessment – mainly comprehensive methods, but also partial techniques - and referring them to undertakings efficiency calculation which comprises cost-effectiveness evaluation, risk analysis, and investment decision taking. Business case (BC), as one of the comprehensive methods of project assessment, is simultaneously the main subject in PRINCE2 (PRoject IN Controlled Environments). It is for this reason that the case study for BC is based on this recognised method of project management. This article contains also the proposals of solutions of discerned problems within project assessment.**

I. Introduction

SITUATIONS of assessment occurring in project management are largely diversified and require the use of appropriate methods adjusted to each of them. A correctly and reliably carried out assessment will support the manager in taking conscious decisions as to the projects which should be invested in.

Speaking about assessment we usually mean definition, estimation, and valuation of something. Assessment in relation to projects means the „functional value, i.e. the whole of the project features determining its ability to meet specific needs" [9].

Choosing any tool for project assessment we expect that it will first ascribe to them specific parameters of assessment, second – classify projects, third – enable a comparison of projects, and fourth – enable following the progress of project works.

Each project should cause positive effects consisting in generation of profits and negative effects related to incurring of inputs to obtain new values. Therefore, the main components of project assessment are inputs and profits. Such perspective combines the most important aspects of project assessment, i.e. assessment of its result and assessment of its course [2].

The final results of the projects are always an outcome of inputs and profits. The inputs are treated comprehensively, i.e. as the consumption of all sorts of means – both countable and such which cannot be expressed in monetary units. Benefits are understood as various positive effects of projects and may be nominal, tangible and intangible.

A summary evaluation independent of the type of the project is the total result which is a difference of benefits and inputs. If the benefits and inputs may be expressed monetarily, the total result of assessment is profit. Many techniques have been worked out for this case. They are called the investment account techniques, because they are used in assessment of investment undertakings. The following techniques of investment undertakings assessment may be singled out:

- simple techniques of absolute assessment – e.g. payback period (PP), accounting rate of return (ARR),
- discount techniques of absolute evaluation – e.g. gross present value (GPV), internal rate of return (IRR), profitability ratio (PR), techniques of discounted period of return and their modifications [14],
- techniques of relative efficiency account [14].

Commercial projects are assessed using the monetary techniques of assessment:

- simple – such as : simple rate of return (return on equity - ROE, return on investment - ROI), PP, ARR,
- comprehensive (discount) – discounted payback period (DPP), net present value (NPV), IRR, modified internal rate of return (MIRR) [14]-[15]-[16].

The project in which only inputs may be expressed monetarily requires different techniques of assessment, such as: cost benefit analysis and cost effectiveness analysis. The advantage of those techniques is shown in points as a result of multi-dimensional assessment in points. When in the cost benefit analysis the benefit estimated in points includes the probability of its occurrence, it becomes a cost effectiveness analysis.

When neither benefits nor inputs may be expressed monetarily, the total result of assessment is profitability. In this case it consists of their determination by multi-criterial assessment in points and comparison of the obtained values, e.g. as the quotient of the value of profits in points and the point-wise value of input.

If the profit may be expressed monetarily, and the input is not considered (little importance, problems with estimation), the projects are assessed according to the account of incomes. Otherwise, when benefits are not considered and the input may be estimated in monetary units, assessment is based on the costs account.

When inputs can be determined neither monetarily nor non-monetarily, assessment is made as an analysis of the project's functional value or as analysis of effectiveness.

Insignificance of benefits during project assessment and possibility of only non-monetary expression of input cause the need of the point assessment of the input value.

Taking an investment decision within the project efficiency account may refer to [1]: a single project (absolute or time-related decision), variants of the project or projects competing for common limited resources, including the capital (relative or portfolio decision).

II. Classifications of Project Assessment Methods

The project assessment methods constitute an extensive collection where various groups may be singled out due to: application area, scope of problems, details of recommendations.

Table I presents classifications of project assessment methods, including the mentioned items as the division criteria.

TABLE I.
CLASSIFICATIONS OF PROJECT ASSESSMENT METHODS

Classification criterion of assessment methods	
APPLICATION AREA	
Universal	Special
DETAILS of RECOMMENDATIONS	
General	Detailed
SCOPE of PROBLEMS	
Comprehensive	Partial

In project assessment both universal methods (usable in assessments of any type) and special methods (usable in project management assessments, e.g. the Earned Value method – assessment of project implementation advancement) may be applied.

Methods containing general recommendations are considered as general methods of project assessment, whereas those which present recommendations precisely and accurately are determined as detailed ones.

Partial methods refer to partial processes and problems within the project assessment. They are called techniques and may be used in various stages of project management and in different phases of its life cycle.

Comprehensive methods comprise with their recommendations the whole process of project assessment. These methods of project assessment comprise: feasibility studies (hereinafter referred to as FS), business plans of the project, business cases (BC), and cost benefit analysis. The characteristics which should describe the methods to make them considered as comprehensive were presented in Table II.

TABLE II.
SPECIFICITY OF COMPREHENSIVE METHODS OF PROJECT EVALUATION

Characteristics	**Description of characteristic**
Completeness	Detailed description of all issues important for project estimation
Perspectiveness	Including into the description the whole period of preparation, performance and use of the project
Accuracy of assumptions and reliability of data	Data are derived from trustworthy sources and enabling the preparation of reliable evaluation results
Internal compliance	Subordination of individual components to assumptions and their non-contradiction
Reality	Reality-consistent presentation of circumstances affecting implementation of the project and its solutions
Variants	Analysis of possible solutions in several variants
Flexibility	Predispositions to introduce amendments, changes and supplements connected with inflow of new information
Operations	Possibility to translate the method description into concrete decisions
Comprehensibility	Adjustment of the contents, volume and form of method description to recipients' needs and requirements
Communicativeness	Explicit and comprehensible transmission of the contents of the method to all potential users
Extensiveness of the stage of determining the assessment objectives	In case of FS and BC this stage consists even in examining the circumstances of future functioning of assessment objects and designing them according to these conditions

All comprehensive methods of the projects are in many elements similar to each other but due to the differences occurring between them they were discussed in separate parts of the article.

III. Feasibility Study

A. Description of the method

Feasibility study is defined as:

- "A short, preliminary study undertaken to assess the validity of a full-scale project" [17],
- formal study to determine the probability of success of a particular project or achieve a particular result [18].

"The purpose of the feasibility study tool is to identify whether the concept of a project is viable." The study contents seven parts: "executive summary, background information, description of current situation/problem, description of proposed idea, project timelines, feasibility review board, go/no-go decision. Dow mentions "types of

feasibility studies used today: schedule: analyze how long it will take a project or process to complete and what go/no-go decision point will be; organizational: analyze what the impacts would be on costs and resources if the company decides to reorganize their current resources base; legal: analyze whether it is worth pursuing a particular litigation; technical: analyze if a technical concept will work within the current environment; cultural: analyze whether offshore teams and onshore teams can communicate and effectively execute a project; construction: analyze if it is cost effective to construct a building, based on the height and location; environmental: analyze whether the environmental conditions at the particular location are suitable" [19].

The methodology of creating feasibility study is similar to the methodology of problem solving. It has also much in common with the methods of scientific work, and it consists of the following parts: precise problem definition, project limits indication, identify the characteristics and functions of a good solution to the problem, description of alternative solutions, ranking of alternative solutions, conclusions from the analysis of alternative solutions and recommendation the best solution, determine the timing and expected costs of the project [20].

FS is one of the complex methods of project evaluation and it is used to check to what extent, by what means and at what time the project can be realized. The method consists of five parts: technology and system feasibility, economic feasibility, legal feasibility, operational feasibility, schedule feasibility. It should be also taken into account: market and real estate feasibility, recourse feasibility, cultural feasibility [21].

The number of parts of the method is different depending on the author (from five to eight), and each of them could be used in some types of projects.

By Newton "feasibility is the review of the project in more detail" [22]. This method may include activities such as technical tests, market research and assessment of the impact of the project on the organization. After the completion of the feasibility study the cost, duration and the outcome of the project should be known.

"Feasibility studies (…) reduce the risk of incorrectly accepting or rejecting a project. Although it can be considered as a stage in a project's lifecycle. (…) Feasibility studies have a cost and absorb resources, so in turn they must be reviewed and prioritized. (…) The decision whether to undertake a feasibility study is a trade-off between the cost and the value of the information determined [22].

The feasibility study should be carried out to provide the information needed to determine whether a project should proceed. It includes: technical feasibility to determine whether a project will successfully create the expected deliverables, commercial feasibility to determine whether a project will achieve its business case, market feasibility (usually in the case of new products) to determine whether the business's customers will buy the product, organizational feasibility to determine the operational impact of making the change resulting from a project successfully, exploring requirements and designs to produce more accurate plans, costs and resource profiles for a project, exploring project options.

Feasibility studies allow you to determine beyond any doubt whether the problem can be solved at all, or whether it is possible to use the opportunity. Usually they are created for the management board. Feasibility study consists of eight parts: abstract, defined business problem or business opportunity, requirements and purpose of the study, description of evaluated options, assumptions made in the study, users affected by introductions changes, financial commitments, recommended procedures [23].

As you can see there are a lot of definitions of feasibility studies, but the most important characteristics of this study is that it is a short, complex, preliminary study, made for the management board, undertaken to assess the validity of a project.

B. Reference to project efficiency

The efficiency of the projects in relation to the projects is defined as a relationship between total expenditure and the effects and the evaluation of the results concerning their utility, which answers the question of whether the information needs of users of information system have been met. Three main streams of IT projects evaluation have been classified [24]:

- technical and functional trend, which assumes that the effects of investment in information systems are short-term and have no connection with the business strategy; assumptions of this trend are correct in relation to simple automation systems,
- economic and financial trend, which treats IT investments as aimed at increasing business efficiency or extend it; the evaluation moves here from the project treated in isolation to the quality of its products or services provided to internal and external customers; techniques assessments of projects derived from the management of value may be used herein among others,
- trend of possible interpretations, resulting from the specificity of investments; it takes into account the entire life cycle of the project, including the expenditure and benefits in its course, and the emphasis is on decision-making context in which the project exists.

Table III contains a comparison of these trends [25].

TABLE III.
COMPARISON TRENDS OF EVALUATION IT PROJECTS

Dimension	Trend		
	Technical and functional	**Economic and financial**	**Possible interpretations**
Objective	Technical efficiency, IT resource control, cost of maintaining the system	Quality and rate of utilization the system and the effects of its introduction	Solutions sensitive to context, learning of organization

Object of the evaluation, used criteria	IT system, automation, cost reduction	Product of IT system: productivity, enterprise value, user satisfaction	Wallets of IT systems, measurement of indirect effects
Time horizon	Ex-ante and ex-post investment, system lifecycle	Ex-ante and ex-post in relation to the life cycle of the system	Perpetual effects management
The role of people in the evaluation process	IT experts	IT experts, financial managers	Participants in the evaluation process, internal and external customer of IT services
Used methodology	Related to the quality and costs	Orientation to economics, financial and behavioural	Development of meta-methodology
Assumptions	Cost efficiency	System efficiency	Understanding the problem

Currently multi-criteria projects evaluation methods are often used. They include [26]: scoring method, AHP method, PROMETHEE-II method.

Scoring method is the most frequently used multi-criterial method. It allows you to list the ranking of decision variants based on the score, which projects received in each category. There are different versions of the method, simple and complex. Simple version assumes that each criterion has the same maximum number of points. The final evaluation of variant is the sum of all the points awarded in all criteria. The complex method involves the granting of weight to each criterion due to its validity. Criteria can be also described as linear functions. An important assumption of the method is that the criteria are independent in terms of preferences, that means the one criterion does not depend on the value which takes the other one. A similar to scoring method is the SMART method (Simple Multi-Attribute Ranking Technique). It assumes the existence of an additive utility function, which can be described as non-linear function.

AHP method (Analytic Hierarchy Process), like the scoring method, involves weighing of criteria. Rating variant is the sum of ratings of individual criteria. In the method, decision maker deliver his/her opinion on relations between variants. The opinion is expressed verbally using a nine-point scale for comparison. Ranking decision variants in relation to the criteria is calculated as a weighted average of the ratings which options have obtained due to the individual criteria. A limitation of the use of method is that the project must have a small number of variants and variants cannot be dependent on each other. Development of AHP method taking into account the linkages between criteria and feedback relationships between the variants and the criteria is the ANP method (Analytic Network Process).

In the PROMETHEE-II method (Preference Ranking Organization METHod for Enrichment of Evaluation) it is built variants ranking decision as in the AHP method. But the options are compared automatically based on the information provided by the decision maker. The decision maker determines the value of the difference between the variants that one variant was the preferred relative to the other.

Each method is applicable to multi-criteria evaluation of projects in certain specific cases.

C. Case study

In the literature it is described the problem of selecting IT project using AHP method [27]. The company is to be implemented management support system and owners have to choose contractor for the implementation of IT system among three alternative projects. Evaluation of projects is based on the methodology proposed by Parker [28, 29].

The criteria consist of three factors and they make up to maintain the company's competitiveness: the financial contribution (the value to achieve, acceleration, restructuring, innovation, efficiency, productivity, NPV, IRR), support projects providing management information (the reaction of competitors, compliance with the strategy and structure, organizational risk), technological requirements (technological risk, providing innovation, compatibility with existing IT, uncertainty of the construction project).

Assessment of the criteria for each of the remaining criteria is based on a scale proposed by Saaty [30].

TABLE IV.
GRADING SCALE IN THE AHP METHOD

Definition		Factor
Equally important	Activities contribute identically to aim	1
Slightly more important or preferred	Experience and judgment slightly favours one activity over the other	3
More important or strongly preferred	Experience and judgment strongly favours one activity over the other	5
More important or very strongly preferred	Activity is strongly favourably and its dominance is demonstrated in practice	7
Extremely important or more preferred	Evidence favouring one activity over the other is the greatest possible in order affirmation	9
Intermediate values	Expressive identification between two basic values of the scale	2,4,6,8

Table V shows the matrix of relationships between different criteria in the presented case study of multi-criteria selection of the project implementation the enterprise management system (relationships are assessed by the decision-maker). Vector the matrix of domination of criteria allows the estimation of the relative importance of each criterion in relation to the overall objective, which is to maintain the competitiveness of the company.

TABLE V.
MATRIX EVALUATION CRITERIA

Criteria	**Efficiency**	**Business support**	**Future importance**	**Technological risk**
Efficiency	1	1/5	1/7	3
Business support	5	1	1/3	5

Future importance	7	3	1	7
Technological risk	1/3	1/5	1/7	1
Inconsistency = 0.09				
Scale vector	0.092	0.282	0.574	0.052

Next the matrices of evaluations for alternative projects were built (Table VI).

TABLE VI.
MATRICES OF EVALUATION ALTERNATIVE PROJECTS (P1, P2, P3)

Efficiency	**P1**	**P2**	**P3**
P1	1	3	5
P2	1/3	1	3
P3	1/5	1/3	1
Inconsistency = 0.04			

Business support	**P1**	**P2**	**P3**
P1	1	1/5	3
P2	5	1	7
P3	1/3	1/7	1
Inconsistency = 0.06			

Future importance	**P1**	**P2**	**P3**
P1	1	1/9	1/7
P2	9	1	3
P3	7	1/3	1
Inconsistency = 0.08			

Technological risk	**P1**	**P2**	**P3**
P1	1	3	7
P2	1	1	5
P3	1/7	1/5	1
Inconsistency = 0.06			

Finally the evaluation of each project according to each criteria was summarized.

TABLE VII.
EVALUATION OF PROJECTS

Project	Criteria				**Evaluation**
	Efficiency	Business support	Future importance	Technological risk	
P1	0.637	0.188	0.055	0.649	0.178
P2	0.258	0.731	0.655	0.279	0.616
P3	0.105	0.081	0.290	0.072	0.206
Inconsistency = 0.08					

The overall rating of projects allows to establish the ranking of solutions P2, P3, P1 (Table VII). Project P2 has been rated highest, it has a significant advantage over alternative projects P3 and P1. According to the assessment using multi-criteria AHP method, the company should implement a management IT system using the offer of organization which has presented project P2.

The final decision about project execution can be based on some complex method of project evaluation or on project efficiency. Previously discussed feasibility study can include elements specified in chapter IV, at least as followed: technology and system feasibility, economic feasibility, legal feasibility, operational feasibility, schedule feasibility.

Considering which method of projects assessment to choose when we need to choose one IT project among several projects, or deciding to start a new IT project it should be noted that a complex assessment methods of projects evaluation helps us choose the best project among several alternative projects. While the feasibility study of the project is a detailed and comprehensive analysis of a specific project. Developing such a document is expensive and usually it is performed for one project only. In this case study AHP method allows you to choose the best variant of the project. The final decision on the project can be taken on the basis of this analysis. However, you can perform a feasibility study for project P2. Although the feasibility study of the project is costly, it gives us more certainty that the implementation of the project will bring the company the desired results and will be successful.

IV. BUSINESS PLAN

A. Description of the method

Business plan is defined as:

- a plan of launching a business or as an action plan and development of the company; it is a special case of economic plan [31];
- a set of document developed by entrepreneur during preparation process of launching of the new project, showing its strategy and structure [32];
- a description method of a business and evaluation of the prospect of execution [4].

Business plan of the project is a study of the planned economic project which contains: purpose of analysis; circumstances of implementation; assessment of the advisability, feasibility and effectiveness evaluation. Business plan can be used for comprehensive evaluation of projects of small range and complexity [4].

Business plan refers to both results and costs and it shows project as a product market intended for potential customers. Business plan contains: objectives, impacts and process of the project.

Business plan is characterized by [4]:

- specificity – business plan must include: detail information of the: market, enterprise, project and planned actions,
- comprehensiveness - business plan must include all aspects of the planned activities (market, technical, personnel, organizational and financial activities),
- long-term effect – business plan is mostly a long-term plan, rarely annual.

Structure of the business plan depends on its purpose. General scheme of business plan includes four elements: general information – abstract, market conditioning of the project, operation conditioning of the project, assessment of the project's consequences (Table VIII; [33]).

TABLE VIII.
GENERAL SCHEME OF BUSINESS PLAN

No.	**Description of the item**
1	**General information** - front page and table of contents - subject of the business plan - basic information - performer of business plan - current events and approvals **Abstract**
2	**Market conditioning of the project** - users and sponsors of the project - stakeholders of the project

	- external and internal conditions of the project - expected benefits of the project
3	**Operation conditioning of the project** - tasks and process of the project - employment, equipment and resources of the project - subcontractors and suppliers of the project - organization and management of the project - costs of the project (budget)
4	**Assessment of the project's consequences** - benefits - expenses and costs - risk analysis - evaluation (economical) - evaluation indicators - recommendations

An exemplary structure of business plan of venture investment is presented in Table IX.

TABLE IX.
AN EXEMPLARY STRUCTURE OF BUSINESS PLAN OF VENTURE INVESTMENT EVALUATION CRITERIA

No.	Chapter
1	Abstract
2	General information about project
3	Planned location of the investment
4	Market analysis
5	Competetive analysis
6	Marketing strategy
7	Technology of production
8	Costs of production
9	Organizational plan
10	Project schedule
11	Project budget
12	The financial part
13	Summary

Business plan of the project starts with an abstract in which the most important conclusions and a summary of entire plan should be included. This part of the plan should be designed very carefully as it is always read in detail during pre-selections of the projects.

Second chapter should contain basic information about the project: name of the project, information about participants, localization and information about lead organization.

Actual state supply, state demand and actual prices of product or services on the market are shown in the market analysis. This part of analysis is, in most cases, based on forecasts as investment can be realized in a new sector.

The fifth chapter gives information about main market competitors by analyzing their strengths and weaknesses. The marketing strategy includes main components of market activity such as: product, prices, distribution and promotions and can be found in chapter number six.

In a description of technology of production main steps of technological process and evaluation of its modernity should be characterized. Technology of production can be original investor's solution or a typical solution. This chapter should also include environmental legislation and information about certificates and licenses acquisition.

Determination of equipment's life time, development of modernization plan and repair plan are also necessary. Production is seasonal in many types of business therefore, the business plan should answer the question on how seasonality affects financial results (incomes and expenses). Chapter number eight covers estimation of production's costs or service delivery.

Organizational plan determines how the investment will be managed in the implementation phase and in the operational phase. Organizational scheme is presented in the chapter which shows work division and presents organization of key functions, like: supply, production and distribution.

Investment implementation schedule is described in chapter number ten. It should include all main investment tasks with the assume time of their implementation.

Detailed budget project should be developed in 11th chapter.

Economic and financial analysis is based on the financial plan and contains financial evaluation, profitability evaluation and risk assessment.

The most important data and conclusions are included in the last chapter.

Responsibility problem is associated with evaluation of the business plan. Business plan is used mainly for certain decision-making which results in specific measurable amount of expenses. Comprehensiveness is the most important advantage of business plan. Significant disadvantages include statistics and descriptive form of business plan.

B. Reference to project efficiency

If a long term calculation is assumed, every project can be consider as effective. Therefore, more precise definition of efficiency is the ratio investment results in a specific period of restoration capital time to investment's expenditures.

The investment efficiency account is a very important part of business plan which can be determine in a pre-investment phase (ex ante effectiveness account) and in operational phase (ex post effectiveness account). An ex ante effectiveness account is more important, from the point of view of business plan preparation, as it is a basis for investment decisions.

Assessment of investment effectiveness is carried out with the use of several tools which include:

- statistical methods for assessing the effectiveness of investment: payback investment rate, payback/return period,
- dynamical methods for assessing the effectiveness of investment: updated net value, discounted payback investment rate, discounted payback/return period, internal rate of interest.

Simpler statistical methods do not include variable time value of money which is why these methods are accounted as less useful.

The last element of the economic and financial analysis of the project is financial risk assessment of investment. Projects that are financially viable may be financially too risky to be selected for implementation. Risk covers many

types of risks, including: the risk of contract, the risk of supply, investment risk, financial risk, credit risk, operational risk, transportation risk, insurance risk, price risk, currency risk and inflation risk.

Each business plan contains many assumptions about investment, costs, prices, demand, inflation etc. Effectiveness of planned investment is determined under assumptions which do not have to be confirm.

Investor who develops business plan should identify factors of financial risk and should also attempt to measure the risk. Financial risk can be measure by following methods: the scenario method, sensitivity analysis, analysis of the breakeven point.

Final evaluation of business plan comprises four elements: assessment of formal correctness, assessment of methodological correctness, assessment of accepted data, formulated assumptions and accounting evaluation.

Common errors and data manipulation in business plans mostly rely on [31]: overpricing, costs reducing, skipping some expenditure and costs, the discount rate reducing, inflate production capacity, the need of current assets reducing, accepting unrealistic growth rates of production and sales.

Business plan usually consists of four elements (Fig. 1).

I **Informational part**	**II** **Market's part**
III **Operational part -** **Expenses and costs**	**IV** **Evaluation – comparison of benefits and expenditures**

Fig. 1 Business plan

First part, informational part presents subject of business plan, performers and basic data of the project. The second - market's part contains internal and external benefits of the project. The third part determines tasks, employment and management styles of the project. The result of the third part is to determine expenditures and costs developed as a project budget. The last part of business plan is a comparison of benefits and expenditures of the project with the use of: cash flow statement, balance sheet, or income statement. Business plan assessment methods depend on needs.

V. BUSINESS CASE AND COST BENEFIT ANALYSIS

A. Description of business case

Business case is a document prepared usually in organization which performs the project for its own needs. It may be prepared for every project, to support its planning and decision-taking. It is a method of assessing the business benefits of analysed project. During the project performance this method is used to analyse the impact of obtained partial results on expected business benefits. Analyses used in business cases are mainly of quantitative nature.

Based on estimated costs, benefits and savings as well as risks, BC involves all changes in business area which the project affects and description of the causes of the undertaking.

In practice it is mostly used in the ICT sector (where all benefits from implementation of information systems are necessary) and sporadically for social projects, although e.g. in Great Britain this document is obligatory for all projects undertaken by public entities.

The following types of business case are singled out [4]: strategic business case – general document indicating the relations between the project and organization strategy, full business case – document containing detailed plans of project performance and cost benefit analyses, ongoing business case – document precisely determining the inputs on works (usually within the nearest stage of the project).

BC does not have any strictly defined and mandatory structure, as it depends on the project specificity, i.e. its duration, budget, branch in which the employer is functioning etc. M. Trocki [2] repeats (after Taschner) that BC should consist of eight parts presented in Table X.

BC is one of the fundamental terms in PRINCE2. It plays a strategic role in the project assessment process, because it is assumed that the undertaking may last as long as this document gives affirmative answers to questions about the need, feasibility, profitability and cost-effectiveness of investing into the project.

It is an element of documentation which initiated the project. It gives rise to the decision to start, continue, interrupt or completely withdraw from the project. BC is being updated throughout the project life cycle [3]-[11].

BC consists of two documents:

1. Outline of the business case (introduction and basic information about the project: title of the project and possibly subtitle, author of the document and its recipient, date of the document preparation and submission, generally determined BC area, defined goals of the project, purpose of BC preparation).
2. Detailed business case (DBC) – its most important element is assessment of the project cost-effectiveness.

A very important element of DBC is definition of the pattern according to which the project implementation variants will be described, because BC should contain a description of several possible methods of achieving the same goal. The indicated methods should enable a comparison of the variants of this undertaking [5].

The basic element of DBC is presentation of possible variants of the project performance. Each of the variants requires a detailed feasibility study [6].

According to the PRINCE2 (2009) method the project requires first of all focussing on business aspects starting from the reasons for which it was launched till it was closed [10].

TABLE X.
PARTS OF BUSINESS CASE

Part name	Description
Macroeconomic part	It comprises the most important macroeconomic information influencing the project, subjecting it to analysis and formulating conclusions
Tax-related part	It contains tax analyses necessary for assessment of the project
Financial part	It involves determination of the project financial needs, indicating and choice of financing sources and preparing the cash flow plans
Market part	Market analyses connected with the result and conditions of its market performance
Marketing part	Market analyses are the starting point for marketing surveys determining market effects of project implementation
Operational part	It describes technical conditions of project implementation and its effects
Investment part	Information from all parts is focused in investment part, where the project's financial assessment is made, using the investment efficiency account method
BC results	Each BC should refer to free and comprehensive decisions consisting of the choice from at least two alternatives; the decision consequences should wholly or largely be expressed in monetary units; importance of the decision consequences should determine the inputs on BC; The last part of BC should contain: a short summing up of the project goals, expected benefits, necessary inputs, the most important risks and list of recommendations related to the project implementation formula

The main and obligatory element of business case is a list of expected benefits and optional components of the cost benefit analysis and assessment of investment.

B. Description of cost benefit analysis

Cost benefit analysis (CBA) consists in determining and comparing the expected costs and benefits from variants of the project to choose the best and most profitable variant.

The cost benefit analysis usually consists of the following parts [7]-[12]-[13]: identification of the project, defining the goals, feasibility study, economic analysis, multi-criterial analysis, other criteria of evaluation, sensitivity analysis and risk evaluation.

The results of the cost benefit analysis are often presented in the so called cost-benefit matrix [12] (Fig. 2).

The projects placed - in result of analysis - in area I usually are not referred to performance. The possibility to perform the area II projects (they lead to significant benefits but simultaneously require quite high inputs) is limited, because they require special conditions to be performed, e.g. foundation of consortia, special companies etc. The area III projects are considered to be dangerous because of the temptation to implement them which resulted from low costs. However, they do not provide sufficient benefits, therefore other performance variants should be taken into account. Most demanded is the performance of area IV projects because these are most advantageous.

C. Reference to projects efficiency account

I **LOW BENEFIT** **HIGH COST**	**II** **HIGH BENEFIT** **HIGH COST**
III **LOW BENEFIT** **LOW COST**	**IV** **HIGH BENEFIT** **LOW COST**

Fig. 2 Cost-Benefit Matrix

Business case usually supports taking of investment decisions i.e. the situations where decisions are made about alternative possibilities of using financial means in the project. Owing to BC at least the financial consequences of those decisions may be analysed, but also their non-financial effects may be considered. So BC is a practical use of the investment efficiency account in project management.

Assessment of the project cost-effectiveness as the most important component of DBC in PRINCE2 comprises analysis of joint benefits and adverse effects with the project performance costs and future maintenance of its final products. For the financial part PRINCE2 recommends here: analyses of complete costs and benefits, net costs and products. Recommended for the financial part of PRINCE2 are: analyses of total costs and benefits, net costs and benefits, return on investment, simple payback period, discounted methods, current net value or analysis of project sensitivity to disturbances.

The CBA part involving the financial analysis should show the project profitability and its financial sustainability by solving the following problems: choice of the time horizon, determination of total inputs and incomes, calculation of residual value at the end of the year, determination of the inflation factor, choice of an appropriate discount rate, financial calculation or economic rate of return and the method of using those indices in project assessment. The project effects prognosis should be made for its performance time and the period allowing to show its effects in close and further perspective.

During economic analysis carried out at CBA the costs and notable socio-economic benefits of the project are determined. If it is possible, the benefits for external environment should be expressed in monetary units, Otherwise, ascribed to those benefits should be an appropriate numerical value enabling to bring them down to rational values. Both all the costs and social benefits expected for various years should be discounted to the basic year value or using a harmonized discount rate for a given sector of economy or region. An alternative approach is calculation of internal economic rate of return or economic current net value.

TABLE XI.
SIMPLIFIED BUSINESS CASE FOR THE PROJECT A WITH COST BENEFIT ANALYSIS AND INVESTMENT APPRAISAL

YEAR	0	1	2	3	4	5	**VALUES**
Costs (in thousands of PLN)	-100	-20	-20	-20	-40	-30	
Benefits (in thousands of PLN)	0	40	80	100	100	100	
Cash flow (in thousands of PLN)	-100	20	60	80	60	70	**58**
Cumulative cash flow (in thousands of PLN)	-100	-80	-20	60	120	190	
Discount ratio	1.00	0.94	0.88	0.83	0.78	0.74	
Cash flow after discounting (rounded up to thousands of PLN)	-100	19	53	66	47	52	$\sum CF_t = 237$
Cumulative cash flow after discounting (in thousands of PLN)	-100	-81	-28	38	85	137	**NPV = 137**

D. Case study

Let us consider two investment projects: project A and project B. Both have identical performance time reaching 5 years and identical investment inputs amounting to 100 000 PLN. In the case of project A the following fluxes of financial surpluses (CF) are forecast: at the end of the first year – 20 000 PLN, the second year – 60 000, the third year – 80 000, the fourth year – 60 000 and the fifth year – 70 000 PLN (line 3 in Table IV). In project B the forecast financial surpluses at the end of each of the periods are identical and amount to 58 000 PLN.

Simplified BC including the cost benefit analysis and investment assessment is presented for project A in Table XI, whereas for project B in Table XII.

Actually, introduced to pattern BC are all costs (the first lines in Table XI and Table XII) with tangible benefits (the second lines in these tables), which gives cash flows for the projects (the third lines), equal to benefits (incomes) decreased by costs.

The cost benefit analysis is aimed at discerning the moment when the first incomes from the project appeared. They are then assessed using a discount rate. In the fifth line for each period the discount ratio is calculated. The assumed (in these examples) rate of return within a year is 6.3% for every project.

The discount ratio for a given period is treated similarly as weight while counting the weighted average, except that in the NPV case it is the „weighted total". Pursuant to this premise, a further stage is discounting of cash flows (the sixth lines in Table XI and Table XII) by multiplying the value of cash flows from a given period (the third line) by the value of the discount ratio (the fifth line). Subsequently, at the intersection of the sixth line and the seventh column the total of discounted cash flows is calculated ($\sum CF_t$).

On the other hand, the aim of the whole investment is to determine the NPV value, otherwise called the updated net value or the present net value. NPV is a method of assessment of the tangible investment economic efficiency but also an indicator determined according to this method.

In the present situation, NPV is considered as an indicator constituting a difference between the sum of discounted cash flows and initial inputs.

It is assumed that the investment should pay for itself in the period not longer than 2 years. The period of return on inputs in the case of project A amounts to 2.4 years, and in the case of project B it reaches 1,9 years. The calculations used the formula in which inputs are compared with cumulated positive cash flows and then we should observe when the sum is zero. Project B is better than project A, because it provides a faster return on inputs and does not

TABLE XII.
SIMPLIFIED BUSINESS CASE FOR THE PROJECT B WITH COST BENEFIT ANALYSIS AND INVESTMENT APPRAISAL

YEAR	0	1	2	3	4	5	VALUES
Costs (in thousands of PLN)	-100	-20	-20	-20	-40	-30	
Benefits (in thousands of PLN)	0	78	78	78	98	88	
Cash flow (in thousands of PLN)	-100	58	58	58	58	58	**58**
Cumulative cash flow (in thousands of PLN)	-100	-42	16	74	132	190	
Discount ratio	1	0.94	0.88	0.83	0.78	0.74	
Cash flow after discounting (rounded up to thousands of PLN)	-100	55	51	48	45	43	$\sum CF_t = 242$
Cumulative cash flow after discounting (in thousands of PLN)	-100	-45	6	54	99	142	**NPV = 142**

exceed the assumed two-years' period of the investment pay-back.

NPV for project A amounts to 137 000 PLN, and for project B – 142 000 PLN (intersection of the seventh line and the seventh column in Table XI and Table XII). In NPV we accept only projects with NPV higher than zero, and we reject the other ones. The decision about the choice of a specific project is correct for the specified interest rate.

Of the two projects excluding each other we choose the project with a higher NPV. In the given case it is project B which not only provides a faster return of inputs but it also provides an additional surplus of 142 000 PLN.

Implementation of business case in organization changes the way of thinking about project initiatives, because it requires explicit defining of profits from performance of the undertaking. Problems with indicating the profits or inability to measure the profits demonstrate that the suggested project has significant drawbacks.

An important advantage of the use of BC is the necessity to prepare some variants of the project performance, which gives the organization's managers more decision-making possibilities e.g. as to alternative investment methods. On the other hand, the need to include many complex aspects constitutes the greatest drawback of this document.

e-mail: {jerzy.korczak, marcin.hernes, maciej.bac}at ue.wroc.pl

Abstract—The paper presents issues related to developing methods for fundamental analysis used to expand capabilities of multi-agent trading system, to better predict the financial market. The fundamental analysis indicators can be used as confirmation of decisions generated by other strategies of the system. The first part of the article discusses briefly the fundamental analysis issues in relation to the online trading on FOREX market. The statistical analysis of correlations of the different time series indicators and algorithms of fundamental analysis agents are examined. The final part discusses the results of the performance evaluation of selected investment strategies, including fundamental–based agents.

I. Introduction

In trading support systems, the advices might be computed by one or many algorithms, or by one or many software agents using one or many information sources. An overview of of the agents operating on financial markets has already been given by B. LeBaron [1]. Currently, most trading systems are based on one or only a few algorithms. For example, the solutions described by L. Mendes, P. Godinho and J. Dias [2] use genetic algorithms to perform analysis on the basis of historical quotations. The system described by J.R. Thompson, J.R. Wilson and E. P. Fitts [3] is based on the multifractal time series. In the system described in [4, 5] technical analysis indicators are used. There are many solutions based on multi-agent approach. H. C. Aladag, U. Yolco and E. Egrioglu [6] present an evaluation of the portfolio optimisation strategies by three agents: rational agent, interference agent, and technical analysis agent. P. Singh and B. Borah [7] apply a multi-agent system where the agents' intelligence is based on fuzzy expert system. O. Badawy and A. Almotwaly [8] developed the neural networks and neuro-fuzzy computing for taking into account the geometrical patterns of the financial data. M. Aloud, E.P.K. Tsang and R. Olsen [9] introduce an agent-based model for simple prediction of financial markets, where each agent predicts the development of selected subsets of the assets pairs in real time by separately examining the similarities between ask and bid assets histories. P. Kaltwasser [10] describes an agent that uses multiple behavioral techniques to make bidding decisions in the face of market uncertainty. J. Glattfelder, A. Dupuis and R. Olsen [11] develop a system that supports multiple strategies, but they use only moving-average crossover strategies in the current stage of development. The paper by R. Barbosa and O. Belo [12] describes a multi-agent system that consists of a set of trading models such as an ensemble of classifiers, regression models, case-based reasoning, and an expert system. F. H. Westerhoff [13] presents a system where two groups of agents applying the methods of fundamental and technical analysis try to shape market dynamics.

Summing up, more often the trading advice is provide by multiple software agents that use mainly technical analysis. However, many papers related to economic basics [e.g. 14, 15, 16] state that using a fundamental analysis is also necessary for supporting trading decisions. A few of solutions combine fundamental analysis and behavioral sentiments.

Our platform, called A-Trader [17, 18], allows for the implementation of various algorithms or trading decision support methods [e.g. 19, 20]. The A-Trader is aimed at supporting trading decisions on the FOREX market (Foreign Exchange Market). On FOREX currencies are traded in pairs, for example USD/PLN, EUR/GBP. In general, trader on FOREX can open/close long/short positions. A long position relies on "*buying low and selling high*" in order to achieve a profit.. A short position, instead, relies on "*buying high and selling low*". On FOREX, when one currency in a pair is rising in value, the other currency is declining, and vice versa [18]. The A-Trader receives tick data which are aggregated to minute (M1, M5, M15, M30), hour (H1, H4), day (D1), week (W1) and month (MN1). The A-Trader mainly supports High Frequency Trading (HFT) [17], and puts strong emphasis on price formation processes, short-term positions, fast computing, and efficient and robust indicators [19].

High frequency traders seek profits from the market's liquidity imbalances and short-term pricing inefficiencies. Access to quote data must be near real time. Therefore systems supporting trading must provide as soon as possible advice as to which position should be taken: open, close or no entry (do nothing).

The architecture of A-Trader and the description of the different groups of agents have already been detailed [17, 18]. In general, the agents applied technical and behavioral analysis in order to support trading decisions.

The aim of this paper is to present methods for fundamental analysis used to improve the trading efficiency of A-Trader. These methods take into consideration both HFT and also different time resolutions (multiresolution is an integral part

of A-Trader: from M1 to MN1 periods). Multiresolution is very important issue due to different time periods needed for fundamental analysis on FOREX market. The macro-economic indicators (e.g. inflation, Gross Domestic Product) are characterized by low fluctuation. (analysis of these indicators is usually performed monthly).

The first part of the article briefly discusses the fundamental analysis issues in relation to the FOREX market. Next, the statistical analysis of correlations of the different time series indicators and algorithms of fundamental analysis agents are examined. The final part discusses the results of the performance evaluation of selected investment strategies, including fundamental– based strategies.

II. Fundamental analysis on FOREX market

The main assumption of fundamental analysis is the notion of equilibrium. At any considered time, a currency pair should trade at a particular rate that balances trade and investment flows. Fluctuations in market risk affect a rate that may be well above or below what financial-economic conditions justify [15]. Unlike technical analysis, fundamental analysis doesn't become less profitable when competition increases. If market dynamics raise interest rates, in consequence a currency will rise proportionately. This cause will not be undone if too many people are aware of it. On the contrary, it will become even stronger [15].

Putting it briefly, FOREX fundamental analysis concerns the following:

1. Driving supply and demand in the market currencies.
2. Economic indicators and asset markets.
3. Indexes.
4. Political and social powers.

There are two major factors affecting *the supply and demand balance*: interest rates and the state of international trade [22]. Interest rates can have either a strengthening or weakening effect on a particular currency. The high interest rates attract foreign investment, which will strengthen the local currency. Stock market investors often react to interest rate increases by selling off their holdings. How changes in central bank interest rates impact exchange rates are described by following overarching forces: interest rate parity and the carry trade. Emerging (growth) currencies tend to trade in direct proportion to relative interest rate levels, since higher rates attract speculative investors. Recall that investors in the carry trade seek to profit from positive interest rate differentials; hence, the higher the interest rate, the more attractive the corresponding currency [17]. An international trade balance arises if the economy shows a deficit (more imports than exports) which mean that money is flowing out of the country to purchase foreign-made goods, and this may have a devaluing effect on the currency [27]. A decent fundamental analysis comprises the examination of *macroeconomic indicators* and *asset markets*, when evaluating a country's currency. Macroeconomic indicators include figures such as [10, 15, 16, 23]:

1) Growth rates, measured by Gross Domestic Product.
2) Inflation.
3) Unemployment.
4) Balance of payments.
5) Market correlations, such as [16, 24]:
   - gold prices ratio: when gold goes up, the USD often goes down (and vice versa); therefore, an inverse relationship appears between gold and USD ,
   - oil prices ratio: the economies of oil-dependent countries weaken as oil prices rise; in such situation a trader can consider buying currencies of commodity-based economies like Australia or Canada or selling oil-dependent currencies.
6) Productivity.
7) Purchasing Managers' Index (PMI), based on new orders, inventory levels, production, supplier deliveries and the employment environment.

Asset markets comprise stocks, bonds and real estate. Other indicators that may be considered are the Consumer Price Index (CPI), Durable Goods Orders, Producer Price Index (PPI), and retail sales.

Index correlations also have influence on currency quotations [25]. Examples of indexes are:

- S&P 500 is an index which includes the 500 companies with the largest capitalization companies listed on the New York Stock Exchange and NASDAQ,
- FTSE 100 is a share index of the 100 companies listed on the London Stock Exchange with the highest market capitalization,
- WIG index is listed on the Warsaw Stock Exchange; it includes shares listed on the Polish market.

Political considerations impact the level of confidence in a nation's government, the climate of stability and level of certainty [25].

The trading advices generated by agents based on fundamental analysis are used as confirmations of a buy/sell decision suggested by technical analysis–based agents or behavioral–based agents.

III. Comparison of correlation of selected fundamental analysis factors and FOREX quotations

As was stated in the previous section, the fundamental analysis factors (macro-economic indicators) of a given country are often correlated with its currency quotation.. Fig. 1 presents the example of correlation inflation, oil price, and S&P 500 index with USD/GBP quotations in 2015 (monthly). On the basis of visual analysis of this chart, we can draw the conclusion that in particular periods most of the macro-economic indicators are correlated with USD/GBP quotations. For example, taking into consideration the period May-June, the USD/GBP quotations rise and inflation and S&P 500 also rise (while the oil quotation falls); taking into

consideration the period November – December, the USD/GBP quotation rises and inflation, S&P500, and oil also rise.

In order to determine the correlation between these factors, the Mann-Kendall test was used. The non-parametric Mann-Kendall test is commonly employed to detect monotonic trends in series of environmental data, climate data or hydrological data [24]. For two trends correlation a tau Kendall ratio was calculated that counts the number of pairwise disagreements between two time series. The larger the distance, the more dissimilar the two series are [24]. If tau Kendall value is near 1 or -1, then two time series are correlated, if it is near 0, then time series are independent.

For example, for the time series presented on Fig 1 (period - 2015 year) tau Kendall correlation values are the following:

- USD/GBP vs. inflation: 0,1,
- USD/GBP vs. oil: – 0.04,
- USD/GBP vs. S&P500: – 0.2.

According to this metric, the macroeconomic values are not strongly correlated with the USD/GBP quotation, whereas if we look at the chart, they seem to be correlated. This may result from tau Kendall specifics and also from time-shift of the trend change considered quotation and indicators. For example, the USD/GBP quotation starts rising in April, the S&P500 also in April, but inflation starts rising in May or oil starts rising in March. Therefore, macro-economic indicators can be used mainly for confirmation of long time trends of FOREX quotations.

IV. Description and Evaluation of the Fundamental Analysis Agents

Input signals of fundamental analysis agents appear with different frequency. One of them is available in high time periods, for example quarterly, monthly, weekly, like the Inflation PPI M/M, Net Capital Inflows, Change of employment M/M, and Industrial production.

These signals are very important in establishing and confirming long time trends. According to the rule „*Trend is your friend*", investing in pursuance of the trend should gain more profits. The Elliott wave theory says that movements in line with the trend are longer and more dynamic. This indicator may be a good advisor in the investment strategy. But it is not enough in the high frequency trading strategy where trades are frequent and positions are opened only for a short time. This indicator can therefore be taken only as advice, not as a signal to open position. The actual macro-economic situation of the country is the real important indicator. Namely, the main stock exchange indicators such as S&P500 and FTSE 100 are the main advising factor and trigger for making a trade. Principal goods such as gold and oil are also included, and they usually function as short time indicators.

Neural networks have already demonstrated great potential for discovering non-linear relationships in time-series. The published results of forecasting financial data are particularly good [21, 26, 27]. Therefore, we took the decision to make use of the neural network model as a predictor.

In general, our fundamental analysis agents were built on the Multi-Layer Perceptron model. The diagram of the agent operation is schematically presented in Fig 2. It uses the sigmoid activation function and the back-propagation learning algorithm. Long and short term fundamental indicators were taken into account. The input vector contained the long term indicators and the last sequences of S&P500, FTSE 100, oil and gold tics. As output, changes in USD/GBP rates were expected. In the learning process, the output values of the neural network were shifted by T_n units in time.

The trading strategy of the fundamental analysis agent can be specified as follows:

```
Input: q_FTSE100 =<q_ftse1, q_ftse2, .... q_ftseM>
    // FTSE100 quotations,
   q_S&P500=<q_s&p1, q_s&p2, .... q_s&pM>
   // S&P500 quotations
   q_GOLD=<q_gold1, q_gold2, .... q_goldM>
   // GOLD quotations
   q_OIL=<q_oil1, q_oil2, .... q_oilM>
   // OIL quotations
   i_Inflation // M/M inflation change
   i_NCI // Net Capital Inflows change
   i_COE // Change of employment M/M
   i_IP // Industrial Production M/M change
```

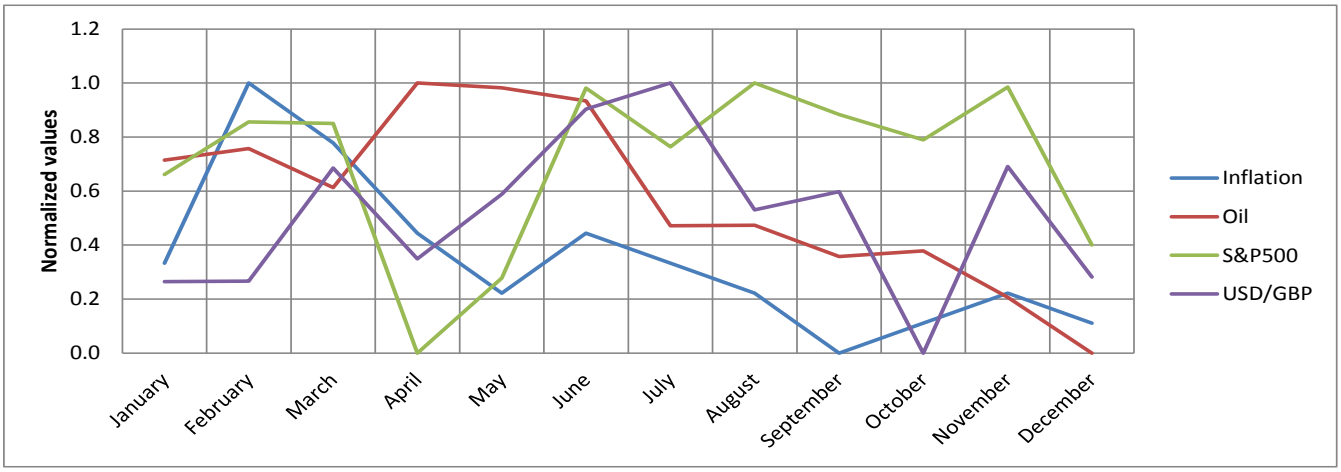

Fig. 1. The example of correlation between inflation, oil prices and S&P 500 index with USD/GBP quotation in 2015 (monthly).

```
    thresholdopen   //threshold   level   for   open
    //long/close short //position
    thresholdclose   //threshold   level   for   close
    //long/open short //position
Output: The fuzzy logic recommendation D
    // (range [-1..1]).
BEGIN
    if
        CheckPerformanceLevel()
    then
        BeginLearningProcess();
        p_USD/GBP_M+3      :=      Multi-layerPerceptron
        (q_FTSE100,          q_S&P500,          q_GOLD,
        q_OIL,i_Inflation, i_NCI, i_COE, i_IP);
        //Prediction of USD/GBP value change
        if
          p_USD/GBP_M+3 > thresholdopen
        then
          D:= heuristic_open(p_USD/GBP_M+3);
        else if
          p_USD/GBP_M+3 < thresholdclose
        then
          D:= heuristic_close(p_USD/GBP_M+3);
        otherwise  D:= heuristic_do_nothing
    END
```

From the point of finance, the fundamental analysis agent is founded on money flow interpretation. For instance, if the S&P 500 is falling and FTSE 100 is rising, one can suppose that investors exchange their S&P shares for USD, then they exchange USD to GBP, then they buy FTSE 100 shares. So if they buy GBP for USD, the value of GBP to USD should rise.

In A-Trader, an evaluation of selected agents is performed with the use of the following measures (ratios):

- rate of return (ratio x_1),
- the number of the transaction,
- gross profit (ratio x_2),
- gross loss (ratio x_3),
- the number of profitable transactions (ratio x_4),
- the number of profitable consecutive transactions (ratio x_5),
- the number of unprofitable consecutive transactions (ratio x_6),
- Sharpe ratio (ratio x_7)

$$S = \frac{E(r) - E(f)}{|O(r)|} \cdot 100\% \quad (1)$$

where:
$E(r)$ – arithmetic average of the rate of return,
$E(f)$ – arithmetic average of the risk-free rate of return,
$O(r)$ – standard deviation of rates of return.

- the average coefficient of volatility (ratio x_8) is the ratio of the average deviation of the arithmetic average multiplied by 100% and is expressed:

$$V = \frac{s}{|E(r)|} \cdot 100\% . \quad (2)$$

where:
V – average coefficient of variation,
s – average deviation of the rates of return,
E(r) – arithmetic average of the rates of return.

- the average rate of return per transaction (ratio x_9), counted as the quotient of the rate of return and the number of transactions.

For the purpose of the comparison of the agents' performance, the following evaluation function was elaborated:

$$y = (a_1 x_1 + a_2 x_2 + a_3 (1 - x_3) + a_4 x_4 + a_5 x_5 + \ldots$$
$$+ a_6 (1 - x_6) + a_7 x_7 + a_8 (1 - x_8) + a_9 x_9) \quad (3)$$

where x_i denotes the normalized values of the ratios. Coefficients a_1 to a_{10} may be also determined by the investor in accordance with his/her preferences (for instance, the user may determine whether is interested in the higher rate of return with a simultaneous higher risk level or lower risk level, but simultaneously agrees to a lower rate of return). These functions allow for determining the best strategies for the user in a given time period. Coefficients a_1 to a_{10} can be used also for creating different users' profiles (allow for personalization of A-Trader).The function is given the values

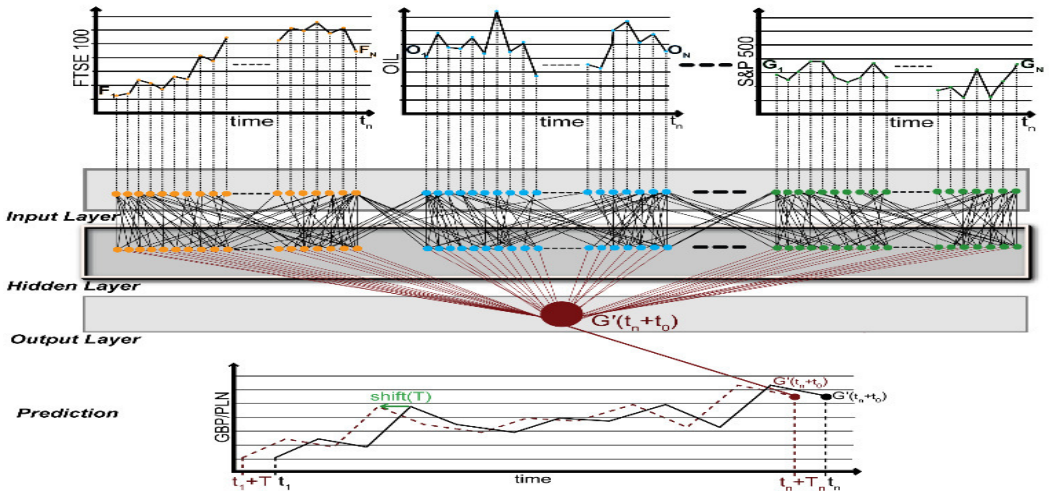

Fig. 2 Fundamental Analysis Agent

from the range [0..1], and the agent's efficiency is directly proportional to the function value.

V. EXPERIMENTS

The agent's performance analysis was carried out for data within the M1 period of quotations from the FOREX market. For the purpose of this analysis, the test was performed in which the following assumptions were made:

1. USD/GBP quotes were selected from randomly chosen periods (each - 1440 quotations), notably:
   - 15-03-2016, 0:00 am to 15-03-2016, 23:59 pm,
   - 16-03-2016, 0:00 am to 16-03-2016, 23:59 pm,
   - 22-03-2016, 0:00 am to 22-03-2016, 23:59 pm,
2. At the verification, the trading signals (for open long/close short position equals 1, close long/open short position equals -1) were generated by the strategies *FundamentalStrategy* and *Technical Strategy*.
3. It was assumed that decisions' probability levels for open/close position are determined by the genetic algorithm (on the basis of earlier periods).
4. It was assumed that the unit of performance analysis ratios (absolute ratios) are pips (a pip is equivalent to the final number in a currency pair's price).
5. The transaction costs were directly proportional to the number of transactions.
6. The capital management - it was assumed that in each transaction the investor engages 100% of the capital held at the leverage 1:1. The investor may define another capital management strategy.
7. The results obtained by the tested agents were compared with the results of the *Buy-and-Hold* benchmark (a trader buys a currency at the beginning and sells a currency at the end of a given period).

Table 1 presents the results obtained in the particular periods. In general, it may be noted that strategies generated not only profitable decisions. However, the rate of return cannot be the only measure taken into account in the performance evaluation. Very important are also other ratios, among other risk involved in the investment.

The evaluation function provides the fast choice of the best strategy. It may be noted that the values of efficiency ratios of particular strategies differ in each period. Values of this function oscillate in the range from 0.02 to 0.51. Therefore use of this function allows for reducing the deviation of the values of the ratios.

The results of the experiment allow us to state that the ranking of strategies' evaluation differs in particular periods. In the first period, the *TechnicalStrategy* was the best strategy, the *FundamentalStrategy* was ranked higher than *B&H benchmark*. In the second period also the *TechnicalStrategy* was ranked highest, but *FundamentalStrategy* was ranked lower than *B&H*. Considering the third period, it may be noted that the *FundamentalStrategy* was the best strategy, although the *Rate of Return* of this strategy was not highest.

The highest value of evaluation function of *FundamentalStrategy* (in third period) results from the highest *Average Rate of Return per Transaction* and low risk measures' values. The *B&H* benchmark was ranked lowest in two periods, and in the first and third periods it generated the losses. It should be noted that in the second period, the upward trend was observed, therefore *B&H*'s *Rate of Return* was positive. The first and the third periods show a downward trend, and therefore the *B&H*'s *Rate of Return* is negative. Taking into consideration all the periods, it may be stated that there is no one strategy ranked highest most often. Also, strategies achieving the highest *Rate of Return* were not always ranked in the highest positions. *TechnicalStrategy* always was characterized by greater number of transactions than *FundamentalStrategy*. However, *FundamentalStrategy* is characterized by highest Rate of Return per Transaction, than *TechnicalStrategy*. Both, *TechnicalStrategy* and *FundamentalStrategy* are characterized by low level of risk. This results mainly from the fact that these strategies take into consideration decisions generated by large numbers of agents.

During performing the experiments, a problem with neural network learning, was also observed. Values of the input

TABLE I.
PERFORMANCE ANALYSIS RESULTS

Ratio	FundamentalStrategy			TechnicalStrategy			B & H		
	Period 1	Period 2	Period 3	Period 1	Period 2	Period 3	Period 1	Period 2	Period 3
Rate of return [pips]	9	-66	28	56	132	48	-143	89	-160
The number of transactions	4	7	5	39	52	42	1	1	1
Gross profit [pips]	11	61	43	125	124	93	0	89	0
Gross loss [pips]	17	37	28	65	81	49	-143	0	-160
The number of profitable transactions	3	3	3	27	38	27	0	1	0
The number of profitable consecutive transactions	2	2	2	11	6	4	0	1	0
The number of unprofitable consecutive transactions	1	3	2	2	2	1	1	0	1
Sharpe ratio	0.55	1.8	0,78	0.91	2.60	1.38	0	0	0
The average coefficient of volatility [%]	1.66	0.36	1.94	1.86	0.24	0.92	0	0	0
The average rate of return per transaction	2.25	-9,43	5,6	1.43	2.54	1.14	-143	89	-160
Value of evaluation function (y)	**0.43**	**0.19**	**0.51**	**0.49**	**0.43**	**0.47**	**0.08**	**0.38**	**0,02**

vectors was very similar, thus learning process was not always convergent. It may result from long-time fluctuations of fundamental indicators in relation to short-time fluctuation of currencies quotations.

VI. Conclusion

The fundamental analysis implemented as investment strategy in A-Trader can be used as confirmation of decisions generated by other strategies. However, investing only on the basis of FundamentalStrategy does not allow us to achieve a satisfactory rate of return. Often, fundamental analysis indicators are time-shift in relation to currency value (for example, changes in oil prices or S&P500 quotations presented in fig 1 go faster than the USD/GBP trend). Thus, although we see on the chart a correlation between fundamental analysis indicators and currency quotations, the Mann-Kendall test has not confirmed this correlation, due to the time-shift. This implies the need for further research work on developing the fundamental strategy to take into consideration the time-shift phenomenon and on improving methods for neural network learning adjusted to fundamental indicators' values.

***Abstract*—A real-world company asked us to solve emerging problem related to the flow of the documents: some of the documents had been lost. We used methods of process mining to solve this problem. We found an error in the information system. Moreover, our analysis of the flow of the documents led to the conclusion that the business processes did not meet the company's needs, and with our help they were redesigned and reimplemented. This research gave an additional important insight to process mining methodology — in order to extract knowledge about business processes that is useful for the decision makers, it is crucial to create algorithms capable of collaborating with human experts.**

I. Introduction

IN CONTEMPORARY business enterprises the complexity of real-world processes has to be perceived as one of the greatest obstacles in achieving effectiveness. More and more enterprises face with the problem of redesigning their business processes in order to survive in the global economy. The competitive market creates the demand for high quality services at lower costs and with shorter cycle times. Even relatively small companies are frequently confronted — in their daily routines — with processes of very high complexity. In such environment business processes must be identified, described, understood and analyzed to find inefficiencies, which cause financial losses.

One way to achieve it is modeling. Business modeling is the first step towards defining a software system. It enables companies to look afresh at how to improve organization and to discover the processes that can be solved automatically by software that will support the business. However, as it often happens, such a developed model corresponds more to how people think of the processes and how they wish the processes would look like, than to the real processes as they take place.

Another way is by extracting information from a set of events gathered during executions of a process. Process mining [1], [2], [3], [4], [5], [6], [7], [8], [9] is a new and prosperous technique that allows to extract a model of a business process based on information gathered during real executions of the process. The methods of process mining are used when there is no enough information about processes (i.e. there is no a priori model), or there is a need to check whether the current model reflects the real situation (i.e. there is a priori model, but of a dubious quality). One of the crucial advantages of process mining over other methods is its objectiveness — models discovered from real executions of a process are all about the real situation as it takes place, and not about how people think of the process, and how they wish the process would be like. In this case, the extracted knowledge about a business process may be used to reorganize the process to reduce its time and cost for the enterprise.

Table I shows a typical event-log gathered from a flow of documents in a company. This event-log is a list of entries that contain information about observable actions of a process:

- "Actor" is someone who triggered the event; in our example an "Actor" is described by his full name (we left visible only two first letters of actors' surname)
- "Time Stamp" is the exact time of the event; in example from Table I "Time Stamp" indicates the exact date and time when the event occurred
- "Event" is an observable action of the event (we shall assume, that we are given only some rough information about the real actions); in example from Table I there are four possible types of events:
  - "*Created*" — starting point of approval process triggered by new document that was created in the system
  - "*GL app*" — first level of acceptance ; "Actor" is directly responsible for the area, which document content concerns. Approval confirms that the description coincides with reality
  - "*Quality app*" — second level of acceptance ; "Actor" is a Quality Engineer and confirms that the change does not have negative impact in quality area
  - "*APU app*" — 3rd and last approval level ; "Actor" is an Area Supervisor/Manager and confirms that the organization is ready for this kind of described change and costs regarded with it were included in forecast (money, which have to be spent are booked)
  - "*Approved*" — document has been confirmed by all required employees and is registered in SAP
  - "*Rejected*" — document has been rejected in approval path ; rejection reason attached to this document
- "Case ID" is an instance of the process that executed the event

The column "Case ID" allows us to divide a list of events on collections of events corresponding to a particular executions of the process (i.e. to a particular instance of the process). The

column "Time Stamp" makes it possible to linearly order each of the collections.

Figure 1 shows a model recognized from the log presented on Table I.

The aim of this paper is to show how methods of process mining can be applied to solve difficult problems in a real-world company. A company asked us to solve emerging problem related to the flow of documents: some of the documents had been lost. In the first case an error in the information system was identified and fixed. It also turned out, that the flow of the documents had been broken and after our analysis the whole process was redesigned and reimplemented.

Other examples of process mining usability in real-world companies are described in:

- *Process Mining in Healthcare*[11]
- *Process Mining Methodology for Health Process Tracking Using Real-Time Indoor Location Systems*[12]
- *A general divide and conquer approach for process mining*[17]
- *Process Mining Applied to the Test Process of Wafer Steppers in ASML*[13]

Health care process is modern subject for process mining researchers. One of the best environments for flow tracking are areas where human behaviors influence is the highest possible. Human errors, flow deviations, workarounds can be detected by process mining tools.

Our research gave an additional important insight to process mining methodology — in order to extract knowledge about business processes that is useful for the decision makers, it is crucial to create algorithms capable of collaborating with human experts. Optimization algorithms have been researched in the area of decision support [10], but much less is known about algorithms for process mining in this context. One of the most significant methods is an explanation and justification of a mined model. This requirement stems from real business cases, where the best model becomes useless if it is not accepted by the decision maker. The lack of acceptance of a business process model can be due to several reasons: undisclosed user preferences; new constraints; a different evaluation; or simply a misunderstanding of the proposed model.

The paper is structured as follows. We checked ProM tools usability in Section II, where present complete document flow analysis. Readers can find there complex problem resolved after data extraction and analysis. We described results after document flow update that are effect of our common work with a company experts in *conformance checking* process [16]. We conclude the paper in Section III.

II. DOCUMENT FLOW ANALYSIS

Flow of the documents, which approvals are required is important due to financial control requirements. Unsupported flow occurrence might be a source of abuses, human errors or problems to meet customer expectations. Corporations have to take care about transparency of financial status required by internal procedures and headquarters policies. Internally developed solution has to ensure document approvals in line with employees permissions. This kind of software is vulnerable to errors. Bug can be source of problems like embezzlement results, communication errors or wrong conclusions. Part of organization that is responsible for programming or management has to ensure that the implemented program works according to the established process.

A. Background

Real-world company has a problem with documents flow. They had mismatch between documents' flow system results and Financial Department's reports. Company's manager contacted us and ordered a complete service of process analysis. The company has implemented Microsoft Sharepoint to ensure proper flow of documents. Each document contains information about produced parts and represents their market value in currency. Developed addon is programmed with optional paths, which are depended on the value of created document. There is additional flow rule that the specialist opinion is needed in particular cases. This specialist is quality engineer. The higher value of a document is, the longer approvals path is required and the people involved in the acceptance process of the document have to be higher in the organization structure. Document creation or approval are triggers for system that generates event logs.

Financial controller and area supervisor have found a problem with budget forecasts. Anomaly was detected by differences in spending calculated by Financial Department and other department manager. Rules in the system looked fine, because each spending value was bigger than specified amount that had to be approved by the department manager. Operation Manager was informed about the situation and commissioned

the analysis. The analysis detected source of anomalies and after that Operation Manager gave instructions how to prevent such anomalies in the future.

Figure 1 presents a diagram mined by ProM Casual Activity Graph. A diagram is consistent with the flow implemented in Sharepoint. It shows that there are 3 levels of approval, but flow depends on specificity of a particular document, which path might be different. Collected logs contains 3 roles in approval system.

B. First level of process analysis CSV to XES

- Events log extraction from Sharepoint application to CSV file.
- CSV text file have to be imported to ProM and transformed to XES
- Analysis of imported data has to be preceded by questions, which may show proper direction of next mining methods

In process mining it is important to understand the data that have been collected. Without this knowledge it may be hard to extract any reasonable conclusion. The analysis of received data should be supported by a person who has theoretical knowledge about the assumptions. Too big deviations in comparison to process draft in organization might warn us about low data quality, which can be source of negative consequences in further analysis.

C. XES log summary

After CSV event log transformation to XES format ProM gives access to the document summary. One of the views is XES log summary where we found information about wrong starting point with 0,06% occurrences value. APU app is 3rd level approval in Figure 1. This is a point, which has to be verified during process exploration. It looks that a process was started from 3rd level acceptance even before its creation.

D. Directly follows graph extracted by ProM

ProM addon generates diagrams where nodes are events and edges are connections between them [15]. This visualization presents process steps flow, which are connected by arrows with labels presenting quantity of occurrences. Figure 1 is a directly follows graph mined from XES log. It transfers event logs into visualization of process steps.

Connection from 3rd role in acceptance process with an event announcing the creation of the document is an anomaly in this flow. The assumption is that the document has to be created before approval. Both in XES summary (Section II-C) and in Figure 1 is visible unusual event.

E. Extracting single case visualization

Process mining helped us with understanding the above anomaly, and we used an inductive visual miner (IvM [14]), which is dedicated ProM tool. It is able to extract information about process for every single instance and to visualize it. IvM allows to track the flow for every process step by graphical user interface. Inductive visual miner includes a functions

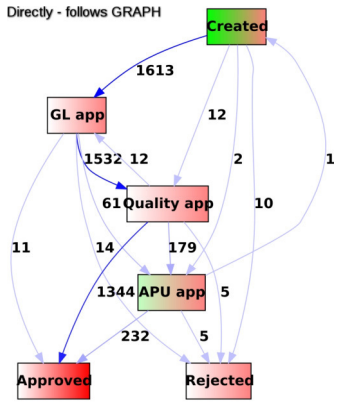

Figure 1. Process discovered by ProM from event log presented in Table I.

based on click event that allow us to extract additional information about process steps or single cases.

Figure 1 APU app(roval) was performed before document creation. Logs visualization shows that the next approval steps were performed even with this anomaly. Analyze of this case led to modifications in path structure. Additional check conditions were added to ensure proper document flow. The source of this problem was in improper database management and software bug. System changed first and second level of approval fields to empty but APU acceptance field did not. Modified document has APU acceptance from previous flow cycle. Trigger for process of documents' approval is document creation. After that instance of process have to be verified by authorized employees. Graph on Figure 1 shows that the created documents are addressed to GL app (first level of approval) in most of cases. This people are able to physical confirmation of compliance created document with the actual situation in the factory. They are working in 3 shift model so verification of documents is possible 24h per working days.

F. System validation after updates

Event logs were imported to ProM two months after system update. In order to confirm that a document approval path is in compliance with procedures. XES event log summary shows single starting point "Created". This summary confirms that the starting point is common and correct for each process instance. Process mining tools help corporation experts in analysis approvals path. Process approval path was redesigned to be in compliance with organization structure. This change is reducing human error risk by change that requires minimum 2 employees approval. Each step in approval path has a possibility to reject a document as like as in previous system version. Obligatory Quality approval step increased description coincidence with reality, because person responsible for that in 1st step knows about further Quality verification.

III. CONCLUSIONS

We investigated how methods of process mining can be applied to solve difficult problems in a real-world company. The paper shows that ProM functionality enables us to take

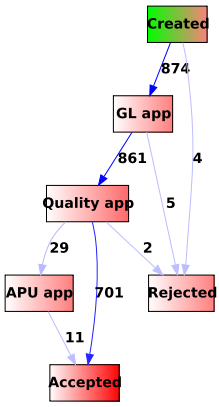

Figure 2. Document flow after system update

a look on processes not only from the designer perspective but also from the perspective of the production environment. IT systems are integral part of companies and sources of important data. Such data should be collected by system administrators, as they are valuable input in process extraction. Event logs gathered during execution of business processes present the reality in an objective way. Therefore, it is crucial to use them in further process optimization. They allow to look at the business process from the production perspective. Process mining has to be supported by people, who understands the relationship between discovered actions. The corporation that we worked with, solved emerging problem related to the flow of documents: some of the documents had been lost. An error in the information system was identified and fixed. It also turned out, that the flow of the documents had been broken and after our analysis the whole process was redesigned and reimplemented. The results obtained in process mining were the most important inputs for the system developers. The developers were able to prepare patches that fixed the problems. Process extraction realized by process mining tools was helpful in problem understanding and fixing. User friendly flow's representation combined with experts knowledge can be the key to successful system patch preparation and implementation.

Our research gave an additional important insight to process mining methodology — in order to extract knowledge about business processes that is useful for the decision makers, it is crucial to create algorithms capable of collaborating with human experts. Optimization algorithms have been researched in the area of decision support, but much less is known about algorithms for process mining in this context. One of the most significant methods is an explanation and justification of a mined model. This requirement stems from real business cases, where the best model becomes useless if it is not accepted by the decision maker. The lack of acceptance of a business process model can be due to several reasons: undisclosed user preferences; new constraints; a different evaluation; or simply a misunderstanding of the proposed model. In future work we should focus more on human-computer interaction in process mining algorithms and systems.

***Abstract*— In present, dynamically developing organizations, that often realize business tasks using the project-based approach, effective project management is of paramount importance. Numerous reports and scientific papers present lists of critical success factors in project management, and communication management is usually at the very top of the list. But even though the communication practices are found to be associated with most of the success dimensions, they are not given enough attention and the communication processes and practices formalized in the company's project management methodology are neither followed nor prioritized by project managers. This paper aims at supporting project managers and teams in more effective implementation of best practices in communication management by proposing a set of communication management patterns, which promote a context-problem-solution approach to communication management in projects.**

I. Introduction

COMMUNICATION management is deemed by many as one of the most important knowledge areas in project management and a very complex one at the same time. It is affected by many factors, like characteristics of project stakeholders, project environment, project communication structure, communication properties, physical and psychological barriers [1]. Research has shown that there is a direct connection between communication and a project's outcome, which is determined by the design of the communication environment of the project [2]. Project communication and networking skills are considered to be the life blood of project management leadership [3] and awareness of the potential offered by efficient communication is an essential prerequisite for success in the business world [4].

Project management methodologies, frameworks and sets of principles like Project Management Body of Knowledge, Prince 2, Adaptive Project Framework, Agile Software Development, Scrum, and others, include rules, hints and procedures regarding various communication management aspects, which in most cases should be sufficient to properly manage communication in a project team. The reason why this is not always the case is that, many IT companies do not actually follow any of these methodologies when realizing projects (for example, 30% of the companies surveyed in [5]) and those that do, tend to concentrate on other project management knowledge areas, which seem more important, like scheduling, cost management, etc. There are also numerous cases of project failures [6], that could be linked to poor communication management (among others [7], [8]).

Thus it seems important to constantly promote good communication management practices and look for new ways to support project managers and team members in better realization of communication and documentation processes in their projects. That is the main goal behind the communication management patterns proposed in this paper – to give project teams an additional tool in a form of a list of patterns for controlling, managing and effective realization of communication and documentation processes. The idea behind patterns is that they provide general, reusable solutions to common problems, and as such are useful for the project team. Communication management patterns described in this paper are based on two main sources of information - communication management best practices identified in subject literature and results of a survey conducted among IT project managers.

The following, second section of the paper, provides evidence on the significance of project communication management knowledge area based on existing literature. In section III, the definition of a pattern is given and some examples of pattern usage are described. The essential fourth section of the paper begins with a definition of the project communication management pattern and on that base subsequent communication management patterns are defined. Conclusions and future research directions end the paper.

II. Significance Of Project Communication Management

The successful implementation of a project depends on its appropriate management in a number of areas, as described in detail by e.g. Kerzner [9], Schwalbe [10], and Meredith and Mantel [11]. One of the areas of project management identified within numerous methodologies and frameworks is

This publication was financed from the funds of the Faculty of Economics and Management, University of Szczecin.

communication management, which is considered to be of crucial importance to the success of a project (among others [12], [13]), in particular IT projects [14] especially those carried out by dispersed teams [15], [16], [17], [18], [19]. On the one hand importance of this knowledge area is emphasized by most stakeholders, but on the other hand, the communication processes and practices formalized in the company's project management methodology are neither followed nor prioritized by project managers [20]. For instance, recent research on utilization of project communication management methodologies in industrial enterprises in Slovak Republic revealed that 66% of the surveyed enterprises had not prepared any written document (methodology, process steps, etc.) to manage project communication [21].

Also Papke-Shields and co-authors, in their research on the use of project management practices and the link thereof to project success, discover that practices related to communication are not given enough attention, while at the same time communication practices are found to be associated with most of the success dimensions [22]. Most of the communication process in a project is usually done without proper planning, driven mostly by personalities and preferences rather than by needs, protocols and procedures [23].

Effective communication techniques and appropriate leadership styles are emphasized by Nguyen as the success factors for building and managing high performance global virtual teams [24]. Communication management is highly influenced in intercultural project teams by such factors as language, race, age, gender, religion, beliefs, habits, etc., whose analysis is essential if the project is to be accomplished with success [25].

According to PMI's Pulse research, 55 percent of project managers agree that effective communication with all stakeholders is the most critical success factor in project management [26]. Effective project communications ensure that the right information reaches the right person at the right time and in a cost-effective manner. Communication is the key to keeping team members, managers, and stakeholders informed and on track to pursue the project objectives, as well as to identifying issues, risks, misunderstandings, and all other challenges to project completion. Effective communication is a critical element of team effectiveness, both in traditional and virtual teams [27] and it is much more than message exchange, rather a way in which project managers generate the grounds for a project [28].

III. Definitions And The Use Of Patterns

One of the general definitions of a pattern states that it is "a regular and intelligible form or sequence discernible in the way in which something happens or is done" or "an excellent example for others to follow" [29]. Design patterns are used to represent knowledge that is based on experiences captured in several real world projects and is widely accepted. This representation is often used for describing and presenting the gained knowledge. There are similar concepts to the concept of a pattern – success factor, success models, success measures, reference architectures, best practices, worst practices, barriers, facilitators or incentives [30].

Different definitions for a pattern exist, but they all include a common ground – patterns are general, reusable solutions to common problems and are dependent on their context [31]. They are based on the philosophy of pattern languages, first proposed by architect Christopher Alexander, which is now widely applied in many other professional areas to encompass creative human actions ([32] and works cited therein).

The following subsections describe the structure and format of patterns defined in three knowledge areas – design patterns in software engineering, knowledge management patterns and collaboration patterns. These examples have served as a reference for the structure of communication management patterns defined in the subsequent section.

A. Design Patterns in Software Engineering

In the software discipline, a pattern describes a problem, which occurs recurrently and supports a solution to that problem in a given context. The pattern has four essential elements: the pattern name, the problem, which describes when to apply the pattern (it explains the actual problem and its context), the solution, which describes the elements that make up the design, their relationships, responsibilities and collaborations (this is an abstract description, a template of a solution), and the consequences – the results and trade-offs of applying the pattern.

To describe each design pattern, a consistent format has been used, including specific sections like: pattern name, intent (explains what the design pattern does, what particular issue/problem it addresses), motivation (a scenario illustrating a design problem and how the pattern solves it), applicability (situations when the design pattern can be applied, examples of poor designs where the pattern could be applied), structure (a graphical representation of classes in the pattern, accompanied with interaction diagrams), participants (classes participating in the design pattern and their responsibilities), collaborations (how the participants collaborate to carry out the responsibilities), consequences (the trade-offs and results of using the pattern), implementation (pitfalls, hints, techniques useful in pattern implementation), sample code, known uses (examples of the pattern found in real systems, related patterns (which patterns are closely related to each other). Each defined design pattern is described according to the above mentioned sections, which makes them easier to use, learn and compare [33].

B. Knowledge Management Patterns

Knowledge management patterns state lessons learned and best practices for the structuring of knowledge, the design of

knowledge management systems, and the development of underlying ontologies. Patterns in knowledge management represent also a form of language that helps knowledge engineers to communicate about knowledge and knowledge management systems.

A knowledge pattern is defined as a general, proven, and beneficial solution to a common, reoccurring problem in knowledge design, i.e., the structuring and composition of the knowledge or the ontology defining metadata and potential relationships between knowledge components. Knowledge management patterns are described in seven groups regarding different aspects of knowledge: content, usage, ontology, presentation, transfer, knowledge management systems organization and social knowledge management. Each pattern is described according to a template including the following sections: name, issue (problem addressed by the pattern), q-effect (what knowledge quality aspects are affected by the pattern and if it is a positive, negative or neutral effect), solution (principal solutions underlining the pattern), causes (basic causes of the pattern) [30].

C. Collaboration Patterns

Collaboration patterns strive to verbalize tips on achieving teamwork that creates new values. They are used to help teams achieve creative collaboration through their interactions and discover methods to engage in effective teamwork.

Each collaboration pattern comprises of two main parts – the first one, giving a brief idea of the pattern, including the following elements: name, one-liner (short description of the pattern), illustration and quotes related to the pattern, and the second part, offering more details, with the following sections: context, problem, forces, solution, actions and consequences, which describe how things can change when a certain pattern is applied [34].

There are also other views on collaboration patterns, like the Schadewitz's design patterns for cross-cultural collaboration [35].

According to the classification proposed by Verginadis et al. [36], the project communication management patterns, specified in the subsequent section, could be considered as a specific kind of patterns in collaborative work, and precisely classified as "an approach that aims to directly assist participants", and "which requires manual intervention".

IV. Project Communication Management Patterns

A. Definition of a Project Communication Management Pattern

The definition of the project communication management pattern proposed in this subsection is a result of the analysis of patterns and their frameworks developed in different disciplines, and combining selected aspects of these patterns with project communication management characteristics and practices.

Project communication patterns have been grouped into four categories according to the communication management practice categories described in [37] – informational (regarding generation, collection, dissemination, storage, and disposition of project information), strategic (connected with communication planning and project environment), emotional (concerning the building of trust and relationships) and practical (connected with clear and positive communication and behavior rules). Within each category, several communication management patterns were defined. Each pattern comprises of the following sections: pattern name, context, problem, solution, q-effect (what communication quality aspects are affected by the pattern and if it is a positive or a negative influence), applicability (situations, teams and projects where the communication management pattern should be applied), participants (parties participating in the communication/documentation process and their responsibilities), consequences (the trade-offs and results of using the pattern), implementation (pitfalls, hints, techniques useful in the pattern implementation), and related patterns.

For specifying q-effect the following communication quality aspects were considered: clearness and cohesion, adequate level of detail, right time, meeting needs of communicating participants, engaging right people, guarantee of uniform understanding of the content, communication workflow supporting openness, redundancy and feedback.

Solution within a pattern describes what actions should be undertaken to realize the pattern and the communication management goal that it supports.

The project communication management patterns described in the subsequent subsections are based on two main sources of knowledge. The first source are communication management best practices described in literature [38]–[43], [16] and thoroughly discussed in [37], and the second source are the opinions gained from practitioners (mostly project managers realizing IT projects) from 10 national and international IT companies operating in Poland. A structured interview with both closed and open-ended questions was used to obtain their opinions.

B. Informational Communication Management Patterns

Within the informational category, three communication management patterns have been specified: Communication schedule, Project knowledge center and Diversity of communication means. According to the survey, carried out among practitioners, all the following patterns are known to almost all of them and used in their companies. In one case it has been stated that the Communication schedule pattern is an intrinsic element of the communication plan, which is prepared at the start of the project realization.

Table I provides characteristics of the three project communication management patterns from the informational category, developed according to the defined template.

For the sake of brevity the pattern section names were abbreviated as follows: Cx (context), Pr (problem), S (solution), Q (q-effect), A (applicability), P (participants), Cq (consequences), I (implementation) and RP (related patterns).

TABLE I.
COMMUNICATION MANAGEMENT PATTERNS WITHIN THE INFORMATIONAL CATEGORY

Communication schedule	
Cx	The project team is dispersed, some team members are in different time zones; according to the project communication plan project partners should inform each other of the project status to get feedback and encourage involvement.
Pr	Communication between team members is too scarce, team members limit communication to sending reports, while direct communication takes place only in emergency situations.
S	Prepare a communication time schedule, including bilateral communication between particular team members, as well as multilateral audio/video conferences among wider forum of team members; communication participants possibilities and preferences concerning communication medium and time zone shifts should be taken into account.
Q	Positive on the following communication quality aspects: up to date information on the project tasks status; redundancy, feedback. Negative on the following communication quality aspects: in case of multilateral audio/video conferences too many participants taking part may cause the communication to be ineffective and irritating (technical problems are more likely to appear) and not engaging the right people.
A	The pattern can be used for any kind of project and team, although it is especially useful for dispersed teams and bigger projects longer than three months.
P	Any team member that is included in the communication time schedule; team members are responsible for adhering to the time schedule or timely informing about any derogations; a very important issue in realizing this pattern is engaging only the concerned team members in multilateral conferences (thematic groups).
Cq	Ensures regular communication among team members, adjusted to their working day schedules and communication preferences, and keeps everybody informed about the status of project tasks and encourages instant feedback.
I	Setting up a communication time schedule requires time, effort, cooperation and goodwill of team members, so that it is adhered to and beneficial; the more parties and localizations the more difficult it becomes; it should be agreed upon during the project kick-off meeting, accompanied by a clear message of its goal and instructions of realization; using such tools as shared calendars and communication matrix can be useful.
RP	*Clear rules at the start*
Project knowledge center	
Cx	Communication in the project team is performed in different ways; many people use e-mail as the primary communication medium, and send various elements of the project documentation this way. Others prefer communication via Instant Messaging (IM) and attaching files to conversations. Still others would rather talk on the phone and deliver files on a pen drive.
Pr	Many elements of the project documentation remain only in mail boxes/computers/pen-drives of individual team members and project knowledge in their heads; different versions of the same documents are created and their subsequent synchronization is very cumbersome; some information is lost or finding it is time-consuming; certain project knowledge is lost when a team member leaves the team.
S	Ensuring a project repository – project knowledge center, where project files are placed, stored and shared; a web portal with a wiki feature, group-work tool or project management software with the file versioning and change tracking functionalities can be used for that purpose; to wean team members from sending project documents as attachments to e-mails, a special function could be embedded in the e-mail program, which would display a message asking the user if the attached file should not rather be placed in the repository, instead of being sent.
Q	Positive on the following communication quality aspects: clearness and cohesion, up-to-date project documentation, adequate level of detail and communication workflow supporting openness. Negative on the following communication quality aspects: in case the repository is unordered and unclear the adequate level of detail, clearness and cohesion are no longer attained.
A	The pattern should be used for any kind of project and team, because even small projects and small teams produce project documentation which should be made available to the team and the cumulated knowledge may prove useful in future projects.
P	All team members producing any kind of project documentation or content; team members are responsible for uploading any project-related documentation in an orderly manner, established upfront or developed in the initial phase of the project realization.
Cq	Ensures a common project documentation reference center available to all team members, taking into account given user access rights, with up-to-date project documentation and orderly history. Project documentation is not hidden in the mail boxes of individual team members and a project knowledge base is being built. Team members do not have to communicate or send specific information separately to all interested parties but just link them to the appropriate place in the project knowledge center.
I	Setting up a project knowledge center requires using appropriate tools and setting certain procedures, so that the repository is easy to use and is effective in storing and sharing information; it is usually a software application chosen and used by the project team for many projects. Problems which may arise concern effective organization of the repository and a need for training team members how to use versioning tools. The chosen tool usually requires configuration effort and expertise and some systems are expensive. Sometimes documents sharing between the customer and the developer is not at all possible due to security issues.
RP	-

Diversity of communication means	
Cx	It happens that tools used in the project team impose the way of communication among team members, limiting it mainly to written communication (e.g. to have a permanent evidence of discussions and arrangements). Team members hardly talk to each other personally; this is particularly common in the case of international and distributed teams.
Pr	Focusing mainly on one way of communication, whether oral or written, hampers the implementation of the project, in the first case because of the transience of oral arrangements, in the second case, because of possible problems with understanding the intentions or the lack of instant response. In the case of written real time communication (using IM) the typing speed can be a problem, while for oral communication a poor knowledge of a foreign language can be a barrier.
S	The solution to the problems associated with using mainly one communication means is to promote diversity in the ways of communication, and while preserving the principles of the *Project knowledge center* pattern, emphasize the importance of oral communication, which should support mutual understanding between team members and unite the project team.
Q	Positive on the following communication quality aspects: meeting needs of communicating participants (as some team members are comfortable with written communication, while others need to communicate also orally), guarantee of uniform understanding of the content, redundancy and instant feedback (in case of oral communication). Negative on the following communication quality aspects: in case of excessive diversity, project documentation consistency and cohesion is hard to maintain.
A	The pattern should be used carefully, taking into account the communication culture of the project team, level of project language knowledge of team members and security issues (some communication tools may be considered as not secure).
P	All team members, and especially the project manager should take into account personal predispositions of each member to avoid forcing them to use communication means which they are not comfortable with.
Cq	Diversity of communication, on the one hand enriches and facilitates communication among team members, but on the other hand, if not appropriately managed, may cause communication chaos, with some information being lost in oral conversations or time wasted during too frequent and ineffective meetings.
I	The written form of communication, especially the part concerning communicating project results and producing project documentation, should be arranged at the beginning and organized into effective and easy to understand and follow procedures, which should be realized by all team members (see *Clear rules at the start* pattern). One of the most effective oral communication means are stand-up meetings, known from the agile project management approach, which are a quick and effective way to find out what is the status of project tasks, who needs help, or who is not working properly. It is also a perfect way for team members to get to know each other. It is however important that the project manager, or leader does not dominate these meetings. In case of dispersed teams video-conference stand-up meetings can be organized. In case of traditional meetings their costs (time, travel) must be taken into account and planned in advance.
RP	*Clear rules at the start, Project knowledge center*

C. Strategic Communication Management Patterns

Another three communication management patterns have been defined within the strategic category: Clear rules at the start, Cultural and language competencies and Client's power scope. These patterns were also acknowledged and used by most of the surveyed practitioners, although Cultural and language competencies pattern was not used by more than one third of them because their project teams were not culturally or linguistically diverse. Others argued that both Clear rules at the start, as well as Client's power scope, are part of the communication plan and need not to be separately described, but that is the role of patterns to highlight specific problematic areas to which solutions are proposed – in the case of Clear rules at the start pattern, preparing a high-quality communication plan is actually the suggested solution.

Table II provides an overview of the three project communication management patterns from the strategic communication management practice category.

TABLE II.
COMMUNICATION MANAGEMENT PATTERNS WITHIN THE STRATEGIC CATEGORY

Clear rules at the start	
Cx	It sometimes happens that while planning various aspects of the project (project tasks, responsible team members, schedule and budget), the area of communication and documentation management is neglected. There is no regular contact with the client to inform them about the progress of the project and for keeping in touch for quick reaction to possible changes and new requirements. If there are no assigned tasks and people associated with the management and implementation of communication, nobody will take care of it.
Pr	There are no designated persons and tasks related to planning and managing communication and documentation processes. Team members feel no need to communicate the status of their tasks, nor do they feel responsible for informing the client about the status of the project.
S	Development of a clear, practical and high-quality communication plan with assigned persons responsible for communication management, description of communication and documentation tasks – the ones to be carried out by specific individuals and those which are the responsibility of all members of the project team. In the case of distributed teams, it is particularly important to include the *Communication schedule* pattern. In the case of various language speaking teams, a common project communication language should be established.
Q	Positive on the following communication quality aspects: meeting needs of communicating participants. Negative on the following communication quality aspects: in case of excessive formalism and bureaucracy participants may be discouraged to communicate effectively.
A	The pattern should be used for any kind of project and team, although it is especially useful for teams with different working cultures and fixed price projects.

P	Every project stakeholder should be included in the communication plan. All persons assigned to any communication and documentation tasks should be clearly informed of their responsibilities at the beginning of the project realization.
Cq	Ensures that all team members and project stakeholders know their communication and documentation responsibilities. Client is instantly informed about the status of the project tasks. It is, however, important to let the communication plan evolve and alter throughout the project, to make it better tailored to the given project and team.
I	Preparing a high-quality communication plan requires time and effort, so that it is then easy to realize and not burdensome for the project team; too much formalism may discourage the team; the communication plan should be communicated already during the project kick-off meeting, or at least during the initiation phase of the project.
RP	*Communication schedule*
Cultural and language competencies	
Cx	In the case of multicultural teams or teams whose members come from different language areas, difficulties in communication, due to problems with mutual understanding, may appear. This situation may affect the members of one team or members of two collaborating teams (the client's side team and the developer's side team).
Pr	Problem with the lack of cultural and/or language competence of team members, which hinders communication and mutual understanding, and thereby successful realization of the project.
S	Team members should be prepared for the environment in which they are going to work and familiarized with the rules and customs prevailing in the country of other team members. Necessary language skills should also be checked to ensure comfortable communication.
Q	Positive on the following communication quality aspects: clearness and cohesion, meeting needs of communicating participants, guarantee of uniform understanding of the content.
A	The pattern is suitable for teams working in multicultural and international projects.
P	All team members engaged in an international/multicultural project, who are responsible for communication and documentation tasks.
Cq	Culturally and linguistically competent team members facilitate communication and make the internal cooperation easier and more efficient.
I	Having culturally and linguistically competent team members is not always possible or easy to achieve. Learning a foreign language is a long process and getting to know different culture is difficult. If there is at least one competent person in the project team they can train the team. It is also a good idea to promote and use "project culture", which is above local cultures of particular team members. In case of language problems in written communication, such tools as online translators or spell-checkers can be used. For oral communication a linking-person, who can freely communicate with both parties, is a solution.
RP	-
Client's power scope	
Cx	A strategic issue in project implementation is to clarify the scope of power on the client's side. This is particularly necessary in case of problems with precise determination of requirements or their frequent changes. In order to ensure smooth communication between the project team and the client's team, it is important to establish the competence scope.
Pr	The project team does not know who, on the client's side, is responsible for making and communicating decisions concerning the project, as well as who to contact in problematic issues.
S	Project manager must ensure that the client has appointed a person or persons who will be responsible on the client's side for making and communicating decisions throughout the project, and who should be contacted in problematic issues.
Q	Positive on the following communication quality aspects: clearness and cohesion, engaging the right people, communication workflow supporting openness.
A	The pattern is applicable to any team and project, because clear definition of responsibility for making decisions is always desirable.
P	All team members, project manager, client's team.
Cq	Clearly defined responsibility for certain competence areas. Clear decision-making procedure. Clearly defined deadlines for document verification and approval. Effective problem reporting.
I	Client's power scope should be defined at the very beginning of the project realization (communication aspects should be included in the communication plan – *Clear rules at the start* pattern). It is however important to be flexible and ready for negotiations of responsibilities and authorities. It is a good practice to assign representatives on both sides – mutual counterparts. Using the same standards for communication or process templates can also be helpful. Problems in implementing the pattern may arise in the case of dominant position of the client and reluctance to compromise, fear of making decisions, not properly chosen/prepared team on the client's side, conflicts within the client's team.
RP	*Clear rules at the start*

D. Emotional Communication Management Patterns

The emotional category of communication management practices comprises of another three patterns: Fostering direct communication, Visits and team rotations and Appreciating the team. Most of the practitioners, who were surveyed, knew all three patterns and used them in their project teams. One of them was however very sceptic towards the Fostering direct communication pattern, claiming that the pattern should actually be quite the contrary, because people tend to waste a lot of time on unproductive and ineffective talks and meetings.

The above mentioned patterns from the emotional communication management practice category are described in table III.

TABLE III.
COMMUNICATION MANAGEMENT PATTERNS WITHIN THE EMOTIONAL CATEGORY

Fostering direct communication	
Cx	Absorbed in work and rushed by deadlines, project team members often do not have time for direct talks with each other or with team members on the client's side. It also happens that the management restricts such direct contacts (chats in the hallway or through IM), treating it as a waste of time and delaying tasks.
Pr	Team members are alienated and feel discomfort associated with inability to satisfy human needs, these associated with direct contact with another person. Such reduction of direct communication restrains the team from uniting, understanding each other's needs and hinders comprehension.
S	Project manager should promote direct communication between team members, as well as with members of the team on the client's side. This may be achieved in various ways, through the use of *Communication schedule* pattern that takes into account the direct methods of communication (in the case of distributed teams, at least audio- or videoconferencing), through the use of social networking tools ("virtual water cooler"), where team members could talk informally, and through regular project meetings (stand-up meetings, reviews).
Q	Positive on the following communication quality aspects: meeting needs of communicating participants, guarantee of uniform understanding of the content, communication workflow supporting openness, redundancy, feedback.
A	The pattern should be used for any kind of project and team, although in the case of distributed teams "direct" usually means audio or videoconferences, as face-to-face meetings are costly and time-consuming.
P	All project team members should be able to take advantage of this pattern, although project manager should track the impact of direct communication on project performance.
Cq	May prove very beneficial to the project and the team if properly used; both formal and informal direct communication fosters better mutual understanding, team uniting, issues resolving. It must be however properly managed and monitored to prevent team members from wasting too much time and delaying realization of tasks – this mainly concerns poorly prepared meetings.
I	As far as formal communication is concerned, stand-up meetings can bring much profit, because they convey both information and emotions and let the team get to know each other better. Informal communication can be supported by social networking tools, informal chat-rooms or a common meeting room (in case of local teams). Use of the *Visits and team rotations* pattern is also a method of fostering direct communication and letting different team members get to know each other. Access to direct communication should also be made easy by supporting a list of team members' phone numbers, IM contact details, etc.
RP	*Communication schedule, Visits and team rotations, Diversity of communication means*
Visits and team rotations	
Cx	A very important aspect in project realization is the mutual trust and understanding of team members. If the direct contact of the contractor's team with the client's team is limited to the kick-off meeting and a few other project meetings, then it is hard to achieve.
Pr	Lack of trust and willingness to communicate within the project team, because of the lack of direct contact and familiarity of team members.
S	A possible way to solve this problem are regular visits of individual team members at the client's/contractor's site, as well as delegating a team member to the client's/contractor's site to facilitate communication. In the latter solution, rotation can also be used, so that different team members can get to know each other, and thus break the communication barrier.
Q	Positive on the following communication quality aspects: meeting needs of communicating participants, communication workflow supporting openness, feedback.
A	The pattern is suitable for certain projects and environments, because usually a single team member has too scarce knowledge of the project and sending the whole team is neither possible nor effective; beneficial mostly in big projects with distributed teams.
P	Only willing team members should be chosen for delegation to other locations, to avoid discontent and frustration experienced by people forced to leave their home city and family for a longer period of time. Shorter visits should be realized by all key team members.
Cq	Building non-professional relations among team members fosters effective and direct communication (relation with *Fostering direct communication* pattern). Delegated team members facilitate communication between the client's team and the contractor's team.
I	Realization of the pattern should be preceded by an analysis of predispositions and willingness of individual team members to delegations, so that appropriate plan of visits and team rotation can be developed and included in the budget. In reasonable circumstances bonuses or family delegations can be offered.
RP	*Fostering direct communication*
Appreciating the team	
Cx	In the course of project realization team members notice errors or possibilities for better solutions to various problems. However they do not always have the opportunity to express their views, to give advice or share opinions, or they do not know how and where it can be done. With some team members this may cause frustration and decrease motivation, others may not care about it, but the failure to take their opinions into account may prove to be unfavorable for the project.
Pr	The project management does not enable team members to share opinions, to formulate proposals or comments related to the implementation of the project. They cannot express their feelings, thoughts and remarks, and feel unappreciated and their motivation to work decreases.
S	Encouraging team members to share their thoughts, remarks and opinions. This can be achieved, inter alia, by reserving a project portal section for this purpose. This section can also be used by the project management to formulate requests for support and advice, which would give the team a sense of appreciation of their value and trust.
Q	Positive on the following communication quality aspects: meeting needs of communicating participants, communication workflow supporting openness, feedback.

A	The pattern is applicable to any team and project, because every team member should have an opportunity to share their thoughts and opinions and all team members need to feel appreciated. It is especially beneficial in long-term projects where constant improvement of work quality should take place.
P	All team members should have the opportunity to take advantage of this pattern. Project manager should be open to remarks from the team.
Cq	Appreciated project team is motivated to work towards successful realization of the project; useful remarks and suggestions are collected and may be applied to foster better project development; alarming situations are exposed and appropriate actions can be undertaken.
I	The pattern may be realized in many different ways – devoting time during project meetings for team opinions, remarks, suggestions; reserving a project portal section for this purpose or a thematic mailbox; organizing surveys, retrospection sessions. This pattern is connected with *Clear rules at the start*, *Communication schedule* and *Fostering direct communication* patterns, because all of them strive for letting team members communicate what they want, need or should communicate in a way which is the most suitable for them. The effort of organizing and analyzing surveys, mailboxes, retrospection sessions or portal sections should be included in the budget and schedule plan, to avoid situation that all information is collected in vain.
RP	*Clear rules at the start, Communication schedule, Fostering direct communication*

E. Practical Communication Management Patterns

Within the last, practical category, two more communication management patterns have been identified: Basic communication principles and Synchronous working environments. Only one of the surveyed practitioners has not heard about or used the first pattern, while the second one was recognized by all, but not used by more than one third, as it was deemed suitable mainly for big projects.

In table IV the two remaining patterns from the practical communication management practice category have been depicted.

TABLE IV.
COMMUNICATION MANAGEMENT PATTERNS WITHIN THE PRACTICAL CATEGORY

Basic communication principles	
Cx	This pattern applies to the basic principles, which should be observed by all project team members, and of which they should be aware in order to maintain transparency and positive nature of communication.
Pr	Misunderstandings, hostility or animosity among team members.
S	Reminding team members about the basic principles of transparent, effective and positive communication, and desired behavior, that is, among others: justifying requests, asking rather than telling, keeping promises and showing up for appointments (also virtual ones), writing positive emails (even criticisms and dissatisfaction can be expressed in a positive way); it is also a good practice to set the maximum time for response to an email, to ensure the dynamics of asynchronous communication.
Q	Positive on the following communication quality aspects: clearness and cohesion, meeting needs of communicating participants.
A	The pattern can be used for any kind of project and team, although it is especially useful for immature and inexperienced teams, or where there are many introverts, team members are age or culture diversified.
P	All project team members should communicate obeying the rules presented in this pattern, although for some of them, especially the experienced and mature ones, they may seem obvious.
Cq	Good atmosphere in the team, clear and positive relations among team members and their responsible behavior – all promoting successful project completion.
I	Usually the basic principles of transparent, effective and positive communication is something that every person knows and feels, and it should not be required to state it explicitly, but in the cases mentioned above it may be desired to bring them to the attention of some team members. If possible communication rules should be agreed upon together by the whole team, preferably during the kick-off meeting.
RP	-
Synchronous working environments	
Cx	In certain environments and usually big projects, it is desirable to have similar project setup and roles for better and easier synchronization of communication and work.
Pr	Cooperating teams in different locations greatly differ from each other both in terms of composition and way of working, making it difficult for communication and cooperation between them.
S	Provide a similar composition of the teams and work procedures in all locations in order to facilitate cooperation and communication.
Q	Positive on the following communication quality aspects: engaging the right people.
A	This pattern applies to big and long-term projects carried out by two teams in different locations – the client's and the contractor's team.
P	Team members playing similar roles in both teams.
Cq	Synchronized working environments on the client's and contractor's side, with defined roles and responsibilities; easier direct communication due to existence of counterparts.
I	Defining a process with roles definition, responsibilities, authorities and templates could be used to set up the synchronous working environments of the cooperating teams.
RP	-

V. Conclusion

The eleven project communication management patterns presented in this paper aim at supporting project managers and teams in effective implementation of communication management practices based on a context-problem-solution approach. The four groups they are arranged into address various aspects of project management and types of encountered problems.

There are at least two main future research directions that can enrich the body of knowledge on project communication patterns. The first is to assess implementation conditions, dependencies and effectiveness of the patterns specified in this paper. The second is to look for and identify more common project communication patterns. Both require conducting a more extensive survey among project-based companies.

Acknowledgment

Special thanks to all the professionals from the project management field who devoted their precious time to share their experiences, knowledge and opinions on the topic of communication management patterns in project teams in their companies.

***Abstract*—The operating environment of Small and Medium-sized Enterprises (SMEs) is more uncertain and risky comparing to big enterprises. The SMEs managers often face insufficient funds and lack of domain expertise to undertake important financial decisions. Moreover they are often unaware of opportunities offered by financial institutions. Therefore there is a growing need for intelligent and interactive web-based tools integrating data and providing information from heterogeneous sources, oriented on risk-detection and decision support for small and medium enterprises. In this paper the semantic Web services platform has been proposed, which integrates the internal data from the company's databases and external Web resources to perform dynamic evaluation of the financial position of enterprise. The designed platform detects signals indicating the need for action, and it composes a process choosing available Web services aiming at improving the company's financial situation.**

COMPETITIVE challenges on a global market require decision makers of small and medium enterprises (SMEs) to have up-to-date and relevant knowledge of the economic situation of the company and its environment. Managers must have the possibility to identify and analyze all indicators that may have impact on the operations of the enterprise and moreover they have to react to market changes and take the appropriate actions. In a world teeming with overwhelming amount of data accessible by the World Wide Web analyzing information becomes very difficult. Discovering and understanding all dependences between various financial ratios while taking into account economic trends is crucial because they alert one to anomalies and threats [1].

Unfortunately, many of the managers of the SMEs lack expertise or meaningful experience in financial domain as well as the potentials the Web services can bring to the business. Furthermore, SMEs operate in a definitely more uncertain and risky environment than big enterprises. A complex and dynamic market changes have much more impact on SMEs' financial situation than on big companies. Tolerance of mistakes is narrower [2], [3]. Usually financial expertise is either not available or too expensive for the managers of SMEs. Big companies, in contrast, have at their disposal strategic consultation and elaborated procedures to solve problems. The SMEs cannot achieve this level of expertise due to the lack of skilled personnel and financial resources. The decision makers often act intuitively so the rationality of their decisions may be questionable. Especially in exceptional and unusual cases intuition alone can be unreliable [4]. According to Dane and Pratt [5], the effectiveness of intuitive decision-making depends on the decision-maker's level of expertise on the subject at hand.

Therefore there is a growing need for intelligent and interactive Web-based tools integrating data and providing information from heterogeneous sources, oriented on risk-detection and decision support.

The diversity of solutions and opportunities in the field of integrating data from many sources have grown with the emergence of the semantic Web services which on the one hand provide intelligent search capabilities and on the other, they offer business process automation. The semantic Web shares many goals and issues with Decision Support Systems (DSS), e.g., being able to precisely interpret data, in order to deliver relevant, reliable and accurate information to a manager. Semantic Web technologies have been used in DSS during the past decade to solve a number of different tasks, such as information integration, sharing, Web service annotation, discovery, knowledge representation and reasoning [6].

There are a lot of publications discussing technical issues and challenges in this field. However a relatively small number of literature describes the subject from the managerial point of view, particularly: how to use Web services in an innovative way to improve the agility and efficiency of business processes and how this technology can be used to bring competitive advantage for the SMEs..

In this paper the semantic Web services platform has been proposed, which integrates the internal data from the company's databases and external Web resources to detect signals (factor changes) indicating the need for decision action, then it composes a process of available Web services aiming at improving the company's financial situation.

The work contributes to the domain of early warning systems and decision support systems.

The structure of the paper is as follows. Section 2 presents a brief state of the art of the domain of Web services and financial early warning systems. Section 3 explains the advantages of semantic Web services comparing to traditional approach. In the section 4 the components of the Web services-based platform for decision support are presented. In order

to illustrate the idea of using Web services in a business process an example of financial decision-support system is presented in the section 5. In the example, a part of early warning system and financial ontology will be integrated into semantically rich business processes.

I. Overview of the literature

Semantic Web services (SWS) have been extensively discussed in the literature in many contexts [7], [8]. The theoretical benefits of semantics as well as their potential impact on operational management are well known concepts. Semantic Web solutions integrated with the company's IT systems may support managers in composing the instances of business processes. However the automation is usually possible in streamlined processes with limited number of alternative flows.

In the research related to Web services, several platforms and languages have been presented that allow easy integration of heterogeneous systems. In particular Universal Description, Discovery, and Integration (UDDI) [9], Web Services Description Language (WSDL) [10], Simple Object Access Protocol (SOAP) [11] and REST [12], which define standard ways for service discovery, description and invocation. There are other initiatives such as Business Process Execution Language for Web Service (BPEL4WS) [13] and DAML-S Service Model [14] that are focused on service compositions where a flow of a process is known a priori.

There is a growing consensus that simple functional descriptions of Web services are not sufficient to develop intelligent and dynamic processes, characterized by the high degree of heterogeneity, autonomy, and distribution of service providers on the Web [15]. Due to the increasing availability of Web services that offer similar functionalities with different characteristics there is a need for more sophisticated discovery processes to match user requests [16].

The key issue to address is modeling of composition of Web Services, which should be integrated into real business processes. The focus is on the activities of discovery and selection that are required to identify the relevant Web services and to include them in a business process [17]. The idea is that a number of SWSs can meet some basic requirements specified by a manager. Then, the manager needs to be supported in choosing which one of the above SWSs better fulfills his needs. The selection and invocation of the best (according to a set of criteria) service can be automatic, or left to the discretion of a human requester [18].

Ontologies are increasingly used in describing complex data, processes and services on the Web. Here the concept of using semantics to support decision making has been proposed with particular emphasis on early warning models. There are a lot of methods and techniques of early warning and warning forecasting models that can be used by the managers of SMEs. The choice of the method is an open question because there is no synthetic indicator that would aptly describe the financial condition of the company. The prospecting works illustrate models of [19]: E.I. Altman, M. Tamari, R.J. Taffler, M. Blum, S. Appetiti, R. Edminster, E.B. Deakin, M. Zmijewski, W. H. Beaver.

Most of the aforementioned methods generate a warning signal informing mainly about threats inside the company, but also about unnoticed opportunities for further development of the company. Therefore it can be a single information or a set of information thanks to which one can predict future threats in the firm's development.

Currently organizations have a growing need for intelligent systems that can assist managers by gathering and analyzing information, making recommendations, supporting business decisions, and implementing business workflows [20]. Therefore interoperability and transparency of the technology are very important, so the managers could concentrate on the substantial aspects of the decision making process.

As the surveys conducted in different countries show [21], [22], [23], many managers of small businesses do not have grounded financial knowledge, many of them are self-taught, learn from an accountant, a consultant, or a bookkeeper. Today many important financial services companies use Web APIs to offer their customers, their staff, and their business partners new tools that streamline operations. Therefore it is possible to harness the exposed Web services to compose a process or a few variants of processes that fulfill the company's current needs. The proposition presented hereby is based on ontologies as the means of knowledge representation and interpretation of current company's financial situation. The possible actions that can be taken are suggested on the base of accessible financial Web Services. The services can be dynamically composed into the company's processes.

The next section presents the advantages of using semantic Web services in contrast to the traditional Web services approach.

II. From traditional to semantic web services

In traditional scenario Web services initially composed by the developer using Business Process Execution Language for Web Service (BPEL). Currently, the services are discovered by matching the service request parameters to the predefined keywords in service descriptions. This means that the process is known a-priori without any possibility to choose the best from some alternative process flows.

Semantic Web services are discovered by high level match-making techniques [24], whereas non-semantic Web services discovery methods use information retrieval techniques [25] based on keyword matching.

The traditional solution has serious limitations due to natural language descriptions, which may or may not be available and their analysis requires human intervention. The service publishers sometimes leave the service descriptions blank in the UDDI registries. In such a case even keyword matching based approach does not work.

To address the syntactical limitations of business processes and services the semantic enhancement of Web services descriptions with ontologies can be a solution. Semantic Web services enable a dynamic composition of Web services. In this case, Web services are composed at run-time: the participants of a composite Web service are discovered

dynamically based on a variety of concerns: availability, load-balancing, cost, quality of service (QoS), etc. [26 p.251].

According to a definition by Moreau et al. [27] Semantic Discovery is the process of discovering services capable of meaningful interactions, even though the languages or structures, of their descriptions may be different. Moreover, since ontologies and Web services are developed independently the service request and advertisement can be annotated with multiple ontologies, thus facilitating better efficiency [28].

In the Web services based DSS complex scenario, it is difficult to find specific Web services to meet the requirements of the decision makers. The situation becomes even more complicated when there is no single Web service which could satisfy all of the requirements but it can only be achieved with a combination of several Web services [29].

Many business applications are built on the base of different Web services available on the Internet. These applications are highly dependent on discovering relevant and efficient web service. The discovered Web service must match with the input, output, preconditions, effects and service quality parameters specified by the user. Modeling of composition of Web services is based on algorithms for comparing available services with identified business process requirements.

Web services developed by different vendors are usually published on the Internet using Universal Description, Discovery and Integration (UDDI) [30] which are XML-based registers of services. Search in UDDI is based on keyword matching which is not efficient as huge number of Web services may match a keyword and it is difficult to find the right one. Modern approaches take advantage of semantic Web concept where Web service matching is done using ontologies. Discovering Web services automatically without manual work is an important concern [31].

Web services can be developed using different protocols, and tools. The chosen standard implies the way the service can be discovered and invoked. There are several application programming interface (API) standards in use, of which the most current is Representational State Transfer (REST) [12]. REST is a network architecture paradigm relying on standard transport protocols like HTTP, without the use of an additional messaging layer. A service call is handled via its URI. "REST provides a set of architectural constraints that, when applied as a whole, emphasizes scalability of component interactions, generality of interfaces, independent deployment of components, and intermediary components to reduce interaction latency, enforce security, and encapsulate legacy systems" [32]. Services developed in accordance with the REST paradigm are often called RESTful services. The World Wide Web is the key example of the REST design.

REST has a lower barrier to entry versus other approaches such as SOAP, RPC or CORBA. As a programming approach, REST is a lightweight alternative to the aforementioned solutions in terms of complexity of coding. Another advantage is good performance and simplicity of HTTP used to make calls between machines. A single URL is enough to call a service and the HTTP reply is the raw result data — not embedded inside any code so it can be directly used without the need of parsing. Moreover the RESTful services can be invoked using a Web browser alone so it is easy to write and test applications.

However there is no standard way to publish and discover REST services (such as Web Services Description Language (WSDL) in SOAP approach where all the service descriptions are stored in a centralized UDDI registry). Many attempts were made in order to resolve this issue (the popular ones are WADL and RAML projects), but none of them has been commonly accepted by the community of REST developers. Therefore there is a challenge of adding semantics to the RESTful services [33] and it is still an active field of research and development.

Companies can benefit from exploiting semantic Web services in many aspects of their business. On the strategic level, the SWS give the possibility to build highly maintainable applications and profit from a loosely coupled architecture which facilitates the cooperation between the company and its business partners. On a tactical level, a company may reuse the ontologies that have been created for SWS in the other areas such as knowledge management and Business Intelligence. On the operational level the company can benefit from streamlined operations and data integration.

III. Components of the platform for supporting financial decision-making

The World Wide Web allows managers to access the information from the large database repositories globally. In general the information can be used to reduce the risk of financial decisions. The large amount of information (some examples are provided later in Table II) and diversity of structures of data sources make it difficult to find the right information, therefore semantic Web technologies are crucial to improve the efficiency of discovery, automation, integration and reuse of data. Semantic Web technologies also provide support for interoperability problem which cannot be resolved with Web technologies of the previous generation.

The overall framework of the semantic Web services-based decision support system can be schematically illustrated on Figure 1. The source of information for business processes are transactional systems such as ERP, data warehouses, BI and the environment of the company. The external information is imported into the system by the means of Web services, which are dynamically discovered on the Internet according to the criteria defined in the business process models. The information from the internal and external sources is combined and presented to the manager to support the decision making process and to suggest alternatives for the decision maker to consider.

However the broad scope of Web services and opportunities offered by Web financial platforms creates a possibility to automate the process of consulting and decision making. The schema of the process of decision making is presented on figure 2.

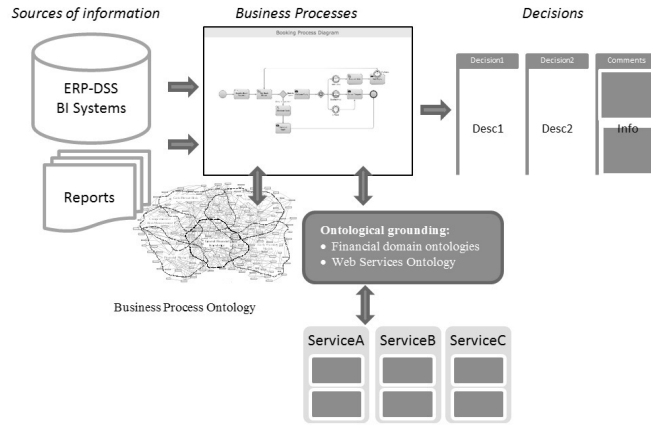

Fig. 1 Functional components of the platform

The process depicted above is written in human-readable BPMN syntax, but it can be translated into an executable BPEL process. That is not simple because of conceptual mismatch between the two process modeling languages which differ in their expressive power [34].

Some of the activities in the process can be executed automatically by discovering, selecting and invoking a proper Web service. This steps in the process diagram are marked with the sprocket icon (in BPMN) which means automation by calling the Web service (or set of Web services) that are able to perform an action predefined in the diagram.

The request for the financial data for the analysis can call the services which pull out the data from the enterprise systems and external Web services that provide data about market (for example stock prices of competitors, annual earnings, prices of products or other financial ratios). The data provided that way can be then used to further analyses and interpretations of KPIs (Key Performance Indicators), which is the next step in the process. Extracting the data from external resources offering RESTful services can be done in multiple ways. There are many existing conceptual models for service descriptions such as: SAWSDL, WSMO-Lite, hRESTS or Swagger.

In order to reduce the amount of manual effort required for finding, combining and using services, it is necessary to provide a common vocabulary. An interesting and well documented approach to provide common semantic model of Web services is the Minimal Service Model (MSM). Driven by the idea of Semantic Web and Linked Data MSM is written in RDFS. The Minimal Service Model defines services as having a number of operations, each of which have input and output messages and faults. Web APIs are also supported through the definitions of URI template, and the HTTP method [35 p.246].

Having the framework for semantic description of Web services the next thing is to build the database of instances referencing to the Web services that can be potentially useful in the financial Decision Support System.

In the case of traditional SOAP-based architectures it is quite easy to find the services because they are described and published in WSDL files which are indexed by popular search engines. The service discovery can be done for example by using Google with the search parameter ".... filetype:wsdl". Also the registers (UDDI) can be used (e.g. SeekDa.com or ServiceFinder) that crawl the Web for WSDL files. However as far there is no straightforward unified way to find RESTful Web services because it is hard to distinguish between URI of RESTful Web service and other Web resources (e.g. Web sites URLs).

The most accurate way to find RESTful services is to browse the web pages of their providers. The well-known global data providers that may offer financial services or economic data that can be used to support managerial decisions are for example: Quandl, Xignite, Bloomberg, online banks and other financial institutions .

The mentioned Minimal Service Model ontology can constitute a data structure for a triple store (RDF database such as Virtuoso) of instances. The advantage of this RDF-based solution is its flexibility and openness for adding new data structures describing new frameworks of services description. Moreover the triple stores offer exhaustive searching capabilities by the possibility to use semantic query languages (e.g. SPARQL).

The next issue is to dynamically embed the selected services into the business process definition.

As it was mentioned before there are a few points in the process flow where the services can be used: to gather data needed for the assessment of the company's financial situation and for suggesting possible alternatives (selected Web services that are relevant) for decision makers.

Because business process descriptions are constructed in their specific modelling languages such as BPMN or BPEL there is a need to do semantic mapping between the process descriptions and the services from the RDF database. For example the REST URL to get StockQuotes of 5 companies (Microsoft, Inter Corporation, SODR Gold Trust, Silver Wheaton Corp Common Shares and MarkWest Energy Partners) may be the following:

```
https://www.westwind.com/West-
WindWebToolkit/Samples/Rest/StockSer-
vice.ashx?Method=GetStockQuotes&symbol-
List=msft,intc,gld,slw,mwe
```

As it can be seen there are some terms in the URL that can be ambiguous for automatic recognition and mapping to the terms used in the business process model. For example in business process model an activity could be named: "Compare the stock prices of the competitors". This is compound activity that should invoke a few services to provide required data. The above REST request on stock quotes of 5 companies could be used. So there is a need to "know" that GetStockQuotes is one of the tasks in the considered activity.

Also the abbreviations of the companies' names can be ambiguous (there can be full names used in the process model) so there is a need to provide a dictionary / thesauri of the names and abbreviations. The components of the proposed solution are illustrated on Fig. 3.

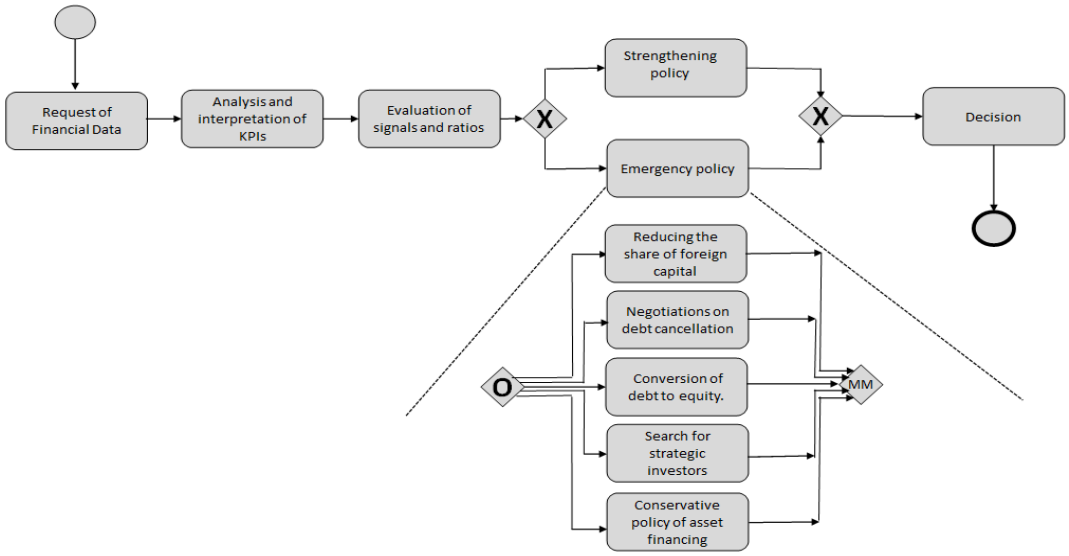

Fig. 2 The BPMN diagram of the process of financial decision-making

Irrespectively of the approach chosen (RESTful or SOAP-based Web services) the functioning of the platform can be described in the following steps:

1. The manager defines goal and requested QoS parameters
2. The system checks for available services (exposed by B2B partners, administration institutions, banks etc.). The ontology is used to identify the services that are relevant to the manager's request.
3. The SWS system extracts data about the user from IT Systems.

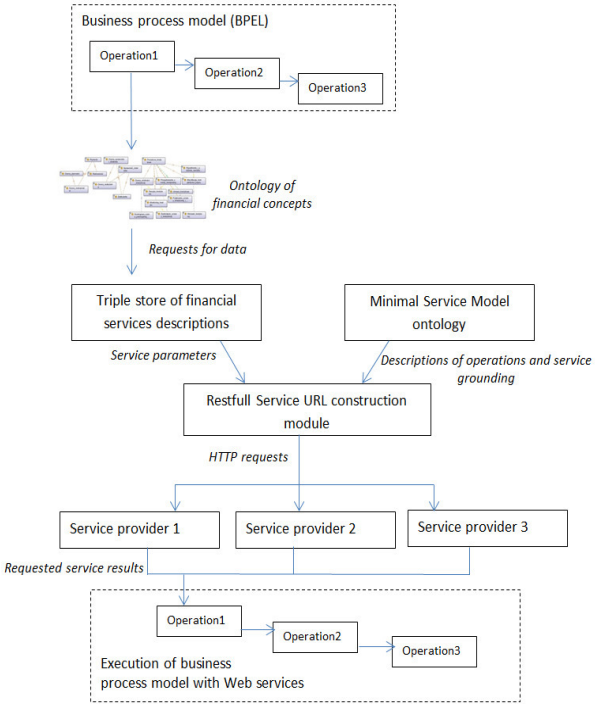

Fig. 3 The platform components with data flow

4. Reasoning capabilities are used to rate the services. In this step the user's profile and requirements are considered.
5. Highest rated services are chosen and are recommended for the manager.
6. The user receives offers ordered by their ratings.
7. The user can decide on the best way to perform a process. The manager can refer to the financial ontology at any time there is a need for additional explanations.
8. The corrections to the ontology can be made on the base of the manager's feedback.

The set of ontologies describing concepts, relations and functions related to the assessment of economic situation of the company was used. In the example described hereby, particularly the ontology of early warning signals pointing to financial difficulties were taken into account. The ontology facilitates the interpretation of warning signals by the manager. A part of the ontology has been presented on Fig. 2.

While conducting the analysis the manager has access to a domain ontology that includes concepts associated with models and methods of early warning and notions related with data from financial reports. These concepts can be linked with their instances – values in data bases, reports and documents to be used to determine the warning signals . The manager is supported by financial ontology while evaluating economic situation of the enterprise. The ontology helps to interpret the data coming from the ERP system, for example to determine and interpret ROA, ROE and many other ratios. The fragment of this ontology is illustrated on Fig.4.

The business processes depicted as a diagram in the center of Fig. 1 in the real scenario are defined in Business Process Execution Language - BPEL (also WS-BPEL, BPEL4WS) . BPEL provides the possibility to invoke Web services in a predefined sequence. Each business process defined in BPEL can be exposed as a Web service and included into other processes.

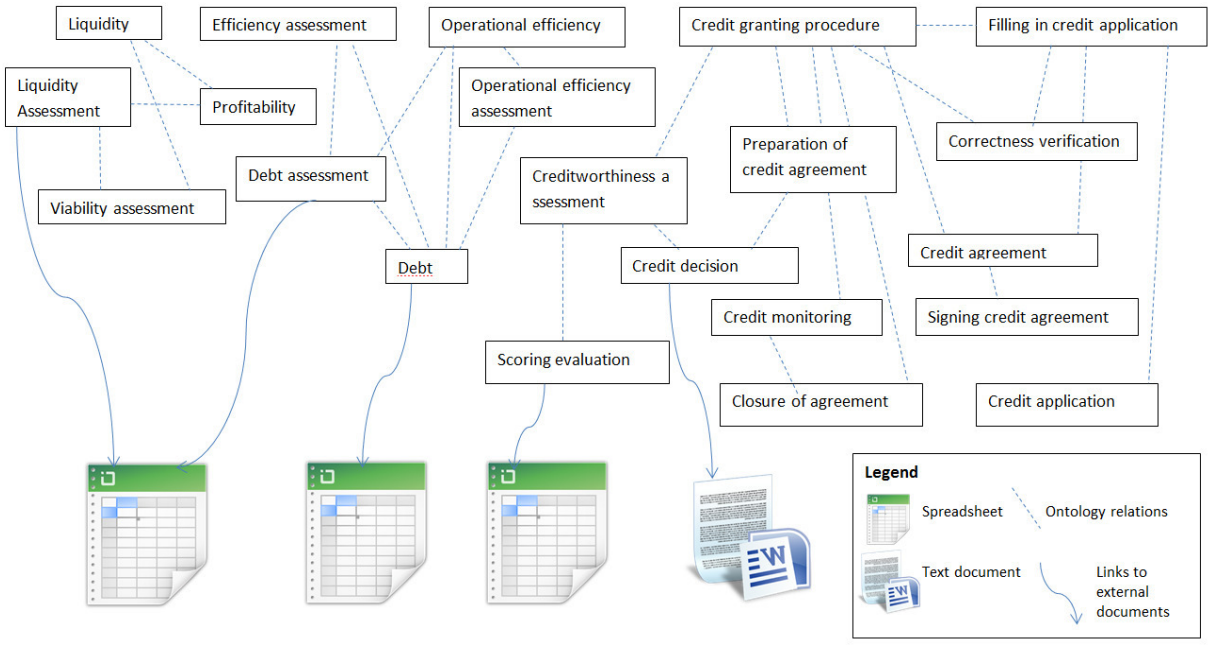

Fig. 4 Fragment of financial ontology with links to external documents

BPEL is using WSDL [36] descriptions to identify partner services, i.e. services are identified by port types and operations in the process models. As a result only services that implement a concrete interface can be used which is a major deficiency of BPEL [37].

Semantic Web Services (SWS) aim at eliminating this deficiency by automation of the development of Web service based applications through the use of ontologies. By providing formal descriptions with well-defined semantics, SWS facilitate the machine interpretation of Web Service – functional and not functional – properties. Significant results in the field of SWS are already available, in terms of reference ontologies, e.g. OWL-S [38] and WSMO [7]. The two ontologies represent different approaches to specify semantic information for Web services in order to enable automatic service discovery, composition and execution.

The OWL Profile ontology contains semantically enriched information about Web service and it is used as both an advertisement for the service and as a request to find a service on the basis of matching semantics. A first significant difference between the two approaches is that OWL-S does not separate what the user wants from what the service provides. In WSMO there is a property referred to as a goal, which specifies what the user wants and the Web service description defines what the service provides through its capability [39].

Common underlying idea behind all the semantic approaches is the dynamic selection, composition and mediation - on the basis of available semantic descriptions – of the most adequate Web resources (services and data) to accomplish the specified processes [40]. Current research efforts are investigating how SWS can be effectively applied in real world business scenarios and integrated with enterprise information systems.

It is easy to see the benefits of semantics in many application areas. For example in financial domain, a major area of financial business is the provision, selling, and management of mortgages. This is a compelling business: the provider (i.e. the bank) earns money by selling a mortgage contract, and the client is naturally interested in the cheapest offer that suites his needs. Usually, clients consider several offers and compare these in detail with respect to the monetary amount in question. For example, if several banks provide their mortgage offers via semantically described Web services, we can easily imagine an application that compares the offers and automatically selects the one which is most suitable for the customer's needs [7 p.168].

IV. Example Scenario of Financial Decision-Making

Semantic Web services can be used in many ways in an enterprise architecture, the most typical examples include supply chain management and business integration among multitude applications. One of the main advantages of SWSs is their reusability. The composition of new services by dynamically invoking the existing SWSs creates the possibility to perform very complex tasks in business processes. However, in this section the simple example of early warning system was chosen to illustrate the concept of semantic Web services integration with business processes.

The financial signals are the most popular and the broader group of quantifiable signals. They are generated on the basis of deviations from desired single values (or groups of values) of financial parameters or ratios. Selected warning signals designated on the basis of specific financial parameters are presented in Table I. It should be noted that these are example signals and their interpretation related to different areas of finances.

TABLE I.
EXAMPLE CRITERIA OF ASSESSMENT OF FINANCIAL CONDITION OF THE ENTERPRISE

Ratio	Evaluation criteria		
	Good	Average	Bad
Asset Turnover	>.40	.25 - .40	<.25
Current Ratio	>1.5	1.0 -1.5	<1.0
Debt to Asset	<.30	.30 - .50	>.60
Operating Expense	<.65	.65 - .80	>.80
Operating Profit Margin	>.15	.05 - .15	<.05
Return on Assets	>.10	.50 - .40	<.05

To illustrate, the case study concentrates on the values of ratios which indicate bad situation of the company. Moreover, it has to be stressed that during the analysis of the financial situation of the company many other ratios can be used. It is easier to determine potential problem areas when industry benchmarks are available, they can be provided by many Web portals (such as: finance.google.com, finance.yahoo.com, bizminer.com, bizstats.com).

The rank of generated warning signals can differ. Let us consider the case of using semantic services related to so called strong warning signal in the area of funding structure. This signal means high probability of financial difficulties resulting i.e. in bankruptcy.

To solve the problem the manager should take appropriate decisions associated with:

- reducing third party equity,
- negotiations on the cancellation of debt,
- the debt-to-equity swap,
- searching for strategic investors.
- conservative policy of financing current assets.

Currently financial advisory consultants offer their services to address the aforementioned problems. Their work is to find and suggest solutions and the best alternatives.

As it was mentioned before, Web services can be implemented also for taking actions as the response to the early warning signals and to put into practice the emergency policy. Ontology of financial knowledge is the foundation of the described platform. The comprehensive financial ontology takes on the role of the consultant – on the one hand it helps the manager to take decisions by improving the efficiency of analysis and increasing the capacity of understanding of financial data, and on the other hand it is needed for automatic discovery and selection of proper Web services which provide the managers with current data and financial services.

The activities included in the emergency policy are defined in the financial ontology. For example the warning signals may suggest negotiations on debt cancellation or reduction. The activities aiming at this goal may include looking for debt consolidation loans, so the system may find Web services of banks that offer debt consolidation loans and send requests to the banks' Web APIs. The requests would include parameters such as the amount of the company's debts and the deadlines of payment. Then the system can choose the best offers of banks, present them to the manager. After the manager's decision the system sends needed information to the selected bank to make finance agreement.

It is worth noticing that the aforementioned suggested actions would have strategic implications if implemented, so the decision to a high degree depends on how the given company views and solves important issues. There are many behavioral issues (such as risk aversion of the managers) that influence the choice of strategic actions. These issues cannot be resolved automatically, but the role of the proposed system is to present alternative ways of action.

The operations management problems are more relevant for automatic (or semi-automatic) handling, so the usability of the proposed system can be illustrated. The example of such problem can be liquidity analysis. The term refers to an enterprise's state of financial health. Liquidity is the ability of an organization to meet its short-term financial obligations. This issue is a major source of concern for small and medium business managers as bank loans are becoming too expensive to maintain.

Liquidity management encompasses the management of cash balances, including short-term funding and investments for excess cash. The alternatives for raising cash during temporary shortages and the opportunities to invest excess cash on a short-term basis are important to the functioning of an organization [41].

In the early-warning system the data for calculating liquidity ratios (ie. current ratio) are taken from financial statements such as: balance sheet, income statement and the statement of cash flow.

Early warning systems can spot liquidity risks by looking at both historical and projected financials. A low liquidity ratio could signal the company is suffering financial troubles.

However, a very high liquidity ratio isn't good either; it may indicate that the company is too focused on liquidity to the detriment of efficiently utilizing capital to grow and expand its business. According to the calculated values of the liquidity ratios the appropriate actions can be suggested by the system. A company can improve its liquidity ratios by raising the value of its current assets, reducing current liabil-

TABLE II.
EXAMPLES OF WEBSITES OFFERING RESTFUL WEB SERVICES IN FINANCIAL DOMAIN

URL	Description
http://www.bloomberg.com/company/	The established service provides free, unrestricted access to raw data for customers for its financial market information. The same publish/subscribe and request/response interactions available via its proprietary interface can be accessed via API. This functionality gives access to data on current market trades, either real-time or delayed, along with reference data on reference data, historical information, and records of intraday trading.
http://www.gaincapital.com/liquidity-api-trading.shtml	Capital offers a full range of CFD markets including indices, commodities, FX, bonds, interest rates and equities
https://angel.co/	AngelList is a community of startups and investors with the goal of making fund raising efficient. Angel investors are listed along with contact information which startups can use to set up introductions. The AngelList API provides developers with a RESTful interface to the AngelList data set. Data includes followers, reviews, startups and more. Responses are formatted in JSON and JSONP.
https://api.mattermark.com/	The Mattermark REST API allows to query expansive dataset of companies. It gives access to all data available by website interface, as well as the time series data about companies. It offers access to companies' profiles, investors and funding events.
https://www.lendingclub.com/developers/api-overview.action	Offers REST API for services such as: personal and business loans and investing.

ities by paying off debt, or negotiating delayed payments to creditors. There are many solutions for resolving liquidity problem that can be suggested by the system and appropriate Web services can be found.

The procedure of the system's functioning contains the following steps:

a) an overall assessment of the firm's financial condition,

b) referring to the financial early-warning ontology to find possible corrective and preventive actions,

c) browsing available and relevant Web services to find sources of financing (such as: credits, new investors, business angels etc.),

d) analysis of risk and costs of the alternatives,

e) presenting the simulations to the manager,

f) successive, iterative searching of the alternatives of the highest efficiency.

Over the last few years, RESTful Web services have become popular due to their simplicity in publishing and consuming Web resources and better alignment with modern Web applications. The examples of sites offering Web services in financial domain are presented in Table II.

The proposed solution for supporting financial decision making by exploiting Web services works in the Web environment and can also be exposed as a compound sem-antic Web service (i.e. in the cloud). The main challenge in building the platform is to find and provide the relevant Web services from many providers which could be useful in financial decision making. It is also very important to maintain and update the base whenever there are important changes brought by the service providers considering the service parameters and when new services and providers appear on the market.

The second challenge is semantic description of the Web services which on one hand should be matched with the concepts from financial ontology and on the other hand their technical details, input and output and parameters should be identified and described semantically.

It is worth to notice that there are attempts to unify access to Web Services particularly facing the problem of the lack of the registers of RESTful services. The solutions (for example iServe [42] are not domain-oriented and do not offer ontological support for matching the services with business process models. There is no Web platform that would offer a full range of specific services for supporting managers in taking financial decisions. There are many applications, which let managers to monitor financial KPIs and visualize them in the form of manager's cockpit. The detailed review of the solutions was presented in [43]. Although many functions were offered, none of them was integrated with external web services to support managers in taking actions by suggesting specific services offered by banks and other financial institutions.

V. CONCLUSION

Web services are currently a preferred way to architect and provide complex services, there are many technical considerations in the literature regarding this field and many competing standards arise. The usability and efficiency of the proposed platform to a large degree depends on available Web services exposed by financial institutions therefore there is a challenge of integrating services from many providers, where the semantic Web technology can help.

There are several limitations while using financial measures, which can be addressed by semantic Web services. Financial ratios highlight the situation of the enterprise but their interpretation is needed to give answers to problems. Financial ontologies can be valuable source of expertise for managers in this field. The measures of the economic condition of the company are as accurate as the data used to calculate them. Semantic Web services offered by trusted companies can provide data of good quality that can be used for industry-specific benchmarks.

At the moment, the development of the described platform is on its first, conceptual stage. Although, it should be noted that some ontologies have already been elaborated and applied in the area of early warning and decision support system InKoM [44]. Ontologies build with one purpose in mind, such as early warning system, can be reused in other areas because the knowledge codified this way is independent of technical solutions.

The main challenge and future work direction in the described approach is the segmental breakdown of financial policies and procedures into granular steps that can be performed by relevant Web services. Current work is also directed towards finding the most efficient solution for the Web services discovery and specification.

ACKNOWLEDGMENT

First of all I would like to express my gratitude to Jerzy Korczak, Wroclaw University of Economics, Poland, for providing access to the financial ontologies developed within the project InKoM and his valuable comments to the draft of the paper. I also thank Bogdan Franczyk, University of Leipzig and Maciej Pondel, Intratic Software Solutions for Business, for comments and suggestions on the technical details of RESTful Web services. I thank Jolanta Chluska, Czestochowa University of Technology, and Piotr Oleksyk Wroclaw University of Economics for consultation on the financial issues.

***Abstract*—One of the contemporary problems, and at the same time a big opportunity, in business networks of supply chains are the issues associated with the vast amounts of data arising there. The data may be utilized by the decision support systems in supply chains; nevertheless, often there are information privacy problems. The supply chains in cloud will need appropriate administration for support of privacy aspects of cooperating business units existing in big data ecosystems. In this paper we analyze the possibility of utilizing the big data technology for supporting business processes optimization with respect of the privacy regulations in supply chains under the usage of the big data analytics lifecycle. We present our approach on an example of a business process in logistics.**

I. Introduction

THE emergence of Big Data is creating significant new opportunities for business to achieve added value and competitive advantage. Nevertheless the huge volume of data, the complexity of new data types and structures and the speed of new data creation cause problems in utilizing it in established business solutions like SCM Supply Chain Management [1] to attain the competitive advantages. From the business point of view using Big Data in the viable ways in the logistics requires gradual convergence between the Big Data Analytics Lifecycles process stages on one side and established ways of business process modeling in logistics on the other. What's more the emergence of data deluge and diversity of data types cause problems to be solved in the context of business process modeling. Additionally the security and privacy of data in logistics have to be treated in a way appropriate for business stakeholders.

In the paper we will approach the problem of utilization of vast amounts of data in supply chains with respect of the data privacy issues. We will investigate the big data ecosystem, and the process of big data analytics. We consider the big data analytics process from a supply chain perspective with emphasis on showing the differences between the traditional approach and the approach by using big data. The proposal of the modeling of data as an integration solution for business process management in supply chains networks we have already presented in [2], and [3]. We also have considered the research problems associated with big data utilization in logistics and supply chains design and management in [4]. In this paper we mainly review possible changes in the business processes which result from the above stated requirements and further implications based on big data analytics lifecycle, regarding privacy aspects.

The supply chains define the network that comprehends all the organizations and activities associated with the flow and transformation of goods from the raw material stage, through to the end user, as well as the associated information flow [5]. In the paper we will concentrate on the networked supply chain activities and flow of information.

In the inter-organizational information systems, which link the companies to their suppliers, distributors and customers, a movement of information through electronic links takes place across organizational boundaries, between separately owned organizations. It requires not only the electronic linkage in form of basic electronic data interchange systems (as for purchase orders), but also interactions in complex cash and information management systems or by access to shared technical databases. So the problems with the privacy are very persistent in supply chains contexts.

A business process consists of one or more than one related activities that together respond to a business requirement for an action [5]. The processing steps in a workflow may undertake numerous transformations of data (geographic, technological, linguistic, syntactical and semantic transformations), communication is an important part of the process and (e-) business processes exist within certain environments. In the dynamic business environment, such as networks of venture participants involved in value chains in logistics, where data is forwarded among different enterprises, the appropriate arrangements of privacy aspects are essential.

Therefore, as stated previously, in our paper we will analyze how the big data analytics results can influence the business processes and their privacy aspects. For this aim the rest of the paper is organized as follows.

In Section 2 we characterize the main features of big data, the big data ecosystem elements. In Section 3 we summarize the big data analytics lifecycle process phases, key stakeholders and artifacts. In Section 4 we consider privacy regarded from the perspective of enterprises collaborating in logistics. We also give an example of a business process using big data analytics results in near-real-time in a supply chain. In the example we show how it can support privacy

978-83-60810-90-3/$25.00

from the perspective of enterprises. In the last Section we conclude our work.

II. Big Data

The big scale usage of available and generated data is made possible for organizations owing to cloud computing paradigms, such as Infrastructure as a Service (IaaS), Storage as a Service, which revolutionized the way the computing infrastructures are used [6]. As big data is referred to data that goes beyond the processing capacity of the conventional data base systems. In addition to this aspect that it is big, e.g. a huge number of small transactions, or (continuous) data streams from sensors, mobile devices etc., it may move too fast, or do not fit the structure of traditional (i.e., relational) database architectures.

According to [7] when we denote a big amount of data as "big data" it has to cover the three "Vs" (features) such as: volume, velocity and variety. Another authors (e.g. [8], [9]) add another V-features like value or veracity.

The first feature - volume of big data - denotes its massive character. The big volume of data is beneficial for the data analysts. It may improve the analytics models by having more cases available for forecasts and increase the number of factors to be considered in the models making them more accurate. Nevertheless, the volume feature bears potential challenge for the IT infrastructures to deal with big amounts of data, especially taking into account its second feature – velocity.

The second feature of big data is the velocity in which data flows into organization or the expected response time to the data. Big data may arrive quickly - in real-time, or near real-time. If data arrives too quickly the IT infrastructures of the organization may be not able to respond timely to it, or even to store all of it. Such situations may lead to data inconsistencies [10].

The third feature of big data is the variety of data. Big data may have diverse structures and forms, not falling into the rigid relational structures of SQL databases without loss of information. Some of data may be saved as blobs in inside traditional data bases. Therefore the IT infrastructures for big data are denoted as NoSQL, what means the data is "not only SQL" [9]. Several examples for diverse kinds of data are standard business documents, transactional records, and unstructured data in form of images, recordings, HTML documents (web pages), text messages and email messages, streams from meters and environments sensors, GPS tracks, click streams from Web queries, social media updates, data streams from machines' communication or wearable computing sensors, and many others.

The data deluge possibly useful for enterprises, especially involved in SCM is driven nowadays by many factors like data created by the traditional IT devices, mobile devices, Internet and social network users, GPS systems and sensor nets.

The flood of data comes into existence with the images and videos uploaded in the www, video surveillance in enterprises and cities, medical information recordings, mobile devices of the users (phone calls, text messages, mobile application usage, online games), smart devices (TV sets and receivers, smart private and industry buildings, electric grids), traditional devices (computers, game boxes, video games, e-books, etc.) and non traditional IT devices such as GPS navigation systems, earth data processing devices, radio-frequency identification (RFID) readers, ATMs, credit card readers, sensor nets and Internet of Things.

To each Gigabyte of the collected information the additional Petabyte meta-information is added. All this create a landscape of the emerging big data ecosystem.

The main player in the system are [11] the data devices, data collectors, data aggregators and data users, buyers. The data devices are the above stated originators of data deluge.

The main data collectors include information broker in Internet, the government using analytics services, medical institutions and their appliances, employers.

The marketers and private investigators can act as data aggregators by using the obtained data and transforming and packaging it for diverse stakeholders interested in conducting campaigns for users with high likelihood willing to get or buy a specific service.

The users and buyers of data are financial institutions, retail, phone and TV providers, media archives and so on. They also purchase data from third parties which enables more targeted marketing campaigns.

The collected data can be used for forecasting of the user behavior and suggesting and recommending services for user intended willing to pay for it.

Broadly speaking, the main types of data structures for big data are structured data (the most minor part), semi-structured data (slightly bigger ratio of big data), quasi-structured data (a big part of data) and unstructured data (building the majority of big data). The structured data type are such known from traditional databases and warehouse applications processing (OLAP, RDBMS, spreadsheets). The semi-structured data enables its relative easy parsing (e.g., XML-data files), while the quasi-structured data can be formatted only by using appropriate tools with much effort and possible inconsistencies occurring. On the other hand, the unstructured data does not possess an inherent structure.

III. Big Data Analytics Lifecycle Process

Conducting big data science ventures differs from approaches for projects using SQL data and Business Intelligence BI methods and tools applied for data analysis aims [3]. The approach used for big data is more explorative in its nature as well as there are additional key stakeholders involved in process stages.

The process can be easier handled by dividing it phases with clear defined milestones, involved stakeholder's responsibilities and artifacts. It is according to widely accepted divide and conquer principle in computer science. It does not strictly mean a waterfall process with no returns to the previous phases but the process is a guideline for the development process which is iterative and incremental in its nature.

The process for big data projects can be divided in phases such as [11]:

- Data discovery,
- Data preparation,
- Model planning,
- Model execution,
- Communicating results
- Operationalizing the results.

As mentioned above, several of the phases can be performed simultaneously as a project work. The iterative process in the subsequent phases can proceed forwards or sometimes backward, dependent on the yes/no decision at the milestones, or a deeper insight of the problem not enough realized in the earlier phases. It may include not understanding of the problem domain, stakeholder requirements or insufficient data available to solve the given project problems. First we regard the process stakeholders, then we give a description of the process stages with regard to the stakeholder roles and their important activities and deliverables within the phases.

In each phase there as workflows to fulfill the project aims in each phase and artifacts to be delivered by the project stakeholders.

The key stakeholders roles involved in big data projects [4] and [11] are the:

- Project sponsor,
- Business user,
- Project manager,
- Business intelligence analyst,
- Database administrator,
- Data engineer
- Data scientist.

The project sponsor sets priorities and metrics for the projects and establish the desired project outcomes. The business users as the experts in the business domain can provide guidance to the project requirements recovery and operationalizing the results of the big data analytics and also are those user who directly benefits from the results of the big data project. The project manager ensures the proper project scheduling according to key project's objectives and milestones. The business intelligence analyst is responsible for creating dashboards and reports and have knowledge in proper data feeds and sources. The database administrator is responsible for provision and configuration of the database environment in order to support the analytics needs of the project; he enables the access to the needed databases and data sets and ensures the desired security levels of the data repositories.

The first five roles are good known from the usual software projects, however the roles of data engineer and data scientist are new. The role of the data engineer is needed in context of the usage of analytic sandbox workspace and fulfills the needs of data preparation for data manipulation (extracts, transformation and loading). The data scientist provides expertise needed for accurate application of analytical techniques and enables the right choices for given business problems. We already explained in detail the skills and background of such roles as data engineer and data scientist in our paper [4].

The six stage process for big data analytics project starts with the first, the discovery phase. In this stage where the project team became acquainted with the business domain and accesses the resources needed for conducting the project. The team should familiarize itself with the project data. The accomplishment manner of this phase is dependent of the team experience in the past in similar projects. The main deliverables in this phase include framing of the business problem as an analytics challenge and formulating the initial hypotheses for data analytics.

In the second, the data preparation phase, the team prepares the analytics sandbox with the data required and conducts the ELTL operations (Extract, Load, Transform, Load) on the data in the sandbox workspace [11]. In this phase the team further familiarize with the available data and if required have to decide how to obtain the required, but at the moment not available data. It this phase the usage of technologies like Hadoop [12] may be needed.

In phase three, the model planning phase, the project team needs to decide the usage of the methods, techniques and workflows to be followed in the subsequent phases, especially in the next one. The dependencies between the variables have to be established, the key variables have to chosen and the most appropriate models types have to be selected.

In the next, the model building phase, the models recommend in the previous phase have to be developed and executed together with the appropriate data sets [4]. If the IT project environment will appear not to be sufficient for the project aims, the needed adaptations and hardware platform changes (parallelization or change to faster hardware) have to be fulfilled in this phase.

The fifth phase, which assignment is to communicate results consists of summarizing the project results such as key finding, quantification of business value and communicating the between the project stakeholders. In this phase the project aims success or failure will be decided according to the criteria determined in the first phase.

In the last operationalize phase, the final deliverables of the conducted project will be released in form of presentations, final reports, briefings, code, technical descriptions and documents etc. The form of the documents will be dependent on the recipient stakeholder type. The business value of the project should be conveyed to the key stakeholders. Moreover, after successfully running all the project phases the pilot project implementing the models in the production environment might be launched.

IV. Privacy From The Perspective Of Enterprises

From the perspective of enterprises data protection in business processes can be seen from two different perspectives. The first one is considering the security and privacy of sensitive business data which belongs to the enterprise or its supply chain [13]. It could be enterprises important operational data or the processed data of the customers, which is aggregated while doing own business or won in other man-

ner like big data analytics. From this perspective, where it is enterprises who can fall prey to data leaks, it is vital for them to protect important information which is needed for successful operation or maintaining of a competitive advantage. This situation was recently addressed by several solution frameworks or software platforms which take care for the data exchange and access management in supply chains. We refer to the examples of PREsTiGE platform or Aniketos [14], which organize and manage data access rights in business processes. However, they only treat explicit data and do not provide strategies for management of big data and its analysis.

Other point of view the protection of the privacy of individuals [15], i.e. current or potential clients, employees and other actors whose data is aggregated by enterprises in the course of their business processes. From this perspective – where enterprises are seen as potential benefiter of extrinsic information - the important points are developing and staying compliant with the privacy policy of the enterprise and above all staying in accordance with law in order to make safe both the individuals as well as enterprises.

Governments and several organizations developed regulations, guidelines and proposals for dealing with personal data. These are legal laws, or frame conditions for professional work with personal data.

The European Union's Data Protective Directive is most advanced and restrictive among world's data privacy laws. It contains several points which must be followed by entrepreneurs. In the USA, the Federal Trade Commission proposed a three step framework, consisting of the demands of privacy by design, simplified choice and greater transparency. Other recent development of American administration is Privacy Bill of Rights which includes demands individual control, transparency, respect for context, security, access and accuracy, focused collection, and accountability.

In the literature there are several privacy requirements concepts defined which are proposed for the processes which deal with personally-identifiable information (PII) and are component of the legal regulations. Shown below important hallmarks for dealing with PII in enterprises identified in the literature [16], shall be regarded in the big data applications.

Authorization verifies who has the right to access the data or can use specific activities. In the field of business processes and especially big data it is not an easy task to draw a clear line about such requirements like separation and binding of duties since the data and possible operations on them can be so different in their nature that it is not possible to model every feasible use option. Nevertheless binding of duty can be used for setting additional responsibilities for the data or activity user of the business process. In the same way some actions can be excluded which may help maintaining privacy in the big data field, i.e. by lowering the chances of de-anonymization. Authentication is accountable for the verification if the current user is one of the user authorized for the data or service use. Confidentiality postulates to keep the architecture, process and the whole environment in such state that the data stays protected from all non-authorized actors. Audit-ability is incorporated to that the process can be reviewed for keeping the privacy rights. Data integrity demands that the integrity of the original data has to be preserved after a processing failure. The data has to remain consistent, accurate and correct.

Since the demands regarding PII coming from the law regulations and internal privacy policies are very high therefore the procedures to fulfill them are correspondingly complex. One of the first questions which arise for enterprises is when the aggregated data has to be treated as personally identifiable. This is particularly complicated when big data comes in picture since with the ongoing technology development amounts of various data grow even more rapidly and cannot be thoroughly inspected as fast as they are collected. It demands elaborately designed analysis to assess if the conclusions drawn from the data will fall into the PII category. The technology advances enable easier identifying of specific person with growing amounts of data which only seem to have no correlation. In the end one can never be sure if apparently minor extension of the collected data won't enable the identification of individuals, and possession of such PII could harm the legal laws or cause negative effect on public opinion and therefore on the enterprises reputation.

Further step of this thinking is how the data can be processed that it will not fall in the PII category anymore.

In the next Section we propose the integration of big data analysis in business processes so that privacy will be regarded in everyday work of enterprises.

V. Business Process Modeling Practices For Supply Chains Architectures In Cloud

As stated in the above Section, privacy is an important part to regard in the business processes. While doing business the enterprises must adhere to legal law regulations and must comply with standards set in their own or in branch policies. It is often not apparent and not easily recognizable within standard business process if and when the stored data and usage of has to adhere to the above mentioned standards. It demands special steps within process which can help noticing potentially susceptible usage and unwilled consequences.

When thinking about the steps the first one would be to identify when the process and its data moves into the domain of PII. This could be done thanks to big data analysis, which can be seen a part of business process. Such analysis could be triggered by several stakeholders or events. Secondly if the data is identified as one which falls under the legislative of privacy, then actions must be undertaken in order to desensitize the contents and make it usable for business. Data after such processing must be replaced with the previous data.

It also must be analyzed why and how the data was aggregated to the level which does not comply with the standards and how this can be avoided in the future. It must be noted that the causes can be multifold and shall not be explicitly seen as enterprises misdemeanor, since these are often external circumstances which take the data out of balance. Such

circumstances are sourcing of data with previously not known contents, lack of overview on the available data, lack of thorough analysis of the new data in regard on relations with the already available data, changes in the permissions for the owned data, changes in the regulations and laws. As soon as the causes are known process changes must be made in order to avoid reoccurrence of similar situation in the future.

As an example let consider a web shop which plans to establish new service: delivery within one hour in a big city. The service itself will incorporate live tracking of traffic and weather situation, which will be used for delivery feasibility in the one hour time frame. To offer the service a warehouse will be established in the area which covers the service. The warehouse will be rather small, since in a big city area the costs are high. Because of the warehouse capacity restrictions, the products offered for sale will be studiously chosen. The options for opening other warehouse for better service or its expansion will be analyzed too. The goods shall bring good profit per warehouse area, so they must have high turnover or have a good profit margin. New opportunities for the goods will be continuously searched, i.e. the shop will also analyze their standard delivery shop and look for articles which are often ordered together. They will also review the preferences of the area population in order to offer better article range. The goods have to fit to the transport means (lorry, car, motorbike, cycle, etc.) which will be provided - at different cost - by external providers.

As described above the process uses big data and big data analytics at least two layers. First one is associated with the data related to transport used for the ordering process and assessing delivery time and service feasibility. Second is for optimization of product assortment at the warehouse or assessment if additional warehouse(s) would increase the profit.

First category extensively uses real-time data, needed for prompt delivery. This incorporates real time analysis of traffic data at the area of covered by the service, as well as observing current weather situation. Also the fleet of couriers is tracked at real-time, with detailed information about delivery duration. This feedback helps to choose right means of transport, e.g. a motorbike or a car. This data contains personal identifiable information – about the driver performance - as well.

Second level of big data analysis uses the data related to customers and predicts their buying preferences in order to adjust selection of the products available at the warehouse; it could show that new products or their varieties shall be offered, or that nearby area would be ideal candidate for expansion with additional transport means (i.e., e-bike) or with another warehouse. The data used for this analysis is won in multiple ways. It can be data feed in from social networks, where the engine is looking for activities of persons living in the area of warehouse delivery radius. It can look for the groups people living there belong, seek for their hobbies, music, films, sports, lifestyle, books, health interests. The machines can track and deliver the data of their clickstreams, friend lists, follows, likes and tweets. Also text mining of news sites and feeds, online newspapers, blogs, and public chats can be conducted in order to detect new social trends and needs. Although collecting such data may provide high-grade information about the needs of the inhabitants of the area, the risks for harming the privacy rights is clearly recognizable even for a layman. At the same time even for professionals it is very hard to interpret if privacy rights are harmed with ongoing data aggregation.

This shows that in both cases - transport and order data analysis, and population/trend analysis – it is not possible to assess in the real time, which information can be aggregated and stored, and when the thin border between preserving and breaking privacy is crossed. There is a need for deeper privacy rights compliance analysis for the aggregated data, which could be compared to the actual business analysis looking for business process optimization. In ideal case such privacy analysis should be done before the business analysis is conducted.

VI. Conclusion

Within the emerging big data ecosystem there are new groups of players, and also key roles for stakeholders. Big data analytics lifecycle is more exploratory in the nature as conventional processes, and requires a new approach. The process includes six main stages as: data discovery, data preparation, model planning, model execution, communicating results and operationalizing the results. The process itself is iterative and recurring while few phases can be carried out simultaneously as a project work.

The aim of this paper is to present the impact of big data analytics on business process modeling practices for supply chains architectures in which the modeling of privacy and security aspects play a significant role for the businesses, as they have to hold on to privacy laws like the European Data Protection Directive. The global players, as well as smaller businesses using big data, must be thoughtful about their data aggregation and analytics practices, in order to hold to those regulations. Some examples are capabilities of big data analytics which may interfere with privacy rights, like re-identification of (sensitive) data owners, profiling, amassing granular information about a person, and other uses, which go beyond the purpose and use restrictions, or the requirement of data minimization, data security, etc. Other open questions and discussions are the use of derived information based on personal data, as well as empowerment of consumers to manage their data. Supply chains are using nowadays huge amounts of data available in batch-time, online, as well as other diverse data.

As stated in [4] the data analytics involves descriptive analytics, predictive analytics and prescriptive analytics. Business Intelligence methods and tools using structured data, manageable data sets and traditional data sources can be utilized for diverse queries and providing answers for common questions of what happened in the past and why it did. Going beyond structured data requires usage of data science methods for conducting predictive analytics and data mining techniques for optimization, predictive modeling and forecasting. It will not only foster resolving reporting questions,

but also forecasting of what and why will happen. Moreover it may also support the operationalization of the key outputs of the analytic process.

Considering the data analytics process for big data described in Section 2, the sharing of the results within organization is conducted in the phase 6 (operationalization of analysis results), which is aimed at effective passing the outcomes of the analysis to the stakeholders, who are responsible to address them with appropriate actions and changes in the existing business process, so that the proposed changes and customizations can be efficiently integrated. The results of the analysis in form of describing and reporting change instructions and proposals for the business intelligence analysts will have a technical character and be in form of technical graphs like density plots, histograms etc.

If the data analysts shall detect that privacy rights may be harmed, then the suspect data sets shall be removed from the analysis. One must realize that removing parts of data will lead to results with lesser granularity but this is a price which must be paid to stay on the safe side and compliant with the privacy rights.

In the future we will investigate how big data analytics of privacy aspects could influence the established business process modeling methods, models and tools (e.g. BPMN [17]).

***Abstract*—Today's business is more and more organized in collaborative networks. Although decision makers know the benefits of collaboration, they are afraid of losing control of their data, which is one of the main impediments for Cloud Computing. We propose a novel cloud based approach for collaboration in business processes with guaranteed control of the privacy of the data. The platform ensures the compliance with the companies' privacy policies and laws. The paper shows the definition of privacy policies and how they are converted into a well established access control language. An example helps to clarify the methods.**

I. Introduction

ALMOST ten years ago, in 2008, Thomas J. Bittman, vice president of Gartner Research, published his view on future Cloud Computing development. Back in the beginning of Cloud Computing, cloud services were build on proprietary architectures of few dominant cloud service providers, e.g. Google, Amazon and Microsoft. The main problem in these times was the missing interoperability and compatibility of the cloud services of different cloud service providers. During the second phase the vertical supply chain distinguished itself as first ecosystems of smaller cloud companies emerged within the Cloud Computing market. New cloud service providers use the proprietary Cloud platforms of the dominant providers of the first phase to provide their own services. During the last phase these smaller cloud service providers unite to form horizontal federations. This union increased their earnings by expanding their capacities while reducing the costs at the same time through more efficient resource allocation. In parallel, open interoperability standards of service communication in intercloud-environment have been developed[1].

In the past years more and more companies adopted Cloud Computing by integrating cloud services into their supply chain. Especially in Germany the use of Cloud Computing in companies has increased from 2011 to 2014 by 16 percent, almost every second company is consuming at least one cloud service[2]. These cloud services reach from Infrastructure as a Service to Software as a Service. Especially the Software as a Service provides an tremendous number of services for every kind of task that can be achieved by software. Unfortunately these services are often provided by smaller cloud service providers while the cooperation between them, i.e. Bittman's third phase, is not well established. Every service has it's own interfaces with different message formats, even two services that provide the same functionality can differ in message format, behaviour, and constraints. According to an interview among approx. 120 german small and medium sized companies the target group of these services, i.e. these companies, does not have the knowledge how to tackle this problem.

In [3] we have proposed an architecture of a platform that enables those companies to consume cloud services of different clouds. The platform offers the features of a business process management system by orchestrating the individual cloud services in business processes that have been modelled by the consumers, i.e. the companies. Hence, we call this approach and the service provided by the platform Business Process as a Service.

In the interview mentioned before we discovered that most of the companies who do not consume cloud services are reluctant because of a fear of losing control of their data, which is even more important because of the hacks of global players (e.g. Sony) in the past months. But also those companies who consume at least one cloud service are concerned because of privacy issues. [4] comes to the same conclusion.

So one of the main challenges for such a platform is preserving the privacy of the data and the compliance with privacy laws while the business process is executed. This becomes even more important when multiple companies are involved in one business process and need to share data to each other. In [5] we have proposed an approach for secure service interaction, which has shown it's feasibility in multiple tests. The architecture proposed in [3] also provides a component

The work presented in this paper was funded by the German Federal Ministry of Education and Research under the projects PREsTiGE (BMBF 16KIS0082K) and LSEM (BMBF 03IPT504X).

for adding privacy policies to the business processes and the individual activities which are evaluated and enforced by the platform while the business processes are executed.

This paper discusses a new and flexible approach to define privacy policies for data that is transmitted while a business process is executed.

The remainder of this paper is structured as follows. After a brief presentation of the platform's architecture and the relevant components, the concepts behind the privacy policies for collaborative business processes is shown. The next section shows the translation of these policies into machine readable and evaluateable form. The algorithm for the translation is applied to an example based on a logistics use case. The paper is completed by a conclusion, which also reveals open tasks and questions.

II. Architecture of the platform

This section gives a very brief overview on the architecture of the platform for privacy preserving collaborative business processes.

The platform first presented in [3] is shown in Fig. 1. The components are represented as rectangles, their interfaces are shown as the lines between the components.

The most important component of the platform is the business process management system, which is located in the center. The business processes are modeled by the user with the configurator, which also enables the user to define process and activity related privacy policies and asign them to the appropriate objects. Privacy policies that are not related to one particular process or activity are defined in the privacy management component, which also stores the privacy policies defined in the configuator. The privacy management passes all known privacy policies to the identity and access management system (IAMS).

When the BPMS executes a business process and reaches an activity that needs some data as input to call the cloud service related to this activity, the BPMS queries the IAMS whether the service is allowed to access this data in the current context. If the IAMS grants access to the data (with potential obligations) the BPMS instantiates a gateway that takes care of a secure service interaction as described in [3]. The gateway also takes care of the obligations for data access.

The components of the platform provide RESTful web services to communicate. The communication is secured by SSL and client certificates. User data, except for the companies' core data, is held within the BPMS, there is no interface which offers the data to other components or external users other than through gateways, which ensures that no unauthorized entity can access data.

III. Privacy policies for collaborative business processes

This section describes in detail our approach for defining privacy policies in the context of collaborative business processes. One of our main requirements for the approach was to provide the companies with a tool that they could understand.

To define privacy policies that can be evaluated automatically and be used to decide whether a service is allowed to access some data or not we rely on use access control approaches. Basically there are four different types of access control. The mandatory access control and discretonary access control where applied in computer systems in the 70s of the last century. While mandatory access control describes security from the system itself by policies like "access is only granted from localhost", discretionary access control assigns each identity the appropriate access rights.[6] Mandatory access control is still used nowadays, e.g. SElinux is applying this approach [7].

In the late 80s and early 90s more and more users where using computer systems, hence assiging each individual user, i.e. identity, the correct access rights was not feasible any more. So in the beginning of the 90s role based access control emerged [8]. Role based access control assigns roles to identities and access rights are assigned to roles. This approach is used in Linux and Windows file systems and almost every modern software. Roles can be organized hierarically as shown in Fig. 2. [9], [10], [11]

Because of the well established application of role based access control our first approach for defining privacy policies was to apply role based access control.

During multiple workshops with local companies we discovered that the companies do not think about privacy identically. One common thing is that all companies separated the actors who want to access data into groups. But while some companies had have a very easy and strict approach for group setup, others could not clearly tell us which companies are member of which group. Instead they used phrases like "The driver of the truck while he is in the destination city is allowed to get the recipient's phone number to call the recipient to tell him his arrival time". This simple phrase contains the following information:

- The basic role of the person requesting access to the recipient's phone number is *driver*.
- The person requesting access to the recipient's phone number has to be located in the city where the shipment has to be delivered.
- Even if the first two conditions are met, the driver is only allowed to get the phone number if he want's to use it to call the recipient to announce his arrival.

This simple policy cannot be represented easily with roles because the location of the driver is changing over time. To tackle such requirements the research community followed two core approaches: extend role based access control with additional features, e.g. context or attributes, and creating a new access control model. [10]

Following the role based access control [12] has developed an access control model, which extends role based access control for virtual organizations. Unfortunately this model does not cover business processes, workflows, and cloud computing. Other approaches in this direction do cover business processes but leave out the cooperational aspect. Ref. [13], [14], [15] proposed and evaluated an extended role based access control

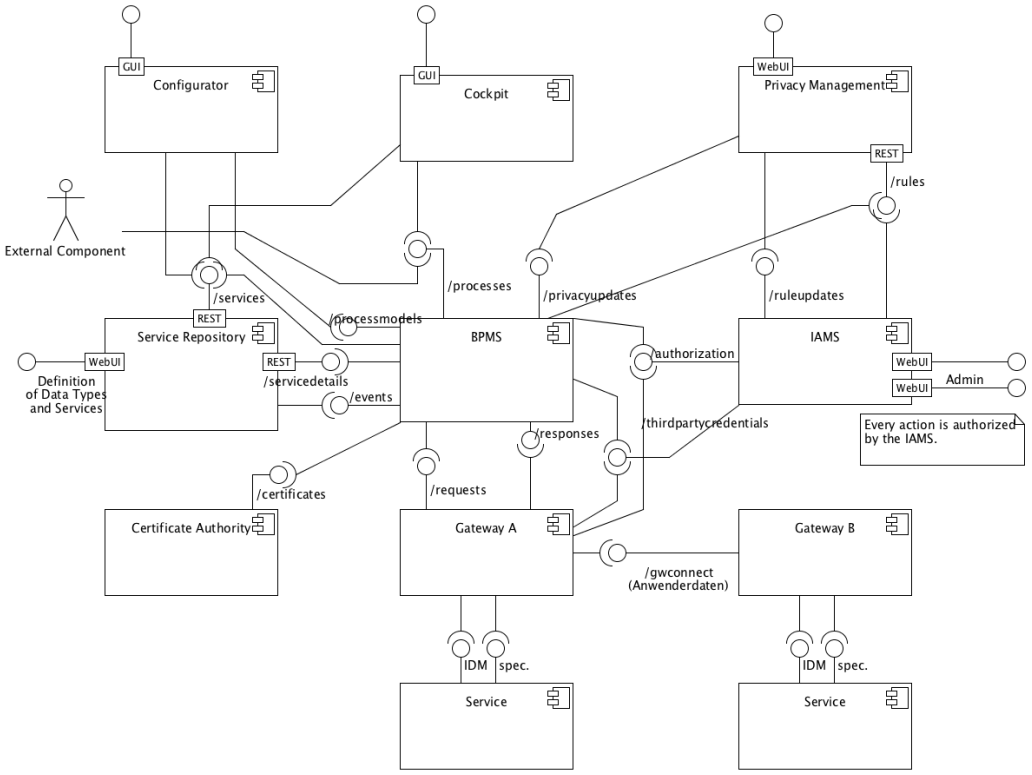

Fig. 1. Architecture of the platform for secure and privacy preserving collaborative business process as a service

model for team collaboration and workflows in the health sector.

All of the proposed models do not provide the flexibility in policy definition language that was needed by the participants of our workshops.

To achieve a maximum flexibility the research community developed a novel approach, the attribute based access control. In attribut access control policies are based on attributes of subjects and objects. According to [16] attribute based access control is:

"An access control method where subject requests to perform operations on objects are granted or denied based on assigned attributes of the subject, assigned attributes of the object, environment conditions, and a set of policies that are specified in terms of those attributes and conditions."[16]

The entity requesting access is called a subject. Typical attributes of subjects are their id, e.g. username, company name, and name of the department. The data that subjects want to access is called object or resources. A policy in attribute based access control is a triple of a subject, a resource, an operation, where the operation describes what access type the subject wants to have, and a result, e.g. grant or deny access. A policy can also comprise one or more conditions.

The policy "The driver of the truck while he is in the destination city is allowed to get the recipient's phone number to call the recipient to tell him his arrival time." consists of:

Subject The driver of the truck who is located in the destination city.
Resource Recipient's phone number
Operation Read
Condition Current activity in the workflow is "call recipient for dispatch notification"
Result Permit

The remainder of this section presents our approach on applying attribute based access control for privacy preservation to collaborative business process as a service. Privacy of data is always specified by the owner of the data, i.e. the entity who has created it.

First of all, in our platform business processes consist of activities that call external cloud based web services. Hence, there are two very basic roles in our platform. A process designer is an entity that models the business process, that is responsible for the correctness of the process itself, and that offers the resulting business process as a service to its customers. The second role is the service provider. A service provider is an entity that provides the external services that are beeing orchestrated in the business process by the process designer.

Our approach enables both roles to define their privacy policies independently from each other. It also includes privacy policies defined by law. Hence, the combined privacy policy consists of three columns as shown in Fig. 3 that can be

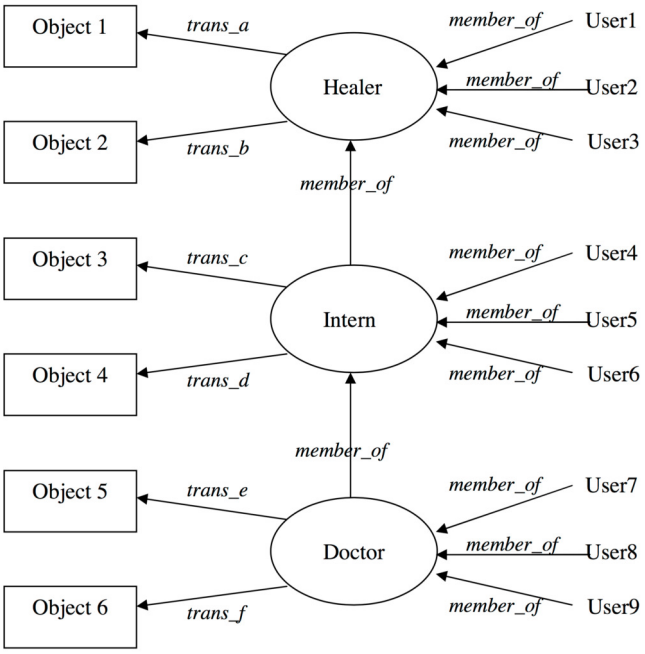

Fig. 2. Role based access control [11]

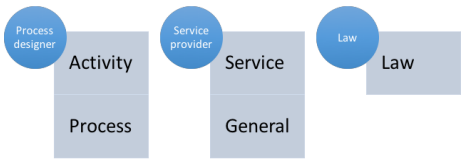

Fig. 3. Three columns of privacy policy process designer, service provider, and law

evaluated independently. The combined privacy policy results in permit if all three columns result in permit, else it results in deny.

To simplify the process of policy definition and to reduce redundancy in policies we provide each role with two levels of policies.

First a process designer can specify general privacy policies that are valid for the whole business process. E.g. a process designer may restrict access to all data to companies that are located in the Europe Union to ensure no data is transfered to other countries. Such privacy policies are visualized as tables where the objects are in the rows while the subjects are located in the columns. The cells contain either permit or deny depending on whether or not the subject is allowed to access the object. The subjects are defined by filters using attributes. So in this example the subject filter would be:

Companies meeting the condition: all locations have an attribute country with the a value that is in a list of the countries of the European Union.

The relevant section of the table for the privacy policy "Data can only be accessed by European companies." is shown in Fig. 4. Apart from the groups created by the process designer, every table does have an additional column *Default*. The

Object	Default	EU Companies
All data	deny	permit

Fig. 4. Privacy policy "Data can only be accessed by European companies." in table form

Object	Default	EU Companies
Parent	deny	permit
Child	permit	n/s

Fig. 5. Expandable objects in table to define a privacy policy for a child element different from the privacy policy for the parent element

algorithm to select the correct column when the evaluation of a policy, i.e. table, takes place is select the rightmost column whose filter does accept the subject, where Default accepts every subject.

The rows of the table represent the objects, i.e. the data the policy is about. The data is organized in an object hierarchy. Objects can be expanded to define policies for child elements as shown in Fig. 5. This table also states that EU Companies have unspecified access to the object Child. The evaluation algorithm handles *t/s* as if this column does not exist. The only column that is not allowed to have *t/s* is the *Default* column since else there would be no result for the evaluation of the policy.

The process level privacy policy applies to all data created by activities of the business process, i.e. it is assigned to all activities. If the process designer wants to define a different policy for a specific activity he defines a privacy policy on activity level. Privacy policies on acitivity level are evaluated before the process level privacy policies, i.e. activity level overrides process level. On activity level even the *Default* column can be set to *n/s*. If the evaluation of activity level policy results in *n/s* the policy on process level is evaluated.

The groups of subjects of a process designer's privacy policies can use both, companies and roles of the business process, as target. In case the process designer wants to use a business process role as the subject's filter, the systems shows up a list of the names of all swim lanes of the process. The process designer selects the appropriate entries and specifies the access rights as he does for company based filters.

The second role, i.e. the service providers, can define privacy roles that are applied to all data generated by their services in any business process. This is done on the level *General*. The definition of the policies follows the same concepts as for the process designer's policies. A service provider can override his general privacy policies by setting up a service specific privacy policy.

The third type of privacy policies are laws. Laws are provided by the platform provider as is and are not represented in a easy to read form as the process designer's and service provider's policy are.

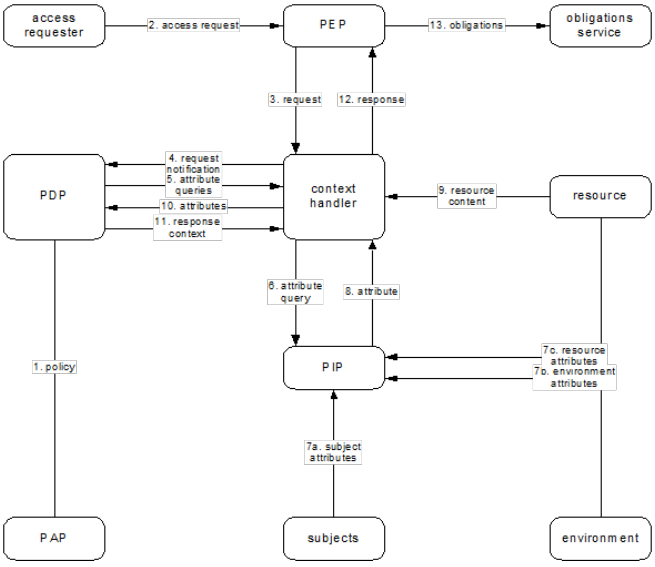

Fig. 6. Architecture and workflow of XACML 3.0 [18]

IV. Translation to XACML

This section shows how the process of transformation from table form to machine readable form of privacy policies works. As standard policy language and architecture we have selected XACML which is a well established and accepted language and architecture to define attribute based access control policies. XACML is available in version 3.0 since the beginning of 2013 [17]. Unfortunately the support by tools is not very well at this time. Most of the tools are not available for the current XACML version, others are available but are not passing the conformance tests. Fortunately AT&T published the source code of a XACML 3.0 implementation that is almost complete. The project is in a frozen state and will become an Apache Incubator Project [18].

The core architecture of XACML 3.0 is depicted in Fig. 6. Applied to our platform's architecture the PDP is the IAMS, the PEP is the BPMS and the PAP is the Privacy Management.

The document specified by the XACML language specification is xml based and specifies three main elements: *PolicySet*, *Policy*, and *Rule*.

The root element of the XACML document is either *PolicySet* or *Policy*. A *PolicySet* can contain any number of *PolicySets* or *Policies*, while a *Policy* can only contain *Rules*. A *Rule* is a single expression with an effect and a condition. Each level of these elements can have a target. Targets are used as a very easy and fast selector for applicable section of the XACML-document. Hence, target provide limited functionality but spead up evaluation time of the XACML-document tremendously.

XACML adopts the attribute based access control structure of subjects, resources, conditions, and actions. This simplifies the algorithm for translating out table based privacy policies to XACML based ones. The algorithm consists of n main steps:

1) Creation of missing tables on activity / service level

Algorithm 1 Evaluate all cells of a activity table to either permit or deny

Require: table is not empty
Ensure: $\forall$ cell $\in$ table : cell=permit or deny

```
expand all object
for all rows from top to bottom do
  for all cells from right to left do
    if cell is N/S then
      if cell in default column is N/S then
        if cell in corresponding column in process level
        table is N/S then
          cell ← value of the cell in default column of
          process level table
        else
          cell ← value of the cell in corresponding col-
          umn of process level table
        end if
      else
        cell ← value of the cell in default column
      end if
    end if
  end for
end for
```

2) Evaluation of each cell of the activity / service level tables
3) Translation of each activity / service level table into XACML
4) Combination of the XACML fragments into the target XACML documents

The algorithm is executed separately for process designer and for service provider privacy policies. For process designer view the algorithm first identifies all activities of the business process that have to privacy policy table asigned and creates such a table with all cells set to *n/s*. This ensures that all activities can be handles the same way. The second step is the most important one. In this step all *n/s* values are evaluated to either permit or deny according to the algorithm 1.

After this step there are privacy policy tables for each activity of the process containing only permit or deny. These tables are now translated into XACML policies. Each table is transferred into a *PolicySet*. The target of this *PolicySet* is set to "resource:generator:activityid equals activity-id". The resource:generator:activityid is an attribute that is derived at runtime from the context of the BPMS. The *PolicySet* contains a *Policy* per attribute of the objects and a *Rule* per column of the table. The target of the *Policy* is set to "resource-id equals objectname:attributename", where objectname ist the name of the object and attributename is the name of the attribute of the current row. The rule's effect is set to the cell's value. In rules we do not use target's but we use condition's instead, since condition's are more powerful. The condition of the rule is set according to the subject filter of the column.

When all tables are translated into XACML *PolicySets*, all *PolicySets* are put together in one *PolicySet*. This PolicySet

has "process-id equals id of the process" set as target. This *PolicySet* is the first of the three document types needed by our platform, the process related document. The platform holds one document of this type per business process.

The second document type handles the service provider's privacy policies. The platform creates one document that contains all privacy policies of all services of all service providers. The steps are very similar to the ones for the process designer's privacy policies. The following steps are executed for every service provider.

First it is ensured that there is a privacy policy table for every service. If one is missing, the system generates a table containing only *n/s* in all cells. After this step an algorithm similar to algorithm 1 is applied, with service provider level tables instead of process level tables. The result of this step is a set of privacy policy tables, one for each service, containing only permit or deny.

Each table is transformed into a *PolicySet* with the target set to "resource:generator:serviceid equals service-id", where service-id is replaced with the current service-id and resource:generator:serviceid is derived from the context of the BPMS at runtime. This *PolicySet* contains one *Policy* per attribute of the objects. The *Policies* contain one *Rule* per column as for the process based documents. All *PolicySets* of all Services are combined together into one *PolicySet* that is the second document type of the platform.

The third document type is produced by the platform provider and contains a *PolicySet* containing *Policies* for each law that is relevant to the platforms privacy preservation feature.

The process flow of this algorithm will be explained with an example in the next section.

V. Example

The algorithm presented in the previous section will be processed in this section based on the following simple use case of the logistics sector. Due to the big similarity between the process designer's and the service provider's version of the algorithm this example is focussing on the service provider's privacy policies.

In this use case there is only one resource object called *address* containing the child elements *street*, *zipcode*, and *city*. Furthermore there is a service provider called ACME that is offering two services ACME-DE and ACME-WW to the platform. The company ACME has created two subject filters, one is named "GoodRelations" and contains companies that ACME likes to work with, and one is named "NeverAgain", this filter contains companies who ACME does not want to work with again any more.

ACME defines the default privacy policy as follows. Companies are allowed to access the zipcode and the city of an address but not the street. Companies matching the filter GoodRelations are allowed to access the street, companies matching the filter NeverAgain are not allowed to access the zipcode. This general privacy policy is represented in Fig. 7.

Attribute	Default	GoodRelations	NeverAgain
Address			
Street	Deny	Permit	Deny
Zipcode	Permit	N/S	Deny
City	Permit	N/S	N/S

Fig. 7. Privacy policy for service providers on global level of ACME

Attribute	Default	GoodRelations	NeverAgain
Address			
Street	Deny	Permit	Deny
Zipcode	N/S	Permit	Deny
City	Permit	Permit	N/S

Fig. 8. Privacy policy for service providers for service ACME-DE of ACME

In addition ACME defines a privacy policy for its service ACME-DE as follows. Companies should not be able to access a streetname but should be able to access the city of an address. Companies that ACME has good relation with are allowed to access the whole address generated by the service ACME-DE and companies that ACME has made bad experiences with are not allowed to access streetnames or zipcodes of addresses generated by the service ACME-DE. No statement is made for zipcode for default companies and city for companies matching the filter NeverAgain. The resulting table form of the privacy policy is shown in Fig. 8.

ACME does not define a special privacy policy for the service ACME-WW.

The first step is to create a privacy policy table for every service. There is already a privacy policy table for ACME-DE but none for ACME-WW. Hence, the system creates such a table with only *N/S* in the cells as shown in Fig. 9.

In the next step the *N/S* entries of the privacy policy tables of each service are evaluated to either permit or deny. This is shown in Fig. 10 and Fig. 11. The arrows show the source of the entry.

While the process for ACME-DE is easy, the process for ACME-WW needs some explaination. For example the cell Zipcode / GoodRelations contains *N/S* in the service specific table. During evaluation the algorithm first looks up the value

Attribute	Default	GoodRelations	NeverAgain
Address			
Street	N/S	N/S	N/S
Zipcode	N/S	N/S	N/S
City	N/S	N/S	N/S

Fig. 9. Privacy policy for service providers for service ACME-WW of ACME

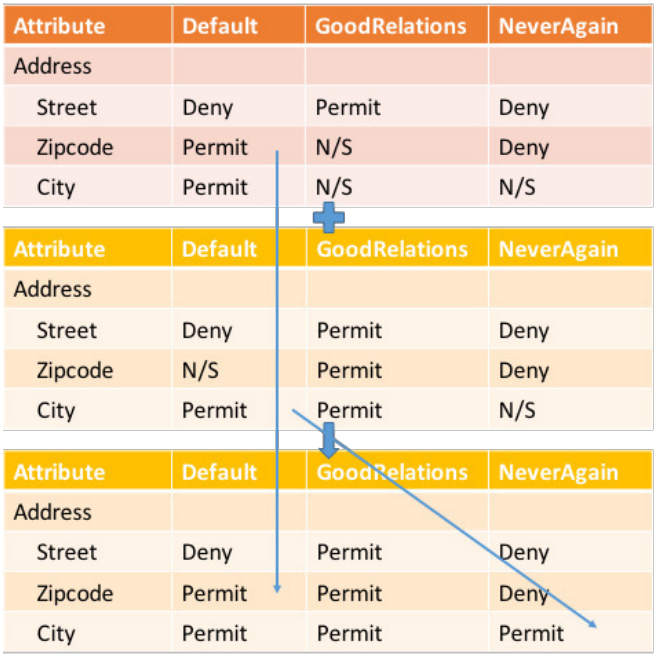

Fig. 10. Resulting privacy table for ACME-DE

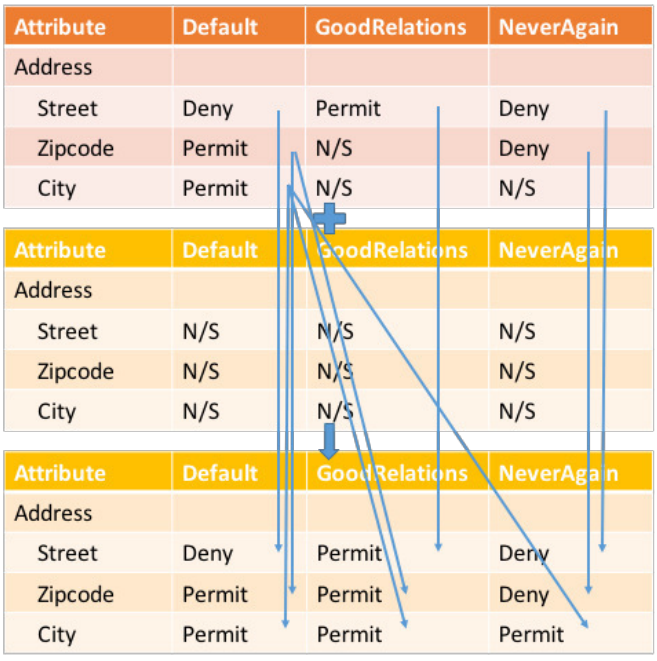

Fig. 11. Resulting privacy table for ACME-WW

in the default column for Zipcode in the service specific table. There it reads *N/S*, too. Hence, the algorithm looks up the value of the cell Zipcode / GoodRelations in the global level privacy policy table of ACME. There access control is set to *N/S* once again. So finally the algorithm falls back to the cell Zipcode / Default where it finds the resulting Permit.

For the transformation of the privacy policy tables to XACML we assume that the filters are based on company names, although they good have any complexity. The companies' names are kept in the XACML attribute *urn:prestige:iams:ldap:Company:Name*. The resulting XACML portion for the service ACME-DE is shown below.

  <Description>Default for Street</
      Description>
  <Target/>
 </Rule>
</Policy>
<!-- Skipping policies for zipcode and
    city -->
</PolicySet>
```

The resulting *PolicySets* for ACME-DE and ACME-WW will be combined and transferred by the Privacy Management to the IAMS. The same procedure applies to the business process related privacy policies.

VI. Conclusion

In this paper we have proposed a novel approach for defining privacy policies in business process and Cloud based scenarious. The definition is done by the end users with an easy to understand table based presentation and at the same time offers enough flexibility to fit the needs of the users. We have evaluated the approach with members of the target

group and found that it is feasible and easy to use. Especially the definition of global policies and local policies only where necessary was rated very good.

The technical implementation of the platform is working and fast enough even for a big number of policies. We have tested the platform with 500 services and a business process containing 40 activities. Every XACML request, i.e. request for privacy policy evaluation, was answered within a maximum of 27 ms over local network with no significant CPU load.

In the near future we will try to improve our platform especially in terms of visualization of privacy policies. Above all at the moment the definition of subject filters is either flexible or easy to use, depending on whether the user uses a code view or a list to select the companies from. We are planing to provide the user with a tool to define the filters using a set of attributes and a graphical editor to arrange those attributes.

Another task for the future is to perform system tests and experiments of the whole platform with companies in controlled laboratory and real world, as well.

***Abstract*—The author presents a novel declarative approach to modeling, solving and decision support for supply chain problems as a declarative decision support framework. The proposed framework makes it possible to ask different types of questions (general, specific, logical etc.). The implementation of the framework was performed in the CLP (Constraint Logic Programming) environment.**

To increase the efficiency of the framework, particularly in the area of optimization made its integration with MP (Mathematical Programming) environment. The paper also presents the implementation of illustrative model, using the proposed framework. In addition, an efficiency analysis of the presented solution in relation to the application of mathematical programming have been conducted.

I. Introduction

THE ssupply chain (SC) is commonly seen as a collection of various types of companies (raw materials, production, trade, logistics, transport, etc.) working together to improve the flow of products, information and finance. As the words in the term indicate, the supply chain is a combination of its individual links in the process of supplying products (material/products and services) to the market.

There is a considerable literature on the supply chain management problems [1,2].

The major difficulties that appear in supply chain management (SCM) include large amount of information and multiple constraints relating to each participant in the management process. These participants share many of those constraints and information items [3], which further complicates the management. The constraints have various characters and structures. The most common are the constraints related to resources, time, finance, transportation, environment, business, law and safety. They can be linear constraints, non-linear, binary integer and logical. Managers/Decision makers are typically interested in feasibility and/or optimality of the decisions they make in the environment with many constraints. The most natural way to support the decision makers is to enable them to ask questions and obtain answers within acceptable time.

Good environments for the modeling of constraints, questions and logical conditions include declarative environments, CLP (Constraint Logic Programming) in particular.

Our motivation was to develop a framework for the modeling and decision support for supply chain management problems. The use of this framework would help obtain quick answers to key questions (Is it possible…?, What If…?, What is the minimum/maximum..?) asked by managers/decision makers.

This paper proposes the concept of a declarative decision support framework for supply chain problems and presents its implementation in the CLP environment. The illustrative example shows the potential of the framework.

The remainder of the article is organized as follows. Section 2 presents problem statement, research methodology, contribution etc. The concept and implementation aspects of a declarative decision support framework are provided in Section 3. Computational examples, tests of the implementation platform and discussion are presented in Section 4. Possible extensions of the proposed approach as well as the conclusions are included in Section 5. .

II. Problem statement and methodology

Most of the SC decision and optimization problems are modeled and solved by operations research (OR) methods. The vast majority of the literature reviewed [1,2,3,4], have formulated SC models as linear programming (LP), integer programming (IP) and mixed integer linear programming (MILP) problems. Declarative environments such as CLP facilitate problem modeling and introduction of logical and symbolic constraints [5,6]. Unfortunately, high complexity and the multiple types of constraints of decision-making models as well as combinatorial nature contribute to poor efficiency of modeling in OR methods and inefficient optimization in CLP. Therefore, a new approach to modeling and solving such problems was developed [7,8,9,10]. A declarative environment was chosen as the best structure for this approach especially in modeling [5]. Mathematical programming environment was used for problem optimization [11]. This integrated approach is the basis for the creation of the implementation environment to support managers.

A. Problem description –illustrative example

The problem of supply chain management considered here refers to the supply chain in which:

- the supply chain consists of factories, distribution centers and customers (Fig. 1);
- customer orders are executed by deliveries from distribution centers;
- distribution centers are supplied by the factory;
- transport is multimodal (several modes of transport, a limited number of means of transport for each mode);
- the environmental aspects of use of transport modes are taken into account;
- different products are combined in one batch of transport;
- the cost of supplies is presented in the form of a function (in this approach, linear function of fixed and variable costs).

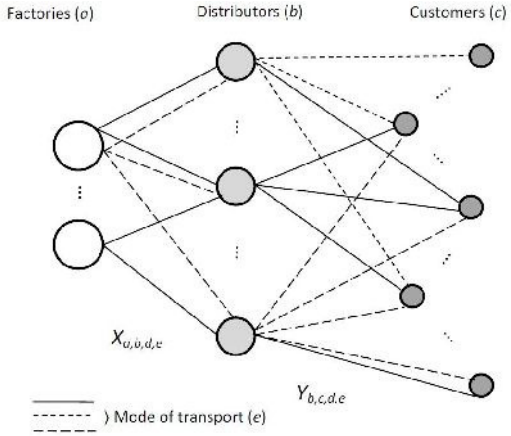

Fig. 1 The structure of supply chain for illustrative example

There are many decision and optimization problems in such supply chain management environment. Specific management problems are presented in the form of questions (possible questions (Q_i) for illustrative example are shown in Table I), which have to meet the reference set of constraints. Indices, and decision variables for the illustrative example have been reported in Table II. The set of reference constraints (1).. (22) for the illustrative example was created and its mathematical/formal notation is included in Appendix A. Brief description of reference set of constraints has been provided below.

Production capacity constraint (1) determines that all deliveries of product *d* produced by the manufacturer *a* and delivered to all distributors *b* using mode of transport *e* do not exceed the manufacturer's production capacity.

Demand constraint (2) covers all customer *c* demands for product *d* ($Z_{c,d}$) through the implementation of delivery by distributors *b* (the values of decision variables $Y_{b,c,d,e}$). The flow balance of each distributor *b* corresponds to balance constraint (3). The possibility of delivery is dependent on the distributor's technical capabilities – capacity constraint (4). Time constraint (5) ensures the terms of all deliveries are met. Transport cconstraints (6a), (6b), (7) guarantee deliveries with available transport taken into account. Constraints (8), (9), (10) set values of decision variables based on binary variables Tc_b, $Xa_{a,b,e}$, $Ya_{b,c,e}$. Dependencies (11) and (12) represent the relationship based on which total costs are calculated. In general, these may be any linear functions. The remaining constraints (13)..(22) arise from the nature of the decision variables.

TABLE I.
THE SET OF QUESTIONS (INCLUDING BUT NOT LIMITED TO)

Question	Description
Q_1	What is the minimum overall cost of timely supply?
Q_2	Can timely supply be realized at the set cost of transportation *Kt*?
Q_3	What is the minimum environmental cost *Ks* of timely supply ?
Q_4	What is the minimum cost of timely supply with the use of no more than *N* distribution centers?
Q_5	Is timely supply possible without the use of transport means *dx*?
Q_6	Is timely supply possible with the following numbers of transport means *d1,d2,d3*?
Q_7	Can timely supply be realized at the set production cost *Kp*?
Q_8	What is the minimum cost of supply execution if transport means *d1*, *d2* cannot be used simultaneously by distribution center *S1*?

Decision variables of this problem are shown in Table II.

TABLE II.
INDICES AND DECISION VARIABLES

Symbol	Description
Indices	
d	product type (d=1..D)
c	delivery point/customer/city (c=1..C)
a	manufacturer/factory (a=1..A)
b	distributor /distribution center (b=1..B)
e	mode of transport (e=1..e)
A	number of manufacturers/factories
C	number of delivery points/customers
B	number of distributors
D	number of product types
E	number of mode of transport
Decision Variables	
$X_{a,b,d,e}$	delivery quantity of product *d* from manufacturer *a* to distributor *b* using mode of transport *e*
$Xa_{a,b,e}$	if delivery is from manufacturer *a* to distributor *b* using mode of transport *e* then $Xa_{a,b,e}=1$, otherwise $Xa_{a,b,e}=0$
$Xb_{a,b,e}$	the number of courses from manufacturer *a* to distributor *b* using mode of transport *e*
$Y_{b,c,d,e}$	delivery quantity of product *d* from distributor *b* to customer *c* using mode of transport *e*
$Ya_{b,c,e}$	if delivery is from distributor *b* to customer *c* using mode of transport *e* then $Ya_{b,c,e}=1$, otherwise $Ya_{b,c,e}=0$
$Yb_{b,c,e}$	the number of courses from distributor *b* to customer *c* using mode of transport *e*
Tc_b	if distributor *b* participates in deliveries, then $Tc_b=1$, otherwise $Tc_b=0$

III. A DECLARATIVE DECISION SUPPORT FRAMEWORK FOR SUPPLY CHAIN MANAGEMENT PROBLEMS-CONCEPT AND IMPLEMENTATION

The declarative decision support framework was proposed for supply chain management problems. The concept is based on the declarative programming paradigm, which allows high level programming with the use of predicates and facts. Due to the character of problems in the supply chain management, CLP (Constraint Logic Programming) was selected from among many declarative options. The implementation of the framework was performed with the use of ECL^{i}PS^e [5,12].

The following general assumptions were applied:

- possibility of modeling constraints of any type;
- automatic generation of implementation models in the form of MILP models;
- data recorded as facts.

Figure 2 presents the general concept of the framework. The framework comprises several phases: modeling, presolving, generating and solving. It has two inputs and uses the set of facts. Inputs are the set of questions and the set of constraints to the reference model of a given problem. Based on them, the primary model of the problem is generated as a CLP model, which is then presolved. The built-in CLP method (constraint propagation [5,6]) and the method of problem transformation designed by the authors [8,9] (Section 3A) are used for this purpose. Presolving procedure results on the transformed model CLP^T. This model is the basis for the automatic generation of the MILP (Mixed Integer Linear Programming) model, which is solved in MP (with the use of an external solver or as a library of CLP). The general concept of the framework consists in modeling and presolving of a problem in the CLP environment with the final solution (including optimization) found in the MP environment. This approach is the result of experience as well as extensive research devoted to both environments and their integration [10,13,14,15,16,17]. In all its phases, the framework uses the set of facts having the structure appropriate for the problem being modeled and solved (Fig. 2). The set of facts is the informational layer of the framework, which can be implemented as a relational database, XML database, etc.

The functional layer comprises adequate sets of predicates: P_1 (CLP model generation), P_2 (CLP model presolving through constraint propagation and transformation, post-transformation generation of CLP^T model), and P_3 (generation of the final MILP^T model in the format of the MP solver).

The presolving phase is an important element of the framework as it makes it possible to simplify the model for the problem being solved and to reduce the combinatorial search space.

For the presolving phase to be effective, unfeasible combinations of model dimensions have to occur. In practice, unfeasible combinations of the index of decision variables and/or facts occur. The proposed framework uses constraint propagation and transformation for the presolving procedure. Constraint propagation is a concept and method that appears in constrained-based environments. Constraint propagation embeds any reasoning which consists in explicity forbiding values from some varable domain of a problem, because all constraints can not be satisfied otherwise [6].

Transformation transforms decision variables of the problem along with constraints and facts. The transformation of facts for the illustrative example is shown in Fig. 3, and the post-transformation variables are compiled in Table AII.

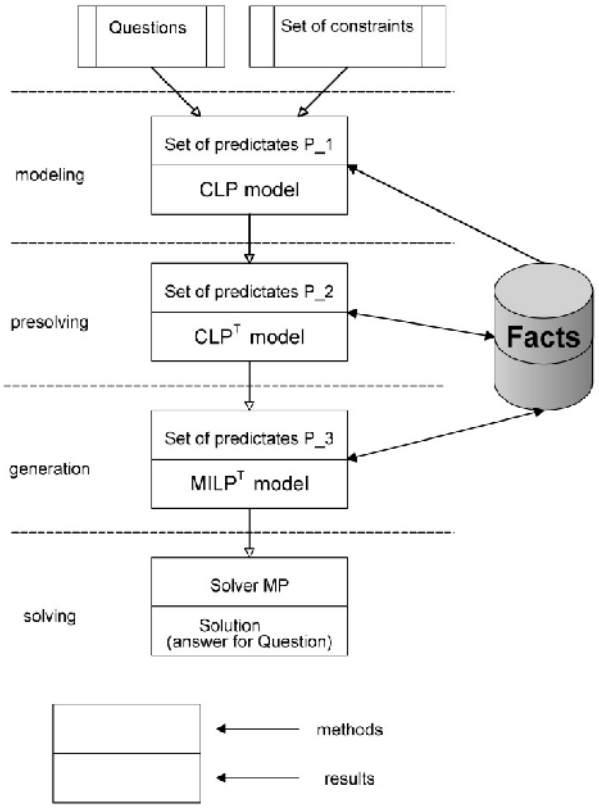

Fig. 2 A concept of a declarative decision support framework

A. Transformation of the problem-presolving phase

In the case of the problem presented, the transformation consisted in changing the problem representation from graph to routing. Instead of analyzing all possible trnasport connections from the factory to the distribution center and then from the center to the customer, only the feasible connections (factory-center-customer) were generated and named routes. This resulted in the removal of certain indices and in the aggregation of other indices for decision variables, parameters, etc., which eventually led to the reduction in the number of decision variables and constraints [7,8]. The new set of decision variable, constraints and facts was the basis for creating the CLP^{T}model.

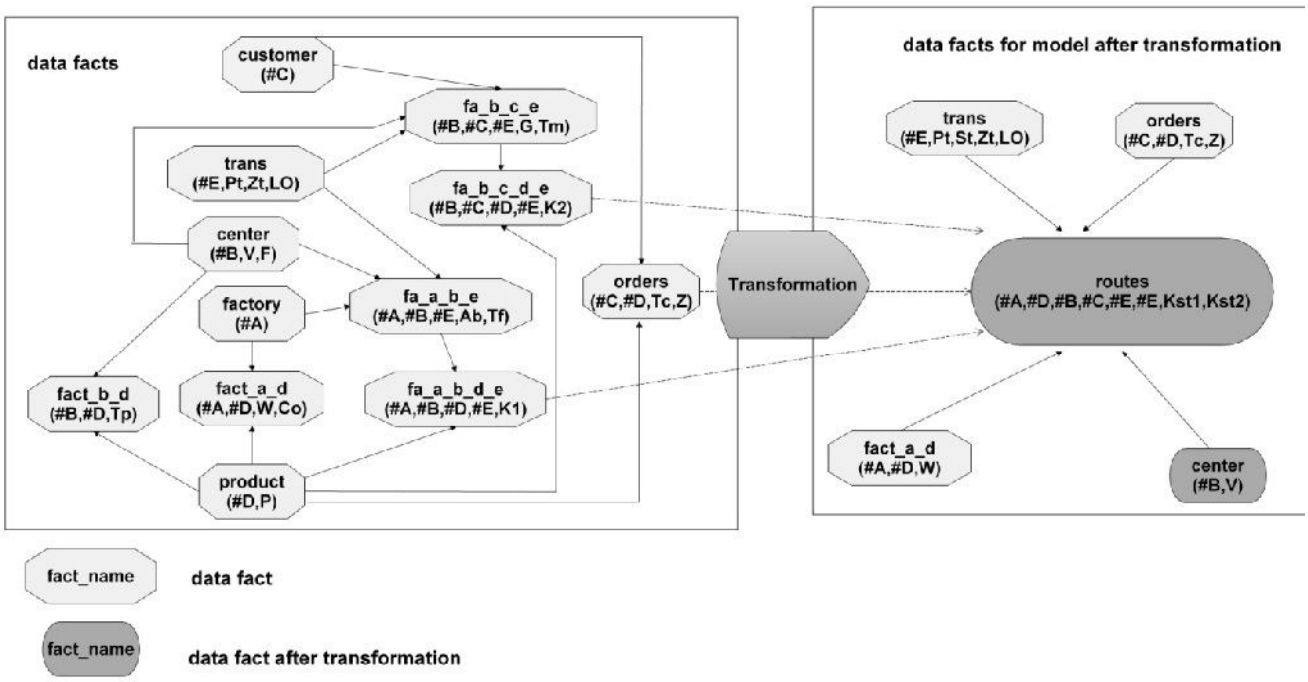

Fig. 3 Structure of facts for illustrative example before and after transformation

IV. COMPUTATION EXAMPLES FOR ILLUSTRATIVE MODEL

In order to verify and evaluate the proposed approach, many numerical experiments were performed. All the examples relate to the supply chain with five factories *(a=1..5),* four distributor centers *(b=1..4)*, fifteen customers *(c=1..15),* four modes of transport *(e=1..4),* and fifteen types of products *(d=1..15)* and fifty orders *(No)*.

All data instances for these experiments were recorded in the form of facts and included Appendix B. The structure of facts and their description has been shown in Fig. 3 and Table V.

Computational experiments consisted in asking questions Q_1..Q_8 to illustrative example. For each question was generated and solved suitable implementation model using declarative decision support framework. The answers to these questions are shown in Table III.

The answer to question Q_1 is the minimum entire cost of timely delivery all orders (Table III). This cost is the aggregate costs of the entire chain and consists of five elements (23). The first element comprises the fixed costs associated with the operation of the distributor involved in the delivery (e.g. distribution centre, warehouse, etc.). The second element corresponds to environmental costs of using various means of transport. Those costs are dependent on the number of courses of the given means of transport, and on the other hand, on the environmental levy, which in turn may depend on the use of fossil fuels and carbon-dioxide emissions. The third and fourth element determined by the cost of transportation. The last element is the cost of production. The answer to question Q_2 defines the feasibility of timely supply/delivery at the set (closed) transportation cost (25). Table II shows two versions of the question with different parameters. The answer to question Q_3 determines minimum environmental costs (26) of timely delivery (Table I).

Two versions of the answer to question Q_4 are shown in Table III. These versions define the minimum overall cost of timely delivery when two distribution centers are used (Q_4_A) and when one distribution center is used (Q_4_B).

The possibility of executing timely delivery without the use of selected transportation means is defined in the answer to question Q_5 (three versions of the question are shown in Table III). The answer to question Q_6 specifies the possibility of timely delivery at the set number of each transportation means (Table III).

The possibility of executing timely delivery at the established, closed production cost (24) is included in the answer to question Q_7. Table III shows three versions of the answer. The answer to question Q_8 specifies the minimum cost of timely delivery at the logical condition met, ruling out the possibility of that the selected center can be used concurrently by two different transportation means.

In the second phase of the experiments, a comparative analysis was performed for questions Q_1 and Q_8 (most compute-intensive of all) for different numbers of orders (No) in two environments (declarative decision support framework ($MILP^T$) and MP (MILP)) to evaluate the effectiveness and efficiency of the proposed framework relative to the classical MP environment.

Obtained more than 50-fold reduction of time searching for solutions (Table IV). This is due to the fact that the application of the framework has allowed the up to 50-fold

reduction of integer decision variables up to 20-fold reduction of constraints (Table IV).

No-the number of orders; **Vint**-the number of integer decision variables, **C**-the number of constraints, **T**-time of finding solution (in seconds)

TABLE V.
STRUCTURE OF THE FACTS FOR ILLUSTRATIVE EXAMPLE

Fact	Description
product(#D,P).	products , D-product ID, P-the capacity occupied by product.
factory(#A).	factories , A-factory ID.
fact_a_d(#A,#D,W,Co)	products in factories, A-factory ID, D-product ID, W-production capacity at factory A for product D, Co-the cost of product D in factory A.
center(#B,V,F)	distribution centers, B-center ID, V-maximum capacity, F-the fixed cost of distribution center.
fact_b_d(#B,#D,Tp)	products in distribution centers, B-center ID, D-product ID, Tp-the time needed for distributor B to prepare the shipment of product D.
trans(#E,Pt,Zt,Od)	transportation, E-number of mode of transportation, Pt-the capacity of transport unit, St-payload ,Zt-the number of transport units using mode of transportation E, Od-the environmental cost
customer(#C)	customers, C-ustomer ID
fa_a_b_e(#A,#B,#E,Ab,Tf)	delivery from factory to distribution center using mode of transportation E, A-factory ID, B-center ID, E-number of mode of transportation, Ab-the fixed cost of delivery, Tf-the time of delivery
fa_b_c_e(#B,#C,#E,G,Tm)	delivery from distribution center to customer using mode of transportation E, B-center ID, C-customer ID, E-number of mode of transportation, G-the fixed cost of delivery, Tm-the time of delivery
fa_a_b_d_e(#A,#B,#D,#E,K1)	the variable costs of delivery of product, A-factory ID, B-center ID, D-product ID, E-number of mode of transportation, Ks3-the variable cost of delivery of product from factory to distribution center (optional)
fa_b_c_d_e(#B,#C,#D,#E,K2)	the variable costs of delivery of product, B-center ID, C-customer ID, D-product ID, E-number of mode of transportation, Ks4-the variable cost of delivery of product from distribution center to customer (optional)
orders(#C,#D,Tc,Z)	orders, C-customer ID, D-product ID, the cut-off time of delivery to customer of product, Z-customer demand for product

V. CONCLUSIONS

Two types of questions can be asked in the proposed declarative decision support framework.

General questions may require domain solution, which in practice determines the availability of capacity, the number of transport units, timely supply etc. The specific wh-questions will in practice define the best, fastest, cheapest, or the most expensive of the possible solutions. To obtain answers to these questions, optimization is necessary. Both

question types can contain logical conditions relating, for example, to the disjoint use of transport units, distributors, etc. The illustrative example shows only part of potential of the framework designed to increase both the speed and the size of the problems solved (Table IV).

This is particularly evident if we compare the possibilities of the framework in relation to the classical approach based on mathematical programming (Table IV).

Further work will consist in the implementation of more complex models [18], uncertainty, fuzzy logic etc. [19], and as a cloud internet application [20]. New questions will be implemented to broaden the scope of decision support.

It is also considering development of models to take account product demand interdependencies [21]. In the future it is planned to integrate framework with ERP and APS systems [22]. It is planned to also use a hybrid approach to optimize the use of graphs, for example, to image retrieval [23].

APPENDIX A

TABLE A1
SUMMARY PARAMETERS

Symbol	Description
	Input parameters
F_b	the fixed cost of distributor/distribution center *b*
P_d	the area/volume occupied by product *d*
V_b	distributor *b* maximum capacity/volume
$W_{a,d}$	production capacity at factory *a* for product *d*
$Co_{a,d}$	the cost of product *d* at factory *a*
$R_{b,d}$	if distributor *b* can deliver product *d* then $R_{b,d}=1$, otherwise $R_{b,d}=0$
$Tp_{b,d}$	the time needed for distributor *b* to prepare the shipment of product *d*
$Tc_{c,d}$	the cut-off time of delivery to the delivery point/customer *c* of product *d*
$Z_{c,d}$	customer demand/order *c* for product *d*
Zt_e	the number of transport units using mode of transport *e*
Pt_e	the capacity of transport unit using mode of transport *e*
$Tf_{a,b,e}$	the time of delivery from manufacturer *a* to distributor *b* using mode of transport *e*
St_e	the payload of transport unit using mode of transport *e*
$K1_{a,b,d,e}$	the variable cost of delivery of product *d* from manufacturer *a* to distributor *b* using mode of transport *e*
$R1_{a,b,e}$	if manufacturer *a* can deliver to distributor *b* using mode of transport *e* then $R1_{a,b,e}=1$, otherwise $R1_{a,b,e}=0$
$A_{a,b,e}$	the fixed cost of delivery from manufacturer *a* to distributor *b* using mode of transport *e*
$Koa_{b,c,e}$	the total cost of delivery from distributor *b* to customer *c* using mode of transport *e*
$Tm_{b,c.e}$	the time of delivery from distributor *b* to customer *c* using mode of transport *e*
$K2_{b,c,d,e}$	the variable cost of delivery of product *d* from distributor *b* to customer *c* using mode of transport *e*
$R2_{b,c,e}$	if distributor *b* can deliver to customer *c* using mode of transport *e* then $R2_{b,c,e}=1$, otherwise $R2_{b,c,e}=0$
$G_{b,c,e}$	the fixed cost of delivery from distributor *b* to customer *c* using mode of transport *e*
$Kog_{b,c,e}$	the total cost of delivery from distributor *b* to customer *c* using mode of transport *e*
Od_e	the environmental cost of using mode of transport *e*
CW	Arbitrarily large constant

***Abstract*—In this article we analyze the problem of optimal location of transportation hubs in Warsaw, namely the Park and Ride location problem (*P&RP*). We take into account the expected travel time using public transport between particular points of the trip. In the currently existing *P&R* system we have 14 hub locations, and in this case the maximum travel time exceeds 50 minutes. The *P&R* problem can be reduced to the centers location problem (in our particular approach - the dominating set problem, *DS*), which is an *NP* hard problem. In order to determine the optimal locations for *P&R* two methods: the greedy and the tabu search algorithms were chosen and implemented. According to the computational experiments for the travel time restriction to 50 minutes, we obtain the *DS* composed of 3 hubs, in contrast to the existing 14 elements. The analysis of the *P&R* location in time domain is presented in this article in the context of further development of the Warsaw public transportation network, which seems to be interesting.**

I. Introduction

THIS article is devoted to the **Park & Ride** facilities location problem (*P&RP*) for the case of public transportation network of Warsaw [1], [9], [19]. Data used in the analysis of this problem were obtained from the official website of the **Public Transport Authority** in Warsaw [22].

In the previous approach to solve *P&RP* [18], the transport network graph was modeled as follows. The set of vertices represented the collection of bus stops and there was an edge between a pair of vertices if and only if there was a possibility of getting from one stop to another by bus, without any transfers. This model was, obviously, too simple and impractical: only one, and the real transportation mode was taken into consideration (buses), real travel times were irrelevant (e.g there existed some edges that represented travel times exceeding 90 minutes).

In this article we propose a much more precise model. The graph is modeled with application of real-world information about expected travel times between pairs of stops (including all modes of transit as well as transfers). This model takes also into consideration a rather common situation in which a pair of stops does not share any line but distance between them is very short (for example less then 50 meters). In the new model such vertices should be merged together. Using the **Open Trip Planner** (*OTP*) open-source software package the estimated travel time distances were computed.

Our research consists in applying the vertex domination methods in graphs to a real-life public transportation network.

II. Basic mathematical definitions

This section provides some basic notation, following [8], [6]. A **graph** is a representation of a set of objects, where some pairs of objects are connected by links. The interconnected objects are represented by mathematical abstractions called vertices, and the links that connect pairs of vertices are called edges. More formally, a **graph** is an ordered pair $G = (V, E)$ comprising a set V of **vertices** or **nodes** together with a set E of **edges**, which are 2-element subsets of V (E is a subset of $V \times V$). An **undirected** graph is the one in which edges have no orientation. The edge (a, b) is then identical to the edge (b, a). A vertex v is adjacent to u if and only if $(v, u) \in E$. Let $N(v) = \{u \in V : (v, u) \in E\}$ be an open **neighborhood** for a given vertex v.

A **dominating set** for a graph G is a subset D of V such that every vertex not in D is adjacent to at least one member of D [7], [11], [12]. This problem is strongly related to a problem well known in computational geometry, the **art gallery problem**. The domination number $\gamma(G)$ is the number of vertices in a smallest dominating set for G. The ***k*-dominating set problem** concerns testing whether $\gamma(G) = k$ for a given graph G and a natural number k; it is a classical ***NP*-complete** decision problem in computational complexity theory [15]. According to the theorem of Ore [5], if $G = (V, E)$ is a graph without isolated vertices, then the complement of a minimal dominating set of G is also a dominating set of G. This implies that every such graph has two disjoint dominating sets and hence, $\gamma(G) \leq \frac{1}{2} Card(V)$.

978-83-60810-90-3/$25.00

A **hypergraph** is a generalization of a graph in which an edge can connect any number of vertices [3]. Formally, a hypergraph *H* is a pair $H = (X, F)$, where *X* is a set of elements called vertices, and *F* is a set of non-empty subsets of *X* called **hyperedges**. Let *F* be a subset of $P(X) \setminus \{\emptyset\}$, where $P(X)$ is the power set of *X* and $F(x) = \{f \in F : x \in f\}$ for $x \in X$. A hypergraph is also called a **set system** or a family of sets drawn from the universal set *X*. The **rank** of hypergraph *H* is the size of the largest hyperedge in *H*. A **set covering** of a hypergraph $H = (X, F)$ is a subfamily *C* of *F*, such that the union of hyperedges from *C* equals the universe of vertices. A **transversal** (or **hitting set**) of a hypergraph $H = (X, F)$ is a subset *T* of *X* that has a nonempty intersection with every edge. The notions of hitting set and set covering are equivalent. The **decision versions** of the **hitting set** and **set covering** problems are ***NP*-complete**. The **greedy algorithm** for set covering chooses the sets according to one rule: at each stage, choose the hyperedge that contains the largest number of uncovered elements. This algorithm actually achieves an **approximation ratio** $\frac{Card(C)}{Card(Opt)}$ (*Opt* is an optimal set covering) of *h(rank)*, where $h(n)$ is the n^{th} harmonic number. This value is approximately given by: $\mathcal{O}((1 + \log(Card(V)))$. We can construct a dual algorithm for a hitting set problem, for which the performance ratio is: $\mathcal{O}((1 + \log(Card(F)))$.

Algorithm 1 The Greedy set covering method

input: hypergraph $H = (X, F)$;
output: set covering *C*;
$U := X$; $C := \emptyset$;

while($C \neq X$)**do** {
  select *S* from *F* such that
    maximizes $Card(S \cap U)$;
  $U := U \setminus S$;
  $C := C \cup \{S\}$;
  }
return: *C*;

It is interesting that there exists a pair of **polynomial-time reductions** between the **minimum dominating set problem** and the **minimum set covering problem**. These reductions show that an efficient algorithm for the minimum dominating set problem would provide an efficient algorithm for the set covering problem and vice versa. According to the above presented facts, the greedy algorithm provides a factor $1 + \log(Card(V))$ approximation of a minimum dominating set. Let us consider a reduction from the dominating set problem to the set covering problem. For any given graph $G = (V, E)$ with $V = \{1, 2, ..., n\}$, construct a hypergraph $H = (X, F)$ as follows: the universe *X* is *V*, and the family of hyperedges *F* is $\{F_1, F_2, ..., F_n\}$ such that F_v consists of the vertex *v* and all vertices adjacent to *v* in *G*. Hence, if *D* is a dominating set for *G*, then $S = \{S_v : v \in D\}$ is a feasible solution of the set covering problem, with $Card(C) = Card(D)$. Conversely, if $S = \{S_v : v \in D\}$ is a feasible solution of the set covering problem, then *D* is a dominating set for *G*, with $Card(D) = Card(C)$. Hence, the greedy algorithm provides a factor $1 + \log(Card(V))$ approximation of a minimum dominating set.

Problems of finding the best location of facilities in networks or graphs abound in practical situations, such as determining locations for factories, assembly plants or warehouses, as well as in airline crew scheduling. One of the well known facility location problems is the **vertex *k*-center problem**, where given *n* cities and distances between all pairs of cities, the aim is to choose *k* cities called **centers** so that the largest distance of any city to its nearest center is minimal. Let $G = (V, E)$ be a complete undirected graph with edge costs satisfying the triangle inequality (for a given **metric** $d : E \to R$), and *k* be a positive integer not greater than $Card(V)$. For any subset *S* of *V* and a vertex $v \in V$, define: $d(v, S)$ to be the length of the shortest edge from *v* to any vertex in *S*. The **vertex *k*-center problem** is to find such a subset *S* of *V*, where $Card(S) \leq k$, which minimizes: $max(d(v, S))$ for $v \in V$. The vertex *k*-center problem is *NP*-hard. In this paper we solve the *k*-center problem as a series of a minimum dominating set problems.

A set of different approaches (like: tabu search, variable neighborhood search) to solve the *k*-center problem was given by authors [17]. Parallely, the various greedy methods were proposed in the following publications [13], [14].

III. Problem definition

This article is devoted the *P&R* facilities location problem (*P&R*) in public transportation network of Warsaw. The problem is to find a set of stops such that in the worst case scenario using the public transport each trip will take no more than assumed *k* minutes. In this paper we propose the application of two methods: the *greedy algorithm* and the *Tabu Search*.

The *k*-Park&Ride Problem

Input: Given $G = (V, E)$—transport network,
  $d : E \to R^+$—an average distance
    between two vertices,
  $k \in R^+$ - time limit;
Output: Find $S \subseteq V$ such that:
  (*) for each $v \in V$: $\min_{s \in S} d(v, s) \leq k$,
  (**) $minCard(S)$.

IV. Our approach

In this chapter the data characteristics and the solution construction method are presented.

A. Data

The dataset that we are working on consists of coordinates of all public transportation stops in the city of Warsaw and complete schedules for different mass transit modes (buses, trams, metro and passenger trains). There are about **4000 stops** within the city limits and **317 different routes** each with 1-4 unique trips.

The data containing stops, routes and schedules is made available by the Public Transport Authority in Warsaw. However, the files are not shared in any standarized format and thus require parsing to be suitable for processing. Several software tools have been developed by the authors in order to work with this data (parsers, graph builders). They usually consist of over 4 million connections divided in multiple sections. The first step is to parse the file into *JSON* format. The second one is to convert it to the *GTFS* using our tools. *GTFS* is the required format to use *OTP* implementation of the **Raptor** algorithm [2] to find the shortest paths in multi-modal transportation network with a schedule. In our case, over 16 million requests had to be sent to instances of *OTP* servers in order to fill the adjacency matrix of the graph.

B. Methods

We model the network in a time oriented manner, using average travel times between each pair of stops as the weights of the edges in the **graph *G***. In order to achieve this, we have converted the data to *Google Transit Feed Specification* and used *Open Trip Planner* (*OTP*) to calculate the shortest trips between all stops in a given time lapse. The *OTP* application is an open-source tool for journey planning in multi-modal transit networks.

Given a complete directed graph G, in which the weight w of the edges represents the average travel time between the stops, we choose the parameter k measured in minutes as a cut-off value and construct a new **graph *H*** such that:

$$V(H) = V(G),$$
$$E(H) = \{e \mid e \in E(G),\, w(e) \leq k\}.$$

We then use H as an input to the *minimal Dominating Set* algorithms in order to approximate the smallest subset of stops that allows us to reach all other stops within the given time bounds. Information about the density of Warsaw's mass transit network with respect to different values of k is presented in Table 1.

TABLE I
DENSITY AND NUMBER OF EDGES WITH RESPECT TO PARAMETER k

k [min]	**Edges**	**Density**
15	679296	≈ 0.04
30	3863959	≈ 0.23
45	9121623	≈ 0.55
53	11916338	≈ 0.72

Our Approach to The *k*-Park&Ride Problem

1) Construct a complete directed graph *G=(V, E)*, where $d(v, u)$ is the average travel time for $(v, u) \in E$ (obtained from the application of the *OTP* package),
2) Construct a graph *H* based on graph *G* with respect to the time limit *k*,
3) Find a *minimal Dominating Set* for a given graph *H* using the Tabu Search or a greedy method.

Two *minimal Dominating Set* approximation methods were used in our computations. We applied the greedy algorithm and the metaheuristic tabu search method. Both approaches were implemented by us in *Python* programming language with extensive use of *NumPy* library for fast matrix operations.

V. RESULTS

We prepared computation experiments based on typical PC (Intel i5 2.7 Ghz 8GB Ram) using the followin software: OSX El Capitan 10.11.14 (clients and computations), Ubuntu 14.04 (server OTP), Python 3.5.0, iPython 4.0.0, NumPy 1.10.1, python-geojson, environment PyCharm, iPython Notebook, Vizualization: MapBox and Ruby on Rails,

We achieved the following results in terms of the time complexity:

1) The Greedy Set Covering in dependency of *k*:

k [min]	15	30	45	53
Comp.time	≈ 16.4	≈ 5.3	≈ 4.61	≈ 3.52

2) The OTP - 16 000 000 queries ($\approx$ 111 hours).
3) The Tabu Search in dependency of k (time for 100 iterations):

k [min]	15	30	45	53
Comp.time	≈ 4.1	≈ 4.2	≈ 4.5	≈ 5.0

The Park and Ride system in Warsaw consists currently of 14 parkings and they form a dominating set under our model when the time trip is $k \geq 53$ minutes. According to the computational results based on the new model these locations ensure that the longest journey from them to any stop will not exceed 53 minutes (they form a dominating set when $k \geq 53$). Under the same constraint (maximum 53 minutes travel time) we have found dominating sets of sizes 5 (greedy) and 3 (tabu search). It is interesting to note that when the maximum of travel time is limited to 30 minutes, the cardinality of the calculated dominating sets, as well as the locations of parkings are similar to those of the already existing facilities in Warsaw. This might suggest that small improvements/changes to the existing park and ride system might be very beneficial in terms of maximum journey distance (cutting it down from 53 to 30 minutes).

TABLE II
CARDINALITY OF DOMINATING SETS FOUND BY DIFFERENT METHODS

	***k* (min)**			
Algorithm	15	30	45	53
Greedy	69	15	8	5
Tabu search	62	12	5	3

However, we can achieve domination in this network by selecting only 3 nodes (see Figure 2).

VI. CONCLUSIONS

In this article we describe the analysis of the optimal location of transport hubs in Warsaw, in the context of the Park

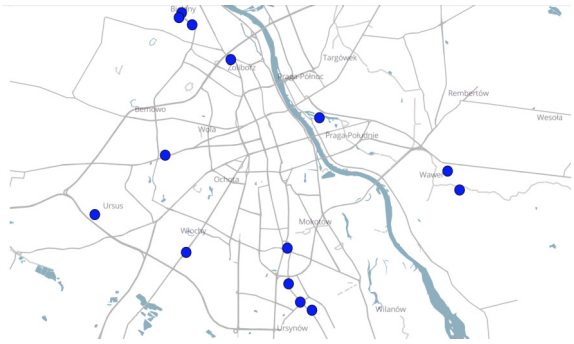

Fig. 1. Existing Park and Ride facilities

Fig. 2. Dominating set of cardinality 3 for $k = 53$ (tabu search)

Fig. 3. Dominating set of cardinality 12 for $k = 30$ (tabu search)

and Ride location problem. We took into account the expected travel time between two particular points. This problem was reduced to the problem of determining the centers in the sense of the dominating set. Data for our research were obtained and collected from the website of the public transport authority. In order to establish the format, the data was converted to *JSON* a format, and then to the *GTFS* one. Using the *OTP* package we computed the expected journey times between all pairs of stops in Warsaw public transport. In the currently existing *P&R* system we have 14 locations, and in this case the maximum travel time exceeds 50 minutes. In order to determine the optimal locations for *P&R* two methods: the greedy and the tabu search algorithms have been implemented (in *Python*). The result obtained imply the dominating set consisting of 3 stops, in the contrast to the existing 14 *P&R* parks. For the

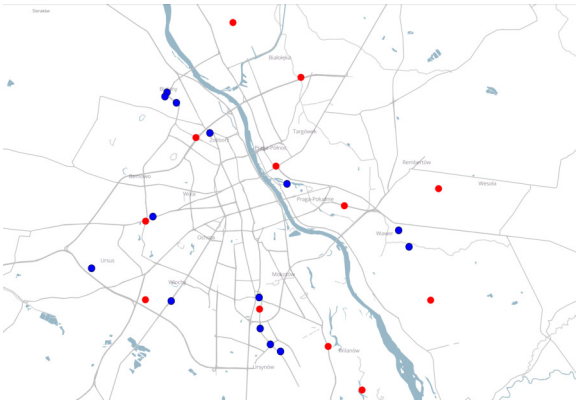

Fig. 7. Dominating set of cardinality 12 for $k = 30$ (red dots) and existing $P\&R$ (blue dots) (tabu search)

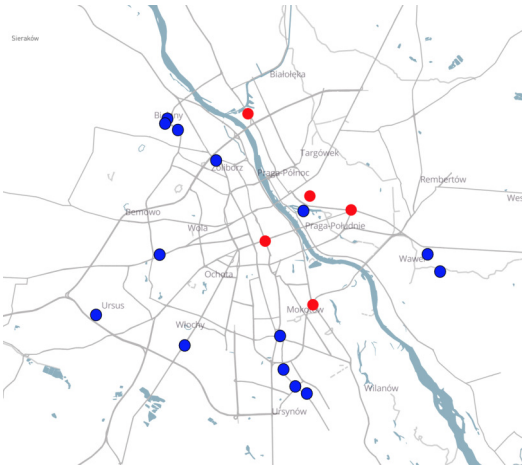

Fig. 8. Dominating set of cardinality 5 for $k = 53$ (red dots) and existing $P\&R$ (blue dots)(greedy algorithm)

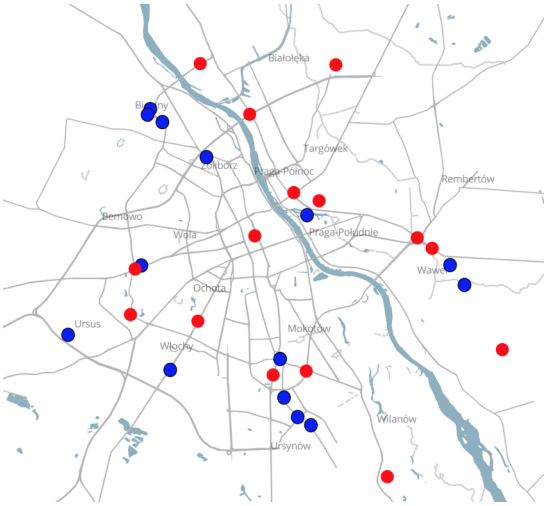

Fig. 9. Dominating set of cardinality 15 for $k = 30$ (red dots) and existing $P\&R$ (blue dots)(greedy algorithm)

assumed 30 minutes time limit, the result consists of 12 stops. This analysis seems to be interesting in the context of further development of the *P&R* system. To summarize, the aim of the *P&R* system is not only to discharge the traffic directed to the city center, but also to enable passengers to conveniently travel to different locations. Unfortunately, we can not say this about the existing solution.

***Abstract*—With gamification, design elements known from games can be used to increase employees' engagement and improve users' experience. This paper points to Enterprise Information Systems as a viable point of implementation of gamification. There are three relevant questions: what gamification actually consists of, why it is worthwhile to apply it in Enterprise Information Systems, and how to implement it properly. The paper aims to answer them.**

I. Introduction

FOURTEEN years have passed since Nick Pelling coined the term of *gamification* [1, p. 5]. The "use of game elements to increase engagement and make life and work more fun" (as it was neatly defined by Mark Schreiber [2]), despite the criticism (see e.g. [3, p. 18] and works cited therein), has already found its way into such diverse areas as, among others, marketing [4] and knowledge management [5], banking [6] and education [7], production environments [8] and tourism [9], and even scientific research [10].

This paper investigates the application of gamification in Enterprise Information Systems (EIS), understood as "software systems that integrate the business processes of organizations to improve their functioning" [11]. Gamification does not aim at redefining the business processes, but on affecting how they are experienced [12]. The underlying software plays an important role as it allows to automate tracking participants' actions, register their achievements, and pass relevant feedback [13].

The paper aims to provide answers to the three basic questions: what actually forms the applied gamification, what can be the reasons for making use of it in Enterprise Information Systems, and how to implement it there properly. The structure of the paper has been modeled appropriately into three sections, ending with the conclusion.

II. What the applied gamification consists of

Although a definition of gamification has already been provided, even the reading of thirty definitions gathered by Andrzej Marczewski [2] does not tell what a gamified system actually consists of. In order to explain that, it is necessary to look at the actual components of gamification.

One of the most widely known lists of gamification elements is the one devised by Kevin Werbach and Dan Hunter [14]. They classify them into dynamics ("the big-picture aspects of the gamified system"), mechanics ("the basic processes that drive the action forward and generate player engagement"), and components (the "more-specific forms that mechanics or dynamics can take").

The dynamics include:

- *constraints* – limitations or forced trade-offs,
- *emotions* driving players, such as: curiosity, competitiveness, frustration, happiness etc.,
- *narrative* – the storyline of the game,
- *progression*, measuring players' development,
- *relationships* – players' social interactions.

The mechanics include:

- *challenges* – tasks that require effort to solve,
- *chance*, bringing in randomness to the game,
- *competition* between players or groups of them,
- *cooperation*, requiring players to work together to achieve a shared goal,
- *feedback* providing players with information about how they are doing,
- *resource acquisition* – allowing players to gather useful or collectible items,
- *rewards* given for some action or achievement,
- *transactions* – allowing item trading between players,
- *turns* – sequential participation by players,
- *win/loss/draw states* – objectives that make one player/team the winner and the others the losers.

What Werbach and Hunter call components includes:

- *achievements* – defined objectives,
- *avatars* – player's character visual representation,
- *badges* – visual representations of achievements,
- *boss fights* – rare, extremely hard challenges,
- *collections* – sets of items/badges to accumulate,
- *combat* – a defined battle, typically short-lived,
- *content unlocking* – additional game content available after players reach certain objectives,

The publication was financed from the funds of the Department of Engineering of Information Systems at the Faculty of Economics and Management of University of Szczecin for maintaining research potential.

- *gifting* – players' ability to share their resources,
- *leaderboards* that visually present player's achievements in relation to other players,
- *levels* that define steps in players' progression,
- *points* which measure players' progression,
- *quests* – sets of tasks with objectives and rewards,
- *social graphs* that represent players' network of contacts within the game,
- *teams* – groups of cooperating players,
- *virtual goods*, which have perceived value.

A much more comprehensive list of gamification components can be found in the Octalysis framework developed by Yu-Kai Chou [15]. He clusters them into eight categories, labeled as "core drives" of gamification.

The first drive is epic meaning & calling. Its components help players justify devoting their time to the game. They are supposed to make players believe that they are doing something great (*narrative*, *higher meaning*) or were "chosen" to do something (*elitism*, *humanity hero*, *destiny child*), or that they have got some gift that others have not (*beginners luck*, *free lunch*). Players may also feel attached to the game world elements they created (*co-creator*).

The development & accomplishment components exploit the players' internal drive to make progress in absolute (*points*, *progress bar*) or relative terms (*leaderboards*), acquire (*step-by-step tutorial*) and develop skills (with *badges* as achievement symbols), overcome challenges (chosen from *quest list*, or the final *boss fights*), and receive due appreciation for it (*fixed action rewards*, *win prize*, *high-five*, *crowning*, *level-up symphony*, *aura effect*).

The empowerment of creativity & feedback components give players the decisive power (*general's carrot*) and engage them in a creative process, where they have to repeatedly figure things out (*evergreen mechanics*, *blank fills*) and try different combinations (*real-time control*, *chain controls*) possibly using approaches unavailable earlier (*milestone unlock*, *boosters*) after receiving *instant feedback* or hints (*choice reception*). They may also have a chance to opt out of a given challenge (*voluntary autonomy*).

The ownership & possession components give players the feeling of owning something (*virtual good*, *avatar*), so that they want to make what they own better (*build from scratch*) while progressing in the game (*learning curve*) and own even more (*earned lunch*, *collection set*). The players' attachment to their belongings can be augmented by letting them constantly observe what they have (*monitoring*) and have them protect it from dangers (*protection*). The feeling of possession can also be extended to other players one has invited to the game (*recruitment*).

The social influence & relatedness components refer to activities inspired by what other people think, do, or say as well as the desire to draw closer to people, places, or events that players can relate to. It includes making personal relations publicly observable (*friending*), having veteran players as guides (*mentorship*, which also makes the beginner players more attached to the specific culture, as well as helps veteran players stay engaged in the game), cooperating with other players to solve difficult challenges (*group quest*), showing other players one's accomplishments, either explicitly (*bragging*) or implicitly (*touting*), having a place to chat about a variety of topics (*water cooler*), gifts or rewards that players can only receive from other players (*social treasure*), encouraging players to generously give, expecting the recipients to give back somehow (*thank-you economy*), and making social interactions technically very easy to perform (*social prod*).

The scarcity & impatience components address the human tendency to want things they cannot have. They include constantly showing an item that a player cannot easily get (*dangling*), having something accessible only at specified time (*appointment dynamics*), or in *fixed intervals*, or after meeting specified conditions (*moats*), showing time after which something becomes inaccessible (*countdown*), changing the pace at which progress can be made (*throttles*), and requiring players to collect multiple pieces to earn the actual reward (*prize pacing*).

The unpredictability & curiosity components exploit the human infatuation with experiences that are uncertain and involve chance and the natural curiosity to explore. They include surprises (*Easter eggs*), also in form of unexpected rewards (*sudden rewards*), *oracle effect* that makes player expect an event to happen in the future (and wonder whether it will actually happen), quests within quests (*mini quests*), *glowing choice* which leads players in the right direction by appealing to their curiosity, lotteries that some player has to win each period, with actions available that increase one's chance (*rolling rewards*), *random rewards* that recreate the excitement that children have opening gift boxes, and playing small pranks on players (*mischief*).

The loss & avoidance components motivate players with a threat of losing something they have attained. They include *sunk-cost tragedy* (players continue the game, because they spent a lot of time playing so far), *progress loss* (if players stop playing, they lose what they earned), *fear of missing out* (players are aware that when they do not participate, things happen that could benefit them), *evanescence opportunity* (which will disappear if a player does not perform certain action), *scarlet letter* (a shame of not having something all the good players have), *status quo sloth* (wanting to continue the game with the same behavior), and marking the loss in a special way (*weep tune* and *visual grave*).

III. Why apply gamification to EIS

There are various reasons given why gamification can be helpful for an enterprise. The primary argument is the link between games and intrinsic motivation, which can be exploited with gamification. All the seven main intrinsic motivators identified by Thomas W. Malone and Mark R. Lepper (i.e., challenge, curiosity, control, fantasy, cooperation, competition and recognition [16, p. 230 and

242]) can be effectively addressed in a gamified system (see section II). And that the lack of motivation is a serious issue in enterprises can be seen, e.g., from the results of the long-term Gallup poll showing that 70% of American workers are not engaged at work [17].

There are also other reasons provided in the literature (see e.g. [18] and works cited therein). One is the lack of goal prioritization making employees overladen with both present activities and development opportunities losing interest in taking actions that are not needed at the moment, but will be crucial in the future. A gamified system can both rank the possible actions in terms of their relative value to the enterprise, and provide a path of development to follow.

The second reason is the coming of the new generation of employees: Generation Z, *digital natives*, who have different expectations from work and communication habits than previous generations. A gamified system can use the type of communication they are familiar with, and work as a bridge between them and the older employees.

Another one is the omnipresence of stress in many corporate environments, which leads to lower productivity, problems with interpersonal communication, and even physical and psychic health issues. A well-designed gamified system can both address some causes of stress (with its informal communication and a clear system of priorities) and aid in stress relief (with relaxing side activities and mood-improving feedback it offers).

Regardless of what the reason is, there are numerous examples of successful enterprise gamification [19].

Moving on to the details of gamification in Enterprise Information Systems, Table I lists its possible uses grouped in four categories, consisting of those related to the improvement of: work performance, work attitude, social relations, and on-boarding and training processes. Note that the list is not exhaustive, as it is up to the creativity of a designer to find a combination of gamification components that would address particular goals that the enterprise management may consider important.

TABLE I.
POSSIBLE USE OF GAMIFICATION IN EIS

Practice	Expected benefit	Relevant component
Performance		
Bundle tasks and split rewards	Users are motivated to work consistently, and complete related tasks together	Collection set, Prize pacing
Define rush hours when productivity is most needed	Users should increase their effort at the right time	Appointment dynamics, Fixed intervals
Differentiate the rewards for completing various tasks	Users are directed to the most important tasks at a given moment	Fixed action rewards, Virtual good
Mark very hard tasks	Users can prepare better for a big challenge	Boss fights
Reward what every user should do	Users are motivated to catch up with others	Scarlet letter
Visualize relative employees' performance	Users are motivated to rise over others	Leaderboards
Visualize the distance to the goal	Users are motivated to finish the current task	Progression bar
Visualize the time left	Users are motivated to hasten their work	Countdown
Work attitude		
Announce crucial events that will come later	Users are curious of what will actually happen	Oracle effect
Define penalties for failing to complete a task	Users appreciate what they have attained and could lose	Points, Protection, Progress loss
Leave users some degree of freedom	Users feel they have control of what they do	General's carrot, Voluntary autonomy
Let users improve or customize the system	Users feel attached to what they created	Co-create
Provide a chance of surprise	The monotony of repetitive tasks is shunned	Easter eggs, Random rewards, Mischief
Provide a chance to shine for everyone	Even lagging users can have their moment of glory	Rolling rewards
Remind users the importance of their role	Users are aware of the value of their contribution	Elitism, Humanity hero
Remind users the enterprise mission	Users feel they are part of something big and good	Higher meaning
Reward completion even of the simplest tasks	Users feel their effort is recognized	Fixed action rewards, Virtual good, High-five

TABLE I (CONTINUED).
POSSIBLE USE OF GAMIFICATION IN EIS

Practice	Expected benefit	Relevant component
Visualize how the results of repetitive tasks accumulate	Users comprehend the magnitude of their everyday work	Points, Progression bar
Visualize possible big rewards	Users are aware of what they can gain if they stay engaged	Dangling
Visualize the progress a user has made so far	Users comprehend the progress they made which should increase their self-esteem	Levels, Badges, Monitoring
Social relations		
Let employees collaborate on tasks	Arduous tasks can be finished on time and knowledge is transferred from the more to the less experienced users	Group quest
Let users boast their accomplishments	Users can share their gladness with others	Bragging, Touting
Let employees visualize their relations	Social relations are improved	Friending
Let users discuss freely	Users get to know each other, share experiences and ideas	Water cooler
Let users help each other	Knowledge is transferred from the more to the less experienced users and their social relations are improved	Thank-you economy
Let users reward each other	Users feel their effort is recognized and their social relations are improved	Social treasure, Virtual good
Make it fast and easy to interact with others	Social interactions do not hurt productivity much	Social prod
On-boarding and training		
Appoint more difficult tasks to users as they make progress	Users do not get bored or frustrated with tasks that are too easy or too hard for them	Milestone unlock, Learning curve
Celebrate passing important steps of development	Users feel the progress they make matters	Level-up symphony, Aura effect
Communicate action results immediately	Users know when they do well	Instant feedback
Guide users in their steps	Users know what to do to progress	Step-by-step tutorial, Choice reception
Introduce users to the organizational culture	Users adapt faster to the organization	Narrative
Let experienced users guide new ones	Knowledge is transferred from experienced to novice users and social relations are created	Mentorship
Make the first steps easier for beginner users	Users get a positive first impression	Beginners luck, Free lunch, Boosters
Make users improve their weak sides before they can move on	Users' skill development is more balanced	Moats

IV. HOW TO PROPERLY IMPLEMENT GAMIFICATION IN EIS

The successful implementation of gamification in EIS is a matter of primary importance, as a failed attempt will bring costs in morale and productivity, notwithstanding the cost of the implementation itself.

It is therefore strongly advised to carry it out in a carefully planned manner. The first thing is to follow a proven procedure, such as the player experience design process proposed by Brian Burke [1], which includes seven steps respectively devoted to: (1) business outcomes and success metrics, (2) target audience, (3) player goals, (4) engagement model, (5) play space and journey, (6) game economy, and (7) repetitive playing and testing (highly possibly leading back to one of the previous steps).

Mario Herger convincingly argues that gamification should be focused on value creation for the players, and only through it the value for the organization should be created [20]. While the player's value creation does not automatically translate into an organization's value creation, but also the value created for an organization may be larger than the value for an individual player. He also lists three types of reactions that should be achieved with gamification: Aaah-effect (the act of delight), Aha-effect (the act of revelation) and the Haha-effect (the act of amusement).

Fabian Groh provides eleven design principles for implementing gamification [21]: (1) connect to personal goals, (2) connect to a meaningful community of interest, (3) create a meaningful story, (4) beware of social context

meanings, (5) provide interesting challenges, (6) provide clear, visual, varying, and well-structured goals, (7) provide juicy feedback, (8) beware of unintended behaviors, (9) play is voluntary, (10) beware of losing autonomy, and (11) beware of devaluating activities.

Ethan Mollick and Nancy Rothbard highlight the role of consent, understood as the active cooperation of workers with managerial goals, owing to the fact that gamification is not driven organically by employees, but instead imposed from the top by managers [22, p. 14]. They therefore point to the importance of three indicators of consent, i.e. clearly understanding the rules of the game, perceived sense of justice and fairness, and active engagement.

The last aspect that needs to be addressed is the technology of implementation. The gamification subsystem can be developed as a module of an EIS or a separate gamification software that has to be integrated with the main system. A generic platform for enterprise gamification, based on service-oriented and event-driven principles, as well as best practices, and targeted for both modern and legacy systems, was proposed by Philipp Herzig *et al*. [23].

V. Conclusion

Gamification is able to make the employees' experience of performing tedious and repetitive tasks more enjoyable, rise their engagement, improve their attitude towards work, and, consequently, increase their productivity.

The rich portfolio of successful gamification projects makes it something too promising to ignore for enterprises in the world of scarce opportunities for gaining competitive advantage (*cf*. the *scarlet letter* gamification component).

The Enterprise Information Systems, due to their prevalence in today's organizations, are viable points of implementation of gamification spanning over different business processes and addressing various types of employees' activity.

This paper provided answers what the gamification amounts to in practice (with a catalog of gamification components in section II), why it can be useful to implement it in an EIS (with explanations for why it can work and a list of possible uses in section III), and how to do it right (with implementation guidelines in section IV).

***Abstract*—The MCDA methods are used in order to solve complex decision-making problems which require considering many interrelated criteria. They are also the basis of DSS. Nevertheless, these dependencies between criteria can have an influence on the obtained solution. A class of decision-making problems, in which there are intercriteria dependencies, are decisions in the sustainability area, e.g. selection of a location and a design of an RES-based power station. The article presents a complex model, taking into consideration dependencies between criteria.**

I. Introduction

ONE of the greatest challenges of energy-saving in Poland and other countries of the world is its adaptation to the demands of low carbon economy characterized mostly by the use of renewable energy sources (RES) [1].

The Polish Energy Law Act, which is a source of renewable energy, defines the following: wind energy, solar energy, geothermal energy, sea wave and tidal energy, river fall energy, biomass energy, energy from landfilled biogas and biogas produced in the process of sewage disposal and treatment or decomposition of plants and animal remains [4]. Among the above-mentioned RES, the greatest potential for energy production, which can be found in Poland and the EU have wind farms [2], [3].

The selection of a location [5] and of a project design [6] will lead to the successful implementation of a wind farm project. These choices determine the efficiency of wind power plants and also have an effect on the environment, benefits and costs [7]. The problems of location selection and project design selection, as well as other decision factors related to RES management, are multi-criteria decision-making problems which require the examination of many contradictory and mutually correlated criteria which encompass technological, economic, environmental and social issues [5], [6], [8], [9]. Decision-making methods which consist of a sole criterion are unable to cope efficiently with such decision problems [10]. While solving such problems, multi-criteria decision analysis (MCDA) methods can be applied, as they can handle complex decision processes, multiple and conflicting evaluation criteria, different scenarios, preferences of decision-makers, several sources of uncertainty and specific time frames [11] [12]. Many Decision Support Systems (DSS) are based on MCDA methods and algorithms and used for solving environmental problems and those relating to the power industry [13]. DSS provide knowledge indispensable for making decisions and maximize the results of processes of decisions, by lifting cognitive, special and economic restrictions of the decision-maker [14].

The aim of this article is to establish a multi-criteria decision model, based on MCDA methods, which solve a decision problem comprising of the selection of a location and a project design of an onshore wind farm. The model should not bypass the complexity of the decision problem, but should take into account mutual dependencies between criteria and the influence of some criteria on other ones. This model could become a DSS engine for RES management, while paying particular attention to wind farms.

Section II displays the analysis of the explanations on decision support related to the design and construction of wind farms. The pre-selection of evaluation criteria of wind farm location and design was made according to the implementation of the analysis. The evaluation criteria were incorporated into a decision model, which was presented in Section III. Section IV contains a summary of research results, and further research directions are also pointed out.

II. Literature review

Publications regarding the decision for support in wind energy mostly include the construction of decision models as well as that of DSS and GIS (Geographical Information System) systems.

An example of constructing a decision model for the selection of a wind farm location is [15]. In this paper, evaluation criteria and their importance were presented in a decision model for the sake of selecting a wind farm location. On the other hand, in [16] a decision model was devised in order to compare different RES technologies (wind energy received the highest rank), and it subsequently modified in order to select a location of an onshore wind farm. The issue of devising a decision model for the

selection of an onshore wind farm location is also dealt with in [17], and an offshore one received a similar treatment in [5]. GIS decision systems were suggested, amongst other things in [18], [19], [20], [21]. These systems evaluate the potential of onshore areas regarding the situation of wind farms nearby. Similarly, in [22] a GIS was presented; itallowed the evaluation of a location of hybrid power stations based on wind and solar energies. In [23], a GIS-based DSS system analyzing the potential of onshore wind farm locations was discussed. The problem of the construction of a DSS for selecting an offshore wind location was attempted in [24], [7]. As far as decision problems relating to the project design of a wind farms are concerned, these were discussed in [6], [25]. The technical aspects of wind turbines are also related to farm designs[8] as well as wind farm development evaluation, in the bigger picture [26].

The AHP (Analytic Hierarchy Process) [27] method is used in selecting a location or a design of a wind farm, both in its crisp and fuzzy [28] [29] versions. It is primarily employed to determine the importance of criteria. A generalization of AHP, namely ANP (Analytic Network Process) [30], and different variants of the ELECTRE method are rarely used. Other MCDA methods, such as DEMATEL, OWA, SAW, PROMETHEE, NAIADE, TOPSIS, VIKOR, Lexicographic method and the conjunctive method, etc are also incidentally used. [31]. It should be noted that, in order to solve decision-making problems related to wind energy, decision models are used, and these are characterized by various complexities. The amount of criteria considered while selecting a location or a design of a wind firm ranges from 6 [19] to 35 [6]. These criteria are often interrelated and interdependent. For example, in this publication [6], the following criteria were used: generating cost, generating profit, and payback period. It can be easily seen that the payback period results from, among other things, a calculation of costs and profits.

III. The Proposed Decision Model for DSS

The construction of the decision model was done in the following manner:

1) The preparation of a set of criteria and sub-criteria for the evaluation of locations and designs of onshore wind farms,
2) The analysis of sub-criteria and indication of relationships and dependencies which occur place between them,
3) The presentation of sub-criteria dependencies in a networking decision model.

On the basis of the literature analysis presented in Section II, a set of criteria for the evaluations of locations and designs of onshore wind farms was prepared and displayed in Table I. The sub-criteria section was shown as well.

Next, the sub-criteria were analyzed and their interdependencies were explained.

C1.1The wind conditions influence the output power which is obtained from a wind turbine, at a specific wind speed and consequently, the desired amount of energy is generated. Generally, a stronger wind generates more energy; however, the wind should not be too strong, as most wind turbines switch off when the wind reaches the speed of about 25-30 m/s [8]. The wind speed is essential, depending on the height at ground level. Most towers which have turbines mounted onto them are 50-100m high [32], therefore the wind speed at the height of ca. 100m is crucial.

TABLE I.
CRITERIA AND SUB-CRITERIA FOR EVALUATING LOCATIONS AND DESIGNS OF ONSHORE WIND FARMS

Criteria		Sub-criteria		References
C1	Technical	C1.1	Average wind speed at the height of 100m	[5], [6], [15], [17], [19]-[21], [23], [24], [26]
		C1.2	Output power of wind turbine	[8]
		C1.3	Power grid voltage on the site of connection	[26]
C2	Economic	C2.1	Yearly amount of energy generated	[6], [7], [25]
		C2.2	Investment cost	[5]-[7], [16], [25]
		C2.3	Operational costs per year	[5], [6], [16], [25]
		C2.4	Incomes from generated energy per year	[26]
		C2.5	Profits from generated energy per year	[5], [6], [24]
		C2.6	Payback period	[5]-[7]
C3	Social	C3.1	Number of generated workplaces	[5], [6], [15]
		C3.2	Social acceptance	[16], [25]
C4	Spatial and environmental	C4.1	Distance from power grid connection	[20]-[24]
		C4.2	Distance from the road network	[15], [18]-[23]
		C4.3	Location in Natura 2000 protected area	[7], [19], [22], [23]

C1.2 The maximum output power of a turbine is achieved at a specific wind speed, which is critical. If the wind speed is lower, then the output power is equally lower.

C1.3 Voltages of the national power grid, which are used in Poland, amount to 110kV, 220kV, 400kV and 750kV [33]. The voltage of a power grid is an essential sub-criterion, since changes in the wind speed cause frequency, voltage and power fluctuations in the grid connected to a wind turbine [34]. Such fluctuations may, in turn, cause damage to transmission lines of the grid or transformers. Such a hazard is more likely in the case of high-voltage wind farms (from several dozens of MW) to a low-voltage grid (110kV) [35].

C2.1 We have mentioned above that the amount of energy generated is directly affected by the output power of wind turbines installed in the wind farm. The yearly amount of energy generated by a wind farm is presented, in its simplest form, in the formula (1):

$$E = \sum_i W_{out}(t_i) * 8760 \qquad (1)$$

where: E – yearly amount of energy generated [MWh], $W_{out}(t_i)$ – output power of an i-th turbine [AMW], 8760 – the number of hours in a year [Ah].

C2.2 The overall investment costs consist mostly of the costs of purchasing and installing turbines, towers and their foundations, the costs of preparing a wind farm design, as well as the costs of connecting a wind farm to the power grid [36]. The amount of capital investment for an onshore wind farm in Poland, depending on the technology applied, varies from 4.5 million to 7.5 million PLN/MW [37].

C2.3 The operational costs also include the operation, repairs and servicing of the devices, leasing costs of the land, management, insurance, taxes and charges, the energy consumption of the wind farm, as well as balance costs. It is estimated that the operation costs of a wind farm in Poland in 2011, in total, amounted to 83 PLN per one MWh of the energy generated by the wind farm [36].

C2.4 The income from the energy production is a product of generated (and sold) amount of energy and its price. An average sales price of the electric energy on the competitive market in Poland in the third quarter of 2015 amounted to ca. 173 PLN/MWh [38]. However, a new law defining RES auctions has been recently introduced. RES-based power stations can participate in such auctions. When an auction is won, the power station has the certainty that the Polish state will purchase from them the energy at a set price for a period of 15 years [39]. The reference price of the onshore wind energy for an RES auction, which is generated in a wind farm of combined power greater than 1MW in 2016, amounts to 385PLN/MWh [40].

C2.5 In simple terms, a yearly profit from selling the energy can be determined as being the difference between incomes from the energy sales and operational costs incurred to generate the energy sold.

C2.6 The payback period determines a period of time after which capital expenditure incurred through the construction of a wind farm will pay for itself. The payback period is, in fact, a ratio of investment costs to a yearly profit generated by the wind farm.

C3.1 The construction of new wind farms and maintenance of existing ones generate workplaces related to the preparation of the investment, its operation, maintenance, repairs and equipment servicing. Estimates for Poland suggest that the installation of 10MW in a given year generates 39 direct and 75 indirect workplaces. The maintenance of 10MW, in turn, is connected with the employment of 5 workers in subsequent years [41].

C3.2 Social acceptance refers to benefits, threats and inconveniences for a local community. Research results highlight that the high level of acceptance for the wind energy is declared by about 12% of Polish citizens, low – 3%, whereas 85% of Polish citizens accept the wind energy to a certain degree. [42]. It is unlikely that potential workplaces can positively influence the social acceptance of constructing a wind farm.

C4.1 The distance from a power grid connection is related with the facility of connecting the wind farm to the power grid. Such a connection should be as close as possible, since it reduces the possibility of potential problems on a transfer line related to the quality and stability of power supply [43].

C4.2 The distance from the road is important during the construction period. A short distance from main roads enables the comfortable delivery of construction elements, such as masts or rotors, to the site. One needs to understand that, as far as Poland is concerned, the road infrastructure is usually poorly developed in the areas with good wind conditions, [44].

C4.3 The Natura 2000 protected areas are breeding and resting sites for rare and endangered fauna and flora, as well as some rare natural habitats which are crucial to the European Community [45]. Locations which form part of the Natura 2000 protected areas are more likely to encounter difficulties with investment, since some potentially negative acts towards the sites are prohibited. It is possible to obtain permits to carry out actions which negatively impact the sites [45]; however, these are connected with incurring financial outlays and downtimes in the construction of a wind farm. It should be noted that, according to Polish law, wind farms and other buildings cannot be situated within national and landscape parks or nature reserves [45].

On the basis of the individual analysis of sub-criteria one can easily determine their dependencies and relationships. These dependencies of one criterion onto another are illustrated by a graphic outline of the decision model presented in Figure 1.

IV. Conclusions

The complex decision model, prepared by the authors of this article was prepared, in order to deal with the problem of selection of the location and design of a wind farm. Therefore, it takes into consideration complex dependencies between decision-making criteria (sub-criteria) and consequently, it can be more precise than decision models which assume independence between criteria.

The precision of a decision model is particularly important in Decision Support Systems; the latter recommend pareto optimal solutions to decision-makers. In the case of a less accurate decision model which does not take into consideration interdependencies of criteria, recommendations obtained in DSS can be inexact. Therefore, the designed decision model can be used as a DSS decision engine.

The verification of the prepared decision model should be carried out while taking into account the decision problem in the field of wind energy. Unfortunately, most MCDA methods, which form the foundation of DSS, assume that the independency between criteria is to simplify the decision-making process. These methods cannot be easily applied to more challenging decision-making problems [46] because, if redundant criteria are used in the model, one can reach an incorrect solution [47]. Therefore, an essential factor is a proper selection of an MCDA method [48], [31] which would make it possible to build a complex decision-making

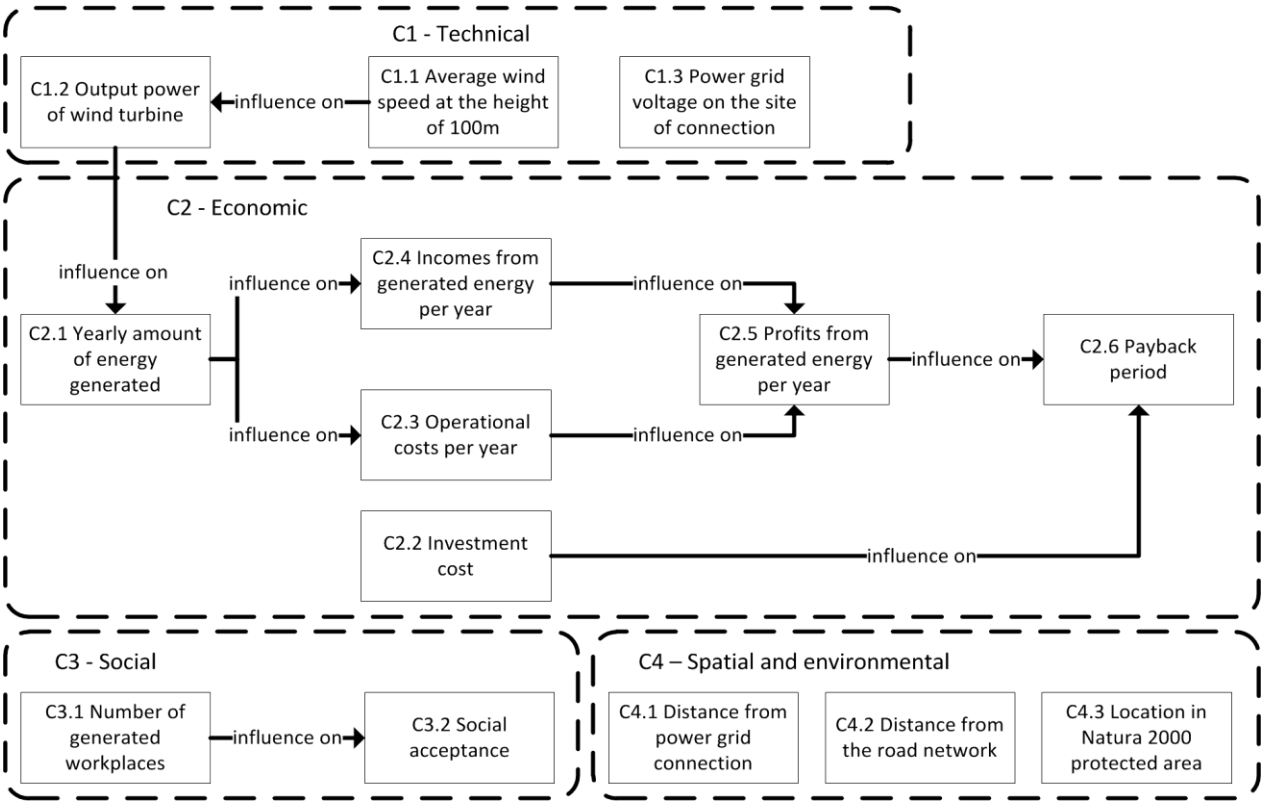

Fig. 1 Dependencies between criteria considered in the decision model

model for DSS, while taking into consideration mutual dependencies between criteria. The methods which allow the observation of the influence of individual criteria on other ones in the model are ANP [49], [30] and DEMATEL [50], [24].

The decision model which has been designed should evidently be used on a continuous basis. The best course of action would be to add criteria and sub-criteria of evaluations of wind farms, as well as other RES factors to the model. It would also be interesting to present the decision model in the form of an ontology [51], which would enable the deduction of new information from the model [52], [53]. The performance of the model would also move in a smoother manner towards the application of DSS in other situations.

11th Conference on Information Systems Management

THIS event constitutes a forum for the exchange of ideas for practitioners and theorists working in the broad area of information systems management in organizations. The conference invites papers coming from two complimentary directions: management of information systems in an organization, and uses of information systems to empower managers. The conference is interested in all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in an organization. Moreover, the papers that discuss the uses of information systems and information technology to automate or otherwise facilitate the management function are specifically welcome.

TOPICS

- Management of Information Systems in an Organization:
  - Modern IT project management methods
  - User-oriented project management methods
  - Business Process Management in project management
  - Managing global systems
  - Influence of Enterprise Architecture on management
  - Effectiveness of information systems
  - Efficiency of information systems
  - Security of information systems
  - Privacy consideration of information systems
  - Mobile digital platforms for information systems management
  - Cloud computing for information systems management
- Uses of Information Systems to Empower Managers
  - Achieving alignment of business and information technology
  - Assessing business value of information systems
  - Risk factors in information systems projects
  - IT governance
  - Sourcing, selecting and delivering information systems
  - Planning and organizing information systems
  - Staffing information systems
  - Coordinating information systems
  - Controlling and monitoring information systems
  - Formation of business policies for information systems
  - Portfolio management,
  - CIO and information systems management roles

EVENT CHAIRS

- **Arogyaswami, Bernard,** Le Moyne University, USA
- **Chmielarz, Witold,** University of Warsaw, Poland
- **Karagiannis, Dimitris,** University of Vienna, Austria
- **Kisielnicki, Jerzy,** University of Warsaw, Poland
- **Ziemba, Ewa,** University of Economics in Katowice, Poland

PROGRAM COMMITTEE

- **Abu-Shanab, Emad,** Yarmouk University, Jordan
- **Alghamdi, Saleh,** University of Sussex, United Kingdom
- **Bialas, Andrzej,** Institute of Innovative Technologies EMAG, Poland
- **Bicevska, Zane,** DIVI Grupa Ltd, Latvia

***Abstract*—The highly competitive global environment of the last few decades has urged companies to rely on Information Systems (IS) in order to improve customer service, reduce costs and increase productivity. In that direction, Enterprise Resource Planning (ERP) systems are being used as significant strategic tools that provide competitive advantages and lead to operational excellence. Despite that, ERP implementation projects are complicated, costly and include high failure risks. The present study aims (a) to develop and (b) empirically test a conceptual framework that investigates the factors affecting ERP system effective implementation in Small and Medium Enterprises (SMEs). The examination of the conceptual framework was made with the use of a newly-developed structured questionnaire that was distributed to a group of Greek SMEs. After the completion of the research period, 159 usable questionnaires were returned. The reliability and the validity of the questionnaires were thoroughly examined, while research hypotheses were tested using the "Structural Equation Modeling" (SEM) technique. Results offer interesting empirical observations and managerial implications.**

I. Introduction

THE business world has been hugely transformed during the last few decades [1]. Globalisation, increasing competition, constant change in the external environment, and private sector growth are among the most significant changes in the global business environment [2]. These transformations have urged most companies to adapt in order to survive [1] [3] [4].

More specifically, organisations aim at maintaining or improving the level of their competitiveness by using Information Systems (IS) in order to reduce costs, increase customer satisfaction, and improve business processes [5]. According to various authors [3] [6] [7], this drive for achieving higher levels of productivity, effectiveness, and performance is urging organisations to adopt Enterprise Resource Planning (ERP) systems. Tsai, Li, Lee and Tung [4] argue that, since their introduction in the early 1990s, ERP systems have become the centre of modern business.

ERP systems are Information Systems (IS) that facilitate the integration of business processes across functional units, using a common database and shared information [4] [6] [8]. According to Garg and Garg [8], this "enables the decision-making process to be timely, consistent and reliable across organizational units and geographical locations" (p. 424).

ERP implementation has various benefits throughout the organisation: elimination of redundant information, drastic declines in inventory, reduction of production cost, better understanding of the changing customer needs, more efficient management of the extended network of suppliers and customers, increased productivity, improved response time, and decreased production cycle [5] [8] [9] [10] [11]. Considering these benefits, it is not surprising that ERP systems are being treated as a major development in the world of business, and have been accepted as a standard business software over the last fifteen years [8] [12].

However, ERP implementation requires considerable financial resources, while the whole implementation project is considered complex, lengthy, and quite challenging [9] [13]. As a result, the success rate of such projects is considered to be quite disappointing [14] [15] [16]. More specifically, Samuel and Kumar [17], argue that the success rate is, only, around 50%, while approximately 90% of ERP implementation projects are late, or over budget. On the same vein, Umble and Umble [18] reported failure rates between 50% and 75%. Therefore, additional empirical studies are necessary in order to assist companies in increasing the success rates of ERP implementation projects.

Under that context, the aim of the present study is twofold: (a) develop an original conceptual framework (research model) examining the impact of various research factors on ERP implementation success, (b) empirically test that framework, using data from Small and Medium Enterprises (SMEs) located in Greece (empirical research).

(a) The development of the conceptual framework was based on two methodological steps: firstly, a review of the literature identified the factors that were used by previous studies as antecedents of ERP implementation success; secondly, a panel of experts was used in order to discuss these factors and provide a list of the most significant ones. That approach was selected due to the significant number of factors that have been proposed in the relevant literature. More specifically, the members of the research team used the opinions of experienced practitioners as a criterion for selecting a specific set of factors from the extensive list that

This work was not supported by any organization.

was provided from the literature review analysis. It is strongly argued that randomly selecting the research factors of the proposed conceptual framework would have resulted in the limited reliability of the present research.

(b) The empirical examination of the conceptual framework (that was crystallised after the literature review analysis and the completion of the qualitative research) was conducted on a sample of Greek SMEs. More specifically, a newly-developed structured questionnaire was used in order to collect the appropriate primary data. The questionnaire was distributed to 421 companies, while 159 usable questionnaires were, finally, returned. Advanced statistical techniques (EFA, CFA) were used in order to enhance the validity and reliability of the results, while research hypotheses were tested using the "Structural Equation Modeling" (SEM) technique.

The present study makes an effort to point out areas that companies should emphasize in order to successfully adopt ERP systems and, therefore, harvest their potential benefits. Its contribution lies in this enhanced approach. In synopsis, the study contributes in the following areas:

- It focuses on Small and Medium enterprises (SMEs), an approach that has found limited empirical investigation in the international literature. The literature review analysis underlined that the contemporary research mostly examines the implementation of ERP systems in large organizations.
- It examines the antecedents of ERP implementation success in SMEs of a European country. The literature review analysis that was conducted failed to recognise enough similar studies.
- It uses a qualitative research in order to recognise the most important antecedents of ERP implementation success and, then, develops a conceptual framework based on these factors. According to the best of the researchers' knowledge, such an approach is unique in the relevant literature. Moreover, it is significant, since previous studies used factors that were randomly selected from the literature, without a solid empirical basis [8] [19] [20] [21].
- It can be perceived as a reference point for future studies, since it offers a critique concerning the multitude of ERP implementation antecedents that have been examined in the international literature.
- Its results may be generalized in other developed countries with similar characteristics, and produce valuable managerial lessons for practitioners in these countries.

The following section includes a review of the relevant literature, while section three presents the conceptual framework of the study. The fourth section includes the research methodology. Results and conclusions are discussed in sections 5 and 6 respectively.

II. Literature Review

A. Critical success factors

Critical Success Factors (CSFs) have been introduced during the 1960s, as a concept that would assist companies to achieve their goals and enhance their overall competitiveness [22] [23] [24]. According to Ram and Corkindale [22], CSFs constitute a systematic way of identifying key business areas that require constant management attention. On the same vein, Rockart [23] argues that the results obtained in these critical areas, if satisfactory, are able to significantly enhance organisational performance. In plain words, CSFs assist managers to directly affect a specific outcome, by proactively taking necessary actions in certain areas [25].

Not surprisingly, the concept of CSFs gained wide recognition in the Information Systems domain and, consequently, in the context of ERP systems [6]. Since high failure rates of ERP implementation projects have been observed by numerous studies [14] [15], many scientists have attempted to investigate the factors that may enhance the whole implementation process. According to Ram, Corkindale and Wu [19], a large number of CSFs have been identified throughout the international literature.

Indeed, the literature review analysis that was conducted revealed that the relevant literature includes numerous studies that have, mostly, been published during the last 15 years [24]. Among these studies, some are theoretical [26], some others are empirical [8] [9] [27], while just a few have adopted the case-study approach [28].

According to Saade and Nijher [24], despite the growth in the investigation of CSFs regarding ERP implementation, there is a long way before the empirical contribution can be considered to be substantial. Moreover, most of the empirical studies that have been conducted [8] [9] [21], incorporated a limited number of critical factors in their analysis, failing to draw a more complete picture of the phenomenon. Finally, despite the wide range of CSFs proposed in the literature, many organisations continue to experience failures and difficulties in implementing ERP systems [19], thus, calling for additional research.

More significantly, according to Ram and Corkindale [22], there is a lack of an established process for the identification of CSFs. Various authors use subjective criteria in order to select the critical factors utilised in their studies, something that results in a lack of objective approaches. The present study heals that gap in the relevant literature, by developing a conceptual framework that was crystallised after a coherent two-step approach (literature review analysis and consultation with experienced practitioners / focus-group methodology).

B. Previous studies

Numerous empirical studies have investigated the critical success factors for ERP system implementation. The present study conducted an extensive review of the relevant literature, in an effort to grasp a spherical view of the subject and, therefore, better define its scope. The following paragraphs present a brief analysis of a representative sample of previous empirical studies.

Saini, Nigam, and Misra [15] examined the success factors for implementing ERP systems at Indian SMEs. Their sample included 164 companies, while the empirical data were analysed using the statistical z-test. Support was found for all hypotheses, arguing that technological factors

(e.g. system testing, IT infrastructure), people factors (e.g. cross-functional team, morale of the implementation team), and organizational factors (e.g. adaptability to changes, comprehensiveness of the implementation strategy) have a direct impact on the success of ERP implementation [15].

Garg and Chauhan [20] explored the factors affecting the success of ERP implementation in the Indian retail sector. Their conceptual framework, which included various critical success factors, explained 62,7% of the variations of ERP implementation success. As with Saini, Nigam, and Misra [15], organizational, technological, and people-related factors were found to be significant antecedents of ERP implementation success. Additionally, the impact of project management was, also, identified as being significant [20]. Garg and Garg [8] in another similar study that was, also, conducted in the Indian retail sector, found out that strategic, technological, people and project management factors have a positive influence on ERP implementation success.

Chien, Lin, and Shih [10] investigated the impact of centrifugal and centripetal forces on team cohesion and successful ERP implementation. Their empirical results were based on a survey of 305 Taiwanese SMEs. It was found that centripetal forces have a significant impact on ERP implementation, while the same was not verified for centrifugal forces, as well. Finally, team cohesion seemed to moderate the relationship between centripetal forces and ERP implementation performance [10].

Zabjek, Kovacic, and Indihar Stemberger [9] identified business process management as an important antecedent of ERP effective implementation. Their analysis was based on 152 questionnaires collected from Slovenian companies. They concluded that top management support, change management and business process management have a positive impact on successful ERP implementation [9]. The same authors conducted another similar research [16], obtaining identical results. On the same vein, Garg and Agarwal [21], also, underlined the significance of top management commitment, user involvement, business process reengineering, project management and ERP teamwork and composition on the success of ERP implementation [21].

Li, Markowski, Xu, and Markowski [29] used Structural Equation Modeling (SEM) in order to analyze data from 154 manufacturing companies operating in the USA. Their analysis revealed that Total Quality Management (TQM) is an important predecessor of ERP implementation. Chou, Hung, and Chang [30] focused on ERP organizational fit and knowledge transfer. They concluded that ERP success is influenced by organizational fit (data fit, process fit, user fit), ERP knowledge factors (e.g. shared understanding), and ERP communication factors (e.g. communication decoding competence), either directly or indirectly [30].

On a different approach, Amid, Moalagh, and Ravasan [31] focused on Critical Failure Factors (CFFs), rather that Critical Success Factors (CSFs). Firstly, they conducted semi-structured interviews with practitioners, identifying 47 failure factors. Secondly, they collected empirical data with the use of a structured questionnaire. Using Exploratory Factor Analysis (EFA), they classified CFFs in seven large groups (vendor and consultant, human resources, managerial, project management, processes, organizational, technical). Their research was conducted on a developing country, namely Iran [31].

Wee [32] underlined the importance of formulating an overall ERP architecture before the deployment of the system, since only in such a way the need for reconfiguration during, or after, its real-time implementation will significantly diminish. Similar views were supported by other authors, arguing that the use of proper and formal modelling methods, tools and architectures is necessary for ERP implementation success [33]. Ferratt, Ahire, and De [34] argued that implementing organisations need to follow the basics of project management and, simultaneously, adopt the best industry practices in order to successfully implement an ERP system.

Ngai, Law, and Wat [35] focused on the importance of national culture and country-related characteristics on ERP implementation success. Sheu, Chae and Yang [36] underlined the impact of different cultural backgrounds, while Tarafdar and Roy [37] analysed the cultural issues that a typical Indian firm, usually, faces when implementing an ERP system. Finally, Lee, Lee, and Kang [38] argued that implementation success largely depends upon the attitude of the employees towards the whole ERP project.

As it became evident from the previous paragraphs, contemporary research includes a wide range of critical factors predicting ERP implementation success, ranging from vendor selection [39], to project management aspects [14] [40]. However, most of these studies are focused on larger enterprises [41]. On the other hand, ERP adoption by SMEs has traditionally received less attention from the international literature. According to Poba-Nzaou, Raymond and Fabi [41], this represents an area for additional research, especially since SMEs face greater difficulties in adopting ERP systems.

In summary, the literature includes the following gaps: (a) There is a multitude of critical success factors (antecedents) that have been used in order to predict ERP implementation success. Therefore, one is unable to determine which are actually the most important. The need for additional research is imperative; (b) The focus on SMEs has been limited; (c) Very few studies have utilised specific criteria for selecting certain factors, and excluding others, from their analysis. Selecting factors without justification is considered as a significant limitation; (d) Few of the published empirical studies were carried out in European countries; (e) Very few studies built on previous research. The present study was designed so as to cover these limitations (research gaps) found in the relevant literature.

III. Conceptual framework

As mentioned earlier, the present study aims to: (a) built a coherent conceptual framework including the most significant antecedents of ERP implementation success and (b) test that framework gathering quantitative data.

The literature review analysis that was conducted prior to the development of the conceptual framework of the present study revealed that numerous factors have been used in order to predict ERP implementation success. Therefore, an important challenge was to decide upon the factors that were going to be incorporated into the proposed conceptual framework. The main objective was to construct a conceptual framework that incorporates the most significant factors used in the literature. Moreover, the incorporated factors were expected to have a high degree of relevance with the overall context of the study (Greek SMEs).

In order to address that critical issue, a qualitative research was conducted prior to the quantitative research. More analytically, a 'panel of experts' was formed in order to evaluate the factors that have been used in the relevant literature and assist in selecting the most appropriate ones for the proposed conceptual framework of the present study. More specifically, the focus group methodology was used.

This approach offers certain benefits: (a) the selection of the factors that were, finally, incorporated in the proposed conceptual framework was not conducted according to the subjective judgment of the researchers, but was a result of a more coherent and objective procedure, (b) the proposed conceptual framework has a strong basis on the opinions of experienced practitioners (managers of SMEs), (c) the selection of factors with low significance was avoided. It is believed that the random selection of the research factors, without any theoretical or empirical justification, would have resulted in the limited reliability of the present study.

In order to enhance the validity of the qualitative research, two sessions held in different geographical areas were conducted. All companies were selected in random, using data from the Chamber of Commerce. Each focus group included five managers of SMEs. This approach is in line with the main principles of the focus group methodology [42], since there was an appropriate number of participants for each session, two different sessions with different participants were conducted, while the represented companies were randomly selected.

The participants of each group were given (in paper) an extensive list of factors that have been used in the literature in order to predict ERP successful implementation. Then, a detailed conversation was conducted, with two members of the research team acting as moderators [43]. Each focus group took approximately two hours. Notes were taken during each session by a second moderator, while additional notes were added after reviewing the recorded sessions. After long discussions and deliberations, each focus group unanimously chose the nine most important factors of the provided list. The two focus groups agreed, with minor exceptions, in the same factors.

The conceptual framework of the present study incorporates these nine (independent) factors, resulting from the qualitative research, and one dependent factor, namely ERP implementation success. Additionally, 'organisational impact' was added in the proposed conceptual framework, in order to investigate the effect of ERP implementation on various measures of organisational performance.

The nine independent factors are listed below: Top management support, Organizational culture, External pressure, Vendor support, Project management, Training, User involvement, Business Process Reengineering, Implemented modules.

A. Top management support could be easily defined as the involvement of business executives in the areas related with ERP implementation [44]. It has been highlighted, by several authors, as a critical factor for the successful implementation of ERP systems [14] [45] [46].

Ngai, Law, and Wat [35] argued that senior executives play a significant role in ERP implementation success, since these projects are, usually, time consuming and demand extensive financial support. Senior management has two roles during implementation: supplying funds and offering leadership [14]. Al-Mashari, Al-Mudimigh, and Zairi [47] insisted that senior management support should be offered, without disruption, during the whole implementation period. The tasks of senior executives when implementing ERP projects include: communicating the strategy to all business employees, setting limitations, proving engagement, and setting reasonable goals [46]. Participation, support, and senior-level sponsorship are dimensions that have been found to significantly affect ERP implementation [48] [49].

ERP implementation does not, exclusively, evolve around software reengineering. On the contrary, it includes the extensive restructuring of business processes. Consequently, senior executives must clearly, publicly and truly indicate their support (economic or not), in order to highlight the priority given to implementation [48] [49]. Therefore:

H1: Top management support has a direct positive effect on ERP implementation success.

B. Organizational culture represents the shared ideologies, standards, convictions that have an impact on organizational attitudes and activities [50].

A common culture, shared between various organizational members, has an impact on the willingness to change, e.g. to adopt a new Information System. Research has shown that organizational culture is quite significant for the success of most organizational changes [51] [52]. Jarvenpaa and Staples [52] argue that there should be a fit between the culture of the organization and the nature of the changes that may occur from implementing an ERP system.

Additionally, according to Jones, Cline, and Ryan [51], organizational culture has an effect on employee behavior towards knowledge sharing, while knowledge sharing is crucial for the successful implementation of ERP systems. Ruppel and Harrington [53] argue that organizational culture has an effect on the implementation of intranet and other information systems used inside the organisation. Hence, it can be hypothesised that:

H2: Organizational culture has a direct positive effect on ERP implementation success.

C. Sometimes, the implementation of an ERP system does not have intrinsic motives. On the contrary, companies are being forced to implement an Information System, either by

their supply chain partners or by their competitors [54] [55]. In the first case, implementation becomes a prerequisite for the continuous cooperation with a partner (supplier and/or customer), while in the second case, the adoption decision is based on the need to follow the competitors, and, hence, avoid any possible downturn from not doing so [56].

In the present study, it is hypothesised that when companies find themselves under pressure from the external environment, they tend to try harder to achieve their desired goals. Therefore, the higher the external pressure, the more successful the implementation of the ERP system.

H3: External pressure has a direct positive effect on ERP implementation success.

D. Vendor support is offered from software retailers and/or consulting companies [4]. In most of the cases, the retailer is, also, the consultant during, or after, the implementation.

Vendor support includes user training, extended technical assistance during and after the implementation, maintenance, updates, etc. Additionally, vendors offer analytical advice concerning the selection of the appropriate ERP software [57] [58]. According to Wang, Lin, Jiang, and Klein [57], vendors significantly enhance the effectiveness of the implemented system, via experience sharing and knowledge transfer.

Through continuous collaboration, formal training and knowledge dissemination, consultants assist their costumers in receiving the full benefits of the implemented system [57] [59]. The trustworthiness of the vendor is extremely important in determining the success, or the failure of the whole effort [60]. Koh, Simpson, Padmore, Dimitriadis, and Misopoulos [60] found out that the close relationship with the vendor is a critical success factor for the implementation of an ERP system.

H4: Vendor support has a direct positive effect on ERP implementation success.

E. The implementation of an ERP system is a risky and complex project [21]. As it is evident, such projects acquire excellent management, since numerous stakeholders (different business units, suppliers, customers, vendors/ consultants) are deeply involved [15] [20]. The manager of an ERP project should bear in mind different timetables, various milestones, equipment requirements, workforce availability, and budget needs [49]. Hence, successful implementation is synonymous with the management of a plethora of tasks. All these tasks should be carefully monitored and managed.

More specifically, standard meetings and reports should be provided for all project collaborators. Effective project management is very crucial, since implementation success is, usually, assessed on the basis of budget and time compliance [21]. Executives expect the implementation period to be completed on time, and on budget.

H5: Project management has a direct positive effect on ERP implementation success.

F. Training is considered to be a basic parameter in every ERP implementation project [45] [46]. Hong and Kim [27] argue that training should be provided before, during and after implementation, while both technical and procedural issues should be carefully addressed. Finally, in-house training (on-the-job training) appears to be the most efficient choice, between all available methods [14].

Dezdar and Ainin [61] argued that sufficient training allows employees to efficiently utilize the implemented ERP system. More specifically, training enhances the skills and increases the practical expertise of real-time users [62]. Nah, Zuckweiler, and Lau [63] found out that adequate training enhances implementation success, while lack of training undermines the whole process. Additionally, sufficient training builds a positive climate towards the implemented system, thus, increasing its use and overall acceptance. Moreover, training enhances the ease of use, which in turn increases the probability for system success [62].

H6: Training has a direct positive effect on ERP implementation success.

G. User involvement is one of the most influential factors in ERP implementation projects [14] [27] [47]. Numerous studies argue that users should be actively involved before and during the entire ERP implementation process [8]. This will ensure that the system has a better fit with business processes, since its development will be based on real needs. Moreover, the acceptance of the ERP system will be increased, since users will have participated in its development. Finally, resistance to change will be significantly decreased [8] [47].

According to various authors [20], user involvement increases user satisfaction and user acceptance, by developing realistic expectations about the capabilities of the system. Additionally, user involvement increases the perceived level of control, through user participation in the entire project [20]. When all the above conditions are being successfully met, the implementation of the ERP system will be much more efficient.

H7: User involvement has a direct positive effect on ERP implementation success.

H. Business Process Reengineering (BPR) is the fundamental rethinking and drastic redesign of business processes, in order to achieve improvements in critical measures, such as cost, quality, delivery, and speed [49] [64]. ERP implementation requires such a radical redesign of business processes, since the new ERP system is expected to drastically change several aspects of doing business [40].

It is the ERP system that underlines the necessity for BPR and forces the organization to redefine and redesign work flows in order to fit the new software [40]. Reengineering business processes in a way that makes them compatible with the implemented system appears as an important antecedent of ERP implementation success [64].

H8: Business Process Reengineering (BPR) has a direct positive effect on ERP implementation success.

I. ERP systems may be implemented in modules. A company does not have to conduct a full scale implementation; on the contrary, certain modules could be implemented on the basis of its special needs and requirements [65]. According to Yeh, Yang, and Lin [66], it would be unwise to avoid implementing most of the available modules, since only full implementation really ensures the expected benefits. Some empirical studies have argued that there is a relationship between the number of implemented modules and the functional effectiveness of the ERP system [67]. After all, the more modules a company implements, the higher its benefits from cross-operational cooperation [65].

H9: The number of implemented modules has a direct positive effect on ERP implementation success.

J. The construct of "organizational performance", as it has been captured in the present study, includes measures of multiple dimensions, such as productivity, cycle time, cost reduction, information flow, and customer satisfaction. Its main goal is to include both qualitative and quantitative measures of organisational performance. Law and Ngai [68] followed a similar approach. Many previous studies have investigated the impact of ERP implementation on firm performance [69] [70], while its impact on organisational performance has received less empirical examination. Therefore, it is hypothesised:

H10: ERP implementation success has a direct positive effect on organizational performance.

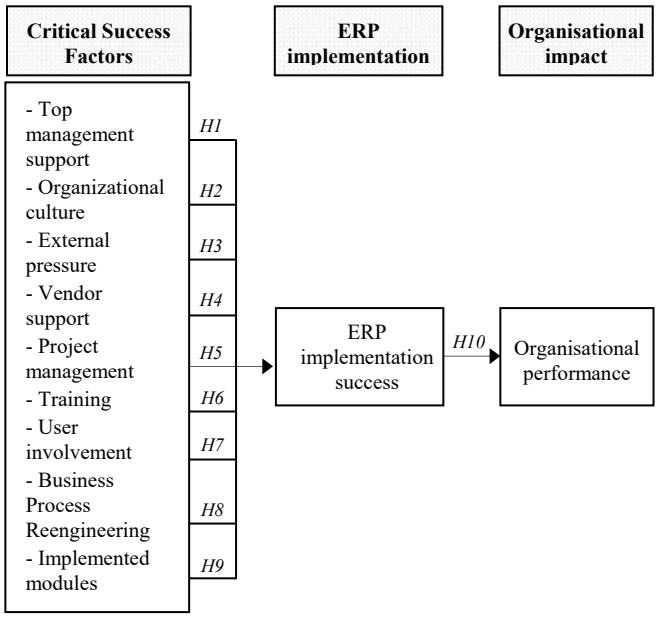

Fig. 1 The proposed conceptual framework

The synthesis of the hypotheses presented above formulates the proposed conceptual framework of the present study (Fig. 1). It should be underlined that, according to the best of the researcher's knowledge, such a conceptual framework (combination of factors) has never been examined before in the literature.

IV. Research Methodology

A. Population of the study

The population of the present study includes Greek Small and Medium Enterprises (SMEs) that have implemented an ERP system. There are no available official data that can define the population of the study on numerical terms.

SMEs are considered to be the heart of the Greek economy, since they represent 99% of the total number of companies. In 2010, there were 742.000 SMEs, with 2.512.493 employees, which represent more than 75% of total employment, well above the EU average. Greece has a very high share of SMEs, particularly micro enterprises, compared to the EU average (Annual Report on EU SMEs 2010/2011, 2011).

B. Measurement

The proposed conceptual framework was tested with the use of a newly-developed structured questionnaire. The measurement of the eleven research factors was conducted with the use of multiple questions (items) that were adopted from the international literature [14] [15] [20] [27] [51] [52] [54] [55] [56] [58] [59] [65] [66] [68]. All questions were translated to Greek and then back to English by another person, in order to detect any discrepancies. The five-point Likert scale was used for the measurement of all factors.

C. Data collection

Data concerning companies that could possibly be included in the sample were obtained via the web sites of the leading ERP system providers operating in Greece. Since no other database including companies using ERP systems exist, the use of the certain method was the only one able to provide usable information. Totally, 678 companies that have implemented an ERP system were identified. The questionnaire and a cover letter including clarifications, was sent to the IT managers of these companies.

Questionnaires were sent only after a telephonic contact with the IT manager in each company has been established. After making all necessary telephone calls, 421 questionnaires were distributed to 421 companies that agreed to participate in the survey. The research period lasted three months (March to May 2015). Totally, 165 questionnaires were returned, and after conducting all necessary controls 159 were used for data analysis. The 159 questionnaires represent a very satisfactory response rate (38%). The majority of the participating companies are small sized (less than 100 employees), something that is in line with the country's average firm size.

D. Reliability and validity

The questionnaire that was used in the present study was rigorously tested for its content and construct validity.

The test for the content validity was conducted via a pilot study. More specifically, a draft of the final questionnaire was sent to four practitioners and two academics, in order to test whether it met all theoretical and practical requirements.

TABLE I. ESTIMATION OF UNIDIMENSIONALITY AND RELIABILITY

Factors	*KMO*	*Bartlett's Test*	*Eigen-value*	*TVE*	*Cronbach Alpha*
Top management support	0,736	139,2[a]	2,546	67,3%	0,789
Organizational culture	0,894	214,9[a]	2,871	71,5%	0,823
External pressure	0,779	77,5[a]	1,371	68,4%	0,801
Vendor support	0,831	145,6[a]	2,874	81,7%	0,745
Project management	0,799	154,2[a]	1,741	84,7%	0,771
Training	0,854	95,5[a]	2,713	71,9%	0,723
User involvement	0,736	214,3[a]	2,124	76,2%	0,755
Business Process Reengineering	0,711	325,3[a]	2,587	74,1%	0,737
Implemented modules	0,857	217,6[a]	1,342	83,4%	0,741
ERP implementation success	0,839	169,7[a]	1,619	84,5%	0,901
Organisational performance	0,759	171,3[a]	2,391	88,6%	0,733

[a.] $p<0,01$

TABLE II. ESTIMATION OF THE GOODNESS OF FIT

Factors	*Normed X^2*	*C.R.*	*V.E.*	*RMSEA*	*CFI / GFI*
Top management support	1,57	0,78	65,6%	0,077	0,94 / 0,96
Organizational culture	2,67	0,74	69,4%	0,053	0,97 / 0,97
External pressure	3,15	0,86	0,81%	0,067	0,99 / 0,97
Vendor support	3,52	0,82	0,76%	0,084	0,91 / 0,93
Project management	2,19	0,76	0,67%	0,075	0,99 / 0,98
Training	1,97	0,77	0,63%	0,063	0,90 / 0,93
User involvement	2,37	0,69	0,57%	0,086	0,95 / 0,99
Business Process Reengineering	2,45	0,73	0,81%	0,059	0,90 / 0,90
Implemented modules	2,65	0,83	0,74%	0,061	0,91 / 0,96
ERP implementation success	2,77	0,77	0,64%	0,074	0,93 / 0,91
Organisational performance	1,61	0,74	0,61%	0,081	0,93 / 0,95

TABLE III. RESULTS OF THE STRUCTURAL MODEL

Causal Paths (hypotheses)		*Estimate*	*p*	*Result*
H1	Top management support → ERP implementation success	0,26	0,000	Accepted
H2	Organizational culture → ERP implementation success	0,23	0,000	Accepted
H3	*External pressure → ERP implementation success*	-	*0,098*	*Rejected*
H4	Vendor support → ERP implementation success	0,36	0,011	Accepted
H5	*Project management → ERP implementation success*	-	*0,267*	*Rejected*
H6	Training → ERP implementation success	0,29	0,000	Accepted
H7	User involvement → ERP implementation success	0,26	0,000	Accepted
H8	Business Process Reengineering → ERP implementation success	0,35	0,000	Accepted
H9	*Implemented modules → ERP implementation success*	-	*0,164*	*Rejected*
H10	ERP implementation success → Organisational performance	0,34	0,003	Accepted

To test the construct validity, each research factor was evaluated: (a) for its unidimensionality and reliability (Table I), (b) for its goodness of fit to the proposed research model (Table II). The examination of the unidimensionality of each factor was conducted using Explanatory Factor Analysis (EFA) [71]. Moreover, 'Cronbach Alpha' was used for estimating each factor's reliability. All tests concluded that the scales used are valid and reliable.

The evaluation of the goodness of fit of each research factor to the proposed model was conducted using Confirmatory Factor Analysis (CFA). All tests produced satisfactory results (see Table II for the main results).

V. EMPIRICAL RESULTS

A. Model valuation

The examination of the proposed conceptual framework was conducted using the "Structural Equation Modeling" (SEM) technique [72] [73] [74]. To evaluate the fit of the overall model the chi-square value ($X^2 = 49,7$) and the p-value ($p = 0,000$) were estimated. These values indicate a satisfactory fit. However, the sensitivity of the X^2 statistic to the sample size enforces to control other supplementary measures of evaluating the overall model, such as the "Normed-X^2" index (3,1), the RSMEA index (0,077) the CFI (0,99) and the GFI (0,97), that all indicate a good fit.

B. Hypothesis testing

Seven hypotheses were found significant (H1, H2, H4, H6, H7, H8, H10), while three hypotheses were rejected by the empirical data (H3, H5, H9). After reviewing the empirical results, the following observations can be made:

A. The successful implementation of an ERP system has its roots on vendor support, training, and user involvement. These three factors were found to have the strongest impact on the main dependent factor of the present study (ERP implementation success). According to these empirical results, the present study proposes a mechanism that will drive implementation success. Various organisations may utilise this mechanism in order to experience a seamless implementation process. It includes three steps, each describing tasks that should be performed before, during and after the implementation of an ERP system.

Firstly, before the implementation, companies should spend their limited time and resources in selecting the appropriate software retailer. A good fit between the two seems to be very crucial for implementation success. Moreover, employees should be involved in the decision to adopt an ERP system. Executives should take employee attitudes and beliefs under serious consideration. In general, employees should feel like an integrated part of the whole process, while the adoption of the new system should not be understood as a decision that has been forced upon them. Only when employees fell like they have contributed to the implementation initiative, will they accept the changes that may occur. On a more practical level, the contribution of employees before the implementation is crucial for ensuring that the system will be designed in order to have a better fit with existing business practices.

Secondly, during the implementation period (that may be quite short, especially in micro-enterprises), vendors should adopt an analytical (linear) approach. Initially, the most

technological-ready employees should be selected in order to test the implemented system. Then, its advantages should be underlined and communicated amongst all personnel. After that, initial training should take place. The main goal is to initiate the system after all employees have been fully involved in the whole process.

Thirdly, after the implementation period, continuous training should be offered by the vendor (or another consultant). After all, the first month following the implementation of the new ERP system is extremely crucial. Employees should feel that the new system enhances their job, while resulting in many other organisational benefits.

B. No matter how important the role of vendor support (r=0,36), training (r=0,29), and user involvement (r=0,26), the support of top management has, also, been underlined as a significant antecedent of ERP implementation success (r=0,26). Without any doubt, executives should demonstrate their belief on the implemented system, mostly by ensuring its funding and setting the example for its use.

C. Moreover, the empirical data revealed that Business Process Reengineering (BPR) is a quite significant factor (r=0,35). This finding adds further support to the previous observations, arguing that BPR should be a priority for vendors, employees and executives.

D. Additionally, organizational culture (with emphasis on knowledge-sharing) affects implementation (r=0,23). This factor cannot be easily enhanced prior or during the implementation period, since its development is, usually, a result of the unique history of the organisation.

Finally, the relationship between ERP implementation success and organisational performance has been verified by the empirical data (r=0,34). Concerning the strength of that relationship (R^2=26%, including direct and indirect effects), it should be noted that when examining complex phenomena, like organisational performance, even a relatively small predictive power seems to be satisfactory.

VI. Conclusions

The present study was motivated by specific gaps that were recognised in the relevant literature of the specific field. In order to cover these gaps, the present study used an extensive literature review and qualitative data (focus group sessions with managers of SMEs) in order to develop a conceptual framework that investigated the antecedents of ERP implementation success. Moreover, this framework was tested with the use of a newly-developed structured questionnaire (quantitative data) on a sample of Greek SEMs that have implemented and ERP system.

That specific approach offered certain advantages: focus groups offered practical knowledge concerning the factors with the most significant impact on ERP implementation, while the quantitative research revealed which of these factors are actually significant. The contribution of the study lies on this enhanced approach. More specifically, it offers the necessary ground for comparison and replication. Its conceptual framework may be replicated from future studies, while other scientists may employ its twofold approach as a basis for their future empirical investigation.

The proposed conceptual framework of the study included nine antecedents of ERP implementation success. These factors are perceived as Critical Success Factors (CSFs) for successful ERP implementation. Empirical data were analysed using the "Structural Equation Modeling" (SEM) technique, while the validity and the reliability of all research factors were evaluated with the use of enhanced statistical methods (EFA, CFA).

According to the results of the statistical analysis, six of the antecedents included in the research model of the present study were found to have a direct (positive) effect on successful ERP implementation. Additionally, the predictive power of the proposed model was found to be very satisfactory. More specifically, the six antecedents can explain the variance of ERP successful implementation by 72% (R^2 = 0,72). On the other hand, three research factors (external pressure, project management, implemented modules) were not found to have an effect on the successful implementation of an ERP system.

Therefore, it is concluded that when implementing an ERP system, organisations should focus on the following six factors: Top management support, Organizational culture, Vendor support, Training, User involvement, Business Process Reengineering. The present study argues that the enhancement of these Critical Success Factors should be conducted before, during and after ERP implementation. Partial focus will only limit their positive effect.

In general, it is concluded that ERP implementation success is a result of intangible factors (organisational culture), people-related factors (vendor support, training, user involvement), and proper leadership (top management support). Moreover, reengineering, a more practical issue of implementation, is also a prerequisite for success.

Previous studies conducted in other geographical regions of the European continent (e.g. Eastern and Central Europe) have found similar results. For example, Ziemba and Kolasa [61] found that top management support, user involvement and process management have an impact on information systems projects, while Bradley [62] concluded that the determinants of enterprise system adoption success are user involvement, user empowerment, system reliability and cooperation with the system supplier (vendor).

The present study is somehow limited by the poor definition of its population. This limitation is inherent to all studies of the field, since a complete list of companies that have implemented an ERP system can not be found in most databases. Further research is suggested with larger samples that would, probably, offer more information and strengthen the results of the present study. Moreover, it would be interesting to examine more factors and gather primary data from all company personnel, so as to achieve a more complete view of the subject under investigation.

***Abstract*—Enterprise Resource Planning (ERP) systems have established a reputation in the world of business as indispensables tools that integrate all departments and functions across a company into a single computer system. However, implementing an ERP system does not always result in enhanced organizational performance. In order to ensure successful implementation, companies should study the critical factors having an impact on the whole procedure. In this context, the present study proceeds in developing and testing an original conceptual framework (research model), which explores the factors having an impact on ERP implementation success (internal environment, technology-related issues, implementation team, end-users), as well as the impact of the implementation itself on organisational performance. The proposed conceptual framework was tested, using a newly-developed structured questionnaire, in a sample of 204 Greek companies that have already implemented an ERP system. The Structural Equation Modelling (SEM) technique was used in order to test the research hypotheses.**

I. Introduction

THE explosive growth of Information and Communication Technologies (ICTs) (Information Systems, Enterprise Application Systems, Internet Technologies) has influenced, to a great extent, the way modern organizations operate in the business environment [1] [2]. Technological advances make information easily accessible, providing greater awareness of international economic opportunities [3].

Enterprise Resource Planning (ERP) systems are software systems which can be customized to integrate the business processes of a company, in such a way, that they are visible and accessible by the management in real-time [4]. An ERP system, designed to serve the modern sophisticated management, enables its users to coordinate key business practices across functions more efficiently, collect corporate data more holistically and offer optimal control over the operations of the organisation [5].

When an ERP system is successfully implemented, it promises to manage and integrate all business processes and functions within an organization [6] [7]. The integration, brought by ERP implementation, helps organizations to increase and improve their overall market position, in order to gain competitiveness in a rapidly changing business environment [8]. It also helps different divisions share data and knowledge, reduce costs and improve management of business processes [9] [10].

Due to the potential benefits of ERP systems, most of the organizations invested both time and money in their implementation [11]. However, ERPs have a reputation of costing a lot of money and providing limited results [10]. Some of the causes, cited in the relevant literature, for failed ERP projects include: poor project management planning, lack of business management support, unexpected return on investments, insufficient education and training, and, finally, weakness to redesign business processes [12] [13] [14].

Successful ERP implementation is quite valuable to many organizations, as it provides with numerous benefits. This explains why an ERP system is generally considered to be a vital component for enhancing organizational performance [15] [16] [17] [18] [19] [20] [21].

The ERP literature includes various studies investigating the factors having an impact on the effective implementation of ERP systems [8] [22]. On the other hand, there are fewer studies examining the impact of ERPs on different measures of business success [5] [15] [21] [23]. Despite that, the literature review analysis that has been conducted, failed to identify any empirical studies adopting a multidimensional approach, incorporating both antecedents and outcomes.

The present study aspires to bridge that gap in the relevant literature, developing and testing a three-dimensional conceptual framework (research model). More specifically, the first dimension includes the antecedents of ERP successful implementation (internal environment, technology-related issues, implementation team, end-users), the second dimension the implementation itself (information quality, system quality, service quality), while the third dimension includes three measures of organisational performance (internal efficiency, competitiveness, profitability).

Therefore, the main objective of the study is to identify the factors that drive ERP implementation success, and, consequently, measure the effect of implementation on organization performance. The measurement of each of the

This work was not supported by any organization.

three dimensions is being conducted with the use of multiple measures (sub-factors).

The examination of the proposed conceptual framework was made with the use of a newly-developed structured questionnaire that was distributed to a group of Greek companies. The Structural Equation Modelling (SEM) technique was used in order to test the research hypotheses. The present study is empirical (it is based on primary data), explanatory (examines cause and effect relationships), deductive (tests research hypotheses) and quantitative (analyses quantitative data collected with the use of a structured questionnaire). Its results may be useful for managers, business analysts and IT analysts in dealing with the implementation of ERP systems.

The following section includes a review of the literature; section three presents the conceptual framework of the study, while section four includes the research methodology. Results and conclusions are discussed in sections 5 and 6 respectively.

II. Literature review

An ERP system entails long-term application processes (strategic level) and short-term applications (operational level). As a consequence, it is a given fact that ERP implementation cannot be imposed overnight [24]. On the contrary, it involves constant modifications and gradual implementation, so that in the end it will meet specific needs and bring out desirable end results [25].

Several studies have attempted to describe the critical success factors associated with the implementation and final use of ERP systems [24]. For example, Hong and Kim [26] identified the fit between the ERP system and the organizational climate as a crucial predictor of implementation success. They, also, argued that ERP implementation affects most of the business processes, and influences users directly [26].

Since ERP implementation will, most likely, affect the whole organization, reengineering of business processes is also required for business success [14]. Al-Mashari, Al-Mudimigh and Zairi [14] developed a theoretically and practically grounded taxonomy of ERP critical success factors. They argued that critical factors should gap the bridge between ERP implementation and (a) business processes, (b) Information Technology (IT), (c) structure, (d) culture and management systems, and (e) strategy.

Motwani, Subramanian and Gopalakrishna [27] conducted a comparative case study of four firms that implemented an ERP system, arguing that an evolutionary implementation process, which is supported by careful change management, network relationships and cultural readiness, can lead to successful implementation. Somers and Nelson [28] listed 22 critical success factors and categorized them according to the stage of implementation. They argued that package selection is among the most significant factors.

Ram, Wu and Tagg [29] built a conceptual model exploring the impact of two critical success factors (training and education, and system integration activities) on ERP implementation effectiveness.

Ifinedo and Nahar [30] found out that system quality and information quality are considered as the most important dimensions in the assessment of ERP success. Similarly, Chien and Tsaur [31] concluded that system quality, service quality and information quality seem to be the most important factors when implementing an ERP system. Similar lists of factors have been proposed by several other authors [10] [32].

Esteves and Pastor [33] made a distinction between the strategic and tactical factors, and the technological and organizational factors of implementation. Holland, Light and Gibson [34] grouped critical success factors into two categories: the strategic factors that span during the whole implementation project, and tactical factors that can be applied to particular parts of the project.

Loh and Koh [35] presented a framework of critical success factors in small and medium sized enterprises (SMEs), concluding that the most important factors are: project champion, project management, business plan and vision, and top management support [35]. Hustad and Olsen [36] concluded that SMEs have different challenges than larger organisations, mostly because of their limited resources and competencies [36].

Despite numerous implementation challenges and high implementation costs, ERP systems have become popular, and both small and large companies implement ERP systems in order to remain competitive. However, in some cases, ERP implementation can be very risky and, if organizations do not pay much attention to their limitations and requirements, results may be very unsatisfactory [12] [37].

According to Somers and Nelson [28], everyone who uses ERP systems needs to be trained on how they work and how they relate to business process, early on the implementation phase. Inadequate training and education could be considered as a significant reason for many ERP projects failures [10] [14]. Additionally, proper ‘package’ selection plays a vital role in successful implementation of ERPs, as it is one of the most important steps [10] [28].

During ERP implementation, business process reengineering should take place, in order to take full advantage of the new system [14] [34]. In addition, getting people educated, or trained, and keeping them informed throughout the whole implementation process should be amongst the first organisational priorities [28]. Moreover, through intensive guided learning, superior training and special knowledge activities, ERP consultants can help clients acquire the necessary knowledge for successful implementation [38]. Since users are an integral part of the attempted changes, the ones that will participate in the design and the implementation of new administration procedures must be sufficiently trained [34].

As demonstrated above, a significant number of studies on ERP implementation have been conducted. Many of these studies investigate the critical success factors for ERP implementation, and assist practitioners towards selecting the most suitable ERP software. Moreover, the studies of Al-Mashari, Al-Mudimigh and Zairi [14] and Umble, Haft and Umble [10] appear to be among the most cited papers in the ERP literature (423 and 636 citation respectively: data acquired from the 'Scopus' database, November 2015).

The present study conducted an analytical review of the ERP literature, and developed a conceptual framework that is a synthesis of previous contributions. More specifically, a list including the factors that have been used in order to predict ERP implementation success has been developed, while the most significant factors were, finally, incorporated in the proposed conceptual framework. In comparison with previous studies, the present empirical research does not only examine the antecedents, but, also, includes the outcomes of ERP implementation in its analysis.

III. Conceptual framework

Successful ERP implementation requires the coordination of many activities and a close cooperation between managers, employees, IT specialists, business analysts and consultants [39]. Therefore, any theoretical framework concerning ERP implementation effectiveness should include various dimensions in its analysis.

Based on the literature review analysis that was conducted prior to the development of the conceptual framework, the present study classified the antecedents of ERP implementation into four distinct categories (dimensions): (1) internal environment, (2) technology-related issues, (3) implementation team, (4) end-users. Additionally, each category (dimension) was determined with the use of several factors.

The selection of all research factors was a result of a specific procedure: (1) the Scopus database was used in order to identify previous studies concerning the antecedents of ERP implementation success (65 relevant studies were identified), (2) an extensive list, including the factors used in these studies, was constructed, (c) factors were given a significance index, based on the findings of each study, (d) each factor was categorized into one of the four pre-determined categories (dimensions), (e) the factors with the highest significance index in each category were, finally, selected.

The present study adopts a unique approach on the ERP literature. Instead of, only, examining the antecedents of ERP implementation success, the outcomes of the implementation procedure were, also, taken into consideration. Thus, an original three-dimensional conceptual framework (research model) was developed (see Fig. 1).

A. Internal environment

Successful implementation cannot be achieved, only by managers. Effective leadership is needed in order to achieve the desirable goals [35]. Organizations should, also, review their organizational culture and attitude towards change, before implementing an ERP system [40]. In this study, the dimension of "internal environment" includes four factors (top management support, business process reengineering, organizational culture, change management).

Top management support has been emphasized as a crucial factor in successful ERP implementation by previous studies [10] [14] [41]. Al-Mashari, Al-Mudimigh and Zairi [14] suggested that top management support should not only be offered during the initiation and facilitation stage, but throughout the entire ERP implementation process. Umble, Haft and Umble [10] claimed that successful ERP implementation requires the commitment and constant participation of top management. In a different case, the project is most likely to fail, or fail to deliver the full range of forecasted benefits [11] [12] [42].

Business process reengineering (BPR) has been, often, proposed as a critical success factor for ERP implementation [29]. Typically, BPR is carried out in order to restructure non-value-adding operations, reduce the complexity of business processes and eliminate inefficient processes [43]. Reengineering aims at making the necessary adjustments in order to take full advantage of the new processes offered by the ERP system [44]. Therefore, organizations should be willing to adjust their processes, so as to fit with the new software and minimize the degree of customization needed [34]. Most experts agree that software customization results in higher implementation costs and longer implementation period. Therefore, companies should keep the ERP package "as it is", as much as possible, and reengineer their business processes to conform to the package [45].

An organisational culture of shared values and common objectives is crucial for business success [46]. Organizations should built an organizational culture that is open to change [32], since openness to change plays a pivotal role in today's business environment. When organisational members have different cultures, beliefs and values, they, also, have different perceptions on various organizational changes [47]. In other words, organizational culture is a critical success factor for a project that requires significant changes [48]. Consequently, when the culture of an organisation is prone to change, ERP implementation is made quite easier.

Finally, Motwani, Subramanian and Gopalakrishna [27] argued that ERP projects that are supported by top management, but are not accompanied by adequate change management strategies are likely to fail. On the contrary, an implementation process backed with change management strategies and network relationships has been found to have a positive effect on implementation success [49]. Change management is a primary concern for many organizations involved in ERP implementation [50]. Research has shown that effective change management is critical to successful implementation [28]. Therefore, it is hypothesised:

H1: Internal environment has a positive impact on ERP implementation success.

B. Technology-related issues

During ERP implementation, various technological-related issues need to be addressed. More specifically, (a) the appropriate ERP package should be carefully selected [28]; (b) the overall support provided by the vendor should be taken under serious consideration [51]; and (c) the fit between the implemented system and the technological infrastructure of the organization should be examined [52]. The present study posits that all these dimensions (package selection, consultant (vendor) support, IT infrastructure) have a cumulative effect on ERP implementation success.

The selection of an ERP system, being among the first steps of implementation, appears as a critical factor [6]. After all, the package that will be selected will determine, to a great extend, the success of the project [10] [14]. Despite the fact that almost all ERP packages can be customized according to specific needs, customisation is very expensive and, usually, problematic [53]. Choosing the ERP package that best suits organisational needs and processes is critical to ensure successful implementation [6] [28].

However, no matter how important is to select a compatible ERP package, organizations should, also, select the appropriate vendor that will be able to offer full support. Troubleshooting is necessary for ERP implementation, so as to prepare for unexpected circumstances or, even, crises. This is an ongoing process, since the vendor (consultant) is obligated to assist in all stages on the implementation process [14] [32]. ERP adopting companies have to work closely with ERP vendors in order to determine possible software problems.

Finally, the appropriate IT infrastructure is necessary for the implementation of an ERP system [54]. Since most of ERP transactions are conducted in real-time, a reliable intranet, or local area network needs to be in place [32]. A company with a satisfactory level of IT infrastructure can be expected to implement new technologies, like ERP systems, more successfully than other companies, with low degree of IT readiness. From all the above, it is hypothesised:

H2: Technology has a positive impact on ERP implementation success.

C. Implementation Team

An effective implementation team is a key factor for every successful ERP project. The ERP team should consist of the best people in the organization [8] [22] [32]. At the same time, the implementation strategy is, also, critical, since it will assist the entire organization to adjust its business processes. In addition, a successful ERP implementation process requires excellent project management. Implementation team, the third antecedent of ERP implementation success, includes these three sub-factors (project team, project management, implementation strategy).

First of all, it must be made clear that an ERP implementation project involves all the departments of an organization [55]. According to Bhatti [54], the ERP project team includes: employees, managers, IT personnel, top management, the ERP vendor, and management consultants. Selecting the right employees to take part in the implementation process is critical for its success. The success of ERP projects is related to the skills, knowledge, abilities and experiences of project team members [55] [56].

As stated above, ERP implementation is a multi-level task, involving all business activities, and, often, requiring between one and two years of continuous effort [19] [20]. Therefore, an effective project management strategy should be in place in order to control the whole implementation process. ERP project management includes a clear definition of implementation objectives, the development of both work and resource plans, and a detailed tracking of project progress [34] [57].

Also, an ERP implementation strategy determines how the transfer from the legacy system to the new ERP system will be organised. Adopting an efficient strategy is of vital importance, since strategy sets the whole framework of implementation [58]. Without proper strategy, the whole implementation project is very likely to fail [58] [59].

It is hypothesised that all the above will have a cumulative positive effect on ERP implementation:

H3: Implementation team has a positive impact on ERP implementation success.

D. End-Users

Previous research has shown that no IT-based innovation can be successfully implemented without employee participation [60]. The attitude of end-users toward the ERP system has an impact on implementation success [61]. Characteristics of end-users have been identified as predictors of ERP implementation success, since the full benefits of the ERP system cannot be utilised until end-users are using it properly [10]. In this study, the dimension of "end-users" includes three factors (user involvement, training and education, employee skills).

User involvement is one of the most cited critical success factors in ERP implementation projects [14] [33]. Participation in the ERP implementation process raises the understanding of the new system and helps achieving better use [62]. Despite the level of training employees get during the implementation process [63], their involvement during the whole process is a very critical factor [10].

ERP requires a critical mass of employee knowledge in order to solve real problems within the company [18] [22] [64]. Everyone who uses the ERP system should be trained and educated on how the system works and how it can be used in everyday operations [28]. Organizations should provide training opportunities, on a regular basis, in order to improve the skills and knowledge of their employees. Sufficient training and education can increase the probability of ERP implementation success [32] [45].

Successful ERP implementation demands the constant cooperation of business experts, internal staff and external consultants, as well as the involvement of end-users in

different project phases [32] [54]. Employee skills are very important, since they ensure that the technical and organizational aspects of the project run efficiently [34]. Without the appropriate skills of real system users, the ERP implementation is difficult to be successful.

It is hypothesised that all those factors will have an impact on ERP implementation success:

H4: End-users have a positive impact on ERP implementation success.

E. Impact on organizational performance

ERP implementation success can be measured using two different approaches. Some researchers have proposed quantitative financial measures (e.g. ROI, market share), while some others have proposed qualitative ones (e.g. decision making improvement) [31]. Dezdar and Ainin [11] argued that ERP implementation success depends on the evaluation of its actual users.

Shang and Seddon [43] stated that successful completion of ERP projects has a positive impact on organizational performance. That was supported by Ifinedo and Nahar [30], who claimed that the IS success model of Delone and McLean [65] leads to improvement in organizational performance, through three key antecedents: system quality, information quality and service quality. Consequently, the present study examined whether these three dimensions have an impact on organizational performance.

Information quality refers to the accuracy, timeliness, completeness and consistency of the information provided by the ERP system [31]. If the product (information provided by the ERP) is not delivered on time (timeliness) and does not conform to the needs of its customers (ERP users), then the latter will be dissatisfied and the company will lose business [66]. On the other hand, increased information quality will have a positive organizational impact, in terms of customer satisfaction and, thus, overall organizational performance will increase.

H5a: Information quality has a positive impact on organizational performance.

A well-designed ERP system is necessary for gaining organizational benefits. According to Chien and Tsaur [31], system quality is measured in terms of ease-of-use, functionality, reliability, flexibility and data quality. The expected benefits of system quality include cost reduction, enhanced performance and improved efficiency [67]. On the other hand, a system that is neither well designed nor user-friendly will, probably, create the risk of system failure [68].

H5b: System quality has a positive impact on organizational performance.

Service quality is measured via the reliability, assurance and responsiveness of ERP service providers [31]. This dimension includes the overall quality of services that a particular Information System (IS) provides to an organisation [69]. According to Gorla and Wong [70], service quality is positively associated with organizational impact.

H5c: Service quality has a positive impact on organizational performance.

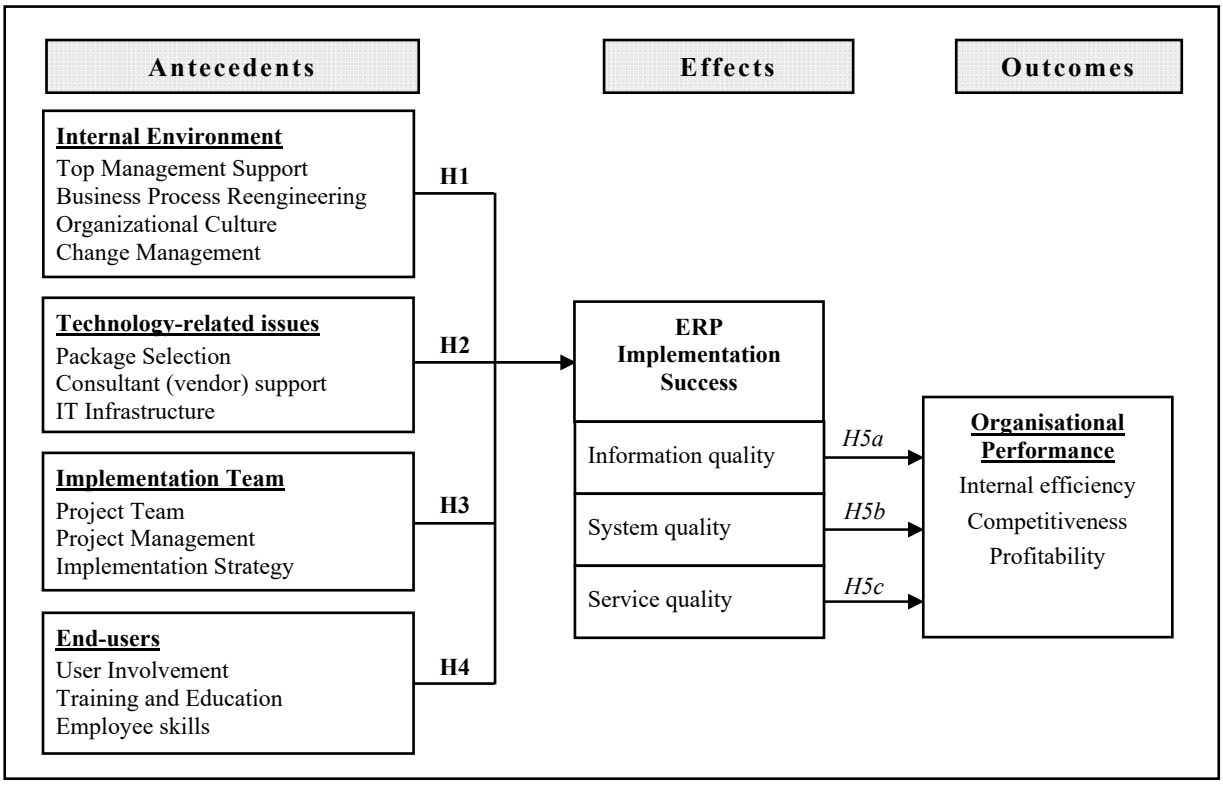

Fig 1. The Proposed Conceptual Framework of the study.

IV. Research methodology

A. Population of the study

The proposed conceptual framework was tested on a sample of Greek companies that have implemented an ERP system. Data concerning the target population were obtained via the web sites of various ERP system providers operating in Greece. Totally, 617 companies that have implemented an ERP system were identified.

B. Measurement

A structured questionnaire, designed specifically for this empirical study, was used in order to collect the appropriate empirical data. All items used to measure the various research factors have been adopted by previous studies [6] [7] [10] [26] [27] [30] [31] [32] [41] [42] [45] [50] [54]. The five-point Likert scale was used for the measurement of all research factors. In total, ninety (90) items were used for the measurement of all research factors.

C. Data collection

IT managers were selected as key respondents, due to their experience and expertise. Questionnaires were sent after telephonic contact with the IT manager. After making all necessary arrangements, 467 questionnaires were distributed to 467 companies that agreed to participate in the survey. The research period lasted three months (October to December 2015). 213 questionnaires were returned, but after conducting all necessary controls 204 were used for data analysis. The 204 returned questionnaires represent a very satisfactory response rate of 43,6%.

D. Validity and reliability

During the construct validity test, each factor (see Table I) was evaluated (a) for its unidimensionality and reliability, (b) for its goodness of fit to the proposed model. The examination of the unidimensionality of each factor was conducted using Explanatory Factor Analysis (EFA). Moreover, Cronbach Alpha was used for estimating the reliability of the same factor. The evaluation of the goodness of fit of all factors was conducted using Confirmatory Factor Analysis (CFA). All tests concluded that, after the extraction of relatively few items, the scales used for the measurement of the research factors are valid and reliable. Table I presents the main results.

V. Empirical results

The conceptual framework was tested using the Structural Equation Modeling (SEM) technique. The estimation of the structural model was conducted with the Maximum Likelihood Estimation method [71].

After experimenting with various different models, it was decided that “organisational performance” should not be

measured as coherent factor (structure), since the use of its various dimensions offered more in depth information about the investigated phenomenon. More specifically, as it can be seen in Fig. 2, the model that was finally examined includes three dimensions, with a total of ten factors.

In order to evaluate the fit of the overall model the chi-square value (X^2 = 194,61) and the p-value (p = 0,0647) were estimated. These values indicate a good fit of the data to the overall model. However, the sensitivity of the X^2 statistic to the sample size suggests the adoption of other measures for evaluating the overall model, such as the "Normed-X^2" index (2,95), the RSMEA index (0,057) the CFI (0,973) and the GFI (0,967), that all indicate a good fit.

Fig. 2 demonstrates the overall model, along with the path coefficients. In general, the results reveal the mechanism through which the antecedents of ERP implementation are affecting the various dimensions of organizational performance. Both direct and indirect effects are being examined, thus, enhancing the understanding of the investigated phenomenon. The main findings of the study are summarised below:

- Overall, the empirical results confirmed that the research model has satisfactory predictive power, since it can significantly explain the variance of the main dependent factors of the present study ("internal efficiency" by 31%, "internal competitiveness" by 51% and "profitability" by 35%). Moreover, the variance of "system quality" is explained by 78%, "service quality" is being explained by 32%, and "information quality" by 21%.
- While the relationship between several factors was not supported by the empirical data, partial support has been found for most of the hypotheses of the proposed model.
- More specifically, only one of the four antecedents included in the proposed conceptual framework (namely, "end-users") has an impact on all three dimensions capturing ERP implementation success (full support for Hypothesis 1). On the contrary, all other three antecedents have a direct impact on one dimension of ERP implementation success (partial support of Hypotheses 2, 3 and 4). More specifically, "internal environment" and "technology-related issues" have an impact on "system quality", while "implementation team" has an impact on "information quality".
- These findings underline the significance of the human factor in ERP implementation success. It seems that the end-users of the ERP system are the cornerstones for successful implementation. Implementing organizations need to take under serious consideration the involvement of end-user in the whole implementation process, provide training and education, while focusing on increasing their overall IT skills. Bradford and Florin [45], Dezdar and Ainin [22] found similar results.
- Moreover, according to the empirical results, the antecedents of ERP implementation success should be considered as a coherent bundle of activities. Implementing companies should focus on all of these dimensions, since their simultaneous enhancement has a commutative impact on the effectiveness of the implementation process. Nevertheless, focusing on end-users should become the first priority.

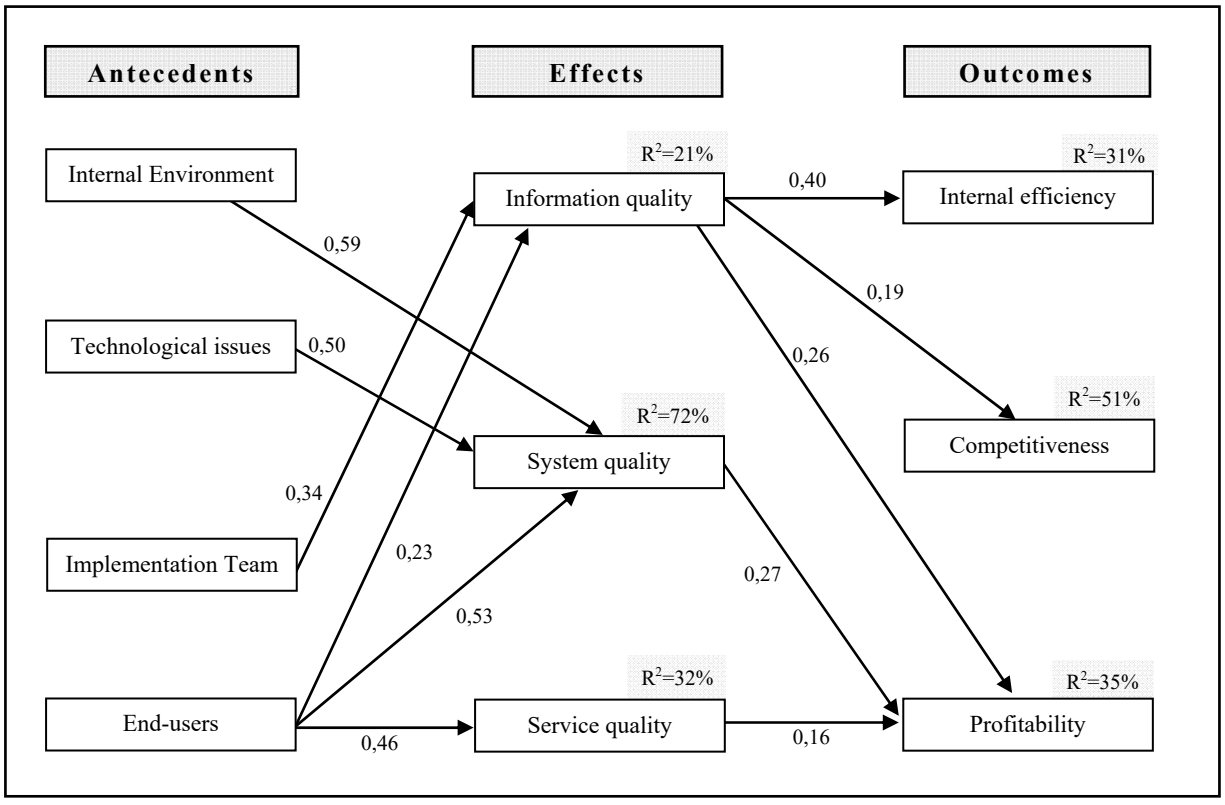

Fig. 2. Main empirical results (all paths are statistically significant).

- The empirical results offer full support for hypothesis 5a, arguing that "information quality" has an impact on all dimensions measuring "organizational performance". Partial support is being offered for hypotheses 5b and 5c, since "system quality" and "service quality" have an impact on "profitability". Despite the little empirical research that has been conducted on the relationship between ERP and organizational performance, the very few existing studies support these results [16] [17] [18] [20].
- The significance of the three-dimensional approach (antecedents, effects and outcomes) introduced in the present study lies in the interrelationships between various research factors. For example, the proposed model explains 51% of the variance in "competitiveness" (outcome). As it can be seen on Fig. 2, there is only one factor having a direct positive effect on "competitiveness" ("information quality", r = 0,19). Despite that, two of the antecedents included in the model ("implementation team", and "end users") have an indirect effect on "competitiveness", through "information quality". Only through that mechanism, the 51% of explained variance can be justified.
- Therefore, based on the above, it can be concluded that enhanced competitiveness is a direct result of information quality, but, despite that, end-users of the ERP system and the team which is responsible for the implementation both have a significant strengthening effect on that relationship. Mapping down these complex relationships has been one of the most important contributions of the present study. Managers are urged to bear in mind the existence of these causal effects, since their main objective should be the enhancement of organizational performance.

VI. Conclusions

The present study developed an conceptual framework that has never been used in the international ERP literature. Future studies can adopt the same approach, further highlighting the relationship between critical factors for ERP implementation success, ERP implementation, and organisational performance. Its main contribution lies on its implemented methodology and conceptualisation.

The empirical results enhance the understanding of the DeLone and McLean Information System (IS) success model [65] [69]. More specifically, a direct effect between "information quality", "system quality" and "service quality" and various measures of organisation performance has been established. On the contrary, the DeLone and McLean model [65] [69] argue that these dimensions have an indirect effect on organisational performance (through "user satisfaction" and "intention to use"). The support of a direct relationship, found in the present study, can be attributed to its conceptualization: the simultaneous examination of antecedents, effects and outcomes increases the explanatory power of the proposed model, offering a more complete picture of ERP implementation.

First and foremost, the empirical results highlight the significance of "end-users" in implementation effectiveness. Among all the antecedents of ERP implementation success, the dimension capturing the contribution of "end-users" on the whole process has the most significant effect. Previous studies [22] [41] have provided similar results, but very few have adopted such a methodological approach, using multiple factors for the measurement of each antecedent of ERP implementation success. For example, Zhang, Lee, Huang, Zhang and Huang [41] have, also, developed an ERP implementation success framework, but their empirical analysis was qualitative (case study research).

Secondly, since all four antecedents influence, each in a different degree, the three dimensions of implementation success, it is concluded that companies should focus on their collective enhancement. After all, all of these four factors (antecedents) have an indirect effect on organisational performance. For instance, the factor measuring the characteristics of the "implementation team" has an indirect impact on "internal efficiency", "competitiveness" and "profitability", through "information quality". Such a conceptual framework, taking under consideration both direct and indirect effects between antecedents and final outcomes, has very seldom been introduced in the ERP literature.

Thirdly, "information quality" appears as the most significant aspect of the implementation process, since it has a direct effect on all performance measures. According to previous studies [14], enhanced information quality during ERP implementation leads to increased performance. Information quality can help organizations choose different supply resources, hence, produce with lower costs and, therefore, develop competitive advantages, while increasing their competitiveness and internal efficiency.

The proposed model has adequate explanatory power, since it explains a significant percentage of the variance of all three main dependent factors. More specifically, it can predict 51% of the variance in business competitiveness, underlining the effect of ERP implementation on measures that previous studies have neglected [22] [43]. The enhanced power of the model lies in its three-dimensional approach, investigating both direct and indirect effects.

On a practical level, the present study offers a comprehensive list of factors having an impact on the successful implementation of an ERP system. Managers should focus on the enhancement of the most significant of these factors, identifying specific objectives for achieving successful implementation and increased performance. Finally, the present study underlines the mediating role of ERP implementation success in the relationship between various antecedents and final outcomes. It seems that such an approach can better describe the hypothesised relationships, since the effects of the four antecedents need to be translated into tangible benefits (information, system, and service quality) in order to have a positive impact on performance.

The study is somehow limited by the poor definition of its population. This limitation is inherent to all studies of the field, since a complete list of ERP implementing companies is not easy to acquire. Further research is suggested with larger samples that would, probably, offer more information and strengthen the results of the present study. Moreover, it would be interesting to examine more factors and gather primary data from all company personnel, so as to achieve a more complete view of the subject under investigation.

Abstract—**The article presents a proposal to extend the functionality and knowledge of Business Intelligence systems to answer the requirements of managers of small and medium-sized enterprises (SMEs). It concerns two major aspects of the system, i.e. the interface that takes into account the level of knowledge of the manager, and supports the interpretation of economic and financial information using the built-in domain ontologies. The project is related to the design of smart decision support systems based on financial ontology and on the model of manager knowledge created by eye tracking analysis. An experiment was carried out on real financial data extracted from the database of Business Intelligent BINOCLE, developed by Bilander Co. To create a model of manager knowledge, a number of financial analysts, experts and economists were invited to analyze the pre-defined financial reports. Their tasks were observed and analyzed by the eye-tracking system StudioTM, Tobii. The logs of the system as well as the financial ontology have been used to develop the intelligent interface of a Decision Support System.**

I. Introduction

Decision-making in small and medium-sized enterprises is an extremely difficult process. The most important problems of the functioning of such enterprises are operational continuity, ensuring the ongoing customer service and support as well as technological aspects. Managing a business requires access to the appropriate information system that must always go hand in hand with the methods of financial analysis, allowing managers to monitor the changes in the environment, identify the different types of risk, choose appropriate forms of insurance against these risks, and follow appropriate scenarios of development. Each of the scenarios predicts future financial situations using the methods and tools of financial analysis. Managers of small and medium-sized enterprises (SMEs), on the one hand, are usually confronted with the barriers and limits on information, and on the other hand are able more easily to control costs and expenses using an individual, simplified information processing system, regardless of the requirements of accounting standards. It may be difficult for them to access prospective information allowing the evaluation of the anticipated environment changes.

Managers of SMEs need solutions that support their decisions based on transactional data which, after being processed by the tools of financial analysis, allow them to prepare the draft of decision. Today's information technology assures managers access to the multi-dimensional data stored in various data-bases and enables them to perform multi-criteria analysis. The problem appears, among others, to lie in the excessive numbers of reports which are generated by transactional and executive information systems. In the process of management, the information overload significantly reduces the ability to make the right decision.

In SMEs, financial forecasts needed to make good business decisions oriented towards improving financial efficiency and dynamic development are very often prepared in a cursory manner or simply ignored. This is mainly due to lack of time, and not to sufficient and limited managerial knowledge.

The aim of the article is to point out the possibilities of building the model of financial knowledge for managers in Business Intelligence system using eye tracking tools[1], and applying the model to interpret reported economic data. Data from eye-tracking illustrates not only the perception of the economic reports by a manager, but also enables the manager to identify schemes analysis and determine the level of his or her knowledge. It facilitates also the establishment of a manager knowledge profile and, consequently, it creates a possibility of adapting the interface to an individual's skills. In the project, the whole process of analysing financial data will be supported by built-in ontologies of economic and financial knowledge which is essential for SME managers. This will be possible thanks to research focusing on the development of an intelligent interface supporting interpretation of economic information, which also is associated with modeling of managerial knowledge. The described approach is a continuation of the construction of the intelligent cockpit for managers (InKoM project), whose main objective was to facilitate financial analysis and the

[1] Eye tracking is a collection of techniques for the measurement, acquisition and analysis of data about the position and movements of the eyeballs. It provides a quantitative measurement without referring to subjective, verbal relationships of the respondent [http://eyetracking.pl].

evaluation of the economic status of the company on a competitive market [1].

The structure of the article is as follows. The next section focuses on the issues related to management-based analysis, particularly in relation to SMEs. The next section briefly refers to the Business Intelligence (BI) system in the context of the Key Performance Indicators (KPI) used to build an ontology of economic and financial knowledge. Section 4 is devoted to the modeling of managerial knowledge, together with a synthetic description of the eye-tracking results. The article concludes with a summary of work to date.

II. Supporting of managerial analysis

Management of the SME is a very complex and difficult task. In such organizations, resources for wider financial and accounting services are usually limited. Often, these tasks are assigned to accountants who are excessively burdened with operational activities and supervision of the correct tax settlements. Managers of SMEs often have to focus on the technological problems related to the core business, which limits the possibility of financial projections associated with the preparation of the right decisions to ensure financial security and dynamic development based on improving financial efficiency.

Financial analysis allows the interpretation of the information necessary for the ongoing management of an enterprise[2]. Managers of SMEs are expected to find support in the following areas:

- assessment of the project's effectiveness - the answer to the question whether the achieved profits are adequate to the funds involved, and how to compare the results with other companies with similar operations;
- assessment of cash flows - whether it is possible to repeat a generated surplus in the following periods or whether it will no longer occur in the future.

The main activities of the SMEs are focused on business operations. Information processing and related decisions concern the core activities of the company, and are associated with its specificity and membership in a particular industry. An important element of operational management in SMEs is to control liquidity, while it should be emphasized that classical liquidity ratios used in large companies cannot be always directly applied to SMEs. In this view it is worth designing solutions that make use of analytical accounting records to project liquidity on a monthly basis. There is no doubt that this kind of analysis of liquidity, taking into account the size of the entity, the specificity of the industry, and the type of offered products or services is not possible without expert knowledge. On the basis of empirical studies we found that information requirements for short term management concern [2] information about liquidity, information on revenues generated by the company, and information on costs incurred. But for the long-term management area, information is needed: about the company's indebtedness, about the profitability of planned investments, and about the financial situation of the branch.

The process of decisions support made needs - firstly - the decomposition and the proper selection of management instruments. Managing medium-sized enterprises requires information about the possibility of gridlock preventing stable business in the near future. Secondly, there is a need to acquire information to generate the appropriate level of profit and a minimum level of margins in order to make the right choices. They are focused on obtaining information on opportunities to increase revenue or to carry out activities aimed at cost minimization.

Regarding long-term decisions, managers of small companies are not able to relate to the use of advanced solutions for e.g. capital budgeting. They need analytical models that enable them to identify signals indicative of the need for investment decisions and the level of resources involved. With regard to medium-sized enterprises, this type of analysis should be augmented by simulations on the effectiveness of individual organizational units (responsibility centers) and the profitability of equity involved.

Acquisition of information to support such decisions is possible mainly through the use of patterns developed by experts in financial management. Unfortunately, it is impossible in this case to use the universal solutions - in this case it is necessary to dispose over an intelligent system that using expert knowledge provides ready-made decisions, taking into account the specific nature of the company[3] .

Also important are analysis of the index of debt level and the use of static and dynamic methods of estimating the profitability of investment. For organizations with greater economic importance, the study should be completed by:

- the use of the Balanced Score Card and the early warning system,
- analysis of indicators of debt service, study of the cost of capital: domestic and foreign capital, the weighted average cost of capital,
- pro-forma financial statements - as information about the financial effects of planned long-term actions,
- evaluation of the company's profitability: return on sale ratios, return on assets and equity - to various cuts in the financial results,

[2] It should be emphasized that the selection of appropriate methods of analysis of the financial requirements of SME managers is necessary to determine the company's ability to continue its operations, and to define financial needs, budgets and capital resources of financing assets, signs of danger and risk of changes in the competitive position and trends in various business areas.

[3] The management of long-term financial analysis conducted by managers of small businesses should include: a preliminary analysis of financial statements, ratio analysis, information on liquidity ratios, evaluation of static measures of liquidity, turnover ratios of inventories, receivables and payables analysis, analysis of the operating cycle in terms of the efficiency of indicators of capital engagement, productivity of assets and equity, and information on current and future income and expenses.

- methods of budgeting process.

Generally, the support of decision-making is based on the generation of ready-made paths, together with projections of the effects of planned decisions. For example, in a system of the Binocle Bilander company which is classified as a category of Business Intelligence systems, there are many useful and powerful functionalities that make possible multivariate analysis of financial data. However, due to the limited resources of SMEs, it is necessary to develop ready-made reporting and decision paths for managers and owners of SMEs. These reports and patterns of decision-making should take into account inter alia the support for operational and financial planning, and risk analysis (in particular, the risk of bankruptcy). In addition, they may include support in investment decisions and measuring the effectiveness of the company as a whole and its individual organizational units.

In addition, to improve the decision-making processes in SMEs, three important issues should be taken into account:

- number of KPIs (key measures of achievement),
- methods of forecasting and simulation to facilitate taking corrective actions,
- standard indicators for SMEs needed for benchmarking.

Also crucial is a selection of available reports (option in the Binocle system) to present the most important information for the manager. If needed, these reports may be further detailed.

III. KPI IN BUSINESS INTELLIGENCE SYSTEMS

Both in business practice and in literature one can find different definitions of Business Intelligence (BI). The main goal of each form of BI is to gain access in a timely manner to relevant data to allow making the best decision at a given time [3; 4]. An important element of BI systems is also the visualization of the calculated KPIs. These indicators are the basis of decision-making both at strategic as well as tactical and operational level. The usefulness of indicators depends on the manager's understanding of the concepts, measures and structural links involved. Leading financial analysis of the indicators the manager examines their semantic relationships. The essence of the evaluation is the appropriate computing and use of indicators derived from different financial statements (including balance sheet, profit and loss statement,…). The usability of economic analysis depends on, among other things, the manager's exact understanding of the existing structural semantic links, and relations between indicators and economic terms. According to the degree of data aggregation, the measures might be global or partial, where the indicators can be summed up, differentiated, multiplied or divided.

Ratio analysis used to assess the activities of the company has both advantages and disadvantages. Among the first are: the ease of measurement, the availability of source data, the ability to identify critical areas of economic activities, the universality of the indicators, allowing, among other things, the conduct of comparative analyses with other companies. While the disadvantages are: no indication of the reasons for unfavorable events, the risk of misinterpretation of measures, the lack of universal standard ratios. Finding the causes of adverse events, and taking note of the positive factors, can facilitate the evaluation of the data by analyzing the semantic relationships between economic indicators.

Most BI systems (referred to as traditional BI systems or BI 1.0) are primarily intended for managers who are familiar with data models and are able to build all kinds of scenarios analysis [5]. The literature points to the creation of the next generation BI systems, known as Business Intelligence 2.0 [6; 7]. These systems are characterized by properties such as event management and analysis in real-time, direct access to information at different levels of enterprise management, predictive analytics, enhanced interactive visualization, intuitive interface, support for semantic information retrieval, and widespread and mobile access data (described in [6]). A characteristic feature of this new generation of BI systems is the reliance on the ontology and semantic retrieval of information. In architecture, there are new elements, such as ontology, ontology services and application domain ontology. The use of ontologies and visual information retrieval within analytical tools can be helpful to solve the following problems [8, p. 215]:

- definition of business rules in order to get proactive information and advice in the decision-making process,
- specification of semantic layer describing the relationships between different economic concepts,
- presentation of business information,
- the rapid modification of existing databases and data warehouses.

Development of BI systems is progressing towards the use of visual information retrieval based on a semantic Web. One of the main artifacts in the emergence of the semantic Web is an ontology. In the framework of the project we have elaborated the ontology, covering the scope and the data discussed in the paper.

IV. ONTOLOGICAL FOUNDATION

One way to represent knowledge in information systems is an ontology. In the literature, you can find many definitions of ontology. However, most often the term refers to the definition given by T. Gruber, who describes it as "an explicit specification of a conceptualization" [9, p. 907]. So ontology is a model that defines formally the concepts of a specific area and the semantic relations between them. In literature research of an ontology using in BI systems are described [10; 11;12;13; 14; 15].

Many research projects show that creating an ontology of economic and financial indicators is advantageous in decision making [8]. This is important, because there is no single universal system of economic indicators that would be used in all organizations. Besides, a lot of companies use a number of assessment models of business based on the analysis of various indicators. An ontological approach to modeling

domain knowledge was proposed in the project "Intelligent dashboard for managers (InKoM)" (described in [1; 16]). The main objective of the project was to create an intelligent cockpit for managers of small and medium-sized enterprises, which facilitates analysis and interpretation of the economic situations of the company, and supports analysis of economic and financial data Three new components of the cockpit are important: the financial ontology, the data mining algorithms, and the mechanism of deep retrieval on the Internet. This solution has enabled adequate, expandable and adaptable mapping of economic and financial knowledge, without having to modify the existing system of TETA BI. The new system significantly extended the usefulness of the existing Decision Support System [17].

In developing an intelligent interface, the ontological approach was completed by eye-tracking methods. Available in the BI system, a visual presentation of data permits one quickly to assess the economic situation and take appropriate action. To discover a way of analysing financial reports and statements managers, financial analysts, and students of economics participated in the experiments. The eye-tracking logs during the reading of these documents were used to discover the patterns of operations and to model the financial knowledge of each of the participants. The concepts and analytical operations performed by each manager were matched with the financial ontology available in the system.

V. Case Study – Evaluation of a Company's Profitability

Profitability analysis is necessary to assess the effectiveness of an economic entity. Sales revenues are essential to generate cash inflows that feed any company. These cash flows are used not only to purchase materials, services, and other goods, but also to make investments in fixed assets and working capital necessary to sustain ongoing operations. Profit is, however, a universal measure used in assessment of the financial situation. Unfortunately, the fact that an increase in revenues and earnings does not always generate cash inflows triggers off a serious risk of misinterpretation. Thus, the lack of cash inflows may generate serious financial problems. Profitability analysis without taking into account changes in cash position may yield wrong business decisions [18]. This is why the use of an ontology that describes in detail the issue of profitability allows one to avoid the risk of misinterpretation.

Managers of SMEs require a strong semantic reach and easy to use methods and techniques to support decision making. The aim of the experiment was to examine the usefulness of a financial ontology in the analysis of selected financial indicators and metrics in supporting operational decision making. Participants in the experiment had access to the system containing financial reports and ontology diagrams supporting the analysis of corporate profitability. For the purposes of our research, the balance sheet and profit and loss account of a real company were submitted. The financial statement included information that indicated the seemingly positive performance of the case company. In the periods analyzed, however, serious problems occurred due to bad debts. Those problems should have been perceived by the analyst as threatening the loss of the rationale behind the going concern's basic assumption, i.e. the ability to function without the threat of liquidation for the foreseeable future.

The experiment was initiated by the analysis of an internal managerial report containing widely used measures of financial situation, namely: liquidity profitability, debt, and turnover ratios. The most important factor directly observed by the participants of the experiment was a significant increase in profitability in the analyzed period.

In order to explain the profitability ratio correctly there was a need to take advantage of the ontology describing the issue of profitability, which is presented in Figure 1.

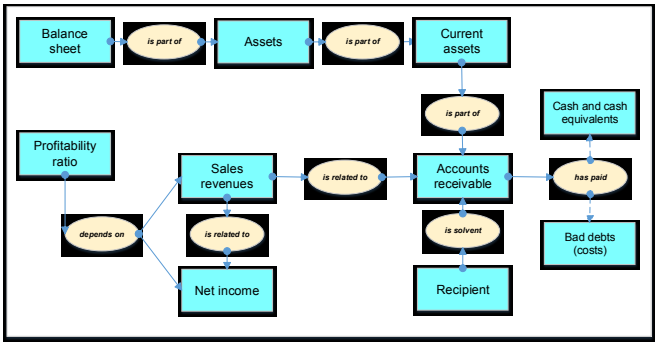

Fig. 1. Ontology: view of profitability

Profitability is the most important measure of effectiveness while running a business. According to the scheme presented in Figure 1, profitability is dependent on sales revenue and total net profit earned by the company. The aim of profitability analysis is to obtain information about the amount of the surplus earned from the sale which remains at the disposal of managers. Ontology describing corporate profitability allows the manager to properly analyze the growth of profitability ratio. It is necessary to examine the increase in revenues, net income as well as changes in cash amount and accounts receivable. According to the ontology, an increase in both profitability and accounts receivable is an unfavorable symptom. A positive sign suggested by the ontology was the increase in profitability along with the increase in cash.

Rate of return on sales is one of the key measures of operational efficiency, which informs us about the margin that has been realized on sales. Increasing ratio of return on sales is a positive symptom for the company because it may confirm that the proper decisions were made with regard to cost reduction or making good business deals allowing the company to increase sales revenues in excess of costs [19, pp. 135–164].

Profit margin, on the one hand, indicates the actual part of company revenues which remains at the disposal of managers and contributes to cover operating costs. On the other hand, profit earned may be used to increase equity or be paid out to the owners as dividends. The greatest disadvantage of return on sales ratio is that it is computed on the accrual basis [20].

The most fundamental concept of accounting is accrual principle that is a requirement of both International Financial Reporting Standards and Generally Accepted Accounting Principles. This concept requires keeping a record of business transactions (such as the rise in revenues or accounts receivable) in the period in which they actually occur, not in the period in which the cash flows related to them occur.

This means that sales transactions recorded as revenues in the accounting system increase net income, which, however, due to various external factors, may never be realized in the form of actual cash inflows (e.g. due to the bankruptcy of the recipient or the initiation of legal proceedings on claims, etc.).

According to the ontology presented in Figure 1, as the profitability increases it is necessary to check whether the increase in revenues is reflected in actual cash flows which are needed in running a business on a daily basis. Increase in profitability may be also triggered off by the increase in accounts receivable, which might be perceived as an unfavorable symptom.

Cash inflows from sales are the most important components of cash flows from operating activities as, in the opinion of many scholars, the most important element of cash flow statement, because in this part information about the most common business operations has been aggregated. This is a segment which usually generates excess cash that is used to finance investment processes, and to purchase fixed assets and intangible assets, as well as to repay financial obligations [2]. The shortage of cash flows from operating activities occurring in subsequent years should be perceived as an unfavorable symptom, because that usually indicates impending bankruptcy if the appropriate remedial steps are not taken.

The problem that causes significant misinterpretations in the proper assessment of the rate of return on sales is the issue of the so-called bad debts. The most common reason for the financial problems of many small and medium-sized companies is a problem with collection of accounts receivables. In such cases credit risk is understood as a potential loss due to the lack of collection of receivables. According to legal requirements in Poland, if there are any doubts with regard to the possibility of collecting receivables, these should be regarded as uncollectable bad debts. Thus, bad debts are those whose probability of recovery is low or close to zero. These accounts are a serious problem for the company, because they require to deal with impairment as well as legal enforcement proceedings that may be problematic.

In the experiment, it was noted that the increase in profitability is due to the accrual principal, and thus virtual, because as revenues significantly increased, accounts receivable increased even more, as presented in Figure 2. The decision maker using financial reports and ontology is guided through analytical steps, which are labeled on Figure 2 with numbers from 1 to 8.

In the analyzed period, sales revenues increased from 732 thousand PLN to 813 thousand PLN. According to the ontology, it is not recommended to base analysis solely on revenue growth, because the comprehensive analysis must include the detailed examination of changes in receivables. In the analyzed period, accounts receivable in the balance sheet increased dramatically from 145 thousand PLN to 321 thousand PLN. Thus, the ontology allows to avoid a threat of misinterpretation with regard to an apparent increase in profitability.

Financial analysis of a company's standing should be comprehensive. The example of such analysis with regard to profitability is presented in Figure 2. Based on the ontology, it is not sufficient to analyze managerial reports containing financial indicators, but it is necessary also to focus on the selected items from the financial statement. In order to properly explain the increase in profitability, the analyst is required to deal with percentage change analysis with regard to:

- revenues from sales,
- net income,
- short-term receivables,
- cash and cash equivalents.

Comprehensive analysis of the most important factors affecting the level of profitability ratio should be completed by sending a warning signal from the decision support system. As presented in Figure 2, the warning signal indicates that there is a need to take a decision to amend the sales process management. In the analysed case, in order to improve average collection of receivables it is recommended to:

- apply debt collection and enforcement techniques (in a short-term transaction),
- look for customers in different market segments, who do not have problems with paying on time (in a long-term one).

Suggestions proposed by the decision support system should be considered against the market conditions and customs of the local industry. Excessive use of debt collection activities can generate a negative signal to potential new customers who will search for suppliers among competing companies patiently waiting for payment. Such actions to be taken by managers were suggested by means of the warning signal generated by the system as it was presented in Figure 2.

Changing the segment of the target market may be feasible in the long term, thus such a decision should be preceded by insightful analysis. Moreover, it is necessary to examine the potential impact of restructuring on the future performance of the company. In addition, it is necessary to analyse the company's ability to carry out the investment project oriented towards the company's adjustment to new customers.

Any decision should be revised using the same techniques that helped to identify the original problem. In our experiment, we studied the financial performance demonstrated by the company that was achieved in the subsequent period. In Figure 3, we present an analysis of the research findings and their interpretation.

1

Managerial report		2012	2013
Profitability ratio	%	15,6%	19,2%

3

Profit and loss account		2012	2013
Sales revenues	PLN	732 167,0	812 967,0
Net income	**PLN**	**114 435,0**	**156 097,0**

5

Balance sheet / Assets		2012	2013
Accounts receivable	PLN	145 567,0	321 170,0

7

Balance sheet / Assets		2012	2013
Cash and cash equivalents	PLN	245 138,0	249 876,0

6 What was the change in cash?

8 **INTERPRETATION:**
Virtual increase in profitability

SUGGESTION:
Extensive debt collection activities

Fig. 2. Supporting the proper interpretation of profitability ratios (task 1)

1

Managerial report		2013	2014
Profitability ratio	%	19,2%	21,6%

3

Profit and loss account		2013	2014
Sales revenues	PLN	812 967,0	978 045,0
Net income	**PLN**	**156 097,0**	**211 078,0**

5

Balance sheet / Assets		2013	2014
Accounts receivable	PLN	321 170,0	339 067,0

7

Balance sheet / Assets		2013	2014
Cash and cash equivalents	PLN	249 876,0	311 479,0

6 What was the change in cash?

8 **INTERPRETATION:**
Satisfactory increase in profitability

SUGGESTION:
Continuation of existing practices

Fig. 3. Supporting the proper interpretation of profitability ratios (task 2)

Analysis of the solutions applied in the previous period allows them to be considered as accurate. Figure 3 presents the performance of the company, among which the most important signal is the increase in sales revenue and the

increase in cash flow. Simultaneously, the level of accounts receivable has stabilized. Figure 3 presents the financial performance of the case company. Similarly to Figure 2, in Figure 3 we labeled analytical steps to be performed by the decision maker with numbers from 1 to 8. Among other measures, the most important signs are the increase in revenues from 813 thousand PLN to 978 thousand PLN and an increase in cash amount from 250 thousand PLN to 311 thousand PLN while the short-term receivables amounts remained stable (not exceeding 10%).

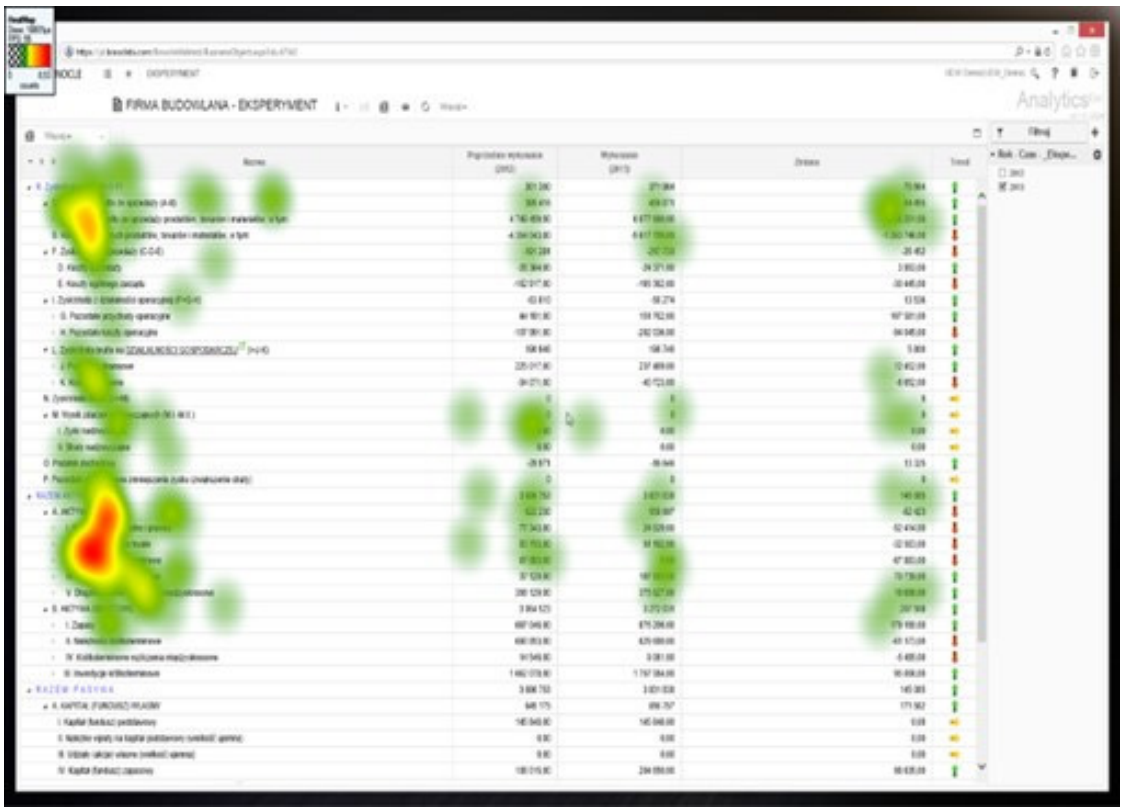

Fig. 4. Example heat map

This highlights the relevance of decisions taken by means of a decision support system based on a developed ontology. The proper interpretation of the information contained in the financial statements varies depending on the qualifications of novices and experienced managers. Novices only paid attention to the increase in revenues and profit growth, but neglected the change in accounts receivables. Most of the experienced managers focused their attention on the growth of accounts receivables. The behavioral patterns of experienced managers confirmed the usefulness and comprehensiveness of the ontology. Bad debts are a serious problem which should be analyzed first, before the revenue growth. Decision making without the use of ontology may lead to wrong conclusions, e.g. introducing sales promotion to increase sales growth. Using the ontology enabled the appropriate decisions to be made with respect to receivables management.

Comprehensive insight into both the selected managerial indicators and metrics as well as the changes in the value of chosen items from the financial statement is required for the proper interpretation of a company's performance. This would not be possible without the use of systematic knowledge in the form of ontology. Ontology is therefore an essential element of the decision support system that allows us to make the right business decisions oriented toward company development and avoiding the threat of bankruptcy.

VI. Approach to Modelling of Managerial Knowledge

In the construction of a new decision support system interface, an important role is played by the manager profile, in particular identifying his or her financial and economic knowledge. There are a number of methods for knowledge and reactions modelling of managers: crowdsourcing [21], testing physiological brain [22], explorations of the observation of the manager's eye movements, otherwise called eye tracking. In the project this last test method was applied. Eye tracking provides the opportunity to obtain various results, among which may be mentioned: the raw data, the scanning path, and a heat map. Figure 4 illustrates the sequence of analysis of the Balance Sheet by a manager. The diagram shows the parts of the document which have particularly attracted the attention of the manager: the area

close to the color red. Green areas on the thermal map show other areas for attention.

The results of the experiments raised three questions: (1) how and why does the experienced manager proceed; (2) how to identify the short-comings and errors committed by inexperienced managers, and (3) how to recognize a manager's fatigue and stress. The answers to these and other questions provided patterns of schematic perception of economic information. Using process mining methods, the preliminary rules and sequences of activities were discovered for novices and managers with experience. Raw quantitative data, collected by tracking software, can be analysed and used in the process of searching for perception patterns. As a result of the transformation of the data, it is possible to obtain a model of the analytical operations of managers. Such data, along with analytical models and ontology of financial analysis, are the basis of an intelligent decision support system. Patterns, models of financial analysis, and ontology are considered as knowledge in an intelligent financial decision support system.

VII. Conclusions and future research

This article presents a new attempt to create an intelligent interface for a Decision Support System. The idea was founded on the use of domain ontology and methods of patterns discovery of managerial knowledge from eye-tracking logs. The studies show that managers of small and medium-sized enterprises often have little benefit from achievements in the field of broadly understood financial analysis and IT technology, to strengthen their competitive position on the market and maintain financial credibility. The problem is often caused by the lack of the knowledge required to correctly interpret the financial reports as well as economic indicators. Also, they have difficulty with the knowledgeable use of the information systems that contain too many functions and tools that exceed their knowledge and skills. Usually, numerous ways of reporting, and the complex visualization tools, deepen the difficulties in the perception of the financial situation of an enterprise and its environment.

The use of improved visualization and access to semantic searches are primary characteristics of the BI 2.0 system. One of the main artefacts in semantic networks is the ontology of business information. A created ontology is required in which data and relationships of objects from various fields of knowledge are defined.

The experiments showed the usefulness of ontology where each concept and relationship can be considered in a multifaceted way. In the case studies, we have demonstrated that decision making without the use of ontology may lead to wrong conclusions, e.g. introducing sales promotion to increase sales growth. Analysis of indicators alone without relation to other components of financial reporting can lead to the choice of improper interpretations. Ontology is therefore an essential element in the decision support system that allows a manager to make correct business decisions oriented toward company development and avoiding the threat of bankruptcy.

The use of eye-tracking allowed us to develop preliminary patterns of analysis of financial reports and interpret the most important indicators.

The sequences of actions, discovered on the basis of the eye-tracking of experts, allows for defining of best practices to analyze financial data. However, these patterns are not sufficient to generate the interface. They must be associated with the financial ontology that help to interpret the data and provide adequate recommendations.

Preliminary results of the experiments demonstrated large differences between the experienced managers and novices in the manner of data perception and a way of analysis of financial reports. To develop a user-oriented interface, further in-depth studies on identifying the level of manager knowledge are needed. The project will be continued, especially on modeling of manager knowledge using eye-tracking. Models of patterns exploration in analytical sequences of actions will also be developed.

Acknowledgements. The authors thank the staff and the companies Bilander and Tobii for their support in developing the prototype. Thanks go also to the financial experts: Wojciech Hasik, Mariola Kotłowska and Wojciech Ostojski, and students of the Faculty of Management, Informatics and Finance of Wrocław University of Economics.

***Abstract*—Information and communication technologies (ICTs) can enhance the knowledge sharing by lowering temporal and spatial barriers between prosumers and enterprises, and improving access to prosumers' knowledge for enterprises. A major challenge for enterprises involves investing in the appropriate ICTs that help facilitate prosumers' knowledge engagement and knowledge transfer. The purpose of the paper is to indicate which ICTs are currently used and expected to be used by prosumers for knowledge sharing. The reported outcomes are the result of a questionnaire survey that yielded responses from 783 Polish and 171 UK based prosumers. The results indicate the primary ICT choices for use and expected use by Poland and UK based prosumers revealing important differences between these countries. The mobile applications being favored amongst the UK respondents whereas the dedicated enterprise website is the favored ICT amongst Polish respondents. Further, the variety of ICTs provided by enterprises may be too limiting to promote the type of knowledge sharing and communications expected to reassure the prosumers.**

I. Introduction

Knowledge is currently viewed as a fundamental driver for the commercial success of enterprises and is crucial to their competitive advantage [1]-[4]. Moreover, customer knowledge becomes an essential intangible asset for every line of business [5], leads to better response and respect toward customers [6], [7], makes a contribution toward new and innovative products [8], [9], contributes to the improvement of business value [10], and enhances the competitiveness of businesses [11].

Consumers who share their knowledge with enterprises with the aim of creating values and benefits for enterprises and their own consumption are known as "prosumers," whereas the process in which they share knowledge with enterprises is consistent with the notion of "prosumption" [12]-[17]. In general, prosumption refers to situations in which prosumers share knowledge not only with enterprises, but also with other prosumers to produce things of value for enterprises, and also for themselves.

Given that advances in ICTs have made it easier to share knowledge and these ICT developments have made the world increasing interconnected, many enterprises recognise there are challenges to employ the appropriate ICTs to facilitate knowledge sharing with prosumers. In considering the complexity of prosumption, prosumers' knowledge sharing initiatives and the variety of ICTs, enterprise must often confront these challenging tasks in deciding what type of ICTs to deploy in support of their prosumption initiatives.

The existing studies mostly examine ICTs for knowledge management in enterprises [18]-[23]. Researchers argued that ICTs play an important role in acquiring, codifying, storing, creating, sharing and applying knowledge that can be crucial for effective decision making and control at all levels.

The authors of this paper, following an extensive review of the literature, did not uncover any deep studies to interpret how ICTs support prosumers' knowledge sharing with enterprises. This reveals a need to study the ICTs that should be adopted and used by enterprises to better enable prosumers' knowledge sharing. Therefore, conducting research among prosumers and enterprises should contribute to greater understanding of the use of ICTs for prosumers' knowledge sharing and should help fill the gap in the existing body of knowledge.

In light of the above limitations, this paper focuses on investigating the choice of ICTs supporting prosumers' knowledge sharing in Poland and the UK. Its aim is to indicate the ICTs that are currently used by prosumers in comparison with the preferred ICTs expected to be used by prosumers.

The paper is structured as follows. Section I is an introduction to the subject. Section II states the theoretical background of ICTs for supporting prosumers' knowledge sharing and poses a research question. Section III describes the research methodology. Section IV presents the research findings on ICTs used and expected to be used by prosumers to facilitate knowledge sharing. Section V provides the study's contributions and limitations, and implications for the findings and considerations for future investigative work.

II. Theoretical Background And Research Question

A. Concept of prosumption and prosumer

The concept of prosumption has emerged from consumption theory. It focuses on the role that can be played by pro-active consumers willing to cooperate with enterprises.

The term '*prosumer'* was coined by Toffler [15]. According to him, selected enterprises' tasks (mainly manual

tasks), previously performed by enterprises' employees, are increasingly performed by consumers in accordance with the *do-it-yourself* principle, and by implication consumers become co-creators of products and services. Indeed, the terms of prosumption and prosumer have evolved over the years [24], [25]. As a result, modern approaches to prosumption differ greatly from Toffler's proposal. Table 1 presents the characteristics of two approaches to prosumption: Toffler's approach versus the modern approach. The modern approach to prosumption emphasizes the creativity of prosumers, as well as being connected to the value of prosumers' knowledge for enterprises. Enterprises can use their knowledge to attain business goals and, as a consequence, engage prosumers in business tasks.

B. Prosumers' knowledge sharing with enterprises

Prosumers' knowledge is the most important asset for most sectors engaged in contemporary business and is one of the most important contributors in improving business value and enhancing business performance [6], [27]-[30]. It is categorized into three types [31], [32]:

- *Knowledge about prosumers* represents both prosumers' needs and requirements; it may encompass characteristics in prosumers' behavior, their demographics and previous purchasing patterns; it may allow an understanding of prosumers' motivation in order to adjust and personalize products' or services';
- *Knowledge for prosumers* is created to satisfy prosumers' needs; it may include knowledge about enterprises, products and services; it may support prosumers in their buying cycle, impact on prosumers' perception of enterprises and offers, and become the base of knowledge from prosumers; and
- *Knowledge from prosumers* is created through the prosumers' experience with enterprises; it may embrace ideas, thoughts, reviews, opinions, discussions, advice and rankings that enterprises receive from their prosumers and use them to enhance their products and services.

The sharing of these various kinds of prosumers' knowledge between the prosumers and enterprises is critical in order to produce things that are of value not only for enterprises but also for prosumers. It could be characterized as a process in which prosumers' knowledge is exchanged among prosumers and enterprises. In this process prosumers share what they have learned and transfer what they know to enterprises that have a business interest in it and that have found this new knowledge to be useful for business improvement [33]. In this process the value of knowledge appreciates when it is shared [34].

In this study, the term "prosumers' knowledge sharing" means providing *knowledge from prosumers* (prosumers' ideas of products developments and creation, thoughts, reviews, opinions, discussions, advice and rankings) to enterprises and other prosumers. This approach is in line with the proposal of Wang and Noe, who distinguished knowledge sharing from knowledge exchange [35].

TABLE I.
NATURE OF PROSUMPTION

Toffler's approach	**Modern approach**
Prosumer's role	
Less complex tasks, previously carried out by enterprises' employees are performed by prosumers	• Sharing knowledge and experience with enterprise • Participating in enterprise business processes
Prosumer's knowledge	
Tasks performed by prosumers were tightly connected with their manual skills	Prosumers' knowledge is a source of innovative, creative business solutions, and processes improvement
Prosumer's relationship with enterprises	
Static, based on taking over of less important tasks from employees and performing them themselves	Active, based on collaboration, co-participation, co-design, and co-creation
Prosumers' communication with enterprises	
One-way, impeded, most often indirect	Two-way, multi-channel, easy and direct
Main advantages for enterprises	
Delegating simple tasks and activities to prosumers	• Using prosumers' knowledge for achieving business goals • Following prosumers' needs • Establishing relationships with prosumers and prosumer-friendly images of enterprises • Supporting enterprises' business processes by prosumers' knowledge
Main advantages for prosumers	
Self-service accordance with prosumers expectations	• Expressing own opinions about enterprises and their products • Adjusting products or services to own needs • Getting various types of financial and non-financial rewards

Source: own elaboration on the basis of [26].

According to them, "knowledge exchange includes both knowledge sharing (or employees providing knowledge to others) and knowledge seeking (or employees searching for knowledge from others)." It should however be noted that "knowledge sharing" can be also used interchangeably with "knowledge exchange" [36].

C. ICTs supporting prosumers' knowledge sharing

Some studies show that ICTs, especially CRM systems [37], Business Intelligence systems [38], and social media [39]-[44] can be used for knowledge management.

Additionally, researchers have examined ICT-tools for knowledge sharing [19], [45]. Jiebing, Bin, and Yongjiang [46] provided a conceptual framework to explore the linking mechanisms between customer knowledge management and ICT-based business model innovation. Studies concerned with the role of ICTs in knowledge sharing enlist such primary technologies as blogs, e-mail systems, e-collaborative systems, e-forums, knowledge repository, instant messaging, audio conferencing, podcasts, video conferencing, and wiki in the context of challenges faced by the practitioners in distributed projects [47] or in the context of Nonaka and Takeuchi's SECI model [48]. The focus of the SECI model on knowledge creation explores the cycle of generating tacit knowledge through to explicit knowledge and recreating tacit knowledge. The knowledge change in the SECI model is summarised as tacit to tacit (Socialization), tacit to explicit (Externalization), explicit to explicit (Combination), explicit to tacit (Internalization) [48], [49].

Only a few of the studies explore the application of social media for sharing customer knowledge. For example Chua and Banerjee [40] presented how Starbucks redefined the roles of its customers through the use of social media by transforming them from passive recipients of beverages to active contributors of innovation. Jalonen [50] explored the interplay between knowledge and emotion in the organisational knowledge creation process in the context of social media. Okazaki et al. [51] found a clear connection among customer engagement, prosumption, and Web 2.0 in a context of service-dominant logic. Moreover, they identified social networks created by prosumers. Based on the literature review, Zembik [52] explored various types of social media and their role as source of knowledge about, for, and from customers. Ziemba and Mullins [32] proposed the conceptual customer stratification framework which explains the stages required by a business to observe customers social media discussions.

D. Research question

After extensively searching through the literature, it was observed that there is a research gap in the existing body of knowledge related to ICTs used currently by prosumers and expected to be used by them to support prosumers' knowledge sharing. Also there is no research focusing on comparative analysis between less developed countries (like Poland) and better developed (like the UK) in the above mentioned area. In order to bridge the gap this study examines ICTs facilitating Polish and UK based prosumers' knowledge sharing and focuses on addressing the following research question:

RQ: Which ICTs facilitating prosumers' knowledge sharing are currently used and expected to be used by prosumers?

III. Research Methodology

Research methods included a critical review of the literature, logical deduction, case studies, a survey questionnaire, and statistical analysis. The research process followed the following steps.

The first step. The critical review of existing studies related to "prosumption," "prosumer," "customer," "consumer," "knowledge," "knowledge sharing," "ICT," "information technology" enabled to examine some ICTs supporting prosumers' knowledge sharing. The review embraces five bibliographic databases: Ebsco, ProQuest, Emerald Management, Scopus and ISI Web of Knowledge.

The second step. Interpretation of the case studies reporting prosumers' knowledge sharing informed the identification of the ICTs that are used by prosumers to share knowledge with enterprises.

The third step. An initial pilot survey questionnaire was designed. The questionnaire was divided into two parts. After a few demographics questions all participants were obliged to answer the question: *Have you ever assessed or commented on products or companies, proposed products improvements to the companies or designed new products?* This question enabled the division of respondents into consumers (not active in this area) and prosumers (active ones). The questionnaire contained questions concerning specified ICTs employed by enterprises to support prosumers' knowledge sharing. The questions were: (1) Which ICTs offered by enterprises have you used to share your knowledge, ideas and proposals about products or enterprises? (2) If you could in a free and unlimited way share your knowledge about products or enterprises, propose ideas of products developments or design new products – please indicate which ICTs would you like to use? The former question was directed only to prosumers. The latter was directed to both – prosumers and consumers. Various kinds of ICTs were listed for those questions. For each listed ICTs the respondents could choose one of five responses, according to a 5-point Likert scale: (1) definitely not (never), (2) probably not, (3) I don't know (no answer), (4) probably yes, (5) definitely yes (many times).

The fourth step. In November 2014 the more in-depth pilot survey was conducted in Poland. The purpose was substantive and methodological scrutiny of the questionnaire. To conduct reliability analysis, Cronbach's coefficient alpha was used. Cronbach's alpha for 16 analyzed items was 0.881. Hinton et al. [53] suggested four different ranges of reliability, i.e. the excellent range (0.90 and above), the high

(0.70-0.90), the high moderate (0.50-0.70) and the low (0.50 and below). Thus, it can be concluded that the scale had high reliability and it could be used in the research process. Moreover, substantive scrutiny of the questionnaire enabled the researchers to perform minor changes in order to improve the quality of the questionnaire.

The fifth step. Applying the CAWI (Computer-Assisted Web Interview) method and employing the Polish platform Ankietka.pl, and the English platform Bristol Online Survey (BOS), hosted at the University of Bristol, the survey questionnaires was uploaded to the websites. Data collection took place between the end of December 2014 and March 2015 in Poland, and between February and April 2016 in the United Kingdom. In Poland, the designed sample size was 2.500 people, comprising people of different age, gender, and ICT skills. In the UK the online survey letter and URL was initially posted to 1000 individuals comprising people of different age, gender, and ICT skills, and presented to a random sample of the target population. Using online tools permits contact with an accessible audience as the survey appears on search engine lists due to metatags and appropriate placing of keywords.

After screening the responses and excluding outliers, there was a final research sample of 783 usable, correct and complete questionnaires from Poland and 171 from the United Kingdom. The data was stored in Microsoft Excel format. The demographic analysis of the research sample is presented in Table 2.

The sixth step. As the process of collecting data was completed the reliability was calculated. The Cronbach's alpha coefficient with all 16 items confirmed a high internal consistency (0.882). Additionally, the values of Cronbach's alpha for each item, with the assumption that a given item was deleted, were calculated. The Cronbach's alpha values for the items were between 0.883 and 0.845. The results showed that the removal of some items would not lead to the improvement of internal consistency among items on the scale. Overall, the original alpha scores with all 16 items show a strong internal consistency and reliability.

The seventh step. In order to answer the research questions the statistical analysis was employed. The descriptive analysis of ICTs was prepared; the mean, median, mode, and distribution of ICTs used and expected to be used by prosumers were calculated.

IV. Research Findings

A. ICTs used and expected to be used by prosumers

In order to answer the research question, detailed analysis concerning ICTs used and expected to be used by prosumers, to share knowledge about products or enterprises, propose ideas of products developments or design new products, was made. The results are presented in Table 3.

"Used ICTs" reflect which ICTs are currently offered by enterprises to prosumers and used by them to share knowledge. It is noticeable that ICTs used by Polish and UK

TABLE II.
DEMOGRAPHIC ANALYSIS OF THE RESEARCH SAMPLE

	Poland		**United Kingdom**	
Demographic profile	**Number of respondents**	**Percentage of respondents**	**Number of respondents**	**Percentage of respondents**
Gender				
female	599	76.5%	98	57.30%
male	184	23.5%	73	42.70%
Age				
Builders generation – over 65 years old	14	1.8%	8	4.68%
Baby-Boomers generation – 51–65 years old	35	4.5%	25	14.62%
X generation – 36–50 years old	108	13.8%	67	39.18%
Y generation – 21–35 years old	369	47.1%	68	39.77%
Z generation – less than 21 years old	257	32.8%	3	1.75%

Source: own elaboration.

based prosumers varies a lot. Polish prosumers mainly use enterprises' websites (the mean value is 3.72), e-mails (the mean value is 3.52), and Internet forums (the mean value is 3.40). UK based prosumers mainly use mobile applications (the mean value is 4.01), Facebook fanpages (the mean value is 3.78), and enterprises' specialized applications (the mean value is 3.59). Interestingly, the Facebook fanpages result for the median and mode values are 4.00 for 'used ICT' for both the UK and Poland prosumers. It means that the majority of prosumers have ticked the answer 'probably yes', so they probably were using these ICTs to share knowledge with enterprises or other prosumers.

It is useful to underline, that differences between the mean values of a number of used ICTs are significant in both countries. The most substantial difference relates to mobile applications – the mean value is 2.56 for Poland, whereas it is 4.01 for UK. Similarly, the mean value of enterprises' specialized applications is 2.40 for Poland, whereas it is 3.59 for the UK. It indicates that UK based prosumers use those ICTs more frequently than Polish ones. The outcomes show that Polish prosumers use only popular information websites more frequently than UK based prosumers. The mean value is 2.82 and the mode value is 4.00 for Poland, whereas the mean value is 2.33 and the mode value is 2.00 for UK. Admittedly, the differences between the mean values are not significant for mobile applications and enterprises' specialized applications. Nonetheless, the mode values analysis shows that the majority of Polish prosumers have chosen the answer 'probably yes', so popular information websites are probably offered to them by enterprises; whereas the majority of UK based prosumers have chosen the answer 'probably not', so these websites are probably offered to them but these are not the preferred prosumer exchange choice.

The overall analysis of used ICTs shows that UK based prosumers use ICTs for knowledge sharing more frequently than Polish ones. In addition, Polish prosumers use mainly standard and well known ICTs, whereas UK based prosumers use the latest kinds of ICTs.

"Expected ICTs" reflect which ICTs are needed by prosumers to share knowledge. The research findings show that UK based prosumers mainly expect to engage using mobile applications. The mean value is 3.74. The median and mode values are 4.00. Furthermore, they expect to engage directly with enterprises' websites and Facebook fanpages (the mean values are 3.53 in both cases). Polish

TABLE III.
ICTS USED AND EXPECTED TO BE USED BY POLISH AND UK PROSUMERS ENGAGED IN KNOWLEDGE SHARING

ICTs	'Used ICTs'						'Expected ICTs'					
	POLAND			UK			POLAND			UK		
	Mean	Median	Mode	Mean	Median	Mode	Mean	Median	Mode	Mean	Median	Mode
E-mails	3.52	4	4	3.34	4	4	3.77	4	4	3.29	4	4
Internet forums	3.40	4	4	3.33	4	4	3.54	4	4	3.18	4	4
Enterprises' websites	3.72	4	4	3.53	4	4	4.00	4	4	3.53	4	4
Popular information websites	2.82	3	4	2.33	2	2	3.44	4	4	2.53	2	2
Industry specialized portals	2.87	3	4	3.26	4	4	3.57	4	4	3.25	4	4
Mobile applications	2.56	2	1	4.01	4	4	3.28	4	4	3.74	4	4
Enterprises' specialized applications	2.40	2	1	3.59	4	4	3.43	4	4	3.25	4	4
File sharing portals	2.54	2	1	2.96	2	2	3.16	3	4	2.87	2	2
Facebook fanpages	3.11	4	4	3.78	4	4	3.38	4	4	3.53	4	4
Crowdsourcing portals	1.61	1	1	2.26	2	2	2.34	2	2	2.33	2	2
Business blogs	1.98	2	1	2.51	2	2	2.85	3	4	2.64	2	2
Private blogs	2.18	2	1	2.24	2	2	2.73	3	2	2.25	2	2
Online auctions	2,99	3	4	2,47	2	2	3,07	3	4	2,40	2	2
Price comparison websites	2,99	3	4	2,92	3	4	3,38	4	4	2,77	2	2
Enterprises' helplines/ helpdesks	2.15	2	1	3.13	4	4	2.52	2	2	3.01	3	4
Online surveys	3.16	4	4	2.99	3	2	3.10	3	4	2.89	2	2

Source: own elaboration.

prosumers mainly expect to engage via enterprises' websites. The mean, median and mode values are 4.00. They also choose e-mails (the mean value is 3.77) and industry specialized portals (the mean values is 3.57).

The overall analysis of ICTs presented in Table 3 shows that in the case of Poland all the mean values of *"used ICTs"* (except for online surveys) are lower than the mean values of "*expected ICTs*". It may show that ICTs which are currently offered to Polish prosumers by enterprises may not meet their expectations. Thus, Polish prosumers would like enterprises to offer them a greater range of ICTs. It could influence their willingness to share their knowledge with enterprises. In the case of UK based prosumers the majority of the reported mean values for "*expected ICTs*" are slightly lower than the mean values for "*used ICTs*" (11 from 16). It may illustrate that ICTs which are currently offered to UK based prosumers by enterprises meet or even slightly exceed their expectations. Four ICTs are expected to be used to a higher degree than are currently used and are referred to as popular information websites, crowdsourcing portals, business blogs and private blogs. Perhaps an indication of a willingness to switch one ICT channel for another one where these ICTs may be seen to be more specific to envelop a critical mass of 'close' engagement and discussion which enhances the prosumers effort. Only one channel that of enterprises' websites reported the same median for expected ICTs and used ICTs. The differences between the mean values are not significant in any case.

In order to compare ICTs used and expected to be used by prosumers of both countries two analyses are presented below. The analyses embrace only these prosumers who ticked (4) or (5) answering the questionnaire questions. It is indicating that they probably or definitely use or expect to use ICTs to share knowledge.

B. ICTs used by prosumers – distribution analysis

The research findings identify the ICTs used by Polish and UK based prosumers to enable knowledge sharing with enterprises as shown in Figure 1.

Figure 1 shows that there are no significant differences between Polish and UK based prosumers related to standard ICTs used by them, such as e-mails, Internet forums, enterprises' websites, and price comparison websites. Nonetheless, there are significant differences concerning other ICTs used by Polish and UK based prosumers.

The biggest differences pertain to mobile applications (indicated by 88.2% of UK based prosumers in relation to 33% of Polish prosumers), enterprises' specialized applications (indicated by 71.1% of UK based prosumers in comparison with 25.5% of Polish prosumers), and enterprises' helplines/ helpdesks (indicated by 56.6% of UK based prosumers in relation to 18.8% of Polish prosumers). The outcomes show also that only in two cases – which are online auctions and popular information websites, Polish prosumers use them in a considerably greater range then UK. For example, online auctions were indicated by 46.6% of Polish prosumers in relation to 25% of UK based prosumers. Similarly, popular information websites were indicated by 39.7% of Polish prosumers in relation to 17.1% of UK based prosumers. Overall the analysis shows that UK based prosumers use and probably engage with UK based enterprises where the choice of ICTs for knowledge sharing is a more extensive range than the Polish enterprise ICT offer.

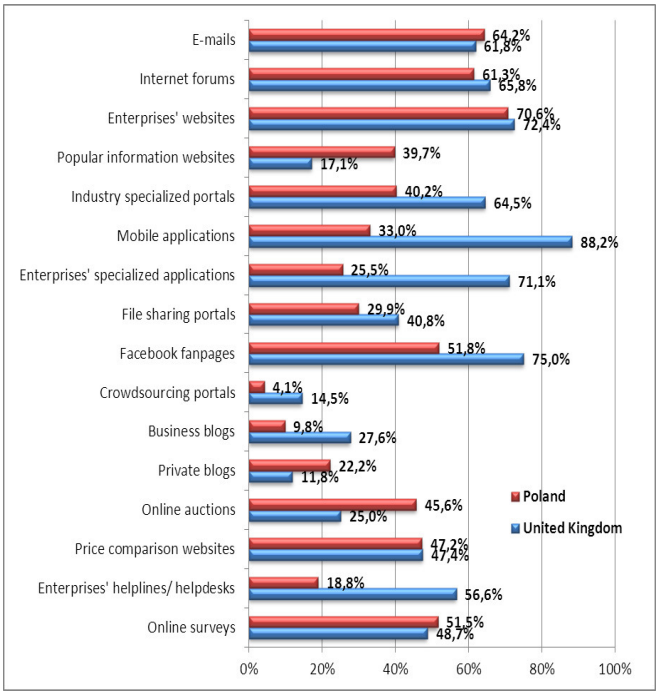

Fig. 1. ICTs used by prosumers for knowledge sharing
Source: own elaboration

C. ICTs expected to be used by prosumers – distribution analysis

The research findings of ICTs expected to be used by Polish and UK based prosumers for their knowledge sharing with enterprises is shown in Figure 2.

Figure 2 shows that in eleven cases (from a total of 16) Polish prosumers more frequently expect ICTs for knowledge sharing than UK based prosumers. The biggest difference relates to popular information websites indicated by 58.2% of Polish prosumers and 24.6% of UK based prosumers. Whereas, UK based prosumers more frequently expect enterprises' helplines/ helpdesks than Polish prosumers. This is indicated by 49.1% of UK based prosumers and 22.2% of Polish prosumers. Similarly, mobile applications are expected by 75.4% of UK based prosumers and 50.1% of Polish prosumers. The considerable difference relates also to online auctions indicated by 41.3% of Polish prosumers and 21.6% of UK based prosumers, as well as to price comparison websites indicated by 55% of Polish prosumers and 38.6% of UK based prosumers.

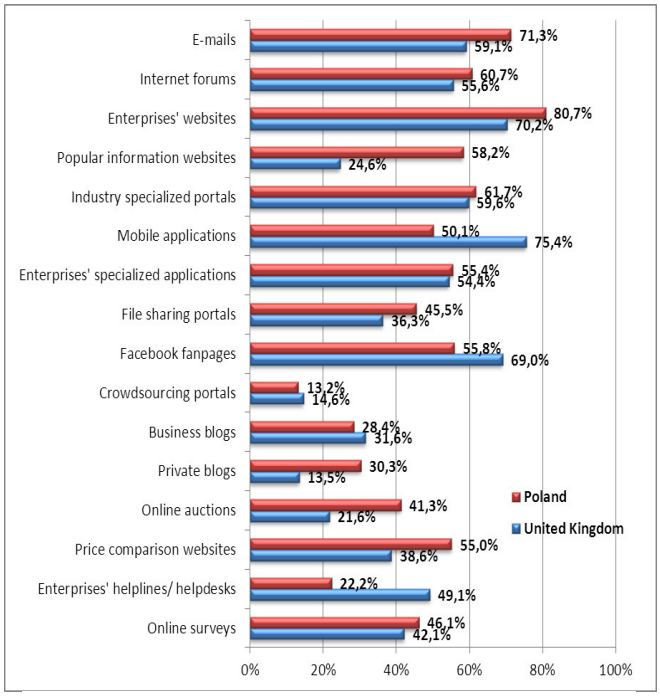

Fig. 2. ICTs expected to be used by prosumers for knowledge sharing
Source: own elaboration

Generally, the prosumers usage and expectations of ICTs for knowledge sharing are only slightly different in the UK. It may show that enterprises offer those ICTs for knowledge sharing that are expected by enterprises. Whereas, the prosumers usage and expectations of ICTs for knowledge sharing are significantly different in Poland. It may show that currently the enterprises do not meet their expectation.

V. Discussion of Findings

The trends identified in the demographics breakdown for the Polish and UK based respondents follow a similar pattern to those outlined in Smith [54]. Consistent with other studies females are more inclined to respond to surveys questioning the use and intended use of ICTs for knowledge sharing with enterprises as our findings show for Poland as well as the UK respondents.

There were similarities in the categorization of participants in the age categories, in the case of the builders generation the responses were 1.8% from Poland and 4.68% from the UK, and would not be unexpected given the training and technical competences of this generation and their culture of communicating more face-to-face rather than through online questionnaires. Also generation Y responses were 41.7% from Poland and 39.77% from the UK and this age category expect to use devices to communicate online and are comfortable with this mode of communication. These outcomes are consistent with research from authors [55], [56] whose goal was to elaborate critical success factors for ICTs adoption by people in Poland. The overall analysis of outcomes also shows differences between these generations. For generation Y it is self-satisfaction with e-products and e-services delivered by enterprises and public administration that is crucial, whilst for builders generation their awareness of ICTs is critical.

The differences reflected in the categorization of participants presents an interesting breakdown, where generation X reported Poland responses as 4.5% whereas 14.62% for the UK responses since this age range in the UK use technology in the workplace or home, are often self-taught in using technology and commit time to engaging in knowledge sharing. Generation X in responses from Poland was 13.8% while UK was 39.18% and this is a marked difference in responses indicating a possible culture of more accepted online communication in the UK for this age range. Finally generation Z indicated Poland at 32.8% whereas UK was only 1.75%, an interesting marked differences in responses and this needs further research to determine if the survey was more visible to this age range in Poland where their use of technology is embedded in their everyday social interactions. However, the research reported [55] indicated that for Polish generation X the most crucial success factors for ICT adoption is the need to make one's own live easier, whilst for Polish generation Z it is the financial situation of the household. It may partially explain the difference relating to generation Z prosumers. Polish prosumers use ICTs to enhance the opportunities of financial benefits or merits.

The educational differences reported between Poland and UK respondents fit well with the categorization of age responses especially as few responses from both countries were from those who are less educated, showing educational attainment may be an indicator for participating in knowledge sharing.

The respondent's place of residence was equally captured for both countries with half of the respondents from both countries living in a city with a population of more than 100.000, and this is interesting as the greater the chances to communicate offline in larger population centers the more likely the respondents are to use time for online communication, and this is a cultural communication shift noted in other recent studies.

The results indicated no significant differences between Polish and UK based prosumers in their use of standard ICTs, such as e-mails, Internet forums, and websites of enterprises. The most substantial difference in the ICTs used and expected by prosumers relates to mobile applications – the mean value is 2.56 for Poland (33%), whereas it is 4.01 for UK (88.2%) and this is consistent with research to support this use of mobile as an enabler of knowledge sharing.

The overall analysis of ICTs used shows that UK based prosumers use ICTs for knowledge sharing more frequently than Polish ones and this may be associated with levels of education achieved as there was almost twice as many UK (52.05%) responses than Polish respondents (27.7%) with higher education attainment.

The findings also show that mobile applications are the *'expected ICTs'* needed by UK based prosumers to share

knowledge, followed by use of Facebook fanpages and enterprises' websites. Whereas, Polish prosumers mainly expect to engage with use of enterprises' websites, followed by e-mails and industry specialized portals. Interestingly, crowdsourcing portals and blogs are those ICTs which, UK based and Polish prosumers, do not expect or cite a preference to use.

The findings also show that Polish prosumers more frequently expect to use ICTs for knowledge sharing than UK based prosumers who have an expectation to use the enterprises' helplines/ helpdesks instead or to complement their online initiated discussions.

A recommendation is that the enterprises need to take consideration of the culture of contemporary communication choices associated with the wide age ranges of prosumers. Finally the enterprises need to embed a comprehensive choice of ICT's particular to their prosumers needs to actively encourage knowledge sharing.

VI. Conclusions

A. Research contribution

This work contributes to existing research on prosumption, especially prosumers' knowledge sharing with the use of ICTs by:

- Indicating the ICTs currently used by prosumers to promote knowledge sharing with enterprises; and
- Indicating the ICTs expected to be used by prosumers to stimulate knowledge sharing with enterprises.

Firstly, this study indicates that mobile application use is expected to a greater degree by UK based prosumers. However, they also expect to use the enterprises' helplines/ helpdesks indicating the diverse expectations and somewhat divergent needs of UK based prosumers and the opportunities this presents to enterprises.

Secondly, the outcomes show that ICTs which are currently offered to UK based prosumers by enterprises meet or even slightly exceed their expectations. However, the prosumers usage and expectations of ICTs for knowledge sharing are significantly different in Poland suggesting that the enterprises do not meet their expectation, and this may result in less engagement in knowledge sharing.

B. Implication for research and practice

This study can be useful for researchers. They may use this methodology and do similar analyses with different sample groups in Poland, United Kingdom, and other countries; additionally many comparisons between different groups and countries can be made. Moreover, the methodology constitutes a very comprehensive basis for identifying ICTs to support knowledge sharing, both, about prosumers, as well as for and from prosumers, but researchers may develop, verify and improve this methodology and its implementation. In addition, researchers may use these research findings and employ them in studies of enterprises. Their goal could be the analysis of ICTs and the possibilities of adjusting them to the expectations of prosumers.

Moreover, for practitioners, the results of this study can be used to improve activities aimed at prosumption adoption, especially helping them understand which ICTs should be used to support prosumers' knowledge sharing.

C. Limitations and future research

As with many other studies, this study has its limitations. The first one was the selection of the survey respondents. Most of them were young people below 35 years old. It is advisable to extend the future research to elderly persons, inter alia prosumers 50+.

The second limitation was the relatively low number of respondents from United Kingdom in comparison with the number of respondents from Poland. Resulting from the low UK responses and timing of the survey the research will continue in the UK to ensure a higher response rate for deeper analysis. Since the initial results reveal interesting findings the research will continue to generate a higher response rate, and for this reason this paper is rather preliminary, and recognizes the analysis are not to be generalized. Therefore the research will be extended with detailed analysis in further works.

As the third limitation, it is possible to specify a methodological limitation. The research sample embraced only prosumers, not enterprises. It is advisable to extend the research to enterprises. All these above issues should be carefully considered and assimilated in the future works.

Acknowledgment

This research has been supported by a grant entitled "Transformation of business and public administration by information technology and information systems" from the University of Economics in Katowice, Poland, 2014-2016.

Abstract— **Providing financial e-services in the all areas involves taking decisions processes. Existing systems, also multi-agent systems, usually include only one of the earlier mentioned areas, and they are closed systems, available only to a small group of users. In addition, agents' knowledge in these systems is characterized by a certain degree of heterogeneity. Since in the decisive process one final decision is required, knowledge shall be automatically integrated. The aim of this paper is presentation of the author's method for knowledge integration in multi-agent decision support system of financial e-services. The first part of paper presents an architecture of the developed system, functioning of selected agents and a structure of agents' knowledge representation. Next, the developed method for integration of knowledge has been described. The last part of paper presents the results of research experiment to evaluate the effectiveness of the system and the developed method.**

I. Introduction

In the era of e-economy one can observe a sudden increase in the level of offered e-services connected with finances, embracing all financial services available to clients via the Internet [1]. The Polish Agency for Enterprise Development [2] has defined financial e-services as all operations connected with finances conducted via electronic media. These types of services are provided within the following areas [2, 3, 4]:

- investment (securities, currencies),
- banking,
- insurance,
- financial consulting,
- managing one's own finances,
- payments.

Providing financial e-services in the mentioned areas involves taking decisions processes. These processes most often need to be executed in a near-real time, and they are always characterized by a certain degree of risk. They are often supported by multi-agent decision support system [5]. Such system may generate decisions constituting hints or tips to investors, or alternatively decisions may be taken automatically (taking into account criteria specified by an investor – e.g. return rate, risk). However, existing systems usually include only one of the earlier mentioned areas, and they are closed systems, available only to a small group of users. It needs to be noticed that in multi-agent decision support system, agents use various sources of data and different methods of supporting decisions. Consequently, variants of decisions presented by individual agents may differ. Therefore, agents' knowledge is characterized by a certain degree of heterogeneity. Since in the decisive process one final decision is required, knowledge shall be automatically integrated. The integration shall be performed in relation to a given area, and also in relation to all areas financial e-services are provided.

Related works on the subject also mention various methods of knowledge integration, for example negotiations [6], or deduction-calculation methods [7]. Negotiations enable effective integration of knowledge by reaching a compromise, however they require exchanging a large number of communications between agents, which results in decreased efficiency of the multi-agent system. The deduction-calculation methods (e.g. ones based on the theory of games, classical mechanics, or methods of choice) enable one to obtain a great computational or calculation capacity of a system, however they do not guarantee a proper result of knowledge integration [8]. Thus, applying negotiation or deduction and calculation methods cannot guarantee an adequate level of satisfaction from taken decisions. In order to eliminate the presented problems, consensus methods may be applied which enable integration of knowledge in a real time and guarantee reaching a good compromise at a lower level of risk, which may consequently lead to selecting decisions producing profits satisfactory for a decision maker [8, 9]. In a consensus each party/side is taken into account, each party "loses" the least, and each one contributes to the consensus, and all parties accept the consensus, so the consensus constitutes a representation of all agents.

The aim of this paper is presentation of the author's method for knowledge integration in multi-agent decision support system for financial e-services. The first part of paper presents an architecture of the developed system, functioning of selected agents and a structure of agents' knowledge representation. Next, the developed method for integration of knowledge has been described. The last part of paper presents the results of research experiment to evaluate the effectiveness of the system and the developed method.

II. ARCHITECTURE OF SYSTEM AND DESCRIPTION OF SELECTED AGENTS

Multi-agent decision support system for financial e-services consist of following elements:

1. Collectives of agents. The purpose of the members of the collective is the analysis of information from the market, generating a decision and taking an action. Each agent in the collective running on the basis of a different method of decision support. Each collective makes decisions from a different area (for example, Collective 1 makes the banking decisions, Collective 2 makes the investment decisions, Collective 3 makes the insurance decisions). Collective members knowledge state is represented by uniform structure (described in section V).
2. Knowledge integration module, which integrate the knowledge of individual members of the collectives (by using a consensus method - integration is performed independently for each collective). One, final decision is determined (for each collective determined a separate decision). The final decision is then presented to users.
3. Users - financial investors or software agents making decisions on behalf of the investor.

In our prototype of system, agents running in order to determine decisions in the area of investment and banking use methods of technical analysis, fundamental analysis, artificial intelligence (such as genetic algorithms, artificial neural networks, expert systems), two collectives : financial investments and banking. The next part of paper describes functioning of randomly selected agents: *MixedTechnical*, *BollingerPlus* and *Fundamental*.

A. . The MixedTechnical agent

MixedTechnical agent has been developed on the Java Agent Development Framework (JADE), which is a platform to facilitate the creation of agents and multi-agent systems in the Java programming language [10]. Agent generates buy/sell decisions on the basis of commonly used technical analysis indicators (Lento, 2008): Average Directional Index (ADX), Relative Strenght Index (RSI), Rate of Change (ROC), Commodity Channel Index (CCI), Moving Average of Oscillator (OsMA), Moving Average Convergence Divergence (MACD), Stop and Reverse (SAR), Williams %R, Moving Average (MA). Agent generates decisions depending on what the decision is suggested by a larger number of indicators used. Agent's knowledge is represented by using three-values logic (value „1" denotes „buy" decision, value „-1" denotes „sell", decision, value „0" denotes „do nothing").

B. . The BollingerPlus agent

The BollingerPlus agent is created on the basis of the Bollinger Bands indicator [11]. These bands are volatility constraints placed above and below a moving average. Volatility is expressed by the standard deviation, which changes as volatility increases and decreases.

The bands automatically widen when volatility increases and narrow when volatility decreases. The buy decision's probability level is calculated when the price is close to the upper Bollinger Band or breaks above it, and the sell decision is calculated when the price is close to the lower Bollinger Band or falls below it.

C. The Fundamental agent

Agent *Fundamental* makes decisions using fundamental analysis. For this purpose he performs the analysis of text documents [1] containing the experts' opinions on the economic situation or the organization's situation. The main purpose of the analysis is to determine the general sentiment of opinion, i.e. to determine whether the opinion is positive (suggesting a "buy" decision) or negative (suggesting a "sell" decision) or neutral (suggesting the "leave unchanged" decision). The analysis is done by the agent built by using The Learning Intelligent Distribution Agent (LIDA) architecture [12]. The advantage of this architecture is its emergent-symbolic character, making it possible to process both structured (numerical and symbolic) and unstructured (stored in natural language) information. This agent consist of following modules: sensory memory, perceptual memory, workspace, episodic memory, declarative memory, attentional codelets, global workspace, action selection, sensory-motor memory. The functioning of the agent is performed in the frame a cognitive cycle.

Considering the process of analysis of expert opinions, the environment of agent functioning is a set of text documents containing these opinions (opinions are placed e.g. on financial portals). Agent looking for opinions, and then stores them in a repository (system's database).

Text analysis is performed in the following way:

1. A semantic network containing terms and connections between them is created in the perceptual memory on the basis of a learning set. The perceptual memory stores also synonyms and different variations of words (thesaurus). In the perceptual memory of LIDA agents terms are represented by means of nodes, whereas connections are represented by means of links.
2. Individual text documents are added one by one into the sensory memory.
3. Opinions are analyzed by codelets, i.e. programs which search through texts according to certain criteria specified by means of configuration parameters.
4. Results of analysis, in the semantic network form, are transferred to the workspace (a current situational model is created).
5. In the next step, the situational model is passed to the global workspace and from the procedural memory the following patterns of action are automatically selected: „saving results of opinion analysis into a data base and „loading next opinion into the sensory memory".

[1] Text documents' analysis, performed by LIDA agent, has been characterized in work [13] in details.

III. METHOD FOR KNOWLEDGE REPRESENTATION

Each agent running within the given collective presents its decision in the form of a specific structure of knowledge. In the considered system a structure developed by [10] has been used. The structure is definied as follows:

Definition 1

A structure for representation a decision D of finite set of financial assets[2] $E=\{e_1,e_2,\ldots,e_N\}$ is called a sequence:

$D=\left\langle\{EW^+\},\{EW^\pm\},\{EW^-\},Z,SP,DT\right\rangle$ where:

1) $EW^+=\left\langle e_o,pe_o\right\rangle,\left\langle e_q,pe_q\right\rangle,\ldots,\left\langle e_p,pe_p\right\rangle$.

Couple $\left\langle e_x,pe_x\right\rangle$, where: $e_x\in E$ and $pe_x\in[0,1]$ denote a financial asset and this asset's participation in set EW^+.

Financial asset $e_x\in\left\langle e_x,pe_x\right\rangle$ is denoted by e_x^+ when $\left\langle e_x,pe_x\right\rangle\in EW^+$. The set EW^+ is called a positive set; in other words, it is a set of financial assets with respect to which an agent has the knowledge or information that they should be buy.

2) $EW^\pm=\left\langle e_r,pe_r\right\rangle,\left\langle e_s,pe_s\right\rangle,\ldots,\left\langle e_t,pe_t\right\rangle$.

Couple $\left\langle e_x,pe_x\right\rangle$, where: $e_x\in E$ and $pe_x\in[0,1]$ denote a financial asset and this asset's participation in set $EW^\pm$.

Financial asset $e_x\in\left\langle e_x,pe_x\right\rangle$ is denoted by $e_x^\pm$ when $\left\langle e_x,pe_x\right\rangle\in EW^\pm$. The set $EW^\pm$ is called a neutral set, in other words, it is a set of financial assets, with respect to which an agent has no knowledge or information whether to buy or sell them. If these assets are held by an investor, they should not be sold, or if they are not in the possession of the investor, they should not be bought.

3) $EW^-=\left\langle e_u,pe_u\right\rangle,\left\langle e_v,pe_v\right\rangle,\ldots,\left\langle e_w,pe_w\right\rangle$.

Couple $\left\langle e_x,pe_x\right\rangle$, w here: $e_x\in E$ and $pe_x\in[0,1]$, denote a financial asset and this asset's participation in set EW^-.

Financial asset $e_x\in\left\langle e_x,pe_x\right\rangle$ is denoted by e_x^- when $\left\langle e_x,pe_x\right\rangle\in EW^-$. The set EW^- is called a negative set; in other words it is a set of financial assets with respect to which an agent has the knowledge or information that they should be sell.

4) $Z\in[0,1]$ - decision rate of return forecast.

5) $SP\in[0,1]$ - degree of certainty of rate Z. It can be calculated on the basis of the level of risk related to the decision.

6) DT - date of decision.

IV. METHOD FOR KNOWLEDGE INTEGRATION

Fig 1 presents schema of the knowledge integration process.

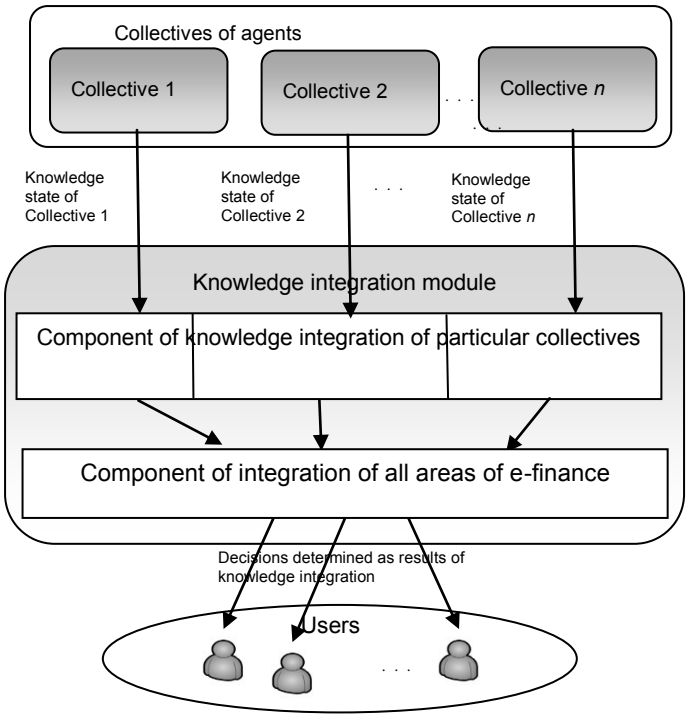

Fig. 1. Schema of the knowledge integration process

In order to knowledge integration, a consensus algorithm is used, formally defined as follows:

Input: Profile (set) $A=\{A^{(1)}, A^{(2)}, \ldots. A^{(M)}\}$consist of M structures of knowledge.
Output: Consensus
$CON=\left\langle CON_+, CON_\pm, CON_-, CON_Z, CON_{SP}, CON_{DT}\right\rangle$ for profile A.
START
1: $CON_+, CON_\pm, CON_- = \varnothing$, $CON_Z, CON_{SP}, CON_{DT} = 0$.
2: $CON_Z = \frac{1}{M}\sum_{i=1}^{M} Z^i$.
3: $CON_{SP} = \frac{1}{M}\sum_{i=1}^{M} SP^i$.
4: $CON_{DT} = \frac{1}{M}\sum_{i=1}^{M} DT^i$
let $d := \sum_{i=1}^{M}\left[\Psi\left(CON, A^{(i)}\right)\right]^2$ **and** $j:=1$.
5: If $e_j \in CON_+$ **then** $CON':=\left\langle CON_+\setminus\{e_j\}, CON_\pm, CON_-, CON_Z, CON_{SP}, CON_{DT}\right\rangle$
Go to:8,
If $e_j \notin CON_+$ **then** go to: 6.
6: If $t_+(j) = 0$ **then** go to: 9.

[2] assets including cash assets as a contractual right to receive cash assets , the right to exchange financial instruments with another entity under favorable conditions, and equity instruments issued by other entities [14].

7: If $e_j \cap CON \neq \emptyset$ **and** $e_j \in CON_{\pm}$ **or** $e_j \in CON_{\pm}$ **then**

$CON' = \langle CON_+ \cup \{e_j\}, CON_{\pm} \setminus \{e_j\}, CON_- \setminus \{e_j\}, CON_Z, CON_{SP}, CON_{DT} \rangle$

If $e_j \cap CON = \emptyset$ **then**

$CON' = \langle CON_+ \cup \{e_j\}, CON_{\pm}, CON_-, CON_Z, CON_{SP}, CON_{DT} \rangle$

8: If $\sum_{i=1}^{M} \left[\Psi(CON', A^{(i)})\right]^2 < d$ **then** $d := \sum_{i=1}^{M} \left[\Psi(CON', A^{(i)})\right]^2$ **and** $CON := CON'$.

9: If $e_j \in CON_{\pm}$ **then** $CON' := \langle CON_+, CON_{\pm} \setminus \{e_j\}, CON_-, CON_Z, CON_{SP}, CON_{DT} \rangle$. Go to: 12.

If $e_j \notin CON_{\pm}$ **then** go to: 10.

10: If $t_{\pm}(j) = 0$ **then** go to: 13.

11: If $e_j \cap CON \neq \emptyset$ **and** $e_j \in CON_+$ **or** $e_j \in CON_-$ **then**

$CON' = \langle CON_+ \setminus \{e_j\}, CON_{\pm} \cup \{e_j\}, CON_- \setminus \{e_j\}, CON_Z, CON_{SP}, CON_{DT} \rangle$

If $e_j \cap CON = \emptyset$ **then**

$\langle CON_+, CON_{\pm} \cup \{e_j\}, CON_-, CON_Z, CON_{SP}, CON_{DT} \rangle$.

12: If $\sum_{i=1}^{M} \left[\Psi(CON', A^{(i)})\right]^2 < d$ **then**

$d := \sum_{i=1}^{M} \left[\Psi(CON', A^{(i)})\right]^2$ **and** $CON := CON'$, go to: 13.

else go to: 16.

13: If $e_j \in CON_-$ **then**

$CON' = \langle CON_+, CON_{\pm}, CON_- \setminus \{e_j\}, CON_Z, CON_{SP}, CON_{DT} \rangle$ **and** go to: 16.

14: If $t_-(j) = 0$ **then** go to: 17.

15: If $e_j \cap CON \neq \emptyset$ **and** $e_j \in CON_+$ **or** $e_j \in CON_{\pm}$ **then**

$CON' = \langle CON_+ \setminus \{e_j\}, CON_{\pm} \setminus \{e_j\}, CON_- \cup \{e_j\}, CON_Z, CON_{SP}, CON_{DT} \rangle$

If $e_j \cap CON = \emptyset$ **then**

$CON' = \langle CON_+, CON_{\pm}, CON_- \cup \{e_j\}, CON_Z, CON_{SP}, CON_{DT} \rangle$.

16: If $\sum_{i=1}^{M} \left[\Psi(CON', A^{(i)})\right]^2 < d$ **then**

$d := \sum_{i=1}^{M} \left[\Psi(CON', A^{(i)})\right]^2$ **and** $CON := CON'$.

17: If $j<N$ **then** $j := j+1$. Go to: 2

else: STOP.

STOP.

V. RESEARCH EXPERIMENT

The aim of the experiment was to examine the effectiveness of the system and developed method for knowledge integration. The collective knowledge of agents on the area of investment and knowledge integration module (named Agent Supervisor), was evaluated. Data from randomly selected quotations has been used (Sygnity company). Test was conducted, which the following assumptions:

1. Quotations from randomly selected periods was used:
   - 01-02-2016 9.30 to 06-02-2016 17.00,
   - 08-02-2016 9.30 to 13-02-2016 17.00,
   - 15-02-2016 9.30 to 20-02-2016 17.00.
2. Following agents was evaluated:
   - MixedTechnical,
   - BollingerPlus,
   - Fundamental,
   - Supervisor.
3. It was assumed that the initial capital, which has an investor is 1000 PLN, and the rate of return on investment assumed difference between that amount and the amount the investor will have the last sell transactions in a given period. The rate of return is expressed in nominal units (PLN).
4. The transaction cost was not considered.
5. It was assumed that in each transaction the investor engages 100% of the capital held.
6. Analysis of the quality of collective knowledge was carried out using the following measurement (ratios):
   - rate of return (ratio x_1),
   - the number of profitable transactions (ratio x_2),
   - the number of unprofitable transactions (ratio x_3),
   - the average rate of return per transaction (r. x_4),
   - Sharpe ratio (ratio x_5),
   - the average coefficient of variation (ratio x_6).

   In order to comparison quality of collective knowledge, the following function was used[15]:

$$y = (a_1 x_1 + a_2 x_2 + a_3 (1 - x_3) + a_4 x_4 + a_5 x_5 + a_6 (1 - x_6)).$$

   where x_i denote the normalized values of ratios mentioned in item 6 from x_1 to x_6. It was adopted in the test that coefficients a_1 to a_6=1/6.
7. The results obtained by the tested agents were compared with the results of the Buy-and-Hold (B&H) benchmark [3]– table 1.

Summing up the results of the evaluation of knowledge of a group of agents and the *Supervisor* agent one may notice that in the considered periods their decisions generated both profits as well as losses. While evaluating the efficiency of the system one needs to take into account not only the return rate but also other indicators, including the level of risk connected with an investment, which the evaluation function employed in the article enables. In the first period, *BollingerPlus* proved to be the best agent, and the remaining agents got a higher note than the *B & H* benchmark note. In the second period, the *Supervisor* agent received a note higher that the remaining agents and the *B & H* benchmark. Taking into account the third period, one may notice that the ranking of notes looks similar to the second period.

Taking into consideration all the periods one may conclude that most often (2 of 3 periods) the highest note was given to the *Supervisor* agent, even though the return rate achieved by the agent had not always been the highest one. The note however results from a low level of risk connected with investing on the basis of decisions generated as a result of knowledge integration. However, in all periods, the *MixedTechnical* agent received low notes as due to a relatively high level of risk it generated little return rates. The *Fundamental* agent received average level notes in all periods which may be connected with the fact that the agent generated a very small number of decisions.

[3] benchmark is also implemented as agent's algorithm.

TABLE I.
RESULTS OF AGENTS PERFORMANCE ANALYSIS

Agent's name	Period	Rate of return	Number of transaction		Rate of return per transaction	Sharpe ratio	Average coeffecient of variation	Evaluation function
			profitable	unprofitable				
MixedTechnical	1	3,25	5	3	0,41	0,46	23,72	0,25
	2	-83,68	4	7	-7,61	-1,03	14,18	0,18
	3	34,17	4	1	6,83	0,57	6,44	0,50
BollingerPlus	1	10,10	5	2	1,44	0,64	18,29	0,51
	2	-15,14	3	5	-1,89	-0,43	7,83	0,34
	3	25,48	5	2	3,64	0,29	11,87	0,42
Fundamental	1	2,43	4	2	0,41	0,78	8,21	0,26

. On the basis of the research experiment one can draw the conclusion that integration of agents' knowledge enables selecting decisions which produce benefits satisfactory to a user. Integration of knowledge performed by the Supervisor agent using consensus determining algorithm is performed in a near to real time. The agent selects a final decision on the basis of suggestions generated by all remaining agents, which consequently leads to a decreased level of risk.

VI. CONCLUSION

Functioning of a multi-agent decision support system for financial e-services requires continuous, automatic integration of agents' knowledge. The process enables the elimination of decisions generated by group members whose knowledge status has been evaluated as being poor, which means that decisions taken by such agents may most of the time bring unsatisfactory results. Thanks to that, their influence on the final decision established with the use of knowledge integration module and presented to a user is eliminated. Additionally developed algorithm enables taking into account summed-up knowledge of a group as it includes knowledge of all members of a group. The issues discussed in the paper imply further research concerning, for example, implementation of agents performing behavioural analysis and developing a multistep method of integration which would include improving knowledge of agents.

***Abstract*—This paper aims to contribute to the better understanding, and in consequence, better development and implementation of crowdfunding projects for filmmaking. This study covers two areas of analysis: project-level research and founders-level (creators-level) research. In the first area, the article presents an analysis of documentary film projects based on descriptive statistics and the clustering of the film projects. In the second area, the paper sheds light on the Polish filmmakers' attitude to crowdfunding, and this analysis was based on a survey. This exploratory study led to the following conclusions: 1. The descriptive statistics indicate that the 'average documentary film' on the Polish market reaches a higher level of funding compared to non-documentary projects, and higher numbers of supporters. 2. The film projects on the Polish crowdfunding platforms can be segmented into six clusters. 3. The survey conducted among Polish filmmakers indicates that the experts strongly differed in their views about crowdfunding in general, and specifically, in the crowdfunding for documentary films. Such diversity of opinions and attitudes may be linked to the novelty of crowdfunding and therefore, the experts' difficulty of assessing the present and future role of crowdfunding for filmmaking. 4. This study shows that over 85% of experts agree with the sponsor's involvement with film production. Such a high level of expert agreement is important as nowadays 'being a prosumer' is one of the major trends of consumer behavior.**

I. Introduction

THE magnitude of crowdfunding has been steadily growing: in 2014 the global total volume of funding was about 16.2 billion US$ compared to 0.8 billion US$ in 2010 (Belleflamme, Omrani, & Peitz, 2015), the European Commission recorded the growth of crowdfunding platforms from 445 million euro in 2011 to 1 billion euro in 2013 (Borello, De Crescenzo, & Pichler, 2015), and World Bank predicts that crowdfunding will reach 93 billion US$ by 2025 (Kshetri, 2015). Although, crowdfunding covers very different kinds of projects, the cultural industries, such as film, music and video games have been taking a large share of the crowdfunding market (Boeuf, Darveau, Legoux, 2014). Major crowdfunding platforms gather thousands of artistic projects, e.g. on 1 May 2016, on Kickstarter there were over 294 thousand projects in all artistic categories, nearly 55 thousand projects in the category of video/film, and within this category over 600 'live' projects (kickstarter.com, 01.05.206).

In Poland crowdfunding is still in the very early stages of introduction to possible adopters, both to funders (called also sponsors or backers) and founders (project creators). So far, Polish crowdfunding platforms have attracted a relatively small group of users, for example, on 2 May, 2016 the crowdfunding platform polakpotrafi.pl reported 2263 projects in all categories (polakpotrafi.pl, 02.05.2016). However, we presume that the near future would bring further expansion of crowdfunding on the Polish market due to various factors, for instance, diminishing barriers for Internet payment and growing user knowledge about crowdfunding.

The academic research of crowdfunding is still in the nascent stage, especially if we consider the research conducted in a part of a particular domain, e.g. the crowdfunding for disruptive innovations, or the crowdfunding for art and cultural events. This article aims to fill the gap in the understanding of crowdfunding in the domain of film production. In this study we particularly focus on crowdfunding projects linked to documentary films.

The paper is structured as follows: in the next section we discuss the research problem and the scope of the conducted analyses, and then we present the context of research. The third section focuses on the analysis of the documentary films on selected crowdfunding platforms (Kickstarter, polakpotrafi.pl, and wispieramkulture.pl). This overview of the film projects is followed by a presentation of the results of a survey conducted among Polish filmmakers. Finally, the last part of the article highlights the conclusions, and future research.

I. THE RESEARCH PROBLEM

A. The scope of research

Our research aims to contribute to better understanding the process of film crowdfunding, with particular focus on documentary films and the Polish filmmaking industry. In this article, we present a study conducted in the following two areas:

A. the overview of the film and documentary film projects on selected crowdfunding platforms;
B. the Polish filmmakers' attitudes to crowdfunding;

B. Overview of film and documentary film projects on the selected crowdfunding platform

The idea of crowdfunding began from the crowdfunding of small-scale music and film projects (Hörisch,2015). Nowadays, it seems that crowdfunding covers almost all kinds of human activities (from art, technology, medicine, scientific discovery to film production), and crowdfunding projects significantly vary in time duration (from 'one-time' events to projects enabling the expansion of business ventures). In literature, crowdfunding is classified into four different models (see - Ryu & Kim, 2016; Lam, & Law, 2016), although in practice crowdfunding can be based on their variations (see – Vasileiadou, Huijben, & Raven, 2015). The main crowdfunding models are: donation-based crowdfunding, lending-based crowdfunding, reward-based crowdfunding, and equity-based crowdfunding.

The majority of the film projects are based on a reward-based crowdfunding in which the funders receive different kinds of rewards as compensation for their support. In some situations, funders make a very small donation (for example, 5 zł) without even expecting a reward at all (donation-based crowdfunding). In most projects, the creator of the project (the founder) offers the film (DVD or online viewing) as a reward, therefore film crowdfunding can be perceived as pre-ordering the product by the potential audience. The creator often encourages the crowdfunders to participate and co-create the final product (e.g. playing parts in the film), and therefore the crowdfunder acts as a prosumer.

Apart from financing the project, crowdfunding can play other roles, for example being a way of promotion or a tool of validating the potential market for ideas (Hörisch, 2015). These two roles can be noticed also in film projects, as crowdfunding can bring public attention to a particular movie production (promotion role), and – if the project fails in funding – it may be a signal that the idea was not properly developed (the validation).

The knowledge of the project creator in how to develop the project, (for example, what level of financing is feasible, how to reward the backers), is crucial for enhancing the project's probability to meet the financial goal (the requested financial support). On many reward-based crowdfunding platforms (e.g. Kickstarter.com or polakpotrafi.pl) if the project does not meet the threshold of funding, the money returns to the backers, therefore reaching the financial threshold for each project determines the project's actual execution. Any crowdfounder must consider that many factors may constitute the success or failure of crowdfunded projects, for example: the entrepreneur's social capital (see – Zheng et al., 2014), the entrepreneur's network of close contacts (Mendes-Da-Silva et. al, 2016), the way in which the project demonstrates its legitimacy (Frydrych et al., 2014), or the level of required funding, the time of project duration, and its contribution frequency from sponsors (Cordova, Dolci, & Gianfrate, 2015).

This study focuses on the analysis of crowdfunding for documentary film projects on the Polish market. To what extent does the funding of these film projects vary? Do most projects aim for very high or low funding? What is the 'average' level of funding, or number of sponsors?

To analyze crowdfunding for filmmaking we gathered the data from two selected Polish reward-based crowdfunding platforms – polakpotrafi.pl and wspieramkulutre.pl. The analyses were based on the descriptive statistics and K-Means analysis aiming to identify the clusters of film projects. To better understand the features of Polish crowdfunding compared to global platforms, we also conducted an analysis of selected documentary film projects on Kickstarter.

C. The filmmakers' attitudes to crowdfunding

The future of crowdfunding for films is, and will be, affected by the filmmakers' knowledge and attitude to the crowdfunding phenomenon. How do the professional filmmakers perceive the role of crowdfunding? What kind of barriers do they perceive for film crowdfunding? Do they agree with sponsor participation and film co-creation as a possible reward? In what way do experts assess the probability of success for documentary films? We looked for the answers by conducting a survey among the professionals. In April 2016, 37 respondents - Polish film producers and students of film production – took part in the survey, and filled in a questionnaire. As film production students are more likely to seek new funding sources compared to well-known producers, the opinion of this group is especially interesting and can be an indicator of crowdfunding development in the near future.

II. THE CONTEXT OF RESEARCH

In this section of the article, we would like to point to the following aspects of crowdfunding: the type of crowdfunding platforms, the sponsors, and developing the reward options.

A. Type of crowdfunding platforms

To date, equity-based crowdfunding (in which the founders agree on sharing the profit) is much less popular and takes a much smaller part of the crowdfunding market than reward-based crowdfunding, however, its popularity may grow in future (Son Turan, 2015). With reference to filmmaking, we would like to point to the following two examples:

- British film project - The Age of Stupid - in which the profits were pledged to crowdfunders (Belleflamme, Lambert, & Schwienbacher, 2014).
- CinemaShares.com – the crowdfunding platform which allows movie fans to buy shares of film projects (see - https://cinemashares.com, 02.05.2016).

B. The sponsors

Drivers and deterrents of crowdfunding differ from the perspective of the creator, funder (sponsor) and crowdfunding platforms (see – Kuti, & Madarász, 2014/3). So far, there is little knowledge about the specific sponsors' needs, behavior, motivation or characteristics in crowdfunding for filmmaking.

The study of Ryu, & Kim (2016) is helpful in the understanding of the film crowdfunders' characteristics, although the study covers different kinds of projects (not only films). The authors identified four types of crowdfunding sponsors, which are named descriptively as 'angelic backers', 'reward hunters', 'avid fans' and 'tasteful hermits'. These identified clusters of sponsors differ not only in their characteristics (for example, the value of philanthropic and reward motivation), but also they tend to pledge money at different stages of the project life-cycle: from project launching to project closing. Ryu, & Kim (2016) also pointed out that the project genre determines what kind of sponsor group is attracted, and the authors stated that "[a]ngelic backers tended to support films, plays, and charity projects, while reward hunters were more focused on art and design and game projects" (p. 49). The study of Galuszka, & Bystrov (2014) which refers to the music industry, showed that the sponsor's motivation is not only connected with financial reward, but also to the willingness to support their favorite artists or the fandom.

Another important aspect is the viewer's satisfaction. In this field, the research of Xu et al. (2016) can bring an interesting insight, although again, the study embraces different types of projects (not necessarily films). Xu et al. (2016) examined the sponsor's satisfaction, and the ascendant factors from an asymmetrical perspective and configurational models. The authors pointed to the role of project implementation perspective, project novelty, sponsor participation, entrepreneur activeness and sponsor demographics as the important variables influencing sponsor satisfaction.

C. Developing the rewards options

Thürridl, & Kamleitner (2016) examined different types of rewards in the crowdfunding (in general, not only film), indicating their important features, such as purpose/reward type, tangibility, scarcity, geographical location, monetary value/reward tier, recognition, level of collaboration, and the core future. Their study showed that the most popular strategies of rewarding sponsors in the film category are 'Add-On Highly Appreciated' and 'Top it Up'. In 'Top it Up' the rewards accumulate when a sponsor selects more valuable options, for example: for selecting the first tier the sponsor receives a 'thank you e-mail', but the second tier includes the reward from the first option, and additional benefits e.g. DVD film copy. 'Add-On Highly Appreciated' strategy underlines the value of the recognition of sponsor contribution to the project, for example, the filmmaker puts the name of the sponsor in the film credits.

In many cases of film crowdfunding, the crowdfunders pre-order the final product as a reward, which means that they take the risk that the film (final product) would not meet their expectations or the film would not be produced at all. Although fraud is possible in crowdfunding, the study conducted by Mollick (2014) indicates that very few projects failed to deliver the promised products, although delivery was often late. Some crowdfunding platforms, e.g. the crowdfunding platform Seed&Spark, offer the possibility to see the accepted movies on its website (https://www.seedandspark.com/, 03.05.2016), which may be a factor in enhancing the sponsor's trust to the founder.

III. THE OVERVIEW OF THE DOCUMENTARY FILMS ON CROWDFUNDING PLATFORMS

A. Global crowdfunding platform – kickstarter.com

Kickstarter is one of the major reward-based crowdfunding platforms, at the time of writing, for creators from the US, the UK, Canada, Australia, New Zealand, the Netherlands, Denmark, Ireland, Norway, Sweden, Germany, France, Spain, Italy, Austria, Belgium, Switzerland, and Luxembourg. In order to overview the characteristics of the documentary film projects on kickstarter.com, we looked into data from two samples:

a. Sample 1 - On 13 April 2016 the search engine on kickstarter.com showed 14 920 projects classified as "documentary projects in film/video on Earth'. For further analysis, we selected 100 projects using, as the criterion, 'the end day' - the first listed project will end in 2 hours, the last project will end in 19 days. In the next step, from this list we selected 19 projects which had reached the level of successful funding at the moment of sampling (note – 1. as some of these 19 successful projects still had a few more

days for running, the actual funding for these projects may be higher than we captured in our sample; 2. other projects from our sample list may well reach the level of funding in the next few days, but as they were not successful at the moment of sampling we did not include them for further analysis)

b. Sample 2 - On 1 May, 2016, the search engine of the Kickstarter.com platform showed 15 014 projects categorized as 'documentary projects in film/video on Earth'. In the next step, we entered in search the criterion of 'the most funded', and we sampled the 10 top projects.

The most funded documentary film project (sample 2) gathered over 1 mil US$ with support from over 8 500 backers (see Tab. I). The average funding for the top ten projects was over 476 thousand dollars with support from over 7 thousand backers. The top ten projects raised over 4.7 mil US$ altogether.

The 19 successful documentary projects analyzed from sample 1 raised US$ 240 994 altogether, with the average project receiving over 16 thousand dollars due to attracting over 160 backers. The overfunding for the 19 projects was 52% on average, meaning that the average project received more than one and a half times the funding that the founders applied for. Moreover, the 'average project' from the 'top 10' was overfunded by more than two times.

B. Polish crowdfunding platforms – polakpotrafi.pl and wspieramkulture.pl

For the analysis of Polish crowdfunding, we looked into the projects listed on two platforms: polakpotrafi.pl and wspieramkulture.pl. We gathered the data about the successful projects categorized as a film (on wspieramkulture.pl) or video/film (on polakpotrafi.pl), which were listed on these platforms in April 2016. It led to the analysis of 29 successful projects on wspieramkulture.pl and 108 successful projects on polakpotrafi.pl. In the next step of analysis, we classified 41 (38%) projects of the 108 projects as documentary films on polakpotrafi.pl, and 6 projects (21%) of the 29 projects as documentary films on wspieramkulture.pl. As the documentary films could have different features, we adopted a 'soft' approach for classification - taking as the main criterion to what extent the film is based on facts.
