These activities sometimes require additional effort that may depend on the data. Hence, they may not always be fully automated. For example, in the discussed case study of forwarding contracts, we ingest three data sources: *css_main*, *css_routes*, and *fuel_prices* tables (cf. Section IV-A). However, to integrate *css_routes*, we have to aggregate the data first. We execute this with the aggregating query: *SELECT AVG(.), MIN(.), MAX(.), SUM(.), COUNT(.)... GROUP BY id_contract* for each interesting variable in the table. Considering that the attributes obtained in this way are not intended for financial settlements but to feed the machine learning procedure, a vital extension of our approach would be to rely on approximated results of SQL instead of exact ones [31]. Approximate query engines can generate summaries of Big Data sets much faster with only a slight loss in precision, which may be negligible in model generalization [32], [33].

Instead of using all the SQL results for fitting the predictive model, the outcomes of the aggregation queries are transformed with PCA, and several first components are integrated into the main data. The schematic view of this process, related to the discussed case study, you may find on the left part of Figure 1. In general, whenever the encoding of categorical features into numerics significantly increases data sparsity, the derived variables are encoded with PCA, and a few first

components are kept. At the same time, the rest may be omitted. To provide an example, in Figure 2, we present the variance explained by the first 10 principal components (PC) of one-hot encoded `first_load_country` attribute.

The central part of the pipeline is selecting the training set, i.e., features and instances, to achieve the best performance and robustness of the models. In the developed approach, we iteratively draw a subset of attributes and instances as a ratio of the original data controlled by two thresholds: ω_r and ω_c (cf. Algorithm 1). In the next step, we train the selected predictive model (e.g., XGBoost or LightGBM) [34]. Since we fit the predictive model to significantly smaller data chunks, we naturally minimize the time of this process. The selection of training subsets is random and independent from each other. Hence, this process may also be easily parallelized, e.g., by drawing several subset candidates simultaneously and training the models in parallel. We also see a potential to extend our framework with the heuristic search over the subsets of attributes and features to reach the optimal quality (i.e., minimize reported error) faster [35]–[37], and to introduce more advanced feature selection techniques [26]. In this context, granular feature selection techniques could be a perfect fit [38], including r-C-reducts, bi-reducts [39], or reviving the concept of dynamic reducts [40]. Besides more advanced feature selection algorithms, instance selection has space for improvement as well. Ordering the records by date and considering only the newest instances while drawing the subsets for training data is one of many possible ideas. Combining those in an ensemble could yield interesting results.

Data:

- *dataTrain*, *dataTest* - training and test data
- θ - acceptable RMSE threshold
- ϑ - stability threshold for RMSE
- ρ - expected resilience level
- ω_r and ω_c - instance and feature selection thresholds
- *score()*- quality measure, e.g., RMSE
- *N* - maximal number of unsuccessful attempts

Result: *ensemble of models*

```

/* Initialization */
ensemble ← ∅; k ← 0
validationSet ← dataTrain.sample
dataTrain ← dataTrain \ validationSet
while |ensemble| < ρ ∧ k < N do
  trainSet ← draw ωr rows and ωc cols from dataTrain
  model ← trainXGBT(trainSet)
  Θt ← score(model, trainSet)
  Θv ← score(model, validationSet)
  if Θt < θ ∧ Θv < θ ∧ |Θt - Θv| < ϑ then
    k ← 0
    ensemble ← ensemble ∪ {model}
  else
    k ← k + 1
end
end
return ensemble;

Algorithm 1: Resilient and stable ensemble blending

Each model fitted on training subsets is assessed with the ε -constrained approach to handle multiple quality criteria, as

Fig. 2: Variance explained by the first ten PCA components of one-hot encoded `first_load_country` attribute.

presented in Algorithm 1. In particular, the primary objective function is to minimize an error measure, e.g., RMSE. We guarantee that each of the trained models yields an error lower than the predefined threshold θ on validation data. Furthermore, we introduce a stability threshold ϑ to avoid overfitting. We calculate it as an absolute difference between errors reported on training and validation sets in each round. The best models are blended to form an ensemble of possibly diverse models. The additional parameter ρ determines the number of models within the ensemble to provide a certain resilience level in case some of the models were put out of action.

In the future, we plan to extend a multicriteria evaluation with a specific approach to assure difference between the models explicitly. One of the possible solutions could be measuring the distances between the reported scores on a validation set. Alternatively, we may assure the feature importance rankings reported by models are possibly dissimilar (cf. Figures 4). Another approach to construct ensembles of possibly diverse models could be achieved by referring to r-C-reducts on nonoverlapping feature subsets or by ensuring constraints between attribute sets [10], [41]. A combination of the above techniques would also be an exciting future research direction, primarily since many attributes are somehow related,

Fig. 3: Histogram of the target variable (expenses) in the experimental data (on top) and the FedCSIS competition’s final dataset (bottom).

e.g., principal components generated from the same original features or all the columns in databases referring to the same source of knowledge. Combining these techniques with state-of-the-art instance selection and training set selection methods would also be of great importance [42].

Both in wrapper search and model training, we focused mainly on XGBoost [43]. However, we also complemented it with an evaluation of LightGBM [34]. We conducted grid search model parameter tuning for best performing data subsets in the feature selection stage. This part was conducted iteratively and was alternated with the wrapper-based feature selection. Such an iterative approach allowed us to, over time, fine-tune the wrappers’ configuration. In the future, we plan to continue experiments with more advanced techniques of searching the hyper-parameter space in order to optimize the model faster and more efficiently [44].

IV. EXPERIMENTS

A. Data

The data sets contain 6 years of history of orders appearing on the transport exchange, along with details such as the type of order, basic characteristics of the shipped goods (e.g., dimensions, special requirements), as well as the expected route that a driver will have to cover (cf. Table I). In particular, the training data consist of two tables: `css_main_training.csv` and `css_routes_training.csv`, and the additional data table containing historical wholesale fuel prices for the period of training and test data. The first file (i.e., `css_main_training.csv`) contains basic information about the contracts, and the second one (i.e., `css_routes_training.csv`) describes the main sections of the planned routes associated with each contract. In both tables, the first column (i.e., `id_contract`) contains identifiers that allow matching records from `css_main_training.csv` and `css_routes_training.csv` files. Additionally, the second column in the `css_main_training.csv` file (i.e., `expenses`) contains information about the prediction target. Values in this column are available only for the training data.

B. Task and experimental setup

In our study, we investigated the task of predicting the costs related to the execution of forwarding contracts, which was defined within the 8th data mining competition organized online on the KnowledgePit platform in association with the Federated Conference on Computer Science and Information Systems (FedCSIS’22). The task is to design an accurate method for regression of costs associated with forwarding contracts [45], based on contract data and planned routes (cf. Section IV-A). The quality of predictions was evaluated with the RMSE measure. The experiments were also planned to validate the relation between training speed and the size of training data, controlled with the ω_r and ω_c parameters.

Many threats may impact the models’ performance or impede their operations, including missing data or software errors. Therefore, the experimental setup was designed to also evaluate the resilience of the final solution, understood as the RMSE error achieved when some models within the ensemble cannot be applied (e.g., due to a software error or missing data attributes). However, up to our knowledge, there is no established methodology allowing us to assess the resilience of the ML models. One of the approaches could be to randomly delete subsets of test data, e.g., by dropping particular columns. It is, however, not straightforward how to implement this kind of test. Shall we randomly drop a certain percent (e.g., 5% or 10%) or number (3 or 5) of all columns? For data sets containing 20000 attributes, such operation may have minimal impact on predictive models [6], [17]. Or shall we drop the model’s most important feature(s)? Different approaches would be preferable for other modeling techniques. Consider a random forest that relies on many redundant weak tree models, XGBoost where particular predictors are boosting the formerly selected ones, or a single tree that depends on just a few attributes with one surrogate or verifying cut per split

TABLE I: Competition data description

Data type	Example columns	Description	Processing
Categorical data	id_payer, id_currency, direction, load_size_type, service_type, contract type, first_load_country, last_unload_country	Information about transport type, start and destination country, contract currency	one-hot encoding and PCA
GPS data	first_load_lat, first_load_lon, last_unload_lat, last_unload_lon, route_start_lat, route_start_lon, route_end_lat, route_end_lon	GPS coordinates of transport start and end points	NA
Numerical data	km_total, km_empty, km_nonempty, prim_ferry_line, ferry_duration, ferry_intervals, max_weight	Information about total distances to be covered with each mode of transport, weight of the payload, current fuel prices, aggregated information about the planned route	Aggregation
Binary data	refrigerated, if_empty	Additional information about the payload, for example if it was refrigerated	NA
Date data	route_start_datetime, route_end_datetime	When the service was executed	NA

[46]. In our case, we decided to implement a straightforward approach that may be dedicated to the ensembling techniques. Namely, we were dropping randomly selected models from the ensemble to measure the impact of such an operation on the RMSE.

In the conducted experiments, we used the features extraction, dimensionality reduction, model training, and resilient ensemble blending method, as described in Section III. As the base model, we used XGBoost a [24]. We optimized the model parameters only once on the selected subset of data with the grid search procedure, and since it was not the major point of our research, we kept those parameters later unchanged. The ω_r and ω_c parameters were set to 0.5, meaning that each of the xgbt models within the ensemble was trained on a random subset of 50% features and 50% instances from the training set. The expected model quality threshold θ was set to 0.17, which corresponds to 2.5% of the median expenses in data (cf. Figures 3). The robustness threshold ϑ was 0.02, and the resilience threshold ρ was 10. To visualize the results, we use box plots - a standard way of displaying data distribution by encoding their five key characteristics: minimum, first quartile (Q1), median, third quartile (Q3), and maximum. For the purpose of evaluation, we split the data into three sets: training, validation, and test. The first two constituted a part of the training procedure. The last was used only for evaluation. Furthermore, we present the results achieved by our method within the "FedCSIS 2022 Challenge: Predicting the Costs of Forwarding Contracts" on the preliminary and final competition data.

C. Results

Figure 5 shows how the values of RMSE are spread out for ensemble models on the training, validation, and test data. The results show that RMSE for training, validation, and test dataset are very close to each other avoiding model overfitting. This confirmed that the ensemble yields not only satisfactory quality but also guarantees high robustness and stability, which is especially visible between validation and test sets (cf. Figure 5). This confirms the effectiveness of the multicriterial evaluation, such as acceptable RMSE threshold θ and stability threshold for RMSE ϑ , which are applied while selecting the ensemble models. When we compare the

results achieved by our method within our experimental setup with the results achieved during the FedCSIS 2022 Challenge: Predicting the Costs of Forwarding Contracts, we may notice it yielded very similar results on both preliminary and final data sets, 0.165 and 0.161, respectively. The results confirm the predictability, repeatability, and stability of the proposed method.

Next, we evaluate the resilience of our solution. In this experiment, we randomly deleted 1, 3, 5, 7, and 9 models from the ensemble to simulate the scenario when some models would be unavailable. Then, we calculated RMSE against the test dataset. We repeated the procedure 10 times and plotted the results in Figure 6. The results show that RMSE is slightly decreasing when deleting some models from the ensemble. However, the largest impact was spotted when deleting the majority of the models (9 out of 10). In fact, this leads us to investigate the most important features which are very correlated or have a high impact on the target variable. Therefore, we calculated the F-score based on the Information Gain (IG) measure. It is worth noting that IG in the decision/regression tree-based models is a measure of how much information a feature provides about the target feature.

Figure 4 shows the relative importance of features for two selected XGBoost models from the ensemble. The values on the x-axis show the average gain for the top ten features across all splits where those features were used. Observably, the proposed training set selection procedure allowed us to train several significantly different models that rely on different features, which leveraged ensemble smoothing and enabled the high resilience of the final solution. Considering the importance of features for 10 XGBoost models constituting the final solution (cf. Fig 4), we may notice that only seven features were relatively impactful (i.e., F-score > 100) for more than one model, namely: diff_start_end_days, diff_start_end_weeks, direction_PC1, km_nonempty, km_total, last_unload_country_PC2, last_unload_country_PC5.

For some of the potential threats, like data deficiencies, we may notice that several attributes were derived from the same (or similar) sources of information, e.g., features derived from the start and end dates or principal components of one-hot-encoded last_unload_country. Thus, in such a case,

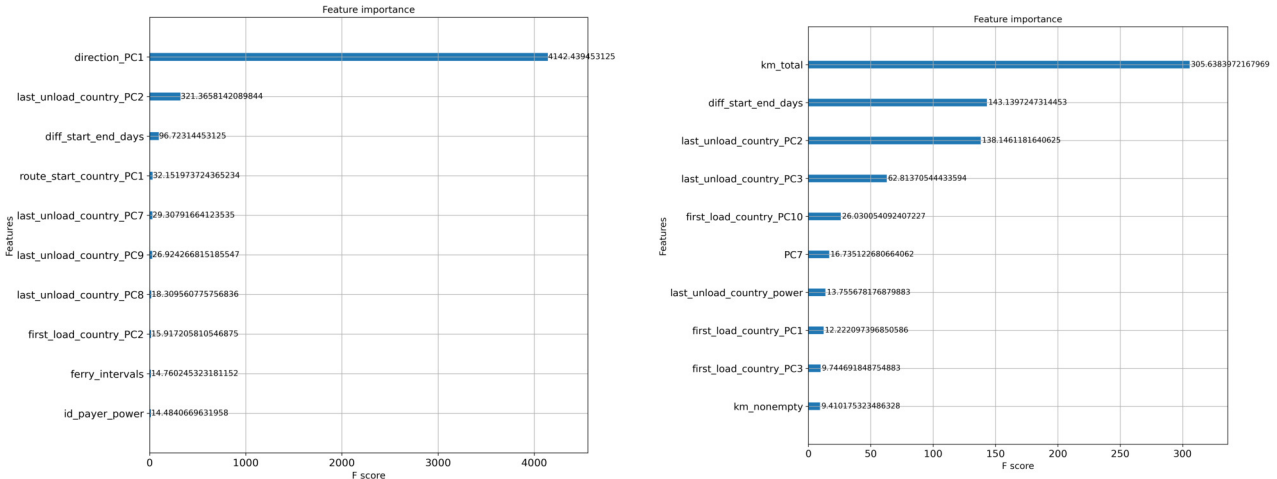

Fig. 4: Feature importance reported by two XGBoost models trained on different subsets of features and instances.

Fig. 5: RMSE comparison for ensemble models.

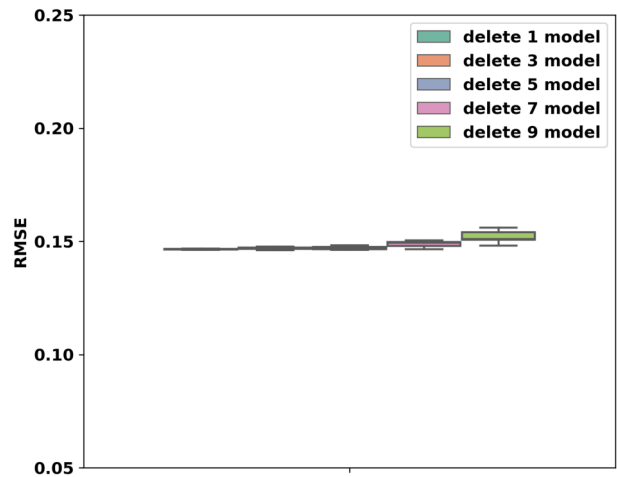

Fig. 6: Resilience comparison for ensemble models.

applying a more formal methodology for resilience assessment would be advisable and may be considered a valid future research direction. Another valuable extension of the proposed framework would be to include information from experts in the machine learning process to ensure that the features which, according to the experts, have high importance are selected in at least some of the ensemble components [26], [47].

Finally, we focus on measuring the speed and cost-effectiveness of the solution. This factor has recently gained a lot of attention because, in many practical applications of ML, like recommender or threat detection systems, the predictions are highly influenced by the most recent data. Thus, the model must be continually retrained to consider the most recent information, and it is very important to make a balance between speed and accuracy. In our proposed solution, this can be achieved by training data sets of randomly selected chunks of data. Figure 7 shows the time taken for building the XGBoost model using 100%, 75%, 50%, and 25% of

data rows (cf. ω_T parameter) in the training data set, with the unchanged model hyper-parameters. This experiment was repeated 10 times, considering different (randomly chosen) data rows in each run. Furthermore, in Figure 8, we also plot RMSE each XGBoost model would achieve in FedCSIS'22 data competition. We may notice that depending on the data subset, the final model quality varies and slightly decreases along with the declining size of training data chunks.

V. SUMMARY

The industrial machine learning applications today involve the development and deployment of MLOps pipelines, which consist of automated activities that were once manually performed by data analysts, including data ingestion and pre-processing, feature extraction and selection, model fitting, etc. These solutions are designed to ensure the quality of predictions during the production use of forecasting models, which may be months or even years. Quality assurance in such a long period requires the development of a repeatable

Fig. 7: Training speed comparison.

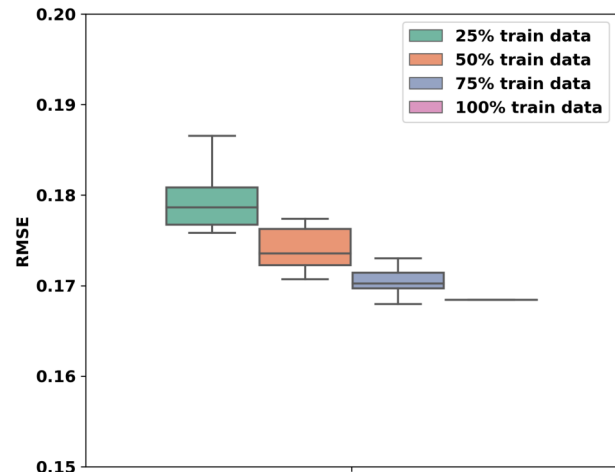

Fig. 8: RMSE comparison before/after deleting data rows.

learning procedure to (re)train the models in case of shifts or drifts in data. Furthermore, apart from confirming the model's accuracy, it is expected to assure many quality criteria, such as stability, resilience, and low computational cost, in a fast and reliable way.

In this study, we present the ML pipeline that considers several qualities of the models in a multicriterial manner. Besides assuring RMSE optimization, our solution also ensures robustness, resilience, and instant (re)training time. The developed pipeline consists of several states, including pre-processing, feature extraction, dimensionality reduction, robust model training, and resilient ensemble blending. In this paper, we also elaborate on several promising future research directions, including applying more advanced features and instances selection techniques, incorporating experts' knowledge into the machine learning processes, ensuring the ensemble diversity more explicitly, or providing a formal methodology to assess the resilience of the predictive models.

We confirmed the qualities of our pipeline with the versatile experimentation on the real data from international freight forwarders and by participating in an international data mining competition organized along to FedSCSIS'22 conference. The achieved RMSE is comparable to the best and most complex models reported by 135 teams from 24 countries in the FedCSIS contest, meanwhile conforming to more requirements. We may conclude that the proposed solution provides high-quality results with excellent resilience and stability, and the models are developed within seconds of training on low-cost compute resources. In the future, we plan to augment the developed framework with the discussed extensions and subject it to in-depth experimental analysis on a more significant number of real data sets from various fields, including the mining industry [17], [18], fire service [28], FMCG [3], cloud resource management [15], and for predicting escalations in customer support [48]. We believe that the developed approach will be equally effective in all those applications.

Prediction of the Costs of Forwarding Contracts with Machine Learning Methods

Stanisław Kaźmierczak

Faculty of Mathematics and Information Science,
Warsaw University of Technology, Warsaw, Poland
Email: stanislaw.kazmierczak@pw.edu.pl

Abstract—This paper summarizes experiments conducted and findings related to FedCSIS 2022 Challenge that we participated in. The task was to develop a predictive model that estimated costs pertained to the execution of forwarding contracts (FC). We thoroughly analyze the dataset and present steps performed in the data preprocessing stage. Then we describe our approach to building a predictive model, which placed us eighth out of 135 teams. In the end, a wide range of ideas for further research is provided.

Index Terms—forwarding contracts, data preprocessing, machine learning

I. INTRODUCTION

DUE TO the specialization of work, the economy of production scale, and mass consumption, places where products are manufactured do not coincide with places where the demand for them is reported. Therefore, transportation is essential to bridge the gap between the buyer and the seller. It is a part of a logistic chain and plays a crucial role in attaining its primary goal – resource optimization.

Freight forwarding is an activity consisting in organizing the transport of goods. The forwarding company performs various activities for the client related to the organization of transportation, starting from adjusting the means of transportation through consulting in the field of cargo transport and ending with unloading the goods. Forwarder operates on the freight exchange, a place of information exchange between carriers and forwarding companies. Its purpose is to facilitate communication and accelerate the conclusion of transactions in the economic sector of transport.

Forwarder's work consists in searching orders on freight exchange, evaluating them, and selecting profitable ones. The ultimate goal is to sign an FC. It is an agreement whereby the freight forwarder makes a commitment for the sender or recipient of the goods to transport them to the place of delivery, not conducting the carriage himself but finding the carrier who will carry the goods. The forwarder signs a carriage contract on his behalf but for the account of the sender or recipient.

This study describes the model created to predict the costs related to the execution of FCs. Such a model aims to support freight forwarders in selecting profitable contracts.

II. RELATED LITERATURE

Increased interest in predicting the cost of transport has been observed among researchers since the late 1990s. Various means of transport, parts of the world as well as predictive

methods were analyzed. This section summarizes more significant, in our opinion, studies.

In [1], the authors investigated factors that affected transportation costs. They applied the tobit model to find that infrastructure is its most important determinant in the considered area. Other crucial factors included details of geography, administrative barriers, and the structure of the shipping industry.

The authors of [2] used regression-based methods to examine the determinants of shipping costs to the US. It was found that distance, containerization, and efficiency of a port were significant factors influencing freight. The study provided some examples of how private involvement in port management along with labor reform and reduced monopoly power led to efficiency and lower costs.

Reference [3] studied the impact of port characteristics on international maritime transport costs. It considered 16 Latin American countries and maritime trade transactions in containerizable goods. The authors employed a regression model and proved that doubling port efficiency in a pair of ports would have the same impact on international transport costs as halving the distance between them.

The authors of [4] created a microeconomic model of interregional freight transportation. They utilized an ordinary least squared regression model and showed that besides determinants of transport cost incorporated in the model, the degree of competition also played a significant role in freight charge prediction.

Reference [5] is another paper focused on the prediction of costs of maritime transport, more precisely, logistics costs in container ports. The authors applied transaction cost economics (TCE) to support and explain empirical findings. They found that the quality of port infrastructure, port services, and port connectivity are among the most important determinants of logistics costs in container ports.

In [6], the authors summarized crucial findings from previous studies related to the estimation of transport costs. Most of the approaches concentrated only on statistical analysis or employed regression-based methods.

To our knowledge, there is no study that elaborates on more sophisticated machine learning (ML) methods and considers various means of transport. We hope that our study contributes to filling this gap.

III. DATASETS

The dataset contains orders that appeared in the freight exchange and were accepted by a large Polish company. Training samples come from the period between January 2016 and November 2020, while test instances from the period between September 2020 and November 2021. It means that train orders are generally followed by test ones. There are two main reasons why the test set partially overlaps the train set: complex orders from the training part that require a long time to complete, as well as some reversed start and end times (the end time is earlier than the start time) in 452 orders. Order details such as its type, basic characteristics of the shipped goods, along with the expected route that a driver will have to cover are provided. Input columns are the same for both training and test sets except for the target variable – costs of individual orders – which is given in the case of the former one and needs to be predicted in the case of the latter.

A. Dataset description

In more detail, the training set consists of two tables: *css_main_training.csv* and *css_routes_training.csv*. The former contains fundamental information about the contracts. It has 330 055 rows and 36 columns. The latter describes the main sections of the planned routes associated with each contract. It consists of 1 189 654 rows and 60 columns. The first column of each table contains contract identifiers that allow matching records from both tables. *css_main_training.csv* contains a column with the prediction target. Analogously, the test set consists of two tables: *css_main_test.csv* and *css_routes_test.csv*. Their structure is the same as corresponding training tables, but the column with the prediction target is empty. The first table consists of 72 452 records, while the second – 325 222 records. Additionally, *fuel_prices.csv* contains wholesale prices of three different types of fuel for the period of training and test data. More details about data and the competition itself are provided in [7].

B. Data analysis

In the case of the analyzed dataset, there are three types of data: numerical, categorical (including binary), and text (only one column of this type – requirement related to the temperature). In terms of most features, we can observe significant skewness (numerical columns) or noticeable imbalance (binary columns), which is generally not positive from a machine learning perspective.

Each order in the main table is timestamped. Thus, if orders are grouped, columns may be viewed as time series. We stick to the most important column, *expenses*, which is the target variable. Fig. 1 depicts expenses from orders grouped by different time periods. Several conclusions can be drawn. First, orders that are planned to start on Friday are the most expensive, and those beginning during a weekend – the cheapest. Conversely, orders scheduled to be finished on a weekend are high-priced. Second, throughout a year, there are peaks in cost irrespective of whether we consider the beginning or end of the order. It concerns both fixed

and floating holidays. Finally, one may observe that contracts planned to be accomplished in the summer months are cheaper than those in other parts of the year.

The results obtained in standard cross-validation in which training and test instances are mixed in terms of timestamp were approximately 10% better than those registered on the competition platform in which training samples are followed by test ones. It suggests that data or/and concept drift occurs. The difference in the distribution of some features between the training and test data is not a sufficient explanation of this phenomenon. There is no statistically significant difference in the distribution of the target variable. As the last step, we applied TSNE to map training and test instances to the 2D plane. We did not observe any significant dissimilarities between both types of samples. Fig. 2 depicts the results of the algorithm. Data/concept drift needs further investigation we did not manage to perform before the end of the competition.

IV. DATA PREPROCESSING

Quality data is necessary for machine learning models to operate efficiently. In general, data preparation requires more time and effort than actual modeling [8]. In this section, we present preprocessing steps that made our data prepared to build a predictive model.

A. Main tables

- 1) All data except the following columns were loaded: *temperature*, *first_load_lat*, *first_load_lon*, *last_unload_lat*, *last_unload_lon*, *route_start_lat*, *route_start_lon*, *route_end_lat*, *route_end_lon*.
- 2) The following columns were one-hot encoded: *direction*, *id_service_type*, *contract_type*, *id_payer*, *first_load_country*, *last_unload_country*, *route_start_country*, *route_end_country*, *id_currency*, *prim_train_line*, *load_size_type*, *prim_ferry_line*.
 - a) *id_payer* was limited to 50 payers with the most numerous contracts within both train and test set.
 - b) In terms of *prim_train_line* and *prim_ferry_line*, the additional category representing missing values was created (in other one-hot encoded columns, there were no missing values).

B. Routes tables

- 1) The following columns were loaded: *id_contract*, *external_fleet*, *id_vehicle*, *id_trailer*, *if_empty*, *ferry*, *train*, *step_type*, *country_code*, *id_vehicle_model*, *id_vehicle_type*, *vehicle_type*, *vehicle_capacity_type*, *trailer_generator*, *id_trailer_model*, *id_trailer_type*, *ferry_line*, *train_line*.
- 2) The following columns were one-hot encoded: *country_code*, *id_vehicle_model*, *id_vehicle_type*, *vehicle_capacity_type*, *step_type*, *trailer_generator*, *id_trailer_model*, *id_trailer_type*, *ferry_line*, *train_line*, *vehicle_type*.
 - a) For all columns other than *step_type*, the additional category representing missing values was created

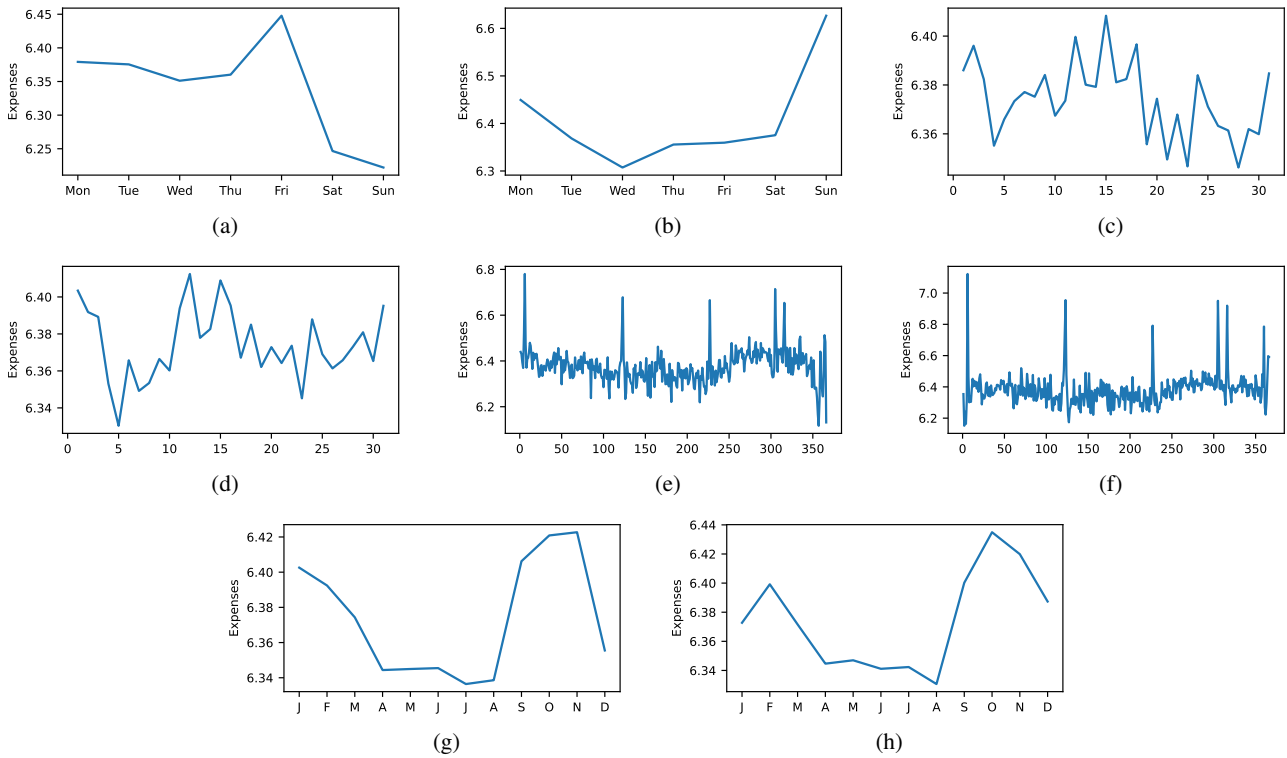

Fig. 1: Expenses (target variable) as a function of time. In the consecutive subfigures, orders are grouped by: (a) and (b) – day of a week, (c) and (d) – day of a month, (e) and (f) – day of a year, (g) and (h) – month of a year. Subfigures (a), (c), (e), and (g) relate to the planned time of the beginning of a route, subfigures (b), (d), (f), and (h) – to the planned time of the end of a route.

Fig. 2: TSNE applied to compare training and test instances.

(in the *step_type* column, there were no missing values).

- 3) Aggregation: instances were grouped by *id_contract*, and values from all other columns were summed for each contract. One more column reflecting the number of routes per contract was added.
- 4) Above data frames with routes were merged with the main data frames on the *id_contract* column which was

then removed.

C. Fuel prices

- 1) *disel_type2_price* column was added to the above merged data frames based on date.
 - a) *disel_type1_price* and *disel_type3_price* were not utilized since their Pearson correlation with *disel_type2_price* ranges between 0.98 — 0.99.

D. Data transformations

- 1) *ferry_intervals* was the only column with missing values. They were imputed on the basis of *ferry_duration*. If *ferry_duration* equals 0, then *ferry_intervals* is also 0. Otherwise, *ferry_intervals* is imputed with 1.
- 2) Time correction: if *route_end_datetime* was earlier than *route_start_datetime*, the values were swapped.
- 3) New features being the product of *disel_type2_price* and features related to distance (*km_empty*, *km_nonempty*, *km_total*, *km_train*, *ferry_duration*) were created. They should reflect the total cost of fuel related to particular contracts.
- 4) Additional features created:
 - a) *duration_h* — the difference expressed in hours between *route_end_datetime* and *route_start_datetime*.

- b) *start_day_of_week* and *end_day_of_week* — days of week related to *route_start_datetime* and *route_end_datetime*, respectively.
 - c) *day_of_year* — day of a year, ranges from 1 to 365 (in the case of the leap year, 1 was subtracted from all days after 29th February to be consistent with common years; it turned out that the predicted prices are highly correlated with some dates, especially related to festivals); one-hot encoded.
- 5) After all the aforementioned transformations, *route_start_datetime* and *route_end_datetime* columns were ultimately removed from the data frame.
 - 6) Eventually, the data frame contained over 1000 columns. Features were assessed using XGBoost's *feature_importance* property. For final modeling, different number of the most valuable features were left (more details are provided in Section V).

V. PREDICTION RESULTS

The task of the created models was to predict the actual costs of individual orders as accurately as possible. Such models aim to assist freight forwarders in picking beneficial contracts. The quality of algorithms is evaluated using the RMSE measure.

The whole code was written in Python 3.7. Neural networks were created in Keras 2.3.1. Gradient boosting was implemented with the *xgboost* 1.0.2 package. In terms of all other machine learning algorithms, *scikit-learn* 0.24.2 was applied. If not mentioned otherwise, hyperparameters were left at their default settings.

The best results were obtained by XGBoost built on the most valuable 200 or 500 features mentioned in Subsection IV-D. It is not a surprise in terms of the tabular data since XGBoost is the top choice on the Kaggle platform in such cases as well. In terms of hyperparameter tuning, we selected hyperparameters and their considered value range as suggested in [9] and [10]. Due to time constraints, we optimized them one by one, assuming fixed (default) values for the others. It turned out that the following values brought the best results: *subsample* – 1, *max_depth* – 6, and *eta* – 0.3.

The final solution was constituted by the averaging ensemble of three XGBoost models with *n_estimators* set to 205 and built on all, 500, and 200 most valuable features, respectively. The RMSE obtained amounted to 0.1529, which placed us eight out of 135 teams.

It is worth mentioning that many algorithms other than XGBoost, were analyzed (we submitted 108 valid solutions). Before focusing on XGBoost, we tested a wider range of algorithms – linear regression, random forest, and different neural architectures. All of them were more than 10% worse than the final solution.

VI. CONCLUSIONS AND FURTHER IDEAS

In this paper, we present our approach to building a model able to predict costs related to FC. Despite many conducted

experiments and the reasonable score achieved, we still see a lot of room for improvement.

First, concept/data drift was detected but not addressed successfully. It requires further investigation. We believe that the application of some dedicated methods (please refer to [11]) may lead to prediction enhancement.

Second, data aggregation requires more experiments. In the current approach described in subsection IV-B, values from the routes table are summed for each corresponding contract. Such a method may cause the loss of some valuable information.

Third, we believe that there is still some uncovered potential in neural networks. Neural architectures are relatively hard to tune and prone to overfitting due to their complexity. Even if they do not outperform XGBoost, they can constitute a valuable element of the ensemble model by increasing its diversity.

Next, it may be worth looking one more time at encoding categorical features with a large number of values, e.g., *id_payer*. On the one hand, we should not expand a feature space massively. On the other, we must not allow valuable information to be lost.

Last but not least, it is worth taking a closer look at the feature selection. We applied a simple approach based on XGBoost's *feature_importance* property. However, this method does not take into account feature correlation. We strongly believe that the application of some more sophisticated feature selection algorithms along with other aforementioned ideas will further boost the prediction quality.

XGBoost meets TabNet in Predicting the Costs of Forwarding Contracts

Aleksandra Lewandowska
 Silesian University of Technology, Poland
 aleklew480@student.polsl.pl

Abstract—XGBoost and other gradient boosting frameworks are usually the default choice for solving classification and regression problems for tabular data, especially in data science competitions, as they often, combined with proper data pre-processing and feature engineering, supply high accuracy of predictions. They are also fast to learn, easy to tune, and can supply a ranking of variables, making interpretation of learned models easier. On the other hand, deep networks are the top choice for complex data, such as text, audio, or images. However, despite the many successful applications of deep networks, they are not yet prevalent on tabular ones. It may be related to difficulties in the choice of the proper architecture and its parameters. A solution to this problem may be found in recent works on deep architectures dedicated to tabular data, such as TabNet, which has recently been reported to achieve comparable or even better accuracy than XGBoost on some tabular datasets. In this paper, we compare XGBoost with TabNet in the context of the FedCSIS 2022 challenge, aimed at predicting forwarding contracts based on contract data and planned routes. The data has a typical tabular form, described by a multidimensional vector of numeric and nominal features. Of particular interest is investigating whether aggregation of predictions derived from XGBoost and TabNet could produce better results than either algorithm alone. The paper discusses the competition solution and shows some added experiments comparing XGBoost with TabNet on competition data, including incremental model re-building and parameter tuning. The experiments showed that the XGBoost and TabNet ensemble is a promising solution for building predictive models for tabular data. In the tests conducted, such an ensemble achieved a lower prediction error than each of the algorithms individually.

I. INTRODUCTION

ALMOST every company collects data on their products, services, or customers. Analyzing such data helps companies make informed business decisions to increase their profits. One example of such analysis is the task defined in the FedCSIS 2022 challenge [1], involving cost prediction of forwarding contracts based on contract details and planned routes. In that case, such cost estimation may support selecting the most profitable contracts.

Many examples of predictive analytics for supporting companies in increasing or maintaining their profits can be found [2]. Recommender systems [3], [4] may suggest to customers what products they may be interested in, thereby increasing the chances of buying a product. Predicting customer lifetime value [5] helps to select the top customers to whom more attention should be paid. Churn prediction [6], [7] can reduce customer losses.

Data collected by companies about customers, contracts, or products are often stored in database tables consisting of various attributes (nominal, numerical, date-time), thus their natural form for analytics is tabular, with mixed types of features. Over the past several years, gradient boosting frameworks have become particularly popular for analyzing such data, as combined with appropriate data pre-processing and feature engineering, they often achieve superior accuracy. In contrast, deep learning methods are the default choice for unstructured data, such as images, audio, or text. Deep networks are not often applied to tabular data, which may be due to the difficulty of selecting an appropriate architecture suitable for analyzing heterogeneous tabular formats. Therefore, several deep architectures dedicated to tabular data have been proposed over the past few years, such as TabNet [8], Net-DNF [9], Node [10], and TabTransofmer [11].

This paper attempts to apply one of those tabular-specific deep networks, namely TabNet, to forwarding contracts data in the context of the FedCSIS 2022 challenge, and compare it with XGBoost [12], one of the most popular gradient boosting frameworks. Of particular interest is investigating whether combining the two methods could produce better results than either algorithm alone. We also investigate the performance of the algorithms over time, training them in an incremental fashion. Section II describes the competition solution. In this section are described: data pre-processing steps and modelling, XGBoost hyper-parameters tuning, Tabnet hyper-parameters tuning and linear combination of both models as a result to the problem. Section III summarizes the work.

II. COMPETITION SOLUTION

A. Competition data-sets

Competition consists of five data-sets: **test data set (main table)**, **test data set (routes table)**, **training data set (main table)**, **training data set (routes table)** and **fuel prices**. Test and training data sets differ in the fact that test data set does not include the estimated cost column, which is used for evaluation purposes. The presented solution's data pre-processing process is divided into two separate steps: **routing table** and **main table** pre-processing.

B. Routing table data pre-processing

In the first step, we selected and added new features, and aggregated the data by contract id. We identified the data that was missing in a significant manner and in the process

of simplification we removed those features from further processing.

The percentage of missing values in particular columns is respectively about 54.5% and 30.6%. Therefore, the number of columns in this step has significantly dropped.

The columns describing respectively longitude and latitude were dropped as extracted information can be found in other features, like the distance between starting and ending points.

The subset of features that have not been dropped can be associated with different transport methods. The present methods are ferry, train, truck (which can be considered as conventional transportation method).

To each method we have defined added features, which measure how much has been transported over how long time or distance. Created features:

- Train (weight-distance) feature = $train_km * kg_current$
- Ferry (weight-time) feature = $ferry_duration * kg_current$
- Truck (weight-distance) feature = $km * kg_current$

As multiple records are used to define a particular transportation process, we decided to aggregate the features left. After the pre-processing process the routing table is summarized with one record per each contract.

C. Main table data pre-processing

Main table includes 36 columns, and only 8 of them has missing values. Only 3 columns include more than 50% of missing values. Therefore, those columns have been dropped.

In the first step we have extracted date and time information from **route_start_datetime** and **route_end_datetime** columns. From those columns we have extracted **year, month, day of the week, hour, the difference between start and the end** of the transportation process and converted those two columns into columns having **unix time** (which defines the number of epochs since 01-01-1970).

In the next step we put our attention towards the processing of categorical data, which can be shown on the feature **id_payer**. From the training set we selected the payers that accounted for over 1000 orders and then we applied one hot encoding technique. All not accounted payers are categorized as others. The same approach was used for: **currencies, first load country, last unload country**. Other categorical features were treated in a different manner. As the number of unique values was small enough, instead of using one hot encoding technique we have decided to assign a numerical value to each of values included within each category. To each value we assigned an integer, in our case we did not concern ourselves with the order of assigned numerical values. The numerical values used are integers from 0 to n where n depends on the number of unique values present in a particular categorical column.

Features for which assignment was applied are: **contract type, load size type** and **direction**. Then newly created features and other non-categorical features were joined with the data set created in the earlier step.

The resulting data set constitutes the input for our XGBoost and TabNet models. The same steps were applied towards test data sets in both routing table and main table data sets.

D. TabNet - training and evaluation

TabNet is an "interpretable canonical deep tabular data learning architecture." [2] The parameters that influence the training process of the model are: **optimizer** and **learning rate, hyper-parameter tuning, training process**. We used **Adam optimizer** and **exponentially decreasing learning rate of first value 2e-2**.

After choice of the optimizer and the learning rate we could turn to **hyper-parameters tuning**. For the training process we selected 4 parameters for testing [8]:

- **n_a** - "Width of the decision prediction layer. Bigger values give more ability to the model with the risk of over-fitting."
- **n_b** - "Width of the attention embedding for each mask. According to the paper $n_d = n_a$ is usually a good choice."
- **batch size** - "Number of examples per batch. Large batch sizes are recommended."
- **n_steps** - "Number of steps in the architecture (usually between 3 and 10)"

To select the most suitable parameters for our problem, we have used the technique called **Grid Search**. To use this technique, firstly we had to define the range of the parameters that we wanted to check during testing. Next, we would try all possible combinations, train the model and evaluate the performance. Selected parameter ranges are: **n_a = n_b** \in {4, 8, 18}, **n_steps** \in {3, 5, 7}, **batch size** \in {1024, 2048}, **mask type** \in {"sparsemax", "entmax"}. The table below represents a subset of results of all performed experiments. Model consistently has performed better for **mask type = "sparsemax"** and only results with such value are presented.

Width	Steps	Batch	RMSE Val	RMSE Pre
8	5	2048	0.1634	0.1719
8	5	1024	0.1608	0.1720
8	3	1024	0.1587	0.1734
8	7	1024	0.1757	0.1751
4	7	2048	0.1646	0.1752
8	3	2048	0.1618	0.1772
4	5	1024	0.1661	0.1774
8	7	2048	0.1665	0.1782
4	3	1024	0.1687	0.1779
4	3	2048	0.1667	0.1875
4	5	2048	0.1670	0.2387
4	7	1024	0.1647	0.2704

TABLE I
RESULTS OF HYPER-PARAMETER TESTING, TABNET

Width - n_a, n_b
Steps - n_steps
Batch - batch_size
RMSE Val - RMSE value, calculated on the validation set
RMSE Pre - RMSE value, calculated on the preliminary testing set

The training data set has been sorted first based on the unix epoch value of route_start_datetime column. The validation set consists of the last 10% of the sorted rows of the data set.

The sorting took place because we want our model that has been trained on the archived records to perform well on the incoming data. The main goal is to predict future values.

This exactly describes the training process that took place. In the first iteration we trained our model only on the first 10% of the data set and evaluated it on the following 10%. Therefore, only 20% has been used at this step. In the next iteration we have moved the 10% used for evaluation into the training set, on which model has been additionally trained. Then the following 10% has been used for evaluation purposes. This process was taking place incrementally, till the moment in which the model was trained on 90% of the data and evaluated on the last 10%. The RMSE value evaluated at this step is denoted as RMSE Val. However, for our model to perform well on the test data set, the model should be trained on almost all available records. For that reason, we have moved the following 8.5% from the local validation set used for evaluation and additionally trained the model, which was then evaluated on the last 1.5% of the ordered training data set. Then we considered a TabNet model trained on 98.5% of the data set as a fully trained model, which then was evaluated on the preliminary testing set, supplied by the FedCSIS 2022 competition, which is the subset of the full testing data set. The results are available in I. Hyper-parameters of the model that **performed best** are:

$n_a = n_b = 8$, $n_steps = 5$, batch size = **2048**, mask type = "sparsemax"

The results of evaluation are: local validation = **0.1634**, preliminary validation = **0.1719**, final result = **0.1713**.

The results obtained for the model with **default hyper-parameters** are: local validation = **0.1587**, preliminary validation = **0.1733**, final result = **0.1735**

We can see that the model has improved, but not in a significant manner. In comparison to the model which obtained the best results on the preliminary test data set, both models differ by the **batch size**, and **n_steps** which are respectively **1024** and **3** for the model trained with default hyper-parameters.

E. XGBoost - training and evaluation

XGBoost "is an optimized distributed gradient boosting library"[3]. XGBoost model consists of two steps: **training** and **evaluation**. Those processes are quite similar to the processes that were described in the TabNet section of this paper. The training process is similar to the TabNet training process with a subtle differences. Similarly we use **Grid Search** technique for finding the optimal hyper-parameters for our model. The hyper-parameters that were tuned are:

- **learning rate** - "Step size shrinkage used in update to prevents over-fitting." [12]
- **min split loss** - "Minimum loss reduction required to make a further partition on a leaf node of the tree." [12]
- **max depth** - "Maximum depth of a tree. Increasing this value will make the model more complex and more likely to over-fit." [12]
- **colsample by tree** - "The subsample ratio of columns when constructing each tree" [12]

The defined ranges of interest are: **learning rate** $\in \{0.05, 0.85, 0.15\}$, **min split loss** $\in \{0, 0.1, 0.2\}$, **max depth** $\in \{3, 4, 5\}$, **colsample by tree** $\in \{0.55, 0.65, 0.75\}$.

Rate	Loss	Depth	Colsample	RMSE Val	RMSE Pre
0.085	0.2	5	0.65	0.1511	0.1617
0.150	0.2	4	0.65	0.1555	0.1623
0.150	0	4	0.75	0.1561	0.1623
0.085	0.2	4	0.75	0.1536	0.1626
0.085	0.1	5	0.65	0.1519	0.1628
0.085	0.2	5	0.75	0.1523	0.1629
0.150	0.2	4	0.75	0.1523	0.1632
0.085	0.1	4	0.75	0.1536	0.1633
0.085	0.1	4	0.65	0.1527	0.1636
0.05	0.2	5	0.75	0.1527	0.1636
0.05	0.2	5	0.65	0.1523	0.1653

TABLE II
RESULTS OF HYPER-PARAMETER TESTING, XGBOOST

*Results were sorted by RMSE Pre value

Rate - learning rate

Loss - min split loss

Depth - max depth

Colsample - colsample by tree

RMSE Val - RMSE value, calculated on the validation set

RMSE Pre - RMSE value, calculated on the preliminary testing set

The training process is quite like TabNet's training process described earlier. In the first iteration XGBoost model is trained only on 10% of the training data, and then evaluated on the following 10%. In the next iteration XGBoost model is trained on the 20% of the training data set and then evaluated on the following 10%. This process takes place till the model is trained on 90% of the data set. Then the model is trained enough that we can calculate RMSE Val value, evaluating the model on the last 10% of the training data set. Afterwards XGBoost model is trained on 100% of the training data set, and then model is evaluated on the preliminary testing data set and full testing data set. It is worth mentioning that in each iteration like in the last stage of training (training on the 100% of the data set) model is basically trained from zero - created is new instance of the model, and the model gets trained. In comparison to TabNet that makes a significant difference as TabNet model uses warm training (with use of already pretrained weights as a baseline for the model training). The XGBoost model that performed best:

Type	Learning Rate	Loss	Depth	Colsample
Best	0.085	0.2	5	0.65
Default	0.3	0	6	1

TABLE III
HYPER-PARAMETERS - BEST AND DEFAULT MODELS XGBOOST

We can notice that the default model has performed significantly worse than tuned model.

F. Combination of XGBoost and TabNet models

The final model is a combination of XGBoost and TabNet models both.

Fig. 1. Training results of XGBoost model depending on the used hyper-parameters

Type	Local Val	Preliminary Val	Final Result
Best	0.1511	0.1617	0.1608
Default	0.1739	0.2365	0.2362

TABLE IV
RESULTS - BEST AND DEFAULT MODELS XGBOOST

Results are generated independently for each one of the models. Then we use the assigned weights to generate the final results. The main problem at this stage was finding the right weights. For simplicity we have decided to check 10 different pairs. Starting with XGBoost being assigned 0 and TabNet 1, incrementing the weight assigned to the XGBoost by 0.1 and decreasing the weight assigned to TabNet by 0.1. Ultimately Fig. 1. depicts the preliminary and final evaluation of the generated results. We can notice that the best RMSE is generated for 0.6 assigned to XGBoost and 0.4 assigned to TabNet with final results of **0.1565** for preliminary validation and **0.1559** as a final result. It is worth noticing that XGBoost has significantly outperformed TabNet, with TabNet's results of **0.1719** and **0.1713** and XGBoost **0.1617** and **0.1608** as preliminary and final results respectively.

III. CONCLUSIONS

In this paper, we have introduced the approach that we have used for FedCSIS 2022 Challenge. We have described the data pre-processing, handling the missing data and two models that we have used for our solution: **XGBoost** and **TabNet**. It is also worth noticing that the process of training the XGBoost model takes much less time in comparison to the process of training the TabNet model. Although the result is worse than the baseline solution, we can notice how the combination of both models can outperform those two models working separately. Although XGBoost has significantly outperformed the TabNet model itself, the combination of both models has quite significantly outperformed both models working alone.

Abstract—When selling goods abroad or bringing them into the country from foreign partners, we face the problem of delivery. The division of responsibilities related to this between the manufacturer and the recipient sometimes varies. In such a situation, it is reasonable to use the services of a forwarding company. Then a forwarding contract is concluded, which specifies the details of the service, but the most important issue remains the selection of its price. In this paper, we present results obtained using the LightGBM method on the forwarding contracts pricing challenge held as part of the FedCSIS 2022 conference.

Index Terms—data mining competition, LightGBM, forwarding contracts

I. INTRODUCTION

A FORWARDING contract is a contract in which one of its parties – the forwarder undertakes to perform various services related to transportation in the course of his own business, such as sending or receiving a shipment, and the other party – to pay remuneration in return. A good forwarder will not only efficiently organize transportation but will also help reduce the cost of the transaction. However, to remain price competitive and still make a profit, he must have a good tool for predicting the cost of executing such a contract.

To predict forwarding contract costs based on tabular data we can use various machine learning methods [1]. We decided to use a gradient boosting algorithm, especially LightGBM, because of its speed and accuracy.

The rest of this paper is structured as follows. We first present the related work and then we give a short description of FedCSIS 2022 challenge. In Section IV we describe the data processing steps. Section V contains the description of the model used in our experiment. Next section presents results. Finally, in Section VII we summarize the findings and discuss possible future work.

II. RELATED WORK

Gradient boosting is a machine learning technique, which produces a prediction model in the form of an ensemble of weak prediction models, mainly decision trees. It creates the model like other boosting methods do, but it generalizes them by allowing optimization of an arbitrary differentiable loss function. Gradient boosting was first presented in 1997 [2],

and has been refined over the last decade. There are many different implementations:

- XGBoost – an algorithm written by Tianqi Chen [3]. Probably the best known and most used implementation.
- LightGBM – Microsoft’s algorithm [4].
- Catboost – an algorithm by the Russian company Yandex, designed to deal with categorical data [5].

LightGBM has many of XGBoost’s advantages, including sparse optimization, parallel training, multiple loss functions, regularization, bagging, and early stopping. A main difference between the two lies in the construction of trees. LightGBM does not grow a tree level-wise – row by row. Instead it grows trees leaf-wise. Besides, LightGBM does not use the sorted-based decision tree learning algorithm as XGBoost. Instead, it implements a highly optimized histogram-based decision tree learning algorithm, which yields great advantages on both efficiency and memory consumption. The LightGBM algorithm utilizes two novel techniques called Gradient-Based One-Side Sampling and Exclusive Feature Bundling which allow the algorithm to run significantly faster while maintaining a high level of accuracy.

We can find many examples of LightGBM being used in machine learning competitions [6].

III. FEDCSIS 2022 CHALLENGE

A. Data

The available training data set [7] contains a five-year history of contracts accepted by a Polish company. It consists of two main tables. The first one contains basic information about the contracts (36 features), and the second one describes the main sections of the planned routes associated with each contract (60 features). In the train set, we have 330 055 contracts and in the test set, we have 72 452 contracts. In addition, participants had an additional table (4 features) containing historical wholesale fuel prices.

B. Task

The theme of the competition was to forecast the costs associated with the execution of forwarding contracts, based on data from contracts and planned routes. The goal of the

competition was to prepare and develop a model that forecasts the costs of individual orders as accurately as possible.

C. Evaluation

The solutions were assessed by the root mean square error:

$$\text{RMSE} = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2},$$

where y_i is an observed value, \hat{y}_i is a predicted value and n is the number of data records in the data set.

Initial scores were evaluated via the KnowledgePit online platform [8] and published on a challenge leaderboard calculated on a small subset of the test set fixed for all participants. The final score was published after the challenge using the remainder of the test data set.

IV. DATA PROCESSING

Data from both main tables were used for training. Since the data in the second table contains at least 2 rows for each contract (one row for each route step), it needs to be processed accordingly. In this case, the choice was made to include information for step two of the planned route with each contract. In addition, average monthly fuel prices are added for each contract, calculated from an additional third table, based on the month the route began. This resulted in a training data size of $330\ 055 \times 98$. Descriptions of each column can be found on the competition page [8].

A. Adding new features

Intuitively, an important factor affecting the price of the contract is the route duration, so a new column was created: `hours_diff` – the difference between `route_end_datetime` and `route_start_datetime` expressed in hours. The natural logarithms (with a lower bound equal to -1) of the following features were then created: `hours_diff`, `km_total`, `km_nonempty`, `km_empty`, `train_km`. Pearson correlation coefficients increased significantly for the first three characteristics listed. For example, for `hours_diff` it is 0.63, but for its logarithmic version, we get 0.89.

The numerical columns `train_intervals` and `ferry_intervals` were transformed into categorical variables with values of "0", "1", and "2+", which correspond to their numerical values.

At this point, it is worth mentioning that we used the Microsoft's FLAML library [9] (version 1.0.1). It contains many facilities, one of which is the automatic generation of the following numeric features for each datetime feature: year, month, day, minute, second, day of the week, day of the year, and quarter.

B. Repairing route datetime data

Real-world data from companies typically contains human errors. This case is no different. By checking in how many cases `route_start_datetime` is later than `route_end_datetime` we get 47 (0.01%) samples in the training set and as many as 405 (0.56%) in the test set. We see that for the training set, this is a

very small number of examples that could easily be removed. However, in the case of the test set, this could determine the outcome of the competition.

Unfortunately, we don't know what this data should look like. Nevertheless, in reviewing this data, there are two types of errors:

- 1) Dates are in the wrong order.
- 2) The month or day was entered incorrectly.

The `route_start_datetime` and `route_end_datetime` are based on the `estimated_time` column from the second table, which contains information about the planned time of arrival at a given route step point, so it was the values from this column that were corrected. This was done with a simple script and then verified manually. Incorrect datetimes typically occurred for the first 2 or 3 steps within a given contract and were the same with date accuracy (no time information). For each contract, initial datetimes equal in date were selected. For simplicity, we will use a single date. In the first case the difference between the selected date with the last date was checked, if they were less than 14 days then selected datetimes were moved to the last places. If a type 1 error was not detected, the presence of a type 2 error was checked. Here we compared the number of days for the selected date and the next date after it (let's call it a comparison date). Assuming we have 1 after 31 and each month has 31 days, then if all we had to do was increase the number of days of the selected date by a maximum of 7 to get the number of days of the comparison date, we set the month and year of the selected datetimes to the largest possible so as not to exceed the comparison date. Any other instances, e.g., incorrectly entered days, were corrected manually through individual decisions.

C. Deleting some data

Often, some of the data we have is unnecessary and may even degrade the performance of the model. By comparing the values of the `id_currency` column, we can see that the training set has 6 unique additional values than the test set. Similarly, for the `step_type` feature from the second table, we obtain one unique redundant value in the training set. The temperature column, which reports the temperature level in a refrigerated trailer, was removed due to the high percentage of missing values (89% in both the training and test sets) and the way the values in it were recorded. This is string-type data with individual temperatures, temperature ranges, or additional information about the cooling mode. We have 760 unique values in the training set, 194 in the test set, and 99 values common to both sets.

After removing such contracts from the training set, and after removing the `id_contract` and temperature columns, we obtain a data set of size $329\ 349 \times 102$. These operations did not result in a large reduction of the data set, as the number of rows decreased by only 0.21%, but we still got rid of unnecessary data.

FLAML automatically discards features with constant values during training. In this case, we had 5 such features, all from the second table: `step`, `train`, `train_km`, `train_line`, `tail_fin`.

Fig. 1. Relationship between km_total and hours_diff (test set).

V. MODEL

A. Training strategy

LightGBM models, among other things, automatically perform feature selection and handle missing values. So what remains is the selection of appropriate hyperparameters. The FLAML library has solutions for this purpose. It offers two methods to optimize hyperparameters: CFO [10] and Blend-Search [11]. Both methods require a low-cost initial point from which the search begins if such a point exists. In the case of the former, the search gradually moves toward higher-cost regions if needed. It is a local search. The latter method combines the local with global search, i.e., it starts checking new starting points before the local search reaches full convergence. We used the “auto” mode to select the method, which should result in the selection of the CFO.

B. Output scaling

Since the training set contained data from 2016-01 to 2020-10 and the test set from 2020-09 to 2021-11, we decided to scale the model output. Outputs for the 2020 test data were multiplied by 0.998, while outputs for subsequent months of 2021 were multiplied by 1.001, 1.002, up to 1.011.

A measure like RMSE is sensitive to single, large errors. Thus, model errors for outliers can significantly degrade the final result, and the occurrence of outliers can be easily observed in Fig. 1. Hence, the idea was born to additionally scale values for samples that may be outliers. Thus, in the next step, for the selected points suspected of being outliers, the corresponding model results were multiplied by 1.01.

C. Outlier detection

Some of the most popular methods for finding outliers are isolation forest [12] and local outlier factor [13]. An isolation forest was chosen because of its shorter operating time.

In this case, it is necessary to pass only numeric type features to the model. The datetime type features have been removed and the corresponding year, quarter, month, and day of week features have been added in their place. In addition, the data set was expanded to include values for step one and last step from the second table (in some cases step two = last step). Next, columns with constant values and categorical features with more than 5% of missing values were removed. In other cases, they were imputed with the most frequent value. 2 of them were two-valued, so they were mapped to binary values. The Target Encoder was then fitted on the training set, i.e. the average target value for each class was taken.

The popular open-source machine learning library scikit-learn [14] (version 1.0.2) was used to train the model (with default hyperparameters). Mentioning this is important for the interpretation of the results since in this implementation the scores returned by the isolation forest can take negative values.

For points for which the isolation forest score was less than -0.05 , were from 2021, and hours_diff was greater than 50 the final values were increased an additional 1%.

VI. EXPERIMENTAL RESULTS

A. Hyperparameter tuning

The final solution was created using an Intel Core i5-8300H processor and 16 GB of RAM (DDR4, 2400 MHz) on Microsoft Windows 10. It was found after 1617 seconds, with the search time set at 1800 seconds. During this time, the model scored 12 times better on the validation set (10% of the training set). To evaluate the quality of the model, we used the same measure as in the competition, the RMSE. After 33 seconds, we reached an RMSE of 0.1438, and the final model obtained an RMSE of 0.1298. Increasing the search time to 2700-3600 seconds can achieve an RMSE of 0.1265, but such models gave very poor results on the public competition test set, for instance: RMSE = 0.1530.

B. Obtained model

The selected model consists of 5243 trees, with a maximum number of 509 leaves in a single tree, the exact values of all tuned hyperparameters [9] can be found in Table I. Unfortunately, due to the size of the trees, we cannot visualize them in a meaningful way, but for practical reasons, the importance of individual features during prediction is useful. For this purpose, we will use total gain [3]. The features with the highest values are shown in Fig. 2. Unsurprisingly, we see that the distance traveled and the route time have a very large impact on the final prediction result.

On the public part of the test set, the model achieved a score of 0.1458. Here we can see that correcting the dates in Section IV-B was the right thing to do, because without it we achieved a score of 0.1469.

TABLE I
FINAL HYPERPARAMETERS (TO FIVE DECIMAL PLACES).

Hyperparameter	Value
n_estimators	5243
num_leaves	509
min_child_samples	8
learning_rate	0.01079
log_max_bin	6
colsample_bytree	0.34362
reg_alpha	0.00198
reg_lambda	0.01343

Fig. 2. The 15 features with the highest value of total gain. The features in the first table have been colored in blue, and those in the second in green.

C. Model output handling

The scaling idea was born out of the large discrepancy between the results on random subsets of the training data and the public portion of the test set. After using scaling of the model output described in Section V-B to the model from Section VI-B, our result improved. In this configuration, the RMSE on the public part of the test set is 0.1438. As can be seen, the intuition was correct, since linear dependencies with a precision of one month should be easily learned by the model, so they were not present in the training data. The reason may have been inflation was not openly recorded in the data.

Since such simple scaling does not exhaust the possibilities for improving the score, we used the isolation forest to look for values worth further improving. As a result, the RMSE changed from 0.1438 to 0.1434.

VII. CONCLUSIONS

This paper presents a powerful regression model that can deliver excellent predictions of the costs of forwarding contracts. We chose the LightGBM, because of its simplicity and

speed. The model achieved the performance of the RMSE score of 0.1420 on a test set placing fourth (out of more than 50 teams that added a total of nearly 2 000 correctly formatted solutions) in the FedCSiS'2022 competition. Our model lost by only 2.606% to the best solution and lost only 0.9155% to third place. At the same time, it was better than the baseline model (baseline model placed fifth) by 3.873%. Worth adding, that the model got better final results than the results on the preliminary data set (0.1434). In addition, it is worth emphasizing that all calculations were performed in less than an hour on the average CPU.

The solution is pretty simple, so we have a lot of options here in terms of future work. For example, the topic of scaling model output is not exhausted. The idea of scaling outputs for points suspected of being outliers came up on the last day of the competition, so this was tested very briefly. So it is worth checking the outputs for other points suspected of being outliers and other multipliers. Taking it a step further, it is possible to see if the multiplier can be calculated for each point separately depending on some features.

 Email: lpodlowski@opi.org.pl; mkozłowski@opi.org.pl

Abstract—This article presents an application of an XGBoost and deep neural network ensemble as a solution for a task assigned at the FedCSIS 2022 Challenge: Predicting the Costs of Forwarding Contracts. We demonstrate that prediction quality can be improved by combining the two approaches. We present a neural network architecture based on three independent flows. We then discuss the influence of long short-term memory units on the risk of overfitting. Finally, we show that the static XGBoost model can complement a neural network that processes dynamic data.

Index Terms—XGBoost; deep neural network; LSTM; Costs of Forwarding Contracts

I. INTRODUCTION

COST estimations are an imperative factor in business decisions in the transport sector. Researchers have demonstrated that due to a variety of dependencies, the price estimation of shipments in the shipping industry is frequently complex. Based on these studies, shipment pricing methods can be classified into two major classes: scenario-based pricing methods and algorithmic pricing. This article focuses on the former.

We concentrate on the logistical problem of predicting the costs of executing forwarding contracts. Our work relates closely to the FedCSIS 2022 Challenge: Predicting the Costs of Forwarding Contracts¹, which was organised in association with the Conference on Computer Science and Information Systems (<https://fedcsis.org/>). The competitors were tasked with designing high-quality methods for predicting the costs associated with forwarding contracts based on many features that describe key contract data and planned routes.

The competitors' task involved developing a predictive model that assessed the actual costs of individual orders as accurately as possible. Such models will be used in the future to support freight forwarders in the selection of profitable contracts.

II. RELATED WORK

The need for transportation arises from the need to move goods from one place to another in line with consumer demand. Sea transportation is one of the cheapest and oldest modes of transportation of goods. During the last twenty years, seaborne trade has accounted for approximately 80% of the

world's and 90% of developing countries' total trade volume. According to recent statistics, since the 1980s, global seaborne trade has increased in size almost threefold, and containerised trade has increased also [1]. The goods delivered to major sea ports are next distributed by road or by rail. The global weight of loads in ports and the density of road/railway link networks continues to increase steadily. This means that the problem of optimal planned deliveries has become a significant challenge.

The article of Joo, Min, and Smith [2] presents an entire framework for benchmarking freight rates based on current and historical data. This is one of the first articles to examine shipping cost differentials between different shippers and to determine their causes.

The authors of [3] address the research gap of optimal spot shipment price calculation based on current shipment demand and available shipping capacity. The authors gathered data from various sources to generate a shipping dataset for 2016–2018. They use regression and correlation analysis to quantify their research outcomes.

A fuzzy regression forecasting model was introduced in [4] to forecast demand by examining the current international air cargo market. The difficulty of such forecasting derives primarily from individuals' differing perceptions of their socioeconomic environments and their competitiveness when evaluating risk. The main purpose of using fuzzy regression is to resolve these uncertainties and specificities while accommodating individuality.

Many long-term and long-distance transportation services are offered now via various types of auction; firms in the sector must deliver competitive prices if they want to win the competitions. The article of Nataraj et al [5] explores the application of forecasting and statistical learning methods to enhance the competitiveness of firms when applying for tenders. The authors use time series analysis to: (i) forecast the long-term cost of logistics services; and (ii) construct 'risk-aware' intervals for the prices to be offered in bids.

Yang and Mehmed [6] adopt an artificial neural network to forecast shipping freight rates. The key objective of their work is to improve the forecasting accuracy of traditional time series analysis. They evaluate the accuracy of their forecasting models using the mean square error with historical data. The authors used two different dynamic artificial neural network models, NARNET and NARXNET, and compared their per-

¹<https://knowledgepit.ml/fedcsis-2022-challenge/>

formance. The experimental results suggest that, in general, NARXNET outperforms NARNET in all forecast horizons. This reveals the importance of the information contained in forward freight agreements in improving forecasting accuracy.

In 2022, Adrian Viellechner defended his PhD dissertation [7] on the application of machine learning models to transportation forecasting. First, Viellechner analyses the container shipping industry to predict delays of vessels. In his second study, he presents how machine learning methods can be applied to predict spot rates in container shipping. With accuracy of 89%, his forecasts support the decision-making of various shipping players in the negotiation of transportation contracts. By proposing prediction solutions that feature high accuracy, robustness, and applicability in practice, Viellechner's dissertation demonstrates that machine-learning-based solutions enhance effectiveness in transportation.

III. PROBLEM DESCRIPTION

The problem involves predicting the current costs of individual orders using detailed information, such as the type of order, the basic characteristics of the shipped goods (e.g. dimensions, special requirements), and the expected route that a driver would traverse. Using machine learning approaches, our goal is to create an accurate regressive method for predicting the costs associated with forwarding contracts; one that is based on contract data and planned routes. We evaluate the regression models using the root mean square error measure.

IV. DATA

The accuracy of the forwarding contract cost prediction method depends heavily on the quality and quantity of the training data.

The datasets made available to the competitors contained six years of order history that appeared on the transport exchange, along with details such as the type of order, the basic characteristics of the shipped goods (e.g. dimensions, special requirements), and the expected route that a driver would traverse. More details about competition and data are presented in [8].

V. DATA PROCESSING

A. Data preprocessing

The initial step of the data's preprocessing involved translating categorical features into one-hot encoding. We set the minimum threshold for any categorical value at 2,500; if the value occurred fewer times than this threshold, we translated it as 'unknown'. We used a regex-based method to extract minimal and maximal temperatures. When information about temperature was unavailable, we filled it in with a constant value of 35. We assumed that high temperatures did not increase contract costs, and that 35 was a neutral value. Since the dataset does not contain this value in the temperature column, it allows the model to handle situations when the absence of temperature data is relevant for undisclosed reasons. Our future experiments showed temperature information increased prediction quality. Based on date information associated with

journey start dates, we matched fuel prices and added them as an additional column to each row.

We will refer to the dataset outlined above as our base set. We adopted a different approach for the neural network and XGBoost models to use the additional data included in the sequences of steps corresponding to each row from the base set. For XGBoost, we aggregated additional information, such as how many times an external fleet was used in the transport process, or how many times a specific country was visited. For the neural network, we removed some columns from the sequence data, such as cargo hold height and width, and treated this data as a fixed-size window of twelve steps. Approximately 0.4% of the sequences included in training set were longer, which forced us to cut off the sequences' tails to a fixed twelve-length size. Approximately 99.6% of sequences were shorter; to solve this difficulty, we padded the sequences with zero vectors. We choose sequences size respect to balance between computation complexity and prediction quality. We found out based on the cross-validation that lower sequence size increased prediction error.

Our first experiments revealed large differences between the cross-validation results and the preliminary scores. This led us to the conclusion that our models were overfitted. These differences disappeared, however, after we disabled the shuffling of the data during the cross-validation procedure. We supposed that the dates included in the training set could lead to the model becoming overfitted.

We assumed that date relations with target values would suppress the recognition of other patterns. To avoid this situation in our subsequent experiments, we prepared an additional set with the date information removed to make it more difficult for the model to build a relation between start times and predicted expenses.

VI. PREDICTION MODELS

We used two different models: XGBoost and a deep neural network(DNN). We intended to compare the approaches and to verify whether the two models could be complementary in the regression problem embedded in sparse space. Significant differences exist in the training data prepared for each model. XGBoost naturally models static data and cannot handle dynamic data directly. For this reason, all information from the sequences is aggregated then presented as scalar values for each row from the base set. This method introduces the risk of eliminating important information from the data included in the order of steps in a sequence.

The deep neural network can handle dynamic data using a recurrent approach. We used popular long short-term memory units, which are known for their high efficiency and have proved their worth in a wide range of fields, including machine translation [9], financial market forecasting [10] and air quality prediction [11].

Long short-term memory is commonly used with one-hot encoding in various problems, such as electric load forecasting [12] and the construction of intelligent agents that play video games [13]. We used long short-term memory to enable the

models to extract important information from the order of sequences, encode it in a static space, and use it with the static data included in the base set.

We encoded the date as a number of minutes starting from 1st January 2016. We allowed XGBoost to operate on date information; we removed this information from the dataset of the deep neural network, however. For the final prediction, we used the strategy of split data set into 75% train and 25% test. For XGBoost this split was done randomly but for a DNN we used the oldest 25% of data as a validation set.

A. XGBoost

From a theoretical perspective, tree-based methods should naturally fit to data with mixed domain values. This suggests that any ensemble of trees is an effective choice for concatenate categorical features with other domains, such as the distance between two cities or temperature. Tree-based methods are limited to static data, which could lead to the loss of important information from the sequences. We accepted that risk and selected XGBoost as our base model.

Our first experiments were based on a fourfold cross-validation method. We achieved an impressive root mean square deviation of 0.1324. However, our preliminary result, evaluated on a small part of the test set, was 0.4047, which was significantly worse. In this paper we call this model XGBoost CV-optimized. We observed that the root mean square deviation based on cross-validation increased to 0.158 when we disabled data shuffling. This suggests that the data contained some undisclosed information associated with time, which led to overfitting. From this point, we based each step only on 75% of the data; we used the remainder as a validation set for the training procedure. The experimental values are presented in Table I.

To prevent overfitting, we explored the possibility of increasing the model's regularisation parameters. We decreased subsampling to 0.8, which forced the model to randomly skip some rows in training iterations. We also increased the regularisation λ parameter, which corresponds to L2 regularisation. This approach forced our model to become more conservative and less likely to overfit. Adjusting both parameters decreased the gap between the final score and the cross-validation result. Our experiments failed to reveal any opportunity to increase the α parameter, which corresponds to L1 regularisation without significantly lowering the quality of the model's predictions.

To find a reason for the high error of XGBoost CV-optimized predictions, we compared feature importance tables of our models. We recognized that the CV-optimized model increased the importance of specific categorical values. The biggest difference was the importance of the 'unknown' *prim ferry line* value generated by the procedure described in V. Importance for this value increased from 0.0001 to 0.08. We also noticed that XGBoost CV-optimized tended to be more confident on every localization feature corresponding to country code like *route start country* or *first unload country*.

B. Deep neural network

Our second model was based on a neural network. We decided to allow fully-connected layers to encode the inputs before we concatenated them into fully-connected layers operating on the whole data. The input was divided into three independent flows:

1) *localisation data*: static data from the base set, including all information about geolocalisation associated with route starts and ends, as well as first loadings and last unloadings. These vectors contained latitudes, longitudes, and country codes.

2) *general data*: static data from the base set, including all information not included in the localisation data.

3) *sequence data*: vectors that represent fixed-size sequences of route steps. Applying long short-term memory units enabled us to handle dynamic data and to transform sequences to static fully-connected rectifier layers.

To prevent overfitting and the local minima trap, we added small Gaussian noise layers to the inputs. These layers guarantee the training process to be out of balance, which prevents the local minima trap. The amount of information in a weight can be controlled by adding Gaussian noise and the noise level can be adapted during learning to optimise the trade-off between the expected squared error and the information in the weights' [14]. Adding noise to the input also enabled us to control the degree of fitting to the data. Additionally, we used dropout with $p = 0.4$ to each layer, which decreased the probability of the model's overfitting [15]. The network architecture is presented in Figure 1.

For the training network, we used the Adam optimiser [16]. Adam automatically adapts parameters to training, which enabled us to avoid the arduous process of training tuning on the mixed domains. We repeated the training process after the competition ended to gain greater insight into the deep neural network's results. For this training, we used all of the testing data as a validation set. We present a chart of root mean square errors during the training process in Figure 2. We can observe that the training process is highly chaotic initially, and that the validation root mean square errors rapidly reduce to 0.158 – 0.16 before stabilising. It is noteworthy that the chart begins from the twentieth epoch. The best result achieved in this experiment was 0.1564.

To analyse the influence of the sequential data flow processed using long short-term memory units, we prepared an additional deep neural network with similar architecture, but without the sequential data flow. The error observed in the training process is presented in Figure 3. We made two key observations associated with the overfitting risk:

- The deep neural network with long short-term memory tends, as it continues to train, to enlarge the gap between training and the validation data much faster than the network without sequential data flow. This could be the result of the network's increased capacity, or could suggest that information about the order of the sequences misdirects the training process. Both reasons lead easily to overfitting.

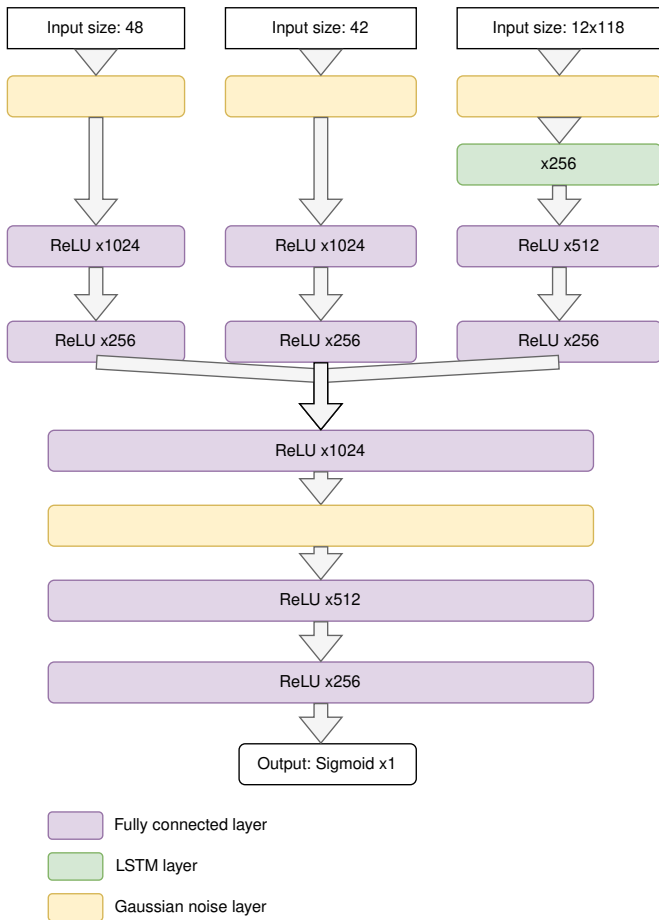

Fig. 1. The architecture of the deep neural network used as one of the solutions to a defined problem.

- The deep neural network without long short-term memory tends to gain and lose the optimisation target in each epoch in an increasingly synchronised manner. The shapes of the training and validation error curves correlate more closely on this network.

We conclude that long short-term memory would extract important information from the dataset and increase prediction quality but should be used carefully because of the overfitting problem.

VII. RESULTS

To generate the final prediction, we used an ensemble of the XGBoost and deep neural network models as the arithmetic mean of both predictions. As illustrated in Table I and Figure 4, this ensemble reaches the best result of 0.1498. This root mean square error value is significantly better than the results of the individual models, demonstrating clearly that the deep neural network and XGBoost extracted different information from the complementary data. In the training process, we used the splitting data strategy described in VI. This strategy lets us have better control over the overfitting.

Fig. 2. The root mean square errors during the deep neural network's training process. The blue series represents error on the training data; the orange series represents error on the whole validation set—which corresponds directly to the final scores of the competition.

Fig. 3. The root mean square errors during the training process of the neural network without sequential data flow. The blue series represents error on the training data; the orange series represents error on the whole validation set—which corresponds directly to the final scores of the competition.

Our cross-validation-optimised XGBoost model reaches a root mean square error of only 0.404, which is significantly worse than the other models. We failed to identify precisely which factor caused the overfitting. Future experiments that focus on the analysis of smaller parts of the dataset should be performed to gather detailed information on this problem.

VIII. CONCLUSIONS

This article presents our solution to the FedCSIS 2022 Challenge: Predicting the Costs of Forwarding Contracts. During our experiments, we identified an overfitting problem, which had a significant impact on subsequent steps. We prepared two approaches: XGBoost and a deep neural network. We demonstrated that the application of a long short-term memory

TABLE I

EXPERIMENTAL RESULTS: PREDICTION QUALITY ROOT MEAN SQUARE ERRORS BASED ON CROSS-VALIDATION AND PRELIMINARY SCORES

Model	CV	Preliminary	Final score
XGBoost	0.153	0.1522	0.15252
XGBoost CV-optimized	0.1324	0.4047	0.40394
Deep Neural Network	0.1581	0.1585	0.15815
Ensemble	-	0.1500	0.14978

Fig. 4. Root mean square errors based on three experiments: fourfold cross-validation (blue), preliminary scores, and final scores.

layer to sequential data improves the results; however, it also increases the probability of overfitting. We demonstrated that combination of the deep neural network and XGBoost is potentially complementary, significantly increases prediction quality, and serves as a possible solution for mixing dynamic data with the static XGBoost approach.

 hieuvq@vng.com.vn

Abstract—A common business practice for transportation forwarders is to bid for shipping contracts at the transport or freight exchanges. Based on the detailed contract requirements they try to estimate the total expected cost of its execution and accordingly bid with the fixed price in advance for delivering such shipping service at the prescribed specification and schedule. The capability to accurately predict the cost of contract execution is the critical factor deciding about the profitability of offered shipping services as well as the amount of business drawn from freight exchanges. However, given highly volatile nature of the transport services ecosystem, it is difficult to simultaneously account for countless dynamically changing factors like fuel prices, currency exchange rates, temporal and spatial multitude of routing and implied traffic risks, the properties of cargo and shipping vehicles etc., which leads to big cost under- or over-estimation resulting with loss-making contracts or equally painful missed revenue opportunities. In the context of FedCSIS 2022 data mining competition we propose an accurate and robust predictor of the cost of forwarding contracts built upon the detailed contract data using the ensemble of the state-of-the-art gradient boosting-based regression models. Our established feature engineering framework combined with deep parametric optimization of the individual models and multi-faceted diversification techniques guiding hybrid final model ensembles were instrumental to outperform all the competitive predictors and win the FedCSIS 2022 contest.

Index Terms—Cost Prediction of Forwarding Contracts, Gradient Boosting Trees, CatBoost, XGBoost, LightGBM, Stacking, Diversity, Model Diversification, Ensemble Learning.

I. INTRODUCTION

WITH the development of IoT (Internet of things), e-commerce and continuous globalization, the business providing logistics service and involving supply chain for supply chain planning functions or transport management has become increasingly important. Big data analytics for intelligent transportation and prediction analysis with machine learning techniques have boosted management of transportation and logistics by providing intelligent solutions aiming for more efficient and safer transportation at cheaper cost. In the recent years, the technologies of data mining and machine learning have been applied to investigate a range of issues in international freight transportation, supply chain and logistics management, e.g. driver behavior analysis [2], [3], origin-destination parameter estimation [4], pavement maintenance [5], traffic control and forecasting [6], [7], [8], freight logistics [9], air traffic management [10], vehicle classification [11], travel time prediction [12], traffic pattern analysis [13], freight

demand prediction [14], traffic volume forecasting [15], transportation cost forecasting [16], etc. A good literature review regarding utilizing machine learning on freight transportation and logistics applications has been published in [18].

The objective of the FedCSIS 2022 challenge [1]¹, which is in cooperation with PTI and QED Software and sponsored by Control System Software², is to forecast the costs of forwarding contracts, which are, although rather useful in the business providing logistics service or involving supply chains, quite challenging since it can be affected by many static/dynamic and internal/external factors. Besides contract nature and transportation arrangement, the actual transportation cost is constrained by the factors such like fuel prices, currency exchange, drivers behavior, weather, traffic, market demand, etc [16]. There is quite little work published in the literature on cost prediction of forwarding contracts. In [17], AI based models were developed to predict the long-term cost of the logistics service, and attempted to construct a risk-aware interval for the prices to be offered in the bid, aiming to boost competitiveness in the application for tenders. In addition, historical data was used to develop statistical learning models for predicting the success likelihood of a tender based on the actual data and predicted service prices achieved from previous stage. The work proposed in [16] identified the most significant predictive criteria by a trapezoidal neutrosophic fuzzy analytical hierarchy process (TNF-AHP) and based on the criteria found the transportation cost was predicted with an artificial neural network (ANN) model, which, claimed by the authors, can also be employed in supply chain management and inventory control management.

In this paper, an ensemble learning model based on gradient boosting decision trees together with efficient feature engineering and model hyper-parameter optimization has been developed for predicting the costs of forwarding contracts to complete the task given in FedCSIS 2022 challenge. Gradient boosting decision trees (GBDT), developed in the late nineties, is a commonly used boosting methods for solving regression and classification problems in the form of an ensemble of decision trees as weak prediction model, which achieves state-of-the-art results for many commercial and academic applications [19], [20]. In the GBDT, each new model correlates

¹<https://knowledgepit.ai/fedcsis-2022-challenge/>

²<https://controlsystem.com.pl/>

to the negative gradient of the system's loss function that is minimized by using the gradient descent method, which is successively fitted to delivery better estimation of dependent variables via training, resulting in gradual improvement of prediction accuracy. Three efficient GBDT implementations, i.e. XGBoost, CatBoost, and lightGBM, which have shown their powerful learning capabilities by many winning teams in a number of machine learning competitions, are employed to construct the ensemble learning model for forecasting the cost of contract forwarding in our method.

The remainder of the paper is organized as follows. The FedCSIS 2022 Challenge is briefly described in Section II. Data transformation and feature engineering is presented in Section III, followed with the description of the gradient boosting models, model diversity, and ensemble learning in Sections IV, V and VI, respectively. The experimental results in Section VII. Concluding remarks are provided in Section VIII.

II. FEDCSIS 2022 CHALLENGE

The FedCSIS 2022 data mining competition focused on the prediction of the costs of forwarding contracts' execution based on 6 years of detailed history of orders on the European transport exchange. The data contained both the general information about the contracts as well as detailed data of planned routes' segments including geo-located and timed path, specification of shipping vehicles and cargo and even financial details including daily currency rates and wholesale fuel prices. The objective of the competition was to develop a prediction model to accurately estimate the total cost of the contract execution based on all available data. The competitors were provided with the training data from 330055 contracts along with the true realized cost, as well as the testing data from 72452 contracts but without the realized cost. The knowledgepit.ai platform³, on which the competition was hosted operated a leaderboard, which provided the feedback to the competitive model prediction submissions in a form of the preliminary RMSE score⁴ computed over the unknown 10% of the testing set, while the final RMSE score for the complete testing set - constituting the final results, were provided after the submissions' closure.

III. DATA TRANSFORMATION AND FEATURE ENGINEERING

The data provided by the competition organizers included already a well curated, cleaned and carefully selected set of features, however only main dataset providing general contract details was organized in a tabular format of one row (record) per forwarding contract. The extended route data, on the other hand, contained detailed records of between 1 and 31 subsequent steps of the planned route segments of the same contract and hence it became immediately clear that in order to build a competitive cost prediction model all the individual steps data would have to be incorporated hence eventually somewhat aggregated per each contract. We

have developed a generic aggregation filter and applied it all useful columns of the detailed route segments dataset to achieve per-contract aggregates. For numerical columns eleven self-explanative aggregators were applied: 'first', 'last', 'min', 'max', 'argmin', 'argmax', 'mean', 'mode', 'sum', 'range', 'std'. For categorical columns the aggregation treatment was made dependent on the number of unique values. For more than 100 unique values the occurrence of each value was considered sparse enough to limit the aggregation to just the four operators of 'first', 'last', 'mode', 'nuq', where 'nuq' simply denotes the number of unique elements. For categorical columns with fewer than 100 unique values aside of the above-mentioned 4 categorical aggregators we have also applied one-hot-encoding on the original feature and with thereby up to 100 new numerical columns we have applied again all the 11 above-mentioned numerical aggregators to receive quite a large number of final features in the order of thousands. To avoid redundancy and wasteful poor quality features we have automatically eliminated duplicate features and removed features with at most one unique value different than nan/null, which typically resulted in the final set of up to 2000 features.

We have also included features that measured country disagreement between the origin and destination, extracted days of the week, various expected segment duration and the prices of different type of fuel during the trip segment days. Among the alternative but less successful data preprocessing techniques we have explored flattening all trip segments along the single contract record of up to 31 possible segments as well as organizing the data as sequences of consistent route step segments.

IV. GRADIENT BOOSTING MODELS

Preliminary experiments on the main dataset very clearly revealed that gradient boosting models performed by far the best in terms of the reference predictive accuracy and actually quite well in terms of the computational cost, even comparing to simple linear regression and by far comparing to deep networks. Among gradient boosting models XGBoost, LightGBM, CatBoost were used and subsequently optimized throughout the competition. Their variants trained on different parameters were utilized for second level ensembles both executed by simple aggregation and by stacked retrained ensemble of gradient boosting model versions.

A. Individual models' parametric optimization

Current state of the art Machine Learning models are highly customized and flexible to accommodate a very wide range of different options, versions and parametric settings during the model build. Gradient boosting models are good examples of such models with tens of algorithmic, representational, modelling and statistical parameters available to tune in to best fit or represent the data and ultimately to learn robust regression function between the inputs and the continuous output that generalizes well on the previously unseen data.

Given a set of distinct models each with a large numbers of parameters to tune we have decided to apply fast greedy,

³<https://knowledgepit.ai/>

⁴https://en.wikipedia.org/wiki/Root-mean-square_deviation

rotational grid search for each of the gradient boosting models: XGBoost, CatBoost and LightGBM. Each optimizable parameter, whether numerical or categorical is assigned up to 5 unique values comprehensively covering the domain of this parameter. Contrary to the exhaustive parametric grid search, which given the numbers of parameters in our case would prove intractable, our method incrementally finds local optimum of a specific parameter with remaining staying fixed, before rotationally progressing to the next until no improvement can be found from any local change. To further boost the reliability of the best found configurations of parameters we have applied 5-fold cross-validation to rule out accidentally high performance, yet as a consequence to limit an additional cost of cross-validation the process of local optima search for each parameter was reduced to just a pair of neighbouring checks: above and below the current value per turn and shifting the current optimal to the value for which the maximum performance improvement was reported.

This parameters optimization process is terminated when no improvement in cross-validated RMSE performance was found from any local changes of parameters.

V. MODEL DIVERSIFICATION TECHNIQUES

Well performing but diverse models produce diverse outputs which after aggregation produce significant reduction of both variance and bias error components. The critical challenge here is how to develop diverse but well performing models and also to which degree worse performing but quite diverse models are still worth combining to achieve the performance gain. We have developed two generic diversification methods applicable to gradient boosting models. The first method focuses on maximizing the number and magnitude of differences between as many parameters as possible of the same model. The second method takes specific categorical focal feature with a few unique values and proceeds with training an array of models specific to each of the unique value of the focal feature. Both method yield good results with parametric-diversity achieving lower levels of output decorrelation but higher individual performances, while decompositional-diversity achieving higher diversity but lower performance mainly due to smaller number of training examples to train on.

A. Parametric model diversification

Parametric model diversification method was developed in conjunction with the parametric model optimization discussed above. The method simply retains model parametric configurations and the corresponding regression accuracy throughout the optimization process and tries to establish the the population of the best performing model versions with the most diverse configurations of the parameters. To assess the level of diversity among model versions' parametric configurations we developed a simple disagreement measure adding up the differences in grid positions of all parameters conceptually similar to the City Block (Manhattan) distance metric. Once all parameter configurations encountered throughout the optimization are evaluated in terms of their performance P and the diversity

measure D , the final step involves selecting k best model versions from the performance-diversity profile which could be associated with the normalized ratio of $D/RMSE$ assuming our performance measure is $P = 1/RMSE$. Selected models versions outputs are then subsequently aggregated using the simple average operator.

B. Decompositional model diversification

It is known that certain level of model diversity, seen as the level of disagreement among model outputs, could be achieved by the training on mutually exclusive data sets. This effect can be further reinforced if the instead of training on random partitions of the training set, model versions are trained on partitions associated with the different values of certain categorical variables as they typically represent significantly different subsets of the available data. It can be justifiable argued, though, that any limitation or reduction of the training set size exposed to the model is likely to reduce its predictive performance. While it indeed could be the case, particularly for the small training data sets, we argue and have experimentally verified that when the data set is large enough and the categorical variable has only very few unique values, the benefits from combining the outputs from that way diversified model versions outweigh the negligible reduction in performance of a single model trained on the whole set. Given all our models utilize the decision tree construction mechanism in the back end, such guided data partitioning could be considered as a forced first splits that branch out into several categorical-variable-value specific tree-based model versions. Given 300k+ size of the training set we have identified several suitable categorical variables with only a few unique values and trained boosting models on subsets corresponding to specific values of these variables obviously without this variable included in the training process. Trained model versions were then applied separately to the testing sets to generate the outputs which were finally combined with the simple mean operator to produce a single output. Figure 1 comparatively illustrates how the decompositional model diversification differs from the traditional individual model build along the training and testing processes.

VI. ENSEMBLE MODEL

In the construction of the final ensemble, we have utilized 3 baseline gradient boosting models: XGBoost (XGB), LightGBM (LGBM), and CatBoost (CatB) subjected to both parametric (DivP) and decompositional (DivD) diversification filters. Diversification techniques are designed to improve the classifier generalization performance by first expanding it into a number of diverse versions, train them on a whole or subsets of the training set and apply them to the testing set before merging the model versions' outputs back together by a simple aggregation. To further boost diversity but also in a search for better complementary predictive performance we have trained all baseline regression models with their DivP/D filters on two different subsets of features generated by our feature engineering engine. The only difference between these two

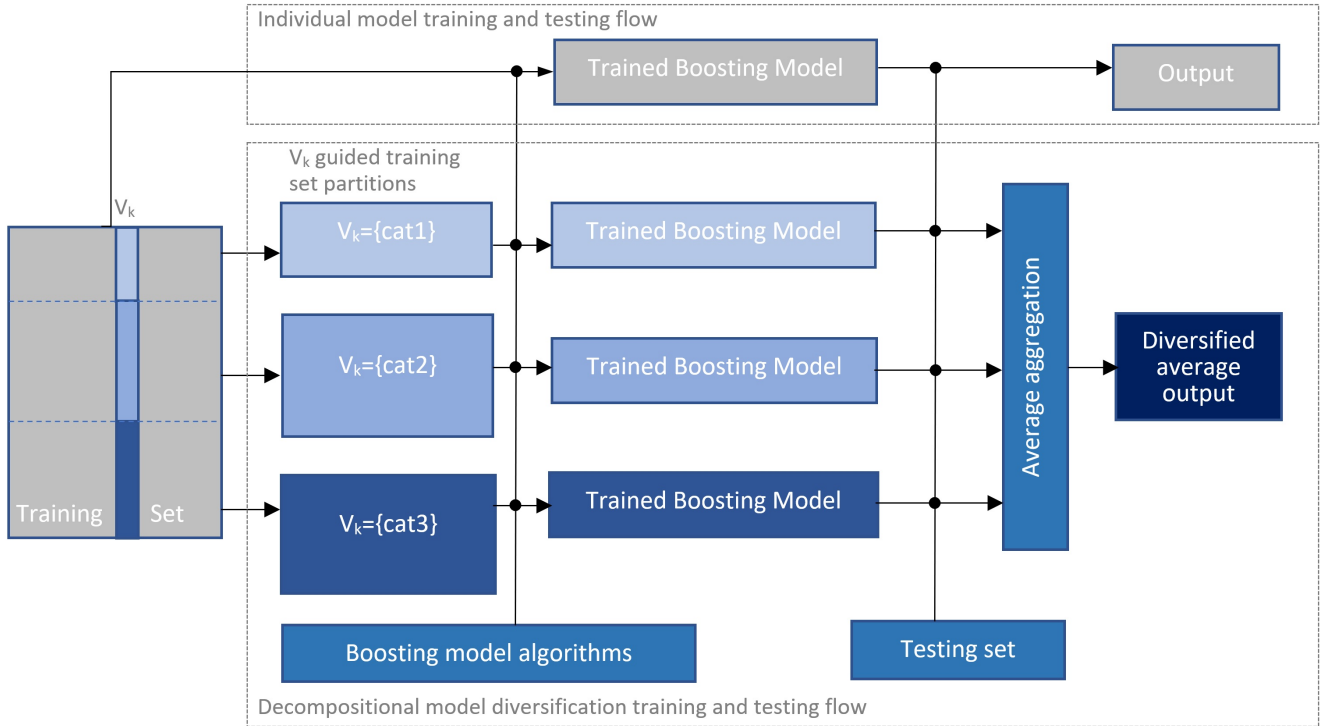

Figure 1. Decompositional model diversification compared to traditional individual model training and testing flow chart.

feature subsets were that the second set included many more sparse columns extracted from much more prolific application of one-hot-encoding to categorical features.

Moreover, in a search for further performance gains we have added another stacked layer of simple linear regression trained on the outputs from diversified baseline models. To properly accommodate stacking layer the training data were split into two parts, one used for building the baseline models and their diversified versions, while the other for learning the parameters of the linear regression in the stacking layer.

Eventually all diversified individual model outputs along with the outputs from linear regression based stacking were averaged together. The architecture or rather flow chart of the final ensemble is depicted in Figure 2.

VII. EXPERIMENTAL RESULTS

To establish a baseline predictability for the presented problem of forwarding cost prediction we first optimized individual gradient boosting models: XGB, LGBM and CatB on two above-mentioned subsets of extracted features and received the following RMSE results along with the optimal parameters returned by the optimization process.

1) Feature set 1 with 894 features:

- CatB (learning rate 0.05, depth 8, iterations 2000): 0.1442
- LGBM (learning rate 0.02, depth 8, iterations 2000): 0.1444
- XGB (learning rate 0.02, depth 1000, iterations 1000): 0.1496

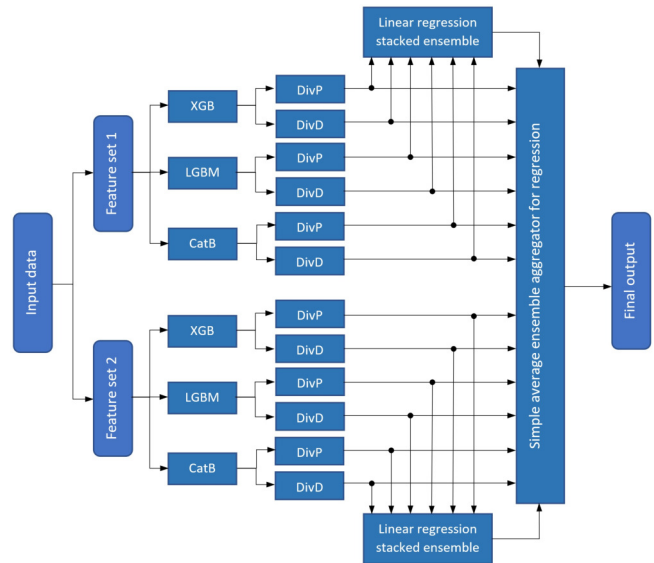

Figure 2. Flowchart of the final ensemble model.

2) Feature set 2 with 3431 features:

- CatB (learning rate 0.05, depth 8, iterations 2000): 0.1513
- LGBM (learning rate 0.02, depth 8, iterations 2000): 0.1494
- XGB (learning rate 0.02, depth 1000, iterations 1000): 0.1640

Secondly, linear regression stacking models were trained on the outputs from the diversified individual models and reported the preliminary RMSE performance of:

- Stacking model with 894 features: 0.1441
- Stacking model with 3431 features: 0.1465

The final predictions are achieved by ensemble averaging of the outcomes from both stacking models along with diversified individual baseline models, yielding the RMSE around 0.141.

A. Visual efficient performance-diversity horizon method for a robust ensemble composition

Even though the ensemble model illustrated in Figure 2 resulted with the best preliminary performance, the journey of incremental model build and performance improvement led to hundreds of model output submissions as potential solutions each with different performance and mutual dependency with the other solutions. Given the submissions represented the outputs from multiple different models with many different versions of the training data, parametric setups and model design choices we have considered them as a final-stage resource for potential further performance improvement through simple aggregation. The question posed in this stage was: given n model outputs with preliminary RMSE scores is it possible to improve the best model result and if so how to achieve the biggest possible improvement.

The intuition backed by the bias-variance error decomposition theorem suggested that the best results should be achieved by combining the outputs from the best performing (model) solutions that differ the most from each other, inline with the diversification techniques discussed in section V. At the final stage when only model outputs and their preliminary scores were available the natural disagreement or resultant diversity measure that could be computed upon the model outputs was an average from the correlation coefficients between the specific model output and all the rest in the considered pool of solutions. After computing such outputs' diversity c_i for all solutions with the preliminary RMSE scores $e_i < 0.152$ we have plotted all such best solutions from our submissions as points (c_i, e_i) on the 2-dimensional diagram depicting dependency $e = f(c)$, as shown in Figure 3.

The points stretching along the bottom horizon approximately marked by the dashed line represent the continuum of the best performing and at the same time the most diverse solutions and are expected to be the most promising choices for final stage combination to achieve the performance improvement. Rather than arbitrarily take some solution for combination along such horizon we have developed a simple greedy algorithm to choose the best solution candidates from around the the horizon for final combination. The greedy sequence in our case is starting from the best performing model in the bottom right corner and then adding the next best model but only out of the more diverse solutions, i.e. from the top solution as a pivot the next solution added is represented by the lowest point to the left from the current pivot. Then the pivot is shifted to the newly added point and process repeats until no more points can be added. Such greedy sequential

addition leads to the staircase connected set of points marked in black along the diversity horizon. The final stage is testing at what point such greedy sequence does not improve the overall ensemble performance any more.

Such method of output-level ensemble combination is particularly effective when a large number of black-box models are suddenly at the disposal and a quick decision is needed on which models' outputs are best to aggregate to maximally reduce the overall predictive error. In our cases the team merger pose an exact situation as described above and following a quick testing a final ensemble output has been generated by aggregation of the outputs from the first 11 models along the diversity horizon, and yielded the top predictive RMSE error below 0.14 and even better result on the full testing set, thereby securing the first place in the FedCSIS 2022 competition.

VIII. CONCLUSIONS

We have attempted to improve predictive performance of the already highly robust regression models from the gradient boosting family: XGBoost, LGBM, CatBoost. To achieve that we have proposed a range of model diversification methods coupled with various ensemble combination schemes. Compositional diversity forced by training on significantly different input data subsets, combined with actively encouraged parametric diversity led to an improvement in performance achieved from aggregation of the expanded diverse model versions, additionally boosted with linear regression based stacking and output level selection of the most efficient ensemble candidates in terms of the performance-diversity trade-off. The proposed ensemble has been applied to the complex problem of advance prediction of the total realized cost of forwarding contracts' based on a variety of data coming in different forms and types, in the competitive setup of the FedCSIS 2022 data mining challenge. Our proposed solution scored the first place in this challenge producing the lowest (RMSE) error below 0.14, which corresponds to only 2% in relative cost in monetary units. The proposed solution can enable forward contractors to better estimate their expected shipment cost, further reducing their business risks and boosting the efficiency across transport services domain.

Abstract—Finding an optimal machine learning model that can be applied to a business problem is a complex challenge that needs to provide a balance between multiple requirements, including a high predictive performance of the model, continuous learning and deployment, and explainability of the predictions. The topic of the FedCSIS 2022 Challenge: ‘Predicting the Costs of Forwarding Contracts’ is related to the challenges logistics and transportation companies are facing. To tackle these challenges, we established an entire Machine Learning framework which includes domain-specific feature engineering and enrichment, generic feature transformation and extraction, model hyperparameter tuning, and creating ensembles of traditional and deep learning models. Our contributions additionally include an analysis of the types of models which are suitable for the case of predicting a multi-modal continuous target variable, as well as an explainable analysis of the features which have the largest impact on predicting the value of these costs. We further show that ensembles created by combining multiple different models trained with different algorithms can improve the performance on unseen data. In this particular dataset, the experiments showed that such a combination improves the score by 3% compared to the best performing individual model.

Index Terms—Costs of Forwarding Contract, explainability, prediction ensembles, Diversified Ensemble Learning

I. INTRODUCTION

TO BE competitive in the market, companies need to be able to utilize all available data and perform analytics to identify hidden patterns [1]. This can allow them to improve their processes, better understand their customers, and make predictions (e.g. churn prediction, service-outage prediction, fraud detection, etc.). To achieve such goals, companies are facing a variety of challenges, ranging from data integration from a variety of sources [1] and finding suitable machine learning models that are both performant but also practical and explainable [2], to maintaining the corresponding infrastructure. To perform such analytical data processing and machine learning on a large scale, companies require a complex computing infrastructure and methods that will minimize their

total cost of ownership [3], and yet scale the computation to multiple nodes [4].

In this paper, we focus on the problem of finding an optimal machine learning algorithm that can be easily applied in a real-life business domain, meaning it should achieve high predictive performance, continuous learning and deployment, and explainability of the models and their predictions. The topic of the FedCSIS 2022 Challenge, hosted on the KnowledgePit portal is ‘Predicting the Costs of Forwarding Contracts’ [5]. The competition addresses the challenges of transportation, shipping, and logistics companies related to their digital transformation. Particularly, the benefits of the research boosted by this competition for such companies can be multi-fold:

- Identify reasons and circumstances that lead to increased transportation costs.
- Improve companies’ planning to lower the costs, and generally, improve their investment strategy.
- Help companies in selecting contracts that maximize their profits by predicting the forwarding (i.e., delivery) contract cost.

Similar real-world challenges were addressed at previous competitions on the KnowledgePit platform, such as predicting escalations in customer support [6], network device workload prediction [7], suspicious network event recognition [8], and predicting victories in video games [9], to name a few. These papers also demonstrate how predictions from individual solutions could be integrated into diversified ensembles to create more powerful and more robust models.

For the case study on which we focus in this paper, we choose to use the XGBoost model with a grid search with 5-fold cross-validation [10], due to its extensive use in retail sale predictions [11]. We also use Random Forest models with grid search, as well as deep learning models that are commonly used in demand forecasting in multi-channel retail [12]. Finally, the Linear Regression models are one of the most commonly used simple models for price prediction in industry

^{*}These authors contributed equally to this work.

settings [13]. All hyper-parameter tuning is done via exhaustively searching a specified subset of the hyper-parameter space of the given model. The validation is performed using a 5-fold cross-validation, which balances validation speed and metric accuracy of the test data.

The rest of the paper is structured as follows. Section II reviews the most important related works. Section III describes the experimental setup and multiple validation procedures we used to evaluate each model we have developed in this study. Section IV describes the preprocessing of the data, including data transformations and aggregations. Subsection IV-A contains information on the preprocessing implemented over the main table training and testing data, and subsection IV-B includes the preprocessing information for the routes table training and testing data. The section V describes the implemented feature selection methods. The experiments, including model hyper-parameter tuning, training, and evaluation techniques are described in section VI, along with an overview of the final scores of the implemented models. The paper concludes with section VIII where we give a brief overview of the entire Machine Learning workflow, limitations to the study, and opportunities for further work and improvement of the methods.

II. LITERATURE REVIEW

Even though similar challenges have been extensively studied in other industries, this problem is fairly new in the logistics sector. Authors of [14] analyze the shipping cost differences between various carriers, and attempt to identify opportunities for reducing transportation costs.

Similarly, in [15], authors utilize neural networks to forecast shipping freight rates and compare them with traditional time series analysis models. The key objective of their work is to improve the forecasting accuracy of traditional time series analysis. In relation to the competition task, this article also highlights the importance of the information contained in forwarding freight agreements in relation to predictive accuracy.

Another interesting approach is presented in [16], where the impact of the demand and cargo capacity on the shipping price is identified. Forecasting of the long-term cost of logistics contracts is particularly important in long-term agreements with upfront-defined prices, such as in various types of tenders and auctions. On one hand, the bids should be attractive so that the contract can be won, while still being profitable for the logistic company. This challenge was researched in [17], which utilized historic data to train the models.

On a related topic, Men et al. [18] use an ensemble of mixture density neural networks for the purpose of short-term wind speed and power forecasting. They show that this methodology works well for multi-step ahead prediction. Additionally, [19] illustrates the use-case of multi-observation and multi-dimensional data cleaning methods for applying machine learning algorithms. In this study [19], the authors use transactions from the Lending club data set for training tree-based models to predict peer-to-peer (P2P) loan default and observe that the LightGBM algorithm, using multiple

observational data, has the best performance. In many cases, it has been shown that decision tree-based methods significantly outperform linear models for predicting complex response variables, such as the example of predicting accrual expenses in a balance sheet by utilizing the unused vacation time of employees [20].

The scientific community has placed a massive effort into studying individual algorithms (e.g. ensemble algorithms, various deep learning architectures, etc.). Additionally, some studies also focus on finding ways to utilize the diverse algorithms and integrate their predictions. This process is often referred to as diversified ensemble learning and aims to find the best classification algorithms (out of many heterogeneous classification algorithms) and an optimal method to combine them [2]. Note that the individual algorithms used in a diversified ensemble could be ensembles on their own (e.g., XGBoost [21] or Random Forest [22]), so the term diversified ensemble learning refers to another layer of integration. Some methods train another classifier whose inputs are the predictions of the individual classifiers [23] or use other ways of voting. In this paper, algorithms perform weighted voting based on empirically identified weights.

III. VALIDATION PROCEDURE

As in all practical machine learning problems, the experimental setup concerning the training/validation/test split should resemble the natural chronological and logical process as closely as possible, so that the models built are valid and robust over time. In that regard, we attempted to split the training dataset into two subsets, one for training and one for validation, in a way that we thought would most resemble the natural setting in which the data was collected. Considering that this is a very practical problem coming from the industry, any results of the transformation and validation methods should be applicable in a production setting.

That being said, we considered the *id_payer* column, the client identifier, as special because it gave us the ability to use it primarily for splitting the original training set into our training and validation subsets. For this purpose, we first analyzed the frequency of rows in the main table per *id_payer*, dubbing it *number_of_contracts*. We noticed the huge discrepancy in the frequency of contracts, ranging from just a few to upwards of thousands. Therefore, we tried several approaches in how we considered this fact:

- **Split by alternating frequency of records per *id_payer*.** In this approach, we ordered the *id_payer* records by the *number_of_contracts*, and we assigned them to our training or validation split in alternating order. The idea was that roughly 50% of the records will be our training set, and the other 50% will be the validation set. One additional benefit of this approach was that it made sure that the *id_payer* column would not have an effect on the prediction. With this approach we are very conservative to overfitting, trying to train the models on one subset of the data, and applying the models to a completely new set of data. Indeed, our

first submissions showed that our own validation results were considerably worse than the leaderboard results, but were still consistent when comparing different algorithms or feature subsets (the better models per our internal evaluation were also better on the leaderboard).

- **Time-sensitive split.** We also tested splitting the data in such a way that the older contracts (records with an earlier start date) were in the training set, while newer records were in the validation set. This approach mitigates the previous conservativeness, by allowing the same clients to be in the training and validation set, while also allowing some new clients to appear in the validation set.

After the initial testing of the previous approaches, we noticed that the hyper-parameter tuning procedures performed on our hold-out training set (a subset of the competition training set) were not fully applicable when we used the whole training dataset provided in the competition. Namely we used our hold-out training set and the remaining of the training set to learn the hyper-parameters. Then, we compared two models trained with the same hyper-parameters – one using the hold-out training set, and another trained on the full training dataset. The former performed significantly better on the leaderboard result, even though it was trained on smaller data set. With this counter-intuitive finding that contradicts the common principle that more training data is better, and having a very limited time for this competition, we decided to use 5-fold cross-validation in the remaining experiments so that we can use the full training dataset for making the final test predictions. Despite that, we strongly believe that further experiments in the validation procedure are needed to properly tackle the problem.

IV. DATA PREPROCESSING

After the initial data exploration phase, we decided to primarily focus on the main table and extract whichever knowledge we can from it, before proceeding with utilizing the detailed table of expected routes.

A. Main Table

Firstly, the *prim_train_line* and *prim_ferry_line* features were not used, due to the high missing data ratio (between 80% and 90% missing from the total number of observations). Additionally, these columns had unstandardized data (e.g., temperature ranges or temperature and unit combined strings in the same column as a descriptive field, etc.) For the remaining columns which had missing data, we applied mean (for continuous columns) or median filling (for nominal data).

The transformations done on the Main Table were split into two major types:

- One-hot encoding of categorical (nominal) data. We considered utilizing the Weight of Evidence [24] approach, but considering that the categorical features had a relatively small number of different values, the one-hot encoding technique was considered sufficient.

- Combinations of two or more features to create a new meaningful feature. Such features were a result of calculations based on the columns that contain date or timestamp information.

1) *Nominal to numeric features with one-hot encoding:* The one-hot encoding was done to maximize data balance while minimizing the loss of information. Binary features or features with a few different values were transformed with classic one-hot encoding. The features with over 15 values were split into 3 major categories: low-frequency categories (those that had appeared under 1000 times in the data set), high-frequency categories (those that had appeared over 1000 times in the data set), and the highest frequency category of the feature was separated as an individual category.

2) *New domain-specific features based on other features:*

a) *Date-time related features:* A combining of two or more features was done for the *route_start_numeric* and *time_taken_minutes* features. The *route_start_numeric* is the difference in days between the minimum date found in the dataset (i.e., 1/1/2016), and the start date of the specific route. This was done by using the *route_start_datetime* feature, and finding the number of days between it and 1/1/2016. Similarly, the *time_taken_minutes* is the time the complete route is estimated to take in minutes. This is calculated by finding the difference in minutes between the *route_start_datetime* and *route_end_datetime* features.

b) *Geo-spatial features:* To enhance the geo-spatial information about the routes, we created a new feature, using the Euclidean distance [25] between the *route_starting_point* and *route_ending_point*. This calculation uses the latitude and longitude values of the original points. Additionally, we used the geo-spatial (Haversine) distance [26], given in the competition dataset.

B. Routes table

The initial experiments were conducted using only data from the Main Table. To further improve model performance in later experiments, we enriched the dataset with aggregate features extracted from the Routes Table.

The columns which had missing data were very sparse in the general case. Moreover, the lack of entries seemed correlated in most cases. For this reason, we decided to ignore such columns and do not create features based on them, especially considering the limited time we had for experiments. Still, we believe that more sophisticated data imputation methods could be explored in the future, or at least to prepare some bins of values in cases when such data is available. The ignored columns for this reason were: *ferry_line*, *train_line*, and another 17 columns whose names started with *vehicle_* or *id_vehicle_*.

We have extracted the aggregate features by grouping the dataset based on the column *id_contract*. Before the aggregation, one-hot encoding was performed on the *step_type* feature with the goal of extracting the number of steps of each type that were taken in one route. The following features were extracted for each route:

- *num_steps_with_vehicle* - the number of rows having *id_vehicle* equal to 1
- *num_steps_with_trailer* - the number of rows having *id_trailer* equal to 1
- *num_steps* - the maximum from the *step* column values within one *id_contract* partition
- *num_steps_A* - the number of steps of type A
- *num_steps_B* - the number of steps of type B
- *num_steps_D* - the number of steps of type D
- *num_steps_F* - the number of steps of type F
- *num_steps_K* - the number of steps of type K
- *num_steps_N* - the number of steps of type N
- *num_steps_O* - the number of steps of type O
- *num_steps_P* - the number of steps of type P
- *num_steps_R* - the number of steps of type R
- *num_steps_S* - the number of steps of type S
- *num_steps_W* - the number of steps of type W
- *num_steps_Z* - the number of steps of type Z
- *num_steps_A* - the number of steps of type A
- *num_steps_empty* - number of the steps in which the *if_empty* flag was equal to 1
- *num_external_steps* - the number of the steps in which the flag *external_fleet* was 1
- *max_loaded_kg* - the maximum *kg_load_unload*
- *max_unloaded_kg* - the minimum of *kg_load_unload*
- *average_load_step* - the mean of the feature *kg_current*
- *max_load_step* - the maximum of the feature *kg_current*
- *min_load_step* - the minimum of the feature *kg_current*
- *num_steps_ferry* - the number of steps in which the flag *ferry* was equal to 1
- *num_steps_train* - the number of steps in which the flag *train* was equal to 1
- *total_km_train* - the sum of *train_km* for each step
- *max_time* - the maximum of the feature *estimated_time* in each step
- *min_time* - the minimum of the feature *estimated_time* in each step
- *km_per_step* - the mean value of the feature *km* in each step
- *km_nonempty_max* - the maximum value of the feature *km_nonempty*
- *km_nonempty_total* - the sum of *km_nonempty* in each step
- *average_time_per_step_minutes* - the average of the time difference in minutes for each step

V. FEATURE SELECTION METHODS

A. Manual Filtering of Correlated Features

This method was used for training the Linear Regression models. Since the Maximum likelihood (MLE) estimations [27] can be highly disturbed by correlated features, we decided to manually remove features with correlations greater than 0.6 in absolute value. For this purpose, we calculated the Pearson

Correlation [28] between each pair of continuous variables in the main dataset. We only calculated the correlations between the continuous features from the main dataset in order to exclude the features that have a high correlation from the feature engineering step for training the linear regression models.

The linear regression models were only trained using the uncorrelated features from the main dataset, plus higher degrees of some of the most important features chosen by applying domain knowledge. These features include the total kilometers, the time taken and the maximum weight. This was done in order to use the results of the most basic linear regression models as an internal evaluation baseline for all the other trained models.

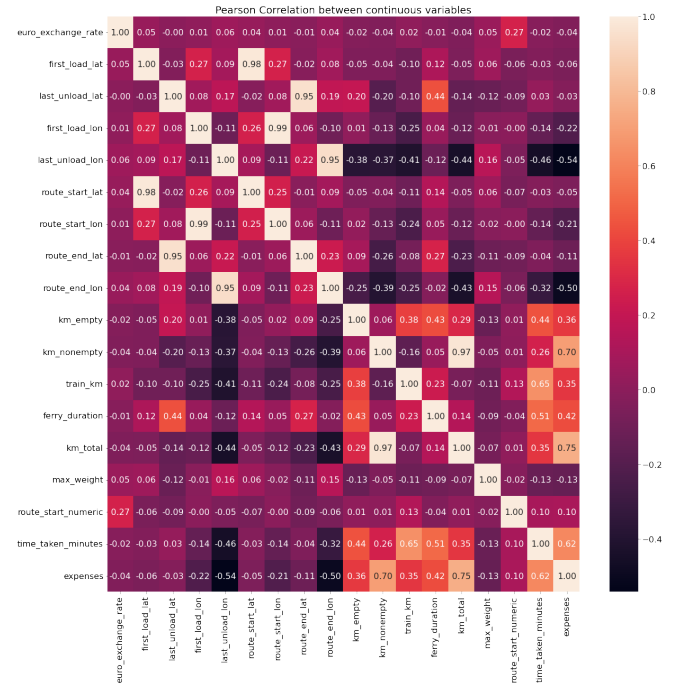

Fig. 1. **Main table extracted continuous features correlation.** This figure presents the Pearson Correlation coefficients calculated between each pair of continuous features from the main table.

The experiments for the Linear Regression models were conducted using only the Main Table data. The correlation map of the continuous features is displayed in Figure 1. As it is evident from the figure, a lot of features have high correlations (positive and negative), so removing these dependencies was one of the feature selection methods we implemented.

B. XGBoost Feature Importance

Another method for feature selection was using the built-in feature importance metric from the Extreme Gradient Boosting model (XGBoost) for regression. The process of optimizing this model is detailed in section VI.

Figure 2 represents the feature importance obtained from XGBoost on the full dataset (containing the main table and routes table data). As we can see from the figure, only one

feature, namely *direction_d* (a binary feature stating whether the direction is d or not) dominates the rest of the features in the dataset.

Sometimes, these built-in feature importance estimates can be inaccurate, as we suspected in this case. The reason behind this is that XGBoost weights the features based on the frequency of splitting, gain and coverage metrics. In the case of categorical variables, the frequency of splitting can be very low, since there are few possible split points, contributing to an overall lower importance than the actual one for categorical variables. Additionally the gain for continuous features can be lower than that of the categorical ones since more split points are possible to be made which in turn can rule out fewer examples in each split compared to the categorical features.

In our case we are creating shallow individual decision trees as weak learners. This means that we have fewer levels in each tree, thus splitting by a binary (or categorical) feature, which is correlated with the target variable, can have a higher value for the gain compared to a continuous feature which is correlated with the target variable because the continuous feature might rule out fewer examples in each split. In turn, this can result in inaccurate calculations of the overall feature importance when using a mix of categorical and continuous features.

For this reason, we further try to extract the important features using wrapper methods [29] over the XGBoost algorithm, which is explained in the following subsection.

C. Boruta search with Shapley values

Boruta search [30] is a wrapper algorithm originally built over the Random Forest classification model, but further extended for all types of decision tree-based models and regression. The method implements feature selection by creating copies of the original features and shuffling them to remove any correlation with the target variable. These features are called shadow features. The algorithm then compares the shadow features' Z-scores [31] to the original features' Z-scores. Each feature that fails a two-sided test for significant difference of importance with the shadow feature with maximum importance is removed from the dataset. The feature importance, in this case, was measured using Shapley values [32]. The Shapley values are often used as a method for explainable AI (XAI) because they reveal the average marginal contribution of a feature value across all possible coalitions.

The results of implementing this feature selection method over the XGBoost algorithm are shown in Figure 3. A total of 48 features were identified as important, and their importance compared to the shadow features is displayed in the figure.

From the figure, we can again see that the features *euclidean_distance*, *direction_d*, and *km_total* dominate in their importance for the algorithm compared to all of the other features in the dataset, which means that their impact is most significant in determining the *expenses* variable's values.

VI. RESULTS

A. Linear Regression

The Linear Regression models were first experimented with by using the features in the main table and standardizing them according to the needs of the algorithm. The *ferry_intervals*, *train_intervals*, and *id_service_type* features were scaled using the Min-Max scaling, while all other features that were continuous were scaled using the Standard scaling [33]. The root mean squared error (RMSE) of this primary model, using the train/validation split for validation, was 0.6703. The RMSE of this model on the leaderboard was 0.4598.

The same model was later modified to include only the features that are not correlated, according to the OLS [34] statistical test for feature relationships and the correlations represented in Figure 1. Using only those features, the model had a RMSE of 0.6942 on the validation data set, and a RMSE of 0.5027 on the leaderboard.

Finally, the squared values of the features *km_total*, *max_weight* and *time_taken_minutes* were added to the model. This improved the model's RMSE on the validation set to 0.5713, and the RMSE of the test set to 0.4309. The coefficients and their significance are shown in Figure 4.

We can see that all of the features have significant coefficients according to the reported p-value. In this case, the total number of features for training the model was 15. Since linear regression might not estimate the coefficients right in the case of a large number of features, we decided to further go with other non-linear models that better handle a large number of features.

Moreover, we examined that the target variable is multimodal, meaning that any model which expects a Gaussian distribution of the target variable will not be suited well in this scenario. For this reason, we mainly focus on tree-based models and ensembles. We further try Gaussian Mixture distributions with neural networks, but due to the time limit, we did not have the resources to optimize these types of models.

B. Extreme Gradient Boost Regression

The first XGB Regressor model that was built only on the main table dataset included *alpha_booster*, *eta*, *lambda*, and *max_depth* as hyper-parameters in the tuning job, using Bayesian Search [35] to find the optimal values. This resulted in an average of 0.34 RMSE on the 5-fold cross-validation, and a 0.1735 RMSE on the leaderboard.

The model was later improved with the addition of the routes table, as well as the selected features from the Boruta Shap search, which resulted in improving the RMSE of the CV to approximately 0.18 and 0.15, respectively on the 5-fold cross-validation and improving the test RMSE on the leaderboard to 0.1649 and 0.1622 respectively.

C. Random Forest

The first Random Forest model was built on the transformed features of the main table. Hyperparameter optimization was done on the *max_depth*, *min_samples_leaf* and

Fig. 2. **XGBoost built-in feature importance for the merged dataset.** This figure represents the feature importance of the main table and the routes table. The horizontal axis represents the features, while the vertical axis represents their corresponding impact on the prediction of the target variable. Only features having an importance greater than 10^{-5} are shown.

Fig. 3. **Extracted features using Boruta search with Shapley values as an evaluation metric.** The green rectangles represent the original features, while the blue rectangles represent the min, max, mean, and median shadow features. The vertical axis represents the Z-score for each feature.

max_features hyper-parameters. All Random Forest models in this competition had *n_estimators* set to 200. This resulted in a RMSE of 0.0476 on the 5-fold cross-validation, and a RMSE of 0.1726 on the test data.

The model was later improved by using a deeper grid search on all features from the merged main and route tables. This time, *max_depth*, *max_features*, *min_samples_leaf* and *min_samples_split* were optimized using 5-fold cross-validation, which resulted in the validation RMSE being 0.0234. The test results had a RMSE of 0.1625.

Both Random Forest models were clearly over-fitted, however, we tackled that issue with the different Ensembles of models later on.

D. Deep Learning Models

A few feed-forward neural networks were implemented using different configurations. The neural networks were trained on the full dataset. The networks only included dense layers and the main activation function used in the hidden layers was ReLU [36]. We experimented with a few regularization

techniques including dropout, batch normalization, and kernel regularization with L2 [37].

From the conducted experiments, we concluded that adding regularization caused the model to underfit the training data. Moreover, batch normalization caused a significant performance degradation in this case.

For the output layer, we tried two activation functions, namely softplus [38] and linear. In this case, the same network configuration had better performance using the linear activation instead of softplus.

The model which obtained the best results had the following configuration:

- Dense(128, activation=relu)
- Dense(64, activation=relu)
- Dense(64, activation=relu)
- Dense(1, activation=linear)

The results of this model were RMSE of 0.1683 on the random validation split of 20% training data and RMSE of 0.1775 on the leaderboard, respectively.

Adding more layers results in better model performance, however, it also causes the model to overfit the data in the early stages of training.

Since the neural networks approximate a Gaussian-like distribution, they are not quite suitable for the multimodal target in this case. We additionally tried Mixture Distribution

networks but did not have the resources to optimize these models. A basic model with the following configuration of two dense layers with 100 neurons and ReLU activation each for approximating the parameters of the distribution, resulted in a RMSE of 0.1868 on the leaderboard.

E. Diversified Ensemble Models

Ensemble methods [39] were used in order to compensate for models which might be overfitted or underfitted in the data, and further use the errors the models make in a way to further tune the final predictions.

One of the ensemble methods used was model stacking. For this type of ensemble, we used the best performing XGBoost model using the features extracted with the Boruta search method and additionally re-trained a Bagging model of 100 linear regressions with the same features.

The outputs from these models were then fed to another linear regression model, which learned the weights to assign to each individual model, thus creating a weighted ensemble. This approach resulted in a 0.1631 RMSE on the leaderboard and a RMSE of approximately 0.06 on the validation data. This means that the stack resulted in obvious overfitting.

We further experimented with the same approach using a decision tree in the last layer instead of a Linear regression, for learning the weights in the ensemble, however, this resulted in a more overfit model, with a RMSE of 0.1805 on the leaderboard.

Since this approach resulted in fast overfitting, we decided to abandon it.

The other method of ensembling the models that we attempted was a simple weighted Ensemble. Using a combination of the Linear Regression models, the XGBoost models, the Random Forest models, and the feed-forward neural network models, we attempted to manually adjust the weights that these models had on the final outcome. The best Ensemble was found to be an equal weights Ensemble between the highest-scoring Random Forest model, and highest scoring XGBoost model, which had a validation RMSE of 0.1318, and a test RMSE of 0.1586.

We then tried another ensemble, which used the underfitted feed-forward neural network with a weight of 0.2, the highest-scoring XGBoost model with a weight of 0.4, and the highest-scoring Random Forest model with a weight of 0.4, all trained on the features chosen with the Boruta search method. We expected that the feed-forward neural network would generally make mistakes in the opposite direction of the Random Forest and XGBoost models, and therefore contribute to the reduction of the average mistake. The weight of the feed-forward neural network model is low, however, due to its larger average errors. This resulted in an Ensemble with a validation RMSE of 0.1856, and a test RMSE of 0.1567, our best score in this competition.

F. Model evaluation

In this subsection, we present the results of the individual models which were optimized and chosen for creating ensembles in the final stage of experimentation. Table I shows the

models, their training configurations, the features they used, and their validation and leaderboard RMSE scores.

The final 3 models which were chosen for the competition include:

- Ensemble using the best performing feed-forward neural network, Random Forest, and XGBoost models
- Ensemble using only the best performing Random Forest and XGBoost models (excluding models which expect Gaussian distributions of the target variable)
- The best performing Random Forest which uses the features chosen with the Boruta search method to avoid over-smoothing or overfitting the ensemble methods

VII. DISCUSSION AND FUTURE WORK

The top-performing models were the XGBoost and Random Forest models, strongly outperforming the Linear Regression models and slightly outperforming the feed-forward neural network models. This was expected, due to the multi-modal nature of the target variable, which is hard to estimate using models that expect a Gaussian distribution of the target.

Moreover, the ensembles of diverse models performed the best out of all the predictive options. They used weights that were calculated using the inverse of the RMSE scores of the cross-validation of the models they were composed of. The singular Linear Regression models were not used in the Ensembles due to their massive underperformance compared to the other three model types. However, they were used with the bagging regressors, but this approach also underperformed compared to the non-linear approaches.

Hyper-parameter optimization on all models was performed using the grid search algorithm, with 5-fold cross-validation, and RMSE as a metric to evaluate performance. Grid search was used because it is one of the most thorough hyper-parameter tuning algorithms. Given more time, we would have expanded the search space of the grid search of all models.

According to the Boruta search for feature importance, the *eucledian_distance*, *direction_id*, and *km_total* columns were considered the most important for determining the *expenses* value, with starting and ending locations of low-frequency destinations being some of the least important features. This further implies that the distance of the route is the most important deciding factor in the final expenses of forwarding contracts.

The main challenge in working with this dataset was the limited information we had on the meaning of some of the given features. With better information on the features, the data engineering process, as well as the model building process, would have been more specific and exhaustive.

While experimenting with the aforementioned validation procedures in section III, we noticed that some additional features could be extracted from the *id_payer* column, considering that it, in its original form, is not applicable as a feature. Such derived features could be:

- *num_previous_contracts* - the number of previous contracts (before this contract date) for the same client (*id_payer*)

- *average_cost_previous_contracts* - the average cost of previous contracts (before this contract date) for the same client (*id_payer*)
- *average_duration_previous_contracts* - the average duration of previous contracts (before this contract date) for the same client (*id_payer*)
- *average_length_previous_contracts* - the average length of previous contracts (before this contract date) for the same client (*id_payer*)
- *ratio_length_previous_contracts* - the ratio of current length divided by the average of previous contracts (before this contract date) for the same client
- *cost_most_similar_contract* - the cost of the previous contract with the most similar length, adjusted by the difference in exchange ratios

Considering that computation of such features should be properly handled and should be closely integrated with the training-validation split process, we did not utilize them. Despite that, we believe that there is merit in further experimenting with them.

Although it was considered, fuel prices were ultimately not used in the prediction of the target variable. This was due to the uncertainty of the availability of current fuel prices, making using them a potential data leak.

Finally, the usage of external public datasets could have vastly improved the predictions of all models. Unfortunately, due to time restrictions, we were unable to properly search for, test, and use any relevant public dataset.

VIII. CONCLUSION

The original goal of the challenge was to use preprocessing methodologies, Machine Learning algorithms and feature selection methods, in order to most accurately predict the costs related to the execution of forwarding contracts in a transporting company. Using feature engineering techniques, as well as a weighted diversified ensemble of XGBoost, Random Forest, and deep learning models (a feed-forward neural network), we were able to predict the expenses of the forwarding contracts with a RMSE of 0.1573.

In this paper, all missing data was imputed using mean filling and median filling. However, in the future, more sophisticated methods for data imputation can be utilized, such as Multiple Imputation by Chained Equations [40] or Regression Imputation [41].

In a broader context, we can conclude that in real-life business problems, domain knowledge and information are essential. With manual feature extraction that reflects the domain knowledge, valuable features could be created that improve the model performance. Likewise, without the domain knowledge, the model validation from a practicality and explainability perspective could be limited.

Abstract—Predicting the cost of forwarding contracts is a typical problem that logistics companies need to solve in order to optimize their business for a better profit. This is the challenge defined in the FedCSIS 2022 Competition where a five-year history of contract data and their delivery routes from a large Polish logistics company are provided to train a Machine Learning model. In addition to the contract data, historical wholesale fuel prices and euro exchange rates at the contract time are also provided. To address this challenge, we first designed a basic solution where we focused on feature engineering to find good impact features for the model. After that, the same set of features were used to train two different models: one using XGBoost and the other using LightGBM. The average predictions of the two boosting models were then used as the predictions for the next post-processing step. Finally, in the post-processing step, we designed and trained a simple linear regression model to capture the average monthly changes of the contract cost, given the changes of the fuel prices and euro exchange rates. These captured changes were used to post-process (adjust) the predictions in the previous step to address the issue that tree-based models could not predict the value that they did not see before. While the basic solution with careful feature selection gave us a place in the top-5, our post-processing strategy in the last step helped us win the 3rd prize in the competition.

Index Terms—Logistics, Forwarding Contract Cost Prediction, Gradient Boosting Trees, XGBoost, LightGBM, Linear Regression, Feature Engineering, Post-Processing.

I. INTRODUCTION

MANY logistics companies are on the road to digital transformation and employ AI/Machine Learning technologies to support and optimize their daily business. One of the key challenges that these companies are facing is to predict to cost of a delivery/forwarding contract in which an accurate prediction result can help the logistics companies in many aspects of which three typical ones are listed below:

- To maximize revenue by selecting profitable contracts.
- To identify issues and optimize operations to reduce costs.
- To get better planning in contract execution.

The challenge of predicting the cost of forward contract is exactly the objective of the FedCSIS 2022 [1] competition ¹, which is in cooperation with PTI and QED Software and sponsored by Control System Software ² – a software company that has been delivering solutions for the Transportation, Spedition, and Logistics industry for 20 years. In this competition, a

five-year history of contract data and their delivery routes together with wholesale fuel prices and euro exchange rates at the contract time are provided. Specifically, two types of data sources are provided. While the first data source contains basic information about the contracts, the second one describes the main sections of the planned routes associated with each contract. Given the data, when we performed exploration data analysis (EDA), we could see that the amount of data is not big, there are not much information in the contract to analyse, and the number of provided features in the contract data is small. As a result, we believed that the most important factor to design and train a good prediction model is in the feature engineering process where (1) We need to generate extra features to be used, in addition to the existing provided features and (2) useful features should be carefully selected for the model. With respect to this point, our first contribution in this paper is in this feature engineering process. Once we got the selected features, we then simply trained two boosting tree models: XGBoost and LightGBM and obtained the average predictions from the two models as the forecast.

Our second contribution in this paper is a simple and effective approach to post-process the predictions to capture the trends in contract costs. Basically, it is well-known that using tree-based models in the presence of trends over time can lead to inaccurate results. The reason is in the way tree-based models make predictions. For example, Decision Trees make regression predictions by seeing which “leaf” the data point belongs to and assigning the average of the target variable from the training set to that point. In this case, they fail to accurately predict values they have not already seen, and values from a significantly different population (perhaps after some trend in time) will cause the model to make inaccurate predictions. Random Forests and Gradient Boosting Tree algorithms suffer the same problem because their results are averages results of Decision Trees. In this competition, when we performed EDA, we could see the fuel prices have steadily increased in the past couple of years. Euro exchange rates have also increased during the time of the test set. As a result, there should be an increase trend in the average cost of the contracts in the test set, which may not be well captured by the models in the previous step. Therefore, we designed and trained a simple linear regression model to capture the trend in the average cost of forwarding contracts and use this model’s result to post-process the predictions from tree-based models. This post-

¹<https://knowledgepit.ml/fedcsis-2022-challenge/>

²<https://controlsystem.com.pl/>

processing step did help to uplift our prediction model and brought us to the 3rd position in the final ranking list.

To summarize, our contributions are twofold:

- We present our feature engineering process in which we first share how to generate extra features using route information and then select good features having impacts to the forecast model from a set of candidate features.
- We introduce a simple linear regression model used in the post-processing step to overcome an issue of tree-based models in capturing trends in contract costs.

For the rest of the paper, we organize the content as follows. The background and related work are introduced in Section II. An overview of the competition challenge is described in Section III. The details of the proposed method are presented in two sections, where Section IV is dedicated for feature engineering and feature selection while Section V shows details of the model design, focusing on the linear regression model used in the post-processing step. Finally, conclusions are given in Section VI.

II. RELATED WORK

The costs of forwarding contracts can be affected by many factors, which, besides contract nature and transportation arrangement, fuel prices, currency exchange trends are decisive too. The actual transportation cost is also constrained by some factors such like behavior of drivers, weather, traffic, market demand, etc., accurately forecasting the cost is, thus, challenging, but critical in the business providing logistics service or involving supply chains [5].

Artificial intelligence techniques empowered solutions have been investigated to solve transportation problems in both industry and academy. A logit neural network (NN) based mode selection model was developed to address border transportation in [11]. Freight demand was predicted for inter-modal terminals by NNs in [12]. Traffic volume in non-urban highways under heterogeneous conditions and vehicle counts were predicted by developing a NNs based model in [13].

There is, however, quite little work published in the literature on cost prediction of forwarding contracts. The work in [14] developed AI based models to predict the long-term cost of the logistics service, and attempted to construct a risk-aware interval for the prices to be offered in the bid, aiming to boost competitiveness in the application for tenders, and in addition, historical data was used to develop statistical learning models for predicting the success likelihood of a tender based on the actual data and predicted service prices achieved from previous stage. In [5], a trapezoidal neutrosophic fuzzy analytical hierarchy process (TNF-AHP) was proposed to determine the most significant criteria that were used to predict transportation cost by an artificial neural network (ANN) model, which, claimed by the authors, can be also used in supply chain management and inventory control management.

Boosting is a popular technique used in machine learning to reduce errors in predictions from which to improve the accuracy of machine learning models. The basic idea of boosting approach is to combine a set of weak models into a strong

and robust model, which is able to reduce the prediction bias [6], [7]. Gradient boosting (GB) is an extension of boosting, in which the process of additive generation of weak models is based on a gradient descent algorithm over an objective function [8]. Gradient boosting decision tree (GBDT) is an ensemble model of decision trees, used as weak learners in the gradient boosting ensemble model. In each iteration of its training process, a new decision tree is added to the pool, which tries to increasingly learn on mistakes of decision trees already in the pool by fitting the negative gradients (or residual errors) [9], [10].

III. COMPETITION DESCRIPTION

The challenge of the FedCSIS 2022 [1] is to predict the cost of forward contracts, using five-year history of contract data and their delivery routes together with wholesale fuel prices and euro exchange rates at the contract time. The data is provided in three different files as follows:

- Main contract data: contain general information of forward contracts that are ready to be used as features to train a model. The data is stored in two .csv files: “css_main_training.csv” and “css_main_test.csv”.
- Contract route data: provide detailed information about routes of forward contracts, which can be used to generate extra features (note that some basic route features are already created in the main contract data). The data is stored in two .csv files: “css_routes_training.csv” and “css_routes_test.csv”.
- Wholesales fuel prices: store average fuel prices at monthly level throughout the time of forward contracts in a single .csv file, “fuel_prices.csv”.

The accuracy of the prediction model is measured by the Root Mean Square Error (RMSE) metric. Note that the purpose of using RMSE is to give higher penalty for large errors compared to smaller ones because the errors are squared before they are averaged.

IV. FEATURE ENGINEERING

The process of feature engineering, which typically includes feature generation at first, followed by feature selection using Greedy Forward Search, Greedy Backward Search, and finally SHAP analysis [15] for feature importance, is clearly presented in this paper [16]. Thus, in this section, we simply discuss which sources we used to generate our features as well as the list of our selected features.

In general, the features that were used to train our models to predict the cost of forward contracts were generated in the two basic steps. In the first step, we executed “feature generation” during which extra features are generated from the first two data sources: “main training data” and “contract route data”. After that, we performed “feature selection” to determine the usefulness of generated features based on their impact on the performance of our models and finally chose which are the features that should be included in training our final models. In general, our features could be classified into “basic features” which are available in the “main contract

data” and “extra features” which are generated in the feature generation process.

A. Basic features

We use all available features in the “main training data” but one and they are all good features in the top-20 important features returned by our model. The only exception is from the “euro_exchange_rate”, which we thought to be an important feature, but the model told us otherwise. We tried a number of ways to utilize the “euro_exchange_rate” such as using it as a single feature, identifying trend up or down in the exchange rates, or converting it into a mean-encoding feature. But, none of the above approaches was succeeded. As a result, we did not use the “euro_exchange_rate” in the main model. However, it turned out that this feature was still useful in the linear regression model that we employed later in our post-processing step presented later in Section V.

B. Extra features

Extra features are mainly generated from “css_routes” files. These features help to identify special properties of the routes from which giving the model better forecast accuracy. They include the following sets of features:

- The route statistics features: include the number of route segments, the number of route segments with and without cargo, and the number of route segments where starting and ending points are in the same country (or in different countries). These features give us extra information on how big or complexity the forward contract is, in addition to the existing “km distance” feature.
- The gap feature between “km distance” and “Haversine distance”: this feature provides us how easy or hard a contract forward can be executed. Picture that if the “Haversine distance” is short while the “km distance” is long, the implication is that it is not easy or straightforward to move directly from the start to the end of the contract as some detour may be required in the trip.
- The statistics of vehicles and trailers used in the trip: include the average of axle counts from all vehicles and trailers, the average of kerb weight from all vehicles and trailers, the average of vehicle engine capacity and the average of trailer payload. These features tell us how heavy the cargo is in the trip, in addition to the “max weight” feature in the main contract data.
- The features about distance between the route start and the point where the cargo is loaded first as well as distance between the route end and the point where the cargo is last unloaded. These features tell us the percent utilization of vehicles in the contract.

In addition to route features, as we have a text describing the temperature requirement in the main contract data, we generated the following temperature requirement features, which are good features for the model because the forward contract cost should be higher if there are special requirements for the temperature such as frozen or automatic. Specifically, these features include:

- The range of temperature (low and high) if they are mentioned in the text field. Otherwise, they are left with NULL values. In some cases, where a fixed temperature is required, we set equal values for both the low temperature and high temperature.
- One-hot encoding features for the top-5 important words detected from the text such as frozen, continuous, or automatic. These words are created simply by getting the top-5 words returned from “CountVectorizer” after removing stop words.

Finally, as we have the time when the trip starts and ends in the main contract data, we generate these following extra time related features:

- The weekdays where the trip starts and ends as the cost could be different if we start or end the trip at different days of the week. For example, the trip starts or ends during the weekend may lead to a higher contract cost.
- Similar to the above case, the hour of day where the trip starts and ends also have impacts on the contract cost. A night time start or end is expected to have a higher cost compared to other time of the day.
- Finally, the day of month where the trip starts and ends and the duration (in terms of hours and days) of the trip also contribute to changes in the contract cost.

C. Model design and implementation

Given the list of good features obtained in the above feature engineering step, we simply designed and trained two boosting trees: XGBoost and LightGBM, using the same set of features and the final prediction is the average predictions returned from the two models. As you can expect, the combination of the two models using the same set of features does not help to make much improvement in the model accuracy. Instead, we employ this strategy simply to get a stable prediction result as our main concern is always the overfitting issue given the small amount of data used for the public leaderboard, which we experienced in the past two competitions of 2020 [2], [3] and was presented in the paper [4].

V. FORECAST POST-PROCESSING WITH LINEAR REGRESSION

As discussed in Section IV, we could not utilize the euro exchange rates in the main model. Similarly, when we tried to add wholesale fuel prices to the main model, it does not have a positive impact. However, when we looked at the changes in both euro exchange rates and fuel prices, we could see that during the period of testing, there was a significant increase in both euro exchange rates and fuel prices. As discussed in Section I, since using tree-based models in the presence of trends over time can lead to inaccurate results, this section introduces our solution to address this issue. Specifically, we will present a design and implementation of a simple linear regression model to predict monthly changes in the average contract costs in Section V-A and then use the predicted result to adjust the predictions returned by the main model in Section V-B.

A. Forecasting trend in contract costs

To detect trend in contract costs, we built a simple model to detect the correlation between changes in euro exchange rates and fuel prices and changes in the average contract cost at the monthly level. Note that here we assume that the types of executing contracts each month follow a similar distribution. As the impact of euro exchange rates and fuel prices could be different given different trip distance (e.g., short distance trip may be more or less sensitive to the euro exchange rates and fuel price changes compared to long distance trip) and whether train routes or ferry routes are involved in the trip, we need to consider this factor into the model. In the end, we trained a linear regression model using the following features aggregated at the monthly level:

- The minimum, mean, and maximum of euro exchange rates as well as fuel prices.
- The distance group which we defined based on the total km of the trip. In our solution, we split contracts equally into 4 groups having total km greater than 820, between 430 and 820, between 230 and 430, and less than 230.
- The last features are indicators of whether the trip has train routes or ferry routes.

The training target of the model is the average contract costs each month obtained from the training data set. Once the model is trained, we use it to predict the average contract costs for months in the test data set.

B. Post-processing predictions

Given the predicted average contract cost of a month returned from the above linear regression model (let's call it A), we compare it against the average predicted contract costs returned from our main model trained with boosting trees presented in Section IV (let's call it B), three cases may happen:

- If A is equal to B , our two prediction models are aligned. It is good and we should not do anything for post-processing.
- In cases A is less than B , there could be a down trend in the average contract costs that fail to be captured by our tree-based models, and hence the models generate over-forecast. In this case, we first compute $\delta = B - A$ and then subtract δ from all predictions returned from the main model.
- In cases A is greater than B , it is opposite as there could be an up trend that the tree-based models fail to capture, and hence we need to add in a $\delta = A - B$ for all predictions made by the main model.

It is interesting to note that in our case, the linear regression model always returned a higher prediction for the average contract costs. It means that there should be an expected increase in the contract costs, given the hike of the euro exchange rates and the fuel prices during the period of time used for testing. In our solution, by applying this post-processing step, we could see a score improvement of 0.006 in the Public Leader Board,

which is a good improvement, given that even good features could only help to improve score of 0.002 to 0.003.

VI. CONCLUSIONS

In this paper, we presented our solution to win the 3rd prize of the FedCSIS 2022 Challenge. There are two key factors leading to the effectiveness of our solution. The first one is a process of feature engineering to generate extra useful features and then carefully select features for the model. The second one is a solution for post-processing the predictions in order to capture changing trends in the forward contract costs, which otherwise are failed to get in the main tree-based models. They were both discussed in the paper.

Abstract—Predicting the cost of forwarding contract is a severe challenge to road transport management system. The transportation cost of a forwarding contract often depends on many factors. It is hard for humans to evaluate the various factors in transportation and calculate the cost of forwarding contract. In this paper, we propose an approach to address such a problem by following the sequence of machine learning steps which consist of data analysis, feature engineering and model construction. First, we conduct a detailed analysis of the given data. Then, we generate effective features to characterize the cost of forwarding contract and eliminate redundant features. Finally, in the model construction phase, we propose a gradient boosting decision tree based method to train and predict the cost of forwarding contract. The proposed approach achieves RMSE scores of 0.1391 on the test set, which is the 2nd final score in the competition.

Index Terms—cost prediction, gradient boosting, model ensemble

I. INTRODUCTION

COST PREDICTION is widely used in various fields, such as transportation[1], cybersecurity[2], construction[3], and healthcare[4]. Cost prediction is generally a method of studying historical data and predicting future costs. Effective cost prediction can help businesses better control costs and adjust management strategies for the future in a timely manner, allowing them to gain a competitive advantage. Transportation cost prediction is one of the aspects of cost prediction. Anitha and Patil [1] predicted the transportation costs using a regression algorithm, which assisted the retail sector predict the cost incurred for logistics. In the freight company, predicting the costs of freight forwarding contracts by using historical data can help freight companies better understand the causes of costs and select profitable contracts. Thus, from both academia and industry, predicting transportation costs has drawn a lot of attention. Accurate transportation cost prediction is still a challenging problem.

Based on the same background, the FedCSIS 2022 Challenge: Predicting the Costs of Forwarding Contracts[5] released the task to develop a predictive model that assesses the actual costs of individual orders as accurately as possible. In this challenge, six years of history of contract data and planned routes are provided. The key to the problem is to find the factors related to the cost.

* Corresponding author

In this paper, we propose an approach for predicting the cost of forwarding contracts using the gradient boosting method. First, we analyse the data given in this challenge and have a clear understanding of the meaning of each feature. The data analysis step also provides guidance for the following feature engineering. Then, in feature engineering, we generate the features that can effectively characterise the costs of forwarding contracts from contract data, planned routes, and historical wholesale fuel prices. We also remove redundant features after feature generation. The redundant feature elimination can reduce training time and the impact of noise on the training model. Finally, in the model construction phase, we propose a gradient boosting based method to train and predict the costs related to the execution of forwarding contracts. We introduce the model stacking mechanism as an ensemble method to enhance generalisation performance, which is a frequently used strategy in machine learning competitions. The experiments and competition results have both shown the effectiveness of the proposed approach.

In summary, this paper makes the following contributions:

- We analyse the given data and provide guidance for the following feature engineering. The guidance helps to generate effective features in feature engineering.
- We generate effective features from contract data, planned routes, and historical wholesale fuel prices for cost prediction. The generated features can improve the prediction performance significantly. And we also remove redundant features to reduce training time and the impact of noise on the training model.
- We propose an effective stacking approach using a gradient boosting based method to train and predict the costs of forwarding contracts, which achieves RMSE scores of 0.1402 on the preliminary testing subset and 0.1391 on the complete testing set. And we get the 2nd final score in the competition.

The remainder of this paper is structured as follows: Section II introduces the FedCSIS'22 challenge. Section III provides the analysis of the data and the details of our proposed approach. Section IV shows the results of the experiments. Finally, conclusions are drawn in Section V.

Fig. 1. Overview of proposed approach

II. FEDCSIS 2022 CHALLENGE

In this section, we will briefly introduce the FedCSIS 2022 Challenge, titled as Predicting the Costs of Forwarding Contracts.

The task in this challenge is to predict the costs related to the execution of forwarding contracts based on contract data and planned routes. Accurate cost prediction of forwarding contracts can support freight forwarders in selecting profitable contracts. The data provided in the challenge is collected by Control System Software, which is a software company that has been delivering solutions for the transportation, spedition, and logistics industry for 20 years[6].

The data set provided in this challenge contains a six-year history of orders appearing on the transport exchange. Details of the dataset are presented in the Section III. The aim of the competition is to develop a predictive model using the training set that assesses the actual costs of individual orders as accurately as possible.

The preliminary scores of submitted solutions are computed on a small subset of the testing data and published on the public leaderboard. The final evaluation is published using all of the test records after the competition ends.

III. METHODOLOGY

In this section, we describe in detail our proposed approach for predicting the cost of forwarding contracts. An overall framework of our proposed approach is provided in Figure 1. The approach includes data analysis, feature engineering, and model construction.

A. Data Analysis

TABLE I
BRIEF VIEW OF THE COMPETITION DATA

Data	Format	Size (train/test)
Main Table	csv	69.9 MB / 14.2 MB
Routes Table	csv	204 MB / 58.2 MB
Fuel Prices	csv	68.1 KB

There are two data tables and an additional set of data provided in this competition. A brief view of the data is shown in Table I. The main table contains basic information about the contracts, and the routes table describes the main sections of the planned routes associated with each contract. The main table and routes table are linked by “id_contract”. One contract usually consists of several route sections. The additional set

of data is fuel prices, which contains historical wholesale fuel prices for the period of training and test data.

The main table records the details of individual contracts. The main table contains unique contract ids and their related information, as well as the expenses of each contract. The associated information of a contract id includes 1) the general information of contract such as payer, currency, direction, contract type, service type, duty count, planned time. 2) the basic characteristics of the shipped goods, such as refrigeration, temperature, and maximum weight. 3) expected route information, such as longitude and latitude of loading and unloading positions, longitude and latitude of route start and end positions, kilometers to be covered according to the route plan, ferries and trains usage. As these data are important to predict the cost of forwarding contract, they form the core set of features used to train our model.

The route table records the main sections of each contract’s planned route. The route table has more detailed information about the planned route, which contains all route steps of each contract. The associated information of a route step includes 1) general information of route step such as the sequence number, step type, latitude and longitude of the end route step point, city, address, and estimated time. 2) information of ferry and train usage. 3) the vehicle and trailer status information. These data contain information about all of the route steps, which can help our model understand the specific route composition in a contract and assess the cost of a contract at the granularity of route step.

The fuel price table records historical wholesale fuel prices from 2016-01-01 to 2021-11-30, which covers the period of training and test data. This table describes three different types of fuel price information. The cost of transportation can be directly affected by the price of fuel. Thus, it is also an important component of freight forwarding contract costs.

Among these data tables, the main table provides the base information for the competition task. We can explore the properties for further feature engineering when we have a clear understanding of the meaning of the data and features. First, we analyse the expenses column, which is a continuous value to indicate the cost of forwarding contract. The min value of expenses is 2.879139, and the max value is 9.598065. It can be regarded as a regression task. Then, we find that the route table contains information about all route steps, and the fuel price table can indicate the fuel price at the time of the contract. The route table and fuel price table can provide more specific

information for predicting the cost of forwarding contract. Thus, it is necessary to extract more information related to the cost from the route table and fuel price table. This makes for more targeted feature engineering and more representative extracted features.

B. Feature Engineering

Following the data analysis phase described above, we generate three types of new features from the main table, route table, and fuel price table. We remove redundant features after all new features have been generated. In the following subsections, three types of new features and the process feature selection are comprehensively presented.

1) *Main Table Features*: Main table features are mainly generated from the main data table summarizing contract’s definition and can indicate the transportation costs. As the temperature feature is quite messy, we perform a simple data clean to correct the temperature in different formats. Then, we generate a series of new features to characterise the cost of contract. The generated features of main table can be divided into three parts: 1) basic features such as duration time, the haversine distance from route start to end location and load to unload location, the ratio of kilometers to be covered with empty trailer and so on. 2) cross features such as “direction×contract_type”, “first_load_country×last_unload_country, and so on. The cross features can characterize the links between different category features. 3) time features such as the year of route start time, the quarter of route start time, and so on. The time features can characterize the impact on costs at different times.

2) *Route Table Features*: Route table features are mainly generated from the route data table based on “id_contract”. Each contract has a different number of route sections. We aggregate the section attributes of each contract in different ways. For numerical attributes, we aggregate them by count, sum, and ratio operations. We also use statistical methods like mean, max, min, and median to summarise the numerical features of each contract. For category attributes, we aggregate them by counting their occurrences. Moreover, we count top 1000 cities and address to characterize the geographical situation of each contract.

3) *Fuel Price Features*: Fuel price features are mainly extracted from the fuel price data table. As it is generally to assess the cost before the contract starts, we directly merge the fuel price into each contract that matches the route start time. The merged fuel prices can represent current fuel price levels at the beginning of the contract.

4) *Feature Selection*: The feature set has over 2600 features after all the new features generated. We remove any features that are redundant or duplicate. A redundant feature is defined as the percentage of the value of a particular feature that is greater than 99.9%. Finally, we get 1092 features after simple feature selection.

C. Model Construction

Gradient boosting decision tree[7] is an model which uses decision tree as weak learner and improves model quality with

a boosting strategy[8]. The gradient boosting based method has been shown to achieve superior performance in various machine learning tasks, such as prediction[9] and ranking[10]. Due to its excellent performance and high accuracy, we choose the gradient boosting based method as our base model. There are multiple implementations of gradient boosting based method, like XGBoost[11], LightGBM[12], and CatBoost[13].

In model construction, we try various gradient boosting based methods to train the selected features and select the best method as the base model of our final solution. We finally choose LightGBM as our base model for its ability to handle the high dimensions of features and high efficiency. We also propose an ensemble approach, which introduces the model stacking mechanism, to improve the generalisation performance. The generalisation ability of an ensemble approach is usually much stronger than that of base learners[14].

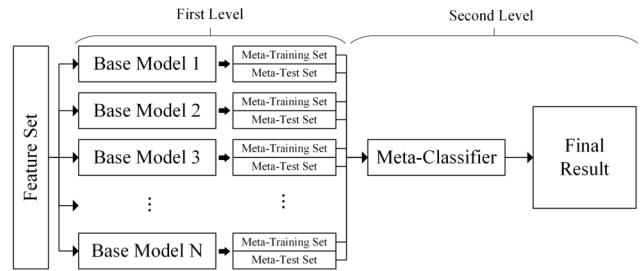

Fig. 2. The framework of proposed ensemble approach

The proposed ensemble approach can be separated into two levels, as shown in Figure 2. First, the training set is split into two parts, one part is used for first-level model training which is LightGBM, the other part, along with the test set, is used for prediction by the trained first-level model. Then, we use the predicted results from the first-level model to train the meta classifier. Typically, the meta classifier is a simple linear model. Therefore, we choose ridge regression as the meta classifier. The predicted result of the meta-classifier is our final result.

IV. EXPERIMENT AND RESULT

A. Experiment Setup

1) *Environment*: The operating environment is Ubuntu 21.10, memory at 128GB, an Intel Xeon Silver 4210 CPU @ 2.20GHz, with 40 physical processors.

2) *Toolkit*: For feature engineering implementation, we use Pandas 1.2.4, Numpy 1.20.1 to generate new features. We also use LightGBM 3.3.2 as the implementation of our base model.

3) *Evaluation Metric*: We take the root mean square error (RMSE) as the evaluation measurement, which is exactly the same as the evaluation criterion used for the competition.

B. Experiment Result

To ensure the scores between the local validation and the actual testing results remain within a certain range, it is important to have a good validation strategy. Cross-validation is a resampling method that uses different portions of the data to test and train a model on different iterations. In typical

cross-validation, the training and validation sets must cross over in successive rounds such that each data point has a chance of being validated against[15]. Since the labels are continuous values, we use the standard k -fold cross-validation as our local validation strategy. To determine the value of k , we tried different values of k and eventually found that the gap between local validation and online validation was smallest when $k = 3$. Thus, we set $k = 3$ and the gap between our local validation score and the public leaderboard score was less than 0.014.

In the experiment, we use different feature sets to evaluate each set's performance and the improvement of the model stacking. The experimental results are shown in Table II. In this table, "Baseline" represents the feature set contained in the original main data table, "FeatureSet₁" represents the merging feature set of the original main data table and generated main table features, "FeatureSet₂" represents the merging feature set of FeatureSet₁ and generated route table features, "FeatureSet₃" represents the merging feature set of FeatureSet₂ and generated fuel price features, and "Stacked" represents the model stacking based on the FeatureSet₃.

TABLE II
THE EXPERIMENTAL RESULTS OF DIFFERENT FEATURE SETS

Feature Set	RMSE Score(Local Validation)
Baseline	0.1463
FeatureSet ₁	0.1398
FeatureSet ₂	0.1276
FeatureSet ₃	0.1275
Stacked	0.1267

From Table II, it can be derived that: 1) From the result of training each feature set, the RMSE score get smaller and the performance gets better as the feature increase. The local validation result of FeatureSet₃ is 0.1275, which improves 0.0188 RMSE scores compared to the Baseline. The experimental results prove the effectiveness of our proposed feature engineering. 2) Comparing the base model and stacked model, the stacked model "Stacked" has 0.1267 RMSE scores, which improves by 0.0008 RMSE scores compared to the base model FeatureSet₃. The results of the comparison show that the model stacking strategy can improve the generalisation performance of the base model. Both the results of local validation and the public leaderboard can prove the effectiveness of our proposed approach.

V. CONCLUSION

In this work, we propose a gradient boosting based approach to predict the cost of forwarding contracts. We first analyse the data related to the freight forwarding contracts and provide the guidance for the feature engineering. Then, we focus on the feature engineering step to generate new features from the given data which can effectively characterise the cost of contracts. Finally, we present an ensemble approach that introduces the model stacking mechanism to improve the generalisation performance of base models. Both the results of our self-validation and the competition have shown that our

proposed approach is competitive. Future work can focus on trying a deep learning model as the base model for modelling the contract data and considering time as a trend factor for the features.

Computer Science and Systems

CSS is a FedCSIS track aiming at integrating and creating synergy between FedCSIS technical sessions which thematically subscribe to more technical (or applicable) aspects of computer science and related disciplines. The CSS track spans themes ranging from hardware issues close to the discipline of computer engineering via software issues tackled by the theory and applications of computer science, and to communication issues of interest to distributed, smart, multimedia and network systems.

The track is oriented on the research where the computer science meets the real world problems, real constraints, model objectives, etc. However the scope is not limited to applications, we all know that all of them were born from the innovative theory developed in laboratory. We want to show the fusion of these two worlds. Therefore one of the goals for the track is to show how the idea is transformed into application, since the history of modern science show that most of successful research experiments had their continuation in real world. CSS track is going to give an international panel where researchers will have a chance to promote their recent advances in applied computer science both from theoretical and practical side.

SCOPE

- Applied parallel and distributed computing and systems
- Applied system architectures and paradigms
- Problem-oriented simulations and modelling
- Applied methods of multimodal, constrained and heuristic optimization
- Applied computer systems in technology, medicine, ecology, environment, economy, etc.
- Theoretical fundamentals of the above computer sciences developed into the practical use
- Hardware engineering

Track includes technical sessions:

- Actors, Agents, Assistants, Avatars (1st Workshop 4A'22)
- Computer Aspects of Numerical Algorithms (15th Workshop CANA'22)
- Concurrency, Specification and Programming (30th International Symposium CS&P'22)
- Multimedia Applications and Processing (15th International Symposium MMAP'22)
- Scalable Computing (12th Workshop WSC'22)

Block Subspace Iteration Method for Structural Analysis on Multicore Computers

Sergiy Fialko

Tadeusz Kosciuszko Cracow University of Technology
 ul. Warszawska 24 St., 31 155 Kraków, Poland
 Email: sergiy.fialko@gmail.com

Abstract—The block subspace iteration method for problems of structural dynamics oriented on multi-core computers is presented to extract the natural vibration frequencies and modes. The investigation is focused on multithreaded parallelization of all principal stages of the method allowing to determine up to several thousand eigenpairs even for design models with a lot of very close or multiple eigenfrequencies.

I. INTRODUCTION

MODERN design finite-element models of buildings and structures usually have a dense spectrum of natural vibration frequencies. Mathematically, the problem is reduced to solving a partial generalized algebraic eigenvalue problem of a large dimension

$$\mathbf{K}\mathbf{v}_i - \lambda_i \mathbf{M}\mathbf{v}_i = 0, \quad i \in [1, n]. \quad (1)$$

Here \mathbf{K} is a sparse symmetric positive definite stiffness matrix, \mathbf{M} – diagonal or sparse symmetric semi-definite mass matrix, $\{\lambda_i, \mathbf{v}_i\}$ – eigenpair, N – dimension of the problem (1), n – number of required eigenpairs.

Requirements of seismic norms to determinate such a number of eigenpairs, which will provide a sufficiently high percentage of modal masses [1], [2] for each of the seismic input directions, leads to the fact that for many design models, with dimensionality, $N = 2,000,000 \div 6,000,000$ often has to obtain several thousands of eigenpairs [3].

The vast majority of such calculations are carried out by small and medium-sized design bureaus, so the main tool for numerical solutions of such problems are multi-core computers with shared memory, on which the solution of such problems by conventional methods can take from several hours to several days. Thus, increasing the performance of numerical methods for solving problem (1) for large design models with a large number of required eigenpairs is of great importance.

Both the Lanczos method and the subspace iteration method can be seen as varieties of the Arnoldi method [4]. However, within the framework of this article, we will confine ourselves to treating these methods as a kind of inverse matrix iteration method.

In the existing FEA software for the problems of structural dynamics, various versions of the block Lanczos method with spectral transformations [5], [6], etc. are very popular. The block version of the Lanczos method allows us

to confidently solve problems for which there are a large number of multiple or almost multiple eigenfrequencies, in other words, the spectrum of eigenfrequencies has the area of condenses. Spectral transformations of type

$$\mathbf{M}\mathbf{v}_i - \frac{1}{\lambda_i - \sigma} (\mathbf{K} - \sigma\mathbf{M})\mathbf{v}_i = 0, \quad i \in [1, n], \quad (2)$$

where σ - shift, first, allow us to better separate the close eigenfrequencies, which speeds up the convergence of the method, and secondly, divide the desired frequency interval to relatively small sub-intervals, limiting the dimension of the reduced problem on the Krylov subspace even in the case when we need to determine several thousand eigenpairs. At the same time, the maximum dimension of the reduced problem on the Krylov subspace does not depend on the number of required eigenpairs, which provides a quasi-linear computational complexity of the method instead of the quadratic computational complexity typical for versions of the method operating on the single frequency interval.

With the development of multi-core computers with shared memory, it turned out that existing implementations of the Lanczos method face difficulties in multi-threaded parallelization. One of the reasons that reduce the effectiveness of parallelization is the dimensionality of Krylov's subspace changing from step to step. Our observations have shown that while the dimension of the Krylov subspace is approximately within the first third of the maximum dimension in the current frequency interval, it is not possible to effectively use all the cores of the processor.

The disadvantage of a simple version of the subspace iteration method [1] (section 14-6) is the quadratic increase in the time of solving the problem with an increase in the number of required eigenpairs, which makes it practically unacceptable for the class of problems presented here.

The block version of the shifted subspace iteration method [7] corrects many shortcomings of the previous version of the algorithm. The essence of the method is that the iterations are performed in a block of a fixed dimension, which is much smaller than the number of required eigenpairs. As soon as converged eigenpairs appear in the block, the corresponding eigenvectors are placed in the special storage, excluded from the block, and in their place are created new start vectors that

This work was supported by IT Company SCAD Soft (www.scadsoft.com)

are linearly independent of each other and orthogonalized both to the remaining vectors in the block and to the previously converged eigenvectors. At each step of the method, all the vectors in the block are orthogonalized to the previously converged eigenvectors in order to avoid duplication of eigenpairs. At each step of the method, all the vectors in the block are orthogonalized to the previously converged eigenvectors in order to avoid duplication of eigenpairs. These orthogonalization procedures are a bottleneck that limits the use of this method for problems in which several thousand eigenpairs need to be extracted.

A similar drawback is the version of the method of conjugated gradients with preconditioning and spectral transformations [3].

In this article, we present a block version of the subspace iteration method with spectral transformations as an alternative to the block Lanczos method. The dimensionality of Krylov's subspace remains constant all the time, which makes it possible to effectively use the capabilities of modern multi-core computers. Spectral transformations accelerate the convergence of the method by dividing the close natural frequencies, and most importantly, they make it possible to divide the frequency interval into computationally independent sub-intervals and provide a quasi-linear dependence of the solving time of the problem on the number of required eigenpairs.

II. PARALLEL BLOCK SUBSPACE ITERATION METHOD WITH A SPECTRAL TRANSFORMATIONS

A. Foundation

Before proceeding to the presentation of the proposed method, let us first give a simple algorithm of the subspace iteration method, corresponding to the one described in [1], but at the same time, we will take into account the impact of the shift σ . Let the approximation of the eigenvectors \mathbf{v}_i^k , forming a rectangular matrix be known at step k

$$\mathbf{Q}^k = \{\mathbf{v}_1^k, \mathbf{v}_2^k, \dots, \mathbf{v}_m^k\}, \quad (3)$$

where

$$\begin{aligned} (\mathbf{v}_i^k)^T \mathbf{M} \mathbf{v}_j^k &= \delta_{ij}, \\ (\mathbf{v}_i^k)^T (\mathbf{K} - \sigma \mathbf{M}) \mathbf{v}_j^k &= \begin{cases} 0, & i \neq j \\ \neq 0, & i = j \end{cases} \quad i, j \in [1, m], \end{aligned} \quad (4)$$

δ_{ij} is a Kronecker symbol, m – block dimension (Krylov subspaces dimension). Perform an iteration step with the inverse matrix for the expression (2):

$$(\mathbf{K} - \sigma \mathbf{M}) \overline{\mathbf{Q}}^{k+1} = \mathbf{M} \mathbf{Q}^k. \quad (5)$$

Matrix $\overline{\mathbf{Q}}^{k+1}$ contains improved approximations of eigenvectors compared to the matrix \mathbf{Q}^k , but $\mathbf{K} - \sigma \mathbf{M}$ and \mathbf{M} orthogonality of vectors $\overline{\mathbf{v}}_i^{k+1}$, $i \in [1, m]$ is lost. Therefore, the next step is to orthogonalize the column vectors of the matrix $\overline{\mathbf{Q}}^{k+1}$:

$$\mathbf{v}_i^{k+1} = \sum_{j=1}^m q_{i,j}^{k+1} \overline{\mathbf{v}}_j^{k+1}, \quad i \in [1, m]. \quad (6)$$

Substituting (6) in (2), we get an algebraic generalized eigenvalue problem in the subspace S_m formed by the vectors $\overline{\mathbf{Q}}^{k+1}$:

$$\frac{1}{\lambda_i - \sigma} (\{\mathbf{k}\} - \sigma \{\mathbf{m}\}) \mathbf{q}_i - \{\mathbf{m}\} \mathbf{q}_i = 0, \quad i \in [1, m], \quad (7)$$

where $\{\mathbf{k}\} = \mathbf{Q}^T \mathbf{K} \mathbf{Q}$, $\{\mathbf{m}\} = \mathbf{Q}^T \mathbf{M} \mathbf{Q}$, $\mathbf{q}_i = \{q_{i,1}, q_{i,2}, \dots, q_{i,m}\}^T$ is a vector of dimension m containing the expansion coefficients (6). Here, the upper subscript $k+1$ is omitted for the sake of brevity. Problem (7) is equivalent to a simpler problem:

$$\{\mathbf{k}\} \mathbf{q}_i - \lambda_i \{\mathbf{m}\} \mathbf{q}_i = 0, \quad i \in [1, m], \quad (8)$$

which is solved by using the LAPACK procedures implemented in the Intel Math Kernel Library [8]. Having determined at step $k+1$ the approximations of eigenvalues and eigenvectors in subspace S_m , we obtain approximations of eigenvectors (Ritz vectors) in the source space of dimension N :

$$\mathbf{Q}^{k+1} = \overline{\mathbf{Q}}^{k+1} \{\mathbf{q}^{k+1}\}, \quad (9)$$

where $\{\mathbf{q}\} = \{\mathbf{q}_1, \mathbf{q}_2, \dots, \mathbf{q}_m\}$. This ensures the

$\mathbf{K} - \sigma \mathbf{M}$ and \mathbf{M} orthogonality of the vectors \mathbf{v}_i^{k+1} , $i \in [1, m]$, since

$$\begin{aligned} (\mathbf{v}_i^{k+1})^T \mathbf{M} \mathbf{v}_j^{k+1} &= (\mathbf{q}_i^{k+1})^T (\mathbf{Q}^{k+1})^T \mathbf{M} \mathbf{Q}^{k+1} \mathbf{q}_j^{k+1} = \\ &= (\mathbf{q}_i^{k+1})^T \{\mathbf{m}^{k+1}\} \mathbf{q}_j^{k+1} = \delta_{ij} \end{aligned}, \quad (10)$$

and

$$\begin{aligned} (\mathbf{v}_i^{k+1})^T \mathbf{K}_\sigma \mathbf{v}_j^{k+1} &= (\mathbf{q}_i^{k+1})^T (\mathbf{Q}^{k+1})^T \mathbf{K}_\sigma \mathbf{Q}^{k+1} \mathbf{q}_j^{k+1} = \\ &= (\mathbf{q}_i^{k+1})^T \{\mathbf{K}_\sigma^{k+1}\} \mathbf{q}_j^{k+1} = \begin{cases} 0, & i \neq j \\ \neq 0, & i = j \end{cases}, \end{aligned} \quad (11)$$

where $\mathbf{K}_\sigma = \mathbf{K} - \sigma \mathbf{M}$, $\{\mathbf{k}_\sigma\} = \{\mathbf{k}\} - \sigma \{\mathbf{m}\}$.

Here, the central moment that ensures the convergence of the method is the expression (5). Stages (6) to (9) provide the orthogonality of the improved Ritz vectors and prevent duplication of eigenpairs. Let's expand the expression (5) according to the eigenvectors of the problem (2) and multiply left by \mathbf{v}_j^T :

$$\sum_{i=1}^m \alpha_i^{k+1} (\mathbf{K} - \sigma \mathbf{M}) \mathbf{v}_i = \sum_{i=1}^m \alpha_i^k \mathbf{M} \mathbf{v}_i \cdot |\mathbf{v}_j^T, \quad j \in [1, m]. \quad (12)$$

Here $\mathbf{v}_i^k = \sum_{i=1}^m \alpha_i^k \mathbf{v}_i$, \mathbf{v}_i^k is an approximation of eigenvector

\mathbf{v}_i in the iteration step k . Taking into account the orthogonality of eigenvectors and the norming conditions with respect to the matrix \mathbf{M} , and also applying the expression for Rayleigh's quantity $\lambda_i = \mathbf{v}_i^T \mathbf{K} \mathbf{v}_i$ for the problem (1), we get:

$$\alpha_i^k = \left(\frac{1}{\lambda_i - \sigma} \right)^k \alpha_i^0, \quad i \in [1, m], \quad (13)$$

from which it follows that the closer the shift σ to the eigenvalue λ_i , the faster will be the convergence of the iterative process $k = 1, 2, \dots$ to eigenpair $\{\lambda_i, \mathbf{v}_i\}$. Figure 1 presents a typical pattern of convergence of eigenvalues around the shift σ : the closer the eigenvalue λ_i is to the shift σ , the faster “on average” the Ritz pair $\{\lambda_i^k, \mathbf{v}_i^k\}$ converges to the corresponding eigenpair $\{\lambda_i, \mathbf{v}_i\}$ with the required precision.

Fig. 1 Typical convergence of eigenfrequencies for methods based on shifted inverse iterations

The phrase "on average" should be understood in the statistical sense, since the rate of convergence depends not only on the difference $\lambda_i - \sigma$, but also on the selection of the initial approximation determined by α_i^0 coefficients. Thus, with the help of a proper selection of the shift value σ , we can control the position of the "center of convergence" on the axis λ . The information provided is well known and is presented here to facilitate understanding of the further presentation.

B. Block subspace iteration method

The disadvantage of the algorithm outlined above is that, with an increase in the number of required eigenpairs, the dimension m of the subspace increases, which leads to a rapid increase in the duration of such an analysis. To overcome this drawback, we divide the frequency interval into the subintervals, keeping a relatively small value of the parameter m , and also use multi-threaded parallelization. Unfortunately, the amount of RAM of modern multi-core computers does not allow us to concurrently solve the plurality of problems (2) for different shift values σ , as is done for distributed memory systems, so we parallelize the separate stages of the method.

The following Algorithm 1 presents the proposed approach. Step 1 performs the starting initialization of the method – it creates m orthogonal and \mathbf{M} – orthonormal vectors forming the rectangular matrix \mathbf{Q}^0 . *LeftMark* and *Rightmark* correspond to the left and right borders of the subinterval on the axis λ (Fig. 2), and *no_conv_modes* means the number of converged eigenpairs.

Fig. 2 Next frequency subinterval preparation

Algorithm 1. General algorithm of the block subspace iteration method with spectral transformation.

1. Creation of m linearly independent vectors \mathbf{Q}^0 according (3). Set $k = 1$; $no_conv_modes = 0$; $LeftMark = RightMark = 0$; $\sigma = 0$.
2. **while** $no_conv_modes < nModes$ **do**
3. Check status of vectors \mathbf{Q}^k in block.
4. Inverse iteration step (5).
5. Create subspace matrices $\{\mathbf{k}\}^k$ and $\{\mathbf{m}\}^k$.
6. Solve reduced eigenvalue problem (8).
7. Calculate new Ritz vectors (9).
8. $k++$.
9. **end while**

Algorithm 2. Check status of vectors \mathbf{Q}^k in block

1. **parallel for** $i = 1; i \leq m; ++i$ **do**
2. $\mathbf{r}_i^k = \mathbf{K}\mathbf{v}_i^k - \lambda_i^k \mathbf{M}\mathbf{v}_i^k$
3. **if** $\|\mathbf{r}_i^k\|_2 / \|\lambda_i^k \mathbf{M}\mathbf{v}_i^k\|_2 < tol$
4. $conv_i = true$;
5. **else**
6. $conv_i = false$;
7. **end of parallel for**
8. *SetShiftProc()*;
9. **if** $\sigma_{new} == \sigma$ **then**
10. **return**;
11. **else**
12. $\sigma = \sigma_{new}$;
13. **end if**
14. $\forall \lambda_i \in [LeftMark, RightMark]$ store $\{\lambda_i, \mathbf{v}_i\}$ as a final results. Put: $list_new_vect \leftarrow i$.
15. $LeftMark = RightMark$;
16. **Parallel for** $i \in list_new_vect$ **do**
17. Generate new start vectors instead of stored eigenvectors, orthogonalize them against all remaining vectors in the block and normalize $\mathbf{v}_i^T \mathbf{M}\mathbf{v}_i = 1$.
18. **end of parallel for**

Loop **while** (steps 2 – 9) works until the number of required eigenpairs $nModes$ are defined.

In step 3, the status of vectors in the block is checked - Algorithm 2. In a parallel loop **for** (steps 1 – 7), the residual vector \mathbf{r}_i^k is determined. If the condition of step 3 is satisfied, this means that this Ritz pair has been converged with the required precision set by the *tol* parameter, and the i^{th} element of the *conv* array is assigned to *true*.

The *SetShiftProc()* procedure (step 8) calculates the number of converged eigenpairs, starting with *LeftMark* until the first non-converged Ritz pair meets, and the position *RightMark* (Fig. 2) is determined. Thus, segment $[LeftMark, RightMark]$ contains only eigenvalues for converged

eigenpairs. The transition to a new subinterval (change in the value of the shift σ) is carried out when the following two conditions are satisfied:

- The number of converged eigenpairs on the segment $[LeftMark, \sigma]$ will be equal to $NoNegSignes - no_conv_modes$. Here, $NoNegSignes$ is the number of sign changes on the main diagonal of the factorized matrix $\mathbf{K} - \sigma\mathbf{M}$ (the number of eigenvalues enclosed in the interval from zero to σ), and no_conv_modes is the number of converging eigenpairs, which should be equal to the number of eigenvalues enclosed in the interval from zero to $LeftMark$ (Sylvester's theorem of inertia).
- The number of converged eigenpairs on the $[LeftMark, RightMark]$ segment is not less than the specified $IncrEigVect$ value.

The first condition ensures that there are no skipped eigenfrequencies during the transition from one subinterval to another, and the second is necessary to ensure a sufficient number of iterations of the method for reliable prediction of the $RightMark$ value.

As soon as the above conditions are satisfied, a transition to a new subinterval is carried out: a new shift value is calculated as $\sigma_{new} = (\lambda^* + \lambda^{**})/2$, where λ^* is an approximation of eigenvalue locating on a value $IncrEigVect$ from rightmost converged eigenvalue belonging to segment $[LeftMark, RightMark]$, and λ^{**} is the next eigenvalue – see Fig. 2. To ensure the computational stability of the proposed algorithm, the prediction λ^{**} must be made with sufficient accuracy, which depends on the dimension of the block m and the value of the $IncrEigVect$ parameter. The recommended values of these parameters are discussed in section III, E.

If at least one of the above conditions is not fulfilled, the shift value does not change, there is no transition to a new subinterval, the exit from Algorithm 2 (step 9) is performed and the iterations in this \mathbf{Q}^k block continue. Otherwise, the σ shift value is changed and the transition to a new frequency interval is made (step 12). All converged eigenpairs in the $[LeftMark, RightMark]$ segment are the final result and are placed in special storage on disk (step 14) and the $LeftMark$ value is reset (step 15). Then, in a parallel region (steps 16 – 18), new starting vectors are generated in the addresses of converged eigenvectors, orthogonalized against themselves, as well as against the remaining vectors in the block and normalized, after which we proceed to step 4 of Algorithm 1.

If at this step k there is a change in the magnitude of the shift σ , the factorization of the matrix $\mathbf{K} - \sigma\mathbf{M}$ is performed. Otherwise, the lower triangular matrix with the previous factorization is used. Forward-back substitutions are then performed. Multithreaded parallelization is used when calculating the rectangular matrix of the right parts (5) is performed. To factorize the matrix, the PARFES solver [9] designed specifically for multi-core computers with shared memory is used. Also, a parallel method [10] is applied to perform forward-back substitutions.

Fig. 3 Subdivision the matrix \mathbf{Q} between threads

Calculation of projection matrices $\{\mathbf{k}\}^k = (\mathbf{Q}^k)^T \mathbf{K} \mathbf{Q}^k$ and $\{\mathbf{m}\}^k = (\mathbf{Q}^k)^T \mathbf{M} \mathbf{Q}^k$ in subspace $S_m = \text{span}\{\mathbf{v}_i^k \in \mathbf{Q}^k\}$ (Algorithm 1, step 5), is produced using multithreading.

To do this, the matrix \mathbf{Q} (the iteration number k is omitted) is divided into blocks $\mathbf{Q}_1, \mathbf{Q}_2, \dots, \mathbf{Q}_{np}$, where np is the number of threads and $m_{loc} = m/np$ is the number of vectors in each block \mathbf{Q}_p , $p \in [1, np]$ (Fig. 3). If the dimension m of the iterated block \mathbf{Q} is not multiple to the number of threads, then for the last block is taken $m_{loc} = m - (np - 1)m/np$, where $(np - 1)m/np$ is the integer part of this expression. The mapping of blocks $\mathbf{Q}_1, \mathbf{Q}_2, \dots, \mathbf{Q}_{np}$ onto threads is shown in Fig. 3. Each thread performs a task:

$$\{\mathbf{k}_{ip}\} = \mathbf{Q}^T \mathbf{K} \mathbf{Q}_{ip}, \quad \{\mathbf{m}_{ip}\} = \mathbf{Q}^T \mathbf{M} \mathbf{Q}_{ip}, \quad ip \in [1, np]. \quad (14)$$

First, the sparse matrix \mathbf{K} is multiplied by a dense rectangular matrix $\mathbf{B}_{ip} = \mathbf{K} \cdot \mathbf{Q}_{ip}$, and then $\{\mathbf{k}_{ip}\} = \mathbf{Q}^T \mathbf{B}_{ip}$ is calculated. Similarly, the dense matrix $\{\mathbf{m}_{ip}\}$ is evaluated.

The generalized eigenvalue problem (8) in the S_m subspace (Algorithm 1, step 6) is solved using the LAPACK procedure of the Intel MKL library [8], after which the vectors \mathbf{v}_i^{k+1} , $i \in [1, m]$ are determined (9), using a parallel version of the $dgemm$ procedure from the Intel MKL library (Algorithm 1, step 7).

III. NUMERIC RESULTS

Numerical results have been obtained on computer with 12-core Intel® Core™ i9-9920X CPU 3.50 GHz processor, 128 GB RAM, 64-bit Windows 10 Pro OS. This processor supports SIMD instructions AVX512F and FMA, has 512-bit registers that allow loading eight double words and simultaneously perform 8 multiplications and 8 additions.

The main attention is paid to the analysis of the time of solving the problem and the acceleration of the main stages of the proposed approach with an increase in the number of threads. The comparison is made with the block Lanczos method with spectral transformations [6], developed for the SCAD FEA software [11] and using the same PARFES solver to solve systems of linear algebraic equations with sparse symmetric matrices as the proposed approach. In addition, a

multi-threaded parallelization of all the main stages of the Lanczos method was performed.

Design models are taken from the collection of problems of SCAD Soft – IT company, the developer of SCAD, one of the most widespread FEA software for the analysis and design of building structures in CIS countries, which has a certificate of compliance with regional building codes and a license for use in the design of nuclear power facilities.

A. Example 1

Figure 4 presents a design model of multistorey building comprising 4,262,958 equations. 500 eigenpairs are extracted. Such number of eigenpairs ensures the sum of modal masses 90% for each seismic input direction and satisfies requirements of the seismic building codes.

Dimension of block is accepted as $m = 96$ and parameter – $IncrEigVect = 15$. Table I depicts the total duration for the entire time of solving the problem of each basis stage of the proposed parallel block subspace iteration method (PBSI) depending on the number of threads. The number of threads does not exceed the number of physical core. This used thread binding to logical processors, where only one thread runs on each physical core. With the exclusive use of a computer for only one computing task, this strategy allows us to achieve the greatest performance and speed up the method while increasing the number of threads.

Fig. 4 Multistorey building 4,262,958 equations.

S_{12}	3.63	8.73	5.23	6.56	2.89	7.61	5.94

TABLE II.
DURATION OF THE BASIC STAGES OF THE BLOCK LANCZOS METHOD WITH SPECTRAL TRANSFORMATIONS, S

# threads	Generation of Lanczos vectors	Reorthogonalization	Subspace eigenvalue problem	Check of precision	Total
1	7516	3769	1230	319	13264
2	4445	2225	1238	235	8196
4	2741	1310	1227	214	5472
6	2655	1374	1218	189	5029
8	2222	945	1229	192	4480
10	2208	936	1224	180	4360
12	2194	937	1256	198	4343
S_{12}	3.43	4.02	0.98	1.61	3.05

The column «Check status of Q^k vect.» shows the duration of step 3 of Algorithm 1, the column «Factorization» – shows the duration of factorization of the sparse matrix $K - \sigma M$ by the PARFES solver [9], and the column «Resolution» depicts the time spent on performing multiplication of the mass matrix M by a rectangular matrix Q^k and on forward-back

substitutions (5). At least for the diagonal mass matrix used in this problem, the main time of this step is forward-back substitutions, since the calculation of MQ^k is performed in about 5 seconds. The column «Subspace matrices» presents the time of evaluation of matrices $\{k\}$ and $\{m\}$ (step 5, Algorithm 1). The column «Improved Ritz vectors» depicts

the time of the improved Ritz vectors evaluation \mathbf{Q}^{k+1} (step 7, Algorithm 1), the column «Rest» demonstrates the time of all remaining operations which are parallelized too, and column «Total» – total time for solution of problem. Reduced generalized eigenvalue problem on subspace S_m (step 6, Algorithm 1) is solved in sequential mode, and the total duration of this stage for the given problem is about 0.2 s.

The last row shows the speedup for 12 threads: $S_{12} = T_1/T_{12}$, where T_1 is the total time of this stage on one thread, and T_{12} is on 12 threads.

The total speedup of the PBSI method is 5.94 on 12 threads, with the highest speedup achieved at the matrix factorization stage and the lowest – at the improved Ritz vector calculation stage. Taking into account that the duration of this stage is about an order of magnitude less than the duration of forward and back substitutions, we conclude that the bottlenecks of the proposed method are the stages "Check status of \mathbf{Q}^k vect." and forward-back substitutions, having a speedup 3.63 and 5.23, respectively.

The forward and back substitution algorithms are presented in details in [10]. It also shows that the greater the number of right-hand sides, the higher the speedup of this algorithm with increasing the thread number. In the block Lanczos method [6], we usually have 7 right-hand sides and speedup does not exceed 2.5. The proposed approach has much more than 7 right-hand sides, so the speedup of forward-back substitutions is higher compared with the block Lanczos method.

Table II shows the results for the block Lanczos method with spectral transformations. The basis stages here are "Generation of Lanczos vectors", "Reorthogonalization", "Subspace eigenvalue problem", "Check of precision". Factorization of the $\mathbf{K} - \sigma\mathbf{M}$ matrix is performed with each change in the shift σ . The factorization time of the matrix and the time of forward and back substitutions are included in the total time of the "Generation of Lanczos vectors" stage. The "Subspace eigenvalue problem" stage is executed on a single thread. The total speedup of the block Lanczos method was almost two times worse than the PBSI method, and the total duration of the solution on 12 threads was 1.7 times longer.

B. Example 2

Figure 5 presents a design model of a shopping and entertainment center (TRK), containing 2,442,846 equations. Here we use an abbreviator TRK in the original (Ukrainian) language.

Fig. 5 Design model of a shopping and entertainment center (TRK), 2,442,846 equations.

Unlike the previous one, this design model, due to its low height, has much greater rigidity in the horizontal direction, which leads to slow convergence of the corresponding sums of modal masses. To achieve 90% of the sums of modal masses for each of the directions of seismic excitation, it was necessary to extract 2270 eigen pairs. At many parts, the natural vibration frequency spectrum undergoes condensation – Table III. In red color, especially close eigenfrequencies are highlighted.

For the PBSI method, the following parameter values are accepted: $m = 96$, $IncrEigVect = 15$. The duration of solving the problem on 12 threads is 6,729 seconds.

The time to solve this problem by the block Lanczos method is 11,883 s. Thus, the proposed PBSI method was 1.77 times faster than the block Lanczos method.

C. Example 3

Figure 6 shows a design model of an industrial building comprising 1,807,218 equations. The bearing system of such a structure is the cross walls and floors (Fig. 7), which generates a huge number of local natural vibration modes, which practically do not contribute anything to the sums of modal masses both in horizontal directions and in vertical. To achieve 90% of the sum of modal masses in all directions, 20,352 eigenpairs had to be determined for this task.

For the PBSI method, the following parameter values are accepted: $m = 96$, $IncrEigVect = 15$. The duration of solving the problem on 12 threads is 45,819 s. The duration of solving the same problem by the block Lanczos method is 61,910 s.

Fig. 6 Design model of industrial building – 1,807,218 equations.

Fig. 8 Sum of modal masses in each seismic input direction

Fig. 8 shows the process of increasing the sums of modal masses with an increase in the number of eigenpairs taken into account in the modal analysis. Here $SUM\{M_x\}$, $SUM\{M_y\}$, $SUM\{M_z\}$ are the sums of modal masses in directions OX, OY, and OZ correspondingly. This problem is an excellent test for checking the computational stability and reliability of methods for determining the frequencies and modes of natural oscillations since to achieve at least 90% of the sums of modal masses in the horizontal and vertical directions, it was necessary to extract more than 20,000 eigenvalue pairs.

D. Example 4.

Design model of multistorey building is shown in Fig. 9 and Fig. 10. This model comprises 2,002,428 equations and has a complex shape of the spatial configuration.

Fig. 7 Fragment of industrial building.

Fig. 9 Multistorey building of complex shape, 2,002,428 equations

Fig. 10 Fragment of multistorey building of complex shape.

Fig. 11 Typical natural vibration mode for one from floor slabs.

A lot of local vibration modes (Fig. 11) making a very small contribution to the sum of modal masses turn out determination a large number of eigenpairs for seismic analysis – 1048 eigenpairs are required to obtain 90 % of the modal masses sum in horizontal directions and 75% in vertical (Fig. 12). This problem contains the condensation parts of the eigenvalue spectrum, one of which is presented in table IV. In red color, especially close eigenfrequencies are highlighted.

Fig. 11 demonstrates typical vertical vibrations of floor slabs. There are many such floors in the design model, so there are a large number of very close natural frequencies. In addition, the corresponding local forms of oscillation give a small contribution to the seismic response of the system, so it is necessary to determine a large number of eigenpairs to obtain reliable seismic response.

Fig. 12 demonstrates a slow increase of the sums of modal masses.

For the PBSI method, the following parameter values are accepted: $m = 96$, $IncrEigVect = 15$. The duration of solving

the problem on 12 threads is 2,687 s. The duration of solving the same problem by the block Lanczos method is 4,200 s.

E. Reasoning about the parameters that control the convergence and numerical stability of the PBSI method.

The convergence rate and computational stability of the proposed method are determined by the values of the parameters m and $IncrEigVect$. It is desirable that the value of m be a multiple of the number of threads np . Then the number

of vectors in each subblock \mathbf{Q}_p , $p \in [1, np]$ (Fig. 3) will be the same, which will favorably affect the balance of the computational load between threads. If the values of the parameter m are too small, the Ritz pairs located to the right of *RightMark* are determined with insufficient accuracy, which often leads to an unreliable forecast when choosing a new value of the shift of the new σ – Fig. 2. In this case, it may turn out that at the new frequency interval, the number of natural frequencies of *NoNegSignes* – *no_conv_modes* enclosed between the shift value σ and *LeftMark* – significantly exceeds the *IncrEigVect*, which often leads to a loss of convergence of the iterative process. Another danger of not having enough iterations in a given frequency interval is that there will be skipped some of the natural frequencies in the [*LeftMark*, *RightMark*] segment, and then the condition that number of converged eigenpairs on the segment [*LeftMark*, σ] must be equal to *NoNegSignes* – *no_conv_modes* (see the description of the SetShiftProc() procedure) will never be fulfilled – there will be an emergency interruption of the calculations after the control number of iterations exceeds.

Too small values of the *IncrEigVect* parameter lead to insufficient accuracy in determining Ritz pairs (too few iterations in a given frequency interval), and too large – to shift the new σ to the right boundary of the interval.

Testing of a large number of different tasks from the SCAD Soft collection showed that the values of the parameters m and *IncrEigVect*, close to optimal, are as follows: $m \in [96, 192]$, *IncrEigVect* $\in [10, 30]$. In this case, lower m values correspond to smaller *IncrEigVect* values.

It should be noted that when debugging the block Lanczos method with spectral transformations [6], we encountered similar problems when choosing the values of the parameters that ensure the computational stability and convergence of the method.

IV. CONCLUSION

The considered class of problems often requires determining a large number of natural vibration frequencies and modes to satisfy to requirements of seismic codes. In addition, in many cases, due to the presence of a large number of local oscillation modes, there are areas of condensation of the natural frequency spectrum. These features lead to the fact that the considered class of problems requires the development of effective numerical methods for their solution.

The parallel block method of subspace iteration proposed in this paper, designed to solve large-scale problems of determining the natural vibration modes and frequencies of buildings, structures, and deformable solids on multi-core computers with shared memory, demonstrates a shorter analysis time and greater speedup with an increase in the number of threads than the block Lanczos method with spectral transformations [6], which has been used in many industrial software over the years.

ACKNOWLEDGMENT

The author is deeply grateful to IT company SCAD Soft for providing a collection of real-life problems with the design models created by SCAD Office users.

Flexible user query order for the speculative query support in RDBMS.

Anna Sasak-Okon

Abstract—This paper concerns speculative query execution support for RDBMS based on the dynamic analysis of input (user) query stream. A middleware called the Speculative Layer is presented. Based on a specific multigraph representation of groups of consecutive input queries, called the Speculation Window, the Speculative Layer generates speculative queries for look-ahead execution. These speculatively obtained results are then used while executing user queries. This paper shortly presents the structure of the Speculative Layer and the adopted graph modelling method. Then, a new strategy of queries in the Speculation Window is introduced. Depending on the availability of executed speculative queries results we allow order of user queries in the Speculation Window changes. If a user query was to be executed without the speculative support, we prefer to delay its execution in favour of one of the consecutive user queries, expecting that speculative results obtained in the nearest future will be useful for the delayed query. The experimental results presented in a multithreaded environment, cooperating with a SQLite database, show that the proposed strategy reduces the number of user queries executed without the speculative results. Additional series of experiments verifies that the certain parameters describing the speculative support system, like Speculation Window size, are properly chosen.

I. INTRODUCTION

SPECULATIVE Parallelization, sometimes called Optimistic Parallelization[1] is a technique which allows parallel execution of code fragments that were originally intended for a sequential run. To ensure correctness, speculative results must be verified to avoid dependence violations. In such case a violating thread and its results are usually discarded and restarted with updated data [7][8][9]. The practical use of the speculative approach in relational databases usually supports single queries, ranked queries [14] or transactions (speculative transaction protocols) [12][13] by performing some anticipated, potentially useful operations or subqueries out of its standard order [10] or in advance based on received earlier tips [11]. There are also papers, like [15][16], which focus on multiple query optimization although without the concept of the speculative execution.

Graph structures often used as a formalism helping represent and analyse queries are very popular as they naturally represent and model entities and their relationships [17][18].

It should be noted that none of the described above optimization methods aims at speculative support which covers need of many future queries at a time. Saving the results obtained speculatively reminds caching methods [19][20][21][22], but

instead of history based methods we prefer to analyse queries which are waiting for execution in the nearest future and support them with data prepared in advance. The speculative execution model we introduced in our previous papers [2][3][5][6] focuses on parallelised speculative support for execution of input (user) query streams. It includes a multi-threaded middleware called the Speculative Layer, which is situated between user applications and the RDBMS. The aim of the Speculative Layer is to choose and execute speculative queries. These speculative results stored in the main memory structures called Speculative DB constitute quick access data set available while executing user queries. The process of choosing speculative queries to be executed is called the Speculative Analysis. The Speculative Analysis is performed continuously for groups of consecutive user queries called the Speculation Window (SW). For each Speculation Window a specific graph representations of each user query are created, which are then combined into one multigraph according to the defined set of rules.

The Speculation Window (SW) moves over the user query queue by one query. So far, for each SW, the first in order user query was executed nonspeculatively with or without the use of speculative results. In this paper we propose a new strategy for a nonspeculative query execution which is dependent on the availability of the speculative results. If a first query in the SW would have to be executed without speculative results we allow to replace it with a next query in the SW which has at least one executed speculative query assigned. We assume that one of the speculative results obtained in the nearest future will be useful for the delayed query. Speculation Window moves after the execution of the nonseculative query and we repeat the attempt to execute the first user query nonspeculatively.

The remaining text of the paper is composed of 3 parts. In the first part a general structure of the Speculative Layer is presented. We describe rules for query graphs creation and the process of Speculative Analysis resulting in optimally defined set of speculative queries ready for use. Section III describes the new strategy for the nonspeculative query execution. Section IV contains results of two series of experiments. First series of experiments presents effectiveness comparison between the Speculative Layer execution with old and new strategies for the nonspeculative query execution. The second series of experiments verifies the validity of the parameter

describing the size of the Speculation Window chosen for the previous versions of the speculative algorithm.

II. THE SPECULATIVE LAYER

Fast evolution of online activities induced development of database applications with the specific characteristics. These applications are intensively used as products browsing tools and thus execute many queries of a specific structure. Such queries are created by shop users who define search criteria, directly influencing attributes and conditions in the SELECT and WHERE query clauses. Therefore, the consecutive queries contain some common constituent operations, whose results, if executed speculatively can be used many times.

The above observations were an inspiration to propose a dynamic speculative support for execution of sql user queries. This model is implemented as an additional multithreaded middleware called the Speculative Layer and is located between user database applications and the RDBMS. The stream of user queries forms a queue which is continuously analysed by the Speculative Layer. The analysis (Speculative Analysis) is performed for the consecutive user queries grouped in a structure called the Speculation Window (SW) which slides on the query stream. Each user query is represented by its query graph created with a set of defined rules. Then, the single query representations for each Speculation Window are merged together to create a joint representation of the whole query group in the form of query Multigraph (Q_M).

The Speculative Layer is implemented to support and analyse CQAC (Conjunctive Queries with Arithmetic Comparisons) queries with functionality extended by two more allowed operators: IN for value sets and LIKE for strings comparisons. Additionally we allow a nested query in a WHERE clause returning a value for the attribute condition (...WHERE...attribute operator (SELECT...FROM...WHERE...)).

The aim of the Speculative Analysis process is to identify some common constituent operations in user queries which are then used to generate new queries, called the Speculative Queries. For this, an extended version of Q_M is created called Speculative Query Multigraph (SQ_M). It contains speculative edges which are a special type of edges which mark potential speculative queries. Based on the speculation result we introduce two types of speculative queries: **Speculative Parameter** or **Speculative Data** Queries. As there is allowed possibility of the modifying query occurrence in the query stream, and thus in the Speculation Window, we introduce additional type of speculative edges called **Speculative State**. Details of the strategy for modifying query handling process can be found in [6]. Fig.1 presents the SQ_M created for the following component queries:

- (Q_1) SELECT $A_{1,2}, A_{1,3}$ FROM R_1 WHERE $A_{1,2} = 4$
- (Q_2) SELECT $A_{2,2}, A_{2,3}, A_{1,3}$ FROM R_1, R_2 WHERE $A_{1,4} = A_{2,1}$ AND $A_{2,2} > 7$
- (Q_3) SELECT $A_{1,2}, A_{2,2}$ FROM R_1, R_2 WHERE $A_{1,4} = A_{1,2}$ AND $A_{1,3}$ LIKE '%xx' AND $A_{2,2} < 2$
- (Q_4) SELECT $A_{2,2}, A_{2,3}$ FROM R_2 WHERE $A_{2,2} > 5$

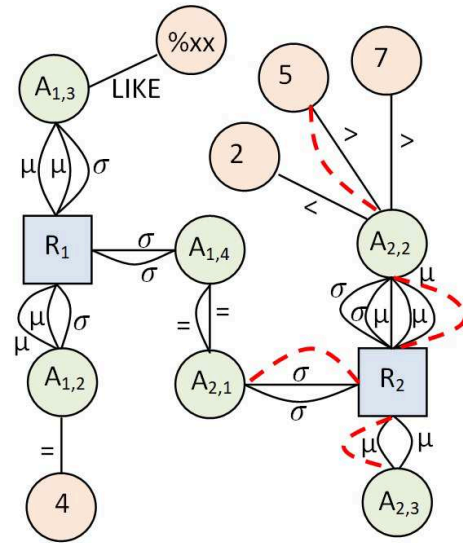

Fig. 1. Query Multigraph representing four user queries.

It has also Speculative Data edges inserted (red striped lines) which represent one of 5 possible speculative queries to be executed for this SW: (sq_1) SELECT $A_{2,1}, A_{2,2}, A_{2,3}$ FROM R_2 WHERE $A_{2,2} > 5$. Such speculative query results, if executed, can be used while executing two user queries from this SW: Q_2 and Q_4 .

Chosen speculative queries are executed in parallel with the original user queries and its results are stored in a dedicated RAM memory database structure called the Speculative DB. The data from the Speculative DB is ready to be used during execution of input user queries, called nonspeculative queries, minimizing disk database reads.

The original user query executed for each Speculation Window (so far it was always the first query in the SW) is called the nonspeculative query. If there are executed speculative queries assigned to the nonspeculative query it is transformed to use them, otherwise it is executed without the speculative support. Each user query can be executed with the use of the speculative results prepared for each relation present in its FROM clause. More details about algorithms implemented for query graph manipulation and strategies of multiple speculative queries results combining for the execution of one user query can be found in [4] and [3]. After the nonspeculative query's results are returned to the user, the SW moves by one query. As a result, the representation of the executed user query in the Q_M is replaced by the representation of the next user query from the queue, which just entered the Speculation Window. The SW move is followed by the aforementioned Speculative Analysis process to generate a new group of speculative queries for execution. Described operational scheme is repeated until there are user queries waiting for execution.

Based on previous experiments presented in [2] the Speculation Window size was set to 5 and the number of active threads for each SW was set to 3 (bigger SW or more

threads didn't provide further improvement in user queries execution). One thread is always dedicated to the execution of the nonspeculative user query, so the remaining two threads can execute chosen Speculative Queries. From the group of awaiting Speculative Queries generated in the process of the Q_M Speculative Analysis, two of them can be chosen for execution. The highest execution priority is always assigned to speculative queries which can be used by the highest number of user queries. Additionally, we consider values of two defined size reduction metrics for speculative queries - Vertical and Horizontal Selectivity (for definition see [5]). As we want to avoid creating full copies of database relations in the RAM memory we look for speculative queries with possibly low values of these metrics. If it was not possible for a particular Speculation Window to choose a new speculative query for execution, the speculative thread would report a nojob status for this SW. Executed Speculative Queries are registered on the list and assigned to user queries which can then use their results.

III. A NEW STRATEGY FOR THE SW EXECUTION

The old execution strategy for the Speculation Window (SW) was fixed, i.e. the nonspeculative query was always the first query in the SW. This way, we kept the execution order of user queries risking that for some of them the speculative results might not be ready yet.

New strategy allows the nonspeculative query not to be the first one in the SW. If the first query in the SW would be executed without the use of the speculative results, then a next query in the SW which can be executed with already obtained speculative query results is executed nonspeculatively. This way, the speculative algorithm has a chance to prepare and execute new speculative query/queries whose results will be beneficial for the delayed user query. The expected execution time reduction provided by the use of the speculative results should outweigh the potential execution delay.

Such situation is presented in Fig.2. We can see a Speculation Window containing 5 user queries (Q_2-Q_6). Below each blue user query square, there are orange circles containing ids of the executed speculative queries assigned to a particular user query for the potential use. The first query in the SW has no executed speculative queries assigned (no circles below). Thus, we look for the next query in the SW which could be executed with the use of the speculative results. The Q_3 user query is then executed nonspeculatively with the use of one of two assigned speculative queries (in certain cases it is possible to use more than one speculative result for one user query). Then SW moves, the nonexecuted Q_2 remains in it, while the Q_3 is replaced by the next query from the user query queue.

IV. EXPERIMENTAL RESULTS

A. Test Environment and Queries

The Speculative Layer is implemented in C++ with the multithreaded execution with the Pthread library. The SQLite 3.8.11.1 engine is used as a database management system. For the experiments we used the database structure and

Fig. 2. New nonspeculative query execution strategy.

data (8 relations, 1GB data) from the well known database benchmark TPC-H [23]. Additionally, a set of 8 Query Templates was prepared and used to generate 3 sets of 1000 input queries each, with random values used in the attribute conditions in WHERE clauses. Structures of the T1-T8 templates are listed below with the following notation: TemplateId:RelationName(number of WHERE conditions referring to its attributes,...,RelationName(number of WHERE conditions...))

T1: LINEITEM(1 with a nested query)

T2: LINEITEM(4), PART(2)

T3: PART(3), PARTSUPP(1)

T4: LINEITEM(4), ORDERS(3), CUSTOMER(1)

T5: LINEITEM(3), PART(4), PARTSUPP(1)

T6: LINEITEM(3), ORDERS(1), CUSTOMER(1), PART(2)

T7: LINEITEM(3), ORDERS(1), CUSTOMER(1), PART(2), PARTSUPP(1)

T8: UPDATE ORDERS

Templates T2-T7 are Select query templates which join from two to five database relations. Template T1 refers to one relation but includes a nested query in its WHERE clause. T8 represents modifying queries. Each test queries set contains approximately 4% of modifying queries and 96% of select queries with the same density for each of T1-T7 templates.

B. A New Nonspeculative Query Execution Strategy

First, we have compared how the new nonspeculative query execution strategy for the Speculation Window affects the execution of user queries. For this, we compare the results obtained with the old execution strategy (nonspeculative query is always the first one in the SW) with the new strategy (nonspeculative query is the first query in the SW which can use already obtained speculative query results). The experiment was conducted for the Speculation Window size=5 and 3 active threads. Fig.3 presents average execution times obtained for each query template depending on how many speculative query results were used (from 0-red bars to 3-yellow bars speculative queries results for one user query). We can see that each speculative query used, provides further reduction in the user query execution time. The highest speedups are obtained for T5 and T7 templates. These user queries have considerably longer execution times if executed without the speculative support (approximately 163 and 181 sec.). With

Fig. 3. The average execution time for 7 query templates with and without use of the speculative query results.

three speculative queries results used (one speculative query for each relation appearing in a query) we managed to significantly reduce their execution times (up to 9 times shorter). For the remaining templates the average time reduction is approximately 2 times. We have next studied how the new strategy influenced the general numbers of queries executed with or without the speculative support. The new strategy reduced the number of user queries executed without the use of the speculative result from approximately 113 to 57 (for 1000 user queries), which is almost two times less. The query order change (id est. as a nonspeculative query was executed a user query not being the first in the SW), was reported 132 times and concerned 58 user queries. The maximal delay of the first query in the Speculation Window execution was 4, with average delay for the whole set equal 2.59.

C. Speculation Window Size

As the implementation of the new strategy for the nonspeculative query choice provided considerable reduction in the number of user queries executed without the speculative support, we decided to run a new series of experiments to verify, if the Speculation Window (SW) size change can provide any further benefits. Table 1 presents the results we obtained for the SW sizes from 5 to 15. The size of the SW equals the number of user queries used to form a Query Multigraph. We can see that with the growing size of the SW, the number of nojob reports is also growing significantly, up to 232 for the SW size=15. The reason for this is that with bigger Speculation Windows (and bigger multigraphs) sizes, each SW move is still replacing only one user query in the multigraph structure. Such structure change is not enough to generate new and unique speculative queries for execution. Thus we can see, that the total number of executed speculative queries for the test set is actually decreasing. Even though each executed speculative query is assigned to more user queries for potential use (on average 1.98 for SW size 5 to 3.56 for SW size 15) it doesn't influence (preferably reduce) the number of user

queries executed without the speculative support. The reduced number of queries obtained for SW=5 decreases further for SW size 6 to reach an average value around 33 for bigger Speculation Windows.

Four bottom rows of Table 1 present results characteristic for the new strategy of nonspeculative query execution. We can see that the number of the user queries whose execution were delayed due to missing speculative query results, varies around 60 and doesn't seem to be dependent on the SW size. However, the bigger SW gets, the execution delay of such queries grows up to 13 steps for the SW size 15, which is not an advantageous feature. Too long delays would require a new mechanism preventing query starvation, when the waiting time predominate the potential benefits from using the speculative query results.

D. Modifying Queries

In Section IV(A), it was said that the query test sets contained approximately 4% of modifying queries. Since the modifying query enters the Speculation Window until it reaches its head and is executed as a nonspeculative query, it endangers all speculative queries to be executed on invalid data. Just after the execution of a modifying query a validation process is executed for the queries marked with the Speculative State. The aim of that process is to save (positive validation) as many speculative results as possible from being deleted. For the execution of the whole query test set with the old strategy an approximate number of 40 speculative results (for 1000 user queries) were saved from being deleted and 22 had to be deleted due to negative validation. Experiments show, that the new strategy for the nonspeculative query execution doesn't interfere with the strategy for the modifying query handling presented in [6]. For the SW size 5 numbers of deleted and saved queries remains almost unchanged. With the growing size of the Speculation Window the number of deleted speculative results grows slowly to reach an approximate value of 36 queries for the SW size 15. The number of queries endangered with invalid data and saved from being deleted grows faster and reaches an approximate value of 130 for the biggest SW, which in general doesn't seem to have a negative influence on the speculative execution.

V. CONCLUSION

The paper describes a new strategy for the nonspeculative query execution in the speculative query execution support system called the Speculative Layer. We now allow to change the order of user queries execution, if the first query in the Speculation Window would have to be executed without the use of the speculative results. The first series of experimental results for the test database and three sets of 1000 input queries each, reduced the number of user queries executed without the use of the speculative results by approximately 50%, thus in general, almost 95% of user queries were executed with the use of at least one speculative query results. The proposed speculative support provides the query average execution time reduction up to 9 times for long running queries

TABLE I
EXECUTION RESULTS OBTAINED FOR DIFFERENT SIZES OF THE SPECULATION WINDOW

(approximately 2 times for the whole test set). The execution order change was reported for approximately 58 queries, with the maximal execution delay of 4 queries (average delay 2.59). With the second series of experiments we have proved that the SW size equal 5 is a good choice. Changes in the SW size provided minor changes in the number of queries executed with the use of the speculative results. On the other hand, the average delay of a nonspeculative query execution, grew for the bigger SWs from 2.59 to 6.09.

Further work will focus on the development of an even more flexible user query execution strategy for a Speculation Window. A concept of a Variable Shift Speculation Window will be considered, which includes more than one user query executed as a nonspeculative query for each SW, depending on the available speculative results.

15th Workshop on Computer Aspects of Numerical Algorithms

NUMERICAL algorithms are widely used by scientists engaged in various areas. There is a special need of highly efficient and easy-to-use scalable tools for solving large scale problems. The workshop is devoted to numerical algorithms with the particular attention to the latest scientific trends in this area and to problems related to implementation of libraries of efficient numerical algorithms. The goal of the workshop is meeting of researchers from various institutes and exchanging of their experience, and integrations of scientific centers.

TOPICS

- Parallel numerical algorithms
- Novel data formats for dense and sparse matrices
- Libraries for numerical computations
- Numerical algorithms testing and benchmarking
- Analysis of rounding errors of numerical algorithms
- Languages, tools and environments for programming numerical algorithms
- Numerical algorithms on coprocessors (GPU, Intel Xeon Phi, etc.)
- Paradigms of programming numerical algorithms
- Contemporary computer architectures
- Heterogeneous numerical algorithms
- Applications of numerical algorithms in science and technology

TECHNICAL SESSION CHAIRS

- **Bylina, Beata**, Maria Curie-Skłodowska University, Poland
- **Bylina, Jaroslaw**, Maria Curie-Skłodowska University, Poland
- **Stpiczynski, Przemyslaw**, Maria Curie-Skłodowska University, Poland

PROGRAM COMMITTEE

- **Anastassi, Zacharias**, ASPETE School of Pedagogical and Technological Education, Greece
- **Brugnano, Luigi**, Università di Firenze, Italy
- **Burczynski, Tadeusz**, Polish Academy of Sciences, Poland
- **Czachórski, Tadeusz**, Institute of Theoretical and Applied Informatics, Polish Academy of Sciences, Gliwice, Poland

Abstract—In this paper, we present the application of three automatic source-to-source compilers to code implementing McCaskill’s bioinformatics algorithm. It computes probabilities of various substructures for RNA prediction. McCaskill’s algorithm is compute and data intensive and it is within dynamic programming. A corresponding programming code exposes non-uniform dependences that complicate tiling of that code. The corresponding code is represented within the polyhedral model. Its optimization is still a challenging task for optimizing compilers employing multi-threaded loop tiling. To generate optimized code, we used the popular PLuTo compiler that finds and applies affine transformations, the TRACO compiler based on calculating the transitive closure of loop dependence graphs, and the newest polyhedral tool DAPT implementing space-time tiling. An experimental study fulfilled on two multi-core machines: an AMD Epyc with 64 threads and a 2x Intel Xeon Platinum 9242 with 192 threads demonstrates considerable speedup, high locality, and scalability for various problem sizes and the number of threads of generated codes by means of space-time tiling.

I. INTRODUCTION

McCASKILL’S algorithm is an efficient dynamic programming one to return the value of the computed partition function $Z = \sum_P \exp(-E(P)/RT)$, where P represents all possible nested structures formed by a given RNA sequence S , $E(P)$ is the energy of structure P , R is the gas constant, and T represents temperature [1].

The approach computes the structure probabilities of each individual base pair in the RNA sequence. These probabilities are used for simultaneous folding and alignment in algorithms to predict an RNA structure with a maximum expected accuracy (MEA) [2].

Each base pair of a structure contributes a fixed energy term E_{bp} independent of its context. Under such an assumption, a partition function for a sub-sequence from position i to position j is represented with table $Q_{i,j}$, while table $Q_{i,j}^{bp}$ holds the values of the partition function of the sub-sequences for a base pair or 0 when base pairing is absent.

The following calculations are used to compute the values of the partition functions and inserted as elements of tables $Q_{i,j}$ and $Q_{i,j}^{bp}$.

$$Q_{i,j} = Q_{i,j-1} + \sum_{i \leq k < (j-1)} Q_{i,k-1} \cdot Q_{k,j}^{bp}$$

Listing 1. Code of the McCaskill partition function computation.

```

if (N>5 && l>=0 && l<=5)
  for (i=N-1; i>=0; i--)
    for (j=i+1; j<N; j++){
      Q[i][j] = Q[i][j-1];
      for (k=0; k<j-i-1; k++){
        Qbp[k+i][j] = Q[k+i+1][j-1] *
                      ERT * paired(k+i, j-1);
        Q[i][j] += Q[i][k+i] * Qbp[k+i][j];
      }
    }
    
```

$$Q_{i,j}^{bp} = \begin{cases} Q_{i+1,j-1} \cdot \exp(-E_{bp}/RT) & \text{if } S_i, S_j \text{ can form} \\ & \text{base pair} \\ 0 & \text{otherwise} \end{cases}$$

Listing 1 presents the code implementation computing $Q_{i,j}$ and $Q_{i,j}^{bp}$ filled with random double values (data in arrays do not affect the speed of the code). ERT is equal to $\exp(-E_{bp}/RT)$. To simplify target tiled code generation, we replaced k with $k+i$ and the innermost loop boundaries from 0 to $j-i-1$.

Many algorithms in bioinformatics are within dynamic programming (DP). Programming loop nests implementing those algorithms can be represented within the polyhedral model. That model is used in many optimization compilers, which automatically generate efficient parallel tiled code. However, the code implementing McCaskill’s algorithm exposes non-uniform dependences that make it difficult effective parallelization and tiling of that code.

A polyhedral optimizer generally improves code locality by means of loop tiling, which groups loop statement instances within smaller blocks (tiles). This allows for reuse provided that the block fits in cache. In parallel tiled code, tiles are enumerated as indivisible macro statements. This increases the granularity of parallel code that often improves the performance of that code executed in parallel systems with shared memory.

Dynamic programming codes expose non-uniform dependences, which limit applying commonly known optimization techniques such as permutation, diamond tiling [3], or index

set splitting [4] very well trained, for example, on stencils.

II. OPTIMIZING COMPILERS USED FOR EXPERIMENTS

Modern automatic optimizing compilers, for example, PLuTo [5], demonstrate the success of using the polyhedral model. PLuTo extracts and applies affine functions to parallelize and tile serial code. Target parallel tiled code demonstrates good efficiency on modern multi-core computers with shared memory in particular for stencils.

For a given loop nest statement, compilers based on affine transformations use the relation $[I] \rightarrow [t = C * I + c]$, where I is the loop statement iteration vector; t is the time assigned to execute iteration I ; $C * I + c$ represents the affine function. When two statement instances get the same execution time, they can be run in parallel. To extract the unknown matrix C and unknown vector c , firstly, for each loop nest statement, time-partition constraints are formed by applying extracted dependences. Then the time-partition constraints are resolved for elements of matrix C and elements of vector c .

The PLuTo engine is used in other compilers, for example, in Apollo[6], PPCG [7], PTile[8], and Autogen framework [9] as well as in commercial IBM-XL and R-STREAM from the Reservoir Lab [10].

TRACO is based on the slicing framework introduced in paper [11]. It calculates the transitive closure of a dependence graph, which is used to fulfill corrections of original rectangular tiles. The goal of the correction is to eliminate all cycles among target tiles. This allows us to enumerate target tiles in lexicographic order.

After tile correction, the inter-tile dependence graph does not contain any cycle and any technique of loop nest parallelization can be used to generate parallel code, details are presented in paper [12]. TRACO uses the commonly known wave-fronting technique for tiled code parallelization. For its implementation, it applies the ISL library.

PLuTo and TRACO have some limitations. PLuTo may not find the number of linearly independent solutions to time partitions constraints that is equal to the number of the loops surrounding a loop nest statement. This reduces the dimension of target tiles and as a consequence target code locality may be low. For example, it is not able to tile each loop nest for the Nussinov and Knuth algorithms [13], i.e., instead of 3D tiles it generates only 2D tiles. TRACO, in general, may generate irregular tiles that reduce code locality and worsen multiple thread work balance [14].

To generate regular code and increase tile dimension, DAPT implements space-time tiling. First DAPT generates space tiles according to the technique presented in paper [15]. Then it splits each space tile into multiple time slices. Each time slice is represented with a number of time partitions found by means of the ISL scheduler. The number of time partitions within the time slice is defined by the user. As a result, the tile dimension is increased by one. Target code enumerates smaller tiles (time slices) within each space tile. This increases code locality due to increasing the probability of catching all the

data associated with each smaller tile in cache provided that the number of time partitions forming the time slice is chosen properly.

However, each of the mentioned above automatic source-to-source compilers is able to generate tiled code for the McCaskill algorithm and we conducted a comparison analysis of the performance of codes generated by them on two modern multi-core machines.

III. EXPERIMENTAL STUDY

In this section, we present the results of an experimental study with PLuTo, TRACO, and DAPT codes implementing the McCaskill partition function computation. All target parallel tiled codes were compiled using the Intel C++ Compiler (icc) and GNU C++ Compiler (g++) with the -O3 flag of optimization.

To carry out experiments, we used two multi-processor machines: an 2x Intel Xeon Platinum 9242 CPU (2.30GHz, 2x96 threads, 71,5 MB Cache, compiler icc 21.3.0, 2019), and an AMD Epyc 7542 (2.35 GHz, 32 cores, 64 threads, 128MB Cache, compiler g++ 9.3.0, 2019).

The code generated with DAPT is presented in Listing 2, while the codes generated with PLuTo and TRACO can be found at https://github.com/markpal/NPDP_Bench/blob/main/mcc/mcc_dapt.cpp, they are too long to be inserted in this paper.

It is worth noting that tiles generated with TRACO are irregular, they can be fixed or parametric (the size of such tiles is unbounded). PLuTo generates regular fixed tiles except from boundary ones.

Space-time tiling implemented in DAPT generates regular tiles and the tile dimension is one more than that of tiles generated with PLuTo.

In all examined compilers, for parallelism representation, the OpenMP standard is used. For different sizes examined by us, by means of experiments, we discovered that the best tile size for the TRACO target code is 1x128x16. This means that the outermost loop in the loop nest should not be tiled. For the target code generated with PLuTo, the best tile size is 16x16x16. For the DAPT code, the optimal size is 16x16x16 for space slices and the size of the time slice (the number of time partitions within the space tile) is 2.

The McCaskill code can be tiled by all the compilers used for us for experiments. However, only TRACO and DAPT allow us to generate parallel tiled code. The serial code generated with PLuTo is very cache-efficient, but PLuTo is unable to extract any affine schedule allowing for parallelism of target code. TRACO generates target code applying the transitive closure of the dependence graph for the McCaskill loop nest, then it builds a relation representing inter-tile dependences. Finally, using that relation, it applies the ISL scheduler to extract a valid tile schedule, which is used to generate parallel tiled code. DAPT applies the wave front technique to generate target parallel tiled code.

Tables 1 and 2 hold execution times (in seconds) for the PLuTo, TRACO, and DAPT codes for various RNA sequence

Listing 2. Parallel tiled loop nests of the McCaskill algorithm generated with DAPT.

```

1  if ( l >= 0 && l <= 5 && N >= 6 ) {
2  for(w0 = -1; w0 <= (N - 1) / 8; w0 += 1) {
3  #pragma omp parallel for
4  for(h0 = max(w0 - (N+7) / 8 + 1, -((N+5) / 8)); h0 <= min(0, w0); h0 += 1) {
5  for(i0 = max(max(-N+2, -8*w0 + 8*h0-6), 8*h0); i0 <= min(0, 8*h0+7); i0++) {
6  for(i1 = max(8*w0 - 8*h0, -i0+1); i1 <= min(N-1, 8*w0 - 8*h0 + 7); i1++) {
7  Q[-i0][i1] = Q[-i0][i1 - 1];
8  for (i3 = 0; i3 < -1 + i0 + i1; i3 += 1) {
9  Qbp[-i0+i3][i1] = ((Q[-i0+i3+1][i1-1] * (ERT)) * paired((-i0+i3), (i1-1)));
10 Q[-i0][i1] += (Q[-i0][-i0 + i3] * Qbp[-i0 + i3][i1]);
11 }}}}

```

lengths on an Intel Xeon Platinum 9242 (192 hardware threads) and an AMD Epyc 7542 (64 hardware threads), respectively. Figures 1 and 3 show the speed-up (a ratio of T_1 over T_n , where T_1 and T_n are execution times for one and n threads used for code running, respectively) of parallel tiled programs for RNA sequence sizes from 1000 to 10000 for an Intel Xeon Platinum 9242 (192 hardware threads) and an AMD Epyc 7542 (64 hardware threads), respectively. Figures 2 and 4 show how target code speed-up depends on the number of threads for an Intel Xeon Platinum 9242 (192 hardware threads) and an AMD Epyc 7542 (64 hardware threads), respectively, for $N = 5000$ (roughly the size of the longest human mRNA).

Analyzing the presented results of experiments, we may state that the DAPT code overcomes considerable those of PLuTo and TRACO ones. The TRACO code overcomes that of PLuTo for eight and more threads. The worse efficiency of the TRACO code for a few thread numbers is caused with the irregularity of the target code (see the previous section).

IV. CONCLUSION

We presented the results of a comparative performance analysis of three tiled codes generated with optimizing compilers PLuTo, TRACO, and DAPT for the McCaskill partition function calculation. The best performance demonstrates the DAPT code due to the fact that it applies space-time tiling

TABLE II
EXECUTIONS TIME OF THE PARALLEL TILED CODES FOR AN AMD EPYC 7542 USING 64 HARDWARE THREADS.

N	Serial	PLuTo	TRACO	Dapt
1000	0,87	0,63	2,89	0,54
2000	10,22	5,28	10,33	2,05
3000	46,19	18,99	31,46	3,02
4000	129,29	56,33	70,56	4,94
5000	289,41	127,89	137,64	9,74
6000	572,61	246,36	241,06	17,35
7000	999,91	413,36	373,89	26,58
8000	1567,43	607,81	553,21	40,39
9000	2231,09	932,75	779,01	59,63
10000	3043,21	1299,29	1096,88	81,72

allowing us to increase the tile dimensionality by one in comparison with that of PLUTO. That makes all tiles to be regular and of fixed size. A proper choice of a tile size allows us to hold all the data associated with each tile in cache that increases code locality.

Abstract—High-level loop transformations are a key instrument to effectively exploit the resource in modern architectures. Energy consumption on multi-core architectures is one of the major issues connected with high-performance computing. We examine the impact of four loop transformation strategies on performance and energy consumption. The investigated strategies include: loop fission, loop interchange (permutation), strip-mining, and loop tiling. Additionally, a column-wise and row-wise store formats for dense matrices are considered. Parallelization and vectorization are implemented using OpenMP directives. As a test, the WZ factorization algorithm is used. The comparison of selected strategies of the loop transformation is done for Intel architecture, namely Cascade Lake. It has been shown that for WZ factorization, which is an example of an application in which we can use the loop transformation, optimization towards high-performance can also be an effective strategy for improving energy efficiency. Our results show also that block size selection in loop tiling has a significant impact on energy consumption.

Keywords: energy saving, energy consumption, RAPL, WZ factorization, multicore architecture

I. INTRODUCTION

WITH the growing demand for high-performance computing, new architectures have emerged which unfortunately consumes more and more energy. Reducing energy consumption in these architectures is one of the major challenges. The current research trends based on performance studies [12], [13], [16] and comparisons are to develop hardware and software to achieve the best performance and energy compromise. One of the aspects of creating energy-aware software is the optimization of implementation of complex numerical algorithms. Such complex algorithms include loops, in particular nested ones. Nested loops are an important structure bearing a great deal of the parallelism and vectorization possibilities. However, to parallelize them efficiently, the programmer has to make some decisions about applying various transformations. An example of such loops is matrix algorithms, like matrix multiplication or different kinds of factorizations, widely investigated in the literature [3], [1].

In the work [2], we studied loop transformations for nested loops on multicore architectures on the example of a factorization similar to the LU factorization, namely, the WZ factorization [19]. The WZ factorization has some nontrivial

data dependencies and the compiler is not able to efficiently optimize the algorithm. We have chosen the following four: loop fission, loop interchange (loop permutation), strip-mining, and loop tiling.

In this article, we investigate the impact of these four loop transformations on performance and energy consumption for the WZ factorization on multicore architecture. We describe in detail two block-related transformations (strip-mining and loop tiling). We are making theoretical and experimental considerations about the size of the blocks. Additionally, we consider column-wise and row-wise storage formats for dense matrices. The OpenMP standard is used for parallelization and vectorization of the code. The Intel RAPL (Running Average Power Limit) [7], [9] interface is used as a source of information on energy consumption.

The main contributions of this article are the following:

- results of the tests from the evaluation of the execution time and energy consumption for four loop transformations of the WZ factorization for various data sizes on Intel architecture — namely, Cascade Lake;
- conclusions on the impact of the four loop transformations on the execution time and energy consumption;
- analysis of the correlation between performance and energy consumption for four loop transformations.

This paper is organized as follows. Section II presents a few related works on loop transformations and energy consumption/performance analysis for modern computer architectures and systems. Section III discusses the four loop transformations applied here for the WZ factorization and studies block size for tiled transformation. In Section IV, we concentrate on the details of conducting tests and on the discussion and explanation of the results. In Section V, we present the conclusions of the numerical experiments and further research directions.

II. RELATED WORKS

When high-performance computing is considered, energy consumption is one of the most important challenges. These challenges are analyzed on many levels. In particular, the works of [11], [13], [16] dealt with the topic of energy

Fig. 1: The output of the WZ factorization — forms of the matrices \mathbf{W} (left) and \mathbf{Z} (right).

consumption in the context of using the OpenMP standard for multi-core computers with shared memory.

The key to software optimization in terms of the performance for algorithms that include nested loops is the right choice of the appropriate loop transformations. Loop transformations are a research topic for various automatic optimization techniques [8], [10], [14], [15] as well as for manual conversion of application code [5], [17], [18] so as to obtain the best possible performance on modern multi-core architectures.

In many numerical algorithms where dependencies between data are very complicated, even such tools as efficient optimizing compilers are not able to transform the code to use the potential of modern processors. The authors of [3], [1], present algorithms for solving systems of equations, trying to improve their performance, in particular in parallel. Improvement in performance was obtained by appropriate transformation of the underlying algorithm using looping tiling and appropriate data structures. There are currently not too many studies in the literature about both efficiency and energy consumption in the context of loop transformations. In our work, we study a numerical algorithm (the WZ factorization), in which, loops are transformed. This algorithm concerns numerical linear algebra, in particular solving systems of equations on multi-core architectures using OpenMP in the context of performance and energy consumption.

III. WZ FACTORIZATION

The WZ factorization (Figure 1) was introduced in [4]. It was a new method for parallel solving of systems of linear equations on computers containing many data processing units and it was an alternative to the well-known LU factorization.

The WZ factorization is based on the decomposition of the square matrix \mathbf{A} into two matrices: \mathbf{W} i \mathbf{Z} . All the matrices which we consider are dense ones. They are stored as one-dimensional arrays in one of the two formats: column-wise or row-wise.

The basic algorithm for the WZ factorization for an even size of the matrix (we only consider even sizes — without loss of generality) is shown in Figure 2.

The loop transformation consists in replacing itself with an equivalent loop containing the structured block. Some

```

for(k = 0; k < n/2-1; k++) {
    p = n-k-1;
    akk = a[k][k];    akp = a[k][p];
    apk = a[p][k];    app = a[p][p];
    detinv = 1 / (apk*akp - akk*app);
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
                * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
                * detinv;
        for(j = k+1; j < p; j++)
            a[i][j] = a[i][j]
                    - w[i][k]*a[k][j]
                    - w[i][p]*a[p][j];
    }
}

```

```

for(k = 0; k < n/2-1; k++) {
    .
    .
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
                * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
                * detinv;
    }
    for(i = k+1; i < p; i++)
        for(j = k+1; j < p; j++)
            a[i][j] = a[i][j]
                    - w[i][k]*a[k][j]
                    - w[i][p]*a[p][j];
}

```

Fig. 3: The algorithm after the fission of the i -loop — pseudocode. This algorithm matches the row-wise layout.

well-known transformations considered are: loop fission, loop interchange (permutation), strip-mining, tiling.

A. Loop fission and permutation

Loop fission (also called loop distribution) breaks a loop into multiple loops over the same index range but each taking only a part of the loop's body. Its purpose is to achieve better utilization of locality of reference — isolate parallelizable loops create independent loops, hence creating separate tasks. Its result is shown in Figure 3.

In the fission algorithm (Figure 3) it is possible to use the loop interchange (for the j -loop and the second i -loop). The loop interchange transformation switches the order of loops' nesting (consists in replacing the internal loop with the external one). The purpose of such a transformation is to improve data locality or increase parallelism and vectorization. The algorithm from Figure 3 is denoted as `fission-ij`. Its result is shown in Figure 4.

```

for(k = 0; k < n/2-1; k++) {
    .
    .
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
                * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
                * detinv;
    }
    for(j = k+1; j < p; j++)
        for(i = k+1; i < p; i++)
            a[i][j] = a[i][j]
                    - w[i][k]*a[k][j]
                    - w[i][p]*a[p][j];
}

```

B. Strip-mining and loop tiling

Access to the main memory in our algorithm takes a lot of time. It is a well-known fact that the cost of accessing the memory is much higher than the cost of computations. We can even figure the number of memory reads and writes (C_M) and compare it to the number of floating-point operations (C_F). After some simple calculations we obtain:

$$C_M = \frac{7}{6}n^3 + O(n^2),$$

$$C_F = \frac{2}{3}n^3 + O(n^2).$$

Thus, the ratio of memory access to computations is:

$$\frac{C_M}{C_F} \approx \frac{7}{4}.$$

This means that we need a lot of memory access to perform our algorithm — almost two memory accesses for one floating-point operation. So, it is the main obstacle to utilizing the computing power of modern processors fully. A manner to solve this problem is to use the cache memory (which is much faster than the main memory) efficiently. Of course, the size of the cache memory is too small to house all the data needed in the algorithm.

Strip-mining is a loop transformation that consists in replacing one loop with two nested loops. One of them (inner) is appropriate for vectorization (it is quite short and with a unit stride), and another (outer) is longer and its step is equal to the full number of iterations in the inner one. The transformation pays only when the original loop is rather long.

A loop in the process of strip-mining is divided into two loops, where the inner one has $BLOCK_SIZE$ iterations and the outer one has $n/BLOCK_SIZE$ iterations (n is the number of iterations in the original loop). The strip-mining alone can have some positive impact on the performance (by easing the automatic vectorization process).

One of the widely used techniques which allow for improving performance is loop tiling which consists in connecting

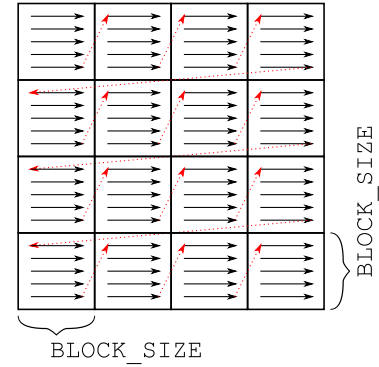

Fig. 5: Computing sequence after loop tiling (black: computations in blocks; red: order between blocks).

strip-mining with loop interchange. The main aim of this technique is to reduce the number of reads from and writes to the main memory by improving the spatial and temporal data locality, and hence by better utilizing the hierarchy of the memory — especially the cache memory by lessening the rate of cache misses. It is also useful for vectorization — both automatic and explicit — and for parallelization.

After such a transformation, the order of the computations changes (see Figure 5), although without the change of the result.

In such a process we improve the temporal and spatial locality of the data. By dividing the data into pieces of $BLOCK_SIZE$, we cause them to fit in cache memory (we mean level 1 cache here) and stay there as long as needed to conduct current computations. This minimizes the frequency of cache memory swaps. Too big $BLOCK_SIZE$ and the data would not fit into the cache, too small $BLOCK_SIZE$ and the swapping frequency rises. Moreover, to facilitate the vectorization, we wanted to make $BLOCK_SIZE$ a multiple of the SIMD register. Unfortunately, in most of the iterations of both the i -loop and j -loop, the first and the last iteration is chopped. For this reason, we broadened the first and the last iteration to full $BLOCK_SIZE$. It does not change the results of the algorithm (additional operations are beyond the non-zero elements of the resulting matrices), although, it forces the machine to make some more computations (in Figure 6, the red color denotes the redundant computations) — the bigger $BLOCK_SIZE$ the more additional computations are needed. The advantage is the possibility of vectorizing evenly all the iterations.

To achieve this, we make every outer loop start with a nearest full multiple of $BLOCK_SIZE$ (rounded down) and we make every inner loop iterate through a whole $BLOCK_SIZE$. Moreover, all the matrices were allocated with the memory alignment suitable for the used architecture.

Figure 7 shows the original algorithm after parallelization, with strip-mining of the j -loop (the full loop tiling is impossible due to the infeasibility of the loop interchange). Figure 8 presents the fission algorithm with full loop tiling. The function $RDTTNM()$ (stands for *round down to the nearest*

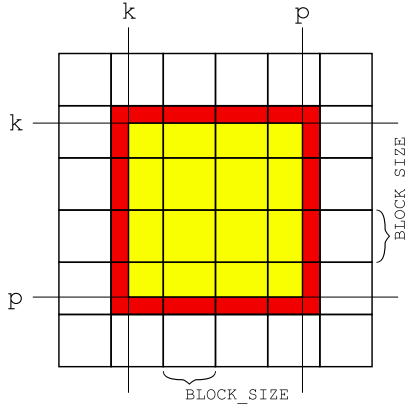

Fig. 6: Computations in the k th step of the algorithm after loop tiling (yellow: necessary computations; red: needless computations).

```

for(k = 0; k < n/2-1; k++) {
    . . .
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
            * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
            * detinv;
        start = RDTNM(k+1, BLOCK_SIZE);
        for(jj = start; jj < p;
            jj += BLOCK_SIZE) {
            __assume(jj % BLOCK_SIZE == 0);
            for(j = jj; j < jj+BLOCK_SIZE;
                ++j)
                a[i][j] = a[i][j]
                    - w[i][k]*a[k][j]
                    - w[i][p]*a[p][j];
        }
    }
}

```

Fig. 7: Strip-mining in the basic algorithm — pseudocode.

multiple) can be defined as a macro:

```
#define RDTNM(a, r) (((a)/(r))* (r))
```

In Figures 7 and 8, we use the compiler clause `__assume` which tells the compiler that a given condition is fulfilled — here, we declare that `ii` and `jj` are multiples of the `BLOCK_SIZE` which facilitates the vectorization.

Table I shows the computation overhead for the algorithm after loop tiling (red in Figure 6) — as a function of the size n of the matrix and of the `BLOCK_SIZE` (b).

Figure 9 shows the dependencies (black arrows) between the input data (green and blue dots) and the results (red dots) of the innermost loop in the k th step of the WZ factorization. We can see that — with no regard to the matrix memory layout (even for more complex layouts [6]) — the results of the computations depend on the data from various areas of the memory, so the loop tiling can give very limited performance improvements.

Here, the OpenMP standard is used for parallelization and vectorization code for all loop transformations. The more outer `i`-loop or `ii`-loop is parallelized with the `pragma parallel`

```

for(k = 0; k < n/2-1; k++) {
    . . .
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
            * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
            * detinv;
    }
    start = RDTNM(k+1, BLOCK_SIZE);
    for(ii = start; ii < p;
        ii += BLOCK_SIZE) {
        for(jj = start; jj < p;
            jj += BLOCK_SIZE) {
            __assume(ii % BLOCK_SIZE == 0);
            for(i = ii; i < ii+BLOCK_SIZE;
                ++i) {
                __assume(
                    jj % BLOCK_SIZE == 0);
                for(j = jj; j < jj+BLOCK_SIZE;
                    ++j)
                    a[i][j] =
                        a[i][j]
                        - w[i][k]*a[k][j]
                        - w[i][p]*a[p][j];
            }
        }
    }
}

```

Fig. 8: Loop tiling in the fission algorithm — pseudocode.

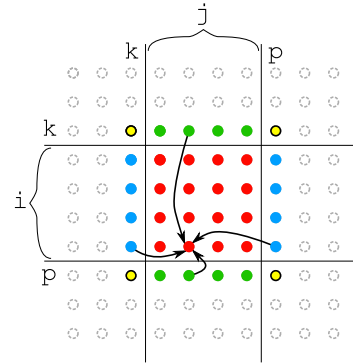

Fig. 9: The arrows show the data dependencies for updating an element of the array a in the k th step. Grey, green and yellow elements have their final values in the k th step; yellow ones are needed to compute `detinv` in this step; blue ones are elements of the array w computed in the middle loop of this step; red ones are updated in the innermost loop with the use of two blue elements and two green elements each.

loop and the most inner `j`-loop is vectorized with the `pragma simd` — details in [2].

IV. NUMERICAL EXPERIMENT – METHODOLOGY AND RESULTS ANALYSIS

A. Methodology

We test two types of versions of the WZ factorization algorithm:

- the basic algorithm presented in Figure 2 for the matrix stored in memory in two formats: a row-wise (basic-row) and column-wise (basic-col);

TABLE I: The ratio of the excess computations in the algorithm after loop tiling to the computations in the basic algorithm (n is the size of the matrix; b is the BLOCK_SIZE).

	$b = 8$	16	32	64	128	256	512
$n = 1024$	2.06%	4.44%	9.28%	19.24%	40.33%	87.21%	199.71%
2048	1.03%	2.21%	4.59%	9.42%	19.38%	40.48%	87.35%
3072	0.68%	1.47%	3.05%	6.24%	12.75%	26.29%	55.46%
4096	0.51%	1.10%	2.28%	4.66%	9.50%	19.46%	40.55%
5120	0.41%	0.88%	1.82%	3.72%	7.57%	15.44%	31.94%
6144	0.34%	0.73%	1.52%	3.10%	6.29%	12.80%	26.34%
7168	0.29%	0.63%	1.30%	2.65%	5.38%	10.93%	22.41%
8192	0.26%	0.55%	1.14%	2.32%	4.70%	9.53%	19.49%
9216	0.23%	0.49%	1.01%	2.06%	4.17%	8.46%	17.25%
10240	0.21%	0.44%	0.91%	1.85%	3.75%	7.60%	15.47%
11264	0.19%	0.40%	0.83%	1.68%	3.41%	6.89%	14.02%
12288	0.17%	0.37%	0.76%	1.54%	3.12%	6.31%	12.82%
13312	0.16%	0.34%	0.70%	1.42%	2.88%	5.82%	11.81%
14336	0.15%	0.31%	0.65%	1.32%	2.67%	5.40%	10.95%
15360	0.14%	0.29%	0.61%	1.23%	2.49%	5.04%	10.20%
16384	0.13%	0.27%	0.57%	1.16%	2.34%	4.72%	9.55%
32768	0.06%	0.14%	0.28%	0.58%	1.17%	2.35%	4.73%

- the algorithms with the fission loop transformation and loop interchange, that is: `fission-row-ij` (Figure 3) and `fission-row-ji` (Figure 4) for the row-wise layout and `fission-col-ij`, `fission-col-ji` for the column-wise layout;

and two types of versions of WZ factorization block algorithms:

- the strip-mining algorithms: `basic-row-sm-b`, `basic-col-sm-b`;
- the loop tiling algorithms: `fission-row-ij-lt-b`, `basic-row-ji-lt-b`, `fission-col-ij-lt-b`, `fission-col-ji-lt-b`.

In the notation `sm` is short for strip-mining, `lt` for loop tiling, and b is the BLOCK_SIZE. The following block sizes are checked: 8, 16, 32, 64, 128, 256, 512.

All versions have been implemented in C++ with vectorization and parallelization.

For testing, we used a double-precision square matrix of random values. The size of the smallest matrix is R (rows times columns). All sizes are shown in Table II.

TABLE II: Characteristics of the test data sizes.

Data size	n	Number of cells ($n \times n$)	[GB]
R	8192	67108864	0.5
2.25R	12288	150994944	1.125
4R	16384	268435456	2
16R	32768	1073741824	8

The performance and energy consumption tests of the proposed versions of the WZ algorithm were carried out on the following computing platform equipped with a modern multi-core processor with the following parameters and software:

- processor: Intel(R) Xeon(R) Gold 5218R (2.10 GHz; HT; 2×20 cores);
- operating system: CentOS 7.5 with Linux kernel 3.10.0;

- compiler: Intel ICC 14.0.2 with compiler options
`-qopenmp -O3 -ipo -no-prec-div`
`-fp-model fast=2`

To analyze the impact of all versions of the algorithm on energy consumption, we used measurements from the RAPL (Running Average Power Limit) interface. We used RAPL because the article [9] has shown that it gives the correct measurement results.

B. Execution Time. Matrix layout and loop interchange

First, we measure the execution time of the following versions of WZ factorization algorithm: the basic algorithm and the loop fission algorithm for the matrix stored in memory in two formats: a row-wise and column-wise manner and loop interchanged the order of the i -loop and j -loop. Therefore, we test 6 versions of the algorithm:

- `basic-row`
- `basic-col`
- `fission-row-ij`
- `fission-row-ji`
- `fission-col-ij`
- `fission-col-ji`

We test all these versions on 40 threads as well as on 80 threads with running HT. The results are presented in Figure 10. Both graphs on the vertical axis have execution time and on the horizontal axis the data size. Also, both of them show lines with points indicating the time of the algorithm for different data sizes. The graph in Figure 10a shows the runtime of the algorithm running on 40 threads, whereas the graph in Figure 10b shows the runtime of 80 threads, respectively. In both graphs we see 6 lines, each of them concerns one version of the algorithm according to the legend. Also in both cases, the lines for the `basic-row`, `fission-row-ij`, and `fission-col-ji` algorithms almost overlap. As we can see from the graphs, the above-mentioned versions also have the shortest runtime. Table III shows the speedup we get

(a) 40 threads

(b) 80 threads

Fig. 10: Execution time of versions of WZ factorization algorithm for different data sizes.

on 80 threads compared to 40 threads for each version of the tested WZ algorithm, which is defined as follows:

$$S = \frac{T_{40th}}{T_{80th}}$$

where parameter T_{40th} denotes the execution time of the algorithm run on 40 threads and T_{80th} denotes the execution time of the algorithm run on 80 threads.

TABLE III: Relative speedup of versions of WZ algorithm operating on 40 and 80 threads (T_{40th}/T_{80th}).

	R	2.25R	4R	16R
basic-row	0.91	0.95	0.88	0.85
basic-col	1.21	1.15	1.26	1.49
fission-row-ij	0.93	0.81	0.70	0.85
fission-row-ji	1.11	1.03	1.21	1.41
fission-col-ij	1.22	0.88	1.15	1.44
fission-col-ji	0.96	0.89	0.90	0.96

Based on Table III, we can observe that, regardless of the size of data, the acceleration of the operating time between the operation on 40 threads and on 80 threads is of a similar order. In Table III, the bold lines refer to the versions, which, as we could see in the graphs in Figure 10, fared better in terms of runtime, i.e. `basic-row`, `fission-row-ij`, and `fission-col-ji`. We can see for them that running them on 80 threads causes an increase in the runtime (values below 1), contrary to expectations. However, we can also notice that some algorithms speed up when they are run on 80 threads (values above 1) but this applies to versions which, as we could see from the graphs in Figure 10, had a longer runtime. For those versions of the algorithm that perform better in terms of runtime, the machine parameters are sufficient, therefore running HT for them does not improve their runtime. On the other hand, for those that perform weaker in terms of runtime, the capabilities of the machine are not sufficient, therefore HT improves the runtime.

Although 80 threads give these versions some speedup, they still perform worse in runtime than `basic-row`, `fission-row-ij` or `fission-col-ji`. We can see that

the versions with the shortest runtimes, i.e. `basic-row`, `fission-row-ij`, and `fission-col-ji`, perform better in terms of time on 40 threads. Therefore, we will conduct further tests only for the algorithm operating on 40 threads. We will carry out further considerations by selecting one version of the basic algorithm and one version of the fission algorithm. In the case of the basic version of the algorithm, we will choose the one for which we had a better runtime, i.e. `basic-row`.

However, in the case of fission versions, we have two versions, the runtime of which is better than the others and comparable to `fission-row-ij` and `fission-col-ji`, that is, those where the loop order was consistent with the matrix layout, therefore it is not surprising that they perform similarly. For further considerations, we will decide on any one of them, e.g. `fission-row-ij`, with the same matrix representation — row-wise — as for the chosen basic version.

Of the two algorithm versions selected for further tests, `basic-row` tends to perform slightly better than `fission-row-ij` in terms of runtime for different data sizes (at up to 12%).

C. Energy Consumption. Matrix layout and loop interchange

The graph from Figure 11 shows the energy consumption in joules for the `basic-row` (red) and `fission-row-ij` (blue) versions for all four data sizes.

We can see that less energy is consumed by the `basic-row` algorithm, we see this for each data size but it is a small amount between 1% and 11% percent. (respectively for data sizes: 10.33%, 1.33%, 10.98%, 2.63%). We can also observe that as the data size increases, the energy consumption also varies proportionally, and it is the following increase:

$$c_e(k) = k^{\frac{3}{2}}$$

where k is the data size growth factor in our case equal respectively: 1, 2.25, 4 and 16.

Fig. 11: Energy consumption for `basic-row` and `fission-row-ij` algorithms for different data sizes.

In general, energy consumption is to be expected proportional to the number of operations performed, and this is proportional to $k^{\frac{3}{2}}$.

TABLE IV: Energy consumption ratios as the data size increases.

	R	2.25R	4R	16R
<code>basic-row</code>	1	3.59	8.54	64.72
<code>fission-row-ij</code>	1	3.26	8.6	59.6
$c_e(k)$	1	3.37	8	64

Table IV shows how many times the energy consumption of individual versions has increased for each data size in relation to the energy consumption for the data size R.

D. Execution Time. Strip-mining and loop tiling

Now we will consider the block version of WZ factorization with strip-mining and loop tiling. We will only consider the algorithm implementations that gave the best results in the tests from the previous sections, limiting ourselves to two of them: `basic-row` and `fission-row-ij`. The effect of different `BLOCK_SIZE` on the efficiency will be tested experimentally. We will receive the following versions of the algorithm for further testing:

- `basic-row-sm-b`
- `fission-row-ij-lt-b`

The following block sizes (b) will be tested: 8, 16, 32, 64, 128, 256, 512. In total, 14 different versions of the algorithm will be tested. Our goal is to experimentally investigate which block size will work best in terms of the algorithm's runtime.

In Figure 12 we have graphs showing the runtime of the `basic-row-sm-b` versions for different block sizes b . Each graph deals with the operation of the algorithm on a different size of data. We can see that for individual data sizes (that is: R, 2.25R, 4R, 16R), the block algorithm is the fastest for the block sizes: 64, 64, 256 and 256, respectively, and the slowest

for the block sizes: 8, 16, 8 and 8, respectively. The summary of these observations is presented in Table V.

In Table V the columns present information about the algorithm operating on the specified data size, that is, R, 2.25R, 4R, and 16R, respectively. The last line shows the percentage profit between the slowest and the fastest version of the algorithm, i.e. the profit resulting from the selection of the best-performing block size for the `basic-row-sm-b` versions of the algorithm and the specified data size.

Summarizing the data collected in Table V, we can see that we cannot clearly indicate one block size that would give equally good results for all data sizes. One can notice that for smaller data sizes: (R, 2.25R), the smaller block works better, while for larger data sizes (4R, 16R), the larger block works better. However, we can clearly see which block size perform the worst, these are smaller block size. We can then conclude that small blocks work poorly.

TABLE V: The best and the worst block size due to the `basic-row-sm-b` versions runtime for different data sizes.

	R	2.25R	4R	16R
min. time [s]	8.67	28.90	68.54	556.17
The best block size	64	64	256	256
max. time [s]	11.26	32.53	85.32	601.59
The worst block size	8	16	8	8
max-mix [s]	2.58	3.63	16.78	45.42
%	23%	11%	20%	8%

Let's see what the situation looks like for the `fission-row-ij-lt-b` versions of the algorithm. In Figure 13 we have graphs showing the runtime of the `fission-row-ij-lt-b` versions for different block sizes. Here each graph deals with the operation of the algorithm on a different size of data too. We can see that for individual data sizes the algorithm is the fastest for the block sizes: 8, 8, 64, and 64, respectively, and the slowest for the block sizes: 512, 512, 8, and 8, respectively. The summary of these observations is presented in Table VI.

TABLE VI: The best and the worst block size due to the `fission-row-ij-lt-b` versions runtime for different data sizes.

	R	2.25R	4R	16R
min. time [s]	11.00	34.03	89.69	681.83
The best block size	8	8	64	64
max. time [s]	18.77	48.78	198.51	1904.31
The worst block size	512	512	8	8
max-mix [s]	7.77	14.75	108.82	1222.48
%	41%	30%	55%	64%

Looking at Figures 12, 13 and Tables V, VI, we can see that the `basic-row-sm-b` versions of the algorithm is better in terms of runtime than the `fission-row-ij-lt-b` versions, regardless of the selection of the block size. In the case of the `fission-row-ij-lt-b` versions of the algorithm, we can no longer conclude that, in general, regardless of the size of the data, small blocks perform worse. However, we

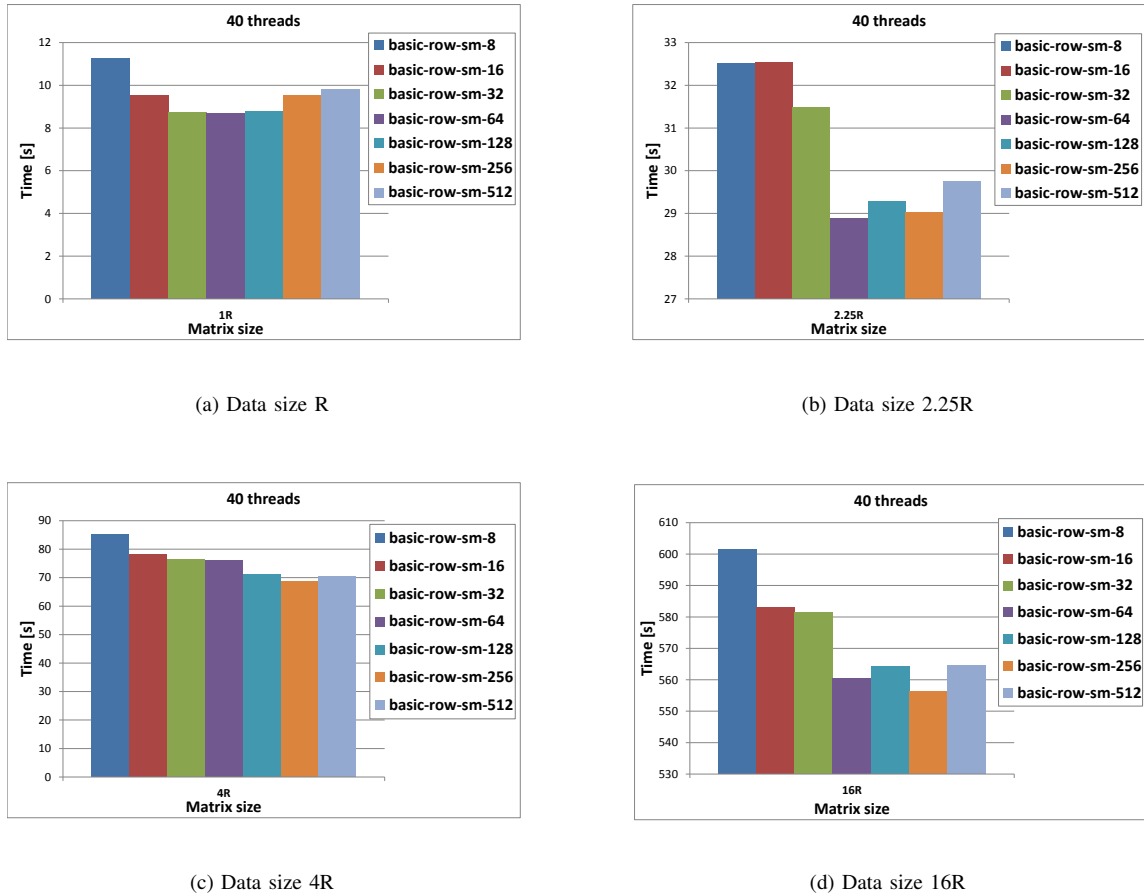

Fig. 12: Execution time of `basic-row-sm-b` versions for different data sizes and different block sizes.

can still observe that as the data size increases, the block size that works best also grows.

From the tables above, we can see that choosing the correct block size can save up to 23% of the time of the `basic-row-sm-b` versions of the algorithm (Table V), and even 64% in the case of the `fission-row-ij-lt-b` versions of the algorithm (Table VI).

E. Energy Consumption. Strip-mining and loop tiling.

Tables VII and VIII provide a summary of the energy consumption during the operation of the various versions of the tested algorithms. The last line shows the percentage energetic profit between the most and the least energy-consuming version of the algorithm, i.e. the profit resulting from the selection of the best-performing block size for the algorithm and the specified data size. Accordingly, Table VII presents data for the `basic-row-sm-b` versions of the algorithm and Table VIII for the `fission-row-ij-lt-b` versions.

We can see that choosing the right block is very important because it can save us 22% of energy consumption in the case of the `basic-row-sm-b` version of the algorithms (Table VII) and up to 61% of energy consumption in the case of the `fission-row-ij-lt-b` versions of the algorithm (Table VIII).

TABLE VII: The best and the worst block size due to energy consumption of the `basic-row-sm-b` algorithm for different data sizes.

	R	2.25R	4R	16R
min [J]	1687.53	6152.07	14925.4	118442.00
The best block size	64	64	256	256
max [J]	2159.86	6827.51	18542.5	129889.00
The worst block size	8	16	8	8
max-mix [J]	472.32	675.44	3617.03	11447.00
%	22%	10%	20%	9%

TABLE VIII: The best and the worst block size due to energy consumption of the `fission-row-ij-lt-b` algorithm for different data sizes.

	R	2.25R	4R	16R
min [J]	2189.55	7180.41	18640.1	143575.00
The best block size	32	8	64	64
max [J]	3863.04	10154.80	39273.60	370432.00

max-mix [J]	1673.49	2974.36	20633.60	226858.00
%	43%	29%	53%	61%

F. Time execution-energy trade-off

Although this is usually the case, the best runtime does not always result in the best energy consumption. We can see it

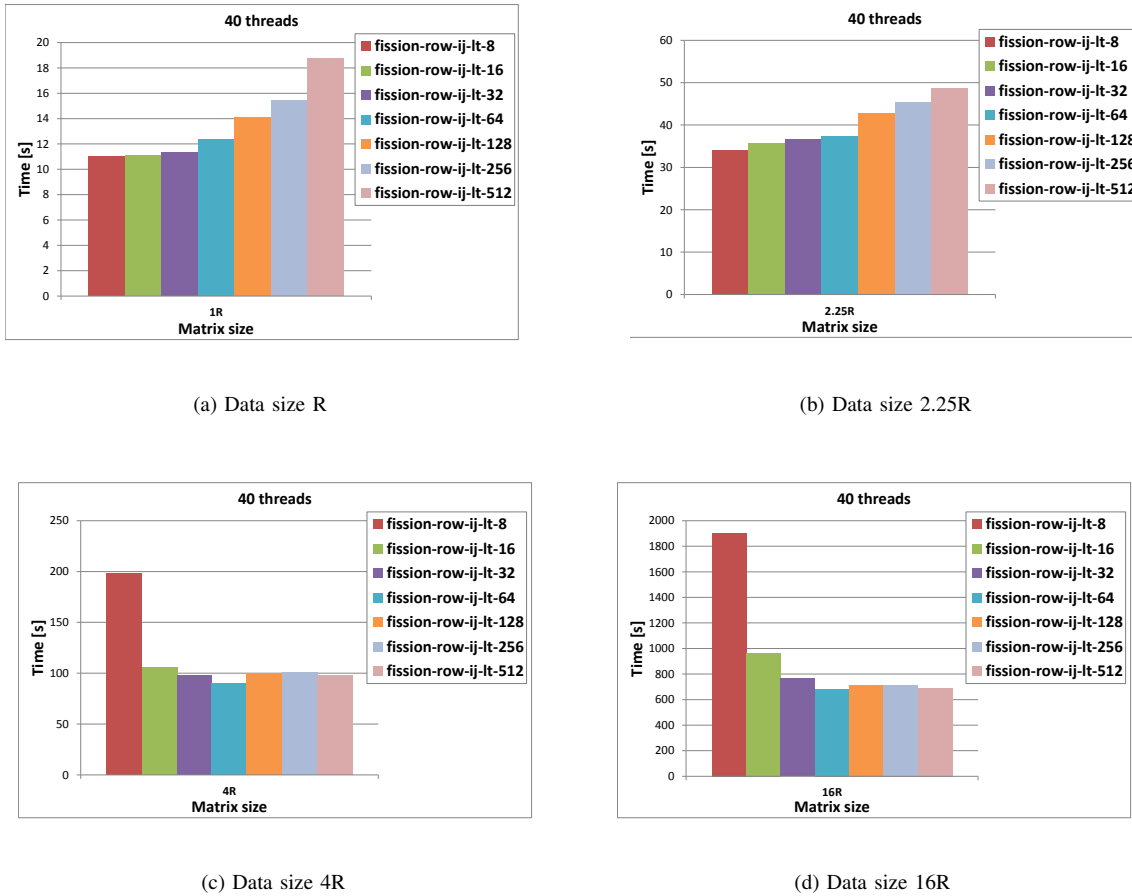

Fig. 13: Execution time of `fission-row-ij-lt-b` versions for different data sizes and different block sizes.

in Tables VI and VIII which show data from experiments on block versions of the fission algorithm, where for the size R , data block size giving the best result in terms of runtime is 8, while the best in terms of consumption energy proved to be 32.

Finally, we present in Table IX a summary of energy consumption, performance, and energy efficiency of the algorithm versions, which are the best during the experiences, for the largest tested data size (16R).

Analyzing the data in Table IX, we can see that `basic-row-sm-256` is the best among the best versions of the algorithm. In terms of energy efficiency, it is 6% better than the second in line, i.e. `basic-row`. However, for smaller data sizes, it turned out to be the best version `basic-row-sm-64` (see Table V and Table VII).

V. CONCLUSION

This article investigates four loop transformation strategies for the WZ factorization, namely: loop fission, loop interchange (permutation), strip-mining and loop tiling. The loop transformation affects both runtime and energy consumption. It can have both a positive effect in reducing runtime and energy consumption and a negative effect in increasing runtime

and energy consumption. Measurements were made on a 2nd Generation Intel Xeon Scalable Processors using the Intel RAPL interface.

Our experiments have shown that the `basic-row` version is definitely better in terms of runtime than the `basic-col`. The advantage of the former is the greater, the larger the size of the data we process and our tests show that it ranges from 19 to even 60 times faster, it is `basic-row`, we can see it in the graph in Figure 10. The first described experiments also showed that HT does not bring benefits in our case.

Our tests have also shown that the loop interchange transformation we propose has a large impact on the reduction of calculation time and energy consumption. The versions for which the loop interchange was compatible with the matrix representation, i.e. `fission-row-ij` and `fission-col-ji`, perform better in terms of operating time. They fell out the better, the larger the size of the data was processed and our experiments showed that it was from 6 to 16 times faster than in the case of a loop interchange inconsistent with the matrix representation. So we should never choose a loop interchange inconsistent with the matrix representation.

However, when comparing the energy consumption for the `basic-row` and `fission` versions with the loop interchange

TABLE IX: Energy efficiency for four best versions of the algorithm (dataset: 16R).

Versions	Time [s]	Total energy [J]	Performance [Gflops/s]	Energy efficiency[Gflops/J]
basic-row	582.63	125098.72	40.26	0.19
fission-row-ij	588.15	128481.50	39.88	0.18
basic-row-sm-256	556.17	118442.28	42.17	0.20
fission-row-ij-lt-64	681.83	143574.55	34.40	0.16

consistent with the matrix representation `fission-row-ij`, we saw that the `basic-row` version was slightly better from 1% to 11% less energy consumption (Figure 11). So the fission transformation won't pay off.

Finally, our experiments have shown that the best version among block versions depends on the data size, and here block size must be selected experimentally. The only thing we can see is that as the data size increases, the block size also increases. It may turn out that if the block size is poorly selected, the energy consumption may be higher by up to 61%. For 16R data size, they are versions `basic-row-sm-256` and `fission-row-ij-lt-64` which works the best (see Table IX). Moreover, we can say that regardless of the size of the data, the application of the strip-mining transformation worked best. For data size 16R the `basic-row-sm-256` version turned out to be the most profitable, as can be seen in Table IX. On the other hand, the transformation of loop tiling does not pay off because it causes a lot of complications in the code and it gives a slight extension of the runtime and slightly higher energy consumption.

Future work includes extending our experimental comparison to a wide range of architectures, including graphics cards. In addition, we will evaluate the performance impact of various runtime systems for OpenMP configurations and loop transformation energy for the WZ and the three decomposition main kernels in dense linear algebra algorithms (Cholesky, LU, and QR).

Abstract—When testing whether a continuous variable differs between categories of a factor variable or their combinations, taking into account other continuous covariates, one may use an analysis of covariance. Several post-hoc methods, such as Tukey’s honestly significant difference test, Scheffé’s, Dunn’s, or Nemenyi’s test are well-established when the analysis of covariance rejects the hypothesis there is no difference between any categories. However, these methods are statistically rigid and usually require meeting statistical assumptions. In this work, we address the issue using a random forest-based algorithm, practically assumption-free, classifying individual observations into the factor’s categories using the dependent continuous variable and covariates on input. The higher the proportion of trees classifying the observations into two different categories is, the more likely a statistical difference between the categories is. To adjust the method’s first-type error rate, we change random forest trees’ complexity by pruning to modify the proportions of highly complex trees. Besides simulations that demonstrate a relationship between the tree pruning level, tree complexity, and first-type error rate, we analyze the asymptotic time complexity of the proposed random forest-based method compared to established techniques.

I. INTRODUCTION

COMPARING a continuous variable’s means of two or more categories (or their combinations) of one or more factor variables and detecting significant mutual differences, if any, is very common in applied statistics. Particularly when the dependent variable needs to be adjusted by other continuous covariates, an analysis of covariance (ANCOVA) is a tool of choice [1].

Since the analysis of covariance tests whether there is, in general, a difference between at least two categories of a given factor, the big question is to determine where exactly the statistical difference is, i. e., which two (or more) exact

categories of the factor are those the significant difference arises from.

For this reason, post-hoc tests are usually applied to identify the significantly different categories of their combinations. Some of them are quite established, for instance, Tukey honestly significant difference (HSD) test [2], Scheffé’s test [3], Dunn’s test [4], or, if needed, Nemenyi’s test with a reduced amount of assumptions required to be met [5].

However, the covariance analysis and the post-hoc tests are limited by relatively tough statistical assumptions, usually in terms of normality of independence of observation subsamples. Furthermore, empirically, when there are multiple methods for one task, that usually implies each method is limited somehow and, consequently, there is no "apriori first choice" method routinely working in all situations.

This work introduces a new post-hoc method based on a random forest algorithm to overcome the mentioned. Each classification tree the random forest model consists of has got its complexity, i. e. number of leaf nodes, by which it can classify into only one or more categories of observations than only one. The continuous dependent variable and continuous covariates are the variables by which an entry sample of observations is split into subsamples, using logical formulas with the variables and searched cut-offs. Considering the categories given by the factor variable (or more factor variables) entering the analysis of covariance, these may be refined as an output for the random forest algorithm, not only as an input for the analysis of covariance. If the number of trees in the random forest model with sufficient complexity, i. e. classifying into two or more factor categories or their combinations, is high enough, then the hypothesis that there is no statistical difference between the two categories is hardly

likely. As a tuning parameter, the pruning level may affect how complex the trees in a random forest are.

After the well-established methods revisiting, we describe principles behind the random forest-based algorithm for post-hoc testing, derive the asymptotic time complexity of the proposed method, and estimate a feasible number of trees in the random forest model regarding the number of other factors and continuous covariates. Eventually, we do simulations to compare the new method to others, i. e. established ones, and, particularly, describe a relationship between the random forest tree pruning level and tree complexity and the model's first-type error rate.

II. PRINCIPLES AND ASSUMPTIONS OF ANALYSIS OF COVARIANCE AND POST-HOC TESTS REVISITED

In this section, we recapitulate basic principles of analysis of covariance and commonly used post-hoc tests to refresh their logic and mention their assumptions and limitations.

A. Analysis of covariance (ANCOVA) – principles, assumptions, and limitations

Principles of ANCOVA. Analysis of covariance is a linear model standing in between analysis of variance (ANOVA) [6] and linear regression [1], [7]. While the analysis of variance assumes there is a continuous dependent variable and independent categorical factors, linear regression allows for independent covariates as the analysis of covariance. However, compared to the linear regression, it estimates effect sizes as excesses above or below covariate variable average and enables to elegantly estimate an explained variability proportion of the continuous dependent variable by covariates. Furthermore, analysis of variance is performed particularly when continuous covariates are not of much interest compared to the factors. That being said, inference tests for coefficients of the covariates are usually skipped.

A model of the analysis of covariance, including $k \in \mathbb{N}$ categorical factor variables and $m \in \mathbb{N}$ continuous covariates, is for i -th observation from $n \in \mathbb{N}$ observations in total, as follows,

$$y_i = \mu + \sum_{j=1}^k \delta_j + \sum_{l=1}^m \beta_l x_{i,l} + \varepsilon_i, \quad (1)$$

where y_i is a value of the dependent continuous variable for i -th observation, μ is a grand total mean of the dependent variable, δ_j is an effect of j -th factor on i -th observation, with $\forall j \in \{1, 2, \dots, k\}$, β_l is a coefficient (slope) of l -th covariate, with $\forall l \in \{1, 2, \dots, m\}$, $x_{i,l}$ is a value of l -th covariate for i -th observation, and ε_i is a residual term of i -th observation, respectively.

Firstly, coefficients β_l for $\forall l \in \{1, 2, \dots, m\}$, listed in a vector $\boldsymbol{\beta} = (\beta_1, \beta_2, \dots, \beta_m)^T$, are estimated as those

minimizing the sum of residuals [8] from formula (1), ignoring (not yet estimated) effects δ_j of the factor variables, thus,

$$\begin{aligned} \boldsymbol{\beta} &= \arg \min_{\boldsymbol{\beta}_l \in \mathbb{R}^m} \left\{ \sum_{i=1}^n \varepsilon_i^2 \right\} \Big|_{\forall j \in \{1, 2, \dots, k\}: \delta_j = 0} = \\ &= \arg \min_{\boldsymbol{\beta}_l \in \mathbb{R}^m} \left\{ \sum_{i=1}^n \left(y_i - \left(\mu + \sum_{l=1}^m \beta_l x_{i,l} \right) \right)^2 \right\} = \\ &= \arg \min_{\boldsymbol{\beta}_l \in \mathbb{R}^m} \left\{ \sum_{i=1}^n \left(y_i - \mu - \sum_{l=1}^m \beta_l x_{i,l} \right)^2 \right\}. \quad (2) \end{aligned}$$

So far, considering formula (2) the analysis of covariance is similar to the linear regression. Secondly, once the vector $\boldsymbol{\beta} = (\beta_1, \beta_2, \dots, \beta_m)^T$ of linear coefficients is estimated, a part close to multifactorial analysis of variance follows. A total sum of squares, $SS_{\text{tot}} = \sum_{i=1}^n (y_i - \bar{y})^2$, describing total variability of the dependent variable [9], is corrected (reduced) by variability explained by the continuous covariates, SS_{β_l} , getting SS_{tot}^* , so

$$\begin{aligned} SS_{\text{tot}}^* &= SS_{\text{tot}} - SS_{\beta_l} = \sum_{i=1}^n (y_i - \bar{y})^2 - \sum_{l=1}^m \frac{\text{cov}(\mathbf{y}, \mathbf{x}_l)^2}{\text{var}(\mathbf{x}_l)} = \\ &= \sum_{i=1}^n (y_i - \bar{y}^*)^2, \quad (3) \end{aligned}$$

considering a vector of the dependent variable $\mathbf{y} = (y_1, y_2, \dots, y_n)^T$, a vector of l -th covariate $\mathbf{x}_l = (x_{1,l}, x_{2,l}, \dots, x_{n,l})^T$, and grand mean \bar{y}^* adjusted by the correction.

Finally, k -way analysis of variance for the coefficients δ_j estimation is applied. The null hypothesis claiming that j -th factor does not affect the dependent continuous variable, i. e. $H_0 : \delta_j = 0$, is formulated k -times and tests using the adjusted sum of squares, SS_{tot}^* , decomposed into component for the factors and for the residuals. Using formula (3) and assuming j -th factor has got n_j categories and c -th category has got $n_{j,c}$ observations, the decomposition is as follows [9],

$$\begin{aligned} SS_{\text{tot}}^* &= \sum_{i=1}^n (y_i - \bar{y}^*)^2 = \sum_{j=1}^k \sum_{c=1}^{n_j} \sum_{i=1}^{n_{j,c}} (y_i - \bar{y}^*)^2 = \\ &= \sum_{j=1}^k \sum_{c=1}^{n_j} \sum_{i=1}^{n_{j,c}} (y_i - \bar{y}_{j,c} + \bar{y}_{j,c} - \bar{y}^*)^2 = \\ &= \sum_{j=1}^k \sum_{c=1}^{n_j} \sum_{i=1}^{n_{j,c}} (y_i - \bar{y}_{j,c})^2 + \sum_{j=1}^k \sum_{c=1}^{n_j} (\bar{y}_{j,c} - \bar{y}^*)^2 = \\ &= \sum_{j=1}^k SS_{j\text{-th factor}} + SS_{\varepsilon} \quad (4) \end{aligned}$$

where $SS_{j\text{-th factor}}$ is sum of squares for j -th factor, SS_{ε} is sum of squares for residuals, and $\bar{y}_{j,c}$ is an average of all values that belong to c -th category of j -th factor. Consequently, using

formula (4), the null hypothesis $H_0 : \delta_j = 0$ for j -th factor is rejected on confidence level $1 - \alpha$ if and only if

$$F = \frac{SS_{j\text{-th factor}}/(n_j - 1)}{SS_{\varepsilon}/(n + k - 1 - \sum_{j=1}^k n_j)} \geq F_{1-\alpha} \left(n_j - 1, n + k - 1 - \sum_{j=1}^k n_j \right), \quad (5)$$

where $F_{1-\alpha}(df_1, df_2)$ is $(1-\alpha)$ -th quantile of Fisher-Snedecor distribution with df_1 and df_2 degrees of freedom, respectively. Rejecting the null hypothesis for j -th factor does not determine which categories of the factor mutually differ significantly, though.

Assumptions and limitations of ANCOVA. Analysis of covariance assumes that residuals are independent, i. e. for each $r, s \in \{1, 2, \dots, n\}$ so that $r \neq s$ is $\text{cov}(\varepsilon_r, \varepsilon_s) = 0$, and of the same variance, i. e. for each $r \in \{1, 2, \dots, n\}$ is $\varepsilon_r = \sigma^2 < 0$. Moreover, the residuals should be normally distributed, i. e. for each $r \in \{1, 2, \dots, n\}$ is $\varepsilon_r \sim \mathcal{N}(0, \sigma^2)$ [1].

B. Post-hoc tests – principles, assumptions, and limitations

Assuming the null hypothesis has been rejected for j -th factor, one would like to determine which exact two or more categories of the factor significantly differ. Let us mark average values of observations that belong to categories c_r and c_s of j -th factor, with $r, s \in \{1, 2, \dots, n_j\}$, as μ_r and μ_s . Usually, the categories c_r and c_s of j -th factor significantly differ when some inequality using data parameters or estimates holds, as showed below applying the mathematical notation from formulas (4) and (5). The decision process may be repeated for each pair of categories r, s of j -th factor to research all possible differences.

1) *Tukey honestly significant differences (HSD) test:* Based on Tukey, averages of the categories c_r and c_s significantly differ if

$$\frac{|\mu_r - \mu_s|}{\hat{\sigma} \sqrt{2/n}} \geq q(\alpha, k, n - k), \quad (6)$$

where $q(\alpha, k, n - k)$ is studentized critical value for confidence level α and σ^2 is residuals' variance, n is sample size and k is the number of factors.

Tukey HSD method assumes that subsamples for compared categories are independent, of the same variability (*homoskedasticity*), and follow normal distribution [2].

2) *Scheffé's test:* Following Scheffé's (unweighted) test, averages of the categories c_r and c_s significantly differ if

$$|\mu_r - \mu_s| \geq \sqrt{(k - 1) \cdot F_{1-\alpha}(df_1, df_2) \cdot SS_{j\text{-th factor}}}, \quad (7)$$

where $df_1 = n_j - 1$ and $df_2 = n + k - 1 - \sum_{j=1}^k n_j$.

Scheffé's test is less limited than Tukey's HSD test since there is no explicit assumption of any normal distribution of observations; however, it has lower statistical power, though [3].

3) *Dunn's test:* Transforming values of dependent variable y_i that belong to the categories c_r and c_s from initial continuous ones to their ranks, we get their averages \bar{w}_r and \bar{w}_s . Dunn's test recommends considering the categories c_r and c_s as different when

$$|\bar{w}_r - \bar{w}_s| \geq z_{1-\alpha/2} \cdot \sqrt{\frac{\frac{n(n+1)}{12} + \sum_{t \in |\bar{w}_r - \bar{w}_s|} \left(n_t^3 - \frac{n_t}{12(n-1)} \right)}{\left(\frac{1}{n_{c_r}} + \frac{1}{n_{c_s}} \right)}}, \quad (8)$$

where t is a possible tied value of the ranks w_r and w_s , n_t is a count of tied ranks at value t , and n_{c_r} and n_{c_s} are numbers of observations in categories c_r and c_s , respectively.

While assumption-free, Dunn's test may fail to identify significant differences between categories due to its low statistical power [4].

4) *Nemenyi's test:* Similarly to Dunn's test, assuming average ranks \bar{w}_r and \bar{w}_s of the categories c_r and c_s , these significantly differ if

$$|\bar{w}_r - \bar{w}_s| \geq q(\alpha, k, n - k) \cdot \sqrt{\frac{n(n+1)}{24} \cdot \left(\frac{1}{n_{c_r}} + \frac{1}{n_{c_s}} \right)}, \quad (9)$$

where $q(\alpha, k, n - k)$ is studentized critical value for confidence level α , n is sample size, k is the number of factors, and n_{c_r} and n_{c_s} are numbers of observations in categories c_r and c_s , respectively.

Nemenyi's test is nonparametric and robust enough, but may suffer from low statistical power, though [5].

III. PRINCIPLES AND ASSUMPTIONS OF THE RANDOM FORESTS

In advance of the proposed method introduction we shortly point out important pieces of knowledge about classification trees and random forests.

A. Classification trees – principles and assumptions

Classification trees from the CART family of trees (classification and regression trees) split a hyperspace of $k \in \mathbb{N}$ explanatory variables (continuous or categorical) into disjunctive hyper-rectangles, fitting simple (constant) models there by minimizing a given criterion [10].

An observation given by a vector of values $\mathbf{x}_i = (x_{i,1}, x_{i,2}, \dots, x_{i,k})^T$ is classified into one of m classes of a target variable by a set of rules that comes from node formulas, created throughout the tree is growing, as described in Fig. 1. Initially, the root covers all observations till a node rule, i. e. a found explanatory variable and a cut-off value minimizing the given criterion partitions the dataset into two parts. Each part is then again split by a new rule set for a child node. The process is recursively repeated by growing the tree, by which a set of node rules successively splits the input dataset into more parts that are mutually more and more different. The process of the tree growing, called a top-down induction of a decision tree (TDIDT), is stopped by a stopping criterion, e. g. maximum of leaf (ending) nodes, maximum tree deepness level, etc.

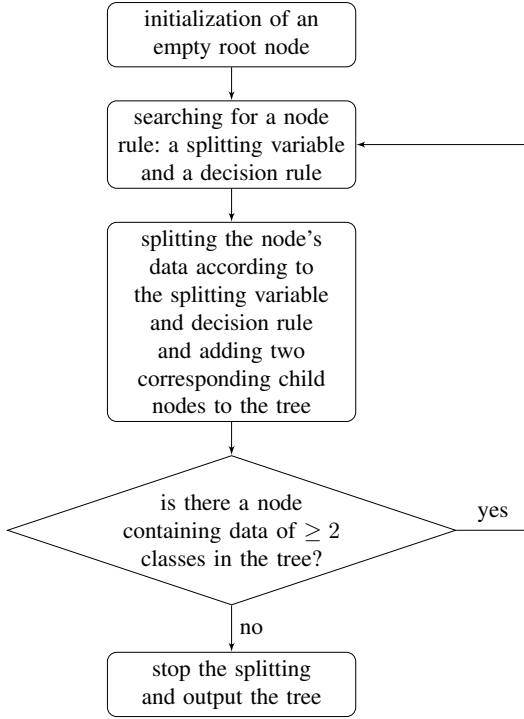

Fig. 1. A top-down induction of a decision tree (TDIDT).

Let $\sigma(\bullet)_j$ be a proportion of all observations that belong – by rules of all nodes from root to leaf one – to a target class j . A leaf node n_t classifies into the class c_f^* if $c_f^* = \operatorname{argmax}_{f \in \{1, 2, \dots, n_j\}} \{\sigma(\bullet)_f\}$. Since each node is through the tree growing a leaf one (for a limited time), the criterion has to be minimized in searching for node n_t rule. There are several commonly used criteria, also called *impurity measure*, $Q_{n_t}(T)$, such as misclassification error (10), Gini index (11), or deviance (cross-entropy) (12),

$$Q_{n_t}(T) = 1 - \sigma(\bullet)_f, \quad (10)$$

$$Q_{n_t}(T) = \sum_{j=1}^m \sigma(\bullet)_j (1 - \sigma(\bullet)_j), \quad (11)$$

$$Q_{n_t}(T) = - \sum_{j=1}^m \sigma(\bullet)_j \cdot \log \sigma(\bullet)_j. \quad (12)$$

One can easily see that the lower the impurity measure is, the higher $\sigma(\bullet)_f$, i. e. a proportion of a target class f in the node n_t , has to be, as expected.

Classification trees, as depicted in Fig. 1, in order to minimize the leaf nodes impurity, tend to overfit the node rules on a given dataset, which is done by the tree's typical "overgrowing", i. e. high complexity. To avoid this, besides some other naive approaches, *pruning* is commonly applied. Firstly, let us use usually defined *cost-complexity function*,

$$C_\kappa(T) = \sum_{n_t \in \{\mathbf{n}_t\}} |\{\mathbf{x}_{n_t}\}| \cdot Q_{n_t}(T) + \kappa \cdot |\{\mathbf{n}_t\}|, \quad (13)$$

where $\{\mathbf{n}_t\}$ is a set of leaf nodes of the tree and $\{\mathbf{x}_{n_t}\}$ is a set of all observations constrained by rules coming from the root till the node n_t . The idea of the pruning is to find a subtree T_κ so that $T_\kappa \subset T$ for a given κ that minimizes the statistics $C_\kappa(T)$, i. e. $T_\kappa = \operatorname{argmin}_T \left\{ \sum_{n_t \in \{\mathbf{n}_t\}} |\{\mathbf{x}_{n_t}\}| \cdot Q_{n_t}(T) + \kappa \cdot |\{\mathbf{n}_t\}| \right\}$.

The $\kappa \geq 0$ is a tuning parameter that governs the trade-off between a high tree complexity and size (for low values of κ) and tree parsimony and reproducibility to other datasets (for large values of κ).

B. Principles of the random forests

Random forests are finite sets of (distinct) classification trees, described in detail above, each classifying a k -dimensional observation, $\mathbf{x}_i = (x_{i,1}, x_{i,2}, \dots, x_{i,k})^T$, into one of $m \in \mathbb{N}$ target classes [11]. The final class $c_f^* \in \{1, 2, \dots, n_j\}$ of a k -dimensional observation is the one the largest subset of the random forest's trees classifies it into¹, i. e., $c_f^* = \operatorname{argmax}_{f \in \{1, 2, \dots, n_j\}} \{\# \text{ of trees classifying into the class } c_f\}$.

What is worth to be mentioned is that only $k^* < k$ variables are considered as possible partitioning variables in node rules. The subset of k^* variables from the original k explanatory variables is selected randomly using bootstrapping; that ensures the pre-selected k^* variables are mutually independent enough. A flowchart of the random forest model building is in Fig. 2.

Neither classification trees nor random forests have important assumptions or limitations worth speaking off.

IV. THE PROPOSED METHOD FOR POST-HOC TESTING

In this section, we introduce a novel alternative for post-hoc testing based on a random forest algorithm. Considering the ANCOVA notation, categories of a factor that contains statistically different effects on the continuous dependent variable are leaf node classes each tree of a random forest classifies into. The dependent variable and the covariates, and other factor variables, if any, are entry variables that serve for node rules if needed. Each tree of the random forest model can either classify only into one category (as a root node tree) or into two or more categories, based on its complexity (size). For details, see Fig. 3.

The more trees of sufficient complexity can classify into the classes (categories) in the forest, the more likely we can reject the null hypothesis that there is no difference between the effects of the factor's categories on the dependent variable. This is formally done by ANCOVA, too. What is more, if a proportion of trees classifying into two given categories is large enough, considering all trees, the given two categories seem to be of statistically different effect on the dependent variable [12].

A proportion of trees classifying into two or more categories to all trees in the random forest is close to a point estimate

¹In case of a tie, i. e. there are two or more target classes the maximum forest's trees classify the observation into, one of them is picked randomly.

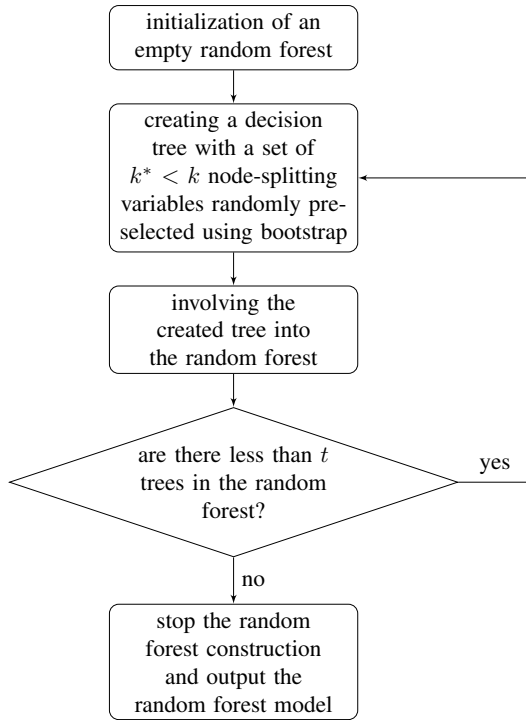

Fig. 2. A construction of the random forest model involving t decision trees.

of the p -value. The p -value is the probability we incorrectly reject the null hypothesis of no different effects of the factor categories on the dependent variable, assuming the null hypothesis is true. Thus, the method also provides statistical inference as a post-hoc test. Since we could modify a random forest's tree complexity (size), i. e. also tendencies to classify either only into one or into two or more classes, by pruning and the tuning parameter κ , we may control the first-type error rate, i. e. the incorrect rejection of the null hypothesis when it is true, of the random forest model as inferential post-hoc test. The proposed method is due to the random forest algorithm behind almost assumption-free.

Besides the derivations of the inferential properties of the method, we also discuss the method's asymptotic time complexity and do a simulation study with varying κ tuning parameters to describe a relationship between the parameter and the method's first-type error rate.

A. Statistical inference behind the proposed method

Using the mathematical notation from previous sections, let us assume the ANCOVA already rejected the null hypothesis that the j -th factor does not affect the dependent variable. Thus, the question is what two (or more) categories of j -th factor are significantly different so that the factor influences

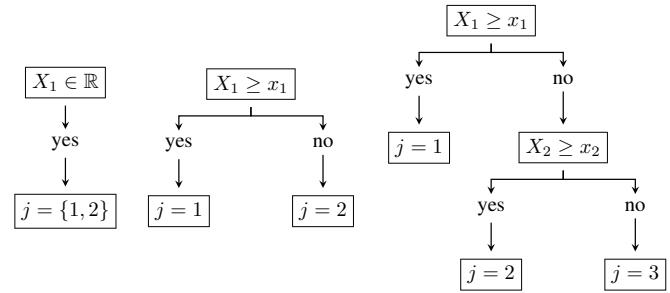

Fig. 3. An example of a root node tree (on the left) not able to classify into any class unambiguously, an example of a tree with sufficient complexity (in the middle) able to classify into two classes ($j = 1$ and $j = 2$), and an example of a tree with sufficient complexity (on the right) able to classify into three classes ($j = 1$, $j = 2$, and $j = 3$).

the dependent variable².

Intuitively, when a large number of the (appropriately pruned) trees of the random forest model can classify into two given classes, i. e. categories, then one can hardly suppose the categories are statistically without a difference.

Similarly to the post-hoc tests, let the null hypothesis H_0 claim that there is no statistical difference between the given two categories c_r and c_s of j -th factor. The alternative hypothesis H_1 claims the contradiction, so

H_0 : No statistical difference between categories c_r and c_s .

H_1 : Statistical difference between categories c_r and c_s .

Whenever a post-hoc test rejects the null hypothesis H_0 in favor of the alternative hypothesis H_1 , the case is equivalent to a situation the test's p -value is lower than or equal to a prior set significance level α , usually equal to 0.05.

By definition, the p -value is a probability of gaining data at least as extreme as the data actually observed, assuming the null hypothesis is true. Let t_c be a number of trees in the random forest model that are in contradiction to the null hypothesis (under the null hypothesis assumption). Then, the value of t_c is equal to the number of all trees classifying, besides other classes, into given two classes (categories) c_r and c_s ; showing that there is a difference between the two classes. Let the $\mathcal{I}_{c_r, c_s}(\tau)$ be an identifier function returning 1 if and only if the tree τ classifies into the classes (categories) c_r and c_s (regardless whether it classifies into other classes, too), thus,

$$\mathcal{I}_{c_r, c_s}(\tau) \begin{cases} 1, & \text{tree } \tau \text{ classifies into categories } c_r \text{ and } c_s, \\ 0, & \text{otherwise.} \end{cases}$$

We can derive

$$t_c = \sum_{\forall \tau \in \text{random forest}} \mathcal{I}_{c_r, c_s}(\tau),$$

²Supposing all categories of j -th factor are similar and mutually without significant differences, then the categorization of j -factor would not result in null hypothesis rejection about no effect of j -th factor on the dependent variable. That is a contradiction, so, there should be two or more different categories of j -th factor.

and assuming the random forest model contains exactly $t \in \mathbb{N}$ trees, and all trees are induced randomly regardless of their complexity³, the p -value is estimated by \hat{p} as

$$\begin{aligned} \hat{p} &= P(\text{getting data at least as extreme as the observed} \mid H_0) = \\ &= P\left(\sum_{\forall \tau \in \text{random forest}} \mathcal{I}_{c_r, c_s}(\tau) \geq t_c \mid H_0\right) = \\ &= P\left(\sum_{\forall \tau \in \text{random forest}} \mathcal{I}_{c_r, c_s}(\tau) \in \{t_c, t_c + 1, \dots, t\}\right) = \\ &= \frac{|\{t_c, t_c + 1, \dots, t\}|}{t} = \\ &= \frac{t - t_c + 1}{t} = \\ &= 1 - \frac{t_c - 1}{t}. \end{aligned} \quad (14)$$

Thus, formula (14) shows that the p -value's estimate is equal to the fraction of $1 - \frac{t_c - 1}{t}$. Intuitively, supposing the initial number t_c of trees in the random forest model that are complex enough to classify, besides others, to categories c_r and c_s is generally low. In that case, such a model is not "much" in contradiction to the null hypothesis about no differences between the two categories. Thus, when the t_c is relatively low, the fraction p -value $= 1 - \frac{t_c - 1}{t}$ is relatively high and close to 1, so, unlikely lower than $\alpha (= 0.05)$. The null hypothesis probably fails to be rejected. However, for high values of t_c , i. e. when there are many trees in the forest with sufficient complexity classifying into the two categories c_r and c_s (thus, in contradiction to the null hypothesis), then – since the high value of t_c – the fraction p -value $= 1 - \frac{t_c - 1}{t}$ is relatively low and perhaps below the α level. Consequently, the null hypothesis is likely rejected.

Indeed, the κ parameter determines how complex the trees in the random forest are or how radical the pruning of the trees is. Investigating formula (13), one can realize that if $\kappa = 0$, then there is no penalization for large tree complexity, so trees in the random forest are generally very complex (i. e., of large size). So, whenever there are at least two observations, one from c_r category and the other from c_s category of j -th factor, all trees in the forest would classify those observations into their categories, i. e. that for each tree τ is $\mathcal{I}_{c_r, c_s}(\tau) = 1$, which results into $t_c = \sum_{\forall \tau \in \text{random forest}} \mathcal{I}_{c_r, c_s}(\tau) = t$, and, thus, p -value estimate is $p\text{-value} = 1 - \frac{t_c - 1}{t} = 1 - \frac{t - 1}{t} = \frac{1}{t} \approx 0$. Finally, if $p\text{-value} \approx 0$, then also $p\text{-value} \approx 0 < \alpha$ which, consequently, results into the null hypothesis rejection. However, when the null hypothesis rejection is often, it is also very likely a *false* rejection, that increases the first-type error rate. High chance of the null hypothesis rejection means also the high statistical power, though, i. e. the case when the incorrect null hypothesis is *correctly* rejected.

For $\kappa > 0$, the penalization for tree complexity (size) is applied, so, the trees' complexity (size) decreases, and, thus, if not all, many of the trees do not classify into both

c_r and c_s categories. This means that there are trees τ in the random forest so that $\mathcal{I}_{c_r, c_s}(\tau) = 0$, and, finally, $t_c = \sum_{\forall \tau \in \text{random forest}} \mathcal{I}_{c_r, c_s}(\tau) < t$. So, p -value estimate is $p\text{-value} = 1 - \frac{t_c - 1}{t} > 0$, and it could be below or above the α level.

B. A feasible low bound of the number of trees t in the random forest

Adopting the ANCOVA mathematical notation, when two categories c_r and c_s of j -th factor are compared using the random forest-based method, other $k - 1$ factors, together with m covariates and the originally dependent continuous variable, play as input variables for node decision rules. Assuming that ℓ -th factor contains $n_\ell \geq 2$ categories and cut-offs for the covariates are usually estimated as midpoints of covariates' ranges, splitting the ranges into a number of categories to be classified into, i. e. n_c , we may estimate a minimum number of mutually different trees. Each mentioned feature could be or could not be included in a tree; that being said, the number of all combinations of $k - 1$ factor node rules is at least $2^{\prod_{\ell \in \{1, 2, \dots, k\} \setminus j} n_\ell} \geq 2^{2^{k-1}}$, and the number of all combinations of m covariates and the dependent variable, split into n_j intervals, is at least n_j^{m+1} . Thus, the minimum number of mutually different trees and, thus, the feasible low bound of the random forest trees' number is

$$t > 2^{\prod_{\ell \in \{1, 2, \dots, k\} \setminus j} n_\ell \cdot n_j^{m+1}} \geq 2^{2^{k-1} \cdot n_j^{m+1}}.$$

Furthermore, since the number of trees t determines decimal precision of p -value estimate based on formula 14, if we ask for decimal precision of $d \in \mathbb{N}$ digits, then the minimum number of trees in the random forest is about

$$t > 10^{d+1},$$

to ensure feasible precision for d -th decimal digit.

C. A brief asymptotic time complexity analysis of the proposed method

The random forest model consists of classification trees as atomic units, constructed following the flowchart 1 and algorithm 1. A decision tree is induced until the moment all its leaf nodes include only observations of one category of j -th factor, i. e. a sequence of node rules coming from root node till the leaf one successively limits the entry dataset to one-class observations [13]. When the categories are well balanced across the dataset, each binary partitioning halves them, and the tree average depth is around $\log_2 n$ levels; thus, the asymptotic time complexity is also $\Theta(\log_2 n)$, assuming one split of a node takes one time atomic unit. However, if the categories are totally unbalanced, each splitting cuts the current dataset of size n^* into 1 and $n^* - 1$ observations, which takes n steps in total. Then, tree depth is n , so the asymptotic time complexity is $\Theta(n)$. Assuming there are $k - 1$ factors, m covariates and the originally dependent variable, i. e. $k - 1 + m + 1 = k + m$ variables, searched through averagely $\frac{n}{2}$ observations within each node splitting, the asymptotic time complexity of one tree induction $\Theta(\dagger)$

³This is ensured by the bootstrapped selection of $k^* < k$ node rule variables.

is therefore between $\Theta(\log_2 n)$ (best-case scenario) and $\Theta(n)$ (worst-case scenario),

$$\begin{aligned} \Theta\left(\frac{(k+m)n}{2} \log_2 n\right) &\leq \Theta(\dagger) \leq \Theta\left(\frac{(k+m)n^2}{2}\right), \\ \Theta\left(\frac{(k+m)n}{2} \log_2 n\right) &\leq \Theta(\dagger) \leq \Theta\left(\frac{(k+m)n^2}{2}\right), \\ \Theta((k+m)n \log_2 n) &\lesssim \Theta(\dagger) \lesssim \Theta((k+m)n^2). \end{aligned} \quad (15)$$

Algorithm 1: The top-down induction of decision trees (TDIDT) following the logic of the flowchart 1

Data: a $n \times (m+k)$ dataset of n observations, with j -th target factor, $k-1$ factors, m covariates, and one dependent continuous variable

Result: a classification tree

```

1  $T = (\{\mathbf{n}\})$  // a tree  $T$  with a set ;
2 // of nodes  $\mathbf{n}$ ;
3  $\{\mathbf{n}\} = \{\text{root}\}$  // initially, the tree  $T$ 
  ;
4 // is a root;
5  $\sigma(\bullet)_j$  // a node criterion;
6 while  $\exists$  a node  $\in \{\mathbf{n}\}$  so that data constrained by all
  node rules coming from root to the node belong to
   $\geq 2$  classes do
7   find for the node a splitting variable and splitting
  point minimizing the  $\sigma(\bullet)_j$ ;
8   add to the node two child nodes  $n_{\text{left}}$  a  $n_{\text{right}}$ ;
9    $\{\mathbf{n}\} := \{\mathbf{n} \cup \{n_{\text{left}}, n_{\text{right}}\}\}$ ;
10   $T := (\{\mathbf{n}\})$  // update the tree using;
11  // the new node set  $\mathbf{n}$ ;
12 end
13 a completely induced tree  $T$ ;
```

Since a random forest contain t trees, each built in $\Theta(\dagger)$ time by (15), the entire random forest asymptotic time complexity construction $\Theta(\ddagger)$ is

$$\begin{aligned} \Theta\left(t \frac{(k+m)n}{2} \log_2 n\right) &\leq \Theta(\ddagger) \leq \Theta\left(t \frac{(k+m)n^2}{2}\right), \\ \Theta(t(k+m)n \log_2 n) &\lesssim \Theta(\ddagger) \lesssim \Theta(t(k+m)n^2). \end{aligned} \quad (16)$$

One model of the random forest provides one (point) estimate of the p -value using the formula (14), enabling to statistically distinguish between two categories. In comparison, the estimation of the decision rules for post-hoc tests using formulas (6), (7), (8), and (9) usually take only several linear steps, assuming the $\text{SS}_{j\text{-th factor}}$ in (7) term is precalculated. Fortunately, the time complexity (16) is still polynomial. Furthermore, since the building of the random forest with the complexity of (16) is based on independent trees induction, it could be parallelized; then, if the random forest building would be parallelized into $\pi \leq t$ independent slave processes each

inducing a bunch of $\frac{t}{\pi} \in \mathbb{N}$ trees, the time complexity (16) would be reduced to

$$\begin{aligned} \Theta\left(t \frac{(k+m)n}{2\pi} \log_2 n\right) &\leq \Theta(\ddagger) \leq \Theta\left(t \frac{(k+m)n^2}{2\pi}\right), \\ \Theta\left(\frac{t}{\pi}(k+m)n \log_2 n\right) &\lesssim \Theta(\ddagger) \lesssim \Theta\left(\frac{t}{\pi}(k+m)n^2\right). \end{aligned}$$

V. SIMULATION STUDY

To compare the established post-hoc tests with the proposed method, particularly its first-type error rate, we run a simulation study generating many $n \times (k+m+1)$ datasets with n observations, k factor variables, m covariates with various relationships between the variables, and, lastly, with the continuous dependent variable. For each post-hoc test, i. e. Tukey HSD test, Scheffé's test, Dunn's test, Nemenyi's test, and random forest-based method, we compare two categories of a selected factor so that the categories have significantly non-different averages within the continuous dependent variable and check how many times the methods claim there is a significant difference. Thus, in theory, we measure the first-type error rate. The simulation was repeated for different κ parameter values to illustrate how the value of κ determines the first-type error rates in the new method, i. e., what are ideal κ values to control the first-type error rate on a feasible level.

The datasets were generated as follows. One of the k factors, let's say the j -th one, contained two categories, c_r and c_s , following a normal distribution with the same average of the continuous dependent variable, i. e. $\mathcal{N}(0, 1^2)$. Other $k-1$ factors always split the dependent continuous variable into 2 to 4 categories with random averages from $\mathcal{N}(\mu, \sigma^2)$, where $\mu \in \langle -1, 1 \rangle$ and $\sigma^2 \in \langle 0, 2 \rangle$. Furthermore, the covariates also followed normal distribution $\mathcal{N}(\mu, \sigma^2)$, where $\mu \in \langle -1, 1 \rangle$, $\sigma^2 \in \langle 0, 2 \rangle$, and correlations \mathbf{r} between the dependent continuous variable and covariates were randomly from $\mathbf{r} \in \langle -0.5, 0.5 \rangle$. The continuous variable was dependent for all post-hoc tests with exception of the proposed method, where j -th factor is as dependent one.

There were $\eta = 1000$ datasets, as depicted above, generated in total, and for each $\kappa \in \{0.1, 0.3, 0.5, 0.7, 0.9\}$. The number of trees in each random forest was always $t = 1000$. Numbers of cases where p -value was lower than or equal to $\alpha = 0.05$ regardless of the post-hoc test were summed up, indicating the point estimates of the first-type error rates, as illustrated in table I. The simulation study was performed using R programming language and environment [14]. There are more numerical applications of R language to various fields in [15]–[23].

While the established post-hoc tests returned point estimates of the first-type error rate about 0.050 (regardless of κ since their formulas (6), (7), (8), and (9) are not functions of the κ), point estimates of the first-type error rates output by the introduced method progressively decreased with increasing value of κ , see table I.

However, since the proposed random forest-based algorithm for categories' averages comparison is data-determined and heuristic, it is nontrivial to suggest specific values of the

TABLE I

POINT ESTIMATES OF THE FIRST-TYPE ERROR RATES FOR POST-HOC TESTS, I. E. TUKEY HSD TEST (T-HSD), SCHEFFÉ'S TEST (SchT), DUNN'S TEST (DT), NEMENYI'S TEST (NT), AND THE PROPOSED METHOD (RF-T) FOR DIFFERENT VALUES OF TUNING PARAMETER κ , BASED ON THE SIMULATION DESCRIBED ABOVE.

	method					κ

pruning parameter κ to reach a given level of the first-type error rate.

Still, as indicated by the derived theory and simulation study, the higher the pruning parameter κ is, the higher penalization for too complex trees in a random forest is. Thus, the less complex the trees in a random forest are, which results in lower trees' ability to classify into two or more classes of the factor variable and, consequently, the lower first-type error rate of the random forest as an inferential algorithm.

VI. CONCLUSION

When searching for statistical differences between categories' averages of a given factor, once analysis of covariance is performed, post-hoc tests may identify which two or more categories have significantly different impacts on the dependent continuous variable average. However, the post-hoc tests are usually limited by rigid statistical assumptions.

In this work, we introduced a novel method for post-hoc testing based on a random forest algorithm. Rather than a statistical comparison of dependent variable's averages for two factor categories and evaluation of its effect size, the proposed technique refines the logic of testing. The factor with compared categories becomes an output variable, i. e., its categories populate leaf nodes of the model trees, and other factors, initially dependent continuous variable and covariates, if any, serve input variables, i. e., as quantities in node rules. The higher the random forest model trees' complexity, i. e., size is, the more likely the trees classify into (besides others) the two compared categories, and, thus, the null hypothesis claims there is no statistical difference between the compared categories' averages is more likely to be rejected. Furthermore, since trees' pruning level determines the trees in the random forest model complexity, a tuning parameter affecting the significance of the pruning also changes trees' complexity and, consequently, the probability of correctly rejecting the

null hypothesis. Finally, the tree pruning may modify the first-type error rate, too. The asymptotic time complexity of the random forest-based post-hoc method is usually higher than the complexities of the established procedures but is still polynomial and might be parallelized.

Therefore, the introduced random forest-based method seems to be a valid alternative to other, commonly used post-hoc tests.

30th International Symposium on Concurrency, Specification and Programming

THE symposium on Concurrency, Specification, and Programming is the series of meeting formerly organized every even year by Humboldt University of Berlin and every odd year by Warsaw University. It deals with formal specification of concurrent and parallel systems, mathematical models for describing such systems, and programming and verification concepts for their implementation. The symposium has a tradition dating back to the mid-seventies; since 1993 it was named CS&P. During the past 30 years, CS&P has become an important forum for researchers from European and Asian countries.

TOPICS

The list of topics includes, but is not limited to:

- Mathematical models of concurrency
- Formal specification languages
- Theory of programming
- Model checking and testing
- Multi-agent systems
- Rough sets
- Verification
- Formal aspects of knowledge management
- Knowledge discovery and data mining
- Soft computing
- Applications, e.g. in Robotics

TECHNICAL SESSION CHAIRS

Abstract—Security Games have been used in several different fields to randomise the division of limited resources and thus maximise the possibility of securing a set of targets. For this very practical purpose it is natural to consider primarily mixed strategies, but such focus omits some theoretical properties of the games discussed. In this paper we discuss the existence and properties of pure Nash equilibria in security games. We give an overview of the basic observations that can be made in this setting. We also recognize an interesting problem in a case with multiple players playing a security game asynchronously, propose an algorithm for finding a strategy for any given player in the mentioned case and prove that the strategy profile resulting from the algorithm is in fact a Nash equilibrium and, even stronger, a subgame perfect equilibrium. We think that these findings are a nice supplement of the practical approach to Security Games and allow to form new research questions.

I. INTRODUCTION

Since its conception in the previous century, Game Theory provided a language which has been used to discuss, among other things, how businesses compete on a given market, how to model predator-pray interactions in the animal kingdom and, most famously, how to behave during an interrogation. This should come at no surprise as, at its core, game theory describes conflict between autonomous entities and such beings can be recognized in almost any setting.

One of the most basic concepts that was necessary to define in this field from the very beginning, is how to recognize whether any decision made by an entity is good or not. Typically it is decided by considering the potential outcome, which is provided by knowing the decision process of all of the players, and testing whether it has a desired set of properties.

One of the most known descriptions of a good strategy profile is the Nash equilibrium [1]. While it has its own drawbacks, it provides a reasonable set of assumptions on the behaviour of the players and always exists in finite games with mixed strategies.

A mixed strategy is when the decision process of a player is given by a probabilistic function over the possible actions, and thus is great to describe the uncertainty in decision making. In contrast we have pure strategies, where a player chooses one action. There is no guarantee that there is a Nash equilibrium consisting of only of pure strategies, which makes it a very interesting decision question, that has been studied for several classes of games [2] [3].

An interesting type of game, for which pure strategies were not considered, are the so called security games. Based on an

idea by Stackelberg [4], these games divide the players into two groups, of which one declares their strategies before the other, and tries to find a Nash equilibrium in such setting. This approach has been successfully applied in several systems, like the security checkpoint schedule in LAX airport [5], planning US Air Marshals flight security patterns [6], preventing poaching [7] and other cases. While it should be obvious why limiting yourself to just pure strategies in security games is not the best thing to do from a practical point of view, we found the theoretical properties of this model to be interesting and this paper, which is based on a PhD thesis [8], provides some insights to the approach.

The structure of this paper is the following: In section 2 we provide the basic definitions needed for the discussion and observations that can be made about pure strategies in security games. In next section we discuss deeper a specific case where we have multiple defenders playing asynchronously and recognize which game theory concepts should be used to find the strategies in that setting. Section 4 contains the algorithm for choosing a strategy for each player and the proof that the resulting strategy profile is a subgame perfect equilibrium. In the final section we will briefly summarize our observations and recognize further possible areas of inquiry.

II. BASIC DEFINITIONS AND OBSERVATIONS

As a *game in normal form* we recognise a tuple (N, A, u) where: N is a finite set of players, indexed by i ; $A = A_1 \times \dots \times A_n$ where A_i is a finite set of actions available to player i . Each vector (a_1, \dots, a_n) in A is called an *action profile*; $u = (u_1, \dots, u_n)$, where $u_i : A \rightarrow \mathbb{R}$ is a *valuing function* for player i . In our cases we will assume that the goal of each player is to get the largest possible value from their valuing function. Moreover in the games we will be discussing any action will be corresponding to choosing an object to protect and thus we sometimes use the expressions *committing to an action* and *picking an object* interchangeably, hopefully not causing too much confusion. The assignment of probabilities by a player to his set of available actions is called a *strategy* and the decision on the probabilities is called *committing to a strategy*. If the assignment gives one of the actions probability 1 then it is called a *pure strategy*. Any other strategy is called *mixed*. A *strategy profile* is a vector containing strategies of all players in a given game. To formalize the concepts of good strategies we define a *best response* for the player i to an action

vector a_{-i} (an action vector without the i -th position) is an action $a \in A_i$ such that for all a' in A_i we have $u_i(a_{-i}, a) \geq u_i(a_{-i}, a')$. A strategy $a = (a_1, \dots, a_n)$ is a *Nash equilibrium* iff for all i in $\{1, \dots, n\}$ a_i is a best response to a_{-i} .

Now we can move on to define security games, in which we divide the players in to two groups, one of which declares their strategies before the other. We call the first group the defenders and the second group is called the attackers. In any case an action done by a defender is interpreted as defending a specific object, corridor, monument etc. and an action chosen by the attacker is assaulting it. For it to be a security game, the valuation function has to have an additional property: if the attacker chose to attack an undefended target his valuation function will be higher than if the target was defended. Symmetrically the valuation function for the defender should be worse when an undefended object has been attacked, then if a defended object has been attacked.

While the properties of the valuation function play a crucial role in finding mixed strategies in Security Games, there are not that important when we assume that only pure strategies are available to the players. In the case of pure strategies in security games it is sufficient to just consider the strategies of the defenders. Now let us think what will happen, if all of the defenders have to commit to a strategy at the same time. Obviously, they want their most valued object to be protected and they have no way to coordinate with other players. If for each of them the most valuable object is different, then we will have a Nash equilibrium.

If two players value one object the most we have an interesting situation: on one hand if they are rational they should pick the most valued object, but that will lead to a strategy profile that is not a Nash equilibrium, as if only one of them would switch to his second best object, he would increase his valuation function. On the other there is no rational way for any of those players to make a different decision as they are risking lesser value if both of them choose their second best option. So we would have a situation where there may exist a pure Nash equilibrium, but there is no way for the players to achieve it. This problem could disappear, if the defenders themselves played in a given order, but it may not be the case, and will be the topic of our next inquiry.

III. MULTIPLE DEFENDERS IN AN ASYNCHRONOUS GAME

Let us consider a security game with n defenders and one attacker. Each action of a defender consists of picking an object to defend. The defenders commit to their pure strategies in a given order. The valuation function for each player is given as the sum of all values of the objects picked by all of the players. This model describes a sequential game which can be described as a game in Extended Form. Full formal definitions of an Extended Form game, Nash equilibrium and a sub-game perfect equilibrium in such games can be found in handbooks like [9] or [10]) We will describe the basic intuitions behind those concepts.

We can represent a game in Extended Form as a tree in which: each vertex represents the state of the game at the

moment, the root being the game before any move was made, and each leaf describing each possible outcome of the game, each edge represents an action that the current player can choose and connects the vertex corresponding to the game state before that action to the vertex with the game state after that action. With this representation any sub-tree that starts in a vertex and consists of all the edges and vertices below is also a game and is called a *sub-game*.

Any game in extended form can be translated into normal form and thus we can use the definitions of Nash equilibrium and best response in this context. There is a problem however, as the Nash equilibrium does not have to be optimal on sub-games. A *sub-game perfect equilibrium* is a Nash equilibrium that is also a Nash equilibrium on all of their sub-games.

Now if we have the complete game tree, it is easy to see that we can find a best response for any player simply by backtracking the expected results from the leaves to the current situation. This is unfeasible, as the whole game tree will grow exponentially with respect to the number of players and possible actions. To get rid of this problem, instead of trying to find a whole strategy, we will try to identify a good move and argue that there exists a sub-game perfect equilibrium in which this was the best response.

Consider a game G with the set of actions A and a strategy profile s for G . A sequence $(a_1, \dots, a_n) \in A^n$ is a *result* of strategy s if, and only if starting in the root of the game tree and moving down an edge only if it is the action indicated by the strategy s , the actions the edges traveled through form the sequence (a_1, \dots, a_n) .

We say a sequence of actions (a_1, \dots, a_n) is called *reasonable* if there exists a strategy profile that is a sub-game perfect equilibrium, such that (a_1, \dots, a_n) is a result of s .

Thus we can simplify our problem and instead of finding a strategy profile which should describe actions taken in any possible situation, just find an sequence of actions and argue that they are a result of a good strategy profile.

IV. MAIN RESULT

We will present now the algorithm for finding good move for each player. The algorithm in itself is fairly simple and easily works in polynomial time.

A. Algorithms for decisions

The basic algorithm

Input: A - set of available actions; V - the valuation matrix; i - the index of the player making the decision;

Output: (a_i, \dots, a_n) the predicted choices of actions for players i to n .

- 1) Delete all columns for actions that have already been chosen.
- 2) Define k as the number of rows in the matrix.
- 3) Find in the last row the column in which there is the most valuable object for the k -th player (if more than one pick at random).
- 4) Mark this object as a_k .
- 5) Remove the last row from the matrix.

6) Repeat steps 1-4 until a_i is defined.

The modified algorithm

Input: A - set of available actions;

V - the valuation matrix;

i - the index of the player making the decision;

(a_1, \dots, a_n) - sequence of choices of actions predicted by the original algorithm;

Output: (a'_i, \dots, a'_n) the predicted choices of actions for players i to n .

- 1) Delete all columns for objects that have already been chosen.
- 2) Define k as the number of rows in the matrix.
- 3) Find in the last row the column in which is the most valuable object for the k -th player (if more than one and a_k is available pick a_k else pick at random).
- 4) Mark this object as a'_k .
- 5) Remove the last row from the matrix.
- 6) Repeat steps 1-4 until a'_i is defined.

B. Proofs of reasonability

To prove that the sequence provided by the basic algorithm is reasonable we will use the following lemma, which shows that if we have a sequence predicted by the basic algorithm and we remove one object from the set of possible objects, then using the modified algorithm for a player will have an output which will differ from the original output at most at one choice.

Lemma 4.1: Let (a_1, \dots, a_n) be the result of using the basic algorithm on the game G with the set of actions A . By running the modified algorithm for the game G , sequence (a_1, \dots, a_n) and set of objects $A \setminus \{a\}$, where $a \in A$, will give a sequence (a'_1, \dots, a'_n) which will differ from (a_1, \dots, a_n) in at most one element and only if $a \in \{a_1, \dots, a_n\}$.

Case 1: First let us consider the case in which $a \notin \{a_1, \dots, a_n\}$. In this case the resulting sequence will be identical to the original. As in step 4 of the modified algorithm for the k -player the action a_k will still be available and the valuation of objects has not changed, it will be chosen by the k -th player.

Case 2: Now consider the case in which $a \in \{a_1, \dots, a_n\}$. Let us assume that $a = a_k$ for some $1 \leq k \leq n$. Since none of the values have changed and the players from $k + 1$ to n will still have their previous choices available, the algorithm will pick those objects. Of course player k cannot choose a_k because it is not in the set of possible actions. The modified algorithm finds a new object for him which we will mark as a' . It cannot be that $a' = a_i$ for $i > k$ because these objects are already unavailable for the algorithm by now. If $a' \neq a_i$ for all $i < k$ then this will be the only change result of the algorithm, because then all of the objects the modified algorithm has to pick in case of ties are available as in case 1. If $a' = a_i$ for some $i < k$, then it will be assigned to player k , but we have a problem with the assignment for player a_i . Running the modified algorithm for players from $i + 1$ to $k - 1$ will give the same result as the original, by the same reasoning as before. For player i we can repeat the same reasoning as

we did for the player k . As in each such repetition the index will get smaller and the sequence is finite, such replacement will happen only a finite number of times and will result in a sequence which differs only in one element from the original sequence.

Theorem 4.2: Let (a_1, \dots, a_n) be the result of using the algorithm on the game G with the set of objects A . Then (a_1, \dots, a_n) is reasonable.

We will prove this by assigning a move each vertex in the game tree and arguing that we can construct a sub-game perfect equilibrium for the game G for which (a_1, \dots, a_n) is the result. The proof goes by induction on the number of players. The case of $n = 1$ is trivial.

$n = 2$: We have one vertex corresponding to the decision of player 1 from which descent m edges corresponding to all possible actions for player 1. We put a_2 on all vertices of player 2 except the one connected to the edge a_2 . There we can use the modified algorithm on the sequence (a_1, a_2) and the set of objects $A \setminus \{a_2\}$ to find one to put on this vertex. We put a_1 on the root. It should be easy to see that this assignment will produce a sub-game perfect equilibrium with the sequence (a_1, a_2) as a result.

$n - 1 \Rightarrow n$: Now we assume that we can assign moves tree for any game G with $n - 1$ players a given set of objects A which constructs a sub-game perfect equilibrium and a sequence given by the algorithm is the result. We will show how to use this to assign moves in a tree for any game with n players and a sequence (a_1, \dots, a_n) given by the algorithm. We start from a tree for the game G with all vertices empty. For every vertex connected to the root we will run the modified algorithm on the game G without player 1, sequence (a_2, \dots, a_n) , and set of objects $A \setminus \{a\}$, where a is the label of the edge between this vertex and the root. By our inductive assumption, we can construct a full strategy on the subtree starting from that vertex, which has the desired properties and has (a'_2, \dots, a'_n) , given by the modified algorithm, as a result. We can see that by discarding the object a for this whole subtree we can be sure that, as long as we pick the proper object for the root, the whole strategy will stay a perfect subgame equilibrium. What is left is to show that there are no better actions to put at the root than a_1 . Consider first edges a which are not in the set $\{a_2, \dots, a_n\}$. If player one was to pick one of them the result of playing the subtree under that edge, by the lemma, is exactly the sequence (a_2, \dots, a_n) , so it only could be beneficial for him if $v_1^a > v_1^{a_1}$ which is contrary to the way we picked a_1 . Suppose now that player 1 could benefit from committing to an action a from the set $\{a_2, \dots, a_n\}$. By the lemma the resulting sequence (a, a'_2, \dots, a'_n) differs in at most one element from the sequence (a_1, \dots, a_n) . If it differs, then for it to be beneficial it had to be the case that this one action has a greater value for player 1 than a_1 , which is in contrary with the way a_1 was chosen. So there is no action which grants a better result for player 1 than choosing a_1 . We put a_1 on the root getting a proper assignment to the tree which can construct a perfect su-game equilibrium with the result (a_1, \dots, a_n) thus completing the construction.

With multiple preferred objects it could happen that the whole outcome of the game is very different from what the players predicted and in fact the outcome does not have to be a sub-game perfect equilibrium, which would undermine the validity of the reasonable move as a good strategy concept. The next theorem proves that no matter how often the players were wrong in their predictions the whole outcome will be in fact reasonable.

Theorem 4.3: Let G be a game with n players and the set A of available objects. Player 1 uses the basic algorithm to obtain the sequence (a_1^1, \dots, a_n^1) and picks a_1^1 . Then player 2 uses the basic algorithm on the set $A \setminus \{a_1^1\}$, obtains the sequence $(a_1^2, \dots, a_{n-1}^2)$ and commits to a_1^2 . The following players continue in a similar fashion cutting the set of objects. Then the sequence $(a_1^1, a_1^2, \dots, a_1^n)$ is reasonable.

The proof goes by induction on the number of players. The case $n = 1$ is trivial.

$n = 2$: As in the previous proof we have one vertex corresponding to the decision of player 1 from which descent m edges corresponding to all possible actions for player 1. We put a_1^1 on the one vertex of player 1. We put a_1^2 on all vertices of player 2 except the one connected to the edge a_1^2 . We use the modified algorithm for the sequence (a_1^1, a_1^2) and the set of objects $A \setminus \{a_1^2\}$ to find what to place on the last vertex. This strategy will have (a_1^1, a_1^2) as a result. As to show that the assignment can be used to construct a sub-game perfect equilibrium it suffices to notice that even if $a_1^2 \neq a_2^1$ both must be equally valued by player 2 because the algorithm gave those two elements as a possible move of player 2 on two different occasions, while both those actions were available to the player.

$n - 1 \Rightarrow n$: We assume that we can build a strategy tree for any game G with $n - 1$ players and a given set of actions A which is *PSE* and the proper sequence is the result. To show the result for n players we start with a game tree with all vertices empty. For every vertex connected to the root we run the modified algorithm on the game G without player 1, sequence (a_1^2, \dots, a_1^n) and the set of actions $A \setminus \{a_1^1\}$, where a_1^1 is the label of the edge between this vertex and the root. By the inductive assumption the sequence (a_1^2, \dots, a_1^n) is reasonable for the proper sub-game, so the result of the modified algorithm is also reasonable and a sub-game perfect equilibrium can be constructed on this subtree. It remains to argue that after putting a_1^1 in the root the strategy we get a similar result. It is important to notice that the sequence $(a_1^1, a_1^2, \dots, a_1^n)$ is a possible result of using the regular algorithm for the game G with n players and set of objects A . Thus we can use the lemma for all the subtrees. So we can use the exact same argument as in the proof of the previous theorem to show that player 1 cannot benefit from changing committing to another move than a_1^1 .

We can notice that this proof provides more than just the answer to this specific case. First of we didn't explicitly stated if there always exists a pure Nash equilibrium in the case of simultaneous moves by the defenders. We can see that any sub-game perfect equilibrium provided by our algorithm will

remain a Nash equilibrium, if all of the moves are made at the same time and so we see that a pure Nash equilibrium always exists in this case. If we would like to consider a case in which some of the defenders have the resources to defend more than one object we can simulate that by adding copies of that player's valuations to the valuation matrix and dividing one defender with n resources into n players with one resource and identical valuations.

V. SUMMARY

In this paper we have discussed the properties of pure strategies in security games. We recognized which part of the model can be omitted in this situation and which can be redefined to simplify the model. We introduced a situation in which the defenders pick actions in a sequential order, we proved that a pure strategy equilibrium exists in such setting, that we can find a move corresponding to such an equilibrium in polynomial time, and used this construction to prove the existence to a pure Nash equilibrium in the general case of synchronous play of the defenders, as well as when the defenders have more than one resource to use.

As for future directions, the problem discussed in this paper assumed no possibility of communication between the defenders and we think that any query in that direction could be interesting. Also we can see that the result of the game in our case could depend heavily on the order in which the players were able to commit to their strategy. As so, we think that that finding out how much trying to coordinate the players, via an additional player or otherwise, could affect the possible result, or even finding out exactly how many different results can be achieved from a given game in any ordering, could pose also an interesting challenge.

Abstract—Formal reasoning about the correctness of safety-critical system properties is crucial since such systems may impact their environment when malfunctioning. The Rail Safe Transport Application (RaSTA) Protocol is a protocol for systems used in railway applications such as signaling. It claims to provide highly available and timely communication based on the application’s demands. We investigate timeliness, i.e., the property that application data do not become obsolete.

We analyze the protocol’s specification and provide assumptions necessary to resolve imprecisions. Under the specified error model, we find that the deadlines proposed bound until messages are considered timely is too restrictive, disabling RaSTA’s mechanisms to recover from lost messages in time. We formalize the specification of timeliness to provide a counterexample for the proposed bound and create an improved bound that does not lead to violated deadlines under the same assumptions and error model.

I. INTRODUCTION

THE *Rail Safe Transport Application (RaSTA)* [1] is a protocol used in railway signaling technology between diverse communication endpoints. It is independent of the overlaying application. Since it may be usable for *safety-critical* applications, its correctness is essential. The object of this paper is to formally verify the correctness of a part of the RaSTA protocol. We formally investigate RaSTA’s timeliness property using networks of timed automata and the tool Uppaal for formal reasoning [2].

RaSTA’s specification rests upon natural language. The interpretation of such a specification often relies on either explicit or implicit assumptions, allowing to focus on aspects considered necessary while abstracting from others. Those assumptions pose the danger of creating a model that cannot reflect the wanted properties. The following quote from Sir Tony Hoare shows that formal approaches are a necessary and helpful tool to discuss such assumptions:

The job of formal methods is to elucidate the assumptions upon which formal correctness depends.

In this investigation, we discuss necessary assumptions about imprecisions in RaSTA’s specification, prove that the bound for messages’ timeliness given in RaSTA’s specification is insufficient, and provide an improved bound.

The remainder of this paper is structured as follows: Section II provides an overview of the normative requirements applicable to RaSTA and an overview of the protocol itself, including assumptions made in the RaSTA specification. Section III introduces the formal semantics of networks of timed automata

and Uppaal. In Section IV we present our model and the evaluation of RaSTA’s timeliness property. Finally, section V gives a conclusion of our work.

II. RASTA PROTOCOL

The RaSTA [1] protocol is specified in a pre-standard by the DKE/UK 351.3, a national working committee of the Association for Electrical, Electronic and Information Technologies for railway signaling facilities. It is used in railway signaling technology to achieve safe and highly available communication.

A. Requirements

Strict normative requirements exist, as safety is a crucial concern in this field. RaSTA implements the requirements of [3] for safe communication in open communication systems of category 2, including networks consisting of safety-critical and non-safety-critical systems that can read, write, process, and transmit data. Safety-critical systems use safety-critical transmission functions, assuring Authenticity, Integrity, Timeliness, and Sequence of sent messages. Specifically, RaSTA defines timeliness as a state in which information is available in time according to the requirements. The number of users is generally unknown, as well as their application. Thus unknown amounts of data in arbitrary formats are sent in such networks. There might be routing and management facilities and the communication media may be prone to unforeseen external faults. Authorized access with malicious intentions is explicitly negligible in this category. Thus no cryptographic means are enforced.

The system’s functionality must ensure the aforementioned properties of safety-critical transmission functions. The implementation of such a system implies an evaluation of possible safety threats. Appropriate means must be used to mitigate these threats. In [3], a list of specific safety means is provided, consisting of short descriptions and their requirements.

B. Architecture

RaSTA is implemented between a typical communication stack’s application layer and the transport layer, as pictured in Figure 1. There are only a few requirements on the transport layer, making RaSTA suitable for different scenarios: It must be possible to send messages to specific receivers. The network, including the communication partners, must process the messages in a best-effort manner. It is unnecessary to

Fig. 1: Architecture of the RaSTA Protocol Stack

TABLE I: Protocol Data Unit of the SRL

Byte(s)	Content
0 - 1	length
2 - 3	type
4 - 7	receiver ID
8 - 11	sender ID
12 - 15	sequence number
16 - 19	confirmed sequence number
20 - 23	timestamp
24 - 27	confirmed timestamp
28 - 28+k-1	payload (k bytes)
28+k - (28, 35, 42)+k	safety code

enforce deadlines, but safety reasons imply fast transmission and adequate quality. Reference [1] states that *commercial of the shelf* transport services such as UDP or TCP are well suited.

RaSTA introduces two new layers between application and transport: the upper *Safety- and Retransmission-Layer (SRL)* and the lower *Redundancy-Layer (RL)*, also shown in Figure 1. The SRL provides a safe communication mechanism for networks according to [3], while the RL aims to provide a highly available communication service via so-called *Redundancy-Channels*. The RL uses multiple transport layer channels (possibly with different transport services) for redundant communication. In this way, messages that get lost or altered on a single transport channel do not affect the communication on SRL-level. Since most of the means to ensure the necessary properties reside in the SRL, this paper only briefly covers the RL.

Table I shows the design of the *Protocol Data Unit (PDU)* of the SRL. We omit a representation of the RL at this point.

The SRL makes use of *IDs* for sender and receiver to ensure authenticity as well as a *safety code* based on the message digest 4 (MD4) [4] algorithm to ensure integrity. Depending on the individual requirements, the latter can take either all, a few, or none of the result's bytes. The protocol uses the *sequence number (SN)* and the *confirmed sequence number (CS)* to maintain the correct sequence of all communicated messages: With each communicated message, *SN* gets incremented. At the same time, *CS* represents the last received *sequence number* of the communication partner. Both *timestamp (TS)* and *confirmed timestamp (CTS)* fields

are used to ensure timeliness. Here, *TS* represents the time at which the sender created the message, and *CTS* represents the last received timestamp of the communication partner, analog to the confirmed sequence number. The insurance of both Sequence and Timeliness requires additional logic, discussed in the protocol specification.

The RL has a more lightweight PDU. There are two primary choices: it uses CRC for its *check code* with different possible configurations. Also, using an additional *sequence number* ensures noticing any race conditions between messages via the individual transport channels. Please note that additional logic is necessary to ensure a correct transmission on the receiver side.

C. Protocol specification

Since RaSTA is a relatively new protocol stack, there is not much work regarding formalizing and verifying its properties, even though its usage in safety-critical scenarios. However, a shortcoming is using MD4 as safety code as described in section II-B, shown by [5]. Here, possible changes to the protocol stack extend RaSTA's abilities to withstand attacks such as the injection of forged messages or replay attacks. Such malicious attacks are not in the scope of RaSTA's requirements for category 2 networks according to [3], but it raises the question if these assumptions are valid in the use case of railway signaling.

RaSTA defines message types for the SRL, used in different situations. Figure 2 shows the abstract state machine for the SRL. Defined are *Connection Request (ConnReq)*, *Connection Response (ConnResp)*, *Disconnect Request (DiscReq)*, *Heartbeat (HB)*, *Data*, *Retransmission Request (RetrReq)*, *Retransmission Response (RetrResp)*, and *Retransmitted Data (RetrData)* messages, from which *Data*, *RetrData* and *HB* messages are defined as relevant for time monitoring. Using the first two message types, connections are established and set up by performing a handshake between both communication partners. This is visualized in Figure 2 with arrows (a), (b), and (c). A *Disconnect Request* message is sent prior to closing an established connection or to indicate errors during the establishment or regular transmission. The corresponding transitions shows Figure 2 as dashed arrows. The communication partners monitor the connection quality via messages of type *HB*. Such Heartbeats are automatically sent after a defined time interval during which no other messages were sent. Application messages carrying a payload are transmitted as *Data* messages. The remaining message types handle error situations: A lost message leads to a corrupted sequence of messages is corrupted. The receiver can recognize this situation, in which he sends a *RetrReq* message. Figure 2 reflects this situation with transition (d). The original sender of the lost or corrupted message answers with a *RetrResp* message (corresponding to transition (f) in Figure 2), after which he repeats all messages with an unconfirmed sequence number as *RetrData* messages. To finalize, a *Data* or *HB* message is sent to indicate that the retransmission is completed, returning to normal operation by transition (e) in Figure

Fig. 2: Abstract State Machine of the SRL [1]

2. Finally, transition (g) corresponds to the situation where another message gets lost during a running retransmission, where another retransmission is initiated.

Besides the abstract states shown in Figure 2, each instance has to manage an internal state, consisting, among other things, of a set of sequence numbers, timestamps, and timers:

- SN_T : the sequence number of the next transmitted message
- SN_R : the expected sequence number of the next received message
- CS_T : the confirmed sequence number of the next transmitted message
- CS_R : the confirmed sequence number of the last received message
- TS_R : the last received timestamp
- CTS_R : the last received confirmed timestamp
- T_{HB} : a timer representing the remaining time until the instance has to send a new message
- T_{DL} : a timer representing the remaining time in which received messages are considered timely

The maximum values for the timer T_{DL} and T_{HB} are defined as configurable parameters, depending on the applications demands. We use $T_{DL,max}$ and $T_{HB,max}$ to represent them.

To transmit data, the sender has to create a new PDU according to Table I using $SN = SN_T$, $CS = CS_T$, $CTS = TS_R$, and $TS = t$, where t is the sender's current timestamp. After creating and sending the message, SN_T is incremented ($SN_T = SN_T + 1$) and T_{HB} is reset to $T_{HB,max}$. The sender has to store a copy of the message until a message with $CS \geq SN$ is received.

The message receiver has to check the sequence of SN , CS , and CTS . First, plausibility checks evaluate if $SN - SN_R$ is below a configured limit. Also, $CS_R \leq CS < SN_T$ has to hold, stating that the received and confirmed sequence number is plausible, too. If these conditions do not hold, the receiver discards the message. Otherwise, he performs more vigorous checks on SN and CTS . A boolean variable $SNinSeq$ is set to true, if $SN_{PDR} = SN_R$ holds. Also, another boolean variable $CTSinSeq$ is set to true, if for messages relevant for time monitoring $0 \leq CTS - CTS_R < T_{DL,max}$ holds. Note that the receiver does not discard the messages if the

Fig. 3: Adaptive Channel Monitoring

checks result in negative results. The state transitions shown in Figure 2 depend on these variables. Summarizing the resulting behaviors, if $CTSinSeq$ does not hold, the receiver responds by sending a *DiscReq* and closing the connection. If $SNinSeq$ does not hold, the receiver initiates retransmission of all messages with unconfirmed sequence numbers (i.e. $CS_T \leq SN < SN_T$).

D. Timeliness in RaSTA

RaSTA ensures timeliness by applying a concept called *Adaptive Channel Monitoring (ACM)*. The necessary information is included in each SRL-PDU but will be evaluated only for time monitoring relevant messages. According to [1], clocks may not be synchronized and can have different resolutions, consequentially disallowing the interpretation of timestamps of the communication partner.

ACM applies the *Double-Timestamp-Principle*, defined in [3] to check the message round trip times on both communication partners. A sent message carries the sender's local timestamp in TS . Upon receiving this message, the receiver stores this exact value as $TS_R = TS$ in his local state. The following answer of the receiver will carry the confirmed timestamp $CTS = TS_R$ back to the original sender, allowing the round trip time calculation as $RTT = t - CTS$ where t is the current timestamp. A message's timeliness is analyzable by constraining the round trip time since this value overestimates the timestamp of the send-event. Since multiple messages can carry the same CTS value, a round trip completes once a message with a new, greater CTS value arrives. This fact naturally implies that the original sender sent a message with $TS > t$ in the meantime. This message also starts the next round trip, overlapping the current one. This is visualized in Figure 3 for an error-free communication.

After a message with a specific new value of CTS arrives, the receiver updates CTS_R in the local state. All later messages with $CTS = CTS_R$ are considered timely, if

they arrive in an interval of length $T_{DL,max}$ since CTS_R . If another message with $CTS > CTS_R$ arrives, the stored value of CTS_R will be replaced by the new one, indicating that no further messages with the old CTS value should arrive anymore.

To implement these conditions, [1] uses the timer T_{DL} , which is reset with each update to CTS_R to $T_{DL} = T_{DL,max} - RTT$. If this timer reaches its limit, arriving messages may carry outdated information, which would be the case when $CTS = CTS_R$. Figure 3 visualizes this timer as dashed and dotted lines where the dashed portion represents the actual timer running while the dotted portion corresponds to the time since the reference point or until the deadline, respectively.

As $T_{DL,max}$ is a configurable parameter, it is possible to adjust it according to the application's needs. However, [1] states that $T_{DL,max}$ should include enough buffer to take possible retransmissions into account, and gives the following suggestion for its minimal value:

$$T_{DL,max} > 3 \cdot T_{HB,max} + 2 \cdot (T_{AB} + T_{BA}) + T_{RL,seq} \quad (1)$$

Here, according to [1], $T_{HB,max}$ refers to the communication partner's maximum time between two consecutive messages. T_{AB} and T_{BA} indicate the worst-case transmission time of the channel from sender to receiver, where A and B are the communication partners, and $T_{RL,seq}$ indicates the maximum time a message can get delayed in the RL because of race conditions.

As specified in [1], the reasoning behind this formula is as follows: the round trip time of a message can be overestimated by $T_{HB,max} + T_{AB} + T_{BA}$, a lost message will be noticed at worst after $2 \cdot T_{HB,max}$ and the following retransmission can be estimated as $T_{AB} + T_{BA}$, which sums up to the right hand side of Equation 1.

This bound results in an assumed error model where only one message per round trip can be lost. We examine this bound and see it as problematic since it introduces artificial dependencies between the communication partners and their communication channels: As soon as one channel loses one message, the other must deliver correct messages. This assumption is unrealistic since, in reality, the channels themselves cannot share such information.

E. Assumptions regarding RaSTA's specification

Before modeling RaSTA's communication to show timeliness, we need to state some assumptions regarding open or imprecisely defined aspects.

1) *Violation of message sequence*: Since the RL aggregates multiple transport connections between sender and receiver to a single redundancy channel, the correct order of the messages has to be assured since race conditions along the individual channels can occur. The configuration parameter $T_{RL,seq}$ states the delay of messages to be able to restore sequence before delivery to the SRL. We assume that this parameter is set to 0, effectively allowing messages to overtake

each other unhandled. This assumption is reasonable since the SRL notices the incorrect message sequence in the same way a lost message would, triggering the retransmission.

2) *Immediate Responses*: The specification [1] is unclear about internal delays of messages that should be transmitted immediately. This delay is significant in the case of a retransmission of unconfirmed messages. We assume that no additional delay is introduced between two such messages, effectively sending all of them in the correct order simultaneously.

3) *Handshakes*: We focus on analyzing timeliness for the central part of the protocol: The data exchange, in essence, by the behavior of a message's round trip. By that decision, we exclude the handshake to establish the connection and any disconnection semantics. The initial handshake includes a final time-critical heartbeat message. However, this message must be sent immediately after receiving the connection response message. Thus, it will set the initial reference point for the upcoming data exchange. If the receiver discards the message, the handshake fails, and the connection is not established.

Additionally, we reduce the second part of the retransmission handshake, i.e., the *RetrResp*, *RetrData*, *HB* sequence to transmit all missing messages to a single *RetrResp* message. This reduction is feasible since we use the assumptions in Section II-E2, together with the transmission error model. The handshake is only carried out when a communication partner previously discarded a message. Hence, during this handshake, no further messages are discarded. All messages are sent without any delays. Hence, the retransmitting side immediately sends the (final) heartbeat message carrying the $CTS > t$ information. This assumption allows us to abstract from the specific messages to be confirmed.

F. Discussion of RaSTA's timelines property

A derivation of Equation 1 according to [1] is given in section II-D. However, we like to point out that the interpretation of $T_{HB,max}$ as the communication partners parameter is not feasible for all scenarios.

Under the assumption that only one message per round trip can get lost, there are, in essence, two different scenarios that lead to retransmission, shown in Figure 4. Both scenarios share the loss of the information used to finish the round trip, i.e., a timestamp $TS > t$ or a confirmed timestamp $CTS > t$. We describe these scenarios from the view of the final $CTS > t$ message, as the receiver will consider this message's timeliness. Hence, communication partner A is the receiver while B is the sender in the scenarios. In Figure 4a, the receiver's first message containing $TS > t$ is lost during transmission. Subsequently, the sender discards the following message also carrying this information. Since the message sequence is not correct at this point, the sender initiates retransmission. He continues to send heartbeat messages containing the $CTS = t$ information until the finalization of the retransmission. We omitted them for readability reasons. In the worst case, a heartbeat containing $CTS = t$ is sent just before the $TS > t$ information reaches the sender, leading

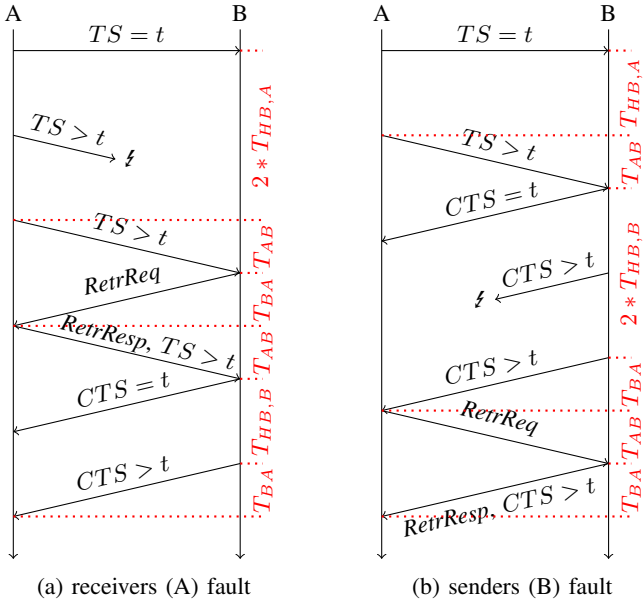

Fig. 4: Retransmission scenarios

to sending the $CTS > t$ information with the next heartbeat. Figure 4a also shows the individual worst case delays.

Accumulated, they lead to the following upper bound shown in Equation 2:

$$T_{DL,A} = 2 \cdot T_{HB,A} + T_{HB,B} + 2 \cdot (T_{AB} + T_{BA}) \quad (2)$$

Analogously, we show the situation where the sender's first message containing $CTS > t$ is lost in Figure 4b. The receiver's message containing $TS > t$ arrives at the sender just after a message containing $CTS = t$ was sent. Hence, the $CTS > t$ is sent as the next heartbeat and gets lost. The receiver discards the next heartbeat since the message sequence is incorrect. At this point, the receiver initiates the retransmission. After this retransmission, the $CTS > t$ information reached the receiver. Equation 3 presents the according upper bound.

$$T_{DL,B} = 2 \cdot T_{HB,B} + T_{HB,A} + 2 \cdot (T_{AB} + T_{BA}) \quad (3)$$

Since both scenarios can occur under our assumptions, we propose to use the maximum of both as the bound for the deadline, referred to by $T'_{DL,max}$, as shown in Equation 4.

$$T'_{DL,max} > \max(T_{DL,A}, T_{DL,B}) \quad (4)$$

Please note that we used $T_{HB,\cdot}$ and $T_{DL,\cdot}$ to indicate $T_{HB,max,\cdot}$ and $T_{DL,max,\cdot}$ for spacing reasons. In the following sections, we show a formal analysis of both limits presented in Equations 1 and 4 using timed automata supported by Uppaal.

III. TIMED AUTOMATA AND UPPAAL

To check the correctness of both limits presented in Equations 1 and 4, we modeled the interesting aspects of RaSTA as timed automata and checked this model with the help of Uppaal.

A. Uppaal

Uppaal [6], [2] is described as "an integrated tool environment for modeling, validation, and verification of real-time systems modeled as networks of timed automata, extended with data types (e.g., bounded integers, arrays)." It is developed jointly by Basic Research in Computer Science at Aalborg University in Denmark and the Department of Information Technology at Uppsala University in Sweden.

Many applications of Uppaal in scientific case studies are shown on Uppaal's website [2], such as the verification of different versions of the well-known Fischer Protocol [7] for mutual exclusion in [8]. Nevertheless, also industrial protocols such as the Philips Audio Protocol for exchange of control information [9], or the Bang and Olufsen Audio/Video Protocol for transmission of messages between audio and video components over a single bus [10] have been model checked by Uppaal. Primarily the latter was known to be faulty. Uppaal's generation of (erroneous) traces allowed us to find the error. Also, Uppaal was used to find and verify a fix for this problem.

B. Modelling

Timed automata exist in multiple flavors, but they generally combine the known concept of finite state machines and clocks, unique variables used to represent time. Uppaal uses a dense time model, where clocks evaluate real numbers and advance synchronously. For evaluation, Uppaal can express clock valuations as symbolic constraints, thus reducing the state space by collapsing all clock valuations that share common properties. Further, Uppaal allows systems to be modeled as networks of timed automata by composition from individual automata. Every automaton may engage in (enabled) transitions, also used to synchronize multiple automata. [11]

In [11], the definition of the Timed Automata used in Uppaal is as follows:

A timed automaton \mathcal{A} is a tuple (L, l_0, C, A, E, I) , where L is a set of locations, l_0 is the initial location, C is the set of clocks, A is a set of actions, co-actions and the internal τ -action, $E \subseteq L \times A \times B(C) \times 2^C \times L$ is a set of edges between locations with an action, a guard and a set of clocks to be reset, and $I : L \rightarrow B(C)$ assigns invariants to locations.

Reference [11] also provides the definition and semantics of a network of timed automata, consisting of n timed automata $\mathcal{A}_i, 1 \leq i \leq n$. The location vector $\vec{l} = (l_1, \dots, l_n)$ corresponds to the locations of each individual automation. Further, the invariants are merged to an invariant function over the location vectors $I(\vec{l}) = \wedge_i I_i(l_i)$. Finally, the notation $\vec{l}[l'_i/l_i]$ denotes the location vector where the i th element l_i is replaced by l'_i .

The semantics are then given by [11] as follows: Let $\mathcal{A}_i = (L_i, l_i^0, C, A, E_i, I_i)$ be a network of timed automata and $\vec{l}_0 = (l_1^0, \dots, l_n^0)$ the vector of initial locations. The semantics is defined as a labelled transition system $\langle S, s_0, \rightarrow \rangle$ with $S \subseteq (L_1 \times \dots \times L_n) \times \mathcal{R}^C$ as the set of states, $s_0 = (\vec{l}_0, u_0)$ is the initial state and $\rightarrow \subseteq S \times S$ is the transition relation such that:

- $(\bar{l}, u) \xrightarrow{d} (\bar{l}, u+d)$ if $\forall d' : 0 \leq d' \leq d \implies u+d' \in I(\bar{l})$, and
- $(\bar{l}, u) \xrightarrow{a} (\bar{l}[l'_i/l_i], u')$ if $\exists l_i \xrightarrow{\tau g r} l'_i : u \in g, u' = [r \mapsto 0]u$ and $u' \in I(\bar{l}[l'_i/l_i])$.
- Further, $(\bar{l}, u) \xrightarrow{a} (\bar{l}[l'_j/l_j, l'_i/l_i], u')$ if $\exists l_i \xrightarrow{c?g_i r_i} l'_i \wedge l_j \xrightarrow{c!g_j r_j} l'_j : u \in (g_i \wedge g_j), u' = [r_i \cup r_j \mapsto 0]u \wedge u' \in I(\bar{l}[l'_j/l_j, l'_i/l_i])$

Hence, possible transitions are categorized in *delay* and *action* transitions. The former are described by $(\bar{l}, u) \xrightarrow{d} (\bar{l}, u+d)$, letting the system evolve in time for d time units by mapping each clock $c \in C$ to the value $u(c) + d$, if the invariants of all locations aren't violated for any time point until the delay has occurred. The latter corresponds to a single edge or a pair of edges in the automaton. Here, either a single automaton or a pair of automata in the network change their locations according to action a in $(\bar{l}, u) \xrightarrow{a} (\bar{l}[l'_i/l_i], u')$ and $(\bar{l}, u) \xrightarrow{a} (\bar{l}[l'_j/l_j, l'_i/l_i], u')$ respectively. Either are only possible if their guards are satisfied. Taking the transition resets all referenced clocks, and the resulting locations' invariants must be satisfied. When two automata perform such a pairwise transition, it is also necessary to label the transitions by corresponding co-actions, expressing active and passive synchronization at these points.

Uppaal extends such networks of timed automata with many features shown in the following list, as well as other constructs borrowed from C-like programming languages such as arrays, initializers, record- and custom-types as functions. [11]

- *Templates* for instantiating automata
- Invariants over *internal state variables*
- *Non-deterministic choice* of binary synchronization channels when multiple co-actions are possible
- *Urgent and committed locations* which disallow the passage of time

Within such templates, Uppaal uses additional labels for locations and edges, which allow to define the behavior of the automaton in an easy way, for example, to express a location's invariants. Actions can have *select* labels, which can be used to non-deterministically bind values from a given range to variables which can then be used in the remaining labels of the action. Also, *guards* enable actions upon fulfillment or disable them in case of violation. *Synchronization* labels allow the use of synchronization channels, where edges with complementary synchronization labels $c!$ and $c?$ over a shared channel c synchronize on taking the $c!$ labeled action, reassembling co-actions. Finally, *update* labels can alter the current internal state by changing variables' values or assigning values to clocks. [11], [12]

Figure 5 shows an example of a timely bounded synchronous communication channel. We use this channel to model the communication between two RaSTA communication partners. Messages are accepted from the sender via the `send?` co-action, transiting from the `Idle` to the `Transmitting` location. The variable `content` refers to the channel's content, taken from whatever resides in `data_send`, the senders send buffer. To reduce the state space, the send buffer is

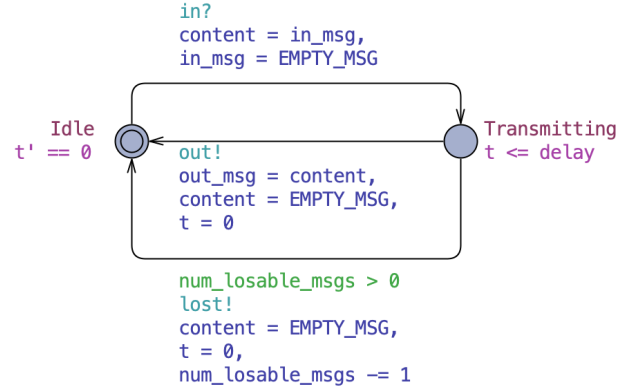

Fig. 5: Model of the RaSTA Communication Channel

reset to empty as soon as the channel has accepted the message. As long as $t \leq \text{delay}$, the channel may reside in the `Transmitting` location, transitions back to `Idle` are possible immediately. There are two possible transitions corresponding to the correct and faulty transmission. In the latter case, the channel's content is not altered and copied into the receive buffer. Instead, the `lost!` co-action indicates an altered message to discard. The clock t is reset when transiting back to `Idle`, where it is stopped via the location's invariant. These measures are also made to reduce the state space.

To define a model, Uppaal uses a *system definition*, which allows instantiating templates to *processes*. Here, it is possible to bind the template's parameters to actual values or define partial instantiations to reuse similar processes. They are composed concurrently to a system by enumerating them after the `system` keyword.

C. Verification

Uppaal allows checking different properties for a system via model checking. Queries to the model express these properties using a simplified version of *Timed Computation Tree Logic (TCTL)* [13]. Queries consist of the path- and state formulae, where state formulae describe individual states and path formulae quantify over the model's traces. Uppaal does not allow the nesting of path formulae [11]. Such formulae are categorized depending on their semantic and matched runs. We explain the used state formulae and safety formulae in the following sections. Additionally, the standard version of Uppaal supports reachability formulae and liveness formulae. Note that many extensions extend classical Uppaal, for example, by examining statistical properties.

1) *State Formulae*: State formulae express the properties of individual states without considering the model's behavior. They are similar to guards in that they are described by side-effect-free expressions, for instance, $x == 42$. Besides statements over internal variables, it is also possible to test if a automaton A is in a certain location l by the expression $A.l$. Internal state variables of a single Automaton are accessible in the same way. Further, deadlocked states (where no outgoing action transitions from the state or delayed successors are possible) can be expressed via the keyword `deadlock`. [11]

2) *Safety Formulae*: Safety Formulae describe that *something bad will never happen*. A general technique is to express something bad in the model's terms, for instance, the violation of a deadline, and then invariantly assure that the model never fulfills this condition. Analogously, the model must fulfill *something good* invariantly. Uppaal uses TCTL formulae $A\Box\phi$, which are expressed in Uppaal as $A[\]\ \phi$ for a state formula ϕ , expressing that ϕ must be true for all reachable states. [11]

IV. VERIFYING TIMELINESS

While it is possible to build a system in Uppaal reassembling the whole SRL and find a suitable formula to describe timeliness in this model, we decided to abstract from this approach for multiple reasons. First, we are only interested in the property of timelines. Therefore, it is feasible to abstract from unnecessary parts of the protocol. Our model abstracts the exact Protocol Data Unit shown in Table I while keeping each message's sequence and time information. Note that it is possible to omit *CS* since the receiver will discard messages if the plausibility checks fail as described in section II-C. Also, by maintaining an appropriate communication channel model, one can abstract from the RL, leaving only a concentrated portion of the protocol for verification. It is possible to reduce this model further since we are only interested in the timeliness of a single message, expressed as a round trip as shown in Figure 3. This reduction is possible since RaSTA claims to ensure timeliness for all time-critical messages, so it is sufficient to find a single situation where RaSTA fails to do so to show the violation of this property. This reduction aims to find a Uppaal model with only a few locations and internal state variables.

Most model checking tools try to explore the whole state space of the model by finding all possible execution paths and states on them. This approach becomes infeasible quickly since the number of possible states grows exponentially with the number of used internal state variables. Ultimately, this *state space explosion* leads to an infeasible time demand for evaluating the properties. There exist ways to approach this problem, such as symmetry reductions, but especially for software verification, this problem is still not solved [14]. This issue emphasizes the importance of a compact and abstract model.

A. Modelling assumptions

We discussed some possible abstractions and why they are feasible at the beginning of this section. Such abstractions' bases are usually on assumptions that restrict the system's modeled behavior in a certain way. While such abstractions allow the formulation of a simpler model, it is essential to ensure that the result is still a valid model of reality, including all necessary aspects of the system to reason about the properties of interest. Otherwise, the model might still be correct but becomes irrelevant since it does not lead to any desired statements.

We have shown assumptions necessary to formalize the specification of RaSTA in Section II-E. The following sections discuss the consequences of formalization and make assumptions regarding which aspects the model of the protocol stack needs and which can be abstracted.

1) *Redundancy Channels*: As described in section II-E1, we assume that the redundancy channels used in the RL lead to possible violations of message sequence. Since we are not interested in showing availability improvements, we decided to abstract from the RL and model only the SRL. The underlying communication channels are seen as per message, meaning that a new virtual communication channel is available for each message. Since Uppaal supports the dynamic instantiation of templates only for statistical queries, we have to limit ourselves to a constant number of available channels, thus limiting the number of messages sent simultaneously. Since, in real-world scenarios, communication always is limited by a specific throughput, we find this assumption feasible. We restrict our analysis to the case where $T_{AB} < T_{HB,max,A}$ and analogously for the values of B. This restriction allows the assumption of FIFO channels so messages cannot overtake each other. Alternating messages during transmission, leading to discarding the message by its receiver, is still possible. Such errors have the same impact on possible retransmissions initiated by the SRL.

2) *Message semantics*: Heartbeat and Data messages share the same information except for an empty application payload. The sender sends Heartbeat messages only when the application is ready to send (*Data*) messages in a defined time interval since the last message. Since RaSTA is independent of the overlying application, we can use this fact to abstract from both message types and reduce them to a single kind of message.

3) *Timestamp relationship*: Since we aim to show timeliness for a single message round trip, we can abstract from the specific values of the timestamps and use a relative representation during this round trip. Additionally, such a relative representation can abstract from the actual values since only the relationship between their corresponding send- and receive-events is necessary to capture the behavior, as shown in Figure 3. Hence, we directly represent the relationship between the ongoing time and the messages *TS* and *CTS* values using state variables.

4) *Message Sequence*: Another critical assumption is that the specific values of the sequence numbers and confirmed sequence numbers do not matter to show the timeliness of a single message. The sequence numbers are used to trigger retransmission if *SNinSeq* is false, as described in Section II-C. The receiver sets this flag if two consecutive messages do not have consecutive sequence numbers. To be able to abstract from the specific values, we inform the receiver of a message about the alternation of the message. In reality, the receiver would check the message's integrity via the safety code and discard it if the check fails. Hence, we update *SNinSeq* before the reception of the following message. The receiver can then react appropriately based on this information by

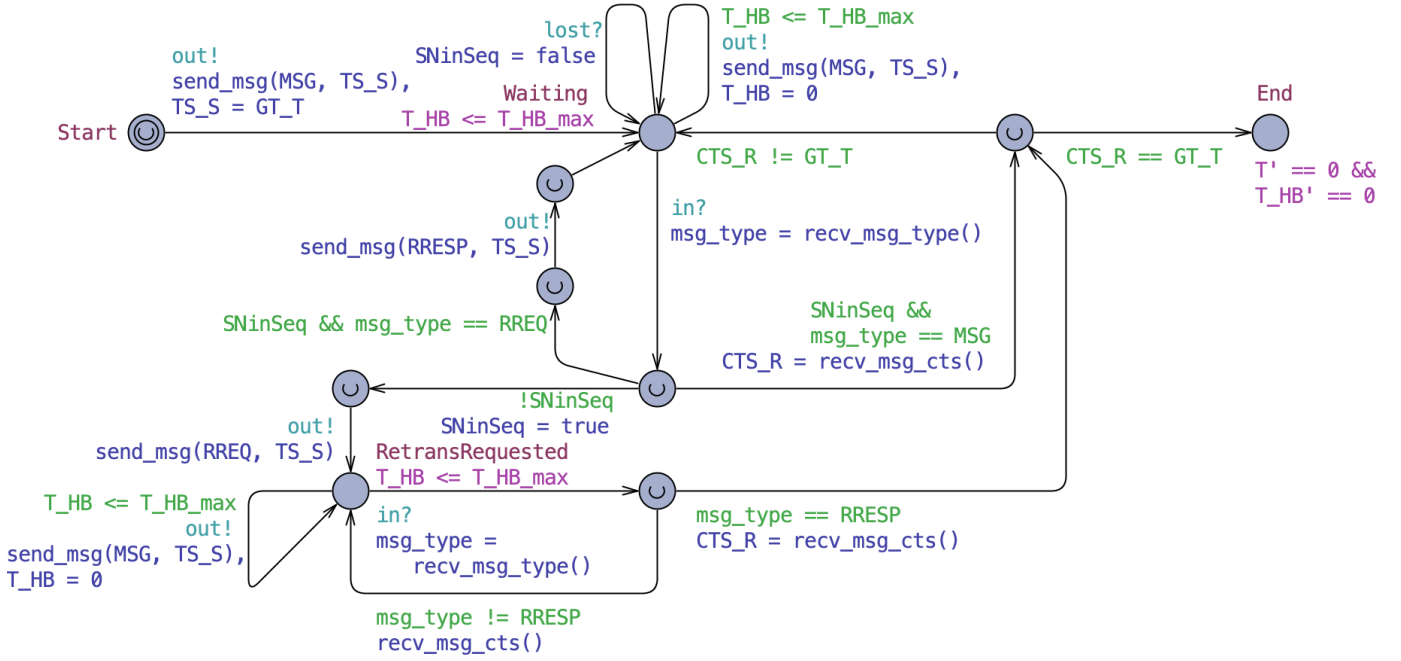

Fig. 6: Model of the RaSTA Receiver

engaging in a retransmission handshake.

5) *Immediate Responses:* We assume that the sender will not delay messages from being sent immediately. There are two significant points in the protocol where this is important: The initial *ConnReq*, *ConnResp*, *HB* handshake to establish the connection and the handshake to perform retransmission, including the transmission of the *RetrData* messages carrying the previously lost messages. As stated in II-E2, [1] covers this not explicitly: The visualizations show a delay of one time unit per message while the descriptions state that the sender has to send messages immediately.

6) *Number of retransmitted messages:* When a message is lost, the sender of this message must retransmit all unconfirmed messages, as described in Section II-C. Such messages may be sent before the modeled round trip. Hence, it is impossible in our model to find a representation of the messages to be retransmitted. However, the only information about these messages we care about is if one of them will complete the current round trip. Especially the final *HB* message will contain the $CTS > t$ information. Therefore, we reduced the set of retransmitted messages to a single one carrying the relevant information. This reduction is feasible since we already assumed that there is no additional delay between immediately sent messages in Section IV-A5.

B. Model and Verification

In this section, we show our model and the analysis of the SRL of RaSTA in Uppaal based on the assumptions shown in the previous sections. Since we want to model a single round trip, our model uses asymmetrical behavior, even if the RaSTA protocol is symmetrical after connection establishment. Hence, individual templates in Uppaal model sender and receiver.

The channel is also an individual template model, which is instantiable multiple times to enable communication between sender and receiver.

Since we abstract from the specific values of the timestamps, it is necessary to model the relation between the reference point t^* when the receiver sends an initial message and the values of TS_R and CTS_R . We defined constant values EQ_T and GT_T to express if a received (confirmed) timestamp is equal to or greater than t^* . Transmitted messages carry this information instead of concrete time information.

Both sender and receiver use a clock T_{HB} . This clock represents the time since sending the last heartbeat message. With appropriate location invariants and action guards, we enforce that both communication partners never send two consecutive messages more than T_{HB_max} time units apart, where the concrete value depends on the chosen parameter for sender and receiver. Additionally, we use a clock T for the receiver model to indicate the current time during the round trip, by which the receiver determines the duration until the arrival in the *End* location, where this clock is stopped.

Further, sender and receiver use urgent states whenever a message is received and during retransmissions. This reflects that the time for the evaluation of the messages header and the decision of the upcoming actions is negligible and serves as an implementation of assumption in section II-E2.

The upcoming sections describe the individual templates.

1) *Receiver:* The Receiver's model is shown in Figure 6. As the evaluation of a message's round trip time depends on a defined reference timestamp, the receiver starts sending a message carrying its current timestamp t^* in TS , which is implemented in the `send_msg(MSG, TS_S)` update. At this point TS_S has the value EQ_T and is updated to GT_T

Fig. 7: Model of the RaSTA Sender

after the message is sent. The receiver will use this information for sending all further messages. He will reside in the location *Waiting* until either a new message has to be sent or a message is received or indicated as lost. By the assumption in section IV-A2, we abstract from distinct *HB* and *Data* messages at this point. We do not abstract from *RetrReq* messages. Such messages are identified via the *msg_type* variable and handled appropriately. The clock T_{HB} together with the location's invariant and the transition guards constrain the time between sending such messages. When a message is indicated as lost, the receiver sets $SNinSeq = false$. In reality, this would happen later when the following message is received, but since this is causally dependent on a lost message in our model, we decided to set this flag at this point. When a message is received, the receiver checks $SNinSeq$ and either updates its CTS_R value based on the information in the message or triggers retransmission. If the message is a *RetrReq*, indicated by $msg_type == RREQ$, the according *RetrResp* message is sent immediately, carrying GT_T as its timestamp. By assumption in Section II-E3, this is the only message necessary to complete this retransmission in our model. Otherwise, and when no retransmission is necessary, the receiver either returns to the *Waiting* location when the received CTS value is less or equal to t^* , i.e., $CTS_R != GT_T$. In the same case, he moves to the *End* location, indicating that a new reference timestamp was confirmed by the sender via $CTS_R == GT_T$, thus ending the round trip. If retransmission is necessary, the receiver will initiate the corresponding handshake by sending the *RREQ* message

and transitioning to the *RetransRequested* location. Here the receiver continues to send messages as in the *Waiting* location and waits until the retransmitted messages arrive. All other messages with $msg_type != RRESP$ are ignored, their information will be part of the *RetrResp* message. Upon receiving his message, the receiver evaluates the contained CTS_R as for regular messages.

2) *Sender*: In our model, the sender takes the role of sending the messages whose timeliness is subject to verification. The sender starts by receiving the reference point t^* as its first message, represented by the value of TS_R , which is EQ_T at this point. At this point, the sender transitions into the *Responding* location. From here on, the model is similar to the receiver, differing only in interpreting the message's timing information. Where the receiver uses this information in the CTS_R variable, the sender uses it to update the state of the TS_R variable. Also, the *End* location is absent since the sender is not informed about finishing the round trip.

3) *Channel*: As described in Section IV-A1, we model the *RL* and underlying channels as per message. Uppaal supports the dynamic instantiation of templates only for statistical queries. Hence we are forced to limit our model by over-approximating the number of sent messages. At this point, a single channel will act synchronously, only accepting messages for transmission when it is in *Idle* and only allowing the delivery returning from the *Transmitting* location, as shown previously in Figure 5. As long as the channel is in location *Idle*, its clock t is stopped at 0 by the location's invariant. When a message is accepted via the *in?* co-action, the channel transitions to the *Transmitting* location, and

after at most the worst-case transmission delay delay the message is either delivered or lost. Both cases are modeled as a transition back to the `Idle` state, resetting both the internal state of the channel and its local clock t . Only for successful transmission, the channel copies the message to the receiver's buffer `out_msg`, the receiver is synchronized here via the `out!` co-action. The co-action `lost!` is used for a faulty transmission, where the channel ignores the message's contents. In the case of an erroneous transmission, the channel also decrements the variable `num_losable_msgs` to 0 to indicate that no further messages should be lost.

4) *Verification and Results:* Since, in our model, the absence of missed deadlines describes timeliness, the formulation of the property is possible as a safety formula, stating that there is no case of deadline violation. We checked both the original value shown in Equation 1 as well our adapted deadline shown in Equation 4 via the following formulae for verification in Uppaal, where both the values for $T_{DL,max}$ and $T'_{DL,max}$ are calculated as the bounds based on the parameters for the heartbeat and worst-case transmission times in Uppaal.

$$A\Box(\text{Receiver.End} \implies \text{Receiver.T} \leq T_{DL,max}) \quad (5)$$

$$A\Box(\text{Receiver.End} \implies \text{Receiver.T} \leq T'_{DL,max}) \quad (6)$$

Since Uppaal doesn't allow symbolic constants for model parameters, we used the values $T_{HB,max,A} = 5$, $T_{HB,max,B} = 3$, and $T_{AB} = T_{BA} = 1$, resulting in the bounds $T_{DL,max} = 13$ and $T'_{DL,max} = 17$. With these values, we could show that the proposed bound $T_{DL,max}$ by [1] is violated while our bound is still satisfied.

Even though we aim to instantiate channels for each message individually, the increased state space limits the feasibility of the evaluation. We decided to restrict the channel model to FIFO channels by instantiating only one pair of channels between sender and receiver. As shown in section IV-A1, this limits the validity of our results to the case where $T_{AB} < T_{HB,max,A}$, as in this case, heartbeats are not affected by unavailable channels.

We were able to show for a few selected values that this property holds, but a general statement for all possible assignments is not possible in this way. However, our model can be used to verify the timeliness of a concrete RaSTA communication instance within our assumptions.

V. CONCLUSION AND FUTURE WORK

Safety-critical systems, such as railroad communication networks, demand a clear and comprehensible analysis of all aspects that potentially affect the correctness and safety of the user and the environment. Our analysis shows where the specification of RaSTA is unclear regarding timeliness. We were able to show that the recommended deadline for the RaSTA communication protocol is not guaranteed to hold for the corresponding error scenario. This inherent violation

demonstrates that using formal methods for software verification is a viable approach not only to show formal correctness where necessary but also to elucidate underlying assumptions.

While we were able to show that the proposed bound is not sufficient, we could not provide a complete formal verification of the correctness of our bound. This open end is caused primarily by inherent problems of model checking, e.g., the state space explosion when stepping back from specific abstractions, such as using concrete timestamps instead of our approach. We aim to encounter the use of more general communication channels by lifting our FIFO assumption. Also, we will deal with more complex scenarios, for example, where the worst-case transmission delay is higher than the deadline for sending heartbeats.

Channel-Less Process Communication

Tomas Plachetka

Abstract—A channel is an abstract data structure which allows for passing messages from one process to another one. We propose several variants of OCCAM, a minimalistic programming language in which a program consists only of processes and channels. The variants differ in how channels are accessed by processes. We prove that all these variants are equally expressive, i.e. an arbitrary OCCAM program can be simulated in any of the variants and the other way around. A particularly interesting variant is to assign exactly one channel to each parallel process. This makes the concept of channels redundant, provided that the parallel processes are named. The simulation techniques can be applied to a variety of abstract models and practical systems.

I. INTRODUCTION

CHANNELS are widely used in abstract models of communicating parallel processes [1], [2], [3], [4], as well as in computer programming languages [5], [6], [7] [8], [9], [10], and hardware descriptions [11], [12], [13]. In operating systems, Unix pipes [14] directly correspond to channels.

The main contribution of this paper is showing a transformation of a channel-based programming language to an equally expressive programming language in which channels and processes become a single entity. We illustrate this transformation on OCCAM [5], [15], which is based on the synchronous abstract model CSP (Concurrent Sequential Processes) [1] and belongs to practical programming languages whose semantics has been formally defined [16], [17], [18], [19], [20]. Although OCCAM is “pure and small”, a sharper Ockham’s razor trims it even more. Along with channels, we also eliminate nesting of parallel processes and the ALT constructor from OCCAM.

The motivation of this work is not solely theoretical. Many programming languages build on a message passing paradigm without channels, e.g. MPI [21], Erlang [22] and Akka (JVM) [23]. An important question is whether the absence of channels is restraining. This paper suggests a negative answer. A consequence is that channel-based (OCCAM-like) programming languages are intrinsically redundant.

The paper is organised as follows. Section II presents a relevant subset of the OCCAM language (leaving out unnecessary details, occasionally using an abbreviated syntax). In Section III, it is shown that nesting of parallel processes can be replaced by a flat process structure (a variant OCCAM-1PAR). In Section IV, the directional graph interconnection of processes and channels is replaced with a hypergraph

interconnection which uses shared channels (OCCAM-SH). In Section V, a concrete hypergraph structure is proposed which leads to a unification of process and channel identifiers, i.e. to a channel-less model (OCCAM-CL). All the variants OCCAM, OCCAM-1PAR, OCCAM-SH, and OCCAM-CL are equally expressive. Section VI concludes the paper.

II. OCCAM

OCCAM was targeted to Transputers [24], single-chip computers specifically designed to support parallel programming. Transputers could be easily connected to form a network, process scheduling and communication were implemented in the hardware. Although Transputers were discontinued in 1990’s, they could in some parameters compete with contemporary computers (e.g. context switch below 1 μ sec still belongs to the fastest ever). OCCAM found its followers, e.g. OCCAM- π [7] and Rain [8].

An OCCAM program consists of a finite number of processes and a finite number of channels; these numbers are known before the program starts and do not change in runtime. A process in OCCAM is either an atomic process ($:=$, assignment; $?$, input from a channel; $!$, output to a channel; SKIP, which does nothing and terminates), or a compound process. Constructors of compound processes (SEQ, PAR, IF, WHILE, ALT) combine processes into a single one. Processes in the SEQ constructor are executed sequentially in the given order, i.e. when a process terminates, the following one becomes active. SEQ terminates when its last mentioned process terminates. The constructors IF, WHILE and the assignment process behave in a common way, except for IF, in which the conditions are always tested in the order they are written, and (only) the process under the first satisfied condition becomes active (IF terminates when this process terminates).

The replicator FOR can be used with constructors. Replication works as a macro expansion. For example, SEQ $i=0$ FOR 2 p expands to SEQ p p , with $i = 0$ in the first replica of the process p , and $i = 1$ in the second one. This corresponds to a sequential repetition of the process p in a for-loop.

The scope of a variable is limited to the process following the variable’s declaration (e.g. INT v :), including processes nested in that process (variables used in replicators are not declared). Usual primitive types are available. The only compound type is an array, indexed from 0.

Processes of the PAR constructor run in parallel and have read-only access to variables which are shared in their scopes. A process is allowed to change (using $:=$ or $?$) only the

This research has been supported by the grant 1/0601/20 of the Slovak Scientific Grant Agency VEGA.

variables which it does not share with another parallel process. The only way how parallel processes may influence one another is via channels which are declared as variables of type `CHAN`. `PAR` terminates when all its processes terminate.

Channels in OCCAM are unidirectional and unbuffered. Each channel connects exactly two parallel processes—one reads from the channel, the other one writes to the channel. Parallel processes can be depicted as vertices and channels as edges of a directed graph (an edge points from the writer to the reader). Reading from a channel (`?`) blocks until a `!` process writes to the channel; and conversely, writing to a channel (`!`) blocks until a `?` process reads from the channel). The corresponding `?` and `!` both terminate after the message has been transferred across the channel from the `!` process to the `?` process. A message is a finite sequence of values (of primitive types or arrays).¹

The `ALT` constructor multiplexes reading from several input channels.² While reading from each single input channel would block, the `ALT` constructor blocks. When reading at least one input channel would terminate (we say that such a channel is readable), a message is read from one readable channel and a process in the corresponding branch takes over. When this process terminates, then `ALT` terminates.

The choice of the readable channel inside the `ALT` constructs and the scheduling of the parallel processes is not under program's control. The scheduler executing the program is unpredictable (nondeterministic) in making these choices. This does not mean that it has to be "random". For example, it is allowed to (but does not have to) prioritise the readable channels in the order they are mentioned in `ALT` constructs. Similarly, it is allowed to (but does not have to) prioritise the execution of active parallel processes in the order they are mentioned in `PAR` constructs. A correct program must guarantee its intended behaviour for all possible schedules.

Processes and channels are static, i.e. they are constructed before the execution of a program. During the execution, each process is in one of the following states: active, passive, blocked. The program evolves according to the rules described above (see [18] for details). At the beginning of the execution of a program, the first process is active, all other processes are passive. A termination of an active process does not mean that the process ceases to exist—it just changes its state to passive. The program execution terminates when there are no active processes. (We can distinguish between a "correct termination" where all processes are inactive, and a deadlock where at least one process is blocked.)

¹Although OCCAM requires a declaration of types of messages which are passed over channels (so-called protocols, e.g. `CHAN OF INT; BOOL ch;`, we consistently use type-less channel declarations throughout the paper. These correspond to `CHAN OF ANY` declarations in OCCAM, where the programmer is responsible for ensuring that the sequences of values in messages transferred over a channel from a `!` process are of the same types as the corresponding variables in a `?` process (so that an incoming message can be stored to the variables in the `?` process).

²For the sake of simplicity, we do not consider `ALT` with boolean expressions attached to the channel inputs (so-called guarded `ALT`).

Fig. 1 shows two OCCAM programs used as running examples throughout the paper. The programs simulate each other. For an arbitrary schedule, both programs terminate and the variable m attains values 0, 1, 2, 3 in one of the following orderings: [0, 1, 2, 3], [0, 1, 3, 2], [1, 0, 2, 3], [1, 0, 3, 2]. The actually observed ordering depends on a concrete schedule. For an arbitrary schedule of P_1 , a schedule of P_2 exists such that the orderings match, and vice versa. Moreover, there is a bijective correspondence of processes which run in parallel in P_1 and P_2 , regardless of their nesting in `PAR` constructs (we refer to line numbers in P_1 and P_2): [5, 5], [11, 12], [12, 13]. In this sense, P_1 and P_2 are equivalent.

Fig. 1. Two OCCAM programs (running examples)

In the sequel, we only deal with one-sided simulations in which P' is constructed from P by replacing its fragments of code. In all proofs, we give a construction of P' which preserves parallelism of P (as the simulations are one-sided, we only insist on an injective mapping of parallel processes of P to P' ; e.g. additional parallel processes can be added to P' in a simulation. A programming language L is *at least as expressive* as a programming language L' , if there is an algorithm (compiler) which translates an arbitrary program P' in L' to a program P in L which simulates P' . Two programming languages L and L' are *equally expressive*, if L is at least as expressive as L' , and vice versa.

III. OCCAM WITH A SINGLE TOP-LEVEL `PAR` CONSTRUCTOR (OCCAM-1PAR)

Theorem 1: OCCAM with a single top-level `PAR` constructor (OCCAM-1PAR) is as expressive as OCCAM.

Proof: We need to show that an arbitrary OCCAM program can be simulated by an OCCAM program which uses exactly one `PAR` which is the top-level process. Consider an arbitrary OCCAM program. All channel declarations are moved to the top-level `PAR` (collisions of channel names are resolved by using fresh names). We will refer to processes of `PAR`s in the OCCAM program as child processes. Each child process is moved to the top-level `PAR`, together with declarations of all variables in its scope (including shared variables used in replicators). A new local integer variable `terminate` is declared in the child process; and two new channels are declared in the top-level `PAR`, we will call

them $ch.s$ (start) and $ch.e$ (end). A child process is started when it receives a message beginning with `FALSE` from the channel $ch.s$. This message also contains values of all the variables shared for reading between the parent and the child. When the child finishes its original program, it sends an acknowledgement to the channel $ch.e$. The parent (the sequence which replaces the `PAR`) starts its children and waits for their acknowledgements. Just before its own termination, the parent terminates its children. ■

Fig. 2 shows the translation of the program P_1 (Fig. 1) to an OCCAM-1PAR program P_3 with a single top-level `PAR`.

IV. OCCAM WITH SHARED CHANNELS (OCCAM-SH)

Recall that a channel in OCCAM connects two parallel processes. OCCAM-SH is an interesting variant in which channels are shared, i.e. a channel can be simultaneously accessed by arbitrarily many parallel processes for both reading and writing. When several `!` processes simultaneously write to a channel, then they are blocked until a `?` process reads from the channel. When several `?` processes simultaneously read from the same channel, they are blocked until a `!` process writes to the channel. When one or more `?` processes read from a channel and one or more `!` processes write to the channel, then eventually one of the `?` processes and one of the `!` processes are chosen for communication. This choice is made arbitrarily (i.e. the scheduler can freely decide which processes it chooses for communication). Then the message is passed from the chosen `!` process to the chosen `?` process and then these two processes terminate. Unlike in OCCAM, there is no `ALT` constructor in OCCAM-SH. Furthermore, OCCAM-SH programs use only one top-level `PAR` constructor.

It turns out that in spite of the absent `ALT` constructor, OCCAM-SH is a generalisation of OCCAM. We will show how an arbitrary OCCAM-1PAR program can be translated to an OCCAM-SH program which simulates the former one. This translation requires that the parallel processes and channels have identifiers. The order in which a parallel process appears in the single `PAR` constructor) will serve as its identifier. Analogously, channels are numbered in the order they are declared (to keep the notation simple, a channel identifier will serve as the channel's number). Let the numbering start with 0, let N denote the number of processes.

Theorem 2: OCCAM-SH is at least as expressive as OCCAM.

Proof: We have already proved that an arbitrary OCCAM program can be simulated by an OCCAM-1PAR program. It remains to show how the `ALT` constructors of OCCAM-1PAR are simulated in OCCAM-SH. Consider an OCCAM-1PAR program. For each parallel process p , merge all the channels from which the process reads to a single channel $ch.in_p$. This shared channel will be the only one which the process p will read, and p will be its only reader (there may be more than one writer, though). Declare arrays `INT pending.ch[N]` and `MSG pending.msg[N]` in the scope of each parallel process, where `MSG` is the type of messages transferred in the OCCAM-1PAR program. Initialise

```

Fig. 2. OCCAM \rightarrow OCCAM-1PAR ($P_1 \rightarrow P_3$)

the array `pending.ch[N]` with values `-1`, i.e. insert the following sequence after the initial `SEQ` in each process:

```

SEQ i = 1 FOR NP
  pending.ch[i] := -1

```

Replace each `ch ! m` of the parallel process w with

```

BOOL ack:
SEQ
  ch.in_r ! w; ch; m
  ch.in_w ? ack

```

where r is the identifier of the process which reads the channel ch in the original OCCAM program.

Replace each

ALT

$ch_0 ? m$
 b_0

...

$ch_k ? m$
 b_k

of the parallel process r with the sequence

INT w, ch :

BOOL consumable:

SEQ

consumable := FALSE

WHILE NOT consumable

SEQ

$w := 0$ -- look for a consumable message

WHILE ($w < NP$) AND ($pending.ch[w] \neq ch_0$) ...

AND ($pending.ch[w] \neq ch_k$)

$w := w + 1$

IF

$w < NP$

SEQ -- found a consumable message

$m := pending.msg[w]$

$ch := pending.ch[w]$

consumable := TRUE

TRUE -- otherwise save another message

SEQ

$ch.in_r ? w; ch; m$

$pending.ch[w] := ch$

$pending.msg[w] := m$

IF -- execute the corresponding branch of **ALT**

$ch = ch_0$

SEQ

$ch.in_w ! TRUE$

$pending.ch[w] := -1$

b_0

...

$ch = ch_k$

SEQ

$ch.in_w ! TRUE$

$pending.ch[w] := -1$

b_k

Treat each $ch ? m$ as

ALT

$ch ? m$
SKIP

and use the translation above.

Hence, each $!$ subsequently blocks until it is acknowledged by the **ALT**ing process. The **ALT**ing process reads all incoming messages, but acknowledges only those which have been consumed by the **ALT** of the **OCCAM-IPAR** program. ■

Theorem 3: **OCCAM** is at least as expressive as **OCCAM-SH**.

Proof: We present a construction which replaces shared channels with directed channels which connect exactly two processes. Let N denote the number of parallel processes in the **OCCAM-SH** program. For each shared channel ch , an additional parallel process $sh.ch$ is created which relays the communication on the shared channel using **OCCAM** channels. These $sh.ch$ processes terminate when all the other parallel processes terminate. A process $sh.ch$ is connected via three channels with each parallel process p ($p = 0, \dots, N-1$) of the **OCCAM-SH** program: $ch.r_{sh.ch}[p]$, $ch.w_{sh.ch}[p]$ and

$ch.d_{sh.ch}[p]$. All these channels are declared as global. The first two channels are oriented towards $sh.ch$, the third one towards the parallel process p .

The program of a process $sh.ch$ is:

BOOL terminate:

INT out, t.count:

MSG m:

SEQ

t.count := 0

WHILE t.count < N

SEQ

ALT -- pick a reader

$ch.r_{sh.ch}[0] ? terminate$

out := 0

...

$ch.r_{sh.ch}[N-1] ? terminate$

out := N - 1

IF

terminate

t.count := t.count + 1

TRUE -- otherwise

ALT -- pick a writer, deliver m to the reader

$ch.w_{sh.ch}[0] ? m$

$ch.d_{sh.ch}[out] ! m$

...

$ch.w_{sh.ch}[N-1] ? m$

$ch.d_{sh.ch}[out] ! m$

Replace each $ch ? m$ of the parallel process r in the **OCCAM-SH** program with the sequence

SEQ

$ch.r_{sh.ch}[r] ! FALSE$

$ch.d_{sh.ch}[r] ? m$

Replace each $ch ! m$ of the parallel process w with $ch.w_{sh.ch}[w] ! m$.

Insert $ch.r_{sh.ch}[p] ! TRUE$ at the end of each parallel process p of the **OCCAM** program. ■

V. CHANNEL-LESS OCCAM (OCCAM-CL)

OCCAM-SH1 is a stricter variant of **OCCAM-SH** in which each parallel process p is allowed to read only from one channel $ch.in_p$, whereby p is the only process which reads from the channel $ch.in_p$. We call this variant channel-less, because the identifiers of channels unify with the identifiers of processes. The processes can be numbered in the order they appear in the single **PAR** constructor.

Theorem 4: **OCCAM-SH1** and **OCCAM-SH** are equally expressive.

Proof: An **OCCAM-SH1** program is also an **OCCAM-SH** program. Conversely, consider an arbitrary **OCCAM-SH** program. Translate it to **OCCAM** and then back to **OCCAM-SH** using compilers from the proofs of Theorem 3 and Theorem 2. This yields an **OCCAM-SH1** program. ■

OCCAM-CL syntactically removes the redundancy related to channels from **OCCAM-SH1**. An arbitrary **OCCAM-SH1** program can be rewritten to **OCCAM-CL** as follows:

- Remove all channel declarations.
- Replace each $ch ? m$ with $? m$.
- Replace each $ch ! m$ with $p ! m$, where p is the identifier of the process which reads the channel ch .

Figure 3 illustrates the correspondence between OCCAM-SH1 and OCCAM-CL.

<pre> 1: Program P₄ 2: CHAN ch0, ch1, ch2: 3: PAR 4: INT m: 5: SEQ -- process 0 6: SEQ i = 0 FOR 2 7: SEQ j = 0 FOR 2 8: ch0 ? m 9: ch1 ! TRUE 10: ch2 ! Fig. 3. Hand-made translations of the OCCAM program P_1 (Fig 1) to OCCAM-SH1 (left) and OCCAM-CL (right)

VI. CONCLUSIONS

We proposed a programming language OCCAM-CL which differs from OCCAM (only) in having no nested PAR processes, no ALT constructors, and—most importantly—no channels. In spite of this, OCCAM-CL is as expressive as OCCAM. We proved this using several OCCAM variants and compilers which translate programs from one variant to any other one. These compilers preserve parallelism of programs as well as their message complexity (up to a constant multiplicative factor). A similar result was published in [25] for a lambda calculus with typed asynchronous channels and a lambda calculus with typed actors.

When it comes to writing an actual compiler, the choice between OCCAM-CL and OCCAM is not just a matter of taste. Apparently, writing a parser for OCCAM-CL is easier, but there are more subtle reasons for favouring OCCAM-CL. For example, OCCAM requires that each channel connects exactly two parallel processes (one reader, one writer). However, its syntax does not prevent the programmer from violating this requirement. It is up to the compiler or a run-time system to detect such a violation.

The channel-less approach can be found in actor models [26] as well as in contemporary programming languages, e.g. Erlang and Akka. A subsequent extension of Akka with the channel concept is in the light of our results a backward step. It does not increase expressiveness, unnecessarily increases the complexity of the language and the compiler, and increases the structural complexity of programs which mix the channel and channel-less paradigms.

Improvement of design anti-pattern detection with spatio-temporal rules in the software development process

Łukasz Puławski

Email: lpulawski@mail.mimuw.edu.pl

Abstract—In [1] we presented a framework for mining spatio-temporal rules in the software development process. The rules are based on specific relations between structures of the source code which relate both to spatial (e.g. a direct call between methods of two classes) and temporal dependencies (e.g. one class introduced into the source code before the other) observed in the process. To some extent, spatio-temporal rules allow us to predict where and when certain design anti-patterns will appear in the source code of a software system. This paper presents how, with slight modifications, such framework can be used to improve the quality of detecting a few popular design anti-patterns, such as Blob, Swiss Army Knife, YoYo or Brain Class. In the proposed method, we not only check the structure of a piece of the source code, but we also analyse its spatio-temporal relations. Only on the basis of the two analyses can we decide if the given piece of code is an anti-pattern. Experimental validation shows that the addition of spatio-temporal perspective improves detection of anti-patterns by 4% in terms of F-measure.

I. INTRODUCTION

DESIGN *anti-pattern* is a commonly used, bad solution for a recurring problem in software design. Software developers, when faced with a common design problem, tend to reinvent the solutions that are well-known for their bad properties and widely discussed in available literature (see [2]). This phenomenon is definitely due to many sophisticated reasons, which are discussed in a variety of scientific and popular publications (see [3]). The following paragraphs give a few examples of design-anti-patterns.

Base bean is an anti-pattern in object-oriented design, where the base class is a collection of numerous utility methods used by its subclasses. Such a design breaks some fundamental concepts of object-oriented programming: The relation between subclass and superclass does not resemble the actual domain model, the superclass has many responsibilities and it usually does not store any state useful for subclasses.

Brain class and God Class are similar anti-patterns that refer to classes that provide too much complexity and tend to centralize logic of some area of the system. The difference between God class and Brain class is that the former is a large controller class that depends on data from the surrounding classes, whereas the latter does not use the data from other classes, tends to be more cohesive and encapsulates the logic in its own complex methods (see [4], [5], [6], [7]).

Swiss Army Knife, (abbreviated as SAK) is an excessively complex class with numerous unrelated utility methods. It

tends to appear when the creator attempts to provide a routine for all possible uses of the class or make a single class serve many complex unrelated functions (see [8], [9] and [6]).

YoYo is an anti-pattern in which the flow control is scattered over complicated inheritance structure, so that in order to understand the algorithm in the source code, one has to switch between many classes within a common inheritance tree (see [10], [11], [6]).

Design anti-patterns make the software more complex, harder to maintain and defect-prone (see [12], [13], [14], [15]). This is why their detection is a primary concern in software engineering.

II. DESIGN ANTI-PATTERN DETECTION

The objective of design anti-patterns detection is to provide an automated method for the discovery of fragments of the program source code which constitute a design anti-pattern. To make this task more formal we will use graph-theoretical terms.

A. Software as a graph

We can treat the source code of the system written in Java as a multigraph called *software snapshot* according to the following rules: The nodes of the multigraph are all the *source code entities*, namely: packages, interfaces, classes, fields, methods (including constructors). They can be connected by labeled edges according to the following rules:

- There is an edge (e_1, e_2) labeled 'contain' iff the source code of the entity represented by e_2 is contained in the source code of the entity represented by e_1 (we will assume that classes and interfaces are contained in packages),
- There is an edge (e, c) labeled 'variable' iff the body of the entity represented by e declares at least one variable of the type represented by class c . Each such declaration corresponds to a single edge.
- There is an edge (m, c) labeled 'parameter' iff the method represented by entity m declares at least one formal parameter of the type represented by c . Each such declaration corresponds to a single edge.
- There is an edge (c_1, c_2) labeled 'extend' iff the class represented by c_1 is a direct subclass of the class represented by c_2 or the class represented by c_1 is an implementation

of the interface represented by c_2 . Each such class extension or interface implementation corresponds to a single edge.

- There is an edge (e, m) labeled 'call' iff the body of the entity represented by e contains at least one call of a method represented by the method entity m . Each such call corresponds to a single edge.
- There is an edge (e, f) labeled 'refer' iff the body of the entity represented by e contains at least one reference to the field represented by the field entity f . Each such reference corresponds to a single edge.
- There is an edge (f, c) labeled 'type' iff c represents a class that is a declared type of the field represented by f or a declared return type of a method declared by f .

Additionally, each node of the graph may be described by a set of applicable *software metrics* that measure its complexity (see [16]). For greater consistency we will assume that the values of metrics form a vector of additional labels of the node. Consequently, we can treat a software snapshot as a node-labeled and edge-labeled multigraph. This allows us to remain in the graph-theoretical domain. The list of metrics that are used is given in the following subsection:

B. Software metrics

- **Data abstraction coupling**
This metric is applicable for class entities and measures how many instances of other classes are instantiated within the source code of a given class.
- **Fan out**
This metric is similar to *Data abstraction coupling*, which measures the number of classes a given class depends on.
- **Cyclomatic complexity and NPath complexity**
These two metrics measure the complexity of a code block. Cyclomatic complexity, based on the classic work [17], denotes the number of decision point instructions within the body block increased by 1. The NPath complexity (see [18]) denotes the theoretical maximum number of different acyclic execution paths that could go through the code block.
- **NCSS - the number of lines of the source code in each entity (file, class, method)**
This simple metric measures how many lines of code a given file, class or method take. Technically, the evaluations do not count empty lines or lines with comments, so that it approximates the actual size of the respective source code fragment.
- **Lack of cohesion of methods (LCOM1, LCOM2, LCOM3, LCOM4, TCC)**
LCOM is a suite of software metrics that evaluate the design of a given class by quantitative analysis of relations between its methods and attributes (see [19]). LCOM1 is defined as the difference between the powers of two sets: the set of all pairs of different methods that use a non-empty disjoint set of class attributes and the set of all pairs of different methods that use at least one

attribute altogether. If the result is negative, the value of this metric is set to 0.

LCOM2 and LCOM3 metrics are defined for the class and the formulae to evaluate them, are based on the following notions: m - the number of methods in a class, A - the set of attributes of a class, m_a - the number of methods that access attribute a :

$$LCOM2 = 1 - \frac{\sum_{a \in A} m_a}{m * |A|}$$

$$LCOM3 = \frac{m - \frac{1}{|A|} \sum_{a \in A} m_a}{m - 1}$$

LCOM2 corresponds to the fraction of methods that do not access a specific attribute normalized over all attributes. LCOM3 is similarly normalized with respect to attributes and methods and its value may range from 0 to 2.

LCOM4 (see [20]) is expressed in terms of a graph of inter-method dependencies. We say that two methods are dependent iff one of them calls the other one or there is at least one attribute used by both methods. The number of connected components in such a graph is the value of LCOM4. Instead of looking at relations between methods and attributes within a single class, we can in a similar manner measure the relation between methods of a given class, with the use of Tight Class Cohesion (TCC) metric (see [21]). TCC is defined as the number of pairs of methods that invoke one another divided by the number of all such pairs.

- **Depth of inheritance tree (DIT)**
This metric is applicable to classes only. It measures the number of nodes on the path in the inheritance tree from the node representing the `java.lang.Object` class to the node representing the given class. Large value of this metric indicates a deep inheritance tree, which might indicate the presence of a *Yo-yo* design anti-pattern.
- **Fan in (FI)**
A metric dual to the *Fan out*. It measures the number of other classes that depend on a given class. The greater the value, the more likely it is that a change in the class will affect other fragments of the software source code.

In this context we can formalize the problem of detecting design anti-patterns as the problem of finding all such subgraphs of the software snapshot that correspond to instances of these anti-patterns. For practical reasons we will only consider subgraphs that satisfy the following Definition 1:

Definition 1 (containment-completeness): Let $SSn = (V, E)$ be a software snapshot, where V is a set of nodes and E is a multi-set of labeled edges. We will say that subgraph $g = (V_g, E_g)$ of SSn is *containment - complete*, if for any $n_1 \in V_g$, if there is a node $n_2 \in V$ such that n_2 is connected by 'contain' edge with n_1 in SSn then $n_2 \in V_g$.

We apply this constraint on the subgraphs, since we want the analysed subgraphs to resemble a consistent fragment of the source code with its natural hierarchical structure. For

example, if we take a subgraph with a node that corresponds to a class, we also want methods and fields of this class to be part of the subgraph. Therefore, in all the following considerations a *subgraph* always means a *containment-complete subgraph*.

C. Detectors of design anti-patterns

The following paragraphs provide a semi-formal description of method of detecting specific design anti-patterns used in this research. Each detection strategy is derived from existing research mentioned in the respective subsections below, but they are adapted to the graph-theoretical model described in Section II-A. In order to enhance comprehension, detection methods are described in mixed graph-theory and software-engineering terms. Each description can be translated to purely graph-theoretical terms so that for any subgraph of a software snapshot we can always tell if it satisfies the conditions described below. A exemplary rationale on how the conceptual definition can be translated to graph-theoretic model is given for the first detector only. Similar reasoning for other types of anti-patterns can be found in the articles referred to in the respective following subsections.

1) *Swiss army knife*: A *Swiss Army Knife (SAK)* for short, is an excessively complex class interface. It is present when e.g. the creator attempts to provide a method for all possible uses of the class or make a single class serve many complex unrelated functions. Methods described or referenced in [8], [9], [6] and [22] provide a semi-formal description of the pattern as *a class with many unrelated methods with high complexity which implements many interfaces*. Clearly, this can be translated to the graph-theoretical language in the context of a software snapshot: a class with many interfaces corresponds to each node such that paths which start from it and contain edges of type 'extend' and 'implement' reach many nodes which represent interface entity. A complex method is simply a method with high values of the complexity metrics such as *NPath complexity* or *cyclomatic complexity*. Additionally, if a class is intended to serve many purposes, one can expect that it has methods that are being called by many other classes. This conceptual description can be translated in the formal graph-theoretical definition described below:

Definition 2 (foreign call): Let c_1 and c_2 be two classes such that they are not connected by a path build from edges labeled 'extend'. Every call from a method contained in c_2 is a *foreign call* for class c_1 .

Swiss Army Knife is each class c that satisfies the following conditions:

- c has more than 6 methods,
- the value of metric LOC for c exceeds 150,
- the sum of cyclomatic complexity of methods contained in c exceeds 30,
- the sum of NPath complexity of methods contained in c exceeds 120,
- the number of non-trivial methods contained in c multiplied by the average NPath complexity of such methods exceeds 160,

- the number of methods called by a foreign call exceeds 2,
- the number of foreign calls exceeds 7.

2) *Anemic entities*: Anemic entities are classes which only store data and do not provide any functionality (see [23], [24]). A straightforward, naive approach for detecting this pattern is to take classes which have:

- many fields,
- only accessor methods (i.e. methods with a single line of code, which refer to only a single field and have cyclomatic and NPath complexity equal to one),
- default and possibly an initializing constructor.

This heuristic turns out to be inaccurate. Therefore, we need to define two notions: an *effectively trivial method* and a *complex constructor*.

A method m is *effectively trivial* if :

- The class c in which m is contained has field f of type t such that m refers to f and either m has 1 argument of type t and *void* return type or it has 0 arguments and return type t ,
- m has at most 5 lines of code,
- m has cyclomatic complexity not greater than 3.

The constructor con contained in c is complex iff:

- The number of arguments of con exceeds the number of fields contained in c ,
- the lines of code in con exceeds 150% of the number of fields contained in c ,
- the cyclomatic complexity of con exceeds 150% of the number of fields contained in c .

This allows us to provide a formal definition for anemic entity: A class is an *Anemic Entity* iff:

- it has more than 8 fields,
- it has more than 8 methods,
- all methods but one are trivial or *effectively trivial*,
- there are no complex constructors contained in c ,
- all subclasses of c satisfy the above four conditions.

3) *Blob (also known as God Class)*: (see [4], [5], [6], [7]). Entity c is considered a Blob iff:

- c calls more than 7 effectively trivial methods of other classes,
- proportion of the number of effectively trivial methods of other classes called by c to the number of other methods of other classes called by c exceeds 0.6,
- the sum of cyclomatic complexity of its non-trivial methods exceeds 55,
- the value of the metric TCC does not exceed 0.3.

4) *Brain class*: (see [4], [5], [6], [7]). Entity c is considered brain class iff

- c is not a God Class, as defined in the preceding subsection,
- c has more than 2 non-trivial methods with more than 4 outgoing edges of type 'call' and more than 15 lines of code (controller methods),
- c calls more than 5 trivial methods of other classes,

- proportion of the number of trivial methods of other classes called by c to the number of non-trivial methods of other classes called by c does not exceed 0.6,
- the number of calls to trivial methods divided by the number of lines of the source of c is smaller than 0.2,
- the value of tight class cohesion metric for c does not exceed 0.5,
- One of the following conditions is true:
 - sum of cyclomatic complexity of methods contained in c exceeds 50 and the value of NCSS metric for c exceeds 400,
 - sum of cyclomatic complexity of methods contained in c exceeds 90 and the value of NCSS metric for c exceeds 50,

5) *Base Bean*: (see [25]) *Base Bean* is a class which only provides utility methods for its subclasses.

A method m contained in class c is an *utility method* iff:

- m is neither a constructor nor a trivial method,
- m does not refer to any field contained in c , nor to a field in any direct or indirect superclass of c ,
- there is no path that connects m with field f contained in c or one of its direct or indirect superclasses, such that the last edge on this path has a label 'refer' and all other edges have a label 'call'.

Conceptually, a utility method is a non-trivial method that does not modify the state nor does it orchestrate other methods contained in the class it is defined in or any of its ancestors and is used only by its descendants.

A class c is *Base Bean* iff:

- it has more than 2 utility methods,
- c has at least 5 direct or indirect subclasses,
- the number of incoming edges of type 'call' from the hierarchy of c to utility methods contained in c exceeds 2.

6) *Yo-yo*: (see [10], [11], [6]). A containment-complete sub-graph induced by nodes $Y = \{e_1, \dots, e_n\}$ is a *YoYo* iff:

- Each pair $(e_i, e_j) \in Y \times Y$ is connected by a path constructed from edges of type 'extend', where each edge is treated as undirected,
- the longest path between any two nodes from Y constructed from such edges exceeds 5,
- the number of edges (m_1, m_2) with label 'call' or 'refer' such that m_2 is not a trivial method and there are edges $(m_1, e_i), (m_2, e_j)$ with label 'contain', $i \neq j$ exceeds 5.
- there is no super-set of nodes $Y' \supseteq Y$ such that graph induced by Y' satisfies the above three conditions.

7) *Data Clumps*: (see [15], [26], [27], [28]) a *Data Clump* is an anti-pattern that occurs when a group of data items are being passed together in the source code. This informal definition can be rephrased formally:

Let $parameters(m)$ denote set of entities connected with m by an edge labeled 'parameter'. A set of method entities $M = \{m_1, \dots, m_n\}$ is a *Data Clump* iff:

- n exceeds 3,

- $|parameters(m_i)|$ exceeds 3 for each i ,
- for each pair (m_i, m_j) such that $i \neq j$ and m_i and m_j are connected by 'call' edge, $|parameters(m_i) \cap parameters(m_j)| = \min(|parameters(m_i)|, |parameters(m_j)|)$,
- there is no such superset of M that satisfies the above conditions.

8) *Circular dependency*: *Circular dependency* is a relation between two or more software entities transitively contained in different packages which either call each other directly or indirectly to function properly. We can translate this into graph theoretical terms:

A pair of classes (c_1, c_2) forms a circular dependency iff:

- there exist two different packages p_1, p_2 such that there are edges $(c_1, p_1) (c_2, p_2)$ with label 'contain',
- there are two methods m_1, m_2 , such that there are edges (m_1, c_1) and (m_2, c_2) with label 'contain',
- there is a path build only from edges labeled 'call' from m_1 to m_2 and another such path from m_2 to m_1 .

9) *Detection quality*: The detection quality of purely static methods of identification of design anti-patterns described in the preceding subsections is presented in Table I.

Table I

THE TABLE SHOWS THE QUALITY OF DETECTION OF INSTANCES OF THE DESIGN ANTI-PATTERNS. THE COLUMNS CORRESPOND TO A RANGE OF ANTI-PATTERN TYPES WHEREAS THE ROWS PRESENT DIFFERENT SOFTWARE SYSTEMS. THE DETECTION METHODS ARE DESCRIBED IN SUBSECTIONS II-C1–II-C8 ABOVE. EACH CELL CONTAINS TWO NUMBERS: PRECISION/RECALL. SAK = SWISS ARMY KNIFE, BI = BLOB, DC = DATA CLUMPS, BB = BASE BEAN, BC = BRAIN CLASS, YY = YoYo, AE = ANEMIC ENTITY.

III. SPATIAL RELATIONS

Since design anti-patterns are subgraphs of one common graph, we can introduce the notion of distance between two patterns defined as the length of the shortest path that connects nodes from these subgraphs:

Definition 3 (closeness and remoteness of patterns): Let $PI_1 = (V_1, E_1)$ and $PI_2 = (V_2, E_2)$ be subgraphs of software snapshot SSn . We will say that

PI_1 and PI_2 are d -distance-close iff $d(PI_1, PI_2) \leq d$, where $d(PI_1, PI_2, SSn) = \min_{v_1 \in V_1, v_2 \in V_2} dist(v_1, v_2, SSn)$ where $dist(a, b, G)$ is the distance between vertices a and b measured as the shortest path between them in the multigraph G treated as undirected graph.¹

¹This makes dist symmetric.

Similarly: PI_1 and PI_2 are *d-distance-remote* iff $d(PI_1, PI_2) > d$.

IV. SOFTWARE EVOLUTION

Usually software development is done in the *source code management* system that allows us to track all changes done to the source code. Each individual modification of the source code is called *commit* and is identified by unique number called *revision*. Commit has precise date, author and a set of modifications to the source code files. If we take the commits from a single main development branch, we can order them linearly according to the commit date. The code at each revision has a corresponding software snapshot, thus we can treat linearly-ordered sequence of such snapshots as a model of *software evolution*.

One specific design anti-pattern can be observed at multiple revisions. The set of all such revisions will be called the *lifespan* of a pattern. Clearly, the lifespan can be divided into intervals of maximum lengths such that the corresponding pattern instance is not observed in the revision that directly precedes the left end of this interval nor is it observed in the revision that directly follows the right end of this interval. Each such interval will be called *occurrence* of the pattern. Please note that each pattern instance can potentially have more than one occurrence, as e.g. a certain software structure can be removed and then added again to the source code.

V. SPATIO-TEMPORAL RELATIONS

If we take two different patterns PI_1 and PI_2 and their two occurrences $l_1 = (l_{start}^1, l_{end}^1)$ and $l_2 = (l_{start}^2, l_{end}^2)$, we can tell the *temporal* relation between l_1 and l_2 (e.g. l_1 may directly precede l_2 when $l_{end}^1 = l_{start}^2$). In order to model the temporal relations we use Allens interval algebra in this research (see [29]), which introduces 13 different possible relations which comprise equality and 6 pairs of invertible relations.

We will say that Allens relation between l_1 and l_2 defined above is *non-inverted* iff $l_{start}^1 < l_{start}^2 \vee (l_{start}^1 = l_{start}^2 \wedge l_{end}^1 < l_{end}^2)$. Conceptually it means that l_1 *takes place before* some non-degenerated sub-interval of l_2 . In other words, l_2 will last for some time after l_1 has started. The non-inverted relations of these pairs are given in the following list:

- 1) l_1 *takes place before* l_2 if there exists a revision s such that $(l_{end}^1 < s < l_{start}^2)$
- 2) l_1 *meets* l_2 ($l_{end}^1 = l_{start}^2$)
- 3) l_1 *overlaps* l_2 ($l_{start}^1 < l_{start}^2 < l_{end}^1 < l_{end}^2$)
- 4) l_1 *starts* l_2 ($l_{start}^1 = l_{start}^2 \wedge l_{end}^1 < l_{end}^2$)
- 5) l_1 *contains* l_2 ($l_{start}^1 < l_{start}^2 < l_{end}^1 < l_{end}^2$)
- 6) l_1 *is finished by* l_2 ($l_{start}^1 < l_{start}^2 \wedge l_{end}^1 = l_{end}^2$)

Each Allens operator A has its inversion A^{-1} (which is also an Allens operator) defined by: xAy iff $yA^{-1}x$.

Let $0 < d_c < d_r$ be two fixed natural numbers which we will associate with d_c -distance-closeness and d_r -distance-remoteness relation respectively. If l_1 and l_2 are in A Allen relation and at some revision graph induced by nodes of PI_1 is d_c -distance-close to graph induced by nodes of PI_2 , then

we will say that these two occurrences are in A - d_c -distance-closeness *spatio-temporal relation*. If these graphs are d_r -distance-remote at all revisions we will say that they are in A - d_r -distance-remoteness *spatio-temporal relation*. Please note that the above definitions are also valid if PI_1 and PI_2 are never observed together at a single revision.

If we take a single occurrence l_1 of some anti-pattern PI_1 ($[l_1, PI_1]$), we can tell all its spatio-temporal relations to all other occurrences of other anti-patterns. Each such relation can be characterized by three arguments:

- T - the type of other anti-pattern ($T \in \{\text{BLOB, SAK, Base Bean, YOYO, Brain Class, Data Clump, Anemic Entity, Circular Dependency}\}$),
- A - the non-inverted Allen algebra relation ($A \in \{\text{takes place before, meets, overlaps, starts, contains, is finished by}\}$) and
- $s \in \{\text{remote, close}\}$ - which determines if we are talking about A - d_c -distance-closeness or A - d_r -distance-remoteness *spatio-temporal relation*.

Therefore, for each triplet (T, A, s) we can tell how many respective spatio-temporal relations to $[l_1, PI_1]$ exist in the software evolution. This yields a vector in $\mathcal{N}^{(8 \times 6 \times 2)}$ space which provides information about the number of all spatio-temporal relations of occurrence $[l_1, PI_1]$ in the entire evolution. The dimension of this space is related to the Cartesian product of:

- all types of anti-patterns described in Section II (8),
- the number of non-inverted Allen relations (6) and
- the number of types of different spatial relations from Definition 3 (2).

Consequently, the occurrence of an anti-pattern is described by a vector of 96 natural numbers.

Please note that the notions of closeness and remoteness from Definition 3, as well as the notions of lifespan, occurrence and spatio-temporal relations, are defined in such a way that they are also applicable to any sub-graph that can be observed in snapshots of the software evolution. Thus, we can compute the aforementioned 96 attributes for any occurrence of such a subgraph.

In ([1]) we argued that such a vector appears to be very specific for occurrences of design anti-patterns. This phenomenon may be interpreted as a tendency for certain design anti-patterns to appear close to each other (spatial relation) and one after another (temporal relation). They can therefore be used to predict areas in the source code, where design anti-pattern may appear in the future. In this research we will use similar framework to improve detection quality for detectors described in Section II.

A. Spatio-temporal rules

We will describe a method of mining *spatio-temporal rules* which allows us to reason about spatio-temporal relations in the entire software evolution. We will construct these rules by applying a rule-based machine-learning classification algorithm on specially prepared decision table. The following paragraphs describe how this table is constructed.

In Section V we argued that for any occurrence of design anti-pattern and any occurrence of any other subgraph of software snapshot we can compute a vector of 96 attributes that describe its spatio-temporal relations. For each occurrence of design anti-pattern PI of type t (e.g. Blob) we will insert one row to the decision table, with 96 conditional attributes and decision= t . We will call this a positive row for t (e.g. positive row for Blob). To balance this we will pick a random subgraph that does not correspond to anti-pattern t and has the same number of nodes as PI and insert it into decision table with 96 conditional attributes computed likewise. For such a row we will set decision=NOT_ t (e.g. NOT_Blob). We will call such a row a negative row for t (e.g. negative row for Blob).

The decision table constructed according to the above description has 97 columns and the number of rows is twice the number of occurrences of all design anti-patterns in the entire software evolution. We can partition this table into smaller tables by selecting only positive and negative rows for only single type t of anti-patterns (e.g. we only take rows with decision Blob and NOT_Blob). Each such sub-table is in fact a perfectly balanced binary decision table that can be used to train a machine-learning classification algorithm that produces a classifier in the form of a set of classification rules. We will call these rules *spatio-temporal rules* for t and the classifier will be called *spatio-temporal classifier* for t . Technically, the classifier, given a vector of 96 natural numbers, outputs either t or NOT_ t .

If we take occurrence l of some subgraph g in the software evolution we can compute 96 attributes for it and apply a spatio-temporal classifier on such a vector. Conceptually, the classifier for type t can tell if the given graph occurrence resembles a design anti-pattern t occurrence in terms of its spatio-temporal relations. We can use this observation to introduce an improved spatio-temporal detector for t . This concept is described in the following section.

VI. SPATIO-TEMPORAL DETECTORS OF ANTI-PATTERNS

Let us assume that some subgraph g , that is part of a software snapshot at revision r , is considered to be an anti-pattern of type t by a respective detector described in Section II. If we have a spatio-temporal classifier for t , then we can find its output for the occurrence of g at revision r according to the method described in the preceding Section V-A. In the proposed approach we will consider g to be an actual anti-pattern of type t iff the output of the spatio-temporal classifier was also t . Conceptually, in this detection strategy we combine a purely static definition of design anti-patterns given in Section II with spatio-temporal knowledge about the evolution of the software. We will consider a graph to be an actual anti-pattern, only when both premises hold.

Clearly, such a compound classifier can reduce the number of false positives but also increase the number of false negatives, thus it does not necessarily improve the quality of an anti-pattern detection. However, in practice, it appears that such a construct improves the classification quality by an

average of 4% in terms of F-measure, if we mine the spatio-temporal rules from the very beginning of software evolution and use them to identify static patterns in a separate, final period of this evolution. Details of the experimental setting is given in the following Section VII.

VII. EXPERIMENTAL VALIDATION

The experiments were run on the evolution of the following open-source software:

- Argouml ([30], [31], [32]) is a simple UML editor, which used to be popular. The SCM of this software (along with Xerces2j and Jhotdraw) is frequently used as the source of data in mining software repositories research. The analyzed evolution of this software spans from January 1998 to December 2011.
- Struts1 ([33], [34], [35]) is a java web framework, which was popular 20 years ago. The analyzed evolution of this software spans from May 2000 to December 2008.
- Xerces2j ([36], [34], [35]) is a popular Java XML Parser. The analysed software evolution spans from November 1999 to May 2008.
- Elasticsearch ([37], [38]) is a popular search engine. The analyzed evolution of this software spans from February 2010 to September 2017.
- JHotdraw ([39], [40]) is a Java framework for 2D graphics. The analyzed evolution of this software spans from October 2000 to November 2012.
- Lucene-solr ([41], [42], [35]) is a popular search engine. The analyzed evolution of this software spans from September 2001 to November 2016.
- Wildfly ([43], [44], [45]) is a popular Java application server. The analyzed evolution of this software spans from June 2010 to June 2013.

For each system, the spatio-temporal classifier, based on C4.5 Boolean classifier, was trained on the sub-evolution built from the first 70% revisions of the respective system. The closeness and remoteness spatial relations were defined by $d_c = 1$ and $d_r = 2$ respectively (see Section III). The detection quality was tested on each commit of the sub-evolution which consisted of the last 30% of revisions. Table II shows the cases, where the result of detection was different. In two cases the quality decreased by 6-11%, and in all other cases it improved by 1-14% in terms of F1. There was an average improvement of 4%.

VIII. CONCLUSIONS

In our previous work ([1], [46]) we analyzed the phenomena of spatio-temporal relations between occurrences of anti-patterns in the software evolution. This paper presents how spatio-temporal rules can help to slightly improve the quality of detection of a few anti-patterns: We combine typical static detectors derived from existing state-of-the-art detection methods with additional knowledge that comes from analysis of the spatio-temporal relations in the software development process.

Dataset	APT	Spatial Prec./Rec.	Spatio-temp. Prec./Rec.	Change of F1
elastic	BB	0.71 / 0.88	1.0 / 0.54	0.89
argouml	Bl	0.9 / 0.76	1.0 / 0.76	1.05
elastic	Bl	0.83 / 0.9	1.0 / 0.88	1.08
Xerces	Bl	0.91 / 0.69	1.0 / 0.69	1.04
elastic	BC	0.87 / 0.84	1.0 / 0.81	1.05
argouml	SAK	0.78 / 1.0	1.0 / 0.94	1.11
elastic	SAK	0.78 / 0.99	1.0 / 0.99	1.14

Xerces	SAK	0.8 / 0.89	1.0 / 0.65	0.94
Xerces	YoYo	0.98 / 1.0	1.0 / 0.99	1.01
			Average	1.04

Table II

IMPACT OF SPATIO-TEMPORAL RULES ON STATIC DETECTION QUALITY. THE TABLE PRESENTS HOW SPATIO-TEMPORAL RULES CHANGE THE QUALITY OF DETECTION OF SPATIAL DETECTORS DESCRIBED IN SUBSECTIONS II-C1–II-C8. THIRD COLUMN PRESENTS PRECISION/RECALL OF PURELY STATIC DETECTION. THE FOURTH COLUMN PRESENTS PRECISION/RECALL AFTER ADDING SPATIO-TEMPORAL RULES. APT = ANTI-PATTERN TYPE, BB = BASE BEAN, BL = BLOB, BC = BRAIN CLASS, SAK = SWISS ARMY KNIFE, F1 = F-MEASURE.

The experimental validation shows that in most cases the prediction quality was identical, with an observable difference only in a few cases described in Table II above. It was worse in only two cases, and on average in improved by 4% in terms of F-measure, which is a harmonic mean of precision and recall.

A. Future work

The following paragraphs provide some proposals for applications and modifications of the proposed framework, which yield to future research in the topic.

In this paper we have presented how spatio-temporal rules can be used to improve the quality of prediction of static pattern detection. The same rules can be used to predict where certain types of anti-patterns may appear in the future in the software source code.

In the method described herein, spatio-temporal rules were trained and used within the same software system. However, it is possible that rules trained on the evolution of one software system can be interpreted within another system. By doing so we may answer if there are universal spatio-temporal rules that model typical spatio-temporal phenomena in the software development process that hold across many projects.

The proposed framework is specifically suited for Java programming language, but can be easily adopted to other programming languages as well. It would require changing the definition of the software snapshot multigraph.

Allens algebra is a helpful formalism, but it can arguably be too simplifying when it is used to model temporal relations between intervals of revisions in the software development process. For example, it cannot measure temporal proximity between intervals. Please note that relation between the separated intervals of revisions are indiscernible in terms of Allens theory in two cases: when they are separated by a single commit and when they are separated by thousands of commits. Thus Allens algebra could be replaced by alternative formalism, which would incorporate more accurate model of temporal relations.

In this research we have assumed time to be linear (i.e. commits are linearly ordered), as we have considered commits from only a single main development branch. In fact, the software development process typically uses many parallel branches and cross-branch merges (see [47]). To cover such phenomena, the time representation in the proposed framework should be replaced with a more versatile model, such as e.g. CTL.

This research is based on the concept of a spatio-temporal relation to occurrences of anti-patterns described in Section II. But it can easily be adapted so that we can use other subgraphs in place of anti-patterns. For example we could use frequent subgraphs ([48]) or graphs built from frequently modified source code entities ([49]).

B. Threats to validity

Drawing general conclusions from empirical studies based on just a few software systems is always difficult, because of the complexity of the matter and the variety of different sources of data. This paper is based on data gathered from systems that share a common characteristic: they are open-source, non-commercial systems, developed by the community for many years. It may appear that software developed differently (e.g. by smaller teams, commercially, with closed source) tends to evolve differently.

Anti-patterns are very infrequent in relation to all possible containment-complete subgraphs in the software, as the number of the latter is exponential in relation to the number of software entities in the source code. To have a balanced set of examples, we have randomly selected sub-set of such subgraphs to construct a decision table described in Section V-A. Even though the results presented in Section VII were stable with multiple repetitions of the experimental reproduction, this fact presumably introduces some randomness in the results.

15th International Symposium on Multimedia Applications and Processing

SFTWARE Engineering Department, Faculty of Automation, Computers and Electronics, University of Craiova, Romania “Multimedia Applications Development” Research Centre

BACKGROUND AND GOALS

Multimedia and information have become ubiquitous on the web and communication services, creating new challenges for detection, recognition, indexing, access, search, retrieval, automated understanding, processing and generation of several applications which are using image, signal or various multimedia technologies.

Recent advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices—such as laptops, iPods, personal digital assistants (PDA), and smartphones—have stimulated the rapid development of intelligent applications. These key technologies by using Virtual Reality, Augmented Reality and Computational Intelligence are creating a recent multimedia revolution which will have significant impact across a wide spectrum of consumer, business, healthcare, educational and governmental domains. Yet many challenges remain.

We welcome papers covering innovative applications, practical usage but also theoretical aspects of the above mentioned trends. The key objective of this session is to gather results from academia and industry partners working in all subfields of multimedia and language: content design, development, authoring and evaluation, systems/tools oriented research and development. We are also interested in looking at service architectures, protocols, and standards for multimedia communications—including middleware—along with the related security issues. Finally, we encourage submissions describing work on novel applications that exploit the unique set of advantages including home-networked entertainment and games. However, innovative contributions which don't exactly fit into these areas are also welcomed to this session.

The Multimedia Applications and Processing (MMAP) will provide an opportunity for researchers and professionals to discuss present and future challenges as well as potential collaboration for future progress in the field. The MMAP Symposium welcomes submissions of original papers concerning all aspects of multimedia domain ranging from concepts and theoretical developments to advanced technologies and innovative applications. MMAP invites original previously unpublished contributions that are not submitted concurrently to a journal or another conference. Papers acceptance and

publication will be judged based on their relevance to the symposium theme, clarity of presentation, originality and accuracy of results and proposed solutions.

CALL FOR PAPERS

MMAP 2022 is a major forum for researchers and practitioners from academia, industry, and government to present, discuss, and exchange ideas that address real-world problems with real-world solutions.

The MMAP 2022 Symposium welcomes submissions of original papers concerning all aspects of multimedia domain ranging from concepts and theoretical developments to advanced technologies and innovative applications. MMAP 2022 invites original previously unpublished contributions that are not submitted concurrently to a journal or another conference. Papers acceptance and publication will be judged based on their relevance to the symposium theme, clarity of presentation, originality and accuracy of results and proposed solutions.

BEST PAPER AWARD

A best paper award will be made for work of high quality presented at the MMAP Symposium. Award comprises a certificate for the authors and will be announced on time of conference. Selected papers will be invited to high IF journals organized for the participants of MMAP.

- Authors should submit draft papers (as Postscript, PDF or MSWord file).
- The total length of a paper should not exceed 10 pages IEEE style (including tables, figures and references). IEEE style templates are available here.
- Papers will be refereed and accepted on the basis of their scientific merit and relevance to the workshop.
- Preprints containing accepted papers will be published on a USB memory stick provided to the FedCSIS participants.
- Only papers presented at the conference will be published in Conference Proceedings and submitted for inclusion in the IEEE Xplore@database.
- Conference proceedings will be published in a volume with ISBN, ISSN and DOI numbers and posted at the conference WWW site.
- Conference proceedings will be submitted for indexation according to information here.
- Extended versions of selected papers presented during the conference will be published as Special Issue(s).
- Organizers reserve right to move accepted papers between FedCSIS events.

WINNERS OF MMAP 2019 BEST PAPER AWARD

- Depth Map Improvements for Stereo-based Depth Cameras on Drones. Authors: Daniel Pohl (Intel Corporation), Sergey Dorodnicov (Intel Corporation).
- Information theoretical secure key sharing protocol for noiseless public constant parameter channels without cryptographic assumptions. Authors: Valery Korzhik, Vladimir Starostin, Muaed Kabardov, Aleksandr Gerasimovich, Victor Yakovlev, Aleksey Zhuvikin (The Bonch-Bruевич Saint-Petersburg State University of Telecommunications), Guillermo Morales-Luna (Computer Science Department CINVESTAV-IPIV, Mexico City, Mexico).

Abstract—This paper presents a modified Iterative Closest Point (ICP) algorithm based on a suitable selection of initial points and local optical flow to speed up registration of static scenes with high accuracy. The biggest disadvantages of using standard ICP algorithm are appropriate initialization and effective matching point step in each iteration. In the proposed modification we deal with these problems and optimize this method for Augmented Reality application. As this application uses RGB-D images sequence the changes between consecutive key-frames are small. Therefore only small subset of the source image key-points is selected using scale-space pyramid and FAST approaches. It leads to the significant reduction of the number of the processed image points. Since the point matching technique using local optical flow is applied, in each optimization step of ICP the costly point matching procedure can be abandoned. The proposed approach has been validated by the numerical examples.

I. INTRODUCTION

THE reconstruction of the geometry of the environment from a movable camera is a well studied problem in the category of computer vision topics. In theory, the determination of the trajectory is already possible with the use of only a few reference points traced in real time [1]. However, the smaller number of tracked points makes the solution more sensitive to data noise. Recently, we have seen significant progress in the development of methods for dense 3D reconstruction from many images. Unfortunately, many of these proposed approaches are not able to work in real time [2]. In addition, they usually require a large number of calibrated images, making them unsuitable for live reconstruction from one movable camera. On the other hand, there are many approaches for the reconstruction of dense depth maps from pairs of images [3]. While these approaches have been shown to provide excellent results in dense depth estimation, they are usually computationally too expensive for real-time applications.

In this article we propose modification of the first block of Iterative Closest Point (ICP) method - looking for a match of the identities of the points in each iteration. It has been replaced with the previous step using local optical tracking. This approach, perhaps surprisingly, does not involve a significant loss of speed, but allows a significant reduction in the amount of data while increasing accuracy. The modified ICP method was designed for Augmented Reality (AR) applications. AR

is the computer vision system integrating computer generated virtual information with the real world environment in the form of image, sound or video. The added information, usually virtual objects, has to be precisely aligned with the real world. Image registration is the key element of AR algorithm. The ICP method was first presented by Besl and Mackay in 1992 (see [4]). This method is more concept then solid algorithm. The first step, i.e., the initial selection of the points is the most important step to enforce ICP method to be convergent to global rather than to local minimum. There is always a trade off between using feature points or dense data. In literature ICP approach is based on feature extracting methods as in [5]. It leads to long computational time and low quality of point cloud to be augmented in final step of AR image generation. Therefore in this paper, we present different approach than proposed in literature for initial points selection and matching based on scale-space and Features from Accelerated Segment Test (FAST) [6], [7] approaches as well as local optical flow method. The selected set of points may contain outliers. However, in the proposed method there is no separate mechanism for removing such points. Outliers are removed in the optical tracking procedure if they do not meet the stability criteria of this procedure. As a result, we get a set of points that no longer contain outliers. Finally in the last step the error metric is minimized to find the six parameters of the transformation, i.e. the rotation matrix and the translation vector. The main focus is on the speed of convergence and the accuracy of the final transformation and the application it to construct AR image. The performance of the ICP method depends mainly on the data and proper initialization. If some a-priori assumption concerning the similarity of the frames can be made, the quality of matching is much better. Therefore in this paper, we assume that point clouds are constructed from two following frames of a video sequence. The pixel brightness is also assumed not to change significantly on those two consecutive frames.

II. RELATED WORK

A. Geometric Registration

Most of the registration methods operate on candidate correspondences. Popular method use point to point matches

based on local geometric descriptors [8], other defines correspondence on pairs or tuples of points [9]. When candidate correspondences are collected, alignment is estimated attractively from sparse subset to correspondence. This iterative process is typically based on variant of randomized algorithms like RANSAC [8], [9]. When the data is noisy and the surfaces only partially overlap, existing pipelines often require many iterations to sample a good correspondence set and find a good reasonable alignment. In many applications we have a priori knowledge that stream of consecutive data observation has relatively small transformations. This approach is known in literature as local refinement where rough initial alignment is known and the result is tight registration usually based on denser correspondence compared to global alignment [10]. ICP method and its modifications are popular for local refinement. The simplest algorithm of the ICP starts with initial alignment and alternates between establishing correspondence via find the closest point and recalculate the alignment based on the current correspondence set. ICP can give an accurate result when initiated near the optimal position, but it is unreliable without such initialization. In many papers [11], [12] are explored different approaches to increase ICP sensitivity to local optima. There are many modification of ICP method based on correspondence or transformation parameter estimation step modifications [5]. Park [11] proposed modification where he used geometry as well as intensity of RGB color value. This approach is valid when registration use data stream from the source when conditions are not changed like frame stream where camera intrinsic parameters are the same. The accumulated 3D model can be either in the form of a volumetric representation [12], a 3D point cloud [13] or a set of depth maps.

B. Optical flow of feature points

Optical flow is popular method of image processing when there is a need to know the movement (speed and direction) of the part of the image. According to Akpınar et al. [14], optical flow estimation algorithms can be grouped according to the theoretical approach while interpreting optical flow. These are differential techniques, region-based matching, energy-based methods and phase-based techniques. There are two groups of optical flow methods. The first is local optical flow introduced by Lucas-Kanade [15], and the second global optical flow introduced by Horn and Schunck [16]. In this paper we mostly focus on geometric aspect of registration then local optical flow is more suitable [7], [17]. Input data stream consists color RGB intensity frames and depth information.

III. PROPOSED ALGORITHM

A. Overview

Our goal is to calculate the rigid body motion transition T consisting of translation t and rotation R that minimizes the difference between the two sets of points O and M . In the next subsections, the process of locating, matching, and filtering the appropriate feature points is described and the following section presents the proposed pose estimation calculation.

B. Finding and Matching Visual Features

An RGB-D image consists of a color image I and a depth image D recorded in the same coordinate frame. We assume to have a pair of RGB-D (I_i, D_i) and (I_j, D_j) images and an initial T^0 transformation that roughly aligns (I_i, D_i) to (I_j, D_j) . Also $p = (u, v)^T$ is the pixel in (I_i, D_i) and $p' = (u', v')^T$ is the corresponding pixel in (I_j, D_j) . The goal is to find the optimal transformation that densely aligns the two RGB-D images. Here we assume that the individual frames are not distant in time, so that the color intensity of the pixels does not change rapidly and the initial match T^0 can be equal to the identity matrix. The first step of registration is to select feature points using FAST method on RGB image. For image I FAST point detecting method gives set of feature points P . In order to avoid the problem with the scale and the high speed of moving individual points, a scale pyramid is built. The original RGB image I is used in first layer, then the size of image is divided by 2 and the resultant image, the same procedure is repeated until the image becomes too small. As a result the set $N = \{P_k\}$ of points is obtained where k is number of layers in pyramid. Then local optical flow method is used for tracking of selected points $N_{i \rightarrow j}$ from image I_i on consecutive image I_j . Let $O_{i \rightarrow j}$ be the set of successfully tracked points and $C_{i \rightarrow j}$ their movement vectors. Then the projections π of the RGB-D image pixel $p = (u, v)^T$, $d = D(p)$ over 3D space is done using

$$\Pi(u, v, d) = \left[\frac{(u - c_x)d}{f_x}, \frac{(v - c_y)d}{f_y}, d, 1 \right]^T, \quad (1)$$

where f_x and f_y are the camera focal lengths and (c_x, c_y) is the principal point. The inverse projection function π^{-1} is defined as follow

$$\pi^{-1}(x, y, z, 1) = \left(\frac{xf_x}{z} + c_x, \frac{yf_y}{z} + c_y, z \right)^T. \quad (2)$$

Using the projection π over points set $O_{i \rightarrow j}$ the 3D point set is obtained.

$$W_{i \rightarrow j} = \pi(O_{i \rightarrow j}) \quad (3)$$

In practice, the depth component in an RGB-D image need not always be defined. Then such a pixel cannot be projected into 3D space. In that case such pixels are not used for 3D projection. Set $W_{i,j}$ is also called point cloud. The photometric objective is to find transformation T satisfying:

$$p = \pi^{-1}(T\pi(p', D(p'))). \quad (4)$$

Projection of pixels p and p' should be the same point in 3D space

$$\pi(p, D(p)) = T\pi(p', D(p')). \quad (5)$$

C. Pose estimation

The ICP consist of two steps correspondence estimation and transformation parameter estimation. In the first iteration we consider two consecutive image frames: current (I_i, D_i) and

registered (I_j, D_j) . The objective of correspondence estimation step of ICP is to build mapping function ϕ which define correspondence between I_i and I_j

$$p = \phi(p'). \quad (6)$$

In the proposed method function ϕ is defined by $C_{i \rightarrow j}$ and it does not have to be recalculated at each loop step. The transformation parameters estimation is done by looking for transformation T that minimize objective function

$$\begin{aligned} T_{n+1} &= \operatorname{argmin}_T \sum_{i=1}^O \|\pi(p_i, D(p_i)) - \\ &\quad T_n \pi(p'_i, D(p'_i))\|^2 \\ &= \operatorname{argmin}_T \sum_{i=1}^O \|\pi(\phi(p'_i), D(\phi(p'_i))) - \\ &\quad T_n \pi(p'_i, D(p'_i))\|^2, p_i, p'_i \in O \end{aligned} \quad (7)$$

where n is iteration step counter. The computations may be completed when the predetermined number of iterations have been performed or when the estimate of T is sufficient. Optimization problem (7) is solved using Gauss-Newton method. In each iteration, we linearize T locally as a 6 elements vector $\xi = (\omega_1, \omega_2, \omega_3, t_1, t_2, t_3)$. ξ contains rotation component ω and a translation component t .

$$T \approx \begin{pmatrix} 1 & -\omega_3 & \omega_2 & t_1 \\ \omega_3 & 1 & -\omega_1 & t_2 \\ -\omega_2 & \omega_1 & 1 & t_3 \\ 0 & 0 & 0 & 1 \end{pmatrix} T^n \quad (8)$$

Using the Gauss-Newton optimization scheme, we calculate ξ by solving the linear system

$$J_r^T J_r \xi = -J_r^T r \quad (9)$$

where r is the residual vector and J_r is Jacobian. In each optimization step n , r and J_r are calculated. Then T_n is obtained from ξ (see equation 8). Next T is updated by T_n using transformation to $SE(3)$ group.

IV. NUMERICAL EXPERIMENTS

Publicly available sequenced RGB-D framesets were used for the qualitative evaluation of the method proposed in this paper. All datasets used for test were published by Sturm [10]. RGB-D frames were registered using Microsoft Kinect device. Along with the images, the proposed benchmark dataset also provides the real trajectory taken by the camera acquired by an external, high-precision motion interception system.

A. Performance comparison

The performance comparison is summarized in the Table I. Processing time and error were calculated for different RGB-D sequences. Processing time was calculated as average of the time for registration consecutive frames. Mean error was calculated as the difference between benchmark trajectory and method calculated trajectory. Proposed method was compared to standard ICP implementation.

Algorithm 1 RGB-D images alignment

Require: Pair of RGB-D images $(I_i, D_i), (I_j, D_j)$, initial transformation T^0

Ensure: T registration transformation from frame i to j
 Build scale pyramid for RGB images I_i, I_j
 Calculate feature points using FAST method $N = \{P_k\}$
 Calculate local optical flow for points N and get $O_{i \rightarrow j}, C_{i \rightarrow j}$
 Project N into 3D space using projection equation (1)
while not converged **do**
 $r \leftarrow 0, J_r \leftarrow 0$
 Use $C_{i \rightarrow j}$ as correspondence between points from frames i and j
 Solve equation (9) to get ξ
 Update T using equation (8) and map to $SE(3)$
end while

TABLE I: Speed comparison of proposed method and ICP

Dataset	Proposed method		ICP method	
	Processing time [ms]	Mean error [m]	Processing time [ms]	Mean error [m]
fr1/xyz	0.123	0.251	0.182	0.511
fr1/rpy	0.128	0.262	0.195	0.25
fr2/xyz	0.131	0.17	0.152	0.19

B. Scene reconstruction

Single frame reconstruction is presented on Figure 1. Top row presents RGB image and depth component that is used for projection. Bottom row contains 3D projections of frame and camera location related to scene.

C. Augmented Reality application

Proposed method was used to build AR system as example of usage. Image 2 presents RGB frames and model position for different views as well as final AR image. In this case, the model image in the appropriate position is presented on the RGB image frame. The problem of obscuring an object added by scene elements is not considered.

V. CONCLUSION

The article presents an approach to the problem of image registration in a multi-frame sequence. The proposed method uses information obtained by an RGB-D camera moving in a static environment and is compared to the ICP method, another popular approach often used in similar applications. Its performance was assessed in terms of accuracy and processing time on the benchmark data sets. The proposed method achieved an average accuracy of 12% better than ICP and the processing time on average 37% better than ICP. The proposed algorithm works for both consecutive images and multiple image frames. The novelty of the use of local optical flow allows for better results than in the case of the classic ICP algorithm. The application of the proposed method has been shown on the example of AR. Information from previous frames is accumulated in the form of a point cloud. This

Fig. 1: Single frame projection into 3D scene.

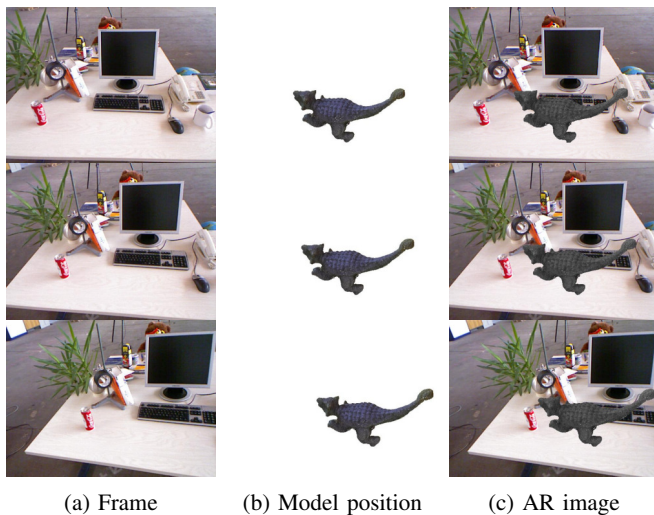

Fig. 2: AR system based on proposed registration method.

feature can be used in applications where 3D reconstruction plays an important role. In this article we not deal with the loop closure problem. However this method potentially could be used for simultaneous location and mapping algorithm (SLAM) application as well. This will be studied in future work.

Abstract—In order to speed up the process of rendering scenes containing many light sources, spatial data structures are used, which allow the number of lights processed for each pixel to be reduced during lighting computation. Examples of algorithms using such data structures are clustered shading and hybrid lighting. Alongside the rendering time, it is important to consider memory consumption resulting from processing a large number of lights. This paper presents a novel modification of the hybrid lighting algorithm using an octree that allows for a significant reduction in the amount of memory required to store the data structure.

The proposed modification uses an octree to store the information about the rendered space. Detailed analysis of the proposed algorithm, and numerical results obtained for various 3D scenes, as well as different input data, all prove that the proposed method significantly reduces the memory required to store lists of lights used by the algorithm.

I. INTRODUCTION

IN RECENT years during the creation of virtual scenes, a lot of emphasis has been put on rendering visually realistic scenes. Rendering scenes containing multiple light sources requires calculating for each pixel a list of lights that affect its color. The most commonly used type of light is a point light with a limited range. Such lights can be represented as spheres in a rendered scene. The process of rendering a scene containing multiple light sources is therefore equivalent to determining for each rendered point which spheres contain this point. Fig. 1 shows an example scene for this problem containing 1 000 000 lights.

In the case of scenes with a large number of lights a naive approach of checking the distance between each rendered point and each light source requires a large number of operations. Improving rendering performance can be achieved by parallelization and by using spatial data structures to approximate light distribution in the scene space. These data structures are used during lighting computations to reduce the number of lights that are processed for each rendered point, which results in lower rendering times.

Another major concern in the rendering process, alongside the number of performed operations, is the memory complexity of the algorithm. Operating with a large amount of memory can often create a bottleneck while processing and visualizing complex scenes.

Research funded by the grant of Faculty of Mathematics and Information Science no. 504/04628/1120, Warsaw University of Technology

II. RELATED WORK

Research on the optimization of rendering has been conducted for over 50 years. Most of the algorithms used to efficiently render scenes with multiple lights use an additional data structure, describing scene geometry as well as lights placed in the scene, in order to decrease the time required for the calculation of lighting for each pixel. In these algorithms data structures allow a list of lights that potentially affect rendered geometry to be determined. The final decision on whether or not a light should affect a given pixel is made for each pair (pixel and light), based on the position of the shaded point and the position of the light source and, optionally, the normal vector in this point. The usage of the aforementioned data structures decreases the set of lights that are considered for a given pixel, which results in shorter rendering times.

One of the methods of rendering scenes containing many light sources is an algorithm using g-buffers [2], which are separate buffers used to store partial data, such as world position, normal vector or material properties, used in lighting computations in the final stage of frame rendering in which the final color displayed on the screen is calculated. Areas affected by lights are represented by spheres and each of those spheres is then rasterized onto the screen, and lighting data for each pixel in the area taken up by the light is updated. This solution is not efficient on modern GPUs [3] as rendering each frame requires multiple reads and writes to g-buffers, which significantly slows down the overall rendering process.

One of the most popular algorithms used to render scenes containing many light was the tiled shading algorithm [4], in which the rendered frame is divided into rectangular tiles (Fig. 2). Each tile is associated with a list of lights that affect any part of the scene contained in that tile. This additional data structure is used during final pixel color calculation. However, for each shaded pixel not all lights assigned to a corresponding list affect its color. Increasing the number of tiles can result in fewer lights to process for each pixel but processing more tiles requires additional operations and memory.

The part of the scene being rendered is divided only vertically and horizontally during tile construction. If a tile contains objects that are close to the camera and objects that are far from the camera (an example of such situation is presented in Fig. 3), lights affecting any of these objects will be processed for all of them. This can lead to many operations being performed unnecessarily as these lights are unlikely to affect all of the geometry contained in the tile.

There has been developed a modification of the tiled shading algorithm, a 2.5D culling [5], aiming to reduce the number of lights assigned to each tile in the case of a discontinuous geometry. For each tile, the geometry's range of depth is calculated and this range is divided equally into a fixed number of cells which contain the actual lists of lights.

An extension of the method of dividing space in three dimensions was proposed in the clustered shading algorithm [6]. In this algorithm all of the pixels of the rendered image are divided into groups (clusters) and a list of lights is assigned to each such cluster, in a similar way to the tiled shading algorithm. Clusters are created based on the three-dimensional position of shaded pixels as well as, optionally, a normal vector at that point. As described by Olsson et al. the depth of the rendered scene can be divided uniformly in either screen space or view space, or one can perform an exponential depth division in which resulting cells' dimensions are as equal as possible. During each frame of the rendering process, the lights are organized into a bounding volume hierarchy (BVH), a tree structure that allows for fast queries for all the lights that affect a given part of space. The tree is constructed in parallel, using the bottom-up approach. Then the bounding box of each cluster is used to determine a set of lights that possibly affect pixel samples in the cluster, and the normal vectors of cluster samples are used to discard lights that cannot affect any sample in the cluster.

There were also optimization attempts using the graphics pipeline to organize lights into lists assigned to different parts of the scene. The hybrid lighting algorithm [7] uses rectangular billboards to approximate the location of each light and to assign lights to appropriate lists. As with the clustered shading algorithm, the rendered space is divided into cells of a three-dimensional array. The billboards are rendered in a resolution corresponding to the vertical and horizontal array dimensions, and analytical calculations (the intersection of a sphere representing the area affected by the light and a ray originating from the camera) are performed to determine the range of cells in the depth affected by the light.

Complex spatial data structures can be implemented efficiently using graphics cards, allowing for parallel construction which results in lower building times. Tree structures are often used to organize points in space, e.g. for dealing with the level of detail [8] or multi-dimensional data clustering [9]. Trees allow the space to be divided into either regular cells [8], [9] or using hyper-planes which divide the space into two sub-spaces, each containing a subset of points [10].

The graphics pipeline has also been used to build this type of structure. Crassin et al. [11] describe a parallel algorithm for constructing an octree by inserting leaves into the partially constructed tree. To ensure that no two threads try to insert children nodes into the same parent node at the same time, a mutex for each node is used. The algorithm uses a separate buffer to store all nodes that cannot be inserted at a given moment and iterates until all of the nodes are inserted into the tree.

Another approach to rendering scenes with many light sources is taken in the tiled light trees algorithm [12]. Instead of the discrete division of the rendered space in all three dimensions, the lights are assigned to two-dimensional tiles, in a similar way to the tiled shading algorithm. However, in each tile a "light tree" (a variant of an interval tree), organizing lights in the depth of the scene, is constructed. During the final shading process for a given pixel, a tree from the tile in which the pixel is located is queried in the logarithmic time for the set of lights that can affect the pixel's color.

III. ALGORITHM DESCRIPTION

The developed algorithm is based on the hybrid lighting algorithm [7]. The algorithm's major novelty is its utilization of an octree for lights' spatial organization combined with dynamic analysis of the scene: tree leaves are only created in the presence of a scene's geometry. In this way, the memory needed for the tree's representation is minimized. Another optimization extends the basic tree properties: lights can be stored not only in the leaves but also in the internal nodes. This allows the information about a light to be stored in a single node if it is assigned to the lists of all its children nodes. The tree's creation is therefore faster, since there is just one insertion operation instead of many.

One of the improvements in the tree's construction is the adaptive space division during the tree's creation, instead of equal division in all directions. A bigger tree is created but only a fragment of it is used while the rest, laying outside of the divider region, is ignored. An example of this approach is presented in Fig. 4. The number of tree cells in each direction is equal to the lowest power of 2 equal or greater to the highest array dimension. This solution does not add any significant computation or memory cost due to the sparse structure of the octree used in the implementation.

The octree is constructed in each frame, before the light assignment operation. This operation is split into two steps: determining a list of cells containing the scene's geometry present in the rendered frame and building an octree containing these cells. In order to calculate a list of unique cells, first -

Fig. 2. Division of a rendered frame into 32 tiles vertically and 32 tiles horizontally (*Sponza* scene [1]).

Fig. 3. Close-up of one of the tiles (outlined in red) of an image rendered using the tiled shading algorithm (*Sponza* scene [1]) in which there are many geometry discontinuities. Continuous parts of the geometry are highlighted in the same color.

for each pixel of a rendered scene - the cell which the pixel belongs to is determined and its index is stored in a list. Then, repetitive values are removed from the list.

Two methods of removing repetitive elements have been proposed. The first method uses two functions commonly used in parallel computing: sorting and removing consecutive repeating elements on a list. One possible optimization of this process entails also removing consecutive repeating elements from the list before sorting. This optimization exploits the fact that all cell indices are written to the list row by row and many consecutive indices on the list are equal. This results in a certain amount of the list's elements being removed, which reduces the time needed to sort the entire list.

The second method of removing repeating elements from the list exploits a fact that all indices are from a small, finite range, bounded by the array dimensions. This makes it possible to use bitmasks to store the information about the presence of a cell in a frame. Moreover, the cells' indices are correlated with the two-dimensional tile of the image the pixel belongs to. This fact allows for easier parallel processing of the cells: all pixels from a given tile are processed by threads from the same warp, and the atomic operations (synchronized between threads in a single warp) are used to mark the presence of a given cell. The bitmasks are therefore stored in a separate list, each 32-bit element of the list representing 32 consecutive cells within the same two-dimensional tile. In the list containing the bitmasks, a parallel scan counting the

Fig. 5. The process of checking if a light can be assigned to the inner node of a quadtree. The node represents a group of 4×4 cells. The distance is checked from the light source O to each cell corner marked in blue. The light's range is represented by the yellow circle. In the example shown in the figure on the left, one of the points (marked in red) is farther from the light source than the light's range, therefore this light isn't assigned to the leaf marked in yellow so it cannot be assigned to the processed node. In the example shown in the figure on the right, all marked points are within range of the light, thus this light can be assigned to the processed node.

number of set bits is performed to determine the starting index in the resulting list under which the cells' indices should be written. In the final step, the list of unique cells present in the rendered frame is filled using the bitmask list.

The approach to building an octree described by Crassin et al. [11] has been adapted to the CUDA framework. All of the cells from the list computed in the previous step are inserted into the tree. This tree is then used during the assignment of lights to lists associated with each cell.

The process of assigning lights to lists is similar to the original algorithm, in which the lights' locations and ranges are approximated by billboards. The main difference is that after determining the cells which the light should be assigned to, for each cell a path in the octree (from the root to the leaf corresponding to the cell) is traced to check whether or not the light can be assigned to one of the internal nodes. For each node on this path, the distance from the light source to the innermost corners of the outermost cells of a group is compared to the light range. If all of the corners are within the range of the light, a light is assigned to this inner node and the rest of the path to the leaf is ignored. A 2D example of this process is shown in Fig. 5. All the calculations are performed in view-space because then the corner of each of the cells has a constant position. Moreover, it is possible to calculate the view-space position of each cell corner in advance and read it from the additional buffer instead of calculating it every time it is used.

During the final shading process the lights are read from all the lists corresponding to nodes on a path from the octree root to the leaf representing the cell the shaded pixel is in.

IV. RESULTS

The described algorithm was subjected to a series of tests to determine its effectiveness in comparison to the clustered shading and hybrid lighting algorithms. We concentrated on comparing the memory required by algorithms, as minimizing the memory requirements was the main purpose of the proposed modification. All reported results were obtained on a PC

Fig. 6. *Cornell Box* test scene with 2000 lights spaced uniformly in the scene volume.

Fig. 7. *Bars* test scene with 50000 lights spaced uniformly in the scene volume.

with an Intel Core i7-9750H CPU 2.6 GHz and 16 GB RAM, supplied with an NVIDIA GeForce RTX 2060 Mobile (1920 CUDA cores) 6 GB GDDR6 with CC 7.5. All algorithms were implemented using C++17 with *Direct3D 11* [13] and *CUDA* [14] libraries and were implemented for the deferred shading pipeline.

The algorithms were tested on 4 different scenes with 3 different distributions of light positions. Images were rendered at a resolution of 1920×1080 pixels. In each test the camera moved along a predetermined path. To minimize the impact of the operating system's background work on rendering times, each test was repeated 5 times, and the results were averaged for each frame.

Three of the four test scenes, *Cornell Box*, *Sponza* [1] and *Rungholt* [1], are commonly used as a benchmark for evaluating rendering algorithms, and the other one, *Bars*, contains many vertical bars, and was created to test the algorithms on a scene containing many geometry discontinuities. All scenes, along with the light distribution used in them, are shown in Figs. 6, 7, 8 and 9.

The lights in all test scenes were distributed randomly, using one of three distributions: uniform distribution in the scene's volume; uniform distribution on the scene's geometry; groups of lights distributed uniformly in the scene's volume. The

Fig. 8. *Sponza* [1] test scene with 50 000 lights spaced uniformly on the scene's geometry surface.

Fig. 9. *Rungholt* [1] test scene with 1 000 groups each containing 1 000 lights spaced uniformly in the scene volume.

lights' ranges were generated based on a uniform distribution between a minimum and maximum range, different for each scene. For the uniform distribution around the scene's volume, each coordinate of the light's position was generated independently of another, based on the scene's bounding box. In the uniform distribution around the scene's geometry, a random triangle from a fixed number (1 000 in the case of the performed tests) of the biggest triangles was selected at random, with the probability of being chosen proportional to the triangle's area. Then, a random point on a chosen triangle was generated and a light was placed in a position within the predefined distance of the chosen point along the triangle's normal vector. To generate groups of lights, the positions of the groups' centers were generated around the scene's volume. Then, for each group, a fixed number of lights' positions were generated using the truncated normal distribution [15] with the expected value equal to the generated group's center.

A number of tests were performed to determine the impact of each parameter on the average rendering time of each scene. In each test case, parameter configurations differed by a single parameter. As a base configuration we assumed:

- the division of the rendered image into 30×17 tiles;
- exponential depth division in the view-space;
- the unique cell list determination method using bitmasks;

Fig. 10. Rendering time for each frame of the *Bars* test scene with different tile counts.

- precomputing the positions of cell corners.

Two different tile counts were compared with the base one: 32×32 and 60×34 tiles. In all test scenes, the lowest average time was achieved in the configuration using 30×17 tiles. The rendering times for each frame of the scene *Bars* are shown in Fig. 10. Table I shows the average results for all test scenes.

Two configurations with uniform depth division in the screen-space were tested: into 128 and into 256 cells. In the case of the *Cornell Box* and *Sponza* scenes, notably higher average rendering times were seen in the configuration with a higher cell number, whereas in the other two scenes a higher cell count resulted in lower average rendering times. Uniform depth division into 128 and 256 cells in the view-space was also tested. As with the screen-space division, whose cell count resulted in lower average rendering times, the rendering times differed between scenes. Notably, for the *Rungholt* scene the differences between the average rendering times were negligible. Table II shows the averaged results for all of the four described depth division methods for all test scenes.

Figs. 11, 12, 13 and 14 show the rendering times of each frame for the three tested methods of depth division. For the uniform divisions, a division resolution resulting in the lowest average rendering times was chosen. For the *Bars*, *Sponza* and *Rungholt* scenes, screen-space division resulted in significantly higher rendering times than the exponential division in the view-space. Uniform division in the view-space resulted in similar rendering times to exponential division for the *Cornell Box* and *Rungholt* scenes, but the rendering times for uniform division were higher than the exponential one for the *Bars* and *Sponza* scenes. In the case of the *Rungholt* scene

AVERAGE TIME [MS] OF FRAME RENDERING USING THE DESCRIBED ALGORITHM FOR FOUR DIFFERENT DEPTH DIVISIONS.

Test scene \ Cell count in depth	128 (screen-space)		256 (screen-space)		256 (view-space)	
<i>Cornell Box</i>	12.02	14.39	12.46	11.43		
<i>Bars</i>	40.97	39.78	20.03	26.23		
<i>Sponza</i>	99.44	106.25	60.14	73.66		
<i>Rungholt</i>	149.20	136.82	61.16	61.19		

Fig. 11. Rendering time of each frame for the *Cornell Box* test scene for the three depth division methods.

Fig. 12. Rendering time of each frame for the *Bars* test scene for the three depth division methods.

(Fig. 14), there were three parts of the test (at the beginning, in the middle and at the end), in which screen-space division resulted in significantly higher rendering times compared with the other methods. In these parts of the test, the camera was far from the scene geometry and a large area of the scene was visible.

Three methods of obtaining the list of cells filled with geometry were compared: using bitmaps, sorting and removing consecutive repeating elements, and removing consecutive repeating elements before sorting. These configurations were tested on the *Bars*, *Sponza* and *Rungholt* scenes. Fig. 15 shows the obtained results for the *Rungholt* scene. Table III shows

the averaged results for all the test scenes. In all cases the lowest average time was achieved using the bitmasks and the highest time was seen using the sorting-based method without removing the repeating elements beforehand.

A version of the algorithm in which the cells’ corner positions were precomputed was also compared with a version in which the positions were calculated each time they were used. These configurations were also tested on the *Bars*, *Sponza* and *Rungholt* scenes. For all of these scenes, precomputing the cells’ corner positions resulted in significantly lower average rendering times than calculating them every time. Fig. 16 shows the results for the *Sponza* scene. Results for all of the tested scenes are shown in Table IV.

The proposed algorithm was compared in terms of rendering time and memory occupancy with the clustered shading and the original hybrid lighting algorithms. The algorithms were compared using the *Sponza* and *Rungholt* scenes with a variable number of lights, with lights being placed on the scene’s geometry in the *Sponza* scene, and with groups of lights in the *Rungholt* scene. Two configurations of the hybrid algorithm and the octree-based modification were tested, differing in the number of tiles used to divide the rendered image: 30×17 and 60×34 . This resulted in tiles of 32×32 and 64×64 pixels respectively. In the case of the clustered shading algorithm, tile sizes of 16×16 and 32×32 pixels were used. Depth was divided using the exponential division method, and a configuration of the clustered shading algorithm without using normal vectors during cluster creation was chosen.

Figs. 17 and 18 show the average rendering times for each tested algorithm variant. The octree-based algorithm

	<i>Bars</i>	22.37	29.13	+30.2%	24.07	+7.6%
	<i>Sponza</i>	78.02	84.29	+8.0%	78.78	+1.0%
	<i>Rungholt</i>	63.32	70.66	+11.6%	64.55	+1.9%

TABLE IV

AVERAGE TIME [MS] OF FRAME RENDERING USING THE DESCRIBED ALGORITHM FOR TWO METHODS USED TO CALCULATE CELLS' CORNER POSITIONS.

Test scene	Cells' corner position calculation method	precomputing	calculating each time	
			calculating each time	
	<i>Bars</i>	22.37	26.56	+18.8%
	<i>Sponza</i>	78.02	95.66	+22.6%
	<i>Rungholt</i>	63.32	69.05	+9.1%

Fig. 16. Rendering time of each frame for the *Sponza* test scene depending on the method used to calculate the cells' corner positions.Fig. 17. Average rendering time of the *Sponza* scene depending on the total number of lights in the scene, for each tested algorithm. The tile size, in pixels, is written in parentheses.

wasn't tested for the *Sponza* scene for the light count above 30 000 because of a rapidly rising rendering time for the increasing number of lights. In both test scenes the octree-based algorithm with a tile size of 32×32 saw significantly higher (by 11% – 392%) rendering times than the rest of the algorithms. The configuration with tiles of size 64×64 pixels, for up to 5 000 lights for the *Sponza* scene and up to 90 000 for the *Rungholt* scene, achieved lower (by 16% – 17%) rendering times than both configurations of the clustered shading algo-

rithm. For higher numbers of lights, the octree-based algorithm was slower than the clustered shading algorithm by up to 131% for the *Sponza* scene and up to 75% for the *Rungholt* scene.

Figs. 19 and 20 show the average sum of lights on the lists of lights depending on the total number of lights in a scene. As each light can be assigned to more than one list, the sum of light list elements may be bigger than the number of lights in a scene.

Fig. 18. Average rendering time of the *Rungholt* scene depending on the total number of lights in the scene, for each tested algorithm. The tile size, in pixels, is written in parentheses.

On average, the lowest total number of light list elements was achieved in the case of the octree-based algorithm with a tile size of 64×64 pixels. For the *Sponza* scene, there were at least 65% fewer elements compared with the other two algorithms, and for the *Rungholt* scene – at least 23% fewer. In the case of the *Sponza* scene, the proposed method with tiles measuring 32×32 pixels resulted in a lower total number of list elements (by 30% – 40%) than in the case of the original, unmodified version of the hybrid lighting algorithm with tiles that were twice as big.

V. SUMMARY

The results obtained in the tests show that both the scene geometry and the lights’ distribution are important factors impacting the rendering time.

Using an octree to store the lists of lights allows for a significant reduction (up to 65%) in the number of elements on the lists compared with the other tested algorithms. This resulted in fewer list insertion operations that needed to be performed for each frame. However, additional checks performed in order to determine whether or not a light could be stored in an internal node resulted in an overall slower algorithm than the original version.

The approach of using billboards to approximate the lights’ positions and ranges resulted in many calculations that were repeated by multiple threads. As each billboard’s pixel is potentially processed by a different thread, each thread has to check if the light affects all nodes in a group independently of other threads. One idea for modifying the described algorithm

Fig. 19. Total number of light list elements averaged for all frames (*Sponza* scene) depending on the total number of lights in a scene, for each tested algorithm. The tile size, in pixels, is written in parentheses.

Fig. 20. Total number of light list elements averaged for all frames (*Rungholt* scene) depending on the total number of lights in a scene, for each tested algorithm. The tile size, in pixels, is written in parentheses.

is to adapt this method so that one light is processed entirely by a single thread.

Another modification that could result in shorter rendering times is to replace the sparse octree representation with full three-dimensional arrays, each representing one octree level. This modification would make it possible to read information about any node, without the necessity of tracing a path from the octree's root.

Another aspect of rendering scenes with many lights is accounting for multiple shadow sources. Shadow rendering poses a serious challenge, especially in the presence of many light sources, as both the rendering times [16] and shadow quality [17] have to be considered.

Encrypting JPEG-compressed Images by Substituting Huffman Code Words

Marek Parfieniuk

Abstract—This paper presents a method for encrypting JPEG-coded images that preserves both compression ratio and format of a bit stream. Such solutions allow for selectively hiding information: image contents can be encrypted, while in-file meta-data remain readable. Our algorithm is a symmetric, polygram substitution cipher, as it replaces Huffman code words and rearranges value bits that describe the main results of the Discrete Cosine Transform (DCT) of a pixel block: the DC coefficient and the first non-zero AC coefficient. Both length and format of a file are preserved, because bits are modified under constraints on their numbers. Such encryption is a kind of post-processing of a compressed bit stream, and thus it can be built on the top of an existing JPEG codec, without accessing its internals. Compared to previous similar solutions, our approach better hides image contours, exchanging AC for DC energy. Our work also reveals some properties of Huffman code tables and bit streams related to the JPEG standard.

I. INTRODUCTION

IN RECENT years, one can notice research efforts to combine the JPEG standard for image coding with data encryption [1]. Format-preserving approaches to joint encryption-compression are less efficient, more difficult to implement, and less secure than general-purpose ciphers. Nevertheless, they are useful, allowing for selective encryption, i.e. for protecting only a subset of information contained in a file [2].

In this paper, we propose a method for format-compliant encryption of JPEG files that is based on substituting and restructuring pairs of variable-length code words under constraints on the total number of bits in a pair. These modifications are made to only code words related to the main results of the Discrete Cosine Transform (DCT) and quantization: to the DC coefficient and to the first non-zero AC coefficient.

As a couple of data units is replaced in accordance with a cryptographic key, our solution is a polygram substitution cipher. Consisting in post-processing of encoding results, it can be built on the top of an existing JPEG codec, without accessing its internals.

Similar known approaches, [3]–[5], modify DC coefficients separately from AC ones. So they have little effects on image contours, unless coefficients are exchanged among blocks of 8×8 pixels. Our solution is able to exchange DC for AC energy of one image block, so as to better hide the latter, buffering the minimum number of bits.

This paper additionally reveals some new facts on the default Huffman dictionaries and on statistics of code words in JPEG bit streams.

II. ENTROPY CODING OF DCT COEFFICIENTS IN THE JPEG STANDARD

The JPEG standard specifies that an image to be compressed is divided into blocks of 8×8 pixels, and each block is converted into a vector of 64 coefficients, which then are entropy coded. The conversion consists in computing the 2-D DCT of the block, quantizing the resulting matrix, and taking quantized elements in the zig-zag order.

The first of 8×8 DCT outputs is called the DC (direct-current) coefficient, as it is the average value of all pixels of a block. The remaining 63 outputs are called AC (alternate-current) coefficients, because they reflect deviations from the average value, of various frequencies.

For two consecutive blocks of 8×8 pixels, the average pixel intensities, or the DC coefficients, often have similar values. Therefore, it is advantageous to encode the difference between them, by using two variable-length code words. The first one has a length of $2 \leq h_0 \leq 9$ bits and results from Huffman encoding of $0 \leq v_0 \leq 11$, the index of the value category that embraces the difference value. The second code word comprises v_0 bits which point out a particular value in the category. The first bit represents the sign of the difference, whereas the remaining bits determine its magnitude.

Table I lists the categories and Huffman code words used to encode DC coefficients. The lower magnitudes of the values that comprise a category, the fewer values in this category. So, a shorter the code word is assigned to its index, in order to achieve data compression.

A non-zero quantized AC coefficient is usually preceded by a series of zero-valued ones. Thus its value is encoded together with the number of the latter, by using two code words. For the k th non-zero coefficient, in the zig-zag order, the first word comprises $2 \leq h_k \leq 16$ bits and is obtained by Huffman encoding of the (r_k, v_k) pair, where $0 \leq r_k \leq 15$ is the number of the zero-valued AC coefficients that precede this non-zero one, and $1 \leq v_k \leq 10$ is the index of the category that embraces the value of this coefficient. The second word comprises v_k bits, which determine a value in the v_k th category. As zero-valued quantized AC coefficients often occur in long runs, and non-zero ones often have small magnitudes, compression can be achieved by assigning shorter words to (r_k, v_k) pairs that describe such occurrences.

Two special Huffman code words occur without value bits.

TABLE I
VALUE CATEGORIES AND HUFFMAN CODE WORDS FOR ENCODING DIFFERENCES BETWEEN DC COEFFICIENTS OF IMAGE LUMINANCE

v_0	Value range	Huffman code word	h_0
0	0	00	2
1	± 1	010	3
2	-3, -2, 2, 3	011	3
3	$\pm(4, \dots, 7)$	100	3
4	$\pm(8, \dots, 15)$	101	3
5	$\pm(16, \dots, 31)$	110	3
6	$\pm(32, \dots, 63)$	1110	4
7	$\pm(64, \dots, 127)$	11110	5
...
11	$\pm(1024, \dots, 2047)$	11111110	9

The EOB (End-of-Block) word is placed after the codes of the last non-zero AC coefficient, so as to tell that the remaining ones are zero. The ZRL (Zero-run-length) word represents a series of 16 zero AC coefficients between non-zero ones.

III. ENCRYPTING JPEG BIT STREAMS BY SUBSTITUTING HUFFMAN CODE WORDS

A. Substitution idea and constraints

Polygram substitution ciphers replace several symbols of a text with the same number of other letters. Following this idea, we have shown in [6] that Huffman-encoded data can be encrypted by substituting pairs of code words. Herein, we adapt this approach to JPEG bit streams, in which Huffman code words are interleaved with value bits, and thus they need to be substituted somewhat tricky. Moreover, it is pointless to modify all code words, as the contents of an image is described primarily by the main quantized coefficients of the DCT of an 8×8 pixel block: the DC one and the first non-zero AC one.

So, we propose to encrypt JPEG-encoded images by processing them block-by-block, by substituting Huffman code words that describe categories of the aforementioned coefficients and by moving bits between the code words that describe coefficient values. As the cipher should not enlarge files, we allow only such substitutions that

$$\underline{h}_0 + \underline{h}_1 = h_0 + h_1 \quad \text{and} \quad \underline{v}_0 + \underline{v}_1 = v_0 + v_1 \quad (1)$$

where underlines denote the lengths of code words that replace the original ones. These constraints ensure that a substitution changes neither the total length of Huffman code words nor the total number of value bits, $\underline{h}_0 + \underline{h}_1 + \underline{v}_0 + \underline{v}_1 = v_0 + v_1 + h_0 + h_1$.

The constraints can be explained by using Table II. It lists 12-bit, equal-length combinations of DC- and AC-related code words and value bits. The combinations have been grouped with respect to the total number of the value bits, $v_0 + v_1$. A combination can be substituted for each other of the same group, but not for one of another group.

B. Encryption procedure

Both encryption and decryption of our cipher can be explained by using the data flow shown in Fig. 1.

Assuming that the method is applied to an existing JPEG bit stream, the first step is to scan the stream in order to determine the Huffman code words and value bits that describe the DC and AC coefficients of interest of a subsequent block of 8×8

TABLE II
ALL 12-BIT COMBINATIONS OF DC- AND (AFTER "-") AC-RELATED HUFFMAN CODE WORDS AND VALUE BITS (DENOTED AS "x", BEING 0 OR 1), GROUPED WITH RESPECT TO THE TOTAL NUMBER OF VALUE BITS

DC-AC code words	h_0	h_0	v_0	v_1	r_1	$v_0 + v_1$	$h_0 + h_1$
00-111111000x	2	9	0	1	8	1	11
00-111111001x	2	9	0	1	9		
00-111111010x	2	9	0	1	10		
00-11111001xx	2	8	0	2	2	2	10
010x-1111010x	3	7	1	1	5		
010x-1111011x	3	7	1	1	6		
00-1111001xxx	2	7	0	3	1		
011xx-111010x	3	6	2	1	3	3	9
011xx-111011x	3	6	2	1	4		
011xx-11011xx	3	5	2	2	1	4	8
100xxx-11100x	3	5	3	1	2		
00-11010xxxxx	2	5	0	5	0		
011xx-1011xxx	3	4	2	3	0	5	7
101xxxx-1100x	3	4	4	1	1		

pixels. If the method has to be integrated with a JPEG encoder, than it can be applied to quantized coefficients before forming a bit stream. Knowing the code words, or coefficient values, one can determine $(h_1 + h_0)$ and $(v_1 + v_0)$ and decide whether substitution is possible. If so, then these bit counts point out the group of $N \geq 2$ pairs of code words that can be exchanged for each other in accordance with (1).

Let us assume that the members of the substitute group are ordered, so that they form an array and can be indexed by the numbers from 0 to $(N - 1)$. If i_{original} is the index of the pair of original code words, than by adding (modulo N) a pseudorandom offset we obtain the index of a substitute pair:

$$i_{\text{substitute}} = \text{mod}(i_{\text{original}} + \text{randi}(N), N) \quad (2)$$

The "mod" function gives the remainder after division, and is used to ensure that $0 \leq i_{\text{substitute}} < N$, like i_{original} . The "randi" produces a pseudorandom integer from the discrete uniform distribution over $[1, N]$. This function is assumed to use a pseudorandom number generator whose output can be controlled by using the cryptographic key as the seed.

The Huffman code words determined by $i_{\text{substitute}}$ are submitted to the output (encrypted) bit stream, followed by the original value bits, rearranged in accordance with \underline{v}_0 and \underline{v}_1 that match the substitutes. The cipher does not affect bits that describe the rest of AC coefficients of the given pixel block.

C. Decryption procedure

By detecting and analysing a pair of DC- and AC-related code words of the encrypted bit stream, one can determine the substitute group and $i_{\text{substitute}}$. The original code words are pointed by the inverse of (2)

$$i_{\text{original}} = \text{mod}(i_{\text{substitute}} - \text{randi}(N), N) \quad (3)$$

provided that, at both encryption and decryption sides of a flow of JPEG-compressed pictures, (i) members of a substitute group are ordered in the same way, (ii) the same cryptographic key is used as the seed of the pseudorandom generator behind the "randi" function, when the processing of a bit stream starts, and (iii) 8×8 pixel blocks are processed in the same order.

Obviously, in addition to recovering the Huffman code words, it is necessary to accordingly rearrange the value bits.

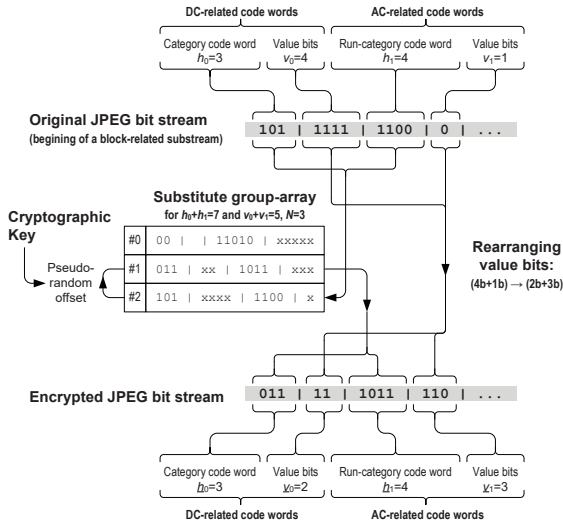

Fig. 1. Encryption of JPEG bit streams by length-constrained substitution of Huffman code words and rearrangement of value bits.

IV. SUBSTITUTION LIMITATIONS

For most images and quality settings, code words can be substituted sufficiently often to make it impossible to recover a readable, quality image from an encrypted bit stream, without knowing the cryptographic key. However, when an image is encoded with low-quality settings, pixel blocks might occur to which the proposed cipher cannot be applied. The default Huffman dictionaries determine not so many pairs of code words that have no substitutes, but the majority of the replaceable combinations of bits occur only occasionally when compressing natural images.

A. Substitution limitations by Huffman code tables

The JPEG standard specifies the default dictionaries of Huffman code words. The tables for luminance contain 12 words for encoding differences between DC coefficients and 161 words for encoding AC coefficients. These words can be combined into $12 \times 161 = 1932$ DC-AC pairs, which can be grouped with respect to both the total length of Huffman code words and the total number of the value bits that must accompany them. If a resulting group comprises two or more pairs of code words, then these DC-AC pairs can be substituted for each other in accordance with (1).

The sizes of the groups can be visualized by colors as in Fig. 2. The bit numbers related to the axes determine a group, and are coordinates of the small square whose color reflects the number of pairs in this group, in accordance with the legend.

Groups exist such that a pair of code words has as many as several dozen of substitutes. But some groups comprise only one combination of Huffman code words, which cannot be substituted. The great majority of the pairs, 1892 (98%) of them, have at least one potential substitute.

Table III lists the DC-AC pairs of code words that cannot be substituted. Moreover, the cipher cannot be applied to blocks for which all quantized AC coefficients are zero, i.e. when the DC-related bits are followed by the EOB special code word.

Fig. 2. Numbers of DC-AC pairs of default code words that can be substituted in accordance with (1).

TABLE III
PAIRS OF DC- AND (AFTER "-") AC-RELATED DEFAULT CODE WORDS THAT CANNOT BE SUBSTITUTED IN ACCORDANCE WITH (1)

#	DC- and AC-related code words and value bits (denoted as "x")	h_0	v_0	h_1	v_1	r_1	$h_0 + h_1$	$v_0 + v_1$	$h_0 + v_0 + h_1 + v_1$
1	00-00x	2	0	2	1	0	4	1	5
2	00-01xx	2	0	2	2	0	4	2	6
3	010x-00x	3	1	1	2	0	5	2	7
4	011xx-1100x	3	2	4	1	1	7	3	10
5	100xxx-1100x	3	3	4	1	1	7	4	11
6	011xx-100xxx	3	2	3	3	0	6	5	11
7	100xxx-100xxx	3	3	3	3	0	6	6	12
8	110xxxx-01xx	3	5	2	2	0	5	7	12
9	100xxx-1011xxxx	3	3	4	4	0	7	7	14
10	100xxx-11010xxxx	3	3	5	5	0	8	8	16

12	101xxxx-1111000xxxxxx	3	4	7	6	0	10	10	20

B. Substitution limitations by image contents

The essence of the JPEG standard lays in the adjustment of entropy codes to statistics of quantized DCT coefficients of an average, natural image. By lowering the quality settings, one quantizes DCT coefficients more roughly, and thus decreases differences between DC coefficients, increases the number and seriality of zero-valued AC coefficients, and decreases magnitudes of non-zero ones. The reconstructed image looks worse, but it is described by a shorter bit stream.

Shortening of code words results in an increased probability that they cannot be replaced in accordance with our cipher. Moreover, it decreases the number of substitutes, when code words can be replaced. Both these issues can be explained by using Table IV and Fig. 3, which show properties of bit streams that result from JPEG-encoding of the Lena image for various quality settings.

In Table IV, one can see that decreasing quality increases the number of pixel blocks which are described by only DC-related bits, followed by the EOB code word, so that our cipher cannot be applied. Such situations do not occur for higher-quality settings, $Q > 75\%$, but become frequent for $Q < 50\%$.

In Fig. 3, the color of a small square shows how many blocks of an image are described by code words and value bits, whose lengths and numbers, respectively, are given by the coordinates of the square. When the quality is decreased, the distribution of code words shifts toward the origin: shorter ones occur more frequently, while longer ones disappear.

The problem becomes clear after comparing the plots in Fig. 3 to that in Fig. 2. The former overlap little with the

Fig. 3. Occurrence frequencies of DC-AC pairs of code words for the Lena image (512×512 pixels).

TABLE IV
PROPERTIES OF JPEG BIT STREAMS OF THE LENA IMAGE

Quality [%]	Ratio [bpp]	PSNR [dB]	Percentage of blocks with the DC coefficient followed by N nonzero AC coefficients [%]				
			$N = 0$	$N = 1$	$N = 2$	$N = 3$	$N \geq 4$
100	4.93	47.34	0	0	0	0	100
90	1.78	39.92	0	0	0	0.02	99.98
75	0.98	37.40	0.29	1.46	4.27	6.98	86.98
50	0.63	35.55	6.22	11.49	13.62	10.88	57.76
25	0.43	33.57	22.31	19.11	13.28	8.10	37.18

TABLE V
PERCENTAGES OF 8×8 PIXEL BLOCKS FOR WHICH THE DC-AC CODE WORDS CAN BE SUBSTITUTED IN ACCORDANCE WITH OUR CIPHER

Quality [%]	Lena	Baboon	Barbara	Boat
	Percentage of blocks [%]			
100	84.49	88.84	85.81	84.17
90	84.47	88.33	85.37	78.83
75	81.98	80.85	80.46	71.02
50	69.60	73.04	69.82	55.93
25	51.63	68.60	57.39	43.77

latter even for higher-quality compression. For lower-quality settings, the overlap is even smaller, and, what is even worse, it occurs at the region, in Fig. 2, that is related to code words that cannot be substituted or belong to substitute groups that comprise very few pairs of code words.

So, in order to evaluate the probability that our cipher can be applied to a pixel block of a given image, for given quality settings, one should determine the corresponding data distributions like those illustrated in Fig. 3 and combine it with that that is shown in Fig. 2.

Table V shows summaries of such evaluations for several well-known test images. In particular, it lists the percentages of 8×8 blocks to which our cipher can be applied. They are satisfactory: for reasonable quality settings, our cipher is able to modify considerable areas of an image.

A related measure of security is the average number of substitutes per block. For these images, it varies from 1.3–1.9 to 2.9–3.0, for quality settings from 25% to 100%, respectively. By raising these numbers to the power of the number of blocks in an image, one can estimate the number of substitution combinations that must be reviewed in a brute force attack on our cipher. Obviously, it is virtually impossible to recover a quality image, without knowing the secret key.

V. CIPHER EVALUATION

A. Conceptual contribution

Our idea is related to encrypting data by altering Huffman tables in accordance with a cryptographic key [7], [8]. However, we noticed no similar solutions, which would be based on modifying both Huffman code words and value bits, of DC and AC DCT coefficients. In most works, AC- and DC-related code words are transformed independently, so encryption-related changes to the bit stream are less deep than in our cipher, unless coefficients are exchanged among blocks of 8×8 pixels, which requires complicated data buffering.

By modifying together DC and AC coefficients of one pixel block, our method is able to more affect the latter, or image contours, without referring to other blocks.

A value of our works is also in providing arguments to question the claims of [9], in which Huffman coding has been evaluated as being unsuitable to encryption aimed at format compliance and file size preservation.

B. Cipher manifestation in images and its strength

Figure 4 shows the Lena test image, and results of straightforward (without decryption) decoding of a corresponding JPEG bit stream that had been encrypted using our method. The reconstructed image is unreadable, mainly because of rapid changes in average intensity of pixel blocks.

Unfortunately, an attacker can easily retrieve contours of images from encrypted files. It is sufficient to only set all DC coefficients to zero, and then to decode a picture without care about decryption. Fig. 5 shows results of such decoding of the Lena image from original and encrypted bit streams. Even though edges are reconstructed incorrectly, they appear in correct blocks, forming contours.

This weakness is not specific for our cipher. It characterizes virtually all JPEG-compliant and file-size-preserving approaches to joint compression-encryption, being related to the JPEG coding principle of processing images block-by-block. A cipher cannot modify the contour location without moving information from block to block. So most publications about extending JPEG coding with encryption describe some method of exchanging pixels or (encoded) DCT coefficients among blocks [3], [5]. They destroy contours but at the costs of buffering an entire image and of increasing file size. Our solution could as well be combined with such a method.

Fig. 4. Lena image and corresponding picture decoded without taking into consideration that JPEG bit streams have been encrypted.

Fig. 5. Non-DC contents of the Lena images: original and decoded without taking into consideration that JPEG bit streams have been encrypted.

C. Inconsistencies in DC and AC coefficients

Our cipher might produce files that are logically inconsistent. In Fig. 4, artifacts result mainly from that encrypted code words might describe differences that sum up to values of the DC coefficient that are outside the allowed range $\pm 2^{11}$, for luminance. A decoder silently converts an incorrect value into a number in the range, by overflow, or saturation.

The issue is known, and some methods have been proposed to handle it [3], [10], but they are based on simultaneously processing many blocks of 8×8 pixels. The problem seems to be neglected in some works, in which DC-related Huffman code words are left untouched, and only value bits are modified simply, by pseudorandomly changing only value sign or by XOR-ing more bits with pseudorandom patterns [11], [12].

In most of works that modify the DC coefficient, the file size is not preserved [13]–[15].

A related problem is that encrypted AC code words might describe so long runs of zero-valued AC coefficients, that the 64-element vector is too short to put all coefficients into it. We noticed no publications which would discuss this, even though the issue can be caused by some known ciphers, like those of [4] and [16] that shuffle AC-related code words inside a block and among blocks, respectively.

D. Computational load and memory consumption

Considerable computations or memory are necessary to determine substitutes of code words. A slower but memory-efficient approach is to determine a substitute on-the-fly, by scanning Huffman tables provided by a JPEG codec. Alternatively, an array of arrays can be prepared that stores information about substitute groups. It would occupy an additional

memory much larger than that of the Huffman dictionary, but substitutions could be realized quickly by using $(h_1 + h_0)$ or $(v_1 + v_0)$ as an index into the array of code-word groups.

VI. CONCLUSION

From the point of view of practice, our cipher rather only slightly outperforms the known approaches to combining JPEG compression with encryption. However, it can be evaluated as conceptually subtle and sophisticated, being based on nuances related to JPEG Huffman dictionaries of code words and to distributions of quantized DCT coefficients. To the best of our knowledge, this is the first paper that demonstrates and analyses these nuances, via unique plots and tables.

12th Workshop on Scalable Computing

THE world of large-scale computing continuously evolves. The most recent addition to the mix comes from numerous data streams that materialize from exploding number of cheap sensors installed “everywhere”, on the one hand, and ability to capture and study events with systematically increasing granularity, on the other. To address the needs for scaling computational and storage infrastructures, concepts like: edge, fog and dew computing emerged.

Novel issues involved in “pushing computing away from the center” did not replace open questions that existed in the context of grid and cloud computing. Rather, they added new dimensions of complexity and resulted in the need of addressing scalability across more and more complex ecosystems consisting of individual sensors and micro-computers (e.g. Raspberry PI based systems) as well as supercomputers available within the Cloud (e.g. Cray computers facilitated within the MS Azure Cloud).

Addressing research questions that arise in individual “parts” as well as across the ecosystem viewed from a holistic perspective, with scalability as the main focus is the goal of the Workshop on Scalable Computing. In this context, the following topics are of special interest (however, this list is not exhaustive).

TOPICS

- General issues in scalable computing
 - Algorithms and programming models for large-scale applications, simulations and systems
 - Large-scale symbolic, numeric, data-intensive, graph-oriented, distributed computations
 - Fault-tolerant and consensus techniques for large-scale computing
 - Resilient large-scale computing
 - Data models for large-scale applications, simulations and systems
 - Large-scale distributed databases
 - Load-balancing / intelligent resource management in large-scale applications, simulations and systems
 - Performance analysis, evaluation, optimization and prediction
 - Scientific workflow scheduling
 - Data visualization
 - On-demand computing
 - Virtualization supporting computations
 - Volunteer computing
 - Scaling applications from small-scale to exa-scale (and back)
 - Big data real-time computing / analytics

- Economic, business and ROI models for large-scale applications
- Emerging technologies for scalable computing
 - Cloud / Fog / Dew computing architectures, models, algorithms and applications
 - High performance computing in Cloud / Fog / Dew
 - Green computing in Cloud / Fog / Dew
 - Performance, capacity management and monitoring of Cloud / Fog / Dew configuration
 - Cloud / Fog / Dew application scalability and availability
 - Big Data cloud services
 - Architectures for large-scale computations (GPUs, accelerators, quantum systems, federated systems, etc.)
 - Self* and autonomous computational / storage systems

TECHNICAL SESSION CHAIRS

Khaos: Dynamically Optimizing Checkpointing for Dependable Distributed Stream Processing

Morgan K. Geldenhuys*, Benjamin J. J. Pfister*, Dominik Scheinert*, Lauritz Thamsen[‡], and Odej Kao*
 Technische Universität Berlin, Germany, {firstname.lastname}@tu-berlin.de
[‡] University of Glasgow, United Kingdom, lauritz.thamsen@glasgow.ac.uk

Abstract—Distributed Stream Processing systems are becoming an increasingly essential part of Big Data processing platforms as users grow ever more reliant on their ability to provide fast access to new results. As such, making timely decisions based on these results is dependent on a system’s ability to tolerate failure. Typically, these systems achieve fault tolerance and the ability to recover automatically from partial failures by implementing checkpoint and rollback recovery. However, owing to the statistical probability of partial failures occurring in these distributed environments and the variability of workloads upon which jobs are expected to operate, static configurations will often not meet Quality of Service constraints with low overhead.

In this paper we present Khaos, a new approach which utilizes the parallel processing capabilities of cloud orchestration technologies for the automatic runtime optimization of fault tolerance configurations in Distributed Stream Processing jobs. Our approach employs three subsequent phases which borrows from the principles of Chaos Engineering: establish the steady-state processing conditions, conduct experiments to better understand how the system performs under failure, and use this knowledge to continuously minimize Quality of Service violations. We implemented Khaos prototypically together with Apache Flink and demonstrate its usefulness experimentally.

Index Terms—Distributed Stream Processing, Chaos Engineering, Quality of Service, Cloud, Parallel Profiling, QoS Modeling, Runtime Optimization

I. INTRODUCTION

WITH the growing necessity to quickly process large volumes of unbounded data, Distributed Stream Processing (DSP) systems are becoming an increasingly essential part of data processing environments. It is here where events must traverse a graph of streaming operators to allow for the extraction of results, which are at their most valuable closest to the time of data arrival. Data streams are continuously generated in a variety of contexts such as sensors in IoT network, network monitoring, financial fraud detection, click stream analytics, spam filtering, and social media [1], [2]. DSP systems are not only required to offer near to real-time processing latencies at high throughput rates, but also to recover from the various types of failures that inevitably occur in these environments.

DSP jobs are, in principle, required to operate indefinitely on unbounded streams of continuous data and exhibit heterogeneous modes of failure as they continue to run over long periods of time [3]. Consequently, DSP systems such as Apache Storm [4], Apache Spark [5], or Apache Flink [6] feature high availability modes and fault tolerance mechanisms that allow for results to be consistent in the presence of

partial failures. However, the complexity with which these systems are composed makes estimating how a system will perform through manual manipulation of the configuration sets a hard problem to solve. This is complicated by the fact that DSP jobs operating in an environment where streaming workloads change over time will make any static configuration selections obsolete in short order. This is especially relevant when considering critical jobs where the presence of Quality of Service (QoS) constraints dictate the minimum level of performance that is to be expected. It is therefore essential when optimizing the fault tolerance mechanism of DSP jobs to not only understand how configuration impacts upon recovery times as well as end-to-end processing latencies, but to ensure that the system is capable of reacting to changing workloads.

Checkpointing mechanisms are among the most popular and effective techniques for achieving fault tolerance in real world processing systems and consequently a number of methods for auto-configuration of checkpointing have been proposed. Most of them try to optimize the checkpoint interval by means of predicting or utilizing failure rates [7], the Mean Time To Failure (MTTF) [8]–[10], or recovery times [11], whereas some approaches even employ advanced multi-level checkpointing [12]–[17]. Yet, the majority of such methods either assume static workloads, consider solely offline optimization, or are primarily designed for high-performance computing (HPC) environments, which renders them not suitable for real-world DSP systems. Therefore, a workload-adaptive DSP configuration optimization approach, paired with a systematically attempt to evaluating DSP failure recovery performance executing in production-like environments, is needed.

In this paper we present Khaos, a novel approach for the automatic runtime optimization of DSP fault tolerance configurations. Borrowing from the principles of Chaos Engineering [18], Khaos achieves this by executing a three phase plan: Firstly, establishing the steady-state by recording and then analyzing the streaming workload of a targeted DSP job to identify interesting points for failure injection; Secondly, by taking advantage of container orchestration cloud technologies to replicate multiple pipelines in parallel where the workload is replayed, and then utilizing fine-grained failure injection together with an anomaly detector trained on normal pipeline executions to measure recovery times across a range of configuration settings and throughput rates; and thirdly, by taking the information gathered during profiling to train analytical models to monitor for when recovery times and latencies

would exceed user-defined QoS constraints and automatically optimize for better fault tolerance configurations at runtime. To determine if violations should be acted upon immediately or deferred for later, Khaos makes use of Time Series Forecasting (TSF) to predict future workloads. Khaos is applicable for users willing to initially accept an increased level of resource utilization to ensure optimized execution over the longer term.

The remainder of the paper is structured as follows: Section II explores the related work regarding DSP systems and their fault tolerance mechanisms as well as adaptive checkpointing schemes. Section III presents our approach to automatically optimizing the fault tolerance mechanism of targeted DSP jobs operating on variable workloads; Section IV describes our evaluation through performing two experiments; and Section V summarizes our findings.

II. RELATED WORK

In this section we examine how fault tolerance is handled in three popular DSP systems as well as work most related to our own, aimed at adaptive checkpointing and failure injection.

A. Distributed Stream Processing Systems

In DSP, checkpointing is the most popular fault tolerance mechanism for real world systems. One of the first widely used large-scale DSP systems is Apache Storm [4], which guarantees that in the event of failure, messages are re-processed by using a mechanism of upstream operator backup and message acknowledgements. Although such a mechanism does guarantee messages are processed at least once, it also results in duplicate messages passing through the system and, therefore, falls short of the exactly-once processing guarantees needed by many modern DSP jobs.

Apache Spark Streaming [5], on the other hand, is designed around the idea of micro-batching where messages are grouped together in an attempt to overcome the overhead caused by message-level synchronization. Here, micro-batches either succeed or are recomputed when failures occur. It uses periodic checkpointing to truncate the RDD lineage graph and save both metadata and data to reliable storage. This technique allows for exactly-once processing of messages.

Apache Flink [6] is a well-known DSP system, which likewise provides exactly-once processing guarantees through periodically creating and saving a distributed snapshot of the global state [19]. It achieves this by passing streaming barriers through the execution graph from source to sink operators. At the arrival of a barrier, each operator performs a checkpoint of the local state and then passes the barrier on to all output edges. A checkpoint is considered complete when all operators have completed their individual checkpoints.

B. Adaptive Checkpointing

A number of approaches have been proposed that optimize the fault tolerance configuration parameters by finding an optimal checkpoint interval (CI) to improve performance. Our previous work [11] focused on predicting recovery times

and then optimizing the CI with regards to a single user-defined QoS constraint. However, this approach is aimed at scenarios where jobs process a static workload, i.e. throughput does not change over time. In the closely related area of research, we published an approach which uses *times series forecasting* to optimize the resource utilization of DSP jobs executing in environments where the workload is expected to change over time [20]. A group of approaches focuses on determining the mean time to failure (MTTF) of cluster nodes and then adaptively fitting a CI that minimizes the time lost due to failure [8]–[10]. These approaches, however, are more appropriate to high-performance computing (HPC) clusters and batch processing jobs as they rely on jobs having a finite execution time as part of their calculations. Specific to DSP systems, [7] incorporates failure rates in an attempt to fit the CI based on the MTTF. However, unlike Khaos, optimizations are not performed at runtime and therefore dynamic workloads are not taken into account. Additionally, it does not incorporate the total time needed to recover to processing events at the latest timestamp nor consider any user-defined QoS constraints for its optimization step.

Other approaches have been proposed using multi-level checkpointing schemes to resolve the issue of checkpoint/recovery overhead [12]–[17]. Different checkpointing levels are used, which in turn are more flexible than traditional single-level schemes as it can consider multiple-failure types with each having a different checkpoint/recovery cost associated. Likewise, differing checkpoint levels can be associated with different storage types, which is usually not possible with single-level checkpoints. In [21], a two-level checkpointing model is proposed: checkpoint level 1 deals with errors with low checkpoint/recovery overheads such as transient memory errors, and checkpoint level 2 deals with hardware crashes such as node failures. These approaches are specific to HPC environments and need adaption before vendors can consider implementing them in DSP systems.

C. Failure injection

Here we present approaches which use failure injection as a means of gaining a greater insight into how systems perform when things go wrong. Failure injection for distributed systems is realized in [22] using virtualization at a low level. Both machines and networks are virtualized, and a failure injection is performed by uncontrolled shutdown of machines. The authors whole approach is accurately described as an emulation platform. In contrast, Khaos utilizes modern container orchestration technologies for deploying DSP pipelines and thus eases the emulation furthermore. In another work, fault injection is used in [23] to assess the effectiveness of partial fault tolerance techniques in DSP applications. The authors identify four metrics that can be used to evaluate the impact of faults in different stream operators with respect to predictability and availability. To reduce the number of required fault injection targets when evaluating a target application, their framework pre-analyzes the data flow graph. An approach that combines fault injection and data analytics is motivated in [24]. Here,

a database of failures is populated during a profiling phase, and queried during execution of production DSP jobs. The database is specifically used to help identify root causes of failures observed by providing injected faults that generated similar processing flows.

Netflix injects failures into its production system using its Chaos Automation Platform (ChAP) and Failure Injection Testing (FIT) tools [25]. ChAP performs Chaos experiments on a small, randomly selected percentage of live traffic. ChAP deploys two scaled-down clusters of the Netflix service, one to serve as the performance baseline, the other to serve as a canary group. FIT injects either error responses or increases latency to simulate failure scenarios [26] for the canary group and the results are compared against the baseline. Results of the Chaos experiment are evaluated by performing anomaly comparisons to detect statistically significant deviations between the normal state and Chaos experiment [25].

III. APPROACH

This section describes in detail the various phases of our approach Khaos, right after a general overview.

A. Idea Overview

The configuration of a fault tolerance mechanism has a direct impact both on the performance and availability of any running DSP job. Khaos borrows from the principles of Chaos Engineering and takes advantage of the massively parallelizable capabilities of container orchestration cloud technologies to provide an automated runtime approach for tuning the fault tolerance configuration of targeted DSP jobs. It achieves this by first conducting parallel profiling runs where failures are injected into short-lived profiling jobs, each testing a variation of the configurations, and gathering metrics related to the latencies and recovery times. These results are then used to train two multivariate runtime models that, when combined, provide a mechanism whereby user-defined performance and availability constraints are monitored for violations. Should this occur, the system can be automatically reconfigured to provide the best trade-off between constraints.

The cost of reconfiguration should likewise be taken into account, as it requires a full restart of the job with several current DSP implementations, albeit without having to reprocess any messages that might have accumulated during the downtime. This is because controlled restarts perform a system save immediately before making the change and therefore no consumer lag can build up. In order to do this we make use of TSF to determine if a reconfiguration should be performed at the current point in time, or if the decision can be deferred to the next optimization cycle. The logic behind this is that if the workload is expected to decrease substantially, then a reconfiguration is not necessary. Overall, such an optimization approach is imperative when operating in an environment where the workload changes dynamically over time and any static configurations are essentially made obsolete immediately. In order to achieve this, our approach is subdivided into

three distinct phases that are executed sequentially. Next we describe each of these phases and provide formal definitions.

B. Phase 1: Establishing the Steady State

The first phase focuses on capturing and establishing the steady state that describes job performance under failure-free conditions. A graphical overview of this phase can be seen in Figure 1(a). Consider a production-level DSP job a user would like to have adaptively optimized. The job is executing in a containerized environment, consuming a variable workload from a streaming platform, and metrics are gathered in a time series database. On initialization, Khaos connects to the streaming platform and begins recording the incoming event stream. It does this for a finite amount of time k as defined by the user and ideally should contain the maximum range of throughput rates as expected under normal processing loads across that period. For best results, DSP jobs processing a stationary data stream would best fit our approach. When considering any single timestamp t_i within this recording period, we can define the set of arriving events as $E^{(t_i)} = \{e_1^{(t_i)}, e_2^{(t_i)}, \dots, e_{n-1}^{(t_i)}, e_n^{(t_i)}\}$, where n denotes the number of arriving events in that timestamp. Consequently, the full set D of events arriving across all timestamps during the recording period is defined as

$$D = \{E^{(t_1)}, E^{(t_2)}, \dots, E^{(t_{k-1})}, E^{(t_k)}\}. \quad (1)$$

As Khaos is concerned with injecting failures into a running system to gain an understanding of how recovery times differ across various configurations, it needs to select a set of points over the full range of observed throughput rates where failures can be injected when the dataset is replayed. Therefore, a continuous function W of time t is extracted from D representing the workload over time and is defined by

$$W(t) = |E^{(t)}| \quad (2)$$

This function is analyzed to find a set of equidistantly spaced throughput rates between the minimum and maximum observed workloads and their corresponding timestamp values. Importantly an averaging window is used to smooth the workload function and remove outliers. Formally, we identify

$$\begin{aligned} t_{\min} &= \arg \min_{0 \leq j \leq k} W(j) \\ t_{\max} &= \arg \max_{0 \leq j \leq k} W(j) \end{aligned} \quad (3)$$

as the points in time with minimum and maximum workload. Subsequently, we find m equidistant points and arrive at a set F of timestamps representing the *failure points*, i.e.

$$\begin{aligned} F &= \{t_{\min}, t_{\min+h}, \dots, t_{\max-h}, t_{\max}\}, \\ h &= (t_{\max} - t_{\min}) / (m - 1). \end{aligned} \quad (4)$$

Since F is a set of timestamps, the corresponding set of throughput rates TR can be defined as

$$TR = \{W(f) | f \in F\}. \quad (5)$$

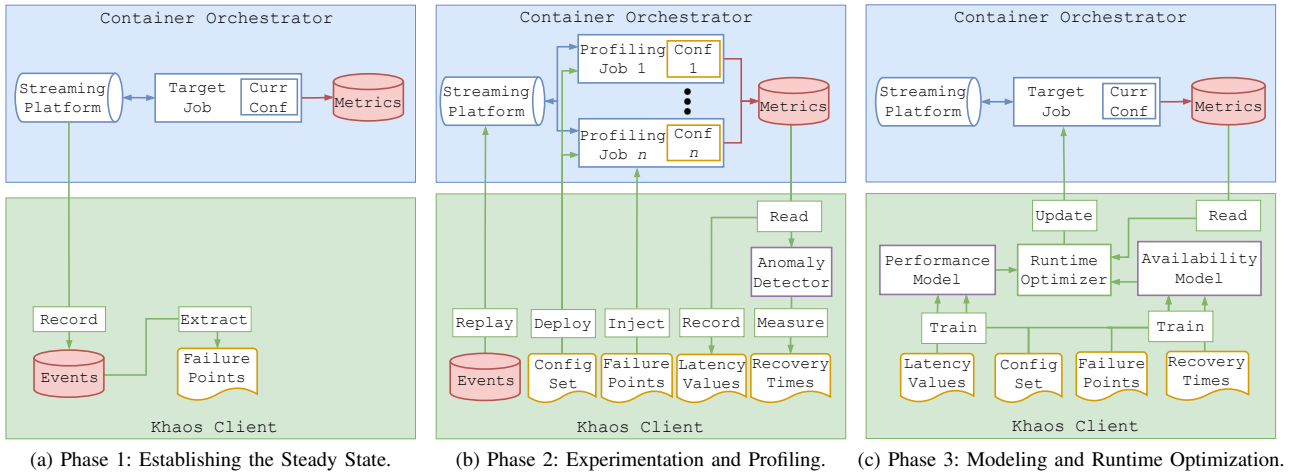

Fig. 1: Overview of Khaos.

On the conclusion of phase 1, the steady state of the production DSP job has been explored and the dataset D , failure points F and corresponding throughput rates TR are available for use in the next phase.

C. Phase 2: Experimentation and Profiling

The second phase focuses on performing experiments in an environment that is as similar as possible to production with the goal of gathering metrics data using the same DSP job but executed across a closed range of configuration settings. In order to do so we take advantage of container orchestration cloud technologies to rapidly replicate multiple profiling pipelines in parallel, record their operational latencies under differing throughput rates, and then use fine-grained failure injection together with an anomaly detector A to measure recovery times. Figure 1(b) provides a graphical overview of this phase and illustrates the interactions between components.

Concerning configuration of the fault tolerance mechanism, we are most concerned with the checkpoint interval, defined as the frequency with which the checkpoint process is initiated. It is by varying the CI that we are able to configure the fault tolerance mechanism, where higher values represent possible longer recovery times and, conversely, lower values represent faster recovery times. Varying the checkpoint interval will have an impact on both the overall performance and availability of the system. For the CI, we seek to investigate a range of z equidistantly spaced values given a minimum value and a maximum value. We effectively obtain a set of concrete configurations C with $z = |C|$ analogue to the procedure for F . Thus, we can test all configurations in C at the same time, i.e. arriving at as many deployments as configuration values.

After the parallel profiling jobs have been instantiated, each timestamp in the failure points F is registered with a built-in failure injector. This is so that when the timestamp, and therefore the associated throughput rate, is realized, Khaos will inject a failure concurrently into each one of the parallel deployments. Once this has been completed, Khaos will begin

replaying the dataset D at the same rate at which it was recorded. All parallel profiling jobs will read from the same source to which the data is being replayed. It is important to note that this is a separate messaging queue to the one being consumed by the production job. At the point before injecting the failure, an average latency measurement is taken for each of the parallel deployments forming the set L with

$$L = \{l_i^{(j)} | 1 \leq i \leq m, 1 \leq j \leq z\}, \quad (6)$$

where $l_i^{(j)}$ is the average latency measurement corresponding to the i -th failure injection into the j -th deployment. Although the full recorded dataset can be replayed, to reduce resource utilization during profiling, the user can specify a time interval where events just prior to and after the points of failure injection can be replayed thus limiting time spent in this phase. At the same time, performance metrics are gathered across all parallel deployments in order to measure recovery times. The metrics we are most concerned with include:

- **Input Throughput:** Measured in events per second, this value represents the sum of the events entering the source operators of the DSP job per second.
- **Average Consumer Lag:** Measured in number of events, this value represents the number of events accumulated in the messaging queue waiting to be consumed by the source operators of the DSP job.

In order to measure how long it takes for the DSP job to recover after experiencing a failure, the aforementioned metrics are used to train an anomaly detection algorithm on positive executions, i.e. let the function $s : X \rightarrow X$ perfectly represent the metrics data stream such that for any given data point $x \in X$ the prediction is always $s(x) = x$. Assuming most data collected in the recording period is normal, the algorithm can learn to detect deviations from the expected normal behaviors and therefore will report an anomalous behavior if a configurable threshold based on a window of

past errors is hit. Measuring the length of time the system was in an anomalous state is therefore equivalent to the recovery time. In order to accomplish this, we utilize an online ARIMA method motivated in [27] for our implementation.

It is important to note that in this context, the recovery time is not only referring to the time the system is in an inconsistent state before processing resumes. For systems employing checkpoint and rollback recovery strategies, processing will start at a previous saved offset and then attempt to catch up to the latest offset, all while new events are continuously arriving. It is this length of time, from when the failure occurs to the point at which processing is once again producing results at the latest offset, that we are interested in measuring, as it is a more accurate reflection of availability. Thus, we define the set of recovery times as measured by the anomaly detector as

$$R = \{r_i^{(j)} | 1 \leq i \leq m, 1 \leq j \leq z\}. \quad (7)$$

Consequently, the lengths of the observed recovery times in R are influenced by two main factors: the variable nature of the workload, i.e. the changing number of messages arriving per second over time; and the point at which the failure occurs relative to the next checkpoint completed successfully. As we intend to create a prediction model in the next phase using the recovery time observations, these factors need to be considered as they introduce variance influencing comparability, thus making our models unusable without further adaptations. Concerning the workload, we make the assumption that over these shorter time periods where recovery takes place, i.e. less than 15 minutes, the changing throughput rates would average out over time. Therefore, a constant workload can be assumed. However, the point at which the last checkpoint completed successfully will differ across failures and will directly impact the number of messages that need to be reprocessed, thus increasing or decreasing the recovery time. Therefore, for the purposes of our work, we only consider the worst-case scenario, i.e. we assume failures occur at the point right before the next checkpoint completes successfully. As such, for profiling runs, we measure the distance in time until the next checkpoint is scheduled to start, and inject the failure just prior to this point.

At the conclusion of the profiling runs, the parallel deployments are deleted and the resources are released, with the profiling sets C , TR , L , and R being passed into the third and final phase addressing modeling and runtime optimization.

D. Phase 3: Modeling and Runtime Optimization

The third and final phase is intended to execute indefinitely while continuously optimizing the targeted DSP job by monitoring for violations of two user-defined QoS constraints: l_{const} which defines an upper bound on the average end-to-end latency; and r_{const} which defines an upper bound on predicted recovery time. A violation of either constraint triggers a reconfiguration of the system where a new CI is chosen. Care must be taken when choosing a new CI value, as increasing the frequency with which checkpoints are performed will result

in better recovery times but could likewise negatively impact latencies and vice versa. Therefore, we formulate this as an optimization problem where the objective is to select a CI that minimizes for both performance and availability. A graphical representation can be seen in Figure 1(c).

In order to achieve this, we train two multiple regression models using the data gathered in the preceding two phases. The performance model M_L aims at finding a mapping such that $M_L : C, TR \rightarrow L$, whereas the recovery time model M_R is configured as $M_R : C, TR \rightarrow R$. Once both models have been trained with our observed values, metrics from the targeted DSP job are continuously gathered and evaluated. For performance violations, Khaos compares the current average end-to-end latency to the performance constraint l_{const} . As end-to-end latencies tend to be quite volatile, our previously fitted models likely contain noise for which we need to account when making actual predictions. Thus, we employ a correction approach for the prospective prediction error to localize predictions to the current cluster conditions. Khaos keeps track of the latency observations over the past k optimization iterations, averages across the k pairwise fractional differences given the current latency, and then uses this estimated rescaling factor p to rescale the predicted value obtained from our model. For recovery time violations, it determines the average throughput rate and together with the current CI uses M_R to predict the recovery time considering the worst case scenario.

However, reconfiguration is not without its own cost and requires a full restart of the job. Therefore, when violations of the constraints are detected, Khaos will determine whether or not a reconfiguration should be performed immediately or if this decision should be deferred until the next optimization cycle. In order to achieve this, a TSF model is trained on the incoming message rate and a multi-step ahead forecast is performed should a violation be detected. If the prospective incoming message rate is expected to decrease significantly, i.e. more than 10%, from the current point in time until the next optimization run is executed, then the decision to reconfigure can be delayed. Otherwise, the reconfiguration can proceed as per normal. The goal of reconfiguration is to select a CI value that results in the furthest distance from the two upper bounds that satisfies both. Formally, this multi-objective optimization problem can be formulated as

$$\begin{aligned} \min_C \quad & Q_R + Q_L^* + |Q_R - Q_L^*| \\ \text{s.t.} \quad & Q_R < r_{\text{const}}, \\ & Q_L^* < l_{\text{const}}, \\ & Q_R, Q_L^* > 0. \end{aligned} \quad (8)$$

Here, Q_R is the fraction $\frac{M_R(C, TR_{\text{avg}})}{r_{\text{const}}}$ between the prediction of the recovery time model and the corresponding constraint. The same applies to the latency model, except that Q_L^* describes the fraction after rescaling, i.e. $Q_L^* = p \cdot Q_L$. Given our configuration set C and the current average throughput rate TR_{avg} , we aim at finding a value for the CI that satisfies both objectives individually. If minimizing the above expression

finds a new value for the CI, which is predicted to be more performant, then the system is reconfigured should the expected workload not decrease and monitoring continues.

IV. EVALUATION

Now we show that Khaos is both practical and beneficial for DSP through experimentation. The prototype, data, and experiment artifacts can be found in the following repository¹.

A. Experimental Setup

Resource	Details
OS	Ubuntu 18.04.3
CPU	Quadcore Intel Xeon CPU E3-1230 V2 3.30GHz
Memory	16 GB RAM
Storage	3TB RAID0 (3x1TB disks, linux software RAID)
Network	1 GBit Ethernet NIC
Software	Java v1.11, Flink v1.12, Kafka v2.6, ZooKeeper v3.6, Docker v19.3, Kubernetes v1.18, HDFS v2.8, Redis v5.0, Prometheus v2.25

TABLE I: Cluster Specifications

Our experimental setup consisted of a co-located 50-node Kubernetes [28] and HDFS [29] cluster as well as a 3-node Apache Kafka² cluster configured to have 8 partitions and a replication factor of 3. Node specifications and software versions are summarized in Table I. A single switch connected all nodes. Each experiment consisted of a Kubernetes namespace containing: an Apache Flink³ native session cluster with all jobs set to have a parallelism of 4; and a single Prometheus⁴ time series database was used for the gathering of metrics. The Yahoo Streaming Benchmark (YSB) experiment additionally made use of a Redis⁵ database. Regarding end-to-end latency measurements, averages were taken over the 99th percentile in order to filter outliers during normal failure free operations. The timeout interval for Flink taskmanager nodes is 50s as per the default settings. Importantly, for both experiments QoS constraints for performance and availability were set at 1000ms for end-to-end latencies and 240s for recovery times respectively. Each experiment was conducted 5 times with the median selected for our results and discussion.

B. IoT Vehicles Experiment

We created a simulation that mapped the streets and intersections of an area of central Berlin, Germany. In this area a number of vehicles were generated travelling along various routes and providing an update message every 1 second. Each update message contained the vehicle_ID, vehicle_type, geolocation, speed, direction, and event_time. This IoT Vehicles streaming dataset was generated using Sumo [30] and the number of concurrent vehicles, i.e. the workload, is based on

the TAPASCologne scenario⁶. For this experiment, a 7-day streaming dataset was generated using random seeds to create variability across the various days. Throughput rates over time can be seen in Figure 2(a).

A DSP job was created that processes the streaming vehicle data. It consisted of the following streaming operations: read an event from Kafka; deserialize the JSON string; filter update events not within a certain radius of a designated geo-point where vehicles are to be monitored; take a 3s sliding window with a slide of 1s where all update events are of the same vehicle ID and calculate the vehicle's average speed; generate a notification for vehicles that have exceeded the speed limit; enrich notification with vehicle type information from data stored in system memory and write it back out to Kafka.

C. YSB Experiment

This experiment is based on the Yahoo Streaming Benchmark⁷. It implements a simple streaming advertisement job where there are a number of advertising campaigns and a number of advertisements for each campaign. The authors of the benchmark created a Kafka Producer application that would generate a constant stream of events containing, among other things, an event_time, an event_type, and an ad_id. We created a generator that was combined with a click-through rate dataset⁸ to create the workload for this experiment. This workload can be in Figure 2(b).

The job of the benchmark is to read various JSON events from Kafka, identify relevant events, and store a windowed count of these events per campaign in Redis. The job consists of the following operations: read an event from Kafka; deserialize the JSON string; filter out irrelevant events (based on type field), take a projection of the relevant fields (ad_id and event_time), join each event by ad_id with its associated campaign_id stored in Redis; take a 10s windowed count of events per campaign and store each window in Redis along with a timestamp of when the window was last updated. the purposes of our experiments, we modified the Flink benchmark by enabling checkpointing and replacing the handwritten windowing functionality with the default Flink implementation. Although doing so decreases the update frequency to the length of each window, results should be accurate and more interesting for our experiments due to the accumulated windowing operator state at each node.

D. Experimental Results & Discussion

The results of both experiments will now be presented and discussed in further detail. The effectiveness of our approach was evaluated against 5 baseline runs, which were executed in parallel to ensure cluster conditions were commensurate. For baseline runs, a range of static CI values were selected and streaming jobs started using these configurations. Each job consumed the same stream of events. Static CI values included 10, 30, 60, 90, and 120 seconds respectively. Over

(a) IoT Vehicles Experiment.

(b) YSB Experiment.

Fig. 3: Latency (L.) violations, normalized recovery times (R.T.), and normalized recovery time violations.

the course of each experiment, 12 failures were injected at similar times across all jobs. Failure selection was based on different throughput levels which can be seen for both experiments in Figure 2(c) and Figure 2(d). To ensure results were comparable, failures were injected at the end of the CI. This is inline with our assumption of the worst case scenario, i.e. a failure occurs just before the next checkpoint completes successfully and therefore maximizing recovery times.

Concerning the predictive models trained as part of the profiling phase for each experiment, the results of a post execution error analysis can be seen in Table II(a) and Table III(a). These results measured the average percent error between predicted and actual observations for both latencies and recovery times across the full duration of the experiments. Latency values were collected as part of the optimization loop and recovery times were measured when failures were injected. The results show that on average latency predictions were within 9% and 12% of expected and recovery time predictions were within 13% and 7% of expected. Considering the presence of this error within our predictions, we conclude that it was accurate enough for the optimization step to make good CI selections. We previously described our failure injection procedure highlighted in Figure 2(c) and Figure 2(d), we will now describe the bottom section of this figure. Associated results for these experiments can be seen in Table II(b) and Table III(b). During optimization, Khaos triggers reconfigurations of the CI in order to account for changes in latency and prospective recovery times. We observed in total three reconfigurations for the IoT Vehicles Experiment, and two reconfigurations for the YSB Experiment. It can be seen that the CI is often set to a lower value with increasing throughput rates. This is expected, as formulated recovery time constraints can likely not be fulfilled when maintaining a high CI value. In general, the few reconfigurations result from our method requiring one of the constraints to be fulfilled in order to conduct an optimization step. Consequently, reconfigurations are applied sparsely, and CI configurations in-between observed violations are not guaranteed to be optimized if both constraints are intermittently jointly violated. An example for this can be seen in Figure 3(a) with recovery time violations for Khaos, indicating that CI updates were aborted at some point.

Regarding the violation of formulated performance and availability constraints, we report in Figure 3 the fraction of time the latency constraint was not fulfilled, and normalize the measured recovery times accordingly such that the resulting bars are aligned for Khaos. This allows us to better assess the relation of both objectives for the utilized static CI values, i.e. our baselines. It can be clearly showed that the CI has an impact on latencies, i.e. with more frequent checkpoints being performed, latencies are higher and vice versa with recovery times. This often leads to violations of the respective formulated constraints. In our conducted experiments, this is less problematic for smaller CI values, which is also what Khaos often defaults to (see Figure 2). An exception to this is the 10s CI illustrated in Figure 3(a), which performs poorly due to a failure injection during catch-up from a previous failure.

However, while certain static CI configurations show comparably good results, this is restricted to our exemplary streaming jobs only, i.e. the discovered CIs are not a general solution. Based on the results presented in Table II(b) and Table III(b), we can surmise that Khaos produces better average latencies overall than the high frequency CI configurations. Likewise the percentage of latency violations were commensurate with these configurations. At the same time, Khaos produced fewer recovery time violations indicating that it provides a balance of both within the user-defined constraints. It is important to note that while individual static configurations might marginally outperform Khaos for a specific job and workload, the benefits of such a selection will not generalize if the jobs and/or workloads change.

V. CONCLUSION

In this paper we presented Khaos, an approach which borrows from the principles of Chaos Engineering to allow for the automatic runtime optimization of DSP fault tolerance configurations. It makes use of parallel profiling runs and failure injection to capture metrics, which are in turn used to model the performance and availability of targeted DSP jobs executing on variable workloads. It does this in order to monitor for runtime violations of user-defined QoS constraints and, should a violation be detected, can search for and select near-optimal CI configurations, which provide a balance of both. Through our experiments we showed that Khaos is able to optimize the CI configuration variable in order to minimize both latency and recovery time violations while outperforming most static configurations. For future work we intend to investigate the feasibility of a continuous optimization routine which takes periods of low utilization into consideration.

ACKNOWLEDGMENT

Abstract—In order to realize collaboration on a global scale, academic research requires often large quantities of data to be shared between geographically dispersed organizations. The requirement to protect and govern data in a network of loosely coupled, autonomous institutions is an incentive for decentralized solutions, where the participants are in full control of their data without trusting a third-party provider to store and process the data. In order to increase data availability and fault tolerance in decentralized collaborative systems, we propose a layer, which is based on replication and decentralized authority over the data. The solution consists of an idea of peer-sets, which are groups of peers implementing collective data management, a consensus protocol which synchronizes a distributed ledger between peers, and an atomic commitment protocol used to implement optional two-way references between documents. This architecture may be utilized in various decentralized collaborative data-sharing systems, such as Onedata.

I. INTRODUCTION

DEMAND for global data access and data availability is growing due to increasing globalization and scale. It is especially evident in research, where often large quantities of data need to be shared upon request easily between geographically dispersed groups of people. High data availability and safety is usually a requisite in order to perform large scale computations. For instance, the eXtreme-DataCloud project [1] developed smart orchestration tools and building blocks of software, which provide storage federation with transparent or quasi-transparent data access for large and geographically distributed datasets. This project was dedicated to prominent research communities from various domains: LifeScience, Biodiversity, Clinical Research, Astrophysics, High Energy Physics, and Photon Science.

Collaboration between researchers may be backed by scientific organizations, which are autonomous and often do not have any written agreements between them. Each organization manages its own data, which may reside on various storage systems in different clouds. The requirement to protect and govern their data in a network of loosely coupled, autonomous institutions makes it difficult to constrain data sharing software to be centralized. Instead, decentralized solutions are more suitable in such cases, because the participants are in full control of their data and they may decide what is shared to whom, without trusting a third-party provider to store and

process the data. Examples include ScienceMesh [2], which tries to connect existing storage systems and services using a common API, or Onedata [3], which delivers a service allowing to create a global network of independent storage providers.

High data availability in collaborative systems is crucial, but is also more difficult to accomplish in decentralized environments. When a party experiences a failure, all of its data becomes unavailable to others, whom parts of the data have been shared with. The problem is more complex, because not only may collaborators want to access the shared data, but also modify it—all of it during the outage of the original organization’s infrastructure. These scenarios show a demand not only for decentralized architecture of data sharing systems, but also for decentralized authority over shared data, i.e. a possibility to modify it collectively by each one of its owners—collaboration between organizations often results in a joint work, and it is not uncommon for people to be parts of multiple organizations at once. In this paper, we propose an architecture of a layer of data-sharing systems, which ensures high availability and fault tolerance, and is based on a global, decentralized network of peers. The novelty of our proposal lies in dividing the global network into smaller peer-sets, which allow unrestricted global collaboration, at the same time limiting the flow of information between peers to the required minimum.

II. RELATED WORK

The concept of decentralized collaboration and data-sharing has been studied for years. Onedata is an important example, the goal of which is to achieve collaboration in global networks of autonomous organizations. It provides a service called Onezone, which implements a common layer between different storage providers and enables universal user authentication [4]. Other notable work include ScienceMesh [5], which provides an ecosystem—common interfaces and tools in order to connect existing heterogeneous services. Its goal is to allow collaboration using, for instance, share-with flows or data synchronization. It is relatively simple and does not implement more advanced solutions, such as complex organizational structures.

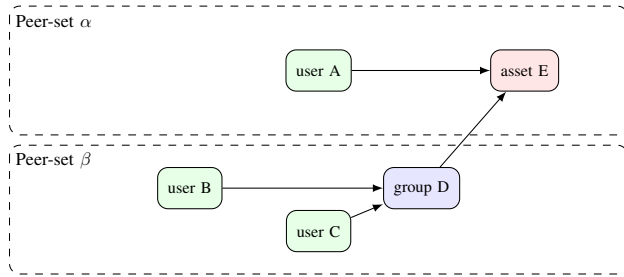

Fig. 1. Exemplary organizational structure spanned across two peer-sets.

It is possible to create a global network of independent peers using various DHT implementations, but they have inherent problems with security in trustless environments. Blockchain [6], on the other hand, ensures Byzantine Fault Tolerance and can be used both for decentralized storage [7], and for decentralized collaboration [8]. Blockchain is problematic due to its publicness—in situations where data is to be kept private its use is limited. In order to constrain possible participants and limit public access, permissioned blockchains may be used. However, they require a central authority responsible for authorization which undermines their decentralization. Irrespectively of the type of blockchain used, the primary issue is related to the commitment of organizations to handle a global chain and store data accessible to other blockchain participants regardless of their willingness to collaborate.

III. OUR PROPOSAL

We propose a decentralized architecture of a layer of data-sharing systems with goals of increasing data availability and fault tolerance. It is achieved by utilizing decentralized authority over the data and replicating it over several peers. This section also includes a discussion on protocols and structures of the data used. We target the metadata used to describe organizational structures, users, groups, etc., but the architecture overall may be used for more generic document-like data with optional two-way references between them.

A. Architecture

We assume that the system stores and allows access to “objects”, which represent arbitrary metadata. Objects may have relations between them, which are represented as two-way references. For instance, in case of organizational structures, an object may represent a user, a group, or an asset. Relations may represent memberships, in case of users and groups, or access grants, in case of assets (cf. Fig. 1).

Objects are decentralized by nature—each object is owned by some organization—a peer. For instance, an object representing a user may be owned by its university (an organization), along with his groups. Collaboration between different organizations happens when users belonging to each have common relations, e.g. they are both members of the same group.

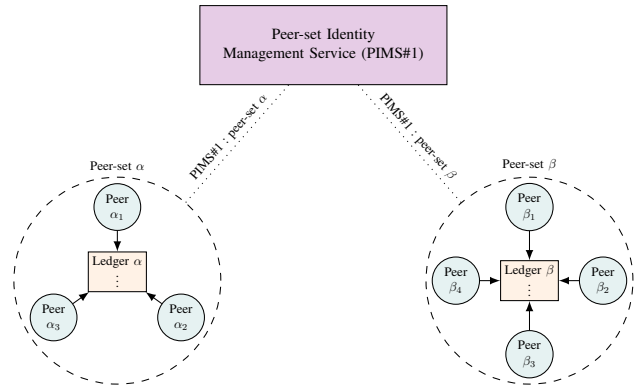

Fig. 2. Exemplary logical structure of peer-sets: each peer-set stores its own ledger, whereas PIMSeS resolve peers inside peer-sets.

Fig. 3. Exemplary network consisting of PIMSeS and peers divided into peer-sets; one peer may belong to an arbitrary number of peer-sets, peer-sets may consist of arbitrary numbers of peers.

We propose an idea of a “peer-set”—a group of peers which collectively manages a set of objects (cf. Fig. 2 and 3). This concept increases data availability and fault-tolerance, because objects are not managed in a centralized manner, but rather are managed collectively by multiple peers. This way, users with multiple affiliations may be naturally managed by a peer-set consisting of organizations they are part of. Groups and assets may be spanned across organizations which support the work they are used for, or they may be backed up to other peers provided by the organization. Every peer-set is a closed group, which may be created by a user, given permissions from each peer. We assume that every member of a peer-set is not malicious, and the peer-set creator trusts each peer to store and manage the data, thus we do not consider Byzantine faults.

In order to increase flexibility, our proposal also includes mutability of peer-sets. This allows users to dynamically add or remove a peer from the peer-set, which improves data availability.

B. Peer-set ledger structure and consensus protocol

A fundamental problem in distributed systems is coordinating multiple peers to agree on some common value, i.e. reach *consensus*. Consensus protocols—created to solve this problem—have to be fault tolerant, as an arbitrary set of participating peers may fail at any moment. The conventional consensus protocols include Paxos [9] along with its modifica-

TABLE I
PEER-SET α LEDGER CONTENTS

#	Peer-set α
4	Add relation “group D from β ” \rightarrow “asset E”
3	Add relation “user A” \rightarrow “asset E”
2	Add object “asset E”
1	Add object “user A”

TABLE II
PEER-SET β LEDGER CONTENTS

#	Peer-set β
6	Add relation “group D” \rightarrow “asset E from α ”
5	Add relation “user C” \rightarrow “group D”
4	Add relation “user B” \rightarrow “group D”
3	Add object “group D”
2	Add object “user C”
1	Add object “user B”

tions, such as Multi-Paxos [10] or EPaxos [11]. There are also alternatives, such as Raft [12] or Zab [13]. Some consensus protocols may also be categorized as Byzantine fault-tolerant, which imposes a weaker condition on the type of faults that may happen—instead of only assuming crashes, they allow an arbitrary failure, including malicious misbehaving, such as forging counterfeited messages. Such consensus protocols include proof-of-work or proof-of-stake [14], both of which are used mainly in public blockchain networks [6]. There are also BFT versions of consensus protocols used outside of blockchain, such as PBFT [15].

In case of peer-sets, all peers inside them need to synchronize and decide on common state of the managed objects. Thus, we propose a peer-set history structure based on a distributed ledger, which consists of a list of incremental changes to the objects. The ledger is synchronized between peers using a consensus protocol based on examples mentioned above. Every peer may propose a change which extends the ledger by a new entry. Tables I and II depict exemplary ledger contents of respectively peer-set α and peer-set β , which are consistent with the state shown in figure 1. Solutions such as QLDB [16] may be used as an implementation for the ledger.

Our approach assumes not only data replication, but also a mechanism of data validation, where peers decide whether the common state is valid. This mechanism prevents one peer from suggesting a change that others may disagree with, and ensures that more than half of the peers accepted the change.

The proposed peer-set ledger structure is akin to a classic permissioned blockchain, however the global ledger is divided into multiple, separate ledgers maintained by a large number of peer-sets, which together participate in a global network.

C. Object and peer-set identification

One of the challenges in decentralized systems is object identification. A popular way of identifying objects in such

environments is *content addressing*. This method is usually based on attaching a cryptographic hash function’s digest of an object to its identifier. It addresses objects by their content instead of their location—it implies increasing data availability, but at the same time it restricts its modifications as every change generates a new identifier, and the old one becomes outdated. A well-known example is the BitTorrent protocol [17] which stores hashes inside torrent files or magnet links. Other uses include IPFS with CIDs [7], or Git with commit/tree/blob hashes [18].

When data is subject to change, content addressing becomes difficult to apply and other solutions are required. Standard identification methods, such as URLs, persistent identifiers, or handles [19], are content-agnostic, but in turn have fixed location, which undermines the decentralized nature of object storage and limits possibilities to migrate the data. Alternatives include *decentralized identifiers* (DIDs) [20], which are designed to identify and verify digital entities in decentralized web applications, and to provide a way of interacting with them. Blockchain also provides a possibility to store a public collection of peer-set identification records in a decentralized manner. However, all parties would have to agree to participate in a public network and to process the chain, which may discourage potential users.

Our architecture assumes both decentralized nature and possibility to modify data along with its owners. We propose a hybrid object identification system, which is based on a decentralized network of *peer-set identity management services* (PIMS), which are responsible for providing and managing information about peer-sets. An identifier to an object consists of three parts: 1) PIMS identification, 2) peer-set identification, and 3) object identification. The first part unambiguously identifies the service, which shares information about the peer-set upon request, using the second part of the identifier. This way, the user of the identifier may learn about the current state of the peer-set, without the need to change the identifier or waive the decentralized nature of the system (cf. f2). PIMSes are meant to be provided by organizations and create a decentralized network themselves.

Peer-set identity management services also have to implement specific identity management policies. Peer-sets are designed to be self-governing, so actions which modify a peer-set (such as adding a new peer, or removing an existing one) need to be established by the peer-set itself. Such requirement makes managing the data dependent on the data itself, which additionally justifies creating a dedicated service. For instance, adding a new peer D to a peer-set consisting of peers A , B , and C , may require approvals of D and majority of $\{A, B, C\}$.

D. Atomic commitment between peer-sets

Our proposal also takes into account atomic commitment between peer-sets. It may be used for instance to implement two-way relations between objects originating from different peer-sets. The atomic commitment ensures that two different peer-sets either both commit a change, or both ignore it (cf. entry 4 in table I and entry 6 in table II). We take into

consideration two ways of ensuring atomic commitment in our proposal.

Let us assume an atomic commitment between peer-sets A , B , and C , each one consisting of an arbitrary number of peers denoted A_0 , A_1 , etc. The first approach is to treat $\{A, B, C\}$ as one single database divided into three shards A , B , and C . Each shard contains a number of replicas, which are represented by peers. Using this interpretation we can use existing atomic commitment protocols which are designed for shards of replicas [21], but requires cooperation with the consensus protocol.

The second approach is to treat each peer-set as an entity and synchronize commitment between two representative peers. A special entry is added to the ledger, which represents an ongoing atomic commitment between peer-sets. This entry is used as a way of synchronizing state between all peers inside each of the peer-sets, and is used to implement a higher-level commitment protocol, which does not have to assume multiple replicas. Examples of such protocols include two-phase commit protocol (2PC), along with variations and improved versions such as 2PC* [22].

IV. FUTURE WORK

The problem of increasing data availability and fault tolerance in decentralized collaborative systems is very broad and complex. This publication aims to designate a vision of our solution, which is based on replication and decentralized authority over data, and outline directions of its development. We propose an architecture of a layer of data-sharing systems, consisting of

- peer-sets, which implement a decentralized mechanism of collaboration between peers,
- peer-set identity management services, which allow discovery and identification of peer-sets, and
- atomic commitment protocol, which enables performing atomic changes between peer-sets in order to implement e.g. two-way relations between objects.

Discussions in section III are entry points to more detailed research in each subject. We plan to evaluate several consensus protocols in terms of usability and integrate them with the idea of voting and validating changes by peers. In case of atomic commitment, we want to implement and compare the two proposed solutions. Finally, we plan to create a proof-of-concept of the whole system along with detailed description and evaluation. We also intend to integrate our solution with Onedata by providing an integration layer with GraphSync—the metadata synchronization protocol.

V. ACKNOWLEDGEMENTS

This scientific work was published in part by an international project co-financed by the program of the Minister of Science and Higher Education entitled “PMW” in the years 2021–2023; contract No. 5193/H2020/2021/22. Network Systems and Applications

MODERN network systems encompass a wide range of solutions and technologies, including wireless and wired networks, network systems, services, and applications. This results in numerous active research areas oriented towards various technical, scientific and social aspects of network systems and applications. The primary objective of Network Systems and Applications conference track is to group network-related technical sessions and promote synergy between different fields of network-related research.

The rapid development of computer networks including wired and wireless networks observed today is very evolving, dynamic, and multidimensional. On the one hand, network technologies are used in virtually several areas that make human life easier and more comfortable. On the other hand, the rapid need for network deployment brings new challenges in network management and network design, which are reflected in hardware, software, services, and security-related problems. Every day, a new solution in the field of technology and applications of computer networks is released. The NSA track is devoted to emphasizing up-to-date topics in networking systems and technologies by covering problems and challenges related to the intensive multidimensional network developments. This track covers not only the technological side but also the societal and social impacts of network developments. The track is inclusive and spans a wide spectrum of networking-related topics.

The NSA track is a great place to exchange ideas, conduct discussions, introduce new ideas and integrate scientists, prac-

tioners, and scientific communities working in networking research themes.

TOPICS

- Networks architecture
- Networks management
- Quality-of-Service enhancement
- Performance modeling and analysis
- Fault-tolerant challenges and solutions
- 5G developments and applications
- Traffic identification and classification
- Switching and routing technologies
- Protocols design and implementation
- Wireless sensor networks
- Future Internet architectures
- Networked operating systems
- Industrial networks deployment
- Software-defined networks
- Self-organizing and self-healing networks
- Multimedia in Computer Networks
- Communication quality and reliability
- Emerging aspects of networking systems

Track 3 includes technical sessions:

Abstract—One of the recent challenging but vital tasks in graph theory and network analysis, especially when dealing with graphs equipped with a set of nodal attributes, is to discover subgraphs consisting of highly interacting nodes with respect to the number of edges and the attributes' similarities. This paper proposes an approach based on integer programming modeling and the graph neural network message-passing manner for efficiently extracting these subgraphs. The experiments illustrate the proposed method's privilege over some alternative algorithms known so far, utilizing several well-known instances.

Index Terms—Graph partitioning, Network analysis, Integer programming, Message passing, Local search.

I. INTRODUCTION

WHEN studying graphs/networks, we usually face collections consisting of nodes with common topological and nodal attribute characteristics. More specifically, sets of highly interactive vertices are likely to yield and share common relationships and properties. In this sense, in all scientific fields where graphs are somehow implicated, one of the challenging tasks would be to efficiently partition the given graph into a number of dense subgraphs consisting of massively connected vertices that share similar properties. These subgraphs are well known as *communities*, and naturally, the process of identifying them is referred to as the *community detection problem*. Detecting communities has become one of the fundamental subjects in the field of network analysis and graph theory and has numerous applications in a wide range of areas, including the analysis of Social/Biological/Cosmological networks [1], [2], [3], [4] and WEB [5]. It also plays a crucial role in the domain of Network Design problems [6], Signal Processing [7], Image Segmentation [8], Pattern Recognition [9], and Data Mining [10].

Crucial in this domain is a more formal representation of a graph: A pair $G = (V, E)$ with the set of vertices V and edges E . Subsequently, from the perspective of graph topological structure, a *community* can be contemplated as a subset $C \subseteq V$ with a high density of edges between nodes inside C and a low density of edges connecting C to the other subsets. Accordingly, one can define the community detection problem as *partitioning* V into a set of disjoint communities $\mathbf{C} = \{C_1, C_2, \dots, C_k\}$.

In fact, mining high-quality communities usually coincides with finding a measure that estimates the goodness of communities. In the literature, a large number of such quality measures have been proposed for evaluating the superiority of partitioning from the viewpoint of topological structures. Among them, one of the most widely used and well-known is *Modularity*, introduced by Newman [11]. Intuitively, for a community C , Modularity is the number of edges inside C subtracted by the expected number of such edges, whereat the expected number of edges can be derived by corresponding to G , a randomized graph (called the *Null model*) with exactly the same vertices and the same degree of G , in which edges are placed randomly. More specifically if d_i and m are, respectively, the degree of node i and the number of edges in G , the probability of existing an edge between nodes i and j in such a graph is $\frac{d_i d_j}{2m}$. This is because, first, each node is assigned the number of stub links exactly equal to its edges (Fig. 1a, 1b). Afterward, each of the two stub edges will be joined at random (Fig. 1c). Consequently, the Modularity value for a community C can be defined as the number of edges within C in G minus the number of edges within C in a Null model of G . Thus, Modularity for partitioning \mathbf{C} can then be expressed as

$$Q(\mathbf{C}) = \frac{1}{2m} \sum_{i,j \in V} [a_{i,j} - \frac{d_i d_j}{2m}] \xi(i, j), \quad (1)$$

where $A = (a_{i,j})$ be the adjacency matrix of G , where $a_{i,j}$ is one when there is an edge between node i and node j , and zero otherwise; n is the number of vertices in G . In addition, $\xi(i, j)$ is one if i and j are in the same community and zero otherwise.

As a result, high-quality communities can be determined as the ones with a high value of Modularity. However, despite Modularity's advancements in finding high-quality communities in a wide range of graphs, it is known to suffer from limitations (see [12], [13], for example). In particular, as pointed out in [14], since Modularity only considers the existing edges of the network, it qualifies the goodness of the discovered communities by only measuring how good the partitioning fits the existing edges. This is indeed a drawback

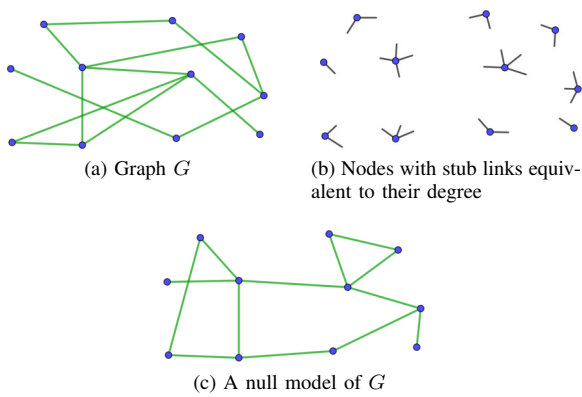

Fig. 1: A Null model associated with a given Graph G .

because the disconnected nodes (absent links) that lie in the same community are not taken into account.

On the other hand, *Max-Min Modularity* [14], as one of the successful extensions of Modularity, is able to significantly improve the accuracy of the measure by compensating for the Modularity quantity when disconnected nodes are in the same community. More precisely, it is assumed in [14] that (in addition to the graph G) a zero-one *relation matrix* $U = (u_{i,j})$ is given that defines whether every pair of disconnected nodes of the network is related or not: $u_{i,j}$ is one when disconnected nodes i and j are *related*, and zero otherwise. Max-Min Modularity, in fact, tries to take into account the importance of the *indirect* connections between disconnected nodes by penalizing the Modularity measure when *unrelated* nodes are in the same community: Consider a complemented graph $G' = (V, E')$, where E' contains an edge between every pair of disconnected nodes of G that is unrelated; i.e., there is an edge between i and j in G' if there is not such an edge in G and also $u_{i,j}$ is zero. Max-Min Modularity, then, aims at maximizing the Modularity in G as well as minimizing Modularity in G' simultaneously. Mathematically speaking, if $A' = (a'_{i,j})$ is the adjacency matrix of G' , d'_i is the degree of node i in G' , and m' is the number of the edges in G' , then Max-Min Modularity Q_{MM} of a given partition \mathcal{C} of V is defined as follows:

$$Q_{MM}(\mathcal{C}) = \sum_{i,j \in V} \left[\frac{1}{2m} (a_{i,j} - \frac{d_i d_j}{2m}) - \frac{1}{2m'} (a'_{i,j} - \frac{d'_i d'_j}{2m'}) \right] \xi(i, j). \quad (2)$$

We refer to the problem of finding a partition of the network that maximizes Max-Min Modularity as the *Max-Min Modularity Maximization* problem.

As a crucial remark, we can note that not only is the Max-Min Modularity Maximization problem categorized in the class of NP-hard problems [15], making it hard to find an efficient optimization algorithm, but it also suffers from a major drawback: Max-Min Modularity strongly depends on the accuracy of the given relation matrix, meaning that the quantity of the measure might be heavily affected by the node relationships defined by the user/oracle in the first place. De-

spite Ferdowsi and Khanteymooari [16] succeeded in proposing a systematic approach for unveiling the relation between non-adjacent vertices, from a more critical point of view, one could argue that both Modularity and Max-Min Modularity, like many other community discovery methods, only utilize topological information of nodes, naively overlooking a rich set of nodal attributes (e.g., user profiles of an online social network or textual contents of a citation network), which is abundant in all real-life networks [17].

In this regard, recently, an emerging domain of deep learning for graphs has ensured the design of more accurate and scalable algorithms. However, despite these approaches achieving outstanding results in graph-related tasks like link prediction and node classification [18], fairly little concentration has been committed to their application on unsupervised learning that encompasses the community detection problem. This is primarily because graph embedding methods can ideally align with (semi-)supervised learning approaches; however, they cannot be naturally generalized to the unsupervised learning manners since it is not very simple to find a proper loss function to govern the back-propagation updating procedure. Despite that, several deep learning-based unsupervised graph algorithms have been proposed [19], [20], [21], but they all suffer from a not accurate choice of a loss function that can authoritatively extend the model to unsupervised vision. The diverse results obtained by these approaches over the same input instances can prove this claim.

Main contribution: In this work, we introduce a refined model for the Max-Min Modularity that empowers us to find high-quality communities with simultaneously taking the graph's topological structure and the nodal attributes into account. In the sequel, we involve the Modularity metric to mine the communities consisting of densely connected vertices. In addition, we provide a technical introduction to *Graph Neural Network (GNN)* formalism, a dominant and fast-growing paradigm for deep learning with graph data, whose ability is to use nodes' features and local structure to generate embeddings. Utilizing the general concept of GNN feed-forward message passing, we devise an efficient mechanism for extracting the information induced by propagating nodes' properties throughout the network, leading to a perfect systematic characterization of the relation matrix. Everything combined, we introduce the advanced Max-Min Modularity scheme and express it with a standard integer programming formulation. Ultimately, by solving the model using a robust approach consisting of a row/column generation technique for solving the model's linear relaxation version and a local search manner for obtaining integer solutions, we identify the final communities.

The paper is organized as follows: the rest of this section focuses on providing a brief literature review. In Section II, we first restate the Modularity Maximization problem in terms of an integer programming model. We then devise a method for providing a refined relation matrix. Afterward, gathering all things together, we extend the primary Max-Min Modularity model and present an integer programming formulation for

it. Next, in Section III, we introduce the employed solution approach that leads to discovering high-quality communities. Section IV eventually focuses on various experiments, confirming the proposed method's high performance.

A. Related Works

Several approaches have been proposed in the literature to detect communities in networks; see, for example, the survey conducted by Souravlas et al. [22]. However, despite a large number of these techniques, relatively little work solves the problem using mathematical programming techniques. Especially in the case of Modularity maximization, few results have been established [23], [24], [25], [26]. On the other side, Chen et al. [14] illustrated that maximizing the Modularity alone does not usually lead to superior communities. Based on their findings, one of the significant drawbacks of Modularity is its sheer dependence on the (existing) links, meaning that, Modularity only focuses on discovering communities in which the number of interactive edges (links) is as many as possible. At the same time, it does not pay any attention to the missing links. This is while just as existing links can play an essential role in analyzing networks, so do the absent links. Therefore, new extensions of Modularity emerged subsequently, one of the most successful of which is the already mentioned: Max-Min Modularity [14]. Nevertheless, as discussed, Max-Min Modularity itself suffers from a critical issue: the nonexistence of a systematic way for proposing the so-called relation matrix, which is required to express the relationship between non-adjacent nodes. In this respect, Ferdowsi and Khanteymooori [16] succeeded in offering an analytical procedure to address this deficiency, generalize the conventional Max-Min Modularity, and provide an efficient local search-based algorithm to discover high-quality communities by considering both existing and missing links.

On the other side, in the past few years, most research has surged toward deep learning methods due to their power to achieve unprecedented results. These techniques aim at embedding nodes into a low-dimensional, dense vector space [27], [28]. However, unfortunately, a vast number of these methods lack the strength of encountering attributed graphs in which nodes are equipped with a set of features, and this is while we are now most surrounded by attributed networks everywhere [19]. It is worth mentioning that a few deep-learning methods have been recently proposed that consider attributed network embedding [29], [30], though most of them employ a matrix factorization manner, which endures some critical boundaries. More precisely, the representation capability of a matrix factorization-based approach is found to be more inadequate than a neural network-based method [31]. Besides, one could also argue that the majority of these proposals only rely on supervised graph algorithms, and therefore, usually fail to perform the community detection task, which can be categorized as an unsupervised assignment in graph problems [32], [33]. And the rests, which are designed for unsupervised learnings, still cannot find a promising loss function that can

lead to fine communities for various given graph instances [34], [19].

II. MODEL SKETCHING

In this section, we first recite the so-called Modularity Maximization problem in terms of an integer programming formulation, enabling us to discover communities with respect to the topological aspects of a given graph. Afterward, we explain the Graph Neural Network message passing method that facilitates us to devise a procedure for determining an accurate relation matrix for the Max-Min Modularity problem. This achievement then hopefully leads to a proper integer formulation for our advanced Max-Min Modularity problem that can be used to efficiently capture communities with respect to simultaneously taking both topological and attributes aspects into consideration.

A. Topology extraction

Let the binary variable x_{ij} indicate if nodes i and j belong to the same community or not; the value of x_{ij} is zero if nodes i and j belong to the same community, and one otherwise. Let $I_{all} = \{(i, j) \in V^2 \mid i < j\}$; and $q_{ij} = a_{i,j} - \frac{d_i d_j}{2m}$, for each $(i, j) \in I_{all}$. As described in [25], the Modularity Maximization problem can be formulated in terms of the following integer linear program:

$$\max \frac{1}{m} \sum_{(i,j) \in I_{all}} q_{ij}(1 - x_{ij}) \quad (\text{IP-M})$$

$$x_{ij} + x_{jk} - x_{ik} \geq 0 \quad \forall i < j < k \quad (3)$$

$$x_{ij} - x_{jk} + x_{ik} \geq 0 \quad \forall i < j < k \quad (4)$$

$$-x_{ij} + x_{jk} + x_{ik} \geq 0 \quad \forall i < j < k \quad (5)$$

$$x_{ij} \in \{0, 1\} \quad \forall (i, j) \in I_{all} \quad (6)$$

Constraints (3)-(5) guarantee that if i and j are in the same community and j and k are in the same community, then so are i and k . We refer to the relaxation of (IP-M), obtained by replacing the constraints $x_{ij} \in \{0, 1\}$ by $x_{ij} \in [0, 1]$, as (LP-M).

As discussed in [23] and [35], solving IP-M can soundly provide us with communities consisting of highly interactive edges. It is, however, incontrovertible that maximizing Modularity cannot help us tackle the attributed graphs. Consequently, to address this deficiency, our goal is to design an advanced model for the Max-Min Modularity problem so that nodal attributes are also effectively involved in the community mining process. In order to do that, we first provide a way to exploit the information diffused via nodes' features.

B. Attribute extraction

In this section, which establishes the core part of this research, we utilize the *Graph Neural Network (GNN) message-passing* framework to provide a systematic and accurate way of defining a *relation matrix* that perfectly depicts the similarity between nodes by analyzing the information spread by the attributes. More precisely, we aim to feed the nodal attributes to a GNN message passing to create single representation

Fig. 2: A scheme of the encoder approach. The encoder maps the node u to a low-dimensional embedding z_u .

vectors, each of which captures a node's structure as well as the feature information.

To motivate our discussion, we initially raise the notion of *node embedding*, which seeks to encode nodes as low-dimensional vectors that summarize their structural graph position and the information of their local graph neighborhood. In other words, node embedding aims to project vertices into a latent space, where geometric relations in this latent space correspond to relationships (e.g., edge existence or similarity) in the original graph or network. In this fashion, an encoder can be referred to as a function that maps each node $u \in V$ to vector embedding $z_u \in \mathbb{R}^d$ (i.e., z_u corresponds to the embedding for node $u \in V$) (See Fig. 2).

We now turn our attention toward one of the substantial encoder models: *Graph Neural Network (GNN)*, a broad framework for defining deep neural networks on graph data. The elucidative characteristic of a GNN is that it adopts a form of neural message passing in which vector messages are exchanged between nodes and updated using neural networks [36]. In each message-passing iteration of a GNN, a hidden embedding $h_u^{(k)}$ corresponding to each node $u \in V$ is updated according to information aggregated from u 's graph neighborhood $\mathcal{N}(u)$. Informally speaking, to each node $u \in V$ one can correspond a so-called *computational graph* that accumulates the information propagated from u 's neighbors, and in turn, the messages coming from these neighbors are based on information aggregated from their respective neighborhoods, and so on. Fig. 3 exemplifies a two layers computational graph. From the mathematical perspective, GNN message-passing procedure can be expressed as follows. Suppose that each node u is associated with a d -dimensional attribute vector that we represent with $X_u \in \mathbb{R}^d$. Then, the k -th embedding layer $h_u^{(k)}$, corresponding to node $u \in V$, can be obtained by the following recursive formula:

$$h_u^{(k)} = \sigma(W^{(k)} \sum_{v \in \mathcal{N}(u)} h_v^{(k-1)} + b^{(k)}), \quad (7)$$

where $h_u^{(0)} = X_u$ and $W_{d \times d}$ is a trainable matrix, which weights the nodes' attributes. Moreover, let σ denotes an elementwise non-linearity (e.g., a *tanh* or *Relu*). Furthermore, $b^{(k)} \in \mathbb{R}^d$ is the bias term, which can be often omitted for the sake of simplicity, but including it could be important to obtain high-quality performance. As can be inferred from (7), first, the messages incoming from the neighbors are summed;

Fig. 3: Two layers computational graph corresponding to node A . The model aggregates messages from A 's local graph neighbors, and in turn, the messages coming from these neighbors are based on information aggregated from their respective neighborhoods.

then, the neighborhood information with the node's previous embedding is combined using a linear combination; finally, an elementwise non-linearity is applied.

Now, in order to transform the node-level equation (7) into something we can implement, we can come up with the following graph-level definition of the model:

$$H^{(k)} = \sigma(AH^{(k-1)}W^{(k)}), \quad (8)$$

where $H^{(k)} \in \mathbb{R}^{|V| \times d}$ is the matrix of node representations at layer k in the GNN, with each node corresponding to a row in the matrix.

However, despite the straightforward intuition behind the update procedure (8), considerably notable is its two limitations. The first one is the non-consideration of the attributes of each node itself. This is crucial since the effectiveness of GNN becomes severely limited, as the information coming from the node's neighbors cannot be differentiated from the information from the node itself. This restriction originates from the fact that self-loops are not taken into account in the adjacency matrix A . The problem, however, can be easily resolved by substituting A with $A + I$, where $I \in \mathbb{R}^{n \times n}$ is the identity matrix that lets the self-loops also be involved. Another issue that may raise concern regarding (8) is the non-normality of features, which can indeed lead to numerical instabilities. However, fortunately, to also prevent this shortcoming, it seems convincing to apply the symmetric normalization as it has turned out to drive powerful dynamics [37]. For doing this, it is sufficient to replace $A + I$ with the normalization term $D^{-\frac{1}{2}}(A + I)D^{\frac{1}{2}}$, where $D \in \mathbb{R}^{n \times n}$ is the degree matrix. As a result, in the case of a basic GNN, we can end up with the following graph level definition of the model:

$$H^{(k)} = \sigma(D^{-\frac{1}{2}}(A + I)D^{\frac{1}{2}}H^{(k-1)}W^{(k)}) \quad (9)$$

It is worth pointing out that since our goal is to employ the feed-forward message passing exclusively and not to implement the back-propagation procedure, training the weight matrix W is not specifically part of our requirements. Instead, the only thing that matters to us is finding a final vector representation for each node by which we can sufficiently reflect the similarities among nodes with respect to the information that originates/propagates from attributes. For this reason, we can

safely omit W from (9) and obtain the following embedding matrix H .

$$H^{(k)} = \sigma(D^{-\frac{1}{2}}(A + I)D^{\frac{1}{2}}H^{(k-1)}) \quad (10)$$

One important insight that could be gained by (10) is that GNN feed-forward message passing is capable of effectively encoding neighborhood information in such a way that after performing the updating procedure for a number of layers, similar nodes in the graph will tend to have analogous final embedding representation [38]. This is primarily due to the fact that each node inherits the information (attributes) from its neighborhood.

Accordingly, any techniques for computing the distance between each pair of final vectors representation could naturally lead to obtaining the similarities between the corresponding vertices with respect to their attributes. In this work, we employ the well-known *z-Normalized Euclidean Distance* to measure the similarities between nodes. In this fashion, the distance between two vectors is defined as the Euclidean distance between the normal form of the two vectors, where the normalized form associated with each sequence is obtained by transforming the vector so it has a mean distribution $\mu = 0$ and standard deviation $\sigma = 1$. More explicitly, given two nodes i and j , with the corresponding vector embeddings $H_i^{(k)} \in \mathbb{R}^d$ and $H_j^{(k)} \in \mathbb{R}^d$, at layer k , we define $x_{ij}^* = \frac{\|H_i^{(k)} - H_j^{(k)}\|_2}{2\sqrt{d}}$ to be their z -score normalized Euclidean distance, where $\|\cdot\|_2$ is the Euclidean norm, $\widehat{H_i^{(k)}} = \frac{H_i^{(k)} - \mu_{H_i^{(k)}}}{\sigma_{H_i^{(k)}}}$, $\mu_{H_i^{(k)}}$ is the distribution mean, and $\sigma_{H_i^{(k)}}$ is the standard deviation of the vector $H_i^{(k)}$. It is not difficult to check that for any given $i, j \in V$, we have $x_{ij}^* \in [0, 1]$ [39] and that x^* preserves the triangle inequality. Subsequently, x^* forms a metric space, which we denote by *Embedding Distance (ED)*, on graph G . Clearly, the larger the obtained ED between two nodes, the less similarity between them.

C. Advanced Max-Min Modularity Model

As already mentioned, the larger x_{ij}^* is, the less likely it is that i and j are similar, that is, the less correlated they are, and therefore, the more likely they are to be in distinct communities. This intuition and also the fact that the Modularity Maximization problem can be nicely expressed for weighted graphs [40] persuade us to propose an advanced Max-Min Modularity model by recharacterizing the relation matrix and so the complemented weighted graph $G' = (V, E')$ using ED. Accordingly, we define the relation matrix $A' = (a'_{i,j})$ and G' ($(a'_{i,j})$ represents the weight of the edge between nodes i and j in G') as follows:

$$a'_{i,j} = \begin{cases} x_{ij}^* & \text{if } a_{i,j} = 0 \text{ and } i \neq j \\ 0 & \text{otherwise} \end{cases} \quad (11)$$

Given a relation matrix $A' = (a'_{i,j})$, and noticing that in the induced metric ED, Constraints (3)-(5) guarantee the

triangle inequality, for any $i, j, k \in V$, the advanced Max-Min Modularity Maximization problem can be formulated as the following IP:

$$\begin{aligned} \max \quad & \sum_{(i,j) \in I_{all}} \left(\frac{q_{ij}}{m} - \frac{q'_{ij}}{m'} \right) (1 - x_{ij}) \quad (\text{IP-MM}) \\ & (3), (4), (5) \\ & x_{ij} \in \{0, 1\} \quad \forall (i, j) \in I_{all}, \end{aligned}$$

where $q'_{ij} = a'_{i,j} - \frac{d'_i d'_j}{2m'}$, for each $(i, j) \in I_{all}$; $d'_i = \sum_{j=1}^n a'_{i,j}$, and $m' = \sum_{(i,j) \in I_{all}} a'_{i,j}$. We refer to the relaxation of IP-MM, obtained by replacing the constraints $x_{ij} \in \{0, 1\}$ by $x_{ij} \in [0, 1]$, as (LP-MM).

Considerably important is the fact that maximizing IP-MM coincides with simultaneously maximizing the modularity over the original given graph G and minimizing the modularity over the complemented graph G' , determined by the proposed message-passing approach. Whereas the first component makes sure to return communities, each consisting of densely connected nodes, the latter attempts to extract the communities containing vertices with the most similar attributes possible.

III. SOLUTION APPROACH

Efficiently solving (IP-MM) consists of two main parts: 1) optimally solving (LP-MM) and 2) accurately rounding the obtained fractional solutions to the integer ones.

For the first task, we use the row/column generation algorithm proposed in [16] that perfectly works for (LP-MM) as well since the two models are identical apart from using different relation matrices. A summary of the applied row/column generation technique is as follows. First, consider the following sub-problem (LPs-MM(\mathcal{I})) of (LP-MM) consisting of all pairs in $I = \{(i, j) \in I_{all} \mid c_{ij} > 0\}$ and some pairs in $I' = \{(i, j) \in I_{all} \mid c_{ij} \leq 0\}$:

$$\begin{aligned} \max \quad & \sum_{(i,j) \in I} c_{ij}(1 - x_{ij}) + \sum_{(i,j) \in \mathcal{I} \cap I'} c_{ij}(1 - x_{ij}) \quad (\text{LPs-MM}(\mathcal{I})) \\ & x_{ij} + x_{jk} - x_{ik} \geq 0 \quad \forall (i, j), (j, k), (i, k) \in I \cup \mathcal{I}, c_{ij} \geq 0 \vee c_{jk} \geq 0 \quad (12) \\ & x_{ij} - x_{jk} + x_{ik} \geq 0 \quad \forall (i, j), (j, k), (i, k) \in I \cup \mathcal{I}, c_{ij} \geq 0 \vee c_{ik} \geq 0 \quad (13) \\ & -x_{ij} + x_{jk} + x_{ik} \geq 0 \quad \forall (i, j), (j, k), (i, k) \in I \cup \mathcal{I}, c_{jk} \geq 0 \vee c_{ik} \geq 0 \quad (14) \\ & x_{ij} \in [0, 1] \quad \forall i < j, (i, j), (j, k), (i, k) \in I \cup \mathcal{I} \quad (15) \end{aligned}$$

Be advised that (LPs-MM(\emptyset)) generates the smallest formulation while (LPs-MM(I')) is equivalent to (LP-MM) itself. Moreover, point out that (LPs-MM(\mathcal{I})) delivers an upper bound of the optimal value of (LP-MM) that never gets worse by adding variables [16]. Above all, however, as Theorem 3.1 in [16] depicts, if an optimal solution $\bar{x}^* = (x_{ij}^*)_{(i,j) \in I \cup \mathcal{I}}$ to (LPs-MM(\mathcal{I})) satisfies the following condition (*), then $(x_{ij}^*)_{(i,j) \in I_{all}}$ is an optimal solution to (LP-MM), where

$$x_{ij}^* = \begin{cases} \bar{x}_{ij}^* & ; (i, j) \in I \cup \mathcal{I} \\ 1 & ; \text{otherwise} \end{cases} \quad (16)$$

and

$$(*) \begin{cases} x_{ij}^* + x_{jk}^* \geq 1; (i, j), (j, k) \in I \cup \mathcal{I}, c_{ij} \geq 0 \vee c_{jk} \geq 0, (i, k) \in I' - \mathcal{I} \\ x_{ij}^* + x_{ik}^* \geq 1; (i, j), (i, k) \in I \cup \mathcal{I}, c_{ij} \geq 0 \vee c_{ik} \geq 0, (j, k) \in I' - \mathcal{I} \\ x_{jk}^* + x_{ik}^* \geq 1; (j, k), (i, k) \in I \cup \mathcal{I}, c_{jk} \geq 0 \vee c_{ik} \geq 0, (i, j) \in I' - \mathcal{I} \end{cases}$$

This fact leads to the following efficient row/column generation procedure for optimally solving (LP-MM):

- Start solving (LPs-MM(\mathcal{I})) with $\mathcal{I} = \emptyset$ and adding those $x^* \in I' - \mathcal{I}$ that violate inequalities in (*) in each iteration, until an optimal solution to (LPs-MM(\mathcal{I})) satisfies (*).
- In each repeat, employ a row generation technique for solving (LPs-MM(\mathcal{I})):
 - 1) Obtain an optimal solution \bar{x}^* by solving (LPs-MM(\mathcal{I})) with no constraints.
 - 2) verify whether all constraints of (LPs-MM(\mathcal{I})) are satisfied by \bar{x}^* . If not, add the violated ones and solve (LPs-MM(\mathcal{I})).
 - 3) Update \bar{x}^* and repeat step (2).
- By having the optimal solution \bar{x}^* to (LPs-MM(\mathcal{I})), determine the optimal solution x^* to (LP-MM) by Equation (16).

To accomplish the second task, we can again apply the rounding algorithm proposed in [16], which can be shortly expressed as follows. Point out that the fractional optimal solution to (LP-MM) provides us with a metric space, where the distance between every pair of nodes is at most one. Let us call this metric *LP distance*. It is apparent that in an integral solution, the distance between each pair of nodes is either zero (implying that these two nodes belong to the same community) or one (inferring that these two nodes belong to separate communities). The rounding task is to push (some of) the nodes so as to determine a final valid *configuration* of the points in which the distance between every pair of nodes is either zero or one. Obviously, such a valid configuration correlates with a feasible integral solution \hat{x} to (IP-MM): $\hat{x}_{ij} = 0$, for points i and j which are co-located; and $\hat{x}_{ij} = 1$, for those with the distance one from each other. The main idea of the local search-based rounding procedure is to explore such promising configurations (using the LP information) and find a configuration leading to a solution (partitioning) whose max-min modularity value (2) is (locally) optimal.

Assume that \bar{x} is the optimal fractional solution to (LP-MM), obtained by the mentioned row/column generation technique. As explained above, to compute an integral solution to (IP-MM), we need to determine a set of final locations at distance one from each other (we refer to these final locations as community centers) and move the nodes to these centers so as to obtain a valid configuration. In fact, to compute an integral solution, we only need to determine a set of distinct centers, since we can then simply move each point to the closest center (with respect to the LP distance) and obtain a corresponding integral solution: for each pair i and j , $\hat{x}_{ij} = 0$ if i and j are co-located; and 1 otherwise. Therefore, the only task of the utilized local search algorithm is to determine a good set of final centers.

More precisely, the local search algorithm works as follows: Randomly pick a subset of V as initial centers. As discussed above, move other vertices to these centers to form a solution (partitioning) and then compute the max-min modularity value

TABLE I: Networks under study

1	CiteSeer [41]
2	Arnetminer [42]
3	Caltech36 [43]
4	Reed98 [43]
5	Facebook348 [38]

of the resulting partitioning; see (2). The local search technique tries to improve the max-min modularity value by adding and/or deleting a center to/from the set of centers at a time. The local search movement that yields the most significant improvement in the max-min modularity value is selected at each iteration. The algorithm terminates when no improving local search move exists.

IV. COMPUTATIONAL RESULTS

This section presents a comprehensive performance evaluation for the proposed method using five well-known real-world networks listed in Table I. Ground truth (i.e., the optimal community structures) is available and known for each of these networks, and therefore, one can easily measure the quality of a community detection algorithm by estimating the similarities between the communities obtained by the algorithm and the ground truth. For doing this, we use the well-known performance metrics *Adjusted Rand Index* and *Normalized Mutual Information*, explained in the following subsection.

A. Performance metrics

Suppose that for a given graph G , $\mathcal{C}(\mathcal{A}) = \{C_1, \dots, C_k\}$ and $\mathcal{C}' = \{C'_1, \dots, C'_{k'}\}$ be respectively a set of communities obtained by an algorithm \mathcal{A} and the ground truth.

Although NMI [44] is a well-known clustering comparison metric, it can perfectly evaluate the similarity between the optimal communities and those discovered by an algorithm. The NMI value corresponding to the algorithm \mathcal{A} can be written as

$$NMI = \frac{-2 \sum_{x=1}^{|\mathcal{C}|} \sum_{y=1}^{|\mathcal{C}'|} \frac{|C_x \cap C'_y|}{n} \log\left(\frac{n|C_x \cap C'_y|}{|C_x||C'_y|}\right)}{\sum_{x=1}^{|\mathcal{C}|} \frac{C_x}{n} \log\left(\frac{C_x}{n}\right) + \sum_{y=1}^{|\mathcal{C}'|} \frac{C'_y}{n} \log\left(\frac{C'_y}{n}\right)} \quad (17)$$

In the case where the detected communities are identical to the ground truth, the NMI takes its maximum value one, while in the case where the two sets totally disagree, the NMI score is zero. Generally, the more the NMI, the better community structures have been found.

Adjusted rand index (ARI) [45], associated with algorithm \mathcal{A} , measures the similarity between $\mathcal{C}(\mathcal{A})$ and \mathcal{C}' as follows

$$ARI = \frac{2(a \times d - b \times c)}{(a + b) \times (b + d) \times (a + c) \times (c + d)} \quad (18)$$

where a , b , c and d are respectively the number of vertex pairs that are in the same community in both $\mathcal{C}(\mathcal{A})$ and \mathcal{C}' , in the

Fig. 4: Average normalized ARI and NMI performance rank of different algorithms applying to the real-world networks, presented in Table I. The average NMI and ARI values obtained by our method are respectively equal to 0.39 and 0.46.

same community in $\mathcal{C}(\mathcal{A})$ but not in \mathcal{C}' , in the same community in \mathcal{C}' but not in $\mathcal{C}(\mathcal{A})$, and in different communities in both $\mathcal{C}(\mathcal{A})$ and \mathcal{C}' . Like the NMI measure, the value of *ARI* varies between 0 and 1, and the higher its value is, the more similarity is between the communities obtained by algorithm \mathcal{A} and the grand truth of G .

B. Experiments

In what follows, we provide a process for comparing the performance of our proposed algorithm against five powerful rival algorithms: *Node2Vec* [28], *Neural-Brane* [19], *DeepWalk* [27], *Line* [46], and *Text-Associated DeepWalk (TADW)* [30]. These are all state-of-the-arts for integrating both network topology and nodal attributes for graph representation learning.

All algorithms are implemented with C++, and CPLEX optimizer 12.9 is used for solving linear programming.

Fig. 4 provides a comprehensive comparison by evaluating communities in terms of the average ARI and NMI ranks over all datasets. It is apparent that the proposed method significantly outperforms other algorithms in the sense that the communities it discovered are much more similar to the ground truths than those obtained by the other methods.

Although the results obtained in Fig. 4 perfectly illustrate the proposed method’s superiority and reliability against some other state-of-the-art algorithms, it could still be worth investigating the role of the applied GNN feed-forwards message passing procedure in improving the communities. For doing this, we compute the value of NMI associated with each of the networks’ obtained final communities in terms of different hidden layer numbers k . In this regard, $k = 0$ refers to the case when the embedding layer is not applied, and only Modularity is employed to identify communities with respect to the graph’s topological structure. Fig. 5 shows the results.

Fig. 5: The computed NMI corresponding to the final communities of each of the networks, provided in Table I, with respect to different values of k .

It is apparent from the results that, first of all, maximizing the Modularity alone (i.e., only relying on topological aspects and ignoring the nodal attributes) cannot lead to promising results. Furthermore, considerably notable is the approving effect of increasing the number of hidden layers. The more the value of k , the more accurate the embedding vector representation becomes due to the more information diffused through the neighboring vertices. However, interestingly enough, from a certain point on, increasing k does not influence the quality of communities, and this is primarily due to the fact that after a certain number of updates, each of the embedding vectors starts to converge.

V. CONCLUSION

In this work, we built a community discovery method on the basis of the mathematical programming formalism and the graph neural network feed-forward message passing manner. We managed to propose a systematic way to generate an authentic relation matrix for the Max-Min Modularity problem centered on an efficient node embedding technique, which enabled us to model the standard integer formulation for the Max-Min Modularity Maximization problem. A successful row/column generation technique and a local search-based rounding algorithm facilitated us in solving the model accurately and capturing the communities of a given attributed network. Furthermore, the proposed computational experiments showed that our results highly resemble the optimal solutions and that our algorithm outperforms the previous well-known algorithms.

□

Abstract— The article presents the assessment of the potential accuracy of the location of the terrestrial radio signal source in the Rice channel using the received signal filtering and the non-linear regression function. The basic assumption for the parameterization of the channel was to use a drone with a simple antenna system and Received Signal Strength analysis from multiple measurement points (Multilateration location). Preliminary results under Rice-typical channel conditions indicate position estimation errors of the order of 60 meters for $K=7$, which in the assumed network structure is approximately 10% of the actual average distance. By using properly parameterized filtration systems (Kalman algorithm and Moving Average algorithm set), it is possible to increase this accuracy by one-third of the initial value.

I. INTRODUCTION

THE problem of locating the source of radio radiation is very broad. This task can be viewed as a service to a locator or located user. The method of its implementation varies depending, for example, on the type of services (military or civil), type of system, technical capabilities of devices (e.g. antenna set), conditions in which the task is performed (e.g. type of land cover, user traffic characteristics). In the changing world of technology, one of the recently popular branches of development is the area related to the use of unmanned aerial vehicles [1]-[3]. They are of course used for different purposes and hence can be classified differently.

This study assumes the use of simple, small Unmanned Aerial Vehicles (UAV) with an uncomplicated antenna system (omnidirectional antenna with low gain) and limited computing possibilities (e.g. [4]—[5]). These types of UAVs are relatively cheap and can perform various types of services in a team (e.g. a swarm of UAVs). The article considers the operation of a single UAV, which uses Received Signal Strength (RSS) recorded during the flight and the Multilateration method [6] to locate the radio signal source. Location methods based on RSS measurement belong to the Range Based group and are used relatively easily, realizing location with moderate accuracy, which can be increased by increasing the number of bearing points.

Technical details such as the curvature of the Earth resulting from geodetic corrections are omitted in the study.. The results of the analysis shed additional light on the

potential averaged efficiency of using simple, single UAVs in the process of locating the radiation source based on a blind flight over the area of network operation, when the UAV performs other functions simultaneously [7].

Chapter 2 is a reference to the state of knowledge in the analyzed area. The following chapters describe the network structure (Chapter 3), the radio channel model (Chapter 4), the location method and filtering algorithms for the channel response (Chapter 5), and the results of simulation analyzes (Chapter 6).

II. RELATED WORKS

The use of UAVs to locate the source of radio radiation, both indoor and outdoor, is currently the subject of several research and applications. Depending on the goals to be achieved and the technical capabilities of tracking systems and radiation sources, various types of location methods are proposed in [8]—[13]. Others are used in military applications, others in civil applications.

In a situation where advanced technical support from ground nodes cannot be expected, the possibility of using a simple and easy to implement location method based on the measurement of the RSS is often considered (e.g. [14]—[17]). Such algorithms, in connection with the situation when we have a large number of measurement values (the UAV carries out a relatively large number of measurements during the flight while performing other tasks (e.g. securing the network integrity [7], [18]) may offer increased location accuracy, by using the so-called Multilateration algorithms (unlike Trilateration, when the location is based on information from only 3 measurement points [19].

When assessing the possible location accuracy, it should be taken into account that the channel distortions on the Air to Ground connections depend mainly on the type of terrain [20], however, it can be assumed that due to the elevation of the UAV above the ground level, signal fading is not very deep [21] and we often deal with a Rice channel with a coefficient from $K = 7$ to $K = 14$. Nevertheless, increasing the accuracy of the location requires additional filtration operations, the most popular of which are Kalman filtration [22] and the so-called Moving Average.

III. THE NETWORK STRUCTURE

From the point of view of the ground station location algorithm itself, the structure of the network does not matter much. However, to cover the issue in more practical reality,

□ This work was financed by the Military University of Technology under research project no. UGB/22-744/2022/WAT on "Modern radio technologies in military communication systems".

it was assumed that the task of the UAV, which performs the network flight and records signals from terrestrial [7] radio sources, is to indicate the location of nodes beyond the network coverage (not connected, Fig. 1) to undertake subsequent actions to connect them with the rest of the network (e.g. by sending retranslation drones). To average the results, tests were carried out for 4 different route cases, differing in the value of the parameter R , which can be interpreted as the turning radius of the UAV.

The following main assumptions were made about such a network:

1. The terrestrial network is relatively stationary
2. Network nodes do not support UAV measurements (they do not have GPS receivers).

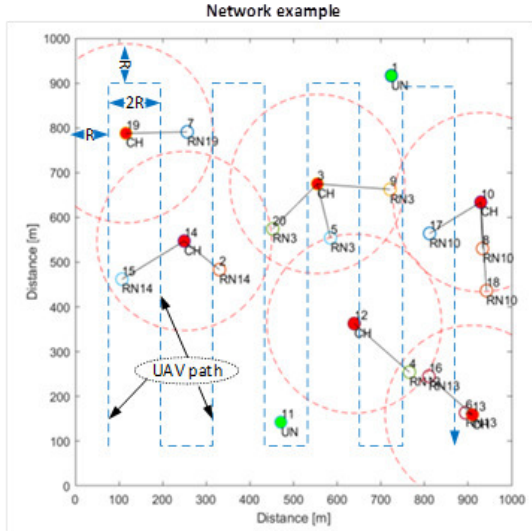

Fig. 1 An example of the location of 20 nodes of a clustered network. RN - Regular Node, CH - Cluster Head (red), UAV - Unmanned Aerial Vehicle (blue line), UN - Unknown Node (green, the disconnected node)

IV. THE RADIO CHANNEL MODEL

The characteristics of the radio channel for the case considered in the material (ground-air link of UAV) mainly depend on the following factors:

1. Drone flight altitudes.
2. UAV flight speed and associated Doppler shift.
3. Land cover (city, suburban area, mountainous area, etc.).
4. Network operating frequencies.
5. Volatility of the above-mentioned factors.

An overview of these types of channels can be found e.g. in [20]. Additional discussion of this type of propagation conditions, e.g. in [18]. The conditions assumed in this study assume an outdoor LOS (Line of Sight) link modelled by the Rice radio channel. According to the guidelines contained in [21], the K factor characterizing the depth of decays ranges from 7 to 14.

We can write down that for the Rice channel:

1. K factor being the ratio of the power of the direct ray to the value of the sum of the powers of the other reflected components

$$K = \frac{\vartheta^2}{2\delta^2}. \quad (1)$$

2. Ω factor as total received power

$$\Omega = \vartheta^2 + 2\delta^2. \quad (2)$$

The amplitude of the received signal is defined as:

$$\vartheta^2 = \frac{K}{1+K} \Omega \text{ and } \delta^2 = \frac{\Omega}{2(1+K)}; \quad (3)$$

and we write the probability density function as:

$$f(x) = \frac{2(K+1)x}{\Omega} \exp\left(-K - \frac{(K+1)x^2}{\Omega}\right) I_0\left(2\sqrt{\frac{K(K+1)}{\Omega}}x\right). \quad (4)$$

Exemplary realizations of the amplitude of the signal received by the UAV for the values of the coefficients $K = 7$ during a single flight over the network (along the selected route) are shown in Fig. 2. The model did not take into account the Doppler shift and antenna characteristics, assuming low UAV speed and omnidirectional characteristics of the antenna with zero gain.

Fig. 2 The amplitude of the signal in the Rice channel for the coefficient $K = 7$

V. DESCRIPTION OF THE LOCATION METHOD

As mentioned in Chapter 2, you can find many literature sources describing different kinds of localization methods. However, if we accept the above-mentioned organizational and technical constraints imposed on network and UAV devices, the problem narrows significantly. In addition, it is worth noting that the assessment of the accuracy of the location in the Rice channel presented in this article is based on the assumption that we have a large set of measurement data, which results in the use of Multilateration algorithms [23], [6], Fig. 3.

Having the bearings from many points, we can save the estimated distance from the localized point in the form:

$$d_i^2 = (x_i - x)^2 + (y_i - y)^2, \quad (i = 1, 2, \dots, n), \quad (5)$$

where:

d – estimated distance from the localized point,
 x_i – coordinate x of DF no. i ,
 y_i – coordinate y of DF no. i .

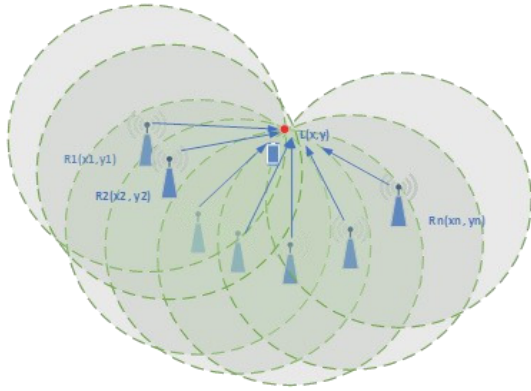

Fig. 3 An example of a directional finding using the Multilateration method with the use of n Directional Finders (DF). $L(x, y)$ - position of the localized station

The position of the signal source can be expressed, for example, in a general form as a solution to the algebraic equation [24]:

$$\begin{bmatrix} 1 & -2x_1 & -2y_1 & -2z_1 \\ 1 & -2x_2 & -2y_2 & -2z_2 \\ 1 & -2x_3 & -2y_3 & -2z_3 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & -2x_n & -2y_n & -2z_n \end{bmatrix} \begin{bmatrix} x^2 + y^2 + z^2 \\ x \\ y \\ z \end{bmatrix} = \begin{bmatrix} d_1^2 - x_1^2 - y_1^2 - z_1^2 \\ d_2^2 - x_2^2 - y_2^2 - z_2^2 \\ d_3^2 - x_3^2 - y_3^2 - z_3^2 \\ \vdots \\ d_n^2 - x_n^2 - y_n^2 - z_n^2 \end{bmatrix} \quad (6)$$

where z - coordinate z (in a spatial case).

Here, to determine the estimate of the radio signal source location, the MATLAB nonlinear regression function was used, giving the model function in the form $\text{modelfun} = @(b, X) (\text{abs}(b(1) - X(:, 1)).^2 + \text{abs}(b(2) - X(:, 2)).^2).^(1/2)$ and the starting point of searching for the optimal solution (position of the target station) in the center of the monitored plane.

To increase the accuracy of the location, the measured signal was pre-filtered. For comparison, Kalman filtering and 7 different Moving Average algorithms were used (Fig. 4).

In addition, before performing the proper location calculation, taking into account the fact that the filtered signal is subject to a time shift (delay), a corresponding correcting time shift and averaging window for the Moving Average methods were made individually for each filter result.

This action was aimed at minimizing the vector distance between the distorted original signal and the filtered signal according to the relationship:

$$\text{MinDistance} = \min \left| \sum_{i=1}^n \sqrt{R_i^2 + Y_i^2} - \sqrt{R_i^2 + Yf_i^2} \right|, \quad (7)$$

where:

- R_i – i -th point of the UAV route,
- Y_i - i -th RSS level of measured signal,
- Yf_i - i -th RSS level of filtered signal.

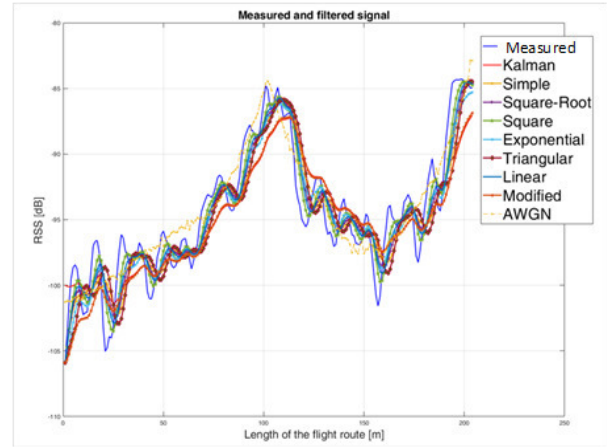

Fig. 4 The effect of applying filtration using various algorithms

This action resulted in a significant reduction in tracking errors.

VI. SIMULATION RESULTS

I. System parametrization

The simulations were carried out in the MATLAB R2021b simulation environment (9.11.0.1769968) using the parameters presented in Table . 30 channel conditions randomization was performed for each set value of the R and K parameters.

TABLE I.
SIMULATION PARAMETERS

Parameter	Value
Channel models	AWGN, Rice
K factor of Rice channel	7 to 14
Noise Variance	1
Number of UAV	1
The number of random repetitions of each case	30
Number of measures	In the range from 144 to 362 depending on the UAV route.
R [m]	100, 150, 200, 250

II. Results

The results of the simulation tests are shown in Fig.5 and Fig.6. It can be initially concluded that each of the filtration methods increases the efficiency of localization to a similar degree. The final error, in the analyzed cases, is the smaller the smaller the value of the K coefficient (channel with deeper fades), and for $K = 7$ it is about one-third smaller than the original value (Fig. 5).

The highest potential in the discussed distortion filtration process, in the range of small K values, is shown by Kalman filtration and the Simple Moving Average.

VII. CONCLUSION

The article assesses the accuracy of the location of the radio ground station in the Rice Channel based on RSS level measurements by the UAV flying around the entire network deployment area. As a result of the application of the Multilateration method and the nonlinear regression function

supported by the filtering algorithms of the measured signal, the location accuracy was improved by several to several dozen meters depending on the depth of the decays (the greater the effect, the deeper the value of the decays). The further direction of work will be related to research using other types of channels and verification of the obtained results in real channel conditions.

1st Workshop on Complex Networks: Theory and Application

IN the nature and the world around us, we can observe many network structures that interconnect various elements such as cells, people, urban centers, network devices, companies, manufacturing machines, etc. Most of them have the nature of evolving networks whose structure changes over time. The analysis of such systems from the complex networks point of view allows for better understanding of the processes within them, which can be used to optimize their structure, improve their management methods, detect failures, improve their operating efficiency and plan their development and evolution.

The main goal of this event is to exchange knowledge and experience between specialists from different areas who in their research and design work use theories and solutions characteristic for complex systems. We believe that the meeting will create new ideas and concepts that will affect the development of contemporary methods of design, operation and analysis of network systems.

TOPICS

The list of topics includes, but is not limited to:

- Complex networks architecture
- Large scale networks analytics
- Mathematical and numerical analysis of networks
- Modeling of computer networks
- Cognitive networks
- Visualizations of network processes
- Dynamics on networks
- Biological and physical models on networks
- Dynamic modification of communication protocols parameters for enterprise and ISP systems
- Complex network management
- Performance modeling and analysis in complex networks
- Network function virtualization

- Social networks
- Graph theory and network algorithm application
- Evolving networks
- Detection of anomalies in the functioning of an enterprise-class computer network element
- Predictive maintenance
- Network technologies supporting society 5.0 and education 5.0
- Architecture for next-generation network applications
- Distributed complex systems for remote working and collaboration
- Algorithms for controlling and monitoring complex computer networks

TECHNICAL SESSION CHAIRS

Abstract—The article presents the problem of the complexity of prediction and the analysis of the effectiveness of selected IT tools in the example of the Covid-19 pandemic data in Poland. The study used a variety of tools and methods to obtain predictions of extinct infections and mortality for each wave of the Covid-19 pandemic. The results are presented for the 4th wave with a detailed description of selected models and methods implemented in the prognostic package of the statistical programming language R, as well as in the Statistica and Microsoft Excel programs. Naive methods, regression models, exponential smoothing methods (including ETS models), ARIMA models, and the method of artificial intelligence - autoregressive models built by neural networks (NNAR) were used. Detailed analysis was performed and the results for each of these methods were compared.

I. INTRODUCTION

PREDICTION is the process of making certain anticipations with a definable probability of how phenomena will develop in the future. It derives from the field of statistics. It is rational in nature and uses data from the past in its course. Forecasting is used in various areas, such as predicting the weather, electricity consumption, product prices, etc. The resulting forecasts can provide valuable information and help in making decisions about future activities.

Predicts makes it possible to determine the possible future values of a time series. Various methods are available for their determination. They are based on mathematical models that describe the values of the series. The models may take into account many factors, e.g. historical values of the series, values of predictors, characteristics of the series, etc. A model is created by performing a series analysis and parameter estimation based on the data at hand.

Since the beginning of the Covid-19 pandemic, many disease prediction models have emerged, shaping the interest of the media, policymakers, and the broader public [1, 2]. However, forecasting the future development of a pandemic is challenged by the inherent uncertainty rooted in many "unknown unknowns," not only about the contagious virus itself, but also the human, social, and political factors that coevolve and keep the future of the pandemic open. Fore-

casting models have varying degrees of predictive accuracy. Researchers have attempted analyses during previous epidemics of the 21st century, namely SARS, H1N1, and Ebola. As reported in [1, 3], predictions of Ebola deaths have often been far from the ultimate reality, with a strong tendency to overestimate. It is therefore important to communicate the uncertainty of such analyses. The Covid-19 pandemic spread rapidly around the world, and researchers attempted to estimate the risk. Many researchers around the world have used various prediction techniques such as the Susceptible-Infected-Recovered model, Susceptible-Exposed-Infected-Recovered model, and Automatic Regressive Integrated Moving Average (ARIMA) model to predict the spread of this pandemic. The ARIMA technique has not been extensively used in Covid-19 forecasting by researchers due to the claim that it is not suitable for use in complex and dynamic contexts. However, in [4], the authors proposed the use of time series algorithms, Autoregressive Integrated Moving Average (ARIMA) and Autoregressive (AR). ARIMA-based models showed promising results compared to AR-based models. However, the most difficult challenge was parameter identification due to the sudden increase-decrease trend in coronavirus cases. The proposed work presents prediction quality scoring metrics for both models. In [5], verification was performed to see how accurate the best-fit predictions of the ARIMA model were with the actual values reported after the entire prediction period. The results showed that despite the dynamic nature of the disease and the continuous changes made by the Kuwaiti government, the actual values for most of the observed period were within the prediction limits of our chosen ARIMA model with a 95% confidence interval. Another direction taken by the researchers is to apply machine learning (ML) based forecasting mechanisms. ML models have long been used in many application domains that required the identification and prioritization of adverse threat factors. In the paper [6], four standard prediction models such as linear regression (LR), least absolute shrinkage and selection operator (LASSO), support vector

machine (SVM), and exponential smoothing (ES) were used to predict risk factors. The results proved that ES performs best among all the models used, followed by LR and LASSO, which perform well in predicting new confirmed cases, mortality, and recovery rate, while SVM performs poorly in all prediction scenarios given the available data set.

The author's paper [7] proposes an approach to forecasting the spread of pandemics based on a vector autoregression model. Time series of the number of new cases and the number of new deaths were combined to obtain a common prediction model. Test results based on data from the United Arab Emirates, Saudi Arabia, and Kuwait showed that the proposed model achieved a high level of accuracy, outperforming many existing methods, which can be a valuable tool in pandemic management.

The pandemic has shown that having knowledge and prediction of its spread will allow one to respond appropriately and attempt to undertake containment. Results obtained in [8] using a network model based on long-short-term memory (LSTM) have shown promise. The proposed model was used to predict the dates when other countries would be able to contain the spread of Covid-19.

In [9], the authors presented the results of a study on developing a neural network model for predicting the spread of Covid-19. They proposed a predictor based on a classical approach with a deep architecture that learns using the NAdam training model. Official data from government and open source repositories were used for training. The results of the proposed model showed high accuracy, which reached more than 99% in some cases.

The scope of this paper is to use different forecasting methods and to compare the results obtained for a given set of data from the course of the Covid-19 pandemic in Poland. The aim is to analyze the correctness and degree of fit of the forecasts obtained using different algorithms.

In the analysis, we used data on the daily incidence and death rates registered in Poland during the Covid-19 pandemic. On their basis, mathematical models were created, and then forecasts of subsequent values for time horizons of different lengths were carried out. In this way, possible scenarios for the course of the pandemic were presented.

The paper is divided into five chapters. The introduction provides a review of the literature and recent trends used in the prediction of Covid-19 pandemic trends. Chapter 2 characterizes the methods and IT tools used in the study such as regression and ARIMA models, methods based on neural networks, and main packages in R, Statistica, and Excel environments. Chapter 3 presents the selected issue of forecasting the evolution of a pandemic. Chapter 4 presents a description of the experiments and a comparative analysis of the results of prediction methods for the 4th wave of the pandemic in Poland. The summary, conclusion, and scope of future research are presented in Chapter 5.

II. PREDICTION METHODS AND IT TOOLS

The paper presents various techniques used in time series prediction - from simple ones, such as naive methods, through adaptive models and autoregressions to more advanced ones, such as ARIMA models or neuro-networks. The obtained models will be evaluated in terms of their fit to historical realizations of the series and the quality of generated forecasts. In addition, the use of selected software tools useful in forecastings such as Microsoft Excel, Statistica, and RStudio environment using R language developed for statistical purposes is presented. We use regression models which is a statistical method of describing utilizing a function the dependence of the values of some variables (explanatory) on the values of others (explanatory, predictors) [10], and autoregressive (AR) models describe the explanatory variable as a function of its lagged values [11-12]. Prediction is also possible based on neural network-based models. Artificial neural networks have a layered structure, which includes neurons that in a simplified way mimic the operation of cells found in the human brain. With the use of neural networks, it is possible to model the autoregression of time series. It consists in feeding the network input with delayed values of time series. An example of such solution implementation is `nnetar()` function from FORECAST package where one-way neural networks with one hidden layer (NNAR models) are used therefore forecasting [13-15].

III. FORECASTING THE EVOLUTION OF A PANDEMIC USING VARIOUS IT TOOLS AND METHODS

The subject of this study is data related to the course of the Covid-19 pandemic in Poland. The decision to use the results from their timeliness and availability at the time of work creation. The collected data describe the daily numbers of infections, deaths, and tests performed between 05.03.2020 and 25.10.2021. They form a time series that will be used to test the effectiveness of different prediction methods.

To simplify the code of scripts, functions were prepared to create graphs using methods provided by the ggplot2 package of R language. To validate the quality of models and forecasts, functions were created to calculate the values of error measures (ME, MAE, MSE, RMSE, MAPE) and to select the objects of models and forecasts that are characterized by the most satisfactory features (Table I) [12-15].

The fitting of models to historical data and forecasts generated by them are presented in Fig. 1. Figure shows the fit of the finally selected models to the training series and a comparison of the generated forecasts for the 30-day horizon with the test series. The forecast charts also show the ranges for the 80% and 95% confidence levels.

IV. TIME SERIES ANALYSIS OF PANDEMIC WAVE 4 DEATH NUMBERS

The following methods were selected to forecast the values of death numbers for the 4th wave (time period from 26.09.2021 to 25.10.2021):

- R - simple naive method,
- R - seasonal naive method,
- R - incremental naive method,
- R - linear regression model including linear trend and seasonal variables built on training time series with observations from 17.07.2021 to 25.09.2021),

- R - ETS(A,Ad,A) model estimated using historical values of death numbers from 05.03.2020 to 25.09.2021,
- R - ARIMA($2,1,2$)($0,1,1$) model built on the basis of modified by adding constant 1 and undergoing Box-Cox transformation training time series with observations from 05.03.2020 to 25.09.2021,
- R - NNAR($22,1,12$) model selected based on the training series with observations from 05.03.2020 to 25.09.2021,
- Statistica - Holt model estimated based on the training series with observations from 28.03.2020 to 25.09.2021,
- Statistica - Winters model estimated based on modified (addition of constant 1 and natural logarithmization) training time series with values from 28.03.2020 to 25.09.2021.
- Statistica - ARIMA($3,1,3$)($2,1,2$) model built based on modified by adding constant 1 and undergoing natural logarithmization training time series with observations from 28.03.2020 to 25.09.2021,
- Microsoft Excel - ETS(A,A,A) model estimated from the modified training series with death numbers from 28.03.2020 to 25.09.2021.

We concluded that predictions obtained using the Winters method in the Statistica program are characterized by very large values in comparison with predictions created by other methods. They differed significantly from the test (actual) values and were therefore not considered in further analyses. The predictions (excluding those mentioned) are shown in the graph (Fig. 2).

Fig. 2 Comparison of predictions with actual death counts for the 4th wave

Ex post forecast error measures were calculated. The calculation of MAPE values omitted cases for which the value of observations in the test series was equal to 0 (27.09.2021, 04.10.2021, 11.10.2021, and 25.10.2021). The most satisfactory predictions were obtained from the ARIMA(3,1,3) (2,1,2) model in Statistica software.

V. CONCLUSION

The study used a variety of tools and methods to obtain projections of expired infection and death rates for each wave of the Covid-19 pandemic. Forecasting was performed using models and methods implemented in the forecast package of the statistical programming language named R and the programs Statistica and Microsoft Excel. With the first tool, naive methods, regression models, exponential smoothing methods (including ETS models), ARIMA models, and artificial intelligence method - autoregressive models built by neural networks (NNAR) were applied for the examined time series. In Statistica software, modules were used to create predictions based on exponential smoothing methods and ARIMA models. In the case of Excel, predictions were obtained using prediction sheets.

MAE, RMSE, and MAPE error measures were used to verify the quality of the applied models and methods. Based on their values calculated for the training time series, a preliminary selection of the best variants of methods and models within one category was made (e.g. selection of the best regression model from among models taking into account

various predictors). The final selection of the best solution for a particular time series was based on the values of the ex-post forecast error measures (calculated for the test set). Based on the analysis of the final results (forecasts obtained with the selected methods), based on the values of the test error measures, the solutions that allowed obtaining the most satisfactory predictions were indicated. For the time series of infection rates, a multiplicative variant of the Winters method from the family of exponential equalization methods was selected as the best forecasting method. For the time series of deaths, the use of ARIMA models was selected as the best approach.

Abstract—Denotational semantic model and its implementation in C/C++ are presented for a virtual machine executing programs written in the CPDev development environment according to IEC 61131 standard. Programs written in IEC ST language are compiled to control-oriented intermediate language designed specifically for the machine. Architecture of the machine and its operation are represented by formal semantic model which assigns abstract algebraic objects to denote machine behaviour. Execution of intermediate language instructions is described in details by denotational semantic equations followed strictly by C/C++ implementations to assure reliability of the machine.

I. INTRODUCTION

THE concept of virtual machines as platforms for software execution had a significant impact on computer science for almost half a century [1], [2]. A virtual machine (VM) is understood as a kind of processor with a certain instruction set and data types, which is implemented by software on particular hardware platforms. A VM processes an intermediate code generated by a compiler from a source program. The concept of VMs has been gaining importance due to the widespread use of the Java [3] and the .NET [4], [5]. Solutions based on VMs have some important advantages, namely a) source program and intermediate code are independent of target platforms, b) one compiler is sufficient, c) programs are executed in safe environments. The disadvantages include slower execution of the intermediate code and the need to develop a runtime environment suitable for the target platform.

This paper deals with the development of a runtime environment for control programs written according to the standard IEC 61131 [6]. The IEC standard defines the programming languages: Structured Text (ST), Instruction List (IL), Ladder Diagram (LD), Function Block Diagram (FBD) and Sequential Function Chart (SFC). Here, employing the VM concept appears to be particularly justified in order to cope with the large variety of target platforms. The CPDev engineering environment [7] uses this concept to program controllers according to the IEC standard. It consists of a compiler translating ST to intermediate code and a VM-based runtime system written in C. Initially, small and medium-scale controllers were considered [8]. Recently, however, motivated by applications with extensive calculations, arose the need to extend the CPDev compiler and its VM. Therefore, some additional assumptions were imposed, namely:

- to develop a semantic model of the machine and its intermediate language followed by a C implementation,
- to achieve scalability of the machine depending on the particular hardware and application requirements,

The model formalizes the VM description as an interpreter of the intermediate code, including instruction and operand decoding, and low-level operations while executing the instructions. Denotational semantics [9], [10] appropriate to formally describe programming languages are applied [11], [12]. For denotations the λ -notation is adequate and, therefore, applied [9], [13].

II. VIRTUAL MACHINE ARCHITECTURE

The architecture of the VM includes [14]: code and data memories, stacks and registers. The instruction processing module fetches successive instructions from *Code memory* and executes them acquiring values of operands either from *Data* or *Code memory*. Results are stored in *Data memory*.

Registers: The program counter is kept in the *CodeReg* register. The data base register *DataReg* is set by calls to and returns from subprograms, including function blocks and functions. When entering a subprogram the current values of *CodeReg* and *DataReg* are pushed onto *Code stack* and *Data stack*. The machine also includes the *Flags* register with status flags signaling errors or unusual situations.

VMASM intermediate language: The virtual machine operates as an interpreter of assembly code called VMASM (VM Assembler). The syntax is:

```
[ :label ] instruction [ operand1 ] [, operand2 ] ...
```

Instruction set: Functions and system procedures are two kinds of virtual machine instructions. Examples are shown in Table I.

The compilation of the simple ST instruction

```
MOTOR := (START OR MOTOR) AND NOT STOP;
```

is presented in Listing 1. At first, the variables *START* and *MOTOR* are ORed and the result is stored in a temporary variable ?LR?A03. If it is zero, JZ jumps to :?A02, where MCD sets *MOTOR* to 0 interpreted as FALSE. If ?LR?A03 is not zero, the function NOT performs logical negation of STOP storing the result in ?LR?A05. If it is zero, JZ jumps to the

TABLE I
SELECTED FUNCTIONS AND PROCEDURES

Mnemonic	Meaning	Operator
Functions		
ADD	Addition	+ (arithm.)
SUB	Subtraction	- (arithm.)
GT	Greater	>

JZ ?LR?A03, :?A02
NOT ?LR?A05, STOP
JZ ?LR?A05, :?A02
MCD MOTOR, #01, #01
JMP :?E08
:?A02
MCD MOTOR, #01, #00
:?E08
```

III. SCALABILITY

The data types and instructions of the VMASM language are defined in XML-formatted library configuration files (LCF).

Types and instructions: A portion of type definitions is shown in Listing 2. By applying `deny-type` one can restrict some data types. Aliases to existing types and special types not specified in the IEC standard can be defined, too.

Listing 2. Type definition

```
<deny-type name="LREAL" />
<type name="USINT" implement="alias">
  <alias name="BYTE"/>
</type> ...
```

Functions: The definition of one in the group of ADD functions is presented in Listing 3. The virtual machine code `vmcode` consists of two bytes, with the first one 01 identifying the group, whereas the second *2 indicates a flexible number of inputs (*) and identifies the data type (2) processed. The two components of `vmcode` are called group and type identifier, and are denoted by `ig` and `it`. By choosing an appropriate `it`, type-specific functions such as `ADD:SINT`, `ADD:INT`, etc. are defined.

Listing 3. Function definition

```
<function name="ADD" vmcode="01*2" return="INT">
```

```
<operands>
  <op no="*" name="a*" type="INT"/>
</operands>
</function> ...
```

Procedures: All system procedures are identified by `ig=1C`. The second byte `it` of `vmcode` indicates a particular procedure. The definitions of `JNZ` and `CALB` are shown in Listing 4. `JNZ` executes a conditional jump to `:gclabel`, `CALB` calls the subprogram at `:gclabel`.

Listing 4. Procedure definitions

```
<sysproc name="JNZ" vmcode="1C01">
  <op no="0" name="cnd" type="BOOL"/>
  <op no="1" name="clbl" type=":gclabel"/>
</sysproc>
<sysproc name="CALB" vmcode="1C16">
  <op no="0" name="inst" type=":rdlabel"/>
  <op no="1" name="clbl" type=":gclabel"/>
</sysproc>
```

Operand types: The following types are available:

- `:gclabel` `:gdlabel` – global pointer (address) to *Code/Data memory*,
- `:rclabel` `:rdlabel` – address relative to actual content of code/data register,
- `:imm` – immediate value (direct, constant).

IV. SEMANTIC MODEL

Semantic models provide formal descriptions of programming languages [11], [15]. In case of VMASM, the model consists of domains describing the virtual machine's states, memory functions, value interpreters relating memory to VMASM types, limited range operators, and a universal semantic function.

Semantic domains: The domain *BasicTypes* consists of four sets reflecting the memory sizes of the VMASM types. The domain *Address* specifies 16- or 32-bit implementation. The general domain *Memory* is a function mapping *Address* to *Byte1*. *Stack* models a sequence (*) of *Address* domains (Kleene closure).

$$\text{BasicTypes} = \text{Byte1} + \text{Bytes2} + \\ + \text{Bytes4} + \text{Bytes8}$$

$$\text{Address} = \text{if } \text{AddressSize} = 2 \text{ then} \\ \text{Bytes2} \text{ else } \text{Bytes4}$$

$$\text{Memory} = \text{Address} \rightarrow \text{Byte1}$$

$$\text{CodeMemory} = \text{Memory}$$

$$\text{Stack} = \text{Address}^*$$

$$\text{CodeStack} = \text{Stack}$$

$$\text{CodeReg} = \text{Address}$$

$$\text{Flags} = \text{Bytes2}$$

State: The purpose of program execution is to change the current state into a new one. The state of the VM is a Cartesian product of memory domains, stacks, registers and flags, i.e.

$$\text{State} = \text{CodeMemory} \times \text{DataMemory} \times$$

$$\begin{aligned} & \times \text{CodeStack} \times \text{DataStack} \times \\ & \times \text{CodeReg} \times \text{DataReg} \times \text{Flags} \end{aligned}$$

Model functions: The functions presented below model low-level operations executed on memory, stacks and flags.

- Get data from memory (read)

$$\begin{aligned} G1BM &= (\text{Address} \times \text{Memory}) \rightarrow \text{Byte1} \\ G2BM &= (\text{Address} \times \text{Memory}) \rightarrow \text{Bytes2} \\ G4BM &= (\text{Address} \times \text{Memory}) \rightarrow \text{Bytes4} \\ G8BM &= (\text{Address} \times \text{Memory}) \rightarrow \text{Bytes8} \end{aligned}$$

- Get address from memory

$$\text{GetAddress} = (\text{Address} \times \text{Memory}) \rightarrow \text{Address}$$

- Memory update (write)

$$\begin{aligned} U1BM &= (\text{Address} \times \text{Memory} \times \text{Byte1}) \rightarrow \text{Memory} \\ U2BM &= (\text{Address} \times \text{Memory} \times \text{Bytes2}) \rightarrow \text{Memory} \\ U4BM &= (\text{Address} \times \text{Memory} \times \text{Bytes4}) \rightarrow \text{Memory} \\ U8BM &= (\text{Address} \times \text{Memory} \times \text{Bytes8}) \rightarrow \text{Memory} \end{aligned}$$

- Memory move (copy)

$$\text{MemMove} = (\text{Address} \times \text{Memory} \times \text{Address} \times \text{Memory} \times \text{Byte1}) \rightarrow \text{Memory}$$

The two *Addresses* represent source and target, respectively with *Byte1* denoting number of bytes being moved.

- Stack functions

$$\begin{aligned} \text{Push} &= (\text{Stack} \times \text{Address}) \rightarrow \text{Stack} \\ \text{Pop} &= \text{Stack} \rightarrow (\text{Address} \times \text{Stack}) \end{aligned}$$

Value interpreters: The following sample functions provide numerical interpretations of memory chunks.

$$\begin{aligned} \text{BoolOf} &= \text{Byte1} \rightarrow \text{BOOL} \\ \text{FromBool} &= \text{BOOL} \rightarrow \text{Byte1} \\ \text{IntOf} &= \text{Bytes2} \rightarrow \text{INT} \\ \text{FromInt} &= \text{INT} \rightarrow \text{Bytes2} \\ \text{DIntOf} &= \text{Bytes4} \rightarrow \text{DINT} \\ \text{FromDInt} &= \text{DINT} \rightarrow \text{Bytes4} \\ \text{LIntOf} &= \text{Bytes8} \rightarrow \text{LINT} \\ \text{FromLInt} &= \text{LINT} \rightarrow \text{Bytes8} \end{aligned}$$

Limited range operators: The virtual machine executes arithmetic operations in limited ranges, dependent on the particular types. For signed integers addition \oplus is defined by

$$\begin{aligned} a \oplus b &= \text{if } (a + b) \geq 0 \\ &\text{then } (a + b) \bmod (-\text{MinRange}(a)) \\ &\text{else } (a + b) \bmod (-\text{MinRange}(a) + 1) \end{aligned}$$

where *MinRange* for SINT, INT, DINT and LINT means -128 , -32768 , -2^{31} or -2^{63} , respectively. For unsigned integers USINT, UINT etc. we have

$$a \oplus b = (a + b) \bmod (\text{MaxRange}(a))$$

where *MaxRange* means 256, 65536 etc.

Unification: The operator $:=$ used in expression unifies both sides. If the right side is an expression, then the left side is a variable with the value of the right side (assignment). If the left side is a tuple and the right side a variable, then the variable is split into the tuple's components.

Universal semantic function: To jointly express the concept of decoding group and type, followed by execution of a particular instruction, one may define a universal function covering all instructions

$$\mathcal{U}[\text{any_instruction}] = \text{State} \rightarrow \text{State} \quad (1)$$

Internally, after decoding *ig* and *it*, this function calls a specific function of the form

$$\mathcal{C}[\text{instruction}] = \text{State} \rightarrow \text{State} \quad (2)$$

Instruction decoding: Instruction decoding can formally be expressed by the denotational semantic equation shown in Listing 5. According to [9] or [13], the λ -expression has the form of $\lambda s. \text{body}$, where *s* denotes the current state and *body* determines the value returned by the function. The *body* consists of a sequence of operations, the first of which splits current state *s* into a tuple composed of model components. The other operations decode the values of identifiers *ig* and *it*, update the code register to *cr*₂ and, by means of **match ... with** statements, call particular \mathcal{C} functions. The result provided by \mathcal{C} defines the new state *s*₁ returned by the function \mathcal{U} .

Listing 5. Denotational equation for the function \mathcal{U}

$$\begin{aligned} \mathcal{U}[\text{any_instruction}] &= \\ &\lambda s. (\text{cm}, \text{dm}, \text{cs}, \text{ds}, \text{cr}, \text{dr}, \text{flg}) := s \\ &\text{ig} := G1BM(\text{cr}, \text{cm}) \\ &\text{cr}_1 := \text{cr} \oplus 1 \\ &\text{it} := G1BM(\text{cr}_1, \text{cm}) \\ &\text{cr}_2 := \text{cr}_1 \oplus 1 \\ &\text{s}_1 := \text{match ig with} \\ &\quad | 01 \rightarrow \text{match it with} \\ &\quad \quad | 22 \rightarrow \mathcal{C}[\text{ADD:INT:r:op1:op2}] \\ &\quad \quad \quad (\text{cm}, \text{dm}, \text{cs}, \text{ds}, \text{cr}_2, \text{dr}, \text{flg}) \\ &\quad \quad | 32 \rightarrow \mathcal{C}[\text{ADD:INT:r:op1:op2:op3}] \\ &\quad \quad \quad (\text{cm}, \text{dm}, \text{cs}, \text{ds}, \text{cr}_2, \text{dr}, \text{flg}) \\ &\quad \quad | \dots \\ &\quad \quad \text{end} \\ &\quad | \dots \\ &\quad \text{end} \\ &\text{s}_1 \end{aligned}$$

V. DENOTATIONS AND IMPLEMENTATIONS

Denotational equations modeling the VMASM instructions have the common form $\mathcal{C}[\dots] = \lambda s. \text{body}$ where the dots on the left side are replaced by the descriptor of a particular instruction. Splitting current state *s* into components through unification

$$(\text{cm}, \text{dm}, \text{cs}, \text{ds}, \text{cr}, \text{dr}, \text{flg}) := s \quad (3)$$

is the first operation in *body*.

Assume that while calling a particular function \mathcal{C} by the universal function \mathcal{U} , the code register *cr* points to the first operand. (actually *cr*₂ in Listing 5). If the operand is a variable

or label, then its value, i.e. address, is acquired from code memory cm by

$$operand := GetAddress(cr, cm) \quad (4a)$$

In case of a global variable or label, $operand$ stands for a direct address in data or code memory. If, however, the operand is a local variable of a subprogram, then the value $operand$ means an address relative to the current value of data base register dr , which was set earlier by a subprogram call. Therefore, the address of a local variable is obtained by adding

$$operandaddr := dr \oplus operand \quad (4b)$$

The value of a variable, here shown for a Boolean, in data memory dm is read out and interpreted by composition

$$BoolOf(G1BM(operandaddr, dm)) \quad (5)$$

If an instruction has another operand, the code register cr is incremented to point to the next memory location by

$$cr_1 := cr \oplus AddressSize \quad (6)$$

Defining the new state s_1 as the tuple

$$s_1 := (cm, \dots) \quad (7)$$

is the last operation in $body$, with the dots being replaced by new values of the data memory (if updated), stacks, etc.

Basic procedures: The denotational equation of the unconditional jump JNZ is presented in Listing 6 and subprogram call CALB in Listing 7.

Listing 6. Denotation of JNZ procedure

```

C[[JNZ:cnd:clbl]] = λs.
  (cm, dm, cs, ds, cr, dr, flg) := s
  cnd := GetAddress(cr, cm)
  cndaddr := dr ⊕ cnd
  cr1 := cr ⊕ AddressSize
  clbl := GetAddress(cr1, cm)
  cr2 := cr1 ⊕ AddressSize
  ctl := BoolOf(G1BM(cndaddr, dm))
  s1 := match ctl with
    | true → (cm, dm, cs, ds, clbl, dr, flg)
    | false → (cm, dm, cs, ds, cr2, dr, flg) end
s1

```

Listing 7. Denotation of CALB procedure

```

C[[CALB:inst:clbl]] = λs.
  (cm, dm, cs, ds, cr, dr, flg) := s
  inst := GetAddress(cr, cm)
  iad := dr ⊕ inst
  cr1 := cr ⊕ AddressSize
  clbl := GetAddress(cr1, cm)
  cr2 := cr1 ⊕ AddressSize
  s1 := (cm, dm, Push(cs, cr2), Push(ds, dr), clbl, iad, flg)
s1

```

The equation of JNZ has two operands, the conditional variable cnd in data memory and the code label $clbl$ as before. The address $cndaddr$ is determined according to (4a) and (4b) (with the content dr of the data base register equal

to zero in case of a global variable). The code register is incremented to cr_1 to obtain the address $clbl$ and, then, to cr_2 pointing to the next instruction. The Boolean value ctl controlling execution is determined as in (5). Depending on ctl , the code register of s_1 includes either $clbl$ or cr_2 .

The first operand of CALB is the label of an instance in data memory for which the subprogram beginning at the label $clbl$ is executed. The instance address iad and the subprogram address $clbl$ are determined as before. cr_2 points to the next instruction. Since the contents of cr_2 , dr must be remembered for the subprogram return, they are pushed onto corresponding stacks.

Listing 8 shows C implementation of the JNZ and CALB. All system procedures having the common group identifier IC are handled by a single general function IG_SYSPROC_1C, with type identifier it as its parameter. The command switch selects a particular procedure. Each of the code segments sets $codeReg$ to a new value depending on the respective meaning. CALB also modify $dataReg$.

Listing 8. Implementations of JNZ and CALB procedures

```

void IG_SYSPROC_1C(BYTE it) {
  switch(it) {
    case 0x01: /* JNZ conditional jump */ {
      ADDRESS cndaddr = dataReg + GetCodeAddress();
      ADDRESS clbl = GetCodeAddress();
      BOOL ctl = BOOLOf(G1BMData(cndaddr));
      if (ctl) codeReg = clbl;
    } break;
    case 0x16: /* CALB call a function block */ {
      ADDRESS iad = dataReg + GetCodeAddress();
      ADDRESS clbl = GetCodeAddress();
      push_CodeStack(codeReg);
      push_DataStack(dataReg);
      dataReg = iad;
      codeReg = clbl;
    } break;
    ... /* other procedures */
    default: /* unknown code */
      flags |= FAULT;
      break; }
}

```

Selected functions: The semantics of function NOT presented in Listing 9 negates the value stored at $op1$. The addresses $raddr$, $op1addr$ are determined as before, followed by the Boolean value bv obtained as in (5). By means of the function $U1BM$ (Sec. IV) the value at $raddr$ in data memory dm is then updated. That value is determined from bv by the $FromBool$ and **match ... with** construct. um denotes the new state of the data memory. The C implementation of the NOT function presented in Listing 10 corresponds directly to its semantics.

In the case of the function EQ (Listing 11) two LINT operands $op1$, $op2$ are checked for equality. The Boolean value cmp follows from comparison (=) of the LINT numbers determined by $LIntOf$. The updated data memory in s_1 is the result of invoking $U1BM$. The byte stored at $raddr$ is given by $FromBool(cmp)$. The function IG_EQ_12 from Listing 12 implements the comparison EQ for all relevant data types (group) via a parameterized macrodefinition EQ_TYPE.

The value of an operand of a particular TYPE is determined in EQ_TYPE by the function TYPE##Of with given sizeof(TYPE).

Listing 9. Denotation of NOT function

```

C[[NOT:r:op1]] = λs.
  (cm, dm, cs, ds, cr, dr, flg) := s
  r := GetAddress(cr, cm)
  raddr := dr ⊕ r
  cr1 := cr ⊕ AddressSize
  op1 := GetAddress(cr1, cm)
  opladdr := dr ⊕ op1
  cr2 := cr1 ⊕ AddressSize
  bv := BoolOf(G1BM(op1addr, dm))
  um := U1BM(raddr, dm, FromBool(match bv with
  | true → false
  | false → true end))
  s1 := (cm, um, cs, ds, cr2, dr, flg)
s1

```

Listing 10. Implementation of NOT function

```

ADDRESS raddr = dataReg + GetCodeAddress();
ADDRESS opladdr = dataReg + GetCodeAddress();
BOOL bv = BOOLOf(G1BMData(opladdr));
U1BM(raddr, FromBOOL(
  bv ? FALSE : TRUE ));

```

Listing 11. Denotation of EQ function

```

C[[EQ:LINT:r:op1:op2]] = λs.
  (cm, dm, cs, ds, cr, dr, flg) := s
  r := GetAddress(cr, cm)
  raddr := dr ⊕ r
  cr1 := cr ⊕ AddressSize
  op1 := GetAddress(cr1, cm)
  opladdr := dr ⊕ op1
  cr2 := cr1 ⊕ AddressSize
  op2 := GetAddress(cr2, cm)
  op2addr := dr ⊕ op2
  cr3 := cr2 ⊕ AddressSize
  cmp := LIntOf(G8BM(op1addr, dm))
  = LIntOf(G8BM(op2addr, dm))
  s1 := (cm, U1BM(raddr, dm,
  FromBool(cmp)), cs, ds, cr3, dr, flg)
s1

```

Listing 12. Implementation of EQ function

```

#define EQ_TYPE(TYPE) \
case IT_EQ_##TYPE & 0x000F: {\
  ADDRESS raddr = dataReg + GetCodeAddress(); \
  ADDRESS opladdr = dataReg + GetCodeAddress(); \
  ADDRESS op2addr = dataReg + GetCodeAddress(); \
  TYPE op1 = TYPE##Of(GetMemData(opladdr, sizeof(TYPE)\
  )); \
  TYPE op2 = TYPE##Of(GetMemData(op2addr, sizeof(TYPE)\
  )); \
  BOOL cmp = op1 == op2; \
  U1BM(raddr, FromBOOL(cmp)); \
break;

void IG_EQ_12(BYTE it) {
  switch (it & 0x0F) {
    EQ_TYPE(SINT);
    EQ_TYPE(INT);
    EQ_TYPE(DINT);

```

```

EQ_TYPE(LINT);
... /* other types */
default: /* unknown code */
  flag |= FAULT;
}
return; }

```

VI. CONCLUSION

Architecture, VMASM intermediate language, and denotational semantic model have been presented for a virtual machine executing IEC control programs. The machine's scalability covers the address size, available data types and instructions. A semantic model was developed to enhance software quality. Denotational equations modeling VMASM instructions are directly followed by C implementations.

Abstract—The article presents a prototype indoor space mapping solution using RFID transponders. The autonomous robot reads the information they contain using a set of several readers, which improves the process. The design of the robot prototype is based on the STM32 NUCLEO module. Two types of transponder grids are considered, square and triangular. Simulation results for both grid types show the efficiency of reading information from transponders by the moving robot.

Unfortunately, reading the information does not provide knowledge about the location of the object on a surface or in space. Therefore, quickly reaching the correct object can be a problem. Therefore, in the field of RFID systems, the problem of mapping the space in which transponders are located is an important research area [12], [13], [14], [15], [16], [17], [18].

I. INTRODUCTION

AUTONOMOUS navigation robots are currently the subject of much research, and the RFID technique [1], [2], [3] is often used in experimental developments as part of a robot navigation and indoor mapping system [4], [5]. Such systems are used to identify objects with passive or semi-passive tags equipped with a writable memory with an information capacity far superior to the currently used barcodes [1]. RFID systems can be used in many areas, particularly in the ISM field (Industrial, Scientific, Medical). Building exploration, surface, and space mapping using such robots is also a promising area of research [6], [7]. Complex systems consisting of a robot group can also pose communication challenges [8], [9].

A great advantage of RFID systems is that the information can be read from multiple tagged objects simultaneously. A robot that is equipped with an RFID reader can use information and coordinates stored in RFID transponders embedded in walls, floors, doors, and furniture [10], [11]. This is illustrated in Fig. 1.

Fig. 1: The use of RFID transponder grids for indoor mapping with a robot

Fig. 2: An overview of the autonomous robot

It has also been noted that it is possible to use this technique in a different way and attempt to determine the position of a mobile robot equipped with an RFID reader based on the readings and analysis of the signals obtained when reading information from tags placed at known locations [19], [20], [21], [22]. Many of the existing studies are based on the use of the RSSI (received signal strength index) method [22], [23]. This is sometimes extended with methods related to odometry and the use of EKF filtering to increase the accuracy of position estimation [24]. There are also original solutions based, for example, on the phase measurement of the signal reflected from the transponder and carrying the information read from the transponder [25].

However, the above-mentioned studies mainly cover a very obtuse mathematical apparatus and almost completely ignore the issue of location support with data stored in the transponder memory. This gap was very quickly recognized, which resulted in the development of various solutions using RFID transponders to determine the location and orientation of a robot equipped with an RFID reader, starting from simple solutions with information on how the robot should read the stored transponders [26] to advanced systems using measurement of the power of the signal reflected from RFID transponders placed in a grid [27].

II. PROPOSED SOLUTION

This work considers a room mapping system using a robot with four readers and the components shown schematically in Fig. 2. The nature of RFID systems must consider the fact that uninterrupted operation of readers is necessary to provide power to transponders deployed in space and to correctly read information from their memory.

Due to the principle of operation, it is possible to distinguish two types of solutions that determine the energy transmission in RFID systems. The first are systems operating on the principle of inductive coupling, and the second is propagation coupling. The energy transferred between the reader and the transponder is transmitted through a magnetic field (Fig. 3),

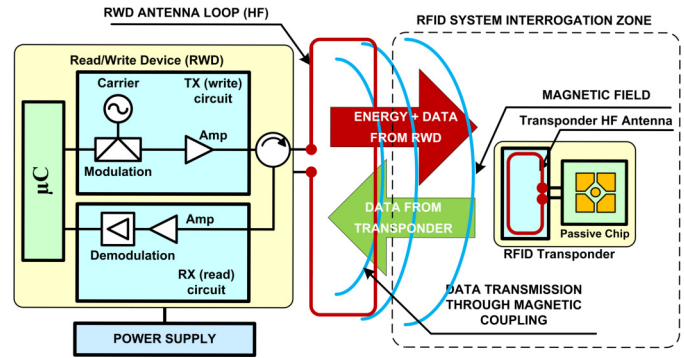

Fig. 3: General scheme of the RFID identification system

and its amount depends on the surface and mutual position of the receiving and transmitting antennas. For proper operation of the system, it is necessary to activate the RFID transponder antenna with resonant frequency, because it causes maximal current flow in the antenna circuit.

Passive transponders are mostly used with inductive coupling. In the basic scenario each transponder transmits its serial number as long as it is in the area of correct reader operation. The maximum range is achieved when the magnetic field lines generated by the reader antenna are perpendicular to the winding plane of the badge antenna coil. If the field lines are parallel to the coil, the connection does not occur, and no power is provided. The maximum range of readers is mostly limited by administrative restrictions on the maximum allowable intensity of the magnetic field produced by the reader antenna.

Propagation coupling is used for communication in the UHF band. Here, in contrast to inductive coupled systems, the far-field region is used, and it is assumed that the electromagnetic field strength is independent of the presence of transponders in the field of the reader antenna. The information exchange between transponders and a reader is based on the modulation of magnetic field modulation.

The performance of an RFID system can be comprehensively described by the idea of interrogation zone. It describes field, energy and communication issues of RFID system components [28]. Proper estimation of this area allows a wider implementation of multiple object identification. Due to the different modes of operation, the interrogation zone is defined differently for inductive and propagation systems. However, in both cases, energy is transferred through radio waves, so each must comply with acceptable radiation standards based on CEPT/ERC 70-03 recommendations. Based on these guidelines, the minimum field strength needed to power the transponders can be determined [29]. Like any electrical/electronic equipment, a robot is a potential source of electromagnetic interference and must be designed in accordance with the requirements of EMC Directive 2014/30/EU. There are no subject standards for this class of equipment yet, so the evaluation must be done according to the requirements of the general standard IEC 61000-6-3 [29].

III. RFID TRANSPONDER ARRANGEMENT

Thanks to the use of a grid of RFID transponders (sensors), it is possible to build an environment that will determine the coordinates of the sensors, memorize parameters of the environment and the motion path of moving objects. Thus, this approach makes it possible to implement a control system for an autonomous mobile object [30]. The distribution of transponders, the correlation of distances between them and the area of correct operation of the RFID system significantly affects the number of simultaneously detected transponders. A larger number of transponders in the interrogation zone requires a longer time needed for transponder recognition (use of multiple identification algorithm, reading of data contained in memory of individual transponders). On the other hand, the time influences, to a large extent, parameters of movement of a mobile object, and mainly determines its movement speed. However, temporary lack of transponders in the interrogation zone causes, that the mobile navigation system loses for some time the actuality of position data.

Among the many possibilities for the deployment of transponders in the considered area, two rational solutions can be distinguished as shown in Fig. 4 with triangle and square distribution of transponders. If the activity areas of individual transponders have a circular shape (with radius R), according to the theoretical premises of total area coverage [31], the most economical solution is to locate transponders in the vertices of an equilateral triangle (with side length: $R\sqrt{3}$). However, the problem is more complicated, because this arrangement is superimposed by the area of correct operation of the RFID system (Interrogation Zone - IZ), which is usually approximated to the shape of a circle of radius R [32].

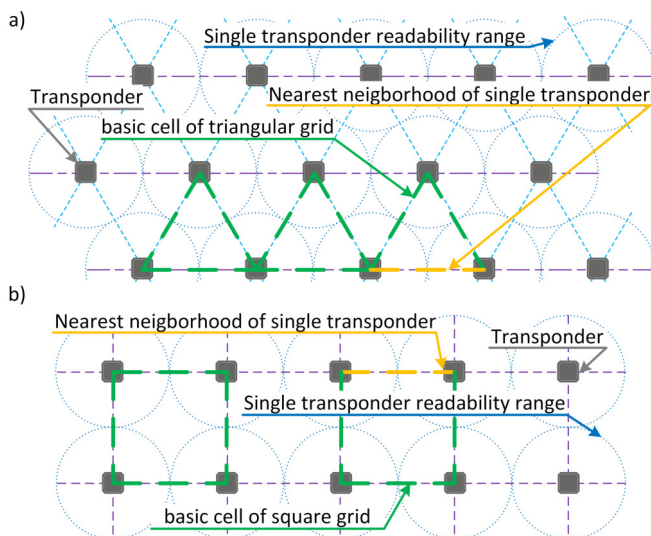

Fig. 4: The structure of transponders deployment: a) triangle, b) square

Fig. 5: Perspective view of the robot prototype

IV. THE MOBILE ROBOT

The robot built in this work is intended to be a mobile structure moving inside a building, i.e., in a closed and highly confined space. In order to reduce the likelihood of potential problems during the construction and use of the RFID system, the support structure was made entirely of materials that do not cause wave interference during RFID reader operation, i.e., plastic. A central STM32 NUCLEO-F303RE microprocessor unit with additional electronic components, such as a position sensor and a Bluetooth module, was placed on the support structure in the central part of the robot. The RFID readers were mounted in the robot, two per side in two different planes, horizontally and vertically, respectively. Additionally, a distance sensor has been placed at the front of the robot to detect and avoid obstacles. A Lipo battery pack is used as the power source for the robot.

For primary structure a LEGO mechanical components and drive assemblies were used to build the robot. The drive system consists of two servos. Each of them has an internal reduction gear, so their maximum torque is 8 N/cm and their maximum holding torque is 12 N/cm. In addition, the accuracy of the internal rotation sensor is 1 degree. On the prepared drive base, a skeleton of the supporting structure was mounted, to which the remaining components were then attached, such as: ultrasonic distance sensor, Bluetooth module eight RFID readers (Fig. 5); and indirectly through a special extension overlay: multiplexer, two motor control systems, microprocessor system, 9DoF inertial navigation unit.

V. RESULTS

An application in MathCad was developed for the computer simulation of selected structures of the distribution of transponders on a surface. Two types of structures were analyzed: a square grid and a triangular grid. The sizes of the surface on which the transponders are distributed can be freely defined, but since the structures in question are regular,

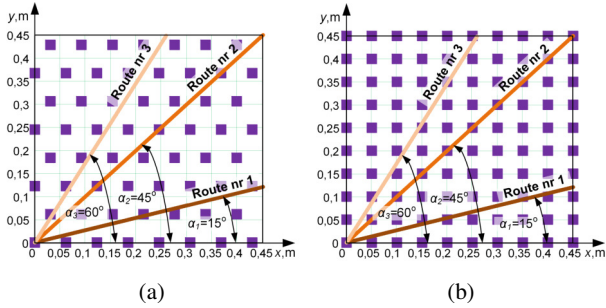

Fig. 6: Assumptions to the simulation process for grid configurations: a) triangle, b) square

the analysis of a limited area of this surface is sufficient for simulation purposes. This is shown in Figure 6.

For comparison purposes, identical areas of $0.45\text{m} \times 0.45\text{m}$ were assumed for both grid configurations. The distances between transponders, respectively for the triangular grid D_T and the square grid D_K , can be defined independently for both cases, but they are in close relation to each other. The case where for both structures, for any antenna position of the reader-programmer system with respect to the transponders, there is at least one transponder in the interrogation zone was chosen as the most reasonable one. The cases omitted are, in which, during movement, the control system does not detect any transponder and must use more advanced algorithms to correctly determine the location. The above assumption leads to the relationship:

$$D_T = 3/2 * \sqrt{3/2} * D_K \quad (1)$$

Considering relation (1), $D_K = 0.05\text{m}$ was assumed, while $D_T = 0.092\text{m}$. The mobile object can move in any direction and according to any defined trajectory, but for simplicity of calculations, it was assumed that the movement will take place only along a straight line, for three different directions (Fig. 6), respectively: Route No. 1, Route No. 2 and Route No. 3). The shape of the region of correct operation was assumed to be a circle with a defined radius R (Fig. 7). The x-axis was discretized by running 100 equidistant lines, and the steps of analyzing individual motion trajectories correspond to their projections on the x-axis, for successive discretization steps. It follows from this that the scope of the analysis of the successive steps is limited to the shortest projection of the motion trajectory on the x-axis. This is the projection of Route 3 and determines the range of analysis in the interval $\langle 0; 0.26 \text{ m} \rangle$.

In order to illustrate the problem in question, below is an analysis of a selected case of configuration of spatial distribution of tags in correlation with the size of the interrogation zone of the RFID system. Fig. 8 compares the number of transponders in the interrogation zone for the selected structures of their distribution: square grid and triangular grid, respectively, when changing the position of the RWD system antenna according to the assumed motion trajectories.

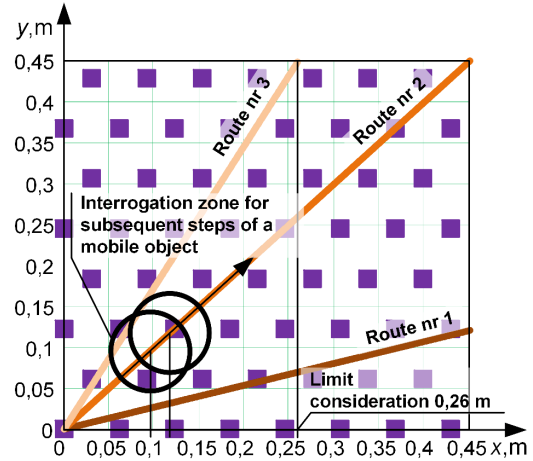

Fig. 7: Interrogation zone and limit consideration

The structure of transponder distribution has a significant influence on the number of transponders, located in the interrogation zone, as well as the dynamics of changes of this number. For comparison purposes, a statistical analysis was performed according to the relation:

$$S_{r_{KwTr}} = \frac{\sum l_{IdKw_k} - l_{IdTr_k}}{l_{IdKw_k}} * 100 \quad (2)$$

where: k is the step of the mobile object (interrogation zone) along the x-axis, l_{IdKw} - number of transponders in the interrogation zone of the RFID system for a square grid, l_{IdTr} - number of transponders in the interrogation zone of the RFID system for a triangular grid. The number of transponders is greater for the square grid, on average by more than 30%. For example: for road 1: $S_{r_{KwTr}} \approx 33\%$, for road 2: $S_{r_{KwTr}} \approx 35\%$, and for road 3: $S_{r_{KwTr}} \approx 29\%$. The

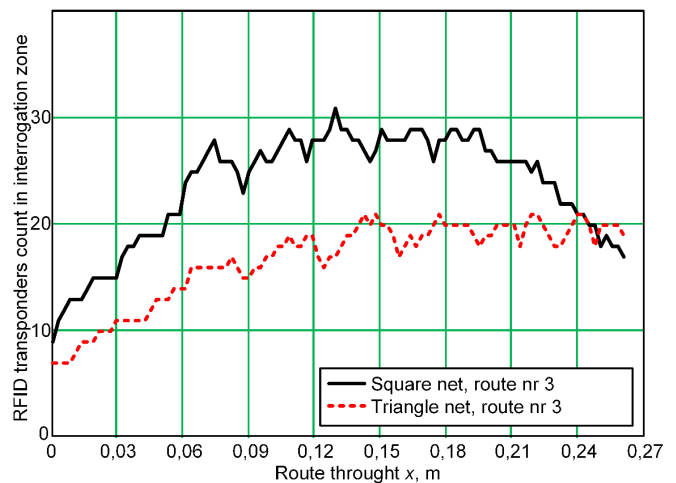

Fig. 8: RFID transponders count in interrogation zone with radius $R = 0.15\text{m}$

observed, rapid increase in the number of transponders in the first phase of traffic (slope of characteristics for road x up to about 0.12m) is caused by reaching the point where there is a full coverage of the IZ into the zone marked with transponders.

The above conclusions lead to the conclusion that the higher resolution of the transponders with respect to the interrogation zone, results in a percentage of more information for a square grid than for a triangular grid. This situation significantly affects the need to process more data in order to decide the next step in the movement of the mobile object, and thus requires an increase in the computing power of the control system or a reduction in the maximum speed of movement of the mobile object.

ACKNOWLEDGMENT

This project is financed by the Minister of Education and Science of the Republic of Poland within the “Regional Initiative of Excellence” program for years 2019–2022. Project number 027/RID/2018/19, amount granted 11 999 900 PLN.

6th Workshop on Internet of Things—Enablers, Challenges and Applications

THE Internet of Things is a technology which is rapidly emerging the world. IoT applications include: smart city initiatives, wearable devices aimed to real-time health monitoring, smart homes and buildings, smart vehicles, environment monitoring, intelligent border protection, logistics support. The Internet of Things is a paradigm that assumes a pervasive presence in the environment of many smart things, including sensors, actuators, embedded systems and other similar devices. Widespread connectivity, getting cheaper smart devices and a great demand for data, testify to that the IoT will continue to grow by leaps and bounds. The business models of various industries are being redesigned on basis of the IoT paradigm. But the successful deployment of the IoT is conditioned by the progress in solving many problems. These issues are as the following:

- The integration of heterogeneous sensors and systems with different technologies taking account environmental constraints, and data confidentiality levels;
- Big challenges on information management for the applications of IoT in different fields (trustworthiness, provenance, privacy);
- Security challenges related to co-existence and interconnection of many IoT networks;
- Challenges related to reliability and dependability, especially when the IoT becomes the mission critical component;
- Zero-configuration or other convenient approaches to simplify the deployment and configuration of IoT and self-healing of IoT networks;
- Knowledge discovery, especially semantic and syntactical discovering of the information from data provided by IoT.

The IoT technical session is seeking original, high quality research papers related to such topics. The session will also solicit papers about current implementation efforts, research results, as well as position statements from industry and academia regarding applications of IoT. The focus areas will be, but not limited to, the challenges on networking and information management, security and ensuring privacy, logistics, situation awareness, and medical care.

TOPICS

The IoT session is seeking original, high quality research papers related to following topics:

- Future communication technologies (Future Internet; Wireless Sensor Networks; Web-services, 5G, 4G, LTE, LTE-Advanced; WLAN, WPAN; Small cell Networks...) for IoT,
- Intelligent Internet Communication,
- IoT Standards,
- Networking Technologies for IoT,
- Protocols and Algorithms for IoT,
- Self-Organization and Self-Healing of IoT Networks,
- Object Naming, Security and Privacy in the IoT Environment,
- Security Issues of IoT,
- Integration of Heterogeneous Networks, Sensors and Systems,
- Context Modeling, Reasoning and Context-aware Computing,
- Fault-Tolerant Networking for Content Dissemination,
- IoT Architecture Design, Interoperability and Technologies,
- Data or Power Management for IoT,
- Fog—Cloud Interactions and Enabling Protocols,
- Reliability and Dependability of mission critical IoT,
- Unmanned-Aerial-Vehicles (UAV) Platforms, Swarms and Networking,
- Data Analytics for IoT,
- Artificial Intelligence and IoT,
- Applications of IoT (Healthcare, Military, Logistics, Supply Chains, Agriculture, ...),
- E-commerce and IoT.

The session will also solicit papers about current implementation efforts, research results, as well as position statements from industry and academia regarding applications of IoT. Focus areas will be, but not limited to above mentioned topics.

TECHNICAL SESSION CHAIRS

- **Cao, Ning**, College of Information Engineering, Qingdao Binhai University
- **Chudzikiewicz, Jan**, Military University of Technology, Poland

Wireless Agent-based Distributed Sensor Tuple Spaces using Bluetooth and IP Broadcasting

Stefan Bosse

University of Bremen, Dept. of
 Computer Science, and Institute
 for Digitization
 28359 Bremen, Germany
 Email: sbosse@uni-bremen.de

Abstract— Most Internet-of-Things (IoT) devices and smart sensors are connected via the Internet using IP communication directly accessed by a server that collect sensor information periodically or event-based. The spatial context (the environment in which the sensor or devices is situated) is not reflected accurately by Internet connectivity, and which is additionally not everywhere available. In this work, smart devices communicate connectionless and ad-hoc by using low-energy Bluetooth broadcasting available in any smartphone and in most embedded computers. Bi-directional connectionless communication is established via the advertisements and scanning modes. The communication nodes can exchange data via functional tuples using a tuple space service on each node. Tuple space access is performed by simple event-based agents. The Bluetooth Low Energy Tuple Space (BeeTS) service enables opportunistic, ad-hoc and loosely coupled device communication with a spatial context.

INTRODUCTION AND OVERVIEW

THE number of embedded systems grows exponentially. Ubiquitous and pervasive computing introduced visible and non-visible low-resource and mobile devices. Most Internet-of-Thing (IoT) devices and smart sensors are still connected via the Internet using IP communication that are accessed by a server that collect sensor information periodically or event-based. Internet access is not everywhere available. Additionally, the residential time of mobile devices can be short, not suitable for ad-hoc connection-based and negotiated communication. Finally, the spatial context (the environment in which the sensor or device is situated) is not considered (or inaccurately determined) by Internet connectivity. even new 5G technologies will not fully solve context-aware communication [1]. In this work, smart devices communicate connectionless and ad-hoc by using low-energy Bluetooth available in any Smartphone and in most embedded computers, e.g., the Raspberry PI or ESP32 devices. Bi-directional connectionless communication is established via the advertisement and scanning modes used in parallel. The communication nodes can exchange small data or functional tuples using a tuple space service. Mobile devices act as tuple carriers that can carry tuples between

different locations. Additionally, UDP-based Intranet communication can be used to connect tuple spaces.

Tuple spaces are widely used for data storage for loosely coupled distributed data processing systems. The Bluetooth Low Energy Tuple Space (BeeTS) service is a lazy distributed tuple space server and client. BeeTS uses Bluetooth and UDP broadcasting for tuple space interaction and tuple exchange. BeeTS supports tuples with an arity up to 4.

A tuple space provides a spatial context, i.e., tuple space access (by mobile devices) is limited to nearby devices, well suited for mobile networks [2]. Distributed tuple spaces can be connected by routers using IP communication if available. The router composes global space sets by tuple exchange and replication using hybrid rule- and event-based agents. These rules can be changed at run-time and the code can use Machine Learning algorithms to optimally distribute tuples under resource and spatial constraints.

The novelty of this work is two-folded. Firstly, an ubiquitous radio broadcast medium is used for low-distance communication in ad-hoc mobile networks combined with a unified tuple space paradigm. Secondly, the tuple space communication is performed by simple reactive event-based agents programmed in JavaScript that can be sent to a node via the tuple space operations, too. Agent-based message routing [3] is well suited in highly dynamic and unstructured network environments. The generative tuple space paradigm is well suited for ad-hoc mobile networks [4], especially if this paradigm is coupled with the agent paradigm [5].

COMMUNICATION

It is assumed that there is a broadcast medium B , e.g., using radio waves, which can reach a number of nodes $N_B = \{n_i\}_{i=1}^k$ defining a receive area/range coverage $C(B, N)(t)$ that changes over time t . B can send broadcast messages m to all listening nodes reachable by B . The set of nodes within B can vary on time and spatial scale. Furthermore, it is assumed that there is a probability $p_i(m, r_{i,j}, [t_0, t]) \in [0, 1]$ that a message m is received by a node i sent by node j in distance r within a time interval $[t_0, t]$. These two assumptions are fundamental for the proposed distributed tuple spaces.

It is assumed that single packets that can be send over B are strictly limited by a small number of bits, e.g., 200-300 Bits. This requires a compact and optimized message format, discussed in the next sub-section.

There are seven different message types:

- *OUT* stores a tuple in all tuple spaces receiving this message;
- *RD* and *INP* requesting tuples from all receiving tuple spaces;
- *TEST* checks for the existence of a tuple or set of tuples;
- *TUPLE* is either an initial message sending this tuple to all receiving nodes without; storing the tuple in the respective tuple space, or a reply to a tuple request;
- *IAMHERE* and *WHERE* messages are used for node search.

The message format consists of a message header and the data payload. The sequence number is required to detect the reception of multiple copies of the same message, a prerequisite for deployment with the Bluetooth device back-end that sends a message multiple times. The signature byte specifies the following tuple data pay-load. Depending on the back-end communication device and the supported packet format, the number of pay-load bytes can be very small. The signature field specifies the type of each tuple element with a tuple limit of four elements. For Bluetooth advertisement packages there is $N_{BLE}=32$, for the UDP back-end it is at most $N_{UDP}\geq 512$. The message header and the data payload is encoded in an BLE advertisement packet using one device local name attribute (ASCII85 encoded) and seven 16 Bit service UUID attribute fields.

In contrast to typical tuple space services, the tuple operations are not atomic here. They can be executed at any given time point t in the near future or never, and the set of reachable tuple spaces that execute the request is not bound and can be zero. There is no assumption that neither a message arrives at a specific node nor that request is processed successfully. There are filter rules processed by agents that can be prevent tuple operation execution, too. That means, the *INP* operation is only a suggestion to all receiving tuple spaces to remove a matching tuple. All operations pose a probabilistic behaviour, i.e., there is a probability ≥ 0 that a message is processed.

The encoding of tuples is done automatically. Before a tuple is encoded and packed, a signature is derived, numbers are classified either in integer 16 Bit or float 32 Bit values depending on the actual value.

Devices can access remote tuple spaces of nearby neighbouring nodes (typically in the range of 1-10m) by using BLE broadcasting (called ble-ts). A device in advertisement mode will send out periodically advertisement message that contain a small payload depending on the advertisement message class. In this work, the pay-load is

limited to 32 Bytes. There are 40 RF channels in BLE, each separated by 2 MHz (centre-to-centre). Three of these channels are called the primary advertising channels (labelled 37, 38, and 39), while the remaining 37 channels are called the secondary advertisement channels (they are also the ones used for data transfer during a connection). The primary channels are switched randomly in periods. On the other side, the scanning devices has to switch the (primary) receiving channels randomly, too. There is a probability p , that an advertisement packet is received if both scanner and advertiser are switch on the same channel and if there is no other sending within the receiving range creating collision (invalidation of the message).

In addition to the BLE broadcast communication, nodes that are connected to a local IP network can exchange tuple requests via UDP broadcast messages (called udp-ts). Although, UDP messaging is theoretically reliable, UDP broadcasting via wireless connections is not supported. Security is provided by a symmetric two-way encryption with format-preserving encryption of tuple messages using byte look-up tables.

BEETS

The principle network architecture combining Bluetooth and UDP-IP broadcast communication technologies is shown in Fig. 1. Tuple messages can either be sent via Bluetooth advertisement (based on [7]) or via single UDP packets within a local IP network. BeeTS is programmed entirely in JavaScript and can be executed by node.js with a Bluetooth socket modules for BLE access, the *noble* module for the central BLE part, and *bleno* for the peripheral part. Note that BeeTS uses the peripheral and central (master) mode simultaneously (advertising and scanning), requiring a Bluetooth device with version ≥ 4.0 . BeeTS is basically a small library module written in JavaScript. Smartphones act as mobile devices and provide both a rich set of sensors and BLE connectivity. Each communication back-end can receive tuple requests. If there is a listener installed for tuples (with pattern matching), incoming tuples (*TUPLE* message) can be consumed by the listener or not. Otherwise, incoming tuples are stored in the local tuple space.

There are agents acting as a bridge between the communication back-end and the tuple space. They can filter incoming messages and decide to reply immediately, to access the tuple space, or to discard the message. Agents are functional code that listen to incoming tuple requests. There can be more than one agent. Communication between agents is established via the tuple space, too.

A broadcast message sending via BLE enables the advertisement mode of the device for a specific time interval $[ts,te]$, shown in Fig. 1 (a). The duration of the time interval Δt determines the receiving probability, the collision probability (if more than one station is sending), the number of advertisement packets that contain the message m , and the number of different messages that can be sent per second. The interval time Δt must at least $3 \times t_{sw}$, with t_{sw} as the

average channel switching time of the sender (and receiver). It is assumed that the sender and receiver have the same switching time, typically 100 ms. Important to note that channel switching introduces small dead time intervals (about 1-10ms). A suitable value for Δt is about 500ms.

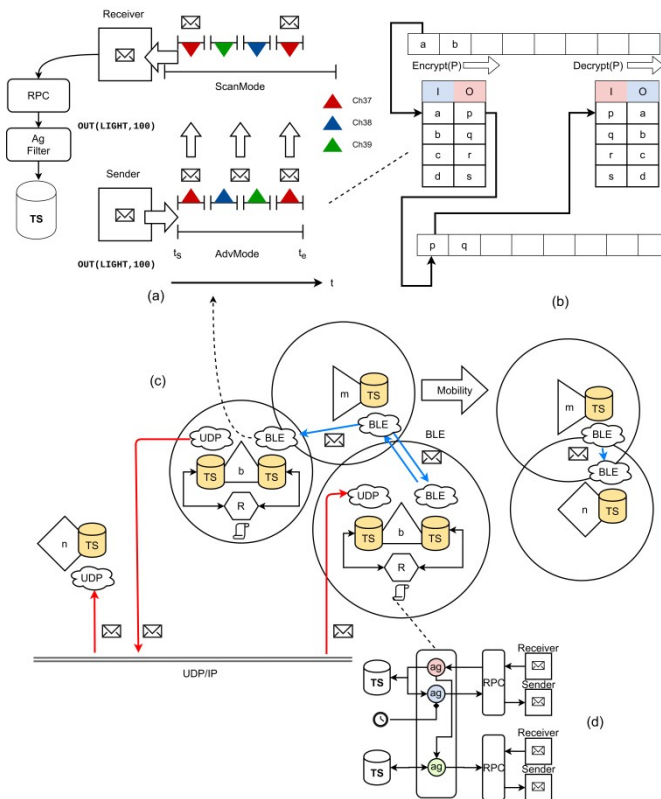

Fig. 1. (a) BLE communication (b) Security by FPE (c) The hybrid network architecture using BLE and UDP-IP broadcast communication; n: stationary node, b: Stationary beacon, m: Mobile node, TS: Tuple space, R: Rule-based router (d) Message routing by agents between different TS

Each physical communication interface (BLE/UDP) is attached to its own tuple space, i.e., there are two distributed space sets connected via BLE and UDP, respectively. This division is grounded in the spatial context of tuple spaces. Using BLE communication only nearby nodes can insert or remove tuples, whereas UDP communication enables tuple exchange over short and large distances, too. Tuple exchange between BLE and UDP tuple spaces is provided by a customisable router, shown in Fig. 1 (c). Application-specific routing rules (functional code) provide transfers based on patterns and content of tuples. The rule set is dynamic and can be changed at run-time. The router extends the visibility and scope of tuples based on adaptive code. The code can use Machine Learning, e.g., reinforcement learning, to improve tuple space distribution. The routers connect local spaces and compose organised global spaces.

Each time a message is received it is passed to the Remote Procedure Call layer (RPC). Among the message data, the sender MAC ID, a time stamp, and the signal strength is added to the message.

The BeeTS framework basically provides a communication platform using radio communication like Bluetooth or WLAN. The communication bandwidth of various devices can be significantly limited (e.g., in the case of Bluetooth advertisement mode that can be only 2 messages/second). One main feature of BeeTS nodes is the capability to execute event-based reactive agents programmed in JavaScript that perform, e.g., filtering of incoming tuple space requests. An agent is functional data consisting of private body variables (including functional values) and event handlers that are activated by incoming messages, sensors (if the host platform provides them), periodically, or only one time. Agents are executed in sandboxed containers and are used for message filtering and routing between different tuple spaces, shown in Fig. 1 (d). The format-preserving encryption of tuple messages using look-up tables is shown in Fig. 1 (b).

USE-CASE: DISTRIBUTED SMART BUILDING CONTROL

This use-case deploys three different node classes implementing a distributed building light control system:

1. Stationary beacons (Raspberry 3) equipped with BLE and WLAN connectivity and supporting ble- and udp-connected tuple spaces in both test and production deployment;
2. Mobile devices (battery powered RP Zero stacked with a smartphone for testing, stand-alone smartphone in production systems) supporting ble- and udp-connected tuple spaces only in production environments;
3. A central monitoring and light control service supporting udp-connected tuple spaces.

Each node deploys at least one event-based agent that implements necessary node operations like interaction with mobile devices or users, and tuple filtering and bridging. Beacons consume and aggregate mainly sensor data from mobile (sensorised) devices like smartphones and forward micro-surveys from the central server to mobile devices. But beacons can initiate and manage micro-surveys, too. To minimise the number of sent tuples via the BLE device, the mobile nodes monitor the user behaviour by analysing the accelerometer and gyroscope sensors. Updates of light sensor tuples are only sent if either the light conditions changes or the mobile device was moved in space. For rapid prototyping, smartphones are using generic Web browser loading an application page from the locally attached Raspberry PI zero bundled with the smartphone. All sensor data is sent to the embedded computer that executes the mobile application logic and that performed the BLE communication.

Mobile devices use their light sensor in conjunction with accelerometer and gyroscope sensors to estimate the ambient

light conditions and the user mobility by classifying the user activity in rest, smartphone use, and movement phases.

The measured light sensor data is processed by a sensor agent that tries to estimate if the smartphone is currently exposed to external light or if it is stored in a box. If external light is detected, sensor light tuples are sent via BLE. Nearby beacons distributed in the building about every 10-20m (and one per room/floor) collect these tuples and send aggregated sensor light values to the central server via udp-connected tuple spaces.

Among sensor tuples, there are micro-survey tuples that are sent from a beacon (initially delivered by the central server via the UDP tuple space) to mobile devices. If a device supports HMI (e.g., a smartphone), a short question is posted to a chat dialogue platform embedded either. The user can answer the question and the answer is passed back to the beacon (or any other beacon due to movement). The beacons collect the micro-survey replies and forward them to the central server.

For the evaluation of the loss rate of BLE tuple space communication, a partial set-up was chosen with four beacons at four different spatial positions and four mobile devices here all at the same position. An average loss below 10% can be achieved within a radius of about 5m. Some nodes can communicate over larger distances up to 10m. The tuple message send time interval has no significant impact on the loss rate within time interval [500s,2000s] and with this (small) set-up. If the number of nodes within the radio range increases, the loss rate will increase.

CONCLUSION

In this work, The Bluetooth Low Energy Tuple Space (BeeTS) service enables opportunistic, ad-hoc and loosely coupled device communication with distributed tuple spaces that are used to exchange data between devices providing a spatial context with respect to data and communication. Smart devices access the tuple spaces by tuple message communication using event-based agents. The communication is connectionless and ad-hoc by using low-energy Bluetooth broadcasting available in any Smartphone and in most embedded computers, e.g., the Raspberry PI devices. Bi-directional connectionless communication is established via the advertisement and scanning modes used in parallel by transferring encoded tuple messages. Mobile devices act as tuple carriers that can carry tuples between different locations. Additionally, UDP-based Intranet communication can be used to connect tuple spaces. with spatial context. Multiple independent tuple spaces can be serviced on one network node bridged by agents. Among the tuple spaces, BeeTS implements simple reactive event-based agents. These agents perform tuple space management, interaction between devices and users, and they act as tuple filters and forwarders between multiple tuple spaces. A preliminary study showed the suitability of the broadcast communication for distributed ad-hoc networks preserving a spatial context lacking in other approaches. Analysis showed

a low loss of BLE broadcast messages (about 10-20%) but higher and unpredictable loss rates of UDP broadcast communication using WLAN, even if N:1 unicast communication was used to simulate broadcast messages.

APPENDIX: EXAMPLE AGENT

The following example shows an event-based agent programmed in JavaScript reacting on tuple messages. It consists of body variables and the event section. A specific tuple space can be selected.

```
var agent = {
  x : 0,
  y : 0,
  ..
  on : {
    'ts.udp:(TIME,?):' : function (ev) {
      ts.ble.notify(ev.tuple);
      return consumed?;
    },
    'ts.ble:(SENSOR,?,?,?):' : function (ev) {
      log(ev.tuple, ev.from, ev.rssi)
      ts.udp.out(['EVENT',
        JSON.stringify(ev.tuple),
        ev.from, ev.time]);
      return consumed?;
    },
    init : function () {
      this.x=random(1,1000);
    },
    1000 : function (counter) {
      // called each 1000 ms
      return true
    },
    'sensor.light:abs(sensor-sensor0)>50' :
      function (ev) {
        if (ev.sensor>500)
          ts.ble.notify(['ALARM',
            'LIGHT', 'HIGH']);
      }
  }
},
Agent.create(agent);
```

Abstract—Modern embedded systems’ increasing complexity and varied safety levels make it hard to coordinate all functionalities within a single run-time environment. Access to more advanced and capacious hardware changes the trend from utilising many separated platforms into one managing the whole compounded airborne system. Providing an appropriate isolation and synchronisation level is achievable only by adapting an operating system with separation mechanisms into UAV systems. This paper introduces Phoenix-RTOS, the microkernel structured real-time operating system designed to be consistent with aerospace standards DO-178C and ARINC 653. The current market offers many counterparts like VxWorks, Integrity 178, PikeOS and many others. These products are well known and used in leading-edge avionics and space projects. However, it is not possible to use them in many low-budget projects due to the high price. The Phoenix-RTOS differs from others and is an open-source project becoming a standard solution for energy, gas meters and UAV systems.

In this paper, we focus on the currently designed mechanisms of microkernel architecture for providing a mixed-criticality system, particularly for compliance with ARINC 653. Engineers have been identifying time and space partitioning issues to cope with tight worst-case execution bounds of critical tasks.

I. INTRODUCTION

THE Unmanned Air Vehicles (UAV) market increased significantly in recent years. However, plans about flying machines carrying out missions of particular importance (e.g. transport of hazardous substances and medical supplies) above our heads in inhabited areas cannot become a reality without ensuring the high safety standards of airborne systems. According to European Union regulations introduced in 2019 [1], the UAV can be allowed to conduct a mission in the urban environment only after a positive certification process conducted by the civil aviation agencies such as European Union Aviation Safety Agency (EASA) or Federal Aviation Agency (FAA). To reduce the time of the certification process, the manufacturers choose certified Real-Time Operating Systems (RTOS) to run their critical and non-critical applications. The current market offers several operating systems compliant with aviation standards, but only large companies can afford them due to high license costs. To overcome this obstacle Phoenix Systems has started working on Phoenix-RTOS 178 version compliant with aviation standards [1]. Making a system as an open source product allows manufacturers with a limited budget to enter the market. The new version of the Phoenix-

RTOS is designed to comply with DO-178C and ARINC 653 standards described in the next paragraph.

A. Aviation Standards

Standards play a crucial role in the aerospace industry. One of the most important is DO-178C, the fulfilment of which allows usage software in airborne devices. DO-178C defines five levels of failure caused by software: catastrophic, hazardous, major, minor, and no effect. Moreover, it defines five corresponding Design Assurance Levels (DAL) from the most rigorous level A to level E. Depending on the DAL level, tenants’ appropriate process management has to be fulfilled. Another one, Aeronautical Radio Incorporated (ARINC) standard focuses on technical aspects that define a series of detailed rules for a dedicated area, like data transmission protocols, cockpit user interfaces, and many others. The aerospace projects are always compliant with DO-178C, however meeting the ARINC standards depends on project’s requirements. The best policy for operating system development for critical applications is described in standard ARINC 653. Running different critically level software on the same hardware platform is the primary domain of Integrated Modular Avionics (IMA). To realize an IMA approach in RTOS, the Partitioning Operating System (POS) concept should be introduced to support spatial and time partitioning [10]. In the avionics industry, the Avionics Application Standard Software Interface, called APEX provided by ARINC 653, has been introduced as a set of guidelines to provide a standardized interface between POS and avionics applications [10]. The leading role of the ARINC 653 is to improve the safety and certification process of safety-critical systems and outline the architectures approach for POS’s engineers [10]. More details about APEX are presented in the fourth section.

B. History of Phoenix-RTOS

The idea for writing a new RTOS originates from the Warsaw University of Technology where the prototype of Phoenix-RTOS was developed from scratch as a master thesis [1] in 1998. The rapidly growing Internet of Things (IoT) market resulted in an industry need where a new operating system with efficient implementation and rich functionalities to be required.

Due to this fact, the second version of Phoenix-RTOS was developed by Phoenix Systems and widely implemented in data concentrators for the smart grid, smart energy meters and smart gas meters. Phoenix-RTOS 2 is recognized on the market as a real-time system for the smart grid and software-defined solutions.

The third version of the system based on a microkernel architecture has been developed to be easily used in microcontroller-based low power devices and more advanced processors. The new approach provided in version three allows the use of Phoenix-RTOS on a broad range of processors architecture from the smallest ones like ARM Cortex-M, to more those complex like ARM Cortex-A, ia32 or RISC-V [1]. Employing the Phoenix-RTOS in version three to the energy meters sector has proven its applicability for high complexity systems which work in harsh environments. The experience obtained in the industry moved the company forward in achieving the next milestone to make Phoenix-RTOS consistent with DO-178C standard in a design assurance level A.

Phoenix-RTOS compliant with DO-178C is developed as an open-source project under the BSD license. From the time of writing this paper, only several open-source competitors supporting ARINC 653 have been found, which are described in the third chapter. The rest of the systems for critical purposes are commercial. It is strongly believed that by providing the system as an open-source product, the gap in the market is filled for projects with a limited budget, and the topic of critical systems will be covered.

This paper presents our consideration for partitioned based microkernel development in Phoenix-RTOS. A current trends analysis in the industry has been conducted and there are visible alternatives that can be offered by the open-source product. The research focuses on implementing microkernel mechanisms to support spatial and time partitioning to fill ARINC 653 requirements.

II. MIXED CRITICALITY SYSTEM

Operating systems for critical purposes should be highly reliable. As is considered in *Tanenbaum et al.* [5] they should not be interrupted entirely or halted to recover from a failure that occurs in a module that is not in the critical execution path of a service or an internal operation [4]. To achieve this goal, operating systems should provide safety and security functionalities not to allow the non-critical zone's fault to propagate to a critical one. Safety and security functions seem to be similar, and although these terms have common elements, they differ. This chapter presents the concept of safety-critical and security-critical systems in more detail. The next one presents examples of systems divided into appropriate categories.

A. Safety-critical

The main challenge tackled by a safety-critical system is to provide a clear border between different critical zones called partitions. Due to this fact, these kinds of operating systems

are often called partitions kernels. Partitioning mechanisms should provide spatial and temporal separation [2]. Moreover, the partition kernel is in charge of resources management such as I/O devices to permit access to only assigned parts of the system. To enforce spatial separation, each individual partition runs in a hardware-protected address space. For this purpose, the Memory Management Unit (MMU) performs mapping of virtual to physical addresses. To enforce time separation, each partition and thread have a dedicated time slot of the CPU in which the actions have to be completed. The static analysis is obligatory to define the Worst-Case Execution Time (WCET) of each running partition and process. Based on the WCET the best scheduling algorithm is selected to take control of the CPU when attempts of time overrun occur. The central concept of a safety system requires static resource allocation for partitions and static analysis of system performance. Safety-critical systems are compliant with DO-178C and ARINC 653. However, standards do not impose requirements describing how spatial and time separation should be performed. The chosen solutions can differ between individual systems.

B. Security-critical

The security-critical systems originate from the concept of Multiple Independent Levels of Security (MILS) specification, which is a high-assurance architecture based on separation and information flow security [3]. The foundation of MILS is a Separation Kernel (SK), which is responsible for adherence of data isolation, damage limitation and resource partitioning. SK extends partitioning kernels of sets of specific functionalities to enforce security separation, and information flow [2]. The security requirements are known as Common Criteria (CC) [3] establishing seven Evaluation Assurance Levels (EAL) from 1 to 7, which is the most rigorous. Moreover, CC defines robust requirements dedicated to an operating system called Separation Kernel Protection Profile (SKPP). To obtain satisfying certification for EAL7, the partitioning mechanisms have to be rigorously verified using formal methods [3]. Compared to partitioning kernels, SK provides a more dynamic environment that does not have to be known ahead of time. The typical approach to realizing separation kernel is based on embedded hypervisor and software virtualization mechanisms. The hypervisor layer manages the system resources and virtual partitions, which are capable of running guest operating systems with different levels of critically [2].

III. BACKGROUND AND RELATED WORK

Operating systems for critical applications is a complex topic that demands a considerable workloads and financial resources. Due to this fact, only several companies can deliver reliable products. The most known and widely used systems on the market are presented in the following subsections. The last paragraph is devoted to open source projects.

A. Lynx Software Technologies

The Lynx Software Technologies has on offer two operating systems for critical application: LynxOS-178 and LynxSecure.

The first version of the system, LynxOS-178, is a safety-critical system. It meets the DO-178C DAL A regulations and supports POSIX, and APEX standards [6]. However, this version of OS would not meet the highest EAL7 criteria, which require formal mathematical methods to prove the security of SK. For this reason, LynxSecure is introduced to provide a separation kernel based on hypervisor virtualization. The second version OS design includes safety and security domain isolation, trusted execution environments and reference monitor plugins such as firewalls and encryption [6]. A popular solution for complex systems is to use LynxSecure to provide secure partitioning and LynxOS-178 to launch critical applications compliant with APEX.

B. GreenHills

INTEGRITY 178 is a world-leading RTOS for safety and security applications certified both to the highest level of DO-178C DAL A and SKPP/EAL6+ [7]. The producer claims tasks protection in the guaranteed time window domain. The space domain is arranged by static memory allocation and hardware enforcement of MMU for each partition. The system isolates applications and data into different security domains to ensure the MILS environment. As a separation kernel, INTEGRITY 178 provides a virtualization layer in the userspace instead of in the kernel [7].

The GreenHills also offers a version for multicore architectures - INTEGRITY 178 tuMP. As one of the few systems that provide full flexibility in choosing the software multi-processing architecture, ranging from simple Asymmetric Multi-Processing (AMP) to modern Symmetric Multi-Processing (SMP) to Bound Multi-Processing (BMP) for the highest combination of determinism and utilization [7].

C. WindRiver

The WindRiver company takes a similar approach as Lynx Software Technologies. In the offer can be found two versions of software for critical purposes. The first one VxWorks 653 is compliant with DO-178B/C DAL A and ARINC 653 [8]. The second one VxWorks MILS provides compliance to SKPP using a hypervisor. To combine safety and security mechanisms, two versions of WindRiver products are used side by side.

D. SYSGO

The flag product of SYSGO company is a PikeOS compliant with DO-178C DAL B and ARINC 653 [2]. Although the system provides safety and security-critical mechanism, it is not compliant with SKPP. PikeOS offers a separation kernel-based hypervisor with multiple partitions for many other operating systems and applications [9]. The engineers from SYSGO developed a similar concept as the GreenHills company for INTEGRITY-178. The PikeOS does not need an external hypervisor, its internal layer provides security and virtualization between partitions.

E. Open Source Systems

According to a survey presented by researchers in [2], the majority of open-source projects are academic implementations. Special consideration should be given to POK and XtratuM operating systems due to compliance with ARINC 653. However, none of them is compliant with DO-178C. Furthermore, there are other systems worth mentioning like Quest-V or Muen. Although they provide some mechanism of spatial and temporal partitioning of resources, they do not comply with any of the considered standards.

IV. ARINC 653

The primary objective of ARINC 653 is to fulfil the IMA requirements to provide an environment for the independent execution of avionics applications utilizing different critical levels. The majority scope of the regulation defines the Application Programming Interface (API) between the operating systems and avionics applications. One of the benefits of standard usage is to provide high portability of avionics software to run on different operating systems.

The standard consists of five parts [11]. Part 0 describes a general overview about ARINC 653. Part 1 summarises the required services to be supported by APEX and part 2 reports extended services. Section B in chapter fourth, precisely presents the services concepts. Part 3 of ARINC 653 is divided into two parts: 3A and 3B, and provides a guideline for conformity tests for both required and extended services. Part 4 defines a subset of API specified by part 1. Finally, part 5 describes recommended capabilities for multicore applications. The conformance of the APEX API to the ARINC 653 standard is validated by passing all of test suites defined by part 3 of the standard.

A. General architecture

Fig. 1 shows the example architecture of a system compliant with ARINC 653. The integrated module represents a complete RTOS which consists of a core module and applications. The Core Software (CSW), referred to as the operating system and hardware layer applying many processors, each consisting of one or more processor cores [11]. CSW should provide the ARINC 653 interface, health monitoring system, two level scheduler and suitable time and space separation based on configuration data. The highest layer of the IMA architecture presents either application software partitions and system partitions. The first ones are restricted to using only ARINC 653 calls to interface to the system [11]. The second ones are partitions specific for the operating system requiring interfaces outside of the APEX scope. They manages system specific task such as device drivers or fault management schemes [11] which are not defined by ARINC 653. Both of them are subject to robust space and time partitioning.

B. Static System Configuration

According to the specification, a partition is a program in an application environment that consists of text, data section, stack, own context, and configuration attributes [11]. In this

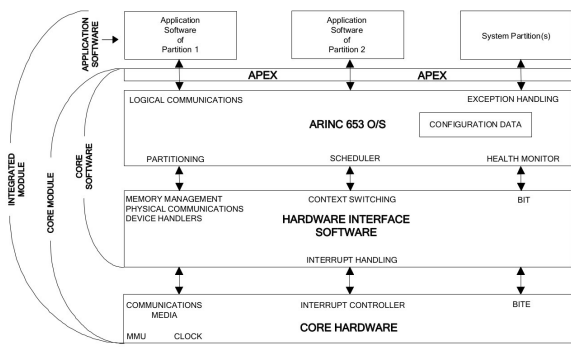

Fig. 1. Example of Integrated Module Architecture [11].

case, a process is a programming unit contained within a partition that executes concurrently with other processes within the same partition [11]. In other words, the process in ARINC 653 glossary corresponds to a thread running inside a process, and the partition refers to a process in UNIX like systems.

Each of the partitions and processes are described by system configuration files. They contain detailed information about the demand for system resources, communication ports, execution windows and scenarios for health monitor systems. The most popular approach for APEX environment description is an Extensible Markup Language (XML) or AADL language.

V. PHOENIX-RTOS 178

Phoenix-RTOS 178 is a new version of the system compliant with DO-178C and ARINC 653, based on the Phoenix-RTOS version three. The new approach follows the rules for mixed safety-critical systems to provide a reliable and robust run-time environment for the avionics industry.

This chapter focuses on the system architecture to explain how spatial and time separation is resolved in Phoenix-RTOS 178. The presented solutions have been developed and deployed on the Zedboard platform, equipped with a Xilinx Zynq-7000 dual-core ARM Cortex-A9 processor family.

A. System Architecture

The system architecture consists of a bootloader and a kernel. The first one, Phoenix-RTOS loader (PLO) can be treated as a first-stage and a second-stage bootloader. Acting as the first-stage bootloader, PLO configures the memory controllers and various supported devices on a dedicated platform. It is also responsible for preparing the board for the kernel and performing built-in tests (BITs) to check correctness of the operation of the critical peripherals. The second-stage bootloader loads the operating system and selected partitions from storage devices to the memory. The fig. 2 shows PLO Command-Line Interface (CLI). Configuration data about the system setup is passed to the kernel by a structure called syspage. The syspage contains all information about board configuration and partition descriptions compliant with ARINC 653 standard. The second system's component is a kernel responsible for providing spatial and time separation by memory and threads

management modules. The system is startup by the initial thread being in charge of launching the health monitor, system and user partitions with resources assigned to them by the setup data. After the successful initialization phase, the chosen scheduler algorithm is launched. The fig. 3 shows Phoenix-RTOS providing interaction with user via Phoenix-RTOS shell. The essential kernel's safety-critical mechanisms are described in the next two chapters.

B. Spatial Separation

The crucial element of the system for critical purposes is providing spatial separation for partitions. In Phoenix-RTOS 178, this mechanism is implemented using multi maps and an MMU controller. The multi maps approach allows the simultaneous use of different memory devices such as on-chip RAM (OCRAM) or DDR SDRAM. This solution provides additional physical separation. User is able to use a specific memory for dedicated purposes. If there is a requirement to use the memory with a fast access for critical application, the OCRAM should be chosen. The memory virtualization is provided by the MMU controller and configured based on the information about accessible volatile memory described by the PLO in the syspage.

Another essential element embedded into the memory management module is a caching policy. Phoenix-RTOS 178 invalidates and cleans executable pages and allows the user to define uncacheable memory regions independently.

The memory virtualization provides the same linear memory map for each partition. Switching between them provides an additional delay in changing the MMU controller's translation table. To avoid an overhead, the Address Space Identifier (ASID) mechanism is added to the memory management module to assign a memory map to the partition. Furthermore, the spatial separation is in charge of controlling of the mapping

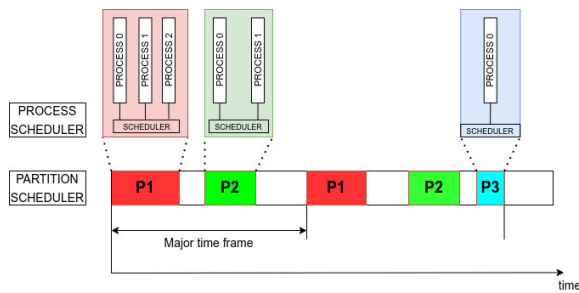

Fig. 4. Example of partition and processes scheduling.

I/O devices' memory to only one partition to not allowing sharing resources.

C. Time Separation

A robust and reliable scheduling policy is an essential element of the operating system to perform critical tasks on time. In an environment compliant with ARINC 653, a two-level scheduler should be introduced. The fig. 4 shows an illustrative scheduling policy for mixed-criticality systems.

The first scheduler supervises the partition work. The most common algorithm for hard real time embedded systems is the Rate Monotonic (RM) scheduling with a fixed priority [12]. In the presented example, each partition has: an assigned priority, WCET, Average Case Execution Time (ACET) and period. The critical partitions have the highest priority allowing to preempt the other ones and to meet deadlines. Making a static analysis using the integration tool, it is possible to verify whether the system is feasible and all partitions can meet their deadlines with the assumed values.

The second scheduler is responsible for scheduling processes within a partition. The ARINC 653 allows to choose a dedicated scheduling policy or the default one is selected.

Keeping WCET bounds of partitions depend on the internal mechanism of the operating system. The common problem for RM scheduling policy is a priority inversion, causing deadlock between partitions or processes. To avoid this situation, the synchronization mechanisms owning dynamic changing priority to the highest one sharing amongst other partitions or threads.

D. APEX Interface

Realization of the APEX services in Phoenix-RTOS 178 is performed using systems calls to the kernel. The interface is implemented in the form of a static library linked to the partition executive file. The library interface checks the correctness of the given arguments and passes them via the Application Binary Interface (ABI) to the kernel running in a privileged mode.

The microkernel architecture provides a message passing interface between servers. The communication services like

inter-partition communication use the exact mechanism. The other ones use a dedicated system calls to perform the action defined in ARINC 653.

VI. CONCLUSION

In this paper, we presented the research work on the mechanisms for integrating critical and noncritical software management by safety operating systems. The growing UAV market and its application will need to use reliable RTOS compliant with DO-178C and ARINC 653. Phoenix-RTOS 178, as an open source project, will be the best choice for manufacturers entering the market with a limited budget.

The presented work shows working Phoenix-RTOS on the Zynq-7000 platform commonly used in airborne systems. Our goal was to highlight the basic concepts of mixed criticality systems and explain the general architecture of Phoenix-RTOS 178. Future work includes completing time and space separation mechanisms as well as the APEX interface in Phoenix-RTOS 178.

VII. ACKNOWLEDGEMENTS

The presented concepts are the part of the project - *Phoenix-RTOS 178 - new version of the Phoenix-RTOS operating system dedicated for implementation of systems compliant with the guidelines of the DO-178C safety standard* developed by the Phoenix Systems Sp. z o.o.. The project POIR.01.01.01-00-1412/19-00 is co-financed as a grant agreement by European Union represented by the National Centre for Research and Development (NCBiR) in Poland.

□ **Abstract**— There is an increasing demand for capturing reliable data from IoT network devices. Due to the limited capabilities of such devices to process and store sensitive data and the range and performance of the communication link, it is a significant challenge to develop a secure solution for symmetric key distribution. This paper presents a secure data exchange protocol for a cryptographic key generation, renewal, and distribution (KGR) system. The Trusted Platform Module (TPM) supports the trust establishment, key generation, all cryptographic procedures of the KGR system and secure data exchange in the described protocol. The protocol uses the MQTT (Message Queuing Telemetry Transport) service, which IoT devices widely use.

I. INTRODUCTION

IN many systems where symmetric cryptography has been decided upon, the challenge of securely generating, renewing and distributing symmetric cryptographic keys must be met. For traditional IT systems, solutions of this type are familiar. A more significant challenge is to develop a solution for scenarios where IoT sensor nodes are the data source. The reason is that sensor nodes are usually built on devices with limited capabilities. These limitations include memory size, processing power, limited power source, and the short range of the wireless link used. Using a certification authority (CA) to build trust structures in such systems is difficult or impossible. Hence, in the cryptographic key distribution system and in systems that receive those keys, trust structures must be created locally with the support of electronic circuits such as TPM or Zymkey¹.

Large networks of sensor nodes are usually divided into groups of cooperating devices to find a compromise between the limited capabilities of IoT devices and security requirements (e.g., confidentiality, integrity, availability, etc.). This group of devices uses group key management (GKM) for key distribution. Dammak et al. in [1] presented an extensive analysis of the properties of GKM systems

depending on their applications. The analysis included: wireless body area networks (WBANs) [2], wireless sensor networks (WSNs) [3], cloud computing [4], wireless IPv6 networks [5], and IoT [6][7]. The result of this analysis is the following conclusions. Performance degrades quickly when many devices form a single group and when group members change frequently. The problem of key renewal when devices join/leave a group is not fully resolved. The Decentralized Lightweight Group Key Management architecture for Access Control, presented in [1], attempts to solve the problems mentioned in the above analysis.

The article presents a secure data exchange protocol, the most critical component of the cryptographic key generation, renewal, and distribution (KGR) system. The developed security mechanisms use a hardware-based Trusted Platform Module (TPM) to establish local trust structures and ensure secure storage and data exchange on IoT network node resources. The developed protocol guarantees security regardless of the protection applied to the MQTT service used, which is an essential advantage for applications in federated environments.

II. CONCEPT OF A DATA EXCHANGE PROTOCOL

A. Characteristics of the cryptographic key generation and renewal system

The system of generation, renewal, and distribution of cryptographic keys (KGR) for a hybrid environment, in which a protected exchange of data between domains of sensor nodes and traditional systems (IT systems) will be required, is presented in figure Fig. 1.

Clients of the KGR system can be sensor node networks and traditional IT systems. Sensor node networks are organized as secure sensor node domains [9][10]. Only representatives (Gateway nodes) of secure sensor node domains and representatives of other systems participate in distributing cryptographic keys in the KGR system. Each gateway node works as a sink node for data originating from domain nodes or the IT system and as an emitter of data

□ This work was supported by the UGB-798 university project.

¹ <https://www.zymbit.com/zymkey>

originating outside for domain nodes or nodes of the IT system.

Fig. 1 The way various domains and IT systems cooperate with the key server

Fig. 2 Components of the KGR system

In the KGR system (Fig. 2), the source of cryptographic keys will be a separate node KS (Key Server) to which the N_1, N_2, \dots, N_n nodes (gateway nodes of domains and IT systems) will have access. The AC (Authorization Center) node is also a system component. It will be responsible for managing the KS node and adding new identifiers for the authorized N nodes in the KS node resources.

The MQTT protocol will be used to exchange data to facilitate key distribution for IoT networks. The protocol is event-driven, and data exchange between nodes is based on the publish /subscribe (Pub/Sub) pattern. The sender (Publisher) and receiver (Subscriber) are isolated from each other and use so-called "topics" to communicate. The intermediary of data exchange is a node called an MQTT broker.

B. Assumptions for the KGR system

Since one of the data exchange parties may be a mobile IoT network node, which is classified as a restricted device [11], it is assumed that the KGR system should satisfy the following assumptions:

- for the generation of symmetric cryptographic keys, the KGR system will use a high entropy random number generator (e.g., quantum random number generator),
- the KGR system is available on the Internet,
- the KGR system only handles requests from authorized clients,
- the KS node will obtain data about authorized clients from the AC node,

- the client can be implemented in hardware, but can also be a software component that is installed on a node that acts as a Gateway,
- the MQTT protocol will be used to distribute cryptographic keys,
- each KGR node uses a local trust structure that is constructed using the TPM module,
- sensitive data stored in the resources of each node and data transmission between nodes are cryptographically protected,
- each of the N-type nodes must be appropriately prepared and then registered in the KGR system before it can start normal working - registered nodes before they begin their activities are authenticated,
- a hardware TPM module supports all cryptographic procedures in the KGR system. TPM is an implementation of a standard developed by the Trusted Computing Group [12].

C. Procedures implemented in the KGR system

When creating a secure system and hardware and software configurations, secure procedures for using such a system and procedures for decommissioning it must be prepared. Procedures in the KGR system are implemented in two phases.

In the first phase, procedures are executed that prepare the KS node and N nodes for cooperation. These procedures include, but are not limited to, initializing the KS node, preparing credentials for the N nodes, and initializing and registering N nodes in the KS node resources.

In the second phase, procedures for generating and distributing symmetric keys for N nodes, renewing these keys, and secure data exchange between N nodes are performed. Only the procedures of the second phase will be described in detail later.

Fig 3 shows how data is exchanged between the nodes of the KGR system during the procedures mentioned above. The MQTT service is used in the KGR system only as an intermediary for data exchange and is neither the source nor the destination of the generated keys. Fig 4 shows the communication structure of the KGR system.

Fig. 3 The method of data exchange in the KGR system

MQTT service to exchange data requires defining a string called "topic". The main task of the MQTT broker is to forward messages published in a given "topic" by one client to clients subscribing to data with this "topic". To increase the security level in the KGR system, the content of each "topic" is random and known only to both parties of the

message exchange. In the description, strings related to the "topic" will be marked as TOPICn. Table 1 shows the purpose of the "topic" strings used.

Fig. 4 The communication structure of the KGR system

TABLE 1.
LIST OF TOPICS USED BY THE NODES.

topic	node	purpose
TOPIC0	KS	for each N node for the first request during the registration procedure
TOPIC1	KS	for subsequent requests from the given N node during the registration procedure
TOPIC2	N	for requests from KS node (i.e., published by KS node)
TOPIC3 _m	N _m	for requests from N _m node (published by N _m node)
TOPIC4 _m	N _m	for publishing to N _m node

The rest of the paper describes the symmetric key generation and distribution procedure in detail.

III. DATA EXCHANGE PROTOCOL FOR THE KEY GENERATION AND DISTRIBUTION PROCEDURE

A. Procedure description

For simplicity in the following description, we will assume that the key set will be generated for a pair of nodes N1 and N2. Node N1 will initiate the key generation procedure.

The procedure for generating and distributing symmetric keys consists of three stages:

- a) requesting symmetric keys,
- b) delivery of symmetric keys to the requesting and destination nodes,
- c) confirmation of delivery of keys to the destination node.

This procedure requires the following conditions, which are provided in the first phase of KGR system preparation (not described here):

- the KS node is initialized and subscribes to TOPIC0 and TOPIC1 topics,
- the N-type nodes for which keys are to be generated must be registered in the KS node's resources, and each node subscribes to a TOPIC2 topic.

Meeting these requirements means that each N-type node has a local trust structure generated and has keys to secure data exchange between these nodes and the KS node.

An Encrypt-then-MAC (EtM) [13] approach requiring two keys will be used to secure data exchange. The AES algorithm will be used for encryption, and the HMAC algorithm for hash determination - both of which are supported on hardware by the TPM module. During one key generation operation, the node KS will prepare the

symmetric key NNSK (*Node to Node Security Key*), the initialization vector for this key, and the key NNSKsign (*Node to Node Security Key for signing*). Both these keys will be used only by nodes N1 and N2. A single key generation and distribution operation require performing the following actions:

- node N1 sends a request to node KS to generate a symmetric key pair for nodes N1 and N2,
- the KS node generates the NNSK key and the NNSKsign key and temporarily stores them,
- KS node sends the generated data to N1 and N2 nodes,
- the N2 node sends an acknowledgement of receipt of the keys to the N1 node via the KS node,
- after sending this acknowledgement, the KS node removes the NNSK and NNSKsign keys from its resources.

Fig. 5 shows the sequence diagram for these activities.

Fig. 5 Sequence diagram of key generation and distribution for node pair N1 and N2

The procedure results are the secure distribution of the generated keys and the contents of TOPIC3 and TOPIC4 to the N1 and N2 nodes. Nodes N1 and N2 will use the topics for subsequent secure data exchange among themselves using the MQTT service.

B. Frame structure description

The key generation and distribution procedure uses a data exchange protocol that utilizes six types of frames. For authenticated encryption data exchange will be used Encrypt-then-MAC (EtM) approach using the key pair, which are known only to the pair of nodes N_i and KS and was established during the registration procedure of node N_i. The list of these frames is as follows:

- **nnsk_key_req** - request to generate a new set of keys for N1 and N2 nodes - sending TOPIC generated by N1 for publishing by N2 node, which will act as TOPIC3,

N_ID1 - ID of requesting N node
 N_ID2 - ID of destined N node
 TOPIC - Topics subscribed by N_ID1 node (TOPIC3)
 HMAC - Digital signature of the frame

- **nnsk_key_ans** - response to keys request - sending a set of keys and initialization vector,

N_ID1 - ID of requesting N node
 N_ID2 - ID of destined N node
 NNSK - Node to Node Security Key + Initialization Vector
 NNSKsign - Node to Node Security Key for signing
 HMAC - Digital signature of the frame

- **nnsk_adv_req** - advertisement of generating a new set of keys on the initiative of node N1 - sending a set of keys, initialization vector, and TOPIC3,

N_ID – ID of requesting N node (N_ID1)
 NNSK – Node to Node Security Key + Initialization Vector
 NNSKsign – Node to Node Security Key for signing
 TOPIC – Topics subscribed by requesting node (TOPIC3 by N_ID1)
 HMAC – Digital signature of the frame

- **nnsk_adv_ans** - confirmation of receipt of the set of keys - sending TOPIC generated by N2 for publishing by N1 node, which will act as TOPIC4,

N_ID1 – ID of Secnd element from pair (N1, N2)
 N_ID2 – ID of requesting node (N1)
 TOPIC – Topics subscribed N2 node and for publishing by N1 node
 HMAC – Digital signature of the frame

- **nnsk_conf_req** - confirmation of delivery of a set of keys for N2 - sending TOPIC generated by N2 for publishing by N1 node,

N_ID1 – ID of requesting N node
 N_ID2 – ID of destined N node
 TOPIC – Topic subscribed by N2 node for publishing by N1 node
 HMAC – Digital signature of the frame

- **nnsk_conf_ans** - confirmation of the end of key distribution for a pair of nodes (N1, N2),

N_ID1 – ID of requesting N node
 N_ID2 – ID of destined N node
 HMAC – Digital signature of the frame

Fig. 6 shows the basic sequence diagram illustrating the operation of the data exchange protocol during the generation and distribution of the key set for a pair of nodes (N1, N2) for a use case in which the distribution procedure proceeds correctly. Diagram in Fig. 6 also includes the actions performed by the nodes involved in the data exchange during this procedure.

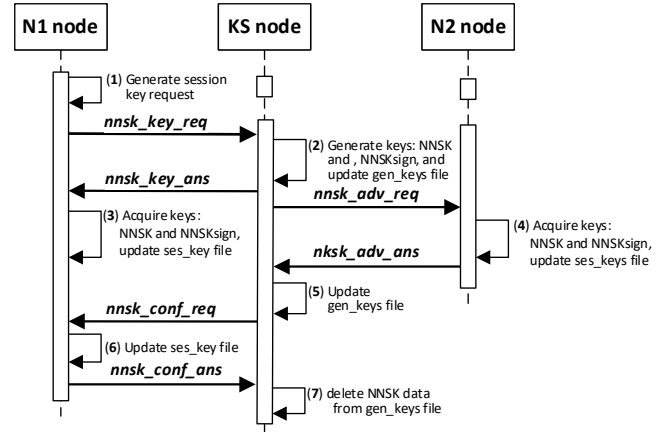

Fig. 6 Sequence diagram for key generation and distribution protocol

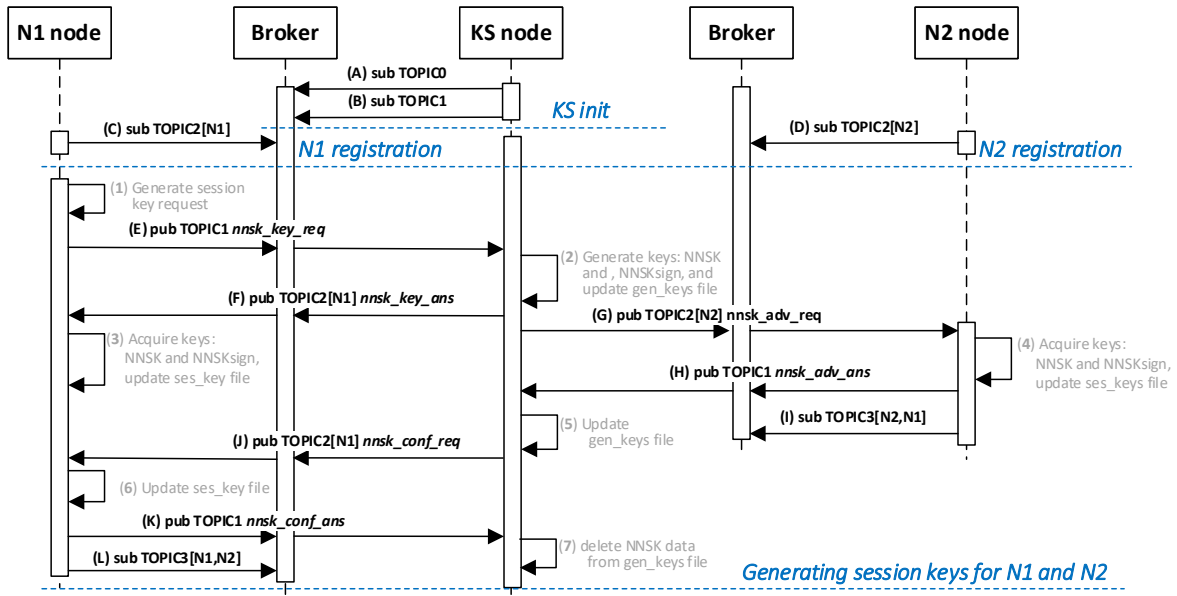

Fig. 7 The sequence diagram of the data exchange in the MQTT service for the generation and distribution key procedure.
 Legend: **sub TOPIC** - subscription to the topic broker "TOPIC", which is known to all nodes
sub TOPIC[Ni] - subscription to the "TOPIC" topic broker, which is known only to Ni and KS nodes
sub TOPIC[N1, N2] - subscription to the "TOPIC" topic broker, which is known only for N1 and N2 nodes
pub TOPICi nnsk_xxx_yyy - publishing a frame "nnsk_xxx_yyy" with the topic "TOPICi", where xxx={key, adv, conf}, yyy={req, ans}

In the MQTT service used to exchange data via the described protocol, a service broker plays the role of an intermediary. An important role is played in this service by appropriately using topics when sending data. Fig. 8 shows a sequence diagram illustrating data exchange in the MQTT service for the cryptographic key set distribution protocol.

C. Experiment description

To verify the operation of the KGR system, in particular the protocol for generating and distributing cryptographic keys, a lab bench was used that included four nodes (Fig. 9). One node played the role of KS, and two nodes played the role of N. The fourth node was a broker for the MQTT service. The experiments used Mosquitto 1.5.1 software, which implements the MQTT 3.1.1 protocol.

Each node of the lab bench was implemented in Python on a Raspberry Pi 3 platform with the Raspbian Buster system. The KS, N1, and N2 nodes were equipped with a Trusted Platform Module (TPM) 2.0 (the LetsTrust TPM). In the KGR system, TPM modules were the source of random numbers. It supported cryptographic procedures to generate keys, secure data exchange between nodes, and protect data stored in the resources of the KS, N1, and N2 nodes.

Fig. 8 View of lab bench for testing the KGR system.

During the testing of the KGR system, several experiments were conducted to confirm the correctness of the system's operation. They covered the procedures for preparing the KS node, distributing credentials for N-type nodes, registering N-type nodes in the KS node resources, and the procedure for generating and distributing keys for N-type nodes described in this paper.

IV. CONCLUSIONS

The described protocol for secure data exchange is the main component of the KGR system. This protocol provides secure distribution of cryptographic keys over the MQTT service IoT devices often use. This protocol can be used for

IoT devices and other IT systems that interact with IoT devices. Advantages of the protocol include:

- data exchange between the components of the KGR system is cryptographically secured,
- topics used in the MQTT service have random values and are known only to the nodes that use these topics - the KGR system also provides secure distribution of these topics,
- sensitive data of the KGR system nodes are cryptographically secured,
- the TPM module supports all cryptographic procedures,
- MQTT service broker is only an intermediary of data exchange and does not participate in any other way in procedures performed in the KGR system.

Abstract—The federated nature of many crucial Internet of Things (IoT) applications introduces several challenges from a security perspective. To address critical challenges related to the authentication and secure communication of IoT devices operating in federated environments, we propose a new authentication and key exchange protocol based on a distributed ledger. Our protocol uses the unique configuration fingerprint of an IoT device and does not require secure storage in participating IoT devices. To validate the correctness of our design, we have performed formal modeling and verification of the security properties, using two different verification tools: Verifpal and the Tamarin prover.

I. INTRODUCTION

THE APPLICATIONS of Internet of Things (IoT) expand rapidly to many mission-critical areas, such as smart health care and Humanitarian Assistance and Disaster Relief (HADR) [1]. Many of these applications are based on the concept of *federation* in which IoT devices operated by different federated partners must communicate with each other securely.

Many protocols are used for authentication and key exchange between devices described in the literature. An overview of such protocols is presented in [2]. The proposed solutions are based on a variety of approaches, including Public Key Infrastructure (PKI) [3], blockchain [4, 5, 6], and shared keys [7, 8]. An advantage of our proposal is its focus on the federated environment, where devices belonging to one organization (and regulated by its security policy) can be accessed and used by other organizations belonging to the federation.

Federating separate IoT administrative domains introduces several challenges from a security perspective. One of the fundamental challenges is establishing an effective identity and access management (IAM) framework, which is necessary to ensure trust and secure communication between federated IoT devices [9]. The particularly critical IAM challenge is the authentication and authorization of federated IoT devices.

To address these challenges, we propose in Section II a Lightweight Authentication and Key Exchange Protocol for Federated IoT (LAKEPFI) that supports flexible authenticated

key exchange based on Hyperledger Fabric (HLF) [10]. The solution uses the unique configuration fingerprint of an IoT device and does not require secure storage space in participating devices. Our protocol enables secure communication of heterogeneous federated IoT devices, including devices equipped with additional security hardware, such as Physical Unclonable Functions (PUF) [11], and devices characterized by very limited computing resources such as Arduino.

Constructing a new security protocol is an error-prone process. Therefore, it is essential to verify its security properties using various techniques. The process of verifying the security properties of protocols is a common operation. Any protocol used to communicate with devices must undergo this process. In this article, we will focus on describing the verification of the security properties of the developed protocol. For this purpose, we used two tools: Verifpal and Tamarin. These tools have previously been used for the verification of some commonly used IoT communication protocols [12].

In Section III we briefly introduce formal modeling and verification approaches that can be used to validate the security properties of LAKEPFI. In Sections IV and V, we present and discuss formal modeling and verification of the security properties of LAKEPFI using Verifpal and the Tamarin prover. In particular, our aim is to prove formally that the designed protocol provides: 1) message secrecy; 2) message authentication; 3) freshness.

II. LIGHTWEIGHT AUTHENTICATION AND KEY EXCHANGE FOR FEDERATED IOT DEVICES

A. Federated IoT architecture

The main goal of the proposed protocol is to establish efficient and secure communication between devices belonging to different organizations. The main participants in this protocol are IoT devices that belong to other organizations and services on the organization's side: the application gateway and distributed ledger.

Fig. 1 shows the general architecture of the components that are used in the LAKEPFI.

The IoT device consists of two components:

Fig. 1. Component architecture and interconnection scheme.

- 1) AA Service (Authentication and Authorization Service), responsible for communicating with the application gateway using the solution we describe;
- 2) User App, the user application that connects to the AA service is agnostic to our framework. Each user application uses a unified interface provided by the AA service.

Our protocol is an application layer protocol, and although it can be used in combination with existing lower-level security protocols to provide increased defense-in-depth, it is agnostic to these lower-layer protocols. In our proof of concept, for efficiency reasons, Constrained Application Protocol (CoAP) [13] with Concise Binary Object Representation (CBOR) [14] is used for communication between the device and the application gateway (AG). Communication between the application gateway and distributed ledger nodes uses Transport Layer Security (TLS). The application gateway is responsible for the following:

- 1) Conversion from CoAP to TLS and vice versa, due to the fact that Hyperledger Fabric requires TLS with certificates, while IoT devices must use lightweight protocols;
- 2) Filtering out of invalid and malicious messages;
- 3) Load balancing, therefore, ensuring that the IoT device does not need to know the whole distributed ledger architecture, which can change.

The last component is the distributed ledger node, which stores all smart contracts and has access to all channels. In our implementation, we used Hyperledger Fabric as a distributed ledger implementation. The Hyperledger Fabric Node consists of two services:

- 1) *Peer*, responsible for the verification and recording of transactions in the distributed ledger;
- 2) *Orderer*, responsible for the creation of a block.

B. Description of the protocol

The proposed protocol is based on the use of unique parameters of the IoT device for its authentication. Within this protocol, three main methods are described:

- 1) Registration of an IoT device in a distributed ledger;
- 2) Communication of an IoT device with a distributed ledger node;

- 3) Communication between IoT devices, especially those belonging to different organizations within the federation.

C. Registration phase

The first operation is device registration. This is required for the device to communicate with other devices and services. The registration process can be performed in two different ways: 1) connect directly to the application gateway; or 2) put the device at the destination and secure the communication for the duration of the registration with a one-time login and password. During the registration phase, the device sends values to the application gateway for the parameters that define the device. Each parameter should have an appropriate entropy. This is a kind of fingerprint from the IoT device. Depending on the capabilities of the IoT device, the parameters recorded in the array may include the following:

- 1) Unique configuration data - in this case, the unique data of the device is used. It can be hardware data, e.g., device serial number, memory card serial number, etc., and it can be software data, e.g., partition IDs, file system IDs, keys stored on the device,
- 2) PUF data - data from the PUFs embedded in the IoT device,
- 3) Random strings (for example, keys) - in this case, the device generates random strings with required entropy and needs to store them securely. This method is used only if neither 1) nor 2) can be used.

In the first and second cases, the device does not store the key in its storage; it is enough to hold a program to obtain values of specific parameters. The device performs an appropriate operation to obtain parameters, e.g., a system command to obtain a particular parameter. The second and third cases are prepared for devices with a minimum of 50 kB RAM and 250 kB flash memory, that is, the so-called class C2 [15]. However, in case 2, the device must support PUF.

In the registration process, a set of parameters P_A consisting of its parameters $\{p_1, p_2, \dots, p_n\}$ is written in the distributed ledger DL . The communication diagram is shown in Fig. 2. As written in the beginning of this section, there are two options for securely sending P_A from the IoT device A to the application gateway AG . After receiving the array P_A , the application gateway AG generates a new identifier ID_A for the device A . The ID_A along with the parameter array P_A is stored in the

Fig. 2. Communication between the IoT device and a ledger node during the registration phase

distributed ledger DL . After the success of storing these data in the ledger DL , a response is generated to the IoT device A . In the response, the identifier ID_A and the current timestamp t are sent to the device ID_A in encrypted form E_A . The encryption key K is generated by the distributed ledger node DL_i . This key K is the result of a hash function from the concatenation of a subset $\{1, \dots, n\}$: $PN_{DL \rightarrow A} = \{n_1, n_2, \dots, n_k\}$ of the parameters $K = H(p_{n_1} | p_{n_2} | \dots | p_{n_k})$ sent by the device. The parameters used for encryption are chosen at random. In addition to ciphertext $E_A = E[K; nonce; (ID_A, t)]$, where $E[\cdot]$ is the encryption function to encrypt (ID_A, t) using K and $nonce$, AG also sends the identifier in plaintext ID_A , the nonce value $nonce$, and the identifiers of the parameters $PN = \{p_{n_1}, p_{n_2}, \dots, p_{n_k}\}$, whose values were used to create the key K , are also sent.

Based on the number of parameters $PN = \{p_{n_1}, p_{n_2}, \dots, p_{n_k}\}$ that are sent in the response, the device knows which parameters were used to generate the key K so it can recreate the key K and thus decrypt the message. After decryption, it checks if the timestamp t sent in reply differs more than 5 seconds from the current one. Then it checks if the identifier ID_A sent in plaintext and the ciphertext E are the same. If all these operations were successful, the device is registered and then uses the received identifier ID_A and the generated set of parameters P_A .

D. Communication procedure between IoT device and distributed ledger node

When a device A communicates with an application gateway AG that will perform a task, the device A encrypts the data $data$ it wants to send to the gateway AG in the same way as described for the process of generating a response from the ledger DL during device registration. The communication diagram is shown in Fig. 3. The device A selects a subset of parameters $\{1, \dots, n\}$: $PN_{A \rightarrow DL} = \{n_1, n_2, \dots, n_k\}$ and generates a key $K_{A \rightarrow DL} = H(H(p_{n_1}) | H(p_{n_2}) | \dots | H(p_{n_k}))$ from them. The key $K_{A \rightarrow DL}$ together with the random generated nonce value $nonce_{A \rightarrow DL}$ is used to encrypt the data $data$ and the current timestamp $t_{A \rightarrow DL}$: $E_{A \rightarrow DL} = E[K_{A \rightarrow DL}; nonce_{A \rightarrow DL}; (data, t_{A \rightarrow DL})]$. To the application gateway AG , device AA sends: an identifier ID_A , a nonce $nonce_{A \rightarrow DL}$, parameter numbers $PN_{A \rightarrow DL}$ that define the parameters used to generate the key $K_{A \rightarrow DL}$ and a ciphertext $E_{A \rightarrow DL}$. The application gateway AG sends these data to the distributed ledger node DL_i to decrypt the ciphertext $E_{A \rightarrow DL}$. The distributed ledger node DL_i is capable of generating a key $K_{A \rightarrow DL}$ based on the number of parameters $PN_{A \rightarrow DL}$ and

Fig. 3. Communication between an IoT device and the distributed ledger

the identifier ID_A . Using this key $K_{A \rightarrow DL}$ and the nonce value $nonce_{A \rightarrow DL}$ it performs decryption of the ciphertext $E_{A \rightarrow DL}$. The timestamp $t_{A \rightarrow DL}$ stored in the ciphertext $E_{A \rightarrow DL}$ and the current one are verified. If the ciphertext $E_{A \rightarrow DL}$ was successfully decrypted and the timestamp $t_{A \rightarrow DL}$ is correct, the application gateway AG receives the encrypted $data$. Based on $data$, it determines what should be executed and performs the requested operation. The response $response$ is generated in the same way. The device A receives the identifier ID_A , the new nonce value $nonce_{DL \rightarrow A}$ used in the response $response$ encryption process, the parameter numbers $PN_{DL \rightarrow A}$ that define the parameters used to generate the key $K_{DL \rightarrow A}$ and the ciphertext $E_{DL \rightarrow A} = E[K_{DL \rightarrow A}; nonce_{DL \rightarrow A}; (response, t_{DL \rightarrow A})]$. The device A after receiving the message is capable of generating the key $K_{DL \rightarrow A}$ and thus decrypting the ciphertext $E_{DL \rightarrow A}$ and getting the response $response$.

E. Communication procedure between IoT devices

To communicate with each other, it is necessary to authenticate the devices that want to communicate with each other and verify that such communication is authorized. The communication diagram is shown in Fig. 4. The device that wants to establish communication is the device A with ID_A . This device sends the ID_B of the device B to the application gateway AG . The device A can get the ID_B of device B in many ways, e.g., it can receive the ID_B of device B from another device, it can have a record that needs to communicate with that device, or device B can announce that it has a certain type of information. The identifier ID_B is secured in a way that is identical to the data in the device communication process with the distributed ledger DL described in the previous subsection. The application gateway AG sends the request to decrypt to the distributed ledger node DL . The node DL returns the decrypted identifier ID_B . The application gateway AG then sends a request to create a key $K_{A \leftrightarrow B}$ for communication between devices A and B . DL verifies based on the rules stored in the DL authorization channel whether A and B can communicate. If so, then it generates the key $K_{A \leftrightarrow B}$. To create a key $K_{A \leftrightarrow B}$, DL selects a subset of k -elements of $p_{n_1}, p_{n_2}, \dots, p_{n_k}$ from the parameter array P_B of the device B , which is stored in the ledger. The key $K_{A \leftrightarrow B}$ is constructed similarly to the previous processes; only in this case is the current timestamp $t_{A \leftrightarrow B}$ is also included: $K_{A \leftrightarrow B} = H(p_{n_1} | p_{n_2} | \dots | p_{n_k} | t_{A \leftrightarrow B})$. The response to device A must send the key $K_{A \leftrightarrow B}$, timestamp $t_{A \leftrightarrow B}$, and parameter numbers $PN_{A \leftrightarrow B}$ that were created to create the key $K_{A \leftrightarrow B}$. The response is secured in the same way as in the previous

Fig. 4. The procedure of communication between IoT devices

cases. The device A decrypts the message in the same way as in the previous case. If everything is correct, the device A can now send *data* to the device B . To do this, it has to generate a new nonce $nonce_{A \rightarrow B}$. Using the key $K_{A \leftrightarrow B}$ received in the response and the nonce value $nonce_{A \rightarrow B}$, it can encrypt *data* and the timestamp $t_{A \leftrightarrow B}$ that will be sent to the device B : $E_{A \rightarrow B} = E[K_{A \leftrightarrow B}; nonce_{A \rightarrow B}; (data, t_{A \leftrightarrow B})]$. Then device A sends to device B : $ID_A, PN_{A \leftrightarrow B}, t_{A \leftrightarrow B}, nonce_{A \rightarrow B}, E_{A \rightarrow B}$.

The device B after receiving the message can decrypt the ciphertext $E_{A \rightarrow B}$ because the key $K_{A \leftrightarrow B}$ was created by the distributed ledger node DL based on the parameters P_B of the device B and the timestamp $t_{A \leftrightarrow B}$. Using the key $K_{A \leftrightarrow B}$ and the nonce $nonce_{A \rightarrow B}$, the device B decrypts the ciphertext $E_{A \rightarrow B}$. If device B successfully decrypts the ciphertext $E_{A \rightarrow B}$, this means that the key $K_{A \leftrightarrow B}$ has been created by the distributed ledger node DL and, therefore, has been issued to the authorized entity A . To secure the response, the device B uses the same key $K_{A \leftrightarrow B}$ but with a new nonce value $nonce_{A \leftarrow B}$. Furthermore, the new timestamp $t_{A \leftarrow B}$ is generated in ciphertext. The new ciphertext is built: $E_{A \leftarrow B} = E[K_{A \leftrightarrow B}; nonce_{A \leftarrow B}; (result, t_{A \leftarrow B})]$. Therefore, the answer contains: $ID_B, PN_{A \leftrightarrow B}, nonce_{A \leftarrow B}, t_{A \leftrightarrow B}, E_{A \leftarrow B}$.

III. MODELING AND VERIFICATION

Building a secure communication protocol requires verification of its security properties. Such properties include, for example, authentication of the communicating parties, the confidentiality and integrity of the transmitted data, and the equivalence property; that is, an attacker cannot distinguish between any two stages of the protocol.

Formal verification can confirm (or deny) that the protocol is secure. A protocol can be mathematically formalized by [16]:

1) *Symbolic (Dolev-Yao [17]) model*, in which cryptographic primitives are represented as black boxes, messages are terms in these primitives, and the attacker is restricted to using these primitives. This model makes the execution of automatic proofs relatively easy. The symbolic model is robust to attacks if no attack can occur for each trace. By trace, we mean one run of the protocol. Research progress on this type of model is considered highly advanced.

2) *Computational model*, in which messages are strings of bits, cryptographic primitives are functions that operate on these strings, and the attacker is any probabilistic Turing machine. This mode is generally used by cryptographers. A computational model is robust to attacks if no attack can occur for every trace except those with a negligibly small probability. The computational model is more realistic, but still, since it is only a model, it will not give us an answer to whether the developed protocol is resilient to some attacks, such as side-channel or physical attacks. In the case of computational models, most of the time, cryptographic properties have to be proven manually. The proofs in this model are more difficult to perform and analyze. This type of modeling is much less mature. Therefore, we did not use this type of modeling.

It is worth mentioning that, regardless of the modeling approach used, even minor changes to the protocol require a revision of the model used for the analysis. Examples of tools that use the symbolic model include:

- 1) AVISPA [18] uses a modular and expressive High-Level Protocol Specification Language (HLPSL). It supports many back-end tools to verify a model, and the result of the model verification is easy to interpret. The implemented techniques offer protocol analysis, such as protocol falsification (by finding an attack on the input protocol) and abstraction methods for finite and infinite sessions, among others. AVISPA is currently not widely used in papers.
- 2) Verifpal [19] uses an intuitive language to describe the model and the result is easy to interpret. Verifpal can validate forward secrecy, key compromise, impersonation, and other advanced queries. It also supports unbounded sessions, fresh and random values, and other valuable features of the symbolic model. However, users cannot define their primitives. It is one of the youngest tools and is still being actively developed.
- 3) ProVerif [20], like the previous tools, provided predefined and reusable primitives. However, contrary to AVISPA and Verifpal, new primitives can also be defined. The way of modeling in ProVerif is similar to the approach used in Verifpal and AVISPA, but ProVerif uses a different verification method. If ProVerif checks that a security property is fulfilled, then it is indeed so, but ProVerif cannot always prove the properties of the tested protocol.
- 4) Tamarin prover [21] in its capabilities and popularity is similar to ProVerif; Tamarin prover has a different way of modeling protocols than the other tools. In the case of the Tamarin prover, we model the rules of transition between states in the protocol, while every operation within the protocol is modeled in other protocols. Each rule in Tamarin prover has an input (describes what it takes in), an output (what the result is), and facts. The proof in the case of Tamarin is to verify whether the

lemma we describe is true or not. Similarly to ProVerif, the Tamarin prover is not always able to prove the properties of the tested protocol.

For the analysis of our protocol, we have selected Verifpal and Tamarin. These formal verification tools are described in more detail in the next section. Both Verifpal and Tamarin are widely accepted and are currently used by researchers and practitioners to analyze security protocols. Verifpal supports fast modeling of a protocol and verification of its basic properties (message secrecy and authentication). On the other hand, the Tamarin prover is a more powerful tool that can allow us to verify a protocol in more detail. Both tools also verify the model automatically. Note that these tools work with an unbounded number of sessions, making the problem undecidable [16].

When modeling a security protocol, several issues need to be taken into account [22]:

- 1) One should assume the correctness of low-level cryptography mechanisms; for example, when using encryption or random value generation, one should assume that these functions work correctly.
- 2) Appropriate assumptions should be made about external services, e.g., network services such as time servers and trusted third parties.
- 3) Since protocol messages often need to pass through various middle boxes, such as firewalls and guards, and the protocol participants may be mobile or connected via unreliable communication channels, it has to be assumed that the messages may have different forms or may not reach the other participant.
- 4) Some protocols require early negotiation to determine the cryptographic primitives to be used, which affect the level of security and performance.
- 5) The reaction of participants to the occurrence of an error should be appropriately modeled, as proper error handling affects the security of the protocol.

Verifpal offers a more native way of writing the protocol, making it more readable and easier to learn. Verifpal defines two types of an attacker. The first type is *active attacker*, which can intercept all protocol messages, modify them, and inject his messages. The second type is *passive attacker*, which can only intercept messages sent between protocol participants. An attacker is free to use any combination of actions available to him. Verifpal has defined cryptographic primitives such as (a)symmetric encryption, authenticated encryption [23], Diffie-Hellman key exchange, digital signature, and a secure hash function. Verifpal does not allow for the definition of additional cryptographic primitives. The verification result is easy to interpret; precise information about what has been changed and what property is not met. Verifpal is one of the few tools that examines the unlinkability property. Unlinkability is a situation where for two observed values, the adversary cannot distinguish between a protocol execution in which they belong to the same user and a protocol execution in which they belong to two different users [19].

Tamarin prover offers automatic and interactive theorem proving models [21]. Although the Tamarin prover automatically generates proofs, user interaction is sometimes required. The result of the proof itself also brings inconclusiveness to the problem. The analysis is based on labeled multiset rewriting rules to specify protocols and adversary capabilities, a guarded fragment of first-order logic to determine security properties and functions, and equational theories to model the algebraic properties of cryptographic protocols. Furthermore, all events related to security properties are annotated with a time point $t \in Q$, and a basic comparison of time points can be used. Tamarin prover applies a constraint-solving algorithm based on backward search and heuristics that attempts to validate or falsify security properties. This approach requires significant knowledge and experience in formal modeling [24]. Therefore, modeling the protocol using the Tamarin prover is complex, and the result of model verification is also rather difficult to interpret.

IV. VERIFPAL

Modeling in the Verifpal tool first involves specifying the participants (parties) who will use the protocol. In the model itself, we define what operations a participant will perform and what data are transmitted between them. Finally, there are questions about the security properties of the data transmitted between participants. The role of Verifpal is to confirm the secrecy of transmitted data, confirm its authentication, and verify its freshness. Using Verifpal, three LAKEPFI operations were modeled:

- 1) Device registration,
- 2) Communication IoT device with Hyperledger Fabric,
- 3) Communication IoT device with other IoT device.

In this article, we will only describe in detail the operation of communicating an IoT device with a Hyperledger Fabric node because the other operations are very similar to this one. However, we will discuss model verification results for all three operations at the end of this subsection. During modeling, we followed the rules described in the III section.

First, we configure the mode in which the attacker should operate. In our case, an active attacker can influence the messages sent. Then, we define what the device knows. The device *DeviceA* knows its *ID*, which is public, so it also knows *HLF* (Hyperledger Fabric node) and the attacker. Additionally, the device knows the secret data *dataA* it wants to send. In the real-life protocol flow, the device generates the parameter numbers *paramnumbersAS* that are used to create the key. However, in the case of the protocol model, these values are not generated, but are sent and therefore must be included in the message.

The device generates timestamp *timestamp* and nonce *nonceAS*. In a real-life protocol flow, the device would now generate the *keyAS* key based on the set of specific parameter values. However, Verifpal does not allow this operation. Therefore, *keyAS* is generated as a random value. The device concatenates *dataA* and *timestamp*. The result of this

concatenation is then encrypted using *keyAS* and *nonceAS*. The result of encryption is the ciphertext *EdataAS*.

```
attacker[active]
principal DeviceA[
knows public ID
knows private dataA
generates paramnumbersAS
generates timestamp
generates nonceAS
knows private keyAS
dataToEncryptAS = CONCAT(dataA , timestamp)
EdataAS =
  AEAD_ENC(keyAS , dataToEncryptAS , nonceAS)
]
```

The *DeviceA* sends to *HLF* the *paramnumbersAS*, *nonceAS* and the ciphertext *EdataAS*. This information is learned by the attacker at this point.

```
DeviceA -> HLF: paramnumbersAS , nonceAS , EdataAS
```

HLF also knows the key *keyAS*, which should normally be generated using *paramnumbersAS* and a set of parameters. Then using *keyAS* and *nonceAS* it decrypts *EdataAS*. The result is split, leading to the data *DataAS* and the timestamp *timestampFromA*. In real implementation, the current timestamp is compared with *timestampFromA*, while in Verifpal, the ASSERT function does not affect anything. *HLF* generates a response *reply*, which will be sent to *DeviceA*. It also generates a new timestamp *timestampToA* and *paramnumbersSA* that, like *paramnumbersAS*, are not used but are sent. The *reply* is concatenated with *timestampToA*. The result is encrypted using a new key *keySA* and a new value *nonceSA*. A ciphertext *EdataSA* is created. As before, the new key is generated as if it were a random value, rather than derived from *paramnumbersSA* and the parameter array. Of course, the key *keySA* is marked as private, so it is not known to the attacker.

```
principal HLF[
knows private keyAS
DdataAS = AEAD_DEC(keyAS , EdataAS , nonceAS)
DataAS , timestampFromA = Split(DdataAS)
generates timestampNow
_ = ASSERT(timestampFromA , timestampNow)
generates reply
generates timestampToA
generates paramnumbersSA
dataToEncryptSA = CONCAT(reply , timestampToA)
generates nonceSA
knows private keySA
EdataSA =
  AEAD_ENC(keySA , dataToEncryptSA , nonceSA)
]
```

HLF sends *paramnumbersSA*, *nonceSA*, and *EdataSA* to *DeviceA*. At this point, the attacker learns these values.

```
HLF -> DeviceA: paramnumbersSA , nonceSA , EdataSA
```

The final step is for *DeviceA* to decrypt the response. For this, *DeviceA* knows the key *keySA*, which, as in the previous steps, is not created from *paramnumbersSA* and the parameter array. The ciphertext *EdataSA* is decrypted using *keySA* and *nonceSA*. Finally, the timestamp contained in the ciphertext is compared with the current one.

```
principal DeviceA[
knows private keySA
DdataSA = AEAD_DEC(keySA , EdataSA , nonceSA)
DataSA , timestampFromHLF = Split(DdataSA)
generates timestampNowReply
_ = ASSERT(timestampNowReply , timestampFromHLF)
]
```

The very end of the above listing defines queries concerning the properties that Verifpal has to check. For each operation, there are three properties: confidentiality of transmitted data, authentication of transmitted data, and freshness.

```
queries[
confidentiality? dataToEncryptSA
confidentiality? dataToEncryptAS
authentication? DeviceA -> HLF: EdataAS
authentication? HLF -> DeviceA: EdataSA
freshness? EdataAS
freshness? EdataSA
]
```

When verifying the registration operation and communication of the IoT device with the Hyperledger Fabric node, Verifpal found no errors and therefore confirmed confidentiality, authentication, and freshness.

On the other hand, for the third operation, communication between IoT devices, Verifpal found two errors: failure to authenticate *HLF* and lack of freshness when sending data from *HLF* to *DeviceA*. However, both errors are false positives. In both cases, Verifpal sets the value of *nonceSA* to nil (null), and this situation in a real run will return an error and *DeviceA* will reject the message. As we mentioned in Section III, modeling does not assume error handling, and here we have a good example.

In Verifpal, we had to apply some simplifications:

- 1) The key is a generated value, not a value generated from the parameters of device;
- 2) The parameters themselves are also a generated value and not a list with numbers;
- 3) There is no way to compare timestamps (although there is an ASSERT function, which is not used in Verifpal).

V. TAMARIN PROVER

The approach to modeling in Tamarin prover is quite different from that in Verifpal. For the Tamarin prover, think of a protocol as a set of states where information not passed to another state is forgotten. The conditions themselves are written as lemmas, which the Tamarin prover verifies. As with Verifpal, Tamarin prover allowed us to confirm secrecy, authenticity, and freshness. In the case of the Tamarin prover, three operations have been modeled:

- 1) Device registration,
- 2) Communication IoT device with Hyperledger Fabric,
- 3) Communication IoT device with other IoT device.

As in Section IV, we will describe in detail the operation of communicating an IoT device with a Hyperledger Fabric node. At the end of this section, we present the results for both operations.

First, we need to define the operations that we will use. The value after / indicates the number of arguments that the

operation will take. In addition, two functions are defined: decrypt and verify.

```
theory Device2Ledge
begin
functions:
aead/3, decrypt/2, verify/3, true/0
equations: decrypt(aead(k, p, a), a, k)=p
equations: verify(aead(k, p, a), a, k)=true
```

In the first rule, we generate a key that is shared between two parties. The function Fr means that key is random. Like Verifpal, here there is no possibility of generating the key as described in the actual implementation. In the set of facts, we specify that $Client$ and HLF know our key. We send the associated client $Client$ with the key key and the HLF node HLF with the same key to the next state.

```
rule Setup:
[ Fr(~key) ]
--[ID_Client($Client,~key),
  ID_Server($HLF,~key)]->
[!Identity($Client, ~key),
 !Identity($HLF, ~key)]
```

The next state takes in a new nonce value $nonce$ that is generated on input to this state, and two bindings, $Client$ and HLF with the key key . In the set of facts, we have written that there is communication between the client and the server using the key key and the value $nonce$. The output is a state in which we send a message from $Client$ to HLF with $nonce$ and the ciphertext $aead(key,'Data', nonce)$.

```
rule Client_1:
[ Fr(~nonce), !Identity($Client, key),
 !Identity($HLF, key) ]
--[Client2HLF($Client,$HLF,
 <key,~nonce>)]->
[ Out(<$Client,$HLF,~nonce,aead(key,
 'Dane',~nonce)>)]
```

The next rule defines a state that takes as input the newly generated nonce value $nonce2$, the binding of HLF to key , and the message from the previous state. In the set of facts, we define that there is communication between HLF and $Client$ using key and $nonce2$, and we verify the message. When leaving this state, we send a message from HLF to $Client$ with $nonce2$ and a response $reply$ encrypted with key and $nonce2$.

```
rule HLF_1:
let EncMessage = aead(key,'Dane',nonce)
in
[ Fr(~nonce2),!Identity($HLF, key),
 In(<$Client,$HLF,nonce,EncMessage>) ]
--[ HLF2Client($HLF,$Client,
 <key,~nonce2>),
  Eq(verify(EncMessage,nonce,key),true)
 ]->
[ Out(<$HLF,$Client,~nonce2,
 aead(key,'Respond',~nonce2)>)]
```

In the last rule, we define that the state receives as input a binding between $Client$ and key , as well as a message from HLF to $Client$. In the set of facts, we verify the message. This state is the final state.

```
rule Client_2:
```

```
let EncMessageFromHLF =
  aead(key,'Respond',nonce2)
in
[ Fr(~nonce3),!Identity($Client, key),
 In(<$HLF,$Client,nonce2,EncMessageFromHLF>) ]
--[Eq(verify(EncMessageFromHLF,nonce2,
 key),true)]->
[ ]
```

In addition, we have defined some restrictions. The first two restrictions specify that $Client$ cannot communicate with $Client$ and HLF cannot communicate with HLF . In $DenyClient2Client$, we define that when $Client$ sends a message to HLF , $Client$ cannot create a message and send it to itself. Similarly, in the $DenyServer2Server$ constraint, we specify that a HLF node cannot send a message to itself.

```
restriction DenyClient2Client:
"
All Client HLF key nonce #i. (
  Client2HLF(Client,HLF,<key,nonce>) @ #i
  & not(Client = HLF)
) ==> not (Ex #j nonce2 .
Client2HLF(Client,Client,<key,nonce2>) @j)
"
restriction DenyServer2Server:
"
All Client HLF key nonce #i. (
  HLF2Client(HLF,Client,<key,nonce>) @ #i
  & not(Client = HLF)
) ==> not (Ex #j nonce2 .
HLF2Client(HLF,HLF,<key,nonce2>) @j)
"
```

For the $dual_clients$ restriction, we specify that there do not exist two $Clients$ with the same key .

```
restriction dual_clients:
"
All Client key #i. (
  ID_Client(Client,key) @ #i
) ==> not (Ex #j Client2 .
ID_Client(Client2,key) @j)
"
```

The first lemma defines the secrecy of the key. For each $Client$, HLF , Key , two $nonces$ and two moments i and j in the situation: when there is a connection of $Client$ to HLF at moment i and HLF to $Client$ at moment j and moment j is after i and $Client$ cannot also be HLF then there is no such moment k that there is a revealed Key at moment k .

```
lemma Key_Secrecy:
"
All Client HLF Key nonce nonce2 #i #j. (
  Client2HLF(Client,HLF,<Key,nonce>) @ #i &
  HLF2Client(HLF,Client,<Key,nonce2>) @ #j &
  #i < #j &
  not (Client = HLF)
) ==> not (Ex #k1 . K(Key) @ #k1)
"
```

In the second lemma, we check the freshness. For each client $Client$ and node HLF and key t and two moments i and j in the situation: when there is a connection from $Client$ to HLF at moment i and HLF to $Client$ at moment j and moment j is after i where there are:

- 1) There is no such user *Client2* at moment *i1* that there is communication from *Client2* to *HLF* with the same key *KeyCH* at moment *i1* when *i* is equal to *i1*;
- 2) There is no user *HLF2* at moment *j1* that there is communication from *HLF2* to *Client* with the same key *KeyHC* at moment *j1* when *j* is equal to *j1*.

```

lemma freshness :
"
All Client HLF KeyCH KeyHC #i #j . (
Client2HLF(Client,HLF,KeyCH) @ #i &
HLF2Client(HLF,Client,KeyHC) @ #j &
#i < #j &
not(Client = HLF)
)==> (not (Ex Client2 #i1 .
Client2HLF(Client2,HLF,KeyCH)
@i1 & not (#i1 = #i)) & not (Ex HLF2 #j1 .
HLF2Client(HLF2,Client,KeyHC)
@j1 & not (#j1 = #j)))
"

```

For *Client* authentication, you need to prove that *Client* has a key that is used to protect the data before sending them. To do this, we have defined that for any *Client*, *HLF*, *nonce*, and *nonce2*, at moments *i* and *j*, there is a communication between *Client* and *HLF* where *HLF* sends a response to the request of *Client* and there is always a moment *k* such that *Client* has the *key* that was used to secure the communication before starting that communication.

```

lemma auth_Client :
"
All Client HLF key nonce nonce2 #i #j . (
Client2HLF(Client,HLF,<key,nonce>) @ #i &
HLF2Client(HLF,Client,<key,nonce2>) @ #j &
#i < #j &
not(Client = HLF)
)==> Ex #k . ID_Client(Client,key)
@k & #k < #i
"

```

The same is true for *HLF* authentication; it must also have *key* before communication can begin where *key* is used.

```

lemma auth_HLF :
"
All Client HLF key nonce nonce2 #i #j . (
Client2HLF(Client,HLF,<key,nonce>) @ #i &
HLF2Client(HLF,Client,<key,nonce2>) @ #j &
#i < #j &
not(Client = HLF)
)==> Ex #k . ID_Server(HLF,key)@k & #k < #i
"

```

In the Tamarin prover, we used the same simplifications as in Verifpal:

- 1) The key is a generated value, not a value generated from the parameters of *devic*;
- 2) The parameters themselves are also a generated value and not a list with numbers;
- 3) There is no way to compare timestamps.

As with Verifpal, Tamarin prover also confirmed key secrecy, freshness, and authentication of the *Client* and the *HLF* node during communication of the IoT device with the Hyperledger Fabric node. We also verified secrecy, authentication, and message freshness for the other operations.

In both cases, the result was positive. Both tools enforced identical constraints on us. Using the two tools allowed us to confirm that the protocol we developed is secure and provides the required security features. Using two tools reduced the probability that our proposed protocol did not meet our criteria because both tools use different deduction mechanisms.

VI. CONCLUSIONS AND FUTURE WORK

We have performed a formal modeling of the LAKEPFI protocol and presented the results of the analysis of its security properties. For our modeling and analysis, we have used two complementary formal verification tools, Verifpal and Tamarin. By choosing tools that use significantly different protocol models, we tried to minimize the possibility of erroneous verification. Based on the models developed using these tools, we verified the security properties of the protocol, such as message secrecy, authentication, and freshness. The choice of tools used to verify the protocol was not straightforward. We did not find a tool that was able to completely model our protocol. After testing many tools, we chose two that were closest to meeting our requirements. The difficulty in modeling our protocol lies mainly in generating the key to authenticate communication.

In the case of both tools, successful modeling of LAKEPFI required introducing some specific assumptions and simplifications. For example, the key is a randomly generated value; not a value generated explicitly from the device parameters. We have previously checked the randomness property of the created keys and, therefore, consider this assumption valid. Another limitation is that it is impossible to generate an array and randomly select the values from which the key should be created. Therefore, the array indexes are sent explicitly, which may affect the verification results. The final limitation is the inability to compare timestamps. In Verifpal, the possibility of evaluating values of timestamps is limited to the (unused) ASSERT function, while in Tamarin, one can define which events follow each other in time. However, one cannot compare the variables that store timestamps. The result of the time comparison influences the result of the execution of the protocol. If their difference is too significant, the message is considered invalid. Moreover, both tools that we used verify symbolic models. A symbolic model abstracts away the details of cryptographic operations and does not consider all implementation details, which could be seen as its limitation.

As part of future work, we plan to verify selected security properties of the LAKEPFI protocol in the computational model and validate the correctness and security of our implementation of the protocol. We also plan to test the performance of the protocol by experimenting with different use cases and configurations of the federated IoT environment.

Abstract—Many high-impact Internet of Things (IoT) scenarios, such as humanitarian assistance and disaster relief, public safety, and military operations, require the establishment of a secure federated IoT environment. One of the critical challenges in the implementation of federated IoT solutions involves establishing a secure and authenticated key management mechanism. We propose and validate in a laboratory environment a novel federated IoT onboarding and key management solution. Our dl-mOT protocol integrates an efficient identity-based modified Okamoto-Tanaka (mOT) protocol with a distributed ledger in order to establish an anchor of trust between federation members.

I. INTRODUCTION

MANY high-impact Internet of Things (IoT) scenarios, such as Humanitarian Assistance and Disaster Relief (HADR), public safety, and military operations, require the establishment of a secure federated IoT environment. Such a federation may involve entities with limited a priori trust relationships and generally rely on the integration and reuse of resources belonging to individual partners.

As an example, we consider a natural disaster, such as an earthquake, tornado, or flood, that affects a smart city. In such a scenario, military forces can be requested to assist local government agencies in delivering essentials, such as food and medical supplies, as well as medical and search and rescue support. One of the important operational priorities is to increase the number of information sources available to improve Situational Awareness (SA). To optimize the efficiency and effectiveness of their efforts, first responders can rely on data retrieved from the surviving smart city infrastructure. Such infrastructure may comprise sensors, actuators, and communication equipment, for example, traffic light posts with cameras for traffic flow monitoring, pollution and weather sensors, smart transportation networks, and smart power grids. To augment these capabilities, which can be degraded by a disaster, military forces can also deploy their own sensors at key locations, the data from which can be shared with local authorities and civilian responders and used to establish a common SA [1].

II. FEDERATED IOT ENVIRONMENT

An example of a federated IoT environment that was proposed for use within military and HADR operations is

presented in Fig. 1.

Fig. 1. Blockchain-based key management solution for IoT.

We can identify four types of components of such a federated IoT system:

- 1) IoT devices: Sensors and actuators, belonging to and operated by a specific organization and thus constituting a single security domain.
- 2) Edge nodes: These are gateway or sink nodes, facilitating communication within a single security domain and between devices belonging to different security domains. Edge nodes can also function as distributed ledger nodes.
- 3) Distributed ledger nodes: These are nodes participating in a permissioned distributed ledger. They represent different organizations participating in the federation. In the case of organizations operating an own IoT system, an

edge node can also play the role of a distributed ledger node. In the presented application, DL is responsible for authentication, authorization and for sharing the key for communication with IoT devices with each other. The ledger stores all the information necessary to perform the above operations. Each data saving transaction must be carried out only after fulfilling the conditions specified in the smart contract. In the case of Hyperledger Fabric, the smart contract is called chaincode. Because we use Hyperledger Fabric in our work, we will also rely on the naming convention used there.

- 4) End-user services: These are the primary consumers of sensor data and actuation capability offered by the IoT devices. Interaction between services and IoT devices is mediated via the federated distributed ledger. End-user services expose capabilities offered by a federated IoT system to the end-users.

In such an environment, IoT devices can communicate directly with each other, as well as with the edge nodes. A specific organization owns each IoT device, but to provide the required resilience and effectiveness of operation, it is desirable that once a federation is established, a device can communicate with any edge node belonging to the federation. Furthermore, a federation-wide federated access control policy can be maintained to define authorized direct communication patterns between IoT devices within and between organizations.

During the operational phases, IoT devices send data and requests to the edge node that acts as a mediator between IoT devices and distributed ledger nodes. Authorization to read and write data to the ledger is obtained by execution of a smart contract. The smart contracts can also be used to perform some processing of the data, e.g., data filtering, aggregation, or labeling.

III. CHALLENGES

The most critical challenges related to the interconnection of civilian and military communications and information systems (CIS) are related to security. In particular, the federated CIS needs to support controlled and timely information sharing between federation partners, meeting both stringent need-to-know constraints defined by the military partners, as well as responsibility-to-share requirements of effective execution of joint emergency response activities. Ensuring interconnection of military systems, usually compliant with specific military standards such as NATO Standardization Agreements (STANAGs), with their civilian counterparts, largely relying on open or commercial standards, introduces another layer of complexity and specific challenges. However, these interoperability issues are likely to decrease in the future due to an increasing focus on dual use of many of the new technologies, such as 5G, and an increasing focus of the military on cost-effectiveness of CIS implementation through the use of commercial-of-the-shelf (COTS) technologies and related civilian and open standards.

Federated emergency response and disaster recovery operations can be conducted in a broad spectrum of settings: in form of a peacetime support to civilian authorities as well as response to terrorist activities and humanitarian disasters in conflict regions. Therefore, in context of the CIS security, we need to consider presence of a powerful and technically sophisticated adversary, interested in disrupting response or using it as an opportunity to infiltrate or damage CIS of military partners. Such an attacker can compromise an arbitrary number of devices belonging to a specific federated organization. In the context of resilience to attacks, we differentiate between two types of devices. First type consists of devices equipped with a secure element (or a trusted processing module) that can provide reasonable resistance to access to secret data stored in the device, so that it can be assumed that for duration of a specific military operation, the data remains secret. Second type of devices is not equipped with any hardware security mechanisms - therefore, once compromised, any secret data stored at the device can be read and modified by the attacker. We assume that although attacker can compromise an arbitrary number of IoT devices, edge nodes and distributed ledger nodes belonging to specific federated organization, the attacker cannot compromise majority of the federated organizations. In particular, we assume that an attacker is not able to control majority of the distributed ledger nodes, representing different federated organizations, and thus a secure consensus and secure execution of distributed application (or so-called chain code) within distributed ledger is possible. Furthermore, we assume that although an attacker can inject malicious input data from the compromised nodes but all data is verified at the distributed ledger by means of smart contracts before it is written to the ledger and also before it is read.

IV. SECURITY REQUIREMENTS

The security mechanism should satisfy several specific requirements of the federated CIMIC. In federated operations, exact trust relationships between federation members might not be known in advance of device initialization. Therefore, a device might need to be re-authorized for operation within the specific federated environment and reconfigured to enable end-to-end encrypted information sharing between a sensor or actuator of one nation and a command and control system of another nation. The proposed mechanisms must be able to function in an adversarial environment, where static or cloud infrastructure might not be accessible for prolonged periods of time. To support IoT devices, security mechanisms must be efficient with respect to computing power and memory required. Similarly, they must scale well to scenarios that involve hundreds of devices and adapt to different communication patterns. For extremely constrained devices or when modification of device configuration is not possible, the use of an edge node or a digital twin for security adaptation should be considered in order to ensure secure integration with data consumer applications. Finally, we also need to ensure some typical security requirements. Perfect forward secrecy stipulates that compromise of a session secret shall not affect

the security of any previous or future sessions. Furthermore, compromise of any device and a master secret stored on the device should not affect the security of the system as a whole and the security of other devices. The system design should also support a change of cryptographic mechanisms, providing the ability to withstand new and emerging threats, such as quantum computing.

One of the critical challenges when implementing federated IoT solutions consists of bootstrapping and maintaining the system's security. To ensure the confidentiality and integrity of communication channels between IoT devices, a secure and authenticated key management mechanism must be implemented. Such a key management mechanism needs to fulfill several specific requirements:

- 1) Federated operations: The mechanism shall be compatible with federated operations, where the exact trust relationships between federation members might not be known in advance of device initialization. Therefore, there might be a need for a device to be re-authorized for operation within the specific federated environment.
- 2) Resilience and fault tolerance: The mechanism should function also in adversary environment, where some of static or cloud infrastructure is not directly accessible from an IoT device.
- 3) Support for constrained devices: The part of the key management mechanisms executed at the end-devices should be computationally efficient with respect to required computing power and memory.
- 4) Scalability: the mechanism needs to scale well to scenarios involving potentially hundreds of devices and adapt to different communication patterns, including both fully distributed scenarios and edge scenarios where end-devices communicate to a gateway connected to a backbone network.
- 5) Perfect forward secrecy: compromise of a session secret does not affect the security of any previous and future sessions
- 6) Robustness against compromise of individual devices: compromise of any device and of a master secret stored in the device should not affect the security of a system as a whole and security of other devices. This implies in particular that any potential key generation and device authentication authority needs to be implemented using a threshold-based approach.
- 7) Cryptographic agility: The system should support the change of cryptographic mechanisms, providing the ability to withstand new and emerging threats, such as quantum computing.
- 8) Increased security guarantees for key material: none of the federated organizations is able to obtain the cryptosystem master key.

V. DL-MOT: DISTRIBUTED LEDGER IMPLEMENTATION OF THE MODIFIED OKAMOTO-TANAKA PROTOCOL

To meet the challenges defined in Section III, we propose a novel key management solution for IoT devices that integrates

with a permissioned distributed ledger. The integration of the distributed ledger is a novel element that provides increased robustness against attacks on key generation and authentication authority.

In an IoT system, there are substantial differences between the computational capabilities of various devices. Therefore, our design aims at optimizing computational overhead induced on constrained IoT devices in exchange for much higher overhead on the edge nodes side, that are significantly more powerful.

The proposed solution is based on the Okamoto-Tanaka identity-based key management protocol, initially proposed in [2] and further extended in [3] and [4]. We further modify the protocol by implementing a distributed key generation authority based on a distributed ledger. Integration of a distributed ledger into identity-based cryptographic solutions can be seen as a more general and reusable security pattern; its applications in the context of privacy protection have been discussed in [5].

Since the concept of identity-based public-key cryptography was introduced in [6], many identity-based authenticated key exchange protocols have been proposed [7]–[9]. Most of the proposed protocols rely on elliptic curve pairings that are computationally very expensive and hard to implement in constrained devices. In the context of an IoT, a one-round ID-based key exchange with forward secrecy over the Rivest-Shamir-Adelman algorithm (RSA) group is a much more compelling choice. Moreover, although in data-centric federated systems, attribute- or identity-based encryption can be used to enable an efficient and effective enforcement of access control policies through data encryption, there is an inherent problem with pairing-based cryptography: There is no way to perform pairing operations (to generate private keys) in a decentralized and accountable manner. Therefore, it is difficult or impossible to maintain the principles of zero-trust architecture in the system.

When it is possible to securely store key material on an IoT device, e.g. using a Trusted Processing Module (TPM), we propose using *dl-mOT*, an enhanced version of the modified Okamoto-Tanaka (mOT) protocol [3]. The mOT protocol enables two parties to use their identities to establish their common secret keys without sending and verifying public key certificates. We further enhance the mOT protocol by integrating it with a distributed ledger. In this way, we address some inherent weaknesses related to the use of identity-based cryptography. In particular, we mitigate key, escrow, remove a single point of failure, and add strong accountability for key generation events.

The advantage of the dl-mOT protocol is its computational and communication efficiency and ease of implementation. The protocol can be implemented with short exponents, e.g., 160-bit exponents with a 1024 bit modulus. Moreover, operating over an RSA group enables the implementation of multiparty computation protocols, such as distributed exponentiation and multiparty generation of an RSA modulus.

Another essential feature of the dl-mOT protocol is the

support for perfect forward secrecy (PFS) [10] that was identified as one of the key security requirements in our federated environment. Perfect forward secrecy means that the leakage of a long-term key used by an entity does not compromise the security of session keys established by that entity. Moreover, dl-mOT allows spontaneous decentralized device-to-device interactions, without any request to the edge node or distributed ledger. Edge nodes are only involved in secure onboarding of the sensor into the federation. Device bootstrapping is a subprocess of onboarding and requires just enough information exchange between a device and the network to establish a secure channel.

A. Onboarding

In the mOT protocol, a Key Generation Center (KGC) chooses the RSA parameters $N = pq$, exponents d, e , and a random generator g of the cyclic subgroup of quadratic residues QR_N . The parameters p, q, d , and e are random and safe primes, that is, a prime p is safe iff $\frac{p-1}{2}$ is also a prime. KGC publishes values N, e, g , as well as two hash functions H and H' as a set of public parameters P . During the onboarding phase, every device receives from the KGC a unique identity id_D and a corresponding private key $S_D = H(id_D)^d \bmod N$. It is important to note that the mOT software requires the storage of secure private keys on the sensors, which is not always possible.

B. Operational phase — Point-to-point communication scenario

Communicating devices are already onboard, which means that they have their identities and secrets $S_A = H(id_A)^{d_i} \bmod N_i$. Now, a dynamic asynchronous secure channel may be established. In the key agreement phase, devices A and B choose ephemeral private exponents x and y , respectively. Bar notation denotes single domain keys, and hats distinguish multi-domain keys establishment. Each device can calculate

$$\begin{array}{ccc} A & \xrightarrow{\alpha = g^x S_A \bmod N} & B \\ A & \xleftarrow{\beta = g^y S_B \bmod N} & B \end{array}$$

Fig. 2. mOT key agreement

the mOT session key in the following way:

$$\bar{K}_A = (\beta^e / H(id_B))^{2x} \bmod N, \quad (1)$$

$$\bar{K}_B = (\alpha^e / H(id_A))^{2y} \bmod N. \quad (2)$$

Both values are equal since:

$$\begin{aligned} \bar{K}_A &= (\beta^e / H(id_B))^{2x} = \\ &= \left((g^y H(id_B)^d)^e / H(id_B) \right)^{2x} = \\ &= (g^{ey} H(id_B)^{ed} / H(id_B))^{2x} = \\ &= (g^{ey} H(id_B)^1 / H(id_B))^{2x} = g^{2xye} = \bar{K}. \end{aligned} \quad (3)$$

Analogically, $\bar{K}_B = \bar{K}$. The mOT session key K is established with a key derivation function H' :

$$K = H'(\bar{K}, id_A, id_B, \alpha, \beta). \quad (4)$$

C. Multi-domain KGC setting

In our setting, each IoT device belongs to an organization that operates its own security domain and the KGC. In a federated IoT environment, devices from different organizations, and thus belonging to different security domains, should be able to execute the key agreement protocol and communicate.

Each organization i operates its own KGC_i with public parameters P_i , as previously described, and secret key d_i , such that $e_i d_i = 1 \bmod \phi(N_i)$.

The device A belonging to the organization operating KGC_i receives during onboarding a secret $S_A = H(id_A)^{d_i} \bmod N_i$. The identity of the device consists of $H(id_A)$ and P_i . Similarly, the device B belonging to the organization that operates KGC_j has a secret $S_B = H(id_B)^{d_j} \bmod N_j$ with public parameters P_j . Consider

$$E = \text{lcm}(e_1, e_2) \quad (5)$$

$$\hat{g} = (g_i \bmod N_i, g_j \bmod N_j) \quad (6)$$

$$\hat{N}_i = (N_i^{E/e_i} \bmod N_i, 1 \bmod N_j) \quad (7)$$

$$\hat{N}_j = (1 \bmod N_i, N_j^{E/e_j} \bmod N_j) \quad (8)$$

Both communicating sensors compute a pair of values $\bmod N_i N_j$:

$$\hat{S}_A = (S_A \bmod N_i, 1 \bmod N_j) \quad (9)$$

$$\hat{S}_B = (1 \bmod N_i, S_B \bmod N_j) \quad (10)$$

respectively. Device A chooses an ephemeral random integer x and computes

$$\hat{X} = \hat{g}^x \bmod N_1 N_2 \quad (11)$$

and sends to B value

$$\hat{\alpha} = \hat{X} \hat{S}_A \bmod N_1 N_2. \quad (12)$$

The device B chooses a random secret y and sends to A the value:

$$\hat{\beta} = \hat{Y} \hat{S}_B \quad (13)$$

where

$$\hat{Y} = \hat{g}^y. \quad (14)$$

Finally, A computes the shared secret \hat{K} :

$$\begin{aligned} \hat{K} &= \left(\frac{\hat{\beta}^E}{\hat{B}} \right)^{2x} = \left(\frac{\hat{Y}^E \hat{S}_B^E}{\hat{B}} \right)^{2x} = \hat{g}^{2xyE} \left(\frac{\hat{S}_B^E}{\hat{B}} \right)^{2x} = \\ &= \hat{g}^{2xyE} \bmod N_1 N_2. \end{aligned} \quad (15)$$

The device B performs an analogous computation. Similarly as within a single organization, at the end, both devices make a hash of the shared secret and the identities of both parties:

$$K = H'(\hat{K}, id_A, id_B, \hat{\alpha}, \hat{\beta}). \quad (16)$$

The boot-strapping process (considered as a subprocess of onboarding) can be repeated during the lifetime of a device and requires direct communication to the edge node and identity registration in the distributed ledger.

D. Multiparty private exponentiation

In the scenarios presented, the KGCs are the only parties that own the master secrets of the cryptosystems. When onboarding an IoT device within a domain, an exponentiation using a secret exponent known to the KGC is required. With the help of a bit-decomposition [11], we have constructed a constant-round protocol for multiparty private exponentiation where several KGCs participate in secret key generation (since attaching a new device implies private key generation which is single integer exponentiation). Multiparty exponentiation in the IoT device setup phase eliminates the single point of storing master secrets and supports zero-trust architecture principles. We assume that federated organizations share the domain master secret and perform their part of the exponentiation process to achieve strong accountability of the onboarding process and to weaken requirements for trust into edge nodes. The bit-decomposition private exponentiation is computationally expensive and a significant amount of research has been devoted to improve its performance [12], [13]. However, in our scenario, it is performed by relatively powerful KGC nodes and only during the onboarding of an IoT device. The classical approach to distributed modular exponentiation on arithmetic circuits relies on bit-decomposition, which was first proposed in [11]. To achieve an exponentiation protocol with a public base b and secret exponent e , the authors of [11] propose a method for securely bit-decomposing the inputs (bd) secretly shared l -bit exponent e into bits, using the so-called fan-in multiplications. We assume that there exists a function:

$$[e]_{bits}bd([e]) \quad (17)$$

that receives a secret shared input $[e]$ and returns its shared bit-decomposition $[e]_{bits}$, so that it produces l shares:

$$([a_0], [a_1], \dots, [a_{l-1}]) \quad (18)$$

where $a_i \in \{0, 1\}$. The final result of the exponentiation is then the product of the decomposed multiplications:

$$\prod_{i=0}^{l-1} ([a_i]b^{2^i} + [1] - [a_i]). \quad (19)$$

The identity of an IoT device is public, while its private key is generated using KGC secrets and multiparty private exponentiation. The objective is to improve the auditability of the onboarding process (or bootstrapping, understood as a subprocess of onboarding) and make it impossible for a single compromised or malicious KGC node to add devices to the domain. This was achieved through integration of bit-decomposition with a distributed ledger, ensuring that every decomposed multiplication, performed in support of private exponentiation, left a trail on the distributed ledger. It means that federated organizations share their KGC secrets, and

each execution of multiparty exponentiation is registered in distributed ledger so that it is known among federation which organizations took part in the sensors onboarding process.

E. Use of trusted execution environment

In our initial proof-of-concept KGCs master-secrets escrow problem was solved by encapsulation into Intel Software Guard Extensions (SGX) enclave. Intel SGX is an implementation of the concept of a trusted execution environment in Intel CPUs that allows users to define secure enclaves. Secure enclaves are regions of memory whose content is protected and unable to be read or saved by any process outside the enclave itself. Combining chaincode with SGX makes it possible to run applications that demand privacy, such as distributed exponentiation combiners, which was first proposed in [14]. In our initial design, a KGC enclosed in a secure enclave acted as an oracle for distributed ledger chaincode, and there was no risk of keys compromise, but still the enclaves where only parties where keys were stored and enclave availability was necessary. But only the master-secrets distribution and multiparty exponentiation weakened the nodes availability requirement sufficiently, so that zero-trust architecture principles can be satisfied.

Intel SGX comes with two advantages. The first is that enclaves provide confidentiality and integrity of any code and data inside the enclave. The second advantage of enclaves is a mechanism that allows remote parties to verify the identity of the enclaves via a process called attestation. Intel SGX provides applications with the ability to create areas in memory called enclaves that provide confidentiality and integrity for the code/data running inside it, even in the presence of buggy or malicious privileged software or actor. Attestation is a process that allows remote parties to verify the identity of a piece of software. The remote party can use Intel's SGX attestation hosted service to verify the quote before provisioning any secrets into the enclave. Intel SGX also supports cryptographic binding of secrets to an enclave, the so-called *sealing*. Any enclave can use a hardware-generated key, called a sealed key, to encrypt the secrets with the key. The key is available only to the owner enclave running on the same platform. This is crucial for key material management.

VI. PERFORMANCE DISCUSSION

An important practical question is the prediction of the performance of the dl-mOT in various configurations of a federated IoT environment. The main aspects of performance analysis are related to the overheads introduced by onboarding, key management, and recording of transactions in the distributed ledger.

A. Onboarding overhead

dl-mOT protocol requires a secure channel or controlled environment for the onboarding phase. During device onboarding, an RSA group element, that is, a 1024-bit private key, and a hash result, that is, a 256-bit value, must be transmitted. These values (in total 160 bytes) must be stored securely on

the sensor device. There is no computational overhead for the sensor during the onboarding phase. However, there is a computational cost induced by a device onboarding on the KGC side. In the single-domain scenario, this computational overhead comprises one exponentiation and two hash operations. In a distributed multiparty scenario, the computational cost is significant, as described in V-D, but all computations occur on nodes without significant computational restrictions.

B. Key management overhead

The communication overhead of the operational phase of dl-mOT is as in the original Diffie-Hellman protocol and requires two messages with a single RSA group element. After these messages have been exchanged, the symmetric key with full Perfect Forward Secrecy against active attackers is established and remains confidential to all parties, including the federated organization and KGC. Furthermore, due to the identity-based properties of mOT, there is no communication overhead related to certificate transmission that is typical for the authenticated Diffie-Hellman (DH) key exchange protocol. The computational cost of key establishment using the dl-mOT protocol, when used with short exponents, is very low. dl-mOT is more efficient than any RSA-based key agreement protocol and any authenticated DH protocol over Z_p^* for large prime and much more efficient than any of the ID-based protocols based on elliptic curve pairings. The dl-mOT protocol is less efficient than protocols using elliptic curves, but only for keys longer than 2048 bits.

C. Distributed ledger overhead

In the dl-mOT scenario considered, a distributed ledger is used to generate identity-based keys for IoT devices, which can be further used for secure communication with the distributed ledger nodes and the IoT peer nodes. Our target environment consists of a distributed ledger based on Hyperledger Fabric. Furthermore, we assume the use of a policy that specifies that any two organizations are sufficient to sign the transaction. Our prediction is that more nodes result in shorter delay times; that is, the median delay related to the generation of private keys and the recording of public key parameters in the distributed ledger is shorter for more nodes.

The performance of the dl-mOT solution directly depends on the performance and scalability of the distributed ledger, and in the case of our design on Hyperledger Fabric performance, which acts as a trustworthy storage for validated and reliable data.

When writing data to the ledger, the number of requests (or transactions) that can be processed increases with the number of nodes that participate in the ledger from each organization. However, the transaction processing time will also increase as the number of federated organizations that need to accept (sign) a transaction increases. To counteract the performance penalty introduced with the increasing number of federated organizations, an appropriate endorsement policy can be used in Hyperledger Fabric. The endorsement policy determines how many organizations are needed to approve the transaction.

If the endorsement policy requires fewer organizations to accept a transaction, the ledger performance and, therefore, the performance of dl-mOT will increase.

When reading data from a ledger, no consensus among organizations is required, and therefore, the performance depends only on the number of available ledger nodes; i.e., the more nodes are available, the higher performance of the ledger.

VII. RELATED WORK

The interoperability aspects of civilian IoT platforms have been discussed in several earlier papers. A high-level architecture for semantic and syntactic interoperability between cloud-based IoT platforms has been proposed in [15]. A multiauthority access control framework for federated cloud IoT platforms has been presented [16]. This earlier work differs significantly from our contribution and is not directly applicable to military and civil-military scenarios. First, we consider the federation and interoperability of IoT systems in multiple layers. In HADR and military operations, we cannot rely on universal availability of cloud connectivity, but we also target disadvantaged and adversary environments, which may rely on locally deployed IoT enclaves and edge nodes interconnected via private and proprietary links. Moreover, most of the earlier work does not consider explicitly resilience and survivability aspects - the distribution is interpreted rather in context of preserving control, than providing reliability and fault tolerance. In our solution, we focus on ensuring that during the operational phase, i.e. after onboarding, the IoT devices and end users can be authenticated and authorized by any other node belonging to federation, thus mitigating some of the risks related to defects, environmental faults, and adversarial activity.

Several ongoing activities focus on the development of secure and interoperable onboarding and configuration management mechanisms for IoT devices [17], [18]. Our proposed key management protocols are aligned with the frameworks presented in [19] and [20].

The use of blockchains in the context of IoT applications was a topic of several recent surveys, for example, [21]–[23]. However, in the context of our solution, the most relevant work is related to key and access management, as well as the performance evaluation of blockchain-based applications.

The use of blockchain to implement a key management approach in a federated environment with smart vehicles was investigated in [24]. A pairwise key management scheme based on a transitory system-wide secret has been discussed in [25]. The use of randomness obtained from IoT devices for the generation of cryptographic material has been mainly investigated in the context of taking advantage of Physical Unclonable Functions (PUF) [26], [27]. An excellent study of various sources of secure PUFs is provided in [28].

The performance of blockchain, when used to store data obtained from IoT devices, has been studied in [29]. Similarly, the performance of Solidity smart contracts implemented in Ethereum for the management of access to IoT devices is investigated in [30]. This investigation was further extended

in [31], where a comparison of the performance of blockchain-based access management with an alternative CoAP-based solution is presented. The applicability of the Ethereum smart contract for access control in the IoT is also discussed in [32].

We also chose to provide identity-based authenticated key exchange in our device network as a solution for environments where the operation of traditional public key infrastructure (including its various phases of a life cycle, such as certificates dissemination and revocation) is too costly in terms of bandwidth, on-device storage, and computation. Since it is possible to store additional key material in an IoT device, we propose using a modified Okamoto-Tanaka (OT) protocol [2] adapted to the decentralized setting. Our solution is based on [3], which introduced a protocol called mOT. The OT protocol enables two parties to use their identities to establish their common secret keys without sending and verifying public key certificates.

As noted in [3] in terms of computational effort, the OT protocol is more efficient than any RSA-based key agreement protocol and any authenticated Diffie-Hellman protocol over Z_p^* for large prime. OT protocol is incomparably more efficient than any of the ID-based protocols based on elliptic curve pairings. OT is pretty close in terms of computational efficiency to the certificate-based MQV protocol, which runs over elliptic curves, while mOT runs over RSA composites. The cost of MQV on-line is slightly larger than that of OT, but OT requires a setup phase. For moderate security parameters (1024-bit RSA), OT has a computational advantage over MQV, but for larger modulus (above 2000 bits), the advantage is on the elliptic-curve side.

Current key management protocols [15], [16] do not offer such a combination of properties.

We aim to provide a two-message identity-based key exchange, maintaining low computational and communication overhead, achieving the PFS property, and allowing sensors to communicate without interaction with edge nodes. Since the federated IoT environment includes trusted edge nodes, our protocol also allows the implementation of a multiauthority case in which IoT devices from two separate domains (connected to a single edge node) can establish a secret key. In such a case, each edge node plays the role of an independent key generation center (since it belongs to a trusted network or at least a semi-trusted network).

OT framework can also be used as an enabler to implement the Self-Sovereign Identities (SSI). The objective of SSI is to provide subjects with complete control of their own digital identities [33]. There are two standard approaches to SSI, namely, Decentralized Identifiers (DID) and Verifiable Credentials (VC) [34] - both of them rely on public-key cryptography. To control a specific DID, a subject just has to own a private key associated with a public key in the DID document. Although DID focuses on cryptographic identification, VC provides authenticated and privacy-aware attribute disclosure. The mentioned SSI approaches mean that devices need to be able to execute encryption algorithms based on asymmetric keys, which can be challenging in devices with

limited processing and energy resources, and cope with the communication overhead of transmitting metadata, such as DID and VC. Furthermore, in the IoT world, low communication overhead plays a vital role, as wireless communication protocols often offer relatively small packet sizes. In particular, low-energy protocols such as Long Range Radio (LoRa) and Bluetooth Low Energy (BLE) have maximum packet sizes of 222 and 244 bytes, respectively, and the mentioned approaches require at least 512 bytes or more, which means that additional mechanisms are required, for example, for message partitioning and lost packet control.

Therefore, although SSI may improve security and privacy protection for IoT devices, new, more efficient cryptographic methods need to be identified to ensure its successful deployment in the IoT environment. In particular, power and communication constraints of small devices in large distributed networks suggest the benefits of using a one-round authenticated key exchange (AKE) protocol in the IoT environment. Our proposed approach revisits the classic Okamoto-Tanaka protocol [3] that realizes single-round key agreement and exchange with perfect forward secrecy, using a single group element per message and maintaining low computational and communication overhead, avoiding the need to distribute large public key certificates.

VIII. CONCLUSIONS AND FUTURE WORK

We have presented dl-mOT, a novel key management solution for federated IoT environments. Our solution integrates an efficient identity-based mOT protocol with a distributed ledger. It relies on a distributed ledger to establish an anchor of trust between federation members.

Our work focused only on a subset of challenges related to the implementation of an operational federated IoT environment. In particular, we have not discussed how the resources available in the federation can be discovered or how to achieve secure time synchronization. We plan to investigate the possible integration of our key management approach with other open frameworks, such as Tesseract E4¹, to implement a solution that can be validated in practice. Moreover, public-key algorithms that we use in our current implementation of the distributed ledger are susceptible to quantum computing attacks. Although it is possible to modify Hyperledger Fabric to use customized public-key cryptography, the integration of quantum-safe algorithms into our solution is left for future work.

Abstract—Increasing amount of devices in our daily life are equipped with sensors that transfer information to a cloud solution where the data is finally analysed. By improving the data intelligence on the edge, the data transfer can be reduced, which not only saves bandwidth and thus reduces energy consumption, but also leads to increased privacy protection. In this paper, we propose a privacy-friendly water leakage detection approach for various kind of water meters (optical and digital) performed on a very constrained, wireless devices.

I. INTRODUCTION

THE amount of IoT devices on our homes increases for several years already. While most of them promise easier living and higher comfort, the actual applications are often neither environment nor privacy friendly. In this paper, we introduce a water leakage detection algorithm that takes both into account by running analytics directly on a long-living, energy-saving device in a privacy-preserving manner. For this, we apply a very lightweight data compression at the edge that enables leakage detection and significantly reduces the bandwidth needed to transfer the data from the edge to a central cloud device. By this, public as well as private buildings all over the world can profit from a solution that is easy to install and that reduces the waste of fresh water. This work was performed in close collaboration between Sirris and Shayp, who are leading specialists in water efficiency and monitoring, such that the evaluation of the approach was performed on real-world data.

The remainder of this paper is organized as follows: We will first provide an overview of current solutions in section II, before describing the technical setup in section III. In section IV we will explain in detail our solution for an on-the-edge leakage detection that respects privacy aspects. Its evaluation will be discussed in V-1 on both, artificial and real-world data before concluding in section VI.

II. RELATED WORK

Recently, several solutions on leakage detection by smart meters were suggested. The common approach entails a connected device at water meter level, which sends pulse data to a cloud back-end for further collection and analysis. Hence, the leakage detection is executed only in the cloud [1], [2], [3]. In [1], a solution for remote monitoring of water consumption and leakage detection is discussed. The setup consists of a water meter is connected to an Arduino micro-controller that

sends the data to a Raspberry Pi gateway. Only from there, the data is hourly transferred to a cloud back-end that the end user can consult. From a hardware point of view, this solution is error prone as the two-fold messaging can lead to data loss and increased latency. Further, a wall socket has to be available in the vicinity of the water meter which makes it hard to generalise the solution.

The leakage detection suggested by the authors is performed at cloud level and consists of the detection of four different scenarios: (i) a negative consumption trend, which indicates a problem with the data transfer; (ii) a continuous water flow over 24 hours, which indicates a strong leakage; (iii) a coincidence with the last two measurements, which also indicates a leakage; and finally (iv) a significant deviation from the historical consumption. However, this solution suffers from a cold-start problem for detecting leakages reliably. Further, some of the rules are only meaningful in residential buildings, as e.g. hospitals can indeed show a significant hourly water consumption throughout an entire day.

Similarly, in [3], a wireless open source middleware was developed. Also here, the data is collected locally via an edge gateway but the leakage detection is only performed at cloud level. The empiric algorithm looks for the absence of water consumption during a specific interval across the day that deviates from historical consumption. With this rather rough estimate, it is possible to detect leakages in residential buildings, but it will probably fail in other types of buildings like hospitals, which were not investigated in the publication.

The solution presented in [4] makes use of wireless, battery-driven vibration sensors, instead of directly measuring the water consumption. Increasing vibrations in a pump indicate a pipe burst in the network. The proposed system uses a lightweight edge anomaly detection algorithm based on compression rates. The leakage detection splits the data x from the stream into two equally long sequences of length w_{stream} , e.g. at time t , the data sequences consist of $[x(t - 2w_{stream}, \dots, x(t - w_{stream}))]$ and $[x(t - w_{stream}, \dots, x(w_{stream}))]$. For both, they apply miniLZO compression [5]. When the compression rate changes significantly from one window to the next, they assume that a leakage occurred. By using lossless compression in their lab-based test rig, the authors could reduce communication by 90% compared to periodical messaging which leads to an increasing battery lifetime. While this algorithm offers very

suitable performance for big pipes and big bursts, it does not detect small leakages that are most common in residential households or schools [6]. Further, the authors do not consider privacy or security aspects critical when reducing the amount of messages sent. In case of a residential building, the number of messages being sent can already leak private information on the consumption pattern of this particular household. Lack of messages poses a more critical security thread as one can assume people are away.

III. TECHNICAL SETUP

Shayp's solution for monitoring water consumption and detecting anomalies in water usage consists of a wireless water meter reading device. It has long-range, battery-powered data logger compatible with all pulse-ready meters, specifically designed to withstand water immersion, harsh conditions and ensure an ideal performance in deep indoor situations. This is enabled using a Narrowband IoT (NB-IoT) connection to a back-end cloud. In addition of being low-power, this radio standard also offers a very good connectivity, allowing communication inside deep basements where water meters are usually to be found. Coupled to the periodic sending schema as explained below and thanks to the low-power micro-controller of the device, NB-IoT allows to meet a 10-year battery lifetime.

Through a pulse emitter placed on the water meter, the water consumption takes the form of pulses, each of which, depending on the water meter, corresponds to a certain amount of water (typically 1L or 10L) consumed per defined time window. A sensor connected to the pulse emitter detects these pulses. The data logger collects these pulses and sends this consumption data to a cloud back-end where water consumption analysis and leak detection take place.

1) *Periodic sending schema*: Shayp's device aggregates hourly consumption data in periods of 30 s and then sends a message to the cloud. Although the message length is 512 bytes, the actual used space is about 152 bytes (32 bytes for payload and 120 bytes for 120 data points). This results in 360 unused bytes in a message.

2) *Cloud solution for leakage detection*: Currently, Shayp supports leakage detection at the cloud level. For residential buildings this takes between 1-3 hours, while corporate buildings vary from 3 up to 24 hours. This is due to the complex water consumption pattern for buildings such as schools and hospitals, where water usage is constant. The lack of on-device analytics and the hourly message pattern prevent any anomaly detection in less than an hour. The data made available for this research consists of the number of consumption pulses and the estimated leakage size in pulses per 30 seconds. Further, information about the type of building, e.g. a public building or a private household, is provided.

With the method described in this publication, we improve the detection time even further (<1h for residential, <3h for corporate) by applying a lightweight analysis executed on the device at near real-time. This should however not hamper the lifetime of the battery, which ideally could even be extended

to up to 16 years, which is the expected life time of water meters.

IV. LEAKAGE DETECTION

In this work, we introduce a leakage detection algorithm operating on a very constrained edge device based on data compression. The algorithm has to fulfill the following requirements in order to be applicable in real-world scenarios:

- 1) Minimal power consumption in order to guarantee at least 16 years of battery lifetime.
- 2) Fast leakage detection such that a warning can be sent with short delay (<1h for residential, <3h for corporate buildings).
- 3) Preserve the privacy of the underlying data

Interestingly, the three points above contradict each other: i.e. in order to increase the battery lifetime, the device should send as few messages as possible. But with less messages, it is harder to detect leakages early enough. One solution could be to only send messages once water consumption was measured and a risk of leakage was detected. Though, under this assumption, privacy and security in households or corporate buildings are at risk, as in this case an attacker can easily derive consumption patterns by profiling the message sending patterns.

In order to deal with these contradicting requirements, we developed a leakage risk assessment at the edge based on the compression of the consumption data. This approach is combined with a leakage-sensitive random messaging schema in order to ensure privacy preservation.

1) *Data Consumption Compression*: Per message, 480 bytes of data can be sent. In order to use this space as efficiently as possible, while not losing information, we apply a lightweight lossless sequential compression. We either use:

- 1) Fibonacci codes [7] on the unprocessed sequence, as it has proven to be very robust and efficient [8].
- 2) A combination of run-length encoding (RLE) [9] and Fibonacci codes where in a first step we apply RLE and only after Fibonacci codes.

For each device, more than 200.000 data points were used. One can see that the overall performance of the combined compression (RLE + Fibonacci) leads to better results, hence higher compression rates, for most devices (Fig. IV-1). Nevertheless, two extreme outliers can easily be detected, i.e. the two devices at the bottom rows, namely *NE83A580* and *N389F2E8*. By analysing the statistics of the consumption and leakage pulses given in Table I, it is possible to explain why the compression is so different in these cases: For (*N389F2E8*), the overall consumption is high such that the raw Fibonacci encoding is less effective as the strings encoding the integers are becoming longer. The mean leakage pulses for this device is NaN, as no leakage was detected by the leakage detection algorithm that is used in production. For *NE83A580*, the difference in compression between the sole Fibonacci encoding and combined compression indicates that the consumption values are fluctuating a lot such that the hardly any longer periods of

Fig. 1. Compression ratio for all devices for the two different compression approaches.

TABLE I

the same (or no) consumption are given in the data. This gives a hint for (continuous) leakage in the data as also indicated by the high number of mean leakage pulses given in Table I. We will in more detail discuss the results per device in subsection V-2.

2) *Anomaly detection*: In most production-ready solutions, leakages in water supply are detected at cloud level [3], [1] where sufficient computational resources and historical consumption data are available. The approach we present here aims at estimating the risk of a leakage at edge level as early as possible. For this, we use the specific consumption patterns of a leaking asset. In case of a leakage, the consumption pulses $c(t)$ of a specific strength occur very regularly - the consumption of a leakage. Mathematically speaking, we define $\delta = |F(c(t_m))| |RLF(c(t_m))|^{-1}$, where $|F(c(t_m))|$ is the length of the Fibonacci code of the consumption sequence $c(t_m)$ during a time window t_m , and $|RLF(c(t_m))|$ is the length of the combined compression (RLE + Fibonacci encoding) of the same sequence. Based on δ , we define the binary variable $L(c(t_m))$ indicating whether a leakage was detected in sequence $c(t_m)$ as being 1 for $\delta > \epsilon$ and 0 otherwise, where ϵ , the leakage threshold, is a free parameter of the model. This inflation given by a high δ -value can be used for leakage detection. In the case of a comparably strong leakage, the combination of RLE and Fibonacci codes is about twice as long as the sequences encoded by Fibonacci codes.

The overall idea is similar to the one in [4] but while they compare the compression in two consecutive windows, we

compare the compression of the data within the same window with two different compression algorithms. This does not only reduce the possible alarm delay as our window can be shorter, it also takes into account the specific consumption pattern in case of a leakage.

3) *Random sending schema*: The sending schema is crucial in order to fulfill the requirements listed in the beginning of Section IV. When sending as few messages as possible the battery lifetime is strongly extended. The simplest solution is thus sending a message once the message space of 480 bytes is filled or a specific anomaly is detected. However, water consumption in residential buildings, similar to electricity consumption [10], is highly privacy sensitive. Even if we assume that the messages are properly and strongly encrypted, an attacker can deduce information on the consumption pattern and the presence of inhabitants by only counting the number of messages per time interval. Though a schema in which messages are sent in regular intervals prevents this possible privacy breach, it should be avoided: In order to increase the battery lifetime, the regular sending interval should be as large as possible but this leads to a significantly delayed leakage detection. For this reason, we suggest a privacy-preserving sending schema based on random timing as sketched, described in detail below. The algorithm takes the following variables as input:

- T : the expectation time for sending a message,
- ϵ : The leakage threshold as defined above
- ω : the look-back window on which to calculate the leakage risk, e.g. 2 hours
- n_{\max} : the maximal warnings to send per detected leakage
- R : the *force* radius
- ζ : a constant that defines noise in the sending pattern.
- b : The maximal sending time, e.g. 24 hours.

In a first step, we draw a random sending time interval t_i for $i \in \mathbb{N}_0$ from a truncated exponential distribution $f_T(t|\lambda, b)$ for $0 < t \leq b$ where $\lambda = \frac{1}{T} > 0$ and save it to the list of *random times*. We use a truncated function in order to ensure that messages are sent within time b (e.g. 24h). Every time a new sensor measurement is available (in our case every 30s), we run the following steps:

- 1) Calculate the encoding values of the sequence in the look-back window $F(c(\tau_j^i))$ and $RLF(c(\tau_j^i))$, where τ_j^i is the time of the j -th measurement in the i -th message.
- 2) If $\tau_j^i = t_i$, hence the time when the message should be sent, send the message with content (leakage risk, encoded sequence) and then calculate the average of the last R sending times from the *random times* list. We use this average sending time T^* in order to calculate the next random sending time t_{i+1} drawn from the distribution

$$f(t_{i+1}|\lambda, b) = \frac{\frac{1}{\lambda} \exp\left(-\frac{t}{\lambda}\right)}{1 - \exp\left(-\frac{b}{\lambda}\right)} \text{ with } \lambda = T + K \frac{T - T^*}{T^*}. \quad (1)$$

We can see this similarly to a canonical description of a confined ideal gas in an external potential [11], where

T is the equilibrium value and the potential is given by the earlier sending of a message due to a detected leakage. The system is pushed back to equilibrium with the artificial temperature K . We then add the calculated next sending time t_{i+1} to the list of random sending times and set $i = i + 1$ and $j = 0$.

- 3) Otherwise, if $\tau_j^i \neq t_i$, calculate δ from $F(c(\tau_j^i))$ and $RLF(c(\tau_j^i))$. In case $\delta > \epsilon$, hence $L(c(t_m)) = 1$ and the number of sent warnings $n < n_{\max}$, draw a normally distributed random number $r = \mathcal{N}(\zeta, 0.2\zeta)$. In case $\tau_j^i < (n + 1)r$, send the message. We use this in order to add an additional level of randomness to the sending pattern as well as to prevent too many warnings for the same detected and continuous leakage. The factor $n + 1$ gives here an additional damping. Just as above, calculate the new random sending time as given in eq. (1) and add it to the list of sending times.
- 4) In all other cases, wait for the next measurement.

In the next section, we will evaluate our approach on artificial as well as real-world data. We will judge our method by the accuracy of the detected leakages, the number of sent messages, which indicates the battery consumption on the device and will further perform an analysis on the distribution of sending times.

V. EVALUATION

In this section, we will evaluate the proposed leakage detection and messaging algorithm on the edge with respect to the leakage detection accuracy and privacy preservation. In order to perform the analysis of the leakage detection performance, we will not only use the real-world consumption data but also artificially created data as in that case the actual starting point of the leakage is exactly known and we can perform exact statistics on leakage detection time. For privacy evaluation, we will use the real-world data only.

1) *Artificial data*: In order to create the artificial data, we extract the daily consumption per weekday from the data without leakages. For this, we first manually remove the consumption pulses related to leakages from the time series data from device *N96A1423*, which is a school building. Hence, the general consumption patterns for weekdays are very different from those on weekends but also the overall consumption per day is quite irregular. For each day of one year of artificial data, we select every 30 seconds randomly a consumption value from the same time and day of week from the historical consumption. We add some normally distributed noise from $r = \mathcal{N}(0, 0.2)$ and round the resulting value to an integer. In this way, the overall consumption pattern per day of the week is kept. Based on this consumption without leakages, we add pulses of leakages of different severity (S), different strength (s) and different length (Δt) to create the final artificial consumption. The severity S defines how strong the leakage is, i.e. if $S = n > 1$ at every $1/n$ -th pulse, s pulses are added to the normal consumption for the following measurement during Δt .

Fig. 2. Time until detection for different pulse severity and strength calculated on artificial data.

Fig. 3. Accuracy (top) and F1-score (bottom) of the leakage detection on the edge for all devices compared to the cloud solution. The color of the bars indicates the artificial temperature K .

With an overall accuracy of more than 93% and a F1-score of 90% over all samples, our edge algorithm performs very well even on 30 s data granularity. Further, the detection time (Fig. 2) on the edge ranges from less than 30 min from leakages with $S = 2$ to about one hour for leakages with lower severity. This fulfills the requirements of leakage detection of 1-3 hours as defined above.

2) *Real-world data*: For the evaluation of the leakage detection performance on the real-world data, we use the cloud-based leakage detection as ground truth. We expect our accuracy to be slightly lower, as we might detect leakages earlier. Hence, the ground truth does not yet indicate a leakage

Fig. 4. Kullback-Leibler divergence for all devices given by the different colors. The size of the markers indicates the artificial temperature K .

though it has already started. In Fig. 3, we show the accuracy and the F1-score. For 80% of devices, the accuracy is higher than 0.8, while for one of the remaining devices (*NE83A580*), the ground truth data is missing. Further, the F1-score, the ratio of correctly detected instances of leakages, are similarly high as the accuracy. Note that the devices with a F1-score of zero are those devices that have (quasi) no leakages (c.f. Table I). For both devices (*NEC592E3*, *NEEB3006*), we only see a leakage in the first 5 minutes of the full data set which rather indicates a misclassification due to a cold start problem. The devices with lower F1-score, namely *N08FCFD4* and *NF112C6C*, are a school and a sports facility, respectively. By analysing the data in more detail, the following factors lead to a reduced accuracy and F1-score: i.e. first, for *N08FCFD4*, the average leakage is at 0.049 pulses, hence every twentieth pulse indicates a leakage. With the current threshold, this leakage is too weak to be detected reliably. However, for such a weak leakage, which is probably a dripping water tap, the timely detection is less crucial. For the latter, device *NF112C6C*, we can see that at the time when the actual leakage begins, the leakage detection at the edge triggers a warning almost 24 hours earlier than the cloud algorithm, which explains the reduced and in this case misleading F1-score.

Additionally, in order to ensure that it is not possible to extract privacy-sensitive information from the number of message that are sent, we calculate the Kullback-Leibler (KL) divergence $D_{KL}(P||Q)$ [12]. We chose the KL divergence as it is usually used in adversarial Neyman–Pearson tests for identifying distribution differences [13]. For P , we derive the discrete distribution from a sample of random variables drawn from the truncated exponential distribution as given in equation (1) derived from as many samples as messages were sent (for each device and temperature) with $T^* = T$. Q is the discrete distribution derived from the random sending times when applying our algorithm. We use it as a measure of information gained when approximating the truncated exponential distribution P with the out-of-equilibrium distribution Q that enables early leakage warnings.

In Fig. 4 the divergence is shown against the number of send messages for all devices (color) and for different artificial temperatures (size). There is no clear correlation between the artificial temperature and the KL-divergence and hence does not change anything in the information that can be extracted from the distribution. On the contrary, the KL is clearly related to the number of messages being sent. Hence, over long run times of the algorithm, the KL divergence decreases such that no private information can be extracted from the distribution of messages sending times.

VI. CONCLUSION AND NEXT STEPS

We introduced an on-the-edge water leakage detection approach that addresses three contradicting requirements: (i) an overall reduced number of messages in order to extend the device’s battery lifetime, (ii) early-alarmed in case of a detected leakage on the edge, and (iii) a privacy-ensuring message sending schema. The approach is based on lightweight

compression performed on the edge in order to timely detect leakages and on random messaging for privacy protection. We evaluated it against artificial as well as against real-world data from devices installed in different types of buildings, such as private households and public buildings. In both cases, we observe a high leakage detection accuracy as well as a timely detection of the leakage, fulfilling the industrial requirements.

As next steps, we plan to further improve our approach by considering building-type specific leakage detection. Additionally, we will analyse our approach on pipe bursts, which show a very specific pattern. From our initial results, we see already that we receive reliable warnings also for those. Further, we will perform an on-the-edge battery lifetime study in order to give a realistic estimation when applying our approach in production.

Abstract—In the context of IoT (Internet of Things), Device Management (DM), i.e., remote administration of IoT devices, becomes essential to keep them connected, updated and secure, thus increasing their lifespan through firmware and configuration updates and security patches. Legacy DM solutions are adequate when dealing with home devices (such as Television set-top boxes) but need to be extended to adapt to new IoT requirements. Indeed, their manual operation by system administrators requires advanced knowledge and skills. Further, the static DM platform — a component above IoT platforms that offers advanced features such as campaign updates / massive operation management — is unable to scale and adapt to IoT dynamicity. To cope with this, this work, performed in an industrial context at Orange, proposes a self-adaptive architecture with runtime horizontal scaling of DM servers, with an autonomic Auto-Scaling Manager, integrating in the loop constraint programming for decision-making, validated with a meaningful industrial use-case.

I. INTRODUCTION

WITH Device Management (DM), an operator or a service provider is able to remotely manage connected devices deployed at the customer’s premises. The main DM features are [1]: (i) Provisioning: which targets device initial and in-life configuration, (ii) Monitoring: which allows detecting anomalies such as malfunctioning devices using log traces and data collection, (iii) Maintenance: which allows firmware and configuration updates, and (iv) Troubleshooting: which is remote actions to fix service and device errors.

Currently, DM solutions are widely deployed and mainly used for Smart Home service management. However, IoT platforms with DM features and standards have been developed to incorporate DM features such as firmware and configuration update, for two reasons : one is to accommodate the expansion of the Internet of Things (IoT) that offers a wide range of new smart applications [2] (e.g., Smart City, Smart Building, Smart Industry), the other is for environmental reasons of sustainability (e.g., device reuse, and lifespan enhancement).

While connectivity and cloud analytics are considered essential aspects of an IoT architecture, one of the most critical is the management of IoT [3]. This will help register connected devices, bring them online efficiently, ensure that they work properly and securely after being deployed, and send configuration or firmware updates remotely. However, with a very large number of IoT devices distributed across one or more geographic locations, monitoring and maintaining these devices can be an overwhelming task if done at the individual

physical level. Moreover, the conventional centralized DM approach becomes a serious limitation.

To face these limitations, this work is performed in an industrial context at Orange, and proposes an approach to self-adaptive Device Management for the IoT using constraint solving, validated on an industrial use-case. We introduce a new IoT DM architecture based on an autonomic manager, called Auto Scaling Manager (ASM). We have leveraged the MAPE-K (Monitor-Analyze-Plan-Execute over a shared Knowledge) Autonomic Computing reference architecture [4] to build this manager that is able to manage the DM system and adapt at runtime the required number of DM servers to handle the evolution of both the IoT device fleet and the physical infrastructure. Furthermore, a constraint programming model [5] is integrated into this manager and used for decision-making on the placement of DM service within the infrastructure.

The adaptive solutions for the scaling and placement of distributed components is a well-known topic in the context of distributed systems and the Constraint Programming (CP) has also used for a variety of real-world optimisation problems including placement problem. However, our main contribution involves a Constraint Programming-based autonomic loop approach in the context of DM IoT. In which, the system information is gathered and analyzed at runtime, in order to dynamically revise and adapt the constraint optimization criteria.

We evaluate experimentally the feasibility of our approach considering a privacy use-case. The objective is to analyze the ASM behavior in terms of adaptation decisions and to show how it scales horizontally, with respect to the evolution of both the DM system and the physical infrastructure. Our contributions are:

- An autonomic DM architecture for IoT devices to handle the device fleet evolution at runtime. For that, a Constraint Programming paradigm is integrated into an autonomic feedback loop.
- An experimental validation of the architecture for a privacy scenario.

The paper is structured as follows. Section II covers the background and the related work for the good understanding of our work. Section III states the targeted problem. Section IV details our proposed architecture. Section V details our

experimental evaluation and results. The last section concludes our paper and raises some future perspectives.

II. STATE OF THE ART

A. Device Management in IoT Context

DM operations are performed remotely via a management server, managed by a DM operator, that sends out the management operations to the management clients, hosted on the managed devices to ensure their proper functionality. The server and clients communication is based on dedicated protocols, e.g., TR-069 [6], OMA Lightweight Machine to Machine (*LWM2M*) [7].

DM of IoT is vital to maintain the proper functionality of IoT devices, keep them secure, and ensure the evolution and maintenance of their growing number, while anticipating new demands for devices and services. Compared to the legacy DM, new challenges are faced [8], [9]: *(i)* Heterogeneity: moving from a limited set of device types to a wide variety of devices [2], *(ii)* Dynamicity: moving from rather stable internal states, i.e., battery and network conditions, towards versatile states [10], *(iii)* Privacy: many IoT services leverage sensor data to adapt to the local context. It is critical to adapt these services to protect end users privacy and customers confidential and personal information [11], and *(iv)* Scalability: moving from a few devices managed by centralized systems to a massive number of devices that needs a distributed management.

In the works [12], [13], authors proposed: *(i)* automating of DM operations, and *(ii)* adjusting the execution speed of the campaign firmware update to device and infrastructure capabilities, i.e., hardware, current load and network congestion to address IoT heterogeneity and dynamism. Their adaptation strategy is based on operational measures, e.g., the error rate of DM operations and the infrastructure response time. Our work takes a further step towards scalability and privacy management by distributing DM operations close to the customer's premises based on Edge Computing.

Cloud computing consists in delivering computing and storage services over the Internet. It offers the advantages of flexibility and the ability to store/analyze data. However, when cloud computing is used for IoT, new challenges emerge.

With the huge number of heterogeneous IoT devices, IT operational bandwidth (BW) consumption is significant, especially from managing device provisioning, commissioning, decommissioning, and ensuring firmware upgrades. Further, as more devices appear, there is a need for a scalable DM solution to adapt to varied deployment scenarios and enable seamless integration and management of these distributed devices. We believe that Edge Computing, with all its features, has a promising potential to ensure end-users privacy (among other benefits as security and latency) when performing DM operations, compared to a centralized DM platform hosted in the cloud.

Fig. 1: MAPE-K Autonomic Loop, problem in reference [4]

B. Autonomic Computing

Autonomic Computing (AC) is defined as the self-management capabilities of a system [14] to respond to the increasing system administration complexity. It has proven to be effective in minimizing administrator involvement in the computer systems management, where an autonomic system is able to adapt to both external and internal changes by re-configuring itself (Fig. 1 shows the AC reference architecture).

Due to the huge number of heterogeneous devices involved in IoT system, the manual management and maintenance is impractical. In [15], the authors advocated that to address the problems of manual management, automatic approaches is needed. In their study, they stated why autonomic computing is useful and how to use it in the IoT context. Furthermore, automated architectures for IoT DM have been proposed in [13], [12] for automated device targeting (i.e., defining the appropriate devices for a DM operation) and for detecting errors/anomalies before generalizing patching to all target devices in a given fleet).

C. Service Placement in Fog and Edge using Constraints

Given the massive number of IoT devices, along with their related applications, the applications deployment in the Fog/Edge is needed to cope with the latency and privacy requirements [16]. This placement problem has been addressed in the literature [16], [17], [18] with several solutions based on different application scenarios, e.g., monolithic applications, network assumptions, e.g., infinite link bandwidth, and objective functions e.g., latency, cost. These solutions can be classified as follows: *(i)* Exact solution using Integer Linear Programming (ILP) [19]/ Constraint Programming [20], *(ii)* Approximations, and *(iii)* Heuristics [21] and Meta-heuristic, e.g., Genetic Algorithm (GA).

The placement solutions, that mainly rely on ILP or on heuristic approaches, are not generic enough to deal with the features of all applications [20], as they are: *(i)* uneasily extensible to incorporate new application / infrastructure features or to integrate new placement constraints and *(ii)* non-upgradable to exploit any user-implied resolution approach.

CP has these following appealing features: *(i)* It provides a generic and easy-to-upgrade service placement, *(ii)* It provides a faster solution even in a reasonably large scale environment (in [20] it is compared to and outperformed other algorithms such as ILP and GA with 1200 nodes), and *(iii)* The CP code is small and easy to implement. Thus, CP seems attractive to

adopt it for DM problem (More details in Sec. V). Many open-source CP solvers are available, such as the Choco solver [22] and OR-tools [23] and other commercial solvers, such as IBM CPLEX CP Optimizer [24].

For solving the Service Placement Problem (SPP), different optimization strategies are proposed in the literature [18], [16]. We distinguish two categories: (i) mono-objective that optimizes only one objective function, and (ii) multi-objective optimization that optimizes simultaneously many objective functions. These optimization functions are: (i) Latency: for delay-sensitive applications, (ii) Resource utilization: such as minimizing used bandwidth, (iii) Cost: There are two types of costs: the networking cost for data transmission charges and associated expenses, and other expenses related to storage, migration, and so on, (iv) Energy consumption: it includes when the service is sent by the end-user to the Edge device, when the Edge node processes the service; and when the Edge needs the Cloud, and (v) Other metrics: such as congestion ratio, i.e., ratio between the service links requirements and the physical links capacity.

D. State of the Art Synthesis

Device management is a fundamental issue, especially when it comes to the IoT environment, with its emerging challenges. To cope with these challenges, Autonomic Computing with its self-management capabilities, appears as an attractive solution for managing the DM system. Further, leveraging the benefits of the Edge Computing paradigm, we aim to provide the DM operations for IoT clients in a distributed manner to meet both the clients' requirements and the providers' concerns.

To this end, relying on Edge Computing together with Autonomic Computing MAPE-K architecture, we provide an autonomic manager with the ability for autonomous horizontal scaling in terms of the number of DM servers to adapt to the evolution of both the DM device fleet and the physical infrastructure. Learning from the literature and moving a step further, we rely on Constraint Programming to model and solve at runtime the DM placement problem by integrating a CP solver into the autonomic loop of our proposed autonomic manager. Moreover, to the best of our knowledge, our work is the first work that tackle the DM of IoT devices in a distributed manner.

III. PROBLEM DEFINITION

Deploying and managing large fleet of IoT devices is challenging due to their geographical distribution [25] and it can be an overwhelming task if done at the individual physical level. Ensuring the up-to-date state of this fleet is perturbed by fleet composition variations or by the availability of new firmware or configuration. The variation depends on two types of events: Device arrival which corresponds to the first connection of a customer's newly acquired object that usually comes with an outdated factory-installed firmware; and Device departure that occurs when an owner unsubscribes to an operator's offer, requiring a configuration to reset the device

to factory settings or when a device shuts down their network access to save energy for instance.

As a result, there is a strong and growing need for an autonomous system to manage the device fleet. This feature can considerably reduce the time and effort required to sustain the health and the performance of devices throughout their lifecycle. The automation of the DM system was considered in works [12], [13] which gave us a starting point for our work.

Moreover, when it comes to firmware updates, e.g., security patches or other updates, called over-the-air (OTA) updates, the conventional centralized DM approach becomes a serious limitation since designing a DM system to handle hundreds of devices is entirely different from designing one to handle billions. The consumption of IT bandwidth resulting from managing these devices will be significant. Therefore, an elastic DM system is very essential to ease and ensure secure, fast and proper batch updates for device fleet while removing the pressure on both the nodes that host the DM components and the links that are used for server-clients communication by scaling well to manage this huge device fleet.

Knowing that, the Edge computing architecture, which brings essential data processing capabilities close to the network edge, provides a compelling solution for IoT DM use case that addresses the following issues.

- Save Bandwidth: DM operations do not have to be sent over long routes between the server hosted in a data center and the end devices. With Edge Computing, the DM operations could be provided through the distributed servers via different Edge nodes at different locations near to the end users;
- Guarantee the privacy: Management of IoT end devices locally (e.g., gateway at the client geographical place) or in the proximity of the end devices could ensure the user's privacy. Given this privacy need, a DM server can be restricted to be deployed on specific areas (zone), namely Dedicated Zones (DZs). For example, a factory requiring device operations to be performed inside its LAN (Local Area Network);
- Support devices mobility: Edge computing is better suited to support end-user mobility than the centralized DM platform and to enable the seamless firmware updates management while ensuring the required latency.

IV. PROPOSED DM ARCHITECTURE

The proposed architecture for self-adaptive IoT DM is depicted in Fig. 2. It allows the dynamic horizontal scaling of the distributed DM servers based on designated policies (e.g., physical resource utilization thresholds, Privacy requirement).

It has two main layers: (i) Control layer which is comprised of a centralized autonomic manager called ASM and a system administrator that represents an external manager-to force external actions when needed or to give high-level objectives - and (ii) Infrastructure layer that involves the physical nodes/links that hosts the Administrative layer, i.e., DM servers, and the IoT devices.

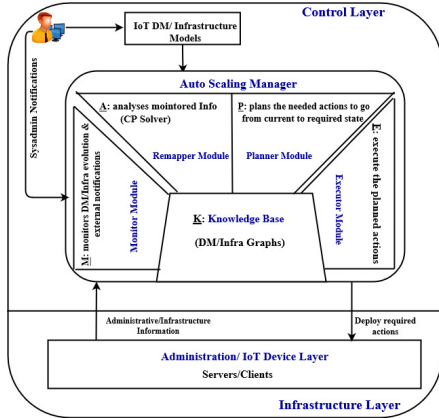

Fig. 2: Self-adaptive IoT DM Architecture based on MAPE-K reference

Fig. 3: Input Graph Models

This architecture is based on two main models, depicted as graphs, which represent the DM system and the underlying infrastructure (more details in Sec. V). On the one hand, the infrastructure model (Fig. 3(a)) is dedicated to the specification of the underlying topology that will host the DM service components. On the other hand, the DM system model (Fig. 3(b)) is intended to the representation of the DM system entities along with their requirements (i.e., servers and clients).

The lifecycle associated with this architecture involves these two models that will evolve over time, e.g., arrival/departure of DM clients, failures in infrastructure nodes/links. These models are used as the input of a specific constraint program integrated into the (Re)Mapper module of the ASM. In the Sec. IV-A, we explain ASM in more details.

A. Auto Scaling Manager (ASM)

This autonomic manager is built following the MAPE-K architecture and is responsible for managing of the DM system from its design till the end of the system's lifecycle. Thus, the objective is to specify a particular DM system /Infrastructure topology to be modeled, by a system administrator or DM service provider, and then handled at runtime. This implies making horizontal scaling decisions of the DM servers to adapt to any new condition dynamically, i.e., adding/removing one or more DM servers at runtime. This work is realized through the following modules:

- Monitor module: is responsible of observing the evolution of both DM system and infrastructure and forwarding the information to the Remapper module for analysis;
- (Re)Mapper module: analyses the information from the system administrator or the Monitor to decide on the

target state of the DM system and then it solves the DM system placement within infrastructure (See Sec. V) ;

- Planner module: Based on the Mapper information, it extracts and selects the required actions to move to the required state of DM system (e.g., add/remove DM server(s)/client(s));
- Executor module: is responsible of deploying the required actions planned by the Planner module.

Finally, the Knowledge Base contains graph models of current and past infrastructure and DM service configurations.

B. ASM Work Methodology

The autonomic feature of the ASM is based on MAPE-K loop (in Fig. 2). It has three inputs: DM system/ Infrastructure models and the selected objective defined manually by the System administrator at initial step, named *Design time*. The infrastructure/DM graph models and the initial placement solution for DM system, along with the fore-coming graphs and placement solutions, will be stored in the ASM's Knowledge base. The output of the ASM is the DM servers that needs to be launched/stopped on particular infrastructure nodes along with their binding with their clients.

These graph models serve as an input to a CP solver that is integrated into the analyzer step, i.e., (A in Fig. 2). In this work, we consider the constraint satisfaction programming for solving the DM placement problem which provides at design time a feasible placement of the DM system within current infrastructure. However, this module is generic in that different placement approaches could be selected for both mapping/remapping steps.

Thereafter, the System evolution will be gathered by the Monitor which involves- based on the adopted scenario: (i) changes in the underlying infrastructure (e.g., node arrival/departure, resources loads), (ii) changes in the DM system (e.g., clients arrival/ departure), and (iii) other system administrator notifications, such as updating the solver objective to accommodate an urgent security campaign firmware updates instead of "normal" firmware/ configuration updates (M in Fig. 2).

The monitored information is passed to the analysis step, whenever a new change is observed. The analyser takes into account the last system state stored in its knowledge base. As a result, a new graph(s)- that reflects the new requirements and changes- will be generated and the constraint solver will be called to decide on the mapping of the new system's elements. Thus, the (Re)mapper module will be called first at the design step and then whenever a new information is observed and transmitted by the Monitor.

After receiving this information, the planner (P in Fig. 2)) produces a set of actions to be applied to move from the current system state to the target one by extracting the difference between the current and the target mapping, to do only necessary actions (e.g., decide the required number of server/client to be started/stopped). Finally, the Execution step applies these actions (E in Fig. 2)).

Fig. 4: Integrating CP in the ASM MAPE-K architecture

This whole process, after the design step, will be repeated in a loop based on the monitored information and the runtime conditions imposed by the Administrator. We further show in Fig. 4 how the constraint programming is integrated within ASM (Re)mapper.

Finally, in the case that the monitor detects a reconfiguration need and a CP solver is called, we may obtain that no feasible placement solution is found, for example, because there are no enough resources in the infrastructure while satisfying all required constraints. Thus, the Remapper module might need to wait for some time, so that other services release some infrastructure resources or some clients leave to try again with the solver. In such case, the ASM will keep the last solution and a notification will be sent to the system administrator.

C. Supported Use-Cases

The need for DM system reconfiguration is based on the targeted evolution type. Different changes may result in a need for a new system configuration in the DM context. Privacy is an important concern that is adopted in this work [11], where a client may need to be managed by a specific DM server or a DM server placed in a specific area due to some privacy considerations (e.g., the IoT device(s) belongs to a private enterprise or for a VIP (Very Important Person)). Thus, whenever new IoT devices ask to join the system and get registered and managed by a DM server, these newcomers will need some resources (e.g., CPU (Central Processing Unit) and RAM (Random Access Memory)) along with a specific privacy constraint. Further, IoT devices might leave the system so we need to stop the related DM clients, which results in reducing the pressure on the currently running servers.

Any DM system evolution at runtime observed by the Monitor (through an external notification issued by the administrator) will be reported to and analyzed by the Remapper. In case new devices arrival, ASM will individually check their privacy requirements to see if they can be registered with one of the existing servers. If the current servers cannot satisfy the new devices, a new server(s) need to be added the DM system, so a new DM graph will be generated to reflect the new system and the constraint solver will be called to decide on placement of the new graph.

While privacy is considered in our work to trigger the scaling process, but it is just a use-case, as there are other situations that might require adaptation and that can be handled by our proposed architecture. For example, adding more DM

servers to adapt to the increased number of IoT devices communicating with a single server, and then balancing the load among these servers instances represent a new motive for scaling to avoid the stress on one server and efficiently manage the huge device fleet. In such scenario, any information leading to redeployment/instantiation need will generate a new DM graph and launch again the CP solver.

The inform storm represents a real life use-case when a huge amount of IoT devices reboot at one time, e.g., after a power breakdown. Another use-case is the smart vehicles [26] which consists of numerous sensors and actuators that automate various tasks, such as traffic monitoring and braking. In this scenario, it is necessary to keep the vehicle's firmware up-to-date, and to provide a convenient solution to the problem of installing a new firmware that could be released to fix bugs or provide new functionality. A significant challenge with this use-case is the mobility, where a vehicle may disconnect from a certain DM server placed on a specific Edge node and require to reconnect to an alternate DM server according to its current geographic location. By automatically scaling new DM servers and placing them close to the moving vehicle, this mobility problem can be handled.

V. DM SERVERS PLACEMENT PROBLEM

The mathematical formulation of the placement problem given in [20] is strongly aligned with our DM service placement problem. Therefore, we have benefited from this model and modified the following parts to comply with our needs. In the first update, we have changed the definition of the proposed locality constraint (See Sec. V-B). Instead of enforcing some service components to be placed on specific physical nodes, we have introduced the dedicated zones to which each physical node belongs. Then, each DM component will have a privacy requirement regarding the accepted zone of the hosting node.

Another variation is the optimization objective. Here, we have proposed a multi-objective optimization to decide at runtime which objective we need to optimize (more details in Sec. V-C). Further, the CP solver is integrated in a feedback loop in order to make adaptation decisions at runtime.

A. System Model

1) *Infrastructure model*: It is defined as a directed graph $G^I = \langle H, \epsilon \rangle$, where H is the physical nodes (e.g., Edge and IoT devices) and $\epsilon = H \times H$ is the network links between the nodes : $\forall h \in H; \exists U(h)$ where $U(h) = (CPU, RAM, DZ)$

In the infrastructure graph, we defined for each node its available CPU and RAM resources in addition to its own dedicated zone. For the physical links, we define the available bandwidth and latency as follows:

$\forall e_{i,j} \in \epsilon; \exists LAT(e_{i,j})$ and $BW(e_{i,j})$, where $LAT(e_{i,i} = 0)$ and $BW(e_{i,i} = \infty)$ (In future work, the link type can be added as an additional characteristic).

2) *DM System Model*: We consider that our DM system represents as a service and could be modeled as a graph $G^a = \langle C, L \rangle$, where C is the components of our DM

system and $L = C \times C$ is the communication links between these components.

The nodes of this graph represent the DM servers and clients along with their resources requirement, namely CPU, RAM, and privacy :

$\forall c \in C; \exists u(c)$, where $u(c) = (Rcpu, Rram, Rdz)$ The $(Rcpu, Rram)$ are the resource requirements of each DM components and Rdz is the privacy requirement where each DM system's components need to be placed at some geographical place (e.g., customer premises for privacy issue).

In addition, for the links needed for the communication between the servers and the clients, we define the following requirements: $\forall k \in L; \exists Reqlat(k)$ and $Reqbw(k)$ which is the latency and the bandwidth requirements of the DM system communication links.

3) *Placement*: After modeling both the physical infrastructure and the DM systems as graphs, the next step is to decide where to place all DM system's components and the communication links on the infrastructure physical nodes and links, respectively.

The placement solution must satisfy all the resources requirements of the DM components (namely, CPU, RAM, BW and Latency) while, at the same time, respecting the underlying infrastructure available resources. Based on methods provided in the related work we decide to use the constrained programming approach for solving the placement problem (this choice was justified in the Sec. II).

B. Problem Formulation with Constraint Programming

Here we present the formulation model for the DM placement problem. Inspired by the related work [20], for the technical needs of the modeling (to ensure we have a full connected graph), the infrastructure graph is increased by adding a super-sink node (α), with unlimited resources (CPU, RAM...), to which all graph nodes can access. The links that connect the infrastructure nodes to α , and α to itself, have an infinite capacity. In the following, the variables related to both nodes and links are declared. $\forall k \in L : s = \{s_k \mid k \in [1, |L|]\}$ where s_k is the physical node that hosts the source component of a DM system link (k), where $(s_k \in H)$.

$t = \{t_k \mid k \in [1, |L|]\}$ where t_k is the physical node that hosts the target component of a link (k), where $(t_k \in H)$.

$n = \{n_{k,j} \mid k \in [1, |L|], j \in [1, |H|]\}$ where $(n_{k,j} \in H)$ is the physical node at position (j) in the path of link (k).

$h = \{h_i \mid i \in [1, |C|]\}$ where $(h_i \in H)$ is the physical node that hosts a component (i).

$p = \{p_k \mid k \in [1, |L|]\}$ where $(p_k \in H)$ is the position of the target component(t_k) in the path (n_k).

$a = \{a_{k,j} \mid k \in [1, |L|], j \in [1, |H|]\}$ represents a physical link between $(n_{k,j})$ and $(n_{k,j+1})$ in the path of a DM system's link (k), where $(a_{k,j} \in \epsilon)$.

$b = \{b_{k,j} \mid k \in [1, |L|], j \in [1, |H|]\}$ represents the bandwidth of the physical link ($a_{k,j}$).

Finally, l represents the physical link latency ($a_{k,j}$), where $l = \{l_{k,j} \mid k \in [1, |L|], j \in [1, |H|]\}$

After defining our problem model variables, we present the necessary constraints to be applied to control the possible combinations of values that these variables could obtain.

Constraint 1: *BINPACKING* constraints (knapsack-based reasoning [27]). Here we ensure that the sum of all mapped components demands does not exceed the maximum available CPU and RAM capacities of the infrastructure nodes.,

$$BINPACKING (\langle h, Reqcpu \rangle, CPU)$$

$$BINPACKING (\langle h, Reqram \rangle, RAM)$$

Constraint 2: To fix a DM system's component (i) to a specific location or DZ, we use this locality constraint:

$$DZ(h_i) = Loc(i), \forall i \in C$$

Constraint 3: Node at position (0) in the path (n_k) hosts the source component of a DM communication link (k).

$$n_{k,0} = s_k$$

Constraint 4: Node at position (p_k) in the path (n_k) hosts the target component of a DM communication link (k).

$$n_{k,p_k} = t_k$$

Constraint 5: When the source and the sink components are the same, they will be hosted on the same physical node.

$$s_k = t_k \leftrightarrow p_k = 1$$

Constraint 6: To avoid cycles in a path (n_k), the *ALLDIFFERENT* filtering algorithm [28] is used to prevent similar values for the variable ($n_{k,j}$).

$$ALLDIFFERENT(n_{k,j}, \forall j \in \{1, \dots, |H|\})$$

Constraint 7: Any path (n_k) ends with at least one occurrence of α (the super-sink added node to the infrastructure graph). For that, the *REGULAR* constraint [29] is added to ensure that the corresponding sequence of values taken by variables belong to a given regular language.

$$REGULAR(n_k, "[^\wedge\alpha] + [\alpha] + ")$$

Constraint 8: When two DM communication links (k, k') share a same component, then the physical node that hosts the target component of the first link will be the same node the hosts the source component of the second link. $t_k = s_{k'}$

Constraint 9: This constraint is a *BINPACKING* constraint to respect the bandwidth limit of each physical link.

$$BINPACKING (\langle b, Reqbw \rangle, BW)$$

Constraint 10: These last two constraints concern respecting the latency of each DM communication link, and the end-to-end latency along the path of the DM communication link, respectively:

$$l_{k,j} = LAT(a_{k,j}), \forall k \in L, \forall j \in \{0, \dots, |n_k|\}$$

$$\sum_{j=0}^{|n_k|} l_{k,j} \leq Reqlat(k), \forall k \in L$$

Moreover, in the DM context, the communication link type is an important requirement to be considered when solving the placement problem, where various communication technologies between devices are used such as Wi-Fi, Bluetooth, and ZigBee (based on the IoT device). Thus, when solving the placement problem, the link type could be added to our Infrastructure/DM models to better fit the DM context.

C. DM Optimization Function

Different objective functions have been introduced in the literature (see Sec. II for more details) of placement problem. However, the question that comes to mind is that: **What are**

TABLE I: Objective Optimization Classification

Metric	Description
Resources	Minimize the number of used Nodes
	Minimize the total used links' BW
Load balancing	Maximize each physical node minimum remaining CPU cores
	Maximize each physical link minimum remaining BW
Latency	Minimize the latency for urgent security patches

the optimization metrics to consider in the case of DM service provided to IoT users? To answer this, we provide a simple classification for placement objectives metrics that could fit for the DM context in the Table I. The optimal management of infrastructure resources is an important metric. With the objective *Resource*, we aim to minimize the computational or network resources used. For example, the DM system involves communications between servers and their bulk clients and communication traffic will pass through network links, that are shared with other services/applications, so minimizing network consumption is important for the DM context. However, this goal could imply that some nodes/links are overloaded while others are underloaded.

With the *Load balancing* objective, we aim to reduce the stress on both physical nodes and links (i.e., congestion rate) by balancing the load between the participant nodes and links in our infrastructure by choosing the least loaded nodes and links in the infrastructure. Finally, with the *Latency* objective, given that one of DM's features is to send security patch updates, it becomes necessary to ensure the quick arrival of such updates. To ensure this, we need to minimize the latency between the clients and their own servers.

From the discussion above and given the DM system features, there is no single objective function to be considered statically. Rather, it appears that this function depends on the chosen scenario and the actual communication information exchanged between the servers and their clients. To do this, a multi objective function is introduced with *coefficients* variables (α, β, \dots , etc.) that will be activated/deactivated at run-time by getting the value of 1 or 0, respectively. We formulate the final placement objective as follows:

$$Objective = \alpha Obj1 + \beta Obj2 + \dots$$

For our proof of concept and experimental validation we choose between these objectives: (i) Minimizing the total number of participating nodes, and (ii) Minimizing the total consumed bandwidth. Our optimization objectives are formulated as follow: $Obj1 = Min \sum_{i=0}^{|H|} h_i$, where ($h_i \in H$) is the physical node that hosts a component (i); $Obj2 = Min \sum_{j=0}^{|n_k|} b_{k,j}$, where $b_{k,j} = BW(a_{k,j})$, $\forall a_{i,j} \in \epsilon$.

VI. EXPERIMENTAL VALIDATION

We present here our experimental setup to assess our approach's ability to automatically adapt by horizontal scaling the DM servers number based on both the DM system and the infrastructure's evolution. First, we present our use case and

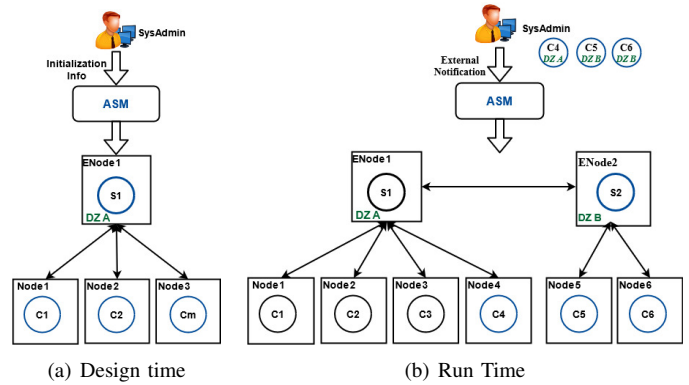

Fig. 5: Privacy Use Case, DM System Evolution

then detail the technical architecture of our setup. Then, we present our environment and ASM implementation.

A. Target Use Case

To assess our architecture, we considered the challenge of preserving the privacy of users who use a set of smart objects connected to each other and, potentially, to other users' objects. In such a case, IoT objects can use and propagate a lot of information about the features they offer and provide sensitive information about the users that they do not intend to reveal, e.g., knowing the features of most adopted objects by users. In this case, users may require their devices to be managed by an authorised server or by a server located in an authorised geographical place.

Therefore, we consider the following use case. Initially (See Fig. 5(a)), the DM system administrator will start a DM server in a specific location in the infrastructure and let the DM clients register to it as it meets their privacy requirements (i.e., based on the server locality). From here, the ASM will be in charge of managing the DM system throughout its life cycle.

After some time, new devices will arrive and ask to join the fleet and register with one of the servers respecting their privacy constraints. The clients information and requirements will be sent to ASM by the administrator via external notifications (See Fig. 5(b)). ASM will analyze this new information and then decide on the right actions to move from the system's current state to a new one that meets all DM components requirements. This involves either connecting each new client to an existing server that meets the privacy constraint, or else by instantiating a new server on a node within an acceptable location, i.e., dedicated zone.

B. Experimental Setup

The ASM inputs are the infrastructure and the DM system models which are generated based on the use case introduced in Sec.VI-A. This subsection details their attributes.

a) *Physical Infrastructure*: The global infrastructure is composed of: (i) 20 Edge nodes with CPU cores between 2 and 12 and available RAM between 2 and 24 GB, (ii) 40 less powerful extreme edge nodes close to IoT devices, namely customer premises nodes, characterized by CPU cores

between 1 and 2 and available RAM between 1 and 2 GB, and (iii) up to 1000 links that connect these nodes randomly with bandwidth up to 5/20 Gbps and latency up to 1/5 ms for the physical links that connect the edges nodes and 1/5 Gbps and latency up to 10/20 ms for the physical links that connect edges nodes to customer premises nodes where each node belongs to a specific zone (for the need of privacy scenario).

The nodes zones is given randomly where $DZ1$ to $DZ6$ is reserved of Edge nodes that will host DM servers and $DZ10$ to $DZ20$ is reserved of customer premises nodes.¹

b) DM Service: For the initial setup we start the DM service with one server and 3 clients managed by this server. After that, the administrator external notifications concerning new IoT clients will arrive following an exponential distribution of mean T_{IA} , where T_{IA} is the mean inter-arrival time of clients arrival notifications (measured in arbitrary time unit). Each DM client has a service time, i.e., the time the client remains in the system is randomly selected following an exponential distribution of mean S . Any notification that cannot be satisfied directly will be kept in a queue for some predefined time, namely Time To Live (TTL), waiting for some resources to be released and become available.

In total, our synthetic external notifications workload for the simulations contains request arrivals made of 40/60/80/100 arbitrary clients. The number of clients that arrive or leave is selected randomly between 1 and 4 client at each notification.

The communication between servers and their clients is done via bindings. The processing, RAM, latency and bandwidth requirements for DM components and binding is chosen in random manner with respect to the available infrastructure resources. Moreover, each DM component requires to be started on a specific dedicated zone within the physical infrastructure (more details in Sec. V).

C. Architecture Implementation

We detail here our choices in terms of architecture and language for the development, illustrated in Fig. 6. The software and modules run locally on a workstation with four physical cores and eight logical computing units of the Intel x86-64 architecture, supported by 32GB of DDR4 with 2133MHz RAM with Linux Debian 10 operating system.

For the mapper module, which solves the DM placement problem based on CP, we have chosen Choco as a solver inspired by the works [20] [16], which is a free and open-source Java library dedicated to constraint programming. The placement problem must be modeled in a declarative way by defining the set of constraints to be satisfied in each solution. Then, it will be solved by alternating constraint filtering algorithms with a search mechanism.

The three remaining modules of the ASM, are developed from scratch in Python. The choice of Python is motivated by its wide collection of libraries and its native compatibility with

¹The processing and the memory capacities for each infrastructure node are chosen randomly from set of values inspired by the most common OpenStack and Amazon EC2 instance types and the links bandwidth and latency values also and number of dedicated zones.

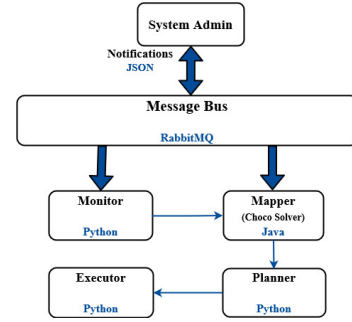

Fig. 6: The Technical Implementation of the Architecture

the JSON [30] data format used by the other components of our architecture (messaging bus). The ASM modules communicate with the system administrator via a common RabbitMQ messaging bus [31]. The RabbitMQ bus allows communication via Message Queuing Telemetry Transport (MQTT) which is a messaging protocol widely used in the context of IoT and compliant with Python.

D. Experimental Results

Our defined simulation scenario aims at initiating a DM service on a physical infrastructure. Later on, at runtime, external notifications about fleet evolution will be launched by the system, triggering our automatic manager to take scaling decisions of the DM servers. All the following experiments were repeated 5 times using 5 different notification workloads with the same parameters.

1) ASM Adaptation Characteristic:

We evaluate here how the ASM can adapt the number of DM servers at runtime to fulfill the new DM clients privacy requirements with a total number of 80 clients that want to join the DM system. Figure 7(a) shows the evolution of number of participated servers to adapt to evolution of DM clients through the time. It starts with the initial configuration of 1 server and 3 clients. From this figure we can see an increase in number of servers as new clients join the system (based on their privacy constraint on the acceptable server). However, when new clients arrive and their privacy requirements can be satisfied by the already running servers there is no need to scale out the DM servers. This explains the situations in the figure where we have new incomers and the number of servers does not increase. For example at the time point of 14 to 15 min, the number of servers is 4 while the number of clients in the system goes from 9 to 13 clients.

On the other hand, when the clients number decreased as they leave the system, Fig. 7(a) shows decreasing in the number of servers. This happens when a server has no more clients, e.g., at the time point of 1 min the ASM scale in the number of servers goes from 3 to 2 servers as the the number of clients goes from 9 to 6 clients. However, not all clients departure leads to ASM taking scale in decisions, as their server still have other clients to manage.

2) Acceptance Ratio:

We study the impact of total number of clients that arrived to the system on the ability to satisfy their joining requests

Fig. 7: Experimental Results

and placing them into the Infrastructure. To that aim, we use the acceptance ratio defined as the number of accepted clients arrival notifications over the total number of arrival notifications. Fig. 7(b) shows the acceptance ratio with respect to 4 different total number of clients that ask to join the DM system with two different infrastructures: (i) Infra.1: composed of 20 Edge nodes & 80 customers premises nodes, and (ii) Infra.2 with 20 Edge nodes & 40 customers premises nodes.

In general, and for both infrastructures, we can expect the acceptance ratio to decrease as the total clients number increases since more clients require devoting more physical resources to place the new clients and server when needed. This trend is confirmed by Fig.7(b). However, the decreasing is negligible and this can be explained by the fact of using a waiting queue for the unaccepted notifications to try again when other clients leave the system and some resources become available. Thus, using this queue allows increasing the acceptance ratio and preventing a sudden drop in its value when the number of clients increases from 40 up to 100 clients. However, with more powerful underlying infrastructure (the blue curve in Fig.7(b)) leads to more acceptance ratio as the network can handle more clients before becoming overloaded. It is worth mentioning that even with 40 clients, we do not have an acceptance rate of 1 as the combination of many constraints, namely CPU/RAM/Bandwidth and privacy, prevents the solver from finding a valid solution.

3) ASM Adaptation Time:

To be acceptable, the time spent by ASM to adapt to DM runtime evolution must be at most of the same order of magnitude as the deployment of the VMs that will host the DM components to not impact the deployment time of the DM service. This time includes the generation of a new DM configuration file, taking scale In/Out decisions and finding an acceptable placement of DM components. For that reason, we force the Choco solver in the Mapper to try to find an optimal solution in no more than 1 minute. It is in the same order of magnitude of the typical time to deploy and boot virtual functions in data centers [32].

Figure 7(c) shows the whisker plot of ASM adaptation time to the system administrator external notifications times for 4 different number of DM clients. It shows that the needed time

by the ASM to adapt to runtime notifications increases rather linearly with number of DM clients and never exceeds one minute, which is affected by the Mapper module time to find the placement solution. This rather linear increase is because an increase of DM clients number incurs a proportional increase in the total number of DM components. These clients do not come at once, but rather in a random group from 1 to 4 clients together. Thus, the size of the placement problem as the size of the DM components is not impacted.

The spread between median and lower quartile is smaller than the spread between median and upper one as most of placements require more time to find a solution of the new DM configuration or to reject the notification and send it to the waiting queue.

Knowing that the number of arrived clients significantly affects the size of problem, and therefore the needed time by solver to find a solution, this case should be considered as a scalability limitation to our solver. The constraint programming solver could not be fast enough and a new heuristics might be considered to find a near optimal placement.

To best of our knowledge this is the first work on distributed IoT DM at the Edge of the network. Thus, many parameters are set with random values and affect our simulation results. The first parameter is the *TTL* value: more *TTL* could increase the acquired acceptance ratio as more resources will be released and become available, but more time is needed to complete a full workload (long waiting queue). The solver maximum allowed time has also a direct impact on both acceptance ratio and ASM adaptation time. Giving more time to Choco solver may increase the acceptance ratio. However, since we are targeting client requests at runtime, it is very important to make a decision as quickly as possible. Moreover, giving more time to the solver cannot guarantee that a solution will be found as the infrastructure might be already overloaded.

Furthermore, since all workloads are randomly generated due to the unavailability of real-world workload- i.e. random arrival rate, service time and resources requirements - running more workloads lead to more consistent results and avoid some ambiguous results, e.g., the median value of the whisker plot for the clients number equal to 60 in Fig. 7(c).

VII. CONCLUSIONS AND PERSPECTIVES

We have addressed the main IoT DM challenges, namely Heterogeneity, dynamicity and scalability. For that purpose, we proposed a self-adaptive DM architecture for IoT with an autonomic manager that is capable of self-scaling the number of DM servers to the fleet changes and requirements at runtime through the distribution of DM operations at the Edge. This autonomic manager relies on a constraint programming solver that is integrated in a feedback loop to decide on DM servers and clients placement while optimizing the infrastructure resources usage. Further, we evaluated this architecture through simulation to the fleet evolution at runtime with a privacy as the target scenario. The results show that our manager is fast enough- only 1 minute- such that one can consider using it in a real environment to handle IoT fleet composition changes at run time and without the need of prior knowledge on the new IoT devices requirements.

For future work, we are investigating our proposal's scaling capability with respect to another scenarios such as physical resources thresholds and DM servers limitations. Also, from the point of view of constraints and models, we want to consider more dynamics (e.g. speed and acceleration of variations) in relation with Control Theory [33]. For interoperability motive, a constraint regarding the management protocol used by the DM server could be considered. Another important enhancement will be testing this architecture with real infrastructure e.g., Grid5000 [34] FIT IoT-LAB Testbed [35].

3rd International Forum on Cyber Security, Privacy and Trust

NOWADAYS, information security works as a backbone for protecting both user data and electronic transactions. Protecting communications and data infrastructures of an increasingly inter-connected world have become vital nowadays. Security has emerged as an important scientific discipline whose many multifaceted complexities deserve the attention and synergy of computer science, engineering, and information systems communities. Information security has some well-founded technical research directions which encompass access level (user authentication and authorization), protocol security, software security, and data cryptography. Moreover, some other emerging topics related to organizational security aspects have appeared beyond the long-standing research directions.

The International Forum of Cyber Security, Privacy, and Trust (NEMESIS'22) as a successor of International Conference on Cyber Security, Privacy, and Trust (INSERT'19) focuses on the diversity of the cyber information security developments and deployments in order to highlight the most recent challenges and report the most recent researches. The session is an umbrella for all cyber security technical aspects, user privacy techniques, and trust. In addition, it goes beyond the technicalities and covers some emerging topics like social and organizational security research directions. NEMESIS'22 serves as a forum of presentation of theoretical, applied research papers, case studies, implementation experiences as well as work-in-progress results in cyber security. NEMESIS'22 is intended to attract researchers and practitioners from academia and industry and provides an international discussion forum in order to share their experiences and their ideas concerning emerging aspects in information security met in different application domains. This opens doors for highlighting unknown research directions and tackling modern research challenges. The objectives of the NEMESIS'22 can be summarized as follows:

- To review and conclude research findings in cyber security and other security domains, focused on the protection of different kinds of assets and processes, and to identify approaches that may be useful in the application domains of information security.
- To find synergy between different approaches, allowing elaborating integrated security solutions, e.g. integrate different risk-based management systems.

- To exchange security-related knowledge and experience between experts to improve existing methods and tools and adopt them to new application areas

TOPICS

- Biometric technologies
- Cryptography and cryptanalysis
- Critical infrastructure protection
- Security of wireless sensor networks
- Hardware-oriented information security
- Organization- related information security
- Social engineering and human aspects in cyber security
- Individuals identification and privacy protection methods
- Pedagogical approaches for information security education
- Information security and business continuity management
- Tools supporting security management and development
- Decision support systems for information security
- Trust in emerging technologies and applications
- Digital right management and data protection
- Threats and countermeasures for cybercrimes
- Ethical challenges in user privacy and trust
- Cyber and physical security infrastructures
- Risk assessment and management
- Steganography and watermarking
- Digital forensics and crime science
- Security knowledge management
- Security of cyber-physical systems
- Privacy enhancing technologies
- Trust and reputation models
- Misuse and intrusion detection
- Data hide and watermarking
- Cloud and big data security
- Computer network security
- Assurance methods
- Security statistics

Abstract—Due to new technologies for connectivity, automotive systems shift from a closed to an open system approach. Therefore, automotive systems have a rising demand for security, letting security be an upcoming field in research and practice. Also, the newly published process standard ISO/SAE 21434 demands adjustments in the development process to address cybersecurity. The unique characteristics of automotive systems leave many approaches from other system types inapplicable. This work concentrates on the risk treatment step in the cybersecurity development process. Due to the vast amount of differing terminology, we see the need to define a flexible taxonomy adaptable to several system types and used in systems with normative references. We use this taxonomy to develop a heuristic approach for risk treatment based on a distinct terminology for security requirements. The presented method is extendable to include several trade-off points.

I. INTRODUCTION

With rising interest in connectivity and Car2X, also automotive security gets into focus. ISO/SAE 21434 [1], the process standard for automotive security, defines the security analysis and risk treatment process into three steps. The process starts with a security relevance evaluation [2] for deriving the first criticality and filtering the targets of evaluation to relevant ones. After that, the risk analysis, followed by the risk treatment step, occurs.

Risk analysis is done on the decomposed system and tells a story about five questions. The question about what can go wrong determines possible damage scenarios, weighted according to their damage potential - how bad is this? The threat identification and attack path analysis show how damage scenarios happen. A defined attacker model answers the question about who can do that, which allows deriving the attack probability. The combination of both impacts (damage potential and required attack potential) determines the risk value and enables a criticality ranking.

Risk treatment uses the impacts and risk numbers to consolidate the story of the different risk analyses in the system. In this step, weighting the impacts allows a fine-granular prioritization of the risks. Defense method assignment leverages the impacts and thereby reduces the risks.

The first arising problem when looking for demands and approaches for risk treatment is the vast amount of different terminology. Unclear terminology makes it difficult to

understand demands and compare approaches. An example is UNECE No. R155 [3]. While its main section uses the term mitigation, the Annex uses security control, measure, and mitigation without proper definition. The same applies to other sources in the literature. Therefore, we see a need to find a distinct definition of the terms used for the risk treatment in automotive systems.

On the other hand, efficient risk treatment demands a structured data basis of the used mitigations. We ground our method on a simple taxonomy based on a distinct terminology with the possibility of transferring it to other system types. The developed defense method catalog is a cross-product of the taxonomy whereby the taxonomy is independent of concrete system information. The presented defense method catalog covers such system-type-related information.

Literature frequently covers risk treatment theoretically, but an efficient and flexible method is missing. Especially methods transferable to different input sources are rare. Most approaches are for particular systems, e.g., service-oriented and web-based systems. Others are implemented in a framework, demanding unique kinds of data sources. We aim for a flexible heuristic approach for risk treatment. Our approach uses general information from risk analysis rather than detailed system models, which makes the approach adaptable to practical settings.

Security requirement demands from system external sources, like normative or organizational policies, are often mixed with requirements related to specifics of the target of evaluation. After risk treatment, applied trade-offs must adhere to a system's external security demands. Otherwise, the system might be cost-effective but infeasible from a legal point of view. Therefore, we observe the origin of the requirements to enable traceability of the security demands.

Risk analysis determines threats to the system based on attack paths. Those have different configurations. Single threats (one-element attack paths) can be compared to single-points-of-failure in reliability or are preparation attacks for other paths. Prioritizing them in the treatment process first mitigates crucial threats (SPOF) and preparation attacks. The latter directly cut attack paths, reducing the effort of treating those. Updating the risks by determining the impact of the defense method on other risks raises the by-catch and reduces the

overall effort of implementing defense methods.

Risk treatment aims to minimize the risk of system threats by either reducing the impact or raising the required attack potential (reducing the attack probability). It is reasonable to prioritize the impacts in the treatment procedure for the efficiency of the process. Those priorities allow trade-offs between different impact categories or attacker model categories in a cost-pressure situation. Our approach aims for a flexible prioritization of the risk treatment procedure and the risk impact categories to allow different trade-off points.

Based on the relation to the automotive industry, the presented work starts with a short introduction of the normative references for risk treatment in automotive development (Section II). In Section III we introduce our taxonomy for security requirements. Section IV covers the approach for risk treatment. Please note that NDA reasons prevent an exhaustive evaluation of our approach. We tried to include several examples in the text, where appropriate. Section V discusses the limitations and possible further trade-offs for our risk treatment method. In Section VI we conclude our contribution and give an outlook for future work.

II. NORMATIVE REFERENCE

Two normative references are relevant for type approval in automotive systems: UNECE No. R155 [3] and ISO/SAE 21434 [1]. The demands of both norms have a different layer of detail.

A. UNECE No. R155

According to UNECE No. R155 [3] the OEM has to protect the vehicle type and to implement “all mitigations [...] which are relevant for the risks identified.” [3].

Besides the general demand for mitigation implementation, UNECE No. R155 has three concrete demands:

- Intrusion-Detection for the vehicles of a certain type
- A central monitoring facility for new threats and vulnerabilities
- The use of up-to-date cryptographic modules

Annex 5 provides a list of possible risks and appropriate mitigations. The mitigations listed in the Annex are not concrete methods, but rather categories of mitigations, e.g., “The vehicle shall verify the authenticity and integrity of messages it receives” [3]. The OEM may differ from the provided list of mitigations if it is insufficient to mitigate a certain risk.

In conclusion, UNECE No. R155 demands risk mitigations according to the provided categories in the Annex. The general demands are only OEM-related, one regarding the monitoring facility, and two vehicle-related demands. There is no suggestion regarding threat mitigation techniques or methods.

B. ISO/SAE 21434

ISO/SAE 21434 [1] describes the clauses in a triple of input, the requirements and recommendations, and the output. Input is the necessary and optional predecessor work products from other clauses. The requirements define the demands of the ISO

and provide possible methods or procedures. Output defines the work products resulting from this clause.

For the risk treatment, ISO/SAE 21434 demands to use the item definition (model of the target of evaluation), the identified attack paths, and the risk values as results from the risk analysis. Optional inputs are cybersecurity specifications (from former development or higher abstraction levels), previous risk treatment decisions, damage scenarios with their impact rating, and attack paths with feasibility ratings.

ISO/SAE 21434 requires the risk treatment for all identified risks by using one or more treatment options. Those options are the classical ones: risk avoidance and reduction, risk-sharing or retaining. The process documentation must record the decision to retain or share risk. Therefore, ISO/SAE 21434 explicitly allows risk acceptance up to a certain level, as long as this threshold and the retained risks are documented.

Like UNECE No. R155, the ISO does not provide possible methods for risk treatment.

III. SECURITY DEFENSE REQUIREMENTS

Our taxonomy of security requirements (see Figure 1) has three different categories: the origin, the type as well as the defense methods. The objective of the taxonomy of security requirements is the use in the risk treatment step. Therefore, the scope is on those requirements that apply to the vehicle and directly influence its behavior. Process requirements (e.g., audit, testing) and supporting processes (e.g., documentation) are related to the ecosystem in the development process and therefore excluded.

A. Related Work

In [4] the authors define several levels for the selection of defense methods. Their categorization is more detailed than our approach, e.g., to the circuit level. Since, in practice, the risk analysis for components is done based on a selected hardware platform, certain levels for hardware cannot be taken into account anymore. Therefore, we decided on more abstract and less detailed control categories. The basis for their approach to risk treatment is a rich and detailed data model. The data model allows a very comprehensive analysis of dependencies between defense methods. On the other hand, this also demands to use their entire framework for the security process. Otherwise, the demanded input data model may be impossible to acquire.

Pfleeger [5] describes a categorization of defense methods. The main categories are encryption, software, hardware, and physical. Typically, encryption is no stand-alone method but a feature of another defense method, e.g., secure boot, TLS. Physical controls like locks on doors are not applicable for vehicle security. Pfleeger integrates defense methods implemented as separate functions like intrusion detection systems and password checkers into software and hardware levels. We decided to differentiate between the level the control has its impact and the technical and functional control categories. Those include all applicable controls Pfleeger mentions, just in a different categorization.

Also [6] describes the categorization of security requirements into different layers. Those are regarding the point where the information lies: internally, externally, or both. Additionally, Chung differentiates between the development stage of the scope of the methods. We concentrate only on the run-time stage of the system and leave process demands aside. Procedural methods cannot be assigned to the system in the risk treatment step but accompany the complete development process. Therefore, they are in the scope of development process design, which is a separate topic.

The literature review of Akhunzada et al. [7] results in a thematic taxonomy regarding the different layers of software-defined networks. The categorization is very comprehensive but not transferable to other system domains. We aim for a more pragmatic taxonomy easily adaptable to other system types.

[8] presents another taxonomy based on literature research. The scope of this work is restricted to software integrity protection techniques. Different system views build the basis for the categorization: system view, defense view, and attack view. The evaluated literature is mapped onto the views and correlations are evaluated. Nevertheless, besides the different scopes, the granularity of the taxonomy is not helpful for our approach. We aim for a flexible approach to clarify the terminology needed for risk treatment to use it for the defense method assignment.

B. Origin

Security Requirements arise from different sources. Those are general conditions and system-related requirements. The former depict system external sources while the latter arises from the security analysis of the target of evaluation.

a) *General conditions*: General conditions are related to the vehicle type. They may not directly support accomplishing a security goal, but non-fulfillment provoke a mission failure.

The most critical source for those requirements is regulatory organizations. Norms like UNECE No. R155 [3] and ISO/SAE 21434 [1], but also country-specific regulations like GB/T 40856-2021 [9] demand certain types of security requirements in a varying level of detail. Examples are the intrusion detection system demand of UNECE No. R155. Those regulatory requirements are relevant for the type approval of the vehicle type. Therefore, a non-accomplishment endangers the possibility of selling the vehicle type, at least in certain countries.

Security-in-depth and security-by-design demand to define certain basic security standards on organizational level [10]. Those are also a source for general conditions. A non-accomplishment of the company policies does not lead to the loss of type approval but endangers the company's internal vehicle audit, e.g., during testing. Also, company policies may have a varying level of detail from distinct methods in a certain variation to general demands.

The nature of general conditions is that they have varying levels of detail. They may not explicitly project to specific defense methods but categories of those. Therefore, they may not directly support accomplishing a security goal (e.g.,

Confidentiality) to a certain degree but demand a defense method that supports this goal. One idea is to formalize them in a logic-based language to define the projections from the policies to their varying level of detail in the defense method catalog.

b) *System-related Requirements*: Requirements that arise from the target of evaluation are system-related. Those depict the necessity for defense methods against the risks evaluated in the risk analysis.

The system-related requirements are distinct since they base on specific risks according to threats against security goals and impacts regarding their damage and attack potential. Therefore, system-related requirements are refinable until they demand a defined variation of specific defense methods.

C. Types of Security Requirements

The type of security requirements defines the nature of the security requirements. The taxonomy categorizes them into those directly recognizable in the resulting system or not.

a) *Measures*: Measures are those requirements that are not directly recognizable in the system. They instead depict system design methods that can be non-technical, procedural, or logical methods against violating a security goal. Examples are the prevention of specific information flows or removing unused software libraries instead of applying expensive defense methods. Measures are typically general conditions or system-related requirements applied to the system during the development process. They are not directly used in the risk treatment step but are rules to verify after risk treatment.

b) *Controls*: Controls are requirements that are directly or indirectly recognizable in the system. Risk treatment refines those requirements till they depict specific defense methods in certain variations. Controls accomplish the means of risk treatment: reduce, detect, or avoid risks entirely. Examples are safeguards on all system levels like access control, Intrusion Detection Systems or secure communication protocols.

The different layers of the controls represent the defense-in-depth onion model: structural, technical, and functional controls. Structural controls are related to the overall system structure, e.g., network segmentation. They answer the question - How does the system structure look to avoid specific threats? Technical controls defend threats from the internal processing or component side. Examples are controls preventing the manipulation of software at rest or during run-time. Functional controls complete the onion model by providing defense on function level. Those controls define the behavior of connections to and within the system, e.g., with communication protocols and access controls.

D. Method categories

The last part of the security requirement taxonomy are the categories of defense methods. Those categories are dependent on the development project and are adjustable for every vehicle type in automotive development projects. This adjustment ensures that the categories are up-to-date and complete.

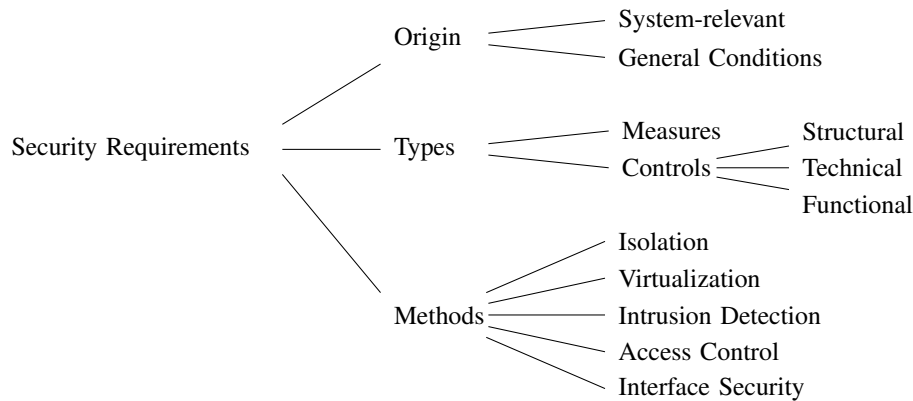

Fig. 1. Taxonomy of security requirements split into origin, types and methods.

In principle, the categories depict classes of defense methods and allow a more straightforward assignment in the risk treatment process. One suggestion is to align the classes with the general conditions, e.g., intrusion detection, isolation, and segmentation. Examples of typical classes for automotive development projects show Figure 1 without a claim for completeness.

E. Catalog of Defense Methods

The presented taxonomy allows a cross-product of types and method categories by assigning concrete defense methods (see Table I).

The assignment clusters the set of available defense methods into the categories from the taxonomy and annotates them with the type of control. Demands from general conditions like state-of-the-art cryptography do not lead to measures assigned to the list of defense methods. Those demands instead limit the scope of the available methods, e.g., non-appropriate cryptographic procedures are not part of the assignment.

Defense methods may be configurable, e.g., secure service-oriented communication (sSOA) with SOME/IP or SOCKS. Those variations can be directly included in the catalog or hidden as variants in the properties of the method. Encryption types are not direct defense methods but used by defense methods, e.g., secure communication protocols. They are therefore variants of the using method.

Defense methods may have no direct impact on the security goals. The impact may be emergent only in combination with other controls, e.g., a hardware security module (HSM) is only helpful in combination with a defense method that uses the cryptographic algorithms and the secure key storage provided by the HSM. Therefore, those methods are not included in the catalog but are variants of the defense method. An example would be TLS in combination with a present HSM [11]. In this case, there would be at least two variants of TLS, with and without an HSM present.

The catalog of defense methods is also subject to change. The catalog needs to be updated and refined in every development cycle, e.g., every vehicle type. Arising new threats

TABLE I
CLASSES AND IMPLEMENTATIONS OF DEFENSE METHODS. COLUMNS ARE THE TYPES OF CONTROLS (S=STRUCTURAL, T=TECHNICAL, F=FUNCTIONAL). ROWS INDICATE THE CLASS HIERARCHY AND EXAMPLES FOR CONCRETE IMPLEMENTATIONS. X INDICATES THAT THIS IMPLEMENTATION CAN BE USED FOR THIS CONTROL TYPE.

Implementations		Control Types		
		S	T	F
Isolation	NW Segmentation			
	VLAN	x		x
	Physical	x		
	Firewall	x	x	x
	Host Segmentation			
	CPU		x	x
Virtualization	SOA Domain			
	Hypervisor			
	Sandboxing		x	x
Intrusion Detection	Runtime			
	IDS	x	x	x
	Logging			x
	Runtime Protection		x	x
	Startup			
	Secure Boot		x	x
Authenticated Boot		x	x	
Interface Security	Communication			
	Secure SOA			x
	TLS			x
	IPsec			x
	SOK			x

may lead to changes during a development cycle. In this case, the responsible security engineers need to be informed about deleted methods and possible substitutions. This accounts also to other system types [10].

F. Properties of Defense Method

Defense methods mitigate threats to security goals. It is possible to derive the threat and damage scenario type from the targeted security goals. Therefore, it is better to assign the security goals as properties of the defense method rather

than the threat and damage scenario types. Following that, the impact on the different security goals is part of the properties. In [5] a range from -2 to +2 for each security goal is suggested. The positive part depicts the advantages of the defense method on security goals, while the negative part illustrates that defense methods may negatively influence certain security goals.

The definition of the effect on the attack potential and types of damage scenarios illustrates a defense method's influence on specific threats. This step reuses the method from the risk analysis, for the attack's potential impact may include the influence on the needed time, knowledge, tools, expertise, and access of the attacker.

The surface, as well as the dependency properties, limit the applicability of defense methods. The surface is regarding the attack surface, which this defense method mitigates. Dependencies relate to supporting processes needed from the technical side for this method (variant) to work or the limited scope of a defense method, e.g., VLAN technology is only applicable for Ethernet LAN.

It is possible to also assign costs for the defense method. Those represent the resource usage in the case of implementing this method. Examples would be processor clocks per byte in the case of DES [12]. In [11] different ways to derive the costs for cryptographic algorithms and examples are provided. Cost definitions allow to include risk treatment directly into resource scheduling procedures [12] which is out of scope in this work.

The different variants of a defense method have their properties assigned. Table II provides an example for securing JTAG. The two variants are disabling JTAG physically, which is the most secure variant but highly influences availability of the system. On the other hand is JTAG security by utilizing cryptography, e.g., SSL [13] which has a compared high effort.

TABLE II
EXAMPLE OF DEFENSE METHOD PROPERTIES FOR SECURING THE JTAG PORT WITHOUT CLAIM FOR COMPLETENESS. THE VALUES FOR COST, IMPACT AND EFFECT ARE VARIABLES TO ASSIGN BASED ON THE GIVEN SETUP.

	Property	Variants	
		Physical (Disable)	Cryptographic
	Technology	JTAG	JTAG
	Costs	0	?
Impact	Confidentiality	+2	+1
	Integrity	+2	+1
	Availability	-2	-1
	Surface	Local	
	Dependencies	-	SSL
	Effect	RAP: ?; DP: ?	

IV. RISK TREATMENT

The goal of risk treatment is twofold: Minimizing the risk, which means reducing the costs of non-implementation of defense methods, and minimizing the effort by reducing the costs of implementing defense methods.

In the security requirement taxonomy, general conditions are relevant for the type approval and/or necessary to fulfill OEM demands. Therefore, their costs for not-implementation are infinite. On the other hand, the costs for implementing general conditions are most of the time variable. They are typically related to categories of defense methods. Therefore, the implementation costs depend on the chosen method of the respective category. For system-related requirements, the costs of not-implementation need to be traded against the implementation costs. In the case of low-rated risks, it may be cheaper not to implement costly defense methods.

Also in settings where the direct implementation costs cannot be taken into account, risk treatment needs to take into account those cost-related problems. This can be done by reducing the overall number of defense methods through structured method assignment, e.g., by first cutting attack paths before treating the complete risk. Another possibility is to assign methods which impact several security goals at once instead of using a method per security goal.

The remaining section proceeds through the complete risk treatment process. Because of the already discussed problems with acquiring the costs of defense methods, we count for efficiency through a structured method assignment, and illustrate possible trade-offs and optimization points.

A. Prerequisites

According to ISO/SAE 21434 [1] risk treatment is related to identified risks and attack paths of the target of evaluation. Concrete, those risks whether the impact is against the road user. While it is possible to consider other impact categories, we will concentrate on those risks. The treatment of other risks is subject to by-catch of assigned methods and trade-offs.

The risks, threats, and attack paths, as well as their impact, are analyzed in the risk analysis step. There are different ways to complete this predecessor process step. Prominent are integrated approaches, e.g., MoRA [14] in the automotive world, or approaches developed for different sub-steps of risk analysis, e.g., attack trees [15] [16] [17] for attack path identification and rating.

For the presented approach, it is reasonable to evaluate the risk values in the risk analysis threefold: The risks against the road user, the OEM, and combined. Those three risks allow different options for trade-offs during or after method assignment. According to damage potentials and assumptions are outputs from the risk analysis steps in ISO/SAE 21434. Assumptions may be regarding the importance of specific damage scenarios and threats or related to other items' security process results. Therefore, they must be considered in the risk treatment because of their impact on threats and damage scenarios and traced for later verification steps.

B. Strategy

In general, risk treatment should be done holistically over the complete system. A global approach demands formal constraints for all defense methods and a distinct format for the input data. The latter is a big problem, especially in distributed

development environments like the automotive industry. Also, clearly defined tools for risk analysis allow different levels of abstraction and typically use natural language to formulate the damage scenarios and threats. Therefore, the bigger the input space for the risk treatment, the more significant the divergence between the input data. This divergence is also because the automotive environment's functionalities and components are diverse. The vehicle combines service-oriented functionalities with hard real-time classic development strands. This problem is minor on a lower level of abstraction, e.g., on the component level. Single components typically combine functionalities from similar development strands and complexity. Therefore, their analysis results are less diverse. Nevertheless, a global brute force approach would lead to a state-space explosion due to the nature of such NP problems.

Another strategy could be to assign all possible defense methods on component level to minimize the impact of a threat. On the one hand, less can be more depending on the defense methods. Assigning more defense methods leads to higher costs and might even lead to new risks to the system. Also, automotive systems are embedded systems with limited resources. Therefore, more defense methods than needed might leave the system infeasible.

An even lower level of abstraction would be assigning the defense methods in the decomposed system to each evaluation target individually. This strategy has the lowest probability of a state-space explosion and is accomplishable by brute force leading to an optimal solution for the different evaluation targets. On the other hand, a complete individual risk treatment might lead to various defense methods deployed to one component and its functionalities. The result is high costs for implementing defense methods and high resource usage, which might leave the system infeasible.

A good strategy for efficient and cost-effective risk treatment is a component-level heuristic approach. The defense methods are assigned where needed based on prioritizing the threats on the system. A by-catch test reveals a positive impact of the defense method on other component parts or functionalities.

a) Possible Heuristics: Related work reveals different possible heuristics for risk treatment. Ruddle et al. [15] present the straightforward idea of highest risk first. Risk is a combination of the damage potential and the required attack potential of the attack path and allows a global ranking of the relative priority. What is not possible is detailed heuristics which, e.g., prefer certain types of damage potentials.

In [10] a prioritization according to the highest impact or the highest likelihood first is suggested. Such a prioritization enables a ranking of risks according to the impact regarding their damage or the attack potential. Depending on the level of detail of the input model, this approach allows even heuristics with several layers, e.g., highest safety impact first.

A prominent approach for risk treatment are the defense-in-depth layers [10]. The idea is to assign defense methods from different types onto the system in order to have an onion-like security defense. While this approach leads to the stated cost

and state-space problems when done globally, the idea can be covered in heuristic approaches by iterating through the defense method types.

Another idea is to group security requirements according to viewpoints [11], e.g., according to the user's view on the system. This approach is highly dependent on the input data model. Therefore, this approach must be integrated into a method suite where the risk analysis produces the according to output. If so, the approach allows, in principle, the same heuristics as highest impact/likelihood first.

We have not found an approach that talks about the influence of attack paths with only one element. That *single risks* are either single points of failure (using the reliability language) or preparation attacks. The first case is essential to solve since these attack paths have only one step to accomplish. For the latter case, prioritizing single risks mitigate parts of several attack paths. This prioritization reduces the overall effort for risk treatment.

b) Heuristic Layers: We propose to use a combined approach as a heuristic. We prioritize single risks before tackling the highest impact first. Also, we state to use the defense-in-depth idea to assign methods from as many control types as possible to result in a layered security defense model.

The prioritization allows the extension to varying levels of detail. Possible additional layers are regarding specific impacts, e.g., safety, or likelihood impacts, e.g., certain attack surfaces, time, or knowledge level first.

C. Input Data Composition

The predecessor step of risk treatment is risk analysis of the decomposed system. An example would be separate risk analysis for each function, and the component in a function-oriented development environment.

Those different risk analysis results need to be composed and prepared for risk treatment in a single model per component. Good preparation allows to allocate defense methods on different abstraction levels and directly test for by-catch in other system parts. In the case of hardware isolation, there should be a grouping according to the units of isolation, e.g., different CPUs or existing virtualization. Otherwise, defense methods' influence or dependencies cannot be determined appropriately. Including the communication paths enables the validation of the defense methods between different communication partners.

Risk treatment according to ISO/SAE 2134 allows excluding those risks or even targets of evaluation whether the risk is below a defined threshold. Nevertheless, defense method assignment on the complete set of risks enables tracing the by-catch of excluded risks and evaluating their resulting risk level. This approach might reveal that even those risks are mitigated onto a deficient level or even entirely and by that follow the rule that someone will carry out every threat [15]. Therefore, the method assignment in our approach takes place on the relevant risks while a final by-catch test allows to have a complete overview over the remaining risk levels.

Depending on the risk analysis method, there are different ways to prepare the input data. Attack trees in the risk analysis lead to a forest of attack trees (one for each threat). The composition of those forests from the different evaluation targets leads to an extensive set of attack trees. Those directly allow deriving cut sets which can be weighted according to the impacts, e.g., attack potential, damage potential, risk. Prioritizing the weights in the assignment step allows efficient allocation of defense methods to the different threats. Depending on the defense methods' influence, this assignment reduces the weights or deletes elements from the cut sets.

Integrated risk analysis approaches have pre-defined data models that might not allow deriving attack trees and using their cut sets to allocate defense methods. In this case, look-ups and filters on the input data, e.g., for risks with a high safety impact, determine the weights. This method might seem more complicated but is automatable in most cases.

D. Approach

Following the presented taxonomy, the approach is twofold. The first step is regarding the general conditions and therefore demands necessary to fulfill. The second step accomplishes the system-related requirements.

a) *General Conditions*: Security requirements from the general conditions have to be applied to all security-relevant items. Therefore, they need no heuristic approach. They can be either applied by hand or by formally defining the rules for assignment, e.g., in a logical language.

General conditions may lead to the assignment of defense method categories (e.g., network segmentation, intrusion detection) or detailed methods (e.g., whitelist firewall on each Ethernet node).

b) *System-related requirements*: For the system-related defense methods algorithm 1 uses a set of *risks* as input. Each risk (line 1) is a set consisting of the *threat*, the *attack path*, the relation to the *item element* and applied defense methods (*applied_means*). The set *applied_means* may not be empty at the beginning since in former development steps already defense methods (e.g., structural network segmentation) may be assigned.

A risk's value is determined by the function *CRITICALITY(risk)* (algorithm 3) which combines the impact functions *DAMAGE_POTENTIAL(risk)* and *REQUIRED_ATTACK_POTENTIAL(risk)*. Those provide the impact level as well as the feasibility test for the defense methods. Please note, that for reasons of space those functions are not defined in detail in the algorithm.

The idea of the algorithm is to assign defense methods to the set of relevant risks R_{rel} as long as their risk value is above the defined threshold *criticality_threshold* (e.g., low).

In the first loop (line 5-8), all risks without an assigned attack path are evaluated. Those are single points of failure or preparation attacks. After they are mitigated, the remaining risks are evaluated in descending order of their impact (second loop, line 10-13).

Function *ASSIGN* (algorithm 2) shows the assignment of defense methods. As long as the risk under consideration is not below the threshold it tries to find a defense method *dm* and assigns it to the risk (loop line 5-23). Through the impact functions (line 10-13) the algorithm tests whether feasibility and properties of the method fit the risk. Therefore, it also takes dependencies and the technology into account. In this step, methods with the highest impact on the risk value are assigned. Other heuristic layers lead to new iteration conditions which can be easily integrated.

To find a defense-in-depth solution, which means using all control categories, the algorithm iterates over the structural, technical, and functional defense methods (line 5, 20, 22) until the risk is mitigated or no possible method is available (*fail* = 3). Other possibilities would be to use as many methods as possible from each category or until the impact is below a defined threshold. Both possibilities have a high probability that only structural defense methods are assigned which is against the defense-in-depth onion model.

In the case where a risk cannot be mitigated, the threat remains in the resulting risk value (line 24). Depending on the type of damage (Safety vs. Financial), other possibilities have to be found for mitigation, e.g., change deployment, add isolation. Therefore, the algorithm leaves this risk for dealing otherwise with it and excludes the risk from the set R_{rel} . This problem should be a corner case since the defense method catalogs provide a variety of possibilities. Nevertheless, such situations are also possible in non-automatic risk treatment procedures.

After each successful assignment, the function tries to assign the defense method to other risks (line 16-18). The assignment test in the impact functions adhere (depending on the defense method) to the units of isolation of the component. For example, a run-time protection mechanism on a virtual machine is only applied to other functions on the virtual machine. This component global assignment applies the by-catch test not only on attack paths but also on component level.

Before mitigating the next risk, the algorithm updates the set of relevant risks R_{rel} .

c) *Trade-offs*: There might be a situation where defense methods with equal impact are possible to assign. The algorithm currently uses the first method found and assigns it to the threat. Without considering costs, other defense methods could be annotated as possible substitutions, leaving the option for the security engineer to swap them.

Defense methods may have several different variants. The algorithm uses the variant with the highest impact. Therefore, one trade-off point is to mark those variant points and annotate the different impacts. The security engineer validates the results and adjusts the method variant to the preferable one. We follow the approach to have a more secure variant than less instead.

Algorithm 1 Handle risks against road user with system-related requirements**Require:**

- 1: risks as array of threat \times attack_path \times Item_element \times applied_means \triangleright at start, for all risks: applied_methods can be $= \emptyset$
- 2: criticality_threshold
- 3: means \triangleright all available means to possibly increase security

Ensure: $\mathbb{R}_{rel} = \emptyset$ \triangleright relevant risks

- 4: $\mathbb{R}_{rel} \leftarrow$ all elements r of risk with $CRITICALITY(r) > criticality_threshold$
- 5: **while** risk $\in \mathbb{R}_{rel}$ with empty attack path exists **do**
- 6: ASSIGN($\mathbb{R}_{rel}, current_risk, criticality_threshold, means$)
- 7: $\mathbb{R}_{rel} \leftarrow$ all elements r of risk with $CRITICALITY(r) > criticality_threshold$
- 8: **end while**
- 9: **repeat**
- 10: $current_risk \leftarrow$ element of \mathbb{R}_{rel} with maximal DAMAGE_POTENTIAL($current_risk$)
- 11: ASSIGN($\mathbb{R}_{rel}, current_risk, criticality_threshold, means$)
- 12: $\mathbb{R}_{rel} \leftarrow$ all elements r of risk with $CRITICALITY(r) > criticality_threshold$
- 13: **until** $\mathbb{R}_{rel} = \emptyset$

Algorithm 2 Assign defense methods to the currently processed risk.

- 1: **procedure** ASSIGN($ref \mathbb{R}, ref current_risk, criticality_threshold, means$)
- 2: **const** means_category \leftarrow [structural, technical, functional]
- 3: $i \leftarrow 0$
- 4: $fail \leftarrow 0$
- 5: **while** $CRITICALITY(current_risk) \geq criticality_threshold$ & $fail \neq 3$ **do**
- 6: $highest_impact \leftarrow 0$
- 7: $highest_impact_mean \leftarrow none$
- 8: **for all** $dm \in means$ **do** \triangleright find mean with highest impact
- 9: **if** $CATEGORY(dm) = means_category[i]$ & $dm \notin current_risk.applied_means$ **then**
- 10: **if** $CRITICALITY(current_risk \text{ with } dm \text{ applied}) > highest_impact$ **then**
- 11: $highest_impact_mean \leftarrow dm$
- 12: $highest_impact \leftarrow CRITICALITY(current_risk \text{ with } dm \text{ applied})$
- 13: **end if**
- 14: **end if**
- 15: **end for**
- 16: **if** $highest_impact_mean \neq none$ **then**
- 17: Apply $highest_impact_mean$ to $current_risk$
- 18: Apply $highest_impact_mean$ to all elements of \mathbb{R} where it can be applied
- 19: **else**
- 20: $fail \leftarrow fail + 1$
- 21: **end if**
- 22: $i \leftarrow (i + 1) \bmod 3$
- 23: **end while**
- 24: **if** $fail = 3$ & $CRITICALITY(current_risk) \geq criticality_threshold$ **then**
- 25: Deal otherwise with $current_risk$
- 26: $\mathbb{R} \leftarrow \mathbb{R} - current_risk$
- 27: **end if**
- 28: **end procedure**

Algorithm 3 Determine updated risk from damage potential and required attack potential.

- 1: **function** CRITICALITY(risk)
- 2: **return** DAMAGE_POTENTIAL(risk) \cdot REQUIRED_ATTACK_POTENTIAL(risk)
- 3: **end function**

V. DISCUSSION

The presented approach is just a starting point for further possible extensions. Therefore, there are some limitations. Also, there are further possible trade-offs when transferring the idea to other system types.

A. Limitations

Automatic assignments of defense methods always have the probability of misjudgment [18]. This limitation also accounts for the current version of the presented approach. Therefore, the result needs to be manually validated.

The current approach excludes compatibility validation of the assigned defense methods for interface security between different security partners. This limitation can lead to inconsistencies between communication partners. In vehicle projects, there are few different defense methods regarding communication interfaces. Also, vehicle software functionalities distribute onto different components. Therefore, a corner case should be items where the communication partner is another functionality on a different component not providing the demanded defense method.

Without an architectural verification method in place, the assumptions regarding communication partners' security risk levels, e.g., secure back-end, need to be verified manually. This verification includes several steps:

- Whether a risk analysis for the communication partner exists.
- If the risks targeted by the assumption are covered
- If the risk treatment properly mitigates these risks.

The risk treatment step results are typically imported into an integrated modeling tool that illustrates the complete vehicle architecture. This process reveals inconsistencies in defense methods between communication partners. Also, assumptions regarding the security level of a communication partner are verifiable in this model.

B. Optimizations

The algorithm in the current form prefers methods that have the highest impact on all threatened security goals. This priority led to the assignment of defense methods that impact more than one security goal before the others. Typically it is cheaper to implement one costly defense method, which impacts more security goals, than to implement several defense methods which target fewer security goals. Nevertheless, this preference might lead to higher costs in some cases. Including the implementation costs into the assignment leads to a higher state space and a more optimal solution regarding the costs.

On the other hand, it is costly and challenging to achieve the implementation costs of the defense methods. Since, for some defense methods, the costs are hardware and implementation-dependent, the costs change for each hardware type. Average costs might prevent this problem while still optimizing the assignment. At least for each vehicle project, the costs have to be newly evaluated when the defense method catalog is updated.

ISO/SAE 21434 clearly defines impacts only to the road user. Therefore, the current version of the algorithm mitigates only threats with an impact on the road user. Typically, threats have an impact on both stakeholders to a varying degree. Only a few threats remain untreated by targeting the threats with impact against the road user. Those are only regarding the OEM, or the impact against the road user is less than the threshold while the impact against the OEM is above the threshold. Untreated threats might benefit from assigned defense methods. A global by-catch test on the complete list of threats reveals such situations. Nevertheless, this is a possible point to optimize the system setup. A second threshold for the OEM impact allows a second run of the algorithm over those threats. Combined with a cost limit OEM-related threats could be mitigated to a certain degree.

For other system types, not every risk needs to be mitigated, e.g., in IT security. In those cases, other trade-offs in the risk treatment are possible, for example: by weighting the attack potential categories or damage potential categories. Other possibilities are to mitigate just certain threat classes.

VI. CONCLUSION AND FUTURE WORK

The presented paper aims to make a step toward an efficient and traceable risk treatment method for automotive development projects, transferable to other system settings. At first, we defined an adjustable taxonomy for the terminology of security requirements. By that, we address the problem of differing terminology in practice and literature. The taxonomy enables building up a database like defense method catalog. Regular updates of the catalog incorporate newly revealed threats.

Our approach for risk treatment has high flexibility regarding the input data. We use general information from risk analysis instead of detailed data models. With this approach, we trade practicability against fine-granular defense method assignment. We know that this approach limits the verification possibility on the architectural level and leaves this for the pen-testing process step. Nevertheless, we think that a pragmatic approach that might overestimate the risks in corner cases with less effort is cheaper in the overall process.

Also, the approach can incorporate different origins of defense methods. Normative and organizational security demands need to be adhered to in the development. Otherwise, the system is infeasible from those points of view. Therefore, we differentiate between those security demands and risks revealed in the risk analysis step. On the one hand, this distinction allows tracing the source of assigned defense methods. On the other hand, this enables trade-offs in the assignment of system-related defense methods.

Efficient risk treatment demands a particular structure in the assignment process. Therefore, we mitigate threats without attack paths first. Single threats are either single-points-of-failure or preparation attacks. The former need mitigations for a high-security defense. The latter have a high by-catch rate since they directly cut attack paths. After that, we prioritize the attack path with the highest impact against the road user.

The decision for the highest impact first, as well as other trade-off points, is easily adjustable. Our approach basis is a heuristic that allows for different trade-offs and cost inclusion.

Especially the incorporation of costs is part of significant future work. Although the costs of the different defense methods are challenging to obtain, they allow optimization and trade-offs in method assignment.

Other future work is regarding the discussed limitations. We aim for a method to incorporate the compatibility between the different components and verify assumptions. This method demands a verification approach on the architectural level refined throughout the complete development process. For that, preliminary work exists [19] [20] [21], which we now want to develop further.

An open question is regarding the incorporation of the negative influence of defense methods on other functionalities [18]. This influence is crucial, especially in optimized and resource constraint systems like the automotive industry. One idea would be to include this in the mentioned verification approach. If the model allows behavioral verification of all system parts, the influence of defense methods can be directly composed into this model.

Universal Key to Authentication Authority with Human-Computable OTP Generator

Sławomir Matelski

 s.matelski@intelco.pl

Abstract—The subject of this paper is an enhanced alternative to the Multi-Factor Authentication (MFA) methods. The improvement lies in the elimination of any supplementary gadgets/devices or theft-sensitive biometric data, by substituting it with direct human-computer authentication optionally supplemented by cognitive biometric. This approach remains secure also in untrusted systems or environments. It allows only one secret as a universal private key for all obtainable online accounts. However, the features of this new solution pretend it to be used by the Authentication Authority with the Single-Sign-On (SSO) method of identity and access management, rather than for individual services. This secret key is used by our innovative challenge-response protocol for human-generated One-Time Passwords (OTP) based on a hard lattice problem with noise introduced by our new method which we call Learning with Options (LWO). This secret has the form of an outline like a kind of handwritten autograph, designed in invisible ink. The password generation process requires following such an invisible contour, similar to a manual autograph, and it can also be done offline on paper documents with an acceptable level of security and usability meeting the requirements for post-quantum symmetric cyphers and commercial implementation also in the field of IoT.

Index Terms—authentication, lattice, OTP, secret key.

I. INTRODUCTION

DUE TO the growing threat of cyber attacks, multi-factor authentication (MFA) or the two-step verification has recently become a cybersecurity standard.

Step 1 - comprises entering a user ID and static password. For security reasons, it is recommended to use different passwords for each online account. As a result, users often adopt insecure password practices (e.g., reuse or weak password) or they have to frequently reset their passwords. Blocki et al. introduced in [7] an innovative Human-Computable Passwords (HCP) scheme, which ensures that even if an adversary has seen one-hundred of the user's passwords still has high uncertainty about remaining passwords. The disadvantage of their scheme is the need to memorize dozens of pictures, mapping to numbers with the help of associated mnemonics.

In such an HCP scheme the user reconstructs each of his passwords by computing the response to a public challenge, by performing simple mathematical operations i.e. addition modulo 10. A similar approach to the idea of password computing is used by our iChip protocol inspired by the topography of electronic microchips and handwriting (Fig. 1).

Fig. 1. Topography of: microchip, iChip, handwriting.

It requires much less effort to remember the secret in the form of only one (but detailed) picture, and only half the time for authentication. As we show in Section VI, it guarantees a safe generation of many thousands of such passwords. What follows, it can be used as an OTP generator as well.

Step 2 - requires usually an additional electronic device (using the same device in both steps may not be safe), that uses an embedded one-time password (OTP) generator or biometrics. In such cases, the OTP is entered into the verification system automatically, e.g., from a smartcard or an IoT device, or by the user after being read from the screen of a token or personal smartphone via SMS or special application. Unfortunately, this solution does not ensure that the device is being used by its owner; it must be always available, and can be stolen, lost, damaged or cloned. Biometric methods are an alternative, but these can be relatively easily cheated by *replay attack* using snooped biometric data, and with help of machine learning or AI algorithm if necessary [18].

The MFA obviously requires more time than entering a regular static password. Therefore, a human generated OTP protocol with comparable authentication time and sufficient security, eliminating the long list of drawbacks mentioned above, stands a chance of mass user acceptance.

Many attempts to achieve this goal have been made for over 30 years since Matsumoto's first publication [1] in 1991, but only two protocols have been commercially implemented: HB presented by Hopper and Blum in [2] and GrIDSure (GS) presented in [19]. We will show further that our iChip scheme has security properties better than HB and usability close to GrIDSure, while eliminating their drawbacks.

- The HB is based on the Learning Parity with Noise (LPN) method, which ensures a high level of security, but the time of ca. 668 sec. needed for authentication by a human is too long to be acceptable. Nevertheless, the properties of this protocol or later improved variants (HB+, HB#) are well suited to applicate in resource-constrained devices, such as Internet of Things (IoT) devices or RFID.

- The GrIDSure scheme has exactly the opposite properties confirmed in [19]: the high usability level and very low level of safety, as only 3 samples of challenge-response pairs are sufficient to reveal the secret. In addition, the entropy of this scheme is also low, as detailed research has shown, that users choose secret patterns that are easy to remember and frequently reused, so its scheme is highly vulnerable to dictionary attacks, as the choice is very limited due to the small grid and the small number of secret objects. The only effective improvement proposed in [20] is the use of a few secrets switched by the Out-of-Band (OOB) channel, but that requires the employment of an additional device that we intend to eliminate.

The iChip has similar usability properties to GrIDSure as the secret pattern of cells in the grid is employed by both schemes. However, the similarity is noticeable only in the so-called generator block. The most significant difference lies in the extraordinary mapping method used in iChip, which makes a huge difference in the key space ($3e+5$ vs $3e+154$), and provides many thousands of times greater resistance against peeping attacks than GS. The conclusions about low practical entropy of GS do not apply to the iChip as getting all the easy-to-remember keys from such a huge key space is a task with a difficulty near to brute-force, which is not feasible for current supercomputers.

As mentioned above, the iChip is applicable also in step 1 of the MFA as one universal secret key to the creation of multiple original static passwords for each online account. However, the first step of MFA is redundant in this case as it relates to the same secret as the OTP generator. On the other hand, instead of the 1st step, we propose a discreet introduction of the 2nd factor in the form of cognitive memory using proposed in Section III-E, and Single Sign-On (SSO) method based on the OAuth2.0 protocol [23] under control of authentication server (as an Authenticating Authority) that owns the user identities and credentials, including the iChip secret key or container with multiple pairs of challenges and hashed OTPs.

The contributions of this work are: the challenge-response cryptographic protocol, based on lattice problem with noise, introduced by our Learning with Options (LWO) method as a more effective new variant of the LPN method of easy OTP computation by a human; a graphical interface for the implementation of that protocol, which allows the user to create his secret in the form of an easy-to-remember image, and a special wizard to compose it; both well-proven in usability and security study discussed after the presentation of mathematical rules, illustrated by examples of the iChip core and its TurboChip overlays; further protocol enhancement against active attacks and by cognitive memory usage.

The completed implementation can be tested in an interactive demo or viewed in a short film, either as a professional tutorial or an alternative version made by children participating in the research process; both available online [25]. It is much more effective to understand than a mathematical description.

II. LEARNING WITH OPTIONS METHOD AS THE MAIN STRENGTH OF THE PROTOCOL

An important element of the iChip scheme is the implementation of the Learning with Rounding (LWR) method, which is an LPN variant of worst-case hard lattice problem included in the lattice-based cryptography. The implementation of core LPN or Learning with Errors (LWE) methods increase the security of any protocol; however, the degree of usability is reduced, and authentication requires much more time, as the user has to perform additional protocol rounds to compensate for rounds lost to incorrect responses due to reduced resistance to random attacks. In contrast, the LWR and described below LWO methods requires only correct responses. The iChip uses Equation 1 in Section III-A, as its base function which satisfies the criteria of the LWR method of deterministic rounding by $x \bmod p$, where $p = 10$ is admittedly too small to effectively introduce noise, but convenient for human computation. This function is a node for the various protocol variants and for our proposed LWO method of introducing noise, which is far more efficient.

III. THE ICHIP AS AN OTP GENERATOR

The iChip is a challenge-response protocol to authenticate the user to the verifier using the shared secret, where the user has to answer the challenge generated by the verifier (server). The way the iChip scheme worked was inspired by the image of the photolithographic mask used to create conductive paths on the surface of PCBs (Printed Circuit Board) or ICs (Integrated Circuits) like shown in Fig.1. The user composes his secret by designing such a layout in a special wizard by drawing a map of blocks B of masking elements as paths conducting the digital signal from input to output; provided from the generator block. These paths will determine the change in value from V_{inp} at the input to V_{out} at the output and define their properties and mutual logical relations. This layer consists of $n \times n$ fields and is represented by the C matrix, containing $n \times n$ cells.

The user specifies his secret key S by specifying a list of b blocks that occupy the fields selected by him from the C matrix, and specifies the block elements that act as input or output. For a short and easy explanation, we will use the example of the secret key illustrated in Fig. 2 or Fig. 4 as an iChip layout and the matrix coordinates of the input and output elements encoded hexadecimal in the associated table, while for the description of the protocol, we will use the Python convention. The C matrix is a set of n^2 random values generated by verifier as $C = [[V_{1,1}, V_{1,2}, \dots, V_{1,n}], \dots [V_{n,1}, V_{n,2}, \dots, V_{n,n}]]$. Each i -th element of block $B[i] = [y_i, x_i, z_i]$ is defined by 3 parameters: row y and column x as field coordinates (y, x) in matrix C , and parameter z defining its state: $z = \{I, O\}$, where: $I = Input$, $O = Output$.

We use also an alternative compact notation of block elements as: $B_j^z[i] = B_j^z[(y_i, x_i)]$. Each block B_j is a list of such elements, divided into two segments for inputs and outputs: $B = [B^I, B^O] = [B[1], B[2], \dots, B[k]]$. A list of b blocks B_j is included in the secret $S = [B_0, B_1, \dots, B_{b-1}]$, where $0 \leq j < b$. The parameters of the algorithm are denoted by four positive integers $N, L, b, k \in \mathbb{N}$, where:

- chip size (the matrices describing both private part of the key and the challenge matrix have size $N = n \times n$);
- parameter describing OTP length, $L \leq 10$;
- maximal number of blocks, for the sake of clarity and memorability we restrict $1 \leq b \leq 10$;
- maximal block length $k \leq 10$;

A. Generating OTP

$G = B_0$ is the first of these blocks in key S , and it is called a generator because it does not contain inputs and the values $V_G = C[G]$ from all its $L = |B_0|$ output elements are mapped by the remaining blocks. The user has to remember the position of all blocks and their order in the S . The verifier generates a challenge matrix C of N random digits. To generate the OTP, the user has to collate the C matrix with the secret key S and calculate all OTP digits, one at each i -th of $L = |\text{OTP}|$ rounds of the protocol in the following 3 steps:

- 1) Read the V_{inp}^i value of the $G[i]$ element in C at position (y_i, x_i) : $V_{inp}^i = C[G[(y_i, x_i)]]$
- 2) Starting from j -th block (where $j = 1$ in the 1st round), search input elements ($z = \text{Input}$) of j -th block for the coordinates (y_i, x_i) such that $V_{inp}^i = C[B_j^I[(y_i, x_i)]]$. If no such coordinates are found in the j -th block, move to the subsequent block. By $j = \phi$ denote the index of the *current block* (ϕ) in which the searched so-called *target input* (ψ) has been found first and let

$$V_{out}^i = C[B_\phi[y, x, z = \text{Output}]].$$

If the search fails for all $j < b$: let $V_{out}^i = V_{inp}^i$.

- 3) The i -th digit of the OTP you will get as

$$\text{OTP}[i] = (V_{inp}^i + V_{out}^i) \bmod 10 \quad (1)$$

To avoid overloading the first blocks, it is recommended to resume the search for V_{inp}^i from the block next to the last searched. For additional security, the following three exceptions/rules (*I, *O, *Θ) have been added to the 2nd step of the algorithm; these significantly increase the resistance of the iChip protocol against passive attacks with a statistical algorithm or Gaussian Elimination. For their consideration let (y_i, x_i) be the coordinates on which the *target input* ψ in B such that $C[B_\phi[\psi]] = V_{inp}^i$ was found first in the challenge matrix.

However, first, we will present a simple example illustrated in Fig. 2 to explain the principle of calculating the OTP without the exceptions mentioned above. Alternatively, it is recommended to watch the short video tutorial [25].

Fig. 2. An example of a secret: block input elements given as black fields and output as blue or light blue fields. The positions of all input and output elements are hexadecimal encoded in the associated table. The first column (&) contains the index of each block. On the right: The challenge matrix.

There are generator block 0 containing 4 light blue cells in the matrix corners and two mapping blocks labeled by their index (1 or 2) in the example above (Fig. 2). In the 1st round, we read the value $V_{inp}^1 = 3$ from the 1st element of generator block at position (0, 0).

We look for this value sequentially in all mapping blocks from 1 to 2. The first occurrence of this value is in the last element of block 2, i.e. $B_2^I[5]$ in cell (6, 6), which is the *target input* $\psi = 5$ in the *current block* $\phi = 2$. Now, we read a value of the output element of this block, which is in cell (8, 4), hence $V_{out}^1 = C[8, 4] = 5$. The 1st round ends with a calculation of the 1st OTP digit according to Equation 1 as:

$$\begin{aligned} \text{OTP}[1] &= (V_{inp}^1 + V_{out}^1) \bmod 10 = \\ &= (C[G[0]] + C[B_2^O[1]]) \bmod 10 = \\ &= (C[0, 0] + C[8, 4]) \bmod 10 = \\ &= (3 + 5) \bmod 10 = 8. \end{aligned}$$

EXTRA RULES / EXCEPTIONS

*I) Let V_{inp}^i be the sum of all input elements of the current block, from ψ to $\psi + n$, where $\psi + n \leq |B_\phi^I|$ and $n \leq 2$:

$$V_{inp}^i = \left(\sum_{k=0}^{n} C[B_\phi[\psi + k]] \right) \bmod q \quad (2)$$

This introduces non-linearity to cryptanalysis and protection against Gaussian Elimination, as the number of arguments in Equation 2 varies randomly in each challenge. Depending on the variant of *I, the q modulus can be 10 or omitted as default.

*O) If the *current block* B_ϕ contains more than one output element $|B_\phi^O| > 1$, then randomly choose one of them as $V_{out}^i = C[B_\phi^O[\text{randrange}(1, |B_\phi^O|)]]$. This is the case of using the LWO method illustrated by Fig. 3: Block 2 with fields labeled by 2 has two outputs/options at positions (3, 1) and (3, 3). If the value searched for is found in this block, then the user has to choose one of these two options at random.

*Θ) If the *current block* B_ϕ has no output $|B_\phi^O| = 0$, then we use the next input instead: $V_{out}^i = C[B_\phi[(\psi + 1) \bmod |B_\phi|]]$.

Fig. 3. An example of secret with exception *O.

Fig. 4. An example of a secret defined by the user and challenge matrix with a schema for determining the 1st digit of OTP.

B. Advanced Example

Based on Fig. 4 we will compute the 6-digit OTP as follows: The generator block contains $V_G = C[G] = [3, 7, 8, 8, 6, 3]$. The 1st element $V_G[1]$ at position (0, 4) has a value of 3. When looking for it sequentially in blocks 1 to 6, it can be found in the 3rd input element of the 1st block $B_1^I[3]$ at position (6, 4), (marked in the red ring as a target input ψ); the output element $B_1^O[1]$ of this block is in cell (3, 3) with a value of 9. The 1st digit of OTP is calculated according to Eq. 1 as $OTP[1] = (3 + 9) \bmod 10 = 2$.

$V_G[2]$ at position (1, 5) has a value of 7, which is also in $B_4^I[2]$ at position (5, a) and the output element $B_4^O[1]$ has a value of 9. Since $\psi = 2 < |B_4^I| = 3$, then due to rule *I: $V_{inp}^2 = C[B_4^I[2]] + C[B_4^I[3]] = 7 + 1 = 8$. Now, according to Eq. 1 we can calculate: $OTP[2] = (8 + 9) \bmod 10 = 7$.

$V_G[3] = 8$ appears in $B_5^I[3]$ at position (c, 6), but this block has 2 output elements $B_5^O[1]$ in cell (d, 7) and $B_5^O[2]$ in cell (e, 7). Therefore due to exception *O, we can choose any of them; assuming we choose the first with value of 4, $OTP[3] = (8 + 4) \bmod 10 = 2$.

$V_G[4] = 8$, hence this round is similar to the previous one, but now, we use the second output $B_5^O[2]$ in cell (e, 7) for our calculations: $OTP[4] = (8 + 0) \bmod 10 = 8$.

$V_G[5] = 6$ appears in $B_7^I[1]$, but this block has 4 inputs, therefore we add three of them to $V_{out}^5 = 1$, hence: $OTP[5] = 6 + 3 + 4 + 1 \bmod 10 = 4$. Entire OTP = [2, 7, 2, 8, 4, 2].

C. TurboChip overlays for the iChip protocol

For a radical reduction of an authentication time, we have developed two variants of TurboChip overlays for the iChip scheme. They only uses 1 round of the base iChip protocol and only needs 1 element in the generator block. In the example below illustrated in Fig.5: Since $V_G = [4]$, then $OTP[1] = (4 + 2) \bmod 10 = 6$. However, we keep this value a secret as $V = 6$ and use it according to FlexiChip or ClickChip. For FlexiChip, we calculate each i -th OTP number as $OTP[i] = (V + C[B_\phi^I[\psi + i]]) \bmod 10$; If $|B_\phi^I| < \psi + i$ then continue in the next block. In this example: $\phi = 1; \psi = 3$, but $|B_1^I| < 3+1$, hence $OTP[1] = V + C[B_2^I[1]] \bmod 10 = 6 + 8 \bmod 10 = 4$; $OTP[2] = 6 + C[B_2^I[2]] \bmod 10 = 6 + 1 \bmod 10 = 7$; e.t.c.

The ClickChip generates response as matrix coordinates instead of digits. This approach requires a bit of proficiency from the user, however, it allows cutting the number of protocol rounds in half. It stands as a good trade-off for it and is explained in the example illustrated in Fig. 5. Determining of 3 matrix coordinates in the range of (-8, -8) to (8, 8), one at each i -th of 3 rounds of ClickChip protocol is as follows:

We go to the i -th element in $j = \phi + i$ block. Now, get the value of this element to calculate the distance of d_i fields, where $d_i = (V + C[B_j^I[i]]) \bmod 10$; to move the virtual pointer on a horizontal, vertical or diagonal line towards the centre of the grid. Important notes: The order of choosing these directions is random, but 1 diagonal and 1 reverse direction must be used if d_i is lower than the distance from the edge of the grid. For long blocks: If $|B_j^I| > 3$ then the counting of d_i cells starts from the element whose value is closest to d_i .

To quickly find the endpoint, move the pointer in jumps a 4 fields, with a help of the coloured background lines.

In our example, the current block $\phi = 1$, therefore, in the 1st round we go to block 2, and get the value of the 1st element in it, hence $d_1 = (6 + 8) \bmod 10 = 4$. Now, we move the pointer e.g., diagonal from a position (-1, -3) to position (3, 1). In the 2nd round $d_2 = (6 + 3) \bmod 10 = 9$, so we click the position (-3, -6). In the 3th round $d_3 = (6 + 7) \bmod 10 = 3$, but to satisfy the protocol rules, we alter the direction to the opposite $d_3 = -3$ and then click the cell (6, 6).

Fig. 5. Secret key and challenge matrix with the schema of the ClickChip for OTP determining protocol.

The variant with an 18x18 grid shown in Fig. 6 is more convenient for moving the pointer in jumps a³ fields. The worst-case probability of randomly hitting the correct OTP is here $p = 3/207 \cdot 2/207 \cdot 1/207 = 7e^{-7}$.

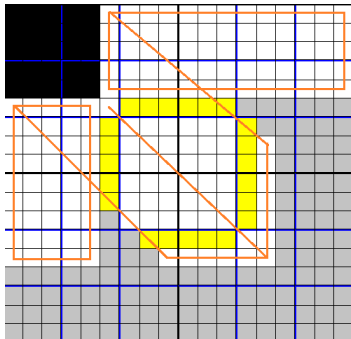

Fig. 6. ClickChip’s grid variant of 18x18 = 324 cells with 25 secret inputs marked in black and the non-clickable area marked in grey.

D. Preliminary stage against active attacks

In this stage, User U and Verifier V swap their roles, so V responds to U’s challenge. V initiates the authentication process by sending a challenge to U. Then, U randomly clicks on any field in C, and the element of the block closest to that field is used as ψ for the calculation of OTP[0]. U remembers it and sends such a challenge to V. In response, V has to calculate the OTP[0] in this same way, and then generate a new challenge, but the value of V_G[0] is set to OTP[0], which is hidden. The next 3 rounds run as usual according to ClickChip.

E. Biometrics, captcha and clock in the iChip scheme

To further strengthen the iChip protocol it is beneficial to increase the entropy of the random option selection in the LWO case by aid of a pseudorandom number generator, the result of which is entered via a cognitive biometric interface working like an OOB channel. This interface (emOTP) is based on the stimulation of emotional states by recalling the knowledge already acquired in the past and preserved in long-term memory. The great advantage of this approach is that the user is not required to remember a secret specially built for this purpose, so they can without much effort, insert a lot of such items into the user’s account profile resources in the form of catchwords or pictures, associated with its evaluation in points: +1 as positive, -1 as negative and 0 as neutral; referring to a universal question, e.g., *Do you like it?* with possible answers: *Yes, No, Neutral*. The response can be effortlessly applied to choose/address 1 of the 2 or 3 options when using the LWO method.

Increasing the range of ratings to 10 points requires changing the above question to *How much do you like it?*. Now, the response ranging from 0 to 9 allows the generator block to be completely replaced. Unfortunately, the limitation of such a generator is its inaccuracy, occurring from poor behavioural repeatability. Nevertheless, due to the LWO, the unintended

incorrect response to the emOTP challenge does not affect the response correctness. Hence, an additional protocol round to compensate for this mistake is not needed. In other cases than the LWO, such a 3 stage emOTP trigger/generator in the iChip protocol can be used as a biometric factor in the MFA. The emOTP criteria should be quick to evaluate and be personal, rather than popular and predictable. The challenge in the form of an image (as an example in Fig. 7) can work well as a captcha at the same time.

Fig. 7. An example of the emOTP challenge and its evaluation depending on the user and not on a statistical basis.

As an alternative and much simpler source of entropy for the LWO method, a random moment of reading seconds from the system clock or user’s watch can be used.

IV. ICHIP FOR A HASH-BASED SIGNATURE

To ensure that the user authorizes the correct message M (e.g. transaction conditions), and not falsified by active adversary, we propose the Human-Hashed variant of (hash-based) message authentication code (MAC). Such a HHMAC can be used offline, i.e. the previously computed SHA-256 function from M and written here as h() is hashed by iChip’s OTP. The iChip-256 variant with N=256 fields layout is the most optimal here. The challenge matrix C created by the RNG is modified by adding one bit of the hashing result H to each of the |C| = 256 elements, where $H = h(M, C)$ is the hash value of a message M and C according to the formula $C'[i] = (C[i] + H_2[i]) \text{ mod } 10$, where $0 \leq i \leq 255$. The user performs the signature by entering the OTP on the keyboard or writing OTP digits on the document containing: a blank iChip grid for global UID (optional), the challenge matrix C’, a QR code specifying the document identifier in the repository for automatic scanning and HHMAC verification.

Fig. 8. A sample signature on a paper document includes: Global UID, Transaction ID, HHMAC, Challenge C’.

V. BRIEF ANALYSIS OF USABILITY

- Intelligibility

Our time-limited study only focused on a small group of children aged 8-10, assuming that the adult performance should be better, because modular addition and abstract thinking are required, which develops with age [16]. For this group, the iChip protocol was compared with that of a board game, more especially the well-known Monopoly or Jumanji, where the throws of the dice symbolize the operation of the generator block, and all the fields on the board forming the track constitute the iChip blocks, which user have to go to achieve the target field/input and finally make a decision according to the rules of the game protocol. The children took 1 standard lesson unit (45') to learn the protocol and the special wizard to design their own microchip.

- Memorizing and Rehearsing

The appropriate distribution of block elements is of major importance for entropy level and easy memorization of the entire structure of the secret. To obtain the maximum practical entropy and to make it easier to remember the secret, a suitable background image is very helpful, which can be built individually by the user or proposed by the wizard as a random structure. It is profitable to draw the secret contours in a single sequence like a short piece of text (e.g., Fig. 1) or a simple shape (e.g., Fig. 5). Additionally, since all key elements are used each time, the whole secret image can be easily remembered after 30-45 minutes of repeated authentication training attempts and frequently refreshed at the use stage.

- Authentication Time

The authentication time is proportional to the user's cognitive workload - ranges from 4 to 8 seconds (≈ 6) in each round of response, depending on the composition of the secret and the user's skill. After several searches, visual perception adapts a parallel analysis approach, i.e. the search for an ψ element with V_{inp} is not performed element-by-element, but in blocks, just like reading a text, with whole words being interpreted, rather than individual letters. Each modular addition and block search require ca. 1 sec. For the user who has to look at the keyboard to enter OTP, it will be easier, and faster, to use voice input, which is also a good source of biometric data and a 3-rd authentication factor. After introducing of TurboChip overlay, the authentication time is significantly reduced up to ≈ 15 seconds if the user becomes an experience in using it.

VI. BRIEF ANALYSIS OF SECURITY

The resistance to a random attack depends on the number of OTP digits calculated by the user. Their number L is arbitrary and depends on the needs of the authentication system, e.g., $L = 6$ like OTP in most e-banking systems. Using the ClickChip overlay slightly weakens the protocol if the attacker records user responses, as it allows to reduce the number of possible click locations from $N = 324$ down to 207 (in the worst case - Fig. 6), however, the probability of $p=7e-7$ of randomly hitting the correct OTP is still lower than for 6 decimal digits, i.e. $p=1e-6$.

The iChip's resistance to active attacks is ensured in the preliminary stage (see Section 3.4) or by the hashing and signing the authenticated message, as the HHMAC is valid only for the signed message (see Section IV).

As the challenge in the iChip protocol is generated full at random, it is fully immune to frequency analysis.

The iChip's entropy is of course lower in practical use than its key size of 512 bits, but much higher than a text password due to large number of possible fonts and their positioning on the large grid or cell order. A good example is the word *iCHIP* used in Fig 1. The number of possibilities for designing this contour is enormous, despite the use of many symmetries compared to the number of combinations that the use of lowercase and uppercase letters offer.

The resistance to brute-force and Grover's quantum algorithm is provided by NP-hard lattice problem and huge keys space (see Table 1), estimated as follows:

$$\frac{N!}{(N-L)!} \cdot \sum_{i=B}^{B+b_0} \left(\sum_{d=1}^k \binom{N-L}{d} \right) \cdot \sum_{j=E}^{E+e_0} \binom{N-L}{j} + \sum_{j=E}^{E+e_0} \frac{(N-L)!}{(N-j-L)!} \quad (3)$$

where:

$N = n \times n$ is the size of Chip's matrix, default 16 x 16

L is the number of OTP digits, default 6

$[B, B + b_0]$ = number of blocks, in the range 3 to 7

$[E, E + e_0]$ = number of input elements in block: 3 to 9

$[0, k]$ = number of output elements in block: 0 to 2 or max. 3

Estimating the resistance of an authentication protocol to peeping attacks is very important, but also highly-complex, especially in the case of iChip, as it can simultaneously use many protocol variants, which interfere with each other and further increase their effectiveness (see Appendix). Therefore, we considered them separately, based on the results of related works: [2], [7], [6].

By using the LPN method or its variants, it is possible to efficiently reduce the amount of information leaked about the secret by random injection of erroneous information in the LWE or deterministic rounding in the LWR. Such leakage can also be reduced by modular reduction $x \bmod p$, or by randomly selecting one of several correct LWO options.

It also works similar to introducing an error in the expected, acceptable narrow range. However, introducing noise too much here increases vulnerability to random attacks as well.

As shown in [7]: The k number of arguments used in the function $f(x_1, x_2, \dots, x_k) = x_1 + x_2 + \dots + x_k \bmod p$ depends on the safety function for the statistical algorithm $r(f) = k/2$, however, f cannot be linear, because then the security for Gaussian Elimination is $g(f) = 0$ and the Equation 1 for LWR implementation in iChip takes only 2 arguments ($k = 2$). Therefore, in this case the secret could be recovered even from $O(n)$ challenge-response samples: $m = n^s$, $s = \min(g, r)$.

TABLE I
COMPARISON OF THE MOST IMPORTANT AND OPTIMAL PARAMETERS.

HGPP [Ref.]	k secret objects	n objects pool	Window size	Key size (bits)	Password space	$s(f)$	Guess Rate /round	No of rounds	\approx Time/Auth. (sec)
HB [2]	15	200	200	70	1.5e+22	2	0.5	20	668
APW [5]	16	200	200	79	8.4e+24	1	0.1	6	348
CAS Hi [4]	60	240	20	187	2.4e+57	1	0.5	20	221
CAS Lo [4]	60	80	80	70	8.9e+21	1	0.25	10	122
Foxtail [3]	14	140	30	60	6.5e+18	1	0.5	20	213
CHC [13]	5	112	83	24	1.4e+8	1	0.22	10	93
HCP [7]	50	50	14	164	1.0e+50	1.5	0.1	6	42
grIDSure [19]	6	25	25	28	2.4e+8	1	0.1	6	4
iChip256	36	256	256	512	3.2e+154	2	0.1	6	36
ClickChip	31	289	289	500	1.7e+150	2	\approx 0.01	3	21
FlexiChip	31	256	256	490	1.0e+146	2	0.1	6	15

Fortunately, the introduction of noise by the LWO method in iChip brings the same effect as LPN in the HB [2], which does not allow the simple use of Gaussian Elimination, and the adversary needs to see $O(n^2)$ samples to reveal the secret, also in the case of secret's low entropy [14].

On the other hand, introducing an exception *I gives up to 2 additional arguments by Eq. 2 to this base function, hence $2 \leq k \leq 4$. The number of these arguments is not constant but varies randomly in each challenge, so the Eq. 1 becomes highly nonlinear, especially since V_{out} is the result of a previously used mapping,

Any statistical adversary needs approximately $m = n^{r(f)/2}$ samples to recover the secret, where n is the key size (512 bits for iChip), therefore, if both exceptions (*I and *O) are used then estimated safety function is limited by: $s = \min(g, r) = \min(2, 2) = 2$, hence $m \approx 262,144$ challenge-response samples are needed to reveal the secret.

We tested the resistance of the protocol against finding the secret key with an advanced Genetic Algorithm, which ran for $m=1,000$, $m=10,000$ and $m=20,000$ samples over several days on a computer with an 18-core CPU (Intel i9). The secret created in the default grid size of $N = 256$ but without exceptions (*I, *O) was found after approx. 2 hours of operation. After introducing the LWO, the cracker found a secret key only for microparameters i.e. $N = 25$ (Fig. 3).

With the simultaneous inclusion of *I and *O exceptions, the 2-days search did not give a correct result even for $N = 49$, represented by the microkey in Fig. 9.

&	Inputs	Outputs
1	2 3 4 5 6 7 8 9	1 2 3 4

The tests conditions and results are available online [25].

VII. RELATED WORK

Referring to the data in Table 1 of the article from 13th NDSS [12] and the latest publications until today, we have compiled in Table 1, the parameters of the best Human Generated Passwords Protocols, that were created in the years 1991-2017 (there is no significant contribution after 2017), as a comparison with iChip. As we can see, the iChip's parameters have a significant advantage over all others, both in terms of security (key size, keyspace, $s(f)$) and usability (secret's memorizing and authentication time closest to grIDSure). Only HB, HCP, and iChip are protected against linearization [9], where $m = O(n^s)$ strongly depends on the key size n .

The enhanced versions of HB+, Foxtail+ also offer protection against active attacks, but only ClickChip and HHMAC are suitable for the user due to the required authentication time.

VIII. CONCLUSIONS

The result of our work are the iChip protocol and two TurboChip overlays, which significantly accelerate the OTP generation process and all these variants meet the safety and usability criteria required for commercial implementation.

- The FlexiChip is our favorite due to the smaller workload for the user and flexibility in generating passwords of any length L from 1 to $k = |S|$. As the video tutorial [25] shows, the 6-digit OTP computation time easily reaches 15 seconds. The protection against active adversary attacks is provided by the HHMAC with use of standard hash algorithm, preferable SHA-256 or SHA-512. Such signature can be also performed by the user offline on paper documents without any gadgets and automatically scanned and loaded into the system, where this signature is verified.

- The ClickChip overlay has the advantage of using the preliminary round to immediately detect an active adversary attacks and is more glamorous, but requires more proficiency in determining matrix coordinates. At the level of quasi automatic distance evaluation, the authentication time could be reduced to even 15 seconds, similar to the FlexiChip.

The iChip protocol parameters are well-suited to applicate also in resource-constrained devices, like IoT or RFID.

APPENDIX A

INCREASING THE ICHIP ENTROPY

In the sample of 920 students of our university, no secret pattern was repeated. However, the entropy of iChip can be effectively increased by further increasing the key size as shown in subsections A and B, or by using of a suitable background image, which can be built individually by the user or proposed by the wizard as a random structure. The visual structure of such a background image (e.g., Fig. 10) provides reference points for easy remembering the image of the secret and thus allows building a secret key with much higher practical entropy.

Fig. 10. An example of a secret key depicting the word *admin* on an individually designed background.

A. The iChip as multi-layout interface with 3D key

The iChip interface allows the user to expand the secret not only in 2 dimensions (row x and column y), but also use the 3rd dimension, i.e., the z parameter used here as a layout index (default $z = 1$), marked in colour of the secret elements and is indicated in the i -th round by $z = V_G[i + 1]$. In this simple way, the key size can even exceed a thousand bits, without increasing the C size, where $N_{|z|=1} = x \cdot y = |C| \approx 256$.

Fig. 11 shows an example of a 3D secret that has been adapted from the secret key in Fig. 4, where $|z| = 2$, $N_2 = 450$, by adding 2 blocks on 4 additional layers resulting in $|z| = 6$ and $N_6 = 3 \cdot N_2 = 1350$.

Fig. 11. An example of a 3D secret on multi-layout iChip.

The zoomed fragment of the challenge image in Fig. 11 shows the first round ($i = 1$) of the OTP calculation: Since $z = V_G[i + 1] = 7$, the search for a value of $V_G[1] = 4$ must start in block 7. It appears in the last element of this block $B_7^I[5]$ at position (6, 2), so we read the value of 3 at the associated output in cell (7, 4) and calculate: $OTP[2] = (V_G[1] + C[(7, 4)]) \bmod 10 = (4 + 3) \bmod 10 = 7$.

B. The iChip as multi-protocol platform

A solution with a large number of protocol variants that can be combined with each other using a simple settings manager is beneficial for increasing its resistance, and makes the scheme more user-friendly, who only needs to know the variants he choose to create his secret. For example, choosing 5 out of 50 variants, the cracker has to check 2,118,760 additional combinations, which must first be analyzed and coded in such a cracker. This number can still expand as each subtle change in protocol represents a new variant that can be created not only by the scientist, but also by the creative user.

The iChip enables the implementation of other Human-Computable Password Protocols, and acts as an open platform for them. We invite other researchers to use it to compose their own licensed variant of HCPP or an adaptation of a previously developed one.

As an example implementation, we used the Foxtail scheme proposed in 2005 by Li and Shum in [3], adapted in 2020 for the needs of IoT in [6]. There are 4 pass-objects in the challenge given in Fig. 12, hence the response $R = 4 \bmod 2 = 0$. For a standard 6-digit OTP, this procedure must be repeated for 20 rounds, each for 1 bit.

Fig. 12. An example of an original Foxtail challenge for 1 bit response marked by the four red rings.

For implementing the Foxtail protocol on the iChip platform, selected input elements are used as a hidden chain of challenge window in the Foxtail schema. To redirect the binary response of Foxtail, we use two output elements appropriate for the expected binary response (0 or 1) and any 3rd output as an option for the LWO method. Therefore, instead of four protocol rounds for each OTP digit, only one round is needed. To define a trigger for switching between Foxtail and iChip subprotocols, we assume that if the value searched for $V_G[i]$ is found in the first block, then all input elements are treated as a challenge for the Foxtail scheme. Otherwise, for the iChip rules. As counted pass-objects, we assume the value of V_{inp}^i . After adapting the example in Fig. 4 for the Foxtail implementation illustrated in Fig. 13: The first element $V_G[1]$ at position (0, 4) has a value of 8, which appears in the first block; therefore, all input elements in S are treated as a Foxtail challenge. As there are 3 entries with the value of 8, in cells [(6, 4), (5, a), (c, 5)], the response is $3 \bmod 2 = 1$.

However, according to the redirection rules, we use this response for binary addressing of the 2nd element from 2 locations: (d, 7) for 0 and (e, 7) for 1.

In cell (e, 7) is a value of 7, therefore, finally: $OTP[1] = (8 + 7) \bmod 10 = 5$. In the 2nd round the $V_G[2] = 1$, which appear at 2 locations only: [(6, 4), (a, a)]. Since, $2 \bmod 10 = 0$, we go to the cell (d, 7) with a value of 6, and calculate $OTP[2] = (1 + 6) \bmod 10 = 7$. The next values in the generator block no longer appear in the first block, so iChip rules apply to them.

Fig. 13. Image of secret key and Foxtail's pass-objects marked by red rings in the challenge.

APPENDIX B

THE ICHIP IMPLEMENTATION IN THE E-BANKING SYSTEM

We have implemented the iChip protocol in the e-banking system, in which it is used both for logging in and for authorizing transactions. The screenshot in Fig. 14, shows a form for entering the personal data and personalizing the virtual token, visualized as an iPad tablet. The form in the background shows a special wizard for designing of a graphic identifier and secret key, i.e. its image on the right side and the associated code table on the left side. This token implements the iChip protocol and the Turbo-Chip overlays. The token window opens on the form to be authorized. The response for the Click-Chip challenge is shown on the token screen.

The e-banking system is available online [25].

Abstract—The standardized security architecture proposed by ETSI for 5G networks provides six security domains covering network access and secure implementation of network services. However, this architecture does not specify detailed solutions for access control for web services and user credentials management. This paper proposes a new access control and service authorization protocol for the network services using MEC edge servers. Our solution does not slow down the performance of services in the 5G network. The advantage of this solution is that it allows you to solve some network security problems resulting from virtualization techniques (SDN and NFV) applied in constructing contemporary mobile networks.

I. INTRODUCTION

THE FIFTH-GENERATION mobile networks are designed to provide network services with extremely high requirements in terms of bandwidth, the number of devices supported, latency, energy consumption, etc., see [1]. It enables the support of participants of mass events with good quality of service, the implementation of real-time services for telemedicine, monitoring and control of technological processes, and many others. However, it may not be possible to simultaneously meet all 5G quality requirements. Therefore, particular configurations of network services, called slices, have been proposed [2], [3]. In slices, the network parameters are adapted to the specific needs of a given application, for example, a virtual industry instance or its particular use case, see [4]. In order to effectively implement network slices designed for the needs of verticals in the 5G network infrastructure, it is necessary using virtualization techniques. 5G networks use SDN technology [5] to implement network traffic management and NFV technology [6] to enable flexible network deployment and dynamic operation. SDN and NFV technologies also allow the use of modern security solutions integrated with a centralized network controller, for example, the IDS / IPS system, see [7]. Another solution that allows improving network service quality is using edge servers with applications designed to support it. This solution is most effectively implemented with the use of MEC (Multi-access Edge Computing) technology, see [8].

Modern mobile networks of the 5th generation (and higher) are a result of the interaction of SDN and NFV virtualization technologies and MEC edge services technology [9]. From a functional point of view, we can call them 5G MEC networks;

they combine mobile access to resources and services of high quality. Organizationally, such networks require the cooperation of many stakeholders participating in the implementation and use of web services. Ensuring the harmonious collaboration of all participants of the network services market while ensuring the necessary quality requirements and network limitations is a major technological challenge. However, providing the quality of a web service in 5G MEC networks cannot be at the expense of security. In particular, resource and service access protection methods can be a network service bottleneck. Therefore, an access control system adapted to the architecture of web services in 5G MEC networks is necessary for their proper functioning.

This paper aims to propose a new access control scheme for 5G MEC-hosted services that guarantees high service efficiency at a level of security similar to other modern network access control systems. It makes the network providers and the MEC-hosted service providers independent of external identity providers. It ensures strong user authorization to use services in the scope compliant with the applicable security policy. In addition, the system optimizes the operation of the network transmitting data related to the service. It also allows, if necessary, to interact with external identity providers in terms of primary user authentication. This system allows for the improvement of accessing services and granting permissions to users and increases the efficiency of the service implementation process.

The rest of the paper is organized as follows. Section II presents the standardized 5G security architecture and its basic access control domains. Section III reviews modern lightweight network authentication protocols that can be used for authentication and authorization on 5G MEC networks. Section IV presents the outline scheme of the 5G MEC access control architecture used in the special use-cases. Section V defines the optimized access control protocol for 5G MEC-hosted services. Section VI proposes possible improvements and optimizations of components, algorithms, and protocols supporting the access control system. Section VII presents the security advantages of the proposed solution and Section VIII concludes the paper and outlines the future work.

II. 5G NETWORKS AND ACCESS CONTROL

The ETSI standard [10] proposes the 5G network security architecture. The architecture covers essential network security

This paper has been supported by The National Center for Research and Development, Poland, under Decision No. DWM/POLTAJ7/9/2020

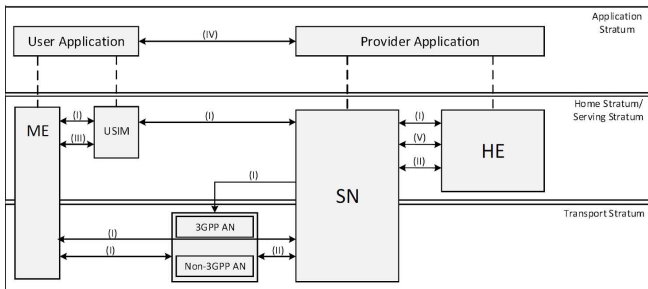

Fig. 1. Overview of the 5G security architecture [10].

elements, particularly network access control and network services access control.

Secure access to 5G MEC web services consists of two steps. The first one is secure 5G network access that enables a UE to authenticate and access the network securely (domain (I) in Fig. 1), including the 3GPP access and Non-3GPP access, and in particular, to protect against attacks on the (radio) interfaces, see [10]. This step is provided by network operators and is based on 5G standardized solutions. The second step is included in the application domain security (marked as domain (IV) in Fig. 1). It consists of security features enabling applications in the user and provider domains to exchange messages securely. This security area is in the competence of the service providers, particularly the MEC services providers. To ensure end-to-end security in 5G networks, the security architecture of the standard [10] should be significantly expanded. We must consider such elements as the end-user devices, the edge server services, and the computing cloud in which the service provider's resources are located in the network. Such an extended security model has been proposed in the paper [11].

The use of MEC technology in 5G networks facilitating the implementation of many services and improving their efficiency requires further expansion of the access control security model. In papers [12] and [13], we proposed a new security architecture with the integrated authorization mechanisms. Before we present our security architecture and the access control security protocols, we will briefly overview the contemporary access control solutions for the web services proposed in the literature.

III. RELATED WORK ON THE ACCESS CONTROL SCHEMES

In mobile networks, the most popular method of access control and authorizing users in web services is applying external identity providers, such as Google, YouTube, Facebook, Okta, Microsoft Active Directory, etc. The offered solutions use well-known authentication and authorization protocols such as OpenId Connect, SAML (Security Assertion Markup Language), and OAuth 2.0. The OpenId Connect [14] is an open standard used for user authentication. It uses JWT (JSON Web Token) to deliver claims about the authentication of an end-user by an authorization server when using a client and other requested claims. SAML [15] plays a similar role but

uses XML to exchange identity credentials and authorization data between identity providers and service providers to verify a user's identity and permissions. OAuth 2.0 provides secure delegated access. The application can take action or access resources from the server on behalf of the user without the user having to share its credentials. It does so by allowing the Identity Provider (IdP) to issue tokens to third-party applications with the user's consent. OAuth 2.0 [16] most often provides authorization services for users who have been authenticated using the OpenId Connect or SAML protocols.

An alternative solution to the authentication and authorization problem may be to use methods that do not require a central identity provider. These include verifiable credentials, decentralized identifiers, and blockchain. Verifiable Credentials (VC) [17] is an open standard for digital credentials. VCs contain such information as context, issuer, type, subject, and identity attributes or a cryptographic proof to ensure their integrity and authenticity. They can be expressed as JWT, see [18]. Decentralized Identifiers (DID) [19] is a type of identifier that enables a verifiable, decentralized digital identity. DIDs contain cryptographic material, verification methods, or service endpoints, which provide a set of mechanisms enabling independent controllers to prove to check the self-sovereign identity, see [20], [21]. Blockchain technology can be an alternative to decentralized authentication and authorization, see, e.g., [22].

In addition to authentication and authorization solutions for services in 5G networks, seen as mobile networks with general architecture, the literature offers proposals for solutions that consider the specific role of edge servers and MEC technology. It is proposed to provide access to enabler systems [23] or proxy servers [24] for user authentication and authorization. In order to improve data transmission, increase its security and improve efficiency, it is proposed to authorize the transmitted packets [25] additionally. Solutions of this type can operate independently or cooperate in identity delivery systems implemented by global suppliers, creating designs with high security, high flexibility, and the necessary autonomy in privacy.

In the literature, you can find works presenting access control protocols prepared especially for the 5G MEC network and services hosted in edge servers. For instance, paper [26] introduced a new access control protocol for the MEC system model and examined this protocol against user privacy requirements when sharing information that is not essential to the edge server-hosted service.

IV. 5G MEC ACCESS CONTROL ARCHITECTURE

Control of access to resources and services is an essential element of computer network security, and in mobile networks, it constitutes the basis for their protection. The access control system is the central element in our proposed 5G MEC network security architecture [12]. This section will outline this architecture, with its security domains and the core component specification. Our security architecture model consists of ten security domains that coexist and cooperate,

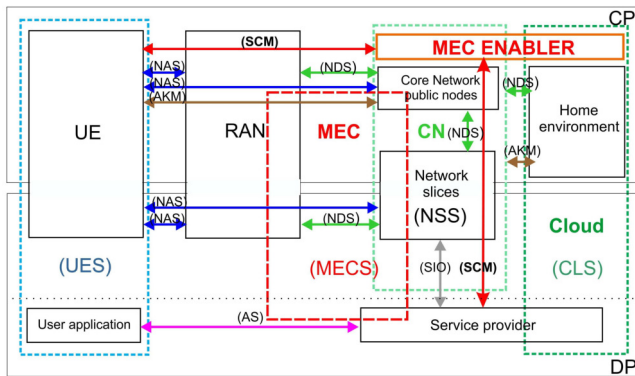

Fig. 2. The high-level access control security architecture in 5G MEC.

providing security services in all aspects of the 5G MEC mobile network functioning. It is related to basic the 5G security architecture presented in Fig. 1 and its extension proposed in [11], however, it contains components required by the MEC technology solutions. It is able to satisfy mobile networks security requirements enabling simultaneously to provide web services satisfying 5G networks' high quality expectations.

The 5G MEC security architecture designed in [12] consists of ten security domains. The number of the domains we consider is higher than those in [10], where six security domains for the 5G network are defined. This is because it must connect four network environments: 5G Core Network (CN), 5G Radio Access Network (RAN), the edge services provided by the MEC technology, and a new module which is the MEC Enabler, see Fig. 2. The domains of responsibility for security in the new architecture partially overlap with the areas proposed in [10]. To a large extent, they implement new security functions resulting from applications of the MEC technology and increase the number of stakeholders in the implementation of mobile network services. Below we present the security domains and their areas of responsibility, see Fig. 2.

- **NAS (Network Access Security)** provides basic security of user data. It includes confidentiality and integrity of signaling and user data between the User Equipment (UE) and the network in the Control Plane (CP) or the Data Plane (DP). It corresponds to the security domain (I) in Fig. 1.
- **NDS (Network Domain Security)** is the secure exchange of signaling and user data between different network entities. It corresponds to the security domain (II) in Fig. 1.
- **UES (User Equipment Security)**: this domain contains software and hardware security at the user's side, including user access to the mobile equipment. It corresponds to the security domain (III) in Fig. 1.
- **AS (Applications Security)** is the support for secure communications between applications in UE and applications offered by the Service Provider. It is under the

control of the end-user or the Service Provider (in the Application sub-Plane).

- **AKM (Initial Authentication and Key Management)**: the security features that enable network functions to communicate securely. It includes mechanisms for authentication and key management that implement the unified authentication framework.
- **SCM (Security Credentials Management)** includes the service authentication and relevant key management between UE and the external data-transmitting network. In our model, the MEC Enabler governs this security domain.
- **SIO (Security Interoperability)** (also via MEC) is the support of the openness of security capability between the 5G network entity and the external Service Provider. It also includes the set of features that enable the stakeholders to know whether a security feature is in operation or not, which is defined as the security domain (VI) in [10].
- **NSS (Network Slices Security)** includes security of slices in terms like access control, authorization, and isolation.
- **MECS (MEC Security)**: protection of Service Provider's software, virtualization platform (VM), and hardware supporting the edge server and the MEC host.
- **CLS (Cloud Security)** includes all solutions to secure resources and communication inside the cloud and the operator's home domain. This domain extends the resources offered by MEC-hosted services to the external cloud resources.

Two other security domains in Fig. 1 are the Application domain security (IV), providing the security features that enable applications in the user domain and the provider domain to exchange messages securely, and the SBA (Service Based Architecture) domain security (V), providing the security features that enable network functions of the SBA architecture to securely communicate within the serving network domain and with other network domains. In our model, their responsibility is distributed over AS, SCM, SIO, NSS, and MECS security domains because of the new important component, the MEC Enabler. The MEC Enabler acts as an AAA (Authentication, Authorization, and Accounting) server for all requests before any connection with MEC. Then, if the request is authorized, the MEC Enabler will properly control the configuration process of access to the MEC infrastructure and will create an information token that will enable to use of selected MEC services, see Fig. 3. The procedure of token creation and protection is an example of the solution analyzed and provided by ETSI (European Telecommunications Standards Institute) [10]. It involves the JSON (JavaScript Object Notation) Web Tokens with the appropriate digital signature, see the series of the RFC documents: [28], [29], [30], [31], [32]. This solution will reduce the management process and network resources' utilization for non-legitimate connections. The MEC Enabler will be responsible for service authentication and relevant

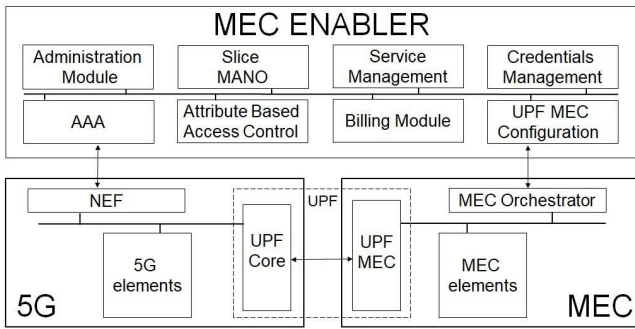

Fig. 3. The new network architecture with the MEC Enabler.

key management between UE and the external data network realizing:

- services for legitimate users of the network,
- services for the secured communication (via slices or protected links),
- main security service for access to the MEC-hosted services,
- management of access rights by credentials,
- giving credentials to the progression of services considered as 5G MEC use cases,
- enabling services in the external operator's domain or over the cloud.
- **Administration Module:** this module supports all management operations and can configure other modules.
- **Slice MANO (Management And Network Orchestration):** the role of this module is to manage the slice life cycle in the MEC area. This manager can also reserve resources for specific slices and mark them according to service type, network identification, or any other rule, [34].
- **Attribute-Based Access Control:** this module stores all policy data about services, slices, available connections, and some other MEC information [35].
- **Service Management:** this module allows checking available services, their utilization, and the number of resources dedicated to them. The specific use cases can also manage the MEC's services lifecycle using MEC orchestrator API. However, it is also necessary to implement load balancing, which analyzes service placement [36].
- **Credentials Management:** this module creates tokens used for authorization of the MEC resources. This module's created token is monitored, refreshed, or deleted according to service needs [37].
- **Billing Module:** this module is dedicated to billing and storing information about MEC usage in different business models [38].
- **UPF MEC Configuration:** this module matches and adequately configures UPF MEC to link proper network slices with dedicated MEC resources [39]. When each slice represents another operator, this module establishes a connection between the operator and the MEC compu-

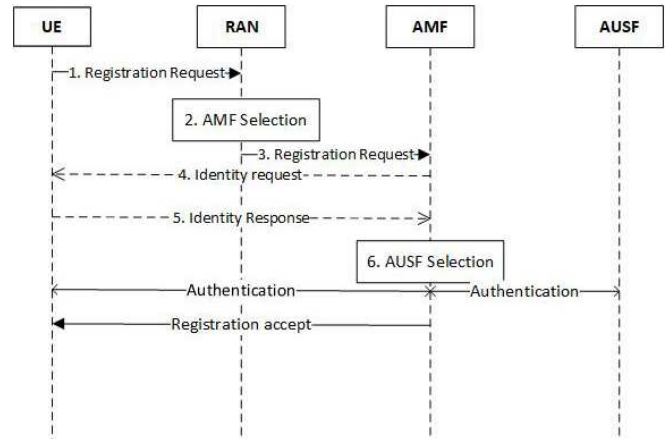

Fig. 4. Process of UE registration to the 5G network

tation part assigned to it.

- **AAA:** this module is responsible for authentication, authorization, and accounting of all requests to MEC services [40]. After positive verification, UPF MEC Configuration Module prepares a network configuration that allows creating a connection with the chosen service, and Credentials Management generates a token for service authorization. Implementation of this module in the MEC Enabler will significantly improve the protection of Edge resources.

V. 5G MEC ACCESS CONTROL PROCEDURE

A. General access control to 5G network

The access control process includes three phases: UE registration to the 5G network, the discovery of proper UPF Core, and access to a MEC service. In the registration part, devices are verified whether they can be connected to the 5G network. In the discovery phase, the network must find a proper UPF that can communicate with the MEC network. Moreover, in this phase possibility of establishing a connection between UPF Core and UPF MEC is checked. Finally, access to selected MEC services is performed when the UPF Core can securely communicate with UPF MEC.

The diagram in Fig. 4 represents the communication flow in phase 1 when the UE tries to register to the 5G network. The flow in the registration phase was created based on the registration procedure shown in ETSI Technical Specification [49]. First of all, UE sends a registration request to the gNB (RAN) with all necessary information about UE (UE context), such as SUCI (Subscription Concealed Identifier), last visited TAI (Tracking Area Identity), Requested NSSA (Network Slice Selection Assistance Information) and many more. Then, the RAN chooses AMF (Access and Mobility Management Function). The AMF performs most of the MME's functions in the 4G network. One of these is UE authentication. AMF sends an identity request to the UE (optional request for additional data), and when it gets a response, AUSF (Authentication Server Function) performs the selection procedure. After that,

authentication messages are exchanged between the AUSF, AMF, and the UE. Finally, if everything goes correctly, the UE is registered as reported by the AMF.

In the phase of discovery proper UPF Core (see Fig. 5), authentication between UE and AUSF is first performed. After that, the AMF module sends a request to SMF (Session Management Function) to start the UPF Core discovery and a selection procedure. In the classical approach to the 5G MEC, network SMF is responsible for UPF management (e.g., configure traffic steering rules), so it must communicate with a new authentication and authorization service to ensure proper access control to MEC. To check if UE can access the MEC service, SMF, through NEF, sends a verification request to MEC Enabler (MEC EBR). The MEC EBR checks if UE via UPF CORE can establish a session with UPF MEC and if UE can use a particular MEC service. As a result of verification, a token is created. The token contains the necessary information as a result of two previous checks. If everything is going well and SMF receives the token, it sends the request to UPF CORE for an update session. Finally, after receiving a response about the correct data update from UPF CORE, a sequence of messages confirming the possibility of sending data from the UE to UPF CORE and UPF MEC is sent.

The final phase of access control to MEC service is internal access in MEC infrastructure (see Fig. 6). UPF MEC sends an application request to TMS (Traffic Management Service). The TMS is responsible for sending service access information to the MEC platforms. The MEC platform chooses adequate service and verifies the received token. After that, the MEC platform sends a request to the selected service; data from the service is sent to the UPF MEC and finally to the UE. In this phase, the proposed message flow is similar to the standard proposed in RFC 7519 for JWT tokens [32], making it easy to implement and use.

The descriptions above relate to the general assumptions made for controlling access to services in the 5G network. In the context of the 5G MEC network, the description should be detailed, and this will be done in the next subsection.

B. Steps of created access control protocol

Before accessing the resources hosted in the MEC environment, some steps should be taken (see Fig. 7). The proposed authorization process includes actions related to registration in the 5G network, which are the first condition for accessing the network [Step 1]. If the first access condition is met, the client will be correctly registered in the network, and then it will be able to try to connect to MEC resources. For this purpose, its request will be authenticated through the second step of the access control process, which verifies whether the request can be authorized by the access server dedicated to the application [Step 3]. After successfully passing the second step, the request is sent for the policy-based access verification [Step 5]. At this point, the access policy is checked based on the knowledge about the device's origin in the network and confirmation of the rights to use the indicated resource. Before making a decision, the policy-based access module

considers many aspects, such as information about the slice from which the request is sent, a destination of the request, the user name, and more. Then, according to the stored policy, MEC Enabler decides whether to send the request to the application or not [Steps 6-7]. Suppose the request complies with the policy and in that case, the network element will be appropriately configured to enable connection from the device to the application located in the MEC [Step 8]. The exact course of the authorization process is presented in the points below:

- 1) The registration request is sent from the User Equipment (UE) RAN Access components:
 - The request is sent to the Access and Mobility Management Function (AMF)
 - Start of the Primary Authentication between UE and Authentication Server Function (AUSF) according to the 5G procedure
 - UE establishes NAS security context with AMF
 - UE initiates the establishment of a new PDU Session by sending NAS message
 - AMF selects V-SMF (Visited Session Management Function) and sends PDU Session context request
 - V-SMF sends PDU Session context response.
 - H-SMF (Home Session Management Function) obtains subscription information from UDM and verifies that UE's request is compliant
 - H-SMF sends EAP Request/Identity message to UE
 - UE sends EAP Response/Identity message
 - H-SMF selects UPF and establishes an N4 Session.
- 2) H-SMF forwards request to UPF
- 3) UPF forwards the request containing EAP Response/Identity message to the MEC Enabler AAA server (ME:AAA).
- 4) AAA module verifies if the sent data are correct. After positive verification, authorized data (user's contextual data and positive authorization) are sent to Slice MANO.
- 5) Slice MANO based on available resources information on local MANO slice resource database extends authorization data with the slice data such as priority of the request, identifiers of requested slice/slices, service localization
- 6) ABAC module checks data collected from Slice MANO in the context of one of the access policies located in a local ABAC policy database. Finally, slice data and ABAC verification information are forwarded to the Credentials Management module after positive verification authorization data.
- 7) Credentials Management entity creates JMAT token based on gathered data from ABAC entity. It sends it with configuration data (service localization, priority of handling requests, required types of UPF, slice ID, and network token) to the UPF Configuration module.
- 8) ME: UPF Configuration module based on configuration data from Credentials Management module sets network configurations on UPF Core and UPF MEC to establish

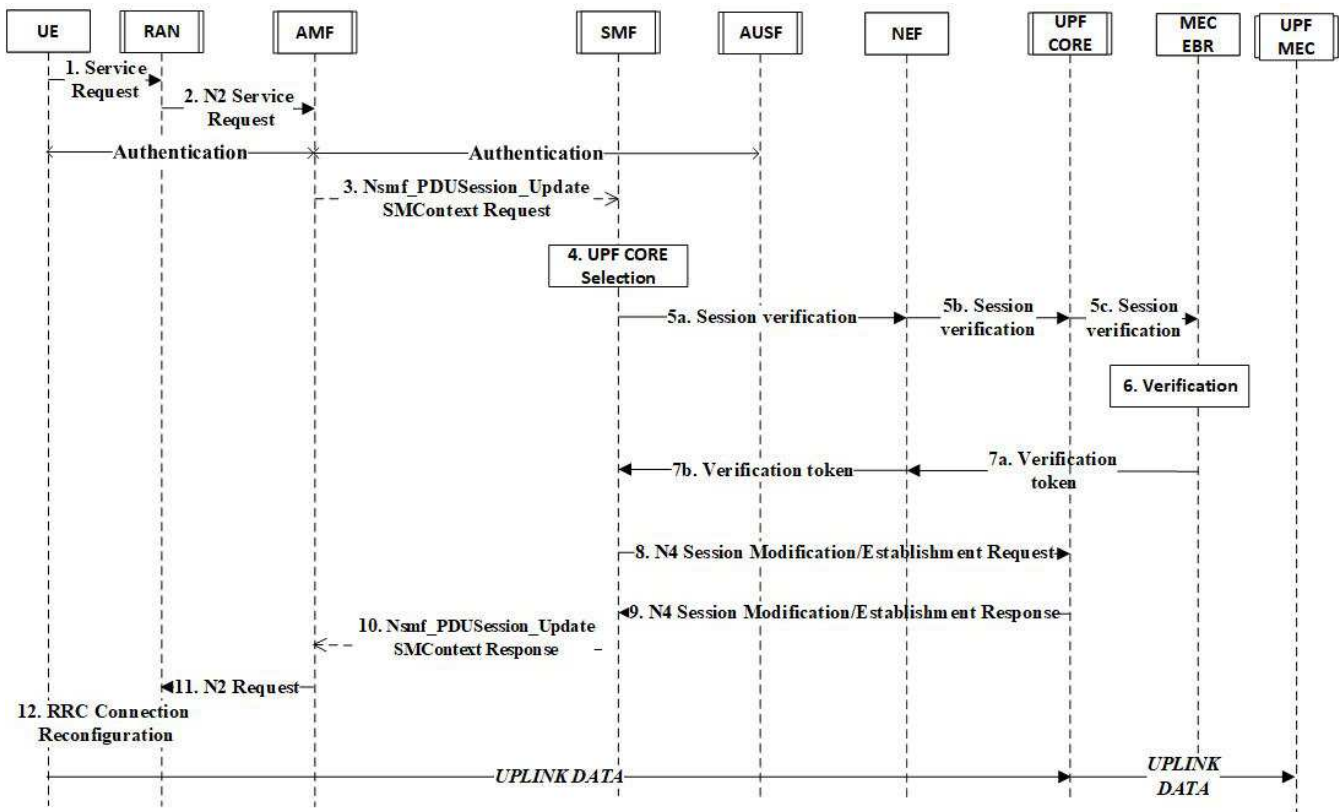

Fig. 5. Process of discovery proper UPF Core

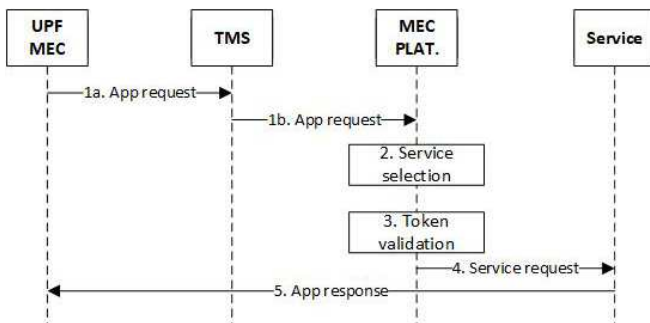

Fig. 6. General process of access to a MEC service

a connection to the service.

- 9) The request is transferred to the service located in the MEC environment.
- 10) UE establishes an End-to-End connection with the requested MEC:App.

As presented in the process description, the central role of the MEC Enabler in the authorization process is to add another access control step (based on verification of additional context information). This step increases the security of connection with the MEC environment and allows the protocol to be extended by other steps in the future. Currently, the policy verification process makes binary decisions - it may allow

access or decline the connection.

Naturally, the data flow from Fig 7 shows the connection part to the MEC service, not the management of the established connection. In addition, the service access token must be verified for its validity (e.g., token lifetime, data validity in the token, etc.).

VI. POSSIBLE IMPROVEMENTS AND OPTIMIZATIONS

This section describes entities that might be improved in the overall architecture presented in this paper.

A. JMAT token generation

In the past, during the design and implementation of JMAT tokens, we decided to improve its structure. The detailed results were described in [13]. Below are the key improvements that reduced the generation time:

- Reorganize the way of storing the data - we utilized a file system with directories and proper file naming as a data structure that exposes the quick find operation.
- Avoid JSON (JavaScript Object Notation) deserialization, also called JSON parsing - deserialization is a widely used operation in Object Oriented Programming, however it might be time-consuming. We decided to utilize the knowledge about the exact object structure that must be deserialized to read needed data.

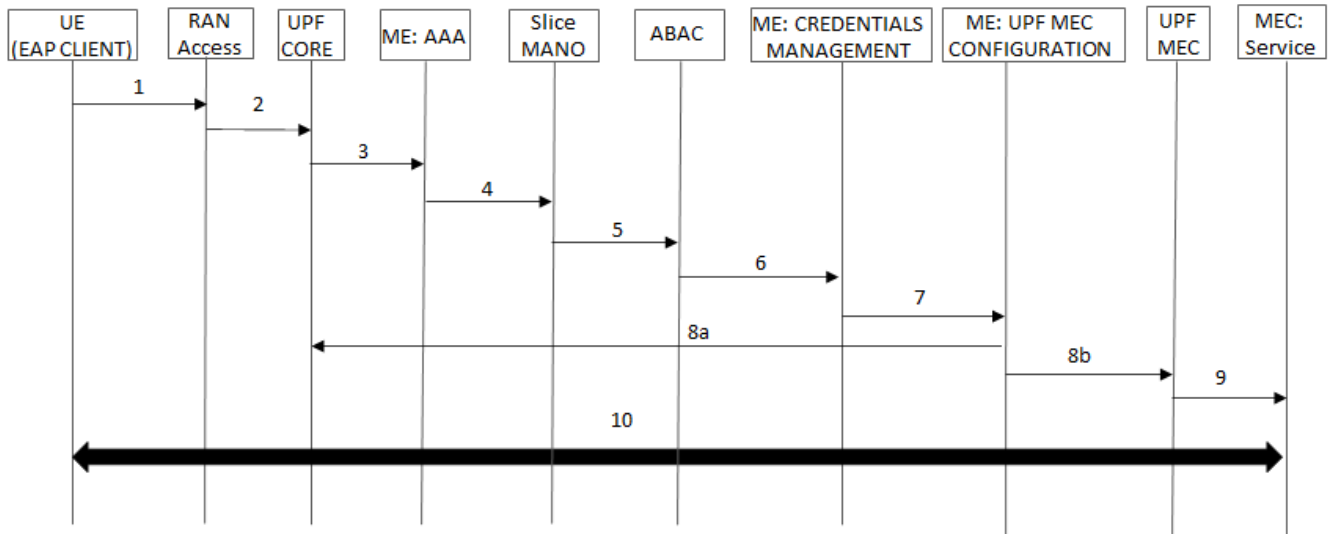

Fig. 7. Steps of created access control protocol

B. Py-ABAC rules and rule evaluation

We utilize ABAC (Attribute-Based Access Control) approach to manage access control to services for users. We use the py-ABAC library, described widely in [27]. Incoming requests might be denied or allowed with py-ABAC policies evaluation during Step 6 in the process in Fig. 5. The py-ABAC engine evaluates the final boolean decision (deny or allow the request) with rules stored in the memory or database. Each rule gives a boolean result, and the final result is calculated by n -ary OR or AND operation over those rules. In the worst scenario, the engine requires all rules to be evaluated to obtain the result. This algorithm could be improved by properly ordering the rules first to check those rules that determine the final decision. As a result, the average time needed for request analysis might decrease if rules are ordered properly. The first rule to evaluate might also be selected by a classification algorithm executed with the request's data and context.

C. Token verification after authorization

According to the concept of MEC Enabler, each first service request must be checked if it is authorized to the service and if it complies with the access policy. After passing the authorization process, an access token is generated. This token contains important information that confirms connection access to the service and data for authentication.

When the service implementation status does not change, the token validation causes unnecessary delays because the other parameters are the same apart from the token validity. Limiting the validation process only to check the token's validity would be sufficient.

When a service implementation status has changed, the token validation should be extended with additional policy verification. It would be sufficient first to limit verification with altered parameters and check if they fulfill policy needs.

The expected benefit is to reduce the time and resources needed for token validation. This approach might expose the authentication engine to some attacks based on token spoofing attempts or cheating the token policy.

D. Early evaluation

Incoming requests require authentication. The system could classify the request as pre-approved or pre-rejected based on the request's header and content (the early evaluation). When the request is pre-approved, the needed resources to establish the connection are collected, and the link is created before the request is authenticated and authorized. The expected benefit is the reduction of the latency for link creation. The main risk is the unavailability of needed resources for other valid requests due to pre-approvals. The classification algorithm might be applied here. Every decision made by the algorithm is validated by the authentication and authorization process, so with every request, the accuracy of the classification might be better. The over-learning problem should be addressed, e.g., by some data retention.

The approved request could be handled by MEC service or external (cloud) service. Thus, the early evaluation might return the following results: deny the request, take by MEC service, handle by cloud service.

VII. SECURITY ASPECTS OF THE PROPOSED SOLUTION

As we presented in the Introduction, the 5G mobile networks take full advantage of virtualization technologies (SDN and NFV) and the location of services in edge servers (MEC) to guarantee the highest quality of services. However, all these technologies require an innovative approach to the problem of network security and the security of MEC applications. On the one hand, virtualization technologies and shared infrastructure increase the network's vulnerability to attacks due to the openness of components that perform data transmission and other

network functionalities. Another issue is the fact that different stakeholders simultaneously use network functionalities. On the other hand, the transparent structure of the network with centralized traffic control allows the creation new level of security supervision. For example, a network controller with SDN technology can validate packages for different aspects. Consequently, it can be used to build a uniform decentralized IDS protection system covering all network nodes and supervising the correctness of packet flow, see [43]. In this case, responsibility for the entire system relies on the controller side. The problem of the effect of using programmable network technology on the network's security is extensively studied and has extensive literature, see, e.g., [44].

Among the various security methods proposed in the modern 5G MEC networks, an independent access control and user rights management system can significantly improve network security. The new access control architecture proposed by us, with the central element of the MEC Enabler, fully meets this expectation. It is compatible with network components belonging to different operators. Thus, in the control plane of SDN-based networks, a crucial vulnerability is the centralized single point control resulting in a global view of the network and exposing the underneath topology of a system [41]. In the literature, the proposed remedy is extending the Open Flow protocol to enable communication of the security policies between the security applications in the Controller to the agents in the switches, see [45]. In our solution, the MEC Enabler can improve the security of connections to the MEC by an additional layer of traffic control. Even when the MEC Enabler system is down, this will not impact the connectivity because the network without additional protection will be managed in a legacy manner (of course, in this case, security improvement done by MEC Enabler will not be available).

In the data plane, a critical vulnerability is that there is no standardized authentication mechanism in the switch for input traffic or incoming buffer data. Thus, erroneous flow alternation is possible. In the literature, the possible solutions could be using a covert channel defender (CCD), which can efficiently detect and prevent rule conflicts in the data plane, see [46]. It can also be an application of the access control scheme dedicated to a network distributed Intrusion Prevention Systems [47]. In our security architecture, the MEC Enabler can authenticate traffic based on JMAT tokens and, what is more, filter all traffic that has no valid token. Authentication done by MEC Enabler is multidimensional and includes more network information about connection such as slice, network provider, requested MEC application, and others.

Finally, a dangerous vulnerability is that there is no mechanism for identity control in the end-host/control channel. In the literature, the proposed solution can be cryptographic unique message identification for each LLDP packet, see [48]. The MEC Enabler can authenticate and check privileges for all MEC connections by analyzing the JMAT token. This type of access policy implemented in the MEC Enabler is essential for all edge systems. It protects its limited resources from unnecessary consumption and against dangerous attacks that

automatically drop before reaching the MEC environment.

VIII. CONCLUSIONS AND FUTURE WORK

In the paper, new access control and service authorization protocol for the network services using MEC edge servers was described. Firstly, we presented the standardized 5G security architecture and its essential access control domains. After that, the reviews of modern lightweight network authentication protocols that can be used for authentication and authorization on 5G MEC networks were specified. Next, we described the newly created access control procedure: starting with the characterization of MEC Enabler as the main element of the proposed solution, through the interaction of all 5G MEC network elements in the implementation of access, and finally presenting the advantages of the solution in terms of security.

In future works, we will focus on testing the created access control process for selected services in our experimental environment. We will extend the test bed with the implementation of new 5G MEC architecture components and prepare their verification in terms of the requirements enforced on 5G network services. Moreover, we plan to optimize the access control system according to several criteria, e.g., the applied resources and operations costs, its impact on QoS/QoE, expected risks and security level (Quality of Protection), etc. Finally, we would like to improve authentication mechanisms in the MEC Enabler by using Machine Learning algorithms for advanced policy analysis to reduce the time needed for the authentication and authorization procedure.

Advances in Information Systems and Technologies

AIST is a FedCSIS conference track aiming at integrating and creating synergy between disciplines of information technology, information systems, and social sciences. The track addresses the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This track takes a socio-technical view on information systems and, at the same time, relates to ethical, social and political issues raised by information systems.

AIST provides a forum for academics and professionals to share the latest developments and advances in the knowledge and practice of these fields. It seeks new studies in many disciplines to foster a growing body of conceptual, theoretical, experimental, and applied research that could inform design, deployment and usage choices for information systems and technology within business and public organizations as well as households.

We call for papers covering a broad spectrum of topics which bring together sciences of information systems, information technologies, and social sciences, i.e., economics, management, business, finance, and education. The track bridges the diversity of approaches that contributors bring to the conference. The main topics covered are:

- Advances in information systems and technologies for business;
- Advances in information systems and technologies for governments;
- Advances in information systems and technologies for education;
- Advances in information systems and technologies for healthcare;
- Advances in information systems and technologies for smart cities; and
- Advances in information systems and technologies for sustainable development.

AIST invites papers covering the most recent innovations, current trends, professional experiences and new challenges in the several perspectives of information systems and technologies, i.e. design, implementation, stabilization, continuous improvement, and transformation. It seeks new works from researchers and practitioners in business intelligence, big data, data mining, machine learning, cloud computing, mobile applications, social networks, internet of thing, sustainable technologies and systems, blockchain, etc.

Extended versions of high-marked papers presented at technical sessions of AIST 2015-2021 have been published with Springer in volumes of Lecture Notes in Business Information Processing: LNBIP 243, LNBIP 277, LNBIP 311, LNBIP 346, LNBIP 380, LNBIP 413 and LNBIP 442.

Extended versions of selected papers presented during AIST 2022 will be published in Lecture Notes in Business Information Processing series(LNBIP, Springer).

- Data Science in Health, Ecology and Commerce (4th Workshop DSH'22)
- Information Systems Management (17th Conference ISM'22)
- Knowledge Acquisition and Management (28th Conference KAM'22)

A Blockchain-Based Self-Sovereign Identity Approach for Inter-Organizational Business Processes

Amal Abid, Saousssen Cheikhrouhou, Slim Kallel, and Mohamed Jmaiel

Abstract—Blockchain presents a promising and revolutionary technology for organizations’ collaboration, particularly for Inter-Organizational Business Processes (IOBP). It addresses the lack-of-trust problem thanks to its transparency and decentralized features. However, while the adoption of Blockchain technology can alleviate some of IOBP’s challenges, it does so at the expense of significant privacy issues. In fact, some process execution data, such as customers’ data or business secrets, cannot be shared across the collaborating organizations owing to regulatory restrictions such as the General Data Protection Regulation (GDPR). To address trust and privacy issues in IOBP, this paper presents a Blockchain-based Self-Sovereign Identity (SSI) approach. The SSI concept is combined with a registry proof smart contract to provide an efficient privacy-preserving solution. The proposed approach is applied to the pharmaceutical supply chain case study and implemented on the Ethereum Blockchain.

Index Terms—Blockchain, BPMN, IOBP, Self-Sovereign Identity

I. INTRODUCTION

BUSINESS processes have become the main factor of organizations to accomplish defined goals and to remain competitive in the dynamic marketplace. Collaboration between organizations, such as in supply chains, is considered essential in a business ecosystem in which organizations focus on their competitive strategy, perform only those operations for which they have expert skills, and enrich their services through partners and suppliers [1], [2].

In an Inter-Organizational Business Process (IOBP), independent organizations operate as collaborators and exchange messages to perform business transactions. This data exchange may be complicated, particularly when safety and confidentiality are intended to be first-class citizens. Collaborators expect to have access to complete process execution data and benefit from maintaining traceability. However, this is difficult to achieve in IOBPs since some process execution data such as customers’ data or business secrets cannot be shared across the collaborating parties owing to regulations and confidentiality restrictions (e.g. General Data Protection Regulation (GDPR) [3]). Furthermore, there is an inherently lack-of-trust problem as organizations are mutually untrusted and IOBP execution can be prone to disagreements on counterfeiting operations. Additionally, IOBP can hardly be established efficiently, since companies generally rely on settled

business processes and existing solutions. In fact, each party has managed information by building its own database. This has led to information silos, however, resulting in serious problems, particularly with respect to verification of data origins. Current systems use a centralized solution to organize their interoperability and cooperation. In this case, one of the actors will be the dominant partner in providing the solution and having access to the data. If instead, the parties choose a third-party solution, this would be costly and still prone to potentially exposing sensitive information.

Recently, Blockchain technology [4], [5] is proposed for IOBP execution to address the lack-of-trust problem, thanks to its nature as distributed, transparent and immutable ledger [6], [7], [8], [9]. While the adoption of Blockchain technology can alleviate some of these challenges, it does so at the expense of significant privacy issues. To overcome these problems, Blockchain can be leveraged in conjunction with Self-Sovereign Identity (SSI).

Self-Sovereign Identity (SSI) represents the recent evolution in identity management systems. In SSI systems, individuals have complete ownership and control over their data. These data that constitute an identity are known as Verifiable Credentials (VCs) and, unlike traditional systems, remain only with the individual. Verifiable credentials can also be owned by organizations as well as individuals. To protect privacy, SSI systems do not record transactions between interacting peers on ledger since they may include or reveal private information. Alternatively, the ledger is harnessed to verify claims using verifiable credentials.

In this line, some initial work is proposed for exploring the combination of Blockchain with Self-Sovereign Identity to address the issues highlighted above [10], [11], [12], [13], [14]. Unfortunately, these approaches focus particularly on the use of Blockchain-based SSI solutions for the customer side (business to customer (B2C)) and disregard their use between organizations (business to business (B2B)), and hence these approaches do not deal with IOBPs. Besides, these solutions do not address the lack of traceability concerns in SSI systems.

In this paper, we propose a Blockchain-based SSI solution for IOBP that ensures confidential inter-organization process execution while providing privacy-preserving traceability.

The main contributions of this paper can be summarized as follows :

- Propose an interoperable SSI interface between inter-organizational processes that exposes its functionality to the cooperative organizations through a common API.

A. Abid, S. Cheikhrouhou, S. Kallel, and M. Jmaiel are with ReDCAD, ENIS, University of Sfax, Sfax, Tunisia

The objective of the proposed SSI interface is to enable confidential collaboration between organizations by providing confidential end-to-end processes without exposing any sensitive data on-chain. It also supports the use of existing systems and databases while incorporating Blockchain technology as a reference for inter-organizational process interaction.

- Propose a Transaction (Tx) Registry Proof that maintains traceability in a private manner. In particular, this Registry Proof records the hash of transactions as well as Decentralized Identifiers (DIDs) of collaborating organizations in the Blockchain to ensure integrity. This can be used as a privacy-preserving trace to validate afterward that a collaborative task was performed in case of conflicts or audits.

To validate the feasibility of the proposed approach, we applied it to a pharmaceutical supply chain as a case study. In fact, the pharmaceutical supply chain is a vastly diversified and complex ecosystem, in which, the secure management of identity and private data is a typical concern. More Precisely, collaborating entities could identify their partners and interact with them using Verifiable Credentials for compliant transactions and information disclosures. This paper also provides an initial implementation and execution. An experimental evaluation shows that the implementation can achieve good results with low gas costs as well as low latency.

The remainder of this paper is organized as follows : Section II briefly introduces some concepts upon which our work is built. Section III explains the proposed approach. Section IV illustrates the pharmaceutical supply chain case study. Section V presents a proof-of-concept implementation. Section VI evaluates our approach. Section VII summarizes related work, and section VIII concludes and suggests future directions.

II. BACKGROUND

This section introduces the main concepts and definitions related to Self-Sovereign Identity (SSI).

Digital identities in today's world rely on the username-password combination method or the federated identity management method. Users are struggling to handle the growing number of passwords within the username-password combination method. Besides, they are vulnerable to password theft techniques including phishing, key-logging, viruses, and malware. They are also unable to efficiently transfer identity-related information from one account to another, and they must go through the hard registration procedure repeatedly, disclosing ID cards, driver's licenses, bank account details, and other personal information [15].

On the other hand, the federated identity management method attempts to alleviate some of these drawbacks with Single Sign-On platforms that transfer identity-related information between services that are linked to the platform. However, users are obliged to accept the terms and conditions because, otherwise, they will be unable to use the system. Additionally, during registration, users should disclose a significant amount of personal information, which causes

privacy issues. This personal information is not protected from unauthorized secondary use [13].

Self-sovereign Identity (SSI) represents the latest evolution and most current stage of digital identities, which is designed to address the issues of all previous stages. Thanks to SSI, users have full control over their data when using enterprises' systems. Besides, they can share only the required piece of information with their consent.

SSI's standards, architecture, and lifecycle are presented as follows.

A. SSI Standards

SSI is based on two standardized pillars. Decentralized Identifiers (DIDs) and their cryptographic counterparts, Verifiable Credentials (VCs), provide a decentralized and privacy-preserving form of digital identity.

- **Decentralized Identifier:** A decentralized identifier (DID) is an innovative type of globally unique identifier created by the World Wide Web Consortium (W3C) working group [16]. The DIDs approach has proven to be popular for associating a globally unique identifier to cryptographic keys and other interaction metadata necessary to prove control of the identifier.
- **Verifiable Credential:** A credential is a document that details the qualification, ability, or authority granted to an individual by a third party having the requisite authority or assumed ability. For example, a driver's license is used to prove that a person is capable of driving a vehicle, a university degree can be used to prove the education level of a person, and a government-issued passport permits people to travel between nations. These physical credentials may include information related to the identifier (e.g., identification number, photo), the issuing authority, particular attributes asserted by the issuing authority, and credential constraints. All the same information that a physical credential represents can be represented by a verifiable credential (VC), defined as a tamper evident credential that has authorship which can be cryptographically verified. The Verifiable Credential Data Model specification became a recommended standard by W3C in 2019 [16].

B. SSI Architecture

Figure 1 depicts the SSI architecture. In this architecture, there are three principal roles: issuer, verifier, and holder. They are briefly presented below:

- **Issuer:** An entity that creates claims within a VC about a subject. Such an entity can be organizations like governments, universities, but also private individuals or objects such as sensors. An issuer transfers VCs to holders.
- **Holder:** An entity that requests or receives VCs from issuers and maintains them in a credential repository/digital wallet. A holder may not always be the (credential) subject. For example, a parent (holder) holding VCs for its child (subject) or a friend (holder) obtaining a prescription at the pharmacy for its sick friend (subject).

Holders can also create Verifiable Presentations (VPs) from Verifiable Credentials and disclose them to a verifier.

- **Verifier:** An entity that intends to verify specific attributes or claims of a subject. It may receive these in the form of VP, which may include those claims from one or more VCs. However, holders have control at all times over which attributes are transferred to the verifier.

As a recent SSI development, DID Communication (DID-Comm) [17] presents an asynchronous encrypted communication protocol. It establishes a cryptographically secure channel for any two software agents (peers) to interact directly or via intermediary cloud agents. In DIDComm, peers who are parties to the connection are individually responsible for the generation of their DID, the key pairs in a DID document, and the subsequent key rotation or revocation of those keys. DIDComm uses information from the DID document, such as the public key and its associated endpoint, to exchange secure messages. It enables distinct entities to connect with each other in a peer-to-peer manner, eliminating the need for a middleman.

This credential exchange protocol supports zero-knowledge proof (ZKP) cryptography using the Camenisch-Lysyanskaya (CL) signature scheme, which enables credential holders to selectively reveal claims to verifiers without any linkage.

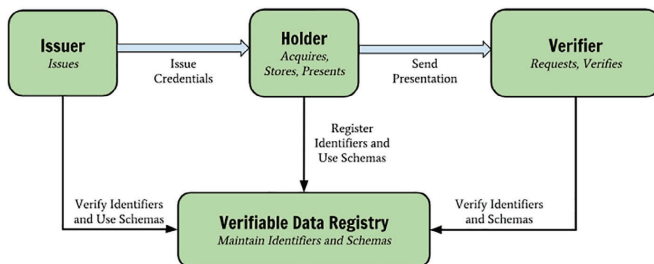

Fig. 1: SSI Architecture [16]

C. SSI Lifecycle Process

The lifecycle of a VC with Camenisch-Lysyanskaya (CL) signature which enables the zero-knowledge proof (ZKP) is detailed as follows:

- The issuer specifies the credential's schema, publishes the credential definition which indicates the intention to post a credential from schema X, signed using key Y, and with revocation strategy Z.
- The issuer generates a DID and correlates it with a public-private key pair. Afterwards, the issuer generates a DID document, signs it, and publishes it to the distributed ledger.
- The issuer collects all the information it intends to include in the credential, containing the information for each attribute specified in the schema defined previously. The issuer constructs the credential by creating a numeric representation of each field and then signs the numeric as well as the text formats of each of the claims using the CL Signature.

- The credential anchors a "link secret" that is known only to the holder (recorded in the holder's wallet), and when a credential is issued to the holder, it encapsulates a cryptographic promise to the "link secret" within another long number that the issuer serves as the credential ID. The "link secret" acts similarly to a watermark stamp. Therefore, the certificate's content is extremely difficult to falsify, proving that the holder owns the stamp and is able to create such a watermark.
- Once the holder owns the VC in his/her digital wallet, he/she can communicate with a verifier and may seek to prove a set of claims created by a specific issuer regarding a subject. The holder receives a request from the verifier for the type of credential it is looking for.
- The holder conducts certain calculations on the VC to prepare it for sharing in a proof presentation. The holder creates a new, never-before-seen credential wrapped inside a proof presentation. This later aggregates and discloses whatever attributes from issued credentials are requested, as well as any predicates, while hiding everything else. The 'proof' block of this new VC is a mathematical proof that the holder actually owns VCs signed by the appropriate issuer, containing the revealed attributes, and conforming to the specified schema.
- The proof also proves that the issuer has not revoked the credentials and that they are bound to the holder because the holder knows the "link secret" that was utilized at issuance. Afterwards, the verifier uses the information received from the holder in the form of a proof presentation to do certain calculations. It should cryptographically verify the validity of the proof. The verifier resolves the issuer's DID and identifies its public key. Then, using the issuer's public key, it validates the provided attributes. The presentation proof may comprise attributes from more than one credential. For each shared attribute, the verifier checks its corresponding credential schema, as well as the issuer's DID/DID document. It employs these two pieces of information to verify the presentation attribute. Each attribute statement in the proof presentation must follow this process. The verifier can be assured that all of the attributes are issued to the holder of the same "link secret".

III. BLOCKCHAIN-BASED SSI APPROACH FOR IOBP

This section provides a detailed description of the proposed approach. This description covers the proposed platform, the involved actors as well as the main process to ensure a secure IOBP communication (see Figure 2).

The main objective of the proposed Blockchain-based SSI solution is to ensure confidential inter-organization process execution while providing privacy-preserving traceability.

A. Platform components

The proposed platform includes three main components: an SSI interface, a private permissioned Blockchain and a Registry Proof smart contract which are described as follows.

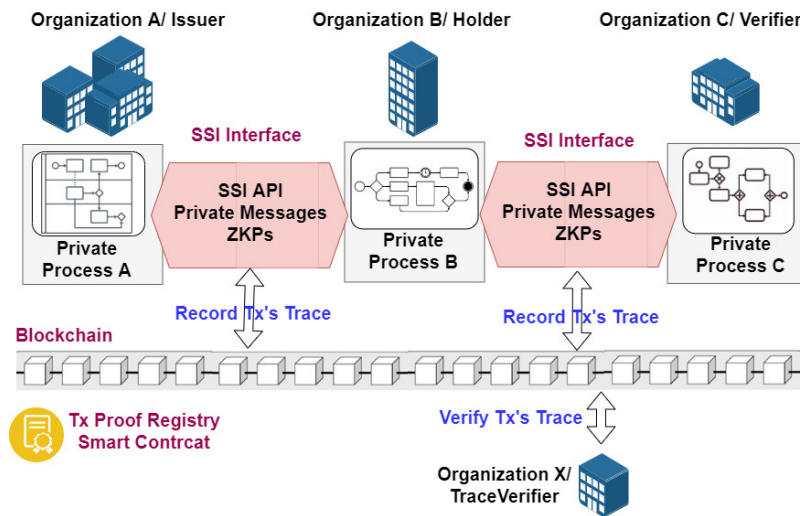

Fig. 2: Proposed approach Overview

- SSI Interface:** The SSI Interface between processes involved in the inter-organizational process presents modular libraries and APIs for Decentralized Identifiers (DID) and Verifiable Credentials (VC). It exposes its functionality to the cooperative organizations through a common interface API (i.e. RESTful API) to ensure interoperability. Therefore, collaborative organizations can keep using existing systems and databases while integrating this RESTful API as a common interface. The proposed SSI interface is aligned with the W3C specification and ensures JWT-based VC issuance, Selective Disclosure Request (SDR), and Verifiable Presentations (VP). Through the proposed SSI interface, each organization can present a DID document maintaining verification methods (i.e. public keys) and service endpoints (e.g., details of messaging service) that other organizations can use to establish interactions. Thus, before engaging in any formal activity in a relationship, two organizations should first mutually resolve each other's DID and acquire the interaction information preserved in the DID document.
- Private permissioned Blockchain:** The proposed platform relies on Ethereum [5] private permissioned Blockchain (i.e. Ethereum Private net) to allow only authorized users to access to the system by verifying their cryptographic keys. Furthermore, in the proposed platform, the Blockchain serves as a tamper-proof verifiable data registry as well as transactions' proof registry.
- Registry Proof Smart Contract:** The transactions' Proof Registry smart contract is proposed to record transactions' trace. Indeed, SSI systems do not offer a native way to record issuance and verification transactions on the Blockchain in order to ensure privacy and protect sensitive data. This can present a gap when audits are needed. Therefore, we propose to record only DIDs of interacting organizations as well as transaction hash to maintain a privacy-preserving trace. The data itself is stored locally off-chain for private process execution. While the proposed approach requires the use of a permis-

sioned Blockchain, a public Blockchain may also be used as a shared reference between collaborative organizations by recording the hash of each DID and the transaction hash.

B. Involved Actors

Many actors are involved in our proposed approach:

- Organizations:** In the proposed approach, each organization can play the role of issuer, holder or verifier when taking part in an inter-organizational process.
 - Issuer** (i.e., Organization A): When an organization issues a verifiable credential, its DID is associated with this credential for further verification. Here the issuer is trusted by different actors belonging to the permissioned Blockchain.
 - Holder** (i.e., Organization B): An organization has full control over its data including sensitive information and any request for accessing these data must necessarily require its confirmation. When performing a collaborative process, an organization can use the Selective Disclosure concept, during message exchange, to share selected pieces of information with interacting parties.
 - Verifier** (i.e., Organization C): An organization can verify the origin of exchanged data by checking digital signatures. Hence, it can confirm the validity and authenticity of shared verifiable credentials.
 - Trace Verifier:** A Trace Verifier is an authorized organization (i.e., Organization X) that has access to the trace provided by the Tx Registry Proof. It can check if an inter-organizational task/activity (i.e., exchange of message) was performed between collaborating parties. We note here that the TraceVerifier is distinct from the Verifier role belonging to the SSI concept.
- In the proposed solution architecture, each role may have multiple instances (i.e., multiple participating issuers, holders, verifiers, and trace verifiers).

C. Process flows

Figure 3 depicts the overview of the interaction between different actors involved in our proposed approach as a BPMN collaboration diagram.

The main interactions are as follows: An Organization A (i.e., Issuer) issues verifiable credentials to an Organization B (i.e., Holder) through message exchange in an inter-organizational collaboration. Afterwards, these verifiable credentials can be presented to an Organization C (i.e., Verifier) which confirms the validity and authenticity of data by verifying the signature of the issuer. The Tx Proof Registry records the transaction hash and the DIDs of interacting parties for both issuance and presentation activities. Consequently, an authorized Organization X (i.e., TraceVerifier) can check if the transaction between collaborating parties is performed.

Listing 1 illustrates the algorithm of the inter-organizational process of data exchange and storage.

This algorithm depicts a secure and private DIDComm between three cooperating organizations. An Organization A (i.e., Issuer) first encrypts and signs a message for Organization B (i.e., Holder). The signature and the cipher text are then sent through organization A's endpoint to organization B's endpoint. The authenticity of the message can be checked, by an Organization C (i.e., Verifier) before executing an IOBP, by resolving the DID and identifying whether it matches organization A's public key. All mentioned interactions are recorded in a privacy-preserving way on a Tx Proof Registry for further traceability by any authorized Organization X (i.e., Trace Verifier).

1. A process task exchanges DIDs with an Organization A (Org_A) (i.e. Issuer) to establish a DIDComm connection channel.
2. The Issuer employ the public key of the AES encryption scheme (pk_{aes}) to encrypt the data.
3. Data Issuer issues Verifiable Credential data (vc_{data}) to the process task with the (pk_{aes}) as an attribute of the credential.
4. Process task accepts and stores the Verifiable Credential in the Organization B (Org_B) (i.e. Holder) wallet.
5. The hash of the transaction ($trans_{proof}$) as well as Organization A (Org_A) and Organization B (Org_B) DIDs are stored on the Proof Registry.
6. Organization B (Org_B) exchange Verifiable Credential data with Organization C (Org_C) through a collaborative process within a DIDComm connection channel.
7. Organization C (Org_C) verifies the Proof Data by checking the signature and DID of the Issuer.
8. If proof data has been verified then
 - 9. Execute the current IOBP
 - 10. Store the hash of the transaction ($trans_{proof}$) as well as Organization B (Org_B) and Organization C (Org_C) on the Proof Registry.
11. An Organization X (Org_X) (i.e. TraceVerifier) can request transaction proof from the Proof Registry.
12. The TraceVerifier Evaluate the transaction proof and send the evaluation result for underlying organizations

Listing 1: Algorithm of SSI applied to IOBP

IV. CASE STUDY: PHARMACEUTICAL SUPPLY CHAIN

The pharmaceutical supply chain is a diversified and complex ecosystem, in which the secure management of identity and sensitive data is a typical issue.

The Drug Supply Chain Security Act (DSCSA) [18] enforces specific requirements on different types of stakeholders: manufacturers, repackagers, wholesale distributors, third-party logistics providers (3PLs), and pharmacies [19]. One such requirement is an extended Know Your Customer' regulation, which requires each entity to confirm that their partners are also authorized. In many situations, the regulation requires interactions between entities without any direct business relationship.

Therefore, to enable interoperability and trust, the pharmaceutical supply chain community has harnessed the power of Blockchain and Decentralized Identifiers (DIDs). Together, they provide all parties with a 'single source of truth' to address challenges, such as master data management and counterfeit detection. At a more essential level, different entities must be able to identify their partners and interact with them using Verifiable Credentials for compliant transactions and information disclosures.

The specific goals of this case study are: (i) authentication of a verification request with a verifiable credential, and (ii) enhanced verification between pharmacies and manufacturers.

Figure 4 shows a simplified model of the pharmaceutical supply chain as a BPMN collaboration diagram. The diagram contains seven pools, one for each involved parties: Raw Material Manufacturer, Pharmaceutical Manufacturer, Hospital Pharmacy, Hospital Healthcare Professional, Patient, Tx Proof Registry, Higher Authority of Drugs, and Pharmaceutical Industry (HADPI).

This diagram depicts many examples of data exchange between cooperative organizations, in which we use verifiable credentials' issuance and verification, such as *Raw Material Credentials*, *Pharmaceutical Credentials*, and *Product Credentials*.

We use colors to explain different roles and interactions. For example, the red color designates the issuance of *Raw Material Credentials* by the *Raw Material Manufacturer* which acts as an Issuer. These credentials are issued to the *Pharmaceutical Manufacturer* which plays the role of Holder. This issuance transaction is recorded in the Tx Proof Registry after its completion. The yellow color highlights how the *Pharmaceutical Manufacturer* can become an Issuer of the *Pharmaceutical Credentials*, while the *Hospital Pharmacy* acts as a Holder. The same interaction is performed between the *Hospital Pharmacy* and the *Hospital Healthcare Provider* (green color). Finally, the *Hospital Healthcare Provider* prepares a Verifiable Presentation to the *Patient* that contains *Pharmaceutical Product Claims* (blue color). Here the *Hospital Healthcare Provider* plays the role of a Holder while the *Patient* acts as a Verifier.

All issuance and verification transactions are recorded on the Tx Proof registry. Consequently, the HADPI can play the role of Trace Verifier, and thus check if transactions are performed between interacting parties.

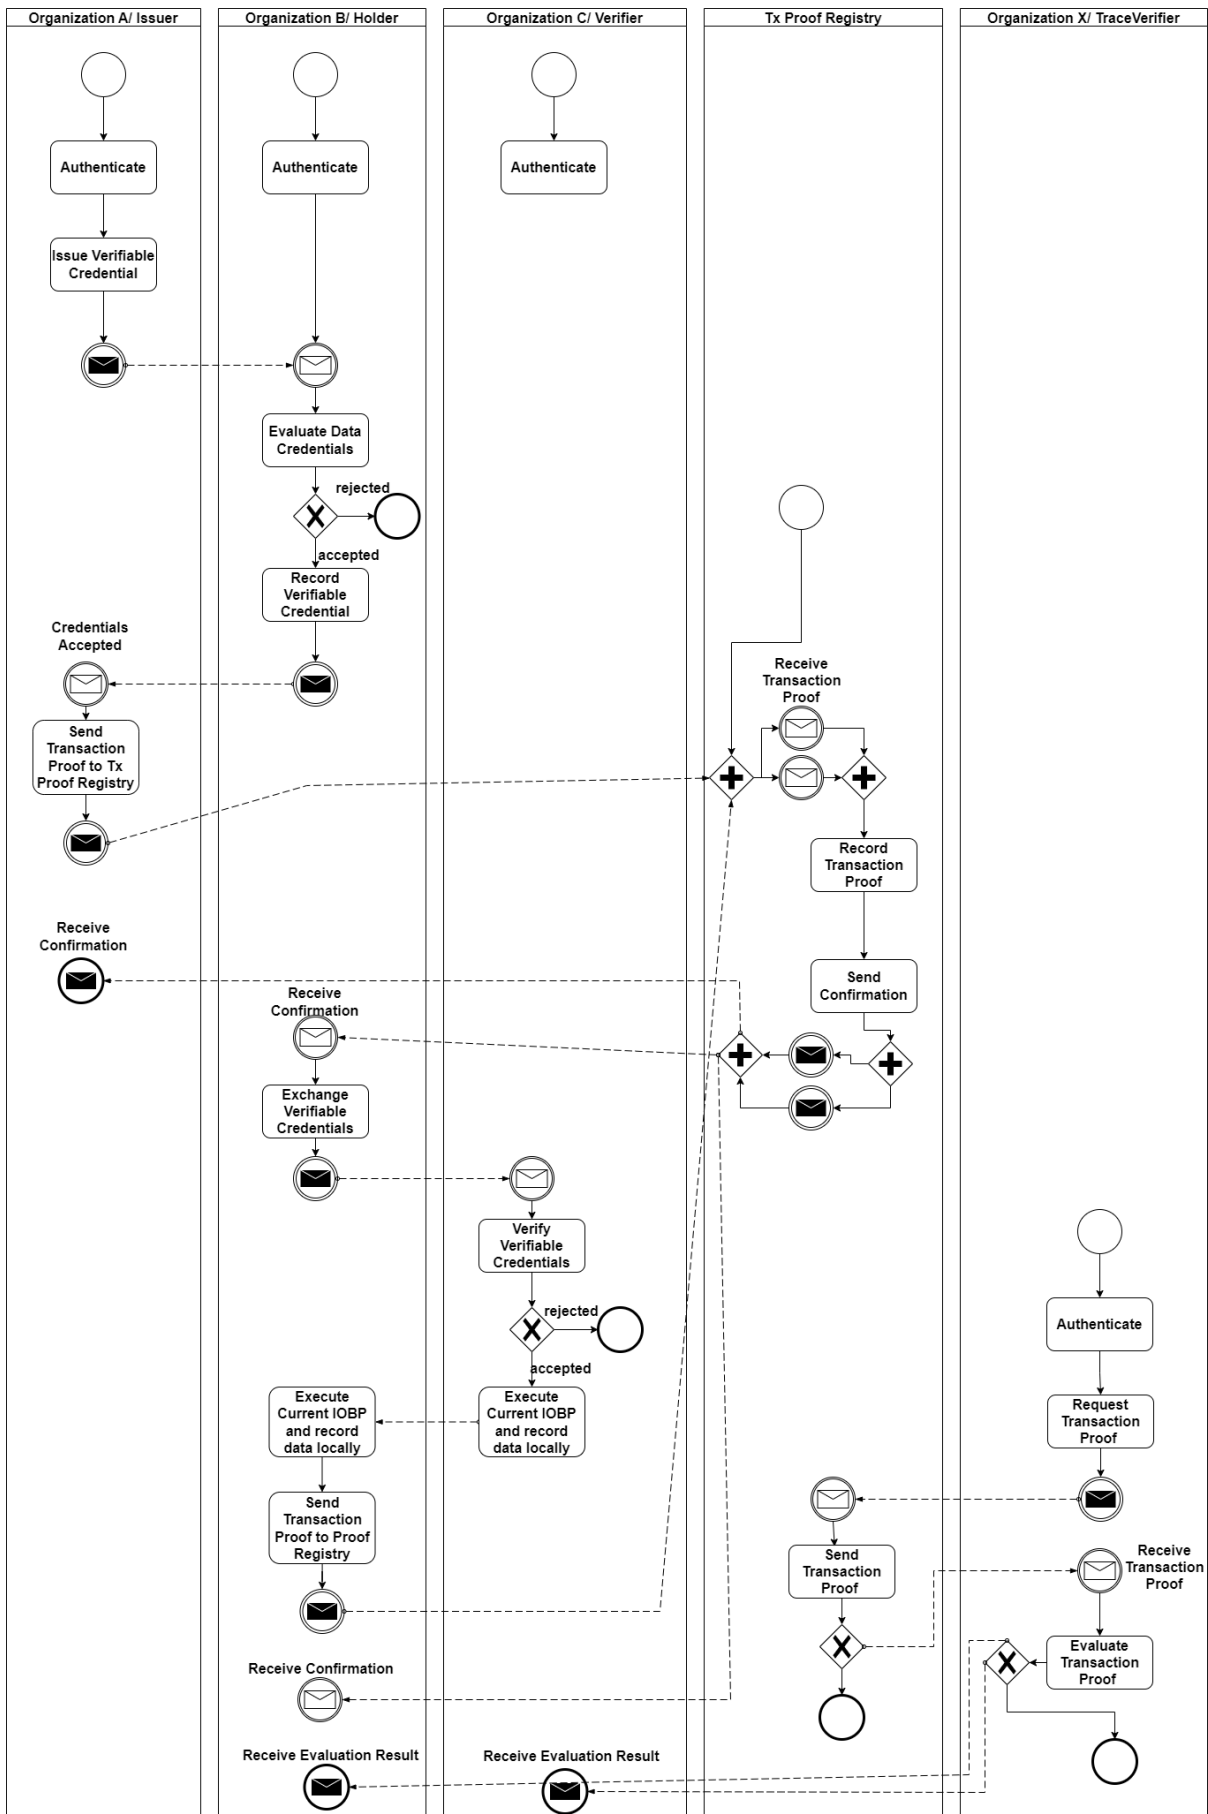

Fig. 3: Generalized BPMN diagram

V. IMPLEMENTATION

This section presents the implementation of the proposed Blockchain-based SSI approach for IOBP. In particular, we detail the implementation of both the SSI interface and the Tx Proof Registry smart contract.

A. SSI interface

In order to implement the SSI interface, we use Veramo [20], an open-source set of modular libraries and APIs for SSI and verifiable credentials. Veramo exposes its functionalities to the cooperative organizations through a common RESTful API. Therefore, collaborative organizations can keep using existing systems and databases, while integrating Veramo RESTful API as a common interface. Additionally Veramo's API is aligned with the W3C specification, and it supports the creation of Ethereum-based and web-based DIDs as well. Besides, the SSI interface ensures JWT-based VC issuance, Selective Disclosure Request (SDR) and Verifiable Presentations (VP).

The first step towards using and accessing the methods of Veramo API is to create a Veramo Agent and export it in the 'VeramoSetup.ts'. As a result, this Agent can be imported and used in the proposed SSI interface. Listing 2 shows an excerpt of the implementation of the Veramo Agent.

```

1 // Core interfaces
2 import { createAgent, IDIDManager } from "@veramo/core";
3 // Core identity manager plugin
4 import { DIDManager } from "@veramo/did-manager";
5 // Credential Issuer
6 import { CredentialIssuer, ICredentialIssuer } from "
7   @veramo/credential-w3c";
8 export const veramoAgent = createAgent<IDIDManager &
9   IKeyManager & IDataStore & IResolver & ... >({ plugins:
10   [ new KeyManager({
11     store: new KeyStore(dbConnection, new SecretBox(secretKey)
12     ),
13     kms: {local: new KeyManagementSystem(), },
14   }]),
15   new DIDManager({ store: new DIDStore(dbConnection),
16     defaultProvider: "did:key",
17     providers: { "did:key": new KeyDIDProvider({ defaultKms:
18     "local", })})
19   }]),
20   new DIDResolverPlugin({ resolver: new Resolver({ key:
21     getDidKeyResolver().key, getUniversalResolverFor(["io",
22     "elem", "sov"], )}),
23   }]),
24   new CredentialIssuer(),
25   new MessageHandler({ ... })),
26   });

```

Listing 2: Excerpt of the Creation of Veramo Agent

To construct the agent, all required plugins must be imported as libraries (Listing 2 lines 1-6) and taken into consideration when the object is initialized (Listing 2 lines 7-18).

After its creation, the Veramo Agent provides basic methods for creating Verifiable Credentials, Verifiable Presentations, verifying messages like JWT credentials and sending presentation requests as Selective Disclosure Requests.

Listing 3 shows an excerpt of the creation of a VC using the Veramo Agent.

```

1 async issueVerifiableCredential(body:
2   IssueCredentialRequest, toWallet: boolean): Promise<
3   IssueCredentialResponse> {
4   try {

```

```

3   body.credential.issuer = {id: body.credential.issuer.
4     toString()};
5   const save: boolean = body.options.save?body.options.save:
6     false;
7   const credential: W3CCredential = body.credential;
8   const verifiableCredential: W3CCredential = await
9     veramoAgent.createVerifiableCredential({ save: false,
10     credential, proofFormat: "jwt", });
11 // Prepare response
12 const result: IssueCredentialResponse = { credential:
13   verifiableCredential, };
14 if (toWallet) {
15   try { // Send VC to another Veramo agent
16     const msg = await veramoAgent.sendMessageDIDCommAlpha1({
17       save: true,
18       data: { from: verifiableCredential.issuer.id, to:
19         verifiableCredential.credentialSubject.id, type: "jwt",
20         body: verifiableCredential.proof.jwt, }, });
21     result.sent = true;
22     return result;
23   } catch (error) {
24     return error; }
25 }
26 return result;
27 } catch (error) {
28   return error; }
29 };

```

Listing 3: Excerpt of the Creation of a VC using the Veramo Agent

The credential object is prepared first (Listing 3 Lines 3-5), and then transformed to a VC using Veramo Agent's methods (Listing 3 line 6). Afterwards, the API response is prepared with the newly created VC (Listing 3 lines 8-10). If an error occurs during issuance, the error is returned as a response to the requester. Alternatively, if the API request specify that the VC should be sent directly to the DID's agent through the messaging endpoint (Listing 3 lines 11-16), it would be handled using the "sendMessageDIDCommAlpha1()" method.

Note that the source code of the proposed SSI interface is available on Github in [21].

B. Tx Proof Registry Smart Contract

The proposed Tx Proof Registry Smart Contract provides a privacy-preserving trace of SSI transactions. Indeed, SSI issuance and verification transactions need to be persistently recorded in a private manner for further verification (i.e. check if these transactions are actually performed). An excerpt of the proposed smart contract is presented in listing 4. It records both DIDs of interacting organizations as well as transaction hash.

```

1 event recordTrace ( address indexed sender , address
2   indexed receiver ,
3   bytes32 txHash )

```

Listing 4: Excerpt of the Proposed Tx Proof Registry Smart Contract

While the proposed approach requires the use of a permissioned Blockchain, a public Blockchain may also be used as a shared reference between collaborative organizations. In this case, we recommend recording the hash of each DID instead of directly recording the DIDs on-chain (see listing 5).

```

1 event recordTrace ( bytes32 indexed sender , bytes32
2   indexed receiver ,
3   bytes32 txHash )

```

Listing 5: Excerpt of Tx Proof Registry Smart Contract for public Blockchain

VI. EVALUATION

This section evaluates the proposed approach and shows its feasibility and efficiency for adoption within a real-world environment including both financial cost and response time.

A. Financial Cost

Transactions on Ethereum Blockchain are subject to a certain fee. Ethereum employs a unit known as gas to calculate the amount of operations required to complete a task such as deploying a smart contract or executing an ABI function. It is always necessary to estimate gas consumption when implementing a smart contract in order to avoid unexpected costs. Therefore, storing data directly on-chain suffers not only from privacy issues but also from being costly.

In the proposed Tx Proof Registry smart contract, only the DIDs of interacting organizations and the hash of the transaction are recorded on-chain, the data itself is stored locally off-chain for private process execution. Table I shows the transaction cost for the execution of 'recordTrace' function as well as the deployment of the Tx Proof Registry smart contract.

TABLE I: Operations' Gas Cost

Operation	Gas
Tx Proof Registry Smart Contract Deployment	362,525
Record Trace ABI call	64,384

B. Response time

The proposed approach is dependent on Ethereum Blockchain's latency. In fact, despite the reduction of data-size recorded on-chain, storing DIDs and transactions' hashes on-chain leads to some overheads. These overheads can be tested by sending simultaneous requests to the Tx Proof Registry Smart Contract. Figure 5 depicts the completion time in seconds (Y axis) of the "TraceRecord" operation where we send between 1 and 800 simultaneous requests (X axis).

Fig. 5: Response Time Evaluation

To sum up, the experimental evaluation shows that the implementation can achieve good results with low gas costs as well as low latency.

VII. RELATED WORK

This section provides an overview of the existing solutions for secure inter-organizational collaborations.

Authors in [10] proposed a distributed Private Data System (PDS) to achieve self-sovereign storage and sharing of private data between multiple organizations through executable choreographies. The users have complete control over their private data and are allowed to share and revoke access to organizations at any time. However, PDS does not leverage the power of Blockchain technology to address consensus problems in a distributed environment. Instead, the PDS's system is composed of nodes spread across the entire Internet managing local key-value databases. This could present a complex infrastructure and require some effort, thus may be inefficient for individuals.

Another interesting work that exploited the strength of the Blockchain technology to ensure privacy-preserving inter-organizational collaborations is proposed in [11]. Authors presented, ID-Service, a platform for designing, implementing, and executing Cross-Organization Workflows' services. It adheres to the concept of security by design in terms of trust, accountability, non-repudiation, and the system's capacity to offer forensic proof of workflow traces, critical actions, and actors' responsibilities and to maintain these features during execution. However, ID-Service does not implement the Self-Sovereign Identity (SSI) model. Consequently, it does not afford any flexibility for identity's self-possession and control.

The SSI approach has mostly been explored in the field of security, privacy, and distributed systems, with little attention paid to information systems research and process perspective. At present, there are only a few academic papers on the application of SSI in business scenarios. They include the application of SSI in know-your-customer processes in banking [22], remote management of industrial equipment [23], payback programs in retail [12], student exchange [24], e-petitions [25], access to public health services [26], assigning medical information to persons without regular identity, e.g. to combat COVID-19 [27]. The majority of these studies represent typical business processes that consider in particular the Consumer-to-Business relationship and omit dealing with inter-organizational collaborations (i.e. Business-to-Business (B2B)). For instance, authors in [12] introduced an SSI-based system for incentivized and self-determined customer-to-business data sharing in a local economy context. Here consumers are not only the owners of their data, but also they can choose what to share and in which granularity to trade their data for financial rewards. In the same direction, authors in [13] presented SSI as a solution to deal with privacy-preserving licensing of individual-controlled data to avoid unauthorized secondary customers' data usage.

The majority of the aforementioned approaches use the SSI concept to ensure data privacy and omit to propose a privacy-preserving solution to trace SSI transactions for further audit requirements. This is presented in a very broad sense in [14]. Authors proposed the concept of a proof registry through a set of technical components, data structures, and process flows, that ensures that proof data can be validated in

case of disputes or audits. However, authors did not provide any implementation nor an example of a smart contract to illustrate/show how the traceability is performed. Besides, authors do not provide a solution for inter-organizational process execution.

Unlike all cited previous work, the proposed approach provides a Blockchain-based SSI solution for inter-organizational processes. Particularly, it proposes an interoperable SSI interface between collaborating organizations as well as a privacy-preserving proof registry for further audits and verification.

VIII. CONCLUSION

In this paper, we proposed a Blockchain-based SSI approach for IOBP. It ensures confidential inter-organization process execution, particularly inter-organization message exchange without exposing any sensitive information on-chain. The SSI concept is combined with a proof registry smart contract to provide a privacy-preserving trace for further audit verification.

In future work, we aim to enhance the proposed proof registry to enable enriched analysis on private data for authorized organizations.

Abstract—The COVID-19 pandemic forced universities to rapidly switch to distance learning, while simultaneously accelerating changes that might facilitate a more inclusive model of education. The goal of the research was to investigate the multi-dimensional aspects of learning online, including students' gender, age, and culture. The research results, based on 1562 survey responses from Polish and Ukrainian students, suggest that there are still differences between men and women as far as digital competences are concerned that might have their background in the traditional perception of gender roles. Besides, the pandemic has accelerated the processes of hardware and software enhancement in order to facilitate online learning, especially in Ukraine, which is mitigating technological exclusion. The possibility of accessing learning resources online, might allow people with lower economic status or women to continue education. The research results might be helpful in the development of future educational policies at Polish and Ukrainian universities.

I. INTRODUCTION

The COVID-19 pandemic has triggered research concerning distance education and the future of education. The main investigated paths include: organisation of online learning [1], [2], students' and teachers' attitude towards distance learning [3], and students' wellbeing [4]. Distance learning has the potential to deepen the equality, fairness, and inclusion among the members of the society. It should be noted that distance learning also gives the opportunity for wider access to education for unprivileged people, i.e. inhabitants of rural areas, poor members of some ethnic groups and/or people with disabilities [5]. However, to the best of our knowledge the topic of opportunities that have arisen during the COVID-19 pandemic for shaping the more inclusive future education has not yet been thoroughly investigated. In recent years, the number of Ukrainian students in Poland has been growing constantly. From the perspective of teaching organisations, it is of great importance to investigate whether there are any differences between Polish and Ukrainian students and between students of different gender or age in case of their online behavioural pattern, as it might influence their attitude to learning in general, and to distance learning in particular. This was the main motivation for our research. More

specifically, we would like to answer the research question: Are there any relationships between gender, age, country and online behaviour before and during the pandemic? In particular we are interested whether there are any differences in: (RQ1) perceived student wellbeing? (RQ2) hours spent online? (RQ3) social behaviour patterns (social cycle)? (RQ4) attitudes towards online communication? (RQ5) attitudes towards online education?

In order to answer the research questions, a joint project was undertaken by the faculty of the Cracow University of Economics (CUE), Poland and the Zhytomyr Polytechnic State University (ZPSU), Ukraine.

II. RESEARCH BACKGROUND

The pandemic forced universities to switch to distance learning and thus provided a unique opportunity to experience this type of learning even by people who previously avoided it. Belan [6] has analysed the attitudes of Polish and Ukrainian students towards remote learning and teaching technologies in training teachers of vocational education. He points out that Polish experience may be used as a benchmark for Ukraine. Basing on that premise the author proposes the modernization of the Ukrainian educational system. Klapkiv and Dluhopolska [7] discuss the challenges and opportunities during the quarantine caused by COVID-19 in Poland and Ukraine. It was indicated that the Ukrainian education system was largely unprepared to tackle these challenges due to the bureaucracy, the process rather than result orientation, educational conformism, and the lack of motivation of the main stakeholders.

The influence of distance education on the mental health of students has been already discussed in research works. For example, the relationship between the neuroticism and the pandemic of Polish and Ukrainian students was examined by Długosz and Kryvachuk [8]. The research indicates that high levels of neuroticism were observed among 61% of respondents from Poland and 47% from Ukraine. The research has also indicated that Ukrainian students better cope with

TABLE I
RESPONDENTS' STRUCTURE

		Poland		Ukraine	
		No.	%	No.	%
Gender	Female	643	64%	234	42%
	Male	357	36%	305	55%
	Not specified	5	0%	18	3%
Age	Young: < 20	143	14%	329	59%
	Medium: 20-24	727	72%	213	38%
	Older: 24+	135	13%	15	3%

quarantine and have better mental health. The problem of mental health deterioration during the pandemic has also been investigated in a broader perspective by Ochnik et al. [9]. The research outcomes indicate that the state of students' mental health is alarming and higher educational institutions (HEIs) should provide psychological support for them. There are also research works that explore a broader perspective of distance education, e.g. the problem of the limitations concerning the continuation of university education [4].

III. RESEARCH METHODS

The research is part of a project undertaken by the faculty of CUE and ZPSU. The goal was to investigate multi-dimensionally the students' perspective of distance learning in the time of the pandemic. Preliminary results of the research that looked at only one country's perspective were published in [10] and [11], with Polish and Ukrainian data respectively. This paper extends these studies by comparing data and providing a multi perspective analysis of respondents' viewpoints, including gender, age, and country.

We gathered the data in May and June 2021 using a questionnaire (see Appendix). In Poland, the survey was sent to students of CUE, mainly representing business studies. 1005 questionnaires were received giving a response rate of 8% (Cochran Formula: the margin of error is equal to 3% with a confidence level of 95%). In Ukraine, the questionnaire was distributed among students of seven universities: Zhytomyr Polytechnic State University, National University of Life and Environmental Sciences, Uman State Pavel Tychyna Pedagogical University, Melitopol State Pedagogical University, Drohobych State Pedagogical University, National Pedagogical University, and Kryvyi Rih State Pedagogical University. In total, we received 557 responses from Ukrainian students. We analysed the data using descriptive statistics.

The respondents' structure presents Table I. As far as respondents' digital competences are concerned, about 40% of respondents from Poland and Ukraine assessed their skills as average, however only 2.4% of Poles assess their skills as below average, while 17% of Ukrainians assess their skills as such. There were visible differences between age groups. It is especially apparent in the Young group, where the results are 0.9% and 13.5%, respectively. Hence, it seems that the Ukrainian student population is much more diversified as far as digital competences are concerned. In both countries men

TABLE II
AVERAGE SELF-PERCEPTION OF WELLBEING

		Poland	Ukraine
Total		2.75	2.78
Gender	Female	2.72	2.74
	Male	2.79	2.82
Age	Young	2.73	2.77
	Medium	2.66	2.78
	Older	3.23	3.00

1-severe deterioration, 2-deterioration, 3-neutral, 4-improvement, 5-considerable improvement

assessed their digital competences higher than women. About 9% of Ukrainians reported constant or frequent technical problems, whereas in Poland only 3%. This indicates the differences between technical environments in Poland and Ukraine. In both countries, women assess their technical conditions slightly better, similarly to the Older group of respondents.

In order to capture the possible changes in students' online behaviour, we assessed the number of "friends", both with respect to online and face-to-face contacts before and during the pandemic. We defined "friends" as people with whom respondents actively maintain contact in the private sphere.

IV. RESULTS

RQ1: Students' Wellbeing. The deterioration in students' wellbeing is visible among both Polish and Ukrainian students at a similar level (Table II). However, the Older Ukrainian group did not notice changes in wellbeing (mean: 3.0), while the Older Polish group reported a slight increase in well-being (mean: 3.23).

RQ2: Hours Spent Online. There was a difference in the time spent online between Polish and Ukrainian students before the pandemic: Ukrainian students on average spent six hours more online per week than Polish students. These differences were visible in all categories. It should be noted that during the pandemic the numbers of hours spent online were almost equal in Poland and Ukraine, respectively 36 and 35 hours per week. However, in both respondent populations, women spent less hours online than men, both before and during the pandemic. Similarly, the number of hours spent online in relation to studies before the pandemic was higher in Ukraine than in Poland, the difference visible in all categories.

Table III shows that online studies contributed mostly to the increase in the number of hours online. In percentage change, 100% means that all of the increase is related to online learning. The values for Poland are close to 100%, hence it seems that the entire change was related to online learning. In the case of Ukraine, except for the Young group, the values are quite distant from 100%, for the Medium group it is 129%, which can be interpreted that online learning forced the resignation from other online activities, while in the case of the Older group, the increase in online activity was related to activities other than learning.

TABLE III
PROPORTION OF THE TOTAL ONLINE ACTIVITY INCREASE ATTRIBUTED TO ONLINE STUDIES AND THE CHANGE OF THE PERCENTAGE OF ONLINE LEARNING IN TOTAL ONLINE ACTIVITIES

		Increase		Change	
		Poland	Ukraine	Poland	Ukraine
Total		97%	110%	17%	8%
Gender	Female	98%	97%	16%	7%
	Male	97%	123%	15%	9%
Age	Young	104%	101%	20%	6%
	Medium	96%	129%	16%	12%
	Older	103%	37%	15%	-8%

In the time spent online related to studies, it is worth noting that in Poland there was an increase in each group (although the increase gets smaller with age), which means that online learning was a significant factor in the increase in time spent online. A similar situation was observed in the Ukrainian Young and Medium groups, but it is interesting that in the Older group we have a decrease, which means that the increase in time spent online was mostly not due to online learning, but other online activities. This can be related to the types of contacts – in the Older Ukrainian group the largest decrease in face-to-face contacts can be observed, with the largest increase in online contacts, which directly translated into increased online activity related not to studies, but to maintaining social contacts.

The share of online learning in the total time spent online increased both in Poland and Ukraine, but it seems that Ukrainians spent proportionally more time on learning online before the pandemic (Table III).

RQ3: Social Pattern Behaviour. There are visible differences in the average number of friends online between Polish and Ukrainian respondents: the average number of contacts online decreased in Poland from 13 to 12 and increased in Ukraine from 11 to 14. On average, the number of face-to-face friends decreased in both populations, however this change was more drastic in the case of Polish respondents (decrease from 16 to 8; among Ukrainian respondents the decrease from 10 to 8) (Table IV shows the changes). Polish respondents keep in touch with online contacts much more intensively than their Ukrainian counterparts. In both respondent groups the increase in constant online communication is visible during the pandemic but more considerable in the case of Polish respondents (16% increase).

RQ4: Attitudes towards Online Communication. The pandemic contributed to a more favourable perception of online communication among Ukrainian respondents (Fig. 1). Although it is difficult to notice any global differences between Poland and Ukraine in terms of age, it is interesting that in terms of communication “constantly” the increase in Ukraine is slight, while in Poland it is significant. There is an increase in the number of online contacts in Ukraine. The number of contacts is growing but their intensity is smaller, unlike in Poland, where we observed a decrease in the number of

TABLE IV
CHANGE IN A NUMBER OF ONLINE AND FACE-TO-FACE FRIENDS

		Online friends		Face-to-face friends	
		Poland	Ukraine	Poland	Ukraine
Total		-1	3	-8	-2
Gender	Female	-1	3	-9	-2
	Male	0	2	-7	-1
Age	Young	-2	3	-7	-2
	Medium	-1	2	-9	-1
	Older	2	4	-7	-5

Fig. 1. Respondents' attitudes towards online communication

contacts, but a visible increase in their intensity.

In all categories, the changes in attitudes towards online communication were slightly positive with a greater difference among females (Table V). In both Poland and Ukraine, we saw a difference according to the age: the scale of positive attitude change in the Older group is much higher than the average. This means that a significant part of this group - forced to use online communication due to the circumstances of the pandemic - gained a more positive opinion of it, while the Young and Medium groups hardly changed their opinion (perhaps because they were already used to this form).

RQ5: Attitudes towards Online Education. Both Polish and Ukrainian men preferred distance learning more than women (before and during the pandemic), but these preferences were stronger among Ukrainian men. However, as Table VI shows, women changed their preferences more than men, in favor of distance learning. Similarly to changes in online communication, we assessed the changes in the attitudes towards online

TABLE V
CHANGES IN ATTITUDES TOWARDS ONLINE COMMUNICATION

		Poland	Ukraine
Average		0.16	0.06
Gender	Female	0.17	0.08
	Male	0.13	0.06
Age	Young	0.05	0.05
	Medium	0.15	0.07
	Older	0.30	0.27

TABLE VI
RESPONDENTS' DISTRIBUTION IN ACCORDANCE TO ATTITUDES'
CHANGES TOWARDS DISTANCE LEARNING

			I do not like	Neutral	I prefer
Total	Poland		5%	-20%	15%
	Ukraine		1%	-10%	8%
Gender	Poland	Female	5%	-23%	17%
		Male	-12%	-16%	13%
	Ukraine	Female	-1%	-12%	12%
		Male	4%	-8%	6%
Age	Poland	Young	-1%	-14%	14%
		Medium	7%	-23%	16%
		Older	3%	-19%	16%
	Ukraine	Young	2%	-9%	7%
		Medium	0%	-7%	7%
		Older	7%	-40%	33%

education. A positive change was visible in both countries (0.25 for Poland and 0.13 for Ukraine, respectively), but greater in Poland. Taking into account the gender criterion, the positive change in attitude was greater in the case of women (especially in the case of Ukraine where it was over three times higher than men). In the Young and Medium groups the scale of changes was similar to the average for both countries, while in the Older group it was greater than average: in the case of Ukraine it is over three times higher than the average.

V. DISCUSSION

The differences between digital competences of Polish and Ukrainian respondents might have three fold explanation: (1) Ukrainian youth enter higher education on average 2 years earlier than their Polish counterparts, which is a huge difference at this age; (2) differences in the level of IT education at the earlier stages, and (3) economic differences between Poland and Ukraine, resulting in lower availability of computer equipment in Ukraine. Interestingly, a much greater share of Ukrainian women than men assessed their IT skills as below average. It seems that Ukrainians are aware of some deficiencies in digital competences, and that is why actions have been taken to develop these skills by students [12], [13].

In general, Ukrainians perceive their technical conditions as worse than Poles. In Ukraine, a lot of students come from villages, without access to the Internet. Ukrainian families on average are much poorer than Polish ones; sometimes Ukrainian students do not have private computers and they can only use computers at universities, having access to the Internet via their mobile phones. Technical problems mainly concern younger Ukrainian respondents, which might be explained by their strong economic dependence on parents (for whom the Internet does not have to be a priority, especially in a generally poor economic condition).

Similarly to the findings in [4] we noticed the deterioration in students' wellbeing. However, contrary to the research

results reported by [8] we did not notice considerable differences in wellbeing deterioration between Polish and Ukrainian respondents: indeed slightly more visible wellbeing deterioration was detected among Polish respondents. At the beginning of the pandemic there were severe restrictions on face-to-face communication, which may be the reason for the deterioration of the wellbeing of respondents. It should be noted that in Ukraine the survey was conducted at the time when learning at universities was on premise (contrary to Poland), hence Ukrainian respondents' memory might fade as far as bad distance learning experience is concerned. Improvement of the wellbeing of the Polish Older group of respondents might be explained by the fact that this group contains students above the age of 24, including part-time students, for whom remote learning is much more attractive due to less organizational effort and resources required to study in this mode.

Some Ukrainian students have limited access to computers and that is why the pandemic has not caused such a great increase in the number of hours spent online like in the case of Polish respondents. Besides, a lot of Ukrainian students take part in distance courses offered by various companies that also increase the total number of hours online. Not surprisingly, learning activities contributed the most to the increase in time spent online during the pandemic. In general, before the pandemic, classes in HEIs in Ukraine (with a few exceptions) were conducted on premise, in connection with which the transition to distance learning caused a sharp increase in the number of hours that Ukrainian students spent online for educational purposes.

There were significant differences in online behaviour patterns between Polish and Ukrainian students: in Ukraine there was a slight decrease in personal contacts and a high increase in online contacts; in Poland there was a huge decrease in face-to-face contacts and a small decrease in online contacts. The decrease in online contacts in Poland might be the result of the decrease in face-to-face contacts – when restrictions were severe and the number of face-to-face contacts decreased, then online contacts resulting from them also decreased. Pandemic regulations were similar, hence the differences between the results might be attributed to culture differences. In Ukraine a lot of families were forced by the pandemic to buy devices that facilitate online communication, and that is why its increase is noticeable.

Interestingly, during the pandemic almost the same numbers of face-to-face contacts were reported in both countries – 8 in Poland and 9 in Ukraine. Maybe this convergence defines the social sphere, but this topic would require further investigation. Differences in the frequency of online communication might be attributed to the differences in device ownership: Polish students usually have computers with Internet access that allow them to communicate constantly or several times a day, whereas some Ukrainian students only use computers with Internet access at campuses, which allows them to communicate online once a day or a few times a week. There is a difference in the behaviour between Poles and Ukrainians: in Poland the decreases in face-to-face contacts

are greater, however it seems that older students in Poland transferred some contacts from face-to-face to online. In the case of Ukraine such an interpretation may apply to all age groups. This might be caused by the increased availability of communication equipment in Ukraine.

In Poland most respondents were neutral towards online communication. This might be explained by the fact that they have had access to this way of communication for a long time and might be tired of it being a part of everyday life. On the contrary, in Ukraine, respondents seem to like this way of communication. Maybe they still treat it as something new that opens up more possibilities.

The quality of distance learning in Ukraine might be lower than in Poland since this country has less experience in this type of teaching, however at the time of conducting the survey students had classes on premise and that is why they might be more in favour of distance learning. In Poland the usage of distance learning was more intense and some students might be fed up with it. Such a recurring difference between the members of the Older group and the other groups may result from the fact that earlier these students had no habit, or even had resistance, to online learning, and using this form, being forced by the pandemic, could significantly change this attitude. Interestingly, women change their attitude towards online learning to much more positive than men, similarly to older students.

In further research, we would like to investigate thoroughly different aspects of online learning, focusing mainly on the perspectives of online learning and the model of education after the pandemic.

APPENDIX

Survey items related to the current study

- 1) Gender; Age
- 2) Digital competences: beginner; below average; average; above average; professional
- 3) Technical conditions (ICT): constant problems; frequent problems; sufficient for basic needs; occasional problems; have no problems
- 4) The number of hours spent online per week (not counting professional work, but including studies) is approximately (up to 15h; 16-25h; 26-35h; 36-45h; over 45h)
- 5) The number of hours per week related to online studies
- 6) Estimated number of friends in regular socializing via electronic media (social media)
- 7) Estimated number of friends in face-to-face contacts
- 8) The frequency of communicating with friends via electronic media (occasionally; a few times a week; once a day; several times a day; constantly)
- 9) Attitude towards Internet communication
- 10) Attitude towards distance learning (e.g. training videos on Youtube)

- 11) Mental health change after switching to distance learning (significantly deteriorated; worsened; no change; improved; significantly improved)

Abstract—Development of information and communication technologies (ICTs) and society are interdependent. Smart City (SC) is one conception emerging as a result of such interdependence. This paper considers evolution of teams, society, SCs, and Information Systems based on Patterns of Primary, Adaptable, Information, and Creative Society. The evolution is described in 16 levels according to the Simple Learning Motivations Hierarchy Model (SLMHM). Success factors of ICT projects and strategy for SC development are discussed from point of view of patterns considered.

I. INTRODUCTION

THERE is a gap between development levels of society and technologies. Such phenomena are observed during globalization processes where developed countries try to adopt technologies in undeveloped ones. Artificial Intelligence (AI) threat to humanity is an example of a gap between levels of society development and ICTs. Another gap relates to 5G cellular networks, where some researchers cannot say if this technology is dangerous, or not [1, 2].

Structure of society patterns, including Initial Formation (IFP), Primary (PSP), Adaptable (ASP), Information (ISP), and Creative (CSP) (the five patterns in further text)[3], is considered. The five patterns are based on idea of four organization cultures, i.e. Impulsive, Dependent, Independent, Interdependent [3, 4]. Development of society and ICT solutions are considered according to 16 levels of the SLMHM model (see [5] and Fig 1 for details). The discussion includes conception of SC [6-12] and several maturity models [8, 10, 12-20]. Understanding of demand in information technologies and information systems (IT/IS) according to the five patterns and SLMHM levels is a success factor of ICT projects.

II. METHODOLOGY, THEORETICAL BACKGROUND, AND RESEARCH QUESTIONS

This research is theoretical and based on observations and literature analyses. The methodology is based on the 1) literature analyses; 2) juxtaposition of the five patterns, SLMHM levels, and IT/IS (see Fig. 1); 3) discussion of findings and their possible practical application.

Ecological, economic, socio-cultural, and political components were proposed to be considered as ones of the Sustainable Information Society (SIS) [21]. Technological, economic, occupational, spatial, and cultural elements of the Information Society were selected [22]. 17 UN sustainable development goals [23] can be achieved by the harmonization of society and the environment. ICTs provide valuable tools for such harmonization allowing intensive information processing and control [3,5]. Rabie describes human society development ages as the following: hunting and gathering, agricultural, industrial, knowledge (post-industrial, the information, the globalization) [24].

Cities worldwide play a prime role in social and economic aspects and have a huge impact on the environment [6]. Although the meaning of SC is not settled yet, there is an agreement on the significant role of ICTs in smart urban development [7]. ICTs are an important tool for the transformation of industrial society into information and knowledge society. It is a networked society, emerging a new social morphology, and gaining economic, social, political, and cultural primacy. Society is constantly changing, either because the economic, social, political, and cultural contexts are increasingly massified, internationalized, and globalized, or because the relations of life, study, work, and capital are changing rapidly and constantly [25].

There are also several mature models allowing to assess how “smart” the city is. The low level of maturity of the SC, the lack of sufficient and real-time data, and the lack of standardization in previous years hampered the development of such models. Citizens are considered “prosumers” of geo-tagged data and content affecting cities’ everyday norms and interactions [8]. The study shows that SC can be considered a socio-technical system [9].

SC Development Maturity Model, defined in [10] consists of five levels: initial, repeated, defined, managed, and optimized, and is built based on six factors for which the maturity is determined on these five levels which are strategic alignment, culture, people, governance, method, and IT/IS.

Software Capability Maturity Model (SW CMM) was developed by the Software Engineering Institute (SEI) at Carnegie Mellon University in 80s-90s as a response to a re-

quest to provide the government with a method for assessing the capability of their software contractors [13]. It should be mentioned, that SW CMM was developed for organizations, but not for country-level projects [14, 15]. Since the introduction of the Capability Maturity Model, many maturity models were developed including Knowledge Management Maturity Model (KMMM) [16].

There are ISO 37xxx standards relating to establishment of SC operating models for sustainable communities [26-28]. There are ranking SC models and experience of ranking cities [11, 29]. The SC Maturity and Benchmark Model have been designed to capture the key aspects of a city's transformation journey to a smarter city. The model allows a city to quickly assess its strengths and weaknesses in five key dimension areas related to city smartness and set clear goals as to how it wishes to transform over the next two-five years [12]. Three maturity models, which approached a city in a holistic way were discussed in [17, 18]. Main maturity model design patterns were identified. Typically, three application-specific purposes of the model used, i.e. descriptive, prescriptive, and comparative are distinguished [19]. Different Maturity Models for Information Systems were studied. The number of levels in the considered models varies from 4 to 6 [20].

Sarkar describes quadri-dimension economy as a part of Progressive Utilization Theory (PROUT) [30]. These 4 parts of economy intuitively match 4 McWinney's realities [31, 32]. Several economic conceptions were taken from Life Cycle Management [33-35] and from the experience economy [36]. Types of dystopia that are described in [37] intuitively match to the considered patterns.

The following research questions are:

RQ1. What are the stages of society development from ICTs point of view?

RQ2. How do stages and trends of society development relate to ICTs and how this relation can be used for ICT projects?

III. THE MODEL

Fig. 1 outlines the five patterns, SLMHM levels, and related IT/IS. The five patterns are similar to the development stages. Main features of the model include:

- society develops consequentially from Initial Formation to Primary, then to Adaptable, then to Information, and finally to Creativity stages;
- SLMHM allows modeling the team/society development by more detailed steps (levels);
- transition to specific level requires satisfaction of requirements of all previous levels;
- there are no clear boundaries between development stages;
- the structure of society contains IFP, PSP, ASP, ISP, and CSP in different proportions;
- the prevailing pattern shows which technologies are demanded;

- applicability to groups of any size, from small teams up to large organizations and society;
- can be integrated with other models vertically (by relevant layers) and horizontally (by breaking up the area of interest into parallel developing parts).

IV. DISCUSSION OF THE FINDINGS

There is intuitive match between the five patterns and different economical (four Whitmore's cultures [4], dimensions of sustainability [33], etc.) and philosophical (PROUT [30], McWinney's realities [31, 32], etc.) conceptions. The match is discussed in detail in [3]. According to [28], the model, presented in Fig. 1 corresponds to all three levels of SC standards: Strategic, Process, and Technical Specifications. There is no direct accordance between the CMM [10] and SLMHM levels. Meanwhile, one can say that some match between CMM and SLMHM levels exists.

Part of the IFP in society can be assessed through a percentage of the informal economy and unemployment rate. So, the contribution of the informal sector, excluding agriculture, to GDP in developing countries is about 16.3% (Venezuela, 2006) up to 61.8% (Benin, 2000) [38]. The study presented in [39] shows higher figures for informal non-agricultural employment – from 46.2% (Hanoi) up to 83.1% (Lomé). One can say that exclusion of the agricultural sector from considering informal employment reflects the fact that the agricultural sector relates to the agricultural age according to Rabie [24], i.e. to the PSP. Entertainment ICT solutions seems the only ICT solutions demanded in this pattern.

PSP represents the structure (skeleton) of the society. Its part can be estimated by level of bureaucracy and traditions. Here database solutions seems the most demanded ones. ASP is based on logic and facts. Industry and production are the main components of the ASP, while analytics and optimization are the main components of ICTs. ISP is characterized by connectivity and networks. The main values of this pattern relate to the human feelings. That's why social media and networks have become so popular nowadays. CSP is the next pattern, characterized by the creativity, ideas, and expansion. The key technologies here are Artificial Neural Networks (ANNs), AI, and blockchain. Although mankind is in the information age (ISP), the entry into the post-information age (age of creativity / CSP) is characterized by the development of these technologies. This is possible because there are no clear boundaries between development stages.

IFP, PSP, and ASP relate to reactive approaches to the changes. IFP is not considered in many cases because it does not relate to a team or complete society. The main aim of ASP is to achieve adaptation to changes and sustainability. ISP and CSP relate to proactive approaches [41] to the changes and sustainable development.

There is a need for a maturity model for maturity modeling [42]. SLMHM can be used to design other development and maturity models.

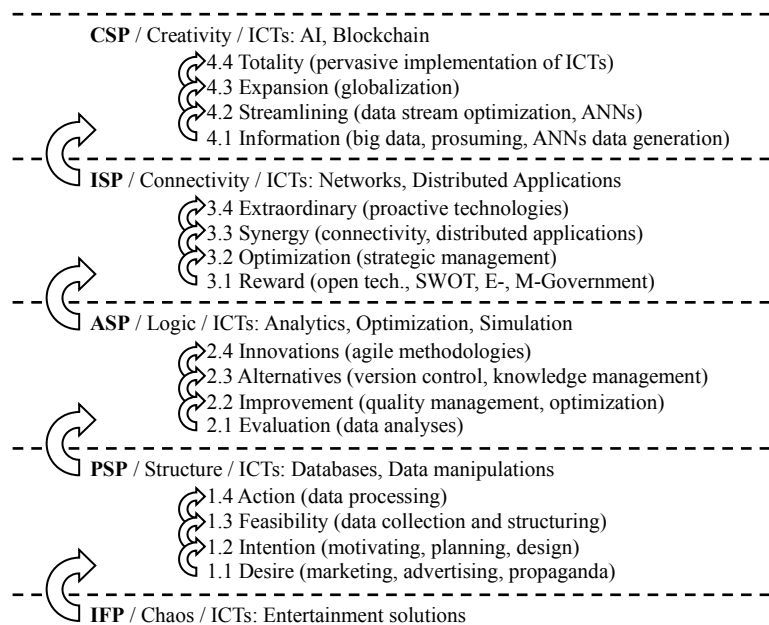

Fig 1. The Five Patterns, SLMHM Levels, and IT/IS

Examples of problems that can be explained by the considered model are presented in Fig. 1. They include:

- AI threat problem. AI relates to CSP. CSP requires developed ISP. ISP is currently developing (information age). It means that developed connectivity is a key to solve such problems;
- teams that have not adopted quality management cannot gain full benefits from technologies relating to SLMHM level 2.3 and higher;
- sustainability can be achieved only if SLMHM level 2.4 is achieved. Sustainable development can be achieved only if SLMHM level 3.4 is achieved;
- stage of society development can be assessed in two ways. 1) by studying the culture; 2) by studying of effectiveness of implemented ICT solutions;
- implementation of higher level technologies in societies with lower level is risky. Assurance that society level is the same or higher than that of implemented IT/IS is a recipe for success;
- implementation of technologies of higher level before appropriate implementation of technologies of lower levels is risky;
- moral decision making by algorithms [43] is not a trivial problem because modern algorithms relate to ASP. At the same time, moral relates to human feelings, in other words, to ISP. The development of ISP is the key to solving the problem.

There are strong reasons to assert that the implementation of ICT solutions in societies with lower level will contribute to raising the society's level, because society and penetrated ICT solutions form one system.

V. CONCLUSION

The five patterns corresponding to the development stages, 16 SLMHM levels, and corresponding ICTs were considered (see Fig. 1). Match of society development level and relevant ICTs is considered as a success factor of ICT projects implementation. The ICT projects are essential in realization of SC conception.

Disadvantages of this research include small scope of this paper, considering ICTs briefly, and theoretical nature of the research. Practical implementation of considered theory requires methodology for assessing levels of society development and high volume of computations [5].

Future research should include detailing of Fig. 1 by adding ICTs and development of society assessment methodology. Practical implementation of the theory has the special interest.

Abstract—For over 21 years Wikipedia has been edited by volunteers from all over the world. Such editors have different education, cultural background and competences. One of the core rules of Wikipedia says, that information in its articles should be based on reliable sources and Wikipedia readers must be able to verify particular facts in text. However, reliability is a subjective concept and a reputation of the same source can be assessed differently depending on a person (or group of persons), language and topic. So each language version of Wikipedia may have own rules or criteria on how the website must be assessed before it can be used as a source in references. At the same time, nowadays there are over 1 billion websites on the Internet and only few developed Wikipedia language versions contain non-exhaustive lists of popular websites with reliability assessment. Additionally, since reputation of the source can be changed during the time, such lists must be updated regularly.

This study presents the result of identification of reliable sources of information based on the analysis of over 200 million references that were extracted from over 40 million Wikipedia articles. Using DBpedia and Wikidata we identified articles related to various kinds of companies and found the most important sources of information in this area. This also allows to compare differences of the source reliability between Wikipedia languages.

I. INTRODUCTION

INFORMATION presented in Wikipedia articles should be based on reliable sources [1]. The source can be understood as the work (book, paper etc.), author, publisher. Such sources must have a proper reputation, should present all majority and significant minority views on some piece of information. Following this rule ensures that readers of the article can be assured that each provided specific fact (piece of information or statement) comes from a published and reliable source. Hence, before adding any information (even if it is a generally accepted truth) to this online encyclopedia, Wikipedia volunteer editors (authors or users) need to ascertain whether the facts put forward in the article can be verified by other people, who read Wikipedia [2].

Few developed language versions of Wikipedia contain non-exhaustive list of sources whose reliability and use on Wikipedia are frequently discussed. Even the English Wikipedia (the largest chapter of the encyclopedia) has such general list with information on reliability for less than 400 websites [3]. Sometimes we can find such lists for specific topics (e.g. video games, films, new Wikipedia articles in English Wikipedia).

It could take a significant human effort to produce a more complete list of assessed internet sources - there are over

billion websites available in the Internet [4], [5] and a lot of them can be considered as a source of information. So, it can be very challenging and time consuming task for Wikipedia volunteers to assess reliability of each source. Moreover, reputation of each website can change with time - hence, such lists must be updated regularly. Additional challenge - each source may have a different reliability score depending on topic and language version of Wikipedia.

More complete and updated list of reliable sources can be useful not only for Wikipedia editors, but also for readers of this popular encyclopedia. The aim of this study is to show some possibilities of automating this process by analyzing existing and accepted content with sources in Wikipedia articles about companies in different languages. This paper uses existing and new models for reliability and popularity assessment of websites. The results show that depending on models it is possible to find such important sources in selected Wikipedia languages. Additionally, we show how the assessment of same sources can vary depending on language of this encyclopedia.

II. RELATED WORKS

Researching the quality of Wikipedia content is a fairly developed topic in scientific works. As one of the key factors influencing the quality of Wikipedia articles is the presence of references, some studies focused on researching information sources. Some of works use the number of references to automatically assess quality of the information in Wikipedia [6], [7], [8]. Such important measures are implemented in different approaches for automatic quality assessment of Wikipedia articles (for example WikiRank [9]). References often contain external links (URL addresses) where cited information is placed. Such links in references can be assessed by indicating the degree to which these conform to their intended purpose [10]. Moreover, those links can be employed separately to assess quality of Wikipedia articles [11], [12].

Some of the studies focused on metadata analysis of the sources in Wikipedia references. One of the previous works used ISBN and DOI identifiers to unify the references and find the similarity of sources between various Wikipedia language editions [13]. It is increasingly common practice to include scientific sources in references of Wikipedia articles. [13], [14], [15], [16]. At the same time, it is worth noting that such references often link to open-access works [17] and recently published journal articles [18]. One of the studies devoted

to the COVID-19-related scientific works cited in Wikipedia articles and found that information comes from about 2% of the scientific works published at that time [19].

News websites are also one of the most popular sources of the information in Wikipedia and there is a method for automatic suggestion of the news references for the selected piece of information [20]. Particularly popular are references about recent content or life events [21]. For example in case of information related to COVID-19 pandemic Wikipedia editors inclined to cite the latest scientific works and insert more recent information on to Wikipedia shortly after the publication of these works [19].

Previous relevant publication [15] to this paper proposed and implemented 10 models for sources evaluation in Wikipedia articles. Results of assessment are also implemented in online tool "BestRef" [22]. Such approaches uses features (or measures) that can be extracted from publicly available data (Wikimedia Downloads [23]), so anybody can use those models for different purposes. One of the recent studies [24] in addition to the proposed models included also a time dimension to show how importance of the given web source of information on COVID-19 pandemic can be changed over different months.

III. REFERENCES EXTRACTION

To be able to extract information about references we prepared own parser in Python and applied it on Wikimedia dumps with articles in HTML format [23]. Table I presents general statistics of the extraction.

External links (or URL addressees) in references were used to indicate main address of the website. However, each web source can use different structure of URL addresses. For example, some of the websites can use subdomains for separate topics of information or news. Another example - some organizational units (e.g. departments) of the same company may post its information on separate subdomains of main organization. To detect which level of domain indicates the source this work uses the Public Suffix List, which is a cross-vendor initiative to provide an accurate list of domain name suffixes [25]. Figure 1 presents example of URL address at fourth level domain with indication of main website.

Fig. 1. Example of URL address at fourth level domain with indication of main organizational website using the Public Suffix List

Reference per Article (RpA) value shows average number of references in Wikipedia articles (in case of table I among

separate language chapter). The highest value of this measure has English Wikipedia - almost 11 references per article. High values of RpA has also French (fr), Greek (el), Japanese (ja) and Russian (ru) Wikipedia.

IV. MODELS FOR WEB SOURCES

Based on previous study [15], this work used following models for sources assessment with changes (described in this section):

- 1) **F**-model – how frequently (*F*) of considered source appears in references.
- 2) **PR**-model – how popular (*P*) are Wikipedia articles in which considered source appears divided by number of the references (*R*) in such articles.
- 3) **AR**-model – how much authors (*A*) edited the articles in which considered source appears divided by number of the references (*R*) in such articles.

One of the most basic and commonly used approaches to assess the importance of a web source is to count how frequently it was used in Wikipedia articles. This principle

was used in relevant studies [26], [13], [27], [18]. So, **F**-model assesses how many times specific web domain occurs in external links of the references. For example, if the same source is cited 25 times in 13 Wikipedia articles (each contains at least one reference with such source), we count the (cumulative) frequency as 25. Equation 1 shows the calculation for **F**-model.

$$F(s) = \sum_{i=1}^n C_s(i), \quad (1)$$

where:

- s is the source, n is a number of the considered Wikipedia articles,
- $C_s(i)$ is a number of references using source s (e.q. domain in URL) in article i .

PR-model uses page views (or visits) of Wikipedia articles for certain period of time divided by the total number of all references in each considered Wikipedia article. Some studies showed correlation between information quality and page views in Wikipedia articles [28], [8], [29]. The more people read a specific Wikipedia article, the more likely its content was checked by part of them (including presence of reliable sources in references). So the more readers see the particular facts in the Wikipedia, the bigger probability that one of such reader will make appropriate edit if such facts are incorrect (or if source of information is inappropriate).

In other words, page views of the particular article usually shows the demand on information from Wikipedia readers. Therefore, visibility of the reference is also important. If more references are presented in the article, then the less visible is a specific source for the particular reader (visitor). At the same time, the more visitors has an Wikipedia article with references, the more visible is particular source in it. Equation 2 shows the calculation using **PR**-model.

$$PR(s) = \sum_{i=1}^n \frac{V(i)}{C(i)} \cdot C_s(i), \quad (2)$$

where:

- s is the source, n is a number of the considered Wikipedia articles,
- $C(i)$ is total number of the references in article i ,
- $C_s(i)$ is a number of the references using source s (e.q. domain in URL) in article i ,
- $V(i)$ is page views (visits) value of article for certain period of time i .

In comparison with previous research [15], for purposes of this study, apart from **PR**-model that uses cumulative page views V from humans (non-bots views) for a recent month (March 2022), additionally **PRy**-model will be used, which takes into account a wider date range - April 2021 - March 2022.

Quality of Wikipedia articles depends also on quantity and experience of authors who contributed to the content. Often articles in Wikipedia with the high quality are jointly created by a large number of different editors and this measure

positively correlates with information quality [30], [31], [32], [33], [29]. To assess popularity of an article from editing users there is a possibility to analyze revision history of the article to find how many authors were involved in content creation/editing. So, **AR**-model shows how popular article is among Wikipedia volunteer editors. Equation 3 presents this model in mathematical form.

$$AR(s) = \sum_{i=1}^n \frac{E(i)}{C(i)} \cdot C_s(i), \text{ where :} \quad (3)$$

- s is the source, n is a number of the considered Wikipedia articles,
- $C(i)$ is total number of the references in article i ,
- $C_s(i)$ is a number of the references using source s (e.q. domain in URL) in article i ,
- $E(i)$ is total number of authors of article i .

In contrast to previous work [15], **AR**-model in this study uses number of authors E that are registered on Wikipedia as users, without bot-users. Names of bots were selected based on the separate page (for example there is a special category in English Wikipedia [34]).

Additionally this study provides **ARe**-model, which is modification of **AR**-model: instead of counting the number of authors of a Wikipedia article, the number of editions of these authors (registered and non-bots) will be taken into account.

V. USING DBPEDIA AND WIKIDATA TO IDENTIFY WIKIPEDIA ARTICLES ABOUT COMPANIES

There are different possibilities to find topic of a particular Wikipedia article. For example, each article can be aligned to multiple categories, corresponding Wikidata item or DBpedia resource can highlight the topic based on properties in statements [29]. Additionally Wikipedia article can be included to different WikiProjects, that indicates interest to its information from groups of Wikipedia editors which focused on a specific topic (e.q. culture, history, military etc.).

This study used data from DBpedia and Wikidata to find Wikipedia articles related to companies. Each of those semantic databases have own advantages and disadvantages which are related to the operating principles and the technologies used.

A. DBpedia

DBpedia [35] is a semantic knowledge base that enriched automatically using structured information from Wikipedia articles in different languages [36], [37]. The resulting knowledge about some subject is available on the Web depending on title of Wikipedia article (as a source of that knowledge). For example, such semantic data about "Meta Platforms" as the DBpedia resource we can find on the page https://dbpedia.org/resource/Meta_Platforms because such data were extracted from the relevant article in English Wikipedia - https://en.wikipedia.org/wiki/Meta_Platforms. At the same time DBpedia has separate knowledge extracted from other language versions and we can find also relevant information on other pages extracted from other Wikipedia chapters. On

such DBpedia pages among different properties we can also find information about the type(s) of subject. In our example "Meta Platforms" aligned to "Company" and other classes of DBpedia ontology [38] and other structures. Such information is can generated automatically based on infoboxes (contained in Wikipedia articles) and their parameters. The figure 2 shows example of infoboxes about "Meta Platforms" company in different Wikipedia languages. DBpedia extracts information about infoboxes based on the source code (wiki code or wiki markup) of the Wikipedia articles.

DBpedia ontology has a hierarchical structure, and if some resource is aligned to other company-related classes, we can use connections between those classes to detect Wikipedia articles related to companies. For example, some of the organizations can be aligned to "Bank", "Publisher", "BusCompany" or other company-related class of DBpedia ontology, and after generalization we can find that all of them are belonging to "Company" class. Based on DBpedia dumps related to instance types [35] ("specific" part of the dumps for each available language) we found that Wikipedia articles can be aligned directly to one of 634 classes from DBpedia ontology. Figure 3 shows those classes distinguishing with larger font size the most popular ones: *Person*, *Species*, *PopulatedPlace*, *Insect*, *Settlement*, *Place* and other. "Company" class is the 20th most popular in such ranking.

It is worth mentioning that DBpedia provides two kinds of dumps that contain information on classification of resources (instances): instance-types (containing only direct types) and instance-types-transitive (containing the transitive types of a resource based on the DBpedia ontology). Such files contain triples of the form '*<resource> rdf:type <class>*' generated by the mappings extraction and other techniques for different language chapters of Wikipedia.

Figure 4 shows the structure of a part of DBpedia ontology with "Organisation" class as a root node. It also presents information about directly alignments to separate classes of this ontology based on English Wikipedia. We can find there numbers based on of instances-types (direct alignment).

If we include also information on transitive types, we will have more resources aligned to same classes by taking into account connections between them in the DBpedia ontology. Figure 5 shows those classes distinguishing with larger font size the most popular ones: *Species*, *Eukaryote*, *Animal*, *Person*, *Location*, *Place* and other. "Company" class is the 34th most popular in such ranking.

After considering transitive DBpedia dumps we have got additionally 20,736 resources (to directly aligned 64,372 resources) in "Company" class - 85,108 in total in that class based on data from English Wikipedia. Next we took similar data extracted by DBpedia from other Wikipedia languages, and finally we got 173,418 unique companies ¹. Further we

¹Unique company in this case means, that separate Wikipedia articles in various languages related to the same company counted as 1 company (instead of counting each Wikipedia article in each language version as a separate company).

used "DBO-companies" for the obtained list of Wikipedia articles about companies based on DBpedia extraction.

B. Wikidata

Wikidata [40] is a semantic knowledge base that works on a similar principles that Wikipedia with one important difference - here we can insert facts about the subjects using statements with properties and values rather than sentences in natural language. Wikidata is also considered as the central data management platform for Wikipedia and most of its sister projects [41].

Each Wikidata item has a collection of different statements structured in the form: "Subject-Predicate-Object". Figure 6 shows Wikidata item Q380 ("Meta Platforms") with some statements.

Based on Wikidata statements we can find items on a specific topic. In our case, we will use the statement "Property:P31 Q783794" ("instance of" - "company"). Listing 1 presents SPARQL query to get such list from Wikidata using its query service [43]. Result of this query is available on the web page: <https://w.wiki/5Bsc>.

```
SELECT ?item WHERE {
    ?item wdt:P31 wd:Q783794 . }
```

Listing 1. SPARQL query to get list of Wikidata items directly connected to "company" item (Q783794) by "instance of" property (P31)

So, based on simple query we have got 12,635 Wikidata items related to companies. However, there are other connections in Wikidata that indicate items related to our topic. Similarly to DBpedia, here we can have also other "sub-classes" or alternatives that can build more complete list of Wikidata items which can give list of appropriate Wikipedia articles. Let's go back to our example on "Meta Platforms" as an Wikidata item showed on the figure 6. We can see, that apart from "company", this item is also aligned to "business" (Q4830453), "enterprise" (Q6881511), "public company" (Q891723) and "technology company" (Q18388277) by "instance of" parameter. Now we will use this information to enrich our query - listing 2 presents such SPARQL query: <https://w.wiki/5Bsw>. This query returned much more Wikidata items (comparing previous one) - 275,944 items. It is important to note, that this number doesn't show directly number of Wikipedia articles related to companies, because not all Wikidata items contains links to at least one Wikipedia article.

```
SELECT ?item WHERE {
VALUES ?com {wd:Q783794 wd:Q4830453
    wd:Q6881511 wd:Q891723 wd:Q18388277}
?item wdt:P31 ?com . }
```

Listing 2. SPARQL query to get list of Wikidata items directly connected to "company" (Q783794), business (Q4830453), enterprise (Q6881511), "public company" (Q891723) and "technology company" (Q18388277) by "instance of" property (P31)

Despite significant increase of Wikidata items based on more complex query, there can be at least one important questions: is the proposed query complete enough to find all (or at least most of) Wikidata items related to companies?

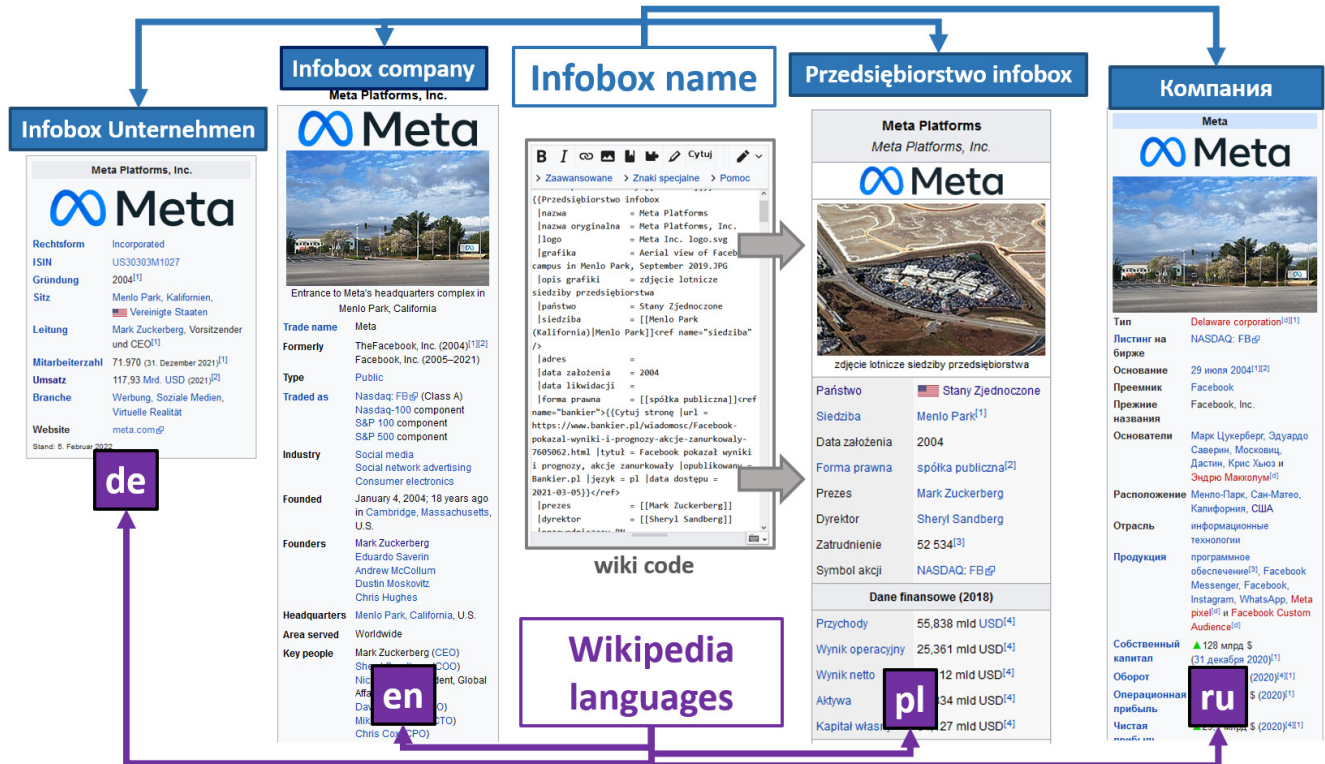

Fig. 2. Infoboxes about "Meta Platforms" company in different Wikipedia chapters

Fig. 3. Popular DBpedia ontology classes that are directly aligned to resources in various languages. Source: own calculations based on DBpedia ontology instance types specific dumps [35].

First, let's try to obtain general statistics on values that are inserted to "instance of" (P31) parameter among over 95 million Wikidata items. To do so, we prepared special algorithm in Python to extract such information from Wikidata

dumps in JSON format [44]. It is worth noticing, that it is possible to construct SPARQL query to solve this task, however due to limitation of the Wikidata query service (such as limited time execution of the query) such statistics and other complex analysis can be done by extracting necessary data from the dump files. Figure 7 shows those items distinguishing with larger font size the most popular ones: *scholarly article* (Q13442814), *human* (Q5), *Wikimedia category* (Q4167836), *temporal range start* (Q523), *Taxon* (Q16521), *infrared source* (Q67206691), *galaxy* (Q318) and other. Overall there are 87501 different alignments ("classes"). Items related to companies, such as "business" (Q4830453), "enterprise" (Q6881511) are on the 39th, 129th place respectively in such ranking.

Next we conduct such analysis only on Wikidata items, which has at least one link to Wikipedia article of one of the 42 considered languages in this study (see table I). Results are shown in figure 8. Now we have got 67,634 different alignments ("classes") and on the top we have: *Wikimedia category* (Q4167836), *human* (Q5), *Wikimedia disambiguation page* (Q4167410), *Wikimedia template* (Q11266439), *human settlement* (Q486972), *Wikimedia list article* (Q13406463), *album* (Q482994), *film* (Q11424), *village* (Q532) and others. Early considered items related to companies now are higher in the ranking: "business" (Q4830453) took 12th place, "enterprise" (Q6881511) took 66th place.

Fig. 7. Popular Wikidata items as a values in "instance of" statements. Source: own calculations based on Wikidata dumps files [44].

Fig. 9. Popular Wikidata items as a values in "instance of" statements. Only Wikidata items with link to at least one Wikipedia article related to DBO-companies. Source: own calculations based on Wikidata dumps files [44].

Fig. 8. Popular Wikidata items as a values in "instance of" statements. Only Wikidata items with at least one link to Wikipedia article from one of 42 considered languages. Source: own calculations based on Wikidata dumps files [44].

at least 200 times to avoid insignificant mistakes that could be done by some users that edit Wikidata. In that case we will have 63 Wikidata items, that can appear in "instance of" (P31) statements as a values. Additionally we removed alignment to "organization" (Q43229) which is too general.

As a result, we have more Wikidata items with articles on the list of companies - overall 291,768 Wikidata items with at least one related Wikipedia article in considered language versions were identified. In further analysis we will use "WCA-companies" for this list.

VI. ESTIMATING THE INFORMATION SOURCES IN WIKIPEDIA ABOUT COMPANIES

This section presents results of assessment of the most important sources of information companies across Wikipedia languages using different models.

Due to the limitation of space, following subsections presents results for the 15 most developed language versions of Wikipedia (with at least 1 million articles, see table I) Additionally, for the charts below, only the websites that appear at least 20 times in the top 100 at each language/model intersection² were selected. The more extended and interactive results can be found in supplementary materials [39].

It is important to note that archive services (such as archive.org) were excluded from analysis, due to the frequent occurrence of such links alongside the original sources in the same reference. If original source is no longer available, such archive services are very important, because Wikipedia readers can verify information, but unavailable original web sources are not a scope of this research. References to Wikipedia itself and Wikidata were also excluded. Links that are automatically inserted to references based on such identifiers as DOI (often links to doi.org) or ISBN (often links to books.google.com) cannot indicate directly the source of information. So such links were not considered in website analysis.

A. DBO-companies

First, we conducted a source analysis for the list of Wikipedia articles that have been generated based on data from DBpedia (see V-A) - "DBO-companies". Figure 10 shows the most important web sources of information on companies described in Wikipedia based with positions in rankings across 15 most developed language versions using five considered models.

Top 10 web sources in DBO-companies across 15 considered languages according to different models are as follows: nytimes.com, reuters.com, youtube.com, bloomberg.com, forbes.com, techcrunch.com, bbc.co.uk, cnn.com, wsj.com, theguardian.com.

²15 languages and 5 models gives 75 such intersections

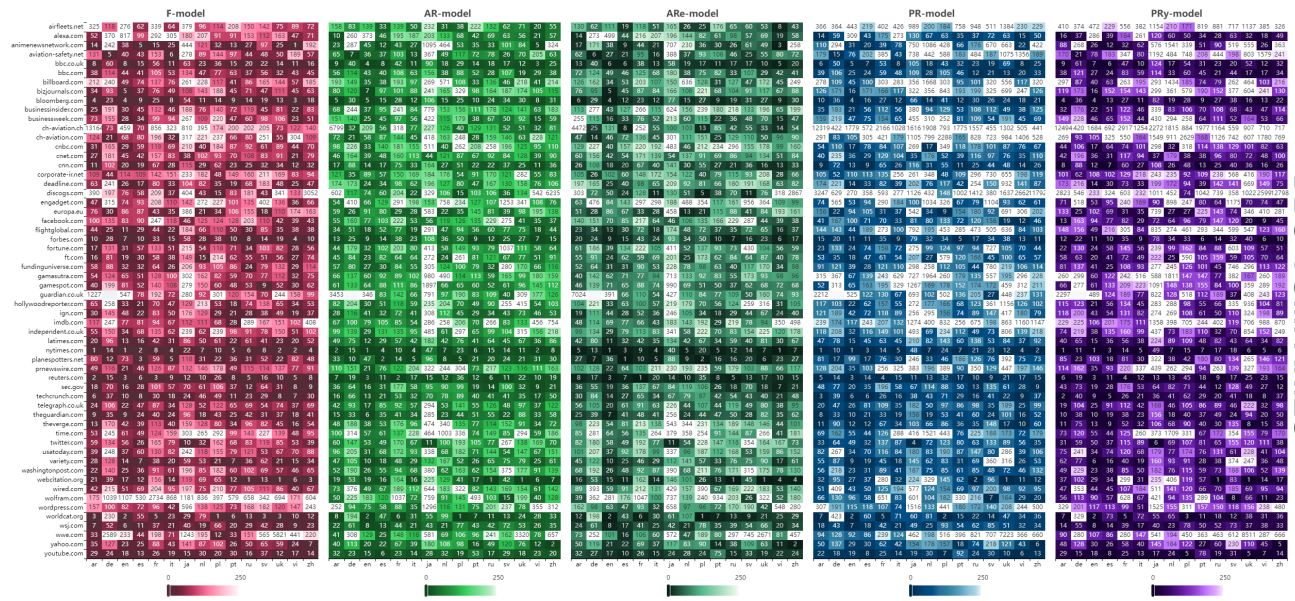

Fig. 10. The most important web sources of information on companies described in Wikipedia based on "DBO-companies" list with positions in rankings across 15 most developed language versions using various models. Source: own calculation based on Wikimedia dumps in April 2022. More extended and interactive version of the heat maps is available in [39]

B. WCA-companies

Figure 11 presents the most important web sources of information on companies described in Wikipedia based on WCA-companies list (described in V-B and V-C) with positions in rankings across 15 most developed language versions using five considered models.

Top 10 web sources in WCA-companies across 15 considered languages according to different models are as follows: nytimes.com, reuters.com, youtube.com, techcrunch.com, forbes.com, bloomberg.com, bbc.co.uk, theguardian.com, wsj.com, cnn.com.

C. Wikipedia languages

Based on average position in rankings calculated using different models we prepared the top 10 most important sources of information about companies in each Wikipedia languages.

Lists of such sources are presented below.

- **Arabic Wikipedia (ar):** grid.ac, nytimes.com, worldcat.org, alexa.com, bbc.co.uk, bloomberg.com, reuters.com, techcrunch.com, theguardian.com, cnn.com
- **Belarusian Wikipedia (be):** webcitation.org, tut.by, belta.by, zvi-azda.by, svaboda.org, nrbf.by, alexa.com, sec.gov, europa.eu, worldcat.org
- **Bulgarian Wikipedia (bg):** capital.bg, brra.bg, dnevnik.bg, webcitation.org, alexa.com, bbc.co.uk, nytimes.com, forbes.com, vesti.bg, q4cdn.com
- **Catalan Wikipedia (ca):** gencat.cat, elpais.com, worldcat.org, enciclopedia.cat, lavanguardia.com, ara.cat, vilaweb.cat, nytimes.com, elpuntavui.cat, elmundo.es
- **Czech Wikipedia (cs):** idnes.cz, justice.cz, worldcat.org, ihned.cz, lupa.cz, novinky.cz, denik.cz, ceskatelevize.cz, e15.cz, zdopravy.cz
- **Danish Wikipedia (da):** dr.dk, business.dk, politiken.dk, borsen.dk, finans.dk, computerworld.dk, berlingske.dk, tv2.dk, ing.dk, nytimes.com

- **German Wikipedia (de):** spiegel.de, zdb-katalog.de, handelsblatt.com, mementoweb.org, heise.de, welt.de, faz.net, sueddeutsche.de, zeit.de, nytimes.com
- **Greek Wikipedia (el):** et.gr, kathimerini.gr, tovima.gr, reuters.com, bbc.co.uk, capital.gr, nytimes.com, youtube.com, worldcat.org, typologies.gr
- **English Wikipedia (en):** nytimes.com, worldcat.org, reuters.com, bbc.co.uk, bloomberg.com, theguardian.com, wsj.com, bizjournals.com, forbes.com, indiatimes.com
- **Esperanto Wikipedia (eo):** staralliance.com, webcitation.org, liberfolio.org, wikimedia.org, wikiwix.com, nytimes.com, vortaro.net, debian.org, elpais.com, bloomberg.com
- **Spanish Wikipedia (es):** elpais.com, issn.org, nytimes.com, elmundo.es, youtube.com, bbc.co.uk, lanacion.com.ar, planespotters.net, reuters.com, abc.es
- **Estonian Wikipedia (et):** postimees.ee, err.ee, delfi.ee, riigiteataja.ee, aripaev.ee, muinas.ee, digar.ee, dv.ee, nasdaqbaltic.com, inforegister.ee
- **Basque Wikipedia (eu):** berria.eus, worldcat.org, argia.eus, elpais.com, euskadi.net, euskadi.eus, eitb.eus, nih.gov, berria.info, diariavasco.com
- **Persian Wikipedia (fa):** bbc.co.uk, bbc.com, webcitation.org, reuters.com, nytimes.com, sec.gov, forbes.com, alexa.com, isna.ir, radiofarda.com
- **Finnish Wikipedia (fi):** yle.fi, hs.fi, kauppaletti.fi, is.fi, forbes.com, talouselama.fi, bloomberg.com, iltalehti.fi, taloussanomati.fi, nytimes.com
- **French Wikipedia (fr):** lesechos.fr, lemonde.fr, reuters.com, lefigaro.fr, worldcat.org, societe.com, zonebourse.com, wikiwix.com, liberation.fr, lexxpress.fr
- **Hebrew Wikipedia (he):** globes.co.il, themarker.com, nli.org.il, ynet.co.il, calcalist.co.il, haaretz.co.il, walla.co.il, tase.co.il, mako.co.il, nytimes.com
- **Croatian Wikipedia (hr):** bbc.co.uk, vecernji.hr, hrt.hr, zse.hr, tportal.hr, nytimes.com, enciklopedija.hr, jutarnji.hr, poslovi.hr, alexa.com
- **Hungarian Wikipedia (hu):** index.hu, origo.hu, hvg.hu, youtube.com, nytimes.com, blog.hu, iho.hu, crt-tv.com, 24.hu, napi.hu
- **Armenian Wikipedia (hy):** webcitation.org, nytimes.com, youtube.com, bbc.co.uk, sec.gov, purl.org, wsj.com, vedomosti.ru, kommersant.ru, forbes.com
- **Indonesian Wikipedia (id):** detik.com, Kompas.com, nytimes.com, forbes.com, worldcat.org, tempo.co, alexa.com, bbc.co.uk, reuters.com, kontan.co.id

VII. CONCLUSION AND FUTURE WORK

This study focused on information sources analysis of Wikipedia about companies in different languages. After extraction over 230 million references there were a process of identification of the main websites address for each URL address. As a result - over 2 million unique websites have been identified. To find important web sources across the languages, topics of the Wikipedia articles were analyzed. Using semantic representation of those information in DBpedia and user-generated knowledge in Wikidata this study shows how to find important web sources across languages based on existing and new models.

Models presented in this work can help not only Wikipedia volunteer editors to select web sites that can provide valuable information on companies, but also can help other Internet users to better understand how to find valuable sources of information a specific topic on the Web using open data from Wikipedia.

We plan to extend this research in future by providing additional features on identification of companies in Wikipedia. Additionally, we plan to provide different organizations to specific sectors (industries) to find the differences between reliability of information sources.

Future work will be focused also on extending reliability models and using different methods on topic classifications. One of the directions is to develop ways of weighting the importance of a reference based on its position within a Wikipedia article. There are also plans on including different measures related to the reputation of Wikipedia authors, protection of the articles, topic similarity and others.

ACKNOWLEDGEMENTS

The project financed within the Regional Initiative for Excellence programme of the Minister of Education and Science of Poland, years 2019-2023, grant no. 004/RID/2018/19, financing 3,000,000 PLN.

Abstract—Allowing access to real legal documents is an important element both for the development of science and the judiciary. On the other hand, protecting information about citizens or organizations, that appear in these documents, is crucial and required by law. Therefore, before the documents are distributed, the data anonymisation process should be carried out. Unfortunately, there is no perfect tool that can automatically anonymise documents in such a way, that the main concept of the document is preserved; especially in the case of documents written in inflectional language. The aim of this article is to show how important (and at the same time how difficult) is the task to identify personal or corporate data of a client, as well as other related personal data in documents that are subject to legal protection. We conducted research aimed at assessing the usefulness of IT techniques as well as decision rules and patterns in the anonymisation of legal documents. A set of real legal documents written in Polish was used for the research in which we identified selected types of data that need to be anonymised. Eventually, the obtained results were assessed by field experts. Additionally, in order to verify the effectiveness of the proposed solution, we conducted research on a set of 50,000 false identities with names, company names, addresses and other confidential information. The collection was created using Fake Name Generator¹. The obtained results from both experiments confirmed that the solutions we proposed is accurate even in the case of real legal documents.

I. INTRODUCTION AND RELATED WORKS

THE PROCESS of anonymising documents is important to protect individuals and institutions from the illegal dissemination of information [1]. However, in the case of legal documents, this is a very difficult process due to unstructured content of the documents [2]. In addition, the provisions of law, i.e. the GDPR [3], will force institutions to appropriately transform their current IT systems in the field of personal data processing. Due to the large variety of document structures and the lack of a uniform system applicable to all judicial

organizations, there is a high risk of privacy breach. Due to the variety of document structures and the lack of a uniform system applicable to all judicial organizations, there is a high risk of privacy breach. For this reason, the anonymisation process is often widely regarded as an expensive and inefficient process [4]. Additionally, due to the low effectiveness of the available data anonymisation tools, the anonymisation process in law firms is most often performed manually by trained employees [5].

In this article, we will look at the theoretical assumptions of a basic IT tool designed to identify selected types of data in text documents. On the other hand, the research goal is to check and evaluate the usefulness of IT techniques as well as decision rules and patterns in the anonymisation of legal documents. In the case of legal documents, data identifying individuals or organizations must be removed, anonymised or pseudonymised from the digital document following the end of the legal service. Authors are convinced that if such data are not manually obliterated - either manually or using a computer-assisted method - any lawyer should delete all documents of clients from law firm's digital media and computers in a time demanded by national regulation of legal occupation or implicit period of time assumed by the professional need (processing by the purpose). By all above mentioned regulations personal data and other types must be deleted or pseudonymised by legal tech. To achieve this goal, a team of coauthors is working on a project designed to build such a technology².

The first step in anonymising text documents is the ex-

²Project developed by Infojura Sp. z o. o. (KRS 0000502117) carried out in the period from 01/01/2022 to 31/12/2023 under the name "Technologies for Automatic anonymisation of Personal Data" in digital documents. It is financed with the support of EU as part of the Regional Operational Program of the Silesian Voivodeship for 2014-2020 (European Regional Development Fund). Action 1.2. Research, development and innovation in enterprises.

¹<https://www.fakenamegenerator.com/>

traction of information that directly identifies individuals or organizations. They are referred to as Named Entities (NE) [6]. Most often, NE are classified into predefined semantic categories, i.e. first name, last name, organization name or location [7], [8]. Natural language processing (NLP) methods are used to automatically recognize NE [9]. For this purpose, Named Entity Recognition (NER) [10] was created. It is the process of locating information in the text, which then becomes a specific category. In addition to the basic categories, i.e. the name of an organization or person, NER has added categories that define time and numerical expressions, such as monetary values [11].

In the process of identifying named entities, the language in which the text document is written is very important. In the case of languages with an extensive morphological structure, the processing of text documents and the extraction of information is very difficult [12]. Therefore, Graliński et al [13] presented a formalism for the rule-based NER. Their research focuses on the use of NER for inflectional languages (especially for Polish and Czech) and the translation of Named Entities. Researchers developed two applications that could be used for machine anonymisation and machine translation. Similarly, J. Pisowski [14] created the formalism of recognizing NE from Polish texts and manually created a set of NER rules for the Polish language.

To assist researchers in sharing raw textual data, Kleinberg et al. [15] proposed the NETANOS anonymisation system that identifies and modifies named entities (e.g. people, locations, times, dates). Bayesian tests showed that NETANOS anonymisation was practically equivalent to human anonymisation. The authors only used NER to detect personal data. Using this method, they hypothesized that the ability to discover the original meaning of anonymised data could ultimately be similar to that of humans if the training data set is large enough.

Unfortunately, the NER in the field of law, despite its importance, is not a well-researched area. Many current approaches use different techniques and classification methods on different datasets [16]. Additionally, most of the obtained anonymisation results are only assessed by experts. For this reason, it is not possible to properly compare the results. However, the proposed solutions make a significant contribution and are the basis for further research. It should be remembered that an additional problem in the field of law is the natural language of legal documents and the different legal provisions in individual countries.

C. Dozier et al. [17] were one of the first to conduct research based on Named Entity Recognition in the legal field. Using the example of American case law, testimonies, pleadings and other legal documents, the authors analyzed the NER. C. Cardellino et al. [18] have developed a tool to identify, classify and link legal NE. The authors focused on four different levels of detail, one of which was NER. They used a Stanford NER [19] support vector machine and a neural network in the learning algorithm. Elena Leitner et al. [20] presented the problem of fine-grained recognition of entities in legal docu-

ments. The authors developed a data set consisting of decisions of German courts, in which the source texts were manually annotated with 19 semantic classes. Then all classes were automatically generalized to seven classes (person, location, organization, legal norm, individual regulation, court order and legal literature). The results obtained show that there is no universal model with the best understanding of all classes.

II. RESEARCH METHODOLOGY

PII (Personally Identifiable Information) data detection algorithms have to be fine-tuned for each case. It is virtually impossible to obtain a high accuracy with low noise on the same pass of detection. Whereas, in the case of data related to digits, even though a number is a valid KRS/NIP (tax identification numbers) value, only semantic context might indicate whether it is a true PII or just a coincidence.

Therefore, in the case of the analysis of specific documents and adapted to a specific language (legal documents prepared in Polish), we proposed to use a combination of this methods:

- Dictionary search. A relatively easy search withing the known dictionary. The example of this method is used in our experiments where searching for first names (both female and male). The names were taken from official PESEL database³. However convenient, this list has a lot of potential to give many false positives, as the PESEL number (unique person identification number) was given to a lot of non-Polish citizens; often with short names being homonyms of common Polish words (like "Na").
- Decision rules and patterns. Using this approach, one is using regular expressions to describe the patterns of potential PII data. For instance, a NIP number is usually consisted of 10 digits divided by hyphens.
- Special type of validation for self-checking numbers. NIP number are self-checking numbers, as they use a Luhn algorithm [21], as well as additional constrains for numbers being valid. Checking this constrains is a great way to decrease greatly the number of false positives.
- Validation using external services is often used for IBAN numbers or KRS numbers in Poland. KRS number is a 10 digit number with no additional constrains, being just a next element in a single sequence of all entities in Poland. Thus, an external validator is used to make sure that the 10 digit number is an actual and up to date KRS for a valid company.
- Heuristic search using some known patterns like "sp z o.o." for a private limited company. Due to law regulations in Poland, some equities need to include mandatory information in company name.

III. COMPUTATIONAL EXPERIMENTS

The research objective of this paper was to investigate the applicability of decision rule and pattern search methods in legal document anonymisation. Therefore, in order to test the

³<https://dane.gov.pl/pl/dataset/1667,lista-imion-wystepujacych-w-rejestrze-pesel-osoby-zyjace>

proposed approach, we conducted two types of experimental studies. In the first one, we wanted to test the efficiency of the proposed solution for large amounts of data – artificial data generated for this purpose. In the second one, we performed the actual anonymisation of legal documents, and their evaluation was done by domain experts.

The first research attempt, related to achieving the stated goal of anonymising selected data in legal documents, was to test the algorithm on artificial data. In this case we used Fake Name Generator⁴ service and generated 50000 fake identities with names, company names, addresses and other sensitive information. Each line in this set should contain exactly one of name, email, phone and company name. The perfect scenario will have a mean value of detection equal to 1 for each column. The data is adapted to the Polish language and contains on average 73 words and 422 characters per line. The data preparation was followed by the application of the proposed solution to each case. The results of the experiments are presented by a box plot (Fig. 1) in which, for each PII, the minimum, 1st, 2nd (median) and 3rd quantile and maximum values are given – often these values are repeated, which is why whole box plots do not appear in the figure.

As it can be seen, in the case of the name, too many values are detected (the maximum found is 8, the median is 2, and the expected value, which is 1, is also the 1st quantile). This is because the first name often appears in the address (e.g. street name established by a famous person); in one line, in addition to the correctly detected name, the one from the address is also recognised. The ideal situation is in the case of e-mail address, where all cases were correctly detected; so was the case of phone number (there, in one case, apart from the correct number, also the false positive is detected). For the KRS number, as it is just a sequential number, false positives were found in different parts of data, as it was the case in first name. In addition to the correctly detected KRS number also NIP number is included – this explains the very low detectability of NIP number. In these experiments, once detected, the element could not be recognised again. We proposed a different approach in later experiments on real data.

The worst situation appears for the company name, which was basically not detected. This is because in our heuristic approach we require the presence of certain keywords. The generator in question was not characterised by the presence of appropriate prefixes in the name. However, in the case of legal documents, such full names are always used.

In order to assess the achievement of the final goal, the proposed method has been applied to a real-life study of a law firm operating in the territory of Poland. Fifteen legal documents written in Polish and concerning different legal scopes and cases were analysed. All documents were originally saved in DOCX format, from which, in order to apply the model, they were converted into text format. The analysis was based on the documents of different length and number of words per line (see Tab. I). It can be observed that the low

Fig. 1. Minimum, maximum, and quantiles for the prepared data

TABLE I
FEATURES OF THE DOCUMENTS ANALYSED

Legal document	# lines	# words	$\frac{\# \text{ words}}{\# \text{ lines}}$
x_1	104	500	4.81
x_2	500	3730	7.46
x_3	121	617	5.10
x_4	335	1800	5.37
x_5	162	1788	11.04
x_6	664	4291	6.46
x_7	59	294	4.98
x_8	399	2906	7.28
x_9	50	130	2.60
x_{10}	57	201	3.53
x_{11}	180	532	2.96
x_{12}	30	74	2.47
x_{13}	139	840	6.04
x_{14}	29	123	4.24
x_{15}	135	1474	10.92
sum	2964	19300	6.51
avg.	198	1287	6.50
median	135	617	4.57

number of words per line is related to the short information provided in the legal document, such as the invoice number or the service name. Therefore, the table I presents the average number of words per line.

In the next step, the fields indicated for anonymisation (with the reason for anonymising an element) were verified by specialists. They verified the PII described in Section II and each time described three known elements of the classification quality assessment:

- TP – true positives, i.e. elements that really should be anonymised for the reason given;
- FP – false positive, i.e. elements for which the indicated reason for anonymisation is not appropriate.
- FN – false negative, i.e. items that should have been anonymised for a given reason but were not.

The evaluation of TN (true negative), i.e. elements that should not be anonymised, was omitted and indeed this was not done. TN was not evaluated because, naturally, all non-annotated words mean true negative for this problem. De facto this is the number of all words in the document, except those in TP, FP and FN.

Analysing the exact anonymisation result given in Tab. II

⁴<https://www.fakenamegenerator.com>

TABLE II
RESULTS OF THE ANONYMISATION OF LEGAL DOCUMENTS

Legal document	name			e-mail			NIP number			phone number			KRS number			company name		
	TP	FP	FN	TP	FP	FN	TP	FP	FN	TP	FP	FN	TP	FP	FN	TP	FP	FN
x_1	5	1	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1

x_5	2	1	0	0	0	0	0	0	0	0	0	0	0	1	0	7	10	0
x_6	3	6	0	3	0	1	3	0	0	0	0	0	4	4	0	6	0	0
x_7	0	1	0	0	0	0	3	0	0	0	0	0	4	3	0	4	1	0
x_8	13	2	0	0	0	0	3	0	0	0	0	0	5	5	0	5	1	0
x_9	7	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
x_{10}	2	2	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	2
x_{11}	4	0	1	0	0	0	6	0	0	0	0	0	3	6	0	10	1	3
x_{12}	3	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
x_{13}	1	0	2	0	0	0	2	0	0	0	0	0	2	2	0	2	0	0
x_{14}	1	0	0	0	0	0	1	0	0	0	0	0	0	1	0	2	0	0
x_{15}	2	0	1	0	0	0	2	0	0	0	0	0	1	2	0	1	0	1

and reading the actual document, it can be seen that in the case of PII-name there are many FP, i.e. false positive indications for anonymisation. This is mainly due to street names (consistent with first name) and first names that are also names of months (e.g. 'Maja'). FN-related errors, on the other hand, occur in the case of an atypical linguistic variant of a name.

E-mail addresses only appeared in one document and were mostly well recognised. The error associated with the address not being found was due to a transcription error (the domain extension was single character). Thus, future consideration could be given to analysing email addresses not only according to the rules, but also assuming human error in the transcription.

The situation looks very good in the case of PII-NIP number, which is a tax identification number that was correctly recognised in all documents. This is largely made possible by the Luhn algorithm. The phone number, on the other hand, did not actually appear in any document, although three times the algorithm incorrectly indicated that the found string of digits was a phone number.

An interesting situation concerns the PII-KRS number, i.e. the national court register number. All KRS numbers were detected (true positive – TP), but also other numbers in the document were incorrectly indicated as KRS. This was most often the case with the NIP number, but there were also other strings of numbers which did not relate to the KRS (it should be noted, however, that in further work, each of the elements indicated in the experiments as KRS should be anonymised anyway – whether as NIP number or national identifier of a person).

Big problems arise in the case of company names. For the analysed data, the algorithm often incorrectly indicated data for anonymisation although it was not necessary (false positive – FP). There were also situations where the company name was not detected at all. However, to sum up the work of the algorithm, in the vast majority of the cases, the algorithm detected company names that should be anonymised.

At the same time, it should be noted that in this type of documents it is a much bigger mistake to omit an element to

TABLE III
RESULTS OF THE ANONYMISATION OF LEGAL DOCUMENTS IN TERMS OF TP, FP, FN AND IN TERMS OF MEASURES TO ASSESS CLASSIFICATION QUALITY: PRECISION, RECALL AND F-SCORE

Legal document	TP	FP	FN	precision	recall	F-score
x_1	6	1	1	0.8571	0.8571	0.8571
x_2	10	23	5	0.3030	0.6667	0.4167
x_3	12	1	1	0.9231	0.9231	0.9231
x_4	11	6	0	0.6471	1.0000	0.7857
x_5	9	12	0	0.4286	1.0000	0.6000
x_6	19	6	1	0.7600	0.9500	0.8444
x_7	11	2	0	0.8462	1.0000	0.9167
x_8	26	3	0	0.8966	1.0000	0.9455
x_9	8	0	0	1.0000	1.0000	1.0000
x_{10}	2	2	2	0.5000	0.5000	0.5000
x_{11}	23	1	4	0.9583	0.8519	0.9020
x_{12}	3	0	0	1.0000	1.0000	1.0000
x_{13}	7	0	2	1.0000	0.7778	0.8750
x_{14}	4	0	0	1.0000	1.0000	1.0000
x_{15}	6	0	2	1.0000	0.7500	0.8571
sum	157	57	18	0.7336	0.8971	0.8072
avg.	10	4	1	0.8080	0.8851	0.8448
median	9	1	1	0.8966	0.9500	0.9225

be anonymised (i.e. those indicated in FN) than to anonymise it incorrectly (in our case FP). In addition, often elements that showed FP for one of the methods were in fact anonymised anyway for another reason. Therefore, in Tab. III, the summary results are presented, in which the reason for anonymisation is not indicated, but only the information whether a given word should be anonymised or not.

With these values, it can be indicated that in all analysed documents 185 words should have been anonymised (out of a total of 19300 words), with 168 words actually detected, 17 words not anonymised (although they should have been), and 57 words incorrectly indicated as requiring anonymisation. This gives a median of 10 words per document (requiring anonymisation) while omitting 1 word per document and indicating 1 additional word incorrectly. This allows us to assess the effectiveness of the solution.

With the values in Tab III, it is possible to calculate measures of classification evaluation, such as *precision* (eq. (1)), *recall* (eq. (2)) and *F-score* (eq. (3)). These are important

measures, where the *precision* determines with what certainty we can trust the classifier that a given element (word) should actually be anonymised, while *recall* determines how many elements (words) that should be anonymised in the document have been indicated as anonymised, and *F – score* is the harmonic mean of *precision* and *recall*.

$$precision = \frac{TP}{TP + FP} \quad (1)$$

$$recall = \frac{TP}{TP + FN} \quad (2)$$

$$F - score = \frac{TP}{TP + 0.5 \cdot (FP + FN)} \quad (3)$$

As mentioned earlier, from the point of view of the anonymisation of legal documents, it is more important to detect the elements that should be anonymised. Therefore, when analysing the results, the recall measure should be optimised first. The results related to the quality assessment of the anonymisation work are presented in Tab. III. In the case of the proposed solution, our method achieves a recall of 89.71% (in terms of the sum of all documents) and 95.00% in terms of the median recall calculated separately for each legal document.

Of course, it is important to note that all the results reported in this section relate to the analysis of only 6 types of PII: name, e-mail address, tax identification number (NIP number), phone number, national court register number (KRS number) and company name. Other data that should actually be anonymised have not been analysed by us at this stage of the project – the proposed solution. For subsequent work, a more sophisticated use machine learning and natural language processing methods is required.

IV. CONCLUSIONS AND FUTURE WORKS

It should be emphasised that the research objective was to analyse a limited range of data – only a selected type of data was anonymised. Thus, we wanted to assess the applicability of IT techniques and decision rules and patterns in document anonymisation. The conducted experiments confirm that the solutions we have applied allow us to obtain good results – this is particularly evident in the case of real legal documents. Therefore, in the future, in addition to improving the rules proposed so far, we believe that it is worth to develop the modelling of machine learning on bigger groups of real legal documents that can be used as learning data in supervised machine learning models.

Future work may include developing a multi-criteria model for multi-step analysis. It is possible to initially verify data on the basis of unit names, and then carry out a thorough analysis on the basis of the content only for selected data. Such a solution is possible with the use of machine learning methods and natural language processing techniques. However, it should be remembered that the task of creating a universal system that would recognize all classes is very difficult, and

the effectiveness of anonymisation largely depends on the structure of the documents that could be referred to given types of legal documents.

Abstract—Nowadays society has transformed performance-related issues into situations that are merely focused on goals and competitiveness, which generates, in IT professionals, the feeling of being under constant pressure due to the need for immediate delivery of results. For this reason, Human Performance Management has become an increasingly essential process inside organizations, through which it is possible to improve, among other things, efficiency, productivity and satisfaction of employees. Its benefits are even more evident in areas such as Information Technology (IT), where evolution, complexity and uncertainty are ever-present factors. Based on this scenario, this study proposes a performance management model for IT professionals, linked to the philosophical current of Humanism and addressing aspects such as equality, respect, participation, competency and personal development. Thus, this research intends to have a positive effect on IT performance (individual/team/organizational), humanizing the relationship between IT employees and their organizations.

Index Terms—performance management, performance appraisal, IT professional, humanism, model

I. INTRODUCTION

HUMAN performance management (HPM) is an essential process inside organizations. The main objective of this type of management is to provide a performance measure for activities carried out by employees, while promotes the improvement of productivity, motivation and satisfaction. Therefore, this process can be considered a structuring basis for developing organizational culture and relationship between organization and its employees [1][2].

The benefits of an effective performance management are even more evident in areas such as Information Technology (IT) where complexity, dynamism and innovation are ever-present factors, requiring professionals to have high levels of knowledge and creativity [3][4][5]. Thus, the main motivation for this study comes from the opportunity to develop an analysis regarding performance management and satisfaction of IT professionals inside organizations, proposing, as a result, a management model composed by a set of guidelines based on the principles of Humanism.

Evaluate IT professionals performance and define the skills needed for the job are not recent concerns [6] [7] [8] [9] [10], however, nowadays society, as a result of economic globalization, has transformed issues related to performance

into situations merely focused on goals and competitiveness, which generates, on IT employees, the feeling of being under constant pressure due to the need for immediate delivery of results.

The high turnover of professionals in Information Technology area [11][12][13] and occupational diseases, like technostress [14], are just some of the problems related to performance management, specially, when it is primarily focused on impersonal behavior, productivity and value delivery.

Given this scenario, several initiatives have emerged seeking to humanize and improve the relationship between employees and organizations [15][16][17][18][19]. Following the same line of thought, the purpose of this research is to define a performance management model for IT professionals linked to the philosophical stance of Humanism, considering, therefore, the issues related to a human centered management and addressing aspects of human nature, such as dignity, limits, aspirations, capabilities and potential.

Other important contributions of this study are focused on: detailing organizational culture concepts and human performance management; humanistic ethics' analysis in corporate environment; knowledge structuring for developing more effective methods of appraisal. Such contributions aims to be adherent to the current and future reality of IT professionals.

This research is believed to be scientifically original, since it proposes, as far as is known, a unique model for human performance management, based on the perspective of IT profile singularities together with extremely important concepts for society, like organizational culture, humanism and ethics.

It also can be justified by the proposition of a management model potentially capable of improve people and organizations, representing an extremely relevant artifact in a context full of uncertainties, challenges and constant transformations. In addition, the results obtained by this research are expected to server as groundwork for future studies focused on producing new knowledge, frameworks and methodologies related to HPM.

The rest of this article is structured as follows: section 2 sets out the theoretical foundation and related works considered for the research; section 3 exposes the context and issues involved

in this study; section 4 describes the scientific methodology employed; section 5 describes the proposed solution; section 6 analyzes and discusses the obtained results; and, finally, section 7 presents the last considerations of the research.

II. LITERATURE REVIEW

A. Organizational Culture Theory

In order to analyze employee performance, engagement and satisfaction in the context of organizations, it is necessary to understand organizational culture and its influence on these factors. [20].

The most commonly used and accepted definition of organizational culture is the one proposed by Schein (1988, p. 7) [21][20][22]:

A pattern of basic assumptions, invented, discovered, or developed by a given group, as it learns to cope with its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore is to be taught to new members as the correct way to perceive, think, and feel in relation to those problems.

As part of the Organizational Culture Theory, Schein (1988) [21] also proposes to describe an organization's culture as a set of levels that represent its elements, as shown in Figure 1.

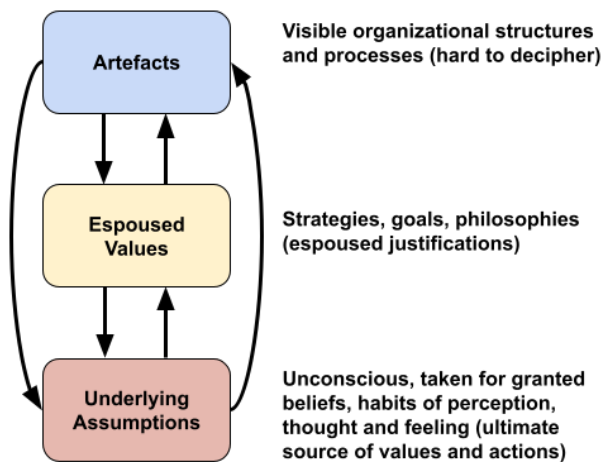

Fig. 1. The Levels of Organizational Culture. Adapted from [21]

In the context of human performance, **Artefacts** represent what people effectively accomplish and which directly reflect on performance and goal achievement. This level is the most evident in the culture, although some organizational actions and structures can be difficult to understand and justify.

The **Espoused Values** are the strategies, objectives, norms and philosophies openly propagated by the organization, aiming, for example, the effectiveness of the performance management. The organization's actions have the most significant effect at this cultural level.

Finally, **Underlying Assumptions** are taken-for-granted beliefs based on thoughts, perceptions, and feelings. At this level,

cultural elements become visible only through the analysis of behavioral patterns. These underlying assumptions exist in order to simplify complex issues of organizational reality, such as the reasons why one person is promoted over another [23].

It is evident that the elements of each level of organizational culture are capable of influencing all the others, however, underlying assumptions of an organization have a great impact on its artifacts, supplanting, in some situations, the influence of declared values [21][23].

Organizational culture can be seen as a preponderant factor in performance management but also as part of the results of this management, that is, by promoting the performance improvement of employees and their teams, organizational culture ends up being directly influenced by this improvement [22].

Regarding the performance of an organization, it is possible to build a culture that emphasizes essential points, such as meritocracy, transparency and recognition [24]. All these positive changes that take place in the organizational culture have the power to provide employees with the possibility to act proactively, identifying, mitigating and eliminating human errors and correcting the organization's vices and weaknesses [25].

A favorable cultural posture results in actions that can, if carried out accordingly, guide the institution towards an effective management of human performance. [25].

B. Human Performance Management

Interest in the effectiveness of Human Resource Management, or its more recent term *Human Management* [26], became more evident and frequent from the 1970s onward [2].

Human Performance Management is one of the main pillars of Human Resource Management and, for this reason, the study of human performance inside organizations also started more than half a century ago [6][7][8][9][10]. Aspects related to this branch of organizational management have, therefore, a rich literature that can be found in the most varied areas of research, such as psychology, administration, sociology, information systems and economics [27][28].

In addition to the Organizational Culture Theory, HPM is based on a wide range of other theories [29][30][31], which demonstrates the high complexity and deepness of the subject.

The Table I presents some fundamental theories to understand and develop Human Performance Management.

Based on the numerous definitions of HPM that can be found in the literature, it can be inferred that Human Performance Management is a cyclical and continuous process that is intended to identify, plan, measure, control and develop performance at work, both individually and as a team, while aligning this performance with the organization's strategic objectives and the value delivery from executed activities [32][26][33][34][35].

HPM is, therefore, a complex process that involves a series of methodologies, techniques and approaches focused on overcoming the challenges and difficulties inherent to this type of management and returning positive results for organizations [36]. Figure 2 presents a holistic and pragmatic

TABLE I
FUNDAMENTAL THEORIES OF HUMAN PERFORMANCE MANAGEMENT [29][30][31]

Theory	Author(s)	Theory	Author(s)

Contract Theory	Oliver Hart and Bengt Holmström	Theory of Individual Differences in Task and Contextual Performance	Stephan J. Motowidlo, Walter C. Borman, and Mark J. Schmit
Two-Factor Theory	Frederick Herzberg	Equity Theory	J. Stacy Adams
Expectancy Theory	Victor Vroom, Lyman Porter and Edward Lawler	Goal-setting Theory	Edwin Locke and Gary Latham
General Systems Theory	Ludwig von Bertalanffy	Organizational Justice Theory	Jerald Greenberg
Theory of Behavioral Engineering Model	Thomas F. Gilbert	Theory of Human Motivation	Abraham Maslow
Achievement Motivation Theory	David McClelland	Theory of the Social Self	George H. Mead
Job Characteristics Theory	Richard Hackman, Edward Lawler, and Gred Oldham	Bases of Social Power Theory	John French and Bertran Raven
Reinforcement Theory	B. F. Skinner	Theory of Social Exchange	George C. Homans

view of the Human Performance Management Framework as proposed by [32].

C. Humanism

Humanism is essentially a philosophical stance that assigns preeminent importance to human beings, their experiences, interests and rights. The hallmark of humanist philosophy is, therefore, the development of people's potential, considering Protagoras' relativism (490-420 BCE) where "man is the measure of all things" [37].

Among all the principles contemplated by humanism, some of them deserve to be highlighted: human value; individual dignity; the pursuit of civic culture; promotion of diversity and equality; and humanistic ethics. [37].

According to humanist ethics, the human being must "be considered as an end and never exclusively as a means or instrument for any purpose external to itself" [38]. Thus, moral rules are defined from the perspective of humanity, that is, *right* is everything that is good for human beings, values their life and develops their capacities, while *wrong* is everything that harms or takes away human dignity, represses individuality and dehumanizes people [38].

One of the main global aspirations of Humanism is found in the Universal Declaration of Human Rights, which establishes a commitment to promote universal respect for and observance of human rights and fundamental freedoms, demonstrating that human beings and their dignity must be above private power in any sphere [39].

Based on the fundamental idea of humanism, many other reflections have been developed, also covering the organizational context [40]. Thus, inside organizations, humanist management must place human dignity and rights as central concerns in all its subjects and methodologies [41]. In this sense, economic transactions are considered, in essence, as relationships between people and, for this reason, organizations need to serve the objectives of humanity and not the opposite. In doing so, people are seen as active and central elements of the economic system and not passive and secondary objects of an economy guided by other goals [41].

In a concise manner, a humanistic management is concerned with human needs and oriented towards the complete and extensive development of human being virtues. [42].

Thus, based on the concepts of this type of management, it is possible to describe a progressive model of 3 levels of entrepreneurial humanism [19][43], as shown in figure 3. In the same sense, humanistic management is composed of 5 dimensions [40]:

- Managerial responsibility
- Employee motivation
- Personal promotion
- Interpersonal relationships
- Organizational culture

Regarding the relationship between technology and humanism, it is important to note that this is not a recent issue [44], but the advancement of Artificial Intelligence and its application in real Information System problems has leveraged new initiatives seeking to discuss this relationship [45][46]. Such efforts are known as Digital Humanism, which has proclaimed and disclosed a manifesto with principles on current and future technological development, as well as, on the co-evolution of technology and humanity [47][46].

D. IT Professional Profile

There is a vast literature devoted to the study of professionals working in the area of Information Technology, there are many documents that analyze or propose aspects related to the profile of this type of profession. Authors from the 60s and 70s were already concerned with the topic and proposed ways of defining and evaluating the fundamental characteristics of these professionals [9][7][6][8][10][48]. On the other hand, more recent studies point to an extremely complex and plural profile, capable of acting in different areas of the organization [49][50][51][52][18].

For this reason, precisely defining the IT professional and his/her profile has become a controversial task, where the conclusion can even be that everyone in the organization is somehow part of the workforce that works in IT area [18]. Despite this, this study proposes and uses a simple and broad

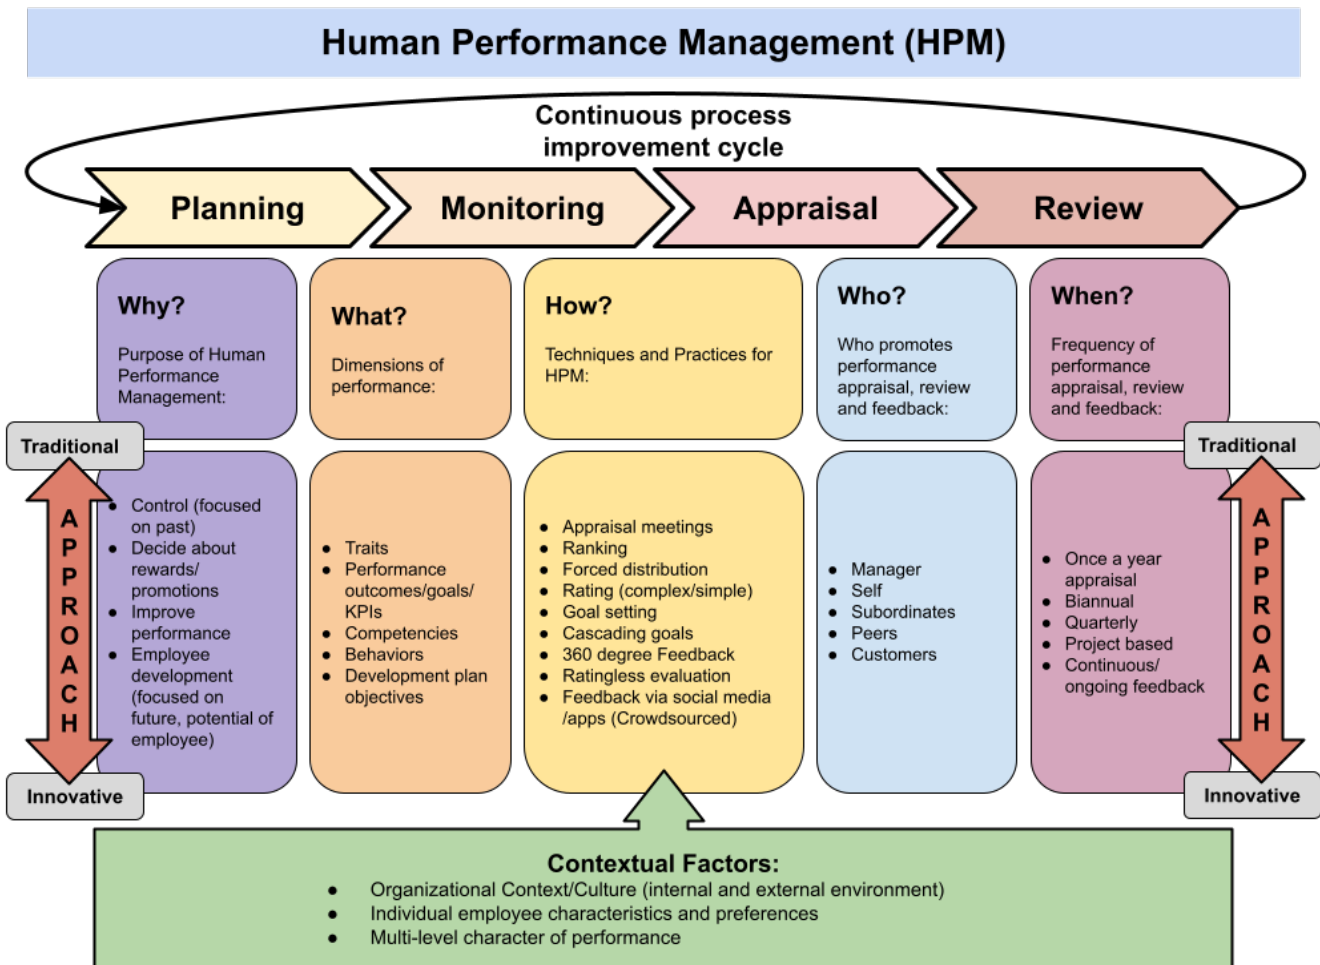

Fig. 2. Human Performance Management Framework. Adapted from [32]

Fig. 3. Levels of Entrepreneurial Humanism. Based on [19].

definition of IT professionals that summarizes the mission of these workers [53][54]:

Professionals who have attributions and perform activities, primarily, aimed at delivering information technology products and services with effectiveness and security.

Based on this definition, this research considered that any professional related directly to Information Technology fields, such as Information Systems (IS), Communications (ICT) and Data Science, is an IT professional.

Even with the diversity of characteristics and classifications pertinent to IT profile, it is possible to identify convergent aspects common to all professionals from this area [50]. The IT employee has unique identity, knowledge, skills, attitudes and interests, his/her focus at work tends to be more centered on technical issues, to the detriment of interpersonal skills such as communication [55]. When compared to professionals from other areas, IT personnel have a greater desire for opportunities, challenges and autonomy [56], in addition, they are motivated by achievements, recognition, constant learning and personal growth [55].

These are also common elements of the IT area [50]:

- Supply and demand for IT professionals continually changing.
- Requirement of a combined set of technical, humanistic and business skills.
- Professional environment in constant change, requiring adaptation and update of specific skills in short periods of time.
- Activities developed are essentially cognitive and difficult to monitor and evaluate.

As mentioned before, the set of required IT skills can be classified into 3 broad categories [50][56]:

- **Technical Skills:** knowledge and competences related to the use and application of technologies.
- **Humanistic Skills:** temperance, resilience, interpersonal relationships (e.g., teamwork, leadership, communication), promotion of well-being.
- **Business Skills:** business domain knowledge, project management, ethics, problem and conflict resolution.

The definitions and all other considerations just presented are what make Information Technology professionals singular inside organizations, demanding differentiated attention and approach from human resource management and, more specifically, from human performance management. [57][55][56][50][54].

III. CONTEXT AND PROBLEM

As demonstrated in Figure 2, Human Performance Management is a complex process that involves numerous variables, methodologies, people and applications. In addition, HPM is based on a vast amount of theories, in the most diverse areas of research, which makes the study on the subject very extensive and deep.

Considering the theories studied, the Organizational Culture theory proved to be the central point of analysis, through which it is possible to understand how the actions defined in the HPM are actually performed and the effects that this management has on employees.

Added to this, there are the unique characteristics of IT professionals and their work environment, which require, from Human Performance Management, a differentiated and individualized treatment for employees working in this area.

The particularities, problems and difficulties faced by Information Technology professionals have been subject of study for many years [51], considering the issues addressed by the researchers, the following items deserve to be highlighted:

- Ethics in IT and Conflicts at work.
- Job or career turnover.
- Gender imbalance/prejudice in IT.
- Treatment of minorities in IT.
- Evolution/Change of project and work models.
- Overload, stress, exhaustion and burnout.
- Work versus social life conflicts.
- Speed of technological evolution.
- Perception of professional stagnation or obsolescence.

It is important to understand that an effective HPM has the power to treat, mitigate or even solve the problems experienced in IT area.

In addition, the philosophical thought of Max Weber (1864-1920) states that work is a source of dignity and nobility for human existence, promoting life and well-being, for oneself and for others [58]. Based on this vision, it is essential to study, develop and encourage a more humane and sustainable organizational management.

In this sense, Teehanke (2021)[43] proposes that human beings should have the following needs considered and managed by organizations:

- Physical and mental health.
- Intellectual development.
- Emotional growth.
- Experiences in the fields of arts, culture and aesthetics.
- Social connectivity.
- Moral and spiritual development.

In order to ensure the true evolution of human performance, HPM must consider the humanistic aspects in its management premises. Thus, it is essential to leave behind the model where workers are seen only as production resources, which need to be monitored and optimized considering only productivity and efficiency [43].

IV. METHODS

In order to develop the solution proposed in this research, the *Design Science Research* paradigm was used [59]. Based on this paradigm, the first 4 steps of the process model proposed by Peffers et al. (2007) [60], known as *Design Science Research Methodology* (DSRM), were carried out, as shown in figure 4.

Thus, this research, which has a qualitative approach and positivist epistemological position, was developed in 4 phases or stages:

- 1) Problem identification and motivation.
- 2) Definition of solution objectives.
- 3) Design and development.
- 4) Demonstration.

In the first stage, an extensive literature review was performed, which made it possible to identify the context and domain of the problem. The motivation and reasons for seeking a solution were also determined, as indicated in Section III.

Continuing in the second phase, with the problem identified, it was possible to establish the objectives of the proposed solution, the assumptions and requirements that the produced artifact should follow. At this point, the need to build a human performance management model specifically focused on information technology professionals was defined, encompassing the precepts and characteristics of humanism.

In the third stage, the design and construction of the proposed model allowed a better understanding of the problem domain and its solution.

Finally, in the last step, the applicability of the model was demonstrated through evaluation methods of static and architectural analysis [59], verifying the structure of the model and studying its suitability to the requirements and theoretical assumptions postulated.

V. RESULTS

Based on the context and issues described in Section III, the present work proposes a humanistic model for performance management focused on developing the needs of IT employees as human beings, guided by the principles of ethics and appreciation of life.

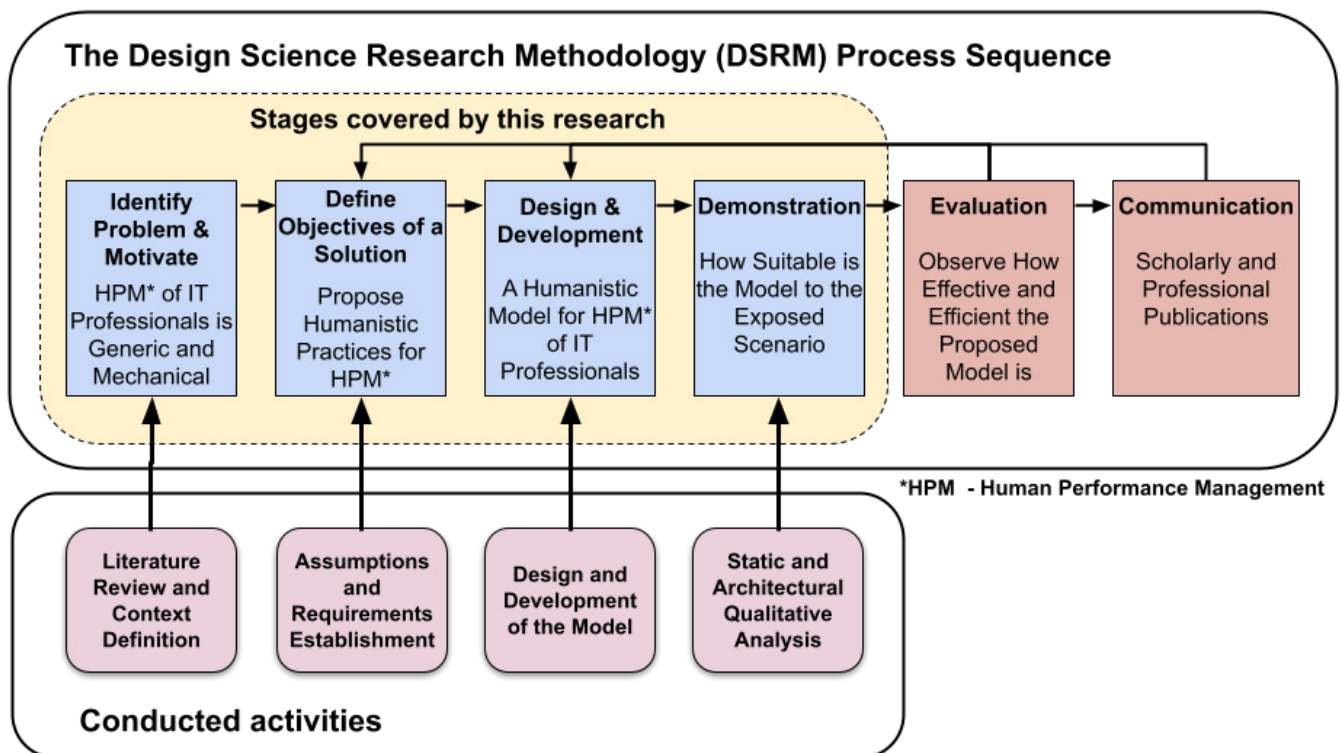

Fig. 4. Research Implementation using the DSRM Process Model. Adapted from [60]

The solution has the following fundamental assumptions and requirements:

- Promotion of the human person: all the steps on the process must preserve and improve IT employees' dignity and expectations;
- Ethics: all tasks related do performance evaluation need to be based on ethics principals defined by society and organizational culture;
- Transparency: actions and decisions of performance management must be communicated widely and transparently;
- Justice, Equality and Inclusion: the process must pursue and guarantee organizational justice, equality and inclusion;
- Objectivity and Celerity: HPM should avoid excessive bureaucracy, prioritizing simplicity, objectivity and celerity;
- Active stakeholder participation: all the steps must permit and promote the participation of organization community;
- Formative Appraisal: performance evaluation must prioritize a formative method (perceptions) over a summative one (grades and rates);
- Respect for individuality and dignity: all persons involved in the process must be treated with respect and dignity;
- Personal and professional development: HPM must ensure the personal and professional development of IT employees.

The details of the proposed model can be seen in Figure 5, there are 4 distinct phases in the human performance

management process (planning, performance appraisal, review, monitoring and improvement), where each step is specified according to humanistic foundations.

As can be seen from the model, **human being** must be the central concern of HPM, this indicates that management success depends, primarily, on how the issues related to humans are treated.

IT Profile is the next element that deserves consideration in the model, this represents all characteristics, skills, competences, knowledge and needs that compose and differentiate IT professionals from the others. The actions taken during the performance management process must respect and consider this profile.

The **planning** stage defines and presents the individual and collective purposes for evolution of human performance of organization's members. Planning must have a person-centered approach, be public and objective, in addition, it must address the personal and professional growth needs of each individual, contemplating the specificity of the IT profile. Its realization has collaborative characteristics, where decisions about what to produce, develop, improve or remedy are taken jointly and equitably.

Performance appraisal has a formative character and occurs continuously, being encouraged and carried out by all members of the organizational community. It does not use a summative method, the absence of values prevents comparisons and, at the same time, develops empathy and critical thinking in employees when interpreting feedback received or

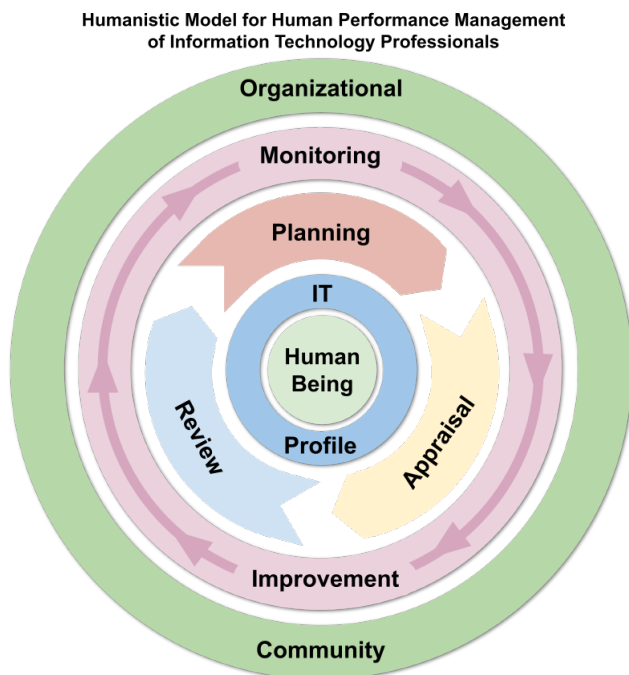

Fig. 5. Humanistic Model for Human Performance Management of Information Technology Professionals.

evaluating a colleague or themselves.

The **review** stage, which is also participatory, analyzes what has been carried out, allowing the necessary points to be adjusted and improving HPM proposals and mechanisms for the new cycle that will begin.

In the **monitoring and improvement phase (follow-up and support)**, the entire organizational community is invited to collaborate with the development of personal and professional goals, both individual and collective, which were defined in the planning stage. This step occurs throughout HPM process and can be executed in the form of mentoring, coaching, physical and mental health support, transfer and promotion of knowledge, among others possibilities. In addition, actions that seek to improve the management process itself are also promoted and encouraged.

VI. DISCUSSION

The analysis of the results relied on the evaluative precepts proposed by Design Science Research [59] and, from there, we sought to understand how adequate the solution is in relation to the human performance management framework (Figure 2), to the humanist principles and to the characteristics and particularities of the IT professional profile.

Regarding the human performance management framework (Figure 2), it is possible to verify that the proposed model is fully adherent to it. The solution presents a management process with well defined phases and elements, deals with organizations' contextual factors and allows the adoption of existing approaches and methodologies related to the field of HPM.

Considering the problem covered in this research in relation to humanist principles and the profile of the IT professional, it is understood that the following points are contemplated in the solution, as proposed by Farah (2000, p. 150) [38]:

- Respect for human beings and equal treatment.
- Improvement of Organizational Justice.
- Concern with personal (physical, mental, moral and spiritual) and professional development (skills, knowledge and technological evolution).
- Planning and evolution of human performance in an appropriate manner, linked to both, personal and organizational, expectations.
- Collaboration in IT talent retention.

This study is considered innovative because it proposes an unprecedented model capable of improving, from a humanist perspective, the human performance management of information technology professionals.

To corroborate this statement, in most of the studies on HPM analyzed by this research, the authors focused on directly applicable methods or management practices for performance evaluation, and, only in few cases, the characteristics of IT professionals are encompassed, however, leaving aside the question of humanism. The authors who dealt with humanistic management, on the other hand, do not, specifically, address performance management or the profile of the IT professional.

VII. CONCLUSIONS

For Humanism, every person is worthy of development [37]. This research was conducted based on this humanistic axiom and it is hoped that this study can somehow contribute to a better and more sustainable world, aware of the importance of valuing life and human dignity.

The limitations of the model and its usage are related to the issues concerning the initial adoption, since the study considered a generic process of HPM, for more specific scenarios or situations, it will be necessary make adaptations and develop extensions in order to deliver the expected results.

As future work, the development of complementary research is indicated, which, based on the proposed model, will produce new artifacts capable of leveraging the evolution of Human Performance Management of Information Technology professionals. Good practices, processes, methodologies, surveys and information systems are just a few examples of important artifacts that can be defined and explored.

4th Workshop on Data Science in Health, Ecology and Commerce

DATA Science in Health, Ecology and Commerce is a forum on all forms of data analysis, data economics, information systems and data based research, focusing on the interaction of those three fields. Here, data-driven solutions can be generated by understanding complex real-world (health) related problems, critical thinking and analytics to derive knowledge from (big) data. The past years have shown a forthcoming interest on innovative data technology and analytics solutions that link and utilize large amounts of data across individual digital ecosystems. First applications scenarios in the field of health, smart cities or agriculture merge data from various IoT devices, social media or application systems and demonstrate the great potential for gaining new insights, supporting decisions or providing smarter services. Together with inexpensive sensors and computing power we are ahead of a world that bases its decisions on data. However, we are only at the beginning of this journey and we need to further explore the required methods and technologies as well as the potential application fields and the impact on society and economy. This endeavor needs the knowledge of researchers from different fields applying diverse perspectives and using different methodological directions to find a way to grasp and fully understand the power and opportunities of data science.

This is a joint track by WIG2, the Scientific Institute for health economics and health service research, the Information Systems Institute of Leipzig University and the Helmholtz Center for Environmental Research.

TOPICS

We embrace a rich array of issues on data science and offer a platform for research from diverse methodological directions, including quantitative empirical research as well as qualitative contributions. We welcome research from a medical, technological, economic, political and societal perspective. The topics of interest therefore include but are not limited to:

- Data analysis in health, ecology and commerce
- Data analysis in climate change adaptation
- Data analysis in commerce
- (Health) Data management
- Health economics
- 5G(/6G) in health
- Data economics
- Data integration
- Semantic data analysis

- AI based data analysis
- Data based health service research
- Smart Service Engineering
- Integrating data in integrated care
- AI in integrated care
- Spatial health economics
- Risk adjustment and Predictive modelling
- Privacy in data science

Abstract—With the emergence of use of Linked Data in different application domains, several problems have arisen, such as data incompleteness. Type detection for entities in RDF data is one of the most important tasks in dealing with the incompleteness of Linked Data. In this paper, we propose an approach based on Deep Learning techniques, using an encoder-decoder model with attention mechanism, embedding layer to extract the features of each subject from the RDF triples and the GRU cells to address the problem of vanishing. We use the DBpedia dataset for the training and test phases. Initial test results showed the effectiveness of our model.

I. INTRODUCTION

IN RECENT years, the Linked Open Data (LOD) cloud has been increasing in popularity. As a result of the success of the LOD, many semantic datasets are freely available on the Web in machine-understandable format (primarily RDF (Resource Description Framework)) related to different domains.

With the emergence of the semantic web and Linked Data, several problems related to data uncertainty have emerged, such as imprecision, incompleteness, etc. The main reason for the appearance of these problems lies in the way of building datasets. These were built from incomplete data, heterogeneous formats, semi-structured data, etc. The anomalies cited above pose problems when using so-called uncertain data in reasoning, decision-making, the generation of new knowledge, etc.

According to [1], few approaches use links among datasets, so they can't able to exploit the endless possibilities with the full knowledge of the Semantic Web.

The approaches that exploit data from only one dataset, they stay below what is possible with Linked Data. The reason of this limitations and difficulties of links discovery in Linked Data applications are:

- The datasets are produced, kept or managed by different organizations in different schemas, models, locations, systems and licenses [2]. There is not any “centralized control system,” therefore, each publisher decides how to produce, manage and publish a dataset based on its needs and choices;
- The development of several applications which are independent of schema.
- The same real-world entities or relationships are referred with different URIs and names and in different languages,

while languages have synonyms and homonyms that make harder that automatic links detection.

- The datasets usually contain complementary information, e.g., consider two datasets about the same domain each modeling a different aspect of the domain. The commonalities between these datasets can be very few and this does not aid automated linking and integration.
- The datasets can contain data that are erroneous, incomplete, out-of-date or conflicting.
- In addition, scalability challenges lie in developing solutions that could exploit the whole LOD as background knowledge by following links autonomously.

To improve the quality of RDF data, we choose to treat incompleteness, more specifically type incompleteness. Indeed, predicting missing types for dataset subjects will provide us with a more complete dataset.

Therefore, the results provided by applications using these datasets will become better. Our solution uses the predicates and objects belonging to the subject to predict its type. With the use of the encoder-decoder model, we will guarantee to extract the semantic relations between predicates and objects. This will improve the accuracy of subject type prediction. The attention mechanism was used to assign high weights to inputs with high importance. In this study, we will work on the DBpedia dataset, applying an approach based on deep learning.

Deep learning techniques have been recently used in many research axes to resolve different types of problems, Artificial intelligence systems use deep learning to solve computational tasks and complex problems quickly [3]. These techniques are very appropriate for dealing with large datasets. They have the ability to analyse and interpret Linked Data, that require efficient and effective tools. So, deep learning techniques are considered to be the most reliable solution that deal with the context of Linked Data, presented by RDF model.

In this paper, we have proposed an encoder-decoder network for multi-labeling. This network incorporates a attention mechanism to model the links between data. Our approach aims to predict missing types for RDF entities using data from their triples.

The remainder of this paper is organized as follows: in Section II, we define some Linked Data concepts. In section III of our paper, we explore the various related works that deal

with the type detection problem. Section IV shows in detail our proposed approach. Section V describes the experimental setup, and Section VI reports the results, followed by a discussion of the results in Section VII. Finally, Section VIII shows the set of perspectives as well as the conclusion of our work.

II. BACKGROUND AND CONTEXT

In this section, we introduce the main principles of Linked Data, we briefly recall some necessary background knowledge including principles of Linked Data, uncertainty, incompleteness, and links detection. We will also look at some areas where linked data can be used to demonstrate its utility.

A. Linked Data

“Linked Data refers to a method of publishing structured data, so that it can be interlinked and become more useful through semantic queries, founded on HTTP, RDF and URIs” [4].

Linked Data is a design principle that presents links between RDF-formatted data published on the web rather than links between documents. This enables machines to explore the web and find other data using the links concept [5].

The various objects in this version of the web are identified by URIs (Uniform Resource Identifier).

Tim Berners-Lee proposed four rules for designing Linked Data, which are explained below:

- Use of URIs to identify objects and concepts.
- Use of the http protocol to allow humans to access sites/data.
- Use of semantic web standards to provide information relevant to URIs.
- Introducing links to other data to give more options when exploring.

B. Uncertainty in Linked Data

Data uncertainty represents the degree of reliability, inaccuracy and imprecision of the data. According to the W3C, uncertainty is either aleatory or epistemic [6].

- Aleatory: characterized by lack of information, incompleteness information, etc. from the world.
- Epistemic: it describes the non-systematic nature of the data (variability, irreducibility) and the natural variability of a system.

C. Incompleteness in Linked Data

Due that there is an overwhelming quantity of heterogeneous data on the web. Integration of data silos provided by the Linked Open Data community can provide information to curate this data and boost the Semantic Web field to its true potential. Nevertheless, even the largest graphs, for example DBpedia, suffer from incompleteness [7]. Linked Data within the enterprise can be plagued with issues of data incompleteness, inconsistency and noise.

Incompleteness in the context of Linked Data can take the form of missing information, incomplete triples, missing links between different resources, etc.

D. Links detection

Published data must be linked to other existing datasets. However, creating links between datasets requires careful analysis, given that the amount of data published is constantly increasing, the links discovery process must be automatic. Consequently, to efficiently build the Web of data, there must be solutions capable of linking data between different datasets of web of data, to detect missing links between data.

The link detection task for Linked Data is seen as a solution for the datasets incompleteness. This task enables us to discover new triples and improves the quality of data delivered to applications and systems using datasets built on Linked Data concepts.

E. Applications of linked data

The Semantic Web and linked data can have a significant impact on a wide range of applications. Here are a few examples:

- Medical field: medical and personal patient data is commonly stored in multiple incompatible systems [8]. This representation may cause issues when integrating the data (incompleteness, errors, etc.), resulting in inaccurate or completely false diagnoses. The use of linked data to represent medical data is viewed as a solution for easing data integration. The incompleteness problem can be solved by using type detection in linked data.
- E-commerce: based on the semantic web, agents collect product data from multiple stores in order to provide the best deals to customers. They can also perform auctions, negotiations, and contract drafting automatically (or semi-automatically).
- Knowledge management in an organization: semantic web techniques are used to provide the possibility of representing knowledge in the form of concepts, allowing leaders to have answers to semantic queries.

III. RELATED WORKS

In this part, we will explore a number of related works that deal with type prediction in RDF datasets.

A statistical heuristic link based type prediction mechanism, has been proposed in [9], this work was evaluated on DBpedia.

In [10], the authors propose a supervised hierarchical SVM classification approach for DBpedia by exploiting the contents of Wikipedia articles.

In [11], the authors propose a multi-label classification algorithm based on word embedding such as Word2Vec, FastText and GloVe in order to capture the semantic aspect between entities and relations.

Another approach named Class Assignment Detector proposed by [12] to detect correct and incorrect classes assignments for entities in RDF data by analyzing class characteristics.

The authors in [13] solved the type prediction problem by using the Twitter profiles of RDF entities. The data extracted from these profiles were used as features in training data in order to facilitate the prediction task.

Another approach proposed in [14] uses word embedding and network embedding to predict the infobox types for Wikipedia articles. This information is useful for the type generation procedure for RDF entities.

In the work done in [15], the authors propose a binary classifier using structural data and based on machine learning techniques to predict the types of RDF entities.

The work carried out in [16] consists in proposing an approach which deals with types prediction by text classification. Two classifiers have been proposed to achieve this task.

Analysis: After studying the different approaches proposed in the literature for type detection in Linked Data, we can deduce that:

- The majority of works do not take into account the semantic relations between the different components of the triples.
- Use of different techniques for links detection in related works, we cite: supervised hierarchical SVM classification, statistical heuristic, machine learning techniques, text classification and word embedding.
 - The SVM algorithm is not appropriate for large datasets and for high number of features.
 - The extraction of features by the programmer is the major disadvantage of machine learning algorithms. As a result, the data quality suffers. On the other hand, this task is performed automatically by neural networks. Deep learning allows for the extraction of more and significant features and thus produces better results.
 - Using word embedding and statistical heuristics to predict types does not allow for the extraction of more significant features from the inputs and the possible semantic relations between triples. This has a negative impact on the results quality.
- The results obtained can be improved by proposing other solutions.
- Several works test their proposed methods on a subset of DBpedia data, but the tested part is not specified in the research works.
- The extraction of semantic relationships between different types (classes) and resources is not addressed in related works.
- The proposed methods do not assign weights to triples based on their importance during the type detection task.

In order to achieve this goal, we propose our approach based on deep learning in order to explore semantic relationships between the different components of RDF triples. We base our choice on deep learning models' ability to learn from large amounts of data. We added the attention mechanism to give a weighting to inputs according to their importance.

Therefore, the main contributions of this paper are:

- A proposition of embedding model, which exploit the semantic relations between RDF triples.

- A neural network based multi-label classification model for predicting type of resource RDF,
- Using the attention mechanism to improve the quality of model. By assigning weights to triples, semantic relationships between RDF resources and types can be extracted.
- Numerical representation (RDF2Vec) of resources and predicates in the DBpedia dataset.
- The type detection task is approached as a sequence-to-sequence problem, where the inputs and outputs are long sequences.

IV. MATERIALS AND METHOD

Before delving into our approach and giving more details, we first start by showing where the missing types problem lies in the ontology proposed by the World Wide Web Consortium (W3C)¹ organization, for modeling uncertain knowledge in the semantic web. This context is presented in Fig. 1. We use deep learning techniques for incompleteness processing.

Detecting links in Linked Data is a solution to identify classes of resources and therefore find new links between data and minimize incompleteness.

The automatic detection of missing types will improve data quality and provide reliable answers to queries launched by the various applications that use Linked Data.

Our solution allows predicting types for resources belonging to RDF datasets based on predicates and object values. It is a model built using deep learning techniques. Google Collaboratory² was used for the training phase using the DBpedia dataset.

A. Modeling problem

Our solution consists in treating the link detection problem as a multi-label classification problem.

Multi-label Classification is the task of assigning data points to a set of classes or categories which are not mutually exclusive, meaning that a point can belong simultaneously to different classes. In multi-label classification, the examples are associated with a set of labels Y from a set of disjoint labels L , $Y \subseteq L$.

The inputs of our model represent the predicates (P_1, P_2, \dots, P_n) and objects (O_1, O_2, \dots, O_n) belonging to a subject S . These inputs are used to predict the output which represents the types of the subject S .

B. Construction steps

The different steps of our model construction are mentioned in Fig. 2.

1) **DBpedia Dataset:** In order to train our model, we will use the DBpedia dataset³. The latter is built according to the Linked Data principles.

¹<https://www.w3.org/>

²<https://colab.research.google.com/>

³<http://gaia.infor.uva.es/hdt/dbpedia2016-10/dbpedia2016-10.hdt>

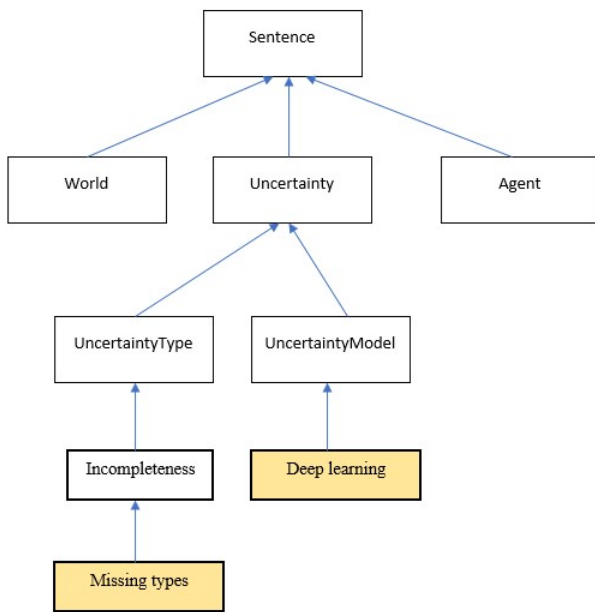

Fig. 1. Types detection in uncertainty ontology

Our dataset is composed of a set of triples (Subject, predicate, object), where the predicate represents the link between the subject and the object.

Our goal is to predict missing types (T_1, T_2, \dots, T_n) for subjects S_i based on their predicates (P_1, P_2, \dots, P_n) and objects (S_1, S_2, \dots, S_n) belonging to our dataset. i.e., for a given subject S_i , we use all its predicates and objects as inputs to predict its different classes or types. As a result, by inferring new triples, we can have a more complete dataset. (S_i, P_i, O_i) .

The first step of our approach is dataset reading, choosing the triples concerned by the different learning phases, as well as transforming the format of these triples into a numerical format.

Once our dataset is ready, we proceed to the pre-processing step, which consists of transforming the format of the triples into a format suitable for deep learning models (numerical representation).

Finally, we limit the number of predicates and objects belonging to each subject (inputs) to 205 objects, with the possible types as outputs.

2) **Pre-treatments:** Data preprocessing is an important or even crucial step for Machine Learning and Deep Learning. Data quality can directly affect the model learnability.

This step consists of transforming data into a more suitable format that can be used by the model. In this step we transformed each subject, object and predicate into numerical format. The numerical representation of inputs and outputs consists of giving numbers for each subject, predicate and

Fig. 2. Steps of our approach to type detection for Linked Data

object. Fig. 3 shows an example of this transformation.

C. Our model proposal

Our model is an encoder-decoder with attention mechanism which is a neural network design pattern that aids in the generation of an output sequence for every input sequence.

As shown in Fig. 4, the architecture is composed of two parts, encoder and decoder. Each part uses deep neural networks, more precisely gated recurrent units (GRU) in order to handle the sequence inputs of variable length.

The attention mechanism is a technique used in neural networks to focus on certain factors that can influence the

Fig. 3. An example of the preprocessing process

Fig. 4. Architecture of our encoder-decoder model with attention mechanism

model quality. The major contribution of this mechanism is to improve the sequence-to-sequence models performance. The details are mentioned in section IV-C4.

Our model uses as input the different predicates and objects belonging to the subject, and the types of the latter as output. We propose an embedding layer for each of the two components of our model (encoder and decoder).

1) **Encoder-Decoder:** The encoder-decoder architecture is used to generate output sequences from input sequences. In our model, we used GRU cells to build each component.

Our encoder is composed of two distinct modules: the Embedding layer, and the generated vector containing the information relating to inputs. This vector is used as the first hidden state of the decoder, in order to guide the decoder in its predictions. In what follows, we will detail how it works.

For our decoder, we distinguish two layers, a GRU layer and a SoftMax layer.

The GRU layer works the same way as the encoder layer with one exception based on Input/Output:

- The decoder takes as initial input the last hidden state generated by the encoder. This hidden state contains the essential information contained in each element of the input sentence.
- Just like the encoder, the decoder has an Embedding layer that generates the Embedding vectors from the numerical

representation of each subject.

- To generate a type T_i at a time step $T S_i$, the decoder takes as input: the hidden state, the output generated at the previous time step $T S_{i-1}$, as well as the Embedding vector.

The SoftMax layer predicts a probability distribution over the possible types, and choose the type with the highest probability.

2) **Embedding layer:** The embedding layer allow a reduced representation of inputs while keeping the semantic links between the subject's components. This layer enables the more features extraction from data.

3) **Gated recurrent units:** Gated recurrent neural networks GRU present a solution to the vanishing gradient problem. They have two gates, one for reset and another for update. They also use a hidden state mechanism, unlike LSTM which use a cell state and 3 gates. We will be able to process long sequences as a result of this.

4) **Attention mechanism:** The attention mechanism manages and quantifies the interdependence within input elements (Self-Attention) and between inputs and outputs (General Attention). This mechanism was introduced to solve one of the problems of sequence-to-sequence models, namely their

inability to provide good results when dealing with long sequences. This problem lies at the decoder level where only the last hidden state generated by the encoder is used as a context vector. An attention weight is generated for each input, giving high weights to the most important inputs in the type prediction phase. These values will be used by the decoder for the type prediction based on the results obtained from the SoftMax layer.

V. EXPERIMENTS

To evaluate the performance of our method, we use the DBpedia in our experimentation, to test the proposed method.

To this end, we use a subset of the dataset from the DBpedia.

A. Dataset

The DBpedia project is a community effort to extract structured information from Wikipedia and to make this information accessible on the Web.

DBpedia is a crowd-sourced community effort to extract structured, multilingual knowledge from the information created in various Wikimedia projects. The DBpedia knowledge bases are extracted from 125 Wikipedia editions. Altogether the DBpedia (2016-10) release consists of 13.1 billion pieces of information (RDF triples) out of which 1.7 billion were extracted from the English edition of Wikipedia, 6.6 billion were extracted from other language editions and 4.8 billion from Wikipedia Commons and Wikidata [17].

In this work, and due to technical constraints (RAM capacity), we used 15292 RDF triples for the different phases. These triples were divided as follows: 60% for the training phase, 20% for the validation phase and 20% for the test phase. the different details are mentioned in the Table I.

B. Hyper parameters

Our model uses the ADAM function as an optimizer and the 'Sparse Categorical Cross Entropy' cost function. The training phase consisted of 81 epochs. The various details are shown in Table II.

VI. RESULTS

To evaluate our method for type prediction in Linked Data, we use the standard evaluation measures: precision, recall and F-measure. In multi label classification, these criteria are defined in the following.

The metrics evaluate the multi-label classification system's performance, on each test example separately by comparing the predicted labels with the gold standard labels for each

TABLE I
THE NUMBER OF RECORDS FOR EACH STEP

Dataset	DBpedia
Training (60%)	9174
Validation (20%)	3059
Test (20%)	3059
Total (100%)	15292

TABLE II
HYPER PARAMETERS VALUES

Hyper parameter	Definition
Optimization function	Function ADAM
Loss function	Sparse Categorical Cross Entropy
Number of GRU Nodes	1024
Batch Size	64
Embedding size	256

test example. We focus on 3 major example-based metrics, as defined in [18] [19]:

$$Precision = \frac{1}{p} \sum_{i=1}^p \left(\frac{TP}{TP + FP} \right) \quad (1)$$

$$Recall = \frac{1}{p} \sum_{i=1}^p \left(\frac{TP}{TP + FN} \right) \quad (2)$$

$$F - measure = \frac{2 \cdot Precision \cdot Recall}{Precision + Recall} \quad (3)$$

Where p is the number of instances in the test set. The true positives (TP) is defined as the labels that are identical to the gold standard labels, false positives (FP) as labels that are not true positives, and false negatives (FN) as the gold standard labels that were missed in the prediction results.

Table III illustrates the different results in two cases: Encoder-decoder model with Attention Mechanism (AM), witch represents our solution, and Encoder-decoder model without attention mechanism.

Histogram in Fig. 5 outline the evaluation results using the standard evaluation measures defined in Table III.

During the training phase, we obtained a cost function value of 0.0217 for our model with attention mechanism and 0.0937 for the model without attention mechanism.

After calculating the recall, precision, and F-measure values, we discovered that our model outperformed the encoder-decoder model without an attention mechanism.

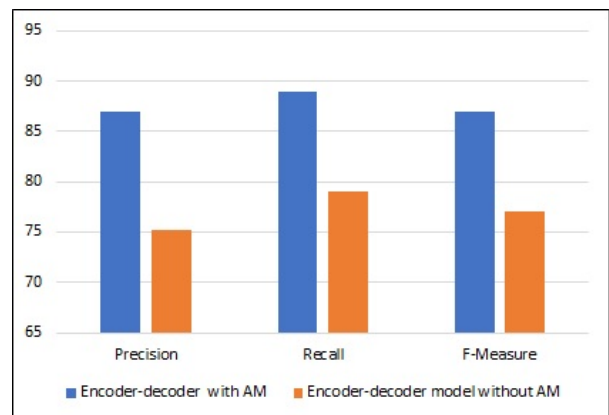

Fig. 5. Histogram of evaluation results

TABLE III
RESULTS OF TYPE PREDICTIONS WITH OUR MODEL AND A SIMPLE
ENCODER-DECODER MODEL

Model	Precision	Recall	F-Measure
Encoder-decoder model with AM	86.92	89.00	87.95
Encoder-decoder model without AM	75.16	79.02	77.04

VII. DISCUSSION

According to the presented results in Table III and Figure 5, we note that our modeling presents a good values for used evaluation metrics, comparing with encoder-decoder model without attention mechanism, witch is presented by 86.92% as precision value, 89.00% as Recall value and 87.95% as F-Measure value.

The results clearly demonstrated the significance of employing the attention mechanism. It enables the assignment of weights to inputs based on their importance. This increases the accuracy of output prediction. GRU cells positively influenced the results quality by making the features extraction task from inputs more efficient.

The results for the encoder-decoder model without an attention mechanism are less impressive because no attention value is assigned to the inputs to guide the type prediction process.

These results can be improved by running the model training phase on more powerful machines and by using larger datasets.

VIII. CONCLUSION

The semantic web community has been researching links detection and enrichment of Linked Data for last years. The volume of the available Linked Data on the web has been increasing considerably, along with the existence of erroneous, incomplete RDF data, kept this area active.

Links detection is a new research area of the Semantic Web which studies the problem of finding semantically related entities lying in different knowledge bases.

One of the most important challenges in Linked Data cloud is predicting the missing links between the entities, which is necessary to facilitate the inter-connectivity of datasets in the LOD cloud, in order to enhance and enrich the information that is known about them. Moreover, in the LOD cloud, information about the same entities is available in multiple datasets in different forms.

Links detection aims to deal with the issue of missing data. The completeness of the data simplifies decision-making and task performance in any field of application, including medical diagnostics, e-commerce and ecological prediction.

In this paper, we have proposed a promising new approach dealing with the type detection problem in Linked Data. We have treated this problem as a multi-label classification task using an encoder-decoder model with attention mechanism, and we have obtained very good results. However, in the

future, we want to validate our approach by testing it on different datasets and comparing it with the results of related works. We intend to propose a method for dealing with all possible semantic links. We also want to use NLP techniques on textual objects and to train our model on large datasets.

Abstract—Companies and even institutions have recently tried to form a reasonable opinion about their products. One way companies can achieve this is to prepare and distribute advertisements. Some advertising media, such as TV commercials, are costly and tiresome, so understanding and modeling some aspects of disseminating product information might be helpful. The article presents a multi-agent model of spreading trust in the product among agents based on fuzzy aggregation norms. When people with a similar opinion about a product discuss it with others or listen to a commercial, their trust increases, so the optimistic fuzzy aggregation norm is applied. When people with different opinions meet, their faith decreases, so the pessimistic norm is applied. In addition, the paper presents a theoretical example of this model application, namely, showing the results of a multi-agent model of spreading confidence in the product and presenting the results of the NetLogo simulation.

Index Terms—trust dissemination, multi-agent model, fuzzy aggregation norms, NetLogo application

I. INTRODUCTION

THE advertisement is present everywhere and slowly has been filling up people's everyday reality, and it is one of the systematic business processes where companies use technology. The methods used for helping people solve different business problems and based on information systems that start as practical business applications should also be analyzed at the conceptual level at the beginning by considering case studies, for example [1], [2].

This paper aims to present a theoretic model of spreading information about a product using fuzzy aggregation norms applicable in the area of product advertisement. The article also deals with searching for a method to observe the dissemination of knowledge about products applying the concept of an agent or an intelligent agent to analyze, model, and visualize the considered process using the NetLogo application. Multiagents' idea is used to analyze customer service, sales, and production scheduling [3], [4].

II. FUZZY LOGIC

When people describe the product, they may use words on the two extreme levels of the scale of product appreciation, like perfect or worst, or some intermediate terms like good, excellent, or wrong. Hence, fuzzy logic is much better to apply than classical logic [5].

L. Zadeh [6] introduced the concept of fuzzy sets. Let X be a non-empty space. Then $A \subseteq X$ is called a fuzzy set if it is a set of pairs $\{(x, \mu_A(x)), x \in X\}$, where $\mu_A : X \rightarrow [0, 1]$ is a membership function. Value $\mu_A(x)$ describes the level of membership of element x to set A .

III. THE FUNCTION OF TRUST DISSEMINATION

The article deals with the dissemination of products of knowledge or the reputation of scientists. Assume that we are

interested in the advertisement for one product, which will be called later the product.

Let \mathcal{A} denote the set of agents - people who might have some knowledge about the product and some level of trust about its quality. Let $T : \mathcal{A} \rightarrow [0, 1]$ be called the trust function. Assume that $A \in \mathcal{A}$ and let us consider five cases:

- $T(A) = 1$, then the trust of agent A is positive and perfect, there is no way to change their minds about the product;
- $T(A) \in (0.5, 1)$, then the agent's trust in the product is high;
- $T(A) = 0.5$, then agent A does not have any knowledge or is perfectly indifferent to the product;
- $T(A) \in (0, 0.5)$, then the trust is low;
- $T(A) = 0$, then agent A does not have any knowledge, or they dislike the product.

Now we will consider the situation when agents meet and discuss the product or get some new information about it from, for example, a TV commercial.

IV. OPTIMISTIC FUZZY AGGREGATION NORMS

The essential characteristic of optimistic fuzzy aggregation norms is that the examined property level is not less than before.

Let $I = [0, 1]$. Then $S_o : I \times I \rightarrow I$ is called an optimistic fuzzy aggregation norm if it fulfills the following conditions for each $x, y \in I$:

- (O1) $S_o(0, 0) = 0$
- (O2) $S_o(x, y) = S_o(y, x)$
- (O3) $S_o(x, y) \geq \max\{x, y\}$

Let us notice that it can be easily seen that

- (O4) $S_o(x, 0) \geq x$ for each $x \in I$
- (O5) $S_o(1, 1) = 1$

Condition (O1) shows that if an agent's trust in the product is 0 and they do not get any new information about it, their faith stays on zero levels (as before). Condition (O2), called commutativity, says that the order of getting pieces of information about the product does not matter. Thanks to condition (O3), we know that the product trust value is not less than the level after the meeting with another agent or watching the ad.

Additionally, condition (O4) indicates that if the level of trust in the product is positive and if the agent does not get any new pieces of information or advertisement, then the level of confidence is not reduced.

Let us choose as an optimistic aggregation norm the following function $S_o(x, y) = x + y - xy$ for each $x, y \in I$. In this case, $S_o(x, 0) = x$ for each $x \in I$.

Let us consider an example. Assume that two agents A_1 and A_2 , with the level of trust $t_1 = 0.6$ and $t_2 = 0.7$ respectively, meet and discuss the quality of the product. To calculate the trust of the agents we apply optimistic fuzzy aggregation norm: $T(A_1) = S_o(A_1, A_2) = t_1 + t_2 - t_1 \cdot t_2 = 0.6 + 0.7 - 0.6 \cdot 0.7 = 0.88$. By (O2), we know that $T(A_2) = S_o(A_2, A_1) = S_o(A_1, A_2) = 0.88$. Hence, the trust of both agents is equal and higher than before the meeting. Let us notice that the trust in the product of both agents in the product is strengthened.

V. PESSIMISTIC FUZZY AGGREGATION NORMS

The essential characteristic of pessimistic fuzzy aggregation norms is that the examined property level is not higher than before.

Let $I = [0, 1]$. Then $S_p : I \times I \rightarrow I$ is called a pessimistic fuzzy aggregation norm if it fulfills the following conditions for each $x, y \in I$:

- (P1) $S_p(1, 1) = 1$
- (P2) $S_p(x, y) = S_p(y, x)$
- (P3) $S_p(x, y) \leq \min\{x, y\}$

Let us notice that it can be easily seen that for each $x \in I$ we have

- (P4) $S_p(x, 1) \leq x$
- (P5) $S_p(0, 0) = 0$

Condition (P1) shows that if an agent believes in a product entirely and they get any new information about it, their belief stays on the same one (maximal) level (as before). Condition (P2), called commutativity, says that the order of getting pieces of information about the product does not matter. Condition (P3) shows that if the level of belief in a given product is not higher than the level of confidence in this product before and the new piece of faith the agent gets while speaking to other agents or the source of advertisement (TV, radio). Additionally, condition (P4) indicates that if the level of belief in a product is positive and if the agent gets the new perfect piece of information or advertisement, then the value of confidence is not increased.

Let us choose as a pessimistic aggregation norm the following function $S_p(x, y) = xy$ for each $x, y \in I$. Then we can easily see that condition (P4) we can write as follows $S_p(x, 1) = x$.

Let us consider an example. Assume that A_1 and A_2 are agents with the level of trust $t_1 = 0.2$ and $t_2 = 0.4$, respectively. After meeting and discussing the quality of the product, we can calculate the trust of the agents applying the pessimistic fuzzy aggregation norm: $T(A_1) = S_p(A_1, A_2) = t_1 \cdot t_2 = 0.2 \cdot 0.4 = 0.08$. By (P2), $T(A_1) = T(A_2)$. Of course, the trust in the product is lower for both agents.

Assume that agent A , with the trust t , does not meet another agent to discuss the product; their faith in the product after some time will be smaller and equal to $T(A) = S_p(t, t)$.

Let us consider another example. Let agent A , with the trust $t = 0.3$, does not discuss the qualities of the product and does not listen to the advertisement, then after some time: $T(A) = S_p(t, t) = 0.3 \cdot 0.3 = 0.09$. As we can quickly notice, their trust in the product lowered. When people do not listen to any information about the product or do not discuss it with other people, their confidence in the merchandise decreases. There is one exception, perfectly convinced people. They do not need any advertisement or talking to other people about the product, and their trust is still on level 1: $T(A) = 1 \cdot 1 = 1$.

VI. MULTI-AGENT MODEL OF THE TRUST-IN-THE PRODUCT DISSEMINATION

Let A be an agent with the level of trust in the product equals $t \in [0, 1]$ in some period. To design the model of the

trust-in-the-product dissemination, let us consider three cases.

- If for a given period, the agent does not meet other agents to discuss the product and does not watch any advertisement; then we can assume that their trust in the product suppresses with the forgetting coefficient F belonging to interval $[0, 1]$.
- If in a given period, the agent is exposed to advertising of the product or is in the shop selling the product, we can assume that their trust in the product increases with the strengthening coefficient $S \in [0, 1]$, which value depends on the level of aggressiveness of this ad.
- If agent A meets other agents A_1, A_2, \dots, A_n with levels of trust in the product equal to t_1, t_2, \dots, t_n , respectively, then A 's confidence in the product also increases. Hence the strengthening coefficient M can be calculated as a maximum of all agents' trust in this merchandise, $M = \max\{t, t_1, t_2, \dots, t_n\}$.

Hence, for the next period of time, agent A trust in the product is calculated in the following way:

$$T(A) = \begin{cases} S_p(t, F) & \text{if } A \text{ has no contact with the advert} \\ S_o(t, S) & \text{if } A \text{ is exposed to the advert} \\ S_o(t, M) & \text{if } A \text{ has meetings with other agents} \end{cases}$$

Let us consider the example. Assume that agent A with the level of the trust in the product equals $t = 0.5$ in January. This agent goes for a winter holiday and does not discuss the product's properties and is not exposed to the advertisement of it in February, so the forgetting coefficient is equal to $F = 0.9$. In March, this agent takes part in the meeting with two agents A_1 and A_2 with the levels of trust in the product equal to $t_1 = 0.3$ and $t_2 = 0.7$ in March. Finally, this agent watches a fascinating film on TV with the product's advert in April, so the strengthening coefficient is equal to $S = 0.8$.

Let $t_{month} = T(A, \text{month})$ denotes this agent's level of trust in the product in the considered month. Hence, $t_{Jan} = T(A, \text{January}) = 0.5$. Next, $t_{Feb} = T(A, \text{February}) = S_p(t_{Jan}, F) = S_p(0.5, 0.9) = 0.5 \cdot 0.9 = 0.45$. Afterwards, $M = \max\{0.45, 0.3, 0.7\} = 0.7$ and $t_{March} = T(A, \text{March}) = S_o(t_{Feb}, M) = S_o(0.45, 0.7) = 0.45 + 0.7 - 0.45 \cdot 0.7 = 0.84$. Finally, $t_{Apr} = T(A, \text{April}) = S_o(t_{March}, S) = S_o(0.84, 0.8) = 0.84 + 0.8 - 0.84 \cdot 0.8 = 0.97$. Thus, the presented multi-agent model can simulate the levels of agents' trust in the product and the influence of other agents and the product advertising on the agents' trust level.

VII. SIMULATION OF THE MODEL OF THE TRUST DISSEMINATION

A multi-agent simulation of the trust dissemination of the product was developed in NetLogo's programmable modeling environment, in which applications coded in NetLogo are very convenient to observe agents (turtles) meeting and changing their opinions about the product.

The simulation started with the group of people represented by gray turtles showing no knowledge about the product and advertising media represented by green squares. The simulation follows the Ant Colony Optimization [7] algorithm, which

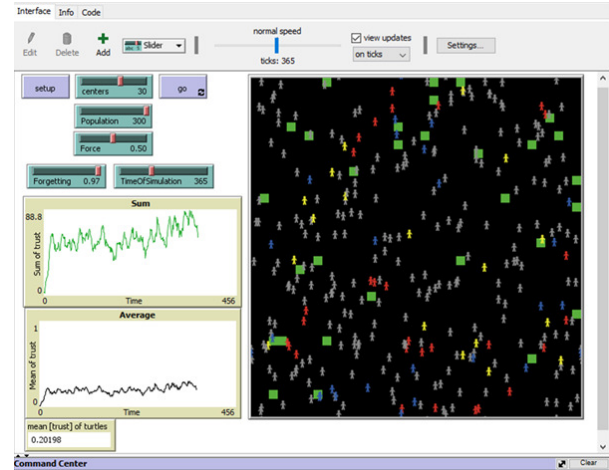

Fig. 1. The screenshot of the middle phase of the application developed for the simulation of the trust in the product

applies probability to solve some computational problems that require looking for paths while traversing plots.

During the simulation, people move, meet other people (during these meetings, they exchange opinions about the product), and meet advertising media (get some information about the product). Initially, the agents' trust in the product is 0, and the media's is 0.9. During the meetings, the product's trust changes according to the fuzzy aggregation norms. Hence, after some time, agents change their colors according to the following rules: they stay gray (the trust is smaller than 0.3), change color to yellow (the trust is between 0.3 and 0.6), - to blue (the trust is between 0.6 and 0.9) or - to red (the trust is greater than 0.9).

VIII. DISCUSSION

According to K. Kubiak, referring to A. Lubecka, the subject of advertising, has become one of the most frequently discussed issues [8]. Institutions that use advertising to influence the expected behavior use various methods of reaching a specific audience [9]. In advertising design, the most commonly used methods are: evoking intense emotional states, making promises (positive and negative), and using the image of a public figure. According to the theory of stereotypes, ad recipients remember these performances as relatively permanent. Time constraints or the size of the advertising space, combined with the willingness to communicate, impose the need to schematize (stereotype) the presented events, so stereotypes are used because they function on the scale of society [8].

Even the most straightforward messages affect the knowledge, emotions, or behavior of the recipient, sometimes regardless of the will of the message sender. However, there are cases of manipulating the other person. However, honesty towards the customer is not the primary determinant of the product promotion process for some advertisers. Persuasive and argumentative techniques may lead to stereotypes' consolidation in the social consciousness [10].

Advertisements influence emotions and affect product ratings and consumer attitudes. Scientists dealing with this topic pointed to the vital role of activating memories by advertising. The strength of emotional reactions also depends on the purpose of viewing the ad. In the minds of consumers, the goals of observing advertisements may be different; for example, some people want to get information about a product or have the pleasure of viewing the aesthetic images. Thanks to cognitive engagement, product information is processed more accurately, and emotional engagement results in a more positive attitude towards advertising. Therefore, referring to memories will increase involvement in processing information about an advertisement, influencing its evaluation and remembering [5].

In increasing skepticism about the content and declining credibility of messages about products and services, customers' opinions are more important. In recent years, word-of-mouth marketing, also known as gossip or recommendation marketing, is becoming more critical. Its popularity results from people's psychological construction because they need to share their opinions with others [14]. Therefore, the companies found their hope in word-of-mouth marketing, that is, a selfless recommendation of products, brands, or services among their families, friends, or strangers [13].

Word-of-mouth marketing is the oldest, best and cheapest marketing tool. When people tell the truth about a product, the effect of such advertising can be striking, but impersonating an ordinary user praising the product can lead to a loss of trust and turn against the trader [13]. Word of mouth marketing distinguishes into two forms, i.e., face-to-face marketing and online communication [11]. eWOM (electronic word of mouth marketing) has recently attracted much interest from researchers. However, with consumers' increasing dependence on information retrieval and the continued growth of social media, the importance of eWOM should not be overstated [12]. Regardless of the proportion of the phenomenon, the strength of adverse opinions is higher than positive ones. Therefore, the company's task is to strengthen positive thoughts, and weaken negative [14].

Being recognized is very important also for researchers. Scientists build their scientific profiles in only one or a few disciplines or scientific fields, and scientometricians try to find factors to estimate their contribution to a specific discipline or a field. One of the models of computer systems for calculating the contribution to research areas in computer science is presented in [15]. Moreover, bibliometricians try to visualize the scientist's contribution to disciplines based on published articles and journals' profiles by choosing the weights of examined fields empirically [16].

IX. CONCLUSIONS

We present a model based on fuzzy aggregation norms to describe spreading information about a product that can be applied in product advertisements. We also use several simulations to test the basic assumptions of the model. Selected

actions with predefined emotional states and parameters were simulated in the NetLogo environment.

Summing up, applying optimistic and pessimistic fuzzy norms has the following properties.

- 1) The situation with increasing and decreasing trust of the product among customers can be modeled and analyzed.
- 2) The influence of Advertising Centers can be modeled.
- 3) The role of word-of-mouth marketing and its influence on product trust dissemination can be described.
- 4) Fuzzy aggregation norms can be used to model the product trust dissemination in marketing.

Abstract—A procedure for detecting cognitive impairment in senior citizens is examined using pupil light reflex (PLR) for chromatic light pulse and a portable measuring system. Features of PLRs of blue and red light pulses are compared. PLRs of elderly subjects were studied in order to develop a procedure for detection of the symptoms of cognitive function impairment using a dementia evaluation test. PLRs of both eyes were measured using blue and red light pulses aimed at either of the two eyes. The features of PLR waveforms for each eye were remained in comparable level for every group of participant. Three factor scores were calculated from the features, and a classification procedure for determining the level of dementia in a subject was created using regression analysis. As a result, the contribution of factor scores for blue light pulses according to a participant's age was confirmed.

Index Terms—Pupil, Pupil Light Reflex, Alzheimer's disease, feature extraction, logistic regression

I. INTRODUCTION

SYMPTOMS of cognitive function impairment are used to diagnose Alzheimer's Disease (AD) and mild cognitive impairment (MCI). A major diagnostic procedure is the Mini-Mental State Examination (MMSE), which is based on a set of face-to-face clinical tests. These require participants to have sufficient communication skills, however. Therefore, a quicker and easier objective procedures should be developed.

The study of conventional pupil light reflex (PLR) activity [1], [2] suggests that as this activity represents to visual information processing of retinal stimuli and the ability to activate neural signal transfers, it should be evaluated as an alternative means of diagnosing cognitive function impairment [3], [4]. Also, PLR responses based on Melanopsin ganglion cells [5], [6], [7] can be applied to the study of aged macular disease (AMD) and AD [5], [6], [8], and the possibility of their use in diagnosing these diseases has been studied [9], [10], [11], [12]. A simple procedure to detect AMD and AD patients is required for medical and clinical staff who treat elderly people [13]. In a sense, a diagnostic procedure using ocular-motors may be an easy way, as it does not require verbal communication.

This research was partially supported by the Japan Science and Technology Agency (JST), Adaptable and Seamless Technology transfer program through target driven R&D (A-STEP) [JPMJTM20CQ, 2020-2022].

The authors have been conducting feasibility studies about conducting PLR observations using a portable measuring system at clinical institutions. During the current survey, additional elderly people were invited to participate and their responses were analyzed. Estimation performance and validity were evaluated. In this paper, the following points are addressed.

- 1) Features of PLRs for blue and red light pulses of the left and right eyes are compared, and the differences are extracted.
- 2) The ability of classifying participants as AD/MCI or normal control (NC) using MMSE score and PLR features.
- 3) The contribution of the participant's age is also examined.
- 4) Prediction performances of participants with AD or MCI procedures are developed and evaluated.

II. METHOD

Pupil light reflex was observed in senior citizens who may be AD patients, pseudo-positive participants, or have no cognitive impairment i.e., normal.

A. Stimuli

Participants were introduced to a temporary dark space, where the 5 following experimental sessions were conducted for 10 seconds each.

- 1) Condition1: Control session without light pulses
- 2) Condition2: Blue light pulse to the right eye
- 3) Condition3: Blue light pulse to the left eye
- 4) Condition4: Red light pulse to the right eye
- 5) Condition5: Red light pulse to the left eye

The experiment is designed to study the influence of light pulses on synaptic connections between both eyes in response to light pulses to either eye. Light pulses transfer from retinal ganglion cells on the irradiated eye to sphincters of both eyes via the Edinger-Westphal Nucleus [14]. The processes of miosis and restoration were observed in all 4 session. A short break to be relax was inserted between each session.

B. Procedure

The size in pixels of pupil responses were measured at 60Hz using an equipment with blue and red light source as shown

Fig. 1. Equipment to observe pupillary changes

TABLE I
FEATURES OF PLR

Variables	Definitions
RA	Relative Amplitude of miosis
t_min	Time at minimum size
diff_min	Minimum differential of size
t_diff_min	Time at minimum differential
diff_max	Maximum differential of size
t_diff_max	Time at maximum differential
diff2_min	Minimum acceleration
t_diff2_min	Time at minimum acceleration
diff2_max	Maximum acceleration
t_diff2_max	Time at maximum acceleration

in Figure 1 (URATANI, HITOMIRU). The light sources were blue (469nm, 14.3cd/m², 6.5lx) and red (625nm, 12.3cd/m², 10.5lx). Both pupil sizes were measured over all conditions. Blink artifacts were removed manually after the measurement.

The experiment was conducted by a clinical physician at a medical institution, and the procedure was approved by an ethics committee at Osaka Kawasaki Rehabilitation University.

C. Participants

The valid data was obtained from 101 participants, 66 females and 35 males. Their mean age was 78.5 and the SD (standard deviation) was 8.9 years. Participants were selected at a medical institute and MMSE test was conducted. The results were classified into three groups according to MMSE scores. These were AD (Alzheimer's disease, with MMSE≤23), MCI(Mild cognitive impairment, with MMSE≤27) and others, whose conditions was NC(Normal Control). The distribution was as follows:

- AD: 31(F:21, M:10), Mean age:83.0, SD:6.3 years.
- MCI: 9(F:5, M:4), Mean age:82.1, SD:6.3 years.
- NC: 61(F:40, M:21), Mean age:75.6, SD:9.2 years.

As the age of participants may influence their condition, four age levels were created: less than 66 years old (0), 66-75 years old (1), 76-85 years old (2), higher than 85 years old (3). Though participants were older persons who might have some health problems, these points were not considered in the following analysis.

III. RESULTS

A. PLR waveforms

An example of PLR waveforms for a NC participant is shown in Figure 2. The horizontal axis represents time, and the

Fig. 2. Examples of PLR of both eyes for four conditions (NC participant, 76yo, M), categories:[light color][irradiated eye]-[observed eye]

Fig. 3. Examples of PLR of both eyes for four conditions (AD participant, 87yo, F), categories:[light color][irradiated eye]-[observed eye]

vertical axis represents pupil size in pixels for the experimental conditions 2~5. There are some differences in pupil size between the left and right eyes at the initial point. The legend "BR-R" means that Right pupil response when Blue light irradiates to Right eye, and also "RL-R" means that Right pupil response when Red light irradiates to Left eye. Also, levels of contraction are different between conditions as in the previous work, which presented PLR responses to blue or red light pulses [6]. Another example of an AD patient is shown in Figure 3. Some typical features are observed such as deviation during the restoration process after the constriction. Several features of waveforms were extracted in order to compare groups of participants in relation to the previous study [12] as shown in Table I.

The first hypothesis is that there is a feature difference between the left and right eyes when light pulses are directed at either eye. The hypothesis was examined using a t-test of features of both eyes, such as between irradiated eye and non-irradiated eye. The features were extracted from standardized waveforms in order to reduce the potential differences.

Fig. 4. Comparison of factor scores between stimuli (f1~f3: factor scores for Factor 1~3)

In the results of the test, there are no significant differences in any of the features. There were a few exceptions, but the results did not coincide with the results of either colour of light pulse.

B. Factor analysis and factor scores

Since every feature includes measurement errors and individual differences, the latent factors are extracted using factor analysis according to the method used in the previous study [12].

The results of factor analysis are shown as a factor loading matrix in Table II. In this paper, three factors are employed, and the overall contribution ratio of the factors is 45.5%. Factor 1 represents the differential rate and acceleration of pupillary change, Factor 2 represents the features of contraction such as relative amplitude and its time, and Factor 3 represents the times for the differential rates and acceleration, as mentioned in Factor 1.

Three factor scores are calculated using the factor loading matrix. When these scores of both eyes are compared, there are also no significant differences.

The factor scores for experimental conditions are summarized and compared in Figure 4. Changes in Factor-2 scores suggest a continuous decrease according to the experimental conditions. Also, there are significant differences in the three factor scores of blue and red stimuli. Within a colour stimulus

condition, there are significant differences in the three factor scores for blue light pulses, and significant differences in Factor-2 scores for red light pulses ($t(402) = 2.13, p < 0.05$). The differences between sessions using the same colour condition should be considered, in particular the differences for blue light should be evaluated separately.

In addition, the factor of age level on factor scores is examined using two-way ANOVA of participant groups and age levels. Though the factor for the participant groups is not significant, the factor for age level is significant for Factor-1 scores ($F(3, 801) = 19.9, p < 0.01$), and the interaction between the two factors (age and participant group) is also significant ($F(2, 801) = 9.4, p < 0.01$). Therefore, the factor of age may affect the differential and the acceleration of pupillary change as presented in Factor-1.

The influence of a subject's level of dementia on PLR features was not confirmed in the above analysis. The factors of stimulus light wavelength and the age of patient were significant and are the major components of the deviation. In order to examine the effectiveness of the extracted features for a prediction of cognitive function impairment, an estimation procedure using a logistic analysis which had been introduced in a previous study [12] was conducted. Here, both MCI and AD patients are merged as the "AD+MCI" group since the number of MCI participants is limited. The probability of cognitive impairment is calculated using factor scores for each participant. As there are no significant differences between eyes, averaged features of responses of both eyes are employed. In considering the differences between session stimuli, two sets of features for blue light conditions and averaged features for red light conditions are introduced, for a total of 9 variables altogether.

Table III shows a summary of several prediction models and AUC (Area under the Curve) as an index of accuracy of binary classification for a ROC (Receiver Operating Characteristic Curve). Since a threshold for the classification may depend on the diagnostic policy such as reducing False positive rate, the accuracy is evaluated using AUC. An example of ROC for Model 2 is illustrated in Figure 5. Model 1 consists of 9 factor scores, Models 2 and 3 include age level or age. Model 4 employs significant contributing variables using a stepwise selection technique. Participant's age information aids classification performance.

Probabilities for the classification of cognitive impairment based on Model-2 are calculated, and the relationships between MMSE scores and the probabilities are summarized in Figure 6. The horizontal axis represents MMSE scores, and the

TABLE III
PREDICTION MODELS USING FACTOR SCORES OF PLRS

Model	Variables	AUC
1	9 factor scores	0.77
2	9 factor scores + age group	0.84
3	9 factor scores + age	0.84
4	Selected variables: 5 factor scores + age group	0.84

Fig. 5. ROC for Model 2 (AUC=0.84)

Fig. 7. Change in probabilities according to participant's age

Fig. 6. Relationship between MMSE scores and computed probabilities

vertical axis represents the probability. Participants who were tested using MMSE are plotted in the figure according to their participant group, AD, MCI or NC. Confirmation of the contribution of a participant's age is shown in Figure 7, where the horizontal axis represents the age. In this figure, cognitive impairment can be observed in subjects over 70 years old, and the probability increases markedly from around 70 onwards. When the threshold for AD+MCI is set to 0.5, 80 percent of participants are classified correctly. The AUC is 0.84 as shown in Table III.

Mean probabilities for the groups of AD+MCI and NC by age level are summarized in Figure 8, in order to evaluate the contribution of age level. Overall, mean probabilities increase with age level. In particular, the probability of AD+MCI increases over age 75 while mean probability of NC remains under 0.5.

Fig. 8. Comparison of mean probabilities between AD+MCI and NC groups

C. Variable selection of the regression function

Model-4 in Table III was generated using a variable selection procedure. All 5 selected variables are factor scores for blue light pulses during two test sessions, and factor scores for red light pulses were not used. The fitting index AUC is comparable with the values of the other functions. This suggests the possibility that prediction can be made using responses to blue light pulses. More detailed points regarding this will be summarized in the following discussion section.

IV. DISCUSSION

In the first hypothesis, cognitive impairment may be affected by the influence of the oculomotor nerve, which connects retinal ganglion cells to the pretectal area on the synaptic path. However, no significant differences in the extracted features were observed during several chromatic light pulses, though there were some differences between the experimental sessions, as shown in Figure 2. One of the possible reasons is the dependence on the accuracy of measurement, because feature extraction is based on point estimation. In particular, the

small pupils of senior citizens may influence the measurement of temporal change of pupil size. Another problem may be that the extracted features focused on the constriction phase of PLRs without allowing for the restoration phase which follows. The PLR difference between the left and right eyes should be measured carefully in considering the above points. During the main analysis, AD+MCI group was set to the specific target of prediction. As a diagnostic application, the level of cognitive impairment need to be able to be estimated using features of PLRs if it is to be would be effective. If it were possible, AD and MCI should be classified using weighted levels.

The factor scores for blue but not red light pulses were selected once more for use in a regression model, following a stepwise procedure. The dominance of blue light pulses for the prediction was confirmed in a previous study [11], [12]. The possible reason for this may be based on the first hypothesis, which could not be confirmed according to the above evaluation, however. Therefore, a more detailed analysis needs to be conducted.

In this study, other metrics of cognitive functional ability have been observed such as VSRAD (Voxel-based Specific Regional analysis system for Alzheimer's Disease), HDS-R (Hasegawa's Dementia Scale-Revised) and MoCA-J (Japanese version of Montreal Cognitive Assessment). The development of an alternative diagnostic procedure which considers the level of cognitive functioning together with these metrics will be a subject of our further study.

V. SUMMARY

A procedure for detecting the level of cognitive impairment of senior citizens is examined using pupil light reflex (PLR) for chromatic light pulses and a portable measuring equipment. Features of PLRs are compared between blue and red light pulses.

- 1) PLRs are compared between left and right eyes when light pulse provides either eye. In addition, the latent factor scores of PLR features are also extracted. There are no significant differences in features and factor scores between the left and right eyes, however.
- 2) Factor scores and participant's ages were analyzed in order to classify individuals into groups such as AD+MCI and NC. Participant's age information contributed to classification of the groups. During the regression analysis using a variable selection procedure, factor scores for blue light pulses were extracted. PLRs for blue light pulses are key to accurate prediction.

A more accurate prediction procedure and method of analysis of the response mechanisms will be subjects of our further study.

Abstract—The paper presents an AI-based model which depending on the input of a woman for a finite number of menstrual cycles helps in determining the possible ovulation dates as well as possibility of some health risks e.g., Premenstrual Syndrome, Luteal Phase Defect etc. The architecture of the model consists of three layers, namely analyzing and detecting the features from a single cycle, analyzing cycle level concepts based on the analyzed features, and analyzing the user’s health risks based on the cycle level concepts accumulated over a finitely many cycles.

I. INTRODUCTION

IN THE last decades, in parallel to the industrial and social progress, several healthcare paradigms have appeared in the scientific medical community. These paradigms are proposing changes in the way in which healthcare is deployed in our society. The image of Traditional Medicine, where physicians are artists that are isolated and taking decisions based only on their knowledge and experience, are changing to a new doctor always connected and with access to the last evidence existing in a globalized world. [1]

As examples of new paradigms of medical treatment author of [1] refers to Evidence-Based Medicine [2], Personalized Medicine [3] etc. The key issue in all of them is to create the protocols and guidelines for medical care by combining the knowledge from the existing literature of medicine, experience of the professionals, as well as the input parameters, habits, life style, and preferences of the individual patients. However, implantation of Evidence-Based medicine and personalized medicine together in a platform of healthcare have some challenges; one way it needs standardization of protocols at least with respect to the consensus of a group, and on the other hand, it needs to be case sensitive by considering treatments

Co-financed by the EU Smart Growth Operational Program 2014-2020 under the project "Developing innovative solutions in the domain of detection of frequent intimate and hormonal health disorders in women of procreative age based on artificial intelligence and machine learning - OvuFriend 2.0", POIR.01.01.01-00-0826/20.

out of the guidelines in the context of the patients who have different responses to the standard treatment.

The concern of this paper is related to what has been mentioned in the paradigmatic change in medical treatment, in particular in the context of infertility [4] which has become a civilization disease. According to statistics every fifth couple, trying to conceive (TTC), has a problem to achieve pregnancy in the first 12 months of efforts, and this tendency is increasing [5]. Moreover, the age of women trying for the first child statistically shifts towards 35, which increases a risk in pregnancy, including the birth of a child with defects.

This paper is in continuation of a series of papers [4], [6]–[8] that attempted to establish a platform, known as OvuFriend 1.0¹, for helping women in determining the possibility of conceiving and understanding the hidden risk of getting related health problems based on their data input. The platform of OvuFriend 1.0 is provided as a mobile app where an user can put the data related to her physical and mental states during a specific menstrual cycle, and the underlying algorithm of the app helps to get an analysis of the possibility of conceiving or not conceiving. As mentioned in [8], OvuFriend 1.0, the result of a R&D project finished in 2020, brought the company OvuFriend a big commercial success because of its underlying AI algorithm [7] dedicated to the prediction and confirmation of ovulation supporting the natural endeavour for family planning methods [9].

As a continuation to the above mentioned achievement the second R&D project, called as OvuFriend 2.0, is aimed at extending the previous platform by adding the ability of analyzing and assessing the risk of having certain health disorders based on the given input of a woman. Identifying the increased risk will give a chance to refer to the right doctor and heal the ailment faster. In particular, the project

¹www.ovufriend.pl

focuses on the analysis of whether a particular user has the possibility of having the risk of Premenstrual Syndrome (PMS²), Luteal Phase Defect (LPD³), benign growths like polyps, fibroids⁴ in the uterus, Polycystic Ovary Syndrome (PCOS⁵) or hypothyroidism⁶. PMS is a combination of symptoms that many women get about a week or two before their period. Severe PMS symptoms may be a sign of premenstrual dysphoric disorder (PMDD). On the other hand, LPD is a health condition that may play a role in infertility. Fibroids and polyps too may cause infertility or recurrent pregnancy loss. This paper focuses on the schemes for detecting PMS, LPD, and other anatomical changes like polyp and fibroids.

The general scheme in OvuFriend 2.0 for having an AI based app determining the possible days of ovulation as well as the possibility of the above mentioned health risks goes to a great extent in the line of Evidence-based Medicine and Personalized Medicine. In particular, the following features, that are included in the model proposed by OvuFriend 2.0, strengthen the support for a Personalized Medicine.

It has three hierarchical levels, known as *Detector level*, *Cycle level*, and *User level*.

- (i) At the *detector's level* the user can put information related to her mental and physical health over one complete cycle. A set of attributes are chosen by the medical experts. Based on the provided input by a particular user the values for those attributes are determined by a team of medical experts and they are tagged against the information details of the patient. So, while preprocessing the data, the model aggregates the perception of the user as well as the knowledge and experience of a team of experts.
- (ii) Based on the values of the attributes from a completed cycle, certain compound concepts such as *ovulation happened*, *days of ovulation*, *follicular phase interval*, *luteal phase interval*, *PMS score* etc are determined. These are called *cycle-level concepts* and for determining such concepts the system is fed with some relevant formulas involving the attributes prefixed at the detector level. These formulas are formulated by abstracting relationships among different attributes as described by a team of medical experts based on their knowledge from the literature and personal experiences. So, in the proposed model the mathematical formulations of the interrelationships among different attribute values are discovered by aggregating a team of medical experts' opinions.
- (iii) In the third level, the system aggregates the data related to

²<https://www.womenshealth.gov/menstrual-cycle/premenstrual-syndrome>

³<https://www.webmd.com/infertility-and-reproduction/guide/luteal-phase-defect>

⁴<https://progyny.com/education/female-infertility/understanding-uterine-fibroids-polyps/>

⁵In this condition the ovaries produce an abnormal amount of androgens, that are usually present in women in small amounts [10].

⁶Hypothyroidism means the thyroid gland does not produce enough thyroid hormones, which can lead to changes in the menstrual cycle. (<https://helloclue.com/articles/cycle-a-z/hypothyroidism-and-the-menstrual-cycle>)

the detector level as well as the cycle level concepts of a particular user for a finitely many cycles. This level focusing on the user's history is known as the *user's level*. The examples of the user level concepts are *risk of PMS*, *risk of LPD*, *risk of infertility* etc. Here, the system calculates the probabilistic ratio of the above mentioned cycle level concepts over the total number of cycles considered for a particular user. Moreover, the system is also fed with a threshold value for each such user level concepts and these threshold values are learned or even adjusted based on the opinions of the medical experts and the histories of already recorded and analysed cases. If the respective ratio for a particular user level concept is greater than the prefixed threshold for that concept the system notifies the user about the possibility of such health risk. So, at this level the threshold, chosen for a particular health risk, is set based on both experts' knowledge and current existing evidences of such cases.

The above discussed general scheme is presented in Fig. 1. The process of determining ovulation was described in the previous publication as part of the scope of the previous project (Ovufriend 1.0) [7].

Thus, as a whole the model endorses a three-layered hierarchical learning and reasoning mechanism based on the knowledge and experiences of a team of medical experts, perceptions of the users, and already recorded evidences to the system. Furthermore, the hierarchy of approximating fuzzy concepts is developed by using the quantifiers of fuzzy linguistic summaries in the process of inferring and making local decisions [11], [12]. From this angle, the model designed in OvuFriend 2.0 complies to a great extent to the need of personalized and evidence based medicine. On the other hand, the model also endorses some features of Interactive Granular Computing (IGrC) [13], [14], by incorporating perception of the current health situation of a woman based on the individual spatio-temporal windows of the physical world and actual physical interactions in the form of measuring attributes in the given space and time windows.

The content of the chapter is organized as follows. Section II presents the development made under OvuFriend 2.0; it is divided into several subsections describing the schemes for determining PMS, analysing the risk of LPD, and indicating anatomical changes related to polyp, fibroids etc. Further in section III, the reference set, used for experiments, is described, and the obtained results are explained in section IV. The paper ends with a concluding section indicating future directions of developing the model.

II. AI ALGORITHMS DETERMINING WOMEN HEALTHCARE RISKS

In this section we would present the framework of OvuFriend 2.0 by describing the AI algorithms and schemes for determining whether an user has the risks of certain health diseases. Specifically, we focus on the health diseases such as PMS, LPD, Fibroids and Polyps. All these schemes are discussed below in separate subsections.

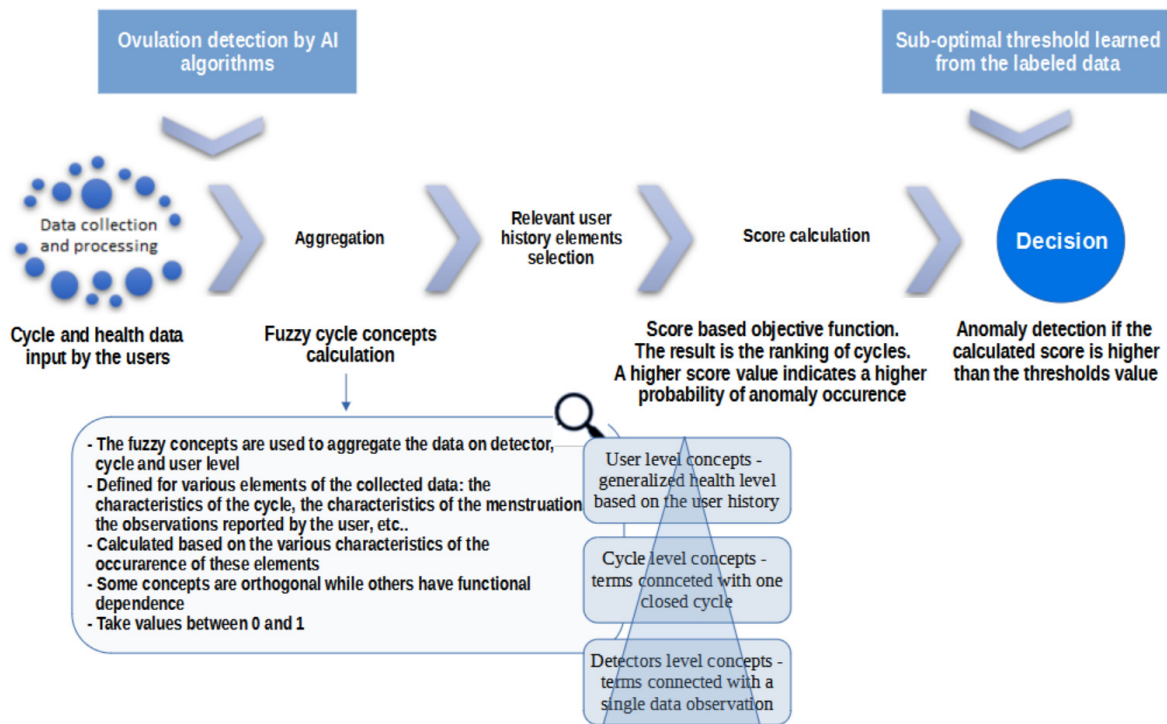

Fig. 1. General scheme for OvuFriend 2.0

A. Scheme to determine risk for PMS

The prerequisite to start this scheme is to collect data related to the physical and mental health of a woman before, during, and after a complete menstrual cycle. After the completion of a cycle, with the gathered data, analysis for the risk of PMS starts. Initially, the data is processed to investigate whether the ovulation has occurred and whether it is possible to determine the day of its occurrence. At this stage all concepts pertaining to the detector level are analysed and determined. For example, if ovulation has been determined, an attempt is made to indicate two intervals of equal length falling into the follicular phase and the luteal phase of the cycle respectively.

The length of the intervals depends on the length of menstruation, the day of ovulation, and the length of the total cycle. A complete cycle means number of days between starting of the menstruation in one month to the starting of the same in the next month. The beginning point of the first interval is chosen as the k -th day after the end of the monthly menstruation of the current month, where the value for k is prefixed in the algorithm. If the length of cycle is x and number of days of the current month menstruation is m , then each interval has to be of length $\frac{x-(k+m)}{2}$ and hence the beginning point and the end point of the first interval are respectively $m+k$ and $\frac{x+(k+m)}{2}$. Consequently, the beginning point of the second interval is $\frac{x+(k+m)}{2}$ and the the end point is x , the last day of the cycle.

Now, if the intervals are successfully determined, the coefficients of occurrence of the physical symptoms and mood

symptoms characteristics of PMS are calculated. The set of mood symptoms is presented in the Fig. 5. This set of symptoms and formulas for calculating the coefficients based on them are defined based on the interactions with a team of medical experts and aggregating their consensus of gathered knowledge and experiences about variations of different moods, feelings and physical impacts observed in women during the menstrual cycles. Each such symptom related to physical or mood aspects is counted and it is checked whether they occur in both the phases or only in the second phase. If there is at least one physical symptom or mood symptom that occurs in both phases, the algorithm reduces the weights in the respective formula calculating the mood feel coefficient or physical feel coefficient. Usually the physical or mood impacts during the second phase are only reflected in the occurrences of PMS, and that is why, while some symptoms are observed in both the phases, the possibility for PMS is decreased by reducing the weights. Finally, by aggregating the number of physical symptoms and the mood symptoms in a particular phase the coefficients are calculated separately for the physical symptoms and the mood symptoms according to the following formulas. Fig. 2 shows the algorithmic flowchart behind the described process for determining the cycle level concept *PMS score*, denoted as PMS_{score} .

Let us denote the two phases as P_1 and P_2 respectively.

$$P_iMoodFeelCoeff = \frac{(SumOfOccurrenceP_iMood)}{K_1 \times PhaseLength} \times \alpha + (1-\alpha) \tag{1}$$

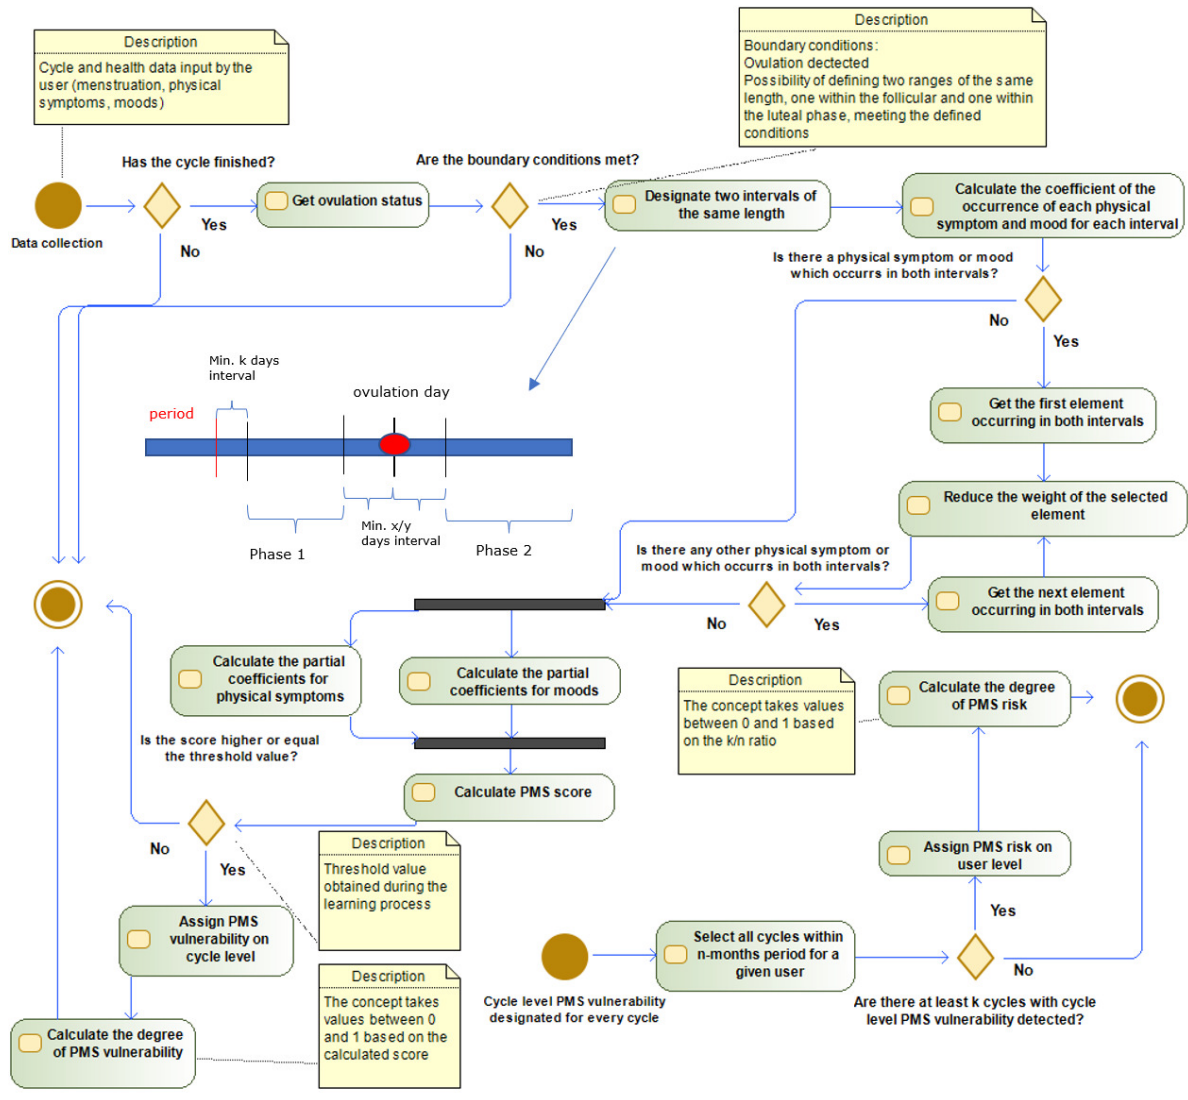

Fig. 2. Complete scheme for calculating PMS risk vulnerability (2 diagrams)

where $i = 1, 2$ and $\alpha \in (0, 1)$,

$$P_2PhysFeelCoeff = \frac{(SumOfOccurrenceP_2Phys)}{K_2 \times PhaseLength} \times \beta + (1-\beta) \quad (2)$$

where $\beta \in (0, 1)$.

The symbols $SumOfOccurrenceP_iMood$ and $SumOfOccurrenceP_iPhys$, used in the above equations, respectively indicate the number of mood and the number of physical symptoms occurred in a particular phase P_i . The symbols K_1 and K_2 represent respectively the total number of all moods and physical symptoms listed in the system. The factors α and β are parameters to control the significance of the given components in the final calculation of the result. The formulas are designed by a team of scientific experts based on the general description given by the medical experts regarding the effect on physical and mental health of women during a cycle as well as keeping into account the observed

patterns of cases available in the record. Based on the above coefficients the cycle-level concept, namely $PMS\ score$ is calculated in accordance to the following formula.

$$PMS_{score} = \frac{P_2MoodFeelCoeff}{P_1MoodFeelCoeff} + \frac{P_2PhysFeelCoeff}{w_1} \quad (3)$$

where w_1 is the weight chosen by a team of medical experts.

At the beginning, the algorithm also fixes a threshold for PMS score by taking into account already available records of patients. The threshold may vary over time based on the changes in the patients' record, and thus, in some sense the underlying algorithm keeps a possibility of learning the threshold for PMS score based on the current evidences. Based on this threshold whether an user has the PMS susceptibility or not is determined just by checking if the obtained score is greater or equal to the prefixed threshold. If during the current

cycle the algorithm determines PMS susceptibility for an user the algorithm passes to the next level where the degree of PMS risk is calculated for a particular user based on the observations of finitely many cycles.

The cycle level compliance data is used to investigate PMS risk at the user level. If over the selected period of n months there are at least k cycles with PMS susceptibility, then the PMS risk is assigned to the user, and its degree is calculated simply by the value of $\frac{k}{n}$ in the range $[0, 1]$. The flowchart, presented in the Figure 2, shows a complete overview of the algorithm specifying PMS susceptibility and PMS risk for a particular user.

B. Scheme to determine risk for LPD

The general prerequisite for running the algorithm to determine the risk of Luteal Phase Defect (LPD) [15] is common to all considered disorders but differs in details. At the beginning stage, preprocessing of the input data and analyzing the detector level concepts such as *whether ovulation has occurred* are performed, and then based on that the boundary conditions are calculated. These conditions are verified using fuzzy quantifiers of linguistic summaries operating on multivariate time series (e.g., the quantifier *exists*) [16]. The specific scheme of LPD differs from that of PMS in the formula that is fed to the algorithm in order to calculate the susceptibility of LPD and then consequently its degree of risk.

Similar like, PMS score, here the AI algorithm is fed with a formula for calculating LPD score, given by the following equation.

$$LPD_{score} = w_1 * LutParameters + w_2 * DecFer \quad (4)$$

Here both $LutParameters, DecFer \in [0, 1]$ and they respectively denote the values for *Luteal Phase Parameters* and *Decreased Fertility*. The *Luteal Phase Parameters* are determined based on the luteal phase length and various other factors related to the analysis of bleeding during the luteal phase. On the other hand, the *Decreased Fertility* concerns about the observation of the period of time in which the attempts are made for conceiving a child, the number of miscarriages (they are estimated on the basis of pregnancy tests performed and the length of the cycle compared to the typical lengths of the cycle and luteal phase for a given user), etc. Both the respective values for $LutParameters, DecFer$ are obtained based on the input data of the particular user; whereas w_1, w_2 are some weights that are chosen by the team of experts based on their collective knowledge regarding which of $LutParameters$ and $DecFer$ are significant to what extent.

Once in the cycle level the algorithm determines the possibility of LPD, it passes to the next level and as in the case of PMS risk the algorithm calculates the degree of risk for LPD; that is, if in the selected period of n months there are at least k cycles with LPD susceptibility, then the LPD risk is simply the value of $\frac{k}{n}$. For an overview of the whole scheme the readers are referred to Fig. 3.

C. Scheme for indicating anatomical changes like polyps and fibroids

As in the cases for PMS and LPD, here also the analysis for the presence of anatomical anomalies starts with the data of a complete cycle of an user. The primary analysis is manifested by focusing on the data related to inter-menstrual bleedings or spots. As usual, initially, the data is processed to investigate whether the ovulation has occurred and whether it is possible to designate a possible ovulation date. At the same time, the detector level concepts are also determined and then cycle label concepts are analyzed in the same fashion as mentioned in the cases of PMS and LPD.

If the required data is obtained during a complete cycle so that the algorithm becomes able to determine the occurrence of ovulation or an-ovulation, the process proceeds to the next stage of the examination of the disease. The cycle level concepts, which are associated to the symptoms characterizing the particular diseases like polyp or fibroids, are selected. On their basis, a score is calculated in accordance to the formula presented below.

$$Score = w_1 * DisMens + w_2 * DecFer + w_3 * PhysSymp \quad (5)$$

Here all the weights w_1, w_2, w_3 are chosen by the team of experts, and $DisMens$, the value for the parameters corresponding to disordered menstruation, $DecFer$, the value for decreased fertility, and $PhysSymp$, the values corresponding to physical symptoms related to such diseases, are obtained from the input data of a particular user. All these values are scaled in the interval $[0, 1]$ based on the information related to inter-menstrual bleeding, long-lasting menstruation, intensity of menstruation, miscarriage, long trying time for conceiving, pelvis pain, polyuria etc.

As before, in this context also if a cycle's score is greater than or equal to the cut-off value, which is set through some learning process, the cycle is assigned anatomical susceptibility at that particular cycle level. Then its grade is calculated in the range of $[0, 1]$ depending on out of n cycles in how many cycles the algorithm agrees with the susceptibility of anatomical changes occurred in the case of a particular user; in other words, it is simply $\frac{k}{n}$ if in k such cycles susceptibility of anatomical changes is detected.

The full scheme for determining the possibility of such diseases as polyp, fibroids, can be visualized in Fig. 4.

III. REFERENCE SET BASED ON EXPERTS KNOWLEDGE

In order to estimate the effectiveness of the algorithms detecting anomalies, a reference set has been created consisting of cycles described by the experts. For each cycle the experts are provided the information e.g., the chance of an anomaly occurrence expressed by a value in the range $[0, 1]$ and a comment explaining the assessment made. They are also provided with a cycle visualization containing the basic data needed to determine the ovulation, as well as the information of already predicted ovulation (product of the Ovufriend 1.0 project). In addition, the visualization contains

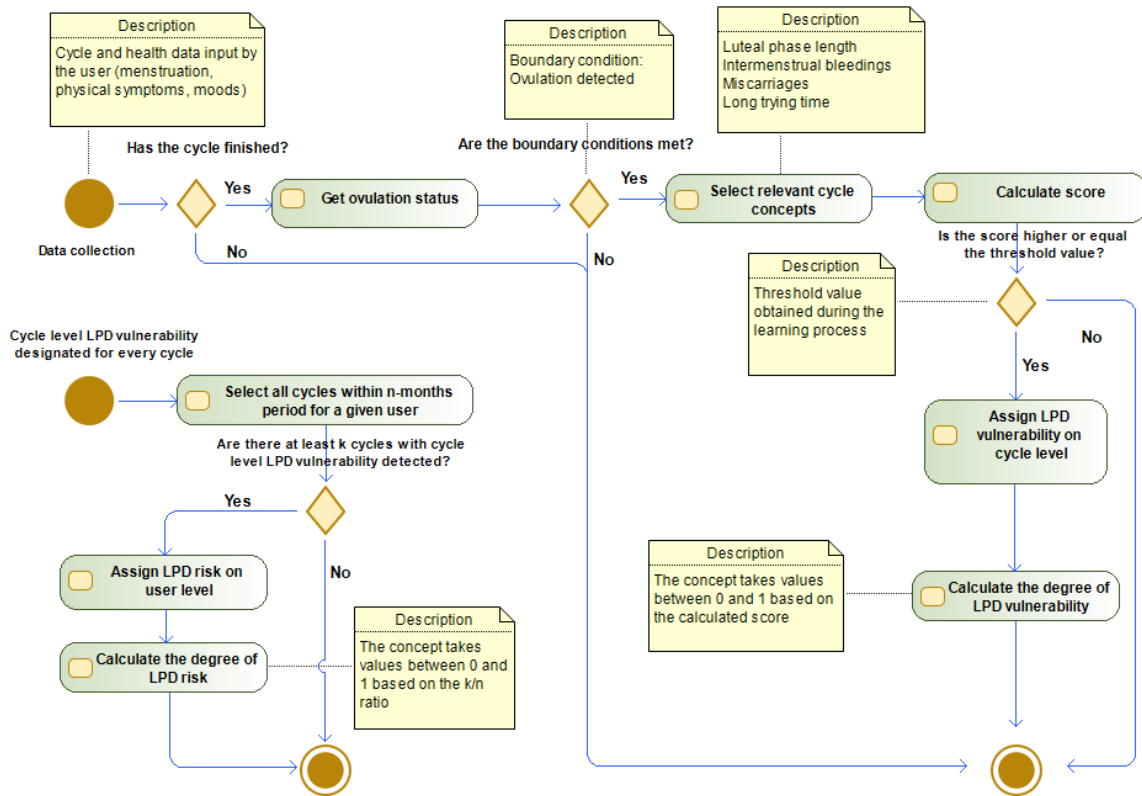

Fig. 3. Complete scheme for LPD risk vulnerability (2 diagrams)

a series of low level data (e.g., group of symptoms) broken down by observation days. As a whole it can be considered as a multidimensional time series indexed with the days of the ovulatory cycle. An example of a visualization labelling form for *PMS* can be found in Fig. 5 [17], and the same for luteal phase deficiency (LPD) can be found in Fig. 6. The form for tagging polyps and fibroids are similar to the one for *LPD*. It is extended with a few additional attributes and it is shown in Fig. 6. The reference set consists of 900 menstrual cycles, and in the category of "Anatomical or hormonal abnormalities with inter-menstrual spots" each cycle is tagged for both the presence of NFL and anatomical changes. The number of items in the set has grown steadily as successive sets of cycles are submitted for tagging. Subsequent sets of cycles are drawn

TABLE I
THE SAMPLE SIZE BY CLASS AND TYPE OF ANOMALY. PC - POSITIVE CLASS, NC - NEGATIVE CLASS

Anomaly	#	PC	% PC	NC	% NC
PMS	300	164	55%	136	45%
LPD	300	147	49%	153	51%
Polyps and Fibroids	300	160	53%	140	47%

on the basis of the given criteria, selected in such a way that it helps to obtain a similar size in the positive class (minimum score 0.5) and the negative class (score below 0.5). The size

of each class, broken down by a group and the types of anomaly, is presented in Table I. In each of the three groups of anomalies, the sample is well-balanced, where the share of the positive class ranges from 49% to 55% of the sample.

IV. EXPERIMENTS AND RESULTS

In order to evaluate the effectiveness of the prototypes of the algorithms, four experiments have been conducted for each of the three disorders. Overall the methodology looks as follows. Each of the experiments involves a different number of repetitions such as 1000, 500, 100, and 10, respectively for ReSample evaluation [18]. Each time 33% of cases from the reference set are drawn. Training is performed on the selected subset, and testing is performed on the remaining 67%. On each iteration, the intersection of both sets remains empty. The values of the cut-off thresholds of rankings for all described disorders are learned in each iteration from training set that consists of 100 cycles (33% of 300 tagged cycles). The test procedure that returned the values for contingency table are processed on 200 cycles each time. Single iteration results are stored in the contingency table. Finally, all TP (True Positive), TN (True Negative), FP (False Positive) and FN (False Negative) are summed and then measures of effectiveness are calculated. The obtained results for 1000 repetitions are presented in the Table II.

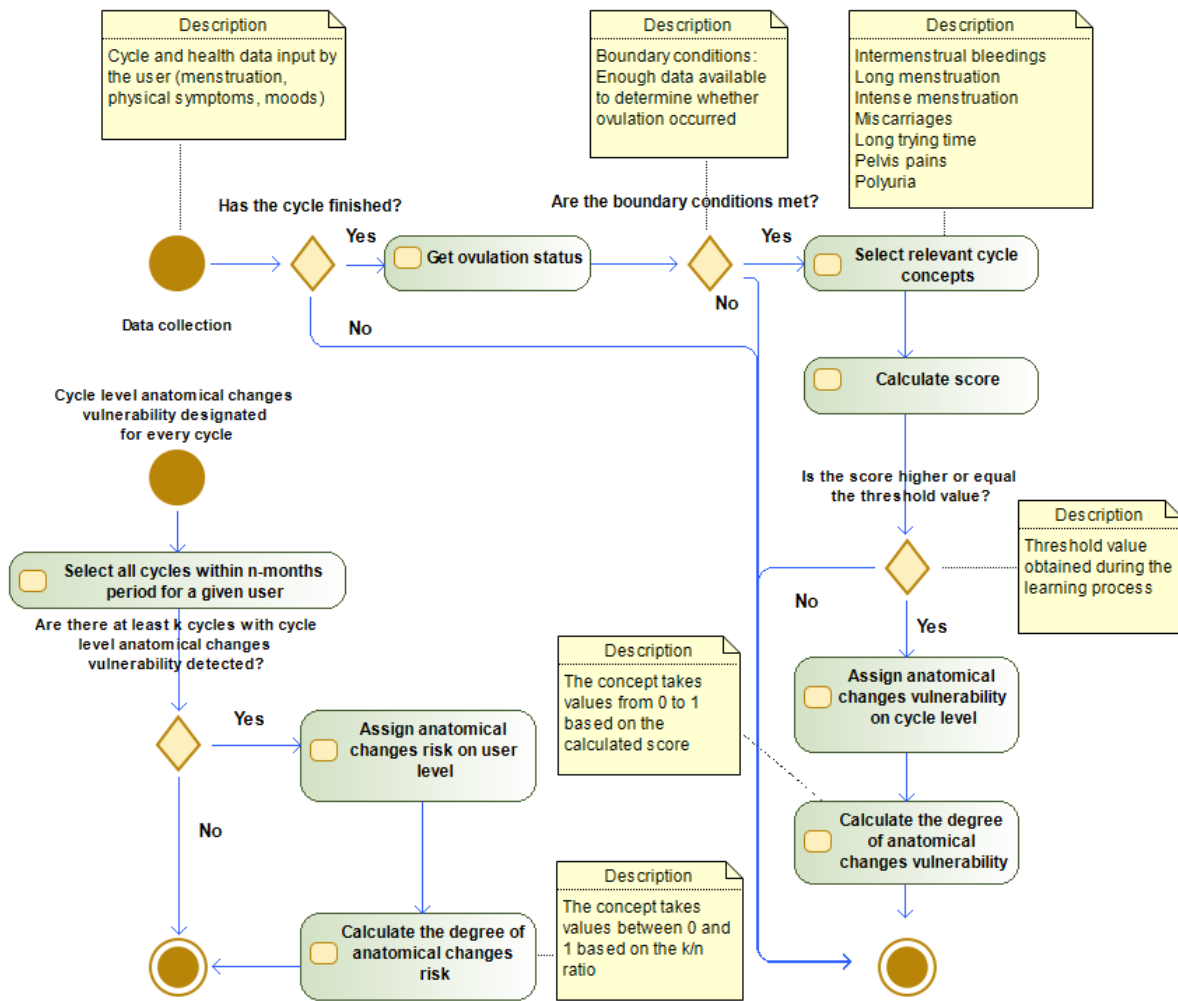

Fig. 4. Complete scheme for determining risk vulnerability of polyps and fibroids (2 diagrams)

The case for TP is assigned when the cycle is tagged with at least 0.5 by the medical experts and the algorithm has calculated the score that positioning the cycle in the positive set of a given disease; on the other hand, the case for FP is assigned when the experts have given mark below 0.5 but the algorithm has classified the case into positive class. The case for TN is obtained when the experts have assigned less than 0.5 and the algorithm has calculated score under the learned threshold. Finally the cases for FN is indicated when the algorithm has calculated the score value under the learned threshold but from the experts it receives a mark greater or equal 0.5. The evaluation results for 500 repetitions are presented in the Table III.

The obtained results for 100 and 10 repetitions are presented in the Table IV and Table V respectively.

In the project, the team of medical experts consists of three

highly qualified medical scientists, and the decisions regarding tagging cycles have been made based on discussion within the team. As the values, selected after tagging, are already agreed with the consensus of the whole team they do not require additional processing in order to be used for evaluation.

The presented results of the experiments concern the first stage of the project, in which the parameters of the algorithms are learned from the tagging of medical experts. The labels were made on the data constituting the subjective observations of the system users and the measurements of the physical parameters (e.g., BBT, cervical mucus, cervix position, etc.) and the subjective labels of the team of experts. In the next stage, the data and the final evaluation will be extended on the real test results, that are used by the doctors to make the diagnosis. In this way, the algorithm will be tested against the real hardcore medical data.

V. CONCLUSION

AI and machine learning based techniques are nowadays prevalent in every sphere of life and the healthcare industry is also not out of that influence of automated decision support. In the Introduction, the terms like personalized medicine and evidence based medicine are presented in the context of the need for a new paradigm of medical treatment. It is expected that in the new context, treating a patient should not be an isolated process conducted by an individual doctor based on his/her knowledge and experience about a particular field of medicine. Moreover, there should be a standardization in the process of treating a particular disease by different doctors.

In this regard, the attempt of OvuFriend 2.0 has been to develop an AI-based model for women health care where based on the input of a particular user the model can suggest the possibility of certain health risks. The architecture of the model is developed in such a way that the system has an

interface of user in order to gather input data as well as an interface of a team of medical experts who based on a consensus creates a protocol for standardizing lowest level concepts, known as detector level concepts, and determining their values. Based on a complete cycle of data and values selected for detector level concepts the next level concepts, known as cycle level concepts, are analyzed and evaluated. Finally, at the highest level, known as user level, the degree of risk for certain cycle level concepts are computed by considering the values obtained for those concepts for a finitely many cycles.

Firstly, the user interface of the model keeps it sensitive to the user's perceptions and thus incorporates the aim of personalized medicine. Secondly, the interface for a team of medical experts keeps the possibility open for discussion, standardization, and revision of the defining criterion for medical concepts, and at the same time the process of treatment

does not remain in the hand of one individual. Thirdly, the underlying AI algorithm has a updating mechanism which with time changes certain thresholds for analyzing health risks based on the already available records of the patients. Thus, the model incorporates a learning mechanism as well as supports the idea of evidence based medicine.

In the present version of the model, there are some aspects where lie the possibility of extension and improvement. Let us list them as immediate directions for future research.

- One of them is to make the two above mentioned interfaces interactive by introducing a language of dialogue [19], [20] so that the underlying treatment protocol can be updated or revised based on even a particular user's input. In the present model, certain weights for a particular health disease does not depend on the input of a

particular user. Incorporating this direction may make the model more dynamic in learning the optimized care for a particular user.

- In the present context, the formulas determining the values for the cycle level concepts and the user level concepts are fixed. In this context also there is a possibility of using machine learning techniques in order to learn a set of possible rules or formulas for diagnosing certain health risks based on the already existing evidences and making the process of diagnosing more flexible and evidence driven.

The current state of the algorithms shows a very good quality of the results achieved by the algorithms, while the real test will be their modernization and incorporation of data from medical examinations into operation. It will be a

17th Conference on Information Systems Management

THIS event constitutes a forum for the exchange of ideas for practitioners and theorists working in the broad area of information systems management in organizations. The conference invites papers coming from three complimentary directions: management of information systems in an organization, uses of information systems to empower managers, and information systems for sustainable development. The conference is interested in all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in organizations. Moreover, the papers that discuss the uses of information systems and information technology to automate or otherwise facilitate the management function are specifically welcome. Papers about the influence of information systems on sustainability are also expected.

TOPICS

- Management of Information Systems in an Organization:
 - Modern IT project management methods
 - User-oriented project management methods
 - Business Process Management in project management
 - Managing global systems
 - Influence of Enterprise Architecture on management
 - Effectiveness of information systems
 - Efficiency of information systems
 - Security of information systems
 - Privacy consideration of information systems
 - Mobile digital platforms for information systems management
 - Cloud computing for information systems management
- Uses of Information Systems to Empower Managers
 - Achieving alignment of business and information technology
 - Assessing business value of information systems
 - Risk factors in information systems projects
 - IT governance
 - Sourcing, selecting and delivering information systems
 - Planning and organizing information systems
 - Staffing information systems
 - Coordinating information systems
 - Controlling and monitoring information systems
 - Formation of business policies for information systems
- Portfolio management,
- CIO and information systems management roles
- Information Systems for Sustainability
 - Sustainable business models, financial sustainability, sustainable marketing
 - Qualitative and quantitative approaches to digital sustainability
 - Decision support methods for sustainable management

Abstract— This study is devoted to process optimization for commercial sharing of e-vehicles. The model describes a system with one-way trips and relocations of e-vehicles between sectors by service personnel according to a dynamically compiled list of service trips. The model includes an algorithm for increasing the expected income, depending on the dynamically selected e-vehicle transfer. The implementation of the MIP (Mixed-Integer Programming) type algorithm pays particular attention to its performance, as optimization should be performed dynamically within few hours' intervals. The developed model has been validated for its practical application in Riga, Latvia.
Keywords- Sharing of e-Vehicles, One-way Trips and Relocations, Mixed-Integer Programming.

I. INTRODUCTION

SUSTAINABLE development requirements in the EU provide guidelines for improving the transport system, first and foremost by reducing CO₂ emissions. One of the possible solutions to achieve the goal is to switch to the use of electric vehicles (e-vehicle). According to [1], e-vehicle sharing systems benefit both users and the society in general. The two main benefits for individual users include reduced personal transport costs and improved mobility. Research has shown that e-vehicle sharing reduces the average number of kilometers travelled by a vehicle and is likely to reduce traffic congestions [2] and CO₂ emissions [3].

Vehicle rental approaches tend to be classified in two large groups [4]: (1) traditional rental—when customers receive and transfer vehicles after use at specially arranged points of leasing firms and rental will take one or more days—and (2) vehicle sharing—when vehicles can be taken for use anywhere, even for a very short period of time, and may be left anywhere at the end of the trip. Vehicle sharing has quickly gained popularity. The growth rate of the service has increased during the COVID-19 pandemic, - as it allows urban populations to avoid the need to travel to their destination via public transport.

The main challenge facing e-vehicle sharing rental systems is to achieve the optimal (the most profitable) deployment of vehicles in a city. This requires relocating e-vehicles quickly to the most profitable sectors of the city which in

turn causes additional costs. The studies [5] show that technical relocation of vehicles take approximately 14% of the total distance carried out by the vehicles. Optimization algorithms are used to give recommendations to system holders on the need to relocate vehicles to achieve a “more cost-effective” deployment and, hence, higher returns.

This study offers an e-vehicle sharing model that considers the dynamics of relocating e-vehicles in a city. The proposed model is designed to fully meet the requirements of real systems and differs from all known solutions.

The paper is structured as follows: a theoretical background on vehicle sharing models (Section 2), an original vehicle sharing model proposed by the authors (Section 3), a short discussion on the research findings (Section 4), and conclusions (Section 5).

II. RELATED RESEARCH

A. Review of Sharing Models

Although scientific literature on e-vehicle sharing is broad, the authors of other works as well as the authors of this study conclude that the scientific literature currently available does not offer a model that, along with parameters such as the number, size and location of charging stations, the size of the car fleet, would also consider the dynamics of vehicle relocations and system balancing when reserving of e-vehicles is used. The existing models [6] and [7] either use station locations without considering vehicle relocations [7] or use station locations, assuming only a limited subset of stations corresponding to the current demand should be serviced [6]. If vehicle relocations are modeled vehicle movements and associated costs are only considered at the end of the operating period (usually daily) and, therefore, affect the size of the available fleet [1].

According to [8] which studies an example of a city in Southern California, even 3–6 vehicles can be sufficient to provide 100 trips daily and achieve optimal customer waiting times. Meanwhile, about 18–24 vehicles would be enough to reduce the number of vehicle relocations. The authors conclude that, in addition to the number of vehicles (per trip), the relocation algorithm and the charging approach used are key factors for the successful use of such a system.

Boyaci [1] highlights the importance of the service level, which, in his view, influences the access of potential users to

The research leading to these results has received funding from the research project "Competence Centre of Information and Communication Technologies" of EU Structural funds, contract No. 1.2.1.1/18/A/003 signed between IT Competence Centre and Central Finance and Contracting Agency, Research No. 1.15 "Use of artificial intelligence for optimization of e-mobility solutions".

e-vehicle stations, i.e. (1) the distance between the location of the e-vehicle and the destination, respectively, from the point of start and arrival of the e-vehicle, and (2) the availability of e-vehicles at stations. On the other hand, the number and size of the stations and the size and availability of the e-vehicle fleet at “real time” at the “particular station” are affected by the costs of establishing and operating the e-vehicle sharing system.

According to the classification of [4], the e-vehicle sharing system analyzed in this paper is:

- (1) a commercial solution as the aim is to generate maximum income,
- (2) station-based – e-vehicles are deployed in any available parking place and the city is divided into areas - stations,
- (3) one-directional as the customer is allowed to not return the e-vehicle to the start point of the trip,
- (4) with relocations as the service staff moves e-vehicles to potentially more favourable places in the city,
- (5) with dynamic booked trips as an e-vehicle may be rented by the customer anywhere, at any time without prior e-vehicle reservation.

Increased profits for commercial e-vehicle sharing can be achieved by supplying vehicles to the places in a city where customers will need them with the highest probability as well as increasing the relocation efficiency. The e-vehicle sharing models proposed by other authors differ significantly from those proposed in this work.

B. Optimization Algorithms

An optimization algorithm that was matching to the task of this study is the Mixed-Integer Programming (MIP) model, which maximizes profits on the assumption that next trips, the availability of fixed stations and availability of relocation staff are known.

The model described in [9] has a deficiency from model of this study. It is designed on the assumption that future trips are known, e.g. customers order the vehicles indicating starting and ending stations and the duration of the trip. Originally, the authors examined the possibility of predicting customer trips based on the data history of many previous trips. However, the experiments failed to obtain a sufficiently reliable forecast for future trips, so this idea was rejected. On the other hand, if the trips forecast is not sufficiently precise, the model defined by [9] does not provide a credible relocation plan, i.e., the vehicles will possibly be moved to places where customers will not need them.

Consequently, the [9] algorithm is not used directly in the study, and the authors have developed an original algorithm.

III. VEHICLE DEPLOYMENT MODEL

The model consists of several successive steps:

- dividing the city into sectors and estimating the costs of moving e-vehicles between sectors,
- identification of repeated trips,

- determining the value of an e-vehicle in a specific sector and time,
- forecasting of booked trips,
- an estimate of the total profitability of the e-vehicle at a given moment before relocation.
- compiling a list of profitable relocations,
- optimization of the relocation execution plan,
- estimation of the total profitability of the e-vehicle after relocation,
- creating of relocations plans.

In this chapter, the model will be discussed informal fleetly, leaving a description of the formalized model to other paper.

A. Station-based Algorithm

According to [9], the continuous division of the transport sharing service area into sectors (other studies referred to as stations) does not significantly affect optimization. Cluster analyzing the history of trips and knowing the specific characteristics of the area, Riga city was divided into sectors as can be seen in Fig. 1.

Fig. 1. Division of Riga, Latvia in sectors (using OpenStreetMap: www.openstreetmap.org/copyright)

However, division of territory into sectors must be carried out under several conditions. First, the sectors need to be relatively small to place a vehicle in the area for the client to reach it within “reasonable” time (the accumulated real data set shows that customers are ready to spend up to five minutes for reaching a vehicle). Secondly, the driving time between two adjacent sectors must be comparable. Thirdly, within one sector, customers' behavior must be comparable, i.e., customers make trips from the respective sector uniformly frequently.

B. Forecasting User Trips

While sharing e-vehicle users in Riga city do not make all requests a day in advance, certain user trips can be scheduled with high possibility, using historical trip data. Using cluster analysis, “routine arcs” can be found: regular trips

that consistently start and end the day from day to day in the same sectors, at approximately the same time.

C. Estimation of Sectors' Income

The purpose of relocation is to place e-vehicle in areas where they are in demand and profits are expected accordingly. In sharing systems with booking in advance, a full estimate of demand and expected profit is known prior to the planning of relocation operations. But in our case, requests are made in real time. Therefore, to take tactical decisions on relocation operations, it is necessary to be able to carry out an alternative assessment to which stations to move the e-vehicles.

One potential solution that this study looks at is the modelling of expected income using historical data. The model of expected incomes describes the average expected benefits over a specific time period from a e-vehicle parked in a particular sector that can be rented by users. The expected income most probably will vary from station to station, as well as it will change over a day: In "peak hours" the expected income will be higher, in "quiet hours" less.

Modelling the expected incomes may not only provide tactical support in the planning of resettlement operations, but also give general impression on the behavior of sharing e-vehicle users. Comparing the expected income at different times, different weekdays, and different stations, it will be possible to draw conclusions that can also help you to make strategic, long-term decisions, such as handling different sectors or deploying charging stations.

D. Estimation of Expected Income Using Historical Data

From the history of e-vehicle rentals in different sectors, you can do an assessment of expected income in each sector for the next day. This data is taken from historical information about e-vehicle rentals.

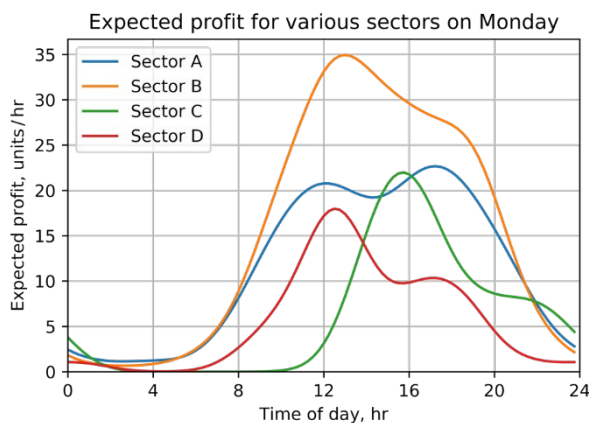

Fig. 2. Expected income for the sectors on Monday

Estimated forecasted incomes on Monday for the four sectors are summarized in Fig. 2. Data shows that there are significant differences between revenues for different sectors, as well as expected income changes by day. Moreover, some of the sectors can be very profitable only in specific time intervals and unprofitable in all others. For example, in the morning it is more convenient to move a car to sector D than

to sector C, but after 1 PM a car in Sector C will be more profitable than a car parked in Sector D.

E. Weekly variations

There is a difference in estimated income for a particular sector between weekdays. From simple assumptions about the behavior of e-vehicle sharing users, there can be expected that demand for shared cars, so expected income, could vary significantly between business days and holidays.

Indeed, such a phenomenon can be observed in the estimated expected income for the sector A, as shown in Fig. 3. Although there is a variation in the expected income between business days, there is a very significant difference in the expected income on holiday.

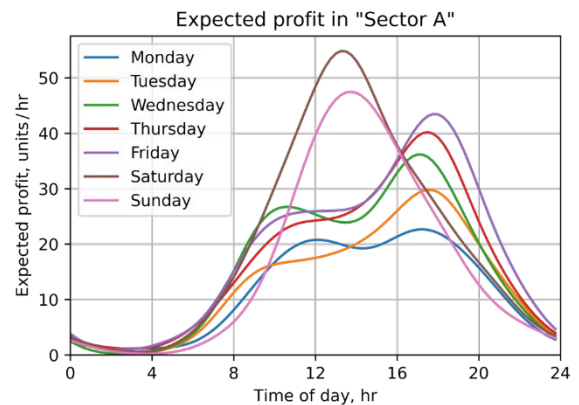

Fig. 3. Expected income in "Sector A" in different days of week

As there is a significant but hard-to-predict difference between weekdays, it is necessary to calculate the expected earnings for each day of the week separately.

F. Variation in Historical Data

A related subject matter related to the modelling of forecasted income from historical data is how old historical data is effectively used. Since the number of shared cars is limited, a full history may be considered for usage to reduce the "noise" in the data gathered. However, as a counter argument for the use of historical data, there can be mentioned that user demand for shared cars is not static but is changing in the result of seasonal or other long-term processes. It is also concluded that, to keep the calculation of the intended income used up to date, the expected in-come should be recalculated on a regular basis.

G. Limitations of the Proposed Method

While the method of estimating the expected income provides a valuable numerical estimate of the cost of parking sharing e-vehicle in specific sectors, effective use of the described method must be aware of its shortcomings and limitations. For example, the method may provide inaccurate results if too many e-vehicles are placed in a particular sector, or the area of the sector is too small. Similarly, it is necessary to have a reliable history of bookings to estimate the expected income, and it may not be available when starting a sharing e-vehicle operation in a new region.

The following chapters describe two main shortcomings and limitations for estimating of the expected income.

H. Linearity Assumption

In the definition and calculation process described above, there is an assumption that the estimated income for a particular e-vehicle parked in a sector does not depend on the total number of parked vehicles in that sector. At a large number of e-vehicle parked in the same sector, you can see that this assumption is flawed; if the number of e-vehicle parked in the sector significantly exceeds the demand for shared e-vehicle in this sector, the average per e-vehicle income will be low.

Information collected from historical data (see Fig. 4) allows you to analyze the veracity of the statement described. The graph shows the average number of rented cars in the sector F over two hours, depending on the number of parked cars in this sector.

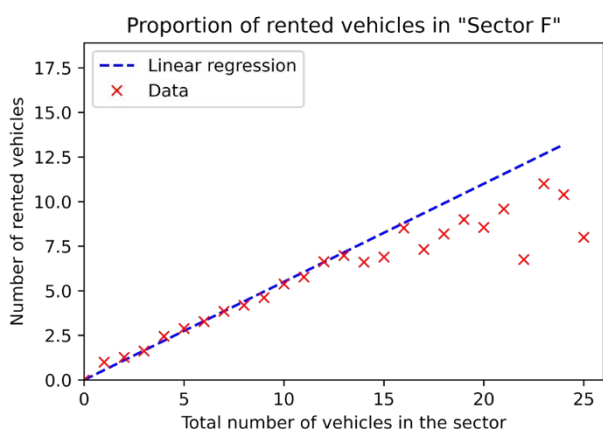

Fig. 4. Proportion of rented cars in "Sector F"

The picture shows that the percentage of cars rented in this sector is almost constant at a small number of cars (55% of the cars located in the sector will be rented within two hours). Hence, the possibility of renting a particular car does not depend on the total number of cars in the sector at low number of available cars. And therefore, the expected per car income does not depend on the total number of parked cars in the sector.

The breakpoint in the sector F, when the described revenue model is ineffective, is around 14 cars. However, the typical number of cars in the sector F is lower, so the described model for calculating the expected income is an acceptable approximation. Similar data analysis and finding a breakpoint can be used to find a flexible demand limit for each sector.

I. Usage of Historical Data

The described method for calculating of expected income is based on the existence of historical data. Unlike demographic-based models, the described model cannot be used when starting a sharing e-vehicle rental system in a new city or expanding operations into new sectors.

Reliance on the historical data prevents a model from rapid responding to changes in demand for shared e-vehicle,

or to price policies. The described expected income estimation algorithm will work most accurately if variations in the shared e-vehicle system are minimal.

Small sectors may lack data to adequately calculate expected income due to data noise. This phenomenon limits the lower size of sectors, thereby affecting the constructing of sectors.

J. Car-sharing Income Optimization by E-vehicle Relocation

Increasing income is possible by moving cars from low-income sectors to higher-potential sectors, but of course considering the costs of relocation. The location of e-vehicles at a given time determines the total value of all e-vehicles. This can be increased by moving the e-vehicle between sectors and finding the optimal location with the highest possible value.

The work of optimization is primarily inspired by the Mixed-Integer Programming (MIP) model proposed by C. Gambella, E. Malaguti, F. Masini, and D. Vigo for optimizing relocation operations in electric car-sharing [9]. The parameters discussed in the previous sections are passed to the optimization algorithm and it finds a new e-vehicle location by sectors that give the highest potential revenue, as well as a relocation plan to obtain this location.

In the case of many sectors and e-vehicles, the work of the algorithm may require significant computational resources/time. Therefore, it was assumed that the optimization algorithm was given a time limit during which the best of the considered variants is found, without guaranteeing to find the optimal solution.

As a result of the optimization algorithm execution, three reports are generated:

- a plan for relocation of e-vehicles between sectors,
- work plan for e-vehicle relocators,
- potential income change report.

IV. RESEARCH FINDINGS

The proposed solution uses historical data of shared e-vehicles — the intensity of trips across different sectors of the city, depending on season, day of week and clock time. This data can be obtained by recording events that the service provider information system can manage. The division of the city into sectors is also carried out using historical data, which in turn affects the permissible set of relocations and their costs. The model described is therefore applicable after the introduction of a shared transport service and the accumulation of historical data.

It should be acknowledged that e-vehicle rental services can be organized in many ways. The company offering services in Riga city, Latvia, provides a dynamic optimization of e-vehicle relocation approach. Obviously, the service capabilities determine the complexity of the model and its effectiveness. The rapid development of IoT will offer ever-new service capabilities that will require ever-new solutions.

This calls into question the need for a single, universal solution.

To estimate the potential income growth that can be achieved by moving e-vehicles between sectors, the relocation for a different number of e-vehicles and sectors was simulated (see Table 1). In the result of the simulation, there was concluded that e-vehicle relocation increases the total income by more than 15%.

Table 1. Potential income increase (results of simulation)

Number of vehicles	Number of relocators	Number of sectors	Number of relocation	Potential income	
				Before	After
12	2	30	9	82.44	167.03
40	5	30	9	502.20	571.85
56	7	30	23	552.72	583.50
60	5	57	22	781.56	952.10

The potential income calculated in the table is an estimate of all cars in the sectors combined. The potential income is, of course, indicative and cannot be determined as an absolute value but its changes show the relative effect of relocations on the potential income.

V. CONCLUSIONS

The study offers a model for the use of shared e-vehicles, described as a commercial system with one-way trips and dynamic relocations of e-vehicles between city sectors, without pre-booked trips. The model consists of the following set of parameters: breakdown of the city in sectors, maximal number of available cars, number of cars per sector, set of possible relocations, parameters characterizing e-vehicle relocations, number of available relocators.

The parameters used in the model allow to describe the operation of a real system:

- The strategic level determines the number of e-vehicle available for sharing and the maximum number of e-vehicle to be placed in each urban sector.
- At the tactical level, historical shared vehicle data allows calculating the profitability of e-vehicle depending on the season, day of the week, usage time and city sector in which e-vehicle is placed.
- At the operational level, the total daily income is estimated as a sum of the average expected income over a specific period of time from all e-vehicle placed in a specific sector that can be rented by users.

The study provides an algorithm that optimizes expected income based on the set of selected relocations using the values of the above parameters. When implementing an algorithm, special attention should be paid to its performance as

optimization must be performed dynamically, within few hours' interval.

The vehicle sharing model proposed in the study is only one step towards an optimal solution. The model only partly describes real-life processes, such as e-vehicle battery capacity and technical parameters and prices. Similarly, the model does not consider cases where it is beneficial for several customers to use the same e-vehicle when a route is agreed. In addition, the work does not analyze the risks posed by concurrent usage of shared e-vehicle. Such a study has been conducted for e-commerce [10] and e-scooters [11]. These issues may be the content of further studies.

Towards Temporal Multi-Criteria Assessment of Sustainable RES Exploitation in European Countries

Aleksandra Bączkiewicz

Institute of Management, University of Szczecin
ul. Cukrowa 8, 71-004 Szczecin, Poland
Email: aleksandra.baczkiewicz@phd.usz.edu.pl

Abstract—This paper aims to introduce a novel Temporal SWARA-SPOTIS method for multi-criteria temporal assessment. The proposed method combines the Step-Wise Weights Assessment Ratio Analysis (SWARA) method for determining the significance values of particular periods and the Stable Preference Ordering Towards Ideal Solution (SPOTIS) method for the multi-criteria assessment. The developed method was applied for assessing the sustainable use of renewable energy sources (RES) by European countries in various branches of the economy and industry, considering multiple criteria and the dynamics of results change over time. The application of the proposed method is presented in an illustrative example covering the assessment of 30 selected European countries over the five years 2015-2019. The presented approach proved its usefulness in the problem investigated and provided reliable results indicating that the best-scored countries regarding sustainable use of RES are dominantly the Nordic countries.

I. INTRODUCTION

RENEWABLE energy sources (RES) play an essential role in the sustainable economy. The increase in RES participation in various domains contributes to limiting greenhouse gas and pollutants emissions and reducing countries' dependence on imports of non-renewable energy sources. The efforts to increase the RES share cover different dimensions. Among them is electricity generation from RES such as Hydro, Wind, Solar, Biomass, Geothermal, and Wave (tidal). Besides, energy policies promoting RES usage include increasing the RES share in energy consumption in transportation and heating and cooling sectors. Thus, appropriate measurement tools are necessary to assess the achievement of planned goals and evaluate regions [1].

Reliable assessment of sustainable RES use requires simultaneous consideration of dimensions such as economic, environmental, and social [1]. The assessment methodology for multi-criteria RES problems should consider different aspects, such as various types of RES, several attributes of the location for RES-generating infrastructures, and different sectors in which RES are produced and consumed [2]. Multi-criteria decision analysis methods (MCDA) fulfill these requirements [3]. Many research papers are focused on evaluating RES problems. Multi-criteria assessment of countries in terms of preparation for the sustainable energy transition was performed using Preference Ranking Organization Method for Enrichment of Evaluation (PROMETHEE) II and Analytical Hierarchy Process (AHP) [1]. A comparative analysis

employing Characteristic Objects Method (COMET), Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS), Vise Kriterijumska Optimizacija I Kompromisno Resenje (VIKOR), and PROMETHEE II, was conducted to assess the European countries in terms of energy consumption with particular attention to RES share [3]. MCDA methods were applied to evaluate infrastructure and technologies for generating electricity from RES. COMET and Stable Preference Ordering Towards Ideal Solution (SPOTIS) were used to evaluate solar panel alternatives regarding selected technical attributes of assessed options [4].

The literature review confirms the usefulness of MCDA methods in the multi-dimensional evaluation of RES for a single moment. However, a clear research gap is visible, including the lack of simultaneous respect for the performance variability over the time analyzed. Several MCDA attempts of temporal approach can be found in the literature, like the TOPSIS-based approach considering the variability of results over time. This approach considers evaluating alternatives using TOPSIS individually for each analyzed year. Results are re-evaluated using TOPSIS and weights assigned to years [5]. The authors of another research adapted the PROMETHEE II method to perform a multi-criteria evaluation of temporal sustainable forest management [6]. This approach aggregates the results of comparing pairs of criteria in each period. The rank relations are converted to preference relations for each pair of alternatives and each period in the next stage. However, the procedure described is complex, making applying to complex hierarchical models containing multiple criteria challenging. This paper introduces the Temporal SWARA-SPOTIS method developed for multi-criteria temporal evaluation. The application of the proposed method is illustrated in the example of a temporal multi-criteria assessment of selected European countries in terms of RES use in various branches of the economy and industry.

The rest of the paper is organized as follows. Section II gives the background and formulas for SWARA-SPOTIS. The following section III introduces the practical problem of sustainability assessment focused on RES exploitation by European countries is introduced. The next section IV presents and discusses research results. Finally, in the last section V conclusions are provided, and future work directions are drawn.

II. METHODOLOGY

A. The Temporal SWARA-SPOTIS method

Step 1. Create the temporal decision matrix $S = [s_{ip}]_{m \times t}$ including in columns the utility function values (weighted normalized average distance values) calculated by SPOTIS for each i th alternative $i = 1, 2, \dots, m$ in p th periods analyzed, where $p = 1, 2, \dots, t$. The SPOTIS steps are presented in [7]. In this research criteria weights were determined using objective weighting method called CRITIC demonstrated in [8].

Step 2. This step involves determining the significance of particular periods using SWARA [9]. Rank periods in descending order according to their significance. Period p_1 is the most significant.

Step 3. Establish comparative importance ratio c among investigated periods. Start with the period p_2 and define how much period p_1 is more significant than p_2 . Determine c_p ratio using values in the range from 0 to 1, analogously to percentage. Value of comparative importance ratio c_1 is determined for periods p_1 and p_2 . Then, identical procedure is followed up to period p_t . Comparative importance determined between p_{t-1} and p_t is denoted by c_{t-1} , where t represents number of all periods to investigate.

Step 4. Compute the coefficient k_p values according to Equation (1), where p represents periods ranked in descending order according to their importance.

$$k_p = \begin{cases} 1, & p = 1 \\ c_p + 1, & p > 1 \end{cases} \quad (1)$$

Step 5. Calculate initial weights v_p for particular periods as Equation (2) presents.

$$v_p = \begin{cases} 1, & p = 1 \\ \frac{v_{p-1}}{k_p}, & p > 1 \end{cases} \quad (2)$$

Step 6. Determine final SWARA weights w_p for each period according to Equation (3).

$$w_p = \frac{v_p}{\sum_{p=1}^t v_p} \quad (3)$$

Step 7. The three final stages involve the Temporal SWARA-SPOTIS assessment of matrix S including SPOTIS utility function values s in the form of weighted average distance values calculated for alternatives for each period p . First step includes determination of the normalized distances d_{ip} for each alternative A_i from Ideal Solution Point S^* according to Equation 4. S^* is represented by S^{min} since the SPOTIS creates rankings by sorting alternatives in ascending order, considering utility function values received by alternatives in each period. Alternative with the lowest utility function value is regarded as the best-evaluated option.

$$d_{ip}(A_i, s_p^*) = \frac{|s_{ip} - s_p^*|}{|s_p^{max} - s_p^{min}|} \quad (4)$$

Step 8. Compute the final temporal utility function values for each alternative as Equation (5) shows

$$d(A_i, s^*) = \sum_{p=1}^t w_p d_{ip}(A_i, s_p^*) \quad (5)$$

where w_p represents SWARA weights assigned for particular periods.

Step 9. Generate the final Temporal SWARA-SPOTIS ranking of evaluated alternatives involving the full investigated time by sorting values $d(A_i, s^*)$ obtained in the previous step in increasing order. The best-evaluated option has the lowest $d(A_i, s^*)$ value. Rankings are compared using two correlation coefficients: Weighted Spearman rank correlation coefficient r_w described in [4] and Spearman rank correlation coefficient detailed in [10]

III. THE PRACTICAL PROBLEM OF EUROPEAN COUNTRIES' CONSIDERING TEMPORAL ASSESSMENT OF RES USAGE

The framework for temporal assessment of sustainable RES using is based on annual data provided by Eurostat in a database collected with the SHARES (SHort Assessment of Renewable Energy Sources) tool [11]. Particular criteria are included in Table I.

TABLE I
CRITERIA FOR SUSTAINABLE RES USING ASSESSMENT.

C_j	Criterion name	Goal	Unit
C_1	Annual electricity generation from Hydro	Max	[% of E]
C_2	Annual electricity generation from Wind	Max	[% of E]
C_3	Annual electricity generation from Solar	Max	[% of E]
C_4	Annual electricity generation from Solid biofuels	Max	[% of E]
C_5	Annual electricity generation from all other renewables	Max	[% of E]
C_6	Annual consumption of renewable electricity in road transport	Max	[% of T]
C_7	Annual consumption of renewable electricity in rail transport	Max	[% of T]
C_8	Annual consumption of renewable electricity in all other transport modes	Max	[% of T]
C_9	Annual consumption of renewable electricity from compliant biofuels in transport	Max	[% of T]
C_{10}	Annual final energy consumption in heating and cooling	Max	[% of H&C]
C_{11}	Annual derived RES based heat in heating and cooling	Max	[% of H&C]
C_{12}	Annual derived RES based heat in heating and cooling for heat pumps	Max	[% of H&C]
C_{13}	Gross final consumption of energy from renewable sources in electricity	Max	[% of G]
C_{14}	Gross final consumption of energy from renewable sources in heating and cooling	Max	[% of G]
C_{15}	Gross final consumption of energy from renewable sources in transport	Max	[% of G]

There are criteria covering generation of electricity from RES (C_1 – C_5) and its consumption (C_6 – C_{15}). Data in the mentioned database are available in the unit KTOE (Thousand tonnes of oil equivalent). However, in an attempt to provide a more reliable and objective assessment, this research employed percentage data representing the share of each measure in each sector. This approach enables the reduction of inequalities between the countries caused by non-modifiable factors such

as area, geographical location, and population, which objectifies the assessment. Therefore, this framework considers RES percentage share in sectors considering all energy sources, such as electricity production (E), energy consumption in transport (T), heating and cooling (H&C), and gross final energy consumption (G). The goal of each criterion is maximization because the assumption of sustainable development is to increase the share of RES in all sectors.

Performance values in the form of percentages of criteria representing the use of RES in particular sectors for 2015–2019 are available in the GitHub repository at [12] in a dataset folder. The results of a multi-criteria temporal assessment concerning sustainable RES are presented in the following section IV.

IV. RESULTS

This section presents the results of the temporal multi-criteria assessment of RES exploitation in European countries performed by the SWARA-SPOTIS method. Criteria weights were determined for each year using the CRITIC method. Then, each decision matrix was evaluated by the SPOTIS method. Next, a decision matrix containing utility function values obtained by countries in each year was created. The next step was determining the significance values for each period using the SWARA method. Then, a decision matrix including SPOTIS utility function values for each year was evaluated using the SWARA weights. The resulting vector with Temporal SWARA-SPOTIS utility function values for each country aggregates annual results into a single score. The obtained Temporal SWARA-SPOTIS utility function values were then ranked in ascending order, according to the SPOTIS rule. It can be observed that Sweden (A_{27}) is the leader of both rankings in all years analyzed. Thus, Sweden is expected to be the ranking leader aggregating the grades achieved in the analyzed period. For the other countries, performing a reliable assessment incorporating the dynamics of performance changes over time is no longer straightforward and intuitive. Instead, it requires using an appropriate methodology, such as Temporal SWARA-SPOTIS. Table II contains the results of the subsequent stages of the SWARA method applied to determine the significance of particular periods.

TABLE II
SWARA WEIGHTS OF PARTICULAR YEARS INVESTIGATED.

Year	c_p	k_p	v_p	w_p
2019	-	1	1.0000	0.3839
2018	0.5	1.5	0.6667	0.2559
2017	0.5	1.5	0.4444	0.1706
2016	0.5	1.5	0.2963	0.1137
2015	0.5	1.5	0.1975	0.0758

The most recent year is considered the most significant, while for the earlier years, the significance gradually decreases. In applied strategy, each subsequent year is 50% more significant than the year preceding. The advantage of the proposed method is that the decision-maker can arbitrarily

model the relevance of each period by setting values of comparative importance ratio c_p for each period. It implies that 2016 is 50% more significant than 2015. For subsequent years, the procedure is analogous. Column w_p contains the final SWARA weights calculated for each period p . Table III includes annual SPOTIS rankings calculated for each country in each period. Columns "TSS" contain rankings provided by the Temporal SWARA-SPOTIS method. Scores (utility function values) of SPOTIS are provided on [12] in folder called results.

TABLE III
RESULTS OF CLASSICAL SPOTIS AND TEMPORAL SWARA-SPOTIS FOR 2015–2019.

A_i	Country	2015	2016	2017	2018	2019	TSS
A_1	Belgium	24	22	23	24	24	24

A_{23}	Romania	11	12	14	16	16	16
A_{24}	Slovenia	20	21	21	22	23	21
A_{25}	Slovakia	21	25	26	26	25	25
A_{26}	Finland	3	6	5	5	5	5
A_{27}	Sweden	1	1	1	1	1	1
A_{28}	United Kingdom	26	23	22	23	18	22
A_{29}	Iceland	8	8	8	7	7	8
A_{30}	Norway	4	3	2	4	4	4

As expected, Sweden (A_{27}) is the best-scored country regarding the sustainable share and use of RES. Austria (A_{20}) took second place. Austria ranked second in 2015 and 2016, dropped to fourth in 2017, and ranked third in 2018 and 2019, despite the worsening performance in 2017–2019. However, the Temporal SWARA-SPOTIS method employs the utility function values obtained in the individual years as performance values, which are more precise than ranks. This feature allows for a more accurate and reliable reflection of the aggregate performance of the countries over the years reviewed. Denmark achieved third place (A_4). This country improved the use of RES in the economy over the years analyzed. It ranked sixth in SPOTIS in 2015, then jumped to fourth place in 2016. In 2017, there was a further promotion of Denmark to third place. In 2018, Denmark again climbed to second place and remained there in 2019. Because most recent years are more relevant, the promotions registered between

2017 and 2019 allowed Denmark to reach the third position in the final ranking despite the sixth place occupied in 2015. Norway (A_{30}) took fourth place in the final ranking. Norway in 2015 was fourth. In 2016, Norway moved up to third place and in 2017 to second place. However, it was again ranked fourth in 2018 and 2019. The greater importance of most recent years caused the better performance in 2016-2017 did not enable Norway to rank higher than fourth in the final ranking. Finland (A_{26}) received fifth place in the final ranking. This country was ranked third in 2015. Then in 2016, Finland dropped to sixth place. In contrast, Norway advanced to fifth place in 2017. Therefore, this country retained a fifth place in the remaining years analyzed. Table IV contains the values of the correlation coefficients r_w and r_s representing the convergence of the final aggregated rankings obtained using Temporal SWARA-SPOTIS with the SPOTIS rankings generated for the individual years analyzed. High values of both correlation coefficients close to 1 indicate high convergence of the compared rankings.

TABLE IV
CORRELATION OF TEMPORAL SWARA-SPOTIS WITH SPOTIS.

Year	2015	2016	2017	2018	2019
r_w	0.9562	0.9835	0.9912	0.9885	0.9906
r_s	0.9448	0.9795	0.9907	0.9867	0.9884

The results confirm that the Temporal SWARA-SPOTIS ranking is more convergent with the most recent analyzed years, 2017-2019, than with the earlier years, 2015-2016. Results are consistent with the assumption that the most recent years are more interesting for decision-makers and reflect appropriately the influence of the weights assigned to the following years by the SWARA method.

V. CONCLUSIONS

This paper demonstrated the application of the newly developed Temporal SWARA-SPOTIS method on the illustrative example of a multi-criteria problem involving evaluating the sustainable use of RES by European countries, considering the dynamics of performance variability over the observed five years. The developed methodology indicated Sweden as the most sustainable country among the investigated European countries. Likewise, other Nordic countries such as Denmark, Norway, and Finland are among the best-ranked countries. Austria is also a well-scored country. The proposed tool has a high potential of usefulness for information systems supporting multi-criteria sustainability assessment taking into account both multiple indicators and dimensions and the variability of results over time.

The proven usefulness of the proposed tool suggests extending the conducted research to explore other MCDA methods and techniques for determining the relevance of periods. An interesting future work direction seems to be an approach adapting the PROMETHEE II method for multi-criteria temporal sustainability assessment. This method appears promising due to its ability to employ different preference functions

and limited criteria compensation. Further research focused on temporal multi-criteria sustainability assessment is also planned to include a study of the impact of other objective criteria weighting methods on the results. Investigating the utility of the proposed sustainability assessment approach based on other RES indicators may also be an interesting research direction.

ACKNOWLEDGMENT

The work was supported by the project financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019-2022, Project Number 001/RID/2018/19; the amount of financing: PLN 10.684.000,00.

Abstract—In recent years, the integration of process design in conjunction with the use of analytical applications to provide information tailored to user requirements to support operational process activities (e.g., Operational BI) has become increasingly widespread. In analytical software development/implementation projects, the insufficient involvement of analytical end users with their process context and the resulting unclear requirements/expected analytical software functions are still one of the main reasons for analytical project failure. Embedded in a Design Science Research Process, this paper shows the shortcomings of existing approaches, tools and models (1. BPMN process model extensions, 2. configurators in analytical applications, 3. models used in analytical implementation projects) for the documentation/conceptual configuration of analytical requirements. As a second part, this paper presents the evaluation results of a new process-oriented and service-based configuration approach for analytical applications, whose practicability, usefulness and acceptance were evaluated in expert reviews and in analytical development projects.

I. INTRODUCTION

A. Main topic and challenges

PROCESS orientation has established itself in corporate practice since the 1990s as a primary structuring approach for corporate organizational forms and as the basis for a (re)organization of operational value-adding activities. In addition to the efficient linking of tasks, which is the initial focus of process-oriented design, the targeted use and visualization of information required in processes is becoming increasingly important [1] in times of advancing digitization and automation of corporate processes [2].

Systems of insight [3] or rather analytical applications have long been used for retrospective analysis of corporate activities for the management under the keyword Business Intelligence (BI). Due to a wider dissemination of analytical information in operational processes and the subsequent process-centric design of static analytical reports and interactive dashboards [4], original focus and functional range of analytical application/BI design [5] have widened. Additional aspects include 1. the trend to a modular analytical application structure [6], 2. the consideration of analytical self-

services [7] and 3. the implementation of real-time monitoring and automatic actions [8], [2] (Section III.A).

Concerning the development of analytical applications, the insufficient inclusion of end users with their process context and the resulting unclear requirements/expected deliverables are repeatedly cited in literature as the main causes for project failure or for the implementation of analytical applications that does not meet user expectations [9], [10]. Own results from interviews and an online survey with experts in analytical requirements management confirm this hypothesis: five of the experts surveyed find inadequately communicated/documented requirements are very frequent, four experts find them rather frequent and only two experts find them less frequent as a main reason for delayed or insufficient implementations of analytical applications.

In addition, practice-oriented literature provides evidence for a number of detailed causes for delays or failure of analytical development projects. Some of them already point out important aspects that must be better taken into account in future user- and process-oriented conceptual analytical application configuration in terms of requirements documentation. These include:

1. Unclear ideas on the users' side about goals, functionalities and detailed system specifications due to insufficiently elaborated and planned project scopes, information needs and use cases [11], [10];
2. Requirements formulated by users in an unclear and/or misleading manner and the resulting misunderstandings among technical developers [12], [9];
3. Data privacy risks known to the process users and not considered right from the start throughout requirements elicitation and documentation [9], [13];
4. Uncoordinated planning and implementation of individual data analyses within overall processes [14] leading to fragmented and insufficiently integrated analytical application landscapes and impeding the data-driven process design.

These aspects suggest the fact that models, configurators and other tools used in the documentation of requirements for process-related analytical applications in implementation projects are apparently insufficient.

B. Objective of the current work

In the context of the above-mentioned challenges, the results presented in this paper show a broad overview about the current state of the art concerning tools and models for configuration and conceptual modeling of analytical applications. The new results extend and supplement an earlier literature review regarding scientific models supporting requirements documentation for analytical applications (c.f. [15], summary in Section III.B) and investigate additional alternatives to configure analytical applications:

- Applicability of process modeling languages to represent information requirements (Section III.C);
- Availability of models for requirements documentation/conceptual configuration provided with analytical application products (Section III.D);
- Use of tools for requirements documentation in analytical development projects (Section III.E).

The results confirm the need for new tools to document/configure user requirements regarding analytical applications from a process-oriented perspective. As a second part of this paper, the authors present detailed results of expert reviews regarding the completeness and usefulness of a new approach for the conceptual configuration of analytical applications based on analytical services (initially presented in [15], short introduction in Section IV.A) and its practicability in the context of process-related analytical requirements documentation proofed in two real projects. This leads to the following two research questions:

RQ1: What support do models and tools from science and practice provide regarding documentation/configuration of process user requirements for analytical applications?

RQ2: To what extent is a configuration approach for analytical services suitable to be used in analytical implementation projects and to solve the identified challenges regarding documentation/configuration of process user requirements for analytical applications?

C. Structure of this paper

After the introduction of the subject area of this paper, the identification of current challenges and relevant process-oriented trends as well as the presentation of the paper's objectives in Section I, Section II presents the research method. Section III provides the current state of the art regarding different tools and models for documenting conceptual requirements for analytical process support in science and practice. Section IV shows the practical relevance of the new process-oriented configuration approach for analytical applications (initially introduced in [15]) based on evaluation results. Section V concludes the paper.

II. RESEARCH METHOD

The research results presented in this article have been elaborated as parts of a wider research project developing a

comprehensive modeling approach for the documentation/configuration of conceptual process user requirements for analytical applications (for further details see [15]). A six-step Design Science Research Methodology Process [16] guides this superordinate research project. Within the first Design Science phase "Problem Identification and Motivation", the following research methods were used to develop the new research results presented in the current paper:

- The modeling language Business Process Model and Notation (BPMN) served as a starting point to find suitable representations to configure analytical process requirements due to its leading position as a worldwide used process-modeling standard [17], [18]. The analysis (Section III.C) encompassed all previous BPMN extensions surveyed by [19].
- Analytical products were analyzed to determine whether they provide pre-built models/configurators for documenting business user requirements (Section III.D). This analysis comprised all 13 analytical products in the quadrants "Leaders", "Visionaries" or "Challengers" of "Gartner Magic Quadrant for Analytics and BI Platforms 2021" [20]. Investigation techniques included both interviews with software providers and the analysis of product information.
- Four interviews were conducted with project managers/experts responsible for requirements management. They confirmed that requirements documentation is still a critical, and so far an insufficiently supported success factor in analytical implementation projects. In addition, an online survey conducted with six experts in analytical requirements management from practice (about 125 participants of an event for analytics specialists were invited via e-mail) provided further feedback regarding the quality of different models, notations and documents used in this area (Section III.E).

In the fifth phase "Evaluation" of the overall Design Science Research Process, the previously developed configuration approach for analytic services and its intended integration into process models [15] was evaluated with regard to its usefulness/practical value (proof of value) [21] and its acceptance by the model users (proof of acceptance) [21], [22]. For this purpose, content-related feedback on the model structure (i.e., regarding the selected analytical services, their relationships to each other (service network) and the design of the service-internal service features) was collected in 12 expert reviews [21] with 17 experts in the field of analytics (project/requirements managers, data scientists). After the final definition of the analytical service network structure (after the third expert review), 13 experts provided an additional quality assessment (Section IV.B). Furthermore, the configuration approach has been tested in two analytical development projects (1. Machining Daily Demand report

for an industrial enterprise; 2. Population Forecasting dashboard for a healthcare company) (Section IV.C).

III. STATE OF THE ART REGARDING THE CONFIGURATION OF ANALYTICAL PROCESS SUPPORT

A. Relevant characteristics for tools/models

Analytical/Bi applications that can be successfully used in practice are characterized by the fact that they provide 1. the right **information** at 2. the right **time** in 3. a suitable **presentation form** and generated with 4. the right **analysis methods** to 5. the right **users** [5]. The following additional design aspects (identified in a literature review) for tools/models supporting the configuration of analytical applications address the denoted detailed causes for delays or failure of analytical development projects mentioned in Section I.A:

6. **Models utilized by business users** (causes 1 + 2): Requirements documentation tools should be designed for users [23] to get them more involved in the analytical design process.
7. **Graphical modeling notation** (cause 2): Graphical models in requirements documentation [24] provide a more intuitive access to conceptual models [25].
8. **Provision of configuration alternatives** (causes 1 + 2): Providing configuration alternatives in analytical requirements models [26] ensures acceleration of selection decisions and reduces the risk of misleading requirements descriptions.
9. **Data privacy** (cause 3): An examination of the planned analytical use cases from a data privacy perspective is an important task within the requirements analysis to prevent extensive adjustments during the implementation of analytical applications [27].
10. **Process-relation** (cause 4): A strong link to process design in the phase of requirements elicitation and requirements documentation [1] has a positive effect on an analytical information provision that is coordinated between the process activities.

To stress the deep integration of operational processes with analytical applications (accompanied and pushed, e.g., by the dissemination of approaches such as "Business Process Intelligence", "Business Activity Monitoring", "Operational BI" [28] and "Context-Oriented Analytical Applications" [29] in research and practice), further important requirements aspects regarding analytical application design (identified in a literature review) must be added:

11. **Service-oriented design**: To support the adjustment of analytical applications due to changing processes [6], the modularized provision of subcomponents of analytical applications as reusable analytical services in terms of service-oriented architectures (SOA) [4], [30] enables customer-centric service provision [31]

as well as the (re)combination of analytical components from different providers [32].

12. **Self-services**: To enable rapid customization of analytical applications [7] due to changes in process information demand, analytical self-service applications should enable process staff to independently adapt or create analytical reports/dashboards, to integrate new data, to check and/or improve data quality and to adjust analytical data models [33].
13. **Automatic actions**: The proliferation of IoT assets and their integration into operational process controls [34], the acceleration of operational applications (e.g., faster data storage structures) and direct interconnections between systems of data origination and data use are drivers for "real-time enterprises" with the ability to react immediately to occurring events [35]. Business Activity Monitoring (BAM) applications [8] monitor process executions to identify threshold violations or error events and support the automated/rule-based execution of actions.

As a consequence of the aspects listed above, tools/models for the conceptual configuration of analytical applications in order to document user requirements should address these various aspects to improve their usefulness for practice. This is examined in more detail in the following subsections.

B. Scientific models to support the configuration of requirements for analytical applications

The structured literature review (presented in more detail in [15]) with regard to scientific models for analytical requirements documentation and configuration encompassed a very broad search space ("requirements" AND "analytical software" OR "information systems") in order to obtain results without restrictions in the perspectives of observation (e.g., business engineering) and business domains (e.g., production). The analysis of 13 identified requirements and configuration approaches [26], [36]-[47] aimed to identify to what extent these approaches comprehensively ("X"), partially ("(X)"), or do not ("-") address the requirement aspects enumerated in Section III.A. The results of this analysis showed that none of these approaches even comes close to addressing all aspects, with major deficits in the areas „provision of configuration alternatives“, „service-oriented design“, „process-relation“, „periodicity“, „presentation“, „automatic actions“, „self-services“ and „data privacy“ (Table I).

C. Representation of information requirements in process modeling languages

In addition to the modeling approaches just described, which focus on the configuration of analytical applications/requirements, process-modeling languages can describe information requirements from the process design

perspective as well. The standard process modeling languages widespread in practice (e.g., Business Process Model and Notation (BPMN), Extended Event Driven Process Chain (eEPK), UML Activity Diagram) contain the so-called information or data objects, which represent informational inputs in or outputs from process activities in graphical process models. However, the information or data objects in the standard versions of the above-mentioned process notations are only black-box objects unveiling just an identifier without further details (e.g., without content specification, the origin of information or the way of information provision). With these modeling objects, it is not possible to provide a comprehensive specification of a desired information provision [48]. The same abbreviated black-box representation applies to process-relevant databases and software applications.

In addition to the standard versions of process modeling notations, a large number of notational extensions especially for BPMN have emerged (surveyed by [19]). Many of them support the representation of technical and data-oriented content not included in this research. This involves the representation of technical data models (e.g., [49]) and the representation of backend data flows, data changes and technical interactions with data stores (e.g., [49], [50]).

Besides these technical approaches, there are also modeling extensions focused on individual domain-specific requirements aspects, which predominantly do not address the specification of analytical requirements. These BPMN model extensions represent process requirements in specific application domains/industries such as disaster management [51]. The only exception is [52], but this approach considers just a very small part of the user-oriented re-

quirement spectrum of analytical applications with the specification of threshold values for specific key figures to support simulation runs (addressing “data/information” and “automatic actions” (c.f. Table I)).

D. Conceptual configurators for analytical application products

The conceptual configuration of analytical products belongs to the product configuration, which pursues the goal of specifying the quality and structure of product-relevant characteristics [53]. The product configuration distinguishes the customer-inherent configuration (customers/users can select product parameters/characteristics freely) as well as the customer-coherent configuration (customers/users can select predefined parameter sets) [53].

First, a configuration system consists of a configuration component as a content-logical model with configuration elements, configuration variants and their relations. Furthermore, a presentation component allows the interaction between the configuration system user and the configuration component [54]. For the implementation of configuration systems in the special context of software configuration, different kinds of configurators/configuration models are applicable [55]: 1. Software reference models to analyze the potentials of a software product including the description of data structures, operational transactions (functions) and supported processes, 2. checklists for the interactive and systematic reduction of the configuration area regarding a (standard) software product by a question and answer dialogue between user and system, and 3. preconfigured systems as exemplary preselected configuration variants for a homogeneous target group. In the case of a flexible conceptual application configuration by users themselves or in

TABLE I.
COMPARISON OF MODELS SUPPORTING THE CONFIGURATION OF REQUIREMENTS FOR ANALYTICAL APPLICATIONS [15]

	Models utilized by business users	Provision of configuration alternatives	Graphical modeling notation	Service-oriented design	Process-relation	Modeling content for analytical requirements							
						Data / information	Periodicity	Presentation	Users	Analysis methods	Automatic actions	Self-services	Data privacy
[40]	-	-	X	-	-	X	-	-	X	-	-	-	-
[37]	X	-	(X)	-	-	X	-	-	X	-	-	-	-
[41]	(X)	-	X	-	-	X	(X)	(X)	X	(X)	-	-	-
[36]	-	-	-	-	-	X	(X)	-	X	-	-	-	(X)
[38]	-	-	X	-	-	X	-	-	-	-	-	-	-
[39]	-	-	X	-	-	X	-	-	X	-	-	-	-
[42]	X	-	X	-	-	X	-	-	-	-	-	-	-
[26]	X	X	-	-	-	-	-	(X)	X	(X)	-	-	-
[43]	X	-	X	-	-	(X)	-	-	-	-	-	-	-
[44]	(X)	-	(X)	-	-	X	-	-	-	-	-	-	-
[46]	(X)	-	(X)	-	-	X	-	-	-	-	-	-	-
[45]	-	-	X	-	-	X	-	-	-	-	-	-	-
[47]	X	-	X	(X)	(X)	(X)	-	-	X	-	-	-	-

direct interaction with the users, the focus in this current work lies on conceptual configuration models in the form of checklists/requirements catalogs.

The availability of analytical self-service functions within software tools, which could also be regarded as a type of user-sided configuration of analytical applications, is deliberately excluded from this study about the provision of configuration systems in practical products. This is due to the use of analytical self-service functions requires certain in-depth technical or data-related knowledge that cannot be assumed from users of analytical applications (especially casual users like telephone agents in call centers). Furthermore, due to a reduction of complexity, analytical self-service functions represent only a limited part of the actual functional range and available design variants of analytical tools, and thus offer self-service users only limited options for system (re-)design and a comprehensive implementation of their requirements.

The analysis of analytical products with regard to pre-built models/configurators for documenting business requirements (e.g., as a support function for implementation projects) included all product vendors except niche players in the "Gartner Magic Quadrant for Analytics and BI Platforms 2021" [20]: Microsoft, Tableau and Qlik in the "Leaders" quadrant; MicroStrategy, Domo and Google (Looker) in the "Challengers" quadrant; and Sisense, ThoughtSpot, Oracle, SAS, SAP, Yellowfin and TIBCO Software in the "Visionaries" quadrant. Within all examined analytical software products, there are no specific models/configurators to support the collection of user requirements. Taking the example of Microsoft Power BI, available limited support in this area includes the specification of textual change requests regarding existing dashboards/reports via a comment function (plain text without structuring guidelines). Furthermore, in some tools it is possible to integrate external software development applications (e.g., Github) to maintain requirements. To support collaborative development, some vendors establish community areas to collect and discuss ideas for further developments/adaptations of the standard functions of the tools. However, this does not serve to specify/configure concrete requirements for individual use cases.

As an example, TIBCO Software explicitly stated that the provision of models for product-specific application configuration/requirements documentation is deliberately not offered as a part of its own tool. This means that software vendors pass the responsibility and the choice of suitable requirements configurators/documentation models to the external implementation partners.

E. Requirements documentation in the context of analytical development projects

Referring to an own online survey (n=6, Section II provide more information about the research method) about tools and models used in analytical implementation projects

for requirements documentation, Table II shows the mentioned models and documents and their prevalence in practice (column "Sum"). Textual and unstructured/less structured use case descriptions are by far the most widespread tool for requirements documentation. It is worth mentioning here that with use case descriptions, the users with their concrete (usage and operating) requirements have already moved into the center of attention, meanwhile conventional formats such as requirements specification sheets seems to play a minor role. They are followed at some distance by both the content-structured requirements catalogs (checklists) and data models. However, data models are not able to provide even a complete picture of the various requirement facets (e.g., with respect to structural and graphical design of user interfaces, access and distribution paths of information) due to their purely data-oriented view.

TABLE II.
ASSESSMENT OF THE COMPLETENESS OF CONTENT

Models/documents	Very good	Good	Less good	Bad	Sum
Textual user story	1	3	2	-	6
Requirements catalog	1	2	-	-	3
Data model	3	-	-	-	3
Requirements specification sheet	-	-	2	-	2
Backlog	-	1	-	-	1
Process description	-	1	-	-	1
Mockup/PoC	1	-	-	-	1

TABLE III.
ASSESSMENT OF THE COMPREHENSIBILITY OF CONTENT FOR ALL STAKEHOLDERS

Models/documents	Very good	Good	Less good	Bad
Textual user story	-	2	3	1
Requirements catalog	2	1	-	-
Data model	2	1	-	-
Requirements specification sheet	-	-	2	-
Backlog	-	1	-	-
Process description	-	-	1	-
Mockup/PoC	1	-	-	-

As expected and in addition to the one-sided (technical) data models and the mockups (belonging rather to the technical implementation area), requirements catalogs perform best in terms of achievable completeness of requirements content (Table II). This happens because requirements catalogs already mention various design alternatives of an analytical application, which can thus be considered or deliberately excluded from the beginning of application development. Requirements catalogs are also obviously well suited to achieve requirements documentations that are under-

standable both for business users and developers (Table III), since here (in contrast to the lower rated purely textual documents) structural relationships and terminologies are already defined [56] to facilitate the creation of a common understanding. Requirements catalogs also reached a positive score regarding the frequency of inconsistencies (Table IV), because a clear requirements structure in catalogs can be recognized and compared more easily than content in unstructured continuous texts (e.g., use case descriptions).

TABLE IV.
ASSESSMENT OF THE FREQUENCY OF INCONSISTENCIES WITH
OTHER MODELS/DOCUMENTS USED FOR REQUIREMENTS
DOCUMENTATION

Models/documents	Very often	Often	Rather often	Less often	Rarely
Textual user story	2	2	1	1	-
Requirements catalog	-	-	-	-	3
Data model	-	-	-	-	3
Requirements specification sheet	1	-	-	1	-
Backlog	-	-	1	-	-
Process description	-	1	-	-	-
Mockup/PoC	-	-	-	-	1

A similar result emerges how data privacy risks are taken into account in requirements documentation (Table V): Text-based documents got a worse score here, while requirement catalogs at least received a better rating. It is remarkable that no model/document was able to achieve a very good rating. This again substantiates the still inadequate consideration of data privacy risks in requirements documentation.

One expert in this survey provided detailed information

TABLE V.
ASSESSMENT OF THE CONSIDERATION OF DATA PRIVACY RISKS

Models/documents	Very good	Good	Less good	Bad
Textual user story	-	2	3	1
Requirements catalog	-	2	1	-
Data model	-	1	-	2
Requirements specification sheet	-	-	1	1
Backlog	-	-	-	1

Mockup/PoC	-	1	-	-

about the specific requirements catalog models used in projects. These are the cross-domain requirements templates according to [56] to create requirements in form of sentences with specific content placeholders in a particular order, which ensures a uniform way of formulating requirements. Unfortunately, this predefined formulation structure alone does not provide any information about the structural and

content design of domain-specific applications and the relevant analytical requirements aspects and variants.

Based on these results, requirements catalogs seem to be best suited for documenting requirements with regard to the design of analytical applications from a practical point of view in terms of a complete, consistent and unambiguous provision of content. Furthermore, a new requirements catalog for analytical applications should encompass the specific functional and non-functional properties of this software domain, as well as actively consider the other model aspects described in Section III.A.

IV. ANALYTICAL SERVICE MODELS FOR THE CONCEPTUAL CONFIGURATION OF ANALYTICAL APPLICATIONS

A. Presentation of the modeling approach

The configuration approach already presented in more detail in [15] enables the configuration of analytical services to document requirements in process contexts. The use of services in the sense of encapsulated functions connected via standardized interfaces [3] allows the flexible conceptual (re-)configuration of analytical applications. The configuration approach is appropriate for different analytical use cases, business domains, data formats as well as analysis methods. It can be classified as a customer-inherent product configuration [53] in order to permit a modular orchestration of analytical components/services.

The configuration approach is based on the distinction of three different configuration areas (cf. [15]):

- Use Case-Specific Configuration Content enables the specification of individual reports/dashboards.
- Configuration Content for Analysis Preparation describes the required functional scope in the area of analytical self-services.
- Use Case-Overlapping Configuration Content addresses design aspects that affect the entire analytical application.

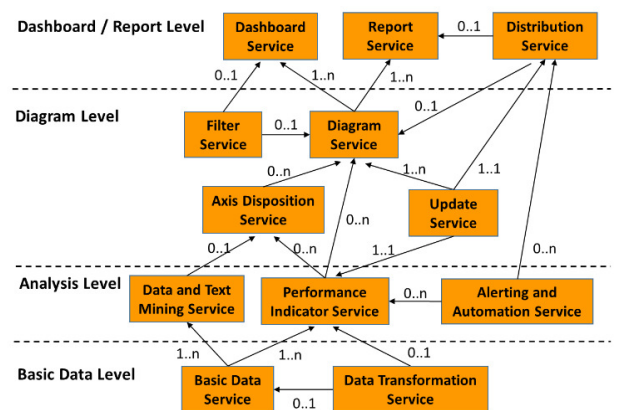

Fig.1 Analytical service types and their interconnections in the configuration area Use Case-Specific Configuration Content [15]

Each configuration area contains a set of analytical service types, which can be configured in more detail (c.f. Fig. 4-7) to describe specific aspects of the analytical application more precisely. Fig. 1 shows the service network for the Use Case-Specific Configuration Content with its associated analytical service types on four levels and their logical interconnections. In this way it describes reports/dashboards, their diagrams as well as the key figures displayed therein and the underlying basic data.

Fig. 2 Modeling objects for the internal configuration of analytical services [15]

Fig. 2 shows the different modeling objects available for the graphical configuration of the specific service features within the individual analytical services (c.f. Fig. 4-7). In order to be able to represent the interconnection of the analytical services needed to configure a specific analytical use case (in terms of a specific dashboard or report) in connection with the related process activity, the analytical services are represented as data objects (e.g., Fig. 3) in BPMN pro-

cess models. To make the respective analytical service types distinguishable, the BPMN data objects bear specific identifiers (c.f. [15]).

B. Results of the expert reviews

Within the intensive review sessions (c.f. Section II), the analytical experts got an overview about the whole configuration approach for analytical services (Section IV.A) concerning the three specific interconnected analytical service type networks (Fig. 1 and [15]) within the three different configuration areas (Section IV.A), and about the numerous service type-specific graphical service feature configurations (e.g., Fig. 4-7). As a result, the experts confirmed that the configuration approach has a predominantly high and increased potential benefit for practice (Table VI). This concerns in particular the areas of unambiguity and completeness of content, modularization of requirements and the possibility of reuse, the identification of new design options, obtaining an overview about analytical process support and using the instantiated models as a starting point for deriving a technical concept. It is also noteworthy that this approach was rated with a predominantly higher added value compared to models previously used in these companies.

C. Presentation of evaluation use cases

Based on the positive evaluation by the experts (Section IV.B), the configuration approach was tested in a healthcare project to develop a dashboard presenting annual **Popula-**

TABLE VI.

ASSESSMENT OF THE POTENTIAL BENEFITS OF THE ANALYTICAL SERVICES CONFIGURATION APPROACH FOR REQUIREMENTS DOCUMENTATION

	High benefit	Increased benefit	Less high benefit	Low benefit	No benefit
Unambiguity of content	9	3	1	-	-
Completeness of content	9	4	-	-	-
Provision of selectable design variants	4	2	2	1	-
Saving of effort in practical projects	3	7	1	2	-
Modular and simple (re-)combination of requirement contents / services	5	4	-	-	-
Recording data privacy-specific conditions of basic data	2	3	2	2	-
Specification of requirements for analytical self-service functions	4	2	1	-	-
Starting point for deriving a technical concept	9	4	-	-	-
Identification of design options not yet considered through proposed configuration content	5	2	-	-	-
Starting point for subsequent adaptations of the analytical software at the same customer	6	5	2	-	-
Starting point for similar future projects with other customers	6	7	-	-	-
Obtaining an overview of the analytical process support	7	6	-	-	-
Representing the sequence of analytical content in processes	5	5	3	-	-
Representing relationships between the individual analytical services via associated BPMN data objects	7	5	1	-	-
	High added value	Increased added value	Less high added value	Low added value	No added value
Added value of the configuration approach to requirements documentation compared to the previous approach in the company	3	7	2	1	-
Added value of the coupled representation of analytical support and user processes compared to the previous requirements documentation in the company	2	8	2	-	-

tion Forecast information in different counties in the federal state of Saxony. In this project, some planning for the dashboard design had already been done before. Based on this, all analytical services needed to describe the entire analytical use case (from the basic data to the key figure calculation and visualization up to the integration in the dashboard) were configured together with three development team members (project manager, data analyst, analytical developer). Due to the numerous design features and design variants considered in the different analytical services, some new facets and features of the dashboard that had not yet been considered in the previous development were identified. The elaborated analytical service models subsequently served as the conceptual basis for further dashboard implementation. The positive feedback from the three experts involved (high benefit: 16 times; increased benefit: 16 times; less high benefit: 3 times; low benefit: 1 time; willingness to use in future projects: 3 out of 3) (Table VI) was clear evidence of the usefulness, acceptance and, in particular, practicability of the configuration approach in implementation projects.

In a second case study, the configuration approach was used to configure a **Machining Daily Demand** report in an industrial enterprise. This case study was not developed in the middle of an ongoing project with analytical experts, but rather at the beginning of the requirements elicitation process together with a requirements provider from the business department. This report should inform a storekeeper in near real-time which parts from stock are needed in which quantities, according to the current planning for the supply of the daily production. To obtain an overview, Fig. 3 shows the process model for this use case with the interconnections of all involved analytical services.

Fig. 3 Process model of the use case Machining Daily Demand

The "Performance Indicator Service" (Indicator-S) (Fig. 4) plays a central role in the use case. The calculation of the indicator "Machining Daily Demand" should not only take into account the "Basic Data Service" (Data-S) "Production Program Data" provided at the beginning of a day's production, but also consider events in the upstream parts flow and the resulting dynamic changes for the supply of the other

parts ("Direct Supply Stream Data" (Fig. 5); c.f. service interconnections in Fig. 3).

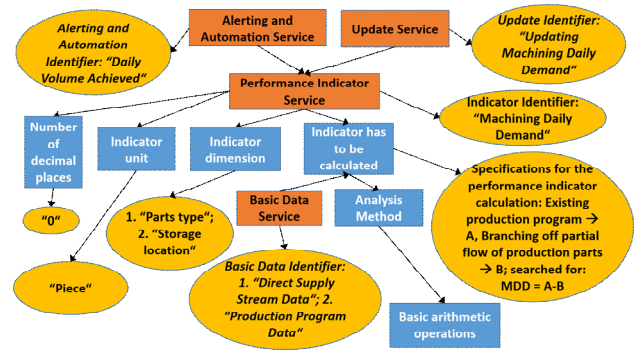

Fig. 4 "Performance Indicator Service" "Machining Daily Demand"

Fig. 5 "Basic Data Services" "Direct Supply Stream Data"

The "Alerting and Automation Service" (Alert-S) defines to monitor the development of the indicator and to trigger an automatic on-screen warning message and a control instruction to a robot if the threshold is exceeded (Fig. 6). Finally, the "Report Service" specifies the access conditions for the prospected user role (storekeeper) (Fig. 7).

Fig. 6 "Alerting and Automation Service" "Daily Volume Achieved"

Fig. 7 "Report Service" "Monitor Updated Daily Program"

V. CONCLUSION

Based on identified challenges in practice for the documentation of process-related requirements in the context of analytical software development in combination with challenges emerging with process-oriented analytics, this work has shown that neither scientific approaches (requirements models for analytical applications; process modeling languages and their language extensions), analytical products nor the textual documents and models predominantly used in implementation projects for requirements documentation are able to sufficiently address these challenges and the essential analytical design aspects. Furthermore, evidence was provided by experts that a service-based conceptual approach for the customer-inherent [53] configuration of analytical services [15] addressing all 13 requirements aspects relevant for analytical application development (Section II-I.A) leads to a predominantly increased to high benefit for analytical development projects.

The applied research design did not comprehensively investigate all facets of this topic, and this leaves opportunities for further research. A more extensive investigation of configuration models used in analytical implementation projects could yield additional design recommendations for the further development of the configuration approach. Furthermore, in the current approach, data objects with a label of the service type and a unique identifier represents the analytical services in the process models. Future research activities could investigate which essential service features from the detailed service models could expand the content to be represented in the data objects (using extension mechanisms for type definitions available in BPMN) to visualize more detailed information about analytical process support directly in the process models.

Abstract—In many cases involving multi-criteria decision-making, we need compromise solutions. This is a crucial aspect due to the specific characteristics of decision problems. However, the proposed compromise approaches are often complex to verify to what extent they are reliable. Therefore, this paper proposes a new iterative approach based on decision option evaluations from selected multi-criteria decision-making methods, i.e., TOPSIS, VIKOR, and SPOTIS. The obtained results have high similarity among each other, which was measured by Spearman’s weighted correlation coefficient and WS ranking similarity coefficient. Furthermore, the proposed approach showed high efficiency and adaptability of the generated results.

I. INTRODUCTION

MANY works propose new approaches related to the topic of multi-criteria decision making, for which conflicting results are obtained compared with classical approaches. In these methods there are a number of parameters that have a great influence on the final evaluations of decision options [1]. Sałabun et al. investigated the effect of normalization and weight selection methods on the final evaluations in selected methods [2]. Ghaleb et al. evaluated the TOPSIS, AHP, and VIKOR methods based on five selected factors [3]. Baydas et al. used the stock price from the finance domain problem as a tool to compare the MCDM methods [4].

Therefore, researchers focus on improving their methods based on compromise solutions. Liao et al. presented an improved SMAA-CO method designed to determine compromise solutions [5]. The approach they presented is characterized by its ability to reflect uncertain preferences of decision-makers with conflicting criteria. Stevic et al. proposed a new compromise MARCOS approach based on ideal solutions and the utility function [6]. The method performed well in a balanced provider selection problem in the healthcare domain, where it remained stable with a large dataset.

A popular approach is voting algorithms to establish a compromise ranking based on reference rankings. One such example is the use of Borda’s approach and Copeland’s method for evaluating the performance of electric vehicle batteries [7]. Approaches based on the Borda and Copeland algorithms have also been used to create a recommendation system based on e-commerce [8] and to select online services [9].

However, these methods mainly focus on rankings in which it is difficult to observe slight differences between the obtained preferences of decision options [10]. Moreover, using methods that suffer from the problem of rank reversal paradox, it is difficult to determine the most compromise ranking.

In this paper, we propose a new method for determining compromise rankings based on reference evaluations. The evaluations of the decision alternatives obtained by the selected methods are used to determine the compromise rankings. The obtained ratings are formed into a decision matrix, where the types of attributes for the newly formed matrix depend on the ranking method. Three multi-criteria decision-making methods such as TOPSIS, VIKOR, and SPOTIS were used in this study.

The main contribution of our work is the concept of a new approach to verifying compromise solutions. Due to the number of existing MCDM approaches, it is necessary to develop compromise methods to produce consistent evaluations and rankings. Therefore, our proposed concept of a compromise approach aims to show the possibility of iteratively determining a compromise ranking based on reference rankings obtained for the original decision matrix.

The remainder of the paper is organized as follows. Section 2 presents descriptions of the TOPSIS, VIKOR, and SPOTIS methods and ranking similarity coefficients. Section 3 presents research on the proposed compromise approach. Finally, Section 4 presents a summary and outlines future research directions.

II. PRELIMINARIES

A. The TOPSIS Method

Technique of Order Preference Similarity (TOPSIS) is based on the ideal solution approach for solving multi-criteria decision problems [11]. The approach evaluates decision alternatives for the distance from a positive ideal solution and a negative ideal solution. TOPSIS is a continuously evolving method capable of solving problems involving uncertain environments [12]. Its basic version can be presented in the following steps:

Step 1. This step includes the determination of a normalized decision matrix. In the vector method used in the presented

work, the square root of all values is calculated. Equations used for profit (1) and cost criteria (2) are presented below.

$$r_{ij} = \frac{x_{ij} - \min(x_j)}{\max(x_j) - \min(x_j)} \quad (1)$$

$$r_{ij} = \frac{\max(x_j) - x_{ij}}{\max(x_j) - \min(x_j)} \quad (2)$$

Step 2. Computation of the weighted values of the normalized decision matrix v_{ij} in accordance with Equation (3).

$$v_{ij} = w_i r_{ij} \quad (3)$$

Step 3. Calculation of the positive ideal solution (PIS) and negative anti-ideal solution (NIS) vectors. The PIS represented by (4) contains the maximum values for every criterion, and the NIS expressed by (5) includes minimum values. It is unnecessary to split the criteria into benefit and cost since the normalization procedure converted the cost criteria to profit criteria.

$$v_j^+ = \{v_1^+, v_2^+, \dots, v_n^+\} = \left\{ \max_j(v_{ij}) \right\} \quad (4)$$

$$v_j^- = \{v_1^-, v_2^-, \dots, v_n^-\} = \left\{ \min_j(v_{ij}) \right\} \quad (5)$$

Step 4. Calculation of distance from PIS by (6) and NIS, by (7) for every alternative under consideration [2].

$$D_i^+ = \sqrt{\sum_{j=1}^n (v_{ij} - v_j^+)^2} \quad (6)$$

$$D_i^- = \sqrt{\sum_{j=1}^n (v_{ij} - v_j^-)^2} \quad (7)$$

Step 5. Calculation of the result for every considered variant by (8). The score ranges from 0 to 1. An alternative that has a preference value closer to 1 is better.

$$C_i = \frac{D_i^-}{D_i^- + D_i^+} \quad (8)$$

B. The VIKOR Method

ViseKriterijumska Optimizacija I Kompromisno Resenje (VIKOR) is a method based on the compromise approach, which evaluates alternatives with conflicting types of criteria [13]. The compromise solution in this method is considered to be the solution that is closest to the ideal. On the other hand, compromise is achieved through mutual concessions. This method can be presented in the following steps:

Step 1. Determination of the best f_j^* and the worst f_j^- value for the function of individual criteria. For benefit criteria, formula (9) is performed

$$f_j^* = \max_i f_{ij}, \quad f_j^- = \min_i f_{ij} \quad (9)$$

while for the cost criteria, formula presented below is applied (10).

$$f_j^* = \min_i f_{ij}, \quad f_j^- = \max_i f_{ij} \quad (10)$$

Step 2. Calculation of S_i and R_i using formulas (11) and (12).

$$S_i = \sum_{j=1}^n w_j \frac{(f_j^* - f_{ij})}{(f_j^* - f_j^-)} \quad (11)$$

$$R_i = \max_j w_j \frac{(f_j^* - f_{ij})}{(f_j^* - f_j^-)} \quad (12)$$

Step 3. Calculation of Q_i using Equation (13).

$$Q_i = v \frac{(S_i - S^*)}{(S^- - S^*)} + (1 - v) \frac{(R_i - R^*)}{(R^- - R^*)} \quad (13)$$

where

$$S^* = \min_i S_i, \quad S^- = \max_i S_i$$

$$R^* = \min_i R_i, \quad R^- = \max_i R_i$$

v means the weight adopted for the strategy of "most criteria". In the calculations in this study v equal to 0.5 was set.

Step 4. Graded variants in S , R and Q are ordering ascending. The outcome is provided in 3 ranked lists.

Step 5. The consensus is suggested regarding the good advantage and acceptable stability concerning vectors received in the preceding stage. The most favourable variant has the lowest value and is the leader of the ranking Q .

C. The SPOTIS Method

Stable Preference Ordering Towards Ideal Solution (SPOTIS) is a newly developed approach robust to the reverse ranking paradox. The approach is based on evaluation concerning the distance from the Ideal Solution Point of the given decision alternatives [14]. Additionally, it allows the introduction of an expert point against which the alternatives are evaluated. It can be presented as follows:

Step 1. Determine the normalized distances computed for Ideal Solution Point as Equation (14) demonstrates.

$$d_{ij}(A_i, S_j^*) = \frac{|S_{ij} - S_j^*|}{|S_j^{max} - S_j^{min}|} \quad (14)$$

Step 2. Calculate weighted normalized distances represented by $d(A_i, S^*) \in [0, 1]$ as Equation (15) shows.

$$d(A_i, S^*) = \sum_{j=1}^N w_j d_{ij}(A_i, S_j^*) \quad (15)$$

The resulting ranking calculated according to $d(A_i, S^*)$ values. Alternatives with lower values of $d(A_i, S^*)$ receive better positions in the ranking. The technique presented in this paper can be demonstrated by an alternative algorithm, included in [14]. However, the authors of this work provided and applied this option because it seems straightforward. Moreover, both versions supply identical outcomes.

D. Similarity coefficients

Ranking similarity coefficients such as the weighted Spearman coefficient r_w and the ranking similarity coefficient WS were used to examine the similarity of the rankings [15], [16]. In the case of the weighted Spearman coefficient, it was designed to reflect the most relevant alternatives that were rated the best. In contrast, the ranking similarity coefficient WS is an asymmetric ranking similarity coefficient where the alternatives at the top are given the most consideration. These coefficients can be represented by the formulas (16) and (17).

$$r_w = 1 - \frac{6 \cdot \sum_{i=1}^n (x_i - y_i)^2 ((N - x_i + 1) + (N - y_i + 1))}{n \cdot (n^3 + n^2 - n - 1)} \tag{16}$$

$$WS = 1 - \sum_{i=1}^n \left(2^{-x_i} \frac{|x_i - y_i|}{\max\{|x_i - 1|, |x_i - N|\}} \right) \tag{17}$$

III. STUDY CASE

Taking advantage of compromise ranking methods is an important topic that often arises in multi-criteria decision-making. We can determine the most flexible ranking under multiple conflicting criteria with them. In the following, we propose a new iterative approach based on the preferences of reference MCDM methods. The whole procedure can be described as follows:

Step 1. Evaluation of the formed decision matrix n by MCDM methods

Step 2. Create a decision matrix based on the ratings of the MCDM methods. Criteria types are determined based on the method's ranking type.

Step 3. Return to step 1 until the ranking $i - 1$ and the ranking i of the selected methods are the same, where ranking $i - 1$ denotes the ranking obtained from the evaluations entering the current decision matrix, and ranking i denotes the currently created ranking.

A decision matrix whose values were randomly generated from a uniform distribution $[0, 1]$ was used for the study. It is created from 4 criteria and 10 alternatives. For each of the considered criteria, the same weight was assigned, and it was assumed that the first two criteria are profit type while the last two criteria are cost type. Finally, the created decision matrix is presented using the table I.

TABLE I: Generated decision matrix consisting of alternatives $A_1 - A_{10}$ and criteria $C_1 - C_4$.

A_i	C_1	C_2	C_3	C_4
A_1	0.989490	0.592018	0.818605	0.031060
A_2	0.083740	0.507472	0.378180	0.976184
A_3	0.445502	0.029106	0.196421	0.897797
A_4	0.408798	0.982134	0.428897	0.126954
A_5	0.471495	0.042197	0.154756	0.379112
A_6	0.205953	0.113477	0.537154	0.396152
A_7	0.481553	0.793211	0.541687	0.265333
A_8	0.515628	0.270621	0.392020	0.281762
A_9	0.789527	0.050453	0.277638	0.179735
A_{10}	0.507601	0.545130	0.644899	0.954265

The obtained preferences of the different alternatives for each iteration are shown using the illustration 1, where 1a represents the preference for the TOPSIS approach, 1b represents the preference for the VIKOR approach, and 1c represents the preference for the SPOTIS approach.

For the TOPSIS approach, stabilization of ratings was faster than for the rest of the methods. For the TOPSIS approach, the range relative to the evaluated decision options increased. The first ratings obtained were in the range $[0.33748, 0.65286]$, while the last ratings were $[0, 1]$. Additionally, the spread of the obtained ratings also changed, where in the first iteration, the standard deviation was 0.11151, while in the last iteration, it was 0.354886.

The stabilization of SPOTIS approach ratings was slightly faster. As with the TOPSIS approach, the range of obtained ratings for subsequent iterations in the VIKOR approach increased. For the first iteration, the obtained preference values were in the range $[0.03838, 1]$, while for the last iteration, the values were in the range $[0, 1]$. The change in scatter of these values, on the other hand, is not as prominent as for the TOPSIS approach. Indeed, for the VIKOR approach, a standard deviation value of 0.32609 was obtained for the first iteration and 0.35500 for the last iteration.

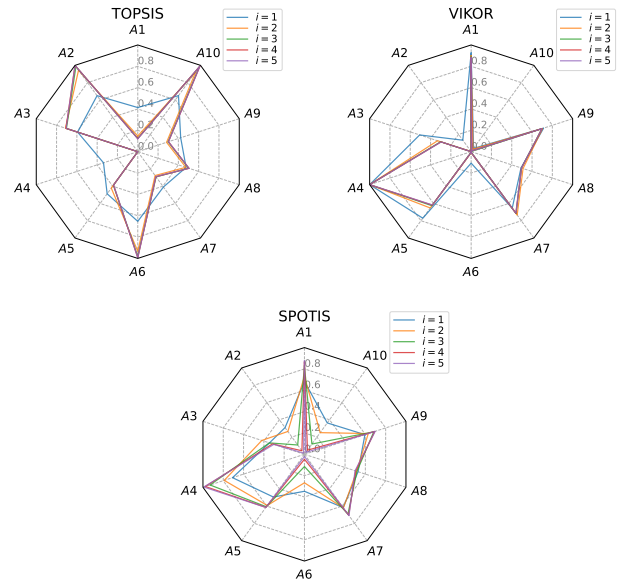

Fig. 1: Obtained preferences for TOPSIS, VIKOR, and SPOTIS methods in subsequent iterations of the proposed approach.

Among the considered methods, the SPOTIS approach had the slowest stabilization of ratings. Ranges of obtained assessments were increasing much slower than in the case of TOPSIS and VIKOR. In addition, the intervals obtained in the last iteration did not reach the limits of the SPOTIS method domain. For the first iteration, the score interval $[0.30921, 0.70877]$ was achieved, while the score interval $[0.01359, 0.99223]$ was achieved for the last iteration. Regarding the

scatter of values, it is similar to the TOPSIS method. In the first iteration, the standard deviation for the scores was 0.14258, while in the last iteration, it was 0.34732.

Using the Figure 3 the obtained rankings for each iteration are shown, where 3a shows the obtained ranking for the TOPSIS method, 3b shows the obtained ranking for the VIKOR method, and 3c shows the obtained ranking for the SPOTIS method.

The TOPSIS method, besides alternative A_4 , also obtained invariant positions in all iterations for two alternatives, i.e., alternative A_3 and alternative A_9 , which obtained fourth and seventh ranking positions, respectively. The only noticeable changes in the ranking positions for this method occurred between iteration one and iteration two.

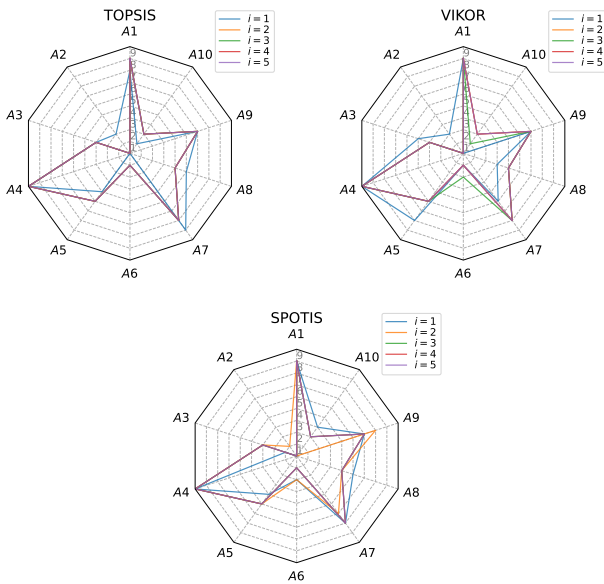

Fig. 3: Obtained rankings for TOPSIS, VIKOR, and SPOTIS methods in subsequent iterations of the proposed approach.

In the case of the VIKOR method, besides alternative A_4 , invariability of position for each iteration is also obtained by alternative A_1 . The alternative A_{10} received the most changes in its ranking position during all iterations, obtaining the first ranking position in the first iteration, obtaining the third-ranking position in the second, fourth, and fifth iterations, and obtaining the second-ranking position in the third iteration.

For the SPOTIS method, in addition to alternative A_4 , alternative A_1 also received an unchanged ranking position of 9. The most significant apparent change in ranking position for this method occurred for alternative A_{10} . In the first iteration, it achieved the fourth-ranking position. The second iteration achieved the first ranking position, and in the rest of the iterations, it achieved the third-ranking position.

A comparison of the rankings from the first and last iteration for the considered TOPSIS, VIKOR, and SPOTIS methods has been shown with the help of Figure 2. Referring to the TOPSIS method, only three alternatives, i.e., A_3 , A_4 , and A_9 are in

the same positions in the first and last rankings. The biggest difference is seen for alternative A_2 , where in the case of the first iteration, it reached the third-ranking position, while in the last iteration, it reached the first ranking position. In the case of the method, the same positions in both considered rankings were achieved by four alternatives A_1 , A_4 , A_6 , and A_9 . Only two alternatives differed by one ranking position. In contrast, four alternatives differed by two ranking positions. The SPOTIS method has the same ranking positions from the last iteration relative to the first iteration. Alternatives A_1 , A_2 , A_4 , A_7 , and A_9 remained in their ranking positions. Only one alternative differed by two positions among the rankings considered.

The Spearman's weighted correlation coefficient values for the individual rankings from iterations $i-1$ and i are presented using the table II. The TOPSIS method achieved the fastest, equally similar rankings, where as early as the third iteration, the value of r_w was 1.0. However, the VIKOR method only achieved this value in the fifth iteration, while the SPOTIS method achieved it in the fourth iteration. The most significant ranking differences are seen in the SPOTIS method, where in the first iteration, the value of r_w between the rankings was 0.85013, and in the second iteration, it was 0.93278.

TABLE II: Spearman weighted coefficient r_w values for $Rank_{i-1}$ and $Rank_i$.

Iteration	Methods		
	TOPSIS	VIKOR	SPOTIS
$i = 2$	0.92286	0.87107	0.85013
$i = 3$	1.0	0.98126	0.93278
$i = 4$	1.0	0.98126	1.0
$i = 5$	1.0	1.0	1.0

The values of the ranking similarity coefficient for the individual rankings from iterations $i-1$ and i are shown using the table III. The differences between the methods show a higher number of iterations in reaching the upper bound value of this coefficient. For example, the TOPSIS method reached the value of 1.0 in 3 iterations, the VIKOR method in 5 iterations, and the SPOTIS method in 4 iterations. Interestingly, the SPOTIS method obtained a lower value of the WS coefficient in iteration 3 than the value of the WS coefficient in iteration 2.

TABLE III: Rank similarity coefficient values WS for $Rank_{i-1}$ and $Rank_i$.

Iteration	Methods		
	TOPSIS	VIKOR	SPOTIS
$i = 2$	0.86730	0.82914	0.83945
$i = 3$	1.0	0.95089	0.83792
$i = 4$	1.0	0.95089	1.0
$i = 5$	1.0	1.0	1.0

IV. CONCLUSION

One of the essential issues of considering multiple MCDM methods evaluating the same set of decision alternatives is

Fig. 2: Visualization of ranking similarity from first iteration and last iteration for TOPSIS, VIKOR and SPOTIS approaches.

the compromise. This paper presents a new iterative approach related to the output values of TOPSIS, VIKOR, and SPOTIS methods to create successive decision matrices. The proposed approach is very flexible and guarantees the reliability of the results, as shown by the tests performed. All considered methods obtained a compromise ranking in a minimal number of iterations. Additionally, each of the considered methods in the last iteration obtained the same ranking as the other methods. High reliability of the obtained results is also guaranteed by the used similarity coefficients of the rankings r_w and WS , which reached the upper values of their ranges.

In future research, it would be helpful to consider the effect of the number of criteria on the number of iterations needed to reach a compromise for the methods. Additionally, it would be helpful to investigate the effect of different weight allocation methods on the final values of the proposed approach. Finally, to adapt the approach in future research, it would need to be verified with the reference ranking. Future research would also need to include a broader validation of the proposed approach with more MCDM methods. In addition, an aspect related to the impact of the number of alternatives and criteria on the final results would need to be addressed.

Abstract—We encounter uncertainty in many areas. In decision-making, it is an aspect that allows for better modeling of real-world problems. However, many methods rely on crisp numbers in their calculations. It makes it necessary to use techniques that perform this conversion. In this paper, we address the problem of score functions assessment regarding their effectiveness and usefulness in the decision-making field. The selected methods were used to convert the intuitionistic fuzzy set matrix into crisp data, then used in the multi-criteria assessment. Managing the theoretical problem showed that the used techniques provide high similarity values. Moreover, they proved to be helpful when dealing with intuitionistic fuzzy sets in the decision-making area.

I. INTRODUCTION

Many multi-criteria decision-making problems are considered in areas where data are represented using crisp numbers [1]. However, uncertainty problems are difficult to represent using this approach. Therefore, many tools based on classical arithmetic methods have been developed to model uncertainty in decision problems [2]. Such tools allow us to model real-world problems more accurately and reflect uncertain knowledge flexibly. Uncertainty modeling tools are often used in multi-criteria decision-making problems due to their high reliability [3].

Several popular tools can be used to represent uncertain knowledge. Among the classical approaches are fuzzy sets (FS), based on the idea related to partial membership [4]. Over the years, fuzzy sets have seen many developments: Hesitant Fuzzy Sets (HFS) [5], Fermatean Fuzzy Sets (FFS) [6], Picture Fuzzy Sets (PFS) [7], or Intuitionistic Fuzzy Sets (IFS) [8]. Indeed, the main advantage of the generalization of fuzzy sets is a new approach to uncertainty modeling that considers new degrees of membership, which gives the expert the ability to adapt to the characteristics of the problem [9].

One of the most popular tools based on the idea of fuzzy sets is Intuitionistic Fuzzy Sets. This tool introduces the possibility of determining the degree of membership and non-membership, thanks to which it is helpful in many areas such as decision-making and medical diagnosis [10], [11]. The wide use of Intuitionistic Fuzzy Sets has led to the development of this approach. A new similarity measure between intuitionistic fuzzy sets was proposed by Gohain et al. [12]. Szmids et al.

proposed a new proposal for attribute selection in models expressed by intuitionistic fuzzy sets [13]. Thao proposed new divergence measures of intuitionistic fuzzy sets from Archimedean t -conorm operators [14].

Using an extension of multi-criteria decision-making methods with fuzzy logic makes it possible to change the problem environment from crisp to uncertain. However, most Multi-Criteria Decision-Making (MCDM) related approaches operate in an environment based on crisp numbers [15]. To convert fuzzy data to crisp data, one can use point functions, whose idea in multi-criteria decision making was originally proposed by Chen and Tan [16]. However, the existence of multiple scoring functions means that their use within the same problem may be characterized by obtaining different results [17]. It creates a research gap that needs to be filled and determines which score function to select so that the results are satisfactory.

In this paper, we used five different score functions to convert Intuitionistic Fuzzy Sets to crisp values and assess the obtained decision matrix with the Measurement Alternatives and Ranking according to COmpromise Solution (MARCOS) method. The simulated data was used as the inputs to show the performance of the presented approach in the theoretical problem. Obtained results were then compared with selected correlation coefficients to point out the similarity of the used paths. The purpose of the study is to indicate the influence of the used score function regarding the differences obtained in multi-criteria ranking.

The rest of the paper is organized as follows. Section 2 presents the preliminaries of the IFS, the scores functions, the MARCOS method and selected similarity coefficients. In Section 3, the study case is shown, where the theoretical problem of the functioning of the different scores function is raised. Section 4 includes the description of the results obtained from the examined research. Finally, in Section 5, the summary is presented, and the conclusions are drawn.

II. PRELIMINARIES

A. Intuitionistic Fuzzy Sets

Definition II.1. An IFS A in a universe X is defined as an object of the following form:

$$A = \{ \langle x_j, \mu_j, \nu_j \rangle \mid x_j \in X \} \tag{1}$$

where $\mu : X \rightarrow [0, 1]$ and $\nu : X \rightarrow [0, 1]$ such that $0 \leq \mu_j + \nu_j \leq 1$ for all $x_j \in X$. The values of μ_j and ν_j represent the degrees of membership and non-membership of $x_j \in X$ in A respectively [17].

For every $A \in IFS(X)$ (the class of IFSs in the universe X), the value of

$$\pi_j = 1 - \mu_j - \nu_j \tag{2}$$

represents the degree of hesitation (or uncertainty) associated with the membership of element $x_j \in X$ in IFS A , where $0 \leq \pi_j \leq 1$.

B. Score Functions

The purpose of the score function is to convert the uncertain data representation to a crisp value. Different approaches to performing such an action obtain diverse values as a final output. Selected score functions and the formulas for their calculations are presented below [17], [18], [19].

$$S_I(X_{ij}) = \mu_{ij} - \nu_{ij} \tag{3}$$

$$S_{II}(X_{ij}) = \mu_{ij} - \nu_{ij} \cdot \pi_{ij} \tag{4}$$

$$S_{III}(X_{ij}) = \mu_{ij} - \left(\frac{\nu_{ij} + \pi_{ij}}{2} \right) \tag{5}$$

$$S_{IV}(X_{ij}) = \left(\frac{\mu_{ij} + \nu_{ij}}{2} \right) - \pi_{ij} \tag{6}$$

$$S_V(X_{ij}) = \gamma \cdot \mu_{ij} + (1 - \gamma) \cdot (1 - \nu_{ij}), \quad \gamma \in [0, 1] \tag{7}$$

where $S_I(X_{ij}), S_{II}(X_{ij}), S_V(X_{ij}) \in [-1, 1]$, $S_{III}(X_{ij}) \in [-0.5, 1]$, and $S_{IV}(X_{ij}) \in [-1, 0.5]$.

C. MARCOS method

The Measurement Alternatives and Ranking according to COMpromise Solution (MARCOS) method was introduced by Željko Stević in 2020 [20] as new multi-criteria decision making method, which was presented on study case of sustainable supplier selection in healthcare industries. This method provides new approach to solve decision problems, as it considers an anti-ideal and ideal solution at the initial steps of consideration of the problem. Moreover it proposes new way to determine utility functions and their further aggregation, while maintaining stability in the problems requiring large set of alternatives and criteria.

Step 1. The initial step requires to define set of n criteria and m alternatives to create decision matrix.

Step 2. Next, the extended initial matrix X should be formed by defining ideal (AI) and anti-ideal(AAI) solution.

$$X = \begin{matrix} & \begin{matrix} A_{I1} \\ A_1 \\ A_2 \\ \dots \\ A_m \\ A_I \end{matrix} \\ \begin{matrix} A_{II} \\ A_1 \\ A_2 \\ \dots \\ A_m \\ A_I \end{matrix} & \begin{bmatrix} x_{aa1} & x_{aa2} & \dots & x_{aan} \\ x_{11} & x_{12} & \dots & x_{1n} \\ x_{21} & x_{22} & \dots & x_{2n} \\ \dots & \dots & \dots & \dots \\ x_{m1} & x_{m2} & \dots & x_{mn} \\ x_{ai1} & x_{ai2} & \dots & x_{ain} \end{bmatrix} \end{matrix} \tag{8}$$

The anti-ideal solution (AAI) which is the worst alternative is defined by equation (9), whereas the ideal solution (AI) is the best alternative in the problem at hand defined by equation (10).

$$AAI = \min_i x_{ij} \quad \text{if } j \in B \text{ and } \max_i x_{ij} \quad \text{if } j \in C \tag{9}$$

$$AI = \max_i x_{ij} \quad \text{if } j \in B \text{ and } \min_i x_{ij} \quad \text{if } j \in C \tag{10}$$

where B is a benefit group of criteria and C is a group of cost criteria.

Step 3. After defining anti-ideal and ideal solutions, the extended initial matrix X needs to be normalized, by applying equations (11) and (12) creating normalized matrix N .

$$n_{ij} = \frac{x_{ai}}{x_{ij}} \quad \text{if } j \in C \tag{11}$$

$$n_{ij} = \frac{x_{ij}}{x_{ai}} \quad \text{if } j \in B \tag{12}$$

Step 4. The weight for each criterion needs to be defined to present its importance in accordance to others. The weighted matrix V needs to be calculated by multiplying the normalized matrix N with the weight vector through equation (13).

$$v_{ij} = n_{ij} \times w_j \tag{13}$$

Step 5. Next, the utility degree K of alternatives in relation to the anti-ideal and ideal solutions needs to be calculated by using equations (14) and (15)

$$K_i^- = \frac{\sum_{i=1}^n v_{ij}}{\sum_{i=1}^n v_{ai}} \tag{14}$$

$$K_i^+ = \frac{\sum_{i=1}^n v_{ij}}{\sum_{i=1}^n v_{ai}} \tag{15}$$

Step 6. The utility function f of alternatives, which is the compromise of the observed alternative in relation to the ideal and anti-ideal solution, needs to be determined. Its done using equation (16).

$$f(K_i) = \frac{K_i^+ + K_i^-}{1 + \frac{1-f(K_i^+)}{f(K_i^+)} + \frac{1-f(K_i^-)}{f(K_i^-)}} \tag{16}$$

where $f(K_i^-)$ represents the utility function in relation to the anti-ideal solution and $f(K_i^+)$ represents the utility function in relation to the ideal solution.

Utility functions in relation to the ideal and anti-ideal solution are determined by applying equations (17) and (18).

$$f(K_i^-) = \frac{K_i^+}{K_i^+ + K_i^-} \tag{17}$$

$$f(K_i^+) = \frac{K_i^-}{K_i^+ + K_i^-} \tag{18}$$

Step 7. Finally, rank alternatives accordingly to the values of the utility functions. The higher the value the better is an alternative.

D. Rank similarity coefficients

In order to compare the performance of the score functions, it would be useful to compare the rankings obtained after evaluating the values calculated using these functions. For this purpose, one can use rank similarity coefficients, which are often used in the literature to compare the resulting rankings. In the case of our study, we decided to use weighted Spearman’s correlation coefficient, which allows comparing rankings considering alternatives rated the best as more significant, and the WS ranking similarity coefficient, which the main assumption that the positions of top of the rankings has a more significant influence on similarity. The formulas for calculation of both coefficients are presented below in equation (19) for weighted Spearman’s correlation and equation (20) for WS rank similarity coefficient.

$$r_w = 1 - \frac{6 \cdot \sum_{i=1}^n (x_i - y_i)^2 ((N - x_i + 1) + (N - y_i + 1))}{n \cdot (n^3 + n^2 - n - 1)} \tag{19}$$

$$WS = 1 - \sum_{i=1}^n \left(2^{-x_i} \frac{|x_i - y_i|}{\max\{|x_i - 1|, |x_i - N|\}} \right) \tag{20}$$

III. STUDY CASE

The use of fuzzy sets in multi-criteria problems is a popular approach to solving problems where uncertainty arises. It allows greater flexibility in modeling input data, thus ensuring that the actual values that determine the parameters can be represented. However, in many cases, the criteria are not considered in a binary way, or the corresponding values are not known precisely. Fuzzy sets are one of the possible ways to represent uncertainty [21]. In the following, we focus our attention on the problem of using Intuitionistic Fuzzy Sets and different score functions to point out differences and similarities in the results obtained by using these tools.

A randomly generated decision matrix of 6 alternatives and 4 criteria was used in the study. Each matrix element is represented in the form of an IFS, where the first value indicates the value of decisiveness, while the second determines the degree of indecisiveness. Then, based on the score functions described above, conversions of the uncertain matrix to a matrices represented in the form of sharp numbers were performed. The generated matrix is shown in Table I.

The purpose of this operation is the need to indicate how a given score function affects the process of converting the data to a crisp form. Furthermore, it is crucial to determine whether the obtained matrices influence the obtained result through a multi-criteria analysis.

IV. RESULTS

A. Small example

Each type of previously presented score function was used to calculate crisp values for the matrix, which were shown in Tables respective to the used function. Table II presents values obtained by use of score function S_I . In the case of this score function, the spread of values in the range $[-1, 1]$ is around 1.69, which might mean that this specific score function differentiates well between alternative values.

TABLE II
CRISP SMALL DECISION MATRIX CALCULATED WITH S_I SCORE FUNCTION.

A_i	C_1	C_2	C_3	C_4
A_1	-0.039081	0.137740	-0.351916	0.691538
A_2	-0.558417	-0.455956	-0.649449	0.010564
A_3	-0.405613	-0.006527	0.361583	0.244181
A_4	-0.211142	-0.122171	-0.596428	0.159583
A_5	0.479454	-0.860203	0.830694	-0.110298
A_6	0.375293	0.328710	-0.797545	-0.822696

In Table III values calculated through execution of score function S_{II} are presented. This function is defined as the degree of membership minus the product of the non-membership and hesitation degrees, and even though it provides values from the same range as S_I , it can be seen that there are less negative values. Moreover, it is clear that in this example, the spread of calculated values is significantly smaller, as in this case, it’s around 0.99.

TABLE III
CRISP SMALL DECISION MATRIX CALCULATED WITH S_{II} SCORE FUNCTION.

A_i	C_1	C_2	C_3	C_4
A_1	0.041174	0.510925	0.243452	0.726737

A_4	-0.141754	0.392034	0.001438	0.324662
A_5	0.506242	-0.056156	0.849442	0.389249
A_6	0.383334	0.368876	-0.004356	-0.014798

The values obtained through the equation of score function S_{III} are shown in Table IV. This specific function operates in the range $[-0.5, 1]$ and is similar to the previous one but subtracts the arithmetic mean of the non-membership and hesitation degrees. As a result, provided values spread around 1.24, which translates into a high differentiation of the individual IFS values from the initial decision matrix.

The function S_{IV} is defined as the arithmetic mean of the membership and non-membership degrees minus the hesitation degree, which operates in the range $[-1, 0.5]$. The spread of the values obtained is around 1.06, which is slightly less than the previous function, but still shows that the IFS values are significantly differentiated from each other.

Values for last score function, namely S_V are presented in Table VI. This function represents a mixed result of positive and negative outcome expectations and operates in the same range as S_I and S_{II} . In this case, no negative values were received even though the range in which operates this function includes negative values. The spread of values received from this function is around 0.85, which is the lowest of presented score functions, considering its range.

Table VII presents preference values calculated by execution of MARCOS method. The values of preference for respective alternatives show the differences between considered score functions. The function S_I has irregular distribution, where only one value is significantly higher than the rest. But in the case of this function, the difference between the highest and lowest value is almost 0.3, which shows that the values do not have a high spread. On the contrary, the score function S_{II} provides a higher spread of 0.426, which might be preferable as it better distinguishes the differences between alternatives.

Score function S_{III} provides the smallest spread of values of all functions, namely 0.047. In such a case, it may be perceived as the difference between alternatives is insignificant, which is rarely preferable in case of decision problems. Evaluated values from score function S_{IV} yielded values that spread around 0.23, which is not the highest of presented score functions but might be useful in some cases. The last score function S_V provided the highest values in this Table, which might be visually better perceived by some decision-makers, as the differences between the alternatives are more readily apparent. The spread is around 0.33, which is the second-highest. Considering those values, functions S_{II} and S_V are the most representative and might be preferred by numerous decision-makers.

Figure 1 presents alternatives ranked by preference obtained through considered score functions. On the graph, the differences in evaluation are clearly visible as, for example, the score function S_{III} and S_I ranked alternative A_1 as the worst. In contrast, score function S_V ranked this alternative as the worst. On the other hand, almost all functions placed alternative A_6 fourth.

Fig. 1. Radar chart of MARCOS rankings.

To better visualize differences between presented score functions, rankings obtained by execution of the MARCOS method were compared using similarity coefficients. The first coefficient, namely Weighted Spearman’s correlation coefficient, is presented in Figure 2 as a correlation matrix in the form of a heatmap. This coefficient shows high similarities of rankings, which resulted through execution of score functions S_{II} and S_V . The previous examination showed that those two functions behave rather similarly, resulting in crisp values of IFS. The next pair of functions that are quite similar is S_{III} and S_I .

Fig. 2. Weighted Spearman’s correlation heatmap of MARCOS rankings for small decision matrix.

Additionally, the rankings were compared using the WS rank similarity coefficient, which as well is presented as a correlation matrix in the form of a heatmap as Figure 3. This coefficient shows which pair of compared rankings are not symmetrical, meaning that rankings are not identical neither the change in position is between exactly the same alternatives. As it can be seen once again, the pair S_I and S_{III} and pair S_{II} and S_V are characterized by a high degree of similarity. Moreover, comparing S_{II} and S_{IV} where S_{II} is treated as yields high similarity.

Fig. 3. WS correlation heatmap of MARCOS rankings for small decision matrix.

B. Big example

The next example that was taken into consideration consists of twenty alternatives and six criteria, which created the decision matrix presented in Table VIII. This approach provides a view of how specific score functions behave in larger multi-criteria decision problems.

Similarly to the smaller example, for a decision matrix consisting of IFS, crisp matrix was calculated using score

The first function, namely S_I yielded results presented in Table X. In this case, the standard deviation is 0.411, which is pretty high considering the range of this function, and it tells us that this specific function provided differentiated results. Moreover, the spread of those values is 1.76, which once again, as in the smaller numerical example, shows that this function makes use of a significant part of the range it operates in.

The results obtained using the S_{II} function are presented in the Table XI. In this case, values are characterized by a standard deviation of 0.29 and a spread of 1.16. Because this function operates in the same interval as S_I , namely $[-1, 1]$, they can be easily compared. And just as in the small numerical example, here too, the function S_{II} achieves smaller values of spread and standard deviation.

The score function S_{III} yielded values presented in Table XII. This function operates in a different range than the two previous. Considering the operative range of this function, the standard deviation value of 0.35 and spread of 1.39 are definitely high values. Results similar to those obtained in the small numerical example show that this function is stable and, at the same time, uses a large part of the interval in which it operates, providing relatively different values for the different alternatives.

Table XIII presents results obtained using function S_{IV} . The calculated spread of values, being around 1.32, similar to the functions S_I and S_{II} shows significant use of the range in which this function operates. Moreover, the standard deviation value of about 0.36 is close to the value obtained by

the function S_{III} , which might indicate that those functions might yield similar results.

Table XIV presents values calculated using function S_V . The standard deviation of calculated values is 0.21, whereas the spread value is 0.88. This function operates in the same range as functions S_I and S_{II} , which makes it the worst in diversifying values in comparison to those two. Even though a small standard deviation and spread characterize those values, this function might be useful when such values are expected.

TABLE XIV
CRISP BIG DECISION MATRIX CALCULATED WITH S_V SCORE FUNCTION.

The rankings obtained using the MARCOS method are grouped in the barplot shown in Figure 4. As can be seen, the obtained rankings differ significantly from each other, highlighting how important it is to choose an appropriate score

function. Additionally, it can be seen that on the podium of the ranking, the functions S_{II} , S_{III} , and S_V behave similarly. Still, in the further positions, significant discrepancies appear.

Fig. 5. Weighted Spearman's correlation heatmap of MARCOS rankings for big decision matrix.

The correlations of the rankings obtained from the big decision matrix data are shown in Figures 5 and 6 using heatmaps. The former, describing values for the weighted Spearman's correlation coefficient, shows high correlation values for all scoring functions, excluding the S_{IV} function. When it was used, the rankings calculated using the MARCOS method were significantly different.

Fig. 6. WS correlation heatmap of MARCOS rankings for big decision matrix

In contrast, the similarity of the rankings calculated with WS coefficient, shown in Figure 6 also indicated that the S_{IV} function showed the least consistent results with the other techniques used. The strongest similarity of rankings could be observed for the pair of methods S_I and S_V , which is 0.99. In contrast, the lowest consistency of rankings is 0.14 for the pair of methods S_{III} and S_{IV} . It indicates a significant discrepancy, which confirms the importance of the influence of the used scoring function on the obtained results.

C. WS comparison

To generalize the results and examine the similarities between the scoring functions used, 1000 simulations were performed for randomly generated decision matrices. Each of the generated matrices was subjected to the techniques described earlier, and the resulting crisp matrices were used in a multi-criteria analysis using the MARCOS method. The figures and tables below show the values calculated for the similarities of the obtained rankings. The WS rank similarity coefficient determined their consistency.

Visualizations for selected scoring functions are presented below, together with tables describing selected statistics of the obtained data. Figure 7 shows the distribution of ranking similarity values for the simulations performed. The rankings obtained using the S_{II} function were compared with the other methods. It is worth noting that for the functions S_{III} and S_V , the similarity of the rankings was high and concentrated in a narrow area. It shows a high consistency in how IFS conversions to crisp values are performed, which translates into high reproducibility in evaluating alternatives.

Fig. 7. Distribution of rankings similarity values using the S_{II} score function.

Table XV contains the statistics calculated from the simulations, including a comparison of the performance of the function S_I with the others. The variance and standard deviation were most negligible for the functions S_{III} and S_V , as confirmed by the data shown in Figure 7. On the other hand, the most significant standard deviation (0.384707) was seen when comparing the results obtained using the S_I function.

TABLE XV
STATISTICS FOR RESULTS OBTAINED USING THE S_{II} SCORE FUNCTION.

S_i	Standard deviation	Variance	Mean
S_I	0.384707	0.147999	0.446851
S_{III}	0.098412	0.009685	0.967222
S_{IV}	0.118155	0.013961	0.276578
S_V	0.060845	0.003702	0.910355

Fig. 4. MARCOS rankings for big decision matrix for S_I - S_V score functions.

Figure 8 shows the similarity distribution obtained for the comparison of results using the S_{III} function together with the other functions. As in the previous case, the highest similarity of rankings was observed for the functions S_{II} and S_V . In addition, the lowest consistency of results was noted when comparing with the ranking obtained using S_{IV} .

Fig. 8. Distribution of rankings similarity values using the S_{III} score function.

In turn, Table XVI describes the statistical values for the data obtained when comparing the rankings of the functions S_{III} with the others. The highest average ranking similarity value is 0.968083 for the method pair S_{III} and S_{II} . It demonstrates the high consistency of the results and shows that the two functions can be used interchangeably without much effect on the rankings in most cases.

TABLE XVI
STATISTICS FOR RESULTS OBTAINED USING THE S_{III} SCORE FUNCTION.

S_i	Standard deviation	Variance	Mean
S_I	0.391059	0.152927	0.452026
S_{II}	0.098297	0.009662	0.968083
S_{IV}	0.125697	0.015800	0.281541
S_V	0.093363	0.008717	0.906154

A visualization of the similarity distribution of the rankings obtained using the scoring function S_{IV} compared to the other functions is shown in Figure 9. It can be seen that none of the techniques used gives a strong rankings correlation. Instead, it causes the results obtained to vary, making it essential to bear in mind that the choice of scoring function directly impacts the results obtained.

Fig. 9. Distribution of rankings similarity values using the S_{IV} score function.

The determined statistical features for the comparisons of the function S_{IV} with the others are listed in Table XVII. The average correlation value oscillates between a value of

0.284001 for feature S_{III} and 0.522578 for feature S_V . It shows that a low consistency of results is obtained regardless of the technique used. On the other hand, the standard deviation for the similarity of the rankings is similar across all functions. It shows that the quality of the correlation is also affected by the input data, which can improve or worsen the consistency of the rankings.

TABLE XVII
STATISTICS FOR RESULTS OBTAINED USING THE S_{IV} SCORE FUNCTION.

S_i	Standard deviation	Variance	Mean
S_I	0.145812	0.021261	0.491630
S_{II}	0.124837	0.015584	0.289953
S_{III}	0.133394	0.017794	0.284001
S_V	0.147851	0.021860	0.522578

The similarity results for the other functions used in the study, i.e., S_I and S_V , show that the first function gives a similar similarity of rankings to the other techniques. Still, it oscillates within a value of 0.4, indicating low consistency of the results. On the other hand, the second function shows a high similarity of performance together with the functions S_{II} and S_{III} . It confirms the trend of possible interchangeable use of these functions in converting IFS to crisp values in multi-criteria problems.

V. CONCLUSION

Decision-making appears in many parts of life, so developing this particular branch of technology is crucial. However, often in decision-making problems, the problem of uncertainty and fuzzy values arise, which makes standard methods inapplicable. For this reason, it is worth taking a closer look at the possibilities of defuzzification of such problems.

In the study carried out, five score functions that allow achieving crisp values from intuitionistic fuzzy sets were compared. Each of the functions allows obtaining completely different values, which ultimately will significantly influence the results of the rankings. The study showed that in the smaller problem, the functions S_I and S_{III} should be preferred in decision-making problems because of the high distinction of individual values between them. However, the more extensive problem and simulations for 1000 decision matrices showed that functions S_{II} , S_{III} and S_V proved to be the most coherent techniques. Moreover, those functions presented high similarity in resulting rankings rendering them equally capable.

In future studies, it would be meaningful to address this issue regarding the reference ranking to compare the performance of the used score functions to indicate their reliability in practical problems. In addition, it would verify the usefulness and effectiveness of presented score functions in the decision-making process, which is obligatory to obtain credible results. In addition, future research would need to consider real decision-making tasks.

Abstract—Sustainable transport can contribute to many beneficial changes, such as reducing greenhouse gas emissions and pollutants into the atmosphere, improving the country’s energy security, and enhancing energy efficiency. Therefore, it is essential to provide a framework for reliable measurement of sustainable transport, enabling its evaluation in terms of diversity and the significance of renewable energy sources (RES). This paper presents a methodological framework for a multi-criteria assessment of sustainable transportation. The proposed framework is based on three multi-criteria decision analysis (MCDA) methods: SPOTIS (Stable Preference Ordering Towards Ideal Solution), ARAS (Additive Ratio Assessment), and TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution). The application of the proposed tool is demonstrated in an illustrative example of the assessment of European countries in terms of the share of alternative fuels in final energy consumption in road transport. The authors used the proposed framework to perform a comparative analysis considering three MCDA methods and two methods for determining the significance of evaluation criteria: equal and entropy weighting methods. The investigation has proven the practical suitability of the proposed tool in the problem of multi-criteria sustainable transport assessment. Furthermore, conducted analysis indicated that Sweden is characterized by the most sustainable transport in terms of significance and share of alternative fuels and RES and their diversification.

I. INTRODUCTION

CURRENT European environmental policy is focused on improving the ecological situation by reducing greenhouse gas (GHG) emissions [1]. The European Union’s goals also cover increasing the share of renewable energy sources (RES) in all fields, including road transport [2]. The road transport sector, dominated by petroleum-derived fuels, is the source of about 25% of total GHG emissions in Europe [3]. As a consequence, the use of alternative fuels that cause less atmosphere pollution and at the same time contribute to increased security of supply and optimal energy storage is widely promoted. The investigation presented in the paper [3] found that the increase in electric vehicles, gas-engine vehicles, and biofuel-powered vehicles contributes to more sustainable energy consumption and reduces carbon emissions.

The long-term goals of the European transport economy are to increase the use of alternative fuels. The strategy set by European Commission includes targets covering 60% reduction in carbon dioxide emissions from transport by 2050 compared to 1990 [4], [5], and 70% reduction of final oil consumption

by 2050. The mentioned strategy also covers reduced increase of congestion implied multimodal solutions and innovative technologies in transport improving energy efficiency [6]. This trend is promoted by technological development and targeted investments. This strategy is justified by the harmful effects of the combustion of conventional fuels on the environment, depletion of sources for conventional fuels, and the aim to reduce dependence on oil imports from countries beyond the European Union [7], [8]. Motor fuels consist of a group of liquid fuels, including gasoline, diesel, biofuels, and a group of gaseous fuels, such as liquefied petroleum gases (LPG). Gasoline is produced by the rectification of petroleum. The advantages of gasoline include its high calorific value, low sulfur content, and resistance to low temperatures. However, some of the disadvantages of gasoline include environmental pollution in its combustion process, depletion of petroleum reserves, and high-cost production. Increasing the popularity of alternative fuels regarding conventional fuels such as gasoline and diesel includes the promotion of fuels derived from sources such as natural gas, LPG, biofuels and hydrogen, and electricity [5]. Electric vehicles do not pollute the atmosphere with exhaust fumes. Moreover, when RES power them, they contribute to reducing carbon dioxide emissions and fossil fuel consumption. Electric vehicles are particularly advantageous in urban areas, where travel distances are usually short [2]. The development of electric vehicles contributes to sustainable transportation in urban areas due to limited emissions and noise. In addition, hybrid vehicles with an internal combustion engine and an electric motor are also being developed to help reduce toxins and carbon dioxide emissions in exhaust gases. Fuels that play a significant role in replacing petroleum-based fuels in road transportation are biogas and natural gas. Natural gas is advantageous compared to petroleum because of less environmental impact and lower cost. Natural gas has good potential as an alternative fuel in road transport due to its contribution to supply security and lower environmental impact than conventional fuels [9]. Currently, the market for natural gas vehicles, including compressed natural gas (CNG) and liquefied natural gas (LNG), is expected to grow, expanding the opportunities for various road participants and contributing to fuel market diversification. On the other hand, the long-term benefits of diesel oil, CNG, and LPG are limited

due to their fossil fuel character [2]. Bioethanol and biodiesel are other fuel types that contribute to making transport less dependent on oil. First generation bioethanol and biodiesel are obtained from agricultural crops, the second generation from lignocellulosic biomass and third generation biofuels are produced from algae. The popularity of biofuels is growing, influenced by environmental regulations [2]. In the case of biofuels, the constant development of technology makes it possible to produce them from different sources. In addition, biofuels are also blended with conventional fuels to reduce environmental pollution. Liquefied petroleum gas (LPG) is an alternative fuel derived from oil and natural gas but can also be derived from biomass. In terms of environmental impact, it is more eco-friendly than conventional fuels as it has lower emissions [10].

Indeed, as can be seen, reliable assessment requires the consideration of many different criteria [11], [12], which in the case of the problem analyzed in this paper are the different types of alternative fuels. Various alternative fuels contribute as a whole to the reduction of carbon dioxide and pollutants to the atmosphere and the reduction of dependence on imported petroleum-based fuels [6]. Moreover, the growing popularity of fuels from RES contributes to the realization of an essential principle of sustainable development, which is increasing the share of RES in all sectors of the economy [13], including road transport [14]. The need to simultaneously consider multiple fuels as criteria for the proposed framework for European country evaluation implies the application of multi-criteria decision analysis (MCDA) methods.

MCDA methods are widely used in transport assessment because they allow for building models with multiple criteria necessary to evaluate and consider them simultaneously. For example, the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) is widely popular among researchers and practitioners due to its wide range of applications in various fields and real-life decision problems [15]. The TOPSIS method was applied for transport assessment concerning energy and environmental efficiency divided into road, rail, and air transport sectors [6]. Multi-criteria evaluation of electric vehicles from the perspective of sustainable transportation priorities often considers comparative analysis involving several MCDA methods. In the framework proposed in [16], the authors used fuzzy extensions of three MCDA methods, including TOPSIS, Simple Additive Weighting (SAW), and Preference Ranking Organization Method for Enrichment of Evaluation (PROMETHEE), due to the necessity to regard the uncertainty occurring in the considered data on parameters and performance of evaluated vehicles, which is represented as interval or triangular fuzzy number (TFN). The vehicle rating for sustainable public transport presented in paper [17] employs a multi-criteria model built for evaluation using the ELECTRE (ELimination Et Choice Translating REality) TRI method. ELECTRE III was used to benchmark the buses recommended for the public transportation sector [18]. The authors of another work applied Multiattribute Utility Theory Approach (MAUT) method to determine consumer preferences

for alternative fuel vehicles [14]. In another research, the Analytical Hierarchy Process (AHP) was employed to evaluate alternative fuels in the context of sustainable transport [19]. Applying a multi-criteria decision analysis model based on the Additive Ratio Assessment (ARAS) method to assess alternative fuels for public transport was the main contribution of work [20]. The above literature review allows concluding that MCDA methods are widely and successfully used to evaluate sustainable transportation in many aspects. However, most research focuses on evaluating different vehicle technologies and fuels. On the other hand, attempts to rank countries concerning the share of alternative fuels in transport are rather limited. Therefore, it motivated the authors of this research to create a methodological framework based on MCDA methods that could support an information system for sustainable transport assessment, focusing on the share of alternative fuels in road transport.

This paper aims to present a multi-criteria approach, including the developed framework for measuring sustainable transport, particularly for assessing European countries considering sustainable energy consumption focused on alternative fuels in road transport. The objective of the research is to identify the country among the analyzed European countries where the share of alternative fuels is the most significant and diversified, which contributes to the reduction of greenhouse gas emissions and pollutants to the atmosphere and increases the country's independence from petroleum-derived fuels imports. The framework comprises a comparative analysis of results obtained using different MCDA methods to provide a reliable assessment [21], [22]. Another goal of the paper was to investigate the comparability of results obtained using three different MCDA methods based on distance measurement to reference solutions. Thus, the proposed approach involves employing three selected MCDA methods, including SPOTIS (Stable Preference Ordering Towards Ideal Solution), ARAS, and TOPSIS, for the multi-criteria evaluation of European countries regarding the share of alternative fuels in final Energy consumption in road transport. SPOTIS is a newly developed MCDA method that was introduced in 2020 [23]. The advantage of the SPOTIS method is resistance to the ranking reversal effect, which means that there is no ranking reversal when a particular alternative is removed or added from the evaluated set [24]. The mentioned advantage is possible because direct comparisons between alternatives are not required. In the SPOTIS approach, options are compared only with the ideal solution constructed by the decision-maker in the procedure of specification minimum and maximum bounds of each criterion which define multi-criteria problem to be solved. An additional advantage of the SPOTIS method is identifying the whole domain model due to building the ideal solution point defining the considered problem [23]. To confirm the results' reliability, the authors compared the results of the SPOTIS method with the results given by two other benchmark MCDA methods, ARAS and TOPSIS. The authors chose both benchmarking methods regarding a similar principle to the SPOTIS method, namely considering

the ideal solution in evaluating alternatives. The ARAS method evaluates alternatives by determining each option's degree of utility (efficiency) concerning the ideal alternative [25]. The TOPSIS method, on the other hand, takes into account their distance from the ideal and anti-ideal solutions in calculating the utility function values for each alternative [26]. In contrast to ARAS and TOPSIS, the SPOTIS method is more flexible because it allows the decision-maker to define the ideal solution independently instead of solely based on the data in the decision matrix [23]. Mentioned MCDA methods, besides providing a decision matrix containing performance values against the criteria, also require assigning a value of each criterion importance to the decision-maker, i.e., a weight. A strategic approach to fulfilling the long-term needs of all modes of transportation is recommended to be based on a full suite of alternative fuels without preference for particular types [9], [27]. The authors assigned equal weights to the criteria with this fact in mind. However, the authors also included in performed analysis objective weights determined by the Entropy method for a more comprehensive and reliable research procedure.

The rest of the paper is organized as follows. Section II provides basic assumptions and mathematical formulas of methods applied in this research. Next, in section III the practical problem of European countries' assessment regarding the share of alternative fuels in consumption in final energy consumption in road transport. Then, in section IV research results are presented. In section V discussion of obtained results is provided. Finally, in the last section VI the summary and conclusions are given, and future work directions are drawn.

II. METHODOLOGY

This section provides the basics and main assumptions of the particular MCDA methods employed in this research and other supporting techniques as criteria weighting methods and correlation coefficients for determining obtained rankings consistency for benchmarking analysis.

A. The SPOTIS Method

The subsequent stages of the SPOTIS (Stable Preference Ordering Towards Ideal Solution) method are given based on [23].

Step 1. Define the MCDA problem by determining the bounds containing the minimum and maximum performance values included in evaluated decision matrix $S = [s_{ij}]_{m \times n}$ for each criterion. The minimum and maximum bounds For each criterion $C_j (j = 1, 2, \dots, n)$ is determined respectively by S_j^{min} and S_j^{max} .

Step 2. Determine the Ideal Solution Point (ISP) represented by S^* . When for the criterion C_j larger score value is preferable, then the ISP for criterion C_j is $S_j^* = S_j^{max}$. From the other side when for the criterion C_j lower score value is favored, then the ISP for criterion C_j is $S_j^* = S_j^{min}$. The ideal multi-criteria best solution S^* is denoted by coordinates $(S_1^*, S_2^*, \dots, S_n^*)$.

Step 3. Determine the normalized distance values d_{ij} based on ISP for each considered alternative A_i according to Equation (1).

$$d_{ij}(A_i, s_j^*) = \frac{|S_{ij} - S_j^*|}{|S_j^{max} - S_j^{min}|} \quad (1)$$

Step 4. Calculate of the weighted normalized averaged distance values for each alternative A_i as Equation (2) shows

$$d(A_i, s^*) = \sum_{j=1}^n w_j d_{ij}(A_i, s_j^*) \quad (2)$$

where w_j represents the weight of j th criterion.

Step 5. Create ranking of evaluated alternatives by sorting $d(A_i, s^*)$ values in ascending order. Alternative with the lowest $d(A_i, s^*)$ value is the best scored option.

B. The ARAS Method

The following stages of the ARAS method are presented below, based on [25].

Step 1. Normalize the decision matrix using the Sum normalization method applying Equation (3) for benefit criteria and Equation (4) for cost criteria.

$$r_{ij} = \frac{x_{ij}}{\sum_{i=1}^m x_{ij}} \quad (3)$$

$$r_{ij} = \frac{\frac{1}{x_{ij}}}{\sum_{i=1}^m \frac{1}{x_{ij}}} \quad (4)$$

where $X = [x_{ij}]_{m \times n}$ represents the decision matrix containing performance values of m alternatives in respect to n evaluation criteria.

Step 2. Calculate the weighted normalized decision matrix $D = [d_{ij}]_{m \times n}$ according to Equation (5)

$$d_{ij} = r_{ij} w_j \quad (5)$$

where w_j denotes j th criteria weight values.

Step 3. Compute the optimality function S_i for each i th alternative as Equation 6 presents.

$$S_i = \sum_{j=1}^n d_{ij} \quad (6)$$

Step 4. Calculate the utility value U_i for each i th alternative according to Equation (7)

$$U_i = S_i / S_o \quad (7)$$

where S_o denotes the optimality function value for the optimal alternative. U_i values are in the range from 0 to 1. The option which has the highest U_i value is regarded as the best scored alternative. Thus, the ranking of the ARAS method is constructed in descending order according to U_i values.

C. The TOPSIS Method

The successive steps of the TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) method are demonstrated as follows, based on [26].

Step 1. Normalize the decision matrix with performance values by chosen normalization technique, for example, the Minimum-Maximum normalization method, as performed in this research. Another normalization method can also be employed for this aim. In the Minimum-Maximum normalization r_{ij} normalized values of decision matrix are calculated by Equation (8) for benefit criteria and (9) for cost criteria.

$$r_{ij} = \frac{x_{ij} - \min_j(x_{ij})}{\max_j(x_{ij}) - \min_j(x_{ij})} \quad (8)$$

$$r_{ij} = \frac{\max_j(x_{ij}) - x_{ij}}{\max_j(x_{ij}) - \min_j(x_{ij})} \quad (9)$$

where $X = [x_{ij}]_{m \times n}$ represents the decision matrix containing performance values of m alternatives in respect to n evaluation criteria.

Step 2. Calculate the weighted normalized decision matrix as Equation (10) presents.

$$v_{ij} = w_j r_{ij} \quad (10)$$

where w_j denotes j th criteria weight values.

Step 3. Determine the Positive Ideal Solution (PIS) using Equation (11) and Negative Ideal Solution (NIS) by Equation (12). PIS includes the maximum values of the weighted normalized decision matrix, while in NIS, its minimal values are contained. Since the normalization of the decision matrix was applied in the previous step, there is no necessity to separate the criteria into profit and cost types.

$$v_j^+ = \{v_1^+, v_2^+, \dots, v_n^+\} = \{\max_j(v_{ij})\} \quad (11)$$

$$v_j^- = \{v_1^-, v_2^-, \dots, v_n^-\} = \{\min_j(v_{ij})\} \quad (12)$$

Step 4. Calculate the distance from PIS (13) and NIS (14) of each alternative. The default measure for distance determination in TOPSIS method is Euclidean distance.

$$D_i^+ = \sqrt{\sum_{j=1}^n (v_{ij} - v_j^+)^2} \quad (13)$$

$$D_i^- = \sqrt{\sum_{j=1}^n (v_{ij} - v_j^-)^2} \quad (14)$$

Step 5. Calculate the utility function value for each evaluated alternative as Equation (15) shows. The C_i value is within the range from 0 to 1, and the alternative with the highest C_i value is the most preferred. Thus, the ranking of the TOPSIS method is constructed by descending ordering of alternatives according to their utility function values.

$$C_i = \frac{D_i^-}{D_i^- + D_i^+} \quad (15)$$

D. The Equal Weighting Method

The equal weighting method is the simplest technique for determining criteria significance values. However, for several MCDA problems assigning equal weights to evaluation criteria is appropriate. Equal weights are determined as Equation (16) shows.

$$w_j = 1/n \quad (16)$$

where n represents number of evaluation criteria.

E. The Entropy Weighting Method

The entropy weighting method is an objective weighting technique based on Shannon's entropy theory. Shannon entropy performs an important role in information theory. For example, entropy is used to measure the information included in data, which is contained in a two-dimensional decision matrix in the case of MCDA problems [1]. The following stages of the Entropy weighting method are given as follows, based on [1].

Step 1. Normalize the decision matrix using sum normalization method to obtain normalized decision matrix $P = [p_{ij}]_{m \times n}$ where $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$, m represents number of alternatives and n denotes number of evaluation criteria.

Step 2. Calculate the entropy value E_j for each j th criterion as Equation (17) shows.

$$E_j = -\frac{\sum_{i=1}^m p_{ij} \ln p_{ij}}{\ln m} \quad (17)$$

Step 3. Calculate d_j value according to Equation (18).

$$d_j = 1 - E_j \quad (18)$$

Step 4. Calculate the entropy weights for each j th criterion as Equation (19) shows.

$$w_j = \frac{d_j}{\sum_{j=1}^n d_j} \quad (19)$$

F. The Weighted Spearman Rank Correlation Coefficient

The r_w correlation coefficient is determined to compare two rankings x and y according to Equation (20). N denotes a number of rank values x_i and y_i [1].

$$r_w = 1 - \frac{6 \sum_{i=1}^N (x_i - y_i)^2 ((N - x_i + 1) + (N - y_i + 1))}{N^4 + N^3 - N^2 - N} \quad (20)$$

G. The Spearman Rank Correlation Coefficient

The Spearman Rank Correlation Coefficient is computed to determine the correlation between two rankings x and y according to Equation (21)

$$r_s = 1 - \frac{6 \cdot \sum_{i=1}^N (x_i - y_i)^2}{N \cdot (N^2 - 1)} \quad (21)$$

where N denotes size of vector x and y [28].

III. THE PRACTICAL PROBLEM OF EUROPEAN COUNTRIES' ASSESSMENT REGARDING ALTERNATIVE FUELS IN TOTAL FINAL ENERGY CONSUMPTION IN ROAD TRANSPORT

This paper aims to assess 32 selected European countries regarding sustainable energy consumption considering alternative fuels in road transport. For this purpose, the authors developed the framework based on annual data on final energy consumption in road transport provided by Eurostat, considering different alternative fuel types [29] (accessed on 2 May 2022). Furthermore, to analyze the up-to-date situation, the authors gathered the most recent data available in the Eurostat database for 2020. This Eurostat frame excludes off-road use of fuels from road transport (for example, cranes and excavators at construction sites, harvesters, and tractors at fields). However, it is included in the respective consumption sector. Road transport includes passenger and freight transport, domestic and international transport, urban and intercity transport performed on public road networks, and publicly accessible private road network, including both the free and the paid part of the road network systems. The authors assessed sustainable energy consumption in road transport by incorporating the percentage share of each considered alternative fuel type in the annual total final energy consumption in road transport. Table I presents alternative fuel types playing the role of evaluation criteria in the proposed framework. Each criterion has to be maximized because the objective is to increase the share of alternative fuels in total road transport fuel consumption. Due to the recommended lack of preference for particular alternative fuel types, each criterion has the same significance value represented by equal weights. The last two columns of Table I provide the significance values of the criteria of the proposed evaluation framework, i.e., the different types of alternative fuels considered.

TABLE I
EVALUATION CRITERIA INCLUDING SHARE OF ALTERNATIVE FUEL TYPES IN TOTAL FINAL ENERGY CONSUMPTION IN ROAD TRANSPORT.

C_j	Criterion name	Unit	Aim	Equal Weight	Entropy Weight
C_1	Blended biodiesels	[%]	Max	0.1111	0.0103
C_2	Liquefied petroleum gases	[%]	Max	0.1111	0.0754
C_3	Blended biogasoline	[%]	Max	0.1111	0.0198
C_4	Natural gas	[%]	Max	0.1111	0.0543
C_5	Pure biodiesels	[%]	Max	0.1111	0.1875
C_6	Biogases	[%]	Max	0.1111	0.1370
C_7	Electricity	[%]	Max	0.1111	0.0770
C_8	Pure biogasoline	[%]	Max	0.1111	0.2403
C_9	Other liquid biofuels	[%]	Max	0.1111	0.1985

Data for the mentioned criteria were collected from the Eurostat database available at the link [29] for 32 selected European countries listed in Table II. The value of each criterion is provided in the Eurostat database in the unit called a Thousand tonnes of oil equivalent (TOE). For a representative and reliable countries assessment in terms of sustainable fuel consumption in transport sustainability, the authors calculated the share of each fuel as a percentage of

total annual fuel consumption based on the available values. Such an approach allows for an individual approach for each country that adequately considers the needs and capacities of countries resulting from independent aspects such as geography, area, and population size.

Figure 1 displays, in the form of a stacked column chart, the percentage of alternative fuels in final Energy consumption in road transport in 2020 for which investigation was performed. The chart analysis allows us to observe the largest share of alternative fuels as a whole in the considered domain for Sweden (SE). Blended biodiesels represent the most significant part of this share (C_1). Apart from that, pure biodiesels (C_5), blended biogasoline (C_3), biogases (C_6), and electricity (C_7) account for a significant share. The chart provided demonstrates the dominance of blended biodiesels (C_1) and LPG (C_2) share among the countries assessed. The countries where energy consumption from electricity in road transport is most noticeable are Norway (NO), Iceland (IS), and Sweden (SE). However, an evaluation based only on the cumulative values of individual fuels is insufficient because it does not allow for simultaneous consideration of the degree of diversification of fuels and decision-makers preferences concerning particular fuels. Therefore, to consider the mentioned aspects, a framework employing MCDA methods is recommended [30].

IV. RESULTS

This section presents the results of each MCDA method individually for the equal and entropy evaluation criteria weights. The results include MCDA utility function values for each alternative, rankings constructed based on them, and analysis of obtained rankings convergence represented by correlation coefficient values.

A. Results for the Equal Weighting Method

Table III contains utility function values and rankings received for evaluated countries concerning equal weights assigned to considered criteria with SPOTIS, ARAS, and TOPSIS methods. For the SPOTIS method, the alternative that received the lowest utility function value is the best-ranked alternative. On the other hand, for the ARAS and TOPSIS methods, the alternative that has the highest utility function value is the best option.

It can be observed that when the criteria are assigned equal weights, all MCDA methods used in this research indicated Sweden (SE) as the country with the most significant share of alternative fuels in final Energy consumption in road transport. Another well-scored country is Norway (NO), ranked second in all rankings. Norway was ranked better than Bulgaria (BG) and Ukraine (UA), although its overall share of alternative fuels is lower. Norway was nevertheless ranked second because it has a more diversified share of alternative fuels than Bulgaria and Ukraine. Therefore, diversification of alternative fuels in final energy consumption in transport is promoted, and MCDA methods enable appropriate reflection of this fact. Norway's share of alternative fuels in road transport consists of a mix covering six different alternative fuel types, namely

Fig. 1. Shares of alternative fuels in annual final energy consumption of evaluated countries in road transport in 2020.

C_1 , C_2 , C_3 , C_4 , C_6 , and C_7 . A particularly favorable result is implicated by the highest percentage of energy consumption of C_7 by Norway. For Bulgaria (BG), the share of four alternative fuel types (C_1 , C_2 , C_3 , and C_4) and the trace share of C_7 are noticeable. In the case of Ukraine (UA), the contribution of only three types of alternative fuels covering C_2 , C_3 , and C_4 is evident. Bulgaria (BG) was ranked third in SPOTIS and TOPSIS, while it was ranked sixth in the ARAS ranking. Bulgaria (BG) was thus rated better than Ukraine (UA), supported by a more diversified alternative fuel mix. The worst-rated country by all MCDA methods applied in the

presented research was Cyprus (CY), which has a low share of only three alternative fuels comprising C_1 , C_2 , and C_3 , with the most significant share of C_1 . Besides the two top places and the last place in the obtained rankings of the evaluated countries, some divergences are noticeable depending on the MCDA method used. The divergences occurring in each ranking are visualized in the column chart in Figure 2. Due to the observed differences in rankings, objective measures of convergence of compared rankings were applied to establish the degree of divergence of particular rankings, which are two ranking correlation coefficients: the Weighted Spearman Rank

Fig. 2. Comparison of rankings obtained using three different MCDA methods for Equal criteria weights.

Correlation Coefficient r_w and the Spearman Rank Correlation Coefficient r_s .

High values of these coefficients close to 1 indicate high convergence of the compared rankings. Figure 3 displays the r_w and r_s coefficient values calculated for the pairwise comparisons of the obtained rankings. The correlation coefficient r_w calculated for the compared SPOTIS and TOPSIS rankings has the highest value, equal to 0.9887. Furthermore, the correlation coefficient r_w between SPOTIS and ARAS

rankings is also high, 0.9417. The lowest correlation of 0.9254 was observed for comparing ARAS and TOPSIS rankings. The values of the second correlation coefficient r_s are similar. High correlation values for comparisons of SPOTIS ranking with rankings provided by benchmarking methods TOPSIS and ARAS confirm the results' reliability.

Fig. 3. Correlation between rankings for Equal criteria weights.

B. Results for the Entropy Weighting Method

This section presents the second part of the research for the evaluation criteria weights determined by the objective Entropy method. This part of the analysis was conducted to objectify the research results. Objective criterion weighting techniques are used to determine criterion weights based on the outcomes of mathematical models. Objective weighting techniques are useful when determining reliable subjective weights by the decision-maker is not possible, for example, due to the lack of experts with the necessary knowledge of the multi-criteria problem to be solved. Figure 4 displays a chart comparing SPOTIS, ARAS, and TOPSIS rankings for entropy weights visually. Table IV contains the utility function values and rankings of applied MCDA methods obtained for evaluated countries. The leader of all rankings is Sweden (SE), as it was noticed for the use of equal criteria weights. Germany (DE) took second place in all rankings employing Entropy criteria weights, which is different from equal criteria weights. Germany was ranked fifth for equal weights by the SPOTIS method, fourth by the TOPSIS method, and third by the ARAS method.

Fig. 4. Comparison of rankings obtained using three different MCDA methods for Entropy criteria weights.

Third place in all rankings was achieved by Luxembourg (LU), which in the case of applying equal weights ranked fourth in ARAS, seventh in TOPSIS, and eighth in SPOTIS. The better performance of Germany and Luxembourg is reflected in the fact that they are the only of the evaluated countries that have a C_9 share in final energy consumption in road transport. In the case of entropy weights, this is the second most important evaluation criterion. The results show that the determined criterion weights are critical for the MCDA evaluation results. For the weights determined by the

entropy method in the problem analyzed in this paper, the highest weight was assigned to criterion C_8 . It is reflected in Spain's better performance (ES) for entropy weights than equal weights. Spain is the only country besides Sweden with a C_8 share in final energy consumption in road transport. Cyprus (CY) was ranked last for entropy criteria weights, as was the case with assigning equal importance to the evaluation criteria.

It can be observed that the convergence of obtained rankings is higher for entropy weights than for equal weights. The high convergence of the rankings is confirmed in Figure 5, displaying the values of correlation coefficients r_w and r_s .

Fig. 5. Correlation between rankings for Entropy criteria weights.

The calculated correlation coefficients are the highest for comparing SPOTIS and TOPSIS rankings (r_w equal to 0.9913 and r_s equal to 0.9912). However, there was also a strong correlation between the SPOTIS and ARAS rankings (r_w equal to 0.9804 and r_s equal to 0.9791). The lowest correlation was observed between the ARAS and TOPSIS rankings. Conducted research showed that the strength of correlation between the determined country rankings for entropy weights is analogous to equal weights. The highest similarity is noticed in the case of SPOTIS and TOPSIS rankings.

The performed investigation proved that Sweden has the most significant and diversified share of alternative fuels in final energy consumption in road transport among 32 European countries evaluated in this research. Furthermore, the high score obtained by this country was confirmed by all MCDA methods, applying both criteria weighting methods.

V. DISCUSSION

It is difficult to compare various alternative fuels because different conflicting goals characterize them. For example, the popularization of electric vehicles contributes to reducing greenhouse gas emissions and may also increase water consumption. Therefore, the sustainability framework recommends evaluating technologies or alternatives by considering multiple dimensions to promote sustainability in each dimension [31], [32], [33]. Many countries intend to replace fossil fuel vehicles with electric vehicles soon. For example, among these countries is Norway, which ranked a high second in this study for equal criteria weights in SPOTIS, ARAS, and TOPSIS and has the largest share of electricity in final energy consumption in road transport [34]. Although the transition to electric vehicles seems promising for sustainable transportation, there are some difficulties such as high purchasing costs, exploitation problems, limited range and long charging times for vehicles, and limited availability of necessary charging infrastructure. Due to the mentioned aspects, it is essential to consider different types of alternative fuels in the sustainable development of transportation. Sweden is a representative example of a country characterized by a high diversification of types of alternative fuels in road transport, identified as the leader of the rankings in this research.

In Sweden, an important goal is the decarbonization process involving increasing the share of alternative fuels in road transport [35]. Therefore, there is considerable interest in exploiting alternative fuels in road transport in Sweden. Biogas is recognized as an alternative fuel in Sweden with significant environmental and social advantages. The technological maturity of biogas is noticeable in the area of biomethane buses. Positive aspects of biogas that public organizations appreciate in Sweden are energy security, nutrient recovery, and reduced environmental pollution. In addition, the Swedish regional transport government contributes to popularizing renewable fuels in the bus fleet [36]. Many public organizations in Sweden focused on bus transportation tendering processes want to contribute to sustainability improvements, including a transformation to reduce fossil fuels and increase renewables in bus transportation. Buses are dominant in public transport in Sweden. Bus fuels in public transport have seen a noticeable transformation over the past two decades. At the beginning of the 21st century, the bus fleet used fossil fuels almost entirely, while in 2017, more than 60% of buses used fuels produced from RES. In Sweden, the transformation towards more alternative fuels for road transport is mainly taking place on a regional level and includes bioethanol, biomethane, biodiesel, HVO (Hydrotreated Vegetable Oil), and most recently, electric buses. Electric buses are very popular, and their role is expected to increase in the future, especially in city centers [37]. The results confirm that diversification and development of alternative fuels at multiple levels contribute to a good evaluation of a country using an evaluation framework that includes different MCDA methods and criteria weighting techniques, as illustrated by an example of Sweden.

VI. CONCLUSIONS

The aim of this paper was to present a methodological framework that can be useful in supporting an information system for measurement and assessment of sustainable transport focused on the share of alternative fuels in final energy consumption in road transport. The application of the proposed framework was demonstrated in the illustrative example of the assessment of 32 selected European countries regarding the importance of the share and diversification of alternative fuels in road transport. The research results proved the usefulness of the presented approach in the analyzed problem of sustainable transport assessment. The applied approach indicated Sweden as the best-evaluated country concerning the criteria in the demonstrated evaluation framework. The obtained results showed that the MCDA-based approach has an advantage over simple aggregation methods. It allows a multidimensional assessment with simultaneous consideration of multiple criteria. Such an approach is compatible with the principle of diversification of alternative fuels in sustainable transport. Moreover, models based on MCDA methods enable prioritization of individual fuel types by assigning them significance values that may be equal or determined by objective or subjective weighting methods.

The results encourage the follow-up of research work in the scope of multi-criteria evaluation of sustainable transport considering different fuel types. Further work includes research on the influence of other methods of prioritizing assessment criteria on the results and exploring other MCDA methods, such as PROMETHEE II, which provides different preference functions [38]. Another interesting research direction is the temporal assessment of sustainable transport, considering the dynamics of performance changes in the analyzed time interval. Further work directions also include consideration of the economic aspects of alternative fuels and the level of self-sufficiency in the context of alternative fuel supply.

ACKNOWLEDGMENT

The work was supported by the project financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019-2022, Project Number 001/RID/2018/19; the amount of financing: PLN 10.684.000,00 (J.W. and A.B.).

Abstract—This study aims at proposing the framework of critical success factors (CSFs) for the adoption of an electronic document management system (EDMS) in government units and at identifying such factors for local government in Poland. The study was based on a literature review, interviews with field experts, and a questionnaire survey. The results suggest a framework of 23 factors that were considered prerequisites for successful EDMS adoption. The factors are grouped into four categories to reflect economic, organizational, technological, and legal issues. Furthermore, nine CSFs for EDMS adoption in Polish local government units were identified. They include legislation imposing the obligation on EDMS adoption, technological readiness, quality of back-office software and its integration with front-office and ERP software, employees' awareness of EDMS adoption, front- and back-office software functionality and scope of its adoption, and information security. It is worth noticing that there are no economic factors in the set of the nine CSFs.

I. INTRODUCTION

In recent years, government units in Poland have been and still are subject to significant organizational and technological changes, like the public administration in the world [1]–[6]. The main goal of the changes is to improve the quality of government services and to adapt them to the constantly increasing demands of customers, especially citizens and businesses [7]–[9]. Information-communication technologies (ICTs) in public administration are necessary to provide an electronic communication contact with the customer, minimizing the number or even eliminating the need for customer visits to a government unit [10]. The implementation of appropriate technological solutions related to the introduction of organizational and legal changes allows government clients to safely submit documents, applications, and letters to government units, and receive responses through the same channel [11].

To meet such challenges, government units adopt ICT to improve customer relations and support internal processes related to document collection and management [12]–[15]. Solutions of this type are called electronic document management systems (EDMS). Generally, EDMS may be defined as “an umbrella concept covering various technologies including document imaging, document retrieval, reporting,

character recognition, document management, workflow, form processing, content management, digital signature management, storage and archiving technologies, business process management, and collaboration.” [16]

In this paper, EDMS is specified as an approach in the electronic management of documents across document entire lifecycle, i.e., ranging from submitting a document by a client to a government unit electronically to a client receiving a response from a government unit electronically. In this approach, paper circulation at each step of the document lifecycle is eliminated. In general, EDMS requires two kinds of software, i.e., front- and back-office software. Front-office software is available for government clients and provides them with electronic forms through which they can submit a relevant document (application, letter) to government units and receive a response.¹ On the other hand, back-office software is available to employees of government units and is used to manage these documents (applications, letters) in government units, i.e., register documents received from clients, manage processes related to these documents, and prepare and send responses to clients.²

The provisions of the law in force in Poland allow government units to resign from paper documents in whole or in part, depending on the type of public service provided [17]. Nonetheless, despite this possibility, a small number of government units decide to switch to EDMS³ as the so-called basic system [18], i.e., one in which all processes and activities related to the provision of individual public services and the handling of related documents take place electronically without the use of paper documents.

However, the studies conducted so far have not analyzed the reasons why processes in government units are still carried out in the traditional – paper system, even though they have the appropriate software. The factors determining EDMS adoption as the basic system were also not analyzed, and no recommendations were given to improve this state of affairs. Such knowledge gaps represent a research gap. Therefore, it allowed us to formulate the research objectives, which are: proposing the framework of critical success factors (CSFs) for the adoption of EDMS in government units and identifying such factors for local government in Poland.

Consistent with the purpose, the remainder of the paper is organized as follows. Section 2 reviews the current research

¹ In Poland, the front-office software that the client uses to submit letters, applications, and documents to government units is called ESP. On the other hand, ePUAP is an example of front-office software that allows clients to submit letters, applications, and documents and receive responses.

² In Poland, such software is called eSOD.

³ In Poland is called EZD.

on CSFs for EDMS adoption in organizations. Section 3 describes the research methodology and the data set used for the empirical work. Based on these data, Section 4 presents the results, including a framework of CSFs for EDMS adoption within government units and an assessment of the factors. Section 5 provides the study's contributions, implications, and limitations as well as considerations for future investigative work.

II. THEORETICAL BACKGROUND

The methodological basis for identifying the determinants of EDMS adoption is provided by the theory of CSFs [19]. According to this theory, CSFs are those areas and operations which determine success in a project and lead to obtaining desired objectives. Pursuant to this theory, it is, therefore, necessary to identify the most significant areas in electronic document management on which activities must be focused to achieve the assumed goal – success in adopting EDMS. This goal is directly related to the elimination of paper documents and the paper flow of documents.

The literature presents the results of research on the determinants of EDMS systems, however, they mainly concern business organizations, and only few relate to public organizations [16], [20].

Smyth pointed out two CSFs for the adoption of EDMS in public organizations, i.e., an information-sharing culture and senior management support [21].

Johnston and Bowen noted that EDMS adoption in organizations requires the engagement of policymakers and EDMS users and EDMS integration with the organization's processes. They also emphasized the necessity to educate, advise, and support EDMS users [22].

Hjelt identified three CSFs for EDMS in business organizations, i.e., EDMS and information quality, support quality (training, guidelines), and technological infrastructure [23].

Dyczkowski, in his research on improving the efficiency of IT projects in public management in Poland, listed among the success factors of IT projects, which is undoubtedly EDMS adoption: involvement of EDMS users, management support, experienced project manager, competent project team, efficient communication in the project team, clear business goals of the project, defined EDMS user requirements, ICT infrastructure standards and linking EDMS adoption goals with the organization's business strategy and with the personal goals of team members (motivation) [24].

Based on the study of Australian local and state government units, Nquyen indicated nine success factors for EDMS in the public sector: adequate and ongoing training and support, top management support, staff recordkeeping awareness and practice, excellent strategies of change management, good project management, motivated great implementation team, clear business vision and plan, system performance monitoring and management, well-prepared file plan [25].

McLeod et al. examined the literature on electronic documents and record management from 1996 to early 2009

[20]. They uncovered 44 case studies of EDMS adoption, of which 16 were related to the public sector. The following CSFs for EDMS projects were indicated: aligning projects with business objectives, chief executive commitment, and support of officers, involving employees at all levels within the organization including external stakeholders. According to the authors, communication, piloting and testing, change management, training, and support for users, policies, and guidelines are as critical as good planning and project management, and the existence or development of necessary "infrastructures" and demonstrating benefits.

Based on insights gleaned from a case analysis of practices and experiences of a local government in the UK, that has implemented an EDMS, Jones identified a set of lessons for EDMS adoption which include feasibility study, senior executive commitment, aligned business strategy, project management, improvements to user ownership, training, system utilization, information management processes, printing strategy, and post-implementation review [26].

Based on the existing studies and content analysis approach, Abdulkadhim et al. indicated 14 common factors related to the adoption of EDMS divided into three types, i.e., organizational, technical, and users [27]. Organizational factors included top management support, budget/cost, strategic plan, legislation environment, and collaboration. Technical factors embraced ICT infrastructure, EDMS implementation team, security and privacy/trust, user requirements, data quality, and system integration. Users factors were related to awareness, staff training, and resistance to change.

Alshibly et al. composed a list of 37 factors that were considered prerequisites for successful EDMS adoption. Then these 37 factors were grouped into six categories, i.e., technological readiness, top management support, training and involvement, resource availability, system-related factors, work environment, and culture [16]. Through a questionnaire survey and factor analysis, the authors confirmed that the factor group "system-related factors" was deemed the most important of all for successful EDMS implementation, followed by "top management support," "resource availability," "training and involvement," "technological readiness," and "work environment and culture."

Aziz et al. identified ten factors based on a literature review, UTAUT (Unified Theory of Acceptance and Use of Technology) and ISSM (Delone-McLean Information System Success Model), as well as experts' opinions. The factors included performance expectancy, effort expectancy, social influence, facilitating condition, system quality, information quality, service quality, the perceived value of records, policy, and security [28].

In summary, the most frequently mentioned success factors are top management support, internal communication, change management, a competent and properly selected project team, training for employees, as well as appropriate hardware and software infrastructure.

III. RESEARCH METHODOLOGY

A multi-step approach was applied in our research methodology:

1. Reviewing the literature. The general purpose of this step was to critically synthesize and appraise the current state of knowledge related to CSFs for EDMS adoption. The search for the appropriate literature began with five bibliographic databases, that is Ebsco, Science Direct, Web of Science, and Scopus. This was achieved by developing a relevant set of keywords and phrases such as “critical success factors,” “CSFs,” “electronic document management” “electronic government,” “success factors,” and “success” in all possible permutations and combinations (taking into consideration the logical AND, and OR as appropriate) and conducting a corresponding search. In addition, Google Scholar was searched to find some relevant literature, especially describing Polish experiences in EDMS adoption for governments. The set of CSFs for EDMS identified in the literature is included in Table I.
2. Defining and verifying the prototype framework of CSFs. This step required a combination of theoretical knowledge and practical experience. Only theoretical knowledge based on the literature review and practical experience based on working in practice can provide insights to indicate meaningful factors influencing e-government. Therefore, the factors indicated based on the literature were analyzed in the context of Polish government circumstances and the prototype CSFs for EDMS adoption were indicated on the basis of action research. The action research means the very close longstanding collaboration of the research team members with public government units in Silesia Province (Poland) which plan, implement, and use EDMS. Then, the 23 prototype CSFs were examined and verified through the means of interviews with field experts, i.e., employees of local and state governments who are responsible for EDMS adoption.
3. Creating the final framework of CSFs. At this stage, a survey questionnaire covering 23 CSFs was prepared. The survey question was: On a scale of 1-5 state to what extent do you agree that the following factors influence the adoption of EDMS in government units? A Likert scale was used to evaluate the strength of the influence of particular factors on EDMS adoption, which represented: 1 – disagree strongly, 2 – disagree, 3 – neither agree nor disagree, 4 – agree, 5 – agree strongly, respectively. Then, the pilot study was conducted in which 28 experts participated. The selection of experts was made in such a manner as to combine the knowledge and experience of scholars, researchers, and practitioners. The experts were employees of local and state government (25) who are responsible for ICTs and e-government adoption, and professors of Polish universities (3) who conduct studies and empirical research on e-government. The pilot study was carried out between May 8, 2017 and June 9, 2017. The variability and reliability analyses (the value of Cronbach’s alpha coefficient was 0.91) of data collected proved the internal consistency of factors and underpinned the reasoning behind the decision to conduct further study of the 23 CSF framework. Additionally, at this step, some

- experts proposed minor changes in the prototype factors related to confusing or incomprehensible statements. It allowed us to elaborate on the final framework of CSFs (Table I) and the final version of the survey questionnaire.
4. Assessing 23 CSFs proposed and identifying CSFs for government units in Silesia Province. Having applied the Computer Assisted Web Interview, the survey questionnaire was uploaded to the website and submitted to all 185 government units in Silesia Province. The respondents were advised that their participation in completing the survey was voluntary. At the same time, they have been assured anonymity and guaranteed that their responses would be kept confidential. The data were collected between July 11, 2017 and September 19, 2017. After screening the responses and excluding outliers, there was a final sample of 110 usable, correct, and complete responses. It means that 60% of all government units from Silesia Province completed their responses fairly, in all respects. The sample ensured that the error margin for the 95% confidence interval was 5%. Government units varied in their types and the number of employees. The data were stored in Microsoft Excel format. Using the Statistica package and Microsoft Excel, the data were analyzed. The descriptive statistical analysis was employed to identify CSFs (Table I). The following statistics were calculated: min, max, mean, median (MDN), standard deviation (SD), and coefficient of variation (CV).

IV. FINDINGS AND DISCUSSION

Based on the literature review (step 1 of the research process), the interviews with experts (step 2 of the research process), and the pilot survey questionnaire (step 3 of the research process), a framework of 23 economic, organizational, technological, and legal CSFs for the adoption of EDMS in government units were identified (Table I).

Table I presents the detailed descriptive analysis of all 23 CSFs examined. Out of these factors, nine factors were identified that obtained the highest values of the arithmetic mean (above 4.0) and the median (equal to 4.0) in the study. These factors have been seen as critical for EDMS adoption as the base system. Using the Pareto [29] principle as critical among 23 factors, it was necessary to focus on five of them, those that determine EDMS adoption to the greatest extent. However, in the end, this number of factors was extended to nine, which was due to the slight differences in the values of their arithmetic means and medians, and expert opinions.

To sum up, the results of statistical analyses allowed us to recommend nine CSFs for EDMS adoption in Polish government units. These are: Legislation imposing the obligation on EDMS adoption (X23); Back-office software functionality and scope of its adoption (X19); Employees’ awareness of EDMS adoption (X4); Quality of back-office software (X14); Integration of back-office and ERP software (X13); Technological readiness (X11); Integration of front-and back-office software (X12); Information security (X18); Front-office software functionality and scope of its adoption (X20).

TABLE I.
A FRAMEWORK OF CSFs FOR THE ADOPTION OF EDMS IN GOVERNMENT UNITS AND DESCRIPTIVE STATISTICS OF 23 CSFs

No	Description	Type*	Min	Max	Mean	MDN	SD	CV (%)
X23	Legislation imposing the obligation on EDMS adoption	L	2	5	4.19	4	0.851	20.31
X19	Back-office software functionality and scope of its adoption	T/O	2	5	4.15	4	0.768	18.50
X4	Employees' awareness of EDMS adoption	O	1	5	4.13	4	1.015	24.58

X10	Management concepts adoption	O	1	5	3.08	3	0.858	27.84

* Notes: E – Economic, O – Organizational, T – Technological, L – Legal

It is worth noticing that there are no economic factors in the set of the nine CSFs. In the opinion of the government units examined, technological, organizational, and legal factors are the most important ones. A critical factor for EDMS adoption is a legal factor, i.e., legislation imposing the obligation on EDMS adoption in government units. Introducing mandatory electronic communication stimulates and accelerates front- and back-office software adoption for document management for a broad range of government processes, government services, relations with government clients, and relations between government employees within government units and between government units. Critical factors also include technological factors, i.e., technological readiness, quality of back-office software, and its integration with front-office and ERP software. Such integration is of great importance in improving the organization of work, processes, and document workflow, e.g., by eliminating duality – the need to conduct double document workflows (paper and electronic). The challenges, benefits, and risks of EDMS adoption also have a critical impact on EDMS adoption. The CSFs for EDMS consist of organizational and technological factors, including organizational solutions and methods, as well as technological issues. One of them is front- and back-office software functionality and the scope of its adoption, i.e., the

usage of EDMS for managing various documents and providing various government services for government clients. Information security, which includes technological solutions, organizational procedures, and legal regulations, is also critical for EDMS adoption.

V. CONCLUSIONS

Generally speaking, the adoption of EDMS poses a challenge and thus is an interesting subject of research. This research puts an effort to make some contribution to the development of studies on EDMS, especially on their successful adoption in government units. It explores the EDMS concept, indicates CSFs for EDMS based on the literature review, and identifies a comprehensive set of CSFs based on action research and expert interviews. Finally, it proposes the framework of CSFs for EDMS adoption. The research findings showed technological, organizational, and legal factors matter in accelerating the ability and willingness of government units to adopt EDMS successfully.

The CSFs framework proposed can be useful for transition, emerging, and developing economies, especially in Central and East Europe. Government practitioners could find answers to an important question: which areas and activities of government units should be a primary focus for achieving

the most satisfying results of transforming traditional document management to electronic document management. This research suggests important issues for programming, building, and developing EDMS.

The framework of critical success factors for EDMS adoption shown in this research should be explored in greater depth. By focusing on longitudinal research and expanding the number of government units examined from various countries, the authors hope to thoroughly verify this framework. Furthermore, there is also a need to conduct more in-depth research on EDMS, especially in: (1) exploring “best practices” to be used to successfully adopt EDMS, (2) investigating the “demand-side” of EDMS from the viewpoint of government units clients, i.e., citizens and businesses view, and (3) identifying strengths, weaknesses, opportunities, and threats of EDMS in government units. Those will be considered as future work.

28th Conference on Knowledge Acquisition and Management

KNOWLEDGE management is a large multidisciplinary field having its roots in Management and Artificial Intelligence. Activity of an extended organization should be supported by an organized and optimized flow of knowledge to effectively help all participants in their work.

We have the pleasure to invite you to contribute to and to participate in the conference "Knowledge Acquisition and Management". The predecessor of the KAM conference has been organized for the first time in 1992, as a venue for scientists and practitioners to address different aspects of usage of advanced information technologies in management, with focus on intelligent techniques and knowledge management. In 2003 the conference changed somewhat its focus and was organized for the first under its current name. Furthermore, the KAM conference became an international event, with participants from around the world. In 2012 we've joined to Federated Conference on Computer Science and Systems becoming one of the oldest event.

The aim of this event is to create possibility of presenting and discussing approaches, techniques and tools in the knowledge acquisition and other knowledge management areas with focus on contribution of artificial intelligence for improvement of human-machine intelligence and face the challenges of this century. We expect that the conference&workshop will enable exchange of information and experiences, and delve into current trends of methodological, technological and implementation aspects of knowledge management processes.

TOPICS

- Knowledge discovery from databases and data warehouses
- Methods and tools for knowledge acquisition
- New emerging technologies for management
- Organizing the knowledge centers and knowledge distribution
- Knowledge creation and validation
- Knowledge dynamics and machine learning
- Distance learning and knowledge sharing
- Knowledge representation models
- Management of enterprise knowledge versus personal knowledge
- Knowledge managers and workers
- Knowledge coaching and diffusion
- Knowledge engineering and software engineering
- Managerial knowledge evolution with focus on managing of best practice and cooperative activities
- Knowledge grid and social networks

- Knowledge management for design, innovation and eco-innovation process
- Business Intelligence environment for supporting knowledge management
- Knowledge management in virtual advisors and training
- Management of the innovation and eco-innovation process
- Human-machine interfaces and knowledge visualization

TECHNICAL SESSION CHAIRS

- **Hauke, Krzysztof**, Wroclaw University of Economics, Poland
- **Nycz, Malgorzata**, Wroclaw University of Economics, Poland
- **Owoc, Mieczyslaw**, Wroclaw University of Economics, Poland
- **Pondel, Maciej**, Wroclaw University of Economics, Poland

PROGRAM COMMITTEE

- **Andres, Frederic**, National Institute of Informatics, Tokyo, Japan
- **Berka, Petr**, Prague University of Economics and Business, Czech Republic
- **Bodyanskiy, Yevgeniy**, Kharkiv National University of Radio Electronics, NURE, Ukraine
- **Chomiak-Orsa, Iwona**, Wroclaw University of Economics and Business, Poland
- **Christozov, Dimitar**, The American University in Bulgaria
- **Chudán, David**, University of Economics, Prague, Czech Republic
- **Hernes, Marcin**, Wrocław University of Economics and Business, Poland
- **Jan, Vanthienen**, Katholieke Universiteit Leuven, Belgium
- **Kliegr, Tomáš**, Prague University of Economics and Business, Czech Republic
- **Kluza, Krzysztof**, AGH University of Science and Technology, Poland
- **Ligęza, Antoni**, AGH University of Science and Technology, Poland
- **Mercier-Laurent, Eunika**, Jean Moulin Lyon 3 University, France
- **Perechuda, Kazimierz**, Wroclaw University of Economics and Business, Poland

- **Schreurs, Jeanne**, Hasselt University, Belgium
- **Singh, Pradeep**, KIET Group of Institutions, Delhi-NCR, Ghaziabad, U.P., India
- **Singh, Yashwant**, Jaypee University of Information Technology Wanknaghat, India
- **Sobińska, Małgorzata**, Wrocław University of Economics and Business, Poland
- **Stankosky, Michael**, The University of Scranton, USA
- **Tanwar, Sudeep**, Institute of Technology, Department of CE, Nirma University, Ahmedabad (Gujarat), India
- **Tyagi, Sudhanshu**, Thapar Institute of Engineering & Technology, India
- **Vasiliev, Julian**, University of Economics – Varna, Bulgaria
- **Zhu, Yungang**, College of Computer Science and Technology, Jilin University, China

Case Study of Designing Interface of the AGH Students Information Bulletin Work Support System

Natalia Nitarska, Krzysztof Kluza, Piotr Wiśniewski, Mateusz Zaremba, Antoni Ligeza

Abstract—In this paper, we present a case study research on designing the system interface for handling organisational processes implemented in the editorial office of the AGH-UST Students Information Bulletin. A study of the basic formal and legal sources, such as regulations and statutes of the organisation, was also carried out for the proper identification of goals, responsibilities, and organisational structure. To deepen this knowledge, social research was carried out, which examined how the users use the current solutions and what their needs are related to the designed system. Based on the research results and the formulated conclusions, the diagrams of business processes carried out in the organisation were created. In the discovered process models, we defined reusable sub-processes using Justified Aggregation of Neighboring Activities. Finally, the information architecture of the target system solution, followed by a medium-fidelity interface were designed.

Index Terms—Business Process Management, BPM, BPMN, process modelling, process models, process knowledge acquisition

I. INTRODUCTION

THE TERM “user experience” was first used in 1993 by Don Norman, who defined his role in the team and job position at Apple Computer Inc. (now Apple Inc.) as a “User Experience Architect” [1]. The company was undoubtedly the forerunner of a breakthrough in thinking about electronic tools used today by a broad and diverse audience. A milestone in thinking about the use of computers and the design of their interfaces was the introduction of the Macintosh computer in 1984 [2]. This was an all-in-one computer with a graphics interface, keyboard, and mouse. Although all of these components had been manufactured and used before, the Macintosh forever changed the perception of what a computer could be used for and who could use it. It was not the unique, exploratory technology behind its success but the well-designed user experience associated with it. The combination of a convenient, intuitive design and an understandable graphical interface meant that computers from laboratories and large companies also moved into homes and became a part of everyday life. Almost 30 years later, our knowledge of interface design has grown so much that, in engaging in this field, we are aware that, in a field so close to human beings, we must take into consideration not only design issues but also psychology, sociology, and many other fields – both technical and humanistic.

In this paper, we discuss the problem associated with the lack of a unified, transparent system for handling work

and processes based on the example of the AGH-UST Media Center at AGH University of Science and Technology in Krakow, Poland. These problems have become particularly noticeable at the time of the organisation’s transition to a remote working mode. The example used in this paper is the design of a process handling interface implemented in one of the four independent editorial boards – the AGH Students’ Information Bulletin. The history of this student magazine dates back to about 1988. Since then, the Bulletin’s editorial team has greatly expanded its scope and today, it not only publishes a periodic student magazine but also maintains a website or podcasts.

Problems in managing the editorial board, which is characterised by frequent replacement of members, became significantly apparent after the transition to a remote mode of operation. When new members are introduced to their procedures completely remotely, and it is impossible to show, add, and explain some processes in person, it is easy to see that functional solutions for coordinating work are introducing mistakes to the new users. In addition, the systems and applications that are used in the organisation not only do not fully meet the needs of its members but using them without discerning the working in the organisation in the land-based mode becomes a challenge.

The purpose of this paper is to present the process of designing a user interface for handling the work of the AGH-UST Student Information Bulletin, being able to almost replace the existing currently used toolbox (tools and platforms), both for project coordination and communication among members. Moreover, the implementation of this system could allow for significant improvement and ease of work for regular members, as well as clearly facilitate the implementation of new, constantly emerging issues organisations. The platform would also allow for more efficient documentation of the work of the editorial board.

This paper is organised as follows: Section II presents the basic principles of user interface design, including the related psychological aspects. Section III presents the motivation behind our research and the analysed problem, including interviews with the study participants. The part of our research that covers process discovery was described in Section IV. We present the final design of the user interface in Section V and finally, Section VI summarises our contribution presented in this paper and provides the overview of the future works.

II. USER INTERFACE DESIGN

According to the book *"Human-Computer Interaction"* [3], the term *HCI* has been in common use since the early 1980s, but research in this area began early in the last century. The original focus was the study of human interaction with machine. As the state of the art and computerization advanced, the focus of the research was changed to human-computer interaction. Information technology (hidden today under the acronym *IT*) is another field that has influenced the development of *HCI*. It is for it today that consideration of *HCI* principles is crucial, as an integral part of the design process. The user (understood as both an individual and a team) interacts with the computer to achieve a specific goal.

A. Shneiderman's Eight Golden Rules of Interface design

A precursor to viewing computer systems from the perspective of the user interface is American computer scientist Ben Shneiderman [4]. Shneiderman today is considered to be one of the third "fathers of User Experience Design". His book *"Designing the User Interface"* [5] published in 1987 was the first complete textbook on how to design user interfaces. Most importantly, the book featured the first set of universal principles for designing UI. The Eight Golden Rules of Dialog Design (*"Eight Golden Rules of Dialog Design"*) and the body of Shneiderman's work and research were also the basis for the development of the field of User Experience Design. Thus, Shneiderman's 8 Golden Principles can be cited [6], [5]:

- 1) **Strive for Consistency**. As the author points out – it is the one most often violated, but failure to follow it is also the easiest to fix and avoid. The principle refers to the need to use the same terminology when giving the same information and marking the same actions, but also to use color codes for interactive and fixed elements, the same icons, call-to-actions, or consistent sequences of actions in similar situations. As defined in the Interaction Design Foundation's article on the Golden Rules – "...the user should be able to use knowledge from one action to perform another." [6]. Situations where consistency is extremely difficult or impossible should be kept to a minimum. Adherence to this principle helps users learn to use the system more quickly and in sequence, achieve their intended goals more quickly.
- 2) **Enable Frequent Users to Use Shortcuts**. As the frequency of system use increases, the desire to reduce the amount of interaction time increases. Hidden commands, remembering once entered data, auto-complete data, and all shortcuts are appreciated by regular users. Following this principle allows users to achieve their goals faster and easier.
- 3) **Offer Informative Feedback**. The principle refers to the fact that with every user action, there should be feedback from the system, telling about the success or lack of success of the action. It is important that the information should be given in an accessible way to the user, rather than being, for example, just a message

about the error code that occurred. The information can be modest for less complex actions, such as displaying the requested information when the user clicks on an item, or more extensive for more complex operations, such as a pop-up with a message about why the action failed.

- 4) **Design Dialog to Yield Closure**. The action the user takes should have a clear beginning and end. This means that the user at each step of the process should know at which point they are. An example of a correct fulfillment of this principle would be the display of a thank you message after a purchase has been made in an online store, or the announcement that data has been successfully updated after the user has made changes to the system.
- 5) **Offer Simple Error Handling**. The system should inform the user of errors it makes, their severity, and type, but should also do so in a manner that is as benign as possible. The interface must not make the user feel guilty for making an error. A way to satisfy this principle might be to indicate specific places, such as form fields, that have been filled in incorrectly or not filled in, rather than having the system reject the entire form only after it has been filled in and submitted without indicating where the error occurred.
- 6) **Permit Easy Reversal of Actions**. The principle refers to allowing the user to reverse their own actions. In performing any action, users will make mistakes, and so the key to reducing their frustration when they make them is to ensure that at any time their mistake can be corrected. Shneiderman also emphasises that knowledge of the ease of undoing actions encourages users to explore unexplored options. Undo options should be possible after a single action as well as a sequence of them.
- 7) **Support Internal Locus of Control**. The principle encourages putting the user in the role of initiator of system actions. The user should feel that it is the user who decides how the system functions - after all, the system is a tool in the user's hand, designed to help the user achieve the desired goal. The user should have a sense of complete control over the processes occurring in the virtual space.
- 8) **Reduce Short-Term Memory Load**. The principle refers to the limited capacity of human short-term memory. To the best of today's knowledge, it can hold 7 plus or minus two items. Therefore, the interface should not require the user to remember more information at once. Additionally, the usage of the interface should be based on recognising elements more than recalling them from memory, which generates more stress for users and consumes more time.

All of the above principles provide a basis for further consideration and development of knowledge about user interface design and human-computer interaction.

B. Ten Usability Heuristics

Another important step in the development of the field of user experience design was Jakob Nielsen's formulation of the 10 Usability Heuristics in 1994. It is a set of ten core principles of interaction design. Nielsen's heuristics are still used today and still form the basis of usable systems design. The content of the heuristics has remained unchanged to this day, but the article in which they were presented was enhanced this year with examples and explanations of the [7]. In reference to Shneiderman's golden rules presented earlier, the essential step seems to be Nielsen's addition of two rules:

- 1) **Match between system and the real world.** The principle refers to enabling users to use the knowledge acquired in the real world to function efficiently in the virtual world. We are talking both about using language familiar to the user, instead of industry jargon, and about following concepts and schemes of operation familiar from the real world. The issue of basing digital products on knowledge about the functioning of the real world was later extended by Don Norman.
- 2) **Aesthetic and minimalist design.** This principle pioneered the perception of aesthetics as an important element of an interface, affecting its perception, and, more importantly, the comfort and effectiveness of its use. Nielsen also cautions against placing redundant information in the interface that is merely decorative or noise. Any unnecessary information distracts from the vital information.

C. Basic psychological concepts related to design

A significant influence on knowledge development in the field of user experience design was Don Norman's book *"The Design of Everyday Things"*, first published in 2002 [8]. It is from it that further concepts that are the basis of today's knowledge in this field were drawn. As Don Norman writes, *"For a product to have transparency, its designers must correctly apply five basic psychological concepts [...], namely affordances, signifiers, constraints, mappings, and feedback. Nevertheless, there is a sixth principle, perhaps the most important of all: the conceptual model of the system"* [9]. Thus, definitions of the basic concepts can be quoted after Norman:

- 1) **Affordances** – is the ability to perform a particular action that an object manifests. Whether an object manifests a given affordance is also dependent on the person who interacts with it. For an adult, a staircase manifests the affordance of ascending or descending it, and from this follows its function – to enable upward or downward movement. For a child who cannot move up or down stairs, stairs will not manifest this affordance, as so they will not serve the same function either. Affordances allow us to identify the function of objects without having to use labels or put additional information on them. The opposite concept to affordances is anti-affordance [10] – the perceived inability

to take a particular action. Importantly, objects should clearly manifest their affordances and anti-affordance so that the user can easily identify them. The problem begins when an object manifests an affordance that is not related to its actual function. This is, for example, a doorknob that manifests an affordance for pressing it, but under pressure, it does not fall at all and does not cause the door to open.

- 2) **Signifiers** – is a specification of how or where an action is performed. Markers can be placed on an object intentionally or be found on it by accident. Markers are often confused with affordances. The concepts are not the same; however, the boundary between the two has also been drawn by Norman – *"Affordances specify what actions are possible. Markers tell you where to perform them. One and the other are necessary"* [9]. Thus, we can call a marker a button in the interface of a system dedicated to cell phones. This marker uses the affordance of touching the screen, which the cell phone had much earlier than the system in it.
- 3) **Constraints** – Constraints (like the knowledge that the user has) can be divided into those that occur in the world and those that occur in the mind. Both types accompany users when using both digital and physical products, and so they should be considered during design:
 - **Boundaries in the world** are those that do not provide a physical way to perform a particular action. This is, for example, the lack of a handle or wheels on a heavy object, the lack of a handle on a door, or the lack of finger holes in a bowling ball,
 - **Boundaries in mind** are related to cultural code, among other things. These are activities that the user must have learned not to do, but the design of the product or system allows for it. It is, for example, the fact that we typically use a computer mouse using our hands, although its design does not preclude using it with our feet or other body parts.
- 4) **Mappings** – (in user experience design) is a way of mapping/showing the relationship between controls and controls. The more natural the mapping, the better the functionality. Norman also distinguished three levels of mapping:
 - **Best mapping** – controls placed on elements controlled.
 - **Second best mapping** – controls placed closest to the controlled elements.
 - **Third of the best mappings** – controls are placed in the same configuration as the controls.
- 5) **Feedback** – this issue has already been directly addressed by one of Goldman's Golden Rules, but has been significantly developed by Norman in *"Design Everyday"* [9]. Among other things, he pointed out

that the type of feedback should be appropriate to the action. Feedback that is too pushy can distract the user and introduce unnecessary chaos. Another mistake to avoid is too much feedback, which is only meant to be part of the process the user goes through, not the backbone of it. In addition to this, the time in which the feedback is given to the user is important. Even a slight delay can cause anxiety, which should be avoided.

- 6) **System conceptual model** – according to an article on mental models on the NNgroup website – “*The conceptual (mental) model of the system is everything the user believes about the system*” [11]. The definition has two important aspects:
- **The conceptual model is based on the user’s knowledge or belief, not on the actual operation and building of the system.** For best results, the conceptual model should be as close as possible to the actual operation of the product.
 - **Every user of the system has their own, different conceptual model of the system.** Consequently, the conceptual model of the designer and the user also differs significantly. The designer’s model is usually based on the greater knowledge of the product that he has. His task, however, is to create the design in such a way that the users’ conceptual models are as close as possible to the actual operation of the system.

All of the above principles and concepts have outlined the theoretical foundations of today’s approach to user experience design, inextricably linked to user interface design.

III. MOTIVATION AND RESEARCH PROBLEM

The main goal of the undertaken activities is to create an interface for the editorial office of the AGH Student Bulletin. In order to achieve the intended purpose, it was necessary to recognise in detail the scope of the needs of the editorial office members. The purpose of the research part of this study was therefore to explore the processes occurring in the editorial office and to create models depicting the tasks and roles of all its departments and external bodies.

One of a major challenges in building complex process models is the identification of sub-processes [12]. The Bulletin is composed of three main departments: journalistic, graphic and promotion and cooperation. Most of the processes are concentrated within them. The projects carried out by the editorial office, however, link the work of all its departments and were therefore treated as sub-processes of the core workflows.

The research included: in part one, an analysis of communication channels and organisational documents provided by the editorial office, and in part two, in-depth individual interviews [13]).

A schematic of the organisational structure of the Media Center is shown in Figure 1, which distinguishes the governing bodies of the Bulletin’s editorial office and those collaborating with it in the processes carried out. The research group consisted of the Editor-in-Chief, his Deputy, and the

heads of the following departments: journalism, graphics, and promotion and cooperation.

A. Interview Structure

The interviews were semi-structured, with detailed questions subject to modification during the interviews. Accordingly, a preliminary scenario was created before the research began.

1) General questions

- How long have you been a member of the Bulletin editorial board?
- How long have you been in your role?
- How many people does the department you manage include?
- How many of them are people who joined you in this semester?
- How many of these people have you worked with for more than a year?

2) Questions about completed projects

- Which projects does your department manage?
- In which other editorial projects are you involved?

3) Identification of responsibilities

- What responsibilities do department members have?
- What are the responsibilities of the person managing the department?
- With what frequency should they be performed?

4) Definition of tools

- What tools (online and offline) do you use in carrying out your responsibilities?
- Can you show me these tools (via the screen share option)?

5) Process discovery

- Imagine that I am a new person in your editorial office. Can you walk me, with the help of screen sharing, through the processes of performing the most important duties in your editorial office/department?

B. Related Works

The main topic discussed in this paper is the user interface design for a work support system. The main principles of building collaborative online applications have been widely discussed since the early 2000s [14]. However, in recent years, one can observe rapid technological developments in the area of Human-Computer Interaction [15] that let the researchers and IT architects look for new ways to improve the overall user experience. In our work, we also mention the role of social media which are increasingly more present as a collaboration tool in companies and organisations [16].

To define use cases for the discussed application, we based our research on Business Process Model and Notation (BPMN), which is a common standard for representing application flows [17]. Although there exist methods to generate

Figure 1. The organisational structure of the AGH-UST Media Center

graphical user interface prototypes based on process models [18], [19], due to large process complexity we decided to perform this action manually.

As it has already been mentioned in this section, one of the significant steps leading to an interface design is the identification and modelling of processes within the organisation. Process discovery can be done using one of the automated process mining techniques [20], one of the common approaches being identifying patterns based on log files [21]. Since the editorial board of the Students Information Bulletin does not use any integrated IT system, automated process mining has been excluded. In such a case, one of the possible approaches is the visual identification of business process elements [22]. In our case, we based our process discovery on user interviews and manual document analysis, analogically to our previous work, where business processes of a training company were identified and discussed [23].

IV. BUSINESS PROCESSES OVERVIEW

This section presents the processes performed in the editorial office, as identified through research. The processes were modelled using BPMN 2.0 notation and described.

The basic structure of the newsletter consists of three departments: journalism, graphic design, and promotion and collaboration. The entire editorial board includes more than thirty members and interns. Each of the departments is run by one managing person. The activities of the entire editorial office are supervised by the Editor-in-Chief and his Deputy.

The main result of the editorial staff’s work is the periodic publication of a magazine – a quarterly – in electronic and printed form. All departments participate in the process of creating the quarterly. The most effective form of distribution

of magazines during the pandemic has become BISdelivery – sending out magazines ordered through a form on the website throughout Poland, in cooperation with the Post Office of AGH-UST. The Bulletin’s editorial staff also maintains a website that publishes both electronic editions of the magazines and self-contained articles.

An additional project carried out by BIS, in cooperation with the editorial office of Radio1.7, is the BIScast – a podcast in which audio versions of texts published in the magazines are created.

In order to identify the processes carried out by the members of the editorial team, the platforms for their mutual communication and the work tools they use were analysed. The most important functions they play in the work of the editorial office have also been identified.

A. Communication Platforms

1) Microsoft Teams

- organising online meetings,
- publishing meeting summaries.

2) Facebook

- publishing meeting summaries.

3) Facebook Messenger

- fast communication in private chats and group conversations.

B. Working Tools

1) Facebook

- publishing marketing material.

2) Instagram

- publishing marketing material.

3) Google Drive

- creating work schedules,
- creating publication schedules,
- storing files with article content and graphics.

4) Adobe Creative Cloud

- creating graphics,
- composing the bulletin and its parts.

5) Canva

- creating graphics for social media.

C. Quarterly Issue

Work on the quarterly begins with a meeting of the entire editorial team, at which the team members, first of all, agree on the theme and the leading color of the graphic design of the latest issue. At this meeting, the key deadlines for the submission of partial texts, their composition, and the deadline for the composition of the entire magazine are also established. After the meeting, all arrangements are written down in form of a post on the Microsoft Teams platform. The first modelled stage of the work is shown in Figure 2.

Figure 2. A BPMN model of the quarterly issue planning process

Next, the process of creating texts in the journalism section begins. The head of the department creates a table on Google Drive that will contain a list of texts for the latest issue. A meeting of the journalism department is held, where the table of topics is completed – each of the members and interns is to propose a topic for at least one article, summarize what the article is supposed to be about, specify the section to which it will be assigned, and complete their name in the "Who proposes?" column. The topics of the texts are free and they are divided into several categories. After the meeting, everyone has time to declare writing at least one of the proposed articles, and then the head of the department assigns proofreaders to specific texts.

The first step in the work of writing a text is to become familiar with its subject matter and necessary sources. Once the text is written, it should be uploaded to the appropriate folder on Google Drive. Later, one should also uncheck the

text upload in the table with texts. The corresponding record then turns red and the proofreader knows that the text is awaiting correction.

The text correction process then begins. Proofreading involves editing the document provided by the editor and giving the editor suggestions on how to avoid further errors, such as through the suggestion option in Google Documents. However, this option is imperfect in that the text creator must manually accept all corrections by the proofreader, or they will not be saved. The proofreader is also obliged to change the file name to "CORR_IN_title" (where IN are the first letters of the proofreader's first name and name) so that when one goes to the "Texts per page" folder, they will know for sure which texts have been corrected. After language proofreading, the proofreader should also uncheck the checkbox in the "Proofreading" column.

After defining all the activities and their sequence, the identification of sub-processes has been conducted. For this task, we used the method called Justified Aggregation of Neighboring Activities, the idea of which is based on graph models [24]. In order to declare a set of activities as a sub-process, the following conditions must be met:

- 1) Activities are connected with a sequence flow.
- 2) There is one clear starting point of the candidate sub-process.
- 3) Outside boundary activities are defined. In order to be considered an outside boundary activity, task or sub-process has to fulfill at least one of the three conditions:
 - its meaning is not related to any of the tasks already included in the candidate sub-process,
 - its responsible function (represented by annotation or a swimlane) is not present in the candidate sub-process,
 - in case of multi instance or recurring activities, its instances do not match with the other activities in the candidate sub-process

The modelled process can be found in Figure 3. One of the identified sub-processes is "Write Text". In this case, *Assign Proofreaders* has been defined as an outside boundary activity, as it is executed by another process stakeholder and is not a multi-instance activity, unlike the other tasks included in the sub-process. The second outside boundary activity is *Proofread Text*. Although it is also a multi-instance activity, its instances involve different participants than those in the case of proofreading.

When all the texts for the quarterly journal are ready, a table is created by the head of the graphics department to divide the further work. The titles and sections of the texts are copied from the table of the journalistic department. For convenience, links to specific documents from the journal section folder are also pasted. The chief then distributes the illustration and composition of the texts among the members and staff.

The issue's editorial cycle includes cover design, photo pages, and cover art for later published podcasts. The cover

Figure 3. The process model of planning, creating and correcting partial texts

photo and photos for the photo pages are obtained by the editors from the Krakow Student Photo Agency. Usually, the photos are also placed on Disk Google.

By the previously agreed date, illustrations for the text and other materials, exported separately in Adobe Illustrator and text filed in Adobe InDesign, should appear in the Google Drive folder. No additional form of proof of submission materials is required.

The next step is the composition of the entire magazine, which the Editor-in-Chief usually does. He then processes the files obtained from all the graphic designers and creates one, preparing the magazine for printing. The modelled process can be seen in Figure 4.

When the quarterly magazine is ready for printing, the preparation of a subpage with its content on the website follows and the preparation of promotional materials begins. In order to plan the work, the promotion and collaboration department uses a spreadsheet, designed in the shape of a calendar. The calendar schedules posts for the following weeks. Often, however, the information in the spreadsheet is inaccurate or selective. First, the type of material to be published regarding the text is determined - a photo or a graphic. This is followed by scheduling the publication of material for specific days and assigning people to perform specific tasks. Materials for posts are prepared in Canva, where

the promotion department works as a team. This means that members can share projects with each other, create templates or use a common content planner. There, posts are created in their entirety because the service also gives the ability to add images and descriptions to specific posts. The final step in the development of the quarterly journal is its distribution. The first form of distribution was direct delivery of printed copies to university departments, student house receptions, and dining facilities. Currently, the distribution consists mainly in sending the magazines (in cooperation with the AGH-UST Post Office) throughout Poland. Orders are collected using a form on the internet website.

D. Website

Only those in charge have the ability to edit the editorial page. Three times a week (on Monday, Wednesday, and Friday), new articles are posted on the website and - once every three months - a subpage with the new quarterly issue.

Each member and intern of the journalism department is required to write at least two articles for the website per month. Once a month, during a meeting, everyone completes their proposed topics in the appropriate table on Google Drive. Afterwards, the editors have time to commit to writing an article (either their own or someone else's). Then the head of the department establishes the schedule for the publication of the texts on the site, and according to this criterion, determines

Figure 4. The process of planning, illustrating, and composing the issue and its parts

when the text should appear on the shared drive, and who is responsible for its correction and publication.

Proofreading is a very important part of the process, without which the text cannot be published on the site. Language proofreading is done by three designated individuals in the department. When scheduling articles for publication, they are also assigned to do proofreading of specific articles.

The article-writing process then begins, which is always preceded by gathering information on the topic. After submitting an article to the disk (as in the table on texts for the quarterly journal), editors check the checkbox located to the left of the record with their text. The record then turns blue and the person assigned to language proofreading knows that the text is awaiting correction. After the linguistic correction, the proofreader should also uncheck the checkbox in the "Correction" column so that the person publishing the article knows that it is ready for publication (after which they should also check the appropriate checkbox indicating that the text has been published).

It turns out that a characteristic system error is that editors often forget to check boxes after the task is done, making the system ineffective because it does not provide reliable information. Therefore, all information must be independently verified, both before proofreading texts and publishing them. The modelled process can be seen in Figure 5.

The graphics department is not involved in the creation of posts for the website; once published, the link to the text is usually shared on Facebook and in Instagrams stories, which are handled by members and interns of the promotions and collaboration department. The posts usually appear on the same days as the texts, namely on Mondays, Wednesdays, and Fridays. The head of the promotion department distributes the posts to the editors on a regular basis, usually by sending them a private message on Facebook with a request to publish on a given day.

The promotions department uses mostly the same spreadsheet to organise their work as they do to create the promotion strategy for the quarterly magazine. The spreadsheet, however, shows only perfunctory information regarding what type of material is published on what day. It lacks information about who is responsible for publishing what materials and when. The table is also not updated on an ongoing basis, so many materials in it are not there and are published spontaneously.

V. DESIGN OF THE SYSTEM INTERFACE

After creating the information architecture diagrams of the panels of each role, their mock-ups and prototype of the system with a medium level of detail were created. This chapter presents a schematic design of the screens that are key to carrying out the processes performed in the editorial office and departments. The layout of each page, the placement of action buttons, labels, and other elements are shown. The prototype was made in grayscale with color coding in places where the type of color indicates the status of the action.

A. Main Page and Task List

Figure 6 shows the screen that is visible after logging in to the panel for users with the role, "Journalism Department". At the very top of the side navigation bar, located on the left side of the screen, are the user's information - first name, last name, department (this information is completed by the administrator when creating a new account), and profile picture (which can be added and changed by the user by clicking on their avatar).

B. Quarterly Issue

Once the theme and color of the quarterly layout have been completed by the administrator, the screen shown in Figure 7 appears in the panel of the journalism department, under the tab, "Quarterly".

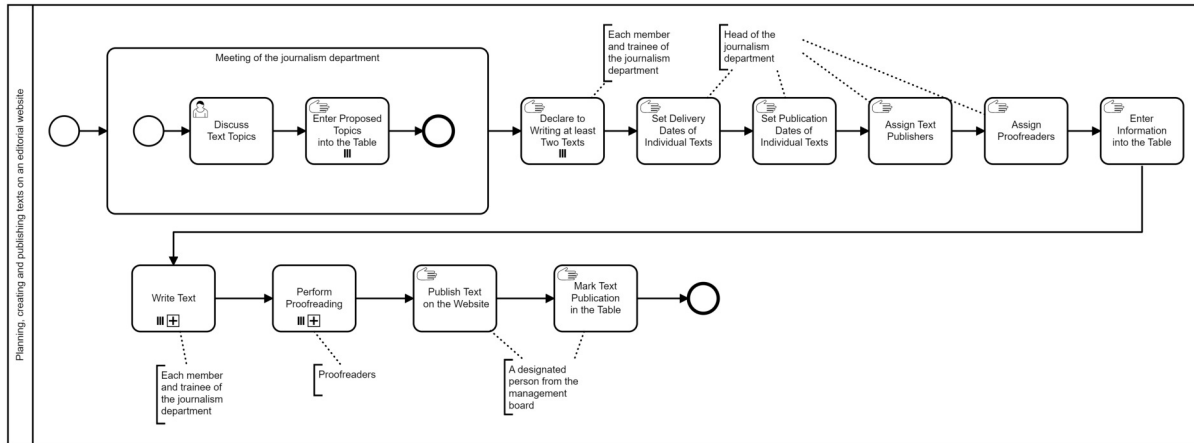

Figure 5. The process model of planning, creating and publishing texts on an editorial website

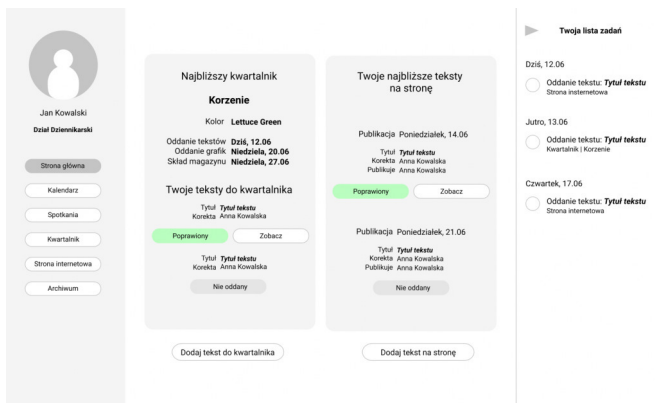

Figure 6. The view of the „Strona główna” (“Home”) tab in the user panel with the role „Dział Dziennikarski” (“Journalism Department”)

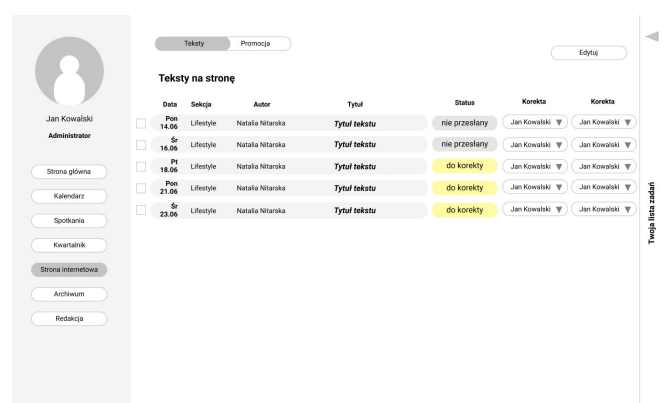

Figure 8. The view of the „Teksty” (“Texts”) subpage in the „Strona internetowa” (“Website”) tab in the user panel of the role „Administrator”

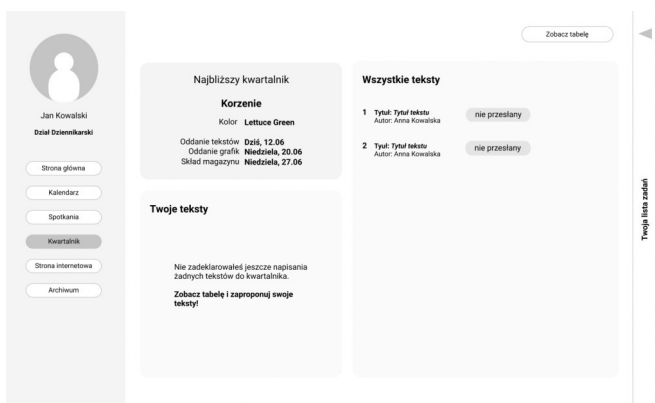

Figure 7. The view of the „Kwartalnik” (“Quarterly”) tab in the user panel of the „Dział Dziennikarski” (“Journalism Department”) role after adding a new quarterly

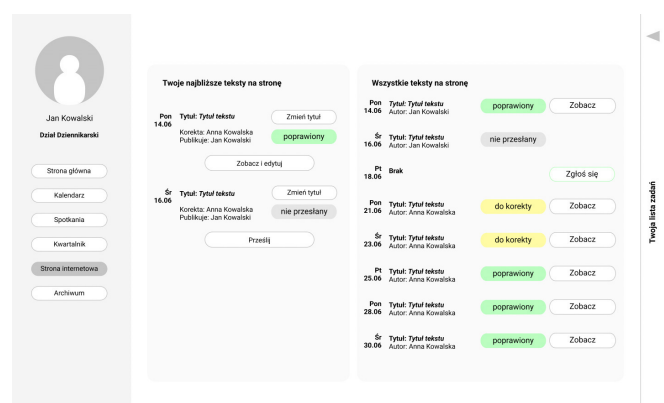

Figure 9. The view of the „Strona internetowa” (“Website”) tab in the user panel of a role „Dział Dziennikarski” (“Journalism Department”)

In the upper left corner of the main part of the screen is a banner with basic information about the upcoming quarterly. Underneath it is a section that displays the texts to which the

user has assigned himself as author. On the right side of the screen there is a section called "All texts", in which all texts for the upcoming quarterly to which an author has contributed are displayed.

C. Website

Figure 8 shows the „Website” tab of the admin panel.

The administrator, using the "Edit" button in the upper right corner of the screen can not only edit record data, but also add new ones according to the website's text publication schedule. By default, a new record will appear for every Monday, Wednesday or Friday, but this can be freely modified by the administrator.

Figure 9 shows the "Website" tab in the panel of the journalism department. The tab is divided into two parts.

On the left side of the screen, there is information about the nearest texts for the website to which the user is assigned – planned publication date, title, who is publishing, and status. Depending on the status of the assignment, there are also buttons for , "Submit" or "View and edit".

On the right side of the screen, information about all planned texts for the website is available, sorted by publication date (from nearest to farthest).

If there are no editors assigned to a particular date, there is a button next to it called "Submit", which the user can use to declare writing a text for a particular date.

VI. CONCLUSIONS

The purpose of this paper was to present step by step our case study of designing a system user interface that greatly enhances and organises the flow of information among members and collaborators of the editorial board of the AGH Student News Bulletin. With the use of various research methods such as observation, social research, and process exploration methods, we analysed the activities executed by the editorial board, communication platforms, and members' working tools. Using knowledge of user interface design, we designed a system interface that effectively reduces the need to use many of these tools and provides a platform through which most of the information needed by the editorial board can be collected and transmitted.

In order to effectively accomplish the stated goal and properly design the system interface, we focused on one of the four editorial offices. This enabled accurate data analysis and the elimination of errors. Using the lessons learned during the research phase, it was possible to design an interface to support the work of the entire organisation.

Further possible activities in the development of the project might be focused on conducting usability tests of the prototype with members of the Bulletin editorial staff. After testing the designed solutions and making necessary corrections, it would be necessary to develop the graphic layer of the project and develop both the front-end (based on the designed user interface) and the back-end for the presented system.

Abstract—The article presents the scope of issues related to knowledge management in models assuming the performance of work outside workplaces and the tools used to disseminate knowledge transfer. Knowledge management and transfer are the cornerstones of any business. They are evidence of market position and competitive advantage. The approach to knowledge transfer tools in remote work models is becoming crucial. On this basis, a research issue was formulated, which concerns knowledge management in hybrid work performance models and ICT tools used. The research objective is to assess knowledge transfer in businesses and identify the most effective ICT tools used by employees to manage knowledge in businesses. In order to solve the research problem, quantitative research was conducted on a randomly selected sample of respondents. Studies have shown that respondents are aware of the importance of knowledge sharing within organizations. They see the benefits and barriers thereof. Their command of knowledge-sharing tools, on the other hand, is moderate. The added value of the article is linking the substantive approach to knowledge transfer itself, taking into account the tools used in the hybrid model. The article indicates the existing connections and perception of the employees themselves.

Index Terms—knowledge, knowledge management, hybrid work model, ICT tools.

I. INTRODUCTION

MODELS of performing work outside the employer's headquarters have gained importance due to the global coronavirus pandemic. This enabled the emergence of a new reality that encompassed all possible employers. This determined the definition - in accordance with the SWOT analysis - of new opportunities, threats, as well as specifying the strengths and weaknesses of this model. Many companies do not have clearly defined strategies for applying remote working models. This raises many doubts among employees, since the coronavirus pandemic has shown that many tasks and duties can be performed in remote models. This is also directly related to maintaining work-life balance, which is becoming increasingly important. There is a growing attention being paid to creating a culture of knowledge sharing by employees in businesses. A culture that is based on openness, trust and a favourable atmosphere. Knowledge is the primary resource of an organization, which testifies to

its market position and competitiveness. Resources, on the other hand, are employees, and in particular their skills and competences, which have open or secret forms of knowledge. The objective of businesses is to create such conditions in which employees will want to exchange their experience and know-how. To make this possible, it is necessary to use tools that will make it possible. These are primarily systems or knowledge bases that employees have access to. The article aims to analyze the knowledge transfer tools used in hybrid work models in businesses.

The article reviews the current literature on the subject, presents the research process methodology and the characteristics of the research sample, presents the research results, refers to the latest report results, and finally summarizes the conclusions.

The author's contribution to the article is as follows:

- carrying out a critical analysis of the research topic,
- referencing the subject matter of the article in the literature overview,
- conducting quantitative research on a random sample of respondents,
- research results constitute added value in the field of management and quality sciences. They indicate the connections in the examined topic.

II. LITERATURE OVERVIEW

The concept of remote work or telework/telecommuting dates back to the 1970s. This was a response to many changes in the processes within businesses. This resulted in the emergence of innovative approaches to shaping new models of work performed outside the employer's headquarters. In 1973, Jack Nilles conducted an experiment that proved that each employee's work can be transmitted through computers or other telecommunications methods. This, in consequence, meant limiting the movement of workers who are required to perform work [1]. This was greatly aided by technological development, which determined the emergence of a new and flexible employment form for employees who could carry out their tasks outside the employer's stationary offices. The approach aims to limit com-

muting costs in addition to saving on commuting time [2]. The possibility of performing duties outside the workplace has been intensified by the increased importance of information and knowledge in relation to goods or products. The development of remote work is the development of information technologies as well as computer science itself, which is a tool in IT architecture [3].

There are many definitions of the term 'remote work'. It is very difficult to cite one that would fully reflect the essence of its meaning. In order to attempt to define remote work, one should draw attention to existing synonyms such as teleworking, virtual officing, remote work, networking, or work from home. It seems that the terms can be used interchangeably, because they mean the same thing. The difference may exist in the basis of employment under which work is performed [4].

TABLE I
Selected definitions of the term of teleworking

A. Jeran (2016)	"Work carried out outside the employer's offices, depending on the form: in the employee's place of residence or another location, sometimes on the move" [5].
M. Hynes (2014)	The possibility of using IT tools that allow one to perform their duties in a different geographical location than the workplace [6].
R. Blanpain (2013)	"Work performed for an employer or client, mainly in a place other than the traditional workplace, using information technologies" [7].
Greenberg and A. Nilssen (2008)	Implementation of new information technologies through tools, including computers, in exchange for employees commuting to the workplace [8].
S. Ciupa (2009)	"A new form of organizing and performing work (...), where the manner and conditions of performance as well as order and organization can be shaped through the use of advanced information and communication technologies" [9].
The Act of 26 June 1974, art. 67, § 1 and 2. Labour Code (1974)	"It may be performed regularly outside the workplace, using electronic means of communication in light of regulations on the rendering of electronic services (teleworking). The teleworker is an employee who performs work (...) and provides the employer with the results of said work, in particular using electronic means of communication" [10].

Source: Own study based on the cited literature

Remote work is a type of flexible work in the scope of dimensions such as: time, location, permanence of relation-

ships, and the type of contracts concluded between the employer and the employee [11].

According to S. Hogarty, the hybrid work model aims to combine elements characteristic of office-based work and performing duties as part of remote work. The goal is to provide the employee with an opportunity to decide how they will perform their work. The hybrid system of work is based on the performance of tasks by employees depending on their preferences and work style. Each employee must have full comfort in performing their duties. There are the following types of hybrid work: "remote first", which means that employees perform their tasks remotely, but can come to the office if necessary. The rotation variant, which consists in establishing a schedule and dividing employees into teams performing work remotely and stationary [12].

The advantages of using a hybrid work model include [13]:

- the possibility of saving time on commuting to the workplace,
- growing importance of work-life balance for employees,
- increase in KPIs in terms of employee satisfaction with and engagement in the performed work,
- greater flexibility in the recruitment carried out by companies, as well as reaching out to "talent",
- ability of maintaining better contacts with clients.

Knowledge management is becoming increasingly important in modern businesses as a foundation of the human resources management strategy. As a result of the end of the industrial era, some of the most important assets are knowledge, information and intellectual capital [14]. The issue at stake is the knowledge of employees itself, which is not the property of the companies [15]. Intensified development of the information society focusing on the knowledge management and distribution plays a key role in all communication progress. Telecommunications and all information technologies determine contacts between people and have a direct impact on teamwork in distributed structures [16].

The word "knowledge" has many definitions in subject literature. According to P. Ducker - knowledge is a type of effective and efficient use of information in taking actions [17]. On the other hand, E. Turban believes that components of knowledge include: truth, beliefs, expectations, ideas, and know-how [18]. S. Galata argues that knowledge is an exceptional and unique resource of an organization that accrues while in use [19].

One of the trends of innovative employee behaviors is the use of creativity based on three competencies, which include: expertise, motivation and creative abilities [20].

Human and intellectual resources have a key impact on building the innovation capacity of businesses where knowledge is a key element. Knowledge management, then, is influenced by the following:

- the education of employees hired by the business,
- skills related to knowledge acquisition and processing,
- openness of employees to improve their qualifications, as well as acquire new knowledge,

- acquired knowledge and experience of the management staff,
- all knowledge regarding the needs of internal and external clients, as well as contractors,
- competency opportunities to create new knowledge,
- cumulative knowledge (codified knowledge) encompassing intellectual property rights,
- possessing competencies related to knowledge acquisition from the external environment [21].

A given organization's management staff will support the knowledge management process, including the knowledge transfer itself, if it is related to obtaining potential benefits [22].

Knowledge management in the Japanese model consists of a process that includes the following elements:

- socialization – assumes experience sharing between employees. Creating hidden knowledge, as well as generating new ideas.
- externalization – that is, manifestation. It is a situation in which hidden knowledge is presented as a metaphor, a hypothesis. Afterwards, it is converted into overt knowledge.
- combination – combining available knowledge through various components. The result is the reaction of new knowledge.
- internalization – involves the permeation of available knowledge into hidden knowledge. It primarily involves education through taking action [23].

The model presented above is the beginning of the SCRUM concepts, which concern the concept of managing organizations in the perspective of project management. It is an operational level based on planning, as opposed to a traditional concept based on control [24].

Hidden knowledge is a type of knowledge that is difficult to articulate through colloquial language [25]. Overt knowledge is created on the foundations of hidden knowledge, which serves as the starting point [26].

In the process model, knowledge management integrates processes such as creating, organizing, collecting, and then utilizing knowledge in the organization [27].

If knowledge management in the process approach constitutes a process, it is possible to distinguish the following sub-processes:

- creation of new knowledge (recognition of new and old knowledge),
- specification of knowledge belonging to the organization,
- checking the knowledge resources,
- ordination of knowledge,
- the possibility of utilizing and promoting knowledge,
- creation of knowledge based on resources [28].

The resource model is based primarily on resources as the basic factor indicating a competitive advantage [29]. However resources, including knowledge, are combined when creating the competitive advantage itself. This determines an exchange of knowledge between employees [30].

Knowledge transfer support tools within organizations include:

- a document circulation system (workflow) that allows for circulation of documents from different sources, but existing within one system, which all employees involved in a given process have access to. The scope of tasks includes: managing document flow, i.e. document life, data import / export.
- a system aimed at supporting group work, which enables joint performance of tasks or projects in distributed structures or in hybrid work models.
- an expert system that enables the use of available knowledge, and related decision-making. The scope of this system includes: a user interface, a knowledge base, a database, and a knowledge base editor.
- an e-learning system for monitoring and reporting progress results in the remote learning of employees.
- a content management system is a tool intended to create websites in the HTML model [31].

The figure below shows the relationship between knowledge management, which, using appropriate tools, affects the work performance in a hybrid model.

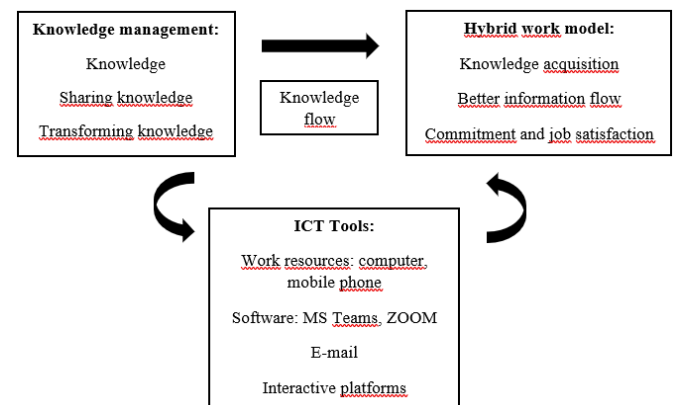

Fig. 1 Relationships between knowledge management and the hybrid work model
Source: Own study

For the purposes of the article, a multi-variant remote work model has been developed, which has a direct impact on knowledge management in businesses. The model was created on the following models: resource-based, process-based and Japanese.

The model's assumptions are as follows:

- knowledge is the strategic and most important pillar of a business,
- knowledge exchange takes place among employees working in a hybrid model,
- knowledge has a multifaceted dimension,
- managing knowledge is a process consisting of its creation, transfer, implementation, sharing, and transformation.
- knowledge is not only information, but also values, emotions, views, and experience,
- ICT tools absolutely affect the transfer of knowledge between employees.

III. METHODS AND MATERIALS

Based on the theoretical section, the following objectives of the conducted research were formulated:

- assessment of tools used by employees during hybrid work,
- assessment of the hybrid work model in businesses,
- assessment of knowledge transfer in businesses.

The article puts forward the following research hypotheses:

H1: Knowledge sharing has a significant impact on employees of companies.

H2: The use of ICT tools positively impacts the use of knowledge in businesses.

H3: Knowledge management depends on the multi-variant model of remote work adopted in the article.

In order to achieve the research objectives, a critical analysis of the subject literature was conducted. Literature studies were conducted using the desk research method utilizing secondary sources. Their objective was to prepare a research tool for conducting empirical analyses. The research was quantitative in nature. A prepared online survey was used as the research tool. The survey was conducted on 08-31.03.2022. Selection of the research sample was random. The study was anonymous and participation in it was voluntary.

The questionnaire consisted of 20 substantive questions and a metric. Some of the questions were open, asking the employee to provide an individual answer, while others were closed questions with the option of choosing one or several answers. The survey was taken by 239 respondents.

TABLE II
Survey results – metric

No	Category	Respondents' answers	Answers In figures	Answers in [%]
1	Gender	Female	150	62,8%
		Male	89	37,2%
2	Age	Under 25 years old	42	17,6%
		25 - 40	90	37,7%
		41 - 60	64	26,8%
		Over 60	43	18%
3	Education	Primary	27	11,3%
		Secondary	133	55,6%
		Higher	79	33,1%
4	Company size	Small	124	51,9%
		Medium	59	24,7%
		Large	56	23,4%

Source: Own study

It should be noted that the research was carried out after a subsequent wave of the COVID-19 pandemic, which lasted from January to February 2022. There is a return of employees to stationary or hybrid work observed in businesses.

IV. RESULTS OF THE CONDUCTED STUDY

The growing popularity of hybrid work requires companies to provide employees with the tools to perform their jobs outside the employer's offices.

The answers to open question concerning the tools necessary to perform duties in a hybrid model are presented in Figure 2. Respondents stated that the computer is a priority (38.3%). It's a basic tool that directly enables performance of work regardless of the employees' geographic location. The knowledge of internet tools enabling remote connection of employees – MS Teams, ZOOM (24.8%) was highly rated. Internet access (19.1%), as well as a mobile phone (5.3%), headphones with a microphone (4.4%), or other electronic devices (0.4%) are also considered necessary. A small number of respondents answered that this question did not apply to them (2.7%).

Fig. 2 Tools necessary to perform duties in a hybrid work model
Source: Own study

Figure 3 presents the factors that respondents believe are in favor of performing work in a stationary model. Over half of the respondents consider contact with other colleagues to be the most important (52.8%). For employees, another important aspect is the greater control they have at work (12.4%) and the ability to focus on their job (6.8%). An equally important issue is access to all tools (8%) such as a printer, scanner or documents, which are only available in the workplace. Respondents also drew attention to the workplace atmosphere (7.2%). This is an extremely important factor which shows that employees feel the need to be at work in a pleasant atmosphere. There were also answers concerning: greater discipline (4%) and willingness to help others (3.2%).

Fig. 3 Factors affecting stationary office work
Source: Own study

The next question in the survey questionnaire concerned the ranking factors that affect job satisfaction in the hybrid model from the most important to the least important. According to respondents, the most important is flexibility, which is closely related to performing tasks outside the employer's headquarters (48.1%). In line with the theory by Jack Nills, respondents note a reduction in time associated with commuting (38.5%). When working from home, an important factor turns out to be the employer's trust in the employee reliably and conscientiously performing their work (29.7%). The answer to this question is related to the following answer of respondents concerning the maintenance of work-life balance (14.6%). Limiting the commute time, along with the employer's full trust in the employee performing their tasks directly affects the ability to maintain work-life balance. For workplaces with an open space, it is important that working from home allows for greater focus (19.7%).

Table 3 presents the results of respondents' answers to questions concerning work models implemented in businesses. The distribution of answers to the question related to the work mode's efficiency is very similar in terms of the stationary work model (36.8) and the hybrid work model (36%). The answers differ in the case of the work model applied in businesses. According to the respondents' answers, organizations prefer to work in a stationary model (44.8%) assuming that employees come to the employer's headquarters to perform their duties. The research shows that hybrid and remote work models are not popular among employers of the randomly surveyed respondent sample. Over half of the respondents (67.8%) believe that meetings with colleagues are a key element of teamwork. Respondents believe that the companies where are employed have provided them with appropriate knowledge and ensured corresponding knowledge carriers to perform their duties.

TABLE III
Results of the survey concerning the performed work model

No.	Question	Answers to the questions asked in the survey	Respondents' answers	Average value	Median	Standard Deviation
1	What mode of work do you consider to be the most effective?	Stationary work model	88	79,67	86	10,40
		Hybrid work model (combining remote and stationary work)	86			
		Remote work model	65			
2	What is the work model solution in your organization?	Stationary work model	107	79,67	91	28,11
		Hybrid work model (combining remote and stationary work)	91			
		Remote work model	41			
3	Do you believe it is necessary to meet your team live?	Yes	162	119,5	162	42,5
		No	77			
4	When performing professional duties from home, do you think that the company has appropriately adapted the transfer of knowledge?	Yes	146	119,5	146	26,5
		No	93			

Source: Own study

Table 4 presents the respondents' answers to questions concerning knowledge transfer within employee relations in businesses. A very important element here seems to be the exchange of knowledge between employees, because it is through their work and effort that organizations implement business strategies and goals. The know-how of employees forms the basis for maintaining business continuity as well as company secrecy. The results presented below show that knowledge transfers are moderate between all employees at different levels in organizations. Most respondents (38.5%) believe that the best knowledge flow occurs in the manager-employee relationship. Top-down communication in this configuration testifies to the transfer of the supervisor's knowledge to their subordinates, including on what task to perform, what data is required, and often these are conversations regarding organizational changes. Communication in the employee-employee relationship was also assessed by respondents as moderate – 33.9%. Respondents gave the worst rating to bottom-up communication, i.e. the flow of knowledge between the employee and the manager – 31.8%.

Knowledge transfer in hybrid work models is primarily the knowledge of digital tools enabling communication between colleagues and the transmission of work results. It is a basic skill determining the digital competencies that are gaining so much importance. The majority of respondents assess their knowledge of online tools at a moderate level (30.5%). Only 11.3% assess their knowledge as very good, while as many as 16.7% of respondents practically do not deal with these types of tools.

TABLE IV
Results of the survey concerning knowledge transfer

No.	Question	Scale (1 – very weak, 2 – weak, 3 – moderate, 4 – good, 5 – very good)				
		1	2	3	4	5
1	How do you assess the flow of knowledge in the employee-to-employee relationship in the hybrid model	38 15,9%	41 17,2%	81 33,9%	54 22,6%	25 10,5%
2	How do you assess the flow of knowledge in the manager-employee relationship in the hybrid model	30 12,6%	36 15,1%	92 38,5%	52 21,8%	29 12,1%
3	How do you assess the flow of knowledge in the employee-manager relationship in the hybrid model	32 13,4%	37 15,5%	76 31,8%	68 28,5%	26 10,9%
4	What is your knowledge of digital tools, e.g. digital platforms, including MS Teams, ZOOM, ClickMeeting	40 16,7%	45 18,8%	73 30,5%	54 22,6%	27 11,3%

Source: Own study

Table 5 presents the correlation results of questions regarding knowledge transfer according to Spearman's ranks. The correlation between the variables is at a very low level.

TABLE V
Spearman's index for the survey results concerning
knowledge transfer

No.	Question	Spearman's rank correlation coefficient - r,
1	How do you assess the flow of knowledge in the employee-to-employee relationship in the hybrid model	-0,1
2	How do you assess the flow of knowledge in the manager-employee relationship in the hybrid model	-0,1
3	How do you assess the flow of knowledge in the employee-manager relationship in the hybrid model	-0,1
4	What is your knowledge of digital tools, e.g. digital platforms, including MS Teams, ZOOM, ClickMeeting	-0,1

Source: Own study

Table 6 presents the results of respondents' answers to questions concerning knowledge management in businesses. The following questions are multiple choice. The respondents believe that the most important sources of knowledge transfer are external training courses (47.7%) and knowledge exchange between employees (44.8%). Respondents use resources such as knowledge repositories in organizations (10.9%) or market research reports (16.3%) the least. As the most important factors influencing knowledge sharing within the organization one may consider: employee trust (46.9%) and respect towards employees (46.9%). It follows that for employees the most as important fundamental the values that directly affect their openness in sharing knowledge. Remuneration was also assessed very highly (39.7%) as a financial motivator. It can be hypothetically assumed that the higher the employees' remuneration, the greater their willingness to share knowledge. The company's organizational culture was rated the lowest – 16.3%. In the subsequent question, respondents had to choose statements that describe their enterprises to the greatest extent, and above all, the organization's attitude to knowledge management. The largest number of respondents (34.7%) replied that knowledge transfer takes place mainly between employees and the knowledge sharing and management within organizations is a key process of the functioning of companies on the market (32.2%). Employees are the greatest source of knowledge in companies, and knowledge exchange is a fundamental element of their business. It should be noted that despite the awareness that the knowledge transfer-related processes are very important and both the management and employees know about it perfectly, simply promotion of a knowledge sharing culture is imperceptible which is evidenced by the respondents' answers in this regard – 12.1%.

This implies that organizations devote insufficient efforts to further intensify the dissemination of the knowledge sharing culture at all organizational levels. In terms of tools used to disseminate knowledge in enterprises, these are: interactive platforms (including e-learning platforms) – 30.1%, e-mails (used by employees to send each other their know-how) – 31%, internal employer tools (which, among others, include

TABLE VI
Results of the survey concerning knowledge management
knowledge transfer

No.	Question	Answers to the questions asked in the survey	Respondents' answers	Average value	Median	Standard Deviation
1	What sources do you consider crucial for knowledge acquisition by employees in businesses?	Training courses provided by external trainers	114	72,5	78,5	28,54
		Training courses conducted by internal trainers	78			
		Knowledge exchange between staff	107			
		Contacts and cooperation with customers	79			
		The Internet	87			
		Knowledge repositories in businesses	26			
		Conferences, symposiums	50			
2	What factors influence eagerness to share knowledge?	Market analysis reports	39	78,44	82,00	24,90
		Trust towards employees	112			
		Respect for employees.	112			
		Organizational culture of the business	70			
		Appropriate motivation	88			
		Remuneration	95			
		Development and training courses	82			
3	Which statements apply to your company?	Organizational culture	39	55,25	47,00	18,59
		Friendly management staff	62			
		Communication channels	46			
		Sharing knowledge is a key process in any business.	77			
		Employees are encouraged to share knowledge.	74			
		Most employees exchange knowledge between one another.	83			
		I feel personal development through knowledge sharing.	50			
4	What tools are used to disseminate knowledge in your organization?	My supervisor notices me sharing knowledge with my coworkers.	42	53,83	56,50	15,82
		My supervisor is happy to share his knowledge with me.	44			
		The organization promotes a culture of knowledge sharing.	29			
		All employees are aware that knowledge sharing is a key element in the implementation of the company's strategy.	43			
		Knowledge repository	50			
		Interactive platforms	72			
		The employer's internal site Intranet	68			
5	What barriers in your opinion may exist to knowledge management in your organization?	Social media	63	51,11	38,00	28,08
		Forum	44			
		E-mail	74			
		Does not have any	26			
		High turnover among employees	64			
		Lack of openness of employees to share knowledge	86			
		Lack of trust	108			
		Common reluctance to share knowledge	53			
		Unadapted IT infrastructure	38			
		No existing communication channels	34			
6	What are the important benefits of knowledge management?	Lack of existing knowledge sharing tools	30	39,83	35,50	16,59
		Lack of funds	28			
		There are no barriers	19			
		Increased engagement and job satisfaction	53			
		Improving the information flow	67			
		Competitive edge	34			
		Better cooperation between organizational units	36			
6	What are the important benefits of knowledge management?	Learning from mistakes	35	39,83	35,50	16,59
		Better resource allocation	14			

Source: Own study

intranet websites) – 28.5%, and communication channels, which include all social media – 26.4%. Attention is drawn to the number of respondents whose employing businesses do not have knowledge dissemination tools implemented – 10.9%.

Barriers preventing smooth knowledge management in businesses are a very important element. Over half of the respondents believe that the lack of trust between employers and employees creates a barrier to the knowledge exchange – 45.2%. The lack of trust is also related to a lack of openness of employees to the knowledge-sharing process itself – 36%. In fact, one clearly results from the other. Trust and openness are closely related and determine the employees' attitudes. The barriers to knowledge management also include a high employee turnover and rotation rate, which is associated with the lack of knowledge transfer between employees – 26.8% and a widespread reluctance to share knowledge – 22.2%. Only 7.9% of respondents believe that there are no barriers affecting processes related to knowledge management within organizations. In terms of benefits, the highest scores were given to: better information and knowledge flow between employees (28%) and commitment and job satisfaction (22.2%) as non-financial motivators. Learning from mistakes (14.6%), as well as better cooperation between organizational units (15.1%) were also highly rated by the respondents.

Figure 4 presents the results of the respondents' answers to the question of what knowledge management model is used in the businesses in which they are employed. The resource model, which assumes that the most important factor in knowledge exchange in organizations is employees, is the most popular among the respondents (38.1%). Slightly fewer responses were obtained by the implemented process model (36.4%), which is characterized by dissemination of knowledge by the company itself serving as the initiator. Also highly rated was the Japanese model (25.5%), which assumes that each employee influences the company's state of knowledge.

Fig. 4 Knowledge management models in businesses
Source: Own study

Figure 5 presents tools for knowledge development in enterprises. Most respondents take advantage of knowledge development through participation in trainings (57.3%), courses (37.2%) and conferences (20.5%). It seems that these forms of development are the most accessible to employees and can be easily utilized. Methods such as coaching (11.3%) or mentoring (7.9%) are much less used. Figure 6, on the other hand, shows the frequency of participation in selected forms of development presented in Figure 5. According to available data, in 2021-2022 almost 38.9% of respondents did not participate in any of the above-mentioned forms of development. Over 30% participated once or twice, while 17.2% participated 3 or 4 times. A small percentage (12.6%) is people, who actively sought ways of development in 2021-2022.

V. RESULTS AND DISCUSSION

The conducted research showed that implementation of hybrid work models is still at an early stage. A significant percentage of respondents, who took part in the survey continue to perform their work in stationary models. Knowledge management in enterprises is a key process. A flexible and continuous flow of information enables employees to efficiently perform their tasks. Respondents notice the importance and necessity of knowledge sharing in favorable conditions. They pay particular attention to openness and trust on the part of employers. They easily identify the benefits of openness, as well as the barriers to knowledge transfers be-

tween colleagues. Digital tools play an important role both in the hybrid work model as well as knowledge management, which enable knowledge transfer in the hybrid model. Studies of this research sample proved that respondents notice the importance of programs such as MS Teams, ZOOM, or ClickMeeting as a basic tool used in performing their duties outside the employer's premises. They state their knowledge of the software at a moderately good level, which means that they use these tools only for occasional meetings. On the other hand, in the global perspective, the tools used to disseminate knowledge in organizations are primarily interactive platforms, which include LMS (Learning Management System) or e-learning platforms. Communication channels such as social media that are available to all employees are very popular. The tools used to popularize knowledge are not only IT programs, but also forms such as training, courses, conferences, studies, or more individualized forms, which include coaching or mentoring generally available to employees.

The results of the research conducted related to the adopted multi-variant remote work model in relation to knowledge management in businesses are as follows:

- employees use ICT tools to perform remote work in order to transfer knowledge. These include MS Teams, ZOOM, interactive platforms, social media and electronic devices,
- the respondents work in a stationary work model, while they expect a hybrid model,
- knowledge exchange between employees flows best in the employee-employee relationship and the manager-employee relationship,
- respondents notice many sources of knowledge management processes. These include: acquiring knowledge through training, sharing knowledge or acquiring it from customers,
- sharing is the first step towards the implementation and dissemination of a knowledge sharing culture.

According to a study by the House of Skills concerning 'Trends in human development for 2022' [32], the results indicate the further development and future of hybrid work in businesses. The challenge will lie in competent management of the dispersed team taking into account employees performing work from offices and homes in real time. However, there is a lack of clear guidance from companies on the use of hybrid work. According to the Gartner report [33], many companies have not yet developed internal strategies for using hybrid work. A study conducted by the Future Business Institute [34] shows that 75% of respondents believe that stationary work should be combined with remote work, i.e. a hybrid model of tasks performance by employees should be established. Merely 12% of respondents are of the opinion that they can only do their work remotely. However, 51% of respondents believe that performing work at home stimulates their innovativeness.

According to a recent survey by The Voice of the European Workforce [35], results show that employees believe that companies that have implemented knowledge transfer

are much more competitive in terms of customer satisfaction and contentment, as well as revenue growth. Employees perceive such companies as innovative and valuable. The future in the dissemination of knowledge lies in tools such as artificial intelligence, databases or natural language processing.

Data from the Future of Jobs Report [36] indicate technologies that can be implemented by businesses by 2025. These include:

- 87% encryption and cybersecurity,
- 86% artificial intelligence,
- 80% the possibility of using cloud tools,
- 73% extension of big data analytics,
- 71% e-commerce,
- 69% development of robotization (automation).

VI. CONCLUSION

In the 1960s, IT systems started being developed to support knowledge management processes in businesses. Their goal was to quickly and easily transfer knowledge between employees or create places where knowledge can be collected and processed. The larger the company's knowledge repository is, the greater its attractiveness on the market. This affects the number of applications sent in by people who want to be employed in a company with a well-established market position. Knowledge determines the decisions made by the management and directly influences strategic actions. Competent knowledge management and transfer also affect the work models in which employees work. Remote or hybrid work models, which combine remote and stationary work, are becoming increasingly common. It is a model that is expected by employees. It refers to maintaining a balance between professional and private life, limiting factors such as the time for commuting to work.

The first research hypothesis (H1) was positively verified: knowledge sharing significantly affects employees. The respondents believe that the knowledge sharing process is a fundamental element in establishing interpersonal relationships, building trust and openness. It is a process that should encourage companies to build a culture of knowledge sharing among employees. Respondents see a direct link and influence on building a company's competitiveness and market position.

The conducted research indicated that employees most often use the tools provided by their employer to transfer knowledge. They also use software intended for knowledge exchange and communicate between employees. These include: MS Teams, ZOOM, ClickMeeting, and many others. It is also worth noting that e-learning platforms or internal employer systems such as the intranet (H2) are used for knowledge exchange. Most respondents believe that performing tasks in a hybrid work model is an effective and efficient solution, while 44.8% of respondents continue to work in a stationary model. The hybrid model allows for individual work, but also the opportunity to meet the team live on days that are scheduled for presence at the workplace. The respondents have no objections to knowledge transfer

that is implemented in their organizations. The best flow of information is in the manager-employee relationship. This is due to the fact that the manager contacts their employee regarding: tasks performed, delegation of duties or providing organizational information. Employees also share information, experience, or various other insights with each other. Respondents value openness and trust on the part of the employer in terms of knowledge transfer. They consider this to be one of the key processes functioning in businesses. There are benefits such as: better information flow, increased engagement, and barriers: lack of trust or widespread reluctance to share knowledge.

The third hypothesis (H3) regarding the relationship between knowledge management and the multi-variant model of remote work adopted in the article was positively verified. According to the conducted research, the model created for the purposes of this article was reflected in the respondents' answers to the survey questions. Both knowledge creation, transfer and transformation are basic processes that affect the flexibility and reach of knowledge transfers. This is done by matching appropriate ICT tools that will correspond to the needs of employees. The direction of the conducted research indicates dissemination of a knowledge sharing culture in organizations. Knowledge is a multi-faceted element. It is not possible to easily determine its components. It also encompasses emotions, feelings, values. Important contributing factors include the workplace atmosphere and a sense of trust.

The study is limited by the fact of including a randomly selected research sample working in companies of all sizes and industries. Therefore, the study has an illustrative dimension.

In the perspective of further research, they should be carried out in specific companies in order to be able to analyze how such companies approach the hybrid model and knowledge management. Research should be carried out taking into account specific industries and professions performed by the respondents. This will allow a clear reference to the results of previous research.

Abstract—The recent advancements in medical science have caused a considerable acceleration in the rate at which new information is being published. The MEDLINE database is growing at 500,000 new citations each year. As a result of this exponential increase, it is not easy to manually keep up with this increasing swell of information. Thus, there is a need for automatic information extraction systems to retrieve and organize information in the biomedical domain. Biomedical Named Entity Recognition is one such fundamental information extraction task, leading to significant information management goals in the biomedical domain. Due to the complex vocabulary (*e.g.*, *mRNA*) and free nomenclature (*e.g.*, *IL2*), identifying named entities in the biomedical domain is more challenging than any other domain, hence requires special attention. In this paper, we deploy two novel bi-directional encoder-based systems, *viz.*, BioBERT and RoBERTa to identify named entities in the biomedical text. Due to the domain-specific training of BioBERT, it gives reasonably good performance for the NER task in the biomedical domain. However, the structure of RoBERTa makes it more suitable for the task. We obtain a significant improvement in F-score by RoBERTa over BioBERT. In addition, we present a comparative study on training loss attained with ADAM and LAMB optimizers.

I. INTRODUCTION

INFORMATION extraction in the biomedical domain involves the identification of the independent pieces of information, for example, cause-effect arguments, causal triggers, adverse drug reaction, *etc.* Automated extraction of information from the biomedical text is an essential facilitator of clinical research and informed diagnosis [1], [2]. The presence of many domain-specific terminologies in biomedical literature makes information extraction a challenging task.

An entity is a word or a sequence of words in the text with a physical existence with different properties. Named entity recognition (NER) is a sub-task of information extraction that seeks to identify and classify named entities as predefined categories in unstructured text. NER always serves as the foundation for many natural language applications such as *question answering*, *text summarization*, and *machine translation*. Biomedical Named Entity Recognition (BioNER) is a task of identifying biomedical named entities such as *gene*, *disease*, *drug*, *species*, *etc.*, in the raw text. Because of the complexity of biomedical nomenclature, BioNER is a more challenging task than NER in general. A gene name often contains a mix of alphabet, digits, hyphens, and other characters, for example, *HIV-1*. The domain frequently uses

abbreviations (“IL2” for “Interleukin 2”). In addition, the same biomedical named entities can be expressed in various forms. For example, gene names often contain alphabets, digits, hyphens, and other characters, thus having many variants (*e.g.*, “HIV-1 enhancer” versus “HIV 1 enhancer”). Moreover, many abbreviations (*e.g.*, “IL2” for “Interleukin 2”) have been used for biomedical named entities. Sometimes, the same entity can have very different aliases (*e.g.*, “PTEN” and “MMAC1” refer to the same gene) [1]. Another challenge of BioNER is the ambiguity problem. The same word or phrase can refer to more than one type of entities or does not refer to an entity depending on the context (*e.g.*, “TNF alpha” can refer to a protein or DNA).

Table I shows a few example sentences from the biomedical domain with the named entities and their types. Named Entity Recognition in the biomedical domain has been tried using various available methodologies and continues to be an active research topic due to the complexity and utility of the problem. BioBERT [3] is a language model trained on biomedical data to produce distributed representation of words. This paper presents a deep neural system for named entity recognition in the biomedical domain using BioBERT. Specifically, in this paper, we deploy two novel bi-directional encoder-based systems, *viz.*, BioBERT and RoBERTa to identify named entities in the biomedical text. Due to the domain-specific training of BioBERT, it gives reasonably good performance for the NER task in the biomedical domain. However, the supportive structure of RoBERTa makes it more suitable for the BioNER task than BioBERT.

II. RELATED WORK

Named Entity Recognition in the biomedical domain is a fundamental text mining task. It has attracted a lot of attention from researchers across different languages. Methodologies applied to this problem range from the traditional rule-based approaches to the most recent deep learning models. Due to the non-standard use of abbreviations, synonyms, synchronizations, ambiguities, and the frequent use of phrases to describe the entities, NER in the biomedical domain is still a challenging task [4].

Rule-based methods rely on hand-crafted rules to identify and classify named entities in text. An exhaustive lexicon almost always boosts the performance of these models. NER

TABLE I
EXAMPLES OF SENTENCES WITH THE NAMED ENTITY ANNOTATIONS

S.No.	Sentences with Annotations
1	Identification of APC2, a homologue of the {adenomatous polyposis coli tumour}_gene suppressor.
2	{Methanoregula formicica}_species sp.nov., a methane-producing archaeon isolated from methanogenic sludge.
3	{IL-2}_gene gene expression and {NF-kappa B}_protein activation through {CD2B}_antibody requires reactive oxygen production by {5-lipoxygenase}_protein.
4	Assymetrical cell division was observed in rod-shaped cells.

tools in the Biomedical domain rely on specific features to capture the characteristics of the different entity classes until recently. For instance, the suffix *-ase* is more frequent in protein names than in diseases; species names often consist of two tokens and have Latin suffixes; chemicals often contain specific syllabi like *methyl* or *carboxyl* [5]. However, hand-crafted semantic and syntactic rules often make these models data specific. Any change in the source of data will drop the performance of the system [5], [6]. As a result, rule-based approaches lead to a high precision but low recall.

Advancements in supervised machine learning were also applied to generic NER. NER can be considered like a multi-class classification or sequence labeling task. The correct selection and engineering of features are vital to the model's performance based on them. Many machine learning models have been tried and researched based on these features. These include Hidden Markov Models (HMMs) [7], decision trees [8], SVMs [9] and Conditional Random Fields (CRFs). A major requirement for supervised machine learning models to perform well is the presence of sufficient labeled/structured data. However, the presence of labeled data is limited, leading to the rise of unsupervised learning approaches. These models tend to focus more on corpus statistics (e.g. IDF), terminologies, and syntactic knowledge KALM [10].

More recently, deep learning methods that can automatically develop and extract features from the raw text are used end-to-end for generic NER. These models generally use character or word-level embeddings such as Word2Vec and GloVe as their basic input. Various models based on CNNs and RNNs have been researched. However, the BiLSTM-CRF model [11] has been most commonly used. Transformer-based models [12] have proven to be superior in quality and also take less time to train. Based on transformers, several pre-trained language models have been released, which on fine-tuning give state-of-the-art performance on various end tasks. These include Generative Pre-trained Transformer (GPT) [13] (left to right architecture) and Bidirectional Encoder Representations from Transformers (BERT) [14] (takes both left and right context). Bio-BERT shows that pre-training BERT on biomedical data significantly improves its performance on end tasks in the biomedical domain. This paper uses BioBERT for named entity recognition in the biomedical domain. However, BioBERT takes a significant amount of time to train; we reduce the training time of BioBERT. We also modify the pre-training settings of BioBERT, which enables us to achieve

TABLE II
STATISTICS OF BIOMEDICAL NER DATASETS

Dataset	Entity Type	No. of annotations
NCBI-Disease [16]	Disease	6881
BC5CDR [17]	Drug/Chem	15411
BC2GM [18]	Gene/Protein	20703
Species-800 [19]	Species	3708

better performance on the end task, that is, Named Entity Recognition in the biomedical text.

III. DATASET

We preprocess the four datasets in the biomedical domain, *viz.*, NCBI-Disease, BC5CDR (drug/chem, disease), BC2GM, and Species-800. The preprocessing of the NCBI-Disease dataset results in fewer annotations than the original dataset because duplicate articles are removed from its training set. The *Species-800* dataset was preprocessed and split as per Pyysalo et al., [15]. The statistics of the biomedical NER dataset are listed in Table II.

IV. METHODOLOGY

This paper presents a deep architecture for the named entity recognition in the biomedical domain. Our system deploys the representations of the words by a domain-specific language model, that is, BioBERT. We further optimize the system for the task using the LAMB optimizer. Furthermore, RoBERTa model is built on top of the BERT model. The architecture similarity with the BERT model makes RoBERTa model suitable for the named entity recognition task. This section describes the algorithm and its components.

A. BioBERT

Text documents in the biomedical domain contain a considerable amount of domain-specific proper nouns, (*e.g.*, *BRACA1*), which requires expertise in the domain to understand named entities. The general-purpose language representation models such as GloVe and Word2Vec give a poor performance for biomedical texts [20], [21]. The distribution of the words shifts from general domain corpora to biomedical corpora; hence direct application of generic word embeddings results in unsatisfactory performance [5], [15], [22]. BioBERT (Bidirectional Encoder Representations from Transformers for Biomedical Text Mining) is trained on the biomedical corpus. First, BioBERT is initialized with weights from BERT; BERT

was pre-trained on general domain corpus to overcome the data sparsity problem and bring more coverage. The main advantage of BERT over previous language model approaches like combinations of LSTMs and CRF is that BERT has relatively a simple architecture based on bidirectional transformers. Based on its last layer representations, BERT computes only token level probabilities in the BIOES format (Begin, Inside, Others). Then BioBERT is trained on biomedical corpora from PubMed. BioBERT is the first domain-specific BERT model which has been trained for biomedical-specific tasks [22].

B. RoBERTa

RoBERTa stands for Robustly Optimized BERT Pre-training Approach. Most of the training procedure of BERT and RoBERTa is common. However, there are a few fundamental structural differences. This section presents the differences between the two models.

1) *Static Masking vs. Dynamic Masking*: BERT relies on randomly masking and predicting tokens. In the original BERT model, each sequence was masked in only ten different ways over 40 epochs. RoBERTa uses dynamic masking in which different mask is generated every time a sequence is fed to the model.

2) *Model Input Format and Next Sentence Prediction*: The BERT model is also trained for the Next Sentence Prediction (NSP) objective along with the masked language modeling objective. The objective of auxiliary Next Sentence Prediction loss is to determine whether the segments belong to the same or different documents. It is equiprobable for document segments to be sampled continuously from the same or distinct documents. RoBERTa, on the other hand, takes a different approach by ignoring the NSP loss. The input representation can be seen as packed with full sentences sampled contiguously from one or more than one documents. The maximum input length is set to 512 tokens.

3) *Training with Large Batches*: The same computational cost models can be made by increasing the batch size and decreasing the number of steps. The original BERT was trained with 256 sequence batch size for 1 million steps via gradient accumulation. This computational cost can approximate the training model for 125k steps with a batch size of 2k or 31k steps for 8k. It can be inferred from previous works done on neural networks that training the model with large mini-batches improves end-to-end performance. RoBERTa uses a batch size of 8k.

4) *Text Encoding*: The difference between the BPE vocabulary of original BERT and RoBERTa lies in the sub-word size, preprocessing of input, and tokenization rule. BERT uses 30k, whereas RoBERTa uses a more extensive vocabulary of 50k subwords. BERT does preprocess of input while RoBERTa expands vocabulary size without additional preprocessing. RoBERTa raises vocabulary size without other tokenization rules.

C. LAMB Optimizer

This paper also shows the efficacy of the Large Batch Optimization (LAMB) algorithm with BioBERT for NER in

TABLE III
BIOBERT TOKEN LEVEL EVALUATION WITH ADAM OPTIMIZER

Dataset	Precision	Recall	F-score	Loss
NCBI Disease	88.8	91.8	90.2	33.71
BC5CDR	89.2	90.5	89.9	37.56
BC2GM	88.7	89.4	89.0	37.56
Species-800	79.1	83.2	81.1	32.89

TABLE IV
BIOBERT TOKEN LEVEL EVALUATION WITH LAMB OPTIMIZER

NCBI Disease	86.9	91.8	90.2	11.26
BC5CDR	89.2	90.5	89.9	10.74
BC2GM	88.7	89.4	88.88	17.17
Species-800	79.1	83.2	80.28	12.52

the biomedical domain. LAMB helps to reduce the training time, and boost performance for text processing task [23]. Large batch training is the key to reducing deep neural networks' training time in a large distributed system. LAMB is a layer-wise adaptive large batch optimization technique. The generalization gap becomes a problem in the case of training large batches models. If direct optimization is performed, it may cause performance degradation. Devlin et al., [24] implemented BERT with a variant of ADAM optimizer, which uses ADAMs optimizer along with weight decay for training. LARS is another successful adaptive optimizer that has been used for large batch convolutional neural networks, but they are not effective for text processing tasks [23]. LAMB has shown superior performance across BERT and ResNet-50 training tasks with minimal hyperparameter tuning. Hence, we train BioBERT with the LAMB optimizer to optimize the training time. In addition, we show the superiority of the LAMB optimizer over the ADAM optimizer for the BioNER task (Section VI).

TABLE V
BIOBERT ENTITY LEVEL EVALUATION

Dataset	Precision	Recall	F-score
NCBI Disease	86.92	89.27	88.08
BC5CDR	92.74	92.79	92.77
BC2GM	83.59	83.39	83.74
Species-800	71.39	76.79	73.99

TABLE VI
ROBERTA ENTITY LEVEL EVALUATION

Dataset	Precision	Recall	F-score
NCBI Disease	87.32	88.84	88.07

BC2GM	93.41	92.16	92.78
Species-800	76.01	84.00	79.81

V. EXPERIMENTAL SETUP

The overall process can be divided into pre-training and fine-tuning BioBERT. The pre-training weights are taken from Cohen and Hunter [2]. The fine-tuning step is problem-specific. For example, the model needs to be fine-tuned for named entity recognition, relation extraction, question-answering, and tasks independently. We fine-tune the BioBERT model for our dataset's named entity recognition task. A batch size of 8 was chosen for fine-tuning. The learning rate was set to $1e-5$, and the model was trained for 10 epochs. F-score is computed at the token level, word level, and entity level, that is, phrase level.

VI. RESULTS

Results are focused on two aspects: the optimizer's performance during training and the F-score for the task. We compare the training Loss by ADAM optimizer and LAMB optimizer. ADAM optimizer is a frequently used optimizer for the classification task. Table III and Table IV present the F-Score obtained with BioBERT at token level with ADAM and LAMB respectively. The last column of Table III and Table IV shows the Loss attained during training with ADAM and LAMB, respectively. We observed a significant difference in the training Loss value with the LAMB optimizer; hence LAMB made the model converge in a significantly shorter time than ADAM. However, there is no significant difference in the F-score obtained with ADAM and LAMB. Table V and Table VI show the comparison between BioBERT and RoBERTa for NER across the four datasets from biomedical domain. We fine-tune both the models on our dataset for the named-entity recognition task. RoBERTa significantly improved the F-score for the named-entity recognition in the biomedical domain.

VII. CONCLUSION

Named entity recognition in the biomedical domain is a challenging task considering the unconstrained nomenclature of the biomedical vocabulary. This paper presents a named-entity recognition system for the biomedical domain. We deploy two pre-trained language models for the task, *viz.*, BioBERT and RoBERTa. Due to the domain-specific training of BioBERT, it gives reasonably good performance for the NER task in the biomedical domain. However, the structure of RoBERTa makes it more suitable for the task. Simple fine-tuning of RoBERTa on the dataset for BioNER boosts the results significantly. Additionally, we show a comparison between the training loss attained with ADAM and LAMB optimizers.

Abstract— The Semantic Web concept is proposing a future concept of the WorldWideWeb (WWW) where both humans and man-made systems are able to interconnect and exchange knowledge. One of the challenges of Semantic Web is smart and trusted accommodation of knowledge in artificial systems so it can be unified, enhanced, reused, shared, communicated and distributed with added aptitude. Our research represents an important component of addressing the above challenge and exciting, cutting-edge exploration trend in the general area of developing tool for intelligence augmentation.

I. INTRODUCTION

MOST experts agree that intelligent non-natural system is yet to be established. The main issue that remains a challenge is securing trust and explainability in such systems. This is where the notion of augmented intelligence comes into play. It is an alternate insight of artificial intelligence (AI) that focuses on AI's enhancing role [1]. Enhancing role of intelligence amplification inspired our initial research idea and vision to develop, expand, and extend an artificial intelligence augmentation system, an architecture that would support smart discovering, capture, adding, storing, improving and sharing information and knowledge among agents, machines, and organizations through experience. Bio-inspiration comes in this case from the fact that in nature experiences that all living organisms (including humans) go through during their operating lives support sustainable development, evolution, and add smartness to all associated functionalities and practices. The significance of experience in biological development cannot be overemphasized. We propose an original experience-based Knowledge Representation (KR) approach in which experiential knowledge is represented by Set of Experience (SOE) and is conveyed into the upcoming by Decisional DNA (DDNA) [2,3].

For the sake of completeness, SOE and DDNA are very briefly introduced here. Set of Experience Knowledge Structure (SOEKS) is a knowledge portrayal structure created to

acquire and store formal decision events in a organized and unambiguous way. It is composed by 4 fundamental elements: variables, functions, constraints, and rules. Variables are commonly used to represent knowledge in an attribute-value form, following the conventional approach for knowledge representation. Functions, Constraints, and Rules of SOEKS are techniques of associating variables. Functions define relationships between a set of input variables and a dependent variable; thus, SOEKS uses functions as a way to create links among variables and to build multi-objective purposes. Constraints are functions that act as a way to limit options, limit the set of possible results, and manage the performance of the system in relation to its aims. Lastly, rules are relationships that operate in the world of variables and express the condition-consequence connection as “if-then-else” and are used to represent inferences and partner actions with the conditions under which they should be executed [3]. Rules are also methods of recording specialist-defined knowledge into the system. The Decisional DNA is a edifice capable of capturing decisional characteristics of an individual or organization and has the SOEKS as its foundation. Several Sets of Experience can be assembled, classified, organized and sorted into decisional chromosomes, which mount up decisional policies for a specific region of decision-making occurrences. The set of chromosomes embrace, lastly, what is called the Decisional DNA (DDNA) [4].

II. DDNA KNOWLEDGE MANAGEMENT IN PRACTICE

DDNA technology has been verified, tested, and applied through numerous real life case studies and implementations. Table I below lists some of the most successful DDNA based real life applications with their references for possible further reading. All of them use our advanced portable and domain independent software representation for SOE and Decisional DNA embedded in DDNA Manager [4].

the treatment of experience in the buildup of the system's meta-knowledge.

D. Idream.Technology: From Individual to Collective Experiential Knowledge Management

The new and the furthestmost large-scale DDNA extension is the drimos® platform from Idream Technology Pty Ltd (www.drimos.ai) (Fig. 2). We have developed social digital platform using collective experience. This DDNA-based application, which commences in mid-2022 after comprehensive one year long design, testing, and validation, projects personalized road-maps to achieve purposes, goals, and aims taking into account individuals' personalities and circumstances. Specific areas of human activities covered within the platform include travel, education, acquisition, and well-being.

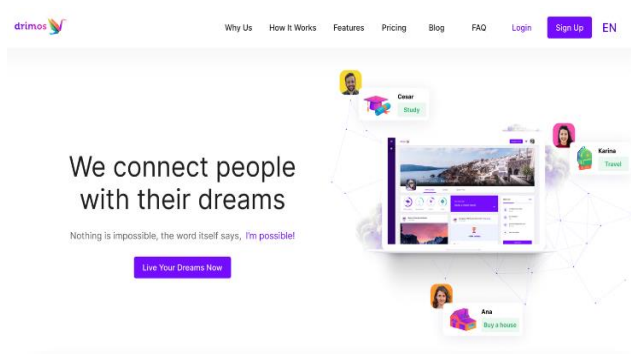

Fig. 2 The AI coaching platform to achieve your goals and dreams – drimos.ai homepage screenshot (from Idream Technology)

The popular existing social platforms personalize members' profiles classifying them by purchasing patterns or consumption of web content. drimos® platform from Idream Technology goes further because it mixes human intelligence with artificial intelligence, identifying how people make decisions. It captures, integrates, stores and reuses thousands of experiences occurring during the process of achieving personal, individual dreams or goals. In other words, it uses collective decision-making experience and applies it to amplify the individual one. As the result, dreamer's profile is presented with a systematic procedure to follow in order to achieve their personal dream or objective.

In terms of augmenting the human intelligence, drimos® considers two important elements to achieve its purpose: (i) a goal setting technique developed by an international expert in this area Karina Sterling (https://www.ted.com/talks/karina_sterling_cumple_tu_sue_no_y_cambia_el_mundo) which strengthens the emotional attachment to goals, and (ii) the capture of day-to-day anonymous experience from dreams/goals achievers which is explicitly formalized into Sets of Experience and added to the drimos® DDNA.

The main technique behind the process of managing experiential knowledge stored in the DDNA, is the

similarity concept based on mathematical distance between Sets of Experience [2,4]. This concept has been successfully used in all applications presented in Table I. In drimos® platform from Idream Technology the similarity notion is applied to the distance among users profiles of the drimos® community. The most similar profiles are chosen by the system to assist in the creation of successful path to reach the goals set up by others. Fig. 3 shows the similarity engine in action, and Fig. 4 presents the screenshot of gamification and set of tasks suggested to the user by the platform based on profiles' similarity.

Fig. 3 Similarity selection

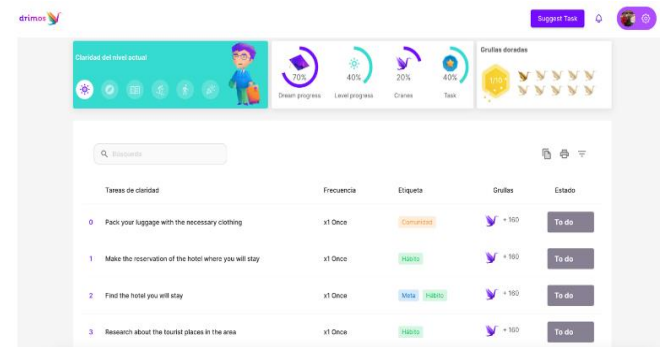

Fig. 4 Screenshot of goal steps with indicators and gamification model

Idream.Technology is a start-up hi-tech company to offer its smart enhancement of dedicated coaching services through drimos® application. It provides DDNA technology based tools to enhance peoples' sustainable development. It addresses global societies by covering English and Spanish speaking regions of the world.

IV. FUTURE OUTLOOK

Set of Experience (SOE) and Decisional DNA (DDNA) concepts are at the beginning of their advance but are already making a difference to knowledge management theory and practice. Future integration of various DDNA extensions would provide an intelligent and sustainable Internet application environment that would enable cybernetic positions (instruments that expediate interoperation among users, applications, and resources) to effectively capture, publish, share and manage explicit knowledge means and

sources. It would also provide support for on-demand services creating vast commercial potential for this technology. Through our approach to knowledge representation and formalization embedded in the concept of Decisional DNA, the future DDNA-based knowledge grid would incorporate epistemology and ontology to reflect human cognition characteristics and adopt the techniques and standards developed during work toward the next-generation, beyond-semantic web.

Software, System and Service Engineering

THE S3E track emphasizes the issues relevant to developing and maintaining software systems that behave reliably, efficiently and effectively. This track investigates both established traditional approaches and modern emerging approaches to large software production and evolution.

For decades, it is still an open question in software industry, how to provide fast and effective software process and software services, and how to come to the software systems, embedded systems, autonomous systems, or cyber-physical systems that will address the open issue of supporting information management process in many, particularly complex organization systems. Even more, it is a hot issue how to provide a synergy between systems in common and software services as mandatory component of each modern organization, particularly in terms of IoT, Big Data, and Industry 4.0 paradigms.

In recent years, we are the witnesses of great movements in the area of software, system and service engineering (S3E). Such movements are both of technological and methodological nature. By this, today we have a huge selection of various technologies, tools, and methods in S3E as a discipline that helps in a support of the whole information life cycle in organization systems. Despite that, one of the hot issues in practice is still how to effectively develop and maintain complex systems from various aspects, particularly when software components are crucial for addressing declared system goals, and their successful operation. It seems that nowadays we have great theoretical potentials for application of new and more effective approaches in S3E. However, it is more likely that real deployment of such approaches in industry practice is far behind their theoretical potentials.

The main goal of Track 5 is to address open questions and real potentials for various applications of modern approaches and technologies in S3E so as to develop and implement effective software services in a support of information management and system engineering. We intend to address interdisciplinary character of a set of theories, methodologies, processes, architectures, and technologies in disciplines such as: Software Engineering Methods, Techniques, and Technologies, Cyber-Physical Systems, Lean and Agile Software Development, Design of Multimedia and Interaction Systems, Model Driven Approaches in System Development, Development of Effective Software Services and Intelligent Systems, as well as applications in various problem domains. We invite researchers from all over the world who will present their contributions, interdisciplinary approaches or case studies related to modern approaches in S3E. We express an interest in gathering scientists and practitioners interested in applying these disciplines in industry sector, as well as public and government sectors, such as healthcare,

education, or security services. Experts from all sectors are welcomed.

TOPICS

Submissions to S3E are expected from, but not limited to the following topics:

- Advanced methodology approaches in S3E – new research and development issues
- Advanced S3E Process Models
- Applications of S3E in various problem domains – problems and lessons learned
- Applications of S3E in Lean Production and Lean Software Development
- Total Quality Management and Standardization for S3E
- Artificial Intelligence and Machine Learning methods in advancing S3E approaches
- S3E for Information and Business Intelligence Systems
- S3E for Embedded, Agent, Intelligent, Autonomous, and Cyber-Physical Systems
- S3E for Design of Multimedia and Interaction Systems
- S3E with User Experience and Interaction Design Methods
- S3E with Big Data and Data Science methods
- S3E with Blockchain and IoT Systems
- S3E for Cloud and Service-Oriented Systems
- S3E for Smart Data, Smart Products, and Smart Services World
- S3E in Digital Transformation
- Cyber-Physical Systems (9th Workshop IWCPS-9)
- Model Driven Approaches in System Development (7th Workshop MDASD'22)
- Software Engineering (42th IEEE Workshop SEW-42)

Extensible Conflict-Free Replicated Datatypes for Real-time Collaborative Software Engineering

Istvan David, Eugene Syriani, Constantin Masson

Department of Computer Science and Operations Research (DIRO) – Université de Montréal, Canada

Email: istvan.david@umontreal.ca, syriani@iro.umontreal.ca

Abstract—Real-time collaboration has become a prominent feature of nowadays’ software engineering practices. Conflict-free replicated data types (CRDT) offer efficient mechanisms for implementing real-time collaborative environments. However, the lack of extensibility of CRDT limits their applicability. This is a particularly important problem in settings relying on complex, non-linear data types. In this paper, we report our results in augmenting primitive CRDT with extension mechanisms. We demonstrate our technique through an example from the realm of model-driven engineering, where graph types are prevalent.

Index Terms—CRDT, Collaborative software engineering, Strong eventual consistency, Concurrency control

I. INTRODUCTION

TODAY’S software engineering is often carried out in distributed settings [1], necessitating advanced coordination mechanisms, such as real-time collaboration. A key challenge in real-time collaboration is to guarantee the convergence of the stakeholders’ local replicas while ensuring timely execution and smooth user experience [2]. Traditional mechanisms that implement locking [3] fall short of addressing this challenge. A more appropriate consistency model for real-time collaboration is strong eventual consistency (SEC) [4]. SEC ensures that (i) the updates will eventually be observed by each stakeholder, and (ii) the local replicas that received the same updates will be in the same state.

Conflict-free replicated Data Types (CRDT) [5] provide an efficient implementation of the SEC model. While CRDT have been successful in supporting real-time collaboration over linear data types, such as text and source code, some applications require more complex data types. For example, graph models are frequently employed in Model-Driven Software Engineering (MDSE) [6]. However, the lack of appropriate extension mechanisms in current CRDT frameworks renders the definition of more complex data types a challenging task.

In this paper, we report on our experiments with extensible CRDT using our prototype framework, CollabServer¹. The contributions include (i) a collection of CRDT primitives; (ii) an extension mechanism for the customization of CRDT; and (iii) performance assessment of the approach. We demonstrate our approach on an illustrative case for Mind map editors, which represents typical modeling environments that require graph semantics to represent models.

C. Masson is currently with Ubisoft, Paris.

II. BACKGROUND

Collaborative Model-Driven Software Engineering: The challenges of distributed software engineering are substantially exacerbated by the complexity of the engineered system that necessitates collaboration between stakeholders of highly diverse expertise. Model-driven software engineering (MDSE) [6] allows stakeholders to reason at higher levels of abstraction and by that, enables aligning the work of diverse stakeholders. Combining the benefits of collaborative software engineering with MDSE, collaborative MDSE [7] has become a prominent paradigm in software engineering practice. Due to the often disparate vocabularies of stakeholders, identifying overlaps between the stakeholders’ concerns is not trivial [8]. This, in turn, renders the detection of conflicts a challenging task. Recent studies [9], [10] show that only one-third of real-time collaborative MDSE solutions provide explicit conflict resolution mechanisms. State-of-the-art tools mostly rely on version control systems to facilitate collaborative MDSE [11]. Other approaches define consistency in terms of bijective correspondence, e.g., by linking elements through correspondence graphs [12], processes [13], or semantic links [14]. However, these techniques do not support real-time collaboration.

Real-time collaboration and CRDT: Sun et al. [2] define four requirements for effective real-time collaboration: (i) convergence of replicas; (ii) user intention preservation; (iii) causality preservation of updates; and (iv) timely execution of updates. CRDT support real-time collaboration by eliminating conflicts between the distributed stakeholders’ operations, without the need for a costly consensus mechanism, while showcasing excellent fault tolerance and reliability properties. Notable open-source CRDT frameworks include Automerge² and Yjs³. Automerge enables real-time collaboration in JavaScript-based systems, based on the JSON format. Yjs uses linked lists as its foundational data type, but the internal representation can be extended to achieve collaboration over complex data types. However, this extension is not trivial.

III. THE COLLABSERVER FRAMEWORK

A. Design principles

1) *Operation-based CRDT*: There are two equivalent approaches to implementing CRDT. State-based CRDT are

²<https://github.com/automerge/automerge>

³<https://github.com/yjs/yjs>

Fig. 1. Total order of updates in the LWW paradigm.

structured in a way that they adhere to a monotonic semi-lattice. Operation-based CRDT require that concurrent operations commute, i.e., irrespective of the order of operations, local replicas converge. We have opted for the operation-based CRDT scheme. This approach, as opposed to state-based CRDT, requires less network bandwidth, because only operations have to be sent through the network. In addition, an operation-based approach is more suitable for integration with external components, such as databases and user interfaces.

2) *Last-Writer-Wins (LWW)*: Automated reconciliation between replicas can be achieved at the application level or at the data level [15]. The LWW paradigm [16] implements the latter and has been widely adopted for operation-based conflict resolution. In LWW, conflicted operations are resolved by timestamps; the data with the more recent timestamp prevails. Fig. 1 shows an example resolution scenario under LWW. User A and User B initially have their local replicas in consistent states. At $t = 1$, User A executes the update $x = 15$. The updated value and the timestamp are propagated to User B. However, before the message arrives, User A executes another update: $x = 20$, at time $t = 2$. The update is propagated to User B. Networks usually do not guarantee order preservation. Thus, the second update may arrive at User B earlier than the first. Upon receiving the update, User B will reconcile this new value with his local replica. User B has $x = 10$ timestamped with $t = 0$; and an update that says $x = 20$ timestamped with $t = 2$. Under the LWW paradigm, the latter value is accepted. Eventually, the first update reaches User B. User B has $x = 20$ timestamped with $t = 2$; and an update of $x = 15$ timestamped with $t = 1$. Under the LWW paradigm, the former value is accepted, leaving the replicas in consistent states.

3) *CRDT tombstone metadata*: To ensure that operations commute, data is never deleted, only flagged as removed (i.e., soft delete). This information is captured in the tombstone metadata with boolean semantics. In an alternative approach by Shapiro et al. [5], dedicated partitions of the specific datatypes are reserved for storing deleted elements (LWW-element-Set). The benefit of our approach is that it reduces the number of elementary data operations upon changes.

4) *Commutativity and idempotence*: Operation-based CRDT assume that operations commute (i.e., $x \circ y = y \circ x$) and are idempotent (i.e., $x \circ x = x$). Traditionally, these properties are ensured by the communication protocol [5]. We have implemented the base type system of CollabServer in a way that commutativity and idempotence are guaranteed by design. As a consequence, CRDT that extend base

TABLE I
COLLABSERVER BASIC TYPES AND THEIR METHODS

Data type	Methods
<i>LWWRegister</i>	<code>query()</code> <code>update(value, timestamp)</code>
<i>LWWSet</i>	<code>query(key)</code> <code>add(key, timestamp)</code> <code>clear(timestamp)</code> <code>remove(key, timestamp)</code>
<i>LWWMap</i>	<code>query(key)</code> <code>add(key, value, timestamp)</code> <code>clear(timestamp)</code> <code>remove(key, timestamp)</code>
<i>LWWGraph</i>	<code>queryVertex(vertexID)</code> <code>addVertex(vertexID, timestamp)</code> <code>removeVertex(vertexID, timestamp)</code> <code>addEdge(source, target, timestamp)</code> <code>removeEdge(source, target, timestamp)</code> <code>clearVertices(timestamp)</code>

CollabServer types are expected to satisfy these properties without further development effort. Commutativity and idempotence are achieved by the combination of *timestamps* and *tombstones*. Timestamps ensure that each replica will order the update operations in the same way. Tombstone metadata ensures that no information is lost.

B. CollabServer CRDT primitives

Table I summarizes the CRDT provided by CollabServer. Every CRDT is equipped with atomic create, read, update, and delete (CRUD) operations. More complex operations can be implemented in specific applications. CollabServer is implemented in C++, using the Standard Template Library (STL) [17]. At the source code level, CollabServer CRDT are implemented as C++ templates, allowing easy extensibility and customization. More information is available in [18] and from the GitHub repository of the project¹. In the following, we briefly discuss the CRDT provided by CollabServer.

1) *LWWRegister*: The *LWWRegister* is the simplest primitive implemented in the CollabServer framework. It stores an atomic value, its timestamp ts , and its tombstone metadata. The `query` method returns the value stored in the register. The `update` method changes this value, as shown in Algorithm 1.

2) *LWWSet*: The *LWWSet* is a monotonically increasing data structure with the usual set semantics. That is, a value can exist in the set only once. The *LWWSet* is implemented as a C++ `HashMap`, with the values stored in the key set, and the associated value set storing the metadata (timestamp and tombstone). The `query` method (Algorithm 2) returns the respective key of the hashmap if it exists and is not marked as removed. The `add` method (Algorithm 3) inserts an element into the set. If the element already exists in the set, its timestamp is updated. If the element does not exist in the set, it is added to the set, along with the required metadata. The `remove` method (Algorithm 4) flags an element as deleted if its `timestamp` is higher than the current timestamp. In case the element is already deleted, its timestamp is updated, and a `false` value is returned. If the requested element is not present in the set, it is added with tombstone metadata that designates a deleted state. The `clear` method executes the `remove` method on every element in the set.

Algorithm 1: `lwregister_update(value, ts)`

```

if value, ts > current_timestamp then
  current_value = value
  current_timestamp = value, ts
  return true
else
  return false

```

Algorithm 2: `lwset_query(key)`

```

element = hashmap[key]
if element is not None AND is not element.value.isRemoved then
  return element.key
else
  return None

```

Algorithm 3: `lwset_add(key, ts)`

```

element = hashmap[key]
if element is not None then
  if ts > element.value.timestamp then
    element.value.timestamp = ts
    if element.value.isRemoved then
      element.value.isRemoved = false
    return true
  return false
else
  element = {key, {ts, false}}
  hashmap.add(element)
  if element.value.timestamp <= lastclear_timestamp then
    element.value.timestamp = lastclear_timestamp
    element.value.isRemoved = true
    return false
  else
    return true

```

3) *LWWMap*: The *LWWMap* stores key-value pairs of data with the keys being stored in an *LWWSet* and the associated value being stored in an *LWWRegister*. By reusing the previously defined LWW types, the API methods of the *LWWMap* can be reduced to the ones defined in Algorithms 1–4.

IV. CUSTOMIZING CRDT

In this section, we demonstrate the extensibility of CollabServer CRDT by (i) constructing a custom physical CRDT, the *LWWGraph* (Section IV-A); and (ii) based on this custom type, constructing a domain-specific type (Section IV-B). For the latter, we use the example of a Mind map editor, providing domain-specific operations for constructing and manipulating a Mind map, such as adding and removing topics; and placing a marker on a topic. Fig. 2 show the extended type system.

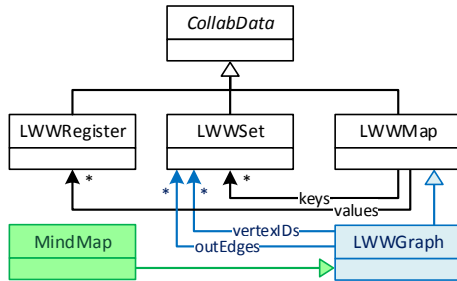

Fig. 2. Type system with the customized types highlighted

A. Constructing custom CRDT: *LWWGraph*

The *LWWGraph* is a directed graph, represented by its adjacency list, stored in an *LWWMap*. Vertex IDs are stored as keys and the vertices are stored as values. There are no restrictions on the type of the vertex ID, it only depends on the specific implementation, and its typing is deferred to the developer. A vertex is defined as a tuple (*content, edges*), describing the content of the vertex and an *LWWSet* of the outgoing edges from this vertex. Each key is the ID of the target vertex. The `queryVertex` method invokes the `query` method on the *LWWMap* storing the adjacency list of vertices, and returns the vertex if exists. Similarly, the `addVertex` method invokes the

Algorithm 4: `lwset_remove(key, ts)`

```

element = hashmap[key]
if element is not None then
  if ts > element.value.timestamp then
    element.value.timestamp = ts
    if not element.value.isRemoved then
      element.value.isRemoved = true
      return true
  return false
else
  element = {key, {ts, true}}
  hashmap.add(element)
  return false

```

`add` method on the *LWWMap* storing the adjacency list. The `removeVertex` method (Algorithm 5) removes a vertex from the graph, and all edges connected to it. If the vertex does not exist yet, it is added in the adjacency list, and the `remove` method of the *LWWMap* is invoked. The `addEdge` method (Algorithm 6) creates a new edge connecting the source vertex with the target vertex. We distinguish between three scenarios. First, we apply `addEdge` on two existing vertices. In this case, the edge is added to the underlying graph; or if the edge already exists, its timestamp is updated. Second, we apply `addEdge` when one or two vertices do not exist. This case occurs when the `addEdge` operation is observed before the `addVertex` operation. To ensure the commutativity of operations, CollabServer implements the `addEdge` method in a way that it also applies `addVertex` on the source and target vertices. Missing vertices are then simply added along with the edge. Receiving a later `addVertex` operation will simply update the timestamps. Third, we apply `addEdge` with the source and/or the target vertex that has already been deleted. This case occurs when the `addEdge` operation is received with the source and/or the target vertex already deleted. The case where `removeVertex` is older than `addEdge` is a trivial one, since `addEdge` also applies `addVertex` as seen earlier. The opposite case (`removeVertex` older than `addEdge`) requires additional steps. First, the edge is created as discussed before.

Algorithm 5: `lwwgraph_removeVertex(vertexID,ts)`

```

removed = adj.remove(vertexID, ts)
vertex = adj.queryCRDT(vertexID)
vertex.edges.clear(ts)
for vertex in adj.iteratorCRDT do
  if vertex.edges.has(vertexID) then
    vertex.edges.remove(vertexID, ts)
return removed

```

Algorithm 6: `lwwgraph_addEdge(src, trgt, ts)`

```

info = {'srcAdded': false, 'trgtAdded': false, 'edgeAdded': false}
info['srcAdded'] = adj.add(src, ts)
info['trgtAdded'] = adj.add(trgt, ts)
vertexSrc = adj.queryCRDT(src)
info['edgeAdded'] = vertexSrc.edges.add(trgt, ts)
if not vertexSrc.edges.queryCRDT(trgt).isRemoved then
  vertexTrgt = adj.queryCRDT(trgt)
  if vertexSrc.isRemoved OR vertexTrgt.isRemoved then
    t = max(vertexSrc.ts, vertexTrgt.ts)
    vertexSrc.edges.remove(trgt, t)
    info.edgeAdded = false
  return info
return info

```

Then, we check if the newly created edge is dangling and remove it. This way, `addEdge` is commutative. Note that, as shown in Algorithm 6, this operation returns more information since additional actions can be performed on the edge or the vertices. The `removeEdge` method (Algorithm 7) removes an edge from the graph. This operation may encounter a situation where the source vertex does not exist yet in the graph. Since all operations are required to be commutative, the source vertex is created with the smallest timestamp and the `isRemoved` flag is set to true. The `clearVertices` method removes all vertices and their associated edges from the graph.

B. Constructing domain-specific CRDT

The construction of custom CRDT is achieved by extending the `CollabData` base type and defining custom operations while ensuring their commutative and idempotent properties. We demonstrate the extensibility of primitive `CollabServer` data types by constructing the *MindMap* CRDT for the `MindmapEditor` application. The *MindMap* type is a graph; each topic and marker of the *MindMap* is a vertex of the graph; edges of the graph connect topics to their parent topic, and markers to the topics they mark. Constructing the *MindMap* requires extending the *LWWGraph* primitive type and augmenting it with domain-specific methods that are commutative and idempotent. The outline of the *MindMap* CRDT is shown in Listing 1. The full implementation is available from the GitHub repository of the project.¹

The methods in Listing 1 reuse the API of the *LWWGraph*; thus, they inherit CRDT properties. The *MindMap* type extends the *LWWGraph* by introducing the notion of *attributes*, for example, for storing the *name* of the *MindMap*. As shown

Algorithm 7: `lwwgraph_removeEdge(src, trgt, ts)`

```

adj.remove(src, Timestamp.MIN)
if src != trgt then
  adj.remove(trgt, Timestamp.MIN)
vertex = adj.queryCRDT(src)
return vertex.edges.remove(trgt, ts)

```

in Listing 2, attributes are added to *LWWGraph*-derivatives by invoking the `add` method of the *LWWMap* that allows storing key-value pairs. The built-in CRDT can be readily reused to construct custom data types. This has been demonstrated in this example, and also in the definition of the *LWWMap* and *LWWGraph* that reuse more primitive `CollabServer` CRDT.

Listing 1. *MindMap* CRDT with domain-specific operations

```

class Topic: Vertex{...}
class Marker: Vertex{...}

class MindMap: LWWGraph{
  void addTopic(const UUID& topicId){
    LWWGraph::addVertex(topicId, Timestamp::now())
    notifyOperationBroadcaster()
  }
  void removeTopic(const UUID& id){}
  void addMarker(const UUID& id){}
  void removeMarker(const UUID& id){}
  void connectTopics(const UUID& t1, const UUID& t2){
    LWWGraph::addEdge(t1, t2, Timestamp::now())
    notifyOperationBroadcaster()
  }
  void putMarker(const UUID& m, const UUID& t){}
  ...
}

```

Listing 2. API for adding attributes to the *MindMap*

```

class MindMap: LWWGraph{
  void addAttribute(
    const UUID& id,
    const std::string& name,
    const std::string& value) {
    //calls the LWWMap super class
    LWWGraph::add(name, value, Timestamp::now())
    notifyOperationBroadcaster()
  }
}

```

V. PERFORMANCE EVALUATION

Although performance was not our primary concern in this exploratory project, we provide a performance evaluation of the framework. As the performance of CRDT is determined by the number of objects present in the application [19], we assess the performance by simulating a scenario in which new vertices and edges are added to a shared model.

Experimental setup: We used the following sequence as a test scenario: $\text{add topic}_i \rightarrow \text{add topic}_j \rightarrow \text{connectTopics topic}_i, \text{topic}_j$. The scenario was executed 50.000 times. That is, 100.000 topics (graph vertices) and 50.000 relationships (edges) were generated. We have executed the test scenario with one, two, and four parallel users, and measured the change in response times. In the case of two and four parallel simulated users, each user carried out

TABLE II
RESPONSE TIMES OF THE 1/2/4 USER CASES

Users	Min [ms]	Response times		
		μ [ms]	σ	Max [ms]
1	0.11	0.94	0.22	17.4
2	0.13	2.06	0.33	17.4
4	0.37	5.92	0.49	17.4

this sequence, adding topics (vertices) and connecting them (by adding edges) to the same shared mind map (graph). The measurements have been executed on a VMWare virtual machine running a 64-bit Ubuntu 20.04.1. OS, with 4GB of memory, and with 4 CPU cores allocated, checked at 2.6 GHz.

Results: To assess the *scalability* of the framework, response times were measured at the local replicas, defined as the time difference between issuing a command in the editor and getting a response. To filter noise, we clipped the sample at $\mu \pm 3\sigma$ (0.2% of the cases). The mean response time in the one-user case shows linear scaling with the number of objects. (Linear regression statistic: $p = 22E - 17$.) We have observed the same linear increase in response times in the two and four-user cases. We have also observed increasing response times with the increasing number of users. Table II shows the mean response time in one, two, and four user cases. The mean response time increased by a factor of 2.2 and 2.8 as the number of users doubled from one to two, and from two to four, respectively. A statistically significant difference is observed in the mean response time of the three cases, as confirmed by a t-test ($\alpha = 0.05$, $p = 2e-11$).

We observed a linear increase in the *memory heap*. The majority of memory consumption is due to C++ node iterators and hashtable objects the `LWWGraph` relies on.

Discussion: We observe a linearly increasing response time and a linearly increasing memory footprint. This is in line with the observation of Sun et al. [20]. We conclude that this performance profile is characteristic of CRDT implementations, and can be effectively treated by suitable garbage collection mechanisms [21]. We consider these results adequate (i) considering the benefits in extensibility `CollabServer` CRDT provide; and (ii) considering that performance was not the primary objective of the current solution.

VI. CONCLUSION

In this paper, we presented an approach for augmenting CRDT with extension mechanisms and demonstrated that the performance repercussions of extensibility are manageable. We provided a family of concurrency control algorithms, ensuring strong eventual consistency and allowing for efficient real-time collaboration. Our algorithms and data types show linear scaling of response time and memory footprint with the number of objects in memory and with users. This is a characteristic performance profile of CRDT. Our results suggest that CRDT can be used in disciplines where customizability is a key factor, such as collaborative modeling using domain-specific modeling languages. In future work, we will investigate garbage collection mechanisms to achieve the

scalability collaborative engineering tools require. We used the takeaways of this exploratory project in the development of our real-time collaborative modeling framework `lowkey` [22].

Abstract—Cyber-Physical Systems (CPS) have a physical part that can interact with sensors and actuators. The data that is read from sensors and the one generated to drive actuators is crucial for the correct operation of this class of devices. Most implementations trust the data being read from sensors and the outputted data to actuators. Real-time validation of the input and output of data for any system is crucial for the safety of its operation. This paper proposes an architecture for handling this issue through smart data guards detached from sensors and controllers and acting solely on the data. This mitigates potential issues of malfunctioning sensors and intentional sensor and controller attacks. The data guards understand the expected data, can detect anomalies and can correct them in real-time. This approach adds more guarantees for fault-tolerant behavior in the presence of attacks and sensor failures.

Index Terms—CPS, robots, software architecture, fault tolerance, resilience, ROS

I. INTRODUCTION

IT IS not always possible to trust sensor data because of reliability issues in sensors, intentional sensor attacks, and issues like EMI interference [1]. Since sensor data are used in control loops, it is better if we could make sure that the data is not compromised and has not deviated from an acceptable range. This problem is very pertinent for control algorithms. In the era of AI solutions, the data streams can determine the success or failure of neural networks or other machine learning algorithms used in the device. Therefore the issue applies to ML solutions.

Using data guards exploits a separation of concerns approach, applicable to off-the-shelf controllers or AI solutions that are complex and hard to understand. Data guards are much more straightforward in their operation and focus on guarding the validity of the data, independently of how complex the controllers or sensors are. Tuning such complex components is difficult and guaranteeing that they will work in all conditions is sometimes impossible. Therefore using data guards before data is fed to the controller is a security and reliability guarantee which enables safer system operation. A further benefit of separating data guards from the rest of the system is that they can be validated separately, as they tend not to contain too much code and complexity. In this respect, they can be similar to the enforcers presented in the literature [2] but are focused on data instead of behavior.

The paper’s main contribution is the proposal of dedicated smart data guards that take care of sensor data in real-time.

The definition of data contracts is another contribution. The enforcement of such contracts in an existing architecture is a way to enhance systems and enforce security and safety properties. The contribution related to this is that we propose to use separation of concerns through data-centric components that abide by the data contracts we define, depending on the data.

The paper starts with analyzing what data protection means and why we need it. Then the next section discusses data contracts and provides formal presentation examples. The following section discusses how they can improve an existing control architecture. A data guard implementation is also discussed. A reference implementation in PX4 is next. The paper ends with future directions and a conclusion section.

II. DATA PROTECTION ANALYSIS

Sensor data requires attention since it is used for control decisions and can affect the safety of a CPS and is therefore critical. Controllers and observers operate by using sensor data, trusting it is correct. Most of the controllers are designed with the assumption of data correctness. In reality, possible attacks and noise in the data, as well as sensor degradation and failure, are facts that cannot be ignored. Both sources of sensor data incorrectness can be dealt with if we take precautions to validate the data in real-time.

A. Sensor Attacks

If we consider a Cyber-Physical System such as an autonomous vehicle or a UAV, there are generally many sensors used by such a system. Some sensors, such as cameras and other object detection sensors, may need to be processed by complex machine learning algorithms to integrate them into the system. Many other sensors, though, are simpler and can generate fewer data per unit of time. The main issue with trusting sensor data is that there is no way to know if the data are valid since there is usually no authentication and encryption of the data sent from the sensors to the controller. There is also no guarantee that the measured physical value is not affected by an attack. A class of attacks can affect physical values without coming into contact with the sensors using EMI or acoustic waves, for example, [3].

An example of a possible attack is an EMI burst that disrupts a sensor ([4]). The other likely attack can happen when the measured data are transferred to the controller, for example,

through CAN bus [5]. Flipping bits or controlling the sensor data bus can be even an easier way to perform an attack. Sensor buses can be in many different forms and can be, for example, i2c or Spi or a dedicated Ethernet and even a wireless connection in some cases [6]. Given that the attack surface is large, we cannot and should not trust sensor data for safety-critical systems. There is a need to add a mechanism to detect and remedy the effects of an attack that manipulates sensor data.

The data coming from sensors could also be encrypted as a security measure, but this is a pretty resource-intensive operation and can severely affect the timing of transporting the data and using it [7]. Controllers are sensitive to delays, and this approach may become impractical for resource-constrained CPS [8]. There are also hardware solutions that enable encryption, but it is unlikely that all the sensors in an AV can be equipped with such capabilities. Therefore, for this study, we can assume that sensor data travels in the open and can be vulnerable to attacks.

B. Data Guard Components

A sensor typically sends a digital stream of bytes representing a physical parameter, for example, position, velocity, or acceleration in the case of UAVs. In the event of a sensor attack or sensor malfunctioning, we can have data that is not physically realistic at a particular moment, based on the system's state. A data guard can use sensor-specific parameters to guarantee the sensor data [9]. For example, the following parameters can be used in a simple universal approach to sensor validation:

- MAX value - The maximum allowed value for all cases
- MIN value - The minimum allowed value for all cases
- MAX delta - The maximum change in unit time
- MIN delta - The minimum change in unit time
- MAX time for stale data - The maximum time when data can stay the same.
- DEFAULT safe value - When the input value is out of bounds or stale, this value can be fed to the controller. Note that in addition to static default values, we can calculate a default based on historical data when we consider that the system operates under normal conditions.

C. Sensor Data

As one possible example we can have a look at a GPS message in the PX4 autopilot which has the following message abbreviated format in Listing 1:

Listing 1 GPS message details

```
uint64 timestamp
int32 lat
int32 lon
int32 alt
...
```

The individual fields of the GPS message are either integers or real numbers. They can be validated as each message

arrives in a software component as part of the system. Such an approach takes care of each message instance but does not help check data deviations between successive message instances. We need an algorithm that contains meta parameters used for all messages, such as delta max, delta min, stale timer values, and default values. All these parameters can be considered as data contract parameters. Each data guard expects the sensor to provide data that is within the data contract parameters [10]. Defining and enforcing such contracts is the main contribution of the paper.

D. Data Guard Utilization

Data guard components can work independently from other components in separate threads. The goal is to provide minimal overhead and be transparent to the rest of the control system. The main goal is to have the guards provide reasonable values when the data stream contains unexpected values. In other words, this is not just filtering specific values but actively reconstructing the sensor data when deemed incorrect. This takes care of spikes or short attacks and can even be used to detect a persistent sensor attack. For example, if the data guard keeps a default value for a certain period, it can then generate a signal indicating that something has gone wrong with that sensor. This is a relatively simple implementation but general enough to be used with many different sensors.

III. DATA CONTRACTS

Software contracts have been used in many aspects of software engineering, especially in designing object-oriented systems [11], [12]. In this work, we extend the software contract concepts to be used for the specification of data guards, used to guarantee specific properties in the sensor data and the data sent to actuators. Contracts are based on assumptions and guarantees and can be applied to software interfaces. The general representation is given through equation 1 [11], [12]:

$$C = A, G \quad (1)$$

Where C is the contract, A is the set of assumptions, and G is the set of guarantees. The contract definition can happen during design time since the sensor and actuator data are usually known to the designer. This allows for a thorough analysis of the data and the associated data contract. We start by defining the assumptions A of our data guard contract can be different for different cases and can be expressed as a set according to 2.

$$A = \{A_i\} \quad (2)$$

The data set of each data source by the following set in 3:

$$D = \{D_i\} \quad (3)$$

, where each data member can have a different type.

Some common assumptions for the data in the set D are:

- expected data should have no overflow or underflow for these data types.

- Another assumption can be that new data will be received with a certain minimum frequency.

The guarantees G can include a different set for different data. According to our running example, the guarantees G can be composed through a set of rules 4:

$$G = \{G_i\} \quad (4)$$

An example set of guarantees based on our example follows:

- No data item will exceed its expected maximum value
- No data item will become less than its expected minimum value
- No two successive values will exceed the maximum allowed delta for that data item. The delta is the difference between two consecutive readings.
- A data item will not be stale longer than the maximum allowed number of readings
- Any reading should not deviate from the average of the last N readings by a certain delta value.
- When any of the above rules are violated, a default value will be provided for each data item

Some examples from the set of guarantees G can be represented mathematically in the following way:

$$G_1 : D_i \leq D_{imax},$$

$$G_2 : D_i \geq D_{imin},$$

$$G_3 : D_{i2} - D_{i1} \leq D_{i\delta}$$

$$G_4 : D_i - D_j \neq 0, \text{ where } j = i + k \text{ over } k \text{ time periods}$$

$$G_5 : D_i \in D_u \Rightarrow D_i = D_d$$

where D_u is unacceptable value and D_d is default value

IV. ATTACK RESISTANT CONTROL ARCHITECTURE

Using our defined data contract from the previous section, we can show the proposed control architecture in figure 1. This type of control architecture is typical for a variety of CPS, including UAVs [13]. It is very similar to the classic control loop architecture with the addition of data guard components for each sensor and a data guard for the controller output. Having a data guard for each sensor makes handling each sensor data stream's timing and specific data characteristics easier. This also allows for the sensor fusion to be done separately. The approach assumes that all data guards will be running in parallel so that the streams coming from sensors and the controller can work independently. It is also possible to place data guards after the fusion block; in some situations, this may be a better approach.

Figure 2 shows a possible architecture of a generic data guard. There are two independent timers for calculating the deltas and for the detection of stale data. Stale data means a faulty sensor or a sensor under constant attack. These parameters can be part of the data contract established for each sensor data stream in the system. The data guard component checks for range violations in each message as well as jumps

in data readings between messages that are not realistic, given the characteristics of a particular sensor. For example, an accelerometer cannot generate impossible values given the abilities of a UAV or UGV.

Fig. 1. Control architecture

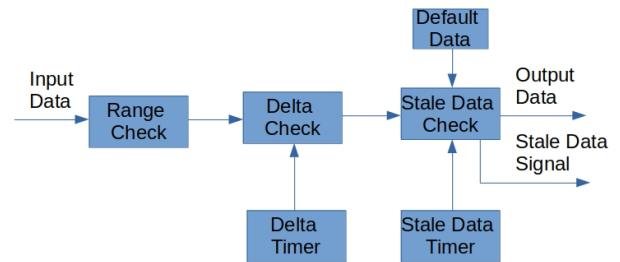

Fig. 2. Data Guard Component

A. Implementation of a Data Guard

Data guards can be implemented in a separate module using a variety of programming languages. For existing systems, they will most likely be in the programming language used to develop the system. Our implementation of a data guard follows the generic approach shown in figure 2. An example algorithm for a data guard is written in pseudo-code in Listing 2. This algorithm utilizes two timers and works continuously on incoming data. The implementation can protect against sudden changes that are not physically expected and can detect if a sensor is faulty and does not function anymore. Generating a signal to the system can be used to make a higher-level decision to enter a different fail-safe mode of control. In that respect, the data guard can be the first level in

Listing 2 Pseudo-code example of a data guard

```

read_value()
if data > max or data < min then
data = default_data
endif
if delta_timer_expiration()
check_delta_max()
check_delta_min()
endif
if delta > delta_max
or delta < delta-min then
data = default_data
endif
if stale_time_expired()
check_for_stale_data()
endif
if stale_data() then
send_stale_alarm()
endif

```

the decision-making when implementing fault-tolerant system-wide behavior.

B. PX4 autopilot as a prototyping platform

PX4 can be used within a Software in the Loop (SITL) environment with Jmavsim, or the Gazebo flight simulator [14]. In either case, the sensors of the drone are part of the simulator, and the data from them is sent periodically to PX4, where the data is analyzed and dispatched to other modules. This is done via the Mavlink protocol, which is a standard protocol for messaging in UAVs [15]. Adding a new custom module and intercepting the data stream from one or more sensors is relatively easy, and this is the chosen approach for the experiments. Similarly, defining new messages and writing code for them is very well supported, and we took advantage of it in this work.

V. REFERENCE IMPLEMENTATION OF DATA GUARDS

Figure 3 demonstrates the reference implementation with the Gazebo simulator and PX4. Gazebo is a physical simulator used to perform robotic vehicle simulations. One excellent characteristic of Gazebo is that it has plugins, which are essentially software modules that the user can add or modify. This allows for easy additions and modifications of the simulator. There are several types of plugins, among which are sensor plugins. There is one sensor plugin for each sensor as part of the PX4 integration with Gazebo. For the purposes of this implementation, the GPS plugin was chosen so that perturbations for the GPS signal could be introduced. A simple scheme such as randomly generating a spike in the altitude by generating a random number every ten readings or so is a simple way to perturb the GPS data stream. This emulates a GPS sensor attack or a malfunction in the GPS module. Gazebo sends all sensor data to PX4 through the Mavlink protocol, including the periodic GPS message.

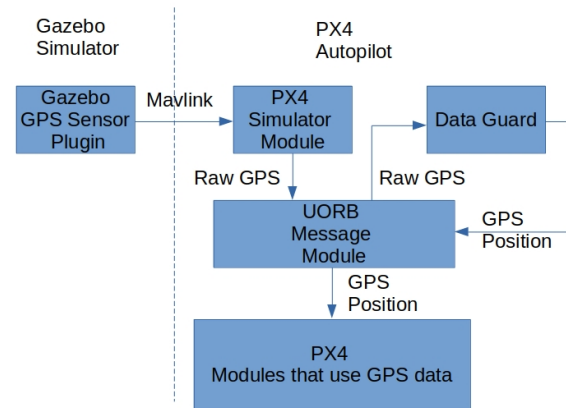

Fig. 3. Reference architecture

The reference implementation is a representative example of the approach based on a popular platform for UAVs and the fact that GPS spoofing is such a common GPS attack. The results show that it is fairly straightforward to introduce a data guard component in a publish-subscriber architecture such as PX4. The same can be done for similar architectures, for example ROS and ROS2 [16], [17]. The performance penalty is minimal if we perform just simple checks. This may not be the case if the data is fairly complex. In this case, our data guard may need to use some ML algorithm or fuzzy logic to achieve its goals. Our experiments showed no degradation of the autopilot's performance, and we expect that in many cases, some spare CPU cycles can be utilized to provide the necessary data protection controllers need.

VI. FUTURE DIRECTIONS

The data guards that we discussed were mainly static as their behavior was specified at design time. However, there may be situations when data fluctuations may require adaptable data guards with more changeable behavior based on ML algorithms. This direction is pretty exciting and also more ambitious. Still, in the era of the ever-increasing use of better hardware and pervasive AI solutions, it is not something that is far from reality. Adaptive behavior has been used in control for a long time, as well as in digital filters. Some of the already established ideas can be applied to complex and variable sensor data with the goal of their online sanitation.

Another possibility is to have an automatic code generator of data guards based on a custom language defining the rules that govern them. This kind of approach can make their implementation even more straightforward and widespread. Automatic code generation can be done from a modeling language or from a data flow language such as Lustre [18]. The objective is to capture the relationships in data processing at a higher level in a fairly representative way and then generate code for the target system. This future direction can be achieved by developing unique tools for the task.

VII. CONCLUSION

This paper demonstrated a flexible architecture for simulating sensor and controller attacks and a mechanism to react to them by introducing data guards. The data guard can be as complex as needed but still be practical for maintaining the real-time response of the system. The approach applies to any sensor and actuator and any controller or module which consumes sensor data. This can include complicated sensors such as image and Lidar sensors. The approach minimizes or eliminates the possibility of affecting the system's stability and normal operation due to sensor data issues. The method is a complementary run-time strategy to data sanitation used during the training of machine learning systems. It makes sensor data more important as part of the set of concerns for robotic systems. Furthermore, the approach applies to the reliability of sensors and malicious modifications of sensor and controller behavior.

Abstract—Application logs record the behavior of a system during its runtime and their analysis can provide useful information. In this article, we propose a method of automated log analysis to discover interactions taking place between applications in an enterprise. We believe that such an automated approach can greatly support enterprise architects in building an up-to-date view of a governed system in a modern, fast-paced development environment. Our contribution is the following: we propose a new method for log template generation called SLT (Simple Log Template), we propose a method of extracting knowledge about application interactions from logs, and we validate the proposed methods on a real system running at Nordea Bank. Additionally, we collect statistical information about application logs from the real-life system, based on which we formulate some observations that support our method.

I. INTRODUCTION

ONE of the challenges faced by enterprise architect teams in large organizations is to ensure an up-to-date overview of the systems they are governing. Traditionally, the governance process relies on manual updates to the system representation stored in the architecture repository. However, in the age of microservices and cloud deployments, where significant changes to architecture can take place overnight, this is barely sufficient. There is a clear need for a better, more automated way of maintaining knowledge about systems across an enterprise.

Automation of system knowledge discovery is a big help for enterprise architects, especially in recent times, when new applications are created at an increasing pace and their architecture changes rapidly. Manually updated architecture repositories no longer keep up with the reality of systems deployed to a production environment. This problem is further emphasized by long, heavy, and manual processes of introducing changes to architecture repositories, which do not fit the time-to-market expectations of the business stakeholders. Having a decent representation of current production deployment allows for reasoning about the architecture, detecting non-compliance with internal or external regulations, and helps the development of the enterprise architecture in a planned direction. It also improves building always up-to-date overview of the enterprise system which is beneficial

not only for architects but for developers, analysts, and testers for building a mental model of the system they are working with. One of the potential approaches is to utilize application logs which provide a common, always up-to-date view of applications during their runtime.

Application logs have several compelling advantages as compared to other sources of knowledge about the system (e.g., documentation or source code). Firstly, logging is the most widespread way of tracking system behavior that is present in software development since its beginning. Thanks to that we can assume that nearly every software system, even legacy, implements some form of logging. In the reality of many enterprises, logs may prove to be the only common source of knowledge about systems still running on main-frame platforms. Secondly, logs (which traditionally are stored as text files) are usually human-readable and therefore are suitable for processing by text tools. Additionally, they are a mixture of technical information and narrative. Lastly, logs usually follow the changes in the source code of applications, so they contain the historical aspect of software evolution. All of that makes application logs a rich source of data for various analyses. Because of our focus on automation of knowledge discovery about systems, we are only interested in automated log analysis. According to [1], automated analysis of application logs is a widely studied discipline with growing interest among researchers in recent years. The most obvious usage of log analysis lies in the *operations* area (*intrusion detection, monitoring*) but its potential in reasoning about the *business domain* or the *design* of the software is also explored.

In this paper, we try to derive knowledge about enterprise systems (specifically about interactions between applications) from application logs. Our work fits in the *design/component dependency inference* area of the landscape of automated log analysis proposed by the authors of [1]. We perform experiments on a real-life system from the banking industry, hosted at Nordea Bank. We contribute to the body of knowledge in the following ways:

- we perform statistical analysis of log files of a subset of logs from a real-life system deployed at Nordea Bank,
- we formulate some general observations about the way logs are typically created by developers,

This work was supported by Gdańsk University of Technology

- based on the defined observations, we propose a new method for log template extraction called SLT (Simple Log Template),
- we propose a workflow for automated discovery of application interactions from their logs,
- we verify our method with logs from a real-life system deployed at Nordea Bank.

The remainder of this paper is organized as follows. Section II discusses related work. In Section III, we present a formal definition of the problem. In Section IV, we perform a statistical analysis of application logs from a subset of applications deployed at Nordea Bank and we formulate observations related to how developers place their log statements in enterprise systems. In Section V, we describe our approach for component dependency inference based on log analysis, while in Section VI, we evaluate this method against the real-life system deployed at Nordea Bank. Section VII presents conclusions from our experiments and outlines the future work.

II. RELATED WORK

Component dependency inference using automated log analysis is rather a niche topic, but some notable recent work is worth mentioning. [2] analyzes web service interactions and tries to correlate web service invocations using IP addresses and invocation statuses found in logs. The authors identify two specific types of interactions: composition (one service orchestrates a series of calls to other services) and substitution (service is called as part of an error-handling scenario after a failed call to another service). The authors assume the availability of IP address information in service logs, which (according to [1]) is true mostly for access logs and network logs that may not be available for applications other than web services. Additionally, basing the analysis on IP address correlation may be very challenging in cloud-hosted applications, where services are replicated, and IP addresses can change dynamically. In contrast, our method puts minimum assumptions on log content and bases the analysis on log messages. The authors of [3] perform a statistical analysis of web service logs to identify a correlation between web services. The analysis includes time correlation, call frequency correlation, and analysis of service response times. The authors define three types of web service interactions: dependency on the data source (multiple web services try to access the same shared resource), hierarchical dependency (one service is invoked by another), and serial execution dependency (one service orchestrates a series of invocations). Similarly, as in the previously mentioned work, the focus is on web services and other types of applications are not considered. [4] describes a Bayesian Decision Theory-based approach to the identification of component dependencies. The authors describe each log message with a key and a set of parameters which are determined by some empirical knowledge and common string extraction. The authors also identify some observations related to logging practices that form the foundation for their algorithm: co-oc-

currence observation (logs of dependent services are time-correlated) and correspondence observation (logs of dependent services often contain some identical parameter). The proposed method is validated using the Hadoop dataset. In our work, we take these ideas further by removing any empirical knowledge needed to extract parameters. We also empirically confirm and further extend the authors' observations regarding logging practices based on application logs from a real-life system at Nordea Bank. Furthermore, we validate our method using a dataset of logs from Nordea Bank, which is expected to be less homogeneous than logs of any shared service platform like Hadoop.

Workflow discovery is a similar research area that aims in recovering whole processes from logs. Although it is not in the scope of this paper, workflow discovery is part of our future work and therefore notable work on this related topic is worth mentioning. [8] uses a process mining approach to discover recursive processes from event logs. The authors of [9] propose a method for triaging production failures that analyses service interactions to identify the failed workflows. The authors of [10] present a method for recovery of Communicating Finite State Machine model that represents service interactions. The proposed approach requires, however, users to input knowledge about the structure of a log file for it to be able to be processed.

Our work also aims to identify real-life logging practices applied by software developers. Similar efforts were presented in [5] where different categories of logging statements used by developers are defined. The authors take the source-code perspective analyzing logging practices from the point of view of a single application. [6] presents a statistical analysis of logging practices in open-source projects and [7] repeats this study for java-based open-source projects. The authors analyze factors such as log density, how meaningful log extracts are for bug-fixing, what are the typical changes to logging code, and how often they occur. In our work, we use logs from a real-life system at Nordea Bank to identify higher-level observations regarding logging statements that represent the intent to specifically track interactions between different applications and thus are useful for analyzing application dependencies.

Log template generation is another area of research, related strictly to log analysis, which aims in discovering templates that describe individual lines in log files. Being able to identify static and variable parts of log entries allows for better reasoning about the log content and is considered the basis of any log analysis task. [14] performs a comparative analysis of various log template generation algorithms. Log-Cluster [11] and DRAIN [12] are two of these algorithms that, according to [14], present respectively the lowest accuracy span and the top accuracy levels over the sample data sets. We picked these algorithms as a benchmark for the method proposed by us.

III. PROBLEM STATEMENT

We aim at inferring knowledge about enterprise systems from application logs. The goal is to provide enterprise architects with a good enough representation of the system that reflects the reality of the production environment. The derived model of the enterprise system needs to support architects' activities related to reasoning about the architecture. An example of such activities is data governance which concentrates on aspects like usage of proper data sources by applications, understanding the semantic relationships between data stored and exchanged between applications, or ensuring assumed data flow. Apart from data governance, common enterprise architects' activities concentrate also on ensuring that processes implemented inside the system fulfill both internal and external regulations. These may include measuring process performance or ensuring certain regulatory constraints are obeyed.

We can assume that the set of applications in the enterprise system is known with a high level of confidence. On the other hand, knowledge of application inter-connections (interactions between applications) from the enterprise perspective is where the confidence decreases. Having hundreds of applications deployed in a bank, this confidence is only as good as the diligence of teams in updating a common architecture repository. Furthermore, basing decisions related to the architecture of an enterprise on human declarations, rather than facts, can lead to false conclusions and not-optimal choices. We consider the problem of increasing the confidence of knowledge about the actual application interactions as the core problem in architecture reverse-engineering.

Let $G(S)=(A,C)$ be an undirected graph representing a real system S , where A is a set of applications constituting S and C is a set of edges representing interactions between the applications. We say that applications A_1 and A_2 are interacting with each other if some data exchange takes place between them. Let $L(S)=\{l_1, l_2, \dots, l_n\}$ be a log of activities collected within system S consisting of n messages. We describe each line of the log by a tuple (t, a, m) where t denotes the date and time of log message creation, a represents the application that created the message, m is the actual log message text.

We define the problem of application interaction discovery from logs as finding an approximate graph $G'(S)=(A,C')$, where C' is an approximation of C , based on the system's log $L(S)$. $G'(S)$ is a graph representing an approximation of system S .

The presented problem definition is extendable and allows inference of other architecture properties on top of the applications' interaction graph. For any property of enterprise system $P(S)$, the problem of architecture property discovery from logs can be defined as finding a function F , such that $P'(S)=F(G'(S), L(S))$ approximates $P(S)$. In this paper, we do not cover solutions to the extensions of the core problems, leaving this for further work.

IV. NORDEA BANK DATA SET

Our work presents an experience of applying log analysis to one of the systems at Nordea Bank, which we will further refer to as NDEASYS. For our experiment and proposed method to be as generally applicable as possible, we picked an application with a relatively big integration part, such that logs created by interacting applications are the most representative. We applied the following criteria:

- team diversity – applications built by teams of different sizes, experiences, locations,
- application diversity – we included both dedicated business applications and shared service platforms (e.g., storage or communication services),
- time diversity – applications built in different periods,
- integration diversity – applications communicating using different interfaces and exchange formats.

Nordea Bank does not enforce any strict, centralized rules on how applications should create their logs (for non-regulatory logging), which additionally removes any accidental correlation between logs because of applications being created in the same company.

The NDEASYS1 dataset consists of logs of six applications whose properties are summarized in Table I. The logs were collected over 12 hours of operation on a random business day in an integrated test environment.

We distinguish between three types of applications that output logs in our data set:

- dedicated – application implementing logic specific to a single business domain,
- technical – application with a minimum amount of business logic, usually providing a support function, e.g., data or interface adaptation,
- shared service – application deployed on a shared platform, following a typical workflow for the platform.

We characterized team diversity by the number of developers and number of locations, they were working from. Time diversity was represented by the development period and the duration of application development. The diversity of integration was characterized by the integration styles used by each application (messaging or remote procedure invocation) and message formats used to exchange data with other applications.

We performed an initial analysis of the NDEASYS1 dataset. Fig. 1 presents a histogram of tokens that are present in the logs of each application. The histogram was created using 1000 bins representing the frequency of token occurrence in a log. We made the following observations with regards to all log files:

- in all the logs there is a clear split between a few very common tokens and a lot of very rare tokens (the histogram is right-skewed, see Fig. 1),
- at integration points, application input is commonly logged,
- shared services tend to log only inputs while dedicated and technical applications – both inputs and outputs.

TABLE I.
CHARACTERISTICS OF THE NDEASYS1 DATASET

App	Log size [MB]	Application diversity	Team diversity		Time diversity		Integration diversity	
		Type	Size	No locations	Dev. period	Dev. duration [months]	Integration style	Format
A	730	dedicated	3	2	2020-2022	24	Messaging, RPI	Swift (ISO15022, ISO 20022), JSON
B	40	technical	1	2	2020	1	Messaging	Swift (ISO15022)
C	100	shared service	2	2	2016-2020	48	RPI	JSON
D	0.2	technical	1	2	2020	6	Messaging	Swift (ISO15022)
E	1600	shared service	3	2	2016-2022	72	RPI	JSON
F	3	shared service	3	2	2016-2022	72	RPI	JSON

We interpret these observations from the point of view of the primary reason for logging, which is failure diagnosis. In the case of application integration, a popular practice is to log identifiers of data exchanged between applications. These identifiers are (to large extent) unique values, which explains the big number of very rare tokens appearing in the log as compared to the few frequent tokens that represent the static part of log messages.

Fig 1. The histogram of token distribution. The horizontal axis represents 1000 bins showing the frequency of token occurrence in each log. The vertical axis is presented on a logarithmic scale and its values describe the number of tokens in each bin.

V. PROPOSED METHOD

Taking the observations presented in Section IV, we propose a method for detecting application interactions from logs leveraging the concept of rare and frequent tokens appearing in log files. Fig. 2. describes the proposed workflow and subsequent sections describe its steps in detail.

A. Log preprocessing

For log files from each application, we perform a minimal level of log preprocessing, which ensures a common view of each log. We introduce minimal assumptions for the content of log files. Each line should contain a *timestamp* and *message* attributes. Additionally, the *source* (the application that created a given line in the log) is determined based on which application the log file belongs to. The process of extraction of the minimum set of information from logs is called log formatting and an example of its output is shown in Fig. 3. In the case of some logs, we also unify data encoding to ensure that logs are comparable between applications. In this step, we perform preprocessing of the *message* attribute by splitting it into individual tokens using a regular expression $[.:A-Za-z0-9_-]+$. Apart from log formatting, we do not apply any application-specific logic requiring expert knowledge. As a result of the log preprocessing step, each log line is described by attributes: *source*, *timestamp*, and *set of tokens*. Example tokens are shown in Table II.

Fig 3. The outcome of the log formatting phase. Colors denote the respective fragments in the raw and the formatted log.

B. Template generation

Template generation is the process of determining some sort of pattern for each log line, which distinguishes the static part of the message from the variable parts. Traditionally, this process aims at providing as precise template as possible, which describes the position of each variable element in a log message. We found such an approach not necessary and giving worse results than the relaxed approach proposed in this paper. A more detailed comparison with commonly used template generation methods is provided in Section V.C.

We introduce the SLT (Simple Log Template) method of template generation, which is a relaxed variant of the Log-Cluster approach described in [11]. As compared to the original method, we do not extract the exact pattern but rather focus on splitting the *message* into a *key* (which represents the static part) and *identifiers* (representing the variable part) while entirely disregarding the position of tokens in the *message*. Such an approach serves two purposes. Firstly, it minimizes the number of templates. Secondly, it is better suited for generating templates for log statements with a variable number of repeated tokens. A typical example is logging of service input/output values which are documents exchanged between applications. Such documents, usually expressed in the XML or JSON format, very often are built on top of data schema with repeated occurrences of data items. Moreover, XML or JSON documents cannot be treated as a regular text because, depending on the schema, the order of appearance of their elements can also be variable. In such cases, extraction of the exact pattern would result in a potentially big

number of complex patterns being generated, depending on the data sample.

Our algorithm consists of two phases. In the first one, we cluster log lines using the *set of tokens*. We 1-hot encode [13] each token and then 1-hot encode each log line using the encoding of the tokens it contains and then run the K-means clustering algorithm. An example of token encoding is presented in Table II. The encoding of the sample log line from Fig. 3. is presented in Fig. 4. The optimal number of clusters is determined by using the silhouette method. The idea is, based on the observations in Section IV, that the same 1-hot encoded log lines would differ from one another only on a few positions, which should cause them to be assembled to the same cluster. The clustering process is performed separately for each *source*. This is to ensure that we do not find by accident common templates across different applications. Additionally, it reduces the clustering problem significantly.

TABLE II.
EXAMPLE OF 1-HOT ENCODING OF THE IDENTIFIED TOKENS

Identified token	Word index in dictionary	1-hot encoding
logger	0	[1, 0, ..., 0]
c.n.t.i.r.q.querycallstats observer	1	[0, 1, 0, ..., 0]
operation	2	[0, 0, 1, 0, ..., 0]
query_latest_in_group	38	[0, ..., 0, 1, 0, ..., 0]
clientId	4	[0, 0, 0, 0, 1, 0, ..., 0]
x	39	[0, ..., 0, 1, 0, ..., 0]
clientlibrary	6	[0, 0, 0, 0, 0, 0, 1, 0, ..., 0]

The outcome of the clustering phase is a set of clusters containing specific log lines for each *source*. Each cluster represents a separate logging statement (log template) and the lines that belong to the cluster – instances of that template. During the second phase, we process each cluster individually and extract *identifiers* from the *message* attribute. We count the frequency of each token appearance in the cluster. We then apply a frequency threshold – tokens appearing less frequently than the threshold are considered the *identifiers*. This is a direct utilization of the observation presented in Fig. 1. Both *key* and *identifiers* are represented as a set of tokens – their order is not considered. An example of such a template is presented in Fig. 4. Although this might result in different templates receiving the same key, we rarely found that to be a case in practice. Usually, logging statements are significantly different from one another which ensures the possibility of precisely locating such a logging statement in the source code of the application during failure diagnosis.

In the end, we combine the identifiers from all the clusters into a single set. The outcome of the template generation process is a mapping of log lines to clusters and a set of tokens that are considered identifiers in each application log.

- data loading – an asynchronous process of delivering data to the system; once data is loaded, it is stored for further processing,
- data processing – a scheduled synchronous process occurring every 15 minutes that performs processing of previously delivered data,
- daily reporting – a scheduled synchronous process executed once per day which aggregates the processed data and delivers them to downstream applications.

Although this paper focuses on direct interactions between applications, awareness of the processes helps in configuring our algorithm to find interactions that appear in logs in distant lines.

B. Evaluation method

We use this knowledge about the system to validate our method. As a main measure of accuracy of our method we chose the F1 score and use it to compare the set of edges identified by our algorithm with the reference set of edges presented in Fig. 5. We do not consider the direction of edges.

C. Template generation algorithm performance

A part of our algorithm is a proposal of a new template generation system, focusing specifically on the detection of identifiers in log files. We evaluate our algorithm by comparing its efficiency to popular template generation algorithms: LogCluster [11] and DRAIN [12]. Table III presents the outcome of this comparison for different types of logs: the time of algorithm execution for each data set, the number of identified clusters, precision, recall and F1 score.

Since both LogCluster and DRAIN are more generic algorithms than ours, we need to define objective comparison

criteria. For the sake of algorithm comparison, we decided to consider the number of identified templates, the F1 score of identifier detection and the speed of the algorithm. Both LogCluster and DRAIN produce a set of templates as an output. We unify these templates as regular expressions, where variable parts of each template are transformed into capturing groups. We then process each line of the log file with all the regular expressions and extract the tokens that were captured. LogCluster and DRAIN are not very consistent in what they consider as a token with our algorithm. To remediate that, we post-process each captured group with the same regular expression that is used in our algorithm for token identification. In the end, we apply the same length-based criterion to decide if a token is a valid identifier. The outcome of this post-processing is, for each log file and a set of templates, a list of identifiers found in the file. The list of identifiers is compared to the ground truth derived from the log dataset using our domain knowledge.

Since all the algorithms can be tuned with hyper-parameters, we measured a wide range of parameter values but for the brevity of presentation, we mention only the best score for each of the algorithms.

To extract the ground truth, for each log file, we collected the list of all tokens and the number of their occurrences. We then traversed the list of tokens from the most to the least frequent applying our domain knowledge to remove all tokens which were not valid identifiers. Part of this process was performed automatically. In this phase, we removed tokens based on their length or type (e.g., dates, IP addresses, or cash amounts were not considered valid identifiers, but are easy to filter out using regular expressions). In the second phase, we performed manual filtering by removing to-

TABLE III.
COMPARISON OF TEMPLATE GENERATION METHODS

Algorithm	Log	Time [s]	Clusters	Precision	Recall	F1 Score
DRAIN	A	95.0	31	0.96	1.0	0.98
	B	10.0	335	0.99	0.94	0.96
	C	39.0	6	0.99	1.0	0.99
	D	1.0	82	n/a	n/a	n/a
	E	342	97	1.0	0.86	0.92
	F	1.0	13	0.97	0.99	0.98
LogCluster	A	20.0	6	1.0	0.93	0.96
	B	1.0	28	2.0	0.018	0.03
	C	8.0	2	1.0	0.79	0.88
	D	0.1	3	0.66	1.0	0.79
	E	34.0	5	1.0	0.85	0.91
	F	0.1	3	1.0	0.95	0.97
SLT	A	185.0	17	0.95	1.0	0.97
	B	1.0	2	0.71	0.99	0.83
	C	46.0	19	0.94	0.99	0.97
	D	0.1	3	0.6	1.0	0.75
	E	380	19	1.0	1.0	1.0
	F	2.0	2	0.76	1.0	0.86

kens that were valid domain-related words. This process was performed for the most frequent tokens (with the number of occurrences higher than 1).

LogCluster is the fastest algorithm among the three. It outperforms the rest by an order of magnitude. It also notes the lowest F1 score, especially for log B. It tends to keep the precision very high with lower recall values. Further analysis of false positives returned by this algorithm shows that it often includes frequent tokens, which are business terms appearing in the log. LogCluster returns fewer and more generic clusters than others.

DRAIN shows the best overall results in terms of F1 score with by far the highest number of clusters returned. The high number of clusters is a result of two aspects: DRAIN not being designed for processing multi-line log entries (similar as LogCluster) and not coping well with log entries of variable length. While the first deficiency is easy to overcome, the second poses a challenge for general use for enterprise-wide log analysis. A typical case for log entries with variable content is logging system inputs, which often come in the form of XML/JSON documents with repeated elements. In such cases, DRAIN extracts each log entry with a given length to a separate template. For long log entries, templates are often very big and hard to process. This finding is in line with the conclusions from the real-life DRAIN application presented in [14].

The SLT approach proposed by us is not far from DRAIN in terms of F1 score, with similar timing performance but outputting the number of clusters that is much more on par with the reality. It copes well with log entries of variable length. One deficiency, that results in lowered precision rates, is falsely identifying rare numbers (e.g., cash amounts) as identifiers. With the approach we have taken, they cannot be distinguished from the true identifiers. This problem needs to be handled in the subsequent processing steps that utilize our algorithm. Overall, we think SLT is a reasonable all-around approach for identifying identifiers in log files of diverse format and content.

D. Results

We ran a series of experiments with our approach using different time windows. For each run of the algorithm, we collected the discovered application interactions, together with the set of identifiers that are found in the logs of both interacting applications within the time window. An example of such output is presented in Table IV, and the respective approximate graph $G'(S)$ is shown in Fig. 6. In Table IV, falsely identified interactions are marked in red.

TABLE IV.
EXAMPLE OF DISCOVERED APPLICATION INTERACTIONS

Interaction	Number of occurrences	Example identifier
(E, A)	47828	5435ab2142314bsw
(C, A)	2156	43543612124
(F, A)	1314	2353518
(F, C)	874	200.0000

(D, A)	77	abhgswe0053
(D, E)	14	2022-01-21
(B, A)	7	basdewe2xyz

In some cases, it is hard to distinguish between an accidental correlation of token values and actual but rare interactions. For example, the (F, C) interaction has a higher number of occurrences than (D, A) but the discovered identifiers actually denote the number of records per second processed by services F and C. Such an accidental correlation of tokens representing data of low variety (e.g. small numbers or dates) is the main source of score deterioration in our method.

Fig 6. An example of graph G' output that represents the approximation of the system, at a window size equal to 20 minutes. Edges marked with red represent falsely discovered application interactions.

We found that applying a proper identifier length criterion allows for maximizing the F1 score of the result. Table V shows the maximum scores achieved for each size of the time window. The maximum overall F1 score of our algorithm was 83%, reached for a time window of 20 minutes which was long enough to detect the interaction between the asynchronous data loading process and the scheduled data processing process. Longer time windows allow us to identify distant correlations at the cost of the decrease in precision (the longer the time window, the higher chance of accidental correlation occurring). At the current stage, our approach tends to discover short-time-distance interactions with high precision. The confidence of interaction detection decreases when searching for distant correlations. This is one of the aspects that are subject to improvement in our future work.

TABLE V.
RESULTS OF OUR METHOD FOR DIFFERENT WINDOW SIZES

Window size [ms]	Number of discovered interactions	Precision	Recall	F1 Score
200	3	1	0.6	0.75
1000	3	1	0.6	0.75

5000	4	0.75	0.6	0.67
10000	4	0.75	0.6	0.67
60000	5	0.8	0.8	0.8
1200000	7	0.71	1	0.83

VII. CONCLUSIONS

In this paper, we presented an approach to discovering the interactions between applications in enterprise systems. We validated our approach with a real-life system deployed at Nordea Bank. Our method could achieve the 83% F1 score of the identified interactions and is a good base for further extension. The biggest challenge is distinguishing rare, actual interactions from accidental data correlation, which we will address in our further study.

As part of our approach, we proposed the SLT method for discovering templates for log entries. We compared this method with other common approaches and found that it provides good-enough F1 score while being able to handle variable log entries, which is one of the main deficiencies of the other methods. We find SLT a good candidate for a template generation method in a general use case when we do not know the exact profile of the logs we are analyzing.

Working on a real-life system allowed us also to provide statistics and conclusions about logs from various types of applications. We found some common patterns of logging activities performed by developers when working with integrated systems which stem from the practical need of developers to be able to perform failure diagnosis. The main conclusion in this area is that logging data identifiers is a common practice in the industry. These observations allow introduction of simplifying assumptions for the general problem of discovering system properties from application logs and help better focus our future work on the problem.

Our future work will focus on two areas: 1) improvement of the current method and 2) working on its extensions to extract other properties of enterprise systems. We see increasing the precision of the identifier detection as the main improvement that would positively influence the F1 score of the overall method. This requires the development of a better way to check if an identifier is valid to decrease the level of accidental correlation of non-identifier tokens. Another area of focus is the performance of our method, improvement of which would allow for the analysis of larger log samples covering longer periods. That would open the possibility to identify very distant interactions (e.g., related to monthly-reporting processes), or validate the method using a larger system.

As for the method extensions, our goal is to discover the fragments of UML diagrams describing the working system. That requires providing means of discovering the system's properties such as:

- processes the system is running (control flow) – scenarios of interactions between applications with their frequency and timing,

- data flow – how data is passed across applications and what are their origins,
- semantic relationships between data – the mapping of data processed by different applications to find a common data dictionary (or even the data model).

We believe that such an overview of the running system would provide enterprise architects with the necessary tools to centrally validate various properties of the system and plan respective actions accordingly.

ACKNOWLEDGMENT

This paper was written in cooperation with the Nordea Bank, which provided the log dataset and an overview of the systems that were subject to this study.

Joint 42nd IEEE Software Engineering Workshop and 9th International Workshop on Cyber-Physical Systems

THE IEEE Software Engineering Workshop (SEW) is the oldest Software Engineering event in the world, dating back to 1969. The workshop was originally run as the NASA Software Engineering Workshop and focused on software engineering issues relevant to NASA and the space industry. After the 25th edition, it became the NASA/IEEE Software Engineering Workshop and expanded its remit to address many more areas of software engineering with emphasis on practical issues, industrial experience and case studies in addition to traditional technical papers. Since its 31st edition, it has been sponsored by IEEE and has continued to broaden its areas of interest.

One such extremely hot new area are Cyber-physical Systems (CPS), which encompass the investigation of approaches related to the development and use of modern software systems interfacing with real world and controlling their surroundings. CPS are physical and engineering systems closely integrated with their typically networked environment. Modern airplanes, automobiles, or medical devices are practically networks of computers. Sensors, robots, and intelligent devices are abundant. Human life depends on them. CPS systems transform how people interact with the physical world just like the Internet transformed how people interact with one another.

The joint workshop aims to bring together all those researchers with an interest in software engineering, both with CPS and broader focus. Traditionally, these workshops attract industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practices. This joint edition will also provide a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

TOPICS

The workshop aims to bring together all those with an interest in software engineering. Traditionally, the workshop attracts industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practice. The workshop provides a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

Topics of interest include, but are not limited to:

- Experiments and experience reports

- Software quality assurance and metrics
- Formal methods and formal approaches to software development
- Software engineering processes and process improvement
- Agile and lean methods
- Requirements engineering
- Software architectures
- Design methodologies
- Validation and verification
- Software maintenance, reuse, and legacy systems
- Agent-based software systems
- Self-managing systems
- New approaches to software engineering (e.g., search based software engineering)
- Software engineering issues in cyber-physical systems
- Real-time software engineering
- Safety assurance & certification
- Software security
- Embedded control systems and networks
- Software aspects of the Internet of Things
- Software engineering education, laboratories and pedagogy
- Software engineering for social media

Abstract—Sentiment Analysis in the Software Engineering community aims to make the development and maintenance of software a better experience by helping provide code and library suggestions, defect-related comments for source code, etc. The manual finding of sentiment-based comments may be an inaccurate prediction and a time-consuming process. Automating the sentiment analysis process by leveraging Machine Learning models can benefit software professionals by giving them insights into other developers and feelings about software products, libraries, development, and maintenance tasks at a glance. This study aims to develop software sentiment prediction models based on comments by (1) identifying the best embedding techniques to represent the word of the comments, not just as a number but as a vector in n-dimensional space (2) finding the best sets of vectors using different features selection techniques (3) finding the best methods to handle the class imbalance nature of the data, and (4) finding the best architecture of deep-learning for the training of models. The developed models are validated using 5-fold cross-validation with four different performance parameters: accuracy, AUC, recall, and precision on three different datasets. The experimental finding shows that the models developed using the word embeddings with feature selection using Deep Learning classifiers on balanced data can significantly predict the underlying sentiments of textual comments.

Keywords—Sentiment Analysis, Software Engineering Tasks, Word Embedding, Feature Selection, Data Imbalance, SMOTE, Deep Learning classifiers

I. INTRODUCTION

SENTIMENT Analysis can be used to gather the opinions and feelings of the consumers regarding social and political opinions, brand loyalty, etc. Sentiment Analysis utilizes natural language processing and machine learning algorithms to draw out textual data's mood, opinions, and feelings. The texts can be product reviews, posts on social media, messages on chat boards, answers to questions on a question-answering website, commit messages by developers, etc [1]. Software developers can utilize the benefits of sentiment analysis to assist them in their development and maintenance activities. They can be well informed about whether a particular software, technology, or tutorial is appropriate for their purposes. Sentiment Analysis can distinguish feedback as being either positive or negative, which helps in development decisions. The application of

sentiment analysis is to find Software professionals' sentiments and mindsets, and it can be approached in two different ways: The first and most straightforward way is to sit down face to face with the software developers, glean insights into their mindset, and evaluate their mood and feelings. Unfortunately, this is a very time-intensive and tedious process to incorporate. So, the other approach is preferred. The other approach uses sentiment analysis to discern the mood and feelings of software developers, from the product reviews, feedback forms, commit messages, etc. An effort is made to identify the positive and negative sentiments of developers. So, we have worked to create a predictive model leveraging natural language processing techniques and machine learning algorithms, to predict and detect the exhibited sentiments, moods, and feelings effectively and efficiently. The datasets are obtained from user's App Reviews, and issues tracked and managed using JIRA, and user's comments and messages on the Stack Overflow platform [1]. For the machine to better understand and analyze the text to improve the predictive model's performance, we must represent words as vectors [2][3].

Word embedding techniques do this by representing words as vectors in an n-dimensional space. This provides a numeric representation to the words, which allows them to be used as input to Machine Learning Models, and it also preserves its syntactic and semantic integrity so that words that are used similarly have similar vector representations. In this study, we use six Word Embedding Techniques to vectorize the textual data, which are Term Frequency and Inverse Document Frequency (TF-IDF), Skip-Gram (SKG), Continuous Bag of Words (CBOW), Global Vectors for Word Representations (GLOVE), Fast Text (FST) and Google News Word to Vector (GW2V) [3]. After applying the word embeddings, we obtain a multitude of features for the data, many of which will be ineffective in the predictive model. To obtain the subset of important features that are to be used as input to the model, we apply six Feature Selection Techniques, namely Principal Components Analysis, Gain Ratio Attribute Eval, Classifier Attribute Eval, Info Gain Attribute Eval, OneR Attribute Eval, and Analysis of Variance (ANOVA) [4]. Analyzing the data after applying the Feature Selection Techniques, it is clear that the data suffer from the class imbalance problem, which

occurs when the number of samples in each class is not the same. If not corrected, this can negatively affect the predictive performance of the model. So, the Synthetic Minority Oversampling Technique (SMOTE) and the Borderline Synthetic Minority Oversampling Technique (Borderline-SMOTE) are applied to balance the data. After we balance the data, we need to compare and evaluate the performance of the different techniques we have applied. To achieve this, we use eight different deep learning classifiers, which are applied by varying the number of Hidden Layers and Dropout Layers. The application of Deep Learning Classifiers to the models developed using different Word Embedding Techniques can help determine the models that can accurately and effectively predict the underlying sentiment in textual data, which can be convenient for a broad scope of Software Development and Maintenance activities. This study also aims to find the Word Embeddings, Feature Selection, and Data Sampling Techniques that provide the most optimal results.

The remainder of the paper is laid out as follows: Section 2 presents a literature review on software sentiment analysis and various word embedding approaches. Section 3 describes the experimental dataset collection as well as the various machine learning algorithms used. The research methodology is described in Section 4 using an architecture framework. In Section 5, the results of the experiments, along with their analysis, are presented. Section 6 shows a comparison of models created using various word-embedding approaches, sets of features, and machine learning models. Finally, Section 7 summarizes the information provided and offers directions for further research.

II. RELATED WORK

There are many methods to acquire features from textual data. Term Frequency and Inverse Document Frequency (TF-IDF) have been used by Rajni Jindal et al. to obtain features from defect descriptions. They've used a Radial Basis function of the Neural Network to classify the defect reports. Based on tangible evidence, they've established that the model predicted high severity defects with significant accuracy and efficiency [5]. Sari and Siahaan have also leveraged Term Frequency and Inverse Document Frequency (TF-IDF) to extract features from defect descriptions. They've applied the InfoGain Feature Selection technique to obtain the set of relevant features. They've built severities prediction models with the assistance of Support Vector Machine to predict severity levels of defects [6]. Sentiment Analysis of Software Engineering Tasks has tremendous potential, but pre-trained models don't accurately predict sentiments in Software Engineering Tasks. Bin Lin et al. applied Deep Learning techniques to an enormous dataset consisting of 40k manually labeled sentences, which were sourced from Stack Overflow. Despite determining all the text's sentiments, it resulted in low accuracy levels and, ultimately, poor results. In a comparison between Stanford CoreNLP and Stanford CoreNLP SO, it was determined that the Stanford CoreNLP SO was a better influence on Sentiment Analysis tools than the Stanford CoreNLP. Another conclusion reached by Bin Lin et al. was that Sentiment Analysis tools that are not specifically trained for Software Engineering data yield disappointing results on Software Engineering datasets [1].

Biswas et al. used software domain-specific Word Embed-

ding learned from Stack Overflow in an attempt to improve the performance of the predictive model. The impact on the performance of Sentiment Analysis tools using Domain-specific Word Embedding and Generic Word Embedding, trained using Google news, were compared. The conclusion reached was that the Generic Word Embedding was better than the Domain-specific Word embedding. Biswas et al. also found that oversampling or a combination of oversampling and undersampling achieves a jump in performance in the handling of compact Software Engineering datasets[2]. R Malhotra et al. have attempted to develop Software Bug Classification (SBC) models that can identify "low", "moderate," and "high" impact levels on Software Bugs. The levels were indicated based on Maintenance Effort (ME), Change Impact (CI), or a product of both. The data is sourced from the changelogs in Google's GIT Repository. Data preprocessing is performed, and the SBC models are developed using six classification techniques. The study assessed three predictors, which were obtained from text mining. After evaluation, it was found that the performance of the combined SBC model showed higher accuracy than the ME or CI SBC models. They also found that the accuracy of the "high" category was superior to that of the other categories [7].

R Malhotra et al. have worked to find out if resampling methods applied to software defect data improve performance. They have used datasets sourced from the Defect Collection and Reporting tool (DCRS) and performed data preprocessing and applied three different resampling methods, and evaluated their performance. The performance of the developed models is evaluated using seven performance measures, accuracy, precision, sensitivity, specificity, G-Mean, and AUC. They have concluded that the application of resampling methods to the maintainability prediction models can accurately predict the minority class [5]. R Malhotra et al. have also attempted to find the effects on the performance of Software Defect Prediction Models after applying resampling techniques. They have applied six oversampling and four undersampling methods to rectify the class imbalance problem. Examining the evaluators, which are: Sensitivity, GMean, Balance, and AUC values, it was found that there was an evident improvement in the values of the evaluators when data resampling methods were applied to the Software Defect Prediction models [8].

Dr. Lov Kumar et al. have worked to automate the process of determining the severity level of a defect in the software. Defect descriptions in the form of text have been tokenized using seven different word embedding techniques. The obtained features are further pruned to achieve an optimal set of relevant features using three different Feature Selection techniques. These features, plagued by the Class Imbalance Problem, have been rid of it by using the Synthetic Minority Oversampling Technique (SMOTE). The performance of the Word Embedding is evaluated using eleven different classifiers. Dr. Lov Kumar et al. have successfully used Word Embeddings, Feature Selection, and Synthetic Minority Oversampling Technique (SMOTE) to assemble a predictive model capable of assigning a severity level to defect descriptions [9]. SentiStrength-SE, which was proposed by Islam et al., achieved 73.85% precision and 85% recall. They call attention to issues commonly faced by Sentiment Analysis Tools, some of which are: Domain-specific meaning of words, Context-sensitive variations in meanings of words, Difficulties in dealing with negation, Sentimental words in copy-pasted content,

Difficulty in dealing with irony and sarcasm, and Wrong detection of proper nouns [3].

III. STUDY DESIGN

This section presents the details regarding various design settings used for this research.

A. Experimental Dataset

The study uses three different experiential datasets to validate our proposed framework. These datasets are used by many software researchers for sentiment analysis [1][2]. The primary objective is to explore different types of embedding, feature selection, data sampling, and different variants of deep-learning on these datasets to predict the sentiments of software engineers. Figure 2 shows the number of positive and negative sentiments for the considered datasets. From Figure 2, we observed that the number of positive sentiments for stack overflow is much higher than negative sentiments. The unequal distribution of data leads to a class imbalance problem.

Fig. 2: Data-Sets

B. Training of Models from Imbalanced Data Set:

After analysis of the data, it becomes quite evident that the data is suffering from a class imbalance problem, i.e., the number of samples in each class is not the same. So, the balancing of data is required to improve the predictive ability of the developed Sentiment Analysis Models. We have performed Synthetic Minority Oversampling Technique (SMOTE) and Borderline Synthetic Minority Oversampling Technique (Borderline-SMOTE) on each dataset to balance the data [10].

C. Word Embedding:

The textual data of the dataset is to be expressed as vectors in relation to each other. Six different word embedding techniques including Term Frequency and Inverse Document Frequency (TF-IDF), Continuous Bag of Words (CBOW), Skip-Gram (SKG), Global Vectors for Word Representation (GLOVE), Google news Word to Vector (GW2V), fasttext (FST) have been applied on the dataset. These techniques were used to represent the textual data as a vector in an n-dimensional space. We have also removed any and all stopwords, bad symbols, and spaces before applying the word embedding techniques. These will now be used to develop models to determine the sentiment of Software Engineering Tasks [9][2].

D. Feature Selection Techniques

The features vectors extracted from word-embedding are used as an input, so, the performance also depends upon the optimization of important features. To extract the important features from the existing set of vectors, we have used six different Feature Selection Techniques such as: Analysis of Variance (ANOVA) is used to find feature having capability to differentiate positive and negative sentiment, correlation attribute evaluation (CORR_ATR) is used to remove highly correlated features, Principal Components Analysis (PCA) is used to find new value of uncorrelated features, Gain ratio, information gain, and OneR are used to rank the features and select best features for sentiment analysis [4][11].

E. Classification Technique:

In this study, we have used eight deep learning models, which use K-Fold Cross-Validation with a k value of 5. We have separated the data into training and testing data subsets. An input layer with a number of neurons equal in quantity to the number of features of the input data is present in every single deep learning model. The models are all constituted of Dense and Dropout layers. The Dense layer's neurons receive inputs from all the neurons present in the previous layer. The Dropout layer's neurons are randomly selected. The dropout value used in this study is 0.2. The output layer has a single neuron that corresponds to the binary classification of either functional or non-functional requirements, and it uses a sigmoid activation function, unlike the other layers, which use the

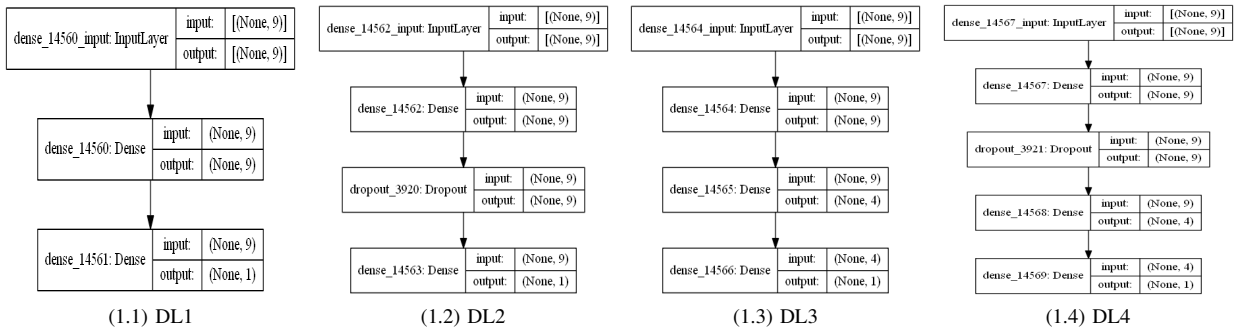

Fig. 1: Deep Learning Architecture

Rectified Linear Activation function (ReLU) as the activation function. Adam is the optimizer used to train the models, with the loss function being the Binary Cross entropy. The number of hidden layers is increased for the other four models. Figure 1 demonstrates the architectures of the models (DL1, DL2, DL3, and DL4). The parameters used to validate the models are: batch size = 30, Dropout = 0.2, and epochs = 100.

IV. RESEARCH METHODOLOGY

The pictorial representation of the proposed framework is provided in Figure 3. We first extract the textual documents from three different SE repositories, i.e., issue trackers, i.e., JIRA issue comments, Stack Overflow discussions contain questions and answers and user reviews on mobile apps using app stores so that their corresponding data may be analyzed. After finding these textual documents, six different types of word-embedding techniques have been used to represent text documents as numerical vectors. Each embedding uses a different way to represent words for text documents with a real-valued vector. The values of these vectors are closer in the vector space for similar words. Next, we have used two different types of sampling techniques, such as: SMOTE and BLSMOTE to handle the class imbalanced nature of datasets. In the next step, we have applied different feature selection techniques to select the best combination of relevant features. The ANOVA test is used to remove insignificant features, PCA is used to remove high correlation between features and find new values of features, gain ratio, information gain, and OneR is used to rank features and select the top best features, and finally, correlation analysis is used to remove highly correlated features. After finding the right sets of features, we have used different variants of deep-learning techniques to train software sentiment, and analysis models. The trained models are validated with a 5-fold cross-validation method, and the performance of these models is compared with the help of four different performance parameters: accuracy, precision, recall, and AUC.

V. EMPIRICAL RESULTS AND ANALYSIS

The primary objective of this work is to analyze the performance of the developed software sentiment analysis models using different variants of deep-learning, word-embedding techniques, features selection techniques, and data sampling techniques with the purpose of investigating how different contexts can impact their effectiveness. The proposed models are validated with three software-related datasets, namely mobile app reviews, Stack Overflow discussions, and JIRA issue comments. Finally, the predictive ability of these models is evaluated using different performance parameters such as accuracy, AUC, precision, and recall. AUC is considered the primary parameter for the model's performance because of its capability to provide good findings in case of imbalanced nature of data. Tables I and II show the performance of models in terms of Precision, Recall, accuracy, and AUC for the AppReview dataset using different variants of deep-learning and feature selection techniques with original data and sampled data. The results for other combinations are similar. The high value of AUC (≥ 0.7) in Tables I and II suggested that the proposed models have the capability to predict the current state of sentiment analysis for software engineering. In the majority of cases, the precision, recall, and AUC values are higher than 0.8. Also, the information present in Tables I and II suggest that the models trained on sampled data have a better ability to predict sentiment as compared to original data. Another finding from Tables I and II is that the models trained on selected sets of features have a high value of precision, recall, and AUC as compared to all features.

VI. COMPARATIVE ANALYSIS

In this section, we have compared the performance of different word embedding techniques, class balancing approaches, feature selection strategies, and deep-learning techniques, which are used for developing sentiment prediction models using Box-plot diagrams and descriptive statistics. We have also performed the Friedman test to find statistical significance differences between different techniques. The hypothesis used to achieve our objective is mentioned below:

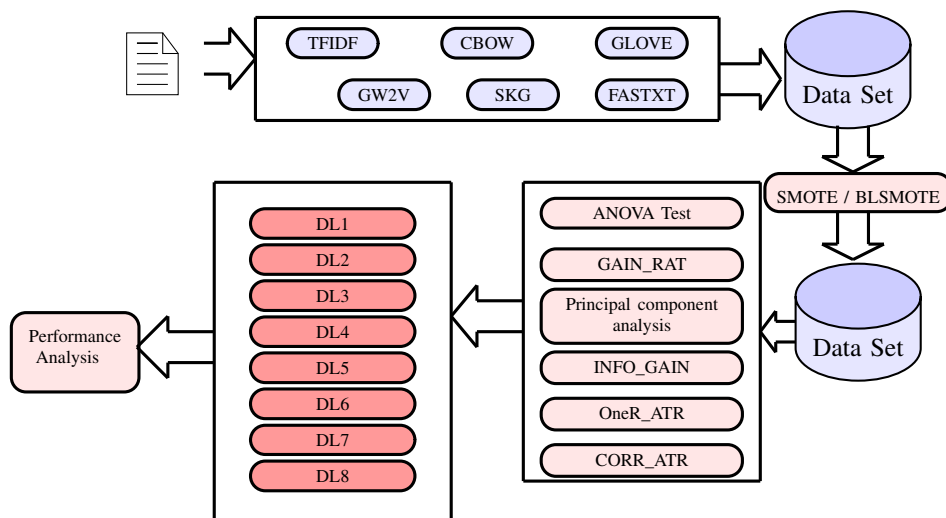

Fig. 3: Framework of proposed work

TABLE I: AppReviews :Precision and Recall

	Precision								Recall							
	DL1	DL2	DL3	DL4	DL5	DL6	DL7	DL8	DL1	DL2	DL3	DL4	DL5	DL6	DL7	DL8

- Word-Embedding Techniques: Null Hypothesis:** There is no significant difference between the models trained by using features extracted by different embedding techniques.
- Feature Selection Techniques: Null Hypothesis:** There is no significant difference between the models trained by using selected sets of features using different feature selection techniques and all features.
- Data Sampling Techniques: Null Hypothesis:** There is no significant difference between the models trained on sampled data and original data.
- Deep-Learning Techniques: Null Hypothesis:** There is no significant difference between the models trained using different variants of deep-learning techniques.

A. Word-Embedding

In this work, six different types of word embedding approaches such as TFIDF, CBOW, GLOVE, GW2V, SKG, and FASTXT have been used to find the numerical vectors of software text comments. To find the best embedding approach, we exploited performance evaluators- Accuracy, Precision, AUC, and Recall, which are computed for models trained

by taking the above embedding techniques as input and trained using different variants of deep-learning with 5-fold cross-validation techniques on sampled as well as original data. Figure 4 visually depicts the model's ability to predict sentiments using different word-embedding techniques, and Table III depicts descriptive statistics of different embedding in terms of accuracy, AUC, precision, and Recall. From Figure 4, it is visible that the models trained by taking numerical

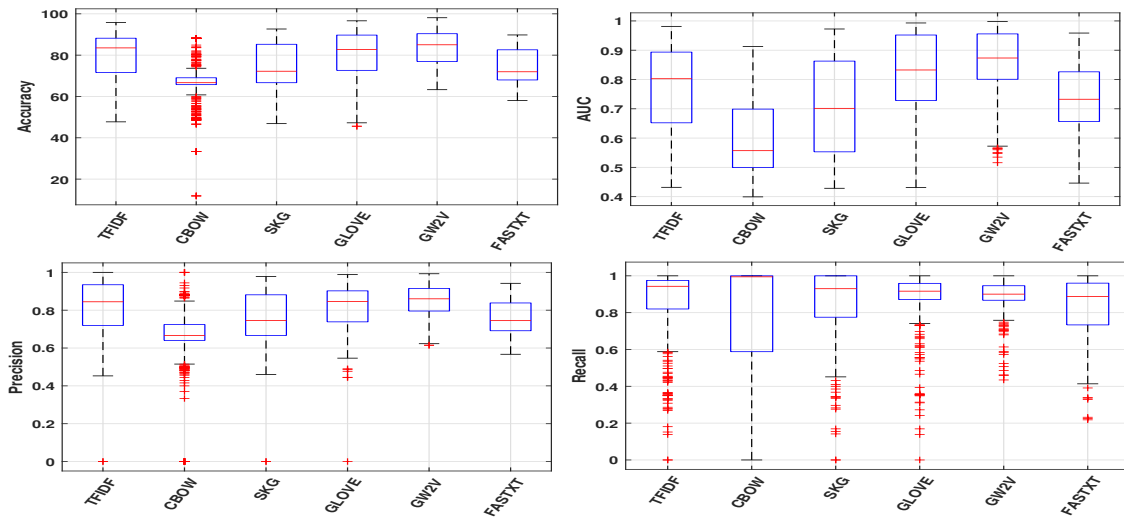

Fig. 4: Performance Box-Plot Diagram: Performance of Different Word Embedding

vectors computed using google word to vector (GW2V) have better capability to predict sentiment as compared to other embeddings. The models trained using GW2V achieved 0.86 average AUC, 0.89 average Recall, 0.85 average precision, and 84.03 average accuracy. Similarly, From Table III, we observed that the models trained using CBOW have the worst performance with 0.60 average AUC, 0.78 average Recall, 0.66 average precision, and 67.49 average accuracy.

Table IV shows the mean ranks using the Freidman test for the various word embedding techniques. We have evaluated

the considered null hypothesis at 0.05 with five degrees of freedom on four different performance parameters such as accuracy, recall, precision, and AUC. The lower value of mean rank represents the best word-embedding techniques for sentiment analysis of software engineering comments. According to information present in Table IV, the models trained using different embedding techniques are significantly different. Similarly, according to information present in Table IV, the models trained using GW2V have a lower mean rank, i.e., 1.91 for accuracy, 1.92 precision, 3.61 recall, and 1.37 AUC representing that the developed models have better prediction capability as compared to other embedding techniques.

B. Feature Selection

In this work, six different types of features selection techniques: significant features calculation using ANOVA test, un-correlated sets of features using PCA, best sets of features using the gain ratio(GAIN_RAT), information gain(INFO_GAIN), oneR attribute evaluation (OneR_ATR), correlation attribute selection (CORR_ATR) have been used to find the best combination of relevant features for software engineering sentiment analysis. We exploited performance evaluators- Accuracy, Precision, AUC, and Recall to find the best feature selection technique that gives us the best sets of features for models trained using different variants of deep-learning with 5-fold cross-validation techniques on sampled as well as original data. Figure 5 visually depicts the model’s ability to predict sentiments using different feature selection techniques and Table V depicts descriptive statistics of different feature selection techniques in terms of accuracy, AUC, precision, and Recall. From Figure 4, it is quite evident that the models trained by taking significant sets of features using the ANOVA test have better capability to predict sentiment as compared to other feature selection techniques. The models trained using ANOVA features achieved 0.85 average AUC, 0.88 average recall, 0.84 average precision, and 83.21 average accuracy. Similarly, From Table V, we observed that the models trained using features selection from OneR_ATR have

present in Table IV shows that the models trained by taking selected significant features using ANOVA as an input have a lower mean rank, i.e., 2.27 for accuracy, 2.21 precision, 3.77 recall, and 1.72 AUC, represent that the developed models have better prediction capability as compared to other features selection techniques.

C. Classification Techniques

The sentiment prediction models for software engineering comments are trained using different variants of deep-learning techniques with a 5-fold cross-validation approach. These trained models' capability is compared using performance parameters such as accuracy, precision, recall, and AUC. Figure 6 depicts the box-plot diagrams of different performance parameters for the models trained using different variants of deep learning. Table VI shows the descriptive statistics in terms of Mean, Median, Min, Max, Q1, and Q3 for different deep-learning techniques. It can be seen from Figure 6 and Table VI that the models trained using DL2, DL3, DL4, and DL5 have similar average values of AUC, i.e., 0.78. Similarly, the DL8 classifier produces models with a minimum average AUC of 0.67.

In this paper, we have also compared the effectiveness of different variants of deep learning using the Friedman test with a significance level of 0.05 and six degrees of freedom on four different performance parameters such as accuracy, recall, precision, and AUC. Table IV shows the mean ranks using the Friedman test for different variants of deep learning. According to the results of the Friedman test, we observed

AUC						
DL1	0.43	1.00	0.76	0.78	0.63	0.90
DL2	0.43	1.00	0.78	0.80	0.68	0.90
DL3	0.44	1.00	0.78	0.80	0.69	0.90
DL4	0.44	1.00	0.78	0.80	0.69	0.90
DL5	0.43	0.99	0.78	0.80	0.68	0.89
DL6	0.43	0.99	0.72	0.71	0.59	0.85
DL7	0.40	1.00	0.73	0.74	0.58	0.86
DL8	0.43	0.99	0.67	0.63	0.51	0.80

that the performance of software sentiment prediction models significantly depends on the architecture of the deep-learning

models. Similarly, the models trained using DL4 have better capability to predict sentiment as compared to other deep-learning techniques.

D. SMOTE

In this study, we have used two different variants of SMOTE techniques to handle the class imbalance nature of data. We have used box-plot and descriptive statistics of performance parameters to find the impact of data sampling techniques on sentiment analysis for software engineering comments. Figure 7 presents a visual representation of the predictive capability of models trained on a balanced dataset versus models learned on an imbalanced dataset. Table VII shows the descriptive statistics in terms of min, max, Mean, Median, Q1, and Q3 for models trained on sampled data and original data. From Figure 7, and Table VI, it can be seen that the models trained on sampled data have better performance as compared to the original data. The trained prediction models on sampled data have 0.76 average AUC, 0.88 average recall, 0.78 average precision, and 76 average accuracies. While, models trained on original data have 0.73 average AUC, 0.81 average recall, 0.82 average precision, and 81.51 average accuracy.

In this paper, the Friedman test with a significance level of 0.05 and two degrees of freedom has been considered to find the significant impact of sampling techniques on model performance. Table IV shows the mean ranks using the Friedman test for SMOTE, BLSTM, and original data. The smaller value of P represents that the models trained on sampled data have significant improvement in performance as compared to the original data. Similarly, the models trained on SMOTE sampled data have better capability to predict sentiments as compared to BLSTM and original data.

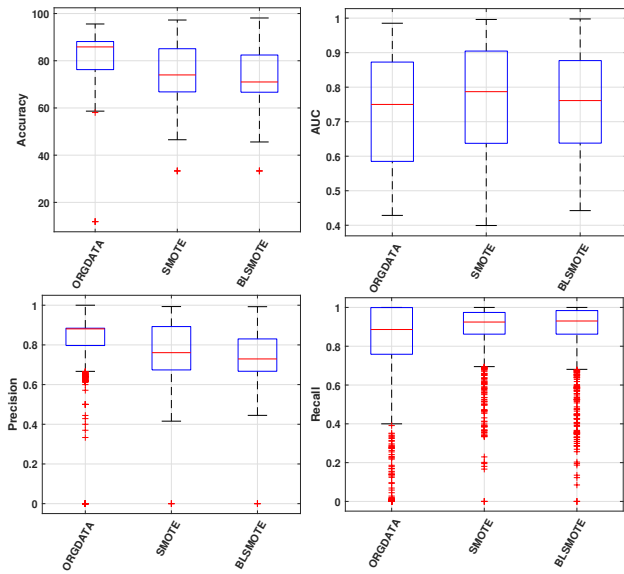

Fig. 7: Performance Box-Plot Diagram: Performance of Original Data and SMOTE

VII. CONCLUSION

Sentiment analysis prediction models for software engineers help in various engineering tasks like analyzing developers' sentiments, evaluating app reviews, users' sentiments of software products, etc. The work presented in this paper is a successful effort in the direction of development of software sentiment models by using different variants of embedding techniques, different methods to find important features, different methods to handle the imbalanced nature of the dataset, and finally, different variants of deep-learning for model development. The performance of the developed models is computed and compared using accuracy, precision, AUC, and recall. We have also applied the Friedman test to statistically examine the performance of models developed using a different combination of features. The major findings

are summarized as follows:

- The high value of AUC for the trained models confirms the capability of the models to predict sentiment based on text comments.
- The use of sampling techniques like SMOTE and BLSMOTE significantly helps in improving the performance of software sentiment prediction models.
- The models trained by using selected sets of features using ANOVA achieved better performance as compared to other techniques.
- The deep learning with one dropout layer and two hidden layers achieved better performance as compared to other combinations.

Abstract—Among the Agile methods, Scrum and Kanban are widely used in software development and they are considered the two most effective ones influencing the direct results of projects. Despite the importance of knowing their relative strengths and advantages and integrating them to achieve better results than individual use, none of the secondary studies provide extensive knowledge on the topic. In this paper, we performed a Systematic Literature Review (SLR) study to investigate the characteristics of the empirical studies which involve Scrum and Kanban by comparing or integrating them. Our final set includes 38 studies posing primary information on the advantages of each method over another one, the properties including artifacts, roles, and events from Scrum and Kanban in combining them in a hybrid way, and the properties of transitions from one to another such as transition directions (Scrum to Kanban, Kanban to Scrum or Scrum/Kanban to Hybrid), transition years, and transition reasons. The outputs can be interesting for both industry and researchers. For example, nearly all of the transitioning organizations are moving from Scrum to Kanban or to hybrid method. Among the reasons for the transitions, the problems experienced with Scrum are remarkable. In comparison, Kanban stands out clearly in a positive way. Almost all of the teams combining both use flow instead of a sprint.

Index Terms—Agile, software development, systematic literature review, SLR, agility, project management.

I. INTRODUCTION

IT IS a fact that due to the evolutionary nature of software development, changing market needs, and evolving technology [1], software projects inevitably change in many aspects including requirements, circumstances, and stakeholders [2], which require agility in complex domains. Based on this natural need for agility, people have invented varying agile approaches and methods to meet the need to be compatible in the market, have shorter development cycles, fewer costs, and have the ability to move and change quickly [3, 4]. Among the agile methods, Scrum and Kanban are common in the software industry [5] and they are considered the two effective agile methods that handle and manage the progress of software development [4, 6, 7].

Deciding on a development approach is one of the critical factors influencing the direct results of projects [8]. There has already been a debate for years about which of these methods (Scrum and Kanban) are preferred [7, 9]. These cases call for a proper and deep understanding of possible

methods, recognizing their strengths and weaknesses, limitations, relative advantages compared to others, context constraints, and so on. For instance, Scrum has limitations directly affecting application results, such as lack of work visibility, local optimization, large-scale implementations, and changing task priorities [10, 11, 12]. Similarly, as all other methods do, Kanban has some problems and challenges as well [13, 14]. Considering the individual limitations and challenges of each method, there are also some views that blending more than one method will yield better results than individual use. For instance, there are views that the limitations in Scrum can be mitigated by using Kanban alongside Scrum and they can complement each other [9, 15, 16, 17].

Some literature review studies have revealed the state of Scrum and Kanban separately. Despite the importance of knowing Agile methods closely, comparing them with each other, and using them together as a possible next step, none of the secondary studies provide extensive knowledge on the topic of comparing and/or integrating Scrum and Kanban to structure information available in the literature and highlight the opportunities for further research and practice.

In this paper, we performed a comprehensive literature review study to investigate the characteristics of the empirical studies which involve Scrum and Kanban by comparing or integrating them. We used a systematic literature review (SLR) as a research methodology which is a common method to conduct a literature review study. We manually searched for the studies published until March 2022 in the electronic digital libraries of scientific literature listed in Table I, and reached and deeply investigated 38 sources that compared or used Scrum and Kanban together.

The remainder of this paper is organized as follows. Section 2 summarizes the related works. In Section 3, we describe the overview research design with research questions and selection process. Section 4 delivers the results of the literature review. In Section 5, we discuss our findings and observations and in Section 6, we deliver limitations of the study and propose suggestions for future work.

II. RELATED WORKS

There are plenty of studies reviewing the Agile methods, comparing them with their characteristics, strengths, weaknesses, similarities, and differences, providing criteria to choose them according to the context of development

including those covered in this study. Apart from those included in our study, there are some other non-empirical studies comparing Scrum and Kanban such as study [18] and books such as [19] (However, as we focus only on empirical studies in our study, we excluded such unempirical ones).

There are some secondary studies close to our scope and systematically review the literature. For instance, study [20] systematically reviews the literature to identify the studies providing practices in requirements specification incorporated into the Agile development methods and delivers a comparison among Scrum, Extreme Programming, and Lean in this regard. From the systematic literature review, they found a total of 12 relevant studies and eight variability and commonality practices between these three methods. Study [21] systematically reviews the literature in order to analyze the current trends of Kanban usage in software development and to identify obtained benefits and involved challenges. Similarly, study [13] conducts a systematic mapping of Kanban literature in software engineering between 2006 and 2016 resulting in 23 primary relevant papers. It provides benefits, challenges and recommended practices of Kanban applications in software development and state-of-the-art opportunities for Kanban research. Similarly, there are many similar studies on Scrum as well. However, we have not found any study that systematically reviews the literature related to comparing and/or combining Scrum and Kanban.

III. RESEARCH DESIGN

This research process has been undertaken as an SLR based on the guidelines proposed by Kitchenham et al. [22]. The following section delivers the method used to conduct this SLR.

The research process starts with defining research goals and questions. After defining search queries and searching in the major digital libraries, we gathered 391 potentially relevant publications. For scanning the retrieved studies, we developed and applied inclusion/exclusion criteria and obtained a final pool of 38 sources. After extracting the data from the sources, the results of SLR are analyzed and the findings are discussed. The remainder of the section concerns the research questions, publication selection process, data extraction and synthesis, quality assessment, and potential threats to validity.

A Research Questions

This study aims to review and classify studies that compare and/or combine Scrum and Kanban. Thus, we set the main goals related to our research 1) identify the studies which compare and/or combine Scrum and Kanban and 2) analyze and synthesize the studies' results. Based on our study's goals, we raise and investigate four main and seven sub-research questions (RQs):

RQ1. Contribution types and research methods:

RQ1.1. Contribution types: How many sources have represented a new software process model, method, metric, or process/workflow in the software development domain using Kanban and Scrum together?

RQ1.2. Research methods: What types of research methods were used in the empirical studies by the authors?

RQ2. Advantages of each method over another one:

RQ2.1. Benefits of Kanban against Scrum: What benefits (quantitative or qualitative) have been reported as a result of applying Kanban against Scrum?

RQ2.2. Benefits of Scrum against Kanban: What benefits (quantitative or qualitative) have been reported as a result of applying Scrum against Kanban?

RQ3. What properties are used from Scrum and Kanban in combining them? What artifacts, roles, and events are combined and customized while combining. We aim to reveal some patterns through the consolidated list of the elements integrated in combinations of Scrum and Kanban.

RQ4. What are properties of the transitions from one method to another?

RQ4.1. What are transitions' directions (From Scrum to Kanban, Kanban to Scrum or Scrum/Kanban to Hybrid)

RQ4.2. Which years did transitions happened?

RQ4.3. What are the transitions' reasons?

B Publication Selection Process

The search process was a manual search of peer-reviewed studies in well-known digital libraries without any specific filter in the year range. Based on the scope of this study, the search string including "Kanban and Scrum" as "intervention" was developed by following the SLR protocol [22, 23]. We did not add "population" related keyword in the string referring to the application area which is software in our study to access the largest possible set, rather, this search was done manually by the authors in the papers. Regarding the search location, we anticipated and were satisfied with the effectiveness of searching in meta-data instead of the full text as the main aim of the paper is a comparison and combination of two methods in the software development domain in different contexts, then it is expected the authors locate the relevant terms in the papers' meta-data. Finally, the search process was done in March 2022 as shown in Table I.

TABLE I. NUMBER OF SOURCES RETRIEVED AND SELECTED BY SEARCH KEYWORDS

Search Library	Place	Search String	#Initially Retrieved	#Selected
Web of Science	Meta-data	Kanban AND Scrum	119	14
Wiley			2	1
Science Direct			6	3
Scopus			179	35
IEEE			62	14
Emerald			2	0
ACM DL			21	3
Total				
Total in Distinct			216	38

After defining the keywords and libraries, a pilot search was done by the first two authors to make sure the search process that would be applied is standard across the research. Based on the scope and context of our study, for the selection of papers, the following propositions of inclusion criteria (IC) and exclusion criteria (EC) in Table II were specified and applied to the papers, by focusing on empirical studies which

applied Scrum and Kanban to compare or integrate into the software development domain. As can be seen in the list, studies suggesting only the use of the Kanban board, which is similar to the Scrum board, and studies examining the use of Scrumban [16] which is also defined as a specific method, are excluded.

During the application of inclusion/exclusion criteria, the papers were examined through their titles and, where necessary, abstracts in order to identify whether they are within our scope. If the abstracts were not sufficient to decide to include or exclude the papers, then, scanning through the full texts of the papers was done to identify potentially relevant ones. After the first two authors of this study identified their selected papers, the paper lists obtained from these authors were then compared to each other until reaching a consensus between them. In this step, exclusions from and inclusions into the list were made, resulting in the final agreed-upon list. The whole search process was coordinated by the third author and reviewed by the fourth author to propose improvements if needed.

In the process, a total number of 391 peer-reviewed studies were returned from the search results as seen in Table I. This initial list included duplicate records since databases we covered perform meta-data indexing of publishing databases we included directly. After removing the duplicate records, the list included 216 distinct records. Out of these 216 papers, 12 papers were investigated only through their titles, 47 of them through their titles and abstracts, and 157 of them through their titles, abstracts, and full texts.

According to the ICs and ECs, 178 papers were excluded as seen in Table II. It is noted that five papers are not accessible by the authors, even though at the first glance, they seem relevant to our study scope. Specific to these five papers, a clear decision could not be made to include or exclude them because the title and summary information were not sufficient to decide and, then, they are excluded because there is no access to the full texts by the authors. We applied EC11 (papers not available in English) either by filtering via the library relevant features allowing eliminating non-English study beforehand or otherwise via manual investigations by the authors. After the manual investigation, the full texts of the five studies were not in English, and then, they were excluded. Consequently, 38 papers that compare and/or combine Scrum and Kanban within the scope of our study were identified. For the whole list, the spreadsheet containing the search results, together with inclusion and exclusion decisions is available online [24].

C. Data Extraction and Synthesis

A data collection form holding information was designed to record the collected information from the identified studies. The collected information ranges from general information about each study such as Author, Title, Year, Venue, Author Affiliation, and Author Country, as well as specific information to answer the research questions.

For the information that is subjective and open to evaluation, first, the relevant information was taken as it is from the relevant study and copied to the Excel file. Such information that is relatively difficult to quantify is such data from the parts about how the methods are combined and how they are superior to each other. Additionally, the parts of the studies including this particular information were highlighted in the original paper for any future references. For this type of data, it was aimed for researchers to have a bias as little as possi-

TABLE II. INCLUSION CRITERIA AND EXCLUSION CRITERIA

ID	Criterion	# of Eliminated Studies
IC1	Papers empirically validated and applied research methods like a case study, survey, action research, interview, simulation, literature review, experiment, focus group, pilot study, and statistical analysis	-
IC2	Papers comparing and/or combining Scrum and Kanban	-
IC3	Papers in software development domain	-
IC4	Conference, workshop, journal or book-chapter papers	-
EC1	Not empiric studies such as idea or opinion papers	26
EC2	Papers not related to comparing or combining Scrum and Kanban	84
EC3	Papers providing only a usage of Kanban board within Scrum	5
EC4	Papers providing only a usage ratio for Scrum and Kanban in any field	6
EC5	Papers providing only usage of Scrumban	1
EC6	Papers in other than the software development domain (for example healthcare, construction, supply chain, education, and teaching)	33
EC7	Papers published in non-peer-reviewed sources such as thesis, web pages, workshop proposals, tutorials, panels, proceeding information and, books.	13
EC8	Secondary studies such as systematic reviews or mapping studies	0
EC9	Papers not accessible by the authors	5
EC10	Duplicate studies	0
EC11	Articles not in English	5

ble and comment on the original data in this way and develop his/her comments gradually. In addition, four randomly selected studies were independently reviewed by the first three authors of this study and jointly evaluated until consensus was reached to ensure a common understanding and the data extraction step is applied in the agreed standard way. The rest of 34 remaining papers were allocated randomly to the first two researchers. The first and second researchers run separate sessions in order to extract the data that serves to answer the research questions by applying detailed and thorough examinations of the relevant studies. The third author coordinated the data extraction process. Consequently, a thorough reading of each of the 38 identified papers was performed to extract relevant information. Once data extraction was complete, the extracted data were closely synchronized and analyzed with the first two authors.

D. Quality assessment

The entire process relies on a search procedure that calls for explicit criteria to validate the quality of the selected candidate papers by ensuring each candidate paper is of adequate standard [22]. Accordingly, a custom quality-assessment-criteria-list and item descriptions were established as shown in Table III.

Each paper has been then assessed against this given set of questions by the assigned authors. A manual inspection was done through the full text investigation carried out to identify

TABLE III. CRITERIA FOR QUALITY ASSESSMENT

Criteria- Statement	Descriptions
QA1- Are contributions of method clear?	Clarity and robustness of the method applied in the study is satisfactory
QA2- Are outcomes as results clear?	Outcomes are clearly delivered and relevant to the method applied
QA3- Is discussion on results clear?	Discussion of the results is satisfactory and based on the results objectively. Validity threats are delivered.
QA4- Does paper have a citation?	Papers published at least two years ago have at least one citation.

each selected paper's quality assessment score. We set a score-weight based on the two values; Satisfactory (1) and Not Satisfactory (0). Accordingly, the evaluations of the papers have been made based on the predefined two values to set their scores yielding a score of four at maximum. It was decided that the studies with a score below two points would be eliminated. After applying the determined quality criteria, the quality scores of each study are as in the Excel Spreadsheet "Demographics & QA" available online at the previously shared Excel. As seen, there existed no studies assigned the lower than the threshold score and no elimination regarding the quality assessment was done.

IV. RESULTS

We present the results and findings of this SLR study concerning RQ1-RQ4. All sources included in this study are listed in a publicly accessible repository available at the previously shared online sheet named "Demographics & QA".

According to the results, 63% (24/38) of the studies are conference papers, 34% are journal articles, and 3% are workshop papers. In terms of venues for the selected 38 papers, "International Conference on Agile Software Development (XP)" is at the top with five papers, followed by "Hawaii International Conference on System Sciences (HICSS)" and "Agile Conference" with three papers for each. Regarding the journal articles, "Journal of Software: Evolution and Process" is the top one with two papers. In terms of the authors' affiliation types, 55% (21/38) of the papers are from academia, 24% from industry, and 21% from industry and academia collaboration. Related to the authors' country distribution, the USA is at the top with nine authors, followed by Norway, New Zealand, Brazil, the UK and Italy with three papers for each, among twenty-two different countries

Fig. 1: Number of sources per year

in total. The contexts of the studies include software development (not specified) with seven papers at the top, software maintenance with three papers, and web-based content management system with two papers respectively. Other contexts include finance and insurance web services, automotive production software, content management system, library information system, data science, software project management, cloud-based software development, video game development, mobile software development and so on, among others. Figure 1 shows the cumulative number of sources per year by considering type (comparing vs. integrating).

Regarding RQ1.1 (Contribution types), Figure 2 depicts the contribution types of the primary sources. As shown, 22 studies do not provide any new model, method, tool, metric or process, as they rather mainly deliver a comparison between the methods or apply them. We see a considerable amount of new model proposals.

Fig. 2: Contribution types

In terms of the research methods used in the empirical studies by the authors (regarding RQ1.2), as seen in Figure 3, the majority of the studies use a case study method, followed by a survey, interview, and simulation.

Fig. 3: Research methods

When it comes to RQ2.1 (Benefits of Kanban against Scrum), Table IV delivers the results. Similarly, Table V depicts results for Scrum Benefits against Kanban (RQ2.2), ordered by "Number of sources". We have added the domain information of each source by using abbreviations; 3D Animation Production as 3D, Agile Application (General) as Agile G., Agile Testing as Test, Automotive as Auto, Broadcasting Software Development as Broadcast, Cloud-based Software Development as Cloud, Content Management System as Content, Data Science Project Management as Data, Finance and Insurance Web Services as Finance,

TABLE IV: KANBAN BENEFITS AGAINST SCRUM

Category	Kanban Benefits against Scrum	Domain	Number of sources - Sources
Process	Flexible and adaptive	Mob, Web, Lrn, Lib, Agile, Game	7- [9], [30], [33], [36], [37], [4], [43]
	Easy for transition and use	Data, Lrn, Agile, Soft	7- [9], [35], [36], [4], [42], [45], [47]
	Efficiency	Soft, Broadcast, Cloud, UX	4- [48], [57], [58], [14]
	Focus on work	Lrn, Soft, Maintenance, Broadcast	4- [36], [54], [55], [57]
	Quality	Agile, Game, Soft P.	4- [9], [4], [43], [53]
	Delivery time	Content, Game	3- [9], [38], [43]
	Visibility	Maintenance, Broadcast, Soft P.	3- [7], [55], [57]
	Performance	Agile, Soft, Maintenance	3- [25], [4], [46]
	Controlling the flow	Web, Cloud	2- [40], [58]
	Delivering value	Lib, Soft	2- [37], [54]
	Project schedule management	Soft P.	2- [7], [53]
	Project resources management	Soft P.	1- [53]
	Project risk management	Soft P.	1- [53]
	Consistency in project management	Soft P.	1- [7]
	Being reliable	Agile	1- [4]
	Better for development with no certain deadline	Lrn	1- [36]
	Better for small and not complex feature development	-	1- [9]
	Closer contacts with users	UX	1- [14]
	Cost-effective	-	1- [9]
	Eliminating excessive and unnecessary meetings	Mob	1- [30]
Less rework	Lib	1- [37]	
Getting fast feedbacks	-	1- [9]	
Traceability	Maintenance	1- [55]	
People	Teamwork	Maintenance, Data	2- [35], [55]
	Collective understanding	Maintenance, Broadcast	2- [55], [57]
	Respect for people and their current states	Soft	1- [42]
	Satisfaction of individual team members	Data	1- [35]
	Less stress	Mob	1- [27]

TABLE V: SCRUM BENEFITS AGAINST KANBAN

Category	Scrum Benefits over Kanban	Domain	Number of sources - Sources
Process	Path clarity, being well-defined	Soft, Video	3- [42], [43], [47]
	Better for development with batched and a block of works	Agile	2- [9], [4]
	Delivery time	Maintenance, Soft	2- [25], [47]
	Better for bigger teams	UX	1- [14]
	Better for development with certain deadline	Lrn	1- [36]
	Better for development within high uncertainty environments	Agile	1- [4]
	Better for the testing process	Test	1- [31]
	Project cost management	Soft	1- [53]
	Detailed tracking and overview of projects	Lrn	1- [36]
	Predictability	Soft	1- [54]
	Specification of customer requirements	Soft	1- [47]
	Easy to manage	Soft	1- [54]
People	Teamwork	Web, Soft	3- [33], [42], [47]
	Empowering	Mob	1- [27]
	Communication	Video	1- [43]

Learning Management System as Lrn, Library Information System as Lib, Mobile Software Development as Mob, Open Source as Open, Software Development (General) as Soft, Software Development Project Management as Soft P., Software Maintenance as Maintenance, System Admin as System, Telecommunication Software Development as Telco, User Experience as UX, Video Game Development as Game, and Web-based Content Management system as Web. In column “Category”, the classified information of each item including process, organization and human dimension is given. The “Organization” category is about making decisions

related to software engineering and development in a business context and aligning software technical decisions with the business goals of the organization [13].

Kanban is regarded as more flexible and adaptive than Scrum without strict time-boxes, roles, rules and sprint constraints. Kanban teams feel more powerful to address their internal processes and respond quickly with its continuous flow management allowing constant re-planning to uncertainty and frequent changes and faster responses. They can deliver results earlier with frequent releases and division of the work in very small-time chunks [37], [48]. Kanban is

also simpler and paves the way to an easier transition with less cost, time, chaos and turbulence. It does not touch titles or positions of people, requiring a lower “patience point” [42]. Thanks to its more “sequential” nature and WIP limits, Kanban seems to be more efficient in distributed context [58]. Using Kanban over its precursor Scrum practices brings advantages in terms of efficiency and focus with WIP limits, stopping context-switching, providing granularity of visualization, gaining a collective understanding of the whole process, less paperwork, and reducing batch size through the pipeline [57], [14].

As reported quantitatively and/or qualitatively by some studies, Kanban provides better quality, project schedule, risk, and resource management, reliability, lead time results, performance, visibility, traceability, teamwork, the satisfaction of individual team members, regular feedback faster, and closer contacts with users. It does not require haste like in Scrum and, therefore, resulted in better quality [4] and less stress [27]. Kanban works better within certain contexts like development with no certain deadline and small and not complex feature development. It allows for identifying reworks at early stages [37]. It has been found that Scrum supports collectivist teamwork, more empowered team members, shared goals and intense communication across the team. Although Scrum has a rigid and routine structure, it provides a path clarity and easiness to manage the processes thanks to its being a well-defined method. According to some results, Scrum provides a better cycle time. Scrum also seems to be more suitable for bigger teams, batched works and developments within high uncertainty environments like for new product development and within certain deadlines. Some of the results quantitatively put forward that it is better than Kanban in terms of project cost management and agile testing processes. Scrum provides better predictability and detailed tracking and overview of projects.

Regarding RQ3 (properties of the proposed combining models), Table VI depicts the results by providing what properties are used from Scrum and Kanban in combining them (M stands for Method). It shows in particular what artifacts, roles, and events are combined and customized while combining Scrum and Kanban. In the Scrum and Kanban integration, numerically speaking, the most used elements are PO (Product Owner), Daily, Sprint Review, Sprint Retrospective, Scrum Team, User Story, Definition of Done, and Sizing from Scrum, and, Pull system, Continuous flow, WIP, and Kanban boards from Kanban. Besides, there are some custom-made elements in their integrations. Notable ones can be listed as follows: simultaneously used number and size-based WIP, iterative movement of the items on the flow, work/hypothesis/experiment/release-based iterations, calendar-based regular or on-demand ceremonies, daily planning, team formations that break the “standard” cross and self-organizing team structures including floating teams, sub-groups/roles and supervisory authority, same/similar-size work items, and product owner teams.

TABLE VI: ELEMENTS USED IN COMBINING

M	Element/Source	Number of sources - Sources
Scrum	PO	11 - [26], [28], [29], [32], [33], [34], [39]-Case1, [40], [41], [49], [56]
	Daily	9 - [26], [28], [33], [38], [41], [44], [49], [51], [52]

	Scrum Team	7 - [26], [28], [39]-Case1, [49], [51], [52], [56]
	Product Backlog	6 - [28], [32], [34], [44], [49], [56]
	User Story	5 - [26], [28], [32], [38], [51]
	Definition of Done	5 - [28], [34], [38], [44], [51]
	Sizing (T-Shirt size, effort-based, planning poker etc.)	5 - [39]-Case2, [40], [49], [51], [56]
	Sprint Review	5 - [28], [34], [38], [44], [49]
	Sprint Retrospective	5 - [28], [34], [38], [44], [49]
	Grooming	3 - [34], [49], [56]
	SM (Scrum Master)	3 - [28], [33], [49]
	Definition of Ready	2 - [28], [51]
	Sprint Planning	1 - [26]
	Minimal Marketable Feature-Sets / Minimum Viable Product	1 - [41]
	Sprint	1 - [26]
	Kanban	Kanban boards
Work in progress (WIP)		10 - [28], [33], [34], [39]-Case1, [40], [44], [49], [51], [52], [56]
Pull system		7 - [34], [38], [40], [41], [44], [51], [56]
Continuous flow		5 - [33], [39]-Case1, [40], [41], [56]
Metrics		3 - [39]-Case2, [40], [44]
Value-stream/chain		2 - [28], [41]
Service level agreement/expectation		2 - [28], [39]-Case2
Size of task is not limited		1 - [56]
Replenishment		1 - [52]
Kanban coach		1 - [52]
Custom	Calendar-based regular ceremonies	4 - [40], [49], [52], [56]
	Work/Experiment/Hypothesis/Release-based iteration planning	4 - [29], [32], [49], [51]

Related to RQ4 (Properties of the transitions from one method to another), the transition directions are from Scrum to Hybrid (11/18), from Scrum to Kanban (5/18), from Waterfall to Hybrid (1), and from Custom to Hybrid (1/18). It can be seen that most of the transitions are to the hybrid methods and predominantly from Scrum. Additionally, Figure 4 and Table VII present transition years, and transition reasons respectively (the studies that explicitly express the transition year form the cumulative A curve, and after adding the five studies that do not explicitly express the transition year from the cumulative B curve when the year of publication is accepted as the transition year).

For the transition reasons, regarding the lack of flexibility and predictability during the fixed sprints and timeboxes, the studies report that sprints are not adequate for frequent, constant, and unexpected changes and (especially external) dependencies in hectic and unstable environments that require quick responses, frequent re-planning, re-prioritization, and a vast amount of mid-iteration updates for dynamism or resulting in non-predictive sprints. These issues make Scrum unsuitable for maintenance teams in which the dynamism is high and estimation is time-consuming and often incorrect. Under these circumstances, it becomes unclear how much teams would deliver in a sprint [40].

Fig. 5: Transition Year

The combination of inaccurate estimates and timeboxes leads to non-sensing estimation activities and, thus, waste and reduced productivity [38], [46]. Some studies indicate that Scrum causes constant strain and quality issues such as increased technical debt, decreased system maintainability, untested implementations, and unmet production maintenance just to meet business time targets leaving little time to “others” including technical and administrative tasks with “no business value” or “little urgency”. Such tasks mostly remain in the background of the business. Study [38] states that developers did not pay enough attention to creating good architectural

designs, rather mainly focused on the short-term goals of the sprints. Short-term sprints also decrease visibility beyond sprints. Some teams regard Scrum as difficult to accept with its revolutionary transformation change proposition [45], “aggressive”, “materialized” and “rigid” structure [42], [46].

TABLE VII. TRANSITION REASONS

Category	Transition reason	Domain	Number of sources
Scrum			
Process	Lack of flexibility and predictability during sprints for frequent/unexpected changes	3D, Telco, Mob, System, Web, Maintenance, Open, Broadcast	11- [28], [29], [32], [33], [34], [40], [44], [45], [55], [56], [57]
	Quality decrease	Telco, Content, Web, Auto, Soft	5- [29], [38], [39], [40], [46]
	Unsuitable for maintenance	System, Maintenance, Soft	4- [34], [44], [46], [55]
	Estimation is time-consuming, non-sensing, or causing delays	Web, Content, Soft	3- [38], [40], [46]
	Scrum ceremonies cost	Mob, Finance	2- [32], [41]
	Lack of work visibility	Maintenance, Finance	2- [41], [55]
	Focusing on short-term goals of sprints	Content	1 - [38]
	Challenges in Sprint-based delivery	Web	1 - [40]
	Increased length of feedback loops	Finance	1 - [41]
	Being rigid	Soft	1 - [46]
	Failed sprints	Soft	1 - [54]
	Reduced productivity	Soft	1 - [46]
	Work items rarely correlated	Web	1 - [40]
	Lack of overall status beyond sprints	3D	1 - [28]
	External dependency	Open	1 - [56]
Ineffective Scrum events	Content	1 - [38]	
Waste	Soft	1 - [46]	
Organization	Challenges in large scale projects	Mob, Content, Soft	3- [32], [38], [46]
	Fragmentation	Web, Content, Telco	3- [29], [38], [40]
	Revolutionary change	Telco	1 - [45]
	Lack of co-location	Web	1 - [40]
	Lack of communication and collaboration	Maintenance	1 - [55]
People	Challenges in having a common language with business	Content	1 - [38]
	Need for deep specialty in teams	Web, Open	2- [40], [56]
	Constant strain	Telco	1 - [29]
	Challenges in being self-organizing teams	Telco	1 - [29]
	Challenges in having cross-functional teams	Web	1 - [40]
Lack of team lead resulting in a stagnation of team development	Telco	1 - [29]	
Kanban			
Process	Lack of control	System	1 - [34]
	Lack of deadlines	System	1 - [34]
People	Not having a feel progressing	System	1 - [34]

This strict position of Scrum also seems problematic when a lack of co-location is present [40]. We have seen some scaling challenges with Scrum including issues in the distributed scenarios, breaking large items down into smaller ones to be squeezed into one sprint, lack of synchronization, and fragmentation caused by isolated and localized Scrum teams. Among other items, specialization in certain parts of systems, dependency on deep specialists, and rarely correlated work items to bunch for/in a sprint are counted. Scrum ceremonies can cause rework, high cost, increasing length of feedback loops, lack of end-to-end work visibility, and lack of visibility within sprints. They, then, are done more and more seldom, shorter and shorter in their duration to finally “die out” [38] or end up with failed sprints [54]. Scrum teams may result in stagnation and having dominant team members and group formations within the team when team members are unchanged [29] or some other issues when teams have a number of part-time resources with varying availability [40]. On the other hand, in Kanban, with the lack of boundaries, teams are prone to drive into “guerilla-style” working and feel a lack of deadlines and no actual sense of progress.

V. DISCUSSION

The fact that the majority of sources were produced by industry-oriented authors, especially as experience and case study papers, indicates that the subject of the study can be considered mainly as a practical-led area and a need by the sector. This shows that the industry is ahead of academia in this regard. The data about a cumulative number of sources per year indicates that the first studies start just after the years when the first Kanban documents were published, the two methods are mostly compared in the first years, and the sources on the integration gained speed later on but have slowed down in recent years, which needs a further investigation. In general, after 2016, a noticeable acceleration in the number of sources draws attention.

Static Entities: It seems that there are some (almost) static entities in Scrum including sprint, time-boxes, and team formations that are found problematic in terms of providing flexibility and agility. Scrum plans and starts the sprint with a prediction for the future, but where the external environment change is high, the sprint predictions become incapable. This indicates that the sprint structure provides low agility in a high change environment. With this level of inflexibility, it seems that one of the areas where Scrum is most incapable is maintenance work. The main reason for Scrum's inadequacy in maintenance works is that these environments have a higher level of change than other environments. With a sprint-based maneuverability, Scrum works more comfortably in environments with low/medium uncertainty. Where the uncertainty is high, the estimations made to fit into this artificial and such static sprints become more meaningless and seen as a waste. All these are mainly why people regard Kanban and continuous flow along with its metrics designed for dynamic work management in the hybrid solutions as more flexible, adaptive, and powerful compared to Scrum.

Packaging work items: Sprint also focuses on packaging work items with a development-oriented perspective so-called the artificial world of development, rather than the real needs of the business world, so-called business-oriented development. In this sense, sprint is also (for example) a method of fragmentation. Even if things are not in a nature to be broken up or to be joined, they are compelled to do so.

Deadlines: Sprint includes deadlines, even measured in seconds; the end of a sprint. With a production-based logic, Scrum locates people as production muscles and expects them to comply with the strict lines, stressing and tiring them out. Estimates for the works to be done within the deadlines continue to be made in Scrum with the classical method logic; The main thing changing is the unit (man/day versus story point). With these concrete “lines” and the “glorification” of business orientation, parts that look inward (to technical sides and systems) may also stay in the background. To assign a static end rather than an end according to the nature of the works creates a meaningless and dangerous dichotomy between the nature of the work and these static ends. It is dangerous because the developers may not always choose the right way (e.g. even if things are not “on the way”, do tests properly). This dilemma paves the way for the sacrifice of more “abstract” concepts such as quality. In order to solve this problem, it is seen that some hybrid solutions are adopting business-work/experiment/hypothesis-based iteration planning solutions, not clock-time-based ones.

Push System: In Scrum, the flow is partially “push” based, where tasks would move to the next step as soon as they completed the previous step [59]. Also, Sprint Planning works for how much work to push (into the sprint) [12]. Scrum further “pushes” the teams to produce shippable products at the end of the sprint [12]. This push and time-box approach in Scrum [39] along with artificial hot deadlines of the sprints may lead to more stress, pressure, and fatigue on the teams and enforce them to compromise on quality. Kanban WIP limits aim to reach a near real-time balance between demands and capacity in a way free of stress for developers. Using a persistent, balanced, and thus, stress-free flow in Kanban facilitates achieving a more sustainable and reliable flow [59] that positively affects the final product and its quality. The pull system applying WIP limits stands as a choice of many hybrid solutions reported in our study.

Inside of the Sprint: In Scrum, the inside of the sprint is like a single station of which WIP is sprint-based. It makes the default, fundamental and granular level of work management level sprint-based. Thus, work management inside a sprint is less trackable. For this reason, congestion and bottlenecks may also occur in certain parts of a sprint. Kanban offers a more effective control mechanism with WIP limits that seem to be widely integrated into the hybrid solutions over controlling capacity and scope of work under high variability in Scrum [40]. In Kanban, each workstation is designed separately and traceability and visibility are provided to all teams and stakeholders through a continuous workstation-based flow on the Kanban board (even not reset at the end of the sprint). Kanban board can be considered as an advanced version of Scrum board in this sense and it can be seen that it is widely preferred among the hybrid solutions.

Scaling, with Isolation: The original Scrum setup is team and sprint-based, posing challenges in large-scale projects. This issue is manifested in our results as fragmentation, challenges in large scale projects, focusing on short-term goals of sprints, lack of overall status beyond sprints, and lack of communication and collaboration issues as shown in our “Transition Reasons” list. On the other hand, Kanban aims to gather the teams around the value streams for customers and address the whole organization by adopting system thinking and Fit-For-Purpose principles [60] on the horizontal axis that starts with the customer and ends with the customer delivery.

The indication of this aim in the hybrid solutions is the use of value-stream/chain.

A sprint backlog is owned by one specific team unlike a Kanban board shared by multiple teams [14]. Similarly, when sprint (specific to a particular team), *self-* organizing and cross-functional team promises come together, an encapsulation, division, and, to an extent, isolation issues occur for the teams. Due to its nature and instinct, sprint is a kind of planning within a particular team, while inter-team planning should be done according to emergent principles and globally. Despite the scaling models, doing this alignment within the teams at longer intervals emerges as a problem in Scrum.

Moreover, In Scrum, breaking the work down into small items regarding the time constraint and reductionist slicing of work can disrupt the holistic view and loss of track of item dependency [14]. Thus, sprint breeds an instinct for a short-term approach. Kanban supports better project management results and team building around common and collective understanding beyond sprints. Work items can be delivered earlier, as Kanban implements WIP in the entire flow and items can behave independently, eliminating [unnecessary] dependency within work items (bundling items in a sprint is a kind of dependency).

Necessities(!): With its flexible structure, Kanban allows teams to be more self-organizing. Thus, activities that are not necessary and done at specific times just to comply with the "necessities" of the framework can be avoided (The calendar-based, not sprint-based events, in the hybrid solutions are a good example of this). Moreover, teams can develop actions in a more sensitive, lively and instantaneous (synchronous) manner in addition to the a-synchronous actions offered by the framework. For example, teams should not wait for the end of the sprint for feedbacks or for the beginning of the sprint for new work to take in.

Scrum provides a form with its "rigid" structure for cultures that need order that is relatively missing in Kanban. In contrast, each "game rule" in Scrum is hand-binding, and Scrum's predictable, rigid, artificial boundaries promise an average-level-performing goal and may hinder average teams from performing higher. "Increasing the length of feedback loop" is an example of this; Because it recommends that feedback is *mainly* managed through an artificial structure, not emergently. Generally speaking, Scrum's addiction to asynchronous communication can be a challenging factor where synchronous communication is the remedy. Scrum events are a sort of prediction. Their ability to manage a different flow is low. On the other hand, since Kanban does not come with a relatively rigid form, it seems more challenging for it to take a shape. Moreover, Kanban teams are expected to be internally motivated. The driving force is internal, not external [as in Scrum]. In teams that do not have this intrinsic strength, therefore, applying Kanban can make the situation worse. Even for motivated teams, being in a homogeneous and flat flow in Kanban may not support the feeling of progress. Against the lack of control, not having a feeling of progress, and lack of deadline matters in Kanban, Scrum's sprint structure comes with solutions.

Transition: The fact that Kanban is closer to Lean as root than Scrum seems to have made it simpler. Scrum, rather, is like a luxury framework with its add-ons at a high cost. This luxury also applies to the transition to it. Even at the entry

level, Scrum requires a threshold to endure, and teams must be accompanied until they pass this threshold in a healthy way. Because the transition steps are bulk, teams suddenly find a more tough challenge and have to deal with it even in the first place. Radical transitions to this rigid and costly structure seem to threaten and wear out the teams.

In Kanban where progress rather than transition is essential, the transformation is easier. Kanban focuses on the flow (process) rather than providing agility through teams' (re)organizations for transitions. Kanban does not also require any strictly pre-defined roles or processes adopted in a revolutionary way like in Scrum, rather recommends an iterative and incremental (shortly agile) way of implementation and an easy way for transition and use. It does not have a special preference and compulsion regarding the setup of the teams. In this sense, with its principle "start with what you do now" and "initially, respect current processes, roles, responsibilities and job titles" [59], it can align and coordinate existing teams at upper levels. However, as reported by study [13], it similarly seems from our results that current studies covered in our work are mostly restricted to process and people levels and have not yet been scaled to the organization level including such as portfolio project levels or being used as a tool for decision-making by management.

Miscellaneous (Unclassified): Kanban does not deal with the types of works in the flow, they are regarded as homogeneous. Scrum, on the other hand, considers the works as complex by default and allows to handle such works according to their nature. Scrum, thus, seems to be more advantageous than Kanban in complex projects.

Scrum is better at cycle time while Kanban is better at lead time. Scrum encourages more collaboration within the team. While Scrum is better in intra-team communication, it seems problematic in inter-team communication. Scrum teams do not always go on the "happy path", the other side of the coin comes to the surface and it is seen that the problems between people (experienced in hierarchical structures) are present to them as well.

Depending on the situation, specialties still seem necessary by considering a balance to strike between specialization and generalization. Although some issues with the PO role generating an extra layer and dependency have been witnessed, the hybrid solutions including the PO role have been commonly observed. It means there seems to be a need for a mediator, the PO role, which acts as a bridge between the customers and the development teams. Having the PO in the process may also ensure that a representative of the customer is involved. The PO can also bring simplicity to the structure.

Both Scrum and Kanban seem to be good in delivery time, tracking and overview of projects, and teamwork. Where one is weak, the other one can be strong. These and similar situations still make these two methods preferable. However, the reported disadvantages of the particular methods (especially Scrum) open gates to integrating the most advantageous part of the methods and eliminating their disadvantages at the same time by hybridizing them.

Regarding the hybrid models, sprint is almost non-existent, instead, flow is extensively used. In relation to this, it is seen that the SM role is also positioned very few. Mostly, the roles and events are integrated from Scrum. One of the

reasons can be an endeavor to use the ready-roles of Scrum that are not defined in Kanban or not abandoning already-used Scrum roles after the transition to a hybrid one. We have seen that Daily is used as a common communication manner in the hybrid models. Nevertheless, it seems that some teams do not prefer to feed a rigid and relatively bloated framework, like Scrum, just for the sake of it. They tend to avoid the high cost of events of Scrum and (seldomly) want to make them when necessary or (mostly) on a calendar base. However, there is a tendency to do the events as routine (calendar/iteration/release) based rather than only as needed. Additionally, there is still a desire to predict the future by the teams, but they do not want to limit themselves to a deadline. In providing forecasting/estimations, there are certain studies that consider not only size but quantity and size criteria together. Some solutions break Scrum's rigid team structure and redesign it according to the needs. Similarly, the solution that converts Kanban's one-way flow to a two-way flow direction is also observed.

We have seen that Scrum has advantages in requirements management phases and many solutions are trying to address these phases with Scrum particles. Especially in this area, there is a preference for the product-based structuring that may be easier to manage with Scrum. In general, while Scrum seems good at defining the projects, Kanban stands out in the development part of it.

In our study results, it has been observed that Kanban provides an advantage over Scrum in general. The results of the study also exhibit a considerable percentage of transitions to hybrid models (from Scrum). Most organizations adopted Scrum before Kanban [24]. This may be one reason why the transitions are mostly from Scrum. On the other hand, studies [38, 46, 55] report that an increasing number of companies previously using Scrum is switching to Kanban due to the issues that Scrum bears.

Considering Kanban's linear and Scrum's deterministic approaches with the effect of the manufacturing sector to a certain extent, one of the recommendations of our work would be to use Scrum and Kanban with the "AND" operator, not "OR" as we have seen how they complement each other and how they produce better solutions together. We recommend providing varying hybrid models relevant to different contexts of organizations. When choosing a method, it is more appropriate to adopt it in a way that will be beneficial to the organizations themselves [14], rather than fully complying with that particular method; it is recommended to blend the methods according to the needs instead of blindly adhering to one method. For such an integration, it is reminded that Kanban is methodology independent; it can be applied to teams implementing Scrum, Extreme Programming, or Waterfall at the operational levels [39]. It is also proposed that articles that are going to be focusing on the integration of multiple Agile methods might be providing more insightful information, especially for the practice.

VI. LIMITATIONS AND FUTURE WORK

The procedures used in our study have limitations in several ways. More likely, we may have missed some relevant studies as we did not include all possible libraries. In particular, we have missed the studies published in non-peer-reviewed resources. Although the studies included and excluded were checked by other researchers, for most of the studies, a single researcher extracted the data from the

included studies. The values of the quality assessment criteria are somewhat subjective. Also, the primary studies' results are context dependent and their generalizability may be low and problematic when ignored.

We are planning a further study that will evaluate the combining models to grab their common patterns from different views and we will recommend our own new model(s) with an eclectic approach. The proposed models will be suited best for certain contexts and be selectable accordingly with guidance to know the cost, trade-offs and (dis)advantages of the selections. Before finalizing the proposed models, we will conduct evaluations with experts in the field of Agile Software Development to develop the model iteratively and incrementally.

Abstract—Software requirement classification is becoming increasingly crucial for the industry to keep up with the demand of growing project sizes. Based on client feedback or demand, software requirement classification is critical in segregating user needs into functional and quality requirements. However, because there are numerous machine learning (ML) and deep-learning (DL) models that require parameter tuning, the use of ML to facilitate decision-making across the software engineering pipeline is not well understood. Five distinct word embedding techniques were applied to the functional and quality software requirements in this study. The imbalanced classes in the dataset are balanced using Synthetic Minority Oversampling technique (SMOTE). Then, to reduce duplicate and unnecessary features, feature selection and dimensionality reduction techniques are used. Dimensionality reduction is accomplished with Principal Component Analysis (PCA), while feature selection is accomplished with the Rank-Sum Test (RST). For binary categorization into functional and non-functional needs, the generated vectors are provided as inputs to eight distinct Deep Learning classifiers. The findings of the research show that using a combination of word embedding and feature selection techniques in conjunction with various classifiers can accurately classify functional and quality software requirements.

Keywords—Functional Requirements, Non-Functional Requirements, Deep Learning, Data Imbalance Methods, Feature Selection, Classification Techniques, Word Embedding.

I. INTRODUCTION

SOFTWARE requirements classification deals with segregating the clients' requirements and demands found in the Software Requirements Specification (SRS) document into functional and non-functional requirements. It is a key step in the software development pipeline which can be automated using Machine Learning techniques. This allows the industry to save on labor expenses, as a domain expert is often required, while also optimizing the process and saving crucial time [1]. A key problem that needs to be addressed during requirements classification is that of the inconsistency in terminology used by the clients and the software engineers. This may lead to misclassification of the software requirements.

Functional requirements are the demands that the end-user defines as critical characteristics that the system should supply

and that can be observed immediately in the finished result. This is how the input to the system, the action to be taken, and the intended output are all defined or stated. The system's basic quality standards, often known as non-functional requirements, include factors like reliability, maintainability, security, and portability [2].

Another problem faced during software requirements classification is the imbalance between the number of instances of functional and non-functional requirements classes. Data imbalance means that the number of instances of minority class are much lower than those of the majority class. Because of the unbalanced distribution of data, classifiers are misled while learning the minority class, resulting in biased and erroneous findings [3]. A good software requirements categorization model will be one that has been trained on a similar distribution of functional and non-functional requirement classes. In this study, this problem is addressed using oversampling through Synthetic Minority Oversampling Technique (SMOTE).

In this paper, we look to solve the above problem, and create highly accurate software requirements classification models which can be reliably used in the industry. The following are the research questions (RQs) that will be used to attain the aforementioned goals.

- RQ1: Which feature extraction technique can best capture the unstructured, textual data present in the SRS document, and convert it to structured data in the form of numerical vectors?
- RQ2: Which feature selection techniques are the best at getting rid of redundant and irrelevant features which may affect the performance of the classification models?
- RQ3: For what structure of the deep learning classifiers do the software requirements classification models achieve the best results?
- RQ4: How does the application of class balancing technique through oversampling affect the performance of the models?

The criteria used to evaluate the performance of the various models are F-measure, accuracy, and Area under the ROC curve (AUC). The Friedman test was used to determine whether an ML technique resulted in a substantial difference in performance. The PROMISE dataset[4] was used in this study, which contains 625 labeled criteria from 15 different projects. The contributions of the study are as follows:

- An extensive comparison of various word embedding techniques for the purpose of feature extraction is provided to analyze which technique is best suited for the SRS document.
- A thorough investigation on the effect of various feature selection techniques on the performance of classification models in software engineering is presented.
- Deep learning classifiers are employed to increase the accuracy of software requirements classification from previous studies, with variations in number of layers, and type of layer being analyzed to find the best deep learning model out of the eight distinct DL classifiers used in this study.
- The study evaluates and analyses the performance of requirements classification models using relevant performance metrics. The study includes a thorough statistical analysis to back up the findings with statistical testing, unlike previous studies.
- The effect of class-balancing techniques on software datasets to build more accurate models is examined.

The remainder of the paper is structured as detailed here: Section II presents a literature review on software requirement classification and various word embedding approaches that are used in this study. Section III describes the experimental dataset collection as well as the various machine learning algorithms used. The research methodology is described in Section IV using an architecture framework. In Section V, the results of the experiments, along with their analysis, are presented. Section VI shows a comparison of models created using various word-embedding approaches, sets of features, and machine learning models. Finally, Section VII summarizes the information provided and offers directions for further research.

II. RELATED WORK

A. Software Requirements Word Embeddings

Navarro-Almanza et al. [5] explore Word2Vec using Skip-Gram to get structured representation for the textual software requirements dataset. The purpose of the Skip-gram model is to anticipate context words. The projection from Skip-Gram is a continuous vector space rendition of the word with a low dimensionality. The models developed achieved a maximum of 0.8 precision, 0.785 recall, and 0.77 F-measure.

To improve how well the word embeddings capture the content of the text, Marcacini et al. [6] analyze the impact of using contextual word embeddings for software requirements. They use the RE-BERT model to obtain the structured data to feed into their hierarchical clustering classifier. BERT is

built on the Transformers architecture and uses a deep neural network. To address the sequence of occurrence of the tokens, a positional embedding is used. Static word embeddings, such as word2vec and FastText, on the other hand, have the issue of having the same embedding regardless of context, which makes structured modeling of software requirements difficult.

B. Classifying Software Requirements

Ott [7] employ two classifiers, Multinomial Naive Bayes, and Support Vector machine for software requirements classification. The classification techniques are applied on two datasets, out of which one is confidential and the other is public. The maximum recall achieved by the Naive Bayes classifier is 0.94, whereas the Support Vector machine achieves a precision of 0.86 in the best model. Baker et al. [8] work on classification of non-functional requirements into their sub-categories. The authors compare the performance of the CNN model with that of an ANN model and results indicate that the CNN model outperforms the ANN on most performance metrics. The ANN consists of one hidden layer of 20 neurons. The ANN model has a precision of 82% to 90%, a recall of 78% to 85%, and the greatest F-score of 84%. With the maximum F-score of 92%, the CNN model obtains precision between 82% and 94%, and recall between 76% and 97%. Rahimi et al. [9] focus on further classifying the functional requirements into six different categories: policy, action constraint, solution, definition, attribute constraint, and enablement. The authors use the ensemble approach which combined five distinct classifiers: support vector classification, support vector machine, decision tree, logistic regression, and Naive Bayes. For each class, accuracy per class as a weight is used to find the most optimal classifier. The best results are obtained using LR, SVC, SVM as the classifiers, which perform better than using all classifiers. An accuracy of 99.45% is achieved in classifying 600 functional requirements.

III. STUDY DESIGN

This section presents the details regarding various design setting used for this research.

A. Experimental Dataset

Cleland-Huang and his team [4] used the same datasets to validate the proposed software requirement solution. Cleland-Huang and his team extracted this data with the help of MS students from DePaul University and rendered it for public research via the PROMISE repository. The functional and non-functional attributes are shown below in Figure 2. The first observation to be made about Figure 2 is that the PROMISE repository is uneven in number of functional and non-functional requirements, with quality requirements accounting for 382 of the 625 total.

B. Training of Models from Imbalanced Data Set:

Several ML algorithms have the issue of neglecting the minority class in unbalanced datasets, despite the reality that performance on those is often what matters. In order to use future ML techniques, it was essential to implement the SMOTE technique on the imbalanced classes in our dataset. SMOTE [10] (Synthetic Minority Oversampling Approach) is

Fig. 2: Data-Sets

a data augmentation technique that duplicates existing minority class instances or generates new minority class instances. It solves the imbalance problem without adding any new data to the dataset, allowing us to employ machine learning techniques afterwards.

C. Word Embedding:

The dataset’s textual data must be expressed as vectors in respect to one another. The dataset was subjected to five different word embedding techniques: Term Frequency and Inverse Document Frequency (TF-IDF), Continuous Bag of Words (CBOW)¹, Skip-Gram (SKG), Global Vectors for Word Representation (GLOVE)², and Google news Word to Vector (GW2V). The aim of these techniques, such as GLOVE, CBOW, etc., is to capture the semantic information in the text, which is not possible with other word-embedding techniques such as TF-IDF. The textual data was represented as a vector in an n-dimensional space using these techniques. Before applying the word embedding techniques, all characters in the requirements are converted to lowercase letters. We deleted any stopwords, bad symbols, and spaces. These will now be

¹<https://towardsdatascience.com/word2vec-skip-gram-model-part-1-intuition-78644e111111>

²<https://nlp.stanford.edu/projects/glove/>

utilized to create models that will classify the requirements into functional and non-functional [11].

D. Feature Selection Techniques

We identify critical feature vectors that impact the performance of the models after doing word embedding on the data. To eliminate redundant and unnecessary features that may have a detrimental impact on the models’ performance, the Rank Sum Test (RST) and Principal Component Analysis (PCA) are used. To see the difference, the performance of models with these features is compared to the performance of models without these features. This phase aids in the reduction of over-training and training time [12].

E. Classification Technique:

The dataset is divided into training and testing subsets and categorized using eight deep learning models using K-Fold Cross-validation with a k value of 5. The structure of the various models is presented below. All models have an input layer with number neurons equal to the number of features of input data. For each subsequent hidden layer, the number of neurons is halved. All layers involved in the Deep Learning models are either Dense layers or Dropout layers. In a Dense layer, each neuron in the layer receives input from all neurons of the previous layer. On the other hand, a Dropout layer randomly selects and omits a certain number of neurons in the layer while training the Deep Learning model. In this work, a dropout value of 0.2 is used. Dropout layers are used to solve the problem of overfitting models. Finally, the output layer consists of only one neuron which contains a binary value corresponding to the binary classification to either functional or non-functional requirements. The activation function for each layer is the rectified linear activation function or ReLU, except the output layer which uses a sigmoid activation function. Binary cross entropy is the loss function that is utilized to train the models with Adam as the optimizer. Figure 3 shows the architecture of the considered deep learning model1, model2, model3, and model4 (DL1, DL2, DL3, and DL4). Similarly, we

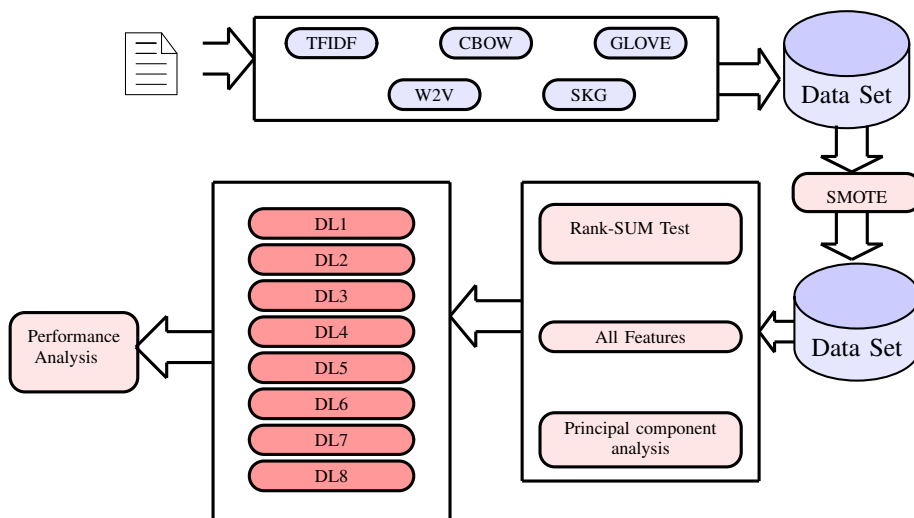

Fig. 1: Framework of proposed work

are increasing the number of hidden layers for four more deep learning models. The above considered models are validated using 5-fold cross-validation with batch size=30, epochs=100, and Dropout=0.2.

IV. RESEARCH METHODOLOGY

Figure 1 provides a full outline of our proposed effort. We started by extracting the software requirements dataset from the PROMISE repository. This data contains labels of the software requirement category it falls under, i.e. functional or non-functional requirements. The data was then subjected to pre-processing techniques like converting all characters to lowercase, removing non-alphanumeric and non-symbol characters, eliminating frequently used words like 'the', and 'a', and other words with lengths less than or equal to two as they do not make a significant impact in the classification. Then, all of the phrases were tokenized to words.

To extract features from this unstructured, pre-processed data, five different word embedding techniques were applied to best capture the information. To account for the imbalance in classes due to 382 instances of quality requirements out of 625, a data oversampling technique in the form of SMOTE was used. Models were trained on both the balanced and imbalanced datasets to compare the effectiveness of the class-balancing. The features acquired after the word embeddings and class balancing needed to be refined to remove redundant and irrelevant features. Feature selection technique in the form of Rank-Sum test, and dimensionality reduction technique in the form of Principal Component Analysis were employed. These two sets of features as well as the set of original features were fed to the Deep Learning classifiers. This was done to help understand the importance of feature selection.

The eight different DL classifiers were trained using 5-fold cross validation. The classifiers have varying layer sizes, and layer types, but certain attributes like the optimizer, loss function, etc. remain constant across the different classifiers. These classifiers are named DL1, DL2, DL3, and so on till DL8. Finally, the performance of the various models developed was measured using accuracy, F-measure, and AUC. This performance was statistically analyzed using box-plots for visual representation, with statistics like mean, maximum, minimum, Q1, and Q3 for each performance metric. Further, any conclusions derived were statistically supported using the Friedman test.

V. EMPIRICAL RESULTS AND ANALYSIS

To categorize software needs into functional or non-functional, we used five distinct word embedding approaches, a class balance strategy, two feature selection strategies, and eight different classification techniques. As a result, a total of 480 [5 word-embedding techniques \times 2 requirements datasets (1 functional requirements dataset + 1 non-functional requirements dataset) \times (1 imbalanced dataset + 1 balanced dataset) \times 3 sets of features \times 8 DL classifiers] models were generated. As shown in Tables I and II, the predictive performance of these trained models is assessed using the F-measure, accuracy and Area Under Curve (AUC) performance metrics.

- The high value of AUC confirms that the developed models have the ability to accurately classify the software requirements into functional and non-functional as almost all the performance values seen on the right side of Table I are greater than 0.75 AUC.
- The models developed using the Deep Learning structure of DL3 have better performance as compared to other classifiers.
- The models trained using neural network with ADAM (NNADAM) training algorithm have better predictive ability as compared LBMF, and SGD training algorithms.
- Simply by observing the values in Table I, we can see the difference SMOTE provides in improving the performance.

VI. COMPARATIVE ANALYSIS

The various models created with using word embedding techniques, class balancing approaches, feature selection strategies, and different classifiers are compared in this section. The comparison is based on statistics such as the area under the ROC curve (AUC), F-measure, and accuracy, with box plots serving as a visualization of the comparative performance. The Friedman test was used in this research to verify the findings. The Friedman test is used to accept or reject the following hypothesis.

- **Null Hypothesis**- There is no substantial difference in the predictive performance of software classification models constructed using different machine learning approaches.
- **Alternate Hypothesis**- The prediction power of software classification models constructed using various ML approaches varies significantly.

With degrees of freedom of 4 for word embedding, 1 for class balancing, 2 for feature selection, and 7 for distinct DL classifier comparisons, the Friedman test was performed with a significance threshold of $\alpha = 0.05$.

A. RQ1: Which feature extraction technique can best capture the unstructured, textual data present in the SRS document, and convert it to structured data in the form of numerical vectors?

In this work, five distinct word embedding approaches were utilized to compute the numerical vector of the functional and quality requirements: TF-IDF, Skip-Gram (SKG), Global Vectors for Word Representation (GloVe), W2V and Bag of Words (CBOW). To assess the prediction abilities of models generated using various word embedding techniques, the AUC, accuracy, and F-measure statistics were used.

1) Box-plot: Word-Embedding: Figure 4 illustrates the result of several word embedding algorithms. Models developed with the word embedding generated by TF-IDF are more reliable than other models, as shown in Figure 4. CBoW models exhibit poor prediction performance when compared to other methodologies. The mean AUC value of TF-IDF models is 0.91, with a maximum AUC of 0.98 and a Q3 accuracy of 0.96, implying that 25% of TF-IDF models have an AUC value

(3.4) DL8

Fig. 3: Deep Learning Architecture

of more than 0.96. The accuracy data and F-measure of these models confirm these findings, revealing that classification techniques based on TF-IDF outperform classification models based on alternative word-embedding techniques.

2) *Friedman Test: Word-Embedding:* In this work, the Friedman Test is also utilized to examine the predictive power of the models created using different word embedding methods. The goal of the test is to see if the null hypothesis is correct. The null hypothesis asserts that "the various word embedding techniques have no discernible impact on the performance of the classification models." Table IV shows the mean ranks for the various word embedding techniques. The lower the mean rank, the better the models' performance. TF-IDF has the lowest mean rank of 1.88, while CBoW has the highest mean rank of 4.88. With a mean rank of 1.96, W2V provides comparable performance to TF-IDF. It's probable that the high performance of the TF-IDF is due to the fact that requirements papers contain numerous comparable phrases and terms. Because of its method of giving weights to each term, TF-IDF can effectively minimize frequent terms used in requirements from creating an effect on classification better than other word-embedding algorithms.

B. RQ2: Which feature selection techniques are the best at getting rid of redundant and irrelevant features which may affect the performance of the classification models?

In the proposed study, we use Rank Sum test and PCA as feature selection procedures, and we use all of the original

features for developing predictive models for requirements categorization in a third set of models. These feature selection procedures were applied to both the functional and quality requirements datasets.

test, is that "the requirements classification models developed using different feature sets do not have a significant difference in their prediction capacity." With two degrees of freedom and a significance threshold of $\alpha=0.05$, the Friedman test was conducted. Table IV shows the mean ranks of the three feature sets. The mean ranks of the Friedman test can be used to differentiate between different feature selection techniques. Lower mean ranks imply better achievement as compared to others. The models trained with the set of RST features had the lowest mean rank (1.47), followed by those trained with the original set of features (1.81), and finally PCA (2.73). The mean ranks show that models perform better when

RST features are included, whereas dimensionality reduction approaches like PCA just regress the models' performance.

C. RQ3: For what structure of the deep learning classifiers do the software requirements classification models achieve the best results?

The study used eight different Deep Learning classifiers to categorize the software requirements. These classifiers are employed in conjunction with various word-embedding techniques and feature selection techniques. The DL binary classification models include models with different layer sizes, and layer types. Hyperparameters such as optimizer, activation function for specific layers, loss function, etc. are kept consistent across different models.

1) Box-plot: Classification Techniques: Figure 6 depicts the accuracy, precision, recall, and AUC statistics for the

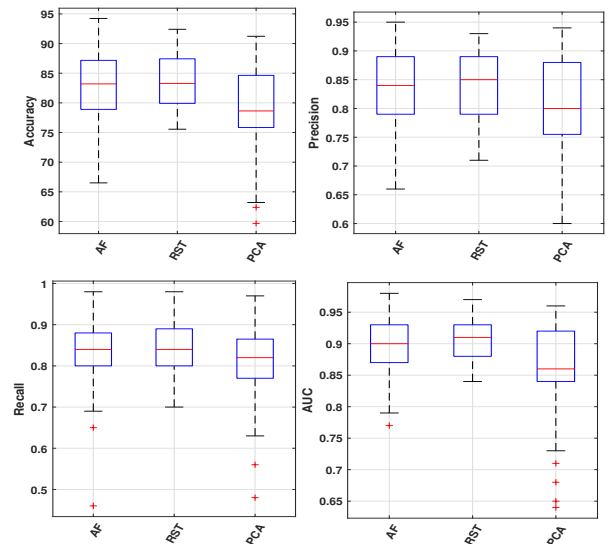

Fig. 5: Performance Box-Plot Diagram: Performance of Different Sets of Features

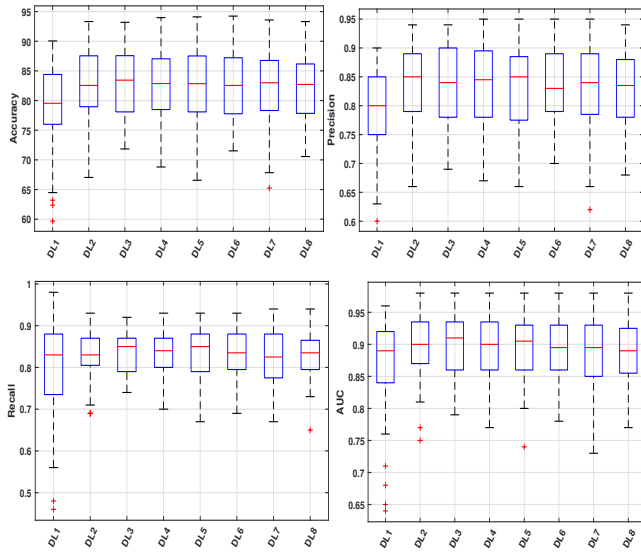

Fig. 6: Performance Box-Plot Diagram: Different Variants of Deep Learning

different classifiers used, including Mean, Median, Min, Max, Q1, and Q3. With a mean AUC of 0.9, the models trained with the DL2, DL3, DL4, and DL5 exhibited relatively similar performance and surpassed the others. The DL1 classifier performed the worst in comparison to other classifiers, with a mean AUC of 0.86. The DL3 classifier produces models with a maximum AUC of 0.98, a minimum of 0.79, a Q1 AUC of 0.86, and a Q3 AUC of 0.94. A box plot is insufficient to discriminate between the DL2, DL3, DL4, and DL5 classifiers.

2) *Friedman Test: Classification Techniques:* The Friedman test is also performed on the performance metrics of the various classifiers in order to statistically compare the models' performance and help differentiate the models where box-plot failed. The goal of the test is to see if the null hypothesis is correct. The null hypothesis for this test is that "the requirements classification models developed utilizing the different classifiers do not have a significant variation in their prediction abilities." With 7 degrees of freedom and a significance level of $\alpha=0.05$, the Friedman test was performed. The mean rank of various classifiers after the Friedman test is shown in Table IV. Table IV shows that DL3 has the lowest mean rank of 3.16, followed by DL2 with 3.25, DL4, and DL5 with 3.65. DL1 and DL8 performed significantly worse with mean ranks of 7.28, and 5.58, respectively.

D. RQ4: How does the application of class balancing technique through oversampling affect the performance of the models?

Based on the data utilized to train the models, there are two types of models presented in this study. One dataset contains imbalanced classes, while the class-balanced dataset is used to train the other set of models.

1) *Box-plot: SMOTE:* Figure 7 presents a visual representation of the predictive ability of models trained on a balanced

2) *Friedman Test: SMOTE:* To evaluate the performance of the two sets of models, the Friedman test is applied to their performance measures on class-balanced and imbalanced datasets. The goal of this test is to accept or reject the null hypothesis, which states that "there is no substantial difference in performance between models trained with balanced or imbalanced classes." With a significance threshold of $\alpha = 0.05$

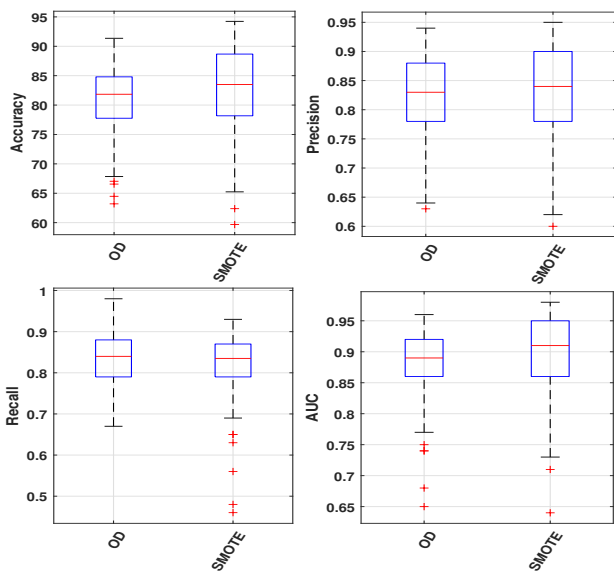

Fig. 7: Performance Box-Plot Diagram: Performance of Original Data and SMOTE

and degrees of freedom of 1, the Friedman test was performed. The models trained on the class-balanced dataset have the lower mean rank of 1.23, while those trained on the imbalanced dataset have the higher mean rank of 1.77.

VII. CONCLUSION

The Deep Learning classifiers used in this work, in conjunction with the word embedding, feature selection, and class balancing techniques have produced a very high accuracy for software requirements classification. The best models can be deployed in industry to do away with the manual classification, which is ailed by the problem of inconsistencies between client and software engineer terminologies [13]. Industry can benefit from the lower costs, and higher efficiency. The key conclusions that we arrived at were as follows:

- Models that utilized features extracted from TF-IDF word embedding performed considerably better than other models.
- Out of the eight DL classifiers used, the models trained with the DL3 classifier had the best results, with the DL2 and DL4 classifiers performing similarly.
- The Rank Sum test-selected features outperformed any other group of characteristics utilized in this work.
- SMOTE-based class balancing improved the performance of requirements categorization models.

According to the results of this study, DL classifiers are critical for more accurate software requirement classification. Future

research can extend this work by classifying the requirements into the subcategories of functional and non-functional requirements. Researchers can also focus on other parts of the software development pipeline, and use the models developed in this work for the requirements classification step.

7th Workshop on Model Driven Approaches in System Development

FOR many years, various approaches in system design and implementation differentiate between the specification of the system and its implementation on a particular platform. People in software industry have been using models for a precise description of systems at the appropriate abstraction level without unnecessary details. Model-Driven (MD) approaches to the system development increase the importance and power of models by shifting the focus from programming to modeling activities. Models may be used as primary artifacts in constructing software, which means that software components are generated from models. Software development tools need to automate as many as possible tasks of model construction and transformation requiring the smallest amount of human interaction.

A goal of the proposed workshop is to bring together people working on MD approaches, techniques and tools, as well as Domain Specific Modeling (DSM) and Domain Specific Languages (DSL) and applying them in the requirements engineering, information system and application development, databases, and related areas, so that they can exchange their experience, create new ideas, evaluate and improve MD approaches and spread its use. The intention is to target an interdisciplinary nature of MD approaches in software engineering, as well as research topics expressed by but not limited to acronyms such as Model Driven Software Engineering (MDSE), Model Driven Development (MDD), Domain Specific Modeling (DSM), and OMG's Model Driven Architecture (MDA).

1st Workshop on MDASD was organized in the scope of ADBIS 2010 Conference, held in Novi Sad, Serbia. From 2012, MDASD becomes a regular bi-annual FedCSIS event.

TOPICS

- MD Approaches in System Design and Implementation – Problems and Issues
- MD Approaches in Software Process Models, Software Quality and Standards
- MD Approaches in Databases, Information Systems, Embedded and Real-Time Systems

Model-Based System Engineering Adoption in the Vehicular Systems Domain

Henrik Gustavsson¹, Eduard Paul Enoiu¹, Jan Carlson¹

¹School of Innovation, Design and Engineering, Mälardalen University, Västerås, Sweden

Abstract—As systems continue to increase in complexity, some companies have turned to Model-Based Systems Engineering (MBSE) to address different challenges such as requirement complexity, consistency, traceability, and quality assurance during system development. Consequently, to foster the adoption of MBSE, practitioners need to understand what factors are impeding or promoting success in applying such a method in their existing processes and infrastructure. While many of the existing studies on the adoption of MBSE in specific contexts focus on its applicability, it is unclear what attributes foster a successful adoption of MBSE and what targets the companies are setting. Consequently, practitioners need to understand what adoption strategies are applicable. To shed more light on this topic, we conducted semi-structured interviews with 12 professionals working in the vehicular domain with roles in several MBSE adoption projects. The aim is to investigate their experiences, reasons, targets, and promoting and impeding factors. The obtained data was synthesized using thematic analysis. This study suggests that the reasons for MBSE adoption relate to two main themes: better management of complex engineering tasks and communication between different actors. Furthermore, engagement, activeness and access to expert knowledge are indicated as factors promoting MBSE adoption success, while the lack of MBSE knowledge is an impeding factor for successful adoption.

I. INTRODUCTION

MODEL-Based Systems Engineering (MBSE) [1] is an approach devised to take care of issues frequently encountered in traditional document-based system engineering (DBSE). In MBSE practice the systems engineering team performs its engineering life cycle activities in a modelling tool, using a dedicated semi-formal modelling language and applying a modelling method, to construct one primary systems engineering artifact — a system model which is inherently coherent and consistent [2]. The great appeal of MBSE is that it, when practiced correctly, promises a return on investment (ROI) that appears late in the Systems Engineering life cycle due to reduced costs in change management. However sometimes stakeholders also incorrectly assume that MBSE makes every systems engineering activity easier and cheaper [2].

Douglass [3] suggests that adoption of MBSE is a challenging change process featuring four partly overlapping phases - assessment, planning, piloting/early adoption, and deployment, where the level of success in each phase depends strongly on the quality of the work that has been done in the previous phase. The empirical results of a study by Rogers and Mitchell suggest that the investment cost for transitioning to MBSE could be considerable and that the adopting organization might have to display patience regarding the ROI [4].

Due to the challenges and the complexity, studying MBSE adoption cases in an industrial context is of high value for other industrial organizations aiming to adopt MBSE. Especially understanding the intentions and related experiences when organizations are setting out for MBSE adoption will provide valuable knowledge upon which future adoptions can be based.

This paper presents an exploratory interview study searching for MBSE adoption purposes, targets and factors promoting or impeding success. The participants in the study were interviewed about their individual experiences related to the above. Three research questions were defined in this study:

- RQ1. What are the primary reasons for and targets in MBSE adoption?
- RQ2. What factors are promoting success in MBSE adoption?
- RQ3. What factors are impeding success in MBSE adoption?

The study was conducted by interviewing practitioners and other stakeholders and applying thematic analysis to the data collected in the interviews to identify themes for each of the research questions. Reasons for MBSE adoption were grouped into two different themes – manage complex engineering tasks better and achieve effective communication and collaboration. Factors promoting MBSE adoption success were also grouped into two different themes – activeness and engagement and access to MBSE expert knowledge. The factors impeding MBSE adoption success were collected under one theme – insufficient MBSE knowledge.

A. Background and Related Work

Douglass [3] suggests that the adoption of a new approach encompassing a new language, such as MBSE with SysML, is characterized by four overlapping phases - assessment, planning, piloting/early adoption, and deployment. In this section, we survey some work related to these MBSE adoption phases.

1) *Reasons and targets*: Mitchell et al. [4], [5] have performed empirical case studies on the transitioning to MBSE in a system-of-systems product family organization. The primary purposes of the transition were to keep up with the increasing workload, increase automation in the systems engineering workflow, eliminate duplicate data, enhance manual quality assurance, enhance change impact analysis, achieve the automated generation of an interface description language, improve data integrity, and reduce the cost of quality assurance. Carroll

et al. [6] have found that the arguments justify MBSE adoption that will enable improvement of engineering efficiency and prevention of costly rework. In addition, Chaudron et al. [7] have synthesized empirical evidence regarding the effectiveness of UML modeling in software development. The study concludes that the two ultimate benefits of UML modeling are improved quality and higher productivity, both of which stem from the direct benefits which UML modeling brings to the developer and the team – UML modeling stimulates the developer to think harder and hence better understand the problem domain and the solution space.

2) *Factors promoting and impeding success:* Mitchell presents some lessons learned from MBSE introduction [5] — there is a big learning curve to consider, the strive for efficiency requires re-engineering the business process, and if consistency is important, one has to manage human resistance.

Amorim et al. [8] have performed a study to find strategies and best practices for MBSE adoption in the embedded systems industry. They conclude that the advantages of MBSE shall be made clear to the adopting team, the organization shall start the adoption on a small scale, and all engineers should get at least basic MBSE training. Hallqvist et al. [9] have done an empirical study on the introduction of MBSE by using systems engineering principles. In their study, they presented several lessons learned, namely to keep the focus on the purpose, start small while thinking big, address all stakeholders, involve people that have gone through a similar process before, have leadership present who understands people, have a communication plan, and consider using prototyping for validating changes. Madni and Purohit [10] proposed a framework for analyzing investments and potential gains when implementing MBSE. Their results support the view that MBSE requires an upfront investment, with gains showing up in later system life cycle stages. They mention several gains of MBSE such as early defect detection, reuse, product line definition, risk reduction, improved communication, usage in the supply chain and standards conformance that are important. Suryadevara et al. [11] imply that significant investment, a considerable learning effort and attainment of good tool interoperability are components required for success. Selberg et al. [12] have studied MBSE adoption in a company, based on which they give recommendations for adopting MBSE. Their recommendations are to clearly define the purpose of the adoption, assemble a core team, plan for the changes, allow sufficient time, and provide sufficient training to all stakeholders.

What is scarce in the current work is granularity and visibility of data associated with parties and phases in MBSE adoption, including parties who have little or no direct contact with the model and including the phases from assessment to deployment. More empirical knowledge is needed on these facets of adoption.

II. METHOD

This study was conducted through semi-structured interviews, following Strandberg [13] as the primary interview guidelines. The interviews were transcribed and then analyzed

using Braun and Clarke's guidelines for thematic analysis [14]. For more information on the method used we refer the reader to the extended technical report of Gustavsson et al. [15].

A. Planning

To plan and keep track of the work, an interview survey plan was written according to the guidelines by Linåker et al. [16]. As the work on the interview study progressed, the plan was also used to record changes. First, a raw survey instrument with 22 questions was created. In a workshop amongst the authors, we refined it and organized it into initial question groups (topics). Then, in a series of iterations, we created and refined a survey instrument. Each interview was planned with a start session where we would explain the purpose and motivation as well as the interview process. The first topic in the instrument focused on the interviewee (e.g., background, work experience and knowledge related to MBSE). In contrast, the last topic was related to successes, setbacks, and other experiences during the adoption and deployment of MBSE.

B. Interviews

We recruited a convenience sample of individuals affiliated with an organization in the embedded system domain. Using a stratified design to ensure experience and specialization diversity related to MBSE, we selected individuals from the following groups: managers, modelers, and model users. The interviewees were selected from a diverse set of MBSE adoption projects inside the company using a convenience sample based on our contacts in the company. In total, we recorded about 11 hours of audio material.

C. Transcription and Thematic Analysis

The interviews were transcribed using reflective journalism transcription [17] into 109 pages of text. During the transcription, we ensured the anonymization of the transcript. Text coding, was done in the following way: One interview was independently coded by all three authors and the three results were compared, discussed and adjusted to build consensus on the procedure. The remaining interviews were coded by two authors independently, and then discussed in a joint workshop to align the alternatives and agree upon a final coding. For the thematic analysis, we used the Braun and Clarke method [14] and the Halcomb data management steps [17]. A preliminary thematic analysis was done by the first author to elicit a first version of the main themes and then thoroughly reviewed by the other authors based on both audiotapes and interview notes. Next, we iterated on the sets of themes. This activity ended with a workshop with all authors where the final set of themes was agreed upon.

III. RESULTS

We start this section with an overview of the organization and interviewees (also outlined in Table I). Then, the main part of this section covers the thematic analysis results, the overall thematic map in Figure 1, and the answers to our research questions. For more details on the results we refer the reader to the extended technical report of Gustavsson et al. [15].

TABLE I: Interview participants including roles in adoption, expertise domain, self rated MBSE knowledge before and after adoption, and the adoption cases in which they were involved

Interviewee	Role in MBSE adoption			Expertise domain	MBSE knowledge		Cases					
	Modeller	Model user	Team manager		Before	After	1	2	3	4	5	
#1	x	x	x	Mathematical modelling, 5 years	1	3	x					
#2			x	Product functions, 27 years	2	5		x				
#3		x		Software design, 6 years	2	2	x					
#4	x		x	Product functions and project management, 8 years	2-3	3			x			
#5		x		Safety related embedded systems engineering, 8 years	2	2	x					
#6	x	x		Safety software architect, 11 years	1	2-3	x					
#7		x		Software development, 18 years	1	4	x					
#8		x		Software development and project management, 20-25 years	1-2	2-3	x					
#9	x			Control and systems engineering, 13 years	1	4		x				
#10	x	x		Subsystems functional design and control system functions, 7 years	0	3	x					
#11	x		x	Mechanical engineering, 30 years	1	2						x
#12	x		x	System design, 15 years	4	3	x				x	

A. Context, Organization and Interviewees

We conducted semi-structured interviews with twelve individuals from the same organization. The organization develops embedded systems in the domain of safety-critical vehicular systems and has more than 35 000 employees over many sites. The company is undergoing a transition to MBSE and has started different adoption initiatives in different sites.

Table I provides some basic information about the interviewees, including their roles and expertise areas. The interviewees were also asked to self-assess their MBSE knowledge before and after the adoption. In total, the interviews covered the experience of the interviewees from five different MBSE adoption cases: Cases 1-4 (Adoptions in the deployment phase) and Case 5 (Adoption in the early adopter/piloting phase). Six interviewees had been in more than one role related to MBSE adoption, and one interviewee had been involved in two different cases. The participants can be categorized in the following roles¹: modellers (seven interviewees), model users (seven interviewees), and team managers (five interviewees). The interviewees have between 5 and 30 years of experience, with an average of 14.4 years. Seven had at least ten years of work experience. Typical domains of expertise for our interviewees were system design and software development, mathematical modelling, mechanical engineering, software architecture, project management and embedded system engineering. Related to their MBSE understanding, most participants rated themselves as having relatively low knowledge before adoption. According to this self-evaluation, most participants have seen their MBSE knowledge improve during their work in each case.

B. RQ1: Primary reasons for adoption and targets in adoption

In this part of the study, we identified two themes. Both themes were related to primary reasons for adoption: to manage complex engineering tasks in a better way and to achieve effective communication and collaboration. Unfortunately, the interview data did not yield any themes on quantified targets.

1) *Theme: Manage complex engineering tasks better:* MBSE was seen as an enabler for managing complex technical

engineering tasks more efficiently and effectively than traditional system engineering methods. The notion of complexity in this context seems to be related to the nature of the technical challenge involved, the sheer size of the task or a combination of the two. An example of such an area was the work related to subsystem interfaces where the model and the modelling tool were considered to provide a better environment: “*MBSE makes interface management very accurate.*” Another area where MBSE was considered to provide an attractive capability was requirements verification: “*The big selling point was left shifting verification of the requirements using simulation.*”. Other areas include system testing, change impact analysis and propagation analysis, product homologation, reuse of design solutions, and software standardization.

2) *Theme: Achieve effective communication and collaboration:* MBSE was regarded as a means to facilitate and enable effective communication and collaboration in a way that is not possible without MBSE. A vision presented by a participant was that the opportunity to represent design in a uniform way in MBSE should be exploited such that it facilitates the communication across the entire MBSE organization, as well as with external stakeholders: “*I think the major objective of MBSE shall be to provide a uniform way of representing the design that we are doing... If you want all the regions to understand what others are doing, and with suppliers and things like that.*”

C. RQ2: Factors promoting success in Adoption

In this part of the study, we identified the following two themes: (i) activeness and engagement as well as (ii) access to expert knowledge.

1) *Theme: Activeness and engagement:* When there were partakers in the team who were active, engaged and persistent, this was associated with MBSE success. The interviews gave observations of managers and model users displaying such qualities. Most of the observations happened when the adoption or deployment was hard going and certain team colleagues were showing a tendency to falter. It was also observed that certain valuable features and instruments for promoting success materialized due to the activeness of the management team. One interviewee stated that the model users being engaged in the modelling tasks had a positive effect on the quality of the requirements derived from the model: “*We*

¹We note here that some participants had overlapping roles as modellers, model users and/or team managers.

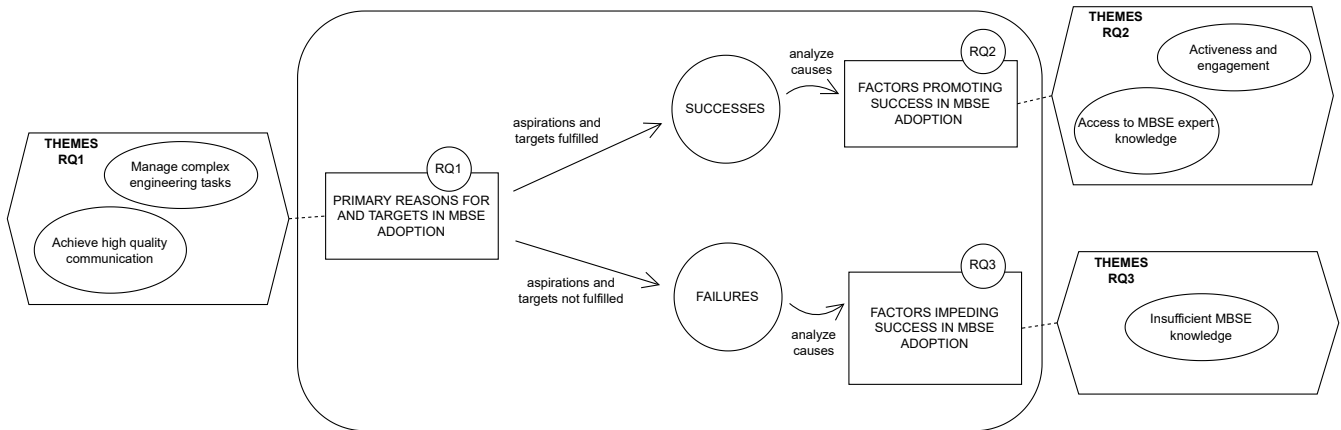

Fig. 1: Overview of the themes and their relation to the research questions.

managed to get the modellers to keep the models updated, then they were thinking a bit extra on their requirements when they were modeling.”

One participant observed that their company management was active in giving their full support to the MBSE adoption including the deployment. This support helped manage resistance and questioning of MBSE in the organization. The interviewee also linked the management support to the institutionalization of an MBSE core team (i.e., expert knowledge) and the accessibility to the model for the whole team. As the management of resistance, the MBSE core team and the team’s model accessibility contributed to the long-term success of the deployment. Related to the successes experienced in the adoption, another participant concluded that these were very much dependent on the adoption team’s engagement and their supporting stakeholders in the initial phase of the adoption. These adoption team members had taken the initiative themselves to learn the subject and their stakeholders had also been very active when soliciting input data.

2) *Theme: Access to MBSE expert knowledge:* A factor behind the MBSE’s success was found to be related to present and readily accessible expertise. The instances showing this in the interviews are: (i) the presence of an MBSE core team that assumed a clear long-term role as MBSE process owner, (ii) the provisioning of continuous team support, and (iii) being attentive and adapting to the needs of the MBSE team. Establishing an MBSE expert inside the modelling team in the very early stage of adoption was also perceived as a factor promoting success. For example, one interviewee had an experience where the expert had defined the MBSE process for the team. Another participant had an experience where the expert had acted as a sounding board for the adopters. The expert had even enabled a doubtful adopter to turn into an enthusiast in this role.

D. RQ3: Factors impeding success in Adoption

In this part of the study, we identified one central theme: insufficient MBSE knowledge.

1) *Theme: Insufficient MBSE Knowledge:* A factor that impedes MBSE adoption success is a lack of knowledge of MBSE. This theme encompasses cognizance on different levels, in diverse areas and among various parties in the MBSE adoption. It appeared in situations when people were, in various ways, dependent on a particular party to make progress in the MBSE adoption. Participants concluded that this involved party had a knowledge gap preventing progress.

An example of such missing knowledge was related to SysML and shown among engineers. While the early phase of SysML adoption among engineers went well, some time into the adoption, an apparent threshold in the overall progress was encountered regarding important concepts in the SysML syntax and semantics. Examples of concepts that caused the adopter’s various degrees of difficulty were the two distinct kinds of flows on activity diagrams, ports, and the internals of blocks. For example, one participant mentioned the following: “When we are getting to more complex things, that is, when we are getting to ports, various types of ports, exactly what they mean and what they do, it is getting more difficult.” There were observations about a weak cognizance of MBSE among people who were not in direct contact with the model, e.g. people in management. When people in management and other stakeholders were approached by adopters regarding issues that the adopters could not resolve among themselves, flaws in the cognizance of MBSE impeded the possibility to support the adopters or act as sounding boards. As the adopters did usually not have the resources needed to resolve the problems this could cause problems to remain unresolved. Among the engineers, the lack of MBSE cognizance can make them nurture expectations that the deliverables of the modelling team will be definitive and that all subsequent collaboration with that team will be superfluous: “People expect that we are going to provide them with requirements and everything will be complete and they can leave from there and they will not have to talk to us anymore.” Insufficient MBSE knowledge could also lead to people comparing model diagrams to other artifacts they could relate to, such as Visio diagrams, whereby

they were resisting and questioning the change. It was difficult to bridge this gap by means of argumentation: “*They just think MBSE is just like Microsoft Paint, you know you draw some pictures, it is just like Visio or something*”

IV. DISCUSSION

For research, the findings in this paper are essential as they bring an industrial experience of MBSE adoption and deployment from industrial practice into academia. By understanding that this is not an insignificant process, additional research is possible. Other researchers could add on and revisit MBSE adoption and deployment in other contexts and possibly investigate the results of this study.

Based on our findings, organizations in the vehicular systems domain adopting and deploying MBSE may want to foster activeness, engagement, and access to MBSE expert knowledge in their teams. In addition, companies should pay special attention to the insufficient MBSE knowledge, especially during the adoption phase. There is relatively little data that supports the research question on quantified targets in MBSE adoption. However, in the responses to the interview question, there is considerably more data about primary reasons for adoption. A few interviewees also expressed satisfaction related to the personal gains in learning a new method. However, when asked to suggest the reasons they thought were behind the positive details, the answers did not provide clear reasons. More research is needed to understand these personal reasons and human aspects of learning MBSE.

When discussing the concept of impeding factors, our results suggest that this is a rather multifaceted topic. First of all, the interview questions were framed to stimulate the interviewees to describe a logically coherent story about the MBSE adoption and deployment. One idea behind the design of the interviews was to avoid retrospectively invented opinions from the interviewees about successes and failures but instead, encourage them to base these ideas on observations as to whether the adoption reasons and targets were met or not. Once the successes or failures had been recollected, the interviewees were asked to consider what could have been the cause of each case. As it turned out, the interviewees had many different ways of expressing successes, failures, and factors promoting success or causing failure. One reason for this is that when asked to name challenges and setbacks, participants proposed a predefined view that seemed necessary to be included in the adoption to make it successful.

V. CONCLUSIONS

We have conducted an interview study of model-based system engineering adoption and deployment in the vehicular domain. The results presented in this paper are based on semi-structured interviews with twelve practitioners with an average work experience of more than fourteen years and thematic analysis to identify major themes around the reasons, targets, and promoting and impeding factors in model-based

system engineering adoption. We discovered that the primary reasons and targets relate to managing complex engineering tasks in better ways and effective communication. Our results suggest that the main factors promoting success are activeness, engagement and access to expert knowledge. A factor that was shown to impede adoption success is the lack of knowledge on different levels and among different parties. Finally, our results show that more research on the model-based system engineering adoption and deployment is needed and that practitioners need to take these aspects more clearly into account.

VI. ACKNOWLEDGMENT

This work has received funding from H2020 under grant agreements No 871319 and No. 737494, from Vinnova through the SmartDelta and MegaM@Rt2 projects and from KKS through ARRAY Academy.

Abstract—Designing and implementing Web Services constitutes a large and constantly growing part of the information technology market. Web Services have specific scenarios in which distributed processes and network resources are used. This aspect of services requires integration with the model checkers. This article presents the experimentation framework in which services can be specified and then formally analyzed for deadlock-freedom, achievement of process goals, and similar features. Rybu4WS language enriches the basic *Rybu* language with the ability to use variables in processes, service calls between servers, new structural instructions, and other constructions known to programmers while remaining in line with declarative, mathematical *IMDS* formalism. Additionally, the development environment allows simulation of a counterexample or a witness - obtained as a result of the model checking - in a similar way to traditional debuggers.

I. INTRODUCTION

ARISING number of available Web Services are used for business processes in the modern world. Interactions with other Web Services are key features in creating more complex scenarios and satisfying business needs. An example of interaction between different services might be a travel agency that uses external services to book hotels, flights, and other facilities. Service for booking flights may use another service for processing a payment that communicates with a bank or credit card provider. Such interaction between many services is called *Web Service composition* [1]. From the computer science point of view, Web Service composition is a distributed system concerned with typical problems like deadlocks or lack of termination.

In Warsaw University of Technology, Institute of Computer Science, an experimentation framework for specification and verification of web services composition was developed. It is based on *IMDS* formalism (Integrated Model of Distributed Systems [2]) and *DedAn* [3] tool to model asynchronous distributed systems and verify them automatically. The user does not need to have deep knowledge about verification methods such as temporal logic and model checking.

A distributed system under verification in *IMDS* formalism is defined as a set of actions used to model the behavior. The declarative input of the *DedAn* environment was designed to structure a set of actions by combining them across servers or agents. While *DedAn* input language is sufficient to specify simple distributed systems, modeling more complex cases is challenging due to various technical difficulties described later in this paper.

To overcome the problem of modeling complex distributed systems, a higher-level language *Rybu* was initially developed [4], which simplifies the modeling of the system by some imperative-style elements and data aggregation. To improve the modeling of Web Service composition, *Rybu4WS* language was created, which is the original contribution of this paper. Moreover, *Rybu4WS* Debugger tool was developed to visualize counterexamples or witnesses caught from *DedAn* directly on the original *Rybu4WS* code. The latter feature is unique among model checking tools: they verify the systems but do not allow to interpret the checking results on the source code of the tested system. The projection of the verification result onto the source form of the specification is one of the most significant achievements of the authors.

This paper is organized as follows: Section 2 covers related work of web service composition. Architecture of the Experimentation Framework is in section 3. Section 4 gives a brief description of *IMDS* formalism and *DedAn* tool. Description of *Rybu4WS* and its syntax can be found in section 5. General conversion rules of *Rybu4WS* code to *IMDS* model are described in section 6. Section 7 contains a description of the *Rybu4WS* Debugger tool. Conclusions and possible future development of our experimentation framework are covered in section 8.

II. RELATED WORK

Labeled Transition Systems (LTS) are alternative approaches for modeling Web Service compositions [5] where transitions between states can represent Web Service interactions. In the mentioned paper, model-checking and temporal

logic properties were used to verify the Web Service composition modeled using this approach.

Existing formalisms like CSP [6] or CCS [7] are well designed to model concurrent systems, but they are hardly suitable for distributed systems. They do not possess asynchronous features needed for modeling true distributed systems. Instead, they rely on synchronous communication in the system, which requires that communicating processes reach given states simultaneously before passing a message. Such a scenario is impossible in Web Services or any other distributed system because components are typically placed on separate machines in different locations. They cannot learn about the other party's state in other ways than by message exchange. However, there were attempts of formal software verification based on Service Component Architecture (SCA) [8] converted into CSP specification [9].

Bandera [10] tool allows the creation of a finite-state transition model directly from Java source code that can be verified in the external model checker. The main goal of this project was to provide automated model extraction from software systems that allows easy verification without manual software analysis and model creation. While automated creation of a model from the source code could be very convenient, generated abstraction might affect the model precision. As an alternative to verification, automated WS testing is proposed. Combinatorial method is described in [11] and metamorphic in [12]. Fault injection testing is presented in [13]. Simulation is covered in [14].

There are also languages specifically designed for writing distributed programs, like SR language (Synchronized Resources) [15] that provide various mechanisms used for concurrent process interaction. However, it lacks the ability of formal verification and is not suitable for model checking.

Widely used in industry WSDL [16] format describes Web Service interfaces for other services or applications. Since WSDL is designed to specify the pure interface of Web Services, it is not possible to define the internal behavior of Web Service, which is necessary for verification against deadlocks or checking termination.

A significant number of studies were conducted about Web Service composition, for example hybrid approach [14]. Report [15] presents different automatic composition approaches. TripICS [16] is an example of a real-life application that uses automatic WS composition for planning trips and travels around the world. It is based on the PlanICS framework to solve automatic composition problems, which uses a combination of SMT-solver and genetic algorithms [16]. Automated WS composition for Financial Decision Support is presented in [17]. Semantic modeling is covered in [21][22].

III. ARCHITECTURE OF THE EXPERIMENTATION FRAMEWORK FOR WEB SERVICE COMPOSITION

To provide efficient experimentation with Web Service Composition, a modular but highly integrated system was created. Rybu4WS program is converted to IMDS form and

checked by DedAn verifier, then the witness/counterexample is caught by the Rybu4WS Debugger which can simulate the verification output directly on the source Rybu4WS code.

When DedAn is run with user interface, additional analysis facilities become available, like export to Uppaal for checking huge systems, graphical simulation over system components [18], counterexample animation, and detailed analysis of individual components' behavior.

IV. IMDS AND DEDAN

IMDS [2] formalism is the key element of the experimentation system. Therefore, it will be discussed first. It is a model of a distributed system using that is constructed over a set of actions. The actions are executed in the environment of servers offering services and traveling agents representing distributed computations. The agents use messages for their traveling between servers where partial computations are performed as the execution of actions. A set of messages in given sequential distributed computation forms an agent. The current configuration of a system is defined as a set of states of all servers and a set of current messages of all agents (one message per agent).

Action is a relation between the input pair (message, state) and output pair (new message, new state). The server in a given state accepts the message, which invokes the action. Action execution changes the state of the server and issues a new message. There is a special case on agent termination, which changes only a state without sending a message. The system in IMDS starts from the initial configuration, which consists of initial states for each server and initial messages for each agent.

Formally, the IMDS action is a quadruple of input items and output items $((message, state) \rightarrow (next\ message, next\ state))$ or a triple $((message, state) \rightarrow (next\ state))$ (agent terminates).

The IMDS formalism can well represent Web Service composition due to the following essential features:

- Locality - there is no global or non-local state in the system, all servers are independent.
- Autonomy of decisions - server autonomously determines the order of message acceptance.
- Asynchrony of actions – always a message waits for an appropriate state or a state waits for matching message.
- Asynchrony of communication - messages are sent through a unidirectional asynchronous channel.

In most cases, the states of servers and the messages of agents can be treated as atomic, and actions are defined as a relation in $(M \times S) \times (M \times S)$ which defines input message, input state, output message, and output state of an action. Agent-terminating actions are defined in $(M \times S) \times (S)$. The action extracts the input pair $(message, state)$ from the input configuration and inserts the pair $(new\ message, new\ state)$ into the output configuration. The execution of actions is assumed to be in interleaving semantics [2].

The IMDS models can be verified using the DedAn environment, which allows to find deadlocks or check possible termination in the modeled system. The input of DedAn was designed to structure a set of actions by combining them across servers or agents. It allows defining server and agent types used to instantiate variables of those types along with linking them using formal and actual parameters.

V. RYBU FOR WEB SERVICES (RYBU4WS)

It should be emphasized that the set of actions of Rybu/Rubu4WS specification is exactly the same as the set of actions in IMDS specification after conversion. The main role of higher level language is to ease the programming. The instructions in Rybu/Rybu4WS group sets of actions into more readable high level actions, and chain the actions as in imperative language programming.

A Rybu [4] system consists of two kinds of servers: reactive servers and threads (processing servers from which the agents originate). The agent starts its run in a thread and invokes services offered by the servers by means of messages. Invoked service executes an action on the server, changing its state. A server replies from the executed action by sending a message back to the thread, prolonging its execution. The Rybu4WS was developed for modeling Web Service compositions, overcoming the limitations imposed by Rybu. It features more advanced functionality, such as:

- server-server communication that allows agents to travel between different servers and execute complex scenarios,
- state variables in grouped processes, which enables the communication between different processes without sending actual IMDS messages,
- termination at any point of execution,
- complex code sequences in reactive server actions instead of trivial state mutation and return value.

Like Rybu, the Rybu4WS system consists of reactive servers and processes (in Rybu: thread). The reactive server is a resource that holds a particular state and offers services. Each service can be guarded by a condition over variables and contains a code sequence for further actions. Process consists of a code sequence that the agent executes to invoke services on reactive servers and does not hold any state.

Rybu4WS introduces a third, more advanced feature called group, which is used to group one or more processes. It gives the possibility to declare shared variables, allowing the creation of more sophisticated scenarios where processes use the same variables within a server to cooperate.

The following listing presents example Web Service composition in Rybu4WS. It consists of services necessary to build a simple book shop service – warehouse, payment, bank. Processes are used to represent the user’s behavior.

```

1 type BOOL = { t, f };
2 server Payment {
3   var s: { none, pending, paid };
4   { Init | s == :none } -> { return :ok; }

```

```

5   { Confirm | s == :pending } -> {
6     s = :paid; return :ok;
7   }
8   { IsPaid | s == :paid } -> { return :t; }
9 }
10 server Bank(p: Payment) {
11   var bal: 0..5;
12   var s: BOOL;
13   { Transfer | bal > 0 && s == :f } -> {
14     s = :t; return :confReq;
15   }
16   { Transfer | bal == 0 || s == :t } -> {
17     return :fail;
18   }
19   { Confirm | s == :t && bal > 0 } -> {
20     bal -= 1; s = :f; p.Confirm(); return :ok;
21   }
22 }
23 server Warehouse() {
24   var x: BOOL;
25   { Reserve | x == :f } -> { x = :t; return :ok; }
26   { Reserve|x == :f } -> { return :outOfStock; }
27   { Dispatch | x == :t } -> { x = :f; return :ok; }
28 }
29 server BookShop(w: Warehouse, p: Payment) {
30   { Begin } -> {
31     match w.Reserve() {
32       :outOfStock -> { return :fail; }
33       :ok -> { p.Init(); return :payReq; }
34     }
35   }
36   { End } -> {
37     match p.IsPaid() {
38       :t -> { w.Dispatch(); return :ok; }
39     }
40   }
41 }
42 var p = Payment() { s = :none };
43 var b = Bank(p) { bal = 3, s = :f };
44 var w = Warehouse() { x = :f };
45 var bs = BookShop(w, p);
46 group BookPurchaseScenario {
47   var action: { idle, none, pay } = :idle;
48   process UserWebInterface {
49     match bs.Begin() {
50       :fail -> { action = :none; terminate; }
51       :payReq -> {
52         match b.Transfer() {
53           :confReq -> {
54             action = :pay; bs.End(); terminate;
55           }
56           :fail -> { terminate; }
57         }
58       }
59     }
60   }
61   process UserMobileApp {
62     wait(action != :idle);
63     if (action == :pay) { b.Confirm(); }
64     terminate;
65   }
66 }

```

A. Reactive servers

The reactive server in Rybu4WS consists of variables, actions, and dependencies.

Variables form the internal state of the server, which can be used in conditions for action and can be mutated by the actions code.

An action defines the behavior of a service. It includes an optional predicate, a condition over state variables used to determine whether an agent can execute the given action in the current server state or not, and a code sequence for execution. The code sequence might contain service calls to other servers, variable mutations, return statements, process termination, or conditional statements. Each service has a unique name used by other servers or processes for calling the service. In case a server state satisfies the predicate of more than one action in a given service, the action to execute is chosen non-deterministically. The code sequence is a sequence of statements executed when an action is invoked.

The collection of other servers needed by the given server is called dependencies. Only servers defined in the dependency list can be called from the server.

In order to use reactive servers, an actual server instance must be created. Initial state and required dependencies must be defined for each reactive server instance. This allows creation of many servers with the same behavior but with different initial states or dependencies.

B. Processes

A process is a code sequence with an accompanying agent. It is used as an entry point for agent execution. Each process is converted into one IMDS server and a single IMDS agent. Ungrouped processes (group will be explained later) can only call instantiated reactive servers in the system and cannot define any variables.

C. Groups

A group is a collection of processes and variables. The group's primary goal is to enable processes to use shared variables for sophisticated business scenarios where processes can communicate without sending actual IMDS messages. Agents are instantiated like in ungrouped processes, one agent per one process, meaning that many agents can work simultaneously on the same variables.

VI. CONVERSION TO IMDS

Rybu4WS language is used only for modeling distributed systems and cannot be directly verified against deadlocks or terminations. For the purpose of verification in the DedAn environment, Rybu4WS code must be converted into IMDS equivalent using a set of unambiguous translation rules. More detailed description of Rybu4WS language and architecture of the environment is available in [19].

It is important to note, that during conversion, the original code locations of each statement are preserved in IMDS states and messages. In a later stage, they are used to visually present deadlock or termination/non-termination sce-

narios directly on the Rybu4WS code after verification in DedAn.

Each Rybu4WS reactive server instance is converted to a state machine. Every state machine represents a single IMDS server.

Server variables are converted to IMDS states exactly like in Rybu - they are defined by a Cartesian product of sets of all possible values of the variables in the server.

The process is converted into a state machine and corresponding agent instance. In comparison to Rybu4WS reactive servers, it does not provide any services that could be externally invoked. The process consists of a single code sequence block that is converted into a state machine and provides a special service used by agent as an entry point.

Group is converted into a single, encompassing state machine by merging state machines created for each process. Additionally, the group can contain variables that are converted as in the reactive servers. Many agents can run concurrently in the same group and share variable values without sending any IMDS message. Each action in the encompassing state machine also includes an agent for which this transition is valid, which means that the agent can travel only within his corresponding code sequence.

VII. RYBU4WS DEBUGGER

The Rybu4WS Debugger [20] is a desktop application that allows Rybu4WS code to be loaded and converted it into a corresponding IMDS representation for the purpose of verification in the DedAn environment. DedAn is invoked automatically (or manually if advanced analysis options are needed) and finds deadlocks/checks termination automatically. It is worth emphasizing that partial deadlocks are identified as well. During verification, a counterexample/witness is elaborated, and visualized in a user-friendly way for the manual analysis. This reverse mapping of the sequence of action onto the source code is achieved because actions in Rybu4WS program are expressed in a more abstract and easily readable form than in IMDS specification. However, the sets of actions in Rybu4WS and IMDS are exactly the same, and the semantics of both specifications is equal.

VIII. CONCLUSIONS

The growing number of designed Web Services requires more and more assistance in the programmer's activities, including verification of whether the designed services behave safely (free from deadlocks), whether they finish in inevitable success (process termination), or whether there is even a possibility of success. Tools based on temporal logic are used to verify such behavior.

The formalism used to describe services should be well-suited to distributed systems: support asynchrony, locality of actions, and autonomy of nodes. Ideally, the specification language can be explicitly used for formal verification. Such a modeling method is IMDS, for which the DedAn verification environment has been built. However, the DedAn input language does not fully meet the requirements of program-

mers; therefore the Rybu language was created and its successor – Rybu4WS. Conveniently for the programmer, it combines the basic IMDS paradigm, adding the possibility of coupling actions in reactive servers. It was achieved using a syntax close to the programmers’ habits, using typical control statements such as conditional branching, loops, and response handlers. Shared variables in process groups allow to easily communicate by mutation of variable values.

The severe limitation of Rybu – allowing the server to be called only from a process – was solved: now a call chain can be created. Additionally, it is possible to terminate the process without returning it to the home server. Communication between servers, declaring shared variables for processes, and termination at any point of execution gives the ability to model Web Service compositions.

The Rybu4WS Debugger tool provides a user-friendly interface that allows analyzing counterexamples similarly to debuggers in usual programming environments. It is a backward engineering principle, seldom observed in typical verifiers: they produce counterexamples or witnesses that are not easy to analyze in the context of the source code.

Rybu4WS can be used to model a wider variety of concurrent distributed systems than just Web Service themes. The development needs of such systems would require additional programming elements, which could eventually lead to the creation of a Domain Specific Language (DSL) family that might be the subject of further research. It is currently impossible to create a circular dependency between reactive servers, meaning that callbacks or recursive calls are not supported. Also, it is not possible for a single agent to ”split” and perform multicast action, i.e., calling multiple services in a parallel manner. That would allow the creation of agents traveling in the distributed system and not returning to the place they originate from.

Beyond Low-Code Development: Marrying Requirements Models and Knowledge Representations

Kamil Rybiński, Michał Śmiałek

Warsaw University of Technology, Poland

Email: {kamil.rybinski, michal.smialek}@pw.edu.pl

Abstract—Typical Low-Code Development platforms enable model-driven generation of web applications from high-level visual notations. They normally express the UI and the application logic, which allows generating the frontend and basic CRUD operations. However, more complex domain logic (data processing) operations still necessitate the use of traditional programming. This paper presents a visual language, called RSL-DL, to represent domain knowledge with complex domain rules aligned with requirements models. The language synthesises and extends approaches found in knowledge representation (ontologies) and software modelling language engineering. Its purpose is to enable a fully automatic generation of domain logic code by reasoning over and reusing domain knowledge. The language’s abstract syntax is defined using a meta-model expressed in MOF. Its semantics is expressed with several translational rules that map RSL-DL models onto typical programming language constructs. The rules are explained informally in natural language and formalised using a graphical transformation notation. It is also supported by introducing an inference engine that enables processing queries to domain models and selecting appropriate invocations to generated code. The presented language was implemented by building a dedicated model editor and transformation engine. It was also initially validated through usability studies. Based on these results, we conclude that declarative knowledge representations can be successfully used to produce imperative back-end code with non-trivial logic.

I. INTRODUCTION

THE TERM “Low-Code Software Development” (LCSD) has emerged as a new approach to application development where only a limited amount of coding is required. Since its emergence around seven years ago [25], the term was used in the industry to label cloud-based development platforms that use visual notations to reduce the need for traditional programming. Research on low-code approaches is currently yet sparse. However, just recently, it has been observed that LCSD can be seen as a subdomain [7] or as overlapping [27] with the Model-Driven Software Development (MDS, MDD), where it concentrates on automatic generation of data-rich web/mobile applications from visual specifications (models).

Our research was done in the context of the ReDSeeDS¹ platform [33]. The system was created before the emergence of the low-code movement, but it certainly fulfils the definition of LCSD. It uses precisely specified requirements models: use cases, scenarios in constrained language, and visual domain vocabularies. Similarly to low-code platforms, these

¹<https://github.com/smialekm/redseeds>

artefacts are represented with a visual language called RSL (Requirements Specification Language) [21]. Specifications expressed in RSL allow for the generation of fully functional UI and application logic code for data-rich web applications. However, based on RSL alone, one cannot generate data processing (domain logic) code beyond simple CRUD, and data persistence operations [39]. Thus, similarly to other low-code platforms, more complex data processing has to be coded manually.

In this paper, we raise the question of representing more complex domain logic at the level of abstraction used by low-code and requirements-based MDD approaches. Inspiration for responding to this question can be drawn from research on ontologies and knowledge representations. These approaches enable the representation of domain knowledge, independently of any technology and any particular problem domain. Our research aims at investigating how the features of ontology-based domain logic representations, especially their reasoning capabilities, can be applied in the context of LCSD.

We present an extension to the RSL mentioned above, which we call RSL-DL (RSL Domain Logic, see the initial version of the language in our previous work [28]). The new language draws several of its constructs from ontology-based knowledge representation approaches. It then extends and combines them with MDD technologies to provide full code generation capabilities. What is important, RSL-DL allows for the generation of fully operational code directly from general domain rules (descriptions of reality) as required by specific requirements models (use cases and their logic). Hence, such generated back-end code is fully compatible with the front-end code generated from RSL specifications. Through this, we demonstrate a visual extension to a low-code language (RSL) that has the potential of eliminating the need to code (in a traditional sense) complex data processing services.

II. MOTIVATION AND RELATED WORK

The term “low-code” was probably first used in a Forrester report [25] only in 2014. Current studies report numerous industry-grade low-code platforms used extensively by professionals [29]. Sparse research results on LCSD can be supported by previous and current research on Model-Driven Web Engineering [17] which can be seen as a predecessor and now a synonym for LCSD. A study by Wakil and Jawani [38]

shows that research on MDWE is already quite broad and mature. LCSD and MDWE approaches are typically based on some form of visual notation (language). Such notations offer high-level representations of the flows of interaction between application users and the system under development. A prominent example in the MDWE domain is the Interaction Flow Modeling Language (IFML) [4]. Other examples – in the LCSD domain – are the Business Process Technology (BPT) language [13] and the Mendix notation [12].

LCSD/MDWE systems have limited capabilities regarding the generation of the domain/business logic code, or more broadly – the system’s back-end. Current LCSD/MDWE languages can support generation of code for elementary CRUD (Create-Read-Update-Delete) operations [3], [26]. Generation of code for more complex data processing (general Domain Logic - DL) is limited by the information scope of the visual language constructs. In this research, we propose new constructs that significantly extend capabilities to generate complex domain logic code. What is important, these new constructs are domain-agnostic, as contrasted with various domain-specific and often very formalised notations (see, e.g. work by Hinchey et al. [14] and Brito et al. [5]).

Our research is in line with the work by Atkinson et al. [2] that shows significant similarities between ontologies and models. The authors argue that the concept of ontology constitutes a subset of the concept of model. Also, Henderson-Sellers [11] points out that a combination of models and meta-models with domain ontologies is helpful in representing vocabularies for specific problem domains. He argues that modelling languages such as UML can describe domain knowledge, but they need particular extensions to provide adequate reasoning support. Our approach goes in this specific direction, as it extends RSL, which is also an extension to UML. In summary, the above discussions give good motivation for our work, where a modelling language that combines ontology constructs is applied to generate code directly from requirements.

Marrying ontologies with models allows applying model-driven techniques and especially model transformations. Appropriate works include more general discussions on introducing comprehensive formalised propositions on meta-models for ontology languages [23], [9]. An example of such a language is CoCoViLa by Haav, and Ojamma [10]. Our current work can be compared or even contrasted with such approaches, as it introduces a common meta-model for a semantically rich language that can express any problem domain. In this context, an essential feature of our approach is its extensive reliance on inference mechanisms, especially for generating data processing code. It is somewhat similar to business rule engines [8]. However, instead of interpreting them during runtime, it generates code fully integrated with the rest of the system. Similarly, our solution can be compared with the approaches that enable code generation directly from ontologies. Stevenson and Dibson [34] propose a tooling framework for generating Java code from OWL specifications. Another example is work by Völkel and Sure

[36] in which Java-based APIs are generated directly from ontologies expressed in RDF Schema.

III. RSL: LOW-CODE AT THE REQUIREMENTS LEVEL

The necessary background to our research on RSL-DL is the Requirements Specification Language and its tooling environment (ReDSeeDS). As we strive to achieve compatibility between these two languages, some aspects of RSL-DL were strongly influenced by RSL. The most important for this purpose are use case scenarios, like the example one shown in Fig. 1. Scenarios consist of sequences of simple subject-verb-object sentences of various types. The most important of them from the point of view of this paper is the ‘Query’ type sentences. These sentences define actions of the system that are performed on certain data elements.

According to RSL semantics rules [31], we can transform scenarios into code. Fig. 2 presents fragments of an application logic class generated from the presented scenario. The class contains methods for handling user interactions, as specified by the ‘Select’ sentences in the scenarios. For instance, the sentence no. 1 is translated into the “summarizeSemesterTriggered” method. Contents of these methods reflect consecutive sentences in the scenarios. ‘Query’ and CRUD type sentences are translated into calls to back-end service operation. For

Name:	Action Type
Summarize semester	
precondition:	
1. Dean's office employee selects summarize semester	Select
2. System fetches students list	Read
3. System prepares semester summarization data	Query
4. System shows semester summarization window	Show
5. Dean's office employee selects accept summarization	Select
6. System closes semester summarization window	Close
7. System realizes semester summarization data	Update
8. System shows semester summarized message	Show
final: success	

Fig. 1. Example scenario

```
public class SummarizeSemesterPresenter extends
    AbstractUseCasePresenter {
    // ...
    public void summarizeSemesterTriggered(){
        studentListDTO =
            service.readStudentList();
        semesterSummarizationDataDTO =
            service.preparesSemesterSummarizationData
                (pstudentListDTO);
        view.showShowSemesterSummarizationWindow(this);
        pageOpened();
    }

    public void saveFinalGradeTriggered(){
        view.closeSemesterSummarizationWindow();
        pageClosed();
        service.realizesSemesterSummarizationData
            (semesterSummarizationDataDTO);
        view.showSemesterSummarizedMessage();
    }
    // ...
}
```

Fig. 2. Presenter code generated for the use case scenario

```

public class ServiceImpl implements IService {
    // ...
    List<SemesterSummarizationDataItemDTO>
    preparesSemesterSummarizationData
        (List<StudentListItemDTO> studentListDTO)
    {}

    void realizesSemesterSummarizationData
        (List<SemesterSummarizationDataItemDTO>
         semesterSummarizationDataDTO)
    {}
    // ...
}

```

Fig. 3. Backend access code generated for the example scenario

instance, the sentence no. 7 is transformed into a call to the “realizesSemesterSummarizationData” service. UI presentation sentences are translated into calls to the View layer. A more detailed discussion of the rules and generated code, including code of the View layer, is presented elsewhere [32].

The relevant parts of the back-end service code generated from the RSL scenario is presented in Fig. 3. It contains an interface implementation with empty methods. The operation parameters are determined from scenario sentences before the appropriate calls. In further sections, we will present the syntax and semantics of RSL-DL that will fill the currently empty method bodies.

IV. RSL-DL SYNTAX

The syntax of RSL-DL aims to represent all information important from the point of view of code generation. It includes detailed dependencies between individual domain elements and proper definitions of the elements themselves. Fig. 4 presents an elementary example of concrete syntactic elements of the language. It contains definitions of four “Identity” type entity notions (student, course, partial grade, weighted grade), describing concrete objects in the specific problem domain. Notions can also have conditions, and in our example, we can see one kind of condition: “inheritance”. Thus, the condition for the “partial grade” notion is that it must follow all the rules for the “weighted grade” notion. In addition to entity notions, we can define property notions, like “grade weight” in Fig. 4. This kind of notions define concrete atomic values and can be used as attributes of other notions, which can be indicated by ‘attribute links’ (lines with a diamond shape).

Relationships in RSL-DL (see “grading” in Fig. 4) are represented by hexagons and can link many notions. To some

Fig. 4. RSL-DL concrete syntax example

extent, this syntax resembles that of UML’s n-ary associations. In our example, the relationship is of type “Data-Based Reference” which is a basic type that reflects the situation where references between objects are contained in their data (e.g. in their attributes). In our current example, “student” and “course” contribute to the relationship “grading” that results with a “partial grade”. Arrow directions distinguish between types of notion participations in the specific relationship. Since a given student can have many partial grades in a course, then the particular participation is marked as ‘multiple’.

The abstract syntax for the above-presented core language elements is presented in Fig. 5a using the MOF notation [22]. The meta-class “DLNotion” represents notions and the meta-class “DLRelationship” represents dependencies between them. Concrete participations of notions in relationships are represented by the meta-class “DLRelationshipParticipation”. The meta-model contains two types of such participations – standard and auxiliary. Standard ones correspond to the main subjects of relationships and are denoted with solid arrows in concrete syntax. Auxiliary ones point to elements that define relationship contexts and are denoted with dashed lines. For example, one could use a relationship context to indicate which object should be used when computing values based on that object’s attributes. In this case, the attributes participate through standard participations, and their ‘parent’ participates through auxiliary participation.

Besides notions, there is a special kind of relationship participants – primitives (“DLPrimitive” meta-class). These elements define general concepts that do not have concrete instances. Examples of such primitives in RSL-DL are “current date”, “number Pi” and “Planck constant”.

As indicated above, notions can have types. The first one (“identity”) was explained in the example above. The “template” type indicates templates that can be used to simplify defining other notions. These two types correspond approximately to concrete and abstract classes of e.g. UML. Two other types define notions whose representatives’ (objects’) roles can change during their lifetime. It is inspired by ontology-based inference engines with their capabilities to “discover” object types or change them dynamically. The “inferred role” type indicates roles that can be inferred, e.g. from various status attributes of an object. The “assigned role” type indicates roles that can be explicitly changed during the lifetime of an object.

More details related to the syntax for notions are shown in Fig. 5b. The “DLProperty” meta-class is used to denote notions with concrete atomic values or value sets. The “DLEntity” meta-class denotes more complex notions that cannot be reduced to single values. The “DLAttributeLink” meta-class allows indicating attribute dependencies between notions. Such links can be marked as ‘derived’, which means that their values need to be inferred from other notions. An important type of notion features are conditions (“DLCondition” meta-class). Their role is to further detail notion characteristics. Apart from the previously described ‘inheritance condition’, two additional condition types exist. The ‘identity condition’ type defines conditions that have to be fulfilled for a given notion’s

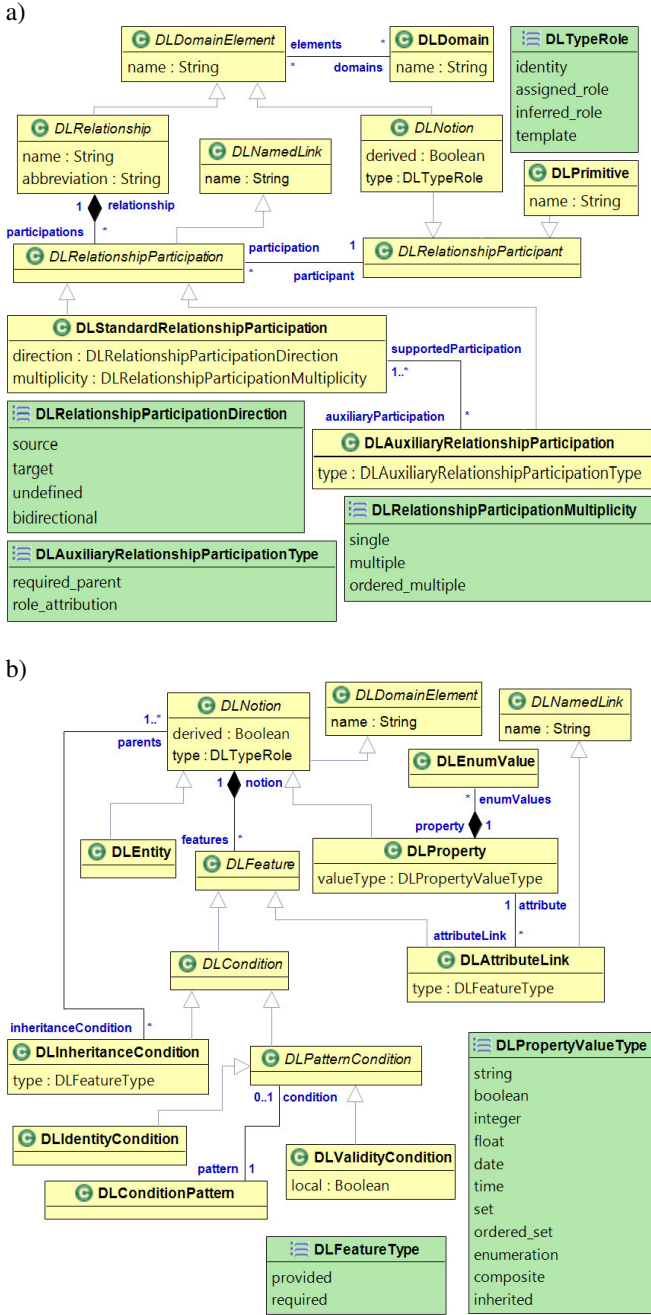

Fig. 5. Meta-model fragments for core RSL-DL elements (a), and for notions (b)

object to make sense. The ‘validity conditions’ type defines conditions that denote the correctness of a given notion’s object. In general, there can exist objects that meet appropriate identity conditions but do not meet validity conditions and thus are treated as invalid but belonging to the given notion. We should note that conditions do not include graphical links to other model elements. It is due to their potential complexity and interweaving. Thus, for instance, inheritance was not represented using a simple arrow as in UML.

Fig. 6. Meta-model details for relationships

Fig. 6 presents the hierarchy of relationships found in RSL-DL. From the conceptual point of view, two main types of dependencies exist between notions in the problem domain that are significant for code generation. It is reflected in RSL-DL through dividing relationships into two categories: transitions (“DLTransition”) and references (“DLReference”). Transitions describe how to obtain notion objects based on other notion objects. References describe specific roles played by objects in relation to other objects. Both relationship categories are further divided based on how they are defined. ‘Transitions’ can be described using simple rules (“DLPatternBasedTransition”) or algorithms consisting of many steps (“DLAlgorithmicTransition”). ‘References’ can be described using rules that define certain conditions (“DLPatternBasedReference”) or take the form of the previously described data-based references (“DLDataBasedReference”). This division of references is inspired by the division into fact and rule spaces found in ontologies. In practice, of all these relationships, the algorithmic transitions are not preferred as they are not fully declarative and thus arguably less usable [15], [37].

Figs. 5b and 6 contain two additional elements: “DLTransitionPattern” and “DLConditionPattern”. Each instance of these two meta-classes contains a string with a textual condition, a specific condition type and optionally – the condition’s subject link. The syntax of the condition is expressed in a language based on the notation used in the Symja library [18]. Some examples of several types of these patterns are given in section VI in descriptions of the generated code.

V. TRANSLATIONAL SEMANTICS RULES

Of the many approaches to define semantics for RSL-DL (treated as a programming language [30]) we choose the translational method, which is more in line with the model-driven paradigm. This approach defines rules that translate specific patterns of RSL-DL constructs into fragments of Java code. Each rule has an informal textual description and is formalised as a procedure in the MOLA graphical model transformation language [16].

Full specification of semantics for RSL-DL consists of 16 translational rules (all the details can be accessed in the Supplement²). The first ten rules define the generation

²<https://github.com/smialekm/redseeds/tree/main/RSL-DL>

of the target Java class structure, including their fields and method signatures. These rules depend only on the structure of notions and relationships between them, found in a particular RSL-DL model. The following two rules additionally use an inference engine and are used to generate method bodies. Rules 13-16 further add to the generation of method bodies. They use a symbolic computation library to transform Symja-based formulas found in pattern condition expressions into the contents of method bodies. The results are used directly or as part of a loop or a condition depending on the pattern type. In summary, each ‘non-trivial’ notion in the source RSL-DL model produces two Java classes. One class represents (in simplified terms) a data transfer object (DTO) corresponding to the given notion. The other class is a utility class that holds various data handling methods. These classes are appropriately amended with CRUD and condition-related operations. The ‘‘DTO’’ classes are also organised in an appropriate inheritance hierarchy. Additionally, supportive classes are created for all the relationships in the model. These classes contain methods that return objects participating in relevant relationships.

As introduced above, all the rules are formalised using MOLA procedures. MOLA uses a declarative-imperative visual syntax presented in Fig. 8 and 9. Its imperative flow definition is based on a notation resembling activity diagrams in UML. Arrows denote control flow. Iteration ‘actions’ are denoted with thick black frames. Rule ‘actions’ constitute the declarative part of the language. Each rule contains a query on objects expressed through a diagram resembling a UML object diagram combined with a MOF meta-model diagram. Black solid lines denote queried objects, while red dashed lines denote created objects. More details and a tutorial can be found in the MOLA handbook [1].

For brevity, we will limit our presentation of rule formalisation to only rule 11. To implement it, we need to use a dedicated inference engine, implemented as part of this work. The engine processes queries derived from ‘Query’ type scenario sentences (see again Fig. 1). For each such query, it produces a sequence of inference rules, where each of the rules is based on domain elements defined within an RSL-DL model. The appropriate sequences can be represented with a meta-model shown in a simplified form in Fig. 7. The meta-model uses a structure of nested ‘‘Rule’’ meta-classes to reflect appropriate sequences of inference invocations needed to solve specific problems. Each ‘‘Rule’’ points to a domain

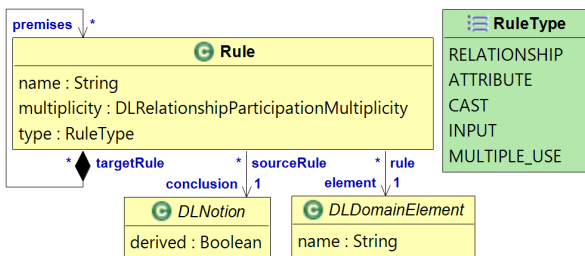

Fig. 7. Inference rule meta-model

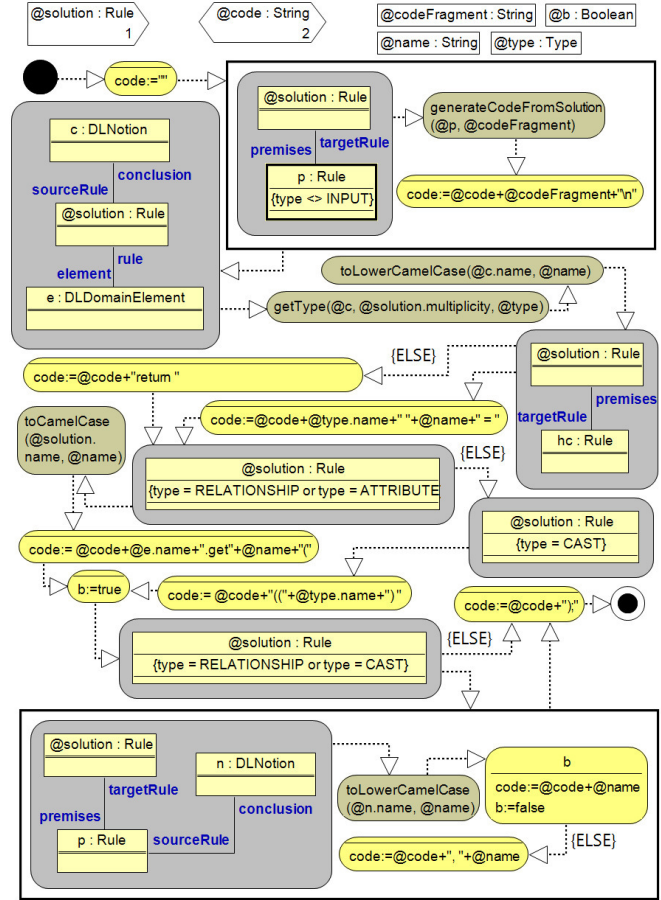

Fig. 8. Algorithm for generating the method body in Rule 11

element (‘‘element’’) that is the basis for generating a specific method according to one of the previous rules. The ‘‘type : RuleType’’ meta-attribute defines the concrete type of such generation. This ‘‘Rule’’ meta-class also points to a ‘conclusion’ that constitutes a specific notion reflecting objects being the inference results. Furthermore, the given rule’s ‘premises’ constitute other rules, preceding this rule in the rule sequence. Base premises that reflect query parameters are represented as additional ‘artificial’ rules.

The algorithm that generates the respective sequence of method invocations from the inference rule structure is presented in Fig. 8. It starts from invoking itself (‘generateCodeFromSolution’) recursively for all the ‘premises’ of the current rule and joining code generated from these premises. If the current element is used as a ‘premise’ in other rules, a proper variable is declared based on the object corresponding to the rule’s ‘conclusion’. Otherwise, a ‘return’ statement is generated. In both cases, the way to obtain the assigned or the returned value depends on the type of the rule. In most cases, such a value is obtained by invoking an appropriate ‘get’ method. This method retrieves an object that corresponds to the ‘conclusion’ and is contained in the class derived from the rule’s ‘element’. Besides, the ‘get’ method’s call accepts

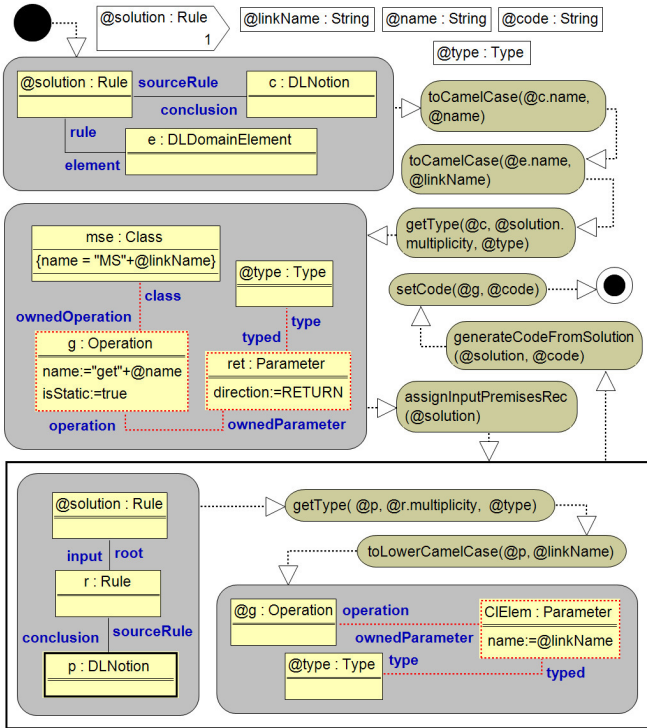

Fig. 9. Formalization of transformation rule 11

parameters that correspond to the rule’s premises.

The actual formalisation of Rule 11 that uses the above algorithm is presented in Fig. 9. It defines a procedure for creating a method, where the method’s contents are generated with the algorithm. The procedure starts by creating a method with the name based on the ‘conclusion’ of the final rule and having the prefix “get”. This method is placed in the class derived from the domain element pointed to by this final rule. The return type of this method again corresponds to the rule’s ‘conclusion’, and the method’s parameters are based on the ‘premises’ within the whole rule sequence.

VI. CASE STUDY

This section will present a selected fragment of a more extensive case study that illustrates several important uses of RSL-DL. The case study refers to the functional requirements specification presented in Section III. Here we will concentrate only on presenting examples of the various concrete RSL-DL language constructs, generated domain logic code, and references to application logic code from Section III.

Fig. 10 involves constructs for checking specific conditions. The model contains elements that describe information related to checking whether the given student is eligible to get a registration for the next semester. It consists of three basic notions – ‘student’, ‘course’ and ‘final grade’. All of them are connected by the “final grading” relationship, which is a data-based reference. It indicates that information about concrete dependencies between representatives of these notions is stored in some data objects. Finally, we define the ‘student to

Fig. 10. RSL-DL model defining eligibility of students to be registered for the next semester

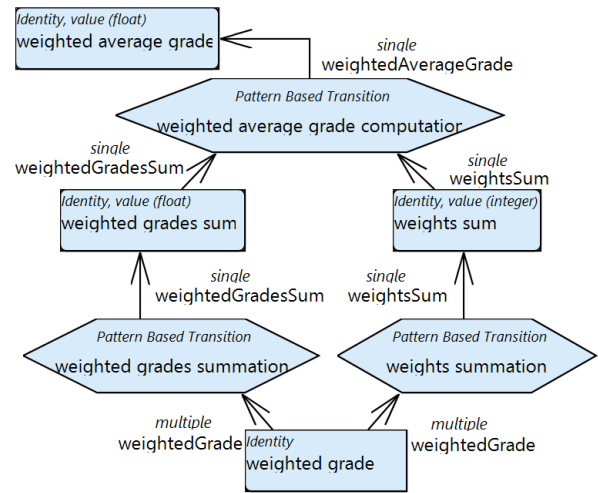

Fig. 11. RSL-DL model containing knowledge about computing of weighted average grades

accept’ relationship that is used to define conditions about students’ eligibility to be registered for the next semester. The concrete condition embedded in this relationship (not shown here) requires that all the final grades for the student’s courses have a value of at least 3 (minimum passing level). The relationship has only one participant – the student, that participates as its target.

Fig. 11 involves constructs for computing values. It contains the ‘weighted average grade computation’ relationship that contains a transition pattern with an equation that computes the weighted average grade. This equation requires two other values represented by the notions ‘weighted grades sum’ and ‘grades sum’. Therefore, the model contains also transitions that allow for the computation of these two values.

The final part of the presented model fragment involves constructs for modifying complex objects and is shown in Fig. 12. The whole modification is handled by the ‘summarize student after semester’ transition, which requires two other transitions: “accept student”, and “fail student”. These transitions will be used interchangeably, depending on the fulfilment of a condition. This condition refers to the ‘student to accept’ relationship presented in Fig. 10. If the student meets the ‘student to accept’ relationship, the ‘accept student’ transition is invoked, while in the opposite case, the ‘fail

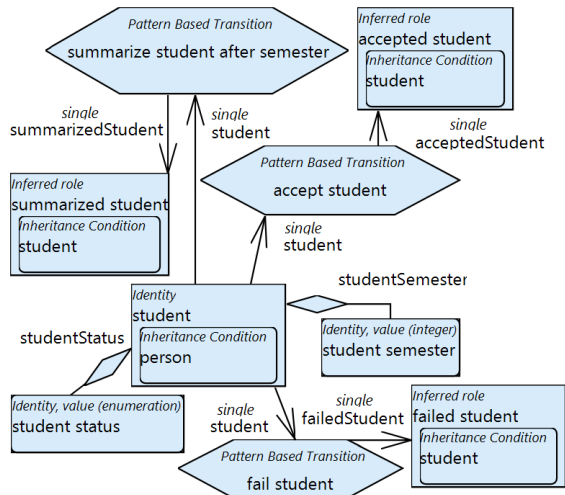

Fig. 12. RSL-DL model containing knowledge about the rules for promoting students to the next level of studies

```

public class MSStudentToAccept {
    public static boolean checkStudentToAccept(
        IMStudent student){
        for (IMFinalGrade $_iter:
            student.getFinalGrades())
            if (!$_iter.getGradeValue()>=3)
                return false;
        return true;
    }
    public static List<IMStudent> getStudents(){
        List<IMStudent> students
            = MSStudent.getStudents();
        List<IMStudent> result
            = new ArrayList<IMStudent>();
        for (IMCourse $_iter:students)
            if (checkStudentToAccept($_iter))
                result.add($_iter);
        return result;
    }
}

```

Fig. 13. Code for checking students' registration eligibility

student' transition is invoked.

The next step in our case study is to generate code. The above specification in RSL-DL was formulated within a dedicated RSL-DL tool. The tool also includes a code generation engine that implements all the rules introduced in the previous section. Here we will present some key fragments of code generated from the above-presented excerpts of the dean office model.

Fig. 13 shows code generated on the basis of the model from Fig. 10. The actual class (MSStudentToAccept) is generated per rule no. 9 (generate classes and static methods from relationships). It is a supportive class that corresponds to the 'student to accept' relationship and contains only static methods. The 'checkStudentToAccept' method was generated based on rule no. 10 (generate existence checking methods). It checks for the eligibility of a given Student to be accepted for the next semester. The student is passed as the parameter of this method. It can be noted that the type of this parameter ('IMStudent') is the class corresponding to the 'student'

```

public class MSWeightedAverageGradeComputation {
    public static double
        getWeightedAverageGrade(double weightedGradesSum,
            int weightsSum){
        return weightedGradesSum/weightsSum;
    }
    public static double
        getWeightedAverageGrade(List<IMPartialGrade> partialGrades){
        List<IMWeightedGrade> weightedGrades
            = new List<IMWeightedGrade>(partialGrades);
        double weightedGradesSum
            = MSWeightedGradesSummation
                .getWeightedGradesSum(weightedGrades);
        int weightsSum = MSWeightsSummation
            .getWeightsSum(weightedGrades);
        return getWeightedAverageGrade(weightedGradesSum,
            weightsSum);
    }
}

```

Fig. 14. Code for computing weighted average grades

notion, generated according to rule no. 1 (generate classes from notions).

The method returns a logical value reflecting the result of the eligibility check. The actual check is based on the contents of the condition pattern in the 'student to accept' relationship (not shown in Fig. 10). This pattern is defined through three values: 1) formula 'gradeValue(\$)>=3', 2) type 'universal quantification', and 3) subject link 'finalGrading(student)' that relates to the 'final grading' relationship. Note that the '\$' sign denotes the target of the 'final grading' relationship, which is the 'final grade' notion. The above formula was transformed into the appropriate 'if' statement in Fig. 13. The 'for' loop is generated based on rule no. 13 (generate condition checking code from condition patterns), considering the above pattern type. This way, the eligibility check is done for all the grades of a particular student.

The second method of this class ('getStudents') applies the above eligibility check to all the students. This method was generated based on rule no. 14 (generate object filtering code from condition patterns), and it filters out all the subjects (here: students) that fulfil an appropriate condition pattern (here: student eligibility check). We should also note that the code for obtaining the list of all students was generated using rule no. 16 (generate auxiliary code).

Fig. 14 shows code generated on the basis of the model from Fig. 11, using data structured according to Fig. 4. This time, the situation is somewhat different to that in the previous code fragments. This part of the code results from answering a query that asks to compute the 'weighted average grade' for the given set of grades. It contains two overloaded methods ('getWeightedAverageGrade'). The second one (with the 'List' parameter) is generated according to rule no. 11. It accepts a list of partial grades and produces a specific average value. The method contains a sequence of method calls that reflect the sequence of inference rules returned by the inference engine (see Fig. 8). The first one of the overloaded methods is called from the second one. Its signature was generated according to rule no. 9. Its body was based on translating a transition pattern with the 'simple' formula 'weightedGradesSum/weightsSum'

```

public class MSummarizeStudentAfterSemester {
    public static List<IMSummarizedStudent> getSummarizedStudents
        (List<IMStudent> students) {
        List<IMSummarizedStudent> result =
            new ArrayList<IMSummarizedStudent>();
        for (IMStudent $_iter:students)
            result.add(getSummarizedStudent($_iter));
        return result;
    }

    public static IMSummarizedStudent getSummarizedStudent
        (IMStudent student) {
        if (MSSStudentToAccept.checkStudentToAccept(student))
            return new MSummarizedStudent(MSAcceptStudent.
                getAcceptedStudent(student));
        return new MSummarizedStudent(MSFailStudent.
            getFailedStudent(student));
    }
}

```

Fig. 15. Code for determining student's eligibility for promotion to the next semester

```

public class ServiceImpl implements IService {
    // ...
    List<SemesterSummarizationDataItemDTO>
        preparesSemesterSummarizationData
            (List<StudentListItemDTO> studentListDTO)
    {
        return MSummarizeStudentAfterSemester.
            getSummarizedStudents(studentListDTO);
    }
    // ...
}

```

Fig. 16. Additional back-end access code

according to rule no. 15 (generate code from transition patterns).

Fig. 15 shows code generated on the basis of the model from Fig. 12. This time we can see only one method ("getSummarizedStudent") generated according to rule no. 9. The method's body is generated on the basis of a 'mapping' transition pattern with the formula 'studentToAccept(student); acceptStudent(student); failStudent(student)'. Formulas for this type of transition patterns are composed of three sections: a 'simple' condition pattern formula and two 'simple' transition pattern formulas (the first one used when the condition is true, and the second one otherwise). Here, the condition pattern refers to the 'student to accept' relationship shown in Fig. 10. Thus, the current method calls the 'checkStudentToAccept' method shown in Fig. 13. Depending on its result, it calls one of two methods resulting from transforming the 'accept student' and 'fail student' relationships. The other method in this class invokes the above described one over a set of appropriate objects (list of students).

Finally, relevant code fragments as presented above, can be now applied to fill-in appropriate empty methods of the back-end service class (see Fig. 3). In our example this pertains to the method that corresponds to a non-CRUD operation. Appropriate additional code is presented in Fig. 16. It contains a simple call to the operation presented in Fig. 15. It is worth noting that such operations are optimised to use only required parameters.

VII. LANGUAGE VALIDATION AND DISCUSSION

To initially validate the presented language, we have used two different approaches. Their aim was to assess certain aspects of the language's usability: understandability and operability. The first approach was to determine language comprehension by its first-time users. It consisted in testing language proficiency, following a brief introduction to the language. The second approach was to determine efficiency of language usage by the users with various experience levels. In both cases, we have used a specially developed RSL-DL editor, used in conjunction with the ReDSeeDS environment.

A. Validation of understandability

The first validation study was conducted with a group of post-graduate computer science students attending the "Model-Driven Software Development" course at the Warsaw University of Technology. The course curriculum included classes on the design and usage of various Domain-Specific Languages. The study was thus well aligned with the aim to acquaint the students with this topic.

The setup of the study was as follows. First, the students attended two lab sessions (four class hours) where they were presented with the RSL and the ReDSeeDS tool. Note that prior to this, the students had no experience with Software Language Engineering but have attended a parallel lecture where they were introduced with the fundamentals of meta-modelling. Next, the students were presented with a brief, one-hour introduction to the language. Then, they have spent two hours solving simple exercises using the aforementioned RSL-DL editor. After this, the students were presented with correct solutions to the exercises. Finally, the students were asked to answer 12 questions in an online questionnaire. All of the questions were single-choice, and referred to specific RSL-DL diagrams. Each question had four possible answers. The first eight questions were related to the understanding of the language syntax, the next three related to language usage, and the final one checked more nuanced usage of the language related to its declarative nature. The students were given one class hour (45 minutes) to finish the questionnaire, but most of them have finished in less than 20 minutes.

The results of the study consist in 42 replies to the questionnaire. The average of correct answers in the whole questionnaire was 69%. For syntax understanding (the first eight questions), it was 75%, for usage understanding (the next three questions), it was 60%, and for the last question it was 40%. Detailed results, together with the question contents are provided in the Supplement.

The relatively low result in the case of the last question can be explained by its advanced nature, going beyond the explanations given to the students. Thus, the 40% can be seen as an unexpectedly good result. It is also worth noting that relatively low percentages of correct answers were associated with questions about differentiation between inferred roles and assigned roles (questions no. 3, 5 and 9). These results were similar to the case of the last question. Further research is

TABLE I
RESULTS OF THE OPERABILITY STUDY

Participant	Task	RSL-DL time	Java time
Author	No. 1	3:00 min.	5:00 min.
Ph.D. Student	No. 1	9:00 min	12:00 min.
Undergrad. Student	No. 1	13:35 min	4:50 min.
Author	No. 2	1:45 min.	3:40 min.
Ph.D. Student	No. 2	4:00 min	10:00 min.
Undergrad. Student	No. 2	16:45 min	5:30 min.
Author	No. 3	4:30 min.	6:00 min.
Ph.D. Student	No. 3	15:00 min	15:00 min.
Undergrad. Student	No. 3	12:25 min	6:20 min.

needed to determine if that was caused by insufficient explanations (this aspect was under-represented in the exercises) or inherent difficulties caused by the language design. In summary, the overall results of this study indicate that the language is comprehensible even after a very short introduction. However, a more thorough validation with statistical analysis is needed to confirm this, and can be seen as future work.

B. Validation of operability

The second validation study was conducted with a group of three software developers with different programming skills. The first person is one of the language authors and thus has very good knowledge of RSL-DL. At the same time, he is an experienced Java programmer. The second person is a Ph.D. student with wide general computer science knowledge and average Java programming experience. The third person is an undergraduate student with more narrow CS knowledge but with relatively high experience in Java programming. The students were not involved in the development of RSL-DL and had no previous knowledge of it.

The study consisted in comparison of coding efficiency and was based on solving specific problems. The setup of the study was as follows. First, the study participants were presented with a 1.5 hour long introduction of RSL-DL and its editor. This included the presentation of three problems: calculation of square mean error (no. 1), calculation of definite integrals (no. 2), and calculation of VAT for product lists (no. 3). The problem formulations involved appropriate formulas and are presented in detail in the Supplement. Next, the participants were supplied with artefacts generated from appropriate RSL specifications (use cases with scenarios) by the ReDSeeDS system. These consisted of pre-initialised RSL-DL models (just the notions) and code skeletons (Data Transfer Objects and method signatures) in Java.

The goal of the participants was to fill-in the provided artefacts to complete domain logic functionality. To prevent from negative bias, the participants were asked to solve the problems using RSL-DL first, and only then to solve them in Java. The participants were also asked to measure time spent on all the tasks. The results of these measurements are given in Table I.

Comparison of times for the three study participants can be treated as rather anecdotal evidence but they give some insight on the productivity of developing domain logic (backend) code

with RSL-DL. As it can be noticed, productivity of RSL-DL development vs. Java development is significantly higher for an experienced RSL-DL user. Also, a less experienced Java programmer (the Ph.D. student) had certain productivity gains. On the other hand, a very experienced Java programmer (the undergraduate student) had performed much better using a traditional programming language. Thus, it can be argued that as general knowledge of developers and their RSL-DL skills raise - productivity gains tend to be significant. It can also be argued that RSL-DL has the potential for extending productivity gains for less experienced programmers. Still, this argumentation has to be acknowledged through a more thorough experimentation with a larger participant scope. This can be seen as future work.

VIII. SUMMARY AND FUTURE WORK

In this paper, we have shown that declarative knowledge representations can be used to produce imperative (3GL) backend code with non-trivial domain logic. Moreover, this code can be interfaced with front-end code produced from low-code specifications that use formalised requirements models (use cases, scenarios). To achieve this, we have used a combination of techniques from model-driven development and ontology-based inference. In this environment, most “programming” activities could be made using a high-level visual language. Thus, programming becomes equivalent to specifying models that define various aspects of the system and its problem domain. An RSL-DL conceptual model can be treated – in fact – as a high-level program that can be executed immediately after compiling it into eg. Java and then – executable code. Moreover, RSL-DL models can be seen as “ontologies as code” [19] and a step towards a “fifth generation language” as postulated by Thalheim and Jaakkola [35].

We see two main areas where our approach can benefit software development: reduction of complexity and increased reuse. The first area is in line with the general goals of the low-code movement – to offer means for reducing accidental (technological) complexity in favour of concentrating on the essential (e.g. domain) complexity (see early insights on this by Brooks [6]). A thorough comparison of complexity between RSL-DL and traditional programming languages, and analysis of reusability can be seen as interesting areas of future work.

Another area for future work is the analysis of RLS-DL usability as a low-code language. Generally, it can be expected that better usability is assured through declarative characteristics of the language (see appropriate comparative analyses [15], [37]). This is in line with our initial studies presented in the previous section. However, to fully support this claim, more extensive experimentation should be conducted.

Other areas which we plan to investigate in the future include better integration with requirements processing mechanisms. One aspect of this is the application of natural language processing. Here, valuable insights can be drawn from the concept of naturalistic programming [24]. This concept postulates the use of natural language elements to design programming languages that are more expressive from the programmers’

point of view. Another interesting approach in this area is that of Mefteh et al. [20]. In this approach, natural language scenarios are transformed into constrained language models expressed in RSL. On the other hand, we also plan to integrate our approach with existing approaches to generate CRUD operations and database schemas directly from requirements models expressed in RSL [39].

As a final remark we address the question of creating a distinct new language as opposed to using an extension to the existing language (e.g. a UML profile). In our opinion, from the practical point of view, both approaches can be seen as equivalent. However, creating a language from scratch favours solutions that go beyond the “beaten path”.

7th Doctoral Symposium on Recent Advances in Information Technology

THE aim of this meeting is to provide a platform for exchange of ideas between early-stage researchers, in Computer Science and Information Systems, PhD students in particular. Furthermore, the symposium will provide all participants an opportunity to get feedback on their studies from experienced members of the IT research community invited to chair all DS-RAIT thematic sessions. Therefore, submission of research proposals with limited preliminary results is strongly encouraged.

Besides receiving specific advice for their contributions all participants will be invited to attend plenary lectures on conducting high-quality research studies, excellence in scientific writing and issues related to intellectual property in IT research. Authors of the two most outstanding submissions will have a possibility to present their papers in a form of short plenary lecture.

Abstract—Currently, it is possible to collect a large amount of data from sensors. At the same time, data are often only partially labeled. For example, in the context of smartphone-based monitoring of mental state, there are much more data collected from smartphones than those collected from psychiatrists about the mental state. The approach presented in this paper is designed to examine if unlabeled data can improve the accuracy of classification tasks in the considered case study of classifying a patient’s state. First, unlabeled data are represented by clusters membership through Fuzzy C-means algorithm which corresponds to the uncertainty of the patient’s condition in this disease. Secondly, the classification is performed using two well-known algorithms, Random Forest and SVM. The obtained results indicate a minimal improvement in the quality of classification thanks to the use of membership in clusters. These results are promising due to both, the accuracy and interpretability.

I. INTRODUCTION

MOTIVATION for this research comes from the practical problem of classifying partially labeled data. Within this work, we concentrate on a particular case study in monitoring the mental state of bipolar disorder (BD) patients which has a large dataset of sensor-based data with labels provided by doctors. Since we are limited by medical labels, the most frequent attempts to predict a patient’s condition come down to using only a small part of the data from the entire set. Such selected data may not contain characteristics for each patient and the obtained results may not be accurate. To alleviate the aforementioned problem, we propose to incorporate the results of clustering into the classification task.

The collection of medical data in our possession indicates to use of a semi-supervised approach. For this purpose, it is worth enabling clustering to extract information from unlabeled data [1]. In related work, the accuracy of classification for patients with bipolar disorder using sensor data amounts to 76% [2]. Some works test the influence of clusters in the classification problems, e.g., [3] and indicate an improvement in the results. Other works include unlabeled data by means of the dynamic incremental fuzzy semi-supervised learning, see e.g., [4].

Experiments are performed on data about voice collected from smartphones of bipolar disorder patients. On the other hand, labels obtained from psychiatrists during visits are valid only for daytime, and of that day only so the amount of those labels is relatively small. Psychiatrists indicate that the symptoms of a given phase are visible several days before the visit, therefore the validity of this label can be extended. That

procedure results in the preparation of a much larger range of data enabling the classification of the patient’s condition. Therefore, we check whether the use of the remaining unlabeled data represented by the membership to clusters improves the quality of the classification labeled data.

II. METHODOLOGY

The idea of the proposed experiment is to verify that unlabeled data assign as a clusters membership has an impact on the classification of patients states.

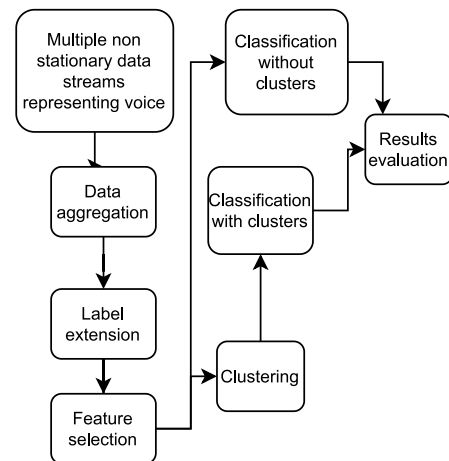

Fig. 1. Process flow

The process flow of the proposed experiment is presented in Figure 1 and in Algorithm 1. The experiment begins with retrieving all available multiple non-stationary data streams representing voice. All frames are then aggregated to the patient’s phone call level with different aggregates methods. Psychiatric assessments obtained during visits, represented as labels are spread around the day of the patient’s visit. Within the feature selection, the top-k most important voice parameters are selected for each patient and aggregated methods. Additionally, all available patient data are clustered to include unlabeled data as well. Simultaneously, the classification of the patient’s condition is carried out on the data containing clusters membership and without this information. Finally, results are evaluated with multiple metrics.

Algorithm 1 Pseudocode of the experiment

```

1 for patient in patients_list:
2   for agg in aggregates:
3     best_features = RFE(no_of_best_parameters = 10)
4     cluster_mmbs = FuzzyCmeans(data[, best_features], unique_visits_no)
5     rf_nocluster = RandomForest(data_without_clusters)
6     rf_withcluster = RandomForest(data_with_clusters)
7     SVM_nocluster = SVM(data_without_clusters)
8     SVM_withcluster = SVM(data_with_clusters)

```

A. Data collection and aggregation

Patients were enrolled and used a dedicated smartphone application in everyday life starting in September 2017 and ending in December 2018. All their recordings were divided into 10-20 ms frames. Next, for those frames, openSMILE [5] library was used to calculate acoustic features. The final dataset contains 86 data streams that describe the main acoustic features of voice such as e.g., loudness, voice energy, pitch, etc. All data from 2018 were selected for the experiment for each of the 6 patients who had several visits in the year of the study where different disease phases were observed.

Due to a large number of frames available for each connection, this data has been aggregated to the level of one phone call using mean, standard deviation, skewness and quartiles. Each of the available 85 voice parameters is aggregated in this way. The data were then normalized. Aggregating the data to the level of the conversation will allow you to slightly reduce the noise of the data and facilitate data processing in subsequent processes.

B. Labels extension

The labels obtained by the patient during the visit are valid only on the day of the visit. The number of labels available for a given patient during the year did not exceed 7 for 1 patient, which is a negligible value throughout the year. The ability to extend the label to days around the visit increases the amount of labeled data. Other studies are considering extending the label to 7 days in advance as symptoms of the patient's condition may already be noticeable prior to the visit. In the present experiment, the label was extended 7 days before the visit and 2 days after the visit. This gives the label a validity period of 10 days. Results received from that method are shown in TABLE I. In an example of first patients with ID 1472 we can observe, that label extension increased the number of phone calls with labels from 42 to 391. There was much more unlabeled data, i.e. 1482, what is worth using it.

C. Feature Selection

To obtain significant voice parameters we apply one of the automatic feature selection methods called Recursive Feature Elimination (RFE) [6]. The idea of the RFE technique is to build a model with all variables and after that, the algorithm successfully removes features until the desired number remains. The current implementation of that method used the Random Forest algorithm to train and create ranking features by importance, discarding the least important features, and

TABLE I
PATIENTS DETAILS

ID patient	No. of visits	No of phone calls in day of visits	No of phone calls for extended label validity	No of all phone calls in 2018
1472	2	42	391	1482
2004	2	16	223	871
2582	3	31	169	645
5656	2	7	29	215
5736	2	20	71	1025
6139	3	22	90	254

re-fitting the model. To find the optimal number of features cross-validation is used with the RFE algorithm to obtain the best scoring collection of features. The final subset used the first 10 best parameters resulting from that method.

Earlier studies [7] have shown that the introduction of the RFE method improves clustering results. In the present work, the RFE method is used for each patient and each data aggregation method separately considering only the labeled data. This allows the best voice parameters to be selected in a tailored way. This set of the 10 most important acoustic parameters is then used in the next stage of the experiment.

D. Clustering

The algorithm used for clustering is Fuzzy C-mean [8] with squared Euclidean distances as a parameter of dissimilarities between observations. We assume a patient may have symptoms of several conditions at the same time during unlabeled days. This happens mainly in a mixed state where the symptoms of mania and depression occur simultaneously. Furthermore, on unlabeled days the patient may not have obvious symptoms characteristic of only one BD state. Such uncertainty resulted in the choice of the Fuzzy C-mean algorithm which introduces cluster membership. In that case, the number of clusters corresponds to the known number of different phases diagnosed in a given patient.

In fuzzy clustering, each observation is "spread out" over the various clusters. The output of that clustering is the membership to each of the clusters. The memberships are nonnegative, and for a fixed observation it sums to 1. So each phone call could be partly assigned to one class and partly to another class. We don't assign a specific cluster to BD state. We just looking for a variety between classes.

Clustering was performed on all available data for each patient (also unlabeled data) in order to capture the variability over all available observations. These data were aggregated

to the level of the patient's conversation and then the 10 most important acoustic parameters were selected by the RFE method.

E. Classification

The classification was made in 2 ways using 2 well-known classifiers, the Random Forest [9] and Support Vector Machine [10]. The first method (lines 5 and 7 in Algorithm 1) assumes that aggregated data with selected voice parameters by the RFE method are classified. The second method (lines 6 and 8 in Algorithm 1) additionally joined the membership of each cluster to that dataset. Clusters membership were used for labeled data only. Then the data is divided into a training set and a test set in the proportion of 75:25 in such a way that each set contains data from each BD patient's state. Predicted classes depend on how many different phases the patient received during the whole study. The classification is performed on each patient for each of the 6 available aggregation methods. The "best aggregate" is then selected according to the Accuracy comparison of each aggregate for that patient. The classification results for the selected aggregate are summed up from all patients and a common confusion matrix is created for the selected algorithm and data without clusters and with clusters. The values in the confusion matrix are presented for the test set not used during training.

F. Evaluation metrics

In total 4 confusion matrices have been created. The first two matrices concern the comparison of values from all patients and their best aggregation methods for the Random Forest algorithm in the first case without the use of clusters and in the second additionally including cluster membership.

The next 2 matrices also compare the values without clusters and with clusters, this time using the SVM algorithm.

Additionally, for each of the above-mentioned matrices, classification coefficients were calculated, such as Accuracy - correctly forecasted patient states concerning all forecasts, Precision - i.e. the fraction of relevant instances among the retrieved instances, and Recall - i.e. the fraction of relevant instances that were retrieved.

III. EXPERIMENTAL RESULTS

A. Selection of aggregation operators and acoustic features

Selecting an appropriate aggregation operator for the acoustic data is not obvious, therefore, several such methods were tested in this study

The best aggregates were selected separately for each patient. The results are presented in TABLE II. The best aggregating methods turned out to be the mean and skewness. They have been selected 7 times. Then Q1 was selected 5 times, Q3 - 3 times, and Standard deviation - 2 times. Interestingly, the Q2 aggregate known as the median was not selected even once. Moreover, the parameters that best characterize the normal distribution, i.e. mean, standard deviation, and skewness, were selected twice as often (16 hits) as the parameters characterizing the quantile distribution (8 hits). The

differences are also noticeable concerning the classifiers used. However, it does not affect their further interpretability.

The relevant acoustic parameters received from RFE methods differ for each model as well. The following 10 parameters were most often selected by the model are: *spectral-RollOff90*, *LOGenergy*, *mfcc 11*, *fband1000-4000*, *f3frequency*, *f2frequency*, *fband0-650*, *hammarbergindex*, *audSpec*, *spectralharmonicity*.

TABLE II
AGGREGATES METHODS SELECTION

	RF non-cluster	RF with cluster	SVM non-cluster	SVM with cluster
<i>aggregate</i>	<i>cardinality</i>			
mean	1	1	2	3
standard deviation	1	0	1	0
skewness	2	2	2	1
Q1	1	2	1	1
Q2	0	0	0	0
Q3	1	1	0	1

B. Classification

1) *Random Forest*: Table III contains the confusion matrices for the test sets from all patients where the data included in the Random Forest classifier did not include cluster membership (left) and where the data contained cluster membership (right). Values on the diagonal of the matrix indicate the correct classification of each of the states. The remaining values indicate what were the forecasts for the remaining cases where the observed label does not agree with the predicted value. The results are promising for both models. The total number of correctly classified for the non-clustering model is 209 and for the clustering model is 211, so we see a slight improvement in the results. The only place where clusters join in shows a slight weakening of the results is in the prediction of the state of depression. The other values are slightly better or equal. However, these differences are subtle, so it should be tested on more examples.

Table IV contains the results calculated based on the above-mentioned confusion matrices. As observed, the precision and recall values for each state are similar or slightly better for the method containing cluster memberships. Accuracy, i.e. the ratio of correctly predicted values to all values, also increases in the method containing clusters from 83.27% to 84.06%.

2) *SVM*: Table III contains the confusion matrix summed for the test set from all patients where the data included in the Support Vector Machine classifier did not include cluster membership (left) and where the data contained cluster membership (right). Results obtained for the SVM are similar to the previously considered RF. The total number of correctly classified for the non-clustering model is 203 and for the clustering model is 210, so there is again a slight improvement. In that case, there is no place where the method using clusters received a worse number of incorrect predicted values in any class.

TABLE III
CONFUSION MATRICES FOR RF AND SVM CLASSIFIERS WITHOUT (LEFT) AND WITH INFORMATION ABOUT MEMBERSHIP TO CLUSTERS.

RF-nc		actual			
		E	X	D	M
predicted	E	79	15	13	1
	X	4	76	0	0
	D	9	0	39	0
	M	0	0	0	15

RF-c		actual			
		E	X	D	M
predicted	E	83	11	13	1
	X	3	77	0	0
	D	12	0	36	0
	M	0	0	0	15

SVM-nc		actual			
		E	X	D	M
predicted	E	79	17	11	1
	X	2	78	0	0
	D	17	0	31	0
	M	0	0	0	15

SVM-c		actual			
		E	X	D	M
predicted	E	82	17	13	1
	X	2	78	0	0
	D	15	0	35	0
	M	0	0	0	15

TABLE IV
RESULTS OF RF AND SVM CLASSIFIERS WITHOUT (LEFT) AND WITH CLUSTERS(RIGHT)

RF-nc	E	X	D	M
precision (PPV)	0.73	0.95	0.81	1
recall (TPR)	0.86	0.84	0.74	0.94
accuracy	83.27%			

SVM-nc	E	X	D	M
precision (PPV)	0.73	0.98	0.65	1
recall (TPR)	0.80	0.82	0.74	0.94
accuracy	80.88%			

RF-c	E	X	D	M
precision (PPV)	0.78	0.96	0.75	1
recall (TPR)	0.85	0.88	0.74	0.94
accuracy	84.06%			

SVM-c	E	X	D	M
precision (PPV)	0.73	0.98	0.70	1
recall (TPR)	0.83	0.82	0.73	0.94
accuracy	81.40%			

Table IV contains the results calculated based on the above-mentioned Confusion Matrix. Values received by that classifier are similar to the previous one. Both precision and recall values for each state are similar or slightly better for the method containing cluster memberships. Accuracy, i.e. the ratio of correctly predicted values to all values, also increases in the method containing clusters from 80.88% to 81.40%.

Results obtained by both classifiers are promising. Both classifiers achieved high precision and recall that indicate the correctly predicted class. Moreover, joining a cluster membership has a slightly better effect on the quality of the classification.

IV. CONCLUSION

Unlabeled data appear to have a positive effect on the accuracy of classifying patients with bipolar disorder. In the study, a model was prepared that fits each patient individually. The presented solution individually sets the list of important acoustic parameters, the appropriate method of aggregating these data, and the number of clusters in which the patient may be. Such a model was compared with a model that did not include membership of clusters (so used amount of data from each patient was used for the model). The presented results indicate that adding information about clusters slightly improves the classification performance. The current results seem to be promising, and the study will be repeated for the remaining patients.

Abstract—In this paper, a least squares method is used to estimate parameter values in the Lotka-Volterra model. The data used are graphics processing units (GPU) shipment worldwide by three key competitors, namely Nvidia, Intel, AMD. The goal is to quantify the parameter values of a model with minimal error in order to qualitatively solve the problem and fit the raw data as closely as possible. Based on the real measurements, the predator between the competitors is recognized through the identification procedure comparing the sign of the coefficients with the original Lotka-Volterra model structure.

I. INTRODUCTION

OUR NATURAL environment is mostly in motion. In order to visualize and model the ever-changing natural environment and, more specifically, population dynamics under a variety of circumstances, the Lotka-Volterra equations have proven to be a useful tool, as long as we build our investigations on some prior assumptions. While these equations can be used for various dynamic scenarios, such as pandemics, they can also be extended to model the dynamics of two species that are sharing a natural habitat, while competing for a certain local resource, instead of one species just hunting the other. During the last years many different contributions appeared in many fields of applications and in different technical estimation and identification contexts [1], [2], [3].

The general goal of modelling is to find a simple model that fits a data set within a predetermined error bound, while still allowing specific properties to be addressed [4]. In this paper, a least squares method is used to estimate the initial parameter values in the Lotka-Volterra model. This algorithm can be used to estimate the initial value of these parameters to be used in more complex adaptive algorithms as for instance proposed in [5]. The data used is graphics processing units (GPU) shipment worldwide by three key competitors, namely Nvidia, Intel, AMD. As the parameter values of the Lotka-Volterra model describe growth, predation and competition between interacting populations, the model can be applied to competing firms in a market of GPUs or similar. The goal therefore is to quantify the parameter values of a model with minimal error in order to qualitatively solve the problem and fit the raw data as closely as possible. The paper is organized

as follows. Section II proposes a general interpretation of the Lotka-Volterra model. In Section III an application to the market of GPUs is described. Results which include a validation of the method using real data and conclusions close the paper.

II. INTERPRETATION OF THE LOTKA-VOLTERRA MODEL

The Lotka-Volterra equations, also known as the predator-prey equations, are two first-order nonlinear differential equations, often used to describe the dynamics of the biological system in which two species interact, one as a predator and the other as prey. The dynamics of the populations are described as follows:

$$\begin{aligned}\frac{dx(t)}{dt} &= \alpha x(t) - \beta x(t)y(t) \\ \frac{dy(t)}{dt} &= \delta x(t)y(t) - \gamma y(t),\end{aligned}\tag{1}$$

where $x(t)$ represents the number of prey (e.g. fish) and $y(t)$ represents the number of predators (e.g. bears). $\frac{dx(t)}{dt}$ and $\frac{dy(t)}{dt}$ represent the growth rates of the populations while t represents the time variable. Greek letters α , β , δ , γ are constant positive real parameters which describe the interaction of the two groups of populations. While the classic model is usually used in biology, there is a wide range of research with modified models in different areas that resemble the context of predator and prey [4], [6].

III. APPLICATION TO THE MARKET OF GPUS

Differential equations or stochastic differential equations are used for modeling random phenomena in the financial field. Due to the application of these tools in the field of financial economics, a large number of scientists research in this area, see [7], [8], [9]. It is known that the parameters of a stochastic model are always deterministically unknown and this justifies the KF approach mentioned above. The parameter estimation problem for economical models has been studied by many scientists, Yu and Phillips [10] utilized a Gaussian method to estimate the parameters of continuous time short-term interest rate models. Faff and Gray [11] considered the estimation of

short-rate models by using a method of moments. Rossi [12] took into consideration particle filters and maximum likelihood estimation for parameter estimation of Cox-Ingersoll-Ross model. In any market with competition, companies are competing for sales of their proprietary goods and services. An example of a generic Lotka-Volterra model describing the dynamics between three competing PC graphics processing units (GPUs) companies, based on a set of statistical data, is used to illustrate the practical application of the proposed method. The statistical data was retrieved from Statista [13] which includes data from 2nd quarter of 2009 to 3rd quarter of 2021, by vendor (Figure 1).

Fig. 1: GPU shipment share worldwide, by vendor, from Q2 2009 to Q3 2021. Source: [13]

From the retrieved data, it can be seen that Intel has the leading position among three firms, while other two firms have a smaller share of the market, therefore are directly competing with each other. This interaction can be modelled using the Lotka-Volterra method and the problem is formulated in terms of a nonlinear dynamical system consisting of three first order differential equations, each containing linear and quadratic terms. The system is linear with regards to the unknown parameters that must be derived from available statistical data. When applying the proposed method to the system, the unknown coefficients are estimated and the closeness of the respective solutions to the statistical data is discussed.

Given a situation where three species x , y and z compete for available resources in a system. In the market of GPUs, three main firms are competing for the attention and resources of similar customers. A Lotka-Volterra model for three competing species is generically represented by:

$$\begin{aligned} \frac{dx(t)}{dt} &= x(t)(a_0 + a_1x(t) + a_2y(t) + a_3z(t)) \\ \frac{dy(t)}{dt} &= y(t)(b_0 + b_1x(t) + b_2y(t) + b_3z(t)) \\ \frac{dz(t)}{dt} &= z(t)(c_0 + c_1x(t) + c_2y(t) + c_3z(t)), \end{aligned} \quad (2)$$

where $x(t)$, $y(t)$, $z(t)$ values are companies' shares in the market and a_i , b_i , c_i ($i = [0, 3]$) are coefficients. To estimate the parameter values of the system of equations (2), the integral method described by [4] was used. As the statistical data is available, it is possible to represent the set of linear equations derived by using the integral method in the matrix form. An example of parameter value estimation for the first firm (Intel) is given below:

$$\underbrace{\begin{bmatrix} d_{1,0} \\ d_{2,1} \\ \vdots \\ d_{n,n-1} \end{bmatrix}}_d = \underbrace{\begin{bmatrix} \bar{x}_{1,0} & \bar{x}_{1,0}^2 & \bar{x}\bar{y}_{1,0} & \bar{x}\bar{z}_{1,0} \\ \bar{x}_{2,1} & \bar{x}_{2,1}^2 & \bar{x}\bar{y}_{2,1} & \bar{x}\bar{z}_{2,1} \\ \vdots & \vdots & \vdots & \vdots \\ \bar{x}_{n,n-1} & \bar{x}_{n,n-1}^2 & \bar{x}\bar{y}_{n,n-1} & \bar{x}\bar{z}_{n,n-1} \end{bmatrix}}_X \underbrace{\begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{bmatrix}}_{\hat{a}}$$

and thus

$$\Rightarrow d = X\hat{a} \quad (3)$$

with

$$d_{j+1,j} = x(t_{j+1}) - x(t_j), j = 0, 1, \dots, (n-1).$$

The matrix X contains the consecutive pair-wise means, namely:

$$\begin{aligned} \bar{x}_{j+1,j} &= (x(t_{j+1}) + x(t_j))/2 \\ \bar{x}_{j+1,j}^2 &= (x^2(t_{j+1}) + x^2(t_j))/2 \\ \bar{x}\bar{y}_{j+1,j} &= (x(t_{j+1})y(t_{j+1}) + x(t_j)y(t_j))/2 \\ \bar{x}\bar{z}_{j+1,j} &= (x(t_{j+1})z(t_{j+1}) + x(t_j)z(t_j))/2. \end{aligned} \quad (4)$$

While the vector a contains the unknown parameters, a least squares method can be used to determine the vector values using the following formula:

$$\hat{a} = (X'X)^{-1}X'd \quad (5)$$

IV. RESULTS

Applying the proposed integral method, the resulting system is given as follows:

$$\begin{aligned} \frac{dx(t)}{dt} &= x(t)(0.1113 - 0.1122x(t) + 0.1749y(t) - 0.3438z(t)) \\ \frac{dy(t)}{dt} &= y(t)(-0.1297 + 0.0041x(t) - 0.3322y(t) + 0.9385z(t)) \\ \frac{dz(t)}{dt} &= z(t)(0.0804 + 0.0496x(t) - 0.5497y(t) - 0.3117z(t)). \end{aligned} \quad (6)$$

The estimated coefficients show that firms Intel and Nvidia are prey, while the firm AMD is the predator given its negative growth rate of -0.1297 . Interestingly the share of Intel is increased by the actions of the predator firm with a coefficient of $+0.1749$ while Nvidia has a negative influence on Intel's growth rate. This can be seen by a positive coefficient of 0.0496 in the third equation. Looking at the second equation of the predator, it can be seen that the first firm is not acting as the primary prey (0.0041), whereas the third firm is the main source of the predator's share growth, as seen by a

large coefficient of 0.9385. Comparing the second and third equations (AMD vs. Nvidia) it is confirmed by the coefficient of -0.5497 that the growth of AMD comes from the decline in the third firm, Nvidia. This supports the idea that these two firms are direct competitors fighting for the remaining market share as seen on Figure 1.

In order to estimate the equilibrium point for each firm, each equation in the system of equations (6) was set equal to zero. The obvious solution for all equations is when $x(t)$, $y(t)$, $z(t)$ are equal to 0. Another solution was found at points of $x(t) = 0.63$, $y(t) = 0.11$, $z(t) = 0.17$ (see calculation in the code provided).

In order to get the values for model data, the Euler method was used. The following figures (2-4) represent the observed data, the results of modelling and forecasted data for three firms. As seen by the results, the model fits well to historical

(a) Model and observed data

(b) Forecasted data

Fig. 2: The results for Intel

data of Intel market share, with R-squared equal to 0.78. The forecast shows that the stable state is reached at 0.63 that corresponds to the previously retrieved point of equilibrium for Intel. The forecast implies that this firm is likely to maintain its dominance in the GPU market over time.

(a) Model and observed data

(b) Forecasted data

Fig. 3: The results for AMD

As for AMD, the predator firm, it is seen that the model does not fit the observed data, which is confirmed by the R-squared value of -0.99 . When finding the R-squared value, if the sum of squares of the residuals is higher than the sum of the squares of the distances of the points from a horizontal line through the mean of all Y values, then R-squared can be negative. This implies that the "best-fit" line fits worse than a horizontal line drawn through the mean of all Y values, for instance if the regression line does not follow the trend of the observed data [14]. However, as seen on Figure 3a, the modelling data nonetheless displays a similar trend as the observed data but prediction tends to be less accurate than the average value of the data set over time. The forecast implies that AMD would lose half of its market share in the near term and will remain at an equilibrium point of 0.11. However, as the model did not fit well to the observed data, it is impossible to suggest the validity of the forecast. The model for Nvidia shows a good fit with R-squared value equal to 0.78 with an equilibrium point at 0.17. The forecast shows that the firm would lose some of its market share but only by a few percentage points.

Fig. 4: The results for Nvidia

V. CONCLUSION

In this paper a research in the market of GPUs with three main competing firms was performed using the Lotka-Volterra model. For parameter values estimation the integral method and least squares algorithm was used. The results indicate that AMD is the predator firm while Intel and Nvidia are its prey. However, the R-squared values of the model show decent values for Intel and Nvidia, while not being a good fit for AMD, the predator firm. It is likely that more data is needed to build a better model for the predator firm. Nevertheless, the results indicate that the Lotka-Volterra model can be applied to investigate the competition of more than two firms in a free market of GPUs, but it requires further investigation and experiments.

Abstract—This paper presents a new approach to the problem of correcting speech recognition errors by means of post-editing. It consists of using a neural sequence tagger that learns how to correct an ASR (Automatic Speech Recognition) hypothesis word by word and a corrector module that applies corrections returned by the tagger. The proposed solution is applicable to any ASR system, regardless of its architecture, and provides high-precision control over errors being corrected. This is especially crucial in production environments, where avoiding the introduction of new mistakes by the error correction model may be more important than the net gain in overall results. The results show that the performance of the proposed error correction models is comparable with previous approaches, while requiring much smaller resources to train, which makes it suitable for industrial applications, where both inference latency and training times are critical factors that limit the use of other techniques.

Index Terms—speech recognition, error correction, post-processing, post-editing, natural language processing

I. INTRODUCTION

AUTOMATIC Speech Recognition (ASR) models have been developed for more than 70 years. During this time, they evolved from machines that could recognize single digits spoken by one person, created for demonstration purposes without production use back in the 1950s [1], to omnipresent voice assistants and speech transcription engines used everyday by millions of people around the world. Although speech recognition technology has reached maturity and is production ready, it is still not perfect. Professional human transcribers do not reach 100% transcription accuracy, and although recent deep neural network-powered speech recognition systems are reported to slightly outperform humans [2], they still make mistakes. Furthermore, the near-perfect results of the Word Error Rate (WER) below 2% are often reported on popular benchmark datasets such as the test subset of the LibriSpeech corpus [3]. When evaluated on corpora from different domains or recorded under different conditions, the results are far from perfect and require adaptation [4]. In real-world production settings, input to a speech recognition system may change frequently, caused by changes in topics that are interesting to users. Changes in the real world, such as the Covid-19 pandemic, influence the vocabulary used by speakers and may lead to out-of-vocabulary errors. The adaptation process of ASR models takes considerable time and resources. In some

settings, direct adaptation of the model is impossible, for example, when using a cloud-based speech recognition service. One way to address the imperfections of speech recognition models mentioned above is to improve their results in a post-editor, a module operating on a textual output of a speech recognition model. Typically, in production environments, the post-editor provides means of correcting ASR errors manually, for example, with hand-written regular expressions. The process of creating and maintaining such corrections is laborious and requires a lot of experience [5]. Therefore, the post-editor can include an error correction model which learns how to correct errors of a particular ASR system. This approach can be applied regardless of an ASR model architecture, also for systems where direct modification of the model is impossible. It requires only text data to train, and its training requires considerably less resources and time than performing the adaptation of a speech recognition model. This paper presents such an error correction model. In Section II we present an overview of previous work on the subject. Section III describes the data used for training and evaluation. Details of the proposed approach are presented in Section IV. Results and conclusions can be found in Sections V and VI.

II. RELATED WORK

For a review of ASR error detection and correction systems together with a description of ASR evaluation metrics see [6]. Cucu et al. [7] propose error correction using SMT (Statistical Machine Translation) model trained on a relatively small parallel corpus of 2000 ASR transcripts and their manually corrected versions. At an evaluation time, the model is used to “translate” ASR hypothesis into corrected form. The system achieves 10.5% relative WER improvement by reducing WER of the baseline ASR system from 11.4 to 10.2. A similar approach, but using a neural LSTM sequence-to-sequence model and trained on a much larger dataset (40M utterances), is presented in [8]. To produce ASR hypotheses, the authors use a speech corpus generated from plain text data with a text-to-speech (TTS) system. In addition to the spelling correction model, authors experiment with improving the results of an end-to-end ASR system by incorporating an external language model and a combination of the two approaches. The proposed system achieves satisfactory results (19% rela-

tive WER improvement and 29% relative WER improvement with additional LM re-scoring, with baseline ASR WER of 6.03) but requires a large speech corpus or high-quality TTS system to generate such corpus from a plain text. One of the recent works [9] presents an error correction model for Mandarin. The authors stress the importance of a low latency of ASR error correction model in production environments and propose a non-autoregressive transformer model, faster than its autoregressive counterparts. The model is modeled on a large, artificially created parallel corpus of correct-incorrect sentence pairs, generated by randomly deleting, inserting, and replacing words in a text corpus. Real ASR corrections dataset is used to fine-tune the model to a specific ASR system. Relative WER reduction reported by authors on a publicly available testset is 13.87, which is slightly worse than autoregressive model (15.53) while introducing a latency that is over 6 times lower (21ms).

A similar approach to the one presented in this work is proposed in [10], but serves different tasks (grammatical error correction), operates on a poorer set of edit operations and uses different tagging models.

III. DATA

We performed experiments for 3 European languages: Spanish, French, and German. The presented error correction models were trained and evaluated on pairs of ASR hypotheses and corresponding reference sentences. To create a corpus of such pairs, recordings from speech corpora for each language were processed using a corresponding model of an end-to-end speech recognition system. Reference transcriptions from speech corpora were paired with their corresponding hypotheses, creating parallel corpora of corrections for each language. To discard any differences caused by different normalization of transcriptions in speech corpora and in ASR output, we additionally performed automatic normalization of both reference and hypotheses sentences by lowercasing, removing punctuation characters and inverse-normalizing numbers. The data preparation pipeline is presented in Figure 1. For an example of a freely available corpus of ASR corrections for Polish prepared with the same pipeline, see [11].

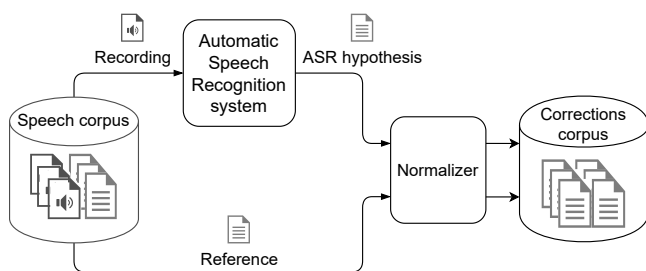

Fig. 1. Data preparation pipeline

Speech corpora, used to create corrections corpora, contain utterances used for virtual assistant development. They include commands and questions targeted at the assistant. Some of them are recorded in a studio for development purposes, and

some originate from usage data, after performing anonymization.

Data statistics are shown in Table I. Data sets were randomly divided into training, development, and test subsets in a proportion 8:1:1.

For a description of tagger training data preparation process, see section IV-A.

IV. METHOD

The proposed error correction method is designed to be precise, easily controllable, and data efficient. In contrast to methods inspired by machine translation, such as [8], our model does not have to model and reproduce all tokens of the output sequence. Instead, it learns only which tokens to modify to correct the sentence. To make it precisely controllable, the error correction mechanism works in two steps. First, a sequence-tagging model assigns a tag to each token in the input sentence. The tag indicates whether the token is correctly recognized or requires correction. In the latter case, the tag specifies an edit operation that is needed to transform the incorrect sentence into a correct one. In the second step, the assigned tags are used to perform edit operations that correct ASR errors. This approach is especially suitable for production settings because it allows one to precisely control which edit operations to include in the model and which edit operations to perform on inference time. The control can be based on scores returned by the tagger (for example, by setting a global scorer threshold) or on rules excluding certain operations in certain contexts from being performed.

A. Tagging data preparation

To train a sequence tagging model, a corpus of ASR hypotheses with assigned edit operation tags is needed. We create it from the parallel corrections corpus described in Section III. First, hypothesis and reference sentences are compared and aligned using Ratcliff-Obershelp algorithm [12] implemented in difflib library [13]. As a result, we get a list of operation codes describing how to turn corresponding parts of the hypothesis into reference. There are four operation codes: "replace", "delete", "insert" and "equal". For parts of a sentence which are not equal, we use a set of conditional rules involving recursively invoking the difflib alignment to tag each token with one of the edit operations. Examples of tags and corresponding edit operations are presented in table II. For an illustrated example of tags generation process, see Figure 2.

The set of available edit operation classes can be adjusted to the needs of a specific speech recognition system and a natural language. Ideally, the set should cover all errors and be as small as possible. If the set is too big, edit operations become

too sparse for the tagger to learn them effectively. Therefore, we chose to prioritize use of most expressive edit operations, like „append_s”, which for example in English could cover most of the errors associated with a singular noun in place of a plural and missing "s" in third-person singular verbs. The same errors could be covered by more precise rules correcting only particular words, e.g. "replace_with_cats" (edit operation assigned to the word "cat"). By using more general operations, the model can generalize to unseen examples of errors. This is where our approach is different from [10] which uses only two main types of operations: KEEP ("None" in our approach), DELETE ("del" in our approach) and can insert any phrase or word from vocabulary V before the current token. Such an approach cannot cover multiple errors with one tag.

Despite using edit operations that cover multiple errors, the edit operations dataset is still sparse. About 15% of edit operations are supported only with one example. To make training more efficient and the model less overfitted to singular examples, we use a cut-off of 150 most frequent edit operations, also filtering-out all which are found only once in the dataset. To differentiate between tokens which are correct and those which errors are not frequent enough, we replace all the filtered edit operations with a special edit operation called "unsupported". This operation tag is present in the training set and the model learns to tag some tokens with it, but when correcting sentences on the inference time, there is no edit operation performed on them. Sequence of edit operations assigned to adjacent tokens can be interdependent - performing only some of them may deteriorate the results. Therefore, when one of the tokens is tagged with "unsupported", all surrounding, non-empty tags are replaced with the "unsupported" tag.

B. Tagging models

We train and evaluate two tagging model types: BERT token classification model and contextual string embeddings model [14], referred later as "Flair". BERT tagger model uses locale variations of BERT transformer: Gbert for German [15], Camembert for French [16] and Beto for Spanish [17]. A single linear layer is added at the output, and the whole network is fine-tuned for the tagging task. Training was performed for 6 epochs, extending the training time did not improve results. The "Flair" model contains Bert models mentioned before, extended with contextual string embeddings [18], LSTM [19] and CRF [20] layers. Training was carried out for a maximum of 100 epochs.

V. RESULTS

Both model types were evaluated using hold-out test sets by calculating WRR (Word Recognition Rate) of original ASR hypotheses and their corrected versions. Table III presents averaged results. As can be seen on an example of German dataset compared with other two - the worse the original ASR results are, the easier for the correction model to achieve higher absolute gains. Therefore, to compare correction models trained on datasets with different original results, we

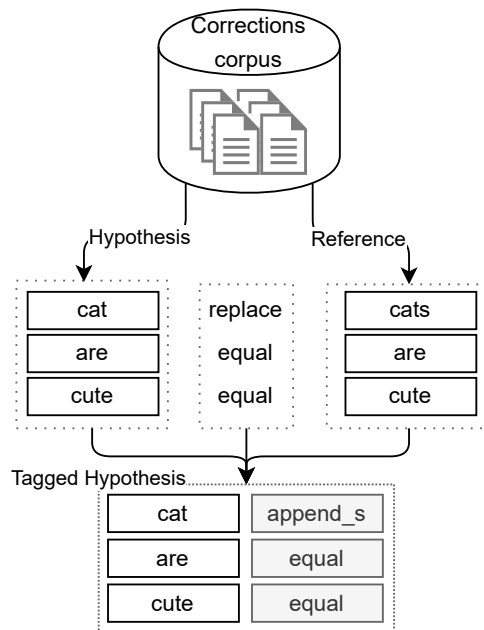

Fig. 2. Tags generation example

calculate a relative WER (Word Error Rate) reduction metric, which is calculated as

$$\frac{WER_{ASR} - WER_{Corrected}}{WER_{ASR}} \quad (1)$$

where WER_{ASR} is WER of ASR system and $WER_{Corrected}$ is WER after applying the correction model. Relative improvements of our models vary between 21% and 24.7%, making them comparable with state-of-the-art results reported in [8], while using much smaller training datasets, without the need of generating synthetic data with TTS engine. The Flair tagger offers slightly better results (except for German, where results are equal).

Table IV presents the time required for training the models and the average times needed to correct a single sentence from the test set. Both training and inference were performed using a machine with a single Tesla P40 GPU.

VI. CONCLUSIONS

We presented a new approach to ASR errors correction problem. As demonstrated using three independent datasets, correction models trained using this approach are effective even for relatively small training datasets. The method allows to precisely control which errors should be included in the model and which of the included ones should be corrected at the inference time. The evaluations performed on the models show that they can significantly improve the ASR results by reducing the WER by more than 20%. All of the models presented offer very good inference latency, making them suitable for use with streaming ASR systems.

TABLE II
EXAMPLES OF EDIT OPERATIONS

name	description	example
del	deletes a token	"a" → ""
append_s	appends given suffix to the token	"cat" → "cats"
add_prefix_	prepends given prefix to the token	"owl" → "howl"
remove_suffix_1	removes 1 character from the end of the token	"cats" → "cat"
remove_prefix_1	removes 1 character from the beginning of the token	"howl" → "owl"
join	joins token with previous one	"book store" → "bookstore"
join_	joins token with previous one using given separator	"long term" → "long-term"
replace_	replaces token with given string	"cat" → "hat"

TABLE III
RESULTS OF ERROR CORRECTION MODELS

		de-DE	es-ES	fr-FR
BERT	base WRR	78.07	90.70	93.51%
	corrected WRR	83.48	92.65	94.97%
	WRR gain	5.41	1.95	1.46
	Rel. WER reduction	24.67%	20.97%	22.50%
Flair	corrected WRR	83.40	92.86	95.04
	WRR gain	5.33	2.16	1.53
	Rel. WER reduction	24.30%	23.23%	23.57%

TABLE IV
TRAINING (IN MINUTES) AND INFERENCE (IN MILLISECONDS) TIMES.

		de-DE	es-ES	fr-FR
BERT	training time	28	40	10
	inference latency	14	14	13
Flair	training time	180	154	67
	inference latency	28	29	18

The presented method is well suited for industrial applications where the ability to precisely control how the error correction model works, as well as small latency, are crucial.
