Abstract

The spin and parity (J^π) assignments in even-even nuclei were reviewed across the nuclear chart using the Evaluated Nuclear Structure Data File (ENSDF). The prevalence of 2_1^+ first or lowest excited states is confirmed. The properties of 0_2^+ , 1_1^- , and 3_1^- lowest excited states were reexamined using the ENSDF data evaluation procedures. The J^π systematic trends and correlations between level quantum numbers and nuclear physics phenomena are discussed.

Keywords: Spin and parity assignments, first-excited states, ENSDF

1. Introduction

Comprehensive information on spin and parity assignments is essential for nuclear structure physics and model development. In the early 50s, Gertrude Scharff-Goldhaber at Brookhaven National Laboratory noticed the prevalence of 2_1^+ spin and parity assignments in even-even nuclei [1]. Later, Beliaev and Zelevinsky at Kurchatov Institute explored this problem theoretically and proposed the nature of low-lying nuclear collective modes is just waves of the pair distortion [2]. In well-deformed nuclei, these waves become rotational states with angular momentum 2, but with a significantly

lower moment of inertia than it would be for a macroscopic solid-body rotation as in a normal Fermi system. The proposed formalism described such fluctuations and quantized them as phonons plus anharmonicity that should be more pronounced than in macroscopic systems. Similar phenomena were investigated in macroscopic superconductors, the so-called Bardasis-Schriffer modes [3, 4].

It is well-established that the ground state spin and parity values for even-even nuclei are 0^+ [5] while excited states assignments are less certain [6, 7, 8]. Historic compilations of the first excited states J^π show the dominance of angular momentum 2 and positive parity [1, 9, 10], and these systematic trends have not been revisited since the 70s [9, 11]. It is time to bridge the gap in the lowest excited state spin and parity trend assessments, update the compilations and study all presently-available data.

2. ENSDF Survey of Even-Even Nuclei

To evaluate spin and parity assignments across the nuclear chart, ENSDF relational database [6, 7] was surveyed using Structured Query Language (SQL) queries at the Nuclear Data Section (NDS), International Atomic Energy Agency. The survey findings are shown in Table 1.

Table 1: ENSDF library [6, 7] first excited states survey J^π values.

J^π	#	%
2_1^+	631	96.0
0_2^+	20	3
1_1^-	2	0.3
3_1^-	2	0.3
$(8_1^-)?,(9_1^-,10_1^-)?$	2	0.3

The table data show that the first excited state spins and parities are known for 657 even-even nuclei, where 2_1^+ states are observed in 631 or 96% of even-even nuclei. Other observed J^π values are 0_2^+ , 1_1^- and 3_1^- . Limited data for ^{254}Rf and ^{270}Ds suggest states with tentative spin and parity assignments of (8^-) and $(9^-,10^-)$, respectively. The level schemes in these two nuclei are fragmented and need further clarifications; they have to be reassessed in the future when more data will be available.

The 2^+ first-excited state assignment is natural for non-spherical rotational nuclei where the nuclear symmetry restricts the positive parity band to $0^+, 2^+, 4^+, \dots$ states

$$J = \begin{cases} 0, 2, 4, \dots & \text{for } K^\pi = 0^+ \\ 1, 3, 5, \dots & \text{for } K^\pi = 0^- \end{cases}, \quad (1)$$

where J is the total angular momentum, and K is the projection of J on the 3-axis in the intrinsic frame. In this case, 2^+ is the first excited positive parity band state, and its energy is defined by the minimum perturbation of the ground 0^+ state. The energies of rotational states are described as

$$E_J = \frac{\hbar^2}{2I} J(J+1) + E_K, \quad (2)$$

where I is moment of inertia, and E_K represents contributions from the intrinsic part of wave function. From formula 2, one can easily deduced a 10/3 ratio between 4_1^+ and 2_1^+ rotational states energies.

Spherical nuclei show a tendency for vibrational states: $2_1^+, 0_2^+, 2_2^+, 4_2^+, \dots$. Other lowest excited state assignments $0^+, 1^-$ and 3^- are found in closed-shell or subshell cases. Despite multiple efforts [1, 2, 9], we do not have a comprehensive nuclear theory that would describe first excited states in even-even nuclei quantitatively [12], and nuclear data re-analysis can help to fill the void.

3. Systematics of $0_2^+, 1_1^-, 3_1^-$, and 2_1^+ Excited States

In the present work, all available experimental data for non 2^+ low-lying states were critically reexamined using the standard ENSDF library procedures [13], and 2^+ data were adopted from the ENSDF library [6, 7] and the dedicated horizontal evaluation of $B(E2\uparrow)$ [14]. Numerical results for 0_2^+ and $1_1^-, 3_1^-$ nuclear levels are shown in Tables 2 and 3 while the complete list of 2_1^+ levels is given in Table 4. Analysis of the Tables 2, 3, and 4 data implies that non 2^+ ($0^+, 1^-$ and 3^-) lowest excited states occur near shell or subshell closure or in self-conjugate ($N=Z$) nuclei. Further examination of the non 2^+ $E4_1^+/E2_1^+$ ratios produces numerical values from 1.058 to 2.072. These values lie below the vibrational nuclei range of 2-2.2 and are completely inconsistent with the 10/3 ratio in rotational nuclei [15], and the nuclear shell model is needed for the interpretation of J^π assignments in the previously mentioned nuclei. Supplementary discussion on level properties is given in the following subsections.

Table 2: List of 0_2^+ Lowest Excited States in Even-Even Nuclei. Tentative spin and parity assignments are shown in parentheses.

3.1. 0_2^+ Excited States

The low-lying 0^+ states in even-even nuclei serve as an indication of shape coexistence [75, 76]. Analysis of the Table 2 data demonstrates that 0^+ first excited states materialize near Z , $N=2,8,20$, $N=40$, and $Z=82$, often in self-conjugate nuclei. The two notable exceptions are ^{44}Ar [21, 77] and ^{72}Kr [32, 78]. Further examination of ^{44}Ar [79] raises serious doubts about the existence of a low-lying 0^+ level at 750 keV due to background spectra interpretations. The situation with the ^{72}Kr 0^+ state is more complex because spin and parity assignments are based on a single measurement [32, 78]. Likely, the 0_2^+ state in ^{44}Ar was erroneously reported in ENSDF while ^{72}Kr needs additional measurements.

Low-lying 0^+ states have been observed in many even-even nuclei. They alter the nuclear structure and decay properties and impact basic and fundamental science applications. ^{96}Zr is a long-lived radioactive isotope that can disintegrate via single and double-beta decay processes. It has many unique properties, including the lowest quadrupole deformation parameter (β_2) of 0.0615(33) [14] and the second-highest $2_1^+ \rightarrow 0_1^+$ transition energy among zirconium nuclei. Fig. 1 data reveal β_2 value in the $N = 56$ ^{96}Zr is surprisingly lower than in the $N = 50$ magic ^{90}Zr . On the surface, it looks like a new “magic” nucleus. At the same time, a recent attempt to calculate ^{96}Zr double-beta decay half-life assuming the present value of quadrupole deformation overestimated experimental half-life by a factor of 80 [80].

To investigate these magic-like properties, we would consider zirconium charge radii [81], two-neutron separation, and nucleon binding energies [82]. The Fig. 2 data on zirconium radii, $2n$ -separation, and binding energies indicate that $N = 50$ is a good magic number in zirconium, and we have to consider additional quantities for an understanding of the above-mentioned phenomena. Complementary analysis of the ENSDF library [6, 7] level schemes reveals intruder bands in $^{90,96,98}\text{Zr}$ as shown in Fig. 3. These bands are positioned below the 2_1^+ state energies, and the low-lying 0_2^+ state points to the shape coexistence phenomenon in zirconium nuclei. Further theoretical analysis [83] shows that both spherically symmetrical and deformed states are present in $^{90,96,98}\text{Zr}$ rendering β_2 values immaterial. This finding concurs with the Beliaev-Zelevinsky hypothesis [2] that the formally-calculated β_2 noticeably smaller than 0.1 is too low for actual (not fluctuational) static deformation. The zirconium nuclei demonstrate the limits of applicability for deformation parameters and the urgent need for comprehensive analyses

based on multiple quantities for the interpretation of nuclear physics observables.

3.2. 1^-_1 and 3^-_1 and Other Excited States

Low-lying 1^- and 3^- states are found in closed-shell carbon, oxygen, gadolinium, and lead nuclei. The nuclear shell model shows that the low-lying excited states in doubly-closed shell nuclei originate from (a) 1p-1h excitations that can have a range of J^π related to the orbits near the Fermi surface and (b) 0^+ 2p-2h and 4p-4h "intruder" states. For ^{14}O and ^{14}C the lowest pair is $\text{p}_{1/2}-\text{s}_{1/2}$ leading to 0^- and 1^- states. Next to this $\text{p}_{1/2}-\text{d}_{5/2}$ configuration results in 2^- and 3^- states. All of these are low-lying excitations in ^{14}O and ^{14}C , and the lowest state is defined by the Hamiltonian. For ^{146}Gd and ^{208}Pb , most of the lowest 1p-1h states change parity and there are many ways to assemble a given J . Thus it is natural that the lowest of these configurations should be the octupole collective 3^- state. These octupole states are experimentally observed, and the 3^-_1 excited-state in the doubly magic nucleus ^{208}Pb is tied to a large octupole collectivity of 34 Weisskopf units (W.u.) [84, 85, 86].

Lastly, the low-lying 1^-_1 states are found in ^{14}C and ^{14}O mirror nuclei with Z, N=8 shell closure. The Z, N=82 shell closures provide two cases of the 3^-_1 states in ^{146}Gd and ^{208}Pb . Table 3 data provide the full list and show the rationale for 1^-_1 and 3^-_1 spin and parity in even-even nuclei.

In ^{254}Rf and ^{270}Ds tentatively-assigned levels (8-) and (9-,10-), respectively, were reported [72, 74, 73]. As available experimental data for excited states for superheavy ($Z>100$) nuclei are generally rare, the listed excited states may or may not be the first excited states.

3.3. 2^+_1 Excited States

Finally, ENSDF library numerical results for the lowest 2^+ excited states are shown in Table 4. The ENSDF library for individual nuclei is generally updated every 10 years or so, and it is educational to compare these data with a $B(E2\uparrow)$ horizontal evaluation [14] that was published six years ago. The comparison finds 10 first excited state half-lives that were introduced recently and absent in the horizontal evaluation. Supplemental analysis of the horizontal evaluation reveals 42 levels $T_{1/2}$ values that are missing in ENSDF. These latter values are included into Table 4 for completeness. This combination of ENSDF and horizontal $B(E2\uparrow)$ evaluations produce the comprehensive up-to-date table for the 2^+_1 states.

Table 4: List of 2^+_1 States in Even-Even Nuclei. Tentative spin and parity assignments are shown in parentheses,* or ** symbols for the nuclei where $T_{1/2}$ values are taken or updated, respectively, using Ref. [14]. † symbol was used to mark nuclei where half-lives were recently updated in ENSDF, and missing in Ref. [14].

4. Conclusions

Spin and parity assignments in even-even nuclei have been a fascinated topic in nuclear physics for the last 70 years. Many new measurements have been conducted in recent years [87], and the data update was a long time overdue. We surveyed first-excited state properties across the nuclear chart using the Evaluated Nuclear Structure Data File (ENSDF) and other available data. The prevalence of 2_1^+ states was confirmed, and properties of 0_2^+ , 1_1^- , and 3_1^- states were reevaluated.

In summary, we would reiterate that there is no comprehensive theoretical explanation for the 2^+ lowest excited state spin and parity dominance in even-even nuclei, and previous theoretical works [2, 9] imply that both neutron and protons should be considered as contributing factors. We hope the current nuclear properties update of 2_1^+ in conjunction with 0_2^+ , 1_1^- , and 3_1^- states would stimulate future theoretical and experimental studies that would help to clarify this phenomenon.

5. Acknowledgments

The authors are indebted to the International Network of Nuclear Structure and Decay Data (NSDD) Evaluators [8, 7] members for their tireless work on the ENSDF library evaluations, Vladimir Zelevinsky (Michigan State University) for useful discussions, and the referee for good comments and productive suggestions that helped to improve the manuscript. Work at Brookhaven was funded by the Office of Nuclear Physics, Office of Science

of the U.S. Department of Energy, under Contract No. DE-SC0012704 with Brookhaven Science Associates, LLC.
