Abstract

The kinetic mixing of two $U(1)$ gauge theories can result in a massless photon that has perturbative couplings to both electric and magnetic charges. This framework can be used to perturbatively calculate in a quantum field theory with both kinds of charge. Here we re-examine the running of the magnetic charge, where the calculations of Schwinger and Coleman sharply disagree. We calculate the running of both electric and magnetic couplings and show that the disagreement between Schwinger and Coleman is due to an incomplete summation of topological terms in the perturbation series. We present a momentum space prescription for calculating the loop corrections in which the topological terms can be systematically separated for resummation. Somewhat in the spirit of modern amplitude methods we avoid using a vector potential and use the field strength itself, thereby trading gauge redundancy for the geometric redundancy of Stokes surfaces. The resulting running of the couplings demonstrates that Dirac charge quantization is independent of renormalization scale, as Coleman predicted. As a simple application we also bound the parameter space of magnetically charged states through the experimental measurement of the running of electromagnetic coupling.

1 Introduction

In 1904 J.J. Thomson [1] recorded a significant fact regarding the interactions of electric and magnetic particles. He considered an electric charge that produces a Coulomb field

$$\vec{E}(\vec{r}) = \frac{eq}{4\pi} \frac{\vec{r} - \vec{r}_e}{|\vec{r} - \vec{r}_e|^3}, \quad (1)$$

where e is the electric coupling and q is the actual (dimensionless) charge of the particle. At some distance away he added a fixed magnetic charge which produces the monopole field

$$\vec{B}(\vec{r}) = \frac{bg}{4\pi} \frac{\vec{r} - \vec{r}_b}{|\vec{r} - \vec{r}_b|^3}, \quad (2)$$

where b is the magnetic coupling and g is the magnetic charge of this particle. Thomson then calculated the angular momentum carried by the electric and magnetic fields and found

$$\vec{L} = \frac{eqbg}{4\pi} \hat{R}, \quad (3)$$

where $\hat{R} = \vec{r}_b - \vec{r}_e$.

This result is suggestive of two properties of electric-magnetic interactions. First, the quantization of angular momentum is directly tied to a quantized relationship between electric and magnetic couplings and charges discovered by Dirac [2]: $eqbg$ must be a multiple of 2π . Second, there is a topological aspect to the interaction of electric and magnetic charges. This follows from the angular momentum having no dependence on the distance between the charges. The direction of the angular momentum is given by the unit vector \hat{R} that points from the electric charge to the magnetic, but the magnitude of the angular momentum has no dependence on the geometry of the system.

It is now fairly widely understood that the resolution of the Weinberg paradox [3] (the non-Lorentz invariance of tree-level electric-magnetic scattering amplitudes) relies on a careful accounting of topological effects [4]: the perturbative Lorentz breaking appears only in topological terms that re-sum to an overall phase, and the phase is trivial multiple of 2π provided that Dirac charge quantization is satisfied. However when considering loop corrections that induce running of the electric coupling, another paradox arises. The first calculation, due to Schwinger [5, 6], indicated that the magnetic coupling runs just as the electric coupling does, but in that case the overall phase discussed above is trivial only at a particular renormalization scale and Lorentz violation would again rear its ugly head.

As emphasized by Coleman [7], a field theorist confronted with Dirac’s charge quantization should ask “At what scale?” That is, given a product of couplings that run with energy scale, why is the product quantized at some particular renormalization scale? The answer is that Dirac charge quantization can only make sense if the product of electric and magnetic couplings is a renormalization group invariant. Thus Coleman concluded that the magnetic coupling runs inversely to the electric running.

Some might be tempted to dismiss the whole Schwinger-Coleman debate as unresolvable, since it must necessarily involve issues of strong coupling. This is not really the case; we can make use of “dark” magnetic monopoles [8], a framework that allows us to work perturbatively with both electric and magnetic charges since the magnetic charge is suppressed by a dimensionless kinetic mixing between the ordinary photon and a massive “dark” photon. The price we must pay is that the magnetic monopoles are confined by a “dark” magnetic flux tube (which can be described perturbatively in an effective theory below the mass of the “dark” Higgs which provided the photon mass) and the fact that the re-summed topological phases are no longer trivial (and depend on the flux tube orientation). However, the point is that the topological terms can still be identified and re-summed, independent of whether the resulting phase is a multiple of 2π or not.

We show in this paper that a proper accounting of topological terms (which should be re-summed into overall phases) allows one to show, using perturbative calculations in momentum space, that Coleman’s argument is correct. However, a systematic analysis for separating the topological pieces from an amplitude is quite subtle. Here we are aided by recasting the calculation in terms of field strength propagators rather than gauge potential propagators. The former have the advantage that they are manifestly gauge invariant. They have been advocated in the past for position space calculations [9–13], but their couplings to currents are quite strange: nonlocal and seemingly dependent on the (non-unique) Stokes surface to which the field strengths couple (as opposed to the currents themselves). Nevertheless, we find that the Stokes surface ambiguity does not appear in scattering amplitudes and we show how to write field strength interactions in a form suitable for momentum space calculations. Without this last step the formalism would just be formalism, unable to aid in practical calculations, for instance those related to the phenomenology of “dark” monopoles [14–18]. An essential ingredient is to have a simple momentum space description of a Stokes surface corresponding to particles with arbitrary momentum. Using these methods we are able to extract the running of both electric and magnetic couplings and verify that their product is renormalization scale independent. The running of the magnetic coupling is also consistent with the results of Seiberg-Witten theory [19] where light, dynamical monopoles can be under perturbative control in the low-energy effective theory.

In the following section we review the past calculations of magnetic charge renormaliza-

tion and the topological aspect of electric-magnetic interactions without invoking a specific Lagrangian formulation. In so doing we find that the topological part of the amplitude can be separated from the dynamical part when the Stokes surfaces bounded by electric or magnetic currents are used. These surfaces can be thought of as sources for the field strength or its dual. This naturally leads to a discussion of objects that map from two-forms, like surfaces and field strengths, to other two-forms. In Sec. 3 we consider these mappings generally and outline many of their properties. In Sec. 4 we show how these objects can be used to make the standard calculations of quantum electrodynamics (QED).

We then generalize to theories with both electric and magnetic interactions, using a single vector potential, and show how the coupling renormalization described by Schwinger appears, along with extra contributions which signal that a subtle mistake has been made. The problem is that topological terms are embedded within the one-loop calculation such that they are difficult to recognize. The careful removal of the topological terms from the perturbation series is shown to produce exactly the renormalization condition obtained by Coleman. In Sec. 5, we confirm these results using Zwanziger's two potential formalism [20] in two ways. In particular, we exhibit a particularly simple and concise language for these calculations in which electromagnetic dualities are manifest. These results are used, in Sec. 6, to find a simple phenomenological constraint on milli-magnetic charged particles from the measured running of the electric coupling. We offer conclusions and outlook in Sec. 7. Technical details related to the derivation of field strength propagators, the surfaces that source field strengths, and the potential based renormalization in the Zwanziger formalism are provided in Appendices A, B, and C, respectively.

2 Review of Past Claims and Counterclaims

Schwinger's classic result on magnetic charge renormalization [5, 6], subsequently supported by other calculations [21–23], is that the electric and magnetic couplings are renormalized by the same function

$$e(\mu) = \sqrt{Z_S(\mu)}e_0, \quad b(\mu) = \sqrt{Z_S(\mu)}b_0, \quad (4)$$

implying that the ratio of the couplings e/b is a renormalization group invariant. In terms of charge quantization this seems to require that $Z_S(\mu)$ is a rational number, which is at odds with the usual understanding of a running coupling.

The alternative result, obtained by Coleman [7] and others [12, 24, 25] is that the electric and magnetic couplings are renormalized exactly inversely

$$e(\mu) = \sqrt{Z(\mu)}e_0, \quad b(\mu) = \frac{b_0}{\sqrt{Z(\mu)}}. \quad (5)$$

In this case the product of the couplings eb is a renormalization group invariant. The usual choice is to take

$$b(\mu) = \frac{4\pi}{e(\mu)} , \quad (6)$$

leading to the Dirac quantization condition on the charges

$$qg = \frac{N}{2} . \quad (7)$$

This result agrees with our usual understanding of running couplings and also indicates why a theory with perturbative electric couplings to the photon implies a non-perturbative magnetic coupling to the photon.

This non-perturbative aspect of theories with both types of charges leads to significant calculational difficulties. A simpler case to analyze is to consider a small kinetic mixing between two $U(1)$ gauge theories where one of the gauge bosons has acquired a mass through a Higgs mechanism. This is one of the standard scenarios for a class of dark matter models [26], and we refer to the massive photon as the “dark” photon. In this scenario the massless photon can have perturbative couplings to both types of charges [8, 14, 15, 27–30], though at least one of the types of particles must be confined by the interactions with the “dark” photon. In particular, if the magnetically charged particles are “dark” (i.e. they only couple to the “dark” photon in the absence of kinetic mixing), then their coupling to the ordinary photon can be arbitrarily small, suppressed by the kinetic mixing. The only “dark” electric charges required are those of the “dark” Higgs, which can be heavy, and integrated out of the theory. These results imply that there is a class of effective theories with perturbative interactions for both electric and magnetic particles with a photon. Still, non-perturbative information is a powerful guide, and the constraint that topological terms must become trivial when Dirac charge quantization is imposed is seen to be extremely helpful.

Theories with both electric and magnetic charges have equations of motion that are just the extended Maxwell equations:

$$\partial_\mu F^{\mu\nu} = eJ^\nu, \quad \partial_\mu {}^*F^{\mu\nu} = bK^\nu , \quad (8)$$

with J^μ the electric current and K^μ the magnetic current and where the dual field strength is defined by

$${}^*F^{\mu\nu} = \frac{1}{2} \varepsilon^{\mu\nu\alpha\beta} F_{\alpha\beta} . \quad (9)$$

One manifestation of the difficult nature of theories with both kinds of charges is the variety of Lagrangian formulations that have been employed to characterize them [31]. In general

one has to sacrifice either manifest Lorentz invariance or manifest locality in order to even write a Lagrangian, so these theories have acquired the nickname “mutually non-local” theories.

Of course, Thomson’s result (3) does not rely on any particular Lagrangian formulation of electrodynamics. Similarly, Weinberg determined a crucial aspect of the quantum field theory of electric-magnetic interactions without assuming any Lagrangian [3]. After defining two vector potentials, one A_μ with local couplings to electric currents and one B_μ with local couplings to magnetic currents, he found the propagator between them to be¹

$$\int d^4x e^{-ik \cdot (x-y)} \langle \mathbf{0} | T \{ A_\mu(x) B_\nu(y) \} | \mathbf{0} \rangle \equiv \Delta_{\mu\nu}^{AB} = -i \frac{\varepsilon_{\mu\nu\alpha\beta} n^\alpha k^\beta}{k^2 (n \cdot k)}, \quad (10)$$

where k^μ is the propagating momentum and n^μ is a constant vector. It is, of course, the dependence on n^μ (and the associated spurious pole) that is most unsettling.

However, this perplexing dependence on n^μ can be tied to the topological nature of Thomson’s calculation. Consider the leading order correlation of an electric current with a magnetic current

$$i\mathcal{M}_0^{JK} = -ieJ^\mu(-i) \frac{\varepsilon_{\mu\nu\alpha\beta} n^\alpha k^\beta}{k^2 (n \cdot k)} (-ib)K^\nu = ieb \frac{\varepsilon_{\mu\nu\alpha\beta} J^\mu K^\nu n^\alpha k^\beta}{k^2 (n \cdot k)}. \quad (11)$$

Using the worldline formulation [10–12, 32, 33] we can write the external currents as

$$J^\mu(x) = q \int_{C_J} dz_J^\mu \delta^{(4)}(x - z_J), \quad K^\mu(x) = g \int_{C_K} dz_K^\mu \delta^{(4)}(x - z_K), \quad (12)$$

where C_J and C_K are the spacetime paths (worldlines) of the electric and magnetic charges, respectively. The mixed propagator in position space is

$$\Delta_{\mu\nu}^{AB}(x-y) = -\Delta_{\mu\nu}^{BA}(x-y) = \frac{1}{4\pi^2} \frac{\varepsilon_{\mu\nu\alpha\beta} n^\alpha \partial^\beta}{n \cdot \partial} \frac{1}{(x-y)^2 + i\epsilon}. \quad (13)$$

We can then write the lowest order tree-level interaction of an electric and a magnetic current as

$$\begin{aligned} \mathcal{M}_0^{JK} &= \int d^4x d^4y J^\mu(x) \Delta_{\mu\nu}^{AB}(x-y) K^\nu(y) \\ &= \frac{ebqg}{4\pi^2} \int dz_J^\mu dz_K^\nu \frac{\varepsilon_{\mu\nu\sigma\rho} n^\sigma \partial^\rho}{n \cdot \partial} \frac{1}{(z_J - z_K)^2}. \end{aligned} \quad (14)$$

¹We use slightly different notation than Weinberg, but an equivalent result.

Using Stokes' theorem,

$$\int_{\partial S} dz^\mu A_\mu = \int_S d^2\sigma_{\alpha\beta}\varepsilon^{\alpha\beta\mu\nu}\partial_\mu A_\nu, \quad (15)$$

on both particle trajectories we find

$$\begin{aligned} \mathcal{M}_0^{JK} &= \frac{ebqg}{4\pi^2} \int d\sigma_{\alpha\beta}^J d\sigma_{\gamma\delta}^K \varepsilon^{\alpha\beta\mu\lambda} \partial_\mu \varepsilon^{\gamma\delta\nu\xi} \partial_\nu \frac{\varepsilon_{\lambda\xi\sigma\rho} n^\sigma \partial^\rho}{n \cdot \partial} \frac{1}{(z_J - z_K)^2} \\ &= \frac{2ebqg}{4\pi^2} \int d\sigma_{\alpha\beta}^J d\sigma_{\gamma\delta}^K \varepsilon^{\alpha\beta\mu\lambda} \partial_\mu (\delta_\lambda^\gamma \partial^\delta n \cdot \partial - \delta_\lambda^\delta n^\delta \partial^2) \frac{1}{n \cdot \partial} \frac{1}{(z_J - z_K)^2}. \end{aligned} \quad (16)$$

Significantly, the first term is independent of n^μ and has the usual massless pole of photon exchange. The second term does depend on n^μ but does not have the usual massless pole. This latter term has been shown to be a pure number given by $4\pi^2$ times the number of intersections of the Stokes surface bounded by the worldline of the electric particle and the surface swept out by the magnetic worldline and the ray along n^μ , see refs. [4, 34, 35]. These papers show that with n^μ chosen to be spacelike it simply represents the direction of the Dirac string, and the surface is just the world-sheet of the Dirac string. The number of intersections is equivalent to the 4D topological linking number of a worldline and a Stokes surface [4]. That such a topological term should appear may be surprising, but it can be understood as a manifestation of Thomson's discovery about the interactions of electric and magnetic charges.

This topological term can confuse the perturbative expansion captured by Feynman diagrams. When we perform calculations we are interested in the perturbation series

$$(1 + ie^2 a_1 + ie^4 a_2 + \dots) e^{i\varphi}, \quad (17)$$

which captures the dynamics of the currents and fields. When theories with electric and magnetic particles are written in terms of surfaces, or two-form interactions, this topological phase φ can be separated from the other field dynamics, keeping it from appearing in perturbative calculations. However, when currents are directly coupled to potentials these terms cannot be fully separated. The perturbation series is then

$$1 + i\varphi + ie^2 a_1 - e^2 a_1 \varphi + ie^4 a_2 - \frac{1}{2} \varphi^2 + \dots \quad (18)$$

In this work we show how to recognize all manifestations of terms like $a_1 \varphi$, which we want to carefully separate from the field dynamics so that they can be re-summed as an overall phase. We show that standard potential calculations very nearly accomplish this,

but run afoul of these mixed terms in loop effects. By organizing the perturbation series in a new way we show how to completely separate the effects of topological terms. This novel organization is completely equal, algebraically, to the usual potential based calculations. However, the seemingly complicated way of writing the amplitudes, and in separating out the topological parts, are most easily understood in the language of mappings from two-forms to two-forms.²

The mappings we are interested can be found in the way the photon field connects the Stokes surfaces bounded by currents. In momentum space the mapping from two-forms to two forms related to photon propagation is

$$\frac{\alpha\beta}{(k)}P_{(k)}^{\gamma\delta} = \frac{1}{2k^2} (\eta^{\alpha\gamma}k^\beta k^\delta - \eta^{\alpha\delta}k^\beta k^\gamma - \eta^{\beta\gamma}k^\alpha k^\delta + \eta^{\beta\delta}k^\alpha k^\gamma) , \quad (19)$$

where $\eta_{\mu\nu}$ is the Minkowski metric, $\eta_{\mu\nu} = \text{Diag}(1, -1, -1, -1)$. While this object is not familiar to most, we see in the following sections that it can be interpreted as being simply proportional to the field strength propagator.

As a simple example, we can see that the mapping $\frac{\alpha\beta}{(k)}P_{(k)}^{\gamma\delta}$ appears when we write the first term of the leading electric-magnetic interaction given in Eq. (16) in momentum space:

$$\begin{aligned} & \frac{eqbg}{2\pi^2} \int d\sigma_{\alpha\beta}^J d\sigma_{\gamma\delta}^K \varepsilon^{\alpha\beta\mu\gamma} \partial_\mu \partial^\delta \frac{1}{(z_J - z_K)^2} \\ &= \frac{qg}{2\pi^2} \int d\sigma_{\alpha\beta}^J d\sigma_{\gamma\delta}^K \frac{1}{4} \varepsilon^{\alpha\beta\mu\nu} (\delta_\nu^\gamma \partial_\mu \partial^\delta + \delta_\mu^\delta \partial_\nu \partial^\gamma - \delta_\nu^\delta \partial_\mu \partial^\gamma - \delta_\mu^\gamma \partial_\nu \partial^\delta) \frac{1}{(z_J - z_K)^2} , \\ &= eqbg \int d\sigma_{\alpha\beta}^J \frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} d\sigma_{\gamma\delta}^K \frac{1}{2} \varepsilon^{\gamma\delta\sigma\rho} d^4 k e^{-ik \cdot (z_J - z_K)} (-2i)_{\mu\nu}^{(k)} P_{*\sigma\rho}^{(k)} , \end{aligned} \quad (20)$$

where we have used a standard result for the double summation of Levi-Civita tensors:

$$-\frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} \frac{1}{2} \varepsilon_{\mu\nu\gamma\delta} = \frac{1}{2} (\eta_\gamma^\alpha \eta_\delta^\beta - \eta_\delta^\alpha \eta_\gamma^\beta) . \quad (21)$$

The second term in Eq. (16), what we somewhat loosely call the topological part of electric-magnetic interactions³, can be written as

$$\begin{aligned} & -\frac{eqbg}{2\pi^2} \int d\sigma_{\alpha\beta}^J \frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} d\sigma_{\gamma\delta}^K \frac{1}{2n \cdot \partial} (\delta_\nu^\gamma \partial_\mu n^\delta - \delta_\mu^\gamma \partial_\nu n^\delta - \delta_\nu^\delta \partial_\mu n^\gamma + \delta_\mu^\delta \partial_\nu n^\gamma) \partial^2 \frac{1}{(z_J - z_K)^2} \\ &= eqbg \int d\sigma_{\alpha\beta}^J \frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} d\sigma_{\gamma\delta}^K \frac{1}{2} \varepsilon^{\gamma\delta\sigma\rho} d^4 k e^{-ik \cdot (z_J - z_K)} (2i)_{\mu\nu}^{(k)} P_{*\sigma\rho}^{(n)} , \end{aligned} \quad (22)$$

²In this work we use the term two-form to apply to antisymmetric tensors like $F_{\mu\nu}$ even when the basis of differentials $F_{\mu\nu} dx^\mu \wedge dx^\nu$ are not explicitly included.

³To be strictly topological the surface must be closed, which can be achieved by splitting the Dirac string into two strings that go off in opposite directions, but the extra effort hardly seems worth it.

where we have used the fact that

$$\partial^2 \frac{1}{(z_J - z_K)^2} = -i4\pi^2 \delta^{(4)}(z_J - z_K) , \quad (23)$$

and the notation

$$\binom{\alpha\beta}{(n)} P_{(k)}^{\gamma\delta} = \frac{1}{2n \cdot k} (\eta^{\alpha\gamma} n^\beta k^\delta - \eta^{\alpha\delta} n^\beta k^\gamma - \eta^{\beta\gamma} n^\alpha k^\delta + \eta^{\beta\delta} n^\alpha k^\gamma) . \quad (24)$$

This shows that, remarkably, the topological term can also be written as a mapping from two-forms to two-forms. Therefore, using such objects allows one to concisely navigate quantum field theories with electric and magnetic interactions. For instance the full mixed electric-magnetic charge interaction can be written as

$$\begin{aligned} & -2ieqbg \int d\sigma_{\alpha\beta}^J \frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} d\sigma_{\gamma\delta}^K \frac{1}{2} \varepsilon^{\gamma\delta\sigma\rho} d^4k e^{-ik \cdot (z_J - z_K)} \left(\binom{(k)}{\mu\nu} P_{*\sigma\rho}^{(k)} - \binom{(k)}{\mu\nu} P_{*\sigma\rho}^{(n)} \right) \\ & = -2ieqbg \int d\sigma_{\alpha\beta}^J \frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} d\sigma_{\gamma\delta}^K \frac{1}{2} \varepsilon^{\gamma\delta\sigma\rho} d^4k e^{-ik \cdot (z_J - z_K)} \binom{(k)}{\mu\nu} P_{\lambda\kappa}^{(k)*} \binom{(n)}{\sigma\rho} P_{\sigma\rho}^{(k)} . \end{aligned} \quad (25)$$

This last version of the interaction does not naively appear to easily separate into topological and dynamical terms, which can make separating out the topological contribution difficult. Contributions exactly like this term appear repeatedly in the potential formulation of loop effects in the quantum field theory of electric-magnetic interactions. It is by identifying and dealing with these terms in one-loop processes that we are able to determine the correct running of electric and magnetic couplings: the running predicted by Coleman.

3 Mappings on the Space of Two-Forms

In what follows we typically consider interactions within the six dimensional space of space-time two-forms. This is essential for readers that want to work through the algebra in the subsequent section. However, those that are satisfied to accept those calculations as correct may skip this section without losing the logical progression of the paper.

The space of two-forms has an identity element and metric given by

$$\alpha\beta I_{\gamma\delta} = \frac{1}{2} (\eta_{\alpha\gamma} \eta_{\beta\delta} - \eta_{\alpha\delta} \eta_{\beta\gamma}) , \quad (26)$$

which can be used to raise or lower the pairs of indices belonging to a two-form. There is also the duality operator on any two-form $F_{\alpha\beta}$

$$\frac{1}{2} \varepsilon^{\alpha\beta\gamma\delta} F_{\alpha\beta} \equiv *F^{\gamma\delta} . \quad (27)$$

When the free indices are contracted which two-form is associated with the duality operator is a matter of choice, that is

$$*A_{\mu\nu}B^{\mu\nu} = A_{\mu\nu}*B^{\mu\nu} . \quad (28)$$

We note that the duality operator is related to the identity by

$$\frac{1}{2}\varepsilon^{\alpha\beta\mu\nu}\frac{1}{2}\varepsilon_{\mu\nu\gamma\delta} = -\alpha^\beta I_{\gamma\delta} , \quad (29)$$

as we saw in Eq. (21). This means that when any dualized indices are contracted with other dualized indices we find

$$*A_{\mu\nu}*B^{\mu\nu} = -A_{\mu\nu}B^{\mu\nu} . \quad (30)$$

Any product of two dualizing operators can be written in terms of the identity operator according to

$$\begin{aligned} & -\frac{1}{4}\varepsilon_{\alpha\beta\gamma\delta}\varepsilon_{\mu\nu\sigma\rho} = \\ & \alpha^\beta I_{\mu\nu} \gamma^\delta I_{\sigma\rho} + \gamma^\delta I_{\mu\nu} \alpha^\beta I_{\sigma\rho} - \alpha^\gamma I_{\mu\nu} \beta^\delta I_{\sigma\rho} - \beta^\delta I_{\mu\nu} \alpha^\gamma I_{\sigma\rho} + \alpha^\delta I_{\mu\nu} \beta^\gamma I_{\sigma\rho} + \beta^\gamma I_{\mu\nu} \alpha^\delta I_{\sigma\rho} , \end{aligned} \quad (31)$$

which also leads to

$$\varepsilon^{\gamma\delta\nu\rho}\varepsilon_{\alpha\beta\mu\rho} = -\delta_\alpha^\gamma (\delta_\beta^\delta \delta_\mu^\nu - \delta_\mu^\delta \delta_\beta^\nu) - \delta_\beta^\gamma (\delta_\mu^\delta \delta_\alpha^\nu - \delta_\alpha^\delta \delta_\mu^\nu) - \delta_\mu^\gamma (\delta_\alpha^\delta \delta_\beta^\nu - \delta_\beta^\delta \delta_\alpha^\nu) . \quad (32)$$

As discussed in Sec. 2, we are particularly interested in a class of operators that map two-forms to two-forms, based on two one-forms q_μ and r_μ . This class is defined by

$$\frac{\alpha\beta}{(q)} P_{(r)}^{\gamma\delta} \equiv \frac{1}{2q \cdot r} (\eta^{\alpha\gamma} q^\beta r^\delta - \eta^{\alpha\delta} q^\beta r^\gamma - \eta^{\beta\gamma} q^\alpha r^\delta + \eta^{\beta\delta} q^\alpha r^\gamma) = \frac{\gamma\delta}{(r)} P_{(q)}^{\alpha\beta} . \quad (33)$$

Notice that this operator is antisymmetric in both the first two and last two indices as required for a mapping from two-forms to two-forms.

Consider the action of this operator on the two-form $s \wedge t = \frac{1}{2}(s_\mu t_\nu - s_\nu t_\mu)$

$$\frac{\alpha\beta}{(q)} P_{(r)}^{\gamma\delta} \frac{1}{2} (s_\gamma t_\delta - s_\delta t_\gamma) = \frac{r \cdot t}{2r \cdot q} (s^\alpha q^\beta - s^\beta q^\alpha) + \frac{r \cdot s}{2r \cdot q} (q^\alpha t^\beta - q^\beta t^\alpha) , \quad (34)$$

$$\frac{1}{2} (s_\alpha t_\beta - s_\beta t_\alpha) \frac{\alpha\beta}{(q)} P_{(r)}^{\gamma\delta} = \frac{q \cdot t}{2r \cdot q} (s^\gamma r^\delta - s^\delta r^\gamma) + \frac{q \cdot s}{2r \cdot q} (r^\gamma t^\delta - r^\delta t^\gamma) . \quad (35)$$

The first line projects into the space of two-forms created by taking the wedge product of a vector with q^μ while the second projects into wedge products with r^μ . The coefficients

of each term are related to the scalar products of r^μ and q^μ for the first and second lines, respectively.

The composition of two of these operators is

$$\binom{\alpha\beta}{(q)} P_{(r)}^{\mu\nu(s)} P_{\gamma\delta}^{(t)} = \frac{(q \cdot t)(r \cdot s)}{(q \cdot r)(s \cdot t)} \binom{\alpha\beta}{(q)} P_{\gamma\delta}^{(t)} + \frac{1}{2(q \cdot r)(s \cdot t)} (q^\alpha s^\beta - q^\beta s^\alpha) (r_\gamma t_\delta - r_\delta t_\gamma) . \quad (36)$$

A few useful special cases are

$$\binom{\alpha\beta}{(q)} P_{(r)}^{\mu\nu(r)} P_{\gamma\delta}^{(q)} = \frac{q^2 r^2}{(q \cdot r)^2} \binom{\alpha\beta}{(q)} P_{\gamma\delta}^{(q)} - \frac{1}{2(q \cdot r)^2} (q^\alpha r^\beta - q^\beta r^\alpha) (q_\gamma r_\delta - q_\delta r_\gamma) , \quad (37)$$

as well as

$$\binom{\alpha\beta}{(q)} P_{(q)}^{\mu\nu(r)} P_{\gamma\delta}^{(q)} = \binom{\alpha\beta}{(q)} P_{(r)}^{\mu\nu(q)} P_{\gamma\delta}^{(q)} = \binom{\alpha\beta}{(q)} P_{\gamma\delta}^{(q)} , \quad (38)$$

and

$$\binom{\alpha\beta}{(q)} P_{(r)}^{\mu\nu(q)} P_{\gamma\delta}^{(r)} = \binom{\alpha\beta}{(q)} P_{\gamma\delta}^{(r)} . \quad (39)$$

These operators can also be composed with the duality transformation

$$\frac{1}{2} \varepsilon^{\alpha\beta\mu\nu} \binom{\alpha\beta}{(q)} P_{\mu\nu}^{(r)} \equiv \binom{* \alpha\beta}{(q)} P_{\gamma\delta}^{(r)} , \quad \binom{\alpha\beta}{(q)} P_{\mu\nu}^{(r)} \frac{1}{2} \varepsilon^{\mu\nu\gamma\delta} \equiv \binom{\alpha\beta}{(q)} P_{(r)}^{*\gamma\delta} . \quad (40)$$

Notice that the location of the $*$ denotes which two indices are contracted with the epsilon tensor. This transformation can also be applied to both sides at once, leading to the identity

$$\frac{1}{2q \cdot r} \varepsilon^{\alpha\beta\mu}{}_\rho \varepsilon^{\gamma\delta\nu\rho} q_\mu r_\nu = \binom{* \alpha\beta}{(q)} P_{(r)}^{*\gamma\delta} . \quad (41)$$

One can then explicitly calculate that

$$\binom{\alpha\beta}{(q)} P_{\gamma\delta}^{(r)} - \binom{(r)}{* \alpha\beta} P_{*\gamma\delta}^{(q)} = \alpha_\beta I_{\gamma\delta} , \quad (42)$$

$$\binom{\alpha\beta}{(q)} P_{\gamma\delta}^{(r)} + \binom{(r)}{* \alpha\beta} P_{*\gamma\delta}^{(q)} = \frac{1}{2} \varepsilon_{\alpha\beta\gamma\delta} . \quad (43)$$

This last identity is related to intersection numbers and linking numbers. If we integrate the Fourier transform of Eq. (43) over the surfaces bounded by the J and K current worldlines we find

$$\int d\sigma_{\alpha\beta}^J d\sigma_{\gamma\delta}^K d^4 k e^{-ik \cdot (z_J - z_K)} \left(\binom{* \alpha\beta}{(n)} P_{(k)}^{\gamma\delta} + \binom{\alpha\beta}{(k)} P_{(n)}^{*\gamma\delta} \right) = \int d\sigma_{\alpha\beta}^J d\sigma_{\gamma\delta}^K d^4 k e^{-ik \cdot (z_J - z_K)} \frac{1}{2} \varepsilon^{\alpha\beta\gamma\delta} . \quad (44)$$

The quantity on the right of the equals sign is the intersection number, it counts the (signed) intersections of the surfaces bounded by J and K , which depends on the choice of surfaces.

The two terms on the left-hand side of Eq. (44) also correspond to intersection numbers. The first is the intersections of the K surface with the surface produced by extending the J trajectory along the direction n^μ , which is related to the linking number between the K trajectory and the surface of J extended along n^μ . If the surface were to close by extending along n^μ and $-n^\mu$ it would be the topological linking number of the two surfaces. What appears in the integral is not quite topological because the surface does not extend in both directions. Just as a closed path and an open path can always be unlinked by continuous deformations in three dimensions, so can a closed path and an open surface in four dimensions. This means the intersection number is geometrical, its value depends on the integration surfaces.

The second term on the left side of Eq. (44) is the intersection number between the J surface and the extension of K along n^μ , which is similarly related to the linking number of J trajectory and the surface of K extended along n^μ and $-n^\mu$. When K is only extended along positive n^μ the intersection only has a geometrical interpretation. The simple algebraic result in Eq. (43) shows how these three intersection numbers are related.

The above identities can also be used to determine that

$$\frac{\alpha\beta}{(q)} P_{(r)}^{\mu\nu(s)} P_{\gamma\delta}^{(t)} = \frac{\alpha\beta}{(q)} P_{(r)}^{*\gamma\delta} - \frac{(q \cdot s)(r \cdot t)}{(q \cdot r)(s \cdot t)} \frac{\alpha\beta}{(q)} P_{(s)}^{*\gamma\delta} + \frac{\varepsilon_{\mu\nu\gamma\delta} r^\mu s^\nu}{2(q \cdot r)(s \cdot t)} (q^\alpha t^\beta - q^\beta t^\alpha) . \quad (45)$$

An important special case that we make great use of when considering the interactions of electric and magnetic currents is

$$\begin{aligned} \frac{\alpha\beta}{(q)} P_{(q)}^{\mu\nu(r)} P_{\gamma\delta} &= \frac{\alpha\beta}{(q)} P_{(q)}^{*\gamma\delta} - \frac{\alpha\beta}{(q)} P_{(r)}^{*\gamma\delta} \\ &= - \frac{*\alpha\beta}{(q)} P_{(q)}^{\gamma\delta} + \frac{*\alpha\beta}{(r)} P_{(q)}^{\gamma\delta} . \end{aligned} \quad (46)$$

It is these two equal forms that encode the topological contributions to electric-magnetic interactions when we take q^μ to be the photon momentum, $q^\mu = k^\mu$, and r^μ to be the reference vector $r^\mu = n^\mu$.

Our understanding of these operators is enhanced by considering $\frac{(k)}{\alpha\beta} P_{\gamma\delta}^{(k)}$. The results above make clear that

$$\frac{(k)}{\alpha\beta} P_{(k)}^{\mu\nu} P_{\gamma\delta}^{(k)} = \frac{(k)}{\alpha\beta} P_{\gamma\delta}^{(k)} , \quad \frac{(k)}{\alpha\beta} P_{(k)}^{\mu\nu} P_{\gamma\delta}^{(k)} = 0 \quad \frac{(k)}{\mu\nu} P_{(k)}^{\mu\nu} = 3 . \quad (47)$$

This indicates that $\frac{(k)}{\alpha\beta} P_{\gamma\delta}^{(k)}$ acts as a projector into a three dimensional subspace of two-forms. What subspace is this? Notice that

$$\frac{(k)}{\alpha\beta} P_{(k)}^{\mu\nu} \frac{1}{2} (k_\mu q_\nu - k_\nu q_\mu) = \frac{1}{2} (k_\alpha q_\beta - k_\beta q_\alpha) . \quad (48)$$

This shows that the projector acts as the identity on k_μ wedged with any one-form. If we imagine spacetime spanned by a basis composed of k_μ and three other vectors then the three dimensional two-form space spanned by the wedge product of k_μ and each of the other vectors is exactly the space ${}^{(k)}_{\alpha\beta}P_{(k)}^{\mu\nu}$ projects into. The orthogonal space is projected into by⁴ ${}^{(k)}_{*\alpha\beta}P_{*\gamma\delta}^{(k)}$.

4 Field Strength Based Perturbation Series using a Single Potential

In this section we show how the the usual QED perturbation series, using a single gauge potential A_μ , can be rewritten in terms of the field strength $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$. This is shown for both tree-level and one loop calculations. The higher loop generalization is straightforward. We find that a projector of the type outlined in the previous section naturally occurs in defining the field-strength propagator. We then show how the theory must be modified to consistently incorporate magnetic currents.

We begin with the usual QED Lagrangian for electric currents

$$\mathcal{L} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - eA_\mu J^\mu . \quad (49)$$

This, along with a gauge fixing term, leads to the standard propagator

$$\int d^4x e^{-ik\cdot(x-y)} \langle \mathbf{0} | T \{ A_\mu(x) A_\nu(y) \} | \mathbf{0} \rangle = -i \frac{\eta_{\mu\nu} - (1-\xi) \frac{k_\mu k_\nu}{k^2}}{k^2 - i\varepsilon} \equiv \langle A_\mu A_\nu \rangle_k . \quad (50)$$

The last definition is simply a way to quickly describe the momentum space propagator. The leading order correlation of two currents, see Fig. 1, is the gauge invariant amplitude

$$i\mathcal{M}_0^{JJ} = -ieJ^\mu (-i) \frac{\eta_{\mu\nu} - (1-\xi) \frac{k_\mu k_\nu}{k^2}}{k^2 - i\varepsilon} (-ie)J^\nu = ie^2 \frac{J^\mu J_\mu}{k^2 - i\varepsilon} , \quad (51)$$

where we have used the fact that $k_\mu J^\mu = 0$. In what follows we typically do not write the $i\varepsilon$ terms for simplicity.

⁴Technically the orthogonal complement projector is $-{}^{(k)}_{*\alpha\beta}P_{*\gamma\delta}^{(k)}$ as is clear from the completeness relation in Eq. (42).

Figure 1: Standard one-photon exchange between electric currents. The blue current denotes that it is electric. The blue photon line denotes a coupling to electric charges without using the Levi-Civita tensor.

The leading correction to this correlation function due to a virtual current loop of electric particles is

$$\begin{aligned}
i\mathcal{M}_{1J}^{JJ} &= -ieJ^\mu(-i)\frac{\eta_{\mu\alpha} - (1-\xi)\frac{k_\mu k_\alpha}{k^2}}{k^2}i\Pi_J^{\alpha\beta}(-i)\frac{\eta_{\beta\nu} - (1-\xi)\frac{k_\beta k_\nu}{k^2}}{k^2}(-ie)J^\nu \\
&= ie^2 J_\alpha \frac{k^2 \eta^{\alpha\beta} - k^\alpha k^\beta}{k^4} \Pi_J J_\beta \\
&= ie^2 \Pi_J \frac{J^\mu J_\mu}{k^2} .
\end{aligned} \tag{52}$$

Here we have used the Ward identity to write

$$\Pi_J^{\mu\nu} = \Pi_J(k^2) (k^2 \eta^{\mu\nu} - k^\mu k^\nu) . \tag{53}$$

Combining the leading term and first correction we have

$$\mathcal{M}_0^{JJ} + \mathcal{M}_{1J}^{JJ} = e^2 \frac{J^\mu J_\mu}{k^2} [1 + \Pi_J] \approx e^2 \frac{J^\mu J_\mu}{k^2 [1 - \Pi_J]} . \tag{54}$$

As expected, we see that the loop correction preserves the form of the interaction and only modifies the coupling. That is, we find that

$$Z_e(\mu) = \frac{1}{1 - \Pi_J(\mu^2)} . \tag{55}$$

Using this photon field formalism one can also determine the propagator of two field strengths. A heuristic derivation is

$$\begin{aligned}
\langle F^{\alpha\beta} F^{\gamma\delta} \rangle_k &= k^\alpha k^\gamma \langle A^\beta A^\delta \rangle_k - k^\alpha k^\delta \langle A^\beta A^\gamma \rangle_k - k^\beta k^\gamma \langle A^\alpha A^\delta \rangle_k + k^\beta k^\delta \langle A^\alpha A^\gamma \rangle_k \\
&= -2i \frac{\alpha\beta}{(k)} P_{(k)}^{\gamma\delta} ,
\end{aligned} \tag{56}$$

Figure 2: One electric loop correction to photon exchange between electric currents.

while two different, careful derivations of the same result are given in Appendix A. Note that this propagator is a projector, a mapping of two-forms to two-forms. The space it projects into is the space of two-forms of the form $V \wedge k$ for any one-form V_μ and k_μ the propagating momentum. We can understand why the field strength propagator might have this form because the field strength, in momentum space, is simply

$$F_{\mu\nu} = i(k_\mu A_\nu - k_\nu A_\mu) = 2ik \wedge A . \quad (57)$$

As k_μ does not belong to the ${}^{(k)}_{*\mu\nu}P_{*\sigma\rho}^{(k)}$ subspace, we see that

$$F_{\mu\nu} = {}_{\mu\nu}J_{\alpha\beta}F^{\alpha\beta} = \left({}^{(k)}_{\mu\nu}P_{\alpha\beta}^{(k)} - {}^{(k)}_{*\mu\nu}P_{*\alpha\beta}^{(k)} \right) F^{\alpha\beta} = {}^{(k)}_{\mu\nu}P_{\alpha\beta}^{(k)} F^{\alpha\beta} . \quad (58)$$

In other words, the field strength is completely contained within the ${}^{(k)}_{\mu\nu}P_{\alpha\beta}^{(k)}$ subspace. This also means that the sourceless Lagrangian can be written as

$$\mathcal{L} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} = -\frac{1}{4}F_{\alpha\beta}{}^{\alpha\beta}I^{\gamma\delta}F_{\gamma\delta} = -\frac{1}{4}F_{\alpha\beta}{}^{\alpha\beta}P_{(k)}^{\gamma\delta}F_{\gamma\delta} . \quad (59)$$

Within the subspace ${}^{(k)}_{\mu\nu}P_{\alpha\beta}^{(k)}$ projects onto it acts as the metric and is, therefore, its own inverse. Therefore, we have some similarity to the usual result that a propagator is given by the inverse of the operator appearing in the quadratic part of the Lagrangian.

Of course, to go through the usual path integral calculation of the two-point function we need a source for $F_{\mu\nu}$. Seeing as J_μ is a one-form and $\frac{1}{2}\varepsilon_{\mu\nu\alpha\beta}J^\alpha$ is a three-form neither can couple directly to $F_{\mu\nu}$. However, the usual Maxwell equation in momentum space is

$$ik_\nu F^{\mu\nu} = eJ^\mu . \quad (60)$$

One, particular, solution of this is

$$F_J^{\mu\nu} = -ie \frac{J^\mu n^\nu - J^\nu n^\mu}{n \cdot k} , \quad (61)$$

Figure 3: Schematic illustration of the surfaces the field strength couples to. The infinite surface is bounded by the worldline associated with the current J^μ and lies along the direction n^μ . The surface formally closes at the point at infinity.

We can then motivate that within the Lagrangian

$$-A_\mu J^\mu \rightarrow -A_\mu \partial_\nu F_J^{\mu\nu} \rightarrow \partial_\nu (A_\mu) F_J^{\mu\nu} = \frac{e}{2} F_{\nu\mu} (-i) \frac{J^\mu n^\nu - J^\nu n^\mu}{n \cdot k} = ie F_{\mu\nu} \frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot k}, \quad (62)$$

where the second arrow denotes integration by parts.

With this source term we can define a Feynman rule for how the field strength is generated by electric currents, though it comes at the cost of introducing a reference vector n^μ . As shown in Appendix B, we interpret these vectors as defining the surface bounded by the worldlines associated with the currents J^μ . Though, in principle, one can imagine different surfaces defined for each current we can also choose to use the same vector to define them all.

These surfaces are of a special type, as shown in Fig. 3. The surface erupts from the particle trajectory, which is its boundary, in the direction n^μ and extends out to infinity. Thus, the surface only closes at infinity. Also, as we take *the* point at infinity to truly be a completion of Minkowski space, every surface of this type, even those associated to different n^μ vectors, intersect at infinity.

That the field strength is sourced by an area is expected. But Stokes' theorem holds for any surface that has the same boundary. It is true, as shown in Appendix B, that the theory is independent of the surface chosen. This turns out to simply follow from the field strength being a closed two-form, or in other words it satisfies the Bianchi identity $\partial_\mu {}^*F^{\mu\nu} = 0$. However, finite surfaces in position space do not lead to simple descriptions in momentum space. The family of surfaces we use are somewhat singular in position space, but are simple to express in momentum space.

Figure 4: One-photon exchange between electric currents (blue) using field strengths. Note that the photon lines couple to the surfaces bounded by the worldlines associated with the currents.

We can also obtain these results from a different starting point. Consider the Lagrangian

$$\mathcal{L} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - F_{\mu\nu}\Sigma_J^{\mu\nu} , \quad (63)$$

where $\Sigma_J^{\mu\nu}$ is the as yet unspecified source of $F_{\mu\nu}$. As any symmetric part of this source disappears from the Lagrangian we simply assume that it is antisymmetric, like $F_{\mu\nu}$. The equations of motion for this theory are

$$-\frac{1}{2}F^{\mu\nu} - \Sigma_J^{\mu\nu} = 0 \Rightarrow F^{\mu\nu} = -2\Sigma_J^{\mu\nu} . \quad (64)$$

This is equivalent to the Maxwell equations if

$$-2\partial_\mu\Sigma_J^{\mu\nu} = J^\nu , \quad (65)$$

which leads directly to the same form obtained above.

With this Lagrangian

$$\mathcal{L}_{\text{QED}} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - eF_{\mu\nu}\frac{1}{2n \cdot \partial}(J^\mu n^\nu - J^\nu n^\mu) , \quad (66)$$

we can use the standard Feynman rules to calculate amplitudes. This still uses the photon degrees of freedom associated with A_μ ; we are simply organizing the calculation in a slightly different way. First, consider the scattering of two electric currents by the exchange of a single photon, as in Fig. 4. The amplitude is calculated to be

$$i\mathcal{M}_0^J = ie\frac{J^\alpha n_1^\beta - J^\beta n_1^\alpha}{2n_1 \cdot k}(-2i)_{\alpha\beta}^{(k)}P_{\gamma\delta}^{(k)}ie\frac{J^\gamma n_2^\delta - J^\delta n_2^\gamma}{2n_2 \cdot k} = ie^2\frac{J^2}{k^2} , \quad (67)$$

which agrees exactly with the usual calculations made with the potential coupling and propagator. This result is also completely independent of the (in principle) distinct reference vectors $n_{1,2}^\mu$ used to define the two Stokes surfaces. In what follows we typically take all surfaces to lie along the same n^μ for simplicity.

Figure 5: One electric loop correction to photon exchange between electric currents using field strengths.

Turning to renormalization, we include a closed loop due to the electrically charged particle within the exchanged photon line. To calculate this quantity we must determine the form of the four index loop function. However, the closed loop still has the same functional form no matter how we describe the photon coupling, it is simply determined by the current. Therefore, we can use this known form, given in Eq. (53), to find

$$\begin{aligned}
{}^{\mu\nu}\Pi^{\sigma\rho} &\equiv \frac{n^\mu\eta^{\nu\alpha} - n^\nu\eta^{\mu\alpha}}{2n \cdot k} \frac{n^\sigma\eta^{\rho\beta} - n^\rho\eta^{\sigma\beta}}{2n \cdot k} \Pi(k^2) (k^2\eta_{\alpha\beta} - k_\alpha k_\beta) \\
&= \frac{\Pi(k^2)}{4(n \cdot k)^2} [k^2 (n^\mu n^\sigma \eta^{\nu\rho} - n^\mu n^\rho \eta^{\nu\sigma} - n^\nu n^\sigma \eta^{\mu\rho} + n^\nu n^\rho \eta^{\mu\sigma}) - (n^\mu k^\nu - n^\nu k^\mu) (n^\sigma k^\rho - n^\rho k^\sigma)] \\
&= \frac{1}{2} \frac{\Pi(k^2)}{(n \cdot k)^2} \left[k^2 n^2 \overset{\mu\nu}{(n)} P_{(n)}^{\sigma\rho} - \frac{1}{2} (n^\mu k^\nu - n^\nu k^\mu) (n^\sigma k^\rho - n^\rho k^\sigma) \right] \\
&= \frac{1}{2} \Pi(k^2) \overset{\mu\nu}{(n)} P_{(k)}^{\alpha\beta} \alpha\beta I_{\gamma\delta} \overset{\gamma\delta}{(k)} P_{(n)}^{\sigma\rho}. \tag{68}
\end{aligned}$$

From the last equality, and the results of Sec. 3, it is simple to calculate that

$$\overset{(k)}{\alpha\beta} P_{\mu\nu}^{\mu\nu} \overset{(k)}{\sigma\rho} \Pi^{\sigma\rho} P_{\gamma\delta}^{\gamma\delta} = \frac{1}{2} \Pi(k^2) \overset{(k)}{\alpha\beta} P_{\gamma\delta}^{\gamma\delta}, \tag{69}$$

which is independent of n^μ ! The full one-loop correction amplitude, shown schematically in Fig. 5, is

$$\mathcal{M}_{1J}^{JJ} = e^2 \Pi_J \frac{J^2}{k^2}, \tag{70}$$

in agreement with the standard potential propagator calculations. We emphasize again that this result is n^μ independent, as expected. It is also unaffected by taking the n^μ 's of the external and virtual currents to be different from each other.

Let us here take stock of what has been accomplished. We have outlined a formalism for calculating in QED that is gauge independent. The definition of the Feynman vertices

does depend on specific Stokes surfaces, but the final results are completely independent of what surfaces are chosen. While this may be somewhat diverting when calculating with only electric charges we see in what follows that the true utility comes when both electric and magnetic charges are present.

4.1 Including Magnetic Charges

How should we include magnetic currents K^μ ? Suppose we simply, and naively, include the coupling term

$$ib^*F_{\mu\nu} \frac{K^\mu n^\nu - K^\nu n^\mu}{2n \cdot k}, \quad (71)$$

in the usual one potential Lagrangian (49). One might guess that K^μ is sourced by ${}^*F_{\mu\nu}$ in the same way that $F_{\mu\nu}$ is sourced by J^μ . We then find the propagator for ${}^*F_{\mu\nu}$ by applying factors of $\frac{1}{2}\varepsilon_{\alpha\beta\gamma\delta}$ to the known $F_{\mu\nu}$ propagator. (This assumes, mistakenly, that the $F_{\mu\nu}$ propagator is unchanged when magnetic currents are included in the theory.) In short, one would naively expect

$$\langle F_{\alpha\beta} F_{\gamma\delta} \rangle_k = -2i {}_{\alpha\beta}^{(k)} P_{\gamma\delta}^{(k)}, \quad \langle F_{\alpha\beta} {}^*F_{\gamma\delta} \rangle_k = -2i {}_{\alpha\beta}^{(k)} P_{*\gamma\delta}^{(k)}, \quad (72)$$

$$\langle {}^*F_{\alpha\beta} F_{\gamma\delta} \rangle_k = -2i {}_{*\alpha\beta}^{(k)} P_{\gamma\delta}^{(k)}, \quad \langle {}^*F_{\alpha\beta} {}^*F_{\gamma\delta} \rangle_k = -2i {}_{*\alpha\beta}^{(k)} P_{*\gamma\delta}^{(k)}, \quad (73)$$

though we see below that these are *not correct*.

To see the problem with these assumptions, consider the one-photon exchange between two magnetic currents. The naive amplitude is

$$\begin{aligned} i\mathcal{M}_0^{KK} &= ib \frac{K^\alpha n^\beta - K^\beta n^\alpha}{2n \cdot k} (-2i) {}_{*\alpha\beta}^{(k)} P_{*\gamma\delta}^{(k)} ib \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} \\ &= 2ib^2 \frac{K^\alpha n^\beta - K^\beta n^\alpha}{2n \cdot k} \left({}_{\alpha\beta}^{(k)} P_{\gamma\delta}^{(k)} - {}_{\alpha\beta} I_{\gamma\delta} \right) \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} \\ &= ib^2 \frac{K^2}{k^2} - ib^2 \frac{K^2 n^2 - (K \cdot n)^2}{2(n \cdot k)^2}, \end{aligned} \quad (74)$$

where we have used the completeness relation (42) in the second line. The additional ‘‘contact’’ term, with no photon pole, in the final result contradicts our expectation for magnetic-magnetic scattering from electric-magnetic duality. That is, we expect that magnetic-magnetic scattering should have the same form as electric-electric scattering.

Remember, however, that we assumed that the field strength propagator was unchanged when we introduce magnetic currents. This assumption must be reexamined. To more carefully include magnetic currents we follow Dirac’s [36] one potential description as extended

in [37, 38] and usefully summarized in the review [31]. Dirac’s formulation of a quantum theory of electric and magnetic particles leads to a Lagrangian “contact” term between the magnetic currents:

$$ib^2 \frac{K^2 n^2 - (K \cdot n)^2}{2(n \cdot k)^2} . \quad (75)$$

This additional “contact” term must be included in our calculations, cancelling the unexpected term in (74) and ensuring that the final results agree with electric-magnetic duality.

The essential point is that if we want to include magnetic charges then we cannot assume that the field strength has the form $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ as this leads to $\partial_\mu {}^*F^{\mu\nu} = 0$. Following in the spirit of [37, 38] we consider

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - \frac{b}{2} \varepsilon_{\mu\nu\alpha\beta} \frac{n^\alpha K^\beta - n^\beta K^\alpha}{n \cdot \partial} \equiv F_{\mu\nu}^A - \frac{b}{2} \varepsilon_{\mu\nu\alpha\beta} \frac{n^\alpha K^\beta - n^\beta K^\alpha}{n \cdot \partial} , \quad (76)$$

where n^μ is any constant vector and

$$F_{\mu\nu}^X = \partial_\mu X_\nu - \partial_\nu X_\mu , \quad (77)$$

for any vector field X^μ . In this definition the operator $(n \cdot \partial)^{-1}$ is understood to act on the magnetic current. This form of the field strength implies that

$${}^*F^{\mu\nu} = b \frac{n^\mu K^\nu - n^\nu K^\mu}{n \cdot \partial} + \varepsilon^{\mu\nu\alpha\beta} \partial_\alpha A_\beta , \quad (78)$$

and hence produces the correct Maxwell equation

$$\partial_\mu {}^*F^{\mu\nu} = bK^\nu , \quad (79)$$

for the conserved magnetic current, $\partial_\mu K^\mu = 0$.

Substituting the form of $F_{\mu\nu}$ given in Eq. (76) into the usual Lagrangian we find

$$\begin{aligned} \mathcal{L} &= -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - e A_\mu J^\mu , \\ &= -\frac{1}{4} F_{\mu\nu}^A F^{A\mu\nu} - e A_\mu J^\mu + b \partial_\beta (A_\mu) \frac{1}{n \cdot \partial} \varepsilon^{\mu\nu\alpha\beta} K_\nu n_\alpha + \frac{b^2}{2(n \cdot \partial)^2} [n^2 K^2 - (n \cdot K)^2] , \end{aligned} \quad (80)$$

where each of the $(n \cdot \partial)^{-1}$ operators are acting one magnetic current. In this case the photon field has the usual coupling to electric currents and a nonlocal coupling to magnetic currents that involves the Levi-Civita tensor. In addition, there is a nonlocal “contact”

interaction between magnetic currents. Despite these new magnetic-magnetic interactions the quadratic part of the A_μ Lagrangian is unchanged. Consequently, we find the same photon propagator and can reproduce all the standard (correct) results for electric-electric interactions.

In addition, we can now evaluate the leading contributions to electric-magnetic scattering

$$\begin{aligned} i\mathcal{M}_0^{JK} &= -ieJ^\gamma(-i)\frac{\eta_{\gamma\mu} - (1-\xi)\frac{k_\gamma k_\mu}{k^2}}{k^2}(-ib)\varepsilon^{\mu\nu\alpha\beta}\frac{K_\nu n_\alpha k_\beta}{n\cdot k} \\ &=ieb\frac{\varepsilon^{\mu\nu\alpha\beta}J_\mu K_\nu n_\alpha k_\beta}{k^2 n\cdot k}. \end{aligned} \quad (81)$$

This agrees exactly with Weinberg's Lagrangian independent result (11). We also find the magnetic-magnetic scattering to be

$$\begin{aligned} i\mathcal{M}_0^{KK} &= -ib\varepsilon^{\mu\rho\sigma\lambda}\frac{K_\rho n_\sigma k_\lambda}{n\cdot k}(-i)\frac{\eta_{\mu\nu} - (1-\xi)\frac{k_\mu k_\nu}{k^2}}{k^2}(-ib)\varepsilon^{\nu\alpha\beta\gamma}\frac{K_\alpha n_\beta k_\gamma}{n\cdot k} + ib^2\frac{n^2 K^2 - (n\cdot K)^2}{(n\cdot k)^2} \\ &= -\frac{ib^2}{k^2(n\cdot k)^2} [K^2(n^2 k^2 - (n\cdot k)^2) - k^2(n\cdot K)^2] + ib^2\frac{n^2 K^2 - (n\cdot K)^2}{(n\cdot k)^2} \\ &= ib^2\frac{K^\mu K_\mu}{k^2}. \end{aligned} \quad (82)$$

Notice that the magnetic-magnetic ‘‘contact’’ term, see Fig. 6, plays a crucial role in this calculation. It cancels contributions from the contracted Levi-Civita tensors in order to produce an amplitude of the same form as in electric-electric scattering, as required by electric-magnetic duality.

One might wonder why it is so much more involved to obtain this simple result for magnetic currents as compared to electric currents. This follows from our choice to give the electric currents priority in the sense of simple local couplings to a conserved current. This imbalance in how we treat potential-current couplings leads to the difference in calculations, even though the end results are essentially identical. Using a more balanced formalism, such as Zwanziger's [20], the calculations for each type of charge are much more similar. We illustrate this in the following section.

Turning to the field strength formalism, we note that the propagator for $F_{\mu\nu}^A$, not $F_{\mu\nu}$, is given by

$$\langle F_{\alpha\beta}^A F_{\gamma\delta}^A \rangle_k = -2i\frac{(k)}{\alpha\beta}\frac{(k)}{\gamma\delta}, \quad (83)$$

because the A_μ propagator has not changed. The form of the $F_{\mu\nu}$ propagator must be different as it does not belong to the subspace of objects that are wedge products with k_μ .

Figure 6: One-photon exchange between magnetic currents and the current-current “contact” term. The photon line is colored blue to indicate that it has the standard, local coupling to electric currents. The photon coupling to (red) magnetic currents includes a factor of the Levi-Civita tensor, which we denote with a purple coloring.

If it were it would satisfy the Bianchi identity, implying no magnetic charges. Therefore, we see that when magnetic currents are included in the theory the form of the $F_{\mu\nu}$ propagator must differ from the standard QED result.

However, we do not need to know the $F_{\mu\nu}$ propagator to calculate one-photon exchange between two currents. The $F_{\mu\nu}^A$ field strength itself has couplings to electric and magnetic currents

$$\begin{aligned} \mathcal{L} &= -\frac{1}{4}F_{\mu\nu}^A F^{A\mu\nu} + eF_{\mu\nu}^A \frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot \partial} + bF_{\mu\nu}^A \frac{\varepsilon^{\mu\nu\alpha\beta} K_\alpha n_\beta}{2n \cdot \partial} + b^2 \frac{n^2 K^2 - (n \cdot K)^2}{2(n \cdot \partial)^2} \\ &= -\frac{1}{4}F_{\mu\nu}^A F^{A\mu\nu} + eF_{\mu\nu}^A \frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot \partial} + b^* F_{\mu\nu}^A \frac{K^\mu n^\nu - K^\nu n^\mu}{2n \cdot \partial} + b^2 \frac{n^2 K^2 - (n \cdot K)^2}{2(n \cdot \partial)^2}. \end{aligned} \quad (84)$$

This way of expressing the Lagrangian is almost what we had guessed for including magnetic currents in QED, except for the “contact” term between magnetic currents. Again, there is no corresponding “contact” term for electric currents because we have chosen a formalism in which electric currents, and only electric currents, have a local coupling to the potential A_μ .

The calculation of electric-electric scattering \mathcal{M}_0^{JJ} is identical to what we found in QED. The tree-level amplitude for magnetic-magnetic scattering is

$$\begin{aligned} i\mathcal{M}_0^{KK} &= ib \frac{K^\alpha n^\beta - K^\beta n^\alpha}{2n \cdot k} (-2i) {}_{*\alpha\beta}^{(k)} P_{*\gamma\delta}^{(k)} (ib) \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} + ib^2 \frac{K^2 n^2 - (K \cdot n)^2}{(n \cdot k)^2} \\ &= 2ib^2 \frac{K^\alpha n^\beta - K^\beta n^\alpha}{2n \cdot k} \left({}_{\alpha\beta}^{(k)} P_{\gamma\delta}^{(k)} - {}_{\alpha\beta} I_{\gamma\delta} \right) \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} + ib^2 \frac{K^2 n^2 - (K \cdot n)^2}{(n \cdot k)^2} \\ &= ib^2 \frac{K^2}{k^2} - ib^2 \frac{K^2 n^2 - (K \cdot n)^2}{(n \cdot k)^2} + ib^2 \frac{K^2 n^2 - (K \cdot n)^2}{(n \cdot k)^2} = ib^2 \frac{K^2}{k^2}. \end{aligned} \quad (85)$$

This calculation is algebraically identical to what we evaluated before. However, it is arguably a simpler way of organizing the calculation. In particular, the need for the “contact” term between magnetic currents is immediately obvious.

We can also understand the scattering of electric and magnetic charges. Because $F_{\mu\nu}^A$ is sourced by J^μ and $*F_{\mu\nu}^A$ is sourced by K^μ , the propagators connecting electric and magnetic currents are

$$\langle F_{\alpha\beta}^A *F_{\gamma\delta}^A \rangle_k = -2i \frac{(k)}{\alpha\beta * \gamma\delta} P^{(k)}, \quad \langle *F_{\alpha\beta}^A F_{\gamma\delta}^A \rangle_k = -2i \frac{(k)}{* \alpha\beta \gamma\delta} P^{(k)}. \quad (86)$$

There is, however, something of an ambiguity because

$$\frac{\alpha\beta}{(k)} P^{*\gamma\delta}_{(k)} = \frac{1}{2} \varepsilon^{\alpha\beta\gamma\delta} - \frac{* \alpha\beta}{(k)} P_{(k)}^{\gamma\delta}. \quad (87)$$

This implies that the electric-magnetic scattering amplitude can be expressed in multiple, equivalent, ways. Allowing the surfaces bounded by the two currents to correspond to distinct vectors n_J^μ and n_K^μ we find

$$\begin{aligned} i\mathcal{M}_0^{JK} &= ie \frac{J^\alpha n_J^\beta - J^\beta n_J^\alpha}{2n_J \cdot k} (-2i) \frac{(k)}{\alpha\beta * \gamma\delta} P^{(k)} (ib) \frac{K^\gamma n_K^\delta - K^\delta n_K^\gamma}{2n_K \cdot k} \\ &= ieb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n_J^\gamma k^\delta}{k^2 n_K \cdot k} \end{aligned} \quad (88)$$

$$\begin{aligned} &= ie \frac{J^\alpha n_J^\beta - J^\beta n_J^\alpha}{2n_J \cdot k} \left(2i \frac{(k)}{* \alpha\beta \gamma\delta} P^{(k)} - i \varepsilon_{\alpha\beta\gamma\delta} \right) ib \frac{K^\gamma n_K^\delta - K^\delta n_K^\gamma}{2n_K \cdot k} \\ &= ieb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n_J^\gamma k^\delta}{k^2 n_J \cdot k} - ieb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n_J^\gamma n_K^\delta}{(n_J \cdot k)(n_K \cdot k)}. \end{aligned} \quad (89)$$

Notice that unlike the interactions of like charges, these scattering amplitudes depend on the n_i^μ , or equivalently on the Stokes surface bounded by the current. The term with the photon pole ($1/k^2$) only depends on one of the surface reference vectors. In the second line it depends on the magnetic Stokes surface. We can, however, exchange the magnetic surface vector for the electric one by introducing a term related to the intersection of the two surfaces, as discussed in Sec. 3. If we choose $n_J^\mu = n_K^\mu$ any difference between the two results vanishes.

4.2 Renormalization Done Wrong

Having determined how to account for mutually nonlocal charge interactions we can consider the contribution of a magnetic loop to the interaction of electric currents. We use the field strength formalism to organize the calculation because it simplifies the algebra. Importantly for this calculation, the magnetic current ‘‘contact’’ term plays no role because

Figure 7: One magnetic (red) loop correction to photon exchange between electric (blue) currents using field strengths. The field strength $F_{\mu\nu}^A$ has direct coupling to electric currents while $*F_{\mu\nu}^A$ couples directly to magnetic currents. The mixed propagator includes the Levi-Civita tensor and is colored purple.

two distinct magnetic currents never exchange a photon. The heart of this calculation, see Fig. 7, is captured by

$$\begin{aligned} \langle F_{\mu\nu}^A *F_{\alpha\beta}^A \rangle_k &= \frac{1}{2} \Pi(k^2) \langle F_{\mu\nu}^A *F_{\alpha\beta}^A \rangle_k \\ &= \frac{1}{2} \Pi(k^2) \langle F_{\mu\nu}^A *F_{\alpha\beta}^A \rangle_k \end{aligned} \quad (90)$$

$$= \frac{1}{2} \Pi(k^2) \langle F_{\mu\nu}^A *F_{\alpha\beta}^A \rangle_k - \frac{1}{2} \Pi(k^2) \langle F_{\mu\nu}^A *F_{\alpha\beta}^A \rangle_k. \quad (91)$$

In contrast to what we found in Eq. (69) for a virtual loop of electric charge, we immediately obtain troubling results. In particular, there is an additional term that does have the same form as the tree-level scattering. One might hope that when contracted with external currents this extra term vanishes, but the one-loop amplitude is actually found to be

$$i\mathcal{M}_{1K}^{JJ} = ie^2 \Pi_K \frac{J^2}{k^2} - ie^2 \Pi_K \frac{J^2 n^2 - (J \cdot n)^2}{(k \cdot n)^2}, \quad (92)$$

where we have suppressed the argument of Π_K , the vacuum polarization function. If one focuses only on the first term then one is tempted to claim that electric and magnetic loop lead to the same kind of renormalization, as Schwinger found. That is, we have

$$\mathcal{M}_0^{JJ} + \mathcal{M}_{1J}^{JJ} + \mathcal{M}_{1K}^{JJ} = e^2 \frac{J^2}{k^2} [1 + \Pi_J + \Pi_K] - e^2 \Pi_K \frac{J^2 n^2 - (J \cdot n)^2}{(k \cdot n)^2}, \quad (93)$$

with both electric and magnetic loops contributing in the same way to the running. However, the fact that this second term, which looks like a “contact” term between electric currents, is generated signals that further thought is required.

One loop corrections to magnetic-magnetic interactions follow a similar form. In this case, however, one must include all four diagrams, see Fig. 8, when considering the virtual

Figure 8: One magnetic loop corrections to photon exchange between magnetic currents using the one potential formalism.

magnetic loop contribution because of the “contact” term. That is, one must include the “contact” terms between the each external magnetic current and the virtual current. The final result is

$$\mathcal{M}_0^{KK} + \mathcal{M}_{1_J}^{KK} + \mathcal{M}_{1_K}^{KK} = b^2 \frac{K^2}{k^2} [1 + \Pi_J + \Pi_K] - b^2 \Pi_J \frac{K^2 n^2 - (K \cdot n)^2}{(k \cdot n)^2}. \quad (94)$$

The form matches the electric-electric case, supporting the notion of electric-magnetic duality within this formalism. In addition, if one does not consider the final term, it appears that both electric and magnetic loops renormalize the magnetic coupling in the same way. Finally, by comparing Eqs. (93) and (94) it seems (if we only consider the terms with the usual photon pole) that both the electric and magnetic couplings are renormalized in the same way, again as Schwinger concluded.

What about renormalization of the mixed propagator? The calculation corresponding to electric-magnetic scattering for a virtual electric loop is

$$\overset{(k)}{\alpha\beta} P_{\mu\nu}^{(k)} \Pi^{\sigma\rho} \overset{(k)}{\sigma\rho} P_{*\gamma\delta}^{(k)} = \frac{1}{2} \Pi(k^2) \overset{(k)}{\alpha\beta} P_{\mu\nu}^{(k)} \overset{(n)}{\mu\nu} P_{(k)\zeta\theta}^{\zeta\theta} I_{\kappa\lambda} \overset{(k)}{\kappa\lambda} P_{(n)\sigma\rho}^{\sigma\rho} \overset{(k)}{*\gamma\delta} P_{*\gamma\delta}^{(k)} \quad (95)$$

$$= \frac{\Pi(k^2)}{2} \overset{(k)}{\alpha\beta} P_{*\gamma\delta}^{(k)}. \quad (96)$$

This implies that

$$i\mathcal{M}_{1_J}^{JK} = ieb\Pi_J \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n_K^\gamma k^\delta}{k^2 n_K \cdot k}. \quad (97)$$

Note that this is independent of the virtual loop reference vector n_V^μ .

When considering a virtual magnetic loop we must include an additional diagram to include the effects of the magnetic “contact” term. Once this has been included we find

$$i\mathcal{M}_{1K}^{JK} =ieb\Pi_K \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n_K^\gamma k^\delta}{k^2 n_K \cdot k} . \quad (98)$$

In total we have

$$\mathcal{M}_0^{JK} + \mathcal{M}_{1J}^{JK} + \mathcal{M}_{1K}^{JK} = eb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n_K^\gamma k^\delta}{k^2 n_K \cdot k} [1 + \Pi_J + \Pi_K] , \quad (99)$$

which again seems to support Schwinger’s result, this time with no additional worrying terms. However, as shown in the following subsection, all of these results are *incorrect*. They include a subtle contribution from topological terms. When these terms are removed the results are significantly modified and agree with Coleman’s characterization of the running couplings.

4.3 Renormalization Done Right

The loop generated “contact” terms in Eqs. (93) and (94) are the loud signal that something is amiss. Let us return to Eq. (90) when calculating the magnetic loop correction to electric-electric interactions.

$$\begin{aligned} \mathcal{M}_{1K}^{JJ} &= ie \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} (-2i)_{\alpha\beta}^{(k)} P_{*\mu\nu}^{(k)} i^{\mu\nu} \Pi^{\sigma\rho} (-2i)_{*\sigma\rho}^{(k)} P_{\gamma\delta}^{(k)} ie \frac{J^\gamma n^\delta - J^\delta n^\gamma}{2n \cdot k} \\ &= 2ie^2 \Pi_K \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} {}_{\alpha\beta}^{(k)} P_{*\mu\nu}^{(k)} \frac{\mu\nu}{(n)} P_{(k)}^{\zeta\theta} I_{\kappa\lambda} \frac{\kappa\lambda}{(k)} P_{(n)*\sigma\rho}^{\sigma\rho} P_{\gamma\delta}^{(k)} \frac{J^\gamma n^\delta - J^\delta n^\gamma}{2n \cdot k} . \end{aligned} \quad (100)$$

Using the identity in Eq. (46), we note that ${}_{\alpha\beta}^{(k)} P_{*\mu\nu}^{(k)} \frac{\mu\nu}{(n)} P_{(k)}^{\zeta\theta}$ can be written in two equal ways

$${}_{\alpha\beta}^{(k)} P_{*\mu\nu}^{(k)} \frac{\mu\nu}{(n)} P_{(k)}^{\zeta\theta} = {}_{\alpha\beta}^{(k)} P_{(k)}^{*\zeta\theta} - {}_{\alpha\beta}^{(k)} P_{(n)}^{*\zeta\theta} , \quad (101)$$

$$= -{}_{*\alpha\beta}^{(k)} P_{(k)}^{\zeta\theta} + {}_{*\alpha\beta}^{(n)} P_{(k)}^{\zeta\theta} . \quad (102)$$

The second term on the right in each of these lines is the topological part of electric-magnetic scattering. It is this term that we need to separate out from the perturbation series. But which of these two ways of expressing the topological term should we use? If we use Eq. (102) then the topological term is projected out because

$$\frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} {}_{*\alpha\beta}^{(n)} P_{(k)}^{\zeta\theta} = 0 . \quad (103)$$

This is simply due to the ${}^{(n)}_{*\alpha\beta}P_{(k)}^{\zeta\theta}$ mapping being from the space orthogonal to objects that are a wedge product with n^μ .

This projecting out might seem at first to be a benefit if it is understood as removing the topological term from the calculation. However, because this term projects out when coupled to the current, the remaining term is still equivalent to the Eq. (101) with the topological term included. Therefore, we can only truly separate the topological term from this calculation by using Eq. (101) and then removing the topological term.

Similarly, we can write the combination of terms of the right-side of the identity operator in two ways:

$${}^{(k)}_{\kappa\lambda}P_{(n)*\sigma\rho}^{\sigma\rho}P_{\gamma\delta}^{(k)} = {}^{(k)}_{\kappa\lambda}P_{*\gamma\delta}^{(k)} - {}^{(k)}_{\kappa\lambda}P_{*\gamma\delta}^{(n)} , \quad (104)$$

$$= -{}^{(k)*\kappa\lambda}P_{\gamma\delta}^{(k)} + {}^{(n)*\kappa\lambda}P_{\gamma\delta}^{(k)} . \quad (105)$$

If we use the top equality then the topological term is projected out and, counterintuitively, it is equivalent to keeping the topological effects. Therefore, we must use Eq. (105) and remove the topological term by hand. If we do not eliminate these topological terms we are, in effect, including four unintended, topological contributions to the scattering we are interested in.

When the topological terms are removed we find the magnetic one-loop contribution to electric-electric interaction is

$$\mathcal{M}_{1K}^{JJ} = -2ie^2\Pi_K \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} {}^{(k)}_{\alpha\beta}P_{*\mu\nu}^{(k)} P_{\gamma\delta}^{(k)} \frac{J^\gamma n^\delta - J^\delta n^\gamma}{2n \cdot k} = -ie^2\Pi_K \frac{J^2}{k^2} . \quad (106)$$

Significantly, no ‘‘contact’’ term is included, there is only a contribution with the expected photon pole, $1/k^2$. We also see that the sign of the contribution from a magnetic loop is opposite to that of an electric loop.

The full one-loop amplitude, with all topological terms removed, is

$$\mathcal{M}_0^{JJ} + \mathcal{M}_{1J}^{JJ} + \mathcal{M}_{1K}^{JJ} = e^2 \frac{J^2}{k^2} [1 + \Pi_J - \Pi_K] \approx e^2 \frac{J^2}{k^2 [1 - \Pi_J + \Pi_K]} . \quad (107)$$

Similarly, the one-loop corrections to magnetic-magnetic scattering with all topological terms removed is

$$\mathcal{M}_0^{KK} + \mathcal{M}_{1J}^{KK} + \mathcal{M}_{1K}^{KK} = b^2 \frac{K^2}{k^2} [1 - \Pi_J + \Pi_K] . \quad (108)$$

Considering the electric and magnetic results, we see that the two couplings run exactly inversely, in agreement with Coleman’s analysis.

This behavior is confirmed by the one-loop corrections to electric-magnetic scattering. The contribution of a virtual electric loop is

$$\begin{aligned}
\mathcal{M}_{1_J}^{JK} &= ie \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} (-2i)_{\alpha\beta}^{(k)} P_{\mu\nu}^{(k)} i^{\mu\nu} \Pi^{\sigma\rho} (-2i)_{\sigma\rho}^{(k)} P_{*\gamma\delta}^{(k)} ig \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} \\
&= 2ieg \Pi_J(k^2) \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} \frac{(k)}{\alpha\beta} P_{\mu\nu}^{(k)} \frac{\mu\nu}{(n)} P_{(k)}^{\zeta\theta} \zeta^\theta I_{\kappa\lambda} \frac{\kappa\lambda}{(k)} P_{(n)}^{\sigma\rho} \frac{(k)}{\sigma\rho} P_{*\gamma\delta}^{(k)} \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} \\
&= 2ieg \Pi_J(k^2) \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} \frac{(k)}{\alpha\beta} P_{\mu\nu}^{(k)} \frac{\mu\nu}{(k)} P_{(n)}^{\sigma\rho} \left(\frac{1}{2} \varepsilon_{\sigma\rho\gamma\delta} - \frac{(k)}{*\sigma\rho} P_{\gamma\delta}^{(k)} \right) \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k}, \quad (109)
\end{aligned}$$

where in the last line we have used the identity in Eq. (87). Notice that the term with a lone epsilon tensor vanishes because it produces

$$\frac{\mu\nu}{(k)} P_{*\gamma\delta}^{(n)} \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} = 0. \quad (110)$$

The remaining term can be written as

$$\mathcal{M}_{1_J}^{JK} = -2ieg \Pi_J(k^2) \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} \frac{(k)}{\alpha\beta} P_{\mu\nu}^{(k)} \left(-\frac{*\mu\nu}{(k)} P_{\gamma\delta}^{(k)} + \frac{*\mu\nu}{(n)} P_{\gamma\delta}^{(k)} \right) \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k}, \quad (111)$$

so that the topological term does not automatically project out. We note, however, that the other term vanishes because

$$\frac{(k)}{\alpha\beta} P_{\mu\nu}^{(k)} \frac{*\mu\nu}{(k)} P_{\gamma\delta}^{(k)} = 0. \quad (112)$$

This means that only the topological term contributes. When this term is removed we simply find that the one-loop contribution to renormalization vanishes. A similar calculation (which includes an additional diagram to include the magnetic ‘‘contact’’ term) also shows that $\mathcal{M}_{1_K}^{JK} = 0$. In total, the one-loop corrections to the mixed propagator vanish, so

$$\mathcal{M}_0^{JK} + \mathcal{M}_{1_J}^{JK} + \mathcal{M}_{1_K}^{JK} = eb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n^\gamma k^\delta}{k^2 n \cdot k}, \quad (113)$$

or in other words, the mixed charge interaction is not renormalized! This, again, is consistent with e and b renormalizing inversely, and the renormalization group invariance of Dirac charge quantization, as argued by Coleman.

In these two subsections we have seen how to understand the apparent contradiction between Schwinger’s and Coleman’s results and the method to reconcile them. The two results are equal up to terms that arise when topological phase terms are included in loop effects. The signal of this problem is the apparent loss of multiplicative renormalization

in the one-loop amplitudes. When these topological pieces are removed, Coleman’s result is recovered. We note also that the naive calculation using the potential A_μ includes the topological phase in loop effects. This is the origin of the extra terms that appeared. The field strength formalism, though not absolutely essential, makes it much simpler to identify and remove the topological terms and to understand them as arising when a worldline and a Stokes surface associated with different types of charges are topologically linked, or when an electric Stokes surface and a magnetic Stokes surface intersect.

For all this success, the single potential formalism is somewhat unwieldy due to the tree-level “contact” term between magnetic currents that must be included. We show in the next sections how the two potential formalism due to Zwanziger [20], can be expressed in terms of field strengths without introducing current-current “contact” terms. Indeed, we find the language of two-form maps is a concise and intuitive way to describe Zwanziger’s Lagrangian and the resulting dynamics. The isolation and removal of the topological terms is also somewhat simplified compared to the one potential formulation.

5 Zwanziger’s Two-Potential Formalism

In the previous section, the single potential Lagrangian gave electric charges a preference in that the gauge potential only had a local coupling to the electric current. Zwanziger has developed a formalism [20] that keeps electric and magnetic currents on a more equal footing, each with local couplings to one gauge potential. However, both of these potentials must be constrained to describe the same photon degrees of freedom.

Using the notation of [8] we can write the Lagrangian describing local electric and magnetic couplings to the photon by

$$\begin{aligned} \mathcal{L} = & -\frac{n^\alpha n^\mu}{2n^2} \eta^{\beta\nu} (F_{\alpha\beta}^A F_{\mu\nu}^A + F_{\alpha\beta}^B F_{\mu\nu}^B) + \frac{n^\alpha n_\mu}{4n^2} \varepsilon^{\mu\nu\gamma\delta} (F_{\alpha\nu}^B F_{\gamma\delta}^A - F_{\alpha\nu}^A F_{\gamma\delta}^B) \\ & - eA_\mu J^\mu - bB_\mu K^\mu, \end{aligned} \tag{114}$$

where A_μ and B_μ are the potentials with local couplings to the electric and magnetic currents, respectively. The Euler-Lagrange equations lead to the usual Maxwell equations of Eq. (8) with

$$F_{\mu\nu} = \frac{n^\alpha}{n^2} (n_\mu F_{\alpha\nu}^A - n_\nu F_{\alpha\mu}^A - \varepsilon_{\mu\nu\alpha\beta} n_\gamma F^{B\gamma\beta}), \tag{115}$$

$${}^*F_{\mu\nu} = \frac{n^\alpha}{n^2} (n_\mu F_{\alpha\nu}^B - n_\nu F_{\alpha\mu}^B + \varepsilon_{\mu\nu\alpha\beta} n_\gamma F^{A\gamma\beta}). \tag{116}$$

However, all these results can be written somewhat more concisely using the two-form mappings defined in Sec. 3, in particular $\binom{(n)}{\alpha\beta} P_{\gamma\delta}^{(n)}$. Recall that such an operator projects

into the space of two-forms that have the form of a wedge product with n^μ . The mapping $-\overset{(n)}{*}\alpha\beta\overset{(n)}{*}\gamma\delta$ maps from and into the orthogonal complement space with

$$\overset{(n)}{\alpha\beta}P_{\gamma\delta}^{(n)} - \overset{(n)}{*}\alpha\beta\overset{(n)}{*}\gamma\delta = \alpha\beta I_{\gamma\delta} . \quad (117)$$

It is a straightforward exercise to show that

$$F_{\mu\nu} = \overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)}F^{A\alpha\beta} + \overset{(n)}{*}\mu\nu\overset{(n)}{*}\alpha\beta F^{B\alpha\beta} , \quad *F_{\mu\nu} = \overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)}F^{B\alpha\beta} - \overset{(n)}{*}\mu\nu\overset{(n)}{*}\alpha\beta F^{A\alpha\beta} . \quad (118)$$

This clarifies the role of the reference vector n^μ in this formalism. The six dimensional space of two-forms is divided into two three dimensional subspaces with $\overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)}$ and $-\overset{(n)}{*}\mu\nu\overset{(n)}{*}\alpha\beta$ playing the role of projectors onto each of them. The field strength $F_{\mu\nu}$ generically has components in each of the subspaces. The part of the field strength that belongs to the $\overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)}$ subspace is $F_{\mu\nu}^A$ while the part in the orthogonal complement is $-\overset{(n)}{*}F_{\mu\nu}^B$.

An essential aspect of this formalism is that changes in n^μ have no physical consequence. Suppose we change $n_\mu \rightarrow n'_\mu$. We may as well keep the length fixed because it divides out of every quantity. This implies that $\overset{\alpha\beta}{(n)}P_{(n)}^{\gamma\delta} \rightarrow \overset{\alpha\beta}{(n')}P_{(n')}^{\gamma\delta}$. We then require

$$\overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')}F^{\mu\nu} \equiv \overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')}F^{A'\mu\nu} = \overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')} \overset{\mu\nu}{(n)}P_{(n)}^{\gamma\delta} F_{\gamma\delta}^A + \overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')} \overset{*}{(n)}P_{(n)}^{\gamma\delta} *F_{\gamma\delta}^B \quad (119)$$

$$\overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')} *F^{\mu\nu} \equiv \overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')} F^{B'\mu\nu} = \overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')} \overset{\mu\nu}{(n)}P_{(n)}^{\gamma\delta} F_{\gamma\delta}^B - \overset{(n')}{\alpha\beta}P_{\mu\nu}^{(n')} \overset{*}{(n)}P_{(n)}^{\gamma\delta} *F_{\gamma\delta}^A \quad (120)$$

This shows that if n^μ is changed that a suitable definition of A'_μ and B'_μ , those that fulfill the equations above, keeps $F_{\mu\nu}$ unchanged. So, while the vector potentials change with n^μ the physical fields do not. In this sense a change in n^μ is something like a gauge transformation of the potentials. This is separate, however, from the invariance of the Zwanziger Lagrangian under the usual, and distinct, gauge transformations of A_μ and B_μ

$$A_\mu \rightarrow A_\mu + \partial_\mu \Lambda_A , \quad B_\mu \rightarrow B_\mu + \partial_\mu \Lambda_B . \quad (121)$$

Because the definition of the field strengths in Eq. (118) is in terms of projectors it is not easily invertible. However, we do note that

$$F^{\mu\nu} \overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)} = F^{A\mu\nu} \overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)} , \quad *F^{\mu\nu} \overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)} = F^{B\mu\nu} \overset{(n)}{\mu\nu}P_{\alpha\beta}^{(n)} . \quad (122)$$

We can also write the kinetic part of the Lagrangian as

$$\mathcal{L} = -\frac{1}{4} \overset{\alpha\beta}{(n)}P_{(n)}^{\mu\nu} (F_{\alpha\beta}^A F_{\mu\nu}^A + F_{\alpha\beta}^B F_{\mu\nu}^B) - \frac{1}{4} \overset{*}{\alpha\beta} \overset{\mu\nu}{(n)}P_{(n)} (F_{\alpha\beta}^B F_{\mu\nu}^A - F_{\alpha\beta}^A F_{\mu\nu}^B) \quad (123)$$

$$= -\frac{1}{4} (F_{\alpha\beta}^A, F_{\alpha\beta}^B) \begin{pmatrix} \overset{\alpha\beta}{(n)}P_{(n)}^{\mu\nu} & -\overset{*}{\alpha\beta} \overset{\mu\nu}{(n)}P_{(n)} \\ \overset{*}{\alpha\beta} \overset{\mu\nu}{(n)}P_{(n)} & \overset{\alpha\beta}{(n)}P_{(n)}^{\mu\nu} \end{pmatrix} \begin{pmatrix} F_{\mu\nu}^A \\ F_{\mu\nu}^B \end{pmatrix} \quad (124)$$

$$= -\frac{1}{4} F_{\mu\nu}^A F^{\mu\nu} - \frac{1}{4} F_{\mu\nu}^B *F^{\mu\nu} . \quad (125)$$

This last way of expressing the Lagrangian is perhaps the most reminiscent of the usual QED Lagrangian.

We can imagine motivating the couplings of two-form fields to the currents similar to Eq. (62). The electric current is a source for $F_{\mu\nu}^A$

$$-eA_\mu J^\mu \rightarrow ieF_{\mu\nu}^A \frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot k} . \quad (126)$$

Similarly, the magnetic current is a source for $F_{\mu\nu}^B$

$$-bB_\mu K^\mu \rightarrow ibF_{\mu\nu}^B \frac{K^\mu n^\nu - K^\nu n^\mu}{2n \cdot k} . \quad (127)$$

The form of loop functions, for both electric or magnetic particles, is also identical to what was found in the previous section (68).

One first finds that the propagators (see Appendix A for the derivation) for both types of field strength are identical

$$\langle F_{\mu\nu}^A F_{\sigma\rho}^A \rangle_k = \langle F_{\mu\nu}^B F_{\sigma\rho}^B \rangle_k = -2i_{\mu\nu}^{(k)} P_{\sigma\rho}^{(k)} . \quad (128)$$

This, in contrast to the single potential formalism, illustrates how both types of charges are treated in the same way, or that the Zwanziger formalism is duality covariant [8]. The propagators quickly lead to the tree level results

$$\mathcal{M}_0^{JJ} = e^2 \frac{J^\mu J_\mu}{k^2} , \quad \mathcal{M}_0^{KK} = b^2 \frac{K^\mu K_\mu}{k^2} , \quad (129)$$

without the need for any current-current ‘‘contact’’ terms.

The mixed propagator, however, has a very significant form which differs from the single potential propagator. Instead, it agrees exactly with the position space version of Weinberg’s mixed potential propagator (25)

$$\langle F_{\mu\nu}^A F_{\sigma\rho}^B \rangle_k = -2i_{\mu\nu}^{(k)} P_{*\sigma\rho}^{(k)} + 2i_{\mu\nu}^{(k)} P_{*\sigma\rho}^{(n)} \quad (130)$$

$$= 2i_{*\mu\nu}^{(k)} P_{\sigma\rho}^{(k)} - 2i_{*\mu\nu}^{(n)} P_{\sigma\rho}^{(k)} \quad (131)$$

$$= -2i_{\mu\nu}^{(k)} P_{(k)*\alpha\beta}^{\alpha\beta(n)} P_{\sigma\rho}^{(k)} . \quad (132)$$

The first two lines show that this propagator includes a term that looks like the single potential mixed propagator, which is n^μ independent. They also contain the topological n^μ dependent term without a photon pole. The first two lines are, of course, equal which, as seen in the previous section, can introduce ambiguity regarding which form to use in

calculations. The final line shows an unambiguous way of encoding this information, but the topological term is not explicitly separated out. As we saw in Sec. 4.3, when removing the topological pieces from loop amplitudes all ambiguity is removed from mixed charge interactions.

While we have emphasized the topological character of the n^μ dependent terms we also note that for tree-level calculations the topological terms project out when connected to the external currents defined above. This might lead one to expect that any subtleties related to these terms has been eliminated from the formalism. However, as we saw with the one potential calculations, this is not quite true of one-loop calculations.

In Appendix C we calculate the naive renormalization of the Zwanziger propagators, employing the usual formalism that one might use in standard QED. We find

$$\begin{aligned}
\mathcal{M}_0^{JJ} + \mathcal{M}_{1_J}^{JJ} + \mathcal{M}_{1_K}^{JJ} &= e^2 \frac{J^2}{k^2} [1 + \Pi_J(k^2) + \Pi_K(k^2)] - e^2 \Pi_K(k^2) \frac{J^2 n^2 - (J \cdot n)^2}{(n \cdot k)^2}, \\
\mathcal{M}_0^{KK} + \mathcal{M}_{1_J}^{KK} + \mathcal{M}_{1_K}^{KK} &= b^2 \frac{J^2}{k^2} [1 + \Pi_J(k^2) + \Pi_K(k^2)] - b^2 \Pi_J(k^2) \frac{K^2 n^2 - (K \cdot n)^2}{(n \cdot k)^2}, \\
\mathcal{M}_0^{JK} + \mathcal{M}_{1_J}^{JK} + \mathcal{M}_{1_K}^{JK} &= eb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n^\gamma k^\delta}{k^2 (n \cdot k)} [1 + \Pi_J(k^2) + \Pi_K(k^2)], \tag{133}
\end{aligned}$$

which is exactly the *incorrect* result we found in Sec. 4.2 by using the one potential formalism and leaving in the topological terms. This emphasizes that the standard methods of renormalization, when using potentials, include the effects of the topological part of electric-magnetic interactions. The value of the field strength methods is that they enable the identification and separation of the topological terms.

To see this, we now calculate the renormalization of the photon propagators using the field strength formalism. The electric-loop corrections to electric-electric scattering and the magnetic-loop corrections to magnetic-magnetic scattering have no mixed charge component and consequently produce the expected (and correct) results. Let us then consider the magnetic-loop correction to electric-electric scattering, as shown in Fig. 9. We find

$$\begin{aligned}
& i\mathcal{M}_{1_K}^{JJ} \\
&= ie \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} (-2i)_{\alpha\beta}^{(k)} P_{(k)*\kappa\lambda}^{\kappa\lambda(n)} P_{\sigma\rho}^{(k)\sigma\rho} P_{(k)}^{\xi\zeta} \frac{i\Pi_K}{2} \xi\zeta I_{\phi\tau}^{\phi\tau} P_{(n)}^{\mu\nu} (-2i)_{\mu\nu}^{(k)} P_{(k)*\theta\psi}^{\theta\psi(n)} P_{\gamma\delta}^{(k)} \cdot ie \frac{J^\gamma n^\delta - J^\delta n^\gamma}{2n \cdot k} \\
&= -2ie^2 \Pi_K \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} \alpha\beta^{(k)} P_{(k)*\kappa\lambda}^{\kappa\lambda(n)} P_{\sigma\rho}^{(k)\sigma\rho} I_{\mu\nu}^{\mu\nu(k)} P_{(k)*\theta\psi}^{\theta\psi(n)} P_{\gamma\delta}^{(k)} \frac{J^\gamma n^\delta - J^\delta n^\gamma}{2n \cdot k}. \tag{134}
\end{aligned}$$

At this point we emphasize that, as we found in the single potential formalism, there are two ways to express the composition of the two-form maps on either side of the identity

Figure 9: One magnetic (red) loop correction to photon exchange between electric (blue) currents using $F_{\mu\nu}^A F_{\mu\nu}^B$ propagators. This propagator includes the Levi-Civita tensor, which is denoted by the purple color.

element:

$${}^{(k)}P_{\mu\nu}^{\alpha\beta(n)} P_{\sigma\rho}^{(k)} = {}^{(k)}P_{\mu\nu}^{(k)} P_{*\sigma\rho}^{(k)} - {}^{(k)}P_{\mu\nu}^{(n)} P_{*\sigma\rho}^{(n)} \quad (135)$$

$$= - {}^{(k)}P_{*\mu\nu}^{(k)} P_{\sigma\rho}^{(k)} + {}^{(n)}P_{*\mu\nu}^{(n)} P_{\sigma\rho}^{(n)} . \quad (136)$$

If we use Eq. (136) to couple to the left-most current of Eq. (134) then the n^μ dependent term projects out. If we use Eq. (135) then we find a topological contribution to the amplitude that does *not* project out! Therefore, in order to remove the topological terms that are confusing the perturbation series we must use Eq. (135) and separate out the ${}^{(k)}P_{\mu\nu}^{(n)}$ term. This choice is *required* because if we use Eq. (136) and remove the (projected out) topological term it is equivalent to using Eq. (135) and retaining n^μ dependent term.

Similarly, if we use Eq. (135) to couple to the right-most current of Eq. (134) then the topological term projects out. We must instead use Eq. (136) and remove by hand the n^μ dependent term. This ensures that we have truly eliminated all topological terms from the calculation. One then finds the one-loop result

$$\begin{aligned} \mathcal{M}_{1K}^{JJ} &= 2e^2 \Pi_K \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} \frac{{}^{(k)}P_{\alpha\beta}^{(k)} P_{*\sigma\rho}^{(k)} I^{\mu\nu} P_{\gamma\delta}^{(k)}}{{}^{(k)}P_{*\mu\nu}^{(k)} P_{\sigma\rho}^{(k)}} \frac{J^\gamma n^\delta - J^\delta n^\gamma}{2n \cdot k} \\ &= -e^2 \Pi_K \frac{J^2}{k^2} . \end{aligned} \quad (137)$$

Thus we see that by fully removing the topological terms we find that the running due to a magnetic loop has the opposite sign to running due to an electric loop. The effect of an electric loop on magnetic-magnetic scattering follows exactly the same form

$$\mathcal{M}_{1J}^{KK} = -b^2 \Pi_J \frac{K^2}{k^2} . \quad (138)$$

These results also connect to the phenomenological calculations related to perturbatively charged magnetic particles in [17]. In that work it is shown that the spurious $1/(n \cdot k)$

Figure 10: One electric (blue) loop correction to photon exchange between an electric current and a magnetic (red) current using $F_{\mu\nu}^A$ and $F_{\mu\nu}^B$ propagators. The electric-electric propagator is colored blue, while the mixed propagator is colored purple.

poles that appear in tree-level electric-magnetic scattering are always cancelled when n^μ is taken to align with the tube of magnetic flux that joins the monopole-antimonopole pair. In the case of a virtual monopole loop, however, it is not clear what value to assign to n^μ as there are no on-shell monopoles with fixed momenta. The above calculation shows that the correct monopole loop corrections to electric-electric scattering are independent of n^μ , obviating the problem of deciding what direction to choose.

We now consider the one-loop corrections to electric-magnetic scattering. Beginning with a loop of electric particles, as in Fig. 10, we find

$$\begin{aligned}
i\mathcal{M}_{1_J}^{JK} &= ie \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} (-2i)_{\alpha\beta}^{(k)} P_{\sigma\rho}^{(k)} P_{(n)}^{\xi\zeta} \frac{i\Pi_J}{2} \xi\zeta I_{\phi\tau}^{\phi\tau} P_{(n)}^{\mu\nu} (-2i)_{\mu\nu}^{(k)} P_{(k)*\theta\psi}^{\theta\psi} P_{\gamma\delta}^{(k)} ib \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} \\
&= 2ieb\Pi_J \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} {}_{\alpha\beta}^{(k)} P_{\sigma\rho}^{(k)} I_{\mu\nu}^{\mu\nu(k)} P_{(k)*\theta\psi}^{\theta\psi} P_{\gamma\delta}^{(k)} \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} .
\end{aligned} \tag{139}$$

For the mixed propagator on the right side of the identity we must use Eq. (136) and remove the topological term. This leads to

$$\begin{aligned}
\mathcal{M}_{1_J}^{JK} &= -2eb\Pi_J \frac{J^\alpha n^\beta - J^\beta n^\alpha}{2n \cdot k} {}_{\alpha\beta}^{(k)} P_{\sigma\rho}^{(k)} I_{*\mu\nu}^{\mu\nu(k)} P_{\gamma\delta}^{(k)} \frac{K^\gamma n^\delta - K^\delta n^\gamma}{2n \cdot k} \\
&= 0 .
\end{aligned} \tag{140}$$

The effect of a magnetic loop follows a similar pattern and also leads to no renormalization, $\mathcal{M}_{1_K}^{JK} = 0$.

In short, we find that after the topological terms have been removed

$$\mathcal{M}_0^{JJ} + \mathcal{M}_{1_J}^{JJ} + \mathcal{M}_{1_K}^{JJ} = e^2 \frac{J^2}{k^2} [1 + \Pi_J(k^2) - \Pi_K(k^2)] , \tag{141}$$

$$\mathcal{M}_0^{KK} + \mathcal{M}_{1_J}^{KK} + \mathcal{M}_{1_K}^{KK} = b^2 \frac{K^2}{k^2} [1 - \Pi_J(k^2) + \Pi_K(k^2)] , \tag{142}$$

$$\mathcal{M}_0^{JK} + \mathcal{M}_{1_J}^{JK} + \mathcal{M}_{1_K}^{JK} = eb \frac{\varepsilon_{\alpha\beta\gamma\delta} J^\alpha K^\beta n^\gamma k^\delta}{k^2 (n \cdot k)} . \tag{143}$$

Again, this shows that electric and magnetic couplings run inversely once the dynamical calculations are free from the topological phase terms. That is,

$$e = e_0 \sqrt{Z} , \quad b = \frac{b_0}{\sqrt{Z}} , \quad (144)$$

with

$$Z(k^2) \approx 1 / [1 - \Pi_J(k^2) + \Pi_K(k^2)] . \quad (145)$$

This form of the running is also obtained in Seiberg-Witten theory [19] in the region of moduli space where there are light magnetic charges [39–41].

5.1 Calculating with $F_{\mu\nu}$

One can also derive these results using the actual field strength $F_{\mu\nu}$ as opposed to the n^μ dependent $F_{\mu\nu}^A$ and $F_{\mu\nu}^B$. We first use the fact that the source terms lie completely within the the two-form subspace spanned by ${}^{(n)}_{\mu\nu}P_{\sigma\rho}^{(n)}$. That is,

$$\frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot k} {}^{(n)}_{\mu\nu}P_{\sigma\rho}^{(n)} = \frac{J_\sigma n_\rho - J_\rho n_\sigma}{2n \cdot k} , \quad (146)$$

and similarly for the magnetic currents. This allows us, by using the identities in Eq. (122), to obtain

$$\begin{aligned} F_{\mu\nu}^A \frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot k} &= F_{\mu\nu}^A {}^{\mu\nu}_{(n)}P_{\sigma\rho}^{(n)} \frac{J_\sigma n_\rho - J_\rho n_\sigma}{2n \cdot k} = F_{\mu\nu}^A {}^{\mu\nu}_{(n)}P_{\sigma\rho}^{(n)} \frac{J_\sigma n_\rho - J_\rho n_\sigma}{2n \cdot k} \\ &= F_{\mu\nu}^A \frac{J^\mu n^\nu - J^\nu n^\mu}{2n \cdot k} . \end{aligned} \quad (147)$$

By a nearly identical calculation we also find

$$F_{\mu\nu}^B \frac{K^\mu n^\nu - K^\nu n^\mu}{2n \cdot k} = {}^*F_{\mu\nu} \frac{K^\mu n^\nu - K^\nu n^\mu}{2n \cdot k} . \quad (148)$$

That is, both $F_{\mu\nu}^A$ and $F_{\mu\nu}$ couple to the same electric source and both $F_{\mu\nu}^B$ and ${}^*F_{\mu\nu}$ couple to the same magnetic source.

By using the definition of $F_{\mu\nu}$ in terms of $F_{\mu\nu}^A$ and $F_{\mu\nu}^B$ in Eq. (118) one can also determine

the field strength propagator. This ends up being a quite simple result

$$\begin{aligned}
\langle F_{\mu\nu} F_{\sigma\rho} \rangle_k &= -2i \binom{(n)}{(k)}{\alpha\beta} P^{\gamma\delta} \left(\binom{(n)}{(\mu\nu)} P_{\alpha\beta}^{(n)} P_{\gamma\delta}^{(n)} P_{\sigma\rho}^{(n)} + \binom{(n)}{*\mu\nu} P_{\alpha\beta}^{(n)} P_{\gamma\delta}^{(n)} P_{*\sigma\rho}^{(n)} \right) \\
&\quad + \langle F^{A\alpha\beta} F^{B\gamma\delta} \rangle_k \left(\binom{(n)}{*\mu\nu} P_{\alpha\beta}^{(n)} P_{\gamma\delta}^{(n)} P_{\sigma\rho}^{(n)} - \binom{(n)}{\mu\nu} P_{\alpha\beta}^{(n)} P_{\gamma\delta}^{(n)} P_{*\sigma\rho}^{(n)} \right) \\
&= -2i \left(\binom{(n)}{\mu\nu} P_{\alpha\beta}^{(n)} P_{(k)\gamma\delta}^{(n)} P_{\sigma\rho}^{(n)} + \binom{(n)}{*\mu\nu} P_{\alpha\beta}^{(n)} P_{(k)\gamma\delta}^{(n)} P_{*\sigma\rho}^{(n)} + \binom{(n)}{*\mu\nu} P_{\alpha\beta}^{(n)} P_{(k)\gamma\delta}^{(n)} P_{\sigma\rho}^{(n)} \right. \\
&\quad \left. - \binom{(n)}{\mu\nu} P_{\alpha\beta}^{(n)} P_{(k)\gamma\delta}^{(n)} P_{*\sigma\rho}^{(n)} - \binom{(n)}{*\mu\nu} P_{\alpha\beta}^{(n)} P_{(n)\gamma\delta}^{(n)} P_{\sigma\rho}^{(n)} + \binom{(n)}{\mu\nu} P_{\alpha\beta}^{(n)} P_{(n)\gamma\delta}^{(n)} P_{*\sigma\rho}^{(n)} \right) \\
&= -2i \binom{(k)}{*\mu\nu} P_{*\sigma\rho}^{(k)} - 2i \binom{(n)}{\mu\nu} P_{\sigma\rho}^{(n)} \\
&= -2i \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} - 2i \binom{(n)}{*\mu\nu} P_{*\sigma\rho}^{(n)} .
\end{aligned} \tag{149}$$

$$= -2i \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} - 2i \binom{(n)}{*\mu\nu} P_{*\sigma\rho}^{(n)} . \tag{150}$$

In the second equality, the last two terms of the second line vanish because we are contracting indices that project into the n^μ subspace and those that project into the orthogonal space. Note that this shows that the topological part of the mixed propagator is projected out and plays no role in this computation. At the same time, the field strength propagator does depend on n^μ . But, unlike the topological terms, there is no mixing of the k^μ terms and the n^μ terms.

Correlators involving $*F_{\mu\nu}$ can be obtained from Eq. (150) by contracting with Levi-Civita tensors. Note that the final two equalities immediately imply that

$$\langle *F_{\mu\nu} *F_{\sigma\rho} \rangle_k = \langle F_{\mu\nu} F_{\sigma\rho} \rangle_k . \tag{151}$$

This underscores the fact that Zwanziger's formalism treats electric and magnetic currents in a duality covariant way, in stark contrast to the single potential formalism. One also finds that

$$\begin{aligned}
\langle *F_{\mu\nu} F_{\sigma\rho} \rangle_k &= -\langle F_{\mu\nu} *F_{\sigma\rho} \rangle_k = -2i \binom{(k)}{*\mu\nu} P_{\sigma\rho}^{(k)} + 2i \binom{(n)}{\mu\nu} P_{*\sigma\rho}^{(n)} \\
&= 2i \binom{(k)}{\mu\nu} P_{*\sigma\rho}^{(k)} - 2i \binom{(n)}{*\mu\nu} P_{\sigma\rho}^{(n)} .
\end{aligned} \tag{152}$$

When contracted with external current Stokes surfaces of the form $J^\mu n^\nu - J^\nu n^\mu$ the terms in the propagators with a star on the n indices project out. This leads to only the photon momentum, k^μ , dependent parts of the propagators contributing and leading to the usual results for electric and magnetic interactions. The one-loop corrections also take the same form, as shown in Fig. 11. For electric-magnetic interactions the vacuum polarization function combines with the propagator, revealing the topological terms that do not project out. When these terms are removed we find the correct running coupling. In this way, one can see all of the tree-level and one-loop results as depending on only the propagator of the physical field strength, $F_{\mu\nu}$.

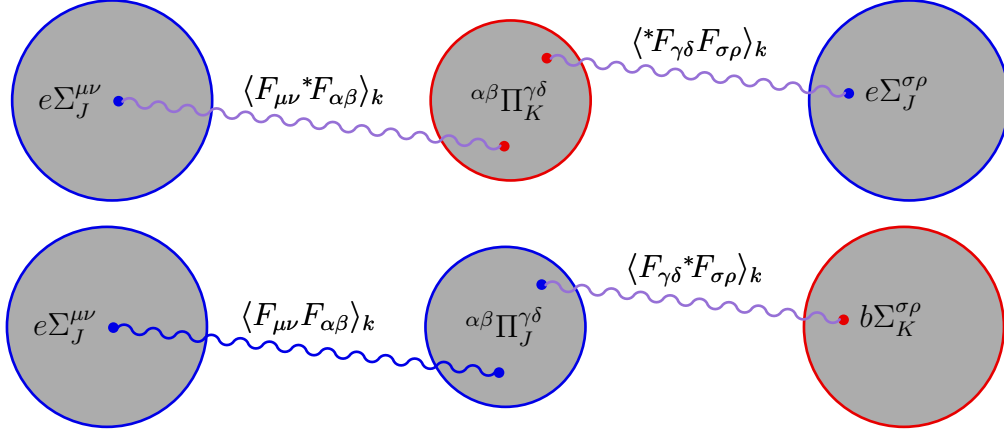

Figure 11: One loop corrections to photon exchange between currents using only $F_{\mu\nu}$ propagators within the Zwanziger formalism. Electric (magnetic) currents and interactions are colored blue (red). Mixed propagators are purple.

6 Bounding Magnetically Charged Particles From Fine-Structure Running

Now that the perturbative contribution of magnetic particles to electric running is understood, we can use the measured running of e to probe the charge and mass of magnetic states. The most precise theory prediction of the running fine structure parameter is $\alpha(m_Z)^{-1} = 128.951 \pm 0.045$ [42]. The most precise measurement of $\alpha(m_Z)$ can be found from [43]. From their figures we extract that at 68% confidence

$$\alpha(m_Z)^{-1} \in [127.3, 129.8] . \quad (153)$$

Recall that the one-loop contribution of a Dirac fermion with electric charge q to the running of e comes from the coefficient of the logarithmically divergent part of the loop function

$$\frac{q^2 e^2}{12\pi^2} . \quad (154)$$

For a scalar of charge q this result is simply divided by 4. This enters into the beta function for e as

$$Q \frac{de}{dQ} = e \frac{q^2 e^2}{12\pi^2} , \quad (155)$$

where Q is the energy scale. Note that this can be written in terms of α as

$$Q \frac{d\alpha}{dQ} = \frac{2q^2\alpha^2}{3\pi} \quad \text{or} \quad Q \frac{d\alpha^{-1}}{dQ} = -\frac{2q^2}{3\pi}. \quad (156)$$

To obtain the effect of a particle with magnetic charge g we use the same loop function formula with $+$ \rightarrow $-$ and $eq \rightarrow 4\pi g/e$. Thus, the coefficient of the logarithmically divergent part of the magnetic loop is

$$-\frac{4g^2}{3e^2}, \quad (157)$$

and the beta function is

$$Q \frac{de}{dQ} = -e \frac{4g^2}{3e^2}. \quad (158)$$

This can also be written in terms of α . We find

$$Q \frac{d\alpha}{dQ} = -\frac{2g^2}{3\pi} \quad \text{and} \quad Q \frac{d\alpha^{-1}}{dQ} = \frac{2g^2\alpha^{-2}}{3\pi}. \quad (159)$$

Clearly, the magnetic charge contributes to the running of α^{-1} exactly the way an electric charge contributes to the running of α .

The one-loop contribution to the value of $\alpha(m_Z)$ from a magnetic fermion with charge g and mass m is simply

$$\alpha(m_Z) - \alpha(m) = -\frac{2g^2}{3\pi} \ln \frac{m_Z}{m}. \quad (160)$$

To agree with the experimental limits we require this modification of $\alpha(m_Z)$ to be less than 5×10^{-5} . This then bounds the possible charges and masses of the magnetic states. The allowed regions of parameter space are shown in Fig. 12 for both scalar (blue) and fermionic (red) magnetic monopoles. These bounds only apply to cases in which the magnetic charge is perturbative, such as what can result from kinetic mixing. The bounds we find are significantly weaker than those which have been already discussed in the literature [15, 16, 18] but show how understanding the effects of virtual magnetic particles on various measured quantities allows for definite physical predictions.

Figure 12: Region of magnetic charge and mass allowed by measurements of the running of e for both scalar (blue) and fermionic (red) magnetic particles.

7 Conclusion

In this work we have outlined a momentum space formalism for tracking the propagating degrees of freedom using field strengths, rather than vector potentials. This method is algebraically equivalent to the usual potential formalism, but provides a useful geometric picture where the field strength couples to a Stokes surface that has a worldline associated with the conserved current for its boundary. These surfaces can be chosen to have a simple implementation in momentum space, but then in position space correspond to an infinite surface along a direction n^μ that closes only at infinity.

This method reproduces all the standard results of QED when restricted to calculations with only electric charges. When magnetic charges are included, both field strength and potential methods produce the same results. These results naively show that electric and magnetic couplings are renormalized in exactly the same way, as Schwinger thought. However, both methods also generate spurious “contact” terms between the currents, signaling a subtle error.

The field strength formalism allows us to carefully remove topological terms that appear in the perturbation series. Following this procedure we show that, when the topological terms are removed for resummation into an overall phase, the current-current “contact” terms are not generated. In addition, we find that the electric and magnetic couplings are

renormalized exactly inversely, in agreement with Coleman, and the renormalization group invariance of the Dirac charge quantization.

These results confirm that the standard method, using a vector potential to calculate the running of the coupling, is dangerously confused by these topological terms. Our field strength–momentum space formalism makes clear how these topological terms affect the results and how to remove them. It also provides a procedure for calculating the effects of magnetic monopole loops, when this is justified by perturbation theory. As an example we have obtained bounds on the mass and charge of “dark” magnetic particles from the measured running of the electric coupling.

It will be interesting to extend this analysis to the running of the CP violating θ parameter, which becomes physical in Abelian theories with both electric and magnetic charges. This formalism should also provide some insight into exactly how kinetic mixing with a “dark” magnetic sector can be induced by loops of heavy particles.

A The Field Strength Propagators

In this section we derive the propagators for the field strength in single potential formulations of QED and for $F_{\mu\nu}^A$ and $F_{\mu\nu}^B$ in Zwanziger’s formalism. We begin by deriving the propagator for $F_{\mu\nu}$ in single potential theories. First, we employ the canonical formalism and then we obtain the same result from the path integral. Then we derive the propagators in the two potential formalism using the path integral.

A.1 Single Potential: Canonical Formalism

In single potential QED, we relate the time ordered product of field strengths to derivatives of time ordered products of potentials. From the Schwinger Dyson equations [44] we find

$$\begin{aligned}
\partial_0 \partial'_0 \langle A_\mu(x) A_\nu(x') \rangle &= \langle \partial_0 A_\mu(x) \partial'_0 A(x')_\nu \rangle + \delta(t-t') \langle 0 | [\partial_0 A_\mu(x), A_\nu(x')] | 0 \rangle , \\
&\quad - \delta'(t-t') \langle 0 | [A_\mu(t, \mathbf{x}), A_\nu(t, \mathbf{x}')] | 0 \rangle , \\
\partial_0 \partial'_i \langle A_\mu(x) A_\nu(x') \rangle &= \langle \partial_t A_\mu(x) \partial'_i A_\nu(x') \rangle + \delta(t-t') \partial'_i \langle 0 | [A_\mu(x), A_\nu(x')] | 0 \rangle , \\
\partial_i \partial'_0 \langle A_\mu(x) A_\nu(x') \rangle &= \langle \partial_i A_\mu(x) \partial'_0 A_\nu(x') \rangle - \delta(t-t') \partial_i \langle 0 | [A_\mu(x), A_\nu(x')] | 0 \rangle , \\
\partial_i \partial'_j \langle A_\mu(x) A_\nu(x') \rangle &= \langle \partial_i A_\mu(x) \partial'_j A_\nu(x') \rangle .
\end{aligned} \tag{161}$$

Here we are using the notation $\langle XY \rangle \equiv \langle 0 | T \{ XY \} | 0 \rangle$ to denote time-ordered, vacuum-to-vacuum amplitudes. In the standard R_ξ gauges we have the following commutators for the vector potential and its time derivatives [45]:

$$[A_\mu(x), A_\nu(x')] = 0 , \tag{162}$$

$$[\partial_t A_\mu(t, \mathbf{x}'), A_\nu(t, \mathbf{x})] = i \left(\eta_{\mu\nu} - \frac{\zeta - 1}{\zeta} \delta_\mu^0 \delta_\nu^0 \right) \delta^3(\mathbf{x} - \mathbf{x}') , \tag{163}$$

where $\eta_{\mu\nu}$ is the Minkowski metric. From these commutators we compute the time-ordered, vacuum-to-vacuum correlation function of the field strength

$$\begin{aligned}
\langle F_{\mu\nu}(x) F_{\sigma\rho}(x') \rangle &= \left(\partial_\mu \partial'_\sigma \langle A_\nu(x) A_\rho(x') \rangle \right)_{[\mu\nu][\sigma\rho]} - \left(\delta(t-t') \delta_\mu^0 \delta_\sigma^0 \langle 0 | [\partial_0 A_\nu(x), A_\rho(x')] | 0 \rangle \right)_{[\mu\nu][\sigma\rho]} \\
&+ \left(\delta_\mu^0 \delta_\sigma^0 \delta'(t-t') \langle 0 | [A_\nu(x), A_\rho(x')] | 0 \rangle \right)_{[\mu\nu][\sigma\rho]} + \left(\delta(t-t') \delta_\mu^i \delta_\sigma^0 \partial_i \langle 0 | [A_\nu(x), A_\rho(x')] | 0 \rangle \right)_{[\mu\nu][\sigma\rho]} \\
&- \left(\delta_\mu^0 \delta_\sigma^j \delta(t-t') \partial'_j \langle 0 | [A_\nu(x), A_\rho(x')] | 0 \rangle \right)_{[\mu\nu][\sigma\rho]}
\end{aligned} \tag{164}$$

The notation $(-)[\dots]$ means to antisymmetrize the parenthetical quantity across the bracketed indices. In simplifying this result we find that all gauge dependent terms cancel

$$\langle F_{\mu\nu}(x) F_{\sigma\rho}(x') \rangle = - \int \frac{d^4 p}{(2\pi)^4} \frac{i}{p^2 + i\epsilon} p_{[\mu} \eta_{\nu][\rho} p_{\sigma]} e^{ip(x-x')} - i \delta_{[\mu}^0 \eta_{\nu][\rho} \delta_{\sigma]}^0 \delta^4(x-x') , \tag{165}$$

but also the appearance of a noncovariant contact term.

How does this term affect the Feynman rules of this theory? In order to use the $\langle F_{\mu\nu} F_{\sigma\rho} \rangle$ correlator in the perturbation expansion we need to directly source the field strength. We

take $\Sigma^{\mu\nu}$ to be whatever function of the fields couples to $F_{\mu\nu}$. By the antisymmetry of $F_{\mu\nu}$ we see that only the antisymmetric part of $\Sigma^{\mu\nu}$ couples to F thus take $\Sigma^{\mu\nu}$ to be antisymmetric in its indices. Starting with the Lagrangian

$$\mathcal{L} = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} - F_{\mu\nu}\Sigma^{\mu\nu} , \quad (166)$$

we find the canonical momenta are

$$\Pi^\mu = \frac{\partial\mathcal{L}}{\partial(\partial_0 A_\mu)} = -F^{0\mu} - 2\Sigma^{0\mu} . \quad (167)$$

From the antisymmetry of $F_{\mu\nu}$ and $\Sigma_{\mu\nu}$ we find that $\Pi^0 = 0$; this is our first constraint. The Hamiltonian is given by

$$\begin{aligned} \mathcal{H} &= \dot{A}_\mu \Pi^\mu - \mathcal{L} \\ &= \frac{1}{2}\|\Pi\|^2 + \Pi \cdot \nabla A^0 + \frac{1}{4}F_{ij}F^{ij} + 2\Pi^i\Sigma^{0i} + 2\Sigma^{0i}\Sigma^{0i} + F_{ij}\Sigma^{ij} . \end{aligned} \quad (168)$$

The secondary constraint is found by demanding that the primary constraint does not evolve in time,

$$0 = \dot{\Pi}^0 = -\frac{\delta\mathcal{H}}{\delta A^0} = \nabla \cdot \Pi \quad (169)$$

Including this in the Hamiltonian, and integrating by parts, we find

$$\mathcal{H} = \frac{1}{2}\|\Pi\|^2 + \frac{1}{4}F_{ij}F^{ij} + 2\Pi^i\Sigma^{0i} + 2\Sigma^{0i}\Sigma^{0i} + F_{ij}\Sigma^{ij} . \quad (170)$$

Thus, the Hamiltonian includes quadratic terms that are explicitly non-negative and independent of all current terms, this is the free Hamiltonian. The Hamiltonian's interaction terms are given by

$$\mathcal{H}_{\text{int}} = 2\Pi^i\Sigma^{0i} + 2\Sigma^{0i}\Sigma^{0i} + F_{ij}\Sigma^{ij} . \quad (171)$$

Having identified the free and interaction parts of the Hamiltonian we can move to the interaction picture. Thus we substitute in our *free field* definition for the canonical momentum ($\Pi^\mu = -F^{0\mu}$) to find

$$\mathcal{H}_{\text{int}} = 2\Sigma^{0i}\Sigma^{0i} + \Sigma^{\mu\nu}F_{\mu\nu} = -2\Sigma_{0\nu}\Sigma^{0\nu} - \mathcal{L}_{\text{int}} . \quad (172)$$

In the canonical picture, the Feynman rules are derived from the Dyson series which depend on the interaction *Hamiltonian* not the interaction *Lagrangian*. When one goes

through the full derivation of the Feynman rules, one finds that the non-covariant terms in the interaction Hamiltonian cancel exactly with the non-covariant terms in the time ordered correlation function for $F_{\mu\nu}$. This same cancellation of noncovariant terms happens in other theories with derivative couplings [46].

Because the argument above was arbitrary with respect to what $\partial_{[\mu}A_{\nu]}$ couples to we see that it also holds for the single potential theory with magnetic monopoles, where the definition of $F_{\mu\nu}$ changes. The addition of the new couplings leads to new non-covariant terms in the interaction hamiltonian which exactly cancel with the terms introduced by new couplings of the non covariant terms in $\langle F_{\mu\nu}F_{\sigma\rho} \rangle$. Thus, we find that in single potential theories that the field strength propagator, which enters into the Feynman rules, is given in momentum space as

$$\langle F_{\mu\nu}F_{\sigma\rho} \rangle_k = -2i_{\mu\nu}^{(k)} P_{\sigma\rho}^{(k)} . \quad (173)$$

This is precisely the form used in the body of the paper, motivated by much simpler arguments.

A.2 Single Potential: Path Integral Formalism

We now derive the $F_{\mu\nu}$ propagator in the path integral formalism and show that we can find it directly without having to worry about noncovariant terms. Start with the generating functional for QED written as,

$$Z[J] \propto \int \mathcal{D}A \delta^\infty(\phi(A)) \exp \left\{ -i \int d^4x \frac{1}{4} F_{\mu\nu} F^{\mu\nu} - i \int d^4x A_\mu J^\mu \right\} \quad (174)$$

where $\phi = 0$ is our gauge fixing constraint and $\delta^\infty(f)$ a functional delta-function. We can change variables from $A_\mu \rightarrow F_{\mu\nu}$ by taking the map

$$F_{\mu\nu} = \partial_{[\mu}A_{\nu]} = \int d^4y \Delta_{\mu\nu,\alpha}(x-y) A^\alpha(y) , \quad (175)$$

where

$$\Delta_{\mu\nu,\alpha}(x-y) = \eta_{\alpha[\mu} \partial_{\nu]} \delta^4(x-y) . \quad (176)$$

We can consider making this change of variables in the path integral. The range of the map is not the space of all two forms, but only exact two forms. Thus, the measure of our transformed integral must include the Bianchi identity constraint through the delta-function

$$\delta^{\infty \times 4}(\partial_\mu^* F^{\mu\nu}) \mathcal{D}F . \quad (177)$$

Here $\mathcal{D}F$ is the measure on the space of all two form fields. With our gauge fixed, this map is a bijection onto its image. This means we can write the inverse map

$$A_\mu(x) = \int d^4y \Delta_{\mu,\alpha\beta}^{-1}(x, y; \phi) F^{\alpha\beta}(y) . \quad (178)$$

This is only properly defined when a particular gauge is chosen. Thus, the inclusion of the dependence on our gauge fixing constraint ϕ . Additionally, note that because our gauge fixing condition could be spacetime dependent Δ^{-1} may not be translation invariant therefore may not be a convolution operator; this motivates the more general form $\Delta^{-1}(x, y; \phi)$ rather than $\Delta^{-1}(x - y; \phi)$. Given this, the interaction term can be written

$$\begin{aligned} \int d^4x J^\mu(x) A_\mu(x) &= \int d^4x J^\mu(x) \int d^4y \Delta_{\mu,\alpha\beta}^{-1}(x, y; \phi) F^{\alpha\beta}(y) \\ &= \int d^4y F^{\alpha\beta}(y) \Sigma_{\alpha\beta}(y) , \end{aligned} \quad (179)$$

where

$$\Sigma_{\alpha\beta}(y) \equiv \int d^4x J^\mu(x) \Delta_{\mu,\alpha\beta}^{-1}(x, y; \phi) . \quad (180)$$

In order to make this change of variables in the path integral we must include a factor of the functional Jacobian determinant in our path integral [47]. The Jacobian is given by,

$$\det \left(\frac{\delta F_{\mu\nu}(x)}{\delta A_\gamma(y)} \right) = \det (\Delta_{\gamma,\mu\nu}(x - y)) . \quad (181)$$

Here we implicitly mean the determinant of the map from gauge fixed potentials to exact two forms, which cannot be zero as this map is invertible. The determinant of the map from arbitrary gauge potentials to arbitrary two forms is certainly zero. This determinant is field independent so it can be brought outside of the path integral and only leads to a change in normalization. This simple result follows from the linear change of variables and would not hold for a nonlinear transformation. For example, the change of variables from potentials to field strengths would likely be significantly more complicated in a nonabelian gauge theory.

Given that Δ is a differential operator its inverse is necessarily nonlocal. We also see that there is a redundancy in the definition of the function which couples to $F_{\mu\nu}$ which comes from the gauge redundancy of A . If we suppose that the current comes from a

closed particle trajectory and then apply Stokes' Theorem we find a coupling that looks like

$$\int d^4x A_\mu(x) J_{\text{Loop}}^\mu(x) = \int d^4x F_{\mu\nu}(x) \Sigma_{\text{Surface}}^{\mu\nu}(x) . \quad (182)$$

As is discussed in Appendix B, this coupling is invariant under a change of surface which leaves the boundary unchanged. Comparing Eqs. (179) and (182) we see that there is a correspondence between Stokes' surface invariance and gauge invariance. It is not clear, however, if this correspondence is one-to-one; for example the equations (179) and (182) can differ by 2π times an integer and still correspond to the same physical coupling.

Still, given a gauge fixing constraint we can find the inverse defined above which leads to a particular coupling to $F_{\mu\nu}$. For example, choosing the familiar Lorenz gauge, $\phi(A) = \partial_\mu A^\mu$, produces

$$A^\nu = \frac{1}{\square} \partial_\mu F^{\mu\nu} , \quad (183)$$

and so to

$$\Sigma^{\mu\nu}(x) = \frac{1}{2} \frac{1}{\square} \partial^{[\mu} J^{\nu]} . \quad (184)$$

Similarly, in axial gauge, $\phi(A) = n_\mu A^\mu$, we find

$$A^\nu = \frac{1}{n \cdot \partial} n_\mu F^{\mu\nu} , \quad (185)$$

and

$$\Sigma^{\mu\nu}(x) = \frac{1}{2} \frac{1}{n \cdot \partial} n^{[\mu} J^{\nu]} . \quad (186)$$

We emphasize the agreement between this expression and the Stokes' surface form derived in Appendix B.

Returning to the generating functional, we see that it can be written as a function of the source Σ

$$Z[\Sigma] \propto \int \mathcal{D}F \delta^{\infty \times 4}(\partial_\mu^* F^{\mu\nu}) \exp \left\{ -i \int d^4x \frac{1}{4} F_{\mu\nu} F^{\mu\nu} - i \int d^4x F_{\mu\nu} \Sigma^{\mu\nu} \right\} . \quad (187)$$

It still remains to consider how to treat the delta function that enforces the Bianchi identity. We write this constraint as

$$\delta^{\infty \times 4}(\partial_\mu^* F^{\mu\nu}) \propto \int \mathcal{D}\Lambda \exp \left\{ -i \int d^4x \Lambda_\nu \partial_\mu^* F^{\mu\nu} \right\} , \quad (188)$$

where $\Lambda_\mu(x)$ is an auxiliary field which takes the form of a Lagrange multiplier. However, we choose to enforce the Bianchi constraint using a different method, similar to that used to derive the potential propagator in the R_ξ gauges of QED. We write the delta-function in Eq. (188) as the following limit

$$\delta^{\infty \times 4}(\partial_\mu {}^*F^{\mu\nu}) = \lim_{\xi \rightarrow \infty} \int \mathcal{D}\Lambda \exp \left\{ -i \int d^4x \left[\Lambda_\nu \partial_\mu {}^*F^{\mu\nu} - \frac{1}{2} \frac{1}{\xi} \partial_\nu \Lambda_\mu \partial^\nu \Lambda^\mu \right] \right\}, \quad (189)$$

After integrating out the auxiliary field we find

$$\delta^{\infty \times 4}(\partial_\mu {}^*F^{\mu\nu}) \propto \lim_{\xi \rightarrow \infty} \exp \left\{ -i \frac{\xi}{8} \int d^4x F_{\mu\nu} \varepsilon^{\mu\nu\alpha\beta} \frac{1}{\square} (\partial_\alpha \eta_{\beta\gamma} \partial_\delta) \varepsilon^{\gamma\delta\sigma\rho} F_{\sigma\rho} \right\}. \quad (190)$$

which implies the generating functional is

$$Z[\Sigma] \propto \lim_{\xi \rightarrow \infty} \int \mathcal{D}F \exp \left\{ -i \int d^4x \frac{F_{\mu\nu}}{2} \left(\frac{\mu\nu I^{\sigma\rho}}{2} + \frac{\xi}{4} \varepsilon^{\mu\nu\alpha\beta} \left(\frac{1}{\square} \partial_\alpha \eta_{\beta\gamma} \partial_\delta \right) \varepsilon^{\gamma\delta\sigma\rho} \right) F_{\sigma\rho} - i \int d^4x F_{\mu\nu} \Sigma^{\mu\nu} \right\}. \quad (191)$$

This shows that to find the $F_{\mu\nu}$ propagator we must invert the kinetic operator given, in momentum space, as

$$\tilde{\mathcal{K}}_{\mu\nu, \sigma\rho} = \frac{i}{2} {}_{\mu\nu} I_{\sigma\rho} + i \frac{\xi}{2} {}_{*\mu\nu} P_{*\sigma\rho}^{(k)} = \frac{i}{2} \left({}_{\mu\nu} P_{\sigma\rho}^{(k)} - (1 - \xi) {}_{*\mu\nu} P_{*\sigma\rho}^{(k)} \right). \quad (192)$$

Given the fact that $-{}_{*\mu\nu} P_{*\sigma\rho}^{(k)}$ is the orthogonal projector to ${}_{\mu\nu} P_{\sigma\rho}^{(k)}$ the inverse can be quickly determined. Therefore, we find the $F_{\mu\nu}$ propagator is given by

$$\langle F_{\mu\nu} F_{\sigma\rho} \rangle_k = \lim_{\xi \rightarrow \infty} -2i \left({}_{\mu\nu} P_{\sigma\rho}^{(k)} - (1 - \xi)^{-1} {}_{*\mu\nu} P_{*\sigma\rho}^{(k)} \right) = -2i {}_{\mu\nu} P_{\sigma\rho}^{(k)}, \quad (193)$$

which is exactly what we found using canonical quantization methods in the previous subsection as well as through the heuristic methods in the body of the paper. We note that this method is very similar to the derivation of the A_μ propagator in R_ξ gauge. The only difference is that after inverting the kinetic operator we must take the limit $\xi \rightarrow \infty$ rather than leave ξ as an arbitrary parameter.

A.3 Two Potential Propagators

While it may seem an interesting problem to derive the two potential field strength propagators in the canonical formalism, the process is much more tedious. The cancellation

of noncovariant terms is not so simple due to the many redundant degrees of freedom that come from describing the two propagating modes by two vector potentials. Rather than illustrate this process we show only the path integral derivation of the field strength propagators, where the extra non-covariant contact terms do not appear.

This follows the same method as in the previous subsection, making the change of variables from $A_\mu \rightarrow F_{\mu\nu}^A$ and $B_\mu \rightarrow F_{\mu\nu}^B$. One finds that the generating functional can be written as

$$Z[\Sigma_J, \Sigma_K] \propto \lim_{\xi_A \rightarrow \infty} \lim_{\xi_B \rightarrow \infty} \int \mathcal{D}F^A \mathcal{D}F^B \exp \left\{ -\frac{1}{2} \int d^4x F_{\mu\nu}^X \mathcal{K}_{XY}^{\mu\nu, \sigma\rho} F_{\sigma\rho}^Y - i \int d^4x F_{\mu\nu}^A \Sigma_J^{\mu\nu} - i \int d^4x F_{\mu\nu}^B \Sigma_K^{\mu\nu} \right\}, \quad (194)$$

here indices $X, Y \in \{A, B\}$ denote the two types of potential. Here the kinetic term is expressed, in momentum space, as

$$\tilde{\mathcal{K}}_{\mu\nu, \sigma\rho}^{XY} = \frac{i}{2} \begin{bmatrix} {}^{(n)}P_{\sigma\rho}^{(n)} + \xi_{A*\mu\nu} {}^{(k)}P_{*\sigma\rho}^{(k)} & -{}^{(n)}P_{*\mu\nu}^{(n)} \\ {}^{(n)}P_{*\mu\nu}^{(n)} & {}^{(n)}P_{\sigma\rho}^{(n)} + \xi_{B*\mu\nu} {}^{(k)}P_{*\sigma\rho}^{(k)} \end{bmatrix}. \quad (195)$$

While we have avoided the tedium of tracking the noncovariant terms that arise in canonical quantization, we do have to confront the inversion of this twelve-by-twelve matrix. However, it does take the form of six-by-six blocks so we can use the standard inversion of block matrices. That is, a block matrix of the form

$$\mathbf{M} = \begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix}, \quad (196)$$

has an inverse which may be expressed in two equivalent ways

$$\begin{aligned} \mathbf{M}^{-1} &= \begin{pmatrix} \mathbf{A}^{-1} + \mathbf{A}^{-1}\mathbf{B}(\mathbf{D} - \mathbf{C}\mathbf{A}^{-1}\mathbf{B})^{-1}\mathbf{C}\mathbf{A}^{-1} & -\mathbf{A}^{-1}\mathbf{B}(\mathbf{D} - \mathbf{C}\mathbf{A}^{-1}\mathbf{B})^{-1} \\ -(\mathbf{D} - \mathbf{C}\mathbf{A}^{-1}\mathbf{B})^{-1}\mathbf{C}\mathbf{A}^{-1} & (\mathbf{D} - \mathbf{C}\mathbf{A}^{-1}\mathbf{B})^{-1} \end{pmatrix}, \\ &= \begin{pmatrix} (\mathbf{A} - \mathbf{B}\mathbf{D}^{-1}\mathbf{C})^{-1} & -(\mathbf{A} - \mathbf{B}\mathbf{D}^{-1}\mathbf{C})^{-1}\mathbf{B}\mathbf{D}^{-1} \\ -\mathbf{D}^{-1}\mathbf{C}(\mathbf{A} - \mathbf{B}\mathbf{D}^{-1}\mathbf{C})^{-1} & \mathbf{D}^{-1} + \mathbf{D}^{-1}\mathbf{C}(\mathbf{A} - \mathbf{B}\mathbf{D}^{-1}\mathbf{C})^{-1}\mathbf{B}\mathbf{D}^{-1} \end{pmatrix}. \end{aligned} \quad (197)$$

To use this formula we make great use of the analysis of two-form mappings in Sec. 3. In particular, we remind the reader of the identities

$${}^{(k)}P_{\mu\nu}^{(k)\alpha\beta} P_{\sigma\rho}^{(n)} = {}^{(k)}P_{\mu\nu}^{(n)} P_{\sigma\rho}^{(k)}, \quad {}^{(k)}P_{\mu\nu}^{(k)\alpha\beta} P_{\sigma\rho}^{(k)} = {}^{(k)}P_{\mu\nu}^{(k)} P_{\sigma\rho}^{(k)}, \quad {}^{(k)}P_{\mu\nu}^{(n)\alpha\beta} P_{\sigma\rho}^{(n)} = {}^{(k)}P_{\mu\nu}^{(n)} P_{\sigma\rho}^{(n)}, \quad (198)$$

along with those obtained by exchanging n^μ and k^μ . It is then straightforward to check that the inverse of the \mathbf{A} block

$$\mathbf{A} = \binom{(n)}{\mu\nu} P_{\sigma\rho}^{(n)} + \xi_A \binom{(k)}{* \mu\nu} P_{* \sigma\rho}^{(k)}, \quad (199)$$

is

$$\mathbf{A}^{-1} = \binom{(k)}{\mu\nu} P_{\alpha\beta}^{(n)} \binom{(n)}{\alpha\beta} P_{\sigma\rho}^{(k)} + \frac{1}{\xi_A} \binom{(n)}{* \mu\nu} P_{\alpha\beta}^{(k)} \binom{(k)}{* \sigma\rho} P_{* \sigma\rho}^{(n)}. \quad (200)$$

We then find that

$$\mathbf{D} - \mathbf{C}\mathbf{A}^{-1}\mathbf{B} = \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(n)} + \xi_B \binom{(k)}{* \mu\nu} P_{* \sigma\rho}^{(k)}, \quad (201)$$

which has the inverse

$$(\mathbf{D} - \mathbf{C}\mathbf{A}^{-1}\mathbf{B})^{-1} = \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} + \frac{1}{\xi_B} \binom{(n)}{* \mu\nu} P_{* \sigma\rho}^{(k)}. \quad (202)$$

Putting all the pieces together we find that the inverse of the entire matrix is given by

$$(\tilde{\mathcal{K}}^{-1})_{\mu\nu, \sigma\rho}^{XY} = -2i \begin{bmatrix} \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} + \frac{1}{\xi_A} \binom{(n)}{* \mu\nu} P_{* \sigma\rho}^{(k)} & \binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(k)} - \binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(n)} - \frac{1}{\xi_A} \binom{(n)}{* \mu\nu} P_{\sigma\rho}^{(k)} \\ -\binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(k)} + \binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(n)} + \frac{1}{\xi_B} \binom{(n)}{* \mu\nu} P_{\sigma\rho}^{(k)} & \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} + \frac{1}{\xi_B} \binom{(n)}{* \mu\nu} P_{* \sigma\rho}^{(k)} \end{bmatrix}. \quad (203)$$

We then take the limit $\xi_A \rightarrow \infty$ and $\xi_B \rightarrow \infty$ to find that the propagators are given by

$$\begin{bmatrix} \langle F^A F^A \rangle_k & \langle F^A F^B \rangle_k \\ \langle F^B F^A \rangle_k & \langle F^B F^B \rangle_k \end{bmatrix} = -2i \begin{bmatrix} \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} & \binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(k)} - \binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(n)} \\ -\binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(k)} + \binom{(k)}{\mu\nu} P_{* \sigma\rho}^{(n)} & \binom{(k)}{\mu\nu} P_{\sigma\rho}^{(k)} \end{bmatrix}. \quad (204)$$

We again find that the simple calculation in the main text is verified by this more rigorous derivation. This can be considered as a consequence of the fact that it is equivalent to invert an operator and then make a linear change of variables or make the change of variables and then invert the operator. The simple calculation corresponds to the first method, while the more in depth calculation done in this appendix corresponds to the second.

B The Field Strength Source

In this appendix we show that the object used to source the field strengths in this paper corresponds to a specific type of Stokes surface in the worldline formalism [32, 33]. In this formalism we consider conserved currents to be particle trajectories in spacetime, that is

$$J^\mu(x) = q \int_0^T d\tau \delta^4(x - z(\tau)) \frac{dz^\mu}{d\tau}, \quad (205)$$

where $z(\tau)$ is a parametrization of our path $\gamma = z([0, T])$. The coupling of the current to a vector potential is

$$\int d^4x J^\mu(x) A_\mu(x) = q \int_0^T d\tau A_\mu(z(\tau)) \frac{dz^\mu}{d\tau} = q \int_\gamma \mathbf{A} , \quad (206)$$

where we use the differential form notation $\mathbf{A} = A_\mu dz^\mu$ in the last equality. We then assume that the trajectory forms a closed loop and apply Stokes' theorem to get

$$q \int_\gamma \mathbf{A} = q \int_S d\mathbf{A} = q \int d\tau d\eta \partial_{[\mu} A_{\nu]}(s(\tau, \eta)) \frac{1}{2} \frac{\partial s^{[\mu}}{\partial \tau} \frac{\partial s^{\nu]}{\partial \eta} . \quad (207)$$

Here $s^\mu(\tau, \eta)$ is a parametrization of the surface S bounded by the current loop. While it is not obvious, this result is independent of the choice of surface.

Consider integrals over two surfaces S_1 and S_2 which share the same boundary loop. Together these surfaces bound some volume V . By applying Stokes' theorem to the difference of these two integrals we find

$$\int_{S_1} d\mathbf{A} - \int_{S_2} d\mathbf{A} = \int_V d^2 \mathbf{A} = \int d\tau d\eta d\zeta \partial_{[\mu} \partial_{\nu} A_{\sigma]} \frac{1}{6} \frac{\partial v^{[\mu}}{\partial \tau} \frac{\partial v^{\nu}}{\partial \eta} \frac{\partial v^{\sigma]}}{\partial \zeta} = 0 , \quad (208)$$

where $v(\tau, \eta, \zeta)$ is a parametrization of the volume V .

This result shows that a local coupling to a potential always has a manifestly surface invariant coupling to the field strength. In particular, Zwanziger's formalism is useful not only because it has local couplings to potentials but also because it has manifest surface invariance in its couplings of the $F_{\mu\nu}^A$ and $F_{\mu\nu}^B$ fields strengths to sources. This is not true for all theories of electric and magnetic charges. In some cases the coupling between field strength and source is only Stokes surface invariant up to linking and intersection numbers [31].

With this invariance in mind we return to surface defined in (207). The surface element in the worldline formalism is given by

$$\Sigma^{\mu\nu}(x) = q \int d\tau d\eta \delta^4(x - s(\tau, \eta)) \frac{1}{2} \frac{\partial s^{[\mu}}{\partial \tau} \frac{\partial s^{\nu]}}{\partial \eta} . \quad (209)$$

In general this depends on our choice of spanning surface. We explore a particular choice in the next subsection that has relevance to the calculations made in this paper.

B.1 Cylindrical Stoke's Surface

Suppose that our surface parameterization is the extrusion of our current loop out to infinity along the direction n^μ . As a technical note, this is not a closed surface and so requires the usual assumption of vanishing boundary conditions in a neighborhood of infinity. This would be parametrized by

$$s^\mu(\eta, \tau) = z^\mu(\tau) + \eta \cdot n^\mu. \quad (210)$$

The surface element is then

$$\Sigma^{\mu\nu}(x) = q \int_0^T d\tau \int_0^\infty d\eta \delta^4(x - z(\tau) + \eta n) \frac{1}{2} \frac{dz^{[\mu}}{d\tau} n^{\nu]}. \quad (211)$$

For a semi-infinite representation of the Dirac string we have that $(n \cdot \partial)^{-1}$ [20] is given by

$$(n \cdot \partial)^{-1}(x) = - \int_0^\infty ds \delta^4(x + ns). \quad (212)$$

This allows us to write the surface as

$$\Sigma^{\mu\nu}(x) = -q \int_0^T d\tau \frac{dz^{[\mu}}{d\tau} n^{\nu]} \frac{1}{2} \frac{1}{n \cdot \partial} (x - z(\tau)). \quad (213)$$

In Fourier space we find

$$\Sigma^{\mu\nu}(x) = q \int \frac{d^4 k}{(2\pi)^4} \int d\tau \frac{dz^{[\mu}}{d\tau} n^{\nu]} \frac{1}{2} \frac{i}{n \cdot k} e^{ik \cdot (x-z)}. \quad (214)$$

We would like to express this in terms of the conserved current. To do this we must express the current in momentum space:

$$J(x) = q \int \frac{d^4 k}{(2\pi)^4} \int d\tau \frac{dz^\mu}{d\tau} e^{ik \cdot (x-z)} = \int \frac{d^4 k}{(2\pi)^4} e^{ik \cdot x} q \int dz^\mu e^{-ik \cdot z}, \quad (215)$$

which shows that the momentum space current is

$$\tilde{J}(k) = q \int d\tau \frac{dz^\mu}{d\tau} e^{-ik \cdot z}. \quad (216)$$

Plugging this into the surface element produces

$$\Sigma^{\mu\nu}(x) = \int \frac{d^4 k}{(2\pi)^4} e^{ik \cdot x} \tilde{J}^{[\mu} n^{\nu]} \frac{1}{2} \frac{i}{n \cdot k}. \quad (217)$$

Therefore, we find that the surface element can be expressed in momentum space in a way that depends only on the current

$$\tilde{\Sigma}^{\mu\nu}(k) = \frac{1}{2} \frac{i}{n \cdot k} \tilde{\mathcal{J}}^{[\mu} n^{\nu]} . \quad (218)$$

Conversely, we see that the momentum space sources of this form correspond to surface integrals of cylinders created by extruding the current loop in the direction of n^μ .

C Naive Potential Renormalization in Zwanziger Formalism

In this appendix we calculate the renormalization of the Zwanziger propagators using the standard, potential-based methods. Our results agree the single potential calculations and with [48], but contradict those of [49].

To accurately calculate what follow it is useful to note that the matrix

$$\mathcal{M}_{\mu\nu} = \eta_{\mu\nu} + \frac{a}{n \cdot k} k_\mu n_\nu + \frac{b}{n \cdot k} k_\nu n_\mu + \frac{c}{n^2} n_\mu n_\nu + \frac{d}{k^2} k_\mu k_\nu + \frac{e}{n \cdot k} \varepsilon_{\mu\nu\alpha\beta} n^\alpha k^\beta , \quad (219)$$

has the inverse

$$\mathcal{M}_{\mu\nu}^{-1} = x_0 \left[\eta_{\mu\nu} + \frac{x_1}{D} \frac{k_\mu n_\nu}{n \cdot k} + \frac{x_2}{D} \frac{k_\nu n_\mu}{n \cdot k} + \frac{x_3}{D} \frac{n_\mu n_\nu}{n^2} + \frac{x_4}{D} \frac{k_\mu k_\nu}{k^2} - \frac{e}{n \cdot k} \varepsilon_{\mu\nu\alpha\beta} n^\alpha k^\beta \right] , \quad (220)$$

where

$$x_0 = \left[1 + e^2 \left(1 - \frac{n^2 k^2}{(n \cdot k)^2} \right) \right]^{-1} , \quad (221)$$

$$x_1 = (1 + b + d)(a - e^2) - \left(d + e^2 \frac{n^2 k^2}{(n \cdot k)^2} \right) \left(a + c \frac{(n \cdot k)^2}{n^2 k^2} \right) , \quad (222)$$

$$x_2 = (1 + a + c)(b - e^2) - \left(c + e^2 \frac{n^2 k^2}{(n \cdot k)^2} \right) \left(b + d \frac{(n \cdot k)^2}{n^2 k^2} \right) , \quad (223)$$

$$x_3 = (1 + b + d) \left(c + e^2 \frac{n^2 k^2}{(n \cdot k)^2} \right) - (b - e^2) \left(c + a \frac{n^2 k^2}{(n \cdot k)^2} \right) , \quad (224)$$

$$x_4 = (1 + a + c) \left(d + e^2 \frac{n^2 k^2}{(n \cdot k)^2} \right) - (a - e^2) \left(d + b \frac{n^2 k^2}{(n \cdot k)^2} \right) , \quad (225)$$

$$D = \left(c + a \frac{n^2 k^2}{(n \cdot k)^2} \right) \left(b + d \frac{(n \cdot k)^2}{n^2 k^2} \right) - (1 + a + c)(1 + b + d) . \quad (226)$$

First, we recall the standard one potential procedure. The propagator is

$$\Delta_{\mu\nu} = \frac{-i}{k^2} \left(\eta_{\mu\nu} - (1 - \xi) \frac{k_\mu k_\nu}{k^2} \right), \quad (227)$$

and the one-particle-irreducible corrections to the propagator take the form

$$i\Pi_{\mu\nu} = i\Pi(k) (k^2 \eta_{\mu\nu} - k_\mu k_\nu). \quad (228)$$

We then include all these effects as a geometric series

$$\begin{aligned} \Delta_{\mu\nu}^R &= \Delta_{\mu\nu} + i\Delta_{\mu}^{\alpha} \Pi_{\alpha}^{\beta} \Delta_{\beta\nu} + \dots = \Delta_{\mu}^{\alpha} [\eta_{\alpha\nu} + i\Pi_{\alpha}^{\beta} \Delta_{\beta\nu} + \dots] \\ &= \Delta_{\mu}^{\alpha} [\eta^{\alpha\nu} - i\Pi_{\beta}^{\alpha} \Delta^{\beta\nu}]^{-1} = \frac{\Delta_{\mu}^{\alpha}}{1 - \Pi} \left(\eta_{\alpha\nu} - \Pi \frac{k_{\alpha} k_{\nu}}{k^2} \right) \\ &= \frac{\Delta_{\mu\nu}}{1 - \Pi} + \frac{i\xi\Pi}{k^2(1 - \Pi)} \frac{k_{\mu} k_{\nu}}{k^2}. \end{aligned} \quad (229)$$

Note that in general the renormalized propagator Δ^R is not simply a rescaling of the bare propagator, except for $\xi = 0$. Or we could also define the renormalized $\xi_R = \xi(1 - \Pi)$

$$\Delta_{\mu\nu}^R = \frac{-i}{k^2(1 - \Pi)} \left(\eta_{\mu\nu} - (1 - \xi_R) \frac{k_{\mu} k_{\nu}}{k^2} \right). \quad (230)$$

Then, we connect this result to the running of the coupling e by considering the interaction between two currents

$$eJ^{\mu} \Delta_{\mu\nu}^R eJ^{\nu} = -iJ^2 \frac{e^2}{k^2(1 - \Pi)}. \quad (231)$$

In general, we use the definition

$$\Delta_{\mu\nu}^R = Z^{-1} \Delta_{\mu\nu}, \quad (232)$$

where the R label implies that the parameters inside are also renormalized.

We now turn our attention to the two potential formalism. The Zwanziger Lagrangian in momentum space is

$$\mathcal{L} = -\frac{1}{2} A_{\mu} \mathcal{K}_{AA}^{\mu\nu} A_{\nu} - \frac{1}{2} B_{\mu} \mathcal{K}_{BB}^{\mu\nu} B_{\nu} + \frac{1}{2} A_{\mu} \mathcal{K}_{AB}^{\mu\nu} B_{\nu} - eJ^{\mu} A_{\mu} - bK^{\mu} B_{\mu}, \quad (233)$$

where

$$\mathcal{K}_{AA}^{\mu\nu} = \frac{1}{n^2} \left[\eta^{\mu\nu} (n \cdot k)^2 - (n \cdot k) (k^\mu n^\nu + k^\nu n^\mu) + (k^2 - \xi_A^2) n^\mu n^\nu \right], \quad (234)$$

$$\mathcal{K}_{BB}^{\mu\nu} = \frac{1}{n^2} \left[\eta^{\mu\nu} (n \cdot k)^2 - (n \cdot k) (k^\mu n^\nu + k^\nu n^\mu) + (k^2 - \xi_B^2) n^\mu n^\nu \right], \quad (235)$$

are symmetric matrices including the gauge fixing terms [50]

$$\mathcal{L}_{\text{G.F.}} = \frac{1}{2n^2} \left[\xi_A^2 (n \cdot A)^2 + \xi_B^2 (n \cdot B)^2 \right], \quad (236)$$

where $\xi_{A,B}$ have mass dimension one. We also have the antisymmetric tensor

$$\mathcal{K}_{AB}^{\mu\nu} = -\mathcal{K}_{BA}^{\mu\nu} = \frac{n \cdot k}{n^2} \varepsilon^{\mu\nu\alpha\beta} n_\alpha k_\beta. \quad (237)$$

The gauge diagonal matrices can be inverted to find

$$\mathcal{K}_{AA}^{-1\mu\nu} = \frac{n^2}{(n \cdot k)^2} \left[\eta^{\mu\nu} - \frac{1}{n^2} n^\mu n^\nu - \frac{1}{\xi_A^2} k^\mu k^\nu \right], \quad (238)$$

$$\mathcal{K}_{BB}^{-1\mu\nu} = \frac{n^2}{(n \cdot k)^2} \left[\eta^{\mu\nu} - \frac{1}{n^2} n^\mu n^\nu - \frac{1}{\xi_B^2} k^\mu k^\nu \right]. \quad (239)$$

But these are not the propagators, they do not take into account the mixing between the fields. We record the useful relation

$$\varepsilon_{\mu\sigma\alpha\beta} n^\alpha k^\beta \varepsilon_{\rho\nu\gamma\delta} n^\gamma k^\delta \eta^{\mu\nu} = \eta_{\sigma\rho} \left[k^2 n^2 - (n \cdot k)^2 \right] + (n \cdot k) (n_\sigma k_\rho + n_\rho k_\sigma) - k^2 n_\sigma n_\rho - n^2 k_\sigma k_\rho \quad (240)$$

The propagators are obtained by writing the kinetic terms as

$$-\frac{1}{2} (A_\mu, B_\mu) \begin{pmatrix} \mathcal{K}_{AA}^{\mu\nu} & -\mathcal{K}_{AB}^{\mu\nu} \\ -\mathcal{K}_{BA}^{\mu\nu} & \mathcal{K}_{BB}^{\mu\nu} \end{pmatrix} \begin{pmatrix} A_\nu \\ B_\nu \end{pmatrix} \equiv -\frac{1}{2} V_\mu^T \mathcal{K}^{\mu\nu} V_\nu. \quad (241)$$

This block matrix can be inverted using the formulae in Eq. (197). We find

$$-i\mathcal{K}_{\mu\nu}^{-1} = \Delta_{\mu\nu} = \begin{pmatrix} \Delta_{\mu\nu}^{AA} & \Delta_{\mu\nu}^{AB} \\ \Delta_{\mu\nu}^{BA} & \Delta_{\mu\nu}^{BB} \end{pmatrix}, \quad (242)$$

where we have defined

$$\begin{aligned}\Delta_{\mu\nu}^{AA} &= -i\mathcal{K}_{AA}^{-1\mu\alpha} \left[\delta_\nu^\alpha - \mathcal{K}_{AB}^{\alpha\beta} \mathcal{K}_{\beta\gamma}^{BB-1} \mathcal{K}_{BA}^{\gamma\delta} \mathcal{K}_{\delta\nu}^{AA-1} \right]^{-1} \\ &= \frac{-i}{k^2} \left[\eta_{\mu\nu} - \frac{n_\mu k_\nu + n_\nu k_\mu}{n \cdot k} + \frac{n^2}{(n \cdot k)^2} \left(1 - \frac{k^2}{\xi_A^2} \right) k_\mu k_\nu \right],\end{aligned}\quad (243)$$

$$\begin{aligned}\Delta_{\mu\nu}^{BB} &= -i\mathcal{K}_{BB}^{-1\mu\alpha} \left[\delta_\nu^\alpha - \mathcal{K}_{BA}^{\alpha\beta} \mathcal{K}_{\beta\gamma}^{AA-1} \mathcal{K}_{AB}^{\gamma\delta} \mathcal{K}_{\delta\nu}^{BB-1} \right]^{-1} \\ &= \frac{-i}{k^2} \left[\eta_{\mu\nu} - \frac{n_\mu k_\nu + n_\nu k_\mu}{n \cdot k} + \frac{n^2}{(n \cdot k)^2} \left(1 - \frac{k^2}{\xi_B^2} \right) k_\mu k_\nu \right]\end{aligned}\quad (244)$$

$$\Delta_{\mu\nu}^{AB} = \Delta_{\mu\alpha}^{AA} \mathcal{K}_{\alpha\beta}^{AB} \mathcal{K}_{\beta\nu}^{BB-1} = \mathcal{K}_{\mu\alpha}^{AA-1} \mathcal{K}_{\alpha\beta}^{AB} \Delta_{\beta\nu}^{BB} = -\frac{i}{k^2} \frac{\varepsilon_{\mu\nu\alpha\beta} n^\alpha k^\beta}{n \cdot k}, \quad (245)$$

$$\Delta_{\mu\nu}^{BA} = \Delta_{\mu\alpha}^{BB} \mathcal{K}_{\alpha\beta}^{BA} \mathcal{K}_{\beta\nu}^{AA-1} = \mathcal{K}_{\mu\alpha}^{BB-1} \mathcal{K}_{\alpha\beta}^{BA} \Delta_{\beta\nu}^{AA} = \frac{i}{k^2} \frac{\varepsilon_{\mu\nu\alpha\beta} n^\alpha k^\beta}{n \cdot k}. \quad (246)$$

These propagators can also be obtained by treating \mathcal{K}_{AB} as a mixing term. For instance, we consider the infinite series of mixings

$$\begin{aligned}&\mathcal{K}_{AA}^{-1\mu\nu} + \mathcal{K}_{AA}^{-1\mu\alpha} \mathcal{K}_{\alpha\beta}^{AB} \mathcal{K}_{\beta\gamma}^{BB-1} \mathcal{K}_{\gamma\delta}^{BA} \mathcal{K}_{\delta\nu}^{AA-1} + \dots \\ &= \mathcal{K}_{AA}^{-1\mu\alpha} \left[\delta_\nu^\alpha - \mathcal{K}_{AB}^{\alpha\beta} \mathcal{K}_{\beta\gamma}^{BB-1} \mathcal{K}_{BA}^{\gamma\delta} \mathcal{K}_{\delta\nu}^{AA-1} \right]^{-1} = i\Delta_{AA}^{\mu\nu}\end{aligned}\quad (247)$$

A nearly identical calculation leads to the B_μ to B_ν propagator. The mixed propagator is obtained from the series

$$\begin{aligned}&\mathcal{K}_{AA}^{-1\mu\alpha} \mathcal{K}_{\alpha\beta}^{AB} \mathcal{K}_{\beta\gamma}^{BB-1} + \mathcal{K}_{AA}^{-1\mu\alpha} \mathcal{K}_{\alpha\beta}^{AB} \mathcal{K}_{\beta\gamma}^{BB-1} \mathcal{K}_{\gamma\delta}^{BA} \mathcal{K}_{\delta\rho}^{AA-1} \mathcal{K}_{\rho\sigma}^{AB} \mathcal{K}_{\sigma\nu}^{BB-1} + \dots \\ &= \mathcal{K}_{AA}^{-1\mu\alpha} \mathcal{K}_{\alpha\beta}^{AB} \mathcal{K}_{\beta\gamma}^{BB-1} \left[\delta_\nu^\gamma - \mathcal{K}_{BA}^{\gamma\delta} \mathcal{K}_{\delta\rho}^{AA-1} \mathcal{K}_{\rho\sigma}^{AB} \mathcal{K}_{\sigma\nu}^{BB-1} \right]^{-1} = i\Delta_{AB}^{\mu\nu}.\end{aligned}\quad (248)$$

To track the effects of renormalization we take $A_\mu \rightarrow \sqrt{Z_A} A_\mu$ and $B_\mu \rightarrow \sqrt{Z_B} B_\mu$. By tracking these changes through the various matrices we find the expected results

$$\Delta_{AA} \rightarrow Z_A^{-1} \Delta_{AA}, \quad \Delta_{BB} \rightarrow Z_B^{-1} \Delta_{BB}, \quad \Delta_{AB} \rightarrow \frac{1}{\sqrt{Z_A Z_B}} \Delta_{AB}. \quad (249)$$

We assume the renormalized propagator $\Delta_{\mu\nu}^R = -i\mathcal{K}_{\mu\nu}^{R-1}$ is related to the bare propagator determined from Eq. (242) by

$$\Delta_{\mu\nu}^{R-1}(k) = \Delta_{\mu\nu}^{-1}(k) - i\Pi_{\mu\nu}, \quad (250)$$

where

$$i\mathbf{\Pi}_{\mu\nu} = i \begin{pmatrix} \Pi_{\mu\nu}^{QQ} & 0 \\ 0 & \Pi_{\mu\nu}^{GG} \end{pmatrix}. \quad (251)$$

Here we have assumed there is no loop that directly connects the two potentials. We can then write the renormalized propagator in terms of the bare propagator

$$\Delta_{\mu\nu}^R(k) = \Delta_{\mu\alpha}(k) [\mathbb{I}_2 \delta_\alpha^\nu - i\mathbf{\Pi}_\alpha^\beta \Delta_{\beta}^\nu]^{-1} \quad (252)$$

We explicitly find

$$\mathbb{I}_2 g_{\mu\nu} - i\mathbf{\Pi}_\mu^\alpha \Delta_{\alpha\nu} = \begin{pmatrix} \mathcal{M}_{\mu\nu}^{QQ} & \mathcal{M}_{\mu\nu}^{QG} \\ \mathcal{M}_{\mu\nu}^{GQ} & \mathcal{M}_{\mu\nu}^{GG} \end{pmatrix} = \begin{pmatrix} \eta_{\mu\nu} - i\Pi_\mu^{QQ\alpha} \Delta_{\alpha\nu}^{AA} & -i\Pi_\mu^{QQ\alpha} \Delta_{\alpha\nu}^{AB} \\ -i\Pi_\mu^{GG\alpha} \Delta_{\alpha\nu}^{BA} & \eta_{\mu\nu} - i\Pi_\mu^{GG\alpha} \Delta_{\alpha\nu}^{BB} \end{pmatrix}. \quad (253)$$

By using the block matrix inversion formulae in Eq. (197) we can write

$$\Delta_{QQ}^R = (\Delta^{AA} - \Delta^{AB} \mathcal{M}_{GG}^{-1} \mathcal{M}^{GQ}) (\mathcal{M}_{QQ} - \mathcal{M}^{QG} \mathcal{M}_{GG}^{-1} \mathcal{M}^{GQ})^{-1}, \quad (254)$$

$$\Delta_{QG}^R = (\Delta^{AB} - \Delta^{AA} \mathcal{M}_{QQ}^{-1} \mathcal{M}^{QG}) (\mathcal{M}_{GG} - \mathcal{M}^{GQ} \mathcal{M}_{QQ}^{-1} \mathcal{M}^{QG})^{-1}, \quad (255)$$

$$\Delta_{GQ}^R = (\Delta^{BA} - \Delta^{BB} \mathcal{M}_{GG}^{-1} \mathcal{M}^{GQ}) (\mathcal{M}_{QQ} - \mathcal{M}^{QG} \mathcal{M}_{GG}^{-1} \mathcal{M}^{GQ})^{-1}, \quad (256)$$

$$\Delta_{GG}^R = (\Delta^{BB} - \Delta^{BA} \mathcal{M}_{QQ}^{-1} \mathcal{M}^{QG}) (\mathcal{M}_{GG} - \mathcal{M}^{GQ} \mathcal{M}_{QQ}^{-1} \mathcal{M}^{QG})^{-1}. \quad (257)$$

If we assume

$$i\mathbf{\Pi}_{\mu\nu} = i(k^2 \eta_{\mu\nu} - k_\mu k_\nu) \begin{pmatrix} \Pi^{QQ}(k^2) & 0 \\ 0 & \Pi^{GG}(k^2) \end{pmatrix}, \quad (258)$$

is a two by two matrix that encodes the quantum corrections to propagators. We have here assumed a tensor structure that is independent of n^μ . This is clearly justified if we confine ourselves to one-loop results, which we assume going forward. We then find

$$\begin{pmatrix} \eta_{\mu\nu} (1 - \Pi^{QQ}) + \Pi^{QQ} \frac{n_\mu k_\nu}{n \cdot k} & -\Pi^{QQ} \varepsilon_{\mu\nu\sigma\rho} \frac{n^\sigma k^\rho}{n \cdot k} \\ +\Pi^{GG} \varepsilon_{\mu\nu\sigma\rho} \frac{n^\sigma k^\rho}{n \cdot k} & \eta_{\mu\nu} (1 - \Pi^{GG}) + \Pi^{GG} \frac{n_\mu k_\nu}{n \cdot k} \end{pmatrix}. \quad (259)$$

These terms can be evaluated using the linear in the Π s results

$$\mathcal{M}_{\mu\nu}^{QQ-1} = \frac{1}{1 - \Pi^{QQ}} \left[\eta_{\mu\nu} - \Pi^{QQ} \frac{n_\mu k_\nu}{n \cdot k} \right], \quad (260)$$

$$\mathcal{M}_{\mu\nu}^{GG-1} = \frac{1}{1 - \Pi^{GG}} \left[\eta_{\mu\nu} - \Pi^{GG} \frac{n_\mu k_\nu}{n \cdot k} \right]. \quad (261)$$

This leads to

$$\begin{aligned} \Delta_{QQ}^R = & \frac{-i}{k^2(1 - \Pi^{QQ})(1 - \Pi^{GG})} \left[\eta_{\mu\nu} - \frac{n_\mu k_\nu + n_\nu k_\mu}{n \cdot k} + \frac{n^2}{(n \cdot k)^2} k_\mu k_\nu \right] \\ & + i \frac{n^2}{(n \cdot k)^2 \xi_A^2} k_\mu k_\nu + \frac{i \Pi^{GG}}{(n \cdot k)^2} (n^2 \eta_{\mu\nu} - n_\mu n_\nu) , \end{aligned} \quad (262)$$

$$\Delta_{QG}^R = \frac{1}{(1 - \Pi^{QQ})(1 - \Pi^{GG})} \Delta_{\mu\nu}^{AB} , \quad (263)$$

$$\Delta_{GQ}^R = \frac{1}{(1 - \Pi^{QQ})(1 - \Pi^{GG})} \Delta_{\mu\nu}^{BA} , \quad (264)$$

$$\begin{aligned} \Delta_{GG}^R = & \frac{-i}{k^2(1 - \Pi^{QQ})(1 - \Pi^{GG})} \left[\eta_{\mu\nu} - \frac{n_\mu k_\nu + n_\nu k_\mu}{n \cdot k} + \frac{n^2}{(n \cdot k)^2} k_\mu k_\nu \right] \\ & + i \frac{n^2}{(n \cdot k)^2 \xi_B^2} k_\mu k_\nu + \frac{i \Pi^{QQ}}{(n \cdot k)^2} (n^2 \eta_{\mu\nu} - n_\mu n_\nu) . \end{aligned} \quad (265)$$

As emphasized in the text, it appears (if we focus only on terms with a k^2 pole) that Z_A and Z_B are equal. The extra terms in the charge-diagonal propagators are also unexpected. In the literature this confusion led to the result first obtained by Schwinger that the electric and magnetic charges are renormalized in the same way. It is has also led to many ad hoc reasons for dropping the terms proportional to the n^μ projector that do not appear in the tree level propagator. In fact, these results exactly match what we determined by using the field strength language when the topological portion of the electric-magnetic interactions are not fully removed from the calculation.
