## Polynomial bounds for monochromatic tight cycle partition in *r*-edge-coloured  $K_n^{(k)}$  $\stackrel{\scriptscriptstyle\vee}{n}$

Debmalya Bandyopadhyay <sup>∗</sup> Allan Lo †

September 2, 2024

#### Abstract

Let  $K_n^{(k)}$  be the complete k-graph on n vertices. A k-uniform tight cycle is a k-graph with its vertices cyclically ordered so that every k consecutive vertices form an edge and any two consecutive edges share exactly k − 1 vertices. A result of Bustamante, Corsten, Frankl, Pokrovskiy and Skokan shows that all r-edge coloured  $K_n^{(k)}$  can be partitioned into  $c_{r,k}$  vertex disjoint monochromatic tight cycles. However, the constant  $c_{r,k}$  is of tower-type. In this work, we show that  $c_{r,k}$  is a polynomial in r.

# 1 Introduction

An r-edge-colouring of a graph or a k-uniform hypergraph is a colouring of its edges with r colours. The set of colours is usually identified with the set  $\{1, 2, \ldots, r\}$ . A monochromatic subgraph of an edgecoloured graph is a subgraph where all the edges are assigned the same colour. On the other hand, a rainbow subgraph is a subgraph all of whose edges have a different colour.

Lehel conjectured that for any 2-edge-colouring of a complete graph, there exist two vertex-disjoint monochromatic cycles (one of each colour) covering all vertices. Isolated vertices and single-edges are considered to be degenerate cycles. For large n, this conjecture was proved by Luczak, Rödl and Szemerédi [\[18](#page-35-0)] using Szemerédi's Regularity Lemma. The bound on n was improved later by Allen [\[1\]](#page-35-1). In 2010, Bessy and Thomassé [\[3\]](#page-35-2) finally resolved this conjecture for all  $n \in \mathbb{N}$ .

When  $r > 3$ , Erdős, Gyárfás and Pyber [\[7\]](#page-35-3) proved that any r-edge-coloured complete graph can be partitioned into  $O(r^2 \log r)$  monochromatic cycles and conjectured that r monochromatic cycles would be enough. This was one of the first instances of using the absorbing method. Gyárfás, Ruszinkó, Sárközy and Szemerédi [\[11](#page-35-4)] improved their result and proved that  $O(r \log r)$  monochromatic cycles suffice. However, Pokrovskiy [\[21\]](#page-35-5) found a counter-example disproving the conjecture. A weaker conjecture was proposed stating that any r-edge-coloured  $K_n$  contains r vertex-disjoint monochromatic cycles covering all but  $c(r)$  of the vertices, where  $c(r)$  is a constant depending only on r. Pokrovskiy [\[20\]](#page-35-6) also proved that  $c(3) \leq 43000$ . Korándi, Lang, Letzter and Pokrovskiy [\[14](#page-35-7)] determined a tight minimum degree threshold for monochromatic cycle partition of edge-coloured graphs, namely they showed that there exists a constant  $c > 0$  such that any r-edge-coloured graph G on n vertices with  $\delta(G) \geq n/2 + cr \log n$ has a partition into  $O(r^2)$  monochromatic cycles.

<sup>&</sup>lt;sup>†</sup>School of Mathematics, University of Birmingham, E-mail: [s.a.lo@bham.ac.uk](mailto:s.a.lo@bham.ac.uk). The research leading to these results was supported by EPSRC, grant no. EP/V002279/1 and EP/V048287/1. There is no additional data beyond that contained within the main manuscript.

A local r-colouring of a graph is an edge-colouring such that every vertex is incident with at most  $r$ edges of distinct colours. Sárközy [\[23](#page-35-8)] showed that any large locally r-coloured  $K_n$  can be partitioned into  $O(r \log r)$  monochromatic cycles.

A k-uniform hypergraph (or k-graph) is a pair  $H = (V(H), E(H))$  where  $E(H) \subseteq {V(H) \choose k}$  $\binom{H}{k}$ . [1](#page-1-0) Let  $K_n^{(k)}$  denote the complete graph on n vertices, where all  $\binom{n}{k}$  $\binom{n}{k}$  edges are present. For positive integers  $1 \leq \ell \leq k \leq n$ , a k-uniform  $\ell$ -cycle is a k-graph with its vertices cyclically ordered so that every edge contains k consecutive vertices and any two consecutive edges share exactly  $\ell$  vertices. Note that 1-cycles are called *loose cycles* and  $(k - 1)$ -cycles are called *tight cycles*.

Lehel's problem has been generalised for hypergraphs and studied for both tight and loose cycles. As in the case of graphs, any set of at most  $k$  vertices is considered as a degenerate cycle. Gyárfás and Sárközy [\[12](#page-35-9)] showed that for loose cycles, every r-edge-coloured  $K_n^{(k)}$  can be partitioned into  $C(k, r)$  vertex-disjoint monochromatic loose cycles. For sufficiently large n, Sárközy [\[22](#page-35-10)] proved that  $50kr \log(kr)$  loose cycles suffice. For an overview of results related to monochromatic partitions of (hyper)graphs we refer the reader to the surveys [\[8\]](#page-35-11) and [\[9](#page-35-12)].

In this paper, we focus on monochromatic tight cycle partition. For  $k = 3$ , Bustamante, Hàn and Stein [\[5\]](#page-35-13) proved that any 2-edge-coloured  $K_n^{(3)}$  contains two vertex-disjoint monochromatic cycles of distinct colours covering all but at most  $o(n)$  vertices. Lo and Pfenninger [\[16\]](#page-35-14) proved the corresponding result when  $k = 4$ . Recently, Pfenninger [\[19](#page-35-15)] generalised the result to all k improving a previous result [\[15](#page-35-16)].

For any  $r, k \geq 3$ , Bustamante, Corsten, Frankl, Pokrovskiy and Skokan [\[4](#page-35-17)] proved that any r-edgecoloured  $K_n^{(k)}$  can be partitioned into at most  $C'(k,r)$  monochromatic tight cycles. They achieved this bound by using the regularity method for hypergraphs, as a result of which the constant  $C'(k,r)$  is a tower bound.

<span id="page-1-1"></span>In this paper we show that  $C'(k, r)$  is a polynomial of r (for fixed k).

**Theorem 1.1.** For all  $r \in \mathbb{N}$  and  $k \geq 3$ , there exists an integer  $n_0 = n_0(r, k)$  such that for all r-edgecoloured  $K_n^{(k)}$  with  $n \geq n_0$ , there exists a monochromatic tight cycle partition of  $V(K_n^{(k)})$  into at most  $(2r)^{2^{k+4}} + 2^{k+8}r \log(2r)$  tight cycles.

We make no attempt to improve the coefficients.

To prove Theorem [1.1,](#page-1-1) we use the absorption method motivated by the works of Erdős, Gyárfás and Pyber  $[7]$  and Gyárfás, Ruszinkó, Sárközy and Szemerédi  $[11]$ , as well as the connected matching method that is often credited to Luczak  $[17]$ . We first reserve a special vertex subset. Then we use a result by Allen, Böttcher, Cooley and Mycroft  $[2]$  (Theorem [2.1\)](#page-2-0) to greedily remove monochromatic tight cycles from the rest of the hypergraph, until there is a small leftover set of vertices. We then use properties of the reserved structures to 'absorb' the leftover set with a few monochromatic tight cycles.

We now outline the layout of the paper. We prove Theorem [1.1](#page-1-1) through a series of reductions. In Section [2,](#page-2-1) we reduce Theorem [1.1](#page-1-1) to the absorbing lemma, see Lemma [2.3.](#page-2-2) Roughly speaking, Lemma [2.3](#page-2-2) finds a vertex set R such that, given any small vertex subset B,  $R \cup B$  can be partitioned into few monochromatic tight cycles. The rest of this paper is focused on proving Lemma [2.3.](#page-2-2) In Sections [3](#page-3-0) and [4,](#page-4-0) we introduce some basic notations and the hypergraph regularity lemma. In Section [5,](#page-7-0) we reduce the size of the small vertex subset  $B$  needed in Lemma [2.3.](#page-2-2) In Section [6,](#page-17-0) we translate the problem into finding rainbow cycle partitions in edge-coloured multigraphs, see Lemma [6.2.](#page-17-1) We prove this lemma in Sections [7](#page-23-0) and [8.](#page-25-0) In Section [9,](#page-33-0) we end the paper with some concluding remarks and further directions. There will be further motivation and discussion in each section.

<span id="page-1-0"></span><sup>&</sup>lt;sup>1</sup>For a set V and  $k \in \mathbb{N}$ ,  $\binom{V}{k}$  denotes the set of all subsets of V of size k.

# <span id="page-2-1"></span>2 Proof of Theorem [1.1](#page-1-1)

We typically assume *n* to be a large integer. Let  $[n] = \{1, \ldots, n\}$  and for integers  $a \leq b$ , let  $[a, b] =$  $\{a, a+1, \ldots, b\}$ . We will use hierarchies in our statements. The phrase " $a \ll b$ " means "for every  $b > 0$ , there exists  $a_0 > 0$ , such that for all  $0 < a \le a_0$  the following statements hold". We implicitly assume all constants in such hierarchies are positive and if  $1/m$  appears we assume m is an integer. For the rest of this paper,  $r$  and  $k$  will denote the number of colours and uniformity of the hypergraph, respectively.

<span id="page-2-0"></span>We first show that one can cover most vertices of an r-edge-coloured  $K_n^{(k)}$  with few vertex-disjoint monochromatic tight cycles. We need the following theorem on the Turán density of tight cycles.

**Theorem 2.1.** (Allen, Böttcher, Cooley, Mycroft [\[2](#page-35-19)]) Let  $1/n \ll \delta$ ,  $1/k \leq 1/3$  and  $\alpha \in [0,1]$ . Let G be a k-graph on n vertices with  $e(G) \geq (\alpha + \delta) {n \choose k}$  $\binom{n}{k}$ . Then G contains a tight cycle of length  $\ell$  for every  $\ell \leq \alpha n$  that is divisible by k.

<span id="page-2-3"></span>**Proposition 2.2.** Let  $1/n \ll \varepsilon, 1/k, 1/r$ . Let  $K_n^{(k)}$  be r-edge-coloured. Then all but at most  $\varepsilon n$  vertices of  $K_n^{(k)}$  can be covered by  $2r \log(1/\varepsilon)$  vertex-disjoint monochromatic tight cycles.

*Proof.* Since  $K_n^{(k)}$  is r-edge-coloured, there exists a monochromatic subgraph G of  $K_n^{(k)}$  such that  $e(G) \geq {n \choose k}$  $\binom{n}{k}/r$  edges. Theorem [2.1](#page-2-0) with  $1/3r, 2/3r$  playing the roles of  $\delta, \alpha$ , respectively, implies that there is a monochromatic tight cycle of length at least  $2n/3r - k \ge n/2r$ . Remove this cycle and repeat  $\frac{1}{2r}$ <sup>i</sup>  $n \leq ne^{-i/2r}$  many vertices left. the argument. After removing *i* tight cycles, there are at most  $\left(1 - \frac{1}{2i}\right)$ By setting  $i = 2r \log(1/\varepsilon)$ , we have at most  $\varepsilon n$  vertices uncovered. □

<span id="page-2-2"></span>We need the following absorbing lemma which will be proved later.

**Lemma 2.3.** Let  $k \geq 3$  and  $1/N \ll 1/r, 1/k$ . Let H be an r-edge-coloured  $K_N^{(k)}$  $N^{\kappa}$ . Then there exists a vertex set  $R \subseteq V(H)$  such that for any  $B \subseteq V(H) \setminus R$  with  $|B| \leq (2r)^{-2^{k+7}} k^{-1} N$ ,  $H[R \cup B]$  can be partitioned into at most  $2^{19}r(2r)^{5\cdot 2^{k+1}} + 3$  monochromatic tight cycles.

We now prove Theorem [1.1](#page-1-1) assuming Lemma [2.3.](#page-2-2)

Proof of Theorem [1.1.](#page-1-1) Let  $\varepsilon^* = (2r)^{-2^{k+7}}k^{-1}$  and  $m = 2^{19}r(2r)^{5\cdot 2^{k+1}} + 3$ . Choose constants  $t_0, \varepsilon_k, \psi$ such that  $1/n \ll 1/t_0 \ll \varepsilon_k \ll \psi \ll 1/r, 1/k$ . By Lemma [2.3](#page-2-2) with n playing the role of N, there exists a vertex set  $R \subseteq V(H)$  such that, for any  $B \subseteq V(H) \setminus R$  with  $|B| \leq \varepsilon^* n$ ,  $H[R \cup B]$  can be partitioned into at most m monochromatic tight cycles. Let  $H' = H \setminus R$  and  $n' = |V(H')|$ . By Proposition [2.2](#page-2-3) with  $\varepsilon^*, n'$  playing the roles of  $\varepsilon, n$ , respectively, all but at most  $\varepsilon^* n' \leq \varepsilon^* n$  vertices of H' can be covered by at most

$$
2r\log(1/\varepsilon^*) = 2^{k+8}r\log(2r) + 2r\log(k)
$$

vertex-disjoint monochromatic tight cycles. Let B be the set of uncovered vertices, so  $|B| \leq \varepsilon^* n$ . Thus  $H[R \cup B]$  can be partitioned into at most m monochromatic tight cycles. This covers up H with at most

$$
2^{k+8}r \log(2r) + 2r \log(k) + m \le 2^{20+5 \cdot 2^{k+1}} r^{5 \cdot 2^{k+1}+1} + 2^{k+8}r \log(2r) \le (2r)^{2^{k+4}} + 2^{k+8}r \log(2r)
$$

 $\Box$ 

vertex-disjoint monochromatic tight cycles. This concludes the proof of the theorem.

#### <span id="page-3-0"></span>3 Notation

We omit floors and ceilings if they do not affect the calculations. For two sets A and B,  $A\Delta B$  denotes their set difference. We often write  $v_1v_2 \ldots v_k$  for  $\{v_1, \ldots, v_k\}$ .

Let G be a graph. The neighbourhood of a vertex u, denoted  $N_G(u)$ , is the set of vertices  $\{v \in$  $V(G) \setminus \{u\} : uv \in E(G)\}.$  The closed neighbourhood of a vertex u is defined as  $\{u\} \cup N_G(u)$  and denoted as  $N_G[u]$ . For a path  $P = v_1 \cdots v_{\ell}$ , the *internal vertices of P*, denoted by  $\text{int}(P)$ , are  $v_2, \ldots, v_{\ell-1}$ . For a vertex set  $U \subseteq V(G)$ , we denote the compliment of U as  $\overline{U}$ . When G is a digraph, its minimum out-degree is denoted as  $\delta^+(G)$ .

Let H be a k-graph. We write  $e(H) = |E(H)|$ . For a set of vertices  $U \subseteq V(H)$ , H[U] denotes the subgraph induced on U. For k-graphs G and H,  $H \backslash G$  denotes the subgraph obtained by deleting  $V(G)$ from H and  $H - G$  denotes the subgraph after deleting  $E(G)$  from  $E(H)$ . For a vertex set  $U \subseteq V(H)$ ,  $H \setminus U = H[V(H) \setminus U]$ . The link graph of a vertex z, denoted by  $H(z)$ , is the  $(k-1)$ -graph on  $V(H)$  so that  $S \in E(H(z))$  if and only if  $S \cup z \in E(H)$ . For  $S \subseteq V(H)$ ,  $N_H(S) = \{T \subseteq V(H) \setminus S : S \cup T \in E(H)\}\$ and  $d_H(S) = |N_H(S)|$ . Denote

$$
\delta_{\ell}(H) = \min_{S \in \binom{V(H)}{\ell}} d(S) \text{ and } \Delta_{\ell}(H) = \max_{S \in \binom{V(H)}{\ell}} d(S).
$$

We write  $\delta$  and  $\Delta$  respectively for the above when  $\ell = 1$ . For vertex sets V and W, we define  $N_H(V, W)$ to be the set  $\{e \in {W \choose k-|V|} : e \cup V \in E(H)\}$ . In particular when  $V = \{v\}$  and  $W = V(H)$ , we have  $|N_H(V, W)| = d(v).$ 

A set of edges  $\mathcal E$  in a k-graph H is called tightly connected if for any pair of distinct edges  $e, f \in \mathcal E$ , there exists a sequence of edges  $e_1, \ldots, e_t \in E(H)$  such that  $e_1 = e, e_t = f$  and for  $i \in [t-1],$  $|e_i \cap e_{i+1}| = k - 1$ . A tight component of a k-graph is a set of edges that is maximal with respect to this property. Note that we treat tight components as k-graphs. A k-partite k-graph  $H$  has a partition of its vertex set into distinct and disjoint vertex classes  $V_1, \ldots, V_k$  such that for any edge  $e \in E(H)$ ,  $|e \cap V_i| = 1$  for each  $i \in [k]$ . For vertex sets  $X_1, \ldots, X_k \subseteq V(H)$ , an  $X_1 X_2 \ldots X_k$ -edge is an edge  $x_1 \ldots x_k$ where for each  $i \in [k]$ , we have  $x_i \in X_i$ .

We work with edge-coloured multigraphs and use the following notation frequently. We denote the edge-colouring by  $\phi$ . Let G be an edge-coloured (multi-)k-graph. The colour set  $\phi(G)$  of G is the set of colours that appear in G. When G is a multi-k-graph, for an edge  $e, \phi(e)$  is known from the context. For a colour subset  $C \subseteq \phi(G)$ ,  $G_C$  is the induced subgraph of G with edges of colours in C after removing any isolated vertices. Let  $c \in \phi(G)$  and  $S \subseteq V(G)$ . We write  $N_{c,G}(S)$  for  $N_{G_c}(S)$  and  $d_{c,G}(S) = |N_{c,G}(S)|$ . We say S sees a colour c in a graph G, if  $d_{c,G}(S) > 0$ . The set of colours that are seen by S is denoted by  $\phi_G(S)$ . We write  $\delta_{\text{mon}}(G) = \min_{c \in \phi(G)} \delta(G_c)$ . Let  $V^*(G) = \{v \in V(G) : |\phi_G(v)| \geq 2\}$  $V^*(G) = \{v \in V(G) : |\phi_G(v)| \geq 2\}$  $V^*(G) = \{v \in V(G) : |\phi_G(v)| \geq 2\}$ . We also define

$$
\delta^*_{\text{mon}}(G) = \min_{v \in V^*(G)} \min_{c \in \phi_G(v)} d_c(v).
$$

An edge-coloured k-graph H is locally r-edge-coloured if any set of  $k-1$  vertices see at most r colours in H. It is easy to check that an r-edge-coloured k-graph is also locally r-edge-coloured. A monochromatic tight component is a tight component that is monochromatic, i.e. between any two edges in the monochromatic tight component there is a monochromatic tight path in a colour fixed for that component. Note that a monochromatic tight component T has colour  $\phi_H(T)$ .

We drop the subscript when the underlying k-graph is clear from context. Additional notation will be introduced within a section if only needed there.

<span id="page-3-2"></span>We use the following three standard concentration inequalities in this work.

<span id="page-3-1"></span><sup>&</sup>lt;sup>2</sup>Note that this is different from the monochromatic colour degree in literature, as  $G_c$  has no isolated vertices.

**Lemma 3.1** (Chernoff Bound c.f. [\[13](#page-35-20), Remark 2.5]). Let  $0 < \delta \leq 3/2$  and  $X \sim Bin(n, p)$ . Then  $\mathbb{P}(|X - \mathbb{E}(X)| \ge \delta \mathbb{E}(X)) \le 2e^{-\frac{\delta^2 \mathbb{E}(X)}{3}}.$ 

Let N, n, m be positive integers such that  $\max\{n, m\} \leq N$ . The hypergeometric distribution Hyp(N, n, m) is the distribution of the random variable X obtained by choosing a set  $\sigma$  of m elements from a set  $\tau$ of N elements, with  $X = |\sigma \cap \tau_n|$  where  $\tau_n$  is a random subset of  $\tau$  with n elements. We need the following concentration inequality for hypergeometric random variables.

<span id="page-4-1"></span>**Lemma 3.2** (Hoeffding's inequality c.f. [\[13](#page-35-20), Theorem 2.10]). Let  $0 < \varepsilon \leq 3/2$  and  $X \sim Hyp(N, n, m)$ . Then  $\mathbb{P}[|X - \mathbb{E}[X]| \geq \varepsilon \mathbb{E}[X]] \leq 2e^{-\frac{\varepsilon^2}{3}}$  $\frac{E}{3}E[X]$ .

<span id="page-4-2"></span>**Lemma 3.3** (Azuma's inequality c.f. [\[13](#page-35-20), Theorem 2.25]). Let  $Z_0, ..., Z_n$  be a martingale with  $|Z_i |Z_{i-1}| \leq c_i$  for all  $i \in [n]$ . Then for all  $a > 0$ ,

$$
\mathbb{P}[|Z_n - Z_0| \ge a] \le 2e^{-\frac{a^2}{2\sum_{i=1}^n c_i^2}}.
$$

## <span id="page-4-0"></span>4 Hypergraph regularity

In this section, we formulate the notion of hypergraph regularity that we use, closely following the formulation from Allen, Böttcher, Cooley and Mycroft [\[2\]](#page-35-19). Recall that a hypergraph  $\mathcal H$  is an ordered pair  $(V(\mathcal{H}), E(\mathcal{H}))$ , where  $E(\mathcal{H}) \subseteq 2^{V(\mathcal{H})}$ . We identify the hypergraph  $\mathcal{H}$  with its edge set  $E(\mathcal{H})$ . A subgraph  $\mathcal{H}'$  of  $\mathcal H$  is a hypergraph with  $V(\mathcal{H}') \subseteq V(\mathcal{H})$  and  $E(\mathcal{H}') \subseteq E(\mathcal{H})$ . It is spanning if  $V(\mathcal{H}') = V(\mathcal{H})$ . For  $U \subseteq V(\mathcal{H})$ , we define  $\mathcal{H}[U]$  to be the subgraph of H with  $V(\mathcal{H}[U]) = U$  and  $E(\mathcal{H}[U]) = \{e \in E(\mathcal{H}) : e \subseteq U\}.$ 

A hypergraph H is called a *complex* if H is down-closed, that is if for an edge  $e \in \mathcal{H}$  and  $f \subseteq e$ , then  $f \in \mathcal{H}$ . A k-complex is a complex having only edges of size at most k. We denote by  $\mathcal{H}^{(i)}$  the spanning subgraph of H containing only the edges of size i. Let P be a partition of  $V(\mathcal{H})$  into vertex classes  $V_1, \ldots, V_s$ . Then we say that a set  $S \subseteq V(\mathcal{H})$  is  $\mathcal{P}\text{-}partite$  if  $|S \cap V_i| \leq 1$  for all  $i \in [s]$ . For  $\mathcal{P}'=\{V_{i_1},\ldots,V_{i_r}\}\subseteq \mathcal{P},$  we define the subgraph of  $\mathcal H$  induced by  $\mathcal P',$  denoted by  $\mathcal H[\mathcal P']$  or  $\mathcal H[V_{i_1},\ldots,V_{i_r}],$ to be the subgraph of  $\mathcal{H}[\bigcup \mathcal{P}']$  containing only the edges that are  $\mathcal{P}'$ -partite. The hypergraph  $\mathcal{H}$  is said to be P-partite if all of its edges are P-partite. We say that  $\mathcal H$  is *s-partite* if it is P-partite for some partition P of  $V(\mathcal{H})$  into s parts. Let H be a P-partite hypergraph. If X is a k-set of vertex classes of H, then we write  $\mathcal{H}_X$  for the k-partite subgraph of  $\mathcal{H}^{(k)}$  induced by  $\bigcup X$ , whose vertex classes are the elements of X. Moreover, we denote by  $\mathcal{H}_{X<}$  the k-partite hypergraph with  $V(\mathcal{H}_{X<}) = \bigcup X$  and  $E(\mathcal{H}_{X<}) = \bigcup_{X' \subsetneq X} \mathcal{H}_{X'}$ . In particular, if H is a complex, then  $\mathcal{H}_{X<}$  is a  $(k-1)$ -complex because X is a set of size  $k.$ 

Let  $i \geq 2$  and let  $\mathcal{P}_i$  be a partition of a vertex set V into i parts. Let  $H_i$  and  $H_{i-1}$  be a  $\mathcal{P}_i$ -partite i-graph and a  $\mathcal{P}_i$ -partite  $(i-1)$ -graph on a common vertex set V, respectively. We say that a  $\mathcal{P}_i$ -partite *i*-set in V is supported on  $H_{i-1}$  if it induces a copy of the complete  $(i-1)$ -graph  $K_i^{(i-1)}$  $i^{(i-1)}$  on *i* vertices in  $H_{i-1}$ . We denote by  $K_i(H_{i-1})$  the  $\mathcal{P}_i$ -partite *i*-graph on V whose edges are all  $\mathcal{P}_i$ -partite *i*-sets contained in V which are supported on  $H_{i-1}$ . Now we define the *density of*  $H_i$  with respect to  $H_{i-1}$  to be

$$
d(H_i \mid H_{i-1}) = \frac{|K_i(H_{i-1}) \cap H_i|}{|K_i(H_{i-1})|}
$$

if  $|K_i(H_{i-1})| > 0$  and  $d(H_i \mid H_{i-1}) = 0$  if  $|K_i(H_{i-1})| = 0$ . So  $d(H_i \mid H_{i-1})$  is the proportion of  $\mathcal{P}_i$ -partite copies of  $K_i^{i-1}$  in  $H_{i-1}$  which are also edges of  $H_i$ . More generally, if  $\mathbf{Q} = (Q_1, Q_2, \ldots, Q_r)$  is a collection of r (not necessarily disjoint) subgraphs of  $H_{i-1}$ , we define  $K_i(\mathbf{Q}) = \bigcup_{j=1}^r K_i(Q_j)$  and

$$
d(H_i \mid \mathbf{Q}) = \frac{|K_i(\mathbf{Q}) \cap H_i|}{|K_i(\mathbf{Q})|}
$$

if  $|K_i(\mathbf{Q})| > 0$  and  $d(H_i \mid \mathbf{Q}) = 0$  if  $|K_i(\mathbf{Q})| = 0$ . We say that  $H_i$  is  $(d_i, \varepsilon, r)$ -regular with respect to  $H_{i-1}$ , if we have  $d(H_i \mid \mathbf{Q}) = d_i \pm \varepsilon$  for every r-set  $\mathbf{Q}$  of subgraphs of  $H_{i-1}$  with  $|K_i(\mathbf{Q})| > \varepsilon |K_i(H_{i-1})|$ . We say that  $H_i$  is  $(\varepsilon, r)$ -regular with respect to  $H_{i-1}$  if there exists some  $d_i$  for which  $H_i$  is  $(d_i, \varepsilon, r)$ -regular with respect to  $H_{i-1}$ . Finally, given an i-graph G whose vertex set contains that of  $H_{i-1}$ , we say that G is  $(d_i, \varepsilon, r)$ -regular with respect to  $H_{i-1}$  if the *i*-partite subgraph of G induced by the vertex classes of  $H_{i-1}$  is  $(d_i, \varepsilon, r)$ -regular with respect to  $H_{i-1}$ . We refer to the density of this *i*-partite subgraph of G with respect to  $H_{i-1}$  as the *relative density of G with respect to*  $H_{i-1}$ .

Now let  $s \geq k \geq 3$  and let H be an s-partite k-complex on vertex classes  $V_1, \ldots, V_s$ . For any set  $A \subseteq [s]$ , we write  $V_A$  for  $\bigcup_{i \in A} V_i$ . Note that, if  $e \in \mathcal{H}^{(i)}$  for some  $2 \leq i \leq k$ , then the vertices of e induce a copy of  $K_i^{i-1}$  in  $\mathcal{H}^{(i-1)}$ . Therefore, for any set  $A \in \binom{[s]}{i}$ <sup>s</sup><sup>[1]</sup>), the density  $d(\mathcal{H}^{(i)}[V_A] | \mathcal{H}^{(i-1)}[V_A])$  is the proportion of 'possible edges' of  $\mathcal{H}^{(i)}[V_A]$ , which are indeed edges. We say that  $\mathcal{H}$  is  $(d_k, \ldots, d_2, \varepsilon_k, \varepsilon, r)$ regular if

- (a) for any  $2 \leq i \leq k-1$  and any  $A \in \binom{[s]}{i}$ <sup>s</sup><sup>[1]</sup>), the induced subgraph  $\mathcal{H}^{(i)}[V_A]$  is  $(d_i, \varepsilon, 1)$ -regular with respect to  $\mathcal{H}^{(i-1)}[V_A]$  and
- (b) for any  $A \in \binom{[s]}{k}$ <sup>[s]</sup>, the induced subgraph  $\mathcal{H}^{(k)}[V_A]$  is  $(d_k, \varepsilon_k, r)$ -regular with respect to  $\mathcal{H}^{(k-1)}[V_A]$ .

For  $\mathbf{d} = (d_k, \ldots, d_2)$ , we write  $(\mathbf{d}, \varepsilon_k, \varepsilon, r)$ -regular to mean  $(d_k, \ldots, d_2, \varepsilon_k, \varepsilon, r)$ -regular. We say that a  $(k-1)$ -complex  $\mathcal J$  is  $(t_0,t_1,\varepsilon)$ -equitable if it has the following properties.

- (a) J is P-partite for some P which partitions  $V(\mathcal{J})$  into t parts, where  $t_0 \leq t \leq t_1$ , of equal size. We refer to  $P$  as the ground partition of  $\mathcal J$  and to the parts of  $P$  as the clusters of  $\mathcal J$ .
- (b) There exists a *density vector*  $\mathbf{d} = (d_{k-1}, \ldots, d_2)$  such that, for each  $2 \leq i \leq k-1$ , we have  $d_i \geq 1/t_1$  and  $1/d_i \in \mathbb{N}$  and  $\mathcal J$  is  $(\mathbf{d}, \varepsilon, \varepsilon, 1)$ -regular.

For any k-set X of clusters of J, we denote by  $\hat{J}_X$  the k-partite  $(k-1)$ -graph  $(\mathcal{J}_X<)^{(k-1)}$  and call  $\hat{J}_X$ a polyad. Given a  $(t_0, t_1, \varepsilon)$ -equitable  $(k-1)$ -complex  $\mathcal J$  and a k-graph G on  $V(\mathcal J)$ , we say that G is  $(\varepsilon_k, r)$ -regular with respect to a k-set X of clusters of J if there exists some d such that G is  $(d, \varepsilon_k, r)$ regular with respect to the polyad  $\hat{J}_X$ . Moreover, we write  $d^*_{G,\mathcal{J}}(X)$  for the relative density of G with respect to  $\hat{\mathcal{J}}_X$ ; we may drop either subscript if it is clear from context.

We can now give the crucial definition of a regular slice.

**Definition 4.1** (Regular slice). Given  $\varepsilon, \varepsilon_k > 0, r, t_0, t_1 \in \mathbb{N}$ , a k-graph G, a  $(k-1)$ -complex  $\mathcal J$  on  $V(G)$ , is a  $(t_0, t_1, \varepsilon, \varepsilon_k, r)$ -regular slice for G if J is  $(t_0, t_1, \varepsilon)$ -equitable and G is  $(\varepsilon_k, r)$ -regular with respect to all but at most  $\varepsilon_k$  $\binom{t}{k}$  $\mathcal{L}_k^{t}$  of the k-sets of clusters of J, where t is the number of clusters of J.

If we specify the density vector  $\bf d$  and the number of clusters t of an equitable complex or a regular slice, then it is not necessary to specify  $t_0$  and  $t_1$  (since the only role of these is to bound d and t). In this situation we write that  $\mathcal J$  is  $(\cdot, \cdot, \varepsilon)$ -equitable, or is a  $(\cdot, \cdot, \varepsilon, \varepsilon_k, r)$ -regular slice for G.

Given a regular slice  $\mathcal J$  for a k-graph  $G$ , we define the d-reduced k-graph  $\mathcal R^{\mathcal J}_d(G)$  as follows.

**Definition 4.2** (The d-reduced k-graph). Let  $k \geq 3$ . Let G be a k-graph and let J be a  $(t_0, t_1, \varepsilon, \varepsilon_k, r)$ regular slice for G. Then, for  $d > 0$ , we define the d-reduced k-graph  $\mathcal{R}_d^{\mathcal{J}}(G)$  to be the k-graph whose vertices are the clusters of J and whose edges are all k-sets X of clusters of J such that G is  $(\varepsilon_k, r)$ regular with respect to X and  $d^*(X) \geq d$ .

<span id="page-6-1"></span>We now state the statement of the Regular Slice Lemma that we need, that is a straightforward consequence of [\[2,](#page-35-19) Lemma 10].

**Lemma 4.3** (Regular Slice Lemma [\[2](#page-35-19), Lemma 10]). Let  $k \geq 3$ . For all  $t_0, r, s \in \mathbb{N}$ ,  $\varepsilon_k > 0$  and all functions  $r' \colon \mathbb{N} \to \mathbb{N}$  and  $\varepsilon \colon \mathbb{N} \to (0,1]$ , there are integers  $t_1$  and  $n_0$  such that the following holds for all  $n \ge n_0$  which are divisible by  $t_1!$ . Let H be an r-edge-coloured  $K_n^{(k)}$  with colour set  $[r]$ . For  $i \in [r]$ , let  $H_i$  denote the monochromatic subgraph of H in colour i. Then there exists a  $(k-1)$ -complex  $\mathcal J$ on  $V(H)$  which is a  $(t_0, t_1, \varepsilon(t_1), \varepsilon_k, r'(t_1))$ -regular slice for each  $H_i$ .

<span id="page-6-0"></span>The following lemma which is a direct generalisation of  $[16, \text{Lemma } 12]$  shows that the union of the corresponding reduced graphs  $\bigcup_{i \in [r]} \mathcal{R}_d^{\mathcal{J}}(H_i)$  is almost complete.

**Lemma 4.4.** Let  $k \geq 3$ ,  $\varepsilon, \varepsilon_k > 0, r \in \mathbb{N}$  and  $r' : \mathbb{N} \to \mathbb{N}$ . Let H be an r-edge-coloured  $K_n^{(k)}$  and for  $i \in [r]$  let  $\mathcal J$  be a  $(\cdot, \cdot, \varepsilon, \varepsilon_k, r')$ -regular slice for each  $H_i$ . Let t be the number of clusters of  $\mathcal J$ . Then, provided that  $d \leq 1/r$ , we have  $\left|\bigcup_{i\in[r]}\mathcal{R}_d^{\mathcal{J}}(H_i)\right|\geq(1-r\varepsilon_k)\binom{t}{k}$  $\binom{t}{k}$ .

*Proof.* Since J is a  $(\cdot, \cdot, \varepsilon, \varepsilon_k, r)$ -regular slice for each  $H_i$  there are at least  $(1 - r\varepsilon_k) {t \choose k}$  $\binom{t}{k}$  k-sets X of clusters of  $\mathcal J$  such that each  $H_i$  is  $(\varepsilon_k, r)$ -regular with respect to X. Let X be such a k-set. Since the  $H_i$ are edge-disjoint and  $\bigcup_{i\in[r]} H_i = H$ , we have  $\sum_{i\in[r]} d_{H_i}^*(X) = 1$ . Hence for some  $i \in [r]$ ,  $d_{H_i}^*(X) \geq 1/r$ and thus, since  $d \leq 1/r$ , we have  $X \in \bigcup_{i \in [r]} \mathcal{R}_d^{\mathcal{J}}(H_i)$ .  $\Box$ 

Let  $r \in \mathbb{N}, 0 < d \leq 1/r, \varepsilon > 0$  and  $0 < \varepsilon_k < 1/2r$ . Let H be an r-edge-coloured  $K_n^{(k)}$  on colour set [r]. Let J be a  $(\cdot, \cdot, \varepsilon, \varepsilon_k, r')$ -regular slice for each  $H_i$  with partition  $P$  of  $V(H)$ . By Lemma [4.4,](#page-6-0) we have  $\left| \mathcal{R}_d^{\mathcal{J}}(H) \right| \geq (1 - r \varepsilon_k) \binom{t}{k}$  $\binom{t}{k} \geq \binom{t}{k}$  $\binom{t}{k}/2$ . Given the following natural edge-colouring, we will be working with an edge-coloured reduced graph. For an edge X in  $\mathcal{R}_d^{\mathcal{J}}(H)$ , let  $e_{H,i}(X)$  denote the number of edges in colour i among the vertex clusters in  $H$  that are induced by vertices in X. Assign each such k-set X the colour i if  $e_{H,i}(X) \ge e_H(X)/r$  (if multiple colours satisfy this, then choose one of them arbitrarily). Note that  $\mathcal{R}_d^{\mathcal{J}}(H)$  is an *r*-edge-coloured *k*-graph with at least  $\binom{t}{k}$  $\binom{t}{k}/2$  edges. We write R for  $\mathcal{R}_d^{\mathcal{J}}(H)$ . For each  $v \in V(\mathcal{R})$ , we denote  $V_v$  to be the cluster of  $\mathcal P$  corresponding to v.

Let H be a k-graph. A fractional matching in H is a function  $\omega : E(H) \to [0,1]$  such that for all  $v \in V(H)$ ,  $\omega(v) \coloneqq \sum_{e \in H: v \in e} \omega(e) \leq 1$ . The weight of the fractional matching is defined to be  $\sum_{e \in H} \omega(e)$ . A fractional matching is tightly connected if the subgraph induced by the edges e with  $\omega(e) > 0$  is tightly connected in H. For a fractional matching  $\omega$ , we write the size of  $\omega$  as  $|\omega| = \sum_{e \in E(G)} \omega(e)$ .

<span id="page-6-2"></span>We would use the following lemma to lift a tightly connected fractional matching in the reduced graph to a monochromatic tight cycle covering almost all vertices in the corresponding clusters.

**Lemma 4.5** ([\[16,](#page-35-14) Lemma 18]). Let  $1/n \ll 1/r'$ ,  $\varepsilon \ll \varepsilon_k, d_{k-1}, \ldots, d_2$  and  $\varepsilon_k \ll \varepsilon' \ll \psi, d_k, \beta, 1/k \leq 1/3$ and  $1/n \ll 1/t$  such that t divides n and  $1/d_i \in \mathbb{N}$  for all  $2 \leq i \leq k-1$ . Let G be a k-graph on n vertices and  $\mathcal J$  be a  $(\cdot,\cdot,\varepsilon,\varepsilon_k,r')$ -regular slice for G. Further, let  $\mathcal J$  have t clusters  $V_1,\ldots,V_t$  all of size  $n/t$  and density vector  $\mathbf{d} = (d_{k-1}, \ldots, d_2)$ . Suppose that the reduced graph  $\mathcal{R}_{d_k}^{\mathcal{J}}(G)$  contains a tightly connected fractional matching  $\varphi$  with weight  $\mu$ . Assume that all edges with non-zero weight have weight at least  $\beta$ . For each  $i \in [t]$ , let  $W_i \subseteq V_i$  be such that  $|W_i| \ge ((1-3\varepsilon')\varphi(V_i)+\varepsilon')n/t$ . Then  $G\left[\bigcup_{i \in [t]} W_i\right]$  contains a tight cycle of length  $\ell$  for each  $\ell \leq (1 - \psi)k\mu n/t$  that is divisible by k.

<span id="page-6-3"></span>Another tool we use in the next section is the notion of a hypergraph being  $(\mu, \alpha)$ -dense. For constants  $\mu, \alpha > 0$ , we say that a k-graph H on n vertices is  $(\mu, \alpha)$ -dense if, for each  $i \in [k-1]$ , we have  $d_H(S) \geq \mu {n \choose k}$  $\binom{n}{k-i}$  for all but at most  $\alpha \binom{n}{i}$  $\binom{n}{i}$  sets  $S \in \binom{V(H)}{i}$  $\binom{H}{i}$  and  $d_H(S) = 0$  for all other  $S \in \binom{V(H)}{i}$  $\binom{H}{i}.$ We use the following result from [\[16\]](#page-35-14).

**Proposition 4.6** ([\[16](#page-35-14), Proposition 5]). Let  $1/n \ll \alpha \ll 1/k \leq 1/2$ . Let H be a k-graph on n vertices with  $|H| \geq (1-\alpha) {n \choose k}$  $\binom{n}{k}$ . Then there exists a subgraph H' of H such that  $V(H') = V(H)$  and H' is  $(1 - 2\alpha^{1/4k^2}, 2\alpha^{1/4k})$ -dense.

### <span id="page-7-0"></span>5 The reduction of Lemma [2.3](#page-2-2)

We now generalise the triangle cycle from Erdős, Gyárfás and Pyber  $[7]$ . Let  $t, k, m$  be positive integers such that  $m = (k-1)t$ . The k-uniform triangle cycle  $T_m^{(k)}$  consists of a k-uniform tight cycle  $a_1 \cdots a_m$ and a vertex set  $B = \{b_1, \ldots, b_t\}$  such that

$$
a_{(k-1)i-(k-2)}a_{(k-1)i-(k-3)}\ldots a_{(k-1)i}b_i a_{(k-1)i+1}\ldots a_{(k-1)i+(k-1)}
$$

is a k-uniform tight path for all  $i \in [t]$  (when subscripts are taken modulo m). Moreover, there is a tight cycle on  $V(T_m^{(k)}) \setminus B'$  for all  $B' \subseteq B$ . Note that  $\Delta(T_m^{(k)}) = 2k$ .

For a k-graph H and  $r \in \mathbb{N}$ , the multicolour Ramsey number  $R_r(H)$  is the minimum positive integer N such that any r-edge-coloured  $K_N^{(k)}$  $N^{(k)}$  contains a monochromatic copy of H. We use the following result of Conlon, Fox and Sudakov on the Ramsey number of hypergraphs with bounded maximum degree, to obtain a monochromatic triangle cycle  $T_m^{(k)}$ .

**Theorem 5.1** (Conlon, Fox and Sudakov [\[6,](#page-35-21) Theorem 5]). Let  $\Delta, k, r \in \mathbb{N}$ . There exists a constant  $c(\Delta, k, r)$  such that if H is a k-graph on n vertices with maximum degree  $\Delta$ , then  $R_r(H) \leq c(\Delta, k, r)n$ .

<span id="page-7-2"></span>Note that  $c(\Delta, k, r)$  is a tower-type function in r and k. Since  $T_m^{(k)}$  has bounded degree, we get the following corollary.

Corollary 5.2. Let  $m, n, r, k \in \mathbb{N}$  and  $1/n \ll \alpha \ll 1/r, 1/k$  be such that  $m = (k-1)\alpha n$ . Then a monochromatic triangle cycle  $T_m^{(k)}$  exists in every r-edge-coloured  $K_n^{(k)}$ .

<span id="page-7-1"></span>The main aim of this section is to reduce Lemma [2.3](#page-2-2) to the following lemma.

**Lemma 5.3.** Let  $k, r \in \mathbb{N}$ ,  $\delta_0 = (2r)^{-2^{k+1}}$  and  $\alpha = 2^5rk(2r)^{2^{k+1}}$ . Let H be an r-edge-coloured  $K_n^{(k)}$ and X, Z be disjoint subsets of  $V(H)$  such that  $|X| \ge \alpha |Z|$ . Then there exists a set C of vertex-disjoint monochromatic tight cycles covering Z with  $|\mathcal{C}| \leq 2^{18} r \delta_0^{-5}$  and  $|V(\mathcal{C}) \cap X| = (k-1)|Z|$ .

Suppose that Lemma [5.3](#page-7-1) holds. A naive approach of proving Lemma [2.3](#page-2-2) is to first reserve a monochromatic  $T_m^{(k)}$  using Corollary [5.2.](#page-7-2) We then apply Lemma [5.3](#page-7-1) with B (from  $T_m^{(k)}$ ) playing the role of X to cover the remaining vertices. However,  $T_m^{(k)}$  obtained is too short (unless the number of cycles we remove using Proposition [2.2](#page-2-3) in the proof of Theorem [1.1](#page-1-1) is a super polynomial of r). In order to achieve this, we use the following lemma, which is motivated by Gyárfás, Ruszinkó, Sárközy and Szemerédi  $[11]$ .

<span id="page-7-3"></span>**Lemma 5.4.** Let  $1/n \ll \psi \ll 1/r, 1/k$ . Let  $\delta_0 = (2r)^{-2^{k+1}}$  and  $\varepsilon^* = (2r)^{-2^{k+7}}/k$ . Let H be an r-edgecoloured  $K_n^{(k)}$ . Then there exists a vertex set  $U^*$  with  $|U^*| \leq 3n/4$  such that, for any vertex subset  $B^*$ of  $V(H) \setminus U^*$  with  $|B^*| = 4\varepsilon^* n$ ,  $H[B^* \cup U^*]$  can be covered by at most  $2^{18}r \delta_0^{-5} + 1$  monochromatic tight cycles and at most  $\psi$ n isolated vertices.

<span id="page-7-4"></span>This lemma will be proved in Section [5.2.](#page-9-0) Observe that this lemma significantly reduces the size of the leftover vertex set. However, we would require precisely  $4\varepsilon^*n$  leftover vertices, which may not be guaranteed by Proposition [2.2.](#page-2-3) We deal with it using the following lemma.

**Lemma 5.5.** Let  $1/n \ll \psi \ll 1/r, 1/k$ . Let H be an r-edge-coloured  $K_n^{(k)}$ . Then there exists a vertex subset  $W \subseteq V(H)$  such that  $n/5r \leq |W| \leq n/4r$  and  $H[W]$  contains a monochromatic tight cycle of length  $\ell$  for all  $\ell \leq (1 - \psi)|W|$  with  $\ell \equiv 0 \pmod{k}$ .

*Proof.* Let  $d_k = 1/r$ ,  $1/n \ll 1/t_1 \ll 1/t_0$  $1/n \ll 1/r', \tilde{\varepsilon} \ll \varepsilon_k, d_{k-1}, \ldots, d_2,$  $\varepsilon_k \ll \varepsilon' \ll \psi \ll 1/r, 1/k.$ 

Let H' be an induced subgraph of H such that  $|V(H')| \equiv 0 \pmod{t_1}$  and  $|V(H \setminus H')| < t_1!$ . By Lemma [4.3](#page-6-1) with H' playing the role of H, there exists a  $(\cdot, \cdot, \tilde{\varepsilon}, \varepsilon_k, r')$ -regular slice  $\tilde{\mathcal{J}}$  with partition  $\mathcal P$ of  $V(H')$ . Let  $m = |V|$  for  $V \in \mathcal{P}$  and  $t = |\mathcal{P}|$ . Note that  $mt \geq n - t_1!$ .

Let  $\mathcal{R} = \mathcal{R}^{\widetilde{\mathcal{J}}}_{d_k}(H')$ . Recall that for each  $x \in V(\mathcal{R})$ ,  $V_x$  denotes the corresponding cluster in  $\mathcal{P}$ . By Lemma [4.4](#page-6-0) (with  $d = d_k$ ), R contains at least  $(1 - r \varepsilon_k) {t \choose k}$  $\binom{t}{k} \geq \binom{t}{k}$  $(k)$  /2 edges. There exists a colour  $j \in [r]$ such that  $|E(\mathcal{R}_j)| \geq {t \choose k}$  $\binom{t}{k}/2r$ . By Theorem [2.1](#page-2-0) with  $\delta = \alpha = 1/4r$ ,  $\mathcal{R}_j$  contains a monochromatic tight cycle  $C = v_1v_2 \ldots v_\ell$  with  $t/5r \leq \ell \leq t/4r$  and  $\ell \equiv 0 \pmod{k}$ . Set  $W = \bigcup_{i \in [\ell]} V_{v_i}$ . Let  $\varphi$  be a fractional matching on C such that for any edge  $e \in E(C)$ , we have  $\varphi(e) = 1/k$ . For  $i \in [\ell]$ , note that  $\varphi(v_i) = 1$ and  $|V_{v_i}| \ge ((1-3\varepsilon')\varphi(v_i)+\varepsilon')m$ . Therefore, Lemma [4.5](#page-6-2) implies our result.  $\Box$ 

#### 5.1 Proof of Lemma [2.3](#page-2-2) assuming Lemmas [5.3](#page-7-1) and [5.4](#page-7-3)

We now prove Lemma [2.3](#page-2-2) assuming Lemmas  $5.3$  and  $5.4$ .

Proof of Lemma [2.3.](#page-2-2) Set

<span id="page-8-1"></span>
$$
\delta_0 = (2r)^{-2^{k+1}}, \ \varepsilon^* = (2r)^{-2^{k+7}}/k, \ \alpha = 2^5 r k (2r)^{2^{k+1}}, \ \alpha_\Delta = 2\alpha \psi \text{ and } \tilde{m} = (k-1)\alpha_\Delta N. \tag{5.1}
$$

By Corollary [5.2](#page-7-2) with  $\alpha_{\Delta}$ ,  $\tilde{m}$  playing the roles of  $\alpha$ , m, respectively, H contains a monochromatic kuniform triangle cycle  $T_{\tilde{m}}^{(k)}$  $T_{\tilde{m}}^{(k)}$ . Note that  $T_{\tilde{m}}^{(k)}$  $\tilde{m}^{(k)}$  contains a vertex-set  $\tilde{B}$  with

<span id="page-8-2"></span>
$$
|\tilde{B}| = \tilde{m}/(k-1) = \alpha_{\Delta} N \tag{5.2}
$$

such that for any  $\tilde{B}' \subseteq \tilde{B}$ , there is a monochromatic tight cycle on  $V\left(T_{\tilde{m}}^{(k)}\right)$  $\left(\bar{m}^{(k)}\setminus \tilde{B}'\right)$ . Note that  $\left|V\left(T_{\tilde{m}}^{(k)}\right)\right|$  $\tilde{m}$  $\Big)\Big| =$  $\tilde{m} + \alpha_{\Delta} N = k \alpha_{\Delta} N$ . Let  $H_1 = H \setminus T_{\tilde{m}}^{(k)}$  $\tilde{m}^{(\kappa)}$  and

<span id="page-8-0"></span>
$$
n = |V(H_1)| = N - k\alpha_\Delta N \ge N/2. \tag{5.3}
$$

Lemma [5.4](#page-7-3) with  $H_1$  playing the role of H implies that there exists a vertex set  $U^* \subseteq V(H_1)$  with  $|U^*| \leq 3n/4$  such that, for any  $B^* \subseteq V(H_1) \setminus U^*$  with  $|B^*| = 4\varepsilon^* n$ ,  $H[B^* \cup U^*]$  can be covered by at most  $2^{18}r\delta_0^{-5} + 1$  vertex-disjoint monochromatic tight cycles and at most  $\psi n$  isolated vertices. Let  $H_2 = H_1 \setminus U^*$  and  $n' = |V(H_2)| = n - |U^*| \ge n - 3n/4 = n/4$ .

By Lemma [5.5](#page-7-4) with  $H_2$ , n' playing the role of H, n, respectively, there exists a vertex subset  $W \subseteq$  $V(H_2)$  with

$$
n/20r \le n'/5r \le |W| \le n'/4r \le n/4r
$$

such that H[W] contains a monochromatic tight cycle of length  $\ell$  for all  $\ell \leq (1 - \psi)|W|$  with  $\ell \equiv$  $0 \pmod{k}$ .

Set  $R = V\left(T_{\tilde{m}}^{(k)}\right)$  $\tilde{m}$  $\bigcup W \cup U^*$ . We now show that R has the desired properties. Let B be a subset of  $V(H) \setminus R$  with

$$
|B| \le \varepsilon^* N \stackrel{(5.3)}{\le} 2\varepsilon^* n.
$$

Let  $\ell$  be the largest integer such that  $\ell \equiv 0 \pmod{k}$  and  $|B| + |W| - \ell \geq 2\varepsilon^* n$ . Since  $\psi \ll \varepsilon^*$ ,  $\ell \leq (1-\psi)|W|$  and therefore there exists a monochromatic tight cycle  $C_1$  in  $H[W]$  of length  $\ell$ . Let  $B^+$ and  $L_1$  be disjoint vertex sets such that

<span id="page-9-1"></span>
$$
B^{+} \cup L_{1} = B \cup (W \setminus V(C_{1})), \ |B^{+}| = 4\varepsilon^{*} n \text{ and } |L_{1}| < k. \tag{5.4}
$$

Thus  $H[U^* \cup B^+]$  can be covered by a set C of monochromatic tight cycles such that  $|\mathcal{C}| \leq 2^{18} r \delta_0^{-5} + 1$ and

<span id="page-9-2"></span>
$$
|U^* \setminus V(\mathcal{C})| \le \psi n \le \psi N. \tag{5.5}
$$

Let  $L = L_1 \cup (U^* \setminus V(\mathcal{C}))$ . We deduce that

$$
|L| = |L_1| + |U^* \setminus V(C)| \stackrel{(5.4), (5.5)}{\leq} k + \psi N \stackrel{(5.1)}{\leq} \alpha_{\Delta} N/\alpha \stackrel{(5.2)}{=} |\tilde{B}|/\alpha.
$$

By Lemma [5.3](#page-7-1) with  $\tilde{B}, L$  playing the roles of X, Z, respectively,  $H[\tilde{B} \cup L]$  contains a set  $\mathcal{C}'$  of vertexdisjoint monochromatic tight cycles such that  $L \subseteq V(C')$  and  $|C'| \leq 2^{18}r\delta_0^{-5}$ . By the property of  $T_{\tilde{m}}^{(k)}$  $\tilde{\tilde{m}}^{\,(\hbar)}$ there exists a monochromatic tight cycle  $C_2$  with vertex set  $V(T_{\tilde{m}}^{(k)})$  $\Big) \setminus (\tilde{B} \cap V(\mathcal{C}'))$ . Thus, we have  $\tilde{m}$ partitioned  $R \cup B$  into monochromatic cycles, namely  $C \cup C' \cup \{C_1, C_2\}$ . The total number of cycles created is at most  $2^{19}r\delta_0^{-5} + 3 = 2^{19}r(2r)^{5\cdot 2^{k+1}} + 3$ . This completes the proof of the lemma.  $\Box$ 

#### <span id="page-9-0"></span>5.2 Proof of Lemma [5.4](#page-7-3)

The proof of Lemma [5.4](#page-7-3) is motivated by Gyárfás, Ruszinkó, Sárközy and Szemerédi [\[11](#page-35-4)]. Let  $t \in \mathbb{N}$ . A t-half dense matching in a k-partite k-graph H with vertex classes  $X_1, \ldots, X_k$  is a matching  $M =$  ${x_{i,1}x_{i,2} \ldots x_{i,k} : i \in [\ell]}$  where for all  $i \in [\ell], x_{i,j} \in X_j$  and for any vertex  $x_1 \in V(M) \cap X_1$ , we have

$$
|\{j \in [\ell] : x_1x_{j,2} \dots x_{j,k} \in E(H)\}| \ge t.
$$

We say a matching M is t-semi-dense if for all  $i \in [\ell]$ , we have

$$
|\{j \in [\ell] : x_{i,1}x_{i,2} \dots x_{i,k-1}x_{j,k} \in E(H)\}| \ge t.
$$

<span id="page-9-5"></span>Note that the order of  $X_1, \ldots X_k$  matters, but it will be clear from context. We shall need the following simple fact.

Fact 5.6. A matching in a 2-graph is t-semi-dense if and only if it is t-half-dense.

<span id="page-9-4"></span>We need the following result by Gyárfás, Ruszinkó, Sárközy and Szemerédi [\[11\]](#page-35-4).

**Lemma 5.7** ([\[11](#page-35-4), Lemma 4]). Every graph of average degree 8k has a connected k-half dense matching.

<span id="page-9-3"></span>Recall that a k-graph H is locally r-edge-coloured if any set of  $k-1$  vertices sees at most r colours in H. We use the following result by Gyárfás, Lehel, Nešetřil, Rödl, Schelp and Tuza  $[10]$ .

**Lemma 5.8** ([\[10](#page-35-22), Corollary 3]). Let G be a graph with average degree d that is r-locally edge-coloured. Then there is a monochromatic subgraph G' such that  $|E(G')| \geq d^2/2r^2$ .

For a k-graph H, we denote by  $\partial H$  the  $(k-1)$ -graph on  $V(H)$  whose edges are all  $(k-1)$ -tuples of vertices contained in some edge in H. Therefore,  $|E(\partial H)| \leq k|E(H)|$ . Recall that a monochromatic tight component is a tight component that is monochromatic, i.e. there is a sequence of edges of the same colour joining any two edges in the monochromatic tight component, such that any two consecutive edges in the sequence share  $k - 1$  vertices.

<span id="page-10-2"></span>The following lemma shows that one can find a linear-sized semi-dense matching in a monochromatic tight component of a locally r-edge-coloured almost complete k-graph.

Lemma 5.9. Let  $0 < 1/t \ll \varepsilon_k \ll \varepsilon_{k-1} \ll \cdots \ll \varepsilon_2 \ll 1/r, 1/k$  and  $\delta(r, k) = \left(2^{2^k+3k-5}r^{2^k-2}\right)^{-1}$ . Let R be a locally r-edge-coloured k-graph on t vertices with  $|E(R)| \geq (1 - \varepsilon_k) {t \choose k}$  $\binom{t}{k}$ . Then there exists a monochromatic tight component of R containing a  $\delta(r, k)t$ -semi-dense matching.

Proof. We prove the lemma by induction on k. Note that

<span id="page-10-0"></span>
$$
\delta(r,2) = (2^5r^2)^{-1} \text{ and } \delta(r,k+1) = \delta(2r^2,k)/2^5r^2. \tag{5.6}
$$

Suppose that  $k = 2$ . The average degree of R is

$$
\frac{2|E(R)|}{t} \ge \frac{2(1-\varepsilon_2)\binom{t}{2}}{t} \ge \frac{t}{2}.
$$

By Lemma [5.8,](#page-9-3) there is a monochromatic subgraph R' such that  $|E(R')| \ge t^2/8r^2$ . The average degree of  $R'$  is

$$
\frac{2|E(R')|}{t}\geq \frac{t}{4r^2}=8\delta(r,2)t.
$$

By Lemma [5.7,](#page-9-4) R' contains a connected  $\delta(r, 2)t$ -half-dense matching. By Fact [5.6,](#page-9-5) we are done.

Thus, we may assume  $k \geq 3$ . By Proposition [4.6](#page-6-3) with  $\varepsilon_k$ , t playing the role of  $\alpha$ , n, respectively, there exists a spanning subgraph  $R'$  of R that is  $(1-2\varepsilon_k^{1/4k^2})$  $\frac{1/4k^2}{k}, 2\varepsilon_k^{1/4k}$  $\binom{1}{k}$ -dense. Let  $\mathcal T$  be the set of monochromatic tight components of R'. For  $T \in \mathcal{T}$ , let  $\phi_{R'}(T)$  be the colour of T. Let

<span id="page-10-1"></span>
$$
n = \frac{t}{8r}.\tag{5.7}
$$

Partition  $V(R')$  into V, W with  $|V| = n$ . Let  $G = (\partial R') [V]$ , so G is a  $(k-1)$ -graph. Note that

$$
|E(G)| \ge {n \choose k-1} - 2\varepsilon_k^{1/4k^2} {t \choose k-1} \ge (1 - \varepsilon_{k-1}) {n \choose k-1}.
$$

For every edge  $e \in E(G)$ , we have

$$
d_{R'}(e, W) \ge |W| - 2\varepsilon_k^{1/4k^2} t \ge |W|/2.
$$

Define an edge-colouring  $\phi_G$  of G with colour set T so that, for an edge  $e \in E(G)$ , we have

$$
\phi_G(e) = T \text{ if } d_{T,G}(e,W) \ge |W|/2r.
$$

If multiple  $T \in \mathcal{T}$  satisfy this, pick one such T arbitrarily.

We now show that G is locally  $2r^2$ -edge-coloured. Suppose for a contradiction, there exists a set S of  $k-2$  vertices  $x_1, \ldots, x_{k-2}$  in G such that  $|\phi_G(S)| \geq 2r^2 + 1$ . Since R' is locally r-edge-coloured, there exist a colour  $c \in \phi(R')$ , vertices  $y_1, \ldots, y_{2r+1}$  and distinct tight components  $T_1, \ldots, T_{2r+1}$  in  $R'$ 

for which  $\phi_{R'}(T_i) = c$  and  $\phi_G(S \cup y_i) = T_i$  for all  $i \in [2r+1]$ . Then there exist distinct  $i, j \in [2r+1]$ such that  $N_{T_i}(S \cup y_i, W) \cap N_{T_j}(S \cup y_j, W) \neq \emptyset$ . Let  $w \in N_{T_i}(S \cup y_i, W) \cap N_{T_j}(S \cup y_j, W)$ . Note that  $y_ix_1 \ldots x_{k-2}wy_j$  is a tight path in R' where both edges are coloured c implying  $T_i = T_j$ , a contradiction.

By our induction hypothesis, G contains a monochromatic  $(k-1)$ -uniform  $\delta(2r^2, k-1)n$ -semi-dense matching  $M^{(k-1)}$  of size  $\ell$ . Note that

$$
\delta(2r^2, k-1)n \le \ell \le n/2 = t/16r.
$$

Let  $T_0 \in \mathcal{T}$  be the colour of  $M^{(k-1)}$  in G. Let  $M^{(k-1)} = \{x_{i,1} \ldots x_{i,k-1} : i \in [\ell]\}$  be such that for each  $i \in [\ell],$  we have  $\overline{2}$ 

$$
|\{j \in [\ell] : x_{i,1} \dots x_{i,k-2} x_{j,k-1} \in E(T_0)\}| \geq \delta(2r^2, k-1)n.
$$

We now extend  $M^{(k-1)}$  to a k-uniform  $\delta(r, k)t$ -semi-dense matching  $M^{(k)}$  in  $T \subseteq R' \subseteq R$  using vertices from W.

Let  $\eta = \delta(2r^2, k-1)$  and  $m = |W|$ . For each  $i \in [\ell]$ , let  $X^i = \{x_{i,1}, x_{i,2}, \ldots, x_{i,k-2}\}$  and let  $X_{k-1} = \{x_{i,k-1} : i \in [\ell]\}.$  Delete some edges in  $T_0[V(M^{(k-1)})]$  if necessary so that for each  $i \in \mathbb{Z}$ [ $\ell$ ], we have  $d_{T_0[V(M^{(k-1)})]}(X^i, X_{k-1}) = \eta n$ . We now choose vertices  $w_1, \ldots w_\ell$  from W in turns such that  $d_{T_0}(X^i \cup w_i, X_{k-1}) \geq \delta(r, k)t$ . Fix  $i \in [\ell]$ . For each  $x' \in N_{G[V(M^{(k-1)})]}(X^i, X_{k-1})$ , we have  $d_{T_0}(X^i \cup x', W) \geq m/2r$ . Therefore,  $T_0$  contains at least  $\eta nm/2r$  many  $x_{i,1} \ldots x_{i,k-2} X_{k-1} W$ -edges. At most  $\ell \eta n \leq \eta n^2/2$  such edges contain a vertex in  $w_1, \ldots, w_{i-1}$ . Thus there exists a vertex  $w_i \in W \setminus \{w_j :$  $j \in [i-1]$  such that

$$
d_{T_0}(X^i \cup w_i, X_{k-1}) \ge \frac{\eta nm/(2r) - \eta n^2/2}{m} \ge \left(\frac{\eta n}{2r}\right) \left(1 - \frac{rn}{m}\right)
$$
  

$$
\ge \frac{\eta n}{4r} = \frac{\delta(2r^2, k-1)n}{4r} \stackrel{(5.6), (5.7)}{\ge} \delta(r, k)t.
$$

Let  $M^{(k)} = \{w_i x_{i,1} \ldots x_{i,k-2} x_{i,k-1} : i \in [\ell] \}$ . Note that  $M^{(k)}$  is the desired k-uniform semi-dense matching.  $\Box$ 

We now convert the semi-dense matching into a half-dense matching. The following lemma finds a half-dense matching in a bipartite graph where we control the vertex set with a large minimum degree. Its proof is based on [\[11,](#page-35-4) Lemma 3]. For a matching M in a graph  $G$ , an M-augmented path is a path in G where every alternate edge is in M.

<span id="page-11-0"></span>**Lemma 5.10.** Let  $1/n \ll \delta \leq 1$  and G be a bipartite graph with vertex classes X and Y such that  $|X|, |Y| \leq n$  and  $|E(G)| \geq \delta n^2$ . Then G contains a matching M such that for all  $x \in X \cap V(M)$ , we have  $d_{G[V(M)]}(x) \geq \delta^2 n/8$ .

Proof. Let  $X' \subseteq X$  and  $Y' \subseteq Y$  be such that  $\delta(G[X' \cup Y']) \geq \delta n/2$ . Let  $m = \min\{|X'|, |Y'|\}$ , so  $m \geq \delta n/2$ .

**Claim 5.11.** There exist subsets  $X^* \subseteq X'$  and  $Y^* \subseteq Y'$  such that  $|X^*| = |Y^*| = m$  and  $\delta(G[X^* \cup Y^*]) \ge$  $\delta^2 n/8.$ 

*Proof of claim.* Suppose that  $|X'| = m$  (and the case  $|Y'| = m$  is proved similarly). Let  $X^* = X'$ . Pick a subset Y<sup>\*</sup> of Y' of size m uniformly at random. Note that for any  $y \in Y^*$ ,  $d(y, X^*) \geq \delta n/2$ . Let  $x \in X^*$ . Note that  $d(x, Y^*) \sim \text{Hyp}(|Y'|, m, d(x, Y'))$  and

$$
\mathbb{E}d(x, Y^*) = \frac{|Y^*|d(x, Y')}{|Y'|} \ge \frac{m(\delta n/2)}{n} \ge \frac{\delta^2 n}{4}.
$$

Applying Lemma [3.2,](#page-4-1) we deduce that for  $x \in X^*$ 

$$
\mathbb{P}\left(d(x,Y^*) < \frac{\delta^2 n}{8}\right) \le 2e^{-\frac{\delta^2 n}{12}}.
$$

Taking a union bound over all  $x \in X^*$ , we have that with high probability,  $\delta(G[X^* \cup Y^*]) \geq \delta^2 n/8$ . Fix such  $X^*$  and  $Y^*$ . In the second control of the second control of the second control of the second control of the second control of

Let  $G^* = G[X^* \cup Y^*]$ . Pick a largest matching  $M^*$  in  $G^*$ . If  $M^*$  is spanning on  $V(G^*)$ , then we are done by setting  $M = M^*$ . Hence we may assume  $Y^* \setminus V(M^*) \neq \emptyset$ . Let  $X_1^*$  be the set of vertices in  $V(M^*) \cap X^*$  that can be reached by an  $M^*$ -augmented path from  $X^* \setminus V(M^*)$ . Observe that  $E(G^*[X_1^* \cup$  $(Y^* \setminus V(M^*))$  =  $\emptyset$ . Otherwise for a vertex  $x \in X_1^*$ , let  $xy$  be an edge in  $E(G^*[X_1^* \cup (Y^* \setminus V(M^*))])$ . There exists an M<sup>\*</sup>-augmented path P between x and  $X^* \setminus V(M^*)$ . But  $(M^* \Delta E(P)) \cup \{xy\}$  is a larger matching, contradicting that  $M^*$  is the largest matching.

Let  $Y_1^* = N_{G^*}(X_1^*) \subseteq V(M^*) \cap Y^*$ , so  $E(G[X_1^* \cup (Y^* \cap V(M^*)) \setminus Y_1^*]) = \emptyset$ . Since  $M^*$  is maximal,  $E(G^* \setminus V(M^*)) = \emptyset$ . On the other hand,  $E(G[X^* \setminus V(M^*), Y^*]) \geq \delta(G^*) > 0$ . Hence  $E(G[X^* \setminus V(M^*), Y^*]) = E(G^*)$  $V(M^*), Y^* \cap V(M^*)]$   $\neq \emptyset$  implying that  $X_1^* \neq \emptyset$ .

Let 
$$
M = M^*[X_1^* \cup Y_1^*]
$$
. We have  $\delta_M(x) \ge \delta^2 n/8$  for all  $x \in X_1^*$ .

<span id="page-12-2"></span>**Proposition 5.12.** Let  $1/t \ll \delta \ll 1/r, 1/k$  and R be a k-graph on t vertices with a  $\delta t$ -semi-dense matching. Then R contains a  $\delta^3 t/2$ -half-dense matching.

*Proof.* Let  $M = \{v_{i,1}v_{i,2}\ldots v_{i,k} : i \in [\ell]\}$  be a  $\delta t$ -semi-dense matching and let  $V_k = \{v_{i,k} : i \in [\ell]\}$ . Note that

<span id="page-12-0"></span>
$$
\delta t \le \ell \le t/2. \tag{5.8}
$$

Let H be the auxiliary bipartite graph with vertex classes  $[\ell]$  and  $V_k$  such that, for each  $i \in [\ell]$  and  $v_{j,k} \in V_k$ , we have  $iv_{j,k} \in E(H)$  if and only if  $v_{i,1}v_{i,2} \ldots v_{i,k-1}v_{j,k} \in E(R)$ . We deduce that

$$
e(H) \ge \delta t \ell \stackrel{(5.8)}{\ge} 2\delta \ell^2.
$$

By Lemma [5.10](#page-11-0) with  $H, \ell, (\delta/2), V_k, [\ell]$  playing the roles of  $G, n, \delta, X, Y$ , respectively, H contains a matching  $M'$  such that, for all  $v \in V_k \cap V(M')$ , we have

<span id="page-12-1"></span>
$$
d_{H[V(M')]}(v) \ge \delta^2 \ell/2 \stackrel{(5.8)}{\ge} \delta^3 t/2. \tag{5.9}
$$

Without loss of generality,  $M' = \{iv_{i,k}\}_{i \in [\ell]}$ . Let  $M'' = \{v_{i,k}v_{i,k-1} \ldots v_{i,1} : i \in [\ell]\}$ . By [\(5.9\)](#page-12-1),  $M''$  is the required half-dense matching.  $\Box$ 

<span id="page-12-3"></span>Corollary 5.13. Let  $1/t \ll \varepsilon_k \ll 1/r, 1/k$ . Let R be an r-edge-coloured k-graph on t vertices with  $|E(R)| \geq (1-\varepsilon_k) {t \choose k}$  $\epsilon_k^t$ ). Then there exists a monochromatic tight component of R containing a  $\left(2^{9k}(2r)^{3\cdot 2^k}\right)^{-1}$  thalf-dense matching.

Proof. Let  $1/t \ll \varepsilon_k \ll \varepsilon_{k-1} \ll \cdots \ll \varepsilon_2 \ll 1/r, 1/k$  and let  $\delta = \left(2^{2^k+3k-5}r^{2^k-2}\right)^{-1}$ . By Lemma [5.9](#page-10-2) there exists a monochromatic tight component of R containing a  $\delta t$ -semi-dense matching. By Proposi-tion [5.12,](#page-12-2) there is a  $\delta^3 t/2$ -half-dense matching in R. Note that

$$
\frac{\delta^3 t}{2} = \frac{t}{2^{3\cdot 2^k+9k-14}r^{3\cdot 2^k-6}} \geq \frac{t}{2^{9k}(2r)^{3\cdot 2^k}}.
$$

This completes the proof of the corollary.

We need the following lemma on bipartite graphs (Lemma  $5.15$ ) for the main result in this subsection. The lemma will enable us to find a suitable fractional matching. To prove it we need the following result by Gyárfás, Ruszinkó, Sárközy and Szemerédi [\[11](#page-35-4)].

<span id="page-13-1"></span>**Lemma 5.14** ([\[11](#page-35-4), Lemma 5]). Let  $1/n \ll c \leq 0.001$  and G be a directed graph on n vertices with minimum out-degree  $\delta^+(G) \geq cn$ . Then there are subsets  $Y \subseteq X \subseteq V(G)$  such that  $|Y| \geq cn/2$  and for all  $x \in X$  and  $y \in Y$ , there are at least  $c^6n$  internally vertex-disjoint paths from x to y of length at  $most\ c^{-3}$ .

<span id="page-13-0"></span>**Lemma 5.15.** Let  $1/n \ll c, \mu < 1$  with  $c + \mu \leq 1/8$ . Let G be a bipartite graph with vertex classes  $X = \{x_i : i \in [n]\}, Y = \{y_i : i \in [n]\}$  and a perfect matching  $M = \{x_i y_i : i \in [n]\}.$  Suppose that for all  $x \in X$ ,  $d(x, Y) \geq \delta n$ . Then there exist disjoint subsets  $I^+$  and  $I^-$  of  $[n]$  with  $|I^+| = |I^-| = \delta n/4$  such that the following hold. Let  $\omega$  be a vertex weighting of G such that we have

<span id="page-13-4"></span><span id="page-13-3"></span>
$$
\omega(y_i) = 1/2 \qquad \text{for all } i \in [n],
$$
  
\n
$$
\omega(x_i) \in [1/2 - c, 1/2] \qquad \text{for all } i \in [n] \setminus I^+,
$$
  
\n
$$
\omega(x_i) \in [1/2, 1/2 + c] \qquad \text{for all } i \in [n] \setminus I^- \text{ and} \qquad (5.10)
$$

$$
\sum_{i \in I^{+}} (\omega(x_{i}) - \omega(y_{i})) = \sum_{j \in I^{-}} (\omega(y_{j}) - \omega(x_{j})) < \frac{\delta^{9}n}{8}.\tag{5.11}
$$

Then G has a fractional matching  $\omega^*$  of weight at least  $\sum_{i\in[n]} \omega(x_i) - \mu n$  such that, for each  $v \in V(G)$ , we have  $1/2 - c \leq \omega^*(v) \leq \omega(v)$  and each non-zero weighted edge has weight at least  $1/8$ .

<span id="page-13-2"></span>*Proof.* We start with the following claim identifying  $I^+$  and  $I^-$ .

**Claim 5.16.** There exists a subset I of  $[n]$  with  $|I| = \delta n/2$  such that for all distinct i,  $i' \in I$ , there are at least  $\delta^6 n$  internally vertex-disjoint M-augmented paths from  $x_i$  to  $x_{i'}$  of the form  $x_i y_{i_1} x_{i_1} \ldots y_{i'} x_{i'}$ .

*Proof of claim.* Define an auxiliary digraph H on X such that  $x_ix_j \in E(H)$  is directed from  $x_i$  to  $x_j$ if  $x_i y_j \in E(G)$ . Note that  $\delta^+(H) \geq \delta n$ . By Lemma [5.14,](#page-13-1) there exists  $X_2 \subseteq X_1 \subseteq X$  such that  $|X_2| \ge \delta n/2$  and every  $x_1 \in X_1$  has at least  $\delta^6 n$  internally vertex-disjoint paths of length at most  $\delta^{-3}$  to every  $x_2 \in X_2$ . Let  $I \subseteq [n]$  with  $|I| = \delta n/2$  be such that  $\{x_i : i \in I\} \subseteq X_2$ . Note that a path  $x_{i_1} \ldots x_{i_\ell}$ in H corresponds to an M-augmented path in G from  $x_{i_1}$  to  $x_{i_\ell}$ , namely  $x_{i_1}y_{i_2}x_{i_2} \ldots y_{i_\ell}x_{i_\ell}$ .

Let I be given by Claim [5.16.](#page-13-2) Partition I into  $I^+$  and  $I^-$  so that  $|I^+| = |I^-| = \delta n/4$ . We write  $X^+ = \{x_i : i \in I^+\}$  and write  $X^-, Y^+, Y^-, M^+$  and  $M^-$  similarly. Let  $\omega$  be a vertex weighting satisfying the assumptions of the lemma.

Define a fractional matching  $\omega_0^*$  on G such that, for all  $xy \in E(G)$  with  $x \in X$  and  $y \in Y$ ,

$$
\omega_0^*(xy) = \begin{cases} \min\{\omega(x), \omega(y)\} = 1/2 & \text{if } xy \in M \setminus M^-, \\ \min\{\omega(x), \omega(y)\} = \omega(x) & \text{if } xy \in M^-, \\ 0 & \text{otherwise.} \end{cases}
$$

For a fractional matching  $\omega^*$  on G, let

$$
||\omega^* - \omega_0^*|| = \sum_{e \in E(G)} |\omega^*(e) - \omega_0^*(e)|,
$$

which denotes the sum of the edge-weight differences between  $\omega^*$  and  $\omega_0^*$ . Let  $\omega^*$  be a fractional matching on G such that

- <span id="page-14-4"></span><span id="page-14-3"></span>(a)  $1/2 - c \le \omega^*(v) \le \omega(v)$  for all  $v \in V(G)$ ;
- <span id="page-14-1"></span>(b)  $\omega^*(x_i y_i) \geq 1/8$  for all  $i \in [\ell];$
- <span id="page-14-0"></span>(c)  $||\omega^* - \omega_0^*|| \leq 2\delta^{-3}(|\omega^*| - |\omega_0^*|);$
- (d)  $\omega^*(v) = \omega(v)$  for all  $v \in V(G) \setminus (X^+ \cup Y^-)$ .

Such an  $\omega^*$  exists by taking  $\omega^* = \omega_0^*$ . We further assume that  $|\omega^*|$  is maximal. We may also assume that  $|\omega^*| < \sum_{i \in [n]} \omega(x_i) - \mu n$  or else we are done. By [\(d\),](#page-14-0) there exist  $x^+ \in X^+$  and  $y^- \in Y^-$  such that

<span id="page-14-2"></span>
$$
\omega(x^{+}) - \omega^{*}(x^{+}), \ \omega(y^{-}) - \omega^{*}(y^{-}) \ge \mu.
$$
\n(5.12)

We aim to add weight to  $x^+$  and  $y^-$ . Let  $x^- = N_M(y^-)$ . Let  $E_0 = \{e \in E(G) : |\omega^*(e) - \omega_0^*(e)| \ge 1/4\}$ . Note that

$$
|E_0| \le \frac{||\omega^* - \omega_0^*||}{1/4} \stackrel{(c)}{\le} 8\delta^{-3} (|\omega^*| - |\omega_0^*|) \stackrel{(d)}{\le} 8\delta^{-3} \left( \sum_{i \in I^+} \omega(x_i) - \omega(y_i) \right) \stackrel{(5.11)}{<} \delta^6 n.
$$

Thus, by the definitions of  $X^+$  and  $X^-$ , there exists an M-augmented path P in G from  $x^+$  to  $x^-$  of length at most  $\delta^{-3}$  with  $E(P) \cap E_0 = \emptyset$ . Without loss of generality, let  $P = x_1 y_2 x_2 y_3 \dots x_{\ell-1} y_{\ell} x_{\ell}$  where  $x_1 = x^+, x_\ell = x^-, y_\ell = y^-$  and  $\ell \leq \delta^{-3}$ . Define the fractional matching  $\omega_1^* : E(G) \to [0,1]$  such that, for any edge  $e \in E(G)$ , we have

$$
\omega_1^*(e) = \begin{cases}\n\omega^*(e) - \mu & \text{if } e = y_i x_i \text{ with } i \in [\ell - 1] \setminus \{1\}, \\
\omega^*(e) + \mu & \text{if } e = x_i y_{i+1} \text{ with } i \in [\ell - 1], \\
\omega^*(e) & \text{otherwise.} \n\end{cases}
$$
\n(5.13)

Note that

<span id="page-14-6"></span><span id="page-14-5"></span>
$$
|\omega_1^*| = |\omega^*| + \mu \tag{5.14}
$$

and for  $v \in V(G)$ ,

$$
\omega_1^*(v) = \begin{cases} \omega^*(v) + \mu & \text{if } v \in \{x^+, y^-\}, \\ \omega^*(v) & \text{otherwise.} \end{cases}
$$

Therefore by  $(5.12)$ , we have that  $\omega_1^*$  satisfies [\(a\)](#page-14-3) and [\(d\).](#page-14-0)

To see  $\omega_1^*$  satisfies [\(b\),](#page-14-4) if  $e \in E(G) \setminus (E(P) \setminus \{x_\ell y_\ell\})$ , then  $\omega_1^*(e) = \omega^*(e)$ . If  $e \in E(P) \setminus \{x_\ell y_\ell\} \subseteq$  $E(G) \setminus E_0$ , then  $|\omega_1^*(e) - \omega_0^*(e)| = \mu$  and so

$$
\omega_1^*(e) \begin{cases} \ge \omega_0^*(e) - 1/4 - \mu \ge 1/8 & \text{if } e \in E(M) \\ \le \omega_0^*(e) + 1/4 + \mu \le 1/2 & \text{if } e \notin E(M). \end{cases}
$$

Thus,  $\omega_1^*$  indeed satisfies [\(b\)](#page-14-4) and moreover is a fractional matching on G.

To verify that  $\omega_1^*$  satisfies [\(c\),](#page-14-1) recall that P has  $2\ell - 1 \leq 2\delta^{-3}$  edges. Therefore, we deduce that

$$
||\omega_1^* - \omega_0^*|| \le ||\omega_1^* - \omega^*|| + ||\omega^* - \omega_0^*|| \le \mu(2\ell - 1) + 2\delta^{-3}(|\omega^*| - |\omega_0^*|)
$$
  

$$
\le 2\delta^{-3}\mu + 2\delta^{-3}(|\omega^*| - |\omega_0^*|) \stackrel{(5.13)}{=} 2\delta^{-3}(|\omega_1^*| - |\omega_0^*|).
$$

Thus,  $\omega_1^*$  satisfies [\(a\)](#page-14-3) to [\(d\)](#page-14-0) and has larger weight than  $\omega^*$ , a contradiction.

We now prove Lemma [5.4](#page-7-3) assuming Lemma [5.3.](#page-7-1) Firstly, we find a monochromatic tightly connected half-dense matching in the reduced k-graph and reserve some unbalanced vertex clusters corresponding to the vertices of the matching, as the vertex set  $U^*$ . We then use Lemma [5.3](#page-7-1) to cover  $B^*$  with a set  $\mathcal C$  of few monochromatic tight cycles using some vertices from  $U^*$ . Finally, we use the half-dense property of the matching and Lemma [5.15](#page-13-0) to find one long tight cycle covering almost all the vertices in  $U^* \setminus V(\mathcal{C})$ .

Proof of Lemma 5.4. Let 
$$
d_k = 1/r
$$
,  $\delta = \left(2^{9k}(2r)^{3 \cdot 2^k}\right)^{-1}$ ,  
\n $1/n \ll 1/t_1 \ll 1/t_0 \ll \varepsilon_k \ll \varepsilon'$ ,  $\mu \ll \psi \ll 1/r, 1/k$ ,  
\n $1/n \ll 1/r'$ ,  $\tilde{\varepsilon} \ll \varepsilon_k, d_2, \ldots, d_{k-1}$ .

Step 1: Defining  $U^*$ .

Let H' be an induced subgraph of H such that  $|V(H')| \equiv 0 \pmod{t_1}$  and  $|V(H \setminus H')| < t_1!$ . By Lemma [4.3](#page-6-1) with H' playing the role of H, there exists a  $(\cdot, \cdot, \tilde{\varepsilon}, \varepsilon_k, r')$ -regular slice  $\tilde{\mathcal{J}}$  with partition  $\mathcal{P}$ of  $V(H')$ . Let  $m = |V|$  for  $V \in \mathcal{P}$ ,  $t = |\mathcal{P}|$  and  $t_0 \le t \le t_1$ . Note that

<span id="page-15-1"></span>
$$
n \ge mt \ge n - t_1! \ge n/2. \tag{5.15}
$$

Let  $\mathcal{R} = \mathcal{R}^{\widetilde{\mathcal{J}}}_{d_k}(H')$ . Note that  $|E(\mathcal{R})| \geq (1 - r\varepsilon_k) \binom{t}{k}$  $\binom{t}{k}$  by Lemma [4.4.](#page-6-0) By Corollary [5.13](#page-12-3) with  $\mathcal{R}, r\varepsilon_k$ playing the roles of  $R, \varepsilon$ , respectively, there exists a monochromatic tight component T of R and a  $\delta t$ -half dense matching M of size  $\ell$ , where

<span id="page-15-0"></span>
$$
\delta t \le \ell \le t/k \le t/2. \tag{5.16}
$$

Let  $M = \{x_i y_{i,2} \dots y_{i,k} : i \in [\ell]\}\$  and  $X = \{x_i : i \in [\ell]\}\$  be such that, for all  $x \in X$ , we have  $|\{i \in [\ell] : xy_{i,2} \dots y_{i,k} \in E(T)\}| \geq \delta t.$ 

Define an auxiliary bipartite graph G on X and  $Y = \{y_1, \ldots, y_\ell\}$  such that  $x_i y_j \in E(G)$  if and only if  $x_i y_{j,2} \dots y_{j,k} \in E(T)$ . Note that M corresponds to a half-dense matching  $M' = \{x_i y_i : i \in [\ell]\}$  in G and for each  $x \in X$ ,

<span id="page-15-2"></span>
$$
d_G(x, Y) \ge \delta t \stackrel{(5.16)}{\ge} 2\delta \ell.
$$

By Lemma [5.15](#page-13-0) with  $\ell, 2\delta$  playing the roles of  $n, \delta$ , respectively, there exist disjoint  $I^+, I^- \subseteq [\ell]$  such that  $(5.16)$  $\sqrt{5.15}$ 

$$
|I^+| = |I^-| = \delta\ell/2 \stackrel{(5.16)}{\geq} \delta^2 t/2 \stackrel{(5.15)}{\geq} \delta^2 (n/2m) - \delta^2 t_1!/(2m) \geq \delta^2 n/4m.
$$

Define  $X^+ = \{x_i \in X : i \in I^+\}$  and define  $X^-, Y^+, Y^-$  similarly. Let

$$
\alpha = 2^5 rk(2r)^{2^{k+1}}, \gamma = 4\varepsilon^* \alpha n/(m|I^+|) \text{ and } \gamma_a = (k-1)\gamma/\alpha = 4\varepsilon^*(k-1)n/(m|I^+|). \tag{5.17}
$$

Note that Lemma [5.15](#page-13-0) also implies that if  $\omega$  is a vertex-weighting satisfying [\(5.10\)](#page-13-4) and [\(5.11\)](#page-13-3) with  $\gamma-\gamma_a, \ell$ playing the roles of c, n, respectively, then G has a fractional matching  $\omega^*$  with  $|\omega^*| \geq \sum_{i \in [\ell]} \omega(x_i) - \mu \ell$ , where each vertex v has weight between  $1/2 - \gamma + \gamma_a$  and  $\omega(v)$  and furthermore each non-zero weighted edge has weight at least 1/8.

For each  $v \in V(\mathcal{R})$ , recall that  $V_v$  is the cluster of P corresponding to v. We pick disjoint  $U_v, A_v \subseteq V_v$ such that

$$
|A_v| = \begin{cases} \gamma m & \text{if } v \in X^+, \\ 0 & \text{otherwise,} \end{cases}
$$
  

$$
|U_v| = \begin{cases} \left(\frac{1}{2} - \gamma + \gamma_a\right)m & \text{if } v \in X^-, \\ \frac{m}{2} & \text{if } v \in V(M') \setminus X^-, \\ \varepsilon'm & \text{otherwise.} \end{cases}
$$

Let  $A = \bigcup_{v \in V(\mathcal{R})} A_v$ ,  $U = \bigcup_{v \in V(\mathcal{R})} U_v$  and  $U^* = U \cup A$ . Therefore, we have  $|A| = |I^+|\gamma m = 4\alpha \varepsilon^* n$ by [\(5.17\)](#page-15-2) and

$$
|U^*| = |U| + |A| = km\ell/2 - (\gamma - \gamma_a)m|X^-| + \varepsilon'm(t - k\ell) + \gamma m|X^+|
$$
  
=  $km\ell/2 + \gamma_a m|X^-| + \varepsilon'm(t - k\ell) = km\ell/2 + 4(k - 1)\varepsilon^* n + \varepsilon'm(t - k\ell)$   
(5.16)  
 $\leq mt/2 + 4(k - 1)\varepsilon^* n + \varepsilon'm(t - k\ell) \leq 3n/4.$ 

Step 2: Verifying properties of  $U^*$ . Let  $B^* \subseteq V(H) \setminus U^*$  be such that  $|B^*| = 4\varepsilon^* n$ .

### Step 2A: Covering  $B^*$ .

By Lemma [5.3](#page-7-1) with  $A, B^*$  playing the roles of X, Z, respectively, there exists a set C of vertex-disjoint monochromatic tight cycles covering  $B^*$  with

$$
|\mathcal{C}| \le 2^{18} r \delta_0^{-5} \text{ and } |V(\mathcal{C}) \cap A| = 4(k-1)\varepsilon^* n = \gamma_a m |I^+|.
$$

### Step 2B: Covering  $U^* \setminus V(\mathcal{C})$ .

Let  $A' = A \setminus V(C)$ , so  $|A'| = (\gamma - \gamma_a)|I^+|m$ . For each  $x \in V(\mathcal{R})$ , let  $A'_x = A' \cap V_x$ , so  $\bigcup_{x \in X^+} A'_x = A'$ . Note that

<span id="page-16-1"></span>
$$
km\ell/2 \le |U \cup A'| \le km\ell/2 + \varepsilon'mt. \tag{5.18}
$$

We define a vertex-weighting  $\omega: V(M') \to [0,1]$  to be such that for  $v \in V(M')$ ,

$$
\omega(v) = \frac{|V_v \cap (U \cup A')|}{m} = \frac{|U_v| + |A'_v|}{m} \begin{cases} \in [\frac{1}{2}, \frac{1}{2} + \gamma] & \text{if } v \in X^+, \\ = \frac{1}{2} - \gamma + \gamma_a & \text{if } v \in X^-, \\ = \frac{1}{2} & \text{if } v \in V(M') \setminus (X^+ \cup X^-). \end{cases}
$$

Firstly, note that

$$
\sum_{i \in I^+} (\omega(x_i) - \omega(y_i)) = \sum_{i \in I^+} \left( \left( \frac{1}{2} + \frac{|A'_{x_i}|}{m} \right) - \frac{1}{2} \right) = \frac{|A'|}{m}
$$

$$
= (\gamma - \gamma_a)|I^+| = \sum_{i \in I^-} (\omega(y_i) - \omega(x_i)).
$$

Also

$$
\sum_{i \in I^+} (\omega(x_i) - \omega(y_i)) = (\gamma - \gamma_a)|I^+| \le \gamma |I^+|
$$
  
\n
$$
\stackrel{(5.17)}{=} 4\varepsilon^* \alpha n/m \stackrel{(5.15)}{\le} 8\varepsilon^* \alpha t \stackrel{(5.16)}{\le} 8\varepsilon^* \alpha \ell/\delta < (2\delta)^9 \ell/8.
$$

Therefore, all the conditions for Lemma [5.15](#page-13-0) (with  $2\delta$  playing the role of  $\delta$ ) are satisfied. Furthermore,  $\sum_{i\in[\ell]} \omega(x_i) = \sum_{i\in[\ell]} \omega(y_i)$ . We deduce that G has a fractional matching  $\omega^*$  with

<span id="page-16-0"></span>
$$
|\omega^*| \ge \sum_{i \in [\ell]} \omega(x_i) - \mu \ell = \sum_{i \in [\ell]} \omega(y_i) - \mu \ell = \left(\frac{1}{2} - \mu\right) \ell,\tag{5.19}
$$

where each vertex v has weight at least  $1/2 - \gamma + \gamma_a$  and at most  $\omega(v)$  and each non-zero weighted edge has weight at least 1/8. Define a corresponding fractional matching  $\omega_H^*$  on H such that for an

edge  $e \in E(H)$ ,  $\omega_H^*(e) = \omega^*(x_i y_j)$  if  $e = x_i y_{j,2} \dots y_{j,k}$  and  $\omega_H^*(e) = 0$  otherwise. Note that  $|\omega_H^*| = |\omega^*|$ . For any vertex  $u \notin V(M)$  we have  $\omega_H^*(u) = 0$ , so  $|V_u \cap (U \cup A')| = \varepsilon'm = ((1 - 3\varepsilon')\omega_H^*(u) + \varepsilon')m$ . For each  $u \in V(M)$ , we have  $\omega_H^*(u) \geq 1/3$  and so

$$
|V_u \cap (U \cup A')| = |U_u \cup A'_u| = \omega(u)m \ge \omega_H^*(u)m \ge ((1 - 3\varepsilon')\omega_H^*(u) + \varepsilon')m.
$$

By Lemma [4.5,](#page-6-2)  $H[A' \cup U]$  contains a tight cycle C of length  $\ell_0$  with

$$
\ell_0 \ge (1 - \psi)k|\omega_H^*|m - k \ge (1 - \psi)(1/2 - \mu)k\ell m - k \ge (1 - \psi)km\ell/2 - \mu km\ell.
$$

Recall that  $\mu, \varepsilon', 1/t \ll \psi$  and  $1/m \ll 1/k$ . Hence,

$$
|(A' \cup U) \setminus V(C)| \stackrel{(5.18)}{\leq} \psi km\ell/2 + \mu km\ell + \varepsilon' mt \leq \psi km\ell \stackrel{(5.16)}{\leq} \psi mt \stackrel{(5.15)}{\leq} \psi nt
$$

<span id="page-17-0"></span>as required.

## 6 Edge-coloured Multigraphs

Let H be a k-partite k-graph with vertex classes  $X_1, \ldots, X_k$  with  $X_i = \{x_{i,j} : j \in [n]\}.$  We denote the 2-blowup of a k-edge by  $K_k^{(k)}$  $k^{(k)}(2)$ . Note that  $K_k^{(k)}$  $(k)$ <sup>(k)</sup>(2) is the complete k-partite k-graph with each vertex class of order 2. We say that an edge-coloured multigraph  $G$  respects  $H$  if the following hold:

- the colour set of G is a subset of  $X_k$ ;
- $V(G) \subseteq \{v_i : i \in [n]\};$
- if  $\phi(v_i v_{i'}) = x_{k,t}$  for some  $t \in [n]$ , then  $\{x_{i,j} x_{i',j} : j \in [k-1]\}$  forms a  $K_{k-1}^{(k-1)}$  $\sum_{k=1}^{(k-1)}(2)$  in  $H(x_{k,t}).$

<span id="page-17-3"></span>There is a natural correspondence between a tight cycle in  $H$  and a rainbow cycle in  $G$ .

**Fact 6.1.** Let H be a k-partite k-graph with vertex sets  $X_1, \ldots, X_k$  such that for  $i \in [k-1], X_i = \{x_{i,j} :$  $j \in [n]$ . Let G be an edge-coloured multigraph respecting H. Suppose that G contains a rainbow cycle  $v_1v_2\cdots v_\ell$  with  $\phi(v_iv_{i+1})=x_{k,i}$  for  $i\in[\ell-1]$  and  $\phi(v_\ell v_1)=x_{1,\ell}$ . Then H contains a tight cycle with vertex set  $\{x_{i,j} : i \in [k], j \in [\ell]\}.$ 

Let G be an edge-coloured multigraph. Recall that  $\phi(G)$  is the set of colours in G and for a colour  $c \in \phi(G)$ ,  $G_c$  is the subgraph with edges only of the colour c and no isolated vertices. The monochromatic colour degree of G to be  $\delta_{\text{mon}}(G) = \min_{c \in \phi(G)} \delta(G_c)$ . A path system is a collection of vertex-disjoint paths. A rainbow path system is a path system such that its union (viewed as a graph) is rainbow. A (rainbow) cycle system is defined similarly. The main goal of this section is to reduce Lemma [5.3](#page-7-1) into the following lemma, which will be proved in the next section.

<span id="page-17-1"></span>**Lemma 6.2.** Let  $1/n \ll \delta_0 \leq 1/8$ . Suppose G is an edge-coloured multigraph on n vertices with  $\delta_{mon}(G) \geq \delta_0 n$  and  $|\phi(G)| \leq \delta_0 n/16$ . Then there exists a rainbow cycle system C with  $\phi(\mathcal{C}) = \phi(G)$  and  $|C| \leq 2^{18} \delta_0^{-5}.$ 

<span id="page-17-2"></span>To reduce Lemma [5.3](#page-7-1) to Lemma [6.2,](#page-17-1) we need the help of the following lemma, which will be proved in the next subsection.

**Lemma 6.3.** Let H be an r-edge-coloured  $K_n^{(k)}$  with disjoint vertex sets X and Z with  $|X| \geq (k-1)|Z|$ . Then for each  $i \in [r]$ , there exist an edge-coloured multigraph  $G^i$  and a subgraph  $H^i$  of H such that

- <span id="page-18-2"></span><span id="page-18-1"></span>(A1)  $H^i$  is a monochromatic k-partite k-graph on vertex classes  $X_1^i, \ldots, X_k^i$  of colour i;
- <span id="page-18-0"></span>(A2)  $\phi(G^i) = X^i_k$ ,  $Z = \bigcup_{i \in [r]} X^i_k$  and  $\bigcup_{j \in [k-1]} X^i_j \subseteq X$ ;
- (A3) if  $H^i$  is not empty, then  $|V(G^i)| = \left(1 \frac{1}{4kr^k}\right) \frac{|X|}{r(k-1)}$ ,  $\delta_{mon}(G^i) \ge (2r)^{-2^k} |V(G^i)|/8$  and  $G^i$  respects  $H^i$ ;
- <span id="page-18-3"></span>(A4) for distinct  $i, j \in [r]$ , we have  $V(H^i) \cap V(H^j) = \emptyset$ .

We now prove Lemma [5.3](#page-7-1) assuming Lemmas [6.2](#page-17-1) and [6.3.](#page-17-2)

*Proof of Lemma [5.3.](#page-7-1)* By Lemma [6.3,](#page-17-2) for each  $i \in [r]$ , there exist an edge-coloured multigraph  $G^i$  and a k-partite k-graph  $H^i$  such that  $G^i$  respects  $H^i$ . Fix  $i \in [r]$ . Observe that if  $H^i$  is not empty, then  $\delta_{\text{mon}}(G^i) \geq \delta_0 |V(G^i)|$  by  $(\mathbf{A3})$  $(\mathbf{A3})$  $(\mathbf{A3})$ . Moreover

$$
\left|\phi(G^{i})\right| \stackrel{\textbf{(A2)}}{\leq} |Z| \leq \frac{|X|}{\alpha} \leq \frac{\delta_0 |X|}{32r(k-1)} \leq \frac{\delta_0}{16} \left(1 - \frac{1}{4kr^k}\right) \frac{|X|}{r(k-1)} \stackrel{\textbf{(A3)}}{=} \frac{\delta_0 |V(G^{i})|}{16}.
$$

By Lemma [6.2](#page-17-1) with  $G^i$  playing the role of G, we deduce that  $G^i$  contains a rainbow cycle system  $\mathcal{C}^i$ with  $\phi(\mathcal{C}^i) = \phi(G^i) = X^i_k$  and  $|\mathcal{C}^i| \leq 2^{18} \delta_0^{-5}$ . By Fact [6.1](#page-17-3) and  $(\mathbf{A1})$  $(\mathbf{A1})$  $(\mathbf{A1})$ ,  $\mathcal{C}^i$  corresponds to a set  $\hat{\mathcal{C}}^i$  of vertex-disjoint monochromatic tight cycles in  $H^i$  covering  $X^i_k$ . Therefore by  $(\mathbf{A4})$  $(\mathbf{A4})$  $(\mathbf{A4})$ ,  $\bigcup_{i\in[r]} \hat{\mathcal{C}}^i$  is a set of vertex-disjoint monochromatic tight cycles covering  $\bigcup_{i\in[r]} X_k^i = Z$ . Note that  $\Big|$  $\left|\bigcup_{i\in[r]}\hat{\mathcal{C}}^i\right| \leq 2^{18}r\delta_0^{-5}.$ This completes the proof of the lemma. П

#### 6.1 Proof of Lemma [6.3](#page-17-2)

We start with the following result, which allows us to partition  $X \cup Z$  into the vertex-disjoint kpartite k-graphs  $H^i$  for  $i \in [r]$ . Let H be an r-edge-coloured k-graph. For vertex sets  $X_1, \ldots, X_k$ , let  $e_j(X_1,\ldots,X_k)$  be the number of  $X_1\ldots X_k$ -edges of colour j in H.

<span id="page-18-5"></span>**Lemma 6.4.** Let  $1/N \ll 1/k$ ,  $1/r \leq 1/2$ . Let H be an r-edge-coloured complete k-partite k-graph with vertex classes  $X_1, X_2, \ldots, X_k$  where for all  $i \in [k-1]$ ,  $|X_i| = N$  and  $|X_k| \leq N$ . Then there exists a partition of  $X_1, \ldots, X_k$  into  $\{X_1^j\}$  $j : j \in [r] \cup \{0\}\}, \ldots, \{X_k^j\}$  $x_{k-1}^j : j \in [r] \cup \{0\}\}, \{X_k^j\}$  $k<sup>j</sup> : j \in [r]$  such that, for each  $i \in [k-1], j \in [r]$  and  $x \in X_k^j$  $\frac{\partial}{\partial k}$ , we have

$$
|X_i^j| = \left(1 - \frac{1}{4kr^k}\right) \left(\frac{N}{r}\right) \ and \ e_j\left(X_1^j, \ldots, X_{k-1}^j, x\right) \ge \frac{\left|X_1^j\right| \cdots \left|X_{k-1}^j\right|}{2r}.
$$

*Proof.* Partition  $X_k$  into  $X_k^1, \ldots, X_k^r$  such that for all  $j \in [r]$  and  $x_k \in X_k^j$  $_{k}^{j},$ 

$$
e_j(X_1,...,X_{k-1},x_k) \geq \frac{|X_1|...|X_{k-1}|}{r}.
$$

<span id="page-18-4"></span>Let  $\varepsilon = (4kr^k)^{-1}$ .

**Claim 6.5.** There exists a partition of  $X_i$  for each  $i \in [k-1]$  into  $X_i^1, \ldots, X_i^r$  such that for all  $j \in [r]$ ,  $\mathbf{x}_i^j$ i  $\Big| - \frac{N}{r}$ r  $\Big| \leq \varepsilon \frac{N}{r}$  $\frac{N}{r}$  and

$$
\left| e_j\left(X_1^j,\ldots,X_i^j,X_{i+1},\ldots,X_{k-1},x_k\right) - \frac{e_j\left(X_1^j,\ldots,X_{i-1}^j,X_i,\ldots,X_k\right)}{r} \right| < \varepsilon N^{k-1}.
$$

*Proof of claim.* We proceed by induction on i. We only prove the base case  $i = 1$  as the rest can be proved analogously.

Let  $X_1 = X_1^1 \cup \cdots \cup X_1^r$  be a random partition of  $X_1$ , where for all  $x_1 \in X_1$  and  $i \in [r]$ ,  $x_1$  is assigned to  $X_1^j$ <sup>j</sup> independently with probability  $1/r$ . Consider  $x_i \in X_i$  for  $i \in [2, k]$  and  $j \in [r]$ . Note that  $\mathbb{E}\left(e_j(X_1^j)\right)$  $\left( \frac{j}{1}, x_2, \ldots, x_k \right) \Big) = \frac{e_j(X_1, x_2, \ldots, x_k)}{r}$  $\frac{(x_2,...,x_k)}{r}$ . If  $e_j(X_1, x_2,...,x_k) \leq \varepsilon N$ , then clearly  $e_j(X_1^i, x_2,...,x_k) \leq \varepsilon N$ . If  $e_j(X_1^j)$  $\{1, x_2, \ldots, x_k\} \geq \varepsilon N$ , then by Lemma [3.1,](#page-3-2) we have

$$
\mathbb{P}\left(\left|e_j(X_1^j, x_2, \ldots, x_k) - \frac{e_j(X_1, x_2, \ldots, x_k)}{r}\right| > \varepsilon \frac{e_j(X_1, x_2, \ldots, x_k)}{r}\right) \leq 2e^{-\frac{\varepsilon^3 N}{3r}}.
$$

Note that  $\mathbb{E}[X_1^j]$  $|1| = N/r$ . By Lemma [3.1,](#page-3-2) we have

$$
\mathbb{P}\left(\left||X_1^j| - \frac{N}{r}\right| > \varepsilon \frac{N}{r}\right) < 2e^{-\frac{\varepsilon^2 N}{3r}}.
$$

Hence by the union bound, with positive probability for all  $j \in [r]$ ,  $i \in [2, k]$  and  $x_i \in X_i$ , we have  $\Big|X_1^j$  $\left| \frac{j}{1} \right| - \frac{N}{r}$  $\Big| < \varepsilon \frac{N}{r}$  and  $\Big| e_j(X_1^j)$  $(x_1^j, x_2, \ldots, x_k) - \frac{e_j(X_1, x_2, \ldots x_k)}{r}$ r  $\vert \leq \varepsilon N$ . Fix such a partition. We have

$$
\left| e_j(X_1^j, X_2, \dots, X_{k-1}, x_k) - \frac{e_j(X_1, X_2, \dots, X_{k-1}, x_k)}{r} \right|
$$
\n
$$
= \left| \sum_{\substack{x_i \in X_i, \\ i \in [2, k-1]}} \left( e_j(X_1^j, x_2, \dots, x_k) - \frac{e_j(X_1, x_2, \dots, x_{k-1}, x_k)}{r} \right) \right| \leq \sum_{\substack{x_i \in X_i, \\ i \in [2, k-1]}} \varepsilon N \leq \varepsilon N^{k-1}.
$$

Fix a partition of  $X_1, \ldots, X_{k-1}$  given by Claim [6.5.](#page-18-4) For each  $i \in [k-1]$  and  $j \in [r]$ , remove additional vertices from  $X_i^j$  $i$  if necessary so that, for all  $i \in [k-1]$  and  $j \in [r]$ ,  $X_i^j$ i  $= (1 - \varepsilon) \frac{N}{r}$  $\frac{N}{r}$ . Let  $X^0_i = X_i \setminus \bigcup_{j \in [r]} X^j_i$  $i$  for each  $i \in [k-1]$ . Each  $X_i^j$  $i$  has at most  $2\varepsilon N/r$  vertices removed. Thus for all  $j \in [r]$  and  $x_k \in X_k^j$  $\frac{\partial}{\partial k}$ , we have

$$
e_j(X_1^j, \dots, X_{k-1}^j, x_k) \ge \frac{e_j(X_1, \dots, X_{k-1}, x_k)}{r^{k-1}} - k\varepsilon N^{k-1} - N^{k-2} \left(\frac{2\varepsilon N}{r}\right)
$$
  

$$
\ge \frac{N^{k-1}}{r^k} - 2k\varepsilon N^{k-1} \ge \frac{N^{k-1}}{2r^k} \ge \frac{|X_1^j| \dots |X_{k-1}^j|}{2r}.
$$

 $\blacksquare$ 

<span id="page-19-0"></span>We need a lower bound on the number of  $K_k^{(k)}$  $k^{(k)}(2)$  in a dense k-partite k-graph H.

**Lemma 6.6.** Let  $1/n \ll 1/k, d \leq 1$ . Let H be a k-partite k-graph with n vertices in each vertex class and  $e(H) \geq dn^k$ . Then there are at least  $d^{2^k} n^{2k}/2$  many  $K_k^{(k)}$  $\binom{k}{k}(2)$  in H.

*Proof.* Let the vertex classes of H be  $X_1, \ldots, X_k$ . For vertices  $x_1, \ldots, x_k \in V(H)$ , we write  $\mathbb{1}(x_1 \ldots x_k)$ for the indicator function  $\mathbb{1}(x_1 \dots x_k \in E(H))$ . For  $j \in [k] \cup \{0\}$ , let

$$
f(j) = \sum_{\substack{x_i \in X_i, x_s, y_s \in X_s, \ v_t \in \{x_t, y_t\}, \\ i \in [k-j]} s \in [k-j+1,k]} \prod_{t \in [k-j+1,k]} (x_1 \dots x_{k-j} v_{k-j+1} \dots v_k).
$$

Note that

<span id="page-20-2"></span><span id="page-20-0"></span>
$$
dn^{k} \le |E(H)| = \sum_{x_i \in X_i, i \in [k]} \mathbb{1}(x_1 \dots x_k) = f(0). \tag{6.1}
$$

<span id="page-20-1"></span>**Claim 6.7.** For  $t \in [k]$ , we have  $n^{2^t k - k - t} f(t) \ge f(0)^{2^t}$ .

*Proof of claim.* For any  $j \in [k-1] \cup \{0\}$ , we apply the Cauchy-Schwarz inequality to obtain

$$
f(j)^{2} = \left(\sum_{\substack{x_{i} \in X_{i}, \ x_{s}, y_{s} \in X_{s}, \\ i \in [k-j-1]}} \sum_{\substack{x_{s} \in X_{i}, \ x_{s}, y_{s} \in X_{s}, \\ x_{i} \in K_{i-j-1}}} \left(\sum_{\substack{x_{k-j} \in X_{k-j}, \\ x_{k-j} \in X_{k-j}}} \prod_{\substack{v_{t} \in \{x_{t}, y_{t}\}, \\ v_{t} \in [k-j+1,k]}} \mathbb{1}(x_{1} \dots x_{k-j}v_{k-j+1} \dots v_{k})\right)\right)^{2}
$$
  
\n
$$
\leq n^{k+j-1} \sum_{\substack{x_{i} \in X_{i}, \ x_{s}, y_{s} \in X_{s}, \\ i \in [k-j-1]}} \sum_{\substack{s \in [k-j+1,k] \\ s \in [k-j+1,k]}} \left(\sum_{\substack{x_{k-j} \in X_{k-j}, \\ x_{t} \in [x_{t}, y_{t}\}, \\ v_{t} \in [k-j+1,k]}} \prod_{\substack{u_{i} \in X_{i-1}, \\ u_{t} \in [k-j+1,k]}} \mathbb{1}(x_{1} \dots x_{k-j-1}v_{k-j} \dots v_{k})\right)^{2}
$$
  
\n
$$
= n^{k+j-1} \sum_{\substack{x_{i} \in X_{i}, \ x_{s}, y_{s} \in X_{s}, \\ v_{t} \in [k-j,k]}} \prod_{\substack{u_{i} \in X_{i}, \ x_{t} \in [k-j,k]}} \mathbb{1}(x_{1} \dots x_{k-j-1}v_{k-j} \dots v_{k})
$$
  
\n
$$
= n^{k+j-1} f(j+1).
$$
 (6.2)

We now prove the claim by induction on t. Note that  $f(0)^2 \leq n^{k-1} f(1)$  by [\(6.2\)](#page-20-0). Suppose that  $t > 1$ . Thus

$$
n^{2^t k - k - t} f(t) \stackrel{(6.2)}{\ge} n^{2^t k - k - t} n^{-(k + t - 2)} f(t - 1)^2 = \left( n^{2^{t - 1} k - k - (t + 1)} f(t - 1) \right)^2 \ge f(0)^{2^t},\tag{6.3}
$$

where the last inequality is due to our induction hypotheses.

The number of  $K_k^{(k)}$  $\binom{k}{k}(2)$  in H is

$$
\sum_{\substack{x_i, y_i \in X_i, v_t \in \{x_t, y_t\}, \\ x_i \neq y_i, \\ i \in [k]}} \prod_{\substack{\mathbb{I}(v_1 \dots v_k) \ge f(k) - kn^{2k-1} \\ t \in [k]}} \mathbb{I}(v_1 \dots v_k) \ge f(k) - kn^{2k-1} \ge \frac{6.7}{n^{2k-k^2}} n^{2k-k^2} f(0)^{2^k} - kn^{2k-1}
$$
\n
$$
\ge n^{2k-k^2} (dn^k)^{2^k} - kn^{2k-1} \ge d^{2^k} n^{2k} / 2.
$$

<span id="page-20-3"></span>We now show that there exists a (non-empty) subgraph  $H_0$  of H such that each edge is in many  $K_k^{(k)}$  $k^{(\kappa)}(2).$ 

**Lemma 6.8.** Let  $1/n \ll d \leq 1$ ,  $k \geq 2$  and  $\gamma = d^{2^k}/2$ . Let H be a k-partite k-graph with n vertices in each vertex class and  $e(H) \geq dn^k$ . Then there exists a subgraph  $H_0$  of H such that  $|E(H_0)| \geq 2^{k-1}\gamma n^k$ and every edge of  $H_0$  is contained in at least  $\gamma n^k/2$  many  $K_k^{(k)}$  $k^{(\kappa)}(2)$  in  $H_0$ .

*Proof.* Define the auxillary 2k-graph A to be such that  $V(A) = V(H)$  and each  $K_k^{(k)}$  $\binom{k}{k}(2)$  of H is an edge of A. By Lemma [6.6,](#page-19-0)  $|E(A)| \geq \gamma n^{2k}$ . If there exists  $S \in {V(\mathcal{A}) \choose k}$  $\binom{(\mathcal{A})}{k}$  such that  $|S \cap V_i| = 1$  for  $i \in [k]$  and  $d_{\mathcal{A}}(S) < (\gamma/2)n^k$ , then we delete all edges in A containing S. Repeat this process and call the resulting 2k-graph  $A'$ . Note that S can be chosen in at most  $n^k$  ways, so

$$
|E(\mathcal{A}')| \ge \gamma n^{2k} - n^k \left(\frac{\gamma n^k}{2}\right) = \frac{\gamma n^{2k}}{2}.
$$

Let  $H_0$  be the subgraph of H induced by  $e \in E(H)$  with  $d_{\mathcal{A}}(e) \geq 1$ . For each  $e \in E(H_0)$ , we have  $d_{\mathcal{A}}(e) \ge \gamma n^k/2$  and therefore e is contained in at least  $\gamma n^k/2$  many  $K_k^{(k)}$  $\binom{K}{k}(2)$  in  $H_0$ . Since each edge can be contained in at most  $n^k$  many  $K_k^{(k)}$  $k^{(\kappa)}(2)$  in  $H_0$ ,

$$
|E(H_0)| \ge \frac{2^k |E(\mathcal{A}')|}{n^k} = 2^{k-1} \gamma n^k
$$

as required.

Let  $S_n$  denote the set of permutations on [n]. The following lemma shows that if the vertices within each class of a  $k$ -partite  $k$ -graph are permuted randomly, then the number of 'horizontal' edges is concentrated around its expectation.

<span id="page-21-0"></span>**Lemma 6.9.** Let  $1/n \ll 1/k \leq 1/2$  and H be a k-partite k-graph with vertex classes  $X_1, \ldots, X_k$ each of size n. Suppose  $\sigma_1, \ldots, \sigma_{k-1} \in S_n$  are chosen independently and uniformly at random. Let  $H_{\sigma_1,...,\sigma_{k-1}} = \{x_{1,\sigma_1(i)} \cdots x_{k-1,\sigma_{k-1}(i)} x_{k,i} : i \in [n] \} \cap E(H)$ . Then

$$
\mathbb{P}\left(\left|\mathbb{E}|H_{\sigma_1,\ldots,\sigma_{k-1}}|-\frac{|E(H)|}{n^{k-1}}\right|>\varepsilon n\right)\leq 2e^{-\frac{\varepsilon^2 n}{32}}.
$$

*Proof.* We consider the martingale obtained by exposing each position of  $\sigma_1, \ldots, \sigma_{k-1}$  in turns as follows. For  $i \in [k-1]$  and  $j \in [n]$ , let  $Z_{i,j}$  be the  $j^{\text{th}}$  exposed position of  $\sigma_i$ . Let

$$
B_0 = \mathbb{E} |H_{\sigma_1,\dots,\sigma_{k-1}}| = \sum_{x_{1,i_1}\dots x_{k-1,i_{k-1}}x_{k,i} \in E(H)} \mathbb{P}(i_1 = \sigma_1(i),\dots,i_{k-1} = \sigma_{k-1}(i))
$$
  
= 
$$
\sum_{x_{1,i_1}\dots x_{k-1,i_{k-1}}x_{k,i} \in E(H)} \prod_{j \in [k-1]} \mathbb{P}(i_j = \sigma_j(i)) = \frac{|E(H)|}{n^{k-1}}.
$$

Define

$$
B_{(i-1)n+j} = \mathbb{E}\left( \left| H_{\sigma_1,\ldots,\sigma_{k-1}} \right| | Z_{1,1},\ldots,Z_{1,n}, Z_{2,1},\ldots,Z_{2,n},\ldots,Z_{i,1},\ldots,Z_{i,j} \right).
$$

Note that  $B_0, \ldots, B_{(k-1)n}$  forms a martingale.

Claim 6.10. For  $t \in [(k-1)n-1]$ , we have  $|B_t - B_{t+1}| \leq 4$ .

*Proof of claim.* For simplicity, we only consider the case when  $t \leq n-1$  (and the other cases are proved similarly). Thus

$$
B_t = \mathbb{E}(|H_{\sigma_1,\ldots,\sigma_{k-1}}||Z_{1,1},\ldots,Z_{1,t}) \text{ and } B_{t+1} = \mathbb{E}(|H_{\sigma_1,\ldots,\sigma_{k-1}}||Z_{1,1},\ldots,Z_{1,t+1}).
$$

If  $t = n - 1$ , then  $B_t = B_{t+1}$ . Thus we may assume  $t \leq n - 2$ . For  $t_1, t_2 \in [n]$ , define  $\pi_{t_1, t_2} : S_n \to S_n$  to be such that for all  $\sigma' \in S_n$  and  $s \in [n]$ ,

$$
\pi_{t_1, t_2}(\sigma')(s) = \begin{cases} \sigma'(t_2) & \text{if } s = t_1, \\ \sigma'(t_1) & \text{if } s = t_2, \\ \sigma'(s) & \text{otherwise.} \end{cases}
$$

Equivalently  $\pi_{t_1,t_2}(\sigma')$  swaps the  $t_1^{\text{th}}$  and  $t_2^{\text{th}}$  position of  $\sigma'$ . For all  $\sigma'_1,\ldots,\sigma'_{k-1} \in S_n$ ,

$$
\left| H_{\sigma'_1,\dots,\sigma'_{k-1}} \Delta H_{\pi_{t_1,t_2}(\sigma'_1)\sigma'_2,\dots,\sigma'_{k-1}} \right|
$$
\n
$$
\leq \left| \{ x_{1,\sigma'_1(i)} \dots x_{k-1,\sigma'_{k-1}(i)} x_{k,i}, \ x_{1,\pi_{t_1,t_2}(\sigma'_1(i))} \dots x_{k-1,\pi_{t_1,t_2}(\sigma'_{k-1}(i))} x_{k,i} : i \in \{t_1, t_2\} \} \right| \leq 4.
$$
\n(6.4)

Let  $A = \{\sigma \in S_n : \sigma(j) = Z_{1,j} \text{ for } j \in [t]\}.$  Given  $Z_{1,1}, \ldots, Z_{1,t}$ , the probability space is now reduced to  $A \times (S_n)^{k-2}$ . Pick  $j_0 \in [n] \setminus \{Z_{1,1} \ldots Z_{1,t}\}$ . Let  $A' = \{\sigma \in A : \sigma(t+1) = j_0\}$ . Note that A can be partitioned into  $\{\pi_{t,j}(A') : j \in [t+1,n]\}.$  Hence the probability space can be partitioned into  ${\lbrace \pi_{t,j}(A') \times (S_n)^{k-2} : j \in [t+1,n] \rbrace}$ . Hence the claim follows by [\(6.4\)](#page-22-0).

By Azuma's inequality (Lemma [3.3\)](#page-4-2), we have

<span id="page-22-0"></span>
$$
\mathbb{P}\left(\left|\mathbb{E}\left|H_{\sigma_1,\ldots,\sigma_{k-1}}\right|-\frac{|E(H)|}{n^{k-1}}\right|>\varepsilon n\right)\le 2e^{-\frac{\varepsilon^2 n}{32}}
$$

as required.

We are now ready to prove Lemma  $6.3$ .

Proof of Lemma [6.3.](#page-17-2) Let

$$
n = \left(1 - \frac{1}{4kr^k}\right) \left(\frac{|X|}{r(k-1)}\right).
$$

Partition X into equally sized subsets  $X_1, \ldots, X_{k-1}$  so that for  $j \in [k-1]$ , we have  $|X_j| = |X|/(k-1) \ge$ |Z|. By Lemma [6.4,](#page-18-5) there exists a partition of  $X_1, \ldots, X_{k-1}, Z$  into  $\{X_1^j\}$  $j : j \in [r] \cup \{0\}\}, \ldots, \{X_k^j\}$  $\frac{j}{k-1}$ :  $j \in [r] \cup \{0\}$ ,  $\{Z^j : j \in [r]\}$  such that for each  $i \in [k-1]$ ,  $j \in [r]$  and  $z \in Z^j$ , we have

$$
\left|X_i^j\right|=n \text{ and } e_j\left(X_1^j,\ldots,X_{k-1}^j,z\right)\geq \frac{\left|X_1^j\right|\cdots\left|X_{k-1}^j\right|}{2r}=\frac{n^{k-1}}{2r}.
$$

For each  $j \in [r]$ , let  $H^j$  be the k-partite k-graph with vertex classes  $X_1^j$  $X_1^j, \ldots, X_{k-1}^j, Z^j$  and  $E(H^j) =$  $E\left(H_j\left[X_1^j\right]\right)$  $\left\{ \begin{matrix} j \\ 1, \ldots, X_{k-1}^j, Z^j \end{matrix} \right\}$ .

Let  $d = (2r)^{-1}$  and  $\gamma = d^{2^k}/2$ . Fix  $j \in [r]$ . Consider  $z \in \mathbb{Z}^j$  and let  $H^j(z)$  be the link graph of z on vertex set  $X_1^j$  $|I_1^j, \ldots, X_{k-1}^j$ . Note that  $|E(H^j(z))| \geq dn^{k-1}$ . By Lemma [6.8](#page-20-3) with  $H^j(z)$  playing the role of H, there exists a  $(k-1)$ -partite  $(k-1)$ -uniform subhypergraph  $J^z$  of  $H^j(z)$  such that  $|E(J^z)| \geq \gamma 2^{k-2} n^{k-1}$  and every edge in  $J^z$  is contained in at least  $\gamma n^{k-1}/2$  many  $K_{k-1}^{(k-1)}$  $_{k-1}^{(k-1)}(2)$  in  $J^z$ . For each edge e in  $J^z$ , let  $J^{z,e}$  be the  $(k-1)$ -partite  $(k-1)$ -graph on vertex classes  $X_1^j$  $x_1^j, \ldots, X_{k-1}^j$  such that  $f$ is an edge in  $J^{z,e}$  if and only if  $e \cup f$  forms a  $K_{k-1}^{(k-1)}$  $(k-1)(2)$  in  $J^z$ . For all  $z \in Z^j$  and  $e \in E(J^z)$ , we have

$$
|E(J^z)| \ge 2^{k-2}\gamma n^{k-1}
$$
 and  $|E(J^{z,e})| \ge \gamma n^{k-1}/2$ .

Let  $X_i^j = \{x_{i,1}, \ldots, x_{i,n}\}$ . Choose  $\sigma_1, \ldots, \sigma_{k-2} \in S_n$  independently and uniformly at random. For a  $(k-1)$ -partite  $(k-1)$ -graph J with vertex classes  $X_1^j$  $x_{k-1}^j$ , let

$$
J_{\sigma_1,\ldots,\sigma_{k-2}} = \{x_{1,\sigma_1(i)}\ldots x_{k-2,\sigma_{k-2}(i)}x_{k-1,i} : i \in [n]\} \cap E(J).
$$

By Lemma [6.9](#page-21-0) we have

$$
\mathbb{P}\left(\left|J^{z}_{\sigma_{1},...,\sigma_{k-2}}\right|<\gamma 2^{k-3}n\right)\leq 2e^{-\gamma^{2}2^{2k-11}n}\text{ and }\mathbb{P}\left(\left|J^{z,e}_{\sigma_{1},...,\sigma_{k-2}}\right|<\frac{\gamma n}{4}\right)\leq 2e^{-\frac{\gamma^{2}n}{512}}.
$$

By the union bound, there exist some  $\sigma_1, \ldots, \sigma_{k-2} \in S_n$  such that for all  $z \in Z^j$  and all  $e \in E(J^z)$ ,

<span id="page-23-1"></span>
$$
\left|J^z_{\sigma_1,\dots,\sigma_{k-2}}\right| \ge \gamma 2^{k-3} n = d^{2^k} 2^{k-4} n \text{ and } \left|J^{z,e}_{\sigma_1,\dots,\sigma_{k-2}}\right| \ge \frac{\gamma n}{4} = \frac{d^{2^k} n}{8} = \frac{(2r)^{-2^k} n}{8}.
$$
 (6.5)

Without loss of generality (by relabelling vertices of  $X_1^j$  $j, \ldots, X_{k-2}^j$  we may assume  $\sigma_1 = \cdots = \sigma_{k-2} = \text{id}.$ For  $z \in \mathbb{Z}^j$ , define the edge-coloured graph  $G_z$  on  $V = \{v_i : i \in [n]\}\$  with colour z to be such that  $v_i v_j \in E(G)$  if and only if  $x_{1,i} \ldots x_{k-1,i} x_{1,j} \ldots x_{k-1,j}$  forms a  $K_{k-1}^{(k-1)}$  $\binom{(k-1)}{k-1}(2)$  in  $J^z$ . Hence after removing isolated vertices from  $G_z$ ,  $\delta(G_z) \ge (2r)^{-2^k} n/8$  by  $(6.5)$ . Let  $G^j = \bigcup_{z \in Z^j} G_z$ . It is easy to check that  $(A1)$  $(A1)$  $(A1)$  to  $(A4)$  $(A4)$  $(A4)$  are satisfied. This completes the proof of the lemma.

# <span id="page-23-0"></span>7 Rainbow Path Systems

From now on, we will work with edge-coloured multigraph  $G$ . Note that the colours of  $G$  are different to those in  $K_n^{(k)}$ . We often assume that  $\delta_{\text{mon}}(G)$  is linear in  $|V(G)|$ . Recall that a *rainbow path system* is a path system (collection of vertex-disjoint paths) such that its union (viewed as a graph) is rainbow. Our first goal is to prove the following result, which shows that there is a rainbow path system in  $G$ with few paths.

<span id="page-23-2"></span>**Lemma 7.1.** Let  $n, d \in \mathbb{N}$  and G be an edge-coloured multigraph on n vertices with  $\delta_{mon}(G) \geq d \geq$  $4|\phi(G)|$ . Then there exists a rainbow path system P such that  $\phi(\mathcal{P}) = \phi(G)$  and  $|\mathcal{P}| \leq 2n/d$ .

<span id="page-23-3"></span>To show this, we need the help of the following proposition which lets us start building  $\mathcal P$  with a rainbow matching.

**Proposition 7.2.** Let G be an edge-coloured multigraph with  $\delta_{mon}(G) \geq 2|\phi(G)| - 1$ . Then there exists a rainbow matching M such that  $\phi(M) = \phi(G)$ .

*Proof.* Without loss of generality let  $\phi(G) = [d]$ . Suppose for some  $i \in [d]$ , we have already found a rainbow matching  $M_{i-1}$  such that  $\phi(M_{i-1}) = [i-1]$ . We now construct  $M_i$  as follows. Since

$$
\delta_{\text{mon}}(G) \ge 2|\phi(G)| - 1 > 2|\phi(M_{i-1})| = |V(M_{i-1})|,
$$

there exists a vertex  $v \in V(G) \setminus V(M_{i-1})$  such that  $N_i(v, \overline{V(M_{i-1})}) \neq \emptyset$ . Pick a vertex  $v' \in N_i(v, \overline{V(M_{i-1})})$ and let  $M_i = M_{i-1} \cup \{vv'\}$ . Let  $M = M_d$ . П

We now present the proof of Lemma [7.1.](#page-23-2)

*Proof of Lemma [7.1.](#page-23-2)* Let P be a rainbow path system of G with  $\phi(\mathcal{P}) = \phi(G)$ , which exists by Proposi-tion [7.2.](#page-23-3) Suppose that  $|\mathcal{P}|$  is minimal. If  $|\mathcal{P}| \leq 2n/d$ , then we are done. So we may assume  $|\mathcal{P}| > 2n/d$ . Let  $\mathcal{P} = \{P_1, P_2, \ldots, P_\ell\}$  be such that  $P_i = v_1^i \ldots v_{q_i}^i$  and without loss of generality  $\phi(v_1^i v_2^i) = i$ . Note that

$$
d_i(v_2^i, \overline{V(\mathcal{P})}) \ge d - |V(\mathcal{P})| \ge d - 2|\phi(G)| \ge d/2.
$$

 $\langle Y_1 \rangle \langle V(P) \rangle \neq \emptyset$ . Let  $w \in (N_i(v_2^i) \cap N_j(v_2^j))$  $\binom{j}{2}$ Hence there exist distinct  $i, j \in [\ell]$  such that  $(N_i(v_2^i) \cap N_j(v_2^j))$  $V(\mathcal{P})$ . Let  $\mathcal{P}' = (\mathcal{P} \setminus \{P_i, P_j\}) \cup \{v_q^j...v_3^j\}$  $\frac{1}{3}v_2^j w v_2^i v_3^i... v_q^i$ . Note that  $\mathcal{P}'$  is also a rainbow path system with  $\phi(\mathcal{P}') = \phi(G)$  and  $|\mathcal{P}'| < |\mathcal{P}|$ . This contradicts the minimality of  $|\mathcal{P}|$ .  $\Box$ 

<span id="page-23-4"></span>The following lemma is our absorption result, the proof of which will be presented in the next section.

**Lemma 7.3.** Let  $1/n \ll \delta$  and G be an edge-coloured multigraph satisfying  $|V(G)| = n$  and  $\delta^*_{mon}(G) \ge$  $\delta n$ . Then there exists a subgraph  $G^*$  of G such that  $|V(G) \setminus V(G^*)|, |\phi(G) \setminus \phi(G^*)| < 2000\delta^{-4}$ . Moreover, for all rainbow paths  $P^*$  in  $G^*$  with  $|V(P^*)| \geq 3$  and vertex sets  $S \subseteq V(G^*) \setminus V(P^*)$  such that  $|V(P^*) \cup V(P^*)| \geq 3$  $|S| \leq \delta n/4$ ,  $G \setminus S$  contains a rainbow cycle  $C^*$  with  $\phi(P^*) \subseteq \phi(C^*) \subseteq \phi(P^*) \cup (\phi(G) \setminus \phi(G^*))$ .

We now prove Lemma  $6.2$  using Lemma [7.3.](#page-23-4) We iteratively reserve a set of vertices and colours, which shall be used to close the rainbow path system constructed at the end, one path at a time.

Proof of Lemma [6.2.](#page-17-1) If  $|\phi(G)| \leq 2^{18} \delta_0^{-5}$  then we have  $\delta_{\text{mon}}(G) \geq 2|\phi(G)|$ . By Proposition [7.2,](#page-23-3) G contains a rainbow matching M such that  $\phi(M) = \phi(G)$ . Since each edge is a degenerate cycle, we are done setting  $C = M$ . Therefore, we may assume  $|\phi(G)| > 2^{18} \delta_0^{-5}$ .

Let  $G^1 = G$ . For each  $j \in [4\delta_0^{-1}]$  in turns, we apply Lemma [7.3](#page-23-4) with  $G^j, \delta_0/2$  playing the roles of  $G, \delta$ , respectively, to obtain a subgraph  $G^{j+1}$  of G such that

$$
|V(G^{j}) \setminus V(G^{j+1})|, \, |\phi(G^{j}) \setminus \phi(G^{j+1})| < 2000(\delta_0/2)^{-4} \le 2^{15} \delta_0^{-4}.
$$

Moreover, for all rainbow paths P in  $G^{j+1}$  with  $|V(P)| \geq 3$  and a vertex set  $S \subseteq V(G^{j+1}) \setminus V(P)$  such that  $|V(P) \cup S| \leq \delta_0 n/8$ ,  $G^{j+1} \setminus S$  contains a rainbow cycle C with

$$
\phi(P) \subseteq \phi(C) \subseteq \phi(P) \cup (\phi(G^j) \setminus \phi(G^{j+1})).
$$

Note that

$$
\delta_{\text{mon}}(G^{j+1}) \ge \delta_{\text{mon}}(G^j) - |V(G^j) \setminus V(G^{j+1})| \ge \delta_{\text{mon}}(G^j) - 2^{15}\delta_0^{-4}
$$
  
\n
$$
\ge \delta_{\text{mon}}(G) - 2^{15}\delta_0^{-4}j \ge \delta_0 n/2.
$$
\n(7.1)

Let  $G^* = G^{4\delta_0^{-1}}$ . Note that

$$
\delta_{\mathrm{mon}}(G^*) = \delta_{\mathrm{mon}}(G^{4\delta_0^{-1}}) \ge \delta_0 n/2 \ge 8\phi(G^*)
$$

and

<span id="page-24-2"></span>
$$
|\phi(G) \setminus \phi(G^*)|, |V(G) \setminus V(G^*)| \le 2^{15} \delta_0^{-4} (4\delta_0^{-1}) = 2^{17} \delta_0^{-5}.
$$
 (7.2)

By Lemma [7.1](#page-23-2) with  $G^*, \delta_0 n/2$  playing the roles of  $G, d$ , respectively, there exists a rainbow path system  $\mathcal P$ such that  $\phi(\mathcal{P}) = \phi(G^*)$  and

<span id="page-24-3"></span><span id="page-24-1"></span>
$$
|\mathcal{P}| \le \frac{2|V(G^*)|}{\delta_0 n/2} \le 4\delta_0^{-1}.\tag{7.3}
$$

Note that

<span id="page-24-0"></span>
$$
|V(\mathcal{P})| = |\phi(G^*)| + |\mathcal{P}| \le \frac{\delta_0 n}{16} + 4\delta_0^{-1} \le \frac{\delta_0 n}{8}.
$$
\n(7.4)

Moreover

$$
\delta_{\text{mon}}(G \setminus V(\mathcal{P})) \stackrel{(7.4)}{\geq} \delta_0 n - \frac{\delta_0 n}{8} \geq \frac{\delta_0 n}{2} \geq 2\phi(G)
$$

and  $\phi(G\setminus V(\mathcal{P}))\supseteq \phi(G)\setminus \phi(G^*)$ . By Proposition [7.2,](#page-23-3) we deduce that there exists a rainbow matching M in  $(G \setminus V(\mathcal{P}))_{\phi(G) \setminus \phi(G^*)}$  with  $\phi(M) = \phi(G) \setminus \phi(G^*)$ . Let  $Q_0 = M \cup \mathcal{P}$ , so  $\phi(Q_0) = \phi(G)$  and

$$
|Q_0| \le |\mathcal{P}| + |\phi(G) \setminus \phi(G^*)| \stackrel{(7.3), (7.2)}{\le} 4\delta_0^{-1} + 2^{17} \delta_0^{-5} \le 2^{18} \delta_0^{-5}.
$$

Let  $P_1, \ldots, P_\ell$  be paths in  $Q_0$  such that for  $j \in [\ell], |V(P_j)| \geq 3$ . Suppose for some  $j \in [\ell - 1] \cup \{0\}$ , we have constructed  $Q_j$  such that

- (i)  $Q_i$  is a union of vertex-disjoint paths and cycles with  $|Q_i| \leq |Q_0|$ ;
- (ii)  $Q_i$  is rainbow with  $\phi(Q_i) = \phi(G);$
- (iii) the paths in  $Q_j$  of order at least 3 are precisely  $P_{j+1}, \ldots, P_\ell$ ;
- (iv) all edges in  $Q_j$  of colours in  $\phi(G^{j+1}) \setminus \phi(G^*)$  form a rainbow matching.

We now construct  $Q_{j+1}$  as follows. Note that  $P_{j+1} \subseteq G^* \subseteq G^{j+1}$ . Let  $S = V(Q_j \setminus P_{j+1}) \cap V(G^{j+1})$ . Note that

$$
|S \cup V(P_{j+1})| \leq |V(Q_j)| \leq |\phi(Q_j)| + |Q_j| \leq |\phi(G)| + |Q_0| \leq \frac{\delta_0 n}{16} + 2^{18} \delta_0^{-5} \leq \frac{\delta_0 n}{8} \frac{\binom{7}{2}}{\frac{\delta_{\text{mon}}(G^{j+1})}{4}}.
$$

By the property of  $G^{j+1}$ , there is a rainbow cycle  $C^{j+1}$  in  $G^{j+1} \setminus S$  such that

$$
\phi(P_{j+1}) \subseteq \phi(C^{j+1}) \subseteq \phi(P_j) \cup (\phi(G^j) \setminus \phi(G^{j+1})).
$$

Since  $\mathcal{P} \subseteq G^*$ , the subgraph  $G_{\phi(C^{j+1})} \cap Q_j$  of  $Q_j$  induced by the colours in  $\phi(C^{j+1})$  is precisely the path  $P_{j+1}$  and single edges of colour in  $\phi(C^{j+1}) \setminus \phi(P_{j+1}) \subseteq \phi(G^j) \setminus \phi(G^{j+1})$ . Let  $Q_{j+1} =$ <br> $(Q_j - G_{\phi(C^{j+1})}) \cup C^{j+1}$ . It is easy to check that (i) to (iv) hold. Finally, note that  $Q_\ell$  consists of  $Q_j - G_{\phi(C^{j+1})}$   $\cup$   $C^{j+1}$ . It is easy to check that (i) to (iv) hold. Finally, note that  $Q_\ell$  consists of cycles and single edges. The proof of the lemma is complete.  $\Box$ 

### <span id="page-25-0"></span>8 Closing rainbow paths

The aim of this section is to prove Lemma [7.3.](#page-23-4) To prove Lemma [7.3,](#page-23-4) we would need to reserve some vertices and colours so that we can close any rainbow path. Ideally our aim is to find a vertex  $v$ , small disjoint vertex sets  $W_1, W_2$  and small disjoint colour sets  $C_1, C_2$  such that for every  $x \in V(G)$  and  $i \in [2]$ , there exists a rainbow path  $P_{i,x}$  from x to v such that  $V(P_{i,x}) \subseteq \{x, v\} \cup W_i$  and  $\phi(P_{i,x}) \subseteq C_i$ . We now reserve the vertex set  $v \cup W_1 \cup W_2$  and colour set  $C_1 \cup C_2$ . Given any rainbow path P with end vertices x and y,  $P \cup P_{1,x} \cup P_{1,y}$  forms a rainbow cycle. This will motivate our definition of a bowtie (see later). First, we need the following definition which describes how to reach a vertex  $v$  through a vertex set  $W$  using a colour set  $C$ .

Recall that  $V^*(G) = \{v \in V(G) : |\phi_G(v)| \geq 2\}$  and for a path  $P = v_1 \dots v_{\ell}$ , we denote  $\text{int}(P) =$  $\{v_i: 2 \leq i \leq \ell-1\}$ . Let G be an edge-coloured multigraph with vertex set V. For  $v \in V$ ,  $C \subseteq \phi(G)$ and  $W \subseteq V$ , define  $U_G(v, C', W)$  to be the subset  $U \subseteq V$  such that for all vertices  $u \in U$ , there is a rainbow path P from v to u with  $\phi(P) \subseteq C$  and  $\text{int}(P) \subseteq W$ . We will always assume that  $\{v\} \cup W \subseteq V^*(G) \cap U_G(v, C, W)$ . Let  $U = U_G(v, C, W)$  and  $g \in \mathbb{N}$ . We say that U is g-maximal in G if for all  $u \in U$ ,  $w_1, w_2 \in V$  and distinct  $c, c_1, c_2 \notin C$  with  $\phi(uw_1) = c_1$  and  $\phi(w_1w_2) = c_2$ ,

$$
d_c(u, \overline{U}), d_{c_1}(w_1, \overline{U}), d_{c_2}(w_2, \overline{U}) < g.
$$

<span id="page-25-1"></span>If U is not g-maximal, then by adding at most two vertices to W and three colours to C, we can enlarge U by at least  $g$ . This leads to the following proposition.

**Proposition 8.1.** Let G be an edge-coloured multigraph. Let  $v \in V^*(G)$  and  $c \in \phi_G(v)$ . Then there exists a colour set  $C \subseteq \phi(G)$  containing c and a vertex-set  $W \subseteq V^*(G) \setminus v$  such that  $U_G(v, C, W)$  is  $g\text{-}maximal, |U_G(v, C, W)| \ge d_c(v) \text{ and } |C|, |W| \le 3|U_G(v, C, W)|/g.$ 

*Proof.* Initially, we set  $W = \emptyset$  and  $C = \{c\}$ . Note that  $U_G(v, C, W) = N_c(v)$ , so  $|U_G(v, C, W)| \ge d_c(v)$ and  $|W|, |C| \leq 3|U_G(v, C, W)|/g.$ 

If  $U_G(v, C, W)$  is g-maximal, then we are done. Suppose that  $U_G(v, C, W)$  is not g-maximal. If there exists  $u \in U_G(v, C, W)$  and a colour  $c' \notin C$  such that  $d_{c'}(u, \overline{U_G(v, C, W)}) \geq g$ , then add  $c'$  to C and u to W. If there exists  $u \in U_G(v, C, W)$ ,  $w \in V^*(G)$  and a colour  $c' \notin C$  such that  $d_{c'}(w, \overline{U_G(v, C, W)}) \ge g$ and  $\phi(uw) \notin \{c'\} \cup C$ , then add  $c', \phi(uw)$  to C and u, w to W. If there exists  $u \in U_G(v, C, W)$ ,  $w, w' \in V^*(G)$  and a colour c' such that  $d_{c'}(w', \overline{U_G(v, C, W)}) \ge g$  and  $\phi(uw), \phi(ww'), c'$  are distinct colours not in C, then add  $c', \phi(uw), \phi(ww')$  to C and  $u, w, w'$  to W.

Note that we still have  $|W|, |C| \leq 3|U_G(v, C, W)|/g$  and  $|U_G(v, C, W)| \geq d_c(v)$ . Note that  $W \subseteq$  $V^*(G)$ . We repeat this process until  $U_G(v, C, W)$  is g-maximal.  $\Box$ 

Recall that  $\delta_{\text{mon}}^*(G) = \min_{v \in V^*(G)} \min_{c \in \phi_G(v)} d_c(v)$ . In other words,  $\delta_{\text{mon}}^*(G)$  is the (non-zero) minimum number of edges seen by a vertex  $v$  in a particular colour, minimised over all the vertices in G that see at least two colours. We are mainly concerned about vertices in  $V^*(G)$  because if a vertex  $v \notin V^*(G)$ , then it cannot be contained in a non-degenerate rainbow cycle. Also recall that the *closed* neighborhood of a vertex w in a graph G is defined as  $\{w\} \cup N_G(w)$  and denoted by  $N_G[w]$ .

<span id="page-26-3"></span>Let  $U = U(v, C, W)$  be g-maximal in G. The following crucial lemma says that if a rainbow path P satisfies  $\text{int}(P) \cap N_{G-G_C}[U] \neq \emptyset$ , then  $\text{int}(P) \subseteq N_{G-G_C}[U]$ .

**Lemma 8.2.** Let  $g \in \mathbb{N}$  and G be an edge-coloured multigraph on n vertices with  $\delta^*_{mon}(G) > g$ . Let  $v \in V(G)$ ,  $W \subseteq V(G)$  and  $C \subseteq \phi(G)$ . Suppose that  $U = U_G(v, C, W)$  is g-maximal. Furthermore let  $G' = G - G_C$  and  $U^* = N_{G'}[U]$ . Then the following hold:

- <span id="page-26-1"></span><span id="page-26-0"></span>(i) for all  $x \in U^* \cap V^*(G')$  and  $c \in \phi(G')$ , we have  $d_c(x, \overline{U}) < g$ ;
- (ii) if P is a rainbow path in G' such that  $\text{int}(P) \cap U^* \neq \emptyset$ , then  $\text{int}(P) \subseteq U^*$ .

*Proof.* Consider  $x \in U^* \cap V^*(G')$  and  $c \in \phi(G')$ . If  $x \in U$ , then since  $c \notin C$ , by the g-maximality of U, we have  $d_c(x, \overline{U}) < g$ . If  $x \in U^* \setminus U$ , then there exists a vertex  $u \in U$  and a colour  $c' \notin C$  such that  $\phi(ux) = c'$ . If  $c' \neq c$ , then  $d_c(x, \overline{U}) < g$  by the g-maximality of U. If  $c = c'$ , then there exists a colour  $c'' \in \phi_{G'}(v) \setminus \{c\}$  as  $v \in V^*(G')$ . By the argument above, we have  $d_{c''}(x, \overline{U}) < g$ . Since  $\delta^*_{\text{mon}}(G) > g$ , we deduce that  $N_{c''}(x,U) \neq \emptyset$ . Pick  $u' \in N_{c''}(x,U)$ . Now,  $\phi(u'x) = c'' \neq c$ . Again by the previous argument we have  $d_c(x,U) < g$ . Hence [\(i\)](#page-26-0) holds.

We now prove [\(ii\).](#page-26-1) Let  $P = x_1 \dots x_\ell$  be a rainbow path in G' with  $\text{int}(P) \cap U^* \neq \emptyset$ . Suppose that  $\phi(x_{j-1}x_j) = j$  for  $j \in [\ell] \setminus \{1\}$ . Furthermore assume that  $x_2 \in U^*$  and  $\ell \geq 4$ . (Indeed, if  $x_i \in U^*$  with  $i \in [3, \ell-2]$ , then consider the two rainbow paths  $x_{i-1}x_i...x_{\ell}$  and  $x_{i+1}x_i...x_1$  separately.) Thus it is enough to show that  $x_3 \in U^*$ , as we can then consider the rainbow path  $x_2x_3...x_\ell$ . If  $x_2 \in U$ , then  $x_3 \in U^*$ . If  $x_2 \in U^* \setminus U$ , then [\(i\)](#page-26-0) implies  $d_2(x_2, \overline{U}) < g$  and so  $N_2(x_2, U) \neq \emptyset$ . Then by g-maximality of  $U, d_4(x_3, \overline{U}) < g$  and so  $N_4(x_3, U) \neq \emptyset$ . Thus  $x_3 \in U^*$  as required.  $\Box$ 

Let G be an edge-coloured multigraph. We say that  $B = (v, C_1, W_1, C_2, W_2)$  is a bowtie in G if  $v \in V(G)$ ,  $W_1, W_2 \subseteq V(G) \setminus \{v\}$  are disjoint,  $C_1$  and  $C_2$  are disjoint nonempty colour sets. Denote  $\phi(B) = C_1 \cup C_2$ ,  $W(B) = \{v\} \cup W_1 \cup W_2$  and for  $i \in [2]$ ,  $U_i(B|G) = U_{G\setminus W_{3-i}-G_{C_{3-i}}}(v, C_i, W_i)$ . A bowtie B is g-maximal in G if for  $i \in [2]$ ,  $U_i(B|G)$  is g-maximal in  $G \setminus W_{3-i} - G_{C_{3-i}}$ .

<span id="page-26-2"></span>The following corollary shows that a g-maximal bowtie exists, which follows from Proposition [8.1.](#page-25-1)

**Corollary 8.3.** Let  $g \in \mathbb{N}$  and G be an edge-coloured multigraph on n vertices. Let v be a vertex such that  $d_{c_1}(v), d_{c_2}(v) \geq g + 3n/g$  for distinct colours  $c_1, c_2$ . Then there exists a g-maximal bowtie  $B(v, C_1, W_1, C_2, W_2)$  such that for  $i \in [2]$ ,  $c_i \in C_i$ ,  $W(B) \subseteq V^*(G)$ ,  $|U_i(B|G)| \ge d_{c_i}(v) - 3n/g$  and  $|\phi(B)|, |W(B)| \leq 6n/q.$ 

*Proof.* Apply Proposition [8.1](#page-25-1) with  $v, c_1, G - G_{c_2}$  playing the roles of  $v, c, G$ , respectively and obtain a colour set  $C_1$  and a vertex set  $W_1$  such that  $c_1 \in C_1$  and  $U_{G-G_{c_2}}(v, C_1, W_1)$  is g-maximal in  $G-G_{c_2}$ and  $|U_{G-G_{c_2}}(v, C_1, W_1)| \ge d_{c_1}(v)$ . Note that

$$
|C_1|, |W_1| \le 3|U_{G-G_{c_2}}(v, C_1, W_1)|/g \le 3n/g.
$$

Let  $G' = G\backslash W_1 - G_{C_1}$ . Apply Proposition [8.1](#page-25-1) again with  $v, c_2, G'$ , playing the roles of  $v, c, G$ , respectively and obtain a colour set  $C_2$  and a vertex set  $W_2$  such that  $c_2 \in C_2$  and  $U_{G'}(v, C_2, W_2)$  is g-maximal in  $G'$ and

$$
|U_{G'}(v, C_2, W_2)| \ge d_{c_2, G'}(v) \ge d_{c_2, G}(v) - |W_1| \ge d_{c_2, G}(v) - 3n/g.
$$

Set  $B = (v, C_1, W_1, C_2, W_2)$ . Note that B is g-maximal and for  $i \in [2]$ ,  $|U_i(B|G)| \ge d_{c_i}(v) - 3n/g$ . Furthermore,

$$
|\phi(B)|,|W(B)|\leq \frac{3}{g}\left(\sum_{i\in[2]}|U_i(B|G)|\right)\leq \frac{6n}{g}.
$$

We now continue our motivation for the proof of Lemma [7.3.](#page-23-4) Recall that our aim is to use a bowtie to close a rainbow path. First, we show that there exist a small set of bowties  $B_1, \ldots, B_t$  such that  ${U_2(B_i|G) : i \in [t]}$  partitions  $V^*(G)$ . This will ensure that any rainbow path can be extended via one of these bowties (but we may not be able to close it).

Let  $d, q \in \mathbb{N}$  and G be an edge-coloured multigraph. Let B be a family of bowties  $B_1, \ldots, B_t$ in G. Let  $\phi(\mathcal{B}) = \bigcup_{i \in [t]} \phi(B_i)$  and  $W(\mathcal{B}) = \bigcup_{i \in [t]} W(B_i)$ . We write  $G - \mathcal{B}$  for  $G \setminus W(\mathcal{B}) - G_{\phi(\mathcal{B})}$ . For a bowtie  $B \in \mathcal{B}$  and  $i \in [2]$ , we denote  $U_i(B|G,\mathcal{B}) = U_i(B|G - (\mathcal{B} \setminus B))$  and  $U_i^*(B|G,\mathcal{B}) =$  $N_{G-G_{\phi(\mathcal{B})}}[U_i(B|G,\mathcal{B})] \cap V^*(G-\mathcal{B})$ . We say  $\mathcal B$  is a  $(d,g)$ -partition of G if the following hold

<span id="page-27-2"></span><span id="page-27-0"></span>(P1) for all  $i \in [2]$  and  $j \in [t]$ , we have  $|U_i(B_j|G,\mathcal{B})| \geq d$ ;

- <span id="page-27-3"></span>(P2)  $W(B_1), \ldots, W(B_t)$  are all disjoint and  $W(\mathcal{B}) \subseteq V^*(G);$
- <span id="page-27-6"></span>(P3)  $\phi(B_1), \ldots, \phi(B_t)$  are all disjoint;

<span id="page-27-1"></span>(P4) for all  $j \in [t]$ ,  $B_j$  is g-maximal in  $G - (\mathcal{B} \setminus B_j);$ 

<span id="page-27-5"></span>(P5) for all distinct  $j, j' \in [t], U^*_2(B_j|G, \mathcal{B}) \cap U^*_2(B_{j'}|G, \mathcal{B}) = \emptyset;$ 

(P6)  $U_2^*(B_1|G,\mathcal{B}), U_2^*(B_2|G,\mathcal{B}), \ldots, U_2^*(B_t|G,\mathcal{B})$  partition  $V^*(G-\mathcal{B})$ .

<span id="page-27-4"></span>We say that B is a weak  $(d, g)$ -partition of G if only  $(\mathbf{P1})$  $(\mathbf{P1})$  $(\mathbf{P1})$  to  $(\mathbf{P5})$  $(\mathbf{P5})$  $(\mathbf{P5})$  hold.

**Fact 8.4.** Let  $d, q, n \in \mathbb{N}$  and G be a graph on n vertices. Let B be a weak  $(d, q)$ -partition of G. Then  $|\mathcal{B}| \leq n/d$ .

*Proof.* Consider  $B \in \mathcal{B}$ . By  $(\mathbf{P1}), |U_2^*(B|G, \mathcal{B}) \cup W(B)| \geq |U_2(B|G, \mathcal{B})| \geq d$  $(\mathbf{P1}), |U_2^*(B|G, \mathcal{B}) \cup W(B)| \geq |U_2(B|G, \mathcal{B})| \geq d$  $(\mathbf{P1}), |U_2^*(B|G, \mathcal{B}) \cup W(B)| \geq |U_2(B|G, \mathcal{B})| \geq d$ . Note that  $U_2^*(B|G, \mathcal{B}) \subseteq$  $V^*(G - B) \subseteq V(G) \setminus W(\mathcal{B})$ . By ([P2](#page-27-2)) and ([P3](#page-27-3)), for any distinct  $B, B' \in \mathcal{B}$ ,

$$
(U_2^*(B|G,\mathcal{B}) \cup W(B)) \cap (U_2^*(B'|G,\mathcal{B}) \cup W(B')) = \emptyset.
$$

Therefore,  $|\mathcal{B}| \leq n/d$ .

<span id="page-27-7"></span>The next lemma shows that one can extend a weak  $(d, q)$ -partition into a  $(d, q)$ -partition.

 $\Box$ 

**Lemma 8.5.** Let  $d, g, n \in \mathbb{N}$  with  $d \geq 4g$  and  $g \geq \max\{3n/g, 12n^2/gd\}$ . Let G be an edge-coloured multigraph on n vertices such that  $\delta^*_{mon}(G) \geq d$ . Suppose  $\mathcal{B}_0$  is a weak  $(d/2, g)$ -partition of G with  $|\phi(\mathcal{B}_0)|, |W(\mathcal{B}_0)| \leq 6n|\mathcal{B}_0|/g$ . Then there exists a  $(d/2, g)$ -partition  $\mathcal{B}^*$  so that  $\mathcal{B}_0 \subseteq \mathcal{B}^*$  and  $|\phi(\mathcal{B}^*)|, |W(\mathcal{B}^*)| \leq$  $6n|\mathcal{B}^*|/g \leq 12n^2/gd$ .

*Proof.* Suppose we have already constructed a weak  $(d/2, g)$ -partition  $\mathcal{B} = \{B_1, \ldots, B_t\}$  with  $\mathcal{B}_0 \subseteq \mathcal{B}$ and  $|\phi(\mathcal{B})|, |W(\mathcal{B})| \leq t(6n/g)$ . By Fact [8.4,](#page-27-4)

$$
t \le 2n/d. \tag{8.1}
$$

Hence

$$
|\phi(\mathcal{B}^*)|, |W(\mathcal{B}^*)| \le \left(\frac{2n}{d}\right)\left(\frac{6n}{g}\right) = \frac{12n^2}{gd}.
$$

We further assume that t is maximal. If B satisfies ([P6](#page-27-5)) then we are done by setting  $\mathcal{B}^* = \mathcal{B}$ .

Thus we may assume that ([P6](#page-27-5)) does not hold. We now construct a bowtie  $B_{t+1}$  as follows. Let  $G' = G - \mathcal{B}$ . Pick  $v^{t+1} \in V^*(G') \setminus \bigcup_{i \in [t]} U_2^*(B_i | G, \mathcal{B})$  and  $c_1, c_2 \in \phi_{G'}(v^{t+1})$ , which exist as  $(\mathbf{P6})$  $(\mathbf{P6})$  $(\mathbf{P6})$  does not hold for B. Note that

$$
\delta_{\text{mon}}^*(G') \ge \delta_{\text{mon}}^*(G) - |W(\mathcal{B})| \ge d - (12n^2/gd) \ge d - g \ge d/2 \ge 2g \ge g + 3n/g.
$$

By Corollary [8.3,](#page-26-2) G' contains a g-maximal bowtie  $B_{t+1}$  such that  $|\phi(B_{t+1})|, |W(B_{t+1})| \leq 6n/g$  and  $W(B_{t+1}) \subseteq V^*(G').$ 

Let  $\mathcal{B}' = \mathcal{B} \cup B_{t+1}$ . Clearly,  $|\phi(\mathcal{B}')|, |W(\mathcal{B}')| \leq (t+1)(6n/g)$ . We now show that  $\mathcal{B}'$  is a weak  $(d/2, g)$ -partition, contradicting the maximality of t. Fix  $i \in [2]$  and  $j \in [t + 1]$ . Note that

$$
\delta_{\text{mon}}^*(G - (\mathcal{B}' \setminus B_j)) \ge d - |W(\mathcal{B}' \setminus B_j)| \ge d - (12n^2/gd) \ge d/2.
$$

Thus,  $|U_i(B_j|G, \mathcal{B}')| \geq \delta_{\text{mon}}^*(G - (\mathcal{B}' \setminus B_j)) \geq d/2$  and so ([P1](#page-27-0)) holds. Note that ([P2](#page-27-2)) and ([P3](#page-27-3)) hold by our construction. For  $j \in [t]$ ,  $B_j$  is g-maximal in  $G - (\mathcal{B} \setminus B_j)$  so it is g-maximal in  $G - (\mathcal{B}' \setminus B_j)$ . Recall  $B_{t+1}$  is g-maximal in  $G' = G - \mathcal{B} = G - (\mathcal{B}' \setminus B_{t+1})$ . Thus  $(\mathbf{P4})$  $(\mathbf{P4})$  $(\mathbf{P4})$  holds for  $\mathcal{B}'$ .

It remains to show ([P5](#page-27-1)) holds for  $\mathcal{B}'$ . For  $i \in [t]$ ,  $U_2^*(B_i|G,\mathcal{B}') \subseteq U_2^*(B_i|G,\mathcal{B})$ . Since  $\mathcal{B}$  is a weak  $(d/2, g)$ -partition of G,  $(\mathbf{P5})$  $(\mathbf{P5})$  $(\mathbf{P5})$  of B implies that  $U_2^*(B_1|G, \mathcal{B}')$ ,...,  $U_2^*(B_t|G, \mathcal{B}')$  are disjoint. Suppose that  $U_2^*(B_{t+1}|G, \mathcal{B}') \cap U_2^*(B_j|G, \mathcal{B}') \neq \emptyset$  for some  $j \in [t]$ . Let  $u \in U_2^*(B_{t+1}|G, \mathcal{B}') \cap U_2^*(B_j|G, \mathcal{B}') \subseteq V^*(G - \mathcal{B})$ and  $c \in \phi_{G-\mathcal{B}'}(u)$ . Note that

$$
d_{c,G-B'}(u) \ge \delta_{\text{mon}}^*(G - B') \ge d - (12n^2/gd) > g.
$$

Lemma [8.2](#page-26-3)[\(i\)](#page-26-0) and ([P4](#page-27-6)) imply that  $d_{c,G-B'}(u,\overline{U_2(B_j|G,B')}) < g$ . Therefore,

$$
d_{c,G}(u, U_2(B_j|G, \mathcal{B}')) \geq d_{c,G}(u) - |W(\mathcal{B}')| - d_{c,G-\mathcal{B}'}(u, \overline{U_2(B_j|G, \mathcal{B}'))}
$$
  
> 
$$
d_{c,G}(u) - \frac{12n^2}{gd} - g \geq \frac{d_{c,G}(u)}{2}.
$$

Similarly, we have  $d_{c,G}(u, U_2(B_{t+1}|G, \mathcal{B}')) > d_{c,G}(u)/2$ . Hence,

$$
|U_2(B_j|G, \mathcal{B}') \cap U_2(B_{t+1}|G, \mathcal{B}')| \ge |U_2(B_j|G, \mathcal{B}') \cap U_2(B_{t+1}|G, \mathcal{B}') \cap N_{c,G}(u)|
$$
  
\n
$$
\ge d_{c,G}(u, U_2(B_j|G, \mathcal{B}')) + d_{c,G}(u, U_2(B_{t+1}|G, \mathcal{B}')) - d_{c,G}(u)
$$
  
\n
$$
> 0.
$$

Let  $w \in U_2(B_j|G, \mathcal{B}') \cap U_2(B_{t+1}|G, \mathcal{B}')$ . Let  $B_{t+1} = (v^{t+1}, C_1^{t+1}, W_1^{t+1}, C_2^{t+1}, W_2^{t+1})$ . Since  $w \in$  $U_2(B_{t+1}|G, \mathcal{B}')$ , there exists a rainbow path  $P = wv_1...v_{\ell}v^{t+1}$  with  $\phi(P) \subseteq C_2^{t+1}$  and  $\text{int}(P) \subseteq W_2^{t+1}$ . By  $(\mathbf{P3}), \phi(P) \cap \phi(B_j) = \emptyset$  $(\mathbf{P3}), \phi(P) \cap \phi(B_j) = \emptyset$  $(\mathbf{P3}), \phi(P) \cap \phi(B_j) = \emptyset$ . We deduce that  $v_1 \in U_2^*(B_j | G, \mathcal{B}')$ . Let  $c_1 \in C_1^{t+1} \cap \phi_G(v^{t+1})$ . Note that

$$
d_{c_1,G'}(v^{t+1}) \ge \delta_{\text{mon}}^*(G') \ge d/2 > |C_2^{t+1}| \ge |V(P)|.
$$

Pick  $v' \in N_{c_1,G'}(v^{t+1}) \setminus V(P)$ . Then the path  $P' = wv_1 \ldots v_{\ell}v^{t+1}v'$  is a rainbow path with  $\phi(P') \cap \phi(B_j) =$  $\emptyset$ . By Lemma [8.2](#page-26-3)[\(ii\),](#page-26-1)  $v^{t+1} \in \text{int}(P') \subseteq U_2^*(B_j|G,\mathcal{B})$ , contradicting the fact that  $v^{t+1}$  was chosen from  $V^*(G') \setminus \bigcup_{i \in [t]} U_2^*(B_i|G, \mathcal{B}).$  $\Box$ 

#### 8.1 Proof of Lemma [7.3](#page-23-4)

We now present the ideas in the proof of Lemma [7.3.](#page-23-4) Let  $d = \delta n$ .

We apply Lemma [8.5](#page-27-7) to obtain a  $(d/2, g)$ -partition B of G. Let P be a rainbow path in  $G-\mathcal{B}$ . Since int(P) ⊆ V<sup>\*</sup>(G – B), we deduce (by ([P4](#page-27-6)), ([P6](#page-27-5)) and Lemma [8.2](#page-26-3)[\(ii\)\)](#page-26-1) that there exists  $B \in \mathcal{B}$  such that  $int(P) \subseteq U_2^*(B|G,\mathcal{B})$ . We now discuss how to augment P into a rainbow cycle using B.

Let  $P = x_1x_2...x_\ell$  with  $\phi(x_1x_2) = 2$  and  $\phi(x_{\ell-1}x_\ell) = \ell$ .

**Case 1:**  $|U_2(B|G,\mathcal{B})| \leq 3d/4$ . By Lemma [8.2](#page-26-3)[\(i\),](#page-26-0) we can find  $x \in U_2(B|G,\mathcal{B})$  to replace both  $x_1$  and  $x_\ell$ in P. This transforms P into a rainbow cycle.

**Case 2:**  $U_2^*(B|G, \mathcal{B}) = U_1^*(B|G, \mathcal{B})$ . By Lemma [8.2](#page-26-3)[\(i\),](#page-26-0) we may assume that  $x_1 \in U_1(B|G, \mathcal{B})$  and  $x_{\ell} \in U_2(B|G,\mathcal{B})$ . Let  $B = (v, C_1, W_1, C_2, W_2)$ . There exists a rainbow path  $P'$  from  $x_1$  to  $x_{\ell}$  through  $v$ such that  $\phi(P') \subseteq \phi(B)$  and  $\text{int}(P') \subseteq W(B)$ . Hence  $PP'$  is a rainbow cycle.

Therefore we would like to ensure Case 1 or Case 2 hold. Our aim is to refine  $\beta$  by replacing bowties with smaller ones so that Case 1 will hold eventually. In particular, we will increase the number of bowties in each step. For simplicity, suppose  $V^*(G - B) = V(G)$ . Note that  $B \in \mathcal{B}$  is gmaximal in  $G - (\mathcal{B} \setminus B)$ . Lemma [8.2](#page-26-3)[\(i\)](#page-26-0) implies that "the subgraph  $H_B$  induced by  $U_2^*(B|G, \mathcal{B})$  satisfies  $\delta^*_{\text{mon}}(H_B) \geq d - g \geq d/2$ ". Hence we can apply Lemma [8.5](#page-27-7) to obtain a  $(d/4, g)$ -partition  $\mathcal{B}'$  of  $H_B$ . Thus, we refine  $\beta$  by replacing  $B$  with  $\beta'$ .

Suppose that we are unable to refine  $\beta$  further and for simplicity  $\beta$  consists of only one bowtie  $B = (v, C_1, W_1, C_2, W_2)$ . If Case 2 fails, then  $U_1^*(B|G, \mathcal{B})$  is smaller than  $U_2^*(B|G, \mathcal{B})$ . We consider the 'swapped' bowtie  $B' = (v, C_2, W_2, C_1, W_1)$  instead. We extend this weak partition  $\{B'\}$  into a  $(d/4, q)$ partition of G (using Lemma [8.5\)](#page-27-7). Note that we increase the number of bowties in the partition.

*Proof of Lemma [7.3.](#page-23-4)* Set  $d = \delta n$ ,  $\gamma = \delta^2/16$  and  $g = \gamma n$ . Note that

$$
d \ge 4g + 2 \text{ and } g \ge \max\{6n/g, 12n^2/gd\}.
$$

Let  $G^0 = G$ ,  $J^0 = G$  and  $H^0 = G$ . By Lemma [8.5](#page-27-7) with  $H^0, d, g, \emptyset$  playing the roles of  $G, d, g, \mathcal{B}_0$ , respectively, we obtain a  $(d/2, g)$ -partition  $\mathcal{B}^1$  of  $H^0$  and  $|\phi(\mathcal{B}^1)|, |W(\mathcal{B}^1)| \leq 2n|\mathcal{B}^1|/g$  and  $W(\mathcal{B}^1) \subseteq$  $V^{*}(H^{0}).$ 

Suppose for some  $i \in \mathbb{N}$  we have already constructed families  $\mathcal{B}^1, \mathcal{B}^2, \ldots, \mathcal{B}^i$  of bowties, edge-coloured multigraphs  $J^0, G^0, H^0, \ldots, J^{i-1}, G^{i-1}, H^{i-1}$  whose properties will be specified later. Let

$$
J^{i} = G^{i-1} - B^{i},
$$
  
\n
$$
G^{i} = J^{i} - \bigcup_{\substack{B, B' \in \mathcal{B}^{i} \\ B \neq B'}} J^{i}[U_{2}^{*}(B|H^{i-1}, \mathcal{B}^{i}), U_{2}^{*}(B'|H^{i-1}, \mathcal{B}^{i})].
$$

In other words,  $G^i$  is obtained from  $G^{i-1} - \mathcal{B}^i$  by removing all edges between  $U_2^*(B|H^{i-1}, \mathcal{B}^i)$  and  $U_2^*(B'|H^{i-1}, \mathcal{B}^i)$  for distinct  $B, B' \in \mathcal{B}^i$ .

Let  $\mathcal{B}_1^i = \{B \in \mathcal{B}^i : |U_2(B|H^{i-1}, \mathcal{B}^i)| \leq 3d/4\}$ . (These will consist of bowties that satisfy Case 1.) Consider  $i \in \mathbb{N}$  and  $B \in \mathcal{B}^i$ . For a bowtie family  $\mathcal{B}'$  in  $H^i$ , define

$$
\partial_{\mathcal{B}'}(B) = \{B' \in \mathcal{B}' : W(B') \subseteq U_2^*(B|H^{i-1}, \mathcal{B}^i)\}.
$$

We say B is covered by  $\mathcal{B}'$  if  $\partial_{\mathcal{B}'}(B) = \{B'\}$  and  $U_2^*(B'|H^i, \mathcal{B}') = U_1^*(B'|H^i, \mathcal{B}')$ . We write  $\partial B$  for  $\partial_{\mathcal{B}^{i+1}}B$ . Let

$$
\mathcal{B}_2^i = \begin{cases} \bigcup \{ \partial B \colon B \in \mathcal{B}^{i-1} \text{ is covered by } \mathcal{B}^i \} & \text{if } i \geq 2, \\ \emptyset & \text{if } i = 1. \end{cases}
$$

(These bowties in  $\mathcal{B}_2^i$  will satisfy Case 2.) Let  $\mathcal{B}_3^i = \mathcal{B}^i \setminus (\mathcal{B}_1^i \cup \mathcal{B}_2^i)$  and

$$
H^i = G^i \setminus \left(V^*(G^i) \setminus \bigcup_{B \in \mathcal{B}^i_3} U^*_2(B|H^{i-1}, \mathcal{B}^i)\right) = G^i\left[(V(G^i) \setminus V^*(G^i)) \cup \bigcup_{B \in \mathcal{B}^i_3} U^*_2(B|H^{i-1}, \mathcal{B}^i)\right].
$$

In other words,  $H^i$  is induced by  $U_2^*(B|H^{i-1}, \mathcal{B}^i)$  for all  $B \in \mathcal{B}_3^i$  and the vertices in  $G^i$  that see at most one colour. From now on, for  $B \in \mathcal{B}^j$ , we write  $U_i^*(B)$  for  $U_i^*(B|H^{j-1}, \mathcal{B}^j)$ . We now list the desired properties of  $G^i$  and  $H^i$ . Suppose that for all  $j \in [i]$ ,

- <span id="page-30-1"></span><span id="page-30-0"></span>(i)  $\mathcal{B}^j$  is a  $(d/4, g)$ -partition of  $H^{j-1}$  with  $|\phi(\mathcal{B}^j)|, |W(\mathcal{B}^j)| < 384\delta^{-3}$  and  $W(\mathcal{B}^j) \subseteq V^*(H^{j-1});$
- <span id="page-30-2"></span>(ii) if  $B' \in \mathcal{B}^{j-1}$  and  $|\partial B'| = 1$ , then B' is covered by  $\mathcal{B}^j$ ;
- <span id="page-30-4"></span>(iii) if  $j \geq 2$ , then  $\mathcal{B}^j = \bigcup_{B \in \mathcal{B}_3^{j-1}} \partial B;$
- <span id="page-30-10"></span>(iv) for all  $B \in \mathcal{B}_3^j$ ,  $|U_2^*(B)| \leq n - j(d/4)$ ;
- <span id="page-30-6"></span>(v)  $\delta_{\text{mon}}(G^j) \ge d - j(g + 12n^2/gd) \ge d - 2gj;$
- <span id="page-30-11"></span>(vi) if  $V^*(H^j)$  is not empty, then  $\delta^*_{\text{mon}}(H^j) \geq d - j(g + 12n^2/gd) \geq d - 2gj$ ;
- <span id="page-30-7"></span>(vii)  $V^*(H^j) \subseteq \bigcup_{B \in \mathcal{B}_3^j} U_2^*(B);$
- <span id="page-30-9"></span><span id="page-30-3"></span>(viii)  $\phi(G^j) = \phi(G^{j-1}) \setminus \phi(\mathcal{B}^j);$ 
	- (ix)  $G^j$  has no edge between  $U_2^*(B)$  and  $V^*(G^j) \setminus U_2^*(B)$  for all  $B \in \mathcal{B}^j$ ;
	- (x) for each  $B \in \mathcal{B}^j$ , B is g-maximal in  $G^{j-1} (\mathcal{B}^j \setminus B)$ .

It should be noted that [\(i\)](#page-30-0) and [\(ii\)](#page-30-1) imply [\(iii\)](#page-30-2) to [\(x\).](#page-30-3) Hence we technically only require  $\mathcal{B}^1,\ldots,\mathcal{B}^j$  to satisfy  $(i)$  and  $(ii)$ . Note that  $(iv)$  implies that

<span id="page-30-5"></span>
$$
i \le 4n/d = 4/\delta. \tag{8.2}
$$

**Case A:**  $V^*(H^i) \neq \emptyset$ . We now construct  $\mathcal{B}^{i+1}$  as follows. We have

$$
\delta_{\text{mon}}^*(H^i) \ge d - 2g(4\delta^{-1}) \ge d/2.
$$

<span id="page-30-8"></span>By Lemma [8.5](#page-27-7) with  $H^i, d/2, g, \emptyset$  playing the roles of  $G, d, g, \mathcal{B}_0$ , respectively, there exists a  $(d/4, g)$ partition B of H<sup>i</sup> with  $|\phi(\mathcal{B})|, |W(\mathcal{B})| \leq 6n|\mathcal{B}|/g = 192\delta^{-3}$ .

**Claim 8.6.** Let B be a  $(d/4, g)$ -partition of H<sup>i</sup> with  $|\phi(\mathcal{B})|, |W(\mathcal{B})| \leq 12n^2/gd$ . Let  $B^+ \in \mathcal{B}^i$  and  $B \in \partial_B B^+$ . Then for  $t \in [2]$ ,  $U_t^*(B|H^i, \mathcal{B}) \subseteq U_2^*(B^+)$ . Moreover, if  $\partial_B B^+ = \{B\}$ , then  $U_2^*(B|H^i, \mathcal{B}) =$  $U_2^*(B^+) \cap V^*(H^i - B).$ 

*Proof of claim.* We prove the case for  $t = 2$  (and the case for  $t = 1$  is proven analogously). Let  $B = (v, C_1, W_1, C_2, W_2)$ , so  $v \in U_2^*(B^+)$ . Suppose there exists a vertex

<span id="page-31-1"></span>
$$
u \in U_2^*(B|H^i, \mathcal{B}) \setminus U_2^*(B^+). \tag{8.3}
$$

Then there exists a rainbow path  $P = vw_1 \dots w_\ell u$  such that  $w_1, \dots, w_{\ell-1} \in W_2$ ,  $\phi(P) \subseteq C_2 \cup \phi(w_\ell u) \subseteq$  $\phi(H^i)$  and  $C_1 \cap \phi(P) = \emptyset$ . Note that

<span id="page-31-0"></span>
$$
|P| \le |W(\mathcal{B})| + 2 \le 192\delta^{-3} + 2 < d/2 \tag{8.4}
$$

and  $u \in V^*(H^i - \mathcal{B})$ . Thus, there exists a colour  $c' \in \phi_{H^i - \mathcal{B}}(u) \setminus \phi(w_\ell v)$ . By [\(vi\),](#page-30-6)

$$
d_{c',H^i}(u) \ge d - 2ig \ge d - \frac{8g}{\delta} \stackrel{(8.4)}{>} |P|.
$$

Pick  $u' \in N_{c',H^i}(u) \setminus V(P)$ . Recall that  $\phi(H^i) \supseteq \phi(\mathcal{B}) \supseteq C_1 \neq \emptyset$ . Pick  $c_1 \in C_1 \cap \phi_{H^i}(v) \subseteq \phi(H^i)$ .  $By (vi),$  $By (vi),$ 

$$
d_{c_1,H^{i-1}}(v) \ge d - 2g(i-1) \ge d - \frac{8g}{\delta} \stackrel{(8.4)}{>} |P| + 1.
$$

Pick  $v' \in N_{c_1,H^{i-1}}(u) \setminus (V(P) \cup \{u'\})$ . Then the path  $P' = v'Pu' = v'vw_1 \ldots w_{\ell}uu'$  is rainbow in  $H^{i-1}$ with

$$
\phi(P') \cap \phi(\mathcal{B}^i) \subseteq \phi(H^i) \cap \phi(\mathcal{B}^i) \subseteq \phi(G^i) \cap \phi(\mathcal{B}^i) = \emptyset
$$

by [\(viii\).](#page-30-7) Recall that  $U_2^*(B^+)$  is g-maximal in  $H^{i-1}-(\mathcal{B}^i\setminus B^+)$ . Lemma [8.2](#page-26-3)[\(ii\)](#page-26-1) implies that  $u \in \text{int}(P') \subseteq$  $U_2^*(B^+)$  contradicting [\(8.3\)](#page-31-1). The moreover statement follows.

For each  $B^+ \in \mathcal{B}^i$  with  $\partial_{\mathcal{B}}B^+ = \{B\}$  that is not covered by  $\mathcal{B}$ , we replace the bowtie  $B =$  $(v, C_1, W_1, C_2, W_2)$  with  $B' = (v, C_2, W_2, C_1, W_1)$ . We call the resulting family  $\mathcal{B}'$ . We now show that  $\mathcal{B}'$  is a weak  $(d/4, g)$ -partition of  $H^i$ . Note that  $(\mathbf{P1})$  $(\mathbf{P1})$  $(\mathbf{P1})$  to  $(\mathbf{P4})$  $(\mathbf{P4})$  $(\mathbf{P4})$  hold. To show  $(\mathbf{P5})$  $(\mathbf{P5})$  $(\mathbf{P5})$ , note that if  $B' \in \mathcal{B}' \setminus \mathcal{B}$ , then there exist unique  $B \in \mathcal{B} \setminus \mathcal{B}'$  and  $B^+ \in \mathcal{B}^i$  with

$$
B = (v, C_1, W_1, C_2, W_2), B' = (v, C_2, W_2, C_1, W_1)
$$
 and  $\partial_B B^+ = \{B\}.$ 

By Claim [8.6](#page-30-8) and the fact  $\partial_{\mathcal{B}}B^+=\{B\}$ , we deduce that

$$
U_2^*(B'|H^i, \mathcal{B}') = U_1^*(B|H^i, \mathcal{B}) \subseteq U_2^*(B^+) \cap V^*(G^{i+1}) = U_2^*(B|H^i, \mathcal{B}).
$$

Recall that B is a  $(d/4, g)$ -partition of  $H^i$ , in particular this implies that  $\{U_2^*(B|H^i, \mathcal{B}) : B \in \mathcal{B}\}\$ are pairwise disjoint. Thus,  $\mathcal{B}'$  satisfies ([P5](#page-27-1)) and is a weak  $(d/4, g)$ -partition. Apply Lemma [8.5](#page-27-7) with  $H^i, d/2, g, \mathcal{B}'$  playing the roles of  $G, d, g, \mathcal{B}_0$ , respectively and obtain  $(d/4, g)$ -partition  $\mathcal{B}^{i+1}$  containing  $\mathcal{B}'$ and satisfying  $W(\mathcal{B}^{i+1}) \subseteq V^*(H^i)$  and

$$
|\phi(\mathcal{B}^{i+1})|, |W(\mathcal{B}^{i+1})| \le 2(6n|\mathcal{B}^{i+1}|/g) \le 24n^2/gd \le 384\delta^{-3}.
$$

**Claim 8.7.**  $\mathcal{B}^{i+1}, G^{i+1}, H^{i+1}$  satisfy [\(i\)](#page-30-0) to [\(x\)](#page-30-3).

Proof of claim. Note that [\(i\)](#page-30-0) holds by construction.

Consider  $B^+ \in \mathcal{B}^i$ . If  $|\partial_{\mathcal{B}}B^+| = 1$  and  $B^+$  is not covered by  $\mathcal{B}$ , then  $|\partial_{\mathcal{B}^{i+1}}B^+| > 1$ . Otherwise  $\partial_{\mathcal{B}}B^+=\partial_{\mathcal{B}^{i+1}}B^+$ . Suppose that  $\partial B^+=\{B\}$ . By ([P6](#page-27-5)) and Claim [8.6,](#page-30-8)  $U_2^*(B|H^i,\mathcal{B}^{i+1})=$  $U_2^*(B^+|H^{i-1},\mathcal{B}^i) \cap V^*(H^i-\mathcal{B}^{i+1})$ . Note that  $B^+$  is covered by  $\mathcal{B}$ , therefore covered by  $\mathcal{B}^{i+1}$ . Thus [\(ii\)](#page-30-1) holds.

Consider  $B = (v, C_1, W_1, C_2, W_2) \in \mathcal{B}^{i+1}$ . For each  $w \in W(B) \setminus \{v\}$ , there is a path from v to w in  $H^i$ . Thus  $W(B)$  is contained in a component of  $H^i[V^*(H^i)]$ . Since  $H^i \subseteq G^i$ , [\(ix\)](#page-30-9) for  $G^i$  implies that  $W(B) \subseteq U_2^*(B^+)$  for some  $B^+ \in \mathcal{B}_3^i$ . Therefore [\(iii\)](#page-30-2) holds for  $G^{i+1}$ .

We now show that [\(iv\)](#page-30-4) holds. Let  $B \in \mathcal{B}_3^{i+1}$ . Then there exists  $B^+ \in \mathcal{B}_3^i$  and  $B' \in \mathcal{B}_3^{i+1}$  such that  $B, B' \in \partial B^+$ . By ([P1](#page-27-0)), ([P5](#page-27-1)) and Claim [8.6,](#page-30-8) we deduce that  $U_2^*(B) \cup W(B)$  and  $U_2^*(B') \cup W(B')$ each has size at least  $d/4$ , are disjoint and contained in  $U_2^*(B^+)$ . Hence,

$$
|U_2^*(B)| \le |U_2^*(B^+) - |U_2^*(B') \cup W(B')|
$$
  
\n
$$
\le n - i(d/4) - (d/4) = n - (i+1)(d/4).
$$

To show [\(v\),](#page-30-10) consider a vertex  $u \in V(G^{i+1})$  and a colour  $c \in \phi_{G^{i+1}}(u)$ . It is enough to show that  $d_{c,G^{i+1}}(u) \geq d - (i+1)(g+12n^2/gd)$ . By [\(v\)](#page-30-10) for  $G^i$ , we have  $d_{c,G^i}(u) \geq d - i(g+12n^2/gd)$ . Then

$$
d_{c,J^{i+1}}(u) \ge d_{c,G^{i}}(u) - |W(\mathcal{B}^{i+1})| \ge d - ig - (i+1)(12n^2/gd).
$$

If  $u \in V(G^{i+1}) \setminus V^*(G^{i+1})$ , then  $d_{c,G^{i+1}}(u) = d_{c,J^{i+1}}(u)$ . If  $u \in V^*(G^{i+1})$ , then by  $(P6)$  $(P6)$  $(P6)$ ,  $u \in U_2^*(B)$ If  $u \in V(G^{\prime}) \setminus V(G^{\prime})$ , then  $u_{c,G^{i+1}}(u) = u_{c,J^{i+1}}(u)$ . If  $u \in V(G^{\prime})$ , then by  $(\mathbf{r} \mathbf{0}), u \in U_2(D)$ <br>for some  $B \in \mathcal{B}^{i+1}$ . Then by g-maximality of B in  $H^i - (\mathcal{B}^{i+1} \setminus B)$ , Lemma [8.2](#page-26-3)[\(i\)](#page-26-0) implies that  $d_{c,G^{i+1}}(u,\overline{U_2^*(B)}) < g$ . We deduce that

$$
d_{c,G^{i+1}}(u) \ge d_{c,J^{i+1}}(u) - d_{c,G^{i+1}}(u,\overline{U_2^*(B))}) \ge d - (i+1)(g+12n^2/gd).
$$

This argument also implies [\(vi\),](#page-30-6) [\(vii\)](#page-30-11) and  $\phi(J^{i+1}) = \phi(G^{i+1})$ . Since  $\delta_{\text{mon}}(G^i) \ge d/4 > |W(\mathcal{B}^{i+1})|$ , we have  $\phi(J^{i+1}) = \phi(G^i) \setminus \phi(\mathcal{B}^{i+1})$  implying [\(viii\).](#page-30-7)

To show [\(ix\),](#page-30-9) consider  $B \in \mathcal{B}^{i+1}$ . Let  $B^+ \in \mathcal{B}^i$  with  $B \in \partial B^+$ . By Claim [8.6,](#page-30-8)  $U_2(B) \subseteq U_2^*(B^+)$ . Hence  $G^{i+1}$  contains no edge between  $U_2^*(B)$  and  $U_2^*(B^+) \setminus U_2^*(B)$ . By [\(ix\)](#page-30-9) for  $G^i$ , there are no edges in  $G^i$  (and so in  $G^{i+1}$ ) between  $U_2^*(B^+)$  and  $V^*(G^i) \setminus U_2^*(B^+)$  in  $G^i$  and so in  $G^{i+1}$ . Thus [\(ix\)](#page-30-9) holds for  $G^{i+1}$ .

Suppose for contradiction [\(x\)](#page-30-3) does not hold. That is, some bowtie  $B \in \mathcal{B}^{i+1}$  is not g-maximal in  $G^{i} - (\mathcal{B}^{i+1} \setminus B)$ . Note that B is g-maximal in  $H^{i} - (\mathcal{B}^{i+1} \setminus B)$ . Let  $B^{+} \in \mathcal{B}^{i}$  with  $B \in \partial B^{+}$ . By [\(ix\),](#page-30-9)  $G^i$  has no edge between  $U_2^*(B^+|H^{i-1}, \mathcal{B}^i)$  and  $V^*(G^i) \setminus U_2^*(B^+|H^{i-1}, \mathcal{B}^i)$ . Thus for any  $v \in V^*(H^i)$ , the neighbourhoods of v are the same in  $H^i$  and in  $G^i$ . Hence any vertices  $u, w, w'$  that could prevent g-maximality must also be contained in  $V^*(H^i)$ . Therefore B is g-maximal in  $G^i - (\mathcal{B}^{i+1} \setminus B)$ . ■

**Case B:**  $V^*(H^i) = \emptyset$ . Set  $C^* = \bigcup_{j \in [i]} \phi(\mathcal{B}^j)$  and  $W^* = \bigcup_{j \in [i]} W(\mathcal{B}^j)$ . Let  $G^* = G^i$ . Clearly,

<span id="page-32-0"></span>
$$
|W^*| \le \sum_{j \in [i]} |W(\mathcal{B}^j)| \stackrel{(i), (8.2)}{\le} (384\delta^{-3})(4\delta^{-1}) < 2000\delta^{-4}.\tag{8.5}
$$

There is a similar upper bound on  $|C^*|$ . Note that  $\phi(G^*) = \phi(G) \setminus C^*$  by [\(viii\).](#page-30-7) Moreover, by [\(v\),](#page-30-10)

$$
\delta_{\text{mon}}(G^*) \ge d - |W^*| \stackrel{(8.5)}{\ge} d - 2000\delta^{-4}.
$$

Consider a rainbow path P in  $G^*$  with  $|V(P)| \geq 3$  and  $S \subseteq V^*(G) \setminus V(P)$  such that  $|V(P) \cup S| \leq d/4$ . We shall find a rainbow cycle  $C^*$  in  $G \setminus S$ , which closes P with  $\phi(P) \subseteq \phi(C^*) \subseteq \phi(P) \cup \phi(G) \setminus \phi(G^*)$ .

**Claim 8.8.** There exists  $j \in [i]$  and  $B \in \mathcal{B}_1^j \cup \mathcal{B}_2^j$  such that  $\text{int}(P) \subseteq U_2^*(B)$ .

Proof of claim. Let  $v \in \text{int}(P) \subseteq V^*(G^*) \subseteq V^*(G)$ . Note that  $V^*(G) = V^*(H^0) \supseteq \cdots \supseteq V^*(H^i) = \emptyset$ . Let  $j \in [i]$  be such that  $v \in V^*(H^j)$  but  $v \notin V^*(H^{j+1})$ . By [\(vii\),](#page-30-11) there exists  $B \in \mathcal{B}_1^j \cup \mathcal{B}_2^j$  such that  $v \in U_2^*(B)$ . By  $(x)$ , B is g-maximal in  $G^{j-1} - (\mathcal{B}^j \setminus B)$ . Therefore Lemma [8.2](#page-26-3)[\(ii\)](#page-26-1) implies that  $\text{int}(P) \subseteq U_2^*$ (B).

Let B and j be as given by the claim. Let  $P = x_1 \dots x_\ell$  with  $\phi(x_1 x_2) = 2$  and  $\phi(x_{\ell-1} x_\ell) = \ell$ . Let  $H'=H^{j-1}-(\mathcal{B}^j\setminus B).$ 

**Case B(i):**  $B \in \mathcal{B}_1^j$ . Note that  $\text{int}(P) \subseteq U_2^*(B) \subseteq V^*(H^{j-1})$ . Moreover,  $|\text{int}(P) \cup S| < d/4$ . Let  $U_2 = U_2(B)$ , so  $|U_2| \leq 3d/4$  as  $B \in \mathcal{B}_1^j$ . By Lemma [8.2](#page-26-3)[\(i\),](#page-26-0)  $d_{2,H'}(x_2, \overline{U_2}) < g$ . Then by [\(vi\),](#page-30-6)

$$
d_{2,H'}(x_2, U_2) > \delta_{\text{mon}}^* \left( H^{j-1} \right) - g - \left| W^* \right| \stackrel{(8.5)}{\geq} d - 2g(j-1) - g - 2000 \delta^{-4} \geq d/2.
$$

Similarly, we have  $d_{\ell,H'}(x_{\ell-1},U_2) \geq d/2$ . We deduce that

$$
|N_{2,H'}(x_2, U_2) \cap N_{\ell,H'}(x_{\ell-1}, U_2) \setminus (S \cup V(P))|
$$
  
\n
$$
\geq d_{2,H'}(x_2, U_2) + d_{\ell,H'}(x_{\ell-1}, U_2) - |U_2| - |S \cup V(P)|
$$
  
\n
$$
> d/2 + d/2 - 3d/4 - d/4 = 0.
$$

Pick  $x \in (N_{2,H'}(x_2, U_2) \cap N_{\ell,H'}(x_{\ell-1}, U_2)) \setminus (S \cup V(P))$ . Then  $C^* = xx_2 \cdots x_{\ell-1}x$  is a rainbow cycle with  $\phi(C^*) = \phi(P)$ .

**Case B(ii):**  $B \in \mathcal{B}_2^j$ . There exists  $B' \in \mathcal{B}_2^{j-1}$  with  $\partial B' = \{B\}$ . Let  $B = (v, C_1, W_1, C_2, W_2)$ . Furthermore,  $V^*(G^j) \cap U_2^*(B') = U_1^*(B) = U_2^*(B)$ . Since P is in  $G^*$ , we have  $\text{int}(P) \subseteq V^*(G^*)$ . Note that B is g-maximal in  $H'$ . We deduce that

$$
d_{2,H'}(x_2, U_1(B|H^{j-1}, \mathcal{B}^j)) \ge \delta_{\text{mon}}^*(H^j) - d_{2,H'}(x_2, U_1(B))
$$
  
(vi), Lemma 8.2(i)  

$$
\ge d - 2gj - g \ge d - (2i + 1)g \stackrel{(8.2),(8.5)}{\ge} |S \cup V(P)| + |V(G) \setminus V(G^*)|.
$$

Pick  $y_1 \in U_1(B) \cap (V(G^*) \setminus (S \cup V(P)))$  such that  $\phi(y_1 x_2) = 2$ . Similarly, we can find a distinct vertex  $y_2 \in U_2(B) \cap (V(G^*) \setminus (S \cup V(P)))$  such that  $\phi(y_2x_{\ell-1}) = \ell$ . Let  $P_{y_1,v}$  be the rainbow path from  $y_1$  to v with  $\text{int}(P_{y_1,v}) \subseteq W_1$  and  $\phi(P_{y_1,v}) \subseteq C_1$ ; and  $P_{v,y_2}$  be a rainbow path from  $y_2$  to v with  $\text{int}(P_{v,y_2}) \subseteq W_2$ and  $\phi(P_{v,y_2}) \subseteq C_2$ . Then  $C^* = y_1 P_{y_1,v} P_{v,y_2} y_2 x_{\ell-1} x_{\ell-2} \dots x_2 y_1$  is a rainbow cycle in  $G \setminus S$ . Note that

$$
\phi(P) \subseteq \phi(C^*) \subseteq \phi(P) \cup \phi(G) \setminus \phi(G^*).
$$

This concludes the proof of the lemma.

# <span id="page-33-0"></span>9 Concluding Remarks

In this work, we showed that there exists a monochromatic tight cycle partition of any large r-edgecoloured  $K_n^{(k)}$  with a number of cycles that is a polynomial of r. For  $k \geq 3$ , it is easy to construct an r-edge-coloured hypergraph which needs at least  $r$  monochromatic tight cycles to partition all the vertices. We show such a construction below for completeness.

**Proposition 9.1.** Let  $k, r \in \mathbb{N}$  such that  $k > 2$ . There exists an r-edge-coloured complete k-graph such that at least r monochromatic cycles are required for a monochromatic tight cycle partition of its vertex set.

*Proof.* Let H be a complete k-graph with vertex set partitioned as  $V = \bigcup_{i \in [r]} V_i$ , where  $V_1 \neq \emptyset$ , for distinct  $i, j \in [r]$ ,  $V_i \cap V_j = \emptyset$  and for each  $i \in [r] \setminus \{1\}$ ,

<span id="page-34-0"></span>
$$
|V_i| > (k-1) \sum_{j \in [i-1]} |V_j|.
$$
\n(9.1)

We colour each  $e \in E(G)$  with colour  $\phi(e) = \min\{i \in [r] : V_i \cap e \neq \emptyset\}$ . Let C be a set of vertex-disjoint monochromatic tight cycles that partition  $V(H)$ . It is enough to show that for each  $i \in [r]$ , there is a tight cycle in  $\mathcal C$  coloured i. Clearly, a monochromatic tight cycle  $C$  that contains at least one vertex from  $V_i$  satisfies  $\phi(C) \leq i$ . Let

$$
\mathcal{C}^{< i} = \{ C \in \mathcal{C} : V(C) \cap V_i \neq \emptyset \text{ and } \phi(C) < i \}.
$$

It suffices to show that  $V_i \nsubseteq V(\mathcal{C}^{&i})$ . Note that each  $C \in \mathcal{C}^{&i}$  satisfies  $|V(C) \cap \bigcup_{j < i} V_j| \geq |V(C)|/k$ and therefore  $|V(C) \cap V_i| \le (k-1) |V(C) \cap \bigcup_{j \le i} V_j|$ . We deduce that

$$
|V(C^{&i}) \cap V_i| \leq \sum_{C \in \mathcal{C}^{&i}} |V(C) \cap V_i| \leq (k-1) \sum_{j \in [i-1]} |V_j| \stackrel{(9.1)}{<} |V_i|.
$$

This completes the proof of the proposition.

When  $k = 2$  and  $r \geq 3$ , Pokrovskiy [\[21](#page-35-5)] showed that there exist infinitely many r-edge-coloured  $K_n$ which require at least  $r + 1$  monochromatic cycles. Lo and Pfenninger [\[16](#page-35-14)] showed that for any  $k \geq 3$ , there are 2-edge-coloured  $K_n^{(k)}$  that cannot be partitioned into two monochromatic tight cycles of distinct colours. It is interesting to consider whether the same holds for  $r$ -edge-coloured complete  $k$ -graphs when  $r, k \geq 3$ .

We believe that an r-edge-coloured  $K_n^{(k)}$  can be partitioned into linearly many monochromatic tight cycles.

**Conjecture 9.2.** Let  $r, k \in \mathbb{N}$  with  $r, k \geq 2$ . Then there exists a constant  $C = C(k)$  such that every r-edge-coloured  $K_n^{(k)}$  can be partitioned into at most  $Cr$  monochromatic tight cycles.

If one can strengthen Lemma [5.3](#page-7-1) to show that  $f(r, k)$  monochromatic tight cycles suffice, then our proof method would imply  $O(r \log r) + 2f(r, k) + 3$  cycles partition any r-edge-coloured  $K_n^{(k)}$ . The  $O(r \log r)$  term corresponds to the number of monochromatic cycles required to cover almost all the vertices.

**Conjecture 9.3.** For all  $r, k \geq 2$ , there exists  $C = C(k)$  such that any r-edge-coloured  $K_n^{(k)}$  contains at most Cr cycles covering  $(1 - o(1))n$  vertices.

Note that the case  $k = 2$  and general r is still open.
