## ABSTRACT

Searches for variations of fundamental constants require a comprehensive understanding of measurement errors. There are several potential sources of error and quantifying each one accurately is essential. This paper examines a source of error that is usually overlooked: the impact of continuum placement error. We investigate the problem using a high resolution, high signal to noise spectrum of the white dwarf G191–B2B. Narrow photospheric absorption lines allow us to search for new physics in the presence of a gravitational field approximately  $10^4$  times that on Earth. Modelling photospheric lines requires knowing the underlying spectral continuum level. We describe the development of a fully automated, objective, and reproducible continuum estimation method. Measurements of the fine structure constant are produced using several continuum models. The results show that continuum placement variations result in small systematic shifts in the centroids of narrow photospheric absorption lines which impact significantly on fine structure constant measurements. This effect should therefore be included in the error budgets of future measurements. Our results suggest that continuum placement variations should be investigated in other contexts, including fine structure constant measurements in stars other than white dwarfs. The analysis presented here is based on Ni v absorption lines in the photosphere of G191–B2B. Curiously, the inferred measurement of the fine structure constant obtained in this paper using Ni v (the least negative of our measurements is  $\Delta\alpha/\alpha = -1.462 \pm 1.121 \times 10^{-5}$ ) is inconsistent with the most recent previous G191–B2B photospheric measurement using Fe v ( $\Delta\alpha/\alpha = 6.36 \pm 0.35_{stat} \pm 1.84_{sys} \times 10^{-5}$ ). Given both measurements are derived from the same spectrum, we presume (but in this work are unable to check) that this  $3.2\sigma$  difference results from unknown laboratory wavelength systematics.

*Keywords:* Methods: data analysis, numerical, statistical – Techniques: spectroscopic – White dwarfs

## 1. INTRODUCTION

This is the first paper in a companion series of two. The second paper applies the methods developed here to a high resolution quasar spectrum.

In searches for spacetime variations of fundamen-

tal constants, it is essential to understand all possible sources of uncertainty, irrespective of a positive detection or upper limit. For absorption line measurements, one source of uncertainty that is often ignored in this context is that associated with imperfections in the continuum level against which absorption takes place. Existing continuum fitting methods, at least those we looked at, do not have the level of automation, reproducibil-

\*lee.chungchi16@gmail.com

<sup>†</sup>jw978@cam.ac.uk

ity, and accuracy required for high precision  $\Delta\alpha/\alpha$  measurements. Therefore, in this paper, we present a new, fully automated, spectral continuum fitting algorithm. This iterative method identifies and removes regions containing spectral features and then fits cubic splines to the remaining data points. The method is applied to a white dwarf spectrum obtained using the Space Telescope Imaging Spectrograph (STIS) on the Hubble Space Telescope (Section 4). By varying the continuum algorithm fitting parameters, i.e. generating different continuum models, we explore how variations in the adopted continuum model impact on measurements of the fine structure constant  $\Delta\alpha/\alpha = (\alpha_z - \alpha_0)/\alpha_0$ , where the subscripts  $z, 0$  indicate redshift and the terrestrial value, and where the fine structure constant  $\alpha = e^2/4\pi\epsilon_0\hbar c$  in SI units.

The analysis in this paper applies specifically to measurements along the lines of [Berengut et al. \(2013\)](#), in which the initial continuum that is fitted to the spectrum to be analysed is never subsequently modified i.e. any potential  $\Delta\alpha/\alpha$  systematic associated with continuum placement uncertainty is not explicitly taken into account. Many previous quasar absorption system  $\Delta\alpha/\alpha$  measurements have also ignored this source of uncertainty. As we discuss shortly,  $\Delta\alpha/\alpha$  measurements in which profile modelling is carried using codes like VPFIT and AI-VPFIT can allow the introduction of additional parameters for fine-tuning the local continuum for each spectral segment fitted, as done in, for example, [Hu et al. \(2021\)](#). In that kind of analysis, the impact of initial continuum placement errors may be much smaller than the effects we report in the present paper.

## 2. LINE SHIFT VS. CONTINUUM SLOPE VARIATION AND POTENTIAL IMPACT ON $\Delta\alpha/\alpha$

Discussions on different methods, in various contexts, for spectral line centroiding are given in [Garnir et al. \(1987\)](#); [Guo \(2011\)](#); [Ipsen \(2017\)](#); [Kandel et al. \(2017\)](#); [Teague & Foreman-Mackey \(2018\)](#); [Rodgers & Iliadis \(2021\)](#). Consider a single absorption line measured relative to a model continuum that is tilted with respect to the true underlying continuum. The measured centroid will be slightly different to that derived using the true continuum, potentially emulating  $\alpha$  variation. Here we develop a simple model to illustrate this effect.

The measured rest-frame frequency  $\omega_z$  of an atomic transition at redshift  $z$  is related to a change in the fine structure constant by

$$\omega_z = \omega_0 + q \left( \frac{\alpha_z^2}{\alpha_0^2} - 1 \right) \quad (1)$$

where  $\omega_0$  is the terrestrial value and  $q$  is the sensitivity coefficient, [Dzuba et al. \(1999a\)](#); [Webb et al. \(1999\)](#). Eq. (1) can be used to obtain

$$\Delta\lambda \approx -\frac{2q\lambda_0^2}{10^8} \frac{\Delta\alpha}{\alpha}, \quad (2)$$

where  $\lambda_0$  is in  $\text{\AA}$ . Taking a representative transition with  $|q_{Niv}| \approx 2000 \text{ cm}^{-1}$  and a rest-frame wavelength  $\lambda_0 = 1500 \text{ \AA}$ , Eq. (2) gives

$$|\Delta\lambda| = 90 \left| \frac{\Delta\alpha}{\alpha} \right|, \quad (3)$$

from which we see that for a  $\Delta\alpha/\alpha$  measurement uncertainty contribution of  $\sim 10^{-6}$ , any wavelength shift  $\gtrsim 10^{-4} \text{ \AA}$  is of concern. To see if this is possible, approximate optical depth using a Gaussian model,

$$\tau_x = \tau_0 \exp\left(-\frac{x^2 \ln 2}{g^2}\right) \quad (4)$$

where  $x = \lambda - \lambda_0$ ,  $\lambda_0$  is the central wavelength,  $\tau_0$  is the optical depth at  $x = 0$ ,  $g = b\lambda_0/c$ ,  $b = \sqrt{kT/m}$ ,  $k$  is Boltzmann's constant,  $T$  is temperature,  $m$  is atomic mass, and  $c$  is the speed of light in vacuum.

The profile intensity is  $I_x = I_0 \exp(-\tau_x)$ , where  $I_0$  is the true continuum. Now introduce a small change on the true continuum, emulating a continuum-fitting uncertainty, parameterised using a multiplicative term, such that the profile intensity becomes

$$I'_x = I_x \left( c_l + c_s \left( \frac{\lambda}{\lambda_0} - 1 \right) \right), \quad (5)$$

where the parameters  $c_l$  and  $c_s$  allow for a level and slope change. This method for continuum adjustment was introduced in VPFIT ([Carswell & Webb 2023](#)). Then, using

$$e^{-\tau_x} = \sum_{n=0}^{\infty} \left( -\frac{\tau_x}{n!} \right)^n, \quad (6)$$

and taking only the first two terms in the expansion such that we are assuming the optically thin case (sufficient for our illustrative purposes here),

$$I_x \simeq I_0(1 - \tau_x). \quad (7)$$

The line centroids using the true continuum, and the continuum after adjustment according to Eq. (5), are given by

$$C = \frac{\int_{-\infty}^{\infty} A_\lambda \lambda d\lambda}{\int_{-\infty}^{\infty} A_\lambda d\lambda}, \quad \text{and} \quad \tilde{C} = \frac{\int_{-\infty}^{\infty} \tilde{A}_\lambda \lambda d\lambda}{\int_{-\infty}^{\infty} \tilde{A}_\lambda d\lambda} \quad (8)$$

where  $A_x = I_0 - I_x$  and where

$$\tilde{A}_\lambda = \frac{A_\lambda}{c_l + c_s x/\lambda_0} \simeq \frac{A_\lambda}{c_l} \left( 1 - \frac{c_s x}{c_l \lambda_0} \right). \quad (9)$$

From the equations above, one can derive  $C = \lambda_0$  and

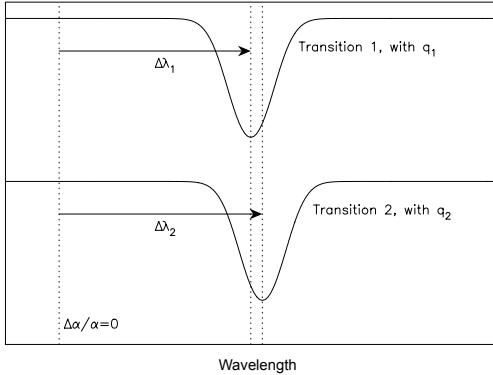

$$\begin{aligned} \tilde{C} &= \lambda_0 + \frac{\int_{-\infty}^{\infty} A_\lambda \left( 1 - \frac{c_s x}{c_l \lambda_0} \right) x dx}{\int_{-\infty}^{\infty} A_\lambda \left( 1 - \frac{c_s x}{c_l \lambda_0} \right) dx} \\ &\simeq \lambda_0 - \frac{g^2}{2 \ln 2} \frac{c_s}{c_l \lambda_0}, \end{aligned} \quad (10)$$

where we have put  $A_\lambda \simeq \tau_\lambda$ . Then, the wavelength shift due to the continuum variation is

$$\Delta\lambda = \tilde{C} - \lambda_0 = -\frac{b^2 \lambda_0}{(2 \ln 2) c^2} \frac{c_s}{c_l}. \quad (11)$$

If we now consider 2 transitions, with sensitivity coefficients  $q_1$  and  $q_2$ , Eqs. (2) and (11) can be used to obtain

$$\frac{\Delta\alpha}{\alpha} = \frac{10^8}{4 \ln 2} \frac{b^2}{c^2 \lambda_0} \frac{1}{(q_1 - q_2)} \frac{c_s}{c_l} \approx \frac{0.04 c_s}{\lambda_0 (q_1 - q_2)}. \quad (12)$$

**Figure 1.** Illustration of 2 transitions used to measure  $\Delta\alpha/\alpha$ , where  $\Delta q \ll |q|$ . Both transitions shift far from their  $\Delta\alpha/\alpha = 0$  positions, but since  $\Delta q$  is small, a pair of lines with this property have (by themselves) little sensitivity to a change in  $\alpha$ . In this case, the denominator in Eq. (12) is small and the measured value of  $\Delta\alpha/\alpha$  is poorly constrained.

where in the last term we have taken an illustrative  $b = 10 \text{ km s}^{-1}$  and used  $c_l \approx 1$  (adjustments to  $c_l$  should not impact on the line position measurement). Recalling that  $c_s$  describes a local continuum tilt with respect to the true value, Eq. (5) can be used (by taking representative values for  $\lambda/\lambda_0$ ) to show that a reasonable expected range for the slope parameter is  $0 \lesssim |c_s| \lesssim 100$ .

For a pair of transitions with  $q_1 \approx q_2$ , as illustrated in Fig. 1, constraints on  $\Delta\alpha/\alpha$  are poor. However, taking the upper limit of  $c_s \sim 100$ , we can use Eq. (12) to approximate the impact on the measured  $\Delta\alpha/\alpha$  associated with a continuum slope uncertainty, of  $\sim 3 \times 10^{-6}$  (representative of best-case  $\Delta\alpha/\alpha$  uncertainties to date, ignoring continuum slope errors). The simple analytic analysis above is only illustrative, because a real measurement involves the simultaneous use of a large number of transitions. Nevertheless, the above suggests that continuum uncertainty may contribute significantly to the overall  $\Delta\alpha/\alpha$  error budget, for this kind of linear regression analysis, motivating the more detailed numerical modelling described in the following Sections.

### 3. CONTINUUM FITTING PROCEDURE

Several continuum fitting algorithms have been reported previously in the literature, mostly for quasar spectroscopy, although none are suitable for our requirement here of fitting the HST/STIS G191–B2B continuum. The particular problem we face is that the G191–B2B HST data exhibit many small-scale undulations against which absorption lines of interest must be measured, as can be seen in e.g. the Appendix spectral plots.

We did not entertain the possibility of using a stellar synthesis code as a means to estimate an underlying continuum because: (i) whilst some undulations are presumably due to blends of weak absorption lines, others (possibly the majority) are caused by imperfect spectral order flattening prior to combination into a co-added one-dimensional spectrum. In any case, incomplete input atomic data may mean that a stellar synthesis code may not identify all weak blends. Comparisons (and discrepancies) between synthetic stellar spectra and observations are given in e.g. Coelho (2014); Coelho et al.

(2020); (ii) our aim was to produce a generalised continuum fitting method, useful for various kinds of astronomical spectra.

Examples of previous continuum fitting procedures include: Eilers et al. (2017) apply a Bayesian method to estimate continuum levels for Lyman alpha forest data. Sánchez-Monge et al. (2018) describe Python software STATCONT. Ciollaro et al. (2014) develop methods applied to Hubble Space Telescope Faint Object Spectrograph and Baryon Oscillation Spectroscopic Survey spectra. Lee et al. (2012); Davies et al. (2018) discuss principal component analysis methods to estimate continua in the Lyman- $\alpha$  forest, for SDSS data i.e. at lower spectral resolution. Pâris et al. (2011) use a PCA method to estimate quasar continua over the full wavelength range. Suzuki et al. (2005) also uses principal component analysis methods to estimate continua in high resolution Lyman- $\alpha$  forest data. Aghaee et al. (2009) compare various Lyman- $\alpha$  forest continuum fitting approaches. Many other methods exist, but we are not aware of any that could provide the level of detail needed for absorption complex modelling in high resolution spectra (and do so in an objective, automated, and reproducible way). Given the lack of any existing suitable method (for our application), we therefore developed the new continuum modelling procedure described next.

The first step towards obtaining the final estimated continuum is to make a preliminary model using cubic splines. To do this we first identify significant absorption and emission profiles in order to be able to fit cubic splines to feature-free spectral segments. The method for identifying features is discussed shortly. One problem to avoid is allowing the continuum model to follow an absorption profile, thereby effectively removing it. For example, consider a shallow absorption profile, spread across  $\sim 2 \text{ \AA}$  such that it is reasonably well fitted by a cubic spline with a knot interval of  $0.5 \text{ \AA}$ , such that the absorption line can be accidentally removed. This problem can be avoided by flagging the data points within the absorption line prior to fitting the cubic spline model. Doing this interactively prior to the continuum fitting stage would be both time consuming and subjective. Therefore, we instead iteratively increase the spline order: the initial model is a single cubic spline, after which the number of knots is doubled at each subsequent iteration. Figure 2 shows two loops: loop A (iterating over stages 2-5) and loop B (iterating over stages 2-6). Each loop has its own specific stopping criterion. These are discussed shortly (Sections 3.5 and 3.6).

#### 3.1. Stage 1: Re-bin and smooth spectrum

The optical depth associated with absorption features in the spectrum is given by

$$\tau_{tot}(\lambda) = \sum_i \tau_{abs}^i(\lambda) \quad (13)$$

where  $\tau_{abs}^i$  is the optical depth associated with an individual  $i^{th}$  absorption line and where the sum is taken over all absorption (or emission) lines present in the model. The observed spectrum is the sum of three terms,

$$I(\lambda) = I_0(\lambda)e^{-\tau_{tot}(\lambda)} + I_{em}(\lambda) + I_n(\lambda), \quad (14)$$

where  $I_0$ ,  $I_{em}$ , and  $I_n$  are the underlying continuum from the object being observed, the emission line spectrum, and noise, respectively. The noise term has several contributions, e.g. photon counting from the object, photon counting from the sky, assuming the spectrum is sky-subtracted, detector read-out noise, detector dark current, cosmic rays, and any detector defects that have not been fully removed in the data pre-processing.

In Stage 1 we smooth the data by convolving the spectrum with a Gaussian function. We first re-bin the spectrum onto a finer grid (with pixel size 1/10 the original value). The re-binned spectrum is then smoothed using a Gaussian. The FWHM of the smoothing Gaussian is taken to be a multiple of the mean original pixel size  $\bar{x}$  (over the entire spectrum). The default pixel space is in Å and in practice a value of  $3\bar{x}$  for the FWHM was found to work well, but this is a user-defined quantity. The observed pixel size is approximately constant in velocity units, so convolution is done in velocity space. This initial smoothing is helpful in the next Stage where we calculate the derivative of the spectrum. Stage 1 is only carried out once - it is not included in subsequent loops (as illustrated in Fig. 2).

### 3.2. Stage 2: Preliminary feature identification

In order to determine whether a pixel in the spectrum falls within an absorption (or emission) feature, or whether it can be considered as a continuum pixel, two properties are examined: the closeness of the pixel intensity to the current continuum estimate and the derivative of the smoothed spectrum. The derivative spectrum is obtained using the re-binned smoothed spectrum from Stage 1.

The first step is to make a preliminary identification of all absorption (or emission) features in the data. To do this we make simple use of the rebinned, smoothed derivative spectrum from Stage 1; the largest  $x\%$  of the data points in that spectrum (across the entire spectrum) are identified (using a simple array sort) and excluded. In practice we found  $x = 30\%$  works well. This process of course identifies line edges where the derivative is high (but also, necessarily) line centres are *not* selected.

Having selected the points as described above, an initial straight line continuum is fitted. This initial continuum will of course be only a very crude representation of the true continuum. Then, now having selected low-slope data points (the remaining  $100 - x\%$ ) and with a preliminary (lowest order) continuum fit, we calculate the normalised chi-squared,  $\chi_\nu^2$  over the selected data points,

$$\chi_\nu^2 \approx \frac{\chi^2}{M_s} \quad (15)$$

$$\chi^2 = \sum_{i=1}^{M_s} \left( \frac{I_i - C_i}{\sigma_i} \right)^2, \quad (16)$$

where  $C_i$  is the current estimated continuum value at  $i^{th}$  pixel,  $\sigma_i$  is the  $1\sigma$  intensity uncertainty, and  $M_s$  is the total number of selected data points. Prior to refinement, with only a crude continuum fit, the initial value of  $\chi_\nu^2 \gg 1$ . To reject data points at line centres we search for pixel values having  $(I_i - C_i)^2 / \sigma_i^2 > \zeta^2 \chi_\nu^2$ , using a default value of  $\zeta = 3$  to correspond approximately to  $3\sigma$  deviations.

### 3.3. Stage 3: Adjust number of knots

At first pass through Stage 3 (when  $K_i = 0$ ), the continuum model is very simple (initially only a straight line) so Stage 3 applies only to higher iterations. During the development of a continuum model, the number of cubic splines increases. It is possible that at certain positions along the spectrum, only a few continuum data points are available to fit. If this happens, that segment of the continuum will of course be poorly determined. Therefore, Stage 3 checks that a sufficiently large number of data points is present between each knot pair. The minimum acceptable number of continuum data points between each knot pair is a user-defined parameter, having a default value of  $k_{merge} = 1/3$ , this parameter being the fraction of pixels available within the range defined by the knot pair. When there are too few continuum data points left between any particular knot pair, the two flanking regions are checked and the test region merged into whichever side region has the least continuum data points (such that the knot spacing is no longer necessarily regular).

### 3.4. Stage 4: Solve for search direction

By the end of Stage 3, the model continuum can comprise a large number of free parameters. The goal is to minimise  $\chi^2$  between the cubic spline model and the set of continuum data points. We do this using a standard non-linear least-squares procedure. The components of the gradient vector  $g(a, b)$  and of the Hessian matrix  $H_{ab}$  are

$$g_a = \frac{\partial \chi^2}{\partial y_a}, \quad (17)$$

$$H_{ab} = \frac{\partial^2 \chi^2}{\partial y_a \partial y_b}, \quad (18)$$

where  $y_a, y_b$  are the knot values (i.e. intensities) at positions  $a$  and  $b$ . Then we apply a standard Gauss-Newton minimisation procedure,

$$H_{ab} p_b = -g_a, \quad (19)$$

where  $p_b$  is the search direction, providing the best-fit set of knot intensities. Detailed descriptions of optimisation methods, including this one, can be found in many books, an excellent example being Gill et al. (1981).

### 3.5. Stage 5: Update parameters

The model continuum parameters are updated (using univariate minimisation) by finding the scalar  $d$  which minimises  $\chi^2$ . The updated parameters are then

$$\bar{y}_b = y_b + p_b \times d. \quad (20)$$

The values of  $\chi_\nu^2$  for the current and previous iterations are compared and if they differ by more than a value of  $\chi_{thres}^2$ , the algorithm returns to an earlier stage (analogous to Stage 2) and re-identifies all absorption and emission features using the newly updated continuum model. This is illustrated in Figure 2 by the ‘‘Refining’’ box. If the difference is smaller than  $\chi_{thres}^2$ , the algorithm moves to Stage 6. The default value of  $\chi_{thres}^2$  is  $10^{-3}$  (although this can be user-defined). Final results are rather insensitive to this parameter.

### 3.6. Stage 6: Increase order of fit

At this stage, the number of cubic spline knots is  $K_i$ .  $K_f$  is the full data range divided by the smallest permitted knot spacing and is a user input, specified to terminate the algorithm. If  $K_i < K_f$ , the algorithm thus iterates further as indicated in Figure 2. We choose the form for the evolution of the number of knots  $K_i \rightarrow K_{i+1}$  to be

$$K_{i+1} = \text{Int} \left( \frac{K_f}{2^{n_i}} \right), \quad (21)$$

where  $n_i = \text{Int}(\log_2 K_f - i + 1)$ , such that the number of knots approximately doubles at each successive iteration.

However, the number of knots used has to be carefully considered. For example, to avoid over-fitting, one should avoid making the knot spacing comparable to or smaller than the width of an absorption line or blended feature. Also, the STIS echelle format means that many spectral orders are pieced together to form a final one dimensional spectrum. The order flattening process is imperfect and small wiggles may remain in the final one dimensional spectrum on scales corresponding to the order separation. Approximately matching the knot density to that scale enables the continuum model to follow these undulations and hence can help remove this effect. Detailed descriptions of STIS data reduction procedures are given in e.g. Ayres (2010, 2022).

### 3.7. Refining: Re-identify Absorption and Emission Lines

If the conditions for further iterations specified in Stages 5 and 6 are satisfied (see Figure 2), the algorithm return to re-identify all absorption and emission features, relative to the current continuum fit. The procedure during refinement is similar to Stage 2:

1. Moving out from an absorption line centre, one can specify a point at which the observed intensity recovers to the underlying continuum level (within some tolerance). Also, once the intensity recovers to the local continuum level, noise fluctuations mean that the derivative is likely to change sign away from the absorption line centre. Thus we locate the point at which the derivative of the smoothed spectrum changes sign, moving outwards from the line centre. These points (left and right of each spectral line centre) provide a *preliminary* estimate of the feature boundaries and hence define an initial set of continuum pixels. However, several further steps refine these initial estimates.
2. Having identified feature edges, i.e. discarded pixels within and near to absorption (or emission) features, we now attempt to put previously excluded pixels back into the set used for continuum fitting. For each pixel in the unsmoothed spectrum, we calculate the intensity difference between it and the current continuum estimate. If the pixel in the unsmoothed spectrum is very close to the current continuum, it can be “re-assigned” as a pixel to be used the continuum fit, whether or not it formed part of the preliminary continuum pixel set. However, to be re-assigned, it must satisfy a second condition: the derivative of the smoothed spectrum at that

point must be below a specified threshold. In this way, additional pixels are picked up to be used in fitting a continuum function.

To express the above more rigorously, let the intensity of the  $i^{\text{th}}$  pixel in the original unsmoothed spectrum be  $I_i$ , with uncertainty  $\sigma_i$ . Also let the intensity of the  $i^{\text{th}}$  pixel in the current continuum estimate be  $C_i$ . Then let

$$\Delta_i = |(I_i - C_i)/\sigma_i|, \quad (22)$$

and  $d_i$  be the derivative of the smoothed original spectrum. We then require both  $\Delta_i$  and  $d_i$  to be smaller than threshold values. The threshold values are defined as follows. For all continuum pixels, we compute the distribution of  $\Delta_i$  and determine its standard deviation,  $\sigma_D$ . The same is done for  $d_i$  to determine  $\sigma_d$ . For a pixel to be “re-assigned” as a continuum pixel, we then require, simultaneously,

$$\Delta_i < \sigma_D \text{ and } d_i < \sigma_d \quad (23)$$

3. A further check is now made on pixels that are deemed to be free from absorption or emission features i.e. pixels that are used to fit a continuum fit to. For this test, we use a normalised spectrum i.e. the original spectrum has been divided by the continuum fit. For each contiguous continuum segment i.e. a set of  $M$  pixels that are all deemed to be continuum pixels, linear regression is used to determine that segment’s slope  $s$  and its uncertainty  $\sigma_s$ . Provided  $s - k\sigma_s \leq 0 \leq s + k\sigma_s$ , that segment remains identified as a continuum segment, where  $k$  is a user defined parameter with a default value of 4.0.

The first two conditions above generally succeed in identifying and excluding strong and relatively narrow absorption lines whilst the third condition helps to identify shallow and weaker lines. These conditions above apply equally the emission lines (with a minus sign on the tests). However, at this stage there may nevertheless still be true continuum pixels that have been discarded. Therefore one further test is done:

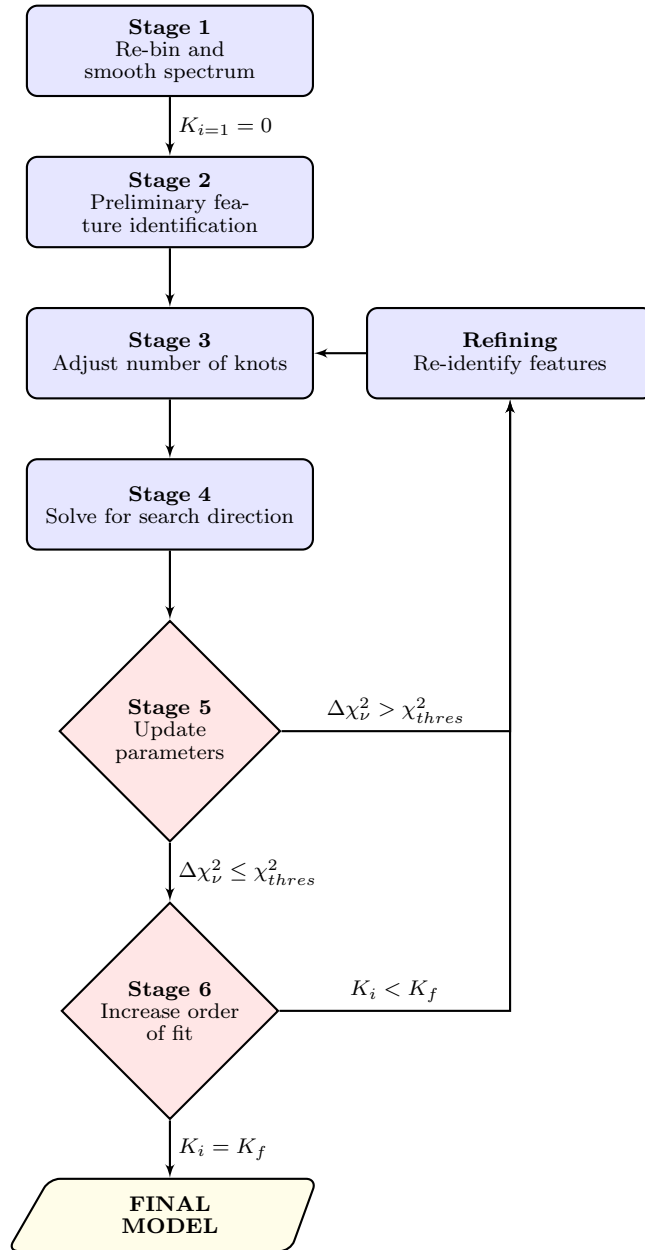

4. Where a contiguous set of  $n$  or more pixels (default  $n = 10$ ) lies *above* the continuum fit, if  $|d_i| < \sigma_d$ , those pixels are re-assigned as being pixels to include in the continuum fit.

The whole process described above is illustrated as a flowchart in Figure 2.

## 4. APPLICATION TO A HIGH RESOLUTION SPECTRUM OF THE WHITE DWARF G191–B2B

### 4.1. Astronomical data

The astronomical data used is the Hubble Space Telescope STIS spectrum of the well known white dwarf G191–B2B. The data were obtained using the E140H grating, with resolution  $R \approx 114,000$  (the highest currently available for UV astronomical spectroscopy), and have a signal to noise  $\sim 100$  per resolution element. A comprehensive description covering both the observational data and the data reduction processes is given in

**Figure 2.** This flow chart summarises the continuum fitting model based on spline fitting with automated line removal.  $K_i$  indicates the number of cubic spline knots used at the  $i^{th}$  iteration.  $K_f$  is the number of knots used for the final best-fit continuum model. See Section 3 for details.

Appendix A of Hu et al. (2019). This object/spectrum was chosen because: (a) several detailed studies of it already exist, including measurements of  $\Delta\alpha/\alpha$ , Berengut et al. (2013); Hu et al. (2021); (b) the STIS echelle instrument format means individual spectral orders are extracted from the detector individually before combination to form a continuous 1-d spectrum. This means the data are fairly “challenging” in that weak undulations in the apparent continuum are present due to imperfect order flattening prior to combination (as seen in the illustrations later in this paper); (c) the spectrum is riddled with hundreds of photospheric absorption lines, Preval et al. (2013), that must be

detected and removed prior to (or in conjunction with) estimating the underlying continuum. Nevertheless, the G140H STIS spectrum of G191–B2B may be considered atypical due to its high signal to noise such that the settings used in the continuum fitting code (Section 3) for this particular spectrum may of course need tuning for other applications.

#### 4.2. Atomic data

In this analysis we opted to use Ni V transitions and atomic data. Ni V wavelengths and energy level measurements have been published in Raassen et al. (1976);

Raassen & van Kleff (1976); Ward et al. (2019). Errors in the published values from Ward et al. (2019) were found and corrected by Kramida et al. (2022). The Ni v wavelengths used in this analysis are those given in the *NIST Atomic Spectra Database database v10*.

In order to assess the impact of variations in the fitted continuum level on  $\Delta\alpha/\alpha$  measurements, we broadly follow the procedures described in Berengut et al. (2013). To do so we require input rest-frame wavelengths and sensitivity coefficients describing wavelength shifts as a function of  $\Delta\alpha/\alpha$  ( $q$ -coefficients), calculated using Eq. (1).

Calculations of sensitivity coefficients applied in an astronomical context were first described in Dzuba et al. (1999b,a). Ni v (and Fe v)  $q$ -coefficients for UV transitions were first reported in Ong et al. (2013). Improved  $q$  calculations are provided in Hu et al. (2021), but only for Fe v and not for Ni v. For the calculations described in the present paper, we have revised the Ni v  $q$ -coefficients given in Ong et al. (2013) using the same methods described in Hu et al. (2021). We therefore do not re-iterate technical details provided in those papers and provide the relevant atomic data tables as online supplementary material, in which the transition frequencies and  $q$ -coefficients are presented in units of  $\text{cm}^{-1}$ .

### 5. $\Delta\alpha/\alpha$ MEASUREMENTS USING DIFFERENT CONTINUUM MODELS

We now show how continuum uncertainty impacts on  $\Delta\alpha/\alpha$  measurements. Our  $\Delta\alpha/\alpha$  analysis for white dwarfs follows that of Berengut et al. (2013), and not the analysis of Hu et al. (2021). The former is far simpler because observed line wavelengths are measured using a simple centroiding procedure – no absorption profile modelling is carried out. In the analysis of Hu et al. (2021), each absorption feature is fitted using one or more Voigt profiles and in this case small variations in the continuum level can give rise to changes in the number of absorption components required, which in turn changes relative positions. The procedure of Hu et al. (2021) has another advantage over that of Berengut et al. (2013); the VPFIT and AI-VPFIT modelling procedures allow for the inclusion of additional free parameters, to refine the local continuum of each spectral segment in the model, as shown in Eq. (5) and discussed in Section 2. We address this in a companion paper, in the same volume of this journal.

Measuring the relative positions of a large number of narrow photospheric absorption lines allows us to explore whether the fine structure constant  $\alpha$  varies in the presence of strong gravity. For discussions on this and general overviews see e.g. Magueijo et al. (2002); Barrow (2005); Flambaum & Shuryak (2008); Uzan (2011); Berengut et al. (2013); Bainbridge et al. (2017); Hu et al. (2021). Repeating measurements using different continuum models quantifies the sensitivity of the measured  $\alpha$  to small variations in the continuum. We therefore generated four example model continua, using knot spacings of 0.5, 0.75, 1.0, and 1.25 Å. The range is intended to bracket (for our specific spectrum i.e. the STIS G191–B2B data) a plausible range of values within which the returned continuum fits look reasonable. Figure 3 illustrates one

continuum model derived using the method described in Section 3 using a knot spacing of 0.75 Å. Plots using other settings are provided as online supplementary material. As can be seen in Figure 3, the data reveal many slight small-scale undulations (discussed earlier in Section 3) that seem to be followed fairly well by this model.

Using these four continua, we then detect absorption lines which are significant at or above  $5\sigma$  (see Table 1). This number of lines identified at or above this significance limit, in the range 1150 Å to 1894 Å, for each of the four knot spacings, is also given in Table 1). Using custom Python code, the observed feature wavelengths were then shifted to the rest-frame using a G191–B2B redshift of  $23.8 \pm 0.03 \text{ km s}^{-1}$  from Preval et al. (2013)). The rest-frame wavelengths were then matched to recently updated Ni v laboratory wavelengths (provided as online supplementary material), where a match was accepted for agreement equal to or better than  $3\sigma$ , allowing for both observational and laboratory wavelength uncertainties. For each knot spacing, a total of 299, 316, 325 and 320 potential Ni v matches were made respectively, of which 258, 270, 281 and 278 have associated  $q$ -coefficients (see Table 1). However, as can be seen in Table D, there are many cases where multiple identifications are possible. All multiple IDs are removed from the linear regression procedure to measure  $\Delta\alpha/\alpha$ . Finally, a visual inspection of Figure 3 shows that there are a few spectral regions that need to be avoided: [1205, 1227], [1238,1241], [1242,1243.5], [1345,1347] Å. All Ni v transition within these 4 windows are discarded.

Having identified the lines to be used, we follow a similar procedure to that used in Berengut et al. (2013). The observed-frame wavelength  $\lambda_{obs,i}$  of the  $i^{th}$  absorption line in the white dwarf photosphere, and the corresponding rest-frame laboratory wavelength  $\lambda_{0,i}$ , are related by

$$\begin{aligned} \frac{\lambda_{obs,i} - \lambda_{0,i}}{\lambda_{0,i}} &= \frac{\Delta\lambda_i}{\lambda_{0,i}} = z - \frac{2q_i\lambda_{obs,i}}{10^8} \frac{\Delta\alpha}{\alpha_0} \\ &= z - Q_i \frac{\Delta\alpha}{\alpha_0} \end{aligned} \quad (24)$$

where wavelengths are in Å,  $q_i$  (in  $\text{cm}^{-1}$ ) is the relative sensitivity of the transition frequency to variation in  $\alpha$ ,  $z$  is the white dwarf redshift (comprising gravitational and kinematic contributions), and  $\Delta\alpha/\alpha = (\alpha_{WD} - \alpha_0)/\alpha_0$ .

A linear regression analysis on the matched Ni v lines is then used to solve for the parameters  $z$  and  $\Delta\alpha/\alpha$ , for each of the four model continua. The results of this are given in Table 1 and, for one example knot spacing, illustrated in Figure 4 (details for all knot spacings are given in the Supplementary Material. The table also gives the reduced chi-squared, which in this case is

$$\chi^2_\nu = \frac{1}{N-2} \sum_{i=1}^N \left( \frac{y_i - (\Delta\lambda/\lambda_0)_i}{\sigma(\Delta\lambda/\lambda_0)_i} \right)^2 \quad (25)$$

Clearly, the  $\chi^2_\nu$  values are larger than the expected value of unity for a good fit to the data. This is unsurprising: the scatter in the “continuum” points fitted will be increased by the presence of weak unidentified absorption lines that were not detected using the  $5\sigma$  detection threshold. Further, the continuum model is likely to be inadequate in places for the instrumental/data process-

**Figure 3.** G191–B2B continuum model with 0.75 Å knot spacing.

**Figure 4.** Eq. (24) for one example trial continuum (0.75Å knot spacing). Grey points were removed when  $\sigma$ -clipping was applied. See Section 5 for details.

| Knot spacing (Å)   | 0.5                | 0.75               | 1.0                | 1.25               |
|--|--------------------|--------------------|--------------------|--------------------|
| <b>5<math>\sigma</math> detections</b>                           | 1566               | 1678               | 1789               | 1752               |
| <b>NiV matches total</b>   | 299                | 316                | 325                | 320                |
| <b>NiV matches having q (no <math>\sigma</math>-clipping)</b>    | 167                | 165                | 163                | 164                |
| $\Delta\alpha/\alpha \times 10^{-5}$                             | $-1.530 \pm 1.101$ | $-1.462 \pm 1.121$ | $-1.624 \pm 1.156$ | $-1.980 \pm 1.150$ |
| $z \times 10^{-5}$   | $7.957 \pm 0.085$  | $7.962 \pm 0.087$  | $7.940 \pm 0.090$  | $7.920 \pm 0.090$  |
| $\chi^2_\nu$   | 1.950              | 1.869              | 1.943              | 1.918              |
| <b>NiV matches having q (after <math>\sigma</math>-clipping)</b> | 125                | 128                | 125                | 127                |
| $\Delta\alpha/\alpha \times 10^{-5}$                             | $-2.153 \pm 1.193$ | $-1.771 \pm 1.187$ | $-2.856 \pm 1.229$ | $-2.625 \pm 1.215$ |
| $z \times 10^{-5}$   | $7.955 \pm 0.092$  | $7.968 \pm 0.092$  | $7.888 \pm 0.095$  | $7.906 \pm 0.095$  |
| $\chi^2_\nu$   | 0.995              | 0.980              | 0.982              | 0.997              |

**Table 1**

The impact of using different white dwarf continuum models on measurements of  $\Delta\alpha/\alpha$ . Four model continua, each corresponding to a different knot spacing. The results show that the additional uncertainty on  $\Delta\alpha/\alpha$  associated by continuum placement variation is comparable to or even larger than the statistical uncertainty. The first row gives the total number of 5 $\sigma$  NiV detections in the HST STIS spectrum. The second row shows the total number of lines identified as potential NiV, matched within 3 $\sigma$  of the Ward et al. laboratory list (allowing for the white dwarf redshift), including multiple potential IDs. Where more than 1 possible match exists (see Appendix D), we discard that line entirely from further analysis. Observed and laboratory wavelength matches were made using the newly calculated NiV  $q$ -coefficients and the Ward et al. (2019) NiV laboratory wavelengths updated as part of this work by A. Kramida. The second block in the table shows measurements for all lines that have  $q$  coefficient calculations (given in Appendix C). The third block shows the same thing as the second block, except deviant points (measured in units of  $\sigma$ ) were iteratively clipped during linear regression until  $\chi^2_\nu \leq 1$ .  $\chi^2_\nu$  is defined by Eq.(25). The other continuum fitting parameter settings are: smoothing FWHM  $3\bar{x}$  (Section 3.1),  $\zeta = 3$  (Section 3.2),  $k_{merge} = 1/3$  (Section 3.3),  $n = 10$  (Section 3.7).

ing reasons explained previously.

### 5.1. Potential bias

The impact of *assuming*  $\Delta\alpha/\alpha = 0$  when matching laboratory and white dwarf lines was discussed in [Hu et al. \(2021\)](#) (see section 5.2 and figure 2 in that paper). That numerical experiment was carried out using Fe V, altering the input assumption multiple times, using a range  $\Delta\alpha/\alpha = \pm 10^3$ , in steps of  $\Delta\alpha/\alpha = 10^{-5}$ . No evidence was seen for bias in the [Hu et al. \(2021\)](#) analysis. Nevertheless, it should not necessarily be assumed that there is no bias in the analysis carried out here using Ni V. It is possible that the assumption of  $\Delta\alpha/\alpha = 0$  when performing line identifications may result in some fraction of false identifications, potentially biasing the slope in Fig. 4. However, our focus in this paper is to explore the impact of continuum placement. A detailed study of this kind of bias, in the sense described above, is beyond the scope of the present work, but we note the potential issue here to motivate explicit checks in future measurements.

## 6. DISCUSSION AND FUTURE WORK

In this work we have developed a new algorithm for continuum fitting high resolution spectra. The method is automated, reproducible, and objective. Here we have applied it to a high-resolution, high signal-to-noise HST/STIS spectrum of the white dwarf G191–B2B. In a companion article we apply it to quasar spectroscopy. Using this algorithm we obtained four different estimates for the underlying G191–B2B continuum in order to examine the impact of continuum placement uncertainties on measurements of the fine structure constant in the strong gravitational field at the G191–B2B photosphere.

An earlier analysis ([Berengut et al. 2013](#)) found anomalous results when comparing  $\Delta\alpha/\alpha$  measurements derived using Fe V and Ni V transitions detected in the G191–B2B photosphere. We draw attention to figure 1 in that paper, where different slopes were found using the linear relationship expressed in Eq.(24); they found  $\Delta\alpha/\alpha = (4.2 \pm 1.6) \times 10^{-5}$  and  $(-6.1 \pm 5.8) \times 10^{-5}$  for Fe V and Ni V respectively. The interpretation suggested in ([Berengut et al. 2013](#)) was that systematics were present in the available Ni V laboratory wavelength measurements.

More recently, [Hu et al. \(2021\)](#) carried out a more detailed analysis using Fe V transitions, using the same astronomical data. The best result found by [Hu et al. \(2021\)](#) is  $\Delta\alpha/\alpha = (6.36 \pm 0.35_{stat} \pm 1.84_{sys}) \times 10^{-5}$ , consistent with the earlier Fe V result from [Berengut et al. \(2013\)](#).

New, independent Ni V laboratory wavelength measurements have been made ([Ward et al. 2019](#)). Also, new sensitivity coefficient ( $q$ ) calculations have been carried out and reported in this paper (Appendix C). These new data thus allow us to re-examine the apparent Fe V/Ni V inconsistency previously reported. Comparing the best available Fe V measurement ([Hu et al. 2021](#)) with the most positive result obtained in the present work (no  $\sigma$ -clipping, 0.75Å knot spacing, see Table 1), a significant ( $3.2\sigma$ ) discrepancy remains (more significant if we take any of the other Ni V measurements obtained in the present work).

Our main results from this work therefore are:

1. Slight changes in the underlying continuum can impact on  $\Delta\alpha/\alpha$  measurements, as illustrated in Table 1; the additional uncertainty on  $\Delta\alpha/\alpha$  associated with continuum placement variations is not negligible compared to the statistical (i.e. covariance matrix) uncertainty on  $\Delta\alpha/\alpha$ .
2. Curiously, the  $\Delta\alpha/\alpha$  measurements we have made, using entirely independent Ni V laboratory wavelengths and new  $q$  coefficients, are still of opposite sign to the Fe V measurements reported in both [Berengut et al. \(2013\)](#) and [Hu et al. \(2021\)](#). The explanation for this continuing significant discrepancy has yet to be found.

There is an important caveat to the first result listed above: the analysis in the present work is based on absorption line centroiding and linear regression method, as for [Berengut et al. \(2013\)](#). A different approach is that of [Hu et al. \(2021\)](#), in which absorption lines are modelled using Voigt profiles. In the latter, the fits to local continuum segments can be refined using additional free parameters included in the non-linear least squares fitting procedure (see [Carswell & Webb 2023](#) for details). That process may substantially reduce the error contribution found here. We have not explored this here for white dwarf spectroscopy, although a companion paper to this one, describing the analysis of the spectrum of quasar PHL957, suggests local continuum refinement dramatically reduces the impact of variations in the initial continuum model.

The results presented in this paper have important implications for the claimed uncertainties in some previously published  $\Delta\alpha/\alpha$  measurements, including the recent measurements of, for example, [Hees et al. \(2020\)](#); [Murphy et al. \(2022\)](#). There are likely to also be significant implications for the achievable precision in forthcoming redshift drift studies ([Sandage 1962](#); [Liske et al. 2008](#)); the results reported here motivate a more careful exploration of the potential systematics that may arise from continuum estimation across the Lyman alpha forest.

## ACKNOWLEDGMENTS

We are most grateful to Alexander Kramida and Tom Ayres for useful communications.

## DATA AVAILABILITY

Based on observations made with the NASA/ESA Hubble Space Telescope, obtained from the data archive at the Space Telescope Science Institute. The STIS spectra of G191–B2B are available from the Barbara A. Mikulski archive. The continuum fitting code described in this paper is available from the authors on request.

## APPENDIX

A. SOLVING FOR  $\Delta\alpha/\alpha$  USING LINEAR REGRESSION

Let  $x = (\alpha/\alpha_0)^2 - 1$ . For the  $i^{\text{th}}$  absorption line,

$$\omega_{rest,i} = \omega_{0,i} + q_i x \quad (\text{A1})$$

where  $\omega_{rest,i}$  is the observed rest-frame frequency of the  $i^{\text{th}}$  line measured in the white dwarf spectrum (i.e.  $\omega_{rest,i}$  does not include the white dwarf redshift, the combined effects of gravitational redshift and line of sight stellar velocity).  $\omega_{0,i}$  is the terrestrial laboratory rest-frame frequency.  $q_i$  is the sensitivity coefficient for that line.  $\omega$  and  $q$  are both in units of  $\text{cm}^{-1}$ . The observed-frame and rest-frame frequencies of the  $i^{\text{th}}$  line measured in the white dwarf spectrum are related by

$$\omega_{rest,i} = \omega_{obs,i}(1 + z) \quad (\text{A2})$$

so Eq. A1 becomes

$$\omega_{obs,i} + z\omega_{obs,i} = \omega_{0,i} + q_i x \quad (\text{A3})$$

Using the approximation  $x \approx 2\Delta\alpha/\alpha_0$ , where  $\Delta\alpha = \alpha - \alpha_0$ , Eq. A3 becomes

$$\omega_{obs,i} - \omega_{0,i} = -z\omega_{obs,i} + 2q_i \frac{\Delta\alpha}{\alpha_0} \quad (\text{A4})$$

so

$$\frac{\omega_{obs,i} - \omega_{0,i}}{\omega_{obs,i}} = -z + \frac{2q_i}{\omega_{obs,i}} \frac{\Delta\alpha}{\alpha_0} \quad (\text{A5})$$

and with  $\lambda$  in  $\text{\AA}$ ,  $\omega = 10^8/\lambda$ ,

$$\frac{\lambda_{obs,i} - \lambda_{0,i}}{\lambda_{0,i}} = \frac{\Delta\lambda_i}{\lambda_{0,i}} = z - \frac{2q_i\lambda_{obs,i}}{10^8} \frac{\Delta\alpha}{\alpha_0} \quad (\text{A6})$$

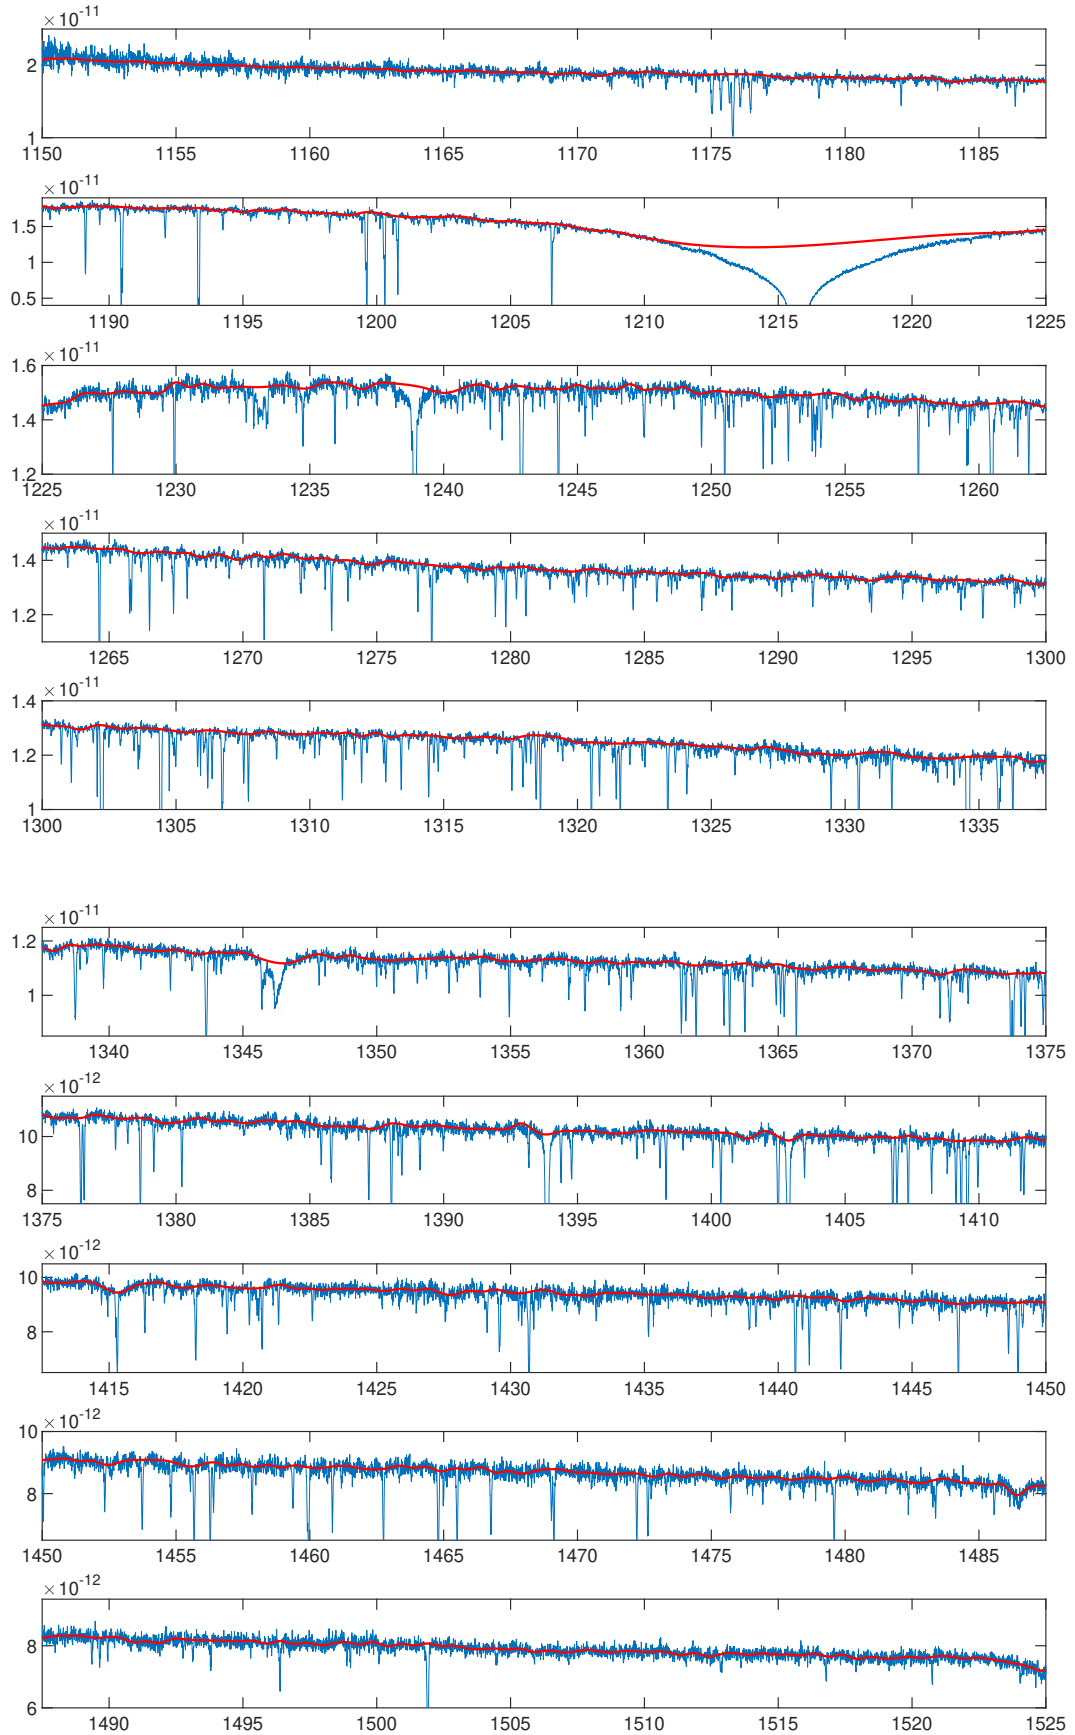

The version of Eq. A6 used in Berengut et al 2013 is,

$$\frac{\Delta\lambda_i}{\lambda_{0,i}} = z - \frac{2q_i\lambda_{0,i}}{10^8}(1+z) \frac{\Delta\alpha}{\alpha_0}. \quad (\text{A7})$$

Eq. A7 thus assumes  $\lambda_{obs,i}/\lambda_{0,i} = (1+z)$ , which is correct if  $\Delta\alpha/\alpha_0 = 0$ , but an approximation otherwise. The exact expression is  $\lambda_{obs,i}/\lambda_{rest,i} = (1+z_i)$ . Whilst both equations give very close results ( $\Delta\alpha/\alpha$  discrepancies are at the  $10^{-8}$  level, well below any realistic experimental error), in this work we use Eq. A6 to solve for the slope and intercept  $\Delta\alpha/\alpha$  and  $z$ .

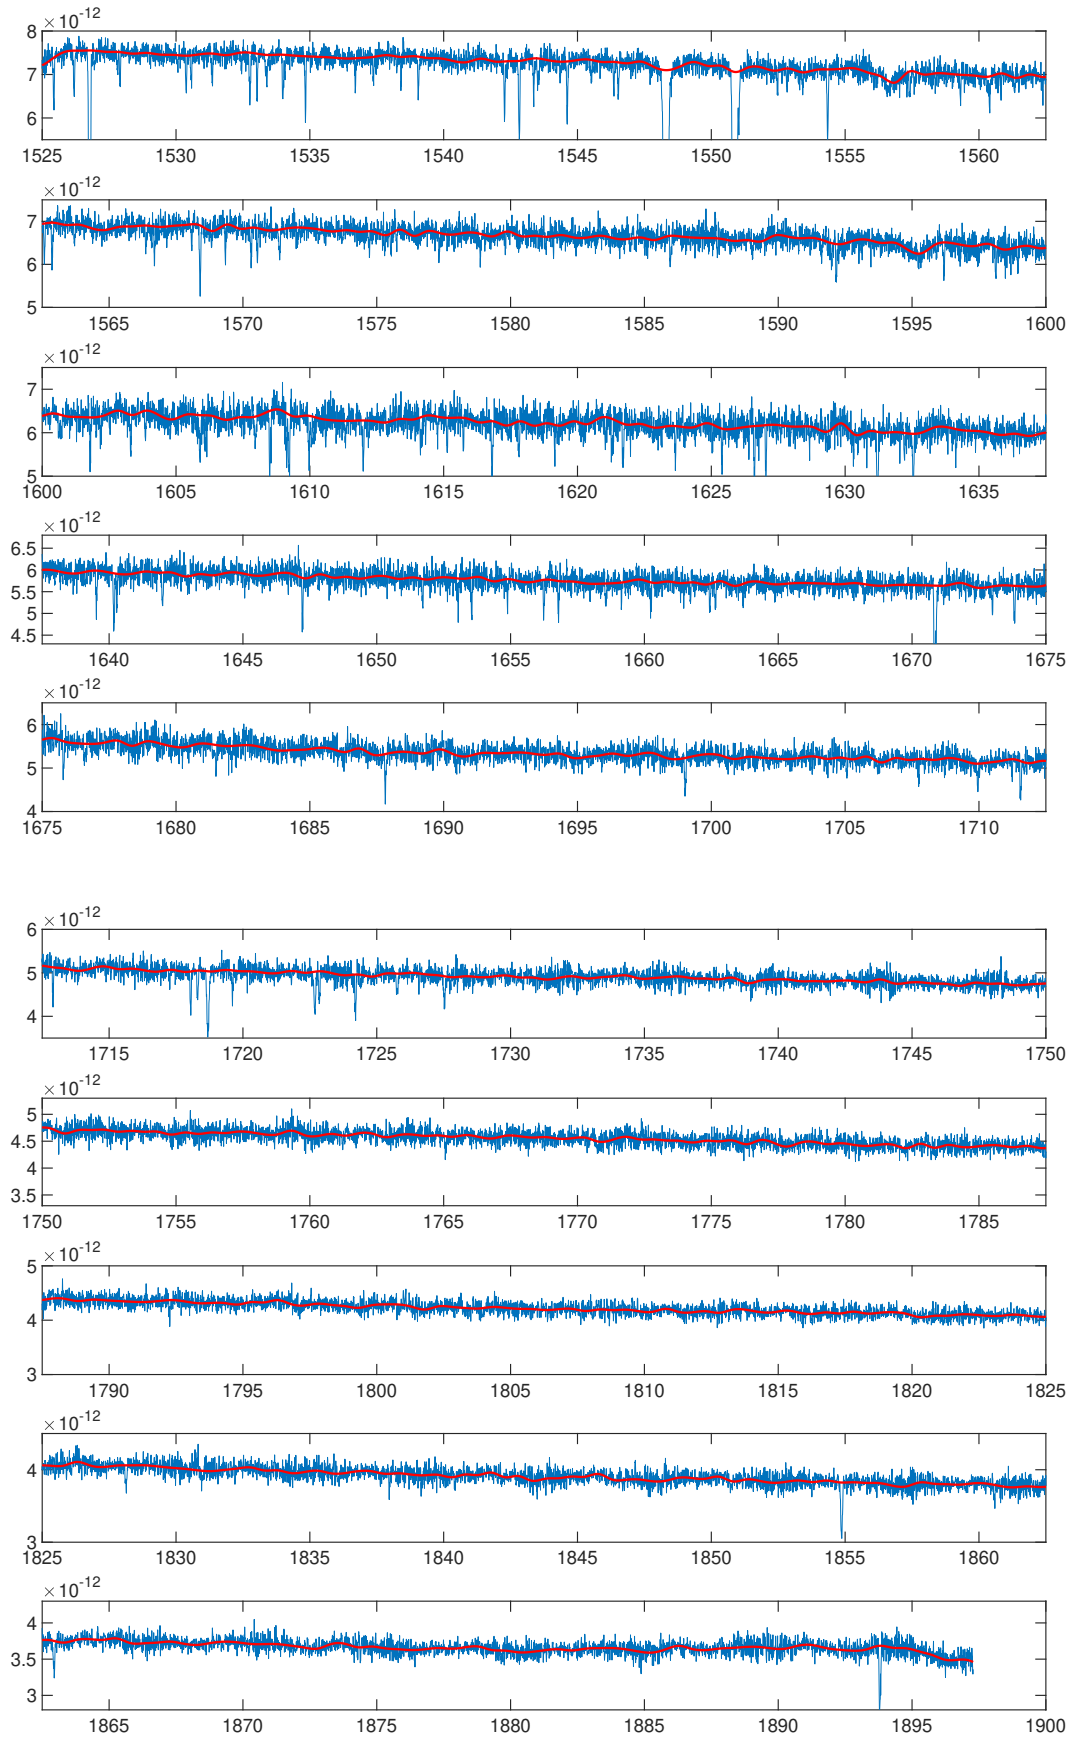

## B. COMPLETE SET OF FIGURES

In the main paper we illustrate only one continuum ( $0.75\text{\AA}$  knot spacing). Here we illustrate the complete set used in these measurements, i.e. continua computed for all four knot spacings: 0.5, 0.75, 1.0,  $1.25\text{\AA}$ .

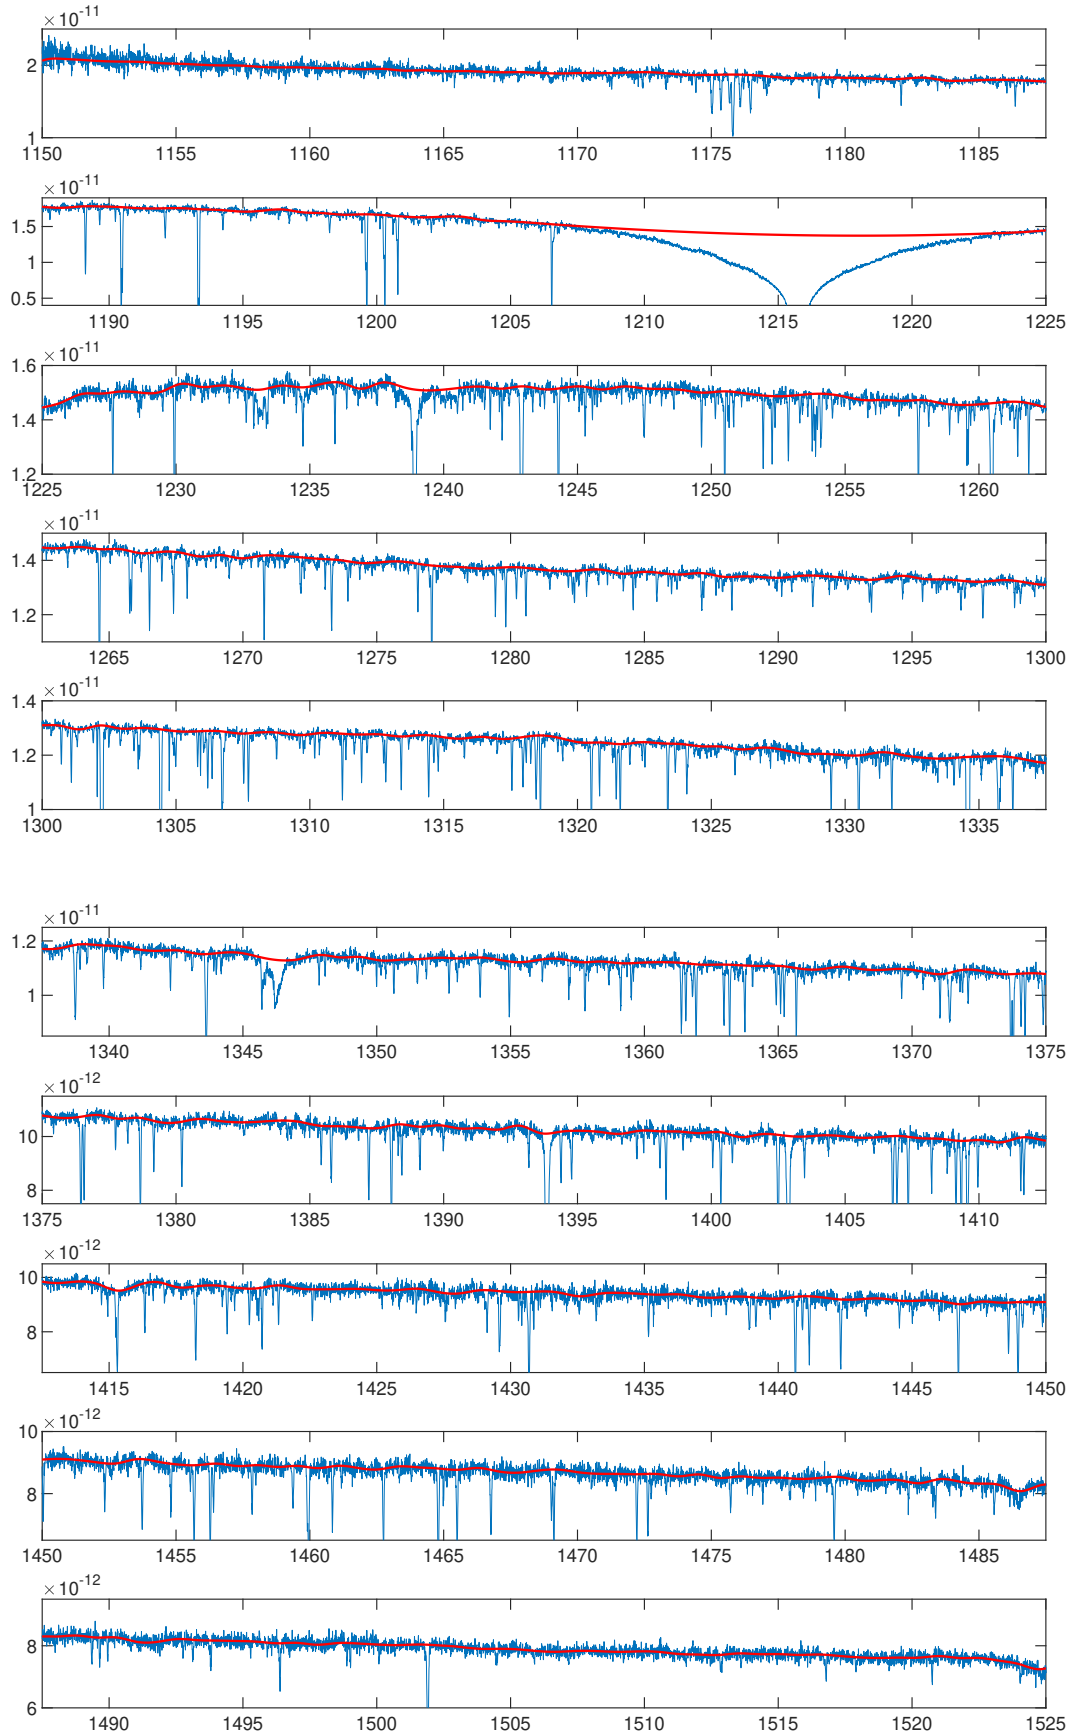

**Figure B1.** G191–B2B continuum model with 0.5 Å knot spacing.

**Figure B2.** G191–B2B continuum model with  $0.5 \text{ \AA}$  knot spacing.

**Figure B3.** G191–B2B continuum model with 0.75 Å knot spacing.

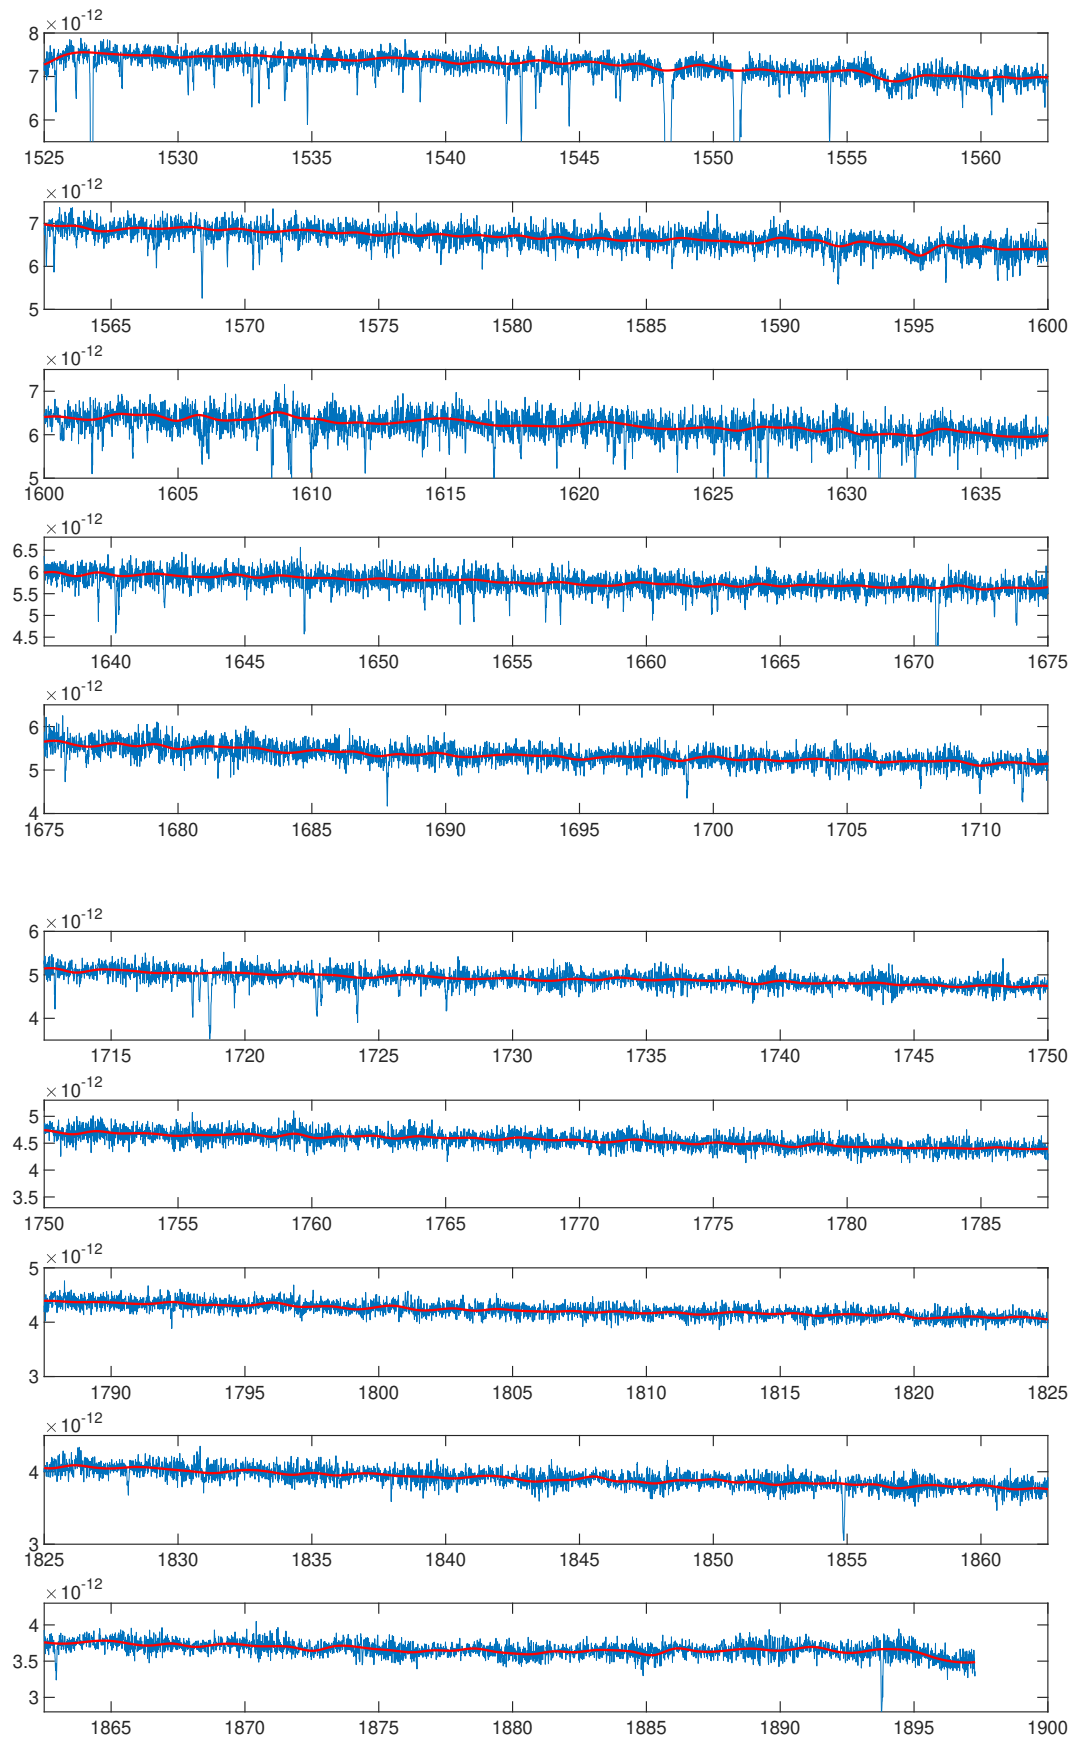

Figure B4. G191-B2B continuum model with  $0.75 \text{ \AA}$  knot spacing.

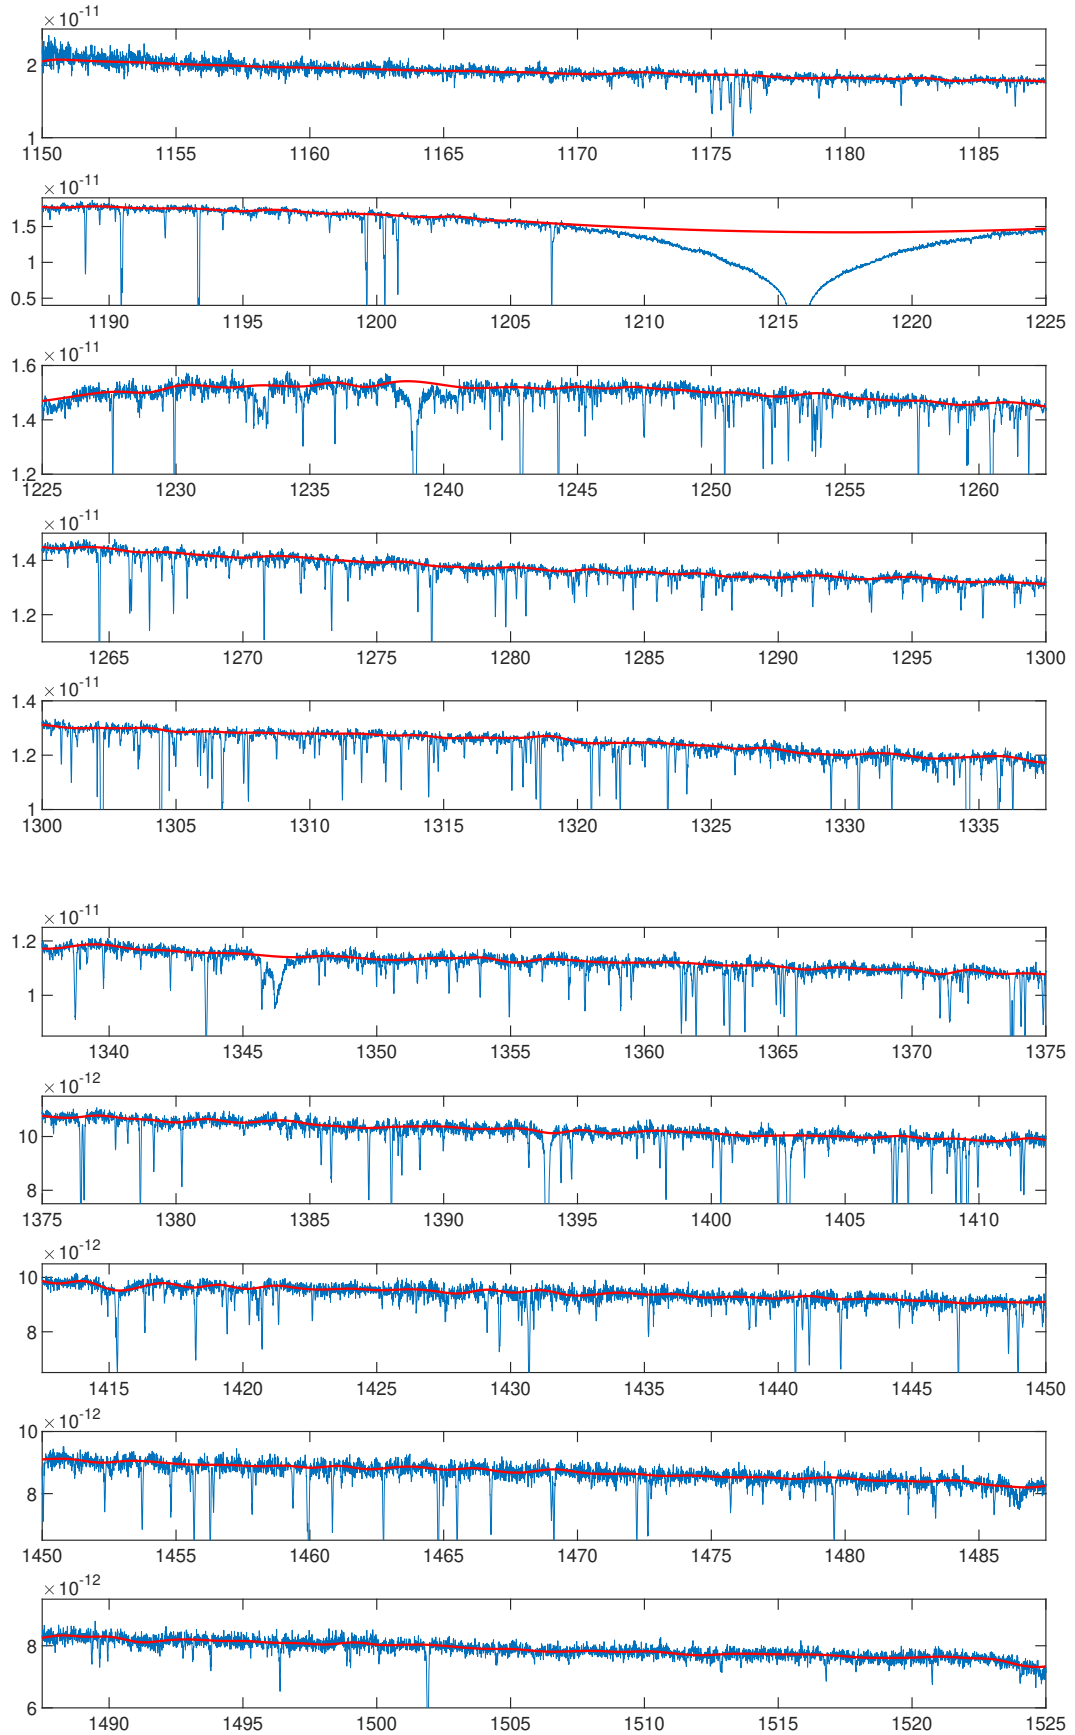

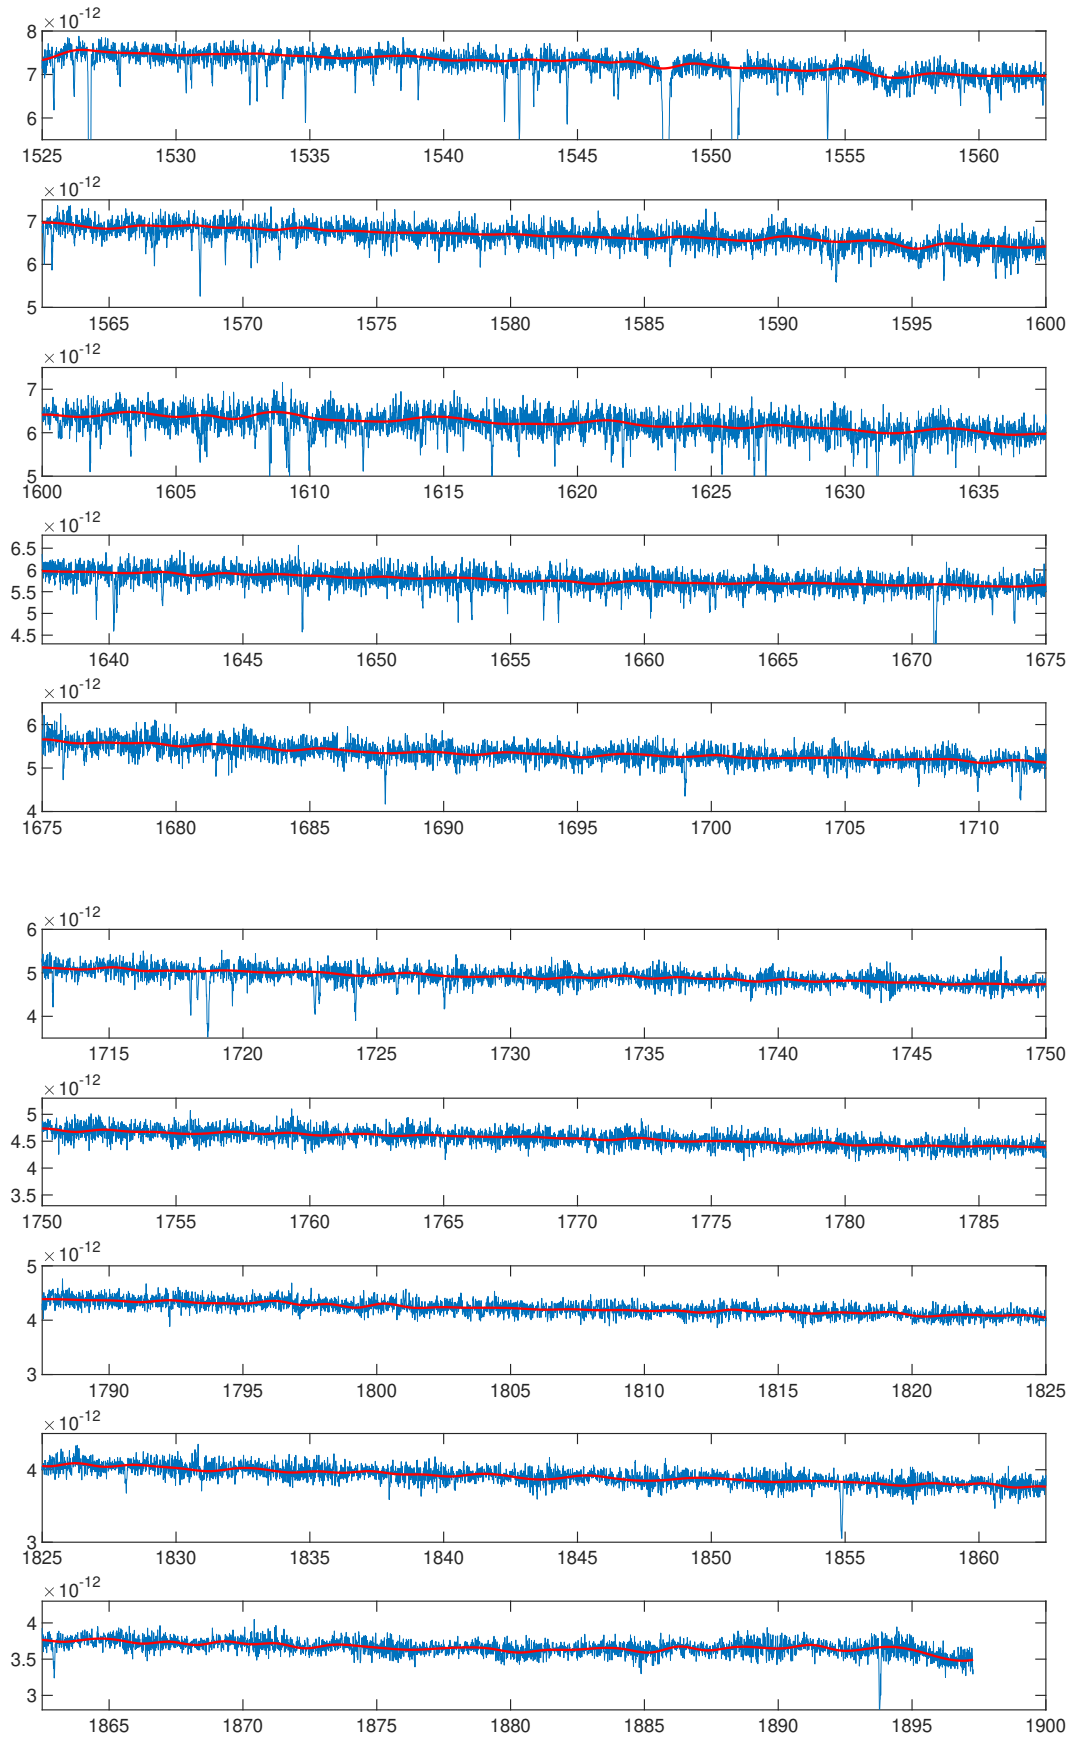

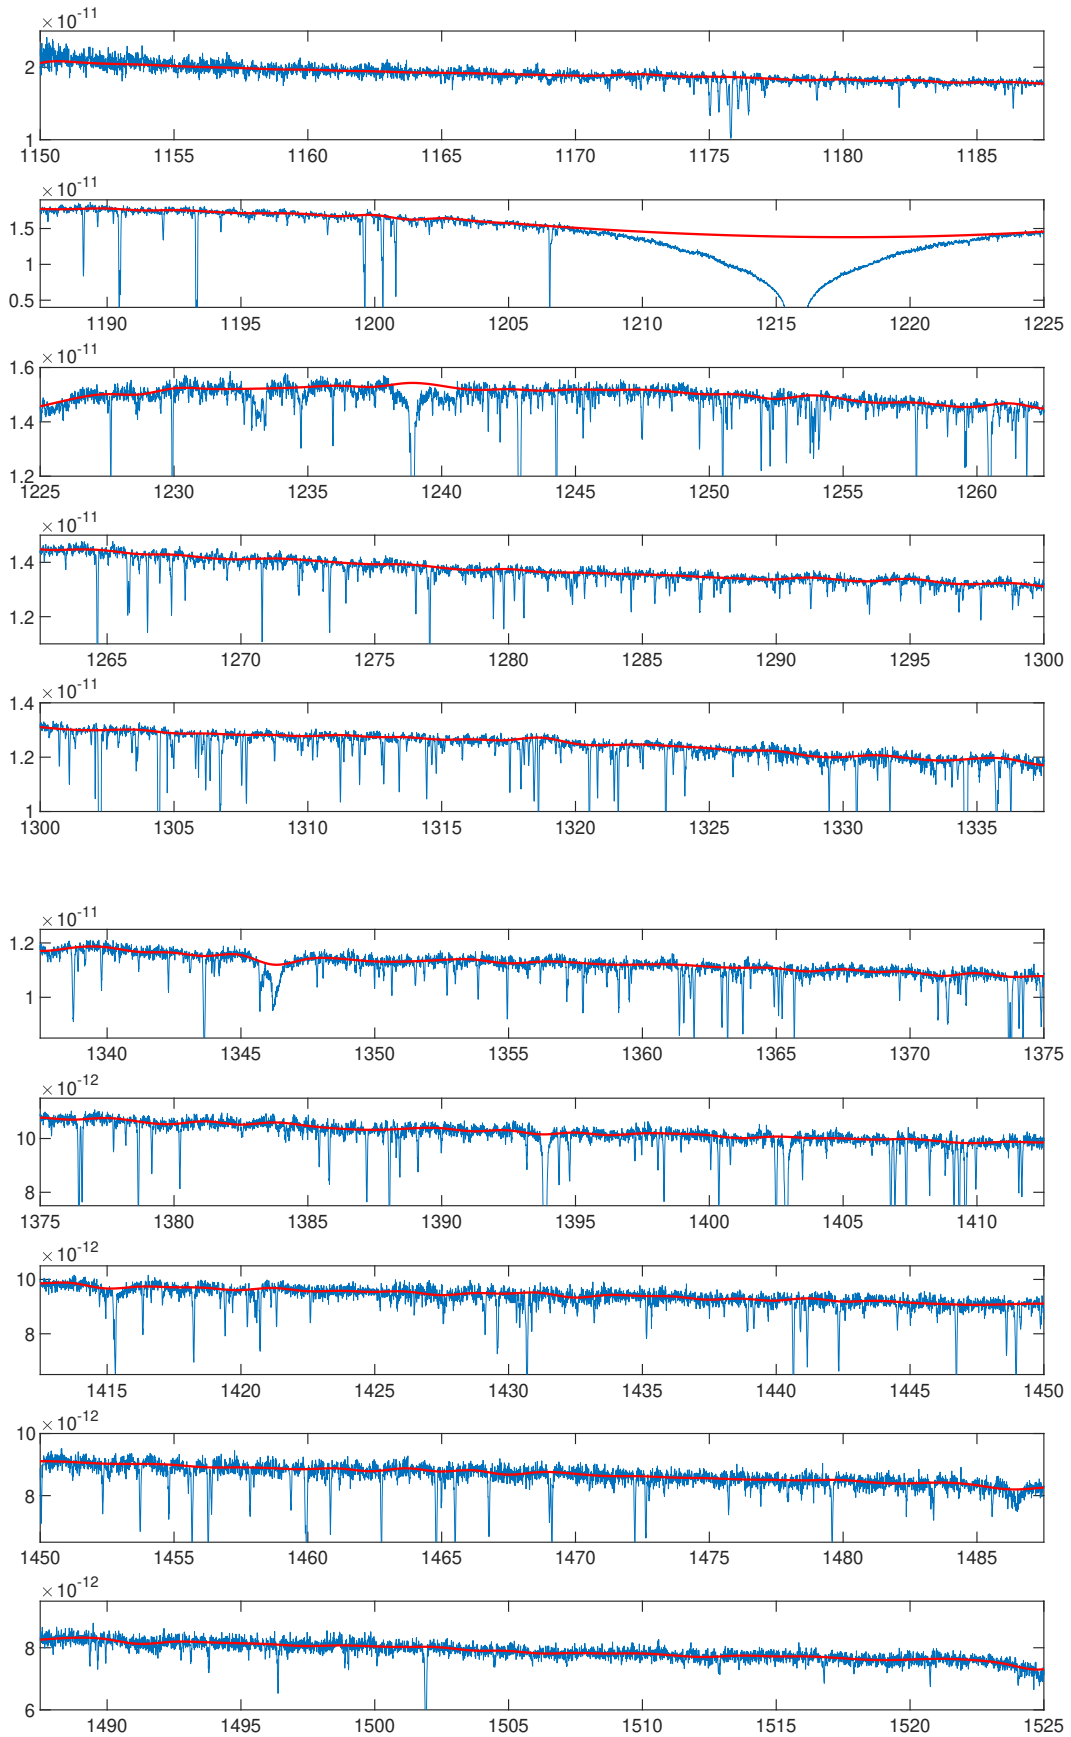

Figure B5. G191-B2B continuum model with 1.0 Å knot spacing.

**Figure B6.** G191–B2B continuum model with  $1.0 \text{ \AA}$  knot spacing.

**Figure B7.** G191–B2B continuum model with 1.25 Å knot spacing.

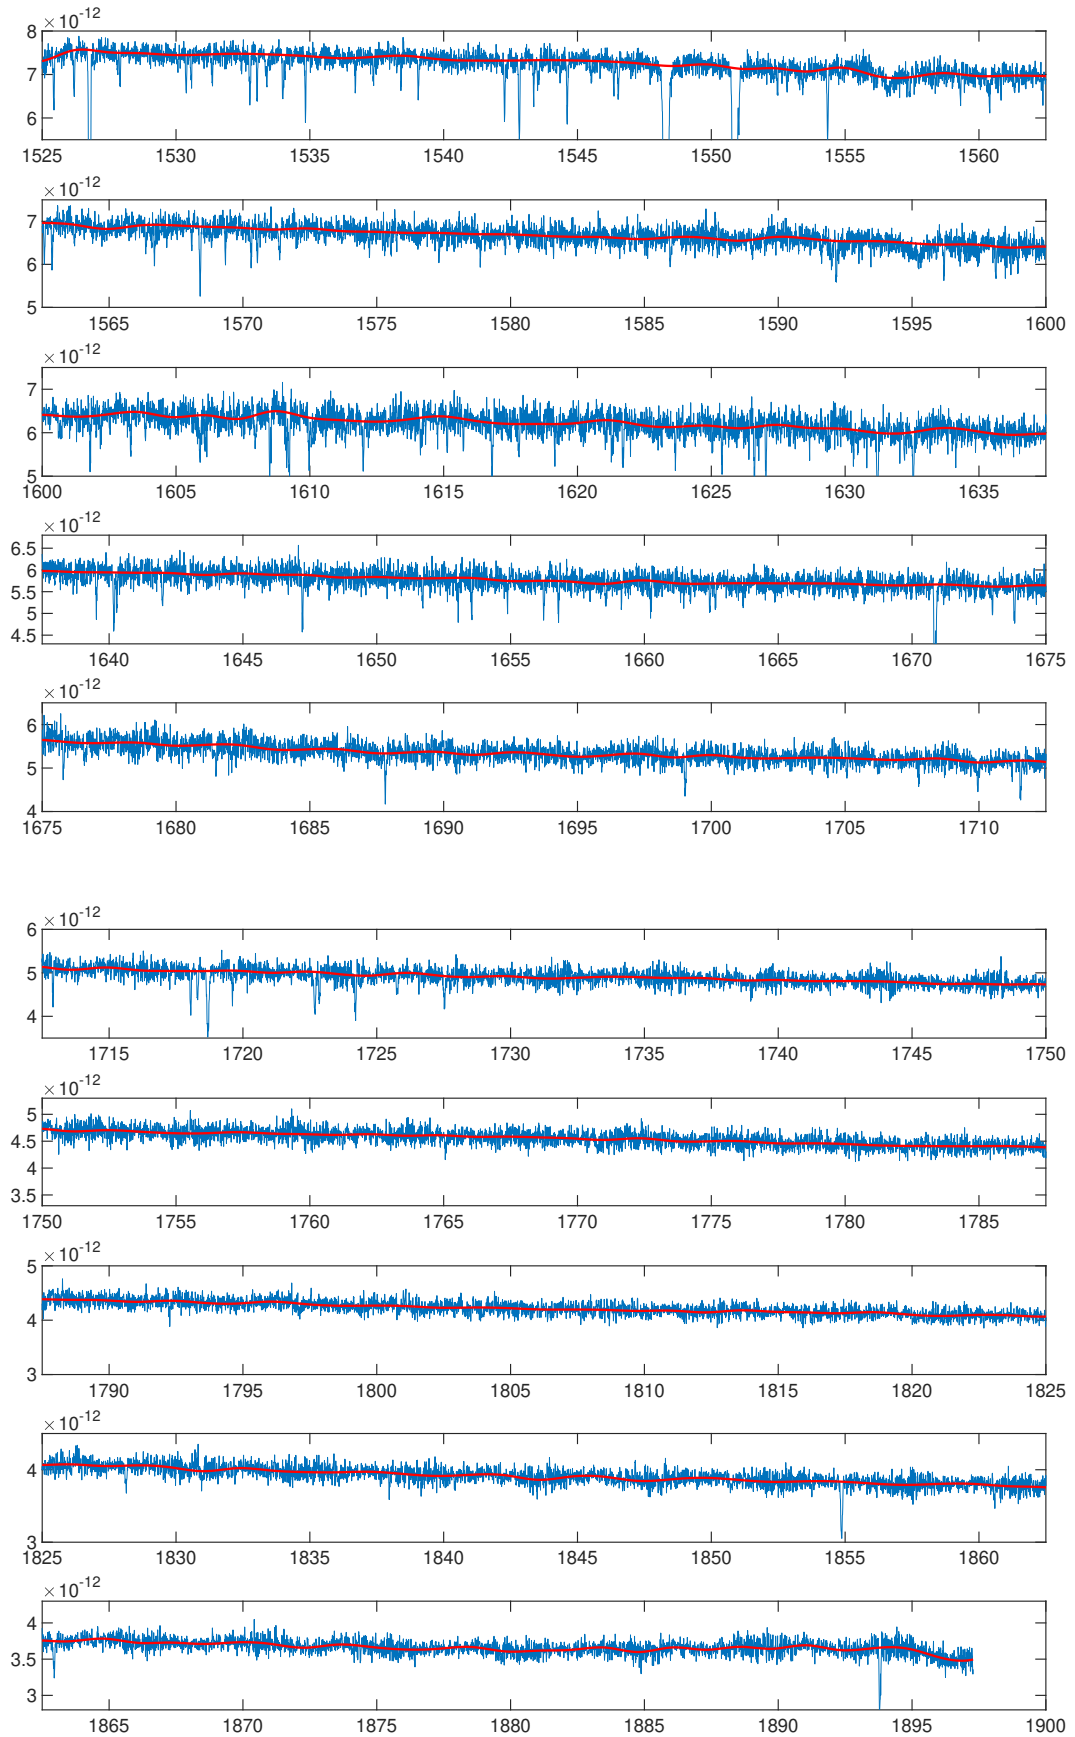

Figure B8. G191-B2B continuum model with 1.25 Å knot spacing.

## C. ATOMIC DATA NiV

Experimental and theoretical data on energy levels of Ni V. For further details about the experimental data see [Kramida et al. \(2022\)](#). Apart from the energies, the theoretical data include calculated Landé  $g$ -factors and sensitivity coefficients  $q$ . The atomic data provided here for NiV is analogous to similar files for FeV provided as supplementary material in [Hu et al. \(2021\)](#). For enquiries about the theoretical data, contact Vladimir Dzuba: [v.dzuba@unsw.edu.au](mailto:v.dzuba@unsw.edu.au).

## D. LINE IDS FOR EACH CONTINUUM MODEL

The columns in the tables in this Section are as follows: ‘lam\_K’ is the laboratory wavelength in Å from [Kramida et al. \(2022\)](#) and ‘error’ is its standard deviation in mÅ. ‘lam\_obs’ is the observed wavelength in Å and ‘error’ is its standard deviation in mÅ. ‘q’ is the sensitivity coefficient in  $\text{cm}^{-1}$  ([Appendix C](#)). ‘lam\_rest’ is the rest-frame observed wavelength in Å (‘lam\_obs’ shifted to the rest frame using the G191-B2B redshift from [Preval et al. \(2013\)](#)). ‘match’ is the absolute difference between the observed and laboratory rest-frame wavelengths in units of 1 standard deviation, allowing for uncertainties on both wavelengths in most cases, except where the uncertainty on the observed wavelength is very small (below 1mÅ, indicated as a ‘-’ in the tables); in those cases, the observed wavelength uncertainty contribution has been ignored. Note that there are multiple potential IDs in many cases. These are left in the Table for illustration, but all multiples are discarded in the linear regression estimates. Further, by visual inspection of the data, the following four spectral ranges are excluded from the tables below and from the linear regression calculations: [1205, 1227], [1238,1241], [1242,1243.5], [1345,1347] Å.

We associate lower and upper energy levels and sensitivity coefficients using the tabulations provided in [Kramida et al. \(2022\)](#) together with the  $q$  values in [Appendix C](#) in the present work. As an illustration, the transition at Ritz wavelength 1202.427Å ([Kramida et al. 2022](#)) has lower level configuration, term, and  $J$ :  $3d^5 (^4G) 4s, ^5G, 4$ , and upper level configuration, term, and  $J$ :  $3d^5 (^4G) 4p, 3F^\circ, 3$ . The associated sensitivities (from [Tables C1 and C2](#)) are -6829 and -3939, such that the  $q$  applicable in [Eq. 24](#) is  $q = +2890$  ([Dzuba et al. 1999b,a](#)).
