

§ 2.1 Objectives of Protection

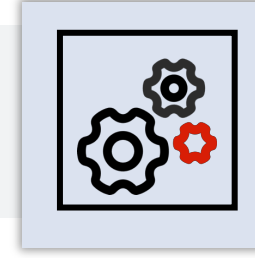

- Prevent harm caused by AI systems

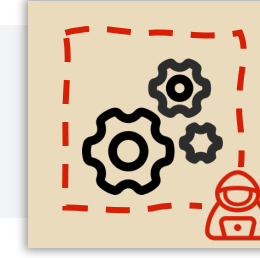

- Protect AI systems from attacks

AI safety directly focuses on preventing harm caused **by** AI systems to environments, while AI security is centered around protecting the AI systems themselves **from** threats.

§ 2.2 Threat Models

- Accidental
- Faults
- Hazards

- Malicious
- Attacks
- Threats

Traditionally, AI safety primarily considers **unintended** hazards, whereas AI security is dedicated to defending against **adversaries**.
– But addressing adversarial threats is now also becoming an important pre-condition for achieving AI safety objectives.

§ 2.3 Problem Framing

- Risk minimization over a natural distribution

- Dynamic
- Adaptive
- Min-Max Games

Many safety problems can be effectively framed as a risk minimization problem over a relatively stable natural distribution. Security problems are inherently min-max games that are dynamic, often leading to an arms race between defenders and attackers.

§ 2.4 Governance and Liability

Safety and security often have nuances in terms of:

- Resource Allocation
- International Collaboration & Negotiation
- Perception & Evaluation in Liability Attribution
-
