## A bstract

U sing Schrodinger Functionalm ethods, we com pute the non-perturbative renorm alisation and renorm alisation group running of several four-ferm ion operators, in the fram ework of lattice simulations with two dynamical W ilson quarks. Two classes of operators have been targeted: (i) those with left-left current structure and four propagating quark elds; (ii) all operators containing two static quarks. In both cases, only the parity-odd contributions have been considered, being the ones that renorm alise multiplicatively. Our results, once com bined with future simulations of the corresponding lattice hadronic matrix elements, may be used for the com putation of phenom enological quantities of interest, such as  $B_K$  and  $B_B$  (the latter also in the static limit).

### 1 Introduction

Hadronic matrix elements of four-fermion operators play an important rôle in the study of CP violation via CKM unitarity triangle analyses, as well as in the understanding of the I = 1=2 enhancement puzzle in K ! decays. The only known technique to compute hadronic matrix elements from rst principles, namely lattice QCD, has long been ham pered by a number of systematic uncertainties. Most notably, the high computational cost of including light dynamical quarks in the simulations has enforced either the quenched approximation, or the use of heavy dynamical quark masses, which necessitate long and potentially uncontrolled extrapolations to the chiral regime. It is thus important to upgrade existing quenched results by the inclusion of dynamical fermion e ects. For recent progress reports on lattice results on avour Physics, see [1].

The present work is a step in this direction. The non-perturbative renorm alisation of four-ferm ion operators, as well as the corresponding renorm alisation group (RG) running between hadronic scales of O ( OCD) and perturbative ones of about 100 G eV, is a necessary ingredient in the process of producing the properly renormalised matrix element in the continuum limit. Quantities that determine these renorm alisation properties have been computed in the quenched approximation, using nite-size scaling techniques, for a broad class of four-ferm ion operators [2[4]. The regularisation of choice was that of non-perturbatively O (a) in proved W ilson quarks and standard plaquette gauge action; the renorm alisation schemes used were of the Schrodinger functional (SF) type. The aim of the present work is to extend these results to QCD with  $N_f = 2$  dynam ical quarks. More speci cally, we present results for: (i) the RG -running of left-left current relativistic four-ferm ion operators; (ii) the RG -running of all B = 2 operators with two static heavy quarks; (iii) the renorm alisation factors that m atch the above operators to their renorm alisation group invariant (RGI) counterparts. The latter have been computed for a regularisation of the relativistic quarks by the non-perturbatively O (a) in proved W ilson action. Prelim inary results have been presented in [5].

As we will point out below, the results of this work are relevant for the com – putation of physical quantities such as the bag parameters  $B_K$  and  $B_B$ . In the quenched approximation, the combination of this renormalisation programme with computations of bare hadronic matrix elements has already produced high precision estimates of a few physical quantities in the continuum [6,7]. Moreover, know ledge of the continuum RG I operators, computed with W ilson fermions, has allowed the determination, through a matching procedure, of the renormalisation factors of the same operators in the N euberger fermion regularisation [8].

The paper is organised as follows. In sect. 2 we introduce the operator basis and the renorm alisation schemes adopted in the present work. We also recall some basic form ulae used for the reconstruction of the operator scale evolution in the SF framework. Sect. 3 is devoted to a detailed description of the lattice simulations and num erical analyses of the operator RG -running. In sect. 4 we discuss the renorm alisation of the four-quark operators at a low energy matching scale. Conclusions are drawn in sect. 5. In order to improve readability, some tables and gures have been collected at the end of the paper.

## 2 De nitions and setup

### 2.1 Renorm alisation of four-ferm ion operators

W e will consider two di erent classes of four-ferm ion (dim ension-six) operators:

$$O_{12}(\mathbf{x}) = \frac{1}{2} \qquad _{1}(\mathbf{x}) \qquad _{12}(\mathbf{x}) \qquad _{3}(\mathbf{x}) \qquad _{24}(\mathbf{x}) \qquad (_{2} \ _{4}) \qquad ; \qquad (2.1)$$

$$O_{12}(\mathbf{x}) = \frac{1}{2} \qquad _{h}(\mathbf{x}) \qquad _{11}(\mathbf{x}) \qquad _{h}(\mathbf{x}) \qquad _{22}(\mathbf{x}) \qquad (_{1} \ _{2}) \qquad ; \qquad (2.2)$$

In the above expressions  $_{k}$  is a relativistic quark eld with avour index k,  $_{h}$  ( $_{h}$ ) are static (anti-)quark elds,  $_{1}$  are D irac (spin) matrices, and the parentheses indicate sum mation over spin and colour indices. In the present form alism, all quark avours are distinct, enabling us to separate the calculation of the scale-dependent logarithm ic divergences, which is the aim of the present work, from the problem of eventual mixing with lower-dimensional operators<sup>1</sup>.

The renorm alisation pattern of the above operators is determ ined by the sym – m etries of the regularised theory. In the the parity-odd sector, com plete bases of operators in the relativistic and static cases are given by

 $Q_{k} 2 O_{VA+AV} O_{VA-AV} O_{SP-PS} O_{SP+PS} O_{TT}; k = 1;...;5;$  (2.3)

$$Q_{k} 2 O_{VA+AV}; O_{VA-AV}; O_{SP-PS}; ; k = 1; ...; 4; (2.4)$$

respectively. The notation is standard and self-explanatory, indicating the operator spin matrices 1, with say,  $O_{VA+AV} = O_{VA} + O_{AV}$ . A full analysis of the renormalisation properties of these operator bases with relativistic W ilson fermions has been performed in [9,10]. A result of these works which is of particular relevance is that, contrary to the parity-even case, characterised by operator mixing due to the explicit breaking of chiral symmetry by the W ilson term in the quark action, the parity-odd operators are protected by discrete symmetries, and hence their renormalisation pattern is continuum -like [11]. We point out that RG -running is identical for parity-even and parity-odd operators of the same chiral representation, since in the continuum limit chiral symmetry is restored. On the other hand, the (physically

<sup>&</sup>lt;sup>1</sup>These power subtractions typically appear for some speci c choices of quark masses and/or avour content (e.g. penguin operators). Their determ ination is independent of that of the logarithm ic divergences, once mass independent renorm alisation schemes are employed.

relevant) m atrix elements of the parity-even operators can be mapped exactly to those of the parity-odd ones via the addition of a chirally twisted mass term to the lattice quark action [6,10,12].

From now on, we will consider the subset of operators

$$Q_1$$
;  $Q_k^{0^+} 2$ ;  $Q_1^+$ ;  $Q_1^+ + 4Q_2^+$ ;  $Q_3^+ + 2Q_4^+$ ;  $Q_3^+ - 2Q_4^+$ : (2.5)

A llthese operators renorm alisem ultiplicatively; i.e. given an operator 0 2 fQ<sub>1</sub>;Q<sub>k</sub><sup>0+</sup> g the corresponding operator insertion in any on-shell renorm alised correlation function is given by

$$O_{R}(x; ) = \lim_{a! 0} Z(g_{0}; a) O(x; g_{0});$$
 (2.6)

where  $g_0$ ; a are the bare coupling and lattice spacing, respectively and is the renormalisation scale. The RG-running of the operator is controlled by the anomalous dimension , de ned by the Callan-Sym anzik equation

$$\frac{\varrho}{\varrho} O_{R}(\mathbf{x}; \mathbf{y}) = (\overline{g}(\mathbf{y})) O_{R}(\mathbf{x}; \mathbf{y}; \mathbf{y}; \mathbf{y})$$
(2.7)

supplem ented by the corresponding RG -equation for the renorm alised coupling  $\overline{g}$  ,

$$\frac{\underline{\theta}}{\underline{\theta}}\overline{g}(\ )=\ (\overline{g}(\ )): \qquad (2.8)$$

In mass-independent renorm alisation schemes, the -function and all anom alous dimensions depend only on the renorm alised coupling  $\overline{g}$ . They admit perturbative expansions of the form

(g) 
$$g^{g! 0} g^{3} b_{0} + b_{1}g^{2} + b_{2}g^{4} + \dots ;$$
 (2.9)

(g) 
$$g^{g! 0} g^{2} 0 + 1g^{2} + 2g^{4} + \dots ;$$
 (2.10)

in which the coe cients  $b_0; b_1; c_0$  are renorm alisation scheme-independent. In particular, the universal coe cients of the -function read

$$b_0 = \frac{1}{(4)^2} \quad 11 \quad \frac{2}{3} N_f \quad ; \qquad b_1 = \frac{1}{(4)^4} \quad 102 \quad \frac{38}{3} N_f \quad ; \qquad (2.11)$$

and the universal leading order (LO ) coe cients of the anom alous dimensions of the operators in Eq. (2.5) are given by

$$_{0}^{+} = \frac{4}{(4)^{2}}; \qquad _{0} = \frac{8}{(4)^{2}}; \qquad (2.12)$$

$${}_{0}^{(1)} = \frac{8}{(4)^{2}}; \qquad {}_{0}^{(2)} = \frac{8}{3(4)^{2}}; \qquad (2.13)$$

$${}_{0}^{(3)} = \frac{10}{(4)^2}$$
;  ${}_{0}^{(4)} = \frac{4}{(4)^2}$ : (2.14)

M or eover, in the SF renorm alisation scheme, the next-to-next-to-leading order (NNLO) coecient  $b_2^{SF}$  of the -function is known to be [13]

$$b_2^{SF} = \frac{1}{(4)^3} 0.483 \quad 0.275N_f + 0.0361N_f^2 \quad 0.00175N_f^3 : (2.15)$$

Upon form al integration of Eq. (2.7), one obtains the renorm alisation group invariant (RG I) operator insertion

$$O_{RGI}(\mathbf{x}) = O_{R}(\mathbf{x}; ) \frac{\overline{g}^{2}()}{4} \exp \left( \begin{array}{c} 2 \ \overline{g}() \\ 0 \end{array} \right) \frac{(g)}{(g)} \frac{\partial}{\partial g} ; \quad (2.16)$$

while the RG evolution between two scales  $_1$ ;  $_2$  is given by the scaling factor

$$U(_{2; 1}) = \exp \left( \begin{array}{c} Z \\ \overline{g}(_{2}) \\ \overline{g}(_{1}) \end{array} \right) dg \frac{(g)}{(g)} = \lim_{a! \ 0} \frac{Z (g_{0}; a_{2})}{Z (g_{0}; a_{1})} :$$
(2.17)

### 2.2 Schrodinger Functional renorm alisation schemes

Eqs. (2.16)-(2.17) are the starting point for the non-perturbative computation of the RG evolution of composite operators. To that purpose we introduce a family of Schrodinger Functional renorm alisation schemes. The latter are dened by setting up the theory on a four-dimensional hypercube of physical size T  $L^3$  with D inichlet boundary conditions in Euclidean time and periodic boundary conditions in the spatial directions, up to a phase . We refer the reader to [14] for an introduction to the SF setup. In the present work we always choose T = L and = 0.5. We also assume that no background eld is present. The renormalisation scale is set as = 1=L.

R enorm alisation conditions are imposed on SF correlators, following  $[2\{4\};$  for the sake of completeness, we brie y outline the method. We rst introduce bilinear boundary sources projected to zero external momentum,

$$s_{1}s_{2}[] = a_{s_{1}}^{6}(x) s_{2}(y);$$
 (2.18)

$${}^{0}_{s_{1}s_{2}}[] = a^{6} {}^{X}_{s_{1}}(x) {}^{0}_{s_{2}}(y) :$$
(2.19)

Here denotes a D irac matrix, the avour indices  $s_{1,2}$  can assume both relativistic and static values and the elds (<sup>0</sup>) represent functional derivatives with respect to the ferm ionic boundary elds of the SF at the initial (nal) time  $x_0 = 0$  ( $x_0 = T$ ). The four-quark operators are then treated as local insertions in the bulk of the SF,

Figure 1: D iagram matic representation of correlation functions: relativistic four-quark correlators F (rst diagram from left), static four-quark correlators F <sup>(k)</sup> (third diagram from left), relativistic boundary-to-boundary correlators  $f_1^{12}$ ,  $k_1^{12}$  (second diagram from left) and static boundary-to-boundary correlators  $f_1^{1h}$  and  $k_1^{1h}$  (fourth diagram from left). Euclidean time goes from left to right. Single (double) lines represent relativistic (static) valence quarks.

giving rise to the correlation functions

$$F_{[A;B;C]}(x_0) = L^{3}h^{0}_{53}[C]Q_1(x) _{21}[A] _{45}[B]i; \qquad (2.20)$$

$$F_{[A;B;C]}^{(k)}(x_0) = L^{-3}h_{3h}^{0}[C]Q_{k}^{0+}(x)_{1h}[A]_{23}[B]i: \qquad (2.21)$$

C learly, the D irac matrices of the boundary sources must be chosen so that the correlators do not vanish trivially (e.g. due to parity).

In the above de nitions a \spectator" light quark has been introduced with avour s = 5 for F and s = 3 for F<sup>(k)</sup>. This quark eld has no W ick contractions with the valence quarks of the operator insertion and propagates straight from the initial to the naltime boundary. Its rôle is merely to allow for parity-even correlators of parity odd four-ferm ion insertions without the need of introducing non-zero external momenta.

In order to isolate the operator ultraviolet divergences in Eqs. (2.20)-(2.21), one has to remove the boundary sources' additional divergences. To this end, we introduce a set of boundary-to-boundary correlators,

$$f_{1}^{s_{1}s_{2}} = \frac{1}{2L^{6}}h_{s_{1}s_{2}}^{0}[5] s_{2}s_{1}[5]i; \qquad (2.22)$$

$$k_{1}^{s_{1}s_{2}} = \frac{1}{6L^{6}} \sum_{k=1}^{X^{3}} h_{s_{1}s_{2}}^{0} [k]_{s_{2}s_{1}} [k]_{s_{2}s_{1}} [k]_{i} ; \qquad (2.23)$$

where the avour indices  $s_{1,2}$  m ay assume once again either relativistic or static values. W ick contractions of four-quark and boundary-to-boundary correlation functions are depicted in Fig.1.

Since the logarithm ic divergences of the boundary elds are removed by multiplicative renorm alisation factors Z and Z<sup>h</sup>, it can be easily recognised that ratios

of correlators such as

$$R (x_0) = \frac{F_{[A;B;C]}(x_0)}{[f_1^{12}]^{3=2} [k_1^{12}]}; \qquad (2.24)$$

$$R^{(k)}(x_0) = \frac{F_{[A;B;C]}^{(k)}(x_0)}{[f_1^{1h}][f_1^{12}]^{1=2} [k_1^{12}]}; \qquad (2.25)$$

are free of boundary divergences for any choice of the parameter . Thus, the operators of interest are renorm alised through the conditions

Z 
$$(g_0; a=L)R$$
  $(T=2) = R$   $(T=2)_{g_0=0}$ ; (2.26)

$$Z^{(k)}(g_0;a=L)R^{(k)}(T=2) = R^{(k)}(T=2)_{g_0=0};$$
 (2.27)

where all correlation functions are to be evaluated at the chiral point.

A crucial observation is that all renorm alisation factors thus obtained are avourblind, in the sense that they rem ove the logarithm ic divergences from any fourferm ion operator of a given D irac structure, irrespective of its speci c avour content. For instance, in H = 2 transitions, such as  $B_{d(s)} = B_{d(s)}$  oscillations in the static limit, one identi es  $_1 = _2 = d(s)$  as a down (strange) quark, and  $_3 = u$  as an up quark; for either avour identi cation the same  $Z^{(k)}$ 's renorm alise the corresponding operator. Similarly, in the relativistic quark case, the dimension-six operator, be it S = 2 (with  $_1 = _3 = s$  and  $_2 = _4 = d$ ) or B = 2 (with  $_1 = _3 = b$  and  $_2 = _4 = d(s)$ ), is renorm alised by the same  $Z^+$ . A lso in this case we note the presence of the spectator quark  $_5 = u$  in the renorm alisation condition. These renorm alisation factors also rem ove the logarithm ic divergences of other dimension-six operators with the same D irac structure but di erent avour content. For example, even if the renorm alisation of som e F = 1 operators is only com plete after power subtractions are taken into account, their logarithm ic divergences are removed by the same Z and Z (k) factors.

A nother issue, related to the above discussion, is that here we are working with N<sub>f</sub> = 2 dynam ical avours. In large-volum e simulations of hadronic matrix elements, the latter would be naturally identied with the up and down sea quarks. However, most matrix elements of interest involve additional propagating physical avours<sup>2</sup>. Thus, it becomes necessary to address the elects of partial quenching, in the context of operator renorm alisation.

Due to their avour-blind nature, the renorm alisation factors and RG running contained in this work account for the scale dependence of any matrix element of four-ferm ion operator, computed on an N  $_{\rm f}$  = 2 sea, provided that partial quenching

 $<sup>^{2}</sup>$ An exception is that of B = 2 oscillations of the B  $_{d}$  m eson in the static lim it.

does not generate extra scale-dependent m ixing, which spoils multiplicative renormalisation. This is indeed the case for F = 2 m eson oscillations, since in the chiral lim it the relevant symmetries (CPS for  $Q_1$  and CPT plus heavy quark spin symmetry for  $Q_k^{0^+}$ ) remain valid and protect these operators from new counterterms. On the contrary, unphysical m ixing, generated by partial quenching, m ay become an issue for F = 1 hadronic decays, at least for penguin contributions [15]. We stress that this problem is not specie to the renorm alisation schemes under consideration.

### 2.3 Step-scaling functions

The non-perturbative study of the RG -evolution of our composite operators is based on the step-scaling functions (SSFs)  $\,$ 

$$(u) = \lim_{a! 0} (u; a=L); \qquad (u; a=L) = \frac{Z(g_0; a=(2L))}{Z(g_0; a=L)} ; (2.28)$$

with Z 2 fZ ;  $Z^{(k)}$ g. According to Eq. (2.17), the SSFs describe the operator RG – running between the scales  $_1 = 1=L$  and  $_2 = 1=(2L)$ . The choice of the ratio  $_1=_2=2$  as the sm allest positive integer is made with the aim of m inim ising the elects of the ultraviolet cuto at nite values of the latter.

In practice, the SSFs are simulated at several values of the lattice spacing for xed physical size (inverse renorm alisation scale) L. The corresponding values of the inverse bare coupling =  $6=g_0^2$  are indeed tuned by requiring that the renorm alised SF coupling  $\overline{g}_{\text{SF}}^2$ , and hence L, are kept constant. The critical mass m<sub>cr</sub> is obtained from the requirement that the PCAC mass vanishes in the O (a) improved theory.

Once (u) is computed at several di erent values of the squared gauge coupling u, it is possible to reconstruct the RG evolution factor U ( $_{pt}$ ;  $_{had}$ ) between a hadronic scale  $_{had}$ , in the range of a few hundred M eV, and a perturbative one  $_{pt}$ , in the high-energy regime. This in turn leads to the computation of the RG I operator of Eq. (2.16), with controlled system atic uncertainties, by splitting the exponential on the rhs of Eq. (2.16), evaluated at =  $_{had}$ , as follow s:

The second factor on the rhs is known non-perturbatively as a product of continuum SSFs (u); cf. Eq. (2.17). The rst factor can be safely computed at next-to-leading order (NLO) in perturbation theory, provided the scale  $_{\rm pt}$  is high enough to render NNLO e ects negligible. The full procedure for the construction of U ( $_{\rm pt}$ ;  $_{\rm had}$ ) has been introduced in [16] for the running quark m ass in the quenched approximation,

| Q                 | A | В | С |     |
|-------------------|---|---|---|-----|
| Q                 | 5 | 5 | 5 | 0   |
| Q <sub>1</sub>    | k | 5 | k | 1   |
| Q 1 <sup>0+</sup> | 5 | 5 | 5 | 1=2 |
| Q 2               | 5 | 5 | 5 | 0   |
| Q 0+<br>3         | 5 | 5 | 5 | 0   |
| Q 4 4             | 5 | 5 | 5 | 0   |

Table 1: 0 ptim al renorm alisation schem es for the various four-quark operators.

and subsequently applied in several contexts (for a recent review, see [17]). The reader is referred to the above-mentioned works for a detailed description of the method. More speci cally, since the present work concerns two-avour QCD, we follow closely the work of ref. [18] on the running quark mass with N  $_{\rm f}$  = 2 dynamical quarks.

Concerning the choice of [  $_{\rm A}$ ;  $_{\rm B}$ ;  $_{\rm C}$  ] and , we observe that in our quenched studies [2,4] we have considered ve possible non-trivial D irac structures that preserve cubic sym m etry at vanishing external m om enta, i.e.

$$[A; B; C] = f [5; 5; 5]; ijk[i; j; k]; [5; k; k];$$

$$[k; 5; k]; [k; k; 5] q \qquad (2.30)$$

(where a sum over repeated indices is understood), and various possible values of the

param eter, nam ely = f0;1=2g for the static operators and = f0;1;3=2g for the relativistic ones. Not all of the resulting renorm alisation schem es were equally well suited to our purposes: some of them were characterised by a RG running with a slow perturbative convergence at NLO; cf. refs. [3,10]. This rendered the matching of perturbative and non-perturbative running at  $_{\rm pt}$  (cf. Eq. (2.29)) less reliable and the system atics hard to control; see sect. 3.3 below for more details. The same considerations are valid in the present case of two dynam ical quarks. For the sake of brevity we will concentrate only in those schem es which have been found to be best behaved in the present unquenched study. These optim all schem es are specified in Table 1. A complete account of our results in all schem es considered is available upon request.

The non-universal two-loop  $\cos$  cients of the anom alous dimensions Eq. (2.10)

for the operators of interest in the aforem entioned optim al schem es read [3,4]

$${}^{+}_{1} = \frac{1}{(4)^{2}} = 0.0828(48) + 0.03200(28) N_{f};$$
 (2.31)

$$L = \frac{1}{(4)^2} = 0.6880(24) + 0.12648(16)N_{\rm f} ; \qquad (2.32)$$

$${}^{(1)}_{1} = \frac{1}{(4)^2} = 1.345(2) + 0.0008(2) N_{f};$$
 (2.33)

$${}_{1}^{(2)} = \frac{1}{(4)^{2}}$$
 1:251(1) + 0:11637(8)N<sub>f</sub>; (2.34)

$${}_{1}^{(3)} = \frac{1}{(4)^{2}} = 0.327(3) + 0.1211(2)N_{f};$$
 (2.35)

$${}^{(4)}_{1} = \frac{1}{(4)^2} = 0.146(1) + 0.06784(8)N_{f} : (2.36)$$

# 3 Non-perturbative com putation of the RG running

## 3.1 Simulations details

O ur sin ulations are based on the regularisation of relativistic quarks by the nonperturbatively O (a) improved W ilson action, with the Sheikoleslam iW ohlert (SW ) coe cient c<sub>SW</sub> determined in [19]. Static quarks have been instead discretised as proposed in [20]. In particular, all results reported in this work refer to the socalled HYP2 action, i.e. the lattice static action of [21], with the standard parallel transporter U (0;x) replaced by the temporal hypercubic link introduced in [22], and a choice of the sm earing parameters ( $_1$ ;  $_2$ ;  $_3$ ) = (1:0;1:0;0:5). The latter m inim ises the quenched static self-energy, providing the largest exponential increase of the signal-to-noise ratio in the static-quark propagator, when com pared to the original E ichten-H ill action. The m inim um of the static self-energy is shifted by internalquark-loops only at NLO in perturbation theory: such shift is thus expected to be relatively sm all.

W ith the above prescriptions, the SSFs have been computed at six di erent values of the SF renorm alised coupling, corresponding to six di erent physical lattice lengths L. For each physical volum e three di erent values of the lattice spacing have been simulated, corresponding to lattices with L=a=6;8;12 (and 2L=a=12;16;24 respectively) for the computation of Z (g<sub>0</sub>; a=L) (and Z (g<sub>0</sub>; a=(2L))).

The gauge con guration ensemble used in the present work (generated with  $N_f = 2$  dynamical fermions) and the tuning of the lattice parameters (; ) have been taken over from [18]. All technical details concerning these dynamical fermion simulations are discussed in that work. The one technical aspect that makes a

signi cant di erence in our case concerns the perturbative value of the boundary improvement coecient c<sub>t</sub> [23]. As pointed out in [18], the gauge congurations at the three weakest couplings have been produced using the one{bop perturbative estimate of c<sub>t</sub> [23], except for (L=a = 6, = 7:5420) and (L=a = 8; = 7:7206). For these two cases and for the three stronger couplings, the two{bop value of c<sub>t</sub> [24] has been used. We have enforced the same c<sub>t</sub> values in the valence propagators. C om parison of the results of two di erent simulations, namely

$$g_{SF}^2 = 1.5031(25)$$
; L=a = 6; = 7.5000; = 0.1338150;  $c_t = \text{one loop}$ ;  
 $g_{SF}^2 = 1.5078(44)$ ; L=a = 6; = 7.5420; = 0.1337050;  $c_t = \text{two loop}$ :

shows that the renorm alisation factor  $Z_P$  of the pseudoscalar density, analysed in [18], is subject to a relative 4 perm ille variation, corresponding to a m ild discrepancy of about 1.5 with regards to our statistical uncertainty. Unfortunately, for the fourferm ion correlation functions this remains true only for the operator  $Q_1$  , while the  $Q_1^+$  and  $Q_k^{0+}$  cases show relative variations of the order of 1–2%, corresponding to di erences of about 2:5 with regards to the statistical precision. W e expect that, for a given renorm alised coupling  $\overline{g}_{s_{\rm F}}^2$ , this e ect diminishes at ner lattice resolutions a=L (i.e. closer to the continuum), while it becomes more pronounced in the strong coupling region, at constant L=a. In principle, this problem can be removed by perform ing all simulations with a two{bop estimate of ct and/or a smaller resolution a=L. As further dynam ical simulations are beyond the scope of the present work, we lim it ourselves in stating that our results are subject to this ill-controlled system atic uncertainty, which, in view of the fact that the one-bop value of  $c_t$  is only used in the weak coupling region, is however not expected to be signi cant for our nal results. In this respect, we have checked that the ( nal) overall result is una ected when either  $c_t$  is employed at this coupling. It is also encouraging that, as we will see below, including or discarding the L=a = 6 data-points in the continuum extrapolations does not alter the nal results signi cantly.

N um erical results are collected in Tables  $8\{10.$  Statistical errors were computed by a jackknife analysis. The estimates of the autocorrelation times, calculated with the autocorrelation function method, them ethod of ref. [25] and the binning method, were found to be compatible.

### 3.2 Continuum extrapolation of the step-scaling functions

Since we do not im plement O (a) improvement of four-fermion operators, the only linear cuto e ects that are removed from (u;a=L) are those cancelled by the SW term in the fermion action. Therefore, we expect SSFs to approach the continuum limit linearly in a=L and correspondingly we to the ansatz

$$(u;a=L) = (u) + (u)(a=L)$$
: (3.1)

| u      | + (u)     | (u )      | <sup>(1)</sup> (u) | <sup>(2)</sup> (u) | <sup>(3)</sup> (u) | <sup>(4)</sup> (u) |
|--------|-----------|-----------|--------------------|--------------------|--------------------|--------------------|
| 0.9793 | 1.010(11) | 0.983(07) | 0.946(08)          | 1.004(07)          | 0.960(05)          | 0.990(05)          |
| 1.1814 | 1.044(15) | 0.965(10) | 0.951(12)          | 0.991(08)          | 0.942(07)          | 0.976(05)          |
| 1.5078 | 1.039(21) | 0.953(11) | 0.932(13)          | 0.987(10)          | 0.932(09)          | 0.970(07)          |
| 2.0142 | 1.040(18) | 0.936(11) | 0.896(11)          | 0.985(10)          | 0.901(09)          | 0.955(08)          |
| 2.4792 | 1.078(35) | 0.879(19) | 0.890(19)          | 0.958(13)          | 0.873(14)          | 0.938(12)          |
| 3.3340 | 1.129(37) | 0.862(25) | 0.784(23)          | 0.938(17)          | 0.798(18)          | 0.905(16)          |

Table 2: Results of the continuum limit extrapolation of the lattice step-scaling functions and <sup>(k)</sup>. Data have been tted from all available lattice resolutions as linear functions in (a=L).

In practice it is often observed that the data corresponding to L=a=8;12 are compatible within errors, whereas the L=a=6 result, bearing the largest cuto e ects, is o . This suggests that, in analogy to [18], a weighted average of the two nest lattice results may be a reliable estimate of the continuum limit value. We have checked that, in most cases, linear ts to all three data-points and weighted averages of the two results from the ner lattices lead to continuum limit estimates, compatible within one standard deviation; cf. Figs. 2, 4 and 6. Fit results are reported in Table 2. Since the discretisation errors are 0 (a) and not 0 ( $a^2$ ) as in [18], we conservatively quote, as our best results, those obtained from linear extrapolations involving all three data-points.

It should be added that, besides the HYP2 action, we have also tried other static quark action varieties, namely the APE and the HYP1 ones (see ref. [20]), which di er from HYP2 by O ( $a^2$ ) lattice artefacts. Since the static four-quark operators are not O (a) in proved, it is reasonable to expect signi cant discretisation e ects at the coarsest lattice spacing, which would enable combined ts of the data from all three actions, constrained to a common value in the continuum limit. Unsurprisingly, the situation turned out to be similar to that of [4], in that data obtained with the above actions do not di er noticeably (even at L/a = 6) and are very strongly correlated. Consequently, a combined continuum extrapolation a ects the continuum limit results only marginally, with the relative error decreasing only by a few percent. For this reason we only quote results from the HYP2 analysis.

### 3.3 RG running in the continuum lim it

In order to compute the RG running of the operators in the continuum limit as described in [18], the continuum SSFs have to be tted to some functional form. The simplest choice is represented by a polynomial

$$(u) = 1 + s_1 u + s_2 u^2 + s_3 u^3 + \dots ; \qquad (3.2)$$

| n | u     | $\hat{c}^{+}$ (L $_{max}^{1}$ ) | Ĉ (L <sub>max</sub> <sup>1</sup> ) | $\hat{c}^{(1)}(L_{max}^{1})$ | $\hat{c}^{(2)}(L_{max}^{1})$ | $\hat{c}^{(3)}(L_{max}^{1})$ | $\hat{c}^{(4)}(L_{max}^{1})$ |
|---|-------|---------------------------------|------------------------------------|------------------------------|------------------------------|------------------------------|------------------------------|
| 0 | 4.610 | 1.246                           | 0.551                              | 0.807                        | 0.680                        | 0.524                        | 0.776                        |
| 1 | 3.032 | 1.225(26)                       | 0.564(10)                          | 0.775(14)                    | 0.732(09)                    | 0.532(08)                    | 0.788(09)                    |
| 2 | 2.341 | 1.212(38)                       | 0.566(14)                          | 0.773(20)                    | 0.751(12)                    | 0.538(11)                    | 0.794(12)                    |
| 3 | 1.918 | 1.205(46)                       | 0.564(16)                          | 0.773(24)                    | 0.759(15)                    | 0.541(13)                    | 0.797(14)                    |
| 4 | 1.628 | 1.202(53)                       | 0.561(18)                          | 0.772(27)                    | 0.762(18)                    | 0.541(14)                    | 0.797(16)                    |
| 5 | 1.414 | 1.201(60)                       | 0.558(20)                          | 0.772(30)                    | 0.763(20)                    | 0.541(15)                    | 0.797(18)                    |
| 6 | 1.251 | 1.201(66)                       | 0.554(21)                          | 0.771(33)                    | 0.763(22)                    | 0.540(17)                    | 0.797(19)                    |
| 7 | 1.121 | 1.202(71)                       | 0.551(22)                          | 0.770(35)                    | 0.763(24)                    | 0.539(18)                    | 0.796(20)                    |
| 8 | 1.017 | 1,202(76)                       | 0.548(24)                          | 0.770(37)                    | 0.762(26)                    | 0.538(19)                    | 0.795(22)                    |

Table 3: Perturbative m atching (cf. Eq. (2.29)) for various choices of the m atching scale  $p_t = 2^n_{had}$ .

whose form is motivated by the perturbative series, with coe cients

$$s_1 = 0 \ln 2$$
; (3.3)

$$s_2 = {}_1 \ln 2 + {}_2 ({}_0)^2 + b_0 {}_0 (\ln 2)^2 :$$
 (3.4)

It is worth stressing that  $s_1$  is universal and independent of N<sub>f</sub>, whereas  $s_2$  carries a dependence upon N<sub>f</sub> via  $b_0$  and 1, with the latter coe cient introducing a scheme dependence. In our ts we truncated the polynom ial at O (u<sup>3</sup>). The ts have been performed with  $s_1$  xed to its perturbative value and  $s_2$ ,  $s_3$  left as free parameters. Fit results are shown in Figs. 3, 5 and 7. Fitted values of  $s_2$  turned out to be close to the perturbative prediction of Eq. (3.4), with the exception of Q  $\frac{0^4}{2}$ .

Once the continuous SSFs have been obtained as functions of the renorm alised coupling, the ratios c (cf. Eq. (2.16)) are obtained recursively. The low energy scale  $_{had} = L_{max}^{-1}$  is implicitly de ned in this work through the condition  $\bar{g}_{sF}^{2}(L_{max}) = 4.61$ , as explained in [18]. This scale is chosen so that the renorm alisation constants Z (g<sub>0</sub>; a  $_{had}$ ) can be computed in the accessible g<sub>0</sub>-range commonly used in large-volume simulations. The non-perturbative RG running of the six operators of interest are shown in Fig.8.

As discussed in our form er quenched study [4], the main criterion for selecting robust schem es am ounts to checking that the system atic uncertainty present in our nal results, due to the NLO truncation of the perturbative matching at the scale  $_{\rm pt}$  2<sup>n</sup>  $_{\rm had}$ , is well under control. This in turn requires an estimate of the size of the NNLO contribution to  $\hat{c}$ . To this purpose we have re-computed  $\hat{c}$  with two different ansatze for the NNLO anom abus dimensions  $_2$ : (i) we set  $j_2 = _1 j = _j j_1 = _0 j$ ; (ii) we perform a two-parameter t to the SSF with  $s_1, s_2$  and to their perturbative values and  $s_3, s_4$  left as free parameters, and then estimate  $_2$  by equating the

resulting value of  $s_3$  to its perturbative expression

$$s_{3} = {}_{2} \ln 2 + [{}_{0} {}_{1} + 2b_{0} {}_{1} + b_{1} {}_{0}](\ln 2)^{2} + + \frac{1}{6} {}_{0}^{3} + b_{0} {}_{0}^{2} + \frac{4}{3} b_{0}^{2} {}_{0} (\ln 2)^{3} :$$
(3.5)

The optimal schemes specified in Table 1 are precisely those for which the aforem entioned determ inations of the elective  $_2$  lead to the smallest discrepancies between the corresponding universal factors c.

The e ect of varying the perturbative matching point in the optimal schemes is described by Table 3. We see that numbers are very stable for n 6, while the uncertainty increases with n due to progressive error accumulation at each step. Final results, reported in the second column of Table 7 refer to n = 7. Note that typical relative errors are as big as 5%, which may result in a sizeable error in hadronic matrix elements, solely due to renormalisation.

## 4 Connection to hadronic observables

Having computed the universal evolution factors  $c(_{had})$ , which provide the RG – running from the low energy matching scale  $_{had}$  to a formally in nite one, we proceed to establish the connection between bare lattice operators and their RG I counterparts. The latter, de ned in Eq. (2.16) from the integration of the Callan-Sym anzik equation, are related to the bare operators used in lattice simulations via a total renorm alisation factor  $Z_{RGI}(g_0)$ , de ned as

$$Z_{RGI}(g_0) = Z(g_0; a_{had})\hat{C}(_{had}):$$
 (4.1)

The  $Z_{RGI}$  factor does not depend on any renorm alisation scale and carries a dependence upon the renorm alisation condition only via cuto e ects.

In order to obtain Z (g<sub>0</sub>; a had), we follow [18] and compute Z (g<sub>0</sub>; a ) at three values of the lattice spacing, namely = f5:20;5:29;5:40g, which belong to a range of inverse couplings commonly used for simulations of two-avour QCD in physically large volumes. Simulation parameters and results are collected in Table 4 for the relativistic operators Q<sub>1</sub> and in Table 5 for the static ones Q<sup>0+</sup><sub>k</sub>.

W hile the simulation at ( = 5:20;L=a = 6) is exactly at the target value for  $\overline{g}_{s_F}^2$  (L<sub>m ax</sub>), corresponding to Z (g<sub>0</sub>; a had), the simulations at the other values require a slight interpolation. We adopt a tansatz, motivated by Eq.(2.16),

$$\ln (Z) = c_1 + c_2 \ln (\overline{g}_{SF}^2); \qquad (4.2)$$

in order to interpolate the Z factors between the values of  $\overline{g}_{SF}^2$  straddling the target value  $\overline{g}_{SF}^2$  ( $L_{max}$ ) = 4:61. Note that the ts take into account the (independent)

|      |         | L=a         | $\overline{g}_{\rm SF}^2$ (L)       | Ζ+                                     | Z                                      |

Table 5: Results for Z<sup>(k)</sup> with  $c_t$  set to its 2{loop value. The values of  $\overline{g}_{s_F}^2$  are from [26]. The hopping parameters used in the simulations are the critical ones ( $_{cr}$ ) of [27].

errors of both Z and  $\overline{g}_{sF}^2$ . M oreover, we have conservatively augmented the terrors by the dimension between the tresults of Eq. (4.2) and the results from a naive two-point linear interpolation in  $\overline{g}_{sF}^2$ . The coe cients c<sub>2</sub> of the ts (4.2) deviate in a range of 7% 30% from the lowest order coe cients  $_0=(2b_0)$ , signalling the presence of m oderate higher-order perturbative e ects.

The resulting numbers for the renorm alisation factors at the low energy matching scale, and also for the RGI renorm alisation factors  $Z_{RGI}(g_0)$ , are collected in Table 6. The rst error of the  $Z_{RGI}'s$  stems from the error of Z factors, whereas the second accounts for the uncertainties in the universal factors c. Note that only the rst of these errors should be added in quadrature to the error of the bare hadronic matrix elements, once these become available from future computations, in order

Table 6: Results for  $Z^+$ ,  $Z^-$ ,  $Z^{(k)}$  and  $Z^+_{RGI}$ ,  $Z^{(k)}_{RGI}$ , for three bare gauge coupling values corresponding to our low energy matching point at  $g^2_{SF} = 4.61$  in the SF scheme.

to obtain the total error of the renorm alised quantity, at a given lattice spacing. The second error, which is entirely unrelated to the discretisation of the theory, should only be added in quadrature to the continuum extrapolated hadronic matrix element. For the sake of convenience, a representation of the num erical results of Table 6 by interpolating polynom ials is also adopted, i.e.

$$Z_{RGI} = a_0 + a_1(52) + a_2(52)^2; \qquad (4.3)$$

which can be used at any intermediate value of between = 5:20 and = 5:40. Fit coe cients are reported in Table 7 for the various operators. The uncertainty of the RGI constants at intermediate points may be easily obtained from those at the simulation points, see Table 6, by linear interpolation.

As a nalrem ark, we observe that the simulation of the renorm alisation factors at = 5:20; L=a = 4 is not at the target value for  $g_{SF}^2$ . We used is as a check of the independence of the  $Z_{RGI}$ , computed via Eq. (4.1) from the low energy matching scale. Speci cally, the two measured values of Z-factors at = 5:20 have been used in order to extrapolate the renorm alisation constants at  $g_{SF}^2$  (L<sub>max</sub>=2) = 3:0318, where the non-perturbative matching with the universal evolution factors chas been subsequently perform ed. R esults turned out to be fully compatible with those quoted in Table 6.

| Q                 | $\hat{c}(L_{max}^{1})$ | a <sub>0</sub> | $a_1$  | a <sub>2</sub> |

Table 7: Universal factors ĉ and coe cients of the interpolating polynom ials of the RG I renorm alisation constants, see Eq. (4.3). Uncertainties are discussed in the text.

### 5 Conclusions

U sing standard SF m ethods, we have perform ed a fully non-perturbative com putation of the renorm alisation and RG running of several four-ferm ion operators in  $N_f = 2 \text{ QCD}$ . We have considered the two operators m ade of four relativistic quark elds with a left-left D irac structure and the com plete basis of operators with two static and two relativistic quarks. The W ilson lattice actions have been in plem ented for both the gauge and the ferm ionic parts, the latter with a non-perturbatively tuned C lover term. The HYP2 discretisation of the static quark turned out to be the less noisy choice, after com parison with other options. Only the parity-odd parts of the operators have been analysed, as their renorm alisation pattern is una ected due to the loss of chiral symmetry by the regularisation.

O ur results are an essential building block for any  $N_f = 2$  computation of quantities like  $B_K$  and  $B_B$ . Nevertheless, their precision is somewhat limited by increased statistical uctuations at the three strongest couplings and by the lack of a fourth, ner, lattice resolution which would improve the continuum extrapolation of the operator SSFs. This could lead to a potentially unsatisfactory total error on hadronic matrix elements. Future re nem ent (besides using a two{loop estimate of  $c_t$  throughout the runs and increased statistics at the three strongest couplings) is necessary, either by simulating closer to the continuum limit, or by completely removing leading order discretisation e ects from the simulations.

Table 8: Numerical values of the renormalisation constants Z<sup>+</sup>, Z and the step scaling functions <sup>+</sup>, at various renormalised SF couplings and lattice spacings. Data at  $\overline{g}_{\text{SF}}^2 = 0.9793$ ; 1:1814; 1:5031 have been obtained with  $c_t$  evaluated in one-loop perturbation theory. The remaining data have been obtained with  $c_t$  evaluated in two-loop perturbation theory.

Table 9: Numerical values of the renorm alisation constants Z  $^{(1)}$ , Z  $^{(2)}$  and the step-scaling functions  $^{(1)}$ ,  $^{(2)}$  with HYP2 action at various renorm alised SF couplings and lattice spacings. Data at  $\bar{g}_{\rm SF}^2$  = 0.9793; 1:1814; 1:5031 have been obtained with  $c_t$  evaluated in one-loop perturbation theory. The remaining data have been obtained with  $c_t$  evaluated in two-loop perturbation theory.

Table 10: Num erical values of the renorm alisation constants Z  $^{(3)}$ , Z  $^{(4)}$  and the step-scaling functions  $^{(3)}$ ,  $^{(4)}$  with HYP2 action at various renorm alised SF couplings and lattice spacings. Data at  $\bar{g}_{\rm SF}^2$  = 0.9793; 1:1814; 1:5031 have been obtained with  $c_t$  evaluated in one-loop perturbation theory. The remaining data have been obtained with  $c_t$  approximated in two-loop perturbation theory.
