# Measurement of <sub>s</sub> with Radiative Hadronic Events

# The OPAL Collaboration

#### Abstract

Hadronic nal states with a hard isolated photon are studied using data taken at centre-ofm ass energies around the mass of the Z<sup>0</sup> boson with the OPAL detector at LEP. The strong coupling  $_{\rm S}$  is extracted by comparing data and QCD predictions for event shape observables at average reduced centre-ofm ass energies ranging from 24 G eV to 78 G eV, and the energy dependence of  $_{\rm S}$  is studied. Our results are consistent with the running of  $_{\rm S}$  as predicted by QCD and show that within the uncertainties of our analysis event shapes in hadronic Z<sup>0</sup> decays with hard and isolated photon radiation can be described by QCD at reduced centre-ofm ass energies. Combining all values from di erent event shape observables and energies gives  $_{\rm S}$  (M  $_{\rm Z}$ ) = 0:1182 0:0015(stat:) 0:0101(syst:).

## 1 Introduction

In the theory of strong interactions, Q uantum C hrom odynam ics (Q C D ) [1{3], the strong coupling constant  $_{\rm s}$  is predicted to decrease for high energy or short distance reactions: a phenom enon known as asymptotic freedom. The values of  $_{\rm s}$  at di erent energy scales have been m easured in e<sup>+</sup> e reactions with di erent centre-of-m ass (cm s) energies ranging from 35 to 209 G eV and con rm the prediction [4{11].

A ssum ing that photons em itted before or immediately after the Z<sup>0</sup> production do not interfere with hard QCD processes, a measurement of  $_{\rm s}$  at the reduced cm s energies,  ${\rm s}^0$ , of the hadronic system is possible by using radiative multi-hadronic events, i.e. e<sup>+</sup> e ! qq events.

M ost photons em itted from the incom ing particles before the  $Z^0$  production (initial state radiation, ISR) escape along the beam pipe of the experiment. Measurements of cross-sections for hadron production with ISR have been presented by the KLOE and BaBar collaborations [12{15]. In e<sup>+</sup> e annihilation to hadrons on the  $Z^0$  peak isolated high energy photons observed in the detector are mostly em itted by quarks produced in hadronic  $Z^0$  decays (nal state radiation, FSR), because on the  $Z^0$  peak ISR e ects are supressed. Measurements of  $_s$  in hadronic events with observed photons have been performed by the L3 and DELPHIC ollaborations [16,17]. The DELPHI collaboration has also measured the mean charged particle multiplicity  $hn_{ch}i(s^0)$  using FSR in [18].

W hen an energetic and isolated photon is emitted in the parton shower the invariant m ass of the recoiling parton system is taken to set the energy scale for hard QCD processes such as gluon radiation. In parton shower m odels [19{21] the invariant m ass of an intermediate parton or the transverse m om entum of a parton branching are used as ordering parameters for the parton shower development. In this picture an energetic and isolated photon m ust be produced at an early stage of the shower evolution and therefore can be used to deduce the scale for subsequent QCD processes. The validity of this m ethod w ill be studied below using parton shower M onte C arb program s.

Here we report on a measurem ent of  $_{\rm s}$  from event shape observables determ ined from the hadronic system in events with observed energetic and isolated photons in the OPAL experiment.

# 2 A nalysis m ethod

The reduced on senergy,  $s^0$ , is de ned by  $2E_{\text{beam}} = 1$ .  $E = E_{\text{beam}}$ , where E is the photon energy and  $E_{\text{beam}}$  is the beam energy. The avour mixture of hadronic events in this analysis is changed compared to non-radiative  $Z^0$  decay events. The fraction of up-type quarks is larger due to their larger electric charge. How ever, since the strong interaction is blind to quark avour in the Standard M odel, as e.g. dem onstrated in [22], the di erence is not taken into account.

The determ ination of  $_s$  is based on m easurem ents of event shape observables, which are calculated from all particles with m om enta  $p_i$  in an event:

 ${\tt Thrust}\,{\tt T}$  . The thrust  ${\tt T}\,$  is de ned by the expression

$$T = \max_{\tilde{n}}^{0} \frac{P}{P_{i}} \frac{1}{\tilde{p}_{i}} \frac{1}{\tilde{p}_{j}}$$
(1)

The thrust axis  $\tilde{n}_T$  is the direction  $\tilde{n}$  which maxim ises the expression in parentheses. A plane through the origin and perpendicular to  $\tilde{n}_T$  divides the event into two hem ispheres H<sub>1</sub> and H<sub>2</sub>.

- H eavy Jet M ass M  $_{\rm H}$ . The hem isphere invariant m asses are calculated using the particles in the two hem ispheres H  $_1$  and H  $_2$ . W e de ne M  $_{\rm H}$  as the heavier m ass, divided by  ${}^{\rm D}\overline{\rm s}$ .
- Jet B roadening variables B  $_{\rm T}\,$  and B  $_{\rm W}\,$  . These are dened by computing the quantity

$$B_{k} = \overset{0}{\underline{P}} \underbrace{\overset{1}{\underline{p}_{1}}}_{2} \underbrace{\overset{1}{\underline{p}_{1}}}_{1} \underbrace{\overset{1}{\underline{p}_{1}}}_{2} \underbrace{\overset{1}{\underline{p}_{1}}}_{1} \underbrace{\overset{1}{\underline{p}_{1}}}_{A}$$
(2)

for each of the two event hem ispheres, H  $_{\rm k}$  , de ned above. The two observables are de ned by

 $B_{T} = B_{1} + B_{2}$  and  $B_{W} = m ax(B_{1}; B_{2})$  (3)

where  $B_T$  is the total and  $B_W$  is the wide jet broadening.

C-parameter C. The linear momentum tensor is de ned by

$$= \frac{\sum_{i=1}^{P} p_{i} p_{i} = j p_{i} j}{\sum_{j=1}^{P} p_{j} j}; \quad ; = 1;2;3:$$
(4)

The three eigenvalues i of this tensor de ne C with

$$C = 3(_{1 2} + _{2 3} + _{3 1}):$$
(5)

Transition value  $y_{23}^{D}$ . This observable is given by the value of  $y_{cut}$  in the D urham algorithm where the number of jets in an event changes from two to three.

In order to verify that using hadronic  $Z^0$  decays <u>w</u> ith hard and isolated nal state radiation allows one to extract <sub>s</sub> at a reduced scale  $S^0$  we employ simulated events. We use the M onte C arlo simulation program s JETSET version 7.4 [19], HERWIG version 5.9 [20] and ARIADNE version 4.08 [21], which have di erent in plem entations of the parton shower algorithm s including simulation of FSR. O ne sam ple contains hadronic  $Z^0$  decays with FSR and ISR (375 k events) while the other sam ples are generated at lower cm s energies without ISR (500 k events each).

W e consider the generated events after the parton shower has stopped (parton-level) and calculate event shape observables using the remaining partons. The elective on s energy  $\overline{s^0}$  is calculated from the parton fourmomenta excluding any nalstate photons and the events are boosted into the ons system of the partons. The samples are binned according to the energy  $E_{FSR}$  of any FSR in intervals of 5 G eV width for  $E_{FSR} > 10$  G eV.

We observe good agreement between the corresponding distributions obtained from the Z<sup>0</sup> sample with FSR and the lower energy samples. For example, Figure 1 shows distributions of the event shape observables 1 T and M<sub>H</sub> for two samples with  $\overline{s^0} = 40$  and 70 G eV. We conclude that within the approximations made in the parton shower algorithms, hadronic Z<sup>0</sup> decays with hard and isplated nal state radiation can be used to extract measurements of s at reduced scales  $\overline{s^0}$ .

# 3 The OPAL D etector and Event Sim ulation

The OPAL detector operated at the LEP  $e^+e^-$  collider at CERN from 1989 to 2000. A detailed description of the detector can be found in [23]. We describe brie y the important parts of the detector for this study. In the OPAL coordinate system, the x axis was horizontal and pointed approximately towards the centre of LEP, the y axis was norm alto the z-x plane, and the z axis was in the e beam direction. The polar angle,

, was measured from the z axis, and the azim uthal angle, % f(x) = 0 , from the x axis about the z axis.

The central detector m easured the momentum of charged particles and consisted of a system of cylindrical drift cham bers which lay within an axial magnetic eld of 0.435 T. The momenta  $p_{xy}$  of tracks in the x-y plane were measured with a precision of  $_{p}=p_{xy}=0.02\%$  0.0015  $p_{y}$  [G eV=c] [24].

The electrom agnetic calorim eters completely covered the azim uthal range for polar angles satisfying joos j < 0.98. The barrel electrom agnetic calorim eter covered the polar angle range joos j < 0.82, and consisted of a barrel of 9440 lead glass blocks oriented so that they nearly pointed to the interaction region. The two endcaps were each made of 1132 lead glass blocks, aligned along the z-axis. Each lead glass block in the barrel electrom agnetic calorim eter was 10 10 cm<sup>2</sup> in cross section, which corresponds to an angular region of approximately 40 40 m rad<sup>2</sup>. The intrinsic energy resolution was  $_{\rm E} = {\rm E} = 0.2\%$  6:3% = E [G eV ] [23].

M ost electrom agnetic showers were initiated before the lead glass mainly because of the coil and pressure vessel in front of the calorim eter. An electrom agnetic presam pler made of limited stream er tubes measured the shower position. The barrel presam pler covered the polar angle range jcos j < 0.81 and its angular resolution for photons was approximately 2 m rad.

JETSET version 7.4 was used to simulate e<sup>+</sup> e<sup>-</sup>! qq events, with HERWIG version 5.9 and ARIADNE version 4.08 used as alternatives. Parameters controlling the hadronisation of quarks and gluons were tuned to 0 PAL LEP 1 data as described in [25,26]. We used HERWIG version 5.8 [20], PHOJET version 1.05c [27,28] and VERMASEREN version 1.01 [29] for two-photon interactions and KORALZ version 4.02 [30] for e<sup>+</sup> e<sup>-</sup>! events. G enerated events were processed through a full simulation of the 0 PAL detector [31] and the sam e event analysis chain was applied to the simulated events as to the data. 4,000,000 fully simulated events were generated by JETSET, 200,000 events, 1,000,000 events and 55,000 events were generated by HERWIG, PHOJET and VERMASEREN while 800,000 events were generated by KORALZ.

## 4 Event Selection

#### 4.1 Hadronic Event Selection

This study is based on a sample of 3 m illion hadronic  $Z^0$  decays selected as described in [32] from the data accumulated between 1992 and 1995 at cm s energy of 91.2 GeV. We required that the central detector and the electrom agnetic calorim eter were fully operational.

For this study, we apply stringent cuts on tracks and clusters and further cuts on hadronic events. The clusters in the electrom agnetic calorim eter are required to have a minimum energy of 100 MeV in the barrel and 250 MeV in the endcap. Tracks are

required to have transverse momentum  $p_T$  150 MeV = c with respect to the beam axis, at least 40 reconstructed points in the jet chamber, at the point of closest approach a distance between the track and the nominal vertex  $d_0 < 2$  cm in the r- plane and  $z_0 < 25$  cm in the z direction. We require at least ve such tracks to reduce background from e<sup>+</sup>e ! <sup>+</sup> and ! qq events. The polar angle of the thrust axis is required to satisfy jcos T j < 0.9, to ensure that events are well contained in the OPAL detector. A fter these cuts, a data sample of 2:4 10<sup>6</sup> events remains.

#### 4.2 Isolated Photon Selection

#### 4.2.1 Isolation Cuts

Isolated photons are selected in these hadronic events as follows. Electrom agnetic clusters with an energy  $E_{EC} > 10 \text{ GeV}$  are chosen in order to suppress background from soft photons coming from the decay of mesons. A coordingly, our signal event is de ned as an e<sup>+</sup> e ! qq event with an ISR or FSR photon with energy greater than 10 GeV. We use electrom agnetic clusters in the polar angle region jcos  $_{EC}$  j < 0:72 corresponding to the barrel of the detector, where there is the least material in front of the lead glass, see F igure 2 a). A lso, the non-pointing geometry of the endcap electrom agnetic calorim eter complicates the cluster shape tting explained below. The number of clusters in the data which satisfy  $E_{EC} > 10 \text{ GeV}$  and jcos  $_{EC}$  j < 0:72 is 1,797,532. A coording to the M onte C arlo simulation, 99.3% of these selected clusters com e from non-radiative multi-hadronic events.

The candidate clusters are required to be isolated from any jets, and from other clusters and tracks:

The angle with respect to the axis of any jet,  $_{iso}$ , is required to be larger than 25, see Figure 2 b). The jets are reconstructed from tracks and electrom agnetic clusters, excluding the candidate cluster, using the D urham algorithm [33] with  $y_{cut} = 0.005$ .

The sum of the momenta  $P_{iso}$  of tracks falling on the calorim eter surface inside a 0.2 radian cone around the photon candidate is required to be smaller than 0.5 G eV =c (F igure 2 c)). The total energy deposition in the electrom agnetic calorim eter within a cone of 0.2 radian around the photon candidate,  $E_{iso}$ , is also required to be less than 0.5 G eV (F igure 2 d)).

A fter the isolation cuts, 11,265 clusters are retained. The fraction of clusters from non-radiative multi-hadronic events is reduced to 52.8%. The background from <sup>+</sup> events (two-photon events) is 0.6\% (0.01\%) [34].

#### 4.2.2 Likelihood Photon Selection

Isolated photon candidates are selected by using a likelihood ratio m ethod [35] w ith four input variables. The rst two variables are jcos  $_{\rm EC}$  j and  $_{\rm iso}$ , de ned above. Two m ore variables, the cluster shape t variable S and the distance between the electrom agnetic calorim eter cluster and the associated presam pler cluster, de ned as follows, reduce the background from clusters arising from the decays of neutral hadrons.

The cluster shape tvariable, S, is de ned by

$$S = \frac{1}{N_{block}} \frac{X}{i} \frac{(E_{m eas;i} E_{exp;i})^2}{\frac{2}{m eas;i}}$$
(6)

where  $N_{block}$  is the number of lead glass blocks included in the electrom agnetic cluster,  $E_{m eas;i}$  is the measured energy deposit in the ith block,  $E_{exp;i}$  is the expected energy deposit in the ith block, assuming that the energy is deposited by a single photon, and  $m_{eas;i}$  is the uncertainty in the energy measured by ith electrom agnetic calorim eter block.  $E_{exp;i}$  is a function of position and energy of the incident photon based on the simulation of the OPAL detector with single photons. The value of S is determined by minimizing Equation (6) under variation of the position and energy of the cluster. For a cluster to be considered further in the likelihood, preselection cuts are applied: we require the number of blocks to be at least two and the value of S after the t to be smaller than 10. The quality of the cluster shape ts depends on the assumed resolution  $m_{eas;i}$ ; this will be studied as a system atic uncertainty.

The variable measures the distance between the electrom agnetic calorim eter cluster and the associated presampler cluster, = m ax(j j; j j), with and the angular separations between the clusters.

The distributions of S and are shown in Figures 2 e) and f). The M onte C arlo distributions in these gures are normalized according to the lum inosity obtained from sm all angle B habha events.

A disagreem ent between data and M onte C arb is seen for S and  $_{\rm iso}$ . The level of agreem ent between data and M onte C arb for the S distribution is studied with photons in radiative m uon pair events and  $^{0}$ s produced in tau pair events. It is con m ed that the M onte C arb adequately reproduces the S distributions [34]. The disagreem ent between data and M onte C arb for distributions of S and  $_{\rm iso}$  stem s from the failure of the M onte C arb generators to correctly predict the rate of isolated neutral hadrons, as explained in Section 4.4. In this analysis, the rate of isolated neutral hadrons used in the background subtraction is estim ated from data by m ethods described in Section 4.4.

The likelihood calculation is performed with reference histograms made for seven subsamples, chosen according to the cluster energy. The cut on the likelihood value is chosen so as to retain 80% of the signal events. The likelihood distributions for data and M onte C arb are shown in F igure 3. It can be seen that the likelihood distributions for signal and background events are well separated for each region of electrom agnetic cluster energy. The correlations between variables are taken into account using the algorithm described in [36]. Electrom agnetic clusters which pass the likelihood selection are regarded as photon candidates. If m ore than one candidate is found in the same event the one with the highest energy is chosen.

## 4.3 Final Data Sam ple

H adronic events with hard isolated photon candidates are divided into seven subsamples according to the photon energy for further analysis. Table 1 shows the mean values of  $\overline{s^0}$ , the number of data events and the number of background events for each subsample.

## 4.4 Background Estimation

A coording to the M onte C arb simulation, the contam ination from pair events is between 0.5 and 1.0%. The impact of this small number of events is further reduced because the value of event shape observables for pair events are concentrated in the lowest bin of the distributions, outside the tting range, so their e ect on the  $_{\rm s}$  ts is negligible. The contribution of two photon processes is less than 0.01% in all subsamples and is ignored.

As mentioned in [37], the JETSET M onte Carlo fails to reproduce the observed rate of isolated electrom agnetic clusters, both for isolated photons and isolated <sup>0</sup>'s. Isolated neutral hadrons are the dom inant source of background for this analysis, and their rate has been estimated from data using the following two methods.

Firstly, with the likelihood ratio method the observed likelihood distributions in the data in bins of photon energy were tted with a linear combination of the M onte C arlo distributions for signal and background events which pass the isolation cuts and likelihood preselection requirements. The overall norm alisation of the M onte C arlo distribution is xed to the number of data events. The tuses a binned maximum likelihood method with only the fraction of background events as a free parameter. Figure 3 shows the t results. The values of 2 = d p f: are between 1.2 and 3.4 for 18 degrees of freedom.

Secondly, with the isolated tracks m ethod the fraction of background from isolated neutral hadrons was estim ated from the rates of isolated charged hadrons. We select from the data tracks which satisfy the same isolation criteria as the photon candidates. The composition of these isolated charged hadrons obtained from JETSET is used to infer the rates of charged pions, kaons and protons. When isospin symmetry is assumed, the rates of neutral pions, neutral kaons and neutrons can be estimated from the rates of charged pions, charged kaons and protons, respectively:

$$R_{0} = \frac{1}{2}R \qquad R_{K_{L}^{0}} = \frac{1}{2}R_{K} \qquad R_{n} = R_{p}; \qquad (7)$$

where  $R_X$  is the production rate of particle X.A coording to JETSET tuned with OPAL data, the rate of isospin symmetry violation is 10% for pions and 5% for kaons and protons. This is assigned as a system atic uncertainty for the isolated tracks method and combined with the statistical uncertainty.

The neutral hadron background fractions estim ated by these two m ethods are shown in Table 1. The statistical errors from the number of data and M onte C arb events from tting the likelihood distributions are shown. The results from the two m ethods are within at m ost three standard deviations of these errors, except in the E bin 35 40 G eV.

The standard analysis will use the likelihood ratio method. Any di erences in the resulting values of  $_{\rm s}$  obtained by using the two background estimate methods will be treated as a system atic uncertainty.

# 5 Measurement of Event Shape Distributions

In this analysis event shape observables as de ned above in section 2 are calculated from tracks and electrom agnetic clusters excluding the isolated photon candidate. The contributions of electrom agnetic clusters originating from charged particles are rem oved by the m ethod described in [38].

W e evaluate the observables in the cm s fram e of the hadronic system. The Lorentz boost is determ ined from the energy and angle of the photon candidate. W hen the fourm om entum of particles in the hadronic system is calculated, electrom agnetic clusters are treated as photons w ith zero m ass while tracks of charged particles are treated as hadrons w ith the charged pion m ass.

D istributions of the event shape observables  $(1 \quad T)$  and  $M_H$  are shown for two cm s energies in Figure 4. The remaining background is removed by subtracting the scaled M onte C arb predictions for non-radiative hadronic events and for pair events using the

background estimates listed in Table 1. The elects of the experimental resolution and acceptance are unfolded using M onte C arb sam ples with full detector simulation (detector correction). The unfolding is performed bin-by-bin with correction factors  $r_i^{D et} = h_i = d_i$ , where  $h_i$  represents the value in the ith bin of the event shape distribution of stable hadrons in the M onte C arb simulation, where \hadrons" are de ned as particles with a m ean proper lifetime longer than 3  $10^{10}$  s.  $d_i$  represents the value in the ith bin of the event shape distribution of the event shape distribution calculated with clusters and tracks obtained from M onte C arb sam ples with detector simulation after the complete event selection has been applied. W e refer to the distributions after applying these corrections as data corrected to the hadron level.

The distributions of the event shape observables 1 T and M<sub>H</sub> for data corrected to the hadron level and corresponding M onte C arlo predictions are shown in Figure  $5^{1}_{p}$ . The M onte C arlo sam ples are generated with cm s energies set to the m ean value of  $s^{0}$  in each subsam ple. In the production of the M onte C arlo sam ples ISR and FSR is switched o and on, respectively. The predictions from the event generators are consistent with the data for all  $s^{0}$  bins. There is sim ilar agreem ent between data and event generator predictions for the other observables.

# 6 Measurement of s

Them easurement of  $_{\rm s}$  is performed by thing perturbative QCD predictions to the event shape distributions corrected to the hadron level for (1 T), M<sub>H</sub> [39], B<sub>T</sub>, B<sub>W</sub> [40,41], C [42,43] and y<sup>D</sup><sub>23</sub> [33,44,45]. The O ( $^{2}_{\rm s}$ ) and NLLA calculations are combined with the ln(R) matching scheme. The elects of hadronisation on event shapes must be taken into account in order to perform the hadron level (hadronisation correction). Preserving the normalisation in the hadronisation correction is not trivial for low  $^{1}$  s<sup>0</sup> sam ples because of large hadronisation corrections. The hadronisation correction is applied to the integrated (cumulative) theoretical calculation to conserve normalisation as in our previous analyses [46,47]. The hadron level predictions are obtained from the cumulative theoretical calculation multiplied by a correction factor R<sup>H</sup><sub>i</sub> = H<sub>i</sub>=P<sub>i</sub>, where P<sub>i</sub> (H<sub>i</sub>) represents the value in the ith bin of the cumulative event shape distribution calculated by M onte C arb simulation w ithout (w ith) hadronisation. The JETSET M onte C arb event generator is used for our central results, while HERWIG and ARIADNE are considered as alternatives for the estimation of system atic uncertainties.

The t of the hadron level QCD predictions to the event shape observables uses a least  $^2$  m ethod with  $_{\rm s}$ (Q) treated as a free parameter. Only statistical uncertainties are taken into account in the calculation of  $^2$ . When the total number of events is small, the dimension between the statistical errors counting larger or smaller numbers of events than the theoretical prediction can bias the tresult. In order to avoid this bias the value of the tted theoretical distribution is used to calculate the statistical error instead of the number of events in each bin of the data distribution. The statistical uncertainty is estimated from the tresults derived from 100 M onte C arb subsamples with the same number of events as selected data events.

The region used in the t is adjusted such that the background subtraction and the detector and hadronisation corrections are small (less than 50%) and uniform in that

<sup>&</sup>lt;sup>1</sup>The values of the six observables at the seven energy points are given in [34] and will be available under http://durpdg.dur.ac.uk/HEPDATA/.

region. The resulting transfers are mainly restricted by the hadronisation corrections. The QCD predictions at  $\overline{s^0} = 78 \text{ GeV}$  the to data after applying the hadronisation correction are shown in Figure 6. Good agreem ent between data and theory is seen. The the values of s and their errors for each event shape observable are shown in Tables 2-5.

## 6.1 System atic Uncertainties

#### 6.1.1 Experim ental Uncertainties

The experim ental uncertainty is estimated by adding in quadrature the following contributions:

the di erence between the standard result and the result when all clusters and tracks are used without correcting for double counting of energy. This variation is sensitive to imperfections of the detector simulation.

the largest deviation between the standard result and the result when the analysis is repeated with tighter selection criteria to elim inate background (standard values in brackets): the thrust axis is required to lie in the range jcos  $_T j < 0.7 (0.9)$ , or the cluster shape variable is required to be smaller than 5 (10), or the isolation angle from any jet is required to be larger than 35 (25).

the di erence between the standard value and the value obtained by repeating the analysis with the background fractions estimated from the rate of isolated charged hadrons as described in Section 4.

the di erence between the standard result and the result when the single block energy resolution is varied to give the expected  $^2$  in the cluster shape ts. This check is made, because the values of  $^2$  in the cluster shape ts depend on the assumed energy resolution.

the maximum dierence between the standard result and the result when the tregions are varied. The lower and upper limit of the tting region are independently changed by 1 bin.

The tighter selection on jcos  $_{\rm T}$  j and the alternative single block energy resolution of the electrom agnetic calorim eter yield the largest contributions to the experim ental system atic uncertainty. The overall resolution and energy scale uncertainty of the electrom agnetic calorim eter have a neglegible e ect on the results of this analysis.

## 6.1.2 Hadronisation Uncertainties

The following variations are performed in order to estimate the hadronisation uncertainties:

the largest of the changes in  $_{\rm s}$  observed when independently varying the hadronisation parameters b and  $_{\rm Q}$  by 1 standard deviation about their tuned values in JETSET [25];

the change observed when the parton virtuality cut-o parameter  $Q_0$  is varied by 1 standard deviation about its tuned value in JETSET;

the change observed when only the light quarks u, d, s and c are considered at the parton level in order to estim ate potential quark m ass e ects;

the di erences with respect to the standard result when HERWIG or ARIADNE are used for the hadronisation correction, rather than JETSET.

W e de ne the hadronisation correction uncertainty by adding in quadrature the deviation when using only light quarks and the larger deviation when using HERWIG or ARIADNE to calculate the corrections. These variations are observed to lead to larger di erences than all other variations, i.e. the main contributions to the hadronisation uncertainties are the choice of hadronisation model and the potential e ect of quark masses.

#### 6.1.3 Theoretical Uncertainties

We x the renorm alisation scale parameter x = Q to 1, where is the energy scale at which the theory is renorm alized and Q is the energy scale of the reaction. A lthough the uncertainty on the choice of the value of x gives a large contribution to the system atic uncertainty, the means of quantifying this uncertainty is essentially arbitrary. We de ne the scale uncertainty as the larger of the deviations of  $_{\rm s}$  when x is changed from 1 to 0.5 or 2.0.

The O ( $\frac{2}{s}$ ) and NLLA calculations are combined with the ln(R) matching scheme. The variation in  $\frac{1}{s}(\frac{1}{s^0})$  due to using dimension atching schemes is much smaller than the renormalisation scale uncertainty [48], and is not included as an additional theoretical system atic uncertainty.

## 6.2 C om bination of <sub>s</sub> R esults

The values of  $_{\rm s}$  obtained for each observable at each energy are used to study the energy dependence of  $_{\rm s}$  and to obtain an overall combined result for  $_{\rm s}$  (M  $_{\rm z}$ ). The individual values of  $_{\rm s}$  as given in Tables 2–5 and shown in Figure 7 are combined taking the correlations between their statistical and system atic errors into account using the method described in [8]. The statistical covariances between results from di erent observables are determined at each energy from 100 M onte C arb subsamples with the same number of events as selected in the data. The experimental system atic uncertainties are assumed to be partially correlated, i.e.  $\cot_{ij} = \min(_{i};_{j})^2$ . The hadronisation and theoretical covariances are only added to the diagonal of the total covariance matrix. The correlations between these uncertainties are considered by repeating the combination procedure with di erent hadronisation corrections (udsc only, HERWIG, ARIADNE) and with di erent renorm alisation scale parameters (x = 2 and 0.5). The system atic uncertainties for the combined value are obtained by repeating the combination for each system atic variation. The resulting values of  $_{\rm s}^{(1)}$  are shown in Table 6 and Figure 8.

Values of s from individual observables at each energy are combined after evolving them to  $\frac{P}{s} = M_z$ . In this case the results are statistically uncorrelated. The correlations between system atic uncertainties are treated as explained above. The results are given in Table 7 and Figure 9.

We also combine the combined values listed in Table 7 taking into account their statistical correlations using the sum of the inverses of the individual statistical covariance matrices at each energy point. The result is

$$_{\rm s}$$
 (M  $_{\rm Z}$ ) = 0:1182 0:0015(stat:) 0:0101(syst:): (8)

and is shown with individual errors in Table 7. Figure 8 shows the evolution of the strong coupling using our result. As a crosscheck on the robustness of the combination procedure we repeat the combination using the combined results at each energy point shown in Table 6 or using all individual results and nd  $_{s}(M_{z}) = 0.1183 \quad 0.0103$  or  $_{s}(M_{z}) = 0.1179 \quad 0.0103$ , respectively.

O ur result is consistent within the statistical and experimental errors with the result from OPAL using non-radiative events in LEP 1 data with the same set of observables,  $_{\rm s}$  (M  $_{\rm Z}$ ) = 0:1192 0:0002(stat:) 0:0050(syst:) [8]. O ur result is also consistent with recent combined values [11,49{51} and results from other analyses using radiative events [16,17]. Figure 10 compares our result with the LEP 1 value for  $_{\rm s}$  from [8] and an average of results from L3 using radiative hadronic Z<sup>0</sup> decays [16]<sup>2</sup>.

The combinations of individual observables at di erent on s energies yield  $^2=d\mathfrak{p}\mathfrak{f}$ : 1=6. The small values of  $^2=d\mathfrak{p}\mathfrak{f}$ : are due to the conservative treatment of hadronisation and theoretical uncertainties. The values of  $^2=d\mathfrak{p}\mathfrak{f}$ : indicate consistency of the individual results with the model of the combination including evolution of results at di erent on s energies to M <sub>z</sub> before the combination.

## 7 Summary

The strong coupling s has been measured at reduced on s energies,  $p \overline{s^0}$ , ranging from 20 G eV to 80 G eV using event shape observables derived from the hadronic system in radiative hadronic events.

Fits of O ( $_{s}^{2}$ ) and NLLA QCD predictions to the six event shape observables 1 T,  $M_{H}$ ,  $B_{T}$ ,  $B_{W}$ , C and  $y_{23}^{D}$  are performed and values of  $_{s}$  are obtained for seven values of  $s^{0}$ . Our results are consistent with the running of  $_{s}$  as predicted by QCD. The values at each  $s^{0}$  are evolved to  $= M_{z}$  and combined for each event shape observable. The combined value from all event shape observables and  $s^{0}$  values is  $_{s}(M_{z}) = 0.1182$ 0:0015(stat:) 0:0101(syst:).

This result agrees with previous OPAL analyses with non-radiative LEP 1 data, with a similar measurement by L3, and with recent world average values, see gure 10. Within errors, QCD is consistent with our data sample of events with isolated FSR. Our result supports the assumption that the elects of high energy and large angle FSR on event shapes in hadronic  $Z^0$  decays can be electively described by QCD with a lower elective on senergy  $\overline{s^0}$ .

# A cknow ledgem ents

W e particularly wish to thank the SL D ivision for the e cient operation of the LEP accelerator at all energies and for their close cooperation with our experim ental group. In addition to the support sta at our own institutions we are pleased to acknow ledge the D epartm ent of Energy, USA,

National Science Foundation, USA,

Particle Physics and Astronom y Research Council, UK,

 $<sup>^{2}</sup>$ The average is calculated using our combination procedure with the values in table 65 of [16]. We assume partially correlated experimental errors and evaluate the hadronisation and theory uncertainties by repeating the combination with simultanously changed input values. The L3 analysis is not checked for sensitivity to the presence of massive b quarks and thus has smaller hadronisation uncertainties.

Table 7: C on bined values of  $_{s}$  (M  $_{z}$ ) and their errors from all photon energy subsamples for a given observable. The nalcombined value of  $_{s}$  (M  $_{z}$ ) is also shown.

Figure 1: The distributions of event shape observables 1 T and M<sub>H</sub> for non-radiative events and radiative hadronic events from the M onte C arlo generators JETSET, HERWIG and ARIADNE as indicated below the gures. The triangles and points show distributions obtained from the Z<sup>0</sup> samples with FSR while the histogram s show distributions from samples generated at lower energies as shown on the gure. The open triangles and solid histogram (solid points and dashed histogram) in each gure correspond to radiatered = 40 (70) G eV.

Figure 2: D istributions of each variable used in the isolated photon selection. The error bars show the statistical errors. M onte C arb distributions are norm alized to the integrated lum inosity of the data and the cross section of the process. A rrow s in the gures show the selected region. D istributions for radiative multi-hadronic events, which are signal events in this analysis, are overlaid on distributions for all multi-hadronic events and events. The distribution of each variable is obtained with the cuts on the preceding variables applied.

Figure 3: Photon likelihood distributions. The error bar shows statistical error. The M onte C arb distributions are norm alised to the total num ber of candidates in the data, and the neutral hadron background fractions are obtained from the ts described in Section 4.4. The arrows indicate the selected regions.

Figure 4: Event shape distributions before background subtraction and detector correction. Two of the six event shape observables, 1 T and M<sub>H</sub>, are shown for the low (38.5 GeV) and high (78.1 GeV)<sup>-</sup> s<sup>0</sup> sam ples. The histogram s show M onte C arlo distributions. The error bars show the statistical errors.

Figure 5: Event shape distributions at the hadron level. The error bars correspond to the statistical and experimental uncertainties described in Section 6.1.1. Two of the six event shape observables, 1 T and M<sub>H</sub>, are shown for the low (38.5 G eV) and high (78.1 G eV)  $s^0$  sam ples. The sm all lines on the error bars show the extent of the statistical uncertainty. The data points are placed at the centres of the corresponding bins. The predictions of JETSET, HERWIG and ARIADNE at the corresponding  $s^0$  values are also shown as lines.

Figure 6: Event shape distributions for data ath  $s^{p}$  = 78:1 G eV and the tted theoretical predictions. The error bars show the statistical errors. The solid lines in the theoretical predictions show the regions used in the t. Three corrections are plotted as \R corr": the detector correction,  $r_{i}^{D et}$  (dashed line), the hadronisation correction,  $R_{i}^{H ad}$  (solid line), and the ratio of distributions after and before background subtraction (dotted line). The hadronisation correction is shown by the ratio of di erential distributions in these gures (see text for details).

Figure 7: Energy dependence of  $_{s}$  for all  $p_{s}$  subsamples. The inner error bars show the statistical and the outer error bars the total uncertainties. The curves and shaded bands show the QCD prediction for the running of  $_{s}$  obtained with the corresponding values of  $_{s}(M_{z})$  with total errors from Table 7.

Figure 8: Combined values of  $_{\rm s}$  from all event shape observables as shown in Table 6. The curve and shaded band show the QCD prediction for the running of  $_{\rm s}$  using the combined value of  $_{\rm s}$  (M  $_{\rm Z}$ ) with total errors.

Figure 9: The values of  $_{s}(M_{z})$  obtained by combining all  $p = \frac{1}{s^{0}}$  samples as shown in Table 7. The inner error bars are statistical, the outer error bars correspond to the total uncertainty. The dashed vertical lines and shaded bands show the LEP 1 results from OPAL [8] using non-radiative events.

Figure 10: C on bined values of  $_{s}(M_{z})$  for all event shape observables and  $p = 10^{-1}$  samples. The error bars show total uncertainties. The results from this analyses with radiative events, from non-radiative events with OPAL LEP 1 data [8] and from L3 radiative events [16] are shown. The PDG [49] value of  $_{s}(M_{z})$  is also shown as the vertical line, with the total uncertainty corresponding to the shaded band.

# Measurement of <sub>s</sub> with Radiative Hadronic Events

# The OPAL Collaboration

#### Abstract

Hadronic nal states with a hard isolated photon are studied using data taken at centre-ofm ass energies around the mass of the Z<sup>0</sup> boson with the OPAL detector at LEP. The strong coupling  $_{\rm S}$  is extracted by comparing data and QCD predictions for event shape observables at average reduced centre-ofm ass energies ranging from 24 G eV to 78 G eV, and the energy dependence of  $_{\rm S}$  is studied. Our results are consistent with the running of  $_{\rm S}$  as predicted by QCD and show that within the uncertainties of our analysis event shapes in hadronic Z<sup>0</sup> decays with hard and isolated photon radiation can be described by QCD at reduced centre-ofm ass energies. Combining all values from di erent event shape observables and energies gives  $_{\rm S}$  (M  $_{\rm Z}$ ) = 0:1182 0:0015(stat:) 0:0101(syst:).

## 1 Introduction

In the theory of strong interactions, Q uantum C hrom odynam ics (Q C D ) [1{3], the strong coupling constant  $_{\rm s}$  is predicted to decrease for high energy or short distance reactions: a phenom enon known as asymptotic freedom . Values of  $_{\rm s}$  at di erent energy scales have been m easured at PETRA and LEP in e<sup>+</sup> e reactions with di erent centre-of-m ass (cm s) energies ranging from 35 to 209 G eV and con rm the prediction [4{11].

A ssum ing that photons em itted before or immediately after the Z<sup>0</sup> production do not interfere with hard QCD processes, a measurement of  $_{\rm s}$  at the reduced cm s energies,  ${\rm s}^0$ , of the hadronic system is possible by using radiative multi-hadronic events, i.e. e<sup>+</sup> e ! qq events.

M ost photons em itted from the incom ing particles before the  $Z^0$  production (initial state radiation, ISR) escape along the beam pipe of the experiment. M easurements of cross-sections for hadron production with ISR have been presented by the KLOE and BaBar collaborations [12{15]. In e<sup>+</sup> e annihilation to hadrons on the  $Z^0$  peak isolated high energy photons observed in the detector are mostly em itted by quarks produced in hadronic  $Z^0$  decays (nal state radiation, FSR), because on the  $Z^0$  peak ISR e ects are suppressed. M easurements of  $_s$  in hadronic events with observed photons have been performed by the L3 and DELPHIC ollaborations [16,17]. The DELPHI collaboration has also measured the mean charged particle multiplicity  $hn_{ch}i(s^0)$  using FSR in [18].

W hen an energetic and isolated photon is emitted in the parton shower the invariant m ass of the recoiling parton system is taken to set the energy scale for hard QCD processes such as gluon radiation. In parton shower m odels [19{21] the invariant m ass of an intermediate parton or the transverse m om entum of a parton branching are used as ordering parameters for the parton shower development. In this picture an energetic and isolated photon m ust be produced at an early stage of the shower evolution and therefore can be used to deduce the scale for subsequent QCD processes. The validity of this m ethod w ill be studied below using parton shower M onte Carlo program s.

Here we report on a measurement of  $_{\rm s}$  from event shape observables determined from the hadronic system in events with observed energetic and isolated photons in the OPAL experiment.

# 2 A nalysis m ethod

The reduced on senergy,  $s^0$ , is defined by  $2E_{\text{beam}} = 1$ .  $E_{\text{beam}}$ , where E is the photon energy and  $E_{\text{beam}}$  is the beam energy. The avour mixture of hadronic events in this analysis is changed compared to non-radiative  $Z^0$  decay events. The fraction of up-type quarks is larger due to their larger electric charge. However, since the strong interaction is blind to quark avour in the Standard M odel, as e.g. demonstrated in [22], the difference is not taken into account. The elects of massive b quarks on hadronization corrections are considered below as a system atic uncertainty.

The determ ination of  $_{\rm s}$  is based on m easurem ents of event shape observables, which are calculated from all particles with m om enta p<sub>i</sub> in an event:

Thrust T. The thrust T is de ned by the expression

$$T = \max_{\hat{n}}^{0} \frac{P_{i} \hat{p}_{i}}{P_{i} \hat{p}_{i}}^{1} \frac{\hat{n}_{j}}{\hat{p}_{i}}$$
(1)

The thrust axis  $\tilde{n}_T$  is the direction  $\tilde{n}$  which maxim ises the expression in parentheses. A plane through the origin and perpendicular to  $\tilde{n}_T$  divides the event into two hem ispheres H<sub>1</sub> and H<sub>2</sub>.

- H eavy Jet M ass M  $_{\rm H}$ . The hem isphere invariant m asses are calculated using the particles in the two hem ispheres H  $_1$  and H  $_2$ . W e de ne M  $_{\rm H}$  as the heavier m ass, divided by  ${}^{\rm D}\overline{\rm s}$ .
- Jet B roadening variables B  $_{\rm T}\,$  and B  $_{\rm W}\,$  . These are dened by computing the quantity

$$B_{k} = \overset{0}{\underline{P}} \underbrace{\overset{1}{\underline{p}_{1}}}_{2} \underbrace{\overset{1}{\underline{p}_{1}}}_{1} \underbrace{\overset{1}{\underline{p}_{1}}}_{2} \underbrace{\overset{1}{\underline{p}_{1}}}_{1} \underbrace{\overset{1}{\underline{p}_{1}}}_{A}$$
(2)

for each of the two event hem ispheres, H  $_{\rm k}$  , de ned above. The two observables are de ned by

 $B_{T} = B_{1} + B_{2}$  and  $B_{W} = m ax(B_{1}; B_{2})$  (3)

where  $B_T$  is the total and  $B_W$  is the wide jet broadening.

C-parameter C. The linear momentum tensor is de ned by

$$= \frac{\sum_{i=1}^{P} p_{i} p_{i} = j p_{i} j}{\sum_{j=1}^{P} p_{j} j}; \quad ; = 1;2;3:$$
(4)

The three eigenvalues i of this tensor de ne C with

$$C = 3(_{1 2} + _{2 3} + _{3 1}):$$
(5)

Transition value  $y_{23}^{D}$ . This observable is given by the value of  $y_{cut}$  in the D urham algorithm where the number of jets in an event changes from two to three.

In order to verify that using hadronic  $Z^0$  decays <u>w</u> ith hard and isolated nal state radiation allows one to extract <sub>s</sub> at a reduced scale  $S^0$  we employ simulated events. We use the M onte C arlo simulation program s JETSET version 7.4 [19], HERWIG version 5.9 [20] and ARIADNE version 4.08 [21], which have di erent in plem entations of the parton shower algorithm s including simulation of FSR. O ne sam ple contains hadronic  $Z^0$  decays with FSR and ISR (375 k events) while the other sam ples are generated at lower cm s energies without ISR (500 k events each).

W e consider the generated events after the parton shower has stopped (parton-level) and calculate event shape observables using the remaining partons. The elective on s energy  $\overline{s^0}$  is calculated from the parton fourmomenta excluding any nalstate photons and the events are boosted into the ons system of the partons. The samples are binned according to the energy  $E_{FSR}$  of any FSR in intervals of 5 G eV width for  $E_{FSR} > 10$  G eV.

We observe good agreement between the corresponding distributions obtained from the Z<sup>0</sup> sample with FSR and the lower energy samples. For example, Figure 1 shows distributions of the event shape observables 1 T and M<sub>H</sub> for two samples with  $\overline{s^0} = 40$  and 70 G eV. We conclude that within the approximations made in the parton shower algorithms, hadronic Z<sup>0</sup> decays with hard and isplated nal state radiation can be used to extract measurements of s at reduced scales  $\overline{s^0}$ .

# 3 The OPAL D etector and Event Sim ulation

The OPAL detector operated at the LEP  $e^+e^-$  collider at CERN from 1989 to 2000. A detailed description of the detector can be found in [23]. We describe brie y the important parts of the detector for this study. In the OPAL coordinate system, the x axis was horizontal and pointed approximately towards the centre of LEP, the y axis was norm alto the z-x plane, and the z axis was in the e beam direction. The polar angle,

, was measured from the z axis, and the azim uthal angle, % f(x) = 0 , from the x axis about the z axis.

The central detector m easured the momentum of charged particles and consisted of a system of cylindrical drift cham bers which lay within an axial magnetic eld of 0.435 T. The momenta  $p_{xy}$  of tracks in the x-y plane were measured with a precision of  $_{p}=p_{xy}=0.02\%$  0.0015  $p_{y}$  [G eV=c] [24].

The electrom agnetic calorim eters completely covered the azim uthal range for polar angles satisfying joos j < 0.98. The barrel electrom agnetic calorim eter covered the polar angle range joos j < 0.82, and consisted of a barrel of 9440 lead glass blocks oriented so that they nearly pointed to the interaction region. The two endcaps were each made of 1132 lead glass blocks, aligned along the z-axis. Each lead glass block in the barrel electrom agnetic calorim eter was 10 10 cm<sup>2</sup> in cross section, which corresponds to an angular region of approximately 40 40 m rad<sup>2</sup>. The intrinsic energy resolution was  $_{\rm E} = {\rm E} = 0.2\%$  6:3% = E [G eV ] [23].

M ost electrom agnetic showers were initiated before the lead glass mainly because of the coil and pressure vessel in front of the calorim eter. An electrom agnetic presam pler made of limited stream er tubes measured the shower position. The barrel presam pler covered the polar angle range jcos j < 0.81 and its angular resolution for photons was approximately 2 m rad.

JETSET version 7.4 was used to simulate e<sup>+</sup> e<sup>-</sup>! qq events, with HERWIG version 5.9 and ARIADNE version 4.08 used as alternatives. Parameters controlling the hadronisation of quarks and gluons were tuned to 0 PAL LEP 1 data as described in [25,26]. We used HERWIG version 5.9 [20], PHOJET version 1.05c [27,28] and VERMASEREN version 1.01 [29] for two-photon interactions and KORALZ version 4.02 [30] for e<sup>+</sup> e<sup>-</sup>! events. G enerated events were processed through a full simulation of the 0 PAL detector [31] and the sam e event analysis chain was applied to the simulated events as to the data. 4,000,000 fully simulated events were generated by JETSET, 200,000 events, 1,000,000 events and 55,000 events were generated by HERWIG, PHOJET and VERMASEREN while 800,000 events were generated by KORALZ.

## 4 Event Selection

#### 4.1 Hadronic Event Selection

This study is based on a sample of 3 m illion hadronic  $Z^0$  decays selected as described in [32] from the data accumulated between 1992 and 1995 at cm s energy of 91.2 GeV. We required that the central detector and the electrom agnetic calorim eter were fully operational.

For this study, we apply stringent cuts on tracks and clusters and further cuts on hadronic events. The clusters in the electrom agnetic calorim eter are required to have a minimum energy of 100 MeV in the barrel and 250 MeV in the endcap. Tracks are

required to have transverse momentum  $p_T$  150 MeV = c with respect to the beam axis, at least 40 reconstructed points in the jet chamber, at the point of closest approach a distance between the track and the nominal vertex  $d_0 < 2$  cm in the r- plane and  $z_0 < 25$  cm in the z direction. We require at least ve such tracks to reduce background from e<sup>+</sup>e ! <sup>+</sup> and ! qq events. The polar angle of the thrust axis is required to satisfy jcos T j < 0.9, to ensure that events are well contained in the OPAL detector. A fter these cuts, a data sample of 2:4 10<sup>6</sup> events remains.

#### 4.2 Isolated Photon Selection

#### 4.2.1 Isolation Cuts

Isolated photons are selected in these hadronic events as follows. Electrom agnetic clusters with an energy  $E_{EC} > 10 \text{ GeV}$  are chosen in order to suppress background from soft photons coming from the decay of mesons. A coordingly, our signal event is de ned as an e<sup>+</sup> e ! qq event with an ISR or FSR photon with energy greater than 10 GeV. We use electrom agnetic clusters in the polar angle region jcos  $_{EC}$  j < 0:72 corresponding to the barrel of the detector, where there is the least material in front of the lead glass, see F igure 2 a). A lso, the non-pointing geometry of the endcap electrom agnetic calorim eter complicates the cluster shape tting explained below. The number of clusters in the data which satisfy  $E_{EC} > 10 \text{ GeV}$  and jcos  $_{EC}$  j < 0:72 is 1,797,532. A coording to the M onte C arlo simulation, 99.3% of these selected clusters com e from non-radiative multi-hadronic events.

The candidate clusters are required to be isolated from any jets, and from other clusters and tracks:

The angle with respect to the axis of any jet,  $_{iso}$ , is required to be larger than 25, see Figure 2 b). The jets are reconstructed from tracks and electrom agnetic clusters, excluding the candidate cluster, using the D urham algorithm [33] with  $y_{cut} = 0.005$ .

The sum of the momenta  $P_{iso}$  of tracks falling on the calorim eter surface inside a 0.2 radian cone around the photon candidate is required to be smaller than 0.5 G eV =c (F igure 2 c)). The total energy deposition in the electrom agnetic calorim eter within a cone of 0.2 radian around the photon candidate,  $E_{iso}$ , is also required to be less than 0.5 G eV (F igure 2 d)).

A fter the isolation cuts, 11,265 clusters are retained. The fraction of clusters from non-radiative multi-hadronic events is reduced to 52.8%. The background from <sup>+</sup> events (two-photon events) is 0.6\% (0.01\%) [34].

#### 4.2.2 Likelihood Photon Selection

Isolated photon candidates are selected by using a likelihood ratio m ethod w ith four input variables, see appendix A for details. The rst two variables are jcos  $_{\rm EC}$  jand  $_{\rm iso}$ , de ned above. Two m ore variables, the cluster shape t variable S and the distance between the electrom agnetic calorim eter cluster and the associated presampler cluster, de ned as follows, reduce the background from clusters arising from the decays of neutral hadrons.

The cluster shape t variable, S , is de ned by

$$S = \frac{1}{N_{block}} X_{i} \frac{(E_{m eas;i} E_{exp;i})^{2}}{\frac{2}{m eas;i}}$$
(6)

where  $N_{block}$  is the number of lead glass blocks included in the electrom agnetic cluster,  $E_{m eas;i}$  is the measured energy deposit in the ith block,  $E_{exp;i}$  is the expected energy deposit in the ith block, assuming that the energy is deposited by a single photon, and  $m_{eas;i}$  is the uncertainty in the energy measured by ith electrom agnetic calorim eter block.  $E_{exp;i}$  is a function of position and energy of the incident photon based on the simulation of the OPAL detector with single photons. The value of S is determined by minimizing Equation (6) under variation of the position and energy of the cluster. For a cluster to be considered further in the likelihood, preselection cuts are applied: we require the number of blocks to be at least two and the value of S after the t to be smaller than 10. The quality of the cluster shape ts depends on the assumed resolution  $m_{eas;i}$ ; this will be studied as a system atic uncertainty.

The variable measures the distance between the electrom agnetic calorim eter cluster and the associated presampler cluster, = m ax(j j; j j), with and the angular separations between the clusters.

The distributions of S and are shown in Figures 2 e) and f). The M onte C arlo distributions in these gures are normalized according to the lum inosity obtained from sm all angle B habha events.

A disagreem ent between data and M onte C arb is seen for S and  $_{\rm iso}$ . The level of agreem ent between data and M onte C arb for the S distribution is studied with photons in radiative m uon pair events and  $^{0}$ s produced in tau pair events. It is con m ed that the M onte C arb adequately reproduces the S distributions [34]. The disagreem ent between data and M onte C arb for distributions of S and  $_{\rm iso}$  stem s from the failure of the M onte C arb generators to correctly predict the rate of isolated neutral hadrons, as explained in Section 4.4. In this analysis, the rate of isolated neutral hadrons used in the background subtraction is estim ated from data by m ethods described in Section 4.4.

The likelihood calculation is performed with reference histograms made for seven subsamples, chosen according to the cluster energy. The cut on the likelihood value is chosen so as to retain 80% of the signal events. The likelihood distributions for data and M onte C arlo are shown in Figure 3. It can be seen that the likelihood distributions for signal and background events are well separated for each region of electrom agnetic cluster energy. E lectrom agnetic clusters which pass the likelihood selection are regarded as photon candidates. If m ore than one candidate is found in the same event the one with the highest energy is chosen.

## 4.3 Final Data Sam ple

Hadronic events with hard isolated photon candidates are divided into seven subsamples according to the photon energy for further analysis. Table 1 shows the mean values of  $\overline{s^0}$ , the number of data events and the number of background events for each subsample.

## 4.4 Background Estimation

A coording to the M onte C arb simulation, the contam ination from pair events is between 0.5 and 1.0%. The impact of this small number of events is further reduced because the value of event shape observables for pair events are concentrated in the lowest bin of the distributions, outside the tting range, so their e ect on the  $_{\rm s}$  ts is negligible. The contribution of two photon processes is less than 0.01% in all subsamples and is ignored.

As mentioned in [35], the JETSET M onte Carlo fails to reproduce the observed rate of isolated electrom agnetic clusters, both for isolated photons and isolated <sup>0</sup>'s. Isolated neutral hadrons are the dom inant source of background for this analysis, and their rate has been estimated from data using the following two methods.

Firstly, with the likelihood ratio method the observed likelihood distributions in the data in bins of photon energy were tted with a linear combination of the M onte C arlo distributions for signal and background events which pass the isolation cuts and likelihood preselection requirements. The overall norm alisation of the M onte C arlo distribution is xed to the number of data events. The tuses a binned maximum likelihood method with only the fraction of background events as a free parameter. Figure 3 shows the t results. The values of 2 = d p f: are between 1.2 and 3.4 for 18 degrees of freedom.

Secondly, with the isolated tracks m ethod the fraction of background from isolated neutral hadrons was estim ated from the rates of isolated charged hadrons. We select from the data tracks which satisfy the same isolation criteria as the photon candidates. The composition of these isolated charged hadrons obtained from JETSET is used to infer the rates of charged pions, kaons and protons. When isospin symmetry is assumed, the rates of neutral pions, neutral kaons and neutrons can be estimated from the rates of charged pions, charged kaons and protons, respectively:

$$R_{0} = \frac{1}{2}R \qquad R_{K_{L}^{0}} = \frac{1}{2}R_{K} \qquad R_{n} = R_{p}; \qquad (7)$$

where  $R_X$  is the production rate of particle X.A coording to JETSET tuned with OPAL data, the rate of isospin symmetry violation is 10% for pions and 5% for kaons and protons. This is assigned as a system atic uncertainty for the isolated tracks method and combined with the statistical uncertainty.

The neutral hadron background fractions estim ated by these two m ethods are shown in Table 1. The statistical errors from the number of data and M onte C arb events from tting the likelihood distributions are shown. The results from the two m ethods are within at m ost three standard deviations of these errors, except in the E bin 35 40 G eV.

The standard analysis will use the likelihood ratio method. Any di erences in the resulting values of  $_{\rm s}$  obtained by using the two background estimate methods will be treated as a system atic uncertainty.

# 5 Measurement of Event Shape Distributions

In this analysis event shape observables as de ned above in section 2 are calculated from tracks and electrom agnetic clusters excluding the isolated photon candidate. The contributions of electrom agnetic clusters originating from charged particles are rem oved by the m ethod described in [36].

W e evaluate the observables in the cm s fram e of the hadronic system. The Lorentz boost is determ ined from the energy and angle of the photon candidate. W hen the fourm om entum of particles in the hadronic system is calculated, electrom agnetic clusters are treated as photons w ith zero m ass while tracks of charged particles are treated as hadrons w ith the charged pion m ass.

D istributions of the event shape observables  $(1 \quad T)$  and  $M_H$  are shown for two cm s energies in Figure 4. The remaining background is removed by subtracting the scaled M onte C arb predictions for non-radiative hadronic events and for pair events using the

background estimates listed in Table 1. The elects of the experimental resolution and acceptance are unfolded using M onte C arb sam ples with full detector simulation (detector correction). The unfolding is performed bin-by-bin with correction factors  $r_i^{D et} = h_i = d_i$ , where  $h_i$  represents the value in the ith bin of the event shape distribution of stable hadrons in the M onte C arb simulation, where \hadrons" are de ned as particles with a m ean proper lifetime longer than 3  $10^{10}$  s.  $d_i$  represents the value in the ith bin of the event shape distribution calculated with clusters and tracks obtained from M onte C arb sam ples with detector simulation after the complete event selection has been applied. W e refer to the distributions after applying these corrections as data corrected to the hadron level.

The distributions of the event shape observables 1 T and M<sub>H</sub> for data corrected to the hadron level and corresponding M onte C arlo predictions are shown in Figure  $5^{1}_{p}$ . The M onte C arlo sam ples are generated with cm s energies set to the m ean value of  $s^{0}$  in each subsam ple. In the production of the M onte C arlo sam ples ISR and FSR is switched o and on, respectively. The predictions from the event generators are consistent with the data for all  $s^{0}$  bins. There is sim ilar agreem ent between data and event generator predictions for the other observables.

# 6 Measurement of s

The measurement of  $_{\rm s}$  is performed by thing perturbative QCD predictions to the event shape distributions connected to the hadron level for (1 T), M<sub>H</sub> [37], B<sub>T</sub>, B<sub>W</sub> [38,39], C [40,41] and  $y_{23}^{\rm D}$  [33,42,43]. The O ( $_{\rm s}^{2}$ ) and NLLA calculations are combined with the ln(R) matching scheme. The elects of hadronisation on event shapes must be taken into account in order to perform the hadron level (hadronisation connection). Preserving the normalisation in the hadronisation connection is not trivial for low  $P_{\rm so}^{\rm D}$  sam ples because of large hadronisation connections. The hadronisation connection is applied to the integrated (cumulative) theoretical calculation to conserve normalisation as in our previous analyses [44,45]. The hadron level predictions are obtained from the cumulative theoretical calculation multiplied by a connection factor  $R_{\rm i}^{\rm Had} = H_{\rm i}=P_{\rm i}$ , where  $P_{\rm i}$  (H<sub>i</sub>) represents the value in the ith bin of the cumulative event shape distribution calculated by M onte C arb simulation w ithout (w ith) hadronisation. The JETSET M onte C arb event generator is used for our central results, while HERWIG and ARIADNE are considered as alternatives for the estimation of system atic uncertainties.

The t of the hadron level QCD predictions to the event shape observables uses a least  $^2$  m ethod with  $_{\rm s}$ (Q) treated as a free parameter. Only statistical uncertainties are taken into account in the calculation of  $^2$ . When the total number of events is small, the dimension between the statistical errors counting larger or smaller numbers of events than the theoretical prediction can bias the tresult. In order to avoid this bias the value of the tted theoretical distribution is used to calculate the statistical error instead of the number of events in each bin of the data distribution. The statistical uncertainty is estimated from the tresults derived from 100 M onte C arlo subsamples with the same number of events as selected data events.

The region used in the t is adjusted such that the background subtraction and the detector and hadronisation corrections are small (less than 50%) and uniform in that

<sup>&</sup>lt;sup>1</sup>The values of the six observables at the seven energy points are given in [34] and will be available under http://durpdg.dur.ac.uk/HEPDATA/.

region. The resulting transfers are mainly restricted by the hadronisation corrections. The QCD predictions at  $\overline{s^0} = 78 \text{ GeV}$  the to data after applying the hadronisation correction are shown in Figure 6. Good agreem ent between data and theory is seen. The the values of s and their errors for each event shape observable are shown in Tables 2-5.

## 6.1 System atic Uncertainties

#### 6.1.1 Experim ental Uncertainties

The experim ental uncertainty is estimated by adding in quadrature the following contributions:

the di erence between the standard result and the result when all clusters and tracks are used without correcting for double counting of energy. This variation is sensitive to imperfections of the detector simulation.

the largest deviation between the standard result and the result when the analysis is repeated with tighter selection criteria to elim inate background (standard values in brackets): the thrust axis is required to lie in the range jcos  $_T j < 0.7 (0.9)$ , or the cluster shape variable is required to be smaller than 5 (10), or the isolation angle from any jet is required to be larger than 35 (25).

the di erence between the standard value and the value obtained by repeating the analysis with the background fractions estimated from the rate of isolated charged hadrons as described in Section 4.

the di erence between the standard result and the result when the single block energy resolution is varied to give the expected  $^2$  in the cluster shape ts. This check is made, because the values of  $^2$  in the cluster shape ts depend on the assumed energy resolution.

the maximum dierence between the standard result and the result when the tregions are varied. The lower and upper limit of the tting region are independently changed by 1 bin.

The tighter selection on jcos  $_{\rm T}$  j and the alternative single block energy resolution of the electrom agnetic calorim eter yield the largest contributions to the experim ental system atic uncertainty. The overall resolution and energy scale uncertainty of the electrom agnetic calorim eter have a neglegible e ect on the results of this analysis.

## 6.1.2 Hadronisation Uncertainties

The following variations are performed in order to estimate the hadronisation uncertainties:

the largest of the changes in  $_{\rm s}$  observed when independently varying the hadronisation parameters b and  $_{\rm Q}$  by 1 standard deviation about their tuned values in JETSET [25];

the change observed when the parton virtuality cut-o parameter  $Q_0$  is varied by 1 standard deviation about its tuned value in JETSET;

the change observed when only the light quarks u, d, s and c are considered at the parton level in order to estim ate potential quark m ass e ects;

the di erences with respect to the standard result when HERWIG or ARIADNE are used for the hadronisation correction, rather than JETSET.

W e de ne the hadronisation correction uncertainty by adding in quadrature the deviation when using only light quarks and the larger deviation when using HERWIG or ARIADNE to calculate the corrections. These variations are observed to lead to larger di erences than all other variations, i.e. the main contributions to the hadronisation uncertainties are the choice of hadronisation model and the potential e ect of quark masses.

#### 6.1.3 Theoretical Uncertainties

We x the renorm alisation scale parameter x = Q to 1, where is the energy scale at which the theory is renorm alized and Q is the energy scale of the reaction. A lthough the uncertainty on the choice of the value of x gives a large contribution to the system atic uncertainty, the means of quantifying this uncertainty is essentially arbitrary. We de ne the scale uncertainty as the larger of the deviations of  $_{\rm s}$  when x is changed from 1 to 0.5 or 2.0.

The O ( $\frac{2}{s}$ ) and NLLA calculations are combined with the ln(R) matching scheme. The variation in  $\frac{1}{s}(\frac{1}{s^0})$  due to using dimension atching schemes is much smaller than the renormalisation scale uncertainty [46], and is not included as an additional theoretical system atic uncertainty.

## 6.2 C om bination of <sub>s</sub> R esults

The values of  $_{\rm s}$  obtained for each observable at each energy are used to study the energy dependence of  $_{\rm s}$  and to obtain an overall combined result for  $_{\rm s}$  (M  $_{\rm z}$ ). The individual values of  $_{\rm s}$  as given in Tables 2–5 and shown in Figure 7 are combined taking the correlations between their statistical and system atic errors into account using the method described in [8]. The statistical covariances between results from di erent observables are determined at each energy from 100 M onte C arb subsamples with the same number of events as selected in the data. The experimental system atic uncertainties are assumed to be partially correlated, i.e.  $\cot_{ij} = \min(_{i};_{j})^2$ . The hadronisation and theoretical covariances are only added to the diagonal of the total covariance matrix. The correlations between these uncertainties are considered by repeating the combination procedure with di erent hadronisation corrections (udsc only, HERWIG, ARIADNE) and with di erent renorm alisation scale parameters (x = 2 and 0.5). The system atic uncertainties for the combined value are obtained by repeating the combination for each system atic variation. The resulting values of  $_{\rm s}$ ( $\frac{1}{{\rm s}^0}$ ) are shown in Table 6 and Figure 8.

Values of  $_{\rm s}$  from individual observables at each energy are combined after evolving them to  ${}^{\rm p}\bar{\rm s}=M_{\rm Z}$ . In this case the results are statistically uncorrelated. The correlations between system atic uncertainties are treated as explained above. The results are given in Table 7 and Figure 9.

We also combine the combined values listed in Table 7 taking into account their statistical correlations using the sum of the inverses of the individual statistical covariance matrices at each energy point. The result is

$$_{\rm s}$$
 (M  $_{\rm Z}$ ) = 0:1182 0:0015(stat:) 0:0101(syst:): (8)

and is shown with individual errors in Table 7. Figure 8 shows the evolution of the strong coupling using our result. As a crosscheck on the robustness of the combination procedure we repeat the combination using the combined results at each energy point shown in Table 6 or using all individual results and nd  $_{s}(M_{z}) = 0.1183 \quad 0.0103$  or  $_{s}(M_{z}) = 0.1179 \quad 0.0103$ , respectively.

O ur result is consistent within the statistical and experimental errors with the result from OPAL using non-radiative events in LEP 1 data with the same set of observables,  $_{\rm s}$  (M  $_{\rm Z}$ ) = 0:1192 0:0002(stat:) 0:0050(syst:) [8]. O ur result is also consistent with recent combined values [11,47{49}] and results from other analyses using radiative events [16,17]. Figure 10 compares our result with the LEP 1 value for  $_{\rm s}$  from [8] and an average of results from L3 using radiative hadronic Z<sup>0</sup> decays [16]<sup>2</sup>.

The combinations of individual observables at di erent on s energies yield  $^2=d\mathfrak{p}\mathfrak{f}$ : 1=6. The small values of  $^2=d\mathfrak{p}\mathfrak{f}$ : are due to the conservative treatment of hadronisation and theoretical uncertainties. The values of  $^2=d\mathfrak{p}\mathfrak{f}$ : indicate consistency of the individual results with the model of the combination including evolution of results at di erent on s energies to M <sub>z</sub> before the combination.

## 7 Summary

The strong coupling s has been measured at reduced on s energies,  $p \overline{s^0}$ , ranging from 20 G eV to 80 G eV using event shape observables derived from the hadronic system in radiative hadronic events.

Fits of O ( $_{s}^{2}$ ) and NLLA QCD predictions to the six event shape observables 1 T,  $M_{H}$ ,  $B_{T}$ ,  $B_{W}$ , C and  $y_{23}^{D}$  are performed and values of  $_{s}$  are obtained for seven values of  $s^{0}$ . Our results are consistent with the running of  $_{s}$  as predicted by QCD. The values at each  $s^{0}$  are evolved to  $= M_{z}$  and combined for each event shape observable. The combined value from all event shape observables and  $s^{0}$  values is  $_{s}(M_{z}) = 0.1182$ 0:0015(stat:) 0:0101(syst:).

This result agrees with previous OPAL analyses with non-radiative LEP 1 data, with a similar measurement by L3, and with recent world average values, see gure 10. Within errors, QCD is consistent with our data sample of events with isolated FSR. Our result supports the assumption that the elects of high energy and large angle FSR on event shapes in hadronic  $Z^0$  decays can be electively described by QCD with a lower elective on senergy  $\frac{1}{S^0}$ .

# A cknow ledgem ents

W e particularly wish to thank the SL D ivision for the e cient operation of the LEP accelerator at all energies and for their close cooperation with our experim ental group. In addition to the support sta at our own institutions we are pleased to acknow ledge the D epartm ent of Energy, USA,

National Science Foundation, USA,

Particle Physics and Astronom y Research Council, UK,

 $<sup>^{2}</sup>$ The average is calculated using our combination procedure with the values in table 65 of [16]. We assume partially correlated experimental errors and evaluate the hadronisation and theory uncertainties by repeating the combination with simultanously changed input values. The L3 analysis is not checked for sensitivity to the presence of massive b quarks and thus has smaller hadronisation uncertainties.

## A Likelihood Ratio Method

The likelihood ratio  $L_{qq}$  is defined by

$$L_{qq} = \frac{L_{qq}}{L_{qq} + \sum_{i} W_{i} L_{bkg,i}}$$
(9)

where  $L_{qq}$  and  $L_{bkg,i}$  are the absolute likelihood values for signal qq events and events from the ith background process. The background likelihood values are weighted by w<sub>i</sub> proportional to the cross section of the ith background process.

The absolute likehood values L are calculated from probability density functions (pdfs)  $p_j(x_j)$  for the input variables  $x_j$ . The pdfs are obtained as so-called reference histogram s from simulated signal and background samples. For the calculation of the pdfs the projection and correlation approximation (PCA) method [50] is used. In brief, each  $x_j$  is transformed to a variable  $y_j$  following a Gaussian distribution using

$$y = {}^{p} \frac{1}{2} \operatorname{erf}^{1} (2F(x) - 1)$$
(10)

where erf<sup>1</sup> is the inverse error function and  $F(x) = \frac{R_x}{x_{m in}} p(x^0) dx^0$  is the cumulative distribution of x. The likelihood L(x) is then given in the PCA by

$$L(\mathbf{x}) = \frac{1}{\sqrt{y}} e^{y^{T}(V^{-1} I)y=2} \sum_{i}^{Y} p_{i}(x_{i}) :$$
(11)

V is the n m covariance matrix of the  $y_j$ , I is the identity matrix and x and y are the vectors of the  $x_j$  and  $y_j$ .

s ( s <sup>0</sup> )	0.1153	0.1242	0.1201	0.1296	0.1353	0.1438	0.1496
Statistical	0.0026	0.0037	0.0039	0.0047	0.0053	0.0064	0.0071
Experimental	0.0068	0.0036	0.0040	0.0069	0.0039	0.0063	0.0077
H adronisation	0.0062	0.0065	0.0072	0.0085	0.0100	0.0122	0.0166
T heory	0.0053	0.0067	0.0063	0.0076	0.0086	0.0099	0.0117

Table 6: Combined values of  $s^{(n-1)}$  and their errors from all event shape variables.

	(1 T	) M <sub>H</sub>	Β <sub>T</sub>	Β <sub>W</sub>	С	У <sub>23</sub>	Combined
$_{\rm s}$ (M $_{\rm Z}$ )	0.1230	0.1187	0.1214	0.1117	0.1195	0.1261	0.1182
Statistical	0.0028	0.0024	0.0021	0.0021	0.0023	0.0031	0.0015
Experimental	0.0050	0.0054	0.0037	0.0033	0.0040	0.0049	0.0038
H adronisation	0.0071	0.0052	0.0080	0.0061	0.0092	0.0105	0.0070
T heory	0.0076	0.0059	0.0081	0.0049	0.0076	0.0045	0.0062

Table 7: C on bined values of  $_{s}$  (M  $_{z}$ ) and their errors from all photon energy subsamples for a given observable. The nalcombined value of  $_{s}$  (M  $_{z}$ ) is also shown.

Figure 1: The distributions of event shape observables 1 T and M<sub>H</sub> for non-radiative events and radiative hadronic events from the M onte C arlo generators JETSET, HERWIG and ARIADNE as indicated below the gures. The triangles and points show distributions obtained from the Z<sup>0</sup> samples with FSR while the histogram s show distributions from samples generated at lower energies as shown on the gure. The open triangles and solid histogram (solid points and dashed histogram) in each gure correspond to radiatered = 40 (70) G eV.

Figure 2: D istributions of each variable used in the isolated photon selection. The error bars show the statistical errors. M onte C arb distributions are norm alized to the integrated lum inosity of the data and the cross section of the process. A rrow s in the gures show the selected region. D istributions for radiative multi-hadronic events, which are signal events in this analysis, are overlaid on distributions for all multi-hadronic events and events. The distribution of each variable is obtained with the cuts on the preceding variables applied.

Figure 3: Photon likelihood distributions. The error bar shows statistical error. The M onte C arb distributions are norm alised to the total num ber of candidates in the data, and the neutral hadron background fractions are obtained from the ts described in Section 4.4. The arrows indicate the selected regions.

Figure 4: Event shape distributions before background subtraction and detector correction. Two of the six event shape observables, 1 T and M<sub>H</sub>, are shown for the low (38.5 GeV) and high (78.1 GeV)<sup>-</sup> s<sup>0</sup> sam ples. The histogram s show M onte C arlo distributions. The error bars show the statistical errors.

Figure 5: Event shape distributions at the hadron level. The error bars correspond to the statistical and experimental uncertainties described in Section 6.1.1. Two of the six event shape observables, 1 T and M<sub>H</sub>, are shown for the low (38.5 G eV) and high (78.1 G eV)  $s^0$  sam ples. The sm all lines on the error bars show the extent of the statistical uncertainty. The data points are placed at the centres of the corresponding bins. The predictions of JETSET, HERWIG and ARIADNE at the corresponding  $s^0$  values are also shown as lines.

Figure 6: Event shape distributions for data ath  $s^{p}$  = 78:1 G eV and the tted theoretical predictions. The error bars show the statistical errors. The solid lines in the theoretical predictions show the regions used in the t. Three corrections are plotted as \R corr": the detector correction,  $r_{i}^{D et}$  (dashed line), the hadronisation correction,  $R_{i}^{H ad}$  (solid line), and the ratio of distributions after and before background subtraction (dotted line). The hadronisation correction is shown by the ratio of di erential distributions in these gures (see text for details).

Figure 7: Energy dependence of  $_{s}$  for all  $p_{s}$  subsamples. The inner error bars show the statistical and the outer error bars the total uncertainties. The curves and shaded bands show the QCD prediction for the running of  $_{s}$  obtained with the corresponding values of  $_{s}(M_{z})$  with total errors from Table 7.

Figure 8: Combined values of  $_{\rm s}$  from all event shape observables as shown in Table 6. The curve and shaded band show the QCD prediction for the running of  $_{\rm s}$  using the combined value of  $_{\rm s}$  (M  $_{\rm Z}$ ) with total errors.

Figure 9: The values of  $_{s}(M_{z})$  obtained by combining all  $p = \frac{1}{s^{0}}$  samples as shown in Table 7. The inner error bars are statistical, the outer error bars correspond to the total uncertainty. The dashed vertical lines and shaded bands show the LEP 1 results from OPAL [8] using non-radiative events.

Figure 10: C on bined values of  $_{s}(M_{z})$  for all event shape observables and  $p = 10^{-1}$  samples. The error bars show total uncertainties. The results from this analyses with radiative events, from non-radiative events with OPAL LEP 1 data [8] and from L3 radiative events [16] are shown. The PDG [47] value of  $_{s}(M_{z})$  is also shown as the vertical line, with the total uncertainty corresponding to the shaded band.
