

# The Fast Tracker real time processor and its impact on the muon isolation, tau & b jet online selections at Atlas

ATL-DAQ-SLIDE-2010-098  
01 June 2010

F. Crescioli for the FTK Collaboration

## Outline

Efficient selection of  $b$ ,  $\tau$ ,  $\mu$ ,  $e$ :  
to be efficient on "light" particles  
( $W$ ,  $Z$ ,  $H$ ...) in terrific pileup

- Why FTK? Timing and Event complexity @High Luminosity
- Physics case: stiff-leptons, b-jets, tau-jets
- FTK architecture

# Why FAST TRACKING is IMPORTANT for

## TRIGGER @ HADRON COLLIDERS WITH HIGH PILE-UP

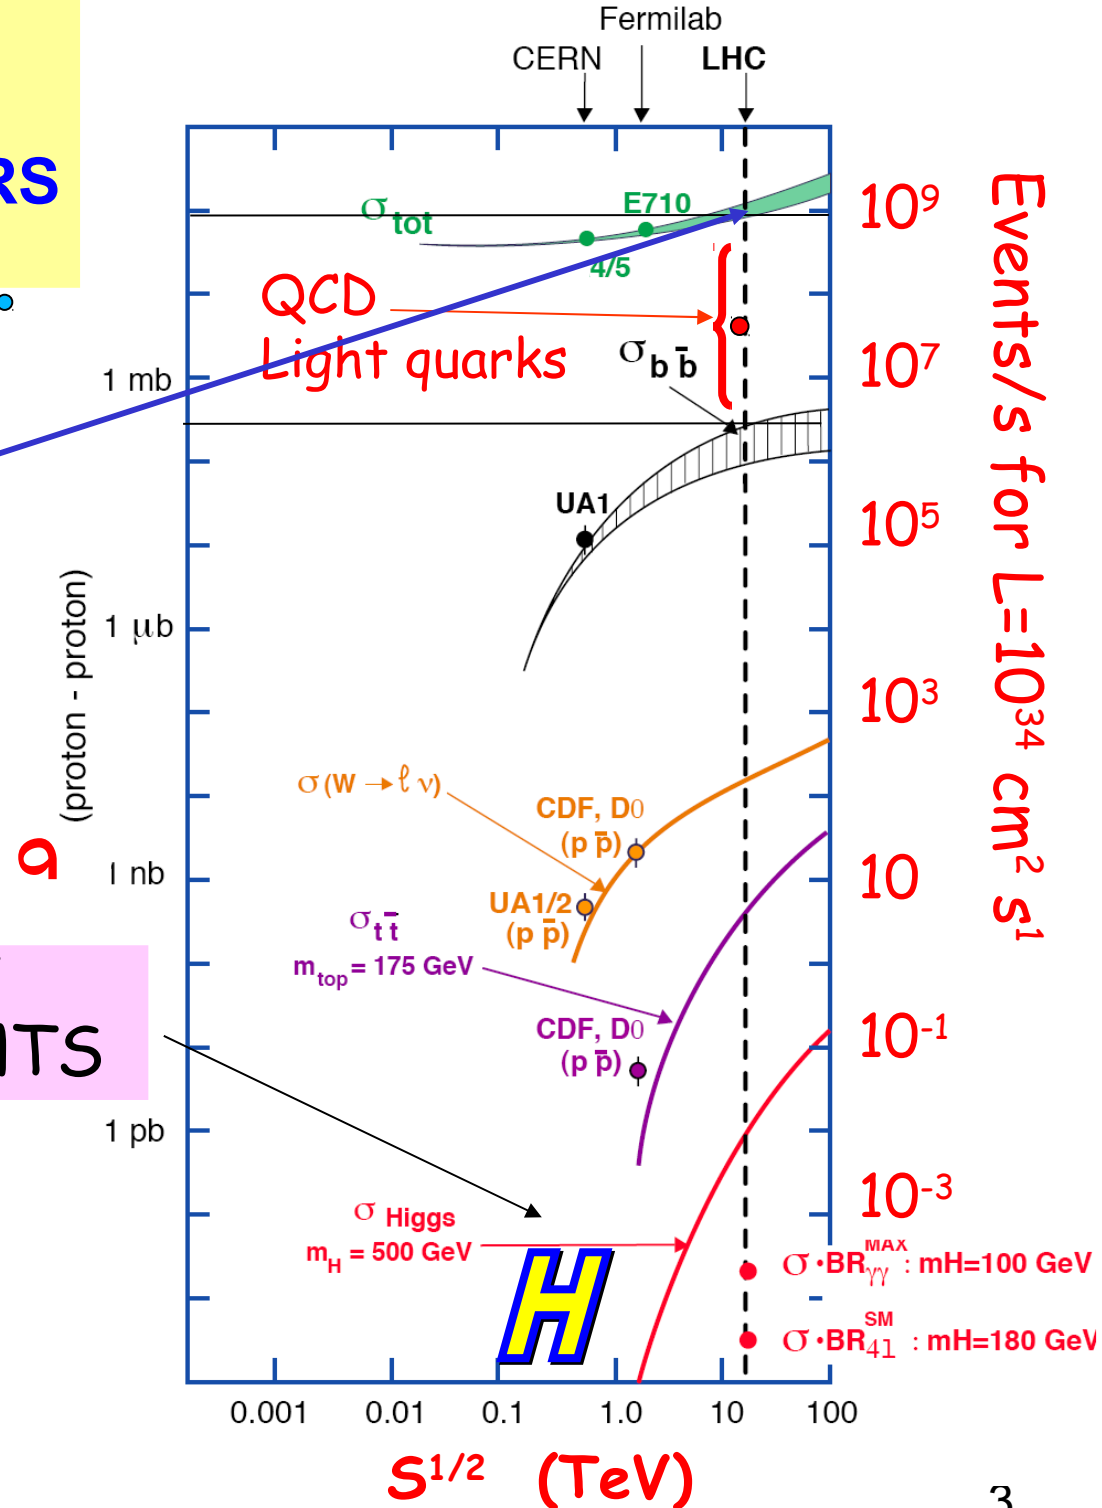

Pile-up: **Hard Life!**

25 events @  $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$   
40 MHz coll. Rate

75 events @  $3 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$   
40 MHz coll. Rate **SLHC**

One of  $10^{12}$

**RARE EVENTS**

# L1-L2 early tracking: a tough problem

30 minimum bias events +  $H \rightarrow ZZ \rightarrow 4\mu$

@LHC (both CMS & Atlas) tracking is missing @L1 and late @L2

Where is the Higgs?

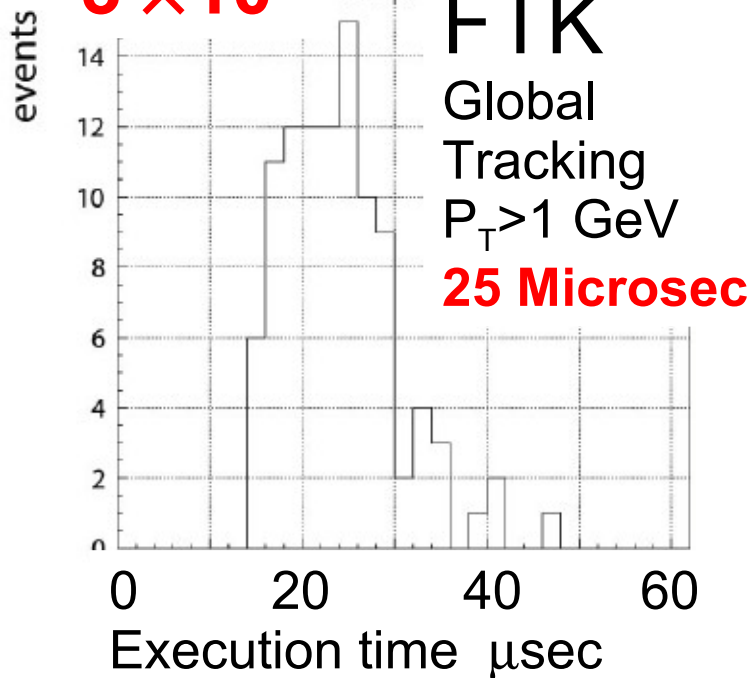

Tracks with  $P_{\perp} > 2 \text{ GeV}$

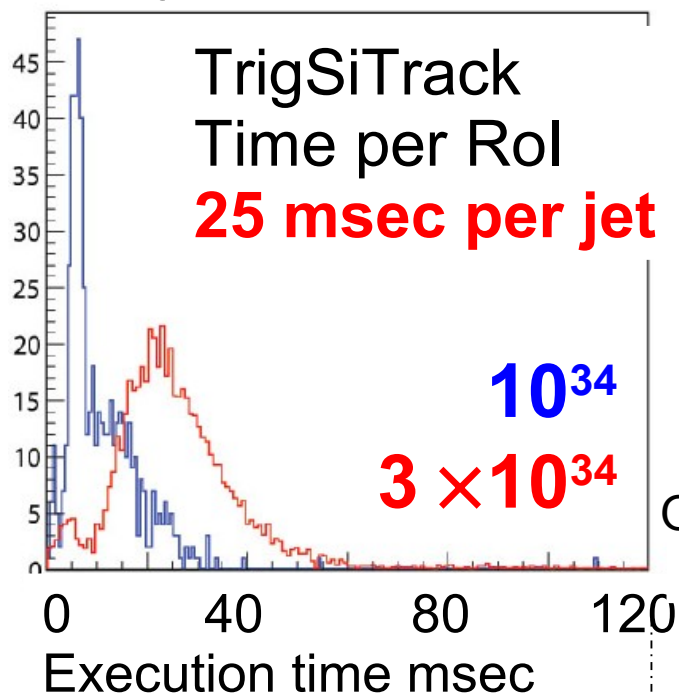

# FTK extremely important @ High Luminosity

## Timing

$3 \times 10^{34}$

L1 jet Threshold = 20 GeV

**WH events @  $3 \times 10^{34}$**   
**average of**  
**40 jet > 70 GeV**  
**per event**

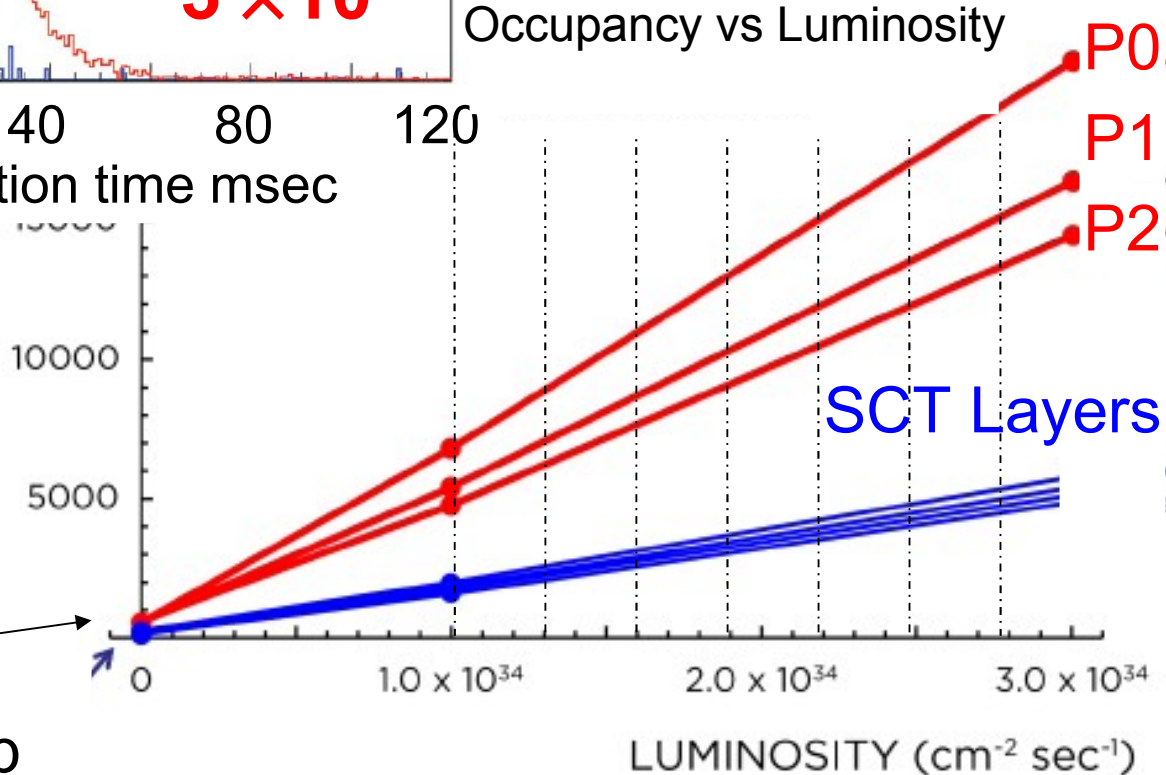

(not yet optimized for high luminosity)

Y intercept:

**Hard scattering!**

negligible compared to pileup

# of ROD Hits

# Why L1-L2 early TRACKING is IMPORTANT?

The most **STANDARD STIFF LEPTON TRIGGERS** based on **ISOLATION** have problems at very high pile-up

The calorimeter tower integrates energy from **all the particles**, also from **Pileup!**

We want **ISOLATION** from **HARD SCATTERING** not from **Pileup!**

Lepton identification: **primary vertices** fast identification  
→ **Isolation** with tracks of  $P_t > T_h$  and from **right vertex**

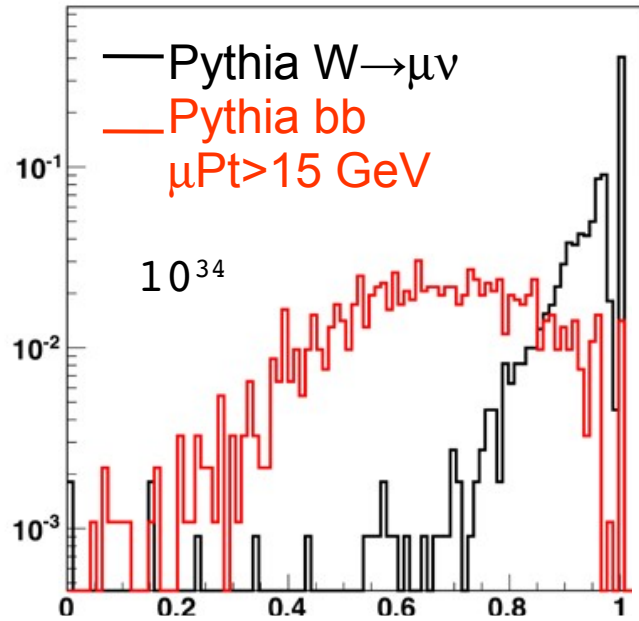

Only 7 vertices: imagine 100!

10 cm/100=1 mm

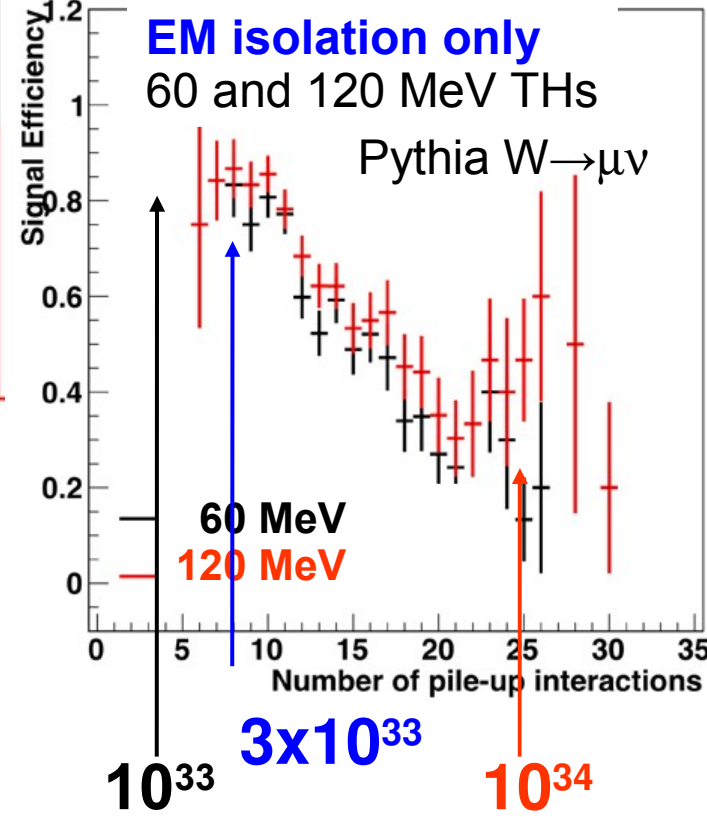

Tracking more stable than **calorimetric isolation** against **pile-up!**

# Why FTK is IMPORTANT? Stiff Muon isolation

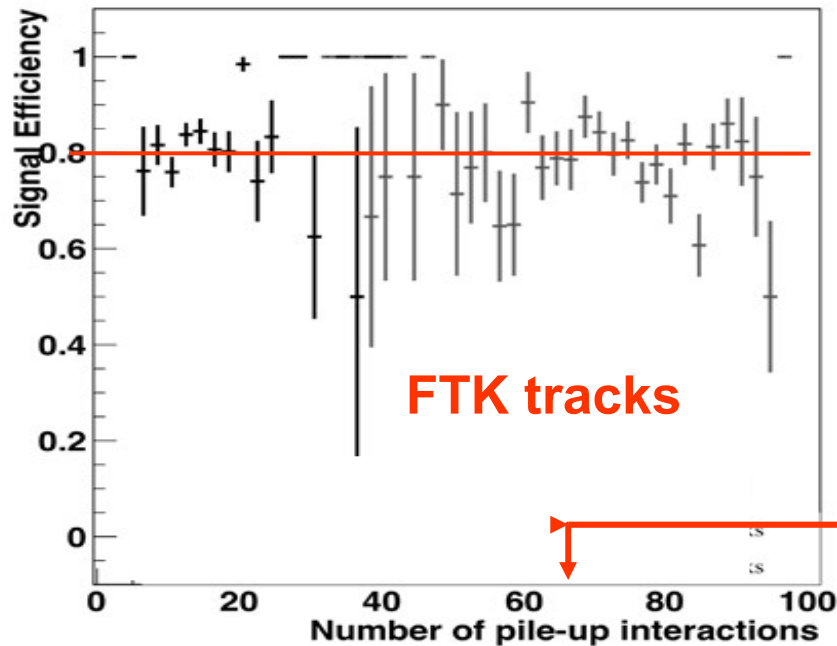

cuts set so that rejection factor for  $bb$  events is **10**.

**EM calorimeter isolation:**  
 energy above 60 MeV in  $0,07 < \Delta R < 0.4$

Tracking isolation:  
 $\mu PT / (PT \text{ sum tracks in } \Delta R < 0.2)$

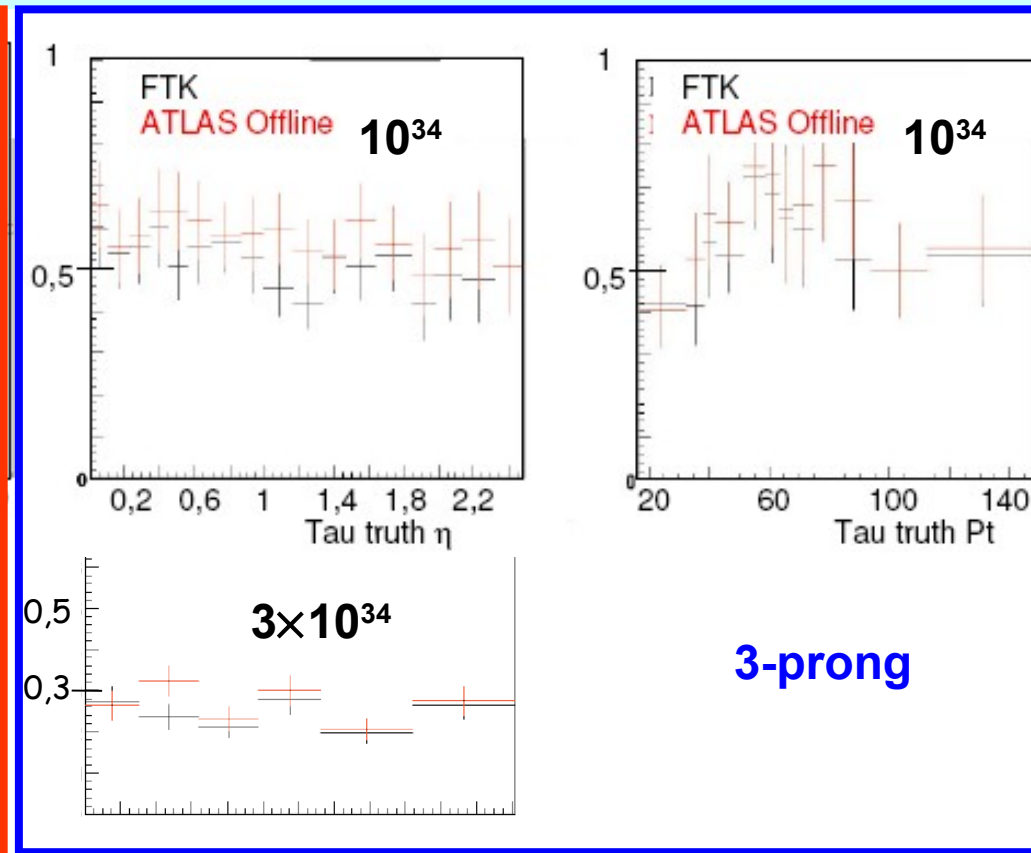

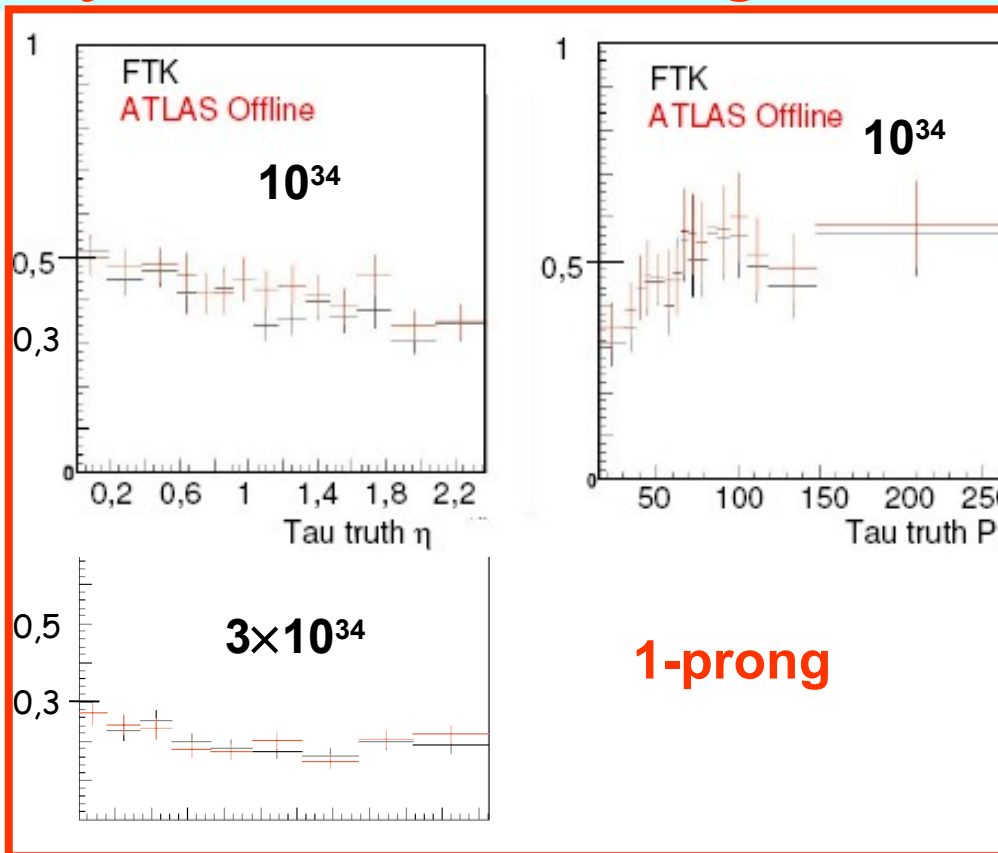

Isolation based on Tracks from primary vertex (Track\_z < 10 mm From  $\mu_z$ )

**EFFICIENCY** from **20%** to **80%**  
 It is better than a factor **4** Luminosity increase!  
**Today CDF HIGGS SEARCH POSSIBLE just BECAUSE of CDF TRIGGER UPGRADES**

# Why Online Tracking is IMPORTANT? Hadronic Taus

EFFICIENCY

EFFICIENCY

leading  $P_T$  track in  $R_I$  ( $R_I=0,35$  around jet axis)

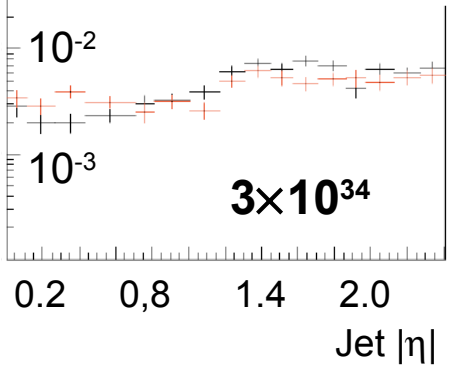

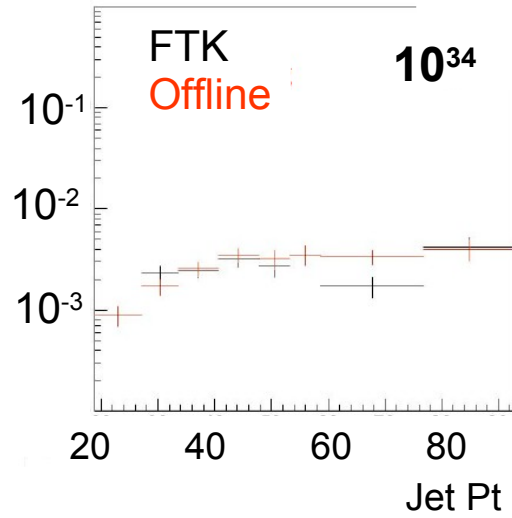

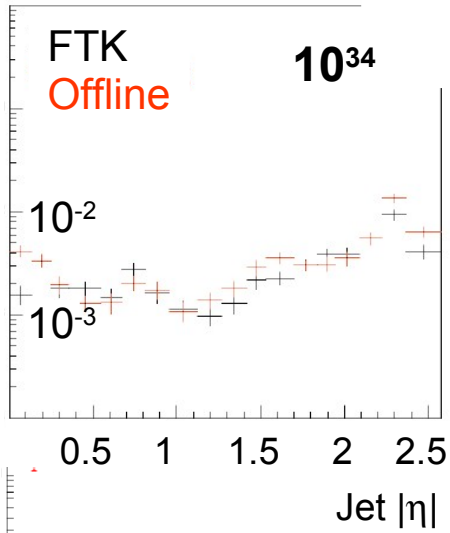

$P_T > 6$  GeV

$R_{sig} = 0,13$  &  $R_{iso}=0,26$  around leading track;

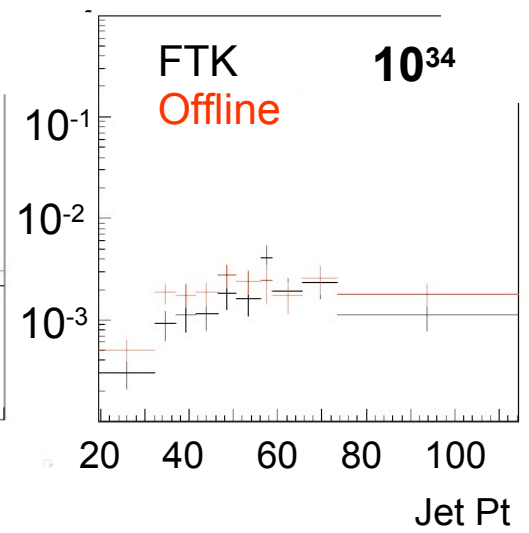

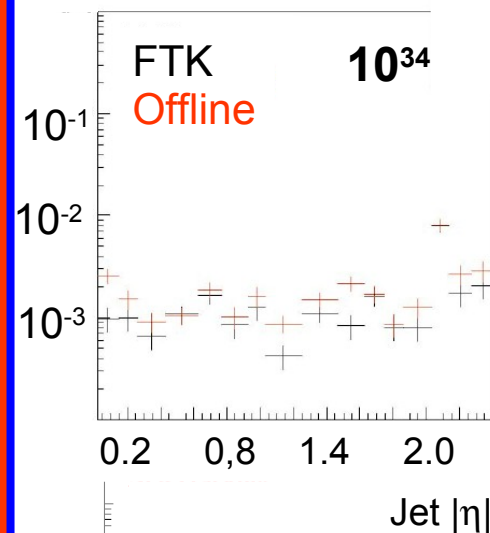

1 (1-prong) or 2-3 (3-prong) tracks in  $R_{sig}$ ;  
no tracks with  $P_T$  above 1.5 GeV in  $R_{iso}$ .

# Efficiency on Jets: FAKES for Had Tau selection

**1-prong**

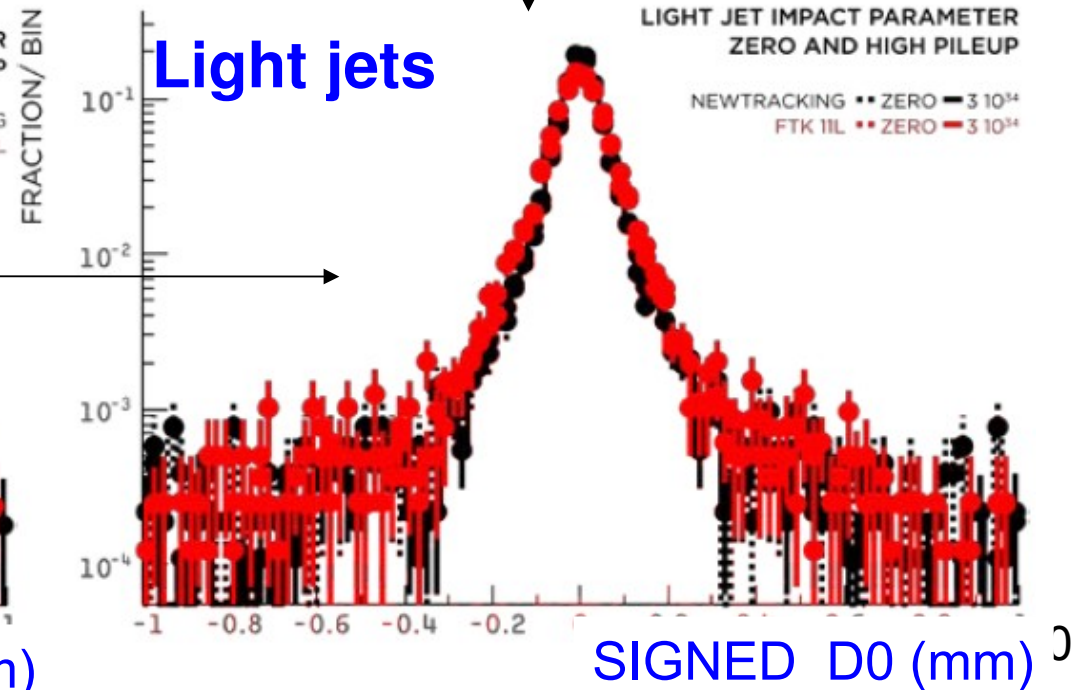

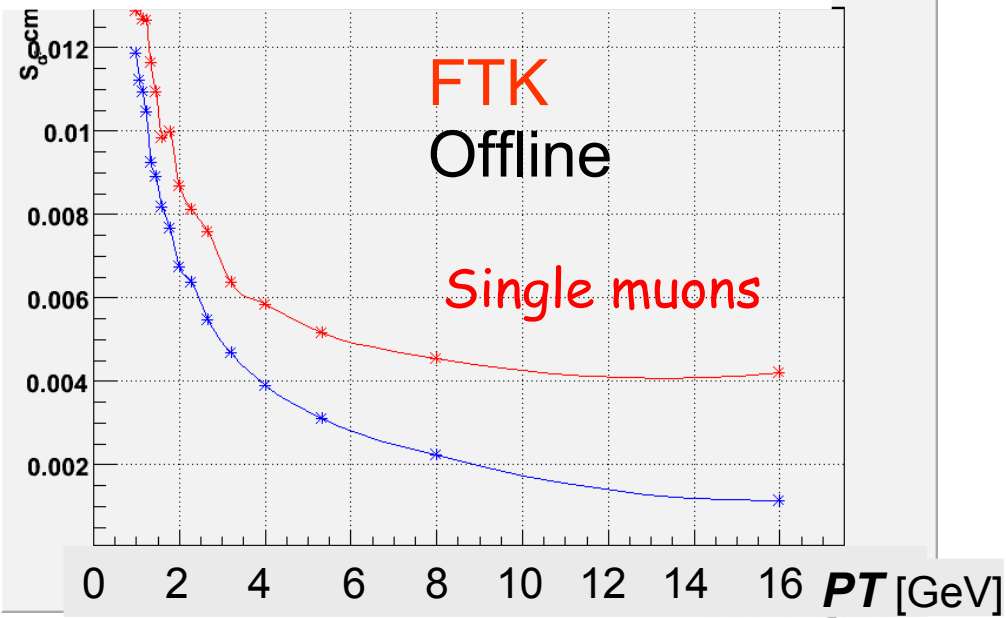

**3-prong**

leading  $P_T$  track

# Why FTK is IMPORTANT? Online b-tag @ATLAS

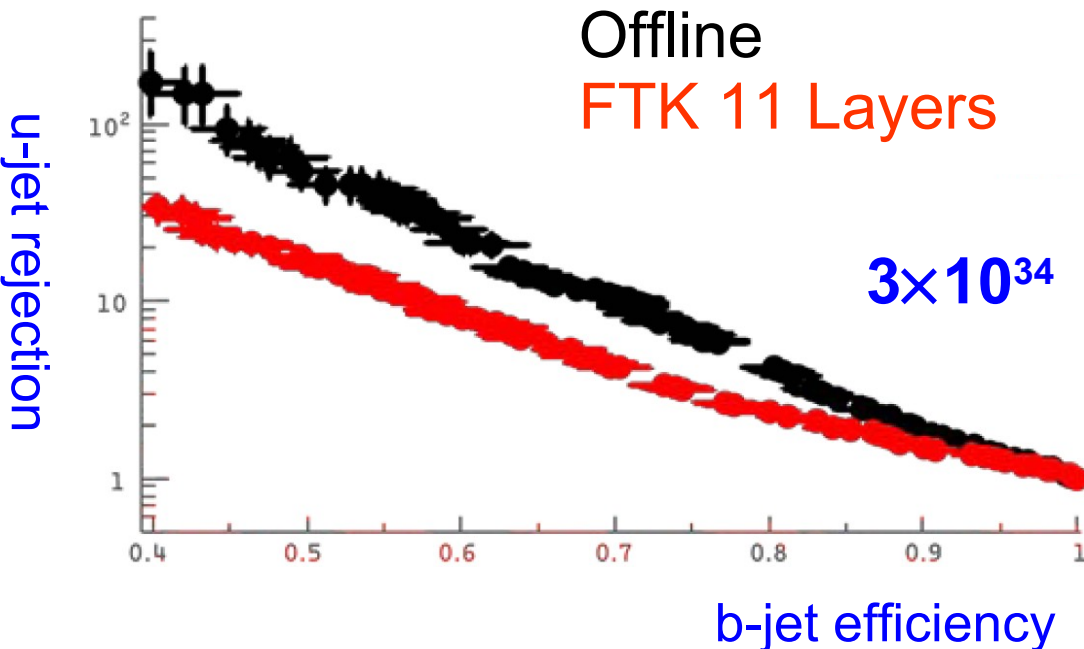

Impact parameter resolution

# Signed D0 significance Likelihood tagging performance

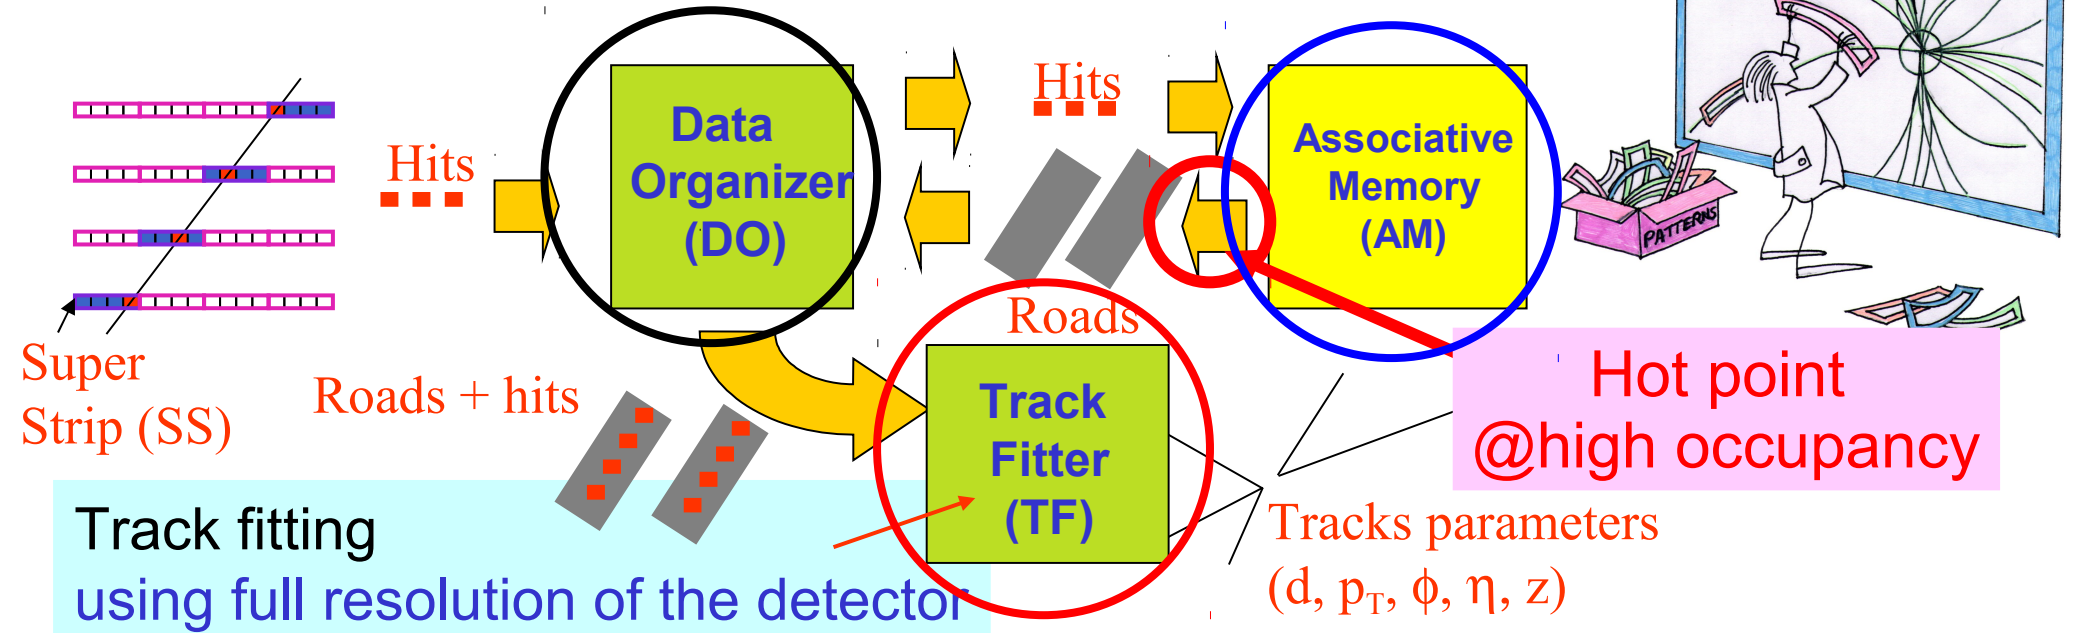

Offline is more stable than FTK when luminosity increases but FTK results are interesting

The CPU time freed for the tracking can be used to implement more complex algorithms like secondary-vertexing

# FTK Architecture

**Tracking in 2 steps:** find **Roads** first (Pattern Matching with Associative Memory, AM) then find **Tracks** inside **Road** (Fit by TF)

Full Resolution Hits

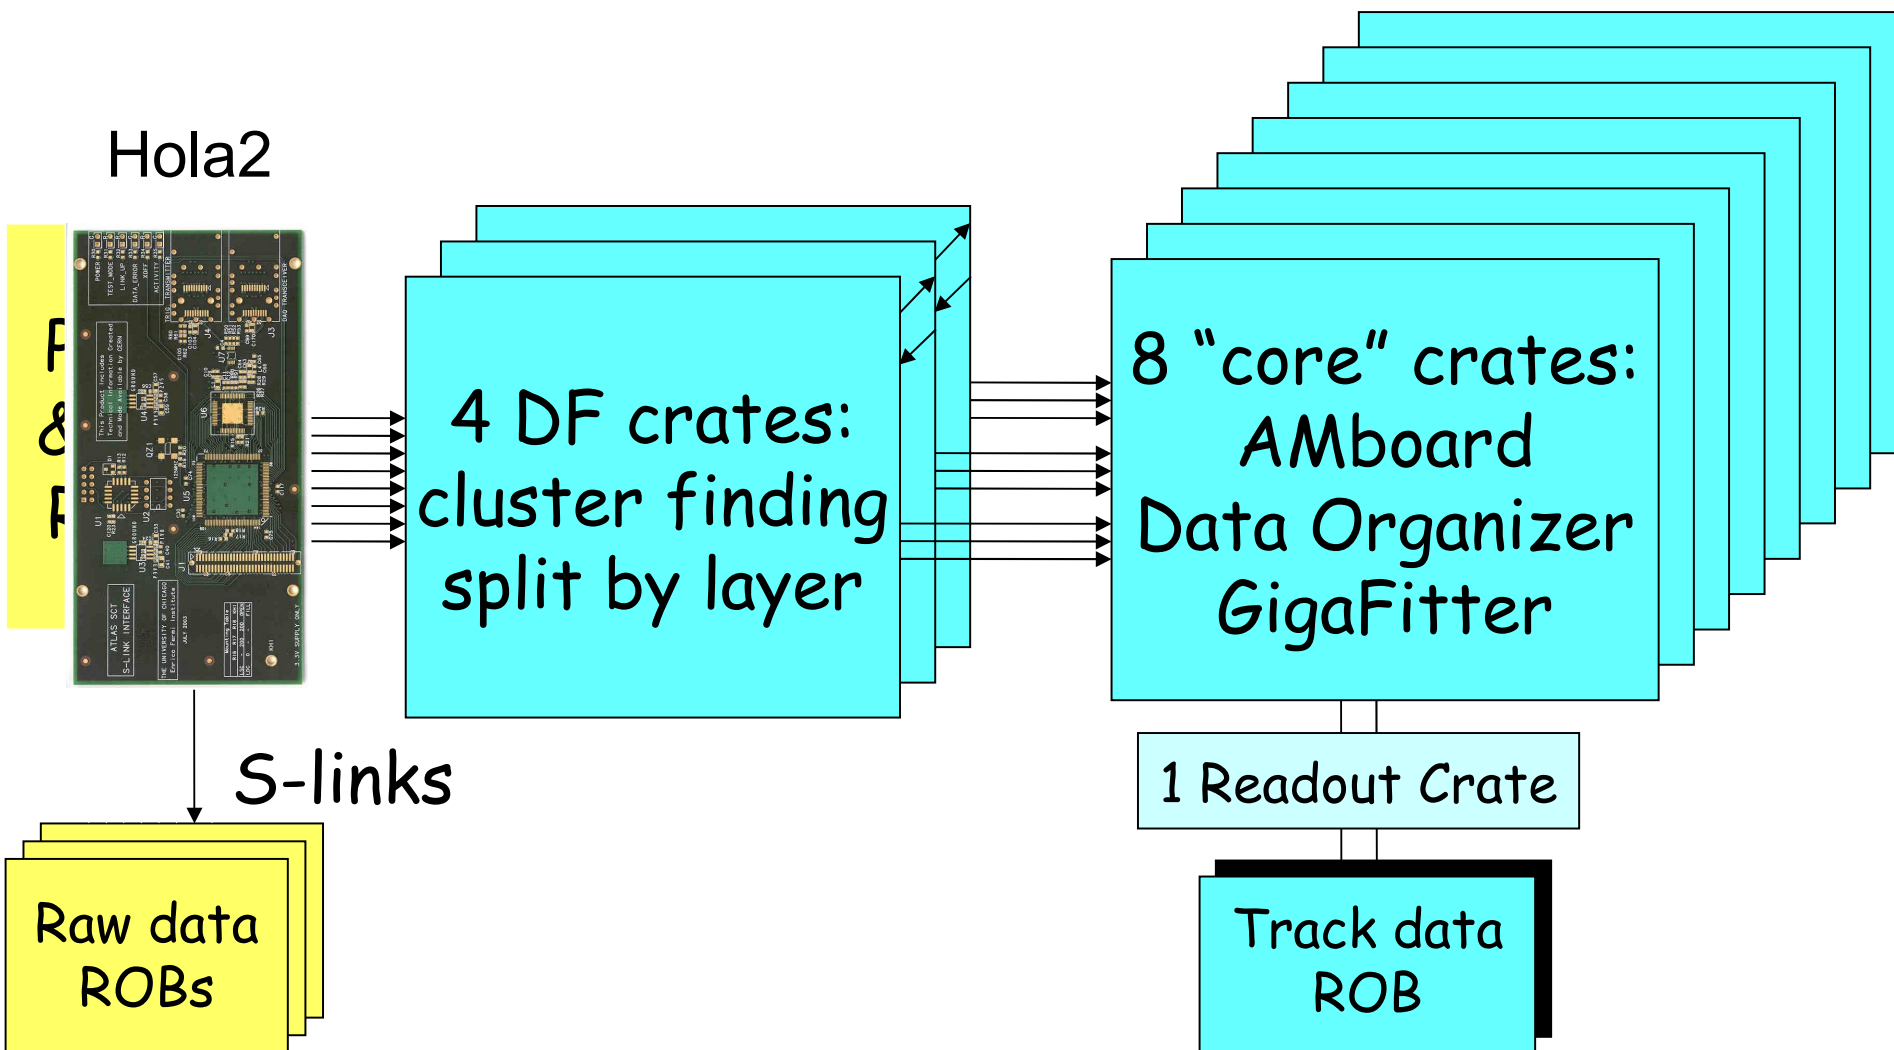

Large SS: a lot of fakes + combinatorics inside roads

Road size: a parameter to balance the AM size & the DO-TF workload

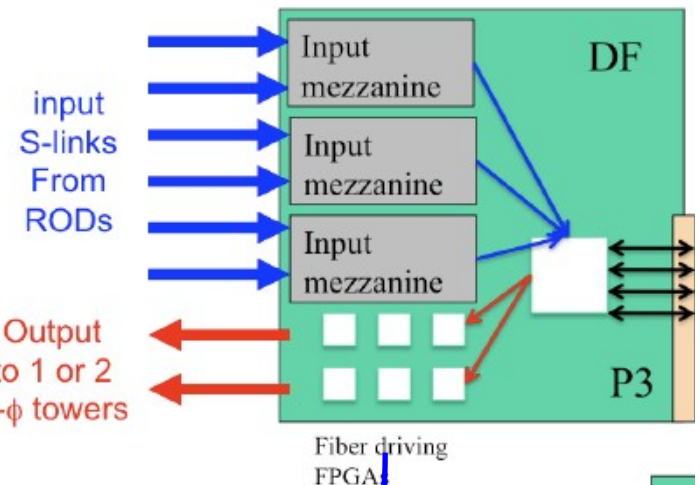

# FTK: Architecture

# 8x core crates

## Data Formatter (DF)

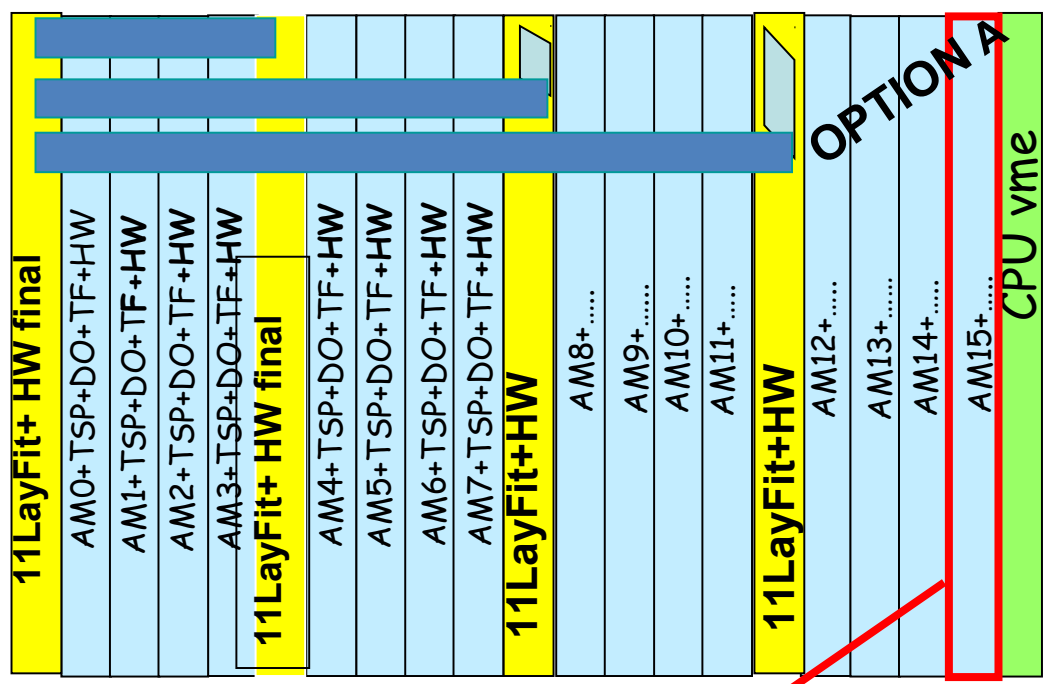

Receives silicon hits.  
Does pixel cluster finding.  
Distributes data to  $\eta$ - $\phi$  towers.

## 4x DF crates

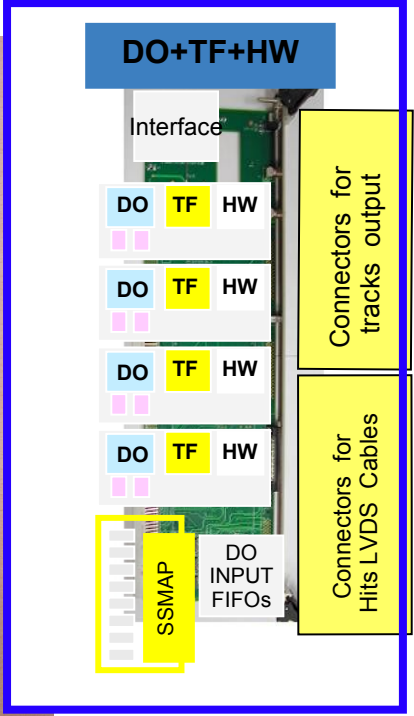

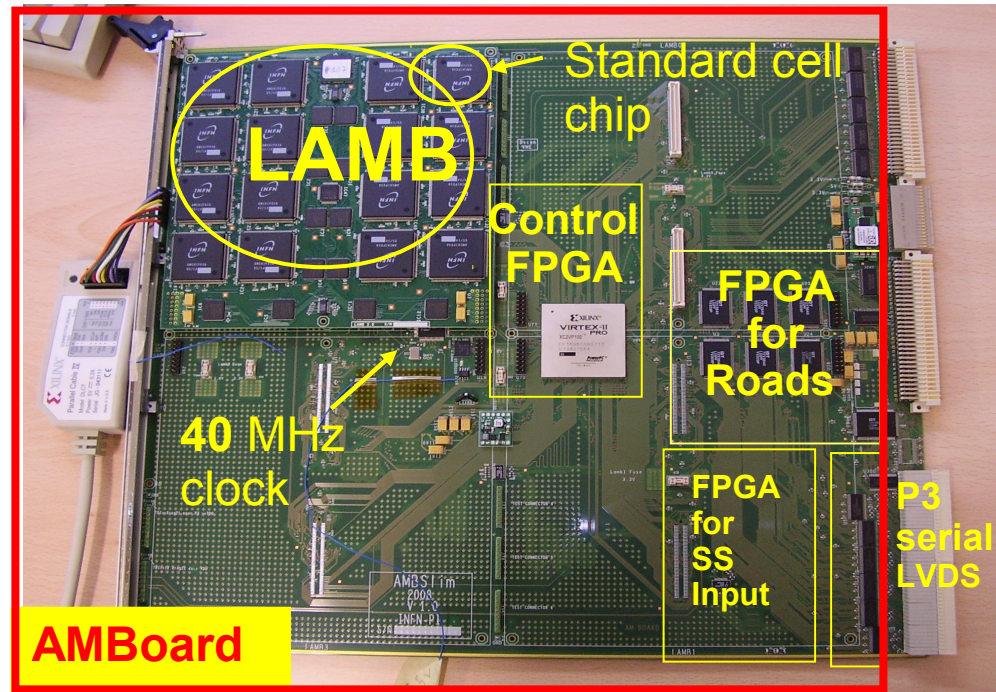

Exchange overlap data over P3 backplane

## Processing Unit

## AUX card

# Conclusions

- Having **high-quality global tracking** at the start of level-2 processing can make a significant contribution to the trigger especially at  $3 \times 10^{34}$
- We have a **preliminary design** that can handle the data flow at that luminosity, will take **less than 100  $\mu\text{s}/\text{event}$** , gives excellent physics performance, and is affordable.
- There is an implementation plan that can start to help ATLAS **early**.

# BACKUP

# FTK-core Basic Architecture 1

IEEE Trans. Nucl. Sci. **51**, 391 (2004)

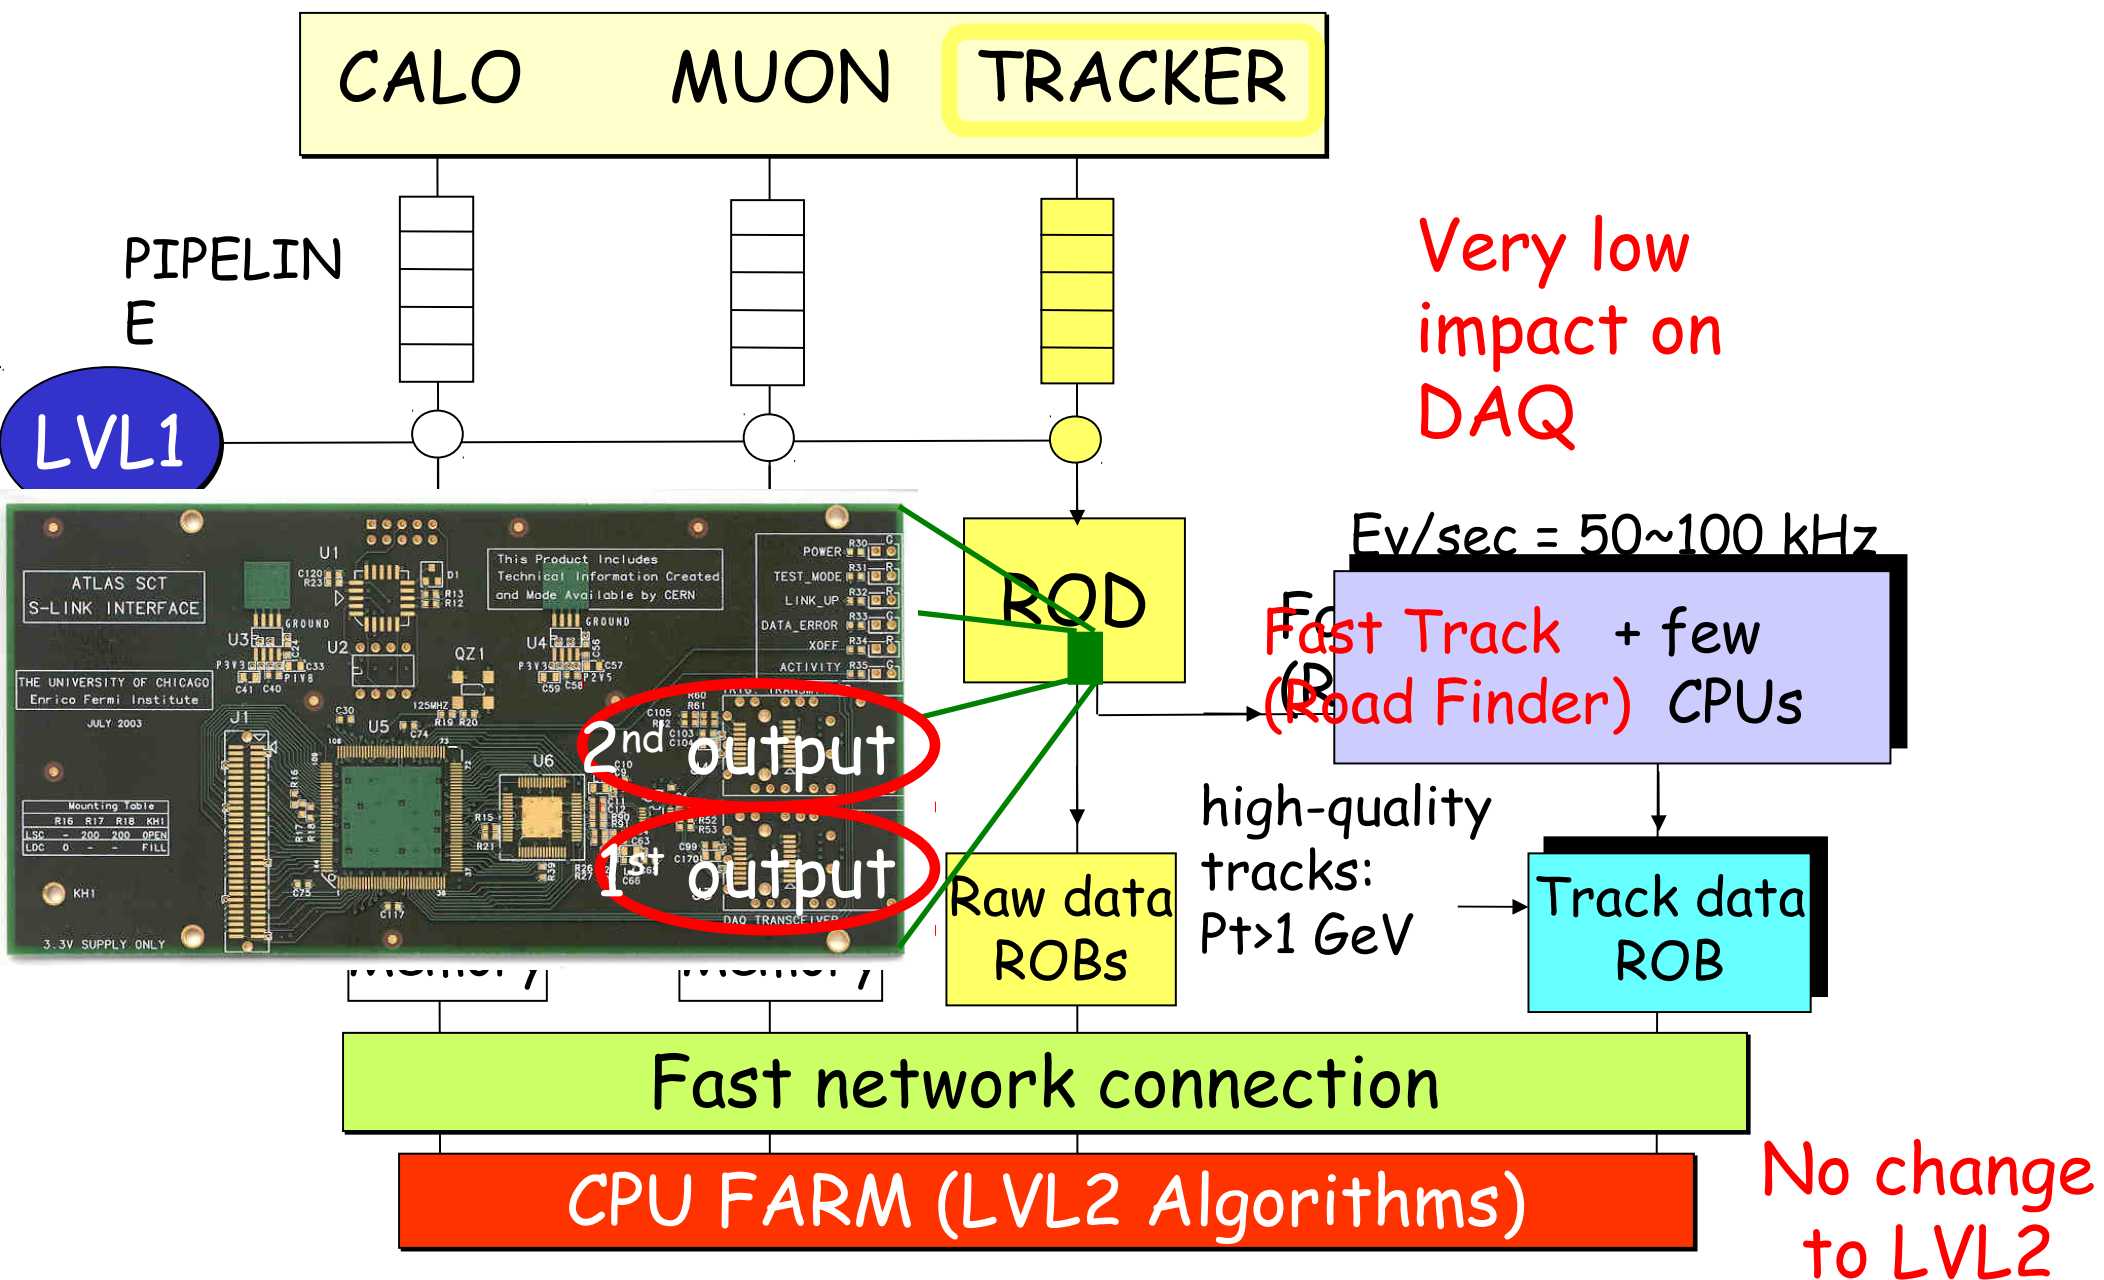

**Goal: High Lum 8  $\phi$  sectors  $\longrightarrow$  8 9U VME crates for the FTK core**

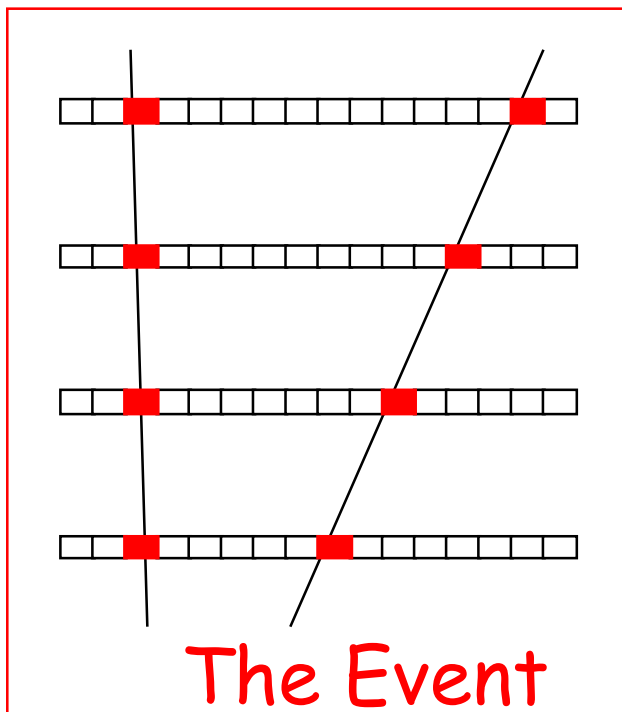

NOTE: The "core FTK" crates do not include the DATA Formatter boards, receiving and Formatting the detector hits

- **All 11 silicon layers** are necessary to reduce fakes at  $10^{34} \text{ cm}^{-1} \text{ s}^{-1}$  & more
- **Overlaps** require hits in a small region to be sent to two neighboring AMs
- Capability of the system to **increase the computing power** for increasing instant Luminosity or unpredicted background:
  1. Possible increase of phi sector number  $\longrightarrow$  more overlaps, more crates
  2. **Introduction of new algorithms – better tuning of existing system**
  3. Technology advancement: denser AM chips, more powerful FPGAs, links....

# Where could we insert FTK?

# TRACKING WITH PATTERN MATCHING

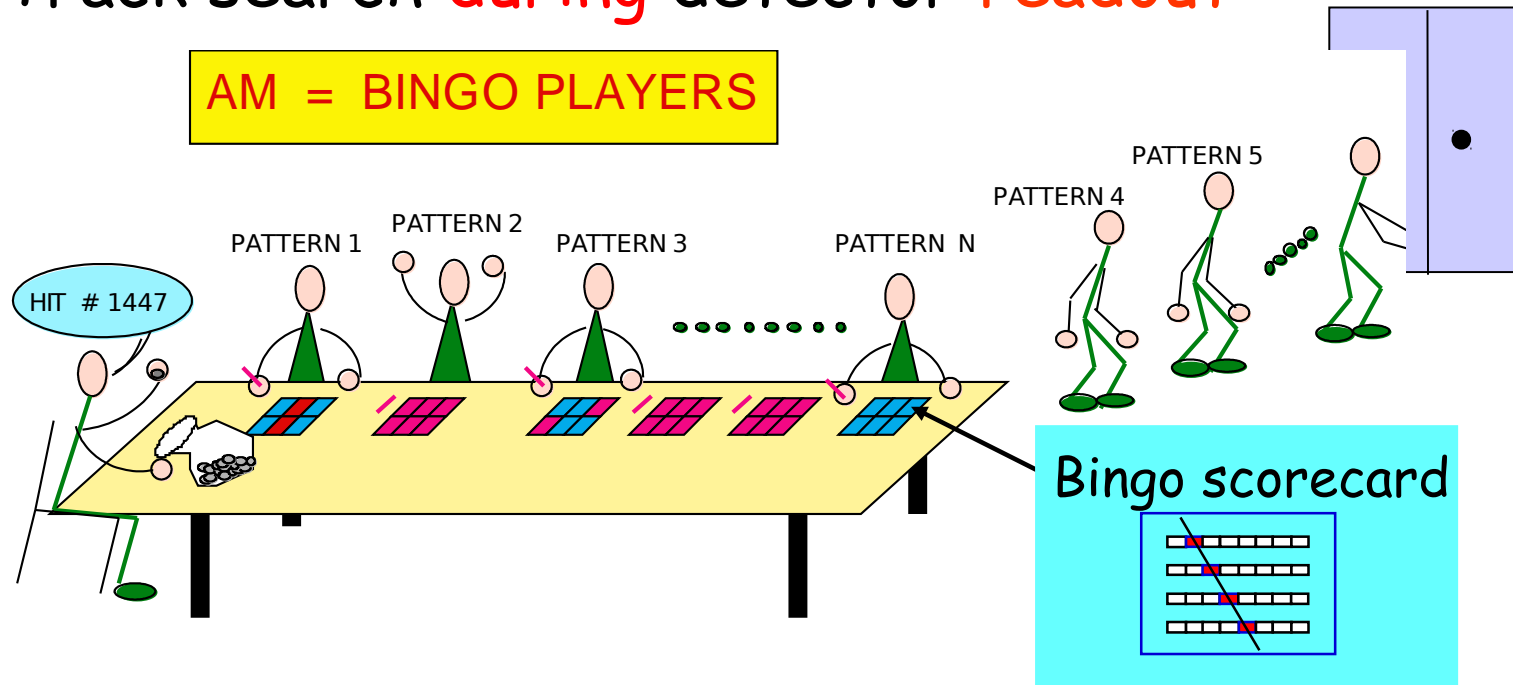

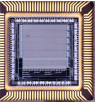

# The *Associative Memory* - AM

Dedicated device - **maximum parallelism**:

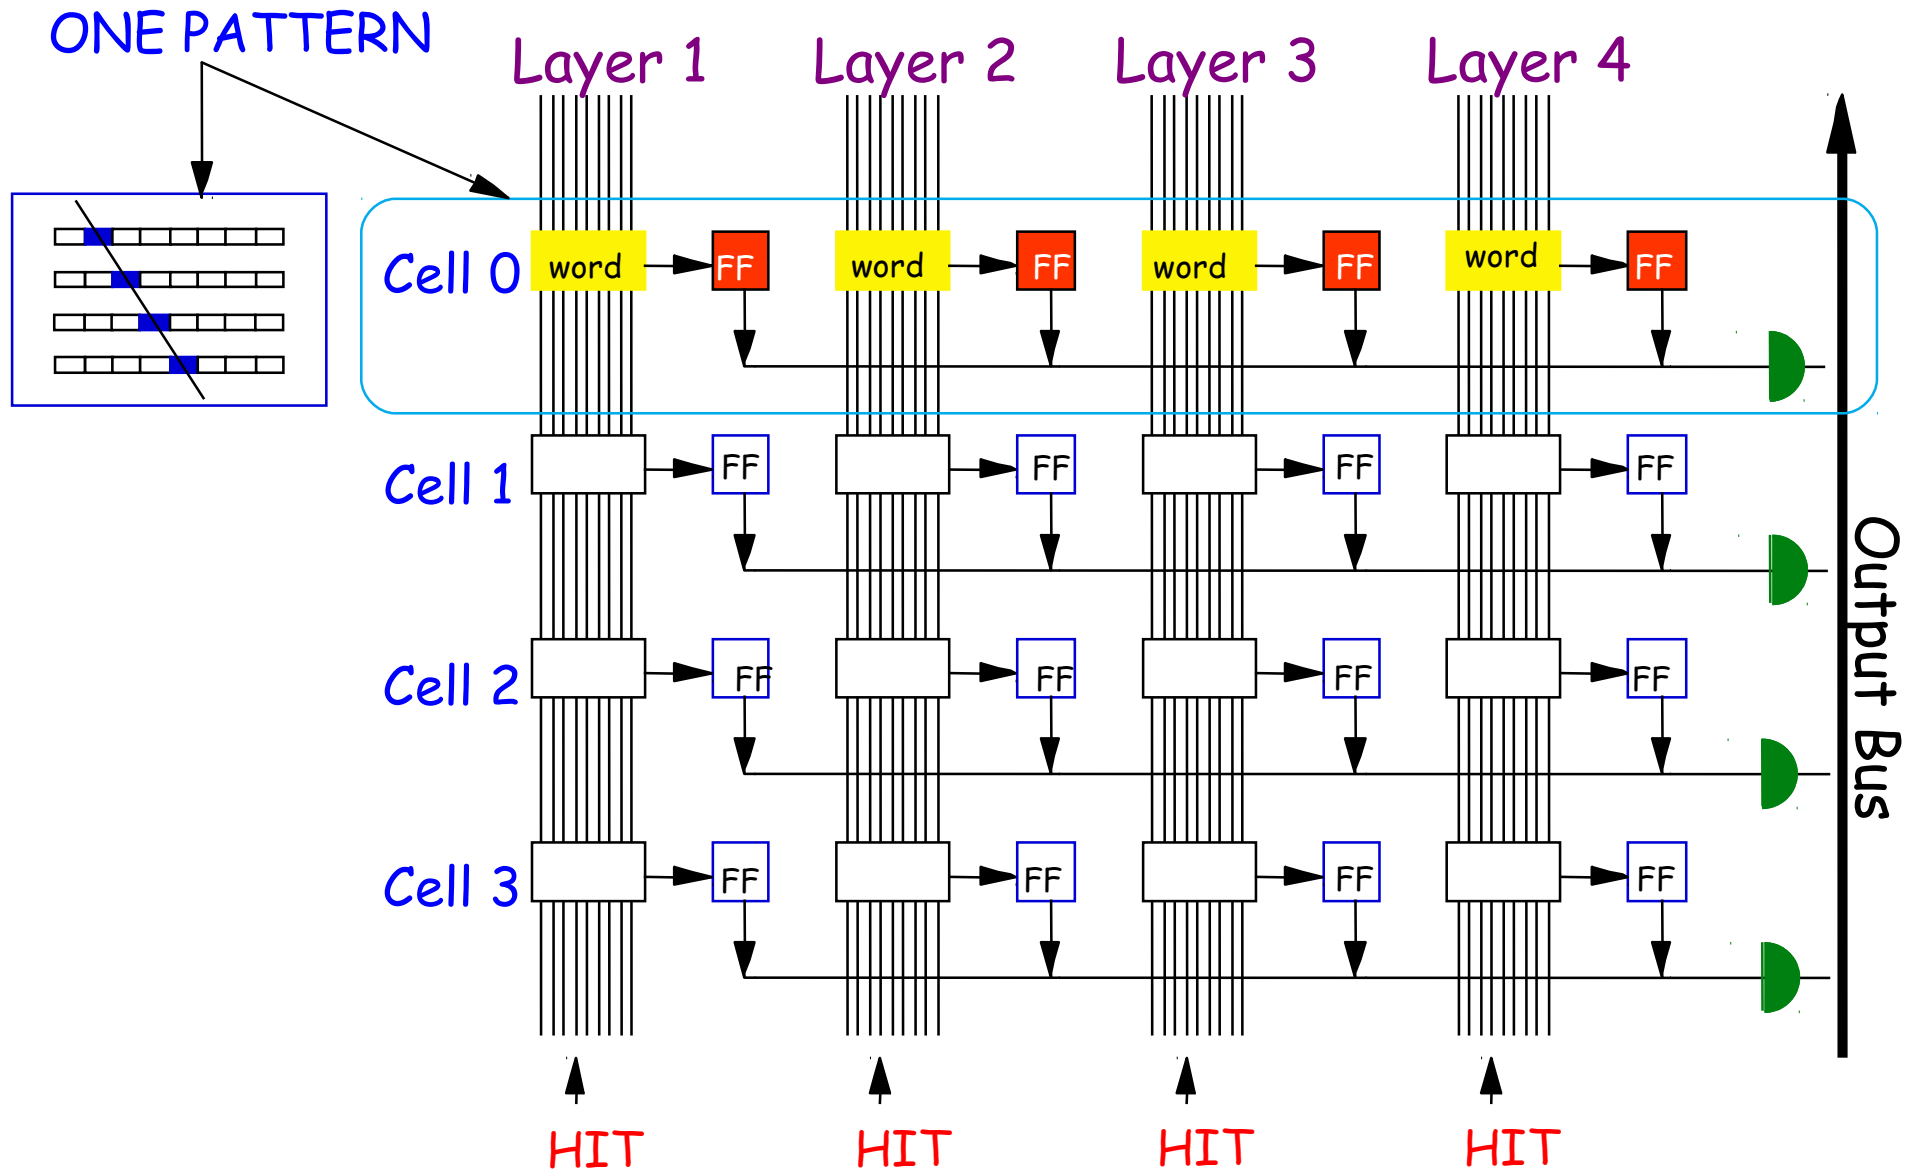

- Each pattern with **private comparator**
- Track search **during detector readout**

AM = BINGO PLAYERS

- **Full custom**  **700 nm: 0,128 6L kpattern/chip**
- **FPGA** **350 nm: 0,128 6L kpattern/chip**
- **standard ce**  **180 nm: 5,0 6L kpattern/chip**
- **new for FTK** **90 nm: ~25 8L kpattern/chip**
- **90 nm 2,5 D: 50 8L kpattern/chip**

# A schematic drawing of the AM

# Which banks we would like to have

What we have now: **Standard Cell 180**  $\mu\text{m}$

**1 pattern/chip** for 6-layer patterns,

**2500 pattern/chip** for 12-layer patterns

“A VLSI Processor for Fast Track Finding Based on Content Addressable Memories”,

**IEEE Transactions on Nuclear Science**, Volume 53, Issue 4, Part 2, Aug. **2006** Page(s):2428 - 2433

**90 nm** technology provides a factor 4  $\rightarrow$  **10000 patterns/chip**

Full custom cell provides at least a factor 2  $\rightarrow$  **20000 patterns/chip**

**8 layers** instead of 12 provides a factor 1,5  $\rightarrow$  **30000 patterns/chip**

**1,5 x 1,5 cm<sup>2</sup> 2D chip = 2 Tiers 1x1 cm<sup>2</sup>**  $\rightarrow$  **60000 patterns/chip**

With a **2 D chip** we gain a factor **25!**

**1 AMboard: 128 chips**  $\rightarrow$  **~8 Mpatterns per board**

**1 Crate: 16 AMboard**  $\rightarrow$  **128 Mpatterns per crate**

*If 2 Tiers of 1,5x1,5 or 4 Tiers 1x1*  $\rightarrow$  **256 Mpatterns per crate**

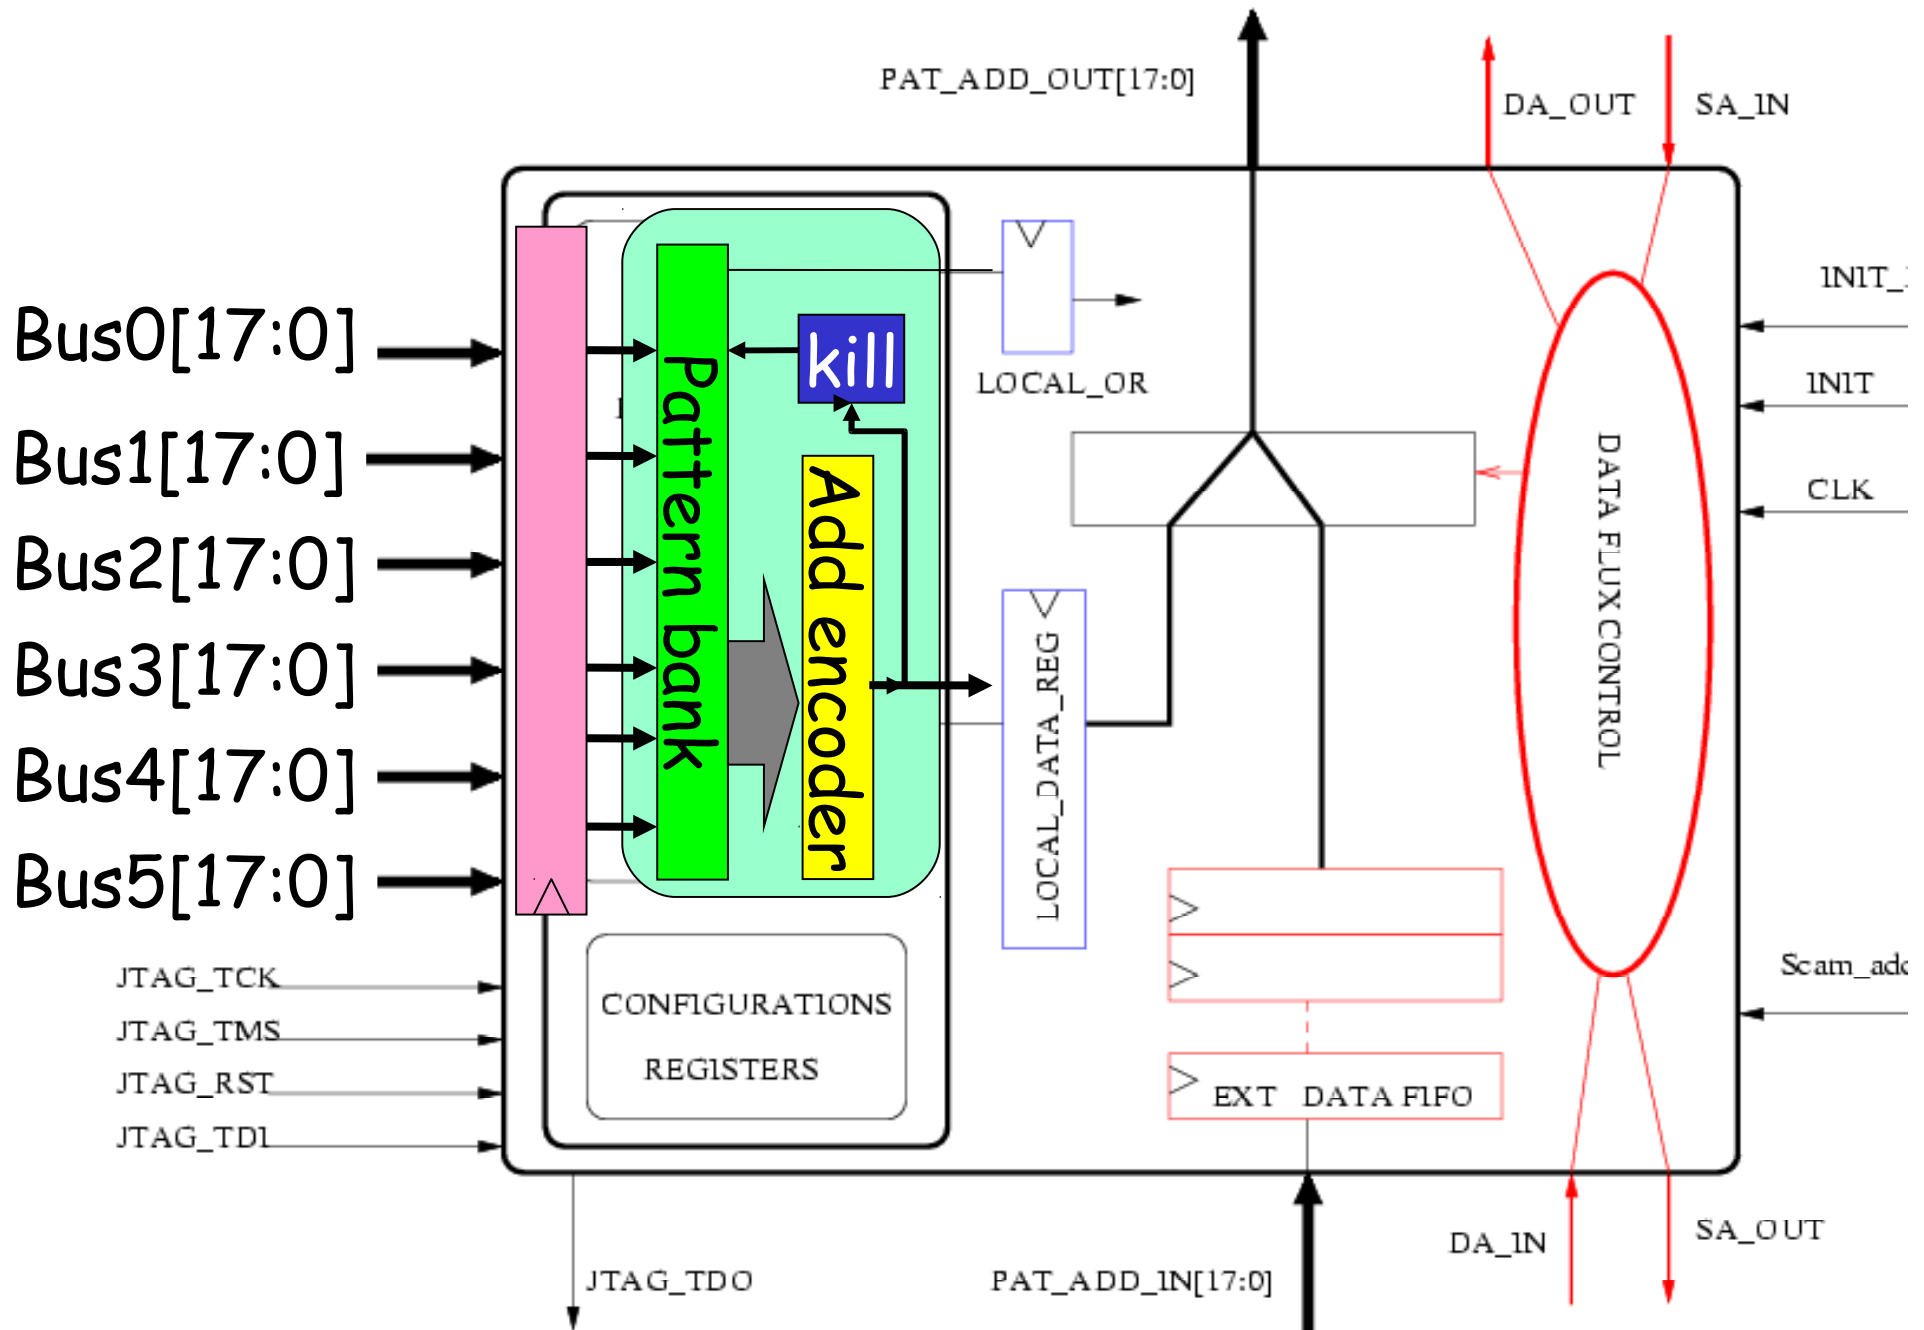

With a 2 Tier - **2.5 D chip** we gain a **factor 50!**

**100 MHz** running clock

**NEXT:  
NEW  
VERSION  
For both  
L1 & L2**

# The CDF final AMchip architecture

# AMCHIP

We are working (L.Sartori, Pisa+ M.Beretta, E. Bossini, Frascati) at the 2010 mini-asic prototype provided of full custom cell (**M. Beretta Frascati**) with **2 main goals**:

1. **Area reduction to obtain higher pattern densities**
2. **Power consumption reduction to be able to use large silicon areas**

Pattern Density/power with respect the CDF chip:

- 90 nm against 180 nm → factor ~4 for area and power consumption reduction  $(V_{90}/V_{180})^{**2}$
- Full custom cell: a factor 2 gain for both area and consumption.

**Future collaboration with Fermilab to stack 2 or 4 tiers with 2.5 D technology**

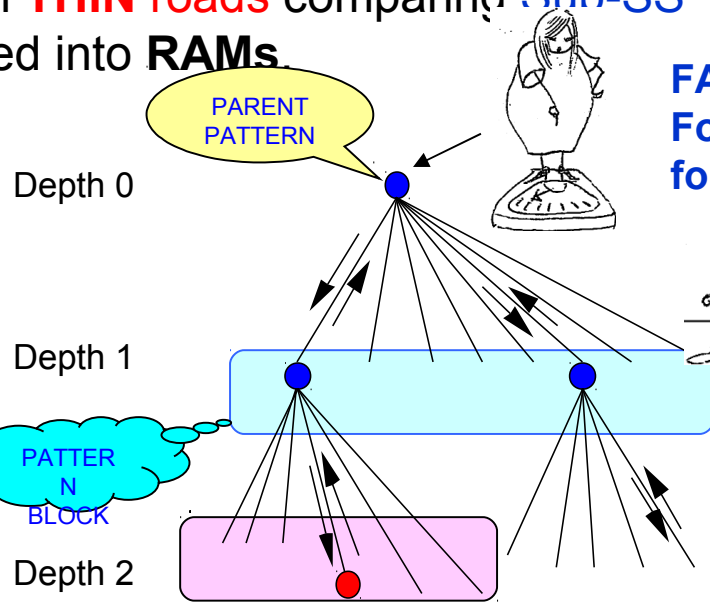

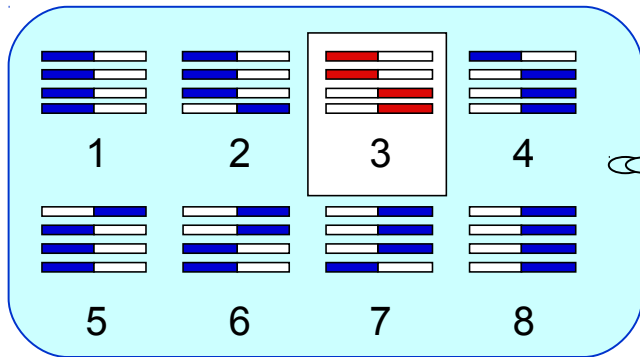

# FTK @ Low - Intermediate Luminosity?

- It is a very important **Hardware & Physics** test before  $10^{34}$  &  $3 \times 10^{34}$ ; test on **real conditions** of the detector; **large impact** on the whole trigger. Study of “minimum bias” **b-tag** and **tau-tag** trigger ( $Z0 \rightarrow bb$ , tau-tau+QCD backg). **Level-2** and **Event Filter** algorithms in CPUs have to take into account new track availability at L2 start.
- **Level-1** has to be re-studied also for **Phase 1**. **Global Level-1** is going to be designed for **Phase 1**. **Influence** of FTK experience on real data.
- Availability of **new phase space regions**, like enlargement of phase space for “**Hadronic Channels**”. This is not included in the **LHC baseline trigger**, neither in **CMS** neither in **Atlas**.  
There could be a new **interest in Atlas in this area**.

# Binary search to go down to better SS resolutions

The **AM chip** for each found road should provide:

- 1) The **Road Identifier** (address)
- 2) The **Bitmap** : one bit per layer, saying which SSs are empty & which are full (11 bits: 11101111111 eg.)
- 3) 4 more bits for each layer, **Sub-SS**, saying which of the 4 SS subdivisions are empty and which are full (4 bits × 11 Layers). The **TSP** will search **THIN roads** comparing **Sub-SS** to **Larger pattern banks** stored into **RAMs**

**FAT ROAD**  
Found by AM (default SS for example)

**THIN ROAD**

**Algorithm:** NIM A287 (1990) 436-438

## Staging

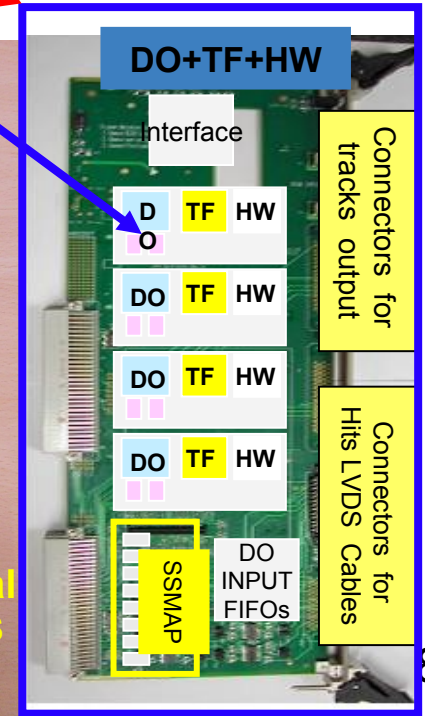

- **Start late this year to assemble a vertical slice in a test stand:**
  - Use existing boards (EDRO board from SLIM5 & AM board)
  - Cover a small projective wedge in the detector
  - Develop the code needed for interaction with ATLAS TDAQ
  - Test new prototype boards as they are produced
  - Connect to the detector when test stand works & dual-output HOLAs are available.
- **Install all dual-output HOLAs during 2012 shutdown**
- **Assemble a system using the existing AM chip adequate for a few  $\times 10^{33}$ .**
- **Expand the system for  $1 \times 10^{34}$ .**
- **Replace AM chips (& LAMBs) for  $3 \times 10^{34}$ .**

# New cleanup functions against Ghosts RoadWarriors - HitWarrior

Nuclear Science, IEEE Transactions on: **The "Road Warrior" for the CDF online silicon vertex tracker** Volume 53, Issue 2, April 2006 Page(s):648 - 652

**RW** works on **SS** before knowing the fit  $\chi^2$   
It deletes ghosts acting on roads that differ **ONLY** for a single **EMPTY SS**

**HW** works on hits after the fits so can choose the best **DUPLICATE!** tracks if they share **N** Hits

**HW** is very efficient deleting ghosts

The fit  $\chi^2$  or more complex criteria can discriminate

Impact parameter  
Significance inside jets  
level-2  $d_0$  likelihood tagger  
offline IP2D algorithm.

## $B_s \rightarrow \mu\mu$ (x3 using soft second $\mu$ )

F. Crescioli

CDF

## $M(\mu\mu)$ invariant mass

Athena + FTKsim

$M(\mu, \mu)$  Bs mass

# LHC SM Higgs Discovery Potential

▪ Sensitivity best at  $m_H = 160 \text{ GeV}/c^2$ :

- Observation possible with  $\sim 1 \text{ fb}^{-1}$  (or improvement of Tevatron limits)

▪ Much more difficult at low mass (preferred region)

- Need at least  $10 \text{ fb}^{-1}$  to cover full mass range

# Bank generated with Athena fully simulated single muons

A. Kapliy (Chicago)  
G. Volpi (Pisa)

SS sizes: in  $z$  → as long as the whole module (144 pixels);  
in  $\phi$  → 50 pixels and 64 SCT strips  
– Default SS size: can be optimized –

Coverage = # evts with (11 hits/11 layers) / # evts

Efficiency = # evts with (11/11) OR (10/11) / # evts

EFFICIENCY allows for a missing LAYER (majority). Blue arrow shows a bank using less majority

# The effect of cleanup for banks of different coverage

**BARREL ONLY- Default SS size**  
 7 L – 5,6 M patterns / region  
 with efficiency ~98%

11 L – 8,4 M patterns / region  
 with efficiency ~85%  
 Coverage ~60%

11 L – 68 M patterns / region  
 with efficiency > 90 %  
 Coverage > 80 %

$\langle \#roads \rangle = 10.6$   
 $\langle roads \rangle = 2.15$  (-80%)  
 $\langle nfits \rangle = 2.2$

$\langle In\text{-}sec \rangle = 4.54$   
 $\langle Cross\text{-}sec \rangle = 2.27$  (-50%)  
 $\langle tracks \rangle = 1.51$

$\langle In\text{-}sec \rangle = 5.72$   
 $\langle Cross\text{-}sec \rangle = 2.29$  (-60%)  
 $\langle tracks \rangle = 1.51$

*Richer banks produce much more ghosts*
