# Angular coefficients of Z bosons produced in pp collisions at $\sqrt{s} = 8$ TeV and decaying to $\mu^+ \mu^-$ as a function of transverse momentum and rapidity

The CMS Collaboration<sup>\*</sup>

## Abstract

Measurements of the five most significant angular coefficients,  $A_0$  through  $A_4$ , for Z bosons produced in pp collisions at  $\sqrt{s} = 8$  TeV and decaying to  $\mu^+ \mu^-$  are presented as a function of the transverse momentum and rapidity of Z boson. The integrated luminosity of the dataset collected with the CMS detector at the LHC corresponds to  $19.7 \text{ fb}^{-1}$ . These measurements provide comprehensive information about Z boson production mechanisms, and are compared to QCD predictions at leading order, next-to-leading order, and next-to-next-to-leading order in perturbation theory.

*Submitted to Physics Letters B*

We report the first measurement of the angular coefficients of Z bosons produced in pp collisions and decaying to muon pairs. These coefficients govern the decay of the Z boson and thereby the kinematics of the lepton. Their values follow from the vector and axial vector (V-A) structure of boson-fermion couplings. The general structure of the lepton angular distribution in the boson rest frame is given by

$$\frac{d^2\sigma}{d\cos\theta^* d\phi^*} \propto \left[ (1 + \cos^2\theta^*) + A_0 \frac{1}{2}(1 - 3\cos^2\theta^*) + A_1 \sin(2\theta^*) \cos\phi^* + A_2 \frac{1}{2}\sin^2\theta^* \cos(2\phi^*) \right. \\ \left. + A_3 \sin\theta^* \cos\phi^* + A_4 \cos\theta^* + A_5 \sin^2\theta^* \sin(2\phi^*) + A_6 \sin(2\theta^*) \sin\phi^* + A_7 \sin\theta^* \sin\phi^* \right]. \quad (1)$$

Here,  $\theta^*$  and  $\phi^*$  are the polar and azimuthal angles of the negatively charged lepton in the rest frame of the lepton pair. In this analysis we choose the Collins–Soper (CS) frame [1] to measure the angular coefficients  $A_i$ , considering the momentum of the beam proton closest in rapidity to the Z boson as “target momentum” [1]. The parameters  $A_0$ ,  $A_1$ , and  $A_2$  are related to the polarization of the Z boson, whilst  $A_3$  and  $A_4$  are also sensitive to the V-A structure of the couplings of the muons. The angular coefficients vanish as the transverse momentum of the Z boson  $q_T$  approaches zero, except for  $A_0$ , which measures the longitudinal polarization with respect to the z axis, and  $A_4$ , the electroweak parity violation term, which reflects the difference of the polarization along the z axis and the strength of V-A couplings.

The only previous measurement of four of the angular coefficients was performed by the CDF Collaboration in  $p\bar{p}$  interactions for  $q_T$  up to 55 GeV [2]. The angular coefficients in pp collisions are expected to differ from those in  $p\bar{p}$  collisions for several reasons. For  $p\bar{p}$  collisions, Z boson production occurs predominantly via the  $q\bar{q}$  annihilation process, whilst for pp collisions there is a significant contribution from the qg Compton process. For the  $q\bar{q}$  process in the CS frame,  $A_0 = A_2 = q_T^2/(M_Z^2 + q_T^2)$  [3–6], where  $M_Z$  is the Z boson mass. For the qg Compton process  $A_0 = A_2 \approx 5q_T^2/(M_Z^2 + 5q_T^2)$  [7]. The relation  $A_0 = A_2$  is known as the Lam–Tung relation [8], reflecting the full transverse polarization of vector bosons coupling to quarks, as well as rotational invariance [9]. Processes containing non-planar configurations (e.g., from higher order multi-gluon emission) smear the transverse polarization, leading to  $A_2 < A_0$  [10]. In contrast to what happens at the Tevatron, the average handedness of Z bosons is nonzero at the LHC, as for the W boson [11–13].

The angular coefficients of Z bosons produced in pp collisions at  $\sqrt{s} = 8$  TeV and decaying to  $\mu^+\mu^-$  are measured as a function of  $q_T$  and rapidity  $y$ . The data sample, taken with the CMS detector at the LHC, corresponds to an integrated luminosity of  $19.7\text{ fb}^{-1}$ . The large Z boson event sample collected by the CMS experiment allows precision measurements of the angular distribution for  $q_T < 200\text{ GeV}$  and  $|y| < 2.1$ . The coefficients, measured as a function of  $q_T$  and  $|y|$ , are compared with three perturbative QCD predictions by FEWZ at next-to-next-to-leading order (NNLO) [14], POWHEG at next-to-leading order (NLO) [15–18], and MADGRAPH at leading order (LO) [19].

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter, and a brass and plastic scintillator hadron calorimeter, each composed of a barrel and two endcap sections. Muons are measured in gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid. Extensive forward calorimetry complements the coverage provided by the barrel and endcap detectors. Muons are measured in the pseudorapidity range  $|\eta| < 2.4$ , with detection planes made using three technologies: drift tubes, cathode strip chambers, and resistive plate chambers.

Matching muons to tracks measured in the silicon tracker results in a relative  $p_T$  resolution for muons with  $20 < p_T < 100$  GeV of 1.3–2.0% in the barrel and better than 6% in the endcaps. A more detailed description of the CMS detector, together with a definition of the coordinate system and the relevant kinematic variables, can be found in Ref. [20]. A particle-flow (PF) event reconstruction algorithm [21, 22] is used in this analysis. It consists of reconstructing and identifying each single particle with an optimized combination of all subdetector information. A trigger for single isolated muon is used, requiring  $p_T > 24$  GeV and  $|\eta| < 2.1$ . The leading reconstructed muon in  $p_T$  is matched to the muon selected by the trigger.

The signal process is simulated using the MADGRAPH 1.3.30 generator [19] with zero to four additional jets, interfaced with PYTHIA v6.4.24 [23] with the Z2\* tune [24]. The matching between the matrix element calculation and the parton shower is performed with the  $k_T$ -MLM algorithm [25]. The CTEQ6L1 [26] parton distribution functions (PDF) are used for the event generation. Multiple-parton interactions are simulated by PYTHIA. The POWHEG generator [15–18] interfaced with PYTHIA and the CT10 PDF set [27] are used as an alternate to test any model dependence in the shapes of the angular distributions.

Background simulations are performed with MADGRAPH ( $W+jets$ ,  $t\bar{t}$ ,  $\tau\tau$ ), POWHEG (single top quark [28, 29]), and PYTHIA ( $WW$ ,  $WZ$ ,  $ZZ$ ). The normalizations of the inclusive Drell-Yan,  $W$  boson [14], and  $t\bar{t}$  [30] distributions are set using NNLO cross sections. For single top quark production a higher order (approximate NNLO [31]) inclusive cross section is used. The generated events are passed through a detector simulation based on GEANT4 [32].

Each muon candidate is required to be reconstructed in the muon detectors and in the inner tracker, and the global track fit is required to have a reduced  $\chi^2 < 10$ . The vertex with the highest sum of  $p_T^2$  for associated tracks is defined as the primary vertex. The distance of the muon candidate trajectories with respect to the primary vertex must be smaller than 2 mm in the transverse plane and 5 mm along the  $z$  axis. The leading (subleading) muon is required to have  $p_T > 25$  (10) GeV and  $|\eta| < 2.1$  (2.4). In order to suppress background events, the muons are required to be isolated from nearby particles. The relative isolation is calculated as the ratio of the scalar sum of  $p_T$  of all PF candidates from the same primary vertex, within a cone of  $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} < 0.4$ , and the  $p_T$  of the muon. For the leading (subleading) muon in  $p_T$ , the relative isolation must be less than 0.12 (0.5). Oppositely charged muon pairs with an invariant mass in the range 81–101 GeV are selected. In the rare case that more than two muons are selected, the muon pair with invariant mass closest to the  $Z$  boson mass is chosen. The muon pair must satisfy  $|y| < 2.1$ ; for higher  $|y|$  the acceptance varies rapidly.

A “tag-and-probe” method [33] is used to measure the efficiencies for track reconstruction, trigger, muon isolation, and muon identification in data and simulation. Efficiency corrections are applied as multiplicative scale factors to the simulation values. The efficiency for track reconstruction is measured in bins of  $\eta$  since the  $p_T$  dependence is weak. The trigger efficiency is determined in bins of  $p_T$  and  $\eta$ , separately for  $\mu^+$  and  $\mu^-$ . The identification efficiency is measured in bins of  $p_T$  and  $\eta$ . Since the subleading muon can point in the direction of the hadronic activity, a looser isolation requirement is used and its efficiency is measured as a function of  $q_T$ ,  $\cos\theta^*$ , and  $\phi^*$ . The efficiency of the isolation requirement for the leading muon is measured as a function of  $p_T$  and  $\eta$  of the muon, as detector effects relate to these variables more directly than to the  $Z$  boson  $q_T$  and  $y$ .

After event selection, the background contribution ranges from  $\sim 0.1\%$  at low  $q_T$  to  $\sim 1.5\%$  at high  $q_T$ . The yields of the backgrounds from  $t\bar{t}$ ,  $\tau\tau$ ,  $WW$ ,  $tW$ , and  $W+jets$  production are estimated from data using lepton flavor universality. Most of these backgrounds typically have two prompt leptons, which may have the same flavor. The  $W+jets$  background is flavor asym-

metric, but its contribution is small. We assume that the ratio of the number of oppositely charged background  $\mu\mu$  and  $e\mu$  events is the same in data and simulation. We use the ratio of the  $e\mu$  yields in data and simulation to normalize the simulation to data.

The acceptance and the efficiency at the event level vary in  $\cos\theta^*$  and  $\phi^*$ , and strongly with  $q_T$  and  $y$ . In order to avoid a bias in the acceptance due to the modeling of the Z boson kinematics, the simulation is reweighted in fine bins of  $q_T$  and  $y$  to match the background-subtracted data distribution. The weights are determined at the reconstruction level and applied at the generator level. The weighting is iterated four times, with negligible change between the second and fourth iteration.

The angular coefficients are measured in eight bins of  $q_T$  and two bins of  $|y|$ , by fitting the two-dimensional  $(\cos\theta^*, \phi^*)$  distribution in data with a linear combination of templates. These templates are built for each coefficient  $A_i$  by reweighting the simulation at generator level to the corresponding angular distribution, as given in Eq. (1). The templates are based on reconstructed muons, and thereby incorporate the effects of resolution, efficiency and acceptance. A template is also built for the term  $(1 + \cos^2\theta^*)$  of Eq. (1). An additional template, with shape and normalization fixed, is developed for fitting the backgrounds. A binned maximum-likelihood method with Poisson uncertainties is employed for the fit. The angular coefficients  $A_5$ ,  $A_6$ , and  $A_7$  are predicted to be very small; they are set to zero and excluded from the fit. Since  $A_0$  through  $A_4$  are sign invariant in  $\phi^*$ , the absolute value  $|\phi^*|$  is used. The fit is made in  $12 \times 12$  equidistant bins in  $\cos\theta^*$  and  $|\phi^*|$ . The statistical uncertainties from the fit are confirmed by comparison with pseudo-experiments.

The angular coefficients  $A_0$ ,  $A_2$ ,  $A_3$ , and  $A_4$  are also measured by an independent analysis similar to that reported in Ref. [2], where one-dimensional (1D) templates produced using POWHEG with NLO CT10 PDFs are fitted to the distributions in  $\cos\theta^*$  and  $|\phi^*|$ . The 1D fit analysis is performed iteratively, so as to be unbiased with respect to the assumed templates and to possible correlations between  $\cos\theta^*$  and  $|\phi^*|$ . The analysis differs in the triggers, estimation of backgrounds, simulation, and selection criteria. The 1D fit analysis uses a sample that requires a dimuon trigger with asymmetric muon  $p_T$  thresholds of 17 and 8 GeV. Both results are consistent within their total systematic uncertainties, excluding uncertainties common to both analyses.

Some examples of the measured  $\cos\theta^*$  and  $|\phi^*|$  distributions from the 1D analysis are given in Fig. 1. The measured and simulated distributions are shown together using the best fit values of the angular coefficients. The shape of the  $\cos\theta^*$  distribution changes with  $q_T$  and  $|y|$  because the acceptance and efficiency in  $\cos\theta^*$  depend strongly on these two variables. For  $|\phi^*|$ , the shape of the distribution changes moderately with  $q_T$ , and is almost insensitive to  $|y|$ . The comparison of data and simulation shown in Fig. 1 gives confidence that the acceptance and efficiency dependences are correctly modeled in the simulation.

Several sources of systematic uncertainties are taken into account. The most significant source is the muon efficiency that includes the trigger, track reconstruction, isolation, and identification. The statistical uncertainties of the measured efficiency scale factors are taken into account by simulating many pseudo-experiments in which the templates are reformed, each time varying the scale factors randomly within the given uncertainty. The systematic uncertainties in the extraction of the efficiency (e.g., background estimates) are also included. Another significant uncertainty stems from the statistical precision of the templates, which is estimated using pseudo-experiments. The pileup uncertainty is estimated by varying the cross section of the minimum bias events by  $\pm 5\%$ . The muon momentum bias is measured in data and simulation, and corresponding corrections are applied [34]. The statistical uncertainties in the

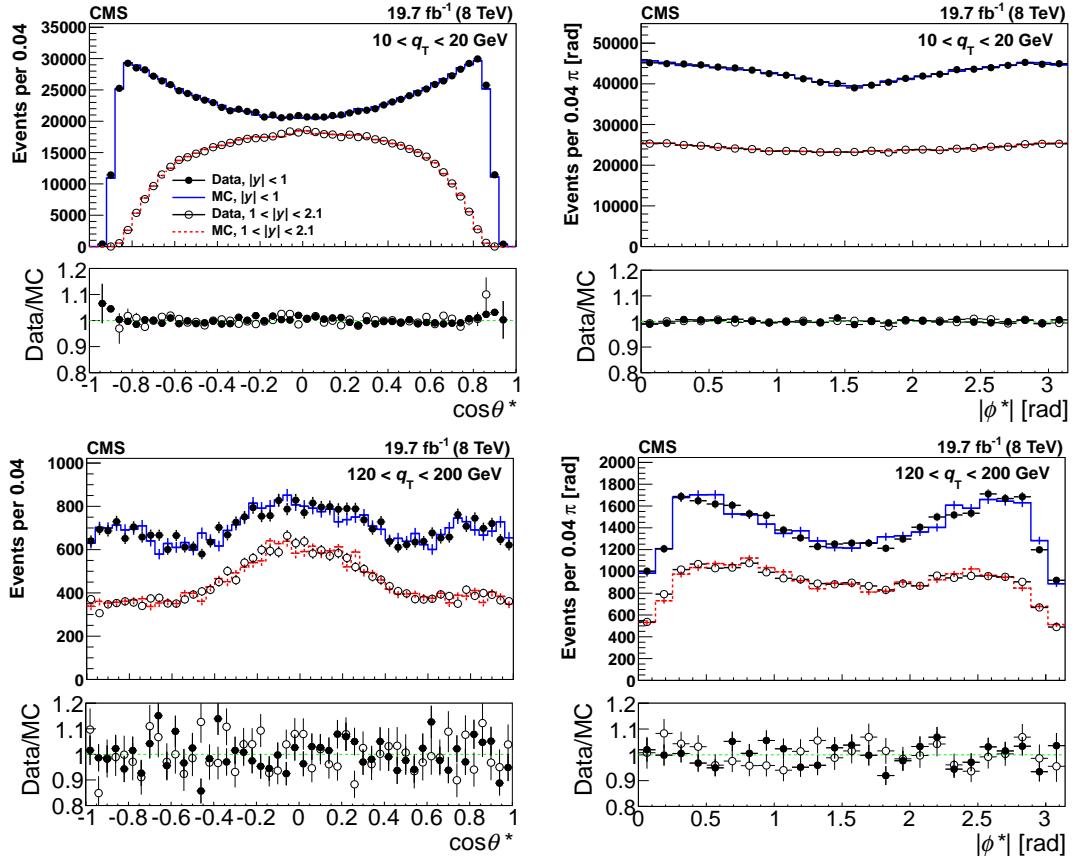

Figure 1: A few examples of the observed 1D angular distributions in  $\cos \theta^*$  (left) and  $|\phi^*|$  (right) compared to the MC simulation using the best fit values of the angular coefficients. The top (bottom) plots show the distributions for  $10 < q_T < 20 \text{ GeV}$  ( $120 < q_T < 200 \text{ GeV}$ ), a region where  $A_0$  and  $A_2$  are small (large). The background-subtracted data points are shown with filled (open) circles for  $|y| < 1$  ( $1 < |y| < 2.1$ ), whilst the corresponding MC results are shown with solid (dashed) lines. Vertical bars represent the statistical uncertainties. The lower panels show the data-to-MC ratios.

muon momentum correction factors are propagated to a systematic uncertainty using pseudo-experiments. In addition, a systematic uncertainty is assessed to take into account possible global offsets from the peak position of the Z boson mass. The systematic uncertainties for the background are estimated by varying the normalization scale factor of the  $e\mu$  sample by 10% and the yields of WZ and ZZ events by 50%. The statistical precision of the iterative reweighting is determined using pseudo-experiments. The difference between the last two iterations is assigned as additional systematic uncertainty. The effect of final-state radiation is taken into account by adding the energy of photons within a cone of radius 0.1 around the muon direction [35]. Weights are applied to the simulation to reflect the difference between a soft-collinear approach and the exact  $O(\alpha_{\text{QED}})$  result and the reconstructed template is rebuilt using the weighted simulation. The difference between templates is used to estimate the systematic uncertainty from final-state radiation. Finally, the acceptance uncertainty, related to the values of  $A_i$  assumed in the simulation, is estimated by reweighting with the fitted values of  $A_i$ , and the difference in results is included as a systematic uncertainty. Generally, the statistical uncertainties dominate in the highest bins in  $q_T$ , whilst the systematic uncertainty in the efficiency tends to be the most important elsewhere. The various systematic uncertainties of the five angular coefficients  $A_0$  to  $A_4$  are presented in Fig. 2.

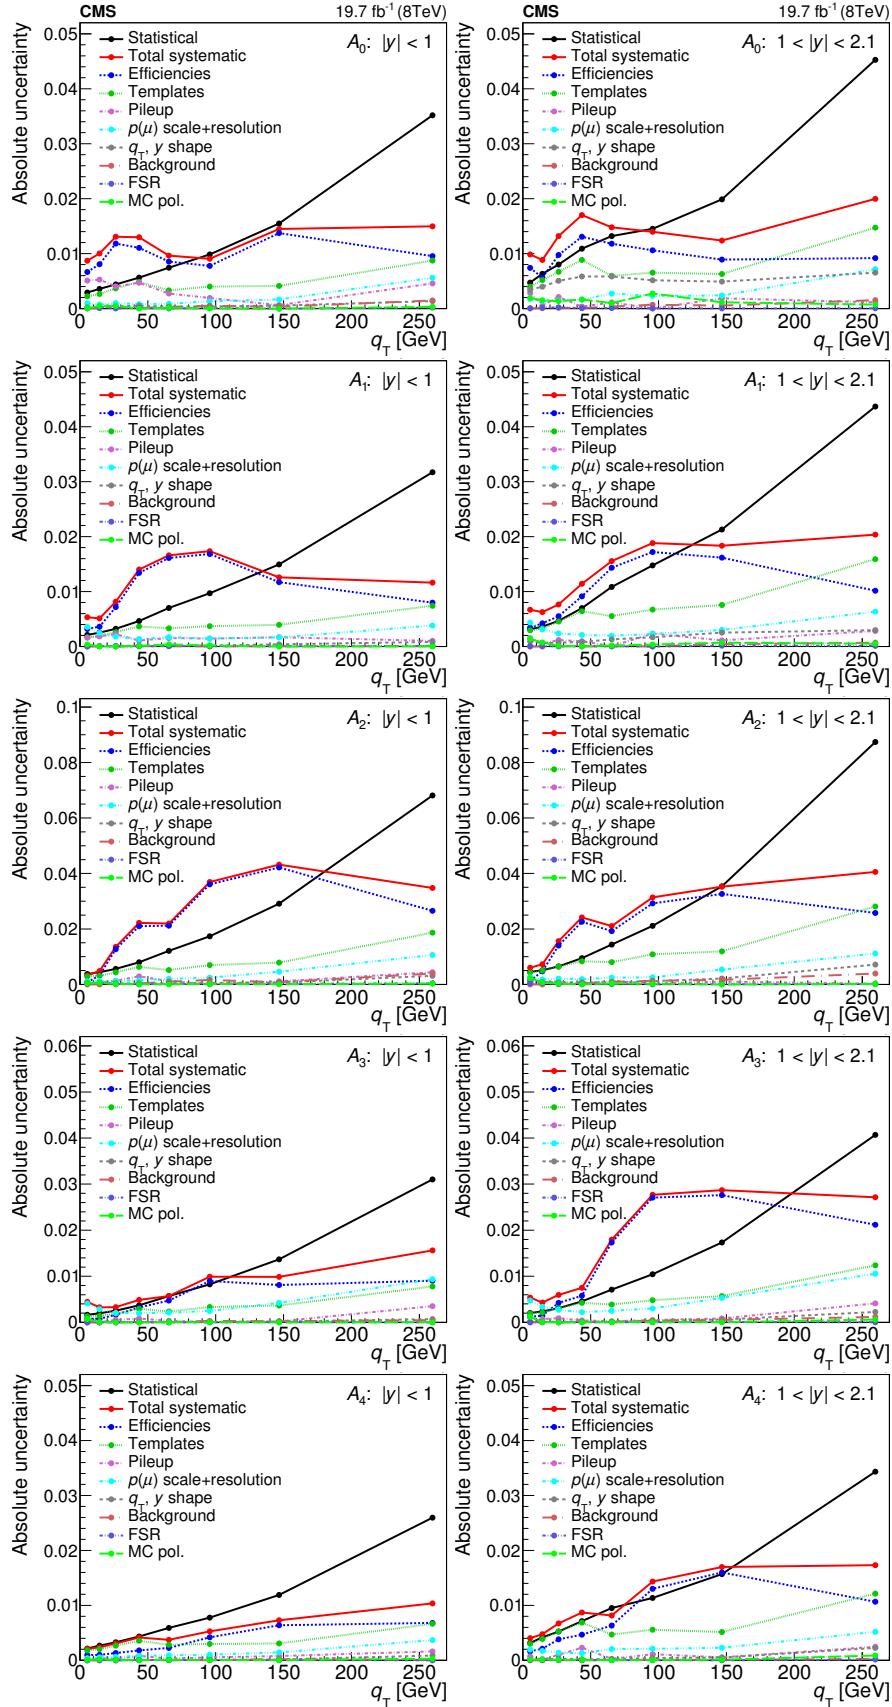

Figure 2: Absolute uncertainties in the five angular coefficients  $A_0$  to  $A_4$ . Each figure shows the  $q_T$  dependence in the indicated ranges of  $|y|$ .

The results of the  $q_T$  and  $|y|$  dependent measurement of the angular coefficients  $A_0$  to  $A_4$  as well as the difference  $A_0 - A_2$  are presented along with MADGRAPH, POWHEG, and FEWZ (at NNLO) calculations in Figs. 3 and 4. The values and uncertainties of the coefficients are provided in Tables 1 and 2. The PDF sets used in the calculations are CTEQ6L for MADGRAPH and CT10 for POWHEG (at NLO) and FEWZ (at NNLO). The MADGRAPH predictions for  $A_4$  are systematically higher than those of POWHEG and FEWZ because MADGRAPH uses a weak mixing angle calculated without considering radiative corrections. The measured  $A_0$  and  $A_2$  coefficients agree better with the prediction of MADGRAPH than with those of POWHEG and FEWZ, especially at high  $q_T$ . At  $q_T = 0$ , the POWHEG prediction for  $A_0$  is negative, which is unphysical and has been traced to approximations in the shower matching algorithm. We find that  $A_0(q_T)$  and  $A_2(q_T)$  are larger in pp collisions than those measured in  $p\bar{p}$  collisions at the Tevatron. The significant contribution from the qg process in pp collisions at the LHC is responsible for this difference. We observe the violation of the Lam–Tung relation ( $A_0 = A_2$ ) anticipated by QCD calculations beyond leading order [36]. We find that  $A_0 > A_2$ , especially for high  $q_T$ . In addition, we measure nonzero values of  $A_1$  and  $A_3$ . The comparison of the results for  $|y| < 1$  and  $1 < |y| < 2.1$  is shown in Fig. 5.

In summary, we presented the five major angular coefficients,  $A_0$  through  $A_4$ , for the production of the Z boson decaying to muon pairs as a function of  $q_T$  and  $|y|$  in pp collisions. These results play an important role in future high-precision measurements, such as the measurement of the mass of the W boson and of the electroweak mixing angle. Some theoretical predictions deviate from the measurements in  $q_T$ . Further refinements of the theory are needed to achieve a better agreement with the experimental results.

## Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWFW and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); MoER, ERC IUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); LAS (Lithuania); MOE and UM (Malaysia); CINVESTAV, CONACYT, SEP, and UASLP-FAI (Mexico); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS and RFBR (Russia); MESTD (Serbia); SEIDI and CPAN (Spain); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

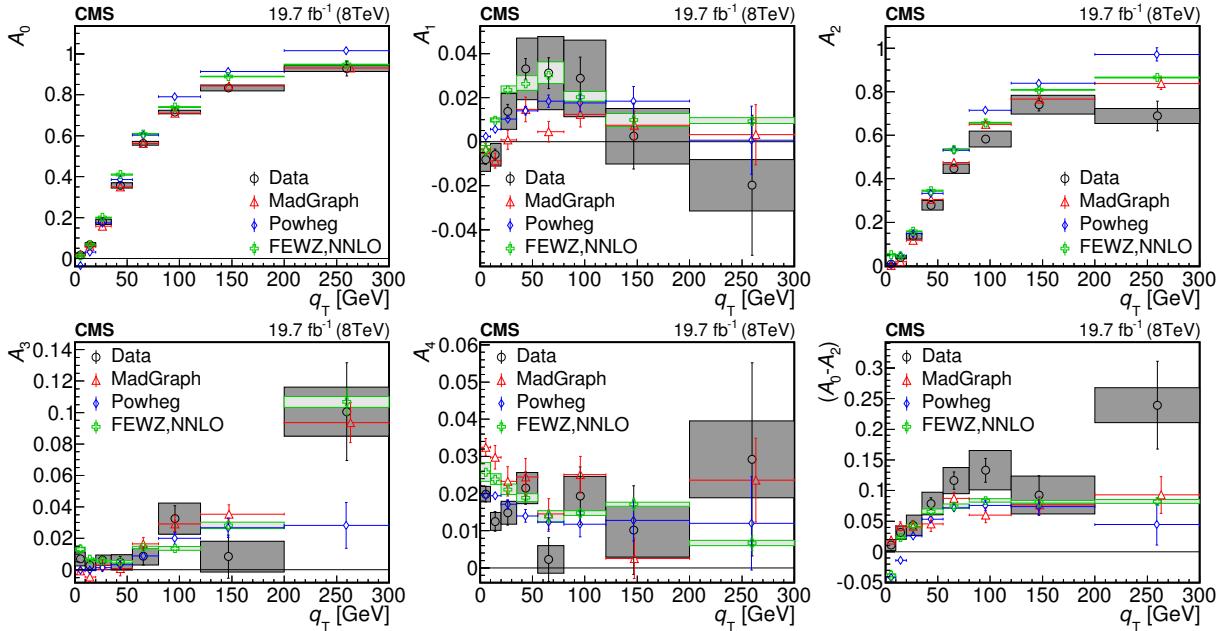

Figure 3: Comparison of the five angular coefficients  $A_i$  and  $A_0 - A_2$  measured in the Collins-Soper frame in bins of  $q_T$  for  $|y| < 1$ . The circles show the measured results. The vertical bars represent the statistical uncertainties and the boxes the systematic uncertainties of the measurement. The triangles show the predictions from MADGRAPH, the diamonds from POWHEG, and the crosses from FEWZ at NNLO. The boxes at the FEWZ values indicate the PDF uncertainties.

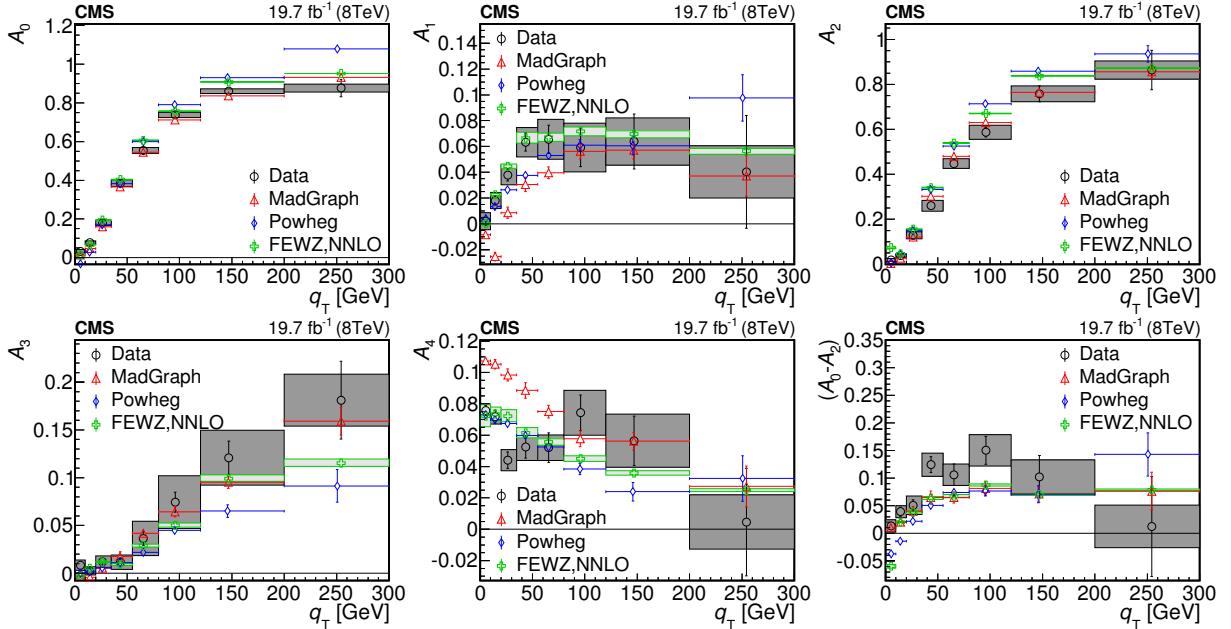

Figure 4: Comparison of the five angular coefficients and  $A_0 - A_2$  under the same conditions as Fig. 3, for the rapidity bin  $1 < |y| < 2.1$ .

of Education, Youth and Sports (MEYS) of the Czech Republic; the Council of Science and Industrial Research, India; the HOMING PLUS program of the Foundation for Polish Science, cofinanced from European Union, Regional Development Fund; the Compagnia di San Paolo (Torino); the Consorzio per la Fisica (Trieste); MIUR project 20108T4XTM (Italy); the Thalis and Aristeia programs cofinanced by EU-ESF and the Greek NSRF; and the National Priorities Research Program by Qatar National Research Fund.

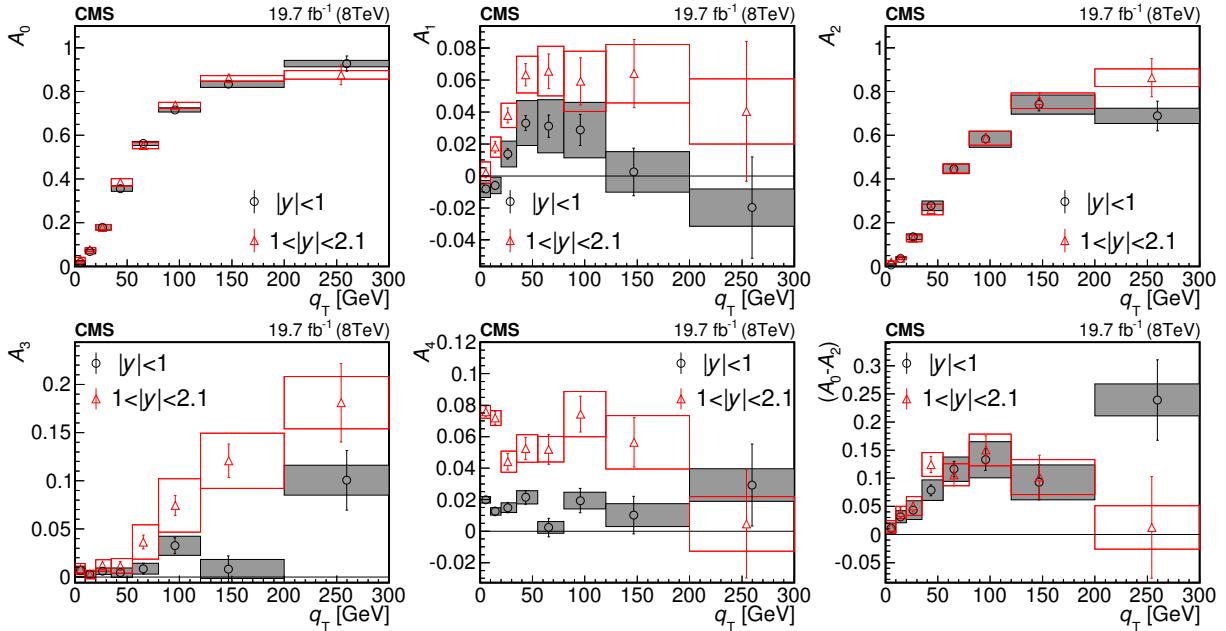

Figure 5: Comparison of the five angular coefficients  $A_i$  and  $A_0 - A_2$  measured in the Collins-Soper frame in bins of  $q_T$  between  $|y| < 1$  (circles) and  $1 < |y| < 2.1$  (triangles). The vertical bars represent the statistical uncertainties and the boxes the systematic uncertainties of the measurement.

†: Deceased

- 1: Also at Vienna University of Technology, Vienna, Austria
- 2: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 3: Also at Institut Pluridisciplinaire Hubert Curien, Université de Strasbourg, Université de Haute Alsace Mulhouse, CNRS/IN2P3, Strasbourg, France
- 4: Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia
- 5: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
- 6: Also at Universidade Estadual de Campinas, Campinas, Brazil
- 7: Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France
- 8: Also at Université Libre de Bruxelles, Bruxelles, Belgium
- 9: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 10: Also at Suez University, Suez, Egypt
- 11: Also at Cairo University, Cairo, Egypt
- 12: Also at Fayoum University, El-Fayoum, Egypt
- 13: Also at British University in Egypt, Cairo, Egypt
- 14: Now at Ain Shams University, Cairo, Egypt
- 15: Also at Université de Haute Alsace, Mulhouse, France
- 16: Also at Brandenburg University of Technology, Cottbus, Germany
- 17: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 18: Also at Eötvös Loránd University, Budapest, Hungary
- 19: Also at University of Debrecen, Debrecen, Hungary
- 20: Also at University of Visva-Bharati, Santiniketan, India
- 21: Now at King Abdulaziz University, Jeddah, Saudi Arabia
- 22: Also at University of Ruhuna, Matara, Sri Lanka
- 23: Also at Isfahan University of Technology, Isfahan, Iran
- 24: Also at University of Tehran, Department of Engineering Science, Tehran, Iran
- 25: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 26: Also at Università degli Studi di Siena, Siena, Italy
- 27: Also at Centre National de la Recherche Scientifique (CNRS) - IN2P3, Paris, France

- 
- 28: Also at Purdue University, West Lafayette, USA
  - 29: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
  - 30: Also at Institute for Nuclear Research, Moscow, Russia
  - 31: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
  - 32: Also at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia
  - 33: Also at California Institute of Technology, Pasadena, USA
  - 34: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
  - 35: Also at Facoltà Ingegneria, Università di Roma, Roma, Italy
  - 36: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
  - 37: Also at University of Athens, Athens, Greece
  - 38: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
  - 39: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
  - 40: Also at Gaziosmanpasa University, Tokat, Turkey
  - 41: Also at Adiyaman University, Adiyaman, Turkey
  - 42: Also at Mersin University, Mersin, Turkey
  - 43: Also at Cag University, Mersin, Turkey
  - 44: Also at Piri Reis University, Istanbul, Turkey
  - 45: Also at Anadolu University, Eskisehir, Turkey
  - 46: Also at Ozyegin University, Istanbul, Turkey
  - 47: Also at Izmir Institute of Technology, Izmir, Turkey
  - 48: Also at Necmettin Erbakan University, Konya, Turkey
  - 49: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
  - 50: Also at Marmara University, Istanbul, Turkey
  - 51: Also at Kafkas University, Kars, Turkey
  - 52: Also at Yildiz Technical University, Istanbul, Turkey
  - 53: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
  - 54: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
  - 55: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
  - 56: Also at Argonne National Laboratory, Argonne, USA
  - 57: Also at Erzincan University, Erzincan, Turkey
  - 58: Also at Texas A&M University at Qatar, Doha, Qatar
  - 59: Also at Kyungpook National University, Daegu, Korea
