

Measurements of $t\bar{t}$ differential cross sections in proton-proton collisions at $\sqrt{s} = 13$ TeV using events containing two leptons

The CMS Collaboration*

Abstract

Measurements of differential top quark pair $t\bar{t}$ cross sections using events produced in proton-proton collisions at a centre-of-mass energy of 13 TeV containing two oppositely charged leptons are presented. The data were recorded by the CMS experiment at the CERN LHC in 2016 and correspond to an integrated luminosity of 35.9 fb^{-1} . The differential cross sections are presented as functions of kinematic observables of the top quarks and their decay products, the $t\bar{t}$ system, and the total number of jets in the event. The differential cross sections are defined both with particle-level objects in a fiducial phase space close to that of the detector acceptance and with parton-level top quarks in the full phase space. All results are compared with standard model predictions from Monte Carlo simulations with next-to-leading-order (NLO) accuracy in quantum chromodynamics (QCD) at matrix-element level interfaced to parton-shower simulations. Where possible, parton-level results are compared to calculations with beyond-NLO precision in QCD. Significant disagreement is observed between data and all predictions for several observables. The measurements are used to constrain the top quark chromomagnetic dipole moment in an effective field theory framework at NLO in QCD and to extract $t\bar{t}$ and leptonic charge asymmetries.

1 Introduction

The top quark could play a central role in the electroweak symmetry breaking mechanism of the standard model (SM) and in numerous physics models beyond the SM (BSM). Measurements of the differential production cross sections for top quark pair ($t\bar{t}$) production test SM predictions, while also probing scenarios of BSM physics. Such measurements also allow determination of the top quark mass (m_t), the strong coupling constant (α_s), and the parton distribution functions (PDFs) of the proton. In this paper the dilepton decay channel of the $t\bar{t}$ process is utilised. Although the dilepton channel has a relatively small branching fraction, it has significantly lower backgrounds than the other $t\bar{t}$ decay channels. As a consequence of the excellent lepton energy resolution, the precise measurement of kinematic observables based on lepton pairs is unique to the dilepton channel. However, because of the presence of two neutrinos in the final state, the measurement of top quark kinematic observables in the dilepton channel requires specialised kinematic reconstruction techniques.

Differential $t\bar{t}$ cross sections have been measured by the ATLAS and CMS Collaborations at the CERN LHC in proton-proton (pp) collisions at centre-of-mass energies of 7, 8, and 13 TeV [1–19]. In this paper, measurements of absolute and normalised differential $t\bar{t}$ cross sections are presented. The measurements are based on either particle-level objects and extrapolated to a fiducial phase space close to that of the detector acceptance or on parton-level top quarks extrapolated to the full phase space. In the absolute measurements, the integrated and differential cross sections are measured simultaneously. In the normalised measurements, the integrated cross sections are not measured and the uncertainties affecting only the normalisations of the differential cross sections in both data and predictions are reduced. The measurements represent the most comprehensive study of $t\bar{t}$ production in the dilepton channel to date. Furthermore, this work includes a more detailed treatment of the systematic uncertainties compared to previous CMS measurements of the $t\bar{t}$ differential cross sections in the dilepton channel at centre-of-mass energies of 7 and 8 TeV, and approximately 17 times more data than the previous CMS measurement at 13 TeV using data recorded in 2015.

The analysis utilises a 13 TeV data sample recorded by the CMS experiment in 2016, corresponding to an integrated luminosity of 35.9 fb^{-1} [20]. The differential cross sections are presented as a function of kinematic observables of the top quarks, their decay products, the $t\bar{t}$ system, and the number of jets in the event.

Results presented at the parton level may be compared to state-of-the-art SM calculations with beyond next-to-leading-order (NLO) precision in quantum chromodynamics (QCD) [21–24]. These comparisons facilitate the extraction of m_t , α_s , and the PDFs. Both parton- and particle-level results may be compared to theoretical predictions from Monte Carlo (MC) generators. The particle-level results do not exhibit the theoretical model dependence of the parton-level results introduced when extrapolating to an experimentally inaccessible phase-space region. This reduced model dependence allows calibration of parton-shower, hadronisation, and underlying-event models within MC generators.

Numerous BSM scenarios that lead to modifications of the $t\bar{t}$ differential cross sections involve the production of new states, e.g. top squarks or Z' bosons [25–27]. The absence of signals of such new states in the LHC data recorded so far suggests that BSM physics might only be directly manifested at an energy scale that is large with respect to the typical scales probed at the LHC. In this case, the new states are only produced virtually at the LHC. These virtual effects can modify the rates and kinematic properties of $t\bar{t}$ events. Theoretically, these effects can be accommodated by adding higher-dimensional operators to the SM Lagrangian in an effective field theory (EFT). The reduced model dependence of the particle-level results makes

them particularly suitable to constrain BSM theories. The generation of predictions for the particle-level observables does not require any detector simulation. Hence, such measurements facilitate a future, global analysis of EFT operators using multiple observables measured by more than one experiment to simultaneously constrain all relevant EFT operators. An anomalous top quark chromomagnetic dipole moment (CMDM) is a feature of BSM models such as two-Higgs-doublet models, supersymmetry, technicolor, and top quark compositeness models [28, 29]. In this paper, the measured particle-level differential $t\bar{t}$ cross section as a function of the azimuthal angle between the two charged leptons is used to constrain the CMDM in an EFT framework. Signals of BSM physics could also appear in $t\bar{t}$ production as anomalous top quark or leptonic charge asymmetries. Hence, we extract these quantities from differential $t\bar{t}$ cross section measurements as a function of the difference in absolute rapidity between the top quark and antiquark, and the difference in absolute pseudorapidity between the charged leptons.

The paper is organised as follows. In Section 2, a brief description of the CMS detector is provided. In Section 3, the simulation of signal and background processes is detailed, followed by the description of the selection of events at the trigger level and in the offline analysis in Section 4. The sources of systematic uncertainties that affect the measurements are discussed in Section 6, along with the methods employed to estimate the size of their effects. In Section 5, details of the objects and phase-space regions used to define the measured observables are provided, together with a description of the unfolding procedure used to determine the particle- and parton-level data. The unfolded data are presented and compared to theoretical predictions in Section 7. In Sections 8 and 9, constraints on the top quark CMDM in an EFT framework and the $t\bar{t}$ and leptonic charge asymmetries are derived from the unfolded data. Finally, the paper is summarised in Section 10.

2 The CMS detector

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter, each composed of a barrel and two endcap sections. Forward calorimeters extend the pseudorapidity coverage provided by the barrel and endcap detectors. Muons are measured in gas-ionisation detectors embedded in the steel flux-return yoke outside the solenoid. Events of interest are selected using a two-tiered trigger system [30]. The first level, composed of custom hardware processors, uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz within a time interval of less than 4 μ s. The second level, known as the high-level trigger (HLT), consists of a farm of processors running a version of the full event reconstruction software optimised for fast processing, and reduces the event rate to around 1 kHz before data storage. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [31].

3 Event simulation

The simulation of physics processes is important in order to estimate event reconstruction and selection efficiencies, resolutions of the event reconstruction, and to provide predictions for the $t\bar{t}$ signal and backgrounds. This motivates the use of MC generators interfaced to a detector simulation. The default simulation setup for the $t\bar{t}$ process is provided at NLO in QCD at the

matrix-element (ME) level by the POWHEG (v.2) [32–35] generator (POWHEG). For this setup, the h_{damp} parameter of POWHEG, which regulates the damping of real emissions in the NLO calculation when matching to the parton shower, is set to $1.58 m_t = 272.72 \text{ GeV}$ as a result of the tuning of this parameter from Ref. [36]. The generated events are subsequently processed with the PYTHIA (v. 8.219) [37] program (PYTHIA), with the CUETP8M2T4 tune [36, 38, 39], for parton showering and hadronisation. In order to compare the predictive powers of alternative ME, parton shower, and hadronisation models, two additional samples are generated using different generator setups. Firstly, a sample is generated using the MADGRAPH5_aMC@NLO [40] (v. 2.2.2) (MG5_aMC@NLO) generator including up to two extra partons at the ME level with NLO precision. In this setup, referred to as “MG5_aMC@NLO+PYTHIA[FxFx]”, MADSPIN [41] is used to model the decays of the top quarks, while preserving their spin correlation, and events are matched to PYTHIA for parton showering and hadronisation using the FxFx prescription [42]. Secondly, a sample is generated with POWHEG at NLO in QCD at the ME level and interfaced with HERWIG++ (v. 2.7.1) [43] with the EE5C tune [44] for parton showering and hadronisation. This setup is referred to as POWHEG+HERWIG++.

Only $t\bar{t}$ events with two electrons or muons that do not originate from the decays of τ leptons or semileptonic b hadron decays are considered as signal, with all other $t\bar{t}$ events regarded as a background, which we refer to as “ $t\bar{t}$ other”. The largest background contributions originate from $t\bar{t}$ other, single top quarks produced in association with a W boson (tW), Z/γ^* bosons produced with additional jets (Z +jets), W boson production with additional jets (W +jets), diboson (WW , WZ , and ZZ) events, and the production of a $t\bar{t}$ pair in association with a Z or W boson ($t\bar{t}+Z/W$). Other backgrounds are negligible in comparison to the uncertainties in the main backgrounds. The W +jets process is simulated at leading-order (LO) precision using MG5_aMC@NLO with up to four additional partons at ME level and matched to PYTHIA using the MLM prescription [45]. The Z +jets process is simulated at NLO precision using MG5_aMC@NLO with up to two additional partons at ME level and matched to PYTHIA using the FxFx prescription. The $t\bar{t}+Z/W$ processes are simulated with MG5_aMC@NLO with NLO precision at ME level and matched to PYTHIA. In the case of $t\bar{t}+W$, one extra parton is simulated at ME level and the calculation is matched to PYTHIA using the FxFx prescription. Single top quark production is simulated with POWHEG (v. 1) [46, 47] using the CUETP8M2T4 tune in PYTHIA. Diboson events are simulated with PYTHIA.

For all $t\bar{t}$ samples, the NNPDF3.0_nlo_as_0118 [48] PDF set is used. Predictions are normalised based on their theoretical cross sections and the integrated luminosity of the data. The cross sections are calculated at the highest orders of perturbative QCD currently available. This corresponds to next-to-NLO (NNLO) for W +jets and Z +jets [49], approximate NNLO for single top quark in the tW channel [50], and NLO calculations for diboson [51] and $t\bar{t}+Z/W$ [52]. The $t\bar{t}$ predictions are normalised to a cross section of $832^{+20}_{-29}(\text{scale}) \pm 35(\text{PDF} + \alpha_s)$ pb calculated with the TOP++2.0 program [53] at NNLO including resummation of next-to-next-to-leading-logarithmic (NNLL) soft-gluon terms, assuming a top quark mass $m_t = 172.5 \text{ GeV}$. Additional proton-proton interactions within the same or nearby bunch crossings (pileup) is simulated for all samples. The interactions of particles with the CMS detector is simulated using GEANT4 (v. 9.4) [54].

4 Event selection

The event selection procedure is designed to select events corresponding to the decay topology where both top quarks decay into a W boson and a bottom quark (b quark), and each of the W bosons decays into a muon or an electron, and a neutrino. Three distinct channels based on the

flavours of the final-state leptons are defined: the same-flavour channels corresponding to two electrons (e^+e^-) or two muons ($\mu^+\mu^-$), and the different-flavour channel corresponding to one electron and one muon ($e^\pm\mu^\mp$). The final results are derived by combining the three channels. At HLT level, events are selected either by single-lepton triggers that require the presence of at least one electron or muon or by dilepton triggers that require the presence of either two electrons, two muons, or an electron and a muon. For the single-electron and single-muon triggers, transverse momentum p_T thresholds of 27 and 24 GeV are applied, respectively. The same-flavour dilepton triggers require either an electron pair with $p_T > 23(12)$ GeV for the leading (trailing) electron or a muon pair with $p_T > 17(8)$ GeV for the leading (trailing) muon, where leading (trailing) refers to the electron or muon with the highest (second-highest) p_T in the event. The different-flavour dilepton triggers require either a muon with $p_T > 23$ GeV and an electron with $p_T > 12$ GeV, or an electron with $p_T > 23$ GeV and a muon with $p_T > 8$ GeV.

The events selected by the trigger are reconstructed offline using a particle-flow algorithm [55]. The particle-flow algorithm aims to reconstruct and identify each individual particle in an event, with an optimised combination of information from the various elements of the CMS detector. Electron candidates are reconstructed from a combination of the track momentum at the main interaction vertex and the corresponding clusters in the ECAL with a Gaussian sum filter algorithm [56]. The electron candidates are required to have $p_T > 25(20)$ GeV for the leading (trailing) candidate and $|\eta| < 2.4$. Electron candidates with ECAL clusters in the region between the barrel and endcap ($1.44 < |\eta_{\text{cluster}}| < 1.57$) are excluded because of less efficient electron reconstruction. A relative isolation criterion $I_{\text{rel}} < 0.0588(0.0571)$ is applied for an electron candidate in the barrel (endcap), where I_{rel} is defined as the sum of the p_T of all neutral hadron, charged hadron, and photon candidates within a distance of 0.3 from the electron in η - ϕ space, divided by the p_T of the electron candidate. In addition, electron identification requirements are applied to reject misidentified electron candidates and candidates originating from photon conversions. Muon candidates are reconstructed using the track information from the tracker and the muon system [57]. They are required to have $p_T > 25(20)$ GeV for the leading (trailing) candidates and $|\eta| < 2.4$. An isolation requirement of $I_{\text{rel}} < 0.15$ is applied to muon candidates with particles within 0.4 of the muon in η - ϕ space included in the calculation of I_{rel} . In addition, muon identification requirements are applied to reject misidentified muon candidates and candidates originating from decay-in-flight processes. For both electron and muon candidates, a correction is applied to I_{rel} to suppress the residual effect of pileup.

Jets are reconstructed by clustering the particle-flow candidates using the anti- k_T clustering algorithm with a distance parameter of 0.4 [58, 59]. Jet momentum is determined as the vectorial sum of all particle momenta in the jet, and is found from simulation to be within 5 to 10% of the true momentum over the whole p_T spectrum and detector acceptance. Pileup can contribute additional tracks and calorimetric energy deposits to the jet momentum. To mitigate this effect, tracks identified to be originating from pileup vertices are discarded, and an offset correction is applied to correct for remaining contributions. Jet energy corrections are derived from simulation to bring the measured response of jets to that of particle-level jets on average. In situ measurements of the momentum imbalance in dijet, photon+jets, Z+jets, and multijet events are used to account for any residual differences in jet energy in data and simulation. Additional selection criteria are applied to remove badly reconstructed jets. Jets are selected if they have $p_T > 30$ GeV and $|\eta| < 2.4$. Jets are rejected if the distance in η - ϕ space between the jet and the closest lepton, $\Delta R(\text{jet}, \text{lepton})$, is less than 0.4. Jets originating from the hadronisation of b quarks (b jets) are identified (b tagged) by combining information related to secondary decay vertices reconstructed within the jets and track-based lifetime information in an algorithm CSV (v.2) [60] that provides a b jet identification efficiency of ≈ 79 –87% and a probability to

misidentify light-flavour jets as b jets of $\approx 10\%$.

The missing transverse momentum vector \vec{p}_T^{miss} is defined as the projection on the plane perpendicular to the beams of the negative vector sum of the momenta of all reconstructed particles in an event. Its magnitude is referred to as p_T^{miss} .

Events are selected offline if they contain exactly two isolated, oppositely charged electrons or muons (e^+e^- , $\mu^+\mu^-$, $e^\pm\mu^\mp$) and at least two jets. At least one of the jets is required to be b tagged. Events with an invariant mass of the lepton pair ($m_{\ell\bar{\ell}}$) smaller than 20 GeV are removed in order to suppress contributions from heavy-flavour resonance decays and low-mass Drell–Yan processes. Backgrounds from Z+jets processes in the e^+e^- and $\mu^+\mu^-$ channels are further suppressed by requiring $m_{\ell\bar{\ell}} < 76$ GeV or $m_{\ell\bar{\ell}} > 106$ GeV, and $p_T^{\text{miss}} > 40$ GeV. The normalisation of the remaining background contribution from Z+jets events, which is large in the e^+e^- and $\mu^+\mu^-$ channels, is determined by applying a factor derived from simulation to the number of Z+jets events observed in data in a control region where $m_{\ell\bar{\ell}}$ is close to m_Z [8, 61]. A correction to account for non-Z+jets backgrounds in the control region is derived from the $e^\pm\mu^\mp$ channel. The shape of the Z+jets background is taken from simulation. Other sources of background such as tW, diboson, $t\bar{t}+Z/W$, $t\bar{t}$ other, misidentified leptons, and leptons within jets are estimated from simulation.

The kinematic observables of the top quarks are estimated via a kinematic reconstruction algorithm [8]. The algorithm examines all combinations of jets and leptons and solves a system of equations based on the following constraints: p_T^{miss} is assumed to originate solely from the two neutrinos; the invariant mass of the reconstructed W boson must equal 80.4 GeV [62]; and the invariant mass of each reconstructed top quark must equal 172.5 GeV. Effects of detector resolution are accounted for by randomly varying the measured energies and directions of the reconstructed lepton and b jet candidates by their resolutions as measured in simulation. This procedure is referred to in the following to as smearing. In addition, the assumed invariant mass of the W boson is smeared according to the Breit–Wigner distribution of W boson masses in simulation. For a given smearing, the solution of the equations for the neutrino momenta yielding the smallest invariant mass of the $t\bar{t}$ system is chosen. For each solution, a weight is calculated based on the spectrum of the true invariant mass of the lepton and b jet system from simulated top quark decays at particle level. The weights are summed over 100 smearings for each combination, and the kinematic observables of the top quark and antiquark are calculated as a weighted average. The smearing procedure increases the fraction of combinations in which a valid solution to the system of equations is found. Increasing the number of smearings beyond 100 did not significantly increase this fraction further. The top quark and antiquark candidates are distinguished according to the charge of the lepton in the chosen solution. The solution with the most b-tagged jets is chosen to represent the top quark momenta. If multiple combinations with the same number of b-tagged jets are found, the combination that yields the maximum sum of weights is chosen. The efficiency of the kinematic reconstruction, defined as the number of events where a solution is found divided by the total number of selected $t\bar{t}$ events, is about 90% in both data and simulation. Events with no valid solution for the neutrino momenta are excluded from further analysis.

After applying the full event selection, 34 890 events in the e^+e^- channel, 70 346 events in the $\mu^+\mu^-$ channel, and 150 410 events in the $e^\pm\mu^\mp$ channel are observed. In all decay channels combined, the estimated signal contribution to the data is 80.6%. In Fig. 1, selected distributions of the kinematic observables and multiplicities of the selected jets (N_{jets}) and b jets ($N_{\text{b jets}}$) are shown. For each distribution, all event selection criteria are applied, with the exception of the $N_{\text{b jets}}$ distribution where no b-tagged jets are required. Figure 2 shows the distributions of the

top quark or antiquark and $t\bar{t}$ kinematic observables (the transverse momenta p_T^t , $p_T^{\bar{t}}$, the rapidities y_t , $y_{\bar{t}}$, and the invariant mass of the $t\bar{t}$ system $m_{t\bar{t}}$). The mismodelling of the data by the simulation, apparent in the tails of the distributions, is accounted for by the corresponding systematic uncertainties, as described in Section 6. Simulation is used to verify that mismodelling of the p_T^t distribution does not bias the results for the differential cross section as a function of p_T^t .

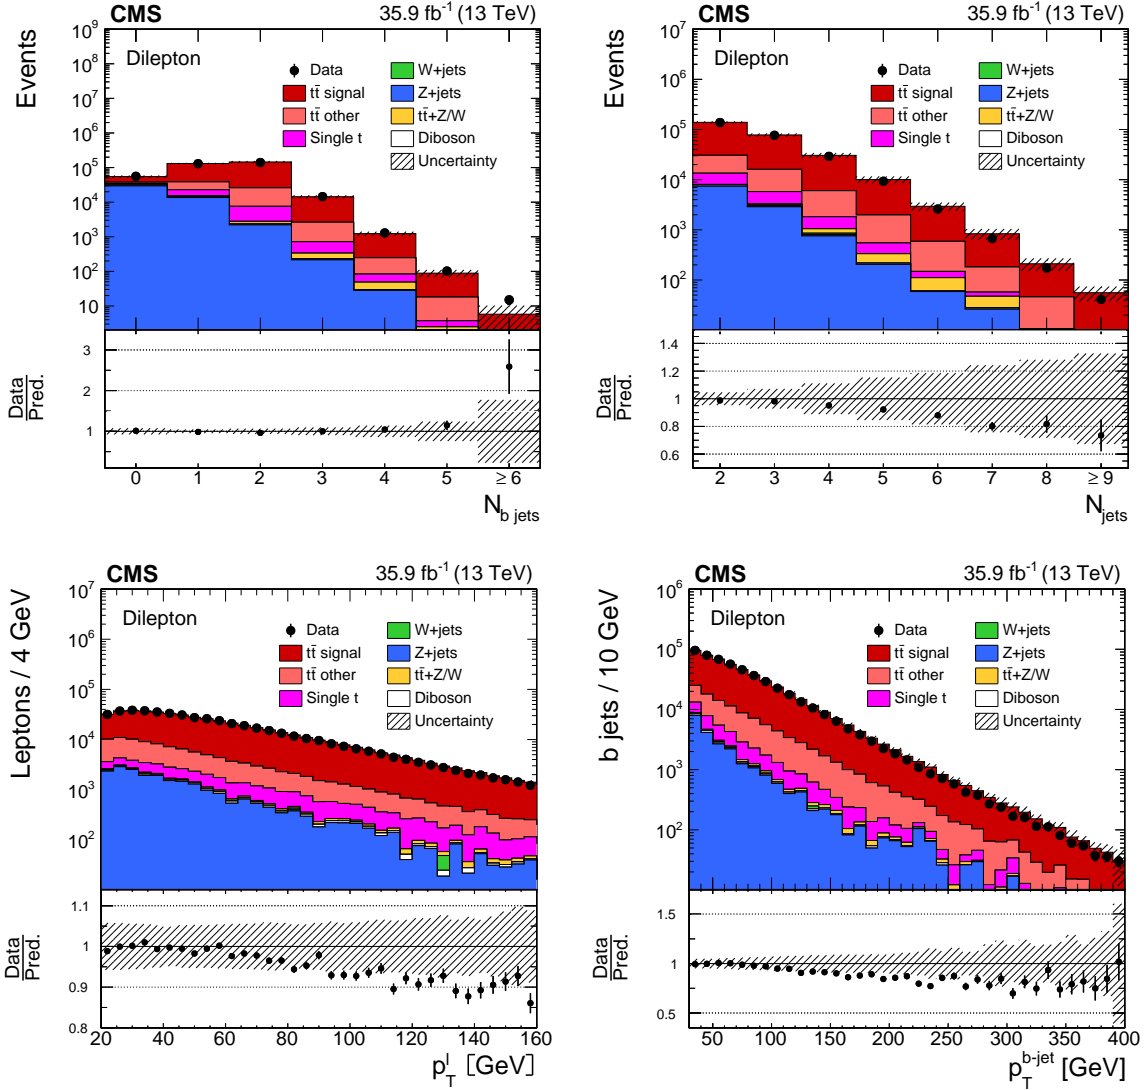

Figure 1: Distributions of the b jet (upper left), and total jet (upper right) multiplicities, and the p_T of the leptons (lower left), and b jets (lower right) are shown for data (points) and simulation (histograms). The $t\bar{t}$ process is simulated with POWHEG + PYTHIA. The vertical bars on the points represent the statistical uncertainties in the data. The hatched regions correspond to the systematic uncertainties in the signal and backgrounds, as described in Section 6. The lower panel of each plot shows the ratio of the data to the predictions from simulation.

Figure 2: Distributions of the p_T (upper row) and rapidities (middle row), at detector level for the top quarks (left column), and $t\bar{t}$ system (right column), and $m_{t\bar{t}}$ (lower plot) are shown for data (points) and simulation (histograms). The $t\bar{t}$ process is simulated with POWHEG + PYTHIA. The vertical bars on the points represent the statistical uncertainties in the data. The hatched regions correspond to the systematic uncertainties in the signal and backgrounds, as described in Section 6. The lower panel of each plot shows the ratio of the data to the predictions from simulation.

5 Differential cross section extraction

For a given variable X , the absolute differential $t\bar{t}$ cross section $d\sigma_i/dX$ is determined via the relation [8]:

$$\frac{d\sigma_i}{dX} = \frac{1}{\mathcal{L}} \frac{x_i}{\Delta_i^X}, \quad (1)$$

where \mathcal{L} is the integrated luminosity of the data, x_i is the number of signal events observed in data for bin i after the background subtraction and correction for the detector efficiencies, acceptances, and bin migration, and Δ_i^X is the bin width. The normalised differential cross section is obtained by dividing the absolute differential cross section by the measured total cross section σ in the same phase space, which is evaluated by summing the binned cross section measurements over all bins of the observable X . The background from other $t\bar{t}$ decays is taken into account, after subtracting all other background components, by correcting the number of signal events in data using the expected signal fraction. The expected signal fraction is defined as the ratio of the number of selected $t\bar{t}$ signal events to the total number of selected $t\bar{t}$ events in simulation. This procedure avoids the dependence on the total inclusive $t\bar{t}$ cross section used in the normalisation of the simulated signal sample.

The finite resolution introduced by the detector response, parton shower, and hadronisation lead to migration of events across bins when correcting the data to both the fiducial phase space based on particle-level objects or the full phase space based on the parton-level top quarks. These effects are accounted for with a regularised unfolding method [8, 63, 64]. For each measured distribution, a response matrix that accounts for migrations and efficiencies is calculated using the default $t\bar{t}$ simulation. For the parton-level measurements in the full phase space, the response matrix also accounts for the branching fraction of $t\bar{t}$ events into two leptons excluding τ leptons. The generalised inverse of the response matrix is used to obtain the unfolded distribution from the measured distribution by applying a χ^2 minimisation technique. Regularisation is applied to suppress nonphysical fluctuations. The regularisation level is determined individually for each distribution using the average squared global correlation method [65]. To keep the bin-to-bin migrations small, the width of the measurement bins are chosen according to their purity and stability. Purity is defined as the fraction of events in a given bin at the detector level that originate from the same bin at the generator level, and stability is defined as the fraction of events in a given bin at the generator level that are reconstructed in the same bin at the detector level. The purities and stabilities are typically $\approx 50\%$, except in the regions where the distributions are steeply rising or falling, where values of 30% are typical. The statistical uncertainty is small in comparison to the systematic uncertainties in all bins. The data in the three channels are combined before unfolding in order to model correlations between channels and reduce statistical uncertainties in poorly populated regions of the unfolding matrix.

For some observables, both the absolute and normalised differential cross sections are measured at both the particle level in a fiducial phase space and at the parton level in the full phase space. This leads to four measurements for each of these observables. The observables related to the kinematics and multiplicities of jets and leptons are determined at the particle level only.

Object and phase-space definitions

The definition of the particle-level objects and the kinematic reconstruction procedure employed to estimate the kinematic properties of the particle-level top quarks are described in Ref. [66]. We detail here the additional event-level requirements that define the fiducial phase-space region in which the particle-level differential cross sections are measured. We require that the W bosons produced from decays of the top quark and antiquark in a $t\bar{t}$ event them-

selves decay to an electron or muon. Events where these W bosons decay to tau leptons are rejected. The requirements of exactly two selected lepton candidates with opposite charges, a dilepton invariant mass greater than 20 GeV, and at least two b jets are also added.

For the parton-level results, the momenta of the parton-level top quarks are defined after QCD radiation but before the top quark decays. The parton-level results are extrapolated to the full phase space using the default simulation.

6 Systematic uncertainties

The systematic uncertainties in the measured differential cross sections are categorised into experimental uncertainties arising from imperfect modelling of the detector response and conditions and theoretical uncertainties arising from the modelling of the signal and background processes. Each systematic uncertainty is determined separately in each bin of the measured differential cross section via a variation of the corresponding aspect of the simulation setup.

A regularised unfolding method, described in Section 5, is used to correct for the migration of events between bins due to the finite detector resolutions and to extrapolate the detector-level data to the fiducial and full phases spaces. The variations are applied both at detector level and in the response matrices that define the unfolding. For each variation, the difference between the varied and nominal results is taken as the systematic uncertainty. The total systematic uncertainty is calculated by adding these differences in quadrature. In this section, each of these applied variations is detailed.

6.1 Experimental sources of uncertainty

In order to account for the differences in trigger efficiencies between data and simulation, scale factors, defined as the ratio of the efficiencies measured in data and simulation, are calculated in bins of lepton η and p_T and applied to the simulation. The efficiencies of the dilepton triggers in data are measured as the fraction of events passing triggers based on a p_T^{miss} requirement that also satisfy the dilepton trigger criteria. As the efficiency of the p_T^{miss} requirement is independent from the dilepton trigger efficiencies, the bias introduced by the p_T^{miss} requirement is negligible. The efficiencies are close to unity in both data and simulation. An uncertainty arising from the modelling of the trigger efficiencies in simulation is estimated by two variations of the scale factors. First, the scale factors are varied within their uncertainties coherently for all leptons. Second, to account for potential differential effects not covered by the coherent variations, simulated events are divided into categories according to the η of the leptons, and the scale factors are varied in opposite directions for each category. A final trigger uncertainty is derived by taking the maximal deviation produced by the two variations in each bin.

The uncertainties from modelling of the lepton identification and isolation efficiencies are determined using the tag-and-probe method with Z +jets event samples [61, 67]. The differences between lepton identification and isolation efficiencies in data and simulation in bins of η and p_T are generally less than 10% for electrons, while differences for muons are negligible. The lepton identification uncertainty is estimated by varying the scale factors within their uncertainties.

The uncertainty arising from the jet energy scale (JES) is determined by varying the 19 sources of uncertainty in the JES in bins of p_T and η and taking the quadrature sum of the effects [68]. The JES variations are also propagated to the uncertainties in p_T^{miss} . The uncertainty from the jet energy resolution (JER) is determined by the variation of the JER in simulation by ± 1 standard deviation in different η regions [68]. An additional uncertainty from the calculation of p_T^{miss} is

estimated by varying the energies of the reconstructed particles not clustered into jets within their respective resolutions and recalculating the p_T^{miss} .

The uncertainty from the modelling of the number of pileup events is obtained by changing the inelastic proton-proton cross section assumed in simulation by $\pm 4.6\%$, corresponding to the uncertainty in the measurement of this cross section presented in Ref. [69].

The uncertainty due to imperfect modelling of the b tagging efficiency is determined by varying the measured scale factor for b tagging efficiencies within its uncertainties. An additional shape uncertainty is determined by dividing the b jet distributions in p_T and η at their medians to form two bins in each variable. The b tagging scale factors in the first bin are scaled up according to their uncertainties, while those in the second bin are scaled down and vice versa. The variations are performed separately for the p_T and η distributions, and independently for heavy-flavour (b and c) and light-flavour (u, d, s, and gluon) jets.

The efficiency of the kinematic reconstruction of the top quarks is found to be consistent between data and simulation within around 0.2%. An associated uncertainty is derived by varying the scale factor that describes the ratio of the kinematic reconstruction efficiency in data and simulation by $\pm 0.2\%$.

The uncertainty in the integrated luminosity of the 2016 data sample recorded by CMS is 2.5% [20] and is applied coherently to the normalisation of all simulated distributions.

6.2 Theoretical sources of uncertainty

The uncertainty arising from the missing higher-order terms in the simulation of the signal process at the ME level is assessed by varying the renormalisation and factorisation scales in the POWHEG simulation up and down by factors of two with respect to their nominal values. In the POWHEG simulation, the nominal scales are defined as $m_t^2 + p_{T,t}^2$, where $p_{T,t}$ denotes the p_T of the top quark in the $t\bar{t}$ rest frame. In total, three variations are applied: one with the factorisation scale fixed, one with the renormalisation scale fixed, and one with both scales varied coherently together. The final uncertainty is taken as the maximum deviation from the nominal prediction from each of the three variations. In the parton-shower simulation, the corresponding uncertainty is estimated by varying the scale of initial- and final-state radiation separately up and down by factors of 2 and $\sqrt{2}$, respectively, as suggested in Ref. [39].

The effect of the uncertainty from the choice of PDF is assessed by reweighting the signal simulation according to the prescription provided for the NNPDF3.0 PDF set [48]. An additional uncertainty is independently derived by varying the α_s value within its uncertainty in the PDF set. The dependence of the measurement on the assumed m_t value is estimated by varying the chosen m_t in the default setup by ± 1 GeV with respect to the default value of 172.5 GeV.

The uncertainty originating from the scheme used to match the ME-level calculation to the parton-shower simulation is derived by varying the h_{damp} parameter in POWHEG by factors of 1.42 and 0.63, according to the results of a tuning of this parameter from Ref. [36].

The uncertainty related to the modelling of the underlying event is estimated by varying the parameters used to derive the CUETP8M2T4 tune in the default setup. The default setup in PYTHIA includes a model of colour reconnection based on multiple-particle interactions (MPI) with early resonance decays switched off. To estimate an uncertainty from this choice of model, the analysis is repeated with three other models of colour reconnection within PYTHIA: the MPI-based scheme with early resonance decays switched on, a gluon-move scheme [70], and a QCD-inspired scheme [71]. The total uncertainty from colour reconnection modelling is esti-

mated by taking the maximum deviation from the nominal result.

The uncertainty from imperfect knowledge of the b quark fragmentation function is assessed by varying the Bowler–Lund function within its uncertainties [72]. In addition, the analysis is repeated with the Peterson model for b quark fragmentation [73]. An uncertainty from the semileptonic branching fraction of b hadrons is estimated by correcting the $t\bar{t}$ simulation to match the branching fraction in Ref. [62]. Since $t\bar{t}$ events containing electrons or muons that originate from τ decays are considered as backgrounds, the measured differential cross sections are sensitive to the value of the τ semileptonic branching fraction used in the simulation. Hence, an uncertainty is derived by varying the branching fractions by 1.5% [62]. Since the b tagging efficiency depends on many simulation parameters, it is recalculated for each variation of the sources of theoretical uncertainty, with the exception of the PDFs, the semileptonic branching fraction of b hadrons, the JES, and the JER. Finally, the normalisations of all backgrounds except $t\bar{t}$ other are varied up and down by $\pm 30\%$ [61].

The total uncertainty in each bin of each measurement is determined by summing the experimental and theoretical uncertainties in quadrature and ranges from 4–25%, depending on the observable and the bin. In Section 7, figures showing the contribution of each systematic uncertainty, the statistical uncertainty, and the total uncertainty in each bin for selected normalised parton-level differential cross sections as a function of top-quark-related kinematic observables are provided. For most bins in a majority of these distributions, the JES is the dominant systematic uncertainty. In the first three bins of the $p_T^{t\bar{t}}$ distribution, the dominant uncertainty arises from the measurement of the energies of reconstructed particles not clustered into jets.

7 Results

In this section, the results of all differential cross section measurements are presented.

7.1 Measured observables

The differential cross sections are measured as functions of numerous kinematic observables of the top quarks and their decay products, the $t\bar{t}$ system, and the total number of jets in the event. These observables are listed below. For one group of observables both parton- and particle-level measurements are presented, while for a second group only particle-level measurements are given.

Observables measured at parton and particle levels:

- p_T of the top quark (p_T^t)
- p_T of the top antiquark ($p_T^{\bar{t}}$)
- p_T of the top quark or top antiquark with largest p_T (p_T^t (leading))
- p_T of the top quark or top antiquark with second-largest p_T (p_T^t (trailing))
- p_T of the top quark in the rest frame of the $t\bar{t}$ system (p_T^t ($t\bar{t}$ RF))
- rapidity of the top quark (y_t)
- rapidity of the top antiquark ($y_{\bar{t}}$)
- rapidity of the top quark or top antiquark with largest p_T (y_t (leading))
- rapidity of the top quark or top antiquark with second-largest p_T (y_t (trailing))
- difference in absolute rapidity between the top quark and antiquark ($\Delta|y|(t, \bar{t})$)
- absolute difference in azimuthal angle between the top quark and antiquark ($\Delta\phi(t, \bar{t})$)

- p_T of the $t\bar{t}$ system ($p_T^{t\bar{t}}$)
- rapidity of the $t\bar{t}$ system ($y_{t\bar{t}}$)
- invariant mass of the $t\bar{t}$ system ($m_{t\bar{t}}$)

Observables measured at particle level only:

- p_T of the lepton (p_T^ℓ)
- p_T of the antilepton ($p_T^{\bar{\ell}}$)
- p_T of the lepton or antilepton with largest p_T (p_T^ℓ (leading))
- p_T of the lepton or antilepton with second-largest p_T (p_T^ℓ (trailing))
- pseudorapidity of the lepton (η_ℓ)
- pseudorapidity of the antilepton ($\eta_{\bar{\ell}}$)
- pseudorapidity of the lepton or antilepton with largest p_T (η_ℓ (leading))
- pseudorapidity of the lepton or antilepton with second-largest p_T (η_ℓ (trailing))
- p_T of the dilepton system ($p_T^{\ell\bar{\ell}}$)
- invariant mass of the dilepton system ($m_{\ell\bar{\ell}}$)
- absolute difference in azimuthal angle between the lepton and antilepton ($\Delta\phi(\ell, \bar{\ell})$)
- difference in absolute pseudorapidity between the lepton and antilepton ($\Delta\eta(\ell, \bar{\ell})$)
- p_T of the b jet with largest p_T (p_T^b (leading))
- p_T of the b jet with second-largest p_T (p_T^b (trailing))
- pseudorapidity of the b jet with largest p_T (η_b (leading))
- pseudorapidity of the b jet with second-largest p_T (η_b (trailing))
- p_T of the $b\bar{b}$ system ($p_T^{b\bar{b}}$)
- invariant mass of the $b\bar{b}$ system ($m_{b\bar{b}}$)
- multiplicity of jets with $p_T^{\text{jet}} > 30 \text{ GeV}$ (N_{jets})

The measurements of top quark p_T are sensitive to higher-order QCD and electroweak corrections in the SM, m_t , PDFs, and potential BSM physics signals. In order to probe the modelling of the top quark p_T as thoroughly as possible, various differential cross sections related to the p_T of top quarks are measured. These include: the separate p_T of the top quarks and antiquarks in the laboratory frame and, in order to suppress the effects of initial- and final-state radiation (ISR and FSR), in the $t\bar{t}$ rest frame (RF), and the largest (leading) and second-largest p_T (trailing) top quark or antiquark in an event. Similarly, the rapidity distributions are determined separately for top quarks and antiquarks, as well as the rapidity of the leading and trailing top quark or antiquark in an event. The differential cross sections as a function of the differences in absolute rapidities between the top quark and antiquark and in absolute pseudorapidities between the lepton and antilepton are measured to allow the extraction of the $t\bar{t}$ and leptonic charge asymmetries described in Section 9. The p_T of the $t\bar{t}$ system and N_{jets} distributions are measured since they are especially sensitive to the higher-order terms in the perturbative calculations. The rapidity and invariant mass distributions of the $t\bar{t}$ system are measured because of their potential to reduce gluon PDF uncertainties at large fractions of the proton longitudinal momentum carried by the gluon. In addition, for small values of $m_{t\bar{t}}$, the $m_{t\bar{t}}$ distribution is sensitive to m_t , while for large values of $m_{t\bar{t}}$, it is sensitive to BSM scenarios in which heavy states decay to $t\bar{t}$ pairs. The measurements of the lepton kinematic observables test the modelling of the top quark decays and spin correlations in the $t\bar{t}$ pair. Measuring the b jet kinematic

observables further tests the modelling of the top quark decays, while also testing the parton shower and hadronisation models.

7.2 Theoretical predictions

All data are compared to predictions from POWHEG+PYTHIA, POWHEG+HERWIG++, and MG5_aMC@NLO+PYTHIA[FXFX]. Where possible, parton-level measurements are also compared to predictions based on the following calculations at beyond-NLO precision:

- A calculation with full NNLO precision in QCD and including electroweak corrections of order $\alpha_S^2\alpha_{EW}$, $\alpha_S\alpha_{EW}^2$, and α_{EW}^3 (NNLO+ α_{EW}^3) [74]. The dynamic renormalisation and factorisation scales are set to $m_T/2$ for p_T^t and $p_T^{\bar{t}}$ and $H_T/4$ for y_t , $y_{\bar{t}}$, $p_T^{t\bar{t}}$, $y_{t\bar{t}}$, $m_{t\bar{t}}$, and $\Delta|y|(t, \bar{t})$, where $m_T = \sqrt{m_t^2 + (p_T^t)^2}$ and H_T is the sum of the top quark and antiquark m_T values. Predictions are provided for both the LUXQED17 [75] and NNPDF3.1_qed PDF [76] sets with $m_t = 173.3$ GeV. In order to probe the sensitivity of the results to the value of m_t , an additional prediction for the LUXQED17 PDF set with $m_t = 172.5$ GeV is provided.
- A prediction [77] that combines the NNLO QCD calculations with the double resummation of soft and small-mass logarithms to NNLL' accuracy, matched with both the standard soft-gluon resummation at NNLL accuracy and the fixed-order calculation at NNLO accuracy (NNLO+NNLL'). These corrections are expected to affect the high-energy tails of the $t\bar{t}$ differential distributions. The calculation is performed using the NNPDF3.1 PDF set [78], and dynamic renormalisation and factorisation scales ($m_t/2$ for p_T^t and $H_T/4$ for $m_{t\bar{t}}$). Predictions are provided for m_t values of 173.3 and 172.5 GeV.
- An approximate next-to-NNLO calculation [22] (aN³LO) based on the resummation of soft-gluon contributions in the double-differential cross section at NNLL accuracy in the moment-space approach. The NNPDF3.0 PDF set is used and m_t is set to 172.5 GeV. The renormalisation and factorisation scales are set to m_T for the p_T^t distribution and m_t for the y_t distribution.
- An approximate NNLO calculation [21] (aN²LO), based on QCD threshold expansions beyond the leading-logarithmic approximation using the CT14nnlo [79] PDF set. The top quark mass and dynamic factorisation and renormalisation scales are set to $m_t = 172.5$ GeV.

The NNLO+ α_{EW}^3 predictions include uncertainties from variations of the renormalisation and factorisation scales and from the PDFs. The NNLO+NNLL' and aN³LO predictions include uncertainties from scale variations only. The aN²LO prediction includes uncertainties from the PDFs only.

For the NNLO+ α_{EW}^3 calculations, predictions for the p_T^t , $p_T^{\bar{t}}$, y_t , $y_{\bar{t}}$, $p_T^{t\bar{t}}$, $m_{t\bar{t}}$, and $\Delta|y|(t, \bar{t})$ distributions are provided. For the NNLO+NNLL' calculation, predictions for the average of the p_T^t and $p_T^{\bar{t}}$ distributions and for the $m_{t\bar{t}}$ distribution are provided. For the aN³LO calculation, predictions for the p_T^t and y_t distributions are provided. For the aN²LO calculation, predictions for the p_T^t distribution and the average of the y_t and $y_{\bar{t}}$ distributions are provided. Since the differences between the averaged predictions and the corresponding separate predictions for top quark and antiquark are expected to be small, the averaged predictions are compared to the top quark distributions in data.

7.3 Commentary on results

All measured differential cross sections, along with figures giving the contribution of each source of uncertainty to the total uncertainty for selected normalised parton-level measurements, are shown in Figs. 3–32. Absolute and normalised results at the particle and parton levels for a given observable are grouped together in each figure. Within the figure, the upper row corresponds to the parton-level measurement in the full phase space, and the lower row to the particle-level measurement in the fiducial phase space. The left column corresponds to the absolute measurement and the right column to the normalised measurement. In each plot the top panel shows the measured differential cross section with the predictions overlaid and the bottom panel shows the ratios of the predictions to the measured distribution and the statistical and total uncertainties in the measured distribution. When predictions with beyond-NLO precision are available, additional figures with comparisons of these predictions to data are included. In addition, the numerical values of the measured differential cross sections in each bin and associated uncertainties for all observables are tabulated in Tables 1–14 in Appendix A for parton level and in Tables 15–47 in Appendix B for particle level.

The results for observables measured only at particle level are shown in Figs. 33–51. Within each figure, the left plot corresponds to the absolute measurements, and the right plot to the normalised measurements. The measurements of the kinematic properties of the leptons and b jets probe the modelling of the $t\bar{t}$ production and top quark decay. Because of the excellent lepton energy resolution, the measurements of the lepton kinematic observables are particularly precise. The measurement of $\Delta\phi(\ell, \bar{\ell})$ is used to constrain the CMDM of the top quark, as described in Section 8. The measurement of N_{jets} probes higher-order corrections in the ME calculations and the modelling of radiation in the parton-shower simulations. The N_{jets} measurement includes the integrated cross section for $N_{\text{jets}} > 7$ in the last bin. For all other observables, the first and last bins include the differential cross section integrated within the bin boundaries only.

In Tables 48–55 in Appendix C, the χ^2 per degree of freedom (dof) and corresponding p -value are shown, quantifying the agreement between the unfolded data and predictions for all the observables. In addition, Figs. 52 and 53 summarise the p -values for each normalised distribution. For most of the measured observables, we find generally good agreement between data and predictions, within the uncertainties in the data. The cases where significant disagreement is observed are now discussed.

Many of the different top quark p_T distributions shown in Figs. 3–11 exhibit significant disagreements between the data and the POWHEG+PYTHIA predictions, varying smoothly from an excess of data for low p_T to a deficit for high p_T . Comparison of the data to the MG5_aMC@NLO+PYTHIA[FXFX] prediction shows a similar excess of data at low p_T but a smaller deficit at high p_T . The POWHEG+HERWIG++ simulation provides a better modelling of the top quark p_T distributions, where a deficit of data for high p_T at the parton level is the only observed disagreement. For all MC-based predictions, the deficit at high p_T is most pronounced for the p_T^{\dagger} (trailing) distribution. Similar patterns of disagreement were observed at $\sqrt{s} = 7, 8,$ and 13 TeV by the ATLAS [5] and CMS [8, 16, 17] Collaborations. The normalised and absolute p_T^{\dagger} and p_T^{\ddagger} distributions show a similar level of disagreement with the beyond-NLO predictions.

In Fig. 24, a significant deficit of data with respect to both the POWHEG+PYTHIA and MG5_aMC@NLO+PYTHIA[FXFX] predictions is observed for large values of p_T^{\ddagger} . Conversely, for the POWHEG+HERWIG++ prediction this deficit is not seen but there is an excess of data at moderate p_T^{\ddagger} . For the NNLO+ α_{EW}^3 predictions shown in Fig. 25, a slight deficit of data at high p_T^{\ddagger} is

apparent. For the $m_{t\bar{t}}$ distributions in Figs. 30 and 31, a significant excess of data with respect to all predictions in the lowest bin is observed. This excess is smaller for predictions with $m_t = 172.5$ GeV, which suggests a lower value of m_t could result in improved agreement for this distribution.

The distributions of kinematic properties of the leptons, b jets, dileptons, and b jet pairs (p_T^ℓ , p_T^b , $p_T^{\ell\bar{\ell}}$, $p_T^{b\bar{b}}$, $m_{\ell\bar{\ell}}$, and $m_{b\bar{b}}$) in Figs. 33–50 exhibit similar disagreements with the predictions as the corresponding top-quark-based observables p_T^t and $p_T^{t\bar{t}}$ with which they are correlated. In Fig. 51, an increasing excess of data over the POWHEG+PYTHIA and POWHEG+HERWIG++ predictions is observed for $N_{\text{jets}} \geq 4$. Conversely, there is good agreement between MG5_aMC@NLO+PYTHIA[FXFX] and data for $N_{\text{jets}} > 3$, but disagreement for $N_{\text{jets}} = 2, 3$.

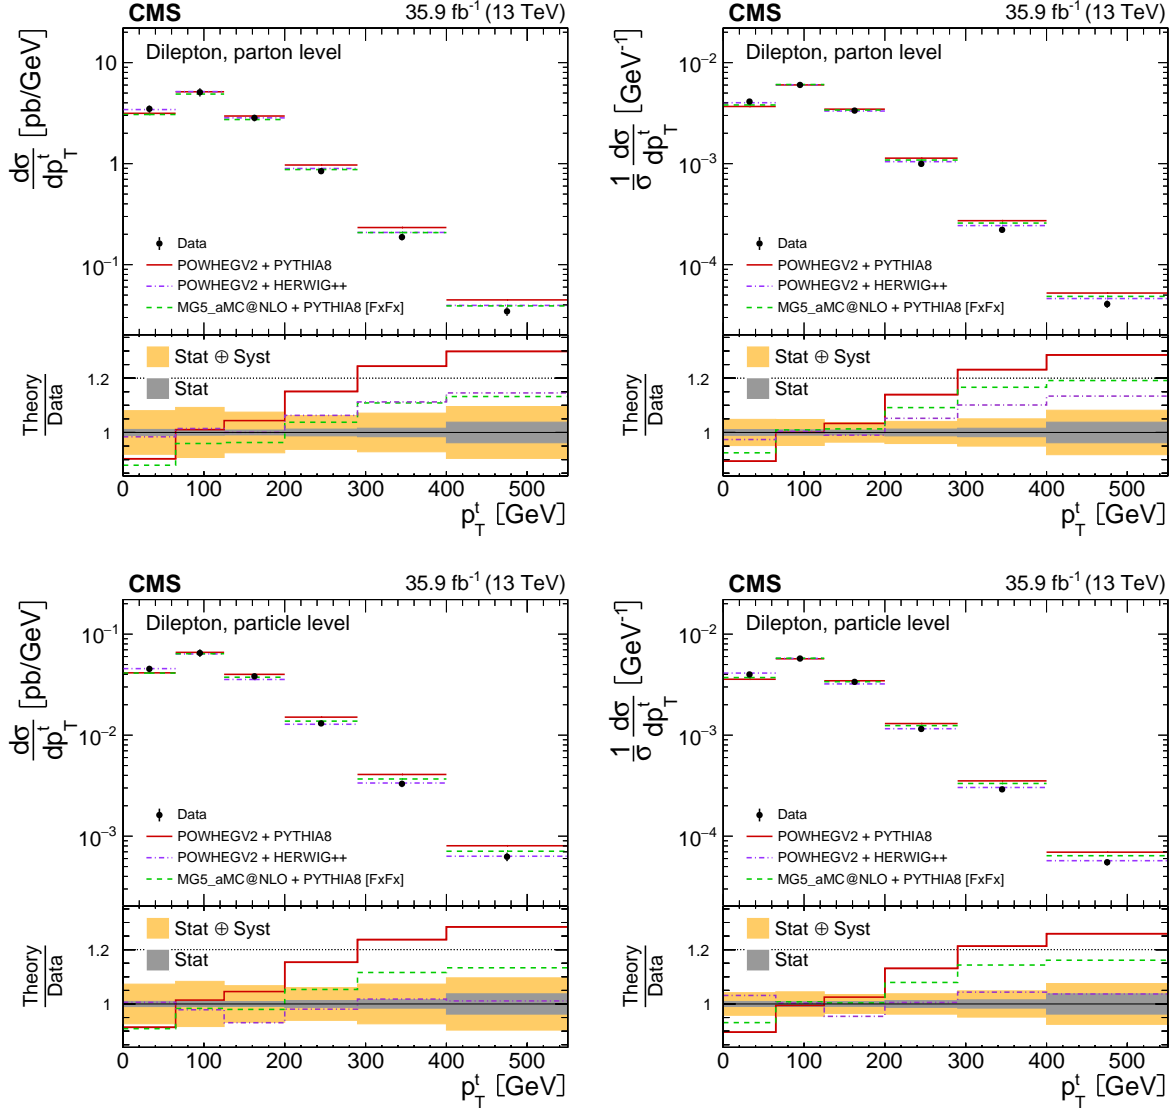

Figure 3: The differential $t\bar{t}$ production cross sections as a function of p_T^t are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

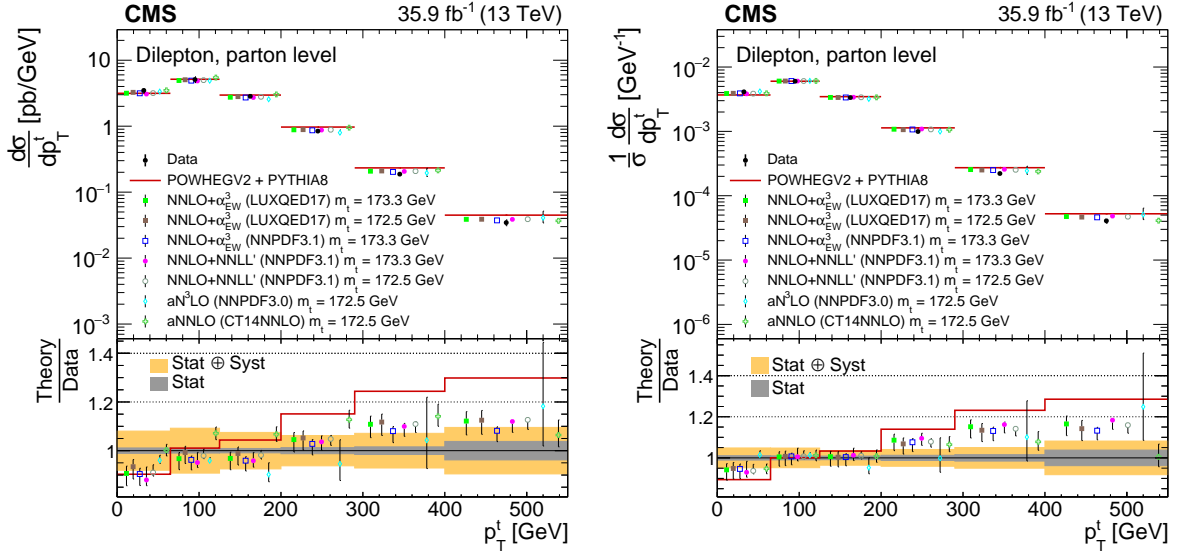

Figure 4: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of p_T^t are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 5: The contributions of each source of systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of p_T^t . The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The statistical and total uncertainties, corresponding to the quadrature addition of statistical and systematic uncertainties, are shown by the dark and light filled histograms, respectively.

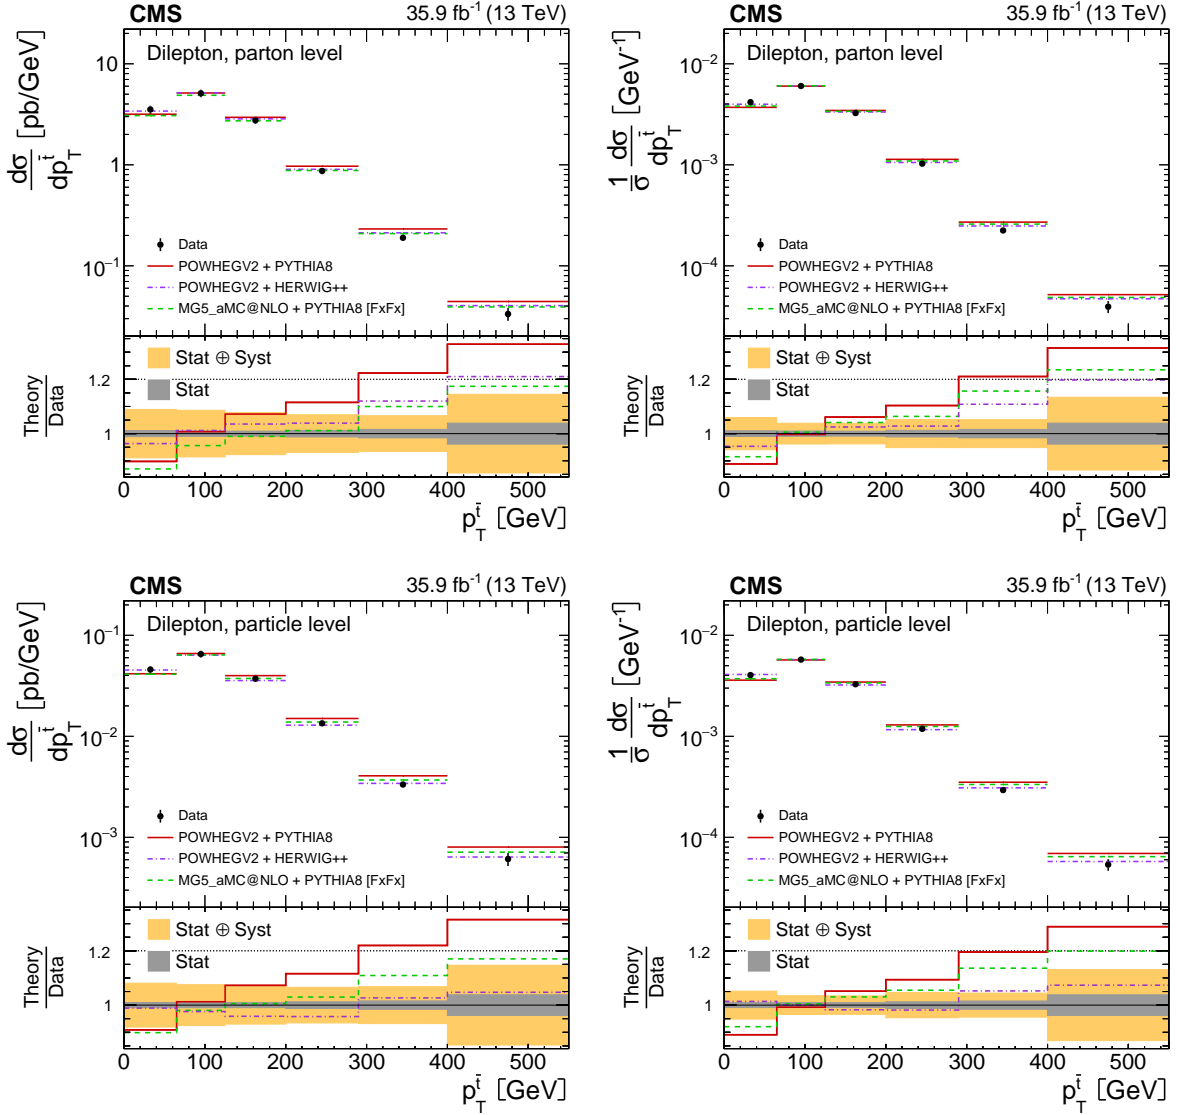

Figure 6: The differential $t\bar{t}$ production cross sections as a function of $p_T^{\bar{t}}$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

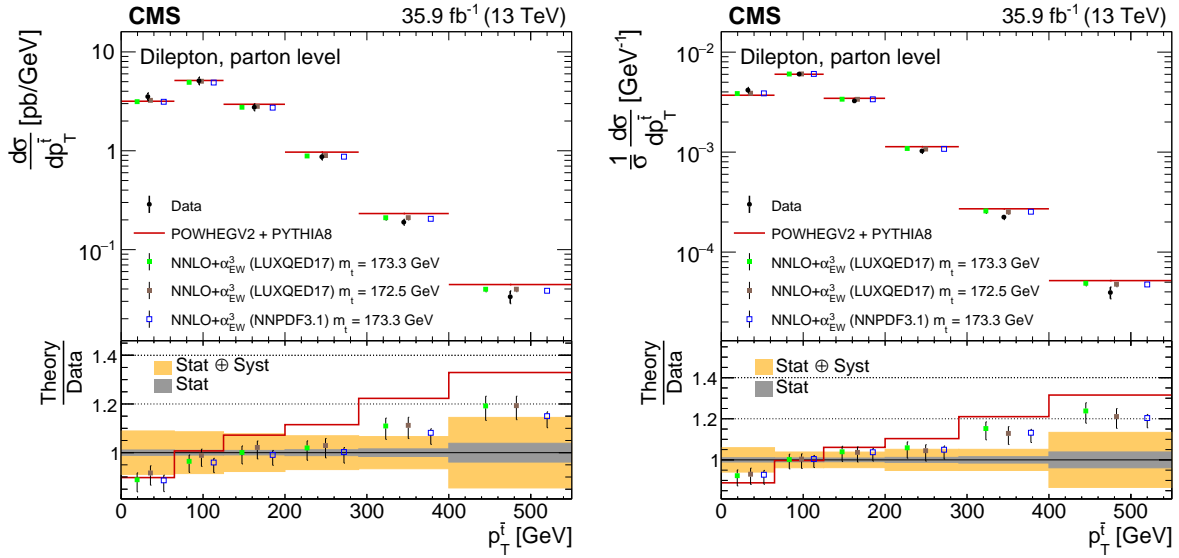

Figure 7: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of p_T^t are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 8: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of p_T^t . The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The statistical and total uncertainties, corresponding to the quadrature addition of statistical and systematic uncertainties, are shown by the dark and light filled histograms, respectively.

Figure 9: The differential $t\bar{t}$ production cross sections as a function of p_T^t (leading) are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 10: The differential $t\bar{t}$ production cross sections as a function of p_T^t (trailing) are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 11: The differential $\bar{t}\bar{t}$ production cross sections as a function of $p_T^t(\bar{t}\bar{t}\text{ RF})$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

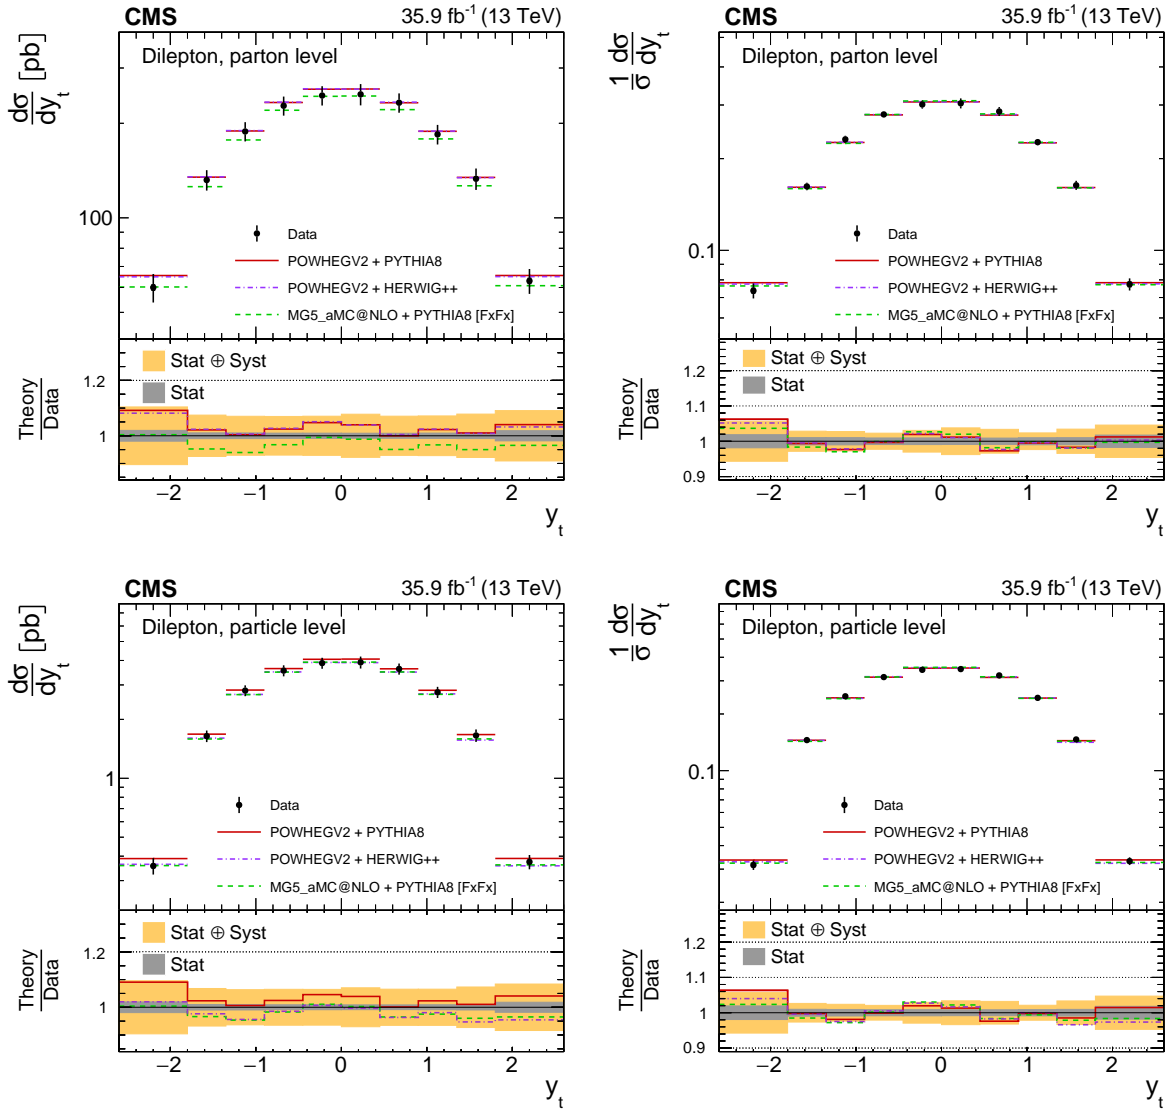

Figure 12: The differential $t\bar{t}$ production cross sections as a function of y_t are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 13: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of y_t are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

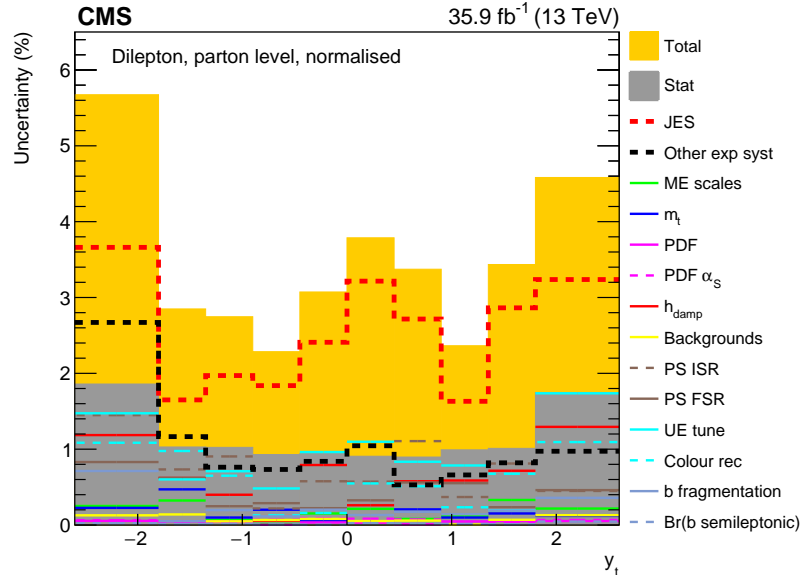

Figure 14: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of y_t . The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The statistical and total uncertainties, corresponding to the quadrature addition of statistical and systematic uncertainties, are shown by the dark and light filled histograms, respectively.

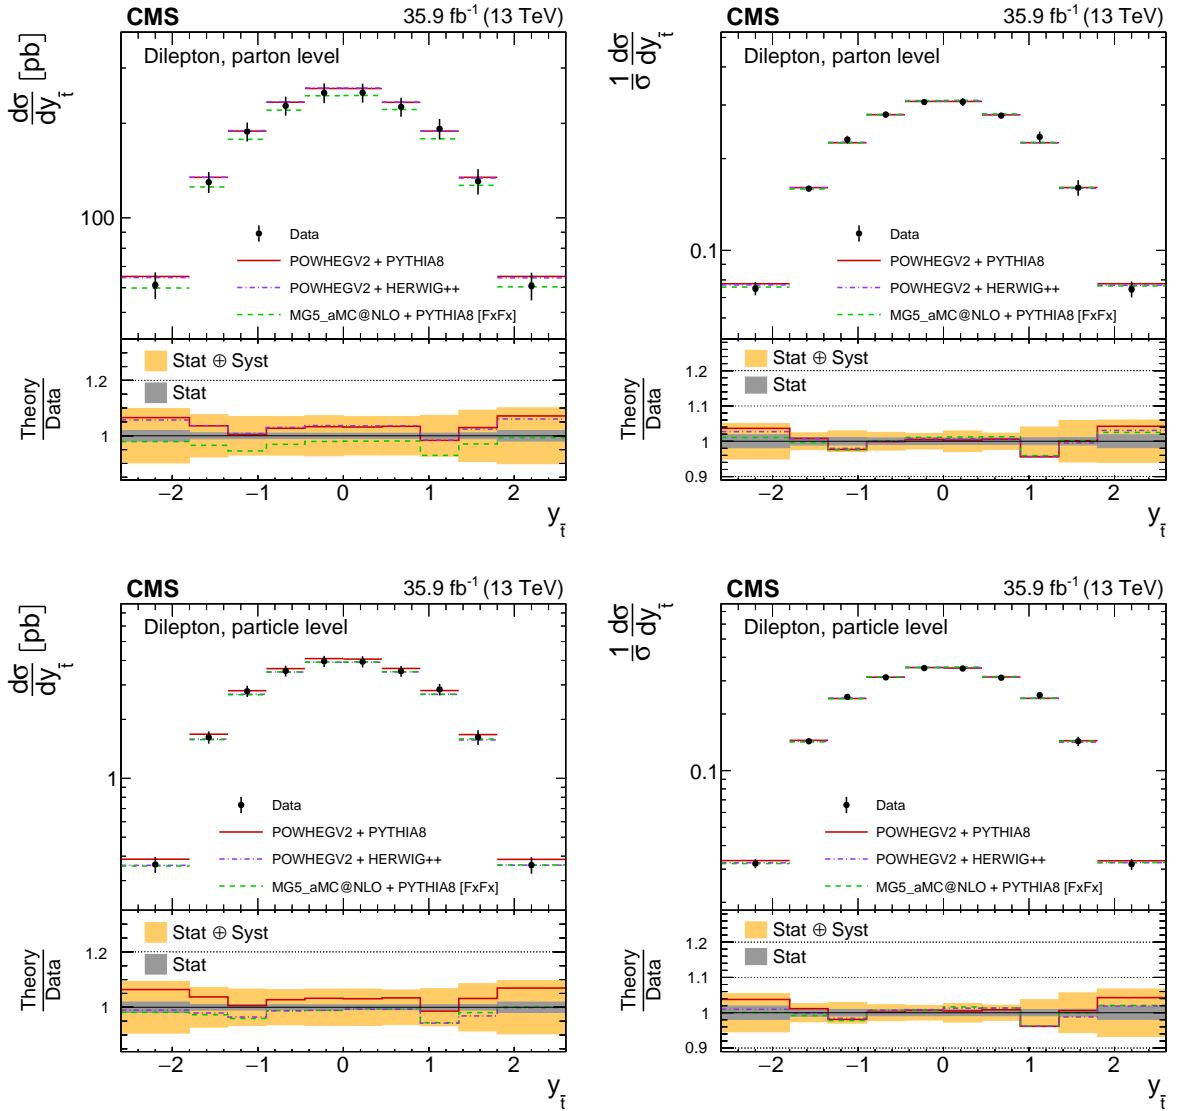

Figure 15: The differential $t\bar{t}$ production cross sections as a function of $y_{\bar{t}}$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

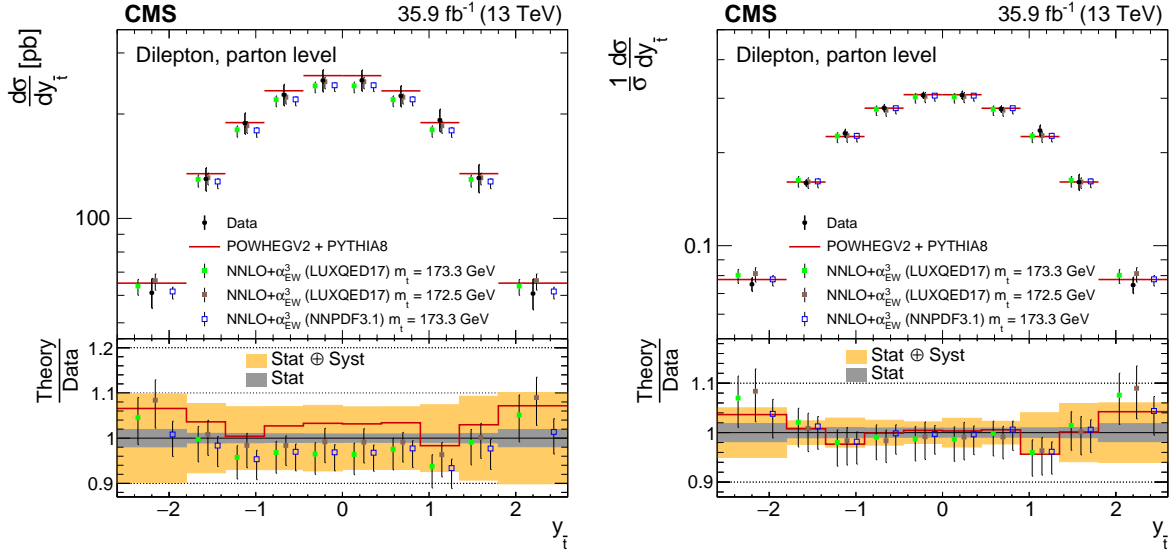

Figure 16: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of $y_{t\bar{t}}$ are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

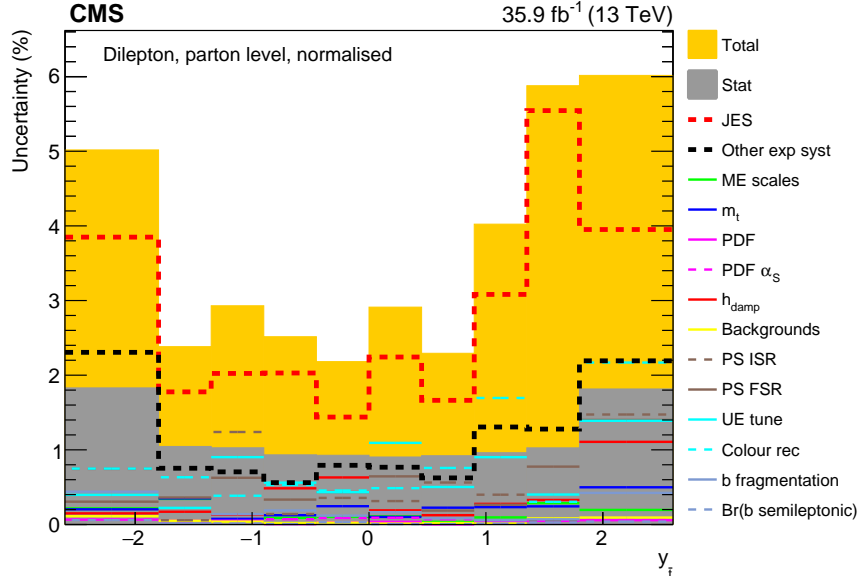

Figure 17: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of $y_{t\bar{t}}$. The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The statistical and total uncertainties, corresponding to the quadrature addition of statistical and systematic uncertainties, are shown by the dark and light filled histograms, respectively.

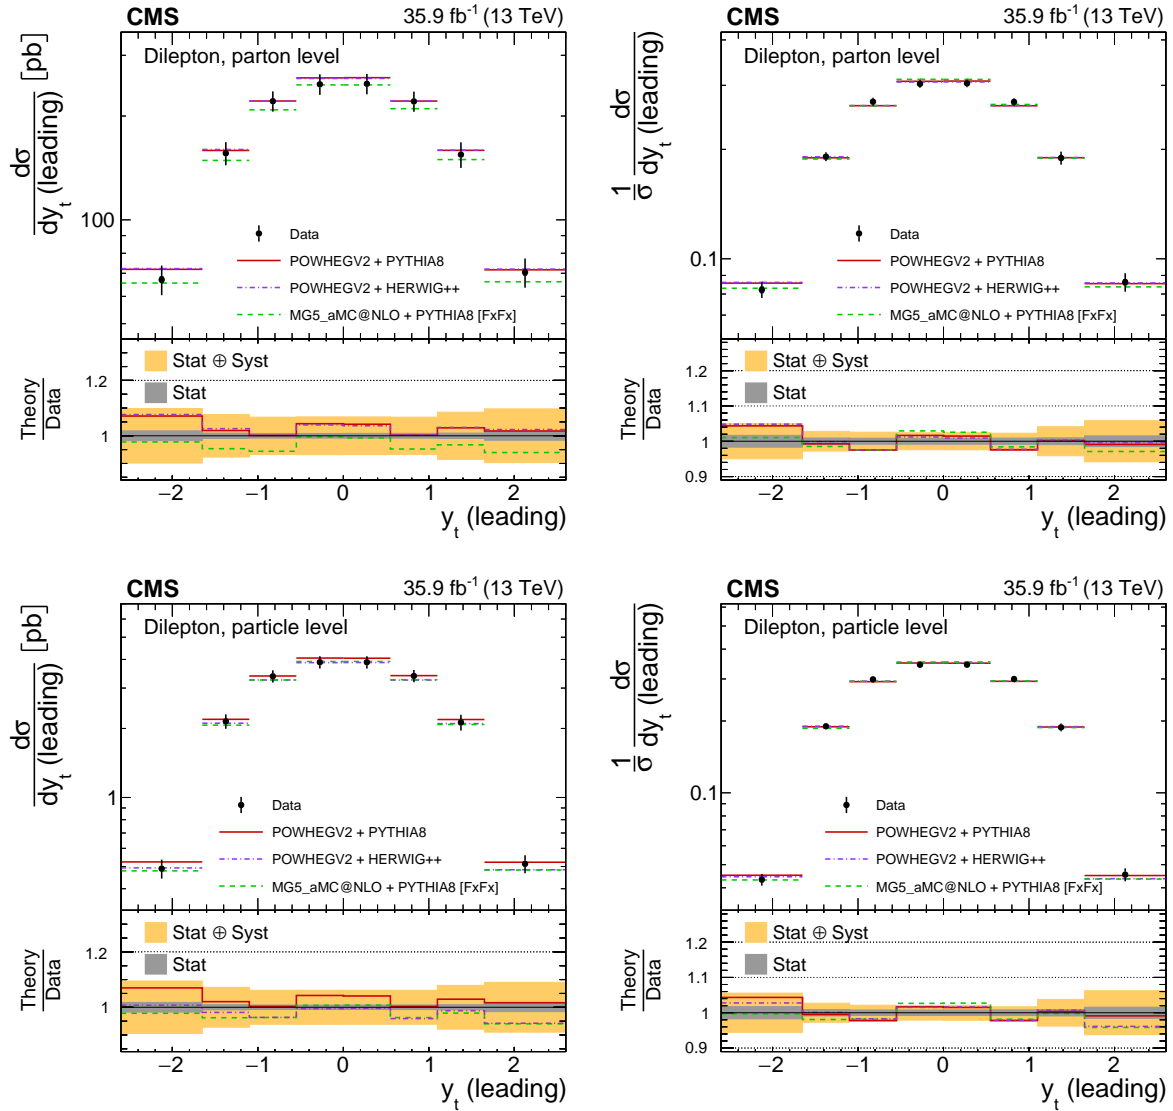

Figure 18: The differential $t\bar{t}$ production cross sections as a function of y_t (leading) are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 19: The differential $t\bar{t}$ production cross sections as a function of y_t (trailing) are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 20: The differential $t\bar{t}$ production cross sections as a function of $\Delta|y|(t,\bar{t})$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 21: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of $\Delta|y|(t, \bar{t})$ are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 22: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of $\Delta|y|(t, \bar{t})$. The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The statistical and total uncertainties, corresponding to the quadrature addition of statistical and systematic uncertainties, are shown by the dark and light filled histograms, respectively.

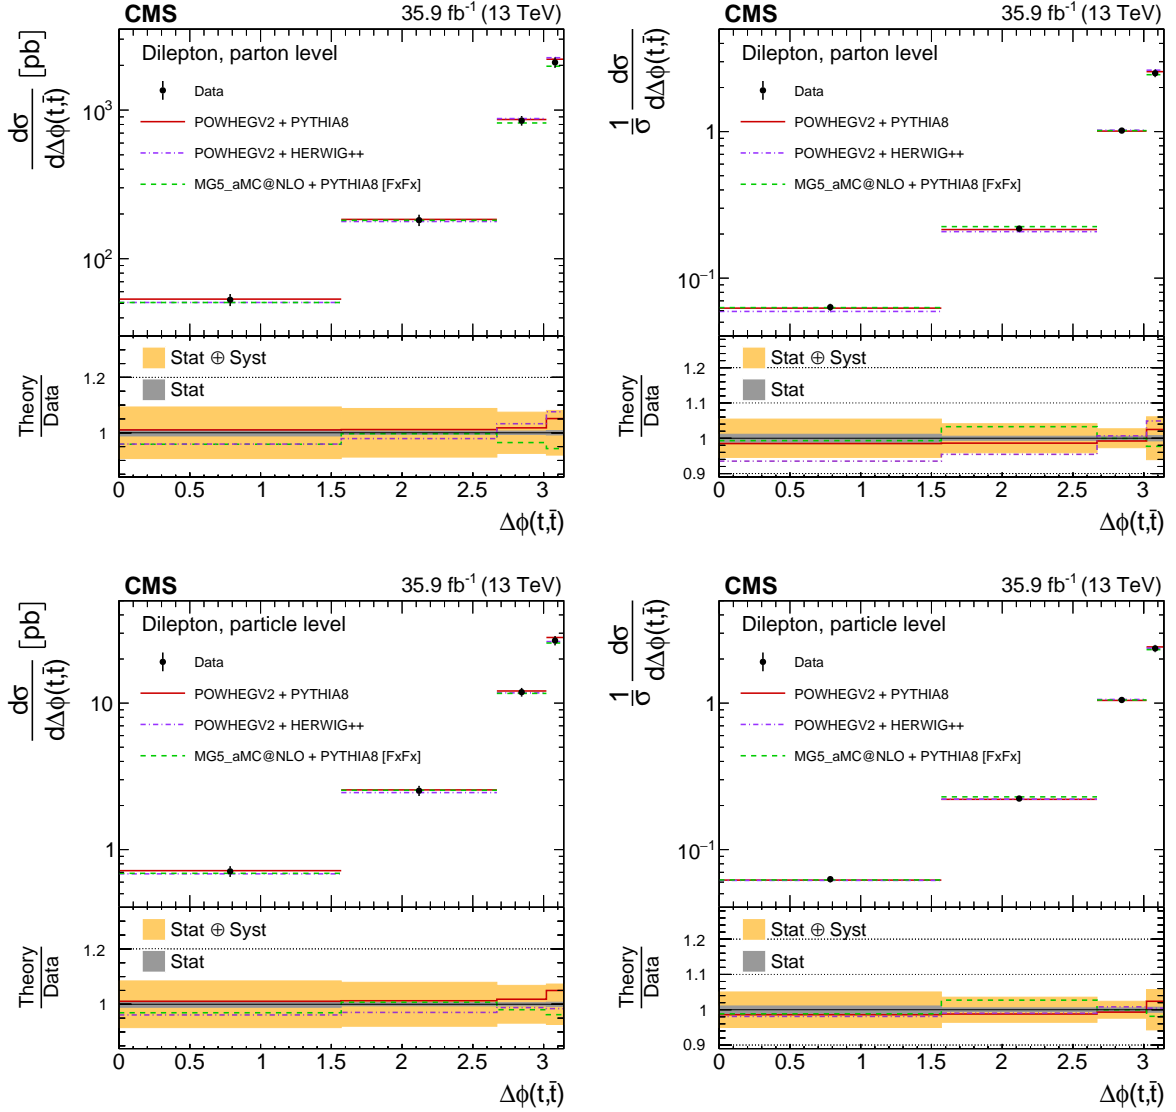

Figure 23: The differential $t\bar{t}$ production cross sections as a function of $\Delta\phi(t,\bar{t})$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 24: The differential $t\bar{t}$ production cross sections as a function of $p_T^{t\bar{t}}$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

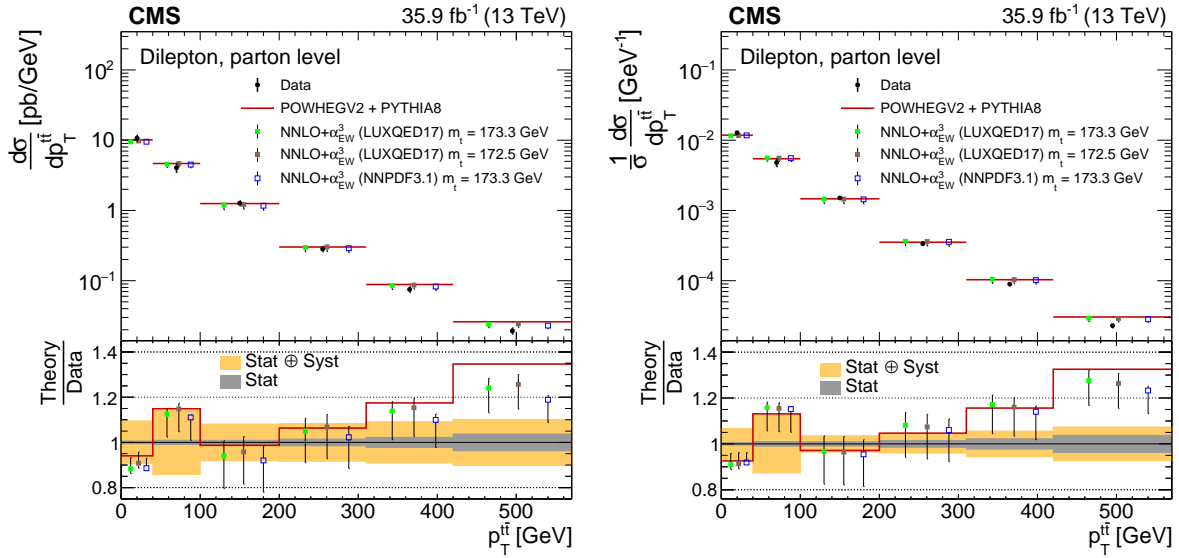

Figure 25: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of $p_T^{t\bar{t}}$ are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 26: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of $p_T^{t\bar{t}}$. The sources affecting the JES are added in quadrature and shown as a single component. As the contribution from unclustered p_T^{miss} is dominant in lower bins, it is shown separately. Additional experimental systematic uncertainties are added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. Related theoretical uncertainties are grouped by colour.

Figure 27: The differential $t\bar{t}$ production cross sections as a function of $y_{t\bar{t}}$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 28: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of $y_{t\bar{t}}$ are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 29: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of $y_{t\bar{t}}$. The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The statistical and total uncertainties, corresponding to the quadrature addition of statistical and systematic uncertainties, are shown by the dark and light filled histograms, respectively.

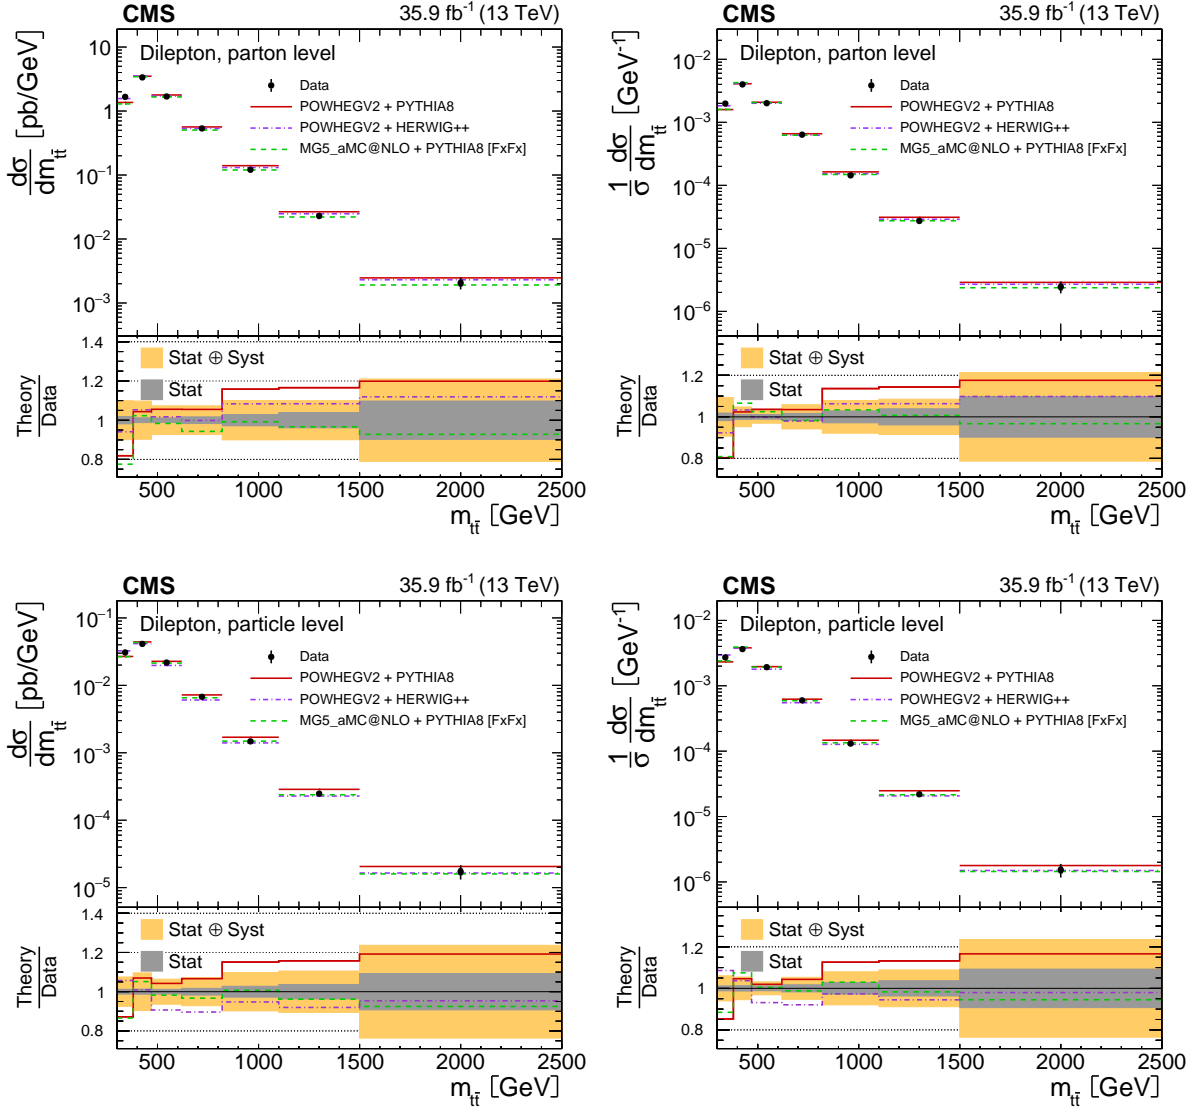

Figure 30: The differential $t\bar{t}$ production cross sections as a function of $m_{t\bar{t}}$ are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right columns correspond to absolute and normalised measurements, respectively. The upper row corresponds to measurements at the parton level in the full phase space and the lower row to the particle level in a fiducial phase space. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 31: The differential $t\bar{t}$ production cross sections at the parton level in the full phase space as a function of $m_{t\bar{t}}$ are shown for the data (filled circles), the theoretical predictions with beyond-NLO precision (other points) and the prediction from POWHEG+PYTHIA (solid line). The vertical lines on the filled circles and other points indicate the total uncertainty in the data and theoretical predictions, respectively. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

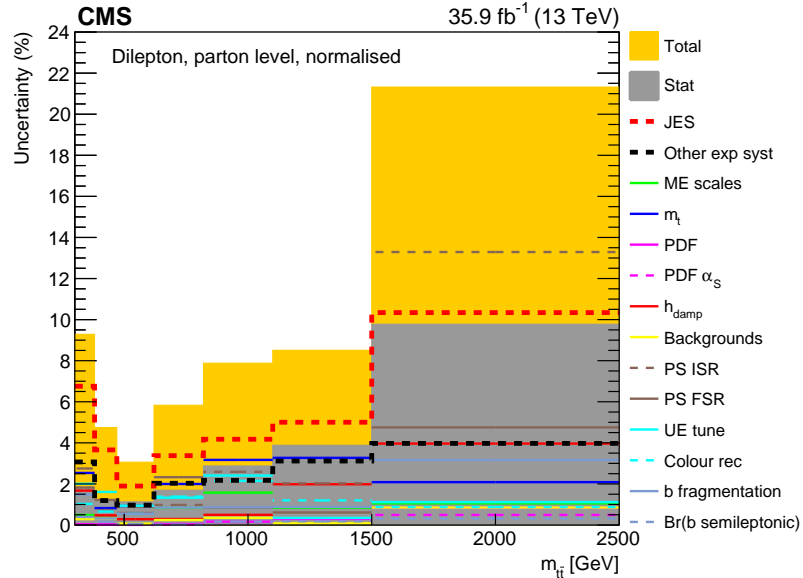

Figure 32: The contributions of each source of systematic uncertainty to the total systematic uncertainty in each bin is shown for the measurement of the normalised $t\bar{t}$ production cross sections as a function of $m_{t\bar{t}}$. The sources affecting the JES are added in quadrature and shown as a single component. Additional experimental systematic uncertainties are also added in quadrature and shown as a single component. Contributions from theoretical uncertainties are shown separately. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 50: The differential $t\bar{t}$ production cross sections as a function of $m_{b\bar{b}}$ in a fiducial phase space at the particle level are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 51: The differential $t\bar{t}$ production cross sections as a function of N_{jets} in a fiducial phase space at the particle level are shown for the data (points) and the MC predictions (lines). The vertical lines on the points indicate the total uncertainty in the data. The left and right plots correspond to absolute and normalised measurements, respectively. The lower panel in each plot shows the ratios of the theoretical predictions to the data. The dark and light bands show the relative statistical and total uncertainties in the data, respectively.

Figure 52: The p -values quantifying the agreement between the data and MC predictions for all normalised measurements are shown. Points situated on the horizontal axis indicate p -values less than 0.001. The upper panel includes distributions measured at parton and particle levels while the bottom panel includes those measured at particle level only.

Figure 53: The p -values quantifying the agreement between theoretical predictions with beyond-NLO precision and the data for selected normalised measurements at parton level are shown. Points situated on the horizontal axis indicate p -values of less than 0.001.

8 Constraining the top quark CMDM

In the SM, the intrinsic spin and colour charge of the top quark give it a small magnetic dipole moment in the colour fields known as the top quark CMDM. An anomalous top quark CMDM is a feature of several BSM scenarios and can affect both the rate and kinematic properties of $t\bar{t}$ production. The top quark may also have an anomalous chromoelectric dipole moment, however in this analysis it is assumed to be zero following the theoretical treatment presented in Ref. [28]. Until recently, the effect of an anomalous CMDM on $t\bar{t}$ production was calculated only at LO in QCD. In Ref. [28], predictions for $t\bar{t}$ production with anomalous CMDM at NLO in QCD in an EFT framework are provided. A comparison of the LO and NLO predictions reveals that the effect of the CMDM on $t\bar{t}$ production is underestimated at LO, and that the NLO predictions have reduced scale uncertainties with respect to those at LO. These two factors allow stronger constraints on the CMDM to be extracted using NLO predictions than with those at LO. In an EFT framework, the scale of new physics (Λ) is assumed to be large with respect to the typical scales probed at the LHC. Under this condition, BSM effects can be modelled in an EFT by adding a fixed set of dimension-6 operators to the SM Lagrangian [80, 81]. An operator commonly referred to as O_{tG} is responsible for anomalous CMDM effects in the EFT [28]. The contribution of O_{tG} to the Lagrangian is parameterized by the dimensionless Wilson coefficient divided by the square of the BSM scale (C_{tG}/Λ^2). The O_{tG} operator results in a new $ggt\bar{t}$ vertex, and modifies the $g\bar{t}t$ vertex, resulting in altered rates and kinematic properties in $t\bar{t}$ production. Furthermore, changes in the chirality of the top quarks induced by O_{tG} modify the spin correlation of the $t\bar{t}$ pair. Thus, both the rate of $t\bar{t}$ production and the difference in the azimuthal angle between the two leptons in dileptonic $t\bar{t}$ events, $\Delta\phi(\ell, \bar{\ell})$, are sensitive to the value of C_{tG}/Λ^2 . The measurement of the absolute differential $t\bar{t}$ cross section as a function of $\Delta\phi(\ell, \bar{\ell})$, in which the total cross section within the fiducial phase space is measured, is used to constrain C_{tG}/Λ^2 . The particle-level measurement in the fiducial phase space is the most appropriate for this purpose since it does not suffer from the model dependence introduced into the parton-level results when extrapolating to the full phase space.

To produce predictions for the $t\bar{t}$ cross section as a function of $\Delta\phi(\ell, \bar{\ell})$ and C_{tG}/Λ^2 , the model described in Ref. [28] is implemented in the MG5_aMC@NLO generator for the ME calculation at NLO in QCD. The parton shower and hadronisation steps are performed by interfacing this setup with PYTHIA. The RIVET framework [82] is used to apply the object definitions and requirements in order to produce particle-level predictions in the fiducial phase space identical to that of the measurements presented in this paper. The normalisations of the predictions are scaled with a K factor to account for the NNLO+NNLL corrections to the inclusive $t\bar{t}$ cross section calculated in Ref. [83]. However, as the acceptance of the fiducial phase space is calculated only at NLO precision, the normalisations of the predictions are not fully NNLO+NNLL precise. Since the p_T^t distribution is poorly modelled by the NLO generators, the predictions are additionally corrected in order to match the p_T^t prediction provided in Ref. [74] that corresponds to NNLO precision in QCD and includes electroweak corrections up to α_{EW}^3 .

The upper left plot of Fig. 54, shows the measured differential cross section as a function of $\Delta\phi(\ell, \bar{\ell})$ along with theoretical predictions for C_{tG}/Λ^2 values of 1.0, 0.0, and -1.0 TeV^{-2} . The high sensitivity of the normalisation of the measured differential cross section and the smaller sensitivity of its shape to the value of C_{tG}/Λ^2 are clearly seen in the lower panel of the left plot of Fig. 54, which displays the ratios of the predictions to the measurements for the three C_{tG}/Λ^2 values. The good agreement between the data and the $C_{tG}/\Lambda^2 = 0.0 \text{ TeV}^{-2}$ prediction corresponding to the SM is also apparent.

A χ^2 minimisation technique is used to constrain C_{tG}/Λ^2 . The χ^2 function is defined as:

$$\chi^2(C_{tG}/\Lambda^2) = \sum_{i=1}^N \sum_{j=1}^N (\text{data}_i - \text{pred}_i(C_{tG}/\Lambda^2)) (\text{data}_j - \text{pred}_j(C_{tG}/\Lambda^2)) \text{Cov}_{ij}^{-1},$$

where data_i and $\text{pred}_i(C_{tG}/\Lambda^2)$ are the measured and predicted differential cross section in the i th bin, respectively, and Cov_{ij}^{-1} is the $(i$ th, j th) element of the inverse of the covariance matrix of the data. The covariance matrix accounts for all systematic and statistical uncertainties, as well as the inter-bin correlations introduced in the unfolding process. The minimisation results in a best fit value of 0.18 TeV^{-2} , corresponding to a χ^2/dof of 0.3. Assuming Gaussian probability density functions for the uncertainties in the unfolded data, confidence intervals (CIs) can be estimated from the values of C_{tG}/Λ^2 for which the $\Delta\chi^2$ reaches certain values. The $\Delta\chi^2$ is defined as the difference in χ^2 from the χ^2 at the best fit value. This procedure yields a 95% CI of $-0.06 < C_{tG}/\Lambda^2 < 0.41 \text{ TeV}^{-2}$. Uncertainties arising from the theoretical predictions are separately estimated. First, the normalisations of the predictions are varied by $+5.8\%$ and -6.2% , corresponding to the addition in quadrature of the uncertainties from variations of the factorisation and renormalisation scales, PDFs, and m_t in the prediction from Ref. [83]. Second, the shapes of the predictions are varied by changing the factorisation and renormalisation scales by factors of 0.5 and 2.0 in the MG5_aMC@NLO simulation. The χ^2 minimisation is repeated for all variations, and the total theoretical uncertainty is determined from the maximally positive and negative effects on the best fit value of C_{tG}/Λ^2 . In the right plot of Fig. 54, the $\Delta\chi^2$ as a function of C_{tG}/Λ^2 is shown. The nominal fit to the data is represented by the solid curve with the $\Delta\chi^2$ values for the 68 and 95% CIs indicated by the horizontal dashed lines. The dark and light regions display the corresponding 68 and 95% CIs, respectively. Since the theoretical uncertainties do not have a clear frequentist interpretation, they are not included in the CIs. Rather, the other two curves in the figure show the results of the fits that produce the maximally positive and negative deviations from the best-fit value when the theoretical predictions are allowed to vary within their uncertainties.

In Ref. [28], 95% CIs of $-0.42 < C_{tG}/\Lambda^2 < 0.30 \text{ TeV}^{-2}$ and $-0.32 < C_{tG}/\Lambda^2 < 0.73 \text{ TeV}^{-2}$ are derived using NLO predictions for the total $t\bar{t}$ cross section as a function of C_{tG}/Λ^2 and measurements from $\sqrt{s} = 8 \text{ TeV}$ CMS data [84] and $\sqrt{s} = 1.96 \text{ TeV}$ Fermilab Tevatron data [85], respectively. The CMS Collaboration has previously used normalised differential $t\bar{t}$ cross sections measured in the full phase space with 8 TeV data to constrain the top quark CMDM [86]. Using relations presented in Ref. [87], these results of Ref. [86] can be converted to a 95% CI of $-0.89 < C_{tG}/\Lambda^2 < 0.43 \text{ TeV}^{-2}$. Thus, the results of this work are consistent with, and improve upon, these previous constraints on C_{tG}/Λ^2 .

9 Extraction of the top quark charge asymmetries

The measurements of normalised differential cross sections as a function of $\Delta|y|(t, \bar{t})$ at parton and particle levels, and as a function of $\Delta\eta(\ell, \bar{\ell})$ at particle level shown in Figs. 20 and 44, respectively, allow the extraction of the $t\bar{t}$ and leptonic charge asymmetries, $A_c^{t\bar{t}}$ and $A_c^{\ell\bar{\ell}}$. These observables are sensitive to a number of BSM scenarios such as axigluon, Z' , and W' states coupling to top quarks [88]. The $A_c^{t\bar{t}}$ and $A_c^{\ell\bar{\ell}}$ asymmetries are defined as:

$$A_c^{t\bar{t}} = \frac{\sigma_{t\bar{t}}(\Delta|y|(t, \bar{t}) > 0) - \sigma_{t\bar{t}}(\Delta|y|(t, \bar{t}) < 0)}{\sigma_{t\bar{t}}(\Delta|y|(t, \bar{t}) > 0) + \sigma_{t\bar{t}}(\Delta|y|(t, \bar{t}) < 0)}, \quad A_c^{\ell\bar{\ell}} = \frac{\sigma_{t\bar{t}}(\Delta\eta(\ell, \bar{\ell}) > 0) - \sigma_{t\bar{t}}(\Delta\eta(\ell, \bar{\ell}) < 0)}{\sigma_{t\bar{t}}(\Delta\eta(\ell, \bar{\ell}) > 0) + \sigma_{t\bar{t}}(\Delta\eta(\ell, \bar{\ell}) < 0)},$$

Figure 54: In the left plot, the differential $t\bar{t}$ cross sections as a function of $\Delta\phi(\ell, \bar{\ell})$ at the particle level in a fiducial phase space described in the text are shown. The points correspond to data and vertical bars on the points give the total uncertainty. The solid lines show the NLO predictions from the MG5_aMC@NLO generator interfaced with PYTHIA for C_{tG}/Λ^2 values of 1.0, 0.0, and -1.0 TeV^{-2} . The lower plot displays the ratio of the theoretical predictions to the data. In the right plot, $\Delta\chi^2$ values from the fit to the data in the left plot are shown as a function of C_{tG}/Λ^2 . The dark curve gives the result of the nominal fit, with the vertical dashed line giving the best-fit value. The two horizontal dashed lines indicate the $\Delta\chi^2$ values for the 68 and 95% CIs. The dark and light bands correspond to those 68 and 95% CIs, respectively. The other curves show the $\Delta\chi^2$ values for fits that give the maximally positive and negative changes in the best-fit value when the theoretical predictions are allowed to vary within their systematic uncertainties.

where $\sigma_{t\bar{t}}$ represents the measured integrated $t\bar{t}$ cross section in the specified range [89]. After the extraction of $A_c^{t\bar{t}}$ and $A_c^{\ell\bar{\ell}}$ from the data, the uncertainties in $A_c^{t\bar{t}}$ and $A_c^{\ell\bar{\ell}}$ are derived by combining the statistical and systematic uncertainties in the data in each bin, while accounting for the inter-bin correlations introduced during the unfolding procedure. The measured charge asymmetries and corresponding uncertainties are: $A_c^{t\bar{t}}$ (parton level) = 0.01 ± 0.009 , $A_c^{t\bar{t}}$ (particle level) = 0.008 ± 0.009 , and $A_c^{\ell\bar{\ell}}$ (particle level) = -0.005 ± 0.004 . In Fig. 55, the central values and the 68 and 95% CI bands are compared with the SM predictions produced with the POWHEG and MG5_aMC@NLO generators interfaced with PYTHIA, and a calculation at NLO precision in QCD and including corrections arising from mixing between QCD and electroweak diagrams, and between QCD and quantum electrodynamics (QED) diagrams taken from Ref. [90]. The results are in good agreement with the SM predictions and represent the first measurement of $A_c^{t\bar{t}}$ and $A_c^{\ell\bar{\ell}}$ with 13 TeV data.

Figure 55: The results of the A_c^x extraction ($x = t\bar{t}$ or $\ell\bar{\ell}$) from integrating the normalised parton- and particle-level differential cross section measurements as a function of $\Delta|y|(t, \bar{t})$ and $\Delta\eta(\ell, \bar{\ell})$ are shown. The central values for the data are indicated by the solid lines with the 68 and 95% CIs represented by the dark and light shaded bands, respectively. The three types of dashed lines indicate the SM predictions produced with the MG5_aMC@NLO and POWHEG generators, both interfaced with PYTHIA, and a calculation at NLO precision in QCD and including corrections arising from mixing between QCD and electroweak diagrams, and between QCD and QED diagrams [90].

10 Summary

Measurements of differential $t\bar{t}$ cross sections using events containing two oppositely charged leptons produced in pp collisions at a centre-of-mass energy of 13 TeV are presented. The data were recorded with the CMS detector in 2016 and correspond to a integrated luminosity of 35.9 fb^{-1} . The differential cross sections are presented as functions of numerous observables related to $t\bar{t}$ production and decay and are based on both particle-level objects in a phase space close to that of the detector acceptance and parton-level top quarks in the full phase space. For each observable, absolute and normalised differential cross sections are presented. Most measured differential cross sections are well modelled by theoretical predictions. However, significant disagreement between the data and Monte Carlo simulation with next-to-leading-order (NLO) precision in quantum chromodynamics is observed for the transverse momentum

of top quarks, leptons, b jets, $t\bar{t}$, $\ell\bar{\ell}$, and $b\bar{b}$ systems, and the invariant mass of the $t\bar{t}$, $\ell\bar{\ell}$, and $b\bar{b}$ systems. Predictions with beyond-NLO precision are generally in closer agreement with the data although some significant discrepancies remain. The jet multiplicity distribution is not well described by any of the Monte Carlo predictions. The absolute particle-level differential cross section as a function of $\Delta\phi(\ell, \bar{\ell})$ is used to constrain the top quark chromomagnetic dipole moment at NLO precision in quantum chromodynamics using an effective field theory framework. The $t\bar{t}$ and leptonic charge asymmetries are measured using 13 TeV data for the first time and found to be in agreement with standard model predictions.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: the Austrian Federal Ministry of Education, Science and Research and the Austrian Science Fund; the Belgian Fonds de la Recherche Scientifique, and Fonds voor Wetenschappelijk Onderzoek; the Brazilian Funding Agencies (CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP); the Bulgarian Ministry of Education and Science; CERN; the Chinese Academy of Sciences, Ministry of Science and Technology, and National Natural Science Foundation of China; the Colombian Funding Agency (COLCIENCIAS); the Croatian Ministry of Science, Education and Sport, and the Croatian Science Foundation; the Research Promotion Foundation, Cyprus; the Secretariat for Higher Education, Science, Technology and Innovation, Ecuador; the Ministry of Education and Research, Estonian Research Council via IUT23-4 and IUT23-6 and European Regional Development Fund, Estonia; the Academy of Finland, Finnish Ministry of Education and Culture, and Helsinki Institute of Physics; the Institut National de Physique Nucléaire et de Physique des Particules / CNRS, and Commissariat à l'Énergie Atomique et aux Énergies Alternatives / CEA, France; the Bundesministerium für Bildung und Forschung, Deutsche Forschungsgemeinschaft, and Helmholtz-Gemeinschaft Deutscher Forschungszentren, Germany; the General Secretariat for Research and Technology, Greece; the National Research, Development and Innovation Fund, Hungary; the Department of Atomic Energy and the Department of Science and Technology, India; the Institute for Studies in Theoretical Physics and Mathematics, Iran; the Science Foundation, Ireland; the Istituto Nazionale di Fisica Nucleare, Italy; the Ministry of Science, ICT and Future Planning, and National Research Foundation (NRF), Republic of Korea; the Ministry of Education and Science of the Republic of Latvia; the Lithuanian Academy of Sciences; the Ministry of Education, and University of Malaya (Malaysia); the Ministry of Science of Montenegro; the Mexican Funding Agencies (BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI); the Ministry of Business, Innovation and Employment, New Zealand; the Pakistan Atomic Energy Commission; the Ministry of Science and Higher Education and the National Science Centre, Poland; the Fundação para a Ciência e a Tecnologia, Portugal; JINR, Dubna; the Ministry of Education and Science of the Russian Federation, the Federal Agency of Atomic Energy of the Russian Federation, Russian Academy of Sciences, the Russian Foundation for Basic Research, and the National Research Center "Kurchatov Institute"; the Ministry of Education, Science and Technological Development of Serbia; the Secretaría de Estado de Investigación, Desarrollo e Innovación, Programa Consolider-Ingenio 2010, Plan Estatal de Investigación Científica y Técnica y de Innovación 2013-2016, Plan de Ciencia, Tecnología e Innovación 2013-2017 del Principado de Asturias, and Fondo Europeo de Desarrollo Regional, Spain; the Ministry of Science, Technology and Research, Sri Lanka; the Swiss Funding Agencies (ETH Board, ETH Zurich, PSI, SNF, UniZH, Canton Zurich, and SER); the Ministry of Science and Technology, Taipei; the Thailand Center of Excellence in Physics, the Institute for the Promotion of Teaching Science and Technology of Thailand, Special Task Force for Activating Research and the National Science and Technology Development Agency of Thailand; the Scientific and Technical Research Council of Turkey, and Turkish Atomic Energy Authority; the National Academy of Sciences of Ukraine, and State Fund for Fundamental Researches, Ukraine; the Science and Technology Facilities Council, UK; the US Department of Energy, and the US National Science Foundation.

Individuals have received support from the Marie-Curie programme and the European Research Council and Horizon 2020 Grant, contract No. 675440 (European Union); the Leventis Foundation; the A. P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science Policy Office; the Fonds pour la Formation à la Recherche dans l'Industrie et dans l'Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the F.R.S.-FNRS and FWO (Belgium) under the "Excellence of Science - EOS" - be.h project n. 30820817; the Ministry of Education, Youth and Sports (MEYS) of the Czech Republic; the Lendület ("Momentum") Programme and the János Bolyai Research Scholarship of the Hungarian Academy of Sciences, the New National Excellence Program ÚNKP, the NKFIA research grants 123842, 123959, 124845, 124850 and 125105 (Hungary); the Council of Scientific and Industrial Research, India; the HOMING PLUS programme of the Foundation for Polish Science, cofinanced from European Union, Regional Development Fund, the Mobility Plus programme of the Ministry of Science and Higher Education, the National Science Center (Poland), contracts Harmonia 2014/14/M/ST2/00428, Opus 2014/13/B/ST2/02543, 2014/15/B/ST2/03998, and 2015/19/B/ST2/02861, Sonata-bis 2012/07/E/ST2/01406; the National Priorities Research Program by Qatar National Research Fund; the Programa de Excelencia María de Maeztu, and the Programa Severo Ochoa del Principado de Asturias; the Thalís and Aristeia programmes cofinanced by EU-ESF, and the Greek NSRF; the Rachadapisek Sompot Fund for Postdoctoral Fellowship, Chulalongkorn University, and the Chulalongkorn Academic into Its 2nd Century Project Advancement Project (Thailand); the Welch Foundation, contract C-1845; and the Weston Havens Foundation (USA).

A Tables of parton-level differential cross sections

All the measured differential cross sections at the parton level are tabulated in Tables 1–14. The statistical and systematic uncertainties are quoted separately for each bin.

Table 1: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of p_T^t are tabulated.

p_T^t [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t}$ [pb/GeV]
[0, 65]	$(4.118 \pm 0.044 \pm 0.194) \times 10^{-3}$	$3.487 \pm 0.039 \pm 0.278$
[65, 125]	$(6.016 \pm 0.059 \pm 0.282) \times 10^{-3}$	$5.094 \pm 0.05 \pm 0.467$
[125, 200]	$(3.352 \pm 0.03 \pm 0.116) \times 10^{-3}$	$2.838 \pm 0.026 \pm 0.211$
[200, 290]	$(9.948 \pm 0.125 \pm 0.386) \times 10^{-4}$	$0.842 \pm 0.011 \pm 0.051$
[290, 400]	$(2.213 \pm 0.035 \pm 0.106) \times 10^{-4}$	$0.187 \pm 0.003 \pm 0.013$
[400, 550]	$(4.074 \pm 0.155 \pm 0.296) \times 10^{-5}$	$(3.45 \pm 0.131 \pm 0.302) \times 10^{-2}$

Table 2: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of $p_T^{\bar{t}}$ are tabulated.

$p_T^{\bar{t}}$ [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^{\bar{t}}}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^{\bar{t}}}$ [pb/GeV]
[0, 65]	$(4.172 \pm 0.044 \pm 0.244) \times 10^{-3}$	$3.532 \pm 0.039 \pm 0.313$
[65, 125]	$(6.031 \pm 0.059 \pm 0.224) \times 10^{-3}$	$5.105 \pm 0.05 \pm 0.436$
[125, 200]	$(3.254 \pm 0.03 \pm 0.12) \times 10^{-3}$	$2.755 \pm 0.026 \pm 0.212$
[200, 290]	$(1.027 \pm 0.013 \pm 0.051) \times 10^{-3}$	$0.869 \pm 0.011 \pm 0.059$
[290, 400]	$(2.239 \pm 0.035 \pm 0.11) \times 10^{-4}$	$0.19 \pm 0.003 \pm 0.012$
[400, 550]	$(3.941 \pm 0.152 \pm 0.506) \times 10^{-5}$	$(3.336 \pm 0.129 \pm 0.466) \times 10^{-2}$

Table 3: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of p_T^t (leading) are tabulated.

p_T^t (leading) [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t(\text{leading})}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t(\text{leading})}$ [pb/GeV]
[0, 65]	$(2.618 \pm 0.033 \pm 0.162) \times 10^{-3}$	$2.221 \pm 0.029 \pm 0.195$
[65, 125]	$(6.046 \pm 0.042 \pm 0.155) \times 10^{-3}$	$5.129 \pm 0.037 \pm 0.403$
[125, 200]	$(3.981 \pm 0.027 \pm 0.111) \times 10^{-3}$	$3.377 \pm 0.024 \pm 0.265$
[200, 290]	$(1.377 \pm 0.013 \pm 0.044) \times 10^{-3}$	$1.168 \pm 0.011 \pm 0.071$
[290, 400]	$(3.227 \pm 0.038 \pm 0.124) \times 10^{-4}$	$0.274 \pm 0.003 \pm 0.017$
[400, 550]	$(6.076 \pm 0.171 \pm 0.439) \times 10^{-5}$	$(5.154 \pm 0.145 \pm 0.466) \times 10^{-2}$

Table 4: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of p_T^t (trailing) are tabulated.

p_T^t (trailing) [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t(\text{trailing})}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t(\text{trailing})}$ [pb/GeV]
[0, 65]	$(5.659 \pm 0.048 \pm 0.232) \times 10^{-3}$	$4.79 \pm 0.043 \pm 0.371$
[65, 125]	$(5.992 \pm 0.068 \pm 0.289) \times 10^{-3}$	$5.071 \pm 0.058 \pm 0.486$
[125, 200]	$(2.641 \pm 0.032 \pm 0.125) \times 10^{-3}$	$2.235 \pm 0.027 \pm 0.162$
[200, 290]	$(6.452 \pm 0.121 \pm 0.441) \times 10^{-4}$	$0.546 \pm 0.01 \pm 0.043$
[290, 400]	$(1.235 \pm 0.03 \pm 0.083) \times 10^{-4}$	$0.105 \pm 0.003 \pm 0.009$
[400, 550]	$(1.949 \pm 0.126 \pm 0.306) \times 10^{-5}$	$(1.65 \pm 0.107 \pm 0.267) \times 10^{-2}$

Table 5: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of p_T^t ($t\bar{t}$ RF) are tabulated.

p_T^t ($t\bar{t}$ RF) [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t(t\bar{t} \text{ RF})}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t(t\bar{t} \text{ RF})}$ [pb/GeV]
[0, 65]	$(4.505 \pm 0.045 \pm 0.218) \times 10^{-3}$	$3.814 \pm 0.041 \pm 0.296$
[65, 125]	$(6.24 \pm 0.065 \pm 0.263) \times 10^{-3}$	$5.282 \pm 0.056 \pm 0.489$
[125, 200]	$(3.149 \pm 0.032 \pm 0.102) \times 10^{-3}$	$2.666 \pm 0.028 \pm 0.191$
[200, 290]	$(8.229 \pm 0.126 \pm 0.405) \times 10^{-4}$	$0.697 \pm 0.011 \pm 0.045$
[290, 400]	$(1.682 \pm 0.032 \pm 0.091) \times 10^{-4}$	$0.142 \pm 0.003 \pm 0.009$
[400, 550]	$(2.64 \pm 0.136 \pm 0.284) \times 10^{-5}$	$(2.235 \pm 0.115 \pm 0.266) \times 10^{-2}$

Table 6: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of y_t are tabulated.

y_t	$\frac{1}{\sigma} \frac{d\sigma}{dy_t}$	$\frac{d\sigma}{dy_t}$ [pb]
[-2.6, -1.8]	$(7.371 \pm 0.137 \pm 0.395) \times 10^{-2}$	$(6 \pm 0.117 \pm 0.614) \times 10$
[-1.8, -1.35]	$0.162 \pm 0.002 \pm 0.004$	$(1.32 \pm 0.014 \pm 0.098) \times 10^2$
[-1.35, -0.9]	$0.231 \pm 0.002 \pm 0.006$	$(1.884 \pm 0.019 \pm 0.131) \times 10^2$
[-0.9, -0.45]	$0.279 \pm 0.003 \pm 0.006$	$(2.274 \pm 0.022 \pm 0.157) \times 10^2$
[-0.45, 0]	$0.301 \pm 0.003 \pm 0.009$	$(2.452 \pm 0.023 \pm 0.172) \times 10^2$
[0, 0.45]	$0.304 \pm 0.003 \pm 0.011$	$(2.474 \pm 0.023 \pm 0.191) \times 10^2$
[0.45, 0.9]	$0.286 \pm 0.003 \pm 0.009$	$(2.326 \pm 0.021 \pm 0.163) \times 10^2$
[0.9, 1.35]	$0.227 \pm 0.002 \pm 0.005$	$(1.844 \pm 0.018 \pm 0.131) \times 10^2$
[1.35, 1.8]	$0.164 \pm 0.002 \pm 0.005$	$(1.331 \pm 0.014 \pm 0.103) \times 10^2$
[1.8, 2.6]	$(7.737 \pm 0.135 \pm 0.328) \times 10^{-2}$	$(6.298 \pm 0.116 \pm 0.561) \times 10$

Table 7: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at parton level in the full phase space as a function of $y_{\bar{t}}$ are tabulated.

B Tables of particle-level differential cross sections

All the measured differential cross sections at the particle level are tabulated in Tables 15–47. The statistical and systematic uncertainties are quoted separately for each bin.

Table 15: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at particle level in the fiducial phase space as a function of p_T^t are tabulated.

p_T^t [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t}$ [pb/GeV]
[0, 65]	$(3.991 \pm 0.037 \pm 0.162) \times 10^{-3}$	$(4.529 \pm 0.043 \pm 0.328) \times 10^{-2}$
[65, 125]	$(5.734 \pm 0.053 \pm 0.251) \times 10^{-3}$	$(6.507 \pm 0.061 \pm 0.538) \times 10^{-2}$
[125, 200]	$(3.369 \pm 0.03 \pm 0.114) \times 10^{-3}$	$(3.823 \pm 0.035 \pm 0.255) \times 10^{-2}$
[200, 290]	$(1.152 \pm 0.014 \pm 0.041) \times 10^{-3}$	$(1.307 \pm 0.016 \pm 0.077) \times 10^{-2}$
[290, 400]	$(2.907 \pm 0.044 \pm 0.134) \times 10^{-4}$	$(3.299 \pm 0.051 \pm 0.236) \times 10^{-3}$
[400, 550]	$(5.515 \pm 0.206 \pm 0.36) \times 10^{-5}$	$(6.259 \pm 0.234 \pm 0.555) \times 10^{-4}$

Table 16: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at particle level in the fiducial phase space as a function of $p_T^{\bar{t}}$ are tabulated.

$p_T^{\bar{t}}$ [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^{\bar{t}}}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^{\bar{t}}}$ [pb/GeV]
[0, 65]	$(4.038 \pm 0.037 \pm 0.205) \times 10^{-3}$	$(4.581 \pm 0.044 \pm 0.368) \times 10^{-2}$
[65, 125]	$(5.746 \pm 0.053 \pm 0.192) \times 10^{-3}$	$(6.519 \pm 0.061 \pm 0.487) \times 10^{-2}$
[125, 200]	$(3.277 \pm 0.03 \pm 0.107) \times 10^{-3}$	$(3.717 \pm 0.035 \pm 0.258) \times 10^{-2}$
[200, 290]	$(1.186 \pm 0.014 \pm 0.053) \times 10^{-3}$	$(1.345 \pm 0.016 \pm 0.087) \times 10^{-2}$
[290, 400]	$(2.937 \pm 0.045 \pm 0.122) \times 10^{-4}$	$(3.332 \pm 0.051 \pm 0.221) \times 10^{-3}$
[400, 550]	$(5.37 \pm 0.204 \pm 0.672) \times 10^{-5}$	$(6.093 \pm 0.231 \pm 0.865) \times 10^{-4}$

Table 17: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at particle level in the fiducial phase space as a function of p_T^t (leading) are tabulated.

p_T^t (leading) [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t(\text{leading})}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t(\text{leading})}$ [pb/GeV]
[0, 65]	$(2.474 \pm 0.028 \pm 0.136) \times 10^{-3}$	$(2.805 \pm 0.033 \pm 0.227) \times 10^{-2}$
[65, 125]	$(5.735 \pm 0.041 \pm 0.145) \times 10^{-3}$	$(6.504 \pm 0.049 \pm 0.462) \times 10^{-2}$
[125, 200]	$(3.937 \pm 0.027 \pm 0.102) \times 10^{-3}$	$(4.465 \pm 0.033 \pm 0.315) \times 10^{-2}$
[200, 290]	$(1.568 \pm 0.015 \pm 0.046) \times 10^{-3}$	$(1.778 \pm 0.017 \pm 0.102) \times 10^{-2}$
[290, 400]	$(4.199 \pm 0.049 \pm 0.141) \times 10^{-4}$	$(4.761 \pm 0.057 \pm 0.297) \times 10^{-3}$
[400, 550]	$(8.319 \pm 0.232 \pm 0.532) \times 10^{-5}$	$(9.434 \pm 0.264 \pm 0.839) \times 10^{-4}$

Table 18: The measured differential cross section and bin boundaries for each bin of the normalized and absolute measurements of the $t\bar{t}$ differential cross section at particle level in the fiducial phase space as a function of p_T^t (trailing) are tabulated.

p_T^t (trailing) [GeV]	$\frac{1}{\sigma} \frac{d\sigma}{dp_T^t(\text{trailing})}$ [GeV ⁻¹]	$\frac{d\sigma}{dp_T^t(\text{trailing})}$ [pb/GeV]
[0, 65]	$(5.535 \pm 0.039 \pm 0.193) \times 10^{-3}$	$(6.287 \pm 0.047 \pm 0.445) \times 10^{-2}$
[65, 125]	$(5.737 \pm 0.058 \pm 0.244) \times 10^{-3}$	$(6.516 \pm 0.067 \pm 0.545) \times 10^{-2}$
[125, 200]	$(2.726 \pm 0.032 \pm 0.114) \times 10^{-3}$	$(3.096 \pm 0.037 \pm 0.202) \times 10^{-2}$
[200, 290]	$(7.709 \pm 0.142 \pm 0.511) \times 10^{-4}$	$(8.756 \pm 0.161 \pm 0.689) \times 10^{-3}$
[290, 400]	$(1.665 \pm 0.038 \pm 0.119) \times 10^{-4}$	$(1.891 \pm 0.044 \pm 0.173) \times 10^{-3}$

C Tables of χ^2/dof and p -values

The χ^2/dof and p -values between data and all theoretical predictions for all measured differential cross sections are tabulated in Tables 48–55. The χ^2/dof and p -value calculations take into account the inter-bin correlations of the data.

Table 48: The χ^2/dof and p -values quantifying the agreement between the three MC predictions and the measured, parton-level normalised cross sections are shown.

	POWHEG+PYTHIA		POWHEG+HERWIG++		MG5_aMC@NLO+PYTHIA[FXFX]	
	χ^2/dof	p -value	χ^2/dof	p -value	χ^2/dof	p -value
p_T^t	43/5	$< 10^{-3}$	6/5	0.269	21/5	$< 10^{-3}$

†: Deceased

1: Also at Vienna University of Technology, Vienna, Austria

2: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France

3: Also at Universidade Estadual de Campinas, Campinas, Brazil

4: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil

5: Also at Université Libre de Bruxelles, Bruxelles, Belgium

6: Also at University of Chinese Academy of Sciences, Beijing, China

7: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia

8: Also at Joint Institute for Nuclear Research, Dubna, Russia

9: Also at Cairo University, Cairo, Egypt

10: Also at Helwan University, Cairo, Egypt

11: Now at Zewail City of Science and Technology, Zewail, Egypt

12: Also at British University in Egypt, Cairo, Egypt

13: Now at Ain Shams University, Cairo, Egypt

14: Also at Department of Physics, King Abdulaziz University, Jeddah, Saudi Arabia

15: Also at Université de Haute Alsace, Mulhouse, France

16: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

17: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland

18: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany

- 19: Also at University of Hamburg, Hamburg, Germany
- 20: Also at Brandenburg University of Technology, Cottbus, Germany
- 21: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary
- 22: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 23: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary
- 24: Also at Indian Institute of Technology Bhubaneswar, Bhubaneswar, India
- 25: Also at Institute of Physics, Bhubaneswar, India
- 26: Also at Shoolini University, Solan, India
- 27: Also at University of Visva-Bharati, Santiniketan, India
- 28: Also at Isfahan University of Technology, Isfahan, Iran
- 29: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 30: Also at Università degli Studi di Siena, Siena, Italy
- 31: Also at Kyunghee University, Seoul, Korea
- 32: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
- 33: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
- 34: Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
- 35: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland
- 36: Also at Institute for Nuclear Research, Moscow, Russia
- 37: Now at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia
- 38: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
- 39: Also at University of Florida, Gainesville, USA
- 40: Also at P.N. Lebedev Physical Institute, Moscow, Russia
- 41: Also at California Institute of Technology, Pasadena, USA
- 42: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
- 43: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
- 44: Also at INFN Sezione di Pavia ^a, Università di Pavia ^b, Pavia, Italy
- 45: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
- 46: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
- 47: Also at National and Kapodistrian University of Athens, Athens, Greece
- 48: Also at Riga Technical University, Riga, Latvia
- 49: Also at Universität Zürich, Zurich, Switzerland
- 50: Also at Stefan Meyer Institute for Subatomic Physics (SMI), Vienna, Austria
- 51: Also at Adiyaman University, Adiyaman, Turkey
- 52: Also at Istanbul Aydin University, Istanbul, Turkey
- 53: Also at Mersin University, Mersin, Turkey
- 54: Also at Piri Reis University, Istanbul, Turkey
- 55: Also at Gaziosmanpasa University, Tokat, Turkey
- 56: Also at Ozyegin University, Istanbul, Turkey
- 57: Also at Izmir Institute of Technology, Izmir, Turkey
- 58: Also at Marmara University, Istanbul, Turkey
- 59: Also at Kafkas University, Kars, Turkey
- 60: Also at Istanbul University, Faculty of Science, Istanbul, Turkey
- 61: Also at Istanbul Bilgi University, Istanbul, Turkey
- 62: Also at Hacettepe University, Ankara, Turkey
- 63: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom

64: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom

65: Also at Monash University, Faculty of Science, Clayton, Australia

66: Also at Bethel University, St. Paul, USA

67: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey

68: Also at Utah Valley University, Orem, USA

69: Also at Purdue University, West Lafayette, USA

70: Also at Beykent University, Istanbul, Turkey

71: Also at Bingol University, Bingol, Turkey

72: Also at Sinop University, Sinop, Turkey

73: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey

74: Also at Texas A&M University at Qatar, Doha, Qatar

75: Also at Kyungpook National University, Daegu, Korea
