Abstract

We investigate the interplay between the enumerative geometry of Calabi-Yau fourfolds with fluxes and the modularity of elliptic genera in four-dimensional string theories. We argue that certain contributions to the elliptic genus are given by derivatives of modular or quasi-modular forms, which may encode BPS invariants of Calabi-Yau or non-Calabi-Yau threefolds that are embedded in the given fourfold. As a result, the elliptic genus is only a quasi-Jacobi form, rather than a modular or quasi-modular one in the usual sense. This manifests itself as a holomorphic anomaly of the spectral flow symmetry, and in an elliptic holomorphic anomaly equation that maps between different flux sectors. We support our general considerations by a detailed study of examples, including non-critical strings in four dimensions.

For the critical heterotic string, we explain how anomaly cancellation is restored due to the properties of the derivative sector. Essentially, while the modular sector of the elliptic genus takes care of anomaly cancellation involving the universal B -field, the quasi-Jacobi one accounts for additional B -fields that can be present.

Thus once again, diverse mathematical ingredients, namely here the algebraic geometry of fourfolds, relative Gromow-Witten theory pertaining to flux backgrounds, and the modular properties of (quasi-)Jacobi forms, conspire in an intriguing manner precisely as required by stringy consistency.

1 Introduction and Overview

Recent developments in the context of the Weak Gravity Conjecture [1], reviewed in [2, 3], have revived interest in string dualities, which underlie the emergence of tensionless strings [4–9] at infinite distance boundaries of moduli space.

Specifically, the previous work [6] initiated a study of the emergence of asymptotically tensionless heterotic strings in $N = 1$ supersymmetric string compactifications in $d = 4$ dimensions. These strings arise as solitonic objects in certain flux compactifications on Calabi-Yau fourfolds in F-theory. In suitable limits, they furnish the dominant degrees of freedom, and become weakly coupled when described in the proper duality eigenframe. The main purpose of that work was to test various Quantum Gravity Conjectures in a controlled four-dimensional setting.¹

The confirmation of the Weak Gravity Conjecture in [4–6] crucially hinged on the modular properties of a certain index-like partition function, the elliptic genus, of the asymptotically tensionless strings. Related aspects of modularity in this context have been discussed in [1, 19–22]. As a somewhat surprising outcome of the analysis in [6], the elliptic genera of four-dimensional strings turn out not to be modular or even quasi-modular.

The goal of the present paper is to study the interplay between geometry and modular properties of elliptic genera in much greater depth. We will observe that the deviation from the expected (quasi-)modularity of the elliptic genus in four dimensions is due to the appearance of derivatives of (quasi-)modular Jacobi forms. These derivatives yield so-called *quasi-Jacobi forms* in the sense of [23, 24], in agreement with general conjectures made in [25]. As we will see, they originate from underlying, formally six-dimensional sectors of the theory. This fact manifests itself in an intriguing way in the geometry of the Calabi-Yau fourfolds and certain threefolds embedded therein. These structures will likely be of use for further applications to non-perturbative, especially non-critical, strings in four dimensions.

In the next subsection we will review known results in order to set the stage, followed by a summary of our findings as a road map. The rest of the text is then devoted to a detailed analysis. In Section 2 we will set up the geometry underlying the fourfold and flux configurations that we consider. The geometric objects which we will study are relative² genus-zero Gromov-Witten, or equivalently BPS invariants on elliptically fibered fourfolds. In Section 3 we relate these invariants to a geometric, generally non-perturbative definition of elliptic genera of four-dimensional strings, with focus on the relationship between their modular properties and the underlying flux configurations. In this context we also observe an intriguing relation between partition functions associated with transversal and non-transversal fluxes, and this turns out to be a manifestation of the elliptic holomorphic anomaly equation of [25]. Our analysis, condensed into Conjecture 2, applies not only to the elliptic genus of solitonic heterotic strings, but also more generally to those of non-critical strings such as four-dimensional versions of E-strings. Section 4 is devoted to the interplay between modularity, elliptic genera and anomaly cancellation, for the special case of a heterotic solitonic string. Specifically, in Section 4.3 we provide a match between the Green-Schwarz terms in the effective action, and the various modular sectors of the elliptic genus. In Sections 5 and 6 we present a detailed technical analysis of several examples for heterotic and non-critical strings. Further mathematical facts are relegated to the Appendices.

¹See [10–16] for a small sample of complementary, quantitative geometrical tests especially of the Swampland Distance Conjecture [17, 18].

²The term relative invariants here refers to invariants for curves of form $C_b + C_{\text{fib}}$, where C_b lies in the base and C_{fib} in the fiber of the elliptic fibration.

1.1 Review of Known Results

An important quantity that captures certain robust features of string theories is the elliptic genus [26–29], which serves as a loop space extension of the ordinary chiral index in quantum field theories. By turning on background fields, a wealth of exact information about the chiral spectrum and its charges can be extracted. In this paper we will mainly consider elliptic genera for four-dimensional string theories in a $U(1)$ gauge background. More concretely, what we will consider are the partition functions in the Ramond-Ramond sector of superconformal worldsheet theories with right-moving supersymmetry, which in $d = 2n + 2$ dimensions are defined as

$$Z(q, \xi) = \text{tr}_{RR} \left[(-1)^{F_R} F_R^n q^{H_L} \bar{q}^{H_R} \xi^J \right], \quad q \equiv e^{2\pi i \tau}, \xi \equiv e^{2\pi i z}. \quad (1.1)$$

Here τ denotes the modular parameter of the toroidal worldsheet, and z represents the background gauge field strength, or fugacity, which couples to a left-moving, holomorphic $U(1)$ current, J . In order to obtain a non-vanishing result, the zero modes are saturated by inserting an appropriate power F_R^n of the right-moving fermion number operator. In the present, four-dimensional, context, we have $n = 1$ and the worldsheet theory possesses $N = (0, 2)$ supersymmetry.

The elliptic genus (1.1) should be contrasted with the familiar one of $N = (2, 2)$ superconformal theories. For these one can refine the elliptic genus in a canonical way as to keep track of the left-moving $U(1)$ superconformal R-symmetry. On the other hand, the current J in the present context is just the worldsheet incarnation of some four-dimensional gauge symmetry, which for concreteness we have taken to be $U(1)$.³ This is a generic, model-dependent symmetry which does not pertain to any left-moving $N = 2$ superconformal algebra.

It is familiar from the earliest works [26–29] that the elliptic genus (1.1), defined as the RR partition function of a weakly coupled, toroidal worldsheet theory, enjoys distinguished transformation properties under the modular group, $SL(2, \mathbb{Z})$: For a string in $d = 2n + 2$ dimensions, it transforms with modular weight $w = -n$. As we will recall later in Section 4, for the special case of a critical heterotic string this has important implications for anomaly cancellation [26, 27, 30, 31] via the Green-Schwarz [32] mechanism.

When the elliptic genus is refined by an extra $U(1)$ gauge background, as considered here, one might expect that it will be promoted to a weak Jacobi form [33–35]. This means that $Z(q, \xi) = \Phi_{-n, m}(\tau, z)$, where $\Phi_{w, m}$ denotes a generic weak Jacobi form of modular weight w and index m (the index m is model dependent and specifies the level of the underlying $U(1)$ Kac-Moody algebra, or equivalently, the spacing of the charge lattice). As summarized in Appendix A.1, such Jacobi forms enjoy distinguished modular and shift transformation properties, which play an important rôle for elliptic genera in general (for a review, see e.g. [36]).

While this expectation is indeed realised in six dimensions, we find that the elliptic genus in four-dimensional string theories is not necessarily a modular or quasi-modular weak Jacobi form, but rather what is known as a quasi-Jacobi form (see again Appendix A.1). This is not in conflict with the arguments of [33] which are based on spectral flow [37], as these arguments do not apply to generic $U(1)$ currents in $(0, 2)$ models. Indeed it is known [38] that (left-right asymmetric) spectral flow is not necessarily a symmetry of the theory. In fact the situation is not that bad, in that the elliptic genus will still be closely related to weak Jacobi forms, albeit in a more intricate way: namely, at least in special situations, as a collection of formally *six-dimensional* elliptic genera in disguise. We will explain these matters, which are among our main findings, in detail in the next subsection.

³In Section 6.1, we will also discuss a non-abelian extension.

Historically the elliptic genus of critical strings as written in (1.1) refers to a weakly coupled, conformal worldsheet theory and as such it is an intrinsically perturbative, one-loop quantity. However, it was later understood how elliptic genera for critical as well as for non-critical strings can also be defined and computed in non-perturbative settings, by resorting to a variety of methods such as mirror symmetry, the topological vertex, localization, and 2d CFT technology [4,6,39–65,65–73]. This has the advantage of being far more general than for perturbative strings based on weakly coupled worldsheet theories, and applies also to non-perturbative heterotic as well as to non-critical strings.

In this paper we will exploit the fact that elliptic genera can be computed geometrically in terms of Gromov-Witten invariants arising in dual string compactifications in M- or F-theory. Most of the work has been done, so far, for six-dimensional theories. Essentially, the idea is to consider solitonic strings that arise in F-theory from D3-branes wrapping some curve, C_b , which lies in the base of an elliptic threefold, Y_3 . In the dual M-theory formulation, the charged excitations of the string wrapped on an extra S^1 correspond to M2-branes on $\mathbf{C} = C_b + n\mathbb{E}_\tau + C_r^f$. Here \mathbb{E}_τ is the elliptic fiber of Y_3 and the other fibral curves C_r^f are associated with the gauge symmetry. The degeneracies that are encoded in the elliptic genus (1.1) then have an interpretation as the genus-zero BPS invariants, $N_{C_b}(n, r)$, associated with \mathbf{C} . These invariants can be assembled into the following free energy, which is defined relative to C_b :

$$\mathcal{F}_{C_b}(q, \xi) = \sum N_{C_b}(n, r) q^n \xi^r. \quad (1.2)$$

Here we assumed just one extra $U(1)$ gauge symmetry.⁴ Physically the M2 brane wrapping numbers n and r correspond to levels and charges of excitations of the solitonic string.

Via duality the free energy $\mathcal{F}_{C_b}(q, \xi)$ can be argued to coincide with the elliptic genus⁵ (1.1) of the solitonic string, upon identifying the modulus of the elliptic fiber with the modulus of the toroidal worldsheet (and similarly for the $U(1)$ fugacity):

$$Z_{C_b}(q, \xi) = -q^{E_0} \mathcal{F}_{C_b}(q, \xi), \quad (1.3)$$

where E_0 is the ground state energy of the Ramond sector of the string worldsheet theory.

In [6] we have addressed the analogous situation for four-dimensional F-theory compactifications on fourfolds, Y_4 , focussing on geometries that lead to dual heterotic strings. This is much more involved not the least because BPS invariants on fourfolds, $N_{\alpha; C_b}$, depend on extra data. Namely they need to be defined [74–77] with respect to some basis of cohomology classes, $\omega^\alpha \in H^{2,2}(Y_4, \mathbb{R})$. In physics terms these data correspond to choices for the background four-flux, $\mathbf{G} = c_\alpha \omega^\alpha$. Thus for a given fourfold Y_4 , we have in general a collection of independent elliptic genera labelled by background fluxes,

$$Z_{\alpha; C_b}(q, \xi) = -q^{E_0} \sum_{n, r} N_{\alpha; C_b}(n, r) q^n \xi^r, \quad (1.4)$$

so that the full elliptic genus for a given flux background \mathbf{G} is given by a linear combination

$$Z_{\mathbf{G}; C_b}(q, \xi) = \sum_{\alpha=1}^{\dim H^{2,2}(Y_4, \mathbb{R})} c_\alpha Z_{\alpha; C_b}(q, \xi). \quad (1.5)$$

⁴The generalisation to multiple $U(1)$ factors should be straightforward, in terms of (quasi-)Jacobi forms with multiple elliptic variables, along the lines of [5].

⁵Throughout this work we are considering genus-zero BPS invariants. In six dimensions, with a suitable omega background turned on, one can define an elliptic genus that also captures higher genus BPS invariants of Calabi-Yau threefolds as in [41]. Note however that for compact Calabi-Yau fourfolds only genus zero and genus one invariants are relevant [74].

As far as the modular properties are concerned, it was found in [6] that depending on the flux sectors labelled by α , the various building blocks $Z_{\alpha;C_b}(q, \xi)$ behave very differently. To be more specific, let us introduce the following symbolic notation (now labelling by modular weight and index rather than by flux and curve):

$$[Z_{-1,m}^*] = [Z_{-1,m}^M] \oplus [Z_{-1,m}^{QM}] \oplus [Z_{-1,m}^{QJ}], \quad (1.6)$$

where the superscripts refer to⁶ “modular”, “quasi-modular” and “quasi-Jacobi”, respectively. We will explain these terms in due course. Note that at this point there is an ambiguity in that any $Z_{-1,m}^{QM}$ is a priori defined only up to a modular piece, and $Z_{-1,m}^{QJ}$ up to modular and quasi-modular pieces. The precise alignment between the modular properties and fluxes in $H^{2,2}(Y_4)$, in relation to the overall geometry of the fourfold Y_4 , will be a main issue in the present paper and will be discussed later in detail.

Let us go through the various components of $[Z_{-1,m}^*]$ and briefly characterize their modular properties. The fully modular piece, $Z_{-1,m}^M$ in (1.6) is, by definition, given by some weak Jacobi form [33–35] (see Appendix A.1). The quasi-modular piece, $Z_{-1,m}^{QM}$, is a benign modification, the only difference being that it is a quasi-modular and not fully modular Jacobi form. By this we mean that besides the ordinary modular Eisenstein series E_4 and E_6 , also the quasi-modular series E_2 appears. As is familiar, this mild violation of modularity can be repaired by replacing E_2 by its modular, but non-holomorphic cousin

$$\hat{E}_2 = E_2 - \frac{3}{\pi \text{Im}\tau}, \quad (1.7)$$

which transforms uniformly with modular weight two. In field theoretic terms, this reflects a regularization ambiguity in the zero mode sector, which is resolved by imposing modular invariance at the expense of holomorphicity.

This is just a manifestation of the celebrated holomorphic anomaly [78], which has many manifestations in physics. In the present context (and for genus-zero invariants) it is well-known [40, 50, 79–83] to mean that the base curve $C_b = C^0$, which corresponds to the heterotic string, splits over certain subloci: $C^0 = C_E^1 + C_E^2$. The curves C_E^i in turn are associated with non-critical E-strings, and the split just reflects the fact that the heterotic string can fractionate into two E-strings [45]. In the dual heterotic language these correspond to having extra 5-branes in the geometry, which means that the quasi-modular sector of the theory is intrinsically non-perturbative as seen from the heterotic perspective. As we will discuss later in Section 4, this will have also a non-trivial bearing on anomaly cancellation, which is closely tied to the modular properties of the elliptic genus.

Finally, most peculiar and thus most interesting is the last component of the elliptic genus, $Z_{-1,m}^{QJ}$, in (1.6). It was found in [6] that it cannot be an ordinary modular or quasi-modular Jacobi form, since it does not obey the characteristic transformation properties (A.1) and (A.2). However it was observed that the coefficients of an expansion in powers of z are quasi-modular forms term by term, so that one can at least assign a uniform overall modular weight, $w = -1$, to it.

1.2 Summary of Present Work

The main new result of the present paper is that the component $Z_{-1,m}^{QJ}$ of the elliptic genus in (1.6) is actually also expressible in terms of the more familiar (quasi)-modular Jacobi forms,

⁶With “modular” (and similarly with “quasi-modular”) we refer in this context to the transformation properties of weak Jacobi forms, which comprise besides (A.1) also the double quasi-periodicity (A.2).

though in an intriguing way. Namely, it is given by a derivative

$$Z_{-1,m}^{QJ}(q, \xi) = \xi \frac{\partial}{\partial \xi} Z_{-2,m}(q, \xi) \quad (1.8)$$

of a partition function $Z_{-2,m}(q, \xi)$ of modular weight -2 and index m . Depending on the geometry it can be either a modular or quasi-modular weak Jacobi form. Thus, just like for the (quasi-)modular sector, the extra sector splits into two, namely into a perturbative and a non-perturbative piece, and we can refine the symbolic decomposition (1.6) as follows:

$$[Z_{-1,m}^*] = \left([Z_{-1,m}^M] \oplus [Z_{-1,m}^{QM}] \right) \oplus \xi \frac{\partial}{\partial \xi} \left([Z_{-2,m}^M] \oplus [Z_{-2,m}^{QM}] \right). \quad (1.9)$$

Accordingly, from now on we will refer to these extra components as the “derivative sector”, which by itself can come in a modular and quasi-modular version.

One main concern in the present paper will be to understand the mathematical origin and physical interpretation of this sector in terms of the underlying fourfold geometry and flux background. More concretely we aim to understand how the set of possible four-form fluxes maps into the space (1.9) of elliptic genera, i.e.,

$$[\mathbf{G}] \longrightarrow [Z_{-1,m}^*]. \quad (1.10)$$

This question will be addressed in Section 3, with special emphasis on geometries that are dual to heterotic strings in Section 3.2. In this concrete setting we can explicitly match the geometrical data to the decomposition (1.9) of the elliptic genus in terms of modular objects. Specifically, we anticipate, as described in our key equation (3.13), that

$$Z_{-1,m} = g^0 Z_{-1,m}^0 + g^E Z_{-1,m}^E + \sum_i g^i \frac{1}{2m} \xi \partial_\xi Z_{-2,m}^i, \quad (1.11)$$

where the index m is determined by a certain topological intersection product to be explained later. The flux-dependent coefficients, g^* , are intersection products as well and are given in eqs. (3.14). The first term in (1.11) represents the fully modular piece of the elliptic genus, while the second constitutes a possible non-perturbative, quasi-modular piece. It originates from a possible blowup of the base threefold, B_3 , which introduces an exceptional divisor, E , and is also associated with non-critical E-strings. As mentioned in the previous section, this generalizes well-known results in six dimensions [50, 82, 83]. The novel piece in four dimensions is then the derivative piece, which is in general given by a sum of terms, as labelled by i in (1.11).

In fact, the derivative structure nicely ties in with statements given in the mathematical literature [24, 25]. In particular it was proven in [24] that elliptic genera will in general lie in the ring of quasi-Jacobi forms, which is a broader notion than just Jacobi or quasi-modular Jacobi forms. It is easy to see from the definitions given in Appendix A, that $Z_{-1,m}^{QJ}$ in (1.8) yields a simple and concrete realization of such quasi-Jacobi forms, which explains the superscript. The paper [25] furthermore conjectured that the generating functions of relative BPS invariants in any elliptically fibered variety can generally be expressed in terms of quasi-Jacobi forms. Our results for Calabi-Yau fourfolds were found in an independent manner, and thus provide a nontrivial check of these conjectures.

Given that the derivative terms do not behave well under either $SL(2, \mathbb{Z})$ transformations (A.1) or under shifts (A.2), one might raise the point of consistency of the physical theories. Specifically the shift $z \rightarrow z + \lambda\tau$, $\lambda \in \mathbb{Z}$, which is a manifestation of spectral flow in the $U(1)$

$$\begin{array}{ccc}
\text{non-transversal flux in } H_{(0)}^{2,2}(Y_4, \mathbb{R}) : & \hat{Z}_{0,m}(q, \xi) & \\
& \downarrow \frac{\partial}{\partial \frac{\text{Im}z}{\text{Im}\tau}} & \\
\text{transversal } U(1) \text{ flux in } H_{(-1)}^{2,2}(Y_4, \mathbb{R}) : & \hat{Z}_{-1,m}(q, \xi) & \frac{\partial}{\partial \frac{1}{\text{Im}\tau}} \\
& \downarrow \frac{\partial}{\partial \frac{\text{Im}z}{\text{Im}\tau}} & \\
\text{non-transversal flux in } H_{(-2)}^{2,2}(Y_4, \mathbb{R}) : & \hat{Z}_{-2,m}(q, \xi) &
\end{array}$$

Figure 1: A sketch of the interplay between elliptic holomorphic anomalies and (almost holomorphic) partition functions, $\hat{Z}_{w,m}(q, \xi)$, pertaining to the various fluxes as classified in (2.17). Here $\hat{Z}_{-1,m}(q, \xi)$ is (the non-holomorphic cousin of) the elliptic genus in four dimensions. Moreover $\hat{Z}_{-2,m}(q, \xi)$ encodes relative invariants of certain embedded threefolds \mathbb{Y}_3^i , which can, at least formally, be associated to elliptic genera in six dimensions.

sector of the theory, would seem to be broken for flux backgrounds that lead to derivative contributions to the elliptic genus.

This is analogous to the problem discussed in the previous section, where the quasi-modular Eisenstein series E_2 appears in the component $Z_{*,*}^{QM}$ of the elliptic genus. In that case, the cure for restoring modular invariance was to add a non-holomorphic piece to E_2 , replacing it by the modular, non-holomorphic weight-two Eisenstein series \hat{E}_2 as in (1.7). In the present context of quasi-Jacobi forms, we have a similar remedy: we can augment the derivative piece by introducing a non-holomorphic term, and declare the following to be the (“derivative” part of the) physical elliptic genus:⁷

$$\hat{Z}_{-1,m}^{QJ}(\tau, z) = \nabla_{z,m} Z_{-2,m}^*(\tau, z) \equiv \left(\partial_z + 4\pi i m \frac{\text{Im}z}{\text{Im}\tau} \right) Z_{-2,m}^*(\tau, z). \quad (1.12)$$

This restores not only the modular $SL(2, \mathbb{Z})$ symmetry (A.1), but also invariance under the shifts $z \rightarrow z + \lambda\tau$, $\lambda \in \mathbb{Z}$, ie., spectral flow. In other words, what we encounter here as a novel phenomenon, on top of the known modular anomaly, is an anomaly of the spectral flow which can be cancelled upon sacrificing holomorphicity.

As we will explain in Section 3.4, eq. (1.12) has an interpretation in terms of an elliptic generalization of the holomorphic anomaly equation [40, 50, 78–83]. It is analogous to the familiar holomorphic anomaly equation, which in essence states that given an almost holomorphic, modular function which depends on \hat{E}_2 , there is a functional identity between the non-holomorphic sector and a derivative with respect to E_2 . More specifically, we trivially infer from (1.12) that

$$\frac{\partial}{\partial \frac{\text{Im}z}{\text{Im}\tau}} \hat{Z}_{-1,m}^{QJ}(\tau, z) = 4\pi i m Z_{-2,m}^*(\tau, z). \quad (1.13)$$

The surprising point is that the image of the derivative yields the generating function of BPS invariants related to a *different* flux sector. Indeed we will find in Section 3.4 that the $Z_{-2,m}^i(\tau, z)$ coincide with invariants related to certain non-transversal fluxes, even though these have no

⁷This does not change the counting of states, since the q -expansion is defined in the regime $\text{Im}\tau \rightarrow \infty$.

interpretation in terms of gauge fluxes in four-dimensional F-theory! See Figure 1 for a sketch of the relations between the various flux sectors.

This makes contact with the work of [76, 77], where the BPS invariants induced by non-transversal fluxes have been observed to organise into quasi-modular partition functions. Moreover in ref. [77] a holomorphic anomaly equation was found that relates flux sectors associated with modular weights $w = 0$ and $w = -2$; the rightmost arrow in Figure 1 refers to this. Our result (1.13) relates the elliptic genus of weight $w = -1$ to a flux sector associated with modular weight $w = -2$. In fact, after translating our setup to the formalism [25], equation (1.13) turns out to be a manifestation of the elliptic holomorphic anomaly equation that was introduced in a more abstract form in that reference.

Moreover, we have found another, related interpretation of the $Z_{-2,m}^i(\tau, z)$: We will see that for certain geometries, the $Z_{-2,m}^i(\tau, z)$ are literally the elliptic genera of certain six-dimensional string theories. For example, in the context of solitonic heterotic strings, where the base threefold B_3 of the elliptic fourfold Y_4 is itself fibered over some surface, B_2 , the $Z_{-2,m}^i$ are labelled by curve classes C_i in B_2 . To each of these C_i we can associate a certain specific threefold, \mathbb{Y}_3^i , which is defined by the restriction of the fourfold to the pullback divisor $p^*(C_i)$ as follows:

$$\mathbb{Y}_3^i := Y_4|_{p^*(C_i)}. \quad (1.14)$$

Here $\{C^j\}$ denotes the basis of curves dual to the basis $\{C_k\}$ on B_2 . This geometric setup is schematically depicted in Figure 2. As we will argue in Section 3.2, the $Z_{-2,m}^i$ just encode the relative BPS invariants of these auxiliary threefolds. This alternative interpretation of the $Z_{-2,m}^i$ then provides an intriguing relationship between background fluxes in $H_{(-2)}^{2,2}$ and the enumerative geometry of the threefolds \mathbb{Y}_3^i . It also gives independent support to some of the conjectures of ref. [25].

In many cases, the embedded threefolds, \mathbb{Y}_3^i , can be Calabi-Yau by themselves for an appropriately chosen basis $\{C^i\}$. Since they are elliptically fibered as well, one can then associate to each of them a chiral, six-dimensional F-theory compactification. We will show that in this situation, the collection of the $Z_{-2,m}^i$ that feature in the sum (1.11) are nothing but the elliptic genera associated with these threefolds \mathbb{Y}_3^i . This phenomenon generalises also to non-critical strings which will be the subject of section 6.

More generally, however, it turns out that the embedded threefolds \mathbb{Y}_3^i are not necessarily Calabi-Yau. We nonetheless conjecture, and support with some arguments, that the $Z_{-2,m}^i$ continue to encode BPS invariants of the embedded threefolds, \mathbb{Y}_3^i . For these cases, an interpretation in terms of elliptic genera likely persists only as a formal analogy.

To support our considerations, we will present a detailed analysis of several examples. In Section 5.1 we will discuss an example where the derivative sector comprises two embedded threefolds both of which are Calabi-Yau. On the other hand, Section 5.2 shows an example with a single embedded threefold, which has negative anti-canonical bundle; the derivative piece of the elliptic genus can then be associated via duality, in a formal sense, to a certain elliptic surface with 36 singular fibers. Furthermore we see in examples that the derivative structure appears even more broadly, and also applies to elliptic genera of non-critical strings. This suggests, as stated in Conjecture 2, that it is a general feature of elliptic genera in four dimensions. In Section 6 we will see how it applies to what we will call *four-dimensional E-strings*,⁸ as well as to a non-critical string arising from a D3-brane wrapping a curve on $B_3 = \mathbb{P}^3$.

⁸It would be interesting to make explicit the relation of these four-dimensional theories to the compactifications of 6d E-string theories with flux, whose study was initiated in [84].

Figure 2: *The derivative contribution to the elliptic genus of a four-dimensional string is captured, in suitable situations, by the relative BPS invariants of certain threefolds \mathbb{Y}_3^i inside the given elliptic fourfold Y_4 . Here we present a sketch of how these threefolds are embedded for the example of a heterotic string. The heterotic string arises in this F-theory geometry from a D3-brane that wraps the rational fiber C^0 in the base threefold, $B_3 \subset Y_4$. The extra two-form fields B_i that are needed for reinstating Green-Schwarz anomaly cancellation arise by expanding the ten-dimensional four-form, \mathbf{C}_4 , with respect to the divisor classes $p^*(C^i)$ for $i = 1, \dots, h^{1,1}(B_2)$.*

From a physics perspective, one may wonder about the Green-Schwarz cancellation of the $U(1)$ gauge anomaly, which is known to be closely tied to the modular properties of the elliptic genus. For the example of a flux background that is dual to the heterotic string, we will show in Section 4 that anomaly cancellation persists also when derivative pieces are present, albeit in a modified way.

As we will recall in Section 4.1, the modular properties of the elliptic genus underlie the standard Green-Schwarz mechanism which involves the universal B -field. The derivative terms in the elliptic genus, Z_{-2}^i , appear precisely when, depending on the geometry and flux, further 2-form fields B_i contribute to the Green-Schwarz mechanism [85].⁹ The additional 2-form fields arise from the curve classes C_i in the base threefold B_2 , which also determine, as per (1.14), the corresponding elliptic threefolds \mathbb{Y}_3^i . To close the circle of ideas, the threefolds in turn encode the BPS invariants pertaining to the i^{th} derivative sector of the elliptic genus, and altogether everything conspires such that anomalies are cancelled.

2 Geometric Foundations

In Section 2.1 we briefly review the geometric definition of BPS invariants for curves on Calabi-Yau fourfolds and their computation via mirror symmetry. In Section 2.2 we then specialise to the relative BPS invariants on elliptic fibrations in the presence of fluxes. These concepts become particularly important in light of F-theory/heterotic duality, whose salient geometric manifestation we recall in Section 2.3.

⁹For clarity we neglect here the quasi-modular sector, which brings in its own B -fields, as explained in Section 4.1.

2.1 BPS Invariants on Calabi-Yau Fourfolds

In this work we investigate the structure of certain integral BPS invariants for Calabi-Yau fourfolds, Y_4 , which are analogous to the familiar integral BPS invariants on Calabi-Yau threefolds. There are two ways to approach the definition of the invariants, either on purely geometric grounds or via mirror symmetry, and we will briefly review both. For more details we refer e.g. to [74–77] and references therein.

We begin with the geometric approach by first defining the (in general rational) Gromov-Witten invariants of a Calabi-Yau fourfold. Consider a curve class $C \in H_2(Y_4, \mathbb{Z})$ and the moduli space of stable holomorphic maps from a Riemann surface of genus g to C with s points fixed, denoted as $\overline{\mathcal{M}}_{g,s}$. This moduli space has expected or virtual (complex) dimension $\dim_{\text{vir}}(\overline{\mathcal{M}}_{g,s}) = 1 - g + s$. For genus $g = 0$ and $s = 1$, the virtual dimension of $\overline{\mathcal{M}}_{g,s}$ is two and thus one can define a topological invariant by, loosely speaking, integrating a suitably quantized element $\mathbf{G} \in H^4(Y_4, \mathbb{R})$ over the moduli space. More precisely, following [74] we denote by μ the virtual fundamental class of $\overline{\mathcal{M}}_{0,1}$ associated with a curve C (with one point fixed). Then this defines the genus-zero Gromov-Witten invariants $n_{\mathbf{G}}(C)$ of C with respect to \mathbf{G} as

$$n_{\mathbf{G}}(C) = \int_{\mu} \text{ev}^*(\mathbf{G}), \quad (2.1)$$

where ev^* is the evaluation map applied to \mathbf{G} . By holomorphicity, this integral is non-zero only if $\mathbf{G} \in H^{2,2}(Y_4, \mathbb{R})$. While Gromov-Witten invariants are in general not integral, there exist related integral BPS invariants for fourfolds which are analogues of the integral BPS invariants of threefolds [86–88]. This was first conjectured in [75] and proven for $g = 0$ in [89]. We will denote these integral BPS invariants by $N_{\mathbf{G}}(C)$. At genus zero, and as long as we do not consider multiples of curve classes, the two notions of invariants are equivalent; throughout this work we will be in this situation and can hence use both notions of invariants interchangeably.

The BPS invariants $N_{\mathbf{G}}(C)$ can be computed by mirror symmetry [90, 91], by interpreting the Calabi-Yau fourfold Y_4 as the compactification space of Type IIA string theory to two dimensions, and the element $\mathbf{G} \in H^{2,2}(Y_4, \mathbb{R})$ as a four-form background flux. The space $H^{2,2}(Y_4, \mathbb{R})$ of supersymmetric flux backgrounds admits a decomposition [90, 92]

$$H^{2,2}(Y_4, \mathbb{R}) = H_{\text{vert}}^{2,2}(Y_4, \mathbb{R}) \oplus H_{\text{hor}}^{2,2}(Y_4, \mathbb{R}) \oplus H_{\text{rest}}^{2,2}(Y_4, \mathbb{R}), \quad (2.2)$$

where the vertical subspace $H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$ is generated by all products of two elements in $H^{1,1}(Y_4)$, while the horizontal subspace $H_{\text{hor}}^{2,2}(Y_4, \mathbb{R})$ is obtained by the variation of Hodge structure from the unique $(4, 0)$ -form on Y_4 . In a flux background given by $\mathbf{G} \in H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$, the $N = (2, 2)$ supersymmetric compactification of Type IIA string theory on Y_4 is partially determined by the free energy, $\mathcal{F}_{\mathbf{G}}(t)$, which depends holomorphically on the Kähler moduli t^a , $a = 1, \dots, h^{1,1}(Y_4)$. The two-point functions for the chiral fields in the effective action associated with the Kähler moduli are then given by [91, 93]

$$C_{ab, \mathbf{G}} = \partial_a \partial_b \mathcal{F}_{\mathbf{G}}(t). \quad (2.3)$$

The free energy $\mathcal{F}_{\mathbf{G}}(t)$, which plays the rôle of a superpotential in two dimensions, encodes the genus-zero invariants as follows: Define first the variables

$$q_a = e^{2\pi i t_a}, \quad a = 1, \dots, h^{1,1}(Y_4), \quad (2.4)$$

and expand a given curve class C_{β} in terms of the basis C_a of $H_2(Y_4)$ with complexified volumes t^a ,

$$C_{\beta} = \beta^a C_a. \quad (2.5)$$

Hence to each curve C_β one can associate the product

$$q_\beta = q_1^{\beta^1} \cdots q_{h^{1,1}(Y_4)}^{\beta^{h^{1,1}(Y_4)}}. \quad (2.6)$$

The free energy $\mathcal{F}_G(t)$ then enjoys a worldsheet instanton expansion of the form

$$\mathcal{F}_G(t) = \sum_{\beta} N_G(C_\beta) \text{Li}_2(q^\beta), \quad N_G(C_\beta) \in \mathbb{Z}, \quad (2.7)$$

where we have suppressed possible classical pieces which are polynomial in t_a . The function $\mathcal{F}_G(t)$, and hence the invariants $N_G(C_\beta)$, can in turn be computed by mirror symmetry: Type IIA string theory on Y_4 with flux $\mathbf{G} \in H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$ is dual to Type IIA string theory on the mirror \tilde{Y}_4 with a dual flux $\tilde{\mathbf{G}} \in H_{\text{hor}}^{2,2}(Y_4, \mathbb{R})$. Under the mirror map the free energy $\mathcal{F}_G(t)$ maps to

$$\mathcal{F}_{\tilde{\mathbf{G}}} = \int_{\tilde{Y}_4} \tilde{\mathbf{G}} \wedge \tilde{\Omega}^{4,0}, \quad (2.8)$$

which is a holomorphic function of the complex structure moduli of \tilde{Y}_4 . It is, in principle, exactly computable as a period integral, which eventually determines the invariants $N_G(C_\beta)$. For more details see [91, 93–95].

2.2 Relative BPS Invariants on Elliptic Calabi-Yau Fourfolds

We now focus on invariants $N_G(C_\beta)$ of those Calabi-Yau fourfolds Y_4 which admit an elliptic fibration of the form

$$\begin{array}{ccc} \pi : & \mathbb{E}_\tau & \rightarrow & Y_4 \\ & & & \downarrow \\ & & & B_3 \end{array} \quad (2.9)$$

The base B_3 of the fibration is a Kähler threefold, which, in order for such a fibration to exist, must have an effective anti-canonical divisor, \bar{K}_{B_3} .

As we will see, for certain choices of curve class C_β and flux \mathbf{G} , the genus-zero invariants $N_G(C_\beta)$ admit yet another interpretation in terms of an elliptic genus of a string. To arrive at this interpretation, we view the Kähler threefold B_3 as the compactification space of F-theory [96] to four dimensions. Compactification of this theory on a further circle, S_F^1 , gives rise to a theory in three dimensions, which coincides with M-theory compactified on Y_4 .¹⁰

We will furthermore assume that the gauge group of the four-dimensional F-theory is non-trivial. For any non-abelian factor G of the gauge group, there must be a divisor b_G on B_3 which is wrapped by a stack of 7-branes. For the geometry of Y_4 , this implies that the generic elliptic fiber \mathbb{E}_τ splits into several holomorphic curves over b_G . In the dual M-theory picture, M2-branes wrapping these fibral curves give rise to the non-abelian gauge bosons that are not in the Cartan subalgebra of G . The fibral curves may split further over curves on b_G , in which case additional matter fields charged under G appear. Even for $G = U(1)$, massless charged matter exists only if the elliptic fiber splits over certain curves on B_3 .

¹⁰The following well-known elements of F-theory are reviewed for example in [97, 98], to which we refer for details and original references.

For definiteness we now focus on gauge group $G = U(1)$. Geometrically, in such situation the fourfold Y_4 then exhibits an extra rational section, S , in addition to the zero-section, S_0 . Associated with S is the divisor class

$$\sigma \equiv \sigma(S) \in H^{1,1}(Y_4), \quad (2.10)$$

which is the image of the Shioda map. It has the defining properties that

$$\sigma \circ \pi^* w_6 = 0, \quad \sigma \circ S_0 \circ \pi^* w_4 = 0 \quad \forall w_6 \in H^6(B_3), \quad w_4 \in H^4(B_3). \quad (2.11)$$

Here and in what follows we use the notation \circ for the intersection product on Y_4 , i.e.,

$$w_a \circ w_b \circ \dots \circ w_{8-a-b-\dots} = \int_{Y_4} w_a \wedge w_b \wedge \dots \wedge w_{8-a-b-\dots}. \quad (2.12)$$

Given σ we can expand the M-theory 3-form as $C_3 = A \wedge \sigma + \dots$, where the 1-form field A becomes the $G = U(1)$ gauge potential in the dual M-theory.

In the language of Type IIB/F-theory, the abelian gauge group is associated with a linear combination of 7-branes, each wrapping a 4-cycle on B_3 . The linear combination of four-cycles associated with the $U(1)$ in this way can be identified with the so-called height-pairing

$$b_{U(1)} \equiv b = -\pi_*(\sigma \circ \sigma). \quad (2.13)$$

As mentioned before, in addition to the gauge potential there will in general be a collection of massless charged matter fields. In the Type IIB/F-theory picture, massless $N = 1$ chiral multiplets with

$$U(1) \text{ charge } Q = r \quad (2.14)$$

arise from open strings stretched between the 7-branes. The open strings give rise to massless states of charge r which are localized on certain (self-)intersecting curves of the 7-branes on B_3 . We will call these ‘‘matter curves’’ and denote them by Σ_r . In the M-theory picture, the charged matter fields are obtained by wrapping M2-branes on curves C_r^f which sit in the fiber of Y_4 over Σ_r . Their charges are determined by the intersection product with the Shioda map:

$$r = \sigma \circ C_r^f. \quad (2.15)$$

Apart from the geometry intrinsic to the fourfold Y_4 , the effective theory also depends on the background flux, which, via the duality to M-theory, is encoded in a flux $\mathbf{G} \in H^4(Y_4, \mathbb{R})$ in M-theory. It is quantized such that $\mathbf{G} + \frac{1}{2}c_2(Y_4) \in H^4(Y_4, \mathbb{Z})$. Importantly for us, the primary vertical subspace $H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$, as sketched in (2.2), receives additional structure if Y_4 is elliptically fibered. In this case, $H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$ is spanned by three different types of 4-forms which can be characterised as follows:

$$H_{\text{vert}}^{2,2}(Y_4, \mathbb{R}) = H_{(0)}^{2,2}(Y_4, \mathbb{R}) \cup H_{(-1)}^{2,2}(Y_4, \mathbb{R}) \cup H_{(-2)}^{2,2}(Y_4, \mathbb{R}) \quad (2.16)$$

with

$$\begin{aligned} H_{(0)}^{2,2}(Y_4, \mathbb{R}) &= \langle (S_0 + \frac{1}{2}\pi^*(\bar{K}_{B_3})) \wedge \pi^*(w_i) \rangle \\ H_{(-1)}^{2,2}(Y_4, \mathbb{R}) &= \langle \sigma(S) \wedge \pi^*(w_i) \rangle \\ H_{(-2)}^{2,2}(Y_4, \mathbb{R}) &= \langle \pi^*(w_i) \wedge \pi^*(w_j) \rangle. \end{aligned} \quad (2.17)$$

Here $\{w_i\}$ is a basis of $H^{1,1}(B_3)$, S_0 denotes the zero-section and $\sigma(S)$ the Shioda map image associated with the additional independent section S , as before. Note that not all elements in the set $\{\pi^*(w_i) \wedge \pi^*(w_j)\}$ are linearly independent within $H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$. As will become clear later, the subscript in $H_{(w)}^{2,2}(Y_4, \mathbb{R})$ refers to the modular weight w of the partition function, $Z_{w,m}$, that is associated with the given flux.

Of special importance for us is the so-called transversal subspace $H_{(-1)}^{2,2}(Y_4, \mathbb{R})$ of $H_{\text{vert}}^{2,2}(Y_4)$. It is orthogonal to the other two subspaces in (2.17), i.e., a flux $\mathbf{G} \in H_{(-1)}^{2,2}(Y_4, \mathbb{R})$ by definition satisfies the two conditions

$$\mathbf{G} \circ \pi^*(w_i) \circ \pi^*(w_j) = 0, \quad \mathbf{G} \circ S_0 \circ \pi^*(w_i) = 0 \quad \forall w_i \in H^{1,1}(B_3). \quad (2.18)$$

The transversality conditions (2.18) ensure that the flux \mathbf{G} , which is a priori defined as background in the M-theory compactification on Y_4 , is compatible with the duality to F-theory on B_3 , in the sense of giving rise to a four-dimensional effective theory with full Poincaré invariance in $\mathbb{R}^{1,3}$. Such transversal fluxes related to the $U(1)$ symmetry will be denoted by

$$\mathbf{G}_{U(1)} = \sigma \wedge \pi^*(F), \quad F \in H^{1,1}(B_3). \quad (2.19)$$

All other elements in $H_{\text{vert}}^{2,2}(Y_4)$, while corresponding to valid flux backgrounds in M-theory or Type IIA string theory, are not liftable to F-theory. In the more general context of M-theory/Type IIA string theory on Y_4 , one can in any case analyse the BPS invariants of an elliptic fibration in a non-transversal flux background, as pioneered in [76, 77].

Let us now recall how the transversal fluxes determine the chiral index of massless charged matter in the context of four-dimensional F-theory compactifications [97]. As noted above, massless matter fields with $U(1)$ charge $Q = r$ are localised on a curve Σ_r on the base B_3 . The fiber over Σ_r contains the curve C_r^f , and an M2-brane wrapping C_r^f gives rise to a BPS particle in the dual M-theory picture. In fact, the fibration of C_r^f defines a surface $\hat{\Sigma}_r$,

$$\begin{array}{ccc} \pi_r : & C_r^f & \rightarrow & \hat{\Sigma}_r \\ & & & \downarrow \\ & & & \Sigma_r \end{array} \quad (2.20)$$

in terms of which the chiral index of massless matter of charge $Q = r$ is computed as

$$\chi_{\mathbf{G}_{U(1)}, Q=r} = n_r^+ - n_r^- = \int_{\hat{\Sigma}_r} \mathbf{G}_{U(1)} = r \int_{\Sigma_r} F = r (\Sigma_r \cdot F). \quad (2.21)$$

The third equality is a consequence of the factorized form (2.19). Furthermore we have introduced, after the last equality, the intersection product on B_3 that we will henceforth denote by a dot.

In fact, the integral invariant $\chi_{\mathbf{G}_{U(1)}, Q=r}$ is exactly the genus-zero Gromov-Witten invariant for the fibral curve C_r^f with respect to $\mathbf{G}_{U(1)}$ [6],

$$\chi_{\mathbf{G}_{U(1)}, Q=r} = n_{\mathbf{G}_{U(1)}}(C_r^f) = N_{\mathbf{G}_{U(1)}}(C_r^f). \quad (2.22)$$

The first equation follows from the geometric definition (2.1) because the moduli space of C_r^f with one point fixed coincides with the surface $\hat{\Sigma}_r$. The second equation holds because for the rational curves in the fiber, $C_r^f = r C_{r=1}^f$ in cohomology; if $n_{\mathbf{G}_{U(1)}}(C_r^f) \neq 0$, there must exist an actual curve in this class in the fiber. Hence the non-vanishing invariants $n_{\mathbf{G}_{U(1)}}(C_r^f) \neq 0$ do not involve multiple wrappings and therefore agree with the BPS invariants $N_{\mathbf{G}_{U(1)}}(C_r^f)$.

More generally, we are interested in the structure of genus-zero integral BPS invariants for curves of the form

$$\mathbf{C} = C_b + n \mathbb{E}_\tau + C_r^f, \quad (2.23)$$

with respect to fluxes in $H_{\text{vert}}^{2,2}(Y_4)$ that satisfy (2.18). We denote these invariants as

$$N_{\mathbf{G}}[C_b + n \mathbb{E}_\tau + C_r^f] =: N_{\mathbf{G};C_b}(n, r). \quad (2.24)$$

As long as C_b is not a multiple of an integral curve class on B_3 , these integral invariants coincide with the Gromov-Witten invariants for the same curve. They are called the *relative Gromov-Witten* invariants with respect to the elliptic fibration π .

These integral invariants can be packaged into a generating function

$$\mathcal{F}_{\mathbf{G};C_b} = \sum_{n,Q} N_{\mathbf{G};C_b}(n, r) q^n \xi^r. \quad (2.25)$$

Here we have defined the variables

$$q = e^{2\pi i \tau}, \quad \xi = e^{2\pi i z}, \quad (2.26)$$

where τ is the Kähler parameter of the generic elliptic fiber \mathbb{E}_τ and z is the Kähler parameter of the fibral curve $C_{r=1}^f$. From the perspective of Type IIA string theory on Y_4 , $\mathcal{F}_{\mathbf{G};C_b}$ contributes to the two-dimensional superpotential $\mathcal{F}(t)$, as defined in (2.7).

As stressed above, in the context of F-theory we must insist that \mathbf{G} is a transversal flux. Under this proviso, (2.25) coincides with the elliptic genus of a four-dimensional solitonic string (up to a prefactor), as will be explained in Section 3.1. On the other hand, for Type IIA compactifications on fourfolds, there is no restriction to transversal flux backgrounds, and one can consider generating functions (2.25) for the other, non-transversal types of flux as well. As exemplified in [76,77], the partition functions for fluxes in $H_{(-2)}^{2,2}(Y_4)$ and $H_{(0)}^{2,2}(Y_4)$ are meromorphic (quasi-)modular forms of weight -2 and 0 , respectively.

2.3 \mathbb{P}^1 -Fibered Base Spaces and F-Theory/Heterotic Duality

As a special case of the structure outlined in the previous section, we now consider the situation where the base space B_3 by itself admits a further, rational fibration with section S_- , possibly blown up along one or several curves on the section. The projection of the rational fibration will be denoted by

$$p: \quad C^0 \rightarrow \begin{array}{c} B_3 \\ \downarrow \\ B_2 \end{array} \quad (2.27)$$

The generic fiber is some rational curve C^0 . Prior to performing any blowup, the fibration can be understood as the projectivised bundle $\mathbb{P}(\mathcal{O} \oplus \mathcal{L})$, where \mathcal{L} is a line bundle on B_2 . This means that the section S_- , which is oftentimes referred to as an exceptional section, has self-intersection $S_- \cdot S_- = -S_- \cdot p^*(c_1(\mathcal{L}))$. One can therefore define another section $S_+ := S_- + p^*c_1(\mathcal{L})$ such that

$$S_- \cdot S_+ = S_- \cdot (S_- + p^*c_1(\mathcal{L})) = 0. \quad (2.28)$$

We can also perform an optional blowup along some curve Γ_a in the base B_2 . After the blow-up, the rational fiber C^0 over the curve Γ_a splits into two rational curves,

$$C^0 = C_{E_a}^1 + C_{E_a}^2. \quad (2.29)$$

The blowup introduces an exceptional divisor E_a , which is itself a \mathbb{P}^1 -fibration over Γ_a . We label the curves $C_{E_a}^1$ and $C_{E_a}^2$ such that $C_{E_a}^2$ is the fiber of the divisor E_a . With this convention the intersection numbers of the exceptional curves $C_{E_a}^{1,2}$ with the sections S_{\pm} and with E_a become

$$\begin{aligned} S_{\pm} \cdot C^0 &= 1, & S_{\pm} \cdot C_{E_a}^1 &= 1 & S_{\pm} \cdot C_{E_a}^2 &= 0 \\ E_a \cdot C^0 &= 0, & E_a \cdot C_{E_a}^1 &= 1 & E_a \cdot C_{E_a}^2 &= -1. \end{aligned} \tag{2.30}$$

This process can of course be repeated for several different curves Γ_a and followed up by successive blowups in the fiber. For simplicity of presentation, however, we assume only one such blow-up locus and hence drop the label a .

Whenever the base B_3 is endowed with such a \mathbb{P}^1 -fibration, F-theory on B_3 has a clearly identifiable heterotic dual [99]. Viewed from the dual, weakly coupled eigenframe, the heterotic string theory appears as a four-dimensional compactification on a certain Calabi-Yau 3-fold \mathcal{Z}_3 . The latter is elliptically fibered over the same base B_2 as before,

$$\begin{array}{ccc} \rho : \mathbb{E}_{\text{het}} & \rightarrow & \mathcal{Z}_3 \\ & & \downarrow \\ & & B_2 \end{array} \tag{2.31}$$

Apart from the geometry of \mathcal{Z}_3 , the dual heterotic theory is determined by a gauge background in form of some polystable $E_8^1 \times E_8^2$ bundle $W = V_1 \oplus V_2$. The particular choice of background depends both on the details of the elliptic fibration Y_4 and on the original F-theory background flux, $\mathbf{G}_{U(1)}$.

Moreover, the optional blow-up along the curve Γ on B_2 on the F-theory side translates to heterotic 5-brane that is wrapped on the same curve Γ in B_2 , now viewed as the base of the heterotic 3-fold \mathcal{Z}_3 . Such compactifications are inherently non-perturbative from the heterotic perspective.

3 Elliptic Genera and the Geometry of Modularity

We are now in a position to discuss the identification of the relative BPS invariants, defined in the previous section, with the degeneracies of states contributing to the elliptic genus of four-dimensional solitonic strings. We state this connection in Conjecture 1 of Section 3.1, which is a four-dimensional version of the correspondence between BPS invariants and elliptic genera in six dimensions [4, 39–44, 49, 50, 57, 61–63, 65, 65, 70–73]. In Conjecture 2 of Section 3.2 we present the modular properties of the four-dimensional elliptic genus. In Section 3.3 we point out an intriguing relation between the derivative sector of the elliptic genus and the BPS invariants of certain threefolds embedded in the Calabi-Yau fourfold. In Section 3.4 we explain how these threefold invariants can alternatively be computed from the non-transversal (-2) -fluxes, even though these do not have a direct interpretation in F-theory. This leads to an elliptic holomorphic anomaly equation.

3.1 The Elliptic Genus of Solitonic Strings in Four Dimensions

From a physical point of view, the main objective of this paper is to obtain a better understanding of four-dimensional critical and non-critical strings. This crucially rests on the observation, which was already put to use in [6], that the generating function (2.25) for the relative genus-zero Gromov-Witten invariants coincides, up to a factor, with the elliptic genus of a solitonic

string. The aim of this section is to spell out this relationship in greater detail and formulate it as a general conjecture that, supposedly, applies to all four-dimensional solitonic strings.

Let us first start by discussing how the solitonic strings arise in our context. Consider an F-theory compactification with base space B_3 . A D3-brane wrapped on a curve C_b in the base B_3 gives rise to a string in the four-dimensional extended spacetime. The worldsheet theory of this string is an $N = (0, 2)$ supersymmetric field theory [100]. One can now define the elliptic genus, as in (1.1), as a trace in the Ramond-Ramond sector of the $N = (0, 2)$ superconformal worldsheet theory of the solitonic string, or equivalently as a partition function on a torus with modular parameter τ . As before, we consider a configuration with four-dimensional gauge group $G = U(1)$, associated with charge operator J . Then the elliptic genus takes the form (1.1):

$$Z_{\mathbf{G}_{U(1)};C_b}(q, \xi) = \text{tr}_{RR} [(-1)^{F_R} F_R q^{H_L} \bar{q}^{H_R} \xi^J] , \quad q = e^{2\pi i \tau}, \quad \xi = e^{2\pi i z}, \quad (3.1)$$

where F_R is the right-moving fermion number. The extra insertion of F_R is needed to saturate the fermionic zero modes in the right-moving sector. The elliptic genus does not only depend on the choice of curve wrapped by the D3-brane, but also on the background flux $\mathbf{G}_{U(1)}$ of the parent F-theory compactification. In order for an F-theory interpretation to exist, this flux must satisfy the transversality conditions (2.18).

As a consequence of the supersymmetry in the right-moving sector, the trace (3.1) is a meromorphic function of q and ξ . It can be expanded as

$$Z_{\mathbf{G}_{U(1)};C_b} = -q^{E_0} \sum_{n \geq 0, r} \mathcal{N}_{\mathbf{G}_{U(1)};C_b}(n, r) q^n \xi^r , \quad (3.2)$$

where

$$E_0 = -\frac{1}{2} \bar{K}_{B_3} \cdot C_b \quad (3.3)$$

is the zero point energy of the string on \mathbb{T}^2 . As we will discuss in a few moments, the degeneracies $\mathcal{N}_{\mathbf{G}_{U(1)};C_b}(n, r)$ at level n and charge r for the flux background $\mathbf{G}_{U(1)}$, are conjectured to agree with the relative BPS invariants $N_{\mathbf{G}_{U(1)};C_b}(n, r)$ that we have defined in the previous section.

For a general curve C_b , the solitonic string that arises from a wrapped D3-brane is generically some strongly coupled, non-critical string in four dimensions [91]. We can distinguish three possible types of strings. First, if C_b is a shrinkable curve, we can decouple the dynamics of the string from the fields in the bulk of the base B_3 by taking the volume of B_3 to infinity. In this case we arrive at a four-dimensional superconformal field theory in the limit of decoupled gravity. An example of such a string would be a D3-brane wrapped on an exceptional curve. For instance, this can be of the form $C_b = C_{E_a}^{1,2}$ as defined in (2.29), with normal bundle $N_{C_b/B_3} = \mathcal{O}_{C_b}(-1) \oplus \mathcal{O}_{C_b}$. Such strings could be viewed as four-dimensional analogs of the familiar E-strings in six dimensions [101–103] and will be discussed in Section 6.1.

There are also non-critical strings associated with curves whose volume cannot be taken to zero without shrinking B_3 . Such non-critical strings cannot be decoupled from gravity. An example would be for instance a curve $C_b = H \cdot H$, where H is the hyperplane class on $B_3 = \mathbb{P}^3$. For this curve the normal bundle is $N_{C_b/B_3} = \mathcal{O}_{C_b}(1) \oplus \mathcal{O}_{C_b}(1)$. This example will be investigated in Section 6.2.

Finally, the case where $N_{C_b/B_3} = \mathcal{O}_{C_b} \oplus \mathcal{O}_{C_b}$ is special: The curve C_b must be the fiber, C^0 , of either a rational fibration of the form (2.27) or of an elliptic fibration. In the first case, a D3-brane wrapped on C^0 gives rise to a solitonic, critical heterotic string.¹¹ In its proper duality eigenframe, this string becomes precisely the fundamental heterotic string compactified on the threefold \mathcal{Z}_3 as given in (2.31), additionally equipped with some gauge bundle W . Moreover the elliptic genus (3.1), as defined via the \mathbf{G} -flux background in F-theory, turns into the (not necessarily perturbative) chiral partition function of that heterotic string compactification. More precisely, the degeneracy $\mathcal{N}_{\mathbf{G};C^0}(n, r)$ counts (with signs) the excitations in the Ramond sector at excitation level n and charge r .

For the critical heterotic string, the vacuum energy in (3.2) is $E_0 = -\frac{1}{2}C^0 \cdot \bar{K}_{B_3} = -1$. The mass of the physical states at excitation level n thus is

$$M^2 = 8\pi T(n - 1), \quad (3.4)$$

where T is the tension of the heterotic string. This identifies $\mathcal{N}_{\mathbf{G}_{U(1)};C^0}(1, r)$ as the chiral index over the massless states of charge r . By duality with F-theory, this spectrum must coincide with the physical massless spectrum in the original F-theory compactification on Y_4 , and therefore the index $\mathcal{N}_{\mathbf{G}_{U(1)};C^0}(1, r)$ must agree with the chiral index (2.21):

$$\chi_{\mathbf{G}_{U(1)},r} = \mathcal{N}_{\mathbf{G}_{U(1)};C^0}(1, r). \quad (3.5)$$

Furthermore recall from (2.22) that $\chi_{\mathbf{G}_{U(1)},r}$ coincides with the genus-zero Gromov-Witten invariant for the fibral curve $C_{Q=r}^f$, which in turn is the same as the BPS invariant $N_{\mathbf{G}_{U(1)}}(C_r^f)$.

This demonstrates that the degeneracies $\mathcal{N}_{\mathbf{G}_{U(1)};C^0}(n = 1, r)$ are computable from certain BPS invariants of Y_4 for the special case of $C_b = C^0$ for which $\mathcal{N}_{\mathbf{G}_{U(1)};C^0}(1, r) = N_{\mathbf{G}_{U(1)}}(C_r^f)$. With the situation in six dimensions serving as inspiration, it is natural to conjecture a far more general connection. More precisely, we conjecture that up to an overall factor of q^{E_0} , the elliptic genus (3.1) for *any* kind of solitonic string agrees with the generating function of relative BPS invariants (2.25) at genus zero:

Conjecture 1 *The generating function $\mathcal{F}_{\mathbf{G}_{U(1)},C_b}$ for the relative BPS invariants at genus zero associated with the base curve C_b , for any four-flux background $\mathbf{G}_{U(1)}$ that satisfies the transversality conditions (2.18), is proportional to the elliptic genus (3.1) for the solitonic string obtained by wrapping a D3-brane on C_b :*

$$Z_{\mathbf{G}_{U(1)};C_b} = -q^{-\frac{1}{2}C_b \cdot \bar{K}_{B_3}} \mathcal{F}_{\mathbf{G}_{U(1)};C_b}. \quad (3.6)$$

In particular the relative BPS invariants for C_b , $N_{\mathbf{G}_{U(1)};C_b}(n, r)$, agree with the index-like degeneracies $\mathcal{N}_{\mathbf{G}_{U(1)};C_b}(n, r)$ of the excitations of the solitonic string at level n and charge r :

$$\mathcal{N}_{\mathbf{G}_{U(1)};C_b}(n, r) = N_{\mathbf{G}_{U(1)};C_b}(n, r). \quad (3.7)$$

¹¹If C^0 is the fiber of an elliptically fibered base B_3 , we expect instead a Type II string dual in a non-geometric background. The six-dimensional version has been discussed in [8]. We will not investigate this type of strings further as their elliptic genus vanishes in four dimensions.

This statement is the analogue of the well-tested duality between certain free energies of elliptic Calabi-Yau threefolds and the elliptic genera of solitonic heterotic and non-critical strings in six dimensions. The new ingredient in four dimensions, of course, is the dependence on the F-theory four-form flux $\mathbf{G}_{U(1)}$ and its respective manifestation in the dual solitonic string.

As a corollary of this proposed general duality and eq. (3.5), the relative BPS invariants $N_{\mathbf{G}_{U(1)};C^0}(1, r)$, where C^0 is the fiber of the \mathbb{P}^1 -fibration B_3 , must agree with the chiral index of states of the F-theory compactification, and thus

$$N_{\mathbf{G}_{U(1)};C^0}(1, r) = N_{\mathbf{G}_{U(1)}}(C_r^f) = \chi_{\mathbf{G}_{U(1)},r}. \quad (3.8)$$

We will demonstrate this identity in the examples of Section 5, via explicit computations in mirror symmetry.

3.2 Modular Properties of Four-Dimensional Elliptic Genera

The elliptic genus has supposedly distinguished modular properties, which reflect its definition as a chiral partition function of a string wrapped on a torus \mathbb{T}^2 with modular parameter τ . For example, the elliptic genus of a perturbative heterotic string in $d = 6$ dimensions with a single $U(1)$ gauge group factor is a meromorphic Jacobi form of weight $w = -(d - 2)/2 = -2$ [26], as recalled in Section 1.1. For more general solitonic strings in six dimensions the elliptic genus is a meromorphic quasi-modular Jacobi form of weight $w = -2$ (see Appendix A). This applies in particular to solitonic strings that are dual to fundamental heterotic strings in the presence of 5-branes [4]. Such modular behaviour is in general agreement with the relation between the elliptic genus and the BPS invariants on elliptic Calabi-Yau threefolds, whose modular properties have been analyzed in [25, 82, 83, 104–106].

One might expect that this simple pattern carries over to the strings obtained by wrapped D3-branes in F-theory compactifications to $d = 4$ dimensions that we consider here. The expectation would be that the elliptic genus should be a meromorphic quasi-modular Jacobi form of weight $w = -(d - 2)/2 = -1$.

As noticed in [6] for the special case of a heterotic string, this is not necessarily the case. Rather, for some explicit examples studied in that work, it was found that the elliptic genus (3.1) can in general also receive contributions which are not given by modular or quasi-modular forms. One of the main observations of the present work is that these contributions, while not modular by themselves, can actually be written as derivatives of modular or quasi-modular Jacobi forms; recall the symbolic representation (1.9) given in the Introduction. Such objects are special examples of so-called *quasi-Jacobi* forms as defined in Appendix A. What we encounter is in fact a concrete realisation of the mathematical conjecture of [25] that relative GW invariants of elliptic fibrations generally assemble into generating functions with values in the ring of quasi-Jacobi forms. In Section 3.3 we will in addition assign a specific geometrical meaning to the (quasi)-modular Jacobi forms whose derivative appears in the elliptic genera, namely in terms of BPS invariants of certain embedded threefolds.

Extrapolating from these observations we make the following general proposal:

Conjecture 2 *The four-dimensional, $U(1)$ refined elliptic genus (3.1) can be written as a sum of meromorphic modular and quasi-modular Jacobi forms of weight $w = -1$ and fugacity index $m = \frac{1}{2}b \cdot C_b$, where b is the height-pairing divisor (2.13), plus derivatives of modular and quasi-modular Jacobi forms of weight $w = -2$ and the same fugacity index. More precisely,*

$$Z_{\mathbf{G}_{U(1);C_b}}(q, \xi) = g^M Z_{-1,m}^M(q, \xi) + g^{QM} Z_{-1,m}^{QM}(q, \xi) + g_{\partial}^M \xi \partial_{\xi} Z_{-2,m}^M(q, \xi) + g_{\partial}^{QM} \xi \partial_{\xi} Z_{-2,m}^{QM}(q, \xi), \quad (3.9)$$

where g^M , g^{QM} , g_{∂}^M , and g_{∂}^{QM} are flux-dependent coefficients and

$$Z_{-1,m}^{M/QM}(q, \xi) = \frac{\Phi_{w,m}^{M/QM}(q, \xi)}{\eta(q)^{12C_b \cdot \bar{K}_{B_3}}}, \quad Z_{-2,m}^{M/QM}(q, \xi) = \frac{\Phi_{w-1,m}^{M/QM}(q, \xi)}{\eta(q)^{12C_b \cdot \bar{K}_{B_3}}} \quad (3.10)$$

with $q = e^{2\pi i\tau}$ and $\xi = e^{2\pi iz}$. Here, the numerators $\Phi_{w,m}^{M/QM}(\tau, z)$ denote generic (quasi-)Jacobi forms of indicated weight and (integer) index given by

$$w = -1 + 6(C_b \cdot \bar{K}_{B_3}), \quad m = \frac{1}{2}(b \cdot C_b). \quad (3.11)$$

As mentioned in the Introduction, the novel (quasi-)modular partition functions $Z_{-2,m}^{M/QM}$ of weight $w = -2$ have the properties characteristic of elliptic genera of chiral, six-dimensional theories. Indeed, we will argue that they encode the relative BPS invariants of certain elliptic three-dimensional sub-manifolds, \mathbb{Y}_3 , of Y_4 .¹² In special cases, when the elliptic threefolds \mathbb{Y}_3 are themselves Calabi-Yau spaces, this assertion can be verified explicitly by mirror symmetry. More generally, we will provide various general consistency checks which support this claim also when \mathbb{Y}_3 is not a Calabi-Yau space. As we will demonstrate in Sections 5 and 6, the general structure we propose can be verified for a variety of examples, in particular for all the three different basic types of base curves, C_b , as characterised in Section 3.1.

Let us illustrate at this point the structure for the important example of the solitonic heterotic string. To this end consider a base B_3 of Y_4 which is the blow-up of a rational fibration (2.27), and for simplicity assume that the blow-up has been performed only over a single curve Γ in the base, B_2 , of this rational fibration. Our notation for this type of geometries has been introduced in Section 2.3. Again we take the gauge group to be $G = U(1)$, so that the only fluxes satisfying the transversality condition (2.18) are the $U(1)$ fluxes (2.19) given by

$$\mathbf{G} = \mathbf{G}_{U(1)} = \sigma \wedge \pi^*(F). \quad (3.12)$$

In this concrete situation, as exemplified in Section 5, one can write the elliptic genus of the heterotic string in the following geometric, closed form:

$$Z_{\mathbf{G}_{U(1);C^0}} = g^0 Z_{-1,m}^0 + g^E Z_{-1,m}^E + \sum_i g^i \frac{1}{2m} \xi \partial_{\xi} Z_{-2,m}^i, \quad (3.13)$$

with flux-dependent coefficients explicitly given by

$$g^0 = F \cdot C^0, \quad g^E = F \cdot C_E^1, \quad g^i = F \cdot b \cdot p^*(C_i). \quad (3.14)$$

¹²As will be clarified in Section 3.3, such a connection to the BPS invariants of three-folds in Y_4 , as defined by (3.19), necessarily arises when the base curve C_b is a fiber over either a surface or a curve. Additional supporting evidence for the latter situation is provided in Section 6.1. See also [107] for the argument in a most general setup.

Here C^0 and C_E^1 denote the curves defined around equation (2.29), the divisor b is the height-pairing as given in (2.13), and the set $\{C_i\}$ is a suitable basis of curves on the base B_2 of B_3 . The latter point will be explained in more detail in Section 3.3. Mathematical and physical constraints restrict the (quasi-) modular forms in (3.13) as follows:

$$\begin{aligned} Z_{-1,m}^0(q, \xi) &= \frac{1}{\eta^{24}(q)} \phi_{-1,2}(q, \xi) \Phi_{12,m-2}^{0,M}(q, \xi), \\ Z_{-1,m}^E(q, \xi) &= \frac{1}{\eta^{24}(q)} \phi_{-1,2}(q, \xi) \left[\Phi_{12,m-2}^{E,M}(q, \xi) + \phi_{-2,1}(q, \xi) E_2(q) \Phi_{12,m-3}^{E,QM}(q, \xi) \right], \\ Z_{-2,m}^i(q, \xi) &= \frac{1}{\eta^{24}(q)} \left[\Phi_{10,m}^{i,M}(q, \xi) + E_2(q) \Phi_{8,m}^{i,QM}(q, \xi) \right]. \end{aligned} \quad (3.15)$$

As always, $\Phi_{w,m}^{*,(Q)M}$ denotes a generic weak Jacobi form of specified weight and index, which can be written as a polynomial in the generators of the ring $J_{w,m}^{*,(Q)M}$ of (quasi-)modular Jacobi forms (see Appendix A.1).

Note that since the weight of the $Z_{-1,m}^*$ is odd, these objects are necessarily proportional to the unique odd-weight generator $\phi_{-1,2}$ of the ring of Jacobi forms. Furthermore, since $\phi_{-1,2} \sim z$, they vanish identically unless we refine the elliptic genus with regard to at least one $U(1)$ factor. Note also that there cannot be a $1/q$ pole in $Z_{-1,m}^*$ because the left-moving ground state is uncharged and so cannot be multiplied by z . Thus the $Z_{-1,m}^*$ are actually holomorphic in q and take a very restricted form, as indicated.

In summary, the relationship (3.13)–(3.15) between flux-dependent geometric intersection data on the one hand, and modular, quasi-modular and derivative sectors on the other, is one of the main results of the present work, and is a concrete manifestation of the map (1.10) mentioned in the Introduction.

3.3 Geometric Interpretation of the Derivative Sector of $Z_{-1,m}(q, \xi)$

We now point out an intriguing interpretation of the derivative contributions, $Z_{-2,m}^i(q, \xi)$, to the elliptic genus, namely in terms of BPS invariants of certain threefold geometries, \mathbb{Y}_3 , which are embedded in the given elliptic fourfold, Y_4 . For the example of the heterotic string, we will be able to explain this interpretation based on our understanding of the moduli space of at least some of the curves whose BPS invariants enter the elliptic genus. The relation between the derivative contributions and certain threefold invariants is, however, not restricted to heterotic strings, as we will show explicitly in Section 6.

To understand the heterotic setup, let us first assume that the Mori cone of effective curves on B_2 is simplicial and identify its generators with the basis $\{C_i\}$ on which the coefficients in the sum (3.13) depends via (3.14). We will drop the assumption of a simplicial Mori cone at the end of this section. The curve classes $b \cdot p^*(C_i)$ in (3.13) can be written as

$$b \cdot p^*(C_i) = 2m C_i + (\text{curve in the fiber of } B_3). \quad (3.16)$$

To see this, note that we can parametrise the height pairing divisor as $b = 2m S_- + b_E E + \sum_i b_i p^*(C_i)$, in agreement with $b \cdot C^0 = 2m$. Then (3.16) follows from the fact that $S_- \cdot p^*(C_i)$ gives back the curve class C_i on B_2 , while the intersection of $p^*(C_i)$ with the divisors E and $p^*(C_j)$ lie entirely in the fiber of the rational fibration B_3 .

Since the curves C_i are the generators of the Mori cone of B_2 , the dual curves C^i on B_2 are generators of the Kähler cone of B_2 , whose closure is contained in the closure of the cone of

effective curves. We assume for simplicity that the C^i are integral, leaving the discussion of a much more general setting to the end of this section. They are given by

$$C^i = \eta^{ij} C_j, \quad \text{where } \eta_{ij} = C_i \cdot_{B_2} C_j, \quad (3.17)$$

and have the important property, characteristic of generators of the Kähler cone, that

$$C^i \cdot_{B_2} C^j \geq 0. \quad (3.18)$$

In particular, since $C^i \cdot_{B_2} C^i \geq 0$, each curve C^i moves in a family on B_2 .

Now, from (3.16) we infer that the dual of the component of $b \cdot p^*(C_i)$ on B_2 is the curve $C^i/2m$. To arrive at integral classes, let us factor out $1/2m$ and consider the pullback $p^*(C^i)$ as a divisor on B_3 . Since each C^i moves in a family on B_2 , so does the divisor $p^*(C^i)$ on B_3 . We can then define a collection of elliptic threefolds, \mathbb{Y}_3^i , by restricting the elliptic fibration of Y_4 to the a *generic* member of this family of divisors:

$$\mathbb{Y}_3^i = Y_4|_{p^*(C^i)}. \quad (3.19)$$

Any single such threefold is by construction an elliptic fibration with projection

$$\pi_i : \mathbb{Y}_3^i \rightarrow \mathbb{B}_2^i, \quad \mathbb{B}_2^i = p^*(C^i). \quad (3.20)$$

In fact, the base $p^*(C^i)$ is a \mathbb{P}^1 -fibration over C^i with generic fiber C^0 (blown up at the intersection of Γ with C^i). See Figure 2 in the Introduction for an illustration.

Depending on whether $C^i \cdot_{B_2} C^i = 0$ or $C^i \cdot_{B_2} C^i > 0$, the anti-canonical bundle of \mathbb{Y}_3^i is either trivial or negative. This follows from the adjunction formula:

$$c_1(\bar{K}_{\mathbb{Y}_3^i}) = c_1(\bar{K}_{Y_4}|_{\mathbb{Y}_3^i}) - c_1(N_{\mathbb{Y}_3^i/Y_4}) = -\pi_i^*(p^*(C^i)|_{p^*(C^i)}) \leq 0. \quad (3.21)$$

Even if \mathbb{Y}_3^i is by itself not Calabi-Yau, we can consider the relative BPS invariants with respect to C^0 on \mathbb{Y}_3^i , denoted by $N_{C^0}^i(n, r)$, and package them into a generating function, $\mathcal{F}_{C^0}^i(\tau, z)$. We propose that these invariants determine the derivative pieces in the elliptic genus (3.13):

$$Z_{-2,m}^i(\tau, z) = -\frac{1}{q} \mathcal{F}_{C^0}^i(\tau, z) = -\frac{1}{q} \sum_{n,r} N_{C^0}^i(n, r) q^n \xi^r. \quad (3.22)$$

The $N_{C^0}^i$ are not to be confused with the invariants $N_{\mathbf{G};C^0}$ of the fourfold Y_4 discussed before, which were defined relative to a transversal four-form flux $\mathbf{G}_{U(1)}$. Rather, we claim that they are relative BPS invariants of a generic member, \mathbb{Y}_3^i , of the family of elliptic threefolds embedded inside Y_4 as in (3.19).

If we assume this, the general considerations of [25] imply that the generating function $Z_{-2,m}^i(\tau, z)$ should be a (quasi-)modular form of weight $w = -2$, regardless of whether \mathbb{Y}_3^i is itself Calabi-Yau or not. In physics terms this can be equivalently understood by first assuming that \mathbb{Y}_3^i is Calabi-Yau and considering F-theory on \mathbb{Y}_3^i as an auxiliary, chiral theory in six dimensions. With our assumption on the nature of the $N_{C^0}^i(n, r)$, the object $Z_{-2,m}^i(\tau, z)$ is then simply the elliptic genus of the $N = (0, 4)$ supersymmetric string obtained by wrapping a D3-brane on C^0 within \mathbb{Y}_3^i . As such, $Z_{-2,m}^i(\tau, z)$ is (quasi-)modular of weight $w = -(d-2)/2 = -2$. In fact, if $c_1(\mathbb{Y}_3^i) = 0$, the fourfold Y_4 is expected to admit a fibration over the curve C_i whose fiber is a generic member of the family \mathbb{Y}_3^i .¹³ That is, there exists a projection

¹³This natural expectation is the direct analogue of the existence of a $K3/T^4$ -fibration for Calabi-Yau threefolds according to Ooguri's criteria [108]. Consistently, note that since \mathbb{Y}_3^i is defined as the restriction of Y_4 to $p^*(C^i)$, where C^i is the curve dual to C_i on B_2 , the intersection product yields $C_i \circ \mathbb{Y}_3^i = 1$, in agreement with the fibration structure (3.23).

$$\rho_i : \mathbb{Y}_3^i \rightarrow \begin{array}{c} Y_4 \\ \downarrow \\ C_i \end{array} \quad (3.23)$$

The underlying six-dimensional theory naturally arises in the decompactification of the base curve C_i and so is well-defined by itself.

By contrast, if $C^i \cdot C^i > 0$, which implies $c_1(\bar{K}_{\mathbb{Y}_3^i}) < 0$, we can view Y_4 only locally as a fibration with fiber \mathbb{Y}_3^i over the normal direction to the divisor $p^*(C^i)$ in B_3 . Since the normal bundle to $p^*(C^i)$ is in this case non-trivial, even in the decompactification limit we cannot define a bona-fide six-dimensional theory by restricting F-theory to \mathbb{Y}_3^i . It is even more intriguing to find that nevertheless $Z_{-2,m}^i(\tau, z)$ behaves in many respects like the elliptic genus of a six-dimensional string even in this case, as will be discussed further in Section 4. In particular, one can formally associate $Z_{-2,m}^i(\tau, z)$ to an elliptic surface with $(24 + 12n)$ singular fibers, where $n = C^i \cdot_{B_2} C^i$. An example will be presented in Section 5.2. In the sequel we will formally relate the $Z_{-2,m}^i(\tau, z)$ to such six-dimensional sectors, with the understanding that a direct interpretation as elliptic genera in six dimensions is possible only if \mathbb{Y}_3^i is Calabi-Yau.

Let us now turn to the crucial claim that $Z_{-2,m}^i(\tau, z)$ encodes the BPS invariants $N_{C^0}^i(n, r)$ pertaining to the threefolds \mathbb{Y}_3^i as shown in (3.22). In the remainder of this section we will prove this assertion at level $n = 1$. To this end we interpret the expression (3.13) for the elliptic genus as a statement about the decomposition of the moduli spaces of curve classes $\mathbf{C} = C^0 + n\mathbb{E}_\tau + C_r^f$ into various components. For the special case where $n = 1$ this will allow us to deduce that the multiplicities $N_{C^0}^i(n = 1, r)$ are indeed BPS invariants on \mathbb{Y}_3^i . Extrapolating this observation to all n then leads to (3.22).

To arrive at this picture, we first define the following generating functions associated with the non-derivative contributions to the elliptic genus (3.13):

$$\mathcal{F}_{C^0}^0(\tau, z) = -qZ_{-1,m}^0 = \sum_{n,r} N_{C^0}^0(n, r) q^n \xi^r, \quad (3.24)$$

$$\mathcal{F}_{C^0}^E(\tau, z) = -qZ_{-1,m}^E = \sum_{n,r} N_{C^0}^E(n, r) q^n \xi^r. \quad (3.25)$$

This is analogous to (3.22), but with the important difference that, unlike the invariants $N_{C^0}^i(n, r)$ which appear in (3.22), the invariants $N_{C^0}^0(n, r)$ and $N_{C^0}^E(n, r)$ do not correspond to BPS invariants of some auxiliary elliptic threefolds. Expanding both sides of (3.13) order by order in q and ξ then gives a relation between the BPS invariants $N_{\mathbf{G};C^0}(n, r)$ in $Z_{\mathbf{G};C^0}$ on the left hand side, and the invariants $N_{C^0}^0(n, r)$, $N_{C^0}^E(n, r)$ and $N_{C^0}^i(n, r)$ on the right.

Recall next that the quantities on the left hand side, $N_{\mathbf{G};C^0}(n, r)$, are the flux dependent, relative Gromov-Witten invariants, as defined in (2.1), for the curve $\mathbf{C} = C^0 + n\mathbb{E}_\tau + C_r^f$. According to (2.1),

$$N_{\mathbf{G}_{U(1)};C^0}(n, r) = \int_{\hat{\Sigma}_{n,r}} \text{ev}^* \mathbf{G}_{U(1)}, \quad (3.26)$$

where we denote by $\hat{\Sigma}_{n,r}$ the class of the moduli space of stable holomorphic maps at genus $g = 0$ and with one point marked associated with $\mathbf{C} = C^0 + n\mathbb{E}_\tau + C_r^f$. When both sides are

expanded in $q^n \xi^r$, the relation (3.13) therefore boils down to the statement that

$$\int_{\hat{\Sigma}_{n,r}} \text{ev}^* \mathbf{G}_{U(1)} = (F \cdot C^0) N_{C^0}^0(n, r) + (F \cdot C_E^1) N_{C^0}^E(n, r) + \sum_i (F \cdot b \cdot p^*(C_i)) \frac{1}{2m} r N_{C^0}^i(n, r), \quad (3.27)$$

where the extra factor of r in front of the $N_{C^0}^i(n, r)$ is caused by the derivative in (3.13).

To interpret (3.27) further, we note that while for general n the moduli spaces $\hat{\Sigma}_{n,r}$ are difficult to construct, we are in a comfortable situation when $n = 1$ and C^0 is the rational fiber of B_3 : The moduli space $\hat{\Sigma}_{1,r}$ is equal to the moduli space of stable holomorphic maps of genus zero for the purely fibral curve C_r^f , up to terms orthogonal to any transversal flux satisfying (2.18). This follows from the identity (3.8), which in turn is a consequence of the duality between F-theory and the heterotic string. Since the moduli space for C_r^f is the surface $\hat{\Sigma}_r$ given in (2.20) with base Σ_r , we know that for transversal flux

$$\int_{\hat{\Sigma}_{1,r}} \text{ev}^* \mathbf{G}_{U(1)} = \int_{\hat{\Sigma}_r} \mathbf{G}_{U(1)} = r (F \cdot \Sigma_r). \quad (3.28)$$

Plugging this into (3.27), which must hold for any element $F \in H^{1,1}(B_3)$, yields

$$\Sigma_r = \frac{1}{r} N_{C^0}^0(1, r) C^0 + \frac{1}{r} N_{C^0}^E(1, r) C_E^1 + \sum_i \frac{1}{2m} N_{C^0}^i(1, r) (b \cdot p^*(C_i)). \quad (3.29)$$

The point is now that, at least for $n = 1$, we can understand why the $N_{C^0}^i(1, r)$ are invariants of the embedded threefolds \mathbb{Y}_3^i : Suppose first that a given threefold \mathbb{Y}_3^i is by itself a Calabi-Yau space. In this case, Y_4 admits a fibration with fiber \mathbb{Y}_3^i over the curve C_i of the form (3.23), see Figure 3. The invariant $N_{C^0}^i(1, r)$ appearing in (3.29) can thus be interpreted as the multiplicity of the base curve C_i of this fibration as a component of the matter curve Σ_r .¹⁴ In other words

$$\Sigma_r = \sum_i N_{C^0}^i(1, r) C_i + (\text{curve classes in the fiber of } B_3). \quad (3.30)$$

The multiplicity $N_{C^0}^i(1, r)$ in the above decomposition is simply given by the number of points on \mathbb{Y}_3^i over which the elliptic fiber degenerates such as to support a state of charge r . Indeed,

$$N_{C^0}^i(1, r) = \Sigma_r \cdot p^*(C^i), \quad (3.31)$$

where we used that $p^*(C^i)$ does not intersect with fibral curves and that $p^*(C^i) \cdot C_j = \delta_j^i$, which follows from the fact that C^i is the curve class dual to C_i on B_2 . But the intersection of Σ_r with the base $\mathbb{B}_2^i = p^*(C^i)$ of \mathbb{Y}_3^i gives exactly the locus on \mathbb{B}_2^i where the fiber of \mathbb{Y}_3^i supports the fibral curve C_r^f . Under the present assumption that C_i are the generators of the simplicial Mori cone, the intersection number $\Sigma_r \cdot p^*(C^i)$ is non-negative and counts the number of points on \mathbb{B}_2^i where the degeneration occurs, in codimension-two on \mathbb{B}_2^i . This identifies $N_{C^0}^i(1, r)$ with the BPS invariant for the curve C_r^f viewed as a curve inside the threefold \mathbb{Y}_3^i . The same argument leading to (3.8), now applied to threefolds, shows that this in turn agrees with the BPS invariant of the curve $C^0 + \mathbb{E}_r + C_r^f$ as a curve inside \mathbb{Y}_3^i . Hence we have shown that the $N_{C^0}^i(1, r)$ are indeed relative BPS invariants of \mathbb{Y}_3^i .

¹⁴To see this, note that $N_{C^0}^i(1, r)$ is the multiplicity of the component $\frac{1}{2m} b \cdot p^*(C_i) = C_i + \dots$ within Σ_r , where we used (3.16).

Figure 3: This figure shows the component of the matter curve Σ_r (drawn in red) along a base curve C_i . It refers to a geometry where the fourfold Y_4 is fibered over C_i with generic fiber \mathbb{Y}_3^i . The issue is to determine the multiplicity $N^i(C_r^f)$ of C_i in the decomposition (3.30), and from the picture we see that it coincides with the number of points on \mathbb{Y}_3^i over which the elliptic fiber \mathbb{E}_τ degenerates. The remaining components of Σ_r in the decomposition (3.30) lie within special fibers of the fibration ρ_i (3.23) and are not depicted.

These considerations continue to hold if \mathbb{Y}_3^i is not a Calabi-Yau space itself, as the argument was purely intersection theoretic. Indeed, the general formalism of [109] implies that the virtual class of the moduli space of curves $C^0 + n\mathbb{E}_\tau + C_r^f$ on \mathbb{Y}_3^i is related to the class of the moduli space on Y_4 by restriction. Our elementary considerations for the special curves above are a manifestation of this.

While it is harder to make this explicit for general wrapping numbers n from first principles, we can at least translate the relation (3.27) into the following geometric statement: Up to terms orthogonal to the transversal subspace of $H_{\text{vert}}^{2,2}(Y_4)$ defined in (2.18), $\hat{\Sigma}_{n,r}$ is equivalent to the class of a fibration of C_r^f over a curve $\Sigma_{C^0,n,r}$ which is given by

$$\Sigma_{C^0,n,r} = \frac{1}{r} N_{C^0}^0(n,r) C^0 + \frac{1}{r} N_{C^0}^{E_1}(n,r) C_E^1 + \sum_i \frac{1}{2m} N_{C^0}^i(n,r) (b \cdot p^*(C_i)). \quad (3.32)$$

Indeed, integrating $\mathbf{G}_{U(1)} = \sigma \wedge \pi^*(F)$ over such a fibration would give a factor of r from the fibral piece along with the class F , precisely as reflected in (3.27).

The crucial claim here, proven above only for $n = 1$, is that the integral numerical coefficients $N_{C^0}^i(n,r)$ are by themselves BPS invariants of the threefolds \mathbb{Y}_3^i embedded in Y_4 . This implies that the objects $Z_{-2,m}^i(\tau, z)$ in (3.22) are modular or quasi-modular Jacobi forms of weight $w = -2$, while the extra factor of r obtained by integration of $\mathbf{G}_{U(1)}$ explains why the $Z_{-2,m}^i(\tau, z)$ appear with a derivative in (3.13). It would be extremely interesting to establish a geometric proof of this interpretation of the $N_{C^0}^i(n,r)$ also for $n > 1$.

We have been assuming that the basis $\{C_i\}$ corresponds to the generators of the simplicial Mori cone of B_2 , so that they are effective and their dual curves satisfy (3.18). However the results do not depend on this restriction. More generally, it suffices to pick a basis of effective

curves C^i defining the threefold geometries \mathbb{Y}_3^i as in (3.19), and to take C_i as the dual basis of 2-cycle classes on B_2 . In general this may imply, first, that not all C_i are effective, and second that $C^i \cdot C^i$ may be negative. The intersection theoretic argument why $N_{C^0}^i(1, r)$ describes BPS invariants on \mathbb{Y}_3^i does not hinge upon effectiveness of C_i , however, since we can view $N_{C^0}^i(1, r)$ simply as the coefficient in the expansion (3.30) in terms of curve classes. In this more general situation, $N_{C^0}^i(1, r)$ may in particular be negative. This is to be interpreted in such a way that the degeneration locus in \mathbb{Y}_3^i where the fiber contains the curve C_r^i occurs in codimension-one on \mathbb{B}_2^i . Note also that if $C^i \cdot C^i < 0$, the curve C^i is rigid and hence also \mathbb{Y}_3^i is rigid as a divisor in Y_4 , but this does not invalidate our arguments either.

The discussion in this section was tailor-made for the special case of heterotic elliptic genera. For non-critical strings the derivative terms in the elliptic genus encode the relative BPS numbers of embedded threefolds sometimes constructed in a slightly different way. For this we refer to Section 6.

3.4 Elliptic Holomorphic Anomaly Equation

So far we have focused in this section on the properties of the relative BPS invariants in transversal flux backgrounds, which were defined via eq. (2.18). This is required for having a four-dimensional interpretation within F-theory on Y_4 , and a meaningful elliptic genus in the first place. We have seen that in general derivative contributions to the elliptic genus appear, such as indicated in (3.13). These take the form of derivatives of Jacobi forms, $Z_{-2,m}^i(q, \xi)$, which encode relative BPS invariants associated with the embedded threefolds, \mathbb{Y}_3^i , of Y_4 .

As previewed in Section 1.2, this results not only in a violation of modular invariance (A.1), but also of the invariance under the transformations $z \rightarrow z + \lambda\tau$ in (A.2), which can be interpreted as spectral flow in the $U(1)$ subsector.¹⁵ From the point of view of the four dimensional elliptic genus, the derivative terms inflict an anomaly on these symmetries, and turn it into a quasi-Jacobi form. However, in analogy to the treatment of the quasi-modular form E_2 , one can cancel these anomalies by trading the derivative terms in $Z_{\mathbf{G}_{U(1)}; C_b}(q, \xi)$ against non-holomorphic derivatives as in (1.12). This means that we pass from the holomorphic, but non-modular elliptic genus $Z_{\mathbf{G}_{U(1)}; C_b}(q, \xi)$ to the almost holomorphic, but modular quantity $\hat{Z}_{\mathbf{G}_{U(1)}; C_b}(q, \xi)$, for which we replace the derivatives $\xi\partial_\xi \equiv \frac{1}{2\pi i}\partial_z$ as follows (see Appendix (A.1)):

$$\xi\partial_\xi \rightarrow \frac{1}{2\pi i} \nabla_{z,m} := \frac{1}{2\pi i} \left(\partial_z + 4\pi i m \frac{\text{Im}z}{\text{Im}\tau} \right). \quad (3.33)$$

The resulting non-holomorphicity of $\hat{Z}_{\mathbf{G}_{U(1)}; C_b}(q, \xi)$ is characterised by the equation

$$\frac{d}{d\alpha} \hat{Z}_{\mathbf{G}_{U(1)}; C_b}(q, \xi) = (2m) g_\partial Z_{-2,m}(q, \xi), \quad \alpha \equiv \frac{\text{Im}z}{\text{Im}\tau}, \quad (3.34)$$

where we parametrise the elliptic genus as in (3.9) and have abbreviated $g_\partial^M Z_{-2,m}^M(q, \xi) + g_\partial^{QM} Z_{-2,m}^{QM}(q, \xi) =: g_\partial Z_{-2,m}(q, \xi)$. This equation is a version of the *elliptic holomorphic anomaly equation* which was introduced in the context of generating functions for relative BPS invariants of elliptic fibrations in [25]. Compared to elliptic genera in six dimensions, which are

¹⁵Originally spectral flow was understood [37] as a property of an $N = 2$ superconformal symmetry on the worldsheet, hence the name, but in essence this notion applies to any $U(1)$ current algebra associated with a free compact boson. We reiterate again that it is not an automatic symmetry of the theory.

lacking a derivative contribution, we see that the appearance of such an elliptic holomorphic anomaly equation is a genuinely new feature in four dimensions.

The elliptic holomorphic anomaly equation admits a beautiful geometric interpretation. Recall that the right-hand side of (3.34) consists of the (quasi-)modular objects, $Z_{-2,m}(q, \xi)$, that encode the relative BPS invariants of the threefolds \mathbb{Y}_3 . Remarkably, as we explain now, the same threefold invariants appear also as fourfold invariants for a suitable choice of non-transversal background flux $\mathbf{G}_{-2} \in H_{(-2)}^{2,2}(Y_4, \mathbb{R})$, as defined in (2.17). We will refer to such non-transversal fluxes as “ (-2) -fluxes” for brevity.¹⁶

In fact, it has already been observed in [76, 77] that the generating function for certain relative genus-zero BPS invariants in a (-2) -flux background is a meromorphic (quasi-)modular form of weight $w = -2$. Such invariants are non-vanishing even in absence of a refinement by an extra gauge symmetry (in F-theory language). This is to be contrasted with the relative BPS invariants for the transversal flux backgrounds that were considered in the previous sections. The important point is that the elliptic holomorphic anomaly equation in its form (3.34) admits a representation in terms of the generating function for a specific type of (-2) -flux. More precisely we have

$$\frac{d}{d\alpha} \hat{Z}_{\mathbf{G}_{U(1)}; C_b}(q, \xi) = Z_{\mathbf{G}_{-2}; C_b}(q, \xi), \quad (3.35)$$

where the (-2) -flux associated with $\mathbf{G}_{U(1)} = \sigma \wedge \pi^*(F)$ is given by

$$\mathbf{G}_{-2} = \pi^*(F) \wedge \pi^*(b). \quad (3.36)$$

Here b is the height pairing associated with the $U(1)$, and, as always, we have defined

$$Z_{\mathbf{G}_{-2}; C_b}(q, \xi) = -q^{-\frac{1}{2}C_b \cdot \bar{K}_{B_3}} \mathcal{F}_{\mathbf{G}_{-2}; C_b}(q, \xi). \quad (3.37)$$

The specific form of \mathbf{G}_{-2} that appears in (3.35) can be deduced from the general considerations of [25] applied to our situation. Alternatively, we can arrive at the same conclusion via more elementary geometric observations based on the results of Section 3.3, which are supported by our detailed analysis of examples in Sections 5 and 6.

For illustration, consider the relative BPS invariants associated with a curve C^0 with zero self-intersection, which figures as the fiber of some rational fibration, $B_3 \subset Y_4$, see (2.27); recall that this is the situation where a solitonic heterotic string appears. In this case the elliptic holomorphic anomaly equation for the elliptic genus (3.13) takes the form

$$\frac{d}{d\alpha} \hat{Z}_{\mathbf{G}_{U(1)}; C^0}(q, \xi) = \sum_i F \cdot b \cdot p^*(C_i) Z_{-2,m}^i(q, \xi) = Z_{\mathbf{G}_{-2}; C^0}(q, \xi), \quad (3.38)$$

for $Z_{\mathbf{G}_{-2}; C_b}(q, \xi)$ as in (3.37). While the first equality follows immediately from (3.13), the second equality is non-trivial and rests on the following geometric considerations: First introduce a convenient basis for the space of non-transversal (-2) -fluxes in $H_{(-2)}^{2,2}(Y_4, \mathbb{R})$:

$$\begin{aligned} \mathbf{G}^i &= \pi^*(S_-) \wedge \pi^*(p^*(C^i)), \\ \mathbf{G}^E &= \pi^*(E) \wedge \pi^*(p^*(C^\Gamma)), \\ \mathbf{G}^0 &= \pi^*(p^*(C^{i_0})) \wedge \pi^*(p^*(C_{i_0})). \end{aligned} \quad (3.39)$$

¹⁶We reiterate from the discussion in Section 2.2 that such fluxes do not admit a lift to F-theory, but define bona fide Type IIA/M-theory backgrounds.

In the notation of Section 2.3, C^Γ denotes a curve class on B_2 with $C^\Gamma \cdot \Gamma = 1$, and we have picked a pair of dual curves C_{i_0} and C^{i_0} on B_2 . The classes \mathbf{G}^E and \mathbf{G}^0 are hence dual to the curves C_E^2 and C^0 in the fiber of B_3 , while \mathbf{G}^i is dual to the curve C^i on B_2 .

The important claim is that the contributions $Z_{-2,m}^i(q, \xi)$ to the elliptic genus (3.13) can be computed as

$$Z_{-2,m}^i(q, \xi) = -\frac{1}{q} \mathcal{F}_{\mathbf{G}^i}(q, \xi), \quad (3.40)$$

while the remaining two basis elements lead to the following vanishing BPS invariants,

$$\mathcal{F}_{\mathbf{G}^E}(q, \xi) = 0, \quad \mathcal{F}_{\mathbf{G}^0}(q, \xi) = 0. \quad (3.41)$$

We will provide arguments for these assertions below. Assuming (3.40) and (3.41) for now, we proceed by expanding (3.37), viewed as class of the (-2) flux, in the above basis as

$$\mathbf{G}_{-2} = \sum_i (F \cdot b \cdot p^*(C_i)) \mathbf{G}^i - (F \cdot b \cdot E) \mathbf{G}^E + (F \cdot b \cdot S_+) \mathbf{G}^0. \quad (3.42)$$

Hence by linearity of the BPS invariants, together with (3.40) and (3.41), it is obvious that

$$Z_{\mathbf{G}_{-2}; C^0}(q, \xi) = \sum_i (F \cdot b \cdot p^*(C_i)) Z_{-2,m}^i(q, \xi). \quad (3.43)$$

This explains also the second equality in the elliptic holomorphic anomaly equation (3.38).

It remains to justify (3.40) and (3.41). While we cannot give formal proofs beyond the non-trivial checks in the examples of Section 5, we provide instead some intuition why (3.40) should hold. To this end, consider the relative BPS invariants $N_{\mathbf{G}^i; C^0}(n, r)$ for $n = 0$ and $r = 0$. According to our claim, these invariants should agree with the threefold invariants $N_{C^0}^i(n, r)$ for $n = 0$ and $r = 0$ in the expansion (3.22) of $Z_{-2,m}^i(q, \xi)$. Our starting point to verify this is the definition of $N_{\mathbf{G}^i; C^0}(n, r)$ as the overlap of the flux \mathbf{G}^i with the virtual fundamental class of the moduli space of the curve C^0 in Y_4 with one point fixed. Since C^0 is fibered over B_2 , this class can be identified with the class of the surface obtained by fibering C^0 over the canonical divisor K_{B_2} ,¹⁷ that is, with the class inside Y_4 given by

$$\mu = S_0 \wedge \pi^*(p^*(K_{B_2})). \quad (3.44)$$

Here S_0 is the zero-section of the fourfold Y_4 . This allows us to compute $N_{\mathbf{G}^i; C^0}(0, 0)$ as

$$\begin{aligned} N_{\mathbf{G}^i; C^0}(0, 0) &= \int_\mu \mathbf{G}^i = S_0 \circ \pi^*(p^*(K_{B_2})) \circ \pi^*(S_-) \circ \pi^*(p^*(C^i)) = p^*(K_{B_2}) \cdot S_- \cdot p^*(C^i) \\ &= C^i \cdot_{B_2} K_{B_2}, \end{aligned} \quad (3.45)$$

where we have used the fact that S_0 is a section on Y_4 and S_- is a section on the \mathbb{P}^1 -fibration B_3 .

The expression for $N_{\mathbf{G}^i; C^0}(0, 0)$ in (3.45), in fact, can be seen to exactly agree with the invariants $N_{C^0}^i(n, r)$ for $n = r = 0$. To see this, suppose first that the curve C^i is a rational curve with $C^i \cdot_{B_2} C^i = 0$. According to the discussion in Section 3.3, in this case the threefold \mathbb{Y}_3^i

¹⁷To understand this claim in physics terms, recall, for instance, how in F-theory on elliptic fourfolds one computes the BPS invariants for the rational fibers of the exceptional divisors appearing in codimension-one: These are obtained by integrating the flux over the restriction of the rational fiber to the canonical class, K_D . Here D is the divisor over which the rational curve is fibered. See for example eq. (9.43) in [97].

is a Calabi-Yau space which is K3-fibered over C^i . The invariant $N_{C^0}^i(n, r)$ for $n = r = 0$ is then simply the BPS invariant for C^0 within the Calabi-Yau threefold \mathbb{Y}_3^i , and hence $N_{C^0}^i(n, r) = -2$. This is because within \mathbb{Y}_3^i , C^0 is fibered over the rational base curve C^i and the (signed) Euler character of its moduli space is the integral $\int_{C^i} K_{C^i}$. By the adjunction formula

$$\int_{C^i} (K_{C^i} - C^i) = C^i \cdot_{B_2} K_{B_2}, \quad (3.46)$$

we see that $\int_{C^i} K_{C^i}$ agrees with $C^i \cdot_{B_2} K_{B_2}$ for the rational curve C^i with $C^i \cdot C^i = 0$.

More generally, even if \mathbb{Y}_3^i is not Calabi-Yau, $N_{C^0}^i(0, 0) = C^i \cdot_{B_2} K_{B_2}$ nonetheless holds. As noted already before, this reflects the fact that, by the results of [109], the virtual class for the moduli space of the curve C^0 on \mathbb{Y}_3^i is related to the class of its moduli space on Y_4 by restriction.

In the examples of Sections 5 and 6, we will indeed observe a precise match between the $N_{\mathbf{G}^i; C^0}(n, r)$ and the invariants $N_{C^0}^i(n, r)$ for zero, but also for non-zero, values of n and r . Beyond such explicit examples it is much harder to make a direct argument for general values, based on the moduli space of curves. At any rate, we will explain the analogue of (3.45) for the elliptic genera also for other types than heterotic strings in four dimensions. Furthermore, it is clear that $N_{\mathbf{G}^0; C^0}(0, 0) = 0$ and $N_{\mathbf{G}^E; C^0}(0, 0) = 0$, because the overlaps in (3.45) vanish geometrically. The vanishing of the invariants at all levels, as claimed by (3.41), will be explicitly verified for the examples further below.

4 Elliptic Genera, Anomalies and Modularity

The observation of the previous sections was that the four-dimensional elliptic genus need not be modular or quasi-modular in the usual sense. Once applied to heterotic strings, this raises the question how this phenomenon is compatible with the structure of anomaly cancellation. In this section we first review the well-known interplay [26, 27] of the elliptic genus of the heterotic string with the structure of 1-loop anomalies and their cancellation by the Green-Schwarz mechanism. We then explain how four-dimensional anomaly cancellation works even when the elliptic genus is not modular but rather has a derivative component, and also discuss the situation when it is quasi-modular rather than fully modular.

In $d = 2n + 2$ dimensions, the 1-loop gauge and gravitational anomalies are characterized by the anomaly polynomial

$$I_{d+2} = \sum_{\mathbf{R}, s} n_s(\mathbf{R}) I_s(\mathbf{R}) \Big|_{d+2}, \quad (4.1)$$

where we sum over all massless particle species of multiplicity $n_s(\mathbf{R})$ in representation \mathbf{R} of the gauge group and with spin s . The $(d + 2)$ -form $I_s(\mathbf{R})|_{d+2}$ is formed by products of the gauge field strength F and the curvature 2-form R . For example, a complex chiral Weyl fermion contributes to (4.1) with

$$I_{1/2}(\mathbf{R}) = \text{tr}_{\mathbf{R}} e^F \hat{A}(T), \quad (4.2)$$

where $\hat{A}(T)$ is the A-roof genus.

In the following we will focus on the gauge anomalies associated with a single $U(1)$ gauge group and define

$$I_{d+2, U(1)} = A^{(d)} F^{\frac{d+2}{2}}. \quad (4.3)$$

Based on the above expressions, the anomaly coefficients $A^{(d)}$ in $d = 6$ and $d = 4$ dimensions are given by:

$$A^{(6)} = \frac{1}{4!} \sum_r n_{1/2}(r) r^4 = \frac{1}{4!} \sum_r n_{\text{half-hyper}}(r) r^4, \quad (4.4)$$

$$A^{(4)} = \frac{1}{3!} \sum_r (n_{1/2}(r) - n_{-1/2}(r)) r^3 = \frac{1}{3!} \sum_r \chi_r r^3. \quad (4.5)$$

Here we sum over the Weyl fermions of $U(1)$ charge r . In $d = 6$ dimensions, if we consider a theory with minimal $N = (1, 0)$ supersymmetry, the number of charged Weyl fermions agrees with the number of half-hypermultiplets of corresponding charge. In $d = 4$ dimensions, the anomaly coefficient involves the chiral index χ_r , i.e., the number of chiral minus anti-chiral Weyl fermions of charge r .

4.1 Modular Elliptic Genera

We will first review anomaly cancellation in the more familiar case of a modular invariant heterotic string elliptic genus. In the present context, this primarily concerns flux compactifications that are dual to perturbative heterotic strings.

Let us recall that the $U(1)$ -refined elliptic genus $Z_{-n,m}(q, z)$ of a perturbative, $d = 2n + 2$ dimensional heterotic string is expected to be a weak Jacobi form [33] of modular weight $w = -n$ and some index m (in this work, $n = 1, 2$ will be relevant). As we have seen, this is not necessarily true in $d = 4$ and so the statements that follow will eventually be adapted to the more general situation. Let us however for the moment assume that $Z_{-n,m}(q, z)$ is a weak Jacobi form, and turn later to the required modifications. See also the remarks in the Introduction and the defining modular transformation properties of Jacobi forms given in (A.1) and (A.2).

From a weak Jacobi form one can always strip off the quasi-modular Eisenstein series E_2 by writing

$$Z_{-n,m}^{(d)}(q, \xi) = e^{\frac{m}{12} E_2 \hat{z}^2} \check{Z}_{-n,m}^{(d)}(q, \hat{z}), \quad \text{where } \xi = e^{2\pi i z} \equiv e^{\hat{z}}, \quad (4.6)$$

so that the remainder,

$$\check{Z}_{-n,m}^{(d)}(q, \hat{z}) = \hat{z}^{n(\bmod 2)} \sum_{k \geq 0} M_{2(k - \lfloor \frac{n}{2} \rfloor)}(q) \hat{z}^{2k}, \quad (4.7)$$

is modular invariant term by term. It involves meromorphic modular forms M_{2l} of weight $2l$ which lie in the ring generated by E_4 and E_6 , divided by $1/\eta^{24}$. The idea of how this modular structure implies the Green-Schwarz anomaly cancellation goes back to [26, 27] and rests on two properties of the elliptic genus:

1) The anomaly coefficient (4.4) is the coefficient of \hat{z}^{n+2} of the elliptic genus at q^0 . More precisely:

$$\begin{aligned} A^{(d)} &= -\frac{1}{2} \frac{1}{(n+2)!} \left[\partial_{\hat{z}}^{n+2} Z_{-n,m}^{(d)}(q, \hat{z}) \right]_{\hat{z}^0 q^0} \\ &= -\frac{1}{2} \left[M_2(q) + \frac{m}{12} E_2 M_0(q) + \frac{1}{2} \left(\frac{m}{12} E_2 \right)^2 M_{-2}(q) + \dots \right]_{q^0}. \end{aligned} \quad (4.8)$$

Key is the observation that due to well-known properties of modular forms, $M_2(q)$ cannot have a constant piece and therefore does not contribute. Thus all contributing terms must involve

E_2 's from the exponential, which brings down powers of $\hat{z}^2 \sim \text{Tr } F^2$ (recall that $F = \hat{z}J$, where J is the charge generator). This is tantamount to saying that the anomaly polynomial must necessarily factorize. This in turn implies that the anomaly can be cancelled; that is, in familiar terms: $I_{2n+4}(F) \sim \text{Tr } F^2 \wedge X_{2n}(F)$.

2) The Green-Schwarz anomaly cancelling term is given by $S_{GS} \sim \int B \wedge X_{2n}(F)$, and its numerical coefficient,

$$A_{GS}^{(d)} \equiv X_{2n}(F)|_{F^n}, \quad (4.9)$$

is computed as a one-loop amplitude in the heterotic string [30, 31]. The integrand is given by the modular invariant coefficient of \hat{z}^n in the elliptic genus. More precisely, what enters is the modified, almost holomorphic elliptic genus, $\hat{Z}_{-n,m}(q, \hat{z})$, for which all occurrences of E_2 's are replaced by their modular invariant, but non-holomorphic version, $\hat{E}_2 = E_2 - \frac{3}{\pi \text{Im}\tau}$. Explicitly:

$$\begin{aligned} A_{GS}^{(d)} &= -\frac{1}{n!} \left[\partial_{\hat{z}}^n \frac{1}{16\pi} \int_{\mathcal{F}_\tau} d\tau \hat{Z}_{-n,m}^{(d)}(q, \hat{z}) \right]_{\hat{z}^0} \\ &= -\frac{1}{16\pi} \int_{\mathcal{F}_\tau} d\tau \left[M_0(q) + \frac{m}{12} \hat{E}_2 M_{-2}(q) + \dots \right] \\ &= -\frac{1}{24} \left[\hat{E}_2 M_0(q) + \frac{1}{2} \frac{m}{12} \hat{E}_2^2 M_{-2}(q) + \dots \right]_{q^0}, \end{aligned} \quad (4.10)$$

where the integration over the worldsheet \mathcal{F}_τ is performed via the formula [31]

$$\int_{\mathcal{F}_\tau} d\tau \hat{E}_2(q)^k M_{-2k}(q) = \frac{2\pi}{3} \frac{1}{k+1} E_2(q)^{k+1} M_{-2k}(q)|_{q^0}. \quad (4.11)$$

Therefore one finds

$$mA_{GS}^{(d)} = A^{(d)}, \quad (4.12)$$

which expresses that the Green-Schwarz term precisely cancels the anomaly. The extra factor of m arises from the Chern-Simons term to which the other leg of the B -field couples, as we will show later.

We can be more explicit if we specify the dimension. In $d = 6$, the scarcity of independent modular forms, plus the requirement that the left-moving ground state be uncharged, implies that the elliptic genus up to order \hat{z}^4 is fixed up to one model dependent parameter besides m , which we denote by c :

$$Z_{-2,m}^{(6)}(q, \hat{z}) = \frac{1}{\eta^{24}} e^{\frac{m}{12} E_2 \hat{z}^2} \left[2E_4 E_6 - \frac{m \hat{z}^2}{12} (2E_6^2 + c(E_6^2 - E_4^3)) + \left(\frac{m \hat{z}^2}{12} \right)^2 E_4^2 E_6 + \mathcal{O}(\hat{z}^6) \right]. \quad (4.13)$$

This then leads to

$$A^{(6)} = mA_{GS}^{(6)} = -6(1+c)m^2. \quad (4.14)$$

For reference, examples of elliptic genera that we will meet again further below are given by

$$Z_{-2,m}^{(6)}(q, z) = \frac{1}{12} \sum_k \frac{n_k}{\eta^{24}} E_{4,\mu_1^k} E_{6,\mu_2^k}, \quad m = \mu_1^k + \mu_2^k, \quad \sum_k n_k = 24, \quad (4.15)$$

where $E_{w,m} = E_{w,m}(q, z)$ are the Eisenstein-Jacobi forms¹⁸ defined in Appendix A. This bilinear form of elliptic genera naturally appears in perturbative heterotic strings compactified on $K3$,

¹⁸Strictly speaking we use for higher levels m here and in the following the integral expansions (A.32-A.34). However their parametric ambiguities do not project down to order \hat{z}^4 , and therefore do not contribute to the anomaly.

with bundles switched on such as to leave a single $U(1)$ unbroken. In this case c is fixed such that

$$A^{(6)} = mA_{GS}^{(6)} = -\sum_k \frac{n^k}{4} ((\mu_1^k)^2 - (\mu_2^k)^2). \quad (4.16)$$

Analogous statements apply to perturbative heterotic strings in $d = 4$. Given the various constraints, we find for the modular part of the elliptic genus:

$$Z_{-1,m}^{(4),M}(q, \hat{z}) = \frac{1}{\eta^{24}(q)} \phi_{-1,2}(q, \hat{z}) \Phi_{12,m-2}^M(q, \hat{z}) \simeq \hat{z} e^{\frac{m}{12} E_2 \hat{z}^2} \left[1 + \mathcal{O}(\hat{z}^4) \right], \quad (4.17)$$

up to an overall numerical factor c . The actual elliptic genus is then obtained by multiplying this with g^M as in (3.9), which depends on the four-form flux that needs to be switched on. The two overall factors fix the elliptic genus up to order \hat{z}^3 and we thus have

$$A^{(4)} = mA_{GS}^{(4)} = -\frac{c}{24} g^M m. \quad (4.18)$$

A four-dimensional analog of (4.15) in terms of natural building blocks of the heterotic string can be written as

$$Z_{-1,m}^{(4),M}(q, \hat{z}) = \frac{1}{12} \frac{1}{\eta^{24}} \left[\frac{1}{\mu_1} (\partial_{\hat{z}} E_{4,\mu_1}) E_{6,\mu_2} - \frac{1}{\mu_2} E_{4,\mu_1} (\partial_{\hat{z}} E_{6,\mu_2}) \right], \quad m = \mu_1 + \mu_2, \quad (4.19)$$

which by virtue of the relations (A.37) is a Jacobi form proportional to $\phi_{-1,2}(q, \hat{z})$ and thus a special case of (4.17). Including the flux dependent pre-factor, it leads to $A^{(4)} = mA_{GS}^{(4)} = -g^M m$. Obviously, if several such terms appear, they can simply be summed over.

The structure of derivatives as exhibited in (4.19) points to a deeper rôle derivatives play for four-dimensional elliptic genera. One can view (4.19) as a special linear combination that happens to be modular, while the other natural combination is precisely of the form of the non-modular, derivative piece of the elliptic genus:

$$\begin{aligned} Z_{-1,m}^{(4),\partial}(q, \hat{z}) &= \frac{1}{\eta^{24}} \partial_{\hat{z}} (E_{4,\mu_1} E_{6,\mu_2}(q, \hat{z})) \\ &= \partial_{\hat{z}} Z_{-2,m}^{(6)}(q, \hat{z}). \end{aligned} \quad (4.20)$$

Of course, in the physical partition function one needs to equip this with an additional flux-dependent prefactor, which we denote by $g^{M,\partial}$.

This leads us to discuss the derivative elliptic genera $Z_{-1,m}^{(4),\partial}(q, \hat{z})$ more generally, and in particular to the question how anomalies can be cancelled in view of the fact that the $Z_{-1,m}^{(4),\partial}(q, \hat{z})$ are not modular invariant, while modular invariance was instrumental in proving anomaly cancellation in the first place.

Note, however, that because of the derivative relationships between the elliptic genus and the anomaly polynomial (4.8) on the one hand, and the anomaly cancelling term (4.10) on the other, it follows that the factorization of the anomaly in 4d is inherited from the six-dimensional one, even though the 4d elliptic genus $Z_{-1,m}^{(4),\partial}(q, \hat{z})$ does not transform as a Jacobi form. Nevertheless, as already noticed in [6], it has good quasi-modular properties at any given fixed order in the \hat{z} -expansion so that a well-defined modular integration, as required in (4.10), can be performed.

More precisely, for a four-dimensional elliptic genus of the derivative form (4.20), expressions (4.8) and (4.10) evaluate to

$$A^{(4),\partial} = -\partial_{\hat{z}}^4 \frac{1}{12} Z_{-2,m}^{(6)}(q, \hat{z}) \Big|_{\hat{z}^0 q^0} = 4A^{(6)} = 4mA_{GS}^{(6)}, \quad (4.21)$$

$$A_{GS}^{(4),\partial} = -\partial_{\hat{z}}^2 \frac{1}{16\pi} \int_{\mathcal{F}} d\tau \hat{Z}_{-2,m}^{(6)}(q, \hat{z}) \Big|_{\hat{z}^0} = 2A_{GS}^{(6)}. \quad (4.22)$$

We can understand the relative factor of 4 between $A^{(4),\partial}$ and $A^{(6)}$ diagrammatically, in that it corresponds to the 4 choices of one of the 4 external legs to be given a VEV in the transition from the quartic six-dimensional anomaly to the cubic four-dimensional anomaly. Similarly the factor of 2 relating $A_{GS}^{(4),\partial}$ and $A^{(6)}$ originates in the choice of two external legs in the six-dimensional Green-Schwarz terms, as compared to the single external leg in its four-dimensional analogue.

The mismatch by a factor of two in the derivative sector,

$$A^{(4),\partial}/(mA_{GS}^{(4),\partial}) = 2, \quad (4.23)$$

indicates that the anomaly is not cancelled by the standard Green-Schwarz term involving the universal B -field. Rather, as we will argue later in Section 4.3, the hidden six-dimensional geometry of the derivative sector will always correlate with the correct number of additional B -fields and their couplings, such that in the end all such anomalies will be cancelled.

Before discussing this point, however, we turn to the other subsector of the $d = 4$ elliptic genus, namely the one for which the elliptic genus is quasi-modular rather than modular.

4.2 Quasi-Modular Elliptic Genera

We have indicated before that for certain fluxes “non-perturbative” elliptic genera can arise that are only quasi-modular, which means that E_2 pieces can appear in $\tilde{Z}_{-n,m}^{(d)}(q, \hat{z})$ even after stripping off the exponential prefactor as in (4.6). For these fluxes the arguments about factorization of the anomaly polynomial do not hold. Moreover the one-loop computation of the standard Green-Schwarz term that involves the universal B -field will in general not be applicable, as it can possibly capture only the perturbative piece of the anomaly, and so further Green-Schwarz terms that involve extra B -fields will necessarily come into play.

Let us be more specific and consider first six-dimensional theories for which the non-perturbative, quasi-modular piece of the heterotic elliptic genus has the form:

$$Z_{-2,m}^{QM}(q, \hat{z}) = \frac{1}{12} E_2(q) Z_{-2,m_1}^E(q, \hat{z}) Z_{-2,m_2}^E(q, \hat{z}), \quad m = m_1 + m_2. \quad (4.24)$$

It arises whenever the curve C^0 associated with the heterotic string splits into two curves C_E^i , each associated to an E-string. In this case, the $U(1)$ indices m_1 and m_2 are determined geometrically as

$$m_1 = \frac{1}{2} b \cdot C_E^1, \quad m_2 = \frac{1}{2} b \cdot C_E^2. \quad (4.25)$$

This is precisely what is reflected by the two factors Z^E , each of which can be associated to the partition function of a non-critical E-string [39]. In fact, its form (up to order \hat{z}^6) is completely fixed by the decomposition (4.6) and by requiring that the ground state is uncharged (no \hat{z} -dependence of the $1/q$ term):

$$Z_{-2,m}^E(q, \hat{z}) = \frac{1}{\eta^{12}} e^{\frac{m}{12} E_2 \hat{z}^2} \left[E_4(q) - \frac{m}{12} \hat{z}^2 E_6 + \frac{1}{2} \left(\frac{m}{12} \hat{z}^2 \right)^2 E_4^2 - \frac{1}{6} \left(\frac{m}{12} \hat{z}^2 \right)^3 E_4 E_6 + \mathcal{O}(\hat{z}^8) \right]. \quad (4.26)$$

As a consequence we can compute the anomaly (4.8) and the putative Green-Schwarz term (4.10) in closed form:

$$A^{(6),QM} = -\frac{1}{4} (m_1^2 + m_2^2), \quad (4.27)$$

$$mA_{GS}^{(6),QM} = -\frac{1}{12} (m_1 + m_2)^2. \quad (4.28)$$

Note that the anomaly nicely separates into independent pieces related to the two individual E-strings, and in particular that cross terms of the form $(\partial_{\hat{z}}^{4-k} Z_{4,m_1}^E)(\partial_{\hat{z}}^k Z_{4,m_2}^E)$, $k = 1, 2, 3$, vanish. This fits the Hořava-Witten picture where the gauge symmetry is localized on two end-of-the-world branes.

More importantly, note that the putative Green-Schwarz term (4.28) does not cancel the anomaly (4.27). Rather, this anomaly is supposedly cancelled by the Chern-Simons terms localized on the heterotic M5-branes that are necessarily present in this situation. Clearly this is a non-perturbative sector of the theory that cannot be captured by any perturbative calculation of the Green-Schwarz term, so that this is entirely as expected.

We now turn to the four-dimensional version of the story. From general properties (such as having no charged ground state) we can infer *a priori* that the quasi-modular piece of the elliptic genus and must be of the highly restricted form

$$Z_{-1,m}^{QM}(q, \hat{z}) = \phi_{-1,2} \phi_{-2,1} E_2 \Phi_{0,m-3} [E_4, E_6, \phi_{0,1}, \phi_{-2,1}] \simeq \hat{z}^3 m e^{\frac{m}{12} E_2 \hat{z}^2} \left[1 + \mathcal{O}(\hat{z}^4) \right], \quad (4.29)$$

up to an overall numerical factor, c . Again we should here keep in mind that for the actual elliptic genus, this expression needs to be multiplied with a flux factor, g^{QM} .

The overall factor of \hat{z}^3 arises from the Jacobi forms of negative weight. An immediate consequence of this is that the naive, perturbative Green-Schwarz term vanishes identically, because according to (4.10) it is determined by a single derivative with respect to \hat{z} . On the other hand, the cubic anomaly will in general be non-zero:

$$A^{(4),QM} = -\frac{c}{12} m g^{QM}, \quad (4.30)$$

$$A_{GS}^{(4),QM} = 0. \quad (4.31)$$

This shows even more clearly than in six dimensions that the quasi-modular part of the anomaly must be cancelled by other, non-perturbative contributions.

In a spirit similar to eq. (4.19) for fully modular elliptic genera, we can write $Z_{-1,m}^{QM}$ in a suggestive form which naturally makes contact to the underlying heterotic/E-string geometry:

$$Z_{-1,m}^{(4),QM}(q, \hat{z}) = \frac{1}{12} \frac{1}{\eta^{24}} E_2 \left[\frac{1}{m_1} (\partial_{\hat{z}} E_{4,m_1}) E_{4,m_2} - \frac{1}{m_2} E_{4,m_1} (\partial_{\hat{z}} E_{4,m_2}) \right], \quad (4.32)$$

where $m = m_1 + m_2$. This being proportional to $\phi_{-1,2} \phi_{-2,1}$ (as per (A.37)) is a special case of (4.29) and leads to

$$A^{(4),QM} = (m_2 - m_1) g^{QM}. \quad (4.33)$$

Recall that the m_i are determined in terms of intersection numbers of the E-string geometry as shown in (4.25), which we will derive in the next section.

By considering the other natural combination of the derivatives, we can capture the quasi-modular, derivative sector as well:

$$Z_{-1,m}^{(4),\partial,QM}(q, \hat{z}) = \partial_{\hat{z}} Z_{-2,m}^{(6),QM}(q, \hat{z}) = \frac{1}{12} \frac{1}{\eta^{24}} E_2 \partial_{\hat{z}} (E_{4,m_1} E_{4,m_2}), \quad m = m_1 + m_2. \quad (4.34)$$

Here we get

$$\begin{aligned} A^{(4),\partial,QM} &= -(m_1^2 + m_2^2) g^{QM}, \\ mA_{GS}^{(4),\partial,QM} &= -\frac{1}{6} (m_1 + m_2)^2 g^{QM}. \end{aligned} \quad (4.35)$$

The quadratic dependence on the indices reflects the six-dimensional origin of the derivative sector. Again, the naive perturbative Green-Schwarz term, $A_{GS}^{(4),\partial,QM}$, does not cancel the anomaly.

4.3 Effective Field Theory and Anomaly Cancellation from Flux Geometry

We now match the Green-Schwarz (GS) terms, as computed from the elliptic genus of F-theory compactifications, with the anomaly cancelling terms that arise in the effective field theory from geometry. The point is to understand how the different modular properties of the various contributions to the elliptic genus reflect the different geometrical origins of the anomaly cancelling terms.

For four-dimensional perturbative heterotic string compactifications on smooth Calabi-Yau spaces with general abelian gauge groups, the Green-Schwarz terms have been analyzed in [85] and extended to non-perturbative models with heterotic 5-branes in [110]. The perturbative GS mechanism does not only involve the universal heterotic 2-form field B^0 , but in general also the 2-form fields dual to the axionic scalars that are obtained from B^0 by dimensional reduction. In the presence of heterotic 5-branes, additional counterterms are induced by the self-dual tensor fields coupling to the 5-branes (see [111–113] for their M-theory origin). This feature is present already in compactifications to six dimensions [114].

In this sub-section we will analyze the field theoretical realization of these Green-Schwarz terms in terms of the elliptic genera discussed in previous section. Our main results can be summarised as follows. Let us first recall how we have determined, in Section 4.1, the 1-loop anomaly coefficients (4.8) in six and four dimensions, via the elliptic genus of the heterotic string. In general, the anomaly coefficients decompose according to the modular and the quasi-modular contributions to the elliptic genus:

$$A^{(d)} = A^{(d),M} + A^{(d),QM}, \quad (4.36)$$

and we have established, for the modular contributions, that

$$A^{(6),M} = m A_{GS}^{(6),M}, \quad A^{(4),M} = m (A_{GS}^{(4),M} + 2A_{GS}^{(4),\partial,M}). \quad (4.37)$$

Here the 1-loop Green-Schwarz term, $A_{GS}^{(d),M}$ is computed from the modular part of the elliptic genus, and in four dimensions we have indicated that there can be an additional derivative part (recall in particular eq. (4.23)). We will find, as expected, that these “modular” Green-Schwarz terms perfectly match the *perturbative* Green-Schwarz terms in the effective action that involve the universal heterotic B-field and, in four dimensions, also the dual axions which relate to the derivative part. Moreover, a possible deficit between this perturbative Green-Schwarz mechanism and the total anomaly will be attributed to the quasi-modular part of the anomaly, $A^{(d),QM}$. This deficit needs to be cancelled via non-perturbative Green-Schwarz terms involving the 5-brane tensor fields as discussed in [110, 114].

Now let us go into the details. In order to avoid the complication of finding heterotic duals [115–118] for F-theory models with abelian gauge groups, we will first perform the computation in the Type IIB/F-theory duality frame. In this way we will arrive at an intersection theoretic interpretation of the Green-Schwarz terms that we computed from the elliptic genus in the previous sections. The form of the Green-Schwarz mechanism in this duality frame has been derived in detail in the literature, beginning with [119] and substantially extended in [120–126]. We can hence be brief and focus on comparing the results of the elliptic genus to the anomaly of the effective action.

In F-theory compactified to d dimensions, the Green-Schwarz counterterms are encoded in the Chern-Simons-type couplings of the Ramond-Ramond 4-form \mathbf{C}_4 to the 7-branes,

$$S_{\text{CS-7}} = -\frac{2\pi}{2} \int_{\mathbb{R}^{1,d-1} \times D_4} \mathbf{C}_4 \wedge \text{tr} e^{F_A} \sqrt{\hat{A}(R)}. \quad (4.38)$$

Here we are assuming that a stack of 7-branes wraps a divisor D_A on the internal space and carries a gauge group G_A . Our conventions for the normalization of the action follows the discussion in [126]. To avoid clutter of notation, we will right away specialise to the situation where the gauge group is given by $G = U(1)$, with field strength F . In this case, the divisor D_A is to be identified with the height-pairing b defined in (2.13) on the internal space. We will furthermore focus purely on gauge anomalies, neglecting gravitational ones. The relevant part of the Cherns Simons couplings then reads

$$S_{\text{CS-7}} = -\frac{2\pi}{2} \int_{\mathbb{R}^{1,d-1} \times b} \mathbf{C}_4 \wedge \frac{1}{2} (F \wedge F) + \dots \quad (4.39)$$

We will first discuss the implications of this Chern-Simons coupling in comparison with the elliptic genus of the dual heterotic string for compactifications to six dimensions. Most of this material is well known.

4.3.1 GS Mechanism in Six Dimensions in Relation to (Quasi-)Modularity

The compactification space of a Type IIB/F-theory in six dimensions is given by the base, B_2 , of an elliptic Calabi-Yau threefold, Y_3 . Let us fix a basis for its (co-)homology,

$$\omega_\alpha \in H^2(B_2), \quad \omega^\alpha \in H_2(B_2), \quad (4.40)$$

with intersection form

$$\Omega_{\alpha\beta} = \int_{B_2} \omega_\alpha \wedge \omega_\beta =: \omega_\alpha \cdot \omega_\beta. \quad (4.41)$$

The intersection form on $H_2(B_2)$ is determined by the inverse matrix, $\Omega^{\alpha\beta}$. In terms of the basis of $H^2(B_2)$ we expand the Ramond-Ramond 4-form field as

$$\mathbf{C}_4 = B^\alpha \wedge \omega_\alpha. \quad (4.42)$$

Note that a D3-brane wrapping some curve $C^I = C^I_\alpha \omega^\alpha$ gives rise to a string that couples locally to the combination

$$B^I = C^I_\alpha B^\alpha. \quad (4.43)$$

By dimensional reduction of the 7-brane Chern-Simons couplings (4.39), we obtain the following Green-Schwarz interactions:

$$S_{\text{GS}} = -\frac{2\pi}{2} \theta_\alpha \int_{\mathbb{R}^{1,5}} B^\alpha \wedge F \wedge F, \quad \theta_\alpha = \frac{1}{2} \int_{B_2} b \wedge \omega_\alpha, \quad (4.44)$$

where b is the height-pairing associated to the $U(1)$ gauge group. By standard arguments these couplings lead to a gauge variation of the effective action which is encoded in an anomaly eight-form, $I_{\text{eff}} = \mathcal{A}_{\text{eff}}^{(6)} F^4$. This then cancels the 1-loop anomaly via:

$$\mathcal{A}_{\text{eff}}^{(6)} = -A^{(6)}. \quad (4.45)$$

This tree-level contribution from the exchange of the various B -fields from the effective action is given by

$$\mathcal{A}_{\text{eff}}^{(6)} = -\frac{1}{2} \theta_\alpha \Omega^{\alpha\beta} \theta_\beta. \quad (4.46)$$

We will now separate the different contributions to $\mathcal{A}_{\text{eff}}^{(6)}$ as based on their respective geometric origin (and later, modularity properties). For this we consider a simplified but prototypical situation that captures all relevant contributions. Following the general philosophy of Section 2.3, we specialise to an F-theory base B_2 which is by itself a \mathbb{P}^1 fibration. While every F-theory base with a standard heterotic dual is a blow-up of a rational fibration, the simplification we are going to make is to consider only a single blowup over a point on the base of this fibration; this of course is easily generalised to an arbitrary sequence of blowups. This means that we consider the blowup of a Hirzebruch surface, which we denote by $B_2 = \text{Bl}^1 \mathbb{F}_n$. For this the homology group of curves is spanned by the classes of the generic fiber f , the exceptional section $S_- = h$ and an exceptional curve C_E^2 . A consequence of the blowup is that the generic fiber splits over a point into two effective curves:

$$f = C_E^1 + C_E^2 = (f - C_E^2) + C_E^2. \quad (4.47)$$

The non-zero intersection numbers between f , h , and C_E^2 are:

$$f \cdot h = 1, \quad h \cdot h = -n, \quad C_E^2 \cdot C_E^2 = -1. \quad (4.48)$$

As will become clear momentarily, a convenient choice of basis for $H_2(B_2)$, which is adapted to the duality with the heterotic string, is given by

$$\{\omega^\alpha\} = \{C^0, \tilde{C}^0, C^E\}, \quad (4.49)$$

where

$$C^0 = f, \quad \tilde{C}^0 = n f + 2h - C_E^2, \quad C^E = C_E^1 - C_E^2 = f - 2C_E^2. \quad (4.50)$$

The intersection form for this basis is

$$\Omega^{\alpha\beta} = \begin{pmatrix} 0 & 2 & 0 \\ 2 & -1 & 0 \\ 0 & 0 & -4 \end{pmatrix}. \quad (4.51)$$

To understand the significance of this basis, note first that the dual basis of $H^2(B_2)$ is given by $\{\omega_\alpha\} = \{\Omega_{\alpha\beta}\omega^\beta\}$ with $\Omega_{\alpha\beta}\Omega^{\beta\gamma} = \delta_\alpha^\gamma$. It reads explicitly:

$$\omega_0 = \frac{1}{4}(C^0 + 2\tilde{C}^0), \quad \tilde{\omega}_0 = \frac{1}{2}C^0, \quad \omega_E = -\frac{1}{4}C^E. \quad (4.52)$$

The point is now that a D3-brane wrapping the curve class C^0 with $C^0 \cdot C^0 = 0$ gives rise to a heterotic string, which can become asymptotically tensionless if the volume of C^0 shrinks to zero size. Moreover this curve class can split further into effective classes as $C^0 = C_E^1 + C_E^2$, and a D3-brane wrapping the two classes gives rise to two non-critical E-strings, respectively. If we correspondingly expand the RR 4-form in the dual divisor classes given in (4.52),

$$\mathbf{C}_4 = B^0 \wedge \omega_0 + \tilde{B}^0 \wedge \tilde{\omega}_0 + B^E \wedge \omega_E, \quad (4.53)$$

it follows from the intersection form (4.51) that the 2-form field B^0 couples only to the heterotic string, and is hence identified with the universal perturbative heterotic B-field.

On the other hand, the 2-form field B^E maps to the anti-self-dual tensor field associated with a heterotic 5-brane that is located at the point on the base of the Hirzebruch surface over which the blowup has been performed. Indeed, we will see that this tensor field couples to

Figure 4: Contributions to the Green-Schwarz mechanism of a six-dimensional F -theory compactification on $B_2 = \text{Bl}^1\mathbb{F}_n$. Only the leftmost contribution is perturbative from the perspective of the dual heterotic string, and matches the fully modular contribution from the elliptic genus.

the linear combination of E-strings from $C^E = C_E^1 - C_E^2$ in the right way to be identified with the tensor field on the heterotic 5-brane. While B^E is anti-self-dual, the perturbative universal B-field B^0 is neither self-dual nor anti-self-dual but can rather be written as a sum of a self-dual and anti-self-dual tensor field. The field \tilde{B}^0 is related to the field dual to B^0 . More precisely, if we were to consider just the Hirzebruch surface $B_2 = \mathbb{F}_n$ without a blowup, the dual heterotic string compactification would be purely perturbative. The analogue of \tilde{C}^0 on \mathbb{F}_n would then be $\tilde{C}_{\text{pert}}^0 = nf + 2h$ with $\tilde{C}_{\text{pert}}^0 \cdot \tilde{C}_{\text{pert}}^0 = 0$, and the associated field $\tilde{B}_{\text{pert}}^0$ is the dual of B^0 . It is this property that has motivated the choice of basis (4.50).

In terms of the decomposition (4.53), we can now read off the Green-Schwarz couplings defined in (4.44) as follows:

$$\theta_0 = \frac{1}{2}\omega_0 \cdot b = \frac{1}{4}m + \frac{1}{4}\tilde{C}^0 \cdot b, \quad (4.54)$$

$$\tilde{\theta}_0 = \frac{1}{2}\tilde{\omega}_0 \cdot b = \frac{1}{4}C^0 \cdot b = \frac{1}{2}m, \quad (4.55)$$

$$\theta_E = \frac{1}{2}\omega_E \cdot b = -\frac{1}{4}(m_1 - m_2). \quad (4.56)$$

Here we have defined

$$m = \frac{1}{2}C^0 \cdot b, \quad m_1 = \frac{1}{2}C_E^1 \cdot b, \quad m_2 = \frac{1}{2}C_E^2 \cdot b, \quad (4.57)$$

with $m = m_1 + m_2$.

As shown in Figure 4, the couplings θ_α give rise to the following tree-level contributions to the anomaly coefficient (4.46):

$$\mathcal{A}_{\text{eff}}^{(6)} = -\frac{1}{2}\theta_\alpha \Omega^{\alpha\beta} \theta_\beta = \mathcal{A}_{\tilde{B}^0-B^0} + \mathcal{A}_{\tilde{B}^0-\tilde{B}^0} + \mathcal{A}_{B^E-B^E}, \quad (4.58)$$

where

$$\mathcal{A}_{\tilde{B}^0-B^0} = -2\tilde{\theta}_0 \theta_0 = -m \left(\frac{1}{4}m + \frac{1}{4}\tilde{C}^0 \cdot b \right), \quad (4.59)$$

$$\mathcal{A}_{\tilde{B}^0-\tilde{B}^0} = \frac{1}{2}\tilde{\theta}_0 \tilde{\theta}_0 = \frac{1}{2} \left(\frac{1}{2}m \right)^2, \quad (4.60)$$

$$\mathcal{A}_{B^E-B^E} = 2\theta_E \theta_E = \frac{1}{2} \left(\frac{1}{2}(m_1 - m_2) \right)^2. \quad (4.61)$$

On the other hand, recall from the previous section that the anomaly (4.8) as encoded in the elliptic genus can be written as a sum of two pieces

$$A^{(6)} = A^{(6),M} + A^{(6),QM}, \quad (4.62)$$

which are associated with the modular and the quasi-modular parts of the elliptic genus, respectively. The quasi-modular part of the six-dimensional anomaly has been computed in full generality in (4.27), and is cancelled by the sum $\mathcal{A}_{\tilde{B}^0-\tilde{B}^0} + \mathcal{A}_{B^E-B^E}$. This then provides the following match between couplings of the effective action and the modular and quasi-modular parts of the elliptic genus:

$$\mathcal{A}_{\tilde{B}^0-B^0} = -A^{(6),M}, \quad (4.63)$$

$$\mathcal{A}_{\tilde{B}^0-\tilde{B}^0} + \mathcal{A}_{B^E-B^E} = -A^{(6),QM}. \quad (4.64)$$

Moreover, from (4.12) we recall that

$$A^{(6),M} = m A_{GS}^{(6),M}. \quad (4.65)$$

By comparison with the above expression for $\mathcal{A}_{B^0-\tilde{B}^0}$, this then identifies the field theoretic coupling θ_0 with the modular contribution to the Green-Schwarz term,

$$A_{GS}^{(6),M} = \theta_0 = \frac{1}{4}m + \frac{1}{4}\tilde{C}^0 \cdot b. \quad (4.66)$$

In turn, these identifications also allow to link the “quasi-modular” pieces of the anomaly, $A^{(6),QM}$, to the presence of non-perturbative heterotic 5-branes [114] as follows: The Green-Schwarz term θ_0 is, up to overall normalization, the Green-Schwarz term of the perturbative heterotic B-field, as obtained by standard dimensional reduction of the perturbative 10-dimensional Green-Schwarz terms. The analogue of this term is present also in heterotic backgrounds without heterotic 5-branes, and consequently is determined by the purely modular piece of the elliptic genus.

By contrast, the anomaly cancelling contributions $\mathcal{A}_{\tilde{B}^0-\tilde{B}^0} + \mathcal{A}_{B^E-B^E}$ are non-perturbative from the heterotic point of view: The first term, $\mathcal{A}_{\tilde{B}^0-\tilde{B}^0}$, arises from the exchange of the dual of the heterotic B-field, \tilde{B}^0 . This coupling is absent in the perturbative cousin of this geometry where there is no blowup and the base B_2 is given by the Hirzebruch surface, \mathbb{F}_n . As noted above, in this case we have $\tilde{C}_{\text{pert}}^0 \cdot \tilde{C}_{\text{pert}}^0 = 0$ and hence the coupling of $\tilde{B}_{\text{pert}}^0$ to itself in (4.78) vanishes. Thus the origin of such a term must be attributed to non-perturbative heterotic 5-branes in the dual heterotic picture, as explained in [114].

Similarly, the second term, $\mathcal{A}_{B^E-B^E}$, must originate from couplings that involve the extra anti-symmetric tensor field B^E living in the worldvolume of the 5-brane. The form of these anomalies likewise matches the results in [114].

In summary, eq. (4.64) shows that the two non-perturbative contributions to the anomaly are beautifully matched by the quasi-modular part of the anomaly, precisely as encoded in the elliptic genus. On the other hand, the corresponding Green-Schwarz terms, $\tilde{\theta}_0$ and θ_E , are not reproduced by $A_{GS}^{(6),QM}$ from the elliptic genus, as the latter is a one-loop quantity that is agnostic about the non-perturbative sector. Only the perturbative, modular contribution $A_{GS}^{(6),M}$ of the elliptic genus matches, as per (4.66), the Green-Schwarz term θ_0 in the effective action.

4.3.2 GS Mechanism in Four Dimensions versus Modularity and Derivative Terms

After this preparation, we now turn to the Green-Schwarz mechanism in four dimensions. The new ingredient, in line with the main theme of this paper, will be the derivative sector of the elliptic genus. As we will see, it encodes the Green-Schwarz mechanism associated with extra, non-universal 2-form fields B^i which arise from the perturbative B-field in ten dimensions by dimensional reduction.

In four dimensions, we reduce the Ramond-Ramond four-form field, \mathbf{C}_4 , into 2-form fields B^α and their dual, zero-form axions c_α by expanding

$$\mathbf{C}_4 = B^\alpha \wedge \omega_\alpha + c_\alpha \omega^\alpha. \quad (4.67)$$

Here $\{\omega_\alpha\}$ is a basis of $H^{1,1}(B)$ and $\{\omega^\alpha\}$ the dual basis of $H^{2,2}(B_3)$, which are defined such that

$$\int_{B_3} \omega_\alpha \wedge \omega^\beta =: \omega_\alpha \cdot \omega^\beta = \delta_\alpha^\beta. \quad (4.68)$$

Plugging this expansion into the 7-brane action (4.39), we can read off the Green-Schwarz terms involving the 2-form fields B^α and the Chern-Simons terms involving their dual axions c_α as follows:

$$S_{\text{CS-7}} = S_{\text{GS}} + S_{\text{CS}} \quad (4.69)$$

$$S_{\text{GS}} = -\frac{2\pi}{2} \theta_\alpha \int_{\mathbb{R}^{1,3}} B^\alpha \wedge F, \quad \theta_\alpha = b \cdot F \cdot \omega_\alpha, \quad (4.70)$$

$$S_{\text{CS}} = -\frac{2\pi}{2} m^\alpha \int_{\mathbb{R}^{1,3}} c_\alpha F \wedge F, \quad m^\alpha = \frac{1}{2} b \cdot \omega^\alpha. \quad (4.71)$$

The tree-level exchange of the B - and c -fields then gives rise to a gauge variation of the effective action, with anomaly six-form given by $I_{\text{eff}} = \mathcal{A}_{\text{eff}}^{(4)} F^3$, where

$$\mathcal{A}_{\text{eff}}^{(4)} = -m^\alpha \theta_\alpha. \quad (4.72)$$

This precisely cancels the field theoretic 1-loop anomaly $A^{(4)}$ as normalised in (4.4):

$$\mathcal{A}_{\text{eff}}^{(4)} = -A^{(4)}. \quad (4.73)$$

As in the six-dimensional setting, we now specialize to a prototypical example that captures all variants of anomaly cancellation. For this we consider a fourfold base, $B_3 \subset Y_4$, which is by itself a \mathbb{P}^1 -fibration over some base space B_2 , and for simplicity of presentation we assume here again that there is only one blow-up divisor, E . We refer to Section 2.3 for our notation for this type of geometries. A basis of $H_2(B_3)$ that is convenient for comparison with the dual heterotic geometry is given by

$$\{\omega^\alpha\} = \{\omega^0 := C^0, \quad \omega^E := C_E^1 - C_E^2, \quad \omega^i := S_+ \cdot p^*(C^i)\}, \quad (4.74)$$

where $\{C^i\}$ is a basis of divisor classes on B_2 . A D3-brane along the rational fiber C^0 of B_3 , or along the exceptional curves $C_E^{1,2}$, gives rise to a heterotic string or two copies of E-strings, respectively. The 2-form fields coupling to these strings are obtained by expanding \mathbf{C}_4 with respect to the basis of dual divisors:

$$\{\omega_\alpha\} = \{\omega_0 := S_- - \frac{1}{2}E, \quad \omega_E := \frac{1}{2}E, \quad \omega_i := p^*(C_i)\}. \quad (4.75)$$

Here, S_- is the exceptional section of the \mathbb{P}^1 -fibration, E is the blowup divisor, and $\{C_i\}$ is a basis of $H^{1,1}(B_2)$ related to $\{C^i\}$ via

$$C^i \cdot_{B_2} C_j = \delta_j^i. \quad (4.76)$$

The corresponding expansion

$$\mathbf{C}_4 = B^\alpha \wedge \omega_\alpha = B^0 \wedge (S_- - \frac{1}{2}E) + B^E \wedge (\frac{1}{2}E) + B^i \wedge p^*(C_i) + \dots \quad (4.77)$$

then defines the various 2-form fields that are relevant for us. First, the field B^0 maps to the perturbative heterotic B-field in four dimensions. Furthermore B^E represents the 2-form field in four dimensions which lives on the worldvolume of the spacetime-filling heterotic 5-brane, which is the geometry that is dual to the blowup on the F-theory side. Finally, the 2-form fields B^i correspond to the 2-forms obtained on the heterotic side by expanding the ten-dimensional magnetic dual six-form, B_6 , on 4-forms $p^*(C_i)$, which are the pullbacks of the 2-form divisor classes on B_2 .

In the basis (4.75), the coefficient of the anomaly (4.72) induced by the Green-Schwarz terms then reads:

$$\mathcal{A}_{\text{eff}}^{(4)} = -(F \cdot b \cdot (S_- - \frac{1}{2}E)) m - (F \cdot b \cdot \frac{1}{2}E) (m_1 - m_2) - (F \cdot b \cdot p^*(C_i)) m^{(i)}, \quad (4.78)$$

where

$$\begin{aligned} m &= \frac{1}{2}(b \cdot C^0), \\ m_1 - m_2 &= \frac{1}{2}(b \cdot (C_E^1 - C_E^2)), \\ m^{(i)} &= \frac{1}{2}(b \cdot S_+ \cdot p^*(C^i)). \end{aligned} \quad (4.79)$$

Now our task is to compare $\mathcal{A}_{\text{eff}}^{(4)}$ with the various modular/quasi-modular/non-modular components of the anomaly $A^{(4)}$, as encoded in the decomposition (3.13) of the elliptic genus. For this we rewrite the latter in terms of a new basis (signified by a tilde) that is adapted to (4.78). This geometrically motivated basis is however not well aligned with modularity, and thus will generically mix the various components of the elliptic genus. Concretely, in our specific prototypical example, and also in all other examples studied in this work, we find that the elliptic genus can be equivalently written as

$$Z_{\mathbf{G}, C^0} = \tilde{g}^0 \tilde{Z}_{-1, m}^0 + \tilde{g}^E \tilde{Z}_{-1, m}^E + \sum_i \tilde{g}^i \left(\tilde{Z}_{-1, m}^i + \frac{1}{2m} \xi \partial_\xi \tilde{Z}_{-2, m}^i \right), \quad (4.80)$$

with the following flux-dependent coefficients:

$$\tilde{g}^0 = (F \cdot b \cdot (S_- - \frac{1}{2}E)), \quad \tilde{g}^E = (F \cdot b \cdot \frac{1}{2}E), \quad \tilde{g}^i = (F \cdot b \cdot p^*(C_i)). \quad (4.81)$$

Here, $\tilde{Z}_{-1, m}^0$ is a modular Jacobi form of weight -1 and index m which is necessarily of the form (4.17), while the remaining contributions mix both modular and quasi-modular pieces. Following our previous notation, we can thus write:

$$\begin{aligned} \tilde{Z}_{*, m}^0 &= \tilde{Z}_{*, m}^{0, M}, \\ \tilde{Z}_{-1, m}^E &= \tilde{Z}_{-1, m}^{E, M} + \tilde{Z}_{-1, m}^{E, QM}, \\ \tilde{Z}_{*, m}^i &= \tilde{Z}_{*, m}^{i, M} + \tilde{Z}_{*, m}^{i, QM}. \end{aligned} \quad (4.82)$$

After these preparations we can now easily compare the various terms of $\mathcal{A}_{\text{eff}}^{(4)}$ in (4.78) with the coefficients (4.80) of the elliptic genus, $Z_{\mathbf{G},C^0}$, by filtering the individual $\tilde{Z}_{*,m}^*$ through the formula (4.8). This leads to the following decomposition of the total anomaly:

$$A^{(4)} =: \tilde{g}^0 A_{\tilde{Z}_{-1,m}^0} + \tilde{g}^E A_{\tilde{Z}_{-1,m}^E} + \sum_i \tilde{g}^i (A_{\tilde{Z}_{-1,m}^i} + A_{\tilde{Z}_{-2,m}^i}). \quad (4.83)$$

Imposing $\mathcal{A}_{\text{eff}}^{(4)} = -A^{(4)}$ we can thus identify¹⁹

$$\tilde{g}^0 A_{\tilde{Z}_{-1,m}^0} = (F \cdot b \cdot (S_- - \frac{1}{2}E)) m, \quad (4.84)$$

$$\tilde{g}^E A_{\tilde{Z}_{-1,m}^E} = (F \cdot b \cdot \frac{1}{2}E) (m_1 - m_2), \quad (4.85)$$

$$\tilde{g}^i A_{\tilde{Z}_{-1,m}^i} + \tilde{g}^i A_{\tilde{Z}_{-2,m}^i} = (F \cdot b \cdot p^*(C_i)) m^{(i)}. \quad (4.86)$$

This generic match between geometric, flux dependent quantities pertaining to the effective action on the one hand, and the various contributions to the elliptic genus on the other, is a central point of the present paper. While we have worked it out here for a prototypical situation which is dual to a heterotic string, it applies also to much more general geometries. However it is difficult to refine these statements without specifying more data explicitly, and this is why we will present in Section 5 some detailed computations for explicit examples. Most importantly, we will see directly how the derivative part of the elliptic genus, encoded in the $\tilde{Z}_{-2,m}^i$, relates to the Green-Schwarz mechanism involving the additional four-dimensional 2-form fields B^i .

Before concluding this section, let us present some further remarks about the Green-Schwarz terms, which are determined by the 1-loop computation shown in eq. (4.10). Like the anomaly (4.83), also the Green-Schwarz terms receive contributions from both the modular and the quasi-modular parts of the elliptic genus:

$$A_{GS}^{(4)} = A_{GS}^{(4),M} + A_{GS}^{(4),QM}.$$

By (4.12), the Green-Schwarz terms computed from the purely modular contributions are guaranteed to match the field theoretic Green-Schwarz terms, which are perturbative in the sense that they are independent of the heterotic 5-branes. Indeed, in the present context, where $Z_{\mathbf{G},C^0}$ is written in the special basis (4.80), anomaly cancellation in the perturbative sector takes the form:

$$A^{(4),M} = m \left(\tilde{g}^0 A_{\tilde{Z}_{-1,m}^0}^{\text{GS}} + \sum_i \tilde{g}^i (A_{\tilde{Z}_{-1,m}^i}^{\text{GS}} + 2A_{\tilde{Z}_{-2,m}^i}^{\text{GS}}) \right). \quad (4.87)$$

From the perspective of the dual heterotic string, this equation comprises the complete perturbative part of the anomaly cancellation mechanism, involving the universal B-field B^0 in the first term and the additional four-dimensional 2-form fields B^i , which are obtained by dimensional reduction of the ten dimensional six-form field, B_6 .

Note the factor of 2 in the last expression, which reflects the relation (4.22) for the derivative part of the elliptic genus. Note also that in (4.87) we did not write any modular contributions from $\tilde{Z}_{-1,m}^{E,M}$, because they must vanish anyway:

$$A_{\tilde{Z}_{-1,m}^{E,M}} = 0, \quad A_{\tilde{Z}_{-1,m}^0}^{\text{GS}} = 0. \quad (4.88)$$

¹⁹Note that one can write the flux-dependent triple-intersections on B_3 directly on Y_4 by exploiting the identity $-\int_{Y_4} \mathbf{G} \wedge \sigma \wedge \pi^* D = F \cdot b \cdot D$ for $\mathbf{G} = \sigma \wedge \pi^* F$.

This is because a fully modular contribution will always produce both the anomaly and its accompanying Green-Schwarz term at the same time, but the latter cannot arise in perturbation theory from the elliptic genus, since it is localized on the brane and thus cannot be captured by the bulk theory. We will find this general expectation confirmed in the computation of explicit examples, in particular by equation (5.92) below.

Similar to the anomalies discussed before, we can also match the Green-Schwarz terms as computed in (4.10) explicitly in terms of the flux geometry, as long as we stay in the fully modular sector. Concretely we find

$$\tilde{g}^0 A_{\tilde{Z}_{-1,m}^0}^{\text{GS}} = (F \cdot b \cdot (S_- - \frac{1}{2}E)). \quad (4.89)$$

The right-hand side is the coefficient of the standard Green-Schwarz term that involves the universal B^0 -field of the heterotic string.

More interesting are the Green-Schwarz terms associated with the derivative, secretly six-dimensional subsector of the theory whose properties are encoded in the embedded threefolds, \mathbb{Y}_3^i . These terms, as computed from the elliptic genus, are expected to agree with the actual counterterms in the effective theory, as long as $\tilde{Z}_{-1,m}^i$ and $\tilde{Z}_{-2,m}^i$ are both fully modular. Following the same line of arguments as before, we find the following identifications between the Green-Schwarz terms as computed from the modular expressions in (4.10) with the intersection numbers of the F-theory flux geometry:

$$\tilde{g}^i (A_{\tilde{Z}_{-1,m}^i}^{\text{GS}} + 2A_{\tilde{Z}_{-2,m}^i}^{\text{GS}}) = \frac{m^{(i)}}{m} (F \cdot b \cdot p^*(C_i)). \quad (4.90)$$

Note that this identification follows from the requirement of anomaly cancellation, i.e., from (4.86) and *imposing* $\mathcal{A}_{\text{eff}}^{(4)} = -A^{(4)}$. It does not *prove* that the anomalies are actually cancelled. To complete a proof, one would need to show that in general the value for A^{GS} in (4.90) as computed from the elliptic genus does actually come out right such as to match the $m^{(i)}$ as determined in (4.79) from the flux geometry in the effective action. While we do not have a general proof for this, we have checked this to be true for the examples presented in the next section. Turning tables round, *assuming* anomaly cancellation gives a prediction for the modular part of A^{GS} in terms of the geometric intersection numbers $m^{(i)}$.

Note that these considerations, and in particular the relation (4.90), do not hold if the elliptic genus has quasi-modular contributions, $\tilde{Z}_{*,m}^{i,QM} \neq 0$: In this case the left-hand side of (4.90), which depends only on the modular parts, is still expected to yield the perturbative Green-Schwarz terms for the fields B^i , but there will be in general additional non-perturbative contributions from the heterotic 5-branes.

In this case, the quasi-modular part of the anomaly, $A^{(4),QM}$, will be non-zero and generically receive two types of contributions:

$$A^{(4),QM} = \tilde{g}^E A_{\tilde{Z}_{-1,m}^{E,QM}} + \sum_i \tilde{g}^i (A_{\tilde{Z}_{-1,m}^i}^{\text{GS}} + 2A_{\tilde{Z}_{-2,m}^i}^{\text{GS}}). \quad (4.91)$$

The first term encodes the part of the anomaly which is cancelled by the Green-Schwarz mechanism involving the B-field B^E from the heterotic 5-branes. From (4.85) we see that the anomaly associated with $\tilde{Z}_{-1,m}^{E,QM}$ is proportional to $m_1 - m_2$. This agrees beautifully with the form of the anomaly computed from the elliptic genus in (4.33), provided $\tilde{Z}_{-1,m}^{E,QM}$ is of the form (4.32). In a sense this predicts that it *must* be possible to write $\tilde{Z}_{-1,m}^{E,QM}$ *must be* as in (4.32), as far as its expansion up to order \hat{z}^3 is concerned.

The second type of contributions in (4.91) must be cancelled by non-perturbative contributions to the Green-Schwarz terms for the additional B^i -fields in four dimensions. Note that $\tilde{Z}_{-1,m}^{i,QM}$ and $\tilde{Z}_{-2,m}^{i,QM}$ are non-zero only if the threefold \mathbb{Y}_3^i , whose BPS invariants are encoded in $\tilde{Z}_{-2,m}^i$, contains the exceptional fibral curves C_E^1 and C_E^2 . This is the case if the class of the blowup curve Γ , when expanded with respect to a chosen basis $\{C_j\}$, has a non-trivial contribution from C_i . In fact, we may assume without loss of generality that Γ is proportional to C_i . By construction this curve maps to the curve wrapped by the NS5-brane on the dual heterotic 3-fold. We can thus conclude a bit more sharply that:

$$A^{(4),QM} = (F \cdot b \cdot \frac{1}{2}E) (m_1 - m_2) + (F \cdot b \cdot p^*(\Gamma)) m_\Gamma, \quad (4.92)$$

where m_Γ is a parameter which we cannot determine from the above considerations alone. However it is reassuring that the general structure of these terms indeed matches the architecture of the abelian heterotic Green-Schwarz mechanism in the presence of 5-branes, as was discussed in [110].

5 Elliptic Genera of 4d Heterotic Strings

So far we have presented generic and prototypical results concerning the modularity of elliptic genera in relation to the background fourfold geometries, Y_4 , and flux configurations, \mathbf{G} . This general structure will now be illustrated by detailed computations for a few examples, for which sharper statements can be made, in particular concerning the structure and rôle of the embedded six-dimensional, derivative sector.

We begin in this section with the elliptic genus of four-dimensional heterotic strings. In the example of Section 5.1, the embedded threefolds that encode the derivative sector are by themselves Calabi-Yau spaces, while in Section 5.2 we discuss an example where the derivative sector encodes the relative BPS numbers of a non-Calabi-Yau threefold.

We will label the examples by the geometry of the base, B_3 , of a given elliptic fourfold fibration, Y_4 . In order to curb mathematical overload of this section, we have relegated further details about the geometry to Appendix B.

5.1 Example 1: $B_3 = dP_2 \times \mathbb{P}_\nu^1$

As our first example we consider F-theory on an elliptic fibration Y_4 whose base B_3 is given by the blow-up

$$B_3 = dP_2 \times \mathbb{P}_\nu^1, \quad (5.1)$$

of the rational fibration $\mathbb{F}_1 \times \mathbb{P}_\nu^1$, where the del Pezzo surface dP_2 is viewed as the blow-up of the Hirzebruch surface \mathbb{F}_1 in one point: Since the Hirzebruch surface is a rational fibration with generic fiber $C^0 = \mathbb{P}_f^1$ and base \mathbb{P}_h^1 , we can view B_3 as the blowup of the rational fibration over the base $B_2 = \mathbb{P}_h^1 \times \mathbb{P}_\nu^1$,

$$p: C^0 \longrightarrow B_3 \\ \downarrow \\ \mathbb{P}_h^1 \times \mathbb{P}_\nu^1 \quad (= B_2), \quad (5.2)$$

where the blowup locus is homologous to \mathbb{P}_ν^1 in B_2 . This type of base spaces fits into the class of geometries described in Section 2.3. In particular, the rational fibration has an exceptional

section S_- , which embeds B_2 into B_3 and which satisfies the relation

$$S_- \cdot S_+ = 0, \quad S_+ = S_- + p^*(\mathbb{P}_\nu^1). \quad (5.3)$$

As a result of the blow-up inherited from dP_2 , the generic rational fiber C^0 splits into a sum of two exceptional curves $C_E^1 + C_E^2$, where C_E^1 and C_E^2 are distinguished by their intersection numbers with S_- as in (2.30). The splitting occurs over a point on \mathbb{P}_h^1 within B_2 . The exceptional divisor E associated with this blowup is thus a fibration of C_E^2 over \mathbb{P}_ν^1 , and since the rational fibration of B_3 is trivial over \mathbb{P}_ν^1 , it is in fact a direct product:

$$E = C_E^2 \times \mathbb{P}_\nu^1. \quad (5.4)$$

As a convenient basis for $H_2(B_3)$ we pick the curve classes

$$C^0 = \mathbb{P}_f^1, \quad C^E = C_E^1 - C_E^2, \quad C_1 = \mathbb{P}_\nu^1, \quad C_2 = \mathbb{P}_h^1. \quad (5.5)$$

Since we will also need the curve classes dual to C_1 and C_2 on B_2 , note that the only non-zero entries of the intersection form $\eta_{ij} = C_i \cdot_{B_2} C_j$ are $\eta_{12} = \eta_{21} = 1$, so that the dual curves $C^i = \eta^{ij} C_j$ on B_2 are

$$C^1 = C_2, \quad C^2 = C_1. \quad (5.6)$$

The choice of basis $\{C_1, C_2\}$ for $H_2(B_2)$ made here corresponds to the generators of the simplicial Mori cone of B_2 , which was advertised as a basis with special properties in Section 3.3; the dual curves, C^1 and C^2 , hence generate the Kähler cone of B_2 . As basis for the divisor group on B_3 we introduce $\{D_\alpha\}_{\alpha=1}^4$, which are defined as

$$D_1 = p^*(C_1), \quad D_2 = S_-, \quad D_3 = p^*(C_2), \quad D_4 = p^*(C_1) + S_- - E. \quad (5.7)$$

In terms of these basis elements D_α , the intersection polynomial and the anti-canonical class are

$$I(B_3) = D_1 D_2 D_3 - D_2^2 D_3 + D_1 D_3 D_4, \quad (5.8)$$

$$\bar{K}_{B_3} = 2D_1 + D_2 + 2D_3 + D_4. \quad (5.9)$$

Having specified some properties of the base, $B_3 = dP_2 \times \mathbb{P}_\nu^1$, we now turn to the structure of the elliptic fibration Y_4 . It has an additional rational section in addition to the zero-section. As reviewed in Section 2.2, this leads to gauge group $G = U(1)$. Moreover we choose a specific fibration [127, 128] for which the height-pairing is given by

$$b = 2\bar{K}_{B_3}. \quad (5.10)$$

Further details of the fibration are provided in Appendix B. The massless matter spectrum comprises states of charge $r = \pm 1$, which are localised in the fiber along the curve $\Sigma_{r=1}$ of class

$$\Sigma_{r=1} = 12\bar{K}_{B_3} \cdot \bar{K}_{B_3} = -84C^0 + 21(b \cdot p^*(C_1)) + 24(b \cdot p^*(C_2)). \quad (5.11)$$

Furthermore we note that the $U(1)$ flux in $H_{\text{vert}}^{2,2}(Y_4, \mathbb{R})$ can be expanded into the divisors D_α as follows:

$$\mathbf{G} \equiv \mathbf{G}_{U(1)} = \sigma \wedge \pi^* F, \quad \text{where } F =: \sum_{\alpha=1}^4 c_\alpha D_\alpha. \quad (5.12)$$

With respect to this flux, given the matter curve (5.11) the chiral index of massless chiral spectrum evaluates to

$$\chi_{\mathbf{G}, r=1} = F \cdot \Sigma_{r=1} = 96c_1 + 48c_2 + 84c_3 + 96c_4. \quad (5.13)$$

5.1.1 Relative BPS Invariants and Elliptic Genus

As outlined in Section 2.2, we can use mirror symmetry, suitably adapted to fourfolds [90, 129, 130], to compute a finite number of relative BPS invariants $N_{\mathbf{G};C^0}(n, r)$. Recall from (5.2) that C^0 is the fiber of B_3 which is wrapped by a D3-brane such as to produce the solitonic heterotic string. These invariants can then be packaged into the elliptic genus and extrapolated to all orders by modular completion.

The results of this computation are sketched in Appendix B. We list here just the lowest order in q :

$$\begin{aligned} Z_{\mathbf{G};C^0} &= -\frac{1}{q} \sum_{n,r} N_{\mathbf{G};C^0}(n, r) q^n \xi^r \\ &= -[96c_1 \xi^{\pm\bar{1}} + 48c_2 \xi^{\pm\bar{1}} + 84c_3 \xi^{\pm\bar{1}} + 96c_4 \xi^{\pm\bar{1}}] + \mathcal{O}(q), \end{aligned} \quad (5.14)$$

where $\xi^{\pm\bar{n}} := \xi^n - \xi^{-n}$. Comparing to (5.13), we confirm the advertised relation (3.8) between the relative BPS invariants at level one, $N_{\mathbf{G};C^0}(1, r)$, and the chiral index $\chi_{\mathbf{G},r=1}$.

Moreover, following the discussion in Section 3.2, we aim to identify the BPS invariants $N_{\mathbf{G};C^0}(n, r)$ as expansion coefficients of Jacobi or quasi-modular Jacobi forms (or their derivatives) of $U(1)$ fugacity index

$$m = \frac{1}{2} C^0 \cdot b = 2. \quad (5.15)$$

Given a sufficient number of known $N_{\mathbf{G};C^0}(n, r)$, we can uniquely determine the elliptic genus as follows:

$$Z_{\mathbf{G};C^0} = (F \cdot C^0) Z_{-1,2}^0 + (F \cdot b \cdot p^*(C_1)) \frac{1}{4} \xi \partial_\xi Z_{-2,2}^1 + (F \cdot b \cdot p^*(C_2)) \frac{1}{4} \xi \partial_\xi Z_{-2,2}^2, \quad (5.16)$$

where

$$Z_{-1,2}^0 \equiv Z_{-1,2}^{0,M} = 84\phi_{-1,2} \quad (5.17)$$

$$Z_{-2,2}^2 \equiv Z_{-2,2}^{2,M} = \frac{1}{12} \frac{1}{\eta^{24}} (14E_4 E_{6,2} + 10E_{4,2} E_6) \quad (5.18)$$

$$Z_{-2,2}^1 \equiv Z_{-2,2}^{1,M} + Z_{-2,2}^{1,QM}, \quad \text{where} \quad (5.19)$$

$$Z_{-2,2}^{1,M} = Z_{-2,2}^2 - \frac{1}{12} \frac{1}{\eta^{24}} E_{4,1} E_{6,1}, \quad Z_{-2,2}^{1,QM} = \frac{1}{12} \frac{1}{\eta^{24}} E_2 E_{4,1}^2.$$

For the definition of the Eisenstein and the Eisenstein-Jacobi forms, recall Appendix A. Moreover the flux dependent coefficients in (5.16) evaluate to

$$\begin{aligned} (F \cdot C^0) &= c_2 + c_4, \\ (F \cdot b \cdot p^*(C_1)) &= 4(c_2 + c_3 + c_4), \\ (F \cdot b \cdot p^*(C_2)) &= 2(2c_1 + c_2 + 2c_4). \end{aligned} \quad (5.20)$$

Thus the elliptic genus $Z_{\mathbf{G};C^0}$ in (5.16) does have the general form as advertised in (3.9), or more specifically in (3.13) and (3.14), with the special feature that for the example at hand there happens to be no four-dimensional quasi-modular term, $Z_{-1,m}^E$. This, in fact, mirrors the absence of a term proportional to C_E^1 in (5.11).

Let us now take a closer look at the derivative sector, ie., at the $Z_{-2,2}^i$ for $i = 1, 2$. According to the arguments given in Section 3.2, the $Z_{-2,2}^i$ are generating functions for the relative BPS

invariants of certain elliptic threefolds \mathbb{Y}_3^i within Y_4 . To verify this in the present example, we follow the general prescription of Section 3.2 and consider the threefolds

$$\mathbb{Y}_3^1 = Y_4|_{p^*(C^1)}, \quad \mathbb{Y}_3^2 = Y_4|_{p^*(C^2)}, \quad (5.21)$$

where, according to (5.6), $C^1 = C_2$ and $C^2 = C_1$. Both threefolds are elliptically fibered with respective base spaces

$$\mathbb{B}_2^1 = p^*(C^1) \simeq dP_2, \quad \mathbb{B}_2^2 = p^*(C^2) \simeq C^0 \times \mathbb{P}_1^1. \quad (5.22)$$

Note that only \mathbb{B}_2^1 contains the blowup locus of B_3 , whereas the rational fiber of \mathbb{B}_2^2 never splits into two exceptional curves.

Furthermore, the normal bundles of both \mathbb{Y}_3^i happen to be trivial:

$$N_{\mathbb{Y}_3^i/Y_4} = \mathcal{O}_{\mathbb{Y}_3^i}. \quad (5.23)$$

This is a consequence of the fact that the \mathbb{Y}_3^i are simply the restriction of the elliptic fibration to $p^*(C^i)$, which in turn have vanishing self-intersection on B_3 and hence trivial normal bundle:

$$N_{\mathbb{B}_2^i/B_3} = \mathcal{O}_{\mathbb{B}_2^i}. \quad (5.24)$$

By the adjunction formula this implies that

$$c_1(\bar{K}_{\mathbb{Y}_3^i}) = c_1(\bar{K}_{Y_4}|_{\mathbb{Y}_3^i}) - c_1(N_{\mathbb{Y}_3^i/Y_4}) = 0, \quad (5.25)$$

and therefore both threefolds are themselves Calabi-Yau spaces; we emphasize that this is a special property of the example at hand. Following the discussion in Section 3.3, we can therefore view Y_4 as a fibration in two ways, namely with generic fiber given by either \mathbb{Y}_3^i over its respective base C_i , for $i = 1, 2$. Furthermore we can conclude from the adjunction formula that the anti-canonical bundle of the base spaces of \mathbb{Y}_3^i is simply the restriction of \bar{K}_{B_3} :

$$\bar{K}_{\mathbb{B}_2^i} = \bar{K}_{B_3}|_{\mathbb{B}_2^i} \otimes N_{\mathbb{B}_2^i/B_3}^{-1} = \bar{K}_{B_3}|_{\mathbb{B}_2^i}. \quad (5.26)$$

The structure of the elliptic fibration of \mathbb{Y}_3^i is inherited by restriction from Y_4 . This means that both threefolds are fibrations with an extra section whose height-pairing is simply given by the restriction of $b = 2\bar{K}_{B_3}$ to the respective bases. See Appendix B for details.

With this preparation we can now compare the expressions $Z_{-2,2}^i$ given in eqs. (5.18) and (5.19) with the elliptic genera of the heterotic strings that are dual to six-dimensional F-theory compactifications on the Calabi-Yau threefolds \mathbb{Y}_3^i . In more detail, the first terms in the expansion of $Z_{-2,2}^i$ are

$$Z_{-2,2}^1 = \frac{2}{q} - (252 + 84\xi^{\pm 1}) - q(116580 + 65164\xi^{\pm 1} + 9448\xi^{\pm 2} + 84\xi^{\pm 3} - 2\xi^{\pm 4}) + \dots \quad (5.27)$$

$$Z_{-2,2}^2 = \frac{2}{q} - (288 + 96\xi^{\pm 1}) - q(123756 + 69280\xi^{\pm 1} + 10192\xi^{\pm 2} + 96\xi^{\pm 3} - 2\xi^{\pm 4}) + \dots \quad (5.28)$$

We have checked by direct computation in Appendix B that these expansions perfectly match the low-lying relative BPS invariants for C^0 , for the elliptic Calabi-Yau threefold fibrations \mathbb{Y}_3^i over dP_2 and \mathbb{F}_0 , respectively. This explicitly demonstrates how the six-dimensional structure encoded in the flux-dependent, four-dimensional elliptic genus (5.16) manifests itself, here in

terms of two embedded Calabi-Yau geometries that can be independently controlled by dialing the flux background.

Alternatively, in terms of the dual heterotic language, one can recognize from (5.18) that $Z_{-2,2}^2$ is nothing but the modular, $U(1)$ refined elliptic genus of a perturbative heterotic string compactification on $K3$ (with some specific bundle background turned on such that only the $U(1)$ gauge symmetry is unbroken). This is most visible when switching off the background gauge field:

$$Z_{-2,2}^2(q, \xi = 1) = \frac{2}{\eta^{24}} E_4 E_6 \equiv Z_{K3}(q). \quad (5.29)$$

On the other hand, note that $Z_{-2,2}^1$ is only quasi-modular, in agreement with the above observation that \mathbb{Y}_3^1 contains the blowup locus. In the dual heterotic language, this corresponds to a non-perturbative background. More precisely, the difference,

$$Z_{-2,2}^1 - Z_{-2,2}^2 = \frac{1}{12} \frac{E_2 E_{4,1}^2}{\eta^{24}} - \frac{1}{12} \frac{E_{4,1} E_{6,1}}{\eta^{24}}, \quad (5.30)$$

is suggestive of a transition where a small instanton has been traded against a heterotic NS5-brane.

Finally, we note that the decomposition of the matter curve $\Sigma_{r=1}$ defined in (5.11) perfectly reproduces the general pattern advertised in eq. (3.29), i.e.,

$$\Sigma_{r=1} = N_{C^0}^0(1, 1) C^0 + \frac{1}{4} N_{C^0}^1(1, 1) (b \cdot p^*(C_1)) + \frac{1}{4} N_{C^0}^2(1, 1) (b \cdot p^*(C_2)), \quad (5.31)$$

with $N_{C^0}^1(1, 1) = 84$ from (5.27), $N_{C^0}^2(1, 1) = 96$ from (5.28) and $N_{C^0}^0(1, 1) = -84$. The latter follows from $Z_{-1,m=2}^0 = 84\phi_{-1,2} = -\frac{1}{q} \sum N_{C^0}^0(n, r) q^n \xi^r = 84(\xi - \xi^{-1}) + \dots$

Let us close this part of the discussion by demonstrating the claim of Section 3.4 that the embedded threefold invariants relative to C^0 have another interpretation in terms of non-transversal (-2) -fluxes. This allows us to explicitly verify the special form of the elliptic holomorphic anomaly equation as given in (3.35). Recall that the non-transversal (-2) -fluxes lie in the space $H_{(-2)}^{(2,2)}(Y_4, \mathbb{R})$ defined in (2.17), and do not lift to fluxes in F-theory. We first need to fix a concrete basis (3.39) for it. Out of the set of all products of elements $\{S_-, E, p^*(C^1), p^*(C^2)\}$, the following four non-vanishing fluxes can be taken as a maximal linearly independent set:

$$\begin{aligned} \mathbf{G}^1 &= \pi^*(S_-) \wedge \pi^*(p^*(C^1)), & \mathbf{G}^2 &= \pi^*(S_-) \wedge \pi^*(p^*(C^2)), \\ \mathbf{G}^E &= \pi^*(E) \wedge \pi^*(p^*(C^1)), & \mathbf{G}^0 &= \pi^*(p^*(C^1)) \wedge \pi^*(p^*(C^2)). \end{aligned} \quad (5.32)$$

By performing analogous computations in mirror symmetry as sketched in Appendix B, we can compute the relative BPS invariants with respect to C^0 in each of these backgrounds. The result is

$$\begin{aligned} \mathcal{F}_{\mathbf{G}^1; C^0} &= -q Z_{-2,2}^1, & \mathcal{F}_{\mathbf{G}^2; C^0} &= -q Z_{-2,2}^2, \\ \mathcal{F}_{\mathbf{G}^E; C^0} &= 0, & \mathcal{F}_{\mathbf{G}^0; C^0} &= 0, \end{aligned} \quad (5.33)$$

where the $Z_{-2,2}^i$ encode the relative BPS invariants for C^0 as a curve within the Calabi-Yau threefolds \mathbb{Y}_3^i , as displayed in (5.27) and (5.28). This confirms the claims stated in eq. (3.40) and (3.41). In particular we confirm the relation (3.45) for the lowest degeneracies in $Z_{-2,2}^i$, because $C^i \cdot_{B_2} K_{B_2} = -2$ for both base curves.

5.1.2 Anomalies and Counterterms

We now show explicitly how the general structure of the $U(1)$ gauge anomaly and its counterterms, as laid out in generality in Section 4, works in this example. First we rewrite the elliptic genus in (5.16) in the form (4.80) as

$$Z_{\mathbf{G};C^0} =: \tilde{g}^0 \tilde{Z}_{-1,2}^0 + \sum_{i=1}^2 \tilde{g}^i \left(\tilde{Z}_{-1,2}^i + \frac{1}{4} \xi \partial_\xi \tilde{Z}_{-2,2}^i \right), \quad (5.34)$$

where the flux dependent parameters

$$\tilde{g}^0 = (F \cdot b \cdot (S - \frac{1}{2}E)) = 4c_1 - 4c_2 + c_3 - 2c_4, \quad (5.35)$$

$$\tilde{g}^1 = (F \cdot b \cdot p^*(C_1)) = 4(c_2 + c_3 + c_4), \quad (5.36)$$

$$\tilde{g}^2 = (F \cdot b \cdot p^*(C_2)) = 2(2c_1 + c_2 + 2c_4) \quad (5.37)$$

multiply the modular Jacobi forms

$$\begin{aligned} \tilde{Z}_{-1,2}^* &\equiv \tilde{Z}_{-1,2}^{*,M} \quad \text{with} \\ \tilde{Z}_{-1,2}^{0,M} &= -12\phi_{-1,2}, \quad \tilde{Z}_{-1,2}^{1,M} = 3\phi_{-1,2}, \quad \tilde{Z}_{-1,2}^{2,M} = 12\phi_{-1,2}. \end{aligned} \quad (5.38)$$

Moreover we write

$$\tilde{Z}_{-2,2}^2 = Z_{-2,2}^{2,M}, \quad \tilde{Z}_{-2,2}^1 = Z_{-2,2}^{1,M} + Z_{-2,2}^{1,QM}, \quad (5.39)$$

as defined in (5.19).

In line of what we pointed out before, the inherently four-dimensional contributions to the elliptic genus are all proportional to the modular Jacobi form $\phi_{-1,2}$. The anomaly and Green-Schwarz term associated with $\phi_{-1,2}$ follow from (4.18) and are given by:

$$\phi_{-1,2} : \quad A^{(4)} = -\frac{1}{6}, \quad A_{GS}^{(4)} = -\frac{1}{12}. \quad (5.40)$$

Anomaly cancellation, $A = mA_{GS}$, is of course automatic as a consequence of modularity.

Consider next the more interesting derivative contributions to the elliptic genus. We have seen that we can formally associate six-dimensional anomalies and Green-Schwarz terms with them. The contributions to the four-dimensional anomaly and GS terms then follow from these via (4.21) and (4.22).

Specifically, recall that $Z_{-2,2}^2$, associated with the embedded threefold \mathbb{Y}_3^2 , is purely modular. Consistent with this, we obtain, by direct evaluation of (4.8) and (4.10), for

$$\tilde{Z}_{-2,2}^2 = Z_{-2,2}^{2,M} : \quad A^{(6),M} = 4, \quad A_{GS}^{(6),M} = 2 \quad (5.41)$$

in agreement with the general formula (4.16). By contrast, $Z_{-2,2}^1$, which is associated with \mathbb{Y}_3^1 , receives both a modular and a quasi-modular contribution. The modular part works out along the same lines as for $Z_{-2,2}^2$. The quasi-modular anomaly and Green-Schwarz terms follow from (4.27) and (4.28), and altogether we find:

$$\begin{aligned} \tilde{Z}_{-2,2}^{1,M} : \quad A^{(6),M} &= 4, & A_{GS}^{(6),M} &= 2, \\ \tilde{Z}_{-2,2}^{1,QM} : \quad A^{(6),QM} &= -\frac{1}{4}(m_1^2 + m_2^2) = -\frac{1}{2}, & A_{GS}^{(6),QM} &= -\frac{1}{12m}(m_1 + m_2)^2 = -\frac{1}{6}, \end{aligned} \quad (5.42)$$

where we used $m_1 = m_2 = 1$ and $m = m_1 + m_2 = 2$.

With everything combined and recalling in particular (4.21), the four-dimensional anomaly thus evaluates to

$$\begin{aligned} A^{(4)} &= A^{(4),M} + A^{(4),QM} & (5.43) \\ A^{(4),M} &= (F \cdot b \cdot (S - \frac{1}{2}E))m + (F \cdot b \cdot p^*(C_2))(m^2 - m) + (F \cdot b \cdot p^*(C_1))(m^2 - \frac{m}{4}) \\ A^{(4),QM} &= (F \cdot b \cdot p^*(C_1))(-\frac{1}{2}). \end{aligned}$$

In total, when all variables are substituted by their definite expressions, this indeed correctly reproduces the 1-loop anomaly:

$$A^{(4)} = 16c_1 + 8c_2 + 14c_3 + 16c_4 = \frac{1}{3!} \chi_{\mathbf{G},r=1}, \quad (5.44)$$

where $\chi_{\mathbf{G},r=1}$ is given in (5.13).

Let us now have a closer look at the Green-Schwarz terms and check anomaly cancellation in particular for the derivative terms of the elliptic genus. We mentioned already that in the fully modular, non-derivative sector, the Green-Schwarz terms are guaranteed to cancel the perturbative anomaly from the perspective of the heterotic string. Indeed the relation (4.89) is obviously satisfied by means of (5.40):

$$\tilde{g}^0 A_{\tilde{Z}_{-1,m}^0}^{\text{GS}} = \frac{12}{12} (F \cdot b \cdot (S_- - \frac{1}{2}E)) = (F \cdot b \cdot (S_- - \frac{1}{2}E)). \quad (5.45)$$

A bit less trivial is the anomaly cancellation in the derivative, but modular subsector. This sector is associated just with \mathbb{Y}_3^2 , since \mathbb{Y}_3^1 involves a quasi-modular piece. Let us thus check the relation (4.90) which arises from $\tilde{Z}_{-1,2}^2$ and $\tilde{Z}_{-2,2}^2$ in the elliptic genus. Explicitly, (5.40), (5.41) and (4.22) when taken together yield

$$\tilde{g}^2 (A_{\tilde{Z}_{-1,m}^2}^{\text{GS}} + 2A_{\tilde{Z}_{-2,m}^2}^{\text{GS}}) = (-\frac{12}{12} + 2 \times \frac{1}{4} \times 2 \times 2) (F \cdot b \cdot p^*(C_2)) = (F \cdot b \cdot p^*(C_2)). \quad (5.46)$$

To compare this to (4.90), which posits that

$$\tilde{g}^2 (A_{\tilde{Z}_{-1,m}^2}^{\text{GS}} + 2A_{\tilde{Z}_{-2,m}^2}^{\text{GS}}) = \frac{m^{(2)}}{m} (F \cdot b \cdot p^*(C_2)), \quad (5.47)$$

we need to know the parameter $m^{(2)}$. While we could not offer in Section 4.3.2 an a priori argument why it always takes the correct value, we find here in the current example by direct computation that

$$m^{(2)} = \frac{1}{2} (b \cdot S_+ \cdot p^*(C_2)) = 2. \quad (5.48)$$

Hence indeed the anomaly is cancelled as expected.

By contrast, for the Green-Schwarz terms derived from $\tilde{Z}_{-1,m}^1$ and $\tilde{Z}_{-2,m}^1$, which exhibit a quasi-modular contribution, we find, using among others, (4.22),

$$\tilde{g}^1 (A_{\tilde{Z}_{-1,m}^1}^{\text{GS}} + 2A_{\tilde{Z}_{-2,m}^1}^{\text{GS}}) = (-\frac{3}{12} + 2 \times \frac{1}{4} \times 2 \times (2 - \frac{1}{6})) (F \cdot b \cdot p^*(C_1)) = \frac{19}{12} (F \cdot b \cdot p^*(C_1)) \quad (5.49)$$

while

$$m^{(1)} = \frac{1}{2}(b \cdot S_+ \cdot p^*(C^1)) = 3. \quad (5.50)$$

Therefore we get a mismatch as compared to (5.49):

$$\frac{m^{(1)}}{m}(F \cdot b \cdot p^*(C_1)) = \frac{3}{2}(F \cdot b \cdot p^*(C_1)), \quad (5.51)$$

which reflects that further Green-Schwarz terms, localized on the heterotic NS5-branes, are needed to fully cancel the anomaly. Nevertheless, the quasi-modular contribution to the anomaly as such, A^{QM} , is of the general form given in (4.92). In our specific example, where $m_1 = m_2 = 1$, the first term in (4.92) actually vanishes.

5.2 Example 2: $B_3 = \text{Bl}^1 \mathbb{H}_1$

As our second example we take the base of the F-theory elliptic fourfold Y_4 to be a blowup of the space \mathbb{H}_1 , which is defined as a \mathbb{P}^1 -fibration over $B_2 = \mathbb{P}^2$ with twist bundle $\mathcal{L} = \mathcal{O}(p^*H)$. Here H is the hyperplane class on B_2 . Since this geometry was discussed already in detail in [6], we can be brief in explaining it.

The blowup is performed over a curve in the class $C_1 = H$ on B_2 and leads to a splitting of the rational fiber C^0 into two exceptional curves, C_E^1 and C_E^2 . As in the case study of Section 2.3, the blowup divisor E is given by a fibration of C_E^2 over C_1 . For our basis of divisors on B_3 we pick

$$D_1 = S_- - E, \quad D_2 = p^*(C_1) - E, \quad D_3 = E. \quad (5.52)$$

In this basis, the anti-canonical bundle reads

$$\bar{K}_{B_3} = 2D_1 + 4D_2 + 5D_3, \quad (5.53)$$

and the intersection form becomes

$$I_{B_3} = 4D_1^3 - 3D_2^3 - 2D_1^2D_3 + 2D_2^2D_3 + D_1D_3^2 - D_2D_3^2. \quad (5.54)$$

The elliptic fibration over the base B_3 is chosen as in the example of Section 5 of [6], to which we refer for further details. It leads to a gauge group $G = U(1)$, and the associated height-pairing takes the form

$$b = 6\bar{K}_{B_3} - 2\beta = 8D_1 + 20D_2 + 22D_3, \quad (5.55)$$

where $\beta = 2D_1 + 2D_2 + 4D_3$. Moreover its intersection numbers with the rational fiber and the exceptional curves are as follows:

$$\begin{aligned} m &= \frac{1}{2}b \cdot C^0 = 4, \\ m_1 &= \frac{1}{2}b \cdot C_E^1 = 1, \\ m_2 &= \frac{1}{2}b \cdot C_E^2 = 3. \end{aligned} \quad (5.56)$$

This fibration gives rise to two types of charged massless matter fields, namely of charges $r = 1$ and $r = 2$. The matter excitations are localised on two curves on B_3 in the respective

classes

$$\begin{aligned}
\Sigma_{r=1} &= 3(6\bar{K}_{B_3} - 2\beta) \cdot (6\bar{K}_{B_3} - 2\beta) - 16(2\bar{K}_{B_3} - \beta) \cdot (3\bar{K}_{B_3} - \beta) \\
&= -123 C^0 - 87 C_E^1 + \frac{45}{2}(b \cdot p^*(C_1)), \\
\Sigma_{r=2} &= (2\bar{K}_{B_3} - \beta) \cdot (3\bar{K}_{B_3} - \beta) \\
&= -\frac{33}{2} C^0 + \frac{3}{2} C_E^1 + \frac{15}{4}(b \cdot p^*(C_1)).
\end{aligned} \tag{5.57}$$

Geometrically, the elliptic fiber over these two curves degenerates such as to contain the rational curves $C_{r=1}^f$ and $C_{r=2}^f$, respectively. Switching on a general transversal $U(1)$ flux in $H_{\text{vert}}^{2,2}(Y_4)$,

$$\mathbf{G} = \mathbf{G}_{U(1)} = \sigma \wedge \pi^* F, \quad F =: \sum_{\alpha=1}^3 c_\alpha D_\alpha, \tag{5.58}$$

produces a chiral spectrum with indices in the respective charge sectors given by

$$\begin{aligned}
\chi_{r=1} &= 12c_1 + 132c_2 + 48c_3, \\
\chi_{r=2} &= 12c_1 + 12c_2 + 48c_3.
\end{aligned} \tag{5.59}$$

5.2.1 Relative BPS Invariants and Elliptic Genus

After this preparation we turn to discussing the elliptic genus for the heterotic string that arises from wrapping a D3-brane on C^0 in presence of the $U(1)$ flux, \mathbf{G} . The relative BPS invariants $N_{\mathbf{G};C^0}(n, r)$ for small values of n have already been computed by mirror symmetry in [6]. It was noted there that for the most general choice of $U(1)$ flux, the elliptic genus is neither modular nor a quasi-modular meromorphic form. This observation was in fact the motivation for the present work.

The new ingredient, according to the general discussion in Section 3.2, is that the “non-modular” component of the elliptic genus is actually a derivative of a quasi-modular form. More specifically, the relative invariants $N_{\mathbf{G};C^0}(n, r)$, as computed in [6], allow to uniquely determine, by modular completion, the elliptic genus as follows:

$$Z_{\mathbf{G};C^0} = g^0 Z_{-1,m}^0 + g^E Z_{-1,m}^E + g^1 \frac{1}{2m} \xi \partial_\xi Z_{-2,m}^1, \tag{5.60}$$

where the index is, as per (5.56), given by $m = 4$. Here the flux-dependent coefficients are

$$g^0 = F \cdot C^0 = c_1, \quad g^E = F \cdot C_E^1 = -c_2 + c_3, \quad g^1 = F \cdot b \cdot p^*(C_1) = 6c_1 + 2c_2 + 6c_3 \tag{5.61}$$

and the quasi-modular or modular forms are given by

$$\begin{aligned}
Z_{-1,4}^0(q, \xi) &= \frac{1}{16} \phi_{-1,2} (21\phi_{0,1}^2 - 23E_4\phi_{-2,1}^2 + 2E_2\phi_{0,1}\phi_{-2,1}) \\
&= 123\xi^{\pm 1} + 33\xi^{\pm 2} + q(981\xi^{\pm 1} + 144\xi^{\pm 2} - 423\xi^{\pm 3}) + \mathcal{O}(q^2)
\end{aligned} \tag{5.62}$$

$$\begin{aligned}
Z_{-1,4}^E(q, \xi) &= \frac{1}{16} \phi_{-1,2} (9\phi_{0,1}^2 + 13E_4\phi_{-2,1}^2 - 22E_2\phi_{0,1}\phi_{-2,1}) \\
&= 87\xi^{\pm 1} - 3\xi^{\pm 2} + q(2169\xi^{\pm 1} - 1584\xi^{\pm 2} + 333\xi^{\pm 3}) + \mathcal{O}(q^2)
\end{aligned} \tag{5.63}$$

$$\begin{aligned}
Z_{-2,4}^1(q, \xi) &= \frac{1}{12\eta^{24}} (10E_{4,3}E_{6,1} + 6E_{4,1}F_{6,3} + 19E_{4,1}G_{6,3} + E_2E_{4,1}E_{4,3}) \\
&= \frac{3}{q} - 30(8 + 6\xi^{\pm 1} + \xi^{\pm 2}) + \mathcal{O}(q).
\end{aligned} \tag{5.64}$$

As always, $\xi^{\pm\bar{n}} := \xi^n - \xi^{-n}$, $\xi^{\pm n} := \xi^n + \xi^{-n}$ and the Jacobi forms are defined in Appendix A.

The form (5.60) of parametrizing the elliptic genus is tuned to mirror the decomposition (5.57) of the matter curves $\Sigma_{r=1}$ and $\Sigma_{r=2}$ in terms of C^0 , C_E^1 and $(b \cdot p^*(C_1))$, and follows the general pattern advertised in (3.29). The BPS invariants entering this latter equation are of course defined in terms of the partition functions (5.62), (5.63) and (5.64) via

$$Z_{w,m}^* = -\frac{1}{q} N_{C^0}^*(n, r) q^n \xi^r. \quad (5.65)$$

Of particular interest for us is the quasi-Jacobi form $Z_{-2,4}^1$ which appears with a derivative in the elliptic genus. In line with our general arguments, we expect that it encodes the relative BPS invariants with respect to C^0 viewed as a curve within an elliptic threefold, \mathbb{Y}_3^1 , in Y_4 . Recall from Section 3.3 that this threefold is constructed as the restriction of the elliptic fibration of Y_4 to the divisor $p^*(C^1) = p^*(C_1)$ on B_3 , which in the present example is topologically a del Pezzo surface, dP_2 . The threefold is therefore elliptically fibered with base $\mathbb{B}_2^1 = p^*(C_1)$, and we denote the projection by

$$\pi_1 : \mathbb{Y}_3^1 \rightarrow \mathbb{B}_2^1. \quad (5.66)$$

By the adjunction formula we find that \mathbb{Y}_3^1 has a non-zero first Chern class:

$$c_1(\bar{K}_{\mathbb{Y}_3^1}) = c_1(\bar{K}_{Y_4}|_{\mathbb{Y}_3^1}) - c_1(N_{\mathbb{Y}_3^1/Y_4}) = -\pi_1^*(p^*(C^1)|_{p^*(C^1)}), \quad (5.67)$$

because the divisor $p^*(C^1)$ has non-vanishing self-intersection on B_3 .

From the point of view of the elliptic fibration, this can also be seen as follows. The anti-canonical class is related to the pullback of the discriminant of the fibration from the base, $\Delta_{\mathbb{Y}_3^1}$, via the relation

$$c_1(\bar{K}_{\mathbb{Y}_3^1}) = \pi_1^*(c_1(\bar{K}_{\mathbb{B}_2^1})) - \frac{1}{12} \Delta_{\mathbb{Y}_3^1}. \quad (5.68)$$

The discriminant $\Delta_{\mathbb{Y}_3^1}$ in turn is inherited from the discriminant of the fibration of the ambient space Y_4 ,

$$\Delta_{\mathbb{Y}_3^1} = \Delta_{Y_4}|_{\mathbb{Y}_3^1} = 12\pi_1^*(c_1(\bar{K}_{B_3})|_{\mathbb{B}_2^1}). \quad (5.69)$$

By the adjunction formula we have

$$c_1(\bar{K}_{\mathbb{B}_2^1}) = c_1(\bar{K}_{B_3}|_{\mathbb{B}_2^1}) - c_1(N_{\mathbb{B}_2^1/B_3}), \quad (5.70)$$

where $c_1(N_{\mathbb{B}_2^1/B_3}) = p^*(C^1)|_{p^*(C^1)}$. Thus altogether we have

$$\Delta_{\mathbb{Y}_3^1} = 12\pi_1^*(c_1(\bar{K}_{\mathbb{B}_2^1})) + 12\pi_1(p^*(C^1)|_{p^*(C^1)}), \quad (5.71)$$

rather than just $\Delta_{\mathbb{Y}_3^1} = 12\pi_1^*(c_1(\bar{K}_{\mathbb{B}_2^1}))$ which would be required for a Calabi-Yau threefold.

Even though \mathbb{Y}_3^1 has a negative anti-canonical bundle, the concept of relative Gromov-Witten invariants still makes sense. Unlike for Calabi-Yau spaces, however, we cannot as easily compute BPS invariants via mirror symmetry and compare them to the invariants $N_{C^0}^1(n, r)$ that are encoded in the expansion of $Z_{-2,4}^1(q, \xi)$.

Despite this technical complication, we can provide some evidence for our conjecture that $Z_{-2,4}^1$ encodes the relative invariants for \mathbb{Y}_3^1 . The following discussion is an illustration of the general arguments in Section 3.3. Recall first that since the elliptic fibration of \mathbb{Y}_3^1 is inherited from Y_4 , we know that it exhibits an extra rational section and that the height-pairing associated with this section is the restriction of the height-pairing b to $p^*(C^1)$. The elliptic fiber of \mathbb{Y}_3^1

degenerates over a number of points on $p^*(C^1)$ in such a way as to contain rational curves C_r^f of $U(1)$ charges $r = 1$ and $r = 2$. Recall Figure 3 for a visualization. The number of points where this happens equals the number of holomorphic fibral curves in class C_r^f on \mathbb{Y}_3^1 , which in turn is computed by the Gromov-Witten invariants $N(C_r^f)$. For Calabi-Yau threefolds whose base is a rational fibration with fiber C^0 , these invariants $N(C_r^f)$ agree with the relative BPS invariants at level $n = 1$, i.e.,

$$N_{C^0}^1(n = 1, r) = N(C_r^f). \quad (5.72)$$

This is the threefold analogue of the relation (3.8) and follows from F-theory–heterotic duality. While strictly speaking we cannot invoke this duality for non-Calabi-Yau threefolds, it is reasonable to assert that (5.72) holds more generally whenever the base of the elliptic threefold is a rational fibration. If we assume this, we have a simple means to test the hypothesis that the invariants defined by $Z_{-2,m}^1$ compute the relative BPS invariants of the non-Calabi-Yau threefold \mathbb{Y}_3^1 , at least at level $n = 1$. This is because the number of degeneration points and hence the BPS invariants $N(C_r^f)$ are easy to determine.

Concretely, as explained in Section 3.3, the number of degeneration points on \mathbb{Y}_3^1 leading to fibral curves C_r^f is simply given by the number of intersection points between the corresponding degeneration locus of Y_4 on B_3 , i.e., the curves Σ_r , and the base of \mathbb{Y}_3^1 , i.e., the divisor $p^*(C^1)$. This yields the BPS invariants

$$N(C_{r=1}^f) = \Sigma_{r=1} \cdot p^*(C^1) = 180, \quad (5.73)$$

$$N(C_{r=2}^f) = \Sigma_{r=2} \cdot p^*(C^1) = 30. \quad (5.74)$$

These values are in perfect agreement with the relative invariants $N_{C^0}^1(n = 1, 1) = 180$ and $N_{C^0}^1(n = 1, 2) = 30$ which appear in the expansion (5.64) of $Z_{-2,4}^1$. We can also reproduce the remaining invariant, $N_{C^0}^1(n = 1, r = 0)$, which according to our conjecture must coincide with the Gromov-Witten invariant for the fibral class \mathbb{E}_τ . For an elliptic Calabi-Yau threefold, this in turn would be given by the negative of the Euler characteristic of the threefold, i.e. by $-\chi(\text{CY3}) = -\int_{\text{CY3}} c_3(\text{CY3}) = -2 \text{ch}_3(\text{CY3})$, where the Chern character is given by $\text{ch}_3 = \frac{1}{2}c_3 - \frac{1}{2}c_1c_2 + \frac{1}{6}c_1^3$. For our *non*-Calabi-Yau threefold \mathbb{Y}_3^1 at hand, we find explicitly that

$$N_{C^0}^1(n = 1, r = 0) = -2 \text{ch}_3(\mathbb{Y}_3^1) = -\int_{Y_4} c_3(Y_4) \wedge \pi^*(p^*(C^1)) = 240, \quad (5.75)$$

which indeed matches the index of the uncharged states in (5.64).

Thus, all in all we have verified that the identity (5.72) holds for our example, and this lends further support to the conjecture that *all* invariants in $Z_{-2,4}^1$ match the relative BPS invariants of the non-Calabi-Yau threefold, \mathbb{Y}_3^1 .

Let us present yet another, more speculative perspective on the significance of the partition function $Z_{-2,4}^1$. Recall that the non-Calabi-Yau space \mathbb{Y}_3^1 is elliptically fibered over the base $\mathbb{B}_2^1 = p^*(C^1)$, which in turn is the blowup of a Hirzebruch surface \mathbb{F}_1 at one point, with its own base C^1 and generic fiber C^0 . This implies that \mathbb{Y}_3^1 also admits a K3-fibration over C^1 ,

$$\begin{array}{ccc} \rho : & \text{K3}_F & \rightarrow & \mathbb{Y}_3^1 \\ & & & \downarrow \\ & & & C^1 \end{array} \quad (5.76)$$

whose fiber K3_F is elliptically fibered over C^0 .

Let us formulate a Weierstrass model for this fibration, and introduce the notation $[a'_1 : a'_2]$ for the homogenous coordinates on the base C^1 , and $[a_1 : a_2]$ for the coordinates on C^0 . Then

a Weierstrass model for the elliptic fibration of \mathbb{Y}_3^1 can be written, away from the exceptional curve of the blown up Hirzebruch surface, as

$$y^2 = x^3 + f(a_i, a'_j) x z^4 + g(a_i, a'_j) z^6, \quad (5.77)$$

where $f(a_i, a'_j)$ is a section of $\Delta_{\mathbb{Y}_3^1}^{1/3}$ and $g(a_i, a'_j)$ is a section of $\Delta_{\mathbb{Y}_3^1}^{1/2}$. The degrees of the discriminant $\Delta_{\mathbb{Y}_3^1}$ on the base and fiber of \mathbb{B}_2^1 follow from (5.71) as

$$\Delta_{\mathbb{Y}_3^1}|_{\mathbb{B}_2^1} = 48 C^0 + 24 C^1. \quad (5.78)$$

Taking into account that C^0 is fibered over C^1 with twist 1 (which is the case for the Hirzebruch \mathbb{F}_1), this means that we can expand f and g as

$$f(a_i, a'_j) = \sum_k f_{12-k}(a'_1, a'_2) a_1^{4-k} a_2^{4+k}, \quad (5.79)$$

$$g(a_i, a'_j) = \sum_k g_{18-k}(a'_1, a'_2) a_1^{6-k} a_2^{6+k}, \quad (5.80)$$

where the subscripts denote the degrees of the polynomials on the fiber coordinates.

Let us pause for a moment and consider instead an elliptic fibration over \mathbb{B}_2^1 which is Calabi-Yau. For this we would have polynomials given by $f_{8-k}(a'_1, a'_2)$ and $g_{12-k}(a'_1, a'_2)$, respectively. This Calabi-Yau threefold could serve as a standard F-theory compactification space to six dimensions. This theory would in turn have a six-dimensional heterotic dual defined in terms of an elliptic surface, $K3_{\text{het}}$, with base C^1 . A Weierstrass model for $K3_{\text{het}}$ would then be obtained by keeping the polynomials $f_{8-k}(a'_1, a'_2)$ and $g_{12-k}(a'_1, a'_2)$ for $k = 0$ [131, 132], i.e.,

$$K3_{\text{het}} : y^2 = x^3 + f_8(a'_1, a'_2) x z^4 + g_{12}(a'_1, a'_2) z^6. \quad (5.81)$$

Now we return to our presently considered geometry, where we deal with the non-Calabi-Yau threefold, \mathbb{Y}_3^1 . A priori, F-theory on this space is not well-defined. Let us nonetheless formally define a dual heterotic background, by keeping the middle polynomials in analogy to the well-established Calabi-Yau case. This leads to the following Weierstrass model

$$\mathcal{E} : y^2 = x^3 + f_{12}(a'_1, a'_2) x z^4 + g_{18}(a'_1, a'_2) z^6, \quad (5.82)$$

which is an elliptic fibration with 36, rather than 24 singular fibers. This defines an elliptic surface \mathcal{E} with

$$\bar{K}_{\mathcal{E}} = -\mathbb{E}_{\tau}, \quad (5.83)$$

where \mathbb{E}_{τ} is the fiber.

It is tempting to interpret $Z_{-2,4}^1(q, \xi)$ as a generalized, refined elliptic genus associated with this elliptic surface. More specifically, if we switch off the $U(1)$ background field, we find

$$Z_{-2,4}^1(q, \xi = 1) = \frac{1}{12\eta^{24}} E_4 (E_2 E_4 + 35 E_6) = \frac{3}{\eta^{24}} E_4 E_6 + \frac{1}{12\eta^{24}} (E_2 E_4^2 - E_4 E_6), \quad (5.84)$$

which is suggestive of a non-perturbative instanton/NS5 brane transition of such a geometry.

Let us come back to a more concrete, definite property of $Z_{-2,4}^1(q, \xi)$ as given in (5.64). Recall the general relationship between the derivative part of the elliptic genus and the partition

functions associated to non-transversal (-2) -fluxes, which was proposed in Section 3.4. If we take as basis for the fluxes in $H_{(-2)}^{(2,2)}(Y_4, \mathbb{R})$

$$\begin{aligned}\mathbf{G}^1 &= \pi^*(S_-) \wedge \pi^*(p^*(C^1)), \\ \mathbf{G}^E &= \pi^*(E) \wedge \pi^*(p^*(C^1)), \\ \mathbf{G}^0 &= \pi^*(p^*(C^1)) \wedge \pi^*(p^*(C^1)),\end{aligned}\tag{5.85}$$

then the associated BPS invariants assemble into the generating functions

$$\mathcal{F}_{\mathbf{G}^1; C^0} = -qZ_{-2,4}^1, \quad \mathcal{F}_{\mathbf{G}^E; C^0} = 0, \quad \mathcal{F}_{\mathbf{G}^0; C^0} = 0.\tag{5.86}$$

Thus we can indeed confirm the purported relationship between the two partition functions, which are associated with transversal $U(1)$ flux and non-transversal (-2) flux, respectively. Moreover, while the vanishing of the last two generating functions is clear on general grounds as for the previous model, it is noteworthy to mention that the lowest BPS number in $Z_{-2,m}^{(1)}$, as read off from (5.64), perfectly matches the intersection theoretic expression (3.45) because $C^1 \cdot_{B_2} K_{B_2} = -3$.

5.2.2 Anomalies and Green-Schwarz Terms

In order to discuss the anomalies in a $U(1)$ flux background, we rewrite the elliptic genus (5.60) into the form (4.80), which is more suitable for comparison with the Green-Schwarz mechanism in the heterotic duality frame. Concretely,

$$Z_{\mathbf{G}; C^0} =: \tilde{g}^0 \tilde{Z}_{-1,m}^0 + \tilde{g}^E \tilde{Z}_{-1,m}^E + \tilde{g}^1 \left(\tilde{Z}_{-1,m}^1 + \frac{1}{2m} \xi \partial_\xi \tilde{Z}_{-2,m}^1 \right),\tag{5.87}$$

for $m = 4$, with the flux dependent coefficients:

$$\tilde{g}^0 = F \cdot b \cdot (S - \frac{1}{2}E) = -9c_1 + 9c_2, \quad \tilde{g}^E = F \cdot b \cdot (\frac{1}{2}E) = 3c_1 + 9c_2 - 6c_3,\tag{5.88}$$

$$\tilde{g}^1 = F \cdot b \cdot p^*(C_1) = 6c_1 + 2c_2 + 6c_3.\tag{5.89}$$

Moreover each term, $\tilde{Z}_{w,m}^* \equiv \tilde{Z}_{w,m}^{*,M} + \tilde{Z}_{w,m}^{*,QM}$, generically splits into a modular and quasi-modular piece. Explicitly:

$$\begin{aligned}\tilde{Z}_{-1,4}^{0,M} &= -\frac{1}{12} \phi_{-1,2} (\phi_{0,1}^2 - E_4 \phi_{-2,1}^2), & \tilde{Z}_{-1,4}^{0,QM} &= 0, \\ \tilde{Z}_{-1,4}^{E,M} &= -\frac{1}{6} \phi_{-1,2} \phi_{-2,1}^2 E_4, & \tilde{Z}_{-1,4}^{E,QM} &= \frac{1}{6} \phi_{-1,2} \phi_{-2,1} E_2 \phi_{0,1}, \\ \tilde{Z}_{-1,4}^{1,M} &= \frac{1}{32} \phi_{-1,2} (3\phi_{0,1}^2 - E_4 \phi_{-2,1}^2), & \tilde{Z}_{-1,4}^{1,QM} &= -\frac{1}{16} \phi_{-1,2} \phi_{-2,1} E_2 \phi_{0,1}, \\ \tilde{Z}_{-2,4}^{1,M} &= \frac{1}{12 \eta^{24}} (10E_{4,3} E_{6,1} + 6E_{4,1} F_{6,3} + 19E_{4,1} G_{6,3}), & \tilde{Z}_{-2,4}^{1,QM} &= \frac{1}{12 \eta^{24}} E_2 E_{4,1} E_{4,3}.\end{aligned}\tag{5.90}$$

Note that all these partition functions have, depending on their modularity properties, the respective general form as advertised in (3.15).

Let us first discuss the anomalies and Green-Schwarz terms derived from the non-derivative (quasi) modular forms in $Z_{\mathbf{G}; C^0}$. These receive contributions only from three independent building blocks, which are readily computed following the general prescription outlined in Sections 4.1

and 4.2:

$$\begin{aligned}
\phi_{-1,2}\phi_{-2,1}^2 E_4 : & & A^{(4),M} &= 0 & & A_{GS}^{(4),M} &= 0 \\
\phi_{-1,2}\phi_{0,1}^2 : & & A^{(4),M} &= -48, & & A_{GS}^{(4),M} &= \frac{1}{m}A^{(4),M} = -12 \\
\phi_{-1,2}\phi_{-2,1}E_2\phi_{0,1} : & & A^{(4),QM} &= 6(m_1 - m_2) = -12, & & A_{GS}^{(4),QM} &= 0.
\end{aligned} \tag{5.91}$$

Recall that the values $m = 4$ and $m_1 = 1$, $m_2 = 3$ were determined from the geometry in (5.56), but we leave the values sometimes unassigned in order to exhibit the structure of the various terms.

Note also in passing that the modular component related to the exceptional curve, $\tilde{Z}_{-1,m}^E$, is proportional to

$$\phi_{-1,2}\phi_{-2,1}^2 E_4 = \mathcal{O}(\hat{z}^5), \tag{5.92}$$

and therefore contributes neither to the anomaly nor to the Green-Schwarz term, in line with an argument made after equation (4.88).

Now we turn to the derivative sector. From $\tilde{Z}_{-2,4}^1$ we first compute the contributions to the six-dimensional anomaly as follows:

$$\begin{aligned}
\tilde{Z}_{-2,4}^{1,M} : & & A^{(6),M} &= 30, & & A_{GS}^{(6),M} &= \frac{1}{4}A^{(6),M}, \\
\tilde{Z}_{-2,4}^{1,QM} : & & A^{(6),QM} &= -\frac{1}{4}(m_1^2 + m_2^2) = -\frac{5}{2}, & & A_{GS}^{(6),QM} &= -\frac{1}{12m}(m_1 + m_2)^2 = -\frac{1}{3}.
\end{aligned} \tag{5.93}$$

This then determines, via (4.21) and (4.22), the contributions $\xi\partial_\xi\tilde{Z}_{-1,4}^1$ to the four-dimensional anomaly and Green-Schwarz terms.

Altogether, the complete anomaly becomes

$$\begin{aligned}
A^{(4)} &= A^{(4),M} + A^{(4),QM} \\
A^{(4),M} &= m(F \cdot b \cdot (S - \frac{1}{2}E)) + (\frac{30}{2} - 48\frac{3}{32})(F \cdot b \cdot p^*(C_1)) \\
A^{(4),QM} &= (m_1 - m_2)(F \cdot b \cdot (\frac{1}{2}E)) + (-\frac{1}{8}(m_1^2 + m_2^2) - \frac{6}{16}(m_1 - m_2))(F \cdot b \cdot p^*(C_1))
\end{aligned} \tag{5.94}$$

and this correctly reproduces the 1-loop anomaly as required:

$$A^{(4)} = 18c_1 + 38c_2 + 72c_3 = \frac{1}{3!} \sum_{r=1}^2 r^3 \chi_r. \tag{5.95}$$

Here χ_r refers to the chiral index in the charge sector r as given in (5.59).

The structure of the anomaly reflects the Green-Schwarz mechanism in the dual heterotic frame explained in Section 4.3.2. In particular, the purely modular contribution from $\tilde{Z}_{-1,m}^0$,

$$\tilde{g}^0 A_{\tilde{Z}_{-1,m}^0} = m(F \cdot b \cdot (S_- - \frac{1}{2}E)), \tag{5.96}$$

maps to the part of the anomaly that is cancelled by the perturbative universal Green-Schwarz term. Moreover, the quasi-modular contribution to the anomaly, A^{QM} , turns out to be of the expected form (4.92). For the derivative terms, the analogue of this would be the relation (4.90), but this can be checked not to hold due to the quasi-modular contributions, in line with general expectations.

6 Elliptic Genera of 4d Non-Critical Strings

Our conjecture of Section 3.2 on the form of four-dimensional elliptic genera is supposed to hold not only for heterotic strings, but more generally also for other, in particular non-critical solitonic strings. In this section we illustrate this by presenting the elliptic genus of two different types of non-critical strings in four dimensions. We begin by discussing the four-dimensional E-string in the next section, followed by a non-critical string obtained in F-theory compactified on $B_3 = \mathbb{P}^3$ in Section 6.2.

6.1 Four-Dimensional E-Strings

The six-dimensional non-critical E-string [39, 40, 80, 101–103, 133, 134] arises in F-theory by wrapping a D3-brane on a rational curve C_E of self-intersection -1 which lies in the base B_2 of some elliptic Calabi-Yau threefold, Y_3 . Such curves have normal bundle $N_{C_E/B_2} = \mathcal{O}_{C_E}(-1)$ and can arise in two different settings: Either C_E is the exceptional section of a Hirzebruch surface $B_2 = \mathbb{F}_1$, or it appears after blowing up a general Hirzebruch surface at a point. After the blowup the rational fiber over the point in the base splits into two exceptional curves C_E^1 and C_E^2 with normal bundle $N_{C_E^i/B_2} = \mathcal{O}_{C_E^i}(-1)$.

We can generalise the notion of an E-string to F-theory compactifications to four dimensions by wrapping a D3-brane on a curve with normal bundle

$$N_{C_E/B_3} = \mathcal{O}_{C_E}(-1) \oplus \mathcal{O}_{C_E}. \quad (6.1)$$

In this paper we will call the strings obtained from D3-branes that wrap such curves *four-dimensional E-strings* and study their elliptic genera. Aspects of four-dimensional analogues of E-string have previously been considered in [91] (see also [135] and [136]). Clearly such strings are special cases of a multitude of non-critical strings that can arise from much more general types of curves. More recently, the compactification of six-dimensional $N = (1, 0)$ SCFTs on Riemann surfaces with fluxes has been a subject of intense study [84, 137–152], and it would be worthwhile to relate our setup to the field theoretic approach, though this will not be the focus of this paper.

The trivial summand \mathcal{O}_{C_E} in (6.1) implies that the curve C_E is fibered over a distinguished normal direction within B_3 , thereby tracing out a rationally fibered divisor which we call D_E . The four-dimensional geometry probed by the E-string is hence a fibration at least locally, where the fiber C_E is either the base of a Hirzebruch surface \mathbb{F}_1 or one of the blowup curves in a rational fibration. We will exemplify both types of geometries and their associated E-string elliptic genera.

From the perspective of geometry alone, one might think that the properties of the resulting four-dimensional E-string are entirely inherited from the six-dimensional E-string which is locally fibered. According to the logic of this paper, this would mean that the four-dimensional E-string elliptic genus would be a derivative of the six-dimensional E-string elliptic genus. This, however, is in general not the case. The definition of the model requires specifying the background flux, and we will see that the latter can introduce genuinely four-dimensional, non-derivative contributions to the elliptic genus, precisely as expressed in the most general form of Conjecture 2 in Section 3.2. This phenomenon is independent of the geometric realisation of the E-string curve, either as the base of a locally fibered Hirzebruch surface or due to a blowup in the fiber of the rational fibration.

6.1.1 E-Strings of Six-Dimensional Origin

As our first example we consider an F-theory compactification for which the base space, B_3 , is of the type introduced in Section 2.3, namely it is a rational fibration by itself: $p : B_3 \rightarrow B_2$. After we perform a blowup over a curve Γ on the base B_2 , the rational fiber C^0 over Γ splits into two exceptional curves C_E^1 and C_E^2 . Each of the two C_E^i is therefore fibered over the curve Γ and the fibration defines two divisors, D_E^i , of the following form:

$$p_E^i : \begin{array}{ccc} C_E^i & \rightarrow & D_E^i \\ & & \downarrow \\ & & \Gamma \end{array} \quad (6.2)$$

Note that in Section 2.3 we had called the divisor $D_E^2 =: E$. Furthermore, as long as we perform only one blowup, which is what we assume from now on, we have $D_E^1 + D_E^2 = p^*(\Gamma)$.

For simplicity we now take the gauge group in four dimensions to be $U(1)$ and consider a background with transversal flux, $\mathbf{G} = \mathbf{G}_{U(1)} \in H_{\text{vert}}^{2,2}(Y_4)$. We will discuss an example with non-abelian gauge group later in Section 6.1.2. We claim that for such a setup, the elliptic genus of the E-string associated with either C_E^1 or C_E^2 can be brought into the following universal form:

$$Z_{\mathbf{G}_{U(1)}; C_E^i}(q, \xi) = \frac{1}{2m_i} (F \cdot b \cdot D_E^i) \xi \partial_\xi Z_{-2, m_i}(q, \xi), \quad m_i = \frac{1}{2} b \cdot C_E^i, \quad (6.3)$$

where Z_{-2, m_i} is the elliptic genus [39, 40] of a six-dimensional E-string with $U(1)$ fugacity index m_i , i.e.:

$$Z_{-2, m_i}(q, \xi) = \frac{1}{\eta^{12}(q)} E_{4, m_i}(q, \xi). \quad (6.4)$$

Furthermore, the degeneracies contained in $Z_{-2, m_i}(q, \xi)$ are the relative BPS invariants for the curve C_E^i within an elliptic threefold embedded into Y_4 .

Let us illustrate this general formula for the E-strings that arise (besides the heterotic string) in the two examples that were discussed in Sections 5.1 and 5.2. First, consider the base $B_3 = dP_2 \times \mathbb{P}_\nu^1$. In the notation of Section 5.1, the two divisors D_E^i defined via (6.2) are immediately identified as

$$D_E^1 = p^*(C_1) - E = D_4 - D_2, \quad D_E^2 = E = D_1 + D_2 - D_4, \quad (6.5)$$

with

$$F \cdot b \cdot D_E^1 = 4c_2 + 2c_3, \quad F \cdot b \cdot D_E^2 = 2c_3 + 4c_4. \quad (6.6)$$

We recall furthermore that in this geometry the geometric intersection numbers $m_i = \frac{1}{2} b \cdot C_E^i = 1$ for both $i = 1, 2$.

As detailed in Appendix B, we can compute by mirror symmetry the lowest-lying relative BPS invariants $N_{C_E^i; \mathbf{G}}(n, r)$ and the associated elliptic genera

$$Z_{\mathbf{G}_{U(1)}; C_E^i} = -q^{-1/2} \sum_{n, r} N_{\mathbf{G}_{U(1)}; C_E^i}(n, r) q^n \xi^r \quad (6.7)$$

as follows:

$$\begin{aligned} Z_{\mathbf{G}_{U(1)}; C_E^1}(q, \xi) &= -(2c_2 + c_3) q^{-1/2} \left((56\xi^{\pm\bar{1}} + 2\xi^{\pm\bar{2}}) + q(1248\xi^{\pm\bar{1}} + 276\xi^{\pm\bar{2}}) + \mathcal{O}(q^2) \right) \\ Z_{\mathbf{G}_{U(1)}; C_E^2}(q, \xi) &= -(c_3 + 2c_4) q^{-1/2} \left((56\xi^{\pm\bar{1}} + 2\xi^{\pm\bar{2}}) + q(1248\xi^{\pm\bar{1}} + 276\xi^{\pm\bar{2}}) + \mathcal{O}(q^2) \right). \end{aligned} \quad (6.8)$$

These are uniquely completed into the exact expressions:

$$Z_{\mathbf{G}_{U(1)};C_E^i}(q, \xi) = \frac{1}{2}(F \cdot b \cdot D_E^i) \frac{1}{\eta^{12}(q)} \xi \partial_\xi E_{4,1}(q, \xi), \quad (6.9)$$

which are in perfect agreement with general pattern (6.3). The threefold whose relative BPS invariants are contained in $Z_{C_E^i; \mathbf{G}}(q, \xi)$ is the Calabi-Yau $\mathbb{Y}_3^1 = Y_4|_{p^*(C^1)}$ introduced already in (5.21). Note that C^1 is the curve dual on B_2 to C_1 , whose class in turn corresponds to the class of the curve Γ over which the E-string curves are fibered as in (6.2). Formula (6.3) is hence very much analogous to the derivative contributions to the heterotic string elliptic genus (5.16) in the same geometry. The difference is that the E-string curves C_E^i are fibered only over Γ , and hence there appears only a single derivative contribution. For the heterotic string, on the other hand, the curve C^0 is fibered over all of B_2 so that we must sum over several contributions, each corresponding to one basis element C_i of $H_2(B_2)$.

As for the example of Section 5.2, we consider the two E-strings in the geometry $B_3 = \text{Bl}^1 \mathbb{H}_1$ with

$$D_E^1 = p^*(C_1) - E = D_2, \quad D_E^2 = E = D_3, \quad (6.10)$$

and

$$(F \cdot b \cdot D_E^1) = -16c_2 + 18c_3, \quad (F \cdot b \cdot D_E^2) = 6c_1 + 18c_2 - 12c_3. \quad (6.11)$$

The geometric intersection numbers are $m_1 = 1$ and $m_2 = 3$. By application of mirror symmetry, we have computed the lowest relative BPS numbers, which assemble into the following expansions:

$$\begin{aligned} Z_{\mathbf{G}_{U(1)};C_E^1}(q, \xi) &= (-8c_2 + 9c_3)q^{-1/2} \left((56\xi^{\pm 1} + 2\xi^{\pm 2}) \right. \\ &\quad + q(1248\xi^{\pm 1} + 276\xi^{\pm 2}) \\ &\quad + q^2(13464\xi^{\pm 1} + 4716\xi^{\pm 2} + 168\xi^{\pm 3}) \\ &\quad + q^3(103136\xi^{\pm 1} + 46008\xi^{\pm 2} + 3744\xi^{\pm 3} + 4\xi^{\pm 4}) \\ &\quad \left. + \mathcal{O}(q^4) \right), \end{aligned} \quad (6.12)$$

$$\begin{aligned} Z_{\mathbf{G}_{U(1)};C_E^2}(q, \xi) &= (c_1 + 3c_2 - 2c_3)q^{-1/2} \left((54\xi^{\pm 1} + 54\xi^{\pm 2} + 6\xi^{\pm 3}) \right. \\ &\quad + q(1080\xi^{\pm 1} + 1188\xi^{\pm 2} + 504\xi^{\pm 3} + 108\xi^{\pm 4}) \\ &\quad + q^2(11016\xi^{\pm 1} + 13122\xi^{\pm 2} + 7350\xi^{\pm 3} + 2376\xi^{\pm 4} + 270\xi^{\pm 5} + 6\xi^{\pm 6}) \\ &\quad + q^3(81216\xi^{\pm 1} + 102060\xi^{\pm 2} + 66264\xi^{\pm 3} + 26244\xi^{\pm 4} + 5400\xi^{\pm 5} + 516\xi^{\pm 6}) \\ &\quad \left. + \mathcal{O}(q^4) \right). \end{aligned} \quad (6.13)$$

These uniquely determine the elliptic genera as follows:

$$Z_{\mathbf{G}_{U(1)};C_E^1}(q, \xi) = \frac{1}{2}(F \cdot b \cdot D_E^1) \frac{1}{\eta^{12}(q)} \xi \partial_\xi E_{4,1}(q, \xi), \quad (6.14)$$

$$Z_{\mathbf{G}_{U(1)};C_E^2}(q, \xi) = \frac{1}{6}(F \cdot b \cdot D_E^2) \frac{1}{\eta^{12}(q)} \xi \partial_\xi E_{4,3}(q, \xi), \quad (6.15)$$

which again illustrates the general claim (6.3). We expect that the invariants encoded in $Z_{\mathbf{G};C_E^i}(q, \xi)$ are the relative BPS invariants with respect to C_E^i within the non-Calabi-Yau threefold \mathbb{Y}_3^1 , which was discussed around eq. (5.66) in the context of the heterotic string.

The two examples discussed so far are special to the extent that the four-dimensional E-string is completely determined by its six-dimensional cousin, as reflected in the purely derivative structure of the elliptic genus. As we will see in the next section, this is no longer the case if the E-string curve lies inside a 7-brane and is threaded by gauge flux.

Before coming to this point, however, we take a brief digression to understand the invariants encoded in $Z_{-2,m_i}(q, \xi)$ via (6.3) also in terms of non-transversal (-2) fluxes, analogous to what we found for the heterotic string. Irrespective of the details of B_2 , we can give the general pattern by first considering the relative BPS invariants for the E-string curves C_E^1 and C_E^2 at $n = 0$ and $r = 0$. The curves C_E^1 and C_E^2 are each fibered over the curve Γ on B_2 . The class of the moduli space of both curves with one point fixed is hence the surface D_E^i on B_3 traced out by this fibration, i.e.

$$\mu(C_E^i) = S_0 \wedge D_E^i, \quad i = 1, 2. \quad (6.16)$$

A non-vanishing BPS number for C_E^i is only possible in a flux background which intersects this surface. It is easy to see which types of 4-form fluxes on B_3 have this property, because the fibration structure of B_3 implies that the only non-vanishing intersections with D_E^i are

$$D_E^1 \cdot S_- \cdot p^*(C) = C \cdot_{B_2} \Gamma, \quad D_E^i \cdot D_E^j \cdot p^*(C) = (1 - 2\delta^{ij}) C \cdot_{B_2} \Gamma. \quad (6.17)$$

Here C represents some curve class on B_2 , and we used the fact that only C_E^1 is intersected by S_- . Whenever C intersects Γ transversally, it is natural to infer from the local nature of the fibration that the 4-forms $S_- \cdot p^*(C)$ and $D_E^i \cdot p^*(C)$ restrict the moduli space of the more general curve $C_E^i + n\mathbb{E}_\tau + C_r^f$ in Y_4 to $Y_4|_{p^*(C)}$. Hence up to normalisation, which is given by the intersection numbers (6.17), we expect to exactly reproduce the BPS numbers as encoded in $Z_{-2,m_i}(q, \xi)$.

This general expectation is perfectly confirmed by computation. For the two E-strings of the model with base $B_3 = dP_2 \times \mathbb{P}_\nu^1$ of Section 5.1 we find, for the basis (5.32) of non-transversal (-2) fluxes

$$\begin{aligned} \mathcal{F}_{\mathbf{G}^1; C_E^1} &= -q^{1/2} \frac{1}{\eta^{12}(q)} E_{4,1}(q, \xi), & \mathcal{F}_{\mathbf{G}^2; C_E^1} &= 0, \\ \mathcal{F}_{\mathbf{G}^E; C_E^1} &= -q^{1/2} \frac{1}{\eta^{12}(q)} E_{4,1}(q, \xi), & \mathcal{F}_{\mathbf{G}^0; C_E^1} &= 0 \end{aligned} \quad (6.18)$$

and

$$\begin{aligned} \mathcal{F}_{\mathbf{G}^1; C_E^2} &= 0, & \mathcal{F}_{\mathbf{G}^2; C_E^2} &= 0, \\ \mathcal{F}_{\mathbf{G}^E; C_E^2} &= +q^{1/2} \frac{1}{\eta^{12}(q)} E_{4,1}(q, \xi), & \mathcal{F}_{\mathbf{G}^0; C_E^2} &= 0. \end{aligned} \quad (6.19)$$

The extra sign in the expression for $\mathcal{F}_{\mathbf{G}^E; C_E^2}$ reflects the fact that $E \cdot C_E^2 = D_E^2 \cdot C_E^2 = -1$. Similarly, for $B_3 = \text{Bl}^1\mathbb{H}_1$ of Section 5.2 for the basis (5.85) of non-transversal (-2) fluxes we have

$$\begin{aligned} \mathcal{F}_{\mathbf{G}^1; C_E^1} &= -q^{1/2} \frac{1}{\eta^{12}(q)} E_{4,1}(q, \xi), \\ \mathcal{F}_{\mathbf{G}^E; C_E^1} &= -q^{1/2} \frac{1}{\eta^{12}(q)} E_{4,1}(q, \xi), & \mathcal{F}_{\mathbf{G}^0; C_E^1} &= 0 \end{aligned} \quad (6.20)$$

and

$$\begin{aligned} \mathcal{F}_{\mathbf{G}^1; C_E^2} &= 0, \\ \mathcal{F}_{\mathbf{G}^E; C_E^2} &= +q^{1/2} \frac{1}{\eta^{12}(q)} E_{4,3}(q, \xi), & \mathcal{F}_{\mathbf{G}^0; C_E^2} &= 0. \end{aligned} \quad (6.21)$$

Hence again certain threefold BPS invariants - here of the E-string curves C_E^i within \mathbb{Y}_3^1 - are obtained as fourfold invariants in suitable, non-transversal (-2) flux backgrounds. This does not mean, however, that *all* relative BPS invariants within a given threefold are generated by one and the same (-2) flux. For instance, the flux \mathbf{G}^1 reproduces the relative BPS invariants of C^0 and C_E^1 within \mathbb{Y}_3^1 , but not of C_E^2 , and \mathbf{G}^E gives the relative BPS invariants for C_E^1 and C_E^2 in \mathbb{Y}_3^1 , but not of C^0 , as comparison with (5.86) and (5.33) shows.

6.1.2 Genuinely Four-Dimensional E-String

While in the previous class of constructions the E-string genera are entirely of six-dimensional origin, we now present an example where one finds in addition a genuinely four-dimensional contribution. The E-string lives inside a stack of 7-branes carrying a gauge sector with $G = SU(2)$. The background geometry, $B_3 = \mathbb{F}_1 \times \mathbb{P}^1$, is detailed in Appendix C. The base is rationally fibered with projection $p : B_3 \rightarrow B_2$ over $B_2 = C_E \times \mathbb{P}^1$, where C_E is the base of \mathbb{F}_1 . A D3-brane wrapping C_E gives rise to a four-dimensional E-string. The E-string curve is trivially fibered over the extra \mathbb{P}^1 , and this fibration traces out the divisor $D_E = C_E \times \mathbb{P}^1$ on B_3 .

The elliptic fibration Y_4 over B_3 models a stack of 7-branes with gauge group $G = SU(2)$ wrapped on the divisor

$$b = C_E \times \mathbb{P}^1. \quad (6.22)$$

Since the E-string curve C_E lies inside the 7-brane divisor b , its intersection number with b is negative,

$$b \cdot C_E = -1. \quad (6.23)$$

In the elliptic fibration over B_3 , the elliptic fiber over b splits into two rational curves which intersect like the nodes of the affine Dynkin diagram of $SU(2)$. Fibered both curves over b defines two exceptional divisors e_0 and e_1 with $e_0 + e_1 = \pi^*(b)$, where the fiber of e_0 is associated with the affine node. The generator of the Cartan $U(1)$ within $SU(2)$ can be identified with the divisor $-e_1$. To understand the normalisation, note that matter excitations in the fundamental representation arise from M2-branes wrapping a curve C^f in the fiber over a curve on b . The holomorphic curve C^f satisfies $-e_1 \circ C^f = 1$, so that matter excitations from an M2-brane along C^f have charge $r = 1$ under the $U(1)$ generated by $-e_1$.

For this geometry we consider a transversal flux background of the form

$$\mathbf{G} = (-e_1) \wedge \pi^*(F), \quad F = c_1 D_1 + c_2 D_2 + c_3 D_3, \quad (6.24)$$

which corresponds to the Cartan $U(1)$ of $SU(2)$. Here

$$D_1 = C^0 \times \mathbb{P}^1, \quad D_2 = C^0 \times \mathbb{P}^1 + C_E \times \mathbb{P}^1, \quad D_3 = p^*(C_E). \quad (6.25)$$

As before, we determine via mirror symmetry a number of relative BPS invariants $N_{C_E; \mathbf{G}}(n, r)$ and so obtain the first terms in the expansion of the elliptic genus. While we refer to eq. (C.11) in the Appendix for more data, we present here just the lowest order in q :²⁰

$$\begin{aligned} q^{1/2} Z_{C_E; \mathbf{G}}(q, \xi) &= q[c_1(16\xi^{-2} - 160\xi^{-1} + 768 - 2400\xi + 5616\xi - 10752\xi^3 + 17920\xi^4 \\ &\quad - 27136\xi^5 + 38400\xi^6 - 51712\xi^7 + 67072\xi^8 + \dots) \\ &\quad + c_3(6\xi^{-2} - 40\xi^{-1} - 472\xi + 2042\xi^2 - 4608\xi^3 + 8192\xi^4 - 12800\xi^5 \end{aligned} \quad (6.26)$$

²⁰Note that the flux labelled by c_2 does not contribute.

$$+18432\xi^6 - 25088\xi^7 + 32768\xi^8 + \dots)] + \mathcal{O}(q^2).$$

The noteworthy feature is that at any given order of q there is an infinite series in ξ . This points to the expansion of a ξ -dependent denominator. Such behaviour is expected from experience with non-critical strings of six-dimensional $N = (1, 0)$ SCFT's with nontrivial gauge symmetry [43, 44, 49, 55, 58–60, 65, 67–69, 72], which are obtained when D3-branes wrap a curve that is also wrapped by 7-branes. In six dimensions, such strings are interpreted as instanton strings with respect to the non-abelian gauge group localized on the stack of 7-branes. The point is that for a coincident 7-brane/D3-brane system, the open strings in the 3-7 sector lead to massless charged chiral fields the $N = (0, 2)$ supersymmetric worldsheet theory, and in turn to charged bosonic excitations in spacetime. These are responsible for the appearance of an ξ -dependent denominator in the elliptic genus.

Our goal is to understand the four-dimensional elliptic genus as the derivative of a six-dimensional elliptic genus, possibly augmented by a genuinely four-dimensional piece. To find the six-dimensional contribution, recall that the curve C_E is trivially fibered over the \mathbb{P}^1 factor in B_3 , thereby tracing out the divisor D_E within B_3 . This suggests that we must consider the E-string within a threefold, \mathbb{Y}_3 , obtained by restricting Y_4 to the fiber of this fibration. This threefold is simply

$$\mathbb{Y}_3 = Y_4|_{D_3}, \quad (6.27)$$

where the divisor D_3 cuts out the Hirzebruch surface \mathbb{F}_1 on B_3 . This threefold happens to be a Calabi-Yau space, and thus we can easily compute the relevant BPS invariants via mirror symmetry. The first terms in the expansion of the elliptic genus for the six-dimensional E-string in \mathbb{Y}_3 leads to the BPS numbers presented in (C.13). These BPS numbers can be identified as the expansion coefficients of

$$Z_{-2,-1}(q, \xi) = -\frac{1}{\eta(\tau)^{12}} \sum_{i=2}^4 \frac{\theta_i(0, \tau)^{10}}{\theta_i(2z, \tau)^2}. \quad (6.28)$$

In accord with our expectations, this coincides with the elliptic genus of an instanton string of a six-dimensional $N = (1, 0)$ SCFT with $SU(2)$ gauge symmetry and $SO(20)$ flavor symmetry [58], in the limit where the chemical potentials of its $SO(20)$ flavor symmetry have been switched off and the only nonvanishing chemical potential is the one for the Cartan generator of $SU(2)$.

While we expect (6.28) to contribute to the elliptic genus of the four-dimensional E-string with a derivative, it turns out that for general Cartan flux \mathbf{G} , the four-dimensional elliptic genus receives in addition a fully modular, non-derivative contribution without a six-dimensional origin. In fact, the elliptic genus of our four-dimensional E-string can be brought into the following form, in full agreement with Conjecture 2 in Section 3.2:

$$Z_{C_E; \mathbf{G}}(q, \xi) = (F \cdot C_E) Z_{-1, m}(q, \xi) + \frac{1}{m} (F \cdot b \cdot D_E) \xi \partial_\xi Z_{-2, m}(q, \xi), \quad (6.29)$$

where²¹

$$m = b \cdot C_E = -1 \quad (6.30)$$

²¹Note that in the definition of m we have not included a factor of $\frac{1}{2}$. This reflects the different normalisation of the $U(1)$ as Cartan subgroup of $SU(2)$, as compared to the non-Cartan $U(1)$'s studied in the other examples in this work. The value of m defined in this way gives the $U(1)$ fugacity index of the modular forms. Correspondingly, the prefactor of the derivative term in (6.29) is $\frac{1}{m}$, rather than $\frac{1}{2m}$.

and the flux-dependent parameters are

$$F \cdot C_E = c_1, \quad F \cdot b \cdot D_E = -c_3. \quad (6.31)$$

Note again that the flux labelled by c_2 does not contribute. The first term,

$$Z_{-1,-1}(q, \xi) = 16i \frac{\theta_1(z, \tau)^{10}}{\theta_1(2z, \tau)^3 \eta(\tau)^9}, \quad (6.32)$$

represents a genuinely four-dimensional contribution to the elliptic genus. Evidently, fluxes for which $F \cdot C_E \neq 0$ affect the spectrum of the solitonic string in a more drastic way if the string lies inside a 7-brane stack, and as a result the four-dimensional E-string can no longer simply be viewed as a fibered version of a six-dimensional E-string. The final expression (6.29) then nicely disentangles via the fluxes the universal six-dimensional contribution and the genuinely four-dimensional contribution to the elliptic genus.

6.2 Four-Dimensional String on $B_3 = \mathbb{P}^3$

As our final example, we present the elliptic genus of a non-critical string that probes a base geometry without any fibration structure. Nonetheless, we will be able to write the elliptic genus in the general form advertised in Section 3.2.

We will consider the simplest possible elliptic fourfold fibration, namely where the base is given by $B_3 = \mathbb{P}^3$. We will focus on the elliptic genus of the non-critical string obtained by wrapping a D3-brane along some curve C_b , whose class is given in terms of the hyperplane class by

$$C_b = H \cdot H. \quad (6.33)$$

To keep things simple, we engineer a gauge group $G = U(1)$ with associated height-pairing $b = 2\bar{K}_{B_3} = 8H$. The details of the geometry can be found in Appendix D. The transversal $U(1)$ flux is of the form

$$\mathbf{G}_{U(1)} = \sigma \wedge \pi^*(F), \quad \text{with } F = cH. \quad (6.34)$$

The elliptic genus of the non-critical string is expected to encode the relative BPS invariants $N_{C_b; \mathbf{G}}(n, r)$ via

$$Z_{\mathbf{G}_{U(1)}; C_b}(q, \xi) = -\frac{1}{q^2} \sum_{n, r} N_{\mathbf{G}_{U(1)}; C_b}(n, r) q^n \xi^r, \quad (6.35)$$

where the prefactor $q^{-2} = q^{-E_0/2}$ reflects the vacuum energy $E_0 = C_b \cdot \bar{K}_{B_3} = 4$ on the string. The lowest invariants can be computed by mirror symmetry as discussed in Appendix D. Exploiting modularity, we can completely determine the elliptic genus as

$$Z_{\mathbf{G}_{U(1)}; C_b}(q, \xi) = (F \cdot C_b) Z_{-1, m}(q, \xi) + \frac{1}{2m} (F \cdot b \cdot H) \xi \partial_\xi Z_{-2, m}(q, \xi), \quad (6.36)$$

where $Z_{-1, m}(q, \xi)$ and $Z_{-2, m}(q, \xi)$ are meromorphic Jacobi forms for which explicit expressions are presented in eqs. (D.11) and (D.12). Moreover, the $U(1)$ fugacity index is given by

$$m = \frac{1}{2} b \cdot C_b = 4, \quad (6.37)$$

while

$$F \cdot C_b = c, \quad F \cdot b \cdot H = 8c. \quad (6.38)$$

Recall that the single flux parameter c is defined in (6.34); since $h^{1,1}(B_3) = 1$ there is not enough room for different types of $U(1)$ fluxes to separate out the modular and derivative components, so that just a single linear combination appears.

We conclude from this example that the four-dimensional elliptic genus can receive a derivative contribution even if the base, B_3 , is not a fibration. The invariants contained in the derivative piece $Z_{-2,4}(q, \xi)$ once more appear in the background of a non-transversal (-2) flux. In the present case, the only non-trivial (-2) flux is of the form

$$\mathbf{G}_H = \pi^*(H) \wedge \pi^*(H). \quad (6.39)$$

For an elliptic fibration over \mathbb{P}^3 without $U(1)$ gauge group, such fluxes were investigated in [76, 77]. As we show in Appendix D, the generating function for the BPS invariants in this flux background precisely encodes the invariants contained in $Z_{-2,4}(q, \xi)$, i.e.

$$\mathcal{F}_{\mathbf{G}_H; C_b} = -q^2 Z_{-2,4}(q, \xi). \quad (6.40)$$

It is interesting to wonder if the invariants $Z_{-2,4}(q, \xi)$ are again the invariants of a certain embedded threefold but we have no evidence that this is the case in this example. In fact, in [107] we will give very direct arguments for the relation between certain (-2) flux invariants and the invariants of embedded threefolds, but these do not apply to the flux background (6.39).

7 Conclusions and Outlook

In this work we have investigated the rich interplay between the modular properties of elliptic genera, the enumerative geometry of genus zero relative BPS invariants on elliptic fourfolds with background fluxes, and the structure of $U(1)$ anomalies for effective field theories in four dimensions. Our analysis has been distilled to Conjecture 2 in Section 3.2, which disentangles the flux-induced elliptic genus in four dimensions into a sum of modular Jacobi forms, quasi-modular Jacobi forms, and derivatives thereof. Our conjecture applies in particular to critical heterotic strings and to non-critical solitonic strings in four dimensions with $N = (0, 2)$ worldsheet supersymmetry. Such theories can be engineered in F-theory as worldvolume theories of D3-branes compactified on curves which lie in the base, B_3 , of an elliptic fourfold Y_4 .

That the elliptic genus in four dimensions is not necessarily a (quasi-)modular Jacobi form *per se* had been explicitly observed already in [6], and is in agreement with the general results of [24] and with the conjecture [25] that the generating functions of BPS invariants of elliptic fibrations are captured in terms of quasi-Jacobi forms. According to Conjecture 2 of the present paper, the non-(quasi-)modular components of the elliptic genus are, in fact, of a simple derivative form. Apart from breaking modular invariance, they also break the elliptic shift symmetry which corresponds to spectral flow in the $U(1)$ current algebra. These anomalies can be remedied at the cost of introducing a non-holomorphic derivative as in (1.12). This results in eq. (1.13), which can be seen as a concrete realization of the elliptic holomorphic anomaly equation that was proposed in [25], thereby giving further support of it.

Our arguments are based on a central observation of this paper, namely that the derivative contributions to the elliptic genus in the presence of transversal flux can be obtained in two a priori independent ways: First, they arise from the partition function of BPS invariants in

the background of non-transversal fluxes. This is in accordance with the elliptic holomorphic anomaly equation that was introduced in [25]. A main result in our work concerns a second, novel interpretation of these invariants, namely as BPS invariants of certain threefolds \mathbb{Y}_3^i that are embedded in Y_4 . Taking the second point of view in fact allowed us to independently derive the elliptic holomorphic anomaly equation.

In special cases, the threefolds \mathbb{Y}_3^i are themselves Calabi-Yau manifolds and their BPS invariants can easily be computed by means of mirror symmetry. By analysing a variety of examples, we find that these BPS invariants indeed match the derivative sector of elliptic genera. This lends strong support to our claims. More generally, the concept of relative BPS invariants is well-defined also for non-Calabi-Yau geometries, and we gather circumstantial evidence that the observed pattern persists for such \mathbb{Y}_3^i . It would be intriguing to develop techniques to compute these invariants more directly, from first principles, in order to compare them with our predictions.

In the special case of a heterotic string, we have been able to prove the geometric interpretation of the BPS invariants in the derivative sector, at least at the first energy level $n = 1$ of the elliptic genus. This rests on the geometric interpretation of the fourfold BPS invariants in terms of the moduli space of curves in the fourfold. It would be desirable to extend this proof to all levels n [107]. This would open up the fascinating possibility of using mirror symmetry on *Calabi-Yau fourfolds* to determine relative BPS invariants of *non-Calabi-Yau threefolds*.

From a physics perspective, the embedded threefolds \mathbb{Y}_3^i can be thought of as formally defining six-dimensional sectors in the following sense. If the \mathbb{Y}_3^i are Calabi-Yau manifolds, the derivative part of the elliptic genus can be literally interpreted as a collection of six-dimensional elliptic genera. For instance, for the case of a heterotic solitonic string, we can go to the dual weakly coupled eigenframe which describes a compactification on a $K3$ surface with gauge bundle. In this case the six-dimensional elliptic genus we talk about is precisely the elliptic genus of such a compactification. We have also discussed the more generic situation where \mathbb{Y}_3^i is not Calabi-Yau: while the arguments are not as sharp, we can still make a formal analogy and consider a dual heterotic geometry associated with some elliptic surface, which however is not a $K3$ surface any longer.

We have illustrated Conjecture 2 by a number of examples covering a variety of four-dimensional, critical as well as non-critical strings, and their elliptic genera. For the special case of the critical heterotic string, the modular properties of the elliptic genus reflect the intricacies of the Green-Schwarz anomaly cancelling mechanism in four dimensions. As described, contrary to what happens in six dimensions, the elliptic genus in four dimensions is not necessarily a (quasi-)modular Jacobi form, and we show in detail how this ties in with anomaly cancellation involving extra B -fields. Specifically, the modular part of the elliptic genus is linked to the universal B -field, while the other sectors reflect the presence of further B -fields, in general of both perturbative and non-perturbative nature.

We have furthermore analysed two types of examples of non-critical strings in four dimensions. The first is a generalisation of the concept of an E-string to four dimensions: Its elliptic genus is generally the sum of a derivative piece (which is related to the familiar six-dimensional E-string), plus a genuinely four-dimensional contribution, whose details depend on the flux background. While the E-strings are special in that they can be decoupled from gravity in four dimensions, we have tested Conjecture 2 also for a non-critical string which is associated with a non-shrinkable curve in \mathbb{P}^3 , so that gravity cannot be decoupled. Clearly the handful of prototypical examples provided in this work only form the beginning of a much more systematic study of elliptic genera of strings in four dimensions.

A Modular Forms

A.1 Rings of Jacobi ($J_{*,*}$), Quasi-Modular Jacobi ($J_{*,*}^{QM}$), and Quasi-Jacobi ($J_{*,*}^{QJ}$) Forms

Jacobi forms [153], as holomorphic functions of two variables, $\Phi(\tau, z) : \mathbb{H} \times \mathbb{C} \rightarrow \mathbb{C}$, are primarily characterized by their simple transformation properties under the modular group:

$$\Phi_{w,m} \left(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d} \right) = (c\tau + d)^w e^{2\pi i \frac{mc}{c\tau + d} z^2} \Phi_{w,m}(\tau, z) \quad \text{for } \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2, \mathbb{Z}), \quad (\text{A.1})$$

$$\Phi_{w,m}(\tau, z + \lambda\tau + \mu) = e^{-2\pi i m(\lambda^2\tau + 2\lambda z)} \Phi_{w,m}(\tau, z), \quad \lambda, \mu \in \mathbb{Z}. \quad (\text{A.2})$$

They possess a Fourier expansion

$$\Phi_{w,m} = \sum_{n \geq 0} \sum_{r^2 \leq 4mn} c(n, r) e^{2\pi i(n\tau + rz)}, \quad (\text{A.3})$$

and are the natural building blocks [33–35] of elliptic genera (1.1) that are refined by an extra $U(1)$ current. There exists an extensive literature about Jacobi forms (for example, besides the original work [153], also [36, 154, 155]), so we can be brief. We just mention here some aspects that are important in this work. A Jacobi form $\Phi_{w,m}(\tau, z)$ is called

- a holomorphic Jacobi form if $c(n, r) = 0$ unless $4mn \geq r^2$,
- a Jacobi cusp form if $c(n, r) = 0$ unless $4mn > r^2$,
- a weak Jacobi form if $c(n, r) = 0$ unless $n \geq 0$.

One furthermore defines a weakly (or nearly) holomorphic Jacobi form by requiring $c(n, r) = 0$ unless $n \geq n_0$ for a negative integer n_0 .

Jacobi forms form a bi-graded ring which we denote by

$$J_{*,*} = \bigoplus_{w,m} J_{w,m}. \quad (\text{A.4})$$

For even weight and integer index, $J_{2k,m}$ is freely generated by $\phi_{0,1}$ and $\phi_{-2,1}$ with coefficients given by polynomials in the Eisenstein series E_4 and E_6 . The Eisenstein series, as well as the generators $\phi_{0,1}$ and $\phi_{-2,1}$, can be expressed in terms of the Dedekind function $\eta(\tau) = q^{\frac{1}{24}} \prod_{n=1}^{\infty} (1 - q^n)$ and the familiar Jacobi theta functions as follows:²²

$$E_4(\tau) = \frac{1}{2} \sum_{\ell=1}^4 \vartheta_{\ell}(\tau, 0)^8, \quad (\text{A.5})$$

²²Note that we adopt conventions different to those of [6].

$$E_6(\tau) = \frac{1}{2} \left(\vartheta_2(\tau, 0)^8 (\vartheta_3(\tau, 0)^4 + \vartheta_4(\tau, 0)^4) + \vartheta_3(\tau, 0)^8 (\vartheta_2(\tau, 0)^4 - \vartheta_4(\tau, 0)^4) - \vartheta_4(\tau, 0)^8 (\vartheta_2(\tau, 0)^4 + \vartheta_3(\tau, 0)^4) \right), \quad (\text{A.6})$$

$$\phi_{-2,1}(\tau, z) = -\frac{\vartheta_1(\tau, z)^2}{\eta^6(\tau)}, \quad (\text{A.7})$$

$$\phi_{0,1}(\tau, z) = 4 \left(\frac{\vartheta_2(\tau, z)^2}{\vartheta_2(\tau, 0)^2} + \frac{\vartheta_3(\tau, z)^2}{\vartheta_3(\tau, 0)^2} + \frac{\vartheta_4(\tau, z)^2}{\vartheta_4(\tau, 0)^2} \right). \quad (\text{A.8})$$

For odd weight and integer index, $J_{2k+1,m}$ has a single extra generator

$$\phi_{-1,2}(\tau, z) = \frac{i\vartheta_1(\tau, 2z)}{\eta^3(\tau)}, \quad (\text{A.9})$$

which implies that any odd-weight Jacobi form of integer index must be proportional to $\phi_{-1,2}$. This is of great significance in the present work, since the relevant elliptic genus of four-dimensional theories has weight $w = -1$ and integer m . Note that the odd generator obeys the relation

$$432\phi_{-1,2}^2 = \phi_{-2,1} \left(\phi_{0,1}^3 - 3E_4\phi_{-2,1}\phi_{0,1} + 2E_6\phi_{-2,1}^3 \right) \quad (\text{A.10})$$

so that effectively it appears at most linearly. So altogether the ring of weak Jacobi forms is generated by

$$J_{*,*} : \{E_4, E_6, \phi_{0,1}, \phi_{-2,1}, \phi_{-1,2}\}, \quad (\text{A.11})$$

modulo the relation (A.10).

For reference, we define $q = e^{2\pi i\tau}$, $\xi = e^{2\pi iz}$, $\xi^{\pm n} = \xi^n + \xi^{-n}$, $\xi^{\pm \bar{n}} = \xi^n - \xi^{-n}$, and $\hat{z} = 2\pi iz$, and list the following expansions:

$$\begin{aligned} \phi_{0,1}(\tau, z) &= 10 + \xi^{\pm 1} + (108 - 64\xi^{\pm 1} + 10\xi^{\pm 2})q + \dots \\ &= 12 + E_2\hat{z}^2 + \frac{1}{24}(E_2^2 + E_4)\hat{z}^4 + \dots, \end{aligned} \quad (\text{A.12})$$

$$\begin{aligned} \phi_{-2,1}(\tau, z) &= -2 + \xi^{\pm 1} - (12 - 8\xi^{\pm 1} + 2\xi^{\pm 2})q + \dots \\ &= \hat{z}^2 + \frac{1}{12}E_2\hat{z}^4 + \frac{1}{1440}(5E_2^2 - E_4)\hat{z}^6 + \dots, \end{aligned} \quad (\text{A.13})$$

$$\begin{aligned} \phi_{-1,2}(\tau, z) &= \xi^{\pm \bar{1}} + (3\xi^{\pm \bar{1}} - \xi^{\pm \bar{3}})q + \dots \\ &= 2\hat{z} + \frac{1}{3}E_2\hat{z}^3 + \frac{1}{180}(5E_2^2 - 2E_4)\hat{z}^5 + \dots \end{aligned} \quad (\text{A.14})$$

Moreover, an important rôle is played by holomorphic quasi-modular forms. The ring of such forms is generated by the Eisenstein series E_4 and E_6 plus

$$E_2(\tau) = \frac{1}{2\pi i} \frac{\Delta'(\tau)}{\Delta(\tau)} = 1 - 24q - 72q^2 + \mathcal{O}(q^3), \quad (\text{A.15})$$

where $\Delta = \eta^{24} = \frac{1}{1728}(E_4^3 - E_6^2)$. As is well-known, it is not fully modular but transforms with an extra piece

$$E_2\left(\frac{a\tau + b}{c\tau + d}\right) = (c\tau + d)^2 E_2(\tau) - \frac{6i}{\pi} c(c\tau + d). \quad (\text{A.16})$$

This modular anomaly can be remedied at the expense of holomorphicity by defining

$$\hat{E}_2(\tau) = E_2(\tau) - \frac{3}{\pi \text{Im}\tau}. \quad (\text{A.17})$$

In this paper we consider two extensions: a simpler one and a more complicated one which contains the first.²³ The simple one is what we call the ring $J_{*,*}^{QM}$ of *quasi-modular* Jacobi forms. It is defined similar to $J_{*,*}$ except that the coefficients are polynomials in E_2 as well as in E_4 and E_6 . That is, its generators are

$$J_{*,*}^{QM} : \{E_2, E_4, E_6, \phi_{0,1}, \phi_{-2,1}, \phi_{-1,2}\}. \quad (\text{A.18})$$

The more complicated extension is obtained by first defining an ‘‘almost holomorphic’’ function on $\mathbb{H} \times \mathbb{C}$ of the form

$$\Phi(\tau, z) = \sum_{i,j \geq 0} \Phi_{i,j}(\tau, z) \left(\frac{1}{\text{Im}\tau} \right)^i \left(\frac{\text{Im}z}{\text{Im}\tau} \right)^j, \quad (\text{A.19})$$

where the sum runs over finitely many terms and the $\Phi_{i,j}(\tau, z)$ are holomorphic (and appropriately convergent). If the non-holomorphic function $\Phi(\tau, z)$ obeys the transformation laws of a Jacobi form as given in (A.1) and (A.2), then the holomorphic first term in the sum is defined to be a *quasi-Jacobi* form:

$$\Phi_{0,0}(\tau, z) \in J_{*,*}^{QJ}. \quad (\text{A.20})$$

Note that $J_{*,*}^{QM} \subset J_{*,*}^{QJ}$ as it corresponds to the special case of almost holomorphic Jacobi forms (A.19) for which $j \equiv 0$. For more thorough definitions, see [23–25].

Summarizing, *quasi-modular* Jacobi forms can be made modular by repairing the anomalous transformation behaviour of the generator E_2 in (A.16) by adding a non-holomorphic piece as in (A.17). This has many known manifestations in the physics literature.

On the other hand, *quasi-Jacobi* forms have a worse transformation behaviour that cannot be remedied in this simple way, and needs extra treatment in the form of $\frac{\text{Im}z}{\text{Im}\tau}$. The quasi-Jacobi forms that appear in this paper all arise as z -derivatives of modular or quasi-modular Jacobi forms. More precisely, if we start from a Jacobi form $\Phi_{w,m}(\tau, z) \in J_{w,m}$ with given weight and index, then

$$\Phi_{w+1,m}(\tau, z) = \nabla_{z,m} \Phi_{w,m}(\tau, z), \quad (\text{A.21})$$

$$\nabla_{z,m} := \partial_z + 4\pi i m \frac{\text{Im}z}{\text{Im}\tau}, \quad (\text{A.22})$$

is almost holomorphic while modular with weight $w + 1$ under the transformations (A.1) and (A.2). This follows from the transformation property of $\alpha \equiv \frac{\text{Im}z}{\text{Im}\tau}$:

$$\alpha \left(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d} \right) = (c\tau + d)\alpha(\tau, z) - cz, \quad (\text{A.23})$$

$$\alpha(\tau, z + \lambda\tau + \mu) = \alpha(\tau, z) + \lambda. \quad (\text{A.24})$$

It then follows that by definition $\partial_z \Phi_{w,m} \in J_{w+1,m}^{QJ}$. Analogous arguments apply if $\Phi_{w,m} \in J_{w,m}^{QM}$.

A.2 Eisenstein-Jacobi Forms

In this section we identify a set of Jacobi forms which are closely related to the Eisenstein series $E_4(\tau)$ and $E_6(\tau)$. This parametrization of the ring of Jacobi forms, $J_{*,*}$, is naturally adapted to the geometries we consider, and makes certain properties more manifest. Specifically, we are interested in holomorphic Jacobi forms $\Phi_{w,m}(q, \xi) = \Phi_{w,m}(\tau, z)$, of weight $w = 4$ or 6 and index m characterized by the following properties:

²³An even more drastic extension would be in terms of more general mock-modular Jacobi forms, see for example ref. [36]. However this appears not to be relevant for the compact geometries we consider.

- $\Phi_{w,m}(q, \xi = 1) \equiv \Phi_{w,m}(\tau, z = 0) = E_w(\tau)$,
- $\Phi_{w,m}(q, \xi) = \sum_{n \geq 0} \sum_{r \in \mathbb{Z}} c(n, r) q^n \xi^r$, where $c(n, r) \in \mathbb{Z}$ and $c(0, r) = \delta_{0,r}$.

We further restrict our attention to Jacobi forms with index $m \leq 4$ and integral expansion coefficients which are relevant to the examples that appear in this paper. It is straightforward to construct explicitly all such forms within the ring $J_{*,*}$. Specifically, for any $w = 4, m \leq 3$, as well as for $w = 6, m \leq 2$, there is a unique such form, which coincides with the Jacobi-Eisenstein series $E_{w,m}$ of [153]. These are given by:

$$E_{4,0} = E_4 = 1 + 240q + \mathcal{O}(q^2), \quad (\text{A.25})$$

$$E_{4,1} = \frac{1}{12} (E_4 \phi_{0,1} - E_6 \phi_{-2,1}) = 1 + (\xi^{\pm 2} + 56\xi^{\pm 1} + 126)q + \mathcal{O}(q^2), \quad (\text{A.26})$$

$$E_{4,2} = \frac{1}{12^2} (E_4 \phi_{0,1}^2 - 2E_6 \phi_{0,1} \phi_{-2,1} + E_4^2 \phi_{-2,1}^2) = 1 + (14\xi^{\pm 2} + 64\xi^{\pm 1} + 84)q + \mathcal{O}(q^2), \quad (\text{A.27})$$

$$\begin{aligned} E_{4,3} &= \frac{1}{12^3} (E_4 \phi_{0,1}^3 - 3E_6 \phi_{0,1}^2 \phi_{-2,1} + 3E_4^2 \phi_{0,1} \phi_{-2,1}^2 - E_4 E_6 \phi_{-2,1}^3) \\ &= 1 + (2\xi^{\pm 3} + 27\xi^{\pm 2} + 54\xi^{\pm 1} + 74)q + \mathcal{O}(q^2), \end{aligned} \quad (\text{A.28})$$

and

$$E_{6,0} = E_6 = 1 - 504q + \mathcal{O}(q^2), \quad (\text{A.29})$$

$$E_{6,1} = \frac{1}{12} (E_6 \phi_{0,1} - E_4^2 \phi_{-2,1}) = 1 + (\xi^{\pm 2} - 88\xi^{\pm 1} - 330)q + \mathcal{O}(q^2), \quad (\text{A.30})$$

$$E_{6,2} = \frac{1}{12^2} (E_6 \phi_{0,1}^2 - 2E_4^2 \phi_{0,1} \phi_{-2,1} + E_4 E_6 \phi_{-2,1}^2) = 1 - (10\xi^{\pm 2} + 128\xi^{\pm 1} + 228)q + \mathcal{O}(q^2). \quad (\text{A.31})$$

On the other hand, for $w = 4, m = 4$ and for $w = 6, m = 3$ and 4, the sought-after Jacobi forms cannot be Jacobi-Eisenstein series, as the latter do not have integer coefficients. For each of these cases there is a one parameter family of Jacobi forms with the required properties, which we denote by $E_{w,m,t}$, $t \in \mathbb{Z}$:

$$\begin{aligned} E_{4,4,t} &= \frac{1}{12^4} (E_4 \phi_{0,1}^4 - 4E_6 \phi_{0,1}^3 \phi_{-2,1} + 6E_4^2 \phi_{0,1}^2 \phi_{-2,1}^2 - 4E_4 E_6 \phi_{0,1} \phi_{-2,1}^3 + (9E_4^3 - 8E_6^2) \phi_{-2,1}^4) - t \Delta \phi_{-2,1}^4 \\ &= 1 + (\xi^{\pm 4} + 56\xi^{\pm 2} + 126\xi^{\pm 1} - t \frac{(1-\xi)^8}{\xi^4})q + \mathcal{O}(q^2), \end{aligned} \quad (\text{A.32})$$

$$\begin{aligned} E_{6,3,t} &= \frac{1}{12^3} (E_6 \phi_{0,1}^3 - 3E_4^2 \phi_{0,1}^2 \phi_{-2,1} + 3E_4 E_6 \phi_{0,1} \phi_{-2,1}^2 - E_6^2 \phi_{-2,1}^3) - t \Delta \phi_{-2,1}^3 \\ &= 1 - (\xi^{\pm 3} + 27\xi^{\pm 2} + 135\xi^{\pm 1} + 178 + t \frac{(1-\xi)^6}{\xi^3})q + \mathcal{O}(q^2), \end{aligned} \quad (\text{A.33})$$

$$\begin{aligned} E_{6,4,t} &= \frac{1}{12^4} (E_6 \phi_{0,1}^4 - 4E_4^2 \phi_{0,1}^3 \phi_{-2,1} + 6E_4 E_6 \phi_{0,1}^2 \phi_{-2,1}^2 - 4E_6^2 \phi_{0,1} \phi_{-2,1}^3 + E_4^2 E_6 \phi_{-2,1}^4) - t \Delta \phi_{0,1} \phi_{-2,1}^3 \\ &= 1 - (4\xi^{\pm 3} + 44\xi^{\pm 2} + 124\xi^{\pm 1} + 160 + t \frac{(1-\xi)^6}{\xi^3} (\xi^{\pm 1} + 10))q + \mathcal{O}(q^2). \end{aligned} \quad (\text{A.34})$$

In the paper, we employ these forms to express the $U(1)$ dependence numerator of the heterotic string elliptic genus on K3, which in the limit $z \rightarrow 0$ reduces to $2E_4(\tau)E_6(\tau)$. In fact, in the examples we make a further specialization and write the elliptic genera in terms of the following set of Jacobi forms:

$$F_{6,3} := E_{6,3,9}, \quad G_{6,3} := E_{6,3,-3}, \quad F_{4,4} := E_{4,4,1}, \quad G_{4,4} := E_{4,4,0}, \quad F_{6,4} := E_{6,4,0}, \quad G_{6,4} := E_{6,4,-1}, \quad (\text{A.35})$$

together with the Eisenstein-Jacobi forms (A.25-A.31).

We note that there exist a number of bilinear relations among this set of Jacobi forms:

$$\begin{aligned}
E_{4,0}F_{4,4} - 4E_{4,1}E_{4,3} + 3E_{4,2}^2 &= 0, \\
E_{4,0}E_{6,2} + E_{4,2}E_{6,0} - 2E_{4,1}E_{6,1} &= 0, \\
E_{4,0}F_{6,3} + 3E_{4,1}E_{6,2} - 9E_{4,2}E_{6,1} + 5E_{4,3}E_{6,0} &= 0, \\
E_{4,0}G_{6,3} - 3E_{4,1}E_{6,2} + 3E_{4,2}E_{6,1} - E_{4,3}E_{6,0} &= 0, \\
E_{4,1}F_{6,3} - 3E_{4,3}E_{6,1} + 2F_{4,4}E_{6,0} &= 0, \\
E_{4,1}G_{6,3} - 3E_{4,2}E_{6,2} + 3E_{4,3}E_{6,1} - F_{4,4}E_{6,0} &= 0, \\
E_{4,0}F_{6,4} - 3E_{4,2}E_{6,2} + 2E_{4,3}E_{6,1} &= 0, \\
E_{4,0}G_{6,4} - 2E_{4,1}G_{6,3} + 2E_{4,3}E_{6,1} - G_{4,4}E_{6,0} &= 0.
\end{aligned} \tag{A.36}$$

Moreover we find that the following relations hold:

$$\begin{aligned}
E_{4,1}\hat{\nabla}E_{4,2} &= 12\Delta\phi_{-1,2}\phi_{-2,1}, \\
E_{4,1}\hat{\nabla}E_{4,3} &= 2\Delta\phi_{-1,2}\phi_{0,1}\phi_{-2,1}, \\
E_{6,1}\hat{\nabla}E_{4,1} &= 144\Delta\phi_{-1,2}, \\
E_{6,1}\hat{\nabla}E_{4,2} = E_{6,2}\hat{\nabla}E_{4,1} &= 12\Delta\phi_{-1,2}\phi_{0,1}, \\
E_{6,1}\hat{\nabla}E_{4,3} &= \Delta\phi_{-1,2}(\phi_{0,1}^2 + E_4\phi_{-2,1}^2), \\
E_{6,2}\hat{\nabla}E_{4,2} &= \Delta\phi_{-1,2}(\phi_{0,1}^2 - E_4\phi_{-2,1}^2), \\
F_{6,3}\hat{\nabla}E_{4,1} &= \Delta\phi_{-1,2}(\phi_{0,1}^2 + 9E_4\phi_{-2,1}^2), \\
G_{6,3}\hat{\nabla}E_{4,1} &= \Delta\phi_{-1,2}(\phi_{0,1}^2 - 3E_4\phi_{-2,1}^2).
\end{aligned} \tag{A.37}$$

The operator $\hat{\nabla}$ acts on a pair of Jacobi forms Φ_{w_1, m_1} , Φ_{w_2, m_2} of nonzero index to produce the a Jacobi form of weight $w_1 + w_2 + 1$ and index $m_1 + m_2$, and has the following definition:

$$\Phi_{m_1, k_1}\hat{\nabla}\Phi_{m_2, k_2} = \frac{1}{m_2}\Phi_{m_1, w_1}(\xi\partial_\xi)\Phi_{m_2, w_2} - \frac{1}{m_1}\phi_{m_2, w_2}(\xi\partial_\xi)\Phi_{m_1, w_1}. \tag{A.38}$$

B 4d Heterotic and E-Strings for $B_3 = dP_2 \times \mathbb{P}_V^1$

Here we will provide details of the geometry of the elliptic Calabi-Yau fourfold, Y_4 , and of the embedded threefolds \mathbb{Y}_3^i , as discussed in Section 5.1.

The toric coordinates of the threefold base

$$B_3 = dP_2 \times \mathbb{P}_V^1 \tag{B.1}$$

are listed in the upper-left part of Table B.1, in terms of the $U(1)$ charges of a gauged linear sigma model (GLSM).

As a basis of $H^{1,1}(B_3)$ we take

$$\begin{aligned}
D_1 &= \nu_{z_0} = f &= p^*(C_1), \\
D_2 &= \nu_{z_3} = h &= S_-, \\
D_3 &= \nu_{x_0} = l' &= p^*(C_2), \\
D_4 &= \nu_{z_1} = f + h - E &= p^*(C_1) + S_- - E.
\end{aligned} \tag{B.2}$$

| | | | | | | | | | | | |
|---------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|---------|---------|---------|---------|
| | ν_{x_0} | ν_{x_1} | ν_{z_0} | ν_{z_1} | ν_{z_2} | ν_{z_3} | ν_{z_4} | ν_u | ν_v | ν_w | ν_s |
| $f - E$ | 0 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 3 | 6 | 0 |
| h | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 2 | 4 | 0 |

| S | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |

Table B.1: GLSM charges of the toric coordinates of the $\text{Bl}_1\mathbb{P}_{112}^2$ fibration over $B_3 = dP_2 \times \mathbb{P}_v^1$. The upper-left part, as separated by the horizontal and the vertical double lines corresponds to the description of the base B_3 alone.

The notation f and h refers to the pullback to B_3 of the respective classes of the fiber and base of the Hirzebruch surface \mathbb{F}^1 whose blowup constitutes dP_2 ; that is, $f \simeq C^0 \times \mathbb{P}_v^1$ and $h \simeq \mathbb{P}_h^1 \times \mathbb{P}_v^1$. The rest of the notation has been introduced in Section 5.1.

We now turn to the geometry of the elliptic fibration $\pi : Y_4 \rightarrow B_3$. The elliptic fiber is constructed as a general hypersurface of degree 4 in $\text{Bl}_1\mathbb{P}_{112}^2$, which is a convenient way of realising a $U(1)$ gauge symmetry via a rank-1 Mordell-Weil group of rational sections [128]. Specifically, the fourfold Y_4 is obtained by the vanishing locus of

$$P_{\text{MP}} := sw^2 + b_0s^2u^2w + b_1suvw + b_2v^2w + c_0s^3u^4 + c_1s^2u^3v + c_2su^2v^2 + c_3uv^3, \quad (\text{B.3})$$

where u, v, w and s are the four homogeneous coordinates of the ambient space $\text{Bl}_1\mathbb{P}_{112}^2$ of the fiber. The coefficients b_i and c_i are sections of appropriate line bundles on B_3 , whose degrees are parametrized by a cohomology class $\beta \in H^2(B_3, \mathbb{Z})$ as follows:

| Sections | b_0 | b_1 | b_2 | c_0 | c_1 | c_2 | c_3 | c_4 |
|----------|---------|-----------------|--------------------------|----------|-------------------------|------------------|--------------------------|---------------------------|
| Classes | β | \bar{K}_{B_3} | $2\bar{K}_{B_3} - \beta$ | 2β | $\bar{K}_{B_3} + \beta$ | $2\bar{K}_{B_3}$ | $3\bar{K}_{B_3} - \beta$ | $4\bar{K}_{B_3} - 2\beta$ |

If we denote by \mathcal{L}_u and \mathcal{L}_s the line bundles of which the coordinates u and v are sections, the remaining fibral ambient coordinates w and s are in turn sections of the bundles,

$$\begin{aligned} v &\in H^0(Y_4, \mathcal{L}_u \otimes \mathcal{L}_s \otimes \mathcal{O}(\beta - \bar{K}_{B_3})), \\ w &\in H^0(Y_4, \mathcal{L}_u^2 \otimes \mathcal{L}_s \otimes \mathcal{O}(\beta)), \end{aligned} \quad (\text{B.4})$$

which can be seen from the defining polynomial (B.3). For the concrete fibration Y_4 we make the following choice:

$$\begin{aligned} \beta &= 4D_1 + 2D_2 + 4D_3 + 2D_4 \\ &= 2\bar{K}_{B_3}, \end{aligned} \quad (\text{B.5})$$

which leads to the toric description for Y_4 as described in Table (B.1).

Moreover, note that the height pairing divisor b of the section S , defined as the image $\sigma(S)$ under the Shioda homomorphism σ [122],

$$b := -\pi_*(\sigma(S) \cdot \sigma(S)), \quad (\text{B.6})$$

takes, taking into account (B.5), the form:

$$b = 6\bar{K}_{B_3} - 2\beta = 2\bar{K}_{B_3}. \quad (\text{B.7})$$

Given this toric data for Y_4 , upon performing appropriate combinatorial computations, e.g., by making use of PALP [156, 157] and SAGE [158], we can easily extract the generators $l^{(a)}$ of the Mori cone, $\mathbf{M}(Y_4)$:

$$\begin{aligned}
l^{(1)} &= (0, 0, 0, 0, 0, 0, 0, 1, 0, 1, -1), \\
l^{(2)} &= (0, 0, 0, 0, 0, 0, 0, -1, 1, 0, 2), \\
l^{(3)} &= (0, 0, 1, 0, 1, -1, 0, -1, 0, 0, 0), \\
l^{(4)} &= (0, 0, 0, 0, -1, 1, 1, -1, 0, 0, 0), \\
l^{(5)} &= (0, 0, 0, 1, 1, 0, -1, -1, 0, 0, 0), \\
l^{(6)} &= (1, 1, 0, 0, 0, 0, 0, -2, 0, 0, 0).
\end{aligned} \tag{B.8}$$

These generators are described in terms of their intersection numbers with the toric divisors $d_\rho := \{\nu_\rho = 0\}$, for $\rho = x_0, x_1, \dots, w, s$, as ordered in Table B.1. The quartic intersection numbers of Y_4 can be obtained via combinatorial computations as well, and we encode them in the following intersection polynomial:

$$\begin{aligned}
I(Y_4) &= 1302J_1^4 + 672J_1^3J_2 + 336J_1^2J_2^2 + 168J_1J_2^3 + 84J_2^4 + 120J_1^3J_3 + 64J_1^2J_2J_3 \\
&+ 32J_1J_2^2J_3 + 16J_2^3J_3 + 180J_1^3J_4 + 96J_1^2J_2J_4 + 48J_1J_2^2J_4 + 24J_2^3J_4 \\
&+ 14J_1^2J_3J_4 + 8J_1J_2J_3J_4 + 4J_2^2J_3J_4 + 14J_1^2J_4^2 + 8J_1J_2J_4^2 + 4J_2^2J_4^2 \\
&+ 120J_1^3J_5 + 64J_1^2J_2J_5 + 32J_1J_2^2J_5 + 16J_2^3J_5 + 14J_1^2J_3J_5 + 8J_1J_2J_3J_5 \\
&+ 4J_2^2J_3J_5 + 14J_1^2J_4J_5 + 8J_1J_2J_4J_5 + 4J_2^2J_4J_5 + 105J_1^3J_6 + 56J_1^2J_2J_6 \\
&+ 28J_1J_2^2J_6 + 14J_2^3J_6 + 14J_1^2J_3J_6 + 8J_1J_2J_3J_6 + 4J_2^2J_3J_6 + 21J_1^2J_4J_6 \\
&+ 12J_1J_2J_4J_6 + 6J_2^2J_4J_6 + 3J_1J_3J_4J_6 + 2J_2J_3J_4J_6 + 3J_1J_4^2J_6 + 2J_2J_4^2J_6 \\
&+ 14J_1^2J_5J_6 + 8J_1J_2J_5J_6 + 4J_2^2J_5J_6 + 3J_1J_3J_5J_6 + 2J_2J_3J_5J_6 + 3J_1J_4J_5J_6 \\
&+ 2J_2J_4J_5J_6,
\end{aligned} \tag{B.9}$$

where J_a are the generators of the Kähler cone that obey

$$\int_{l^{(a)}} J_b = \delta_b^a. \tag{B.10}$$

Equipped with the topological data listed above, we can compute the BPS invariants, $N_{\mathbf{G}; C_b}(n, r)$, to any given order for curves of the form

$$\mathbf{C} = C_b + n\mathbb{E}_r + C_r^f, \tag{B.11}$$

with respect to the transversal $U(1)$ flux

$$\mathbf{G} \equiv \mathbf{G}_{U(1)} = \sigma \wedge \pi^* F, \quad \text{where } F =: \sum_{\alpha=1}^4 c_\alpha D_\alpha. \tag{B.12}$$

The base curves, C_b , that are of interest in our examples are

$$C_b = \{C^0, C_E^1, C_E^2\}. \tag{B.13}$$

These correspond respectively to the heterotic string featuring Section 5.1, and to the two types of E-strings discussed in Section 6.1.

The computation of the BPS invariants proceeds by mirror symmetry, in practice using A. Klemm's Mathematica package `inst.m` and extensions thereof. For this purpose we need to

expand the various curves appearing on the RHS of (B.11) over the Mori cone generators. This is achieved by making use of the explicit form for the curves (B.8), as well as of the intersection data (B.9). This leads to the identification

$$C^0 = l^{(4)} + l^{(5)}, \quad (\text{B.14})$$

$$C_E^1 = l^{(4)}, \quad (\text{B.15})$$

$$C_E^2 = l^{(5)}, \quad (\text{B.16})$$

$$\mathbb{E}_r = 3l^{(1)} + 2l^{(2)}, \quad (\text{B.17})$$

$$C_{r=1}^f = l^{(1)} + l^{(2)}. \quad (\text{B.18})$$

We have calculated the relative BPS invariants up to certain finite degrees, and list them below in terms of the generating functions

$$\mathcal{F}_{\mathbf{G};C_b} = \sum_{n,r} N_{\mathbf{G};C_b}(n,r) q^n \xi^r. \quad (\text{B.19})$$

Concretely, for each of the three base curves (B.13) under consideration, we get

$$\begin{aligned} \mathcal{F}_{\mathbf{G};C^0} &= q[96c_1\xi^{\pm 1} + 48c_2\xi^{\pm 1} + 84c_3\xi^{\pm 1} + 96c_4\xi^{\pm 1}] \\ &\quad + q^2[c_1(69280\xi^{\pm 1} + 20384\xi^{\pm 2} + 288\xi^{\pm 3} - 8\xi^{\pm 4}) \\ &\quad\quad + c_2(99552\xi^{\pm 1} + 29088\xi^{\pm 2} + 480\xi^{\pm 3} - 12\xi^{\pm 4}) \\ &\quad\quad + c_3(65164\xi^{\pm 1} + 18896\xi^{\pm 2} + 252\xi^{\pm 3} - 8\xi^{\pm 4}) \\ &\quad\quad + c_4(134192\xi^{\pm 1} + 39280\xi^{\pm 2} + 624\xi^{\pm 3} - 16\xi^{\pm 4})] \\ &\quad + \mathcal{O}(q^3), \end{aligned} \quad (\text{B.20})$$

$$\begin{aligned} \mathcal{F}_{\mathbf{G};C_E^1} &= q[c_2(112\xi^{\pm 1} + 4\xi^{\pm 2}) + c_3(56\xi^{\pm 1} + 2\xi^{\pm 2})] \\ &\quad + q^2[c_2(2496\xi^{\pm 1} + 552\xi^{\pm 2}) + c_3(1248\xi^{\pm 1} + 276\xi^{\pm 2})] \\ &\quad + q^3[c_2(26928\xi^{\pm 1} + 9432\xi^{\pm 2} + 336\xi^{\pm 3}) + c_3(13464\xi^{\pm 1} + 4716\xi^{\pm 2} + 168\xi^{\pm 3})] \\ &\quad + \mathcal{O}(q^4), \end{aligned} \quad (\text{B.21})$$

$$\begin{aligned} \mathcal{F}_{\mathbf{G};C_E^2} &= q[c_3(56\xi^{\pm 1} + 2\xi^{\pm 2}) + c_4(112\xi^{\pm 1} + 4\xi^{\pm 2})] \\ &\quad + q^2[c_3(1248\xi^{\pm 1} + 276\xi^{\pm 2}) + c_4(2496\xi^{\pm 1} + 552\xi^{\pm 2})] \\ &\quad + q^3[c_3(13464\xi^{\pm 1} + 4716\xi^{\pm 2} + 168\xi^{\pm 3}) + c_4(26928\xi^{\pm 1} + 9432\xi^{\pm 2} + 336\xi^{\pm 3})] \\ &\quad + \mathcal{O}(q^4). \end{aligned} \quad (\text{B.22})$$

Here, the coefficients c_α parametrise the four-form flux \mathbf{G} as in (B.12).

In the main text of the paper we argue that the derivative part of the elliptic genera is given by a formally six-dimensional structure, which manifests itself in terms of the threefolds

$$\pi_i : \mathbb{Y}_3^i \rightarrow \mathbb{B}_2^i, \quad i = 1, 2, \quad (\text{B.23})$$

whose two-fold bases are given by

$$\mathbb{B}_2^i = p^*(C^i). \quad (\text{B.24})$$

Here we will provide some relevant details of these, for the sample geometry we consider. Concretely, we have $C^1 = C_2$ and $C^2 = C_1$ and the respective bases are thus given by

$$\mathbb{B}_2^1 \simeq dP_2, \quad (\text{B.25})$$

$$\mathbb{B}_2^2 \simeq C^0 \times C_2 \simeq \mathbb{F}_0. \quad (\text{B.26})$$

Since the self-intersections of $p^*(C^i)$ vanish on B_3 , the normal bundles $N_{\mathbb{B}_2^i/B_3}$ are trivial and hence so are $N_{\mathbb{Y}_3^i/Y_4}$. This implies that the induced fibrations \mathbb{Y}_3^i are Calabi-Yau threefolds, once again defined by the polynomials of the form (B.3). For the geometries under consideration, the restrictions preserve the arithmetic structure of the sections and are described by the classes of the height-pairings by

$$\mathfrak{b}^i := b|_{\mathbb{B}_2^i} = 2\bar{K}_{\mathbb{B}_2^i}, \quad (\text{B.27})$$

where, in the second step, we have used $b = 2\bar{K}_{B_3}$ and $N_{\mathbb{B}_2^i/B_3} = \mathcal{O}_{\mathbb{B}_2^i}$.

As both of the induced fibrations, \mathbb{Y}_3^1 and \mathbb{Y}_3^2 , are torically constructed, they admit a description in terms of an abelian GLSM, analogous as for Y_4 in Table B.1. The most general such descriptions for the bases (B.25) and (B.26) can be found, for instance, in [4] (see Table 4.2, as well as Table 4.1 with $a = 0$); for the specific fibrations \mathbb{Y}_3^1 and \mathbb{Y}_3^2 under scrutiny, we set $(x, y_1, y_2) = (6, 2, 2)$ in the former case and $(x, y) = (4, 4)$ in the latter. By determining their Mori cones and intersection rings, we can calculate the BPS invariants, $N_{C_b}^i(n, r)$, for the curve classes of the form (B.11) on \mathbb{Y}_3^i , just like it was done for the fourfold Y_4 . As result we present these invariants via their generating functions of the form,

$$\mathcal{F}_{C_b}^i = \sum_{n,r} N_{C_b}^i(n, r) q^n \xi^r, \quad (\text{B.28})$$

for each of the two geometries and base curves (B.13). For \mathbb{Y}_3^1 we get for the heterotic base curve and for the two E-string curves, respectively:

$$\begin{aligned} \mathcal{F}_{C^0}^1 &= -2 + (252 + 84\xi^{\pm 1})q + (116580 + 65164\xi^{\pm 1} + 9448\xi^{\pm 2} + 84\xi^{\pm 3} - 2\xi^{\pm 4})q^2 \\ &\quad + (6238536 + 3986964\xi^{\pm 1} + 965232\xi^{\pm 2} + 65164\xi^{\pm 3} + 252\xi^{\pm 4})q^3 + \mathcal{O}(q^4), \end{aligned} \quad (\text{B.29})$$

$$\begin{aligned} \mathcal{F}_{C_E^{i=1,2}}^1 &= 1 + (138 + 56\xi^{\pm 1} + \xi^{\pm 2})q + (2358 + 1248\xi^{\pm 1} + 138\xi^{\pm 2})q^2 \\ &\quad + (23004 + 13464\xi^{\pm 1} + 2358\xi^{\pm 2} + 56\xi^{\pm 3})q^3 + \mathcal{O}(q^4). \end{aligned} \quad (\text{B.30})$$

On the other hand, since \mathbb{Y}_3^2 does not contain (-1) -curves in its base $\mathbb{B}_2^2 \simeq \mathbb{F}_0$, all we get is invariants for $C_b = C^0$:

$$\mathcal{F}_{C^0}^2 = -2 + (288 + 96\xi^{\pm 1})q + (123756 + 69280\xi^{\pm 1} + 10192\xi^{\pm 2} + 96\xi^{\pm 3} - 2\xi^{\pm 4})q^2 + \mathcal{O}(q^3).$$

C Non-Abelian 4d E-String for $B_3 = \mathbb{F}_1 \times \mathbb{P}_\nu^1$

Here we present some details on the geometry that underlies the four-dimensional E-string model presented in Section 6.1. The base space of the elliptic fourfold Y_4 is given by $B_3 = \mathbb{F}_1 \times \mathbb{P}_\nu^1$, which is related to the base $dP_2 \times \mathbb{P}_\nu^1$ discussed before in Appendix B by a simple blowdown. Hence

$$H^{1,1}(B_3) = \text{Span} \langle l', f, h \rangle, \quad (\text{C.1})$$

with triple intersections

$$I(B_3) = l'(fh - h^2) \quad (\text{C.2})$$

and anti-canonical class

$$\bar{K}_{B_3} = 2l' + 3f + 2h. \quad (\text{C.3})$$

| | ν_x | ν_y | ν_z | ν_{e_1} | ν_{e_0} | ν_{z_1} | ν_{z_2} | ν_{z_3} | ν_{z_4} | ν_{z_5} |

Table C.1: GLSM charges of the toric coordinates of the $\mathfrak{su}(2)$ -enhanced E-string model on $\mathbb{F}_1 \times \mathbb{P}_V^1$.

We construct an elliptic fibration Y_4 with base B_3 and design an $SU(2)$ gauge symmetry over the divisor $b = h$. The model is obtained as the resolution of an $SU(2)$ Tate model [159]. For a flat fibration Y_4 over B_3 , one finds two phases that are related via a flop transition. Both phases lead to the same elliptic genus and in the following we present our analysis for just one phase of our choice. The GLSM data can be found in Table C.1. The Mori cone is generated by the following curves,

$$\begin{aligned}
l^{(1)} &= (1 & 1 & 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0), \\
l^{(2)} &= (0 & 0 & -2 & 0 & 1 & 0 & 1 & 0 & 0 & 0), \\
l^{(3)} &= (-1 & 0 & 1 & 3 & -3 & 0 & 0 & 0 & 0 & 0), \\
l^{(4)} &= (0 & 0 & -1 & 0 & -1 & 1 & 0 & 1 & 0 & 0), \\
l^{(5)} &= (0 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 1 & 1),
\end{aligned} \tag{C.4}$$

and the intersection polynomial reads

$$\begin{aligned}
I(Y_4) &= 3576J_1^4 + 324J_1^3J_2 + 18J_1^2J_2^2 + 1236J_1^3J_3 + 108J_1^2J_2J_3 + 6J_1J_2^2J_3 \\
&+ 424J_1^2J_3^2 + 36J_1J_2J_3^2 + 2J_2^2J_3^2 + 144J_1J_3^3 + 12J_2J_3^3 + 48J_3^4 + 188J_1^3J_4 \\
&+ 18J_1^2J_2J_4 + 68J_1^2J_3J_4 + 6J_1J_2J_3J_4 + 24J_1J_3^2J_4 + 2J_2J_3^2J_4 + 8J_3^3J_4 \\
&+ 200J_1^3J_5 + 27J_1^2J_2J_5 + 3J_1J_2^2J_5 + 70J_1^2J_3J_5 + 9J_1J_2J_3J_5 + J_2^2J_3J_5 \\
&+ 24J_1J_3^2J_5 + 3J_2J_3^2J_5 + 8J_3^3J_5 + 16J_1^2J_4J_5 + 3J_1J_2J_4J_5 + 6J_1J_3J_4J_5 \\
&+ J_2J_3J_4J_5 + 2J_3^2J_4J_5,
\end{aligned} \tag{C.5}$$

where J_a are the Kahler cone generators. As a basis of $H^{1,1}(B_3)$, we can pick

$$\begin{aligned}
D_1 &= \nu_{z_1} = J_4, \\
D_2 &= \nu_{z_2} = J_2, \\
D_3 &= \nu_{z_4} = J_5.
\end{aligned} \tag{C.6}$$

In terms of these, we take $b = D_2 - D_1$, and furthermore the zero-section of the elliptic fibration and the exceptional divisor for the $U(1) \subset SU(2)$ subgroup are

$$\begin{aligned}
Z &= -2J_2 + J_3 - J_4 - 2J_5, \\
e_1 &= -J_1 + 3J_3.
\end{aligned} \tag{C.7}$$

Matter of $U(1)$ charge $r = 1$ arises from an M2-brane wrapping the fibral curve $C_{r=1}^f = l^{(1)}$. The latter has the following intersection numbers

$$Z \circ C_{r=1}^f = 0, \quad (-e_1) \circ C_{r=1}^f = 1. \tag{C.8}$$

The $U(1) \subset SU(2)$ flux is then of the form

$$\mathbf{G} = \pi^* F \wedge (-e_1), \quad F = c_1 D_1 + c_2 D_2 + c_3 D_3. \quad (\text{C.9})$$

The four-dimensional non-critical E-string in question arises as soliton from a D3-brane that wraps the curve $C_E = l^{(4)}$. By mirror symmetry we find that the first terms in the expansion of its elliptic genus

$$Z_{C_E; \mathbf{G}}(q, \xi) = -q^{-1/2} \sum_{n,r} N_{C_E; \mathbf{G}}(n, r) q^n \xi^r \quad (\text{C.10})$$

are given by

$$\begin{aligned} q^{1/2} Z_{C_E; \mathbf{G}}(q, \xi) = & q [c_1 (16\xi^{-2} - 160\xi^{-1} + 768 - 2400\xi + 5616\xi - 10752\xi^3 + 17920\xi^4 \\ & - 27136\xi^5 + 38400\xi^6 - 51712\xi^7 + 67072\xi^8 + \dots) \\ & + c_3 (6\xi^{-2} - 40\xi^{-1} - 472\xi + 2042\xi^2 - 4608\xi^3 + 8192\xi^4 - 12800\xi^5 \\ & + 18432\xi^6 - 25088\xi^7 + 32768\xi^8 + \dots)] \\ & + q^2 [c_1 (48\xi^{-4} - 640\xi^{-3} + 3936\xi^{-2} - 15360\xi^{-1} + 44032 - 101376\xi \\ & + 198816\xi^2 - 345472\xi^3 + 546768\xi^4 - 804864\xi^5 + 1120256\xi^6 + \dots) \\ & + c_3 (20\xi^{-4} - 240\xi^{-3} + 1188\xi^{-2} - 2640\xi^{-1} - 11696\xi + 56156\xi^2 \\ & - 128784\xi^3 + 229356\xi^4 - 358400\xi^5 + 516096\xi^6 + \dots)] \\ & + q^3 [c_1 (96\xi^{-6} - 1440\xi^{-5} + 10272\xi^{-4} - 47040\xi^{-3} + 158592\xi^{-2} \\ & - 427872\xi^{-1} + 975360 - 1946784\xi + 3487872\xi^2 + \dots) \\ & + c_3 (42\xi^{-6} - 600\xi^{-5} + 3960\xi^{-4} - 15840\xi^{-3} + 40854\xi^{-2} - 57432\xi^{-1} \\ & - 154536\xi + 807018\xi^2 + \dots)] \\ & + q^4 [c_1 (160\xi^{-8} - 2560\xi^{-7} + 19776\xi^{-6} - 99840\xi^{-5} + 376480\xi^{-4} \\ & - 1146240\xi^{-3} + 2958848\xi^{-2} - 6680192\xi^{-1} + 13473792 + \dots) \\ & + c_3 (72\xi^{-8} - 1120\xi^{-7} + 8316\xi^{-6} - 39600\xi^{-5} + 136180\xi^{-4} \\ & - 353808\xi^{-3} + 671876\xi^{-2} - 740096\xi^{-1} + \dots)] \\ & + \mathcal{O}(q^5). \end{aligned} \quad (\text{C.11})$$

We can interpret the elliptic genus as the derivative of a formal six-dimensional elliptic genus, possibly augmented by a genuinely four-dimensional piece. The curve C_E is trivially fibered over the \mathbb{P}_l^1 factor in B_3 , thereby tracing out the divisor $D_E = h = D_2 - D_1$ within B_3 . This suggests that we should consider the E-string within the threefold defined by

$$\mathbb{Y}_3 = Y_4|_{\pi^*(l')}, \quad (\text{C.12})$$

where the divisor $l' = D_3$ cuts out the Hirzebruch surface \mathbb{F}_1 of B_3 .

The relative BPS invariants for C_E on \mathbb{Y}_3 can be computed via mirror symmetry as well and be packaged into the partition function

$$\begin{aligned} Z_{-2,m}(q, \xi) = & -q^{-1/2} \\ & - (3\xi^{-2} - 40\xi^{-1} + 198 + 472\xi - 1021\xi^2 + 1536\xi^3 - 2048\xi^4 + 2560\xi^5 \\ & - 3072\xi^6 + \dots) q^{1/2} \end{aligned}$$

$$\begin{aligned}
& -(5\xi^{-4} - 80\xi^{-3} + 594\xi^{-2} - 2640\xi^{-1} + 5788 + 11696\xi \\
& \quad - 28078\xi^2 + \dots)q^{3/2} \\
& -(7\xi^{-6} - 120\xi^{-5} + 990\xi^{-4} - 5280\xi^{-3} + 20427\xi^{-2} + \dots)q^{5/2} + \\
& -(9\xi^{-8} - 160\xi^{-7} + 1386\xi^{-6} + \dots)q^{7/2} + \mathcal{O}(q^{9/2}). \tag{C.13}
\end{aligned}$$

This can be recognised as the series expansion in $q = e^{2\pi i\tau}$ and $\xi = e^{2\pi iz}$ of the following meromorphic Jacobi form of weight $w = -2$ and $U(1)$ fugacity index $m = -1$:

$$Z_{-2,-1}(\tau, z) = -\frac{1}{\eta(\tau)^{12}} \sum_{i=2}^4 \frac{\theta_i(0, \tau)^{10}}{\theta_i(2z, \tau)^2}. \tag{C.14}$$

As discussed in Section 6.1.2, this has the interpretation as the elliptic genus of an instanton string of the six-dimensional SCFT with $SU(2)$ gauge symmetry.

D Non-Critical String for $B_3 = \mathbb{P}^3$

In this Appendix we provide some of the technical details that underlie the example of Section 6.2. It is devoted to a non-critical string obtained by wrapping a D3-brane on the curve $C_b = H \cdot H$ on the base $B_3 = \mathbb{P}^3$ of an elliptic fibration.

The model without $U(1)$ gauge symmetry has been discussed in much detail in [75–77]. Here we consider an extension of this model in order to support a transversal flux in conjunction with a chiral $U(1)$ gauge symmetry, which allows for a nontrivial elliptic genus. For this we implement the gauge symmetry associated with the height-pairing given by $b = 2\bar{K}_{B_3} = 8H$. The fourfold Y_4 we thus consider is characterized by the Mori vectors

$$\begin{aligned}
l^{(1)} &= (-1, -1, 0, 0, 0, 0, 0, 1, 1), \\
l^{(2)} &= (-2, 2, 1, 0, 0, 0, 0, 0, -1), \\
l^{(3)} &= (0, 0, 0, 1, 1, 1, 1, 0, -4). \tag{D.1}
\end{aligned}$$

The intersection polynomial, in terms of the dual basis of Kähler cone generators, reads

$$\begin{aligned}
I(Y_4) &= 1984J_1^4 + 512J_1^2J_2^2 + 128J_2^4 + 28J_1^2J_3^2 + 8J_2^2J_3^2 + 256J_2^3J_1 + 3J_3^3J_1 \\
&+ 1024J_1^3J_2 + 2J_3^3J_2 + 16J_3^2J_1J_2 + 240J_1^3J_3 + 32J_2^3J_3 + 64J_2^2J_1J_3 + 128J_1^2J_2J_3. \tag{D.2}
\end{aligned}$$

Moreover we define the following curve classes

$$\begin{aligned}
C_b &= l^{(3)} \\
\mathbb{E}_\tau &= 3l^{(1)} + 2l^{(2)} \\
C^f &= l^{(1)} + l^{(2)}, \tag{D.3}
\end{aligned}$$

and determine the BPS invariants, $N_{\mathbf{G};C_b}(n, r)$, for the curves of the form

$$\mathbf{C} = C_b + n\mathbb{E}_\tau + C_r^f, \tag{D.4}$$

with respect to fluxes $\mathbf{G} \in H_{\text{vert}}^{2,2}(Y_4)$. As a basis of fluxes we pick

$$\begin{aligned}
\mathbf{G}_{U(1)} &= \sigma \wedge \pi^*(F) \quad \text{with } F = cH, \\
&= \frac{1}{1441} [-156(4J_1^2 + J_1J_3) + 115(4J_2^2 + 8J_1J_2 - 2J_1J_3 + J_2J_3)],
\end{aligned}$$

$$\begin{aligned}
\mathbf{G}_H &= \pi^*(H) \wedge \pi^*(H) = J_3^2, \\
\mathbf{G}_0 &= -8J_3^2 + \frac{1}{1441} [316(4J_1^2 + J_1J_3) - 196(4J_2^2 + 8J_1J_2 - 2J_1J_3 + J_2J_3)].
\end{aligned} \tag{D.5}$$

Above, H denotes the hyperplane class on \mathbb{P}^3 and c a numerical constant. Moreover, as always, σ denotes the Shioda map associated with the $U(1)$ symmetry. This basis leads to a convenient block-diagonal intersection form on $H_{\text{vert}}^{2,2}(Y_4)$ given by

$$\Omega = \begin{pmatrix} -8c^2 & 0 & 0 \\ 0 & 0 & 4 \\ 0 & 4 & 0 \end{pmatrix}. \tag{D.6}$$

We now perform a standard mirror symmetry computation to obtain the Gromov-Witten invariants and assemble them, for each of the above fluxes, into the following partition function²⁴

$$Z_{\mathbf{G};C_b}(q, \xi) := -\frac{1}{q^2} \sum N_{\mathbf{G};C_b}(n, r) q^n \xi^r. \tag{D.7}$$

The fluxes \mathbf{G}_H and \mathbf{G}_0 are the fluxes considered in [76, 77] and are associated with meromorphic modular forms of weight $w = -2$ and $w = 0$, respectively. These are non-transversal fluxes which do not admit a lift to four-dimensional F-theory. On the other hand, the transversal flux $\mathbf{G}_{U(1)}$ leads to the $U(1)$ -refined elliptic genus we are interested in, with modular weight $w = -1$.

In terms of $\xi^{\pm r} = \xi^r + \xi^{-r}$, $\xi^{\pm \bar{r}} = \xi^r - \xi^{-r}$, the first few terms of the expansions take the form

$$\begin{aligned}
\frac{1}{c} Z_{\mathbf{G}_{U(1)};C_b}(q, \xi) &= -\frac{1152}{q} \xi^{\pm \bar{1}} + 576 \left(380 \xi^{\pm \bar{1}} + 127 \xi^{\pm \bar{2}} \right) \\
&\quad - 384q \left(90633 \xi^{\pm \bar{1}} + 53472 \xi^{\pm \bar{2}} + 7825 \xi^{\pm \bar{3}} \right) + \dots
\end{aligned} \tag{D.8}$$

$$\begin{aligned}
Z_{\mathbf{G}_H;C_b}(q, \xi) &= \frac{20}{q^2} - \frac{1536}{q} (3 + \xi^{\pm 1}) + 192 (4161 + 2264 \xi^{\pm 1} + 343 \xi^{\pm 2}) \\
&\quad - 1024q (99294 + 65817 \xi^{\pm 1} + 18666 \xi^{\pm 2} + 1805 \xi^{\pm 3}) + \dots
\end{aligned} \tag{D.9}$$

$$\begin{aligned}
Z_{\mathbf{G}_0;C_b}(q, \xi) &= -\frac{160}{q^2} + \frac{7680}{q} (3 + \xi^{\pm 1}) - 768 (4179 + 2248 \xi^{\pm 1} + 305 \xi^{\pm 2}) \\
&\quad + 512q (393396 + 257535 \xi^{\pm 1} + 68112 \xi^{\pm 2} + 5405 \xi^{\pm 3}) + \dots
\end{aligned} \tag{D.10}$$

Matching against Ansatz of Jacobi forms yields an overdetermined system of equations, and in this way we find the following closed expression for the weight $w = -2$ flux:

$$\begin{aligned}
Z_{\mathbf{G}_H;C_b}(q, \xi) &= \frac{4}{12^4 \eta^{48}} \left[-\frac{5}{72} (35E_4^4 E_6 + 37E_4 E_6^3) \phi_{0,1}^4 \right. \\
&\quad - \frac{1}{432} (835E_4^6 E_6 + 1252E_4^3 E_6^3 + 73E_6^5) \phi_{-2,1}^4 \\
&\quad + \frac{1}{864} (2173E_4^7 + 12406E_4^4 E_6^2 + 2701E_4 E_6^4) \phi_{-2,1}^3 \phi_{0,1} \\
&\quad - \frac{1}{12} (191E_4^5 E_6 + 169E_4^2 E_6^3) \phi_{-2,1}^2 \phi_{0,1}^2 \\
&\quad \left. + \frac{1}{864} (2281E_4^6 + 13342E_4^3 E_6^2 + 1657E_6^4) \phi_{-2,1} \phi_{0,1}^3 \right].
\end{aligned} \tag{D.11}$$

²⁴We have factored out $1/q^2$ in order to account for the vacuum energy of the string.

Moreover we find for the elliptic genus:

$$Z_{\mathbf{G}_{U(1)};C_b}(q, \xi) = (F \cdot C_b)Z_{-1,4}(q, \xi) + \frac{1}{8}(F \cdot b \cdot H)\xi\partial_\xi Z_{-2,4}(q, \xi), \quad (\text{D.12})$$

where

$$Z_{-2,4}(q, \xi) = Z_{\mathbf{G}_H;C_b}(q, \xi) \quad (\text{D.13})$$

and

$$\begin{aligned} Z_{-1,4}(q, \xi) = & \frac{1}{12^4\eta^{48}} \phi_{-1,2} \left[64E_4^2 E_6 (E_4^3 - E_6^2) \phi_{-2,1} \phi_{0,1} + \right. \\ & \frac{1}{6} (134E_4^4 E_6^2 + 29E_4 E_6^4 - 163E_4^7) \phi_{-2,1}^2 \\ & \left. - \frac{1}{6} (13E_4^6 + 166E_4^3 E_6^2 - 179E_6^4) \phi_{0,1}^2 \right] \end{aligned} \quad (\text{D.14})$$

are weak Jacobi forms. In (D.12) we used the fact that $F \cdot C_b = c$ and $F \cdot b \cdot H = 8c$. Notably, (D.13) states that the very same function $Z_{-2,4}(q, \xi)$ figures both as generating function $Z_{\mathbf{G}_H;C_b}(q, \xi)$ for the (-2) -flux, and in the derivative part of the elliptic genus (D.12) associated with the transversal flux $\mathbf{G}_{U(1)}$. This confirms again our expectations.
