

Search for Leptonic Decays of Dark Photons at NA62

The NA62 collaboration¹

¹Full author list given at the end of the Letter.

(Dated: September 19, 2024)

The NA62 experiment at CERN, configured in beam-dump mode, has searched for dark photon decays in flight to electron-positron pairs using a sample of 1.4×10^{17} protons on dump collected in 2021. No evidence for a dark photon signal is observed. The combined result for dark photon searches in lepton-antilepton final states is presented and a region of the parameter space is excluded at 90% CL, improving on previous experimental limits for dark photon mass values between 50 and 600 MeV/ c^2 and coupling values in the range 10^{-6} to 4×10^{-5} . An interpretation of the e^+e^- search result in terms of the emission and decay of an axion-like particle is also presented.

I. INTRODUCTION

The prevalence of dark matter over ordinary matter, one of the unsolved puzzles of the universe, has inspired various extensions of the Standard Model (SM). Some of these predict the existence of an additional $U(1)$ gauge-symmetry sector with a vector mediator field A' known as a “dark photon”.

Minimalistic dark photon models [1, 2] introduce the A' field with mass $M_{A'}$, which interacts with the gauge field B associated with the SM $U(1)$ symmetry through kinetic mixing, with its strength characterised by the coupling constant ε . The dark photon may also interact with additional fields in the dark sector. Under the assumption that $M_{A'}$ is lower than twice the mass of the lightest state in the dark sector, the dark photon decays to SM particles only. Cosmological constraints on the thermal relic density of dark matter favour a dark photon mass range from 1 to 1000 MeV/ c^2 , together with ε within the range 10^{-6} to 10^{-3} [3–5]. In this range of parameters, the decay length of dark photons with momenta exceeding 10 GeV/ c vary from tens of centimetres to hundreds of metres. For masses below 700 MeV/ c^2 , the primary contribution to the dark photon decay width arises from di-lepton final states [6]. Dark photon searches in beam-dump experiments exhibit superior sensitivity within the above parameter space region compared to searches at colliders or in meson decays. An extensive survey of the experimental methods is presented in [7].

Proton interactions in the dump can produce dark pho-

tons by two mechanisms, bremsstrahlung and decays of secondary neutral mesons. The former case is interpreted as a scattering process in the Fermi-Weizsäcker-Williams approximation [8] where a virtual photon is exchanged between the primary proton and a nucleus, resulting in a dark photon and a scattered proton in the final state. In the latter process, a dark photon is emitted alongside a photon or a neutral meson [9]. Decays of $\pi^0, \eta, \eta', \rho, \omega, \phi$ mesons are relevant for this analysis.

The search for a dark photon decaying into e^+e^- is described here. The result of this search in combination with a previous result [10] for the $A' \rightarrow \mu^+\mu^-$ decay is presented.

Axion-like particles (ALPs) are hypothetical pseudoscalar particles arising in many extensions of the SM. A scenario of emission of an ALP coupled to the SM fermionic fields is also considered. In proton-nucleus collisions, an ALP a can be produced in the decays of charged and neutral B mesons as $pN \rightarrow BX$, followed by $B \rightarrow K^{(*)}a$ [11], where K^* is the $K^*(892)$ resonance. In this work, a general scenario where the coupling of ALPs to SM fermions is not uniform (meaning the coupling to leptons could be different from the coupling to quarks) is addressed.

II. BEAMLINER AND DETECTOR

Figure 1 illustrates the NA62 beamline and detector layout. A comprehensive description of these compo-

nents can be found in [12]. In standard operation, kaons are produced by 400 GeV/c protons extracted from the CERN SPS impinging on a beryllium target. In dump-mode operation, the beryllium target is removed, and the protons interact in a 3.2 m long absorber (TAX) equivalent to 19.6 nuclear interaction lengths. The origin of the coordinate system is in the centre of the target. The Z axis points in the proton beam direction, the Y axis points upwards, and the X,Y,Z axes form a right-handed system. The mean position of the primary protons at the TAX entrance is (0, -22 mm, 23 m).

The momenta and directions of charged particles within the fiducial volume (FV) are measured by a magnetic spectrometer (STRAW). A quasi-homogeneous liquid krypton electromagnetic calorimeter (LKr) and a muon detector (MUV3) are used for particle identification. Twelve ring-shaped lead-glass detectors (LAV1–12) record activity originating from secondary interactions. Two scintillator hodoscopes, NA48-CHOD and CHOD, provide trigger signals and time measurements for charged particles with 200 ps and 800 ps resolution, respectively. The ANTI0 scintillator hodoscope [13] is used to detect charged particles produced upstream of the FV. Further details of the beam-dump mode operation are given in [10].

III. ANALYSIS STRATEGY AND EVENT SELECTION

The search is based on the data sample collected in a 10-day period in 2021, corresponding to 1.4×10^{17} protons on TAX (POT). Three trigger lines were implemented: Q1 required at least one signal in the CHOD, downscaled by a factor of 20; H2 required in-time signals in two CHOD tiles; and a control trigger required an LKr energy deposit above 1 GeV.

Two-track final states triggered by the H2 condition are considered. Each track reconstructed by the STRAW must satisfy the following criteria: momentum $p > 10$ GeV/c; extrapolated positions at the front planes of NA48-CHOD, CHOD, LKr, MUV3 within the geometrical acceptance of each detector; extrapolated positions at the first STRAW chamber and LKr front planes isolated from those of other tracks. Each track must be associated with a CHOD signal compatible in space and time. The track time is defined using the time of the associated NA48-CHOD signal if present, otherwise using the time of the associated CHOD signal. Track times must be within 5 ns of the trigger time. Tracks spatially compatible and in-time with an ANTI0 signal or in-time with a LAV signal are rejected.

Any MUV3 signal within a momentum-dependent search radius around the extrapolated track position and within 5 ns of the track time is associated with the STRAW track. An LKr energy deposit $E > 1$ GeV is associated with the track if it is in-time and spatially compatible, accounting for possible bremsstrahlung-induced

energy deposits. Tracks with an associated MUV3 signal and $E/p < 0.2$ are identified as muons. Tracks without associated MUV3 signals, with $(E/p)_{\min} < E/p < 1.05$ are identified as electrons, where $(E/p)_{\min} = 0.95$ for $p < 150$ GeV/c and decreases with momentum otherwise.

Two time-coincident tracks consistent with originating from a common point form a vertex. The presence of exactly one two-track vertex is required, regardless of the total number of tracks in the event. The vertex time is evaluated as the mean time of the two tracks. The vertex position is obtained by the backwards extrapolation of the tracks, accounting for the residual magnetic field in the FV. The data distribution of the vertex longitudinal coordinate (Z_{vtx}) and radial position in the transverse plane (ρ_{vtx}) is shown in Figure 2, without the particle identification (PID) criteria applied. This distribution is dominated by secondary interactions in LAV1–5 and in the front vacuum-tank window. Most reconstructed vertices originate from secondary interactions in LAV5 ($Z \simeq 152$ m). LAV6–12 have larger inner radii (Figure 1) and do not block the resulting particles. It is required that the vertex is reconstructed in the restricted FV, defined as shown in Figure 2, to reject these interactions.

The position of the A' production point is evaluated as the point of closest approach between the A' line of flight, defined by the two-track vertex position and total momentum direction, and the beam line, parallel to the Z axis and defined by the average impact point of the primary protons in the TAX. The signal region (SR) is defined as an ellipse in the plane of the Z coordinate (Z_{TAX}) and the distance between the two lines (CDA_{TAX}):

$$\text{SR} : \left(\frac{Z_{\text{TAX}}[\text{m}] - 23}{12} \right)^2 + \left(\frac{\text{CDA}_{\text{TAX}}[\text{m}]}{0.03} \right)^2 < 1. \quad (1)$$

This condition reduces the signal acceptance by 1.7% as shown by simulation. The control region (CR) used to validate the background estimate is the area outside SR that satisfies:

$$\text{CR} : -4 < Z_{\text{TAX}} < 50 \text{ m and } \text{CDA}_{\text{TAX}} < 0.15 \text{ m.} \quad (2)$$

Both SR and CR are kept masked until validation of the background estimate. The data distribution of e^+e^- vertices in the plane ($Z_{\text{TAX}}, \text{CDA}_{\text{TAX}}$), after applying the full selection except for the LAV and ANTI0 veto conditions, is shown in Figure 3. The full selection removes all events outside SR and CR.

IV. BACKGROUNDS

Mesons produced by proton interactions in the TAX generate a flux of “halo” muons. The dominant background involves vertices in which both particles are created by the same halo muon interacting with the material along the beamline (prompt background). A control data sample is constructed from muons satisfying the Q1 trig-

FIG. 1. Schematic side view of the NA62 setup in 2021. Information from KTAG, GTK, CHANTI, MUV1,2, IRC, and SAC is not used in this analysis. Not all beam elements are shown.

FIG. 2. Distribution of two-track vertex positions in the plane (Z_{vtx} , ρ_{vtx}) for data events, without particle identification requirements. The black contour defines the restricted FV.

FIG. 3. Data distribution in the plane (Z_{TAX} , CDA_{TAX}) for e^+e^- vertices without applying the LAV and ANTI0 veto conditions. CR and SR are masked.

ger and not the H2 trigger. These muons are extrapolated backwards using PUMAS [14] to the upstream plane of the B5 magnet (Figure 1) and are used as input to a GEANT4-based Monte Carlo (MC) simulation [15]. The resulting events constitute the prompt background sample, which is subjected to the signal selection. The size of this control sample is equivalent to that of the data sample. The expected number of e^+e^- vertices reconstructed in the restricted FV derived from this sample has a relative systematic uncertainty of 50% arising from the limited accuracy of the backward extrapolation and forward propagation.

Another possible source of background is the random pairing of e^+ and e^- tracks originating from different primary proton interactions. The combinatorial background component is evaluated using a data-driven approach, with events triggered by the Q1 condition. This approach considers all possible sources of single electrons, including decays and interactions of secondary mesons occurring in the FV, or close to its boundary. Single tracks are paired within a 10 ns time window, building pseudo-events. For

each event, the vertex is reconstructed as in the signal selection, and the event is assigned a weight that accounts for the time window and the downscaling factor of the Q1 trigger. This background is found to be an order of magnitude smaller than the prompt background, and is therefore neglected.

Backgrounds from neutrino interactions and K_L decays are negligible with respect to the prompt background. Tracks with PID other than e^+ or e^- have been reconstructed in the data sample. These extrapolate backwards either to one of the LAV stations (excluded from the FV definition) or to the upstream region and are vetoed by the ANTI0. Finally, the number of $\mu\pi$, μe and $\pi\pi$ vertices reconstructed in the data sample agrees with the expectation derived from the prompt background MC sample.

The expected numbers of background events in CR and SR are calculated using a combination of frequentist and Bayesian techniques. The rejection factors of the LAV and ANTI0 veto conditions and the CR and SR selection requirements are defined as the proportion of e^+e^-

vertices discarded by the corresponding conditions. The posterior probability distribution function (pdf) of each rejection factor is computed from the prompt background sample, assuming a uniform prior and a beta function likelihood. Pseudo-experiments are generated, sampling independently the number of events in the FV and the rejection factors. The expected numbers of background events are

$$N_{\text{bkg}}^{\text{CR}} = 9.7_{-7.3}^{+21.3} \times 10^{-3}, \quad N_{\text{bkg}}^{\text{SR}} = 9.4_{-7.2}^{+20.6} \times 10^{-3} \quad (3)$$

where the uncertainties are quoted at 68% confidence level (CL).

$$L_{s+b} = \rho(\theta|\tilde{\theta}) \frac{e^{-(s(\theta)+b(\theta))}}{N} \prod_i (s(\theta)f_s(x_i; M_{A'}, \varepsilon) + b(\theta)f_b(x_i; M_{A'}, \varepsilon)) \quad (5)$$

is the likelihood of the observed data under the signal-plus-background hypothesis. The product runs over the observed events. The terms $s(\theta)$ and $b(\theta)$ are the numbers of signal and background events in the SR, respectively. The functions f_s and f_b are the signal and background pdfs of the reconstructed mass of the two leptons, x_i . The symbol θ collectively denotes the nuisance parameters: the number of protons on TAX and the expected number of signal and background events in SR. The functions $\rho(\theta|\tilde{\theta})$, where $\tilde{\theta}$ contains the default values of the nuisance parameters, are the systematic error pdfs. These are interpreted as posteriors derived from simulations. The specific functional forms of all pdfs are given Appendix B.

The likelihood of the data under the background-only hypothesis, L_b , has a similar form, with the signal-related components removed. The exclusion contour is obtained by fitting q to the observation, for each value of $M_{A'}$ and ε , maximising separately the numerator and denominator with respect to the nuisance parameters. Pseudo-experiments are generated under both signal-only and signal-plus-background hypotheses, using the respective fitted values θ . The same test statistic is computed for each pseudo-experiment. The distributions of q under these hypotheses are used in the CL_s method to decide whether a specific $(M_{A'}, \varepsilon)$ point is excluded or not at a

V. STATISTICAL ANALYSIS AND RESULTS

The signal simulation, the uncertainty and efficiency of the signal selection and the expected A' yield are discussed extensively in Appendix A. The dominating source of uncertainty in the A' yield is given by the number of primary protons impinging on the TAX and is estimated to be 20%. Additionally, factors such as the size of the signal MC sample and various reconstruction parameters induce a 2.9% uncertainty in the signal selection efficiency. After unmasking the CR, no events are observed, in agreement with the 98.3% probability of observing no counts in the null hypothesis. After unmasking the SR, no events are observed, in agreement with the 98.4% probability of observing no counts in the null hypothesis. The exclusion limits obtained are derived using the CL_s method [16] on a grid of A' mass and coupling values. The test statistic is the profile likelihood ratio [17]:

$$q = -2 \ln \frac{L_{s+b}}{L_b}, \quad (4)$$

where

desired confidence level. The observed and expected exclusion contours at 90% CL, and the expected $\pm 1\sigma$ and $\pm 2\sigma$ bands, in the $(M_{A'}, \varepsilon)$ plane are shown in Figure 4. Previous results [8, 18–30], adapted from the DarkCast package [31], and supernova exclusions [32] are shown as grey areas.

The combination of this $A' \rightarrow e^+e^-$ result with the NA62 $A' \rightarrow \mu^+\mu^-$ result [10] is performed with the same test statistic but with total likelihoods expressed as products of contributions from the individual A' decay channels. The number of protons on TAX is common to both channels, therefore its pdf enters only once in the likelihood function. The exclusion regions obtained at 90% CL are shown in Figure 4.

The interpretation of this e^+e^- result in terms of the emission of ALPs in $b \rightarrow s$ transitions is shown in Figure 5 for a set of ALP mass values. A model-independent approach is used, where the ALP lifetime τ_a , the mass M_a and the product $BR(B \rightarrow K^{(*)}a) \times BR(a \rightarrow e^+e^-)$ are the free parameters [11]. Here, $BR(B \rightarrow K^{(*)}a)$ stands for the sum of these branching ratios of B meson decays (B^+ , B^0 and their antiparticles) weighted by the corresponding production yields in proton-nucleus interaction obtained from the PYTHIA8.2 [34] simulation used in [11]. The same notation was adopted in [10]. The result is found to improve on previous limits in a mass

FIG. 4. Observed and expected exclusion contours, at 90% CL, in the plane $(M_{A'}, \epsilon)$ for the $A' \rightarrow e^+e^-$ analysis (left) and the combined $A' \rightarrow e^+e^-$ and $A' \rightarrow \mu^+\mu^-$ analyses (right) together with the expected $\pm 1\sigma$ (green) and $\pm 2\sigma$ (yellow) bands. Previous results, including the recent FASER result [25] are shown in grey. The NA62 $A' \rightarrow \mu^+\mu^-$ result [10] is shown with a dot-dashed line in the right panel.

FIG. 5. Exclusion region in the plane of the ALP lifetime (τ_a) and the product of branching ratios $BR(B \rightarrow K^{(*)}a) \times BR(a \rightarrow e^+e^-)$ in the search for an axion-like particle a produced in B meson decays (solid curve). Four values of the ALP mass are considered. The region of the parameter space above the black line is excluded at 90% CL. The excluded regions by CHARM [33] measurements are shown as grey-filled areas.

range from 10 to 800 MeV/c^2 .

VI. CONCLUSION

A search for the decay of a dark photon to the e^+e^- final state utilising data taken in beam-dump mode at the NA62 experiment in 2021 is presented. No event is found in the signal region. A statistical combination with a previous search for the $\mu^+\mu^-$ final state by NA62 is performed, extending the previous exclusion limits on dark photons in the mass range from 50 to 600 MeV/c^2 and coupling constant range 10^{-6} to 4×10^{-5} . The excluded region is compatible with thermal relic density constraints. The interpretation of the e^+e^- result in terms of the emission of ALPs coupled to the SM fermionic field is also performed, extending the excluded

regions in a mass range from 10 to 800 MeV/c^2 .

ACKNOWLEDGEMENTS

It is a pleasure to express our appreciation to the staff of the CERN laboratory and the technical staff of the participating laboratories and universities for their efforts in the operation of the experiment and data processing.

The cost of the experiment and its auxiliary systems was supported by the funding agencies of the Collaboration Institutes. We are particularly indebted to: F.R.S.-FNRS (Fonds de la Recherche Scientifique - FNRS), under Grants No. 4.4512.10, 1.B.258.20, Belgium; CECI (Consortium des Equipements de Calcul Intensif), funded by the Fonds de la Recherche Scientifique de Belgique (F.R.S.-FNRS) under Grant No. 2.5020.11

and by the Walloon Region, Belgium; NSERC (Natural Sciences and Engineering Research Council), funding SAPPJ-2018-0017, Canada; MEYS (Ministry of Education, Youth and Sports) funding LM 2018104, Czech Republic; BMBF (Bundesministerium für Bildung und Forschung) contracts 05H12UM5, 05H15UMCNA and 05H18UMCNA, Germany; INFN (Istituto Nazionale di Fisica Nucleare), Italy; MIUR (Ministero dell’Istruzione, dell’Università e della Ricerca), Italy; CONACyT (Consejo Nacional de Ciencia y Tecnología), Mexico; IFA (Institute of Atomic Physics) Romanian CERN-RO Nr. 10/10.03.2020 and Nucleus Programme PN 19 06 01 04, Romania; MESRS (Ministry of Education, Science, Research and Sport), Slovakia; CERN (European Organization for Nuclear Research), Switzerland; STFC (Science and Technology Facilities Council), United Kingdom; NSF (National Science Foundation) Award Numbers 1506088 and 1806430, U.S.A.; ERC (European Research Council) “UniversaLepto” advanced grant 268062, “KaonLepton” starting grant 336581, Europe.

Appendix A: Signal yield and selection efficiency

The expected A' yield for given values of the mass and coupling constant is expressed as

$$N_{\text{exp}} = N_{\text{POT}} \times P(pN \rightarrow A') \times P_{\text{D}} \times \text{BR}(A' \rightarrow l^+l^-) \times A_{\text{sel}}, \quad (\text{A1})$$

where N_{POT} is the number of primary protons impinging on the TAX, $P(pN \rightarrow A')$ is the A' production probability per proton, P_{D} is the probability for the dark photon to decay within the fiducial volume, $\text{BR}(A' \rightarrow l^+l^-)$ is the branching ratio of the A' decay to a lepton pair and A_{sel} is the combined selection and trigger efficiency.

For every spill, the quantity N_{POT} is determined by measuring the proton beam flux. This measurement is performed using a titanium-foil secondary-emission monitor positioned at the target location. The uncertainty on N_{POT} is deduced from the operational experience of these monitors and is estimated to be 20%. This estimation is confirmed by NA62 kaon decay dataset: the count of selected $K^+ \rightarrow \pi^+\pi^+\pi^-$ decays matches the expected number based on the measured proton flux within 20%.

The uncertainty on the A' yield in the case of pro-

FIG. 6. Selection and trigger efficiency (colour scale) for the $A' \rightarrow e^+e^-$ in the plane $(M_{A'}, \epsilon)$. The bremsstrahlung (meson-mediated) production mode is shown in the top (bottom) panel.

duction by bremsstrahlung is given mainly by the uncertainty on the pp scattering cross-section, which is 1%, as estimated from the available data [35]. The branching ratio of neutral meson decays with A' in the final state is evaluated as in [9]. The yield of various neutral mesons in pp interactions at $\sqrt{s} = 28$ GeV contributing to the A' yield is evaluated with PYTHIA8.2 [34]. The meson production cross-sections have been validated against data and their uncertainties are estimated to be at the 20% level [36]. The A' probability to decay within the fiducial volume is computed for each considered point in the parameter space. The $A' \rightarrow e^+e^-$ decay branching ratio is evaluated according to [6].

Monte Carlo simulations of A' production and decay are used to evaluate the combined selection and trigger efficiency at selected values in the $(M_{A'}, \epsilon)$ plane. The A' mass is varied from 5 MeV/ c^2 to 700 MeV/ c^2 , and the A' is forced to decay within the fiducial volume using a uniform decay distribution. Each event is weighted by the decay probability P_{D} , which depends on the coupling constant ϵ . The efficiencies are shown in Figure 6.

The expected $A' \rightarrow e^+e^-$ yield is shown in Figure 7. For comparison, Figure 11 of [10] displays the same quantities for the $A' \rightarrow \mu^+\mu^-$ channel. The bremsstrahlung production mode is dominant, therefore the total uncer-

FIG. 7. Expected number of events in SR (colour scale) for the $A' \rightarrow e^+e^-$ decay in the plane $(M_{A'}, \epsilon)$. The bremsstrahlung (meson-mediated) production mode is shown in the top (bottom) panel. The black contour corresponds to 2.3 events.

tainty on the yield is dominated by the uncertainty on the number of primary protons impinging on the TAX.

The A' mass resolution, $\sigma_{M_{A'}}$, depends on both $M_{A'}$ and ϵ , and differs by production and decay channel. Figure 8 displays this quantity for the $A' \rightarrow e^+e^-$ signal and Figure 12 of [10] for $A' \rightarrow \mu^+\mu^-$.

Table I summarises the uncertainties affecting the signal selection efficiency. The contribution of each source is assessed via a combination of control samples and simulation. The simulation contribution represents a typical value, as it varies with $M_{A'}$ and ϵ .

Appendix B: Probability distribution functions used in the likelihoods

All pdfs used in the likelihoods are defined using the ROOFIT package [37]. In each point of the $(M_{A'}, \epsilon)$ grid used in the determination of the exclusion region, the signal pdfs of the reconstructed di-lepton invariant mass are normal distributions, centred in $M_{A'}$ and with standard deviation equal to $\sigma_{M_{A'}}$ (Figure 8 for the $A' \rightarrow e^+e^-$ channel and Figure 12 of [10] for $A' \rightarrow \mu^+\mu^-$). The background pdf for the di-muon channel is defined as a linear combination of elements in the Bernstein poly-

FIG. 8. Mass resolution (colour scale) in the plane $(M_{A'}, \epsilon)$. The top (bottom) panel refers to bremsstrahlung (meson-mediated) production.

| Source | Uncertainty |
|-------------------------------------|-------------|
| Simulation | 2.1% |
| CHOD association | 0.6% |
| PID | 1.1% |
| Spectrometer quality and resolution | 1.5% |
| Trigger | 0.5% |
| LAV random veto | 0.1% |
| ANTIO random veto | 0.1% |
| Total | 2.9% |

TABLE I. Summary of uncertainties to the signal selection efficiency

mial basis of degree five, with coefficients

$$c = (1.886 \times 10^{-2}, 1.945 \times 10^{-1}, 9.183 \times 10^{-1}, 2.769 \times 10^{-1}, 1.196 \times 10^{-1}, 6.845 \times 10^{-2}), \quad (\text{B1})$$

and by a Landau function with location and shape parameters 14.86 MeV/ c^2 and 3.48 MeV/ c^2 , respectively, for the e^+e^- channel.

The pdf of the number of protons on TAX is a log-normal distribution with median 1.4×10^{17} and shape

parameter 1.2. The background yields are modelled by log-normal distributions as well. The median and shape parameters for the $\mu^+\mu^-$ channel are 0.016 and 1.125,

respectively. For the e^+e^- channel, the parameters are 0.0094 and 4.0.
