# MODEL AGNOSTIC SEARCHES IN FINAL STATES WITH JETS AT ATLAS

ANTONIO D'AVANZO, on behalf of the ATLAS Collaboration

29° Symposium on Particles, String and Cosmology (PASCOS 2024), 09/07/2024, Quy Nhon

# Introduction

- Standard Model (SM) remarkably predictive of experimental results
  - discovery of the Higgs boson in 2012 by ATLAS and CMS
- Open questions: many Beyond Standard Model theories (Dark Matter, Gravity, Hierarchy problem ecc.)
- Search for new resonances decaying into hadronic final states  $jj$  (**jets**) → localized excesses (**bumps**) over expected background  $m_{jj}$

## measurements

# To be or not to be model-dependent?

## Model dependent approach:

- A new well motivated physics-scenario is chosen
- The search is maximized based on signal signatures (supervised machine learning methods)
- Unlikely to be sensitive to different process

## Model independent approach:

- Minimal assumptions of signal properties
- Deviations from background-only hypothesis (methods often provided by Machine Learning)
- Not optimal as model-dependent, but more prone to generality

## In this review

- Full Run 2 (2015-2018,  $140 \text{ fb}^{-1}$ ) of LHC data (beside n. 4), pp centre of mass energy 13 TeV
  - Results interpreted with 95% Confidence Levels
- 1. Search for new phenomena in dijet events using **quark tagging**
- 2. **Weakly-supervised anomaly detection** for resonant new physics in the dijet final state
- 3. **Anomaly detection** search for new resonances decaying into a Higgs boson and a generic new particle X in hadronic final states
- 4. Search for Low-Mass Dijet Resonances Using **Trigger Level Analysis**

# Non supervised Anomaly Detection

- Anomaly Detection (AD) refers to Machine Learning (ML) techniques used to spot these outliers.
- Particle physics → Identification of features of detector data **inconsistent** with the expected background.
- Machine learning techniques exploited: semi-supervised (partial labels), weakly-supervised (noisy labels) and unsupervised (no labels)

Search for new phenomena in dijet events using  
quark tagging

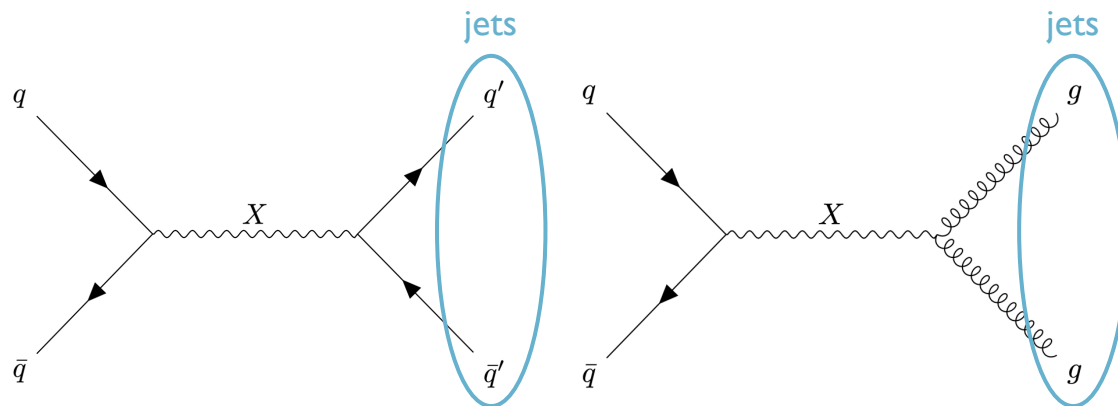

➤ Search for resonant decays of heavy BSM particles strongly coupled to quarks/gluons

➤  $m_{jj}$  spectrum ranges from 1.1 to 8 TeV

➤ **3 signal regions:** Inclusive jets content and 1 or 2 b-jets required

➤ Trigger efficiency cuts on jets kinematics, invariant mass and  $y^* = \frac{y_1 - y_2}{2}$

➤ Results interpreted with many new physics scenarios, but also generic Gaussian-shaped narrow-resonance  $G(m_X, \sigma_X)$

b-tagging: selection on discriminant variable from NN output

- Main QCD background estimated with smoothly falling fit functions on the  $m_{jj}$  distribution
- No significant deviation from background
  - Upper limits on cross sections estimated from fit considering the several signal hypothesis

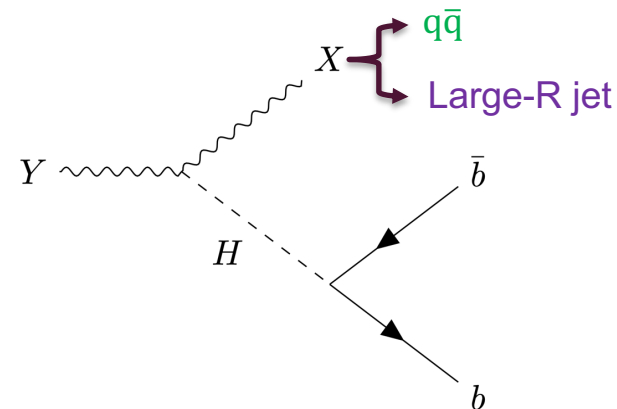

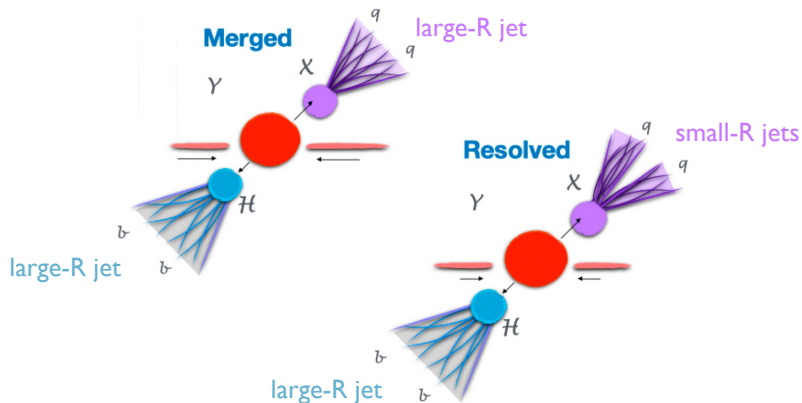

Anomaly detection search for new resonances  
decaying into a Higgs boson and a generic new  
particle X in hadronic final states

# Y → XH overview

- Search for a heavy-mass resonance **Y** decaying in a Higgs boson ( $H \rightarrow b\bar{b}$ ) and a new particle **X** in the fully hadronic channel
- Mass range:  $m_Y$  in 1 - 6 TeV range,  $m_X$  in 65 - 3000 GeV range → boosted regime for H boson
- Signal regions:
  - Model dependent: 2-prong ( $X \rightarrow q\bar{q}$ ) boosted ( $m_X/m_Y < 0.3$ ) and resolved ( $m_X/m_Y > 0.3$ )
  - Model independent: anomalous X hadronic decay in large-R jet

- Background is mainly composed of **QCD dijet events** (~97%), estimated fully data-driven (Machine Learning approach) → more in backup

- X and H candidate associated to pT-leading and –subleading jets, ambiguity resolved by  $H \rightarrow b\bar{b}$  tagger based on Deep Neural Network
  - Discriminant  $D_{Hbb}$  score computed from NN outputs per jet  $\rightarrow$  H candidate chosen by highest score criteria
- H candidate is further tagged if  $D_{Hbb} > 2.44$
- X candidate tagged with discriminant from fully data-driven anomaly detection

- Fully unsupervised (first in ATLAS) variational recurrent neural network (VRNN)
  - Trained over **constituents of jets** with  $p_T > 1.2$  TeV modeled as sequence of four-vectors
- Anomaly score computed from VRNN output
  - Sensitive to alternative X decay hypothesis other than 2-prong (e.g. heavy flavor, three-prong and dark jet)

- Fit performed on final state invariant mass distribution  $m_{jj}$  in SR of data, repeated several times in overlapping bins of the X candidate mass
- Calculated stat-only p-value to test compatibility with background only hypothesis
- Max deviation:  $1.43\sigma$  global significance due to the several search regions defined

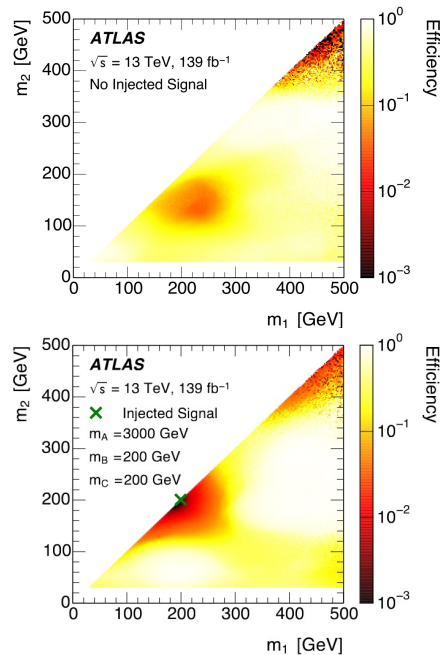

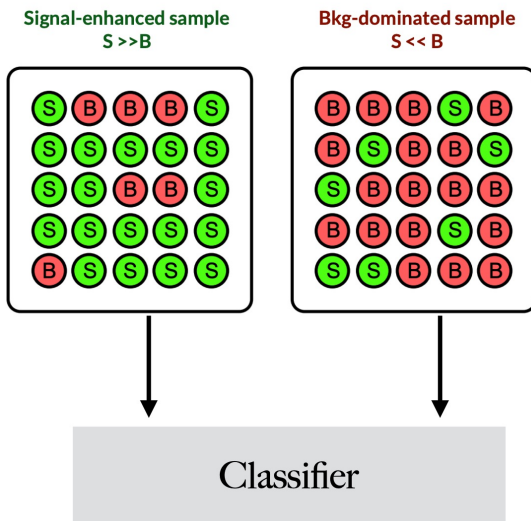

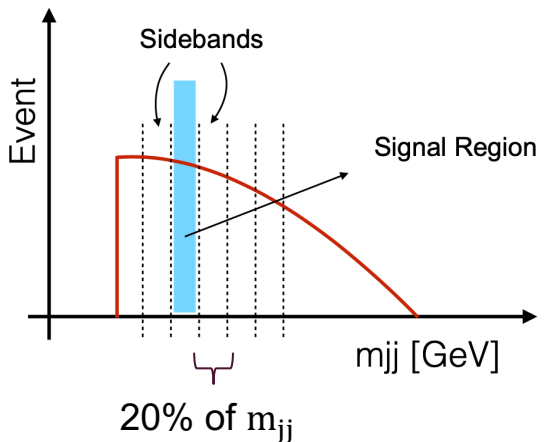

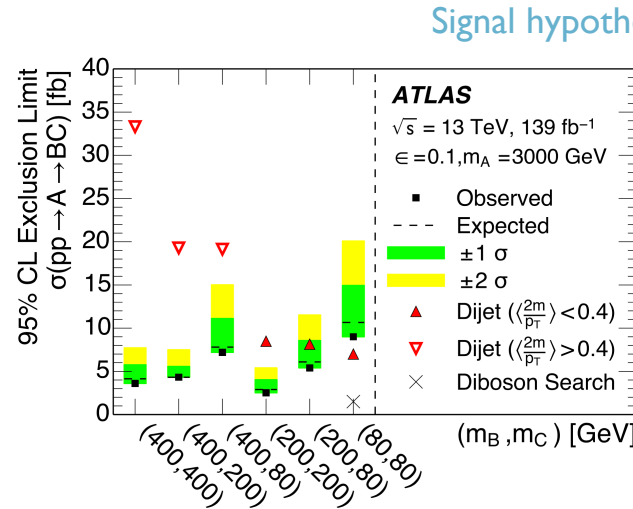

Weakly-supervised anomaly detection for  
resonant new physics in the dijet final state

# CWoLa hunting

- Classification Without Labels (CWoLa) method used for  $A \rightarrow BC$  search
  - mass range: 1.1 -  $\sim 8$  TeV
- 6 signal regions by  $m_{jj}$  splitting, jets mass  $> 30$  and  $< 500$  GeV,  $|\Delta y| < 1.2$
- Classifier trained on two samples **D1** and **D2**, mixtures of signal and background, to produce discriminant output
  - Input variables:  $m_1, m_2$  (pT leading jets)

- Upper limits on signal cross section, benchmark models compared with other diboson searches
  - Different values of signal selection efficiency, 0.1 and 0.01
  - QCD background estimation in SR done with functional fits
- CWoLa performs better when local signal-to-background ratio is high

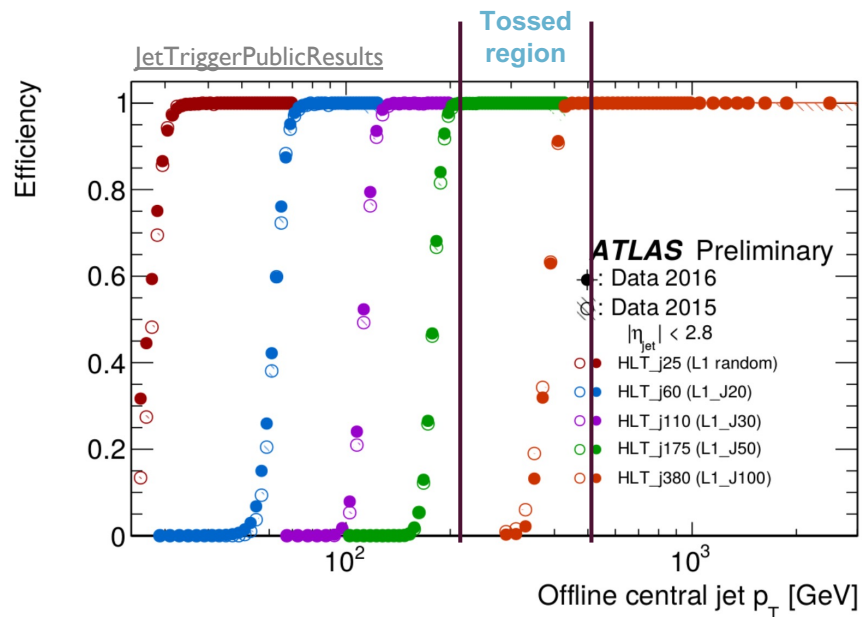

# Search for Low-Mass Dijet Resonances Using Trigger Level Analysis

# Trigger Level Analysis (TLA)

- Low  $p_T$  jets physics (200 – 440 GeV) is tossed in ATLAS due to **trigger** limitations
- ATLAS normally stores the entire detector output for triggered events, limiting the rate at which events can be saved
- Trigger Level Analysis chains record only the output of HLT reconstruction ( $\sim 3\text{ kB/event}$ ) at extremely high rate ( $\sim 3\text{ kHz}$ )
  - Jets included ( $\sim 15\%$  of total trigger decisions)

- Electroweak-TeV scale should be studied thoroughly, as W, Z, Higgs boson and top are all found there
  - Current single jet HLT trigger ( $p_T > 440$  GeV) constraints  $m_{jj} \gtrsim 1.5$  TeV
- TLA can be used to recover sensitivity at the TeV scale! → HLT reconstructed jets and event header
  - No calorimeter cells, constituents, hits or tracks are saved, no offline reconstruction
  - TLA jets calibrated to match offline reconstructed jets
- Model independent, benchmark model used to set upper limits on coupling constant  $g_q$  ( $29.3 \text{ fb}^{-1}$ )

## Benchmark model: DM mediator

- Background estimated with functional fit of subranges with sliding window
- No bump found → factor 2-5x improvement in coupling constant limits w.r.t. other searches for lower masses

# Conclusions

---

- No new interactions and particles since the Higgs boson's discovery → more generic searches opposed to the existing model-dependent analysis standard
- Model agnostic searches with jets in final state becoming a main topic in the ATLAS collaboration
- Exploited LHC Run 2 data collected by ATLAS, also moving on to Run 3 data
  - Run 2: TLA analysis, CWoLa, search for resonances with quark tagging, YXH
  - Run 3: Anomaly Detection with Graph Neural Networks
- Honorable mentions: Anomaly Detection search with Run 2 data ([Phys. Rev. Lett. 132, 081801](#)), search for signatures of Soft Unclustered Energy Patterns
- Take home message: **Model agnostic searches can be a powerful tool that is complementary to beyond standard model dependent searches approach**

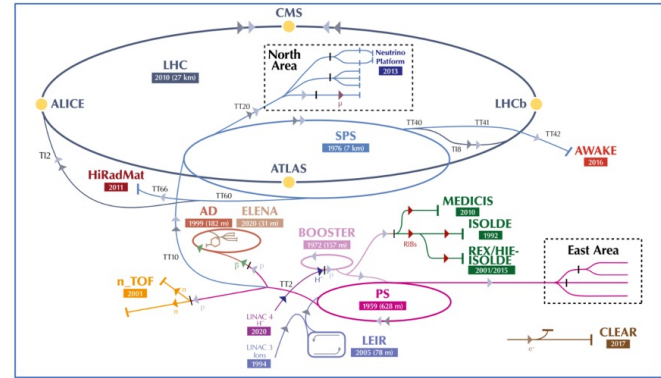

*Stay tuned and thank you  
for your attention!*

BACKUP

# Large Hadron Collider

- Largest and most powerful particle accelerator worldwide;
- **27 km** long tunnel underground provided by superconductive magnets to bend and accelerate particles;
- **13.6 TeV** center of mass energy (July 2022);
- 4 interaction points where main detectors are located: **ATLAS**, **LHCb**, **CMS** and **ALICE**;
- Investigate fundamental particles and forces of the universe; explore **dark matter**, **SUSY** and **Higgs** boson physics;
- **Luminosity**, defined as  $L = \frac{N_1 N_2 f n_b}{4\pi\sigma_x\sigma_y}$ , is a geometric parameter used to measure the **number of collisions** that can be produced in a detector per **cm<sup>2</sup>** and per **second**.

# The ATLAS experiment

ATLAS coordinate system

$$(z, \eta, \phi)$$

Transverse momentum

$$p_T = \vec{p} \cos(\phi)$$

Pseudorapidity

$$\eta = \frac{1}{2} \ln \left( \tan \left( \frac{\theta}{2} \right) \right)$$

Angular separation in  $\eta - \phi$  plane

$$\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2}$$

Multipurpose detectors arranged in concentric layers around the collision point:

Muon spectrometers;

Magnetic system;

Hadronic calorimeter;

Electromagnetic calorimeter;

Inner detectors (trackers).

ATLAS adopts a complex 2-level trigger system for data recording

# Coordinate system

Jets reconstructed using tracks in ID, calorimeter deposits and anti- $k_T$  algorithm.

- **Tile hadronic calorimeter:** 14 mm of iron absorber alternated to a 3 mm sparking plates, in bunches;
- **Liquid Argon end-cap hadronic calorimeter:** copper and tungsten as absorbers and LAr as active component.

Energy resolution

Pseudorapidity range	Energy resolution $\frac{\sigma_E}{E}$
$ \eta  < 3.0$	$\frac{50\%}{\sqrt{E}} \oplus 3\%$
$3.0 <  \eta  < 4.9$	$\frac{100\%}{\sqrt{E}} \oplus 10\%$

Anti- $k_T$  reconstruction algorithm takes topoclusters (clusters of energy deposits in the calorimeters) as input and combine them to form jet cones with characteristic radius R using a distance parameter

# Event Selection in Analysis I

$$y^* = \frac{y_1 - y_2}{2}$$

Category	Inclusive		1b	2b

# YXH background estimation

- Data-driven background estimation since ~97% from QCD di-jet
  - MC simulations are not precise enough!
- Performed by reweighting events with a function  $w(\mathbf{x})$  from CR0 to SR data:

$$w(\vec{x}) = \frac{pdf_1(\vec{x})}{pdf_0(\vec{x})}$$

- $w(\mathbf{x})$  is learned by a Deep Neural Network (DNN) in the training region HSB, validated in LSB and finally extrapolated in the Higgs mass window
- Training performed on data before  $D_{Tracks}^2$  and AS categorization
- DNN with 3 fully-connected inner layers, 20 neurons each, implemented with Keras (Tensorflow backend)

Totally innovative background estimation technique based on DNN data-driven reweighting

DNN input features

H four-momentum

Ntracks associated to H

$p_T, \phi, \eta, m$  of  $p_T$  leading and sub-leading small-R jets associated to H

# Background validation

Merged Region

➤ Since the DNN training is inclusive in X tagging selections, reweighting is applied in AS and  $D_{\text{Tracks}}^2$  regions without retraining

➤ Generally good closure of the background prediction to data is observed in validation region (LSB) for each scenario

➤ Occasional non-closure is taken as a systematic uncertainty of the background estimation method

before reweighting

after reweighting

# ATLAS trigger system

- 23 collisions per bunch crossing every 25 ns → **60TB/s** to store everything!!!
- Selection applied to store only interesting physics; decision took in two steps:
  - L1 trigger, hardware based (100 kHz)
  - High Level Trigger (HLT), software based (~1 kHz)
- Decisions taken based on calorimeter and muon detectors
