Abstract In order to cope with the complexity of the online control system the delegation at CERN Aarnio at CERN Aarnio at CERN Aarnio at CERN Aarnio at al-Queen at al-Queen at al-Queen at C with the CERN OC group-term of the concept for the coding of the control logic department of the control logic this concept is concept interface Barlow at alexperiment is viewed as a collection of objects behaving as finite state machines. These objects are tipically organized in hierarchical structures allowing up to the full automation of the experiment by a a toplevel object This concept has been extended and is beeing re-designed using object-oriented techniques in $SMI++$ for the BaBar experiment at SLAC

Keywords communication- control systems- development environments- object oriented methods-languages and methods-languages and methods-languages and methods-languages and methods-langu

The Online systems of physics experiments are normally composed of several different parts. Most common tasks are

- The Slow Controls System System School Controls and monitors slowly moving technical parameters and settings-temperatures and high voltage temperatures and high voltage of the settings-temperatures and high v ages of each subdetector-bases of each subdetector-bases them on the most of each subdetector-bases of each subd a database.
- The Data According System Data According to the Data Control of the Data According to the Data Control of the D tape
- The Trigger System provides the DAS system with the information on whether or not an event is interesting and should be written to tape
- The Machine Communication Communication System tem controls the exchange of parameters be tween the accelerator control system and the experiment

In previous experiments the control of the different areas was always designed separately by dif ferent experts- using dierent methodologies and tools resulting in a set of dedicated control sys tems

DELPHI decided to take a common approach to the full experiment control \mathcal{A} at al-a-adye at al-a-adye at al-a-adye at al-a-adye at al-a-adye at al-asystem The result was the design of a system that can be used for the control and monitoring of all parts of the experiment-the experiment-the experiment-the experiment-the experimentobtaining a system that is easier to operate- be cause it is homogeneous-distance in the maintain of the state of t and upgrade

2. THE SMI SYSTEM

se to a tool for developing control systems, it is based on the concept of Finite State Machines , a simple state machines are an simple way to make a simple way. to describe control systems- complex systems can be broken down into small and simple FSMs that are higherarchically controlled by other FSMs \mathcal{A}

ing SMI the experiment can be decomposed and described in terms of objects behaving as finite state machines

se represent can represent concrete entitles and represent example an hardware device or abstract entities like a logical subsystem The objects represent ing concrete entities interact with the hardware they model and control through driver processes or proximities are typically organised in the objects are typically organised in the objects are typically organised in the objects are the ob hierarchical structures called domains

The interaction between objects can best be un derstood in the example of Figure

Figure - SMI example

The object model of the experiment is described using State Manager Language Sml and guage allows detailed specication of the objects such as their states- actions and associated condi tions The main characteristics of this language are

Finite State Contracts Controlled Contracts Controlled Contracts Controlled Contracts Controlled Contracts Con

Objects are described as finite state machines. The only attribute of an object is its state. Commands sent to an object trigger actions that can bring about a change in its state

 $S = \frac{1}{2}$ is the set of $S = \frac{1}{2}$

An action on an abstract object is specified by a sequence of instructions-instructions- \mathcal{C} on commands sent to other objects and logical tests on states of other objects Actions on concrete objects are sent off as messages to the Driver Control Processes

Asynchrounous

Several actions may proceed in parallel: a command sent by object-A to object-B does not suspend the instruction sequence of object-A. Only a test by object-A on the state of object-B suspends the instruction sequence of object-A

if object-B is still in transition.

. **The rin**ce refer

Each object can specify logical conditions based on states of other objects of other o satisfied will trigger an action on the local object This provides the mechanism for an ob ject to respond to unsolicited state changes of its environment

- Example of SML code of SML c

```
object : RUN_CONTROL
state : READY
  action : START_RUN
    do MOUNT TAPE
    if TAPE not in_state MOUNTED
      do MOUNT_ERROR ERROR_OBJ
      terminate_action/state=ERROR
    endif
    do START READOUT_CONTROLER
    if READOUT_CONTROLER in_state RUNNING
      terminate_action/state=RUN_IN_PROGRESS
    \sim 100state : RUN_IN_PROGRESS
 when TAPE in_state FILE_FULL
    do PAUSE_RUN
 when READOUT_CONTROLER in_state ERROR
    do ABORT_RUN
  action : ABORT_RUN
    \ddotscobject : READOUT CONTROLER/driver
state : READY
  action : START
  \ldotsstate : RUNNING
  action : PAUSE
```
action : ABORT

The SMI mechanism allows an easy reconfiguration of the system: changes in the hardware can be easily integrated by modifying or replac ing driver processes and logical modications by changing the SMI code The decoupling between the actual actions on the hardware (done by the Driver Processes) and the control logic (residing in the SMI objects) makes the evolution of a system from its first test phase up to final complexity a very smooth process

In DELPHI the full online system is controlled through this mechanism- the various areas of DELPHI have been mapped into SMI domains subdetector domains-domain-domain-domain-domain-domain-TRIGGER domain- etc The full system com prises about 1000 SMI objects in 50 different domains

A high level of automation of the experiment's control system is very important in order to avoid human mistakes and to speed up standard proce dures.

Using the SMI mechanism the creation of a top level domain - BIG BROTHER - containing the logic allowing the interconection of the underlying domains a very extra construction of the control o task

Figure 2. Big Brother Control

Under normal running conditions BIG BROTH ER pilots the system with minimal operator in tervention as shown in Figure In other test and setup periods the operator becomes the top level object- using the userinterfaces he can send commands to any SMI domain

Current online control systems are generally char acterized by a highly distributed architecture; like most computer control systems- they consist of workstations interconnected by a local area net work

SMI takes advantage of distribution- SMI Do mains can run on a variety of computer platforms The cooperation between SMI Domains including all exchanges between objects, were embedded in the the Smith System and the SMI stems related to distribution and the and heterogeneity of platforms are transparently handled by the underlying communication system -DIM (Distributed Information Management System Gaspar and Donszelman-and Donszelman-and Donszelman-and Donszelman-and Donszelman-

DIM's aim is to provide interoperability between applications on different machines in heterogeneous distributed environments

The DIM system was designed and implemented according to the following characteristics

Economic Contract of the Contr

The communication mechanism of DIM was chosen having in mind the asynchrounous char acter of SMI objects and the speed in reacting to changes or error conditions in the system The solution we thought the best is for clients to declare interest in a service provided by a server only once at startup and get updates at an and get updates at an and get updates at an and get update at an and get updates at an and at regular time intervals or when the condition s changes communicated and processes communicated and assumption tion mechanism allowing for task parallelism and multiple destination updates

Transparency is the second that the second state of the second state is a second state of the second state in the second s

At run time no matter where \mathbb{R}^n is a process runs-where a process runs-where a process runs-where \mathbb{R}^n is able to communicate with any other process in the system independently of where the pro cesses are located to release the move freely from one machine to another and all commu nications are automatically reestablished this feature also allows for machine load balancing

Reliability and Rubust and Rubustian

In an environment with many processes- pro cessors and networks-that and networks-that and networksprocess-breakes-breakes-breakes-breakes-breakes-breakes-breakes-breakes-breakes-breakes-breakes-breakes-breakesnot perturbate the rest of the application of the a provides an automatic recovery from crash si tuations or the migration of processes

a any method published mechanism is any mechanism of the p process in the Online System can publish (Server) information and any interface (or any other process) can subscribe (Client) to this informa-A Name Server keeps track of all the Servers and Services available in the system

Servers "publish" their Services by registering to the Name Server (Normally once at startup).

Clients "subscribe" to Services by asking the Name Server which Server provides the Service and the contacting directly the Server Client Contact t's Services are then kept up-to-date in an event arriver mode or at regular time intervals times and the can also send commands to servers.

DIM is responsible for most of the communica tions in the DELPHI online \mathcal{N} is isomorphic DELPHI Online System- in the DELPHI Online System- in the DELPHI online \mathcal{N} used by SMI in order to transfer object states and

community of the user interfaces in order to access in order to access in order to access in order to access in cess SMI or any other necessary information and by many other processes for monitoring or pro cessing activities in the model in the DELPHI environment is makes currently available around 25000 Services provided by Servers and the metal between \mathcal{A} and \mathcal{A} by other experiments at CERN (and of course in Babar

DELPHI's SMI was implemented using ADA, each SMI domain corresponded to a file of SML forming a VMS process- each object beeing mapped in the state of the state is available to a state of the state of the state of the state of the state o able on VMS only

In $SMI++$ - The SML code is parsed and translated into an SMI object database that is then used by generic 'Logic Engines'.

The logic engine has been designed using an Ob ject oriented design tool (Rational Rose/ $C++$) and code in coded in Calledge in Call lated SML representation of the experiment to in stantiate the required objects and then responds to external events to drive the computer model of the experiment

Configuration tools allow the user to specify which objects belong to a specific SMI Domain, an SMI Domain corresponding to a Logic Engine

The design of the project is completed and the implementation is in progress The rst proto type should be working by the end of the year

SMI++ will be available on any mixed environments comprising : VMS (VAX and ALPHA) and University OSF-19 and the Contract of the South Contract of the Contract of the Contract of the Contract of the laris

DIM is already available in the above platforms and on OS9 and is beeing ported to WindowsNT and LINUX

Other available tools are:

allowing the smile strategies the strategies the strategies of the strategies of the strategies of the strategies state of the SMI objects in a Domain and to send commands to them

A DIM Display allowing the visualization of all the servers and clients in a certain DIM environ ment including SMI and driver processes in the small driver processes of the small driver processes in the small usefull for debugging applications

a bis was allowed to be a problem to allow the contract of the contract of the contract of the contract of the dim services in the MI state of SMI states in the WWW SMI states of the WWW SMI states of the WWW SMI states o page can be written in HTML with specic DIM tags containing the service name The DIM tags

are translated when the page is loaded

SMI is a powerfull tool for designing and imple menting control systems- it merges the concepts of object modeling and finite state machines.

The SMI system provides a simple language to model the application and a set of tools to com pile- congure and run your applications on a va riety of platforms

The full control of the DELPHI experiment at CERN is implemented using this system- SMI proved capable of handling the control of different environments such as: data acquisition (including run controls- trigger-trigger-trigger-trigger-trigger-trigger-trigger-trigger-trigger-

Due to the homogeneity in the control of the different parts of DELPHI it was possible to intercon nect the different parts and completelly automate the DELPHI operations in the DELPHI operations of the DELPHI operations in the DELPHI operations of the DELPHI o duced the efforts on maintenance and upgrade of the complete control system of DELPHI

SMI++ implements extensions to the SMI concept and is beein re-designed for use by the BaBar experiment at Stringer the main extensions are more related to more configuration capabilities at runtime- availability on a larger set of platforms in cluding heterogeneous distributed environments and a higher support on graphical tools
