Abstracts.

The positon spectra emitted by  $^{191}\text{Hg}$ ,  $^{193}\text{Hg}$  and their decay products were analyzed with a Gerholm-Lindskog  $\beta$  spectrometer automatically operated. From the analysis of the Fermi-Kuri diagrams, the total decay energies of  $^{191,193}\text{Hg}$  and  $^{191,193}\text{Au}$  were deduced.

1. Introduction

In the present study, the positon spectra emitted in  $^{193\text{m}+193\text{m}}\text{Hg} \rightarrow ^{193}\text{Au} \rightarrow ^{193}\text{Pt}$  and  $^{191}\text{Hg} \rightarrow ^{191}\text{Au} \rightarrow ^{191}\text{Pt}$  decays were measured with a Gerholm-Lindskog  $\beta$  spectrometer. This spectrometer (resolution and transmission  $\approx 3\%$ ) was operated with a twisted baffle, a scanning magnetic field device [1] and an improved magnetic shielding [2]. In such way, radioactive corrections are avoided as well as spectral distortion due to the stray magnetic field at the photomultiplier. All Hg samples used in these measurements were isotopically separated [3,4].

The Fermi-Kuri plots of the positon spectra were obtained using relativistic Fermi functions corrected for atomic screening  $F_0 \text{Lo}^*$  [5]. The different components were interpreted according to the observed half-lives, the experimental Hg, Au and Pt level schemes and intensity balance data.

2. The  $^{193}\text{Hg}$  and  $^{193}\text{Au}$  positon spectra

The high energy component of this complex spectrum decays with the half-life of  $^{193\text{m}+193\text{m}}\text{Hg}$  ( $T_{1/2} (^{193}\text{Hg}) = 3.8 \pm 0.15 \text{ h}$ ;  $T_{1/2} (^{193\text{m}}\text{Hg}) = 11.8 \pm 0.2 \text{ h}$  [3]). From the analysis of the transition intensities balance of  $^{193}\text{Au}$ , this pure high energy component can be attributed to the decay of  $^{193}\text{Hg}$   $3/2^-$  groundstate towards the  $3/2_2^+$  excited level of  $^{193}\text{Au}$ . The intensity of this  $\beta^+$  component can be evaluated from its end point energy ( $E_{\beta\text{max}} = 1287 \pm 15 \text{ keV}$ ),

the relative electron capture plus positon feedings of  $^{193}\text{Au}$  levels and the  $\text{EC}/\beta^+$  ( $= 37$ ) theoretical ratio [5]. The intensity obtained in this way corresponds to  $7.8 \pm 0.7 \beta^+$  emitted for  $10^4$  desintegrations of  $^{193\text{m}+193}\text{Hg}$ .

The low energy positon spectrum decays with the  $^{193}\text{Au}$  half-life ( $T_{1/2} = 17.5 \text{ h}$ ). Two components are brought into evidence by the Fermi-Kuri analysis. On account of the energy difference between their end point energy, they populate the  $1/2_1^-$  and  $3/2_1^-$  levels in  $^{193}\text{Pt}$ . A possible third component could populate the  $3/2_2^-$  level. However, due to the energy loss or scattering in the sample and vacuum chamber and the iron hysteresis optical aberrations, this low energy component cannot be satisfactorily resolved.

Finally, the experimental Q values obtained in the present study are slightly higher than Wapstra-Gove predictions ( $Q(^{193}\text{Hg} \rightarrow ^{193}\text{Au}) = 2340$  and  $Q(^{193}\text{Au} \rightarrow ^{193}\text{Pt}) = 1000 \text{ keV}$  [6]).

3. The  $^{191}\text{Hg}$  and  $^{191}\text{Au}$  positon spectra

The Fermi-Kuri plot of this complex spectrum is very similar to the previous one. Indeed a pure high energy component is brought in evidence and follows the  $^{191}\text{Hg}$  decay ( $T_{1/2} = 31 \text{ mn}$ ). According to intensity balance measurements [7], this high energy component corresponds to the decay of  $3/2^-$  groundstate of  $^{191}\text{Hg}$  towards the  $3/2_2^+$  excited level of  $^{191}\text{Au}$ . The low energy positon spectrum follows the  $^{191}\text{Au} \rightarrow ^{191}\text{Pt}$  decay ( $T_{1/2} = 3,2 \text{ h}$ ). For similar experimental reasons previously quoted, only two components of this complex low energy spectrum can be resolved. They populate the  $3/2_1^-$  groundstate and  $1/2_1^+$  ( $283.9 \text{ keV}$ ) excited level in  $^{191}\text{Pt}$ .

Fig. 2 - Positron spectrum emitted by  $^{191}\text{Hg}$  and  $^{191}\text{Au}$

Finally, the experimental Q values measured for  $^{191}\text{Hg} \rightarrow ^{191}\text{Au}$  and  $^{191}\text{Au} \rightarrow ^{191}\text{Pt}$  decays, agree quite well with the corresponding predictions of Wapstra-Gove ( $Q(^{191}\text{Hg} \rightarrow ^{191}\text{Au}) = 3300$  keV and  $Q(^{191}\text{Au} \rightarrow ^{191}\text{Pt}) = 1900$  keV).
