# Table of Contents

<b>AWS Prescriptive Guidance patterns .....</b>	<b>1</b>
<b>Analytics .....</b>	<b>3</b>
Analyze Amazon Redshift data in Microsoft SQL Server Analysis Services .....	5
Summary .....	5
Prerequisites and limitations .....	5
Architecture .....	6
Tools .....	6
Epics .....	7
Related resources .....	8
.....	10
Summary .....	10
Prerequisites and limitations .....	10
Architecture .....	11
Tools .....	11
Epics .....	13
Related resources .....	17
Automate encryption enforcement in AWS Glue .....	18
Summary .....	18
Prerequisites and limitations .....	18
Architecture .....	18
Tools .....	20
Best practices .....	21
Epics .....	21
Related resources .....	23
Build a video processing pipeline .....	25
Summary .....	25
Prerequisites and limitations .....	25
Architecture .....	26
Tools .....	27
Epics .....	28
Related resources .....	35
Additional information .....	35
Attachments .....	36
Build an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue .....	37

Summary .....	37
Prerequisites and limitations .....	37
Architecture .....	38
Tools .....	40
Epics .....	41
Related resources .....	47
Additional information .....	48
Calculate value at risk (VaR) by using AWS services .....	49
Summary .....	49
Prerequisites and limitations .....	50
Architecture .....	50
Tools .....	52
Best practices .....	53
Epics .....	53
Related resources .....	56
Convert NORMALIZE to Amazon Redshift SQL .....	57
Summary .....	57
Prerequisites and limitations .....	57
Architecture .....	57
Tools .....	58
Epics .....	63
Related resources .....	63
Convert RESET WHEN to Amazon Redshift SQL .....	65
Summary .....	65
Prerequisites and limitations .....	65
Architecture .....	65
Tools .....	66
Epics .....	70
Related resources .....	70
.....	72
Summary .....	72
Prerequisites and limitations .....	73
Architecture .....	73
Tools .....	74
Epics .....	75
Related resources .....	78

---

Attachments .....	78
Ensure Amazon EMR logging to Amazon S3 .....	79
Summary .....	79
Prerequisites and limitations .....	80
Architecture .....	80
Tools .....	81
Epics .....	82
Related resources .....	84
Attachments .....	84
Generate test data using AWS Glue .....	85
Summary .....	85
Prerequisites and limitations .....	85
Architecture .....	86
Tools .....	86
Best practices .....	87
Epics .....	88
Related resources .....	97
Additional information .....	98
Launch a Spark job in Amazon EMR using a Lambda function .....	102
Summary .....	102
Prerequisites and limitations .....	102
Architecture .....	103
Tools .....	104
Epics .....	104
Related resources .....	108
Additional information .....	108
Attachments .....	110
Migrate Apache Cassandra workloads to Amazon Keyspaces .....	111
Summary .....	111
Prerequisites and limitations .....	111
Architecture .....	112
Tools .....	113
Best practices .....	114
Epics .....	114
Troubleshooting .....	127
Related resources .....	127

---

Additional information .....	127
Migrate Oracle Business Intelligence 12C to the AWS Cloud .....	129
Summary .....	129
Prerequisites and limitations .....	129
Architecture .....	130
Tools .....	132
Epics .....	133
Related resources .....	145
Additional information .....	145
Migrate a Kafka cluster to Amazon MSK using MirrorMaker .....	150
Summary .....	150
Prerequisites and limitations .....	150
Architecture .....	151
Tools .....	152
Best practices .....	153
Epics .....	153
Related resources .....	156
Additional information .....	157
Migrate an ELK Stack to the AWS Cloud .....	158
Summary .....	158
Prerequisites and limitations .....	159
Architecture .....	160
Tools .....	163
Epics .....	164
Related resources .....	171
Additional information .....	173
Migrate data to AWS using Starburst .....	174
Summary .....	174
Prerequisites and limitations .....	174
Architecture .....	174
Tools .....	178
Epics .....	179
Related resources .....	182
Optimize the ETL ingestion of input file size .....	184
Summary .....	184
Prerequisites and limitations .....	184

Architecture .....	185
Tools .....	186
Epics .....	186
Related resources .....	189
Additional information .....	189
Orchestrate an ETL pipeline with AWS Step Functions .....	190
Summary .....	190
Prerequisites and limitations .....	190
Architecture .....	191
Tools .....	192
Epics .....	194
Troubleshooting .....	200
Related resources .....	200
Additional information .....	201
Perform ML analytics using Amazon Redshift ML .....	204
Summary .....	204
Prerequisites and limitations .....	204
Architecture .....	205
Tools .....	206
Epics .....	207
Related resources .....	210
Query DynamoDB tables using Athena .....	212
Summary .....	212
Prerequisites and limitations .....	212
Architecture .....	213
Tools .....	214
Epics .....	214
Related resources .....	223
Additional information .....	223
Set up a minimum viable data space .....	225
Summary .....	225
Prerequisites and limitations .....	226
Architecture .....	228
Tools .....	229
Best practices .....	230
Epics .....	231

Troubleshooting .....	285
Related resources .....	285
Additional information .....	285
Set up language-specific sorting for Amazon Redshift query results .....	290
Summary .....	290
Prerequisites and limitations .....	290
Architecture .....	291
Tools .....	291
Epics .....	291
Related resources .....	295
Additional information .....	296
Subscribe a Lambda function to event notifications from cross-Region S3 buckets .....	300
Summary .....	300
Prerequisites and limitations .....	300
Architecture .....	301
Tools .....	302
Epics .....	302
Related resources .....	306
Three AWS Glue job types for converting data .....	307
Summary .....	307
Prerequisites and limitations .....	307
Architecture .....	308
Tools .....	308
Epics .....	309
Related resources .....	311
Additional information .....	312
Attachments .....	318
Visualize Amazon Redshift audit logs using Athena and QuickSight .....	319
Summary .....	319
Prerequisites and limitations .....	319
Architecture .....	320
Tools .....	320
Epics .....	321
Related resources .....	324
Attachments .....	324
Visualize IAM credential reports using Amazon QuickSight .....	325

---

Summary .....	325
Prerequisites and limitations .....	326
Architecture .....	326
Tools .....	327
Epics .....	328
Additional information .....	333
More patterns .....	335
<b>Business productivity .....</b>	<b>337</b>
Set up a highly available PeopleSoft architecture on AWS .....	338
Summary .....	338
Prerequisites and limitations .....	338
Architecture .....	339
Tools .....	343
Best practices .....	344
Epics .....	347
Related resources .....	366
More patterns .....	367
<b>CloudNative .....</b>	<b>368</b>
Monitor SAP RHEL Pacemaker clusters .....	369
Summary .....	369
Prerequisites and limitations .....	369
Architecture .....	370
Tools .....	371
Best practices .....	372
Epics .....	372
Related resources .....	387
Attachments .....	388
Successfully import an S3 bucket as a CloudFormation stack .....	389
Summary .....	389
Prerequisites and limitations .....	389
Architecture .....	389
Epics .....	391
Related resources .....	399
Attachments .....	399
More patterns .....	400
<b>Containers &amp; microservices .....</b>	<b>402</b>

Access container applications on Amazon ECS .....	404
Summary .....	404
Prerequisites and limitations .....	405
Architecture .....	405
Tools .....	407
Epics .....	408
Related resources .....	419
Access container applications on Amazon ECS with an AWS Fargate launch type .....	422
Summary .....	422
Prerequisites and limitations .....	423
Architecture .....	423
Tools .....	425
Epics .....	426
Related resources .....	436
Access container applications privately on Amazon EKS .....	439
Summary .....	439
Prerequisites and limitations .....	439
Architecture .....	440
Tools .....	441
Epics .....	441
Related resources .....	446
Activate mTLS in App Mesh on Amazon EKS .....	447
Summary .....	447
Prerequisites and limitations .....	447
Architecture .....	448
Tools .....	449
Epics .....	449
Related resources .....	453
Additional information .....	454
Automate backups for Amazon RDS for PostgreSQL DB instances .....	455
Summary .....	455
Prerequisites and limitations .....	456
Architecture .....	456
Tools .....	457
Epics .....	458
Related resources .....	464

Additional information .....	465
Automate deployment of Node Termination Handler .....	468
Summary .....	468
Prerequisites and limitations .....	469
Architecture .....	470
Tools .....	471
Best practices .....	472
Epics .....	472
Troubleshooting .....	480
Related resources .....	481
Additional information .....	481
Automatically build and deploy a Java application to Amazon EKS .....	483
Summary .....	483
Prerequisites and limitations .....	483
Architecture .....	484
Tools .....	486
Best practices .....	488
Epics .....	488
Related resources .....	505
Additional information .....	505
Create an Amazon ECS task definition on EC2 instances using Amazon EFS .....	507
Summary .....	507
Prerequisites and limitations .....	508
Architecture .....	508
Tools .....	510
Epics .....	510
Related resources .....	512
Attachments .....	513
Deploy Java microservices on Amazon ECS using AWS Fargate .....	514
Summary .....	514
Prerequisites and limitations .....	514
Architecture .....	514
Tools .....	516
Epics .....	517
Related resources .....	520
Deploy Java microservices on Amazon ECS using Amazon ECR and AWS Fargate .....	522

Summary .....	522
Prerequisites and limitations .....	522
Architecture .....	522
Tools .....	524
Epics .....	525
Related resources .....	530
Deploy Java microservices on Amazon ECS using Amazon ECR and load balancing .....	532
Summary .....	532
Prerequisites and limitations .....	533
Architecture .....	533
Tools .....	535
Epics .....	535
Related resources .....	536
Deploy Kubernetes packages using Amazon EKS and Helm .....	538
Summary .....	538
Prerequisites and limitations .....	538
Architecture .....	539
Tools .....	540
Epics .....	541
Related resources .....	549
Attachments .....	549
Deploy Lambda functions with container images .....	550
Summary .....	550
Prerequisites and limitations .....	550
Architecture .....	551
Tools .....	552
Best practices .....	552
Epics .....	553
Troubleshooting .....	556
Related resources .....	556
Additional information .....	557
Deploy a Java microservice on Amazon EKS and expose it with an Application Load Balancer .....	559
Summary .....	559
Prerequisites and limitations .....	559
Architecture .....	560

---

Tools .....	561
Epics .....	561
Related resources .....	567
Additional information .....	567
Deploy a clustered application to Amazon ECS by using AWS Copilot .....	571
Summary .....	571
Prerequisites and limitations .....	571
Architecture .....	572
Tools .....	573
Epics .....	574
Related resources .....	581
Deploy a gRPC-based application on Amazon EKS .....	582
Summary .....	582
Prerequisites and limitations .....	582
Architecture .....	583
Tools .....	585
Epics .....	586
Related resources .....	593
Additional information .....	593
Deploy and debug Amazon EKS clusters .....	596
Summary .....	596
Prerequisites and limitations .....	596
Architecture .....	597
Tools .....	598
Epics .....	599
Troubleshooting .....	621
Related resources .....	621
Additional information .....	622
Deploy containers by using Elastic Beanstalk .....	625
Summary .....	625
Prerequisites and limitations .....	626
Architecture .....	626
Tools .....	628
Epics .....	628
Related resources .....	631
Additional information .....	631

Generate a static outbound IP address using Lambda and Amazon VPC .....	632
Summary .....	632
Prerequisites and limitations .....	632
Architecture .....	633
Tools .....	634
Epics .....	634
Related resources .....	645
Identify duplicate container images automatically .....	646
Summary .....	646
Prerequisites and limitations .....	646
Architecture .....	647
Tools .....	650
Best practices .....	650
Epics .....	650
Troubleshooting .....	669
Related resources .....	670
Additional information .....	670
Install SSM Agent on Amazon EKS worker nodes .....	676
Summary .....	676
Prerequisites and limitations .....	676
Architecture .....	677
Tools .....	677
Epics .....	679
Related resources .....	681
Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands .....	682
Summary .....	682
Prerequisites and limitations .....	682
Architecture .....	683
Tools .....	684
Epics .....	684
Related resources .....	686
Additional information .....	686
Optimize generated Docker images .....	689
Summary .....	689
Prerequisites and limitations .....	689

---

Architecture .....	689
Tools .....	690
Epics .....	692
Related resources .....	699
Attachments .....	699
Place Kubernetes Pods on compatible nodes in Amazon EKS .....	700
Summary .....	700
Prerequisites and limitations .....	700
Architecture .....	701
Tools .....	703
Epics .....	704
Troubleshooting .....	714
Related resources .....	714
Additional information .....	715
Replicate filtered Amazon ECR container images across accounts or Regions .....	718
Summary .....	718
Prerequisites and limitations .....	718
Architecture .....	719
Tools .....	720
Epics .....	722
Related resources .....	733
Additional information .....	733
Attachments .....	734
Rotate credentials without restarting containers .....	735
Summary .....	735
Prerequisites and limitations .....	736
Architecture .....	736
Tools .....	738
Epics .....	740
Related resources .....	740
Attachments .....	741
Run Amazon ECS tasks on Amazon WorkSpaces .....	742
Summary .....	742
Prerequisites and limitations .....	742
Architecture .....	743
Tools .....	744

Epics .....	744
Related resources .....	751
Attachments .....	752
Run an ASP.NET web API Docker container on AWS .....	753
Summary .....	753
Prerequisites and limitations .....	753
Architecture .....	754
Tools .....	755
Epics .....	756
Related resources .....	764
Run message-driven workloads using AWS Fargate .....	765
Summary .....	765
Prerequisites and limitations .....	766
Architecture .....	766
Tools .....	767
Epics .....	768
Related resources .....	773
Run stateful workloads with persistent data storage .....	774
Summary .....	774
Prerequisites and limitations .....	775
Architecture .....	776
Tools .....	778
Best practices .....	779
Epics .....	780
Related resources .....	798
Additional information .....	799
More patterns .....	800
<b>Content delivery .....</b>	<b>801</b>
Send AWS WAF logs to Splunk using Firehose .....	802
Summary .....	802
Prerequisites and limitations .....	803
Architecture .....	803
Tools .....	805
Epics .....	805
Related resources .....	810
Serve static content in an S3 bucket through a VPC by using CloudFront .....	811

Summary .....	811
Prerequisites and limitations .....	811
Architecture .....	812
Tools .....	814
Epics .....	814
Related resources .....	818
Additional information .....	818
More patterns .....	821
<b>Cost management .....</b>	<b>822</b>
Create detailed cost and usage reports for AWS Glue jobs .....	823
Summary .....	823
Prerequisites and limitations .....	823
Architecture .....	823
Tools .....	824
Epics .....	825
Create detailed cost and usage reports for Amazon EMR clusters .....	829
Summary .....	829
Prerequisites and limitations .....	829
Architecture .....	829
Tools .....	830
Epics .....	831
More patterns .....	834
<b>Data lakes .....</b>	<b>835</b>
Automate data ingestion from AWS Data Exchange into Amazon S3 .....	836
Summary .....	836
Prerequisites and limitations .....	836
Architecture .....	837
Tools .....	838
Epics .....	839
Related resources .....	840
Attachments .....	840
Build a data pipeline to process Google Analytics data using the AWS DataOps Development Kit .....	841
Summary .....	841
Prerequisites and limitations .....	841
Architecture .....	842

Tools .....	843
Epics .....	844
Troubleshooting .....	846
Related resources .....	846
Additional information .....	846
Configure cross-account access to a shared AWS Glue Data Catalog using Athena .....	850
Summary .....	850
Prerequisites and limitations .....	850
Architecture .....	851
Tools .....	852
Epics .....	853
Related resources .....	865
Additional information .....	865
Deploy and manage a serverless data lake on AWS .....	866
Summary .....	866
Prerequisites and limitations .....	867
Architecture .....	867
Tools .....	870
Epics .....	871
Related resources .....	873
Ingest IoT data directly into Amazon S3 .....	874
Summary .....	874
Prerequisites and limitations .....	874
Architecture .....	875
Tools .....	876
Best practices .....	876
Epics .....	877
Troubleshooting .....	883
Related resources .....	884
Additional information .....	885
Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator .....	889
Summary .....	889
Prerequisites and limitations .....	889
Architecture .....	890
Epics .....	891
Related resources .....	897

Additional information .....	897
More patterns .....	898
<b>Databases .....</b>	<b>899</b>
Access on-premises SQL Server data using linked servers .....	901
Summary .....	901
Prerequisites and limitations .....	901
Architecture .....	901
Tools .....	902
Epics .....	903
Related resources .....	906
Additional information .....	906
Add HA to Oracle PeopleSoft on AWS .....	908
Summary .....	908
Prerequisites and limitations .....	909
Architecture .....	909
Tools .....	910
Best practices .....	911
Epics .....	911
Related resources .....	929
Additional information .....	929
Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS ...	932
Summary .....	932
Prerequisites and limitations .....	932
Architecture .....	933
Tools .....	935
Best practices .....	935
Epics .....	936
Related resources .....	941
Automate failover and failback with DR Orchestrator Framework .....	943
Summary .....	943
Prerequisites and limitations .....	943
Architecture .....	945
Tools .....	950
Epics .....	951
Related resources .....	972
Automate the replication of Amazon RDS instances across AWS accounts .....	973

Summary .....	973
Prerequisites and limitations .....	973
Architecture .....	974
Tools .....	976
Epics .....	977
Related resources .....	985
Additional information .....	985
Automatically back up SAP HANA databases .....	988
Summary .....	988
Prerequisites and limitations .....	988
Architecture .....	989
Tools .....	990
Epics .....	991
Related resources .....	995
Block public access to Amazon RDS .....	996
Summary .....	996
Prerequisites and limitations .....	997
Architecture .....	997
Tools .....	998
Epics .....	999
Related resources .....	1002
Additional information .....	1002
Configure read-only routing in an Always On availability group .....	1004
Summary .....	1004
Prerequisites and limitations .....	1004
Architecture .....	1005
Tools .....	1007
Best practices .....	1007
Epics .....	1007
Troubleshooting .....	1011
Related resources .....	1012
Additional information .....	1012
Connect by using an SSH tunnel in pgAdmin .....	1014
Summary .....	1014
Prerequisites and limitations .....	1014
Architecture .....	1015

---

Tools .....	1015
Epics .....	1016
Related resources .....	1019
Convert JSON Oracle queries into PostgreSQL database SQL .....	1020
Summary .....	1020
Prerequisites and limitations .....	1020
Architecture .....	1021
Tools .....	1022
Best practices .....	1023
Epics .....	1023
Related resources .....	1027
Additional information .....	1028
Copy Amazon DynamoDB tables across accounts .....	1051
Summary .....	1051
Prerequisites and limitations .....	1051
Architecture .....	1051
Tools .....	1053
Epics .....	1053
Related resources .....	1057
Copy Amazon DynamoDB tables across accounts .....	1058
Summary .....	1058
Prerequisites and limitations .....	1059
Architecture .....	1059
Tools .....	1060
Best practices .....	1063
Epics .....	1063
Related resources .....	1069
Additional information .....	1069
Attachments .....	1070
Create cost and usage reports for Amazon RDS and Amazon Aurora .....	1071
Summary .....	1071
Prerequisites and limitations .....	1071
Architecture .....	1071
Tools .....	1073
Epics .....	1074
Related resources .....	1077

Emulate Oracle RAC workloads using Aurora PostgreSQL .....	1079
Summary .....	1079
Prerequisites and limitations .....	1079
Architecture .....	1080
Tools .....	1082
Epics .....	1083
Related resources .....	1086
Enable encrypted connections for PostgreSQL DB instances .....	1087
Summary .....	1087
Prerequisites and limitations .....	1087
Architecture .....	1087
Tools .....	1088
Best practices .....	1088
Epics .....	1089
Troubleshooting .....	1095
Related resources .....	1095
Encrypt an existing Amazon RDS for PostgreSQL DB instance .....	1096
Summary .....	1096
Prerequisites and limitations .....	1096
Architecture .....	1097
Tools .....	1098
Epics .....	1099
Related resources .....	1103
Additional information .....	1103
Enforce automatic tagging of Amazon RDS databases at launch .....	1105
Summary .....	1105
Prerequisites and limitations .....	1105
Architecture .....	1106
Tools .....	1106
Epics .....	1107
Related resources .....	1109
Attachments .....	1110
Estimate DynamoDB costs .....	1111
Summary .....	1111
Prerequisites and limitations .....	1112
Tools .....	1112

---

Best practices .....	1112
Epics .....	1113
Related resources .....	1118
Additional information .....	1118
Attachments .....	1122
Estimate storage costs for an Amazon DynamoDB table .....	1123
Summary .....	1123
Prerequisites and limitations .....	1124
Tools .....	1124
Epics .....	1125
Related resources .....	1126
Additional information .....	1126
Attachments .....	1127
Estimate the Amazon RDS engine size for an Oracle database using AWR reports .....	1128
Summary .....	1128
Prerequisites and limitations .....	1128
Architecture .....	1129
Tools .....	1129
Best practices .....	1130
Epics .....	1130
Related resources .....	1156
Export Amazon RDS for SQL Server tables to an S3 bucket .....	1157
Summary .....	1157
Prerequisites and limitations .....	1158
Architecture .....	1158
Tools .....	1159
Epics .....	1160
Related resources .....	1167
Additional information .....	1167
Handle anonymous blocks in Dynamic SQL statements .....	1169
Summary .....	1169
Prerequisites and limitations .....	1169
Architecture .....	1170
Tools .....	1171
Epics .....	1172
Related resources .....	1175

---

Additional information .....	1175
Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible .....	1178
Summary .....	1178
Prerequisites and limitations .....	1178
Tools .....	1179
Epics .....	1179
Related resources .....	1184
Help enforce DynamoDB tagging .....	1185
Summary .....	1185
Prerequisites and limitations .....	1185
Architecture .....	1186
Tools .....	1186
Epics .....	1187
Related resources .....	1190
Attachments .....	1190
Implement cross-Region DR .....	1191
Summary .....	1191
Prerequisites and limitations .....	1191
Architecture .....	1192
Tools .....	1193
Epics .....	1194
Related resources .....	1206
Additional information .....	1207
Migrate 100+ argument Oracle functions to PostgreSQL .....	1208
Summary .....	1208
Prerequisites and limitations .....	1208
Architecture .....	1209
Tools .....	1209
Best practices .....	1210
Epics .....	1210
Troubleshooting .....	1212
Related resources .....	1212
Additional information .....	1212
Migrate Amazon RDS for Oracle DB instances to AMS accounts .....	1214
Summary .....	1214
Prerequisites and limitations .....	1214

---

Architecture .....	1215
Tools .....	1217
Epics .....	1217
Related resources .....	1222
Additional information .....	1223
Migrate Oracle OUT bind variables to PostgreSQL .....	1224
Summary .....	1224
Prerequisites and limitations .....	1225
Architecture .....	1225
Tools .....	1226
Epics .....	1227
Related resources .....	1228
Additional information .....	1228
Migrate SAP HANA to AWS using HSR .....	1233
Summary .....	1233
Prerequisites and limitations .....	1234
Architecture .....	1235
Tools .....	1238
Epics .....	1239
Related resources .....	1246
Additional information .....	1246
Migrate SQL Server to AWS using distributed availability groups .....	1248
Summary .....	1248
Prerequisites and limitations .....	1248
Architecture .....	1249
Tools .....	1250
Best practices .....	1251

# AWS Prescriptive Guidance Patterns

Amazon Web Services (AWS) Prescriptive Guidance patterns provide step-by-step instructions, architecture, tools, and code for implementing specific cloud migration, modernization, and deployment scenarios. These patterns, which are vetted by subject matter experts at AWS, are meant for builders and hands-on users who are planning to, or are in the process of, migrating to AWS. They also support users who are already on AWS and are looking for ways to optimize or modernize their cloud operations.

You can use these patterns to move your on-premises or cloud workloads of varying complexity to AWS and to accelerate your cloud adoption, optimization, and modernization efforts, regardless of whether you're in the proof of concept, planning, or implementation phase of your project. For example, for a cloud migration project:

- In the planning phase, you can evaluate the different options available to migrate to AWS. You can choose the right pattern that fits your needs, depending on whether you want to relocate, rehost, replatform, or rearchitect. You can also understand the different tools available for migration, and start planning to procure licenses or start initial conversations with vendors.
- In the proof of concept and implementation phases, you can follow the step-by-step instructions provided in the pattern to migrate your workload to AWS. Each pattern includes details such as prerequisites, target reference architectures, tools, step-by-step tasks, best practices, troubleshooting, and code.
- If you're already using the AWS Cloud, you can find patterns that will help you modernize, optimize, scale, and secure your use of cloud resources.

# Analyze Amazon Redshift data in Microsoft SQL Server Analysis Services

*Created by Sunil Vora (AWS)*

<b>Environment:</b> PoC or pilot	<b>Source:</b> Amazon Redshift	<b>Target:</b> Microsoft SQL Server Analysis Services
<b>R Type:</b> N/A	<b>Workload:</b> Microsoft	<b>Technologies:</b> Analytics
<b>AWS services:</b> Amazon Redshift		

## Summary

This pattern describes how to connect and analyze Amazon Redshift data in Microsoft SQL Server Analysis Services, by using the Intellisoft OLE DB Provider or CData ADO.NET Provider for database access.

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. SQL Server Analysis Services is an online analytical processing (OLAP) tool that you can use to analyze data from data marts and data warehouses such as Amazon Redshift. You can use SQL Server Analysis Services to create OLAP cubes from your data for rapid, advanced data analysis.

## Prerequisites and limitations

### Assumptions

- This pattern describes how to set up SQL Server Analysis Services and Intellisoft OLE DB Provider or CData ADO.NET Provider for Amazon Redshift on an Amazon Elastic Compute Cloud (Amazon EC2) instance. Alternatively, you can install both on a host in your corporate data center.

### Prerequisites

- An active AWS account
- An Amazon Redshift cluster with credentials

# Architecture

## Source technology stack

- An Amazon Redshift cluster

## Target technology stack

- Microsoft SQL Server Analysis Services

## Source and target architecture

## Tools

- [Microsoft Visual Studio 2019 \(Community Edition\)](#)
- [Intellisoft OLE DB Provider for Amazon Redshift \(Trial\)](#) or [CData ADO.NET Provider for Amazon Redshift \(Trial\)](#)

## Epics

### Analyze tables

Task	Description	Skills required
Analyze the tables and data to be imported.	Identify the Amazon Redshift tables to be imported and their sizes.	DBA

### Set up EC2 instance and install tools

Task	Description	Skills required
Set up an EC2 instance.	In your AWS account, create an EC2 instance in a private or public subnet.	Systems administrator
Install tools for database access.	Download and install the <a href="#">Intellisoft OLE DB Provider for Amazon Redshift</a> (or <a href="#">CData ADO.NET Provider for Amazon Redshift</a> ).	Systems administrator
Install Visual Studio.	Download and install <a href="#">Visual Studio 2019 (Community Edition)</a> .	Systems administrator
Install extensions.	Install the <b>Microsoft Analysis Services Projects</b> extension in Visual Studio.	Systems administrator
Create a project.	Create a new tabular model project in Visual Studio to store your Amazon Redshift data. In Visual Studio, choose the <b>Analysis Services Tabular</b>	DBA

Task	Description	Skills required
	<b>Project</b> option when creating your project.	

## Create data source and import tables

Task	Description	Skills required
Create an Amazon Redshift data source.	Create an Amazon Redshift data source by using the Intellisoft OLE DB Provider for Amazon Redshift (or CData ADO.NET Provider for Amazon Redshift) and your Amazon Redshift credentials.	Amazon Redshift, DBA
Import tables.	Select and import tables and views from Amazon Redshift into your SQL Server Analysis Services project.	Amazon Redshift, DBA

## Clean up after migration

Task	Description	Skills required
Delete the EC2 instance.	Delete the EC2 instance you launched previously.	Systems administrator

# Analyze and visualize nested JSON data with Amazon Athena and Amazon QuickSight

*Created by Anoop Singh (AWS)*

**Environment:** PoC or pilot

**Technologies:** Analytics;  
Databases

**AWS services:** Amazon  
Athena; Amazon QuickSight

## Summary

This pattern explains how to translate a nested, JSON-formatted data structure into a tabular view by using Amazon Athena, and then visualize the data in Amazon QuickSight.

You can use JSON-formatted data for API-powered data feeds from operational systems to create data products. This data can also help you understand your customers and their interactions with your products better, so you can tailor user experiences and predict outcomes.

## Prerequisites and limitations

### Prerequisites

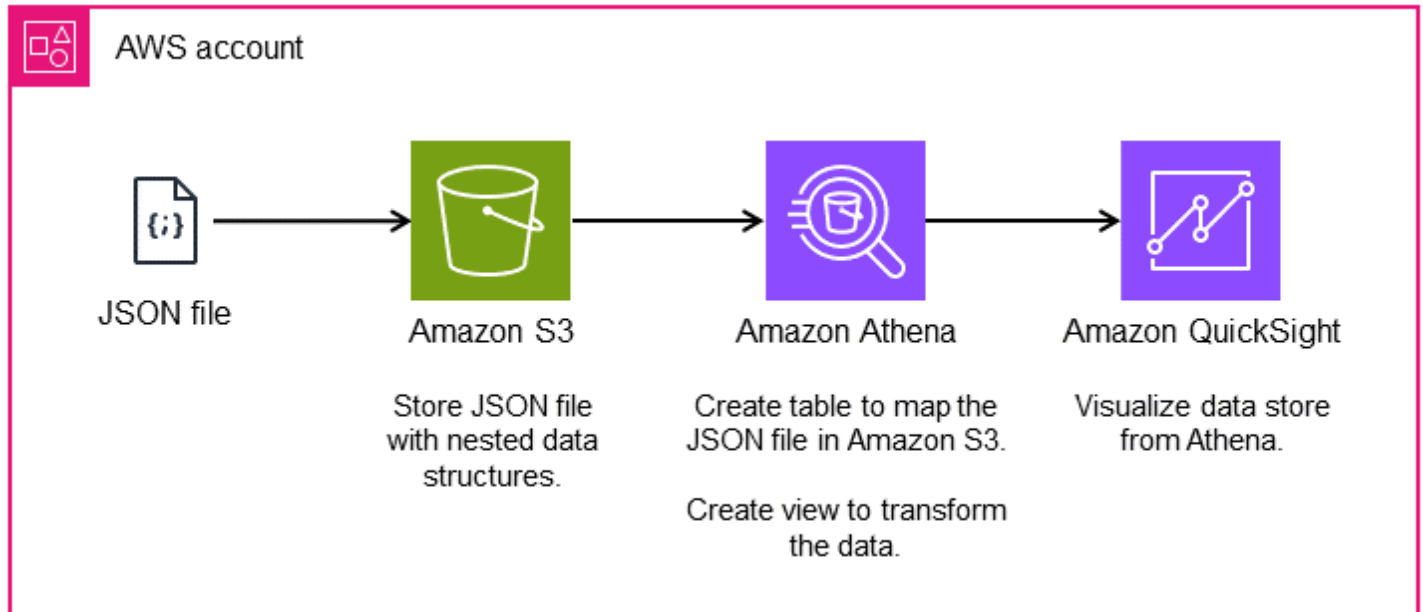

- An active AWS account
- A JSON file that represents a nested data structure (this pattern provides a sample file)

### Limitations:

- JSON features integrate well with existing SQL-oriented functions in Athena. However, they aren't ANSI SQL compatible, and the JSON file is expected to carry each record on a separate line. You might need to use the `ignore.malformed.json` property in Athena to indicate if malformed JSON records should be turned into null characters or generate errors. For more information, see [Best practices for reading JSON data](#) in the Athena documentation.
- This pattern considers only simple and small amounts of JSON-formatted data. If you want to use these concepts at scale, consider applying data partitioning and consolidate your data into larger files.

## Architecture

The following diagram shows the architecture and workflow for this pattern. The nested data structures are stored in Amazon Simple Storage Service (Amazon S3) in JSON format. In Athena, the JSON data is mapped to an Athena data structure. You then create a view to analyze the data, and visualize the data structure in QuickSight.

## Tools

### AWS services

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. This pattern uses Amazon S3 to store the JSON file.
- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL. This pattern uses Athena to query and transform the JSON data. With a few actions in the AWS Management Console, you can point Athena at your data in Amazon S3 and use standard SQL to run one-time queries. Athena is serverless, so there is no infrastructure to set up or manage, and you pay only for the queries that you run. Athena scales automatically and runs queries in parallel, so results are fast, even with large datasets and complex queries.
- [Amazon QuickSight](#) is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data on a single dashboard. QuickSight lets you easily create and

publish interactive dashboards that include machine learning (ML) insights. You can access these dashboards from any device, and embed them into your applications, portals, and websites.

## Example code

The following JSON file provides a nested data structure that you can use in this pattern.

```
{
  "symbol": "AAPL",
  "financials": [
    {
      "reportDate": "2017-03-31",
      "grossProfit": 20591000000,
      "costOfRevenue": 32305000000,
      "operatingRevenue": 52896000000,
      "totalRevenue": 52896000000,
      "operatingIncome": 14097000000,
      "netIncome": 11029000000,
      "researchAndDevelopment": 2776000000,
      "operatingExpense": 6494000000,
      "currentAssets": 101990000000,
      "totalAssets": 334532000000,
      "totalLiabilities": 200450000000,
      "currentCash": 15157000000,
      "currentDebt": 13991000000,
      "totalCash": 67101000000,
      "totalDebt": 98522000000,
      "shareholderEquity": 134082000000,
      "cashChange": -1214000000,
      "cashFlow": 12523000000,
      "operatingGainsLosses": null
    }
  ]
}
```

# Epics

## Set up an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	To create a bucket to store the JSON file, sign in to the AWS Management Console, open the <a href="#">Amazon S3 console</a> , and then choose <b>Create bucket</b> . For more information, see <a href="#">Creating a bucket</a> in the Amazon S3 documentation.	Systems administrator
Add the nested JSON data.	Upload your JSON file to the S3 bucket. For a sample JSON file, see the previous section. For instructions, see <a href="#">Uploading objects</a> in the Amazon S3 documentation.	Systems administrator

## Analyze data in Athena

Task	Description	Skills required
Create a table for mapping the JSON data.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Athena console</a>.</li><li>2. Create a database by following the instructions in the <a href="#">Athena documentation</a>.</li><li>3. From the <b>Database</b> menu, choose the database that you created.</li></ol>	Developer

Task	Description	Skills required
	<p>4. In the query editor, enter a CREATE TABLE statement such as the following:</p> <pre data-bbox="634 380 1029 1331">CREATE EXTERNAL TABLE   financials_json (     symbol string,     financials array&lt;       struct&lt;re portdate: string,           grossprof it: bigint,           totalreve nue: bigint,           totalcash : bigint,           totaldebt : bigint,           researcha nddevelopment:   bigint&gt;&gt;     ) ROW FORMAT SERDE   'org.openx.data.js onserde.JsonSerDe' LOCATION 's3://s3b ucket-for-athena/'</pre> <p>where LOCATION specifies the location of the S3 bucket that contains the JSON file.</p> <p>5. Choose <b>Run</b> to create the table.</p> <p>For more information about creating tables, see the <a href="#">Athena documentation</a>.</p>	

Task	Description	Skills required
Create a view for data analysis.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Athena console</a>.</li><li>2. Create a database by following the instructions in the <a href="#">Athena documentation</a>.</li><li>3. From the <b>Database</b> menu, choose the database that you created.</li><li>4. In the query editor, enter a CREATE VIEW statement such as the following:<pre data-bbox="630 806 1029 1717">CREATE OR REPLACE VIEW financial_json_view AS SELECT symbol, financials[1].report_date one_report_date, -- indexes start with 1 financials[1].total_revenue one_total_revenue, financials[1].report_date another_report_date, financials[1].total_revenue another_total_revenue FROM financials_json where symbol='AAPL' ORDER BY 1</pre></li><li>5. Choose <b>Run</b> to create the view.</li></ol>	Developer

Task	Description	Skills required
	For more information about creating views, see the <a href="#">Athena documentation</a> .	
Analyze and validate the data.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">Athena console</a>.</li> <li>2. In the query editor, run queries by using the view that you created in the previous step.</li> <li>3. Validate the data against the JSON file, to confirm that column names and data types are mapped correctly.</li> </ol>	Developer

## Visualize data in QuickSight

Task	Description	Skills required
Set up Athena as a data source in QuickSight.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">QuickSight console</a>.</li> <li>2. Choose <b>Datasets, New dataset</b>.</li> <li>3. Choose Athena as a data source.</li> <li>4. Choose the database that includes the view that you created.</li> <li>5. Choose the view that you want to create a dataset for.</li> </ol>	Systems administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>6. On the <b>Finish data set creation</b> page, choose <b>Directly query your data</b>.</li><li>7. Choose <b>Visualize</b>.</li></ol>	
Visualize data in QuickSight.	<ol style="list-style-type: none"><li>1. After you visualize the dataset, choose the visuals from the left pane, and choose fields for the dataset. For more information, see the <a href="#">tutorial</a> in the QuickSight documentation.</li><li>2. Save the changes to the analysis.</li><li>3. Choose <b>Publish dashboard</b> to publish the visuals that you created.</li></ol>	Data analyst

# Automate encryption enforcement in AWS Glue using an AWS CloudFormation template

Created by Diogo Guedes (AWS)

<b>Code repository:</b> <a href="#">AWS Glue Encryption Enforcement</a>	<b>Environment:</b> Production	<b>Technologies:</b> Analytics; Security, identity, compliance
<b>Workload:</b> All other workloads	<b>AWS services:</b> Amazon EventBridge; AWS Glue; AWS KMS; AWS Lambda; AWS CloudFormation	

## Summary

This pattern shows you how to set up and automate encryption enforcement in AWS Glue by using an AWS CloudFormation template. The template creates all the required configurations and resources for enforcing encryption. These resources include an initial configuration, a preventive control created by an Amazon EventBridge rule, and an AWS Lambda function.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Permissions to deploy the CloudFormation template and its resources

### Limitations

This security control is regional. You must deploy the security control in each AWS Region where you want to set up encryption enforcement in AWS Glue.

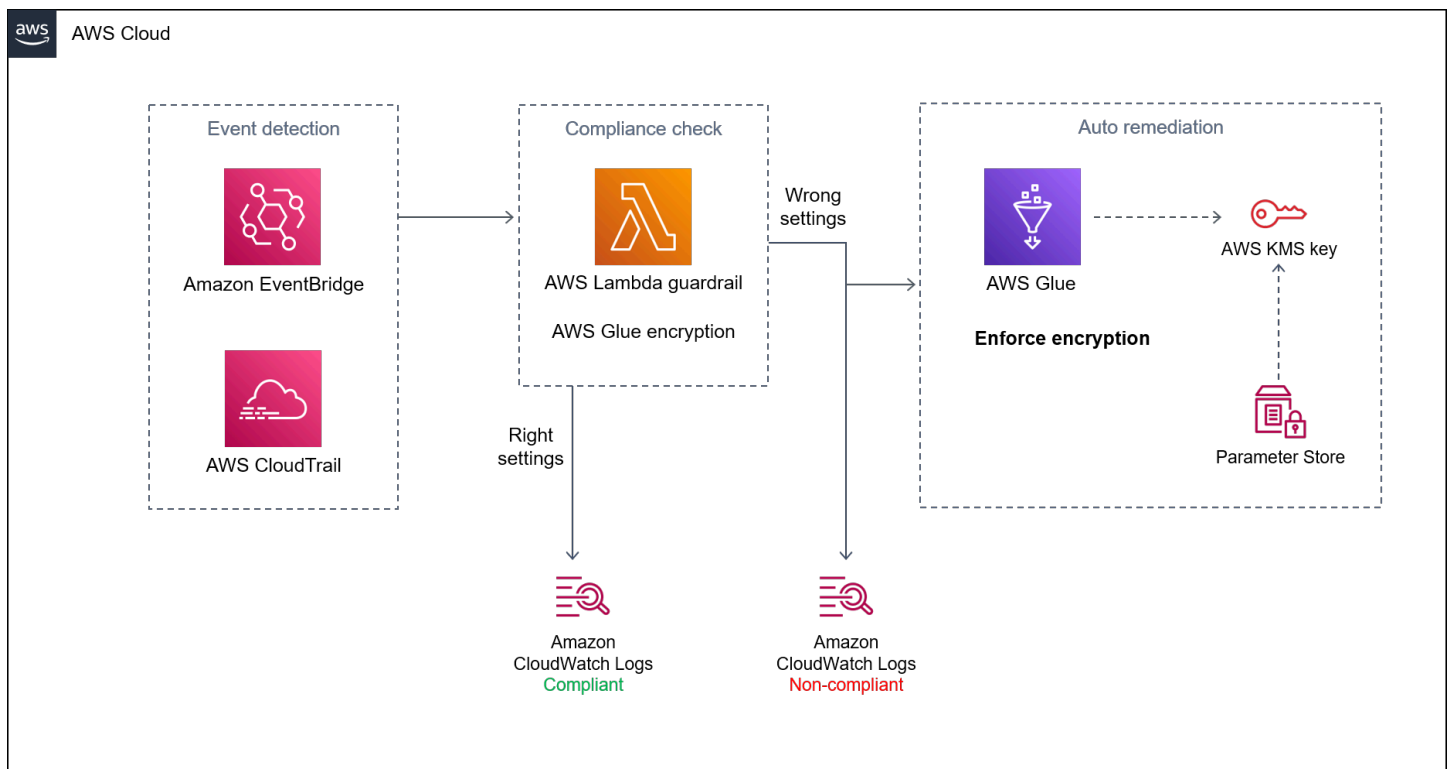

## Architecture

### Target technology stack

- Amazon CloudWatch Logs (from AWS Lambda)
- Amazon EventBridge rule
- AWS CloudFormation stack
- AWS CloudTrail
- AWS Identity and Access Management (IAM) managed role and policy
- AWS Key Management Service (AWS KMS)
- AWS KMS alias
- AWS Lambda function
- AWS Systems Manager Parameter Store

## Target architecture

The following diagram shows how to automate encryption enforcement in AWS Glue.

The diagram shows the following workflow:

1. A [CloudFormation template](#) creates all the resources, including the initial configuration and detective control for encryption enforcement in AWS Glue.

2. An EventBridge rule detects a state change in the encryption configuration.
3. A Lambda function is invoked for evaluation and logging through CloudWatch Logs. For non-compliant detection, the Parameter Store is recovered with an Amazon Resource Name (ARN) for an AWS KMS key. The service is remediated to compliant status with encryption enabled.

## Automation and scale

If you're using [AWS Organizations](#), you can use [AWS CloudFormation StackSets](#) to deploy this template in multiple accounts where you want to enable encryption enforcement in AWS Glue.

## Tools

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CloudTrail](#) helps you enable operational and risk auditing, governance, and compliance of your AWS account.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

## Code

The code for this pattern is available in the GitHub [aws-custom-guardrail-event-driven](#) repository.

## Best practices

AWS Glue supports data encryption at rest for [authoring jobs in AWS Glue](#) and [developing scripts using development endpoints](#).

Consider the following best practices:

- Configure ETL jobs and development endpoints to use AWS KMS keys to write encrypted data at rest.
- Encrypt the metadata stored in the [AWS Glue Data Catalog](#) by using keys that you manage through AWS KMS.
- Use AWS KMS keys to encrypt job bookmarks and the logs generated by [crawlers](#) and ETL jobs.

## Epics

### Launch the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	<p>Download the <code>aws-custom-guardrail-event-driven.yaml</code> template from the GitHub <a href="#">repository</a>, and then <a href="#">deploy</a> the template. The <code>CREATE_COMPLETE</code> status indicates that your template was successfully deployed.</p> <p><b>Note:</b> The template requires no input parameters.</p>	Cloud architect

## Verify the encryption settings in AWS Glue

Task	Description	Skills required
Check the AWS KMS key configurations.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and then open the <a href="#">AWS Glue console</a>.</li> <li>2. In the navigation pane, under <b>Data Catalog</b>, choose <b>Catalog settings</b>.</li> <li>3. Verify that the <b>Metadata encryption</b> and <b>Encrypt connection passwords</b> settings are flagged and configured to use <code>KMSKeyGlue</code>.</li> </ol>	Cloud architect

## Test the encryption enforcement

Task	Description	Skills required
Identify the encryption setting in CloudFormation.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and then open the <a href="#">CloudFormation console</a>.</li> <li>2. In the navigation pane, choose <b>Stacks</b>, and then choose your stack.</li> <li>3. Choose the <b>Resources</b> tab.</li> <li>4. In the <b>Resources</b> table, find the encryption setting by <b>Logical ID</b>.</li> </ol>	Cloud architect

Task	Description	Skills required
Switch the provisioned infrastructure to an uncompliant state.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and then open the <a href="#">AWS Glue console</a>.</li><li>2. In the navigation pane, under <b>Data Catalog</b>, choose <b>Catalog settings</b>.</li><li>3. Clear the <b>Metadata encryption</b> check box.</li><li>4. Clear the <b>Encrypt connection passwords</b> check box.</li><li>5. Choose <b>Save</b>.</li><li>6. Refresh the AWS Glue console.</li></ol> <p>The guardrail detects the uncompliant state in AWS Glue after you clear the check boxes, and then enforces compliance by automatically remediating the encryption misconfiguration. As a result, the encryption check boxes should again be selected after you refresh the page.</p>	Cloud architect

# Build a video processing pipeline by using Amazon Kinesis Video Streams and AWS Fargate

Created by Piotr Chotkowski (AWS) and Pushparaju Thangavel (AWS)

**Environment:** PoC or pilot

**Technologies:** Analytics;  
Media services

**AWS services:** AWS Fargate;  
Amazon Kinesis; Amazon S3

## Summary

This pattern demonstrates how to use [Amazon Kinesis Video Streams](#) and [AWS Fargate](#) to extract frames from a video stream and store them as image files for further processing in [Amazon Simple Storage Service \(Amazon S3\)](#).

The pattern provides a sample application in the form of a Java Maven project. This application defines the AWS infrastructure by using the [AWS Cloud Development Kit \(AWS CDK\)](#). Both the frame processing logic and the infrastructure definitions are written in the Java programming language. You can use this sample application as a basis for developing your own real-time video processing pipeline or to build the video preprocessing step of a machine learning pipeline.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Java SE Development Kit (JDK) 11, installed
- [Apache Maven](#), installed
- [AWS Cloud Development Kit \(AWS CDK\)](#), installed
- [AWS Command Line Interface \(AWS CLI\)](#) version 2, installed
- [Docker](#) (required for building Docker images to use in AWS Fargate task definitions), installed

### Limitations

This pattern is intended as a proof of concept, or as a basis for further development. It should not be used in its current form in production deployments.

## Product versions

- This pattern was tested with the AWS CDK version 1.77.0 (see [AWS CDK versions](#))
- JDK 11
- AWS CLI version 2

## Architecture

### Target technology stack

- Amazon Kinesis Video Streams
- AWS Fargate task
- Amazon Simple Queue Service (Amazon SQS) queue
- Amazon S3 bucket

### Target architecture

The user creates a Kinesis video stream, uploads a video, and sends a JSON message that contains details about the input Kinesis video stream and the output S3 bucket to an SQS queue. AWS Fargate, which is running the main application in a container, pulls the message from the SQS

queue and starts extracting frames. Each frame is saved in an image file and stored in the target S3 bucket.

## Automation and scale

The sample application can scale both horizontally and vertically within a single AWS Region. Horizontal scaling can be achieved by increasing the number of deployed AWS Fargate tasks that read from the SQS queue. Vertical scaling can be achieved by increasing the number of frame-splitting and image-publishing threads in the application. These settings are passed as environment variables to the application in the definition of the [QueueProcessingFargateService](#) resource in the AWS CDK. Due to the nature of AWS CDK stack deployment, you can deploy this application in multiple AWS Regions and accounts with no additional effort.

## Tools

### Tools

- [AWS CDK](#) is a software development framework for defining your cloud infrastructure and resources by using programming languages such as TypeScript, JavaScript, Python, Java, and C#/.Net.
- [Amazon Kinesis Video Streams](#) is a fully managed AWS service that you can use to stream live video from devices to the AWS Cloud, or build applications for real-time video processing or batch-oriented video analytics.
- [AWS Fargate](#) is a serverless compute engine for containers. Fargate removes the need to provision and manage servers, and lets you focus on developing your applications.
- [Amazon S3](#) is an object storage service that offers scalability, data availability, security, and performance.
- [Amazon SQS](#) is a fully managed message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications.

### Code

- A .zip file of the sample application project (`frame-splitter-code.zip`) is attached.

# Epics

## Deploy the infrastructure

Task	Description	Skills required
Start the Docker daemon.	Start the Docker daemon on your local system. The AWS CDK uses Docker to build the image that is used in the AWS Fargate task. You must run Docker before you proceed to the next step.	Developer, DevOps engineer
Build the project.	Download the <code>frame-splitter-code</code> sample application (attached) and extract its contents into a folder on your local machine. Before you can deploy the infrastructure, you have to build the <a href="#">Java Maven</a> project. At a command prompt, navigate to the root directory of the project, and build the project by running the command: <pre>mvn clean install</pre>	Developer, DevOps engineer
Bootstrap the AWS CDK.	(First-time AWS CDK users only) If this is the first time you're using the AWS CDK, you might have to bootstrap the environment by running the AWS CLI command:	Developer, DevOps engineer

Task	Description	Skills required
	<pre>cdk bootstrap --profile "\$AWS_PROFILE_NAME"</pre> <p>where \$AWS_PROFILE_NAME holds the name of the AWS profile from your AWS credentials. Or, you can remove this parameter to use the default profile. For more information, see the <a href="#">AWS CDK documentation</a>.</p>	

Task	Description	Skills required
Deploy the AWS CDK stack.	<p>In this step, you create the required infrastructure resources (SQS queue, S3 bucket, AWS Fargate task definition) in your AWS account, build the Docker image that is required for the AWS Fargate task, and deploy the application. At a command prompt, navigate to the root directory of the project, and run the command:</p> <pre data-bbox="597 871 1027 1031">cdk deploy --profile "\$AWS_PROFILE_NAME" --all</pre> <p>where <code>\$AWS_PROFILE_NAME</code> holds the name of the AWS profile from your AWS credentials. Or, you can remove this parameter to use the default profile. Confirm the deployment. Note the <b>QueueUrl</b> and <b>Bucket</b> values from the CDK deployment output; you will need these in later steps. The AWS CDK creates the assets, uploads them to your AWS account, and creates all infrastructure resources. You can observe the resource creation process in the <a href="#">AWS CloudFormation</a></p>	Developer, DevOps engineer

Task	Description	Skills required
	<p><a href="#">console</a>. For more information, see the <a href="#">AWS CloudFormation documentation</a> and the <a href="#">AWS CDK documentation</a>.</p>	

Task	Description	Skills required
Create a video stream.	<p>In this step, you create a Kinesis video stream that will serve as an input stream for video processing. Make sure that you have the AWS CLI installed and configured. In the AWS CLI, run:</p> <pre data-bbox="594 583 1029 905">aws kinesismedia   --profile "\$AWS_PRO FILE_NAME" create-st ream --stream-name   "\$STREAM_NAME" --data- retention-in-hours   "24"</pre> <p>where <code>\$AWS_PROFILE</code> holds the name of the AWS profile from your AWS credentials (or remove this parameter to use the default profile) and <code>\$STREAM_NAME</code> is any valid stream name.</p> <p>Alternatively, you can create a video stream by using the Kinesis console by following the steps in the <a href="#">Kinesis Video Streams documentation</a>.</p> <p>Note the AWS Resource Name (ARN) of the created stream; you will need it later.</p>	Developer, DevOps engineer

## Run an example

Task	Description	Skills required
Upload the video to the stream.	<p>In the project folder for the <code>sample frame-splitter-code</code> application, open the <code>ProcessingTaskTest.java</code> file in the <code>src/test/java/amazon/awscdk/examples/splitter</code> folder. Replace the <code>profileName</code> and <code>streamName</code> variables with the values you used in the previous steps. To upload the example video to the Kinesis video stream you created in the previous step, run:</p> <pre>amazon.awscdk.examples.splitter.ProcessingTaskTest#testExample test</pre> <p>Alternatively, you can upload your video by using one of the methods described in the <a href="#">Kinesis Video Streams documentation</a>.</p>	Developer, DevOps engineer
Initiate video processing.	<p>Now that you have uploaded a video to the Kinesis video stream, you can start processing it. To initiate the processing logic, you have to send a message with</p>	Developer, DevOps engineer

Task	Description	Skills required
	<p>details to the SQS queue that the AWS CDK created during deployment. To send a message by using the AWS CLI, run:</p> <pre>aws sqs --profile "\$AWS_PROFILE_NAME" send-message --queue-url QUEUE_URL --message-body MESSAGE</pre> <p>where <code>\$AWS_PROFILE_NAME</code> holds the name of the AWS profile from your AWS credentials (remove this parameter to use the default profile), <code>QUEUE_URL</code> is the <b>QueueUrl</b> value from the AWS CDK output, and <code>MESSAGE</code> is a JSON string in the following format:</p> <pre>{ "streamARN": "STREAM_ARN", "bucket": "BUCKET_NAME", "s3Directory": "test-output" }</pre> <p>where <code>STREAM_ARN</code> is the ARN of the video stream you created in an earlier step and <code>BUCKET_NAME</code> is the <b>Bucket</b> value from the AWS CDK output.</p>	

Task	Description	Skills required
	Sending this message initiates video processing. Alternatively, you can send a message by using the Amazon SQS console, as described in the <a href="#">Amazon SQS documentation</a> .	
View images of the video frames.	You can see the resulting images in the S3 output bucket <code>s3://BUCKET_NAME/test-output</code> where <code>BUCKET_NAME</code> is the <b>Bucket</b> value from the AWS CDK output.	Developer, DevOps engineer

## Additional information

### Choosing an IDE

We recommend that you use your favorite Java IDE to build and explore this project.

### Cleaning up

After you finish running this example, remove all deployed resources to avoid incurring additional AWS infrastructure costs.

To remove the infrastructure and the video stream, use these two commands in the AWS CLI:

```
cdk destroy --profile "$AWS_PROFILE_NAME" --all
```

```
aws kinesisanalyticsv2 --profile "$AWS_PROFILE_NAME" delete-stream --stream-arn "$STREAM_ARN"
```

Alternatively, you can remove the resources manually by using the AWS CloudFormation console to remove the AWS CloudFormation stack, and the Kinesis console to remove the Kinesis video stream. Note that `cdk destroy` doesn't remove the output S3 bucket or the images in Amazon Elastic Container Registry (Amazon ECR) repositories (`aws-cdk/assets`). You have to remove them manually.

# Build an ETL service pipeline to load data incrementally from Amazon S3 to Amazon Redshift using AWS Glue

Created by Rohan Jamadagni (AWS) and Arunabha Datta (AWS)

**Environment:** Production

**Technologies:** Analytics;  
Data lakes; Storage & backup

**AWS services:** Amazon  
Redshift; Amazon S3; AWS  
Glue; AWS Lambda

## Summary

This pattern provides guidance on how to configure Amazon Simple Storage Service (Amazon S3) for optimal data lake performance, and then load incremental data changes from Amazon S3 into Amazon Redshift by using AWS Glue, performing extract, transform, and load (ETL) operations.

The source files in Amazon S3 can have different formats, including comma-separated values (CSV), XML, and JSON files. This pattern describes how you can use AWS Glue to convert the source files into a cost-optimized and performance-optimized format like Apache Parquet. You can query Parquet files directly from Amazon Athena and Amazon Redshift Spectrum. You can also load Parquet files into Amazon Redshift, aggregate them, and share the aggregated data with consumers, or visualize the data by using Amazon QuickSight.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An S3 source bucket that has the right privileges and contains CSV, XML, or JSON files.

### Assumptions

- The CSV, XML, or JSON source files are already loaded into Amazon S3 and are accessible from the account where AWS Glue and Amazon Redshift are configured.
- Best practices for loading the files, splitting the files, compression, and using a manifest are followed, as discussed in the [Amazon Redshift documentation](#).

- The source file structure is unaltered.
- The source system is able to ingest data into Amazon S3 by following the folder structure defined in Amazon S3.
- The Amazon Redshift cluster spans a single Availability Zone. (This architecture is appropriate because AWS Lambda, AWS Glue, and Amazon Athena are serverless.) For high availability, cluster snapshots are taken at a regular frequency.

## Limitations

- The file formats are limited to those that are [currently supported by AWS Glue](#).
- Real-time downstream reporting isn't supported.

## Architecture

### Source technology stack

- S3 bucket with CSV, XML, or JSON files

### Target technology stack

- S3 data lake (with partitioned Parquet file storage)
- Amazon Redshift

### Target architecture

### Data flow

## Tools

- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [AWS Lambda](#) – AWS Lambda lets you run code without provisioning or managing servers. AWS Lambda is an event-driven service; you can set up your code to automatically initiate from other AWS services.
- [Amazon Redshift](#) – Amazon Redshift is a fully managed, petabyte-scale data warehouse service. With Amazon Redshift, you can query petabytes of structured and semi-structured data across your data warehouse and your data lake using standard SQL.
- [AWS Glue](#) – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics. AWS Glue discovers your data and stores the associated metadata (for example, table definitions and schema) in the AWS Glue Data Catalog. Your cataloged data is immediately searchable, can be queried, and is available for ETL.
- [AWS Secrets Manager](#) – AWS Secrets Manager facilitates protection and central management of secrets needed for application or service access. The service stores database credentials, API keys, and other secrets, and eliminates the need to hardcode sensitive information in plaintext format. Secrets Manager also offers key rotation to meet security and compliance needs. It has built-in integration for Amazon Redshift, Amazon Relational Database Service (Amazon RDS), and Amazon DocumentDB. You can store and centrally manage secrets by using the Secrets Manager console, the command-line interface (CLI), or Secrets Manager API and SDKs.
- [Amazon Athena](#) – Amazon Athena is an interactive query service that makes it easy to analyze data that's stored in Amazon S3. Athena is serverless and integrated with AWS Glue, so it can directly query the data that's cataloged using AWS Glue. Athena is elastically scaled to deliver interactive query performance.

## Epics

### Create the S3 buckets and folder structure

Task	Description	Skills required
Analyze source systems for data structure and attributes.	Perform this task for each data source that contributes to the Amazon S3 data lake.	Data engineer
Define the partition and access strategy.	This strategy should be based on the frequency of data captures, delta processing, and consumption needs. Make sure that S3 buckets are not open to the public and that access is controlled by specific service role-based policies only. For more information, see the <a href="#">Amazon S3 documentation</a> .	Data engineer
Create separate S3 buckets for each data source type and a separate S3 bucket per source for the processed (Parquet) data.	Create a separate bucket for each source, and then create a folder structure that's based on the source system's data ingestion frequency ; for example, <code>s3://source-system-name/date/hour</code> . For the processed (converted to Parquet format) files, create a similar structure ; for example, <code>s3://source-processed-bucket/date/hour</code> . For more information about creating S3	Data engineer

Task	Description	Skills required
	buckets, see the <a href="#">Amazon S3 documentation</a> .	

## Create a data warehouse in Amazon Redshift

Task	Description	Skills required
Launch the Amazon Redshift cluster with the appropriate parameter groups and maintenance and backup strategy.	Use the Secrets Manager database secret for admin user credentials while creating the Amazon Redshift cluster. For information about creating and sizing an Amazon Redshift cluster, see the <a href="#">Amazon Redshift documentation</a> and the <a href="#">Sizing Cloud Data Warehouses</a> whitepaper.	Data engineer
Create and attach the IAM service role to the Amazon Redshift cluster.	The AWS Identity and Access Management (IAM) service role ensures access to Secrets Manager and the source S3 buckets. For more information, see the AWS documentation on <a href="#">authorization</a> and <a href="#">adding a role</a> .	Data engineer
Create the database schema.	Follow Amazon Redshift best practices for table design. Based on the use case, choose the appropriate sort and distribution keys, and the best possible compression	Data engineer

Task	Description	Skills required
	encoding. For best practices, see the <a href="#">AWS documentation</a> .	
Configure workload management.	Configure workload management (WLM) queues, short query acceleration (SQA), or concurrency scaling, depending on your requirements. For more information, see <a href="#">Implementing workload management</a> in the Amazon Redshift documentation.	Data engineer

## Create a secret in Secrets Manager

Task	Description	Skills required
Create a new secret to store the Amazon Redshift sign-in credentials in Secrets Manager.	This secret stores the credentials for the admin user as well as individual database service users. For instructions, see the <a href="#">Secrets Manager documentation</a> . Choose <b>Amazon Redshift Cluster</b> as the secret type. Additionally, on the <b>Secret rotation</b> page, turn on the rotation. This will create the appropriate user in the Amazon Redshift cluster and will rotate the key secrets at defined intervals.	Data engineer
Create an IAM policy to restrict Secrets Manager access.	Restrict Secrets Manager access to only Amazon	Data engineer

Task	Description	Skills required
	Redshift administrators and AWS Glue.	

## Configure AWS Glue

Task	Description	Skills required
In the AWS Glue Data Catalog, add a connection for Amazon Redshift.	For instructions, see the <a href="#">AWS Glue documentation</a> .	Data engineer
Create and attach an IAM service role for AWS Glue to access Secrets Manager, Amazon Redshift, and S3 buckets.	For more information, see the <a href="#">AWS Glue documentation</a> .	Data engineer
Define the AWS Glue Data Catalog for the source.	This step involves creating a database and required tables in the AWS Glue Data Catalog. You can either use a crawler to catalog the tables in the AWS Glue database, or define them as Amazon Athena external tables. You can also access the external tables defined in Athena through the AWS Glue Data Catalog. See the AWS documentation for more information about <a href="#">defining the Data Catalog</a> and <a href="#">creating an external table</a> in Athena.	Data engineer

Task	Description	Skills required
Create an AWS Glue job to process source data.	The AWS Glue job can be a Python shell or PySpark to standardize, deduplicate, and cleanse the source data files. To optimize performance and avoid having to query the entire S3 source bucket, partition the S3 bucket by date, broken down by year, month, day, and hour as a pushdown predicate for the AWS Glue job. For more information, see the <a href="#">AWS Glue documentation</a> . Load the processed and transformed data to the processed S3 bucket partitions in Parquet format. You can query the Parquet files from Athena.	Data engineer
Create an AWS Glue job to load data into Amazon Redshift.	The AWS Glue job can be a Python shell or PySpark to load the data by upserting the data, followed by a complete refresh. For details, see the <a href="#">AWS Glue documentation</a> and the <i>Additional information</i> section.	Data engineer

Task	Description	Skills required
(Optional) Schedule AWS Glue jobs by using triggers as necessary.	The incremental data load is primarily driven by an Amazon S3 event that causes an AWS Lambda function to call the AWS Glue job. Use AWS Glue trigger-based scheduling for any data loads that demand time-based instead of event-based scheduling.	Data engineer

## Create a Lambda function

Task	Description	Skills required
Create and attach an IAM service-linked role for AWS Lambda to access S3 buckets and the AWS Glue job.	Create an IAM service-linked role for AWS Lambda with a policy to read Amazon S3 objects and buckets, and a policy to access the AWS Glue API to start an AWS Glue job. For more information, see the <a href="#">Knowledge Center</a> .	Data engineer
Create a Lambda function to run the AWS Glue job based on the defined Amazon S3 event.	The Lambda function should be initiated by the creation of the Amazon S3 manifest file. The Lambda function should pass the Amazon S3 folder location (for example, source_bucket/year/month/date/hour) to the AWS Glue job as a parameter. The AWS Glue job will use this	Data engineer

Task	Description	Skills required
	parameter as a pushdown predicate to optimize file access and job processing performance. For more information, see the <a href="#">AWS Glue documentation</a> .	
Create an Amazon S3 PUT object event to detect object creation, and call the respective Lambda function.	The Amazon S3 PUT object event should be initiated only by the creation of the manifest file. The manifest file controls the Lambda function and the AWS Glue job concurrency, and processes the load as a batch instead of processing individual files that arrive in a specific partition of the S3 source bucket. For more information, see the <a href="#">Lambda documentation</a> .	Data engineer

## Additional information

### Detailed approach for upsert and complete refresh

**Upsert:** This is for datasets that require historical aggregation, depending on the business use case. Follow one of the approaches described in [Updating and inserting new data](#) (Amazon Redshift documentation) based on your business needs.

**Complete refresh:** This is for small datasets that don't need historical aggregations. Follow one of these approaches:

1. Truncate the Amazon Redshift table.
2. Load the current partition from the staging area

or:

1. Create a temporary table with current partition data.
2. Drop the target Amazon Redshift table.
3. Rename the temporary table to the target table.

# Calculate value at risk (VaR) by using AWS services

*Created by Sumon Samanta (AWS)*

**Environment:** PoC or pilot

**Technologies:** Analytics;  
Serverless

**AWS services:** Amazon  
Kinesis Data Streams; AWS  
Lambda; Amazon SQS;  
Amazon ElastiCache

## Summary

This pattern describes how to implement a value at risk (VaR) calculation system by using AWS services. In an on-premises environment, most VaR systems use a large, dedicated infrastructure and in-house or commercial grid scheduling software to run batch processes. This pattern presents a simple, reliable, and scalable architecture to handle VaR processing in the AWS Cloud. It builds a serverless architecture that uses Amazon Kinesis Data Streams as a streaming service, Amazon Simple Queue Service (Amazon SQS) as a managed queue service, Amazon ElastiCache as a caching service, and AWS Lambda to process orders and calculate risk.

VaR is a statistical measure that traders and risk managers use to estimate potential loss in their portfolio beyond a certain confidence level. Most VaR systems involve running a large number of mathematical and statistical calculations and storing the results. These calculations require significant compute resources, so VaR batch processes have to be broken into smaller sets of compute tasks. Splitting a large batch into smaller tasks is possible because these tasks are mostly independent (that is, calculations for one task don't depend on other tasks).

Another important requirement for a VaR architecture is compute scalability. This pattern uses a serverless architecture that automatically scales in or out based on compute load. Because the batch or online compute demand is difficult to predict, dynamic scaling is required to complete the process within the timeline imposed by a service-level agreement (SLA). Also, a cost-optimized architecture should be able to scale down each compute resource as soon as the tasks on that resource are complete.

AWS services are well-suited for VaR calculations because they offer scalable compute and storage capacity, analytics services for processing in a cost-optimized way, and different types of schedulers to run your risk management workflows. Also, you pay only for the compute and storage resources that you use on AWS.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Input files, which depend on your business requirements. A typical use case involves the following input files:
  - Market data file (input to the VaR calculation engine)
  - Trade data file (unless trade data comes through a stream).
  - Configuration data file (model and other static configuration data)
  - Calculation engine model files (quantitative libraries)
  - Time series data file (for historical data such as the stock price for the last five years)
- If the market data or other input comes in through a stream, Amazon Kinesis Data Streams set up, and Amazon Identity and Access Management (IAM) permissions configured to write to the stream.

This pattern builds an architecture in which trade data is written from a trading system to a Kinesis data stream. Instead of using a streaming service, you can save your trade data in small batch files, store them in an Amazon Simple Storage Service (Amazon S3) bucket, and invoke an event to start processing the data.

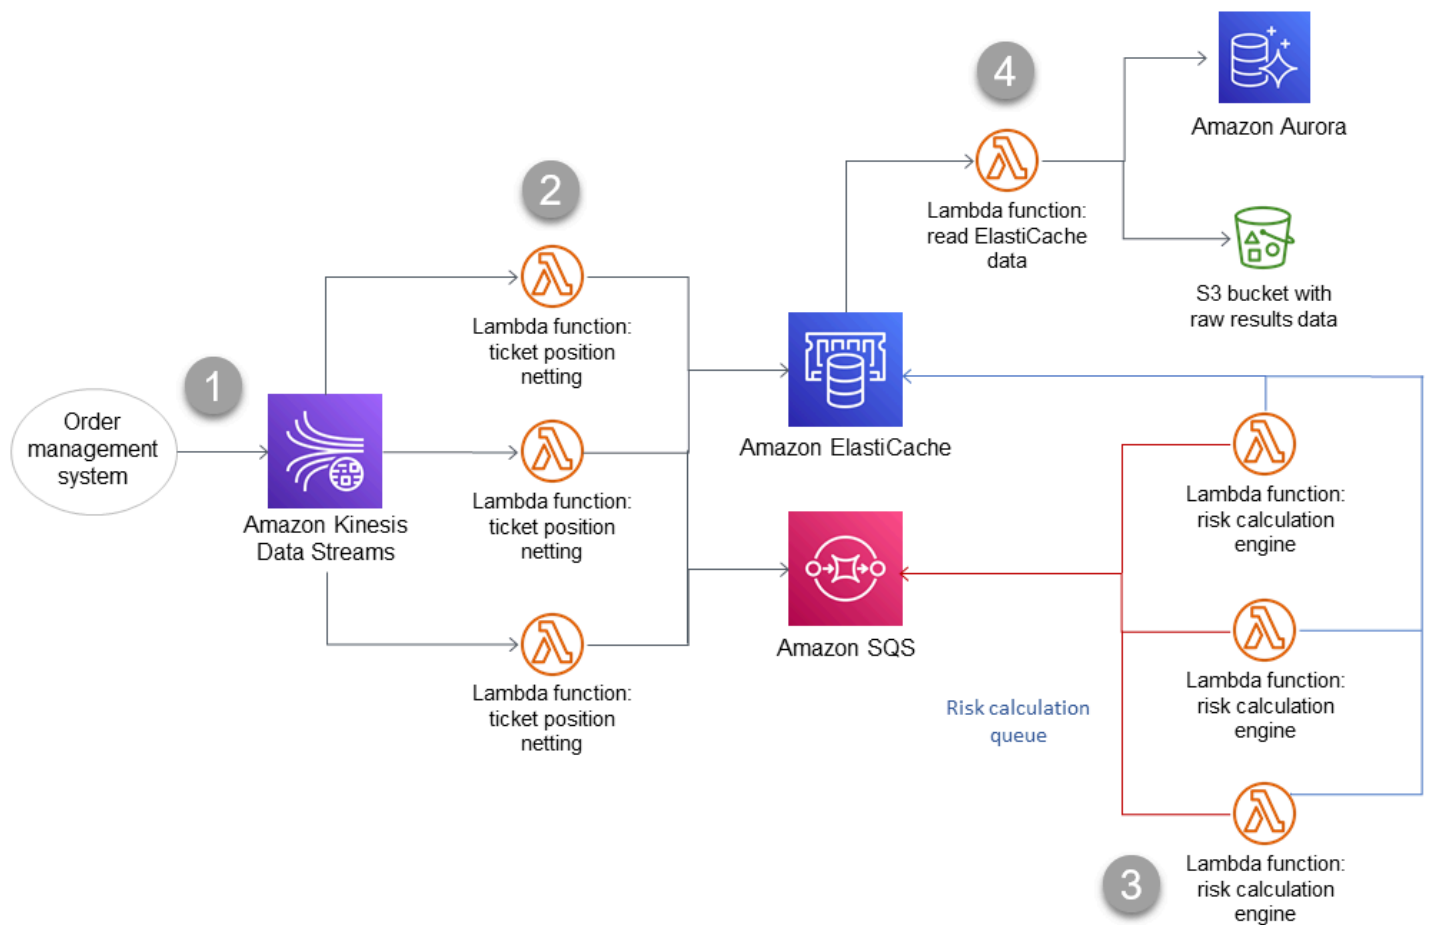

### Limitations

- Kinesis data stream sequencing is guaranteed on each shard, so trade orders that are written to multiple shards are not guaranteed to be delivered in the same order as write operations.
- The AWS Lambda runtime limit is currently 15 minutes. (For more information, see the [Lambda FAQ](#).)

## Architecture

### Target architecture

The following architecture diagram displays the AWS services and workflows for the risk assessment system.

The diagram illustrates the following:

1. Trades stream in from the order management system.
2. The *ticket position netting* Lambda function processes the orders and writes consolidated messages for each ticker to a risk queue in Amazon SQS.
3. The *risk calculation engine* Lambda function processes the messages from Amazon SQS, performs risk calculations, and updates the VaR profit and loss (PnL) information in the risk cache in Amazon ElastiCache.
4. The *read ElastiCache data* Lambda function retrieves the risk results from ElastiCache and stores them in a database and S3 bucket.

For more information about these services and steps, see the *Epics* section.

## Automation and scale

You can deploy the entire architecture by using the AWS Cloud Development Kit (AWS CDK) or AWS CloudFormation templates. The architecture can support both batch processing and intraday (real-time) processing.

Scaling is built into the architecture. As more trades are written into the Kinesis data stream and are waiting to be processed, additional Lambda functions can be invoked to process those trades and can then scale down after processing is complete. Processing through multiple Amazon SQS risk calculation queues is also an option. If strict ordering or consolidation is required across queues, processing cannot be parallelized. However, for an end-of-the-day batch or a mini intraday batch, the Lambda functions can process in parallel and store the final results in ElastiCache.

## Tools

### AWS services

- [Amazon Aurora MySQL-Compatible Edition](#) is a fully managed, MySQL-compatible relational database engine that helps you set up, operate, and scale MySQL deployments. This pattern uses MySQL as an example, but you can use any RDBMS system to store data.
- [Amazon ElastiCache](#) helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.
- [Amazon Kinesis Data Streams](#) helps you collect and process large streams of data records in real time.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Queue Service \(Amazon SQS\)](#) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Code

This pattern provides an example architecture for a VaR system in the AWS Cloud and describes how you can use Lambda functions for VaR calculations. To create your Lambda functions, see the code examples in the [Lambda documentation](#). For assistance, contact [AWS Professional Services](#).

## Best practices

- Keep each VaR compute task as small and lightweight as possible. Experiment with different numbers of trades in each compute task to see which one is most optimized for compute time and cost.
- Store reusable objects in Amazon ElastiCache. Use a framework such as Apache Arrow to reduce serialization and deserialization.
- Consider Lambda's time limitation. If you think your compute tasks might exceed 15 minutes, try to break them down into smaller tasks to avoid the Lambda timeout. If this is not possible, you might consider a container orchestration solution with AWS Fargate, Amazon Elastic Container Service (Amazon ECS), and Amazon Elastic Kubernetes Service (Amazon EKS).

## Epics

### Trade flow to risk system

Task	Description	Skills required
Start writing trades.	New, settled, or partially settled trades are written from the order management system to a risk stream. This pattern uses Amazon Kinesis as the managed streaming service. The trade order ticker's hash is used to put trade orders across multiple shards.	Amazon Kinesis

### Run Lambda functions for order processing

Task	Description	Skills required
Start risk processing with Lambda.	Run an AWS Lambda function for the new orders. Based	Amazon Kinesis, AWS Lambda, Amazon ElastiCache

Task	Description	Skills required
	<p>on the number of pending trade orders, Lambda will automatically scale. Each Lambda instance has one or more orders and retrieves the latest position for each ticker from Amazon ElastiCache. (You can use a CUSIP ID, a Curve name, or an index name for other financial derivative products as a key to store and retrieve data from ElastiCache.) In ElastiCache, the total position (quantity) and the key-value pair <i>&lt;ticker, net position&gt;</i>, where <i>net position</i> is the scaling factor, are updated once for each ticker.</p>	

### Write messages for each ticker into queue

Task	Description	Skills required
<p>Write consolidated messages to the risk queue.</p>	<p>Write the message to a queue. This pattern uses Amazon SQS as a managed queue service. A single Lambda instance might get a mini batch of trade orders at any given time, but will write only a single message for each ticker to Amazon SQS. A scaling factor is calculate</p>	<p>Amazon SQS, AWS Lambda</p>

Task	Description	Skills required
	$d: (old\ net\ position + current\ position) / old\ net\ position.$	

## Invoke risk engine

Task	Description	Skills required
Start risk calculations.	The Lambda function for the risk engine lambda is invoked. Each position is processed by a single Lambda function. However, for optimization purposes, each Lambda function can process multiple messages from Amazon SQS.	Amazon SQS, AWS Lambda

## Retrieve risk results from cache

Task	Description	Skills required
Retrieve and update risk cache.	<p>Lambda retrieves the current net position for each ticker from ElastiCache. It also retrieves a VaR profit and loss (PnL) array for each ticker from ElastiCache.</p> <p>If the PnL array already exists, the Lambda function updates the array and VaR with a scale, which comes from the Amazon SQS message written by the netting Lambda function. If the PnL array isn't</p>	Amazon SQS, AWS Lambda, Amazon ElastiCache

Task	Description	Skills required
	in ElasticCache, a new PnL and VaR are calculated by using simulated ticker price series data.	

## Update data in Elastic Cache and store in database

Task	Description	Skills required
Store risk results.	After the VaR and PnL numbers are updated in ElasticCache, a new Lambda function is invoked every five minutes. This function reads all stored data from ElasticCache and stores it in an Aurora MySQL-Compatible database and in an S3 bucket.	AWS Lambda, Amazon ElastiCache

# Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL

<b>Source:</b> Teradata data warehouse	<b>Target:</b> Amazon Redshift	<b>R Type:</b> Re-architect
<b>Environment:</b> Production	<b>Technologies:</b> Analytics; Databases; Migration	<b>Workload:</b> All other workloads
<b>AWS services:</b> Amazon Redshift		

## Summary

**NORMALIZE** is a Teradata extension to the ANSI SQL standard. When a SQL table includes a column that has a **PERIOD** data type, **NORMALIZE** combines values that meet or overlap in that column, to form a single period that consolidates multiple, individual period values. To use **NORMALIZE**, at least one column in the SQL **SELECT** list must be of Teradata's temporal **PERIOD** data type. For more information about **NORMALIZE**, see the [Teradata documentation](#).

Amazon Redshift doesn't support **NORMALIZE**, but you can implement this functionality by using native SQL syntax and the **LAG** window function in Amazon Redshift. This pattern focuses on using the Teradata **NORMALIZE** extension with the **ON MEETS OR OVERLAPS** condition, which is the most popular format. It explains how this feature works in Teradata and how it can be converted into Amazon Redshift native SQL syntax.

## Prerequisites and limitations

### Prerequisites

- Basic Teradata SQL knowledge and experience
- Amazon Redshift knowledge and experience

## Architecture

### Source technology stack

- Teradata data warehouse

## Target technology stack

- Amazon Redshift

## Target architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern [Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents](#). The migration doesn't automatically convert the Teradata **NORMALIZE** phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in this pattern.

## Tools

### Code

To illustrate the concept and functionality of **NORMALIZE**, consider the following table definition in Teradata:

```
CREATE TABLE systest.project
(
    emp_id          INTEGER,
    project_name    VARCHAR(20),
    dept_id         INTEGER,
    duration        PERIOD(DATE)
);
```

Run the following SQL code to insert sample data into the table:

```
BEGIN TRANSACTION;

INSERT INTO systest.project VALUES (10, 'First Phase', 1000, PERIOD(DATE '2010-01-10',
DATE '2010-03-20')) );
INSERT INTO systest.project VALUES (10, 'First Phase', 2000, PERIOD(DATE '2010-03-20',
DATE '2010-07-15')) );

INSERT INTO systest.project VALUES (10, 'Second Phase', 2000, PERIOD(DATE
'2010-06-15', DATE '2010-08-18')) );
INSERT INTO systest.project VALUES (20, 'First Phase', 2000, PERIOD(DATE '2010-03-10',
DATE '2010-07-20')) );
```

```
INSERT INTO systest.project VALUES (20, 'Second Phase', 1000, PERIOD(DATE
  '2020-05-10', DATE '2020-09-20') );

END TRANSACTION;
```

## Results:

```
select * from systest.project order by 1,2,3;
```

```
*** Query completed. 4 rows found. 4 columns returned.
*** Total elapsed time was 1 second.
```

emp_id	project_name	dept_id	duration
10	First Phase	1000	('10/01/10', '10/03/20')
10	First Phase	2000	('10/03/20', '10/07/15')
10	Second Phase	2000	('10/06/15', '10/08/18')
20	First Phase	2000	('10/03/10', '10/07/20')
20	Second Phase	1000	('20/05/10', '20/09/20')

## Teradata NORMALIZE use case

Now add the Teradata **NORMALIZE** SQL clause to the **SELECT** statement:

```
SELECT NORMALIZE ON MEETS OR OVERLAPS emp_id, duration
FROM systest.project
ORDER BY 1,2;
```

This **NORMALIZE** operation is performed on a single column (`emp_id`). For `emp_id=10`, the three overlapping period values in `duration` coalesce into a single period value, as follows:

emp_id	duration
10	('10/01/10', '10/08/18')
20	('10/03/10', '10/07/20')
20	('20/05/10', '20/09/20')

The following **SELECT** statement performs a **NORMALIZE** operation on `project_name` and `dept_id`. Note that the **SELECT** list contains only one **PERIOD** column, `duration`.

```
SELECT NORMALIZE project_name, dept_id, duration
```

```
FROM systest.project;
```

## Output:

project_name	dept_id	duration
First Phase	1000	('10/01/10', '10/03/20')
Second Phase	1000	('20/05/10', '20/09/20')
First Phase	2000	('10/03/10', '10/07/20')
Second Phase	2000	('10/06/15', '10/08/18')

## Amazon Redshift equivalent SQL

Amazon Redshift currently doesn't support the **PERIOD** data type in a table. Instead, you need to divide a Teradata **PERIOD** data field into two parts: `start_date`, `end_date`, as follows:

```
CREATE TABLE systest.project
(
  emp_id      INTEGER,
  project_name VARCHAR(20),
  dept_id     INTEGER,
  start_date  DATE,
  end_date    DATE
);
```

## Insert sample data into the table:

```
BEGIN TRANSACTION;

INSERT INTO systest.project VALUES (10, 'First Phase', 1000, DATE '2010-01-10', DATE
'2010-03-20' );
INSERT INTO systest.project VALUES (10, 'First Phase', 2000, DATE '2010-03-20', DATE
'2010-07-15');

INSERT INTO systest.project VALUES (10, 'Second Phase', 2000, DATE '2010-06-15', DATE
'2010-08-18' );
INSERT INTO systest.project VALUES (20, 'First Phase', 2000, DATE '2010-03-10', DATE
'2010-07-20' );

INSERT INTO systest.project VALUES (20, 'Second Phase', 1000, DATE '2020-05-10', DATE
'2020-09-20' );

END TRANSACTION;
```

**Output:**

emp_id	project_name	dept_id	start_date	end_date
10	First Phase	1000	2010-01-10	2010-03-20
10	First Phase	2000	2010-03-20	2010-07-15
10	Second Phase	2000	2010-06-15	2010-08-18
20	First Phase	2000	2010-03-10	2010-07-20
20	Second Phase	1000	2020-05-10	2020-09-20

(5 rows)

To rewrite Teradata's **NORMALIZE** clause, you can use the [LAG window function](#) in Amazon Redshift. This function returns the values for a row at a given offset above (before) the current row in the partition.

You can use the **LAG** function to identify each row that begins a new period by determining if a period meets or overlaps with the previous period (0 if yes and 1 if no). When this flag is cumulatively summed up, it provides a group identifier that can be used in the outer **Group By** clause to arrive at the desired result in Amazon Redshift.

Here's a sample Amazon Redshift SQL statement that uses **LAG()**:

```
SELECT emp_id, start_date, end_date,
       (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY
start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project
ORDER BY 1,2;
```

**Output:**

emp_id	start_date	end_date	groupstartflag
10	2010-01-10	2010-03-20	1
10	2010-03-20	2010-07-15	0
10	2010-06-15	2010-08-18	0
20	2010-03-10	2010-07-20	1
20	2020-05-10	2020-09-20	1

(5 rows)

The following Amazon Redshift SQL statement normalizes only on the emp\_id column:

```

SELECT T2.emp_id, MIN(T2.start_date) as new_start_date, MAX(T2.end_date) as
  new_end_date
FROM
( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY emp_id ORDER BY start_date ROWS
  UNBOUNDED PRECEDING) As GroupID
FROM ( SELECT emp_id, start_date, end_date,
          (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY
            start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project ) T1
) T2
GROUP BY T2.emp_id, T2.GroupID
ORDER BY 1,2;

```

**Output:**

```

emp_id | new_start_date | new_end_date
-----+-----+-----
    10 | 2010-01-10    | 2010-08-18
    20 | 2010-03-10    | 2010-07-20
    20 | 2020-05-10    | 2020-09-20
(3 rows)

```

The following Amazon Redshift SQL statement normalizes on both the project\_name and dept\_id columns:

```

SELECT T2.project_name, T2.dept_id, MIN(T2.start_date) as new_start_date,
  MAX(T2.end_date) as new_end_date
FROM
( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY project_name, dept_id ORDER BY
  start_date ROWS UNBOUNDED PRECEDING) As GroupID
FROM ( SELECT project_name, dept_id, start_date, end_date,
          (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY project_name,
            dept_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project ) T1
) T2
GROUP BY T2.project_name, T2.dept_id, T2.GroupID
ORDER BY 1,2,3;

```

**Output:**

```

project_name | dept_id | new_start_date | new_end_date
-----+-----+-----+-----
First Phase | 1000 | 2010-01-10 | 2010-03-20
First Phase | 2000 | 2010-03-10 | 2010-07-20
Second Phase | 1000 | 2020-05-10 | 2020-09-20
Second Phase | 2000 | 2010-06-15 | 2010-08-18
(4 rows)

```

# Convert the Teradata RESET WHEN feature to Amazon Redshift SQL

<b>Source:</b> Teradata data warehouse	<b>Target:</b> Amazon Redshift	<b>R Type:</b> Re-architect
<b>Environment:</b> Production	<b>Technologies:</b> Analytics; Databases; Migration	<b>Workload:</b> All other workloads
<b>AWS services:</b> Amazon Redshift		

## Summary

**RESET WHEN** is a Teradata feature used in SQL analytical window functions. It is an extension to the ANSI SQL standard. **RESET WHEN** determines the partition over which an SQL window function operates based on some specified condition. If the condition evaluates to **TRUE**, a new, dynamic sub-partition is created inside the existing window partition. For more information about **RESET WHEN**, see the [Teradata documentation](#).

Amazon Redshift doesn't support **RESET WHEN** in SQL window functions. To implement this functionality, you have to convert **RESET WHEN** to the native SQL syntax in Amazon Redshift, and use multiple, nested functions. This pattern demonstrates how you can use the Teradata **RESET WHEN** feature and how you can convert it to Amazon Redshift SQL syntax.

## Prerequisites and limitations

### Prerequisites

- Basic knowledge of the Teradata data warehouse and its SQL syntax
- Good understanding of Amazon Redshift and its SQL syntax

## Architecture

### Source technology stack

- Teradata data warehouse

## Target technology stack

- Amazon Redshift

## Architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern [Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents](#). The migration doesn't automatically convert the Teradata **RESET WHEN** phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in the next section.

## Tools

### Code

To illustrate the concept of **RESET WHEN**, consider the following table definition in Teradata:

```
create table systest.f_account_balance
( account_id integer NOT NULL,
  month_id integer,
  balance integer )
unique primary index (account_id, month_id);
```

Run the following SQL code to insert sample data into the table:

```
BEGIN TRANSACTION;
Insert Into systest.f_account_balance values (1,1,60);
Insert Into systest.f_account_balance values (1,2,99);
Insert Into systest.f_account_balance values (1,3,94);
Insert Into systest.f_account_balance values (1,4,90);
Insert Into systest.f_account_balance values (1,5,80);
Insert Into systest.f_account_balance values (1,6,88);
Insert Into systest.f_account_balance values (1,7,90);
Insert Into systest.f_account_balance values (1,8,92);
Insert Into systest.f_account_balance values (1,9,10);
Insert Into systest.f_account_balance values (1,10,60);
Insert Into systest.f_account_balance values (1,11,80);
```

```
Insert Into systest.f_account_balance values (1,12,10);  
END TRANSACTION;
```

The sample table has the following data:

account_id	month_id	balance
1	1	60
1	2	99
1	3	94
1	4	90
1	5	80
1	6	88
1	7	90
1	8	92
1	9	10
1	10	60
1	11	80
1	12	10

For each account, let's say that you want to analyze the sequence of consecutive monthly balance increases. When one month's balance is less than, or equal to, the previous month's balance, the requirement is to reset the counter to zero and restart.

#### *Teradata RESET WHEN use case*

To analyze this data, Teradata SQL uses a window function with a nested aggregate and a **RESET WHEN** phrase, as follows:

```
SELECT account_id, month_id, balance,
```

```
( ROW_NUMBER() OVER (PARTITION BY account_id ORDER BY month_id
RESET WHEN balance <= SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS
BETWEEN 1 PRECEDING AND 1 PRECEDING) ) -1 ) as balance_increase
FROM systest.f_account_balance
ORDER BY 1,2;
```

Output:

account_id	month_id	balance	balance_increase
1	1	60	0
1	2	99	1
1	3	94	0
1	4	90	0
1	5	80	0
1	6	88	1
1	7	90	2
1	8	92	3
1	9	10	0
1	10	60	1
1	11	80	2
1	12	10	0

The query is processed as follows in Teradata:

1. The **SUM(balance)** aggregate function calculates the sum of all balances for a given account in a given month.
2. We check to see if a balance in a given month (for a given account) is greater than the balance of the previous month.

3. If the balance increased, we track a cumulative count value. If the **RESET WHEN** condition evaluates to **false**, which means that the balance has increased over successive months, we continue to increase the count.
4. The **ROW\_NUMBER()** ordered analytical function calculates the count value. When we reach a month whose balance is less than, or equal to, the balance of the previous month, the **RESET WHEN** condition evaluates to **true**. If so, we start a new partition and **ROW\_NUMBER()** restarts the count from 1. We use **ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING** to access the value of the previous row.
5. We subtract 1 to ensure that the count value starts with 0.

### *Amazon Redshift equivalent SQL*

Amazon Redshift doesn't support the **RESET WHEN** phrase in an SQL analytical window function. To produce the same result, you must rewrite the Teradata SQL using Amazon Redshift native SQL syntax and nested sub-queries, as follows:

```
SELECT account_id, month_id, balance,
       (ROW_NUMBER() OVER(PARTITION BY account_id, new_dynamic_part ORDER BY month_id) -1)
       as balance_increase
FROM
( SELECT account_id, month_id, balance, prev_balance,
  SUM(dynamic_part) OVER (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN
    UNBOUNDED PRECEDING AND CURRENT ROW) As new_dynamic_part
FROM ( SELECT account_id, month_id, balance,
  SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN 1 PRECEDING
    AND 1 PRECEDING) as prev_balance,
  (CASE When balance <= prev_balance Then 1 Else 0 END) as dynamic_part
FROM systest.f_account_balance ) A
) B
ORDER BY 1,2;
```

Because Amazon Redshift doesn't support nested window functions in the **SELECT** clause of a single SQL statement, you must use two nested sub-queries.

- In the inner sub-query (alias A), a dynamic partition indicator (**dynamic\_part**) is created and populated. **dynamic\_part** is set to 1 if one month's balance is less than or equal to the preceding month's balance; otherwise, it's set to 0.
- In the next layer (alias B), a **new\_dynamic\_part** attribute is generated as the result of a **SUM** window function.

- Finally, you add **new\_dynamic\_part** as a new partition attribute (**dynamic partition**) to the existing partition attribute (**account\_id**) and apply the same **ROW\_NUMBER()** window function as in Teradata (and minus one).

After these changes, Amazon Redshift SQL generates the same output as Teradata.

## Epics

# Enforce tagging of Amazon EMR clusters at launch

Created by Priyanka Chaudhary (AWS)

**Environment:** Production

**Technologies:** Analytics;  
Security, identity, compliance

**AWS services:** Amazon  
EMR; AWS Lambda; Amazon  
CloudWatch Events

## Summary

This pattern provides a security control that ensures that Amazon EMR clusters are tagged when they are created.

Amazon EMR is an Amazon Web Services (AWS) service for processing and analyzing vast amounts of data. Amazon EMR offers an expandable, low-configuration service as an easier alternative to running in-house cluster computing. You can use tagging to categorize AWS resources in different ways, such as by purpose, owner, or environment. For example, you can tag your Amazon EMR clusters by assigning custom metadata to each cluster. A tag consists of a key and value that you define. We recommend that you create a consistent set of tags to meet your organization's requirements. When you add a tag to an Amazon EMR cluster, the tag is also propagated to each active Amazon Elastic Compute Cloud (Amazon EC2) instance that is associated with the cluster. Similarly, when you remove a tag from an Amazon EMR cluster, that tag is removed from each associated, active EC2 instance as well.

The detective control monitors API calls and initiates an Amazon CloudWatch Events event for the [RunJobFlow](#), [AddTags](#), [RemoveTags](#), and [CreateTags](#) APIs. The event calls AWS Lambda, which runs a Python script. The Python function gets the Amazon EMR cluster ID from the JSON input from the event and performs the following checks:

- Check if the Amazon EMR cluster is configured with tag names that you specify.
- If not, send an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon EMR cluster name, violation details, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code. Or, you can create an S3 bucket for this purpose, as described in the *Epics* section.
- An active email address where you would like to receive violation notifications.
- A list of mandatory tags you want to check for.

### Limitations

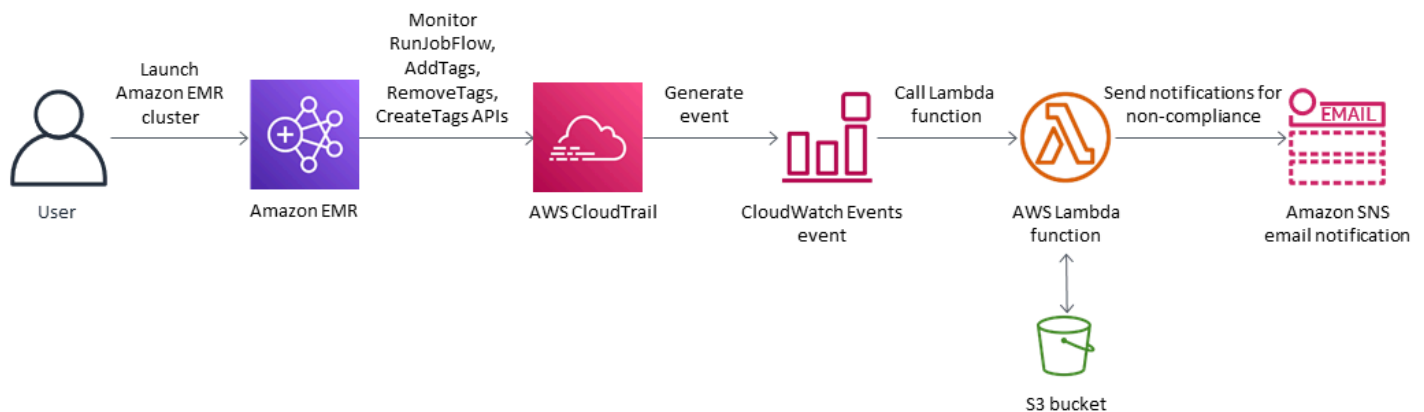

- This security control is regional. You must deploy it in each AWS Region that you want to monitor.

### Product versions

- Amazon EMR release 4.8.0 and later.

## Architecture

### Workflow architecture

### Automation and scale

- If you are using [AWS Organizations](#), you can use [AWS Cloudformation StackSets](#) to deploy this template in multiple accounts that you want to monitor.

## Tools

### AWS services

- [AWS CloudFormation](#) – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- [Amazon CloudWatch Events](#) - Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [Amazon EMR](#) - Amazon EMR is web service that simplifies running big data frameworks and processing vast amounts of data efficiently.
- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

### Code

This pattern includes the following attachments:

- `EMRTagValidation.zip` – The Lambda code for the security control.
- `EMRTagValidation.yml` – The CloudFormation template that sets up the event and Lambda function.

## Epics

### Set up the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the <a href="#">Amazon S3 console</a> , choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the Amazon EMR cluster you want to monitor. An Amazon S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.	Cloud architect
Upload the Lambda code.	Upload the Lambda code .zip file provided in the <i>Attachments</i> section to the S3 bucket.	Cloud architect

### Deploy the AWS CloudFormation template

Task	Description	Skills required
Launch the AWS CloudFormation template.	Open the <a href="#">AWS CloudFormation console</a> in the same AWS Region as your S3 bucket and deploy the template. For more information about deploying AWS CloudFormation templates, see <a href="#">Creating a stack on</a>	Cloud architect

Task	Description	Skills required
	<a href="#">the AWS CloudFormation console</a> in the CloudFormation documentation.	

Task	Description	Skills required
Complete the parameters in the template.	<p>When you launch the template, you'll be prompted for the following information:</p> <ul style="list-style-type: none"><li>• <b>S3 bucket:</b> Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (.zip file).</li><li>• <b>S3 key:</b> Specify the location of the Lambda .zip file in your S3 bucket (for example, <i>filename.zip</i> or <i>controls/filename.zip</i>). Do not include leading slashes.</li><li>• <b>Notification email:</b> Provide an active email address where you want to receive Amazon SNS notifications.</li><li>• <b>Tagging key names:</b> Provide the tags you want to check for, in a comma-separated list (for example, <code>ApplicationID , Environment , Owner</code>). The CloudWatch Events event monitors the cluster for these tags and sends a notification if they aren't found.</li><li>• <b>Lambda logging level:</b> Specify the logging level and frequency for the</li></ul>	Cloud architect

Task	Description	Skills required
	Lambda function. Use <b>Info</b> to log detailed informational messages on progress, <b>Error</b> for error events that would still allow the deployment to continue, and <b>Warning</b> for potentially harmful situations.	

## Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the CloudFormation template deploys successfully, it sends a subscription email to the email address you provided. You must confirm this email subscription to start receiving violation notifications.	Cloud architect

# Ensure Amazon EMR logging to Amazon S3 is enabled at launch

Created by Priyanka Chaudhary (AWS)

**Environment:** Production

**Technologies:** Analytics;  
Security, identity, compliance;  
Serverless

**Workload:** Open-source

**AWS services:** Amazon EMR;  
Amazon S3; Amazon SNS;  
Amazon CloudWatch

## Summary

This pattern provides a security control that monitors logging configuration for Amazon EMR clusters running on Amazon Web Services (AWS).

Amazon EMR is an AWS tool for big data processing and analysis. Amazon EMR offers the expandable low-configuration service as an alternative to running in-house cluster computing. Amazon EMR provides two types of EMR clusters.

- **Transient Amazon EMR clusters:** Transient Amazon EMR clusters automatically shut down and stop incurring costs when processing is finished.
- **Persistent Amazon EMR clusters:** Persistent Amazon EMR clusters continue to run after the data processing job is complete.

Amazon EMR and Hadoop both produce log files that report status on the cluster. By default, these are written to the master node in the `/mnt/var/log/` directory. Depending on how you configure the cluster when you launch it, you can also save these logs to Amazon Simple Storage Service (Amazon S3) and view them through the graphical debugging tool. Note that Amazon S3 logging can be specified only when the cluster is launched. With this configuration, logs are sent from the primary node to the Amazon S3 location every 5 minutes. For transient clusters, Amazon S3 logging is important because the clusters disappear when processing is complete, and these log files can be used to debug any failed jobs.

The pattern uses an AWS CloudFormation template to deploy a security control that monitors for API calls and starts Amazon CloudWatch Events on "RunJobFlow." The trigger invokes AWS Lambda, which runs a Python script. The Lambda function retrieves the EMR cluster ID from the event JSON input and also checks for an Amazon S3 log URI. If an Amazon S3 URI is not found, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification detailing the EMR cluster name, violation details, AWS Region, AWS account, and the Lambda Amazon Resource Name (ARN) that the notification is sourced from.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An S3 bucket for the Lambda code .zip file
- An email address where you want to receive the violation notification

### Limitations

- This detective control is regional and must be deployed in the AWS Regions you intend to monitor.

### Product versions

- Amazon EMR release 4.8.0 and later

## Architecture

### Target technology stack

- Amazon CloudWatch Events event
- Amazon EMR
- Lambda function
- S3 bucket
- Amazon SNS

### Target architecture

## Automation and scale

- If you are using AWS Organizations, you can use [AWS CloudFormation StackSets](#) to deploy this template in multiple accounts that you want to monitor.

## Tools

### Tools

- [AWS CloudFormation](#) – AWS CloudFormation helps you model and set up AWS resources using infrastructure as code.
- [AWS Cloudwatch Events](#) – AWS CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [Amazon EMR](#) – Amazon EMR is a managed cluster platform that simplifies running big data frameworks.
- [AWS Lambda](#) – AWS Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon S3](#) – Amazon S3 is a web services interface that you can use to store and retrieve any amount of data from anywhere on the web.
- [Amazon SNS](#) – Amazon SNS is a web service that coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses.

### Code

- A .zip file of the project is available as an attachment.

# Epics

## Define the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	To host the Lambda code .zip file, choose or create an S3 bucket with a unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. Your S3 bucket needs to be in the same AWS Region as the Amazon EMR cluster that is being evaluated .	Cloud Architect

## Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code to the S3 bucket.	Upload the Lambda code .zip file that's provided in the "Attachments" section to the S3 bucket. The S3 bucket must be in the same Region as the Amazon EMR cluster that is being evaluated.	Cloud Architect

## Deploy the AWS CloudFormation template

Task	Description	Skills required
Deploy the AWS CloudFormation template.	On the AWS CloudFormation console, in the same Region as your S3 bucket, deploy the AWS CloudFormation template that's provided as an attachment to this pattern. In the next epic, provide the values for the parameters. For more information about deploying AWS CloudFormation templates, see the "Related resources" section.	Cloud Architect

## Complete the parameters in the AWS CloudFormation template

Task	Description	Skills required
Name the S3 bucket.	Enter the name of the S3 bucket that you created in the first epic.	Cloud Architect
Provide the Amazon S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, <directory>/<file-name>.zip).	Cloud Architect
Provide an email address.	Provide an active email address to receive Amazon SNS notifications.	Cloud Architect
Define the logging level.	Define the logging level and frequency for your Lambda	Cloud Architect

Task	Description	Skills required
	function. "Info" designates detailed informational messages on the application's progress. "Error" designates error events that could still allow the application to continue running. "Warning" designates potentially harmful situations.	

## Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the template successfully deploys, it sends a subscription email message to the email address provided. You must confirm this email subscription to receive violation notifications.	Cloud Architect

# Generate test data using an AWS Glue job and Python

Created by Moinul Al-Mamun (AWS)

**Environment:** Production

**Technologies:** Analytics  
; CloudNative; Data lakes;  
DevelopmentAndTesting;  
Serverless; Big data

**AWS services:** AWS Glue;  
Amazon S3

## Summary

This pattern shows you how to quickly and easily generate millions of sample files concurrently by creating an AWS Glue job written in Python. The sample files are stored in an Amazon Simple Storage Service (Amazon S3) bucket. The ability to quickly generate a large number of sample files is important for testing or evaluating services in the AWS Cloud. For example, you can test the performance of AWS Glue Studio or AWS Glue DataBrew jobs by performing data analysis on millions of small files in an Amazon S3 prefix.

Although you can use other AWS services to generate sample datasets, we recommend that you use AWS Glue. You don't need to manage any infrastructure because AWS Glue is a serverless data processing service. You can just bring your code and run it in an AWS Glue cluster. Additionally, AWS Glue provisions, configures, and scales the resources required to run your jobs. You pay only for the resources that your jobs use while running.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#) to work with the AWS account

### Product versions

- Python 3.9
- AWS CLI version 2

## Limitations

The maximum number of AWS Glue jobs per trigger is 50. For more information, see [AWS Glue endpoints and quotas](#).

## Architecture

The following diagram depicts an example architecture centered around an AWS Glue job that writes its output (that is, sample files) to an S3 bucket.

The diagram includes the following workflow:

1. You use the AWS CLI, AWS Management Console, or an API to initiate the AWS Glue job. The AWS CLI or API enables you to automate the parallelization of the invoked job and reduce the runtime for generating sample files.
2. The AWS Glue job generates file content randomly, converts the content into CSV format, and then stores the content as an Amazon S3 object under a common prefix. Each file is less than a kilobyte. The AWS Glue job accepts two user-defined job parameters: `START_RANGE` and `END_RANGE`. You can use these parameters to set file names and the number of files generated in Amazon S3 by each job run. You can run multiple instances of this job in parallel (for example, 100 instances).

## Tools

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

## Best practices

Consider the following AWS Glue best practices as you implement this pattern:

- **Use the right AWS Glue worker type to reduce cost.** We recommend that you understand the different properties of worker types, and then choose the right worker type for your workload based on CPU and memory requirements. For this pattern, we recommend that you use a Python shell job as your job type to minimize DPU and reduce cost. For more information, see [Adding jobs in AWS Glue](#) in the AWS Glue Developer Guide.
- **Use the right concurrency limit to scale your job.** We recommend that you base the maximum concurrency of your AWS Glue job on your time requirement and required number of files.
- **Start generating a small number of files at first.** To reduce cost and save time when you build your AWS Glue jobs, start with a small number of files (such as 1,000). This can make troubleshooting easier. If generating a small number of files is successful, then you can scale to a larger number of files.
- **Run locally first.** To reduce cost and save time when you build your AWS Glue jobs, start the development locally and test your code. For instructions on setting up a Docker container that can help you write AWS Glue extract, transform, and load (ETL) jobs both in a shell and in an integrated development environment (IDE), see the [Developing AWS Glue ETL jobs locally using a container](#) post on the AWS Big Data Blog.

For more AWS Glue best practices, see [Best practices](#) in the AWS Glue documentation.

## Epics

### Create a destination S3 bucket and IAM role

Task	Description	Skills required
<p>Create an S3 bucket for storing the files.</p>	<p>Create an <a href="#">S3 bucket</a> and a <a href="#">prefix</a> within it.</p> <p><b>Note:</b> This pattern uses the <code>s3://{your-s3-bucket-name}/small-files/</code> location for demonstration purposes.</p>	<p>App developer</p>
<p>Create and configure an IAM role.</p>	<p>You must create an IAM role that your AWS Glue job can use to write to your S3 bucket.</p> <ol style="list-style-type: none"> <li>1. Create an <a href="#">IAM role</a> (for example, called "AWSGlueServiceRole-smallfiles" ).</li> <li>2. Choose AWS Glue as the policy's trusted entity.</li> <li>3. Attach an <a href="#">AWS managed policy</a> called "AWSGlueServiceRole" to the role.</li> <li>4. Create an inline policy or <a href="#">customer managed policy</a> called "s3-small-file-access" based on the following configuration. Replace "{bucket}" with your bucket name.</li> </ol>	<p>App developer</p>

Task	Description	Skills required
	<pre data-bbox="634 212 1029 1199"> {   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Action":       [         "s3:GetObject",         "s3:PutObject"       ],       "Resource       ": [         "arn:aws:s3:::{buc ket}/small-files/i nput/*"       ]     }   ] } </pre> <p data-bbox="591 1220 1016 1346">5. Attach the "s3-small-file-access" policy to your role.</p>	

## Create and configure an AWS Glue job to handle concurrent runs

Task	Description	Skills required
Create an AWS Glue job.	You must create an AWS Glue job that generates your content and stores it in an S3 bucket.	App developer

Task	Description	Skills required
	<p>Create an <a href="#">AWS Glue job</a>, and then configure your job by completing the following steps:</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">AWS Glue console</a>.</li><li>2. In the navigation pane, under <b>Data Integration and ETL</b>, choose <b>Jobs</b>.</li><li>3. In the <b>Create job</b> section, choose <b>Python Shell script editor</b>.</li><li>4. In the <b>Options</b> section, select <b>Create a new script with boilerplate code</b>, and then choose <b>Create</b>.</li><li>5. Choose <b>Job details</b>.</li><li>6. For <b>Name</b>, enter <b>create_sm all_files</b>.</li><li>7. For <b>IAM Role</b>, select the IAM role that you created earlier.</li><li>8. In the <b>This job runs</b> section, choose <b>A new script to be authored by you</b>.</li><li>9. Expand <b>Advanced properties</b>.</li><li>10 For <b>Maximum concurrency</b>, enter <b>100</b> for</li></ol>	

Task	Description	Skills required
	<p>demonstration purposes.</p> <p><b>Note:</b> Maximum concurrency defines how many instances of the job that you can run in parallel.</p> <p>11Choose <b>Save</b>.</p>	

Task	Description	Skills required
Update the job code.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Glue console</a>.</li><li>2. In the navigation pane, choose <b>Jobs</b>.</li><li>3. In the <b>Your jobs</b> section, choose the job that you created earlier.</li><li>4. Choose the <b>Script</b> tab, and then update the script based on the following code. Update the <code>BUCKET_NAME</code> , <code>PREFIX</code>, and <code>text_str</code> variables with your values.</li></ol> <pre data-bbox="634 947 1029 1837">from awsglue.utils     import getResolvedOptions import sys import boto3 from random import     randrange  # Two arguments args = getResolvedOptions(sys.argv     , ['START_RANGE',     'END_RANGE'])  START_RANGE =     int(args['START_RA     NGE']) END_RANGE = int(args[     'END_RANGE'])  BUCKET_NAME =     '{BUCKET_NAME}'</pre>	App developer

Task	Description	Skills required
	<pre> PREFIX = 'small-fi les/input/' s3 = boto3.res ource('s3') for x in range(STA RT_RANGE, END_RANGE ):     # generate file name     file_name = f"input_{x}.txt"     # generate text text_str = str(randrange(1000 00))+","+str(randr ange(100000))+", " + str(randrange(1000 0000)) + "," + str(randrange(1000 0))     # write in s3 s3.Object(BUCKE T_NAME, PREFIX + file_name).put(Bod y=text_str) </pre> <p>5. Choose <b>Save</b>.</p>	

## Run the AWS Glue job from the command line or console

Task	Description	Skills required
Run the AWS Glue job from the command line.	<p>To run your AWS Glue job from the AWS CLI , run the following command using your values:</p> <pre> cmd:~\$ aws glue start- job-run --job-name </pre>	App developer

Task	Description	Skills required
	<pre>create_small_files --arguments '{"--STAR T_RANGE":"0", "--EN D_RANGE":"1000000"}' cmd:~\$ aws glue start- job-run --job-name create_small_files --arguments '{"--STAR T_RANGE":"1000000" , "--END_RANGE":"20 00000"}'</pre> <p><b>Note:</b> For instructions on running the AWS Glue job from the AWS Management Console, see the <i>Run the AWS Glue job in the AWS Management Console</i> story in this pattern.</p> <p><b>Tip:</b> We recommend using the AWS CLI to run AWS Glue jobs if you want to run multiple executions at a time with different parameters, as shown in the example above.</p> <p>To generate all AWS CLI commands that are required to generate a defined number of files using a certain parallelization factor, run the following bash code (using your values):</p> <pre># define parameters NUMBER_OF_FILES= 10000000;</pre>	

Task	Description	Skills required
	<pre> PARALLELIZATION=50;  # initialize _SB=0;  # generate commands for i in \$(seq 1   \$PARALLELIZATION); do     echo aws glue     start-job-run --     job-name create_sm     all_files --argumen     ts "'{--START_RANG     E":"'\${((NUMBER_OF     _FILES/PARALLELIZA     TION) * (i-1) +     _SB))'',"--END_RAN     GE":"'\${((NUMBER_O     F_FILES/PARALLELIZ     ATION) * (i)))'"}'";     _SB=1; done </pre> <p>If you use the script above, consider the following:</p> <ul style="list-style-type: none"> <li>• The script simplifies the invocation and generation of small files at scale.</li> <li>• Update <code>NUMBER_OF_FILES</code> and <code>PARALLELIZATION</code> with your values.</li> <li>• The script above prints a list of commands that you must run. Copy those output commands, and</li> </ul>	

Task	Description	Skills required
	<p>then run them in your terminal.</p> <ul style="list-style-type: none"> <li>If you want to run the commands directly from within the script, remove the echo statement in line 11.</li> </ul> <p><b>Note:</b> To see an example of output from the above script, see <i>Shell script output</i> in the <i>Additional information</i> section of this pattern.</p>	
Run the AWS Glue job in the AWS Management Console.	<ol style="list-style-type: none"> <li>Sign in to the AWS Management Console and open the <a href="#">AWS Glue console</a>.</li> <li>In the navigation pane, under <b>Data Integration and ETL</b>, choose <b>Jobs</b>.</li> <li>In the <b>Your jobs</b> section, choose your job.</li> <li>In the <b>Parameters (optional)</b> section, update your parameters.</li> <li>Choose <b>Action</b>, and then choose <b>Run job</b>.</li> <li>Repeat steps 3-5 as many times as you require. For example, to create 10 million files, repeat this process 10 times.</li> </ol>	App developer

Task	Description	Skills required
Check the status of your AWS Glue job.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Glue console</a>.</li><li>2. In the navigation pane, choose <b>Jobs</b>.</li><li>3. In the <b>Your jobs</b> section, choose the job that you created earlier (that is, <code>create_small_files</code>).</li><li>4. For insight into the progress and generation of your files, review the <b>Run ID</b>, <b>Run Status</b>, and other columns.</li></ol>	App developer

## Additional information

### Benchmarking test

This pattern was used to generate 10 million files using different parallelization parameters as part of a benchmarking test. The following table shows the output of the test:

Parallelization	Number of files generated by a job run	Job duration	Speed
10	1,000,000	6 hours, 40 minutes	Very slow
50	200,000	80 minutes	Moderate
100	100,000	40 minutes	Fast

If you want to make the process faster, you can configure more concurrent runs in your job configuration. You can easily adjust the job configuration based on your requirements, but keep in mind that there is an AWS Glue service quota limit. For more information, see [AWS Glue endpoints and quotas](#).

### Shell script output

The following example shows the output of the shell script from the *Run the AWS Glue job from the command line* story in this pattern.

```
user@MUC-1234567890 MINGW64 ~
$ # define parameters
NUMBER_OF_FILES=10000000;
PARALLELIZATION=50;
# initialize
_SB=0;

# generate commands
for i in $(seq 1 $PARALLELIZATION);
do
    echo aws glue start-job-run --job-name create_small_files --arguments
    """"{"--START_RANGE":"'${((NUMBER_OF_FILES/PARALLELIZATION) (i-1) + SB))}'", "--
ENDRANGE":"'${((NUMBER_OF_FILES/PARALLELIZATION) (i))}'""";
    _SB=1;
```

done

## FAQ

### *How many concurrent runs or parallel jobs should I use?*

The number of concurrent runs and parallel jobs depend on your time requirement and desired number of test files. We recommend that you check the size of the files that you're creating. First, check how much time an AWS Glue job takes to generate your desired number of files. Then, use the right number of concurrent runs to meet your goals. For example, if you assume that 100,000 files takes 40 minutes to complete the run but your target time is 30 minutes, then you must increase the concurrency setting for your AWS Glue job.

### *What type of content can I create using this pattern?*

You can create any type of content, such as text files with different delimiters (for example, PIPE, JSON, or CSV). This pattern uses Boto3 to write to a file and then saves the file in an S3 bucket.

### *What level of IAM permission do I need in the S3 bucket?*

You must have an identity-based policy that allows Write access to objects in your S3 bucket. For more information, see [Amazon S3: Allows read and write access to objects in an S3 bucket](#) in the Amazon S3 documentation.

# Launch a Spark job in a transient EMR cluster using a Lambda function

Created by Dhrubajyoti Mukherjee (AWS)

<b>Environment:</b> Production	<b>Technologies:</b> Analytics	<b>Workload:</b> Open-source
<b>AWS services:</b> Amazon EMR; AWS Identity and Access Management; AWS Lambda; Amazon VPC		

## Summary

This pattern uses the Amazon EMR RunJobFlow API action to launch a transient cluster to run a Spark job from a Lambda function. A transient EMR cluster is designed to terminate as soon as the job is complete or if any error occurs. A transient cluster provides cost savings because it runs only during the computation time, and it provides scalability and flexibility in a cloud environment.

The transient EMR cluster is launched using the Boto3 API and the Python programming language in a Lambda function. The Lambda function, which is written in Python, provides the added flexibility of initiating the cluster when it is needed.

To demonstrate a sample batch computation and output, this pattern will launch a Spark job in an EMR cluster from a Lambda function and run a batch computation against the example sales data of a fictional company. The output of the Spark job will be a comma-separated values (CSV) file in Amazon Simple Storage Service (Amazon S3). The input data file, Spark .jar file, a code snippet, and an AWS CloudFormation template for a virtual private cloud (VPC) and AWS Identity and Access Management (IAM) roles to run the computation are provided as an attachment.

## Prerequisites and limitations

### Prerequisites

- An active AWS account

### Limitations

- Only one Spark job can be initiated from the code at a time.

## Product versions

- Tested on Amazon EMR 6.0.0

## Architecture

### Target technology stack

- Amazon EMR
- AWS Lambda
- Amazon S3
- Apache Spark

### Target architecture

### Automation and scale

To automate the Spark-EMR batch computation, you can use either of the following options.

- Implement an Amazon EventBridge rule that can initiate the Lambda function in a cron schedule. For more information, see [Tutorial: Schedule AWS Lambda functions using EventBridge](#).
- Configure [Amazon S3 event notifications](#) to initiate the Lambda function on file arrival.

- Pass the input parameters to the AWS Lambda function through the event body and Lambda environment variables.

## Tools

### AWS services

- [Amazon EMR](#) is a managed cluster platform that simplifies running big data frameworks on AWS to process and analyze large amounts of data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Other tools

- [Apache Spark](#) is a multiple-language analytics engine for large-scale data processing.

## Epics

### Create the Amazon EMR and Lambda IAM roles and the VPC

Task	Description	Skills required
Create the IAM roles and the VPC.	If you already have the AWS Lambda and Amazon EMR IAM roles and a VPC, you can skip this step. To run the code, both the EMR cluster and the Lambda function require IAM roles. The EMR cluster also requires a VPC with a public subnet or a private subnet with a NAT gateway. To automatically	Cloud architect

Task	Description	Skills required
	<p>create all the IAM roles and a VPC, deploy the attached AWS CloudFormation template as is, or you can create the roles and the VPC manually as specified in the <i>Additional information</i> section.</p>	
<p>Note the AWS CloudFormation template output keys.</p>	<p>After the CloudFormation template has successfully deployed, navigate to the <b>Outputs</b> tab in the AWS CloudFormation console. Note the five output keys:</p> <ul style="list-style-type: none"> <li>• S3Bucket</li> <li>• LambdaExecutionRole</li> <li>• ServiceRole</li> <li>• JobFlowRole</li> <li>• Ec2SubnetId</li> </ul> <p>You will use the values from these keys when you create the Lambda function.</p>	<p>Cloud architect</p>

### Upload the Spark .jar file

Task	Description	Skills required
<p>Upload the Spark .jar file.</p>	<p>Upload the Spark .jar file to the S3 bucket that the AWS CloudFormation stack created. The bucket name is</p>	<p>General AWS</p>

Task	Description	Skills required
	the same as the output key S3Bucket.	

## Create the Lambda function to launch the EMR cluster

Task	Description	Skills required
Create a Lambda function.	On the Lambda console, create a Python 3.9+ Lambda function with an execution role. The execution role policy must allow Lambda to launch an EMR cluster. (See the attached AWS CloudFormation template.)	Data engineer, Cloud engineer
Copy and paste the code.	Replace the code in the <code>lambda_function.py</code> file with the code from the <i>Additional information</i> section of this pattern.	Data engineer, Cloud engineer
Change the parameters in the code.	Follow the comments in the code to change the parameter values to match your AWS account.	Data engineer, Cloud engineer
Launch the function to initiate the cluster.	Launch the function to initiate the creation of a transient EMR cluster with the Spark .jar file provided. It will run the Spark job and terminate automatically when the job is complete.	Data engineer, Cloud engineer

Task	Description	Skills required
Check the EMR cluster status.	After the EMR cluster is initiated, it appears in the Amazon EMR console under the <b>Clusters</b> tab. Any errors while launching the cluster or running the job can be checked accordingly.	Data engineer, Cloud engineer

### Set up and run the sample demo

Task	Description	Skills required
Upload the Spark .jar file.	Download the Spark .jar file from the <i>Attachments</i> section and upload it to the S3 bucket.	Data engineer, Cloud engineer
Upload the input dataset.	Upload the attached <code>fake_sales_data.csv</code> file to the S3 bucket.	Data engineer, Cloud engineer
Paste the Lambda code and change the parameters.	Copy the code from the <b>Tools</b> section, and paste the code in a Lambda function, replacing the code <code>lambda_function.py</code> file. Change the parameter values to match your account.	Data engineer, Cloud engineer
Launch the function and verify the output.	After the Lambda function initiates the cluster with the provided Spark job, it generates a .csv file in the S3 bucket.	Data engineer, Cloud engineer

                    '--class', 'com.aws.emr.ProfitCalc',
                    's3://your-bucket-name/prefix/lambda-emr/SparkProfitCalc.jar',
                    's3://your-bucket-name/prefix/fake_sales_data.csv',
                    's3://your-bucket-name/prefix/outputs/report_1/'
                ]
            }
        }
    ]
}
)

```

## IAM roles and VPC creation

To launch the EMR cluster in a Lambda function, a VPC and IAM roles are needed. You can set up the VPC and IAM roles by using the AWS CloudFormation template in the Attachments section of this pattern, or you can manually create them by using the following links.

The following IAM roles are required to run Lambda and Amazon EMR.

### *Lambda execution role*

A Lambda function's [execution role](#) grants it permission to access AWS services and resources.

### *Service role for Amazon EMR*

The [Amazon EMR role](#) defines the allowable actions for Amazon EMR when provisioning resources and performing service-level tasks that are not performed in the context of an Amazon Elastic Compute Cloud (Amazon EC2) instance running within a cluster. For example, the service role is used to provision EC2 instances when a cluster launches.

### *Service role for EC2 instances*

The [service role for cluster EC2 instances](#) (also called the EC2 instance profile for Amazon EMR) is a special type of service role that is assigned to every EC2 instance in an Amazon EMR cluster when the instance launches. Application processes that run on top of Apache Hadoop assume this role for permissions to interact with other AWS services.

### *VPC and subnet creation*

You can [create a VPC](#) from the VPC console.

# Migrate Apache Cassandra workloads to Amazon Keyspaces by using AWS Glue

Created by Nikolai Kolesnikov (AWS), Karthiga Priya Chandran (AWS), and Samir Patel (AWS)

<b>Environment:</b> Production	<b>Source:</b> Cassandra	<b>Target:</b> Amazon Keyspaces
<b>R Type:</b> N/A	<b>Workload:</b> Open-source; All other workloads	<b>Technologies:</b> Analytics; Migration; Serverless; Big data

**AWS services:** AWS Glue; Amazon Keyspaces; Amazon S3; AWS CloudShell

## Summary

This pattern shows you how to migrate your existing Apache Cassandra workloads to Amazon Keyspaces (for Apache Cassandra) by using CQLReplicator on AWS Glue. You can use CQLReplicator on AWS Glue to minimize the replication lag of migrating your workloads down to a matter of minutes. You also learn how to use an Amazon Simple Storage Service (Amazon S3) bucket to store data required for the migration, including [Apache Parquet](#) files, configuration files, and scripts. This pattern assumes that your Cassandra workloads are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances in a virtual private cloud (VPC).

## Prerequisites and limitations

### Prerequisites

- Cassandra cluster with a source table
- Target table in Amazon Keyspaces to replicate the workload
- S3 bucket to store intermediate Parquet files that contain incremental data changes
- S3 bucket to store job configuration files and scripts

### Limitations

- CQLReplicator on AWS Glue requires some time to provision Data Processing Units (DPUs) for the Cassandra workloads. The replication lag between the Cassandra cluster and the target keyspace and table in Amazon Keyspaces is likely to last for only a matter of minutes.

## Architecture

### Source technology stack

- Apache Cassandra
- DataStax Server
- ScyllaDB

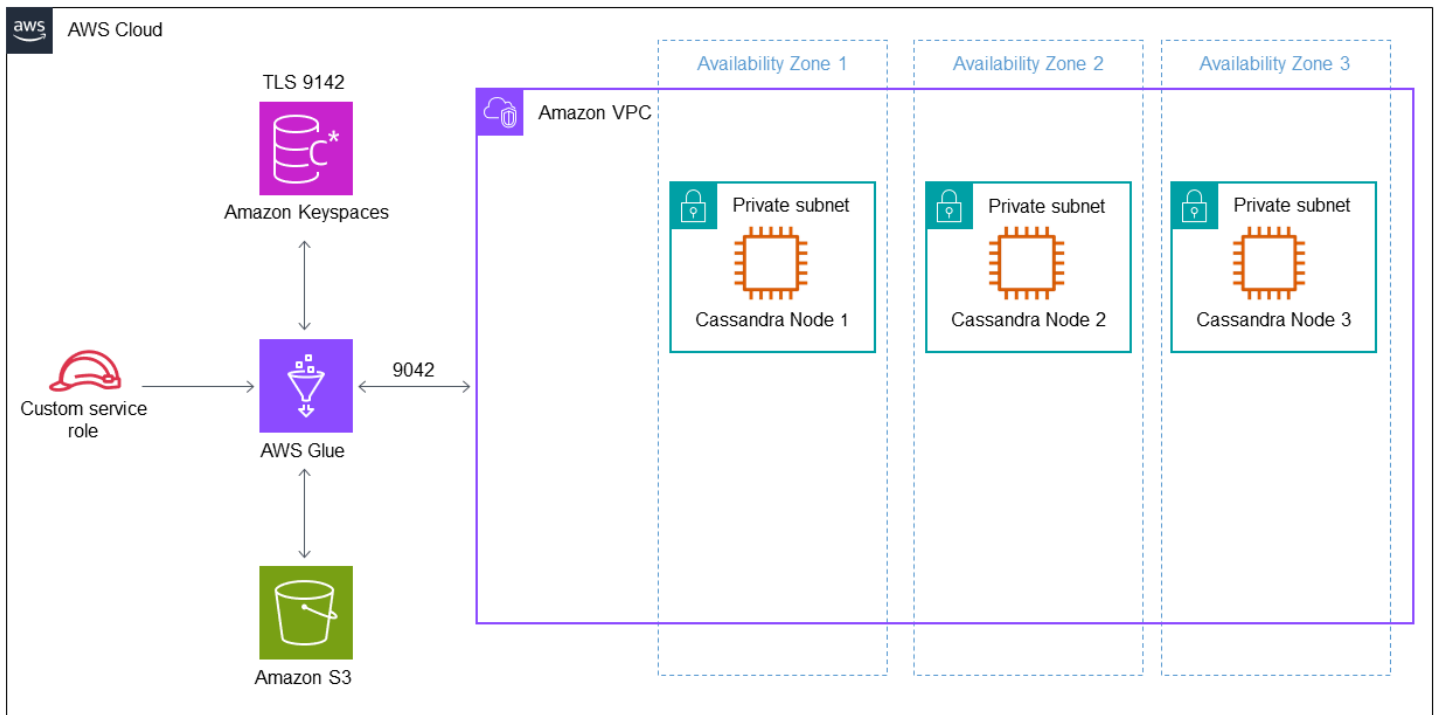

### Target technology stack

- Amazon Keyspaces

### Migration architecture

The following diagram shows an example architecture where a Cassandra cluster is hosted on EC2 instances and spread across three Availability Zones. The Cassandra nodes are hosted in private subnets.

The diagram shows the following workflow:

1. A custom service role provides access to Amazon Keyspaces and the S3 bucket.
2. An AWS Glue job reads the job configuration and scripts in the S3 bucket.
3. The AWS Glue job connects through port 9042 to read data from the Cassandra cluster.
4. The AWS Glue job connects through port 9142 to write data to Amazon Keyspaces.

## Tools

### AWS services and tools

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS CloudShell](#) is a browser-based shell that you can use to manage AWS services by using the AWS Command Line Interface (AWS CLI) and a range of preinstalled development tools.
- [AWS Glue](#) is a fully managed ETL service that helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [Amazon Keyspaces \(for Apache Cassandra\)](#) is a managed database service that helps you migrate, run, and scale your Cassandra workloads in the AWS Cloud.

## Code

The code for this pattern is available in the GitHub [CQLReplicator](#) repository.

## Best practices

- To determine the necessary AWS Glue resources for the migration, estimate the number of rows in the source Cassandra table. For example, 250 K rows per 0.25 DPU (2 vCPUs, 4 GB of memory) with 84 GB disk.
- Pre-warm Amazon Keyspaces tables before running CQLReplicator. For example, eight CQLReplicator tiles (AWS Glue jobs) can write up to 22 K WCUs per second, so the target should be pre-warmed up to 25-30 K WCUs per second.
- To enable communication between AWS Glue components, use a self-referencing inbound rule for all TCP ports in your security group.
- Use the incremental traffic strategy to distribute the migration workload over time.

## Epics

### Deploy CQLReplicator

Task	Description	Skills required
Create a target keyspace and table.	<p>1. Create a <a href="#">keyspace and table</a> in Amazon Keyspaces.</p> <p>For more information on write capacity, see <i>Write unit calculations</i> in the <a href="#">Additional information</a> section of this pattern.</p> <p>You can also create a keyspace by using the <a href="#">Cassandra Query Language (CQL)</a>. For more information, see <i>Create a keyspace by using CQL</i> in the</p>	App owner, AWS administrator, DBA, App developer

Task	Description	Skills required
	<p><a href="#">Additional information</a> section of this pattern.</p> <p><b>Note:</b> After you create the table, consider switching the table to <a href="#">on-demand capacity mode</a> to avoid unnecessary charges.</p> <p>2. To update to throughput mode, run the following script:</p> <pre>ALTER TABLE target_keyspace.target_table WITH CUSTOM_PROPERTIES =   { 'capacity_mode':     { 'throughput_mode':       'PAY_PER_REQUEST' } }</pre>	

Task	Description	Skills required
Configure the Cassandra driver to connect to Cassandra.	<p>Use the following configuration script:</p> <pre data-bbox="607 348 1029 1339">Datastax-java-driver {   basic.request.consistency = "LOCAL_QUORUM"   basic.contact-points = ["127.0.0.1:9042"]   advanced.reconnect-on-init = true   basic.load-balancing-policy {     local-dc-center = "datacenter1"   }   advanced.auth-provider = {     class = PlainTextAuthProvider     username = "user-at-sample"     password = "S@MPLE=PASSWORD="   } }</pre> <p><b>Note:</b> The preceding script uses the Spark Cassandra Connector. For more information, see the reference configuration for <a href="#">Cassandra</a>.</p>	DBA

Task	Description	Skills required
Configure the Cassandra driver to connect to Amazon Keyspaces.	<p>Use the following configuration script:</p> <pre>datastax-java-driver {   basic {     load-balancing-policy {       local-datacenter =         us-west-2     }     contact-points = [       "cassandra.us-west-2.amazonaws.com:9142"     ]     request {       page-size = 2500       timeout = 360 seconds       consistency =         LOCAL_QUORUM     }   }   advanced {     control-connection {       timeout = 360 seconds     }     session-leak.threshold = 6     connection {       connect-timeout = 360         seconds       init-query-timeout =         360 seconds       warn-on-init-error =         false     }     auth-provider = {       class = software.         aws.mcs.auth.SigV4         AuthProvider     }   } }</pre>	DBA

Task	Description	Skills required
	<pre>aws-region = us- west-2 }  ssl-engine-factory {   class = DefaultSs lEngineFactory   } }</pre> <p><b>Note:</b> The preceding script uses the Spark Cassandra Connector. For more information, see the reference configuration for <a href="#">Cassandra</a>.</p>	

Task	Description	Skills required
Create an IAM role for the AWS Glue job.	<p>Create a new AWS service role named <code>glue-cassandra-migration</code> with AWS Glue as a trusted entity.</p> <p><b>Note:</b> The <code>glue-cassandra-migration</code> should provide read and write access to the S3 bucket and Amazon Keyspaces . The S3 bucket contains the .jar files, configuration files for Amazon Keyspaces and Cassandra, and the intermediate Parquet files. For example, it contains the <code>AWSGlueServiceRole</code> , <code>AmazonS3FullAccess</code> , and <code>AmazonKeyspacesFullAccess</code> managed policies.</p>	AWS DevOps

Task	Description	Skills required
Download CQLReplicator in AWS CloudShell.	<p>Download the project to your home folder by running the following command:</p> <pre data-bbox="594 394 1029 951">git clone https://github.com/aws-samples/cql-replicator.git cd cql-replicator/glue # Only for AWS CloudShell, the bc package includes bc and dc. Bc is an arbitrary precision numeric processing arithmetic language sudo yum install bc -y</pre>	
Modify the reference configuration files.	Copy CassandraConnector.conf and KeyspacesConnector.conf to the ../glue/conf directory in the project folder.	AWS DevOps

Task	Description	Skills required
Initiate the migration process.	<p>The following command initializes the CQLReplicator environment. Initialization involves copying .jar artifacts, and creating an AWS Glue connector, an S3 bucket, an AWS Glue job, the migration keyspace, and the ledger table:</p> <pre data-bbox="594 680 1029 1436">cd cql-replicator/glue/bin ./cqlreplicator --state init --sg "sg-1","sg-2" \ --subnet "subnet-XXXXXXXXXXXX" \ --az us- west-2a --region us- west-2 \ --glue- iam-role glue-cassandra- migration \ -- landing-zone s3://cql- replicator-1234567 890-us-west-2</pre> <p>The script includes the following parameters:</p> <ul style="list-style-type: none"><li>• --sg – The security groups that allow access to the Cassandra cluster from AWS Glue and include the self-referencing inbound rule for all traffic</li></ul>	AWS DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>--subnet</code> – The subnet to which the Cassandra cluster belongs</li><li>• <code>--az</code> – The Availability Zone of the subnet</li><li>• <code>--region</code> – The AWS Region where the Cassandra cluster is deployed</li><li>• <code>--glue-iam-role</code> – The <a href="#">IAM role permissions</a> that AWS Glue can assume when calling Amazon Keyspaces and Amazon S3 on your behalf</li><li>• <code>--landing zone</code> – An optional parameter for reusing an S3 bucket (If you don't supply a value for the <code>--landing zone</code> parameter, the <code>init</code> process will try to create a new bucket to store the configuration files, <code>.jar</code> artifacts, and intermediate files.)</li></ul>	

Task	Description	Skills required
Validate the deployment.	<p>After you run the previous command, the AWS account should contain the following:</p> <ul style="list-style-type: none"><li>• The CQLReplicator AWS Glue job and the AWS Glue connector in AWS Glue</li><li>• The S3 bucket that stores the artifacts</li><li>• The target keyspace migration and the ledger table in Amazon Keyspaces</li></ul>	AWS DevOps

## Run CQLReplicator

Task	Description	Skills required
Start the migration process.	<p>To operate CQLReplicator on AWS Glue, you need to use the <code>--state run</code> command, followed by a series of parameters. The precise configuration of these parameters is primarily determined by your unique migration requirements. For example, these settings might vary if you choose to replicate time to live (TTL) values and updates, or you offload objects exceeding 1 MB to Amazon S3.</p>	AWS DevOps

Task	Description	Skills required
	<p>To replicate the workload from the Cassandra cluster to Amazon Keyspaces, run the following command:</p> <pre data-bbox="592 426 1029 1381">./cqlreplicator --state run --tiles 8 \       -- landing-zone s3://cql- replicator-1234567 890-us-west-2 \       --region us-west-2 \       --src- keyspace source_ke yspace \       --src- table source_table \       --trg- keyspace target_key space \       -- writetime-column column_name \       --trg- table target_table -- inc-traffic</pre> <p>Your source keyspace and table are <code>source_keyspace.source_table</code> in the Cassandra cluster. Your target keyspace and table are <code>target_keyspace.target_table</code> in Amazon Keyspaces. The parameter <code>--inc-traffic</code></p>	

Task	Description	Skills required
	<p>helps prevent incremental traffic from overloading the Cassandra cluster and Amazon Keyspaces with a high number of requests.</p> <p>To replicate updates, add <code>--writetime-column regular_column_name</code> to your command line. The regular column is going to be used as the source of the write timestamp.</p>	

## Monitor the migration process

Task	Description	Skills required
<p>Validate migrated Cassandra rows during the historical migration phase.</p>	<p>To obtain the number of rows replicated during the backfilling phase, run the following command:</p> <pre data-bbox="594 1314 1029 1793"> ./cqlreplicator --state stats \                 -- landing-zone s3://cql- replicator-1234567 890-us-west-2 \                 --src- keyspace source_ke yspace --src-table source_table --region us-west-2 </pre>	<p>AWS DevOps</p>

## Stop the migration process

Task	Description	Skills required
<p>Use the <code>cqlreplicator</code> command or the AWS Glue console.</p>	<p>To stop the migration process gracefully, run the following command:</p> <pre data-bbox="594 485 1027 1121"> ./cqlreplicator --state request-stop --tiles 8 \  -- landing-zone s3://cql- replicator-1234567 890-us-west-2 \ --region us-west-2 \  --src- keyspace source_ke yspace --src-table source_table </pre> <p>To stop the migration process immediately, use the AWS Glue console.</p>	<p>AWS DevOps</p>

## Clean up

Task	Description	Skills required
<p>Delete the deployed resources .</p>	<p>The following command will delete the AWS Glue job, connector, S3 bucket, and Keyspaces table ledger:</p> <pre data-bbox="594 1787 1027 1885"> ./cqlreplicator --state cleanup --landing-zone </pre>	<p>AWS DevOps</p>

Task	Description	Skills required
	<pre>s3://cql-replicator-1234567890-us-west-2</pre>	

## Troubleshooting

Issue	Solution
AWS Glue jobs failed and returned an Out of Memory (OOM) error.	<ol style="list-style-type: none"> <li>1. Change the worker type (scale up). For example, change G0.25X to G.1X or G.1X to G.2X. Alternatively, increase the number of DPU's per AWS Glue job (scale out) in CQLReplicator.</li> <li>2. Start the migration process from the point where it was interrupted. To restart failed CQLReplicator jobs, rerun the <code>--state run</code> command with the same parameters.</li> </ol>

## Related resources

- [AWS Glue documentation](#)
- [Amazon Keyspaces documentation](#)
- [Apache Cassandra](#)

## Additional information

### Migration considerations

You can use AWS Glue to migrate your Cassandra workload to Amazon Keyspaces, while keeping your Cassandra source databases completely functional during the migration process. After the replication is complete, you can choose to cut over your applications to Amazon Keyspaces with minimal replication lag (less than minutes) between the Cassandra cluster and Amazon Keyspaces.

To maintain data consistency, you can also use a similar pipeline to replicate the data back to the Cassandra cluster from Amazon Keyspaces.

## Write unit calculations

As an example, consider that you intend to write 500,000,000 with the row size 1 KiB during one hour. The total number of Amazon Keyspaces write units (WCUs) that you require is based on this calculation:

$$\begin{aligned} &(\text{number of rows}/60 \text{ mins } 60\text{s}) \text{ 1 WCU per row} = (500,000,000/(60*60\text{s}) * 1 \text{ WCU}) \\ &= 69,444 \text{ WCUs required} \end{aligned}$$

69,444 WCUs per second is the rate for 1 hour, but you could add some cushion for overhead. For example,  $69,444 * 1.10 = 76,388$  WCUs has 10 percent overhead.

## Create a keyspace by using CQL

To create a keyspace by using CQL, run the following commands:

```
CREATE KEYSPACE target_keyspace WITH replication = {'class': 'SingleRegionStrategy'}
CREATE TABLE target_keyspace.target_table ( userid uuid, level text, gameid int,
description text, nickname text, zip text, email text, updatetime text, PRIMARY KEY
(userid, level, gameid) ) WITH default_time_to_live = 0 AND CUSTOM_PROPERTIES =
{'capacity_mode':{'throughput_mode':'PROVISIONED', 'write_capacity_units':76388,
'read_capacity_units':3612 }} AND CLUSTERING ORDER BY (level ASC, gameid ASC)
```

# Migrate Oracle Business Intelligence 12c to the AWS Cloud from on-premises servers

Created by Lanre (Lan-Ray) showunmi (AWS) and Patrick Huang (AWS)

<b>Environment:</b> Production	<b>Source:</b> On-premises	<b>Target:</b> Amazon EC2, Amazon RDS, Amazon ALB, Amazon EFS
<b>R Type:</b> Replatform	<b>Workload:</b> Oracle	<b>Technologies:</b> Analytics; Databases
<b>AWS services:</b> Amazon EBS; Amazon EC2; Amazon EFS; AWS CloudFormation; Elastic Load Balancing (ELB); AWS Certificate Manager (ACM)		

## Summary

This pattern shows how to migrate [Oracle Business Intelligence Enterprise Edition 12c](#) from on-premises servers to the AWS Cloud by using AWS CloudFormation. It also describes how you can use other AWS services to implement Oracle BI 12c components that deliver high availability, security, flexibility, and the ability to dynamically scale.

For a list of best practices related to migrating Oracle BI 12c to the AWS Cloud, see the **Additional information** section of this pattern.

**Note:** It's a best practice to run multiple test migrations before transferring your existing Oracle BI 12c data to the cloud. These tests help you fine tune your migration approach, identify and fix potential issues, and estimate downtime requirements more accurately.

## Prerequisites and limitations

### Prerequisites

- An active AWS account

- Secure network connectivity between your on-premises servers and AWS through either [AWS Virtual Private Network \(AWS VPN\)](#) services or [AWS Direct Connect](#)
- Software licenses for your Oracle operating system, Oracle BI 12c, Oracle Database, Oracle WebLogic Server, and Oracle HTTP Server

## Limitations

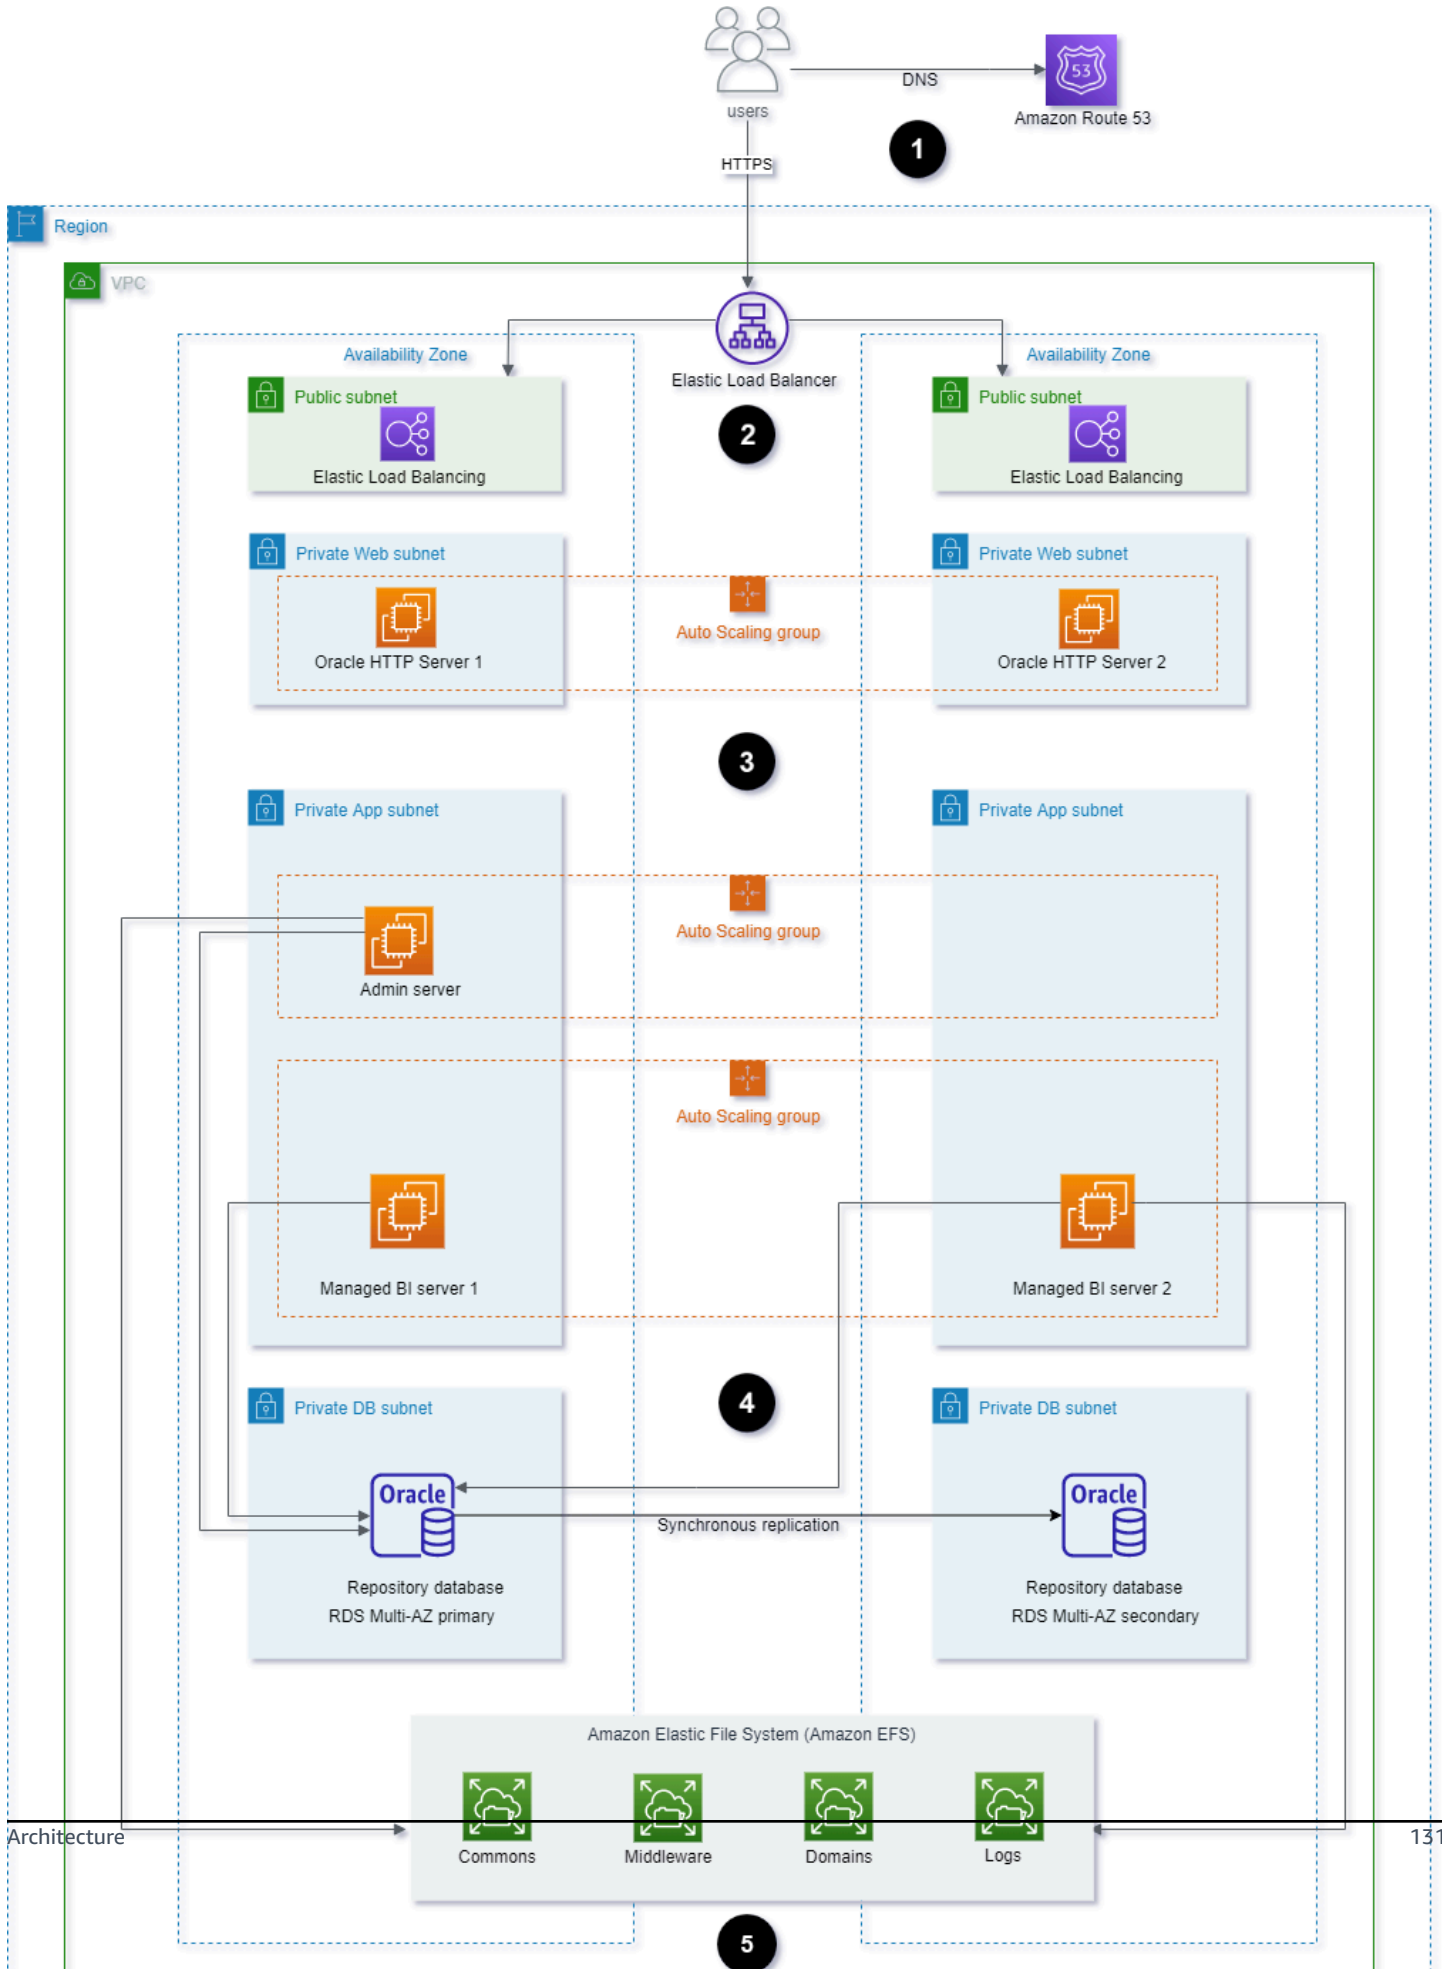

For information about storage size limits, see the [Amazon Relational Database Service \(Amazon RDS\) for Oracle](#) documentation.

## Product versions

- Oracle Business Intelligence Enterprise Edition 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server 12c
- Oracle Database 12c (or newer)
- Oracle Java SE 8

## Architecture

The following diagram shows an example architecture for running Oracle BI 12c components in the AWS Cloud:

This diagram shows the following architecture:

1. Amazon Route 53 provides domain name service (DNS) configuration.
2. Elastic Load Balancing (ELB) distributes network traffic to improve the scalability and availability of the Oracle BI 12c components across multiple Availability Zones.
3. Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling groups host the Oracle HTTP Servers, Weblogic Admin server, and managed BI servers across multiple Availability Zones.
4. Amazon Relational Database Service (Amazon RDS) for Oracle database store BI Server metadata across multiple Availability Zones.
5. Amazon Elastic File System (Amazon EFS) is mounted to every Oracle BI 12c component for shared file storage.

## Technology stack

- Amazon Elastic Block Store (Amazon EBS)
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Elastic File System (Amazon EFS)
- Amazon RDS for Oracle
- AWS Certificate Manager (ACM)
- Elastic Load Balancing (ELB)
- Oracle BI 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server (OHS)

## Tools

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS Certificate Manager \(ACM\)](#) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- [Amazon EC2 Auto Scaling](#) helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Elastic Load Balancing](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- [Oracle Data Pump](#) helps you move data and metadata from one database to another at high speeds.
- [Oracle Fusion Middleware](#) is a suite of application development tools and integration solutions to identity management, collaboration, and business intelligence reporting.
- [Oracle GoldenGate](#) helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.
- [Oracle WebLogic Scripting Tool \(WLST\)](#) provides a command line interface that helps you horizontally scale out your WebLogic clusters.

## Epics

### Assess the source environment

Task	Description	Skills required
Gather software inventory information.	Identify versions and patch levels for each of your source technology stack's software	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
	<p>components, including the following:</p> <ul style="list-style-type: none"><li>• Oracle operating system</li><li>• Oracle Database</li><li>• Oracle BI 12c</li><li>• Oracle WebLogic Server</li><li>• Oracle HTTP Server</li><li>• Java</li></ul>	
Gather compute and storage inventory information.	<p>In your source environment, review current and historical utilization metrics for the following:</p> <ul style="list-style-type: none"><li>• CPU usage</li><li>• Memory usage</li><li>• Storage usage</li></ul> <p><b>Important:</b> Make sure that you account for historical spikes in usage.</p>	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator, System Administrator

Task	Description	Skills required
Gather information about the source environment's architecture and its requirements.	<p>Obtain a full understanding of your source environment's architecture and its requirements, including knowledge of the following:</p> <ul style="list-style-type: none"> <li>• Oracle WebLogic Server domain configuration</li> <li>• Clustering</li> <li>• Load balancing</li> <li>• Connectivity</li> <li>• Availability</li> <li>• Disaster recovery requirements</li> </ul>	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator
Identify Java Database Connectivity (JDBC) data sources.	Gather information about your source environment's JDBC data sources and drivers for each database engine that it uses.	Migration Architect, Application Owner, Oracle BI Administrator, Database Engineer or Administrator
Gather information about environment-specific settings.	<p>Collect information about settings and configurations that are specific to your source environment, including the following:</p> <ul style="list-style-type: none"> <li>• Custom startup and shutdown scripts</li> <li>• Java and other environment variables</li> <li>• Certificates</li> </ul>	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
Identify any dependencies on other applications.	<p>Collect information about integrations in your source environment that create dependencies with other applications.</p> <p><b>Important:</b> Make sure that you identify any Lightweight Directory Access Protocol (LDAP) integrations and other networking requirements.</p>	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

## Design your target environment

Task	Description	Skills required
Create a high-level design document.	Create a target architecture design document. Make sure that you use the information that you collected when assessing your source environment to inform the design document.	Solutions Architect, Application Architect, Database Engineer, Migration Architect
Obtain approval for the design document.	Review the design document with stakeholders and obtain the required approvals.	Application or Service Owner, Solutions Architect, Application Architect

## Deploy the infrastructure

Task	Description	Skills required
<p>Prepare the infrastructure code in CloudFormation.</p>	<p>Create CloudFormation templates to provision your Oracle BI 12c infrastructure in the AWS Cloud.</p> <p>For more information, see <a href="#">Working with AWS CloudFormation templates</a> in the <i>AWS CloudFormation User Guide</i>.</p> <p><b>Note:</b> It's a best practice to create modular CloudFormation templates for each Oracle BI 12c tier, rather than one large template for all of your resources. For more information about CloudFormation best practices, see <a href="#">8 best practices when automating your deployments with AWS CloudFormation</a> on the AWS Blog.</p>	<p>Cloud Infrastructure Architect, Solutions Architect, Application Architect</p>
<p>Download the required software.</p>	<p>Download the following software along with the required versions and patches from the <a href="#">Oracle website</a>:</p> <ul style="list-style-type: none"> <li>• Java JDK8</li> <li>• Oracle WebLogic Server 12c</li> <li>• Oracle BI 12c</li> </ul>	<p>Migration Architect, Database Engineer, Application Architect</p>

Task	Description	Skills required
Prepare the installation scripts.	<p>Create software installation scripts that run a silent install. These scripts simplify the deployment automation.</p> <p>For more information, see <a href="#">OBIEE 12c: How to Perform Silent Installation?</a> on the Oracle Support site. You need an Oracle Support account to view the documentation.</p>	Migration Architect, Database Engineer, Application Architect
Create an Amazon EBS-backed Linux AMI for your web and application tiers.	<ol style="list-style-type: none"> <li>1. <a href="#">Deploy and configure Amazon EC2 instances</a> for your web and application tiers. Make sure that the instances meet the prerequisites for running the following: <ul style="list-style-type: none"> <li>• Oracle operating system environment setup</li> <li>• Oracle operating system user account set up</li> <li>• Java software installation</li> </ul> </li> <li>2. Create Amazon Machine Images (AMIs) of the instances and save copies for future use. For instructions, see <a href="#">Create an Amazon EBS-backed Linux AMI</a> in the <i>Amazon EC2 User Guide for Linux Instances</i>.</li> </ol>	Migration Architect, Database Engineer, Application Architect

Task	Description	Skills required
Launch your AWS infrastructure by using CloudFormation.	<p>Deploy your Oracle BI 12c web and application tiers in modules by using the CloudFormation templates that you created.</p> <p>For instructions, see <a href="#">Getting started with AWS CloudFormation</a> in the <i>AWS CloudFormation User Guide</i>.</p>	Cloud Infrastructure Architect, Solutions Architect, Application Architect

### Migrate Oracle BI 12c to AWS by using a fresh installation

Task	Description	Skills required
Stage the required software.	Stage the required software in a location that is accessible to the Amazon EC2 instances. For example, you could stage the software in Amazon S3 or another Amazon EC2 instance that would be accessible to your web and application servers.	Migration Architect, Oracle BI Architect, Cloud Infrastructure Architect, Solutions Architect, Application Architect
Prepare your repository database for Oracle BI 12c installation.	Create Oracle BI 12c schemas by running the <a href="#">Oracle Repository Creation Utility (RCU)</a> against a new <a href="#">Amazon RDS for Oracle</a> database instance.	Cloud Infrastructure Architect, Solutions Architect, Application Architect, Migration Architect, Oracle BI Architect
Install Oracle Fusion Middleware 12c and Oracle BI 12c.	1. Starting with one Amazon EC2 instance, install Oracle Fusion Middleware 12c	Migration Architect, Oracle BI Architect

Task	Description	Skills required
	<p>infrastructure and OBIEE 12c. For more information, see the following sections of the <i>Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence</i>:</p> <ul style="list-style-type: none"><li>• <a href="#">Starting the infrastructure installer on BIHOST1</a></li><li>• <a href="#">Installing Oracle Business Intelligence in preparation for an enterprise deployment</a></li></ul> <p><b>Note:</b> Use Amazon EFS to host directories that will be shared among Oracle BI 12c cluster nodes.</p> <ol style="list-style-type: none"><li>2. Apply any required patches to the installation.</li><li>3. Create AMIs of the instances and save copies for future use.</li></ol>	

Task	Description	Skills required
Configure your Oracle WebLogic Server domain for Oracle BI 12c.	<p>Configure your Oracle BI 12c domain as a non-clustered deployment.</p> <p>For more information, see <a href="#">Configuring the BI Domain</a> in the <i>Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence</i>.</p>	Migration Architect, Oracle BI Architect
Perform horizontal scale out of the Oracle BI 12c.	<p>Horizontally scale out the single node to the desired number of nodes.</p> <p>For more information, see <a href="#">Scaling out Oracle Business Intelligence</a> in the <i>Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence</i>.</p>	Migration Architect, Oracle BI Architect
Install Oracle HTTP Server 12c.	<ol style="list-style-type: none"> <li>1. Install Oracle HTTP Server 12c on the Oracle web tier Amazon EC2 instances. For instructions see <a href="#">Install Oracle HTTP Server 12c</a> in <i>Install and configure Oracle HTTP Server for Oracle Access Management 12c</i>.</li> <li>2. Apply any required patches to the installation.</li> <li>3. Create AMIs of the instances and save copies for future use.</li> </ol>	Migration Architect, Oracle BI Architect

Task	Description	Skills required
Configure load balancers for SSL termination.	<ol style="list-style-type: none"><li>1. Create or <a href="#">import SSL certificates in ACM</a>.</li><li>2. <a href="#">Associate the SSL certificates with ELB</a>.</li></ol>	Cloud Infrastructure Architect , Migration Architect
Migrate business intelligence metadata artifacts to AWS.	<ol style="list-style-type: none"><li>1. Export Oracle Business Intelligence Application Archive (BAR) files from the on-premises Oracle BI 12c installation. To export the BAR files, use the <a href="#">WebLogic Scripting Tool (WLST)</a> to run the <code>exportServiceInstance</code> command.</li><li>2. Import the on-premises BAR files into the AWS Oracle BI 12c installation. To import the BAR files, run the <code>importServiceInstance</code> WLST command.</li></ol>	Migration Architect, Oracle BI Architect

Task	Description	Skills required
Perform post-migration tasks.	<p>After importing the BAR files, do the following:</p> <ul style="list-style-type: none"> <li>• Configure any additional <a href="#">JDBC data sources</a>.</li> <li>• Install drivers for other data sources like PostgreSQL, or Amazon Redshift.</li> <li>• Configure Oracle <a href="#">LDAP</a>, <a href="#">SSL</a>, <a href="#">single sign-on (SSO)</a>, and <a href="#">WebLogic security store</a>.</li> <li>• Configure AWS Identity and Access Management (IAM) policies.</li> <li>• Activate usage tracking.</li> <li>• Set up integrations to other systems.</li> <li>• Migrate any custom scripts.</li> </ul>	Migration Architect, Oracle BI Architect

## Test the new environment

Task	Description	Skills required
Test the new Oracle BI 12c environment.	<p>Conduct end-to-end testing on the new Oracle BI 12c environment. Use automation as much as possible.</p> <p>Example of testing activities include the following:</p> <ul style="list-style-type: none"> <li>• Validating dashboards, reports, and URLs</li> </ul>	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>User acceptance testing (UAT)</li> <li>Operational acceptance testing (OAT)</li> </ul> <p><b>Note:</b> Conduct additional testing and validation as required.</p>	

### Cut over to the new environment

Task	Description	Skills required
Disconnect traffic to the on-premises Oracle BI 12c environment.	At the appointed cutover window, stop all traffic to the on-premises Oracle BI 12c environment.	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator
Resynchronize the new Oracle BI 12c repository database with the source database.	Resynchronize the Amazon RDS Oracle BI 12c repository database with the on-premises database.  To synchronize the databases, you can either use an <a href="#">Oracle Data Pump refresh</a> or an <a href="#">AWS DMS change data capture (CDC)</a> .	Oracle BI Administrator, Database Engineer/Administrator
Switch your Oracle BI 12c URLs to point to the new AWS environment.	Update the Oracle BI 12c URLs on your internal DNS servers so that they point to the new AWS installation.	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
Monitor the new environment.	Monitor the new Oracle BI 12c environment by using any of the following tools: <ul style="list-style-type: none"> <li>• <a href="#">Amazon CloudWatch</a></li> <li>• <a href="#">Amazon RDS Performance Insights</a></li> <li>• <a href="#">Oracle Enterprise Manager</a></li> </ul>	Oracle BI Administrator, Database Engineer/Administrator, Application Administrator
Get sign-off on the project.	Review the testing results with stakeholders and obtain the required approvals to wrap up the migration.	Application Owner, Service Owner, Cloud Infrastructure Architect, Migration Architect, Oracle BI Architect

- [Using the Oracle Repository Creation Utility on RDS for Oracle](#) (*Amazon RDS User Guide*)
- [Oracle on Amazon RDS](#) (*Amazon RDS User Guide*)
- [Oracle WebLogic Server 12c on AWS](#) (AWS whitepaper)
- [Deploying Oracle Business Intelligence for high availability](#) (Oracle Help Center)
- [Oracle Business Intelligence Application Archive \(BAR\) Files](#) (Oracle Help Center)
- [How to migrate OBI 12c between environments](#) (Oracle Support)

## Additional information

The following is a list of best practices related to migrating Oracle BI 12c to the AWS Cloud.

### Repository databases

It's a best practice to host Oracle BI 12c database schemas on an Amazon RDS for Oracle instance. This instance type provides cost-efficient and resizable capacity while automating administration tasks, such as hardware provisioning, database setup, patching, and backups.

For more information, see [Using the Oracle Repository Creation Utility on RDS for Oracle](#) in the *Amazon RDS User Guide*.

## Web and application tiers

[Memory optimized Amazon EC2 instances](#) are often well suited for Oracle BI 12c servers. Whatever instance type you choose, make sure that the instances that you provision meet your system's memory usage requirements. Also, make sure that you [configure a sufficient WebLogic Java Virtual Machine \(JVM\) heap size](#) based on your Amazon EC2 instance's available memory.

## Local storage

I/O plays an important part in the overall performance of your Oracle BI 12c application. Amazon Elastic Block Store (Amazon EBS) offers different storage classes that are optimized for different workload patterns. Make sure that you choose an Amazon EBS volume type that fits your use case.

For more information about EBS volume types, see [Amazon EBS features](#) in the Amazon EBS documentation.

## Shared storage

A clustered Oracle BI 12c domain requires shared storage for the following resources:

- Configuration files
- Oracle BI 12c singleton data directory (SDD)
- Oracle global cache
- Oracle BI Scheduler scripts
- Oracle WebLogic Server binaries

You can meet this shared storage requirement by using [Amazon EFS](#), which provides a scalable, fully managed elastic Network File System (NFS) file system.

### *Fine tuning shared storage performance*

Amazon EFS has two [throughput modes](#): **Provisioned** and **Bursting**. The service also has two [performance modes](#): **General Purpose** and **Max I/O**.

To fine tune performance, start by testing your workloads in the **General Purpose** performance mode and **Provisioned** throughput mode. Doing these tests will help you determine if those baseline modes are sufficient to meet your desired service levels.

For more information, see [Amazon EFS performance](#) in the *Amazon EFS User Guide*.

## Availability and disaster recovery

It's a best practice to deploy Oracle BI 12c components across multiple Availability Zones to protect those resources in the event of an Availability Zone failure. The following is a list of availability and disaster recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:

- **Oracle BI 12c repository databases:** Deploy a multi-AZ Amazon RDS database instance to your Oracle BI 12c repository database. In a multi-AZ deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different AZ. Running an Oracle BI 12c repository database instance across Availability Zones can enhance availability during planned system maintenance and help protect your databases against instance and Availability Zone failures.
- **Oracle BI 12c Managed Servers:** To achieve fault tolerance, it's a best practice to deploy Oracle BI 12c system components on Managed Servers in an Amazon EC2 Auto Scaling Group configured to span multiple Availability Zones. Auto Scaling replaces faulty instances based on [Amazon EC2 health checks](#). In the event of an Availability Zone failure, Oracle HTTP Servers continue to direct traffic to Managed Servers in the functioning Availability Zone. Then, Auto Scaling launches instances to keep up with your host count requirements. Activating HTTP session state replication is recommended to help make sure that there's a smooth failover of the existing sessions to the functioning Managed Servers.
- **Oracle BI 12c Administration Servers:** To make sure that your Administration Server has high availability, host it in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, set the minimum and maximum size of the group set to **1**. If an Availability Zone failure occurs, Amazon EC2 Auto Scaling starts up a replacement Administration Server in an alternate Availability Zone. To recover any failed underlying hosts within the same Availability Zone, you can activate [Amazon EC2 Auto Recovery](#).
- **Oracle Web Tier servers:** It's a best practice to associate your Oracle HTTP Server with your Oracle WebLogic Server domain. For high availability, deploy your Oracle HTTP Server in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, place the server behind an ELB elastic load balancer. To provide additional protection against host failure, you can activate Amazon EC2 Auto Recovery.

## Scalability

The elasticity of the AWS Cloud helps you scale applications either horizontally or vertically in response to workload requirements.

### *Vertical scaling*

To vertically scale your application, you can change the size and type of the Amazon EC2 instances that are running your Oracle BI 12c components. You don't need to over-provision instances at the start of your deployment and incur unnecessary cost.

### *Horizontal scaling*

Amazon EC2 Auto Scaling helps you horizontally scale your application by automatically adding or removing Managed Servers based on workload requirements.

**Note:** Horizontal scaling with Amazon EC2 Auto Scaling requires scripting skills and thorough testing to implement.

## **Backup and recovery**

The following is a list of backup and recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:

- **Oracle Business Intelligence metadata repositories:** Amazon RDS automatically creates and saves backups of your database instances. These backups are retained for a period of time that you specify. Make sure that you configure your Amazon RDS backup duration and retention settings based on your data protection requirements. For more information, see [Amazon RDS backup and restore](#).
- **Managed Servers, Administration Servers, and Web Tier servers:** Make sure that you configure [Amazon EBS snapshots](#) based on your data protection and retention requirements.
- **Shared storage:** You can manage backup and recovery for files stored in Amazon EFS by using [AWS Backup](#). The AWS Backup service can also be deployed to centrally manage backup and recovery of other services, including Amazon EC2, Amazon EBS, and Amazon RDS. For more information, see [What is AWS Backup?](#) In the *AWS Backup Developer Guide*.

## **Security and compliance**

The following is a list of security best practices and AWS services that can help you protect your Oracle BI 12c applications in the AWS Cloud:

- **Encryption at rest:** Amazon RDS, Amazon EFS, and Amazon EBS all support industry standard encryption algorithms. You can use [AWS Key Management Service \(AWS KMS\)](#) to create and manage cryptographic keys and control their use across AWS services and in your applications. You can also configure [Oracle Transparent Data Encryption \(TDE\)](#) on the Amazon RDS for Oracle database instance that's hosting your Oracle BI 12c repository database.
- **Encryption in transit:** It's a best practice to activate either SSL or TLS protocols to protect data in transit between the various layers of your Oracle BI 12c installation. You can use [AWS Certificate Manager \(ACM\)](#) to provision, manage, and deploy public and private SSL and TLS certificates for your Oracle BI 12c resources.
- **Network security:** Make sure that you deploy your Oracle BI 12c resources in an Amazon VPC that has the appropriate access controls configured for your use case. Configure your security groups to filter inbound and outbound traffic from the Amazon EC2 instances that are running your installation. Also, make sure that you configure [Network Access Control Lists \(NACLs\)](#) that allow or deny traffic based on defined rules.
- **Monitoring and logging:** You can use [AWS CloudTrail](#) to track API calls to your AWS infrastructure, including your Oracle BI 12c resources. This functionality is useful when tracking changes to infrastructure or when conducting a security analysis. You can also use [Amazon CloudWatch](#) to view operational data that can provide you with actionable insight into the performance and health of your Oracle BI 12c application. You can configure alarms and take automated actions based on those alarms, too. Amazon RDS provides additional monitoring tools, including [Enhanced Monitoring](#) and [Performance Insights](#).

# Migrate an on-premises Apache Kafka cluster to Amazon MSK by using MirrorMaker

Created by Han Zhang (AWS) and Tanner Pratt (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> On-premises or self-managed Apache Kafka cluster	<b>Target:</b> Amazon Managed Streaming for Apache Kafka (Amazon MSK)
<b>R Type:</b> Replatform	<b>Workload:</b> Open-source; All other workloads	<b>Technologies:</b> Analytics; Big data; Migration
<b>AWS services:</b> Amazon MSK		

## Summary

This pattern provides guidance for migrating an on-premises, self-managed, or hosted Apache Kafka cluster to Amazon Managed Streaming for Apache Kafka (Amazon MSK). You can also use this pattern to migrate from one Amazon MSK cluster to another.

Apache Kafka includes the MirrorMaker feature, which replicates data between two Kafka clusters. MirrorMaker consists of a collection of *consumers*, which are part of a *consumer group*. The consumers read data from the topics in the source cluster and then pass this data to *producers*, which write the data to the target cluster.

The Amazon MSK documentation contains a [high-level overview](#) of the process to use MirrorMaker version 1.0 to migrate on-premises Kafka clusters to Amazon MSK. This pattern supplements this information by offering comprehensive, step-by-step instructions for using MirrorMaker version 2.0.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Kafka source cluster that is one of the following:

- In an on-premises data center
- Self-managed in the cloud
- Hosted through a partner

## Limitations

- To use MirrorMaker version 2.0, the source cluster must be operating Apache Kafka version 2.4.0 or later. For earlier versions, see the instructions in the [Amazon MSK documentation](#) in order to use MirrorMaker version 1.0.

## Product versions

- MirrorMaker version 2.0
- Apache Kafka version 2.4.0 or later. For more information about the versions of Apache Kafka that Amazon MSK supports, see [Supported Apache Kafka versions](#).

## Architecture

### Source technology stack

- On-premises or self-managed Kafka cluster

### Target technology stack

- Amazon MSK cluster

### Target architecture

The diagram shows the following process:

1. MirrorMaker reads the data from the topics and consumer groups in the source Kafka cluster.
2. MirrorMaker replicates the data and consumer information to the target Amazon MSK cluster.

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Managed Streaming for Apache Kafka \(Amazon MSK\)](#) is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

### Other tools

- [Apache Kafka](#) is an open-source event streaming platform. In this pattern, you use the [MirrorMaker](#) feature of Kafka to perform the cross-cluster migration.

## Best practices

You can run MirrorMaker on in either the source or target environments, but it's recommended that you run it as close as possible to the target cluster. For more information, see [Best Practice: Consume from Remote, Produce to Local](#) in the Apache Kafka documentation.

## Epics

### Create the VPC and target Amazon MSK cluster

Task	Description	Skills required
Create a VPC.	<ol style="list-style-type: none"> <li>1. Create a VPC in the target AWS account. For instructions, see <a href="#">Create a VPC</a>.</li> <li>2. Create three private subnets in different Availability Zones in the new VPC. For instructions, see <a href="#">Create a subnet</a>. Using different Availability Zones provides high availability and fault tolerance.</li> </ol> <p><b>Note:</b> If you are using a public internet connection to migrate the Kafka cluster, create public subnets and <a href="#">enable public access</a> to the Amazon MSK cluster.</p>	AWS systems administrator, DevOps engineer, Cloud administrator

Task	Description	Skills required
Create the Amazon MSK cluster.	Create an Amazon MSK cluster. For instructions, see <a href="#">Creating a cluster using the AWS Management Console</a> or <a href="#">Creating a cluster using the AWS CLI</a> . Configure the cluster to use the VPC and subnets that you created previously.	AWS systems administrator, DevOps engineer, Cloud administrator

## Set up MirrorMaker

Task	Description	Skills required
Install MirrorMaker.	<ol style="list-style-type: none"> <li><a href="#">Launch an EC2 instance.</a></li> <li><a href="#">Connect to your EC2 instance.</a></li> <li>On the EC2 instance, download and extract the latest Kafka release. For instructions, see <a href="#">Quick Start</a> (Kafka documentation).</li> </ol> <p><b>Note:</b> In this pattern, you install MirrorMaker 2.0 as a dedicated MirrorMaker cluster on an Amazon EC2 instance. This option is acceptable for development environments and is the approach used in this pattern. For more information about</p>	AWS systems administrator, Cloud administrator, DevOps engineer

Task	Description	Skills required
	<p>other deployment options for MirrorMaker 2.0, see the <a href="#">Additional information</a> section of this pattern.</p>	
Specify Kafka cluster information.	<p>In the Kafka client installation bin folder, create a <b>mm2.properties</b> file and configure it for your source Kafka cluster. For instructions, see <a href="#">Running a dedicated MirrorMaker cluster</a> (Kafka documentation).</p>	AWS systems administrator, Cloud administrator, DevOps engineer
Start MirrorMaker.	<p>Enter the following command to start MirrorMaker and pass the <b>mm2.properties</b> file.</p> <pre data-bbox="594 1016 1027 1178">\$ ./bin/connect-mirror-maker.sh mm2.properties</pre>	AWS systems administrator, Cloud administrator, DevOps engineer
Monitor the progress.	<p>Check the progress by inspecting the lag between the last offset for each topic and the current offset for the topic MirrorMaker is consuming. For instructions, see <a href="#">Monitoring Geo-Replication</a> in the Kafka documentation.</p>	AWS systems administrator, Cloud administrator, DevOps engineer

## Cut over

Task	Description	Skills required
Stop the consumer applications.	Stop all consumer applications that consume data from the source cluster.	App developer
Start the consumer applications.	Alter the applications bootstrap configuration to point to the destination cluster. Then begin consuming on the target cluster.	App developer
Stop the producers on the source cluster.	When the consumer applications are successfully consuming on the target cluster, stop the producers on the source cluster.	App developer
Start the producers on the target cluster.	Alter the producer's configuration bootstrap servers, and point to the target cluster. Wait for MirrorMaker to finish mirroring all data from source cluster before starting the producers.	App developer
Stop MirrorMaker.	After producers have moved to the target cluster, stop MirrorMaker.	AWS systems administrator, Cloud administrator, DevOps engineer

## Related resources

### AWS resources

- [Migrating clusters using MirrorMaker](#) (Amazon MSK documentation)

- [Amazon MSK migration labs](#) (AWS workshop studio)

### Other resources

- [MirrorMaker 2.0](#) (Apache Kafka Improvement Proposals)
- [Geo-Replication: Cross-Cluster Data Mirroring](#) (Apache Kafka documentation)

## Additional information

This pattern runs MirrorMaker 2.0 as a dedicated MirrorMaker cluster on Amazon EC2. This option is acceptable for development environments. Although it is not discussed in this pattern, you can also run MirrorMaker 2.0 in a Kafka Connect cluster. This deployment option uses a framework within the Kafka ecosystem that improves scaling and maintenance. You deploy the connector into a Kafka Connect cluster with the associated configuration to run the application. The connector can run in *standalone mode* for development or testing or in *distributed mode* for production. For more information, see [Running MirrorMaker in a Connect cluster](#) (Apache Kafka documentation). For more information about other MirrorMaker 2.0 deployment options, see [Walkthrough: Running MirrorMaker 2.0](#) (Kafka documentation).

# Migrate an ELK Stack to Elastic Cloud on AWS

Created by Battulga Purevragchaa (AWS), uday reddy, and Antony Prasad Thevaraj (AWS)

<b>Environment:</b> Production	<b>Source:</b> Elasticsearch	<b>Target:</b> Elastic Cloud
<b>R Type:</b> Replatform	<b>Workload:</b> All other workloads	<b>Technologies:</b> Analytics; Security, identity, compliance
<b>AWS services:</b> Amazon EC2; Amazon EC2 Auto Scaling; Elastic Load Balancing (ELB); Amazon S3; Amazon Route 53		

## Summary

[Elastic](#) has provided services for many years, with their users and customers typically managing Elastic themselves on premises. [Elastic Cloud](#), the managed [Elasticsearch service](#), provides a way to consume the Elastic Stack (ELK Stack) and solutions for [enterprise search](#), [observability](#), and [security](#). You can access Elastic solutions with apps such as Logs, Metrics, APM (application performance monitoring), and SIEM (security information and event management). You can use integrated features such as machine learning, index lifecycle management, Kibana Lens (for drag-and drop visualizations).

When you move from self-managed Elasticsearch to Elastic Cloud, the Elasticsearch service takes care of the following:

- Provisioning and managing the underlying infrastructure
- Creating and managing Elasticsearch clusters
- Scaling clusters up and down
- Upgrades, patching, and taking snapshots

This gives you more time to focus on solving other challenges.

This pattern defines how to migrate on-premises Elasticsearch 7.13 to Elasticsearch on Elastic Cloud on Amazon Web Services (AWS). Other versions might require slight modifications to the processes described in this pattern. For more information, contact your Elastic representative.

## Prerequisites and limitations

### Prerequisites

- An active [AWS account](#) with access to [Amazon Simple Storage Service](#) (Amazon S3) for snapshots
- A secure, sufficiently high-bandwidth [private link](#) for copying snapshot data files to Amazon S3
- [Amazon S3 Transfer Acceleration](#)
- [Elastic Snapshot policies](#) to ensure that data ingestion is archived regularly, either to a sufficiently large local data store or to remote storage (Amazon S3)

You must understand how large your snapshots and the [lifecycle policies](#) for accompanying indexes are on premises before initiating your migration. For more information, [contact Elastic](#).

### Roles and skills

The migration process also requires the roles and expertise described in the following table.

Role	Expertise	Responsibilities
App support	Familiarity with Elastic Cloud and Elastic on premises	All Elastic related tasks
Systems administrator or DBA	In-depth knowledge of the on-premises Elastic environment and its configuration	The ability to provision storage, install and use the AWS Command Line Interface (AWS CLI), and identify all data sources feeding Elastic on premises
Network administrator	Knowledge of on-premises to AWS network connectivity, security, and performance	Establishment of network links from on premises to Amazon S3, with an understanding of connectivity bandwidth

## Limitations

- Elasticsearch on Elastic Cloud is available only in [supported AWS Regions \(September 2021\)](#).

## Product versions

- Elasticsearch 7.13

## Architecture

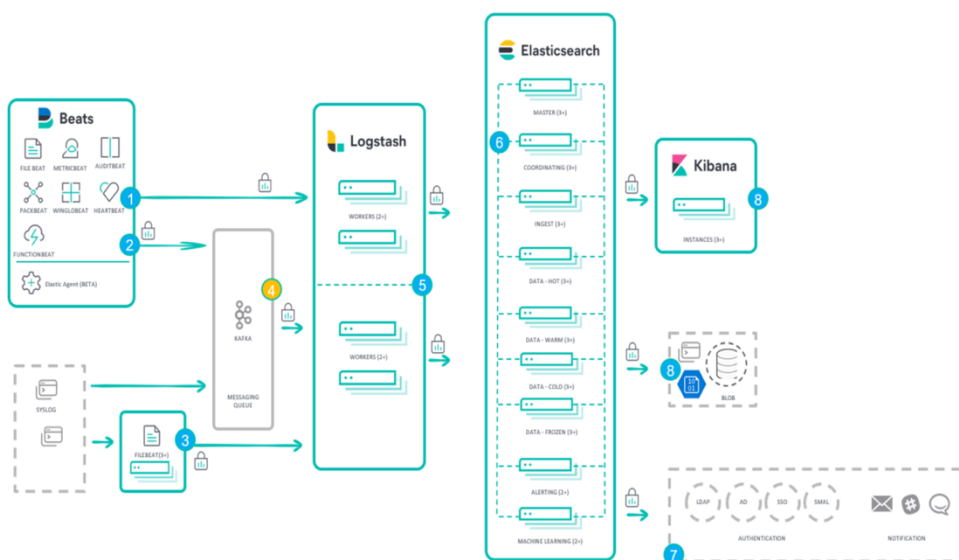

### Source technology stack

On-premises Elasticsearch 7.13 or later:

- Cluster snapshots
- Index snapshots
- [Beats](#) configuration

### Source technology architecture

The following diagram shows a typical on-premises architecture with different ingestion methods, node types, and Kibana. The different node types reflect the Elasticsearch cluster, authentication, and visualization roles.

1. Ingestion from Beats to Logstash
2. Ingestion from Beats to Apache Kafka messaging queue
3. Ingestion from Filebeat to Logstash
4. Ingestion from Apache Kafka messaging queue to Logstash
5. Ingestion from Logstash to an Elasticsearch cluster
6. Elasticsearch cluster
7. Authentication and notification node
8. Kibana and blob nodes

### **Target technology stack**

Elastic Cloud is deployed to your software as a service (SaaS) account in multiple AWS Regions with cross-cluster replication.

- Cluster snapshots
- Index snapshots
- Beats configurations
- Elastic Cloud
- Network Load Balancer
- Amazon Route 53
- Amazon S3

### **Target architecture**

The managed Elastic Cloud infrastructure is:

- Highly available, being present in multiple [Availability Zones](#) and multiple AWS Regions.
- Region failure tolerant because data (indexes and snapshots) is replicated using Elastic Cloud [cross-cluster replication \(CCR\)](#)
- Archival, because snapshots are archived in [Amazon S3](#)
- Network partition tolerant through a combination of [Network Load Balancers](#) and [Route 53](#)
- Data ingestion originating from (but not limited to) [Elastic APM](#), [Beats](#), [Logstash](#)

### High-level migration steps

Elastic has developed its own prescriptive methodology for migrating on-premises Elastic Cluster to Elastic Cloud. The Elastic methodology is directly aligned and complementary to the AWS migration guidance and best practices, including [Well-Architected Framework](#) and [AWS Migration Acceleration Program](#) (MAP). Typically, the three AWS migration phases are the following:

- Assess
- Mobilize

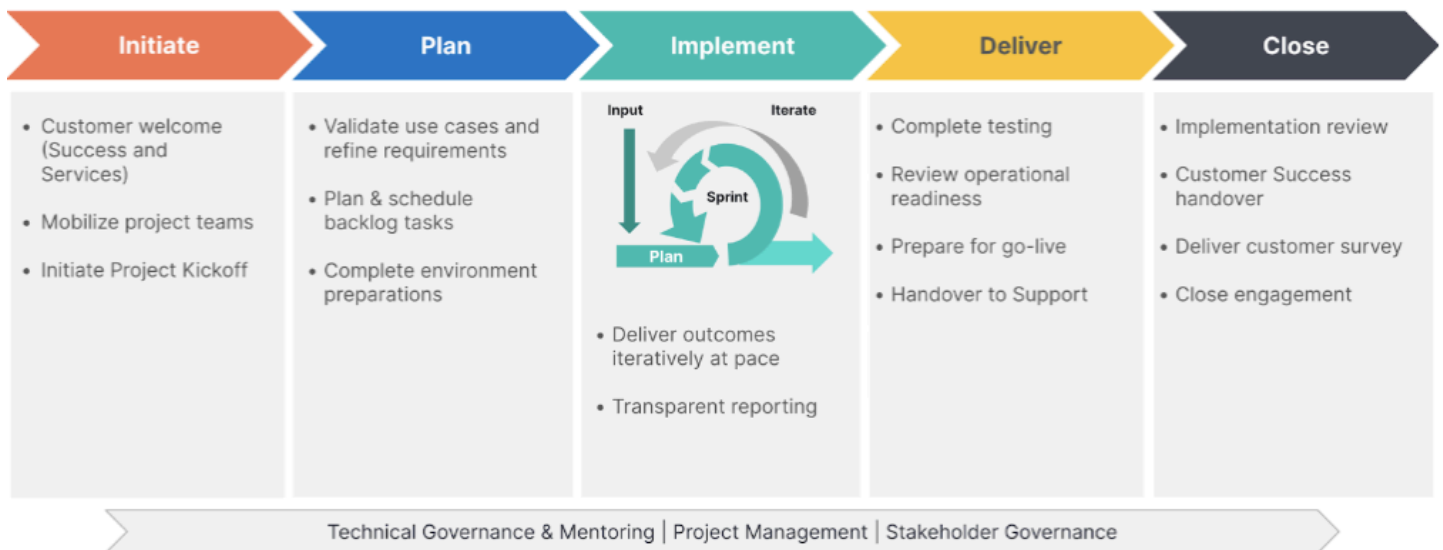

- Migrate and modernize

Elastic follows similar migration phases with complementary terminology:

- Initiate
- Plan
- Implement
- Deliver
- Close

Elastic uses the Elastic Implementation Methodology to facilitate the delivery of project outcomes. This is inclusive by design to ensure that the Elastic, consulting teams, and customer teams work together with clarity to jointly deliver intended outcomes.

The Elastic methodology combines traditional waterfall phasing with Scrum within the implementation phase. Configurations of technical requirements are delivered iteratively in a collaborative manner while minimizing risk.

## Tools

### AWS services

- [Amazon Route 53](#) – Amazon Route 53 is a highly available and scalable Domain Name System (DNS) web service. You can use Route 53 to perform three main functions in any combination: domain registration, DNS routing, and health checking.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses an S3 bucket and [Amazon S3 Transfer Acceleration](#).
- [Elastic Load Balancing](#) – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones.

## Other tools

- [Beats](#) – Beats ship data from Logstash or Elasticsearch
- [Elastic Cloud](#) – Elastic Cloud is a managed service for hosting Elasticsearch.
- [Elasticsearch](#) – Elasticsearch is a search and analytics engine that uses the Elastic Stack to centrally store your data for search and analytics that scale. This pattern also uses snapshot creation and cross-cluster replication.
- [Logstash](#) – Logstash is a server-side data processing pipeline that ingests data from multiple sources, transforms it, and then sends it to your data storage.

## Epics

### Prepare the migration

Task	Description	Skills required
Identify servers running the on-premises Elastic solution.	Confirm that Elastic migration is supported.	App owner
Understand the on-premises server configuration.	To understand the server configuration needed to drive workloads successfully on premises, find the server hardware footprint, network configuration, and	App Support

Task	Description	Skills required
	storage characteristics that are currently in use	
Gather user and app account information.	Identify the user names and app names that are used by the on-premises Elastic environment.	Systems administrator, App support
Document Beats and data shipper configuration.	To document the configurations, look at existing data sources and sinks. For more information, see the <a href="#">Elastic documentation</a> .	App support
Determine the velocity and volume of data.	Establish a baseline for how much data the cluster is handling.	Systems administrator, App support
Document RPO and RTO scenarios.	Document recovery point objective (RPO) and recovery time objective (RTO) scenarios in terms of outages and service level agreements (SLAs).	App owner, Systems administrator, App support
Determine the optimal snapshot lifecycle settings.	Define how often data needs to be secured by using Elastic snapshots <i>during and after</i> the migration.	App owner, Systems administrator, App support
Define post-migration performance expectations.	Generate metrics on current and expected screen refresh, query runtimes, and user interface behaviors.	Systems administrator, App support

Task	Description	Skills required
Document internet access transport, bandwidth, and availability requirements.	Ascertain speed, latency, and resiliency of internet connections for copying snapshots to Amazon S3.	Network administrator
Document current costs of on-premises runtime for Elastic.	Ensure that the sizing of the AWS targeted environment is designed to be both high performing and cost effective.	DBA, Systems administrator, App support
Identify the authentication and authorization needs.	The Elastic Stack security features provide built-in realms such as Lightweight Directory Access Protocol (LDAP), Security Assertion Markup Language (SAML), and OpenID Connect (OIDC).	DBA, Systems administrator, App support
Understand the specific regulatory requirements based on the geographic location.	Ensure that data is exported and encrypted according to your requirements and to any relevant national requirements.	DBA, Systems administrator, App support

## Implement the migration

Task	Description	Skills required
Prepare the staging area on Amazon S3.	To receive snapshots on Amazon S3, <a href="#">create an S3 bucket</a> and a temporary AWS Identity and Access Management (IAM) role with full access to your newly created bucket. For more	AWS administrator

Task	Description	Skills required
	<p>information, see <a href="#">Creating a role to delegate permissions to an IAM user</a>. Use the AWS Security Token Service to <a href="#">request temporary security credentials</a>. Keep the access key ID, secret access key, and session token secured.</p> <p>Enable <a href="#">Amazon S3 Transfer Acceleration</a> on the bucket.</p>	
<p>Install AWS CLI and the Amazon S3 plugin on premises.</p>	<p>On each Elasticsearch node, run the following command.</p> <pre data-bbox="594 873 1026 1031">sudo bin/elasticsearch-plugin install repository-s3</pre> <p>Then reboot the node.</p>	<p>AWS administrator</p>
<p>Configure Amazon S3 client access.</p>	<p>Add the keys created previously by running the following commands.</p> <pre data-bbox="594 1318 1026 1476">elasticsearch-keystore add s3.client.default.access_key</pre> <pre data-bbox="594 1507 1026 1665">elasticsearch-keystore add s3.client.default.secret_key</pre> <pre data-bbox="594 1696 1026 1854">elasticsearch-keystore add s3.client.default.session_token</pre>	<p>AWS administrator</p>

Task	Description	Skills required
Register a snapshot repository for Elastic data	Use the <a href="#">Kibana Dev Tools</a> to tell the on-premises local cluster which remote S3 bucket to write to.	AWS administrator
Configure snapshot policy.	<p>To configure snapshot lifecycle management, on the Kibana <b>Policies</b> tab, choose <b>SLM policy</b>, and define which times, data streams, or indexes should be included, and what names to use.</p> <p>Configure a policy that takes frequent snapshots . Snapshots are incremental and make efficient use of storage. Match your readiness assessment decision. A policy can also specify a <a href="#">retention policy</a> and automatically delete snapshots when they are no longer needed.</p>	App support
Verify that snapshots work.	<p>In Kibana Dev Tools, run the following command.</p> <pre>GET _snapshot/&lt;your_repo_name&gt;/_all</pre>	AWS administrator, App support,
Deploy a new cluster on Elastic Cloud.	<a href="#">Log in to Elastic</a> , and choose a cluster for “observability, search or security” derived from your business findings in the readiness assessment.	AWS administrator, App support

Task	Description	Skills required
Set up cluster key store access.	The new cluster needs access to the S3 bucket that will store the snapshots. On the Elasticsearch Service Console, choose <b>Security</b> , and enter the access and secret IAM keys that you created earlier.	AWS administrator
Configure the Elastic Cloud hosted cluster to access Amazon S3.	<p>Set up new cluster access to the previously created snapshot repository in Amazon S3. Using Kibana, do the following:</p> <ol style="list-style-type: none"> <li>1. Choose <b>Stack Management, Snapshot Settings, RegisterRepo</b>.</li> <li>2. In the <b>Alias</b> field, enter the name of the repository.</li> <li>3. For <b>S3 Client name</b>, choose <b>secondary</b>.</li> <li>4. Add the S3 bucket that you created earlier to the repository.</li> <li>5. Choose <b>Compress snapshot</b>.</li> <li>6. For the <b>Encryption</b> settings, keep the default values.</li> </ol>	AWS administrator, App Support
Verify the new Amazon S3 repository.	Ensure that you can access your new repository hosted in the Elastic Cloud cluster.	AWS administrator

Task	Description	Skills required
Initilaize the Elasticsearch service cluster.	<p>On the Elasticsearch Service Console, initialize the Elasticsearch service cluster from the S3 snapshot.</p> <p>Run the following commands as POST.</p> <pre>*/_close?expand_wildcards=all</pre> <pre>/_snapshot/&lt;your-repo-name&gt;/&lt;your-snapshot-name&gt;/_restore</pre> <pre>*/_open?expand_wildcards=all</pre>	App Support

## Complete the migration

Task	Description	Skills required
Verify that the snapshot restore was successful.	<p>Using Kibana Dev Tools, run the following command.</p> <pre>GET _cat/indices</pre>	App support
Redploy ingestion services.	Connect the endpoints for Beats and Logstash to the new Elasticsearch service endpoint.	App support

## Test the cluster environment and clean up

Task	Description	Skills required
Validate the cluster environment.	After the on-premises Elastic cluster environment is migrated to AWS, you can connect to it and use your own user acceptance testing (UAT) tools to validate the new environment.	App support
Clean-up the resources.	After you validate that the cluster migrated successfully, remove the S3 bucket and the IAM role used for the migration.	AWS administrator

# Migrate data to the AWS Cloud by using Starburst

Created by Antony Prasad Thevaraj (AWS), Shaun Van Staden (Starburst), and Suresh Veeragoni (AWS)

**Environment:** Production

**Technologies:** Analytics;  
Data lakes; Databases

**Workload:** All other workloads

**AWS services:** Amazon EKS

## Summary

Starburst helps accelerate your data migration journey to Amazon Web Services (AWS) by providing an enterprise query engine that brings existing data sources together in a single access point. You can run analytics across multiple data sources to get valuable insights, before finalizing any migration plans. Without disrupting business-as-usual analytics, you can migrate the data by using the Starburst engine or a dedicated extract, transform, and load (ETL) application.

## Prerequisites and limitations

### Prerequisites

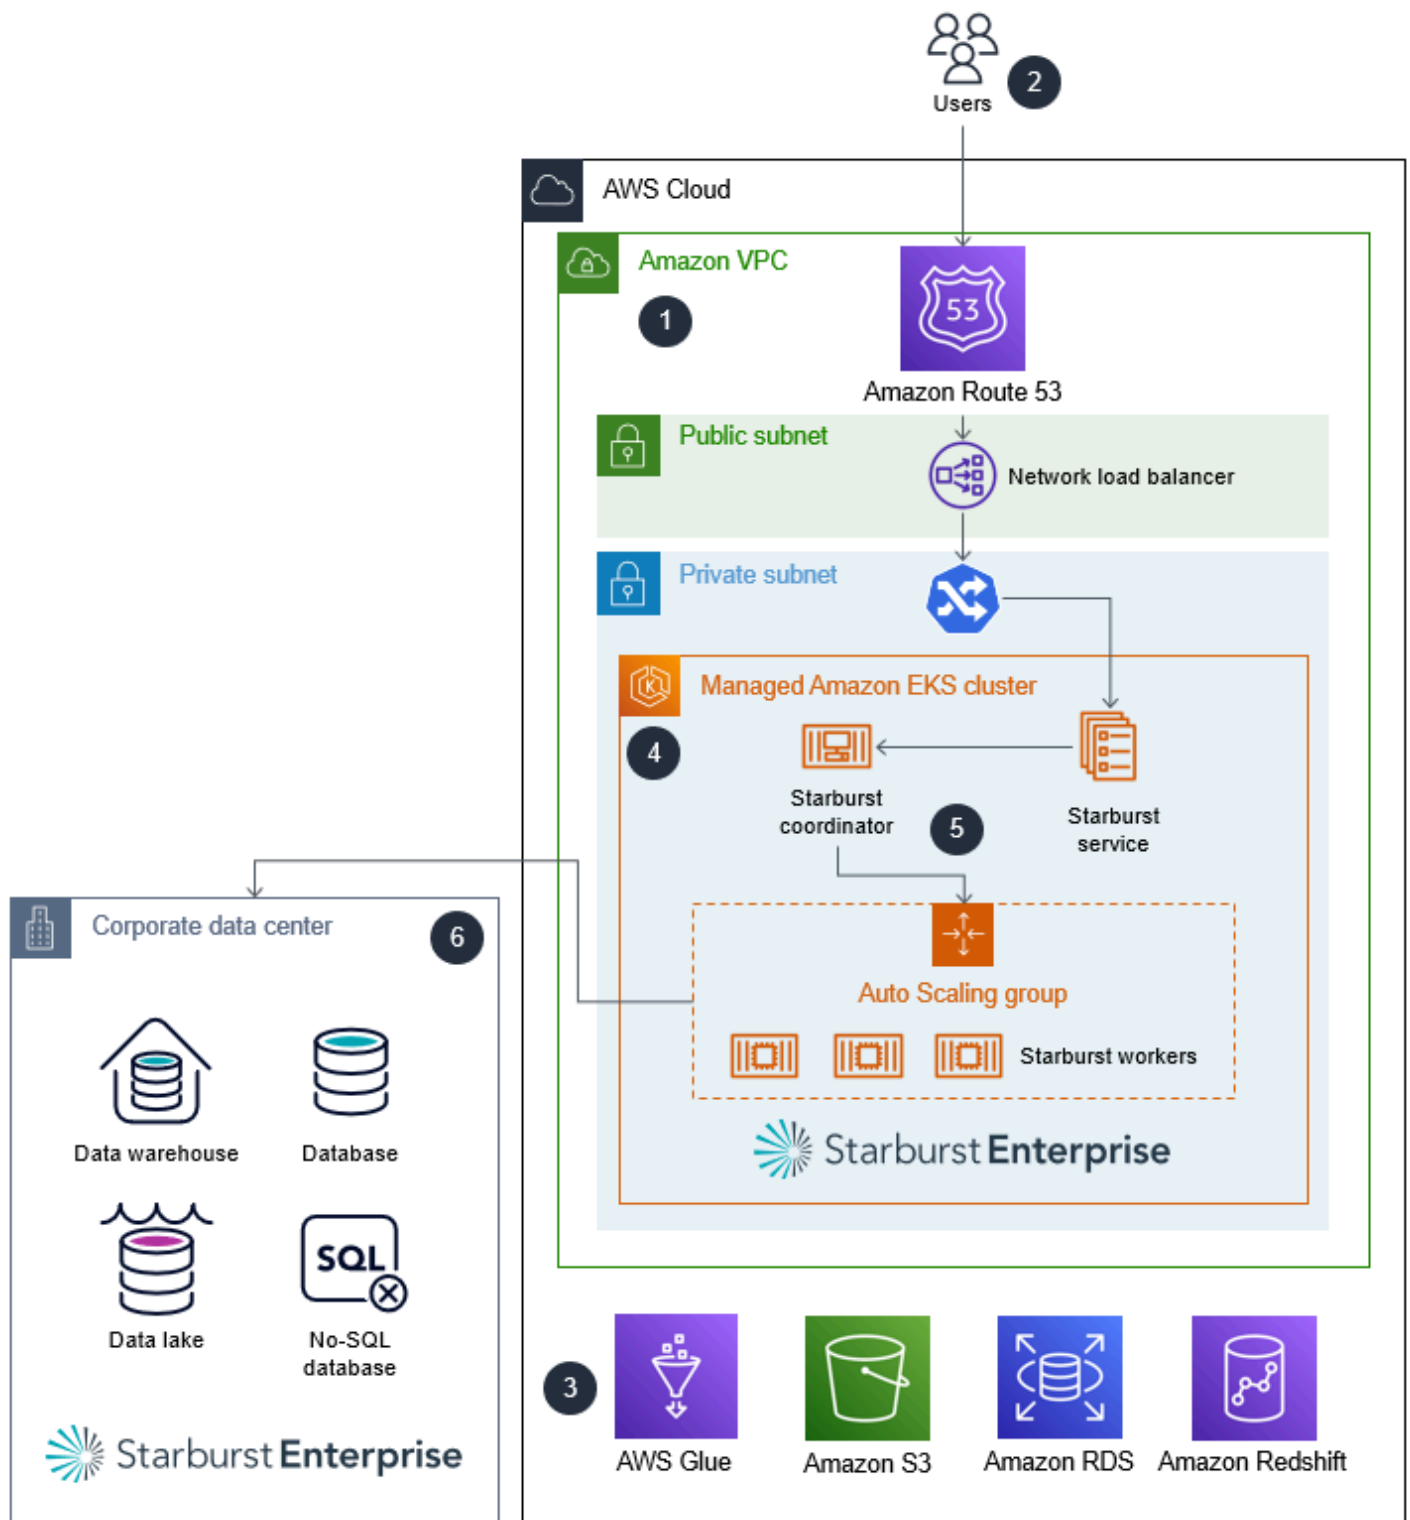

- An active AWS account
- A virtual private cloud (VPC)
- An Amazon Elastic Kubernetes Service (Amazon EKS) cluster
- An Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group
- A list of current system workloads that need to be migrated
- Network connectivity from AWS to your on-premises environment

## Architecture

### Reference architecture

The following high-level architecture diagram shows the typical deployment of Starburst Enterprise in the AWS Cloud:

1. The Starburst Enterprise cluster runs inside your AWS account.
2. A user authenticates by using Lightweight Directory Access Protocol (LDAP) or Open Authorization (OAuth) and interacts directly with the Starburst cluster.
3. Starburst can connect to several AWS data sources, such as AWS Glue, Amazon Simple Storage Service (Amazon S3), Amazon Relational Database Service (Amazon RDS), and Amazon Redshift. Starburst provides federated query capabilities across data sources in the AWS Cloud, on premises, or in other cloud environments.
4. You launch Starburst Enterprise in an Amazon EKS cluster by using Helm charts.
5. Starburst Enterprise uses Amazon EC2 Auto Scaling groups and Amazon EC2 Spot Instances to optimize infrastructure.
6. Starburst Enterprise connects directly to your existing on-premises data sources to read data real-time. In addition, if you have an existing Starburst Enterprise deployment in this environment, you can directly connect your new Starburst cluster in the AWS Cloud to this existing cluster.

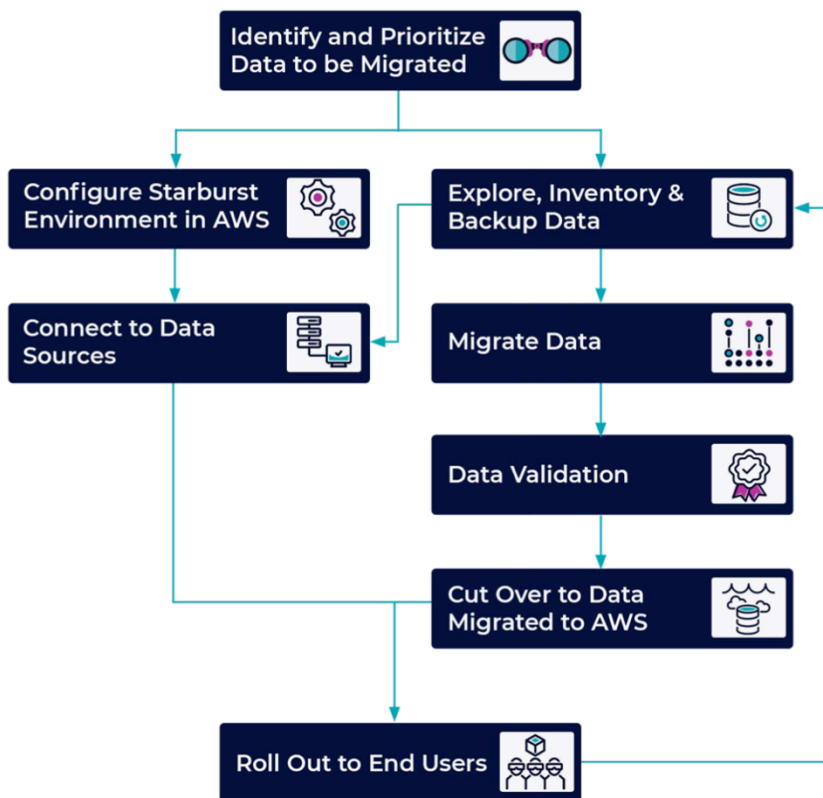

Please note the following:

- Starburst is not a data virtualization platform. It is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- When Starburst is deployed as part of a migration, it has direct connectivity to the existing on-premises infrastructure.
- Starburst provides several built-in enterprise and open-source connectors that facilitate connectivity to a variety of legacy systems. For a full list of connectors and their capabilities, see [Connectors](#) in the *Starburst Enterprise user guide*.
- Starburst can query data in real-time from on-premises data sources. This prevents interruptions of regular business operations while data is being migrated.
- If you are migrating from an existing on-premises Starburst Enterprise deployment, you can use a special connector, *Starburst Stargate*, to connect your Starburst Enterprise cluster in AWS directly to your on-premises cluster. This provides additional performance benefits when business users and data analysts are federating queries from the AWS Cloud to your on-premises environment.

## High-level process overview

You can accelerate data migration projects by using Starburst because Starburst enables insights across all of your data, prior to migrating it. The following image shows the typical process for migrating data by using Starburst.

## Roles

The following roles are typically required to complete a migration using Starburst:

- **Cloud administrator** – Responsible for making cloud resources available to run the Starburst Enterprise application
- **Starburst administrator** – Responsible for installing, configuring, managing, and supporting the Starburst application
- **Data engineer**– Responsible for:
  - Migrating the legacy data to the cloud
  - Building semantic views to support analytics
- **Solution or system owner** – Responsible for the overall solution implementation

## Tools

### AWS services

- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- [Amazon EKS](#) – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

## Other tools

- [Helm](#) – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- [Starburst Enterprise](#) – Starburst Enterprise is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- [Starburst Stargate](#) – Starburst Stargate links catalogs and data sources in one Starburst Enterprise environment, such as a cluster in an on-premises data center, to the catalogs and data sources in another Starburst Enterprise environment, such as a cluster in the AWS Cloud.

## Epics

### Assess the data

Task	Description	Skills required
Identify and prioritize your data.	Identify the data you want to move. Large, on-premises legacy systems can include core data that you want to migrate alongside data that you don't want to move or can't be moved because of compliance reasons. Starting with a data inventory helps you prioritize which data you should target first. For more information, see <a href="#">Get started</a>	Data engineer, DBA

Task	Description	Skills required
	<a href="#">with automated portfolio discovery</a> .	
Explore, inventory, and back up your data.	Validate the quality, quantity, and relevance of the data for your use case. Back up or create a snapshot of the data as needed, and finalize the target environment for the data.	Data engineer, DBA

## Set up the Starburst Enterprise environment

Task	Description	Skills required
Configure Starburst Enterprise in the AWS Cloud.	While data is being catalogued, set up Starburst Enterprise in a managed Amazon EKS cluster. For more information see, <a href="#">Deploying with Kubernetes</a> in the <i>Starburst Enterprise reference documentation</i> . This allows business-as-usual analytics while data migration is in process.	AWS administrator, App developer
Connect Starburst to the data sources.	After you have identified the data and set up Starburst Enterprise, connect Starburst to the data sources. Starburst reads data directly from the data source as a SQL query. For more information, see the	AWS administrator, App developer

Task	Description	Skills required
	<a href="#">Starburst Enterprise reference documentation.</a>	

## Migrate the data

Task	Description	Skills required
Build and run the ETL pipelines.	Begin the data migration process. This activity can occur at the same time as business-as-usual analytics . For the migration, you can use a third-party product or Starburst. Starburst has the capability to both read and write data across different sources. For more information, see the <a href="#">Starburst Enterprise reference documentation.</a>	Data engineer
Validate the data.	After the data has been migrated, validate the data to ensure all required data has been moved and is intact.	Data engineer, DevOps engineer

## Cut over and roll out

Task	Description	Skills required
Cut over the data.	After data migration and validation is complete, you can cut over the data. This involves changing the data	Data engineer, Cutover lead

Task	Description	Skills required
	<p>connection links in Starburst. Instead of pointing at the on-premises sources, you point to the new cloud sources and update the semantic views. For more information, see <a href="#">Connectors</a> in the <i>Starburst Enterprise reference documentation</i>.</p>	
Roll out to users.	Data consumers begin working off the migrated data sources. This process is invisible to the analytics end users.	Cutover lead, Data engineer

# Optimize the ETL ingestion of input file size on AWS

Created by Apoorva Patrikar (AWS)

**Environment:** PoC or pilot

**Technologies:** Analytics;  
Data lakes

**Workload:** Open-source

**AWS services:** AWS Glue;  
Amazon S3

## Summary

This pattern shows you how to optimize the ingestion step of the extract, transform, and load (ETL) process for big data and Apache Spark workloads on AWS Glue by optimizing file size before processing your data. Use this pattern to prevent or resolve the *small files problem*. That is, when a large number of small files slows down data processing due to the aggregate size of the files. For example, hundreds of files that are only a few hundred kilobytes each can significantly slow down data processing speeds for your AWS Glue jobs. This is because AWS Glue must perform internal list functions on Amazon Simple Storage Service (Amazon S3) and YARN (Yet Another Resource Negotiator) must store a large amount of metadata. To improve data processing speeds, you can use grouping to enable your ETL tasks to read a group of input files into a single in-memory partition. The partition automatically groups smaller files together. Alternatively, you can use custom code to add batch logic to your existing files.

## Prerequisites and limitations

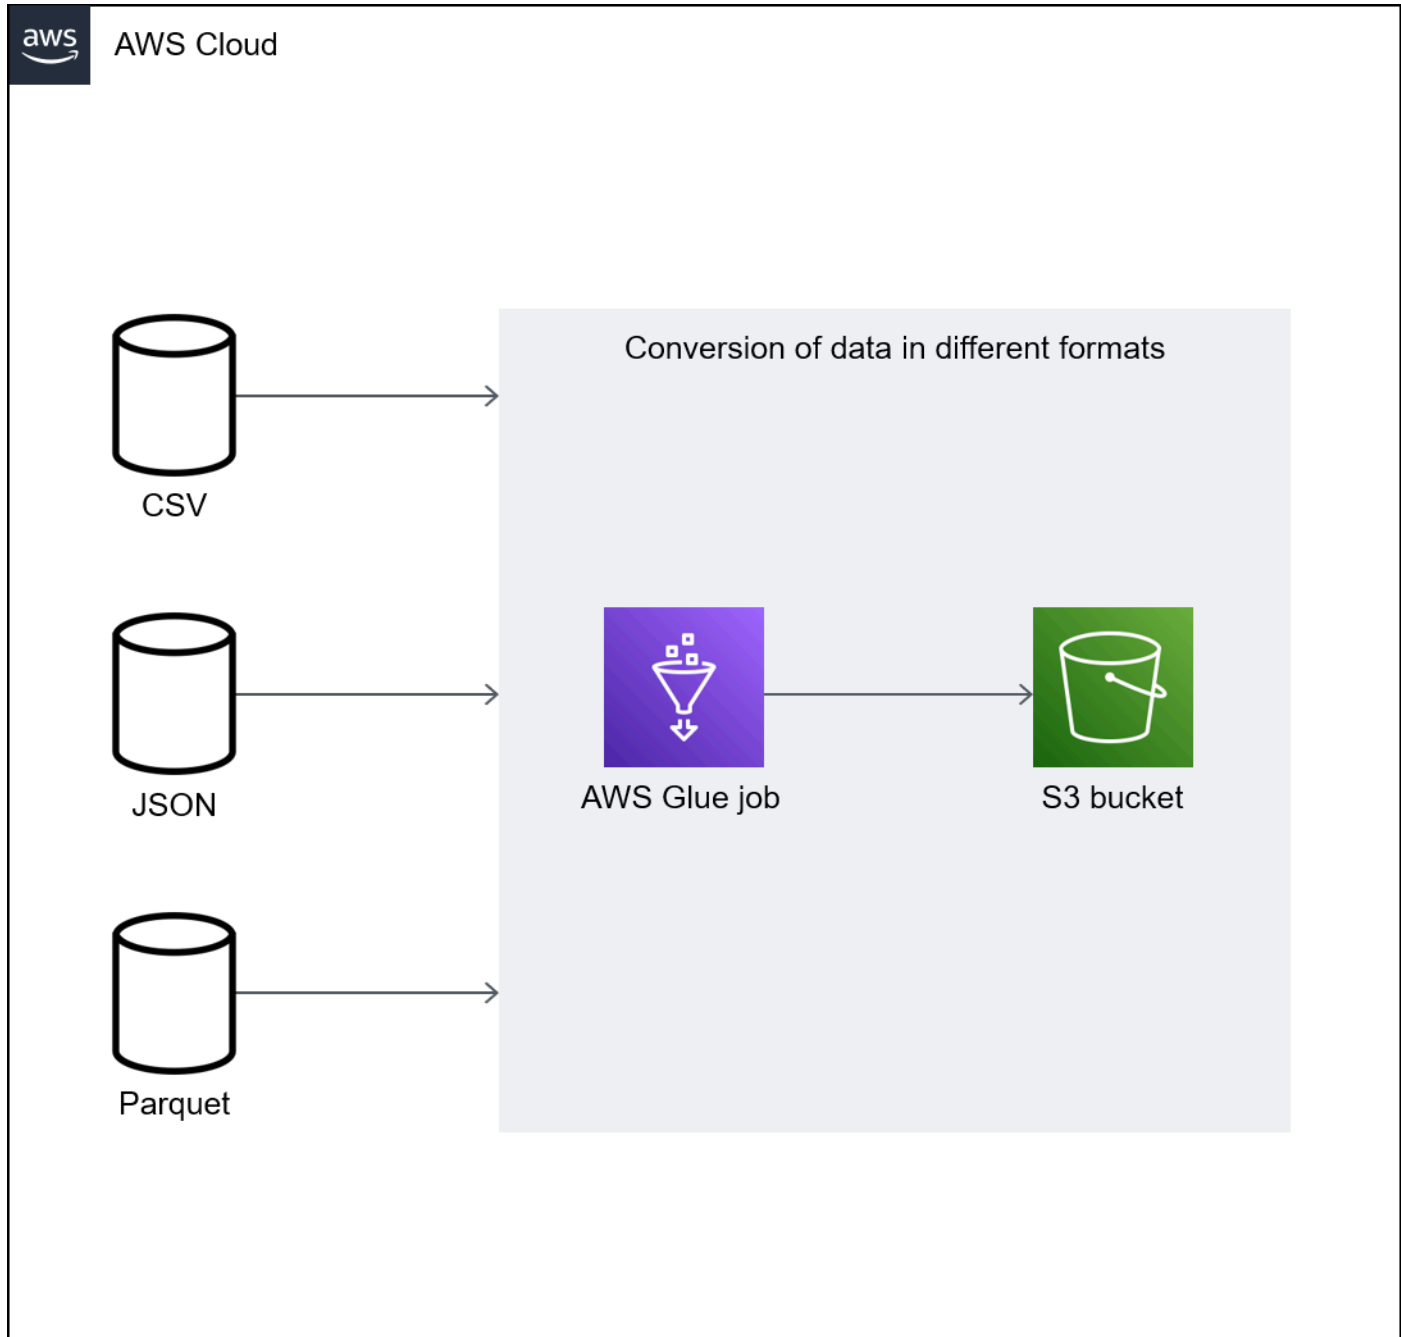

### Prerequisites

- An active AWS account
- One or more AWS glue [jobs](#)
- One or more big data or [Apache Spark](#) workloads
- An [S3 bucket](#)

## Architecture

The following pattern shows how data in different formats is processed by an AWS Glue job and then stored in an S3 bucket to get visibility into performance.

The diagram shows the following workflow:

1. An AWS Glue job converts small files in CSV, JSON, and Parquet format to dynamic frames. **Note:** The size of the input file has the most significant impact on the performance of the AWS Glue job.
2. The AWS Glue job performs internal list functions in an S3 bucket.

## Tools

- [AWS Glue](#) is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

## Epics

### Use grouping to optimize ETL ingestion during reading

Task	Description	Skills required
Specify the group size.	If you have more than 50,000 files, grouping is done by default. However, you can also use grouping for less than 50,000 files by specifying the group size in the <code>connectionOptions</code> parameter. The <code>connectionOptions</code> parameter is in the <code>create_dynamic_frame.from_options</code> method.	Data engineer
Write the grouping code.	Use the <code>create_dynamic_frame</code> method to create a dynamic frame. For example:	Data engineer

Task	Description	Skills required
	<pre data-bbox="609 226 1031 1201"> S3bucket_node1 =   glueContext.create   _dynamic_frame.from   m_options(     format_options={"m     ultiline": False},     connection_type="s     3",     format="json",     connection_options     ={       "paths": ["s3://       bucket/prefix/file.j       son"],       "recurse":       True,       "groupFiles":       'inPartition',       "groupSize":       1048576     },     transformation_ctx     ="S3bucket_node1",   ) </pre> <p data-bbox="592 1243 1031 1564"><b>Note:</b> Use <code>groupFiles</code> to group files in an Amazon S3 partition group. Use <code>groupSize</code> to set the target size of the group to be read in memory. Specify <code>groupSize</code> in bytes (1048576 = 1 MB).</p>	
Add the code to the workflow.	Add the grouping code to your job <a href="#">workflow</a> in AWS Glue.	Data engineer

## Use custom logic to optimize ETL ingestion

Task	Description	Skills required
Choose the language and processing platform.	Choose the scripting language and processing platform tailored to your use case.	Cloud architect
Write the code.	Write the custom logic to batch your files together.	Cloud architect
Add the code to the workflow.	Add the code to your job <a href="#">workflow</a> in AWS Glue. This enables your custom logic to be applied every time the job is run.	Data engineer

## Repartition when writing data after transformation

Task	Description	Skills required
Analyze consumption patterns.	Find out how downstream applications will use the data you write. For example, if they query data each day and you only partition data per Region or have very small output files, such as 2.5 KB per file, then this is not optimal for consumption.	DBA
Repartition data before writing.	Repartition based on joins or queries during processing (based on processing logic) and after processing (based on consumption). For	Data engineer

Task	Description	Skills required
	example, repartition based on byte size, such as <code>.repartition(100000)</code> , or repartition based on columns, such as <code>.repartition("column_name")</code> .	

## Related resources

- [Reading input files in larger groups](#)
- [Monitoring AWS Glue](#)
- [Monitoring AWS Glue using Amazon CloudWatch metrics](#)
- [Job monitoring and debugging](#)
- [Getting started with serverless ETL on AWS Glue](#)

## Additional information

### Determining file size

There is no straightforward way to determine if a file size is too big or too small. The impact of file size on processing performance depends on the configuration of your cluster. In core Hadoop, we recommend that you use files that are 128 MB or 256 MB to make the most of the block size.

For most text file workloads on AWS Glue, we recommended a file size between 100 MB and 1 GB for a 5-10 DPU cluster. To figure out the best size of input files, monitor the preprocessing section of your AWS Glue job, and then check the CPU utilization and memory utilization of the job.

### Additional considerations

If performance in the early ETL stages is a bottleneck, consider grouping or merging the data files before processing. If you have complete control on the file generation process, it can be even more efficient to aggregate data points on the source system itself before the raw data is sent to AWS.

# Orchestrate an ETL pipeline with validation, transformation, and partitioning using AWS Step Functions

Created by Sandip Gangapadhyay (AWS)

**Code repository:** [aws-step-functions-etl-pipeline-pattern](#)

**Environment:** Production

**Technologies:** Analytics; Big data; Data lakes; DevOps; Serverless

**AWS services:** Amazon Athena; AWS Glue; AWS Lambda; AWS Step Functions

## Summary

This pattern describes how to build a serverless extract, transform, and load (ETL) pipeline to validate, transform, compress, and partition a large CSV dataset for performance and cost optimization. The pipeline is orchestrated by AWS Step Functions and includes error handling, automated retry, and user notification features.

When a CSV file is uploaded to an Amazon Simple Storage Service (Amazon S3) bucket source folder, the ETL pipeline starts to run. The pipeline validates the content and the schema of the source CSV file, transforms the CSV file to a compressed Apache Parquet format, partitions the dataset by year, month, and day, and stores it in a separate folder for analytics tools to process.

The code that automates this pattern is available on GitHub, in the [ETL Pipeline with AWS Step Functions](#) repository.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured with your AWS account, so that you can create AWS resources by deploying an AWS CloudFormation stack. AWS CLI version 2 is recommended. For installation instructions, see [Installing, updating, and uninstalling the](#)

[AWS CLI version 2](#) in the AWS CLI documentation. For AWS CLI configuration instructions, see [Configuration and credential file settings](#) in the AWS CLI documentation.

- An Amazon S3 bucket.
- A CSV dataset with the correct schema. (The [code repository](#) included with this pattern provides a sample CSV file with the correct schema and data type that you can use.)
- A web browser that is supported for use with the AWS Management Console. (See the [list of supported browsers](#).)
- AWS Glue console access.
- AWS Step Functions console access.

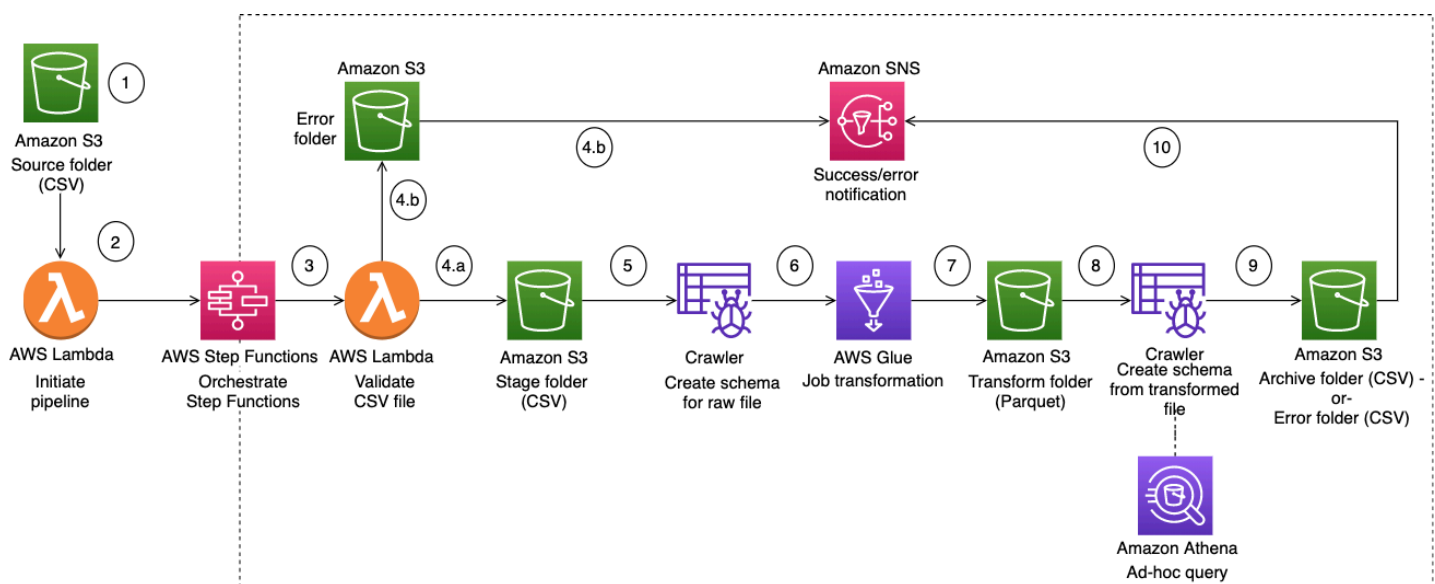

## Limitations

- In AWS Step Functions, the maximum limit for keeping history logs is 90 days. For more information, see [Quotas](#) and [Quotas for standard workflows](#) in the AWS Step Functions documentation.

## Product versions

- Python 3.11 for AWS Lambda
- AWS Glue version 2.0

## Architecture

The workflow illustrated in the diagram consists of these high-level steps:

1. The user uploads a CSV file into the source folder in Amazon S3.
2. An Amazon S3 notification event initiates an AWS Lambda function that starts the Step Functions state machine.
3. The Lambda function validates the schema and data type of the raw CSV file.
4. Depending on the validation results:
  - a. If validation of the source file succeeds, the file moves to the stage folder for further processing.
  - b. If validation fails, the file moves to the error folder, and an error notification is sent through Amazon Simple Notification Service (Amazon SNS).
5. An AWS Glue crawler creates the schema of the raw file from the stage folder in Amazon S3.
6. An AWS Glue job transforms, compresses, and partitions the raw file into Parquet format.
7. The AWS Glue job also moves the file to the transform folder in Amazon S3.
8. The AWS Glue crawler creates the schema from the transformed file. The resulting schema can be used by any analytics job. You can also use Amazon Athena to run ad-hoc queries.
9. If the pipeline completes without errors, the schema file is moved to the archive folder. If any errors are encountered, the file is moved to the error folder instead.
10. Amazon SNS sends a notification that indicates success or failure based on the pipeline completion status.

All the AWS resources used in this pattern are serverless. There are no servers to manage.

## Tools

### AWS services

- [AWS Glue](#) – AWS Glue is a fully managed ETL service that makes it easy for customers to prepare and load their data for analytics.
- [AWS Step Functions](#) – AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the AWS Step Functions graphical console, you see your application's workflow as a series of event-driven steps.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.

- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a highly available, durable, secure, fully managed pub/sub messaging service that enables you to decouple microservices, distributed systems, and serverless applications.
- [AWS Lambda](#) – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

## Code

The code for this pattern is available on GitHub, in the [ETL Pipeline with AWS Step Functions](#) repository. The code repository contains the following files and folders:

- `template.yml` – AWS CloudFormation template for creating the ETL pipeline with AWS Step Functions.
- `parameter.json` – Contains all parameters and parameter values. You update this file to change parameter values, as described in the *Epics* section.
- `myLayer/python` folder – Contains Python packages needed to create the required AWS Lambda layer for this project.
- `lambda` folder – Contains the following Lambda functions:
  - `move_file.py` – Moves the source dataset to the archive, transform, or error folder.
  - `check_crawler.py` – Checks the status of the AWS Glue crawler as many times as configured by the `RETRYLIMIT` environment variable before it sends a failure message.
  - `start_crawler.py` – Starts the AWS Glue crawler.
  - `start_step_function.py` – Starts AWS Step Functions.
  - `start_codebuild.py` – Starts the AWS CodeBuild project.
  - `validation.py` – Validates the input raw dataset.
  - `s3object.py` – Creates the required directory structure inside the S3 bucket.
  - `notification.py` – Sends success or error notifications at the end of the pipeline.

To use the sample code, follow the instructions in the *Epics* section.

# Epics

## Prepare the source files

Task	Description	Skills required
Clone the sample code repository.	<ol style="list-style-type: none"><li>1. Open the <a href="#">ETL Pipeline with AWS Step Functions</a> repository.</li><li>2. Choose <b>Code</b> on the main repository page, above the file list, and copy the URL listed under <b>Clone with HTTPS</b>.</li><li>3. Change your working directory to the location where you want to store the sample files.</li><li>4. At a terminal or command prompt, type the command: <pre>git clone &lt;repoURL&gt;</pre>where &lt;repoURL&gt; refers to the URL you copied in step 2.</li></ol>	Developer
Update parameter values.	<p>In your local copy of the repository, edit the <code>parameter.json</code> file and update the default parameter values as follows:</p> <ul style="list-style-type: none"><li>• <code>pS3BucketName</code> – The name of the S3 bucket for storing the datasets. The</li></ul>	Developer

Task	Description	Skills required
	<p>template will create this bucket for you. The bucket name must be globally unique.</p> <ul style="list-style-type: none"><li>• <code>pSourceFolder</code> – The name of the folder inside the S3 bucket that will be used to upload the source CSV file.</li><li>• <code>pStageFolder</code> – The name of the folder inside the S3 bucket that will be used as the staging area during the process.</li><li>• <code>pTransformFolder</code> – The name of the folder inside the S3 bucket that will be used to store transformed and partitioned datasets.</li><li>• <code>pErrorFolder</code> – The folder inside the S3 bucket that the source CSV file will be moved to if it can't be validated.</li><li>• <code>pArchiveFolder</code> – The name of the folder inside the S3 bucket that will be used to archive the source CSV file.</li><li>• <code>pEmailforNotification</code> – A valid email</li></ul>	

Task	Description	Skills required
	<p>address for receiving success/error notifications.</p> <ul style="list-style-type: none"><li>• <code>pPrefix</code> – A prefix string that will be used in the AWS Glue crawler name.</li><li>• <code>pDatasetSchema</code> – The dataset schema that the source file will be validated against. The Cerberus Python package is used for source dataset validation. For more information, see the <a href="#">Cerberus</a> website.</li></ul>	

Task	Description	Skills required
Upload the source code to the S3 bucket.	<p>Before you deploy the CloudFormation template that automates the ETL pipeline, you must package the source files for the CloudFormation template and upload them to an S3 bucket. To do this, run the following AWS CLI command with your preconfigured profile:</p> <pre data-bbox="594 726 1029 1087">aws cloudformation package --template- file template.yml --s3- bucket &lt;bucket_name&gt; --output-template- file packaged.template --profile &lt;profile_ name&gt;</pre> <p>where:</p> <ul data-bbox="594 1205 1008 1776" style="list-style-type: none"><li>• <code>&lt;bucket_name&gt;</code> is the name of an existing S3 bucket in the AWS Region where you want to deploy the stack. This bucket is used to store the source code package for the CloudFormation template.</li><li>• <code>&lt;profile_name&gt;</code> is a valid AWS CLI profile that you preconfigured when you set up AWS CLI.</li></ul>	Developer

## Create the stack

Task	Description	Skills required
Deploy the CloudFormation template.	<p>To deploy the CloudFormation template, run the following AWS CLI command:</p> <pre data-bbox="594 499 1027 936">aws cloudformation   deploy --stack-name     &lt;stack_name&gt; --templat     e-file packaged.   template --parameter-     overrides file://pa     rameter.json --capabil     ities CAPABILITY_IAM     --profile &lt;profile_     name&gt;</pre> <p>where:</p> <ul data-bbox="594 1056 1019 1339" style="list-style-type: none"><li>• &lt;stack_name&gt; is a unique identifier for the CloudFormation stack.</li><li>• &lt;profile-name&gt; is your preconfigured AWS CLI profile.</li></ul>	Developer
Check progress.	<p>On the <a href="#">AWS CloudFormation console</a>, check the progress of stack development. When the status is CREATE_COMPLETE , the stack has been deployed successfully.</p>	Developer
Note the AWS Glue database name.	<p>The <b>Outputs</b> tab for the stack displays the name of the AWS</p>	Developer

Task	Description	Skills required
	Glue database. The key name is <code>GlueDBOutput</code> .	

## Test the pipeline

Task	Description	Skills required
Start the ETL pipeline.	<ol style="list-style-type: none"> <li>1. Navigate to the source folder (source, or the folder name you set in the <code>parameter.json</code> file) inside the S3 bucket.</li> <li>2. Upload a sample CSV file to this folder. (The code repository provides a sample file called <code>Sample_Bank_Transaction_Raw_Dataset.csv</code> that you can use.) Uploading the file will start the ETL pipeline through Step Functions.</li> <li>3. On the <a href="#">Step Functions console</a>, check the ETL pipeline status.</li> </ol>	Developer
Check for the partitioned dataset.	When the ETL pipeline completes, verify that the partitioned dataset is available in the Amazon S3 transform folder ( <code>transform</code> , or the folder name you set in the <code>parameter.json</code> file).	Developer

Task	Description	Skills required
Check for the partitioned AWS Glue database.	<ol style="list-style-type: none"> <li>1. On the <a href="#">AWS Glue console</a>, select the AWS Glue database created by the stack (this is the database that you noted in the previous epic).</li> <li>2. Verify that the partitioned table is available in the AWS Glue Data Catalog.</li> </ol>	Developer
Run queries.	(Optional) Use Amazon Athena to run ad-hoc queries on the partitioned and transformed database. For instructions, see <a href="#">Running SQL Queries Using Amazon Athena</a> in the AWS documentation.	Database analyst

## Troubleshooting

Issue	Solution
AWS Identity and Access Management (IAM) permissions for the AWS Glue job and crawler	If you further customize the AWS Glue job or the crawler, be sure to grant the appropriate IAM permissions in the IAM role used by the AWS Glue job, or provide data permissions to AWS Lake Formation. For more information, see the <a href="#">AWS documentation</a> .

# Perform advanced analytics using Amazon Redshift ML

Created by Po Hong (AWS) and Chyanna Antonio (AWS)

**Environment:** PoC or pilot

**Technologies:** Analytics;  
Machine learning & AI

**Workload:** All other  
workloads

**AWS services:** Amazon  
Redshift; Amazon SageMaker

## Summary

On the Amazon Web Services (AWS) Cloud, you can use Amazon Redshift machine learning (Amazon Redshift ML) to perform ML analytics on data stored in either an Amazon Redshift cluster or on Amazon Simple Storage Service (Amazon S3). Amazon Redshift ML supports supervised learning, which is typically used for advanced analytics. Use cases for Amazon Redshift ML include revenue forecasting, credit card fraud detection, and customer lifetime value (CLV) or customer churn predictions.

Amazon Redshift ML makes it easy for database users to create, train, and deploy ML models by using standard SQL commands. Amazon Redshift ML uses Amazon SageMaker Autopilot to automatically train and tune the best ML models for classification or regression based on your data, while you retain control and visibility.

All interactions between Amazon Redshift, Amazon S3, and Amazon SageMaker are abstracted away and automated. After the ML model is trained and deployed, it becomes available as a [user-defined function](#) (UDF) in Amazon Redshift and can be used in SQL queries.

This pattern complements the [Create, train, and deploy ML models in Amazon Redshift using SQL with Amazon Redshift ML](#) from the AWS Blog, and the [Build, train, and deploy an ML model with Amazon SageMaker](#) tutorial from the [Getting Started Resource Center](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Existing data in an Amazon Redshift table

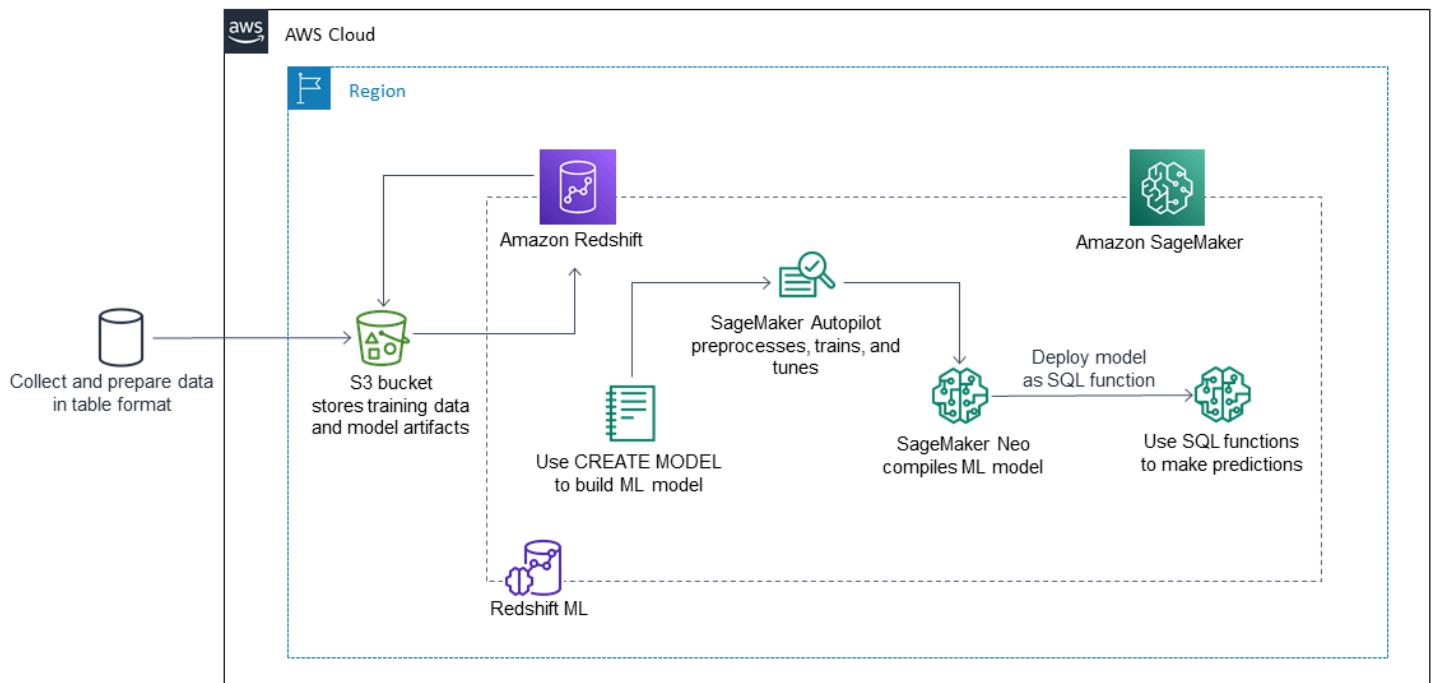

## Skills

- Familiarity with terms and concepts used by Amazon Redshift ML, including *machine learning*, *training*, and *prediction*. For more information about this, see [Training ML models](#) in the Amazon Machine Learning (Amazon ML) documentation.
- Experience with Amazon Redshift user setup, access management, and standard SQL syntax. For more information about this, see [Getting started with Amazon Redshift](#) in the Amazon Redshift documentation.
- Knowledge and experience with Amazon S3 and AWS Identity and Access Management (IAM).
- Experience running commands in AWS Command Line Interface (AWS CLI) is also beneficial but not required.

## Limitations

- The Amazon Redshift cluster and S3 bucket must be located in the same AWS Region.
- This pattern's approach only supports supervised learning models such as regression, binary classification, and multiclass classification.

## Architecture

The following steps explain how Amazon Redshift ML works with SageMaker to build, train, and deploy an ML model:

1. Amazon Redshift exports training data to an S3 bucket.
2. SageMaker Autopilot automatically preprocesses the training data.
3. After the `CREATE MODEL` statement is invoked, Amazon Redshift ML uses SageMaker for training.
4. SageMaker Autopilot searches for and recommends the ML algorithm and optimal hyperparameters that optimize the evaluation metrics.
5. Amazon Redshift ML registers the output ML model as a SQL function in the Amazon Redshift cluster.
6. The ML model's function can be used in a SQL statement.

## Technology stack

- Amazon Redshift
- SageMaker
- Amazon S3

## Tools

- [Amazon Redshift](#) – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- [Amazon Redshift ML](#) – Amazon Redshift machine learning (Amazon Redshift ML) is a robust, cloud-based service that makes it easy for analysts and data scientists of all skill levels to use ML technology.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- [Amazon SageMaker](#) – SageMaker is a fully managed ML service.
- [Amazon SageMaker Autopilot](#) – SageMaker Autopilot is a feature-set that automates key tasks of an automatic machine learning (AutoML) process.

## Code

You can create a supervised ML model in Amazon Redshift by using the following code:

```

“CREATE MODEL customer_churn_auto_model
FROM (SELECT state,
             account_length,
             area_code,
             total_charge/account_length AS average_daily_spend,
             cust_serv_calls/account_length AS average_daily_cases,
             churn
      FROM customer_activity
      WHERE record_date < '2020-01-01'
     )
TARGET churn
FUNCTION ml_fn_customer_churn_auto
IAM_ROLE 'arn:aws:iam::XXXXXXXXXXXX:role/Redshift-ML'
SETTINGS (
  S3_BUCKET 'your-bucket'
);”

```

**Note:** The SELECT state can refer to Amazon Redshift regular tables, Amazon Redshift Spectrum external tables, or both.

## Epics

### Prepare a training and test dataset

Task	Description	Skills required
Prepare a training and test dataset.	<p>Sign in to the AWS Management Console and open the Amazon SageMaker console. Follow the instructions from the <a href="#">Build, train, and deploy a machine learning model</a> tutorial to create a .csv or Apache Parquet file that has a label column (<i>supervised training</i>) and no header.</p> <p><b>Note:</b> We recommend that you shuffle and split the raw dataset into a training set</p>	Data scientist

Task	Description	Skills required
	for the model's training (70 percent) and a test set for the model's performance evaluation (30 percent).	

## Prepare and configure the technology stack

Task	Description	Skills required
Create and configure an Amazon Redshift cluster.	<p>On the Amazon Redshift console, create a cluster according to your requirements. For more information about this, see <a href="#">Create a cluster</a> in the Amazon Redshift documentation.</p> <p><b>Important:</b> Amazon Redshift clusters must be created with the SQL_PREVIEW maintenance track. For more information about preview tracks, see <a href="#">Choosing cluster maintenance tracks</a> in the Amazon Redshift documentation.</p>	DBA, Cloud architect
Create an S3 bucket to store training data and model artifacts.	On the Amazon S3 console, create an S3 bucket for the training and test data. For more information about creating an S3 bucket, see <a href="#">Create an S3 bucket</a> from AWS Quick Starts.	DBA, Cloud architect

Task	Description	Skills required
	<b>Important:</b> Make sure that your Amazon Redshift cluster and S3 bucket are in the same Region.	
Create and attach an IAM policy to the Amazon Redshift cluster.	Create an IAM policy to allow the Amazon Redshift cluster to access SageMaker and Amazon S3. For instructions and steps, see <a href="#">Cluster setup for using Amazon Redshift ML</a> in the Amazon Redshift documentation.	DBA, Cloud architect
Allow Amazon Redshift users and groups to access schemas and tables.	Grant permissions to allow users and groups in Amazon Redshift to access internal and external schemas and tables. For steps and instructions, see <a href="#">Managing permissions and ownership</a> in the Amazon Redshift documentation.	DBA

## Create and train the ML model in Amazon Redshift

Task	Description	Skills required
Create and train the ML model in Amazon Redshift.	Create and train your ML model in Amazon Redshift ML. For more information, see the CREATE MODEL statement in the Amazon Redshift documentation.	Developer, Data scientist

## Perform batch inference and prediction in Amazon Redshift

Task	Description	Skills required
Perform inference using the generated ML model function.	For more information about performing inference by using the generated ML model function, see <a href="#">Prediction</a> in the Amazon Redshift documentation.	Data scientist, Business intelligence user

# Access, query, and join Amazon DynamoDB tables using Athena

Created by Moinul Al-Mamun (AWS)

**Environment:** Production

**Technologies:** Analytics; Databases; Serverless; Big data

**AWS services:** Amazon Athena; Amazon DynamoDB; AWS Lambda; Amazon S3

## Summary

This pattern shows you how to set up a connection between Amazon Athena and Amazon DynamoDB by using the Amazon Athena DynamoDB connector. The connector uses an AWS Lambda function to query the data in DynamoDB. You don't need to write any code to set up the connection. After the connection is established, you can quickly access and analyze DynamoDB tables by using [Athena Federated Query](#) to run SQL commands from Athena. You can also join one or more DynamoDB tables to each other or to other data sources, such as Amazon Redshift or Amazon Aurora.

## Prerequisites and limitations

### Prerequisites

- An active AWS account with permissions to manage DynamoDB tables, Athena Data sources, Lambda, and AWS Identity and Access Management (IAM) roles
- An Amazon Simple Storage Service (Amazon S3) bucket where Athena can store query results
- An S3 bucket where the Athena DynamoDB Connector can save the data in the short term
- An AWS Region that supports [Athena engine version 2](#)
- IAM permissions to access Athena and the required S3 buckets
- [Amazon Athena DynamoDB Connector](#), installed

### Limitations

There is a cost for querying DynamoDB tables. Table sizes exceeding a few gigabytes (GBs) can incur a high cost. We recommend that you consider cost before performing any full table SCAN

operation. For more information, see [Amazon DynamoDB pricing](#). To reduce costs and achieve high performance, we recommend that you always use LIMIT in your query (for example, `SELECT * FROM table1 LIMIT 10`). Also, before you perform a JOIN or GROUP BY query in a production environment, consider the size of your tables. If your tables are too large, consider alternative options such as [migrating the table to Amazon S3](#).

## Architecture

The following diagram shows how a user can run a SQL query on a DynamoDB table from Athena.

The diagram shows the following workflow:

1. To query a DynamoDB table, a user runs a SQL query from Athena.
2. Athena initiates a Lambda function.
3. The Lambda function queries the requested data in the DynamoDB table.
4. DynamoDB returns the requested data to the Lambda function. Then, the function transfers the query results to the user through Athena.
5. The Lambda function stores data in the S3 bucket.

## Technology stack

- Amazon Athena
- Amazon DynamoDB
- Amazon S3
- AWS Lambda

## Tools

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- [Amazon Athena DynamoDB Connector](#) is an AWS tool that enables Athena to connect with DynamoDB and access your tables by using SQL queries.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

## Epics

### Create sample DynamoDB tables

Task	Description	Skills required
Create the first sample table.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">DynamoDB console</a>.</li><li>2. Choose <b>Create table</b>.</li><li>3. For <b>Table name</b>, enter <b>dydbtable1</b>.</li><li>4. For <b>Partition key</b>, enter <b>PK1</b>.</li><li>5. For <b>Sort key</b>, enter <b>SK1</b>.</li></ol>	Developer

Task	Description	Skills required
	<ol style="list-style-type: none"><li>6. In the <b>Table settings</b> section, choose <b>Customize settings</b>.</li><li>7. In the <b>Table class</b> section, choose <b>DynamoDB Standard</b>.</li><li>8. In the <b>Read/write capacity settings</b> section, for <b>Capacity mode</b>, choose <b>On-demand</b>.</li><li>9. In the <b>Encryption at rest</b> section, choose <b>Owned by Amazon DynamoDB</b>.</li><li>10. Choose <b>Create table</b>.</li></ol>	

Task	Description	Skills required
Insert sample data into the first table.	<ol style="list-style-type: none"><li>1. Open the <a href="#">DynamoDB console</a>.</li><li>2. In the navigation pane, choose <b>Table</b>, and then choose your table in the <b>Name</b> column.</li><li>3. Choose <b>Actions</b>, and then choose <b>Create item</b>.</li><li>4. Choose <b>JSON view</b>.</li><li>5. In the title bar of the <b>Attributes</b> editor, turn off <b>View DynamoDB JSON</b>.</li><li>6. In the <b>Attributes</b> editor, enter the following sample data one by one: <pre data-bbox="594 1052 1027 1289">{   "PK1": "1234",   "SK1": "info",   "Salary": "5000" }</pre><pre data-bbox="594 1325 1027 1562">{   "PK1": "1235",   "SK1": "info",   "Salary": "5200" }</pre></li></ol>	Developer

Task	Description	Skills required
Create the second sample table.	<ol style="list-style-type: none"><li>1. Open the <a href="#">DynamoDB console</a>.</li><li>2. Choose <b>Create table</b>.</li><li>3. For <b>Table name</b>, enter <b>dydbtable2</b>.</li><li>4. For <b>Partition key</b>, enter <b>PK2</b>.</li><li>5. For <b>Sort key</b>, enter <b>SK2</b>.</li><li>6. In the <b>Table settings</b> section, choose <b>Customize settings</b>.</li><li>7. In the <b>Table class</b> section, choose <b>DynamoDB Standard</b>.</li><li>8. In the <b>Read/write capacity settings</b> section, for <b>Capacity mode</b>, choose <b>On-demand</b>.</li><li>9. In the <b>Encryption at rest</b> section, choose <b>Owned by Amazon DynamoDB</b>.</li><li>10. Choose <b>Create table</b>.</li></ol>	Developer

Task	Description	Skills required
Insert sample data into the second table.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">DynamoDB console</a>.</li> <li>2. In the navigation pane, choose <b>Table</b>, and then choose your table in the <b>Name</b> column.</li> <li>3. Choose <b>Actions</b>, and then choose <b>Create item</b>.</li> <li>4. In the title bar of the <b>Attributes</b> editor, turn off <b>View DynamoDB JSON</b>.</li> <li>5. In the <b>Attributes</b> editor, enter the following sample data one by one: <div data-bbox="594 995 1027 1234" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>{   "PK2": "1234",   "SK2": "bonus",   "Bonus": "500" }</pre> </div> <div data-bbox="594 1264 1027 1503" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>{   "PK2": "1235",   "SK2": "bonus",   "Bonus": "1000" }</pre> </div> </li> </ol>	Developer

### Create a data source in Athena for DynamoDB

Task	Description	Skills required
Set up the data source connector.	Create a data source for DynamoDB, and then create a	Developer

Task	Description	Skills required
	<p>Lambda function to connect to that data source.</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">Athena console</a>.</li><li>2. In the navigation pane, choose <b>Data sources</b>, and then choose <b>Create data source</b>.</li><li>3. Choose the <b>Amazon DynamoDB</b> data source, and then choose <b>Next</b>.</li><li>4. In the <b>Data source details</b> section, for <b>Data source name</b>, enter <b>testDynamoDB</b>.</li><li>5. In the <b>Connection details</b> section, select a Lambda function that's already deployed or choose <b>Create Lambda function</b> if you don't have a Lambda function to use for this pattern. <b>Note:</b> For more information on creating a Lambda function, see <a href="#">Getting started with Lambda</a> in the Lambda Developer Guide.</li><li>6. (Optional) If you choose <b>Create Lambda function</b>, then you must configure the AWS CloudFormation</li></ol>	

Task	Description	Skills required
	<p>template that's included by the Java application before deploying that stack. The template includes ApplicationName, SpillBucket, AthenaCatalogName, and other application settings.</p> <p><b>Note:</b> After you deploy this Java-based application, the stack creates a Lambda function that enables Athena to communicate with DynamoDB. This makes your tables accessible through SQL commands.</p> <ol style="list-style-type: none"><li>7. Deploy your Lambda function.</li><li>8. Choose <b>Next</b>.</li></ol>	

Task	Description	Skills required
Verify that the Lambda function can access the S3 spill bucket.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Lambda console</a>.</li><li>2. In the navigation pane, choose <b>Functions</b>, and then choose the function that you created earlier.</li><li>3. Choose the <b>Configuration</b> tab.</li><li>4. In the left pane, choose <b>Environment variables</b> , and then confirm that the value for the key is <code>spill_bucket</code> .</li><li>5. In the left pane, choose <b>Permissions</b>, and then in the <b>Execution role</b> section, choose the attached IAM role. <b>Note:</b> You are directed to the IAM role that's attached to your Lambda function in the IAM console.</li><li>6. Confirm that you have write permission on <code>spill_bucket</code> bucket.</li></ol> <p>If you experience errors, see the <i>Additional information</i> section in this pattern for guidance.</p>	Developer

## Access DynamoDB tables from Athena

Task	Description	Skills required
Query the DynamoDB tables.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the <a href="#">Athena console</a>.</li> <li>2. In the navigation pane, choose <b>Data sources</b>, and then choose <b>Create data source</b>.</li> <li>3. In the navigation pane, choose <b>Query editor</b>.</li> <li>4. On the <b>Editor</b> tab, in the <b>Data</b> section, for <b>Data source</b>, choose your data source for <b>Data source</b>.</li> <li>5. For <b>Database</b>, choose your database.</li> <li>6. For Query 1, enter the following query: <code>SELECT * FROM dydbtable1 t1;</code></li> <li>7. Choose <b>Run</b>, and then verify the output in the table.</li> <li>8. For Query 2, enter the following query: <code>SELECT * FROM dydbtable2 t2;</code></li> <li>9. Choose <b>Run</b>, and then verify the output in the table.</li> </ol>	Developer
Join the two DynamoDB tables.	DynamoDB is a NoSQL data store and doesn't support the SQL join operation.	Developer

Task	Description	Skills required
	<p>Consequently, you must perform a join operation on two DynamoDB tables:</p> <ol style="list-style-type: none"><li>1. Choose the plus icon to create another query.</li><li>2. For Query 3, enter the following query:</li></ol> <pre data-bbox="597 646 1026 886">SELECT pk1, salary, bonus FROM dydbtable1 t1 JOIN dydbtable2 t2 ON t1.pk1 = t2.pk2;</pre>	

## Related resources

- [Amazon Athena DynamoDB Connector](#) (AWS Labs)
- [Query any data source with Amazon Athena's new federated query](#) (AWS Big Data Blog)
- [Athena engine version reference](#) (Athena User Guide)
- [Simplify Amazon DynamoDB data extraction and analysis by using AWS Glue and Amazon Athena](#) (AWS Database Blog)

## Additional information

If you run a query in Athena with `spill_bucket` in the `{bucket_name}/folder_name/ format`, then you can receive the following error message:

```
"GENERIC_USER_ERROR: Encountered an exception[java.lang.RuntimeException] from your  
LambdaFunction[arn:aws:lambda:us-east-1:xxxxxx:function:testdynamodb] executed in  
context[retrieving meta-data] with message[You do NOT own the spill bucket with the  
name: s3://test-bucket-dynamodbconnector/athena_dynamodb_spill_data/]
```

This query ran against the "default" database, unless qualified by the query. Please post the error message on our forum or contact customer support with Query Id: [query-id]"

To resolve this error, update the Lambda function's environment variable `spill_bucket` to `{bucket_name_only}`, and then update the following Lambda IAM policy for bucket write access:

```
{
    "Action": [
        "s3:GetObject",
        "s3:ListBucket",
        "s3:GetBucketLocation",
        "s3:GetObjectVersion",
        "s3:PutObject",
        "s3:PutObjectAcl",
        "s3:GetLifecycleConfiguration",
        "s3:PutLifecycleConfiguration",
        "s3:DeleteObject"
    ],
    "Resource": [
        "arn:aws:s3:::spill_bucket",
        "arn:aws:s3:::spill_bucket/*"
    ],
    "Effect": "Allow"
}
```

Alternatively, you can remove the Athena data source connector that you created earlier, and recreate it by using only `{bucket_name}` for `spill_bucket`.

# Set up a minimum viable data space to share data between organizations

Created by Ramy Hcini (Think-it), Ismail Abdellaoui (Think-it), Malte Gasseling (Think-it), Jorge Hernandez Suarez (AWS), and Michael Miller (AWS)

**Environment:** PoC or pilot

**Technologies:** Analytics  
; Containers & microservices; Data lakes; Databases; Infrastructure

**Workload:** Open-source

**AWS services:** Amazon Aurora; AWS Certificate Manager (ACM); AWS CloudFormation; Amazon EC2; Amazon EFS; Amazon EKS; Elastic Load Balancing (ELB); Amazon RDS; Amazon S3; AWS Systems Manager

## Summary

Data spaces are federated networks for data exchange with trust and control over one's data as core principles. They enable organizations to share, exchange, and collaborate on data at scale by offering a cost-effective and technology-agnostic solution.

Data spaces have the potential to significantly drive efforts for a sustainable future by using data-driven problem solving with an end-to-end approach that involves all relevant stakeholders.

This pattern guides you through the example of how two companies can use data space technology on Amazon Web Services (AWS) to drive their carbon emissions–reduction strategy forward. In this scenario, company X provides carbon-emissions data, which company Y consumes. See the [Additional information](#) section for the following data space specification details:

- Participants
- Business case

- Data space authority
- Data space components
- Data space services
- Data to be exchanged
- Data model
- Tractus-X EDC connector

The pattern includes steps for the following:

- Deploying the infrastructure needed for a basic data space with two participants running on AWS.
- Exchanging carbon emissions–intensity data by using the connectors in a secure way.

This pattern deploys a Kubernetes cluster that will host data space connectors and their services through Amazon Elastic Kubernetes Service (Amazon EKS).

The [Eclipse Dataspace Components \(EDC\)](#) control plane and data plane are both deployed on Amazon EKS. The official Tractus-X Helm chart deploys PostgreSQL and HashiCorp Vault services as dependencies.

In addition, the identity service is deployed on Amazon Elastic Compute Cloud (Amazon EC2) to replicate a real-life scenario of a minimum viable data space (MVDS).

## Prerequisites and limitations

### Prerequisites

- An active AWS account to deploy the infrastructure in your chosen AWS Region
- An AWS Identity and Access Management (IAM) user with access to Amazon S3 that will be used temporarily as a technical user (The EDC connector currently doesn't support the use of roles. We recommend that you create one IAM user specifically for this demo and that this user will have limited permissions associated with it.)
- [AWS Command Line Interface \(AWS CLI\)](#) installed and configured in your chosen AWS Region
- [AWS security credentials](#)
- [eksctl](#) on your workstation
- [Git](#) on your workstation

- [kubect1](#)
- [Helm](#)
- [Postman](#)
- An [AWS Certificate Manager \(ACM\)](#) SSL/TLS certificate
- A DNS name that will point to an Application Load Balancer (the DNS name must be covered by the ACM certificate)
- [HashiCorp Vault](#) (For information about using AWS Secrets Manager to manage secrets, see the [Additional information](#) section.)

## Product versions

- [AWS CLI version 2+](#)
- [Postman Collection v2.1](#)

## Limitations

- **Connector selection** – This deployment uses an EDC-based connector. However, be sure to consider the strengths and functionalities of both the [EDC](#) and [FIWARE True](#) connectors to make an informed decision that aligns with the specific needs of the deployment.
- **EDC connector build** – The chosen deployment solution relies on the [Tractus-X EDC Connector](#) Helm chart, a well-established and extensively tested deployment option. The decision to use this chart is driven by its common usage and the inclusion of essential extensions in the provided build. While PostgreSQL and HashiCorp Vault are default components, you have the flexibility to customize your own connector build if needed.
- **Private cluster access** – Access to the deployed EKS cluster is restricted to private channels. Interaction with the cluster is performed exclusively through the use of `kubect1` and IAM. Public access to the cluster resources can be enabled by using load balancers and domain names, which must be implemented selectively to expose specific services to a broader network. However, we do not recommend providing public access.
- **Security focus** – Emphasis is placed on abstracting security configurations to default specifications so that you can concentrate on the steps involved in EDC connector data exchange. Although default security settings are maintained, it's imperative to enable secure communications before you expose the cluster to the public network. This precaution ensures a robust foundation for secure data handling.

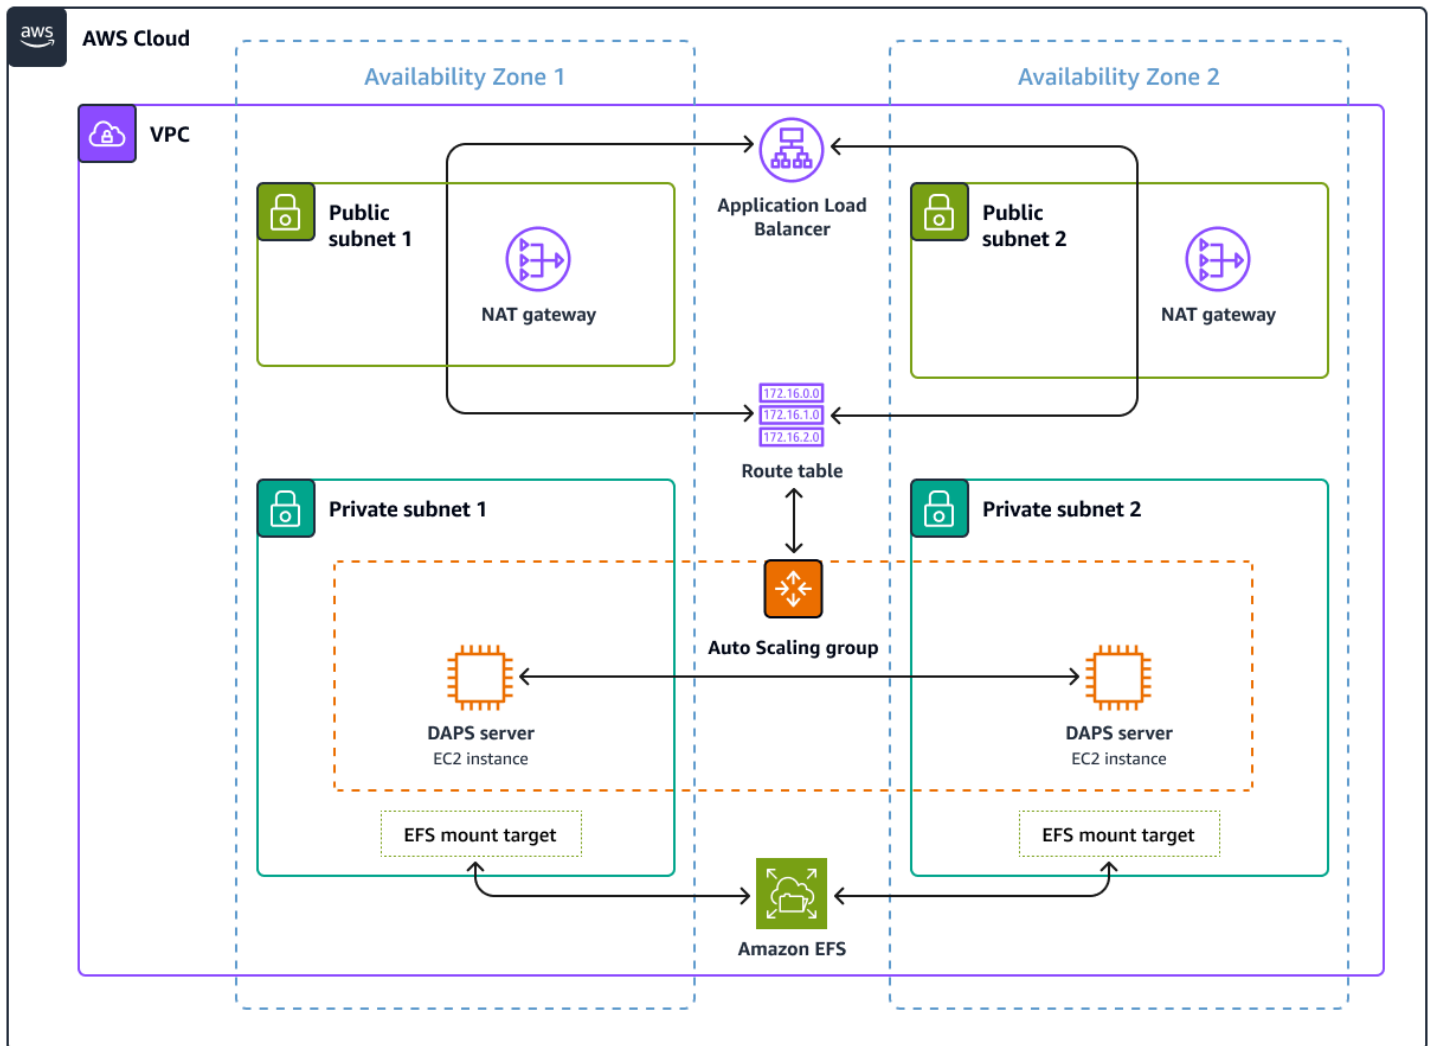

- **Infrastructure cost** – An estimation of the infrastructure’s cost can be found by using the [AWS Pricing Calculator](#). A simple calculation shows that costs can be up to 162.92 USD per month for the deployed infrastructure.

## Architecture

The MVDS architecture comprises two virtual private clouds (VPCs), one for the Dynamic Attribute Provisioning System (DAPS) identity service and one for Amazon EKS.

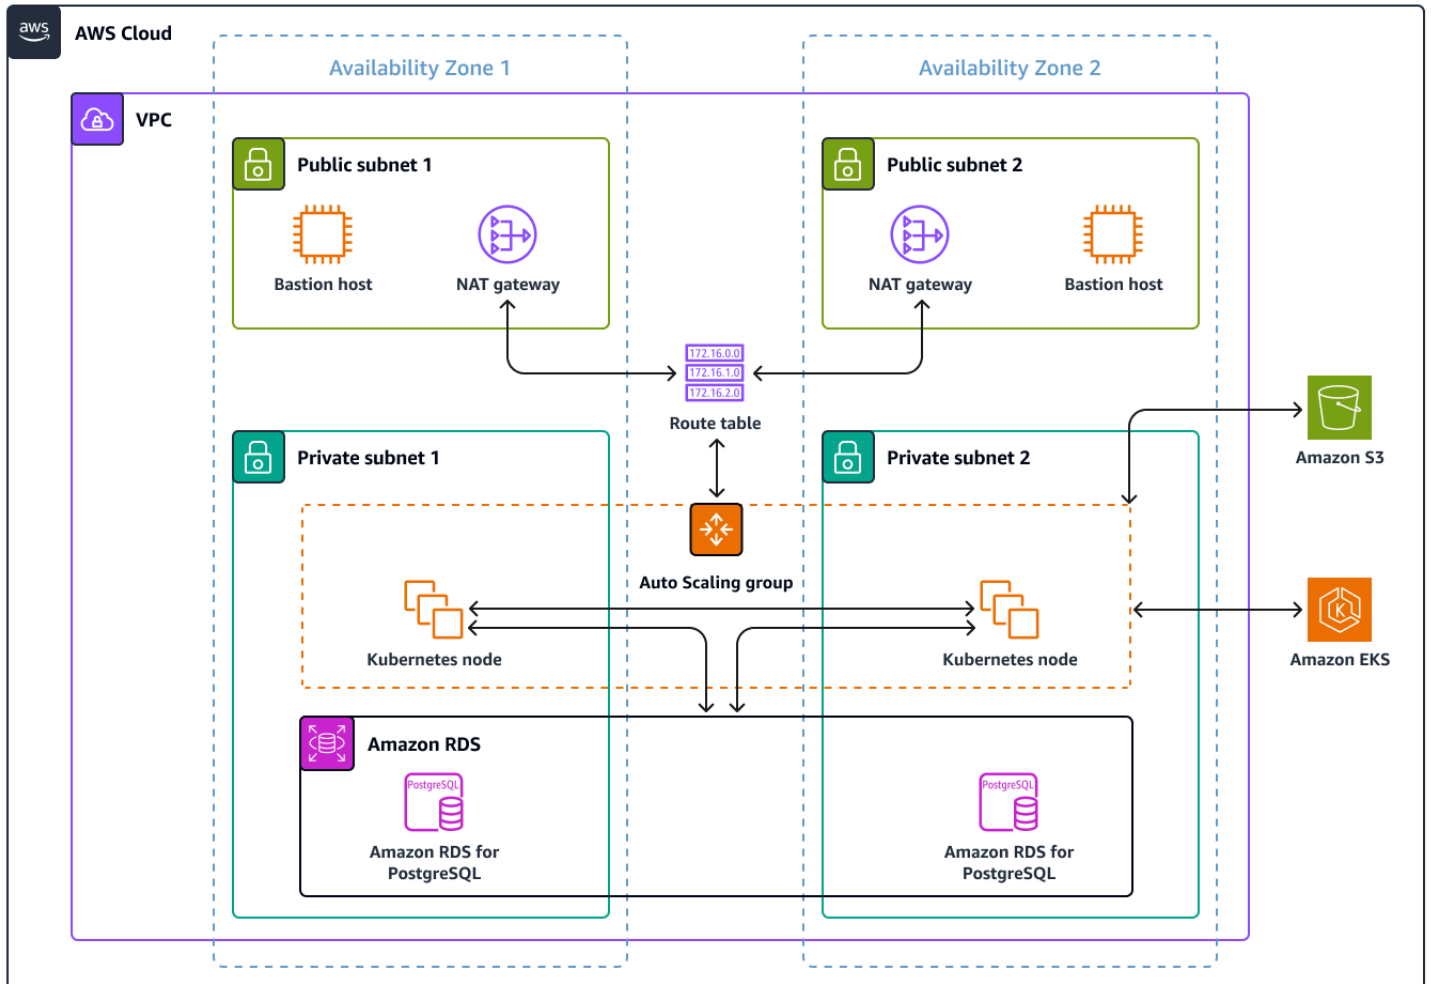

### DAPS architecture

The following diagram shows DAPS running on EC2 instances controlled by an Auto Scaling group. An Application Load Balancer and route table expose the DAPS servers. Amazon Elastic File System (Amazon EFS) synchronizes the data among the DAPS instances.

## Amazon EKS architecture

Data spaces are designed to be technology-agnostic solutions, and multiple implementations exist. This pattern uses an Amazon EKS cluster to deploy the data space technical components. The following diagram shows the deployment of the EKS cluster. Worker nodes are installed in private subnets. The Kubernetes pods access the Amazon Relational Database Service (Amazon RDS) for PostgreSQL instance that is also in the private subnets. The Kubernetes pods store shared data in Amazon S3.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across EC2 instances, containers, and IP addresses in one or more Availability Zones.

## Other tools

- [eksctl](#) is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- [Git](#) is an open source, distributed version control system.
- [HashiCorp Vault](#) provides secure storage with controlled access for credentials and other sensitive information.
- [Helm](#) is an open source package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- [kubectx](#) is a command-line interface that helps you run commands against Kubernetes clusters.
- [Postman](#) is an API platform.

## Code repository

The Kubernetes configuration YAML files and Python scripts for this pattern are available in the GitHub [aws-patterns-edc](#) repository. The pattern also uses the [Tractus-X EDC](#) repository.

## Best practices

### Amazon EKS and isolation of participants' infrastructures

Namespaces in Kubernetes will separate the company X provider's infrastructure from the company Y consumer's infrastructure in this pattern. For more information, see [EKS Best Practices Guides](#).

In a more realistic situation, each participant would have a separate Kubernetes cluster running within their own AWS account. The shared infrastructure (DAPS in this pattern) would be accessible by data space participants while being completely separated from participants' infrastructures.

## Epics

### Set up the environment, and provision an EKS cluster and EC2 instances

Task	Description	Skills required
Clone the repository.	<p>To clone the repository to your workstation, run the following command:</p> <pre>git clone https://github.com/Think-iT-Labs/aws-patterns-edc</pre> <p>The workstation must have access to your AWS account.</p>	DevOps engineer
Provision the Kubernetes cluster and set up namespaces.	<p>To deploy a simplified default EKS cluster in your account, run the following <code>eksctl</code> command on the workstation where you cloned the repo:</p> <pre>eksctl create cluster</pre> <p>The command creates the VPC and private and public subnets that span three different Availability Zones. After the network layer is created, the command creates two <code>m5.large</code> EC2 instances within an Auto Scaling group.</p>	DevOps engineer

Task	Description	Skills required
	<p>For more information and example output, see the <a href="#">eksctl guide</a>.</p> <p>After you provision the private cluster, add the new EKS cluster to your local Kubernetes configuration by running the following command:</p> <pre>aws eks update-kubeconfig --name &lt;EKS CLUSTER NAME&gt; --region &lt;AWS REGION&gt;</pre> <p>This pattern uses the eu-west-1 AWS Region to run all commands. However, you can run the same commands in your preferred AWS Region.</p> <p>To confirm that your EKS nodes are running and are in the ready state, run the following command:</p> <pre>kubectl get nodes</pre>	

Task	Description	Skills required
Set up the namespaces.	<p>To create namespaces for the provider and the consumer, run the following commands:</p> <pre data-bbox="594 394 1026 592">kubect1 create ns   provider kubect1 create ns   consumer</pre> <p>In this pattern, it's important to use <code>provider</code> and <code>consumer</code> as the namespaces to fit the configurations in the next steps.</p>	DevOps engineer

## Deploy the identity service

Task	Description	Skills required
Deploy DAPS by using AWS CloudFormation.	<p>For ease of managing DAPS operations, the DAPS server is installed on EC2 instances.</p> <p>To install DAPS, use the <a href="#">AWS CloudFormation template</a>. You will need the ACM certificate and DNS name from the <i>Prerequisites</i> section. The template deploys and configures the following:</p> <ul data-bbox="594 1696 1026 1789" style="list-style-type: none"> <li>• Application Load Balancer</li> <li>• Auto Scaling group</li> </ul>	DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• EC2 instances configured with user data to install all necessary packages</li><li>• IAM roles</li><li>• DAPS</li></ul> <p>You can deploy the AWS CloudFormation template by signing in to the AWS Management Console and using the <a href="#">AWS CloudFormation console</a>. You can also deploy the template by using an AWS CLI command such as the following:</p> <pre>aws cloudformation   create-stack --stack-n ame daps \   --template-body   file://aws-patterns- edc/cloudformation.yml   --parameters \ ParameterKey=Cer tificateARN,Parame terValue=&lt;ACM Certificate ARN&gt; \ ParameterKey=DNS Name,ParameterValu e=&lt;DNS name&gt; \ ParameterKey=Ins tanceType,Paramete rValue=&lt;EC2 instance type&gt; \ ParameterKey=Env ironmentName,Param eterValue=&lt;Environ ment Name&gt; --capabil</pre>	

Task	Description	Skills required
	<p data-bbox="613 212 854 281">ities CAPABILIT Y_NAMED_IAM</p> <p data-bbox="591 344 1013 663">The environment name is your own choice. We recommend using a meaningful term, such as <code>DapsInfrastructure</code> , because it will be reflected in the AWS resource tags.</p> <p data-bbox="591 709 1021 884">For this pattern, <code>t3.small</code> is large enough to run the DAPS workflow, which has three Docker containers.</p> <p data-bbox="591 930 1024 1539">The template deploys the EC2 instances in private subnets. This means that the instances are not directly accessible through SSH (Secure Shell) from the internet. The instances are provisioned with the necessary IAM role and AWS Systems Manager Agent to enable access to the running instances through <a href="#">Session Manager</a>, a capability of AWS Systems Manager.</p> <p data-bbox="591 1585 1021 1854">We recommend using Session Manager for access. Alternatively, you could provision a bastion host to allow SSH access from the internet. When using the bastion host</p>	

Task	Description	Skills required
	<p>approach, the EC2 instance might take a few more minutes to start running.</p> <p>After the AWS CloudFormation template is successfully deployed, point the DNS name to your Application Load Balancer DNS name. To confirm, run the following command:</p> <pre>dig &lt;DNS NAME&gt;</pre> <p>The output should be similar to the following:</p> <pre>; &lt;&lt;&gt;&gt; DiG 9.16.1-Ub untu &lt;&lt;&gt;&gt; edc-patte rn.think-it.io ;; global options: +cmd ;; Got answer: ;; -&gt;HEADER&lt;&lt;- opcode: QUERY, status: NOERROR, id: 42344 ;; flags: qr rd ra; QUERY: 1, ANSWER: 3, AUTHORITY: 0, ADDITIONAL: 1  ;; OPT PSEUDOSECTION: ; EDNS: version: 0, flags:; udp: 65494 ;; QUESTION SECTION: ;edc-pattern.think- it.io. IN A  ;; ANSWER SECTION:</pre>	

Task	Description	Skills required
	<pre> edc-pattern.think- it.io. 276      IN               CNAME    daps- alb-iap9zmwy3kn8-13287 73120.eu-west-1.el b.amazonaws.com. daps-alb-iap9zmwy3k n8-1328773120.eu-w est-1.elb.amazonaw s.com. 36 IN A  52.208.240.129 daps-alb-iap9zmwy3kn8 -1328773120.eu-wes t-1.elb.amazonaws. com. 36 IN A 52.210.15 5.124                     </pre>	

Task	Description	Skills required
Register the participants' connectors to the DAPS service.	<p>From within any of the EC2 instances provisioned for DAPS, register participants:</p> <ol style="list-style-type: none"><li>1. Run the available script on the EC2 instance by using the root user: <pre>cd /srv/mvds/omejdn-daps</pre></li><li>2. Register the provider: <pre>bash scripts/register_connector.sh &lt;provider_name&gt;</pre></li><li>3. Register the consumer: <pre>bash scripts/register_connector.sh &lt;consumer_name&gt;</pre></li></ol> <p>The choice of the names doesn't impact the next steps. We recommend using either <code>provider</code> and <code>consumer</code> or <code>companyx</code> and <code>companyy</code>.</p> <p>The registration commands will also automatically configure the DAPS service with the needed information fetched from the created certificates and keys.</p>	DevOps engineer

Task	Description	Skills required
	<p>While you are logged in to a DAPS server, gather information needed for later steps in the installation:</p> <ol style="list-style-type: none"> <li>1. From <code>omejdn-daps/config/clients.yml</code> get the <code>client_id</code> for the provider and the consumer. The <code>client_id</code> values are long strings of hexadecimal digits.</li> <li>2. From the <code>omejdn-daps/keys</code> directory, copy the contents of the <code>consumer.cert</code>, <code>consumer.key</code>, <code>provider.cert</code>, and <code>provider.key</code> files.</li> </ol> <p>We recommend copying and pasting the text into similarly named files prefixed with <code>daps-</code> on your workstation.</p> <p>You should have the client IDs for the provider and consumer and should have four files in your working directory on your workstation:</p> <ul style="list-style-type: none"> <li>• Source file name <code>consumer.cert</code> becomes workstation file name <code>daps-consumer.cert</code>.</li> </ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>Source file name <code>consumer.key</code> becomes workstation file name <code>daps-consumer.key</code> .</li> <li>Source file name <code>provider.cert</code> becomes workstation file name <code>daps-provider.cert</code> .</li> <li>Source file name <code>provider.key</code> becomes workstation file name <code>daps-provider.key</code> .</li> </ul>	

## Deploy the participants' connectors

Task	Description	Skills required
Clone the Tractus-X EDC repository and use the 0.4.1 version.	<p>The Tractus-X EDC connector's build requires PostgreSQL (assets database) and HashiCorp Vault (secrets management) services to be deployed and available.</p> <p>There are many different versions of Tractus-X EDC Helm charts. This pattern specifies version 0.4.1 because it uses the DAPS server.</p> <p>The latest versions use Managed Identity Wallet (MIW) with a distributed</p>	DevOps engineer

Task	Description	Skills required
	<p>implementation of the identity service.</p> <p>On the workstation where you created the two Kubernetes namespaces, clone the <a href="#">tractusx-edc repository</a>, and check out the <code>release/0.4.1</code> branch.</p> <pre data-bbox="597 646 1026 1003">git clone https://github.com/eclipse-tractusx/tractusx-edc  cd tractusx-edc  git checkout release/0.4.1</pre>	

Task	Description	Skills required
<p>Configure the Tractus-X EDC Helm chart.</p>	<p>Modify the Tractus-X Helm chart template configuration to enable both connectors to interact together.</p> <p>To do this, you would add the namespace to the DNS name of the service so that it could be resolved by other services in the cluster. These modifications should be made to the <code>charts/tractusx-connector/templates/_helpers.tpl</code> file. This pattern provides a <a href="#">final modified version of this file</a> for you to use. Copy it and put it in the <code>daps</code> section of the file <code>charts/tractusx-connector/templates/_helpers.tpl</code>.</p> <p>Make sure to comment all DAPS dependencies in <code>charts/tractusx-connector/Chart.yaml</code>:</p> <pre>dependencies:   # IDS Dynamic   Attribute Provisioning   Service (IAM)   # - name: daps   # version: 0.0.1   # repository:   "file://./subcharts/   omejdn"   # alias: daps</pre>	<p>DevOps engineer</p>

Task	Description	Skills required
	<pre># condition: install.daps</pre>	

Task	Description	Skills required
Configure the connectors to use PostgreSQL on Amazon RDS.	<p>(Optional) Amazon Relational Database Service (Amazon RDS) instance is not required in this pattern. However, we highly recommend using Amazon RDS or Amazon Aurora because they provide features such as high availability and backup and recovery.</p> <p>To replace PostgreSQL on Kubernetes with Amazon RDS, do the following:</p> <ol style="list-style-type: none"><li>1. Provision the <a href="#">Amazon RDS for PostgreSQL instance</a>.</li><li>2. In <code>Chart.yaml</code>, comment the PostgreSQL section.</li><li>3. In <code>provider_values.yaml</code> and <code>consumer_values.yaml</code>, configure the <code>postgresql</code> section as follows:</li></ol> <pre>postgresql:   auth:     database: edc     password: &lt;RDS PASSWORD&gt;     username: &lt;RDS Username&gt;</pre>	DevOps engineer

Task	Description	Skills required
	<pre>jdbcUrl: jdbc:post gresql://&lt;RDS DNS NAME&gt;:5432/edc username: &lt;RDS Username&gt; password: &lt;RDS PASSWORD&gt; primary:   persistence:     enabled: false readReplicas:   persistence:     enabled: false</pre>	

Task	Description	Skills required
Configure and deploy the provider connector and its services.	<p>To configure the provider connector and its services, do the following:</p> <ol style="list-style-type: none"><li>1. To download the <code>provider_edc.yaml</code> file from the <code>edc_helm_configs</code> directory to the current Helm chart folder, run the following command:  <pre>wget -q https://raw.githubusercontent.com/Think-iT-Labs/aws-patterns-edc/main/edc_helm_configs/provider_edc.yaml -P charts/tractusx-connector/</pre></li><li>2. Replace the following variables (also marked in the file) with their values:<ul style="list-style-type: none"><li>• <code>CLIENT_ID</code> – The ID generated by the DAPS. The <code>CLIENT_ID</code> should be in <code>/srv/mvds/omejdn-daps/config/clients.yml/config/clients.yml</code> on the DAPS server. It should a string of hexadecimal characters.</li></ul></li></ol>	DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>DAPS_URL</code> – The URL of the DAPS server. It should be <code>https://{DNS name}</code> using the DNS name that you set up when you ran the AWS CloudFormation template.</li><li>• <code>VAULT_TOKEN</code> – The token to be used for Vault authorization. Choose any value.</li><li>• <code>vault.fullnameOverride</code> – <code>vault-provider</code> .</li><li>• <code>vault.hashicorp.url</code> – <code>http://vault-provider:8200/</code> .</li></ul> <p>The previous values assume that the deployment name and the namespace name are <code>provider</code>.</p> <p>3. To run the Helm chart from your workstation, use the following commands:</p> <pre>cd charts/tractusx-connector  helm dependency build</pre>	

Task	Description	Skills required
	<pre>helm upgrade -- install provider ./ -f provider_edc.yaml -n provider</pre>	

Task	Description	Skills required
Add the certificate and keys to the provider vault.	<p>To avoid confusion, produce the following certificates outside of the <code>tractusx-edc/charts</code> directory.</p> <p>For example, run the following command to change to your home directory:</p> <pre>cd ~</pre> <p>You now need to add the secrets that are needed by the provider into the vault.</p> <p>The names of the secrets within the vault are the values of the keys in the <code>secretNames:</code> section of the <code>provider_edc.yml</code> file. By default, they are configured as follows:</p> <pre>secretNames:   transferProxyTokenSignerPrivateKey: transfer-proxy-token-signer-private-key   transferProxyTokenSignerPublicKey: transfer-proxy-token-signer-public-key   transferProxyTokenEncryptionKey: transferProxyTokenEncryptionKey</pre>	DevOps engineer

Task	Description	Skills required
	<pre>nAesKey: transfer- proxy-token-encryp tion-aes-key           dapsPriva teKey: daps-private- key           dapsPubli cKey: daps-public-key</pre> <p>An Advanced Encryption Standard (AES) key, private key, public key, and self-signed certificate are generated initially. These are subsequently added as secrets to the vault.</p> <p>Furthermore, this directory should contain the <code>daps-provider.cert</code> and <code>daps-provider.key</code> files that you copied from the DAPS server.</p> <ol style="list-style-type: none"><li>1. Run the following commands:</li></ol> <pre># generate a private key openssl ecparam -name prime256v1 -genkey -noout -out provider- private-key.pem # generate correspon ding public key openssl ec -in provider-private-k ey.pem -pubout -out</pre>	

Task	Description	Skills required
	<pre> provider-public-key.pem # create a self-signed certificate openssl req -new -x509 -key provider-private-key.pem -out provider-cert.pem -days 360 # generate aes key openssl rand -base64 32 &gt; provider-aes.key </pre> <p>2. Before adding the secrets to the vault, convert them from multiple lines to single lines by replacing line breaks with <code>\n</code>:</p> <pre> cat provider-private-key.pem   sed 's/\$/\n/'   tr -d '\n' &gt; provider-private-key.pem.line cat provider-public-key.pem   sed 's/\$/\n/'   tr -d '\n' &gt; provider-public-key.pem.line cat provider-cert.pem   sed 's/\$/\n/'   tr -d '\n' &gt; provider-cert.pem.line cat provider-aes.key   sed 's/\$/\n/'   tr -d '\n' &gt; provider-aes.key.line </pre>	

Task	Description	Skills required
	<pre>## The following block is for daps certifica te and key openssl x509 -in daps-provider.cert - outform PEM   sed 's/ \$/\n/'   tr -d '\n' &gt; daps-provider.cert .line cat daps-provider.key   sed 's\$/\n/'   tr -d '\n' &gt; daps- provider.key.line</pre> <p>3. To format the secrets that will be added to Vault, run the following commands:</p> <pre>JSONFORMAT='{ "cont ent": "%s"}' #create a single line in JSON format printf "\${JSONFO RMAT}\n" "`cat provider-private- key.pem.line`" &gt; provider-private-k ey.json printf "\${JSONFO RMAT}\n" "`cat provider-public- key.pem.line`" &gt; provider-public-ke y.json printf "\${JSONFO RMAT}\n" "`cat provider-cert.pem. line`" &gt; provider- cert.json printf "\${JSONFO RMAT}\n" "`cat</pre>	

Task	Description	Skills required
	<pre data-bbox="646 210 993 766"> provider-aes.key.line`" &gt; provider- aes.json  printf "\${JSONFO RMA} \\n" "`cat daps- provider.key.line`" &gt; daps-provider.key. json printf "\${JSONFO RMA} \\n" "`cat daps- provider.cert.line`" &gt; daps-provider.cert .json </pre> <p data-bbox="630 823 1026 949">The secrets are now in JSON format and are ready to be added to the vault.</p> <p data-bbox="592 976 1026 1102">4. To get the pod name for the vault, run the following command:</p> <pre data-bbox="633 1144 982 1291"> kubectl get pods - n provider egrep "vault NAME" </pre> <p data-bbox="630 1339 1026 1852">The pod name will be similar to "vault-provider-0" . This name is used when creating a port forward to the vault. The port forward gives you to access the vault to add the secret. You should run this from a workstation that has AWS credentials configured.</p>	

Task	Description	Skills required
	<p>5. To access the vault, use <code>kubectl</code> to configure a port forward:</p> <pre data-bbox="630 380 1029 537">kubectl port-forward &lt;VAULT_POD_NAME&gt; 8200:8200 -n provider</pre> <p>You should now be able to access the vault through your browser or the CLI.</p> <p><b>Browser</b></p> <ol style="list-style-type: none"><li>1. Using the browser, navigate to <a href="http://127.0.0.1:8200">http://127.0.0.1:8200</a>, which will use the port forward that you configured.</li><li>2. Log in using the token you that configured previously in <code>provider_edc.yml</code> . In the secrets engine, create three secrets. Each secret will have a Path for this secret value, which is the secret name shown in the following list. Within the secret data section, the name of the key will be content and the value will be the single line of text from the respective file named <code>.line</code>.</li></ol>	

Task	Description	Skills required
	<p>3. The secret names are sourced from the <code>secretNames</code> section in the <code>provider_edc.yml</code> file.</p> <p>4. Create the following secrets:</p> <ul style="list-style-type: none"><li>• Secret <code>transfer-proxy-token-signer-private-key</code> with file name <code>provider-private-key.pem</code>.line</li><li>• Secret <code>transfer-proxy-token-signer-public-key</code> with file name <code>provider-cert.pem</code>.line</li><li>• Secret <code>transfer-proxy-token-encryption-aes-key</code> with file name <code>provider-aes.key</code>.line</li><li>• Secret <code>daps-private-key</code> with file name <code>daps-provider.key</code>.line</li><li>• Secret <code>daps-public-key</code> with file name <code>daps-provider.cert</code>.line</li></ul>	

Task	Description	Skills required
	<p><b>Vault CLI</b></p> <p>The CLI will also use the port forward that you configured.</p> <ol style="list-style-type: none"><li>1. On your workstation, install Vault CLI by following the instructions in the <a href="#">HashiCorp Vault documentation</a>.</li><li>2. To log in to the vault by using the token that you set up in <code>provider_edc.yml</code>, run the following command:</li></ol> <pre data-bbox="634 930 1029 1087">vault login -address= http://127.0.0.1:8 200</pre> <p>With the correct token, you should see the message "Success! You are now authenticated."</p> <ol style="list-style-type: none"><li>3. To create the secrets by using the JSON formatted files that you created previously, run the following code:</li></ol> <pre data-bbox="634 1591 1029 1843">vault kv put -address= http://127.0.0.1:8 200 secret/transfer- proxy-token-signer-p rivate-key @provider -private-key.json</pre>	

Task	Description	Skills required
	<pre>vault kv put - address=http://12 7.0.0.1:8200 secret/ transfer-proxy-token -signer-public-key @provider-cert.json vault kv put -address= http://127.0.0.1:8 200 secret/transfer- proxy-token-encrypti on-aes-key @provider -aes.json  vault kv put -address= http://127.0.0.1:8 200 secret/daps- private-key @daps-pro vider.key.json vault kv put - address=http://12 7.0.0.1:8200 secret/ daps-public-key @daps-provider.cer t.json</pre>	

Task	Description	Skills required
Configure and deploy the consumer connector and its services.	<p>The steps for configuring and deploying the consumer are similar to those you completed for the provider:</p> <ol style="list-style-type: none"><li>1. To copy the <code>consumer_edc.yaml</code> from the <a href="#">aws-patterns-edc</a> repo into the <code>tractusx-edc/charts/tractusx-connector</code> folder, run the following commands:</li></ol> <pre data-bbox="634 810 1029 1247">cd tractusx-edc  wget -q https://raw.githubusercontent.com/Think-iT-Labs/aws-patterns-edc/main/edc_helm_configs/consumer_edc.yaml -P charts/tractusx-connector/</pre> <ol style="list-style-type: none"><li>2. Update the following variables with their actual values:</li></ol> <ul style="list-style-type: none"><li>• <code>CONSUMER_CLIENT_ID</code><ul style="list-style-type: none"><li>– The ID generated by DAPS. The <code>CONSUMER_CLIENT_ID</code> should be in <code>config/clients.yaml</code> on the DAPS server.</li></ul></li></ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• DAPS_URL – The same DAPS URL that you used for the provider.</li><li>• VAULT_TOKEN – The token to be used for Vault authorization. Choose any value.</li><li>• vault.fullnameOverride – vault-consumer</li><li>• vault.hashicorp.url – http://vault-provider:8200/</li></ul> <p>The previous values assume that the deployment name and the namespace name are consumer.</p> <p>3. To run the Helm chart, use the following commands:</p> <pre>cd charts/tractusx-consumer  helm upgrade --install consumer ./ -f consumer_edc.yaml -n consumer</pre>	

Task	Description	Skills required
Add the certificate and keys to the consumer vault.	<p>From a security standpoint, we recommend regenerating the certificates and keys for each data space participant. This pattern regenerates certificates and keys for the consumer.</p> <p>The steps are very similar to those for the provider. You can verify the secret names in the <code>consumer_edc.yml</code> file.</p> <p>The names of the secrets within the vault are the values of the keys in the <code>secretNames:</code> section of the <code>consumer_edc.yml</code> file. By default, they are configured as follows:</p> <pre>secretNames:   transferProxyTokenSignerPrivateKey: transfer-proxy-token-signer-private-key   transferProxyTokenSignerPublicKey: transfer-proxy-token-signer-public-key   transferProxyTokenEncryptionAesKey: transfer-proxy-token-encryption-aes-key</pre>	DevOps engineer

Task	Description	Skills required
	<pre>                dapsPrivateKey: daps-private-key                 dapsPublicKey: daps-public-key</pre> <p>The <code>daps-consumer.cert</code> and <code>daps-consumer.key</code> files that you copied from the DAPS server should already exist in this directory.</p> <ol style="list-style-type: none"><li>1. Run the following commands:</li></ol> <pre># generate a private key openssl ecparam -name prime256v1 -genkey -noout -out consumer-private-key.pem # generate corresponding public key openssl ec -in consumer-private-key.pem -pubout -out consumer-public-key.pem # create a self-signed certificate openssl req -new -x509 -key consumer-private-key.pem -out consumer-cert.pem -days 360 # generate aes key openssl rand -base64 32 &gt; consumer-aes.key</pre>	

Task	Description	Skills required
	<p>2. Manually edit the files to replace line breaks with <code>\n</code>, or use three commands similar to the following:</p> <pre data-bbox="633 430 1031 1617">cat consumer-private-key.pem   sed 's/\$/\n/'   tr -d '\n' &gt; consumer-private-key.pem.line cat consumer-public-key.pem   sed 's/\$/\n/'   tr -d '\n' &gt; consumer-public-key.pem.line cat consumer-cert.pem   sed 's/\$/\n/'   tr -d '\n' &gt; consumer-cert.pem.line cat consumer-aes.key   sed 's/\$/\n/'   tr -d '\n' &gt; consumer-aes.key.line cat daps-consumer.cert   sed 's/\$/\n/'   tr -d '\n' &gt; daps-consumer.cert.line cat daps-consumer.key   sed 's/\$/\n/'   tr -d '\n' &gt; daps-consumer.key.line</pre>	
	<p>3. To format the secrets that will be added to Vault, run the following commands:</p>	

Task	Description	Skills required
	<pre> JSONFORMAT='{"cont ent": "%s"}'  #create a single line in JSON format  printf "\${JSONFO RMAT}\\n" "`cat consumer-private- key.pem.line`" &gt; consumer-private-k ey.json printf "\${JSONFO RMAT}\\n" "`cat consumer-public- key.pem.line`" &gt; consumer-public-ke y.json printf "\${JSONFO RMAT}\\n" "`cat consumer-cert.pem. line`" &gt; consumer- cert.json printf "\${JSONFO RMAT}\\n" "`cat consumer-aes.key.l ine`" &gt; consumer- aes.json  printf "\${JSONFO RMAT}\\n" "`cat daps- consumer.key.line`" &gt; daps-consumer.key. json printf "\${JSONFO RMAT}\\n" "`cat daps- consumer.cert.line`" &gt; daps-consumer.cert .json </pre>	

Task	Description	Skills required
	<p>The secrets are now in JSON format and are ready to be added to the vault.</p> <p>4. To get the pod name for the consumer vault, run the following command:</p> <pre>kubectl get pods -n consumer   egrep "vault NAME"</pre> <p>The pod name will be similar to "vault-consumer-0". This name is used when creating a port forward to the vault. The port forward gives you to access the vault to add the secret. You should run this from a workstation that has AWS credentials configured.</p> <p>5. To access the vault, use <code>kubectl</code> to configure a port forward:</p> <pre>kubectl port-forward &lt;VAULT_POD_NAME&gt; 8201:8200 -n consumer</pre> <p>The local port is 8201 this time so that you can have port forwards in place for</p>	

Task	Description	Skills required
	<p>both the producer and consumer.</p> <p><b>Browser</b></p> <p>You can use your browser to connect to <a href="http://localhost:8201/">http://localhost:8201/</a> to access the consumer vault and create the secrets with names and content as outlined.</p> <p>The secrets and files that contain the content are the following:</p> <ul style="list-style-type: none"><li>• Secret transfer-proxy-token-signer-private-key with file name consumer-private-key.pem.line</li><li>• Secret transfer-proxy-token-signer-public-key with file name consumer-cert.pem.line</li><li>• Secret transfer-proxy-token-encryption-aes-key with file name consumer-aes.key.line</li></ul> <p><b>Vault CLI</b></p>	

Task	Description	Skills required
	<p>Using Vault CLI, you can run the following commands to log in to the vault and create the secrets:</p> <ol style="list-style-type: none"><li>1. Log in to the vault by using the token that you configured within <code>consumer_edc.yml</code> :</li></ol> <pre data-bbox="634 646 1029 808">vault login -address= http://127.0.0.1:8 201</pre> <p>With the correct token, you should see the message "Success! You are now authenticated."</p> <ol style="list-style-type: none"><li>2. To create the secrets using the JSON formatted files that you created previously, run the following code:</li></ol> <pre data-bbox="634 1262 1029 1871">vault kv put -address= http://127.0.0.1:8 201 secret/transfer- proxy-token-signer-p rivate-key @consumer -private-key.json vault kv put - address=http://12 7.0.0.1:8201 secret/ transfer-proxy-token -signer-public-key @consumer-cert.json vault kv put -address= http://127.0.0.1:8 201 secret/transfer-</pre>	

Task	Description	Skills required
	<pre> proxy-token-encryption-aes-key @consumer-aes.json vault kv put -address=http://127.0.0.1:8201 secret/daps-private-key @daps-consumer.key.json vault kv put -address=http://127.0.0.1:8201 secret/daps-public-key @daps-consumer.cert.json </pre>	

### Set up an HTTP client to interact with the management API of the connectors

Task	Description	Skills required
Set up port forwarding.	<ol style="list-style-type: none"> <li data-bbox="592 1066 1031 1199">1. To check the status of the pods, run the following commands: <div data-bbox="630 1234 1029 1436" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre> kubect1 get pods -n provider kubect1 get pods -n consumer </pre> </div> </li> <li data-bbox="592 1451 1031 1768">2. To make sure that the Kubernetes deployments were successful, look at the logs of the provider and consumer Kubernetes pods by running the following commands:</li> </ol>	DevOps engineer

Task	Description	Skills required
	<pre>kubectl logs -n provider &lt;producer control plane pod name&gt; kubectl logs -n consumer &lt;consumer control plane pod name&gt;</pre> <p>The cluster is private and is not accessible publicly. To interact with the connectors, use the Kubernetes port-forwarding feature to forward traffic generated by your machine to the connector control plane.</p> <ol style="list-style-type: none"><li>1. On the first terminal, forward the consumer's requests to the management API through port 8300:</li></ol> <pre>kubectl port-forward deployment/consumer-tractusx-connector-controlplane 8300:8081 -n consumer</pre> <ol style="list-style-type: none"><li>2. On the second terminal, forward the provider's requests to the management API through port 8400:</li></ol>	

Task	Description	Skills required
	<pre>kubectl port-forward deployment/provide r-tractusx-connect or-controlplane 8400:8081 -n provider</pre>	

Task	Description	Skills required
Create S3 buckets for the provider and the consumer.	<p>The EDC connector currently doesn't use temporary AWS credentials, such as those provided by assuming a role. The EDC supports only the use of an <a href="#">IAM access key ID and secret access key combination</a>.</p> <p>Two S3 buckets are required for later steps. One S3 bucket is used for storing data made available by the provider. The other S3 bucket is for data received by the consumer.</p> <p>The IAM user should have permission to read and write objects only in the two named buckets.</p> <p>An access key ID and secret access key pair needs to be created and kept safe. After this MVDS has been decommissioned, the IAM user should be deleted.</p> <p>The following code is an example IAM policy for the user:</p> <pre data-bbox="594 1667 1029 1877">{   "Version": "2012-10-17",   "Statement": [     {</pre>	DevOps engineer

Task	Description	Skills required
	<pre>         "Sid": "Stmt1708 699805237",         "Action": [             "s3:GetObject",             "s3:GetOb jectVersion",             "s3:ListA llMyBuckets",             "s3:ListB ucket",             "s3:ListB ucketMultipartUplo ads",             "s3:ListB ucketVersions",             "s3:PutObject"         ],         "Effect": "Allow",         "Resource": [             "arn:aws: s3:::&lt;S3 Provider Bucket&gt;",             "arn:aws: s3:::&lt;S3 Consumer Bucket&gt;",             "arn:aws: s3:::&lt;S3 Provider Bucket&gt;/*",             "arn:aws: s3:::&lt;S3 Consumer Bucket&gt;/*"         ]     ] } </pre>	

Task	Description	Skills required
Set up Postman to interact with the connector.	<p>You can now interact with the connectors through your EC2 instance. Use Postman as an HTTP client, and provide Postman Collections for both the provider and the consumer connectors.</p> <p>Import the <a href="#">collections</a> from the <code>aws-pattern-edc</code> repository into your Postman instance.</p> <p>This pattern uses Postman collection variables to provide input to your requests.</p>	App developer, Data engineer

### Provide company X carbon-emissions footprint data through the connector

Task	Description	Skills required
Prepare the carbon-emissions intensity data to be shared.	<p>First you need to decide on the data asset to be shared. The data of company X represents the carbon-emissions footprint of its vehicle fleet. Weight is Gross Vehicle Weight (GVW) in tonnes, and emissions are in grams of CO<sub>2</sub> per tonne-kilometer (g CO<sub>2</sub> e/t-km) according to the Wheel-to-Well (WTW) measurement:</p>	Data engineer, App developer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• Vehicle type: Van; weight: &lt; 3.5; emissions: 800</li><li>• Vehicle type: Urban truck; weight: 3.5–7.5; emissions: 315</li><li>• Vehicle type: Medium goods vehicle (MGV); weight: 7.5–20; emissions: 195</li><li>• Vehicle type: Heavy goods vehicle (HGV); weight: &gt; 20; emissions: 115</li></ul> <p>The example data is in the <code>carbon_emissions_data.json</code> file in the <code>aws-patterns-edc</code> repository.</p> <p>Company X uses Amazon S3 to store objects.</p> <p>Create the S3 bucket and store the example data object there. The following commands create an S3 bucket with default security settings. We highly recommend consulting <a href="#">Security best practices for Amazon S3</a>.</p> <pre>aws s3api create-bucket &lt;BUCKET_NAME&gt; --region &lt;AWS_REGION&gt;</pre>	

Task	Description	Skills required
	<pre># You need to add '--create-bucket-c onfiguration # LocationConstraint =&lt;AWS_REGION&gt;' if you want to create # the bucket outside of us- east-1 region  aws s3api put-object --bucket &lt;BUCKET_NAME&gt; \ --key &lt;S3 OBJECT NAME&gt; \ --body &lt;PATH OF THE FILE TO UPLOAD&gt;</pre> <p>The S3 bucket name should be globally unique. For more information about naming rules, see the <a href="#">AWS documentation</a>.</p>	

Task	Description	Skills required
Register the data asset to the provider's connector by using Postman.	<p>An EDC connector data asset holds the name of the data and its location. In this case, the EDC connector data asset will point to the created object in the S3 bucket:</p> <ul style="list-style-type: none"><li>• <b>Connector:</b> Provider</li><li>• <b>Request:</b> Create Asset</li><li>• <b>Collection Variables:</b> Update ASSET_NAME . Choose a meaningful name that represents the asset.</li><li>• <b>Request Body:</b> Update the request body with the S3 bucket that you created for the provider.</li></ul> <pre data-bbox="630 1075 1029 1843">"dataAddress": {   "edc:type":   "AmazonS3",   "name": "Vehicle Carbon Footprint",   "bucketName":   "&lt;REPLACE WITH THE SOURCE BUCKET NAME&gt;",   "keyName":   "&lt;REPLACE WITH YOUR OBJECT NAME&gt;",   "region":   "&lt;REPLACE WITH THE BUCKET REGION&gt;",   "accessKeyId":   "&lt;REPLACE WITH YOUR ACCESS KEY ID&gt;",   "secretAc cessKey": "&lt;REPLACE</pre>	App developer, Data engineer

Task	Description	Skills required
	<pre>WITH SECRET ACCESS KEY&gt;" }</pre> <ul style="list-style-type: none"><li>• <b>Response:</b> A successful request returns the created time and the asset ID of the newly created asset.</li></ul> <pre>{   "@id": "c89aa31c- ec4c-44ed-9e8c-16 47f19d7583" }</pre> <ul style="list-style-type: none"><li>• <b>Collection variable</b> <b>ASSET_ID:</b> Update the Postman collection variable ASSET_ID with the ID that was generated automatically by the EDC connector after creation.</li></ul>	

Task	Description	Skills required
Define the usage policy of the asset.	<p>An EDC data asset must be associated with clear usage policies. First, create the Policy Definition in the provider connector.</p> <p>The policy of company X is to allow participants of the data space to use the carbon-emissions footprint data.</p> <ul style="list-style-type: none"><li>• <b>Request Body:</b><ul style="list-style-type: none"><li>• <b>Connector:</b> Provider</li><li>• <b>Request:</b> Create Policy</li><li>• <b>Collection Variables</b> : Update the Policy Name variable with the name of the policy.</li></ul></li><li>• <b>Response:</b> A successful request returns the created time and the policy ID of the newly created policy. Update the collection variable POLICY_ID with the ID of the policy generated by the EDC connector after creation.</li></ul>	App developer, Data engineer

Task	Description	Skills required
Define an EDC Contract Offer for the asset and its usage policy.	<p>To allow other participants to request access to your data, offer it in a contract that specifies the usage conditions and permissions:</p> <ul style="list-style-type: none"> <li>• <b>Connector:</b> Provider</li> <li>• <b>Request:</b> Create Contract Definition</li> <li>• <b>Collection Variables:</b> Update the Contract Name variable with a name for the contract offer or definition.</li> </ul>	App developer, Data engineer

### Discover the assets and reach agreement on the defined contracts

Task	Description	Skills required
Request the data catalog shared by company X.	<p>As a data consumer in the data space, company Y first needs to discover the data that is being shared by other participants.</p> <p>In this basic setup, you can do this by asking the consumer connector to request the catalog of available assets from the provider connector directly.</p> <ul style="list-style-type: none"> <li>• <b>Connector:</b> Consumer</li> <li>• <b>Request:</b> Request Catalog</li> </ul>	App developer, Data engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <b>Response:</b> All available data assets from the provider together with their attached usage policies. As a data consumer, look for the contract of your interest and update the following collection variables accordingly.<ul style="list-style-type: none"><li>• CONTRACT_OFFER_ID<ul style="list-style-type: none"><li>– The ID of the contract offer the consumer wants to negotiate</li></ul></li><li>• ASSET_ID – The ID of the asset the consumer wants to negotiate</li><li>• PROVIDER_CLIENT_ID<ul style="list-style-type: none"><li>– The ID of the provider connector to negotiate with</li></ul></li></ul></li></ul>	

Task	Description	Skills required
Initiate a contract negotiation for the carbon-emissions intensity data from company X.	<p>Now that you have identified the asset that you want to consume, initiate a contract negotiation process between the consumer and provider connectors.</p> <ul style="list-style-type: none"> <li>• <b>Connector:</b> Consumer</li> <li>• <b>Request:</b> Contract Negotiation</li> <li>• <b>Collection Variables:</b> Update the CONSUMER_CLIENT_ID variable with the ID of the consumer connector to negotiate with.</li> </ul> <p>The process might take some time before reaching the VERIFIED state.</p> <p>You can check the state of the Contract Negotiation and the corresponding Agreement ID by using the Get Negotiation request.</p>	App developer, Data engineer

### Consume the data by using the contract agreement

Task	Description	Skills required
Consume data from HTTP endpoints.	(Option 1) To use HTTP data plane to consume data in the data space, you can use	App developer, Data engineer

Task	Description	Skills required
	<p><a href="https://webhook.site">webhook.site</a> to emulate an HTTP server, and initiate the transfer process in the consumer connector:</p> <ul style="list-style-type: none"><li>• <b>Connector:</b> Consumer</li><li>• <b>Request:</b> Contract Negotiation</li><li>• <b>Collection Variables:</b> Update the Contract Agreement ID variable with the ID of the contract agreement generated by the EDC connector.</li><li>• <b>Request Body:</b> Update the request body to specify HTTP as a dataDestination alongside the webhook URL:</li></ul> <pre data-bbox="625 1155 1031 1711">{   "dataDestination": {     "type":     "HttpProxy"   },   "privateProperties": {     "receiver     HttpEndpoint":     "&lt;WEBHOOK URL&gt;"   } }</pre> <p>The connector will send the information necessary to</p>	

Task	Description	Skills required
	<p>download the file directly to the webhook URL.</p> <p>The received payload is similar to the following:</p> <pre data-bbox="625 457 1029 1528">{   "id": "dcc90391-3819-4b54-b401-1a005a029b78",   "endpoint": "http://consumer-tractusx-connector-dataplane.consumer:8081/api/public",   "authKey": "Authorization",   "authCode": "&lt;AUTH CODE YOU RECEIVE IN THE ENDPOINT&gt;",   "properties": {     "https://w3id.org/edc/v0.0.1/ns/cid": "vehicle-carbon-footprint-contract:4563abf7-5dc7-4c28-bc3d-97f45e32edac:b073669b-db20-4c83-82df-46b583c4c062"   } }</pre> <p>Use the received credentials to get the S3 asset that was shared by the provider.</p> <p>In this last step, you must send the request to the</p>	

Task	Description	Skills required
	consumer data plane (forward ports properly), as stated in the payload (endpoint).	

Task	Description	Skills required
Consume data from S3 buckets directly.	<p>(Option 2) Use Amazon S3 integration with the EDC connector, and directly point to the S3 bucket in the consumer infrastructure as a destination:</p> <ul style="list-style-type: none"><li>• <b>Request Body:</b> Update the request body to specify the S3 bucket as a dataDestination.</li></ul> <p>This should be the S3 bucket that you previously created for storing data received by the consumer.</p> <pre data-bbox="630 982 1029 1875">{   "dataDestination":   {     "type": "AmazonS3",     "bucketName":     "{{ REPLACE WITH THE DESTINATION BUCKET NAME }}",     "keyName":     "{{ REPLACE WITH YOUR OBJECT NAME }}",     "region":     "{{ REPLACE WITH THE BUCKET REGION }}",     "accessKeyId":     "{{ REPLACE WITH YOUR ACCESS KEY ID }}",     "secretAccessKey": "{{ REPLACE WITH SECRET ACCESS KEY }}"   } }</pre>	Data engineer, App developer

Task	Description	Skills required
	<pre> } } } </pre>	

## Troubleshooting

Issue	Solution
The connector might raise an issue about the certificate PEM format.	Concatenate the contents of each file to a single line by adding <code>\n</code> .

## Additional information

### Data space specifications

#### Participants

Participant	Description of the company	Focus of the company
Company X	Operates a fleet of vehicles across Europe and South America to transport various goods.	Aims to make data-driven decisions to reduce its carbon-emissions footprint intensity.

Company Y	An environmental regulatory authority	Enforces environmental regulations and policies designed to monitor and mitigate the environmental impact of businesses and industries, including carbon-emissions intensity.
-----------	---------------------------------------	---

### *Business case*

Company X uses data space technology to share carbon footprint data with a compliance auditor, company Y, to evaluate and address the environmental impact of company X's logistics operations.

### *Data space authority*

The data space authority is a consortium of the organizations governing the data space. In this pattern, both company X and company Y form the governance body and represent a federated data space authority.

### *Data space components*

<b>Component</b>	<b>Chosen implementation</b>	<b>Additional information</b>
Dataset exchange protocol	Dataspace Protocol version 0.8	<ul style="list-style-type: none"> <li>• <a href="#">JSON-LD</a></li> <li>• <a href="#">Data Catalog Vocabulary (DCAT)</a></li> </ul>

## Using AWS Secrets Manager Manager

It's possible to use Secrets Manager instead of HashiCorp Vault as the secrets manager. To do so you, must use or build the AWS Secrets Manager EDC extension.

You will be responsible for creating and maintaining your own image, because Tractus-X doesn't provide support for Secrets Manager.

To accomplish that, you need to modify the build Gradle files of both the [control plane](#) and the [data plane](#) of the connector by introducing your AWS Secrets Manager EDC extension (see [this maven artifact](#) for an example), then build, maintain, and reference the Docker image.

For more insights on refactoring the Tractus-X connector Docker image, see [Refactor Tractus-X EDC Helm charts](#).

For simplicity purposes, we avoid to rebuilding the connector image in this pattern and use HashiCorp Vault.

# Set up language-specific sorting for Amazon Redshift query results using a scalar Python UDF

Created by Ethan Stark (AWS)

**Environment:** Production

**Technologies:** Analytics

**AWS services:** Amazon Redshift

## Summary

This pattern provides steps and sample code for using a scalar Python UDF (user-defined function) to set up case insensitive linguistic sorting for Amazon Redshift query results. It's necessary to use a scalar Python UDF because Amazon Redshift returns results based on binary UTF-8 ordering and doesn't support language-specific sorting. A Python UDF is non-SQL processing code that's based on a Python 2.7 program and runs in a data warehouse. You can run Python UDF code with a SQL statement in a single query. For more information, see the [Introduction to Python UDFs in Amazon Redshift](#) AWS Big Data Blog post.

The sample data in this pattern is based on the Turkish alphabet for demonstration purposes. The scalar Python UDF in this pattern is built to make the default query results of Amazon Redshift conform to the linguistic ordering of characters in the Turkish language. For more information, see *Turkish language example* in the *Additional information* section of this pattern. You can modify the scalar Python UDF in this pattern for other languages.

## Prerequisites and limitations

### Prerequisites

- Amazon Redshift [cluster](#) with a database, schema, and tables
- Amazon Redshift [user](#) with CREATE TABLE and CREATE FUNCTION permissions
- [Python 2.7](#) or later

### Limitations

The linguistic sorting used by the queries in this pattern is case insensitive.

# Architecture

## Technology stack

- Amazon Redshift
- Python UDF

## Tools

### AWS services

- [Amazon Redshift](#) is a managed petabyte-scale data warehouse service in the AWS Cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.

### Other tools

- [Python \(UDFs\) user-defined functions](#) are functions that you can write in Python and then call in SQL statements.

## Epics

### Develop code to sort query results in linguistic order

Task	Description	Skills required
Create a table for your sample data.	<p>To create a table in Amazon Redshift and insert your sample data into the table, use the following SQL statements:</p> <pre>CREATE TABLE my_table (first_name varchar(30));  INSERT INTO my_table (first_name)</pre>	Data engineer

Task	Description	Skills required
	<p>VALUES</p> <ul style="list-style-type: none"><li>('ali'),</li><li>('Ali'),</li><li>('ırmak'),</li><li>('IRMAK'),</li><li>('irem'),</li><li>('İREM'),</li><li>('oğuz'),</li><li>('OĞUZ'),</li><li>('ömer'),</li><li>('ÖMER'),</li><li>('sedat'),</li><li>('SEDAT'),</li><li>('şule'),</li></ul> <p><b>Note:</b> The first names in the sample data include special characters from the Turkish alphabet. For more information about Turkish language considerations for this example, see <i>Turkish language example</i> in the <i>Additional information</i> section of this pattern.</p>	

Task	Description	Skills required
Check the default sorting of the sample data.	<p>To see the default sorting of your sample data in Amazon Redshift, run the following query:</p> <pre data-bbox="597 443 1027 600">SELECT first_name FROM my_table ORDER BY first_name;</pre> <p>The query returns the list of first names from the table that you created earlier:</p> <pre data-bbox="597 806 1027 1482">first_name ----- Ali IRMAK OĞUZ SEDAT ali irem oğuz sedat ÖMER ömer İREM ırmak ŞULE şule</pre> <p>The query results aren't in the correct order because the default binary UTF-8 ordering doesn't accommodate the linguistic ordering of the Turkish special characters.</p>	Data engineer

Task	Description	Skills required
Create a scalar Python UDF.	<p>To create a scalar Python UDF, use the following SQL code:</p> <pre data-bbox="592 346 1031 1871">CREATE OR REPLACE FUNCTION collate_sort (value varchar) RETURNS varchar IMMUTABLE AS \$\$ def sort_str(val):     import string      dictionary = {         'I': 'ı',         'ı': 'h~',         'İ': 'i',         'Ş': 's~',         'ş': 's~',         'Ğ': 'g~',         'ğ': 'g~',         'Ü': 'u~',         'ü': 'u~',         'Ö': 'o~',         'ö': 'o~',         'Ç': 'c~',         'ç': 'c~'     }      for key, value in dictionary.items() :         val = val.replace(key, value)      return val.lower ()      return sort_str( value)</pre>	Data engineer

Task	Description	Skills required
	<pre>\$\$ LANGUAGE plpythonu;</pre>	
Query the sample data.	<p>To query the sample data by using the Python UDF, run the following SQL query:</p> <pre>SELECT first_name FROM my_table ORDER BY collate_order(firs t_name);</pre> <p>The query now returns the sample data in Turkish linguistic order:</p> <pre>first_name ----- ali Ali ırmak IRMAK irem İREM oğuz OĞUZ ömer Ömer sedat SEDAT şule ŞULE</pre>	Data engineer

## Related resources

- [ORDER BY clause](#) (Amazon Redshift documentation)
- [Creating a scalar Python UDF](#) (Amazon Redshift documentation)

## Additional information

### Turkish language example

Amazon Redshift returns query results based on binary UTF-8 sort ordering, not language-specific sort ordering. This means that if you query an Amazon Redshift table containing Turkish characters, then the query results aren't sorted according to the linguistic ordering of the Turkish language. The Turkish language contains six special characters (ç, ı, ğ, ö, ş, and ü) that don't appear in the Latin alphabet. These special characters are placed at the end of a sorted result set based on binary UTF-8 ordering, as the following table shows.

Binary UTF-8 ordering	Turkish linguistic ordering
a	a
b	b
c	c
d	ç (*)
e	d
f	e
g	f
h	g
i	ğ (*)
j	h
k	ı (*)
l	i
m	j
n	k
o	l

p	m
r	n
s	o
t	ö (*)
u	p
v	r
y	s
z	ş (*)
ç (*)	t
ğ (*)	u
ı (*)	ü (*)
ö (*)	v
ş (*)	y
ü (*)	z

**Note:** The asterisk (\*) indicates a special character in the Turkish language.

As the table above illustrates, special character ç is between c and d in Turkish linguistic ordering, but appears after z in binary UTF-8 ordering. The scalar Python UDF in this pattern uses the following character replacement dictionary to replace the Turkish special characters with corresponding Latin-equivalent characters.

Turkish special character	Latin-equivalent character
ç	c~
ı	h~

ğ	g~
ö	o~
ş	s~
ü	u~

**Note:** A tilde (~) character is appended to the end of the Latin characters that replace their corresponding Turkish special characters.

### Modify a scalar Python UDF function

To modify the scalar Python UDF function from this pattern so that the function accepts a locale parameter and supports a multiple transaction dictionary, use the following SQL code:

```
CREATE OR REPLACE FUNCTION collate_sort (value varchar, locale varchar)
RETURNS varchar
IMMUTABLE
AS
$$
def sort_str(val):
    import string
    # Turkish Dictionary
    if locale == 'tr-TR':
        dictionary = {
            'İ': 'ı',
            'ı': 'h~',
            'İ': 'i',
            'Ş': 's~',
            'ş': 's~',
            'Ğ': 'g~',
            'ğ': 'g~',
            'Ü': 'u~',
            'ü': 'u~',
            'Ö': 'o~',
            'ö': 'o~',
            'Ç': 'c~',
            'ç': 'c~'
        }
    # German Dictionary
    if locale == 'de-DE':
```

```
        dictionary = {
            ....
            ....
        }

        for key, value in dictionary.items():
            val = val.replace(key, value)

        return val.lower()

    return sort_str(value)

$$ LANGUAGE plpythonu;
```

The following example code shows how to query the modified Python UDF:

```
SELECT first_name FROM my_table ORDER BY collate_order(first_name, 'tr-TR');
```

# Subscribe a Lambda function to event notifications from S3 buckets in different AWS Regions

Created by Suresh Konathala, Andrew Preston, and Arindom Sarkar

**Environment:** Production

**Technologies:** Analytics

**AWS services:** AWS Lambda;  
Amazon S3; Amazon SNS;  
Amazon SQS

## Summary

[Amazon Simple Storage Service \(Amazon S3\) Event Notifications](#) publishes notifications for certain events in your S3 bucket (for example, object created events, object removal events, or restore object events). You can use an AWS Lambda function to process these notifications according to your application's requirements. However, the Lambda function can't directly subscribe to notifications from S3 buckets that are hosted in different AWS Regions.

This pattern's approach deploys a [fanout scenario](#) to process Amazon S3 notifications from cross-Region S3 buckets by using an Amazon Simple Notification Service (Amazon SNS) topic for each Region. These Regional SNS topics send the Amazon S3 event notifications to an Amazon Simple Queue Service (Amazon SQS) queue in a central Region that also contains your Lambda function. The Lambda function subscribes to this SQS queue and processes the event notifications according to your organization's requirements.

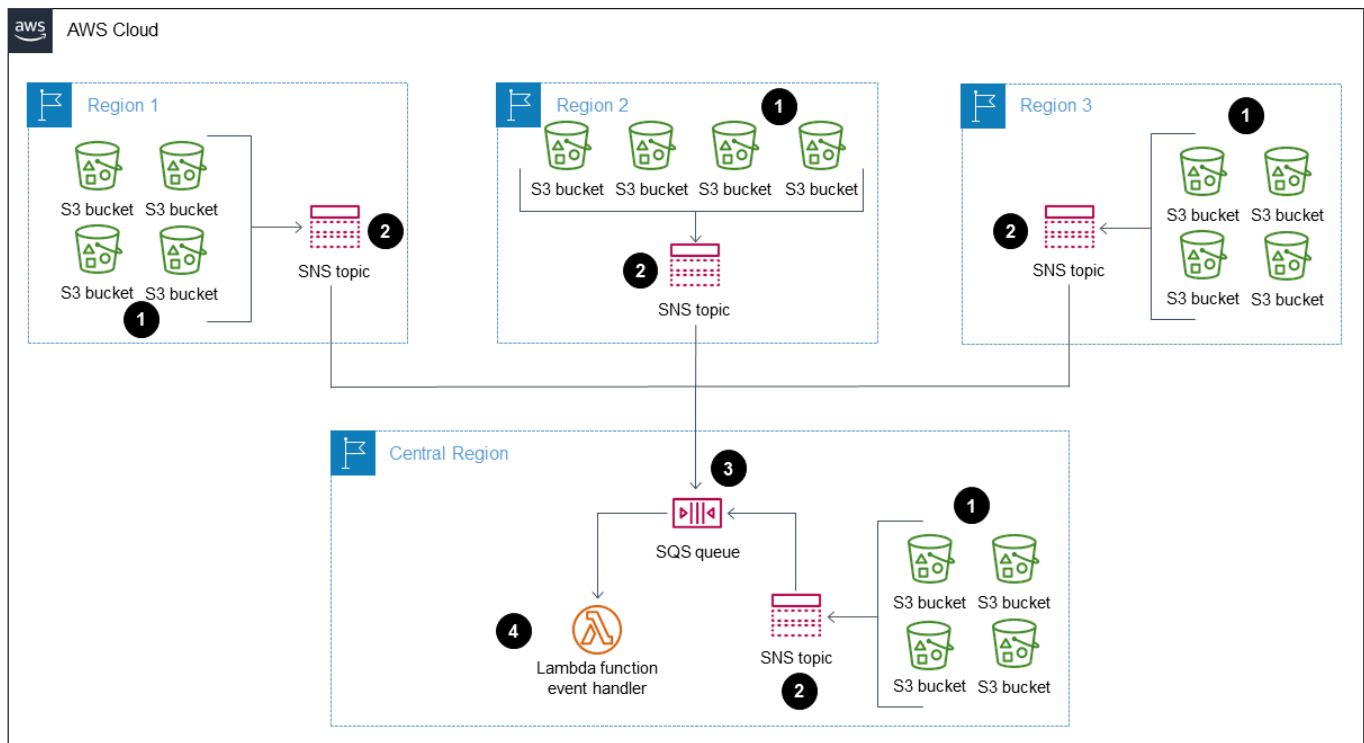

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Existing S3 buckets in multiple Regions, including a central Region to host the Amazon SQS queue and Lambda function.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see [Installing, updating, and uninstalling the AWS CLI](#) in the AWS CLI documentation.
- Familiarity with the fanout scenario in Amazon SNS. For more information about this, see [Common Amazon SNS scenarios](#) in the Amazon SNS documentation.

# Architecture

The following diagram shows the architecture for this pattern's approach.

The diagram shows the following workflow:

1. Amazon S3 sends event notifications about S3 buckets (for example, object created, object removed, or object restored) to an SNS topic in the same Region.
2. The SNS topic publishes the event to an SQS queue in the central Region.
3. The SQS queue is configured as the event source for your Lambda function and buffers the event messages for the Lambda function.
4. The Lambda function polls the SQS queue for messages and processes the Amazon S3 event notifications according to your application's requirements.

## Technology stack

- Lambda
- Amazon SNS

- Amazon SQS
- Amazon S3

## Tools

- [AWS CLI](#) – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.
- [AWS CloudFormation](#) – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.
- [Amazon SQS](#) – Amazon Simple Queue Service (Amazon SQS) offers a secure, durable, and available hosted queue that lets you integrate and decouple distributed software systems and components. Amazon SQS supports both standard and FIFO queues.

## Epics

### Create the SQS queue and Lambda function in your central Region

Task	Description	Skills required
Create an SQS queue with a Lambda trigger.	Sign in to the AWS Management Console and use the instructions from	AWS DevOps, Cloud architect

Task	Description	Skills required
	<p>the tutorial <a href="#">Using Lambda with Amazon SQS</a> in the AWS Lambda documentation to create the following resources in your central Region:</p> <ul style="list-style-type: none"> <li>• A Lambda execution role</li> <li>• A Lambda function to process the Amazon S3 events</li> <li>• An SQS queue</li> </ul> <p><b>Note:</b> Make sure that you configure the SQS queue as the event source for your Lambda function.</p>	

### Create an SNS topic and set up event notifications for the S3 buckets in each required Region

Task	Description	Skills required
<p>Create an SNS topic to receive Amazon S3 event notifications.</p>	<p>Create an SNS topic in a Region that you want to receive Amazon S3 event notifications from. For more information about this, see <a href="#">Creating an SNS topic</a> in the Amazon SNS documentation.</p> <p><b>Important:</b> Make sure that you record your SNS topic's Amazon Resource Name (ARN).</p>	<p>AWS DevOps, Cloud architect</p>

Task	Description	Skills required
Subscribe the SNS topic to the central SQS queue.	Subscribe your SNS topic to the SQS queue hosted by your central Region. For more information about this, see <a href="#">Subscribing to an SNS topic</a> in the Amazon SNS documentation.	AWS DevOps, Cloud architect

Task	Description	Skills required
Update the SNS topic's access policy.	<ol style="list-style-type: none"><li>1. Open the Amazon SNS console, choose <b>Topics</b>, and then choose the SNS topic that you created earlier.</li><li>2. Choose <b>Edit</b> and then expand the <b>Access policy - optional</b> section.</li><li>3. Attach the following access policy to your SNS topic to allow <code>sns:publish</code> permission for Amazon S3 and then choose <b>Save</b>:</li></ol> <pre data-bbox="594 926 1026 1759">{   "Version": "2012-10-17",   "Statement": [     {       "Sid": "0",       "Effect": "Allow",       "Principal": {         "Service": "s3.amazonaws.com"       },       "Action": "sns:Publish",       "Resource": "arn:aws:sns:us-west-2::s3Events-SNSTopic-us-west-2"     }   ] }</pre>	AWS DevOps, Cloud architect

Task	Description	Skills required
Set up notifications for each S3 bucket in the Region.	<p>Set up event notifications for each S3 bucket in the Region. For more information about this, see <a href="#">Enabling and configuring event notifications using the Amazon S3 console</a> in the Amazon S3 documentation.</p> <p><b>Note:</b> In the <b>Destination</b> section, choose <b>SNS topic</b> and specify the ARN of the SNS topic that you created earlier.</p>	AWS DevOps, Cloud architect
Repeat this epic for all required Regions.	<p><b>Important:</b> Repeat the tasks in this epic for each Region that you want to receive Amazon S3 event notifications from, including your central Region.</p>	AWS DevOps, Cloud architect

# Three AWS Glue ETL job types for converting data to Apache Parquet

Created by Adnan Alvee (AWS), Karthikeyan Ramachandran, and Nith Govindasivan (AWS)

**Environment:** PoC or pilot

**Technologies:** Analytics

**Workload:** All other workloads

**AWS services:** AWS Glue

## Summary

On the Amazon Web Services (AWS) Cloud, AWS Glue is a fully managed extract, transform, and load (ETL) service. AWS Glue makes it cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.

This pattern provides different job types in AWS Glue and uses three different scripts to demonstrate authoring ETL jobs.

You can use AWS Glue to write ETL jobs in a Python shell environment. You can also create both batch and streaming ETL jobs by using Python (PySpark) or Scala in a managed Apache Spark environment. To get you started with authoring ETL jobs, this pattern focuses on batch ETL jobs using Python shell, PySpark, and Scala. Python shell jobs are meant for workloads requiring lesser compute power. The managed Apache Spark environment is meant for workloads requiring high compute power.

Apache Parquet is built to support efficient compression and encoding schemes. It can speed up your analytics workloads because it stores data in a columnar fashion. Converting data to Parquet can save you storage space, cost, and time in the longer run. To learn more about Parquet, see the blog post [Apache Parquet: How to be a hero with the open-source columnar data format](#).

## Prerequisites and limitations

### Prerequisites

- AWS Identity and Access Management (IAM) role (If you don't have a role, see the *Additional information* section.)

# Architecture

## Target technology stack

- AWS Glue
- Amazon Simple Storage Service (Amazon S3)
- Apache Parquet

## Automation and scale

- [AWS Glue workflows](#) support full automation of an ETL pipeline.
- You can change the number of data processing units (DPUs), or worker types, to scale horizontally and vertically.

# Tools

## AWS services

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Glue](#) is a fully managed ETL service for categorizing, cleaning, enriching, and moving your data between various data stores and data streams.

## Other tools

- [Apache Parquet](#) is an open-source column-oriented data file format designed for storage and retrieval.

## Configuration

Use the following settings for configuring the compute power of AWS Glue ETL. To reduce costs, use the minimal settings when you run the workload that is provided in this pattern.

- **Python shell** – You can use 1 DPU to utilize 16 GB of memory or 0.0625 DPU to utilize 1 GB of memory. This pattern uses 0.0625 DPU, which is the default in the AWS Glue console.

- **Python or Scala for Spark** – If you choose the Spark-related job types in the console, AWS Glue by default uses 10 workers and the G.1X worker type. This pattern uses two workers, which is the minimum number allowed, with the standard worker type, which is sufficient and cost effective.

The following table displays the different AWS Glue worker types for the Apache Spark environment. Because a Python shell job does not use the Apache Spark environment to run Python, it is not included in the table.

	Standard	G.1X	G.2X
vCPU	4	4	8
Memory	16 GB	16 GB	32 GB
Disk space	50 GB	64 GB	128 GB
Executor per worker	2	1	1

## Code

For the code that is used in this pattern, including the IAM role and parameter configuration, see the *Additional information* section.

## Epics

### Upload the data

Task	Description	Skills required
Upload the data into a new or existing S3 bucket.	Create or use an existing S3 bucket in your account. Upload the <code>sample_data.csv</code> file from the <i>Attachments</i> section, and note the S3 bucket and prefix location.	General AWS

## Create and run the AWS Glue job

Task	Description	Skills required
Create the AWS Glue job.	Under the ETL section of the AWS Glue console, add an AWS Glue job. Select the appropriate job type, AWS Glue version, and the corresponding DPU/Worker type and number of workers. For details, see the <i>Configuration</i> section.	Developer, cloud or data
Change the input and output locations.	Copy the code corresponding to your AWS Glue job, and change the input and output location that you noted in the <b>Upload the data</b> epic.	Developer, cloud or data
Configure the parameters.	<p>You can use the snippets provided in the <i>Additional information</i> section to set parameters for your ETL job. AWS Glue uses four argument names internally:</p> <ul style="list-style-type: none"> <li>• --conf</li> <li>• --debug</li> <li>• --mode</li> <li>• --JOB_NAME</li> </ul> <p>The --JOB_NAME parameter must be explicitly entered on the AWS Glue console. Choose <b>Jobs, Edit Job, Security configuration, script</b></p>	Developer, cloud or data

Task	Description	Skills required
	<p><b>libraries, and job parameters (optional).</b> Enter <code>--JOB_NAME</code> as the key and provide a value. You can also use the AWS Command Line Interface (AWS CLI) or the AWS Glue API to set this parameter. The <code>--JOB_NAME</code> parameter is used by Spark and is not needed in a Python shell environment job.</p> <p>You must add <code>--</code> before every parameter name; otherwise, the code will not work. For example, for the code snippets, the location parameters must be invoked by <code>--input_loc</code> and <code>--output_loc</code>.</p>	
Run the ETL job.	Run your job and check the output. Note how much space was reduced from the original file.	Developer, cloud or data

## Additional information

### IAM role

When you create the AWS Glue jobs, you can use either an existing IAM role that has the permissions shown in the following code snippet or a new role.

To create a new role, use the following YAML code.

```
# (c) 2022 Amazon Web Services, Inc. or its affiliates. All Rights Reserved. This AWS
Content is provided subject to the terms of the AWS Customer
# Agreement available at https://aws.amazon.com/agreement/ or other written agreement
between Customer and Amazon Web Services, Inc.

AWSTemplateFormatVersion: "2010-09-09"

Description: This template will setup IAM role for AWS Glue service.

Resources:
  rGlueRole:
    Type: AWS::IAM::Role
    Properties:
      AssumeRolePolicyDocument:
        Version: "2012-10-17"
        Statement:
          - Effect: "Allow"
            Principal:
              Service:
                - "glue.amazonaws.com"
            Action:
              - "sts:AssumeRole"
      ManagedPolicyArns:
        - arn:aws:iam::aws:policy/service-role/AWSGlueServiceRole
      Policies:
        - PolicyName: !Sub "${AWS::StackName}-s3-limited-read-write-inline-policy"
          PolicyDocument:
            Version: "2012-10-17"
            Statement:
              - Effect: Allow
```

```

        Action:
          - "s3:PutObject"
          - "s3:GetObject"
        Resource: "arn:aws:s3:::*/*"
    Tags:
      - Key   : "Name"
        Value : !Sub "${AWS::StackName}"

Outputs:
  oGlueRoleName:
    Description: AWS Glue IAM role
    Value:
      Ref: rGlueRole
    Export:
      Name: !Join [ ":", [ !Ref "AWS::StackName", rGlueRole ] ]

```

## AWS Glue Python Shell

The Python code uses the Pandas and PyArrow libraries to convert data to Parquet. The Pandas library is already available. The PyArrow library is downloaded when you run the pattern, because it is a one-time run. You can use wheel files to convert PyArrow to a library and provide the file as a library package. For more information about packaging wheel files, see [Providing your own Python library](#).

### *AWS Glue Python shell parameters*

```

from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["input_loc", "output_loc"])

```

### *AWS Glue Python shell code*

```

from io import BytesIO
import pandas as pd
import boto3
import os
import io
import site
from importlib import reload
from setuptools.command import easy_install
install_path = os.environ['GLUE_INSTALLATION']
easy_install.main( ["--install-dir", install_path, "pyarrow"] )

```

```
reload(site)
import pyarrow

input_loc = "bucket-name/prefix/sample_data.csv"
output_loc = "bucket-name/prefix/"

input_bucket = input_loc.split('/', 1)[0]
object_key = input_loc.split('/', 1)[1]

output_loc_bucket = output_loc.split('/', 1)[0]
output_loc_prefix = output_loc.split('/', 1)[1]

s3 = boto3.client('s3')
obj = s3.get_object(Bucket=input_bucket, Key=object_key)
df = pd.read_csv(io.BytesIO(obj['Body'].read()))

parquet_buffer = BytesIO()
s3_resource = boto3.resource('s3')
df.to_parquet(parquet_buffer, index=False)
s3_resource.Object(output_loc_bucket, output_loc_prefix + 'data' +
    '.parquet').put(Body=parquet_buffer.getvalue())
```

## AWS Glue Spark job with Python

To use an AWS Glue Spark job type with Python, choose **Spark** as the job type. Choose **Spark 3.1, Python 3 with improved job startup time (Glue Version 3.0)** as the AWS Glue version.

### *AWS Glue Python parameters*

```
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME", "input_loc", "output_loc"])
```

### *AWS Glue Spark job with Python code*

```
import sys
from pyspark.context import SparkContext
```

```
from awsglue.context import GlueContext
from awsglue.transforms import *
from awsglue.dynamicframe import DynamicFrame
from awsglue.utils import getResolvedOptions
from awsglue.job import Job

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)

input_loc = "bucket-name/prefix/sample_data.csv"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(\
    connection_type = "s3", \
    connection_options = {
        "paths": [input_loc]}, \
    format = "csv",
    format_options={
        "withHeader": True,
        "separator": ",",
    })

outputDF = glueContext.write_dynamic_frame.from_options(\
    frame = inputDyf, \
    connection_type = "s3", \
    connection_options = {"path": output_loc \
        }, format = "parquet")
```

For a large number of compressed big files (for example, 1,000 files that are each about 3 MB), use the `compressionType` parameter with the `recurse` parameter to read all the files that are available within the prefix, as shown in the following code.

```
input_loc = "bucket-name/prefix/"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
    connection_type = "s3",
    connection_options = {"paths": [input_loc],
        "compressionType": "gzip", "recurse" : "True",
```

```

    },
    format = "csv",
    format_options={"withHeader": True,"separator": ","}
)

```

For a large number of compressed small files (for example, 1,000 files that are each about 133 KB), use the `groupFiles` parameter, along with both the `compressionType` and the `recurse` parameters. The `groupFiles` parameter groups small files into multiple big files, and the `groupSize` parameter controls the grouping to the specified size in bytes (for example, 1 MB). The following code snippet provides an example of using these parameters within the code.

```

input_loc = "bucket-name/prefix/"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
    connection_type = "s3",
    connection_options = {"paths": [input_loc],
                          "compressionType":"gzip","recurse" : "True",
                          "groupFiles" : "inPartition",
                          "groupSize" : "1048576",
                          },
    format = "csv",
    format_options={"withHeader": True,"separator": ","}
)

```

Without any change in the worker nodes, these settings enable the AWS Glue job to read multiple files (large or small, with or without compression) and write them to the target in Parquet format.

## AWS Glue Spark job with Scala

To use an AWS Glue Spark job type with Scala, choose **Spark** as the job type and **Language** as **Scala**. Choose **Spark 3.1, Scala 2 with improved job startup time (Glue Version 3.0)** as the AWS Glue version. To save on storage space, the following AWS Glue with Scala sample also uses the `applyMapping` feature to convert data types.

### *AWS Glue Scala parameters*

```

import com.amazonaws.services.glue.util.GlueArgParser val args =
  GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME", "inputLoc",
    "outputLoc")).toArray)

```

## AWS Glue Spark job with Scala code

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.DynamicFrame
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueScalaApp {
  def main(sysArgs: Array[String]) {

    @transient val spark: SparkContext = SparkContext.getOrCreate()
    val glueContext: GlueContext = new GlueContext(spark)

    val inputLoc = "s3://bucket-name/prefix/sample_data.csv"
    val outputLoc = "s3://bucket-name/prefix/"

    val readCSV = glueContext.getSource("csv", JsonOptions(Map("paths" ->
Set(inputLoc))))).getDynamicFrame()

    val applyMapping = readCSV.applyMapping(mappings = Seq(("_c0", "string", "date",
"string"), ("_c1", "string", "sales", "long"),
("_c2", "string", "profit", "double")), caseSensitive = false)

    val formatPartition = applyMapping.toDF().coalesce(1)

    val dynamicFrame = DynamicFrame(formatPartition, glueContext)

    val dataSink = glueContext.getSinkWithFormat(
      connectionType = "s3",
      options = JsonOptions(Map("path" -> outputLoc )),
      transformationContext = "dataSink", format =
"parquet").writeDynamicFrame(dynamicFrame)
  }
}

# Visualize Amazon Redshift audit logs using Amazon Athena and Amazon QuickSight

Created by Sanket Sirsikar (AWS) and Gopal Krishna Bhatia (AWS)

**Environment:** PoC or pilot

**Technologies:** Analytics; Big data; Data lakes

**AWS services:** Amazon Athena; Amazon Redshift; Amazon S3; Amazon QuickSight

## Summary

Security is an integral part of database operations on the Amazon Web Services (AWS) Cloud. Your organization should ensure that it monitors database user activities and connections to detect potential security incidents and risks. This pattern helps you monitor your databases for security and troubleshooting purposes, which is a process known as database auditing.

This pattern provides a SQL script that automates the creation of an Amazon Athena table and views for a reporting dashboard in Amazon QuickSight that helps you audit Amazon Redshift logs. This ensures that users responsible for monitoring database activities have convenient access to data security features.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing Amazon Redshift cluster. For more information about this, see [Create an Amazon Redshift cluster](#) in the Amazon Redshift documentation.
- Access to an existing Athena workgroup. For more information, see [How workgroups work](#) in the Amazon Athena documentation.
- An existing Amazon Simple Storage Service (Amazon S3) source bucket with the required AWS Identity and Access Management (IAM) permissions. For more information, see [Bucket permissions for Amazon Redshift audit logging](#) from [Database audit logging](#) in the Amazon Redshift documentation.

## Architecture

### Technology stack

- Athena
- Amazon Redshift
- Amazon S3
- QuickSight

### Tools

- [Amazon Athena](#) – Athena is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- [Amazon QuickSight](#) – QuickSight is a scalable, serverless, embeddable, machine learning-powered business intelligence (BI) service.
- [Amazon Redshift](#) – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

# Epics

## Configure the Amazon Redshift cluster

Task	Description	Skills required
Enable audit logging for the Amazon Redshift cluster.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console, open the Amazon Redshift console, choose <b>CLUSTERS</b>, and then choose the cluster that you want to enable logging for.</li><li>2. Choose the <b>Properties</b> tab and then enable auditing by following the instructions from <a href="#">Configuring auditing using the console</a> in the Amazon Redshift documentation.</li></ol>	DBA, Data engineer
Enable logging in the Amazon Redshift cluster parameter group.	<p>You can enable auditing of connection logs, user logs, and user activity logs at the same time by using the AWS Management Console, the Amazon Redshift API reference, or AWS Command Line Interface (AWS CLI).</p> <p>For auditing of user activity logs, you must enable the <code>enable_user_activity_logging</code> database parameter. If you only enable the audit logging feature but not the associated parameter</p>	DBA, Data engineer

Task	Description	Skills required
	<p>, the database audit logs the logging information for the connection and user logs but not for the user activity logs. The <code>enable_user_activity_logging</code> parameter is not enabled by default, but you can enable it by changing it from <code>false</code> to <code>true</code>.</p> <p><b>Important:</b> You need to create a new cluster parameter group with the <code>user_activity_logging</code> parameter enabled and attach it to your Amazon Redshift cluster. For more information about this, see <a href="#">Modifying a cluster</a> in the Amazon Redshift documentation.</p> <p>For more information about this task, see <a href="#">Amazon Redshift parameter groups</a> and <a href="#">Configuring auditing using the console</a> in the Amazon Redshift documentation.</p>	

Task	Description	Skills required
<p>Configure S3 bucket permissions for Amazon Redshift cluster logging.</p>	<p>When you enable logging, Amazon Redshift collects logging information and uploads it to log files stored in an S3 bucket. You can use an existing S3 bucket or create a new bucket.</p> <p><b>Important:</b> Make sure that Amazon Redshift has the required IAM permissions to access the S3 bucket. For more information about this, see <a href="#">Bucket permissions for Amazon Redshift audit logging</a> from <a href="#">Database audit logging</a> in the Amazon Redshift documentation.</p>	<p>DBA, Data engineer</p>

### Create the Athena table and views

Task	Description	Skills required
<p>Create the Athena table and views to query Amazon Redshift audit log data from the S3 bucket.</p>	<p>Open the Amazon Athena console and use the data definition language (DDL) query from the <code>AuditLogging.sql</code> SQL script (attached) to create the table and views for user activity logs, user logs, and connection logs.</p> <p>For more information and instructions, see the <a href="#">Create</a></p>	<p>Data engineer</p>

Task	Description	Skills required
	<a href="#">tables and run queries</a> tutorial from the Amazon Athena Workshop.	

## Set up log monitoring in the QuickSight dashboard

Task	Description	Skills required
Create a QuickSight dashboard using Athena as the data source.	Open the Amazon QuickSight console and create a QuickSight dashboard by following the instructions in the <a href="#">Visualize with QuickSight using Athena</a> tutorial from the Amazon Athena Workshop.	DBA, Data engineer

## Related resources

- [Create tables and run queries in Athena](#)

# Visualize IAM credential reports for all AWS accounts using Amazon QuickSight

Created by Parag Nagwekar (AWS) and Arun Chandapillai (AWS)

<b>Code repository:</b> <a href="#">Get Organizational wide visibility of your IAM Credential Reports</a>	<b>Environment:</b> Production	<b>Technologies:</b> Analytics; Advisory; Management & governance; Security, identity, compliance
<b>Workload:</b> All other workloads	<b>AWS services:</b> Amazon Athena; AWS CloudFormation; Amazon EventBridge; AWS Identity and Access Management; Amazon QuickSight	

## Summary

**Warning:** IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

You can use AWS Identity and Access Management (IAM) credential reports to help you meet the security, auditing, and compliance requirements of your organization. [Credential reports](#) provide a list of all the users in your AWS accounts and show the status of their credentials, such as passwords, access keys, and multi-factor authentication (MFA) devices. You can use credential reports for multiple AWS accounts managed by [AWS Organizations](#).

This pattern includes steps and code to help you create and share IAM credential reports for all the AWS accounts in your organization by using Amazon QuickSight dashboards. You can share the dashboards with stakeholders in your organization. The reports can help your organization achieve the following targeted business outcomes:

- Identify security incidents related to IAM users

- Track real-time migration of IAM users to single sign-on (SSO) authentication
- Track AWS Regions accessed by IAM users
- Stay compliant
- Share information with other stakeholders

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An [organization](#) with member accounts
- An [IAM role](#) with permissions to access accounts in Organizations
- AWS Command Line Interface (AWS CLI) version 2, [installed](#) and [configured](#)
- A [subscription](#) to [Amazon QuickSight Enterprise edition](#)

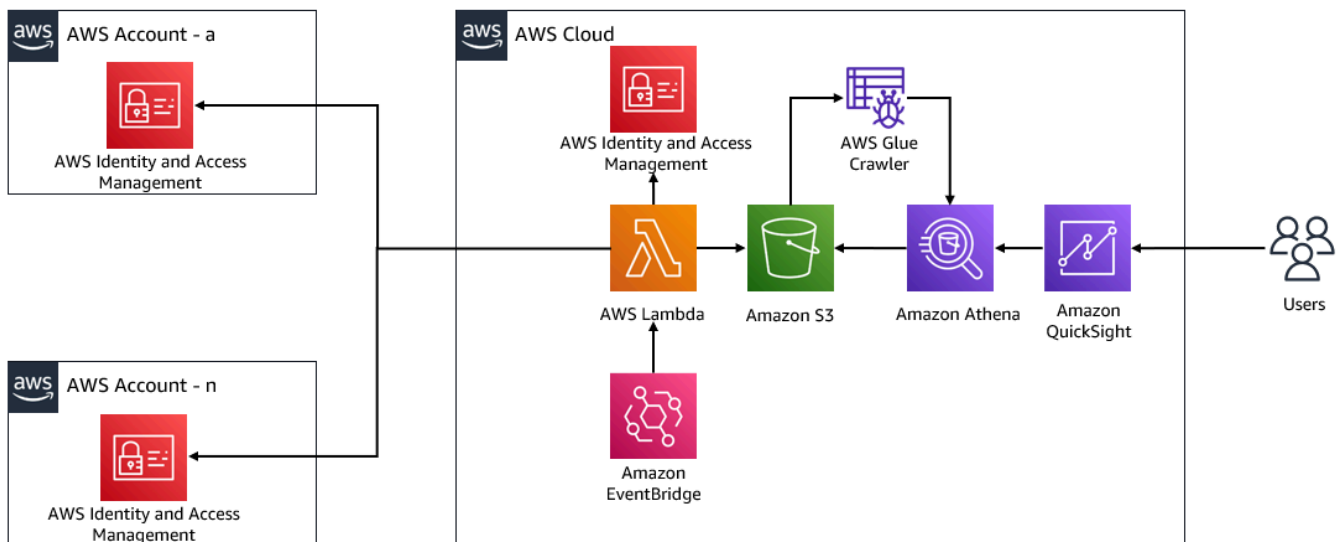

## Architecture

### Technology stack

- Amazon Athena
- Amazon EventBridge
- Amazon QuickSight
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue
- AWS Identity and Access Management (IAM)
- AWS Lambda
- AWS Organizations

### Target architecture

The following diagram shows an architecture for setting up a workflow that captures IAM credential report data from multiple AWS accounts.

1. EventBridge invokes a Lambda function daily.
2. The Lambda function assumes an IAM role in every AWS account across the organization. Then, the function creates the IAM credentials report and stores the report data in a centralized S3 bucket. You must enable encryption and deactivate public access on the S3 bucket.
3. An AWS Glue crawler crawls the S3 bucket daily and updates the Athena table accordingly.
4. QuickSight imports and analyzes the data from the credential report and builds a dashboard that can be visualized by and shared with stakeholders.

## Tools

### AWS services

- [Amazon Athena](#) is an interactive query service that makes it easy to analyze data in Amazon S3 by using standard SQL.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- [Amazon QuickSight](#) is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

## Code

The code for this pattern is available in the GitHub [getiamcredsreport-allaccounts-org](#) repository. You can use the code from this repository to create IAM credential reports across AWS accounts in Organizations and store them in a central location.

## Epics

### Set up the infrastructure

Task	Description	Skills required
Set up Amazon QuickSight Enterprise edition.	<ol style="list-style-type: none"> <li>1. Activate the Amazon QuickSight Enterprise edition in your AWS account. For more information, see <a href="#">Managing user access inside Amazon QuickSight</a> in the QuickSight documentation.</li> <li>2. To grant dashboard permissions, get the Amazon Resource Name (ARN) of the QuickSight users.</li> </ol>	AWS administrator, AWS DevOps, Cloud administrator, Cloud architect
Integrate Amazon QuickSight with Amazon S3 and Athena.	You must <a href="#">authorize</a> QuickSight to use Amazon S3 and Athena before you deploy the AWS CloudFormation stack.	AWS administrator, AWS DevOps, Cloud administrator, Cloud architect

## Deploy the infrastructure

Task	Description	Skills required
Clone the GitHub repository.	<ol style="list-style-type: none"><li>1. Clone the GitHub <a href="#">getiamcredsreport-allaccounts-org</a> repository to your local machine by running the following command: <code>git clone https://github.com/aws-samples/getiamcredsreport-allaccounts-org</code></li></ol>	AWS administrator
Deploy the infrastructure.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">CloudFormation console</a>.</li><li>2. In the navigation pane, choose <b>Create stack</b>, and then choose <b>With new resources (standard)</b>.</li><li>3. On the <b>Identify resources</b> page, choose <b>Next</b>.</li><li>4. On the <b>Specify template</b> page, for <b>Template source</b>, select <b>Upload a template file</b>.</li><li>5. Choose <b>Choose file</b>, select the <code>Cloudformation-createcredrepo.yaml</code> file from your cloned GitHub repository, and then choose <b>Next</b>.</li></ol>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>6. In <b>Parameters</b>, update <code>IAMRoleName</code> with your IAM role. This should be the IAM role that you want Lambda to assume in every account of the organization. This role creates the credential report. <b>Note:</b> The role doesn't have to be present in all accounts at this step of stack creation.</li><li>7. In <b>Parameters</b>, update <code>S3BucketName</code> with the name of the S3 bucket where Lambda can store the credentials for all accounts.</li><li>8. For <b>Stack name</b>, enter your stack name.</li><li>9. Choose <b>Submit</b>.</li><li>10. Note the Lambda function's role name.</li></ol>	

Task	Description	Skills required
Create an IAM permission policy.	<p><a href="#">Create an IAM policy</a> for every AWS account across your organization with the following permissions:</p> <pre data-bbox="594 443 1029 1157">{   "Version": "2012-10-17",   "Statement": [     {       "Effect": "Allow",       "Action": [         "iam:GenerateCredentialReport",         "iam:GetCredentialReport"       ],       "Resource": "*"     }   ] }</pre>	AWS DevOps, Cloud administrator, Cloud architect, Data engineer

Task	Description	Skills required
Create an IAM role with a trust policy.	<ol style="list-style-type: none"><li>1. <a href="#">Create an IAM role</a> for the AWS accounts and attach the permission policy that you created in the previous step.</li><li>2. Attach the following trust policy to the IAM role:</li></ol> <pre data-bbox="597 632 1027 1465">{   "Version": "2012-10-17",   "Statement": [     {       "Effect": "Allow",       "Principal": {         "AWS": [           "arn:aws:iam::&lt;MasterAccountID&gt;:role/&lt;LambdaRole&gt;"         ]       },       "Action": "sts:AssumeRole"     }   ] }</pre> <p><b>Important:</b> Replace <code>arn:aws:iam::&lt;MasterAccountID&gt;:role/&lt;LambdaRole&gt;</code> with the ARN of the Lambda role that you noted previously.</p>	Cloud administrator, Cloud architect, AWS administrator

Task	Description	Skills required
<p>Configure Amazon QuickSight to visualize the data.</p>	<p><b>Note:</b> Organizations typically use automation to create IAM roles for their AWS accounts. We recommend that you use this automation, if available. Alternatively, you can use the <code>CreateRoleforOrg.py</code> script from the code repository. The script requires an existing administrative role or any other IAM role that has permission to create an IAM policy and role in every AWS account.</p> <ol style="list-style-type: none"> <li>1. <a href="#">Sign in to QuickSight</a> with your credentials.</li> <li>2. <a href="#">Create a dataset</a> by using Athena (using the <code>iamcredreportdb</code> database and <code>"cfn_iamcredreport"</code> table), and then automatically <a href="#">refresh the dataset</a>.</li> <li>3. <a href="#">Create an analysis in QuickSight</a>.</li> <li>4. <a href="#">Create a QuickSight dashboard</a>.</li> </ol>	<p>AWS DevOps, Cloud administrator, Cloud architect, Data engineer</p>

## Additional information

### Additional considerations

Consider the following:

- After you use CloudFormation to deploy the infrastructure, you can wait to get the reports created in Amazon S3 and analyzed by Athena until Lambda and AWS Glue run as per their schedules. Alternatively, you can run Lambda manually to get the reports in Amazon S3, and then run the AWS Glue crawler to get the Athena table that's created from the data.
- QuickSight is a powerful tool for analyzing and visualizing data based on your business requirements. You can use [parameters](#) in QuickSight to control widget data based on data fields that you choose. Also, you can use a QuickSight analysis to create parameters (for example, Account, Date, and User fields such as `partition_0`, `partition_1`, and `user` respectively) from your dataset to add controls for the parameters for Account, Date, and User.
- To build your own QuickSight dashboards, see [QuickSight Workshops](#) from the AWS Workshop Studio website.
- To see sample QuickSight dashboards, see the GitHub [getiamcredsreport-allaccounts-org](#) code repository.

## Targeted business outcomes

You can use this pattern to achieve the following targeted business outcomes:

- **Identify security incidents related to IAM users** – Investigate every user across every AWS account in your organization by using a single pane of glass. You can track the trend of an IAM user's most recently accessed individual AWS Regions and the services they used.
- **Track real-time migration of IAM users to SSO authentication** – By using SSO, users can sign in once with a single credential and access multiple AWS accounts and applications. If you're planning to migrate your IAM users to SSO, this pattern can help you transition to SSO and track all IAM user credential usage (such as access to the AWS Management Console or usage of access keys) across all AWS accounts.
- **Track AWS Regions accessed by IAM users** – You can control IAM user access to Regions for various purposes, such as data sovereignty and cost control. You can also track use of Regions by any IAM user.
- **Stay compliant** – By following the principle of least privilege, you can grant only the specific IAM permissions that are required to perform a specific task. Also, you can track access to AWS services, the AWS Management Console, and long-term credentials usage.
- **Share information with other stakeholders** – You can share curated dashboards with other stakeholders, without granting them access to IAM credential reports or AWS accounts.

# Business productivity

## Topics

- [Set up a highly available PeopleSoft architecture on AWS](#)
- [More patterns](#)

# Set up a highly available PeopleSoft architecture on AWS

**Environment:** Production

**Technologies:** Business productivity; Infrastructure; Web & mobile apps; Databases

**Workload:** Oracle

**AWS services:** Amazon EC2 Auto Scaling; Amazon EFS; Elastic Load Balancing (ELB); Amazon RDS

## Summary

When you migrate your PeopleSoft workloads to AWS, resiliency is an important objective. It ensures that your PeopleSoft application is always highly available and able to recover from failures quickly.

This pattern provides an architecture for your PeopleSoft applications on AWS to ensure high availability (HA) at the network, application, and database tiers. It uses an [Amazon Relational Database Service \(Amazon RDS\)](#) for Oracle or Amazon RDS for SQL Server database for the database tier. This architecture also includes AWS services such as [Amazon Route 53](#), [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) Linux instances, [Amazon Elastic Block Storage \(Amazon EBS\)](#), [Amazon Elastic File System \(Amazon EFS\)](#), and an [Application Load Balancer](#), and is scalable.

[Oracle PeopleSoft](#) provides a suite of tools and applications for workforce management and other business operations.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A PeopleSoft environment with the necessary licenses for setting it up on AWS
- A virtual private cloud (VPC) set up in your AWS account with the following resources:

- At least two Availability Zones
- One public subnet and three private subnets in each Availability Zone
- A NAT gateway and an internet gateway
- Route tables for each subnet to route the traffic
- Network access control lists (network ACLs) and security groups defined to help ensure the security of the PeopleSoft application in accordance with your organization's standards

## Limitations

- This pattern provides a high availability (HA) solution. It doesn't support disaster recovery (DR) scenarios. In the rare occurrence that the entire AWS Region for the HA implementation goes down, the application will become unavailable.

## Product versions

- PeopleSoft applications running PeopleTools 8.52 and later

## Architecture

### Target architecture

Downtime or outage of your PeopleSoft production application impacts the availability of the application and causes major disruptions to your business.

We recommend that you design your PeopleSoft production application so that it is always highly available. You can achieve this by eliminating single points of failure, adding reliable crossover or failover points, and detecting failures. The following diagram illustrates an HA architecture for PeopleSoft on AWS.

This architecture deployment uses Amazon RDS for Oracle as the PeopleSoft database, and EC2 instances that are running on Red Hat Enterprise Linux (RHEL). You can also use Amazon RDS for SQL Server as the Peoplesoft database.

This architecture contains the following components:

- [Amazon Route 53](#) is used as the Domain Name Server (DNS) for routing requests from the internet to the PeopleSoft application.

- [AWS WAF](#) helps you protect against common web exploits and bots that can affect availability, compromise security, or consume excessive resources. [AWS Shield Advanced](#) (not illustrated) provides much broader protection.
- An [Application Load Balancer](#) load-balances HTTP and HTTPS traffic with advanced request routing targeted at the web servers.
- The web servers, application servers, process scheduler servers, and Elasticsearch servers that support the PeopleSoft application run in multiple Availability Zones and use [Amazon EC2 Auto Scaling](#).
- The database used by the PeopleSoft application runs on [Amazon RDS](#) in a Multi-AZ configuration.
- The file share used by the PeopleSoft application is configured on [Amazon EFS](#) and is used to access files across instances.
- [Amazon Machine Images \(AMIs\)](#) are used by Amazon EC2 Auto Scaling to ensure that PeopleSoft components are cloned quickly when needed.
- The [NAT gateways](#) connect instances in a private subnet to services outside your VPC, and ensure that external services cannot initiate a connection with those instances.
- The [internet gateway](#) is a horizontally scaled, redundant, and highly available VPC component that allows communication between your VPC and the internet.
- The bastion hosts in the public subnet provide access to the servers in the private subnet from an external network, such as the internet or on-premises network. The bastion hosts provide controlled and secure access to the servers in the private subnets.

## Architecture details

The PeopleSoft database is housed in an Amazon RDS for Oracle (or Amazon RDS for SQL Server) database in a Multi-AZ configuration. The [Amazon RDS Multi-AZ feature](#) replicates database updates across two Availability Zones to increase durability and availability. Amazon RDS automatically fails over to the standby database for planned maintenance and unplanned disruptions.

The PeopleSoft web and middle tier are installed on EC2 instances. These instances are spread across multiple Availability Zones and tied by an [Auto Scaling group](#). This ensures that these components are always highly available. A minimum number of required instances are maintained to ensure that the application is always available and can scale when required.

We recommend that you use a current generation EC2 instance type for the OEM EC2 instances. Current generation instance types, such as [instances built on the AWS Nitro System](#), support hardware virtual machines (HVMs). The HVM AMIs are required to take advantage of [enhanced networking](#), and they also offer increased security. The EC2 instances that are part of each Auto Scaling group use their own AMI when replacing or scaling up instances. We recommend that you select EC2 instance types based on the load you want your PeopleSoft application to handle and the minimum values recommended by Oracle for your PeopleSoft application and PeopleTools release. For more information about hardware and software requirements, see the [Oracle support website](#).

The PeopleSoft web and middle tier share an Amazon EFS mount to share reports, data files, and (if needed) the PS\_HOME directory. Amazon EFS is configured with mount targets in each Availability Zone for performance and cost reasons.

An Application Load Balancer is provisioned to support the traffic that accesses the PeopleSoft application and load-balances the traffic among the web servers across different Availability Zones. An Application Load Balancer is a network device that provides HA in at least two Availability Zones. The web servers distribute the traffic to different application servers by using a load balancing configuration. Load balancing among the web server and application server ensures that load is distributed evenly across the instances, and helps avoid bottlenecks and service disruptions due to overloaded instances.

Amazon Route 53 is used as the DNS service to route traffic to the Application Load Balancer from the internet. Route 53 is a highly available and scalable DNS web service.

## HA details

- **Databases:** The Multi-AZ feature of Amazon RDS operates two databases in multiple Availability Zones with synchronous replication. This creates a highly available environment with automatic failover. Amazon RDS has failover event detection and initiates automated failover when these events occur. You can also initiate manual failover through the Amazon RDS API. For a detailed explanation, see the blog post [Amazon RDS Under The Hood: Multi-AZ](#). The failover is seamless and the application automatically reconnects to the database when it happens. However, any process scheduler jobs during the failover generate errors and have to be resubmitted.
- **PeopleSoft application servers:** The application servers are spread across multiple Availability Zones and have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the application server template. Specifically, *jolt pooling* is enabled, so when an application server

instance goes down, the sessions automatically fail over to another application server, and the Auto Scaling group automatically spins up another instance, brings up the application server, and registers it in the Amazon EFS mount. The newly created application server is automatically added to the web servers by using the `PSSTRSETUP.SH` script in the web servers. This ensures that the application server is always highly available and recovers from failure quickly.

- **Process schedulers:** The process schedulers servers are spread across multiple Availability Zones and have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the process scheduler server template. Specifically, when a process scheduler instance goes down, the Auto Scaling group automatically spins up another instance and brings up the process scheduler. Any jobs that were running when the instance failed must be resubmitted. This ensures that the process scheduler is always highly available and recovers from failure quickly.
- **Elasticsearch servers:** The Elasticsearch servers have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the Elasticsearch server template. Specifically, when an Elasticsearch instance goes down, the Application Load Balancer that serves requests to it detects the failure and stops sending traffic to it. The Auto Scaling group automatically spins up another instance and brings up the Elasticsearch instance. When the Elasticsearch instance is back up, the Application Load Balancer detects that it's healthy and starts sending requests to it again. This ensures that the Elasticsearch server is always highly available and recovers from failure quickly.
- **Web servers:** The web servers have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the web server template. Specifically, when a web server instance goes down, the Application Load Balancer that serves requests to it detects the failure and stops sending traffic to it. The Auto Scaling group automatically spins up another instance and brings up the web server instance. When the web server instance is back up, the Application Load Balancer detects that it's healthy and starts sending requests to it again. This ensures that the web server is always highly available and recovers from failure quickly.

## Tools

### AWS services

- [Application Load Balancers](#) distribute incoming application traffic across multiple targets, such as EC2 instances, in multiple Availability Zones.

- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

## Best practices

### Operational best practices

- When you run PeopleSoft on AWS, use Route 53 to route the traffic from the internet and locally. Use the [failover option](#) to reroute traffic to the disaster recovery (DR) site if the primary DB instance isn't available.
- Always use an Application Load Balancer in front of the PeopleSoft environment. This ensures that traffic is load-balanced to the web servers in a secure fashion.
- In the Application Load Balancer target group settings, make sure that [stickiness is turned on](#) with a load balancer generated cookie.

**Note:** You might need to use an application-based cookie if you use external single sign-on (SSO). This ensures that connections are consistent across the web servers and application servers.

- For a PeopleSoft production application, the Application Load Balancer idle timeout must match what is set in the web profile you use. This prevents user sessions from expiring at the load balancer layer.
- For a PeopleSoft production application, set the application server [recycle count](#) to a value that minimizes memory leaks.
- If you're using an Amazon RDS database for your PeopleSoft production application, as described in this pattern, run it in [Multi-AZ format for high availability](#).
- If your database is running on an EC2 instance for your PeopleSoft production application, make sure that a [standby database is running on another Availability Zone](#) for high availability.

- For DR, make sure that your Amazon RDS database or EC2 instance has a standby configured in a separate AWS Region from the production database. This ensures that in event of a disaster in the Region, you can switch the application over to another Region.
- For DR, use [Amazon Elastic Disaster Recovery](#) to set up application-level components in a separate Region from production components. This ensures that in the event of a disaster in the Region, you can switch the application over to another Region.
- Use Amazon EFS (for moderate I/O requirements) or [Amazon FSx](#) (for high I/O requirements) to store your PeopleSoft reports, attachments, and data files. This ensures that the content is stored in one central location and can be accessed from anywhere within the infrastructure.
- Use [Amazon CloudWatch](#) (basic and detailed) to monitor the AWS Cloud resources that your PeopleSoft application is using in near real time. This ensures that you are alerted of issues instantly and can address them quickly before they affect the availability of the environment.
- If you're using an Amazon RDS database as the PeopleSoft database, use [Enhanced Monitoring](#). This feature provides access to over 50 metrics, including CPU, memory, file system I/O, and disk I/O.
- Use [AWS CloudTrail](#) to monitor API calls on the AWS resources that your PeopleSoft application is using. This helps you perform security analysis, resource change tracking, and compliance auditing.

## Security best practices

- To protect your PeopleSoft application from common exploits such as SQL injection or cross-site scripting (XSS), use [AWS WAF](#). Consider using [AWS Shield Advanced](#) for tailored detection and mitigation services.
- Add a rule to the Application Load Balancer to redirect traffic from HTTP to HTTPS automatically to help secure your PeopleSoft application.
- Set up a separate security group for the Application Load Balancer. This security group should allow only HTTPS/HTTP inbound traffic and no outbound traffic. This ensures that only intended traffic is allowed and helps secure your application.
- Use private subnets for the application servers, web servers, and database, and use [NAT gateways](#) for outbound internet traffic. This ensures that the servers that support the application aren't reachable publicly, while providing public access only to the servers that need it.
- Use different VPCs to run your PeopleSoft production and non-production environments. Use [AWS Transit Gateway](#), [VPC peering](#), [network ACLs](#), and [security groups](#) to control the traffic flow between the [VPCs](#) and, if necessary, your on-premises data center.

- Follow the principle of least privilege. Grant access to the AWS resources used by the PeopleSoft application only to users who absolutely need it. Grant only the minimum privileges required to perform a task. For more information, see the [security pillar](#) of the AWS Well-Architected Framework.
- Wherever possible, use [AWS Systems Manager](#) to access the EC2 instances that the PeopleSoft application uses.

## Reliability best practices

- When you use an Application Load Balancer, register a single target for each enabled Availability Zone. This makes the load balancer most effective.
- We recommend that you have three distinct URLs for each PeopleSoft production environment: one URL to access the application, one to serve the integration broker, and one to view reports. If possible, each URL should have its own dedicated web servers and application servers. This design helps make your PeopleSoft application more secure, because each URL has a distinct functionality and controlled access. It also minimizes the scope of impact if the underlying services fail.
- We recommend that you configure [health checks on the load balancer target groups](#) for your PeopleSoft application. The health checks should be performed on the web servers instead of the EC2 instances running those servers. This ensures that if the web server crashes or the EC2 instance that hosts the web server goes down, the Application Load Balancer reflects that information accurately.
- For a PeopleSoft production application, we recommend that you spread the web servers across at least three Availability Zones. This ensures that the PeopleSoft application is always highly available even if one of the Availability Zones goes down.
- For a PeopleSoft production application, enable jolt pooling (`joltPooling=true`). This ensures that your application fails over to another application server if a server is down for patching purposes or because of a VM failure.
- For a PeopleSoft production application, set `DynamicConfigReload` to 1. This setting is supported in PeopleTools version 8.52 and later. It adds new application servers to the web server dynamically, without restarting the servers.
- To minimize downtime when you apply PeopleTools patches, use the blue/green deployment method for your Auto Scaling group launch configurations for the web and application servers. For more information, see the [Overview of deployment options on AWS](#) whitepaper.

- Use [AWS Backup](#) to back up your PeopleSoft application on AWS. AWS Backup is a cost-effective, fully managed, policy-based service that simplifies data protection at scale.

### Performance best practices

- Terminate the SSL at the Application Load Balancer for optimal performance of the PeopleSoft environment, unless your business requires encrypted traffic throughout the environment.
- Create [interface VPC endpoints](#) for AWS services like such as [Amazon Simple Notification Service \(Amazon SNS\)](#) and [CloudWatch](#) so that traffic is always internal. This is cost-effective and helps keep your application secure.

### Cost optimization best practices

- Tag all the resources used by your PeopleSoft environment, and enable [cost allocation tags](#). These tags help you view and manage your resource costs.
- For a PeopleSoft production application, set up Auto Scaling groups for the web servers and the application servers. This maintains a minimal number of web and application servers to support your application. You can use [Auto Scaling group policies](#) to scale the the servers up and down as required.
- Use [billing alarms](#) to get alerts when costs exceed a budget threshold that you specify.

### Sustainability best practices

- Use [infrastructure as code](#) (IaC) to maintain your PeopleSoft environments. This helps you build consistent environments and maintain change control.

## Epics

### Migrate your PeopleSoft database to Amazon RDS

Task	Description	Skills required
Create a DB subnet group.	On the <a href="#">Amazon RDS console</a> , in the navigation pane, choose <b>Subnet groups</b> , and then create an Amazon	Cloud administrator

Task	Description	Skills required
	RDS DB subnet group with subnets in multiple Availability Zones. This is required for the Amazon RDS database to run in a Multi-AZ configuration.	
Create the Amazon RDS database.	Create an Amazon RDS database in an Availability Zone of the AWS Region you selected for the PeopleSoft HA environment. When you create the Amazon RDS database, make sure to select the Multi-AZ option ( <b>Create a standby instance</b> ) and the database subnet group you created in the previous step. For more information, see the <a href="#">Amazon RDS documentation</a> .	Cloud administrator, Oracle database administrator
Migrate your PeopleSoft database to Amazon RDS.	Migrate your existing PeopleSoft database into the Amazon RDS database by using AWS Database Migration Service (AWS DMS). For more information, see the <a href="#">AWS DMS documentation</a> and the AWS blog post <a href="#">Migrating Oracle databases with near-zero downtime using AWS DMS</a> .	Cloud administrator, PeopleSoft DBA

## Set up your Amazon EFS file system

Task	Description	Skills required
Create a file system.	On the <a href="#">Amazon EFS console</a> , create a file system and mount targets for each Availability Zone. For instructions, see the <a href="#">Amazon EFS documentation</a> . When the file system has been created, note its DNS name. You will use this information when you mount the file system.	Cloud administrator

## Set up your PeopleSoft application and file system

Task	Description	Skills required
Launch an EC2 instance.	<p>Launch an EC2 instance for your PeopleSoft application. For instructions, see the <a href="#">Amazon EC2 documentation</a>.</p> <ul style="list-style-type: none"> <li>For <b>Name</b>, enter APP_TEMPLATE .</li> <li>For <b>OS images</b>, choose <b>Red Hat</b>.</li> <li>For <b>Instance type</b>, choose the instance type that's appropriate for your PeopleSoft application. For more information, see <i>Architecture details</i> in the <a href="#">Architecture</a> section.</li> </ul>	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
Install PeopleSoft on the instance.	Install your PeopleSoft application and PeopleTools on the EC2 instance you created. For instructions, see the <a href="#">Oracle documentation</a> .	Cloud administrator, PeopleSoft administrator
Create the application server.	Create the application server for the AMI template and make sure that it connects successfully to the Amazon RDS database.	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
<p>Mount the Amazon EFS file system.</p>	<p>Log in to the EC2 instance as the root user and run the following commands to mount the Amazon EFS file system to a folder called PSFTMNT on the server.</p> <pre data-bbox="597 537 1027 695">sudo su - mkdir /psftmnt cat /etc/fstab</pre> <p>Append the following line to the <code>/etc/fstab</code> file. Use the DNS name you noted when you created the file system.</p> <pre data-bbox="597 999 1027 1436">fs-09e064308f11453 88.efs.us-east-1.a mazonaws.com:/ / psftmnt nfs4 nfsvers=4 .1,rsize=1048576,w size=1048576,hard, timeo=600,retrans= 2,noresvport,_netdev 0 0 mount -a</pre>	<p>Cloud administrator, PeopleSoft administrator</p>
<p>Check permissions.</p>	<p>Make sure that the PSFTMNT folder has the proper permissions so that the PeopleSoft user can access it properly.</p>	<p>Cloud administrator, PeopleSoft administrator</p>

Task	Description	Skills required
Create additional instances.	Repeat the previous steps in this epic to create template instances for the process scheduler, web server, and Elasticsearch server. Name these instances <code>PRCS_TEMPLATE</code> , <code>WEB_TEMPLATE</code> , and <code>SRCH_TEMPLATE</code> . For the web server, set <code>joltPooling=true</code> and <code>DynamicConfigReload=1</code> .	Cloud administrator, PeopleSoft administrator

### Create scripts to set up servers

Task	Description	Skills required
Create a script to install the application server.	<p>In the Amazon EC2 <code>APP_TEMPLATE</code> instance, as the PeopleSoft user, create the following script. Name it <code>appstart.sh</code> and place it in the <code>PS_HOME</code> directory. You will use this script to bring up the application server and also record the server name on the Amazon EFS mount.</p> <pre>#!/bin/ksh . /usr/homes/hcmdemo/.profile. psadmin -c configure -d HCMDEMO psadmin -c parallelboot -d HCMDEMO</pre>	PeopleSoft administrator

Task	Description	Skills required
	<pre>touch /psftmnt/`echo \$HOSTNAME`</pre>	
<p>Create a script to install the process scheduler server.</p>	<p>In the Amazon EC2 PRCS_TEMPLATE instance, as the PeopleSoft user, create the following script. Name it <code>prcsstart.sh</code> and place it in the <code>PS_HOME</code> directory. You will use this script to bring up the process scheduler server.</p> <pre>#!/bin/ksh . /usr/homes/hcmdemo/.profile /* The following line ensures that the process scheduler always has a unique name during replacement or scaling activity. */ sed -i "s/*PrcsServerName.*`hostname -I   awk -F. '{print "PrcsServerName=PSUNX"\$3\$4}'`/" \$HOME/appserv/prcs/*/psprcs.cfg psadmin -p configure -d HCMDEMO psadmin -p start -d HCMDEMO</pre>	<p>PeopleSoft administrator</p>

Task	Description	Skills required
Create a script to install the Elasticsearch server.	<p>In the Amazon EC2 <code>SRCH_TEMPLATE</code> instance, as the Elasticsearch user, create the following script. Name it <code>srchstart.sh</code> and place it in the <code>HOME</code> directory.</p> <pre data-bbox="594 537 1029 1134">#!/bin/ksh /* The following line ensures that the correct IP is indicated in the elasticse arch.yaml file. */ sed -i "s/. *netw ork.host.*`hostna me -I   awk '{print "host:"\$0}'`/" \$ES_HOME_DIR/config/ elasticsearch.yaml nohup \$ES_HOME_DIR/bin/ elasticsearch &amp;</pre>	PeopleSoft administrator

Task	Description	Skills required
Create a script to install the web server.	<p>In the Amazon EC2 WEB_TEMPLATE instance, as the web server user, create the following scripts in the HOME directory.</p> <p><code>renip.sh</code>: This script ensures that the web server has the correct IP when cloned from the AMI.</p> <pre data-bbox="597 716 1027 1465">#!/bin/ksh hn=`hostname` /* On the following line, change the IP with the hostname with the hostname of the web template. */ for text_file in `find * -type f -exec grep -l '&lt;hostname-of-the- web-template&gt;' {} \;` do sed -e 's/&lt;hostn ame-of-the-web-tem plate&gt;/'\$hn'/g' \$text_file &gt; temp mv -f temp \$text_file done</pre> <p><code>psstrsetup.sh</code> : This script ensures that the web server uses the correct application server IPs that are currently running. It tries to connect to each application server on the jolt port and adds it to the configuration file.</p>	PeopleSoft administrator

Task	Description	Skills required
	<pre data-bbox="609 226 998 1102">#!/bin/ksh c2="" for ctr in `ls -1 / psftmnt/*.internal` do c1=`echo \$ctr   awk -F "/" '{print \$3}'` /* In the following lines, 9000 is the jolt port. Change it if necessary. */ if nc -z \$c1 9000 2&gt; / dev/null; then if [[ \$c2 = "" ]]; then c2="psserver="`echo \$c1`:9000" else c2=`echo \$c2`,`echo \$c1`:9000" fi fi done</pre> <p data-bbox="592 1159 1015 1291"><b>webstart.sh</b> : This script runs the two previous scripts and starts the web servers.</p> <pre data-bbox="609 1348 966 1701">#!/bin/ksh /* Change the path in the following if necessary. */ cd /usr/homes/hcmdemo ./renip.sh ./psstrsetup.sh webserv/peoplesoft/ bin/startPIA.sh</pre>	

Task	Description	Skills required
Add a crontab entry.	<p>In the Amazon EC2 WEB_TEMPLATE instance, as the web server user, add the following line to <b>crontab</b>. Change the time and path to reflect the values you need. This entry ensures that your web server always has the correct application server entries in the configuration.properties file.</p> <pre>* * * * * /usr/homes/hcmdemo/psstrsetup.sh</pre>	PeopleSoft administrator

## Create AMIs and Auto Scaling group templates

Task	Description	Skills required
Create an AMI for the application server template.	<p>On the Amazon EC2 console, create an AMI image of the Amazon EC2 APP_TEMPLATE instance. Name the AMI PSAPPSRV-SCG-VER1 . For instructions, see the <a href="#">Amazon EC2 documentation</a>.</p>	Cloud administrator, PeopleSoft administrator
Create AMIs for the other servers.	<p>Repeat the previous step to create AMIs for the process scheduler, Elasticsearch server, and web server.</p>	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
Create a launch template for the application server Auto Scaling group.	<p>Create a launch template for the application server Auto Scaling group. Name the template PSAPPSRV_TEMPLATE. In the template, choose the AMI you created for the APP_TEMPLATE instance. For instructions, see the <a href="#">Amazon EC2 documentation</a>.</p> <ul style="list-style-type: none"><li>• In the launch template, select the instance type based on your requirements.</li><li>• In the <b>User data</b> field of the <b>Advanced details</b> section, add the following entries. Make sure that the path and user information are correct. You created the <code>appstart.sh</code> script in a previous step.</li></ul> <pre data-bbox="625 1346 1029 1541">#!/bin/ksh su -c "/usr/homes/hcmdemo/appstart.sh" - hcmdemo</pre>	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
Create a launch template for the process scheduler server Auto Scaling group.	<p>Repeat the previous step to create a launch template for the process scheduler server Auto Scaling group. Name the template <code>PSPRCS_TEMPLATE</code> . In the template, choose the AMI you created for the process scheduler.</p> <ul style="list-style-type: none"><li>• In the <b>User data</b> field of the <b>Advanced details</b> section, add the following entries. Make sure that the path and user information are correct. You created the <code>prcsstart.sh</code> script in a previous step.</li></ul> <pre data-bbox="630 1050 1029 1247">#!/bin/ksh su -c "/usr/homes/hcmdemo/prcsstart.sh" - hcmdemo</pre>	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
Create a launch template for the Elasticsearch server Auto Scaling group.	<p>Repeat the previous steps to create a launch template for the Elasticsearch server Auto Scaling group. Name the template <code>SRCH_TEMPLATE</code> .</p> <p>In the template, choose the AMI you created for the search server.</p> <ul style="list-style-type: none"><li>In the <b>User data</b> field of the <b>Advanced details</b> section, add the following entries. Make sure that the path and user information are correct. You created the <code>sichstart.sh</code> script in a previous step.</li></ul> <pre data-bbox="625 1045 1031 1249">#!/bin/ksh su -c "/usr/homes/es/essearch/sichstart.sh" - essearch</pre>	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
<p>Create a launch template for the web server Auto Scaling group.</p>	<p>Repeat the previous steps to create a launch template for the web server Auto Scaling group. Name the template <code>WEB_TEMPLATE</code> . In the template, choose the AMI you created for the web server.</p> <ul style="list-style-type: none"> <li>In the <b>User data</b> field of the <b>Advanced details</b> section, add the following entries. Make sure that the path and user information are correct. You created the <code>webstart.sh</code> script in a previous step.</li> </ul> <pre data-bbox="626 999 1029 1199"> #! /bin/ksh su -c "/usr/homes/hcmdemo/webstart.sh" - hcmdemo </pre>	<p>Cloud administrator, PeopleSoft administrator</p>

## Create Auto Scaling groups

Task	Description	Skills required
<p>Create an Auto Scaling group for the application server.</p>	<p>On the Amazon EC2 console, create an Auto Scaling group called <code>PSAPPSRV_ASG</code> for the application server by using the <code>PSAPPSRV_TEMPLATE</code> template. For instructions, see the <a href="#">Amazon EC2 documentation</a>.</p>	<p>Cloud administrator, PeopleSoft administrator</p>

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>On the <b>Choose instance launch options</b> page, select the correct VPC and then select multiple subnets from different Availability Zones.</li> <li>On the <b>Configure advanced options</b> page, do not select a load balancer.</li> <li>On the <b>Configure group size and scaling policies</b> page, choose settings depending on how much load you want to architect your system for and whether you want to use a scaling policy. We recommend that you set the desired and minimum capacity to 2 at a minimum so that at least one instance is available to service the traffic at any point in time. For more information about Auto Scaling policies, see the <a href="#">Amazon EC2 documentation</a>.</li> </ul>	
Create Auto Scaling groups for the other servers.	Repeat the previous step to create Auto Scaling groups for the process scheduler, Elasticsearch server, and web server.	Cloud administrator, PeopleSoft administrator

## Create and configure target groups

Task	Description	Skills required
Create a target group for the web server.	On the Amazon EC2 console, create a target group for the web server. For instructions, see the <a href="#">Elastic Load Balancing documentation</a> . Set the port to the port that the web server is listening on.	Cloud administrator
Configure health checks.	Confirm that the health checks have the correct values to reflect your business requirements. For more information, see the <a href="#">Elastic Load Balancing documentation</a> .	Cloud administrator
Create a target group for the Elasticsearch server.	Repeat the previous steps to create a target group called PSFTSRCH for the Elasticsearch server, and set the correct Elasticsearch port.	Cloud administrator
Add target groups to Auto Scaling groups.	Open the web server Auto Scaling group called PSPIA_ASG that you created earlier. On the <b>Load balancing</b> tab, choose <b>Edit</b> and then add the PSFTWEB target group to the Auto Scaling group.  Repeat this step for the Elasticsearch Auto Scaling group PSSRCH_ASG to add	Cloud administrator

Task	Description	Skills required
	the target group PSFTSRCH you created earlier.	
Set session stickiness.	<p>In the target group PSFTWEB, choose the <b>Attributes</b> tab, choose <b>Edit</b>, and set the session stickiness. For stickiness type, choose <b>Load balancer generated cookie</b>, and set the duration to 1. For more information, see the <a href="#">Elastic Load Balancing documentation</a>.</p> <p>Repeat this step for the target group PSFTSRCH.</p>	Cloud administrator

## Create and configure application load balancers

Task	Description	Skills required
Create a load balancer for the web servers.	<p>Create an Application Load Balancer named PSFTLB to load-balance traffic to the web servers. For instructions, see the <a href="#">Elastic Load Balancing documentation</a>.</p> <ul style="list-style-type: none"> <li>• Provide the load balancer name.</li> <li>• For <b>Scheme</b>, choose <b>Internet-facing</b>.</li> <li>• In the <b>Network mapping</b> section, select the correct VPC and at least two public</li> </ul>	Cloud administrator

Task	Description	Skills required
	<p>subnets from different Availability Zones.</p> <ul style="list-style-type: none"> <li>In the <b>Listeners and routing</b> section, select the target group PSFTWEB and specify the correct protocol and port number.</li> </ul>	
<p>Create a load balancer for the Elasticsearch servers.</p>	<p>Create an Application Load Balancer named PSFTSCH to load-balance traffic to the Elasticsearch servers.</p> <ul style="list-style-type: none"> <li>Provide the load balancer name.</li> <li>For <b>Scheme</b>, choose <b>Internal</b>.</li> <li>In the <b>Network mapping</b> section, select the correct VPC and private subnets.</li> <li>In the <b>Listeners and routing</b> section, select the target group PSFTSRCH and specify the correct protocol and port number.</li> </ul>	<p>Cloud administrator</p>
<p>Configure Route 53.</p>	<p>On the <a href="#">Amazon Route 53 console</a>, create a record in the hosted zone that will service the PeopleSoft application. For instructions, see the <a href="#">Amazon Route 53 documentation</a>. This ensures that all the traffic passes through the PSFTLB load balancer.</p>	<p>Cloud administrator</p>

# Monitor SAP RHEL Pacemaker clusters by using AWS services

Created by Harsh Thoria (AWS), Randy Germann (AWS), and RAVEENDRA Voore (AWS)

**Environment:** Production

**Technologies:** CloudNative; Infrastructure; Operating systems

**Workload:** SAP

**AWS services:** Amazon CloudWatch; Amazon SNS; Amazon CloudWatch Logs

## Summary

This pattern outlines the steps for monitoring and configuring alerts for a Red Hat Enterprise Linux (RHEL) Pacemaker cluster for SAP applications and SAP HANA database services by using Amazon CloudWatch and Amazon Simple Notification Service (Amazon SNS).

The configuration enables you to monitor SAP SCS or ASCS, Enqueue Replication Server (ERS), and SAP HANA cluster resources when they are in a "stopped" state with the help of CloudWatch log streams, metric filters, and alarms. Amazon SNS sends an email to the infrastructure or SAP Basis team about the stopped cluster status.

You can create the AWS resources for this pattern by using AWS CloudFormation scripts or the AWS service consoles. This pattern assumes that you're using the consoles; it doesn't provide CloudFormation scripts or cover infrastructure deployment for CloudWatch and Amazon SNS. Pacemaker commands are used to set the cluster alerting configuration.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Amazon SNS set up to send email or mobile notifications.
- An SAP ASCS/ERS for ABAP or SCS/ERS for Java, and SAP HANA Database RHEL Pacemaker cluster. For instructions, see the following:

- [SAP HANA cluster setup](#)
- [SAP Netweaver ABAP/Java cluster setup](#)

## Limitations

- This solution currently works for RHEL version 7.3 and later Pacemaker-based clusters. It hasn't been tested on SUSE operating systems.

## Product versions

- RHEL 7.3 and later

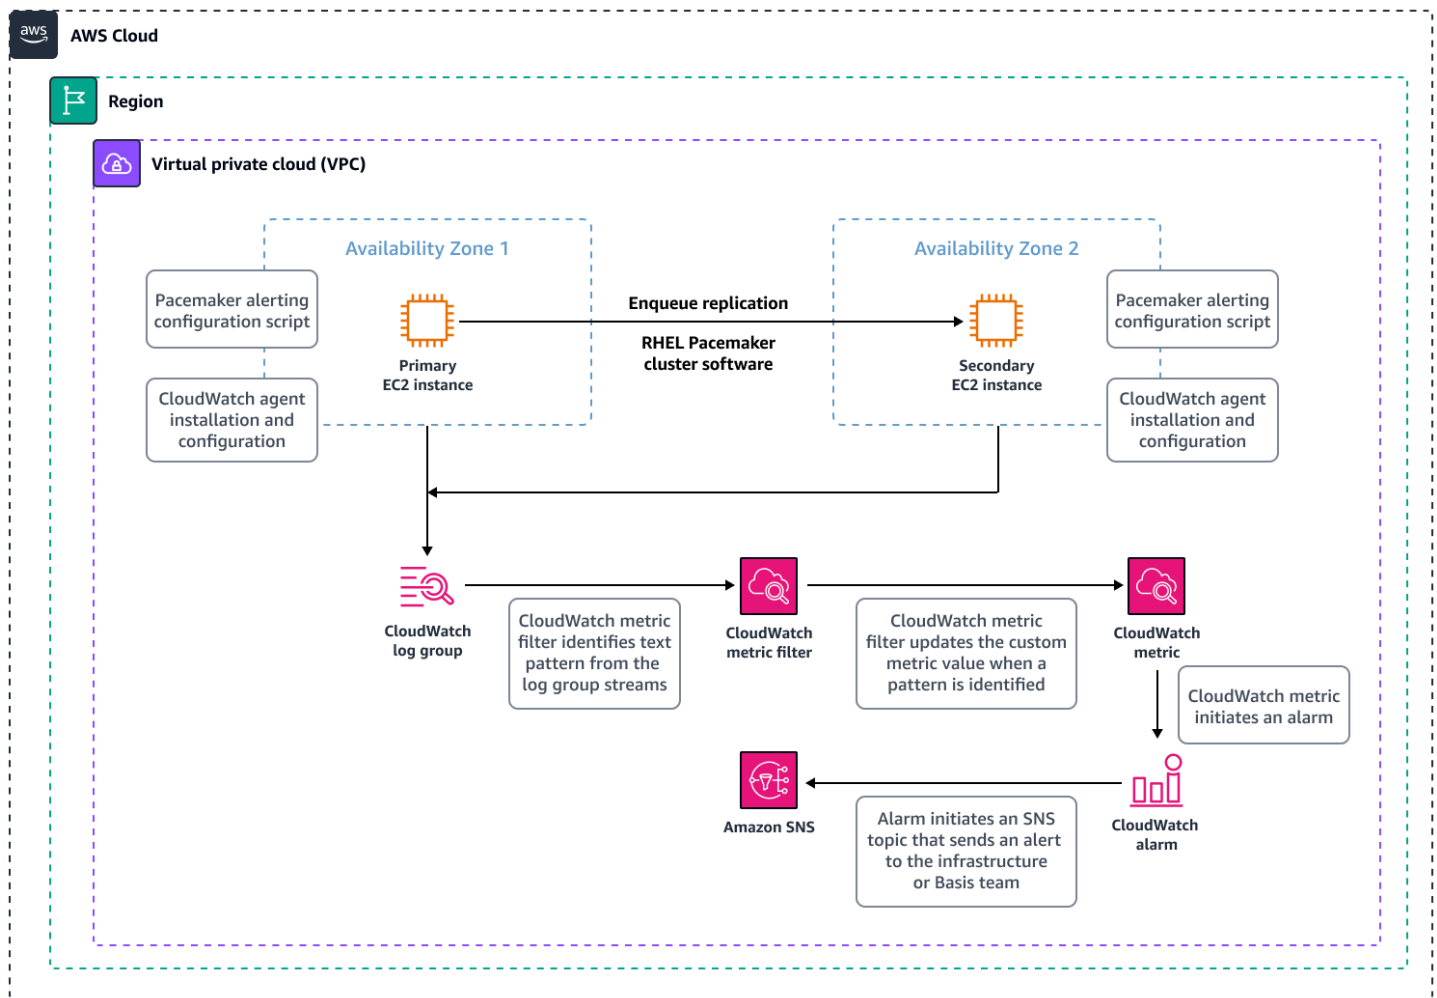

## Architecture

### Target technology stack

- RHEL Pacemaker alert event-driven agent
- Amazon Elastic Compute Cloud (Amazon EC2)
- CloudWatch alarm
- CloudWatch log group and metric filter
- Amazon SNS

### Target architecture

The following diagram illustrates the components and workflows for this solution.

## Automation and scale

- You can automate the creation of AWS resources by using CloudFormation scripts. You can also use additional metric filters to scale and cover multiple clusters.

## Tools

### AWS services

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

## Tools

- CloudWatch agent (unified) is a tool that collects system-level metrics, logs, and traces from EC2 instances, and retrieves custom metrics from your applications.
- Pacemaker alert agent (for RHEL 7.3 and later) is a tool that initiates an action when there's a change, such as when a resource stops or restarts, in a Pacemaker cluster.

## Best practices

- For best practices for using SAP workloads on AWS, see the [SAP Lens](#) for the AWS Well-Architected Framework.
- Consider the costs involved in setting up CloudWatch monitoring for SAP HANA clusters. For more information, see the [CloudWatch documentation](#).
- Consider using a pager or ticketing mechanism for Amazon SNS alerts.
- Always check for RHEL high availability (HA) versions of the RPM package for **pcs**, Pacemaker, and the AWS fencing agent.

## Epics

### Set up Amazon SNS

Task	Description	Skills required
Create an SNS topic.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the Amazon SNS console at <a href="https://console.aws.amazon.com/sns/v3/home">https://console.aws.amazon.com/sns/v3/home</a>.</li> <li>2. On the Amazon SNS dashboard, under <b>Common actions</b>, choose <b>Create Topic</b>.</li> </ol>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. In the <b>Create new topic</b> dialog box, for <b>Type</b>, choose <b>Standard</b>.</li><li>4. For <b>Topic name</b>, enter a name for the topic (for example, my-topic).</li><li>5. Choose <b>Create topic</b>.</li></ol> <p>This creates an SNS topic with a resource policy that lets you publish notifications.</p> <ol style="list-style-type: none"><li>6. Copy the <b>Topic ARN</b> (for example, <code>arn:aws:sns:us-east-1:111122223333:my-topic</code> ). You will use this ARN in a later step.</li></ol>	

Task	Description	Skills required
Modify the access policy for the SNS topic.	<ol style="list-style-type: none"><li>1. On the Amazon SNS console, in the navigation pane, choose <b>Topics</b>, and then choose the topic you created.</li><li>2. Choose <b>Edit</b> and go to the <b>Access policy</b> section.</li><li>3. Make sure that the access policy includes CloudWatch as one of the service principals that are allowed to publish to this topic. For example:<pre data-bbox="630 890 1029 1724">{   "Sid": "Allow AWS CloudWatch to Publish to this SNS topic",   "Effect": "Allow",   "Principal": {     "Service": [       "cloudwat ch.amazonaws.com"     ]   },   "Action": "SNS:Publish",   "Resource": "arn:aws:sns:us-ea st-1:111122223333: my-topic" }</pre></li><li>4. Choose <b>Save changes</b>.</li></ol>	AWS systems administrator

Task	Description	Skills required
Subscribe to the SNS topic.	<ol style="list-style-type: none"><li>1. On the Amazon SNS console, in the navigation pane, choose <b>Subscriptions, Create subscription</b>.</li><li>2. For <b>Topic ARN</b>, paste the ARN that you created in the first task.</li><li>3. For <b>Protocol</b>, choose <b>Email</b>.</li><li>4. For <b>Endpoint</b>, enter an email address for the person or team that is responsible for the SAP Pacemaker cluster and should receive notifications. For example, this can be the email address for the SAP Basis or infrastructure team's distribution list.</li><li>5. Choose <b>Create subscription</b>.</li><li>6. From your email application, open the message from AWS Notifications and confirm your subscription.</li></ol> <p>Your web browser displays a confirmation response from Amazon SNS.</p>	AWS systems administrator

## Confirm the setup of the cluster

Task	Description	Skills required
Check cluster status.	Use the <b>pcs status</b> command to confirm that the resources are online.	SAP Basis administrator

## Configure Pacemaker alerts

Task	Description	Skills required
Configure the Pacemaker alert agent on the primary cluster instance.	<p>Log in to the EC2 instance in the primary cluster and run the following commands:</p> <pre>install --mode=0755 /usr/share/pacemaker/alerts/alert_file.sh.sample touch /var/lib/pacemaker/alert_file.sh touch /var/log/pcm_alert_file.log chown hacluster:haclient /var/log/pcm_alert_file.log chmod 600 /var/log/pcm_alert_file.log pcs alert create id=alert_file description="Log events to a file." path=/var/lib/pacemaker/alert_file.sh pcs alert recipient add alert_file id=my-alert_logfile value=/va</pre>	SAP Basis administrator

Task	Description	Skills required
	<pre>r/log/pcmk_alert_file.log</pre>	
Configure the Pacemaker alert agent on the secondary cluster instance.	<p>Log in to the secondary cluster EC2 instance in the secondary cluster and run the following commands:</p> <pre>install --mode=0755 /usr/share/pacemaker/alerts/alert_file.sh.sample touch /var/lib/pacemaker/alert_file.sh touch /var/log/pcmk_alert_file.log chown hacluster:haclient /var/log/pcmk_alert_file.log chmod 600 /var/log/pcmk_alert_file.log</pre>	SAP Basis administrator

Task	Description	Skills required
<p>Confirm that the RHEL alert resource was created.</p>	<p>Use the following command to confirm that the alert resource was created:</p> <pre data-bbox="594 394 1029 474">pcs alert</pre> <p>The output of the command will look like this:</p> <pre data-bbox="594 632 1029 1188">[root@xxxxxxx ~]# pcs alert Alerts: Alert: alert_file (path=/var/lib/pacemaker/alert_file.sh) Description: Log events to a file. Recipients: Recipient: my- alert_logfile (value=/ var/log/pcmk_alert_ file.log)</pre>	<p>SAP Basis administrator</p>

## Configure the CloudWatch agent

Task	Description	Skills required
<p>Install the CloudWatch agent.</p>	<p>There are several ways to install the CloudWatch agent on an EC2 instance. To use the command line:</p> <ol style="list-style-type: none"> <li>1. Download the CloudWatch agent package:</li> </ol>	<p>AWS systems administrator</p>

Task	Description	Skills required
	<pre>wget https://s3.&lt;region&gt;.amazonaws.com/amazoncloudwatch-agent-region/redhat/amd64/latest/amazon-cloudwatch-agent.rpm</pre> <p>where &lt;region&gt; is the AWS Region where the EC2 instance is located (for example, us-west-2 ).</p> <ol style="list-style-type: none"><li data-bbox="592 766 1026 1087">2. Optional) Verify the package signature. For instructions, see <a href="#">Verifying the signature of the CloudWatch agent package</a> in the CloudWatch documentation.</li><li data-bbox="592 1108 1026 1192">3. Install the package on the first instance:<pre>sudo rpm -U ./amazon-cloudwatch-agent.rpm</pre></li><li data-bbox="592 1402 1026 1486">4. Repeat for the secondary instance.</li></ol> <p>For more information, see the <a href="#">CloudWatch documentation</a>.</p>	

Task	Description	Skills required
Attach an IAM role to the EC2 instance.	To enable the CloudWatch agent to send data from the instances, you must attach the IAM <b>CloudWatchAgentServerRole</b> role to each instance. Or, you can add a policy for the CloudWatch agent to your existing IAM role. For more information, see the <a href="#">CloudWatch documentation</a> .	AWS administrator

Task	Description	Skills required
<p>Configure the CloudWatch agent to monitor the Pacemaker alert agent log file on the primary cluster instance.</p>	<ol style="list-style-type: none"><li>1. Configure the primary cluster instance by running the command: <pre>sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config-wizard</pre></li><li>2. Choose <b>1</b> for Linux, and then select the options for your monitoring strategy.</li><li>3. For the question "<b>Do you want to monitor any log files,</b>" choose <b>Yes</b> and provide the path of the Pacemaker log file from the <b>pcs alert</b> command. In our case, it is <code>var/log/pcm_k_alert_file.log</code>.</li><li>4. Provide the name of the log group and log stream. If you don't specify a log stream, the AWS instance ID is used as the default.</li><li>5. Repeat steps 1-4 for the secondary cluster instance.</li></ol>	AWS administrator

Task	Description	Skills required
Start the CloudWatch agent on the primary and secondary cluster instances.	<p>To start the agent, run the following command on the EC2 instances in the primary and secondary clusters:</p> <pre>sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -s -c file:/opt/aws/amazon-cloudwatch-agent/bin/config.json</pre>	AWS administrator

## Set up CloudWatch resources

Task	Description	Skills required
Set up CloudWatch log groups.	<ol style="list-style-type: none"> <li>1. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a></li> <li>2. In the navigation pane, choose <b>Log groups, Create log group</b>.</li> <li>3. Enter a name for the log group, and then choose <b>Create log group</b>.</li> </ol> <p>The CloudWatch agent will transfer the Pacemaker alert file to the CloudWatch log group as a log stream.</p>	AWS administrator

Task	Description	Skills required
Set up CloudWatch metric filters.	<p>Metric filters help you search for a pattern such as <code>stop &lt;cluster-resource-name&gt;</code> in the CloudWatch log streams. When this pattern is identified, the metric filter updates a custom metric.</p> <ol style="list-style-type: none"><li>1. On the CloudWatch console, in the navigation pane, choose <b>Log groups</b>.</li><li>2. Choose the name of the log group you created in the previous task.</li><li>3. Choose <b>Actions, Create metric filter</b>.</li><li>4. For <b>Filter pattern</b>, enter the filter pattern to use, such as <code>stop ABC_scs</code>, to match the stop event for an SAP SCS cluster resource named <code>ABC_scs</code>.  For more information, see <a href="#">Filter pattern syntax</a> in the CloudWatch documentation.</li><li>5. (Optional) To test your filter pattern, under <b>Test Pattern</b>, enter one or more log events to use to test the pattern. Each log event must be specified on a</li></ol>	AWS administrator, SAP Basis administrator

Task	Description	Skills required
	<p>separate line, because line breaks are used to separate log events in the <b>Log event messages</b> box.</p> <ol style="list-style-type: none"> <li>6. Choose <b>Next</b>, and then enter a name for the filter.</li> <li>7. Under <b>Metric details</b>, for <b>Metric namespace</b>, enter a name for the CloudWatch namespace where the metric will be published (for example, <code>sapcluster_monitoring</code> ). If this namespace doesn't already exist, select <b>Create new</b>.</li> <li>8. For <b>Metric name</b>, enter a name for the new metric (for example, <code>sapcluster_&lt;sid&gt;</code> , where <code>&lt;sid&gt;</code> is the SAP system identification name).</li> <li>9. For <b>Metric value</b>, enter <b>1</b>.</li> </ol> <p>Alternatively, you can enter a token such as <code>\$size</code>. This increments the metric by the value of the number in the <code>size</code> field for every log event that contains a <code>size</code> field.</p> <ol style="list-style-type: none"> <li>10 For <b>Default value</b>, enter <b>0</b>.</li> <li>11 Choose <b>Create metric filter</b>.</li> </ol>	

Task	Description	Skills required
	<p>When the metric filter identifies the pattern in step 4, it updates the value of the CloudWatch custom metric <code>sapcluster_abc</code> to <b>1</b>.</p> <p>The CloudWatch alarm <code>SAP-Cluster-QA1-ABC</code> monitors the metric <code>sapcluster_abc</code> and sends out an SNS notification when the value of the metric changes to <b>1</b>. This indicates that the cluster resource has stopped and action needs to be taken.</p>	

Task	Description	Skills required
Set up a CloudWatch metric alarm for the SAP ASCS/SCS and ERS metric.	<p>To create an alarm based on a single metric:</p> <ol style="list-style-type: none"><li>1. On the CloudWatch console, in the navigation pane, choose <b>Alarms, All alarms</b>.</li><li>2. Choose <b>Create alarm</b>.</li><li>3. Choose <b>Select Metric</b>.</li><li>4. Search for the custom metric <code>sapcluster_monitoring</code> that was created in the previous task.</li><li>5. Choose the metric name for SAP SCS (for example, <code>sapcluster_&lt;abc&gt;</code>), which was also created in the previous task.</li><li>6. On the <b>Graphed metrics</b> tab, set the following:<ul style="list-style-type: none"><li>• For <b>Statistic</b>, choose <b>Maximum</b>.</li><li>• For <b>Period</b>, choose <b>1 minute</b>.</li><li>• For <b>Threshold type</b>, choose <b>Static</b> and set the threshold for <code>sapcluster_&lt;sid&gt;</code> to a value that's greater than or equal to 1.</li></ul></li><li>7. Choose <b>Next</b>.</li></ol>	AWS administrator

Task	Description	Skills required
	<p>8. For <b>Notification</b>, select the SNS topic you created in the first epic.</p> <p>9. For <b>Name</b> and <b>Description</b>, provide the alarm name and a brief description, and then choose <b>Next</b>.</p> <p>10 Choose <b>Create Alarm</b>.</p>	
<p>Set up a CloudWatch metric alarm for the SAP HANA metric.</p>	<p>Repeat the steps for setting up a CloudWatch metric alarm from the previous task, with these changes:</p> <ul style="list-style-type: none"> <li>• For step 5, choose the metric name for SAP HANA (for example, <code>sapcluster_db_&lt;abc&gt;</code> ).</li> <li>• For step 6, set the threshold for <code>sapcluster_&lt;sid&gt;</code> to a value that's greater than 0.</li> </ul>	<p>AWS administrator</p>

# Successfully import an S3 bucket as an AWS CloudFormation stack

Created by Ram Kandaswamy (AWS)

**Environment:** Production

**Technologies:** CloudNative;  
Storage & backup

**AWS services:** Amazon S3;  
AWS CloudFormation

## Summary

If you use Amazon Web Services (AWS) resources, such as Amazon Simple Storage Service (Amazon S3) buckets, and want to use an infrastructure as code (IaC) approach, then you can import your resources into AWS CloudFormation and manage them as a stack.

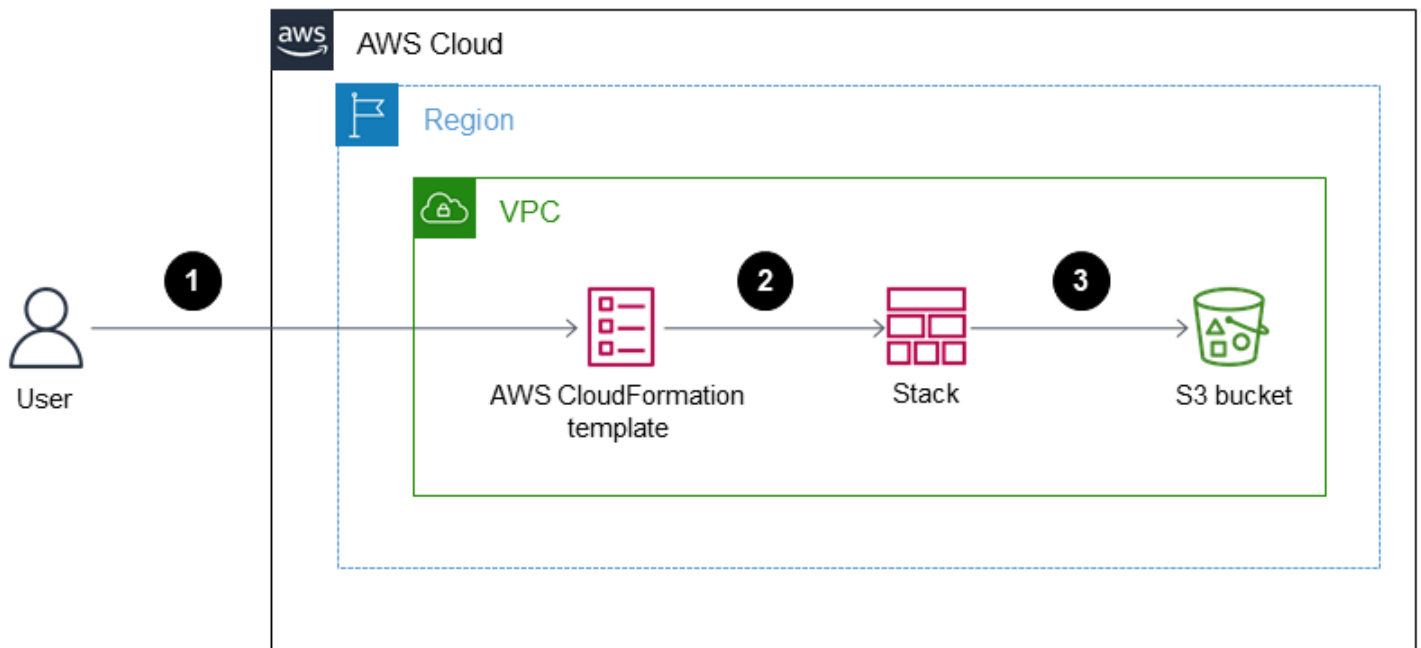

This pattern provides steps to successfully import an S3 bucket as an AWS CloudFormation stack. By using this pattern's approach, you can avoid possible errors that might occur if you import your S3 bucket in a single action.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing S3 bucket and S3 bucket policy. For more information about this, see [What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only](#) in the AWS Knowledge Center.
- An existing AWS Key Management Service (AWS KMS) key and its alias. For more information about this, see [Working with aliases](#) in the AWS KMS documentation.
- The sample CloudFormation-template-S3-bucket AWS CloudFormation template (attached), downloaded to your local computer.

## Architecture

The diagram shows the following workflow:

1. The user creates a JSON or YAML-formatted AWS CloudFormation template.
2. The template creates an AWS CloudFormation stack to import the S3 bucket.
3. The AWS CloudFormation stack manages the S3 bucket that you specified in the template.

### Technology stack

- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- AWS KMS
- Amazon S3

### Tools

- [AWS CloudFormation](#) – AWS CloudFormation helps you to create and provision AWS infrastructure deployments predictably and repeatedly.
- [AWS Identity and Access Management \(IAM\)](#) – IAM is a web service for securely controlling access to AWS services.

- [AWS KMS](#) – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the Internet.

## Epics

### Import an S3 bucket with CMK-based encryption as an AWS CloudFormation stack

Task	Description	Skills required
<p>Create a template to import the S3 bucket and CMK.</p>	<p>On your local computer, create a template to import your S3 bucket and CMK by using the following sample template:</p> <pre data-bbox="594 915 1027 1879"> AWSTemplateFormatVersion: 2010-09-09  Parameters:    bucketName:      Type: String  Resources:    S3Bucket:      Type: 'AWS::S3::Bucket'      DeletionPolicy: Retain      Properties:        BucketName: !Ref bucketName </pre>	<p>AWS DevOps</p>

Task	Description	Skills required

# Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer

Created by Kirankumar Chandrashekar (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; Networking; Security, identity, compliance; Web & mobile apps

**Workload:** All other workloads

**AWS services:** Amazon EC2; Amazon EC2 Auto Scaling; Amazon EC2 Container Registry; Amazon EFS; Amazon RDS; Amazon VPC; Amazon ECS; Elastic Load Balancing (ELB); AWS Lambda

## Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Container Service (Amazon ECS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). Amazon Elastic File System (Amazon EFS) is used if the application requires persistent storage.

The Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

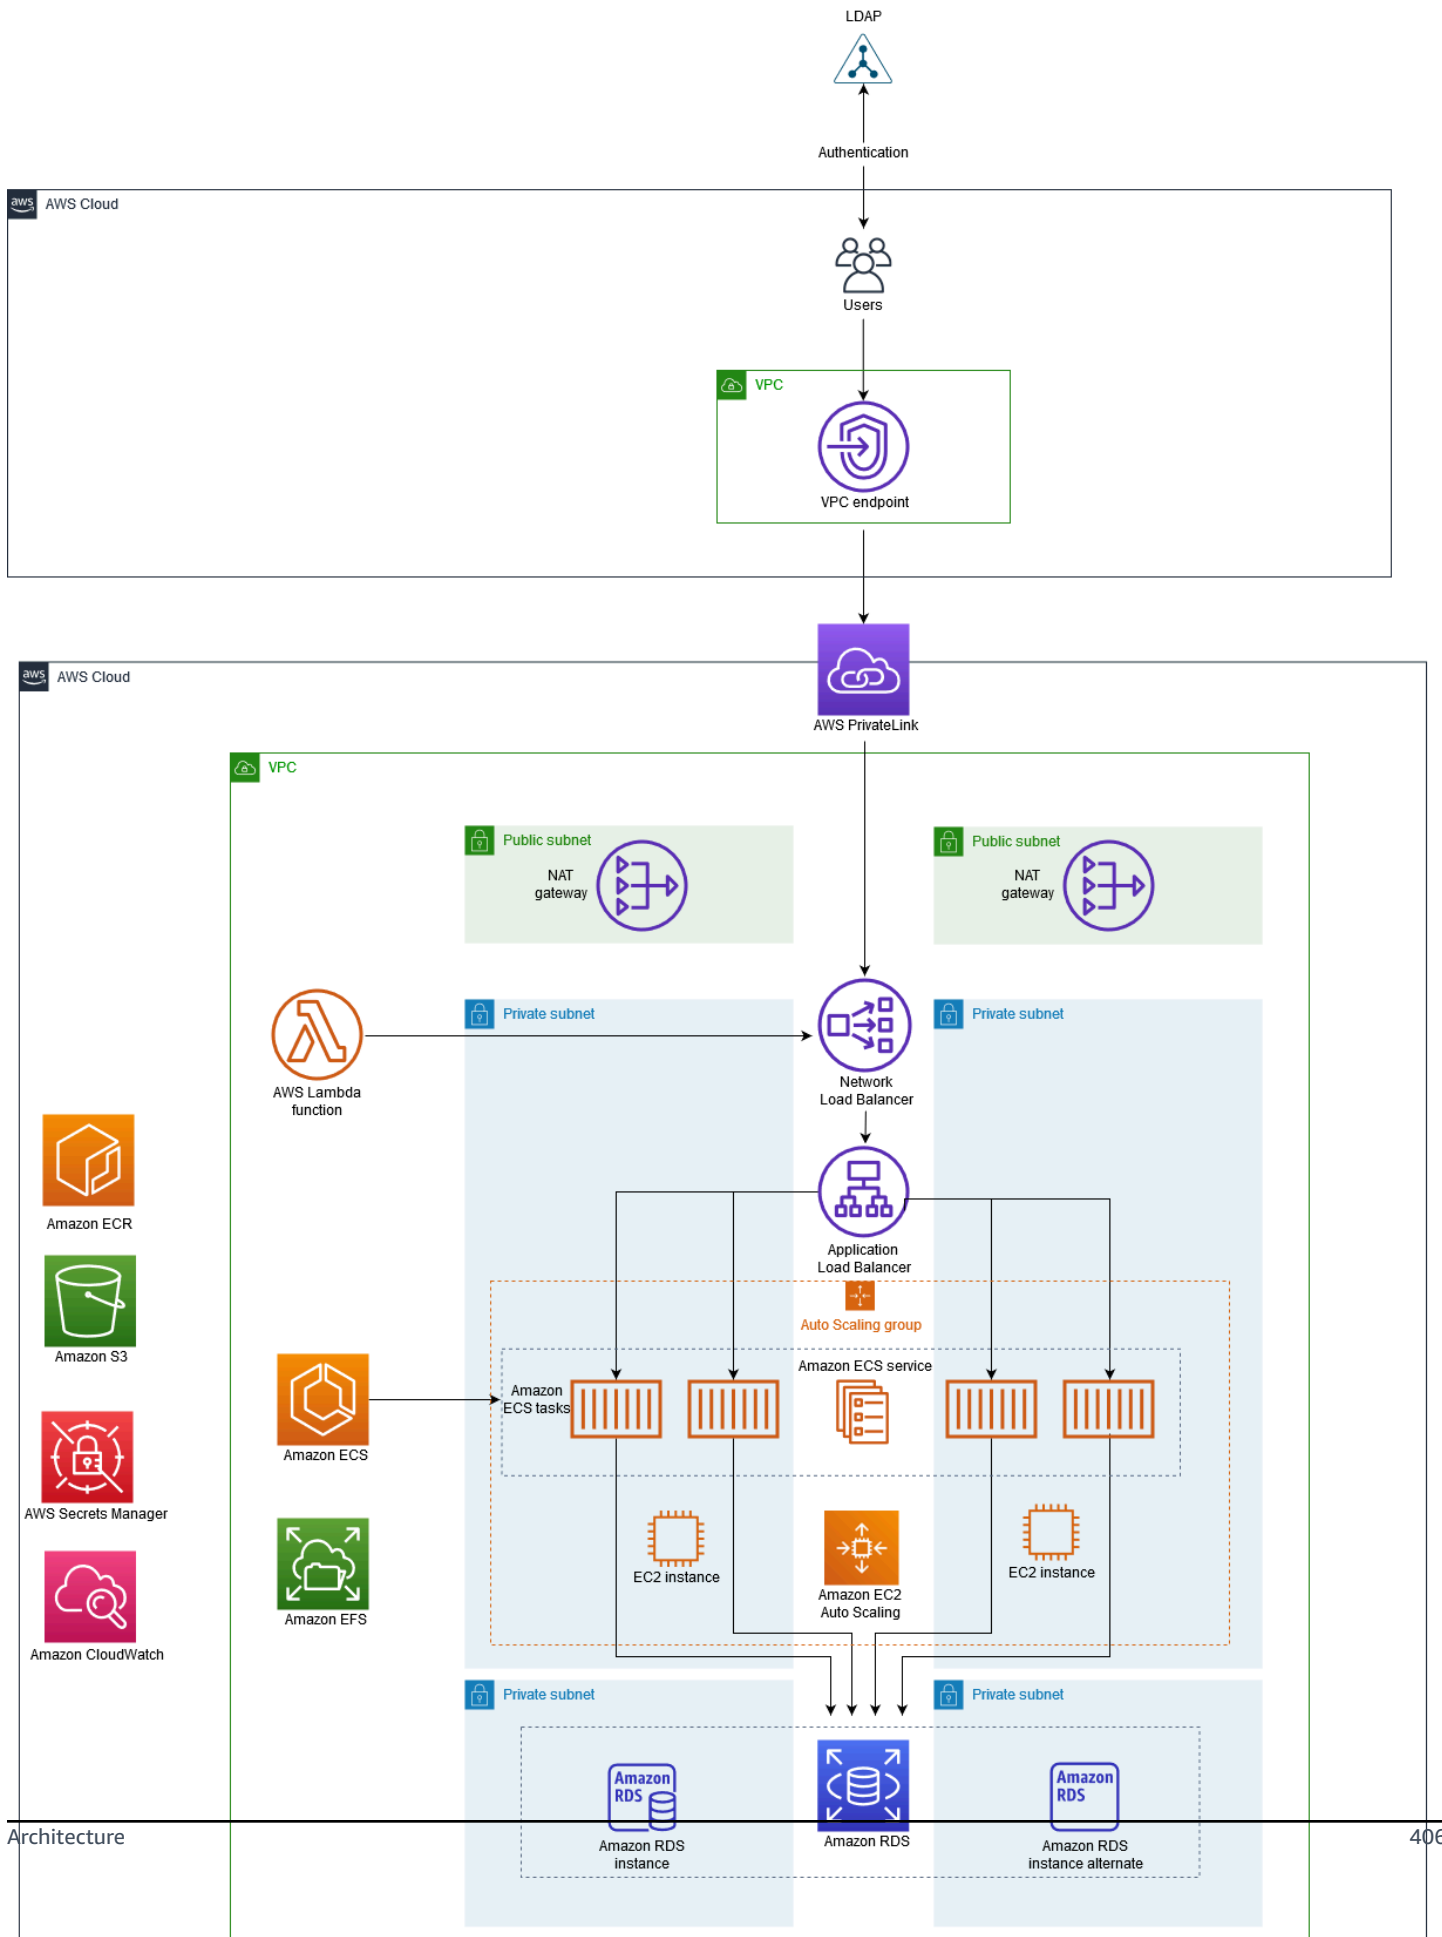

You can also use [AWS Fargate](#) instead of an Amazon EC2 Auto Scaling group. For more information, see [Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [AWS Command Line Interface \(AWS CLI\) version 2](#), installed and configured on Linux, macOS, or Windows
- [Docker](#), installed and configured on Linux, macOS, or Windows
- An application running on Docker

### Architecture

## Technology stack

- Amazon CloudWatch
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon EC2 Auto Scaling
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

### *Automation and scale*

- You can use [AWS CloudFormation](#) to create this pattern by using [Infrastructure as Code](#).

## Tools

- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- [Amazon EC2 Auto Scaling](#) – Amazon EC2 Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application.
- [Amazon ECS](#) – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- [Amazon EFS](#) – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.

- [AWS Lambda](#) – Lambda is a compute service for running code without provisioning or managing servers.
- [Amazon RDS](#) – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- [AWS Secrets Manager](#) – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, by providing an API call to Secrets Manager to retrieve the secret programmatically.
- [Amazon VPC](#) – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- [Elastic Load Balancing](#) – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- [Docker](#) – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

## Epics

	<p>private subnets are for Amazon ECS tasks, and two private subnets are for Amazon RDS databases.</p> <p>4. Specify one NAT gateway for each Availability Zone.</p> <p>5. Choose <b>Create VPC</b>.</p>	

## Create the load balancers

Task	Description	Skills required
<p>Create a Network Load Balancer.</p>	<ol style="list-style-type: none"> <li>1. Open the Amazon EC2 console and choose the AWS Region that contains your VPC.</li> <li>2. Under <b>Load balancing</b>, choose <b>Load balancers</b>, and choose <b>Create load balancer</b>.</li> <li>3. Choose <b>Network Load Balancer</b>, and choose <b>Create</b>.</li> <li>4. On the <b>Configure load balancer</b> page, configure your Network Load Balancer and listener. <b>Important:</b> Make sure you choose your Network Load Balancer's scheme as <b>Internal</b>.</li> <li>5. Choose the applicable security settings,</li> </ol>	<p>Cloud administrator</p>

Task	Description	Skills required
	<p>configure a security group and a target group. Choose <b>Instance</b> or <b>IP</b> as the <b>Target type</b> in the <b>Configure routing</b> section. Make sure you do not register a target.</p> <p>6. When you have configured all the settings, choose <b>Next: Review</b>, and then choose <b>Create</b>.</p>	

Task	Description	Skills required
Create an Application Load Balancer.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 405">1. On the Amazon EC2 console, choose the same Region that contains your VPC.</li><li data-bbox="591 426 1027 604">2. Under <b>Load balancing</b>, choose <b>Load balancers</b>, and choose <b>Create load balancer</b>.</li><li data-bbox="591 625 1027 762">3. Choose <b>Application Load Balancer</b>, and choose <b>Create</b>.</li><li data-bbox="591 783 1027 1056">4. Configure your Application Load Balancer and its listener. <b>Important:</b> Make sure you choose your Application Load Balancer's scheme as <b>Internal</b>.</li><li data-bbox="591 1077 1027 1497">5. Choose the applicable security settings, configure a security group and a target group. Choose <b>Instance</b> or <b>IP</b> as the <b>Target type</b> in the <b>Configure routing</b> section. Make sure you do not register a target.</li><li data-bbox="591 1518 1027 1696">6. When you have configured all the settings, choose <b>Next: Review</b>, and then choose <b>Create</b>.</li></ol>	Cloud administrator

## Create an Amazon EFS file system

Task	Description	Skills required
Create an Amazon EFS file system.	<ol style="list-style-type: none"><li>1. Open the Amazon EFS console, and choose <b>Create file system</b>.</li><li>2. In the <b>Create file system</b> dialog box, enter a name for your file system, and choose your VPC.</li><li>3. Choose <b>Create</b> to create the file system.</li><li>4. Set up and configure your Amazon EFS file system.</li></ol>	Cloud administrator
Mount targets for the subnets.	<ol style="list-style-type: none"><li>1. Return to the Amazon EFS console, and choose <b>File systems</b>. The <b>File systems</b> page shows the Amazon EFS file systems in your account.</li><li>2. Choose the file system that you created, and choose <b>Manage</b> to display the <b>Availability Zones</b>. To add a mount target, choose <b>Add mount target</b>, and add the four private subnets that you created.</li></ol>	Cloud administrator
Verify that the subnets are mounted as targets.	<ol style="list-style-type: none"><li>1. On the Amazon EFS console, choose <b>File systems</b>.</li><li>2. Choose <b>Network</b> to display the list of existing mount</li></ol>	Cloud administrator

Task	Description	Skills required
	targets. Make sure that these include the four subnets that you created.	

### Create an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	Open the Amazon S3 console and create an S3 bucket to store your application's static assets, if required.	Cloud administrator

### Create a Secrets Manager secret

Task	Description	Skills required
Create an AWS KMS key to encrypt the Secrets Manager secret.	Open the AWS Key Management Service (AWS KMS) console and create a KMS key.	Cloud administrator
Create a Secrets Manager secret to store the Amazon RDS password.	<ol style="list-style-type: none"> <li>1. Open the AWS Secrets Manager console, and create a new secret by choosing <b>Store a new secret</b>.</li> <li>2. Choose the KMS key that you created, and store your new secret.</li> </ol>	Cloud Administrator

## Create an Amazon RDS instance

Task	Description	Skills required
Create a DB subnet group.	<ol style="list-style-type: none"><li>1. Open the Amazon RDS console and choose <b>Subnet groups</b>.</li><li>2. Choose <b>Create DB subnet group</b>, and enter a name and description for your DB subnet group.</li><li>3. Choose the VPC that you created earlier, and choose the Availability Zones and subnets. Then choose <b>Create</b>.</li></ol>	Cloud administrator
Create an Amazon RDS instance.	Create and configure an Amazon RDS instance within the private subnets. Make sure that <b>Multi-AZ</b> is turned on for HA.	Cloud administrator
Load data to the Amazon RDS instance.	Load the relational data required by your application into your Amazon RDS instance. This process will vary depending on your application's needs, as well as how your database schema is defined and designed.	Cloud administrator, DBA

## Create the Amazon ECS components

Task	Description	Skills required
Create an ECS cluster.	<ol style="list-style-type: none"> <li>1. Open the Amazon ECS console, and choose <b>Clusters</b>.</li> <li>2. Choose <b>Create clusters</b>, and set up an ECS cluster according to your required specifications.</li> </ol>	Cloud administrator
Create the Docker images.	Create the Docker images by following the instructions in the <i>Related resources</i> section.	Cloud administrator
Create Amazon ECR repositories.	<ol style="list-style-type: none"> <li>1. On the Amazon ECR console, choose <b>Repositories</b>.</li> <li>2. Choose <b>Create repository</b>, and enter a unique name for your repository.</li> <li>3. Configure the repository according to your specifications, including AWS KMS encryption if required.</li> </ol>	Cloud administrator, DevOps engineer
Authenticate your Docker client for the Amazon ECR repository.	To authenticate your Docker client for the Amazon ECR repository, run the <code>aws ecr get-login-password</code> command in the AWS CLI.	Cloud administrator
Push the Docker images to the Amazon ECR repository.	<ol style="list-style-type: none"> <li>1. Identify the Docker image you want to push, and run the <code>docker images</code> command in the AWS CLI.</li> </ol>	Cloud administrator

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>2. Tag your image with the Amazon ECR registry, repository, and optional image tag name combination.</li> <li>3. Push the Docker image by running the <code>docker push</code> command.</li> <li>4. Repeat these steps for all required images.</li> </ol>	
<p>Create an Amazon ECS task definition.</p>	<p>A task definition is required to run Docker containers in Amazon ECS.</p> <ol style="list-style-type: none"> <li>1. Return to the Amazon ECS console, choose <b>Task definitions</b>, and then choose <b>Create new task definition</b>.</li> <li>2. On the <b>Select compatibilities</b> page, select the launch type that your task should use, and choose <b>Next step</b>.</li> </ol> <p>For help with setting up your task definition, see “Creating a task definition” in the <i>Related resources</i> section. <b>Important:</b> Make sure you provide the Docker images that you pushed to Amazon ECR.</p>	<p>Cloud administrator</p>

Task	Description	Skills required
Create an Amazon ECS service.	Create an Amazon ECS service by using the ECS cluster you created earlier. Make sure you choose Amazon EC2 as the launch type, and choose the task definition created in the previous step, as well as the target group of the Application Load Balancer.	Cloud administrator

### Create an Amazon EC2 Auto Scaling group

Task	Description	Skills required
Create a launch configuration.	Open the Amazon EC2 console, and create a launch configuration. Make sure that the user data has the code to allow the EC2 instances to join the desired ECS cluster. For an example of the code required, see the <i>Related resources</i> section.	Cloud administrator
Create an Amazon EC2 Auto Scaling group.	Return to the Amazon EC2 console and under <b>Auto Scaling</b> , choose <b>Auto Scaling groups</b> . Set up an Amazon EC2 Auto Scaling group. Make sure you choose the private subnets and launch configuration that you created earlier.	Cloud administrator

## Set up AWS PrivateLink

Task	Description	Skills required
Set up the AWS PrivateLink endpoint.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, create an AWS PrivateLink endpoint.</li><li>2. Associate this endpoint with the Network Load Balancer, which makes the application hosted on Amazon ECS available privately to customers.</li></ol> <p>For more information, see the <i>Related resources</i> section.</p>	Cloud administrator

## Create a VPC endpoint

Task	Description	Skills required
Create a VPC endpoint.	Create a VPC endpoint for the AWS PrivateLink endpoint that you created earlier. The VPC endpoint Fully Qualified Domain Name (FQDN) will point to the AWS PrivateLink endpoint FQDN. This creates an elastic network interface to the VPC endpoint service that the DNS endpoints can access.	Cloud administrator

## Create the Lambda function

Task	Description	Skills required
Create the Lambda function.	On the AWS Lambda console, create a Lambda function to update the Application Load Balancer IP addresses as targets for the Network Load Balancer. For more information on this, see the "Using static IP addresses for Application Load Balancers" blog post in the <i>Related resources</i> section.	App developer

# Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer

Created by Kirankumar Chandrashekar (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; Networking; Security, identity, compliance; Web & mobile apps

**Workload:** All other workloads

**AWS services:** Amazon EC2 Container Registry; Amazon ECS; Amazon EFS; Amazon RDS; Amazon VPC; Elastic Load Balancing (ELB); AWS Lambda

## Summary

This pattern describes how to privately host a Docker container application on the Amazon Web Services (AWS) Cloud by using Amazon Elastic Container Service (Amazon ECS) with an AWS Fargate launch type, behind a Network Load Balancer, and access the application by using AWS PrivateLink. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). You can use Amazon Elastic File System (Amazon EFS) if the application requires persistent storage.

This pattern uses a [Fargate launch type](#) for the Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end. It can then be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

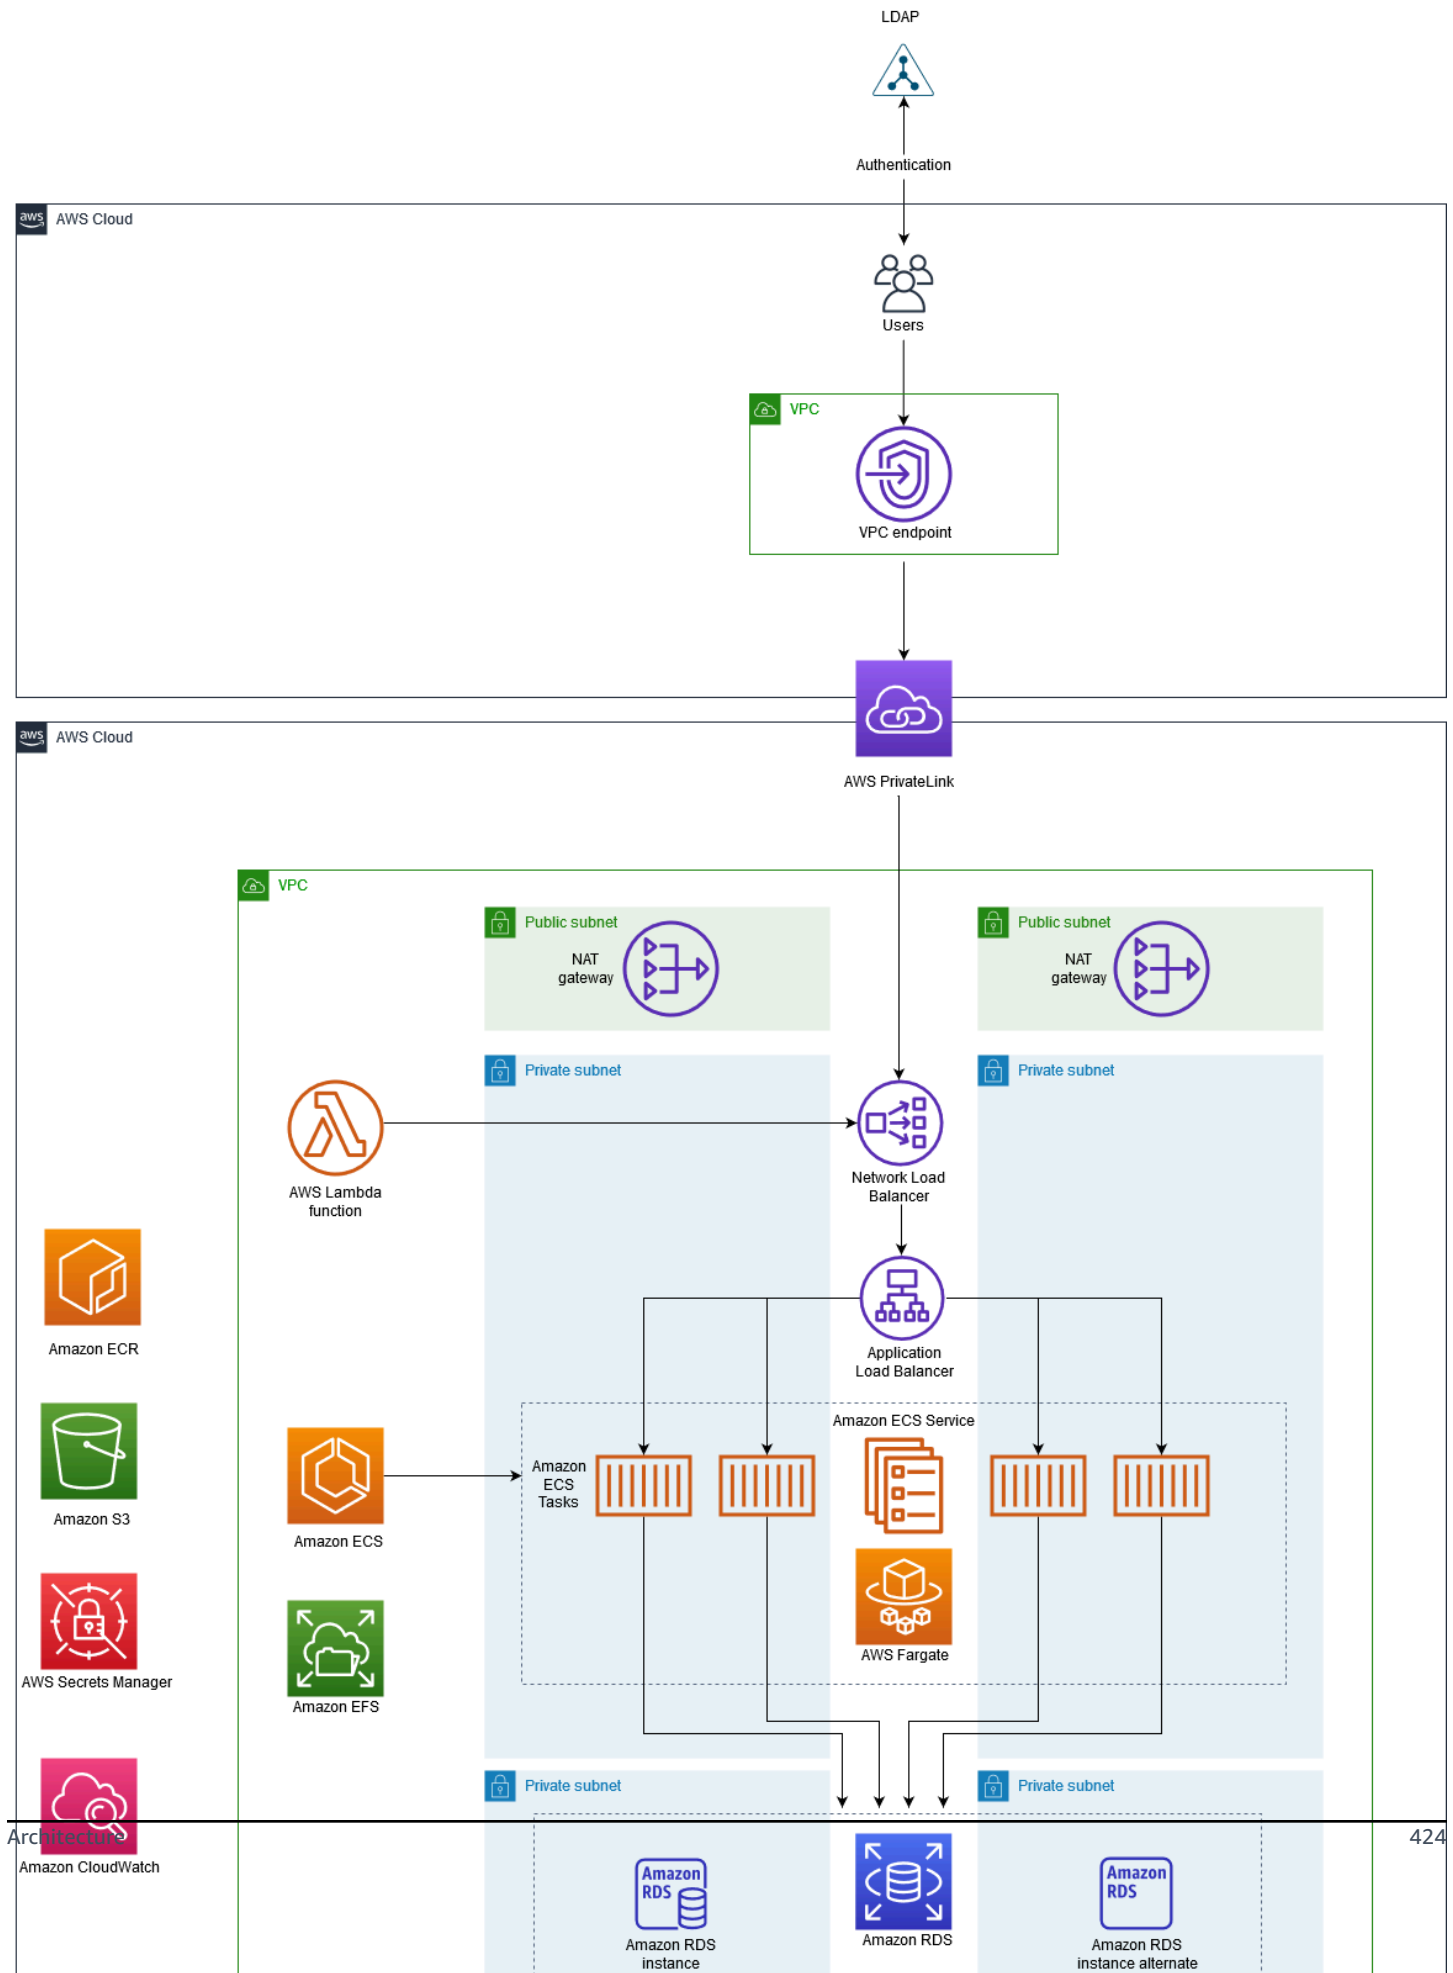

You can use Fargate with Amazon ECS to run containers without having to manage servers or clusters of Amazon Elastic Compute Cloud (Amazon EC2) instances. You can also use an Amazon EC2 Auto Scaling group instead of Fargate. For more information, see [Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [AWS Command Line Interface \(AWS CLI\) version 2](#), installed and configured on Linux, macOS, or Windows
- [Docker](#), installed and configured on Linux, macOS, or Windows
- An application running on Docker

### Architecture

## Technology stack

- Amazon CloudWatch
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon EFS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Fargate
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

## Automation and scale

- You can use [AWS CloudFormation](#) to create this pattern by using [Infrastructure as Code](#).

## Tools

- [Amazon ECS](#) – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- [Amazon EFS](#) – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- [AWS Fargate](#) – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances.
- [AWS Lambda](#) – Lambda is a compute service that lets you run code without provisioning or managing servers.

- [Amazon RDS](#) – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- [AWS Secrets Manager](#) – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [Amazon VPC](#) – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- [Elastic Load Balancing](#) – Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- [Docker](#)– Docker helps developers to easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

# Access container applications privately on Amazon EKS using AWS PrivateLink and a Network Load Balancer

Created by Kirankumar Chandrashekar (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; DevOps; Modernization; Security, identity, compliance

**Workload:** All other workloads

**AWS services:** Amazon EKS; Amazon VPC

## Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Kubernetes Service (Amazon EKS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud.

The Amazon EKS cluster running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

The setup described by this pattern is a secure way to share application access among VPCs and AWS accounts. It requires no special connectivity or routing configurations, because the connection between the consumer and provider accounts is on the global AWS backbone and doesn't traverse the public internet.

## Prerequisites and limitations

### Prerequisites

- [Docker](#), installed and configured on Linux, macOS, or Windows.
- An application running on Docker.

- An active AWS account.
- [AWS Command Line Interface \(AWS CLI\) version 2](#), installed and configured on Linux, macOS, or Windows.
- An existing Amazon EKS cluster with tagged private subnets and configured to host applications. For more information, see [Subnet tagging](#) in the Amazon EKS documentation.
- Kubectl, installed and configured to access resources on your Amazon EKS cluster. For more information, see [Installing kubectl](#) in the Amazon EKS documentation.

## Architecture

### Technology stack

- Amazon EKS
- AWS PrivateLink
- Network Load Balancer

### Automation and scale

- Kubernetes manifests can be tracked and managed on a Git-based repository (for example, on AWS CodeCommit), and deployed by using continuous integration and continuous delivery (CI/CD) in AWS CodePipeline.
- You can use AWS CloudFormation to create this pattern by using infrastructure as code (IaC).

## Tools

- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- [Elastic Load Balancing](#) – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.
- [Amazon EKS](#) – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- [Amazon VPC](#) – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- [Kubectl](#) – Kubectl is a command line utility for running commands against Kubernetes clusters.

## Epics

### Deploy the Kubernetes deployment and service manifest files

Task	Description	Skills required
Create the Kubernetes deployment manifest file.	<p>Create a deployment manifest file by modifying the following sample file according to your requirements.</p> <pre>apiVersion: apps/v1 kind: Deployment metadata:   name: sample-app</pre>	DevOps engineer

Task	Description	Skills required
	<pre>spec:   replicas: 3   selector:     matchLabels:       app: nginx   template:     metadata:       labels:         app: nginx     spec:       containers:         - name: nginx           image:             public.ecr.aws/z9d             2n7e1/nginx:1.19.5           ports:             - name: http               container Port: 80</pre> <p><b>Note:</b> This is a NGINX sample configuration file that is deployed by using the NGINX Docker image. For more information, see <a href="#">How to use the official NGINX Docker image</a> in the Docker documentation.</p>	
Deploy the Kubernetes deployment manifest file.	<p>Run the following command to apply the deployment manifest file to your Amazon EKS cluster:</p> <pre>kubectl apply -f &lt;your_deployment_f file_name&gt;</pre>	DevOps engineer

# Activate mTLS in AWS App Mesh using AWS Private CA on Amazon EKS

Created by Omar Kahil (AWS), Emmanuel Saliu (AWS), Muhammad Shahzad (AWS), and Andy Wong (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices

**AWS services:** AWS App Mesh; Amazon EKS; AWS Certificate Manager (ACM)

## Summary

This pattern shows how to implement Mutual Transport Layer Security (mTLS) on Amazon Web Services (AWS) using certificates from AWS Private Certificate Authority (AWS Private CA) in AWS App Mesh. It uses the Envoy secret discovery service (SDS) API through the Secure Production Identity Framework for Everyone (SPIFFE). SPIFFE is a Cloud Native Computing Foundation (CNCF) open-source project with wide community support that provides fine-grained and dynamic workload identity management. To implement SPIFFE standards, use the SPIRE SPIFFE runtime environment.

Using mTLS in App Mesh offers two-way peer authentication, because it adds a layer of security over TLS and allows services in the mesh to verify the client that's making the connection. The client in the client-server relationship also provides an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client. This helps to verify if the certificate is issued by a trusted certificate authority (CA) and if the certificate is a valid one.

## Prerequisites and limitations

### Prerequisites

- An Amazon Elastic Kubernetes Service (Amazon EKS) cluster with self-managed or managed node groups
- App Mesh controller deployed on the cluster with SDS activated
- A private certificate from AWS Certificate Manager (ACM) that is issued by AWS Private CA

## Limitations

- SPIRE cannot be installed on AWS Fargate because the SPIRE Agent must be run as a Kubernetes DaemonSet.

## Product versions

- AWS App Mesh Controller chart 1.3.0 or later

## Architecture

The following diagram shows the EKS cluster with App Mesh in the VPC. The SPIRE server in one worker node communicates with the SPIRE Agents in other worker nodes, and with AWS Private CA. Envoy is used for mTLS communication between the SPIRE Agent worker nodes.

The diagram illustrates the following steps:

1. Certificate is issued.
2. Request cert signing and certificate.

## Tools

### AWS services

- [AWS Private CA](#) – AWS Private Certificate Authority (AWS Private CA) enables creation of private certificate authority (CA) hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.
- [AWS App Mesh](#) – AWS App Mesh is a service mesh that makes it easier to monitor and control services. App Mesh standardizes how your services communicate, giving you consistent visibility and network traffic controls for every service in an application.
- [Amazon EKS](#) – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

### Other tools

- [Helm](#) – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster. This pattern uses Helm to deploy AWS App Mesh Controller.
- [AWS App Mesh Controller chart](#) – AWS App Mesh Controller chart is used by this pattern to enable AWS App Mesh on Amazon EKS.

## Epics

### Set up the environment

Task	Description	Skills required
Set up App Mesh with Amazon EKS.	Follow base deployment steps that are provided in the <a href="#">repository</a> .	DevOps engineer

Task	Description	Skills required
Install SPIRE.	Install SPIRE on the EKS cluster by using <a href="#">spire_set_up.yaml</a> .	DevOps engineer
Install the AWS Private CA certificate.	Create and install a certificate for your private root CA by following the instructions in the <a href="#">AWS documentation</a> .	DevOps engineer
Grant permissions to the cluster node instance role.	To attach policies to the cluster node instance role, use the code that's in the <a href="#">Additional information</a> section.	DevOps engineer
Add the SPIRE plugin for AWS Private CA.	<p>To add the plugin to the SPIRE server configuration, use the code that's in the <a href="#">Additional information</a> section. Replace the <code>certificate_authority_arn</code> Amazon Resource Name (ARN) to your private CA ARN. The signing algorithm used must be the same as the signing algorithm on the private CA. Replace <code>your_region</code> with your AWS Region.</p> <p>For more information about the plugin, see <a href="#">Server plugin: UpstreamAuthority "aws_pca"</a>.</p>	DevOps engineer

Task	Description	Skills required
Update bundle.cert.	After you create the SPIRE server, a <code>spire-bundle.yaml</code> file will be created. Change the <code>bundle.crt</code> value in the <code>spire-bundle.yaml</code> file from the private CA to the public certificate.	DevOps engineer

## Deploy and register the workloads

Task	Description	Skills required
Register node and workload entries with SPIRE.	To register node and workload (services) with SPIRE Server, use the code in the <a href="#">repository</a> .	DevOps engineer
Create a mesh in App Mesh with mTLS activated.	Create a new mesh in App Mesh with all the components for your microservices application (for example, virtual service, virtual router, and virtual nodes).	DevOps engineer
Inspect the registered entries.	You can inspect the registered entries for your nodes and workloads by running the following command. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>kubectl exec -n spire   spire-server-0 -- /   opt/spire/bin/spire-   server entry show</pre> </div>	DevOps engineer

Task	Description	Skills required
	This will show the entries for the SPIRE Agents.	

## Verify mTLS traffic

Task	Description	Skills required
Verify mTLS traffic.	<ol style="list-style-type: none"> <li>1. From the frontend service, send an HTTP header to the backend service, and verify a successful response with the services that are registered in SPIRE.</li> <li>2. For mutual TLS authentication, you can inspect the <code>ssl.handshake</code> statistic by running the following command. <div data-bbox="630 1146 1029 1386" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>kubectl exec -it \$POD -n \$NAMESPACE -c envoy -- curl http:// localhost:9901/stats   grep ssl.handshake</pre> </div> <p>After running the previous command, you should see the listener <code>ssl.handshake</code> count, which will look similar to the following example:</p> </li> </ol>	DevOps engineer

Task	Description	Skills required
	<pre>listener.0.0.0.0_1 5000.ssl.handshake: 2</pre>	
<p>Verify that certificates are being issued from AWS Private CA.</p>	<p>You can check that the plugins have been configured correctly and certificates are being issued from your upstream private CA by viewing the logs in your SPIRE server. Run the following command.</p> <pre>kubectl logs spire-server-0 -n spire</pre> <p>Then view the logs that are produced. This code assumes that your server is named <code>spire-server-0</code> and is hosted in your <code>spire</code> namespace. You should see successful loading of the plugins and a connection being made to your upstream private CA.</p>	<p>DevOps engineer</p>

## Additional information

### Attach permissions to the cluster node instance role

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ACMPCASigning",
      "Effect": "Allow",
      "Action": [
        "acm-pca:DescribeCertificateAuthority",
        "acm-pca:IssueCertificate",
        "acm-pca:GetCertificate",
        "acm:ExportCertificate"
      ],
      "Resource": "*"
    }
  ]
}
AWS Managed Policy: "AWSAppMeshEnvoyAccess"
```

### Add the SPIRE plugin for ACM

Add the SPIRE plugin for ACM

Change `certificate_authority_arn` to your PCA ARN. The signing algorithm used must be the same as the signing algorithm on the PCA. Change `your_region` to the appropriate AWS Region.

```
UpstreamAuthority "aws_pca" {
  plugin_data {
    region = "your_region"
    certificate_authority_arn = "arn:aws:acm-pca:...."
    signing_algorithm = "your_signing_algorithm"
  }
}
```

# Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch

Created by Kirankumar Chandrashekar (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; Databases; DevOps

**Workload:** All other workloads

**AWS services:** Amazon RDS; AWS Batch; Amazon CloudWatch; AWS Lambda; Amazon S3

## Summary

Backing up your PostgreSQL databases is an important task and can typically be completed with the [pg\\_dump utility](#), which uses the COPY command by default to create a schema and data dump of a PostgreSQL database. However, this process can become repetitive if you require regular backups for multiple PostgreSQL databases. If your PostgreSQL databases are hosted in the cloud, you can also take advantage of the [automated backup](#) feature provided by Amazon Relational Database Service (Amazon RDS) for PostgreSQL as well. This pattern describes how to automate regular backups for Amazon RDS for PostgreSQL DB instances using the pg\_dump utility.

Note: The instructions assume that you're using Amazon RDS. However, you can also use this approach for PostgreSQL databases that are hosted outside Amazon RDS. To take backups, the AWS Lambda function must be able to access your databases.

A time-based Amazon CloudWatch Events event initiates a Lambda function that searches for specific backup [tags applied to the metadata](#) of the PostgreSQL DB instances on Amazon RDS. If the PostgreSQL DB instances have the **bkp:AutomatedDBDump = Active** tag and other required backup tags, the Lambda function submits individual jobs for each database backup to AWS Batch.

AWS Batch processes these jobs and uploads the backup data to an Amazon Simple Storage Service (Amazon S3) bucket. This pattern uses a Dockerfile and an entrypoint.sh file to build a Docker container image that is used to make backups in the AWS Batch job. After the backup

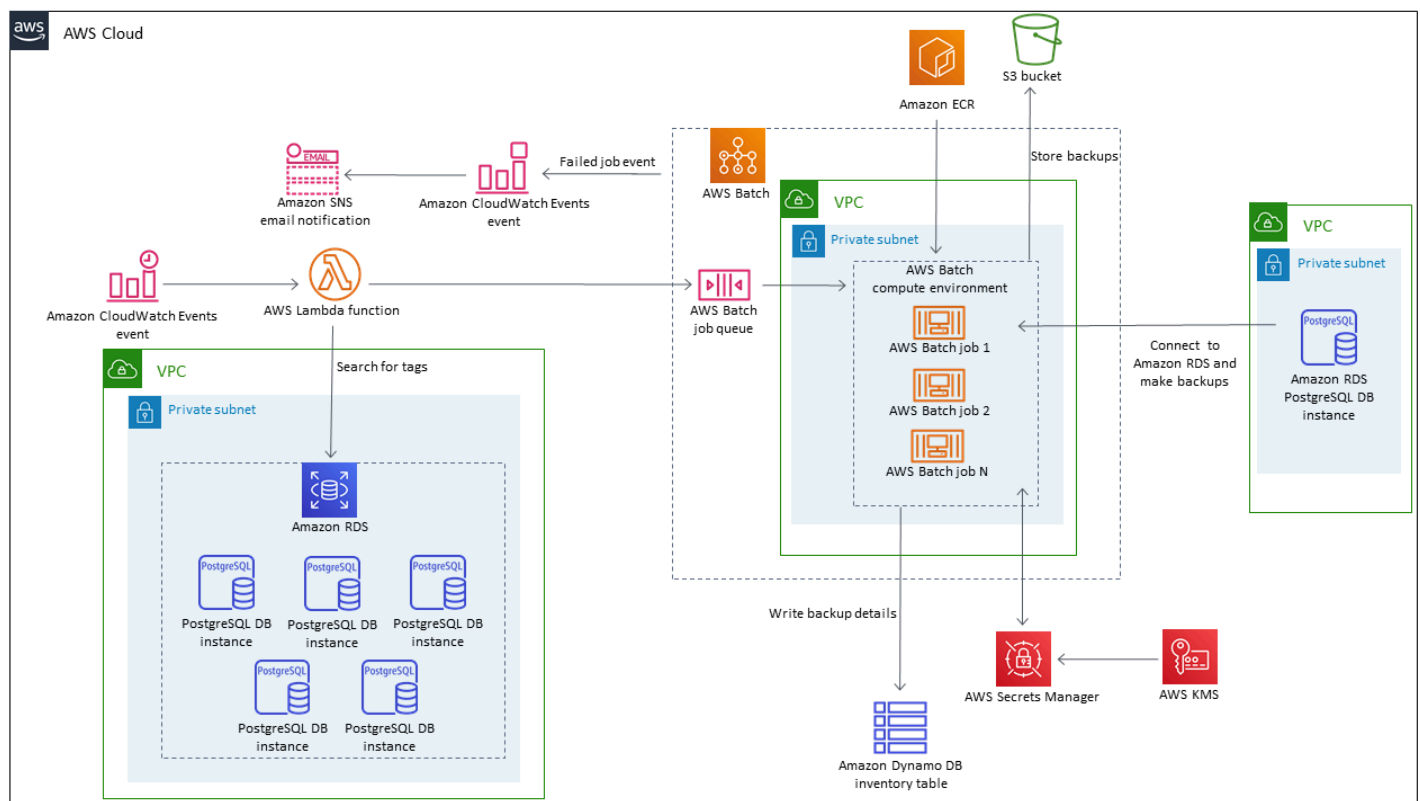

process is complete, AWS Batch records the backup details to an inventory table on Amazon DynamoDB. As an additional safeguard, a CloudWatch Events event initiates an Amazon Simple Notification Service (Amazon SNS) notification if a job fails in AWS Batch.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing managed or unmanaged compute environment. For more information, see [Managed and unmanaged compute environments](#) in the AWS Batch documentation.
- [AWS Command Line Interface \(CLI\) version 2 Docker image](#), installed and configured.
- Existing Amazon RDS for PostgreSQL DB instances.
- An existing S3 bucket.
- [Docker](#), installed and configured on Linux, macOS, or Windows.
- Familiarity with coding in Lambda.

## Architecture

## Technology stack

- Amazon CloudWatch Events
- Amazon DynamoDB
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon RDS
- Amazon SNS
- Amazon S3
- AWS Batch
- AWS Key Management Service (AWS KMS)
- AWS Lambda
- AWS Secrets Manager
- Docker

## Tools

- [Amazon CloudWatch Events](#) – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [Amazon DynamoDB](#) – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- [Amazon RDS](#) – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- [AWS Batch](#) – AWS Batch helps you run batch computing workloads on the AWS Cloud.
- [AWS KMS](#) – AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control the encryption keys used to encrypt your data.
- [AWS Lambda](#) – Lambda is a compute service that helps you run code without provisioning or managing servers.

- [AWS Secrets Manager](#) – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [Docker](#) – Docker helps developers easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Your PostgreSQL DB instances on Amazon RDS must have [tags applied to their metadata](#). The Lambda function searches for tags to identify DB instances that should be backed up, and the following tags are typically used.

Tag	Description
bkp:AutomatedDBDump = Active	Identifies an Amazon RDS DB instance as a candidate for backups.
bkp:AutomatedBackupSecret = <secret_name >	Identifies the Secrets Manager secret that contains the Amazon RDS login credentials.
bkp:AutomatedDBDumpS3Bucket = <s3_bucket_name>	Identifies the S3 bucket to send backups to.
bkp:AutomatedDBDumpFrequency bkp:AutomatedDBDumpTime	Identify the frequency and times when databases should be backed up.
bkp:pgdumpcommand = <pgdump_command>	Identifies the databases for which the backups need to be taken.

## Epics

### Create an inventory table in DynamoDB

Task	Description	Skills required
Create a table in DynamoDB.	Sign in to the AWS Management Console, open the Amazon DynamoDB console, and create a table.	Cloud administrator, Database administrator

Task	Description	Skills required
	For help with this and other stories, see the <i>Related resources</i> section.	
Confirm that the table was created.	Run the <code>aws dynamodb describe-table --table-name &lt;table-name&gt;   grep TableStatus</code> command. If the table exists, the command will return the "TableStatus": "ACTIVE", result.	Cloud administrator, Database administrator

## Create an SNS topic for failed job events in AWS Batch

Task	Description	Skills required
Create an SNS topic.	Open the Amazon SNS console, choose <b>Topics</b> , and create an SNS topic with the name <code>JobFailedAlert</code> . Subscribe an active email address to the topic, and check your email inbox to confirm the SNS subscription email from AWS Notifications.	Cloud administrator
Create a failed job event rule for AWS Batch.	Open the Amazon CloudWatch console, choose <b>Events</b> , and then choose <b>Create rule</b> . Choose <b>Show advanced options</b> , and choose <b>Edit</b> . For <b>Build a pattern that selects events for processing by your targets</b> , replace	Cloud administrator

Task	Description	Skills required
	the existing text with the “Failed job event” code from the <i>Additional information</i> section. This code defines a CloudWatch Events rule that initiates when AWS Batch has a Failed event.	
Add event rule target.	In <b>Targets</b> , choose <b>Add targets</b> , and choose the JobFailedAlert SNS topic. Configure the remaining details and create the Cloudwatch Events rule.	Cloud administrator

### Build a Docker image and push it to an Amazon ECR repository

Task	Description	Skills required
Create an Amazon ECR repository.	Open the Amazon ECR console and choose the AWS Region in which you want to create your repository. Choose <b>Repositories</b> , and then choose <b>Create repository</b> . Configure the repository according to your requirements.	Cloud administrator
Write a Dockerfile.	Sign in to Docker and use the “Sample Dockerfile” and “Sample entrypoint.sh file” from the <i>Additional informati</i>	DevOps engineer

Task	Description	Skills required
	on section to build a Dockerfile.	
Create a Docker image and push it to the Amazon ECR repository.	Build the Dockerfile into a Docker image and push it to the Amazon ECR repository. For help with this story, see the <i>Related resources</i> section.	DevOps engineer

### Create the AWS Batch components

Task	Description	Skills required
Create an AWS Batch job definition.	Open the AWS Batch console and create a job definition that includes the Amazon ECR repository's Uniform Resource Identifier (URI) as the property Image.	Cloud administrator
Configure the AWS Batch job queue.	On the AWS Batch console, choose <b>Job queues</b> , and then choose <b>Create queue</b> . Create a job queue that will store jobs until AWS Batch runs them on the resources within your compute environment. Important: Make sure you write logic for AWS Batch to record the backup details to the DynamoDB inventory table.	Cloud administrator

## Create and schedule a Lambda function

Task	Description	Skills required
Create a Lambda function to search for tags.	Create a Lambda function that searches for tags on your PostgreSQL DB instances and identifies backup candidates. Make sure your Lambda function can identify the <code>bkp:AutomatedDBDump = Active</code> tag and all other required tags. Important: The Lambda function must also be able to add jobs to the AWS Batch job queue.	DevOps engineer
Create a time-based CloudWatch Events event.	Open the Amazon CloudWatch console and create a CloudWatch Events event that uses a cron expression to run your Lambda function on a regular schedule. Important: All scheduled events use the UTC time zone.	Cloud administrator

## Test the backup automation

Task	Description	Skills required
Create an Amazon KMS key.	Open the Amazon KMS console and create a KMS key that can be used to encrypt the Amazon RDS credentials stored in AWS Secrets Manager.	Cloud administrator

Task	Description	Skills required
Create an AWS Secrets Manager secret.	Open the AWS Secrets Manager console and store your Amazon RDS for PostgreSQL database credentials as a secret.	Cloud administrator
Add the required tags to the PostgreSQL DB instances.	Open the Amazon RDS console and add tags to the PostgreSQL DB instances that you want to automatically back up. You can use the tags from the table in the <i>Tools</i> section. If you require backups from multiple PostgreSQL databases within the same Amazon RDS instance, then use <code>-d test:-d test1</code> as the value for the <code>bkp:pgdumpcommand</code> tag. <b>Important:</b> <code>test</code> and <code>test1</code> are database names. Make sure that there is no space after the colon (:).	Cloud administrator

Task	Description	Skills required
Verify the backup automation.	To verify the backup automation, you can either invoke the Lambda function or wait for the backup schedule to begin. After the backup process is complete, check that the DynamoDB inventory table has a valid backup entry for your PostgreSQL DB instances. If they match, then the backup automation process is successful.	Cloud administrator

# Automate deployment of Node Termination Handler in Amazon EKS by using a CI/CD pipeline

Created by Sandip Gangapadhyay (AWS), John Vargas (AWS), Pragtideep Singh (AWS), Sandeep Gawande (AWS), and Viyoma Sachdeva (AWS)

**Code repository:** [Deploy NTH to EKS](#)

**Environment:** Production

**Technologies:** Containers & microservices; DevOps

**AWS services:** AWS CodePipeline; Amazon EKS; AWS CodeBuild

## Summary

On the Amazon Web Services (AWS) Cloud, you can use [AWS Node Termination Handler](#), an open-source project, to handle Amazon Elastic Compute Cloud (Amazon EC2) instance shutdown within Kubernetes gracefully. AWS Node Termination Handler helps to ensure that the Kubernetes control plane responds appropriately to events that can cause your EC2 instance to become unavailable. Such events include the following:

- [EC2 instance scheduled maintenance](#)
- [Amazon EC2 Spot Instance interruptions](#)
- [Auto Scaling group scale in](#)
- [Auto Scaling group rebalancing](#) across Availability Zones
- EC2 instance termination through the API or the AWS Management Console

If an event isn't handled, your application code might not stop gracefully. It also might take longer to recover full availability, or it might accidentally schedule work to nodes that are going down. The `aws-node-termination-handler` (NTH) can operate in two different modes: Instance Metadata Service (IMDS) or Queue Processor. For more information about the two modes, see the [Readme file](#).

This pattern automates the deployment of NTH by using Queue Processor through a continuous integration and continuous delivery (CI/CD) pipeline.

**Note:** If you're using [EKS managed node groups](#), you don't need the `aws-node-termination-handler`.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A web browser that is supported for use with the AWS Management Console. See the [list of supported browsers](#).
- AWS Cloud Development Kit (AWS CDK) [installed](#).
- `kubectl`, the Kubernetes command line tool, [installed](#).
- `eksctl`, the AWS Command Line Interface (AWS CLI) for Amazon Elastic Kubernetes Service (Amazon EKS), [installed](#).
- A running EKS cluster with version 1.20 or later.
- A self-managed node group attached to the EKS cluster. To create an Amazon EKS cluster with a self-managed node group, run the following command.

```
eksctl create cluster --managed=false --region <region> --name <cluster_name>
```

For more information on `eksctl`, see the [eksctl documentation](#).

- AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. For more information, see [Creating an IAM OIDC provider for your cluster](#).

### Limitations

- You must use an AWS Region that supports the Amazon EKS service.

### Product versions

- Kubernetes version 1.20 or later
- `eksctl` version 0.107.0 or later
- AWS CDK version 2.27.0 or later

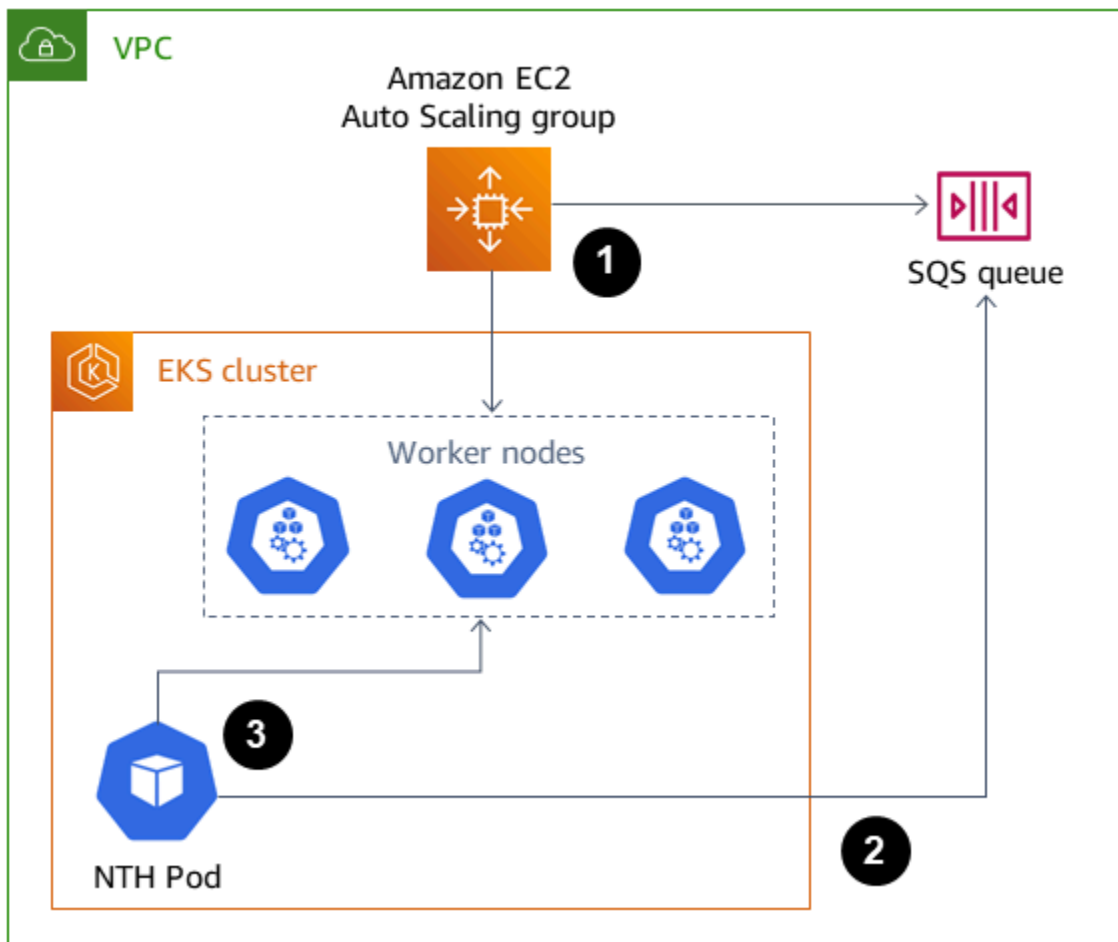

# Architecture

## Target technology stack

- A virtual private cloud (VPC)
- An EKS cluster
- Amazon Simple Queue Service (Amazon SQS)
- IAM
- Kubernetes

## Target architecture

The following diagram shows the high-level view of the end-to-end steps when the node termination is started.

The workflow shown in the diagram consists of the following high-level steps:

1. The automatic scaling EC2 instance terminate event is sent to the SQS queue.
2. The NTH Pod monitors for new messages in the SQS queue.
3. The NTH Pod receives the new message and does the following:
  - Cordons the node so that new pod does not run on the node.
  - Drains the node, so that the existing pod is evacuated
  - Sends a lifecycle hook signal to the Auto Scaling group so that the node can be terminated.

### Automation and scale

- Code is managed and deployed by AWS CDK, backed by AWS CloudFormation nested stacks.
- The [Amazon EKS control plane](#) runs across multiple Availability Zones to ensure high availability.
- For [automatic scaling](#), Amazon EKS supports the Kubernetes [Cluster Autoscaler](#) and [Karpenter](#).

## Tools

### AWS services

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [Amazon EC2 Auto Scaling](#) helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- [Amazon Simple Queue Service \(Amazon SQS\)](#) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

## Other tools

- [kubect](#)l is a Kubernetes command line tool for running commands against Kubernetes clusters. You can use kubectl to deploy applications, inspect and manage cluster resources, and view logs.

## Code

The code for this pattern is available in the [deploy-nth-to-eks](#) repo on GitHub.com. The code repo contains the following files and folders.

- `nth` folder – The Helm chart, values files, and the scripts to scan and deploy the AWS CloudFormation template for Node Termination Handler.
- `config/config.json` – The configuration parameter file for the application. This file contains all the parameters needed for CDK to be deployed.
- `cdk` – AWS CDK source code.
- `setup.sh` – The script used to deploy the AWS CDK application to create the required CI/CD pipeline and other required resources.
- `uninstall.sh` – The script used to clean up the resources.

To use the example code, follow the instructions in the *Epics* section.

## Best practices

For best practices when automating AWS Node Termination Handler, see the following:

- [EKS Best Practices Guides](#)
- [Node Termination Handler - Configuration](#)

## Epics

### Set up your environment

Task	Description	Skills required
Clone the repo.	To clone the repo by using SSH (Secure Shell), run the following the command.	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
	<pre>git clone git@github.com:aws-samples/ deploy-nth-to-eks.git</pre> <p>To clone the repo by using HTTPS, run the following the command.</p> <pre>git clone https://github.com/aws-samples/ deploy-nth-to-eks.git</pre> <p>Cloning the repo creates a folder named <code>deploy-nth-to-eks</code>.</p> <p>Change to that directory.</p> <pre>cd deploy-nth-to-eks</pre>	
Set the kubeconfig file.	<p>Set your AWS credentials in your terminal and confirm that you have rights to assume the cluster role. You can use the following example code.</p> <pre>aws eks update-kubeconfig --name &lt;Cluster_Name&gt; -- region &lt;region&gt;--role- arn &lt;Role_ARN&gt;</pre>	AWS DevOps, DevOps engineer, App developer

## Deploy the CI/CD pipeline

Task	Description	Skills required
Set up the parameters.	<p>In the <code>config/condafig.json</code> file, set up the following required parameters.</p> <ul style="list-style-type: none"><li>• <code>pipelineName</code> : The name of the CI/CD pipeline to be created by AWS CDK (for example, <code>deploy-nth-to-eks-pipeline</code> ). AWS CodePipeline will create a pipeline that has this name.</li><li>• <code>repositoryName</code> : The AWS CodeCommit repo to be created (for example, <code>deploy-nth-to-eks-repo</code> ). AWS CDK will create this repo and set it as the source for the CI/CD pipeline.</li></ul> <p><b>Note:</b> This solution will create this CodeCommit repo and the branch (provided in the following branch parameter).</p> <ul style="list-style-type: none"><li>• <code>branch</code>: The branch name in the repo (for example, <code>main</code>). A commit to this branch will initiate the CI/CD pipeline.</li></ul>	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <code>cfn_scan_script</code> :The path of the script that will be used to scan the AWS CloudFormation template for NTH (<code>scan.sh</code>). This script exists in <code>nth</code> folder that will be part of the AWS CodeCommit repo.</li> <li>• <code>cfn_deploy_script</code> :The path of the script that will be used to deploy the AWS CloudFormation template for NTH (<code>installApp.sh</code>).</li> <li>• <code>stackName</code> : The name of the CloudFormation stack to be deployed.</li> <li>• <code>eksClusterName</code> : The name of the existing EKS cluster.</li> <li>• <code>eksClusterRole</code> : The IAM role that will be used to access the EKS cluster for all Kubernetes API calls (for example, <code>clusteradmin</code> ). Usually, this role is added in <code>aws-auth ConfigMap</code> .</li> <li>• <code>create_cluster_role</code> : To create the <code>eksClusterRole</code> IAM role, enter <b>yes</b>. If you want to provide an existing cluster role in</li> </ul>	

Task	Description	Skills required
	<p>the <code>eksClusterRole</code> parameter, enter <b>no</b>.</p> <ul style="list-style-type: none"> <li>• <code>create_iam_oidc_provider</code> : To create the IAM OIDC provider for your cluster, enter <b>yes</b>. If an IAM OIDC provider already exists, enter <b>no</b>. For more information, see <a href="#">Creating an IAM OIDC provider for your cluster</a>.</li> <li>• <code>AsgGroupName</code> : A comma-separated list of Auto Scaling group names that are part of the EKS cluster (for example, <code>ASG_Group_1, ASG_Group_2</code> ).</li> <li>• <code>region</code>: The name of the AWS Region where the cluster is located (for example, <code>us-east-2</code> ).</li> <li>• <code>install_cdk</code> : If AWS CDK isn't currently installed on the machine, enter <b>yes</b>. Run the <code>cdk --version</code> command to check whether the installed AWS CDK version is 2.27.0 or later. In that case, enter <b>no</b>.</li> </ul> <p>If you enter <b>yes</b>, the <code>setup.sh</code> script will run the <code>sudo npm install -g</code></p>	

Task	Description	Skills required
	<p><code>cdk@2.27.0</code> command to install AWS CDK on the machine. The script requires sudo permissions, so provide the account password when prompted.</p>	
Create the CI/CD pipeline to deploy NTH.	<p>Run the <code>setup.sh</code> script.</p> <pre>./setup.sh</pre> <p>The script will deploy the AWS CDK application that will create the CodeCommit repo with example code, the pipeline, and CodeBuild projects based on the user input parameters in <code>config/config.json</code> file.</p> <p>This script will ask for the password as it installs npm packages with the <code>sudo</code> command.</p>	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
Review the CI/CD pipeline.	<p>Open the AWS Management Console, and review the following resources created in the stack.</p> <ul style="list-style-type: none"><li>• CodeCommit repo with the contents of the nth folder</li><li>• AWS CodeBuild project <code>cfn-scan</code>, which will scan the CloudFormation template for vulnerabilities.</li><li>• CodeBuild project <code>Nth-Deploy</code>, which will deploy the AWS CloudFormation template and the corresponding NTH Helm charts through the AWS CodePipeline pipeline.</li><li>• A CodePipeline pipeline to deploy NTH.</li></ul> <p>After the pipeline runs successfully, Helm release <code>aws-node-termination-handler</code> is installed in the EKS cluster. Also, a Pod named <code>aws-node-termination-handler</code> is running in the <code>kube-system</code> namespace in the cluster.</p>	App developer, AWS DevOps, DevOps engineer

## Test NTH deployment

Task	Description	Skills required
Simulate an Auto Scaling group scale-in event.	<p>To simulate an automatic scaling scale-in event, do the following:</p> <ol style="list-style-type: none"> <li>1. On the AWS console, open the <b>EC2 console</b>, and choose <b>Auto Scaling Groups</b>.</li> <li>2. Select the Auto Scaling group that has same name as the one provided in <code>config/config.json</code> , and choose <b>Edit</b>.</li> <li>3. Decrease <b>Desired and Minimum Capacity</b> by 1.</li> <li>4. Choose <b>Update</b>.</li> </ol>	
Review the logs.	<p>During the scale-in event, the NTH Pod will cordon and drain the corresponding worker node (the EC2 instance that will be terminated as part of the scale-in event). To check the logs, use the code in the <i>Additional information</i> section.</p>	App developer, AWS DevOps, DevOps engineer

## Clean up

Task	Description	Skills required
Clean up all AWS resources.	<p>To clean up the resources created by this pattern, run the following command.</p> <pre>./uninstall.sh</pre> <p>This will clean up all the resources created in this pattern by deleting the CloudFormation stack.</p>	DevOps engineer

## Troubleshooting

Issue	Solution
The npm registry isn't set correctly.	<p>During the installation of this solution, the script installs npm install to download all the required packages. If, during the installation, you see a message that says "Cannot find module," the npm registry might not be set correctly. To see the current registry setting, run the following command.</p> <pre>npm config get registry</pre> <p>To set the registry with <code>https://registry.npmjs.org/</code>, run the following command.</p> <pre>npm config set registry https://registry.npmjs.org</pre>

Issue	Solution
Delay SQS message delivery.	As part of your troubleshooting, if you want to delay the SQS message delivery to NTH Pod, you can adjust the SQS delivery delay parameter. For more information, see <a href="#">Amazon SQS delay queues</a> .

## Related resources

- [AWS Node Termination Handler source code](#)
- [EC2 workshop](#)
- [AWS CodePipeline](#)
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#)
- [AWS Cloud Development Kit](#)
- [AWS CloudFormation](#)

## Additional information

1. Find the NTH Pod name.

```
kubectl get pods -n kube-system |grep aws-node-termination-handler
aws-node-termination-handler-65445555-kbqc7 1/1 Running 0 26m
kubectl get pods -n kube-system |grep aws-node-termination-handler
aws-node-termination-handler-65445555-kbqc7 1/1 Running 0 26m
```

2. Check the logs. An example log looks like the following. It shows that the node has been cordoned and drained before sending the Auto Scaling group lifecycle hook completion signal.

```
kubectl -n kube-system logs aws-node-termination-handler-65445555-kbqc7
022/07/17 20:20:43 INF Adding new event to the event store

# Automatically build and deploy a Java application to Amazon EKS using a CI/CD pipeline

Created by MAHESH RAGHUNANDANAN (AWS), James Radtke (AWS), and Jomcy Pappachen (AWS)

<b>Code repository:</b> <a href="#">aws-cicd-java-eks</a>	<b>Environment:</b> Production	<b>Technologies:</b> Containers & microservices; CloudNative; DevOps; Modernization
<b>Workload:</b> All other workloads	<b>AWS services:</b> AWS CloudFormation; AWS CodeCommit; AWS CodePipeline; Amazon EC2 Container Registry; Amazon EKS	

## Summary

This pattern describes how to create a continuous integration and continuous delivery (CI/CD) pipeline that automatically builds and deploys a Java application with recommended DevSecOps practices to an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud. This pattern uses a greeting application developed with a Spring Boot Java framework and that uses Apache Maven.

You can use this pattern's approach to build the code for a Java application, package the application artifacts as a Docker image, security scan the image, and upload the image as a workload container on Amazon EKS. This pattern's approach is useful if you want to migrate from a tightly coupled monolithic architecture to a microservices architecture. The approach also helps you to monitor and manage the entire lifecycle of a Java application, which ensures a higher level of automation and helps avoid errors or bugs.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.

- AWS Command Line Interface (AWS CLI) version 2, installed and configured. For more information about this, see [Installing, updating, and uninstalling the AWS CLI version 2](#) in the AWS CLI documentation.
- AWS CLI version 2 must be configured with the same IAM role that creates the Amazon EKS cluster because only that role is authorized to add other IAM roles to the `aws-auth` ConfigMap. For information and steps to configure AWS CLI, see [Configuration basics](#) in the AWS CLI documentation.
- AWS Identity and Access Management (IAM) roles and permissions with full access to AWS CloudFormation. For more information about this, see [Controlling access with IAM](#) in the AWS CloudFormation documentation.
- An existing Amazon EKS cluster, with details of the IAM role name and IAM role Amazon Resource Name (ARN) of worker nodes in the EKS cluster.
- Kubernetes Cluster Autoscaler, installed and configured in your Amazon EKS cluster. For more information, see [Cluster Autoscaler](#) in the Amazon EKS documentation.
- Access to code in the GitHub repository.

### *Important note*

AWS Security Hub is enabled as part of the AWS CloudFormation templates that are in the code. By default, after Security Hub is enabled, it comes with a 30-day free trial, after which there is a cost associated with this AWS service. For more information about pricing, see [AWS Security Hub pricing](#).

### **Product versions**

- Helm version 3.4.2 or later
- Apache Maven version 3.6.3 or later
- BridgeCrew Checkov version 2.2 or later
- Aqua Security Trivy version 0.37 or later

## **Architecture**

### **Technology stack**

- AWS CodeBuild
- AWS CodeCommit

- Amazon CodeGuru
- AWS CodePipeline
- Amazon Elastic Container Registry
- Amazon Elastic Kubernetes Service
- Amazon EventBridge
- AWS Security Hub
- Amazon Simple Notification Service (Amazon SNS)

## Target architecture

The diagram shows the following workflow:

1. The developer updates the Java application code in the base branch of the CodeCommit repository, which creates a pull request (PR).
2. As soon as the PR is submitted, Amazon CodeGuru Reviewer automatically reviews the code, analyzes it based on best practices for Java, and gives recommendations to the developer.
3. After the PR is merged to the base branch, an Amazon EventBridge event is created.
4. The EventBridge event initiates the CodePipeline pipeline, which starts .
5. CodePipeline runs the CodeSecurity Scan stage (continuous security).
6. CodeBuild starts the security scan process in which the Dockerfile and Kubernetes deployment Helm files are scanned using Checkov, and application source code is scanned based on

- incremental code changes. The application source code scan is performed by the [CodeGuru Reviewer Command Line Interface \(CLI\) wrapper](#).
7. If the security scan stage is successful, the Build stage (continuous integration) is initiated.
  8. In the Build stage, CodeBuild builds the artifact, packages the artifact to a Docker image, scans the image for security vulnerabilities by using Aqua Security Trivy, and stores the image in Amazon ECR.
  9. The vulnerabilities detected from step 8 are uploaded to Security Hub for further analysis by developers or engineers. Security Hub provides an overview and recommendations for remediating the vulnerabilities.
  10. Email notifications of various phases within the CodePipeline pipeline are sent through Amazon SNS.
  11. After the continuous integration phases are complete, CodePipeline enters the Deploy stage (continuous delivery).
  12. The Docker image is deployed to Amazon EKS as a container workload (pod) by using Helm charts.
  13. The application pod is configured with Amazon CodeGuru Profiler Agent which will send the profiling data of the application (CPU, heap usage, and latency) to Amazon CodeGuru Profiler, which helps developers to understand the behavior of the application.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [Amazon CodeGuru Profiler](#) collects runtime performance data from your live applications, and provides recommendations that can help you fine-tune your application performance.
- [Amazon CodeGuru Reviewer](#) uses program analysis and machine learning to detect potential defects that are difficult for developers to find and offers suggestions for improving your Java and Python code.

- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Security Hub](#) provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

## Other services

- [Helm](#) is an open-source package manager for Kubernetes.
- [Apache Maven](#) is a software project management and comprehension tool.
- [BridgeCrew Checkov](#) is a static code analysis tool for scanning infrastructure as code (IaC) files for misconfigurations that might lead to security or compliance problems.
- [Aqua Security Trivy](#) is a comprehensive scanner for vulnerabilities in container images, file systems, and Git repositories, in addition to configuration issues.

## Code

The code for this pattern is available in the GitHub [aws-codepipeline-devsecops-amazoneks](#) repository.

## Best practices

- The principle of least privilege has been followed for IAM entities across all the phases of this solution. If you want to extend the solution with additional AWS services or third-party tools, we recommend following the principle of least privilege.
- If you have multiple Java applications, we recommend creating separate CI/CD pipelines for each application.
- If you have a monolith application, we recommend breaking the application into microservices as much as possible. Microservices are more flexible, they make it easier to deploy applications as containers, and they provide better visibility into the overall build and deployment of the application.

## Epics

### Set up the environment

Task	Description	Skills required
Clone the GitHub repository.	<p>To clone the repository, run the following command.</p> <pre>git clone https://github.com/aws-samples/aws-codepipeline-devsecops-amazoneks</pre>	App developer, DevOps engineer
Create an S3 bucket and upload the code.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console, open the Amazon S3 console, and then create an S3 bucket in the AWS Region where you plan to deploy this solution. For more information, see <a href="#">Creating a bucket</a> in the Amazon S3 documentation.</li> </ol>	AWS DevOps, DevOps engineer, Cloud administrator, DevOps

Task	Description	Skills required
	<p>2. In the S3 bucket, create a folder named code.</p> <p>3. Navigate to where you cloned the repository. To create a compressed version of the entire code with the .zip extension (cicdstack.zip ) and validate the .zip file, run the following commands in order.</p> <p><b>Note:</b> If the python command fails and states that Python was not found, use python3 instead.</p> <pre>cd aws-codepipeline-d evsecops-amazoneks python -m zipfile -c cicdstack.zip * python -m zipfile -t cicdstack.zip</pre> <p>4. Upload the cicdstack .zip file to the code folder that you previously created in the S3 bucket.</p>	

Task	Description	Skills required
Create an AWS CloudFormation stack.	<ol style="list-style-type: none"><li>1. Open the AWS CloudFormation console and choose <b>Create stack</b>.</li><li>2. In <b>Specify template</b>, choose <b>Upload a template file</b>, upload the <code>cf_templates/codecommit_ecr.yaml</code> file, and then choose <b>Next</b>.</li><li>3. In <b>Specify stack details</b>, enter the stack name, and then provide the following input parameter values:<ul style="list-style-type: none"><li>• <b>CodeCommitRepositoryBranchName</b>: The branch-name where your code will be residing (the default is <b>main</b>)</li><li>• <b>CodeCommitRepositoryName</b>: The name of the CodeCommit repo to be created.</li><li>• <b>CodeCommitRepositoryS3Bucket</b>: The name of the S3 bucket where you created the code folder</li><li>• <b>CodeCommitRepositoryS3BucketObjKey</b>: <code>code/cicdstack.zip</code></li></ul></li></ol>	AWS DevOps, DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <b>ECRRepositoryName:</b> The name of the Amazon ECR repo to be created</li> </ul> <ol style="list-style-type: none"> <li>4. Choose <b>Next</b>, use the default settings for the <b>Configure stack options</b>, and then choose <b>Next</b>.</li> <li>5. In the <b>Review</b> section, verify the template and stack details, and then choose <b>Create stack</b>. The stack is then created, including the CodeCommit and Amazon ECR repositories.</li> <li>6. Note the names of the CodeCommit and Amazon ECR repositories, which will be required for the Java CI/CD pipeline setup.</li> </ol>	
Validate the CloudFormation stack deployment.	<ol style="list-style-type: none"> <li>1. Under <b>Stacks</b> on the CloudFormation console, verify the status of CloudFormation stack that you deployed. The status of the stack should be <b>CREATE COMPLETE</b>.</li> <li>2. Additionally, from the console, validate that CodeCommit and Amazon ECR have been provisioned and are ready.</li> </ol>	DevOps engineer

Task	Description	Skills required
Delete the S3 bucket.	Empty and delete the S3 bucket that you created earlier. For more information, see <a href="#">Deleting a bucket</a> in the Amazon S3 documentation.	AWS DevOps, DevOps

## Configure the Helm charts

Task	Description	Skills required
Configure the Helm charts of your Java application.	<ol style="list-style-type: none"><li>In the location where you cloned the GitHub repository, navigate to the folder <code>helm_charts/aws-proserve-java-greeting</code>. In this folder, the <code>values.dev.yaml</code> file contains information about Kubernetes resources configuration that you can modify for your container deployments to Amazon EKS. Update the Docker repository parameter by providing your AWS account ID, AWS Region, and Amazon ECR repository name. <pre>image:   repository:     &lt;account-id&gt;.dkr.ecr.&lt;region&gt;.amazon</pre></li></ol>	DevOps

Task	Description	Skills required
	<pre>aws.com/&lt;app-ecr-r epo-name&gt;</pre> <p>2. The Java pod's service type is set to LoadBalancer .</p> <pre>service:   type: LoadBalancer   port: 80   targetPort: 8080   path: /hello   initialDelaySecond s: 60   periodSeconds: 30</pre> <p>To use a different service (for example, NodePort), you can change the parameters. For more information, see the <a href="#">Kubernetes documentation</a>.</p> <p>3. You can activate the <a href="#">Kubernetes Horizontal Pod Autoscaler</a> by changing the autoscaling parameter to enabled: true.</p> <pre>autoscaling:   enabled: true   minReplicas: 1   maxReplicas: 100   targetCPUUtilizati onPercentage: 80   # targetMem oryUtilizationPerc entage: 80</pre>	

Task	Description	Skills required
	<p>You can enable different features for the Kubernetes workloads by changing the values in the <code>values.&lt;ENV&gt;.yaml</code> file, where <code>&lt;ENV&gt;</code> is your development, production, UAT, or QA environment.</p>	
Validate Helm charts for syntax errors.	<ol style="list-style-type: none"><li>1. From the terminal, verify that Helm v3 is installed in your local workstation by running the following command. <pre>helm --version</pre><p>If Helm v3 isn't installed, <a href="#">install it</a>.</p></li><li>2. In the terminal, navigate to the Helm charts directory (<code>helm_charts/aws-pr</code> <code>oserve-java-greeting</code>), and run the following command. <pre>helm lint . -f values.dev.yaml</pre><p>This will check the Helm charts for any syntax errors.</p></li></ol>	DevOps engineer

## Set up the Java CI/CD pipeline

Task	Description	Skills required
Create the CI/CD pipeline.	<ol style="list-style-type: none"><li>1. Open the AWS CloudFormation console, and choose <b>Create stack</b>.</li><li>2. In <b>Specify template</b>, choose <b>Upload a template file</b>, upload the <code>cf_templates/build_deployment.yaml</code> template, and then choose <b>Next</b>.</li><li>3. In <b>Specify stack details</b>, specify the <b>Stack name</b>, and then provide the following values for the input parameters:<ul style="list-style-type: none"><li>• <b>CodeBranchName:</b> Branch name of CodeCommit repo, where your code resides</li><li>• <b>EKSClusterName:</b> Name of your EKS cluster (not the <code>EKSCluster ID</code>)</li><li>• <b>EKSCodeBuildAppName:</b> Name of the app Helm chart (<code>aws-proserve-java-greeting</code>)</li><li>• <b>EKSWorkerNodeRoleARN:</b> ARN of the Amazon EKS worker nodes IAM role</li></ul></li></ol>	AWS DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <b>EKSWorkerNodeRoleName:</b> Name of the IAM role assigned to the Amazon EKS worker nodes</li><li>• <b>EcrDockerRepository:</b> Name of Amazon ECR repo where the Docker images of your code will be stored</li><li>• <b>EmailRecipient:</b> Email address where build notifications need to be sent</li><li>• <b>EnvType:</b> Environment (for example, dev, test, or prod)</li><li>• <b>SourceRepoName:</b> Name of the CodeCommit repo, where your code resides</li></ul> <ol style="list-style-type: none"><li>4. Choose <b>Next</b>. Use the default settings in <b>Configure stack options</b>, and then choose <b>Next</b>.</li><li>5. In the <b>Review</b> section, verify the AWS CloudFormation template and stack details, and then choose <b>Next</b>.</li><li>6. Choose <b>Create stack</b>.</li><li>7. During the CloudFormation stack deployment, the owner of the email address</li></ol>	

Task	Description	Skills required
	<p>that you provided in the parameters will receive a message to subscribe to an SNS topic. To subscribe to Amazon SNS, the owner must choose the link in the message.</p> <p>8. After the stack is created, open the <b>Outputs</b> tab of the stack, and then record the ARN value for the <code>EksCodeBuildkuberoleARN</code> output key. This IAM ARN value will be required later for providing the CodeBuild IAM role with permissions to deploy workloads in the Amazon EKS cluster.</p>	

### Activate integration between Security Hub and Aqua Security

Task	Description	Skills required
Turn on Aqua Security integration.	This step is required for uploading the Docker image vulnerability findings reported by Trivy to Security Hub. Because AWS CloudFormation doesn't support Security Hub integrations, this process must be done manually.	AWS administrator, DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>1. Open the <b>AWS Security Hub</b> console, and navigate to <b>Integrations</b>.</li> <li>2. Search for Aqua Security, and select <b>Aqua Security: Aqua Security</b>.</li> <li>3. Choose <b>Accept findings</b>.</li> </ol>	

### Configure CodeBuild to run Helm or kubectl commands

Task	Description	Skills required
Allow CodeBuild to run Helm or kubectl commands in the Amazon EKS cluster.	<p>For CodeBuild to be authenticated to use Helm or kubectl commands with the EKS cluster, you must add the IAM roles to the aws-auth ConfigMap. In this case, add the ARN of IAM role EksCodeBuildkubernetesRole, which is the IAM role created for the CodeBuild service to access the EKS cluster and deploy workloads on it. This is a one-time activity.</p> <p><b>Important:</b> The following procedure must be completed before the deployment approval stage in CodePipeline.</p>	DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 987 485">1. Open the <code>cf_templates/kube_aws_auth_configmap_patch.sh</code> shell script in your Amazon Linux or macOS environment.</li><li data-bbox="592 510 964 684">2. Authenticate to the Amazon EKS cluster by running the following command. <pre data-bbox="634 722 1029 921">aws eks --region &lt;aws-region&gt; update-kubeconfig --name &lt;eks-cluster-name&gt;</pre></li><li data-bbox="592 940 1013 1356">3. Run the shell script by using the following command, replacing <code>&lt;rolearn-eks-codebuild-kubect1&gt;</code> with the ARN value of <code>EksCodeBuildkubernetesRoleARN</code> that you recorded earlier. <pre data-bbox="634 1394 1029 1633">bash cf_templates/kube_aws_auth_configmap_patch.sh &lt;rolearn-eks-codebuild-kubect1&gt;</pre></li></ol> <p data-bbox="592 1703 1008 1833">The <code>aws_auth</code> ConfigMap is configured, and access is granted.</p>	

## Validate the CI/CD pipeline

Task	Description	Skills required
<p>Verify that the CI/CD pipeline automatically initiates.</p>	<p>1. The CodeSecurity Scan stage in the pipeline will usually fail if Checkov detects vulnerabilities in the Dockerfile or Helm charts. However, the purpose of this example is to establish a process of identifying potential security vulnerabilities rather than fixing it through the CI/CD pipeline, typically a DevSecOps process. In the file <code>buildspec/buildspec_secscan.yaml</code>, the checkov command uses the <code>--soft-fail</code> flag to avoid pipeline failure.</p> <pre data-bbox="630 1310 1029 1885"> - echo -e "\n Running Dockerfile Scan" - checkov -f code/app/Dockerfile --framework dockerfile --soft- fail --summary- position bottom - echo -e "\n Running Scan of Helm Chart files" - cp -pv helm_charts/\$EKS_C </pre>	<p>DevOps</p>

Task	Description	Skills required
	<pre data-bbox="646 212 977 800"> ODEBUILD_APP_NAME/ values.dev.yaml helm_charts/\$EKS_C ODEBUILD_APP_NAME/ values.yaml - checkov -d helm_charts/\$EKS_C ODEBUILD_APP_NAME --framework helm -- soft-fail --summary- position bottom - rm -rfv helm_charts/\$EKS_C ODEBUILD_APP_NAME/ values.yaml </pre> <p data-bbox="630 863 1029 1419">For the pipeline to fail when vulnerabilities are reported for the Dockerfile and Helm charts, the <code>--soft-fail</code> option must be removed from the checkov command. Developers or engineers can then fix the vulnerabilities and commit the changes to the CodeCommit source code repository.</p> <p data-bbox="592 1444 1003 1854">2. Similar to CodeSecurity Scan, the Build stage uses Aqua Security Trivy for identifying HIGH and CRITICAL Docker image vulnerabilities before pushing the application to Amazon ECR. In this example, we are</p>	

Task	Description	Skills required
	<p>not making pipeline fail for Docker image vulnerabilities. In the file <code>buildspec/buildspec.yml</code>, the <code>trivy</code> command includes the flag <code>--exit-code</code> with a value <code>0</code>, which is why pipeline doesn't fail when HIGH or CRITICAL Docker image vulnerabilities are reported.</p> <pre data-bbox="630 810 1029 1604"> - AWS_REGION= \$AWS_DEFAULT_REGION AWS_ACCOUNT_ID=\$AWS_ACCOUNT_ID trivy - d image --no-progress --ignore-unfixed -- exit-code 0 --severit y HIGH,CRITICAL -- format template -- template "@securit yhub/asff.tpl" -o securityhub/report .asff \$AWS_ACCO UNT_ID.dkr.ecr.\$AW S_DEFAULT_REGION.a mazonaws.com/\$IMAG E_REPO_NAME:\$CODEB UILD_RESOLVED_SOUR CE_VERSION </pre> <p>For the pipeline to fail when HIGH, CRITICAL vulnerabilities are reported, change the value of <code>--exit-code</code> to <code>1</code>.</p>	

Task	Description	Skills required
	<p>Developers or engineers can then fix the vulnerabilities and commit the changes to the CodeCommit source code repository.</p> <p>3. Docker image vulnerabilities reported by Aqua Security Trivy are uploaded to <b>Security Hub</b>. On the AWS Security Hub console, navigate to <b>Findings</b>. Filter the findings with <b>Record State = Active</b> and <b>Product = Aqua Security</b>. This will list the Docker image vulnerabilities in Security Hub. It can take 15 minutes–1 hour for vulnerabilities to appear on Security Hub.</p> <p>For more information about starting the pipeline by using CodePipeline, see <a href="#">Start a pipeline in CodePipeline</a>, <a href="#">Start a pipeline manually</a>, and <a href="#">Start a pipeline on a schedule</a> in the AWS CodePipeline documentation.</p>	

Task	Description	Skills required
Approve the deployment.	<ol style="list-style-type: none"><li data-bbox="592 226 1026 787">1. After the build phase is complete, there is a deployment approval gate. The reviewer or a release manager should inspect the build and, if all requirements are met, approve it. This is the recommended approach for teams that use continuous delivery for application deployment.</li><li data-bbox="592 808 1026 892">2. After approval, the pipeline initiates the Deploy stage.</li><li data-bbox="592 913 1026 1228">3. After the Deploy stage is successful, the CodeBuild log for this stage provides the URL of the application. Use the URL to validate the readiness of the application.</li></ol>	DevOps

Task	Description	Skills required
Validate application profiling.	<p>After the deployment is complete and the application pod is deployed in Amazon EKS, the Amazon CodeGuru Profiler agent configured in the application will try to send profiling data of the application (CPU, heap summary, latency, and bottlenecks) to Amazon CodeGuru Profiler.</p> <p>For the initial deployment of an application, Amazon CodeGuru Profiler takes about 15 minutes to visualize the profiling data.</p>	AWS DevOps

## Related resources

- [AWS CodePipeline documentation](#)
- [Scanning images with Trivy in an AWS CodePipeline](#) (blog post)
- [Improving your Java applications using Amazon CodeGuru Profiler](#) (blog post)
- [AWS Security Finding Format \(ASFF\) syntax](#)
- [Amazon EventBridge event patterns](#)
- [Helm upgrade](#)

## Additional information

CodeGuru Profiler should not be confused with the AWS X-Ray service in terms of functionality. CodeGuru Profiler is preferred for identifying the most expensive lines of codes, which might cause bottlenecks or security issues, and fix them before they become a potential risk. AWS X-Ray service is for application performance monitoring.

In this pattern, event rules are associated with the default event bus. If needed, you can extend the pattern to use a custom event bus.

This pattern uses CodeGuru Reviewer as a static application security testing (SAST) tool for application code. You can also use this pipeline for other tools, such as SonarQube or Checkmarx. The corresponding scan setup instructions of any of these tools can be added in `buildspec/buildspec_secscan.yaml`, replacing the scan instructions of CodeGuru.

# Create an Amazon ECS task definition and mount a file system on EC2 instances using Amazon EFS

*Created by Durga Prasad Cheepuri (AWS)*

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; CloudNative; Management & governance; Storage & backup; Web & mobile apps

**AWS services:** Amazon ECS; Amazon EFS

## Summary

This pattern provides code samples and steps to create an Amazon Elastic Container Service (Amazon ECS) task definition that runs on Amazon Elastic Compute Cloud (Amazon EC2) instances in the Amazon Web Services (AWS) Cloud, while using Amazon Elastic File System (Amazon EFS) to mount a file system on those EC2 instances. Amazon ECS tasks that use Amazon EFS automatically mount the file systems that you specify in the task definition and make these file systems available to the task's containers across all Availability Zones in an AWS Region.

To meet your persistent storage and shared storage requirements, you can use Amazon ECS and Amazon EFS together. For example, you can use Amazon EFS to store persistent user data and application data for your applications with active and standby ECS container pairs running in different Availability Zones for high availability. You can also use Amazon EFS to store shared data that can be accessed in parallel by ECS containers and distributed job workloads.

To use Amazon EFS with Amazon ECS, you can add one or more volume definitions to a task definition. A volume definition includes an Amazon EFS file system ID, access point ID, and a configuration for AWS Identity and Access Management (IAM) authorization or Transport Layer Security (TLS) encryption in transit. You can use container definitions within task definitions to specify the task definition volumes that get mounted when the container runs. When a task that uses an Amazon EFS file system runs, Amazon ECS ensures that the file system is mounted and available to the containers that need access to it.

## Prerequisites and limitations

### Prerequisites

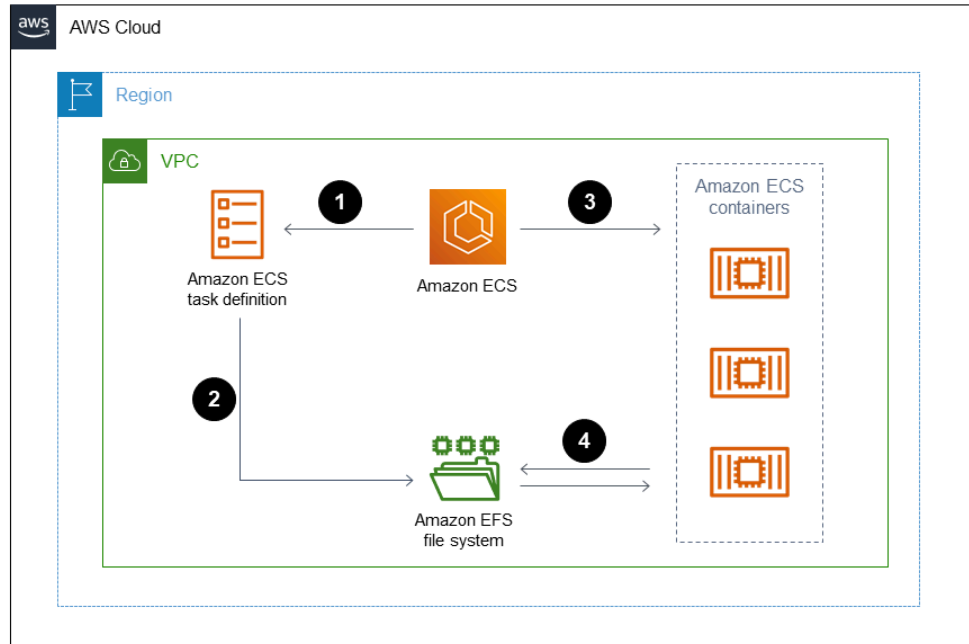

- An active AWS account
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router
- (Recommended) [Amazon ECS container agent 1.38.0 or later](#) for compatibility with Amazon EFS access points and IAM authorization features (For more information, see the AWS blog post [New for Amazon EFS – IAM Authorization and Access Points.](#))

### Limitations

- Amazon ECS container agent versions earlier than 1.35.0 don't support Amazon EFS file systems for tasks that use the EC2 launch type.

## Architecture

The following diagram shows an example of an application that uses Amazon ECS to create a task definition and mount an Amazon EFS file system on EC2 instances in ECS containers.

The diagram shows the following workflow:

1. Create an Amazon EFS file system.
2. Create a task definition with a container.
3. Configure the container instances to mount the Amazon EFS file system. The task definition references the volume mounts, so the container instance can use the Amazon EFS file system. ECS tasks have access to the same Amazon EFS file system, regardless of which container instance those tasks are created on.
4. Create an Amazon ECS service with three instances of the task definition.

### Technology stack

- Amazon EC2
- Amazon ECS
- Amazon EFS

## Tools

- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- [Amazon ECS](#) – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of EC2 instances that you manage.
- [Amazon EFS](#) – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- [AWS CLI](#) – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

## Epics

### Create an Amazon EFS file system

Task	Description	Skills required
Create an Amazon EFS file system by using the AWS Management Console.	<ol style="list-style-type: none"><li>1. <a href="#">Create an Amazon EFS file system</a> and choose the VPC that includes your containers. <b>Note:</b> If you use a different VPC, <a href="#">set up a VPC peering connection</a>.</li><li>2. Note the file system ID.</li></ol>	AWS DevOps

**Create an Amazon ECS task definition by using either an Amazon EFS file system or the AWS CLI**

Task	Description	Skills required
Create a task definition using an Amazon EFS file system.	<p>Create a task definition by using the <a href="#">new Amazon ECS console</a> or <a href="#">classic Amazon ECS console</a> with the following configurations:</p> <ul style="list-style-type: none"><li>• If you use the new console, choose <b>Amazon EC2 instances</b> for <b>App environment</b>. If you use the classic console, choose <b>EC2</b> as the launch type.</li><li>• Add a volume. Enter a name for the volume, choose <b>EFS</b> for volume type, and then choose the file system ID that you noted earlier. For the root directory, choose the Amazon EFS file system path that you want to host on the Amazon ECS container host.</li></ul>	AWS DevOps
Create a task definition using the AWS CLI.	<p>1. To create a JSON template with input parameter placeholders for your task definition, run the following command:</p> <pre>aws ecs register-task-definition</pre>	AWS DevOps

Task	Description	Skills required
	<pre data-bbox="634 205 1027 306">--generate-cli-skeleton</pre> <p data-bbox="594 321 1027 499">2. To create the task definition with the JSON template, run the following command:</p> <pre data-bbox="634 537 1027 772">aws ecs register-task-definition --cli-input-json file://&lt;path_to_your_json_file&gt;</pre> <p data-bbox="594 789 1027 1398">3. Enter the input parameters in your JSON template based on the <code>task_definition_parameters.json</code> file (attached). <b>Note:</b> For more information on input parameters, see <a href="#">Task definition parameters</a> (Amazon ECS documentation) and <a href="#">register-task-definition</a> (AWS CLI Command Reference).</p>

# Deploy Java microservices on Amazon ECS using AWS Fargate

Created by Vijay Thompson (AWS) and Sandeep Bondugula (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Containers	<b>Target:</b> Amazon ECS
<b>R Type:</b> N/A	<b>Technologies:</b> Containers & microservices; Web & mobile apps	<b>AWS services:</b> Amazon ECS

## Summary

This pattern provides guidance for deploying containerized Java microservices on Amazon Elastic Container Service (Amazon ECS) by using AWS Fargate. The pattern doesn't use Amazon Elastic Container Registry (Amazon ECR) for container management; instead, Docker images are pulled in from a Docker hub.

## Prerequisites and limitations

### Prerequisites

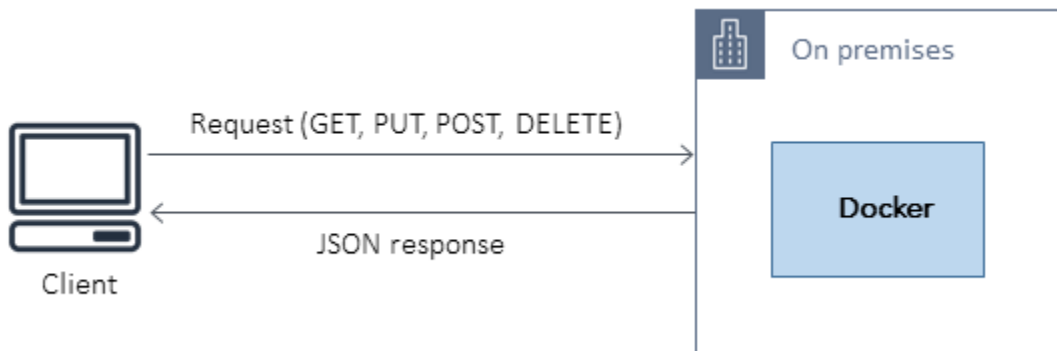

- An existing Java microservices application on a Docker hub
- A public Docker repository
- An active AWS account
- Familiarity with AWS services, including Amazon ECS and Fargate
- Docker, Java, and Spring Boot framework
- Amazon Relational Database Service (Amazon RDS) up and running (optional)
- A virtual private cloud (VPC) if the application requires Amazon RDS (optional)

## Architecture

### Source technology stack

- Java microservices (for example, implemented in Spring Boot) and deployed on Docker

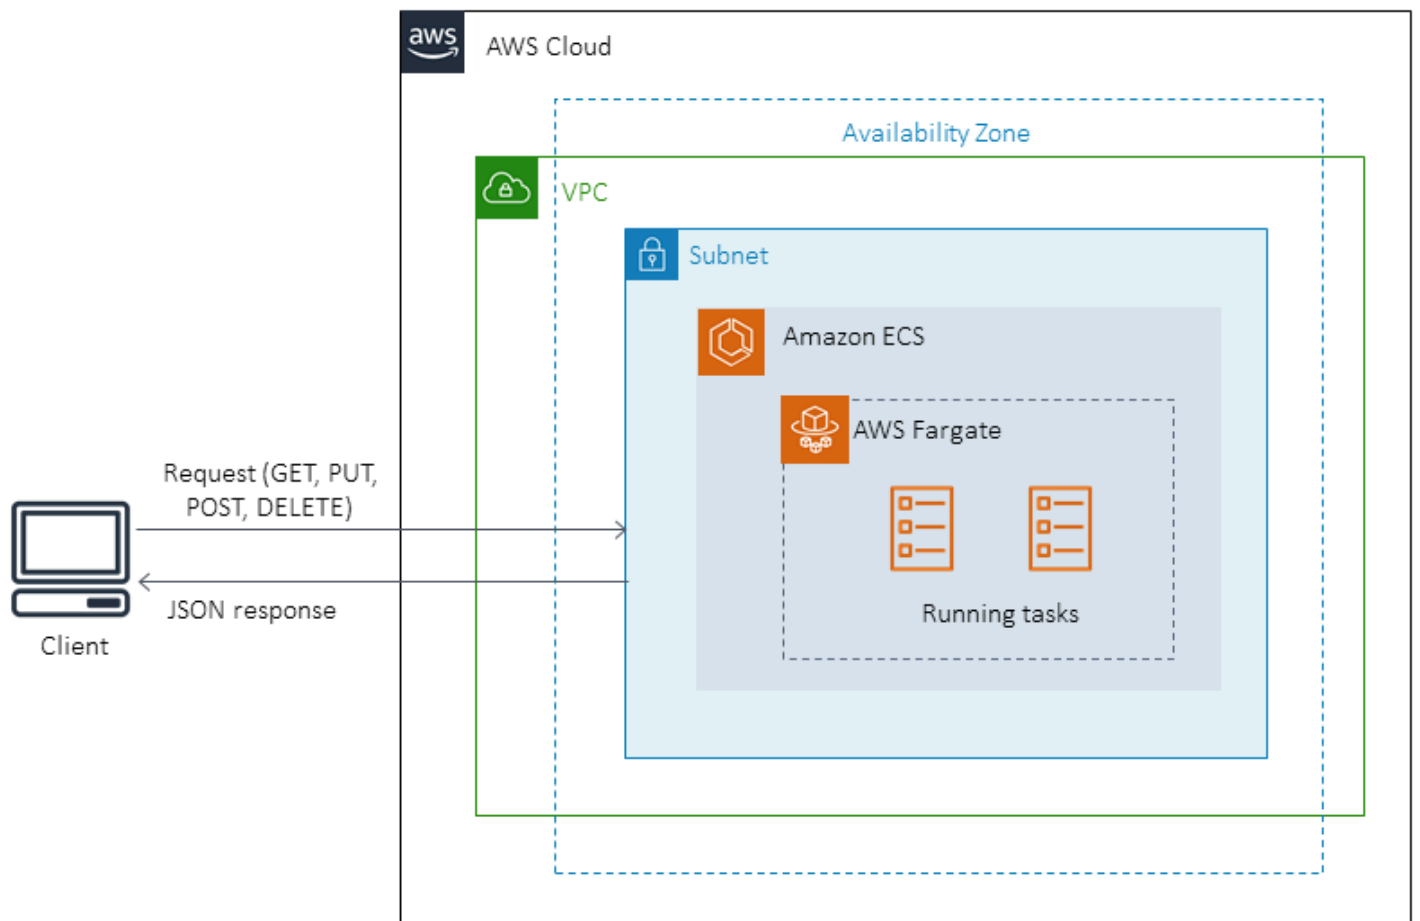

## Source architecture

## Target technology stack

- An Amazon ECS cluster that hosts each microservice by using Fargate
- A VPC network to host the Amazon ECS cluster and associated security groups
- A cluster/task definition for each microservice that spins up containers by using Fargate

## Target architecture

## Tools

### Tools

- [Amazon ECS](#) eliminates the need to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.
- [AWS Fargate](#) helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- [Docker](#) is a software platform that allows you to build, test, and deploy applications quickly. Docker packages software into standardized units called *containers* that have everything the software needs to run, including libraries, system tools, code, and runtime.

### Docker code

The following Dockerfile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```
FROM openjdk:11
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java", "-jar", "Spring-docker.jar"]
```

## Epics

### Create new task definitions

Task	Description	Skills required
Create a task definition.	Running a Docker container in Amazon ECS requires a task definition. Open the Amazon ECS console at <a href="https://console.aws.amazon.com/ecs/">https://console.aws.amazon.com/ecs/</a> , choose <b>Task definitions</b> , and then create a new task definition. For more information, see the <a href="#">Amazon ECS documentation</a> .	AWS systems administrator, App developer
Choose launch type.	Choose <b>Fargate</b> as the launch type.	AWS systems administrator, App developer
Configure the task.	Define a task name and configure the application with the appropriate amount of task memory and CPU.	AWS systems administrator, App developer
Define the container.	Specify the container name. For the image, enter the Docker site name, the repository name, and the tag	AWS systems administrator, App developer

Task	Description	Skills required
	name of the Docker image (docker.io/sample-repo/sample-application:sample-tag-name ). Set memory limits for the application, and set port mappings (8080, 80) for the allowed ports.	
Create the task.	When the task and container configurations are in place, create the task. For detailed instructions, see the links in the <i>Related resources</i> section.	AWS systems administrator, App developer

## Configure the cluster

Task	Description	Skills required
Create and configure a cluster.	Choose <b>Networking only</b> as the cluster type, configure the name, and then create the cluster or use an existing cluster if available. For more information, see the <a href="#">Amazon ECS documentation</a> .	AWS systems administrator, App developer

## Configure Task

Task	Description	Skills required
Create a task.	Inside the cluster, choose <b>Run new task</b> .	AWS systems administrator, App developer

Task	Description	Skills required
Choose launch type.	Choose <b>Fargate</b> as the launch type.	AWS systems administrator, App developer
Choose task definition, revision, and platform version.	Choose the task that you want to run, the revision of the task definition, and the platform version.	AWS systems administrator, App developer
Select the cluster.	Choose the cluster where you want to run the task from.	AWS systems administrator, App developer
Specify the number of tasks.	Configure the number of tasks that should run. If you're launching with two or more tasks, a load balancer is required to distribute the traffic among the tasks.	AWS systems administrator, App developer
Specify the task group.	(Optional) Specify a task group name to identify a set of related tasks as a task group.	AWS systems administrator, App developer
Configure the cluster VPC, subnets, and security groups.	Configure the cluster VPC and the subnets on which you want to deploy the application. Create or update security groups (HTTP, HTTPS, and port 8080) to provide access to inbound and outbound connections.	AWS systems administrator, App developer

Task	Description	Skills required
Configure public IP settings.	Enable or disable the public IP, depending on whether you want to use a public IP address for Fargate tasks. The default, recommended option is <b>Enabled</b> .	AWS systems administrator, App developer
Review settings and create the task	Review your settings, and then choose <b>Run Task</b> .	AWS systems administrator, App developer

## Cut over

Task	Description	Skills required
Copy the application URL.	When the task status has been updated to <i>Running</i> , select the task. In the Networking section, copy the public IP.	AWS systems administrator, App developer
Test your application.	In your browser, enter the public IP to test the application.	AWS systems administrator, App developer

# Deploy Java microservices on Amazon ECS using Amazon ECR and AWS Fargate

Created by Vijay Thompson (AWS) and Sandeep Bondugula (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Containers	<b>Target:</b> Amazon ECS
<b>R Type:</b> N/A	<b>Technologies:</b> Containers & microservices; Web & mobile apps	<b>AWS services:</b> Amazon ECS

## Summary

This pattern guides you through the steps for deploying Java microservices as containerized applications in Amazon Elastic Container Service (Amazon ECS). The pattern also uses Amazon Elastic Container Registry (Amazon ECR) to manage your container, and AWS Fargate to run your container.

## Prerequisites and limitations

### Prerequisites

- An existing Java microservices application running on premises on Docker
- An active AWS account
- Familiarity with Amazon ECR, Amazon ECS, AWS Fargate, and AWS Command Line Interface (AWS CLI)
- Familiarity with Java and Docker software

### Product versions

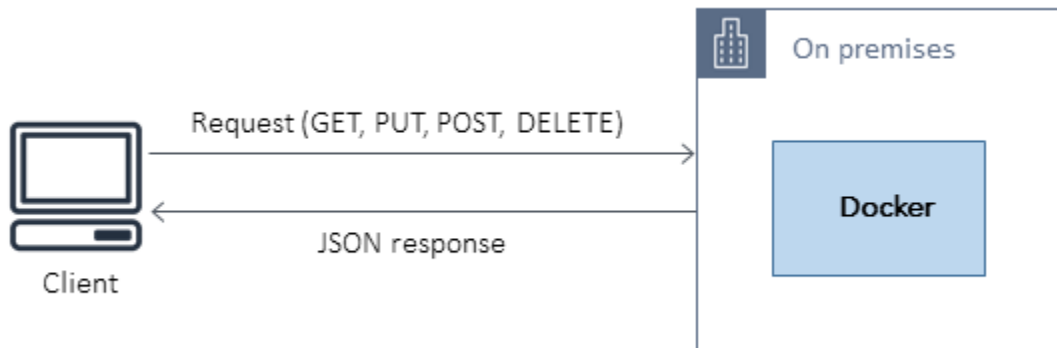

- AWS CLI version 1.7 or later

## Architecture

### Source technology stack

- Java microservices (for example, developed using Spring Boot) and deployed on premises
- Docker

### Source architecture

### Target technology stack

- Amazon ECR
- Amazon ECS
- AWS Fargate

### Target architecture

## Tools

### Tools

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and

operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.

- [AWS Fargate](#) is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.
- [Docker](#) is a platform that lets you build, test, and deliver applications in packages called containers.

## Code

The following DockerFile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```
FROM openjdk:8
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java", "-jar", "Spring-docker.jar"]
```

## Epics

### Create an Amazon ECR repository

Task	Description	Skills required
Create a repository.	Sign in to the AWS Management Console, and open the Amazon ECR console at <a href="https://console.aws.amazon.com/ecr/repositories">https://console.aws.amazon.com/ecr/repositories</a> . Create a private repository. For instructions, see <a href="#">Creating a private repository</a> in the Amazon ECR documentation.	Developer, System Admin

Task	Description	Skills required
Upload the project.	Open the repository and choose <b>View push commands</b> . Follow the steps displayed to upload the project. (These steps work only when you use AWS CLI version 1.7 or later.) When the upload is complete, copy the URL of the build in the repository. You will use this URL when you create a container in Amazon ECS.	Developer, System Admin

## Create and spin up the container

Task	Description	Skills required
Create a task definition.	Running a Docker container in Amazon ECS requires a task definition. Open the Amazon ECS console at <a href="https://console.aws.amazon.com/ecs/">https://console.aws.amazon.com/ecs/</a> , choose <b>Task definitions</b> , and create a new task definition. For more information, see <a href="#">Creating a task definition</a> in the Amazon ECS documentation.	Developer, System Admin
Choose the launch type.	Choose Fargate as the launch type.	Developer, System Admin
Configure the task.	Define a task name and configure the application with	Developer, System Admin

Task	Description	Skills required
	the appropriate amount of task memory and CPU.	
Define the container.	Add the container, providing a name, the URL of the Amazon ECR repository, memory limits, and port mapping. Ports 8080 and 80 are configured for port mappings. Configure the remaining settings based on your application requirements.	Developer, System Admin
Create the task.	When the task and container configurations are in place, create the task. For detailed instructions, see the links in the <a href="#">Related resources</a> section.	Developer, System Admin

## Create an Amazon ECS cluster and configure a service

Task	Description	Skills required
Create or choose a cluster.	An Amazon ECS cluster provides a logical grouping of tasks or services. You can opt to use an existing cluster or create a new cluster. If you decide to create a new cluster, choose the cluster type based on your requirements. In our example, we selected a networking cluster. Provide a name for the cluster and	Developer, System Admin

Task	Description	Skills required
	choose whether you want to create a new virtual private cloud (VPC) to use for Fargate tasks.	
Create a service.	Inside the cluster, choose <b>Create service</b> .	Developer, System Admin
Choose the launch type.	Choose Fargate as the launch type.	Developer, System Admin
Choose task definition, revision, and platform version.	Choose the task that you want to run, followed by the revision of the task definition and the platform version.	Developer, System Admin
Select the cluster.	Select the cluster in which to create your service from the dropdown list.	Developer, System Admin
Provide a service name.	Provide a unique name for the service that you are creating.	Developer, System Admin
Specify the number of tasks.	Configure the number of tasks that should run when the service launches. If you're launching with two or more tasks, a load balancer is required to balance the tasks. The minimum number of tasks to be configured is <b>One</b> .	Developer, System Admin

Task	Description	Skills required
Set the minimum and maximum healthy percentages.	Configure the minimum and maximum healthy percentages for the application, or accept the default option that is provided.	Developer, System Admin
Configure deployment settings.	Choose the deployment type based on your requirements. You can choose a rolling update or a blue/green deployment.	Developer, System Admin
Configure the cluster VPC, subnets, and security groups.	Configure the cluster VPC, the subnets on which you want to deploy the application, and the security groups (HTTP, HTTPS, and port 8080) for providing access to inbound/outbound connections.	Developer, System Admin
Configure public IP settings.	Enable or disable the public IP, depending on whether you want to use a public IP address for Fargate tasks.	Developer, System Admin
Configure load balancing.	Configure the load balancer, if you're launching the service with more than one task. You must create a load balancer and its target group before you launch the service.	Developer, System Admin

Task	Description	Skills required
Configure automatic scaling.	Configure your service to use Amazon ECS Service Auto Scaling to adjust the desired number of tasks up or down, depending on your requirements.	Developer, System Admin
Review settings and create the service.	Review your service settings, and then choose <b>Create service</b> .	Developer, System Admin

## Cut over

Task	Description	Skills required
Test your application.	Test the application by using the public DNS that's created when the task is deployed. If the application has a load balancer, test the application by using it and then cut over.	Developer, System Admin

# Deploy Java microservices on Amazon ECS using Amazon ECR and load balancing

Created by Durga Prasad Cheepuri (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Java	<b>Target:</b> Amazon ECS
<b>R Type:</b> N/A	<b>Technologies:</b> Containers & microservices; Web & mobile apps	<b>AWS services:</b> Amazon ECS

## Summary

This pattern outlines steps for deploying a containerized Java microservices architecture on Amazon Elastic Container Service (Amazon ECS) to make it easier to scale and faster to develop your applications. This helps enable innovation and accelerates time-to-market for new features.

The pattern also uses Amazon Elastic Container Registry (Amazon ECR) to store and manage the Docker-based containers, and an AWS CloudFormation template with a Python script to automate the setup of your infrastructure. The pattern is based on the post [Deploying Java Microservices on Amazon Elastic Container Service](#), which is published on the AWS Compute blog.

Microservices provide an architectural and organizational approach to software development, where software is composed of small, independent services that communicate over well-defined application programming interfaces (APIs). Small, self-contained teams own these services.

Amazon ECS is a highly scalable, high-performance container orchestration service. It supports Docker containers and enables you to run and scale containerized applications on AWS quickly. With Amazon ECS, you no longer have to install and operate your container orchestration software, manage and scale a cluster of virtual machines (VMs), or schedule containers on those VMs.

With simple API calls, you can launch and stop Docker-enabled applications, query the complete state of your request, and access many natural features, such as AWS Identity and Access Management (IAM) roles, security groups, load balancers, Amazon CloudWatch Events, AWS CloudFormation templates, and AWS CloudTrail logs.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Java microservices source code, with Java Development Kit version 1.7 or later
- An access key and secret access key for a user in the account
- AWS Command Line Interface (AWS CLI)
- Java, AWS Software Development Kit (SDK) for Python (Boto3), and Docker software
- Familiarity with the use of the preceding technologies
- Familiarity with AWS services such as Amazon ECS, AWS CloudFormation, and Elastic Load Balancing

## Architecture

### Source technology stack

- Microservices implemented in Java and deployed on Apache Tomcat in an on-premises environment

### Target technology stack

- The Application Load Balancer that inspects the client request. Based on routing rules, the load balancer directs the request to an instance and port from the target group that matches the state.
- A target group for each microservice. The target groups are used by the corresponding services to register available container instances. Each target group has a path, so when you call the way for a particular microservice, it maps to the correct target group. This enables you to use one Application Load Balancer to serve all the microservices, accessed by the path. For example, `https:///owner/*` would map and direct to the Owner microservice.
- An Amazon ECS cluster that hosts the containers for each microservice.
- An Amazon Virtual Private Cloud (Amazon VPC) network for hosting the Amazon ECS cluster and associated security groups.
- An Amazon Elastic Container Registry (Amazon ECR) repository for each microservice.

- A service or task definition for each microservice, which spins up containers on the instances of the Amazon ECS cluster.

### Target architecture

## Tools

- [Amazon ECS](#) – Amazon ECS lets you launch and stop container-based applications with simple API calls, enables you to get the state of your cluster from a centralized service, and gives you access to many familiar Amazon Elastic Compute Cloud (Amazon EC2) features.
- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

## Epics

### Create an AWS CloudFormation template to set up an Amazon ECS cluster to host the Java microservices

Task	Description	Skills required
Provision an Amazon EC2 Linux instance, install Docker, and create a Docker file for each microservice.		Ops
Set up Docker images on Amazon ECR.	Use the Dockerfile for the image to push, build the image, and tag it for your new repository. Do the same for each microservice. Push the newly tagged images to the repository.	Ops
Create an AWS CloudFormation template.	Create an AWS CloudFormation template to provision the virtual private cloud (VPC), Amazon ECS cluster, and Amazon Relational	Ops

Task	Description	Skills required
	Database Service (Amazon RDS).	

## Provision AWS services

Task	Description	Skills required
Create the AWS infrastructure by using the CloudFormation template you created earlier.	Use the Python script at <a href="https://github.com/awslabs/amazon-ecs-java-microservices/blob/master/2_ECS_Java_Spring_PetClinic_Microservices/setup.py">https://github.com/awslabs/amazon-ecs-java-microservices/blob/master/2_ECS_Java_Spring_PetClinic_Microservices/setup.py</a> to invoke the AWS CloudFormation template you created earlier. This template creates the AWS infrastructure you need for the target environment.	Ops
Create Amazon ECR repositories, tasks, services, the Application Load Balancer, and target groups.	The Python script reads the outputs of the AWS CloudFormation template and uses BOTO3 API calls to create Amazon ECR repositories, tasks, services, the Application Load Balancer, and target groups.	Ops

# Deploy Kubernetes resources and packages using Amazon EKS and a Helm chart repository in Amazon S3

*Created by Sagar Panigrahi (AWS)*

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; DevOps

**AWS services:** Amazon EKS

## Summary

This pattern helps you to manage Kubernetes applications efficiently, regardless of their complexity. The pattern integrates Helm into your existing continuous integration and continuous delivery (CI/CD) pipelines to deploy applications into a Kubernetes cluster. Helm is a Kubernetes package manager that helps you manage Kubernetes applications. Helm charts help to define, install, and upgrade complex Kubernetes applications. Charts can be versioned and stored in Helm repositories, which improves mean time to restore (MTTR) during outages.

This pattern uses Amazon Elastic Kubernetes Service (Amazon EKS) for the Kubernetes cluster. It uses Amazon Simple Storage Service (Amazon S3) as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account with a virtual private cloud (VPC)
- An Amazon EKS cluster
- Worker nodes set up within the Amazon EKS cluster and ready to take workloads
- Kubectl for configuring the Amazon EKS kubeconfig file for the target cluster in the client machine
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatically or role) access to Amazon S3 from the client machine
- Source code management and a CI/CD pipeline

## Limitations

- There is no support at this time for upgrading, deleting, or managing custom resource definitions (CRDs).
- If you are using a resource that refers to a CRD, the CRD must be installed separately (outside of the chart).

## Product versions

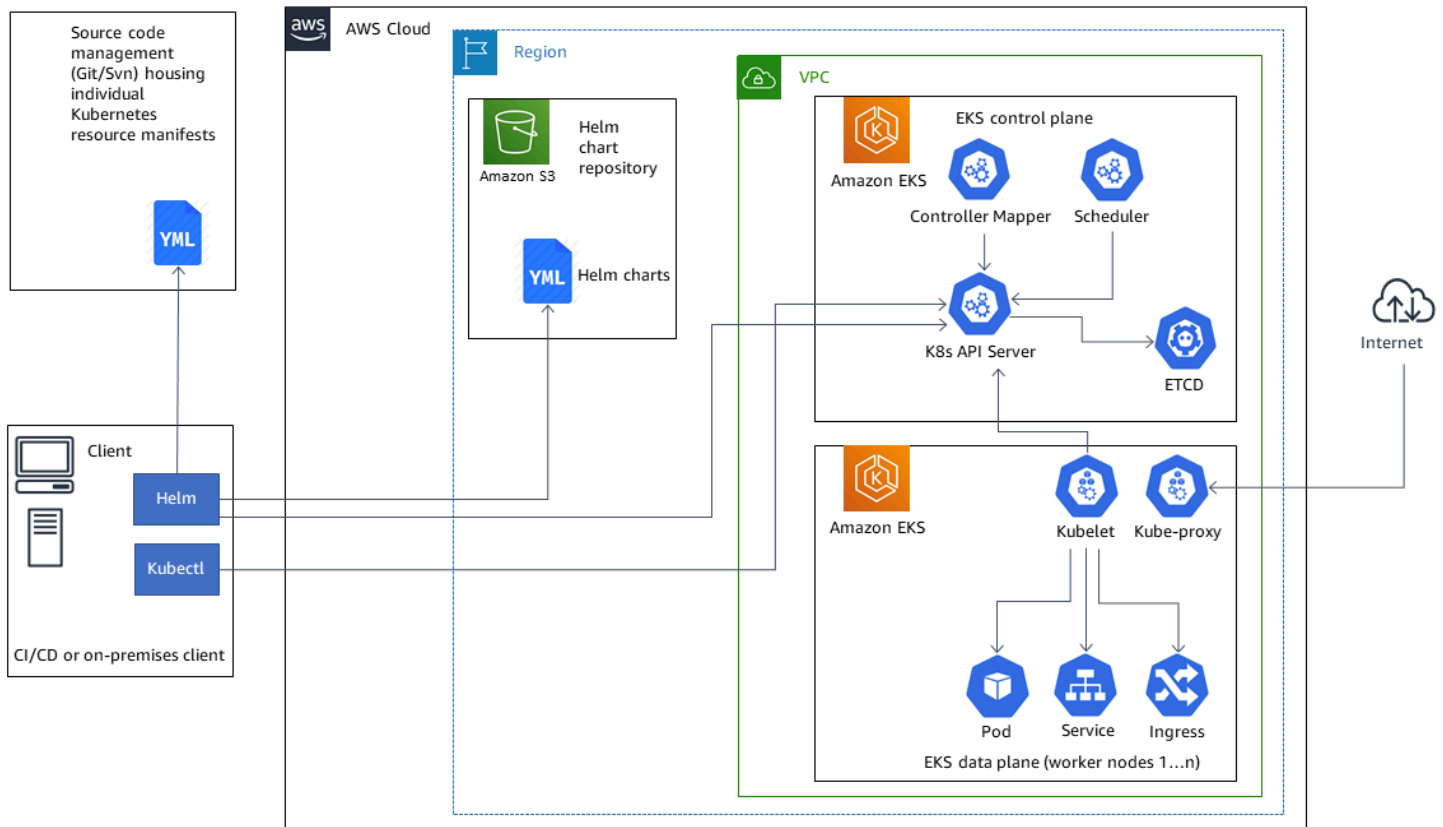

- Helm v3.6.3

## Architecture

### Target technology stack

- Amazon EKS
- Amazon VPC
- Amazon S3
- Source code management
- Helm
- Kubectl

### Target architecture

## Automation and scale

- AWS CloudFormation can be used to automate the infrastructure creation. For more information, see [Creating Amazon EKS resources with AWS CloudFormation](#) in the Amazon EKS documentation.
- Helm is to be incorporated into your existing CI/CD automation tool to automate the packaging and versioning of Helm charts (out of scope for this pattern).
- GitVersion or Jenkins build numbers can be used to automate the versioning of charts.

## Tools

### Tools

- [Amazon EKS](#) – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

- [Helm](#) – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- [Kubectl](#) – Kubectl is a command line utility for running commands against Kubernetes clusters.

## Code

The example code is attached.

## Epics

### Configure and initialize Helm

Task	Description	Skills required
Install the Helm client.	To download and install the Helm client on your local system, use the following command. <pre>sudo curl https://raw.githubusercontent.com/helm/helm/master/scripts/get-helm-3   bash</pre>	DevOps engineer
Validate the Helm installation.	To validate that Helm is able to communicate with the Kubernetes API server within the Amazon EKS cluster, run <code>helm version</code> .	DevOps engineer

## Create and install a Helm chart in the Amazon EKS cluster

Task	Description	Skills required
Create a Helm chart for NGINX.	To create a helm chart named <code>my-nginx</code> on the client machine, run <code>helm create my-nginx</code> .	DevOps engineer
Review the structure of the chart.	To review the structure of the chart, run the <code>tree</code> command <code>tree my-nginx/</code> .	DevOps engineer
Deactivate service account creation in the chart.	In <code>values.yaml</code> , under the <code>serviceAccount</code> section, set the <code>create</code> key to <code>false</code> . This is turned off because there is no requirement to create a service account for this pattern.	DevOps engineer
Validate (lint) the modified chart for syntactical errors.	To validate the chart for any syntactical error before installing it in the target cluster, run <code>helm lint my-nginx/</code> .	DevOps engineer
Install the chart to deploy Kubernetes resources.	To run the Helm chart installation, use the following command. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>helm install --name my-nginx-release --debug my-nginx/ --namespace helm-space</pre> </div> <p>The optional debug flag outputs all debug messages</p>	DevOps engineer

Task	Description	Skills required
	during the installation. The <code>namespace</code> flag specifies the namespace in which the resources part of this chart will be created.	
Review the resources in the Amazon EKS cluster.	To review the resources that were created as part of the Helm chart in the <code>helm-space</code> namespace, use the following command.  <pre>kubectl get all -n helm-space</pre>	DevOps engineer

## Roll back to a previous version of a Kubernetes application

Task	Description	Skills required
Modify and upgrade the release.	To modify the chart, in <code>values.yaml</code> , change the <code>replicaCount</code> value to 2. Then upgrade the already installed release by running the following command.  <pre>helm upgrade my-nginx-release my-nginx/ --namespace helm-space</pre>	DevOps engineer
Review the history of the Helm release.	To list all the revisions for a specific release that have been installed using Helm, run the following command.	DevOps engineer

Task	Description	Skills required
	<pre>helm history my-nginx-release</pre>	
Review the details for a specific revision.	<p>Before switching or rolling back to a working version, and for an additional layer of validation before installing a revision, view which values were passed to each of the revisions by using the following command.</p> <pre>helm get --revision=2 my-nginx-release</pre>	DevOps engineer
Roll back to a previous version.	<p>To roll back to a previous revision, use the following command.</p> <pre>helm rollback my-nginx-release 1</pre> <p>This example is rolling back to revision number 1.</p>	DevOps engineer

### Initialize an S3 bucket as a Helm repository

Task	Description	Skills required
Create an S3 bucket for Helm charts.	Create a unique S3 bucket. In the bucket, create a folder called <code>charts</code> . The example in this pattern uses <code>s3://my-</code>	Cloud administrator

Task	Description	Skills required
<p>Install the Helm plugin for Amazon S3.</p>	<p>helm-charts/charts as the target chart repository.</p> <p>To install the helm-s3 plugin on your client machine, use the following command.</p> <pre>helm plugin install https://github.com/hypnoglow/helm-s3.git --version 0.10.0</pre> <p>Note: Helm V3 support is available with plugin version 0.9.0 and above.</p>	DevOps engineer
<p>Initialize the Amazon S3 Helm repository.</p>	<p>To initialize the target folder as a Helm repository, use the following command.</p> <pre>helm S3 init s3://my-helm-charts/charts</pre> <p>The command creates an <code>index.yaml</code> file in the target to track all the chart information that is stored at that location.</p>	DevOps engineer

Task	Description	Skills required
Add the Amazon S3 repository to Helm.	<p>To add the repository in the client machine, use the following command.</p> <pre>helm repo add my-helm-charts s3://my-helm-charts/charts</pre> <p>This command adds an alias to the target repository in the Helm client machine.</p>	DevOps engineer
Review the repository list.	To view the list of repositories in the Helm client machine, run <code>helm repo list</code> .	DevOps engineer

### Package and store charts in the Amazon S3 Helm repository

Task	Description	Skills required
Package the chart.	To package the <code>my-nginx</code> chart that you created, run <code>helm package ./my-nginx/</code> . The command packages all the contents of the <code>my-nginx</code> chart folder into an archive file, which is named using the version number that is mentioned in the <code>Chart.yaml</code> file.	DevOps engineer
Store the package in the Amazon S3 Helm repository.	To upload the package to the Helm repository in Amazon S3, run the following	DevOps engineer

Task	Description	Skills required
	<p>command, using the correct name of the <code>.tgz</code> file.</p> <pre>helm s3 push ./my-nginx-0.1.0.tgz my-helm-charts</pre>	
Search for the Helm chart.	<p>To confirm that the chart appears both locally and in the Helm repository in Amazon S3, run the following command.</p> <pre>helm search repo my-nginx</pre>	DevOps engineer

### Modify, version, and package a chart

Task	Description	Skills required
Modify and package the chart.	<p>In <code>values.yaml</code>, set the <code>replicaCount</code> value to 1. Then package the chart by running <code>helm package ./my-nginx/</code>, this time changing the version in <code>Chart.yaml</code> to <code>0.1.1</code>.</p> <p>The versioning is ideally updated through automation using tools such as <code>GitVersion</code> or Jenkins build numbers in a CI/CD pipeline. Automating</p>	DevOps engineer

Task	Description	Skills required
	the version number is out of scope for this pattern.	
Push the new version to the Helm repository in Amazon S3.	To push the new package with version of 0.1.1 to the my-helm-charts Helm repository in Amazon S3, run the following command.  <pre>helm s3 push ./my-nginx-0.1.1.tgz my-helm-charts</pre>	DevOps engineer

### Search for and install a chart from the Amazon S3 Helm repository

Task	Description	Skills required
Search for all versions of the my-nginx chart.	To view all the available versions of a chart, run the following command with the <code>--versions</code> flag.  <pre>helm search repo my-nginx --versions</pre> <p>Without the flag, Helm by default displays the latest uploaded version of a chart.</p>	DevOps engineer
Install a chart from the Amazon S3 Helm repository.	The search results from the previous task show the multiple versions of the my-nginx chart. To install the new version (0.1.1) from the	DevOps engineer

Task	Description	Skills required
	<p>Amazon S3 Helm repository, use the following command.</p> <pre>helm upgrade my-nginx- release my-helm-c harts/my-nginx -- version 0.1.1 --namespa ce helm-space</pre>

# Deploy Lambda functions with container images

Created by Ram Kandaswamy (AWS)

<b>Environment:</b> Production	<b>Technologies:</b> Containers & microservices; CloudNative; DevelopmentAndTesting; Serverless	<b>Workload:</b> All other workloads
<b>AWS services:</b> Amazon EC2 Container Registry; AWS Lambda		

## Summary

AWS Lambda supports container images as a deployment model. This pattern shows how to deploy Lambda functions through container images.

Lambda is a serverless, event-driven compute service that you can use to run code for virtually any type of application or backend service without provisioning or managing servers. With container image support for Lambda functions, you get the benefits of up to 10 GB of storage for your application artifact and the ability to use familiar container image development tools.

The example in this pattern uses Python as the underlying programming language, but you can use other languages, such as Java, Node.js, or Go. The pattern uses AWS CodeCommit as the source, but you could also use GitHub, Bitbucket, or Amazon Simple Storage Service (Amazon S3).

## Prerequisites and limitations

### Prerequisites

- Amazon Elastic Container Registry (Amazon ECR) activated
- Application code
- Docker images with the runtime interface client and the latest version of Python

### Limitations

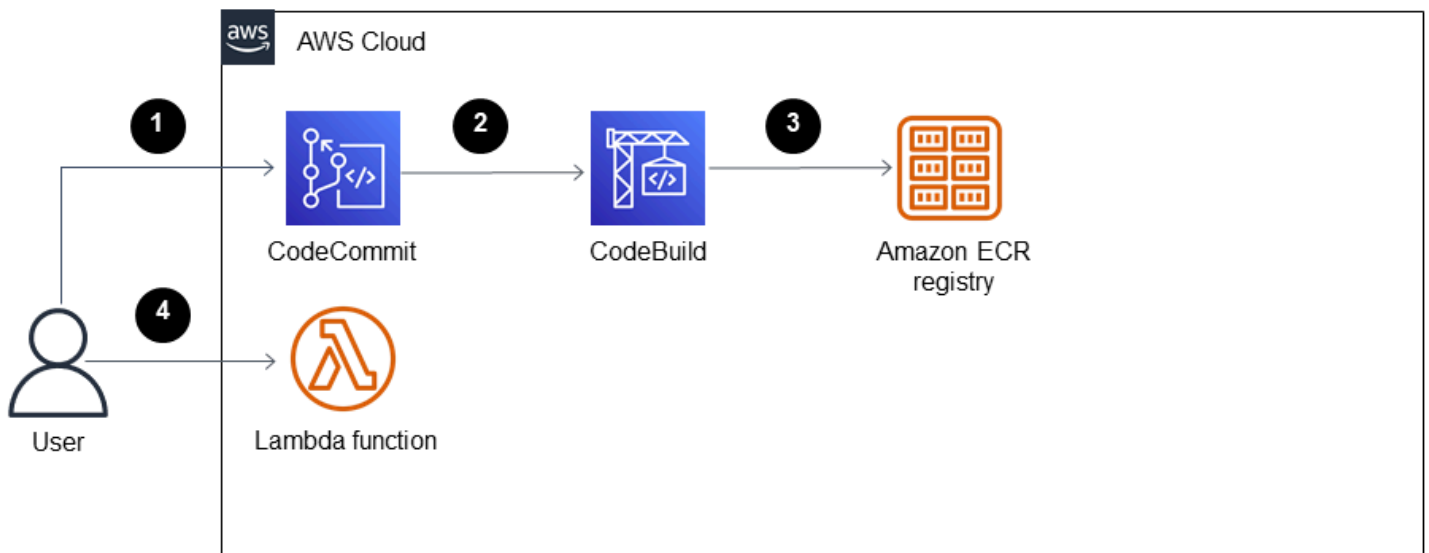

- Maximum image size supported is 10 GB.
- Maximum runtime for a Lambda based container deployment is 15 minutes.

## Architecture

### Target technology stack

- Python programming language
- AWS CodeBuild
- AWS CodeCommit
- Docker image
- Amazon ECR
- AWS Identity and Access Management (IAM)
- AWS Lambda
- Amazon CloudWatch Logs

### Target architecture

1. You create a repository and commit the application code using CodeCommit.
2. The CodeBuild project is initiated when a change is made to CodeCommit, which is used as the source provider.
3. The CodeBuild project creates the Docker image and publishes the image to Amazon ECR.

4. You create the Lambda function by using the image in Amazon ECR.

## Automation and scale

This pattern can be automated by using AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), or API operations from an SDK. Lambda can automatically scale based on the number of requests, and you can tune it by using the concurrency parameters. For more information, see the [Lambda documentation](#).

## Tools

### AWS services

- [AWS CloudFormation Designer](#) provides an integrated JSON and YAML editor that helps you view and edit CloudFormation templates.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeStar](#) is a cloud-based service for creating, managing, and working with software development projects on AWS. For this pattern, you can use AWS CodeStar or another development environment.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

### Other tools

- [Docker](#) is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

## Best practices

- Make your function as efficient and small as possible to avoid loading unnecessary files.

- Strive to have static layers higher up in your Docker file list, and place layers that change more often lower down. This improves caching, which improves performance.
- The image owner is responsible for updating and patching the image. Add that update cadence to your operational processes. For more information, see the [AWS Lambda documentation](#).

## Epics

### Create a project in CodeBuild

Task	Description	Skills required
Create a CodeCommit repository.	Create a CodeCommit repository that will contain the Dockerfile, the <code>buildspec.yaml</code> file, and the application source code. For more information, see the <a href="#">AWS CodeCommit documentation</a> .	Developer
Create a CodeBuild project.	<p>On the CodeBuild console, create a new project that uses the CodeCommit repo and the <code>buildspec.yaml</code> file. You will use the CodeBuild project to create the image.</p> <p>Confirm that privileged mode is enabled. To build Docker images, this is necessary. Otherwise, the image will not build successfully.</p> <p>Provide values for project name and description. For the source provider, choose CodeCommit. For more</p>	Developer

Task	Description	Skills required
	information, see the <a href="#">AWS documentation</a> .	
Edit the Dockerfile.	<p>The Dockerfile should be located in the top-level directory where you're developing the application. The Python code should be in the <code>src</code> folder.</p> <p>When you create the image, use the <a href="#">official Lambda supported images</a>. Otherwise, a bootstrap error will occur, making the packing process more difficult.</p> <p>For details, see the <a href="#">Additional information</a> section.</p>	Developer
Create a repo in Amazon ECR.	<p>Create a container repository in Amazon ECR. In the following example command, the name of the repository created is <code>cf-demo</code>. The repository will be reused in the <code>buildspec.yaml</code> file.</p> <pre>aws ecr create-repository --cf-demo</pre>	AWS administrator, Developer

Task	Description	Skills required
Push the image to Amazon ECR.	You can use CodeBuild to perform the image-build process. CodeBuild needs permission to interact with Amazon ECR and to work with S3. As part of the process, the Docker image is built and pushed to the Amazon ECR registry. For details on the template and the code, see the <a href="#">Additional information</a> section.	Developer
Verify that the image is in the repository.	To verify that the image is in the repository, on the Amazon ECR console, choose <b>Repositories</b> . The image should be listed, with tags and with the results of a vulnerability scan report if that feature was turned on in the Amazon ECR settings. For more information, see the <a href="#">AWS documentation</a> .	Developer

### Create the Lambda function to run the image

Task	Description	Skills required
Create the Lambda function.	On the Lambda console, choose <b>Create function</b> , and then choose <b>Container image</b> . Enter the function name and the URI for the	App developer

Task	Description	Skills required
	image that is in the Amazon ECR repository, and then choose <b>Create function</b> . For more information, see the <a href="#">AWS Lambda documentation</a> .	
Test the Lambda function.	To invoke and test the function, choose <b>Test</b> . For more information, see the <a href="#">AWS Lambda documentation</a> .	App developer

## Troubleshooting

Issue	Solution
Build is not succeeding.	<ol style="list-style-type: none"><li>1. Check if the privileged mode is turned on for the CodeBuild project.</li><li>2. Ensure that the Docker related commands have the necessary permissions. Trying adding sudo to the commands.</li><li>3. Verify that the IAM role associated with CodeBuild has a policy with appropriate actions to interact with Amazon ECR, Amazon S3, and CloudWatch logs.</li></ol>

## Related resources

- [Base images for Lambda](#)
- [Docker sample for CodeBuild](#)
- [Pass temporary credentials](#)

## Additional information

### Edit the Dockerfile

The following code shows the commands that you edit in the Dockerfile.

```
FROM public.ecr.aws/lambda/python:3.11

# Copy function code
COPY app.py ${LAMBDA_TASK_ROOT}
COPY requirements.txt ${LAMBDA_TASK_ROOT}

# install dependencies
RUN pip3 install --user -r requirements.txt

# Set the CMD to your handler (could also be done as a parameter override outside of
  the Dockerfile)
CMD [ "app.lambda_handler" ]
```

The FROM command value corresponds to the Python 3.11 base image that is using the Lambda function in the public Amazon ECR image repository.

The COPY app.py \${LAMBDA\_TASK\_ROOT} command copies the code to the task root directory, which the Lambda function will use. This command uses the environment variable so we don't have to worry about the actual path. The function to be run is passed as an argument to the CMD [ "app.lambda\_handler" ] command.

The COPY requirements.txt command captures the dependencies necessary for the code.

The RUN pip install --user -r requirements.txt command installs the dependencies to the local user directory.

To build your image, run the following command.

```
docker build -t <image name> .
```

### Add the image in Amazon ECR

In the following code, replace aws\_account\_id with the account number, and replace us-east-1 if you are using a different Region. The buildspec file uses the CodeBuild build number to uniquely identify image versions as a tag value. You can change this to fit your requirements.

## The buildspec custom code

```
phases:
  install:
    runtime-versions:
      python: 3.11
  pre_build:
    commands:
      - python3 --version
      - pip3 install --upgrade pip
      - pip3 install --upgrade awscli
      - sudo docker info
  build:
    commands:
      - echo Build started on `date`
      - echo Building the Docker image...
      - ls
      - cd app
      - docker build -t cf-demo:$CODEBUILD_BUILD_NUMBER .
      - docker container ls
  post_build:
    commands:
      - echo Build completed on `date`
      - echo Pushing the Docker image...
      - aws ecr get-login-password --region us-east-1 | docker login --username AWS --
password-stdin aws_account_id.dkr.ecr.us-east-1.amazonaws.com
      - docker tag cf-demo:$CODEBUILD_BUILD_NUMBER aws_account_id.dkr.ecr.us-
east-1.amazonaws.com/cf-demo:$CODEBUILD_BUILD_NUMBER
      - docker push aws_account_id.dkr.ecr.us-east-1.amazonaws.com/cf-demo:
$CODEBUILD_BUILD_NUMBER
```

# Deploy a sample Java microservice on Amazon EKS and expose the microservice using an Application Load Balancer

Created by Vijay Thompson (AWS) and Akkamahadevi Hiremath (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices

**Workload:** Open-source

**AWS services:** Amazon EC2 Container Registry; Amazon EKS; Amazon ECR

## Summary

This pattern describes how to deploy a sample Java microservice as a containerized application on Amazon Elastic Kubernetes Service (Amazon EKS) by using the `eksctl` command line utility and Amazon Elastic Container Registry (Amazon ECR). You can use an Application Load Balancer to load balance the application traffic.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- The AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows
- A running [Docker daemon](#)
- The `eksctl` command line utility, installed and configured on macOS, Linux, or Windows (For more information, see [Getting started with Amazon EKS – eksctl](#) in the Amazon EKS documentation.)
- The `kubectl` command line utility, installed and configured on macOS, Linux, or Windows (For more information, see [Installing or updating kubectl](#) in the Amazon EKS documentation.)

### Limitations

- This pattern doesn't cover the installation of an SSL certificate for the Application Load Balancer.

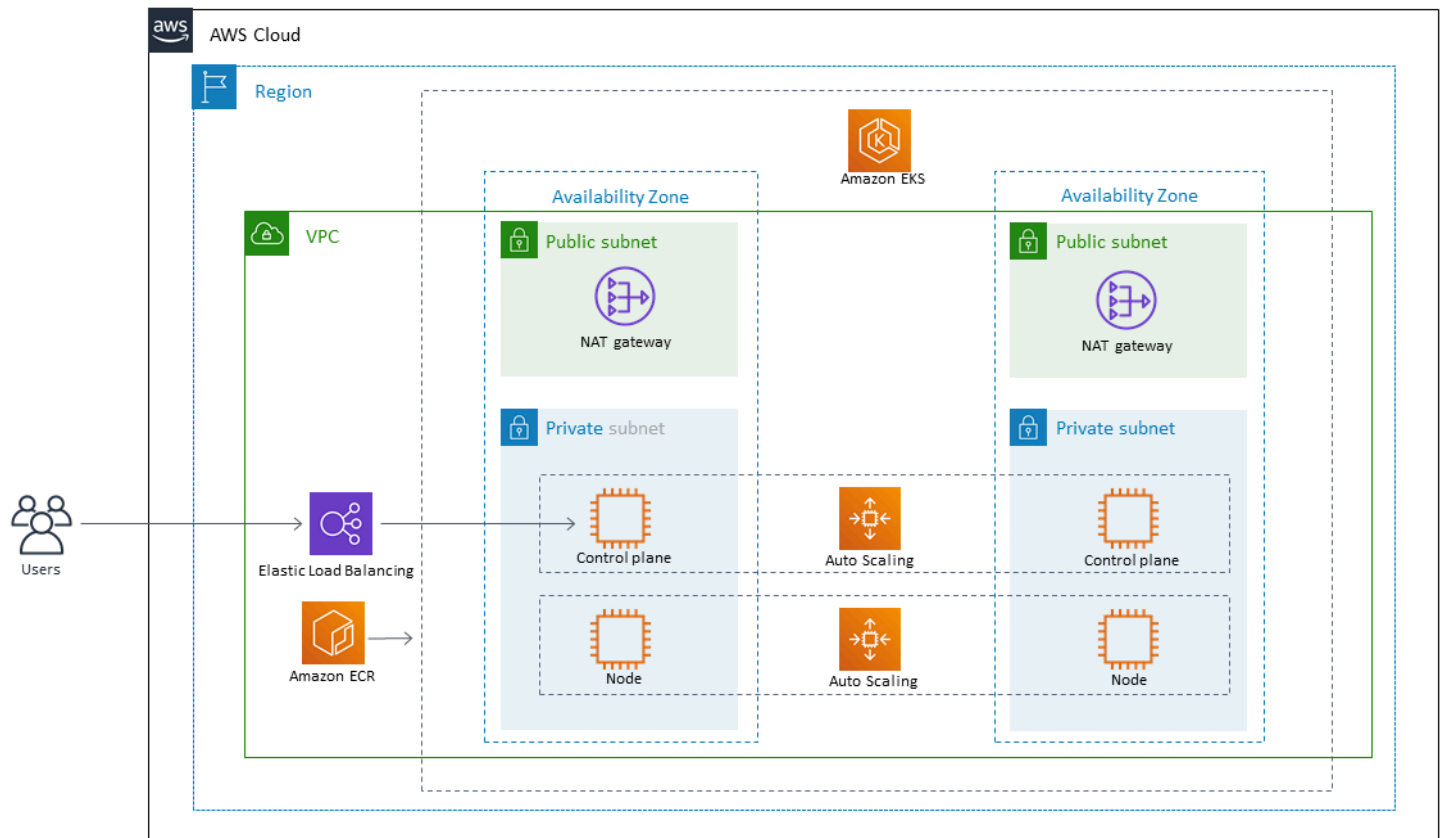

## Architecture

### Target technology stack

- Amazon ECR
- Amazon EKS
- Elastic Load Balancing

### Target architecture

The following diagram shows an architecture for containerizing a Java microservice on Amazon EKS.

## Tools

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Elastic Load Balancing](#) automatically distributes your incoming traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.
- [eksctl](#) helps you create clusters on Amazon EKS.
- [kubectrl](#) makes it possible to run commands against Kubernetes clusters.
- [Docker](#) helps you build, test, and deliver applications in packages called containers.

## Epics

### Create an Amazon EKS cluster by using eksctl

Task	Description	Skills required
Create an Amazon EKS cluster.	<p>To create an Amazon EKS cluster that uses two t2.small Amazon EC2 instances as nodes, run the following command:</p> <pre>eksctl create cluster --name &lt;your-cluster-name&gt; --version &lt;version-number&gt; --nodes=1 --node-type=t2.small</pre> <p><b>Note:</b> The process can take between 15 to 20 minutes. After the cluster is created,</p>	Developer, System Admin

Task	Description	Skills required
	the appropriate Kubernetes configuration is added to your <a href="#">kubeconfig</a> file. You can use the kubeconfig file with <code>kubectl</code> to deploy the application in later steps.	
Verify the Amazon EKS cluster.	To verify that the cluster is created and that you can connect to it, run the <code>kubectl get nodes</code> command.	Developer, System Admin

### Create an Amazon ECR repository and push the Docker image.

Task	Description	Skills required
Create an Amazon ECR repository.	Follow the instructions from <a href="#">Creating a private repository</a> in the Amazon ECR documentation.	Developer, System Admin
Create a POM XML file.	Create a <code>pom.xml</code> file based on the <i>Example POM file</i> code in the <a href="#">Additional information</a> section of this pattern.	Developer, System Admin
Create a source file.	Create a source file called <code>HelloWorld.java</code> in the <code>src/main/java/eksExample</code> path based on the following example: <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>package eksExample; import static spark.Spark.get;</pre> </div>	

Task	Description	Skills required
	<pre data-bbox="609 247 1015 703"> public class HelloWorld {     public static void     main(String[] args) {         get("/", (req,         res) -&gt; {             return             "Hello World!";         });     } } </pre> <p data-bbox="592 741 998 825">Be sure to use the following directory structure:</p> <pre data-bbox="609 867 1015 1375"> ### Dockerfile ### deployment.yaml ### ingress.yaml ### pom.xml ### service.yaml ### src     ### main         ### java             ### eksExample                 ### HelloWorld.java </pre>	
Create a Dockerfile.	Create a Dockerfile based on the <i>Example Dockerfile</i> code in the <a href="#">Additional information</a> section of this pattern.	Developer, System Admin

Task	Description	Skills required
Build and push the Docker image.	<p>In the directory where you want your Dockerfile to build, tag, and push the image to Amazon ECR, run the following commands:</p> <pre data-bbox="594 489 1029 1365">aws ecr get-login   -password --region     &lt;region&gt;  docker login     --username &lt;username   &gt; --password-stdin     &lt;account_number&gt;.d   kr.ecr.&lt;region&gt;.am   azonaws.com docker buildx build --   platform linux/amd64   -t hello-world-java:v   1 . docker tag hello-wor   ld-java:v1 &lt;account_   number&gt;.dkr.ecr.&lt;r   egion&gt;.amazonaws.com/   &lt;repository_name&gt;:v1 docker push &lt;account_   number&gt;.dkr.ecr.&lt;r   egion&gt;.amazonaws.com/   &lt;repository_name&gt;:v1</pre> <p><b>Note:</b> Modify the AWS Region, account number, and repository details in the preceding commands. Be sure to note the image URL for later use.</p> <p><b>Important:</b> A macOS system with an M1 chip has a problem building an image</p>	

Task	Description	Skills required
	that's compatible with Amazon EKS running on an AMD64 platform. To resolve this issue, use <a href="#">docker buildx</a> to build a Docker image that works on Amazon EKS.	

## Deploy the Java microservices

Task	Description	Skills required
Create a deployment file.	<p>Create a YAML file called <code>deployment.yaml</code> based on the <i>Example deployment file</i> code in the <a href="#">Additional information</a> section of this pattern.</p> <p><b>Note:</b> Use the image URL that you copied earlier as the path of the image file for the Amazon ECR repository.</p>	Developer, System Admin
Deploy the Java microservices on the Amazon EKS cluster.	To create a deployment in your Amazon EKS cluster, run the <code>kubectl apply -f deployment.yaml</code> command.	Developer, System Admin
Verify the status of the pods.	<ol style="list-style-type: none"> <li>To verify the status of the pods, run the <code>kubectl get pods</code> command.</li> <li>Wait for the status to change to <b>Ready</b>.</li> </ol>	Developer, System Admin

Task	Description	Skills required
Create a service.	<ol style="list-style-type: none"> <li>1. Create a file called <code>service.yaml</code> based on the <i>Example service file</i> code in the <a href="#">Additional information</a> section of this pattern.</li> <li>2. Run the <code>kubectl apply -f service.yaml</code> command.</li> </ol>	Developer, System Admin
Install the AWS Load Balancer Controller add-on.	<p>Follow the instructions from <a href="#">Installing the AWS Load Balancer Controller add-on</a> in the Amazon EKS documentation.</p> <p><b>Note:</b> You must have the add-on installed to create an Application Load Balancer or Network Load Balancer for a Kubernetes service.</p>	Developer, System Admin
Create an ingress resource.	Create a YAML file called <code>ingress.yaml</code> based on the <i>Example ingress resource file</i> code in the <a href="#">Additional information</a> section of this pattern.	Developer, System Admin
Create an Application Load Balancer.	To deploy the ingress resource and create an Application Load Balancer, run the <code>kubectl apply -f ingress.yaml</code> command.	Developer, System Admin

## Test the application

Task	Description	Skills required
Test and verify the application.	<ol style="list-style-type: none"><li>To get the load balancer's DNS name from the ADDRESS field, run the <code>kubectl get ingress.networking.k8s.io/java-microservice-ingress</code> command.</li><li>On an EC2 instance in the same VPC as your Amazon EKS nodes, run the <code>curl -v &lt;DNS address from previous command&gt;</code> command.</li></ol>	Developer, System Admin

```

# Deploy a clustered application to Amazon ECS by using AWS Copilot

Created by Jean-Baptiste Guillois (AWS), Mathew George (AWS), and Thomas Scott (AWS)

**Code repository:** [Clustered Sample Application demo](#)

**Environment:** Production

**Technologies:** Containers & microservices; Business productivity; CloudNative; DevelopmentAndTesting

**AWS services:** Amazon ECS; AWS Fargate; Amazon ECR

## Summary

This pattern shows how to deploy containers in an Amazon Elastic Container Service (Amazon ECS) cluster in two ways—by using the Amazon Web Services (AWS) Management Console, and by using AWS Copilot—to demonstrate how AWS Copilot simplifies deployment tasks.

Amazon ECS is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster. Your containers are defined in a task definition that you use to run individual tasks or tasks within a service. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.

The AWS Copilot command line interface (CLI) commands simplify building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. The AWS Copilot CLI aligns with developer workflows that support modern application best practices: from using infrastructure as code to creating a continuous integration and continuous delivery (CI/CD) pipeline provisioned on behalf of a user. You can use the AWS Copilot CLI as part of your everyday development and testing cycle as an alternative to the AWS Management Console.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) locally installed and configured to use your AWS account (see the [installation instructions](#) and the [configuration instructions](#) in the AWS CLI documentation)
- AWS Copilot locally installed (see the [installation instructions](#) in the Amazon ECS documentation)
- Docker installed on your local machine (see the [Docker documentation](#))

## Limitations

- Docker enforces pull limits of 100 container images per 6 hours per IP address on the free plan.

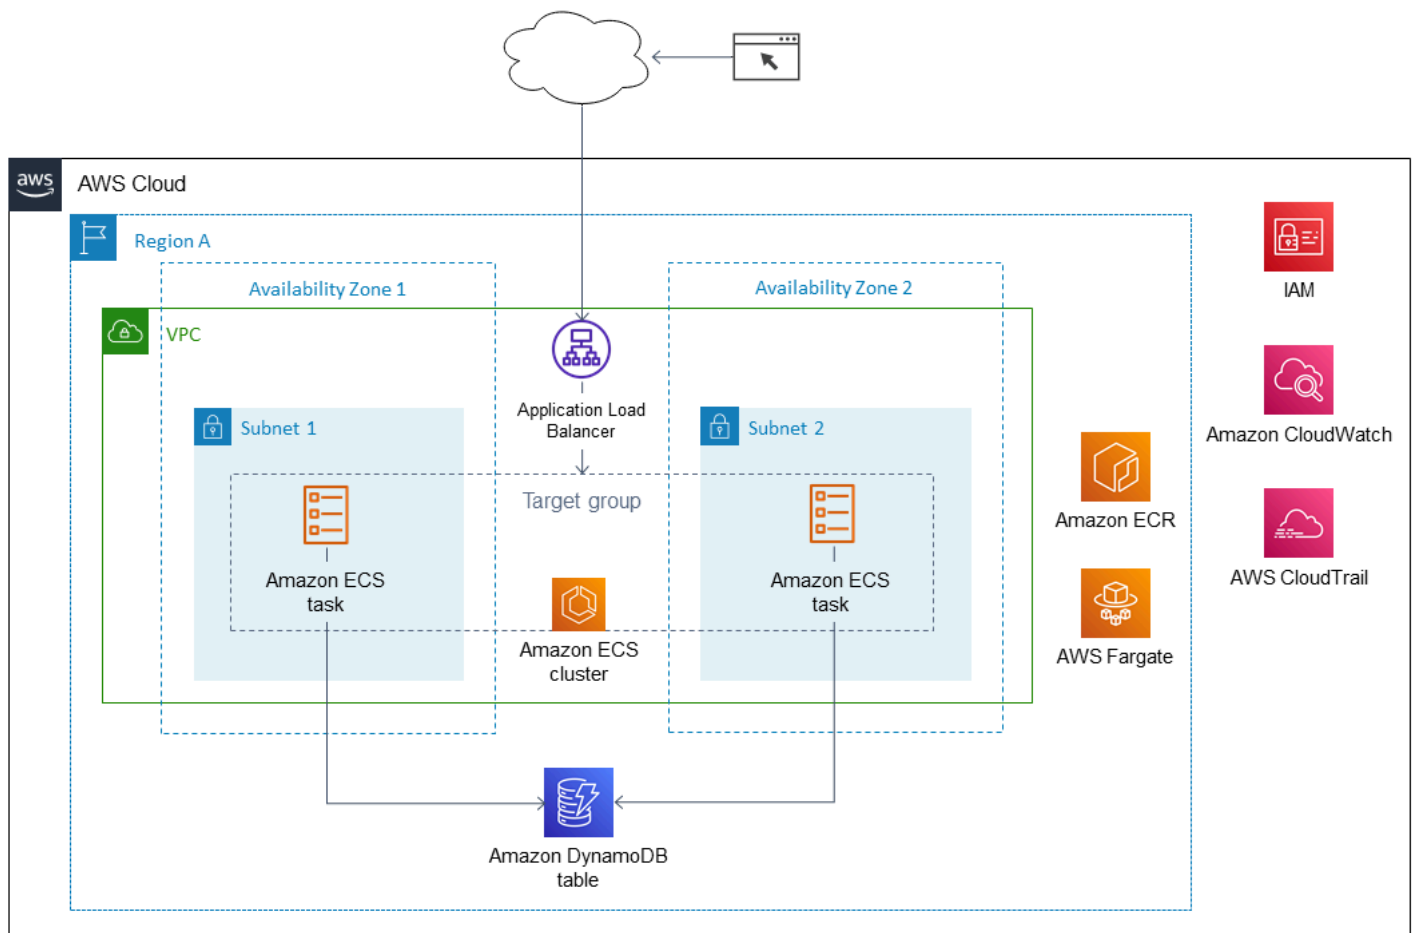

## Architecture

### Target technology stack

- AWS environment set up with a virtual private cloud (VPC), public and private subnets, and security groups
- Amazon ECS cluster
- Amazon ECS service and task definition
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon DynamoDB
- Application Load Balancer
- AWS Fargate
- Amazon Identity and Access Management (IAM)
- Amazon CloudWatch
- AWS CloudTrail

### Target architecture

When you deploy the sample application for this pattern, multiple tasks are created and deployed in separate Availability Zones. Each task stores data in Amazon DynamoDB. When you access the webpage for a task, you can view the data from all other tasks.

## Tools

### AWS services

- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.
- [Amazon ECS](#) – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- [AWS Copilot](#) – AWS Copilot provides a command line interface that helps you launch and manage containerized applications on AWS, including pushing to a registry, creating a task definition, and creating a cluster.

- [AWS Fargate](#) – AWS Fargate is a serverless, pay-as-you-go compute engine that lets you focus on building applications without managing servers. AWS Fargate is compatible with both Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). When you run your Amazon ECS tasks and services with the Fargate launch type or a Fargate capacity provider, you package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and doesn't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task.
- [Amazon DynamoDB](#) – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- [Elastic Load Balancing \(ELB\)](#) – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones. It monitors the health of its registered targets, and routes traffic only to the healthy targets. Elastic Load Balancing scales your load balancer as your incoming traffic changes over time. It can automatically scale to the vast majority of workloads.

## Tools

- [Docker Command Line Interface](#)
- [AWS Command Line Interface \(AWS CLI\)](#)
- [AWS Copilot command line interface](#)

## Code

The code for the sample application used in this pattern is available on GitHub, in the [Cluster Sample Application](#) repository. Follow the instructions in the next section to use the sample files.

## Epics

### Deploy the application stack - option 1 (AWS Management Console)

Task	Description	Skills required
Clone the GitHub repository.	Clone the sample code repository by using the command:	App developer, AWS DevOps

Task	Description	Skills required
	<pre>git clone https://github.com/aws-samples/cluster-sample-app cluster-sample-app &amp;&amp; cd cluster-sample-app</pre>	
Create your Amazon ECR repository.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the Amazon ECR console at <a href="https://console.aws.amazon.com/ecr/repositories">https://console.aws.amazon.com/ecr/repositories</a>.</li><li>2. Choose <b>Create repository</b>.</li><li>3. For the repository name, enter <b>cluster-sample-app</b>.</li><li>4. For all other settings, keep the default values.</li><li>5. Choose <b>Create repository</b>.</li></ol> <p>For more information, see <a href="#">Creating a private repository</a> in the Amazon ECR documentation.</p>	App developer, AWS DevOps

Task	Description	Skills required
Build, tag, and push your Docker image to your Amazon ECR repository.	<ol style="list-style-type: none"><li>1. Select the repository you just created and choose <b>View push commands</b>.</li><li>2. Copy the commands that are displayed and run them locally to build, tag, and push your docker image. These commands will be similar to the following.</li></ol> <p>To authenticate your Docker client to the registry:</p> <pre>aws ecr get-login -password --region &lt;YOUR_AWS_REGION&gt;   docker login --username AWS --password-stdin &lt;YOUR_AWS_ACCOUNT&gt; .dkr.ecr.&lt;YOUR_AWS _REGION&gt;.amazonaws .com</pre> <p>To build your Docker image:</p> <pre>docker build -t cluster- sample-app .</pre> <p>To tag your Docker image:</p> <pre>docker tag cluster- sample-app:latest &lt;YOUR_AWS_ACCOUNT&gt; .dkr.ecr.&lt;YOUR_AWS _REGION&gt;.amazonaws</pre>	App developer, AWS DevOps

Task	Description	Skills required
	<pre>.com/cluster-sample-app:latest</pre> <p>To push the Docker image to your repository:</p> <pre>docker push &lt;YOUR_AWS_ACCOUNT&gt;.dkr.ecr.&lt;YOUR_AWS_REGION&gt;.amazonaws.com/cluster-sample-app:latest</pre>	

Task	Description	Skills required
Deploy the application stack.	<ol style="list-style-type: none"><li>1. Open the AWS CloudFormation console at <a href="https://console.aws.amazon.com/cloudformation/">https://console.aws.amazon.com/cloudformation/</a>.</li><li>2. Choose <b>Create stack</b>.</li><li>3. In the <b>Prepare template</b> section, choose <b>Template is ready</b>.</li><li>4. In the <b>Specify template</b> section, choose <b>Upload a template file</b>.</li><li>5. Choose the local file <code>cluster-sample-app-stack.yml</code> that you cloned from the GitHub repository as the CloudFormation template, and then choose <b>Next</b>.</li><li>6. Enter a name for your stack, and then choose <b>Next</b>.</li><li>7. Keep all default options, and then choose <b>Next</b>.</li><li>8. Review all options, acknowledge the creation of IAM resources, and then choose <b>Create stack</b>.</li><li>9. When your application stack has been deployed, choose the <b>Output</b> tab, copy the URL, and open it in your browser to access the application.</li></ol>	AWS DevOps, App developer

Task	Description	Skills required
	For more information about deploying CloudFormation templates, see <a href="#">Creating a stack</a> in the AWS CloudFormation documentation.	

## Deploy the application stack – option 2 (AWS Copilot CLI)

Task	Description	Skills required
Clone the GitHub repository.	Clone the sample code repository by using the command: <pre>git clone https://github.com/aws-samples/cluster-sample-app cluster-sample-app &amp;&amp; cd cluster-sample-app</pre>	App developer, AWS DevOps
Deploy your container image to AWS by using the AWS Copilot CLI.	Deploy the application in one step by using the following command in the root directory of your project: <pre>copilot init --app cluster-sample-app --name demo --type "Load Balanced Web Service" --dockerfile ./Dockerfile --port 8080 --deploy</pre> <p>You should then be able to access the application by</p>	App developer, AWS DevOps

Task	Description	Skills required
	using the DNS name provided as output.	

## Delete the created resources

Task	Description	Skills required
Delete the resources created through the AWS Management Console.	<p>If you used option 1 (the AWS Management Console) to deploy the application stack, follow these steps when you're ready to delete the resources you created:</p> <ol style="list-style-type: none"> <li>1. Open the CloudFormation console at <a href="https://console.aws.amazon.com/cloudformation/">https://console.aws.amazon.com/cloudformation/</a>.</li> <li>2. Select the stack you created, and then choose <b>Delete</b>.</li> <li>3. Open the Amazon ECR console at <a href="https://console.aws.amazon.com/ecr/repositories">https://console.aws.amazon.com/ecr/repositories</a>.</li> <li>4. Select the repository you created, and then choose <b>Delete</b>.</li> </ol>	App developer, AWS DevOps
Delete the resources created by AWS Copilot.	If you used option 2 (the AWS Copilot CLI) to deploy the application stack, run the following command from the root directory of your project	App developer, AWS DevOps

Task	Description	Skills required
	when you're ready to delete the resources you created:  <code>copilot app delete</code>

# Deploy a gRPC-based application on an Amazon EKS cluster and access it with an Application Load Balancer

Created by Kirankumar Chandrashekar (AWS) and Huy Nguyen (AWS)

**Code repository:** [grpc-traffic-on-alb-to-eks](#)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; Content delivery; Web & mobile apps

**Workload:** All other workloads

**AWS services:** Amazon EKS; Elastic Load Balancing (ELB)

## Summary

This pattern describes how to host a gRPC-based application on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster and securely access it through an Application Load Balancer.

[gRPC](#) is an open-source remote procedure call (RPC) framework that can run in any environment. You can use it for microservice integrations and client-server communications. For more information about gRPC, see the AWS blog post [Application Load Balancer support for end-to-end HTTP/2 and gRPC](#).

This pattern shows you how to host a gRPC-based application that runs on Kubernetes pods on Amazon EKS. The gRPC client connects to an Application Load Balancer through the HTTP/2 protocol with an SSL/TLS encrypted connection. The Application Load Balancer forwards traffic to the gRPC application that runs on Amazon EKS pods. The number of gRPC pods can be automatically scaled based on traffic by using the [Kubernetes Horizontal Pod Autoscaler](#). The Application Load Balancer's target group performs health checks on the Amazon EKS nodes, evaluates if the target is healthy, and forwards traffic only to healthy nodes.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- [Docker](#), installed and configured on Linux, macOS, or Windows.

- [AWS Command Line Interface \(AWS CLI\) version 2](#), installed and configured on Linux, macOS, or Windows.
- [eksctl](#), installed and configured on Linux, macOS, or Windows.
- `kubectl`, installed and configured to access resources on your Amazon EKS cluster. For more information, see [Installing or updating kubectl](#) in the Amazon EKS documentation.
- [gRPCurl](#), installed and configured.
- A new or existing Amazon EKS cluster. For more information, see [Getting started with Amazon EKS](#).
- Your computer terminal configured to access the Amazon EKS cluster. For more information, see [Configure your computer to communicate with your cluster](#) in the Amazon EKS documentation.
- [AWS Load Balancer Controller](#), provisioned in the Amazon EKS cluster.
- An existing DNS host name with a valid SSL or SSL/TLS certificate. You can obtain a certificate for your domain by using AWS Certificate Manager (ACM) or uploading an existing certificate to ACM. For more information about these two options, see [Requesting a public certificate](#) and [Importing certificates into AWS Certificate Manager](#) in the ACM documentation.

## Architecture

The following diagram shows the architecture implemented by this pattern.

The following diagram shows a workflow where SSL/TLS traffic is received from a gRPC client that offloads to an Application Load Balancer. Traffic is forwarded in plaintext to the gRPC server because it comes from a virtual private cloud (VPC).

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- [Elastic Load Balancing](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.

### Tools

- [eksctl](#) is a simple CLI tool for creating clusters on Amazon EKS.
- [kubectx](#) is a command line utility for running commands against Kubernetes clusters.
- [AWS Load Balancer Controller](#) helps you manage AWS Elastic Load Balancers for a Kubernetes cluster.
- [gRPCurl](#) is a command line tool that helps you interact with gRPC services.

## Code repository

The code for this pattern is available in the GitHub [grpc-traffic-on-alb-to-eks](#) repository.

## Epics

### Build and push the gRPC server's Docker image to Amazon ECR

Task	Description	Skills required
Create an Amazon ECR repository.	<p>Sign in to the AWS Management Console, open the <a href="#">Amazon ECR console</a>, and then create an Amazon ECR repository. For more information, see <a href="#">Creating a repository</a> in the Amazon ECR documentation. Make sure that you record the Amazon ECR repository's URL.</p> <p>You can also create an Amazon ECR repository with AWS CLI by running the following command:</p> <pre>aws ecr create-repository --repository-name helloworld-grpc</pre>	Cloud administrator
Build the Docker image.	<p>1. Clone the GitHub <a href="#">grpc-traffic-on-alb-to-eks</a> repository.</p> <pre>git clone https://github.com/aws-samples/grpc-traffic-on-alb-to-eks.git</pre>	DevOps engineer

Task	Description	Skills required
	<p>2. From the root directory of the repository, make sure that the Dockerfile exists and then run the following command to build the Docker image:</p> <pre data-bbox="634 520 1029 680">docker build -t &lt;amazon_ecr_reposi tory_url&gt;:&lt;Tag&gt; .</pre> <p><b>Important:</b> Make sure that you replace <code>&lt;amazon_ecr_repository_url&gt;</code> with the URL of the Amazon ECR repository that you created earlier.</p>	

Task	Description	Skills required
Push the Docker image to Amazon ECR.	<ol style="list-style-type: none"> <li>Run the following command to log in to the Amazon ECR repository: <pre>aws ecr get-login -password --region us-east-1 --no-cli- auto-prompt   docker login --username AWS --password-stdin &lt;your_aws_account_ id&gt;.dkr.ecr.us-eas t-1.amazonaws.com</pre> </li> <li>Push the Docker image to the Amazon ECR repository by running the following command: <pre>docker push &lt;your_aws _account_id&gt;.dkr.e cr.us-east-1.amazo naws.com/helloworl d-grpc:1.0</pre> </li> </ol> <p><b>Important:</b> Make sure that you replace <code>&lt;your_aws_account_id&gt;</code> with your AWS account ID.</p>	DevOps engineer

## Deploy the Kubernetes manifests to the Amazon EKS cluster

Task	Description	Skills required
Modify the values in the Kubernetes manifest file.	<ol style="list-style-type: none"> <li>Modify the <code>grpc-sample.yaml</code> Kubernetes</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>s manifest file in the Kubernetes folder of the repository according to your requirements. You must modify the annotations and host name in the ingress resource. For a sample ingress resource, see the <a href="#">Additional information</a> section. For more information about ingress annotations, see <a href="#">Ingress annotations</a> in the Kubernetes documentation.</p> <p>2. In the Kubernetes deployment resource, change the deployment resource's image to the uniform resource identifier (URI) for the Amazon ECR repository that you pushed the Docker image to. For a sample deployment resource, see the <a href="#">Additional information</a> section.</p>	

Task	Description	Skills required
Deploy the Kubernetes manifest file.	<p>Deploy the <code>grpc-sample.yaml</code> file to the Amazon EKS cluster by running the following <code>kubectl</code> command:</p> <pre>kubectl apply -f ./kubernetes/grpc-sample.yaml</pre>	DevOps engineer

### Create the DNS record for the Application Load Balancer's FQDN

Task	Description	Skills required
Record the FQDN for the Application Load Balancer.	<ol style="list-style-type: none"> <li>Run the following <code>kubectl</code> command to describe the Kubernetes ingress resource that manages the Application Load Balancer: <pre>kubectl get ingress -n grpcserver</pre> <p>Sample output is provided in the <a href="#">Additional information</a> section. In the output, the <code>HOSTS</code> field displays the DNS host name that the SSL certificates were created for.</p> </li> <li>Record the Application Load Balancer's fully qualified domain name</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>(FQDN) from the Address field of the output.</p> <p>3. Create a DNS record that points to the Application Load Balancer's FQDN. If your DNS provider is Amazon Route 53, you can create an alias record that points to the Application Load Balancer's FQDN. For more information about this option, see <a href="#">Choosing between alias and non-alias records</a> in the Route 53 documentation.</p>	

## Test the solution

Task	Description	Skills required
Test the gRPC server.	<p>Use gRPCurl to test the endpoint by running the following command:</p> <pre data-bbox="594 1388 1026 1667">grpcurl grpc.example.com:443 list grpc.reflection.v1alpha.ServerReflection helloworld.helloworld</pre> <p><b>Note:</b> Replace <code>grpc.example.com</code> with your DNS name.</p>	DevOps engineer

Task	Description	Skills required
Test the gRPC server using a gRPC client.	<p>In the <code>helloworld_client_ssl.py</code> sample gRPC client, replace the host name from <code>grpc.example.com</code> with the host name used for the gRPC server.</p> <p>The following code sample shows the response from the gRPC server for the client's request:</p> <pre>python ./app/helloworld_client_ssl.py message: "Hello to gRPC server from Client"  message: "Thanks for talking to gRPC server!! Welcome to hello world. Received message is \"Hello to gRPC server from Client\"" received: true</pre> <p>This shows that the client can talk to the server and that the connection is successful.</p>	DevOps engineer

## Clean up

Task	Description	Skills required
Remove the DNS record.	Remove the DNS record that points to the Application Load Balancer's FQDN that you created earlier.	Cloud administrator
Remove the load balancer.	On the <a href="#">Amazon EC2 console</a> , choose <b>Load Balancers</b> , and then remove the load balancer that the Kubernetes controller created for your ingress resource.	Cloud administrator
Delete the Amazon EKS cluster.	Delete the Amazon EKS cluster by using <code>eksctl</code> :  <pre>eksctl delete cluster -f ./eks.yaml</pre>	AWS DevOps

# Deploy and debug Amazon EKS clusters

Created by Svenja Raether (AWS) and Mathew George (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; Infrastructure; Modernization; Serverless; CloudNative

**Workload:** All other workloads

**AWS services:** Amazon EKS; AWS Fargate

## Summary

Containers are becoming an essential part of cloud native application development. Kubernetes provides an efficient way to manage and orchestrate containers. [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) is a fully-managed, certified [Kubernetes](#) conformant service for building, securing, operating, and maintaining Kubernetes clusters on Amazon Web Services (AWS). It supports running pods on AWS Fargate to provide on-demand, right-sized compute capacity.

It's important for developers and administrators to know debugging options when running containerized workloads. This pattern walks you through deploying and debugging containers on Amazon EKS with [AWS Fargate](#). It includes creating, deploying, accessing, debugging, and cleaning up the Amazon EKS workloads.

## Prerequisites and limitations

### Prerequisites

- An active [AWS account](#)
- [AWS Identity and Access Management \(IAM\)](#) role configured with sufficient permissions to create and interact with Amazon EKS, IAM roles, and service linked roles
- [AWS Command Line Interface \(AWS CLI\)](#) installed on the local machine
- [eksctl](#)
- [kubectl](#)
- [Helm](#)

## Limitations

- This pattern provides developers with useful debugging practices for development environments. It does not state best practices for production environments.
- If you are running Windows, use your operating system–specific commands for setting the environment variables.

## Product versions used

- [AWS CLI version 2](#)
- [kubect1 version](#) within one minor version difference of the Amazon EKS control plane that you're using
- [eksctl](#) latest version
- [Helm v3](#)

## Architecture

### Technology stack

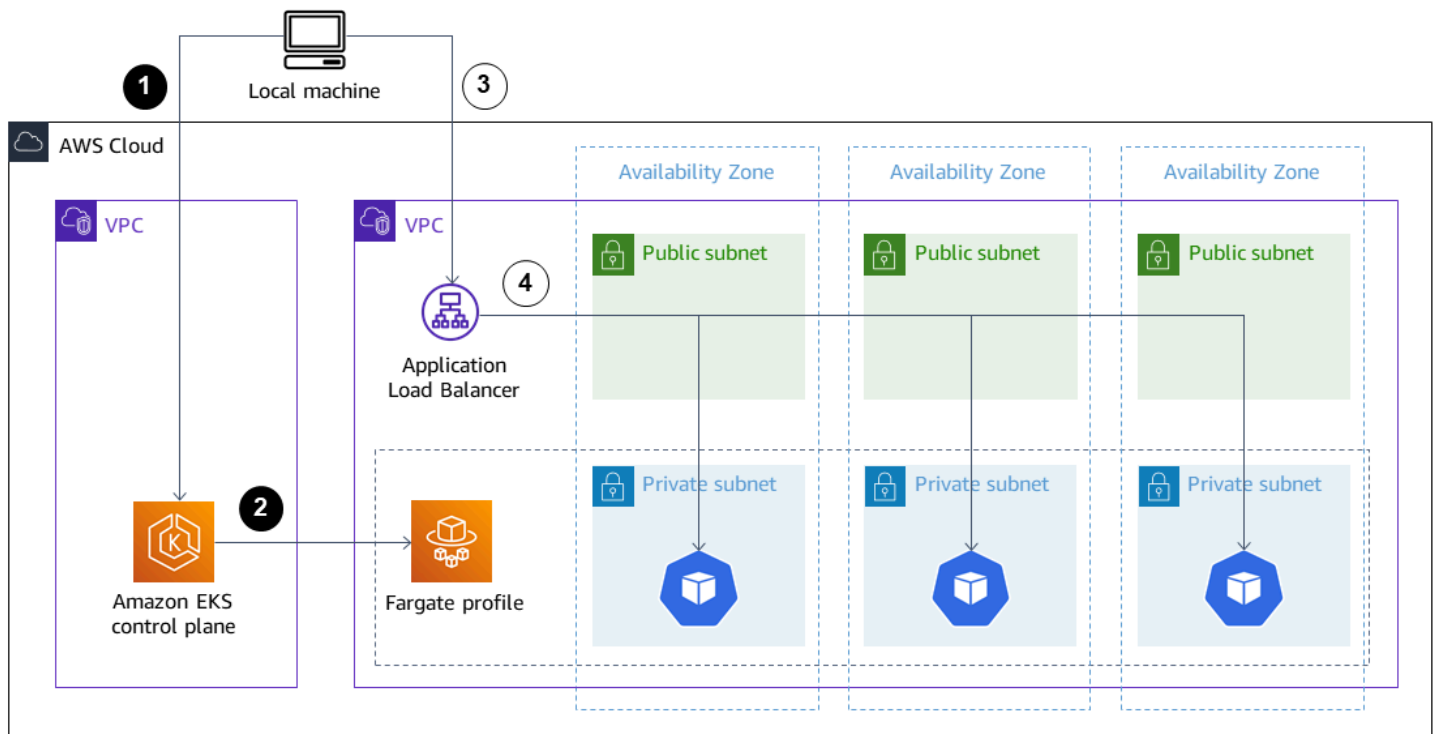

- Application Load Balancer
- Amazon EKS
- AWS Fargate

### Target architecture

All resources shown in the diagram are provisioned by using `eksctl` and `kubect1` commands issued from a local machine. Private clusters must be run from an instance that is inside the private VPC.

The target architecture consists of an EKS cluster using the Fargate launch type. This provides on-demand, right-sized compute capacity without the need to specify server types. The EKS cluster has a control plane, which is used to manage the cluster nodes and workloads. The pods are provisioned into private VPC subnets spanning multiple Availability Zones. The Amazon ECR Public Gallery is referenced to retrieve and deploy an NGINX web server image to the cluster's pods.

The diagram shows how to access the Amazon EKS control plane using `kubect1` commands and how to access the application by using the Application Load Balancer.

1. A local machine outside the AWS Cloud sends commands to the Kubernetes control plane inside an Amazon EKS managed VPC.
2. Amazon EKS schedules pods based on the selectors in the Fargate profile.
3. The local machine opens the Application Load Balancer URL in the browser.
4. The Application Load Balancer divides traffic between the Kubernetes pods in Fargate cluster nodes deployed in private subnets spanning multiple Availability Zones.

## Tools

### AWS services

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes. This pattern also uses the `eksctl` command-line tool to work with Kubernetes clusters on Amazon EKS.

- [AWS Fargate](#) helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones. This pattern uses the [AWS Load Balancer Controller](#) controlling component to create the Application Load Balancer when a [Kubernetes ingress](#) is provisioned. The Application Load Balancer distributes incoming traffic among multiple targets.

## Other tools

- [Helm](#) is an open-source package manager for Kubernetes. In this pattern, Helm is used to install the AWS Load Balancer Controller.
- [Kubernetes](#) is an open-source system for automating deployment, scaling, and management of containerized applications.
- [NGINX](#) is a high-performance web and reverse proxy server.

## Epics

### Create an EKS cluster

Task	Description	Skills required
Create the files.	Using the code in the <a href="#">Additional information</a> section, create the following files: <ul style="list-style-type: none"> <li>• clusterconfig-fargate.yaml</li> <li>• nginx-deployment.yaml</li> <li>• nginx-service.yaml</li> <li>• nginx-ingress.yaml</li> </ul>	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>index.html</code></li></ul>	
Set environment variables.	<p><b>Note:</b> If a command fails because of previous unfinished tasks, wait a few seconds, and then run the command again.</p> <p>This pattern uses the AWS Region and cluster name that are defined in the file <code>clusterconfig-fargate.yaml</code>. Set the same values as environment variables to reference them in further commands.</p> <pre>export AWS_REGION="us-east-1" export CLUSTER_NAME="my-fargate"</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Create an EKS cluster.	<p>To create an EKS cluster that uses the specifications from the <code>clusterconfig-fargate.yaml</code> file, run the following command.</p> <pre data-bbox="594 491 1029 648">eksctl create cluster -f clusterconfig-fargate.yaml</pre> <p>The file contains the <code>ClusterConfig</code>, which provisions a new EKS cluster named <code>my-fargate-cluster</code> in the <code>us-east-1</code> Region and one default Fargate profile (<code>fp-default</code>).</p> <p>The default Fargate profile is configured with two selectors (<code>default</code> and <code>kube-system</code>).</p>	App developer, AWS DevOps, AWS administrator

Task	Description	Skills required
	<p data-bbox="591 226 1024 306">To check the created cluster, run the following command.</p> <pre data-bbox="591 348 1024 464">eksctl get cluster --output yaml</pre> <p data-bbox="591 506 1024 585">The output should be the following.</p> <pre data-bbox="591 627 1024 779">- Name: my-fargate   Owned: "True"   Region: us-east-1</pre> <p data-bbox="591 821 1024 951">Check the created Fargate profile by using the <code>CLUSTER_NAME</code> .</p> <pre data-bbox="591 993 1024 1184">eksctl get fargateprofile --cluster \$CLUSTER_NAME --output yaml</pre> <p data-bbox="591 1226 1024 1499">This command displays information about the resources. You can use the information to verify the created cluster. The output should be the following.</p> <pre data-bbox="591 1541 1024 1866">- name: fp-default   podExecutionRoleARN: arn:aws:iam::&lt;YOUR-ACCOUNT-ID&gt;:role/eksctl-my-fargate-cluster-FargatePodExecutionRole-xxx   selectors:</pre>	<p data-bbox="1066 226 1503 306">App developer, AWS DevOps, AWS systems administrator</p>

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>- namespace: default</li> <li>- namespace: kube-system</li> <li>status: ACTIVE</li> <li>subnets:</li> <li>- subnet-aaa</li> <li>- subnet-bbb</li> <li>- subnet-ccc</li> </ul>	

## Deploy a container

Task	Description	Skills required
<p>Deploy the NGINX web server.</p>	<p>To apply the NGINX web server deployment on the cluster, run the following command.</p> <pre data-bbox="594 1050 1027 1167">kubectl apply -f ./nginx-deployment.yaml</pre> <p>The output should be the following.</p> <pre data-bbox="594 1325 1027 1442">deployment.apps/nginx-deployment created</pre> <p>The deployment includes three replicas of the NGINX image taken from the Amazon ECR Public Gallery. The image is deployed to the default namespace and exposed on port 80 on the running pods.</p>	<p>App developer, AWS DevOps, AWS systems administrator</p>

Task	Description	Skills required
<p>Check the deployment and pods.</p>	<p>(Optional) Check the deployment. You can verify the status of your deployment with the following command.</p> <pre data-bbox="597 489 1027 569">kubect1 get deployment</pre> <p>The output should be the following.</p> <pre data-bbox="597 726 1027 1003">NAME   READY   UP-TO-DATE   AVAILABLE   AGE nginx-deployment   3/3                 3           3                 7m14s</pre> <p>A pod is a deployable object in Kubernetes, containing one or more containers. To list all pods, run the following command.</p> <pre data-bbox="597 1308 1027 1388">kubect1 get pods</pre> <p>The output should be the following.</p> <pre data-bbox="597 1545 1027 1833">NAME   STATUS    READY   AGE      RESTARTS nginx-deployment-xxxx- aaa   1/1     Running 0           94s</pre>	<p>App developer, AWS DevOps, AWS administrator</p>

Task	Description	Skills required
	<pre>nginx-deployment-xxxx- bbb 1/1 Running 0 94s nginx-deployment-xxxx- ccc 1/1 Running 0 94s</pre>	
Scale the deployment.	<p>To scale the deployment from the three replicas that were specified in <code>deployment.yaml</code> to four replicas, use the following command.</p> <pre>kubectl scale deployment nginx-deployment --replicas 4</pre> <p>The output should be the following.</p> <pre>deployment.apps/nginx-deployment scaled</pre>	App developer, AWS DevOps, AWS systems administrator

## Deploy an AWS Load Balancer Controller

Task	Description	Skills required
Set environment variables.	<p>Describe the cluster's CloudFormation stack to retrieve information about its VPC.</p> <pre>aws cloudformation describe-stacks --stack-name eksctl-\$CLUSTER_NAME-cluste</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
	<pre data-bbox="610 212 1011 384">r --query "Stacks[0].Outputs[?OutputKey==`\VPC\`].OutputValue"</pre> <p data-bbox="591 422 961 506">The output should be the following.</p> <pre data-bbox="610 548 1011 741">[   "vpc-&lt;YOUR-VPC-ID&gt;" ]</pre> <p data-bbox="591 779 1024 863">Copy the VPC ID and export it as an environment variable.</p> <pre data-bbox="610 905 1011 1020">export VPC_ID="vpc-&lt;YOUR-VPC-ID&gt;"</pre>	
Configure IAM for the cluster service account.	<p data-bbox="591 1058 1024 1283">Use the <code>AWS_REGION</code> and <code>CLUSTER_NAME</code> from the earlier epic to create an IAM Open ID Connect provider for the cluster.</p> <pre data-bbox="610 1325 1011 1598">eksctl utils associate-iam-oidc-provider \ --region \$AWS_REGION \ --cluster \$CLUSTER_NAME \ --approve</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Download and create the IAM policy.	<p>Download the IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf.</p> <pre data-bbox="594 489 1027 848">curl -o iam-policy.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/main/docs/install/iam_policy.json</pre> <p>Create the policy in your AWS account by using the AWS CLI.</p> <pre data-bbox="594 1003 1027 1320">aws iam create-policy \ --policy-name AWSLoadBalancerControllerIAMPolicy \ --policy-document file://iam-policy.json</pre> <p>You should see the following output.</p> <pre data-bbox="594 1478 1027 1852">{   "Policy": {     "PolicyName":       "AWSLoadBalancerControllerIAMPolicy",     "PolicyId":       "&lt;YOUR_POLICY_ID&gt;",     "Arn": "arn:aws:iam::&lt;YOUR-ACCOUNT</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
	<pre>-ID&gt;:policy/AWSLoadBalancerControllerIAMPolicy",     "Path": "/",     "DefaultVersionId": "v1",     "AttachmentCount": 0,     "PermissionsBoundaryUsageCount": 0,     "IsAttachable": true,     "CreateDate": "&lt;YOUR-DATE&gt;",     "UpdateDate": "&lt;YOUR-DATE&gt;"   } }</pre> <p>Save the Amazon Resource Name (ARN) of the policy as \$POLICY_ARN .</p> <pre>export POLICY_ARN="arn:aws:iam::&lt;YOUR-ACCOUNT-ID&gt;:policy/AWSLoadBalancerControllerIAMPolicy"</pre>	

Task	Description	Skills required
Create an IAM service account.	<p>Create an IAM service account named <code>aws-load-balancer-controller</code> in the <code>kube-system</code> namespace. Use the <code>CLUSTER_NAME</code>, <code>AWS_REGION</code>, and <code>POLICY_ARN</code> that you previously configured.</p> <pre data-bbox="597 684 1027 1276">eksctl create iamserviceaccount \   --cluster=\$CLUSTER_NAME \   --region=\$AWS_REGION \   --attach-policy-arn=\$POLICY_ARN \   --namespace=kube-system \   --name=aws-load-balancer-controller \   --override-existing-serviceaccounts \   --approve</pre> <p>Verify the creation.</p> <pre data-bbox="597 1392 1027 1778">eksctl get iamserviceaccount \   --cluster \$CLUSTER_NAME \   --name aws-load-balancer-controller \   --namespace kube-system \   --output yaml</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
	<p>The output should be the following.</p> <pre data-bbox="597 331 1026 1285">- metadata:   name: aws-load-balancer-controller   namespace: kube-system   status:     roleARN: arn:aws:iam::&lt;YOUR-ACCOUNT-ID&gt;:role/eksctl-my-fargate-addon-iam-serviceaccount-kubernetes-Role1-&lt;YOUR-ROLE-ID&gt;     wellKnownPolicies:       autoScaler: false       awsLoadBalancerController: false       certManager: false       ebsCSIController: false       efsCSIController: false       externalDNS: false       imageBuilder: false</pre>	

Task	Description	Skills required
Install the AWS Load Balancer Controller.	<p>Update the Helm repository.</p> <pre>helm repo update</pre> <p>Add the Amazon EKS chart repository to the Helm repo.</p> <pre>helm repo add eks https://aws.github.io/eks-charts</pre> <p>Apply the Kubernetes custom resource definitions (CRDs) that are used by the <a href="#">AWS Load Balancer Controller eks-chart</a> in the background.</p> <pre>kubectl apply -k "github.com/aws/eks-charts/stable/aws-load-balancer-controller//crds?ref=master"</pre> <p>The output should be the following.</p> <pre>customresourcedefinition.apiextensions.k8s.io/ingressclassparams.elbv2.k8s.aws created customresourcedefinition.apiextensions.k8s.io/targetgroupbindings.elbv2.k8s.aws created</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
	<p>Install the Helm chart, using the environment variables that you set previously.</p> <pre data-bbox="597 380 1027 1014">helm install aws-load-balancer-controller eks/aws-load-balancer-controller \   --set clusterName=\$CLUSTER_NAME \   --set serviceAccount.create=false \   --set region=\$AWS_REGION \   --set vpcId=\$VPC_ID \   --set serviceAccount.name=aws-load-balancer-controller \   -n kube-system</pre> <p>The output should be the following.</p> <pre data-bbox="597 1171 1027 1650">NAME: aws-load-balancer-controller LAST DEPLOYED: &lt;YOUR-DATE&gt; NAMESPACE: kube-system STATUS: deployed REVISION: 1 TEST SUITE: None NOTES: AWS Load Balancer controller installed!</pre>	

Task	Description	Skills required
Create an NGINX service.	<p>Create a service to expose the NGINX pods by using the <code>nginx-service.yaml</code> file.</p> <pre>kubectl apply -f nginx-service.yaml</pre> <p>The output should be the following.</p> <pre>service/nginx-service created</pre>	App developer, AWS DevOps, AWS systems administrator
Create the Kubernetes ingress resource.	<p>Create a service to expose the Kubernetes NGINX ingress by using the <code>nginx-ingress.yaml</code> file.</p> <pre>kubectl apply -f nginx-ingress.yaml</pre> <p>The output should be the following.</p> <pre>ingress.networking.k8s.io/nginx-ingress created</pre>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Get the load balancer URL.	<p>To retrieve the ingress information, use the following command.</p> <pre>kubectl get ingress nginx-ingress</pre> <p>The output should be the following.</p> <pre> NAME                CLASS HOSTS              ADDRESS                  PORTS    AGE nginx-ingress      &lt;none&gt; *                  k8s-defau lt-nginxing-xxx.us -east-1.elb.amazon aws.com            80      80s</pre> <p>Copy the ADDRESS (for example, k8s-default-nginxing-xxx.us-east-1.elb.amazonaws.com ) from the output, and paste it into your browser to access the <code>index.html</code> file.</p>	App developer, AWS DevOps, AWS systems administrator

## Debug running containers

Task	Description	Skills required
Select a pod.	List all pods, and copy the desired pod's name.	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
	<pre data-bbox="597 212 1027 289">kubectl get pods</pre> <p data-bbox="597 327 959 405">The output should be the following.</p> <pre data-bbox="597 443 1027 1276">NAME       STATUS   READY       AGE      RESTARTS nginx-deployment- xxxx-aaa      1/1   Running    0   55m nginx-deployment- xxxx-bbb      1/1   Running    0   55m nginx-deployment- xxxx-ccc      1/1   Running    0   55m nginx-deployment- xxxx-ddd      1/1   Running    0   42m</pre> <p data-bbox="597 1314 1000 1444">This command lists the existing pods and additional information.</p> <p data-bbox="597 1493 1013 1856">If you are interested in a specific pod, fill in the name of the pod you are interested in for the <code>POD_NAME</code> variable or set it as an environment variable. Otherwise, omit this parameter to look up all resources.</p>	

Task	Description	Skills required
	<pre>export POD_NAME="nginx- deployment-&lt;YOUR-POD- NAME&gt;"</pre>	
Access the logs.	<p>Get the logs from the pod that you want to debug.</p> <pre>kubectl logs \$POD_NAME</pre>	App developer, AWS systems administrator, AWS DevOps
Forward the NGINX port.	<p>Use port-forwarding to map the pod's port for accessing the NGINX web server to a port on your local machine.</p> <pre>kubectl port-forward deployment/nginx-d eployment 8080:80</pre> <p>In your browser, open the following URL.</p> <pre>http://localhost:8080</pre> <p>The <code>port-forward</code> command provides access to the <code>index.html</code> file without making it publicly available over a load balancer. This is useful for accessing the running application while debugging it. You can stop the port-forwarding by pressing the keyboard command <b>Ctrl+C</b>.</p>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Run commands within the pod.	<p>To look at the current <code>index.html</code> file, use the following command.</p> <pre>kubectl exec \$POD_NAME -- cat /usr/share/ nginx/html/index.html</pre> <p>You can use the <code>exec</code> command to issue any command directly in the pod. This is useful for debugging running applications.</p>	App developer, AWS DevOps, AWS systems administrator
Copy files to a pod.	<p>Remove the default <code>index.html</code> file on this pod.</p> <pre>kubectl exec \$POD_NAME -- rm /usr/share/ nginx/html/index.html</pre> <p>Upload the customized local file <code>index.html</code> to the pod.</p> <pre>kubectl cp index.html \$POD_NAME:/usr/share/ nginx/html/</pre> <p>You can use the <code>cp</code> command to change or add files directly to any of the pods.</p>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Use port-forwarding to display the change.	<p>Use port-forwarding to verify the changes that you made to this pod.</p> <pre>kubectl port-forward pod/\$POD_NAME 8080:80</pre> <p>Open the following URL in your browser.</p> <pre>http://localhost:8080</pre> <p>The applied changes to the <code>index.html</code> file should be visible in the browser.</p>	App developer, AWS DevOps, AWS systems administrator

## Delete resources

Task	Description	Skills required
Delete the load balancer.	<p>Delete the ingress.</p> <pre>kubectl delete ingress/n ginx-ingress</pre> <p>The output should be the following.</p> <pre>ingress.networking .k8s.io "nginx-in gress" deleted</pre> <p>Delete the service.</p>	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
	<pre>kubectl delete service/n ginx-service</pre> <p>The output should be the following.</p> <pre>service "nginx-service" deleted</pre> <p>Delete the load balancer controller.</p> <pre>helm delete aws-load- balancer-controller - n kube-system</pre> <p>The output should be the following.</p> <pre>release "aws-load- balancer-controller" uninstalled</pre> <p>Delete the service account.</p> <pre>eksctl delete iamservic eaccount --cluster \$CLUSTER_NAME -- namespace kube-syst em --name aws-load- balancer-controller</pre>	

Task	Description	Skills required
Delete the deployment.	<p>To delete the deployment resources, use the following command.</p> <pre>kubectl delete deploy/nginx-deployment</pre> <p>The output should be the following.</p> <pre>deployment.apps "nginx-deployment" deleted</pre>	App developer, AWS DevOps, AWS systems administrator
Delete the cluster.	<p>Delete the EKS cluster by using the following command, where <code>my-fargate</code> is the cluster name.</p> <pre>eksctl delete cluster --name \$CLUSTER_NAME</pre> <p>This command deletes the entire cluster, including all associated resources.</p>	App developer, AWS DevOps, AWS systems administrator
Delete the IAM policy.	<p>Delete the previously created policy by using the AWS CLI.</p> <pre>aws iam delete-policy --policy-arn \$POLICY_ARN</pre>	App developer, AWS administrator, AWS DevOps

## Troubleshooting

Issue	Solution
<p>You receive an <a href="#">error message upon cluster creation</a> stating that your targeted Availability Zone doesn't have sufficient capacity to support the cluster. You should see a message similar to the following.</p> <pre data-bbox="115 611 792 966">Cannot create cluster 'my-fargate' because us-east-1e, the targeted availability zone, does not currently have sufficient capacity to support the cluster. Retry and choose from these availability zones: us-east-1a, us-east-1b, us-east-1c, us-east-1d, us-east-1f</pre>	<p>Create the cluster again using the recommended Availability Zones from the error message. Specify a list of Availability Zones in the last line of your <code>clusterconfig-fargate.yaml</code> file (for example, <code>availabilityZones: ["us-east-1a", "us-east-1b", "us-east-1c"]</code> ).</p>

# Deploy containers by using Elastic Beanstalk

Created by Thomas Scott (AWS) and Jean-Baptiste Guillois (AWS)

**Code repository:** [Cluster](#)  
[Sample App](#)

**Environment:** Production

**Technologies:** Containers & microservices; CloudNative; Modernization

**AWS services:** AWS Elastic Beanstalk

## Summary

On the Amazon Web Services (AWS) Cloud, AWS Elastic Beanstalk supports Docker as an available platform, so that containers can run with the created environment. This pattern shows how to deploy containers using the Elastic Beanstalk service. The deployment of this pattern will use the web server environment based on the Docker platform.

To use Elastic Beanstalk for deploying and scaling web applications and services, you upload your code and the deployment is automatically handled. Capacity provisioning, load balancing, automatic scaling, and application health monitoring are also included. When you use Elastic Beanstalk, you can take full control over the AWS resources that it creates on your behalf. There is no additional charge for Elastic Beanstalk. You pay only for the AWS resources that are used to store and run your applications.

This pattern includes instructions for deployment using the [AWS Elastic Beanstalk Command Line Interface \(EB CLI\)](#) and the AWS Management Console.

## Use cases

Use cases for Elastic Beanstalk include the following:

- Deploy a prototype environment to demo a frontend application. (This pattern uses a Dockerfile as the example.)
- Deploy an API to handle API requests for a given domain.
- Deploy an orchestration solution using Docker-Compose (`docker-compose.yml` is not used as the practical example in this pattern).

## Prerequisites and limitations

### Prerequisites

- An AWS account
- AWS EB CLI locally installed
- Docker installed on a local machine

### Limitations

- There is a Docker pull limit of 100 pulls per 6 hours per IP address on the free plan.

## Architecture

### Target technology stack

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Security group
- Application Load Balancer
- Auto Scaling group

### Target architecture

## Automation and scale

AWS Elastic Beanstalk can automatically scale based on the number of requests made. AWS resources created for an environment include one Application Load Balancer, an Auto Scaling group, and one or more Amazon EC2 instances.

The load balancer sits in front of the Amazon EC2 instances, which are part of the Auto Scaling group. Amazon EC2 Auto Scaling automatically starts additional Amazon EC2 instances to accommodate increasing load on your application. If the load on your application decreases, Amazon EC2 Auto Scaling stops instances, but it keeps at least one instance running.

## Automatic scaling triggers

The Auto Scaling group in your Elastic Beanstalk environment uses two Amazon CloudWatch alarms to initiate scaling operations. The default triggers scale when the average outbound network traffic from each instance is higher than 6 MB or lower than 2 MB over a period of five

minutes. To use Amazon EC2 Auto Scaling effectively, configure triggers that are appropriate for your application, instance type, and service requirements. You can scale based on several statistics including latency, disk I/O, CPU utilization, and request count. For more information, see [Auto Scaling triggers](#).

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS EB Command Line Interface \(EB CLI\)](#) is a command-line client that you can use to create, configure, and manage Elastic Beanstalk environments.
- [Elastic Load Balancing](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

### Other services

- [Docker](#) packages software into standardized units called containers that include libraries, system tools, code, and runtime.

### Code

The code for this pattern is available in the GitHub [Cluster Sample Application](#) repository.

## Epics

### Build with a Dockerfile

Task	Description	Skills required
Clone the remote repository.	<ul style="list-style-type: none"><li>• To clone the repository, run the command <code>git clone https://github.com/aws-samples/</code></li></ul>	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
<p>Initialize the Elastic Beanstalk Docker project.</p>	<p><code>cluster-sample-app.git</code>.</p> <ol style="list-style-type: none"> <li>1. Create a file called <code>aws.json</code> at the root.</li> <li>2. In the <code>aws.json</code> file, add the following code.</li> </ol> <pre data-bbox="630 569 1029 1283"> {   "AWSEBDoc kerrunVersion":"1",   "Image":{     "Name":"c luster-sample-app"   },   "Ports":[     {       "ContainerPort":80     },     {       "HostPort":8080     }   ] } </pre> <ol style="list-style-type: none"> <li>3. Run the command <code>eb init -p docker</code> at the root of the project.</li> </ol>	<p>App developer, AWS administrator, AWS DevOps</p>
<p>Test the project locally.</p>	<ol style="list-style-type: none"> <li>1. Run the command <code>eb local run</code> at the root of the project.</li> <li>2. Test the application by navigating to <code>http://localhost</code>.</li> </ol>	<p>App developer, AWS administrator, AWS DevOps</p>

## Deploy using EB CLI

Task	Description	Skills required
Run deployment command	1. Run the command <code>eb create docker-sample-cluster-app</code> at the root of the project.	App developer, AWS administrator, AWS DevOps
Access the deployed version.	After the deployment command has finished, access the project using the <code>eb open</code> command.	App developer, AWS administrator, AWS DevOps

## Deploy using the console

Task	Description	Skills required
Deploy the application by using the browser.	<ol style="list-style-type: none"><li>1. Open the console.</li><li>2. Navigate to the Elastic Beanstalk console.</li><li>3. Choose <b>Create Application</b>.</li><li>4. For the <b>Application Name</b>, enter <b>Cluster-Sample-App</b>.</li><li>5. Choose <b>Docker</b> as the platform.</li><li>6. Choose <b>Upload your code</b>.</li><li>7. Choose your local <code>.zip</code> file (in the root of the cloned project) or a public Amazon Simple Storage Service (Amazon S3) URL.</li></ol>	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
Access the deployed version.	After deployment, access the deployed application, and choose the URL provided.	App developer, AWS administrator, AWS DevOps

## Related resources

- [Web server environments](#)
- [Install the EB CLI on macOS](#)
- [Manually install the EB CLI](#)

## Additional information

### Advantages of using Elastic Beanstalk

- Automatic infrastructure provisioning
- Automatic management of the underlying platform
- Automatic patching and updates to support the application
- Automatic scaling of the application
- Ability to customize the number of nodes
- Ability to access the infrastructure components if needed
- Ease of deployment over other container deployment solutions

# Generate a static outbound IP address using a Lambda function, Amazon VPC, and a serverless architecture

Created by Thomas Scott (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; DevelopmentAndTesting

**AWS services:** AWS Lambda

## Summary

This pattern describes how to generate a static outbound IP address in the Amazon Web Services (AWS) Cloud by using a serverless architecture. Your organization can benefit from this approach if it wants to send files to a separate business entity by using Secure File Transfer Protocol (SFTP). This means that the business entity must have access to an IP address that allows files through its firewall.

The pattern's approach helps you create an AWS Lambda function that uses an [Elastic IP address](#) as the outbound IP address. By following the steps in this pattern, you can create a Lambda function and a virtual private cloud (VPC) that routes outbound traffic through an internet gateway with a static IP address. To use the static IP address, you attach the Lambda function to the VPC and its subnets.

## Prerequisites and limitations

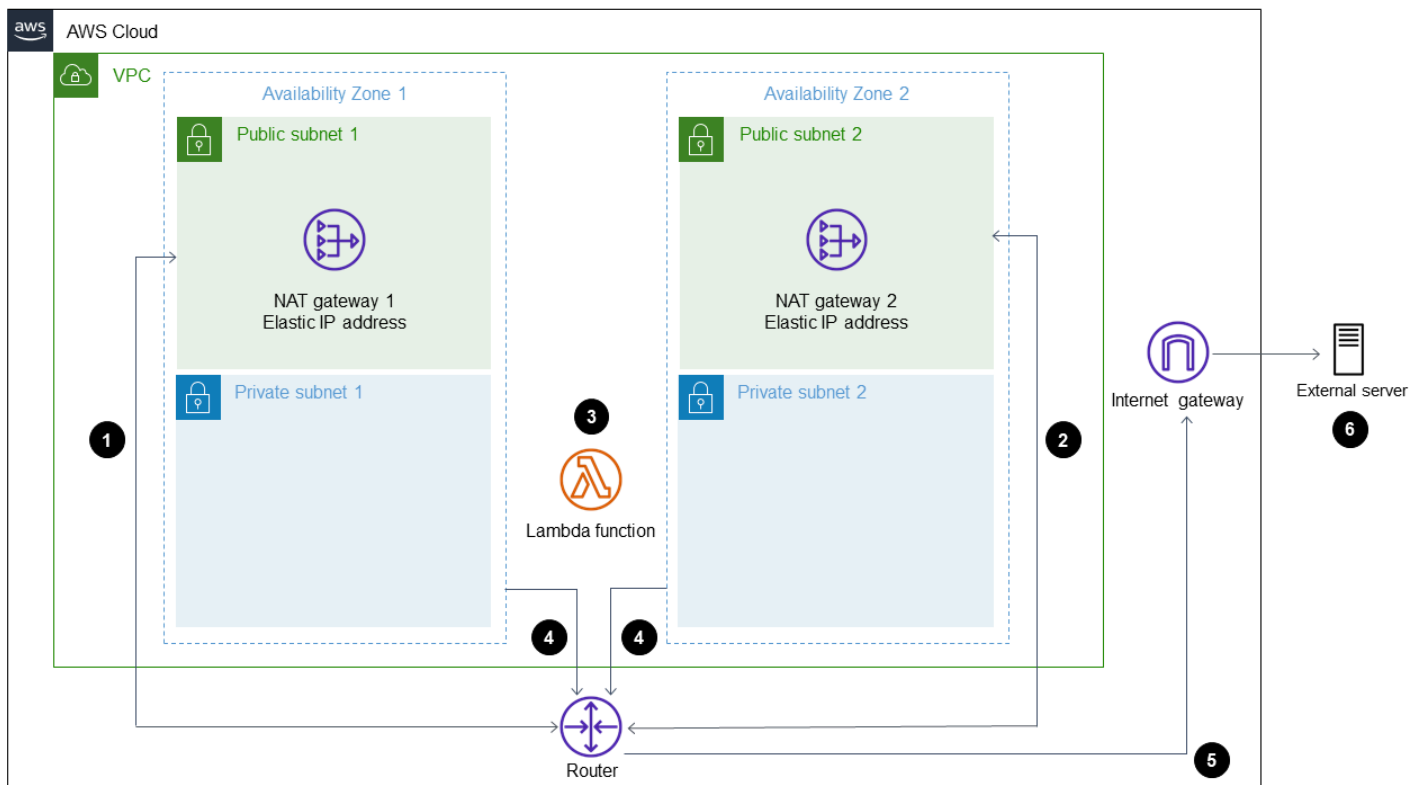

### Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) permissions to create and deploy a Lambda function, and to create a VPC and its subnets. For more information about this, see [Execution role and user permissions](#) in the AWS Lambda documentation.
- If you plan to use infrastructure as code (IaC) to implement this pattern's approach, you need an integrated development environment (IDE) such as AWS Cloud9. For more information about this, see [What is AWS Cloud9?](#) in the AWS Cloud9 documentation.

# Architecture

The following diagram shows the serverless architecture for this pattern.

The diagram shows the following workflow:

1. Outbound traffic leaves NAT gateway 1 in Public subnet 1.
2. Outbound traffic leaves NAT gateway 2 in Public subnet 2.
3. The Lambda function can run in Private subnet 1 or Private subnet 2.
4. Private subnet 1 and Private subnet 2 route traffic to the NAT gateways in the public subnets.
5. The NAT gateways send outbound traffic to the internet gateway from the public subnets.
6. Outbound data is transferred from the internet gateway to the external server.

## Technology stack

- Lambda
- Amazon Virtual Private Cloud (Amazon VPC)

## Automation and scale

You can ensure high availability (HA) by using two public and two private subnets in different Availability Zones. Even if one Availability Zone becomes unavailable, the pattern's solution continues to work.

## Tools

- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- [Amazon VPC](#) – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

## Epics

### Create a new VPC

Task	Description	Skills required
Create a new VPC.	<p>Sign in to the AWS Management Console, open the Amazon VPC console, and then create a VPC named Lambda VPC that has <code>10.0.0.0/25</code> as the IPv4 CIDR range.</p> <p>For more information about creating a VPC, see <a href="#">Getting started with Amazon VPC</a> in the Amazon VPC documentation.</p>	AWS administrator

## Create two public subnets

Task	Description	Skills required
Create the first public subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Subnets</b> and then choose <b>Create Subnet</b>.</li><li>2. For <b>Name tag</b>, enter <code>public-one</code> .</li><li>3. For <b>VPC</b>, choose Lambda VPC.</li><li>4. Choose an Availability Zone and record it.</li><li>5. For <b>IPv4 CIDR block</b>, enter <code>10.0.0.0/28</code> and then choose <b>Create subnet</b>.</li></ol>	AWS administrator
Create the second public subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Subnets</b> and then choose <b>Create Subnet</b>.</li><li>2. For <b>Name tag</b>, enter <code>public-two</code> .</li><li>3. For <b>VPC</b>, choose Lambda VPC.</li><li>4. Choose an Availability Zone and record it. <b>Important</b> : You cannot use the Availability Zone that contains the <code>public-one</code> subnet.</li><li>5. For <b>IPv4 CIDR block</b>, enter <code>10.0.0.16/28</code> and then choose <b>Create subnet</b>.</li></ol>	AWS administrator

## Create two private subnets

Task	Description	Skills required
Create the first private subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Subnets</b> and then choose <b>Create Subnet</b>.</li><li>2. For <b>Name tag</b>, enter <code>private-one</code> .</li><li>3. For <b>VPC</b>, choose Lambda VPC.</li><li>4. Choose the Availability Zone that contains the <code>public-one</code> subnet that you created earlier.</li><li>5. For <b>IPv4 CIDR block</b>, enter <code>10.0.0.32/28</code> and then choose <b>Create subnet</b>.</li></ol>	AWS administrator
Create the second private subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Subnets</b> and then choose <b>Create Subnet</b>.</li><li>2. For <b>Name tag</b>, enter <code>private-two</code> .</li><li>3. For <b>VPC</b>, choose Lambda VPC.</li><li>4. Choose the same Availability Zone that contains the <code>public-two</code> subnet that you created earlier.</li><li>5. For <b>IPv4 CIDR block</b>, enter <code>10.0.0.64/28</code> and then choose <b>Create subnet</b>.</li></ol>	AWS administrator

## Create two Elastic IP addresses for your NAT gateways

Task	Description	Skills required
Create the first Elastic IP address.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Elastic IPs</b> and then choose <b>Allocate new address</b>.</li><li>2. Choose <b>Allocate</b> and record the <b>Allocation ID</b> for your newly created Elastic IP address.</li></ol> <p><b>Note:</b> This Elastic IP address is used for your first NAT gateway.</p>	AWS administrator
Create the second Elastic IP address.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Elastic IPs</b> and then choose <b>Allocate new address</b>.</li><li>2. Choose <b>Allocate</b> and record the <b>Allocation ID</b> for this second Elastic IP address.</li></ol> <p><b>Note:</b> This Elastic IP address is used for your second NAT gateway.</p>	AWS administrator

## Create an internet gateway

Task	Description	Skills required
Create an internet gateway.	<ol style="list-style-type: none"> <li>1. On the Amazon VPC console, choose <b>Internet Gateways</b> and then choose <b>Create internet gateway</b>.</li> <li>2. Enter <code>internet-gateway</code> as the name and then choose <b>Create internet gateway</b>. Make sure that you record the internet gateway ID.</li> </ol>	AWS administrator
Attach the internet gateway to the VPC.	Select the internet gateway that you just created, and then choose <b>Actions, Attach to VPC</b> .	AWS administrator

## Create two NAT gateways

Task	Description	Skills required
Create the first NAT gateway.	<ol style="list-style-type: none"> <li>1. On the Amazon VPC console, choose <b>NAT Gateways</b> and then choose <b>Create NAT Gateway</b>.</li> <li>2. Enter <code>nat-one</code> as the NAT gateway name.</li> <li>3. Choose <code>public-one</code> as the subnet to create the NAT gateway in.</li> <li>4. For <b>Connectivity type</b>, choose <b>Public</b>.</li> </ol>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>5. For <b>Elastic IP allocation ID</b>, choose the first Elastic IP address that you created earlier and associate it with the NAT gateway.</li><li>6. Choose <b>Create NAT gateway</b>.</li></ol>	
Create the second NAT gateway.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>NAT Gateways</b> and then choose <b>Create NAT Gateway</b>.</li><li>2. Enter <code>nat-two</code> as the NAT gateway name.</li><li>3. Choose <code>public-two</code> as the subnet to create the NAT gateway in.</li><li>4. For <b>Connectivity type</b>, choose <b>Public</b>.</li><li>5. For <b>Elastic IP allocation ID</b>, choose the second Elastic IP address that you created earlier and associate it with the NAT gateway.</li><li>6. Choose <b>Create NAT gateway</b>.</li></ol>	AWS administrator

## Create route tables for your public and private subnets

Task	Description	Skills required
Create the route table for the public-one subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Route Tables</b> and then choose <b>Create route table</b>.</li><li>2. Enter public-one-subnet as the route table name and then choose <b>Create route table</b>.</li><li>3. Choose the public-one-subnet route table, choose <b>Edit routes</b>, and then choose <b>Add route</b>.</li><li>4. Specify 0.0.0.0 in the <b>Destination</b> box and then choose the internet gateway ID in the <b>Target</b> list.</li><li>5. On the <b>Subnet associations</b> tab, choose <b>Edit subnet associations</b>, choose the public-one subnet with the 10.0.0.0/28 CIDR range, and then choose <b>Save associations</b>.</li><li>6. Choose <b>Save Changes</b>.</li></ol>	AWS administrator
Create the route table for the public-two subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Route Tables</b> and then choose <b>Create route table</b>.</li></ol>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="591 212 1013 390">2. Enter <code>public-two-subnet</code> as the route table name and then choose <b>Create route table</b>.</li><li data-bbox="591 415 980 594">3. Choose the <code>public-two-subnet</code> route table, choose <b>Edit routes</b>, and then choose <b>Add route</b>.</li><li data-bbox="591 619 992 840">4. Specify <code>0.0.0.0</code> in the <b>Destination</b> box and then choose the internet gateway ID in the <b>Target</b> list.</li><li data-bbox="591 865 984 1234">5. On the <b>Subnet associations</b> tab, choose <b>Edit subnet associations</b>, choose the <code>public-two</code> subnet with the <code>10.0.0.16/28</code> CIDR range, and then choose <b>Save associations</b>.</li><li data-bbox="591 1260 959 1291">6. Choose <b>Save Changes</b>.</li></ol>	

Task	Description	Skills required
Create the route table for the private-one subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Route Tables</b> and then choose <b>Create route table</b>.</li><li>2. Enter <code>private-one-subnet</code> as the route table name and then choose <b>Create route table</b>.</li><li>3. Choose the <code>private-one-subnet</code> route table, choose <b>Edit routes</b>, and then choose <b>Add route</b>.</li><li>4. Specify <code>0.0.0.0</code> in the <b>Destination</b> box and then choose the NAT gateway in the <code>public-one</code> subnet in the <b>Target</b> list.</li><li>5. On the <b>Subnet associations</b> tab, choose <b>Edit subnet associations</b>, choose the <code>private-one</code> subnet with the <code>10.0.0.32/28</code> CIDR range, and then choose <b>Save associations</b>.</li><li>6. Choose <b>Save Changes</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Create the route table for the private-two subnet.	<ol style="list-style-type: none"><li>1. On the Amazon VPC console, choose <b>Route Tables</b> and then choose <b>Create route table</b>.</li><li>2. Enter <code>private-two-subnet</code> as the route table name and then choose <b>Create route table</b>.</li><li>3. Choose the <code>private-two-subnet</code> route table, choose <b>Edit routes</b>, and then choose <b>Add route</b>.</li><li>4. Specify <code>0.0.0.0</code> in the <b>Destination</b> box and then choose the NAT gateway in the <code>public-two</code> subnet in the <b>Target</b> list.</li><li>5. On the <b>Subnet associations</b> tab, choose <b>Edit subnet associations</b>, choose the <code>private-two</code> subnet with the <code>10.0.0.64/28</code> CIDR range, and then choose <b>Save associations</b>.</li><li>6. Choose <b>Save Changes</b>.</li></ol>	AWS administrator

## Create the Lambda function, add it to the VPC, and test the solution

Task	Description	Skills required
Create a new Lambda function.	<ol style="list-style-type: none"> <li>1. Open the AWS Lambda console and choose <b>Create function</b>.</li> <li>2. Under <b>Basic information</b>, enter Lambda test under <b>Function name</b> and then choose the language of your choice under <b>Runtime</b>.</li> <li>3. Choose <b>Create function</b>.</li> </ol>	AWS administrator
Add the Lambda function to your VPC.	<ol style="list-style-type: none"> <li>1. On the AWS Lambda console, choose <b>Functions</b> and then choose the function that you created earlier.</li> <li>2. Choose <b>Configuration</b> and then choose <b>VPC</b>.</li> <li>3. Choose <b>Edit</b> and then choose Lambda VPC and both private subnets.</li> <li>4. Choose <b>Default security group</b> for testing purposes and then choose <b>Save</b>.</li> </ol>	AWS administrator
Write code to call an external service.	<ol style="list-style-type: none"> <li>1. In the programming language of your choice, write code to call an external service that returns your IP address.</li> </ol>	AWS administrator

Task	Description	Skills required
	2. Verify that the returned IP address matches one of your Elastic IP addresses.

# Identify duplicate container images automatically when migrating to an Amazon ECR repository

Created by Rishabh Yadav (AWS) and Rishi Singla (AWS)

**Code repository:** [automated -solution-to-identify-identical-images-between-various-container-repositories](#)

**Environment:** Production

**Technologies:** Containers & microservices; DevOps; Migration; Modernization

**AWS services:** AWS CodeBuild; AWS CodePipeline; Amazon ECR; AWS CodeCommit

## Summary

The pattern provides an automated solution to identify whether images that are stored in different container repositories are duplicates. This check is useful when you plan to migrate images from other container repositories to Amazon Elastic Container Registry (Amazon ECR).

For foundational information, the pattern also describes the components of a container image, such as the image digest, manifest, and tags. When you plan a migration to Amazon ECR, you might decide to synchronize your container images across container registries by comparing the digests of the images. Before you migrate your container images, you need to check whether these images already exist in the Amazon ECR repository to prevent duplication. However, it can be difficult to detect duplication by comparing image digests, and this might lead to issues in the initial migration phase. This pattern compares the digests of two similar images that are stored in different container registries and explains why the digests vary, to help you compare images accurately.

## Prerequisites and limitations

- An active AWS account
- Access to the [Amazon ECR public registry](#)

- Familiarity with the following AWS services:
  - [AWS CodeCommit](#)
  - [AWS CodePipeline](#)
  - [AWS CodeBuild](#)
  - [AWS Identity and Access Management \(IAM\)](#)
  - [Amazon Simple Storage Service \(Amazon S3\)](#)
- Configured CodeCommit credentials (see [instructions](#))

## Architecture

### Container image components

The following diagram illustrates some of the components of a container image. These components are described after the diagram.

### Terms and definitions

The following terms are defined in the [Open Container Initiative \(OCI\) Image Specification](#).

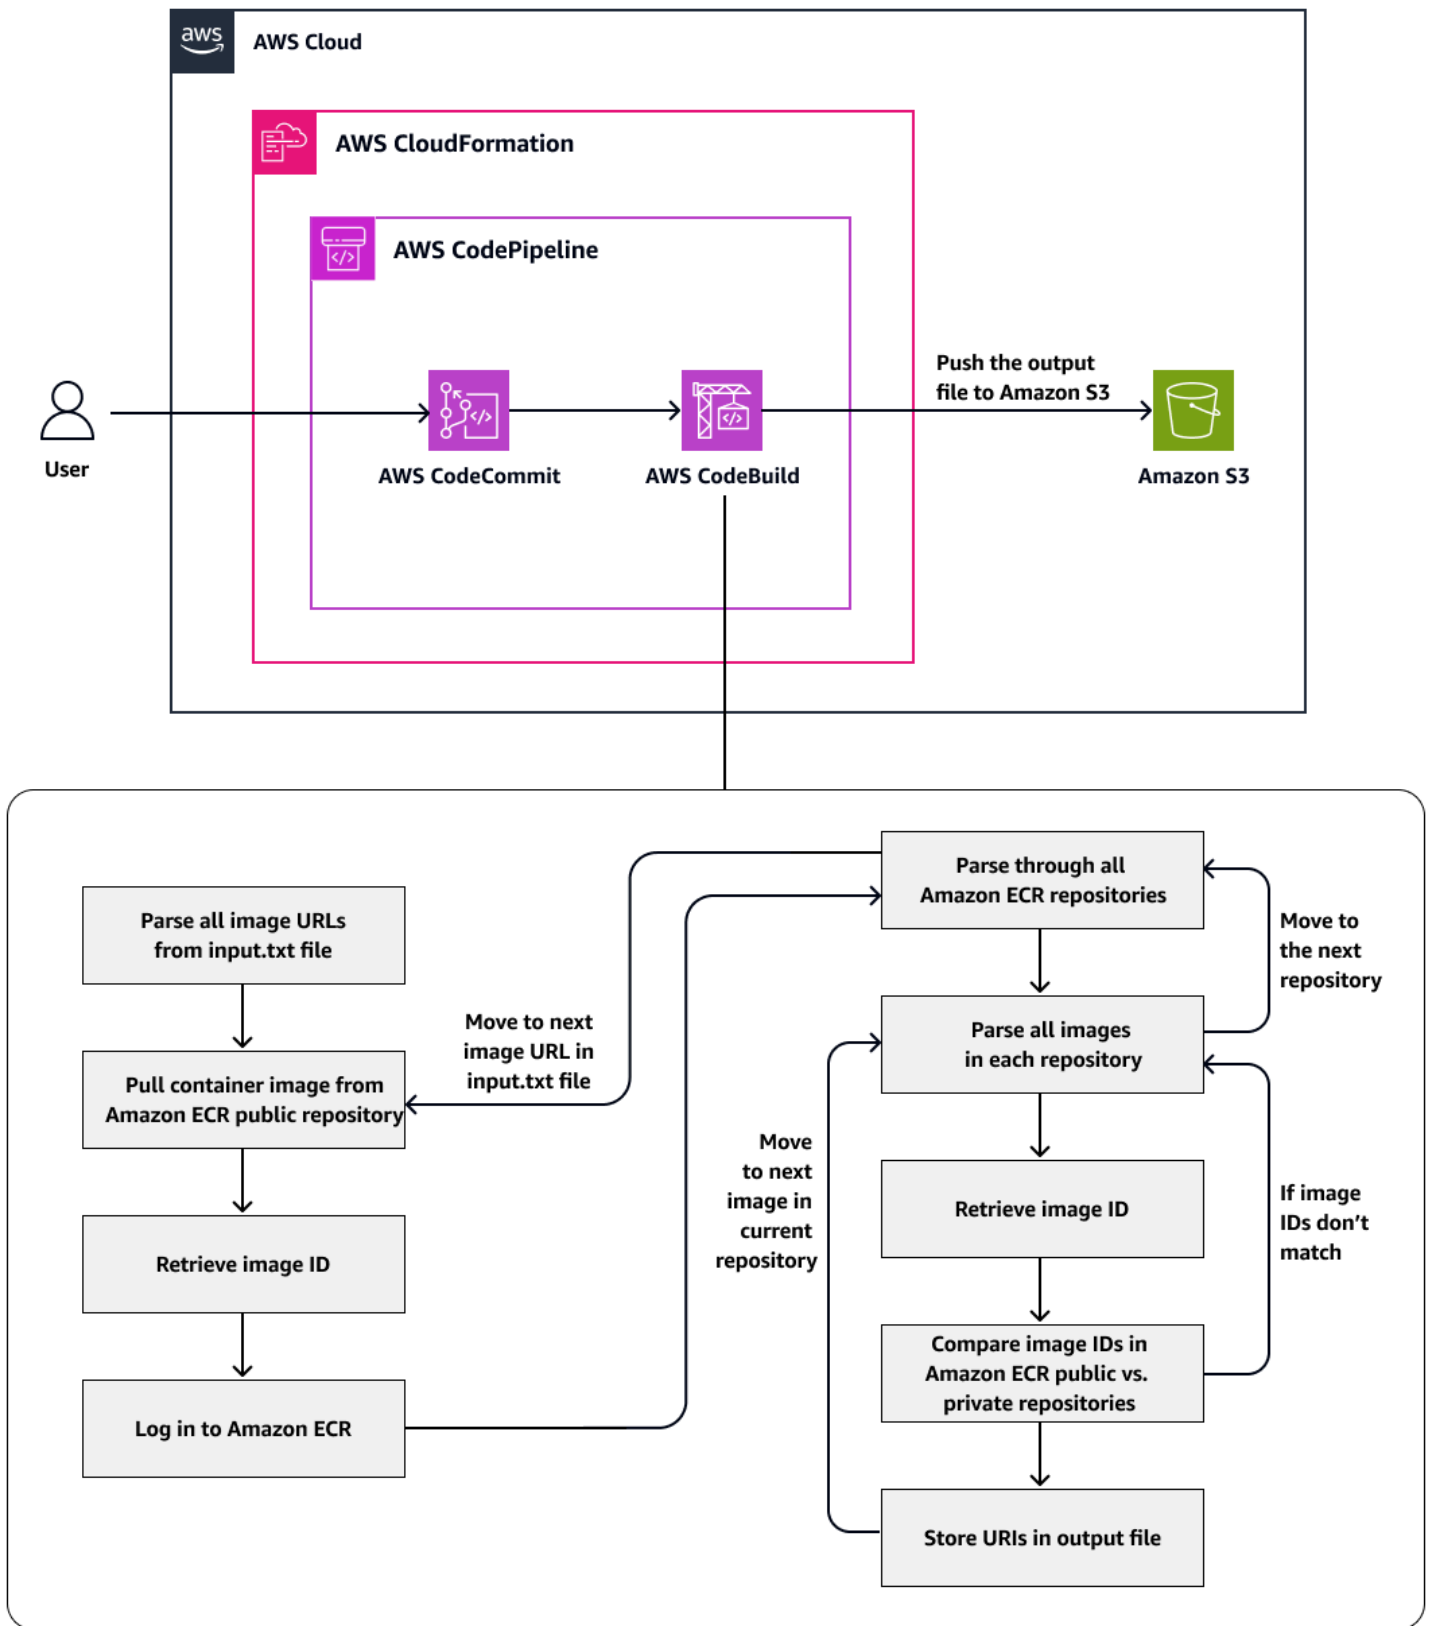

- **Registry:** A service for image storage and management.
- **Client:** A tool that communicates with registries and works with local images.
- **Push:** The process for uploading images to a registry.
- **Pull:** The process for downloading images from a registry.
- **Blob:** The binary form of content that is stored by a registry and can be addressed by a digest.

- **Index:** A construct that identifies multiple image manifests for different computer platforms (such as x86-64 or ARM 64-bit) or media types. For more information, see the [OCI Image Index Specification](#).
- **Manifest:** A JSON document that defines an image or artifact that is uploaded through the manifest's endpoint. A manifest can reference other blobs in a repository by using descriptors. For more information, see the [OCI Image Manifest Specification](#).
- **Filesystem layer:** System libraries and other dependencies for an image.
- **Configuration:** A blob that contains artifact metadata and is referenced in the manifest. For more information, see the [OCI Image Configuration Specification](#).
- **Object or artifact:** A conceptual content item that's stored as a blob and associated with an accompanying manifest with a configuration.
- **Digest:** A unique identifier that's created from a cryptographic hash of the contents of a manifest. The image digest helps uniquely identify an immutable container image. When you pull an image by using its digest, you will download the same image every time on any operating system or architecture. For more information, see the [OCI Image Specification](#).
- **Tag:** A human-readable manifest identifier. Compared with image digests, which are immutable, tags are dynamic. A tag that points to an image can change and move from one image to another, although the underlying image digest remains the same.

## Target architecture

The following diagram displays the high-level architecture of the solution provided by this pattern to identify duplicate container images by comparing images that are stored in Amazon ECR and private repositories.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.

### Code

The code for this pattern is available in the GitHub repository [Automated solution to identify duplicate container images between repositories](#).

## Compare the image manifests

Task	Description	Skills required
<p>Find the manifest of the image stored in the Amazon ECR public repository.</p>	<p>From the terminal, run the following command to pull the manifest of the image <code>public.ecr.aws/amazonlinux/amazonlinux:2018.03</code> from the Amazon ECR public repository.</p> <pre> \$~ % docker manifest inspect public.ecr.aws/amazonlinux/amazonlinux:2018.03 {   "schemaVersion": 2,   "mediaType": "application/vnd.docker.distribution.manifest.list.v2+json",   "manifests": [     {       "mediaType": "application/vnd.docker.distribution.manifest.v2+json",       "size": 529, </pre>	<p>AWS administrator, AWS DevOps, App developer</p>

Task	Description	Skills required
	<pre>        "digest":           "sha256:52db900007           3d93b9bdee6a7246a6           8c35a741aaade05a8f           4febba0bf795cdac02",           "platform": {             "architec             ture": "amd64",               "os":                 "linux"             }           }         ]       }</pre>	

Task	Description	Skills required
Find the manifest of the image stored in the Amazon ECR private repository.	<p>From the terminal, run the following command to pull the manifest of the image &lt;account-id&gt;.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest from the Amazon ECR private repository.</p> <pre data-bbox="594 684 1024 1808">\$~ % docker manifest inspect &lt;account-id&gt;.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest</pre> <pre data-bbox="594 1024 1024 1808">{  "schemaVersion": 2,  "mediaType": "application/vnd.docker.distribution.manifest.v2+json",  "config": {    "mediaType": "application/vnd.docker.container.image.v1+json",    "size": 1477,    "digest": "sha256:f7cee5e1af28ad4e147589c474d399b12d9b551ef4c3e11e02d982fce5eebc68"  },  "layers": [    {</pre>	AWS DevOps, AWS systems administrator, App developer

Task	Description	Skills required
	<pre>"mediaType":   "application/vnd.docker.image.rootfs.diff.tar.gzip",   "size": 62267075,   "digest": "sha256:4ddc0f8d367f424871a060e2067749f32bd36a91085e714dcb159952f2d71453"   } ] }</pre>	

Task	Description	Skills required
<p>Compare the digest pulled by Docker with the manifest digest for the image in the Amazon ECR private repository.</p>	<p>Another question is why the digest provided by the <b>docker pull</b> command differs from the manifest's digest for the image <code>&lt;account-id&gt;.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest</code>.</p> <p>The digest used for <b>docker pull</b> represents the digest of the image manifest, which is stored in a registry. This digest is considered the root of a hash chain, because the manifest contains the hash of the content that will be downloaded and imported into Docker.</p> <p>The image ID used within Docker can be found in this manifest as <code>config.digest</code>. This represents the image configuration that Docker uses. So you could say that the manifest is the envelope, and the image is the content of the envelope. The manifest digest is always different from the image ID. However, a specific manifest should always produce the same image ID. Because the</p>	<p>AWS DevOps, AWS systems administrator, App developer</p>

Task	Description	Skills required
	<p>manifest digest is a hash chain, we cannot guarantee that it will always be the same for a given image ID. In most cases, it produces the same digest, although Docker cannot guarantee that. The possible difference in the manifest digest stems from Docker not storing the blobs that are compressed with gzip locally. Therefore, exporting layers might produce a different digest, although the uncompressed content remains the same. The image ID verifies that uncompressed content is the same; that is, the image ID is now a content addressable identifier (chainID).</p> <p>To confirm this information, you can compare the output of the <b>docker inspect</b> command on the Amazon ECR public and private repositories:</p> <ol style="list-style-type: none"><li>1. Run the following command from your terminal for the image stored in the Amazon ECR public repository.</li></ol>	

Task	Description	Skills required
	<pre data-bbox="633 210 1023 409">\$~ % docker inspect public.ecr.aws/amazonlinux/amazonlinux:2018.03</pre> <p data-bbox="630 441 961 619">For the output from the command, see the <a href="#">Additional information</a> section.</p> <p data-bbox="592 640 1006 871">2. Run the following command from your terminal for the image stored in the Amazon ECR private repository.</p> <pre data-bbox="633 903 1023 1144">\$~ % docker inspect &lt;account-id&gt;.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest</pre> <p data-bbox="630 1176 961 1354">For the output from the command, see the <a href="#">Additional information</a> section.</p> <p data-bbox="592 1438 1006 1564">The results verify that both images have the same image ID digest and layer digest.</p> <pre data-bbox="592 1606 982 1795">ID: f7cee5e1af28ad4e147589c474d399b12d9b551ef4c3e11e02d982fce5eebc68</pre>	

Task	Description	Skills required
	<p>Layers: d5655967c 2c4e8d68f8ec7cf753 218938669e6c16ac13 24303c073c736a2e2a2</p> <p>Additionally, the digests are based on the bytes of the object that's managed locally (the local file is a tar of the container image layer) or the blob that's pushed to the registry server. However, when you push the blob to a registry, the tar is compressed and the digest is computed in the compressed tar file. Therefore, the difference in the <b>docker pull</b> digest value arises from compression that is applied at the registry (Amazon ECR private or public) level.</p> <p><b>Note:</b> This explanation is specific to using a Docker client. You won't see this behavior with other clients such as <b>nerdctl</b> or <b>Finch</b>, because they don't automatically compress the image during push and pull operations.</p>	

## Automatically identify duplicate images between Amazon ECR public and private repositories

Task	Description	Skills required
Clone the repository.	<p>Clone the Github repository for this pattern into a local folder:</p> <pre data-bbox="594 499 1027 816">\$git clone https://github.com/aws-samples/automated-solution-to-identify-duplicate-container-images-between-repositories</pre>	AWS administrator, AWS DevOps
Set up a CI/CD pipeline.	<p>The GitHub repository includes a <code>.yaml</code> file that creates an AWS CloudFormation stack to set up a pipeline in AWS CodePipeline.</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">AWS CloudFormation console</a>.</li><li>2. Create a stack by using the template pipeline <code>.yaml</code> file, which is in the code folder in the cloned repository.</li><li>3. Accept or change the default values of parameters. Specify values for the following:<ul style="list-style-type: none"><li>• Stack name</li></ul></li></ol>	AWS administrator, AWS DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>ArtifactStoreBucketName</code> – An existing S3 bucket that will be used to store AWS CodePipeline artifacts</li><li>• <code>OutputBucket</code> – An existing S3 bucket that will be used to store the URIs for the duplicate images</li><li>• <code>SourceImageFile</code> – An existing text file named <code>input.txt</code> that contains the image URIs from the public repository that will be checked against the Amazon ECR private repository to detect duplication</li></ul> <p>4. Review and adjust stack options, and then choose <b>Submit</b> to run the template.</p> <p>The pipeline will be set up with two stages (<code>CodeCommit</code> and <code>CodeBuild</code>, as shown in the architecture diagram) to identify images in the private repository that also exist in the public repository. The pipeline is configured with the following resources:</p>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• CodePipeline for the orchestration of the deployment pipeline.</li><li>• A CodeCommit repository to store the bash script and input file. The bash script is used to compare the container image IDs in the public and private repositories to find duplications. This check is performed across all the repositories in the specified AWS account in a single AWS Region.</li><li>• A CodeBuild project to invoke the bash script to identify images that are already present in the Amazon ECR repository.</li><li>• Necessary IAM roles to allow access.</li><li>• An S3 bucket to store the output file that contains image URIs.</li><li>• Another S3 bucket to store CodePipeline artifacts.</li></ul>	

Task	Description	Skills required
Populate the CodeCommit repository.	<p>To populate the CodeCommit repository, perform these steps:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">CodeCommit console</a> and navigate to the AWS Region where you created the CloudFormation stack.</li><li>2. Find the repository that you provisioned by using the CloudFormation script from the list, choose <b>Clone URL</b>, and then copy the <b>HTTPS URL</b> protocol to connect to the repository.</li><li>3. Open a command prompt and run the <b>git clone</b> command with the HTTPS URL that you copied in the previous step.</li><li>4. Navigate to the root directory. Create a file named <code>input.txt</code> and populate this file with the Amazon ECR public image registry URIs that you would like to search for in the private Amazon ECR repository.</li><li>5. Copy the files <code>script.sh</code>, <code>buildspec.yml</code>, and <code>input.txt</code> from your local copy of the GitHub</li></ol>	AWS administrator, AWS DevOps

Task	Description	Skills required
	<p>repository <a href="#">Automated solution to identify duplicate container images between repositories</a> to the cloned CodeCommit repository.</p> <p>6. Upload the files to CodeCommit by using these commands:</p> <pre data-bbox="630 674 1029 873">git add . git commit -m "added input files" git push</pre>	
Clean up.	<p>To avoid incurring future charges, delete the resources by following these steps:</p> <ol style="list-style-type: none"><li>1. Navigate to the S3 bucket that stores the CodePipeline artifacts, and empty the bucket.</li><li>2. Navigate to the S3 bucket that stores the duplicate image URIs, and empty the bucket.</li><li>3. Navigate to the CloudFormation console and delete the stack that you created to set up the pipeline.</li></ol>	AWS administrator

## Troubleshooting

Issue	Solution
<p>When you try to push, pull, or otherwise interact with a CodeCommit repository from the terminal or command line, you are prompted to provide a user name and password, and you must supply the Git credentials for your IAM user.</p>	<p>The most common causes for this error are the following:</p> <ul style="list-style-type: none"><li>• Your local computer is running an operating system that doesn't support credential management, or it doesn't have a credential management utility installed.</li><li>• The Git credentials for your IAM user haven't been saved to one of these credential management systems.</li></ul> <p>Depending on your operating system and local environment, you might need to install a credential manager, configure the credential manager that is included in your operating system, or customize your local environment to use credential storage. For example, if your computer is running macOS, you can use the Keychain Access utility to store your credentials. If your computer is running Windows, you can use the Git Credential Manager that is installed with Git for Windows. For more information, see <a href="#">Setup for HTTPS users using Git credentials</a> in the CodeCommit documentation and <a href="#">Credential Storage</a> in the Git documentation.</p>
<p>You encounter HTTP 403 or "no basic auth credentials" errors when you push an image to the Amazon ECR repository.</p>	<p>You might encounter these error messages from the <b>docker push</b> or <b>docker pull</b> command, even if you have successfully authenticated to Docker by using the <b>aws ecr</b></p>

Issue	Solution
	<p><b>get-login-password</b> command. Known causes are:</p> <ul style="list-style-type: none"><li>• You have authenticated to a different Region. For more information, see <a href="#">Private registry authentication</a> in the Amazon ECR documentation.</li><li>• You have authenticated to push to a repository that you don't have permissions for. For more information, see <a href="#">Private repository policies</a> in the Amazon ECR documentation.</li><li>• Your token has expired. The default expiration period for tokens obtained by using the <code>GetAuthorizationToken</code> operation is 12 hours.</li></ul>

# Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet

Created by Mahendra Revanasiddappa (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; DevOps; Infrastructure

**AWS services:** Amazon EKS; AWS Systems Manager

## Summary

**Note, September 2021:** The latest Amazon EKS optimized AMIs install SSM Agent automatically. For more information, see the [release notes](#) for the June 2021 AMIs.

In Amazon Elastic Kubernetes Service (Amazon EKS), because of security guidelines, worker nodes don't have Secure Shell (SSH) key pairs attached to them. This pattern shows how you can use the Kubernetes DaemonSet resource type to install AWS Systems Manager Agent (SSM Agent) on all worker nodes, instead of installing it manually or replacing the Amazon Machine Image (AMI) for the nodes. DaemonSet uses a cron job on the worker node to schedule the installation of SSM Agent. You can also use this pattern to install other packages on worker nodes.

When you're troubleshooting issues in the cluster, installing SSM Agent on demand enables you to establish an SSH session with the worker node, to collect logs or to look into instance configuration, without SSH key pairs.

## Prerequisites and limitations

### Prerequisites

- An existing Amazon EKS cluster with Amazon Elastic Compute Cloud (Amazon EC2) worker nodes.
- Container instances should have the required permissions to communicate with the SSM service. The AWS Identity and Access Management (IAM) managed role **AmazonSSMManagedInstanceCore** provides the required permissions for SSM Agent to run on EC2 instances. For more information, see the [AWS Systems Manager documentation](#).

## Limitations

- This pattern isn't applicable to AWS Fargate, because DaemonSets aren't supported on the Fargate platform.
- This pattern applies only to Linux-based worker nodes.
- The DaemonSet pods run in privileged mode. If the Amazon EKS cluster has a webhook that blocks pods in privileged mode, the SSM Agent will not be installed.

## Architecture

The following diagram illustrates the architecture for this pattern.

## Tools

### Tools

- [kubect1](#) is a command-line utility that is used to interact with an Amazon EKS cluster. This pattern uses `kubect1` to deploy a DaemonSet on the Amazon EKS cluster, which will install SSM Agent on all worker nodes.
- [Amazon EKS](#) makes it easy for you to run Kubernetes on AWS without having to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

- [AWS Systems Manager Session Manager](#) lets you manage your EC2 instances, on-premises instances, and virtual machines (VMs) through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).

## Code

Use the following code to create a DaemonSet configuration file that will install SSM Agent on the Amazon EKS cluster. Follow the instructions in the [Epics](#) section.

```
cat << EOF > ssm_daemonset.yaml
apiVersion: apps/v1
kind: DaemonSet
metadata:
  labels:
    k8s-app: ssm-installer
  name: ssm-installer
  namespace: kube-system
spec:
  selector:
    matchLabels:
      k8s-app: ssm-installer
  template:
    metadata:
      labels:
        k8s-app: ssm-installer
    spec:
      containers:
        - name: sleeper
          image: busybox
          command: ['sh', '-c', 'echo I keep things running! && sleep 3600']
      initContainers:
        - image: amazonlinux
          imagePullPolicy: Always
          name: ssm
          command: ["/bin/bash"]
          args: ["-c", "echo '* * * * * root yum install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_amd64/amazon-ssm-agent.rpm & rm -rf /etc/cron.d/ssmstart' > /etc/cron.d/ssmstart"]
          securityContext:
            allowPrivilegeEscalation: true
      volumeMounts:
        - mountPath: /etc/cron.d
```

```

    name: cronfile
    terminationMessagePath: /dev/termination-log
    terminationMessagePolicy: File
volumes:
- name: cronfile
  hostPath:
    path: /etc/cron.d
    type: Directory
dnsPolicy: ClusterFirst
restartPolicy: Always
schedulerName: default-scheduler
terminationGracePeriodSeconds: 30

```

EOF

## Epics

### Set up kubectl

Task	Description	Skills required
Install and configure kubectl to access the EKS cluster.	If kubectl isn't already installed and configured to access the Amazon EKS cluster, see <a href="#">Installing kubectl</a> in the Amazon EKS documentation.	DevOps

### Deploy the DaemonSet

Task	Description	Skills required
Create the DaemonSet configuration file.	Use the code in the <a href="#">Code</a> section earlier in this pattern to create a DaemonSet configuration file called <code>ssm_daemonset.yaml</code> , which will be	DevOps

Task	Description	Skills required
	<p>deployed to the Amazon EKS cluster.</p> <p>The pod launched by DaemonSet has a main container and an <code>init</code> container. The main container has a <code>sleep</code> command. The <code>init</code> container includes a <code>command</code> section that creates a cron job file to install SSM Agent at the path <code>/etc/cron.d/</code> . The cron job runs only once, and the file it creates is automatically deleted after the job is complete.</p> <p>When the <code>init</code> container has finished, the main container waits for 60 minutes before exiting. After 60 minutes, a new pod is launched. This pod installs SSM Agent, if it's missing, or updates SSM Agent to the latest version.</p> <p>If required, you can modify the <code>sleep</code> command to restart the pod once a day or to run more often.</p>	

Task	Description	Skills required
Deploy the DaemonSet on the Amazon EKS cluster.	<p>To deploy the DaemonSet configuration file you created in the previous step on the Amazon EKS cluster, use the following command:</p> <pre data-bbox="594 489 1027 606">kubect1 apply -f   ssm_daemonset.yaml</pre> <p>This command creates a DaemonSet to run the pods on worker nodes to install SSM Agent.</p>	DevOps

# Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands

Created by Akkamahadevi Hiremath (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; Infrastructure; Operations

**AWS services:** Amazon EKS; AWS Systems Manager; Amazon CloudWatch

## Summary

This pattern provides code samples and steps to install the AWS Systems Manager Agent (SSM Agent) and Amazon CloudWatch agent on Amazon Elastic Kubernetes Service (Amazon EKS) worker nodes in the Amazon Web Services (AWS) Cloud during Amazon EKS cluster creation. You can install the SSM Agent and CloudWatch agent by using the `preBootstrapCommands` property from the `eksctl` [config file schema](#) (Weaveworks documentation). Then, you can use the SSM Agent to connect to your worker nodes without using an Amazon Elastic Compute Cloud (Amazon EC2) key pair. Additionally, you can use the CloudWatch agent to monitor memory and disk utilization on your Amazon EKS worker nodes.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- The [eksctl command line utility](#), installed and configured on macOS, Linux, or Windows
- The [kubectrl command line utility](#), installed and configured on macOS, Linux, or Windows

### Limitations

- We recommend that you avoid adding long-running scripts to the `preBootstrapCommands` property, because this delays the node from joining the Amazon EKS cluster during scaling activities. We recommend that you create a [custom Amazon Machine Image \(AMI\)](#) instead.
- This pattern applies to Amazon EC2 Linux instances only.

3. The user connects to Amazon EC2 by using the SSM Agent and then monitors memory and disk utilization by using the CloudWatch agent.

## Tools

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [AWS Systems Manager Parameter Store](#) provides secure, hierarchical storage for configuration data management and secrets management.
- [AWS Systems Manager Session Manager](#) helps you manage your EC2 instances, on-premises instances, and virtual machines through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).
- [eksctl](#) is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- [kubectx](#) is a command-line utility for communicating with the cluster API server.

## Epics

### Create an Amazon EKS cluster

Task	Description	Skills required
Store the CloudWatch agent configuration file.	Store the CloudWatch agent configuration file in the <a href="#">AWS Systems Manager Parameter Store</a> in the AWS Region where you want to create your Amazon EKS cluster. To do this, <a href="#">create a parameter</a> in AWS Systems Manager Parameter Store and note the name of the parameter (for example, AmazonCloudwatch-linux ).	DevOps engineer

Task	Description	Skills required
	For more information, see the <i>Example CloudWatch agent configuration file</i> code in the <a href="#">Additional information</a> section of this pattern.	
Create the eksctl configuration file and cluster.	<ol style="list-style-type: none"> <li>1. Create an eksctl configuration file that includes the CloudWatch agent and SSM Agent installation steps. For more information, see the <i>Example eksctl configuration file</i> code in the <a href="#">Additional information</a> section of this pattern.</li> <li>2. Create a cluster by running the <code>eksctl create cluster -f cluster.yaml</code> command.</li> </ol>	AWS DevOps

### Verify that the SSM Agent and CloudWatch agent work

Task	Description	Skills required
Test the SSM Agent.	Use SSH to connect to your Amazon EKS cluster nodes by using any of the methods covered in <a href="#">Start a session</a> from the AWS Systems Manager documentation.	AWS DevOps
Test the CloudWatch agent.	Use the CloudWatch console to validate the CloudWatch agent:	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">CloudWatch console</a>.</li><li>2. On the navigation pane, expand <b>Metrics</b> and then choose <b>All metrics</b>.</li><li>3. In the search box on the <b>Browse</b> tab, enter and then choose <b>CWAgent metrics</b> to see the memory and disk metrics.</li></ol>	

## Related resources

## Additional information

### Example CloudWatch agent configuration file

In the following example, the CloudWatch agent is configured to monitor disk and memory utilization on Amazon Linux instances:

```
{
  "agent": {
    "metrics_collection_interval": 60,
    "run_as_user": "cwagent"
  },
}
```

```
"metrics": {
  "append_dimensions": {
    "AutoScalingGroupName": "${aws:AutoScalingGroupName}",
    "ImageId": "${aws:ImageId}",
    "InstanceId": "${aws:InstanceId}",
    "InstanceType": "${aws:InstanceType}"
  },
  "metrics_collected": {
    "disk": {
      "measurement": [
        "used_percent"
      ],
      "metrics_collection_interval": 60,
      "resources": [
        "*"
      ]
    },
    "mem": {
      "measurement": [
        "mem_used_percent"
      ],
      "metrics_collection_interval": 60
    }
  }
}
```

## Example eksctl configuration file

```
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: test
  region: us-east-2
  version: "1.24"
managedNodeGroups:
- name: test
  minSize: 2
  maxSize: 4
  desiredCapacity: 2
  volumeSize: 20
  instanceType: t3.medium
  preBootstrapCommands:
```

```
- sudo yum install amazon-ssm-agent -y
- sudo systemctl enable amazon-ssm-agent
- sudo systemctl start amazon-ssm-agent
- sudo yum install amazon-cloudwatch-agent -y
- sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c ssm:AmazonCloudwatch-linux
iam:
  attachPolicyARNs:
    - arn:aws:iam::aws:policy/AmazonEKSEKSPolicy
    - arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
    - arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
    - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
    - arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

## Additional code details

- In the last line of the `preBootstrapCommands` property, `AmazonCloudwatch-linux` is the name of the parameter created in AWS System Manager Parameter Store. You must include `AmazonCloudwatch-linux` in Parameter Store in the same AWS Region where you created the Amazon EKS cluster. You can also specify a file path, but we recommend using Systems Manager for easier automation and reusability.
- If you use `preBootstrapCommands` in the `eksctl` configuration file, you see two launch templates in the AWS Management Console. The first launch template includes the commands specified in `preBootstrapCommands`. The second template includes the commands specified in `preBootstrapCommands` and default Amazon EKS user data. This data is required to get the nodes to join the cluster. The node group's Auto Scaling group uses this user data to spin up new instances.
- If you use the `iam` attribute in the `eksctl` configuration file, you must list the default Amazon EKS policies with any additional policies required in your attached AWS Identity and Access Management (IAM) policies. In the code snippet from the *Create the `eksctl` configuration file and cluster* step, `CloudWatchAgentServerPolicy` and `AmazonSSMManagedInstanceCore` are additional policies added to make sure that the CloudWatch agent and SSM Agent work as expected. The `AmazonEKSEKSPolicy`, `AmazonEKS_CNI_Policy`, `AmazonEC2ContainerRegistryReadOnly` policies are mandatory policies required for the Amazon EKS cluster to function correctly.

# Optimize AWS App2Container generated Docker images

Created by Varun Sharma (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; Modernization; DevOps

**AWS services:** Amazon ECS

## Summary

AWS App2Container is a command line tool that helps transform existing applications running on premises or on virtual machines into containers, without needing code changes.

Based on application type, App2Container takes a conservative approach to identify dependencies. For process mode, all non-system files on the application server are included in the container image. In such cases, a fairly large image might be generated.

This pattern provides an approach for optimizing the container images generated by App2Container. It is applicable for all Java applications discovered by App2Container in process mode. The workflow defined in the pattern is designed to be run on the application server.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Java application running on an application server on a Linux server
- [App2Container installed and set up](#), with all prerequisites met, on the Linux server

## Architecture

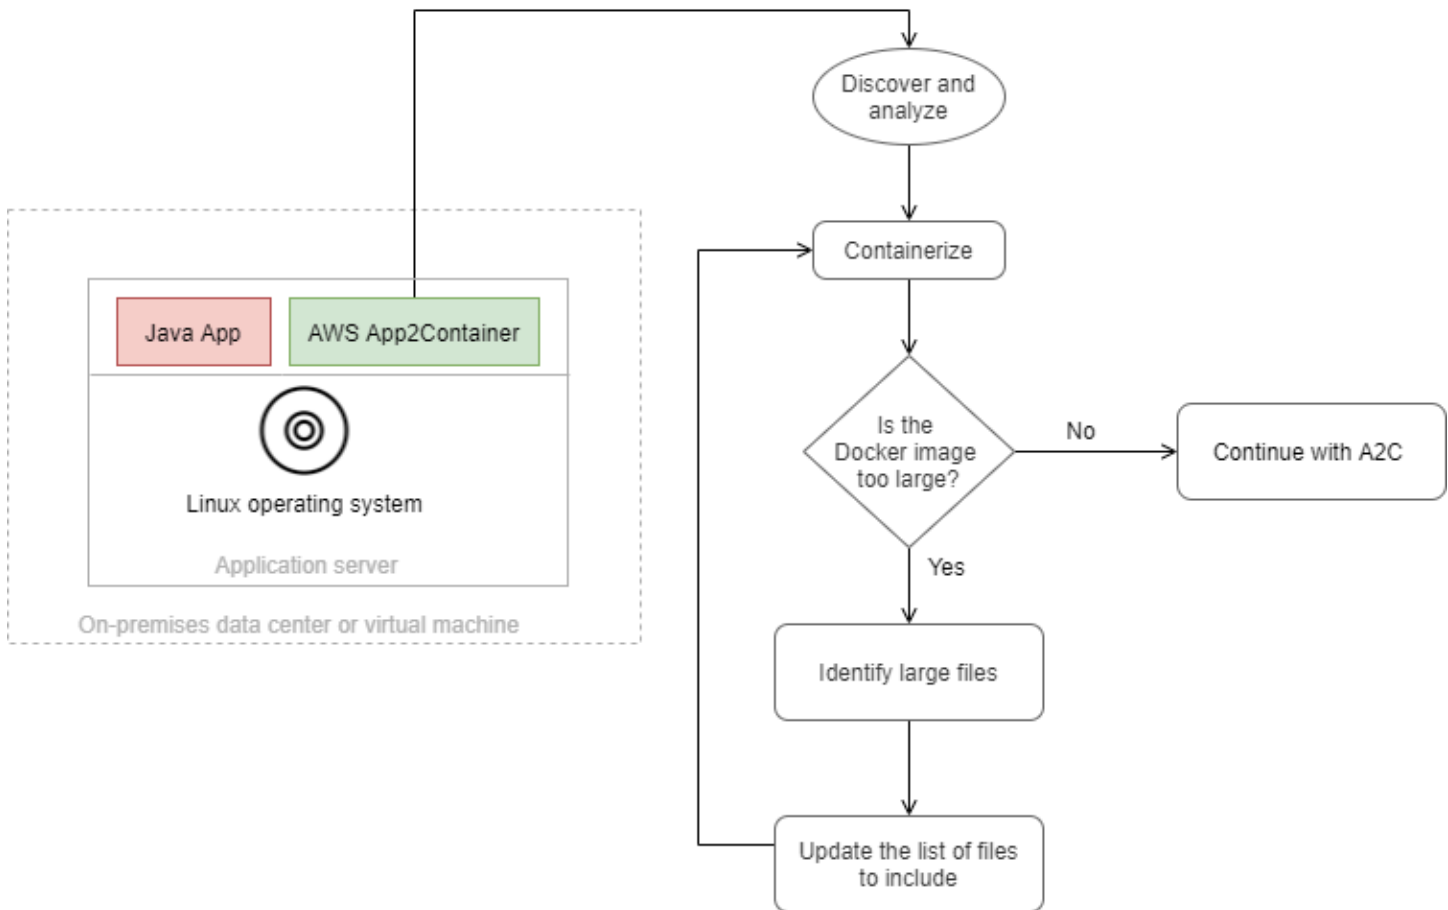

### Source technology stack

- A Java application running on a Linux server

### Target technology stack

- A Docker image generated by App2Container

## Target architecture flow

1. Discover the applications that are running on the application server, and analyze the applications.
2. Containerize the applications.
3. Evaluate the size of the Docker image. If the image is too large, continue to step 4.
4. Use the shell script (attached) to identify large files.
5. Update the `appExcludedFiles` and `appSpecificFiles` lists in the `analysis.json` file.

## Tools

### Tools

- [AWS App2Container](#) – AWS App2Container (A2C) is a command line tool to help you lift and shift applications that run in your on-premises data center or on virtual machines, so that they run in containers that are managed by Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

## Code

The `optimizeImage.sh` shell script and an example `analysis.json` file are attached.

The `optimizeImage.sh` file is a utility script for reviewing the contents of the App2Container generated file, `ContainerFiles.tar`. The review identifies files or subdirectories that are large and can be excluded. The script is a wrapper for the following tar command.

```
tar -Ptvf <path>|tr -s ' '|cut -d ' ' -f3,6| awk '$2 ~/<filetype>$/'| awk '$2 ~/^<toplevel>/'| cut -f1-<depth> -d '/'|awk '{ if ($1>= <size>) arr[$2]+=$1 } END { for (key in arr) { if(<verbose>) printf("%-50s\t%-50s\n", key, arr[key]) else printf("%s,\n", key) } } '|sort -k2 -nr
```

In the tar command, the script uses the following values:

<code>path</code>	The path to <code>ContainerFiles.tar</code>
<code>filetype</code>	The file type to match
<code>toplevel</code>	The top-level directory to match
<code>depth</code>	The depth of the absolute path
<code>size</code>	The size for each file

The script does the following:

1. It uses `tar -Ptvf` to list the files without extracting them.
2. It filters the files by file type, starting with the top-level directory.
3. Based on the depth, it generates the absolute path as an index.
4. Based on the index and stores, it provides the total size of the subdirectory.
5. It prints the size of the subdirectory.

You can also replace the values manually in the tar command.

## Epics

### Discover, analyze, and containerize applications

Task	Description	Skills required
Discover the on-premises Java applications.	To discover all applications running on the application server, run the following command. <pre>sudo app2container inventory</pre>	AWS DevOps
Analyze the discovered applications.	To analyze each application by using the application-id that was obtained in the inventory stage, run the following command. <pre>sudo app2container analyze --application- id &lt;java-app-id&gt;</pre>	AWS DevOps
Containerize the analyzed applications.	To containerize an application, run the following command. <pre>sudo app2container containerize --applica tion-id &lt;application- id&gt;</pre> <p>The command generates the Docker image along with a</p>	AWS DevOps

Task	Description	Skills required
	<p>tar bundle in the workspace location.</p> <p>If the Docker image is too large, proceed to the next step.</p>	

### Identify appExcludedFiles and appSpecificFiles from the App2Container extracted tar file

Task	Description	Skills required
Identify the Artifacts tar file size.	<p>Identify the Container Files.tar file in <code>{workspace}/{java-app-id}/Artifacts</code> , where <code>workspace</code> is the App2Container workspace and <code>java-app-id</code> is the application ID.</p> <pre>./optimizeImage.sh -p / {workspace}/{java-app- id}/Artifacts/Containe rFiles.tar -d 0 -t / - v</pre> <p>This is the total size of the tar file after optimization.</p>	AWS DevOps
List the subdirectories under the <code>/</code> directory and their sizes.	<p>To identify the sizes of the major subdirectories under the <code>/</code> top-level directory, run the following command.</p> <pre>./optimizeImage.sh -p / {workspace}/{java-app-</pre>	AWS DevOps

Task	Description	Skills required
	<pre>id}/Artifacts/ContainerFiles.tar -d 1 -t / -s 1000000 -v /var 554144711 /usr 2097300819 /tmp 18579660 /root 43645397 /opt 222320534 /home 65212518 /etc 11357677</pre>	

Task	Description	Skills required
Identify large subdirectories under the / directory.	<p>For each major subdirectory that is listed in the previous command, identify the sizes of its subdirectories. Use <code>-d</code> to increase the depth and <code>-t</code> to indicate the top-level directory.</p> <p>For example, use <code>/var</code> as the top-level directory. Under <code>/var</code>, identify all the large subdirectories and their sizes.</p> <pre>./optimizeImage.sh -p / {workspace}/{java-app- id}/Artifacts/Containe rFiles.tar -d 2 -t / var -s 1000000 -v</pre> <p>Repeat this process for each subdirectory listed in the previous step (for example, <code>/usr</code>, <code>/tmp</code>, <code>/opt</code>, and <code>/home</code>).</p>	AWS DevOps

Task	Description	Skills required
Analyze the large folder in each subdirectory under the / directory.	<p>For each subdirectory that is listed in the previous step, identify any folders that are required to run the application.</p> <p>For example, using the subdirectories from the previous step, list all the subdirectories in the /var directory and their sizes. Identify any subdirectories that are needed by the application.</p> <pre data-bbox="594 905 1027 1182">/var/tmp     237285851 /var/lib     24489984 /var/cache     237285851</pre> <p>To exclude subdirectories that are not needed by the application, in the <code>analysis.json</code> file, add those subdirectories to the <code>appExcludedFiles</code> section under <code>containerParameters</code>.</p> <p>An example <code>analysis.json</code> file is attached.</p>	AWS DevOps

Task	Description	Skills required
Identify files that are needed from the appExcludes list.	<p>For each subdirectory that is added to appExcludes list, identify any files in that subdirectory that are required by the application. In the analysis.json file, add the specific files or subdirectories in the appSpecificFiles section under container Parameters .</p> <p>For example, if the /usr/lib directory is added to the exclude list, but /usr/lib/jvm is needed by the application, add /usr/lib/jvm to the appSpecificFiles section.</p>	AWS DevOps

### Extract and containerize the application again

Task	Description	Skills required
Containerize the analyzed application.	<p>To containerize the application, run the following command.</p> <pre>sudo app2container   containerize --application-id &lt;application-id&gt;</pre> <p>The command generates the Docker image along with a</p>	AWS DevOps

Task	Description	Skills required
	tar bundle in the workspace location.	
Identify the Artifacts tar file size.	<p>Identify the ContainerFiles.tar file in {workspace}/{java-app-id}/Artifacts , where workspace is the App2Container workspace and java-app-id is the application ID.</p> <pre data-bbox="597 747 1027 989">./optimizeImage.sh -p / {workspace}/{java-app-id}/Artifacts/ContainerFiles.tar -d 0 -t / -v</pre> <p>This is the total size of the tar file after optimization.</p>	AWS DevOps
Run the Docker image.	<p>To verify that the image starts without errors, run the Docker image locally using the following commands.</p> <p>To identify the imageId of the container, use <code>docker images  grep java-app-id .</code></p> <p>To run the container, use <code>docker run -d &lt;image id&gt;.</code></p>	AWS DevOps

# Place Kubernetes Pods on Amazon EKS by using node affinity, taints, and tolerations

Created by Hitesh Parikh (AWS) and Raghu Bhamidimarri (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices

**Workload:** Open-source

**AWS services:** Amazon EKS

## Summary

This pattern demonstrates the use of Kubernetes *node affinity*, *node taints*, and Pod *tolerations* to intentionally schedule application Pods on specific worker nodes in an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud.

A *taint* is a node property that enables nodes to reject a set of pods. A *toleration* is a Pod property that enables the Kubernetes scheduler to schedule Pods on nodes that have matching taints.

However, tolerations alone can't prevent a scheduler from placing a Pod on a worker node that doesn't have any taints. For example, a compute intensive Pod with a toleration can unintentionally get scheduled on a general-purpose untainted node. In that scenario, the *node affinity* property of a Pod instructs the scheduler to place the Pod on a node that meets the node selection criteria specified in the node affinity.

Taints, tolerations, and node affinity together instruct the scheduler to schedule Pods consistently on the nodes with matching taints and the node labels that match the node affinity node-selection criteria specified on the Pod.

This pattern provides an example Kubernetes deployment manifest file, and the steps to create an EKS cluster, deploy an application, and validate Pod placement.

## Prerequisites and limitations

### Prerequisites

- An AWS account with credentials configured to create resources on your AWS account
- AWS Command Line Interface (AWS CLI)

- `eksctl`
- `kubectl`
- [Docker](#) installed (for the operating system being used), and the engine started (for information about Docker licensing requirements, see the [Docker site](#))
- [Java](#) version 11 or later
- A Java microservice running on your favorite integrated development environment (IDE); for example, [AWS Cloud9](#), [IntelliJ IDEA Community Edition](#) or [Eclipse](#) (if you don't have a Java microservice, see the [Deploy a sample Java microservice on Amazon EKS](#) pattern and [Microservices with Spring](#) for help with creating the microservice)

## Limitations

- This pattern doesn't provide the Java code, and it assumes that you are already familiar with Java. To create a basic Java microservice, see [Deploy a sample Java microservice on Amazon EKS](#).
- The steps in this article create AWS resources that can accrue cost. Make sure that you clean up the AWS resources after you have completed the steps to implement and validate the pattern.

## Architecture

### Target technology stack

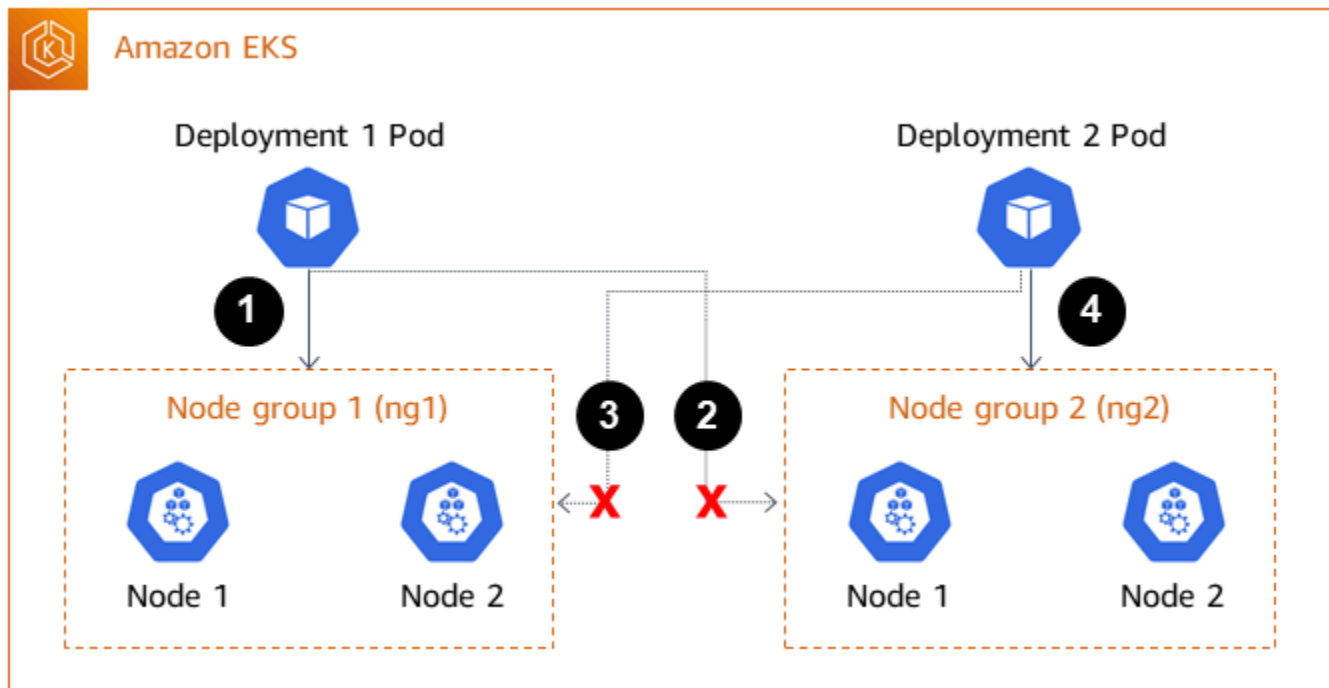

- Amazon EKS
- Java
- Docker
- Amazon Elastic Container Registry (Amazon ECR)

### Target architecture

The solution architecture diagram shows Amazon EKS with two Pods (Deployment 1 and Deployment 2) and two node groups (ng1 and ng2) with two nodes each. The Pods and nodes have the following properties.

Deployment 1 Pod	Deployment 2 Pod	Node group 1 (ng1)	Node group 2 (ng2)
---------------------	---------------------	-----------------------	-----------------------

<b>Toleration</b>	key: classified_workload, value: true, effect: NoSchedule	None	
	key: machine_learning_workload, value: true, effect: NoSchedule		
<b>Node affinity</b>	key: alpha.eksctl.io/nodegroup-name = ng1;	None	nodeGroup s.name = ng1
<b>Taint</b>			key: classified_workload, value: true, effect: NoSchedule  key: machine_learning_workload, value: true, effect: NoSchedule

1. The Deployment 1 Pod has tolerations and node affinity defined, which instructs the Kubernetes scheduler to place the deployment Pods on the Node group 1 (ng1) nodes.
2. Node group 2 (ng2) doesn't have a node label that matches the node affinity node selector expression for Deployment 1, so the Pods will not be scheduled on ng2 nodes.
3. The Deployment 2 Pod doesn't have any tolerations or node affinity defined in the deployment manifest. The scheduler will reject scheduling Deployment 2 Pods on Node group 1 because of the taints on the nodes.
4. The Deployment 2 Pods will be placed on Node group 2 instead, because the nodes don't have any taints.

This pattern demonstrates that by using taints and tolerations, combined with node affinity, you can control placement of Pods on specific sets of worker nodes.

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.

- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [eksctl](#) is AWS equivalent of kubectl and helps with creating EKS.

## Other tools

- [Docker](#) is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- [kubectl](#) is a command-line interface that helps you run commands against Kubernetes clusters.

## Epics

### Create the EKS cluster

Task	Description	Skills required
Create the cluster.yaml file.	<p>Create a file called <code>cluster.yaml</code> with the following code.</p> <pre>apiVersion: eksctl.io/v1alpha5 kind: ClusterConfig  metadata:   name: eks-taint-demo   region: us-west-1  # Unmanaged nodegroups with and without taints. nodeGroups:   - name: ng1     instanceType: m5.xlarge     minSize: 2     maxSize: 3     taints:</pre>	App owner, AWS DevOps, Cloud administrator, DevOps engineer

Task	Description	Skills required
	<pre> - key: classified_workload   value: "true"   effect:     NoSchedule - key: machine_learning_workload   value: "true"   effect:     NoSchedule  - name: ng2   instanceType:     m5.xlarge   minSize: 2   maxSize: 3 </pre>	
Create the cluster by using <code>eksctl</code> .	<p>Run the <code>cluster.yaml</code> file to create the EKS cluster. Creating the cluster might take a few minutes.</p> <pre> eksctl create cluster -f cluster.yaml </pre>	AWS DevOps, AWS systems administrator, App developer

## Create an image and upload it to Amazon ECR

Task	Description	Skills required
Create an Amazon ECR private repository.	To create an Amazon ECR repository, see <a href="#">Creating a private repository</a> . Note the URI of the repo.	AWS DevOps, DevOps engineer, App developer
Create the Dockerfile.	If you have an existing Docker container image that you want to use to test the	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<p>pattern, you can skip this step.</p> <p>To create a Dockerfile, use the following snippet as a reference. If you encounter errors, see the <a href="#">Troubleshooting</a> section.</p> <pre>FROM adoptopenjdk/openjdk11:jdk-11.0.14.1_1-alpine  RUN apk add maven WORKDIR /code  # Prepare by downloading dependencies ADD pom.xml /code/pom.xml RUN ["mvn", "dependency:resolve"] RUN ["mvn", "verify"]  # Adding source, compile and package into a fat jar ADD src /code/src RUN ["mvn", "package"]  EXPOSE 4567 CMD ["java", "-jar", "target/eksExample-jar-with-dependencies.jar"]</pre>	

Task	Description	Skills required
<p>Create the pom.xml and source files, and build and push the Docker image.</p>	<p>To create the pom.xml file and the Java source file, see <a href="#">Deploy a sample Java microservice on Amazon EKS</a> pattern.</p> <p>Use the instructions in that pattern to build and push the Docker image.</p>	<p>AWS DevOps, DevOps engineer, App developer</p>

## Deploy to Amazon EKS

Task	Description	Skills required
<p>Create the deployment.yaml file.</p>	<p>To create the deployment.yaml file, use the code in the <a href="#">Additional information</a> section.</p> <p>In the code, the key for node affinity is any label that you create while creating node groups. This pattern uses the default label created by eksctl. For information about customizing labels, see <a href="#">Assigning Pods to Nodes</a> in the Kubernetes documentation.</p> <p>The value for the node affinity key is the name of the node group that was created by cluster.yaml .</p>	<p>AWS DevOps, DevOps engineer, App developer</p>

Task	Description	Skills required
	<p>To get the key and value for the taint, run the following command.</p> <pre data-bbox="594 380 1026 537">kubectl get nodes -o json   jq '.items[].spec.taints'</pre> <p>The image is the URI of the Amazon ECR repository that you created in an earlier step.</p>	
Deploy the file.	<p>To deploy to Amazon EKS, run the following command.</p> <pre data-bbox="594 873 1026 989">kubectl apply -f deployment.yaml</pre>	App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required
Check the deployment.	<p>1. To check if the pods are READY, run the following command.</p> <pre data-bbox="630 394 1029 512">kubect1 get pods -o wide</pre> <p>If the POD is ready, the output should look similar to the following, with the STATUS as Running.</p> <pre data-bbox="630 768 1029 1323">NAME          READY STATUS       RESTARTS AGE          IP        NODE NOMINATED    NODE READINESS    GATES &lt;pod_name&gt;   1/1 Running      0 12d         192.168.1 8.50        ip-192-16 8-20-110.us-west-1 .compute.internal &lt;none&gt; &lt;none&gt;</pre> <p>Note the name of the Pod and the name of the node. You can skip the next step.</p> <p>2. (Optional) To get additional details about the Pod and check the tolerations on the Pod, run the following command.</p>	App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required
	<pre data-bbox="630 212 1029 327">kubect1 describe pod &lt;pod_name&gt;</pre> <p data-bbox="630 365 1005 495">An example of the output is in the <a href="#">Additional information</a> section.</p> <p data-bbox="591 520 1000 695">3. To validate that the Pod placement on the node is correct, run the following command.</p> <pre data-bbox="630 737 1029 894">kubect1 describe node &lt;node name&gt;   grep -A 1 "Taints"</pre> <p data-bbox="630 932 993 1205">Confirm that the taint on the node matches toleration, and the label on the node matches the node affinity defined in <code>deployment.yaml</code> .</p> <p data-bbox="630 1251 1016 1667">The Pod with tolerations and node affinity should be placed on a node with the matching taints and the node affinity labels. The previous command gives you the taints on the node. The following is an example output.</p> <pre data-bbox="630 1703 1029 1839">kubect1 describe node ip-192-168-29-181. us-west-1.compute.</pre>	

Task	Description	Skills required
	<pre>internal   grep -A 1 "Taints" Taints:   classified_workload=true:NoSchedule    machine_learning_workload=true:NoSchedule</pre> <p>Additionally, run the following command to check that the node on which the Pod is placed has a label matching the node affinity node label.</p> <pre>kubectl get node &lt;node name&gt; --show-labels</pre> <p>4. To verify that the application is doing what it is intended to do, check the Pod logs by running the following command.</p> <pre>kubectl logs -f &lt;name-of-the-pod&gt;</pre>	

Task	Description	Skills required
Create a second deployment .yaml file without toleration and node affinity.	<p>This additional step is to validate that when no node affinity or tolerations are specified in the deployment manifest file, the resulting Pod is not scheduled on a node with taints. (It should be scheduled on a node that doesn't have any taints). Use the following code to create a new deployment file called <code>deploy_no_taint.yaml</code>.</p> <pre data-bbox="597 825 1027 1871">apiVersion: apps/v1 kind: Deployment metadata:   name: microservice- deployment-non-tainted spec:   replicas: 1   selector:     matchLabels:       app.kuber netes.io/name: java- microservice-no-taint   template:     metadata:       labels:         app.kuber netes.io/name: java- microservice-no-taint     spec:       containers:         - name: java- microservice-container -2           image:             &lt;account_number&gt;.d kr.ecr&lt;region&gt;.ama</pre>	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
	<pre>zonaws.com/&lt;repository_name&gt;:latest   ports:     - container Port: 4567</pre>	
<p>Deploy the second deployment .yaml file, and validate Pod placement</p>	<ol style="list-style-type: none"> <li>Run the following command.           <pre>kubectl apply -f   deploy_no_taint.yaml</pre> </li> <li>After the deployment is successful, run the same commands that you ran previously to check the Pod placement in a node group with no taint.           <pre>kubectl describe node   &lt;node_name&gt;   grep   "Taints"</pre> <p>The output should be the following.</p> <pre>Taints: &lt;none&gt;</pre> <p>This completes the testing.</p> </li> </ol>	<p>App developer, AWS DevOps, DevOps engineer</p>

## Clean up resources

Task	Description	Skills required
Clean up the resources.	To avoid incurring AWS charges for resources that are left running, use the following command. <pre>eksctl delete cluster --name &lt;Name of the cluster&gt; --region &lt;region-code&gt;</pre>	AWS DevOps, App developer

## Troubleshooting

Issue	Solution
Some of these commands might not run if your system uses <a href="#">arm64 architecture</a> (especially if you are running this on an M1 Mac). The following line might error out. <pre>FROM adoptopenjdk/openjdk11:jdk-11.0.14.1_1-alpine</pre>	If you have errors when running the Dockerfile, replace the FROM line with the following line. <pre>FROM bellsoft/liberica-openjdk-alpine-musl:17</pre>

# Replicate filtered Amazon ECR container images across accounts or Regions

Created by *Abdal Garuba (AWS)*

**Environment:** Production

**Technologies:** Containers & microservices; DevOps

**AWS services:** Amazon EC2 Container Registry; Amazon CloudWatch; AWS CodeBuild ; AWS Identity and Access Management; AWS CLI

## Summary

Amazon Elastic Container Registry (Amazon ECR) can replicate all container images in an image repository across Amazon Web Services (AWS) Regions and AWS accounts natively, by using the [cross-Region](#) and [cross-account replication](#) features. (For more information, see the AWS blog post [Cross region replication in Amazon ECR has landed](#).) However, there is no way to filter the images that are copied across AWS Regions or accounts based on any criteria.

This pattern describes how to replicate container images that are stored in Amazon ECR across AWS accounts and Regions, based on image tag patterns. The pattern uses Amazon CloudWatch Events to listen for push events for images that have a predefined, custom tag. A push event starts an AWS CodeBuild project and passes the image details to it. The CodeBuild project copies the images from the source Amazon ECR registry to the destination registry based on the details provided.

This pattern copies images that have specific tags across accounts. For example, you can use this pattern to copy only production-ready, secure images to the production AWS account. In the development account, after images are thoroughly tested, you can add a predefined tag to the secure images and use the steps in this pattern to copy the marked images to the production account.

## Prerequisites and limitations

### Prerequisites

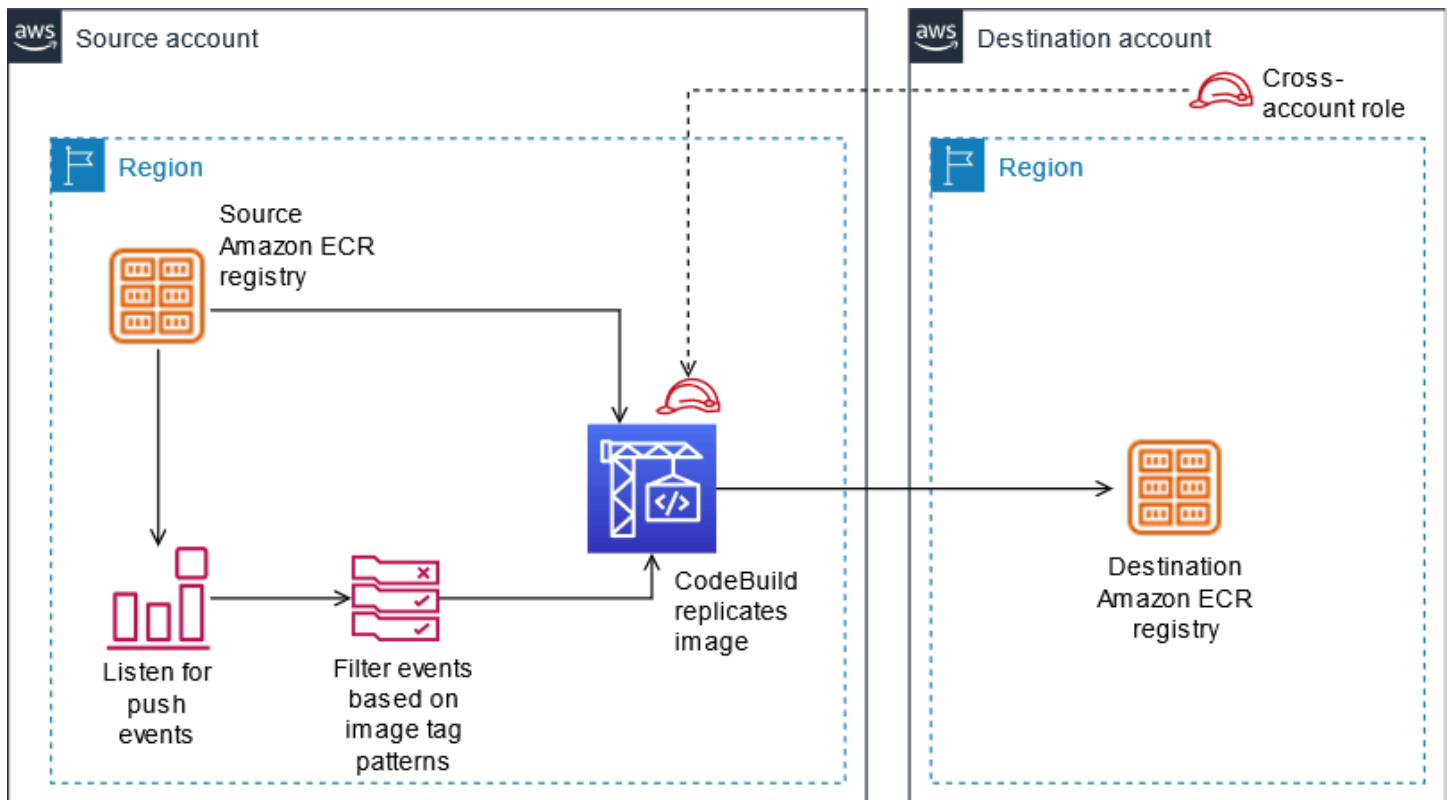

- An active AWS account for source and destination Amazon ECR registries
- Administrative permissions for the tools used in this pattern
- [Docker](#) installed on your local machine for testing
- [AWS Command Line Interface \(AWS CLI\)](#), for authenticating into Amazon ECR

## Limitations

- This pattern watches the push events of the source registry in only one AWS Region. You can deploy this pattern to other Regions to watch registries in those Regions.
- In this pattern, one Amazon CloudWatch Events rule listens for a single image tag pattern. If you want to check for multiple patterns, you can add events to listen for additional image tag patterns.

## Architecture

### Target architecture

### Automation and scale

This pattern can be automated with an infrastructure as code (IaC) script and deployed at scale. To use AWS CloudFormation templates to deploy this pattern, download the attachment and follow the instructions in the [Additional information](#) section.

You can point multiple Amazon CloudWatch Events events (with different custom event patterns) to the same AWS CodeBuild project to replicate multiple image tag patterns, but you will need to update the secondary validation in the `buildspec.yaml` file (which is included in the attachment and in the [Tools](#) section) as follows to support multiple patterns.

```
...
if [[ ${IMAGE_TAG} != release-* ]]; then
...
```

## Tools

### Amazon services

- [IAM](#) – AWS Identity and Access Management (IAM) enables you to manage access to AWS services and resources securely. In this pattern, you would need to create the cross-account IAM role that AWS CodeBuild will assume when pushing container images to the destination registry.
- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is a fully managed container registry that makes it easy to store, manage, share, and deploy your container images and artifacts anywhere. Image push actions to the source registry send system event details to the event bus that is picked up by Amazon CloudWatch Events.
- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed continuous integration service that provides compute power to perform jobs such as compiling source code, running tests, and producing artifacts that are ready to be deployed. This pattern uses AWS CodeBuild to perform the copy action from the source Amazon ECR registry to the destination registry.
- [CloudWatch Events](#) – Amazon CloudWatch Events delivers a stream of system events that describe changes in AWS resources. This pattern uses rules to match Amazon ECR push actions with a specific image tag pattern.

### Tools

- [Docker CLI](#) – Docker is a tool that makes it easier to create and manage containers. Containers pack an application and all its dependencies into one unit or package that can easily be deployed on any platform that supports the container runtime.

## Code

You can implement this pattern in two ways:

- Automated setup: Deploy the two AWS CloudFormation templates provided in the attachment. For instructions, see the [Additional information](#) section.
- Manual setup: Follow the steps in the [Epics](#) section.

### *Sample buildspec.yaml*

If you're using the CloudFormation templates that are provided with this pattern, the `buildspec.yaml` file is included in the CodeBuild resources.

```
version: 0.2
env:
  shell: bash
phases:
  install:
    commands:
      - export CURRENT_ACCOUNT=$(echo ${CODEBUILD_BUILD_ARN} | cut -d':' -f5)
      - export CURRENT_ECR_REGISTRY=${CURRENT_ACCOUNT}.dkr.ecr.
        ${AWS_REGION}.amazonaws.com
      - export DESTINATION_ECR_REGISTRY=${DESTINATION_ACCOUNT}.dkr.ecr.
        ${DESTINATION_REGION}.amazonaws.com
  pre_build:
    on-failure: ABORT
    commands:
      - echo "Validating Image Tag ${IMAGE_TAG}"
      - |
        if [[ ${IMAGE_TAG} != release-* ]]; then
          aws codebuild stop-build --id ${CODEBUILD_BUILD_ID}
          sleep 60
          exit 1
        fi
      - aws ecr get-login-password --region ${AWS_REGION} | docker login -u AWS --
password-stdin ${CURRENT_ECR_REGISTRY}
      - docker pull ${CURRENT_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}
  build:
    commands:
      - echo "Assume cross-account role"
      - CREDENTIALS=$(aws sts assume-role --role-arn ${CROSS_ACCOUNT_ROLE_ARN} --
role-session-name Rolesession)
```

```

- export AWS_DEFAULT_REGION=${DESTINATION_REGION}
- export AWS_ACCESS_KEY_ID=$(echo ${CREDENTIALS} | jq -r
'.Credentials.AccessKeyId')
- export AWS_SECRET_ACCESS_KEY=$(echo ${CREDENTIALS} | jq -r
'.Credentials.SecretAccessKey')
- export AWS_SESSION_TOKEN=$(echo ${CREDENTIALS} | jq -r
'.Credentials.SessionToken')
- echo "Logging into cross-account registry"
- aws ecr get-login-password --region ${DESTINATION_REGION} | docker login -u
AWS --password-stdin ${DESTINATION_ECR_REGISTRY}
- echo "Check if Destination Repository exists, else create"
- |
aws ecr describe-repositories --repository-names ${REPO_NAME} --region
${DESTINATION_REGION} \
|| aws ecr create-repository --repository-name ${REPO_NAME} --region
${DESTINATION_REGION}
- echo "retag image and push to destination"
- docker tag ${CURRENT_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}
${DESTINATION_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}
- docker push ${DESTINATION_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}

```

## Epics

### Create IAM roles

Task	Description	Skills required
Create a CloudWatch Events role.	<p>In the source AWS account, create an IAM role for Amazon CloudWatch Events to assume. The role should have permissions to start a AWS CodeBuild project.</p> <p>To create the role by using the AWS CLI, follow the <a href="#">instructions in the IAM documentation</a>.</p> <p>Example trust policy (trustpolicy.json ):</p>	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Task	Description	Skills required
	<pre data-bbox="609 220 1031 724">{   "Version": "2012-10-17",   "Statement": {     "Effect": "Allow",     "Principal":     {"Service": "events.a mazonaws.com"},     "Action": "sts:Assu meRole"   } }</pre> <p data-bbox="592 766 982 892">Example permission policy (permissionpolicy.j son ):</p> <pre data-bbox="609 934 1031 1438">{   "Version": "2012-10-17",   "Statement": {     "Effect": "Allow",     "Action": "codebuil d:StartBuild",     "Resource":     "&lt;CodeBuild Project ARN&gt;"   } }</pre>	

Task	Description	Skills required
Create a CodeBuild role.	<p>Create an IAM role for AWS CodeBuild to assume, by following the <a href="#">instructions in the IAM documentation</a>. The role should have the following permissions:</p> <ul style="list-style-type: none"><li>• Permission to assume the destination cross-account role</li><li>• Permission to create log groups and log streams, and to put log events</li><li>• Read-only permissions to all Amazon ECR repositories, by adding the <a href="#">AmazonEC2ContainerRegistryReadOnly</a> managed policy to the role</li><li>• Permission to stop CodeBuild</li></ul> <p>Example trust policy (trustpolicy.json ):</p> <pre>{   "Version": "2012-10-17",   "Statement": [     {       "Effect": "Allow",       "Principal": {         "Service": "codebuild.amazonaws.com"       },     }   ], }</pre>	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Task	Description	Skills required
	<pre data-bbox="609 210 1015 420">       "Action":       "sts:AssumeRole"     }   ] } </pre> <p data-bbox="592 462 982 598">Example permission policy (permissionpolicy.json):</p> <pre data-bbox="609 640 1015 1785"> {   "Version":   "2012-10-17",   "Statement": [     {       "Action": [         "codebuild:StartBuild",         "codebuild:StopBuild",         "codebuild:Get*",         "codebuild:List*",         "codebuild:BatchGet*"       ],       "Resource":       "*",       "Effect":       "Allow"     },     {       "Action": [         "logs:CreateLogGroup", </pre>	

Task	Description	Skills required
	<pre data-bbox="609 247 982 1192"> "logs:CreateLogStream",  "logs:PutLogEvents"     ],     "Resource": "*",     "Effect": "Allow"     },     {         "Action": "sts:AssumeRole",         "Resource": "&lt;ARN of destination role&gt;",         "Effect": "Allow",         "Sid": "AssumeCrossAccountArn"     }     ] } </pre> <p data-bbox="592 1260 1006 1438">Attach the managed policy AmazonEC2ContainerRegistryReadOnly to the CLI command as follows:</p> <pre data-bbox="609 1491 982 1806"> ~\$ aws iam attach-role-policy \ --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly \ --role-name &lt;name of CodeBuild Role&gt; </pre>	

Task	Description	Skills required
Create a cross-account role.	<p>In the destination AWS account, create an IAM role for the AWS CodeBuild role for the source account to assume. The cross-account role should allow container images to create a new repository and upload container images to Amazon ECR.</p> <p>To create the IAM role by using the AWS CLI, follow the <a href="#">instructions in the IAM documentation</a>.</p> <p>To allow the AWS CodeBuild project from the previous step, use the following trust policy:</p> <pre data-bbox="594 1171 1029 1730">{   "Version": "2012-10-17",   "Statement": {     "Effect": "Allow",     "Principal": {       "AWS": "&lt;ARN of source codebuild role&gt;"     },     "Action": "sts:AssumeRole"   } }</pre> <p>To allow the AWS CodeBuild project from the previous</p>	AWS administrator, AWS DevOps, Cloud administrator, Cloud architect, DevOps engineer, AWS systems administrator

Task	Description	Skills required
	<p>step to save images in the destination registry, use the following permission policy:</p> <pre data-bbox="592 380 1029 1822">{   "Version":   "2012-10-17",   "Statement": [     {       "Action": [          "ecr:GetDownloadUr         lForLayer",          "ecr:BatchCheckLay         erAvailability",          "ecr:PutImage",          "ecr:InitiateLayer         Upload",          "ecr:UploadLayerPa         rt",          "ecr:CompleteLayer         Upload",          "ecr:GetRepository         Policy",          "ecr:DescribeRepos         itories",          "ecr:GetAuthorizat         ionToken",          "ecr:CreateReposit         ory"        ],</pre>	

Task	Description	Skills required
	<pre> "Resource":   "*",   "Effect":     "Allow"   } ] } </pre>	

## Create the CodeBuild project

Task	Description	Skills required
Create a CodeBuild project.	<p>Create a AWS CodeBuild project in the source account by following the <a href="#">instructions in the AWS CodeBuild documentation</a>. The project should be in the same Region as the source registry.</p> <p>Configure the project as follows:</p> <ul style="list-style-type: none"> <li>• Environment type: LINUX CONTAINER</li> <li>• Service role: CodeBuild Role</li> <li>• Privileged mode: true</li> <li>• Environment image: aws/codebuild/standard:x.x (use the latest image available)</li> <li>• Environment variables: <ul style="list-style-type: none"> <li>• CROSS_ACCOUNT_ROLE_ARN : The Amazon</li> </ul> </li> </ul>	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Task	Description	Skills required
	<p>Resource Name (ARN) of the cross-account role</p> <ul style="list-style-type: none"> <li>• <code>DESTINATION_REGION</code> : The name of the cross-account Region</li> <li>• <code>DESTINATION_ACCOUNT</code> : The number of the destination account</li> <li>• Build specifications: Use the <code>buildspec.yaml</code> file listed in the <a href="#">Tools</a> section.</li> </ul>	

## Create the event

Task	Description	Skills required
<p>Create an events rule.</p>	<p>Because the pattern uses the content filtering feature, you need to create the event by using Amazon EventBridge. Create the event and target by following the <a href="#">instructions in the EventBridge documentation</a>, with a few modifications:</p> <ul style="list-style-type: none"> <li>• For <b>Define pattern</b>, choose <b>Event Pattern</b>, and then choose <b>Custom pattern</b>.</li> <li>• Copy the following custom events pattern sample code into the text box provided:</li> </ul> <pre data-bbox="625 1829 1029 1885">{</pre>	<p>AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer</p>

Task	Description	Skills required
	<pre data-bbox="625 205 1031 823"> "source": ["aws.ecr "], "detail-type": ["ECR Image Action"], "detail": { "action-type": ["PUSH"], "result": ["SUCCESS"], "image-ta g": [{ "prefix": "release-"}] } } </pre> <ul data-bbox="592 840 1031 1323" style="list-style-type: none"> <li>• For <b>Select targets</b>, choose the AWS CodeBuild project, and paste the ARN for the AWS CodeBuild project that you created in the previous epic.</li> <li>• For <b>Configure Input</b>, choose <b>Input Transformer</b>. <ul data-bbox="625 1239 974 1323" style="list-style-type: none"> <li>• In the <b>Input Path</b> text box, paste:</li> </ul> </li> </ul> <pre data-bbox="657 1354 1031 1596"> {"IMAGE_TAG":"\$.de tail.image-tag", "R EPO_NAME":"\$.detai l.repository-name" } </pre> <ul data-bbox="625 1617 974 1701" style="list-style-type: none"> <li>• In the <b>Input Template</b> text box, paste:</li> </ul> <pre data-bbox="657 1732 1031 1864"> {"environmentVaria blesOverride": [ {"name": </pre>

## Validate

Task	Description	Skills required
Authenticate with Amazon ECR.	Authenticate to both source and destination registries by following the steps in the <a href="#">Amazon ECR documentation</a> .	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, DevOps engineer, Cloud architect
Test image replication.	<p data-bbox="592 1228 1027 1606">In your source account, push a container image to a new or existing Amazon ECR source repository with an image tag prefixed with <code>release-</code>. To push the image, follow the steps in the <a href="#">Amazon ECR documentation</a>.</p> <p data-bbox="592 1648 1027 1774">You can monitor the progress of the CodeBuild project in the <a href="#">CodeBuild console</a>.</p>	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer

Task	Description	Skills required
	<p>After the CodeBuild project has completed successfully, sign in to the destination AWS account, open the Amazon ECR console, and confirm that the image exists in the destination Amazon ECR registry.</p>	
<p>Test image exclusion.</p>	<p>In your source account, push a container image to a new or existing Amazon ECR source repository with an image tag that doesn't have the custom prefix.</p> <p>Confirm that the CodeBuild project isn't started, and that no container images appear in the destination registry.</p>	<p>AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer</p>

## Related resources

- [Getting started with CodeBuild](#)
- [Getting started with Amazon EventBridge](#)
- [Content-based filtering in Amazon EventBridge event patterns](#)
- [Delegate access across AWS accounts using IAM roles](#)
- [Private image replication](#)

## Additional information

To automatically deploy the resources for this pattern, follow these steps:

1. Download the attachment and extract the two CloudFormation templates: `part-1-copy-tagged-images.yaml` and `part-2-destination-account-role.yaml`.
2. Log in to the [AWS CloudFormation console](#), and deploy `part-1-copy-tagged-images.yaml` in the same AWS account and Region as the source Amazon ECR registries. Update the parameters as needed. The template deploys the following resources:
  - Amazon CloudWatch Events IAM role
  - AWS CodeBuild project IAM role
  - AWS CodeBuild project
  - AWS CloudWatch Events rule
3. Take note of the value of `SourceRoleName` in the **Outputs** tab. You will need this value in the next step.
4. Deploy the second CloudFormation template, `part-2-destination-account-role.yaml`, in the AWS account that you want to copy the Amazon ECR container images to. Update the parameters as needed. For the `SourceRoleName` parameter, specify the value from step 3. This template deploys the cross-account IAM role.
5. Validate image replication and exclusion, as described in the last step of the [Epics](#) section.

# Rotate database credentials without restarting containers

Created by Josh Joy (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; Databases; DevOps; Infrastructure; Security, identity, compliance; Management & governance

**AWS services:** Amazon ECS; Amazon Aurora; AWS Fargate; AWS Secrets Manager; Amazon VPC

## Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS Secrets Manager to rotate, manage, and retrieve database credentials throughout their lifecycle. Users and applications retrieve secrets with a call to the Secrets Manager API, removing the need to hardcode sensitive information in plaintext.

If you're using containers for microservice workloads, you can securely store credentials in AWS Secrets Manager. To separate out configuration from code, these credentials are commonly injected into the container. However, it's important to rotate your credentials periodically and automatically. It's also important to support the ability to refresh credentials after revocation. At the same time, applications require the ability to rotate credentials while reducing any potential downstream availability impact.

This pattern describes how to rotate your secrets that are secured with AWS Secrets Manager within your containers without requiring your containers to restart. In addition, this pattern reduces the number of credential lookups to Secrets Manager by using the Secrets Manager [client-side caching component](#). When you use the client-side caching component to refresh the credentials within the application, the container doesn't need to be restarted to fetch a rotated credential.

This approach works for Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS).

[Two scenarios are covered](#). In the single-user scenario, the database credential is refreshed on secret rotation by detecting the expired credential. The credential cache is instructed to refresh the secret, and then the application re-establishes the database connection. The client-side caching component caches the credential within the application and helps avoid reaching out to Secrets

Manager for each credential lookup. The credential is rotated within the application without the need to force the credential refresh by restarting the container.

The second scenario rotates the secret by alternating between two users. Having two active users reduces the potential for downtime, because one user's credentials are always active. Two-user credential rotation is helpful when you have a large deployment with clusters in which there might be a small propagation delay of credential updates.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An application running in a container in Amazon EKS or Amazon ECS.
- Credentials stored in Secrets Manager, with [rotation enabled](#).
- A second set of credentials stored in Secrets Manager, if deploying the two-user solution. Code examples can be found in the GitHub repo [aws-secrets-manager-rotation-lambdas](#).
- An Amazon Aurora database.

### Limitations

- This example is targeted for Python applications. For Java applications, you can use the [Java client-side caching component](#) or the [JDBC client-side caching library](#) for Secrets Manager.

## Architecture

### Target architecture

*Scenario 1 – Rotation of a credential for a single user*

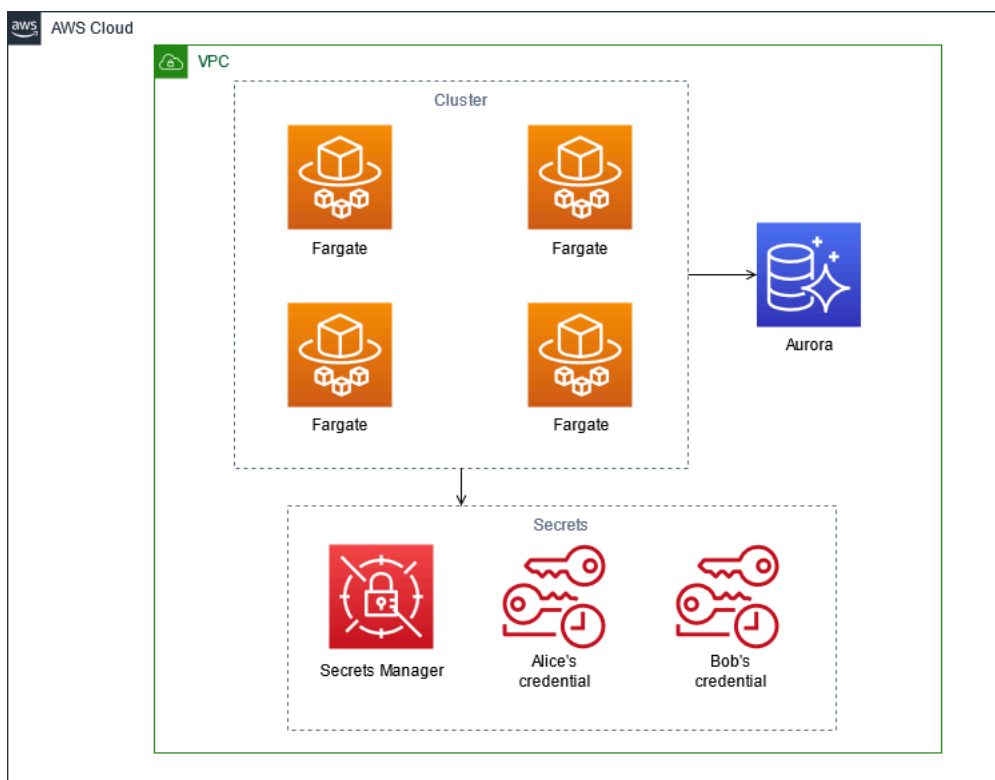

In the first scenario, a single database credential is periodically rotated by Secrets Manager. The application container runs in Fargate. When the first database connection is established, the application container fetches the database credential for Aurora. The Secrets Manager caching component then caches the credential for future connection establishment. When rotation period has elapsed, the credential expires and the database returns an authentication error. The application then fetches the rotated credential, invalidates the cache, and updates the credential cache via the Secrets Manager client-side caching component.

In this scenario, there might be a minimal disruption while the credential is being rotated and stale connections are using the outdated credential. This concern can be addressed by using the two-user scenario.

### Scenario 2 – Rotation of credentials for two users

In the second scenario, two database user credentials (Alice's and Bob's) are periodically rotated by Secrets Manager. The application container runs in a Fargate cluster. When the first database connection is established, the application container fetches the Aurora database credential for the first user (Alice). The Secrets Manager caching component then caches the credential for future connection establishment.

Although there are two users and credentials, one only active credential is managed by Secrets Manager. In this case, the caching component periodically expires and fetches the latest credential. If the Secrets Manager rotation period is longer than the cache timeout, the caching component picks up the rotated credential for the second user (Bob). For example, if the cache expiration is measured in minutes and the rotation period is measured in days, the caching component fetches the new credential as part of its periodic cache refresh. In this way, the downtime is minimized because each user's credential is active for one Secrets Manager rotation.

## Automation and scale

You can use [AWS CloudFormation](#) to deploy this pattern by using [infrastructure as code](#). This builds and creates the application container, creates the Fargate task, deploys the container into Fargate, and sets up and configure Secrets Manager with Aurora. For step-by-step deployment instructions, see the [readme](#) file.

## Tools

### Tools

- [AWS Secrets Manager](#) enables the replacement of hardcoded credentials, including passwords, with an API call to Secrets Manager to retrieve the secret. Because Secrets Manager can automatically rotate the secret according to a schedule, you can replace long-term secrets with short-term ones, reducing the risk of compromise.
- [Docker](#) helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

### Code

#### *Example Python code*

This pattern uses the Python client-side caching component for Secrets Manager to retrieve the authentication credentials when establishing the database connection. The client-side caching component helps avoid reaching out to Secrets Manager each time.

Now, when the rotation period elapses, the cached credential will be expired, and connecting to the database will result in an authentication error. For MySQL, the authentication error code is 1045. This example uses Amazon Aurora for MySQL, though you could use another engine such as PostgreSQL. Upon the authentication error, the database connection exception handling code

catches the error. It then informs the Secrets Manager client-side caching component to refresh the secret, then to reauthenticate and re-establish the database connection. If you are using PostgreSQL or another engine, you must look up the corresponding authentication error code.

The container application can now update the database password with the rotated password without restarting the container.

Place the following code in your application code that handles database connections. This example uses Django, and it [subclasses](#) the database backend with a database wrapper for connections. If you are using a different programming language or database connection library, see your database connection library to review how to subclass database connection retrieval.

```
def get_new_connection(self, conn_params):
    try:
        logger.info("get connection")
        databascredentials.get_conn_params_from_secrets_manager(conn_params)
        conn =super(DatabaseWrapper,self).get_new_connection(conn_params)
        return conn
    except MySQLdb.OperationalError as e:
        error_code=e.args[0]
        if error_code!=1045:
            raise e

        logger.info("Authentication error. Going to refresh secret and try again.")
        databascredentials.refresh_now()
        databascredentials.get_conn_params_from_secrets_manager(conn_params)
        conn=super(DatabaseWrapper,self).get_new_connection(conn_params)
        logger.info("Successfully refreshed secret and established new database
connection.")
        return conn
```

# Run Amazon ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere

Created by Akash Kumar (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; Modernization

**Workload:** All other workloads

**AWS services:** Amazon ECS; Amazon WorkSpaces; AWS Directory Service

## Summary

Amazon Elastic Container Service (Amazon ECS) Anywhere supports the deployment of Amazon ECS tasks in any environment, including Amazon Web Services (AWS) managed infrastructure and customer managed infrastructure. You can do this while using a fully AWS managed control plane that's running in the cloud and always up to date.

Enterprises often use Amazon WorkSpaces for developing container-based applications. This has required Amazon Elastic Compute Cloud (Amazon EC2) or AWS Fargate with an Amazon ECS cluster to test and run ECS tasks. Now, by using Amazon ECS Anywhere, you can add Amazon WorkSpaces as external instances directly to an ECS cluster, and you can run your tasks directly. This reduces your development time, because you can test your container with an ECS cluster locally on Amazon WorkSpaces. You can also save the cost of using EC2 or Fargate instances for testing your container applications.

This pattern showcases how to deploy ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere. It sets up the ECS cluster and uses AWS Directory Service Simple AD to launch the WorkSpaces. Then the example ECS task launches NGINX in the WorkSpaces.

## Prerequisites and limitations

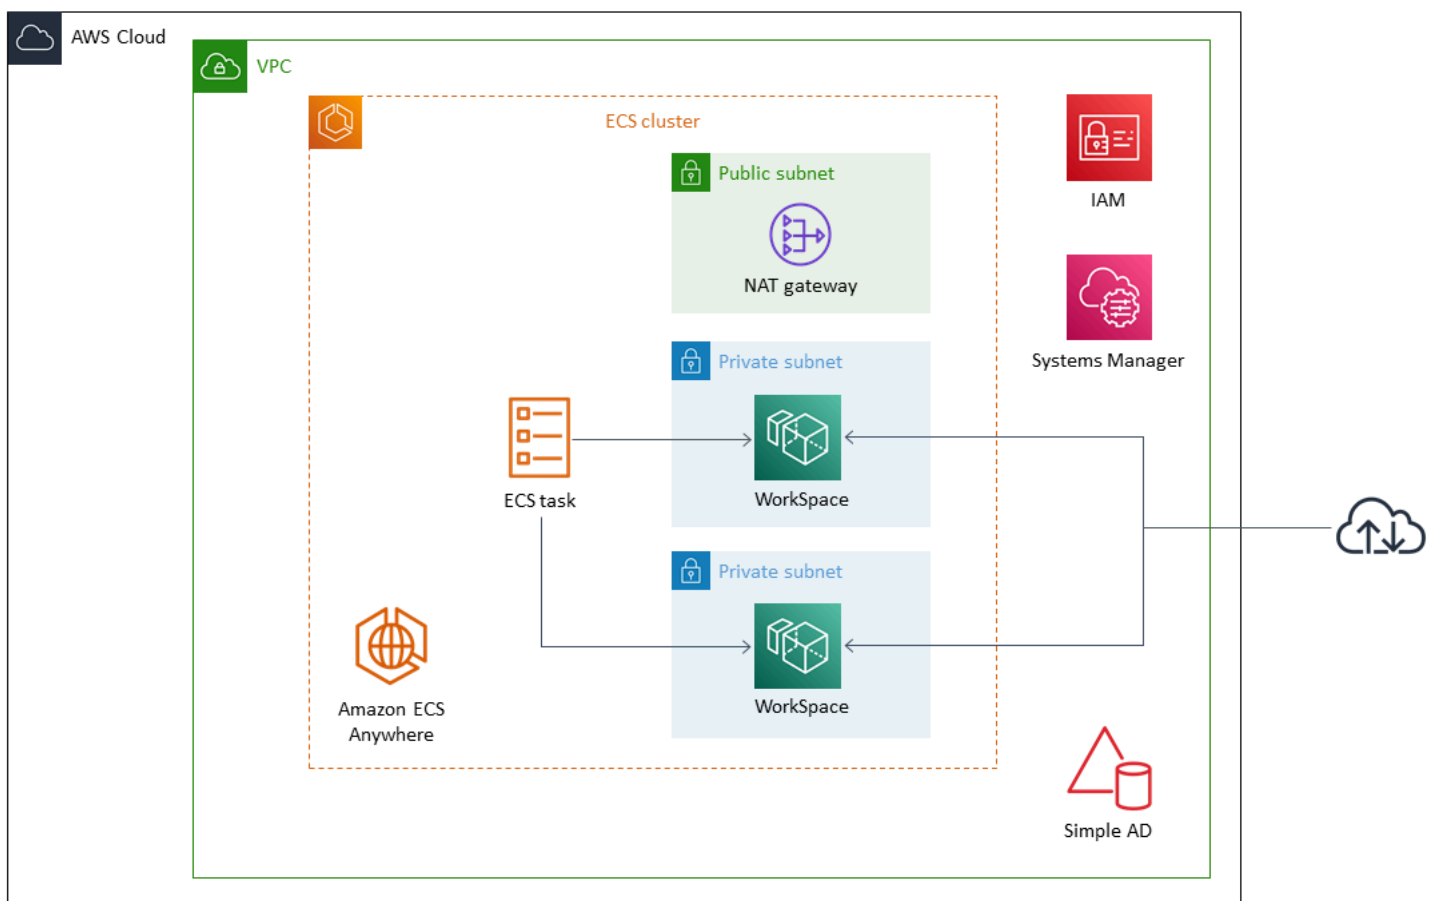

- An active AWS account
- AWS Command Line Interface (AWS CLI)
- AWS credentials [configured on your machine](#)

# Architecture

## Target technology stack

- A virtual private cloud (VPC)
- An Amazon ECS cluster
- Amazon WorkSpaces
- AWS Directory Service with Simple AD

## Target architecture

The architecture includes the following services and resources:

- An ECS cluster with public and private subnets in a custom VPC
- Simple AD in the VPC to provide user access to Amazon WorkSpaces
- Amazon WorkSpaces provisioned in the VPC using Simple AD

- AWS Systems Manager activated for adding Amazon WorkSpaces as managed instances
- Using Amazon ECS and AWS Systems Manager Agent (SSM Agent), Amazon WorkSpaces added to Systems Manager and the ECS cluster
- An example ECS task to run in the WorkSpaces in the ECS cluster

## Tools

- [AWS Directory Service Simple Active Directory \(Simple AD\)](#) is a standalone managed directory powered by a Samba 4 Active Directory Compatible Server. Simple AD provides a subset of the features offered by AWS Managed Microsoft AD, including the ability to manage users and to securely connect to Amazon EC2 instances.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- [Amazon WorkSpaces](#) helps you provision virtual, cloud-based Microsoft Windows or Amazon Linux desktops for your users, known as *WorkSpaces*. WorkSpaces eliminates the need to procure and deploy hardware or install complex software.

## Epics

### Set up the ECS cluster

Task	Description	Skills required
Create and configure the ECS cluster.	To create the ECS cluster, follow the instructions in the <a href="#">AWS documentation</a> , including the following steps: <ul style="list-style-type: none"> <li>• For <b>Select cluster compatibility</b>, choose</li> </ul>	Cloud architect

Task	Description	Skills required
	<p><b>Networking only</b>, which will support an Amazon WorkSpace as an external instance to the ECS cluster.</p> <ul style="list-style-type: none"> <li>Choose to create a new VPC.</li> </ul>	

## Launch Amazon WorkSpaces

Task	Description	Skills required
Set up Simple AD and launch Amazon WorkSpaces.	To provision a Simple AD directory for your newly created VPC and launch Amazon WorkSpaces, follow the instructions in the <a href="#">AWS documentation</a> .	Cloud architect

## Set up AWS Systems Manager for a hybrid environment

Task	Description	Skills required
Download the attached scripts.	On your local machine, download the <code>ssm-trust-policy.json</code> and <code>ssm-activation.json</code> files that are in the <i>Attachments</i> section.	Cloud architect
Add the IAM role.	Add environment variables based on your business requirements.	Cloud architect

Task	Description	Skills required
	<pre>export AWS_DEFAULT_REGION=\${AWS_REGION_ID} export ROLE_NAME=\${ECS_TASK_ROLE} export CLUSTER_NAME=\${ECS_CLUSTER_NAME} export SERVICE_NAME=\${ECS_CLUSTER_SERVICE_NAME}</pre> <p>Run the following command.</p> <pre>aws iam create-role --role-name \$ROLE_NAME --assume-role-policy-document file://ssm-trust-policy.json</pre>	
<p>Add the AmazonSSMManagedInstanceCore policy to the IAM role.</p>	<p>Run the following command.</p> <pre>aws iam attach-role-policy --role-name \$ROLE_NAME --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore</pre>	<p>Cloud architect</p>
<p>Add the AmazonEC2ContainerServiceforEC2Role policy to IAM role.</p>	<p>Run the following command.</p> <pre>aws iam attach-role-policy --role-name \$ROLE_NAME --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceforEC2Role</pre>	<p>Cloud architect</p>

Task	Description	Skills required
Verify the IAM role.	To verify the IAM role, run the following command.  <pre>aws iam list-attached-role-policies --role-name \$ROLE_NAME</pre>	Cloud architect
Activate Systems Manager.	Run the following command.  <pre>aws ssm create-activation --iam-role \$ROLE_NAME   tee ssm-activation.json</pre>	Cloud architect

## Add WorkSpaces to the ECS cluster

Task	Description	Skills required
Connect to your WorkSpaces.	To connect to and set up your Workspaces, follow the instructions in the <a href="#">AWS documentation</a> .	App developer
Download the ecs-anywhere install script.	At the command prompt, run the following command.  <pre>curl -o "ecs-anywhere-install.sh" "https://amazon-ecs-agent-packages-preview.s3.us-east-1.amazonaws.com/ecs-anywhere-install.sh" &amp;&amp; sudo chmod +x ecs-anywhere-install.sh</pre>	App developer

Task	Description	Skills required
Check integrity of the shell script.	<p>(Optional) Run the following command.</p> <pre>curl -o "ecs-anywhere-install.sh.sha256" "https://amazon-ecs-agent-packages-prereview.s3.us-east-1.amazonaws.com/ecs-anywhere-install.sh.sha256" &amp;&amp; sha256sum -c ecs-anywhere-install.sh.sha256</pre>	App developer
Add an EPEL repository on Amazon Linux.	<p>To add an Extra Packages for Enterprise Linux (EPEL) repository, run the command <code>sudo amazon-linux-extras install epel -y</code>.</p>	App developer
Install Amazon ECS Anywhere.	<p>To run the install script, use the following command.</p> <pre>sudo ./ecs-anywhere-install.sh --cluster \$CLUSTER_NAME --activation-id \$ACTIVATION_ID --activation-code \$ACTIVATION_CODE --region \$AWS_REGION</pre>	

Task	Description	Skills required
Check instance information from the ECS cluster.	<p>To check the Systems Manager and ECS cluster instance information and validate that WorkSpaces were added on the cluster, run the following command from your local machine.</p> <pre>aws ssm describe-instance-informati on" &amp;&amp; "aws ecs list-container-instances --cluster \$CLUSTER_NAME</pre>	App developer

### Add an ECS task for the WorkSpaces

Task	Description	Skills required
Create a task execution IAM role.	<p>Download <code>task-execution-assume-role.json</code> and <code>external-task-definition.json</code> from the <i>Attachments</i> section.</p> <p>On your local machine, run the following command.</p> <pre>aws iam --region \$AWS_DEFAULT_REGION create-role --role-name \$ECS_TASK_EXECUTION_ROLE --assume-role-policy-document file://ta</pre>	Cloud architect

Task	Description	Skills required
	<pre>sk-execution-assume- role.json</pre>	
Add the policy to the execution role.	Run the following command. <pre>aws iam --region \$AWS_DEFAULT_REGIO N attach-role-policy --role-name \$ECS_TASK _EXECUTION_ROLE -- policy-arn arn:aws:i am::aws:policy/ser vice-role/AmazonEC STaskExecutionRole Policy</pre>	Cloud architect
Create a task role.	Run the following command. <pre>aws iam --region \$AWS_DEFAULT_REGIO N create-role -- role-name \$ECS_TASK _EXECUTION_ROLE -- assume-role-policy- document file://ta sk-execution-assume- role.json</pre>	Cloud architect
Register the task definition to the cluster.	On your local machine, run the following command. <pre>aws ecs register-task- definition --cli-inp ut-json file://ex ternal-task-defini tion.json</pre>	Cloud architect

Task	Description	Skills required
Run the task.	<p>On your local machine, run the following command.</p> <pre>aws ecs run-task -- cluster \$CLUSTER_NAME --launch-type EXTERNAL --task-definition nginx</pre>	Cloud architect
Validate the task running state.	<p>To fetch the task ID, run the following command.</p> <pre>export TEST_TASKID= \$(aws ecs list-tasks -- cluster \$CLUSTER_NAME   jq -r '.taskArns[0]')</pre> <p>With the task ID, run the following command.</p> <pre>aws ecs describe-tasks --cluster \$CLUSTER_ NAME --tasks \${TEST_TA SKID}</pre>	Cloud architect
Verify the task on the WorkSpace.	<p>To check that NGINX is running on the WorkSpace , run the command <code>curl http://localhost:8080</code> .</p>	App developer

# Run an ASP.NET Core web API Docker container on an Amazon EC2 Linux instance

Created by Vijai Anand Ramalingam (AWS) and Sreelaxmi Pai (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; DevelopmentAndTesting; Web & mobile apps

**Workload:** Microsoft

**AWS services:** Amazon EC2; Elastic Load Balancing (ELB)

## Summary

This pattern is for people who are starting to containerize their applications on the Amazon Web Services (AWS) Cloud. When you begin to containerize apps on cloud, usually there are no container orchestrating platforms set up. This pattern helps you quickly set up infrastructure on AWS to test your containerized applications without needing an elaborate container orchestrating infrastructure.

The first step in the modernization journey is to transform the application. If it's a legacy .NET Framework application, you must first change the runtime to ASP.NET Core. Then do the following:

- Create the Docker container image
- Run the Docker container using the built image
- Validate the application before deploying it on any container orchestration platform, such as Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

This pattern covers the build, run, and validate aspects of modern application development on an Amazon Elastic Compute Cloud (Amazon EC2) Linux instance.

## Prerequisites and limitations

### Prerequisites

- An active [Amazon Web Services \(AWS\) account](#)
- An [AWS Identity and Access Management \(IAM\) role](#) with sufficient access to create AWS resources for this pattern
- [Visual Studio Community 2022](#) or later downloaded and installed
- A .NET Framework project modernized to ASP.NET Core
- A GitHub repository

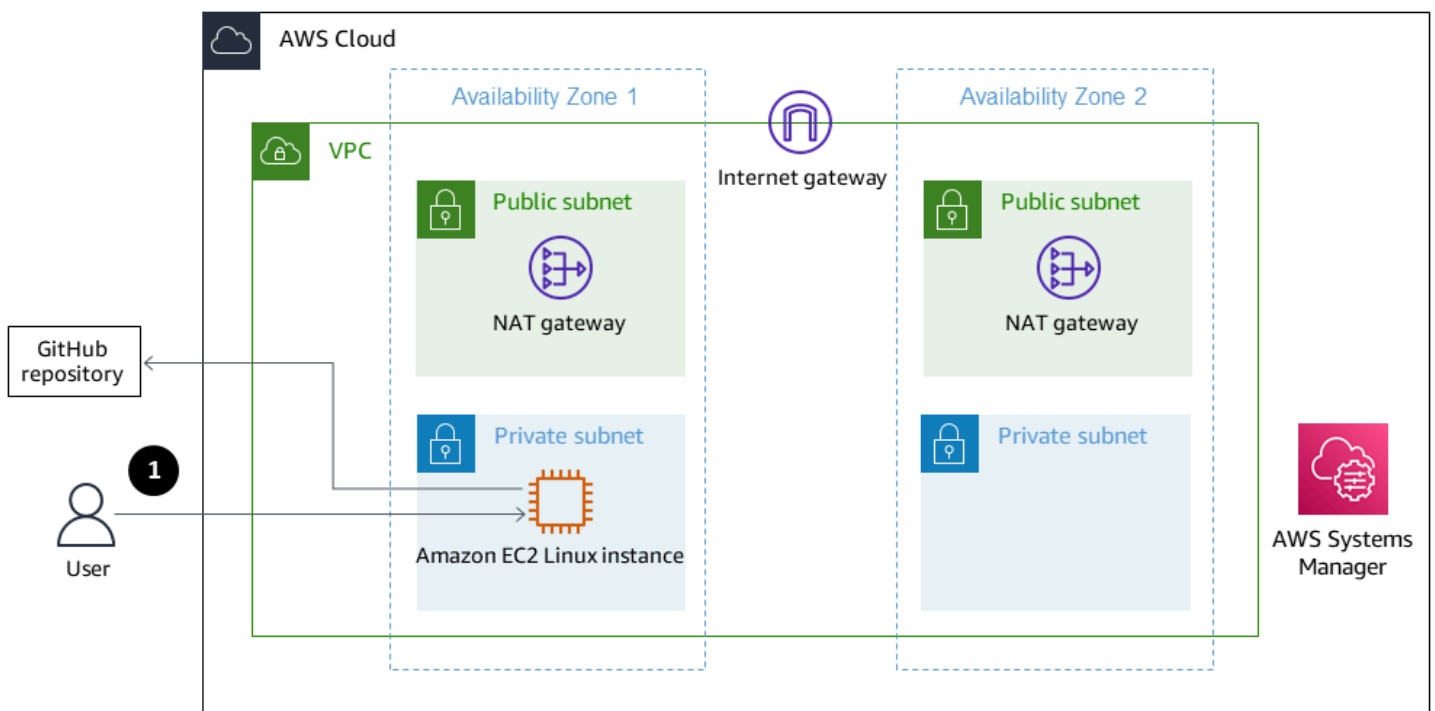

## Product versions

- Visual Studio Community 2022 or later

## Architecture

### Target architecture

This pattern uses an [AWS CloudFormation template](#) to create the highly available architecture shown in the following diagram. An Amazon EC2 Linux instance is launched in a private subnet. AWS Systems Manager Session Manager is used to access the private Amazon EC2 Linux instance and to test the API running in the Docker container.

## 1. Access to the Linux instance through Session Manager

# Tools

### AWS services

- [AWS Command Line Interface](#) – AWS Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services through commands in your command line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console.
- [AWS Management Console](#) – The AWS Management Console is a web application that comprises and refers to a broad collection of service consoles for managing AWS resources. When you first sign in, you see the console home page. The home page provides access to each service console and offers a single place to access the information you need to perform your AWS related tasks.
- [AWS Systems Manager Session Manager](#) – Session Manager is a fully managed AWS Systems Manager capability. With Session Manager, you can manage your Amazon Elastic Compute Cloud (Amazon EC2) instances. Session Manager provides secure and auditable node management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys.

### Other tools

- [Visual Studio 2022](#) – Visual Studio 2022 is an integrated development environment (IDE).
- [Docker](#) – Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

### Code

```
FROM mcr.microsoft.com/dotnet/aspnet:5.0 AS base
WORKDIR /app
EXPOSE 80
EXPOSE 443

FROM mcr.microsoft.com/dotnet/sdk:5.0 AS build
WORKDIR /src
COPY ["DemoNetCoreWebAPI/DemoNetCoreWebAPI.csproj", "DemoNetCoreWebAPI/"]
RUN dotnet restore "DemoNetCoreWebAPI/DemoNetCoreWebAPI.csproj"
COPY . .
WORKDIR "/src/DemoNetCoreWebAPI"
```

```
RUN dotnet build "DemoNetCoreWebAPI.csproj" -c Release -o /app/build

FROM build AS publish
RUN dotnet publish "DemoNetCoreWebAPI.csproj" -c Release -o /app/publish

FROM base AS final
WORKDIR /app
COPY --from=publish /app/publish .
ENTRYPOINT ["dotnet", "DemoNetCoreWebAPI.dll"]
```

## Epics

### Develop the ASP.NET Core web API

Task	Description	Skills required
Create an example ASP.NET Core web API using Visual Studio.	<p>To create an example ASP.NET Core web API, do the following:</p> <ol style="list-style-type: none"><li>1. Open Visual Studio 2022.</li><li>2. Choose <b>Create a new project</b>.</li><li>3. Select the <b>ASP.NET Core Web API</b> project template, and choose <b>Next</b>.</li><li>4. For the project name, enter <b>DemoNetCoreWebAPI</b>, and choose <b>Next</b>.</li><li>5. Choose <b>Create</b>.</li><li>6. To run the project locally, press F5.</li><li>7. Verify that the default <b>WeatherForecast</b> API endpoint is returning the results using <a href="#">Swagger</a>.</li></ol>	App developer

Task	Description	Skills required
	<p>8. Open the command prompt, navigate to the .csproj project folder, and run the following commands to push the new web API to your GitHub repository.</p> <pre data-bbox="630 569 1029 768">git add --all git commit -m "Initial Version" git push</pre>	

Task	Description	Skills required
Create a Dockerfile.	<p>To create a Dockerfile, do one of the following:</p> <ul style="list-style-type: none"><li>• Create the Dockerfile manually using the sample Dockerfile in the <i>Code</i> section. Based on the requirements, select the appropriate .NET base image. For information about .NET and ASP.NET Core related images, see <a href="#">Docker hub</a>.</li><li>• Create the Dockerfile using Visual Studio and <a href="#">Docker Desktop</a>. In the solution explorer, right click on the project, choose <b>Add-&gt;Docker Support</b>. For <b>Target OS</b>, select <b>Linux</b>. Ensure that the new Dockerfile is in the same path as the solution file (.sln).</li></ul> <p>To push the changes to your GitHub repository, run the following command.</p> <pre>git add --all git commit -m "Dockerfile added" git push</pre>	App developer

## Set up the Amazon EC2 Linux instance

Task	Description	Skills required
Set up the infrastructure.	<p>Launch the <a href="#">AWS CloudFormation template</a> to create the infrastructure, which includes the following:</p> <ul style="list-style-type: none"><li>• A virtual private cloud (VPC), using the <a href="#">AWS VPC Quick Start</a>, with two public and two private subnets spanning two Availability Zones.</li><li>• The required IAM role to enable AWS Systems Manager.</li><li>• In one of the private subnets, an Amazon Linux 2 demo instance with the latest SSM Agent. Although this instance doesn't have any direct connectivity from the internet, it can be accessed securely by using AWS Systems Manager Session Manager without requiring a bastion host.</li></ul> <p>To learn more about accessing a private Amazon EC2 instance using Session Manager without requiring a bastion host, see the <a href="#">Toward</a></p>	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	<a href="#">a bastion-less world</a> blog post.	
Log in to the Amazon EC2 Linux instance.	<p>To connect to the Amazon EC2 Linux instance in the private subnet, do the following:</p> <ol style="list-style-type: none"><li>1. # Run message-driven workloads at scale by using AWS Fargate

Created by Stan Zubarev (AWS)

**Environment:** PoC or pilot

**Technologies:** Containers & microservices; Messaging & communications; Databases

**AWS services:** AWS Fargate; Amazon SQS; Amazon DynamoDB

## Summary

This pattern shows how to run message-driven workloads at scale in the AWS Cloud by using containers and AWS Fargate.

Using containers to process data can be helpful when the amount of data an application processes exceeds the limitations of function-based serverless compute services. For example, if an application requires more compute capacity or processing time than what AWS Lambda offers, using Fargate can improve performance.

The following example setup uses the [AWS Cloud Development Kit \(AWS CDK\) in TypeScript](#) to configure and deploy the following resources in the AWS Cloud:

- A Fargate service
- An Amazon Simple Queue Service (Amazon SQS) queue
- An Amazon DynamoDB table.
- An Amazon CloudWatch dashboard

The Fargate service receives and processes messages from the Amazon SQS queue, then stores them in the Amazon DynamoDB table. You can monitor how many Amazon SQS messages are processed and how many DynamoDB items are created by Fargate by using the CloudWatch dashboard.

**Note:** You can also use this pattern's example code to build more complex data processing workloads in event-driven serverless architectures. For more information, see [Run event-driven and scheduled workloads at scale with AWS Fargate](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- The latest version of the [AWS Command Line Interface \(AWS CLI\)](#), installed and configured on your local machine
- [Git](#), installed and configured on your local machine
- The [AWS CDK](#), installed and configured on your local machine
- [Go](#), installed and configured on your local machine
- [Docker](#), installed and configured on your local machine

## Architecture

### Target technology stack

- Amazon SQS
- AWS Fargate
- Amazon DynamoDB

### Target architecture

The following diagram shows an example workflow for running message-driven workloads at scale in the AWS Cloud by using Fargate:

The diagram shows the following workflow:

1. The Fargate service uses [Amazon SQS long polling](#) to receive messages from an Amazon SQS queue.
2. The Fargate service then processes the Amazon SQS messages and stores them in a DynamoDB table.

## Automation and scale

To automate scaling your Fargate task count, you can configure Amazon Elastic Container Service (Amazon ECS) Service Auto Scaling. It's a best practice to configure the scaling policy based on the number of visible messages in your application's Amazon SQS queue.

For more information, see [Scaling based on Amazon SQS](#) in the *Amazon EC2 Auto Scaling User Guide*.

## Tools

### AWS services

- [AWS Fargate](#) helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).

- [Amazon Simple Queue Service \(Amazon SQS\)](#) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.

## Code

The code for this pattern is available in the GitHub [sqs-fargate-ddb-cdk-go](#) repository.

## Epics

### Create and deploy the resources by using the AWS CDK

Task	Description	Skills required
Clone the GitHub repository.	Clone the GitHub <a href="#">sqs-fargate-ddb-cdk-go</a> repository to your local machine by running the following command:  <pre>git clone https://github.com/aws-samples/sqs-fargate-ddb-cdk-go.git</pre>	App developer
Verify that the AWS CLI is configured to the correct AWS account and that the AWS CDK has the required permissions.	To check if your AWS CLI configuration settings are correct, you can run the following Amazon Simple Storage Service (Amazon S3) <a href="#">ls</a> command:  <pre>aws s3 ls</pre> This procedure also requires the AWS CDK to have	App developer

Task	Description	Skills required
	<p>permissions to provision infrastructure within your AWS account. To grant the required permissions, you must create named AWS profile in AWS CLI and export it as an <b>AWS_PROFILE</b> environment variable.</p> <p><b>Note:</b> If you haven't used the AWS CDK in your AWS account before, you must first provision the required AWS CDK resources. For more information, see <a href="#">Bootstrap ping</a> in the <i>AWS CDK v2 Developer Guide</i>.</p>	

Task	Description	Skills required
Deploy the AWS CDK stack to your AWS account.	<ol style="list-style-type: none"> <li>Build a container image by running the following AWS CLI command:  <code>docker build -t go-fargate .</code></li> <li>Open the AWS CDK directory by running the following command:  <code>cd cdk</code></li> <li>Install the required npm modules by running the following command:  <code>npm i</code></li> <li>Deploy the AWS CDK pattern to your AWS account by running the following command:  <code>cdk deploy --profile \${AWS_PROFILE}</code></li> </ol>	App developer

## Test the setup

Task	Description	Skills required
Send a test message to the Amazon SQS queue.	<p>For instructions, see <a href="#">Sending messages to a queue (console)</a> in the <i>Amazon SQS Developer Guide</i>.</p> <p><b>Test Amazon SQS message example</b></p>	App developer

Task	Description	Skills required
	<pre>{   "message": "hello,   Fargate" }</pre>	
Verify that the test message appears in the Fargate service's CloudWatch logs.	Follow the instructions in <a href="#">Viewing CloudWatch Logs</a> in the <i>Amazon ECS Developer Guide</i> . Make sure that you review the logs for the <b>go-fargate-service</b> log group in the <b>go-service-cluster</b> ECS cluster.	App developer
Verify that the test message appears in the DynamoDB table.	<ol style="list-style-type: none"><li>1. Open the <a href="#">DynamoDB console</a>.</li><li>2. In the left navigation pane, choose Tables. Then, select the following table from the list: <b>sqs-fargate-ddb-table</b>.</li><li>3. Choose <b>Explore table items</b>.</li><li>4. Verify that the test message appears in the <b>Items returned</b> list.</li></ol>	App developer

Task	Description	Skills required
Verify that the Fargate service is sending messages to CloudWatch Logs.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">CloudWatch console</a>.</li> <li>2. In the left navigation pane, choose <b>Dashboards</b>.</li> <li>3. In the Custom Dashboards list, select the dashboard named <b>go-service-dashboard</b>.</li> <li>4. Verify that the test message appears in the logs.</li> </ol> <p><b>Note:</b> The AWS CDK creates the CloudWatch dashboard in your AWS account automatically.</p>	App developer

## Clean up

Task	Description	Skills required
Delete the AWS CDK stack.	<ol style="list-style-type: none"> <li>1. Open your AWS CDK directory in the AWS CLI by running the following command: <pre>cd cdk</pre> </li> <li>2. Delete the AWS CDK stack by running the following command:</li> </ol>	App developer

Task	Description	Skills required
	<pre>cdk destroy -- profile \${AWS_PRO FILE}</pre>	
Verify that the AWS CDK stack is deleted.	<p>To make sure that the stack was deleted, run the following command:</p> <pre>aws cloudformation list-stacks --query \ "StackSummaries[? contains(StackName ,'SqsFargate')].St ackStatus" \ --profile \${AWS_PRO FILE}</pre> <p>The <code>StackStatus</code> value returned in the command output is <code>DELETE_COMPLETE</code> if the stack is deleted.</p> <p>For more information, see <a href="#">Describing and listing your stacks</a> in the <i>AWS CloudFormation User Guide</i>.</p>	App developer

# Run stateful workloads with persistent data storage by using Amazon EFS on Amazon EKS with AWS Fargate

Created by Ricardo Morais (AWS), Rodrigo Bersa (AWS), and Lucio Pereira (AWS)

<b>Code repository:</b> <a href="#">Amazon EKS with Fargate and Amazon EFS</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Containers & microservices; Storage & backup
<b>Workload:</b> Open-source	<b>AWS services:</b> Amazon EFS; Amazon EKS; AWS Fargate	

## Summary

This pattern provides guidance for enabling Amazon Elastic File System (Amazon EFS) as a storage device for containers that are running on Amazon Elastic Kubernetes Service (Amazon EKS) by using AWS Fargate to provision your compute resources.

The setup described in this pattern follows security best practices and provides security at rest and security in transit by default. To encrypt your Amazon EFS file system, it uses an AWS Key Management Service (AWS KMS) key, but you can also specify a key alias that dispatches the process of creating a KMS key.

You can follow the steps in this pattern to create a namespace and Fargate profile for a proof-of-concept (PoC) application, install the Amazon EFS Container Storage Interface (CSI) driver that is used to integrate the Kubernetes cluster with Amazon EFS, configure the storage class, and deploy the PoC application. These steps result in an Amazon EFS file system that is shared among multiple Kubernetes workloads, running over Fargate. The pattern is accompanied by scripts that automate these steps.

You can use this pattern if you want data persistence in your containerized applications and want to avoid data loss during scaling operations. For example:

- **DevOps tools** – A common scenario is to develop a continuous integration and continuous delivery (CI/CD) strategy. In this case, you can use Amazon EFS as a shared file system to store configurations among different instances of the CI/CD tool or to store a cache (for example, an Apache Maven repository) for pipeline stages among different instances of the CI/CD tool.

- **Web servers** – A common scenario is to use Apache as an HTTP web server. You can use Amazon EFS as a shared file system to store static files that are shared among different instances of the web server. In this example scenario, modifications are applied directly to the file system instead of static files being baked into a Docker image.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An existing Amazon EKS cluster with Kubernetes version 1.17 or later (tested up to version 1.27)
- An existing Amazon EFS file system to bind a Kubernetes StorageClass and provision file systems dynamically
- Cluster administration permissions
- Context configured to point to the desired Amazon EKS cluster

### Limitations

- There are some limitations to consider when you're using Amazon EKS with Fargate. For example, the use of some Kubernetes constructs, such as DaemonSets and privileged containers, aren't supported. For more information, about Fargate limitations, see the [AWS Fargate considerations](#) in the Amazon EKS documentation.
- The code provided with this pattern supports workstations that are running Linux or macOS.

### Product versions

- AWS Command Line Interface (AWS CLI) version 2 or later
- Amazon EFS CSI driver version 1.0 or later (tested up to version 2.4.8)
- eksctl version 0.24.0 or later (tested up to version 0.158.0)
- jq version 1.6 or later
- kubectl version 1.17 or later (tested up to version 1.27)
- Kubernetes version 1.17 or later (tested up to version 1.27)

---

# Architecture

The target architecture is comprised of the following infrastructure:

- A virtual private cloud (VPC)
- Two Availability Zones
- A public subnet with a NAT gateway that provides internet access
- A private subnet with an Amazon EKS cluster and Amazon EFS mount targets (also known as *mount points*)
- Amazon EFS at the VPC level

The following is the environment infrastructure for the Amazon EKS cluster:

- AWS Fargate profiles that accommodate the Kubernetes constructs at the namespace level
- A Kubernetes namespace with:
  - Two application pods distributed across Availability Zones
  - One persistent volume claim (PVC) bound to a persistent volume (PV) at the cluster level
- A cluster-wide PV that is bound to the PVC in the namespace and that points to the Amazon EFS mount targets in the private subnet, outside of the cluster

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that you can use to interact with AWS services from the command line.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud. In this pattern, it provides a simple, scalable, fully managed, and shared file system for use with Amazon EKS.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or operate your own clusters.
- [AWS Fargate](#) is a serverless compute engine for Amazon EKS. It creates and manages compute resources for your Kubernetes applications.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.

## Other tools

- [Docker](#) is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- [eksctl](#) is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- [kubectrl](#) is a command-line interface that helps you run commands against Kubernetes clusters.
- [jq](#) is a command-line tool for parsing JSON.

## Code

The code for this pattern is provided in the GitHub [Persistence Configuration with Amazon EFS on Amazon EKS using AWS Fargate](#) repo. The scripts are organized by epic, in the folders epic01 through epic06, corresponding to the order in the [Epics](#) section in this pattern.

## Best practices

The target architecture includes the following services and components, and it follows [AWS Well-Architected Framework](#) best practices:

- Amazon EFS, which provides a simple, scalable, fully managed elastic NFS file system. This is used as a shared file system among all replications of the PoC application that are running in pods, which are distributed in the private subnets of the chosen Amazon EKS cluster.
- An Amazon EFS mount target for each private subnet. This provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.
- Amazon EKS, which runs the Kubernetes workloads. You must provision an Amazon EKS cluster before you use this pattern, as described in the [Prerequisites](#) section.
- AWS KMS, which provides encryption at rest for the content that's stored in the Amazon EFS file system.
- Fargate, which manages the compute resources for the containers so that you can focus on business requirements instead of infrastructure burden. The Fargate profile is created for all private subnets. It provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.
- Kubernetes Pods, for validating that content can be shared, consumed, and written by different instances of an application.

## Epics

### Provision an Amazon EKS cluster (optional)

Task	Description	Skills required
Create an Amazon EKS cluster.	If you already have a cluster deployed, skip to the next epic. Create an Amazon EKS cluster in your existing AWS account. In the <a href="#">GitHub Repo directory</a> , use one of the patterns to deploy an Amazon EKS cluster by using Terraform or eksctl. For more information, see <a href="#">Creating an Amazon EKS cluster</a> in the Amazon EKS documentation. Note: In the Terraform pattern, there are also examples showing how to: link Fargate profiles to your Amazon EKS cluster, create an Amazon EFS file system, and deploy Amazon EFS CSI driver in your Amazon EKS cluster.	AWS administrator, Terraform or eksctl administrator, Kubernetes administrator
Export environment variables.	Run the env.sh script. This provides the information required in the next steps. <pre>source ./scripts/env.sh Inform the AWS Account ID: &lt;13-digit-account-id&gt; Inform your AWS Region: &lt;aws-Region-code&gt;</pre>	AWS systems administrator

Task	Description	Skills required
	<p>Inform your Amazon EKS Cluster Name:  <code>&lt;amazon-eks-cluster-name&gt;</code></p> <p>Inform the Amazon EFS Creation Token:  <code>&lt;self-generated-uuid&gt;</code></p> <p>If not noted yet, you can get all the information requested above with the following CLI commands.</p> <pre># ACCOUNT ID aws sts get-caller-identity --query "Account" --output text</pre> <pre># REGION CODE aws configure get region</pre> <pre># CLUSTER EKS NAME aws eks list-clusters --query "clusters" --output text</pre> <pre># GENERATE EFS TOKEN uuidgen</pre>	

## Create a Kubernetes namespace and a linked Fargate profile

Task	Description	Skills required
Create a Kubernetes namespace and Fargate	Create a namespace for receiving the application	Kubernetes user with granted permissions

Task	Description	Skills required
<p>profile for application workloads.</p>	<p>workloads that interact with Amazon EFS. Run the <code>create-k8s-ns-and-linked-fargate-profile.sh</code> script. You can choose to use a custom namespace name or the default provided namespace <code>poc-efs-eks-fargate</code>.</p> <p><b>With a custom application namespace name:</b></p> <pre>export \$APP_NAME SPACE=&lt;CUSTOM_NAME&gt; ./scripts/epic01/ create-k8s-ns-and- -linked-fargate-pr ofile.sh \ -c "\$CLUSTER_NAME" -n "\$APP_NAMESPACE"</pre> <p><b>Without a custom application namespace name:</b></p> <pre>./scripts/epic01/c reate-k8s-ns-and-l inked-fargate-prof ile.sh \ -c "\$CLUSTER_NAME"</pre> <p>where <code>\$CLUSTER_NAME</code> is the name of your Amazon EKS cluster. The <code>-n &lt;NAMESPACE&gt;</code> parameter is optional; if not informed, a</p>	

Task	Description	Skills required
	default generated namespace name will be provided.	

## Create an Amazon EFS file system

Task	Description	Skills required
Generate a unique token.	Amazon EFS requires a creation token to ensure idempotent operation (calling the operation with the same creation token has no effect). To meet this requirement, you must generate a unique token through an available technique. For example, you can generate a universally unique identifier (UUID) to use as a creation token.	AWS systems administrator
Create an Amazon EFS file system.	Create the file system for receiving the data files that are read and written by the application workloads. You can create an encrypted or non-encrypted file system. (As a best practice, the code for this pattern creates an encrypted system to enable encryption at rest by default.) You can use a unique, symmetric AWS KMS key to encrypt your file system. If a custom key is not	AWS systems administrator

Task	Description	Skills required
	<p>specified, an AWS managed key is used.</p> <p>Use the create-efs.sh script to create an encrypted or non-encrypted Amazon EFS file system, after you generate a unique token for Amazon EFS.</p> <p><b>With encryption at rest, without a KMS key:</b></p> <pre data-bbox="597 730 1026 1003">./scripts/epic02/c reate-efs.sh \     -c "\$CLUSTER_NAME" \     -t "\$EFS_CRE ATION_TOKEN"</pre> <p>where \$CLUSTER_NAME is the name of your Amazon EKS cluster and \$EFS_CREATION_TOKEN is a unique creation token for the file system.</p> <p><b>With encryption at rest, with a KMS key:</b></p> <pre data-bbox="597 1486 1026 1801">./scripts/epic02/c reate-efs.sh \     -c "\$CLUSTER_NAME" \     -t "\$EFS_CRE ATION_TOKEN" \     -k "\$KMS_KEY_ALIAS"</pre>	

Task	Description	Skills required
	<p>where <code>\$CLUSTER_NAME</code> is the name of your Amazon EKS cluster, <code>\$EFS_CREATION_TOKEN</code> is a unique creation token for the file system, and <code>\$KMS_KEY_ALIAS</code> is the alias for the KMS key.</p> <p><b>Without encryption:</b></p> <pre data-bbox="597 699 1027 978"> ./scripts/epic02/create-efs.sh -d \   -c "\$CLUSTER_NAME" \   -t "\$EFS_CREATION_TOKEN" </pre> <p>where <code>\$CLUSTER_NAME</code> is the name of your Amazon EKS cluster, <code>\$EFS_CREATION_TOKEN</code> is a unique creation token for the file system, and <code>-d</code> disables encryption at rest.</p>	
Create a security group.	Create a security group to allow the Amazon EKS cluster to access the Amazon EFS file system.	AWS systems administrator

Task	Description	Skills required
Update the inbound rule for the security group.	Update the inbound rules of the security group to allow incoming traffic for the following settings: <ul style="list-style-type: none"> <li>• <b>TCP protocol</b> – port 2049</li> <li>• <b>Source</b> – CIDR block ranges for the private subnets in the VPC that contains the Kubernetes cluster</li> </ul>	AWS systems administrator
Add a mount target for each private subnet.	For each private subnet of the Kubernetes cluster, create a mount target for the file system and the security group.	AWS systems administrator

### Install Amazon EFS components into the Kubernetes cluster

Task	Description	Skills required
Deploy the Amazon EFS CSI driver.	Deploy the Amazon EFS CSI driver into the cluster. The driver provisions storage according to persistent volume claims created by applications. Run the <code>create-k8s-efs-csi-sc.sh</code> script to deploy the Amazon EFS CSI driver and the storage class into the cluster.	Kubernetes user with granted permissions

Task	Description	Skills required
	<pre data-bbox="594 212 1024 369">./scripts/epic03/create-k8s-efs-csi-sc.sh</pre> <p data-bbox="594 407 1008 632">This script uses the <code>kubectl</code> utility, so make sure that the context has been configured and point to the desired Amazon EKS cluster.</p>	
Deploy the storage class.	Deploy the storage class into the cluster for the Amazon EFS provisioner ( <code>efs.csi.aws.com</code> ).	Kubernetes user with granted permissions

## Install the PoC application into the Kubernetes cluster

Task	Description	Skills required
Deploy the persistent volume.	<p data-bbox="594 1150 1024 1329">Deploy the persistent volume, and link it to the created storage class and to the ID of the Amazon EFS file system.</p> <p data-bbox="594 1346 1024 1850">The application uses the persistent volume to read and write content. You can specify any size for the persistent volume in the storage field. Kubernetes requires this field, but because Amazon EFS is an elastic file system, it does not enforce any file system capacity. You can deploy the persistent volume</p>	Kubernetes user with granted permissions

Task	Description	Skills required
	<p>with or without encryption. (The Amazon EFS CSI driver enables encryption by default, as a best practice.)</p> <p>) Run the <code>deploy-poc-app.sh</code> script to deploy the persistent volume, the persistent volume claim, and the two workloads.</p> <p><b>With encryption in transit:</b></p> <pre>./scripts/epic04/deploy-poc-app.sh \   -t "\$EFS_CREATION_TOKEN"</pre> <p>where <code>\$EFS_CREATION_TOKEN</code> is the unique creation token for the file system.</p> <p><b>Without encryption in transit:</b></p> <pre>./scripts/epic04/deploy-poc-app.sh -d \   -t "\$EFS_CREATION_TOKEN"</pre> <p>where <code>\$EFS_CREATION_TOKEN</code> is the unique creation token for the file system, and <code>-d</code> disables encryption in transit.</p>	

Task	Description	Skills required
Deploy the persistent volume claim requested by the application.	Deploy the persistent volume claim requested by the application, and link it to the storage class. Use the same access mode as the persistent volume you created previously. You can specify any size for the persistent volume claim in the storage field. Kubernetes requires this field, but because Amazon EFS is an elastic file system, it does not enforce any file system capacity.	Kubernetes user with granted permissions
Deploy workload 1.	Deploy the pod that represents workload 1 of the application. This workload writes content to the file <code>/data/out1.txt</code> .	Kubernetes user with granted permissions
Deploy workload 2.	Deploy the pod that represents workload 2 of the application. This workload writes content to the file <code>/data/out2.txt</code> .	Kubernetes user with granted permissions

### Validate file system persistence, durability, and shareability

Task	Description	Skills required
Check the status of the <code>PersistentVolume</code> .	Enter the following command to check the status of the <code>PersistentVolume</code> .	Kubernetes user with granted permissions

Task	Description	Skills required
	<pre>kubectl get pv</pre> <p>For an example output, see the <a href="#">Additional information</a> section.</p>	
Check the status of the PersistentVolumeClaim .	<p>Enter the following command to check the status of the PersistentVolumeClaim .</p> <pre>kubectl -n poc-efs-eks-fargate get pvc</pre> <p>For an example output, see the <a href="#">Additional information</a> section.</p>	Kubernetes user with granted permissions

Task	Description	Skills required
Validate that workload 1 can write to the file system.	<p>Enter the following command to validate that workload 1 is writing to /data/out1.txt .</p> <pre>kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -f /data/out1.txt</pre> <p>The results are similar to the following:</p> <pre>... Thu Sep  3 15:25:07 UTC 2023 - PoC APP 1 Thu Sep  3 15:25:12 UTC 2023 - PoC APP 1 Thu Sep  3 15:25:17 UTC 2023 - PoC APP 1 ...</pre>	Kubernetes user with granted permissions

Task	Description	Skills required
Validate that workload 2 can write to the file system.	<p>Enter the following command to validate that workload 2 is writing to /data/out 2.txt .</p> <pre>kubectl -n \$APP_NAME SPACE exec -ti poc-app2 -- tail -f /data/out 2.txt</pre> <p>The results are similar to the following:</p> <pre>... # Send AWS WAF logs to Splunk by using AWS Firewall Manager and Amazon Data Firehose

Created by Michael Friedenthal (AWS), Aman Kaur Gandhi (AWS), and JJ Johnson (AWS)

**Environment:** PoC or pilot

**Technologies:** Content delivery; Security, identity, compliance

**Workload:** All other workloads

**AWS services:** AWS Firewall Manager; Amazon Kinesis Data Firehose; AWS WAF

## Summary

Historically, there were two ways to move data into Splunk: a push or a pull architecture. A *pull architecture* offers delivery data guarantees through retries, but it requires dedicated resources in Splunk that poll data. Pull architectures usually are not real time because of the polling. A *push architecture* in typically has lower latency, is more scalable, and reduces operational complexity and costs. However, it doesn't guarantee delivery and typically requires agents.

Splunk integration with Amazon Data Firehose delivers real-time streaming data to Splunk through an HTTP event collector (HEC). This integration provides the advantages of both push and pull architectures—it guarantees data delivery through retries, is near real-time, and is low latency and low complexity. The HEC quickly and efficiently sends data over HTTP or HTTPS directly to Splunk. HECs are token-based, which eliminates the need to hardcode credentials in an application or in supporting files.

In an AWS Firewall Manager policy, you can configure logging for all of the AWS WAF web ACL traffic in all of your accounts, and you can then use a Firehose delivery stream to send that log data to Splunk for monitoring, visualization, and analysis. This solution provides the following benefits:

- Central management and logging for AWS WAF web ACL traffic in all of your accounts
- Splunk integration with a single AWS account
- Scalability
- Near real-time delivery of log data

- Cost optimization through the use of a serverless solution, so you don't have to pay for unused resources.

## Prerequisites and limitations

### Prerequisites

- An active AWS account that is part of an organization in AWS Organizations.
- You must have the following permissions to enable logging with Firehose:
  - `iam:CreateServiceLinkedRole`
  - `firehose:ListDeliveryStreams`
  - `wafv2:PutLoggingConfiguration`
- AWS WAF and its web ACLs must be configured. For instructions, see [Getting started with AWS WAF](#).
- AWS Firewall Manager must be setup. For instructions, see [AWS Firewall Manager prerequisites](#).
- The Firewall Manager security policies for AWS WAF must be configured. For instructions, see [Getting started with AWS Firewall Manager AWS WAF policies](#).
- Splunk must be setup with a public HTTP endpoint that can be reached by Firehose.

### Limitations

- The AWS accounts must be managed in a single organization in AWS Organizations.
- The web ACL must be in the same Region as the delivery stream. If you are capturing logs for Amazon CloudFront, create the Firehose delivery stream in the US East (N. Virginia) Region, `us-east-1`.
- The Splunk add-on for Firehose is available for paid Splunk Cloud deployments, distributed Splunk Enterprise deployments, and single-instance Splunk Enterprise deployments. This add-on is not supported for free trial Splunk Cloud deployments.

## Architecture

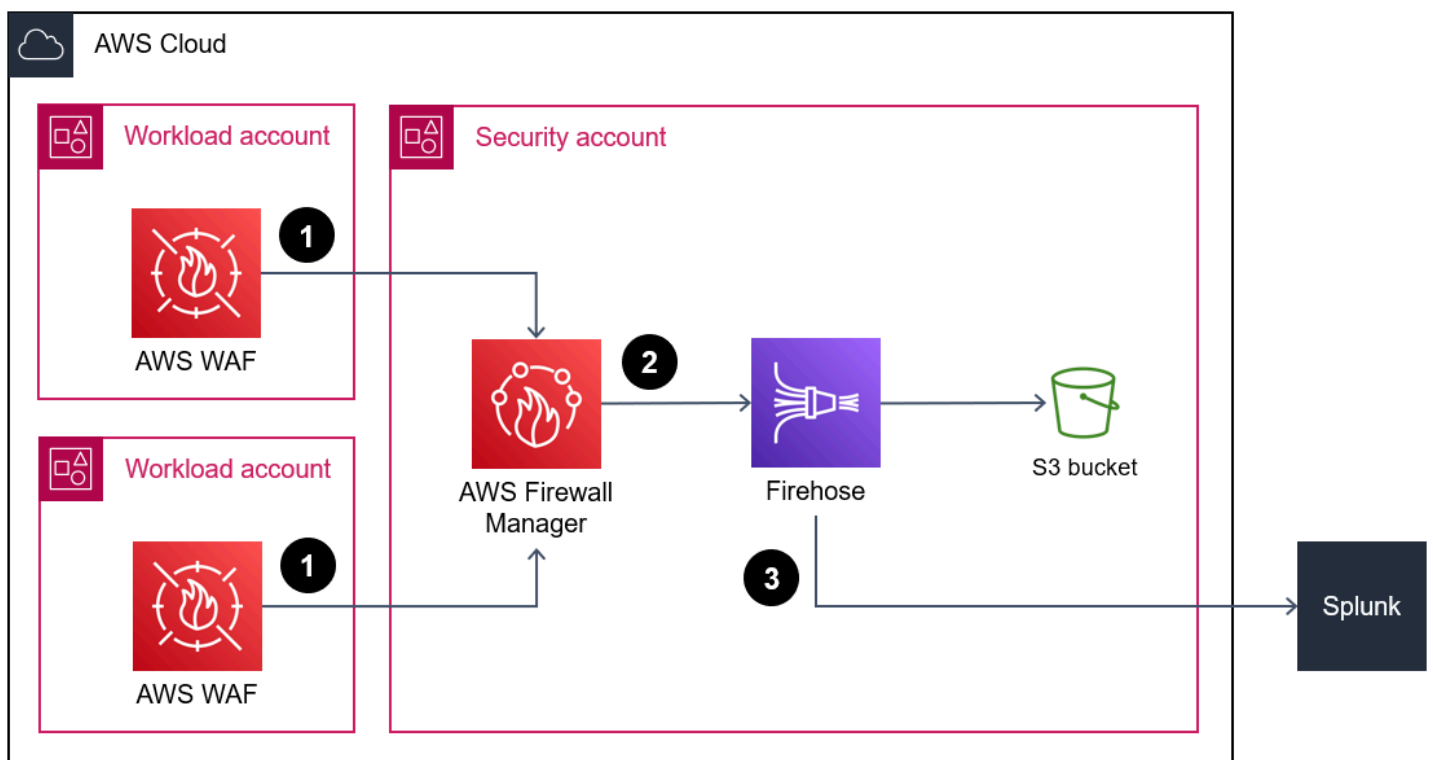

### Target technology stack

- Firewall Manager

- Firehose
- Amazon Simple Storage Service (Amazon S3)
- AWS WAF
- Splunk

## Target architecture

The following image shows how you can use Firewall Manager to centrally log all AWS WAF data and send it to Splunk through Firehose.

1. The AWS WAF web ACLs send firewall log data to Firewall Manager.
2. Firewall Manager sends the log data to Firehose.
3. The Firehose delivery stream forwards the log data to Splunk and to an S3 bucket. The S3 bucket acts as a backup in the event of an error with the Firehose delivery stream.

## Automation and scale

This solution is designed to scale and accommodate all AWS WAF web ACLs within the organization. You can configure all web ACLs to use the same Firehose instance. However, if you want to set up and use multiple Firehose instances, you can.

## Tools

### AWS services

- [AWS Firewall Manager](#) is a security management service that helps you to centrally configure and manage firewall rules across your accounts and applications in AWS Organizations.
- [Amazon Data Firehose](#) helps you deliver real-time [streaming data](#) to other AWS services, custom HTTP endpoints, and HTTP endpoints owned by supported third-party service providers, such as Splunk.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS WAF](#) is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

### Other tools

- [Splunk](#) helps you monitor, visualize, and analyze log data.

## Epics

### Configure Splunk

Task	Description	Skills required
Install the Splunk App for AWS.	<ol style="list-style-type: none"> <li>1. Sign in to your Splunk heavy forwarder. The default URL is <code>http://&lt;IP address&gt;:8000</code>.</li> <li>2. In the left navigation, next to <b>Apps</b>, choose the gear button.</li> <li>3. Choose <b>Browse more apps</b>.</li> </ol>	Security administrator, Splunk administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>4. Search for <b>AWS</b>.</li><li>5. For <b>Splunk App for AWS</b>, choose <b>Install</b>.</li><li>6. Enter your Splunk.com sign-in credentials, accept the terms and conditions, and then choose <b>Login and Install</b>.</li><li>7. Choose <b>Done</b>.</li></ol>	
Install the add-on for AWS WAF.	Repeat the previous instructions to install the <b>AWS Web Application Firewall Add-on</b> for Splunk.	Security administrator, Splunk administrator

Task	Description	Skills required
Install and configure the Splunk add-on for Firehose.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 1705">1. Install and configure the Splunk add-on for Firehose. As part of the installation and configuration, if necessary for your Splunk platform, you set up an HTTP Event Collector and prepare the infrastructure to send the log data to your indexers. See the instructions that correspond to your Splunk deployment:<ul data-bbox="630 856 1027 1285" style="list-style-type: none"><li data-bbox="630 856 1027 982">• <a href="#">Splunk Cloud deployment</a> (Splunk documentation)</li><li data-bbox="630 1012 1027 1138">• <a href="#">Distributed Splunk Enterprise deployment</a> (Splunk documentation)</li><li data-bbox="630 1167 1027 1285">• <a href="#">Single-instance Splunk Enterprise deployment</a> (Splunk documentation)</li></ul><p data-bbox="630 1339 1027 1705"><b>Important:</b> Stop this procedure after you have installed and configured the Splunk add-on. Do not proceed with the instructions for configuring Firehose to send data to the Splunk platform.</p></li><li data-bbox="592 1734 1027 1852">2. Make note of the HTTP event collector token and the HTTP endpoint. You</li></ol>	Security administrator, Splunk administrator

Task	Description	Skills required
	need this value later, when you configure the delivery stream.	

## Create the Firehose delivery stream

Task	Description	Skills required
Grant Firehose access to a Splunk destination.	Configure the access policy that permits Firehose to access a Splunk destination and back up the log data to an S3 bucket. For more information, see <a href="#">Grant Firehose access to a Splunk destination</a> .	Security administrator
Create a Firehose delivery stream.	In the same account where you manage the web ACLs for AWS WAF, create a delivery stream in Firehose. You are required to have an IAM role when creating a delivery stream. Firehose assumes that IAM role and gains access to the specified S3 bucket. For instructions, see <a href="#">Creating a delivery stream</a> . Note the following: <ul style="list-style-type: none"> <li>The delivery stream name must start with <code>aws-waf-logs-</code>.</li> <li>For the source, choose <b>Direct PUT</b>.</li> </ul>	Security administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>For <b>S3 backup mode</b>, choose <b>Backup all events</b>, and then choose an existing bucket or create a new one.</li> <li>For the destination, follow the instructions in <a href="#">Choose Splunk for your destination</a> in the Firehose documentation. For information about the values for Splunk endpoints and endpoint types, see <a href="#">Configure Amazon Data Firehose</a> in the Splunk documentation.</li> </ul> <p>Repeat this process for each token that you configured in the HTTP event collector.</p>	
Test the delivery stream.	Test the delivery stream to validate that it is properly configured. For instructions, see <a href="#">Test using Splunk as the destination</a> in the Firehose documentation.	Security administrator

### Configure Firewall Manager to log data

Task	Description	Skills required
Configure the Firewall Manager policies.	The Firewall Manager policies must be configured to enable logging and to forward logs to the correct Firehose	Security administrator

Task	Description	Skills required
	delivery stream. For more information and instructions, see <a href="#">Configuring logging for an AWS WAF policy</a> .

# Serve static content in an Amazon S3 bucket through a VPC by using Amazon CloudFront

Created by Angel Emmanuel Hernandez Cebrian

**Environment:** PoC or pilot

**Technologies:** Content delivery; Networking; Security, identity, compliance; Serverless; Web & mobile apps

**AWS services:** Amazon CloudFront; Elastic Load Balancing (ELB); AWS Lambda

## Summary

When you serve static content that is hosted on Amazon Web Services (AWS), the recommended approach is to use an Amazon Simple Storage Service (S3) bucket as the origin and use Amazon CloudFront to distribute the content. This solution has two primary benefits: the convenience of caching static content at edge locations, and the ability to define [web access control lists](#) (web ACLs) for the CloudFront distribution, which helps you secure requests to the content with minimal configuration and administrative overhead.

However, there is a common architectural limitation to the standard, recommended approach. In some environments, you want virtual firewall appliances deployed in a virtual private cloud (VPC) to inspect all content, including static content. The standard approach doesn't route traffic through the VPC for inspection. This pattern provides an alternative architectural solution. You still use a CloudFront distribution to serve static content in an S3 bucket, but the traffic is routed through the VPC by using an Application Load Balancer. An AWS Lambda function then retrieves and returns the content from the S3 bucket.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Static website content hosted in an S3 bucket.

### Limitations

- The resources in this pattern must be in a single AWS Region, but they can be provisioned in different AWS accounts.
- Limits apply to the maximum request and response size that the Lambda function can receive and send, respectively. For more information, see *Limits* in [Lambda functions as targets](#) (Elastic Load Balancing documentation).
- It's important to find a good balance between performance, scalability, security, and cost-effectiveness when using this approach. Despite the high scalability of Lambda, if the number of concurrent Lambda invocations exceeds the maximum quota, some requests are throttled. For more information, see Lambda quotas (Lambda documentation). You also need to consider pricing when using Lambda. To minimize Lambda invocations, make sure that you properly define the cache for the CloudFront distribution. For more information, see [Optimizing caching and availability](#) (CloudFront documentation).

## Architecture

### Target technology stack

- CloudFront
- Amazon Virtual Private Cloud (Amazon VPC)
- Application Load Balancer
- Lambda
- Amazon S3

### Target architecture

The following image shows the suggested architecture when you need to use CloudFront to serve static content from an S3 bucket through a VPC.

1. The client requests the URL of CloudFront distribution to get a particular website file in the S3 bucket.
2. CloudFront sends the request to AWS WAF. AWS WAF filters the request by using the web ACLs applied to the CloudFront distribution. If the request is determined to be valid, the flow continues. If the request is determined to be invalid, the client receives a 403 error.
3. CloudFront checks its internal cache. If there is a valid key matching the incoming request, the associated value is sent back to the client as a response. If not, the flow continues.
4. CloudFront forwards the request to the URL of the specified Application Load Balancer.
5. The Application Load Balancer has a listener associated with a target group based on a Lambda function. The Application Load Balancer invokes the Lambda function.
6. The Lambda function connects to the S3 bucket, perform a GetObject operation on it, and returns the content as a response.

## Automation and scale

To automate the deployment of static content using this approach, create CI/CD pipelines to update the Amazon S3 buckets that host websites.

The Lambda function scales automatically to handle the concurrent requests, within the quotas and limitations of the service. For more information, see [Lambda function scaling](#) and [Lambda quotas](#) (Lambda documentation). For the other AWS services and features, such as CloudFront and the Application Load Balancer, AWS scales these automatically.

## Tools

- [Amazon CloudFront](#) speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. In this pattern, you use an [Application Load Balancer](#) provisioned through Elastic Load Balancing to direct traffic to the Lambda function.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

## Epics

### Use CloudFront to serve static content from Amazon S3 through a VPC

Task	Description	Skills required
Create a VPC.	Create a VPC for hosting the resources deployed in this pattern, such as the Application Load Balancer and the Lambda function. For instructions, see <a href="#">Create a</a>	Cloud architect

Task	Description	Skills required
	<a href="#">VPC</a> (Amazon VPC documentation).	
Create an AWS WAF web ACL.	Create an AWS WAF web ACL. Later in this pattern, you apply this web ACL to the CloudFront distribution. For instructions, see <a href="#">Creating a web ACL</a> (AWS WAF documentation).	Cloud architect
Create the Lambda function.	Create the Lambda function that serves the static content hosted in the S3 bucket as a website. Use the code provided in the <a href="#">Additional information</a> section of this pattern. Customize the code to identify your target S3 bucket.	General AWS
Upload the Lambda function.	Enter the following command to upload the Lambda function code to a .zip file archive in Lambda. <pre data-bbox="597 1381 1026 1661">aws lambda update-function-code \ --function-name \ --zip-file fileb://lambda-alb-s3-website.zip</pre>	General AWS

Task	Description	Skills required
Create an Application Load Balancer.	Create an internet-facing Application Load Balancer that points to the Lambda function. For instructions, see <a href="#">Create a target group for the Lambda function</a> (Elastic Load Balancing documentation). For a high-availability configuration, create the Application Load Balancer and attach it to private subnets in different Availability Zones.	Cloud architect

Task	Description	Skills required
Create a CloudFront distribution.	<p>Create a CloudFront distribution that points to the Application Load Balancer you created.</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the CloudFront console at <a href="https://console.aws.amazon.com/cloudfront/v3/home">https://console.aws.amazon.com/cloudfront/v3/home</a>.</li><li>2. Choose <b>Create Distribution</b>.</li><li>3. On the first page of the <b>Create Distribution Wizard</b>, in the <b>Web</b> section, choose <b>Get Started</b>.</li><li>4. Specify settings for your distribution. For more information, see <a href="#">Values that you specify when you create or update a distribution</a>. Note the following:<ol style="list-style-type: none"><li>a. Set the Application Load Balancer as the origin.</li><li>b. In <b>Distribution settings</b>, choose existing web ACLs that you want to apply through AWS WAF. For more information, see <a href="#">AWS WAF web ACL</a>.</li></ol></li><li>5. Save your changes.</li></ol>	Cloud architect

Task	Description	Skills required
	6. After CloudFront creates your distribution, the value of the <b>Status</b> column for your distribution changes from <b>InProgress</b> to <b>Deployed</b> . If you chose to enable the distribution, it will be ready to process requests after the status switches to <b>Deployed</b> .

## Additional information

### Code

The following example Lambda function is written in Node.js. This Lambda function acts as a web server that performs a `GetObject` operation to an S3 bucket that contains the website resources.

```
/**
 * This is an AWS Lambda function created for demonstration purposes.
 * It retrieves static assets from a defined Amazon S3 bucket.
 * To make the content available through a URL, use an Application Load Balancer with a
 * Lambda integration.
 * Set the S3_BUCKET environment variable in the Lambda function definition.
 */

var AWS = require('aws-sdk');

exports.handler = function(event, context, callback) {

    var bucket = process.env.S3_BUCKET;
    var key = event.path.replace('/', '');

    if (key == '') {
        key = 'index.html';
    }

    // Fetch from S3
    var s3 = new AWS.S3();
    return s3.getObject({Bucket: bucket, Key: key},
        function(err, data) {

            if (err) {
                return err;
            }

            var isBase64Encoded = false;
            var encoding = 'utf8';

            if (data.ContentType.indexOf('image/') > -1) {
                isBase64Encoded = true;
                encoding = 'base64'
            }
        })
}
```

```
    var resp = {
      statusCode: 200,
      headers: {
        'Content-Type': data.ContentType,
      },
      body: new Buffer(data.Body).toString(encoding),
      isBase64Encoded: isBase64Encoded
    };

    callback(null, resp);
  }
);
};
```

# Create detailed cost and usage reports for AWS Glue jobs by using AWS Cost Explorer

Created by Parijat Bhide (AWS) and Aromal Raj Jayarajan (AWS)

**Environment:** Production

**Technologies:** Cost management; Analytics

**AWS services:** AWS Billing and Cost Management; AWS Glue

## Summary

This pattern shows how to track the usage costs of AWS Glue data integration jobs by configuring [user-defined cost allocation tags](#). You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for jobs across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level.

## Prerequisites and limitations

### Prerequisites

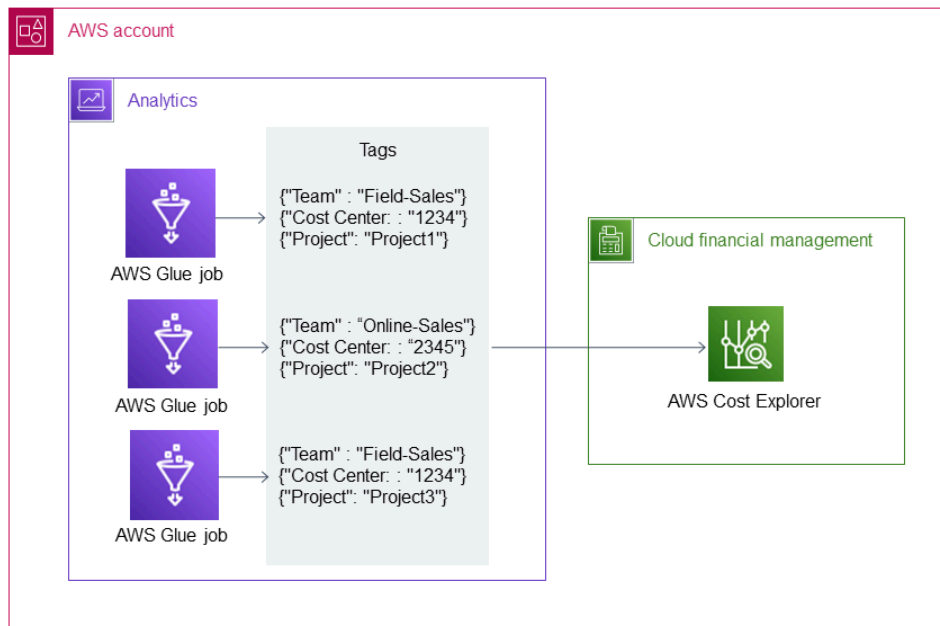

- An active AWS account
- One or more [AWS Glue jobs](#) that have user-defined tags activated

## Architecture

### Target technology stack

- AWS Glue
- AWS Cost Explorer

The following diagram shows how you can apply tags to track usage costs for AWS Glue jobs.

The diagram shows the following workflow:

1. A data engineer or AWS administrator creates user-defined cost allocation tags for the AWS Glue jobs.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.

## Tools

- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [AWS Cost Explorer](#) helps you view and analyze your AWS costs and usage.

# Epics

## Create and activate tags for your AWS Glue jobs

Task	Description	Skills required
Create user-defined cost allocation tags for your AWS Glue jobs.	<p><b>To add tags to an existing AWS Glue job</b></p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management console, and then open the <a href="#">AWS Glue console</a>.</li><li>2. In the left navigation pane, under <b>ETL</b>, choose <b>Jobs</b>.</li><li>3. In the <b>Your jobs</b> section, choose the name of the job that you're tagging.</li><li>4. Choose the <b>Job details</b> tab. Then, expand the <b>Advanced properties</b> section.</li><li>5. For <b>Tags</b>, choose <b>Add new tag</b>.</li><li>6. For <b>Key</b>, enter a name for your tag.</li><li>7. (Optional) For <b>Value</b>, enter a value that you want associated with the key.</li><li>8. (Optional) Repeat steps 5-7 for each tag that you want to create for the job.</li><li>9. Choose <b>Save</b>.</li></ol>	Data engineer

# Create detailed cost and usage reports for Amazon EMR clusters by using AWS Cost Explorer

Created by Parijat Bhide (AWS) and Aromal Raj Jayarajan (AWS)

**Environment:** Production

**Technologies:** Cost management; Analytics; Big data

**AWS services:** AWS Billing and Cost Management; Amazon EMR

## Summary

This pattern shows how to track the usage costs of Amazon EMR clusters by configuring [user-defined cost allocation tags](#). You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- One or more [EMR clusters](#) that have user-defined tags activated

## Architecture

### Target technology stack

- Amazon EMR
- AWS Cost Explorer

### Target architecture

The following diagram shows how you can apply tags to track usage costs for specific Amazon EMR clusters.

The diagram shows the following workflow:

1. A data engineer or AWS administrator creates user-defined cost allocation tags for the Amazon EMR clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.

## Tools

### Tools

- [Amazon EMR](#) is a managed cluster platform that simplifies running big data frameworks on AWS to process and analyze large amounts of data.
- [AWS Cost Explorer](#) helps you view and analyze your AWS costs and usage.

## Epics

### Create and activate tags for your Amazon EMR clusters

Task	Description	Skills required
Create user-defined cost allocation tags for your Amazon EMR clusters.	<p><b>To add tags to an existing Amazon EMR cluster</b></p> <p>Follow the instructions in <a href="#">Adding tags to an existing cluster</a> in the <i>Amazon EMR Management Guide</i>.</p> <p><b>To add tags to a new Amazon EMR cluster</b></p> <p>Follow the instructions in <a href="#">Add tags to a new cluster</a> in the <i>Amazon EMR Management Guide</i>.</p> <p>For more information about how to set up an Amazon EMR cluster, see <a href="#">Plan and configure clusters</a> in the <i>Amazon EMR Management Guide</i>.</p>	Data engineer
Activate the user-defined cost allocation tags.	Follow the instructions in <a href="#">Activating user-defined cost allocation tags</a> in the <i>AWS Billing User Guide</i> .	AWS administrator

# Automate data ingestion from AWS Data Exchange into Amazon S3

*Created by Adnan Alvee (AWS) and Manikanta Gona (AWS)*

**Technologies:** Analytics;  
Data lakes

**Environment:** Production

**AWS services:** Amazon S3;  
Amazon CloudWatch; AWS  
Lambda; Amazon SNS

## Summary

This pattern provides an AWS CloudFormation template that enables you to automatically ingest data from AWS Data Exchange into your data lake in Amazon Simple Storage Service (Amazon S3).

AWS Data Exchange is a service that makes it easy to securely exchange file-based data sets in the AWS Cloud. AWS Data Exchange data sets are subscription-based. As a subscriber, you can also access data set revisions as providers publish new data.

The AWS CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any updates to the data set you have subscribed to. If there is an update, CloudWatch initiates a Lambda function, which copies the data over to the S3 bucket you specify. When the data has been copied successfully, Lambda sends you an Amazon Simple Notification Service (Amazon SNS) notification.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Subscription to a data set in AWS Data Exchange

### Limitations

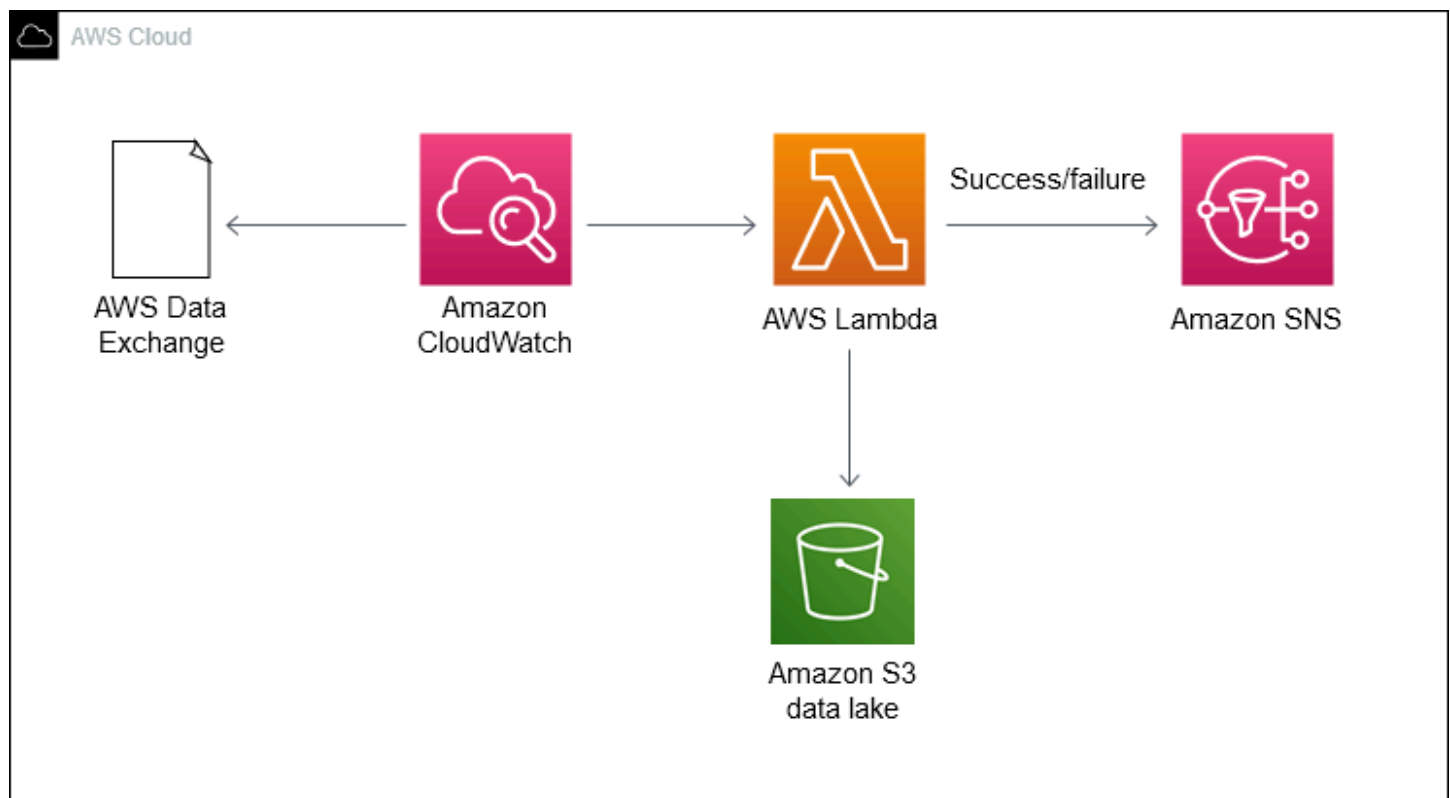

- The AWS CloudFormation template must be deployed separately for each subscribed data set in AWS Data Exchange.

## Architecture

### Target technology stack

- AWS Lambda
- Amazon S3
- AWS Data Exchange
- Amazon CloudWatch
- Amazon SNS

### Target architecture

### Automation and scale

You can use the AWS CloudFormation template multiple times for the data sets you want to ingest into the data lake.

## Tools

- [AWS Data Exchange](#) – A service that makes it easy for AWS customers to securely exchange file-based data sets in the AWS Cloud. As a subscriber, you can find and subscribe to hundreds of products from qualified data providers. Then, you can quickly download the data set or copy it to Amazon S3 for use across a variety of AWS analytics and machine learning services. Anyone with an AWS account can be an AWS Data Exchange subscriber.
- [AWS Lambda](#) – A compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code isn't running. With AWS Lambda, you can run code for virtually any type of application or backend service with zero administration. AWS Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging.
- [Amazon S3](#) – Storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- [Amazon CloudWatch Events](#) – Delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using **cron** or **rate** expressions.
- [Amazon SNS](#) – A web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, AWS Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

## Epics

### Subscribe to a data set

Task	Description	Skills required
Subscribe to a data set.	In the AWS Data Exchange console, subscribe to a dataset. For instructions, see the link in the "Related resources" section.	General AWS
Note the data set attributes.	Note the AWS Region, ID, and revision ID for the data set. You will need this for the AWS CloudFormation template in the next step.	General AWS

### Deploy the AWS CloudFormation template

Task	Description	Skills required
Create an S3 bucket and folder.	If you already have a data lake in Amazon S3, create a folder to store the data to ingest from AWS Data Exchange. If you are deploying the template for testing purposes, create a new S3 bucket, and note the bucket name and folder prefix for the next step.	General AWS
Deploy the AWS CloudFormation template.	Deploy the AWS CloudFormation template that's provided as an attachment to this pattern. Configure	General AWS

Task	Description	Skills required
	<p>the following parameters to correspond to your AWS account, data set, and S3 bucket settings: Dataset AWS Region, Dataset ID, Revision ID, S3 Bucket Name (for example, DOC-EXAMPLE-BUCKET), Folder Prefix (for example, myfolder/), and Email for SNS Notification. You can set the Dataset Name parameter to any name. When you deploy the template, it runs a Lambda function to automatically ingest the first set of data available in the data set. Subsequent ingestion then takes place automatically, as new data arrives in the data set.</p>

# Build a data pipeline to ingest, transform, and analyze Google Analytics data using the AWS DataOps Development Kit

Created by Anton Kukushkin (AWS) and Rudy Puig (AWS)

<b>Code repository:</b> <a href="#">AWS DDK Examples - Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Data lakes; Analytics; DevOps; Infrastructure
<b>Workload:</b> Open-source	<b>AWS services:</b> Amazon AppFlow; Amazon Athena; AWS CDK; AWS Lambda; Amazon S3	

## Summary

This pattern describes how to build a data pipeline to ingest, transform, and analyze Google Analytics data by using the AWS DataOps Development Kit (DDK) and other AWS services. The AWS DDK is an open-source development framework that helps you build data workflows and modern data architecture on AWS. One of the main objectives of the AWS DDK is to save you the time and effort that's typically devoted to labor-intensive data pipeline tasks, such as orchestrating pipelines, building infrastructure, and creating the DevOps behind that infrastructure. You can offload these labor-intensive tasks to AWS DDK so that you can focus on writing code and other high-value activities.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon AppFlow connector for Google Analytics, [configured](#)
- [Python](#) and [pip](#) (Python's package manager)

- Git, installed and [configured](#)
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- AWS Cloud Development Kit (AWS CDK), [installed](#)

### Product versions

- Python 3.7 or later
- pip 9.0.3 or later

## Architecture

### Technology stack

- Amazon AppFlow
- Amazon Athena
- Amazon CloudWatch
- Amazon EventBridge
- Amazon Simple Storage Service (Amazon S3)
- Amazon Simple Queue Service (Amazon SQS)
- AWS DataOps Development Kit (DDK)
- AWS Lambda

### Target architecture

The following diagram shows the event-driven process that ingests, transforms, and analyzes Google Analytics data.

The diagram shows the following workflow:

1. An Amazon CloudWatch scheduled event rule invokes Amazon AppFlow.
2. Amazon AppFlow ingests Google Analytics data into an S3 bucket.
3. After the data is ingested by the S3 bucket, event notifications in EventBridge are generated, captured by a CloudWatch Events rule, and then put into an Amazon SQS queue.
4. A Lambda function consumes events from the Amazon SQS queue, reads the respective S3 objects, transforms the objects to Apache Parquet format, writes the transformed objects to the S3 bucket, and then creates or updates the AWS Glue Data Catalog table definition.
5. An Athena query runs against the table.

## Tools

### AWS tools

- [Amazon AppFlow](#) is a fully-managed integration service that enables you to securely exchange data between software as a service (SaaS) applications.
- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Simple Queue Service \(Amazon SQS\)](#) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Cloud Development Kit \(CDK\)](#) is a framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- [AWS DataOps Development Kit \(DDK\)](#) is an open-source development framework to help you build data workflows and modern data architecture on AWS.

## Code

The code for this pattern is available in the GitHub [AWS DataOps Development Kit \(DDK\)](#) and [Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit](#) repositories.

## Epics

### Prepare the environment

Task	Description	Skills required
Clone the source code.	To clone the source code, run the following command:  <pre>git clone https://github.com/aws-samples/aws-ddk-examples.git</pre>	DevOps engineer
Create a virtual environment.	Navigate to the source code directory, and then run the following command to create a virtual environment:	DevOps engineer

Task	Description	Skills required
	<pre>cd google-analytics- data-using-appflow/ python &amp;&amp; python3 -m venv .venv</pre>	
Install the dependencies.	<p>To activate the virtual environment and install the dependencies, run the following command:</p> <pre>source .venv/bin/ activate &amp;&amp; pip install -r requirements.txt</pre>	DevOps engineer

## Deploy the application that uses your data pipeline

Task	Description	Skills required
Bootstrap the environment.	<ol style="list-style-type: none"> <li>1. Confirm that the AWS CLI is set up with valid credentials for your AWS account. For more information, see <a href="#">Using named profiles</a> in the AWS CLI documentation.</li> <li>2. Run the <code>cdk bootstrap --profile [AWS_PROFILE]</code> command.</li> </ol>	DevOps engineer
Deploy the data.	To deploy the data pipeline, run the <code>cdk deploy --profile [AWS_PROFILE]</code> command.	DevOps engineer

## Test the deployment

Task	Description	Skills required
Validate stack status.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS CloudFormation console</a>.</li><li>2. On the <b>Stacks</b> page, confirm that the status of the stack <code>DdkAppflowAthenaStack</code> is <code>CREATE_COMPLETE</code>.</li></ol>	DevOps engineer

## Troubleshooting

Issue	Solution
Deployment fails during the creation of an <code>AWS::AppFlow::Flow</code> resource and you receive the following error: <code>Connector Profile with name ga-connection does not exist</code>	<p>Confirm that you created an Amazon AppFlow connector for Google Analytics and named it <code>ga-connection</code>.</p> <p>For instructions, see <a href="#">Google Analytics</a> in the Amazon AppFlow documentation.</p>

## Related resources

- [AWS DataOps Development Kit \(DDK\)](#) (GitHub)
- [AWS DDK Examples](#) (GitHub)

## Additional information

AWS DDK data pipelines are composed of one or many stages. In the following code examples, you use `AppFlowIngestionStage` to ingest data from Google Analytics, `SqsToLambdaStage` to handle data transformation, and `AthenaSQLStage` to run the Athena query.

First, the data transformation and ingestion stages are created, as the following code example shows:

```
appflow_stage = AppFlowIngestionStage(
    self,
    id="appflow-stage",
    flow_name=flow.flow_name,
)
sqs_lambda_stage = SqsToLambdaStage(
    self,
    id="lambda-stage",
    lambda_function_props={
        "code": Code.from_asset("./ddk_app/lambda_handlers"),
        "handler": "handler.lambda_handler",
        "layers": [
            LayerVersion.from_layer_version_arn(
                self,
                id="layer",
                layer_version_arn=f"arn:aws:lambda:
{self.region}:336392948345:layer:AWSDataWrangler-Python39:1",
            )
        ],
        "runtime": Runtime.PYTHON_3_9,
    },
)
# Grant lambda function S3 read & write permissions
bucket.grant_read_write(sqs_lambda_stage.function)
# Grant Glue database & table permissions
sqs_lambda_stage.function.add_to_role_policy(
    self._get_glue_db_iam_policy(database_name=database.database_name)
)
athena_stage = AthenaSQLStage(
    self,
    id="athena-sql",
    query_string=[
        (
            "SELECT year, month, day, device, count(user_count) as cnt "
            f"FROM {database.database_name}.ga_sample "
            "GROUP BY year, month, day, device "
            "ORDER BY cnt DESC "
            "LIMIT 10; "
        )
    ],
)
```

```

        output_location=Location(
            bucket_name=bucket.bucket_name, object_key="query-results/"
        ),
        additional_role_policy_statements=[
            self._get_glue_db_iam_policy(database_name=database.database_name)
        ],
    )
)

```

Next, the `DataPipeline` construct is used to "wire" the stages together by using `EventBridge` rules, as the following code example shows:

```

(
    DataPipeline(self, id="ingestion-pipeline")
        .add_stage(
            stage=appflow_stage,
            override_rule=Rule(
                self,
                "schedule-rule",
                schedule=Schedule.rate(Duration.hours(1)),
                targets=appflow_stage.targets,
            ),
        )
        .add_stage(
            stage=sqs_lambda_stage,
            # By default, AppFlowIngestionStage stage emits an event after the flow
            # run finishes successfully
            # Override rule below changes that behavior to call the the stage when
            # data lands in the bucket instead
            override_rule=Rule(
                self,
                "s3-object-created-rule",
                event_pattern=EventPattern(
                    source=["aws.s3"],
                    detail={
                        "bucket": {"name": [bucket.bucket_name]},
                        "object": {"key": [{"prefix": "ga-data"}]},
                    },
                    detail_type=["Object Created"],
                ),
                targets=sqs_lambda_stage.targets,
            ),
        )
        .add_stage(stage=athena_stage)
)

```

```
)
```

For more code examples, see the GitHub [Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit](#) repository.

# Configure cross-account access to a shared AWS Glue Data Catalog using Amazon Athena

Created by Denis Avdonin (AWS)

**Environment:** Production

**Technologies:** Data lakes;  
Analytics; Big data

**Workload:** All other  
workloads

**AWS services:** Amazon  
Athena; AWS Glue

## Summary

This pattern provides step-by-step instructions, including AWS Identity and Access Management (IAM) policy samples, to configure cross-account sharing of a dataset stored in an Amazon Simple Storage Service (Amazon S3) bucket by using the AWS Glue Data Catalog. You can store the dataset in an S3 bucket. The metadata is collected by an AWS Glue crawler and put into the AWS Glue Data Catalog. The S3 bucket and the AWS Glue Data Catalog reside in an AWS account referred to as the *data account*. You can provide access to IAM principals in another AWS account referred to as the *consumer account*. Users can query the data in the consumer account by using the Amazon Athena serverless query engine.

## Prerequisites and limitations

### Prerequisites

- Two active [AWS accounts](#)
- An [S3 bucket](#) in one of the AWS accounts
- [Athena engine version 2](#)
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#) (or [AWS CloudShell](#) for running AWS CLI commands)

### Product versions

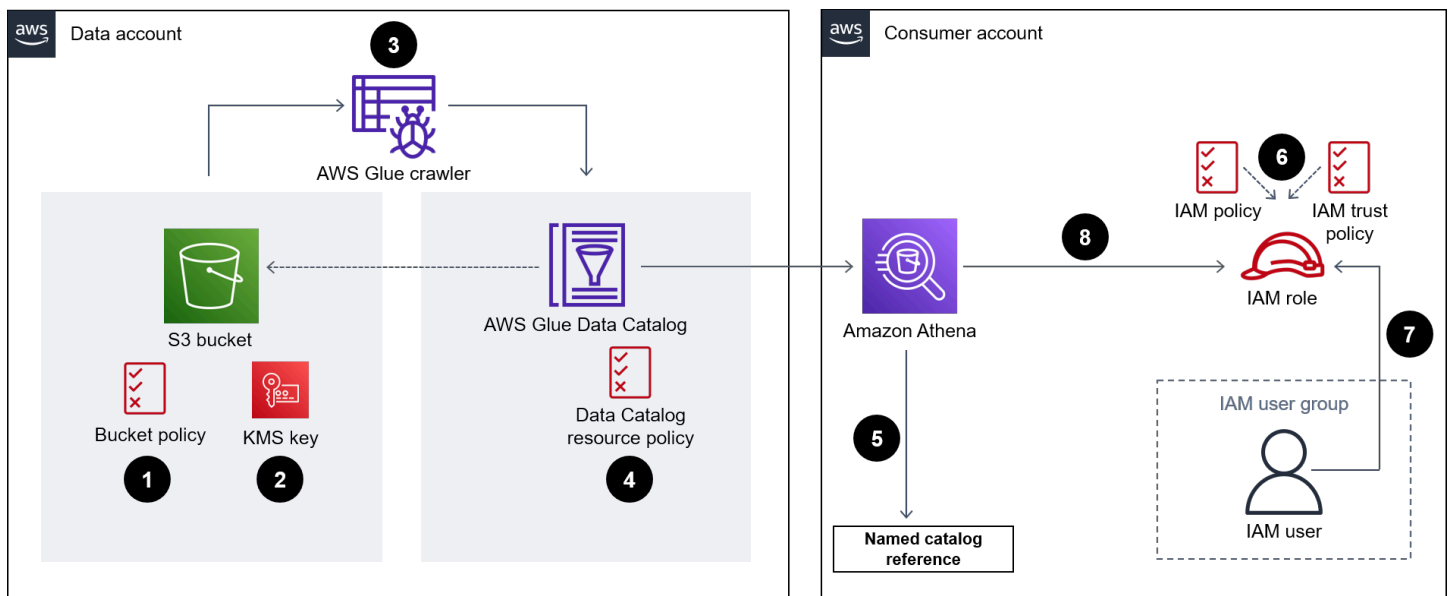

This pattern works with [Athena engine version 2](#) and [Athena engine version 3](#) only. We recommend that you upgrade to Athena engine version 3. If you can't upgrade from Athena engine version 1 to Athena engine version 3, then follow the approach from [Cross-account AWS Glue Data Catalog access with Amazon Athena](#) in the AWS Big Data Blog.

## Architecture

### Target technology stack

- Amazon Athena
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue
- AWS Identity and Access Management (IAM)
- AWS Key Management Service (AWS KMS)

The following diagram shows an architecture that uses IAM permissions to share data in an S3 bucket in one AWS account (data account) with another AWS account (consumer account) through the AWS Glue Data Catalog.

The diagram shows the following workflow:

1. The S3 bucket policy in the data account grants permissions to an IAM role in the consumer account and to the AWS Glue crawler service role in the data account.

2. The AWS KMS key policy in the data account grants permissions to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.
3. The AWS Glue crawler in the data account discovers the schema of the data that's stored in the S3 bucket.
4. The resource policy of the AWS Glue Data Catalog in the data account grants access to the IAM role in the consumer account.
5. A user creates a named catalog reference in the consumer account by using an AWS CLI command.
6. An IAM policy grants an IAM role in the consumer account access to resources in the data account. The IAM role's trust policy allows users in the consumer account to assume the IAM role.
7. A user in the consumer account assumes the IAM role and accesses objects in the data catalog by using SQL queries.
8. The Athena serverless engine runs the SQL queries.

**Note:** [IAM best practices](#) recommend that you grant permissions to an IAM role and use [identity federation](#).

## Tools

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to protect your data.

## Set up permissions in the data account

Task	Description	Skills required
Grant access to data in the S3 bucket.	<p><a href="#">Create an S3 bucket policy</a> based on the following template and assign the policy to the bucket where the data is stored.</p> <pre>{   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Principa 1": {         "AWS": [           "arn:aws:iam::&lt;con sumer account id&gt;:role/ &lt;role name&gt;",           "arn:aws:iam::&lt;dat a account id&gt;:role/ service-role/AWSGl ueServiceRole-data- bucket-crawler"         ]       },       "Action":       "s3:GetObject",       "Resource":       "arn:aws:s3:::data- bucket/*"     }   ] }</pre>	Cloud administrator

Task	Description	Skills required
	<pre>       "Effect":         "Allow",       "Principal": {         "AWS": [           "arn:aws:iam::&lt;consumer account id&gt;:role/             &lt;role name&gt;",           "arn:aws:iam::&lt;data account id&gt;:role/             service-role/AWSGlueServiceRole-data-             bucket-crawler"         ]       },       "Action":         "s3:ListBucket",       "Resource":         "arn:aws:s3:::data-         bucket"     ]   } </pre> <p>The bucket policy grants permissions to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.</p>	

Task	Description	Skills required
(If required) Grant access to the data encryption key.	<p>If the S3 bucket is encrypted by an AWS KMS key, grant <code>kms:Decrypt</code> permission on the key to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.</p> <p>Update the <a href="#">key policy</a> with the following statement:</p> <pre data-bbox="594 716 1027 1623">{   "Effect": "Allow",   "Principal": {     "AWS": [       "arn:aws:iam::&lt;consumer account id&gt;:role/&lt;role name&gt;",       "arn:aws:iam::&lt;data account id&gt;:role/service-role/AWSGlueServiceRole-data-bucket-crawler"     ]   },   "Action": "kms:Decrypt",   "Resource":     "arn:aws:kms:&lt;region&gt;:&lt;data account id&gt;:key/&lt;key id&gt;" }</pre>	Cloud administrator

Task	Description	Skills required
Grant the crawler access to the data.	<p>Attach the following IAM policy to the crawler's service role:</p> <pre data-bbox="594 394 1026 1390">{   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Action":       "s3:GetObject",       "Resource":       "arn:aws:s3:::data-       bucket/*"     },     {       "Effect":       "Allow",       "Action":       "s3:ListBucket",       "Resource":       "arn:aws:s3:::data-       bucket"     }   ] }</pre>	Cloud administrator

Task	Description	Skills required
<p>(If required) Grant the crawler access to the data encryption key.</p>	<p>If the S3 bucket is encrypted by an AWS KMS key, grant <code>kms:Decrypt</code> permission on the key to the crawler's service role by attaching the following policy to it:</p> <pre data-bbox="597 537 1026 936">{   "Effect": "Allow",   "Action": "kms:Decrypt",   "Resource":     "arn:aws:kms:&lt;region&gt;:&lt;data account id&gt;:key/&lt;key id&gt;" }</pre>	<p>Cloud administrator</p>

Task	Description	Skills required
<p>Grant the IAM role in the consumer account and the crawler access to the data catalog.</p>	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">AWS Glue console</a>.</li><li>2. In the navigation pane, under <b>Data Catalog</b>, choose <b>Settings</b>.</li><li>3. In the <b>Permissions</b> section, add the following statement, and then choose <b>Save</b>.</li></ol> <pre data-bbox="592 835 1027 1833">{   "Version" :   "2012-10-17",   "Statement" : [     {       "Effect" :       "Allow",       "Principal" : {         "AWS" :         [           "arn:aws:iam::&lt;consumer account id&gt;:role/           &lt;role name&gt;",           "arn:aws:iam::&lt;data account id&gt;:role/           service-role/AWSGlueServiceRole-data-           bucket-crawler"         ]       },       "Action" :       "glue:*",</pre>	Cloud administrator

Task	Description	Skills required
	<pre data-bbox="609 212 1015 940"> "Resource " : [   "arn:aws:glue:&lt;reg ion&gt;:&lt;data account id&gt;:catalog",   "arn:aws:glue:&lt;reg ion&gt;:&lt;data account id&gt;:database/*",   "arn:aws:glue:&lt;reg ion&gt;:&lt;data account id&gt;:table/*" ] } ] } </pre> <p data-bbox="591 982 1015 1444">This policy allows all AWS Glue actions on all databases and tables in the data account. You can customize the policy to grant only required permissions to the consumer principals. For example, you can provide read-only access to specific tables or views in a database.</p>	

### Access data from the consumer account

Task	Description	Skills required
Create a named reference for the data catalog.	To create a named data catalog reference, use <a href="#">CloudShell</a> or a locally	Cloud administrator

Task	Description	Skills required
	<p>installed AWS CLI to run the following command:</p> <pre data-bbox="594 327 1029 611">aws athena create-data-catalog --name &lt;shared catalog name&gt; --type GLUE --parameters catalog-id=&lt;data account id&gt;</pre>	

Task	Description	Skills required
Grant the IAM role in the consumer account access to the data.	<p>Attach the following policy to the IAM role in the consumer account to grant the role cross-account access to the data:</p> <pre data-bbox="594 489 1027 1814"> {   "Version":     "2012-10-17",   "Statement": [     {       "Effect":         "Allow",       "Action":         "s3:GetObject",       "Resource":         "arn:aws:s3:::data-bucket/*"     },     {       "Effect":         "Allow",       "Action":         "s3:ListBucket",       "Resource":         "arn:aws:s3:::data-bucket"     },     {       "Effect":         "Allow",       "Action":         "glue:*",       "Resource":         [           "arn:aws:glue:&lt;region&gt;:&lt;data account id&gt;:catalog", </pre>	Cloud administrator

Task	Description	Skills required
	<pre data-bbox="609 247 1015 703"> "arn:aws:glue:&lt;reg ion&gt;:&lt;data account id&gt;:database/*",  "arn:aws:glue:&lt;reg ion&gt;:&lt;data account id&gt;:table/*"     ]   } ] } </pre> <p data-bbox="592 741 1015 919">Next, use the following template to specify what users can accept the IAM role in its trust policy:</p> <pre data-bbox="609 961 1015 1753"> {   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Principa l": {         "AWS":         "arn:aws:iam::&lt;con sumer account id&gt;:user/ &lt;IAM user&gt;"       },       "Action":       "sts:AssumeRole"     }   ] } </pre> <p data-bbox="592 1791 1015 1873">Finally, grant user permissions to assume the IAM role by</p>	

Task	Description	Skills required
<p>(If required) Grant the IAM role in the consumer account access to the data encryption key.</p>	<p>attaching the same policy to the user group they belong to.</p> <p>If the S3 bucket is encrypted by an AWS KMS key, grant <code>kms:Decrypt</code> permission on the key to the IAM role in the consumer account by attaching the following policy to it:</p> <pre data-bbox="594 747 1029 1142"> {   "Effect": "Allow",   "Action": "kms:Decrypt",   "Resource":     "arn:aws:kms:&lt;region&gt;:&lt;data account id&gt;:key/&lt;key id&gt;" }</pre>	<p>Cloud administrator</p>
<p>Switch to the IAM role in the consumer account to access data.</p>	<p>As a data consumer, <a href="#">switch to the IAM role</a> to access data in the data account.</p>	<p>Data consumer</p>

Task	Description	Skills required
Access the data.	<p>Query data using Athena. For example, open the Athena query editor and run the following query:</p> <pre data-bbox="594 443 1027 640">SELECT *   FROM &lt;shared catalog name&gt;.&lt;database name&gt;.&lt;table name&gt;</pre> <p>Instead of using a named catalog reference, you can also refer to the catalog by its Amazon Resource Name (ARN).</p> <p><b>Note:</b> If you use a dynamic catalog reference in a query or view, surround the reference with escaped double quotation marks (\"). For example:</p> <pre data-bbox="594 1262 1027 1577">SELECT *   FROM \"glue:ar n:aws:glue:&lt;region &gt;:&lt;data account id&gt;:catalog\".&lt;dat abase name&gt;.&lt;table name&gt;</pre> <p>For more information, see <a href="#">Cross-account access to AWS Glue data catalogs</a> in the Amazon Athena User Guide.</p>	Data consumer

## Related resources

- [Cross-account access to AWS Glue data catalogs](#) (Athena documentation)
- [\(AWS CLI\) create-data-catalog](#) (AWS CLI Command Reference)
- [Cross-account AWS Glue Data Catalog access with Amazon Athena](#) (AWS Big Data Blog)
- [Security best practices in IAM](#) (IAM documentation)

## Additional information

### Using Lake Formation as an alternative for cross-account sharing

You can also use AWS Lake Formation to share access to AWS Glue catalog objects across accounts. Lake Formation provides fine-grained access control at the column and row level, tag-based access control, governed tables for ACID transactions, and other functionality. Although Lake Formation is well-integrated with Athena, it does require additional configuration compared to this pattern's IAM-only approach. We recommend that you consider the decision to use Lake Formation or IAM-only access controls within the wider context of your overall solution architecture. Considerations include what other services are involved and how they integrate with both approaches.

# Deploy and manage a serverless data lake on the AWS Cloud by using infrastructure as code

Created by Kirankumar Chandrashekar (AWS) and Abdel Jaidi (AWS)

**Environment:** Production

**Technologies:** Data lakes;  
Analytics; Serverless; DevOps

**Workload:** All other workloads

**AWS services:** Amazon S3; Amazon SQS; AWS CloudFormation; AWS Glue; Amazon CloudWatch; AWS Lambda; AWS Step Functions; Amazon DynamoDB

## Summary

This pattern describes how to use [serverless computing](#) and [infrastructure as code](#) (IaC) to implement and administer a data lake on the Amazon Web Services (AWS) Cloud. This pattern is based on the [serverless data lake framework \(SDLF\)](#) workshop developed by AWS.

SDLF is a collection of reusable resources that accelerate the delivery of enterprise data lakes on the AWS Cloud and helps with faster deployment to production. It is used to implement the foundational structure of a data lake by following best practices.

SDLF implements a continuous integration / continuous deployment (CI/CD) process throughout the code and infrastructure deployment by using AWS services such as AWS CodePipeline, AWS CodeBuild, and AWS CodeCommit.

This pattern uses multiple AWS serverless services to simplify data lake management. These include Amazon Simple Storage Service (Amazon S3) and Amazon DynamoDB for storage, AWS Lambda and AWS Glue for computing, and Amazon CloudWatch Events, Amazon Simple Queue Service (Amazon SQS), and AWS Step Functions for orchestration.

AWS CloudFormation and AWS code services act as the IaC layer to provide reproducible and fast deployments with easy operations and administration.

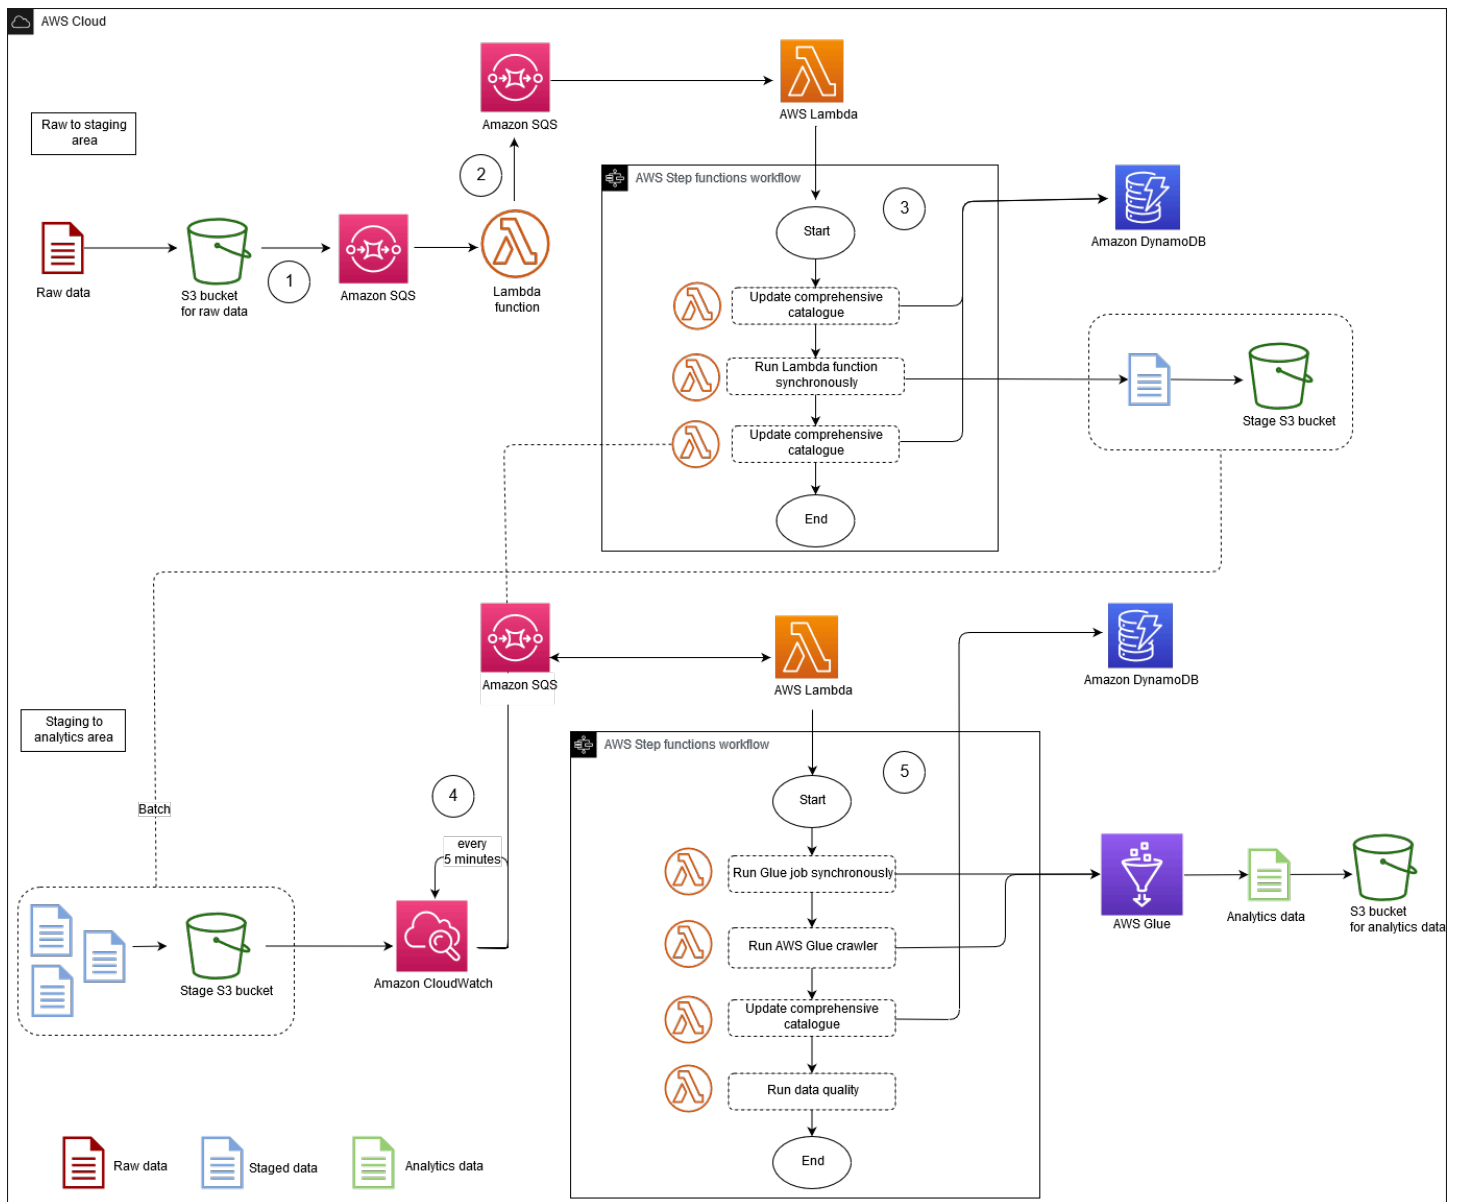

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- [AWS Command Line Interface \(AWS CLI\)](#), installed and configured.
- A Git client, installed and configured.
- The [SDLF workshop](#), open in a web browser window and ready to use.

### Architecture

The architecture diagram illustrates an event-driven process with the following steps.

1. After a file is added to the raw data S3 bucket, an Amazon S3 event notification is placed in an SQS queue. Each notification is delivered as a JSON file, which contains metadata such as the S3 bucket name, object key, or timestamp.
2. This notification is consumed by a Lambda function that routes the event to the correct extraction, transformation, and loading (ETL) process based on the metadata. The Lambda function can also use contextual configurations stored in an Amazon DynamoDB table. This step enables decoupling and scaling to multiple applications in the data lake.
3. The event is routed to the first Lambda function in the ETL process, which transforms and moves data from the raw data area to the staging area for the data lake. The first step is to update the comprehensive catalogue. This is a DynamoDB table that contains all the file metadata of the data

lake. Each row in this table holds operational metadata about a single object stored in Amazon S3. A synchronous call is made to a Lambda function that performs a light transformation, which is a computationally inexpensive operation (such as converting a file from one format to another), on the S3 object. Because a new object has been added to the staging S3 bucket, the comprehensive catalog is updated and a message is sent to the SQS queue waiting for the next phase in the ETL.

4. A CloudWatch Events rule triggers a Lambda function every 5 minutes. This function checks if messages were delivered to the SQS queue from the previous ETL phase. If a message was delivered, the Lambda function begins the second function from [AWS Step Functions](#) in the ETL process.
5. A heavy transformation is then applied on a batch of files. This heavy transformation is a computationally expensive operation, such as a synchronous call to an AWS Glue job, AWS Fargate task, Amazon EMR step, or Amazon SageMaker notebook. Table metadata is extracted from the output files by using an AWS Glue crawler, which updates the AWS Glue catalog. File metadata is also added to the comprehensive catalog table in DynamoDB. Finally, a data quality step leveraging [Deequ](#) is also run.

## Technology stack

- Amazon CloudWatch Events
- AWS CloudFormation
- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- Amazon DynamoDB
- AWS Glue
- AWS Lambda
- Amazon S3
- Amazon SQS
- AWS Step Functions

## Tools

- [Amazon CloudWatch Events](#) – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [AWS CloudFormation](#) – CloudFormation helps create and provision AWS infrastructure deployments predictably and repeatedly.
- [AWS CodeBuild](#) – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) – CodeCommit is a version control service hosted by AWS that you can use to privately store and manage assets (such as source code and binary files).
- [AWS CodePipeline](#) – CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software changes continuously.
- [Amazon DynamoDB](#) – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- [AWS Glue](#) – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics.
- [AWS Lambda](#) – Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [AWS Step Functions](#) – AWS Step Functions is a serverless function orchestrator that makes it easy to sequence AWS Lambda functions and multiple AWS services into business-critical applications.
- [Amazon SQS](#) – Amazon Simple Queue Service (Amazon SQS) is a fully managed message queuing service that helps you decouple and scale microservices, distributed systems, and serverless applications.
- [Deequ](#) – Deequ is a tool that helps you compute data quality metrics for large datasets, define and verify data quality constraints, and stay informed about changes in the data distribution.

### Code repository

The source code and resources for the SDLF are available in the [AWS Labs GitHub repository](#).

## Epics

### Set up the CI/CD pipeline to provision IaC

Task	Description	Skills required
Set up the CI/CD pipeline to manage IaC for the data lake.	Sign in to the AWS Management Console and follow the steps from the <a href="#">Initial setup</a> section of the SDLF workshop. This creates the initial CI/CD resources , such as CodeCommit repositories, CodeBuild environments, and CodePipeline pipelines that provision and manage IaC for the data lake.	DevOps engineer

### Version-control the IaC

Task	Description	Skills required
Clone the CodeCommit repository on your local machine.	Follow the steps from the <a href="#">Deploying the foundations</a> section of the SDLF workshop. This helps you clone the Git repository that hosts IaC into your local environment.  For more information, see <a href="#">Connecting to CodeCommit repositories</a> from the CodeCommit documentation.	DevOps engineer

Task	Description	Skills required
Modify the CloudFormation templates.	<p>Use your local workstation and a code editor to modify the CloudFormation templates according to your use cases or requirements. Commit them to the locally cloned Git repository.</p> <p>For more information, see <a href="#">Working with AWS CloudFormation templates</a> from the AWS CloudFormation documentation.</p>	DevOps engineer
Push the changes to the CodeCommit repository.	<p>Your infrastructure code is now under version control and modifications to your code base are tracked. When you push a change to the CodeCommit repository, CodePipeline automatically applies it to your infrastructure and delivers it to CodeBuild.</p> <p><b>Important:</b> If you use the AWS SAM CLI in CodeBuild, run the <code>aws-sam package</code> and <code>aws-sam deploy</code> commands. If you use AWS CLI, run the <code>aws cloudformation package</code> and <code>aws cloudformation deploy</code> commands.</p>	DevOps engineer

# Cost-effectively ingest IoT data directly into Amazon S3 using AWS IoT Greengrass

Created by Sebastian Viviani (AWS) and Rizwan Syed (AWS)

**Environment:** PoC or pilot

**Technologies:** Data lakes;  
Analytics; IoT

**Workload:** Open-source

**AWS services:** AWS IoT  
Greengrass; Amazon S3;  
Amazon Athena

## Summary

This pattern shows you how to cost-effectively ingest Internet of Things (IoT) data directly into an Amazon Simple Storage Service (Amazon S3) bucket by using an AWS IoT Greengrass Version 2 device. The device runs a custom component that reads the IoT data and saves the data in persistent storage (that is, a local disk or volume). Then, the device compresses the IoT data into an Apache Parquet file and uploads the data periodically to an S3 bucket.

The amount and speed of IoT data that you ingest is limited only by your edge hardware capabilities and network bandwidth. You can use Amazon Athena to cost-effectively analyze your ingested data. Athena supports compressed Apache Parquet files and data visualization by using [Amazon Managed Grafana](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An [edge gateway](#) that runs on [AWS IoT Greengrass Version 2](#) and collects data from sensors (The data sources and the data collection process are beyond the scope of this pattern, but you can use nearly any type of sensor data. This pattern uses a local [MQTT](#) broker with sensors or gateways that publish data locally.)
- AWS IoT Greengrass [component](#), [roles](#), and [SDK dependencies](#)
- A [stream manager component](#) to upload the data to the S3 bucket

- [AWS SDK for Java](#), [AWS SDK for JavaScript](#), or [AWS SDK for Python \(Boto3\)](#) to run the APIs

## Limitations

- The data in this pattern isn't uploaded in real time to the S3 bucket. There is a delay period, and you can configure the delay period. Data is buffered temporarily in the edge device and then uploaded once the period expires.
- The SDK is available only in Java, Node.js, and Python.

## Architecture

### Target technology stack

- Amazon S3
- AWS IoT Greengrass
- MQTT broker
- Stream manager component

### Target architecture

The following diagram shows an architecture designed to ingest IoT sensor data and store that data in an S3 bucket.

The diagram shows the following workflow:

1. Multiple sensors (for example, temperature and valve) updates are published to a local MQTT broker.
2. The Parquet file compressor that's subscribed to these sensors updates topics and receives these updates.
3. The Parquet file compressor stores the updates locally.
4. After the period lapses, the stored files are compressed into Parquet files and passed on to the stream manager to get uploaded to the specified S3 bucket.
5. The stream manager uploads the Parquet files to the S3 bucket.

**Note:** The stream manager (`StreamManager`) is a managed component. For examples of how to export data to Amazon S3, see [Stream manager](#) in the AWS IoT Greengrass documentation. You can use a local MQTT broker as a component or another broker like [Eclipse Mosquitto](#).

## Tools

### AWS tools

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS IoT Greengrass](#) is an open source IoT edge runtime and cloud service that helps you build, deploy, and manage IoT applications on your devices.

### Other tools

- [Apache Parquet](#) is an open-source column-oriented data file format designed for storage and retrieval.
- [MQTT](#) (Message Queuing Telemetry Transport) is a lightweight messaging protocol that's designed for constrained devices.

## Best practices

### Use the right partition format for uploaded data

There are no specific requirements for the root prefix names in the S3 bucket (for example, "myAwesomeDataSet/" or "dataFromSource"), but we recommend that you use a meaningful partition and prefix so that it's easy to understand the purpose of the dataset.

We also recommend that you use the right partitioning in Amazon S3 so that the queries run optimally on the dataset. In the following example, the data is partitioned in HIVE format so that the amount of data scanned by each Athena query is optimized. This improves performance and reduces cost.

```
s3://<ingestionBucket>/<rootPrefix>/year=YY/month=MM/day=DD/
HHMM_<suffix>.parquet
```

## Epics

### Set up your environment

Task	Description	Skills required
Create an S3 bucket.	<ol style="list-style-type: none"> <li>1. <a href="#">Create an S3 bucket</a> or use an existing bucket.</li> <li>2. Create a meaningful <a href="#">prefix</a> for the S3 bucket where you want to ingest the IoT data (for example, <code>s3://&lt;bucket&gt;/&lt;prefix&gt;</code> ).</li> <li>3. Record your prefix for later use.</li> </ol>	App developer
Add IAM permissions to the S3 bucket.	<p>To grant users write access to the S3 bucket and prefix that you created earlier, add the following IAM policy to your AWS IoT Greengrass role:</p> <pre>{   "Version":     "2012-10-17",</pre>	App developer

Task	Description	Skills required
	<pre data-bbox="592 205 1031 1218">    "Statement": [       {         "Sid":         "S3DataUpload",         "Effect":         "Allow",         "Action": [          "s3:List*",          "s3:Put*"         ],         "Resource":         [          "arn:aws:s3:::&lt;ing         estionBucket&gt;",          "arn:aws:s3:::&lt;ing         estionBucket&gt;/&lt;pre         fix&gt;/*"         ]       }     ]   }</pre> <p data-bbox="592 1255 1031 1438">For more information, see <a href="#">Creating an IAM policy to access Amazon S3 resources</a> in the Aurora documentation.</p> <p data-bbox="592 1480 1031 1711">Next, update the resource policy (if needed) for the S3 bucket to allow write access with the correct <a href="#">AWS principals</a>.</p>	

## Build and deploy the AWS IoT Greengrass component

Task	Description	Skills required
Update the recipe of the component.	<p><a href="#">Update the component configuration</a> when you <a href="#">create a deployment</a> based on the following example:</p> <pre data-bbox="594 548 1027 947">{   "region": "&lt;region&gt;",   "parquet_period":   &lt;period&gt;,   "s3_bucket":   "&lt;s3Bucket&gt;",   "s3_key_prefix":   "&lt;s3prefix&gt;" }</pre> <p>Replace <code>&lt;region&gt;</code> with your AWS Region, <code>&lt;period&gt;</code> with your periodic interval, <code>&lt;s3Bucket&gt;</code> with your S3 bucket, and <code>&lt;s3prefix&gt;</code> with your prefix.</p>	App developer
Create the component.	<p>Do one of the following:</p> <ul style="list-style-type: none"><li>• <a href="#">Create the component</a>.</li><li>• Add the component to the CI/CD pipeline (if one exists). Be sure to copy the artifact from the artifact repository to the AWS IoT Greengrass artifact bucket. Then, create or update your AWS IoT Greengrass component.</li></ul>	App developer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• Add the MQTT broker as a component or add it manually later. <b>Note:</b> This decision affects the authentication scheme that you can use with the broker. Manually adding a broker decouples the broker from AWS IoT Greengrass and enables any supported authentication scheme of the broker. The AWS provided broker components have predefined authentication schemes. For more information, see <a href="#">MQTT 3.1.1 broker (Moquette)</a> and <a href="#">MQTT 5 broker (EMQX)</a>.</li> </ul>	
Update the MQTT client.	<p>The sample code doesn't use authentication because the component connects locally to the broker. If your scenario differs, update the MQTT client section as needed. Additionally, do the following:</p> <ol style="list-style-type: none"> <li>1. Update the MQTT topics in the subscription.</li> <li>2. Update the MQTT message parser as needed as messages from each source may differ.</li> </ol>	App developer

## Add the component to the AWS IoT Greengrass Version 2 core device

Task	Description	Skills required
Update the deployment of the core device.	<p>If the deployment of the AWS IoT Greengrass Version 2 core device already exists, <a href="#">revise the deployment</a>. If the deployment doesn't exist, <a href="#">create a new deployment</a>.</p> <p>To give the component the correct name, <a href="#">update the log manager configuration</a> for the new component (if needed) based on the following:</p> <pre data-bbox="591 953 1029 1885">{   "logsUploaderConfiguration": {     "systemLogsConfiguration": {       ...     },     "componentLogsConfigurationMap": {       "&lt;com.iot.ingest.parquet&gt;": {         "minimumLogLevel": "INFO",         "diskSpaceLimit": "20",         "diskSpaceLimitUnit": "MB",         "deleteLogFileAfterCloudUpload": "false"       }       ...     }   } }</pre>	App developer

Task	Description	Skills required
	<pre data-bbox="597 205 1023 384"> }, "periodicUploadIntervalSec": "300" } </pre> <p data-bbox="597 426 1023 604">Finally, complete the revision of the deployment for your AWS IoT Greengrass core device.</p>	

### Verify data ingestion into the S3 bucket

Task	Description	Skills required
Check the logs for the AWS IoT Greengrass volume.	<p data-bbox="597 896 1023 930">Check for the following:</p> <ul data-bbox="597 978 1023 1560" style="list-style-type: none"> <li data-bbox="597 978 1023 1104">• The MQTT client is successfully connected to the local MQTT broker.</li> <li data-bbox="597 1131 1023 1257">• The MQTT client is subscribed to the correct topics.</li> <li data-bbox="597 1285 1023 1411">• Sensor update messages are coming to the broker on the MQTT topics.</li> <li data-bbox="597 1438 1023 1560">• Parquet compression happens at every periodic interval.</li> </ul>	App developer
Check the S3 bucket.	Verify if the data is being uploaded to the S3 bucket. You can see the files being uploaded at every period.	App developer

Task	Description	Skills required
	You can also verify if the data is uploaded to the S3 bucket by querying the data in the next section.	

## Set up querying from Athena

Task	Description	Skills required
Create a database and table.	<ol style="list-style-type: none"> <li><a href="#">Create an AWS Glue database</a> (if needed).</li> <li>Create a table in AWS Glue <a href="#">manually</a> or by running a <a href="#">crawler</a> in AWS Glue.</li> </ol>	App developer
Grant Athena access to the data.	<ol style="list-style-type: none"> <li>Update permissions to allow Athena to access the S3 bucket. For more information, see <a href="#">Fine-grained access to databases and tables in the AWS Glue Data Catalog</a> in the Athena documentation.</li> <li>Query the table in your database.</li> </ol>	App developer

## Troubleshooting

Issue	Solution

## Additional information

### Cost analysis

The following cost analysis scenario demonstrates how the data ingestion approach covered in this pattern can impact data ingestion costs in the AWS Cloud. The pricing examples in this scenario are based on prices at the time of publication. Prices are subject to change. Additionally, your costs may vary depending on your AWS Region, AWS service quotas, and other factors related to your cloud environment.

#### *Input signal set*

This analysis uses the following set of input signals as the basis for comparing IoT ingestion costs with other available alternatives.

<b>Number of signals</b>	<b>Frequency</b>	<b>Data per signal</b>
125	25 Hz	8 bytes

In this scenario, the system receives 125 signals. Each signal is 8 bytes and occurs every 40 milliseconds (25 Hz). These signals could come individually or grouped in a common payload. You have the option to split and pack these signals based on your needs. You can also determine the latency. Latency consists of the time period for receiving, accumulating, and ingesting the data.

For comparison purposes, the ingestion operation for this scenario is based in the us-east-1 AWS Region. The cost comparison applies to AWS services only. Other costs, like hardware or connectivity, are not factored into the analysis.

#### *Cost comparisons*

The following table shows the monthly cost in US dollars (USD) for each ingestion method.

<b>Method</b>	<b>Monthly cost</b>
AWS IoT SiteWise*	331.77 USD
AWS IoT SiteWise Edge with data processing pack (keeping all data at the edge)	200 USD

AWS IoT Core and Amazon S3 rules for accessing raw data	84.54 USD
Parquet file compression at the edge and uploading to Amazon S3	0.5 USD

\*Data must be downsampled to comply with service quotas. This means there is some data loss with this method.

### *Alternative methods*

This section shows the equivalent costs for the following alternative methods:

- **AWS IoT SiteWise** – Each signal must be uploaded in an individual message. Therefore, the total number of messages per month is  $125 \times 25 \times 3600 \times 24 \times 30$ , or 8.1 billion messages per month. However, AWS IoT SiteWise can handle only 10 data points per second per property. Assuming the data is downsampled to 10 Hz, the number of messages per month is reduced to  $125 \times 10 \times 3600 \times 24 \times 30$ , or 3.24 billion. If you use the publisher component that packs measurements in groups of 10 (at 1 USD per million messages), then you get a monthly cost of 324 USD per month. Assuming that each message is 8 bytes (1 Kb/125), that's 25.92 Gb of data storage. This adds a monthly cost of 7.77 USD per month. The total cost for the first month is 331.77 USD and increases by 7.77 USD every month.
- **AWS IoT SiteWise Edge with data processing pack, including all models and signals fully processed at the edge (that is, no cloud ingestion)** – You can use the data processing pack as an alternative to reduce costs and to configure all the models that get calculated at the edge. This can work just for storage and visualization, even if no real calculation is performed. In this case, it's necessary to use powerful hardware for the edge gateway. There is a fixed cost of 200 USD per month.
- **Direct ingestion to AWS IoT Core by MQTT and an IoT rule to store the raw data in Amazon S3** – Assuming all the signals are published in a common payload, the total number of messages published to AWS IoT Core is  $25 \times 3600 \times 24 \times 30$ , or 64.8 million per month. At 1 USD per million messages, that's a monthly cost of 64.8 USD per month. At 0.15 USD per million rule activations and with one rule per message, that adds a monthly cost of 19.44 USD per month. At a cost of 0.023 USD per Gb of storage in Amazon S3, that adds another 1.5 USD per month (increasing every month to reflect the new data). The total cost for the first month is 84.54 USD and increases by 1.5 USD every month.

- **Compressing data at the edge in a Parquet file and uploading to Amazon S3 (proposed method)** – The compression ratio depends on the type of data. With the same industrial data tested for MQTT, the total output data for a full month is 1.2 Gb. This costs 0.03 USD per month. Compression ratios (using random data) described in other benchmarks are on the order of 66 percent (closer to a worst-case scenario). The total data is 21 Gb and costs 0.5 USD per month.

## Parquet file generator

The following code example shows the structure of a Parquet file generator that's written in Python. The code example is for illustration purposes only and won't work if pasted into your environment.

```
import queue
import paho.mqtt.client as mqtt
import pandas as pd

#queue for decoupling the MQTT thread
messageQueue = queue.Queue()
client = mqtt.Client()
streammanager = StreamManagerClient()

def feederListener(topic, message):
    payload = {
        "topic" : topic,
        "payload" : message,
    }
    messageQueue.put_nowait(payload)

def on_connect(client_instance, userdata, flags, rc):
    client.subscribe("#",qos=0)

def on_message(client, userdata, message):
    feederListener(topic=str(message.topic),
        message=str(message.payload.decode("utf-8")))

filename = "tempfile.parquet"
streamname = "mystream"
destination_bucket= "mybucket"
keyname="mykey"
period= 60
```

```
client.on_connect = on_connect
client.on_message = on_message
streammanager.create_message_stream(
    MessageStreamDefinition(name=streamname,
        strategy_on_full=StrategyOnFull.OverwriteOldestData)
    )

while True:
    try:
        message = messageQueue.get(timeout=myArgs.mqtt_timeout)
    except (queue.Empty):
        logger.warning("MQTT message reception timed out")

    currentTimestamp = getCurrentTime()
    if currentTimestamp >= nextUploadTimestamp:
        df = pd.DataFrame.from_dict(accumulator)
        df.to_parquet(filename)
        s3_export_task_definition = S3ExportTaskDefinition(input_url=filename,
            bucket=destination_bucket, key=key_name)
        streammanager.append_message(streamname,
            Util.validate_and_serialize_to_json_bytes(s3_export_task_definition))
        accumulator = {}
        nextUploadTimestamp += period
    else:
        accumulator.append(message)
```

# Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator

Created by Tony Velcich

<b>Source:</b> On-premises Hadoop cluster	<b>Target:</b> Amazon S3	<b>R Type:</b> Rehost
<b>Environment:</b> Production	<b>Technologies:</b> Data lakes; Big data; Hybrid cloud; Migration	<b>Workload:</b> All other workloads
<b>AWS services:</b> Amazon S3		

## Summary

This pattern describes the process for migrating Apache Hadoop data from a Hadoop Distributed File System (HDFS) to Amazon Simple Storage Service (Amazon S3). It uses WANdisco LiveData Migrator to automate the data migration process.

## Prerequisites and limitations

### Prerequisites

- Hadoop cluster edge node where LiveData Migrator will be installed. The node should meet the following requirements:
  - Minimum specification: 4 CPUs, 16 GB RAM, 100 GB storage.
  - 2 Gbps minimum network.
  - Port 8081 accessible on your edge node to access the WANdisco UI.
  - Java 1.8 64-bit.
  - Hadoop client libraries installed on the edge node.
  - Ability to authenticate as the [HDFS superuser](#) (for example, "hdfs").
  - If Kerberos is enabled on your Hadoop cluster, a valid keytab that contains a suitable principal for the HDFS superuser must be available on the edge node.
  - See the [release notes](#) for a list of supported operating systems.

- An active AWS account with access to an S3 bucket.
- An AWS Direct Connect link established between your on-premises Hadoop cluster (specifically the edge node) and AWS.

## Product versions

- LiveData Migrator 1.8.6
- WANdisco UI (OneUI) 5.8.0

## Architecture

### Source technology stack

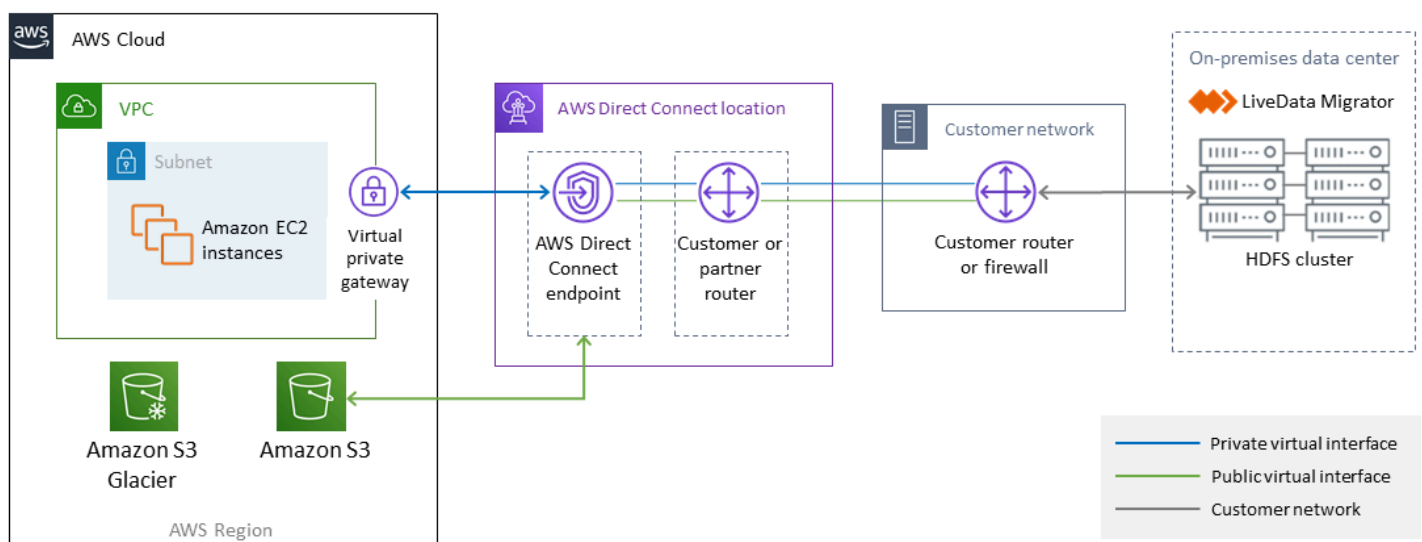

- On-premises Hadoop cluster

### Target technology stack

- Amazon S3

## Architecture

The following diagram shows the LiveData Migrator solution architecture.

The workflow consists of four primary components for data migration from on-premises HDFS to Amazon S3.

- [LiveData Migrator](#) – Automates the migration of data from HDFS to Amazon S3, and resides on an edge node of the Hadoop cluster.
- [HDFS](#) – A distributed file system that provides high-throughput access to application data.
- [Amazon S3](#) – An object storage service that offers scalability, data availability, security, and performance.
- [AWS Direct Connect](#) – A service that establishes a dedicated network connection from your on-premises data centers to AWS.

### Automation and scale

You will typically create multiple migrations so that you can select specific content from your source file system by path or directory. You can also migrate data to multiple, independent file systems at the same time by defining multiple migration resources.

## Epics

### Configure Amazon S3 storage in your AWS account

Task	Description	Skills required
Sign in to your AWS account.	Sign in to the AWS Management Console and open the Amazon S3 console at <a href="https://console.aws.amazon.com/s3/">https://console.aws.amazon.com/s3/</a> .	AWS experience
Create an S3 bucket.	If you don't already have an existing S3 bucket to use as the target storage, choose the "Create bucket" option on the Amazon S3 console, and specify a bucket name, AWS Region, and bucket settings for block public	AWS experience

Task	Description	Skills required
	<p>access. AWS and WANdisco recommend that you enable the block public access options for the S3 bucket, and set up the bucket access and user permission policies to meet your organization's requirements. An AWS example is provided at <a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/example-walkthroughs-managing-access-example1.html">https://docs.aws.amazon.com/AmazonS3/latest/dev/example-walkthroughs-managing-access-example1.html</a>.</p>	

## Install LiveData Migrator

Task	Description	Skills required
<p>Download the LiveData Migrator installer.</p>	<p>Download the LiveData Migrator installer and upload it to the Hadoop edge node. You can download a free trial of LiveData Migrator at <a href="https://www2.wandisco.com/ldm-trial">https://www2.wandisco.com/ldm-trial</a>. You can also obtain access to LiveData Migrator from AWS Marketplace, at <a href="https://aws.amazon.com/marketplace/pp/B07B8SZND9">https://aws.amazon.com/marketplace/pp/B07B8SZND9</a>.</p>	<p>Hadoop administrator, Application owner</p>
<p>Install LiveData Migrator.</p>	<p>Use the downloaded installer and install LiveData Migrator as the HDFS superuser on an edge node in your Hadoop</p>	<p>Hadoop administrator, Application owner</p>

Task	Description	Skills required
	cluster. See the "Additional information" section for the installation commands.	
Check the status of LiveData Migrator and other services.	Check the status of LiveData Migrator, Hive migrator, and WANdisco UI by using the commands provided in the "Additional information" section.	Hadoop administrator, Application owner

### Configure storage through the WANdisco UI

Task	Description	Skills required
Register your LiveData Migrator account.	Log in to the WANdisco UI through a web browser on port 8081 (on the Hadoop edge node) and provide your details for registration. For example, if you are running LiveData Migrator on a host named myldmhost.example.com, the URL would be: <a href="http://myldmhost.example.com:8081">http://myldmhost.example.com:8081</a>	Application owner
Configure your source HDFS storage.	Provide the configuration details needed for your source HDFS storage. This will include the "fs.defaultFS" value and a user-defined storage name. If Kerberos is enabled, provide the principal and keytab location for	Hadoop administrator, Application owner

Task	Description	Skills required
	<p>LiveData Migrator to use. If NameNode HA is enabled on the cluster, provide a path to the core-site.xml and hdfs-site.xml files on the edge node.</p>	
<p>Configure your target Amazon S3 storage.</p>	<p>Add your target storage as the S3a type. Provide the user-defined storage name and the S3 bucket name. Enter "org.apache.hadoop.fs.s3a.SimpleAWSCredentialProvider" for the Credentials Provider option, and provide the AWS access and secret keys for the S3 bucket. Additional S3a properties will also be needed. For details, see the "S3a Properties" section in the LiveData Migrator documentation at <a href="https://docs.wandisco.com/live-data-migrator/docs/command-reference/#filesystem-add-s3a">https://docs.wandisco.com/live-data-migrator/docs/command-reference/#filesystem-add-s3a</a>.</p>	<p>AWS, Application owner</p>

## Prepare for the migration

Task	Description	Skills required
<p>Add exclusions (if needed).</p>	<p>If you want to exclude specific datasets from migration, add exclusions for the source HDFS storage. These</p>	<p>Hadoop administrator, Application owner</p>

Task	Description	Skills required
	exclusions can be based on file size, file names (based on regex patterns), and modification date.	

## Create and start the migration

Task	Description	Skills required
Create and configure the migration.	Create a migration in the dashboard of the WANdisco UI. Choose your source (HDFS) and target (the S3 bucket). Add new exclusions that you have defined in the previous step. Select either the "Overwrite" or the "Skip if Size Match" option. Create the migration when all fields are complete.	Hadoop administrator, Application owner
Start the migration.	On the dashboard, select the migration you created. Click to start the migration. You can also start a migration automatically by choosing the auto-start option when you create the migration.	Application owner

## Manage bandwidth (optional)

Task	Description	Skills required
Set a network bandwidth limit between the source and target.	In the Storages list on the dashboard, select your source storage and select "Bandwidth Management" in the Grouping list. Clear the unlimited option, and define the maximum bandwidth limit and unit. Choose "Apply."	Application owner, Networking

## Monitor and manage migrations

Task	Description	Skills required
View migration information using the WANdisco UI.	Use the WANdisco UI to view license, bandwidth, storage and migration information. The UI also provides a notification system so you can receive notifications about errors, warnings, or important milestones in your usage.	Hadoop administrator, Application owner
Stop, resume, and delete migrations.	You can stop a migration from transferring content to its target by placing it in the STOPPED state. Stopped migrations can be resumed. Migrations in the STOPPED state can also be deleted.	Hadoop administrator, Application owner

## Additional information

### Installing LiveData Migrator

You can use the following commands to install LiveData Migrator, assuming that the installer is inside your working directory:

```
su - hdfs
chmod +x livedata-migrator.sh && sudo ./livedata-migrator.sh
```

### Checking the status of LiveData Migrator and other services after installation

Use the following commands to check the status of LiveData Migrator, Hive migrator, and WANdisco UI:

```
service livedata-migrator status
service hivemigrator status
service livedata-ui status
```

# Access on-premises Microsoft SQL Server tables from Microsoft SQL Server on Amazon EC2 using linked servers

Created by Tirumala Dasari (AWS) and Eduardo Valentim (AWS)

**Environment:** PoC or pilot

**Technologies:** Databases

**Workload:** Microsoft

## Summary

This pattern describes how to access on-premises Microsoft SQL Server database tables running on Microsoft Windows, from Microsoft SQL Server databases running or hosted on Amazon Elastic Compute Cloud (Amazon EC2) Windows or Linux instances by using linked servers.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI (Amazon Machine Image)
- AWS Direct Connect between the on-premises Microsoft SQL Server (Windows) server and the Windows or Linux EC2 instance

### Product versions

- SQL Server 2016 or later

## Architecture

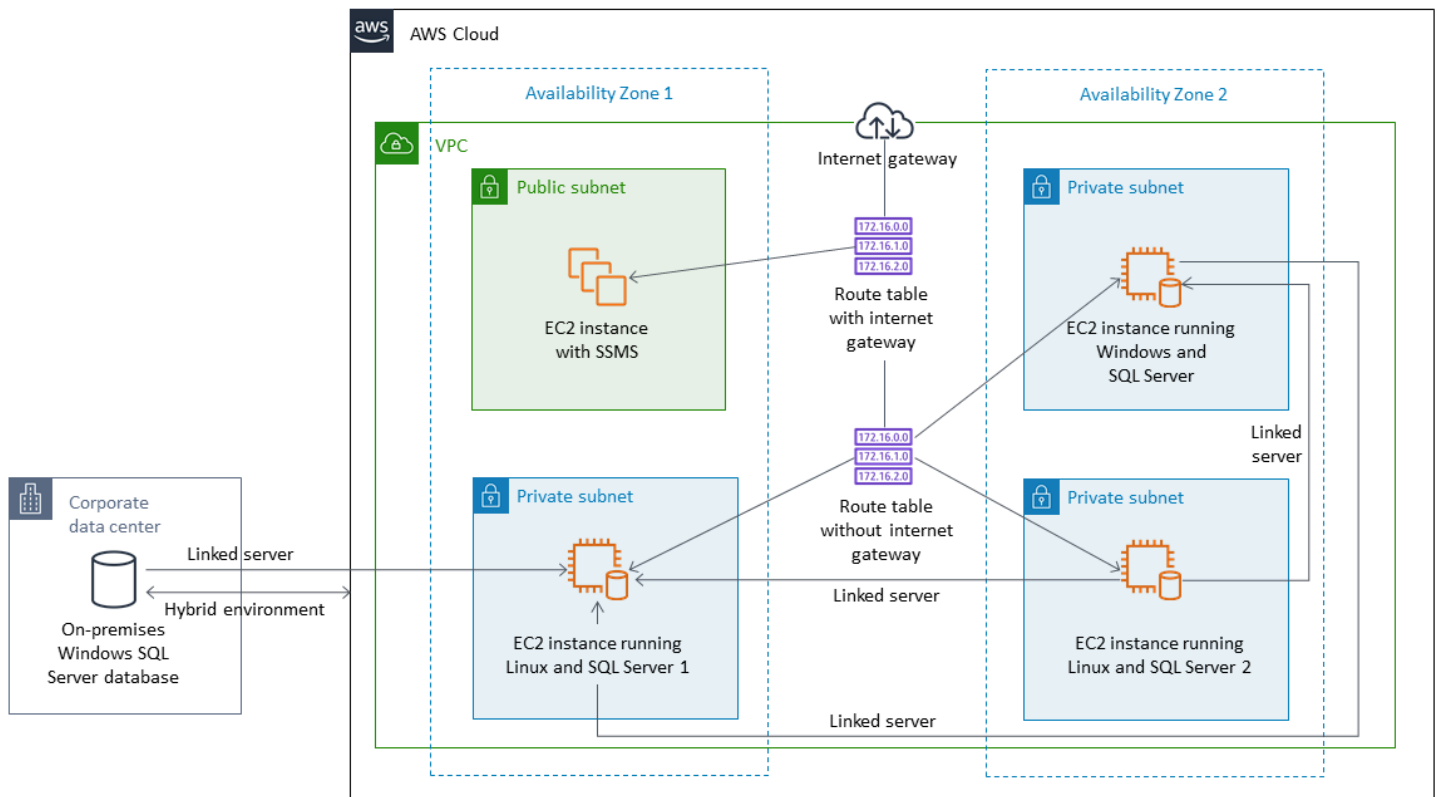

### Source technology stack

- On-premises Microsoft SQL Server database running on Windows
- Amazon EC2 with Microsoft SQL Server running on Windows AMI or Linux AMI

### Target technology stack

- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI
- Amazon EC2 with Microsoft SQL Server running on Windows AMI

## Source and target database architecture

## Tools

- [Microsoft SQL Server Management Studio \(SSMS\)](#) is an integrated environment for managing a SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

## Epics

### Change authentication mode to Windows for SQL Server in Windows SQL Server

Task	Description	Skills required
Connect to Windows SQL Server through SSMS.		DBA
Change the authentication mode to Windows in SQL Server from the context (right-click) menu for the Windows SQL Server instance.		DBA

### Restart the Windows MSSQL service

Task	Description	Skills required
Restart the SQL service.	<ol style="list-style-type: none"> <li>1. In SSMS Object Explorer, choose the SQL Server instance.</li> <li>2. Open the context (right-click) menu.</li> <li>3. Choose <b>Restart</b>.</li> </ol>	DBA

### Create new login and choose databases to access in Windows SQL Server

Task	Description	Skills required
In the Security tab, open the context (right-click) menu for Login and select a new login.		DBA
In the General tab, choose SQL Server authentication,		DBA

Task	Description	Skills required
enter a user name, enter the password, and then confirm the password and clear the option for changing the password at the next login.		
In the Server Roles tab, choose Public.		DBA
In the User Mapping tab, choose the database and schema you want to access, and then highlight the database to select database roles.	Select public and db_datareader to access data from the database tables.	DBA
Choose OK to create a user.		DBA

### Add Windows SQL Server IP to Linux SQL Server host file

Task	Description	Skills required
Connect to the Linux SQL Server box through the terminal window.		DBA
Open the /etc/hosts file and add the IP address of the Windows machine with SQL Server.		DBA
Save the hosts file.		DBA

## Create linked server on Linux SQL Server

Task	Description	Skills required
Create a linked server by using the stored procedures <code>master.sys.sp_addlinkedserver</code> and <code>master.dbo.sp_addlinkedserverlogin</code> .	For more information about using these stored procedures, see the <i>Additional information</i> section.	DBA, Developer

## Verify the created linked server and databases in SSMS

Task	Description	Skills required
In Linux SQL Server in SSMS, go to Linked Servers and refresh.		DBA
Expand the created linked servers and catalogs in the left pane.	You'll see the selected SQL Server databases with tables and views.	DBA

## Verify that you can access Windows SQL Server database tables

Task	Description	Skills required
In the SSMS query window, run the query: <code>"select top 3 * from [sqllin].dms_sample_win.dbo.mlb_data"</code> .	Note that the FROM clause uses a four-part syntax: <code>computer.database.schema.table</code> (e.g., <code>SELECT name "SQL2 databases" FROM [sqllin].master.sys.databases</code> ). In our example, we created an alias for SQL2 in the hosts file, so you don't need to enter the actual NetBIOS	DBA, Developer

Task	Description	Skills required
	name between the square brackets. If you do use the actual NetBIOS names, note that AWS defaults to NetBIOS names like Win-xxxx, and SQL Server requires square brackets for names with dashes.	

## Related resources

- [Release notes for SQL Server on Linux](#)

## Additional information

### Using stored procedures to create linked servers

SSMS doesn't support the creation of linked servers for Linux SQL Server, so you have to use these stored procedures to create them:

```
EXEC master.sys.sp_addlinkedserver @server= N'SQLLIN' , @srvproduct= N'SQL Server'  
EXEC master.dbo.sp_addlinkedsrvlogin  
@rmtsrvname=N'SQLLIN',@useself=N'False',@locallogin=NULL,@rmtuser=N'username',@rmtpassword='Te
```

Note 1: Enter the sign-in credentials that you created earlier in Windows SQL Server in the stored procedure `master.dbo.sp_addlinkedsrvlogin`.

Note 2: `@server` name `SQLLIN` and host file entry name `172.12.12.4 SQLLIN` should be the same.

You can use this process to create linked servers for the following scenarios:

- Linux SQL Server to Windows SQL Server through a linked server (as specified in this pattern)
- Windows SQL Server to Linux SQL Server through a linked server

- Linux SQL Server to another Linux SQL Server through a linked server

# Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica

Created by *sampath kathirvel* (AWS)

**Environment:** Production

**Technologies:** Databases;  
Infrastructure

**Workload:** Oracle

**AWS services:** Amazon RDS

## Summary

To run the [Oracle PeopleSoft](#) enterprise resource planning (ERP) solution on Amazon Web Services (AWS), you can use [Amazon Relational Database Service \(Amazon RDS\)](#) or [Amazon RDS Custom for Oracle](#), which supports legacy, custom, and packaged applications that require access to the underlying operating system and database environment. For key factors to consider when planning a migration, see [Oracle database migration strategies](#) in AWS Prescriptive Guidance.

As of this writing, RDS Custom for Oracle doesn't support the [Multi-AZ](#) option, which is available for [Amazon RDS for Oracle](#) as an HA solution using storage replication. Instead, this pattern achieves HA by using a standby database that creates and maintains a physical copy of the primary database. The pattern focuses on the steps to run a PeopleSoft application database on Amazon RDS Custom with HA by using Oracle Data Guard to set up a read replica.

This pattern also changes the read replica to read-only mode. Having your read replica in read-only mode provides additional benefits:

- Offloading read-only workloads from the primary database
- Enabling automatic repair of corrupted blocks by retrieving healthy blocks from the standby database using the Oracle Active Data Guard feature
- Using the Far Sync capability to keep the remote standby database in sync without the performance overhead associated with long-distance redo log transmission.

Using a replica in read-only mode requires the [Oracle Active Data Guard](#) option, which comes at an extra cost because it is a separately licensed feature of Oracle Database Enterprise Edition.

## Prerequisites and limitations

### Prerequisites

- An existing PeopleSoft application on Amazon RDS Custom. If you don't have an application, see the pattern [Migrate Oracle PeopleSoft to Amazon RDS Custom](#).
- A single PeopleSoft application tier. However, you can adapt this pattern to work with multiple application tiers.
- Amazon RDS Custom configured with at least 8 GB of swap space.
- An Oracle Active Data Guard database license for converting the read replica into read-only mode and using it for offloading reporting tasks to the standby. For more information, see the [Oracle Technology Commercial Price List](#).

### Limitations

- General limitations and unsupported configurations for [RDS Custom for Oracle](#)
- Limitations associated with [Amazon RDS Custom for Oracle read replicas](#)

### Product versions

- For Oracle Database versions supported by Amazon RDS Custom, see [RDS Custom for Oracle](#).
- For Oracle Database instance classes supported by Amazon RDS Custom, see [DB instance class support for RDS Custom for Oracle](#).

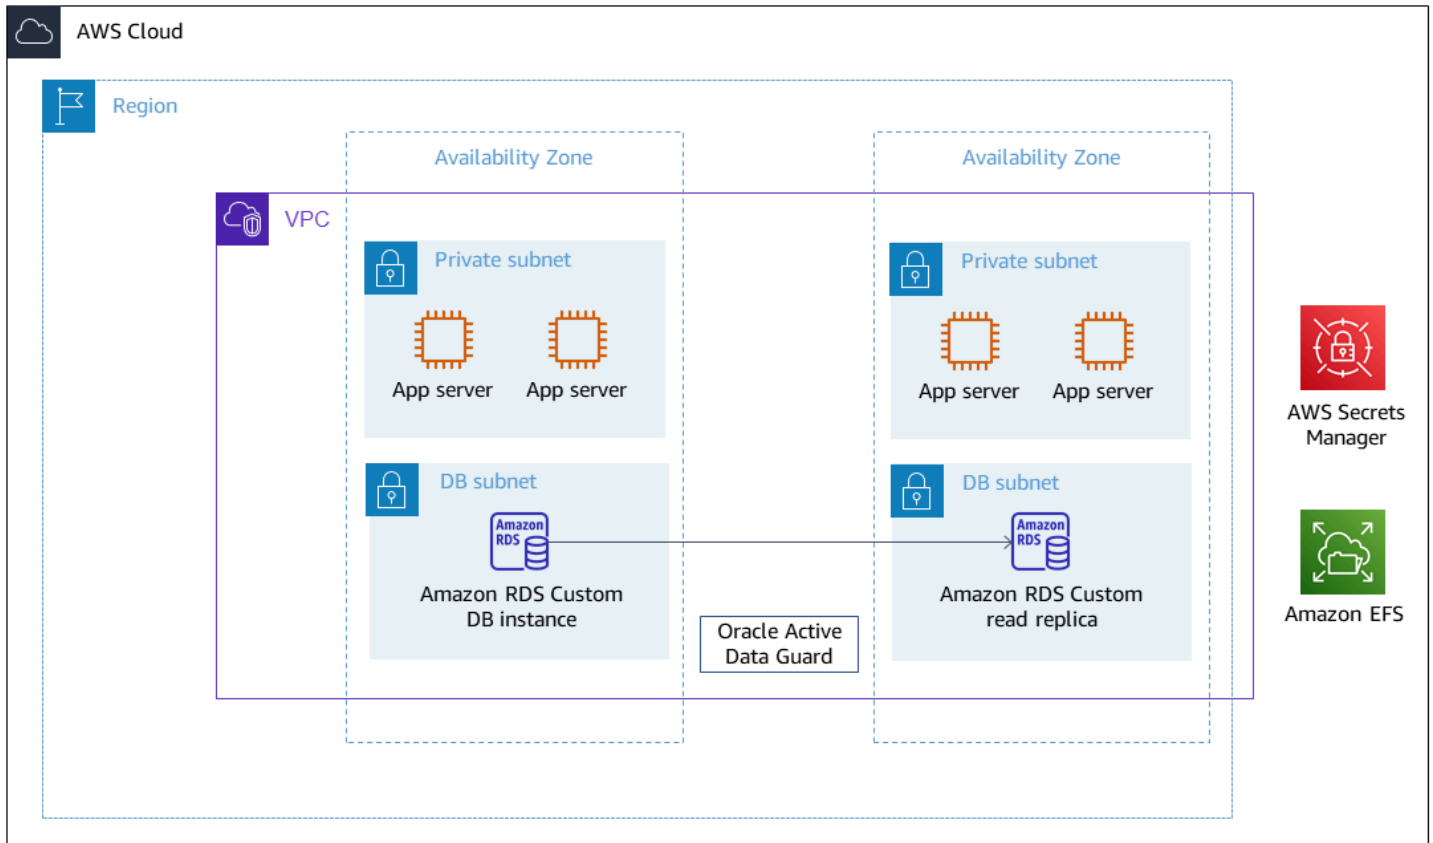

## Architecture

### Target technology stack

- Amazon RDS Custom for Oracle
- AWS Secrets Manager
- Oracle Active Data Guard
- Oracle PeopleSoft application

### Target architecture

The following diagram shows an Amazon RDS Custom DB instance and an Amazon RDS Custom read replica. The read replica uses Oracle Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.

For a representative architecture using Oracle PeopleSoft on AWS, see [Set up a highly available PeopleSoft architecture on AWS](#).

## Tools

### AWS services

- [Amazon RDS Custom for Oracle](#) is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment.
- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager for RDS\_DATAGUARD with the secret name `do-not-delete-rds-custom-+<<RDS Resource ID>>+-dg`.

## Other Tools

- [Oracle Data Guard](#) helps you create, maintain, manage, and monitor standby databases.

## Best practices

To work toward a zero data loss (RPO=0) objective, use the MaxAvailability Data Guard protection mode, with the redo transport SYNC+NOAFFIRM setting for better performance. For more information about selecting the database protection mode, see the *Additional information* section.

## Epics

### Create the read replica

Task	Description	Skills required
Create the read replica.	<p>To create a read replica of the Amazon RDS Custom DB instance, follow the instructions in the <a href="#">Amazon RDS documentation</a> and use the Amazon RDS Custom DB instance that you created (see the <i>Prerequisites</i> section) as the source database.</p> <p>By default, the Amazon RDS Custom read replica is created as a physical standby and is in the mounted state. This is intentional to ensure compliance with the Oracle Active Data Guard license.</p> <p>This pattern includes code for setting up a multitenant</p>	DBA

Task	Description	Skills required
	container database (CDB) or a non-CDB instance.	

## Change Oracle Data Guard protection mode to MaxAvailability

Task	Description	Skills required
Access the Data Guard broker configuration on the primary database.	<p>In this example, the Amazon RDS Custom read replica is RDS_CUSTOM_ORCL_D for the Non-CDB instance and RDS_CUSTOM_RDSCDB_B for the CDB instance. The databases for Non-CDB are orcl_a (primary) and orcl_d (standby). The database names for CDB are rdscdb_a (primary) and rdscdb_b (standby).</p> <p>You can connect to the RDS Custom read replica directly or through the primary database. You can find the net service name for your database in the tnsnames.ora file located in the \$ORACLE_HOME/network/admin directory. RDS Custom for Oracle automatically populates these entries for your primary database and your read replicas.</p>	DBA

Task	Description	Skills required
	<p>The password for the RDS_DATAGUARD user is stored in AWS Secrets Manager, with secret name <code>do-not-delete-rds-custom-+&lt;&lt;RDS Resource ID&gt;&gt;+-dg</code>. For more information on how to connect to an RDS Custom instance using the SSH (Secure Shell) key retrieved from Secrets Manager, see <a href="#">Connecting to your RDS Custom DB instance using SSH</a>.</p> <p>To access the Oracle Data Guard broker configuration through the Data Guard command line (<code>dgmgrl</code>), use the following code.</p> <p><b>Non-CDB</b></p> <pre data-bbox="594 1304 1029 1791">\$ dgmgrl RDS_DATAGUARD@RDS_CUSTOM_ORCL_D DGMGRL for Linux:   Release 19.0.0.0.0 -   Production on Fri Sep 30 22:44:49 2022   Version 19.10.0.0.0   Copyright (c) 1982,   2019, Oracle and/or its   affiliates. ## Additional information

### Select your database protection mode

Oracle Data Guard provides three protection modes to configure your Data Guard environment based on your availability, protection, and performance requirements. The following table summarizes these three modes.

Protection mode	Redo transport setting	Description
<b>MAXIMUM PERFORMANCE</b>	ASYNC	<p>For transactions happening on the primary database, redo data is asynchronously transmitted and written to the standby database redo log. Therefore, the performance impact is minimal.</p> <p>MaxPerformance can't provide RPO=0 because of asynchronous log shipping.</p>
<b>MAXIMUM PROTECTION</b>	SYNC+AFFIRM	<p>For transactions on the primary database, redo data is synchronously transmitted</p>

and written to the standby database redo log on disk before the transaction is acknowledged. If the standby database becomes unavailable, the primary database shuts itself down to ensure transactions are protected.

**MAXIMUM AVAILABILITY**

SYNC+AFFIRM

This is similar to `MaxProtection` mode, except when no acknowledgement is received from the standby database. In that case, it operates as if it were in `MaxPerformance` mode to preserve the primary database availability until it's able to write its redo stream to a synchronized standby database again.

## SYNC+NOAFFIRM

For transactions on the primary database, redo is synchronously transmitted to the standby database, and the primary waits only for acknowledgement that the redo has been received on the standby, not that it has been written to the standby disk. This mode, which is also known as FastSync, can provide a performance benefit at the expense of potential exposure to data loss in a special case of multiple simultaneous failures.

Read replicas in RDS Custom for Oracle are created with maximum performance protection mode, which is also the default protection mode for Oracle Data Guard. The maximum performance mode provides the lowest performance impact on the primary database, which can help you meet the recovery point objective (RPO) requirement measured in seconds.

To work to achieve a zero data loss (RPO=0) objective, you can customize the Oracle Data Guard protection mode to `MaxAvailability` with the `SYNC+NOAFFIRM` setting for redo transport for better performance. Because commits on the primary database are acknowledged only after the corresponding redo vectors are successfully transmitted to the standby database, the network latency between the primary instance and replica can be crucial for commit-sensitive workloads. We recommend performing load testing for your workload to assess the performance impact when the read replica is customized to run in `MaxAvailability` mode.

Deploying the read replica in the same Availability Zone as the primary database provides lower network latency compared with deploying the read replica in a different Availability Zone. However, deploying the primary and read replicas in the same Availability Zone might not meet your HA requirements because, in the unlikely event of Availability Zone unavailability, both the primary instance and read replica instance are impacted.

# Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS

Created by Battulga Purevragchaa (AWS), Krishnakumar Sathyanarayana (PeerIslands US Inc), and Babu Srinivasan (MongoDB)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Microsoft SQL Server	<b>Target:</b> MongoDB Atlas or MongoDB Enterprise Advanced
<b>R Type:</b> Replatform	<b>Workload:</b> Microsoft	<b>Technologies:</b> Databases; Migration

## Summary

This pattern provides guidance for loading MongoDB with near real-world data and assessing MongoDB query performance that is as close to the production scenario as possible. The assessment provides input to help you plan your migration to MongoDB from a relational database. The pattern uses [PeerIslands Test Data Generator and Performance Analyzer](#) to test query performance.

This pattern is particularly useful for Microsoft SQL Server migration to MongoDB, because performing schema transformations and loading data from current SQL Server instances to MongoDB can be very complex. Instead, you can load near real-world data into MongoDB, understand MongoDB performance, and fine-tune the schema design before you start the actual migration.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Familiarity with [MongoDB Atlas](#)
- Target MongoDB schema
- Typical query patterns

## Limitations

- Data load times and performance will be limited by the MongoDB cluster instance size. We recommend that you choose instances that are recommended for production use to understand real-world performance.
- PeerIslands Test Data Generator and Performance Analyzer currently supports only online data loads and queries. Offline batch processing (for example, loading data into MongoDB by using Spark connectors) isn't yet supported.
- PeerIslands Test Data Generator and Performance Analyzer supports field relations within a collection. It doesn't support relationships across collections.

## Product editions

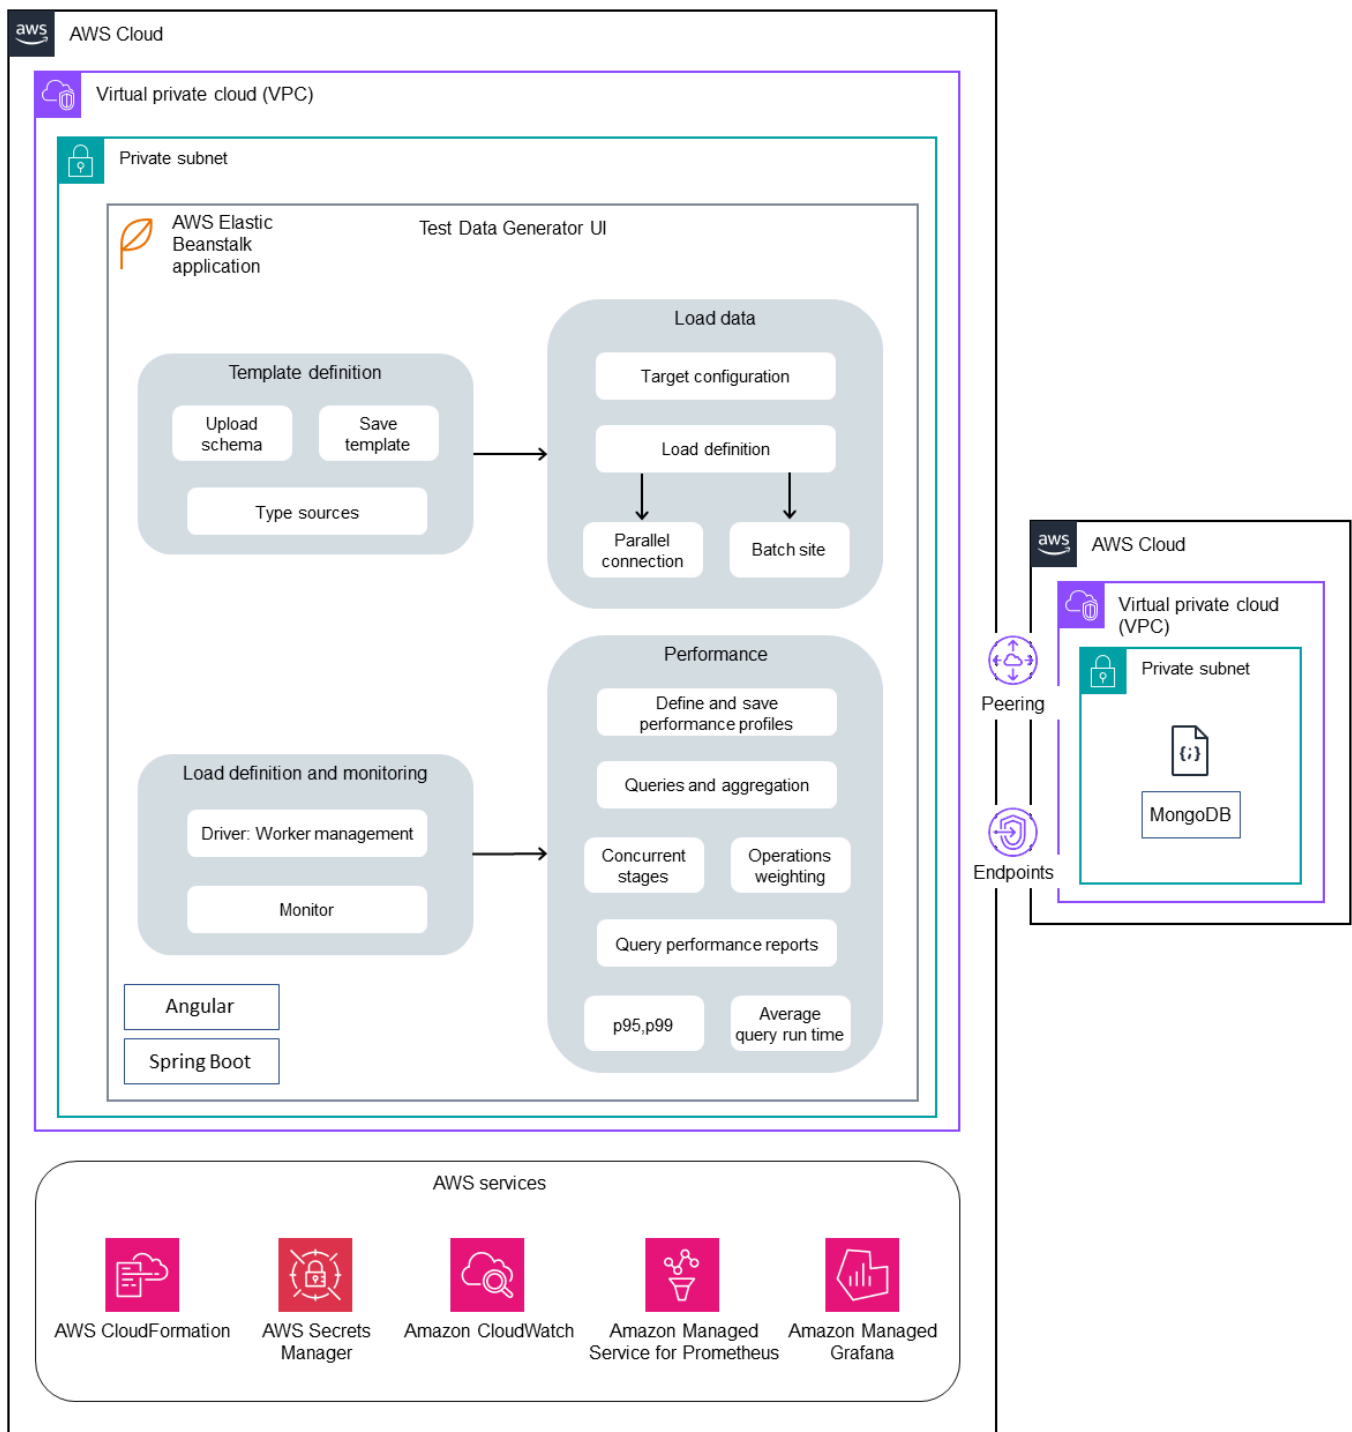

- This pattern supports both [MongoDB Atlas](#) and [MongoDB Enterprise Advanced](#).

## Architecture

### Target technology stack

- MongoDB Atlas or MongoDB Enterprise Advanced

### Architecture

PeerIslands Test Data Generator and Performance Analyzer is built by using Java and Angular, and stores its generated data on Amazon Elastic Block Store (Amazon EBS). The tool consists of two workflows: test data generation and performance testing.

- In test data generation, you create a template, which is the JSON representation of the data model that has to be generated. After you create the template, you can generate the data in a target collection, as defined by the load generation configuration.
- In performance testing, you create a profile. A profile is a multi-stage testing scenario where you can configure create, read, update, and delete (CRUD) operations, aggregation pipelines, the weightage for each operation, and the duration of each stage. After you create the profile, you can run performance testing on the target database based on the configuration.

PeerIslands Test Data Generator and Performance Analyzer stores its data on Amazon EBS, so you can connect Amazon EBS to MongoDB by using any MongoDB-supported connection mechanism, including peering, allow lists, and private endpoints. By default, the tool doesn't include operational components; however, it can be configured with Amazon Managed Service for Prometheus, Amazon Managed Grafana, Amazon CloudWatch, and AWS Secrets Manager if required.

## Tools

- [PeerIslands Test Data Generator and Performance Analyzer](#) includes two components. The Test Data Generator component helps you generate highly customer-specific, real-world data based on your MongoDB schema. The tool is fully UI-driven with a rich data library and can be used to quickly generate billions of records on MongoDB. The tool also provides capabilities to implement relationships between fields in the MongoDB schema. The Performance Analyzer component helps you generate highly customer-specific queries and aggregations, and perform realistic performance testing on MongoDB. You can use the Performance Analyzer to test MongoDB performance with rich load profiles and parameterized queries for your specific use case.

# Epics

## Understand your source data

Task	Description	Skills required
Understand the database footprint of the current SQL Server source.	Understand your current SQL Server footprint. This can be achieved by running queries against the INFORMATION schema of the database. Determine the number of tables and size of each table. Analyze the index associated with each table. For more information about SQL analysis, see the blog post <a href="#">SQL2Mongo: Data Migration Journey</a> on the PeerIslands website.	DBA
Understand the source schema.	Determine the table schema and the business representation of the data (for example, zip codes, names, and currency). Use your existing entity relationship (ER) diagram or generate the ER diagram from the existing database. For more information, see the blog post <a href="#">SQL2Mongo: Data Migration Journey</a> on the PeerIslands website.	DBA
Understand query patterns.	Document the top 10 SQL queries you use. You can use	DBA

Task	Description	Skills required
	<p>the <code>performance_schema</code> <code>.events_statements_summary_by_digest</code> tables that are available in the database to understand the top queries. For more information, see the blog post <a href="#">SQL2Mongo: Data Migration Journey</a> on the PeerIslands website.</p>	
Understand SLA commitments.	<p>Document the target service-level agreements (SLAs) for database operations. Typical measures include query latency and queries per second. The measures and their targets are typically available in non-functional requirements (NFR) documents.</p>	DBA

## Define the MongoDB schema

Task	Description	Skills required
Define the target schema.	<p>Define various options for the target MongoDB schema. For more information, see <a href="#">Schemas</a> in the MongoDB Atlas documentation. Consider the best practices and design patterns based on the table relations. See <a href="#">Data Model Examples and Patterns</a></p>	MongoDB engineer

Task	Description	Skills required
	in the MongoDB documentation for details.	
Define target query patterns.	Define MongoDB queries and aggregation pipelines. These queries are the equivalent of the top queries you captured for your SQL Server workload. To understand how to construct MongoDB aggregation pipelines, see the <a href="#">MongoDB documentation</a> .	MongoDB engineer
Define the MongoDB instance type.	Determine the size of the instance that you plan to use for testing. For guidance, see the <a href="#">MongoDB documentation</a> .	MongoDB engineer

## Prepare the target database

Task	Description	Skills required
Set up the MongoDB Atlas cluster.	To set up a MongoDB cluster on AWS, follow the instructions in the <a href="#">MongoDB documentation</a> .	MongoDB engineer
Create users in the target database.	Configure the MongoDB Atlas cluster for access and network security by following the instructions in the <a href="#">MongoDB documentation</a> .	MongoDB engineer

Task	Description	Skills required
Create appropriate roles in AWS and configure role-based access control for Atlas.	If required, set up additional users by following the instructions in the <a href="#">MongoDB documentation</a> . Configure <a href="#">authentication and authorization</a> through AWS roles.	MongoDB engineer
Set up Compass for MongoDB Atlas access.	Set up the <a href="#">MongoDB Compass GUI utility</a> for ease of navigation and access.	MongoDB engineer

### Set up the base load by using Test Data Generator

Task	Description	Skills required
Install Test Data Generator.	Install <a href="#">PeerIsland Test Data Generator</a> in your environment.	MongoDB engineer
Configure Test Data Generator to generate the appropriate data.	Create a template by using the data library to generate specific data for each field in the MongoDB schema. For more information, see the <a href="#">MongoDB Data Generator &amp; Perf. Analyzer</a> video.	MongoDB engineer
Horizontally scale Test Data Generator to generate the required load.	Use the template you created to start the load generation against the target collection by configuring the required parallelism. Determine the time frames and scale to generate the necessary data.	MongoDB engineer

Task	Description	Skills required
Validate the load in MongoDB Atlas.	Check the data loaded into MongoDB Atlas.	MongoDB engineer
Generate required indexes on MongoDB.	Define indexes as required, based on query patterns. For best practices, see the <a href="#">MongoDB documentation</a> .	MongoDB engineer

## Conduct performance testing

Task	Description	Skills required
Set up load profiles in Performance Analyzer.	Create a performance testing profile in Performance Analyzer by configuring specific queries and their corresponding weightage, duration of the test run, and stages. For more information, see the <a href="#">MongoDB Data Generator &amp; Perf. Analyzer</a> video.	MongoDB engineer
Run performance testing.	Use the performance testing profile you created to start the test against the target collection by configuring the required parallelism. Horizontally scale the performance test tool to run queries against MongoDB Atlas.	MongoDB engineer

Task	Description	Skills required
Record test results.	Record P95, P99 latency for the queries.	MongoDB engineer
Tune your schema and query patterns.	Modify indexes and query patterns to address any performance issues.	MongoDB engineer

## Close the project

Task	Description	Skills required
Shut down temporary AWS resources.	Delete all temporary resources that you used for Test Data Generator and Performance Analyzer.	AWS administrator
Update performance test results.	Understand MongoDB query performance and compare it against your SLAs. If necessary, fine-tune the MongoDB schema and rerun the process.	MongoDB engineer
Conclude the project.	Close out the project and provide feedback.	MongoDB engineer

**Environment:** Production

**Technologies:** Databases ; Infrastructure; Migration; Modernization

**AWS services:** Amazon Aurora; AWS CloudFormation; Amazon ElastiCache; Amazon RDS; AWS Step Functions

## Summary

This pattern describes how to use [DR Orchestrator Framework](#) to orchestrate and automate the manual, error-prone steps to perform disaster recovery across Amazon Web Services (AWS) Regions. The pattern covers the following databases:

- Amazon Relational Database Service (Amazon RDS) for MySQL, Amazon RDS for PostgreSQL, or Amazon RDS for MariaDB
- Amazon Aurora MySQL-Compatible Edition or Amazon Aurora PostgreSQL-Compatible Edition (using a centralized file)
- Amazon ElastiCache for Redis

To demonstrate the functionality of DR Orchestrator Framework, you create two DB instances or clusters. The primary is in the AWS Region us-east-1, and the secondary is in us-west-2. To create these resources, you use the AWS CloudFormation templates in the App-Stack folder of the [aws-cross-region-dr-databases](#) GitHub repository.

## Prerequisites and limitations

### General prerequisites

- DR Orchestrator Framework deployed in both primary and secondary AWS Regions

- Two [Amazon Simple Storage Service](#) buckets
- A [virtual private cloud \(VPC\)](#) with two subnets and an AWS security group

### Engine-specific prerequisites

- **Amazon Aurora** – At least one Aurora global database must be available in two AWS Regions. You can use us-east-1 as the primary Region, and use us-west-2 as the secondary Region.
- **Amazon ElastiCache for Redis** – An ElastiCache global datastore must be available in two AWS Regions. You can use us-east-1 as the primary Region, and use us-west-2 as the secondary Region.

### Amazon RDS limitations

- DR Orchestrator Framework doesn't check the replication lag before doing a failover or failback. Replication lag must be checked manually.
- This solution has been tested using a primary database instance with one read replica. If you want to use more than one read replica, test the solution thoroughly before implementing it in a production environment.

### Aurora limitations

- Feature availability and support vary across specific versions of each database engine and across AWS Regions. For more information on feature and Region availability for cross-Region replication, see [Cross-Region read replicas](#).
- Aurora global databases have specific configuration requirements for supported Aurora DB instance classes and the maximum number of AWS Regions. For more information, see [Configuration requirements of an Amazon Aurora global database](#).
- This solution has been tested using a primary database instance with one read replica. If you want to use more than one read replica, test the solution thoroughly before implementing it in a production environment.

### ElastiCache limitations

- For information about Region availability for Global Datastore and ElastiCache configuration requirements, see [Prerequisites and limitations](#) in the ElastiCache documentation.

## Amazon RDS product versions

Amazon RDS supports the following engine versions:

- **MySQL** – Amazon RDS supports DB instances running the following versions of [MySQL](#): MySQL 8.0 and MySQL 5.7
- **PostgreSQL** – For information about supported versions of Amazon RDS for PostgreSQL, see [Available PostgreSQL database versions](#).
- **MariaDB** – Amazon RDS supports DB instances running the following versions of [MariaDB](#):
  - MariaDB 10.11
  - MariaDB 10.6
  - MariaDB 10.5

## Aurora product versions

- Amazon Aurora global database switchover requires Aurora MySQL-Compatible with MySQL 5.7 compatibility, version 2.09.1 and higher

For more information, see [Limitations of Amazon Aurora global databases](#).

## ElastiCache for Redis product versions

Amazon ElastiCache for Redis supports the following Redis versions:

- Redis 7.1 (enhanced)
- Redis 7.0 (enhanced)
- Redis 6.2 (enhanced)
- Redis 6.0 (enhanced)
- Redis 5.0.6 (enhanced)

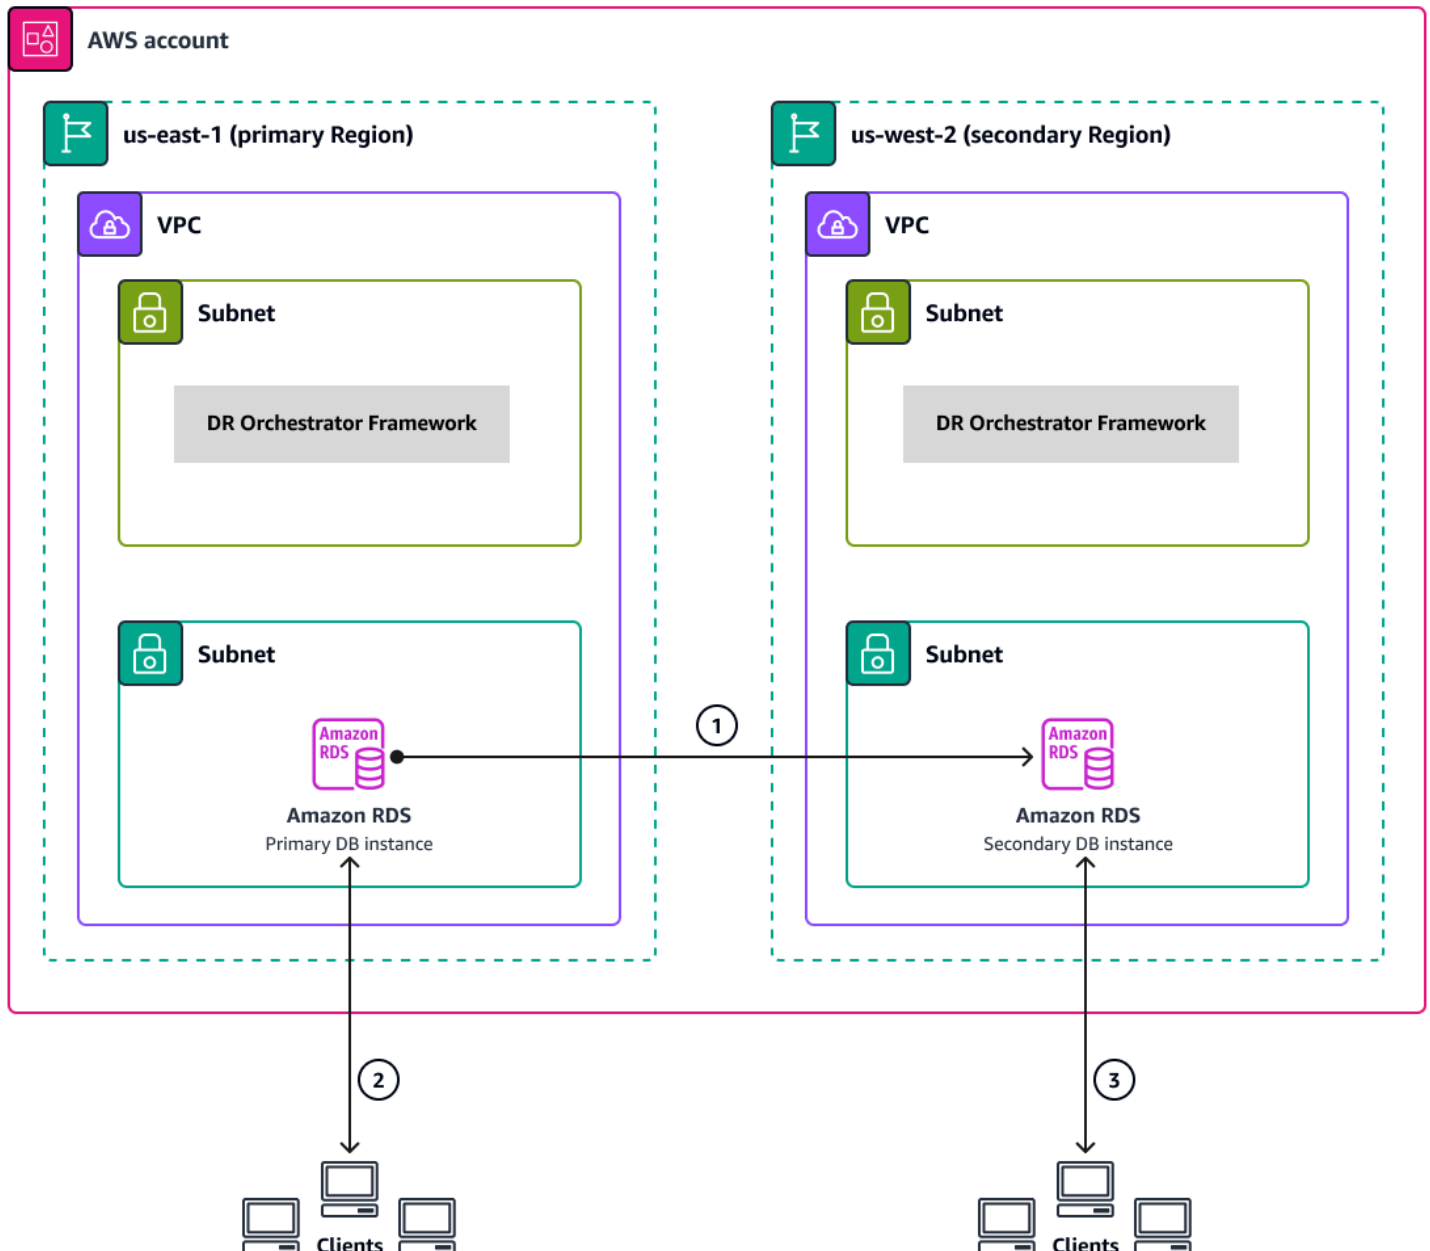

For more information, see [Supported ElastiCache for Redis versions](#).

## Architecture

### Amazon RDS architecture

The Amazon RDS architecture includes the following resources:

- The primary Amazon RDS DB instance created in the primary Region (us-east-1) with read/write access for clients
- An Amazon RDS read replica created in the secondary Region (us-west-2) with read-only access for clients
- DR Orchestrator Framework deployed in both the primary and secondary Regions

The diagram shows the following:

1. Asynchronous replication between the primary instance and the secondary instance
2. Read/write access for clients in the primary Region
3. Read-only access for clients in the secondary Region

## **Aurora architecture**

The Amazon Aurora architecture includes the following resources:

- The primary Aurora DB cluster created in the primary Region (us-east-1) with an active-writer endpoint
- An Aurora DB cluster created in the secondary Region (us-west-2) with an inactive-writer endpoint
- DR Orchestrator Framework deployed in both the primary and secondary Regions

The diagram shows the following:

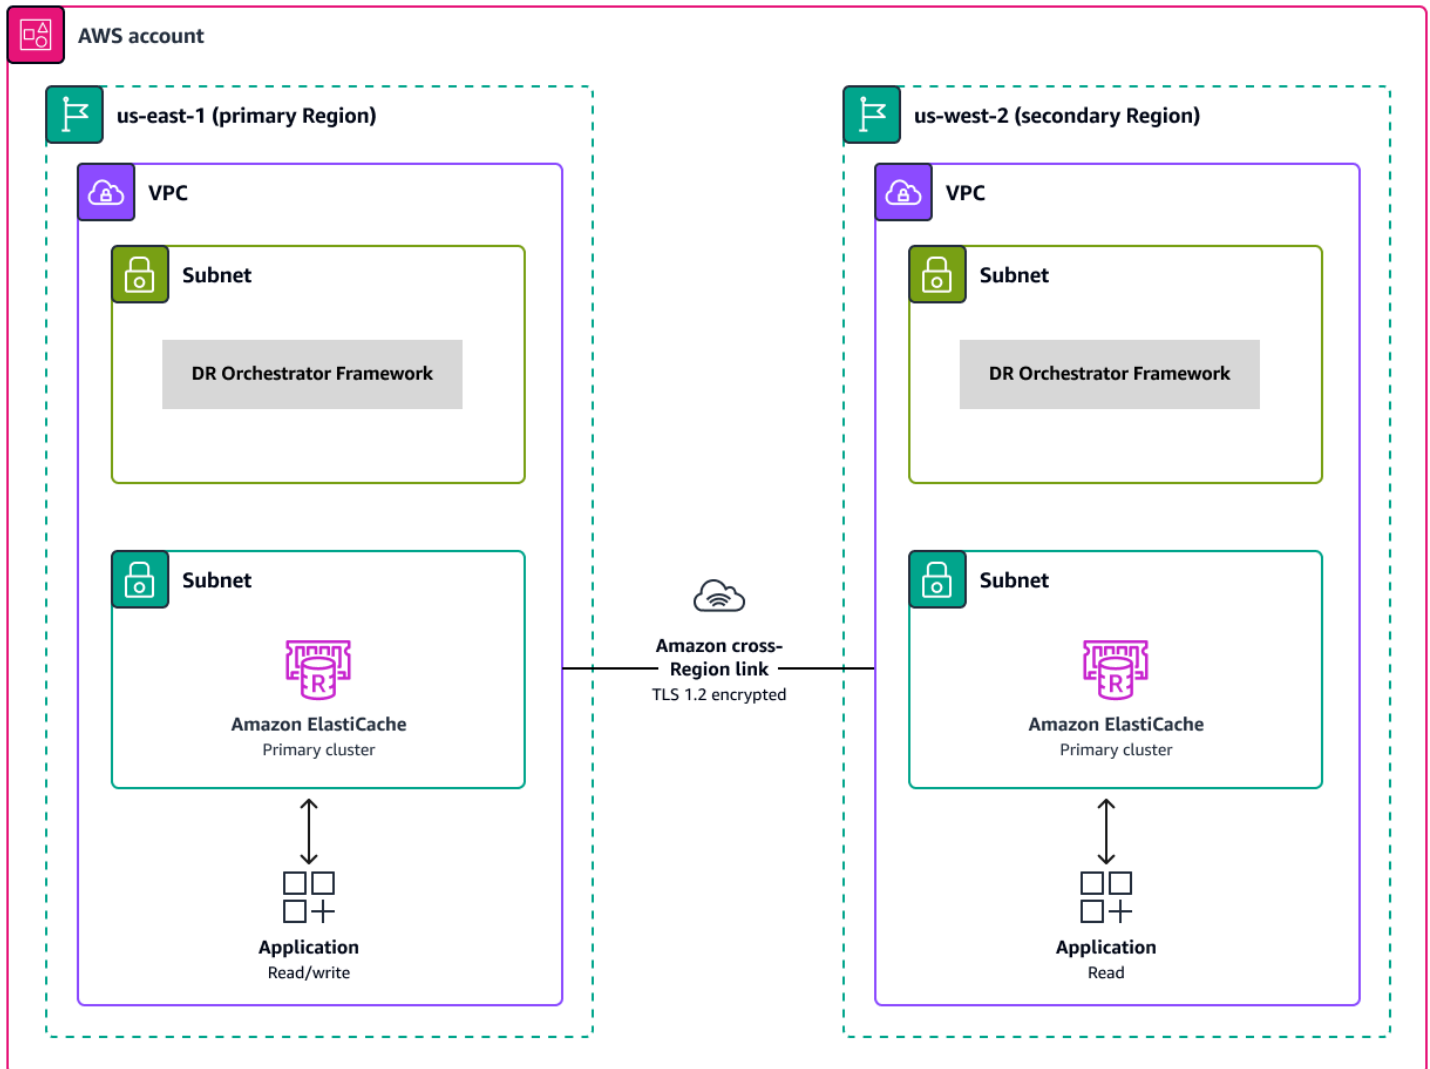

1. Asynchronous replication between the primary cluster and the secondary cluster
2. The primary DB cluster with an active-writer endpoint
3. The secondary DB cluster with an inactive-writer endpoint

### ElastiCache for Redis architecture

The Amazon ElastiCache for Redis architecture includes the following resources:

- An ElastiCache for Redis global datastore created with two clusters:

1. The primary cluster in the primary Region (us-east-1)
  2. The secondary cluster in the secondary Region (us-west-2)
- An Amazon cross-Region link with TLS 1.2 encryption between the two clusters
  - DR Orchestrator Framework deployed in both primary and secondary Regions

## Automation and scale

DR Orchestrator Framework is scalable and supports the failover or failback of more than one AWS database in parallel.

You can use the following payload code to fail over multiple AWS databases in your account. In this example, three AWS databases (two global databases such as Aurora MySQL-Compatible or Aurora PostgreSQL-Compatible, and one Amazon RDS for MySQL instance) fail over to the DR Region:

```
{
  "StatePayload": [
    {
      "layer": 1,
      "resources": [
        {
          "resourceType": "PlannedFailoverAurora",
          "resourceName": "Switchover (planned failover) of Amazon Aurora global
databases (MySQL)",
          "parameters": {
            "GlobalClusterIdentifier": "!Import dr-globalddb-cluster-mysql-global-
identifier",
            "DBClusterIdentifier": "!Import dr-globalddb-cluster-mysql-cluster-
identifier"
          }
        },
        {
          "resourceType": "PlannedFailoverAurora",
          "resourceName": "Switchover (planned failover) of Amazon Aurora global
databases (PostgreSQL)",
          "parameters": {
            "GlobalClusterIdentifier": "!Import dr-globalddb-cluster-postgres-global-
identifier",
            "DBClusterIdentifier": "!Import dr-globalddb-cluster-postgres-cluster-
identifier"
          }
        },
        {
          "resourceType": "PromoteRDSReadReplica",
          "resourceName": "Promote RDS for MySQL Read Replica",
          "parameters": {
            "RDSInstanceIdentifier": "!Import rds-mysql-instance-identifier",
            "TargetClusterIdentifier": "!Import rds-mysql-instance-global-arn"
          }
        }
      ]
    }
  ]
}
```

## Tools

### AWS services

- [Amazon Aurora](#) is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- [Amazon ElastiCache](#) helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud. This pattern uses Amazon ElastiCache for Redis.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, Lambda functions are used by AWS Step Functions to perform the steps.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern supports Amazon RDS for MySQL, Amazon RDS for PostgreSQL, and Amazon RDS for MariaDB.
- [AWS SDK for Python \(Boto3\)](#) helps you integrate your Python application, library, or script with AWS services. In this pattern, Boto3 APIs are used to communicate with the database instances or global databases.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications. In this pattern, Step Functions state machines are used to orchestrate and run the cross-Region failover and failback of the database instances or global databases.

## Code repository

The code for this pattern is available in the [aws-cross-region-dr-databases](#) repository on GitHub.

## Epics

### Install DR Orchestrator Framework

Task	Description	Skills required
Clone the GitHub repository.	To clone the repository, run the following command: <pre>git clone https://github.com/aws-samples/aws-cross-region-dr-databases.git</pre>	AWS DevOps, AWS administrator

Task	Description	Skills required
Package Lambda functions code in a .zip file archive.	<p>Create the archive files for Lambda functions to include the DR Orchestrator Framework dependencies:</p> <pre>cd &lt;YOUR-LOCAL-GIT-FOLDER&gt;/DR-Orchestration-artifacts  bash scripts/deploy-orchestrator-sh.sh</pre>	AWS administrator
Create S3 buckets.	<p>S3 buckets are needed to store DR Orchestrator Framework along with your latest configuration. Create two S3 buckets, one in the primary Region (us-east-1), and one in the secondary Region (us-west-2):</p> <ul style="list-style-type: none"><li>• dr-orchestrator-xxxx-us-east-1</li><li>• dr-orchestrator-xxxx-us-west-2</li></ul> <p>Replace xxxxxx with a random value to make the bucket names unique.</p>	AWS administrator

Task	Description	Skills required
Create subnets and security groups.	<p>In both the primary Region (us-east-1 ) and the secondary Region (us-west-2 ), create two subnets and one security group for Lambda function deployment in your VPC:</p> <ul style="list-style-type: none"><li>• subnet-XXXXXXX</li><li>• subnet-YYYYYYY</li><li>• sg-XXXXXXXXXXXXX</li></ul>	AWS administrator

Task	Description	Skills required
Update the DR Orchestrator parameter files.	<p>In the &lt;YOUR-LOCAL-GIT-FOLDER&gt;/DR-Orchestration-artifacts/cloudformation folder, update the following DR Orchestrator parameter files:</p> <ul style="list-style-type: none"><li>• Orchestrator-Deployer-parameters-us-east-1.json</li><li>• Orchestrator-Deployer-parameters-us-west-2.json</li></ul> <p>Use the following parameter values, replacing x and y with the names of your resources:</p> <pre>[   {     "ParameterKey": "TemplateStoreS3BucketName",     "ParameterValue": "dr-orchestrator-xxxxxx-us-east-1"   },   {     "ParameterKey": "TemplateVPCId",     "ParameterValue": "vpc-xxxxxx"   } ]</pre>	AWS administrator

Task	Description	Skills required
	<pre>        "ParameterKey":         "TemplateLambdaSub netID1",         "Paramete rValue": "subnet-x xxxxx"     },     {         "ParameterKey":         "TemplateLambdaSub netID2",         "Paramete rValue": "subnet-y yyyyy"     },     {         "ParameterKey":         "TemplateLambdaSec urityGroupID",         "Paramete rValue": "sg-xxxxx xxxxx"     } }</pre>	

Task	Description	Skills required
Upload the DR Orchestrator Framework code to the S3 bucket.	<p>The code will be safer in an S3 bucket than in the local directory. Upload the DR-Orchestration-artifacts directory, including all files and subfolders, to the S3 buckets.</p> <p>To upload the code, do the following:</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console.</li><li>2. Navigate to the Amazon S3 console.</li><li>3. Select the dr-orchestrator-xxxxxx-us-east-1 bucket.</li><li>4. Choose <b>Upload</b>, and then choose <b>Add folder</b>.</li><li>5. Select the DR-Orchestration-artifacts folder.</li><li>6. Choose <b>Upload</b>.</li><li>7. Select the dr-orchestrator-xxxxxx-us-west-2 bucket.</li><li>8. Repeat steps 4–7.</li></ol>	AWS administrator

Task	Description	Skills required
Deploy DR Orchestrator Framework in the primary Region.	<p>To deploy DR Orchestrator Framework in the primary Region (us-east-1 ), run the following commands:</p> <pre>cd &lt;YOUR-LOCAL-GIT-FOLDER&gt;/DR-Orchestration-artifacts/cloudformation  aws cloudformation   deploy \   --region us-east-1 \   --stack-name dr-orchestrator \   --template-file   Orchestrator-Deployer.yaml \   --parameter-overrides   file://Orchestrator-Deployer-parameters-us-east-1.json \   --capabilities   CAPABILITY_AUTO_EXPAND CAPABILITY_NAMED_IAM CAPABILITY_IAM \   --disable-rollback</pre>	AWS administrator

Task	Description	Skills required
Deploy DR Orchestrator Framework in the secondary Region.	<p>In the secondary Region (us-west-2 ), run the following commands:</p> <pre>cd &lt;YOUR-LOCAL-GIT-FOLDER&gt;/DR-Orchestration-artifacts/cloudformation  aws cloudformation   deploy \   --region us-west-2 \   --stack-name dr-orchestrator \   --template-file   Orchestrator-Deployer.yaml \   --parameter-overrides   file://Orchestrator-Deployer-parameters-us-west-2.json \   --capabilities   CAPABILITY_AUTO_EXPAND CAPABILITY_NAMED_IAM CAPABILITY_IAM \   --disable-rollback</pre>	AWS administrator

Task	Description	Skills required
Verify the deployment.	<p>If the AWS CloudFormation command runs successfully, it returns the following output:</p> <pre>Successfully created/ updated stack - dr- orchestrator</pre> <p>Alternatively, you can navigate to the AWS CloudFormation console and verify the status of the <code>dr-orchestrator</code> stack.</p>	AWS administrator

## Create the database instances or clusters

Task	Description	Skills required
Create the database subnets and security groups.	<p>In your VPC, create two subnets and one security group for the DB instance or global database in both the primary (<code>us-east-1</code>) and the secondary (<code>us-west-2</code>) Regions:</p> <ul style="list-style-type: none"> <li><code>subnet-XXXXXX</code></li> <li><code>subnet-XXXXXX</code></li> <li><code>sg-XXXXXXXXXX</code></li> </ul>	AWS administrator
Update the parameter file for the primary DB instance or cluster.	In the <code>&lt;YOUR_LOCAL_GIT_FOLDER&gt;/App-Stack</code> folder, update the parameter file for the primary Region.	AWS administrator

Task	Description	Skills required
	<p><b>Amazon RDS</b></p> <p>In the <code>RDS-MySQL-parameter-us-east-1.json</code> file, update <code>SubnetIds</code> and <code>DBSecurityGroup</code> with the names of resources that you created:</p> <pre data-bbox="597 604 1026 1558"> {   "Parameters": {     "SubnetIds":       "subnet-xxxxxx, subnet-xxxxxx",     "DBSecurityGroup":       "sg-xxxxxxxx",     "MySQLGlobalIdentifier": "rds-mysql-instance",     "InitialDatabaseName": "mysql",     "DBPortNumber":       "3789",     "PrimaryRegion":       "us-east-1",     "SecondaryRegion":       "us-west-2",     "KMSKeyAliasName":       "rds/rds-mysql-instance-KmsKeyId"   } } </pre> <p><b>Amazon Aurora</b></p> <p>In the <code>Aurora-MySQL-parameter-us-east-1.json</code> file, update <code>SubnetIds</code> and <code>DBSecurityGroup</code></p>	

Task	Description	Skills required
	<p>yGroup with the names of resources that you created:</p> <pre data-bbox="597 331 1026 1562"> {   "Parameters": {     "SubnetIds":       "subnet1-xxxxxx,su       bnet2-xxxxxx",     "DBSecurityGroup":       "sg-xxxxxxxxxx",     "GlobalClusterIden       tifier":"dr-globaldb-       cluster-mysql",     "DBClusterName":"d       bcluster-01",     "SourceDBClusterNa       me":"dbcluster-02",     "DBPortNumber":       "3787",     "DBInstanceClass":       "db.r5.large",     "InitialDatabaseNa       me": "sampledb",     "PrimaryRegion":       "us-east-1",     "SecondaryRegion":       "us-west-2",     "KMSKeyAliasName":       "rds/dr-globaldb-c       luster-mysql-KmsKe       yId"   } } </pre> <p><b>Amazon ElastiCache for Redis</b></p> <p>In the ElastiCache-parameter-us-east-1.json file, update</p>	

Task	Description	Skills required
	<p>SubnetIds and DBSecurityGroup with the names of resources that you created.</p> <pre data-bbox="597 380 1029 1772">{   "Parameters": {     "CacheNodeType":     "cache.m5.large",     "DBSecurityGroup":     "sg-xxxxxxxx",     "SubnetIds":     "subnet-xxxxxx, subnet-xxxxxx",     "EngineVersion":     "5.0.6",     "GlobalReplicationGroupIdSuffix": "demo-redis-global-datastore",     "NumReplicas": "1",     "NumShards": "1",     "ReplicationGroupId": "demo-redis-cluster",     "DBPortNumber":     "3788",     "TransitEncryption": "true",     "KMSKeyAliasName":     "elasticache/demo-redis-global-datastore-kmskeyid",     "PrimaryRegion":     "us-east-1",     "SecondaryRegion":     "us-west-2"   } }</pre>	

Task	Description	Skills required
Deploy your DB instance or cluster in the primary Region.	<p>To deploy your instance or cluster in the primary Region (us-east-1 ), run the following commands based on your database engine.</p> <p><b>Amazon RDS</b></p> <pre>cd &lt;YOUR-LOCAL-GIT-FOLDER&gt;/App-Stack  aws cloudformation   deploy \   --region us-east-1 \   --stack-name rds-mysql   -app-stack \   --template-file RDS-MySQL-Primary.yaml \   --parameter-overrides     file://RDS-MySQL-parameter-us-east-1.json \   --capabilities     CAPABILITY_AUTO_EXPAND CAPABILITY_IAM \   --disable-rollback</pre> <p><b>Amazon Aurora</b></p> <pre>cd &lt;YOUR-LOCAL-GIT-FOLDER&gt;/App-Stack  aws cloudformation   deploy \   --region us-east-1 \   --stack-name aurora-mysql-app-stack \</pre>	AWS administrator

Task	Description	Skills required
	<pre> --template-file Aurora-MySQL-Primary.yaml \ --parameter-overrides   file://Aurora-MySQL-parameter-us-east-1.json \ --capabilities   CAPABILITY_AUTO_EX   PAND_CAPABILIT   Y_NAMED_IAM CAPABILIT   Y_IAM \ --disable-rollback </pre> <p><b>Amazon ElastiCache for Redis</b></p> <pre> cd &lt;YOUR-LOCAL-GIT-FOLDER&gt;/App-Stack  aws cloudformation   deploy \ --region us-east-1 -- stack-name elasticac he-ds-app-stack \ --template-file   ElastiCache-Primar y.yaml \ --parameter-overrides   file://ElastiCache -parameter-us-east -1.json \ --capabilities   CAPABILITY_AUTO_EX   PAND_CAPABILIT   Y_NAMED_IAM CAPABILIT   Y_IAM \ --disable-rollback </pre>	

Task	Description	Skills required
	Verify that the AWS CloudFormation resources deployed successfully.	

Task	Description	Skills required
Update the parameter file for the secondary DB instance or cluster.	<p>In the &lt;YOUR LOCAL GIT FOLDER&gt;/App-Stack folder, update the parameter file for the secondary Region.</p> <p><b>Amazon RDS</b></p> <p>In the RDS-MySQL-parameter-us-west-2.json file, update SubnetIDs and DBSecurityGroup with the names of resources that you created. Update the PrimaryRegionKMSKeyArn with the value of MySQLKmsKeyId taken from the <b>Outputs</b> section of the AWS CloudFormation stack for the primary DB instance:</p> <pre data-bbox="594 1182 1027 1829">{   "Parameters": {     "SubnetIds":       "subnet-aaaaaaaa,       subnet-bbbbbbbb",     "DBSecurityGroup":       "sg-cccccccc",     "MySQLGlobalIdentifier": "rds-mysql-instance",     "InitialDatabaseName": "mysqldb",     "DBPortNumber":       "3789",     "PrimaryRegion":       "us-east-1",</pre>	AWS administrator

Task	Description	Skills required
	<pre> "SecondaryRegion": "us-west-2", "KMSKeyAliasName": "rds/ids-mysql-ins tance-KmsKeyId", "PrimaryRegionKMSK eyArn": "arn:aws:km s:us-east-1:xxxxxx xxx:key/mrk-xxxxxx xxxxxxxxxxxxxxxx" } } </pre> <p><b>Amazon Aurora</b></p> <p>In the <code>Aurora-MySQL-parameter-us-west-2.json</code> file, update <code>SubnetIDs</code> and <code>DBSecurityGroup</code> with the names of resources you created. # Automate the replication of Amazon RDS instances across AWS accounts

Created by Parag Nagwekar (AWS) and Arun Chandapillai (AWS)

**Environment:** Production

**Technologies:** Databases; DevOps; Serverless; Infrastructure

**Workload:** All other workloads

**AWS services:** AWS Lambda; Amazon RDS; AWS SDK for Python (Boto3); AWS Step Functions; Amazon SNS

## Summary

This pattern shows you how to automate the process of replicating, tracking, and rolling back your Amazon Relational Database Service (Amazon RDS) DB instances across different AWS accounts by using AWS Step Functions and AWS Lambda. You can use this automation to perform large-scale replication of RDS DB instances without any performance impact or operational overhead—regardless of the size of your organization. You can also use this pattern to help your organization comply with mandatory data governance strategies or compliance requirements that call for your data to be replicated and redundant across different AWS accounts and AWS Regions. Cross-account replication of Amazon RDS data at scale is an inefficient and error-prone manual process that can be costly and time-consuming, but the automation in this pattern can help you achieve cross-account replication safely, effectively, and efficiently.

## Prerequisites and limitations

### Prerequisites

- Two AWS accounts
- An RDS DB instance, up and running in the source AWS account
- A subnet group for the RDS DB instance in the destination AWS account

- An AWS Key Management Service (AWS KMS) key created in the source AWS account and shared with the destination account (For more information about policy details, see the *Additional information* section of this pattern.)
- An AWS KMS key in the destination AWS account to encrypt the database in the destination account

### Product versions

- Python 3.9 (using AWS Lambda)
- PostgreSQL 11.3, 13.x, and 14.x

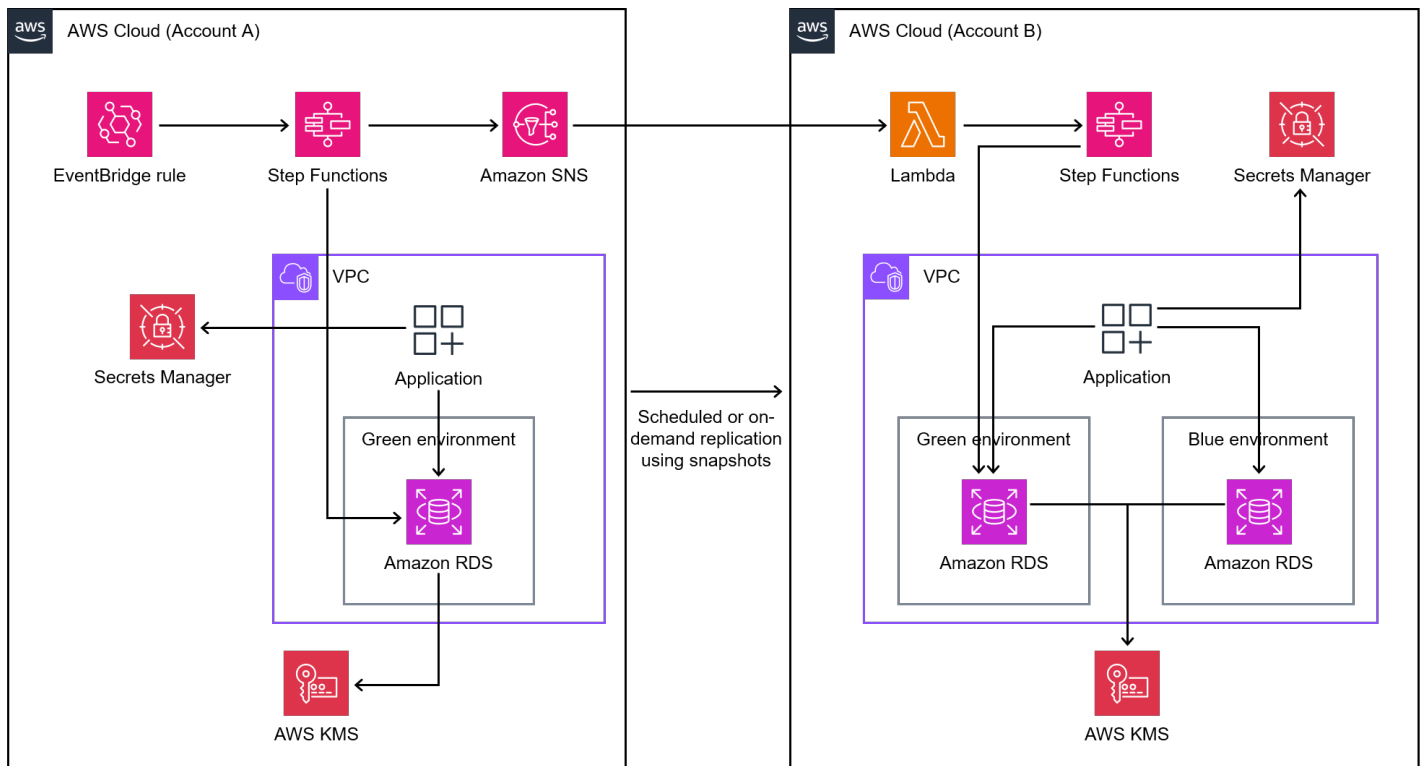

## Architecture

### Technology stack

- Amazon Relational Database Service (Amazon RDS)
- Amazon Simple Notification Service (Amazon SNS)
- AWS Key Management Service (AWS KMS)
- AWS Lambda
- AWS Secrets Manager
- AWS Step Functions

### Target architecture

The following diagram shows an architecture for using Step Functions to orchestrate scheduled, on-demand replication of RDS DB instances from a source account (account A) to a destination account (account B).

In the source account (account A in the diagram), the Step Functions state machine performs the following:

1. Creates a snapshot from the RDS DB instance in account A.
2. Copies and encrypts the snapshot with an AWS KMS key from account A. To ensure encryption in transit, the snapshot is encrypted whether or not the DB instance is encrypted.
3. Shares the DB snapshot with account B by giving account B access to the snapshot.
4. Pushes a notification to the SNS topic, and then the SNS topic invokes the Lambda function in account B.

In the destination account (account B in the diagram), the Lambda function runs the Step Functions state machine to orchestrate the following:

1. Copies the shared snapshot from account A to account B, while using the AWS KMS key from account A to decrypt the data first and then encrypt the data by using the AWS KMS key in account B.
2. Reads the secret from Secrets Manager to capture the name of the current DB instance.
3. Restores the DB instance from the snapshot with a new name and default AWS KMS key for Amazon RDS.

4. Reads the endpoint of the new database and updates the secret in Secrets Manager with the new database endpoint, and then tags the previous DB instance so that it can be deleted later.
5. Keeps the latest N instances of the databases and deletes all the other instances.

## Tools

### AWS tools

- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS SDK for Python \(Boto3\)](#) is a software development kit that helps you integrate your Python application, library, or script with AWS services.
- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications.

### Code

The code for this pattern is available in the GitHub [Crossaccount RDS Replication](#) repository.

## Epics

### Automate the replication of RDS DB instances across AWS accounts with a single click

Task	Description	Skills required
Deploy the CloudFormation stack in the source account.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console for the source account (account A) and open the <a href="#">CloudFormation console</a>.</li><li>2. In the navigation pane, choose <b>Stacks</b>.</li><li>3. Choose <b>Create stack</b>, and then choose <b>With existing resources (import resources)</b>.</li><li>4. On the <b>Identify resources</b> page, choose <b>Next</b>.</li><li>5. On the <b>Specify template</b> page, select <b>Upload a template</b>.</li><li>6. Choose <b>Choose file</b>, select the Cloudformation-SourceAccountRDS.yaml file from the GitHub <a href="#">Crossaccount RDS Replication</a> repository, and then choose <b>Next</b>.</li><li>7. For <b>Stack name</b>, enter a name for your stack.</li><li>8. In the <b>Parameters</b> section, specify the parameters that are defined in the stack template:</li></ol>	Cloud administrator, Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• For <b>DestinationAccountNumber</b>, enter the account number for your destination RDS DB instance.</li> <li>• For <b>KeyName</b>, enter your AWS KMS key.</li> <li>• For <b>ScheduleExpression</b>, enter a <a href="#">cron expression</a> (the default is <b>12:00 am daily</b>).</li> <li>• For <b>SourceDBIdentifier</b>, enter the name of the source database.</li> <li>• For <b>SourceDBSnapshotName</b>, enter the name of the snapshot or accept the default.</li> </ul> <p>9. Choose <b>Next</b>.</p> <p>10 On the <b>Configure stack options</b> page, leave the default values, and then choose <b>Next</b>.</p> <p>11 Review your stack configuration, and then choose <b>Submit</b>.</p> <p>12 Choose the <b>Resources</b> tab for your stack, and then note the Amazon Resource Name (ARN) of the SNS topic.</p>	

Task	Description	Skills required
Deploy the CloudFormation stack in the destination account.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console for the destination account (account B) and open the <a href="#">CloudFormation console</a>.</li><li>2. In the navigation pane, choose <b>Stacks</b>.</li><li>3. Choose <b>Create stack</b>, and then choose <b>With existing resources (import resources)</b>.</li><li>4. On the <b>Identify resources</b> page, choose <b>Next</b>.</li><li>5. On the <b>Specify template</b> page, select <b>Upload a template</b>.</li><li>6. Choose <b>file</b>, select the <code>Cloudformation-DestinationAccountRDS.yaml</code> file from the GitHub <a href="#">Crossaccount RDS Replication</a> repository, and then choose <b>Next</b>.</li><li>7. For <b>Stack name</b>, enter a name for your stack.</li><li>8. In the <b>Parameters</b> section, specify the parameters that are defined in the stack template:<ul style="list-style-type: none"><li>• For <b>DatabaseName</b>, enter a name for your database.</li></ul></li></ol>	Cloud architect, DevOps engineer, Cloud administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• For <b>Engine</b>, enter the database engine type that matches the source database.</li> <li>• For <b>DBInstanceClass</b>, enter the preferred database instance type or accept the default.</li> <li>• For <b>Subnetgroups</b>, enter the existing VPC subnet group. For instructions about creating a subnet group, see <a href="#">Step 2: Create a DB subnet group</a> in the Amazon RDS User Guide.</li> <li>• For <b>SecretName</b>, enter the path and secret name, or accept the default.</li> <li>• For <b>SGID</b>, enter the security group ID of your destination cluster.</li> <li>• For <b>KMSKey</b>, enter the ARN of the KMS key in your destination account.</li> <li>• For <b>NoOfOlderInstances</b>, enter the number of old copies of the RDS DB instances that you want to keep for the rollback.</li> </ul> <p>9. Choose <b>Next</b>.</p> <p>10 On the <b>Configure stack options</b> page, leave the</p>	

Task	Description	Skills required
	<p>default values, and then choose <b>Next</b>.</p> <p>11 Review your stack configuration, and then choose <b>Submit</b>.</p> <p>12 Choose the <b>Resources</b> tab for your stack, and then note the Physical ID and ARN of <code>InvokeStepFunction</code>.</p>	
<p>Verify the creation of the RDS DB instance in the destination account.</p>	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the <a href="#">Amazon RDS console</a>.</li> <li>2. In the navigation pane, choose <b>Databases</b>, and then verify that the new RDS DB instance appears under the new cluster.</li> </ol>	<p>Cloud administrator, Cloud architect, DevOps engineer</p>

Task	Description	Skills required
Subscribe the Lambda function to the SNS topic.	<p>You must run the following AWS Command Line Interface (AWS CLI) commands to subscribe the Lambda function in the destination account (account B) to the SNS topic in the source account (account A).</p> <p>In account A, run following command:</p> <pre>aws sns add-permission \   --label lambda-access \   --aws-account-id \   &lt;DestinationAccount&gt; \   --topic-arn &lt;Arn of \   SNSTopic &gt; \   --action-name Subscribe \   ListSubscriptionsByTopic</pre> <p>In account B, run following command:</p> <pre>aws lambda add-permission \   --function-name &lt;Name \   of InvokeStepFunction \   &gt; \   --source-arn &lt;Arn of \   SNSTopic &gt; \   --statement-id \   function-with-sns \   --action lambda:InvokeFunction \</pre>	Cloud administrator, Cloud architect, DBA

Task	Description	Skills required
	<pre data-bbox="597 205 1026 306">--principal sns.amazo naws.com</pre> <p data-bbox="597 344 1026 424">In account B, run following command:</p> <pre data-bbox="597 462 1026 781">aws sns subscribe \ --protocol "lambda" \ --topic-arn &lt;Arn of SNSTopic&gt; \ --notification-e ndpoint &lt;Arn of InvokeStepFunction&gt;</pre>	

Task	Description	Skills required
Sync the RDS DB instance from the source account with the destination account.	<p>Initiate the on-demand database replication by starting the Step Functions state machine in the source account.</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Step Functions console</a>.</li><li>2. In the navigation pane, choose <b>State machines</b>.</li><li>3. Choose your state machine.</li><li>4. On the <b>Executions</b> tab, select your function, and then choose <b>Start execution</b> to start the workflow.</li></ol> <p><b>Note:</b> A scheduler is in place to help you run the replication automatically on schedule, but the scheduler is turned off by default. You can find the name of the Amazon CloudWatch rule for the scheduler in the <b>Resources</b> tab of the CloudFormation stack in the destination account. For instructions on how to modify the CloudWatch Events rule, see <a href="#">Deleting or Disabling a CloudWatch Events Rule</a> in the CloudWatch User Guide.</p>	Cloud architect, DevOps engineer, Cloud administrator

Task	Description	Skills required
Roll back your database to any of the previous copies when needed.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Secrets Manager console</a>.</li><li>2. From the list of secrets, choose the secret that you created by using the CloudFormation template earlier. Your application uses the secret to access the database in the destination cluster.</li><li>3. To update the secret value from the details page, in the <b>Secret value</b> section, choose <b>Retrieve secret</b> value, and then choose <b>Edit</b>.</li><li>4. Enter the details of the database endpoint.</li></ol>	Cloud administrator, DBA, DevOps engineer

# Automatically back up SAP HANA databases using Systems Manager and EventBridge

Created by Ambarish Satarkar (AWS) and Gaurav Rath (AWS)

<b>Code repository:</b> <a href="#">HDB_Backup_SSM_Document</a>	<b>Environment:</b> Production	<b>Technologies:</b> Databases; Storage & backup
<b>Workload:</b> SAP	<b>AWS services:</b> Amazon EC2; Amazon EventBridge; Amazon S3; AWS Systems Manager	

## Summary

This pattern describes how to automate SAP HANA database backups using AWS Systems Manager, Amazon EventBridge, Amazon Simple Storage Service (Amazon S3), and AWS Backup Agent for SAP HANA.

This pattern provides a shell script-based approach using the `BACKUP DATA` command and removes the need to maintain scripts and job configurations for each operating system (OS) instance across numerous systems.

**Note:** As of April 2023, AWS Backup announced support for SAP HANA databases on Amazon Elastic Compute Cloud (Amazon EC2). For more information, see [SAP HANA databases on Amazon EC2 instances backup](#).

Based on your organization's needs, you can use the AWS Backup service to automatically back up your SAP HANA databases or you can use this pattern.

## Prerequisites and limitations

### Prerequisites

- An existing SAP HANA instance with a supported release in running state on a managed Amazon Elastic Compute Cloud (Amazon EC2) instance that is configured for Systems Manager

- Systems Manager Agent (SSM Agent) 2.3.274.0 or later installed
- An S3 bucket that doesn't have public access enabled
- An `hdbuserstore` key named `SYSTEM`
- An AWS Identity and Access Management (IAM) role for the Automation runbook to run on schedule
- `AmazonSSMManagedInstanceCore` and `ssm:StartAutomationExecution` policies are attached to Systems Manager Automation service role.

## Limitations

- AWS Backint Agent for SAP HANA doesn't support deduplication.
- AWS Backint Agent for SAP HANA doesn't support data compression.

## Product versions

AWS Backint Agent is supported on the following operating systems:

- SUSE Linux Enterprise Server
- SUSE Linux Enterprise Server for SAP
- Red Hat Enterprise Linux for SAP

AWS Backint Agent supports the following databases:

- SAP HANA 1.0 SP12 (single node and multiple nodes)
- SAP HANA 2.0 and later (single node and multiple nodes)

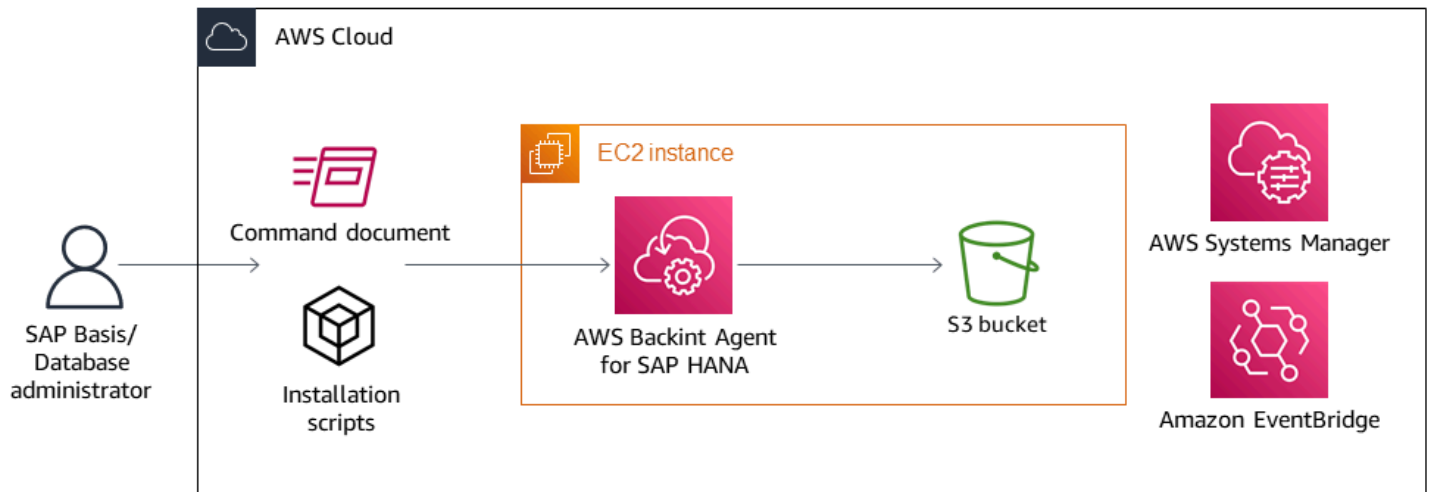

## Architecture

### Target technology stack

- AWS Backint Agent
- Amazon S3
- AWS Systems Manager
- Amazon EventBridge
- SAP HANA

## Target architecture

The following diagram shows the installation scripts that install AWS Backint Agent, the S3 bucket, and Systems Manager and EventBridge, which use a Command document to schedule regular backups.

## Automation and scale

- Multiple AWS Backint Agents can be installed by using a Systems Manager Automation runbook.
- Each run of the Systems Manager runbook can scale to  $n$  number of SAP HANA instances, based on target selection.
- EventBridge can automate SAP HANA backups.

## Tools

- [AWS Backint Agent for SAP HANA](#) is a standalone application that integrates with your existing workflows to back up your SAP HANA database to an S3 bucket that you specify in the configuration file. AWS Backint Agent supports full, incremental, and differential backups of SAP HANA databases. It runs on an SAP HANA database server, where backups and catalogs are transferred from the SAP HANA database to the AWS Backint Agent.
- [Amazon EventBridge](#) is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.

- [Amazon Simple Storage Service \(Amazon S3\)](#) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- [AWS Systems Manager](#) helps you to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources.

## Code

The code for this pattern is available in the [aws-backint-automated-backup](#) GitHub repository.

## Epics

### Create an hdbuserstore key SYSTEM

Task	Description	Skills required
Create an hdbuserstore key.	<ol style="list-style-type: none"> <li>1. Navigate to <code>/usr/sap/&lt;SID&gt;/HDB&lt;InstNo&gt;/exe</code>.</li> <li>2. Run the following command, with XX as the SAP HANA database instance number.</li> </ol> <pre>hdbuserstore -i set SYSTEM &lt;hostname&gt;:3XX13@SYSTEMDB SYSTEM</pre> <p>For example, for an SAP HANA host saphanadb with instance number 00, run the following command.</p> <pre>hdbuserstore -i set SYSTEM saphanadb</pre>	AWS administrator, SAP HANA Administrator

Task	Description	Skills required
	:30013@SYSTEMDB SYSTEM	

## Install AWS Backint Agent

Task	Description	Skills required
Install AWS Backint Agent.	Follow the instructions in <a href="#">Install and configure AWS Backint Agent for SAP HANA</a> in the AWS Backint Agent documentation.	AWS administrator, SAP HANA administrator

## Create the Systems Manager Command document

Task	Description	Skills required
Create the Systems Manager Command document.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the AWS Systems Manager Console.</li> <li>2. Choose <b>Documents</b>, and choose <b>Owned by me</b>.</li> <li>3. Confirm that you are in the same AWS Region as your SAP HANA database.</li> <li>4. Choose <b>Create document, Command or session</b> to create your document.</li> <li>5. Use a unique and descriptive name, with no spaces</li> </ol>	AWS administrator, SAP HANA administrator

Task	Description	Skills required
	<p>(for example, <b>SAP HANA-Backup</b>).</p> <ol style="list-style-type: none"> <li>6. Make sure that <b>Document type</b> is set to <b>Command document</b>.</li> <li>7. Under the <b>Content</b> header, there is some sample code. Make sure that you choose the <b>JSON</b> code type, and replace the code with the code from the HDB_Backup_SSM_Document.json file from the <a href="#">GitHub repository</a>.</li> <li>8. Choose <b>Create document</b>.</li> <li>9. Check your document in the <b>Owned by me</b> section.</li> </ol>	

### Schedule backups on a regular frequency

Task	Description	Skills required
Schedule regular backups using Amazon EventBridge.	<ol style="list-style-type: none"> <li>1. Open the Amazon EventBridge console, choose <b>Rules</b>, and choose <b>Create rule</b>.</li> <li>2. On the <b>Define rule detail</b> screen, enter a unique name and description for your rule, and use the default event bus.</li> </ol>	AWS administrator, SAP HANA administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. Under <b>Rule type</b>, choose <b>Schedule</b>, and choose <b>Next</b>.</li><li>4. On then <b>Define schedule</b> screen, choose the appropriate schedule pattern and cron or rate expression based on the required frequency.</li><li>5. On the <b>Select targets</b> screen, for <b>Target type</b>, choose <b>AWS service</b>. Under <b>Select a target</b>, choose <b>Systems Manager Run Command</b>.</li><li>6. Choose the document that you created earlier.</li><li>7. Under <b>Target key</b> and <b>Target value</b>, provide the instance ID. You can use tag names and tag values to add multiple instances.</li><li>8. Under <b>Configure automation parameters</b>, choose <b>Constant</b> for incremental or differential backups. If you want full backup, choose <b>No Parameters</b>.</li><li>9. Choose whether to create a new role or to use an existing role. If you use an existing role, make sure that it has the policies</li></ol>	

Task	Description	Skills required
	<p>required to invoke the target.</p> <p>10 Keep the default additional settings, and choose <b>Next</b>.</p> <p>11 The <b>Configure tags</b> screen is optional. Choose <b>next</b>.</p> <p>12 On the <b>Review and create</b> screen, review the rule settings, and choose <b>Create</b>. The rule should be successfully created.</p> <p>You can verify backup success from the S3 bucket path.</p> <pre>s3: /&lt;your_bucket_name&gt;/&lt;target folder&gt;/&lt;SID&gt;/usr/sap/&lt;SID&gt;/SYS/global/hdb/backupint/DB_&lt;SID&gt;/</pre> <p>You can also verify backups from the SAP HANA backup catalog.</p>

# Block public access to Amazon RDS by using Cloud Custodian

Created by *abhay kumar (AWS)* and *Dwarika Patra (AWS)*

**Environment:** Production

**Technologies:** Databases;  
Security, identity, compliance

**Workload:** All other  
workloads; Open-source

**AWS services:** Amazon RDS

## Summary

Many organizations run their workloads and services on multiple cloud vendors. In these hybrid cloud environments, the cloud infrastructure needs strict cloud governance, in addition to the security provided by the individual cloud providers. A cloud database such as Amazon Relational Database Service (Amazon RDS) is one important service that must be monitored for any access and permission vulnerabilities. Although you can restrict access to the Amazon RDS database by configuring a security group, you can add a second layer of protection to prohibit actions such as public access. Ensuring public access is blocked will help you with General Data Protection Regulation (GDPR), Health Insurance Portability and Accountability Act (HIPAA), National Institute of Standards and Technology (NIST), and Payment Card Industry Data Security Standard (PCI DSS) compliance.

Cloud Custodian is an open-source rules engine that you can use to enforce access restrictions for Amazon Web Services (AWS) resources such as Amazon RDS. With Cloud Custodian, you can set rules that validate the environment against defined security and compliance standards. You can use Cloud Custodian to manage your cloud environments by helping to ensure compliance with security policies, tag policies, and garbage collection of unused resources and cost management. With Cloud Custodian, you can use a single interface for implementing governance in a hybrid cloud environment. For example, you could use the Cloud Custodian interface to interact with AWS and Microsoft Azure, reducing the effort of working with mechanisms such as AWS Config, AWS security groups, and Azure policies.

This pattern provides instructions for using Cloud Custodian on AWS to enforce restriction of public accessibility on Amazon RDS instances.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [A key pair](#)
- AWS Lambda installed

## Architecture

### Target technology stack

- Amazon RDS
- AWS CloudTrail
- AWS Lambda
- Cloud Custodian

### Target architecture

The following diagram shows Cloud Custodian deploying the policy to Lambda, AWS CloudTrail initiating the `CreateDBInstance` event, and the Lambda function setting `PubliclyAccessible` to false on Amazon RDS.

## Tools

### AWS services

- [AWS CloudTrail](#) helps you audit the governance, compliance, and operational risk of your AWS account.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.

### Other tools

- [Cloud Custodian](#) unifies the tools and scripts that many organizations use to manage their public cloud accounts into one open source tool. It uses a stateless rules engine for policy definition and

enforcement, with metrics, structured outputs, and detailed reporting for cloud infrastructure. It integrates tightly with a serverless runtime to provide real-time remediation and response with low operational overhead.

## Epics

### Set up AWS CLI

Task	Description	Skills required
Install AWS CLI.	To install AWS CLI, follow the instructions in the <a href="#">AWS documentation</a> .	AWS administrator
Set up AWS credentials.	<p>Configure the settings that the AWS CLI uses to interact with AWS, including the AWS Region and the output format that you want to use.</p> <pre>\$&gt;aws configure AWS Access Key ID [None]: &lt;your_access_key_id&gt; AWS Secret Access Key [None]: &lt;your_secret_access_key&gt; Default region name [None]: Default output format [None]:</pre> <p>For more information, see the <a href="#">AWS documentation</a>.</p>	AWS administrator
Create an IAM role.	To create an IAM role with the Lambda execution role, run the following command.	AWS DevOps

Task	Description	Skills required
	<pre>aws iam create-role -- role-name lambda-ex -- assume-role-policy- document '{"Version": "2012-10-17", "Stat ement": [{ "Effect": "Allow", "Principal": {"Service": "lambda.a mazonaws.com"}, "Action": "sts:Assu meRole"}]}'</pre>	

## Set up Cloud Custodian

Task	Description	Skills required
Install Cloud Custodian.	To install Cloud Custodian for your operating system and environment, follow the instructions in the <a href="#">Cloud Custodian documentation</a> .	DevOps engineer
Check the Cloud Custodian schema.	To see the complete list of Amazon RDS resources against which you can run policies, use the following command. <pre>custodian schema aws.rds</pre>	DevOps engineer
Create the Cloud Custodian policy.	Save the code that's under <i>Cloud Custodian policy file</i> in the <i>Additional information</i> section using a YAML extension.	DevOps engineer

Task	Description	Skills required
Define Cloud Custodian actions to change the publicly accessible flag.	<ol style="list-style-type: none"> <li>1. Locate the custodian code (for example, <code>/Users/abcd/custodian/lib/python3.9/site-packages/c7n/resources/rds.py</code> ).</li> <li>2. Locate the <code>RDSSetPublicAvailability</code> class in <code>rds.py</code>, and modify this class by using the code that's under <code>c7n/resources/rds.py</code> file in the <i>Additional information</i> section.</li> </ol>	DevOps engineer
Perform a dry run.	<p>(Optional) To check which resources are identified by the policy without running any actions on the resources, use the following command.</p> <pre>custodian run -dryrun &lt;policy_name&gt;.yaml -s &lt;output_directory&gt;</pre>	DevOps engineer

## Deploy the policy

Task	Description	Skills required
Deploy the policy by using Lambda.	To create the Lambda function that will run the policy, use the following command.	DevOps engineer

Task	Description	Skills required
	<pre>custodian run -s policy.yaml</pre> <p>This policy will then be initiated by the AWS CloudTrail CreateDBInstance event.</p> <p>As a result, AWS Lambda will set the publicly accessible flag to false for instances that match the criteria.</p>	

## Related resources

## Additional information

### Cloud Custodian policy YAML file

```
policies:  
  - name: "block-public-access"  
    resource: rds  
    description: |  
      This Enforcement blocks public access for RDS instances.  
    mode:  
      type: cloudtrail  
    events:  
      - event: CreateDBInstance # Create RDS instance cloudtrail event  
        source: rds.amazonaws.com  
        ids: requestParameters.dbInstanceIdentifier  
        role: arn:aws:iam::1234567890:role/Custodian-compliance-role  
    filters:
```

```
- type: event
  key: 'detail.requestParameters.publiclyAccessible'
  value: true
actions:
- type: set-public-access
  state: false
```

## c7n resources rds.py file

```
@actions.register('set-public-access')
class RDSSetPublicAvailability(BaseAction):

    schema = type_schema(
        "set-public-access",
        state={'type': 'boolean'})
    permissions = ('rds:ModifyDBInstance',)

    def set_accessibility(self, r):
        client = local_session(self.manager.session_factory).client('rds')
        waiter = client.get_waiter('db_instance_available')
        waiter.wait(DBInstanceIdentifier=r['DBInstanceIdentifier'])
        client.modify_db_instance(
            DBInstanceIdentifier=r['DBInstanceIdentifier'],
            PubliclyAccessible=self.data.get('state', False))

    def process(self, rds):
        with self.executor_factory(max_workers=2) as w:
            futures = {w.submit(self.set_accessibility, r): r for r in rds}
            for f in as_completed(futures):
                if f.exception():
                    self.log.error(
                        "Exception setting public access on %s \n %s",
                        futures[f]['DBInstanceIdentifier'], f.exception())

        return rds
```

## Security Hub integration

Cloud Custodian can be integrated with [AWS Security Hub](#) to send security findings and attempt remediation actions. For more information, see [Announcing Cloud Custodian Integration with AWS Security Hub](#).

# Configure read-only routing in an Always On availability group in SQL Server on AWS

Created by Subhani Shaik (AWS)

**Environment:** PoC or pilot

**Technologies:** Databases; Infrastructure

**Workload:** Microsoft

**AWS services:** AWS Managed Microsoft AD; Amazon EC2

## Summary

This pattern covers how to use the standby secondary replica in SQL Server Always On by offloading the read-only workloads from the primary replica to the secondary replica.

Database mirroring has one-to-one mapping. You can't read the secondary database directly, so you must create snapshots. The Always On availability group feature was introduced in Microsoft SQL Server 2012. In later versions, major functionalities have been introduced, including read-only routing. In Always On availability groups, you can read the data directly from the secondary replica by changing the replica mode to read-only.

The Always On availability groups solution supports high availability (HA), disaster recovery (DR), and an alternative to database mirroring. Always On availability groups work at the database level and maximize the availability of a set of user databases.

SQL Server uses the read-only routing mechanism to redirect the incoming read-only connections to the secondary read replica. To achieve this, you should add the following parameters and values in the connection string:

- `ApplicationIntent=ReadOnly`
- `Initial Catalog=<database name>`

## Prerequisites and limitations

### Prerequisites

- An active AWS account with a virtual private cloud (VPC), two Availability Zones, private subnets, and a security group
- Two Amazon Elastic Compute Cloud (Amazon EC2) machines with [SQL Server 2019 Enterprise Edition Amazon Machine Image](#) with [Windows Server Failover Clustering \(WSFC\)](#) configured at the instance level and an Always On availability group configured at the SQL Server level between the primary node (WSFCNODE1) and the secondary node (WSFCNODE2), which are part of the AWS Directory Service for Microsoft Active Directory directory named tagedtalk.com
- One or more nodes configured to accept read-only in the secondary replica
- A listener named SQLAG1 for the Always On availability group
- SQL Server Database Engine running with the same service account on two nodes
- SQL Server Management Studio (SSMS)
- A test database named test

## Product Versions

- SQL Server 2014 and later

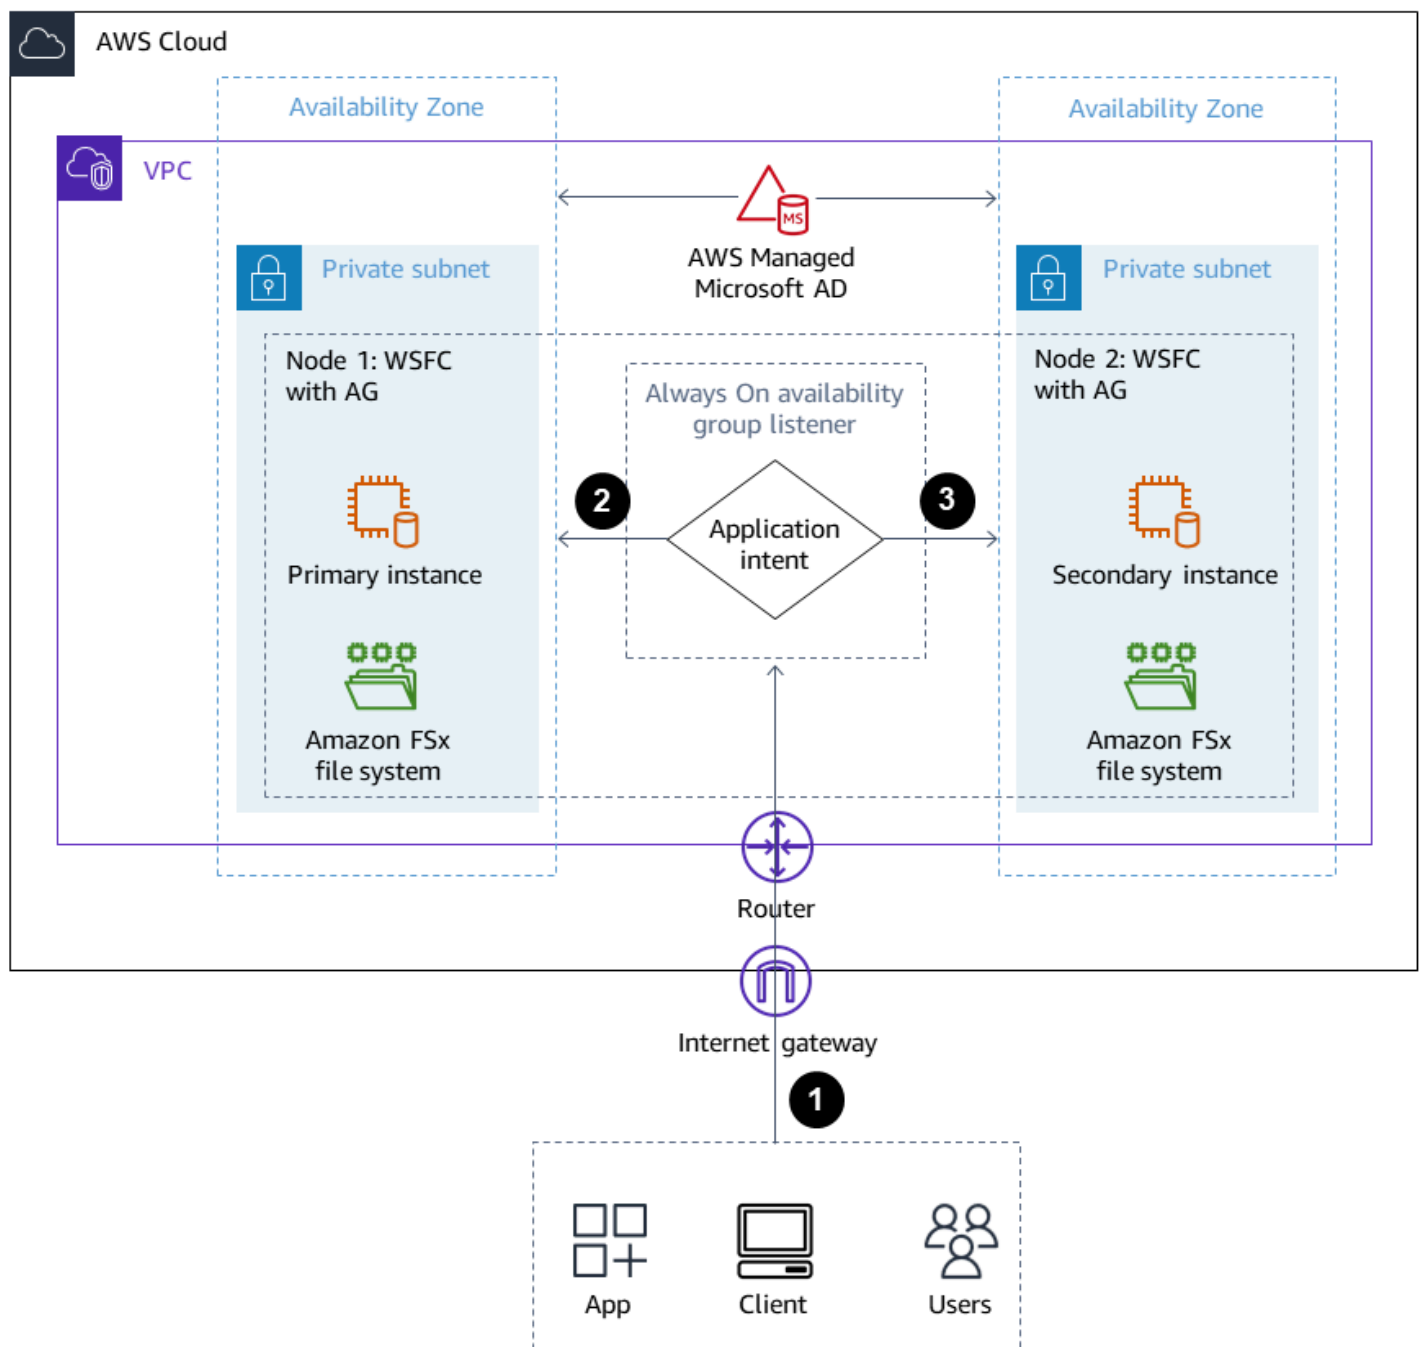

## Architecture

### Target technology stack

- Amazon EC2
- AWS Managed Microsoft AD
- Amazon FSx

### Target architecture

The following diagram shows how the Always On availability group (AG) listener redirects queries that contain the `ApplicationIntent` parameter in the connection to the appropriate secondary node.

1. A request is sent to the Always On availability group listener.
2. If the connection string does not have the `ApplicationIntent` parameter, the request is sent to the primary instance.
3. If the connection string contains `ApplicationIntent=ReadOnly`, the request is sent to the secondary instance with read-only routing configuration, which is WSFC with an Always On availability group.

## Tools

### AWS services

- [AWS Directory Service for Microsoft Active Directory](#) enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon FSx](#) provides file systems that support industry-standard connectivity protocols and offer high availability and replication across AWS Regions.

### Other services

- SQL Server Management Studio (SSMS) is a tool for connecting, managing, and administering the SQL Server instances.
- sqlcmd is a command-line utility.

## Best practices

For more information about Always On availability groups, see the [SQL Server documentation](#).

## Epics

### Set up read-only routing

Task	Description	Skills required
Update the replicas to read-only.	To update both the primary and the secondary replica to read-only, connect to the primary replica from SSMS, and run the <i>Step 1</i> code from the <i>Additional information</i> section.	DBA
Create the routing URL.	To create routing URL for both replicas, run the <i>Step</i>	DBA

Task	Description	Skills required
	2 code from the <i>Additional information</i> section. In this code, tagechtalk.com is the name of the AWS Managed Microsoft AD directory.	
Create the routing list.	To create the routing list for both replicas, run the Step 3 code from the <i>Additional information</i> section.	DBA
Validate the routing list.	Connect to the primary instance from SQL Server Management Studio, and run the <i>Step 4</i> code from the <i>Additional information</i> section to validate the routing list.	DBA

### Test the read-only routing

Task	Description	Skills required
Connect by using the ApplicationIntent parameter.	<ol style="list-style-type: none"> <li>From SSMS, connect to the Always On availability group listener name with <code>ApplicationIntent=ReadOnly;Initial Catalog=test</code> .</li> <li>The connection is established with the secondary replica. To test this, run the following command to show the connected server name.</li> </ol>	DBA

Task	Description	Skills required
	<pre data-bbox="634 212 1029 369">SELECT SERVERPROPERTY('ComputernamePhysicalNetBios')</pre> <p data-bbox="630 407 997 537">The output will show the current secondary replica name (WSFCNODE2 ).</p>	

Task	Description	Skills required
Perform a failover.	<ol style="list-style-type: none"><li>1. From SSMS, connect to the Always On availability group listener name.</li><li>2. Verify that the primary and secondary database are in sync, with no data loss.</li><li>3. Perform a failover so that the current primary replica becomes the secondary replica, and the secondary replica becomes the primary replica.</li><li>4. From SSMS, connect to the Always On availability group listener name with <code>ApplicationIntent=ReadOnly;Initial Catalog=test</code> .</li><li>5. The connection is established with the secondary replica. To test this, show the connected server name by running the following command. <div data-bbox="631 1436 1027 1593" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>SELECT SERVERPROPERTY('ComputerNamePhysicalNetBios')</pre></div><p>It will display the current secondary replica name (WSFCNODE1 ).</p></li></ol>	DBA

## Connect by using the sqlcmd command-line utility

Task	Description	Skills required
Connect by using sqlcmd.	<p>To connect from sqlcmd, run the <i>Step 5</i> code from the <i>Additional information</i> section at the command prompt. After you are connected, run the following command to show the connected server name.</p> <pre>SELECT SERVERPROPERTY('ComputerNamePhysicalNetBios') .</pre> <p>The output will display the current secondary replica name (WSFCNODE1 ).</p>	DBA

## Troubleshooting

Issue	Solution
Creating the listener fails with the message 'The WSFC cluster could not bring the Network Name resource online'.	For information, see the Microsoft blog post <a href="#">Create Listener Fails with Message 'The WSFC cluster could not bring the Network Name resource online'</a> .
Potential issues, including other listener issues or network access issues.	See <a href="#">Troubleshoot Always On Availability Groups Configuration (SQL Server)</a> in the Microsoft documentation.

## Related resources

- [Configure read-only routing for an Always On availability group](#)
- [Troubleshoot Always On Availability Groups Configuration \(SQL Server\)](#)

## Additional information

### Step 1. Update the replicas to read-only

```
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (SECONDARY_ROLE
(ALLOW_CONNECTIONS = READ_ONLY))
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (SECONDARY_ROLE
(ALLOW_CONNECTIONS = READ_ONLY))
GO
```

### Step 2. Create the routing URL

```
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (SECONDARY_ROLE
(READ_ONLY_ROUTING_URL = N'TCP://WSFCNode1.tagechtalk.com:1433'))
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (SECONDARY_ROLE
(READ_ONLY_ROUTING_URL = N'TCP://WSFCNode2.tagechtalk.com:1433'))
GO
```

### Step 3. Create the routing list

```
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH
(PRIMARY_ROLE(READ_ONLY_ROUTING_LIST=('WSFCNODE2', 'WSFCNODE1')));
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (PRIMARY_ROLE
(READ_ONLY_ROUTING_LIST=('WSFCNODE1', 'WSFCNODE2')));
GO
```

### Step 4. Validate the routing list

```
SELECT AGSrc.replica_server_name AS PrimaryReplica, AGRepl.replica_server_name AS
ReadOnlyReplica, AGRepl.read_only_routing_url AS RoutingURL , AGRL.routing_priority
AS RoutingPriority FROM sys.availability_read_only_routing_lists AGRL INNER JOIN
sys.availability_replicas AGSrc ON AGRL.replica_id = AGSrc.replica_id INNER JOIN
```

```
sys.availability_replicas AGRepl ON AGRL.read_only_replica_id = AGRepl.replica_id  
INNER JOIN sys.availability_groups AV ON AV.group_id = AGSrc.group_id ORDER BY  
PrimaryReplica
```

## Step 5. SQL Command Utility

```
sqlcmd -S SQLAG1,1433 -E -d test -K ReadOnly
```

# Connect by using an SSH tunnel in pgAdmin

Created by Jeevan Shetty (AWS) and Bhanu Ganesh Gudivada (AWS)

**Environment:** Production

**Technologies:** Databases;  
Security, identity, compliance

**Workload:** Open-source

**AWS services:** Amazon RDS;  
Amazon Aurora

## Summary

For security reasons, it's always good to place databases in a private subnet. Queries against the database can be run by connecting through an Amazon Elastic Compute Cloud (Amazon EC2) bastion host in a public subnet on the Amazon Web Services (AWS) Cloud. This requires installing software, such as pgAdmin or DBeaver, which are commonly used by developers or database administrators, on the Amazon EC2 host.

Running pgAdmin on a Linux server and accessing it through a web browser requires the installation of additional dependencies, permissions setup, and configuration.

As an alternate solution, developers or database administrators can connect to a PostgreSQL database by using pgAdmin to enable an SSH tunnel from their local system. In this approach, pgAdmin uses the Amazon EC2 host in the public subnet as an intermediary host before connecting to the database. The diagram in the *Architecture* section shows the setup.

**Note:** Ensure that the security group attached to the PostgreSQL database allows connection on port 5432 from the Amazon EC2 host.

## Prerequisites and limitations

### Prerequisites

- An existing AWS account
- A virtual private cloud (VPC) with a public subnet and a private subnet
- An EC2 instance with a security group attached

- An Amazon Aurora PostgreSQL-Compatible Edition database with a security group attached
- A Secure Shell (SSH) key pair for setting up the tunnel

## Product versions

- pgAdmin version 6.2+
- Amazon Aurora PostgreSQL-Compatible Edition version 12.7+

## Architecture

### Target technology stack

- Amazon EC2
- Amazon Aurora PostgreSQL-Compatible

### Target architecture

The following diagram shows using pgAdmin with an SSH tunnel to connect through an internet gateway to the EC2 instance, which connects to the database.

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

## Other services

- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Epics

### Create the connection

Task	Description	Skills required
Create a server.	In pgAdmin, choose <b>Create</b> , and then choose <b>Server</b> . For additional help with setting up pgAdmin to register a server, configure a connection, and connect through SSH tunneling by using the Server Dialog, see the links in the <i>Related resources</i> section.	DBA
Provide a name for the server.	On the <b>General</b> tab, enter a name.	DBA
Enter the database details.	On the <b>Connection</b> tab, enter values for the following: <ul style="list-style-type: none"> <li>• <b>Host name/address</b></li> <li>• <b>Port</b></li> <li>• <b>Maintenance database</b></li> <li>• <b>Username</b></li> </ul>	DBA

Task	Description	Skills required
	<ul style="list-style-type: none"><li data-bbox="592 212 764 243">• Password</li></ul>	

Task	Description	Skills required
Enter the Amazon EC2 server details.	<p>On the <b>SSH Tunnel</b> tab, provide the details of the Amazon EC2 instance that is in the public subnet.</p> <ul style="list-style-type: none"><li>• Set <b>Use SSH tunneling</b> to <b>Yes</b> to specify that pgAdmin should use an SSH tunnel when connecting to the specified server.</li><li>• In the <b>Tunnel host</b> field, specify the name or IP address of the SSH host (for example, 10.x.x.x).</li><li>• In the <b>Tunnel port</b> field, specify the port of the SSH host (for example, 22).</li><li>• In the <b>Username</b> field, specify the name of a user with login privileges for the SSH host (for example, ec2-user).</li><li>• Specify the type of authentication as <b>Identity file</b> so that pgAdmin will use a private key file when connecting.</li><li>• Include the location of the Privacy Enhanced Mail (PEM) file in the <b>Identity file</b> field. The .pem file is the Amazon EC2 key pair.</li></ul>	DBA

Task	Description	Skills required
Save and connect.	Choose <b>Save</b> to complete the setup and connect to the Aurora PostgreSQL-Compatible database by using the SSH tunnel.	DBA

# Convert JSON Oracle queries into PostgreSQL database SQL

Created by Pinesh Singal (AWS) and Lokesh Gurram (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon Aurora; Amazon RDS		

## Summary

This migration process for moving from on-premises to the Amazon Web Services (AWS) Cloud uses the AWS Schema Conversion Tool (AWS SCT) to convert the code from an Oracle database into a PostgreSQL database. Most of the code is automatically converted by AWS SCT. However, JSON-related Oracle queries are not automatically converted.

Starting from Oracle 12.2 version, Oracle Database supports various JSON functions that help in converting JSON-based data into ROW-based data. However, AWS SCT doesn't automatically convert JSON-based data into language that is supported by PostgreSQL.

This migration pattern primarily focuses on manually converting the JSON-related Oracle queries with functions such as `JSON_OBJECT`, `JSON_ARRAYAGG`, and `JSON_TABLE` from an Oracle database to a PostgreSQL database.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An on-premises Oracle database instance (up and running)
- An Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition database instance (up and running)

## Limitations

- JSON-related queries require a fixed KEY and VALUE format. Not using that format returns the wrong result.
- If any change in JSON structure adds new KEY and VALUE pairs in the result section, the corresponding procedure or function must be changed in the SQL query.
- Some JSON-related functions are supported in earlier versions of Oracle and PostgreSQL but with fewer capabilities.

## Product versions

- Oracle Database version 12.2 and later
- Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible version 9.5 and later
- AWS SCT latest version (tested using version 1.0.664)

## Architecture

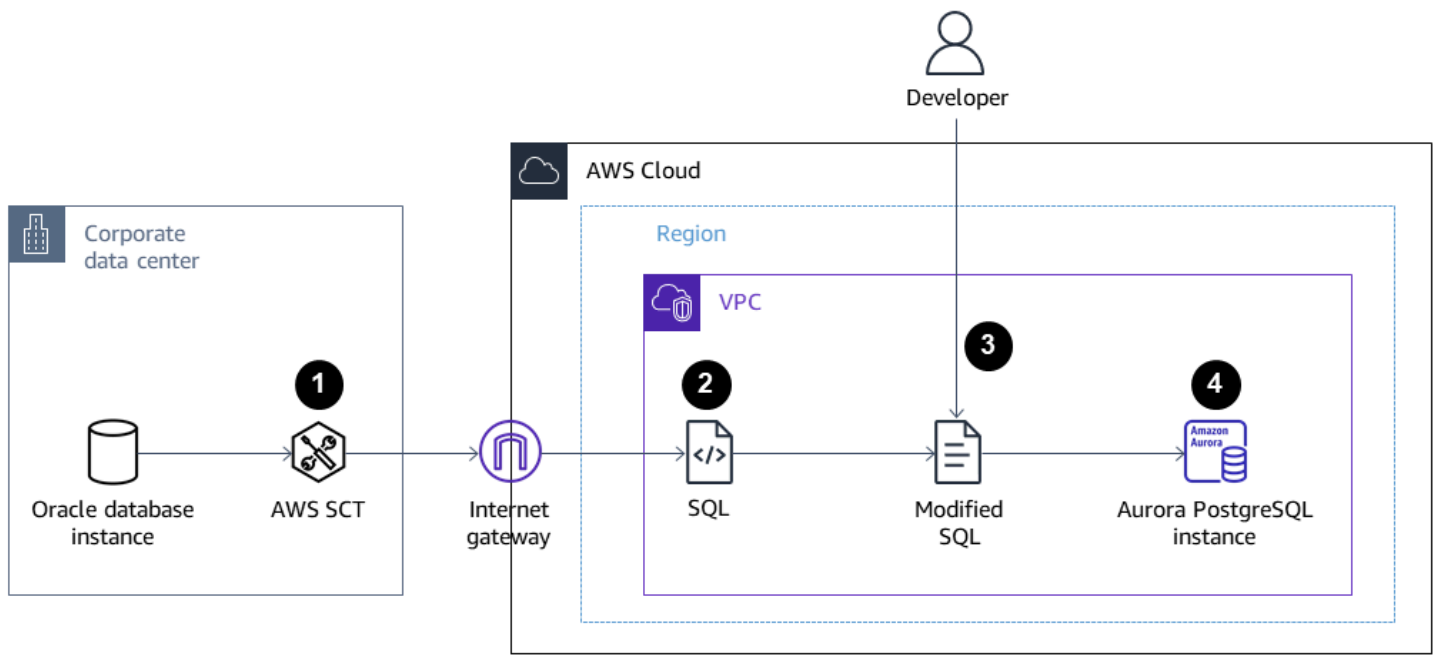

### Source technology stack

- An Oracle database instance with version 19c

### Target technology stack

- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database instance with version 13

### Target architecture

1. Use AWS SCT with the JSON function code to convert the source code from Oracle to PostgreSQL.
2. The conversion produces PostgreSQL-supported migrated .sql files.
3. Manually convert the non-converted Oracle JSON function codes to PostgreSQL JSON function codes.
4. Run the .sql files on the target Aurora PostgreSQL-Compatible DB instance.

## Tools

### AWS services

- [Amazon Aurora](#) is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

### Other services

- [Oracle SQL Developer](#) is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- pgAdmin or DBeaver. [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. [DBeaver](#) is a universal database tool.

## Best practices

Oracle query has type CAST as the default when using the JSON\_TABLE function. A best practice is to use CAST in PostgreSQL too, using double greater-than characters (>>).

For more information, see *Postgres\_SQL\_Read\_JSON* in the *Additional information* section.

## Epics

### Generate the JSON data in the Oracle and PostgreSQL databases

Task	Description	Skills required
Store the JSON data in the Oracle database.	Create a table in the Oracle database, and store the JSON data in the CLOB column. Use the <i>Oracle_Table_Creation_Insert_Script</i> that's in the <i>Additional information</i> section.	Migration engineer
Store the JSON data in the PostgreSQL database.	Create a table in the PostgreSQL database, and store the JSON data in the TEXT column. Use the <i>Postgres_Table_Creation_Insert_Script</i> that's in the <i>Additional information</i> section.	Migration engineer

## Convert the JSON into ROW format

Task	Description	Skills required
Convert the JSON data on the Oracle database.	Write an Oracle SQL query to read the JSON data into ROW format. For more details and example syntax, see <i>Oracle_SQL_Read_JSON</i> in the <i>Additional information</i> section.	Migration engineer
Convert the JSON data on the PostgreSQL database.	Write a PostgreSQL query to read the JSON data into ROW format. For more details and example syntax, see <i>Postgres_SQL_Read_JSON</i> in the <i>Additional information</i> section.	Migration engineer

## Manually convert the JSON data using the SQL query and report the output in JSON format

Task	Description	Skills required
Perform aggregations and validation on the Oracle SQL query.	<p>To manually convert the JSON data, perform a join, aggregation, and validation on the Oracle SQL query, and report the output in JSON format. Use the code under <i>Oracle_SQL_Read_JSON_Aggregation_Join</i> in the <i>Additional information</i> section.</p> <ol style="list-style-type: none"> <li>1. JOIN – The JSON-formatted data is passed as an</li> </ol>	Migration engineer

Task	Description	Skills required
	<p>input parameter to the query. An inner JOIN is made between this static data and the JSON data in the Oracle DB table <code>aws_test_table</code> .</p> <ol style="list-style-type: none"><li data-bbox="592 506 1019 974">2. Aggregation with validation – The JSON data has KEY and VALUE parameters with values such as <code>accountNumber</code> , <code>parentAccountNumber</code> , <code>businessUnitId</code> and <code>positionId</code> , which are used for SUM and COUNT aggregations.</li><li data-bbox="592 999 984 1268">3. JSON format – After the join and the aggregation, the data is reported in JSON format by using <code>JSON_OBJECT</code> and <code>JSON_ARRAYAGG</code> .</li></ol>	

Task	Description	Skills required
<p>Perform aggregations and validation on the Postgres SQL query.</p>	<p>To manually convert the JSON data, perform a join, aggregation, and validation on the PostgreSQL query, and report the output in JSON format. Use the code under <i>Postgres_SQL_JSON_Aggregation_Join</i> in the <i>Additional information</i> section.</p> <ol style="list-style-type: none"> <li>1. JOIN – The JSON-formatted data (tab1) is passed as an input parameter to the WITH clause query. A JOIN is made between this static data and the JSON data, which is in the tab table. A JOIN is also made with the WITH clause, which has JSON data in the <code>aws_test_pg_table</code> table.</li> <li>2. Aggregation – The JSON data has KEY and VALUE parameters with values such as <code>accountNumber</code>, <code>parentAccountNumber</code>, <code>businessUnitId</code>, and <code>positionId</code>, which are used for the SUM and COUNT aggregations.</li> <li>3. JSON format – After the join and the aggregati</li> </ol>	<p>Migration engineer</p>

Task	Description	Skills required
	on, the data is reported in JSON format by using <code>JSON_BUILD_OBJECT</code> and <code>JSON_AGG</code> .	

## Convert the Oracle procedure into a PostgreSQL function that contains JSON queries

Task	Description	Skills required
Convert the JSON queries in the Oracle procedure into rows.	For the example Oracle procedure, use the previous Oracle query and the code under <i>Oracle_procedure_with_JSON_Query</i> in the <i>Additional information</i> section.	Migration engineer
Convert the PostgreSQL functions that have JSON queries into row-based data.	For the example PostgreSQL functions, use the previous PostgreSQL query and the code that's under <i>Postgres_function_with_JSON_Query</i> in the <i>Additional information</i> section.	Migration engineer

      "registrationStatus" : false,
      "status" : "11"
    }
  ]
}
}');

```

### 3. Oracle\_SQL\_Read\_JSON

The following code blocks show how to convert Oracle JSON data into row format.

#### *Example query and syntax*

```

SELECT  JSON_OBJECT(
  'accountCounts' VALUE JSON_ARRAYAGG(
    JSON_OBJECT(
      'businessUnitId' VALUE business_unit_id,
      'parentAccountNumber' VALUE parent_account_number,
      'accountNumber' VALUE account_number,
      'totalOnlineContactsCount' VALUE online_contacts_count,
      'countByPosition' VALUE
        JSON_OBJECT(
          'taxProfessionalCount' VALUE tax_count,
          'attorneyCount' VALUE attorney_count,
          'nonAttorneyCount' VALUE non_attorney_count,
          'clerkCount' VALUE clerk_count
        ) ) ) FROM
  (SELECT  tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END) tax_count,
    SUM(CASE  WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END)
attorney_count,
    SUM(CASE  WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END)
non_attorney_count,

```

```

SUM(CASE WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END)
clerk_count
FROM aws_test_table scco,JSON_TABLE ( json_doc, '$' ERROR ON ERROR
COLUMNS (
  parent_account_number NUMBER PATH
    '$.data.account.parentAccountNumber',
  account_number NUMBER PATH '$.data.account.accountNumber',
  business_unit_id NUMBER PATH '$.data.account.businessUnitId',
  position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'
) AS tab_data
  INNER JOIN JSON_TABLE ( '{
"accounts": [{
  "accountNumber": 42000,
  "parentAccountNumber": 32000,
  "businessUnitId": 7
}, {
  "accountNumber": 42001,
  "parentAccountNumber": 32001,
  "businessUnitId": 6
}]
}', '$.accounts[*]' ERROR ON ERROR
COLUMNS (
  parent_account_number PATH '$.parentAccountNumber',
  account_number PATH '$.accountNumber',
  business_unit_id PATH '$.businessUnitId')
) static_data
ON ( static_data.parent_account_number = tab_data.parent_account_number
  AND static_data.account_number = tab_data.account_number
  AND static_data.business_unit_id = tab_data.business_unit_id )
GROUP BY
  tab_data.business_unit_id,
  tab_data.parent_account_number,
  tab_data.account_number );

```

The JSON document stores the data as collections. Each collection can have KEY and VALUE pairs. Every VALUE can have nested KEY and VALUE pairs. The following table provides information about reading the specific VALUE from the JSON document.

KEY	HIERARCHY or PATH to be used to get the VALUE	VALUE
profileType	metadata -> profileType	"P"

positionId	data -> positionId	"0100"
accountNumber	data -> account -> accountNumber	42000

In the previous table, the KEY profileType is a VALUE of the metadata KEY. The KEY positionId is a VALUE of the data KEY. The KEY accountNumber is a VALUE of the account KEY, and the account KEY is a VALUE of the data KEY.

### Example JSON document

```
{
  "metadata" : {
    "upperLastNameFirstName" : "ABC XYZ",
    "upperEmailAddress" : "abc@gmail.com",
    "profileType" : "P"
  },
  "data" : {
    "onlineContactId" : "032323323",
    "displayName" : "Abc, Xyz",
    "firstName" : "Xyz",
    "lastName" : "Abc",
    "emailAddress" : "abc@gmail.com",
    "productRegistrationStatus" : "Not registered",
    "positionId" : "0100",
    "arrayPattern" : " -",
    "account" : {
      "companyId" : "SMGE",
      "businessUnitId" : 7,
      "accountNumber" : 42000,
      "parentAccountNumber" : 32000,
      "firstName" : "john",
      "lastName" : "doe",
      "street1" : "ret0dertcaShr ",
      "city" : "new york",
      "postalcode" : "XY ABC",
      "country" : "United States"
    },
    "products" : [
      {
        "appUserGuid" : "i0acc4450000001823fbad478e2eab8a0",
```

```

        "id" : "0000000046",
        "name" : "ProView",
        "domain" : "EREADER",
        "registrationStatus" : false,
        "status" : "11"
    }
]
}
}

```

*SQL query that is used to get the selected fields from the JSON document*

```

select parent_account_number,account_number,business_unit_id,position_id from
  aws_test_table aws,JSON_TABLE ( json_doc, '$' ERROR ON ERROR
COLUMNS (
parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
account_number NUMBER PATH '$.data.account.accountNumber',
business_unit_id NUMBER PATH '$.data.account.businessUnitId',
position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'
)) as sc

```

In the previous query, JSON\_TABLE is a built-in function in Oracle that converts the JSON data into row format. The JSON\_TABLE function expects parameters in JSON format.

Every item in COLUMNS has a predefined PATH, and there an appropriate VALUE for a given KEY is returned in row format.

*Result from the previous query*

<b>PARENT_AC COUNT_NUMBER</b>	<b>ACCOUNT_NUMBER</b>	<b>BUSINESS_UNIT_ID</b>	<b>POSITION_ID</b>
32000	42000	7	0100
32001	42001	6	0090

#### 4. Postgres\_SQL\_Read\_JSON

*Example query and syntax*

```
select *
```

```
from (  
select (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER as  
parentAccountNumber,  
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER as accountNumber,  
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER as businessUnitId,  
(json_doc::json->'data'->>'positionId')::VARCHAR as positionId  
from aws_test_pg_table) d ;
```

In Oracle, PATH is used to identify the specific KEY and VALUE. However, PostgreSQL uses a HIERARCHY model for reading KEY and VALUE from JSON. The same JSON data mentioned under `Oracle_SQL_Read_JSON` is used in the following examples.

### *SQL query with type CAST not allowed*

(If you force type CAST, the query fails with a syntax error.)

```
select *  
from (  
select (json_doc::json->'data'->'account'->'parentAccountNumber') as  
parentAccountNumber,  
(json_doc::json->'data'->'account'->'accountNumber')as accountNumber,  
(json_doc::json->'data'->'account'->'businessUnitId') as businessUnitId,  
(json_doc::json->'data'->'positionId')as positionId  
from aws_test_pg_table) d ;
```

Using a single greater-than operator (>) will return the VALUE defined for that KEY. For example, KEY: `positionId`, and VALUE: `"0100"`.

Type CAST is not allowed when you use the single greater-than operator (>).

### *SQL query with type CAST allowed*

```
select *  
from (  
select (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER as  
parentAccountNumber,  
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER as accountNumber,  
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER as businessUnitId,  
(json_doc::json->'data'->>'positionId')::varchar as positionId  
from aws_test_pg_table) d ;
```

To use type CAST, you must use the double greater-than operator. If you use the single greater-than operator, the query returns the VALUE defined (for example, KEY: positionId, and VALUE: "0100"). Using the double greater-than operator (>>) will return the actual value defined for that KEY (for example, KEY: positionId, and VALUE: 0100, without double quotation marks).

In the preceding case, parentAccountNumber is type CAST to INT, accountNumber is type CAST to INT, businessUnitId is type CAST to INT, and positionId is type CAST to VARCHAR.

The following tables show query results that explain role of the single greater-than operator (>) and the double greater-than operator (>>).

In the first table, the query uses the single greater-than operator (>). Each column is in JSON type and can't be converted into another data type.

<b>parentAccountNumber</b>	<b>accountNumber</b>	<b>businessUnitId</b>	<b>positionId</b>
2003565430	2003564830	7	"0100"
2005284042	2005284042	6	"0090"
2000272719	2000272719	1	"0100"

In the second table, the query uses the double greater-than operator (>>). Each column supports type CAST based on the column value. For example, INTEGER in this context.

<b>parentAccountNumber</b>	<b>accountNumber</b>	<b>businessUnitId</b>	<b>positionId</b>
2003565430	2003564830	7	0100
2005284042	2005284042	6	0090
2000272719	2000272719	1	0100

## 5. Oracle\_SQL\_JSON\_Aggregation\_Join

### *Example query*

```

SELECT
  JSON_OBJECT(
    'accountCounts' VALUE JSON_ARRAYAGG(
      JSON_OBJECT(
        'businessUnitId' VALUE business_unit_id,
        'parentAccountNumber' VALUE parent_account_number,
        'accountNumber' VALUE account_number,
        'totalOnlineContactsCount' VALUE online_contacts_count,
        'countByPosition' VALUE
          JSON_OBJECT(
            'taxProfessionalCount' VALUE tax_count,
            'attorneyCount' VALUE attorney_count,
            'nonAttorneyCount' VALUE non_attorney_count,
            'clerkCount' VALUE clerk_count
          ) ) ) )
FROM
  (SELECT
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END) tax_count,
    SUM(CASE WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END)
attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END)
non_attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END)
clerk_count
  FROM aws_test_table scco,JSON_TABLE ( json_doc, '$' ERROR ON ERROR
  COLUMNS (
    parent_account_number NUMBER PATH
    '$.data.account.parentAccountNumber',
    account_number NUMBER PATH '$.data.account.accountNumber',
    business_unit_id NUMBER PATH '$.data.account.businessUnitId',
    position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'
  ) AS tab_data
  INNER JOIN JSON_TABLE ( '{
"accounts": [{
  "accountNumber": 42000,
  "parentAccountNumber": 32000,
  "businessUnitId": 7
}, {
  "accountNumber": 42001,

```

```

        "parentAccountNumber": 32001,
        "businessUnitId": 6
    ]]
}', '$.accounts[*]' ERROR ON ERROR
COLUMNS (
parent_account_number PATH '$.parentAccountNumber',
account_number PATH '$.accountNumber',
business_unit_id PATH '$.businessUnitId')
) static_data
ON ( static_data.parent_account_number = tab_data.parent_account_number
    AND static_data.account_number = tab_data.account_number
    AND static_data.business_unit_id = tab_data.business_unit_id )
GROUP BY
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number
);

```

To convert the row-level data into JSON format, Oracle has built-in functions such as `JSON_OBJECT`, `JSON_ARRAY`, `JSON_OBJECTAGG`, and `JSON_ARRAYAGG`.

- `JSON_OBJECT` accepts two parameters: `KEY` and `VALUE`. The `KEY` parameter should be hardcoded or static in nature. The `VALUE` parameter is derived from table output.
- `JSON_ARRAYAGG` accepts `JSON_OBJECT` as a parameter. This helps in grouping the set of `JSON_OBJECT` elements as a list. For example, if you have a `JSON_OBJECT` element that has multiple records (multiple `KEY` and `VALUE` pairs in the dataset), `JSON_ARRAYAGG` appends the dataset and creates a list. According to the Data Structure language, `LIST` is group of elements. In this context, `LIST` is a group of `JSON_OBJECT` elements.

The following example shows one `JSON_OBJECT` element.

```

{
  "taxProfessionalCount": 0,
  "attorneyCount": 0,
  "nonAttorneyCount": 1,
  "clerkCount": 0
}

```

This next example shows two `JSON_OBJECT` elements, with `LIST` indicated by square braces (`[ ]`).

```
[
  {
    "taxProfessionalCount": 0,
    "attorneyCount": 0,
    "nonAttorneyCount": 1,
    "clerkCount": 0
  },
  {
    "taxProfessionalCount": 2,
    "attorneyCount": 1,
    "nonAttorneyCount": 3,
    "clerkCount": 4
  }
]
```

### Example SQL query

```
SELECT
  JSON_OBJECT(
    'accountCounts' VALUE JSON_ARRAYAGG(
      JSON_OBJECT(
        'businessUnitId' VALUE business_unit_id,
        'parentAccountNumber' VALUE parent_account_number,
        'accountNumber' VALUE account_number,
        'totalOnlineContactsCount' VALUE online_contacts_count,
        'countByPosition' VALUE
          JSON_OBJECT(
            'taxProfessionalCount' VALUE tax_count,
            'attorneyCount' VALUE attorney_count,
            'nonAttorneyCount' VALUE non_attorney_count,
            'clerkCount' VALUE clerk_count
          )
      )
    )
  )
FROM
  (SELECT
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END
```

```

        )      tax_count,
SUM(CASE    WHEN tab_data.position_id = '0100' THEN      1      ELSE
0 END
        )      attorney_count,

SUM(CASE    WHEN tab_data.position_id = '0090' THEN      1      ELSE
0 END
        )      non_attorney_count,

SUM(CASE    WHEN tab_data.position_id = '0050' THEN      1      ELSE
0 END
        )      clerk_count

FROM
aws_test_table scco, JSON_TABLE ( json_doc, '$' ERROR ON ERROR
COLUMNS (
parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
account_number NUMBER PATH '$.data.account.accountNumber',

"businessUnitId": 6
}]
}', '$.accounts[*]' ERROR ON ERROR
COLUMNS (
parent_account_number PATH '$.parentAccountNumber',
account_number PATH '$.accountNumber',
business_unit_id PATH '$.businessUnitId')
) static_data ON ( static_data.parent_account_number =
tab_data.parent_account_number
AND static_data.account_number = tab_data.account_number

AND static_data.business_unit_id =
tab_data.business_unit_id )
GROUP BY
tab_data.business_unit_id,

```

```
        tab_data.parent_account_number,  
        tab_data.account_number  
    );
```

*Example output from the previous SQL query*

```
{  
  "accountCounts": [  
    {  
      "businessUnitId": 6,  
      "parentAccountNumber": 32001,  
      "accountNumber": 42001,  
      "totalOnlineContactsCount": 1,  
      "countByPosition": {  
        "taxProfessionalCount": 0,  
        "attorneyCount": 0,  
        "nonAttorneyCount": 1,  
        "clerkCount": 0  
      }  
    },  
    {  
      "businessUnitId": 7,  
      "parentAccountNumber": 32000,  
      "accountNumber": 42000,  
      "totalOnlineContactsCount": 1,  
      "countByPosition": {  
        "taxProfessionalCount": 0,  
        "attorneyCount": 1,  
        "nonAttorneyCount": 0,  
        "clerkCount": 0  
      }  
    }  
  ]  
}
```

## 6. Postgres\_SQL\_JSON\_Aggregation\_Join

The PostgreSQL built-in functions `JSON_BUILD_OBJECT` and `JSON_AGG` convert the ROW-level data into JSON format. PostgreSQL `JSON_BUILD_OBJECT` and `JSON_AGG` are equivalent to Oracle `JSON_OBJECT` and `JSON_ARRAYAGG`.

*Example query*

```

select
JSON_BUILD_OBJECT ('accountCounts',
  JSON_AGG(
    JSON_BUILD_OBJECT ('businessUnitId',businessUnitId
    , 'parentAccountNumber',parentAccountNumber
    , 'accountNumber',accountNumber
    , 'totalOnlineContactsCount',online_contacts_count,
    'countByPosition',
      JSON_BUILD_OBJECT (
        'taxProfessionalCount',tax_professional_count
        , 'attorneyCount',attorney_count
        , 'nonAttorneyCount',non_attorney_count
        , 'clerkCount',clerk_count
      )
    )
  )
)
from (
with tab as (select * from (
select (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER as
parentAccountNumber,
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER as accountNumber,
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER as businessUnitId,
(json_doc::json->'data'->>'positionId')::varchar as positionId
from aws_test_pg_table) a ) ,
tab1 as ( select
(json_array_elements(b.jc -> 'accounts') ->> 'accountNumber')::integer accountNumber,
(json_array_elements(b.jc -> 'accounts') ->> 'businessUnitId')::integer
businessUnitId,
(json_array_elements(b.jc -> 'accounts') ->> 'parentAccountNumber')::integer
parentAccountNumber
from (
select '{
  "accounts": [{
    "accountNumber": 42001,
    "parentAccountNumber": 32001,
    "businessUnitId": 6
  }, {
    "accountNumber": 42000,
    "parentAccountNumber": 32000,
    "businessUnitId": 7
  }]
}'::json as jc) b)

```

```

select
tab.businessUnitId::text,
tab.parentAccountNumber::text,
tab.accountNumber::text,
SUM(1) online_contacts_count,
SUM(CASE WHEN tab.positionId::text = '0095' THEN 1 ELSE 0 END)
  tax_professional_count,
SUM(CASE WHEN tab.positionId::text = '0100' THEN 1 ELSE 0 END)      attorney_count,
SUM(CASE WHEN tab.positionId::text = '0090' THEN      1 ELSE      0 END)
  non_attorney_count,
SUM(CASE WHEN tab.positionId::text = '0050' THEN      1 ELSE      0 END)
  clerk_count
from tab1,tab
where tab.parentAccountNumber::INTEGER=tab1.parentAccountNumber::INTEGER
and tab.accountNumber::INTEGER=tab1.accountNumber::INTEGER
and tab.businessUnitId::INTEGER=tab1.businessUnitId::INTEGER
GROUP BY      tab.businessUnitId::text,
              tab.parentAccountNumber::text,
              tab.accountNumber::text) a;

```

*Example output from the preceding query*

Output from Oracle and PostgreSQL is exactly the same.

```

{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {

```

```

        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
    }
}
]
}

```

## 7.Oracle\_procedure\_with\_JSON\_Query

This code converts the Oracle procedure into a PostgreSQL function that has JSON SQL queries. It shows how the query transposes JSON into rows and the reverse.

```

CREATE OR REPLACE PROCEDURE p_json_test(p_in_accounts_json IN varchar2,
    p_out_accunts_json OUT varchar2)
IS
BEGIN
/*
p_in_accounts_json paramter should have following format:
    {
        "accounts": [{
            "accountNumber": 42000,
            "parentAccountNumber": 32000,
            "businessUnitId": 7
        }, {
            "accountNumber": 42001,
            "parentAccountNumber": 32001,
            "businessUnitId": 6
        }]
    }
*/
SELECT
    JSON_OBJECT(
        'accountCounts' VALUE JSON_ARRAYAGG(
            JSON_OBJECT(
                'businessUnitId' VALUE business_unit_id,
                'parentAccountNumber' VALUE parent_account_number,
                'accountNumber' VALUE account_number,
                'totalOnlineContactsCount' VALUE online_contacts_count,
                'countByPosition' VALUE
            )
        )
        'taxProfessionalCount' VALUE tax_count,

```

```

        'attorneyCount' VALUE attorney_count,
        'nonAttorneyCount' VALUE non_attorney_count,
        'clerkCount' VALUE clerk_count
        ) ) ) )
into p_out_accunts_json
FROM
    (SELECT
        tab_data.business_unit_id,
        tab_data.parent_account_number,
        tab_data.account_number,
        SUM(1) online_contacts_count,
        SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END) tax_count,
        SUM(CASE WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END)
attorney_count,

```

/

### Running the procedure

The following code block explains how you can run the previously created Oracle procedure with example JSON input to the procedure. It also gives you the result or output from this procedure.

```
set serveroutput on;
declare
v_out varchar2(30000);
v_in varchar2(30000):= '{
    "accounts": [{
        "accountNumber": 42000,
        "parentAccountNumber": 32000,
        "businessUnitId": 7
    }, {
        "accountNumber": 42001,
        "parentAccountNumber": 32001,
        "businessUnitId": 6
    }]
}';
begin
    p_json_test(v_in,v_out);
    dbms_output.put_line(v_out);
end;
/
```

### Procedure output

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    }
  ],
}
```

```
{
  "businessUnitId": 7,
  "parentAccountNumber": 32000,
  "accountNumber": 42000,
  "totalOnlineContactsCount": 1,
  "countByPosition": {
    "taxProfessionalCount": 0,
    "attorneyCount": 1,
    "nonAttorneyCount": 0,
    "clerkCount": 0
  }
}
]
```

## 8.Postgres\_function\_with\_JSON\_Query

### *Example function*

```
CREATE OR REPLACE FUNCTION f_pg_json_test(p_in_accounts_json text)
RETURNS text
LANGUAGE plpgsql
AS
$$
DECLARE
  v_out_accunts_json text;
BEGIN
SELECT
JSON_BUILD_OBJECT ('accountCounts',
  JSON_AGG(
    JSON_BUILD_OBJECT ('businessUnitId',businessUnitId
  , 'parentAccountNumber',parentAccountNumber
  , 'accountNumber',accountNumber
  , 'totalOnlineContactsCount',online_contacts_count,
  'countByPosition',
    JSON_BUILD_OBJECT (
      'taxProfessionalCount',tax_professional_count
    , 'attorneyCount',attorney_count
    , 'nonAttorneyCount',non_attorney_count
    , 'clerkCount',clerk_count
    )))
INTO v_out_accunts_json
FROM (
WITH tab AS (SELECT * FROM (
```

```

SELECT (json_doc::json->'data'->'account'->'parentAccountNumber')::INTEGER AS
  parentAccountNumber,
(json_doc::json->'data'->'account'->'accountNumber')::INTEGER AS accountNumber,
(json_doc::json->'data'->'account'->'businessUnitId')::INTEGER AS businessUnitId,
(json_doc::json->'data'->'positionId')::varchar AS positionId
FROM aws_test_pg_table) a ) ,
tab1 AS ( SELECT
(json_array_elements(b.jc -> 'accounts') ->> 'accountNumber')::integer accountNumber,
(json_array_elements(b.jc -> 'accounts') ->> 'businessUnitId')::integer businessUnitId,
(json_array_elements(b.jc -> 'accounts') ->> 'parentAccountNumber')::integer
  parentAccountNumber
FROM (
SELECT p_in_accounts_json::json AS jc) b)
SELECT
tab.businessUnitId::text,
tab.parentAccountNumber::text,
tab.accountNumber::text,
SUM(1) online_contacts_count,
SUM(CASE WHEN tab.positionId::text = '0095' THEN 1 ELSE 0 END)
  tax_professional_count,
SUM(CASE WHEN tab.positionId::text = '0100' THEN 1 ELSE 0 END)      attorney_count,
SUM(CASE WHEN tab.positionId::text = '0090' THEN      1 ELSE      0 END)
  non_attorney_count,
SUM(CASE WHEN tab.positionId::text = '0050' THEN      1 ELSE      0 END)
  clerk_count
FROM tab1,tab
WHERE tab.parentAccountNumber::INTEGER=tab1.parentAccountNumber::INTEGER
AND tab.accountNumber::INTEGER=tab1.accountNumber::INTEGER
AND tab.businessUnitId::INTEGER=tab1.businessUnitId::INTEGER
GROUP BY      tab.businessUnitId::text,
              tab.parentAccountNumber::text,
              tab.accountNumber::text) a;
RETURN v_out_accunts_json;
END;
$$;

```

### Running the function

```

select      f_pg_json_test('{
"accounts": [{
  "accountNumber": 42001,
  "parentAccountNumber": 32001,
  "businessUnitId": 6

```

```
    }, {
      "accountNumber": 42000,
      "parentAccountNumber": 32000,
      "businessUnitId": 7
    }
  ]
}') ;
```

### Function output

The following output is similar to the Oracle procedure output. The difference is that this output is in Text format.

```
{
  "accountCounts": [
    {
      "businessUnitId": "6",
      "parentAccountNumber": "32001",
      "accountNumber": "42001",
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": "7",
      "parentAccountNumber": "32000",
      "accountNumber": "42000",
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

# Copy Amazon DynamoDB tables across accounts using AWS Backup

Created by Ramkumar Ramanujam (AWS)

**Environment:** PoC or pilot

**Technologies:** Databases;  
Migration

**AWS services:** Amazon  
DynamoDB; AWS Backup

## Summary

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that is in the production environment. As a standard practice, each environment uses a different AWS account.

AWS Backup supports cross-Region and cross-account backup and restore of data for DynamoDB, Amazon Simple Storage Service (Amazon S3), and other AWS services. This pattern provides the steps for using AWS Backup cross-account backup and restore to copy DynamoDB tables between AWS accounts.

## Prerequisites and limitations

### Prerequisites

- Two active AWS accounts that belong to the same AWS Organizations organization
- DynamoDB tables in both the accounts.
- AWS Identity and Access Management (IAM) permissions to create and use AWS backup vaults

### Limitations

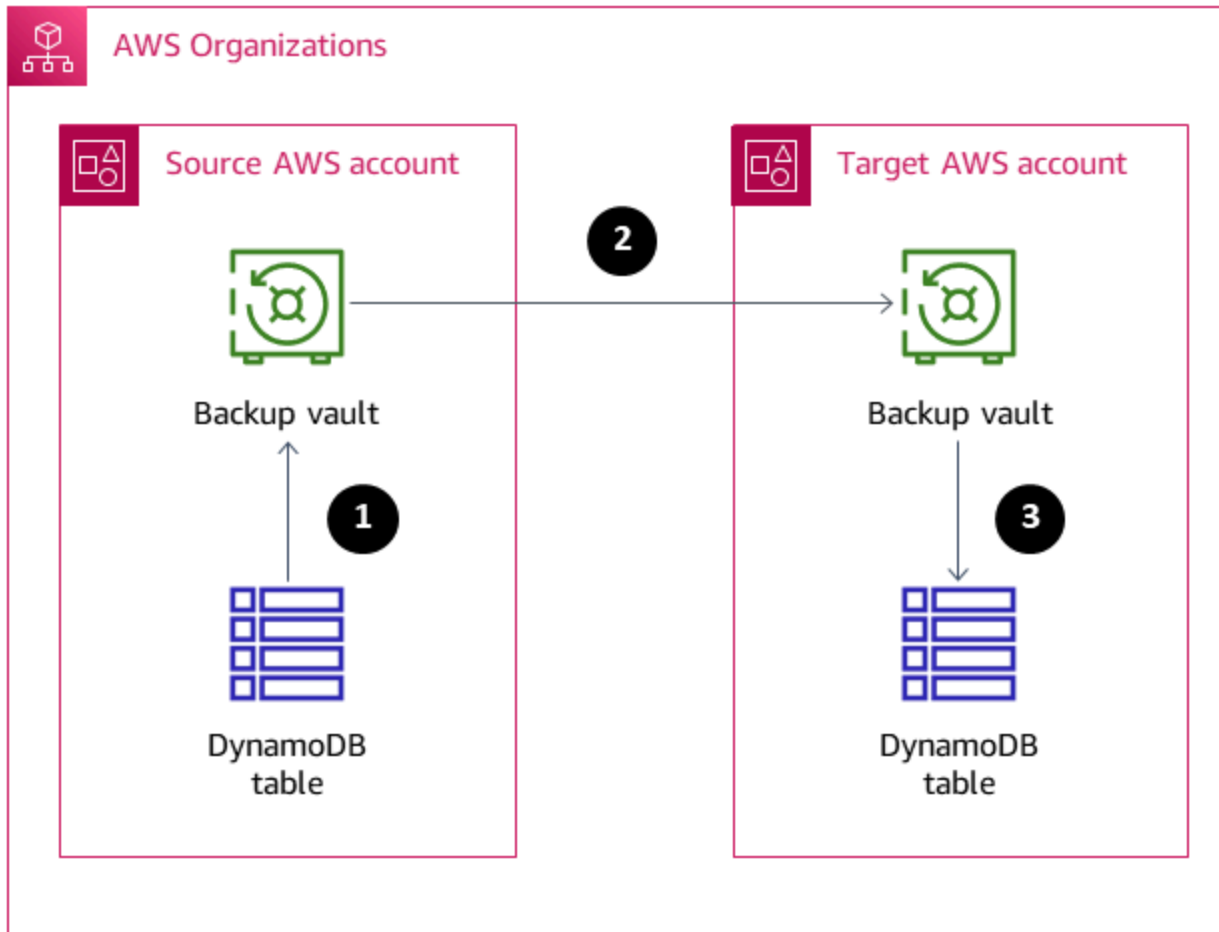

- Source and target AWS accounts should be part of the same AWS Organizations organization.

## Architecture

### Target technology stack

- AWS Backup
- Amazon DynamoDB

## Target architecture

1. Create the DynamoDB table backup in the AWS Backup backup vault in the source account.
2. Copy the backup to the backup vault in the target account.
3. Restore the DynamoDB table in the target account using the backup from the target account backup vault.

## Automation and scale

You can use AWS Backup to schedule backups to run at specific intervals.

## Tools

- [AWS Backup](#) – AWS Backup is a fully-managed service for centralizing and automating data protection across AWS services, in the cloud, and on premises. Using this service, you can configure backup policies and monitor activity for your AWS resources in one place. It allows you to automate and consolidate backup tasks that were previously performed service-by-service, and removes the need to create custom scripts and manual processes.
- [Amazon DynamoDB](#) – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

## Epics

### Turn on AWS Backup features in the source and target accounts

Task	Description	Skills required
Turn on advanced features for DynamoDB and cross-account backup.	<p>In both the source and the target AWS accounts, do the following:</p> <ol style="list-style-type: none"><li>1. On the AWS Management Console, open the AWS Backup console.</li><li>2. Choose <b>Settings</b>.</li><li>3. Under <b>Advanced features for Amazon DynamoDB backups</b>, confirm that <b>Advanced features</b> is enabled, or choose <b>Enable</b>.</li><li>4. Under <b>Cross-account management</b>, for <b>Cross-account backup</b>, choose <b>Enable</b>.</li></ol>	AWS DevOps, Migration engineer

## Create backup vaults in the source and target accounts

Task	Description	Skills required
Create backup vaults.	<p>In both the source and the target AWS accounts, do the following:</p> <ol style="list-style-type: none"><li>1. On the AWS Backup console, choose <b>Backup vaults</b>.</li><li>2. Choose <b>Create Backup vault</b>.</li><li>3. Copy the Amazon Resource Name (ARN) of the backup vault and save it.</li></ol> <p>The ARNs of both the source and the target backup vaults will be required when you copying the DynamoDB table backup between the source account and the target account.</p>	AWS DevOps, Migration engineer

## Perform backup and restore using backup vaults

Task	Description	Skills required
In the source account, create a DynamoDB table backup.	<p>To create a backup for the DynamoDB table in the source account, do the following:</p> <ol style="list-style-type: none"><li>1. On the AWS Backup <b>Dashboard</b> page, choose</li></ol>	AWS DevOps, DBA, Migration engineer

Task	Description	Skills required
	<p><b>Create on-demand backup.</b></p> <ol style="list-style-type: none"><li data-bbox="592 310 993 491">2. In the <b>Settings</b> section, for <b>Resource type</b>, select <b>DynamoDB</b>, and then select the table name.</li><li data-bbox="592 512 987 739">3. In the <b>Backup vault</b> dropdown list, select the backup vault that you created in the source account.</li><li data-bbox="592 760 945 848">4. Select the <b>Retention period</b> that you want.</li><li data-bbox="592 869 1024 957">5. Choose <b>Create on-demand backup</b>.</li></ol> <p>A new backup job is created.</p> <p>To monitor the status of the backup job, on the AWS Backup <b>Jobs</b> page, choose the <b>Backup Jobs</b> tab. All active, in-progress, and completed backup jobs are listed in this tab.</p>	

Task	Description	Skills required
Copy the backup from the source account to the target account.	<p>After the backup job is completed, copy the DynamoDB table backup from the backup vault in the source account to the backup vault in target account.</p> <p>To copy the backup vault, in the source account, do the following:</p> <ol style="list-style-type: none"><li>1. On the AWS Backup console, choose <b>Backup vaults</b>.</li><li>2. Under <b>Backups</b>, choose the DynamoDB table backup.</li><li>3. Choose <b>Actions, Copy</b>.</li><li>4. Enter the AWS Region of the target account.</li><li>5. For <b>External vault ARN</b>, enter the ARN of the backup vault that you created in the target account.</li><li>6. To copy backups from the source account to the target account, in the target account backup vault, enable access from a different account.</li></ol>	AWS DevOps, Migration engineer, DBA

Task	Description	Skills required
Restore the backup in the target account.	<p>In the target AWS account, do the following:</p> <ol style="list-style-type: none"><li>1. On the AWS Backup console, choose <b>Backup vaults</b>.</li><li>2. Under <b>Backups</b>, select the backup that you copied from the source account.</li><li>3. Choose <b>Actions, Restore</b>.</li><li>4. Enter the name of the target DynamoDB table that you want to restore.</li></ol>	AWS DevOps, DBA, Migration engineer

# Copy Amazon DynamoDB tables across accounts using a custom implementation

Created by Ramkumar Ramanujam (AWS)

<b>Environment:</b> Production	<b>Source:</b> Amazon DynamoDB	<b>Target:</b> Amazon DynamoDB
<b>R Type:</b> N/A	<b>Workload:</b> All other workloads	<b>Technologies:</b> Databases

**AWS services:** Amazon DynamoDB

## Summary

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that are in the production environment. As a standard practice, each environment uses a different AWS account.

DynamoDB now supports cross-account backup using AWS Backup. For information about associated storage costs when using AWS Backup, see [AWS Backup pricing](#). When you use AWS Backup to copy across accounts, the source and target accounts must be part of an AWS Organizations organization. There are other solutions for cross-account backup and restore using AWS services such as AWS Data Pipeline or AWS Glue. Using those solutions, however, increases the application footprint, because there are more AWS services to deploy and maintain.

You can also use Amazon DynamoDB Streams to capture table changes in the source account. Then you can initiate an AWS Lambda function, and make the corresponding changes in the target table in the target account. But that solution applies to use cases in which source and target tables must always be kept in sync. It might not apply to development, testing, and staging environments where data are updated frequently.

This pattern provides steps to implement a custom solution to copy a Amazon DynamoDB table from one account to another. This pattern can be implemented using common programming languages such as C#, Java, and Python. We recommend using a language that is supported by an [AWS SDK](#).

## Prerequisites and limitations

### Prerequisites

- Two active AWS accounts
- DynamoDB tables in both the accounts
- Knowledge of AWS Identity and Access Management (IAM) roles and policies
- Knowledge of how to access Amazon DynamoDB tables using any common programming language, such as C#, Java, or Python

### Limitations

This pattern applies to DynamoDB tables that are around 2 GB or smaller. With additional logic to handle connection or session interruptions, throttling, and failures and retries, it can be used for larger tables.

The DynamoDB scan operation, which reads items from the source table, can fetch only up to 1 MB of data in a single call. For larger tables, greater than 2 GB, this limitation can increase the total time to perform a full table copy.

### Architecture

The following diagram shows the custom implementation between the source and target AWS accounts. IAM policies and security tokens are used with the custom implementation. Data is read from Amazon DynamoDB in the source account and written to DynamoDB in the target account.

## Automation and scale

This pattern applies to DynamoDB tables that are smaller in size, around 2 GB.

To apply this pattern for larger tables, address the following issues:

- During the table copy operation, two active sessions are maintained, using different security tokens. If the table copy operation takes longer than the token expiration times, you must put in place logic to refresh the security tokens.
- If enough read capacity units (RCUs) and write capacity units (WCUs) are not provisioned, reads or writes on the source or target table might get throttled. Be sure to catch and handle these exceptions.
- Handle any other failures or exceptions and put a retry mechanism in place to retry or continue from where the copy operation failed.

## Tools

### Tools

- [Amazon DynamoDB](#) – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- The additional tools required will differ based on the programming language that you choose for the implementation. For example, if you use C#, you will need Microsoft Visual Studio and the following NuGet packages:

- AWSSDK
- AWSSDK.DynamoDBv2

## Code

The following Python code snippet deletes and recreates a DynamoDB table using the Boto3 library.

Do not use the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` of an IAM user because these are long-term credentials, which should be avoided for programmatic access to AWS services. For more information about temporary credentials, see the *Best practices* section.

The `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `TEMPORARY_SESSION_TOKEN` used in the following code snippet are temporary credentials fetched from AWS Security Token Service (AWS STS).

```
import boto3
import sys
import json

#args = input-parameters = GLOBAL_SEC_INDEXES_JSON_COLLECTION,
    ATTRIBUTES_JSON_COLLECTION, TARGET_DYNAMODB_NAME, TARGET_REGION, ...

#Input param: GLOBAL_SEC_INDEXES_JSON_COLLECTION
#[{"IndexName":"Test-index","KeySchema":[{"AttributeName":"AppId","KeyType":"HASH"},
{"AttributeName":"AppType","KeyType":"RANGE"}],"Projection":
{"ProjectionType":"INCLUDE","NonKeyAttributes":["PK","SK","OwnerName","AppVersion"]}]}

#Input param: ATTRIBUTES_JSON_COLLECTION
#[{"AttributeName":"PK","AttributeType":"S"},
{"AttributeName":"SK","AttributeType":"S"},
{"AttributeName":"AppId","AttributeType":"S"},
{"AttributeName":"AppType","AttributeType":"N"}]

region = args['TARGET_REGION']
target_ddb_name = args['TARGET_DYNAMODB_NAME']

global_secondary_indexes = json.loads(args['GLOBAL_SEC_INDEXES_JSON_COLLECTION'])
attribute_definitions = json.loads(args['ATTRIBUTES_JSON_COLLECTION'])

# Drop and create target DynamoDB table
dynamodb_client = boto3.Session(
```

```
        aws_access_key_id=args['AWS_ACCESS_KEY_ID'],
        aws_secret_access_key=args['AWS_SECRET_ACCESS_KEY'],
        aws_session_token=args['TEMPORARY_SESSION_TOKEN'],
    ).client('dynamodb')

# Delete table
print('Deleting table: ' + target_ddb_name + ' ...')

try:
    dynamodb_client.delete_table(TableName=target_ddb_name)

    #Wait for table deletion to complete
    waiter = dynamodb_client.get_waiter('table_not_exists')
    waiter.wait(TableName=target_ddb_name)
    print('Table deleted.')
except dynamodb_client.exceptions.ResourceNotFoundException:
    print('Table already deleted / does not exist.')
    pass

print('Creating table: ' + target_ddb_name + ' ...')

table = dynamodb_client.create_table(
    TableName=target_ddb_name,
    KeySchema=[
        {
            'AttributeName': 'PK',
            'KeyType': 'HASH' # Partition key
        },
        {
            'AttributeName': 'SK',
            'KeyType': 'RANGE' # Sort key
        }
    ],
    AttributeDefinitions=attribute_definitions,
    GlobalSecondaryIndexes=global_secondary_indexes,
    BillingMode='PAY_PER_REQUEST'
)

waiter = dynamodb_client.get_waiter('table_exists')
waiter.wait(TableName=target_ddb_name)

print('Table created.')
```

# Best practices

## Temporary credentials

As a security best practice, while accessing AWS services programmatically, avoid using the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` of an IAM user because these are long-term credentials. Always try to use temporary credentials to access AWS services programmatically.

As an example, a developer hardcodes the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` of an IAM user in the application during development but fails to remove the hardcoded values before pushing changes to code repository. These exposed credentials can be used by unintended or malicious users, which can have serious implications (especially if the exposed credentials have admin privileges). These exposed credentials should be deactivated or deleted immediately by using the IAM console or AWS Command Line Interface (AWS CLI).

To get temporary credentials for programmatic access to AWS services, use AWS STS. Temporary credentials are valid only for the specified time (from 15 minutes up to 36 hours). The maximum allowed duration of temporary credentials varies depending on such factors as role settings and role chaining. For more information about AWS STS, see the [documentation](#).

## Epics

### Set up DynamoDB tables

Task	Description	Skills required
Create DynamoDB tables.	<p>Create DynamoDB tables, with indexes, in both source and target AWS accounts.</p> <p>Set the capacity provisioning as on-demand mode, which allows DynamoDB to scale read/write capacities dynamically based on the workload.</p>	App developer, DBA, Migration engineer

Task	Description	Skills required
	Alternatively, you can use provisioned capacity with 4000 RCUs and 4000 WCUs.	
Populate the source table.	Populate the DynamoDB table in the source account with test data. Having at least 50 MB or more of test data helps you to see the peak and average RCUs consumed during table copy. You can then change the capacity provisioning as needed.	App developer, DBA, Migration engineer

### Set up credentials to access the DynamoDB tables

Task	Description	Skills required
Create IAM roles to access the source and target DynamoDB tables.	<p>Create an IAM role in the source account with permissions to access (read) the DynamoDB table in the source account.</p> <p>Add the source account as a trusted entity for this role.</p> <p>Create an IAM role in the target account with permissions to access (create, read, update, delete) the DynamoDB table in the target account.</p>	App developer, AWS DevOps

Task	Description	Skills required
	Add the target account as a trusted entity for this role.	

### Copy table data from one account to another

Task	Description	Skills required
Get temporary credentials for the IAM roles.	<p>Get temporary credentials for IAM role created in source account.</p> <p>Get temporary credentials for IAM role created in target account.</p> <p>One way to get the temporary credentials for the IAM role is to use AWS STS from the AWS CLI.</p> <pre>aws sts assume-role   --role-arn arn:aws:iam::&lt;account-id&gt;:role/&lt;role-name&gt; --   role-session-name   &lt;session-name&gt; --   profile &lt;profile-name&gt;</pre> <p>Use the appropriate AWS profile (corresponding to the source or target account).</p> <p>For more information about different ways to get temporary credentials, see the following:</p>	App developer, Migration engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <a href="#">AWS Security Token Service API Reference</a></li><li>• <a href="#">Getting IAM role credentials for CLI access</a></li></ul>	
Initialize the DynamoDB clients for source and target DynamoDB access.	<p>Initialize the DynamoDB clients, which are provided by the AWS SDK, for the source and target DynamoDB tables.</p> <ul style="list-style-type: none"><li>• For the source DynamoDB client, use the temporary credentials fetched from the source account.</li><li>• For the target DynamoDB client, use the temporary credentials fetched from the target account.</li></ul> <p>For more information about making requests by using IAM temporary credentials, see the <a href="#">AWS documentation</a>.</p>	App developer

Task	Description	Skills required
Drop and recreate the target table.	<p>Delete and recreate the target DynamoDB table (along with indexes) in the target account, using the target account DynamoDB client.</p> <p>Deleting all records from a DynamoDB table is a costly operation because it consumes provisioned WCUs. Deleting and recreating the table avoids those extra costs.</p> <p>You can add indexes to a table after you create it, but this takes 2–5 minutes longer. Creating indexes during table creation, by passing the indexes collection to the <code>createTable</code> call, is more efficient.</p>	App developer

Task	Description	Skills required
Perform the table copy.	<p>Repeat the following steps until all data are copied:</p> <ul style="list-style-type: none"><li>• Perform a scan on the table in the source account, using the source DynamoDB client. Each DynamoDB scan retrieves only 1 MB of data from the table, so you must repeat this operation until all items, or records, are read.</li><li>• For each set of scanned items, write the items to the table in the target account, with the target DynamoDB client, using the <code>BatchWriteItem</code> call in AWS SDK for DynamoDB. This reduces the number of <code>PutItem</code> requests made to DynamoDB.</li><li>• <code>BatchWriteItem</code> has a limitation of 25 writes or puts, or up to 16 MB. You must add logic to accumulate scanned items in counts of 25 before calling <code>BatchWriteItem</code>. <code>BatchWriteItem</code> returns a list of items that could not be successfully copied. Using this list, add retry logic to perform another</li></ul>	App developer

Task	Description	Skills required
	<p>BatchWriteItem call with only those items that did not succeed.</p> <p>For more information, see the reference implementation in C# (for dropping, creating, and populating tables) in the <i>Attachments</i> section. An example table config JavaScript Object Notation (JSON) file is also attached.</p>

- [Using temporary credentials with AWS resources](#)

## Additional information

This pattern was implemented using C# to copy a DynamoDB table with 200,000 items (average item size of 5 KB and table size of 250 MB). The target DynamoDB table was set up with provisioned capacity of 4000 RCUs and 4000 WCUs.

The complete table copy operation (from source account to target account), including dropping and recreating the table, took 5 minutes. Total capacity units consumed: 30,000 RCUs and approximately 400,000 WCUs.

For more information on DynamoDB capacity modes, see [Read/Write capacity mode](#) in the AWS documentation.

# Create detailed cost and usage reports for Amazon RDS and Amazon Aurora

Created by Lakshmanan Lakshmanan (AWS) and Sudarshan Narasimhan

**Environment:** Production

**Technologies:** Databases;  
Cost management; Analytics

**AWS services:** Amazon  
Athena; Amazon Aurora;  
Amazon RDS; AWS Billing and  
Cost Management

## Summary

This pattern shows how to track usage costs for Amazon Relational Database Service (Amazon RDS) or Amazon Aurora clusters by configuring [user-defined cost allocation tags](#). You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level, and then analyze the data in Amazon Athena.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- One or more [Amazon RDS](#) or [Amazon Aurora](#) instances

### Limitations

For tagging restrictions, see the [AWS Billing User Guide](#).

## Architecture

### Target technology stack

- Amazon RDS or Amazon Aurora
- AWS Cost and Usage Report

- AWS Cost Explorer
- Amazon Athena

## Workflow and architecture

The tagging and analysis workflow consists of these steps:

1. A data engineer, database administrator, or AWS administrator creates user-defined cost allocation tags for the Amazon RDS or Aurora clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.
4. A data engineer, database administrator, or AWS administrator creates a [monthly cost allocation report](#).
5. A data engineer, database administrator, or AWS administrator analyzes the monthly cost allocation report by using Amazon Athena.

The following diagram shows how to apply tags to track usage costs for Amazon RDS or Aurora instances.

The following architecture diagram shows how the cost allocation report is integrated with Amazon Athena for analysis.

The monthly cost allocation report is stored in an Amazon S3 bucket that you specify. When you set up Athena with the AWS CloudFormation template, as described in the *Epics* section, the template provisions several additional resources, including an AWS Glue crawler, an AWS Glue database, an Amazon Simple Notification System (Amazon SNS) event, AWS Lambda functions, and AWS Identity and Access Management (IAM) roles for the Lambda functions. As new cost data files arrive in the S3 bucket, event notifications are used to forward these files to a Lambda function for processing. The Lambda function initiates an AWS Glue crawler job to create or update the table in the AWS Glue Data Catalog. This table is then used to query data in Athena.

## Tools

- [Amazon Athena](#) is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- [Amazon Aurora](#) is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.

- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [AWS CloudFormation](#) is an infrastructure as code (IaC) service that allows you to easily model, provision, and manage AWS and third-party resources.
- [AWS Cost Explorer](#) helps you view and analyze your AWS costs and usage.

## Epics

### Create and activate tags for your Amazon RDS or Aurora cluster

Task	Description	Skills required
Create user-defined cost allocation tags for your Amazon RDS or Aurora cluster.	<p>To add tags to a new or existing Amazon RDS or Aurora cluster, follow the instructions in <a href="#">Adding, listing, and removing tags</a> in the <i>Amazon Aurora User Guide</i>.</p> <p><b>Note:</b> For information about how to set up an Amazon Aurora cluster, see the instructions for <a href="#">MySQL</a> and <a href="#">PostgreSQL</a> in the <i>Amazon Aurora User Guide</i>.</p>	AWS administrator, Data engineer, DBA
Activate the user-defined cost allocation tags.	Follow the instructions in <a href="#">Activating user-defined cost allocation tags</a> in the <i>AWS Billing User Guide</i> .	AWS administrator

## Create cost and usage reports

Task	Description	Skills required
Create and configure cost and usage reports for your clusters.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">AWS Billing console</a>.</li><li>2. In the left navigation pane, choose <b>Cost &amp; Usage Reports</b>.</li><li>3. Choose <b>Create report</b>.</li><li>4. Provide a report name, keep the default settings for other options, and then choose <b>Next</b>.</li><li>5. Choose <b>Configure</b> and provide the details of an existing S3 bucket. You can also choose to create a new S3 bucket from this screen. Choose <b>Next</b>.</li><li>6. Verify the default policy that will be applied to your bucket, select the confirmation check box, and then choose <b>Save</b>.</li><li>7. For <b>Report path prefix</b>, specify the prefix you want to prepend to the report name.</li><li>8. For <b>Time granularity</b>, choose <b>Hourly</b>, <b>Daily</b> or <b>Monthly</b>, depending on how often you want data</li></ol>	App owner, AWS administrator, DBA, General AWS, Data engineer

Task	Description	Skills required
	<p>to be collected for the report.</p> <p>9. For <b>Report versioning</b>, choose whether you want new versions of the report to be created separately or overwrite the existing report with each version.</p> <p>10For <b>Enable report data integration for</b>, choose <b>Amazon Athena</b>. Verify that the compression type is set to Parquet.</p> <p>11Choose <b>Next</b>.</p> <p>12Review the report settings, and then choose <b>Review and Complete</b>.</p> <p>The data will be available in 24 hours.</p>	

## Analyze cost and usage report data

Task	Description	Skills required
Analyze the cost and usage report data.	<ol style="list-style-type: none"> <li>1. Set up and use Athena to analyze the report data. For instructions, see <a href="#">Querying Cost and Usage Reports using Amazon Athena</a> in the <i>AWS Cost and Usage Reports User Guide</i>. We recommend</li> </ol>	App owner, AWS administrator, DBA, General AWS, Data engineer

Task	Description	Skills required
	<p>that you use the <a href="#">AWS CloudFormation template provided by Athena</a>.</p> <p>2. Run Athena queries. For example, you can use the following SQL query to check the status of the data refresh.</p> <pre data-bbox="594 663 1029 823">select status from cost_and_usage_data_ a_status</pre> <p>For more information, see <a href="#">Running Amazon Athena queries</a> in the <i>AWS Cost and Usage Reports User Guide</i>.</p> <p><b>Note:</b> When you run your SQL query, make sure that the correct database is selected from the dropdown list.</p>

# Emulate Oracle RAC workloads using custom endpoints in Aurora PostgreSQL

Created by HariKrishna Boorgadda (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Aurora PostgreSQL
<b>R Type:</b> Replatform	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon Aurora; Amazon CloudWatch		

## Summary

This pattern describes how to emulate services in an Oracle Real Application Clusters (Oracle RAC) workload by using Amazon Aurora PostgreSQL-Compatible Edition with custom endpoints that distribute workloads across instances within a single cluster. The pattern shows you how to create [custom endpoints](#) for Amazon Aurora databases. Custom endpoints enable you to distribute and load balance workloads across different sets of DB instances in your Aurora cluster.

In an Oracle RAC environment, [services](#) can span one or more instances and facilitate workload balancing based on transaction performance. Service features include end-to-end unattended recovery, rolling changes by workload, and full location transparency. You can use this pattern to emulate some of these features. For example, you can emulate the ability to route connections for reporting applications.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A [PostgreSQL JDBC driver](#)
- An [Aurora PostgreSQL-Compatible database](#)
- An Oracle RAC database migrated to an Aurora PostgreSQL-Compatible database

## Limitations

- For limitations that apply to custom endpoints, see [Specifying properties for custom endpoints](#) in the Amazon RDS documentation.

## Architecture

### Source technology stack

- A three-node Oracle RAC database

### Target technology stack

- An Aurora PostgreSQL-Compatible database with two read replicas

### Source architecture

The following diagram shows the architecture of a three-node Oracle RAC database.

**Target architecture**

The following diagram shows the architecture of an Aurora PostgreSQL-Compatible database with two read replicas. Three different applications/services are using custom endpoints, which serve different application users and redirect the traffic and load between primary and read replicas.

## Tools

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

# Epics

## Create the Aurora PostgreSQL-Compatible cluster

Task	Description	Skills required
Create a cluster.	To create the cluster, see <a href="#">Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster</a> in the Amazon RDS documentation.	AWS administrator
Create a custom parameter group for the workload.	To create a parameter group, see <a href="#">Creating a DB cluster parameter group</a> in the Amazon RDS documentation.	AWS administrator
Create event notifications and alarms.	<p>You can use event notifications and Amazon CloudWatch alarms to notify you when the cluster changes state and to capture metrics when a predefined threshold is met.</p> <p>To create a CloudWatch alarm, see <a href="#">Create a CloudWatch alarm based on a static threshold</a> in the CloudWatch documentation.</p> <p>To create an event notification, see <a href="#">Creating a CloudWatch Events Rule That Triggers on an Event</a> in the CloudWatch documentation.</p>	AWS administrator

## Add replicas to the Aurora PostgreSQL-Compatible DB cluster

Task	Description	Skills required
Add the read replicas to the cluster.	<ol style="list-style-type: none"> <li>1. <a href="#">Create a read replica</a>.</li> <li>2. Add the read replica to the same Availability Zone that your DB cluster is in. <b>Note:</b> You can use a different Availability Zone if you have requirements that must be met for your failover node.</li> </ol>	AWS administrator
Note the read replica endpoint.	Document your read replica endpoint for later use in creating the custom endpoints.	AWS administrator

## Create custom endpoints

Task	Description	Skills required
Enter a name for the custom endpoint.	For each endpoint that you require, create a unique endpoint name related to your workload or application.	AWS administrator
Add the endpoint members.	Add your read replica endpoints to a custom group. For more information, see <a href="#">Editing a custom endpoint</a> in the Amazon RDS documentation.	AWS administrator
(Optional) Add future instances to the cluster.	If you want to add more replicas or endpoints to the	AWS administrator

Task	Description	Skills required
	custom group, see <a href="#">Adding Aurora Replicas to a DB cluster</a> in the Amazon RDS documentation.	
Create the endpoint.	To create the endpoint, see <a href="#">Creating a custom endpoint</a> in the Amazon RDS documentation.	AWS administrator

### Test application connections by using custom endpoints

Task	Description	Skills required
Share the custom endpoint details with the application that points to your workload.	Add your custom endpoint details to the database connection details in the reporting application that you plan to test.	AWS administrator
Connect the workload by using the custom endpoint.	Validate the custom endpoint details in the reporting application.	AWS administrator
Check the connection details from the database.	<ol style="list-style-type: none"> <li>1. Test the user name and connection count for your application.</li> <li>2. Check the load balancing across your workloads to make sure the connections are distributed across different custom endpoints (primary and read replicas).</li> </ol>	AWS administrator

## Related resources

# Enable encrypted connections for PostgreSQL DB instances in Amazon RDS

*Created by Rohit Kapoor (AWS)*

**Environment:** PoC or pilot

**Technologies:** Databases; Networking; Security, identity, compliance

**Workload:** Open-source

**AWS services:** Amazon RDS; Amazon Aurora

## Summary

Amazon Relational Database Service (Amazon RDS) supports SSL encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your Amazon RDS for PostgreSQL DB instances. By default, Amazon RDS for PostgreSQL uses SSL/TLS and expects all clients to connect by using SSL/TLS encryption. Amazon RDS for PostgreSQL supports TLS versions 1.1 and 1.2.

This pattern describes how you can enable encrypted connections for an Amazon RDS for PostgreSQL DB instance. You can use the same process to enable encrypted connections for Amazon Aurora PostgreSQL-Compatible Edition.

## Prerequisites and limitations

- An active AWS account
- An [Amazon RDS for PostgreSQL DB instance](#)
- An [SSL bundle](#)

## Architecture

## Tools

- [pgAdmin](#) is an open-source administration and development platform for PostgreSQL. You can use pgAdmin on Linux, Unix, macOS, and Windows to manage your database objects in PostgreSQL 10 and later.
- [PostgreSQL editors](#) provide a more user-friendly interface to help you create, develop, and run queries, and to edit code according to your requirements.

## Best practices

- Monitor unsecure database connections.
- Audit database access rights.
- Make sure that backups and snapshots are encrypted at rest.
- Monitor database access.
- Avoid unrestricted access groups.
- Enhance your notifications with [Amazon GuardDuty](#).
- Monitor policy adherence regularly.

# Epics

## Download a trusted certificate and import it into your trust store

Task	Description	Skills required
Load a trusted certificate to your computer.	<p>To add certificates to the Trusted Root Certification Authorities store for your computer, follow these steps. (These instructions use Window Server as a example.)</p> <ol style="list-style-type: none"><li>1. In Windows Server, choose <b>Start, Run</b>, and then type <b>mmc</b>.</li><li>2. In the console, choose <b>File, Add/Remove Snap-in</b>.</li><li>3. Under <b>Available snap-ins</b>, choose <b>Certificates</b>, and then choose <b>Add</b>.</li><li>4. Under <b>This snap-in will always manage certificates for</b>, choose <b>Computer account, Next</b>.</li><li>5. Choose <b>Local computer, Finish</b>.</li><li>6. If you have no more snap-ins to add to the console, choose <b>OK</b>.</li><li>7. In the console tree, double-click <b>Certificates</b>.</li><li>8. Right-click <b>Trusted Root Certification Authorities</b>.</li></ol>	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required
	<p>9. Choose <b>All Tasks, Import</b> to import the downloaded certificates.</p> <p>10 Follow the steps in the Certificate Import Wizard.</p>	

## Force SSL connections

Task	Description	Skills required
Create a parameter group and set the <code>rds.force_ssl</code> parameter.	<p>If the PostgreSQL DB instance has a custom parameter group, edit the parameter group and change <code>rds.force_ssl</code> to 1.</p> <p>If the DB instance uses the default parameter group that doesn't have <code>rds.force_ssl</code> enabled, create a new parameter group. You can modify the new parameter group by using the Amazon RDS API or manually as in the following instructions.</p> <p>To create a new parameter group:</p> <ol style="list-style-type: none"> <li>1. Sign in to the AWS Management console and open <a href="#">the Amazon RDS console</a> for the AWS Region that hosts the DB instance.</li> </ol>	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. In the navigation pane, choose <b>Parameter groups</b>.</li><li>3. Choose <b>Create parameter group</b>, and set the following values:<ul style="list-style-type: none"><li>• For <b>Parameter group family</b>, choose <b>postgres14</b>.</li><li>• For <b>Group name</b>, type <b>pgsql-&lt;database_instance&gt;-ssl</b>.</li><li>• For <b>Description</b>, enter a free-form description for the parameter group you're adding.</li><li>• Choose <b>Create</b>.</li></ul></li><li>4. Choose the parameter group that you created.</li><li>5. From <b>Parameter group actions</b>, choose <b>Edit</b>.</li><li>6. Find <b>rds.force_ssl</b> and change its setting to <b>1</b>.  <b>Note:</b> Conduct client-side testing before changing this parameter.</li><li>7. Choose <b>Save changes</b>.</li></ol> <p>To associate the parameter group with your PostgreSQL DB instance:</p>	

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>1. On the Amazon RDS console, in the navigation pane, choose <b>Databases</b>, and then choose the PostgreSQL DB instance.</li> <li>2. Choose <b>Modify</b>.</li> <li>3. Under <b>Additional configuration</b>, choose the new parameter group, and then choose <b>Continue</b>.</li> <li>4. Under <b>Schedule modifications</b>, choose <b>Apply immediately</b>.</li> <li>5. Choose <b>Modify DB instance</b>.</li> </ol> <p>For more information, see the <a href="#">Amazon RDS documentation</a>.</p>	
Force SSL connections.	<p>Connect to the Amazon RDS for PostgreSQL DB instance. Connection attempts that don't use SSL are rejected with an error message. For more information, see the <a href="#">Amazon RDS documentation</a>.</p>	DevOps engineer, Migration engineer, DBA

## Install SSL extension

Task	Description	Skills required
Install the SSL extension.	<ol style="list-style-type: none"> <li>1. Launch a psql or pgAdmin connection as a DBA.</li> </ol>	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required
	<p>2. Call the <code>ssl_is_used()</code> function to determine if SSL is being used.</p> <pre data-bbox="630 380 1029 457">select ssl_is_used();</pre> <p>The function returns <code>t</code> if the connection is using SSL; otherwise, it returns <code>f</code>.</p> <p>3. Install the SSL extension.</p> <pre data-bbox="630 722 1029 919">create extension sslinfo; show ssl; select ssl_cipher();</pre> <p>For more information, see the <a href="#">Amazon RDS documentation</a>.</p>	

## Configure your PostgreSQL client for SSL

Task	Description	Skills required
Configure a client for SSL.	By using SSL, you can start the PostgreSQL server with support for encrypted connections that use TLS protocols. The server listens for both standard and SSL connections on the same TCP port, and negotiates with any connecting client on whether to use SSL. By default, this is a client option.	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required
	<p>If you're using the psql client:</p> <ol style="list-style-type: none"><li>1. Make sure that the Amazon RDS certificate has been loaded to your local computer.</li><li>2. Launch an SSL client connection by adding the following:</li></ol> <pre data-bbox="630 655 1029 1016">psql postgres -h SOMEHOST.amazonaws .com -p 8192 -U someuser sslmode=v erify-full sslrootce rt=rds-ssl-ca-cert .pem select ssl_cipher();</pre> <p>For other PostgreSQL clients:</p> <ul style="list-style-type: none"><li>• Modify the respective application public key parameter. This might be available as an option, as part of your connection string, or as a property on the connection page in GUI tools.</li></ul> <p>Review the following pages for these clients:</p> <ul style="list-style-type: none"><li>• <a href="#">pgAdmin documentation</a></li><li>• <a href="#">JDBC documentation</a></li></ul>	

## Troubleshooting

Issue	Solution
Cannot download the SSL certificate.	Check your connection to the website, and retry downloading the certificate to your local computer.

# Encrypt an existing Amazon RDS for PostgreSQL DB instance

Created by Piyush Goyal (AWS), Shobana Raghu (AWS), and Yaser Raja (AWS)

**Environment:** Production

**Technologies:** Databases;  
Security, identity, compliance

**AWS services:** Amazon RDS;  
AWS KMS; AWS DMS

## Summary

This pattern explains how to encrypt an existing Amazon Relational Database Service (Amazon RDS) for PostgreSQL DB instance in the Amazon Web Services (AWS) Cloud with minimal downtime. This process works for Amazon RDS for MySQL DB instances as well.

You can enable encryption for an Amazon RDS DB instance when you create it, but not after it's created. However, you can add encryption to an unencrypted DB instance by creating a snapshot of your DB instance, and then creating an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot to get an encrypted copy of your original DB instance. If your project allows for downtime (at least for write transactions) during this activity, this is all you need to do. When the new, encrypted copy of the DB instance becomes available, you can point your applications to the new database. However, if your project doesn't allow for significant downtime for this activity, you need an alternate approach that helps minimize the downtime. This pattern uses the AWS Database Migration Service (AWS DMS) to migrate and continuously replicate the data so that the cutover to the new, encrypted database can be done with minimal downtime.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently, with minimal impact on performance. You don't need to modify your database client applications to use encryption.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An unencrypted Amazon RDS for PostgreSQL DB instance

- Experience working with (creating, modifying, or stopping) AWS DMS tasks (see [Working with AWS DMS tasks](#) in the AWS DMS documentation)
- Familiarity with AWS Key Management Service (AWS KMS) for encrypting databases (see the [AWS KMS documentation](#))

## Limitations

- You can enable encryption for an Amazon RDS DB instance only when you create it, not after the DB instance is created.
- Data in [unlogged tables](#) will not be restored using snapshots. For more information, review [Best practices for working with PostgreSQL](#).
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- AWS DMS does not automatically transfers the Sequences therefore additional steps are required to handle this.

For more information, see [Limitations of Amazon RDS encrypted DB instances](#) in the Amazon RDS documentation.

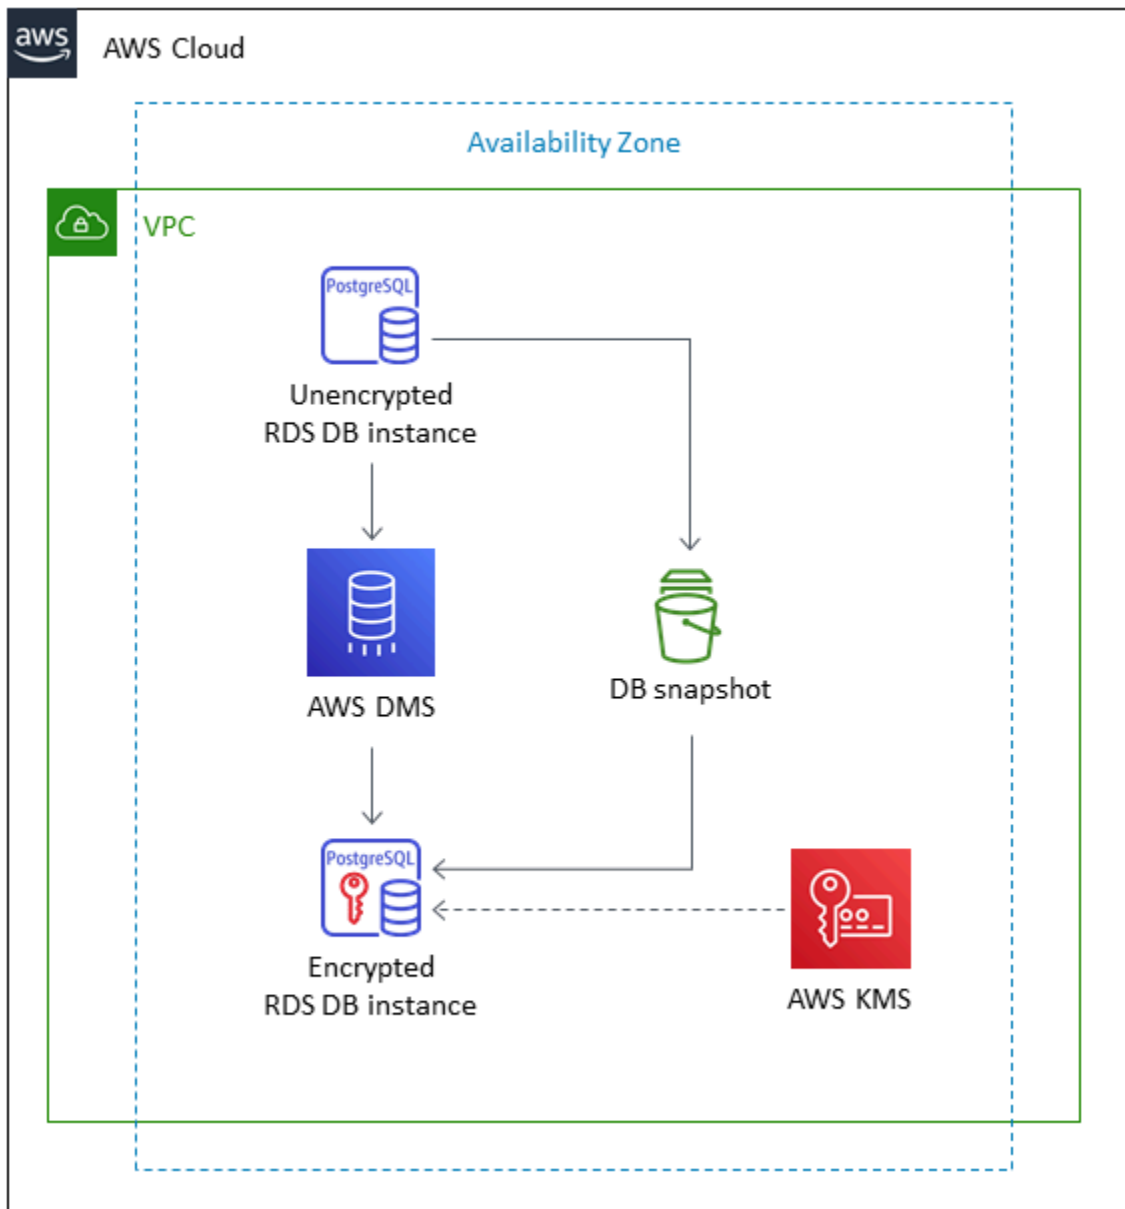

## Architecture

### Source architecture

- Unencrypted RDS DB instance

### Target architecture

- Encrypted RDS DB instance
  - The destination RDS DB instance is created by restoring the DB snapshot copy of the source RDS DB instance.
  - An AWS KMS key is used for encryption while restoring the snapshot.
  - An AWS DMS replication task is used to migrate the data.

## Tools

### Tools used to enable encryption:

- **AWS KMS key for encryption** – When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS

for each AWS Region. For more information about using KMS keys for Amazon RDS encryption, see [Encrypting Amazon RDS Resources](#).

### Tools used for ongoing replication:

- AWS DMS – You can use AWS Database Migration Service (AWS DMS) to replicate changes from the source DB to the target DB. It is important to keep the source and target DB in sync to keep downtime to a minimum. For information about setting up AWS DMS and creating tasks, see the [AWS DMS documentation](#).

## Epics

### Create a snapshot of the source DB instance and encrypt it

Task	Description	Skills required
Check the details for the source PostgreSQL DB instance.	On the Amazon RDS console, choose the source PostgreSQL DB instance. On the <b>Configuration</b> tab, make sure that encryption isn't enabled for the instance. For a screen illustration, see the <a href="#">Additional information</a> section.	DBA
Create the DB snapshot.	Create a DB snapshot of the instance you want to encrypt. The amount of time it takes to create a snapshot depends on the size of your database. For instructions, see <a href="#">Creating a DB snapshot</a> in the Amazon RDS documentation.	DBA
Encrypt the snapshot.	In the Amazon RDS console navigation pane, choose <b>Snapshots</b> , and select the	DBA

Task	Description	Skills required
	<p>DB snapshot you created. For <b>Actions</b>, choose <b>Copy Snapshot</b>. Provide the destination AWS Region and the name of the DB snapshot copy in the corresponding fields. Select the <b>Enable Encryption</b> checkbox. For <b>Master Key</b>, specify the KMS key identifier to use to encrypt the DB snapshot copy. Choose <b>Copy Snapshot</b>. For more information, see <a href="#">Copying a snapshot</a> in the Amazon RDS documentation.</p>	

## Prepare the target DB instance

Task	Description	Skills required
Restore the DB snapshot.	<p>On the Amazon RDS console, choose <b>Snapshots</b>. Choose the encrypted snapshot that you created. For <b>Actions</b>, choose <b>Restore Snapshot</b>. For <b>DB Instance Identifier</b>, provide a unique name for the new DB instance. Review the instance details, and then choose <b>Restore DB Instance</b>. A new, encrypted DB Instance will be created from your snapshot. For more information, see <a href="#">Restoring from a DB</a></p>	DBA

Task	Description	Skills required
	<a href="#">snapshot</a> in the Amazon RDS documentation.	
Migrate data by using AWS DMS.	On the AWS DMS console, create an AWS DMS task. For <b>Migration type</b> , choose <b>Migrate existing data and replicate ongoing changes</b> . In <b>Task Settings</b> , for <b>Target table preparation mode</b> , choose <b>Truncate</b> . For more information, see <a href="#">Creating a task</a> in the AWS DMS documentation.	DBA
Enable data validation.	In <b>Task Settings</b> , choose <b>Enable validation</b> . This enables you to compare the source data to the target data to verify that the data was migrated accurately.	DBA
Disable constraints on the target DB instance.	<a href="#">Disable any triggers and foreign key constraints</a> on the target DB instance, and then start the AWS DMS task. For more information about disabling triggers and foreign key constraints, see the <a href="#">AWS DMS documentation</a> .	DBA

Task	Description	Skills required
Verify data.	After the full load is complete, verify the data on the target DB instance to see if it matches the source data. For more information, see <a href="#">AWS DMS data validation</a> in the AWS DMS documentation.	DBA

### Cut over to the target DB instance

Task	Description	Skills required
Stop write operations on the source DB instance.	Stop the write operations on the source DB instance so that application downtime can begin. Verify that AWS DMS has completed the replication for the data in the pipeline. Enable triggers and foreign keys on the target DB instance.	DBA
Update database sequences	If the source database contains any sequence numbers, verify and update the sequences in the target database.	DBA
Configure the application endpoint.	Configure your application connections to use the new Amazon RDS DB instance endpoints. The DB instance is now encrypted.	DBA, Application owner

## Related resources

- [Creating an AWS DMS task](#)
- [Monitoring replication tasks using Amazon CloudWatch](#)
- [Monitoring AWS DMS tasks](#)
- [Updating the Amazon RDS encryption key](#)

## Additional information

Checking the encryption for the source PostgreSQL DB instance:

Summary			
DB identifier rds-test	CPU 3.17%	Status Available	Class db.t2.micro
Role Instance	Current activity 0 Sessions	Engine PostgreSQL	Region & AZ us-east-1a
Connectivity & security   Monitoring   Logs & events   <b>Configuration</b>   Maintenance & backups   Tags			
Instance			
Configuration	Instance class	Storage	Performance Insights
DB instance id rds-test	Instance class db.t2.micro	Encryption Not Enabled	Performance Insights enabled Yes

Additional notes for this pattern:

- Enable replication on PostgreSQL by setting the `rds.logical_replication` parameter to 1.

**Important note:** Replication slots retain the write ahead log (WAL) files until the files are externally consumed—for example, by `pg_recvlogical`; by extract, transform, and load (ETL) jobs; or by AWS DMS. When you set the `rds.logical_replication` parameter value to 1, AWS DMS sets the `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections` parameters. If logical replication slots are present but there is no consumer for the WAL files retained by the replication slot, you might see an increase in the transaction log disk usage and a constant decrease in free storage space. For more information and steps to resolve this issue, see

the article [How can I identify what is causing the "No space left on device" or "DiskFull" error on Amazon RDS for PostgreSQL?](#) in the AWS Support Knowledge Center.

- Any schema changes that you make to the source DB instance after you create the DB snapshot will not be present on the target DB instance.
- After you create an encrypted DB instance, you can't change the KMS key used by that DB instance. Be sure to determine your KMS key requirements before you create your encrypted DB instance.
- You must disable triggers and foreign keys on the target DB instance before you run the AWS DMS task. You can re-enable these when the task is complete.

# Enforce automatic tagging of Amazon RDS databases at launch

**Environment:** Production

**Technologies:** Databases  
; CloudNative; Security,  
identity, compliance

**AWS services:** Amazon RDS;  
Amazon SNS; AWS CloudTrail;  
Amazon CloudWatch

## Summary

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the Amazon Web Services (AWS) Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

You can use tagging to categorize your AWS resources in different ways. Relational database tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can use Amazon RDS tags to add custom metadata to your RDS DB instances. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor and tag RDS DB instances. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail **CreateDBInstance** event. (CloudTrail captures API calls for Amazon RDS as events.) When it detects this event, it calls an AWS Lambda function that automatically applies tag keys and values that you define. The template also sends out a notification that the instance has been tagged, by using Amazon Simple Notification Service (Amazon SNS).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the Lambda code.
- An email address where you would like to receive tagging notifications.

### Limitations

- The solution supports CloudTrail **CreateDBInstance** events. It does not create notifications for any other events.

## Architecture

### Workflow architecture

### Automation and scale

- You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

## Tools

### AWS services

- [AWS CloudTrail](#) – AWS CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- [Amazon CloudWatch Events](#) – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

## Code

This pattern includes an attachment with two files:

- `index.zip` is a compressed file that includes the Lambda code for this pattern.
- `rds.yaml` is a CloudFormation template that deploys the Lambda code.

See the *Epics* section for information about how to use these files.

## Epics

### Deploy the Lambda code

Task	Description	Skills required
Upload the code to an S3 bucket.	Create a new S3 bucket or use an existing S3 bucket to upload the attached <code>index.zip</code> file (Lambda code). This bucket must be in the same AWS Region as the resources (RDS DB instances) that you want to monitor.	Cloud architect
Deploy the CloudFormation template.	Open the Cloudformation console in the same AWS Region as the S3 bucket, and deploy the <code>rds.yaml</code> file that's provided in the attachment. In the next	Cloud architect

Task	Description	Skills required
	epic, provide values for the template parameters.	

### Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudFormation template and the RDS DB instances that you want to monitor.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, <code>index.zip</code> or <code>controls/index.zip</code> ).	Cloud architect
Provide an email address.	Provide an active email address where you want to receive violation notifications.	Cloud architect
Specify a logging level.	Specify the logging level and verbosity. Info designates detailed informational messages on the application's progress and should be used only for debugging	Cloud architect

Task	Description	Skills required
	. <code>Error</code> designates error events that could still allow the application to continue running. <code>Warning</code> designates potentially harmful situations.	
Enter the tag keys and values for your RDS DB instances.	Enter the required tag keys and values that you want to automatically apply to the RDS instance. For more information, see <a href="#">Tagging Amazon RDS resources</a> in the AWS documentation.	Cloud architect

## Confirm the subscription

Task	Description	Skills required
Confirm the email subscription.	When the CloudFormation template deploys successfully, it sends a subscription email message to the email address you provided. To receive notifications when your instances are tagged, you must confirm this email subscription.	Cloud architect

# Estimate the cost of a DynamoDB table for on-demand capacity

Created by Moinul Al-Mamun (AWS)

**Environment:** Production

**Technologies:** Databases;  
CloudNative; Serverless; Cost  
management

**AWS services:** Amazon  
DynamoDB

## Summary

[Amazon DynamoDB](#) is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision underlying infrastructure. Your single table can grow up to petabytes.

With on-demand capacity mode, you pay per request for the data reads and writes that your application performs on the tables. AWS charges are based on the accumulated read request units (RRUs) and write request units (WRUs) in a month. DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. It supports continuous backup with point-in-time-recovery (PITR). DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges.

To estimate the DynamoDB cost for a project, it's important to calculate how much RRU, WRU, and storage will be consumed at different stages of your product lifecycle. For a rough cost estimation, you can use [AWS Pricing Calculator](#), but you must provide an approximate number of RRUs, WRUs, and storage requirements for your table. These can be difficult to estimate at the beginning of the project. AWS Pricing Calculator doesn't consider data growth rate or item size, and it doesn't consider the number of reads and writes for the base table and global secondary indexes (GSIs) separately. To use AWS Pricing Calculator, you must estimate all those aspects to assume ballpark figures for WRU, RRU, and storage size to obtain your cost estimation.

This pattern provides a mechanism and a re-usable Microsoft Excel template to estimate basic DynamoDB cost factors, such as write, read, storage, backup and recovery cost, for on-demand capacity mode. It is more granular than AWS Pricing Calculator, and it considers base table and GSIs requirements independently. It also considers the monthly item data growth rate and forecasts costs for three years.

## Prerequisites and limitations

### Prerequisites

- Basic knowledge of DynamoDB and DynamoDB data model design
- Basic knowledge of DynamoDB pricing, WRU, RRU, storage, and backup and recovery (for more information, see [Pricing for On-Demand Capacity](#))
- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB GSIs

### Limitations

- The template provides you with an approximate calculation, but it isn't appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
- For a more accurate estimate, you must consider the expected number of writes (insert, update, and delete) and reads for each item in an average month.
- This pattern supports estimating only write, read, storage, and backup and recovery costs for next few years based on fixed data growth assumptions.

## Tools

### AWS services

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

### Other tools

- [AWS Pricing Calculator](#) is a web-based planning tool that you can use to create estimates for your AWS use cases.

## Best practices

To help keep costs low, consider the following DynamoDB design best practices.

- [Partition key design](#) – Use a high-cardinality partition key to distribute load evenly.
- [Adjacency list design pattern](#) – Use this design pattern for managing one-to-many and many-to-many relationships.
- [Sparse index](#) – Use sparse index for your GSIs. When you create a GSI, you specify a partition key and optionally a sort key. Only items in the base table that contain a corresponding GSI partition key appear in the sparse index. This helps to keep GSIs smaller.
- [Index overloading](#) – Use the same GSI for indexing various types of items.
- [GSI write sharding](#) – Shard wisely to distribute data across the partitions for efficient and faster queries.
- [Large items](#) – Store only metadata inside the table, save the blob in Amazon S3, and keep the reference in DynamoDB. Break large items into multiple items, and efficiently index by using sort keys.

For more design best practices, see the [Amazon DynamoDB Developer Guide](#).

## Epics

### Extract item information from your DynamoDB data model

Task	Description	Skills required
Get item size.	<ol style="list-style-type: none"> <li>1. Check how many different types of item you are going to store in your table.</li> <li>2. To calculate the size of each item in kilobytes, add the Key and Value size of each attribute.</li> <li>3. Calculate item size for a base table and for each GSI.</li> </ol>	Data engineer
Estimate the write cost.	To estimate write cost in on-demand capacity mode, first you have to measure how many WRUs will be consumed	Data engineer

Task	Description	Skills required
	<p>in a month. For that, you need to consider the following factors:</p> <ul style="list-style-type: none"><li>• Number of create, update, and delete operations for each item in a month.</li><li>• Number of available GSIs. Consider each index independently.<ul style="list-style-type: none"><li>• Average size of an index item</li><li>• Number of synchronization times on an index</li></ul></li><li>• How many new things (for example, components or products) will be added in the table each month? The number of added things could be different every month, but you can assume an average growth rate based on your business cases.</li></ul> <p>For more information, see the <i>Additional information</i> section.</p>	

Task	Description	Skills required
Estimate the read cost.	<p>To estimate read cost in on-demand mode, first you have to measure how many RRUs will be consumed in a month. For that, you need to consider the following factors:</p> <ul style="list-style-type: none"><li>• Number of available GSIs. Consider each index independently.<ul style="list-style-type: none"><li>• Average size of an index item</li></ul></li><li>• Average number of reads per product per month.</li><li>• Number of total available things (components or products) in the DynamoDB table.</li></ul>	Data engineer, App developer

Task	Description	Skills required
Estimate the storage size and cost.	<p>First, estimate the average monthly storage requirement based on your item size in the table. Then calculate storage cost by multiplying storage size by the per GB storage price for your AWS Region.</p> <p>If you already entered data for estimating the write cost, you don't need to enter it again for calculating storage size. Otherwise, to estimate storage size, you need to consider the following factors:</p> <ul style="list-style-type: none"><li>• Number of data items in a module (product) based on your table design.</li><li>• Average item size in kilobytes.</li><li>• Number of available GSIs. Consider each index independently.<ul style="list-style-type: none"><li>• Average size of an index item</li></ul></li><li>• How many new products will be added in the table each month? The number of new products could be different every month, but you can assume an average growth rate based</li></ul>	Data engineer

Task	Description	Skills required
	on your business cases. This example uses an average of 10 million new products each month.	

### Enter the item and object information in the Excel template

Task	Description	Skills required
Download the Excel template from the Attachments section, and adjust it for your use case table.	<ol style="list-style-type: none"> <li>1. Download the Excel template.</li> <li>2. Adjust the business module and GSIs, based on your table design.</li> </ol>	Data engineer
Enter information in the Excel template.	<ol style="list-style-type: none"> <li>1. Update item information in the sheet. Update data only in orange cells.</li> <li>2. Adjust the object numbers: How much could be added into the table each month?</li> <li>3. Update the WRU and RRU prices per million for your AWS Region.</li> <li>4. Update the storage and backup prices per GB-month for your AWS Region.</li> <li>5. Update the recovery price per GB for your AWS Region.</li> </ol>	Data engineer

Task	Description	Skills required
	In the template, there are three items, or entities: information, metadata, and relationship. There are two GSIs. For your use case, if you need more items, create new rows. If you need more GSIs, copy an existing GSI block, and paste to create as many GSI blocks as you need. Then adjust the SUM and TOTAL column calculations.

- [Best practices for designing and architecting with DynamoDB](#)
- [Getting started with DynamoDB](#)

### Guides and patterns

- [Modeling data with Amazon DynamoDB](#)
- [Estimate storage costs for an Amazon DynamoDB table](#)

## Additional information

### Write cost calculation example

The DynamoDB data model design shows three items for a product, and an average item size of 4 KB. When you add a new product into the DynamoDB base table, it consumes the number of items

\* (item size/1 KB write unit) =  $3 * (4/1) = 12$  WRU. In this example, for writing 1 KB, the product consumes 1 WRU.

### Read cost calculation example

To get the RRU estimation, consider the average of how many times each item will be read in a month. For example, the Information item will be read, on average, 10 times in a month, and the metadata item will be read two times, and the relationship item will be read five times. In the example template, total RRU for all components = number of new components created each month \* RRU per component per month = 10 million \* 17 RRU = 170 million RRU each month.

Every month, new things (components or products) will be added, and the total number of products will grow over time. So, RRU requirements will also grow over time.

- For the first month RRU, consumption will be 170 million.
- For the second month, RRU consumption will be  $2 * 170$  million = 340 million.
- For the third month RRU consumption will be  $3 * 170$  million = 510 million.

The following graph shows monthly RRU consumption and cost forecasting.

Note that prices within the graph are for illustration only. To create accurate forecasts for your use case, check the AWS pricing page, and use those prices in the Excel sheet.

### Storage, backup, and recovery cost calculation examples

DynamoDB storage, backup and restore all are connected with each other. Backup is directly connected with storage, and recovery is directly connected with backup size. As the table size increases, corresponding storage, backup, and restore costs will increase proportionally.

### *Storage size and cost*

Storage cost will increase over time based on your data growth rate. For example, assume that the average size of a component or product in the base table and GSIs is 11 KB, and 10 million new products will be added every month into your database table. In that case, your DynamoDB table size will grow  $(11 \text{ KB} * 10 \text{ million})/1024/1024 = 105 \text{ GB}$  per month. At the first month, your table storage size will be 105 GB, at second month it will be  $105 + 105 = 210 \text{ GBs}$ , and so on.

- For the first month, storage cost will be  $105 \text{ GB} * \text{storage price per GB for your AWS Region}$ .
- For the second month, storage cost will be  $210 \text{ GB} * \text{storage price per GB for your Region}$ .
- For the third month, storage cost will be  $315 \text{ GB} * \text{storage price per GB for your Region}$ .

For storage size and cost for next three years, see the *Storage size and forecasting* section.

### *Backup cost*

Backup cost will increase over time based on your data growth rate. When you turn on continuous backup with point-in-time-recovery (PITR), continuous backup charges are based on average storage GB-Month. In a calendar month, the average backup size would be the same as your table storage size, although the actual size could be a bit different. As new products will be added every month, the total storage size and the backup size will grow over time. For example, for the first month, the average backup size of 105 GB could grow to 210 GB for the second month.

- For the first month, backup cost will be  $105 \text{ GB-month} * \text{continuous backup price per GB for your AWS Region}$ .
- For the second month, backup cost will be  $210 \text{ GB-month} * \text{continuous backup price per GB for your Region}$ .
- For the third month, backup cost will be  $315 \text{ GB-month} * \text{continuous backup price per GB for your Region}$ .
- and, so on

Backup cost is included in the graph in the *Storage size and cost forecasting* section.

### *Recovery cost*

When you are taking continuous backup with PITR enabled, recovery operation charges are based on the size of the restore. Each time that you restore, you pay based on gigabytes of restored data. If your table size is large and you perform restore multiple times in a month, it will be costly.

To estimate restore cost, this example assumes that you perform a PITR recovery one time each month at the end of the month. The example uses the monthly average backup size as the restore data size for that month. For the first month, the average backup size is 105 GB, and for the recovery at end of the month, the restore data size would be 105 GB. For the second month, it would be 210 GBs, and so on.

Recovery cost will increase over time based on your data growth rate.

- For the first month, recovery cost will be 105 GB \* restore price per GB for your AWS Region.
- For the second month, recovery cost will be 210 GB \* restore price per GB for your Region.
- For the third month, recovery cost will be 315 GB \* restore price per GB for your Region.

For more information, see the Storage, backup and recovery tab in the Excel template and the graph in the following section.

### *Storage size and cost forecasting*

In the template, actual billable storage size is calculated by subtracting the free tier 25 GB per month for the Standard table class. In the sheet, you will get a forecasting graph broken out into monthly values.

The following example chart forecasts monthly storage size in GB, billable storage cost, on-demand backup cost, and recovery cost for next 36 calendar months. All costs are in USD. From the graph, it's clear that storage, backup, and recovery costs increase proportionally to increases in storage size.

Note that prices used in the graph are for illustration purposes only. To create accurate prices for your use case, check the AWS pricing page, and use those prices in the Excel template.

# Estimate storage costs for an Amazon DynamoDB table

*Created by Moinul Al-Mamun*

**Environment:** PoC or pilot

**Technologies:** Databases;  
Big data; Cost management;  
Storage & backup

**AWS services:** Amazon  
DynamoDB

## Summary

[Amazon DynamoDB](#) is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision storage. Your single table can grow up to petabytes.

DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. AWS then charges you for the average size of storage in gigabytes. The more that your table grows over time, the more that your storage cost will grow. To calculate storage cost, you can use [AWS Pricing Calculator](#), but you need to provide the approximate size of your table, including global secondary indexes (GSIs), which is really difficult to estimate at the beginning of the project. Also, AWS Pricing Calculator does not consider the data growth rate.

This pattern provides a mechanism and a reusable Microsoft Excel template to calculate DynamoDB storage size and cost. It considers the storage requirements for the base table and the GSIs independently. It calculates storage size by considering the size of your individual items and data growth rate over time.

To get an estimate, insert two pieces of information into the template:

- The individual item size in kilobytes for the base table and GSIs
- How many new objects or products could be added to the table, on average, in a month, (for example, 10 million)

The template will generate a storage and cost forecasting graph for the next three years, which is shown in the following example.

## Prerequisites and limitations

### Prerequisites

- Basic knowledge of DynamoDB, and DynamoDB storage and pricing
- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB global secondary indexes (GSIs)

### Limitations

- The template provides you with an approximate calculation, but it isn't appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
- This pattern supports estimating only storage size and cost for the next few years based on fixed data growth assumptions.

## Tools

### AWS services

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

## Other tools

- [AWS Pricing Calculator](#) is a web-based planning tool that you can use to create estimates for your AWS use cases.

## Epics

### Extract item information from your DynamoDB data model

Task	Description	Skills required
Get item size.	<ol style="list-style-type: none"><li>1. Check how many different types of item you are going to store in your table.</li><li>2. To calculate the size of each item in kilobytes add the Key and Value size of each attribute.</li><li>3. Calculate item size for a base table and for each GSI.</li></ol>	Data engineer
Get the number of objects added in a month.	Estimate how many components, or objects, will be added into the DynamoDB table, on average, in one month.	Data engineer

## Enter the item and object information in the Excel template

Task	Description	Skills required
Download Excel sheet from the attached document, and adjust it for your use case table.	<ol style="list-style-type: none"><li>1. Download the Excel template.</li><li>2. Adjust the business module and GSIs, based on your table design.</li></ol>	Data engineer
Enter information in the Excel template.	<ol style="list-style-type: none"><li>1. Update item information into the sheet.</li><li>2. Adjust the object numbers: How much could be added into the table each month?</li><li>3. Update the storage price per GB-month for your AWS Region.</li></ol>	Data engineer

## Related resources

- [Amazon DynamoDB On-Demand pricing](#)
- [AWS Pricing Calculator for DynamoDB](#)

## Additional information

Note that the attached template forecasts only storage size and cost for Standard storage table class. Based on the forecast for storage costs, and considering individual item size and product or object growth rate, you can estimate the following:

- Data export cost
- Backup and recovery cost
- Data storage requirements.

## Amazon DynamoDB data storage cost

DynamoDB monitors the size of your tables continuously to determine your storage charges. DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled. For more information, see the [DynamoDB Developer Guide](#).

The price for data storage depends on your table class. The first 25 GB stored each month is free if you're using the DynamoDB Standard table class. For more information about storage costs for Standard table class and Standard-Infrequent Access table class in different AWS Regions, see [Pricing for On-Demand Capacity](#).

# Estimate the Amazon RDS engine size for an Oracle database by using AWR reports

Created by Abhishek Verma (AWS) and Eduardo Valentim (AWS)

<b>Environment:</b> Production	<b>Source:</b> Oracle Database	<b>Target:</b> Amazon RDS or Amazon Aurora
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon RDS; Amazon Aurora		

## Summary

When you migrate an Oracle database to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora, computing the CPU, memory, and disk I/O for the target database is a key requirement. You can estimate the required capacity of the target database by analyzing the Oracle Automatic Workload Repository (AWR) reports. This pattern explains how to use AWR reports to estimate these values.

The source Oracle database could be on premises or hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance, or it could be an Amazon RDS for Oracle DB instance. The target database could be any Amazon RDS or Aurora database.

**Note:** Capacity estimates will be more precise if your target database engine is Oracle. For other Amazon RDS databases, the engine size can vary due to differences in database architecture.

We recommend that you run the performance test before you migrate your Oracle database.

## Prerequisites and limitations

### Prerequisites

- An Oracle Database Enterprise Edition license and Oracle Diagnostics Pack license in order to download AWR reports.

## Product versions

- All Oracle Database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c,19c.
- This pattern doesn't cover Oracle Engineered Systems or Oracle Cloud Infrastructure (OCI).

## Architecture

### Source technology stack

One of the following:

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

### Target technology stack

- Any Amazon RDS or Amazon Aurora database

### Target architecture

For information about the full migration process, see the pattern [Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT](#).

### Automation and scale

If you have multiple Oracle databases to migrate and you want to use additional performance metrics, you can automate the process by following the steps described in the blog post [Right-size Amazon RDS instances at scale based on Oracle performance metrics](#).

## Tools

- [Oracle Automatic Workload Repository \(AWR\)](#) is a repository that's built into Oracle databases. It periodically gathers and stores system activity and workload data, which is then analyzed by Automatic Database Diagnostic Monitor (ADDM). AWR takes snapshots of system performance data periodically (by default, every 60 minutes) and stores the information (by default, up to 8 days). You can use AWR views and reports to analyze this data.

## Best practices

- To calculate resource requirements for your target database, you can use a single AWR report, multiple AWR reports, or dynamic AWR views. We recommend that you use multiple AWR reports during the peak load period to estimate the resources required to handle those peak loads. In addition, dynamic views provide more data points that help you calculate resource requirements more precisely.
- You should estimate IOPS only for the database that you plan to migrate, not for other databases and processes that use the disk.
- To calculate how much I/O is being used by the database, don't use the information in the Load Profile section of the AWR report. Use the I/O Profile section instead, if it's available, or skip to the Instance Activity Stats section and look at the total values for physical read and write operations.
- When you estimate CPU utilization, we recommend that you use the database metrics method instead of operating system (OS) statistics, because it's based on the CPU used only by databases. (OS statistics also include CPU usage by other processes.) You should also check CPU-related recommendations in the ADDM report to improve performance after migration.
- Consider I/O throughput limits—Amazon Elastic Block Store (Amazon EBS) throughput and network throughput—for the specific instance size when you're determining the right instance type.
- Run the performance test before migration to validate the engine size.

## Epics

### Create an AWR report

Task	Description	Skills required
Enable the AWR report.	To enable the report, follow the instructions in the <a href="#">Oracle documentation</a> .	DBA
Check the retention period.	To check the retention period of the AWR report, use the following query.	DBA

Task	Description	Skills required
Generate the snapshot.	<pre data-bbox="597 212 1027 369">SQL&gt; SELECT snap_interval,retention FROM dba_hist_wr_control;</pre> <p data-bbox="597 407 1027 779">If the AWR snapshot interval isn't granular enough to capture the spike of the peak workload, you can generate the AWR report manually. To generate the manual AWR snapshot, use the following query.</p> <pre data-bbox="597 814 1027 972">SQL&gt; EXEC dbms_workload_repository.create_snapshot;</pre>	DBA
Check recent snapshots.	<p data-bbox="597 1010 1027 1146">To check recent AWR snapshots, use the following query.</p> <pre data-bbox="597 1182 1027 1612">SQL&gt; SELECT snap_id, to_char(begin_interval_time,'dd/MON/yy hh24:mi') Begin_Interval, to_char(end_interval_time,'dd/MON/yy hh24:mi') End_Interval FROM dba_hist_snapshot ORDER BY 1;</pre>	DBA

## Estimate disk I/O requirements

Task	Description	Skills required
Choose a method.	<p>IOPS is the standard measure of input and output operations per second on a storage device, and includes both read and write operations.</p> <p>If you are migrating an on-premises database to AWS, you need to determine the peak disk I/O used by the database. You can use the following methods to estimate disk I/O for your target database:</p> <ul style="list-style-type: none"> <li>• Load Profile section of the AWR report</li> <li>• Instance Activity Stats section of the AWR report (use this section for Oracle Database 12c or later)</li> <li>• I/O Profile section of the AWR report (use this section for Oracle Database versions before 12c)</li> <li>• AWR views</li> </ul> <p>The following steps describe these four methods.</p>	DBA
Option 1: Use the load profile.	The following table shows an example of the Load Profile section of the AWR report.	DBA

Task	Description	Skills required																																								
	<p><b>Important:</b> For more accurate information, we recommend that you use option 2 (I/O profiles) or option 3 (instance activity statistics) instead of the load profile.</p> <table border="1" data-bbox="592 541 1029 1793"> <thead> <tr> <th></th> <th>Per Seco</th> <th>Per Tran</th> <th>Per Exec</th> <th>Per Call</th> </tr> </thead> <tbody> <tr> <td><b>DB Time</b></td> <td>26.6</td> <td>0.2</td> <td>0.00</td> <td>0.02</td> </tr> <tr> <td><b>DB CPU</b></td> <td>18.0</td> <td>0.1</td> <td>0.00</td> <td>0.01</td> </tr> <tr> <td><b>Backend CPU</b></td> <td>0.2</td> <td>0.0</td> <td>0.00</td> <td>0.00</td> </tr> <tr> <td><b>Redo size (byte)</b></td> <td>2,450.9</td> <td>17,000</td> <td></td> <td></td> </tr> <tr> <td><b>Logi read (block)</b></td> <td>3,370.5</td> <td>23,400</td> <td></td> <td></td> </tr> <tr> <td><b>Block chan</b></td> <td>21,600</td> <td>150,000</td> <td></td> <td></td> </tr> <tr> <td><b>Phys read (block)</b></td> <td>13,500</td> <td>94,400</td> <td></td> <td></td> </tr> </tbody> </table>		Per Seco	Per Tran	Per Exec	Per Call	<b>DB Time</b>	26.6	0.2	0.00	0.02	<b>DB CPU</b>	18.0	0.1	0.00	0.01	<b>Backend CPU</b>	0.2	0.0	0.00	0.00	<b>Redo size (byte)</b>	2,450.9	17,000			<b>Logi read (block)</b>	3,370.5	23,400			<b>Block chan</b>	21,600	150,000			<b>Phys read (block)</b>	13,500	94,400

<b>Total (MB):</b>																										
<b>Redo (MB):</b>	7.6	2.7	4.9																							
<b>Datab (block</b>	17,04	13,57	3,467.3																							
<b>Via Buffer Cache (block</b>	5,898	5,360	537.6																							
<b>Direct (block</b>	11,14	8,214	2,929.7																							

Task	Description	Skills required
Option 4: Use AWR views.	<p>You can see the same IOPS and throughput information by using AWR views. To get this information, use the following query:</p> <pre data-bbox="594 489 1027 1125"> break on report compute sum of Value on report select METRIC_NAME, avg(AVERAGE) as "Value" from dba_hist_sysmetric_summary where METRIC_NAME in ('Physical Read Total IO Requests Per Sec', 'Physical Write Total IO Requests Per Sec') group by metric_name; </pre>	DBA

## Estimate CPU requirements

Task	Description	Skills required
Choose a method.	<p>You can estimate the CPU required for the target database in three ways:</p> <ul data-bbox="594 1587 1027 1818" style="list-style-type: none"> <li>• By using the actual available cores of the processor</li> <li>• By using the utilized cores based on OS statistics</li> </ul>	DBA

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• By using the utilized cores based on database statistics</li></ul> <p>If you're looking at utilized cores, we recommend that you use the database metrics method instead of OS statistics, because it's based on the CPU used only by the databases that you're planning to migrate. (OS statistics also include CPU usage by other processes.) You should also check CPU-related recommendations in the ADDM report to improve performance after migration.</p> <p>You can also estimate requirements based on CPU generation. If you are using different CPU generations, you can estimate the required CPU of the target database by following the instructions in the whitepaper <a href="#">Demystifying the Number of vCPUs for Optimal Workload Performance</a>.</p>	

Task	Description	Skills required
Option 1: Estimate requirements based on available cores.	<p>In AWR reports:</p> <ul style="list-style-type: none"><li>• CPUs refer to logical and virtual CPUs.</li><li>• Cores are the number of processors in a physical CPU chipset.</li><li>• A socket is a physical device that connects a chip to a board. Multi-core processors have sockets with several CPU cores.</li></ul> <p>You can estimate available cores in two ways:</p> <ul style="list-style-type: none"><li>• By using OS commands</li><li>• By using the AWR report</li></ul> <p><b>To estimate available cores by using OS commands</b></p> <p>Use the following command to count the cores in the processor.</p> <pre>\$ cat /proc/cpuinfo   grep "cpu cores" uniq cpu cores      : 4 cat /proc/cpuinfo   egrep "core id physical id"   tr -d "\n"   sed s/physical/\\nphysical/g   grep -v ^\$   sort   uniq   wc -l</pre>	DBA

Task	Description	Skills required
	<p>Use the following command to count the sockets in the processor.</p> <pre data-bbox="597 380 1027 575"> grep "physical id" / proc/cpuinfo   sort -u physical id      : 0 physical id      : 1                     </pre> <p><b>Note:</b> We don't recommend using OS commands such as <b>nmon</b> and <b>sar</b> to extract CPU utilization. This is because those calculations include CPU utilization by other processes and might not reflect the actual CPU that is used by the database.</p> <p><b>To estimate available cores by using the AWR report</b></p> <p>You can also derive CPU utilization from the first section of the AWR report. Here's an excerpt from the report.</p> <pre data-bbox="597 1486 1027 1780"> C DB  Inst Inst Sta Rel RA N Id      nun Tim X &lt;DE XXX 1 05- 12.' NQ           Sep 0           23:(                     </pre>

	Begin	End									
Host Mem (MB):	452,387	452,387.3									
SGA use (MB):	220,544	220,544.0									

Task	Description	Skills required
	<p><b>PGA use (MB):</b> 36,874.0 45,270.0</p> <p><i>Total instance memory in use = SGA + PGA = 220 GB + 45 GB = 265 GB</i></p> <p>Add 20 percent of buffer:</p> <p><i>Total instance memory = 1.2 * 265 GB = 318 GB</i></p> <p>Because SGA and PGA account for 70 percent of host memory, the total memory requirement is:</p> <p><i>Total host memory = 318/0.7 = 464 GB</i></p> <p><b>Note:</b> When you migrate to Amazon RDS for Oracle, the PGA and SGA are pre-calculated based on a predefined formula. Make sure that the pre-calculated values are close to your estimates.</p>	

## Determine the DB instance type of the target database

Task	Description	Skills required
Determine the DB instance type based on disk I/O, CPU, and memory estimates.	<p>Based on the estimates in the previous steps, the capacity of the target Amazon RDS or Aurora database should be:</p> <ul style="list-style-type: none"><li>• 68 cores of CPU</li><li>• 143 MBPS of throughput</li><li>• 4367 IOPS for disk I/O</li><li>• 464 GB of memory</li></ul> <p>In the target Amazon RDS or Aurora database, you can map these values to the db.r5.16x large instance type, which has a capacity of 32 cores, 512 GB of RAM, and 13,600 Mbps of throughput. For more information, see the AWS blog post <a href="#">Right-size Amazon RDS instances at scale based on Oracle performance metrics</a>.</p>	DBA

# Export Amazon RDS for SQL Server tables to an S3 bucket by using AWS DMS

Created by Subhani Shaik (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> RDS	<b>Target:</b> S3
<b>R Type:</b> N/A	<b>Workload:</b> Microsoft	<b>Technologies:</b> Databases; CloudNative
<b>AWS services:</b> AWS DMS; Amazon RDS; Amazon S3; AWS Secrets Manager; AWS Identity and Access Management		

## Summary

Amazon Relational Database Service (Amazon RDS) for SQL Server doesn't support loading data onto other DB engine linked servers on the Amazon Web Services (AWS) Cloud. Instead, you can use AWS Database Migration Service (AWS DMS) to export Amazon RDS for SQL Server tables to an Amazon Simple Storage Service (Amazon S3) bucket, where the data is available to other DB engines.

AWS DMS helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.

This pattern uses AWS Secrets Manager while configuring the AWS DMS endpoints. Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. You can use the service to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets with a call to Secrets Manager, reducing the need to hardcode sensitive information. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. Also, the service is extensible to other types of secrets, including API keys and OAuth tokens. With

Secrets Manager, you can control access to secrets by using fine-grained permissions and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on premises.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An S3 bucket
- A virtual private cloud (VPC)
- A DB subnet
- Amazon RDS for SQL Server
- An AWS Identity and Access Management (IAM) role with access (list, get, and put objects) to the S3 bucket on behalf of the Amazon RDS instance.
- Secrets Manager to store the RDS instance credentials.

## Architecture

### Technology stack

- Amazon RDS for SQL Server
- AWS DMS
- Amazon S3
- AWS Secrets Manager

### Target architecture

The following diagram shows the architecture for importing data from the Amazon RDS instance to the S3 bucket with the help of AWS DMS.

1. The AWS DMS migration task connecting to the source Amazon RDS instance through the source endpoint
2. Copying data from the source Amazon RDS instance
3. The AWS DMS migration task connecting to the target S3 bucket through the target endpoint
4. Exporting copied data to the S3 bucket in comma-separated values (CSV) format

## Tools

### AWS services

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

### Other services

- [Microsoft SQL Server Management Studio \(SSMS\)](#) is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

## Epics

### Configure the Amazon RDS for SQL Server instance

Task	Description	Skills required
Create the Amazon RDS for SQL Server instance.	<ol style="list-style-type: none"> <li>1. Open the AWS Management Console, choose <b>RDS</b>, and use the <b>Standard create</b> option to create an <b>Amazon RDS</b> instance with the required edition, such as SQL Server Express Edition, SQL Server Standard Edition, or SQL Server Enterprise Edition. For the version, choose 2016 or later.</li> <li>2. Under <b>Templates</b>, choose <b>Dev/Test</b>.</li> </ol>	DBA, DevOps engineer
Set up credentials for the instance.	<ol style="list-style-type: none"> <li>1. Enter a name for the instance.</li> <li>2. Provide a <b>username</b> and password for the Amazon RDS instance.</li> </ol>	DBA, DevOps engineer

Task	Description	Skills required
Configure the instance class, storage, auto scaling, and availability.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 835">1. Select the <b>DB instance class</b> from the list: <b>Standard, Memory Optimized, and Burstable</b> classes. Choose the DB instance type that allocates the computational, network, and memory capacity required by the workloads planned for this DB instance. For more information, see the <a href="#">AWS documentation</a>.</li><li data-bbox="592 856 1027 1129">2. Select the Storage Type from the list: <b>General Purpose SSD, Provisioned IOPS SSD, or Magnetic</b>. Allocate the default storage size as required.</li><li data-bbox="592 1150 1027 1329">3. Choose <b>Enable storage autoscaling</b> to increase the Amazon RDS storage based on your capacity planning.</li><li data-bbox="592 1350 1027 1860">4. A Multi-AZ deployment with a replication instance is supported by AWS DMS. In the event of an outage in the Availability Zone, internal hardware, or network, AWS DMS will create a standby instance and provide high availability (HA) through automatic failover to the standby</li></ol>	DBA, DevOps engineer

Task	Description	Skills required
	<p>replicas. Depending on the size of your import, select the appropriate option.</p>	
<p>Specify the VPC, subnet group, public access, and security group.</p>	<p>Select the <b>VPC, DB subnet groups</b>, and <b>VPC security group</b> as required to create the Amazon RDS instance. Follow the best practices, for example:</p> <ul style="list-style-type: none"> <li>• Do not enable public access to the RDS DB instance.</li> <li>• Do not use the CIDR 0.0.0.0/0 in the security groups.</li> <li>• Use only the required IP address and port details to access the RDS instance.</li> </ul>	<p>DBA, DevOps engineer</p>
<p>Configure monitoring, backup, and maintenance.</p>	<ol style="list-style-type: none"> <li>1. Specify the backup options that you want. By default, automated backups are enabled with a retention period of 7 days.</li> <li>2. Choose the appropriate <b>auto minor version upgrade</b> and <b>Maintenance window</b> settings to apply the pending modifications or maintenance to the database by Amazon RDS.</li> <li>3. Choose <b>Create database</b>.</li> </ol>	<p>DBA, DevOps engineer</p>

## Set up the database and example data

Task	Description	Skills required
Create a table and load the example data.	In the new database, create a table. Use the example code in the <i>Additional information</i> section to load data into the table.	DBA, DevOps engineer

## Set up credentials

Task	Description	Skills required
Create the secret.	<ol style="list-style-type: none"> <li>On the console, choose <b>Secrets Manager</b>, and choose <b>Store a new secret</b>.</li> <li>Enter a username and password for the Amazon RDS for SQL Server database.</li> </ol> <p>This secret will be used for the AWS DMS source endpoint.</p>	DBA, DevOps engineer

## Set up access between the database and the S3 bucket

Task	Description	Skills required
Create an IAM role for access to Amazon RDS.	<ol style="list-style-type: none"> <li>On the console, choose <b>IAM</b>, and create an IAM role that gives an S3 bucket read/write access to Amazon RDS.</li> </ol>	DBA, DevOps engineer

Task	Description	Skills required
	2. Under <b>Feature</b> , select <b>S3 Integration</b> .	

### Create the S3 bucket

Task	Description	Skills required
Create the S3 bucket.	To save the data from Amazon RDS for SQL Server, on the console, choose <b>S3</b> , and then choose <b>Create bucket</b> . Make sure that the S3 bucket is not publicly available.	DBA, DevOps engineer

### Set up access between AWS DMS and the S3 bucket

Task	Description	Skills required
Create an IAM role for AWS DMS to access Amazon S3.	Create an IAM role that allows AWS DMS to list, get, and put objects from the S3 bucket.	DBA, DevOps engineer

### Configure AWS DMS

Task	Description	Skills required
Create the AWS DMS source endpoint.	1. On the console, choose <b>Database Migration Service</b> , and choose <b>Endpoints</b> . Create the <b>Source endpoint</b> , selecting	DBA, DevOps engineer

Task	Description	Skills required
	<p>the <b>Select RDS DB instance</b> check box.</p> <p>2. For the Source engine, select <b>Microsoft SQL Server</b>.</p> <p>3. Under <b>Access to endpoint database</b>, choose <b>AWS Secrets Manager</b>, and enter the secret and IAM role that you created earlier, and the database name.</p> <p>4. Test the source endpoint.</p>	
Create the AWS DMS target endpoint.	<p>Create the <b>Target endpoint</b>, selecting Amazon S3 as the <b>Target engine</b>.</p> <p>Provide the S3 bucket name and folder name for the IAM role that you created previously.</p>	DBA, DevOps engineer
Create the AWS DMS replication instance.	<p>In the same VPC, subnet, and security group, create the AWS DMS replication instance. For more information about choosing an instance class, see the <a href="#">AWS documentation</a>.</p>	DBA, DevOps engineer

Task	Description	Skills required
Create the AWS DMS migration task.	To export the data from Amazon RDS for SQL Server to the S3 bucket, create a database migration task. For the migration type, choose <b>Migrate existing data</b> . Select the AWS DMS endpoints and replication instance that you created.	DBA, DevOps engineer

### Export the data to the S3 bucket

Task	Description	Skills required
Run the database migration task.	To export the SQL Server table data, start the database migration task. The task will export the data from Amazon RDS for SQL Server to the S3 bucket in CSV format.	DBA, DevOps engineer

### Clean up resources

Task	Description	Skills required
Delete the resources.	To avoid incurring extra costs, use the console to delete the resources in the following order:  <ol style="list-style-type: none"><li>1. Migration task</li><li>2. Replication instance</li><li>3. Endpoints</li></ol>	DBA, DevOps engineer

Task	Description	Skills required
	4. S3 bucket 5. Database instance	

## Related resources

- [Amazon S3 integration](#)

## Additional information

To create the database and table, and to load the example data, use the following code.

```
--Step1: Database creation in RDS SQL Server
CREATE DATABASE [Test_DB]
ON PRIMARY
( NAME = N'Test_DB', FILENAME = N'D:\rdsdbdata\DATA\Test_DB.mdf' , SIZE = 5120KB ,
FILEGROWTH = 10%)
LOG ON
( NAME = N'Test_DB_log', FILENAME = N'D:\rdsdbdata\DATA\Test_DB_log.ldf' , SIZE =
1024KB , FILEGROWTH = 10%)
GO

--Step2: Create Table
USE Test_DB
GO
Create Table Test_Table(ID int, Company Varchar(30), Location Varchar(20))

--Step3: Load sample data.
USE Test_DB
GO
Insert into Test_Table values(1,'AnyCompany','India')
Insert into Test_Table values(2,'AnyCompany','USA')
Insert into Test_Table values(3,'AnyCompany','UK')
Insert into Test_Table values(4,'AnyCompany','Hyderabad')
Insert into Test_Table values(5,'AnyCompany','Banglore')
```

# Handle anonymous blocks in Dynamic SQL statements in Aurora PostgreSQL

Created by anuradha chintha (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Database Relational	<b>Target:</b> PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle; Open-source	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon Aurora; Amazon RDS		

## Summary

This pattern shows you how to avoid the error that you get when handling anonymous blocks in Dynamic SQL statements. You receive an error message when you use the AWS Schema Conversion Tool to convert an Oracle database to an Aurora PostgreSQL-Compatible Edition database. To avoid the error, you must know the value of an OUT bind variable, but you can't know the value of an OUT bind variable until after you run the SQL statement. The error results from the AWS Schema Conversion Tool (AWS SCT) not understanding the logic inside the Dynamic SQL statement. AWS SCT can't convert the dynamic SQL statement in PL/SQL code (that is, functions, procedures, and packages).

## Prerequisites and limitations

### Prerequisites

- Active AWS account
- [Aurora PostgreSQL database \(DB\) instance](#)
- [Amazon Relational Database Service \(Amazon RDS\) for Oracle DB instance](#)
- [PostgreSQL interactive terminal \(psql\)](#)
- [SQL \\*Plus](#)
- AWS\_ORACLE\_EXT schema (part of the [AWS SCT extension pack](#)) in your target database

- Latest version of [AWS Schema Conversion Tool \(AWS SCT\)](#) and its required drivers

## Architecture

### Source technology stack

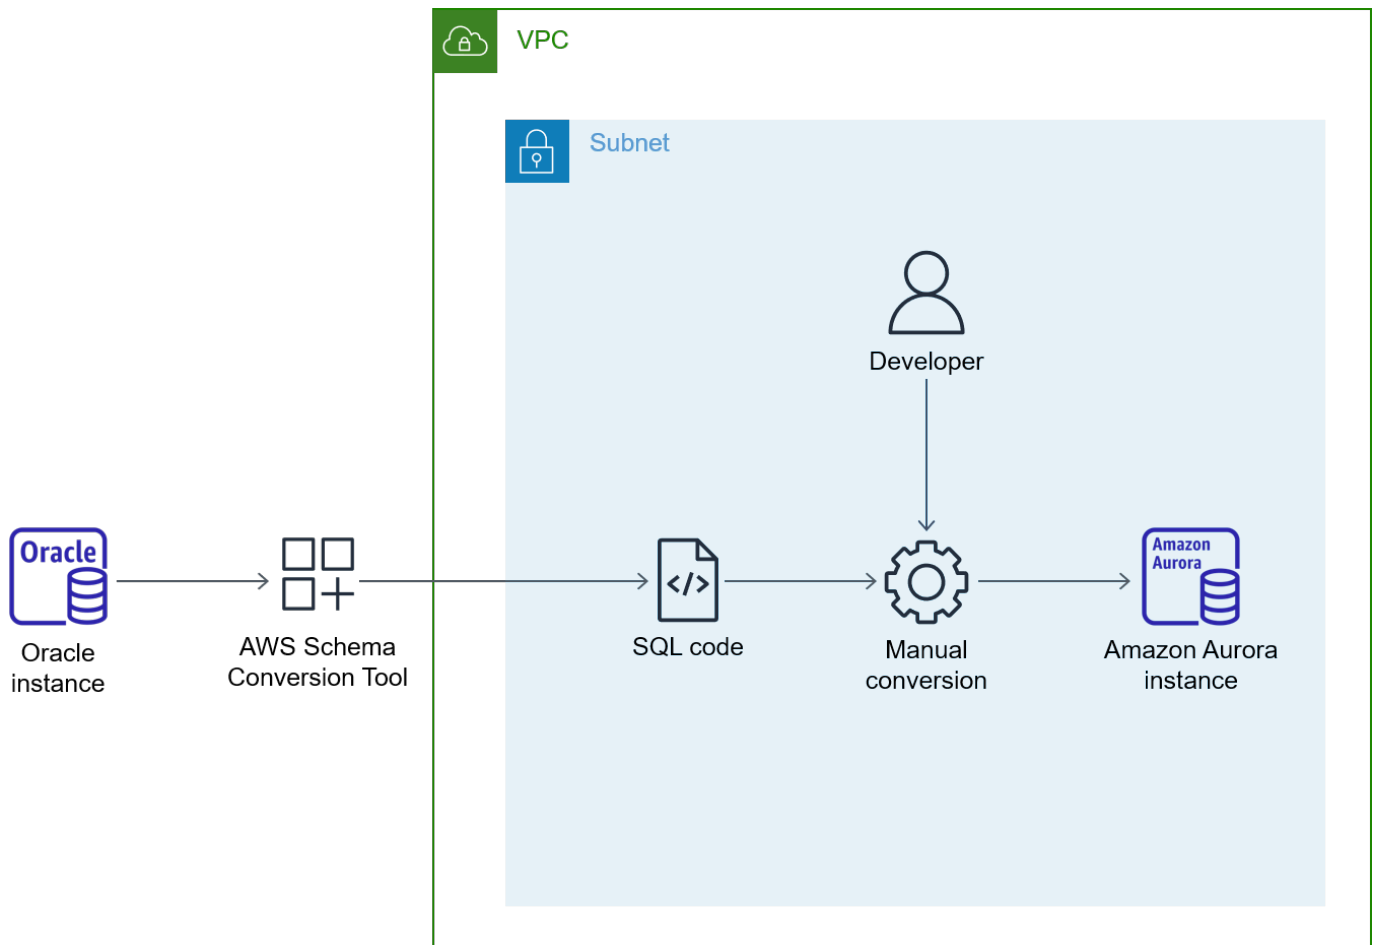

- On-premises Oracle Database 10g and later version

### Target technology stack

- Amazon Aurora PostgreSQL
- Amazon RDS for PostgreSQL
- AWS Schema Conversion Tool (AWS SCT)

### Migration architecture

The following diagram shows how to use AWS SCT and Oracle OUT bind variables to scan your application code for embedded SQL statements and convert the code to a compatible format that an Aurora database can use.

The diagram shows the following workflow:

1. Generate an AWS SCT report for the source database by using Aurora PostgreSQL as the target database.
2. Identify the anonymous block in the Dynamic SQL code block (for which AWS SCT raised the error).
3. Convert the code block manually and deploy the code on a target database.

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Relational Database Service \(Amazon RDS\) for Oracle](#) helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.

- [AWS Schema Conversion Tool \(AWS SCT\)](#) helps you make heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects to a format compatible with the target database.

## Other tools

- [pgAdmin](#) enables you to connect to and interact with your database server.
- [Oracle SQL Developer](#) is an integrated development environment that you can use to develop and manage databases in Oracle Database. You can use either [SQL \\*Plus](#) or Oracle SQL Developer for this pattern.

## Epics

### Configure the Oracle source database

Task	Description	Skills required
Create an Oracle instance on Amazon RDS or Amazon EC2.	<p>To create an Oracle DB instance on Amazon RDS, see <a href="#">Creating an Oracle DB instance and connecting to a database on an Oracle DB instance</a> in the Amazon RDS documentation.</p> <p>To create an Oracle DB instance on Amazon Elastic Compute Cloud (Amazon EC2), see <a href="#">Amazon EC2 for Oracle</a> in the AWS Prescriptive Guidance documentation.</p>	DBA
Create a database schema and objects for migration.	You can use Amazon Cloud Directory to create a database schema. For more information, see <a href="#">Create a Schema</a>	DBA

Task	Description	Skills required
	in the Cloud Directory documentation.	
Configure inbound and outbound security groups.	To create and configure security groups, see <a href="#">Controlling access with security groups</a> in the Amazon RDS documentation.	DBA
Confirm that the database is running.	To check the status of your database, see <a href="#">Viewing Amazon RDS events</a> in the Amazon RDS documentation.	DBA

### Configure the target Aurora PostgreSQL database

Task	Description	Skills required
Create an Aurora PostgreSQL instance in Amazon RDS.	To create an Aurora PostgreSQL instance, see <a href="#">Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster</a> in the Amazon RDS documentation.	DBA
Configure an inbound and outbound security group.	To create and configure security groups, see <a href="#">Provide access to the DB cluster in the VPC by creating a security group</a> in the Aurora documentation.	DBA

Task	Description	Skills required
Confirm that the Aurora PostgreSQL database is running.	To check the status of your database, see <a href="#">Viewing Amazon RDS events</a> in the Aurora documentation.	DBA

## Set up AWS SCT

Task	Description	Skills required
Connect AWS SCT to the source database.	To connect AWS SCT to your source database, see <a href="#">Connecting to PostgreSQL as a source</a> in the AWS SCT documentation.	DBA
Connect AWS SCT to the target database.	To connect AWS SCT to your target database, see the <a href="#">What is the AWS Schema Conversion Tool?</a> in the AWS Schema Conversion Tool User Guide.	DBA
Convert the database schema in AWS SCT and save the automated converted code as a SQL file.	To save AWS SCT converted files, see <a href="#">Saving and applying your converted schema in AWS SCT</a> in the AWS Schema Conversion Tool User Guide.	DBA

## Migrate the code

Task	Description	Skills required
Get the SQL file for manual conversion.	In the AWS SCT converted file, pull the SQL file that requires manual conversion.	DBA

Task	Description	Skills required
Update the script.	Manually update the SQL file.	DBA

## Related resources

- [Amazon RDS](#)
- [Amazon Aurora Features](#)

## Additional information

The following example code shows how to configure the Oracle source database:

```
CREATE or replace PROCEDURE calc_stats_new1 (  
  a NUMBER,  
  b NUMBER,  
  result out NUMBER)  
IS  
BEGIN  
  result:=a+b;  
END;  
/
```

```
set serveroutput on ;  
  
DECLARE  
  a NUMBER := 4;  
  b NUMBER := 7;  
  plsql_block VARCHAR2(100);  
  output number;  
BEGIN  
  plsql_block := 'BEGIN calc_stats_new1(:a, :b,:output); END;';  
  EXECUTE IMMEDIATE plsql_block USING a, b,out output;  
  DBMS_OUTPUT.PUT_LINE('output: '||output);  
  
END;
```

The following example code shows how to configure the target Aurora PostgreSQL database:

```
w integer,
x integer)
RETURNS integer
AS
$BODY$
DECLARE
begin
return w + x ;
end;
$BODY$
LANGUAGE plpgsql;

CREATE OR REPLACE FUNCTION test_pg.init()
RETURNS void
AS
$BODY$
BEGIN
if aws_oracle_ext.is_package_initialized
('test_pg' ) then
return;
end if;
perform aws_oracle_ext.set_package_initialized
('test_pg' );

PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_output', NULL::INTEGER);
PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_status', NULL::text);
END;
$BODY$
LANGUAGE plpgsql;

DO $$
declare
v_sql text;
v_output_loc int;
a integer :=1;
b integer :=2;
BEGIN
perform test_pg.init();
--raise notice 'v_sql %',v_sql;
execute 'do $$ declare v_output_l int; begin select * from test_pg.calc_stats_new1('||
a||','||b||') into v_output_l;
```

```
PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_output', v_output_1) ;
end; $$' ;
v_output_loc := aws_oracle_ext.get_package_variable('test_pg', 'v_output');
raise notice 'v_output_loc %',v_output_loc;
END ;
$$
```

# Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible

Created by Sumana Yanamandra (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle Database	<b>Target:</b> Aurora PostgreSQL-Compatible
<b>R Type:</b> Replatform	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon Aurora		

## Summary

The code you migrate from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition might include overloaded functions. These functions have the same definition—that is, the same function name and the same number and data type of input (IN) parameters—but the data type or the number of output (OUT) parameters might differ.

These parameter mismatches can cause problems in PostgreSQL, because it's difficult to determine which function to run. This pattern illustrates how to handle overloaded functions when you migrate your database code to Aurora PostgreSQL-Compatible.

## Prerequisites and limitations

### Prerequisites

- An Oracle database instance as your source database
- An Aurora PostgreSQL-Compatible DB instance as your target database (see [instructions](#) in the Aurora documentation)

### Product versions

- Oracle Database 9i or later

- Oracle SQL Developer version 18.4.0.376
- pgAdmin 4 client
- Aurora PostgreSQL-Compatible version 11 or later (see [Identifying versions of Amazon Aurora PostgreSQL](#) in the Aurora documentation)

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

### Other tools

- [Oracle SQL Developer](#) is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.
- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Epics

### Create a simple function

Task	Description	Skills required
Create a function in PostgreSQL that has one input parameter and one output parameter.	The following example illustrates a function named <code>test_overloading</code> in Aurora PostgreSQL-Compatible. This function has two parameters: one input text parameter and one output text parameter.	Data engineer, Aurora PostgreSQL-Compatible

Task	Description	Skills required
	<pre>CREATE OR REPLACE FUNCTION public.te st_overloading(     str1 text,     OUT str2 text) LANGUAGE 'plpgsql' COST 100 VOLATILE AS \$BODY\$ DECLARE BEGIN     str2 := 'Success'; RETURN ; EXCEPTION     WHEN others THEN         RETURN ; END; \$BODY\$;</pre>	
Run the function in PostgreSQL.	<p>Run the function that you created in the previous step.</p> <pre>select public.te st_overloading('Te st');</pre> <p>It should display the following output.</p> <pre>Success</pre>	Data engineer, Aurora PostgreSQL-Compatible

## Overload the function

Task	Description	Skills required
Use the same function name to create an overloaded function in PostgreSQL.	<p>Create an overloaded function in Aurora PostgreSQL-Compatible that uses the same function name as your previous function. The following example is also named <code>test_overloading</code>, but it has three parameters: one input text parameter, one output text parameter, and one output integer parameter.</p> <pre data-bbox="594 915 1029 1885">CREATE OR REPLACE FUNCTION public.test_overloading(     str1 text,     OUT str2 text,     OUT num1 integer) LANGUAGE 'plpgsql'  COST 100 VOLATILE AS \$BODY\$ DECLARE str3 text;  BEGIN      str2 := 'Success';     num1 := 100;  RETURN ; EXCEPTION WHEN others THEN</pre>	Data engineer, Aurora PostgreSQL-Compatible

Task	Description	Skills required
	<pre>RETURN ; END; \$BODY\$;</pre>	
<p>Run the function in PostgreSQL.</p>	<p>When you run this function, it fails with the following error message.</p> <pre>ERROR: cannot change return type of existing function HINT:      Use DROP FUNCTION test_over loading(text) first.</pre> <p>This happens because Aurora PostgreSQL-Compatible doesn't support function overloading directly. It can't identify which function to run, because the number of output parameters is different in the second version of the function, although the input parameters are the same.</p>	<p>Data engineer, Aurora PostgreSQL-Compatible</p>

## Apply the workaround

Task	Description	Skills required
<p>Add INOUT to the first output parameter.</p>	<p>As a workaround, modify the function code by representing the first output parameter as INOUT.</p>	<p>Data engineer, Aurora PostgreSQL-Compatible</p>

Task	Description	Skills required
	<pre>CREATE OR REPLACE FUNCTION public.te st_overloading(     str1 text,     INOUT str2 text,     OUT num1 integer) LANGUAGE 'plpgsql'  COST 100 VOLATILE AS \$BODY\$ DECLARE str3 text; BEGIN      str2 := 'Success';     num1 := 100;  RETURN ; EXCEPTION     WHEN others THEN         RETURN ; END; \$BODY\$;</pre>	

Task	Description	Skills required
Run the revised function.	<p>Run the function that you updated by using the following query. You pass a null value as the second argument of this function, because you declared this parameter as INOUT to avoid the error.</p> <pre data-bbox="597 632 1027 793">select public.test_overloading('Test', null);</pre> <p>The function is now created successfully.</p> <pre data-bbox="597 947 1027 1024">Success, 100</pre>	Data engineer, Aurora PostgreSQL-Compatible
Validate the results.	Verify that the code with the overloaded function was converted successfully.	Data engineer, Aurora PostgreSQL-Compatible

# Help enforce DynamoDB tagging

Created by Mansi Suratwala (AWS)

**Environment:** Production

**Technologies:** Databases  
; CloudNative; Security,  
identity, compliance

**Workload:** All other  
workloads

**AWS services:** Amazon  
CloudWatch; Amazon  
DynamoDB; AWS Lambda;  
Amazon SNS

## Summary

This pattern sets up automatic notifications when a predefined Amazon DynamoDB tag is missing or removed from a DynamoDB resource on the Amazon Web Services (AWS) Cloud.

DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability. DynamoDB lets you offload the administrative burdens of operating and scaling a distributed database. When you use DynamoDB, you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling.

The pattern uses an AWS CloudFormation template, which creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any new or existing DynamoDB tagging information by using AWS CloudTrail. If a predefined tag is missing or removed, CloudWatch triggers a Lambda function, which sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket for the Lambda .zip file that contains the Python script for running the Lambda function

## Limitations

- The solution works only when the TagResource or UntagResource CloudTrail events occur. It does not create notifications for any other events.

## Architecture

### Target technology stack

- Amazon DynamoDB
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon S3
- Amazon SNS

### Target architecture

### Automation and scale

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

## Tools

### Tools

- [Amazon DynamoDB](#) – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.

- [AWS CloudTrail](#) – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- [Amazon CloudWatch Events](#) – Amazon CloudWatch Events delivers a near-real time stream of system events that describe changes in AWS resources.
- [AWS Lambda](#) – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

## Code

- A .zip file of the project is available as an attachment.

## Epics

### Define the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket with a unique name that does not contain leading slashes. This S3 bucket will host the Lambda code .zip file. Your S3 bucket must be in the same AWS Region as the DynamoDB resource that is being monitored.	Cloud Architect

## Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code to the S3 bucket.	Upload the Lambda code .zip file provided in the <i>Attachments</i> section to the S3 bucket. The S3 bucket must be in the same Region as the DynamoDB resource that is being monitored.	Cloud Architect

## Deploy the AWS CloudFormation template

Task	Description	Skills required
Deploy the AWS CloudFormation template.	On the AWS CloudFormation console, deploy the AWS CloudFormation template that's provided in the <i>Attachments</i> section. In the next epic, provide values for the parameters.	Cloud Architect

## Complete the parameters in the AWS CloudFormation template

Task	Description	Skills required
Name the S3 bucket.	Enter the name of the S3 bucket that you created or chose in the first epic.	Cloud Architect
Provide the Amazon S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example,	Cloud Architect

Task	Description	Skills required
	<code>&lt;folder&gt;/&lt;file-name&gt;.zip</code> ).	
Provide an email address	Provide an active email address to receive Amazon SNS notifications.	Cloud Architect
Define the logging level.	Define the logging level and frequency for your Lambda function. Info designates detailed informational messages on the application's progress. Error designates error events that could still allow the application to continue running. Warning designates potentially harmful situations.	Cloud Architect
Enter the required DynamoDB tag keys.	Be sure that the tags are separated by commas, with no spaces between them (for example, <code>ApplicationId, CreatedBy, Environment, Organization</code> ). The CloudWatch Events event searches for these tags and sends a notification if they are not found.	Cloud Architect

## Confirm the subscription.

Task	Description	Skills required
Confirm the subscription.	When the template successfully deploys, it sends a subscription email to the email address that you provided. To receive violation notifications, you must confirm this email subscription.	Cloud Architect

# Implement cross-Region disaster recovery with AWS DMS and Amazon Aurora

*Created by Mark Hudson (AWS)*

**Environment:** Production

**Technologies:** Databases

**AWS services:** AWS DMS;  
Amazon RDS; Amazon Aurora

## Summary

Natural or human-induced disasters can occur at any time and can impact the availability of services and workloads running in a given Amazon Web Services (AWS) Region. To mitigate the risks, you must develop a disaster recovery (DR) plan that incorporates the built-in cross-Region capabilities of AWS services. For AWS services that do not inherently provide cross-Region functionality, the DR plan must also provide a solution to handle their failover across AWS Regions.

This pattern guides you through a disaster recovery setup involving two Amazon Aurora MySQL-Compatible Edition database clusters in a single Region. To meet DR requirements, the database clusters are configured to use the Amazon Aurora global database feature, with a single database spanning multiple AWS Regions. An AWS Database Migration Service (AWS DMS) task replicates data between the clusters in the local Region. AWS DMS, however, currently doesn't support task failover between Regions. This pattern includes the steps required to work around that limitation and independently configure AWS DMS in both Regions.

## Prerequisites and limitations

### Prerequisites

- Selected primary and secondary AWS Regions that support [Amazon Aurora global databases](#).
- Two independent Amazon Aurora MySQL-Compatible Edition database clusters in a single account in the primary Region.
- Database instance class db.r5 or higher (recommended).
- An AWS DMS task in the primary Region performing ongoing replication between the existing database clusters.

- DR Region resources in place to meet requirements for creating database instances. For more information, see [Working with a DB instance in a VPC](#).

## Limitations

- For the full list of Amazon Aurora global database limitations, see [Limitations of Amazon Aurora global databases](#).

## Product versions

- Amazon Aurora MySQL-Compatible Edition 5.7 or 8.0. For more information, see [Amazon Aurora versions](#).

## Architecture

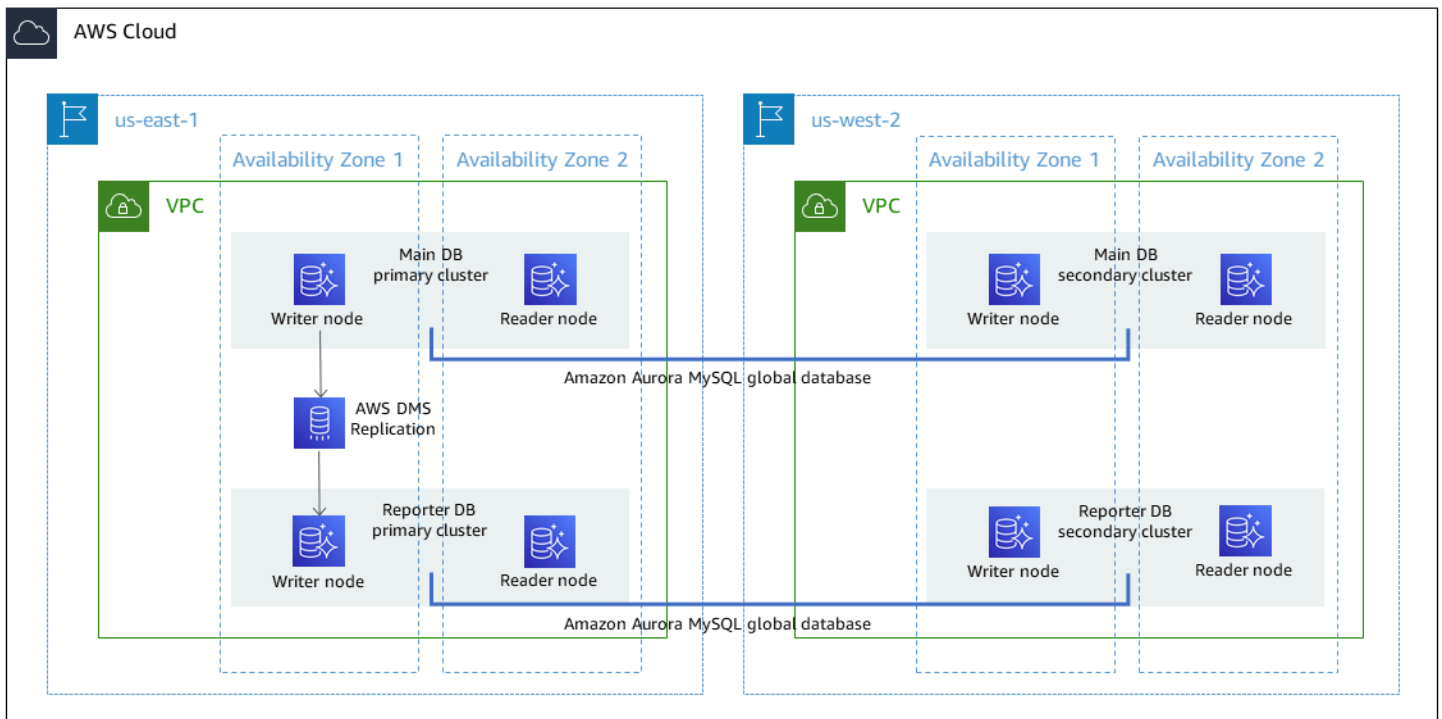

### Target technology stack

- Amazon Aurora MySQL-Compatible Edition global database cluster
- AWS DMS

### Target architecture

The following diagram shows a global database for two AWS Regions, one with the primary main and reporter databases and AWS DMS replication, and one with the secondary main and reporter databases.

## Automation and scale

You can use AWS CloudFormation to create the prerequisite infrastructure in the secondary Region, such as the virtual private cloud (VPC), subnets, and parameter groups. You can also use AWS CloudFormation to create the secondary clusters in the DR Region and add them to the global database. If you used CloudFormation templates to create the database clusters in the primary Region, you can update or augment them with an additional template to create the global database resource. For more information, see [Creating an Amazon Aurora DB cluster with two DB instances](#) and [Creating a global database cluster for Aurora MySQL](#).

Finally, you can create the AWS DMS tasks in the primary and secondary Regions using CloudFormation after failover and failback events occur. For more information, see [AWS::DMS::ReplicationTask](#).

## Tools

- [Amazon Aurora](#) - Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. This pattern uses Amazon Aurora MySQL-Compatible Edition.
- [Amazon Aurora global databases](#) - Amazon Aurora global databases are designed for globally distributed applications. A single Amazon Aurora global database can span multiple AWS Regions. It replicates your data with no impact on database performance. It also enables fast

local reads with low latency in each Region, and it provides disaster recovery from Region-wide outages.

- [AWS DMS](#) - AWS Database Migration Service (AWS DMS) provides one-time migration or on-going replication. An on-going replication task keeps your source and target databases in sync. After it is set up, the on-going replication task continuously applies source changes to the target with minimal latency. All AWS DMS features, such as data validation and transformations, are available for any replication task.

## Epics

### Prepare the existing database clusters in the primary Region

Task	Description	Skills required
Modify the database cluster parameter group.	<p>In the existing database cluster parameter group, activate row-level binary logging by setting the <code>binlog_format</code> parameter to a value of <b>row</b>.</p> <p>AWS DMS requires row-level binary logging for MySQL-compatible databases when performing ongoing replication or change data capture (CDC). For more information, see <a href="#">Using an AWS managed MySQL-compatible database as a source for AWS DMS</a>.</p>	AWS administrator
Update the database binary log retention period.	Using a MySQL client installed on your end-user device or an Amazon Elastic Compute Cloud (Amazon EC2) instance, run the following stored procedure provided by	DBA

Task	Description	Skills required
	<p>Amazon Relational Database Service (Amazon RDS) on the main database cluster's writer node, where XX is the number of hours to retain the logs.</p> <pre>call mysql.rds_set_configuration('binlog retention hours', XX)</pre> <p>Confirm the setting by running the following command.</p> <pre>call mysql.rds_show_configuration;</pre> <p>MySQL-compatible databases managed by AWS purge the binary logs as soon as possible. Therefore, the retention period must be long enough to ensure that the logs are not purged before the AWS DMS task runs. A value of 24 hours is usually sufficient, but the value should be based on the time required to set up the AWS DMS task in the DR Region.</p>	

## Update the existing AWS DMS task in the primary Region

Task	Description	Skills required
Record the AWS DMS task ARN.	<p>Use the Amazon Resource Name (ARN) to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, view the task in the console or run the following command.</p> <pre data-bbox="594 688 1027 810">aws dms describe-replication-tasks</pre> <p>An ARN looks like the following.</p> <pre data-bbox="594 968 1027 1205">arn:aws:dms:us-east-1:&lt;accountid&gt;:task:ANGHFFMPM246X0ZVEUHCNSOVF7MQCLTOZUIRAMY</pre> <p>The characters after the last colon correspond to the task name used in a later step.</p>	AWS administrator
Modify the existing AWS DMS task to record the checkpoint.	<p>AWS DMS creates checkpoints that contain information so that the replication engine knows the recovery point for the change stream. To record checkpoint information, perform the following steps in the console:</p> <ol style="list-style-type: none"><li>1. Stop the AWS DMS task.</li></ol>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>2. Use the JSON editor in the task to set the <code>TaskRecoveryTableEnabled</code> parameter to <b>true</b>.</li> <li>3. Start the AWS DMS task.</li> </ol>	
Validate checkpoint information.	<p>Using a MySQL client connected to the writer endpoint for the cluster, query the new metadata table in the reporter database cluster to verify that it exists and contains the replication state information. Run the following command.</p> <pre style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;">select * from awsdms_control.awsdms_txn_state;</pre> <p>The task name from the ARN should be found in this table in the <code>Task_Name</code> column.</p>	DBA

## Expand both Amazon Aurora clusters to a DR Region

Task	Description	Skills required
Create base infrastructure in the DR Region.	<p>Create the base components required for the creation of and access to the Amazon Aurora clusters:</p> <ul style="list-style-type: none"> <li>• Virtual private cloud (VPC)</li> <li>• Subnets</li> </ul>	AWS administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• Security group</li> <li>• Network access control lists</li> <li>• Subnet group</li> <li>• DB parameter group</li> <li>• DB cluster parameter group</li> </ul> <p>Ensure that the configuration of both parameter groups matches the configuration in the primary Region.</p>	
Add the DR Region to both Amazon Aurora clusters.	Add a secondary Region (the DR Region) to the main and reporter Amazon Aurora clusters. For more information, see <a href="#">Adding an AWS Region to an Amazon Aurora global database</a> .	AWS administrator

## Perform failover

Task	Description	Skills required
Stop the AWS DMS task.	The AWS DMS task in the primary Region will not function properly after failover occurs and should be stopped to avoid errors.	AWS administrator
Perform a managed failover.	Perform a managed failover of the main database cluster to the DR Region. For instructions, see <a href="#">Performing managed planned failovers for Amazon</a>	AWS administrator, DBA

Task	Description	Skills required
	<p><a href="#">Aurora global databases</a>. After failover on the main database cluster is complete, perform the same activity on the reporter database cluster.</p>	
Load data into the main database.	Insert test data into writer node of the main database in the DR database cluster. This data will be used to validate that replication is functioning properly.	DBA
Create the AWS DMS replication instance.	To create the AWS DMS replication instance in the DR Region, see <a href="#">Creating a replication instance</a> .	AWS administrator, DBA
Create the AWS DMS source and target endpoints.	To create the AWS DMS source and target endpoints in the DR Region, see <a href="#">Creating source and target endpoints</a> . The source should point to the writer instance of the main database cluster. The target should point to the writer instance of the reporter database cluster.	AWS administrator, DBA

Task	Description	Skills required
Obtain the replication checkpoint.	<p>To obtain the replication checkpoint, use a MySQL client to query the metadata table by running the following against the writer node in the reporter database cluster in the DR Region.</p> <pre data-bbox="597 583 1026 743">select * from awsdms_control.awsdms_txn_state;</pre> <p>In the table, find the <code>task_name</code> value that corresponds to the AWS DMS task's ARN that exists in the primary Region that you obtained in the second epic.</p>	DBA

Task	Description	Skills required
Create an AWS DMS task.	<p>Using the console, create an AWS DMS task in the DR Region. In the task, specify a migration method of <b>Replicate data changes only</b>. For more information, see <a href="#">Creating a task</a>.</p> <ol style="list-style-type: none"><li>1. In the task settings, use the wizard to specify the following:<ul style="list-style-type: none"><li>• <b>CDC start mode for source transactions</b><ul style="list-style-type: none"><li>– Enable custom CDC start mode</li></ul></li><li>• <b>Custom CDC start point for source transactions</b> – Specify a recovery checkpoint</li></ul></li><li>2. In the <b>Recovery checkpoint</b> box, enter the replication checkpoint value previously obtained through the database query on the <code>awsdms_txn_state</code> table.</li><li>3. In the task settings section, select the JSON editor, and set the <b>TaskRecoveryTableEnabled</b> parameter to <b>true</b>.</li></ol>	AWS administrator, DBA

Task	Description	Skills required
	Set the AWS DMS task <b>Start migration task</b> setting to <b>Automatically on create</b> .	
Record the AWS DMS task ARN.	Use the ARN to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, run the following command.  <pre>aws dms describe-replication-tasks</pre>	AWS administrator, DBA
Validate the replicated data.	Query the reporter database cluster in the DR Region to confirm that the test data that you loaded into the main database cluster has been replicated.	DBA

## Perform failback

Task	Description	Skills required
Stop the AWS DMS task.	The AWS DMS task in the DR Region will not function properly after failback occurs and should be stopped to avoid errors.	AWS administrator
Perform a managed failback.	Fail back the main database cluster to the primary Region. For instructions, see <a href="#">Performing managed planned failovers for Amazon</a>	AWS administrator, DBA

Task	Description	Skills required
	<p><a href="#">Aurora global databases.</a></p> <p>After the failback on the main database cluster is complete, perform the same activity on the reporter database cluster.</p>	
<p>Obtain the replication checkpoint.</p>	<p>To obtain the replication checkpoint, use a MySQL client to query the metadata table by running the following against the writer node in the reporter database cluster in the DR Region.</p> <pre data-bbox="594 842 1027 999">select * from awsdms_control.awsdms_txn_state;</pre> <p>In the table, find the <code>task_name</code> value that corresponds to the AWS DMS task's ARN that exists in the DR Region that you obtained in the fourth epic.</p>	<p>DBA</p>

Task	Description	Skills required
Update the AWS DMS source and target endpoints.	After the database clusters have failed back, check the clusters in the primary Region to determine which nodes are the writer instances . Then verify the existing AWS DMS source and target endpoints in the primary Region are pointing to the writer instances. If not, update the endpoints with the writer instance Domain Name System (DNS) names.	AWS administrator

Task	Description	Skills required
Create an AWS DMS task.	<p>Using the console, create an AWS DMS task in the primary Region. In the task, specify a migration method of <b>Replicate data changes only</b>. For more information, see <a href="#">Creating a task</a>.</p> <ol style="list-style-type: none"><li>1. In the task settings, use the wizard and specify the following:<ul style="list-style-type: none"><li>• <b>CDC start mode for source transactions</b><ul style="list-style-type: none"><li>– Enable custom CDC start mode</li></ul></li><li>• <b>Custom CDC start point for source transactions</b> – Specify a recovery checkpoint</li></ul></li><li>2. In the <b>Recovery checkpoint</b> box, enter the replication checkpoint value previously obtained through the database query on the <code>awsdms_txn_state</code> table.</li><li>3. Also within the task settings section, select the JSON editor and set the <b>TaskRecoveryTableEnabled</b> parameter to <b>true</b>.</li><li>4. Finally, set the AWS DMS task <b>Start migration task</b></li></ol>	AWS administrator, DBA

Task	Description	Skills required
	<p>setting to <b>Automatically on create</b>.</p>	
<p>Record the AWS DMS task Amazon Resource Name (ARN).</p>	<p>Use the ARN to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, run the following command:</p> <pre data-bbox="597 604 1026 722">aws dms describe-replication-tasks</pre> <p>The task name will be needed when performing another managed failover or during a DR scenario.</p>	<p>AWS administrator, DBA</p>
<p>Delete AWS DMS tasks.</p>	<p>Delete the original (currently stopped) AWS DMS task in the primary Region and the existing AWS DMS task (currently stopped) in the secondary Region.</p>	<p>AWS administrator</p>

- [Working with an AWS DMS replication instance](#)
- [Working with AWS DMS endpoints](#)
- [Working with AWS DMS tasks](#)
- [What is AWS CloudFormation?](#)

## Additional information

Amazon Aurora global databases are used in this example for DR because they provide an effective recovery time objective (RTO) of 1 second and a recovery point objective (RPO) of less than 1 minute, both lower than traditional replicated solutions and ideal for DR scenarios.

Amazon Aurora global databases offer many other advantages, including the following:

- Global reads with local latency – Global consumers can access information in a local Region, with local latency.
- Scalable secondary Amazon Aurora DB clusters – Secondary clusters can be scaled independently, adding up to 16 read-only replicas.
- Fast replication from primary to secondary Amazon Aurora DB clusters – Replication has little performance impact on the primary cluster. It occurs at the storage layer, with typical cross-Region replication latencies of less than 1 second.

This pattern also uses AWS DMS for replication. Amazon Aurora databases provide the ability to create read replicas, which can simplify the replication process and the DR setup. However, AWS DMS is often used to replicate when data transformations are required or when the target database requires additional indexes that the source database does not have.

# Migrate Oracle functions and procedures that have more than 100 arguments to PostgreSQL

Created by Srinivas Potlachervoo (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> PostgreSQL
<b>R Type:</b> Replatform	<b>Workload:</b> Open-source; Oracle	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon RDS; Amazon Aurora		

## Summary

This pattern shows how to migrate Oracle Database functions and procedures that have more than 100 arguments to PostgreSQL. For example, you can use this pattern to migrate Oracle functions and procedures to one of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

PostgreSQL doesn't support functions or procedures that have more than 100 arguments. As a workaround, you can define a new data type that has type fields that match the source function's arguments. Then, you can create and run a PL/pgSQL function that uses the custom data type as an argument.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An [Amazon RDS Oracle database \(DB\) instance](#)
- An [Amazon RDS for PostgreSQL DB instance](#) or an [Aurora PostgreSQL-Compatible DB instance](#)

## Product versions

- Amazon RDS Oracle DB instance versions 10.2 and later
- Amazon RDS PostgreSQL DB instance versions 9.4 and later, or Aurora PostgreSQL-Compatible DB instance versions 9.4 and later
- Oracle SQL Developer version 18 and later
- pgAdmin version 4 and later

## Architecture

### Source technology stack

- Amazon RDS Oracle DB instance versions 10.2 and later

### Target technology stack

- Amazon RDS PostgreSQL DB instance versions 9.4 and later, or Aurora PostgreSQL-Compatible DB instance versions 9.4 and later

## Tools

### AWS services

- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

### Other services

- [Oracle SQL Developer](#) is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Best practices

Make sure that the data type that you create matches the type fields that are included in the source Oracle function or procedure.

## Epics

### Run an Oracle function or procedure that has more than 100 arguments

Task	Description	Skills required
<p>Create or identify an existing Oracle/PLSQL function or procedure that has more than 100 arguments.</p>	<p>Create an Oracle/PLSQL function or procedure that has more than 100 arguments .</p> <p>-or-</p> <p>Identify an existing Oracle/PLSQL function or procedure that has more than 100 arguments.</p> <p>For more information, see sections <a href="#">14.7 CREATE FUNCTION Statement</a> and <a href="#">14.11 CREATE PROCEDURE Statement</a> in the Oracle Database documentation.</p>	<p>Oracle/PLSQL knowledge</p>
<p>Compile the Oracle/PLSQL function or procedure.</p>	<p>Compile the Oracle/PLSQL function or procedure.</p> <p>For more information, see <a href="#">Compiling a function</a> in the Oracle Database documentation.</p>	<p>Oracle/PLSQL knowledge</p>

Task	Description	Skills required
Run the Oracle/PLSQL function.	Run the Oracle/PLSQL function or procedure. Then, save the output.	Oracle/PLSQL knowledge

### Define a new data type that matches the source function's or procedure's arguments

Task	Description	Skills required
Define a new data type in PostgreSQL.	<p>Define a new data type in PostgreSQL that includes all of the same fields that appear in the source Oracle function's or procedure's arguments.</p> <p>For more information, see <a href="#">CREATE TYPE</a> in the PostgreSQL documentation.</p>	PostgreSQL PL/pgSQL knowledge

### Create a PostgreSQL function that includes the new TYPE argument

Task	Description	Skills required
Create a PostgreSQL function that includes the new data type.	<p>Create a PostgreSQL function that includes the new TYPE argument.</p> <p>To review an example function, see the <b>Additional information</b> section of this pattern.</p>	PostgreSQL PL/pgSQL knowledge
Compile the PostgreSQL function.	Compile the function in PostgreSQL. If the new data type fields match the source	PostgreSQL PL/pgSQL knowledge

Task	Description	Skills required
	function's or procedure's arguments, then the function successfully compiles.	
Run the PostgreSQL function.	Run the PostgreSQL function.	PostgreSQL PL/pgSQL knowledge

## Troubleshooting

Issue	Solution
The function returns the following error: <b>ERROR: syntax error near "&lt;statement&gt;"</b>	Make sure that all of the function's statements end with a semicolon (;).
The function returns the following error: <b>ERROR: "&lt;variable&gt;" is not a known variable</b>	Make sure that the variable that's used in the function body is listed within the function's DECLARE section.

LANGUAGE plpgsql
COST 100;
```

# Migrate Amazon RDS for Oracle DB instances to other accounts that use AMS

Created by Pinesh Singal (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for Oracle on AWS Managed Services
<b>R Type:</b> Rehost	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases; Migration; Storage & backup
<b>AWS services:</b> Amazon RDS; AWS Managed Services		

## Summary

This pattern shows you how to migrate an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance from one AWS account to another AWS account. The pattern applies to scenarios where the source AWS account doesn't use AWS Managed Services (AMS) but the target account does use AMS. You can complete the migration by using a [request for change \(RFC\)](#) in AMS instead of using the AWS Management Console to perform database operations. This approach provides minimal downtime for a multi-terabyte Oracle source database with a high number of transactions. For example, the downtime for a 400–900 GB database could last for approximately two or three hours. Database migration time is directly proportionate to the size of the Amazon RDS for Oracle DB instance.

**Important:** This pattern requires you to take a database snapshot of the Amazon RDS for Oracle DB instance in a source account, copy the snapshot to a target account that's using AMS, and then create a new DB instance from that snapshot by raising RFCs.

## Prerequisites and limitations

### Prerequisites

- An active AWS account for the source account

- An active AWS account that uses AMS for the target account
- Amazon RDS for Oracle DB instance, up and running

## Limitations

- The same properties or configurations for the DB instances in the source account are copied over to a new target DB instance on AMS.
- The RFC method that's used in this migration approach has limited features to support Amazon RDS for Oracle. You can access the full features of Amazon RDS for Oracle by using an AWS CloudFormation template to perform the database migration.
- You can experience an application outage for several hours because the migration must be completed during scheduled downtime. During downtime, you stop the DB instance in the source account, and then you go live to a new DB instance in the target account.
- This migration approach doesn't apply to the migration of a DB instance from one AWS Region to another Region within the same AWS account.

## Product versions

- Oracle Database Standard Edition 2 (SE2) 12.1.0.2.v2 instance and later on Amazon RDS for Oracle
- Amazon RDS for Oracle 11g is no longer supported (For more information, see [Amazon RDS for Oracle](#) in the Amazon RDS documentation.)

## Architecture

### Source technology stack

- Oracle Database SE2 12.1.0.2.v2 instance on Amazon RDS for Oracle
- Amazon RDS subnet group
- Amazon RDS option group (if needed)
- Amazon RDS parameter group (if needed)
- Amazon Virtual Private Cloud (Amazon VPC) security group
- AWS Key Management Service (AWS KMS) with AWS managed keys or customer managed keys
- AWS Identity and Access Management (IAM) role (if needed)

## Target technology stack

- Oracle Database SE2 12.1.0.2.v2 instance on Amazon RDS for Oracle
- Amazon RDS subnet group
- Amazon RDS option group (if needed)
- Amazon RDS parameter group (if needed)
- Amazon VPC security group
- AWS Managed Services (AMS)
- AWS KMS with AWS managed keys and customer managed keys
- IAM role (if needed)

## Source and target migration architecture

The following diagram shows the migration of an Amazon RDS for Oracle DB instance in one AWS account to an Amazon RDS for Oracle DB instance in another AWS account that uses AMS.

The diagram shows the following workflow:

1. Take a database snapshot of the Amazon RDS for Oracle DB instance in the source account.
2. Copy the snapshot to AMS in the target account.
3. Create a new Amazon RDS for Oracle DB instance from the snapshot in the target account.

## Automation and scale

You can automate and scale the migration by using CloudFormation templates and [creating RFCs in AMS](#). CloudFormation enables you to use all the features of Amazon RDS for Oracle, including the ability to configure and restore the DB instance when you create an Amazon RDS for Oracle DB instance from a snapshot.

## Tools

- [Amazon Relational Database Service \(Amazon RDS\) for Oracle](#) helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Managed Services \(AMS\)](#) helps you operate your AWS infrastructure more efficiently and securely.

## Epics

### Prepare for cutover on the target account

Task	Description	Skills required
Create a custom AWS KMS key.	<ol style="list-style-type: none"><li>1. Raise an automated RFC called <a href="#">Create KMS key</a> to create a custom KMS key from your target account.</li><li>2. Share your custom KMS key with the source account. <b>Note:</b> You can't share Amazon RDS for Oracle DB instances that use the default <a href="#">AWS managed key</a> for Amazon RDS (aws/rds). Instead, share the DB instance by re-encrypting the DB instance from your KMS key.</li></ol>	AWS, AMS

Task	Description	Skills required
Create a security group.	<p>Raise an automated RFC called <a href="#">Create security group</a> to create a security group for your VPC from your target account.</p> <p>Be sure to specify the following:</p> <ul style="list-style-type: none"><li>• New security group name</li><li>• TCP and UDP ingress and egress rules</li><li>• Standard tags</li></ul>	AWS, AMS

Task	Description	Skills required
(Optional) Review your Amazon RDS resources.	<p>The following resources are created when an Amazon RDS for Oracle DB instance is created:</p> <ul style="list-style-type: none"> <li>• Amazon RDS subnet group (based on the subnet ID)</li> <li>• Amazon RDS option group (based on the snapshot of the source DB instance)</li> <li>• Amazon RDS parameter group (based on the snapshot of the DB instance)</li> </ul> <p>If you want to review the Amazon RDS resources that were created when you created your DB instance, then you can <a href="#">connect to your Oracle DB instance</a> and find your subnet group, option group, and parameter group in the Amazon RDS console.</p>	AWS

### Cut over on the source account

Task	Description	Skills required
Stop the application.	Stop the application and its dependent services. You must stop all traffic to the database in the source account.	App owner

Task	Description	Skills required
Take a manual snapshot.	Manually <a href="#">create a DB snapshot</a> of the Amazon RDS for Oracle DB instance in the source account.	AWS
Stop the DB instance.	<a href="#">Stop the Amazon RDS for Oracle DB instance.</a>	AWS
Copy the snapshot.	<a href="#">Copy the DB snapshot</a> to the same source account, and then use the custom KMS key shared from the target account to re-encrypt the copied DB snapshot file.	AWS
Share the snapshot.	<a href="#">Share the new snapshot</a> (copied with the custom KMS key) with the target account.	AWS

### Cut over on the target account

Task	Description	Skills required
Copy the snapshot.	<p>Raise an automated RFC called <a href="#">Copy RDS snapshot</a> to copy the DB snapshot to the same target account and use the default AWS managed KMS key created for re-encryption.</p> <p>This is required to make the target account the owner of the new snapshot and to enable the Amazon RDS for</p>	AWS, AMS

Task	Description	Skills required
	<p>Oracle DB instance created from the snapshot to be associated with the option group, if needed.</p>	
<p>Create a DB instance from the snapshot.</p>	<p>Raise an automated RFC called <a href="#">Create DB from snapshot</a> to create an Amazon RDS for Oracle DB instance from the snapshot.</p> <p>Be sure to specify the following:</p> <ul style="list-style-type: none"> <li>• New snapshot ID created in the previous step</li> <li>• VPC ID</li> <li>• Subnet ID</li> <li>• RDS instance ID</li> <li>• Standard tags</li> </ul>	<p>AWS, AMS</p>
<p>Attach the instance to the security group and make configuration updates.</p>	<ol style="list-style-type: none"> <li>1. Raise a manual RFC called <a href="#">Update Other</a> to attach the Amazon RDS for Oracle DB instance that you created previously with the VPC security group that you created previously.</li> <li>2. Make any additional changes to the Amazon RDS for Oracle DB instance configuration.</li> </ol>	<p>AWS, AMS</p>

Task	Description	Skills required
Test the DB instance.	<p>Test the new Amazon RDS for Oracle DB instance endpoint connectivity by logging into any instance or application server hosted on the same security group and by using telnet to connect to the 1521 port. For more information, see <a href="#">Connecting to an Amazon RDS DB instance</a> in the Amazon RDS documentation.</p> <p><b>Note:</b> If the primary user login credentials are available, you can test the Amazon RDS for Oracle DB instance by logging in from any SQL client (such as Oracle SQL Developer).</p>	AWS, DBA

## Additional information

### Roll back the migration

If you want to roll back the migration, complete the following steps:

1. Raise a manual RFC (Update Other) from the target account to delete the database stack created in the target account.
2. Update the application configuration to point to the Amazon RDS for Oracle DB instance in the source account.
3. Start the Amazon RDS for Oracle DB instance in the source account.

# Migrate Oracle OUT bind variables to a PostgreSQL database

Created by Bikash Chandra Rout (AWS) and Vinay Paladi (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Database Relational	<b>Target:</b> RDS/Aurora Postgresql
<b>R Type:</b> Replatform	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases; Migration

**AWS services:** Amazon  
Aurora; Amazon RDS; AWS  
SCT

## Summary

This pattern shows how to migrate Oracle Database OUT bind variables to either one of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

PostgreSQL doesn't support OUT bind variables. To get the same functionality in your Python statements, you can create a custom PL/pgSQL function that uses the GET and SET package variables instead. To apply these variables, the example wrapper function script that's provided in this pattern uses an [AWS Schema Conversion Tool \(AWS SCT\) extension pack](#).

**Note:** If the Oracle EXECUTE IMMEDIATE statement is a SELECT statement that can return one row at most, it's a best practice to do the following:

- Put OUT bind variables (defines) in the INTO clause
- Put IN bind variables in the USING clause

For more information, see [EXECUTE IMMEDIATE statement](#) in the Oracle documentation.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Oracle Database 10g (or newer) source database in an on-premises data center
- An [Amazon RDS for PostgreSQL DB instance](#) or an [Aurora PostgreSQL-Compatible DB instance](#)

## Architecture

### Source technology stack

- On-premises Oracle Database 10g (or newer) database

### Target technology stack

- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

### Target architecture

The following diagram shows an example workflow for migrating Oracle Database OUT bind variables to a PostgreSQL-compatible AWS database.

The diagram shows the following workflow:

1. AWS SCT converts the source database schema and a majority of the custom code to a format compatible with the target PostgreSQL-compatible AWS database.
2. Any database objects that can't be converted automatically are flagged by the PL/pgSQL function. Objects that are flagged are then manually converted to complete the migration.

## Tools

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.
- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Epics

### Migrate Oracle OUT bind variables by using a custom PL/pgSQL function and AWS SCT

Task	Description	Skills required
<p>Connect to your PostgreSQL-compatible AWS database.</p>	<p>After you've created your DB instance, you can use any standard SQL client application to connect to a database in your DB cluster. For example, you can use <a href="#">pgAdmin</a> to connect to your DB instance.</p> <p>For more information, see either of the following:</p> <ul style="list-style-type: none"> <li>• <a href="#">Connecting to an Amazon RDS DB instance</a> in the <i>Amazon RDS User Guide</i></li> <li>• <a href="#">Connecting to an Amazon Aurora DB cluster</a> in the <i>Amazon Aurora User Guide</i></li> </ul>	<p>Migration engineer</p>
<p>Add the example wrapper function script from this pattern to the target database's main schema.</p>	<p>Copy the example PL/pgSQL wrapper function script from the <b>Additional information</b> section of this pattern. Then, add the function to the target database's main schema.</p> <p>For more information, see <a href="#">CREATE FUNCTION</a> in the PostgreSQL documentation.</p>	<p>Migration engineer</p>
<p>(Optional) Update the search path in the target database's</p>	<p>To improve performance, you can update the PostgreSQ</p>	<p>Migration engineer</p>

Task	Description	Skills required
main schema so that includes the Test_pg schema.	<p>L <b>search_path</b> variable so that it includes the <b>Test_pg</b> schema name. If you include the schema name in the search path, you don't need to specify the name whenever you call the PL/pgSQL function.</p> <p>For more information, see section <a href="#">5.9.3 The Schema Search Path</a> in the PostgreSQL documentation.</p>

## Additional information

### Example PL/pgSQL function

```
/* Oracle */  
  
CREATE or replace PROCEDURE test_pg.calc_stats_new1 (  
    a NUMBER,  
    b NUMBER,  
    result out NUMBER  
)  
  
IS  
BEGIN  
    result:=a+b;  
END;
```

```
/
/* Testing */
set serveroutput on
DECLARE
  a NUMBER := 4;
  b NUMBER := 7;
  plsqli_block VARCHAR2(100);
  output number;
BEGIN
  plsqli_block := 'BEGIN test_pg.calc_stats_new1(:a, :b,:output); END;';
  EXECUTE IMMEDIATE plsqli_block USING a, b,out output; -- calc_stats(a, a, b, a)
  DBMS_OUTPUT.PUT_LINE('output:' ||output);
END;

output:11

PL/SQL procedure successfully completed.

--Postgres--

/* Example : 1 */
CREATE OR REPLACE FUNCTION test_pg.calc_stats_new1(
                                                    w integer,

# Migrate SAP HANA to AWS using SAP HSR with the same hostname

Created by Pradeep Puliampatta (AWS)

<b>Environment:</b> Production	<b>Source:</b> SAP HANA DB on-premises	<b>Target:</b> SAP HANA DB on AWS
<b>R Type:</b> Rehost	<b>Workload:</b> SAP	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> AWS Client VPN; AWS Direct Connect; Amazon EBS		

## Summary

SAP HANA migrations to Amazon Web Services (AWS) can be performed using multiple options, including backup and restore, export and import, and SAP HANA System Replication (HSR). The selection of a particular option depends on the network connectivity between source and target SAP HANA databases, the size of the source database, downtime considerations, and other factors.

The SAP HSR option for migrating SAP HANA workloads to AWS works well when there is a stable network between the source and target systems and the entire database (SAP HANA DB replication snapshot) can be completely replicated within 1 day, as stipulated by SAP for network throughput requirements for SAP HSR. The downtime requirements with this approach are limited to performing the takeover on the target AWS environment, SAP HANA DB backup, and post-migration tasks.

SAP HSR supports the use of different hostnames (hostnames mapped to different IP addresses) for replication traffic between the primary, or source, and secondary, or target, systems. You can do this by defining those specific sets of hostnames under the [system\_replication\_hostname\_resolution] section in `global.ini`. In this section, all hosts of the primary and the secondary sites must be defined on each host. For detailed configuration steps, see the [SAP documentation](#).

One key takeaway from this setup is that the hostnames in the primary system must be different from the hostnames in the secondary system. Otherwise, the following errors can be observed.

- "each site must have a unique set of logical hostnames"
- "remoteHost does not match with any host of the source site. All hosts of source and target site must be able to resolve all hostnames of both sites correctly"

However, the number of post-migration steps can be reduced by using the same SAP HANA DB hostname on the target AWS environment.

This pattern provides a workaround for using the same hostname on source and target environments when using the SAP HSR option. With this pattern, you can use the SAP HANA Hostname Rename option. You assign a temporary hostname to the target SAP HANA DB to facilitate hostname uniqueness for SAP HSR. After the migration completes the takeover milestone on the target SAP HANA environment, you can revert the target system hostname back to the hostname of the source system.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router.
- AWS Client VPN or AWS Direct Connect configured to transfer files from the source to the target.
- SAP HANA databases in both the source and the target environment. The target SAP HANA DB patch level should be equal to or higher than the source SAP HANA DB patch level, within the same SAP HANA Platform edition. For example, replication cannot be set up between HANA 1.0 and HANA 2.0 systems. For more information, see question 15 in SAP Note: 1999880 – FAQ: SAP HANA System Replication.
- SAP application servers in the target environment.
- Amazon Elastic Block Store (Amazon EBS) volumes in the target environment.

### Limitations

The following list of SAP documents covers known issues that are related to this workaround, including constraints regarding SAP HANA dynamic tiering and scale-out migrations:

- 2956397 – Renaming of SAP HANA Database System failed
- 2222694 – When trying to rename the HANA system, the following error appears "Source files are not owned by the original sidadm user (uid = xxxx)"
- 2607227 – hdblcm: register\_rename\_system: Renaming SAP HANA instance failed
- 2630562 – HANA Hostname Rename failed and HANA does not start up
- 2935639 – sr\_register is not using the hostname that is specified under system\_replication\_hostname\_resolution in the global.ini section
- 2710211 – Error: source system and target system have overlapping logical hostnames
- 2693441 – Failed to rename an SAP HANA System due to error
- 2519672 – HANA Primary and Secondary has different system PKI SSFS data and key or unable to check
- 2457129 – SAP HANA System Host Rename is not Permitted when Dynamic Tiering is Part of Landscape
- 2473002 – Using HANA System Replication to migrate scale out system (There are no restrictions provided by SAP in using this hostname rename approach for scale-out SAP HANA systems. However, the procedure must be repeated on each individual host. Other scale-out migration limitations also apply to this approach.)

## Product versions

- This solution applies to SAP HANA DB platform edition 1.0 and 2.0.

## Architecture

### Source setup

An SAP HANA database is installed on the source environment. All the SAP application server connections and DB interfaces use the same hostname for client connections. The following diagram shows the example source hostname hdbhost and its corresponding IP address.

## Target setup

The AWS Cloud target environment uses the same hostname to run an SAP HANA database. The target environment on AWS includes the following:

- SAP HANA database
- SAP application servers
- EBS volumes

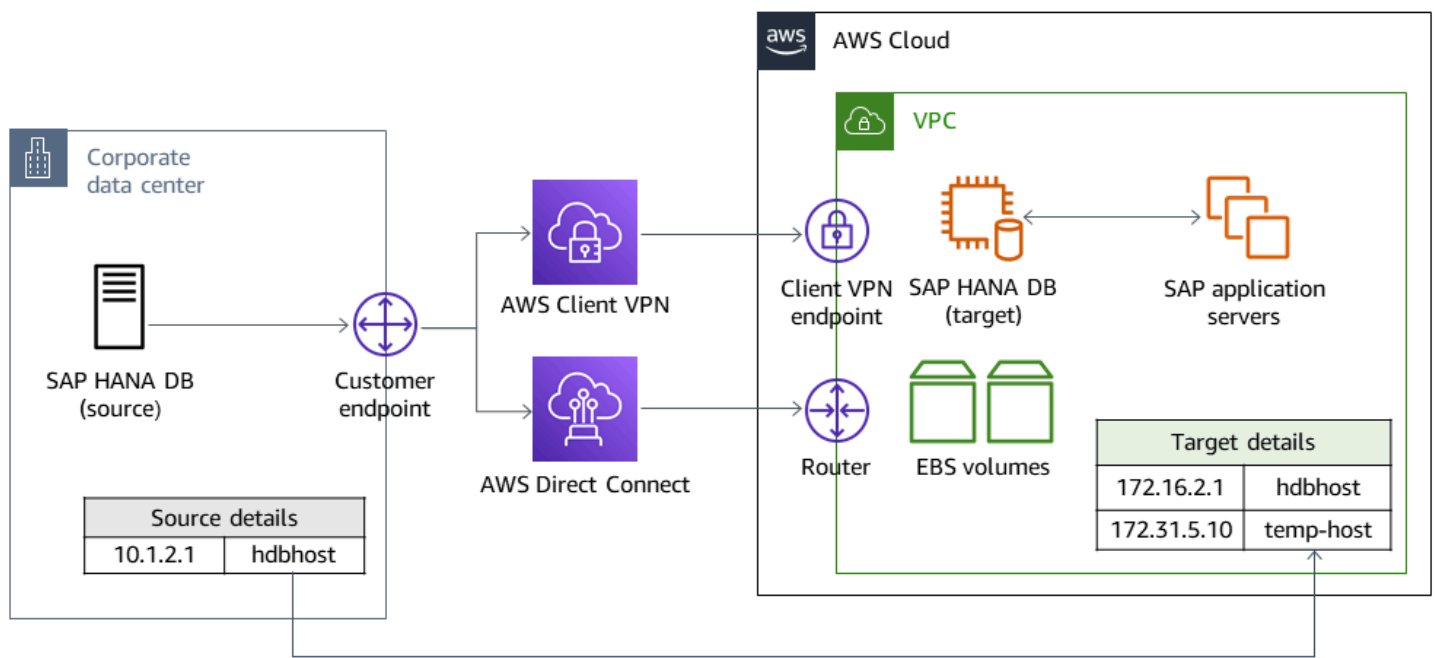

### Intermediate configuration

In the following diagram, the hostname on the AWS target environment is temporarily renamed as temp-host so that the hostnames on the source and target are unique. After the migration completes the takeover milestone on the target environment, the target system virtual hostname is renamed using the original name, hdbhost.

The intermediate configuration includes one of the following options:

- AWS Client VPN with a Client VPN endpoint
- AWS Direct Connect connecting to a router

SAP application servers on the AWS target environment can be installed either before replication setup or after the takeover. However, installing the application servers before replication setup can help with reduction of downtime during installation, configuration of high availability, and backups.

## Tools

### AWS services

- [AWS Client VPN](#) is a managed client-based VPN service that enables you to securely access AWS resources and resources in your on-premises network.
- [AWS Direct Connect](#) links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services, bypassing internet service providers in your network path.
- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

### Other tools

- [SAP application servers](#) – SAP application servers provide programmers with a way to express business logic. The SAP application server performs the data processing based on the business logic. The actual data is stored in a database, which is a separate component.
- [SAP HANA cockpit](#) and [SAP HANA Studio](#) – Both SAP HANA cockpit and SAP HANA Studio provide an administrative interface to the SAP HANA database. In SAP HANA Studio, the SAP HANA Administration console is the system view that provides relevant content for SAP HANA database administration.
- [SAP HANA System Replication](#) – SAP HANA System Replication (SAP HSR) is the standard procedure provided by SAP for replicating SAP HANA databases. The required executables for SAP HSR are part of the SAP HANA server kernel itself.

## Epics

### Prepare the source and target environments

Task	Description	Skills required
Install and configure the SAP HANA databases.	In the source and target environments, ensure that the SAP HANA DB is installed and configured according to SAP HANA on best practices. For more information, see <a href="#">SAP HANA on AWS</a> .	SAP Basis administration
Map the IP address.	In the target environment, ensure that the temporary hostname is assigned to an internal IP address.  1. Assign a secondary IPv4 address to the EC2 instance on the AWS Management Console by navigating to <b>EC2, Instance, Actions, Networking, Manage IP</b>	AWS administration

Task	Description	Skills required
	<p><b>address, Assign new IP address.</b></p> <p>2. To assign the same address to the EC2 network adaptor (NIC), from the operating system, as root user, run the command <code>ip addr add &lt;IP&gt;/32 dev eth0</code>, replacing &lt;IP&gt; with the IP address from step 1.</p>	
Resolve target hostnames.	On the secondary SAP HANA DB, confirm that both hostnames (hdbhost and temp-host ) are resolved for the SAP HANA replication networks by updating the relevant hostnames in the <code>/etc/hosts</code> file.	Linux administration
Back up the source and target SAP HANA databases.	Use SAP HANA Studio or the SAP HANA cockpit to perform backups on the SAP HANA databases.	SAP Basis administration

Task	Description	Skills required
Exchange system PKI certificates.	(Applies only to SAP HANA 2.0 and later) Exchange certificates in the system public key infrastructure (PKI) secure store in the file system (SSFS) store between the primary and secondary databases. For more information, see SAP Note 2369981 – Required configuration steps for authentication with SAP HANA System Replication.	SAP Basis administration

## Rename the target SAP HANA DB

Task	Description	Skills required
Stop target client connections.	In the target environment, shut down the SAP application servers and other client connections.	SAP Basis administration
Rename the target SAP HANA DB to the temporary hostname.	<ol style="list-style-type: none"> <li>As root user, rename the target SAP HANA DB hostname to the temporary hostname by using resident hdb1cm. <div data-bbox="630 1570 1026 1726" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>root \$&gt; cd /hana/shared/&lt;SID/hdb1cm root \$&gt; ./hdb1cm</pre> </div> </li> <li>Choose option 9   rename_system  </li> </ol>	SAP Basis administration

Task	Description	Skills required
	<p>Rename the SAP HANA Database System.</p> <ol style="list-style-type: none"> <li>3. Provide the new name: temp-host .</li> <li>4. You can validate other options as needed. However, be sure that you don't mix up the host rename with a SID change (SAP Note 2598814 – hdblcm: SID rename fails).</li> </ol> <p>The SAP HANA DB stop and start will be controlled by hdblcm.</p>	
Assign replication networks.	<p>In the <code>global.ini</code> file of the source system, under the <code>[system_replication_hostname_resolution]</code> header, provide the source and target replication network details. Then copy the entries to the <code>global.ini</code> file on the target system.</p>	SAP Basis administration
Enable replication on primary.	<p>To enable replication on the source SAP HANA DB, run the following command.</p> <pre>hdbnsutil -sr_enable --name=siteA</pre>	SAP Basis administration

Task	Description	Skills required
Register the target SAP HANA DB as a secondary system.	<p>To register the target SAP HANA DB as a secondary system to source for SAP HSR, choose <b>async</b> replication.</p> <pre data-bbox="597 443 1026 877">(sid)adm \$&gt; HDB stop (sid)adm \$&gt; hdbnsutil - sr_register -name=sit eB -remotehost=hdbhos t / --remoteInstance=00 - replicationMode=async -operationMode=log replay (sid)adm \$&gt; HDB start</pre> <p>Alternatively, you can choose the <code>-online</code> option to register. In that case, you don't need to stop and start the SAP HANA DB.</p>	SAP Basis administration
Validate synchronization.	<p>On the source SAP HANA DB, verify that all the logs are applied on the target system (because it is async replication).</p> <p>To verify the replication, on the source, run the following commands.</p> <pre data-bbox="597 1629 1026 1822">(sid)adm \$&gt; cdp (sid)adm \$&gt; python systemReplicationS tatus.py</pre>	SAP Basis administration

Task	Description	Skills required
Shut down the source SAP application and SAP HANA DB.	During the migration cutover, perform a shutdown of the source system (the SAP application and SAP HANA database).	SAP Basis administration
Perform a takeover at the target.	To perform a takeover at the target on AWS, run the command <code>hdbnsutil -sr_takeover</code> .	SAP Basis administration
On the target SAP HANA DB, turn off replication.	To clear the replication metadata, stop replication on the target system by running the command <code>hdbnsutil -sr_disable</code> .  <b>Note:</b> This is in accordance with SAP Note 2693441 – Failed to rename an SAP HANA System due to error.	SAP Basis administration
Back up the target SAP HANA DB.	After the takeover is successful, we recommend performing a full SAP HANA DB backup.	SAP Basis administration

### Revert to the original hostname in the target system

Task	Description	Skills required
Revert the target SAP HANA DB hostname to the original.	1. To revert the target SAP HANA DB hostname to the original virtual hostname, use resident <code>hdb1cm</code> .	SAP Basis administration

Task	Description	Skills required
	<pre data-bbox="634 226 979 348">root \$&gt; cd /hana/sha red/&lt;SID&gt;/hdblcm root \$&gt; ./hdblcm</pre> <p data-bbox="592 384 997 667">2. Choose option 9   rename_system   Rename the SAP HANA Database System.</p> <p data-bbox="592 585 867 667">3. Provide the new name: hdbhost.</p> <p data-bbox="592 745 1016 1018">You can validate other options as needed. However, be sure that you don't mix up the host rename with a SID change (SAP Note 2598814 – hdblcm: SID rename fails).</p>	
Adjust hdbuserstore.	<p data-bbox="592 1094 1024 1367">Adapt the hdbuserstore details pointing to the source schema/user details. For detailed steps, see the <a href="#">SAP documentation</a>.</p> <p data-bbox="592 1413 1003 1640">To validate this step, run the command <code>R3trans -d</code>. The result should reflect a successful connection to the SAP HANA database.</p>	SAP Basis administration
Start up client connections.	<p data-bbox="592 1686 979 1860">In the target environment, start up the SAP application servers and other client connections.</p>	SAP Basis administration

# Migrate SQL Server to AWS using distributed availability groups

Created by Praveen Marthala (AWS)

<b>Source:</b> SQL Server On-Premises	<b>Target:</b> SQL Server on EC2	<b>R Type:</b> Rehost
<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Databases; Migration	<b>Workload:</b> Microsoft
<b>AWS services:</b> Amazon EC2		

## Summary

Microsoft SQL Server Always On availability groups provide a high availability (HA) and disaster recovery (DR) solution for SQL Server. An availability group consists of a primary replica that accepts read/write traffic, and up to eight secondary replicas that accept read traffic. An availability group is configured on a Windows Server Failover Cluster (WSFC) with two or more nodes.

Microsoft SQL Server Always On distributed availability groups provide a solution to configure two separate availability groups between two independent WSFCs. The availability groups that are part of the distributed availability group don't have to be in the same data center. One availability group can be on premises, and the other availability group can be on the Amazon Web Services (AWS) Cloud on Amazon Elastic Compute Cloud (Amazon EC2) instances in a different domain.

This pattern outlines steps for using a distributed availability group to migrate on-premises SQL Server databases that are part of an existing availability group to SQL Server with availability groups set up on Amazon EC2. By following this pattern, you can migrate the databases to the AWS Cloud with minimal downtime during cutover. The databases are highly available on AWS immediately after the cutover. You can also use this pattern to change the underlying operating system from on-premises to AWS while keeping the same version of SQL Server.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Direct Connect or AWS Site-to-Site VPN
- The same version of SQL Server installed on-premises and on the two nodes on AWS

### **Product versions**

- SQL Server version 2016 and later
- SQL Server Enterprise Edition

## **Architecture**

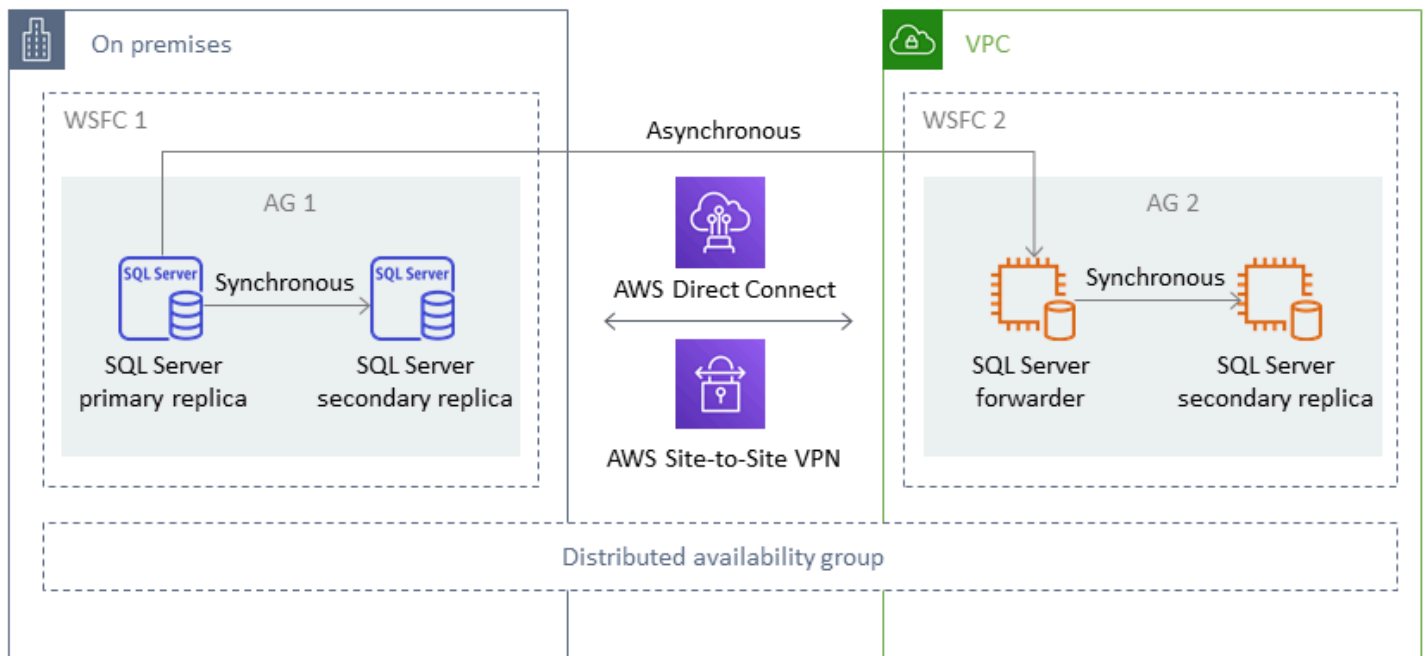

### **Source technology stack**

- Microsoft SQL Server database with Always On availability groups on premises

### **Target technology stack**

- Microsoft SQL Server database with Always On availability groups on Amazon EC2 on the AWS Cloud

### **Migration architecture**

## Terminology

- WSFC 1 – WSFC on premises
- WSFC 2 – WSFC on the AWS Cloud
- AG 1 – First availability group, which is in WSFC 1
- AG 2 – Second availability group, which is in WSFC 2
- SQL Server primary replica – Node in AG 1 that is considered the global primary for all writes
- SQL Server forwarder – Node in AG 2 that receives data asynchronously from the SQL Server primary replica
- SQL Server secondary replica – Nodes in AG 1 or AG 2 that receive data synchronously from the primary replica or the forwarder

## Tools

- [AWS Direct Connect](#) – AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create *virtual interfaces* directly to public AWS services, bypassing internet service providers in your network path.

- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- [AWS Site-to-Site VPN](#) – AWS Site-to-Site VPN supports creating a site-to-site virtual private network (VPN). You can configure the VPN to pass traffic between instances that you launch on AWS and your own remote network.
- [Microsoft SQL Server Management Studio](#) – Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

## Best practices

< **Author remove these notes:** Provide a list of guidelines and recommendations that can help users implement this pattern more effectively.>

## Epics

### Set up a second availability group on AWS

Task	Description	Skills required
Create a WSFC on AWS.	Create WSFC 2 on Amazon EC2 instances with two nodes for HA. You will use this failover cluster to create the second availability group (AG 2) on AWS.	Systems administrator, SysOps administrator
Create the second availability group on WSFC 2.	Using SSMS, create AG 2 on two nodes in WSFC 2. The first node in WSFC 2 will act as the forwarder. The second node in WSFC 2 will act as the secondary replica of AG 2.  At this stage, no databases are available in AG 2. This is	DBA, Developer

Task	Description	Skills required
	the starting point for setting up the distributed availability group.	
Create databases with no recovery option on AG 2.	<p>Back up databases on the on-premises availability group (AG 1).</p> <p>Restore the databases to both the forwarder and the secondary replica of AG 2 with no recovery option. While restoring the databases , specify a location with enough disk space for the database data files and the log files.</p> <p>At this stage, the databases are in the restoring state. They are not part of AG 2 or the distributed availability group, and they are not synchronizing.</p>	DBA, Developer

### Configure the distributed availability group

Task	Description	Skills required
Create the distributed availability group on AG 1.	To create the distributed availability group on AG 1, use the <code>CREATE AVAILABILITY GROUP</code> with the <code>DISTRIBUTED</code> option.	DBA, Developer

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="594 214 1013 340">1. Use LISTENER_URL endpoint addresses for AG 1 and AG 2.</li><li data-bbox="594 365 987 684">2. For AVAILABILITY-MODE, use ASYNCHRONOUS_COMMIT to avoid network latency, if any. This will not impact the performance of the database.</li><li data-bbox="594 709 997 932">3. For FAILOVER_MODE , use MANUAL. It is the only availability mode that works with distributed availability groups.</li><li data-bbox="594 957 1026 1180">4. To restore the databases manually on AG 2 and have more control on larger databases, use MANUAL for SEEDING_MODE .</li></ol>	

Task	Description	Skills required
Create the distributed availability group on AG 2.	<p>To create the distributed availability group on AG 2, use ALTER AVAILABILITY GROUP with the DISTRIBUTED option.</p> <ol style="list-style-type: none"><li>1. Use LISTENER_URL endpoint addresses for AG 1 and AG 2.</li><li>2. For AVAILABILITY-MODE, use ASYNCHRONOUS_COMMIT to avoid network latency, if any. This will not impact the performance of the database.</li><li>3. For FAILOVER_MODE , use MANUAL. It is the only availability mode that works with distributed availability groups.</li><li>4. To restore the databases manually on AG 2 and have more control on larger databases, use MANUAL for SEEDING_MODE .</li></ol> <p>The distributed availability group is created between AG 1 and AG 2.</p> <p>The databases in AG 2 are not yet configured to take part in</p>	DBA, Developer

Task	Description	Skills required
	the data flow from AG 1 to AG 2.	
Add databases to the forwarder and secondary replica on AG 2.	<p>Add the databases to the distributed availability group by using ALTER DATABASE with the SET HADR AVAILABILITY GROUP option in both the forwarder and the secondary replica on AG 2.</p> <p>This starts asynchronous data flow between databases on AG 1 and AG 2.</p> <p>The global primary takes writes, sends data synchronously to the secondary replica on AG 1, and sends data asynchronously to the forwarder on AG 2. The forwarder on AG 2 sends data synchronously to the secondary replica on AG 2.</p>	DBA, Developer

### Monitor asynchronous data flow between AG 1 and AG 2

Task	Description	Skills required
Use DMVs and SQL Server logs.	Monitor the status of the data flow between two availability groups by using dynamic management views (DMVs) and SQL Server logs.	DBA, Developer

Task	Description	Skills required
	<p>DMVs that are of interest for monitoring include <code>sys.dm_hadr_availability_replica_states</code> and <code>sys.dm_hadr_automatic_seeding</code> .</p> <p>For the status of forwarder synchronization, monitor the <i>synchronized state</i> in the SQL Server log on the forwarder.</p>	

## Perform cutover activities for final migration

Task	Description	Skills required
Stop all traffic to the primary replica.	Stop incoming traffic to the primary replica in AG 1 so that no write activity occurs on the databases and the databases are ready for migration.	App owner, Developer
Change the availability mode of the distributed availability group on AG 1.	<p>On the primary replica, set the availability mode of the distributed availability group to synchronous.</p> <p>After you change the availability mode to synchronous, the data are sent synchronously from the primary replica in AG 1 to the forwarder in AG 2.</p>	DBA, Developer

Task	Description	Skills required
Check the LSNs in both availability groups.	Check the last Log Sequence Numbers (LSNs) in both AG 1 and AG 2. Because no writes are happening in the primary replica in AG 1, the data are synchronized, and last LSNs for both availability groups should match.	DBA, Developer
Update AG 1 to the secondary role.	When you update AG 1 to the secondary role, AG 1 loses the primary replica role and doesn't accept writes, and the data flow between two availability groups stops.	DBA, Developer

### Fail over to the second availability group

Task	Description	Skills required
Manually fail over to AG 2.	<p>On the forwarder in AG 2, alter the distributed availability group to allow data loss. Because you already checked and confirmed that the last LSNs on AG 1 and AG 2 match, data loss is not a concern.</p> <p>When you allow data loss on the forwarder in AG 2, the roles of AG 1 and AG 2 change:</p>	DBA, Developer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>AG 2 becomes the availability group with the primary replica and secondary replica.</li> <li>AG 1 becomes the availability group with the forwarder and secondary replica.</li> </ul>	
<p>Change the availability mode of the distributed availability group on AG 2.</p>	<p>On the primary replica in AG 2, change the availability mode to asynchronous.</p> <p>This changes the data movement from AG 2 to AG 1, from synchronous to asynchronous. This step is required to avoid network latency between AG 2 and AG 1, if any, and will not impact the performance of the database.</p>	<p>DBA, Developer</p>
<p>Start sending traffic to the new primary replica.</p>	<p>Update the connection string to use the listener URL endpoint on AG 2 for sending traffic to the databases.</p> <p>AG 2 now accepts writes and sends data to the forwarder in AG 1, along with sending data to its own secondary replica in AG 2. Data moves asynchronously from AG 2 to AG 1.</p>	<p>App owner, Developer</p>

## Perform post-cutover activities

Task	Description	Skills required
Drop the distributed availability group on AG 2.	<p>Monitor the migration for the planned amount of time. Then drop the distributed availability group on AG 2 to remove distributed availability group setup between AG 2 and AG 1. This removes the distributed availability group configuration, and data flow from AG 2 to AG 1 stops.</p> <p>At this point, AG 2 is highly available on AWS, with a primary replica that takes writes and a secondary replica in the same availability group.</p>	DBA, Developer
Decommission the on-premises servers.	Decommission the on-premises servers in WSFC 1 that are part of AG 1.	Systems administrator, SysOps administrator

# Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS

Created by Ramu Jagini (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS
<b>R Type:</b> Replatform	<b>Workload:</b> Open-source; Oracle	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> AWS DMS; Amazon RDS		

## Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to an Amazon Relational Database Service (Amazon RDS) for Oracle database. You can use this pattern to complete your migration with reduced downtime by using Quest SharePlex for synchronous replication.

You must use an intermediate Oracle database instance for your migration because AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source environment. You can use [SharePlex 7.6.3](#) to replicate from previous Oracle database versions to later Oracle database versions. The intermediate Oracle database instance is compatible as a target for SharePlex 7.6.3 and supported as a source for AWS DMS or newer releases of SharePlex. This support enables onward replication of data to the Amazon RDS for Oracle target environment.

Consider that several deprecated data types and features can impact a migration from Oracle 8i or 9i to the latest version of Oracle Database. To mitigate this impact, this pattern uses Oracle 11.2.0.4 as an intermediate database version to help optimize the schema code prior to migrating to the Amazon RDS for Oracle target environment.

## Prerequisites and limitations

### Prerequisites

- An active AWS account

- A source Oracle 8i or 9i database in an on-premises environment
- [Oracle Database 12c Release 2 \(12CR2\)](#) for staging on Amazon Elastic Compute Cloud (Amazon EC2)
- Quest SharePlex 7.6.3 (commercial grade)

## Limitations

- [RDS for Oracle limitations](#)

## Product versions

- Oracle 8i or 9i for the source database
- Oracle 12CR2 for the staging database (must match the Amazon RDS for Oracle version)
- Oracle 12CR2 or later for the target database (Amazon RDS for Oracle)

## Architecture

### Source technology stack

- Oracle 8i or 9i database
- SharePlex

### Target technology stack

- Amazon RDS for Oracle

### Migration architecture

The following diagram shows how to migrate an Oracle 8i or 9i database from an on-premises environment to an Amazon RDS for Oracle DB instance in the AWS Cloud.

The diagram shows the following workflow:

1. Enable the Oracle source database with archive log mode, force logging, and supplemental logging.
2. Restore the Oracle staging database from the Oracle source database by using Recovery Manager (RMAN) point-in-time recovery and [FLASHBACK\\_SCN](#).
3. Configure SharePlex to read redo logs from the Oracle source database by using [FLASHBACK\\_SCN](#) (used in RMAN).
4. Start SharePlex replication to synchronize data from the Oracle source database to the Oracle staging database.
5. Restore the Amazon RDS for Oracle target database by using EXPDP and IMPDP with [FLASHBACK\\_SCN](#).
6. Configure AWS DMS and its source tasks as the Oracle staging database and Amazon RDS for Oracle as the target database by using [FLASHBACK\\_SCN](#) (used in EXPDP).
7. Start AWS DMS tasks to synchronize data from the Oracle staging database to the Oracle target database.

## Tools

- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Quest SharePlex](#) is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.
- [Recovery Manager \(RMAN\)](#) is an Oracle Database client that performs backup and recovery tasks on your databases. It greatly simplifies backing up, restoring, and recovering database files.
- [Data Pump Export](#) helps you upload data and metadata into a set of operating system files called a dump file set. The dump file set can be imported only by the [Data Pump Import](#) utility or [DBMS\\_DATAPUMP](#) package.

## Epics

### Set up SharePlex and the Oracle staging database on Amazon EC2

Task	Description	Skills required
Create an EC2 instance.	<ol style="list-style-type: none"> <li>1. <a href="#">Create an EC2 instance</a>.</li> <li>2. Install Oracle 12CR2 on the EC2 instance to serve as the Oracle staging database.</li> </ol>	Oracle administration
Prepare the staging database.	<p>Prepare the Oracle staging database for restore as an upgrade on Oracle 12CR2 by taking the RMAN backup from the Oracle 8i or 9i database source environment.</p> <p>For more information, see <a href="#">Oracle 9i Recovery Manager User's Guide</a> and <a href="#">Database</a></p>	Oracle administration

Task	Description	Skills required
	<a href="#">Backup and Recovery User's Guide</a> in the Oracle documentation.	
Configure SharePlex.	Configure the SharePlex source as an on-premises Oracle 8i or 9i database, and configure the target as the Oracle 12CR2 staging database hosted on Amazon EC2.	SharePlex, Oracle administration

### Set up Amazon RDS for Oracle as your target environment

Task	Description	Skills required
Create an Oracle DB instance.	<p>Create an Amazon RDS for Oracle database, and then connect Oracle 12CR2 to the database.</p> <p>For more information, see <a href="#">Creating an Oracle DB instance and connecting to a database on an Oracle DB instance</a> in the Amazon RDS documentation.</p>	DBA
Restore Amazon RDS for Oracle from the staging database.	<ol style="list-style-type: none"> <li>1. Take an EXPDP backup from the Oracle staging database server by using FLASHBACK_SCN .</li> <li>2. Restore Amazon RDS for Oracle from the staging database.</li> </ol>	DBA

Task	Description	Skills required
	For more information, see <a href="#">54 DBMS_DATAPUMP</a> in the Oracle documentation.	

## Set up AWS DMS

Task	Description	Skills required
Create endpoints for the databases.	<p>Create a source endpoint for the Oracle staging database and a target endpoint for the Amazon RDS for Oracle database.</p> <p>For more information, see <a href="#">How do I create source or target endpoints using AWS DMS?</a> in the AWS Knowledge Center.</p>	DBA
Create a replication instance.	<p>Use AWS DMS to launch a replication instance for the Oracle staging database to the Amazon RDS for Oracle database.</p> <p>For more information, see <a href="#">How do I create an AWS DMS replication instance?</a> in the AWS Knowledge Center.</p>	DBA
Create and start replication tasks.	Create AWS DMS replication tasks for change data capture (CDC) by using FLASHBACK_SCN from EXPDP (since the	DBA

Task	Description	Skills required
	<p>full load already happened through EXPDP).</p> <p>For more information, see <a href="#">Creating a task</a> in the AWS DMS documentation.</p>	

## Cut over to Amazon RDS for Oracle

Task	Description	Skills required
Stop the application workload.	Stop the application servers and its applications during the planned cutover window.	App developer, DBA
Validate the synching of the on-premises Oracle staging database with the EC2 instance.	<p>Confirm that all messages have been posted for replication tasks from the SharePlex replication instance to the Oracle staging database on Amazon EC2 by performing a few log switches on the on-premises source database.</p> <p>For more information, see <a href="#">6.4.2 Switching a Log File</a> in the Oracle documentation.</p>	DBA
Validate the synching of the Oracle staging database with the Amazon RDS for Oracle database.	Confirm that all your AWS DMS tasks have no lag and no errors, and then check the validation state of the tasks.	DBA
Stop the replication of SharePlex and Amazon RDS.	If both the SharePlex and AWS DMS replications are not	DBA

Task	Description	Skills required
	showing any errors, then stop both replications.	
Remap the application to Amazon RDS.	Share the Amazon RDS for Oracle endpoint details with the application server and its applications, and then start the application to resume business operations.	App developer, DBA

### Test the AWS target environment

Task	Description	Skills required
Test the Oracle staging database environment on AWS.	<ol style="list-style-type: none"> <li>1. Test the SharePlex replication and verify that there are no sync gaps or replication errors on the Oracle staging database.</li> <li>2. Verify that the application behaves as expected through benchmarks defined in the on-premises environment.</li> </ol>	SharePlex, Oracle administration
Test the Amazon RDS environment.	<ol style="list-style-type: none"> <li>1. Verify that all data propagated to Amazon RDS after replication is error free.</li> <li>2. Point another application to the Amazon RDS DB instance, and then run performance tests to verify expected behavior.</li> </ol>	Oracle administration

Task	Description	Skills required
	For more information, see <a href="#">Amazon RDS for Oracle</a> in the Amazon RDS documentation.

# Monitor Amazon Aurora for instances without encryption

Created by Mansi Suratwala (AWS)

**Environment:** Production

**Technologies:** Databases;  
Security, identity, compliance;  
Storage & backup

**Workload:** Open-source; All  
other workloads

**AWS services:** Amazon  
SNS; Amazon Aurora;  
AWS CloudTrail; Amazon  
CloudWatch; AWS Lambda

## Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that you can deploy to set up automatic notifications when an Amazon Aurora instance is created without encryption turned on.

Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

The CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event uses AWS CloudTrail to monitor for any Aurora instance creation or a point in time restoration of an existing instance. The Cloudwatch Events event initiates the Lambda function, which checks whether encryption is enabled. If encryption is not turned on, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

## Prerequisites and limitations

### Prerequisites

- An active AWS account

## Limitations

- This service control works with Amazon Aurora instances only. It does not support other Amazon Relational Database Service (Amazon RDS) instances.
- The CloudFormation template must be deployed for `CreateDBInstance` and `RestoreDBClusterToPointInTime` only.

## Product versions

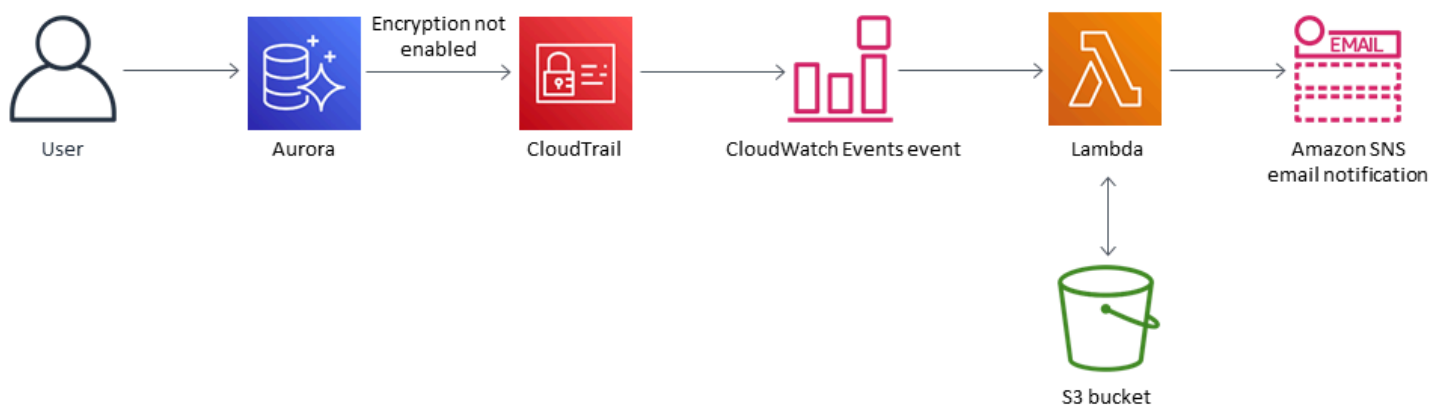

- PostgreSQL versions that are supported in Amazon Aurora
- MySQL versions that are supported in Amazon Aurora

## Architecture

### Target technology stack

- Amazon Aurora
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

### Target architecture

## Automation and scale

You can use the CloudFormation template multiple times for different Regions and accounts. You need to run it only once in each Region or account.

## Tools

### Tools

- [Amazon Aurora](#) – Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL.
- [AWS CloudTrail](#) – AWS CloudTrail helps you manage governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail.
- [Amazon CloudWatch Events](#) – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery using Lambda, HTTP, email, mobile push notifications, and mobile text messages (SMS).

### Code

A .zip file of the project is available as an attachment.

## Epics

### Create the S3 bucket for the Lambda script

Task	Description	Skills required
Define the S3 bucket.	Open the Amazon S3 console, and choose or create an S3	Cloud architect

Task	Description	Skills required
	bucket. This S3 bucket will host the Lambda code .zip file. Your S3 bucket needs to be in the same Region as Aurora. The S3 bucket name cannot contain leading slashes.	

### Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code.	Upload the Lambda code .zip file provided in the <i>Attachments</i> section to the S3 bucket that you defined.	Cloud architect

### Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	On the CloudFormation console, deploy the <code>RDS_Aurora_Encryption_At_Rest.yml</code> CloudFormation template that's provided as an attachment to this pattern. In the next epic, provide values for the template parameters.	Cloud architect

## Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or chose in the first epic.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, <directory>/<file-name>.zip ).	Cloud architect
Provide an email address.	Provide an active email address to receive Amazon SNS notifications.	Cloud architect
Define the logging level.	Define the logging level and frequency for your Lambda function. Info designates detailed informational messages on the application's progress. Error designates error events that could still allow the application to continue running. Warning designates potentially harmful situations.	Cloud architect

## Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the template successfully deploys, it sends a	Cloud architect

Task	Description	Skills required
	subscription email message to the email address provided. To receive notifications, you must confirm this email subscription.

# Monitor Oracle GoldenGate logs by using Amazon CloudWatch

Created by Chithra Krishnamurthy (AWS)

**Environment:** Production

**Technologies:** Databases

**Workload:** Oracle

**AWS services:** Amazon CloudWatch; Amazon SNS

## Summary

Oracle GoldenGate provides real-time replication between Amazon Relational Database Service (Amazon RDS) for Oracle databases, or between Oracle databases hosted on Amazon Elastic Compute Cloud (Amazon EC2). It supports both unidirectional and bidirectional replication.

When you use GoldenGate for replication, monitoring is critical to verify that the GoldenGate process is up and running, to make sure that the source and target databases are in sync.

This pattern explains the steps to implement Amazon CloudWatch monitoring for a GoldenGate error log, and how to set alarms to send notifications for specific events such as STOP or ABEND so you can take appropriate actions to resume replication quickly.

## Prerequisites and limitations

### Prerequisites

- GoldenGate installed and configured on an EC2 instance, so you can set up CloudWatch monitoring on those EC2 instances. If you want to monitor GoldenGate across AWS Regions for bidirectional replication, you must install the CloudWatch agent in each EC2 instance where the GoldenGate process is running.

### Limitations

- This pattern explains how to monitor the GoldenGate process by using CloudWatch. CloudWatch doesn't monitor replication lag or data synchronization issues during replication. You must run separate SQL queries to monitor replication lag or data-related errors, as explained in the [GoldenGate documentation](#).

## Product versions

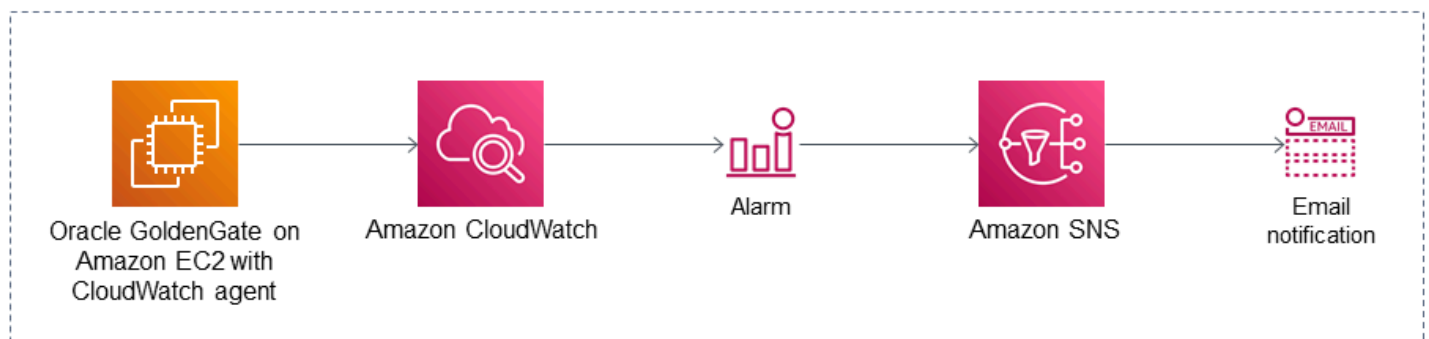

- This document is based on the implementation of Oracle GoldenGate 19.1.0.0.4 for Oracle on Linux x86-64. However, this solution is applicable to all major versions of GoldenGate.

## Architecture

### Target technology stack

- GoldenGate binaries for Oracle installed on an EC2 instance
- Amazon CloudWatch
- Amazon Simple Notification Service (Amazon SNS)

### Target architecture

## Tools

### AWS services

- [Amazon CloudWatch](#) is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- [Amazon SNS](#) is a message notification service that is used in this pattern to send email notifications.

### Other tools

- [Oracle GoldenGate](#) is a data replication tool that you can use for Amazon RDS for Oracle databases or Oracle databases that are hosted on Amazon EC2.

## High-level implementation steps

1. Create an AWS Identity and Access Management (IAM) role for the CloudWatch agent.
2. Attach the IAM role to the EC2 instance where GoldenGate error logs are generated.
3. Install the CloudWatch agent on the EC2 instance.
4. Configure the CloudWatch agent configuration files: `awscli.conf` and `awslogs.conf`.
5. Start the CloudWatch agent.
6. Create metric filters in the log group.
7. Set up Amazon SNS.
8. Create an alarm for the metric filters. Amazon SNS sends email alerts when those filters capture events.

For detailed instructions, see the next section.

## Epics

### Step 1. Create an IAM role for the CloudWatch agent

Task	Description	Skills required
Create the IAM role.	<p>Access to AWS resources requires permissions, so you create IAM roles to include the permissions necessary for each server to run the CloudWatch agent.</p> <p>To create the IAM role:</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the IAM console at <a href="https://console.aws.amazon.com/iam/">https://console.aws.amazon.com/iam/</a>.</li></ol>	AWS general

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. In the navigation pane, choose <b>Roles</b>, and then choose <b>Create role</b>.</li><li>3. For <b>Trusted entity type</b>, choose <b>AWS service</b>.</li><li>4. For <b>Common use cases</b>, choose <b>EC2</b>, and then choose <b>Next</b>.</li><li>5. In the list of policies, select the check box next to <b>CloudWatchAgentServerPolicy</b>. If necessary, use the search box to find the policy.</li><li>6. Choose <b>Next</b>.</li><li>7. For <b>Role name</b>, enter a name for your new role, such as <code>goldengate-cw-monitoring-role</code> or another name that you prefer.</li><li>8. (Optional) For <b>Role description</b>, enter a description.</li><li>9. Confirm that <b>CloudWatchAgentServerPolicy</b> appears under <b>Policy name</b>.</li><li>10. (Optional) Add one or more tags (key-value pairs) to organize, track, or control access for this role, and then choose <b>Create role</b>.</li></ol>	

## Step 2. Attach the IAM role to the GoldenGate EC2 instance

Task	Description	Skills required
Attach the IAM role to the EC2 instance where GoldenGate error logs are generated.	<p>The error logs generated by GoldenGate have to be populated to CloudWatch and monitored, so you need to attach the IAM role you created in step 1 to the EC2 instance where GoldenGate is running.</p> <p>To attach an IAM role to an instance:</p> <ol style="list-style-type: none"><li>1. Open the Amazon EC2 console at <a href="https://console.aws.amazon.com/ec2/">https://console.aws.amazon.com/ec2/</a>.</li><li>2. In the navigation pane, choose <b>Instances</b>, and then find the instance where GoldenGate is running.</li><li>3. Select the instance, and then choose <b>Actions, Security, Modify IAM role</b>.</li><li>4. Select the IAM role created in the first step to attach to your instance, and then choose <b>Save</b>.</li></ol>	AWS general

## Steps 3-5. Install and configure the CloudWatch agent on the Goldengate EC2 instance

Task	Description	Skills required
Install the CloudWatch agent on the GoldenGate EC2 instance.	To install the agent, run the command: <pre data-bbox="594 449 1027 569">sudo yum install -y awslogs</pre>	AWS general
Edit the agent configuration files.	<ol style="list-style-type: none"> <li>Run the following command.             <pre data-bbox="634 728 1027 806">sudo su -</pre> </li> <li>Edit this file to update the AWS Region as necessary.             <pre data-bbox="634 947 1027 1178">cat /etc/awslogs/conf [plugins] cwlogs = cwlogs [default] region = us-east-1</pre> </li> <li>Edit the <code>/etc/awslogs/awslogs.conf</code> file to update the file name, log group name, and the date/time format. You must specify the date/time to match the date format in <code>ggseerror.log</code>; otherwise, the log stream won't flow into CloudWatch. For example:             <pre data-bbox="634 1755 1027 1843">datetime_format = %Y- %m-%dT%H:%M:%S%z</pre> </li> </ol>	AWS general

Task	Description	Skills required
<p>Start the CloudWatch agent.</p>	<pre data-bbox="634 205 1027 386">file = /u03/oracle/ oragg/ggserr.log log_group_name = goldengate_monitor</pre> <p data-bbox="591 422 976 506">To start the agent, use the following command.</p> <pre data-bbox="591 548 1027 663">\$ sudo service awslogsd start</pre> <p data-bbox="591 701 1019 926">After you start the agent, you can view the log group in the CloudWatch console. The log stream will have the contents of the file.</p>	<p>AWS general</p>

## Step 6. Create metric filters for the log group

Task	Description	Skills required
<p>Create metric filters for the keywords ABEND and STOPPED.</p>	<p data-bbox="591 1220 1027 1541">When you create metric filters for the log group, whenever the filters are identified in the error log, it starts an alarm and sends an email notification based on the Amazon SNS configuration.</p> <p data-bbox="591 1583 927 1619">To create metric filters:</p> <ol data-bbox="591 1665 1011 1841" style="list-style-type: none"> <li data-bbox="591 1665 1011 1841">1. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a>.</li> </ol>	<p>CloudWatch</p>

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. Choose the name of the log group.</li><li>3. Choose <b>Actions</b>, and then choose <b>Create metric filter</b>.</li><li>4. For the <b>Filter pattern</b>, specify a pattern such as ABEND.</li><li>5. Choose <b>Next</b>, and then enter a name for your metric filter.</li><li>6. Under <b>Metric details</b>, for <b>Metric namespace</b>, enter a name for the CloudWatch namespace where the metric will be published. If the namespace doesn't already exist, make sure that <b>Create new</b> is selected.</li><li>7. For <b>Metric value</b>, enter 1, because your metric filter is counting occurrences of the keywords in the filter.</li><li>8. Set <b>Unit</b> to <b>None</b>.</li><li>9. Choose <b>Create metric filter</b>. You can find the metric filter that you created from the navigation pane.</li><li>10. Create another metric filter for the STOPPED pattern. Within one log group, you</li></ol>	

Task	Description	Skills required
	can create multiple metric filters and set alarms individually.	

## Step 7. Set up Amazon SNS

Task	Description	Skills required
Create an SNS topic.	<p>In this step, you configure Amazon SNS to create alarms for the metric filters.</p> <p>To create an SNS topic:</p> <ol style="list-style-type: none"> <li>1. Sign in to the Amazon SNS console at <a href="https://console.aws.amazon.com/sns/home">https://console.aws.amazon.com/sns/home</a>.</li> <li>2. In the <b>Create topic</b> box, enter a topic name such as <code>goldengate-alert</code> , and then choose <b>Next step</b>.</li> <li>3. For <b>Type</b>, choose <b>Standard</b>.</li> <li>4. Scroll to the end of the form and choose <b>Create topic</b>. The console opens the new topic's <b>Details</b> page.</li> </ol>	Amazon SNS
Create a subscription.	<p>To create a subscription to the topic:</p> <ol style="list-style-type: none"> <li>1. In the left navigation pane, choose <b>Subscriptions</b>.</li> </ol>	Amazon SNS

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. On the <b>Subscriptions</b> page, choose <b>Create subscription</b>.</li><li>3. On the <b>Create subscription</b> page, choose the <b>Topic ARN</b> field to see a list of the topics in your AWS account.</li><li>4. Choose the topic that you created in the previous step.</li><li>5. For <b>Protocol</b>, choose <b>Email</b>.</li><li>6. For <b>Endpoint</b>, enter an email address that can receive notifications.</li><li>7. Choose <b>Create subscription</b>. The console opens the new subscription's <b>Details</b> page.</li><li>8. Check your email inbox for a message from AWS Notifications, and then choose <b>Confirm subscription</b> in the email.</li></ol> <p>Amazon SNS opens your web browser and displays a subscription confirmation with your subscription ID.</p>	

## Step 8. Create an alarm to send notifications for the metric filters

Task	Description	Skills required
Create an alarm for the SNS topic.	<p>To create an alarm based on a log group-metric filter:</p> <ol style="list-style-type: none"><li>1. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a>.</li><li>2. From the navigation pane, choose <b>Logs</b>, and then choose <b>Log groups</b>.</li><li>3. Choose the log group that includes your metric filter.</li><li>4. Choose <b>Metric filters</b>.</li><li>5. In the <b>Metric filters</b> tab, select the check box for the metric filter that you want to base your alarm on.</li><li>6. Choose <b>Create alarm</b>.</li><li>7. For <b>Conditions</b>, specify the following in each section:<ul style="list-style-type: none"><li>• For <b>Threshold type</b>, choose <b>Static</b>.</li><li>• For <b>Whenever &lt;metric-name&gt; is . . .</b>, choose <b>Greater</b>.</li><li>• For <b>than . . .</b>, specify <b>0</b>.</li></ul></li><li>8. Choose <b>Next</b>.</li><li>9. Under <b>Notification</b>:<ul style="list-style-type: none"><li>• For <b>Alarm state trigger</b>, choose <b>In alarm</b>.</li></ul></li></ol>	CloudWatch

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• For <b>Send notification to following SNS topic</b>, choose <b>Select an existing topic</b>.</li><li>• In the email box, select the Amazon SNS topic that you created in the previous step.</li></ul> <p>10Choose <b>Next</b>.</p> <p>11For <b>Name and description</b>, enter a name and description for your alarm.</p> <p><b>Note:</b> For the description, you can specify the instance name so that the notification email is descriptive.</p> <p>12For <b>Preview and create</b>, check that your configuration is correct, and then choose <b>Create alarm</b>.</p> <p>After these steps, whenever these patterns are detected in the GoldenGate error log file (<code>ggserr.log</code>) that you are monitoring, you will get an email notification.</p>	

## Troubleshooting

Issue	Solution
The log stream from the GoldenGate error log doesn't flow into CloudWatch.	Check the <code>/etc/awlogs/awlogs.conf</code> file to verify the file name, log group name, and the date/time format. You must specify the date/time to match the date format in <code>ggerror.log</code> . Otherwise, the log stream won't flow into CloudWatch.

# Replatform Oracle Database Enterprise Edition to Standard Edition 2 on Amazon RDS for Oracle

Created by Lanre (Lan-Ray) showunmi (AWS) and Tarun Chawla (AWS)

<b>Environment:</b> Production	<b>Source:</b> on-premises	<b>Target:</b> Amazon RDS
<b>R Type:</b> Replatform	<b>Workload:</b> Oracle	<b>Technologies:</b> Databases
<b>AWS services:</b> Amazon RDS		

## Summary

Oracle Database Enterprise Edition (EE) is a popular choice for running applications in many enterprises. In some cases, however, applications use few or no Oracle Database EE features, so there is a lack of justification for incurring huge licensing costs. You can achieve cost savings by downgrading such databases to Oracle Database Standard Edition 2 (SE2) when you migrate to Amazon RDS.

This pattern describes how to downgrade from Oracle Database EE to Oracle Database SE2 when migrating from on premises to [Amazon RDS for Oracle](#). The steps presented in this pattern also apply if your EE Oracle database is already running on Amazon RDS or on an [Amazon Elastic Compute Cloud](#) (Amazon EC2) instance.

For more information, see the AWS Prescriptive Guidance guide on how to [Evaluate downgrading Oracle databases to Standard Edition 2 on AWS](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Oracle Database Enterprise Edition
- A client tool, such as [Oracle SQL Developer](#) or SQL\*Plus, for connecting to and running SQL commands on Oracle database

- Database user for performing the assessment; for example, one of the following:
  - User with sufficient [privileges](#) for running [AWS Schema Conversion Tool \(AWS SCT\)](#) assessment
  - User with sufficient privileges to run SQL queries on Oracle database dictionary tables
- Database user for performing database migration; for example, one of the following:
  - User with sufficient [privileges](#) for running [AWS Database Migration Service \(AWS DMS\)](#)
  - User with sufficient [privileges for performing Oracle Data Pump export and import](#)
  - User with sufficient [privileges for running Oracle GoldenGate](#)

## Limitations

- Amazon RDS for Oracle has a maximum database size. For more information, see [Amazon RDS DB instance storage](#).

## Product versions

The general logic described in this document applies to Oracle versions from 9i and later. For supported versions of self-managed and Amazon RDS for Oracle databases, see the [AWS DMS documentation](#).

To identify feature usage in cases where AWS SCT is not supported, run SQL queries on the source database. To migrate from earlier versions of Oracle where AWS DMS and Oracle Data Pump are not supported, use [Oracle Export and Import utilities](#).

For a current list of supported versions and editions, see [Oracle on Amazon RDS](#) in the AWS documentation. For details on pricing and supported instance classes, see [Amazon RDS for Oracle pricing](#).

## Architecture

### Source technology stack

- Oracle Database Enterprise Edition running on premises or on Amazon EC2

### Target technology stack using native Oracle tools

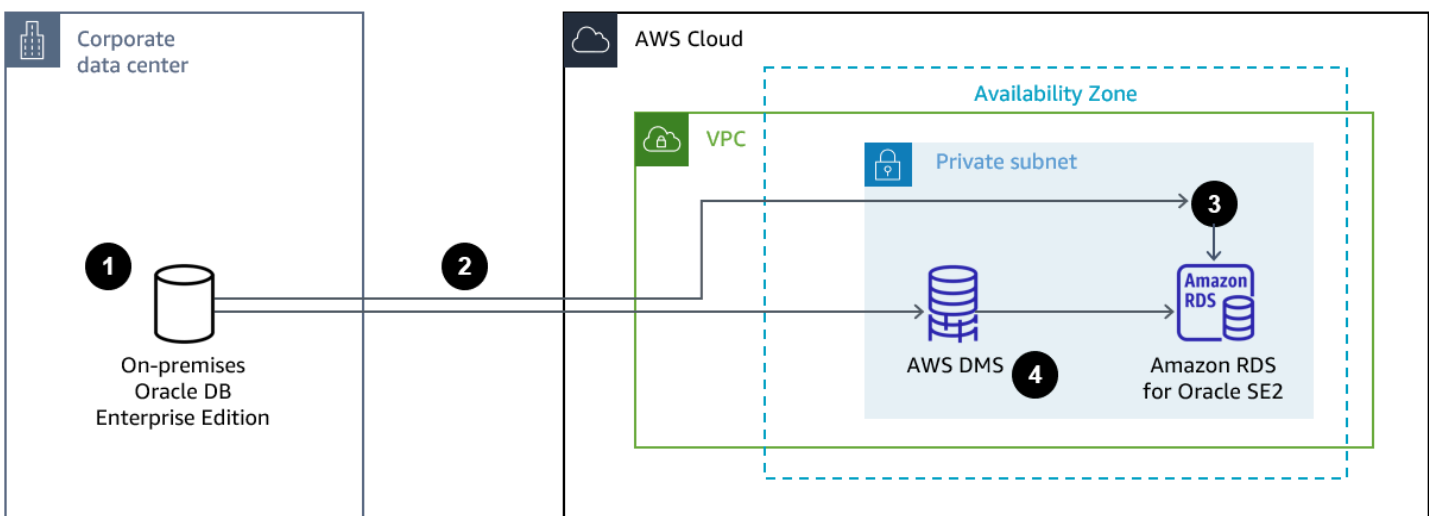

- Amazon RDS for Oracle running Oracle Database SE2

1. Export data by using Oracle Data Pump.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.

### Target technology stack using AWS DMS

- Amazon RDS for Oracle running Oracle Database SE2
- AWS DMS

1. Export data by using Oracle Data Pump with FLASHBACK\_SCN.

2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.
4. Use AWS DMS [change data capture \(CDC\)](#).

## Tools

### AWS services

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.
- [AWS SCT](#) provides a project-based user interface to automatically assess, convert, and copy the database schema of your source Oracle database into a format compatible with Amazon RDS for Oracle. AWS SCT enables you to analyze potential cost savings that can be achieved by changing your license type from Enterprise to Standard Edition of Oracle. The **License Evaluation and Cloud Support** section of the AWS SCT report provides detailed information about Oracle features in use so you can make an informed decision while migrating to Amazon RDS for Oracle.

### Other tools

- Native Oracle import and export utilities support moving Oracle data in and out of Oracle databases. Oracle offers two types of database import and export utilities: [Original Export and Import](#) (for earlier releases) and [Oracle Data Pump Export and Import](#) (available in Oracle Database 10g release 1 and later).
- [Oracle GoldenGate](#) offers real-time replication capabilities so that you can synchronize your target database after an initial load. This option can help reduce application downtime during go-live.

# Epics

## Make a pre-migration assessment

Task	Description	Skills required
Validate database requirements for your applications.	Ensure that your applications are certified to run on Oracle Database SE2. Check directly with the software vendor, developer, or application documentation.	App developer, DBA, App owner
Investigate use of EE features directly in the database.	<p>To determine EE feature use, do one of the following:</p> <ul style="list-style-type: none"><li>• <a href="#">Generate an AWS SCT assessment report</a> for your Oracle EE database. The report tells you which features from your current EE database should be removed if you want to change license types.</li><li>• If you have an Oracle Support account, obtain and run the script <code>options_packs_usage_statistics.sql</code> in <a href="#">Support document 1317265.1</a> to generate a report of options and features that are being used on your Oracle database.</li><li>• Query <a href="#">DBA_FEATURE_USAGE_STATISTICS</a></li></ul>	App owner, DBA, App developer

Task	Description	Skills required
	to display details of all features that are in use.	
Identify use of EE features for operational activities.	<p>Database or application administrators sometimes rely on EE-only features for operational activities. Common examples include online maintenance activities (index rebuild, table move) and use of parallelism by batch jobs.</p> <p>These dependencies can be mitigated by modifying your operations where possible. Identify the use of these features and make a decision based on cost compared with benefits.</p> <p>Use the <a href="#">Comparing Oracle Database EE and SE2 features</a> table as a guide to identify features that are available in Oracle Database SE2.</p>	App developer, DBA, App owner

Task	Description	Skills required
Review workload patterns of the EE Oracle database.	<p>Oracle Database SE2 automatically restricts usage to a maximum of 16 CPU threads at any time.</p> <p>If your Oracle EE database is licensed to use the Oracle Diagnostic Pack, use the Automatic Workload Repository (AWR) tool, or DBA_HIST_* views, to analyze database workload patterns to determine whether the maximum limit of 16 CPU threads will negatively impact service levels when you downgrade to SE2.</p> <p>Ensure that your assessment covers periods of peak activity, such as end of day, month, or year processing.</p>	App owner, DBA, App developer

## Prepare the target infrastructure on AWS

Task	Description	Skills required
Deploy and configure networking infrastructure.	Create a <a href="#">virtual private cloud (VPC)</a> and <a href="#">subnets</a> , <a href="#">security groups</a> , and <a href="#">network access control lists</a> .	AWS administrator, Cloud architect, Network administrator, DevOps engineer
Provision the Amazon RDS for Oracle SE2 database.	Provision the target <a href="#">Amazon RDS for Oracle</a> SE2 database to meet your applications'	Cloud administrator, Cloud architect, DBA, DevOps engineer, AWS administrator

Task	Description	Skills required
	<p>performance, availability, and security requirements. We recommend Multi-AZ configuration for production workloads. However, to improve migration performance, you can defer <a href="#">enabling Multi-AZ</a> until after data migration.</p>	
<p>Customize the Amazon RDS environment.</p>	<p>Configure custom <a href="#">parameters</a> and <a href="#">options</a>, and enable additional <a href="#">monitoring</a>. For more information, see <a href="#">Best practices for migrating to Amazon RDS for Oracle</a>.</p>	<p>AWS administrator, AWS systems administrator, Cloud administrator, DBA, Cloud architect</p>

### Perform the migration dry run and application testing

Task	Description	Skills required
<p>Migrate the data (dry run).</p>	<p>Migrate data from the source Oracle EE database to the Amazon RDS for Oracle SE2 database instance using the approach best suited to your specific environment. Select a migration strategy based on factors such as size, complexity, and the available downtime window. Use one or a combination of the following:</p>	<p>DBA</p>

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>Native Oracle tools such as <a href="#">Oracle Data Pump</a> (recommended), Oracle Import-Export utilities, and <a href="#">Oracle GoldenGate</a>.</li> <li>AWS DMS, using the full load with continuous replication through CDC.</li> </ul>	
Validate the target database.	<p>Perform post-migration validation of database storage and code objects. Review migration logs, and fix any identified issues. For more information, see the guide <a href="#">Migrating Oracle databases to the AWS Cloud</a>.</p>	DBA
Test the applications.	<p>Application and database administrators should conduct functional, performance, and operational tests as appropriate. For more information, see <a href="#">Best practices for migrating to Amazon RDS for Oracle</a>.</p> <p>Lastly, obtain sign-offs on test-results from stakeholders.</p>	App developer, App owner, DBA, Migration engineer, Migration lead

## Cut over

Task	Description	Skills required
Refresh data from Oracle Database EE.	<p>Select a data refresh approach based on the application availability requirement. For more information, see the migration methods in <a href="#">Strategies for Migrating Oracle Databases to AWS</a>.</p> <p>For example, you can achieve near-zero downtime by using tools such as Oracle GoldenGate or AWS DMS with ongoing replication. If the downtime window permits, you can perform the final data cutover using offline methods such as Oracle Data Pump or Original Export-Import utilities.</p>	App owner, Cutover lead, DBA, Migration engineer, Migration lead
Point applications to the target database instance.	Update connection parameters in applications and other clients to point to the Amazon RDS for Oracle SE2 database.	App developer, App owner, Migration engineer, Migration lead, Cutover lead
Perform post-migration activities.	Perform post data migration tasks such as enabling Multi-AZ, data validation, and other checks.	DBA, Migration engineer

Task	Description	Skills required
Perform post-cutover monitoring.	Use tools such as <a href="#">Amazon CloudWatch</a> and <a href="#">Amazon RDS Performance Insights</a> to monitor the Amazon RDS for Oracle SE2 database.	App developer, App owner, AWS administrator, DBA, Migration engineer

# Replicate mainframe databases to AWS by using Precisely Connect

Created by Lucio Pereira (AWS), Balaji Mohan (AWS), and Sayantan Giri (AWS)

<b>Environment:</b> Production	<b>Source:</b> On-premises mainframe	<b>Target:</b> AWS databases
<b>R Type:</b> Re-architect	<b>Workload:</b> All other workloads	<b>Technologies:</b> Databases ; CloudNative; Mainframe; Modernization
<b>AWS services:</b> Amazon DynamoDB; Amazon Keyspaces; Amazon MSK; Amazon RDS; Amazon ElastiCache		

## Summary

This pattern outlines steps for replicating data from mainframe databases to Amazon data stores in near real time by using Precisely Connect. It implements an event-based architecture with Amazon Managed Streaming for Apache Kafka (Amazon MSK) and custom database connectors in the cloud to improve scalability, resilience, and performance.

Precisely Connect is a replication tool that captures data from legacy mainframe systems and integrates it into cloud environments. Data is replicated from mainframes to AWS through change data capture (CDC) by using near real-time message flows with low-latency and high-throughput heterogeneous data pipelines.

This pattern also covers a disaster recovery strategy for resilient data pipelines with multi-Region data replication and failover routing.

## Prerequisites and limitations

### Prerequisites

- An existing mainframe database—for example, IBM DB2, IBM Information Management System (IMS), or Virtual Storage Access Method (VSAM)—that you want to replicate to the AWS Cloud
- An active [AWS account](#)
- [AWS Direct Connect](#) or [AWS Virtual Private Network \(AWS VPN\)](#) from your corporate environment to AWS
- A [virtual private cloud](#) with a subnet that is reachable by your legacy platform

## Architecture

### Source technology stack

A mainframe environment that includes at least one of the following databases:

- IBM IMS database
- IBM DB2 database
- VSAM files

### Target technology stack

- Amazon MSK
- Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon EKS Anywhere
- Docker
- An AWS relational or NoSQL database such as the following:
  - Amazon DynamoDB
  - Amazon Relational Database Service (Amazon RDS) for Oracle, Amazon RDS for PostgreSQL, or Amazon Aurora
  - Amazon ElastiCache for Redis
  - Amazon Keyspaces (for Apache Cassandra)

### Target architecture

#### *Replicating mainframe data to AWS databases*

The following diagram illustrates the replication of mainframe data to an AWS database such as DynamoDB, Amazon RDS, Amazon ElastiCache, or Amazon Keyspaces. The replication occurs

in near real time by using Precisely Capture and Publisher in your on-premises mainframe environment, Precisely Dispatcher on Amazon EKS Anywhere in your on-premises distributed environment, and Precisely Apply Engine and database connectors in the AWS Cloud.

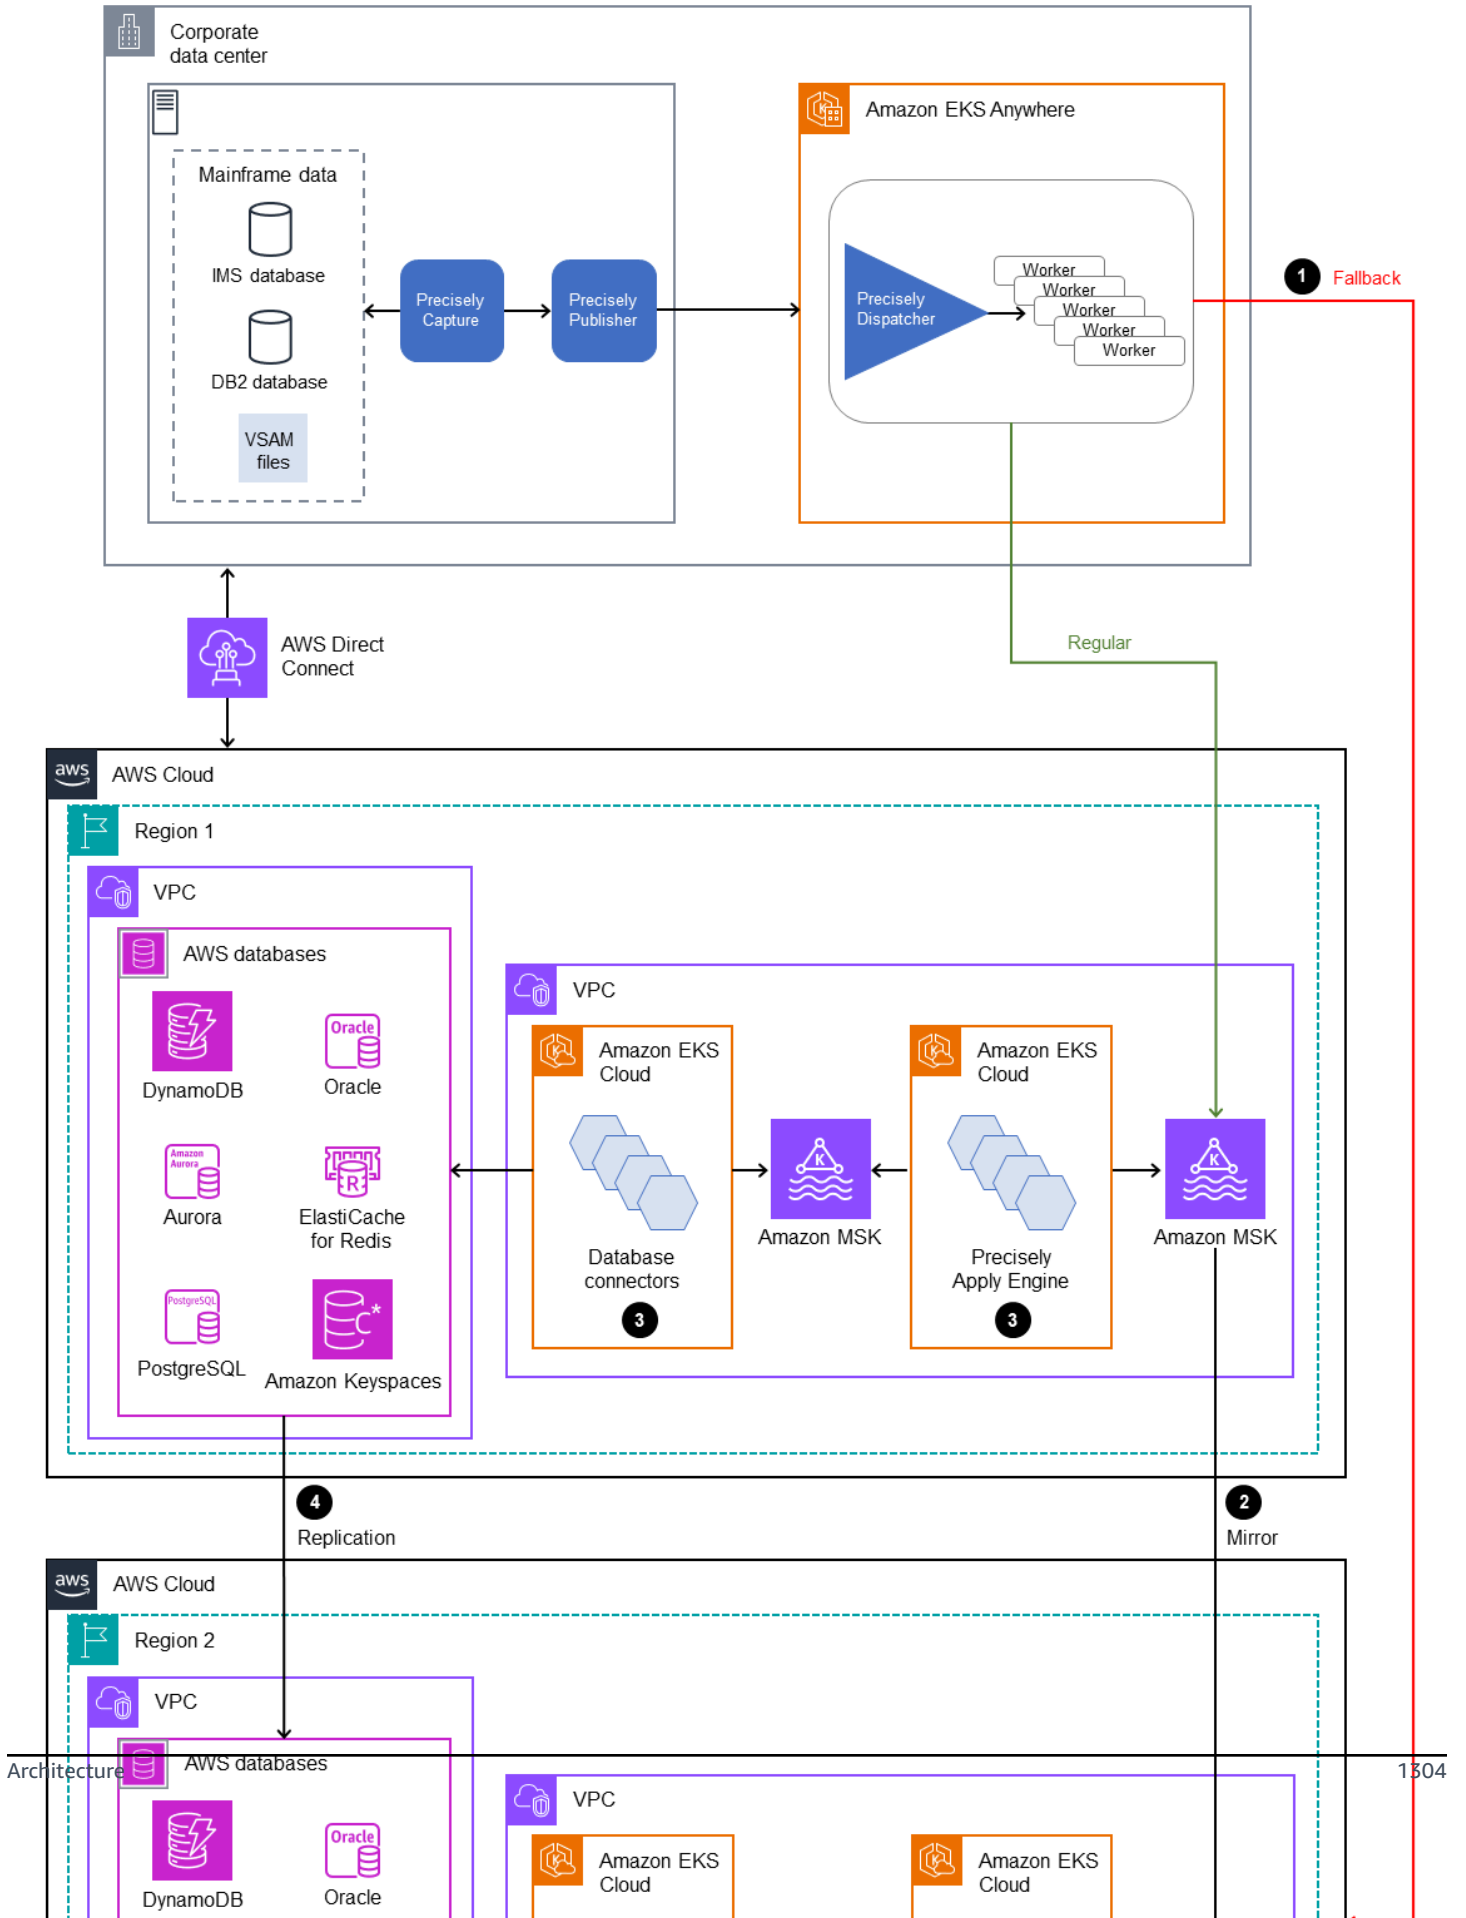

The diagram shows the following workflow:

1. Precisely Capture gets mainframe data from CDC logs and maintains the data in internal transient storage.
2. Precisely Publisher listens for changes in the internal data storage and sends CDC records to Precisely Dispatcher through a TCP/IP connection.
3. Precisely Dispatcher receives the CDC records from Publisher and sends them to Amazon MSK. Dispatcher creates Kafka keys based on the user configuration and multiple worker tasks to push data in parallel. Dispatcher sends an acknowledgment back to Publisher when records have been stored in Amazon MSK.
4. Amazon MSK holds the CDC records in the cloud environment. The partition size of topics depends on your transaction processing system (TPS) requirements for throughput. The Kafka key is mandatory for further transformation and transaction ordering.
5. The Precisely Apply Engine listens to the CDC records from Amazon MSK and transforms the data (for example, by filtering or mapping) based on target database requirements. You can add customized logic to the Precisely SQD scripts. (SQD is Precisely's proprietary language.) The Precisely Apply Engine transforms each CDC record to Apache Avro or JSON format and distributes it to different topics based on your requirements.
6. The target Kafka topics hold CDC records in multiple topics based on the target database, and Kafka facilitates transaction ordering based on the defined Kafka key. The partition keys align with the corresponding partitions to support a sequential process.
7. Database connectors (customized Java applications) listen to the CDC records from Amazon MSK and store them in the target database.
8. You can select a target database based on your requirements. This pattern supports both NoSQL and relational databases.

### *Disaster recovery*

Business continuity is key to your organization's success. The AWS Cloud provides capabilities for high availability (HA) and disaster recovery (DR), and supports your organization's failover and fallback plans. This pattern follows an active/passive DR strategy and provides high-level guidance for implementing a DR strategy that meets your RTO and RPO requirements.

The following diagram illustrates the DR workflow.

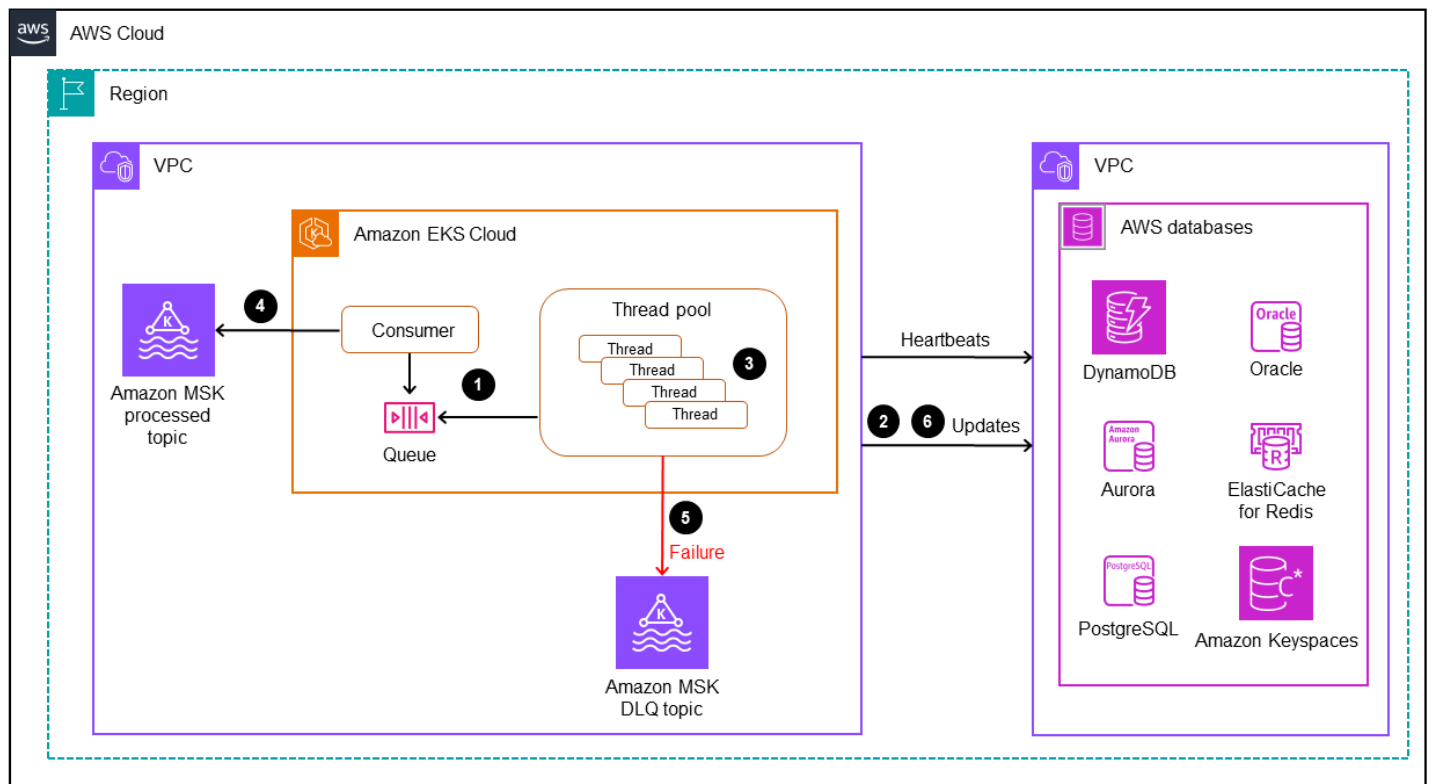

The diagram shows the following:

1. A semi-automated failover is required if any failure happens in AWS Region 1. In the case of failure in Region 1, the system must initiate routing changes to connect Precisely Dispatcher to Region 2.
2. Amazon MSK replicates data through mirroring between Regions, For this reason, during failover, the Amazon MSK cluster in Region 2 has to be promoted as the primary leader.
3. The Precisely Apply Engine and database connectors are stateless applications that can work in any Region.
4. Database synchronization depends on the target database. For example, DynamoDB can use global tables, and ElastiCache can use global datastores.

### *Low-latency and high-throughput processing through database connectors*

Database connectors are critical components in this pattern. Connectors follow a listener-based approach to collect data from Amazon MSK and send transactions to the database through high-throughput and low-latency processing for mission-critical applications (tiers 0 and 1). The following diagram illustrates this process.

This pattern supports the development of a customized application with single-threaded consumption through a multithreaded processing engine.

1. The connector main thread consumes CDC records from Amazon MSK and sends them to the thread pool for processing.
2. Threads from the thread pool process CDC records and send them to the target database.
3. If all threads are busy, the CDC records are kept on hold by the thread queue.
4. The main thread waits to get all the records cleared from the thread queue and commits offsets into Amazon MSK.
5. The child threads handle failures. If failures happen during processing, the failed messages are sent to the DLQ (dead letter queue) topic.
6. The child threads initiate conditional updates (see [Condition expressions](#) in the DynamoDB documentation), based on the mainframe timestamp, to avoid any duplication or out-of-order updates in the database.

For information about how to implement a Kafka consumer application with multi-threading capabilities, see the blog post [Multi-Threaded Message Consumption with the Apache Kafka Consumer](#) on the Confluent website.

## Tools

### AWS services

- [Amazon Managed Streaming for Apache Kafka \(Amazon MSK\)](#) is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without having to install or maintain your own Kubernetes control plane or nodes.
- [Amazon EKS Anywhere](#) helps you deploy, use, and manage Kubernetes clusters that run in your own data centers.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon ElastiCache](#) helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.

- [Amazon Keyspaces \(for Apache Cassandra\)](#) is a managed database service that helps you migrate, run, and scale your Cassandra workloads in the AWS Cloud.

## Other tools

- [Precisely Connect](#) integrates data from legacy mainframe systems such as VSAM datasets or IBM mainframe databases into next-generation cloud and data platforms.

## Best practices

- Find the best combination of Kafka partitions and multi-threaded connectors to balance optimal performance and cost. Multiple Precisely Capture and Dispatcher instances can increase cost because of higher MIPS (million instructions per second) consumption.
- Avoid adding data manipulation and transformation logic to the database connectors. For this purpose, use the Precisely Apply Engine, which provides processing times in microseconds.
- Create periodic request or health check calls to the database (*heartbeats*) in database connectors to warm up the connection frequently and reduce latency.
- Implement thread pool validation logic to understand the pending tasks in the thread queue and wait for all threads to be completed before the next Kafka polling. This helps avoid data loss if a node, container, or process crashes.
- Expose latency metrics through health endpoints to enhance observability capabilities through dashboards and tracing mechanisms.

## Epics

### Prepare the source environment (on premises)

Task	Description	Skills required
Set up the mainframe process (batch or online utility) to start the CDC process from mainframe databases.	<ol style="list-style-type: none"> <li>1. Identify the mainframe environment.</li> <li>2. Identify the mainframe databases that will be involved in the CDC process.</li> </ol>	Mainframe engineer

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 987 579">3. In the mainframe environment, develop a process that launches the CDC tool to capture changes in the source database. For instructions, see your mainframe documentation.</li><li data-bbox="592 600 943 730">4. Document the CDC process, including the configuration.</li><li data-bbox="592 751 992 882">5. Deploy the process in both test and production environments.</li></ol>	
Activate mainframe database log streams.	<ol style="list-style-type: none"><li data-bbox="592 930 1024 1150">1. Configure log streams in the mainframe environment to capture CDC logs. # Schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL by using Lambda and Secrets Manager

*Created by Yaser Raja (AWS)*

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> PostgreSQL on AWS
<b>R Type:</b> N/A	<b>Workload:</b> Open-source	<b>Technologies:</b> Databases
<b>AWS services:</b> AWS Lambda; Amazon RDS; AWS Secrets Manager; Amazon Aurora		

## Summary

For on-premises databases and databases that are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances, database administrators often use the **cron** utility to schedule jobs.

For example, a job for data extraction or a job for data purging can easily be scheduled using **cron**. For these jobs, database credentials are typically either hard-coded or stored in a properties file. However, when you migrate to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora PostgreSQL-Compatible Edition, you lose the ability to log in to the host instance to schedule **cron** jobs.

This pattern describes how to use AWS Lambda and AWS Secrets Manager to schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL-Compatible databases after migration.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database

### Limitations

- A job must complete within 15 minutes, which is the Lambda function timeout limit. For other limits, see the [AWS Lambda documentation](#).
- Job code must be written in a [language supported by Lambda](#).

## Architecture

### Source technology stack

This stack features jobs written in languages such as Bash, Python, and Java. Database credentials are stored in the properties file, and the job is scheduled using Linux **cron**.

### Target technology stack

This stack has a Lambda function that uses the credentials stored in Secrets Manager to connect to the database and to perform the activity. The Lambda function is initiated at the scheduled interval by using Amazon CloudWatch Events.

### Target architecture

## Tools

- [AWS Lambda](#) is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code is not running. With AWS Lambda, you can run code for virtually any type of application or backend service with zero administration. AWS Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging. All you need to do is provide your code in one of the [languages that AWS Lambda supports](#).
- [Amazon CloudWatch Events](#) delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using **cron** or **rate** expressions.
- [AWS Secrets Manager](#) helps you protect secrets for accessing your applications, services, and IT resources. You can easily rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, which eliminates the need to hard-code sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. The service is extensible to other types of secrets, including API keys and OAuth tokens. Secrets Manager enables you to control access to secrets using fine-grained permissions and to audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises.

## Epics

### Store database credentials in Secrets Manager

Task	Description	Skills required
Create a database user for the Lambda function.	It is a good practice to use separate database users for different parts of your application. If a separate database user already exists for your cron jobs, use that. Otherwise, create a new database user. For more information, see <a href="#">Managing PostgreSQL users and roles</a> (AWS blog post).	DBA
Store database credentials as a secret in Secrets Manager.	Follow the instructions in <a href="#">Create a database secret</a> (Secrets Manager documentation).	DBA, DevOps

### Author the code for the Lambda function

Task	Description	Skills required
Choose a programming language supported by AWS Lambda.	For a list of supported languages, see <a href="#">Lambda runtimes</a> (Lambda documentation).	Developer
Write the logic to fetch the database credentials from Secrets Manager.	For sample code, see <a href="#">How to securely provide database credentials to Lambda functions by using AWS</a>	Developer

Task	Description	Skills required
	<a href="#">Secrets Manager</a> (AWS blog post).	
Write the logic to perform the scheduled database activity.	Migrate your existing code for the scheduling job that you're using on premises to the AWS Lambda function. For more information, see <a href="#">Deploying Lambda functions</a> (Lambda documentation).	Developer

### Deploy the code and create the Lambda function

Task	Description	Skills required
Create the Lambda function deployment package.	This package contains the code and its dependencies. For more information, see <a href="#">Deployment packages</a> (Lambda documentation).	Developer
Create the Lambda function.	In the AWS Lambda console, choose <b>Create function</b> , enter a function name, choose the runtime environment, and then choose <b>Create function</b> .	DevOps
Upload the deployment package.	Choose the Lambda function you created to open its configuration. You can write your code directly in the code section or upload your deployment package. To upload your package, go to the <b>Function code</b> section,	DevOps

Task	Description	Skills required
	choose the <b>Code entry type</b> to upload a .zip file, and then select the package.	
Configure the Lambda function per your requirements.	For example, you can set the <b>Timeout</b> parameter to the duration you expect your Lambda function to take. For more information, see <a href="#">Configuring function options</a> (Lambda documentation).	DevOps
Set permissions for the Lambda function role to access Secrets Manager.	For instructions, see <a href="#">Use secrets in AWS Lambda functions</a> (Secrets Manager documentation).	DevOps
Test the Lambda function.	Initiate the function manually to make sure it works as expected.	DevOps

## Schedule the Lambda function by using CloudWatch Events

Task	Description	Skills required
Create a rule to run your Lambda function on a schedule.	Schedule the Lambda function by using CloudWatch Events. For instructions, see <a href="#">Schedule Lambda functions using CloudWatch Events</a> (CloudWatch Events tutorial).	DevOps

## Related resources

# Secure and streamline user access in a Db2 federation database on AWS by using trusted contexts

Created by Sai Parthasaradhi (AWS)

**Environment:** PoC or pilot

**Technologies:** Databases;  
Security, identity, compliance

**Workload:** IBM

**AWS services:** Amazon EC2

## Summary

Many companies are migrating their legacy mainframe workloads to Amazon Web Services (AWS). This migration includes shifting IBM Db2 for z/OS databases to Db2 for Linux, Unix, and Windows (LUW) on Amazon Elastic Compute Cloud (Amazon EC2). During a phased migration from on premises to AWS, users might need to access data in IBM Db2 z/OS and in Db2 LUW on Amazon EC2 until all applications and databases are fully migrated to Db2 LUW. In such remote data-access scenarios, user authentication can be challenging because different platforms use different authentication mechanisms.

This pattern covers how to set up a federation server on Db2 for LUW with Db2 for z/OS as a remote database. The pattern uses a trusted context to propagate a user's identity from Db2 LUW to Db2 z/OS without re-authenticating on the remote database. For more information about trusted contexts, see the [Additional information](#) section.

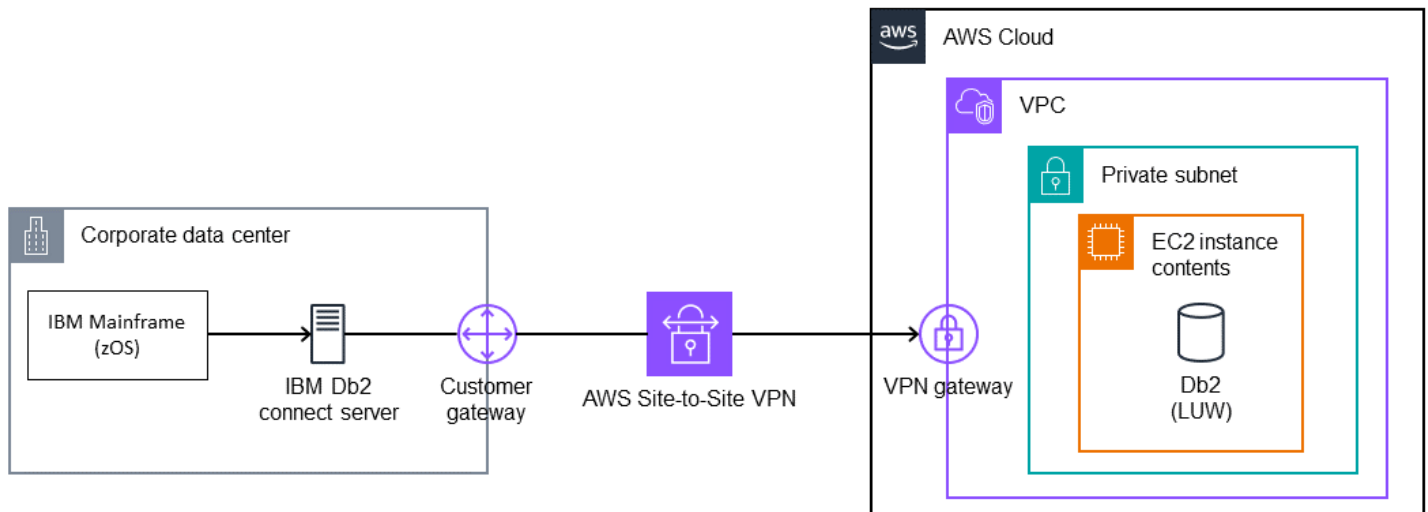

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Db2 instance running on an Amazon EC2 instance
- A remote Db2 for z/OS database running on premises
- The on-premises network connected to AWS through [AWS Site-to-Site VPN](#) or [AWS Direct Connect](#)

# Architecture

## Target architecture

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Site-to-Site VPN](#) helps you pass traffic between instances that you launch on AWS and your own remote network.

### Other services

- [db2cli](#) is the Db2 interactive command line interface (CLI) command.

## Epics

### Enable federation on the Db2 LUW database running on AWS

Task	Description	Skills required
Enable federation on the DB2 LUW DB.	To enable federation on DB2 LUW, run the following command.  <pre>update dbm cfg using federated YES</pre>	DBA
Restart the database.	To restart the database, run the following command.  <pre>db2stop force; db2start;</pre>	DBA

### Catalog the remote database

Task	Description	Skills required
Catalog the remote Db2 z/OS subsystem.	To catalog the remote Db2 z/OS database on Db2 LUW running on AWS, use the following example command.  <pre>catalog TCPIP NODE tcpnode REMOTE mainframehost SERVER mainframeport</pre>	DBA
Catalog the remote database.	To catalog the remote database, use the following example command.	DBA

Task	Description	Skills required
	<pre>catalog db dbnam1 as ndbnam1 at node tcpnode</pre>	

## Create the remote server definition

Task	Description	Skills required
<p>Collect user credentials for the remote Db2 z/OS database.</p>	<p>Before proceeding with the next steps, gather the following information:</p> <ul style="list-style-type: none"> <li>• Db2 z/OS subsystem name – The cataloged Db2 z/OS name on LUW from the previous step (for example, ndbnam1)</li> <li>• Db2 z/OS version – The Db2 z/OS subsystem version (for example, 12)</li> <li>• Db2 z/OS user ID – The user with the BIND privilege, which is needed to create only the server definition (for example, dbuser1)</li> <li>• Db2 z/OS password – The password for dbuser1 (for example, dbpasswd)</li> <li>• Db2 z/OS proxy user – The ID of the proxy user, which will be used to establish trusted connection (for example, zproxy)</li> </ul>	<p>DBA</p>

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• Db2 z/OS proxy password               <ul style="list-style-type: none"> <li>– The password for the zproxy user (for example, zproxy)</li> </ul> </li> </ul>	
Create the DRDA wrapper.	<p>To create the DRDA wrapper, run the following command.</p> <pre data-bbox="597 558 1026 638">CREATE WRAPPER DRDA;</pre>	DBA
Create the server definition.	<p>To create the server definition, run the following example command.</p> <pre data-bbox="597 842 1026 1199">CREATE SERVER ndbserver TYPE DB2/ZOS VERSION 12 WRAPPER DRDA AUTHORIZATION "dbuser1"   PASSWORD "dbpasswd" " OPTIONS ( DBNAME 'ndbnam1', FED_PROXY_USER 'ZPROXY' );</pre> <p>In this definition, FED_PROXY_USER specifies the proxy user that will be used for establishing trusted connections to the Db2 z/OS database. The authorization user ID and password are required only for creating the remote server object in the Db2 LUW database. They won't be used later during runtime.</p>	DBA

## Create user mappings

Task	Description	Skills required
<p>Create a user mapping for the proxy user.</p>	<p>To create a user mapping for proxy user, run the following command.</p> <pre data-bbox="597 499 1027 737">CREATE USER MAPPING FOR ZPROXY SERVER ndbserver OPTIONS (REMOTE_AUTHID 'ZPROXY', REMOTE_PA SSWORD 'zproxy');</pre>	<p>DBA</p>
<p>Create user mappings for each user on Db2 LUW.</p>	<p>Create user mappings for all the users on the Db2 LUW database on AWS who need to access remote data through the proxy user. To create the user mappings, run the following command.</p> <pre data-bbox="597 1136 1027 1413">CREATE USER MAPPING FOR PERSON1 SERVER ndbserver OPTIONS (REMOTE_AUTHID 'USERZID', USE_TRUST ED_CONTEXT 'Y');</pre> <p>The statement specifies that a user on Db2 LUW (PERSON1) can establish a trusted connection to the remote Db2 z/OS database (USE_TRUSTED_CONTEXT 'Y'). After the connection is established through the proxy user, the user can access the</p>	<p>DBA</p>

Task	Description	Skills required
	data by using the Db2 z/OS user ID (REMOTE_AUTHID 'USERZID' ).	

## Create the trusted context object

Task	Description	Skills required
Create the trusted context object.	<p>To create the trusted context object on the remote Db2 z/OS database, use the following example command.</p> <pre>CREATE TRUSTED CONTEXT   CTX_LUW_ZOS   BASED UPON CONNECTION USING SYSTEM AUTHID   ZPROXY   ATTRIBUTES (     ADDRESS '10.10.10.10'   )   NO DEFAULT ROLE   ENABLE   WITH USE FOR PUBLIC   WITHOUT AUTHENTICATION;</pre> <p>In this definition, CTX_LUW_ZOS is an arbitrary name for the trusted context object. The object contains the proxy user ID and the IP address of the server from which the trusted connection must originate. In this example, the server the Db2 LUW database</p>	DBA

Task	Description	Skills required
	on AWS. You can use the domain name instead of the IP address. The clause WITH USE FOR PUBLIC WITHOUT AUTHENTICATION indicates that switching the user ID on a trusted connection is allowed for every user ID. A password doesn't need to be provided.	

## Related resources

- [IBM Resource Access Control Facility \(RACF\)](#)
- [IBM Db2 LUW Federation](#)
- [Trusted contexts](#)

## Additional information

### Db2 trusted contexts

A trusted context is a Db2 database object that defines a trust relationship between a federated server and a remote database server. To define a trusted relationship, the trusted context specifies trust attributes. There are three types of trust attributes:

- The system authorization ID that makes the initial database connection request
- The IP address or domain name from which the connection is made
- The encryption setting for data communications between the database server and the database client

A trusted connection is established when all attributes of a connection request match the attributes specified in any trusted context object defined on the server. There are two types of trusted connections: implicit and explicit. After an implicit trusted connection is established, a user

inherits a role that isn't available to them outside the scope of that trusted connection definition. After an explicit trusted connection is established, users can be switched on the same physical connection, with or without authentication. In addition, Db2 users can be granted roles that specify privileges that are for use only within the trusted connection. This pattern uses an explicit trusted connection.

### *Trusted context in this pattern*

After the pattern is complete, PERSON1 on Db2 LUW accesses remote data from Db2 z/OS by using a federated trusted context. The connection for PERSON1 is established through a proxy user if the connection originates from the IP address or domain name that is specified in the trusted context definition. After the connection is established, PERSON1's corresponding Db2 z/OS user ID is switched without re-authentication, and the user can access the data or objects based on the Db2 privileges set up for that user.

### *Benefits of federated trusted contexts*

- This approach maintains the principle of least privilege by eliminating the use of a common user ID or application ID that would need a superset of all the privileges required by all users.
- The real identity of the user who performs the transaction on both the federated and remote database is always known and can be audited.
- Performance improves because the physical connection is being reused across the users without the need for the federated server to re-authenticate.

# Send notifications for an Amazon RDS for SQL Server database instance by using an on-premises SMTP server and Database Mail

Created by Nishad Mankar (AWS)

**Environment:** PoC or pilot

**Technologies:** Databases;  
Management & governance

**Workload:** Microsoft

**AWS services:** Amazon RDS

## Summary

[Database Mail](#) (Microsoft documentation) sends email messages, such as notifications or alerts, from a Microsoft SQL Server database by using a Simple Mail Transfer Protocol (SMTP) server. The Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server documentation provides instructions for using Amazon Simple Email Service (Amazon SES) as the SMTP server for Database Mail. For more information, see [Using Database Mail on Amazon RDS for SQL Server](#). As an alternative configuration, this pattern explains how to configure Database Mail to send email from an Amazon RDS for SQL Server database (DB) instance by using an on-premises SMTP server as the mail server.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon RDS DB instance running a Standard or Enterprise edition of SQL Server
- The IP address or hostname of the on-premises SMTP server
- An inbound [security group rule](#) that allows connections to the Amazon RDS for SQL Server DB instance from the IP address of the SMTP server
- A connection, such as an [AWS Direct Connect](#) connection, between your on-premises network and the virtual private cloud (VPC) that contains the Amazon RDS DB instance

## Limitations

- Express editions of SQL Server aren't supported.
- For more information about limitations, see [Limitations](#) in *Using Database Mail on Amazon RDS for SQL Server* in the Amazon RDS documentation.

## Product versions

- Standard and Enterprise editions of [SQL Server versions supported in RDS](#)

## Architecture

### Target technology stack

- Amazon RDS for SQL Server database instance
- Amazon Route 53 forwarding rule
- Database Mail
- On-premises SMTP server
- Microsoft SQL Server Management Studio (SSMS)

### Target architecture

The following image shows the target architecture for this pattern. When an event or action occurs that initiates a notification or alert regarding the database instance, Amazon RDS for SQL Server uses Database Mail to send an email notification. Database Mail uses the on-premises SMTP server to send the email.

## Tools

### AWS services

- [Amazon Relational Database Service \(Amazon RDS\) for Microsoft SQL Server](#) helps you set up, operate, and scale a SQL Server relational database in the AWS Cloud.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

### Other tools

- [Database Mail](#) is a tool that sends e-mail messages, such as notifications and alerts, from the SQL Server Database Engine to users.
- [Microsoft SQL Server Management Studio \(SSMS\)](#) is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components. In this pattern, you use

SSMS to run the SQL commands to set up Database Mail on an Amazon RDS for SQL Server DB instance.

## Epics

### Enable network connectivity with the on-premises SMTP server

Task	Description	Skills required
Remove Multi-AZ from the RDS DB instance.	If you're using a Multi-Zone RDS DB instance, convert the Multi-AZ instance to a Single-AZ instance. When you have finished configuring Database Mail, you will convert the DB instance back to a Multi-AZ deployment. The Database Mail configuration then works in both the primary and secondary nodes. For instructions, see <a href="#">Removing Multi-AZ from a Microsoft SQL Server DB instance</a> .	DBA
Create an allow list for the Amazon RDS endpoint or IP address on the on-premises SMTP server.	The SMTP server is outside of the AWS network. On the on-premises SMTP server, create an allow list that permits the server to communicate with the outbound endpoint or IP address for the Amazon RDS instance or the Amazon Elastic Compute Cloud (Amazon EC2) instance hosted on Amazon RDS. This procedure varies from organization to organization.	DBA

Task	Description	Skills required
	For more information about the DB instance endpoint, see <a href="#">Finding the DB instance endpoint and port number</a> .	
Remove port 25 restrictions.	<p>By default, AWS restricts port 25 on EC2 instances. To remove the port 25 restriction, do the following:</p> <ol style="list-style-type: none"><li>1. Sign in with your AWS account, and then open the <a href="#">Request to remove email sending limitations form</a>.</li><li>2. Enter your email address so that AWS Support can contact you with updates about your request.</li><li>3. Provide the required information in the <b>Use case description</b> field.</li><li>4. Choose <b>Submit</b>.</li></ol> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>• If you have instances in more than one AWS Region, then submit a separate request for each Region.</li><li>• It can take up to 48 hours to process your request.</li></ul>	General AWS

Task	Description	Skills required
Add a Route 53 rule to resolve DNS queries for the SMTP server.	Use Route 53 to resolve DNS queries between your AWS resources and the on-premises SMTP server. You must create a rule that forwards the DNS queries to the SMTP server domain, such as <code>example.com</code> . For instructions, see <a href="#">Creating forwarding rules</a> in the Route 53 documentation.	Network administrator

### Set up Database Mail on the Amazon RDS for SQL Server DB instance

Task	Description	Skills required
Enable Database Mail.	Create a parameter group for Database Mail, set the <code>database mail xps</code> parameter to 1, and then associate the Database Mail parameter group with the target RDS DB instance. For instructions, see <a href="#">Enabling Database Mail</a> in the Amazon RDS documentation. Do not proceed to the <i>Configuring Database Mail</i> section in these instructions. The configuration for the on-premises SMTP server differs from Amazon SES.	DBA

Task	Description	Skills required
Connect to the DB instance.	From a bastion host, use Microsoft SQL Server Management Studio (SSMS) to connect to the Amazon RDS for SQL Server database instance. For instructions, see <a href="#">Connecting to a DB instance running the Microsoft SQL Server database engine</a> . If you encounter any errors, see the connection troubleshooting references in the <a href="#">Related resources</a> section.	DBA

Task	Description	Skills required
Create the profile.	<p>In SSMS, enter the following SQL statement to create the Database Mail profile. Replace the following values:</p> <ul style="list-style-type: none"><li>• For <code>profile_name</code> , enter a name for the new profile.</li><li>• For <code>description</code> , enter a brief description of the new profile.</li></ul> <p>For more information about this stored procedure and its arguments, see <a href="#">sysmail_add_profile_sp</a> in the Microsoft documentation.</p> <pre>EXECUTE msdb.dbo.sysmail_add_profile_sp @profile_name = 'SQL Alerts profile', @description = 'Profile used for sending outgoing notifications using OM SMTP Server.';</pre>	DBA

Task	Description	Skills required
Add principals to the profile.	<p>Enter the following SQL statement to add public or private principals to the Database Mail profile. A <i>principal</i> is an entity that can request SQL Server resources. Replace the following values:</p> <ul style="list-style-type: none"><li>• For <code>profile_name</code> , enter the name of the profile you created previously.</li><li>• For <code>principal_name</code> , enter the name of the database user or role. This value must map to an SQL Server authentication user, a Windows Authentication user, or a Windows Authentication group.</li></ul> <p>For more information about this stored procedure and its arguments, see <a href="#">sysmail_add_principalprofile_sp</a> in the Microsoft documentation.</p> <pre>EXECUTE msdb.dbo. sysmail_add_princi palprofile_sp @profile_name = 'SQL Alerts profile', @principal_name = 'public', @is_default = 1 ;</pre>	DBA

Task	Description	Skills required
Create the account.	<p>Enter the following SQL statement to create the Database Mail account.</p> <p>Replace the following values:</p> <ul style="list-style-type: none"><li>• For <code>account_name</code> , enter a name for the new account.</li><li>• For <code>description</code> , enter a brief description of the new account.</li><li>• For <code>email_address</code> , enter the e-mail address to send the Database Mail messages from.</li><li>• For <code>display_address</code> , enter a display name to use for outgoing messages for this account, such as <code>SQL Server Automated Notification</code> . You can also use the value you entered for <code>email_address</code> .</li><li>• For <code>mailserver_name</code> , enter the name or IP address of the SMTP mail server.</li><li>• For <code>port</code>, leave the value of 25.</li><li>• For <code>enable_ssl</code> , leave the value at 1 or enter 0 if you don't want Database</li></ul>	DBA

Task	Description	Skills required
	<p>Mail to encrypt communication by using SSL.</p> <ul style="list-style-type: none"><li>• For <code>username</code>, enter the username for logging on to the SMTP mail server. If the server doesn't require authentication, enter NULL.</li><li>• For <code>password</code>, enter the password for logging on to the SMTP mail server. If the server doesn't require authentication, enter NULL.</li></ul> <p>For more information about this stored procedure and its arguments, see <a href="#">sysmail_add_account_sp</a> in the Microsoft documentation.</p> <pre>EXECUTE msdb.dbo. sysmail_add_account_sp @account_name = 'SQL Alerts account', @description = 'Database Mail account for sending outgoing notifications.', @email_address = 'xyz@example.com', @display_name = 'xyz@example.com', @mailserver_name = 'test_smtp.example .com', @port = 25, @enable_ssl = 1,</pre>	

Task	Description	Skills required
	<pre>@username = 'SMTP-use rname', @password = 'SMTP-pas sword';</pre>	
Add the account to the profile.	<p>Enter the following SQL statement to add the Database Mail account to the Database Mail profile. Replace the following values:</p> <ul style="list-style-type: none"><li>• For <code>profile_name</code> , enter the name of the profile you created previously.</li><li>• For <code>account_name</code> , enter the name of the account you created previously.</li></ul> <p>For more information about this stored procedure and its arguments, see <a href="#">sysmail_add_profileaccount_sp</a> in the Microsoft documentation.</p> <pre>EXECUTE msdb.dbo. sysmail_add_profil eaccount_sp @profile_name = 'SQL Alerts profile', @account_name = 'SQL Alerts account', @sequence_number = 1;</pre>	DBA

Task	Description	Skills required
(Optional) Add Multi-AZ to the RDS DB instance.	If you want to add Multi-AZ with Database Mirroring (DBM) or Always On Availability Groups (AGs), see the instructions in <a href="#">Adding Multi-AZ to a Microsoft SQL Server DB instance</a> .	DBA

# Set up disaster recovery for SAP on IBM Db2 on AWS

**Environment:** Production

**Technologies:** Databases;  
Operations

**Workload:** SAP

**AWS services:** Amazon EC2;  
AWS Elastic Disaster Recovery

## Summary

This pattern outlines the steps to set up a disaster recovery (DR) system for SAP workloads with IBM Db2 as the database platform, running on the Amazon Web Services (AWS) Cloud. The objective is to provide a low-cost solution for providing business continuity in the event of an outage.

The pattern uses the [pilot light approach](#). By implementing pilot light DR on AWS, you can reduce downtime and maintain business continuity. The pilot light approach focuses on setting up a minimal DR environment in AWS, including an SAP system and a standby Db2 database, that is synchronized with the production environment.

This solution is scalable. You can extend it to a full-scale disaster recovery environment as needed.

## Prerequisites and limitations

### Prerequisites

- An SAP instance running on an Amazon Elastic Compute Cloud (Amazon EC2) instance
- An IBM Db2 database
- An operating system that is supported by the SAP Product Availability Matrix (PAM)
- Different physical database hostnames for production and standby database hosts
- An Amazon Simple Storage Service (Amazon S3) bucket in each AWS Region with [Cross-Region Replication \(CRR\)](#) enabled

### Product versions

- IBM Db2 Database version 11.5.7 or later

## Architecture

### Target technology stack

- Amazon EC2
- Amazon Simple Storage Service (Amazon S3)
- Amazon Virtual Private Cloud (VPC peering)
- Amazon Route 53
- IBM Db2 High Availability Disaster Recovery (HADR)

### Target architecture

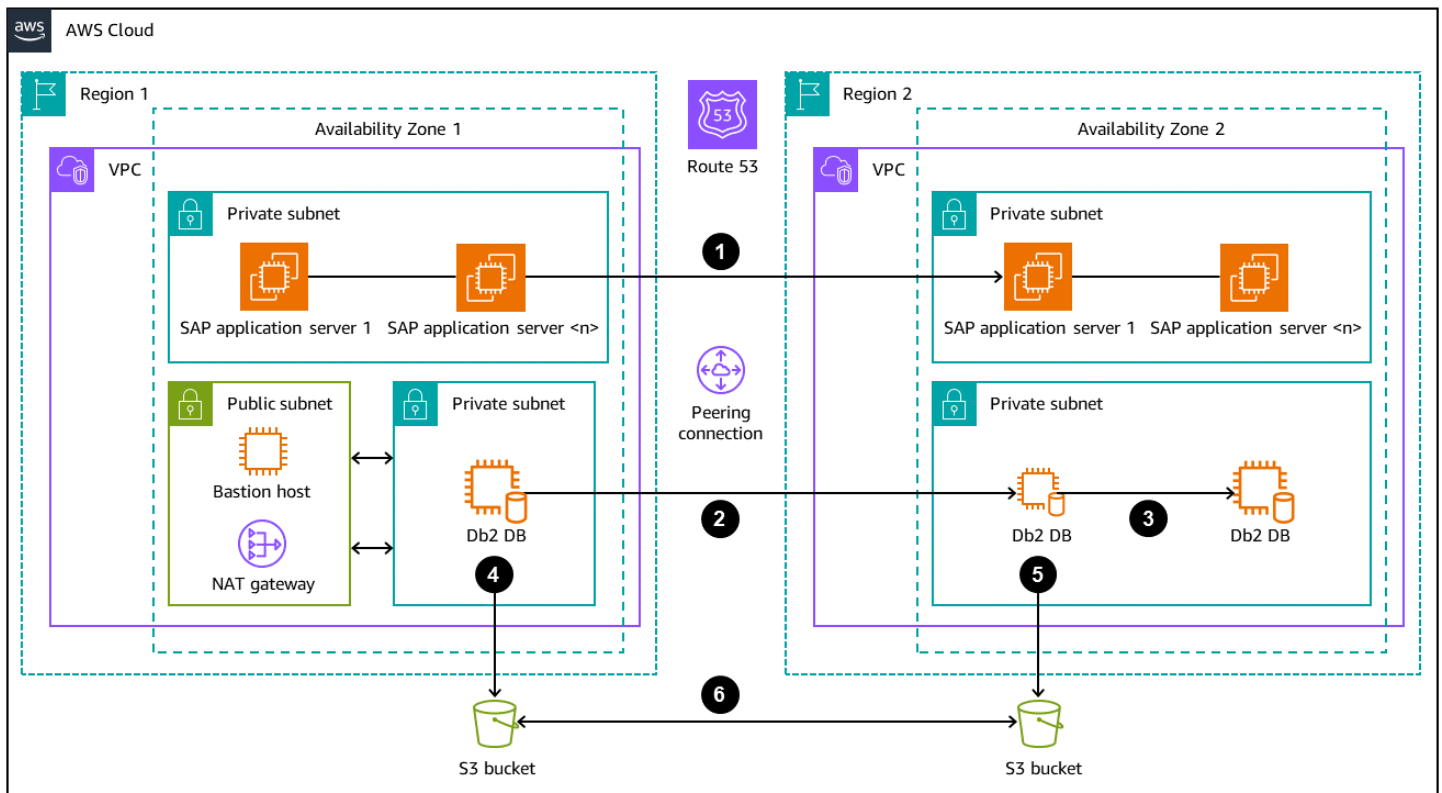

This architecture implements a DR solution for SAP workloads with Db2 as the database platform. The production database is deployed in AWS Region 1 and a standby database is deployed in a second Region. The standby database is referred to as the DR system. Db2 Database supports multiple standby databases (up to three). It uses Db2 HADR for setting up the DR database and automating log shipping between the production and standby databases.

In the event of a disaster that makes Region 1 unavailable, the standby database in the DR Region takes over the production database role. SAP application servers can be built in advance or by using [AWS Elastic Disaster Recovery](#) or an Amazon Machine Image (AMI) to meet the recovery time objective (RTO) requirements. This pattern uses an AMI.

Db2 HADR implements a production-standby setup, where production acts as the primary server, and all users are connected to it. All transactions are written to log files, which are transferred to the standby server by using TCP/IP. The standby server updates its local database by rolling forward the transferred log records, which helps to ensure that it is kept in sync with the production server.

VPC peering is used so that instances in the production Region and DR Region can communicate with each other. Amazon Route 53 routes end users to internet applications.

1. [Create an AMI](#) of the application server in Region 1 and [copy the AMI](#) to Region 2. Use the AMI to launch servers in Region 2 in the event of a disaster.
2. Set up Db2 HADR replication between the production database (in Region 1) and the standby database (in Region 2).
3. Change the EC2 instance type to match the production instance in the event of a disaster.
4. In Region 1, LOGARCHMETH1 is set to db2remote: S3 path.
5. In Region 2, LOGARCHMETH1 is set to db2remote: S3 path.
6. Cross-Region Replication is performed between the S3 buckets.

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses [VPC peering](#).

## Best practices

- The network plays a key role in deciding the HADR replication mode. For DR across AWS Regions, we recommend that you use Db2 HADR ASYNC or SUPERASYNC mode.
- For more information about replication modes for Db2 HADR, see the [IBM documentation](#).
- You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to [create a new AMI](#) of your existing SAP system. You can then use the AMI to recover your existing SAP system or to create a clone.
- [AWS Systems Manager Automation](#) can help with the common maintenance and deployment tasks of EC2 instances and other AWS resources.
- AWS provides multiple native services to monitor and manage your infrastructure and applications on AWS. Services such as Amazon CloudWatch and AWS CloudTrail can be used to monitor your underlying infrastructure and API operations, respectively. For more details, see [SAP on AWS – IBM Db2 HADR with Pacemaker](#).

## Epics

### Prepare the environment

Task	Description	Skills required
Check the system and logs.	<ol style="list-style-type: none"> <li>1. Confirm that the production SAP on Db2 system is set up.</li> <li>2. Confirm that log backup is turned on and configured to save the logs in the S3 bucket. This can</li> </ol>	AWS administrator, SAP Basis administrator

Task	Description	Skills required
	<p>be checked by the Db2 parameter LOGARCHME TH1 .</p> <p>3. Create an AMI of the additional application server.</p>	

## Set up the servers and replication

Task	Description	Skills required
<p>Create the SAP and database servers.</p>	<ol style="list-style-type: none"> <li>1. To deploy the infrastructure for the DR Region, use an AWS CloudFormation script or use an AMI of the production instance. As a part of the pilot light approach, you can use a smaller EC2 instance in the same family as the production instance. For example, if your production instance type is <code>r6i.12xlarge</code> , you can use the <code>r6i.xlarge</code> instance type for the DR build. However, make sure that you allocate the same storage capacity on the DR instance to restore the production database backup.</li> <li>2. Create Amazon Elastic File System (Amazon</li> </ol>	<p>SAP Basis administrator</p>

Task	Description	Skills required
	<p>EFS) mount points for /sapmnt/&lt;SID&gt;/ , and make sure that it is <a href="#">set to be replicated</a> from the primary system.</p> <ol style="list-style-type: none"><li data-bbox="592 457 997 730">3. Take a FULL database backup (online or offline) from the production system. You will use this backup to build the DR database.</li><li data-bbox="592 751 1027 1119">4. In the DR system, use the SAP Software Provisioning Manager (SWPM) system copy method with <b>Using system copy with backup/restore for HA/DR purposes</b> to build the DR SAP system.</li><li data-bbox="592 1140 1013 1465">5. When asked by SWPM, restore the database in DR with the backup that you took from the production. The DR database will be in the rollforward pending state.</li></ol> <p>The rollforward pending state is set by default after the full backup is restored. The rollforward pending state indicates that the database is in the process of being restored and that some</p>	

Task	Description	Skills required
	changes might need to be applied. For more information, see the <a href="#">IBM documentation</a> .	

Task	Description	Skills required
Check the configuration.	<p>1. To set up log archiving for HADR, both the production and DR databases must be able to retrieve logs automatically from all log archive locations. Verify that the LOGARCHMETH1 parameter in the DR database is set to the same location as in the production database. If the same location is not accessible because of Regional limitations, ensure that the DR system can automatically fetch logs from the primary system.</p> <p>2. To enable TCP/IP ports for database replication enablement, modify <code>etc/services</code> in the production and DR hosts by adding the following two entries. In the code, <code>&lt;SID&gt;</code> refers to the System ID (SID) of the Db2 database (for example, PR1).</p> <pre data-bbox="630 1598 1027 1873"> &lt;SID&gt;_HADR_1 55001/tcp          # DB2 HADR Port1 &lt;SID&gt;_HADR_2 55002/tcp          # DB2 HADR Port2 </pre>	AWS administrator, SAP Basis administrator

Task	Description	Skills required
	<p>Confirm that both ports allow inbound and outbound traffic between both the primary and the standby.</p> <p>3. Check <code>/etc/hosts</code> in the production and DR hosts to confirm that hostnames for both production and standby hosts are pointing to the correct IP addresses.</p>	

Task	Description	Skills required
Set up replication from the production DB to the DR DB (using ASYNC mode).	<p>1. In the production database, run the following commands to update the parameters.</p> <pre data-bbox="634 443 1029 1713"> db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_LOCAL_HOST HOST1 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_LOCAL_SVC &lt;SID&gt;_HADR_1 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_REMOTE_HOST HOST2 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_REMOTE_SVC &lt;SID&gt;_HADR_2 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_REMOTE_INST db2&lt;sid&gt; db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_TIMEOUT 120 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_SYNC_MODE ASYNC db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_SPOOL_LIMIT 1000 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING HADR_PEER_WINDOW 240 db2 UPDATE DB CFG FOR   &lt;SID&gt; USING indexrec   RESTART logindexb   uild ON </pre> <p>2. In the DR database, run the following commands to update the parameters.</p>	SAP Basis administrator

	<p>previously set parameter s. For more information about these parameters, see the <a href="#">IBM documentation</a>.</p> <p>3. Start HADR first on the newly created standby database by using the following command.</p> <pre data-bbox="630 674 1029 873">db2 deactivate db &lt;SID&gt; db2 start hadr on db &lt;SID&gt; as standby</pre> <p>4. Start HADR on the production database by using the following command.</p> <pre data-bbox="630 1104 1029 1304">db2 deactivate db &lt;SID&gt; db2 start hadr on db &lt;SID&gt; as primary</pre> <p>5. Check whether the production and standby Db2 databases are in sync and log shipping is ongoing.</p> <p>To monitor HADR replication status, use the following db2pd command.</p> <pre data-bbox="630 1801 1029 1877">db2pd -d &lt;SID&gt; -hadr</pre>	

Task	Description	Skills required
	For more information about monitoring HADR, see the <a href="#">IBM documentation</a> .	

## Test DR failover tasks

Task	Description	Skills required
Plan the production business downtime for the DR test.	Make sure that you plan the required business downtime on production environment for testing the DR failover scenario.	SAP Basis administrator
Create a test user.	Create a test user (or any test changes) that can be validated in the DR host to confirm log replication after DR failover.	SAP Basis administrator
On the console, stop the production EC2 instances.	Ungraceful shutdown is initiated in this step to mimic a disaster scenario.	AWS systems administrator
Scale up the DR EC2 instance to match the requirements.	On the EC2 console, change the instance type in the DR Region.  1. Stop the instance: If the instance is running, you must stop it before you can change its instance type. On the EC2 console, select	SAP Basis Admin

Task	Description	Skills required
	<p>the instance, and choose <b>Stop</b>.</p> <p>2. Modify the instance type: On the EC2 console, select the instance, and choose <b>Actions, Instance Settings, Change Instance Type</b>. Select the instance type that matches the primary instance, and choose <b>Apply</b>.</p> <p>3. Start the instance: After the instance type change is complete, start the instance from the EC2 console by selecting the instance and choosing <b>Start</b>.</p> <p>4. To start the Db2 database, use the following command.</p> <pre data-bbox="630 1266 1029 1423">db2start       db2 start HADR on       db &lt;SID&gt; as standby</pre>	

Task	Description	Skills required
Initiate takeover.	<p>From the DR system (host 2), initiate the take-over process and bring up the DR database as the primary.</p> <pre data-bbox="594 443 1029 562">db2 takeover hadr on database &lt;SID&gt; by force</pre> <p>Optionally, you can set the following parameters to adjust database memory allocation automatically based on the instance type. The INSTANCE_MEMORY value can be decided based on the dedicated portion of memory to be allocated to the Db2 database.</p> <pre data-bbox="594 1102 1029 1577">db2 update db cfg for &lt;SID&gt; using INSTANCE_ MEMORY &lt;FIXED VALUE&gt; IMMEDIATE; db2 get db cfg for &lt;SID&gt;   grep -i DATABASE_ MEMORY AUTOMATIC IMMEDIATE; db2 update db cfg for &lt;SID&gt; using self_tuni ng_mem ON IMMEDIATE;</pre> <p>Verify the change by using the following commands.</p> <pre data-bbox="594 1738 1029 1829">db2 get db cfg for &lt;SID&gt;   grep -i MEMORY</pre>	SAP Basis administrator

Task	Description	Skills required
	<pre>db2 get db cfg for &lt;SID&gt;   grep -i self_tuning_mem</pre>	
<p>Launch the application server for SAP in the DR Region.</p>	<p>Using the AMI that you made of the production system, <a href="#">launch a new additional application server</a> in the DR Region.</p>	<p>SAP Basis administrator</p>
<p>Perform validation before starting the SAP application.</p>	<ol style="list-style-type: none"> <li>1. Validate the <code>/etc/hosts</code> and <code>/etc/fstab</code> entries.</li> <li>2. Mount <code>/sapmnt/&lt;SID&gt;/</code> on the DR system.</li> <li>3. Validate that the DR file system <code>/sapmnt/&lt;SID&gt;/</code> is synced with the production <code>/sapmnt/&lt;SID&gt;/</code>.</li> <li>4. Log in to <code>&lt;sid&gt;adm</code> user, run <code>R3trans -d</code>, and verify the output in the <code>trans.log</code> file. The <code>trans.log</code> file is generated in the same location where you ran the <code>R3trans -d</code> command.</li> </ol>	<p>AWS administrator, SAP Basis administrator</p>

Task	Description	Skills required
<p>Start the SAP application on the DR system.</p>	<p>Start the SAP application on the DR system by using &lt;sid&gt;adm user. Use the following code, in which XX represents the instance number of your SAP ABAP SAP Central Services (ASCS) server, and YY represents the instance number of your SAP application server.</p> <pre data-bbox="597 730 1026 1171"> sapcontrol -nr XX - function StartService &lt;SID&gt; sapcontrol -nr XX - function StartSystem sapcontrol -nr YY - function StartService &lt;SID&gt; sapcontrol -nr YY - function StartSystem </pre>	<p>SAP Basis administrator</p>
<p>Perform SAP validation.</p>	<p>This is performed as a DR test to provide evidence or to check the data replication success to the DR Region.</p>	<p>Test engineer</p>

### Perform DR failback tasks

Task	Description	Skills required
<p>Start the production SAP and database servers.</p>	<p>On the console, start the EC2 instances that host SAP and the database in the production system.</p>	<p>SAP Basis administrator</p>

Task	Description	Skills required
Start the production database and set up HADR.	<p>Log in to production system (host1) and verify that the DB is in recovery mode by using the following command.</p> <pre>db2start db2 start HADR on db P3V as standby db2 connect to &lt;SID&gt;</pre> <p>Verify that the HADR status is connected . Replication status should be peer.</p> <pre>db2pd -d &lt;SID&gt; -hadr</pre> <p>If the database is not inconsistent and is not at connected and peer status, a backup and restore might be required to bring the database (on host1) in sync with the currently active database (host2 in the DR Region). In that case, restore the DB backup from the database in the host2 DR Region to the database in the host1 production Region.</p>	SAP Basis administrator

Task	Description	Skills required
Fail back the database to the production Region.	<p>In a normal business-as-usual scenario, this step is performed in a scheduled downtime. Applications running on the DR system are stopped, and the database is failed back to the production Region (Region 1) to resume operations from the production Region.</p> <ol style="list-style-type: none"><li>1. Log in to the SAP application server in the DR Region, and stop the SAP application.</li><li>2. Unmount <code>/sapmnt/&lt;SID&gt;</code> from the DR system, making sure that the changes are reverse-replicated to <code>/sapmnt/&lt;SID&gt;</code> of the production system.</li><li>3. Log in to the database server (host1) in the production Region, and perform the takeover. <div data-bbox="630 1497 1029 1614" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>db2 takeover hadr on database &lt;SID&gt;</pre></div></li><li>4. - [SAP on AWS – IBM Db2 HADR with Pacemaker](#)
- [Step by Step Procedure to set up HADR replication between DB2 databases](#)
- [Db2 HADR Wiki](#)

## Additional information

Using this pattern, you can set up a disaster recovery system for an SAP system running on the Db2 database. In a disaster situation, business should be able to continue within your defined recovery time objective (RTO) and recovery point objective (RPO) requirements:

- **RTO** is the maximum acceptable delay between the interruption of service and restoration of service. This determines what is considered an acceptable time window when service is unavailable.
- **RPO** is the maximum acceptable amount of time since the last data recovery point. This determines what is considered an acceptable loss of data between the last recovery point and the interruption of service.

For FAQs related to HADR, see [SAP note #1612105 - DB6: FAQ on Db2 High Availability Disaster Recovery \(HADR\)](#). (You need SAP portal credentials to access this note.)

# Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database

Created by Simon Cunningham (AWS) and Nitin Saxena

**Environment:** Production

**Technologies:** Databases;  
Infrastructure

**Workload:** Oracle

**AWS services:** Amazon RDS

## Summary

This pattern describes how you can architect your Oracle E-Business solution on Amazon Relational Database Service (Amazon RDS) Custom for high availability (HA) and disaster recovery (DR) by setting up an Amazon RDS Custom read replica database in another Amazon Web Services (AWS) Availability Zone and converting it to an active standby database. The creation of the Amazon RDS Custom read replica is fully automated through the AWS Management Console.

This pattern doesn't discuss the steps for adding additional application tiers and shared file systems, which can also be part of an HA/DR architecture. For more information about those topics, see the following Oracle Support Notes: 1375769.1, 1375670.1, and 1383621.1 (section 5, *Advanced Cloning Options*). (Access requires an [Oracle Support](#) account.)

To migrate E-Business Suite system to a single-tier, Single-AZ architecture on Amazon Web Services (AWS), see the pattern [Migrate Oracle E-Business Suite to Amazon RDS Custom](#).

Oracle E-Business Suite is an Enterprise Resource Planning (ERP) solution for automating enterprise-wide processes such as financials, human resources, supply chains, and manufacturing. It has a three-tier architecture: client, application, and database. Previously, you had to run your E-Business Suite database on a self-managed [Amazon Elastic Compute Cloud \(Amazon EC2\) instance](#), but you can now benefit from [Amazon RDS Custom](#).

## Prerequisites and limitations

### Prerequisites

- An existing E-Business Suite installation on Amazon RDS Custom; see the pattern [Migrate Oracle E-Business Suite to Amazon RDS Custom](#)
- If you want to change the read replica to read-only and use it to offload reporting to the standby, an [Oracle Active Data Guard database license](#) (see the *Oracle Technology Commercial Price List*)

## Limitations

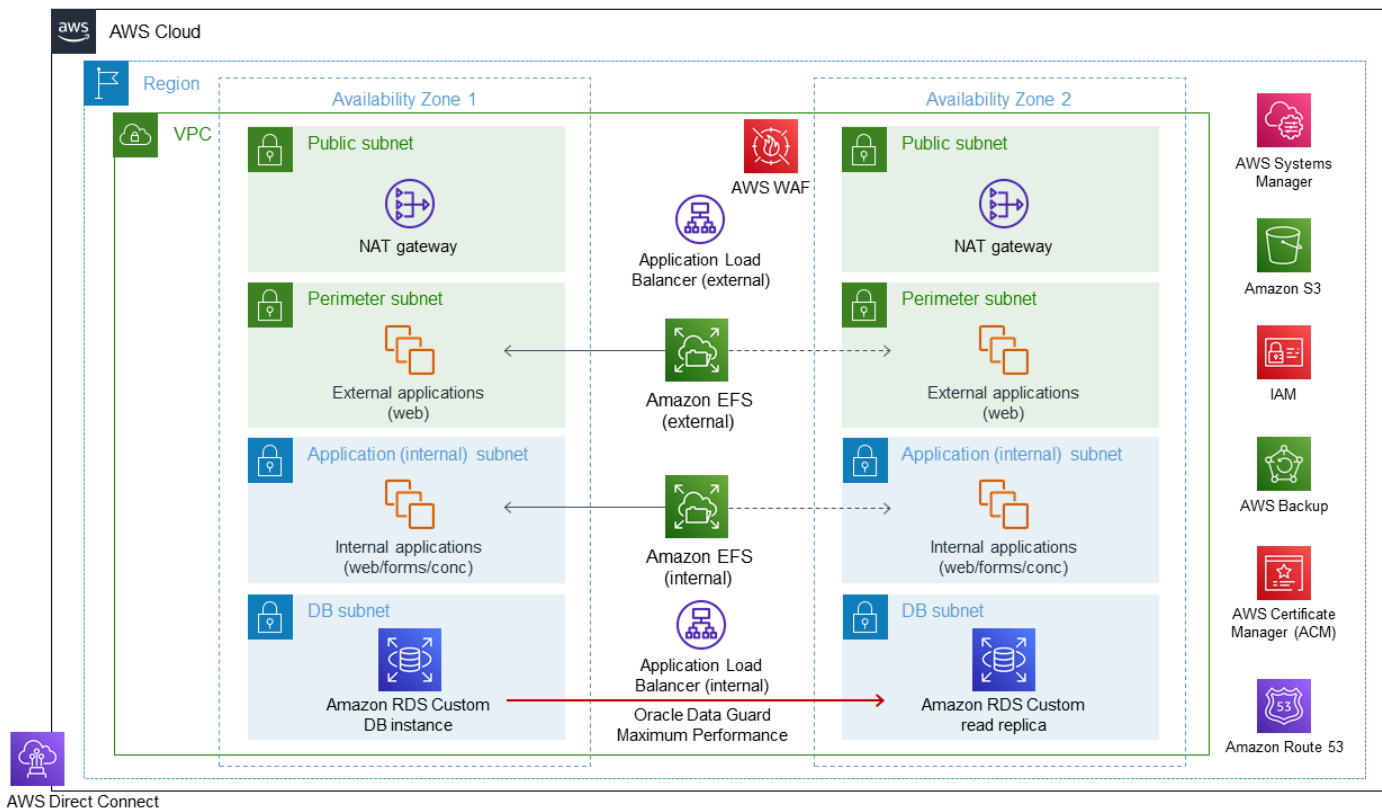

- Limitations and unsupported configurations for [Oracle databases on Amazon RDS Custom](#)
- Limitations associated with [Amazon RDS Custom for Oracle read replicas](#)

## Product versions

For Oracle Database versions and instance classes supported by Amazon RDS Custom, see [Requirements and limitations for Amazon RDS Custom for Oracle](#).

## Architecture

The following diagram illustrates a representative architecture for E-Business Suite on AWS that includes multiple Availability Zones and application tiers in an active/passive setup. The database uses an Amazon RDS Custom DB instance and Amazon RDS Custom read replica. The read replica uses Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.

For more information, see [Working with read replicas for Amazon RDS Custom for Oracle](#) in the Amazon RDS documentation.

The Amazon RDS Custom read replica is created by default as mounted. However, if you want to offload some of your read-only workloads to the standby database to reduce the load on your primary database, you can manually change the mode of mounted replicas to read-only by following the steps in the [Epics](#) section. A typical use case for this would be to run your reports from the standby database. Changing to read-only requires an active standby database license.

When you create a read replica on AWS, the system uses Oracle Data Guard broker under the covers. This configuration is automatically generated and set up in Maximum Performance mode as follows:

```
DGMGRL> show configuration
Configuration - rds_dg
  Protection Mode: MaxPerformance
  Members:
    vis_a - Primary database
    vis_b - Physical standby database
  Fast-Start Failover: DISABLED
  Configuration Status:
```

SUCCESS (status updated 58 seconds ago)

## Tools

### AWS services

- [Amazon RDS Custom for Oracle](#) is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks and operations while making it possible for you, as a database administrator, to access and customize your database environment and operating system.

### Other tools

- Oracle Data Guard is a tool that helps you create and manage Oracle standby databases. This pattern uses Oracle Data Guard to set up an active standby database on Amazon RDS Custom.

## Epics

### Create a read replica

Task	Description	Skills required
Create a read replica of the Amazon RDS Custom DB instance.	<p>To create a read replica, follow the instructions in the <a href="#">Amazon RDS documentation</a> and use the Amazon RDS Custom DB instance you created (see the <a href="#">Prerequisites</a> section) as the source database.</p> <p>By default, the Amazon RDS Custom read replica is created as a physical standby and is in the mounted state. This is intentional to ensure</p>	DBA

Task	Description	Skills required
	compliance with the Oracle Active Data Guard license. Follow the next steps to convert the read replica to read-only mode.	

## Change the read replica to a read-only active standby

Task	Description	Skills required
Connect to the Amazon RDS Custom read replica.	<p>Use the following commands to convert your physical standby database to an active standby database.</p> <p><b>Important:</b> These commands require an Oracle active standby license. To get a license, contact your Oracle representative.</p> <pre> \$ sudo su - rdsdb -bash-4.2\$ sql SQL&gt; select process,s tatus,sequence# from v \$managed_standby;  PROCESS    STATUS SEQUENCE# ----- ARCH      CLOSING           3956 ARCH      CONNECTED           0 ARCH      CLOSING           3955 </pre>	DBA

Task	Description	Skills required
	<pre> ARCH          CLOSING               3957 RFS           IDLE               0 RFS           IDLE               3958 MRP0          APPLYING_LOG               3958 SQL&gt; select name,            database_role,            open_mode from v            \$database;  NAME          DATABASE_ ROLE          OPEN_MODE ----- ----- ----- VIS           PHYSICAL STANDBY MOUNTED SQL&gt; alter database        recover managed standby        database cancel; Database altered. Open the standby database SQL&gt; alter database        open; Database altered. SQL&gt; select name,            database_role,            open_mode from v            \$database;  NAME          DATABASE_ ROLE          OPEN_MODE ----- ----- ----- VIS           PHYSICAL STANDBY READ ONLY                     </pre>	

Task	Description	Skills required
<p>Start media recovery with real-time log apply.</p>	<p>To enable the real-time log apply feature, use the following commands. These convert and validate the standby (read replica) as an active standby database, so you can connect and run read-only queries.</p> <pre data-bbox="597 632 1027 911"> SQL&gt; alter database recover managed standby database using current logfile disconnect from session; Database altered </pre>	<p>DBA</p>
<p>Check the database status.</p>	<p>To check the status of the database, use the following command.</p> <pre data-bbox="597 1115 1027 1633"> SQL&gt; select name, database_role, open_mode from v \$database; NAME          DATABASE_ROLE               OPEN_MODE ----- ----- ----- VIS          PHYSICAL STANDBY READ ONLY WITH APPLY </pre>	<p>DBA</p>

Task	Description	Skills required
Check redo apply mode.	<p>To check redo apply mode, use the following command.</p> <pre> SQL&gt; select process,s tatus,sequence# from v \$managed_standby; PROCESS    STATUS SEQUENCE# ----- ARCH      CLOSING           3956 ARCH      CONNECTED           0 ARCH      CLOSING           3955 ARCH      CLOSING           3957 RFS       IDLE           0 RFS       IDLE           3958 MRP0      APPLYING_LOG           3958  SQL&gt; select open_mode from v\$database; OPEN_MODE ----- READ ONLY WITH APPLY </pre>	DBA

# Set up data replication between Amazon RDS for MySQL and MySQL on Amazon EC2 using GTID

*Created by Rajesh Madiwale (AWS)*

**Environment:** PoC or pilot

**Technologies:** Databases

**Workload:** Open-source

## Summary

This pattern describes how to set up data replication on the Amazon Web Services (AWS) Cloud between an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance and a MySQL database on an Amazon Elastic Compute Cloud (Amazon EC2) instance by using MySQL native global transaction identifier (GTID) replication.

With GTIDs, transactions are identified and tracked when they are committed on the originating server and applied by replicas. You don't need to refer to log files when starting a new replica during failover.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon Linux instance deployed

### Restrictions

- This setup requires an internal team to run the read-only queries.
- The source and target MySQL versions must be the same.
- Replication is set up in the same AWS Region and virtual private cloud (VPC).

### Product versions

- Amazon RDS versions 5.7.23 and later, which are the versions that support [GTID](#)

# Architecture

## Source technology stack

- Amazon RDS for MySQL

## Target technology stack

- MySQL on Amazon EC2

## Target architecture

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Relational Database Service \(Amazon RDS\) for MySQL](#) helps you set up, operate, and scale a MySQL relational database in the AWS Cloud.

## Other services

- [Global transaction identifiers \(GTIDs\)](#) are unique identifiers generated for committed MySQL transactions.
- [mysqldump](#) is a client utility for performing logical backups by producing SQL statements that can be run to reproduce the source database object definitions and table data.
- [mysql](#) is the command-line client for MySQL.

## Epics

### Create and prepare the Amazon RDS for MySQL DB instance

Task	Description	Skills required
Create the RDS for MySQL instance.	To create the RDS for MySQL instance, follow the steps in the <a href="#">Amazon RDS documentation</a> , using the parameter values that are covered in the next task.	DBA, DevOps engineer
Enable GTID-related settings in the DB parameter group.	Enable the following parameters in the Amazon RDS for MySQL DB parameter group.  Set <code>enforce_gtid_consistency</code> to <code>on</code> , and set <code>gtid-mode</code> to <code>on</code> .	DBA

Task	Description	Skills required
Reboot the Amazon RDS for MySQL instance.	A reboot is required for the parameter changes to take effect.	DBA
Create a user and grant it replication permissions.	To install MySQL, use the following commands.  <pre>CREATE USER 'repl'@'%'   IDENTIFIED BY 'xxxx'; GRANT REPLICATI ON slave ON *.* TO   'repl'@'%' ; FLUSH PRIVILEGES;</pre>	DBA

## Install and prepare MySQL on the Amazon EC2 instance

Task	Description	Skills required
Install MySQL on Amazon Linux.	To install MySQL, use the following commands.  <pre>sudo yum update sudo wget https://d ev.mysql.com/get/m ysql57-community-r elease-el7-11.noar ch.rpm sudo yum localinstall mysql57-community- release-el7-11.noa rch.rpm sudo yum install mysql- community-server sudo systemctl start mysqld</pre>	DBA

Task	Description	Skills required
Log in to MySQL on the EC2 instance and create the database.	<p>The database name should be the same as the database name in Amazon RDS for MySQL. In the following example, the database name is <code>replication</code> .</p> <pre>create database replication;</pre>	DBA
Edit the MySQL config file, and restart the database.	<p>Edit the <code>my.cnf</code> file that is located in <code>/etc/</code> by adding the following parameters.</p> <pre>server-id=3 gtid_mode=ON enforce_gtid_consist ency=ON replicate-ignore-db =mysql binlog-format=ROW log_bin=mysql-bin</pre> <p>Then restart the <code>mysqld</code> service.</p> <pre>systemctl mysqld restart</pre>	DBA

## Set up replication

Task	Description	Skills required
Export the data dump from the Amazon RDS for MySQL database.	To export the dump from Amazon RDS for MySQL, use the following command.	DBA

Task	Description	Skills required
	<pre>mysqldump --single-transaction -h mydb.xxxxxxx.amazonaws.com -uadmin -p --databases replication &gt; replication-db.sql</pre>	
Restore the .sql dump file in the MySQL database on Amazon EC2.	To import the dump to the MySQL database on Amazon EC2, use the following command. <pre>mysql -D replication -uroot -p &lt; replication-db.sql</pre>	DBA
Configure the MySQL database on Amazon EC2 as a replica.	To start the replication and to check the replication status, log in to the MySQL database on Amazon EC2, and use the following command. <pre>CHANGE MASTER TO MASTER_HOST="mydb.xxxxxxx.amazonaws.com", MASTER_USER="repl", MASTER_PASSWORD="rep123", MASTER_PORT=3306, MASTER_AUTO_POSITION = 1; START SLAVE; SHOW SLAVE STATUS\G</pre>	DBA

# Transition roles for an Oracle PeopleSoft application on Amazon RDS Custom for Oracle

Created by *sampath kathirvel* (AWS)

**Environment:** Production

**Technologies:** Databases;  
Infrastructure

**Workload:** Oracle

**AWS services:** Amazon RDS

## Summary

To run the [Oracle PeopleSoft](#) enterprise resource planning (ERP) solution on Amazon Web Services (AWS), you can use [Amazon Relational Database Service \(Amazon RDS\)](#) or [Amazon RDS Custom for Oracle](#), which supports legacy, custom, and packaged applications that require access to the underlying operating system (OS) and database environment. For key factors to consider when planning a migration, see [Oracle database migration strategies](#) in AWS Prescriptive Guidance.

This pattern focuses on the steps to perform an Oracle Data Guard switchover, or role transition, for a PeopleSoft application database running on Amazon RDS Custom as the primary database with a read replica database. The pattern includes steps to configure [fast-start failover \(FSFO\)](#). During this process, the databases in the Oracle Data Guard configuration continue to function in their new roles. Typical use cases for Oracle Data Guard switchover are disaster recovery (DR) drills, scheduled maintenance activities on databases, and [Standby-First Patch Apply](#) rolling patches. For more information, see the blog post [Reduce database patching downtime in Amazon RDS Custom](#).

## Prerequisites and limitations

### Prerequisites

- Completion of the [Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica](#) pattern.

### Limitations

- Limitations and unsupported configurations for [RDS Custom for Oracle](#)

- Limitations associated with [Amazon RDS Custom for Oracle read replicas](#)

## Product versions

- For Oracle Database versions supported by Amazon RDS Custom, see [RDS Custom for Oracle](#).
- For Oracle Database instance classes supported by Amazon RDS Custom, see [DB instance class support for RDS Custom for Oracle](#).

## Architecture

### Technology stack

- Amazon RDS Custom for Oracle

### Target architecture

The following diagram shows an Amazon RDS Custom DB instance and an Amazon RDS Custom read replica. Oracle Data Guard provides role transition during failover for DR.

For a representative architecture using Oracle PeopleSoft on AWS, see [Set up a highly available PeopleSoft architecture on AWS](#).

## Tools

### AWS services

- [Amazon RDS Custom for Oracle](#) is a managed database service for legacy, custom, and packaged applications that require access to the underlying OS and database environment.
- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager for RDS\_DATAGUARD with the secret name `do-not-delete-rds-custom-+<<RDS Resource ID>>+-dg`.

### Other services

- [Oracle Data Guard](#) helps you create, maintain, manage, and monitor standby databases. This pattern uses Oracle Data Guard Maximum Performance for transitioning roles ([Oracle Data Guard switchover](#)).

## Best practices

For your production deployment, we recommend launching the observer instance in a third Availability Zone, separate from the primary and read replica nodes.

## Epics

### Initiate role transition

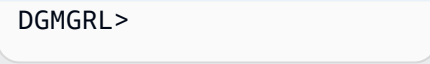

Task	Description	Skills required
Pause database automation for both the primary and the replica.	Although the RDS Custom automation framework doesn't interfere with the role transition process, it's a good practice to pause automation during Oracle Data Guard switchover.	Cloud administrator, DBA

Task	Description	Skills required
	To pause and resume RDS Custom database automation, follow the instructions at <a href="#">Pausing and resuming RDS Custom automation</a> .	

Task	Description	Skills required
Check the Oracle Data Guard status.	<p>To check the Oracle Data Guard status, log in to the primary database. This pattern includes code for using a multitenant container database (CDB) or a non-CDB instance.</p> <p><b>Non-CDB</b></p> <pre data-bbox="597 667 1027 1875">-bash-4.2\$ dgmgrl RDS_DATAGUARD@RDS_ CUSTOM_ORCL_A DGMGRL for Linux:   Release 19.0.0.0.0 -   Production on Mon Nov   28 20:55:50 2022 Version 19.10.0.0.0 Copyright (c) 1982,   2019, Oracle and/or its   affiliates. Verify the instance role on the Amazon RDS console.	After you perform the role switch, the Amazon RDS console shows the new roles under the <b>Replication</b> section on the <b>Connectivity &amp; Security</b> tab under <b>Databases</b> . It might take a few minutes for <b>Replication state</b> to update from empty to <b>Replicating</b> .	DBA

## Configure FSFO

Task	Description	Skills required
Reset the switchover.	Set the switchover back to the primary node.	DBA
Install and start the observer.	An observer process is a DGMGRL client component , typically running in a different machine from the primary and standby	DBA

Task	Description	Skills required
	<p>databases. The ORACLE HOME installation for the observer can be an Oracle Client Administrator installation, or you can install either Oracle Database Enterprise Edition or Personal Edition. For more information about observer installation for your database release, see <a href="#">Installing and Starting the Observer</a>. To configure high availability for the observer process, you might want to do the following:</p> <ul style="list-style-type: none"><li>• Enable <a href="#">EC2 instance automatic recovery</a> for the EC2 instance running your observer. You need to automate the observer startup process as part of the OS startup.</li><li>• Deploy an observer in the EC2 instance and configure an Amazon EC2 Auto Scaling group with size one (1). In the event of EC2 instance failure, the automatic scaling group automatically spins up another EC2 instance.</li></ul> <p>For Oracle 12c Release 2 and later, you can deploy up to</p>	

Task	Description	Skills required
	three observers. One observer is the primary observer, and the rest are backup observers . When the primary observer fails, one of the backup observers takes the primary role.	

Task	Description	Skills required
Connect to DGMGRL from the observer host.	<p>The observer host is configured with <code>tnsnames.ora</code> entries for primary and standby database connectivity. You can enable FSFO with maximum performance protection mode as long as data loss is within the <a href="#">FastStartFailoverLagLimit</a> configuration (value in seconds), However, you must use maximum availability protection mode to work to achieve zero data loss (RPO=0).</p> <p><b>Non-CDB</b></p> <pre>DGMGRL&gt; show configuration; Configuration - rds_dg Protection Mode:   MaxAvailability Members: orcl_a - Primary   database orcl_d - Physical   standby database Fast-Start Failover:   Disabled Configuration Status: SUCCESS (status updated   58 seconds ago) DGMGRL&gt; show configuration lag Configuration - rds_dg Protection Mode:   MaxAvailability</pre>	DBA

Task	Description	Skills required
Modify the standby database to be the failover target.	<p>Connect from either the primary node or the observer node to one standby database. (Although your onfiguration could have multiple standby databases , you need to connect to only one at this time.)</p> <p><b>Non-CDB</b></p> <pre>DGMGRL&gt; edit database   orcl_a set property   FastStartFailoverT   arget='orcl_d'; Property "faststar tfailovertarget"   updated DGMGRL&gt; edit database   orcl_d set property   FastStartFailoverT   arget='orcl_a'; Property "faststar tfailovertarget"   updated DGMGRL&gt; show database   orcl_a FastStart   FailoverTarget; FastStartFailoverTar   get = 'orcl_d' DGMGRL&gt; show database   orcl_d FastStart   FailoverTarget; FastStartFailoverTar   get = 'orcl_a' DGMGRL&gt;</pre> <p><b>CDB</b></p>	DBA

Task	Description	Skills required
	<pre>DGMGRL&gt; edit database orcl_a set property FastStartFailoverT arget='rdscdb_b'; Object "orcl_a" was not found DGMGRL&gt; edit database rdscdb_a set property FastStartFailoverT arget='rdscdb_b'; Property "faststar tfailovertarget" updated DGMGRL&gt; edit database rdscdb_b set property FastStartFailoverT arget='rdscdb_a'; Property "faststar tfailovertarget" updated DGMGRL&gt; show database rdscdb_a FastStart FailoverTarget; FastStartFailoverT arget = 'rdscdb_b' DGMGRL&gt; show database rdscdb_b FastStart FailoverTarget; FastStartFailoverT arget = 'rdscdb_a' DGMGRL&gt;</pre>	

Task	Description	Skills required
Configure FastStartFailoverThreshold for the connection to DGMGRL.	<p>The default value is 30 seconds in Oracle 19c, and the minimum value is 6 seconds. A lower value can potentially shorten the recovery time objective (RTO) during the failover. A higher value helps reduce the chance of unnecessary failover transient errors on the primary database.</p> <p>The RDS Custom for Oracle automation framework monitors database health and performs corrective actions every few seconds. Therefore, we recommend setting FastStartFailoverThreshold to a value higher than 10 seconds. The following example configures the threshold value at 35 seconds.</p> <p><b>Non-CBD or CDB</b></p> <pre>DGMGRL&gt; edit configuration set property FastStartFailoverThreshold=35; Property "faststartfailoverthreshold" updated DGMGRL&gt; show configuration FastStart FailoverThreshold;</pre>	DBA

Task	Description	Skills required
	<pre>FastStartFailover Threshold = '35' DGMGR&gt;</pre>	

Task	Description	Skills required
<p>Enable FSFO by connecting to DGMGRL from the primary or observer node.</p>	<p>If the database doesn't have <a href="#">Flashback Database</a> enabled, the warning message <code>ORA-16827</code> appears. The optional flashback database helps automatically reinstate failed primary databases to a point in time before failover if the <a href="#">FastStartFailoverAutoReinstate</a> configuration property is set to <code>TRUE</code> (which is the default).</p> <p><b>Non-CDB</b></p> <pre>DGMGRL&gt; enable fast_start failover; Warning: ORA-16827: Flashback Database is disabled Enabled in Zero Data Loss Mode. DGMGRL&gt; DGMGRL&gt; show configuration Configuration - rds_dg Protection Mode: MaxAvailability Members: orcl_a - Primary database Warning: ORA-16819: fast-start failover observer not started orcl_d - (*) Physical standby database Warning: ORA-16819: fast-start failover observer not started</pre>	<p>DBA</p>

Task	Description	Skills required
	<p>Fast-Start Failover: Enabled in Zero Data Loss Mode Configuration Status: WARNING (status updated 29 seconds ago) DGMGRL&gt;</p> <p><b>CDB</b></p> <pre>DGMGRL&gt; enable fast_start failover; Warning: ORA-16827: Flashback Database is disabled Enabled in Zero Data Loss Mode. Task	Description	Skills required
	<pre> Observer 'ip-10-0-1-56' started The observer log file is '/home/oracle/observer_ip-10-0-1-56.log'.  DGMGRL&gt; show configuration Configuration - rds_dg   Protection Mode:   MaxAvailability   Members:     rdscdb_a - Primary database     rdscdb_b - (*)   Physical standby database Fast-Start Failover:   Enabled in Zero Data Loss Mode Configuration Status: SUCCESS (status updated 12 seconds ago) DGMGRL&gt;  DGMGRL&gt; show observer; Configuration - rds_dg   Primary:   rdscdb_a   Active Target:   rdscdb_b Observer "ip-10-0-1-56" - Master   Host Name:     ip-10-0-1-56   Last Ping to Primary:     1 second ago   Last Ping to Target:     2 seconds ago DGMGRL&gt; </pre>	

Task	Description	Skills required
Verify the failover.	<p>In this scenario, a failover test can be performed by manually stopping the primary EC2 instance. Before stopping the EC2 instance, use the <code>tail</code> command to monitor the observer log file based on your configuration. Use DGMGRL to log in to standby database <code>orcl_d</code> with user <code>RDS_DATAGUARD</code>, and check the Oracle Data Guard status. It should show that <code>orcl_d</code> is the new primary database.</p> <p><b>Note:</b> In this failover testing scenario, <code>orcl_d</code> is the non-CDB database.</p> <p>Before failover, the flashback database has been enabled on <code>orcl_a</code>. After the former primary database returns online and starts in MOUNT state, the observer reinstates it into a new standby database. The reinstated database acts as the FSFO target for the new primary database. You can verify the details in observer logs.</p> <pre>DGMGRL&gt; show configuration</pre>	DBA

Task	Description	Skills required
	<pre> Configuration - rds_dg Protection Mode:   MaxAvailability Members: orcl_d - Primary   database Warning: ORA-16824 : multiple warnings,   including fast-start failover-related warnings, detected for the database orcl_a - (*) Physical standby database (disabled) ORA-16661: the standby database needs to be reinstated Fast-Start Failover:   Enabled in Zero Data   Loss Mode Configuration Status: WARNING (status updated   25 seconds ago) DGMGRL&gt; </pre> <p>The following shows example output in <code>observer.log</code> .</p> <pre> \$ tail -f /tmp/observer.log Unable to connect to database using rds_custom_orcl_a [W000 2023-01-1 8T07:50:32.589+00:00] Primary database cannot be reached. ## Configure connectivity between the Oracle Peoplesoft application and the database

Task	Description	Skills required
Create and start the service in the primary database.	<p>You can avoid application configuration changes during a role transition by using a TNS entry that contains both the primary and standby database endpoints in the configuration. You can define two role-based database services to support both read/write and read-only workloads. In the following example, <code>orcl_rw</code> is the read/write service that's active on the primary database. <code>orcl_ro</code> is the read-only service and is active on the standby database that has been opened in read-only mode.</p> <pre data-bbox="594 1262 1027 1873">SQL&gt; select name,open _mode from v\$database; NAME OPEN_MODE ----- ORCL READ WRITE SQL&gt; exec dbms_serv ice.create_service ('orcl_rw','orcl_r w'); PL/SQL procedure successfully completed . SQL&gt; exec dbms_serv ice.create_service</pre>	DBA

Task	Description	Skills required
	<pre> ('orcl_ro','orcl_r o'); PL/SQL procedure successfully completed .  SQL&gt; exec dbms_serv ice.start_service( 'orcl_rw'); PL/SQL procedure successfully completed . SQL&gt; </pre>	
<p>Start the service in the standby database.</p>	<p>To start the service in the read-only standby database, use the following code.</p> <pre> SQL&gt; select name,open _mode from v\$database; NAME OPEN_MODE ----- ORCL READ ONLY WITH APPLY SQL&gt; exec dbms_serv ice.start_service( 'orcl_ro'); PL/SQL procedure successfully completed . SQL&gt; </pre>	DBA

Task	Description	Skills required
Automate starting the service when the primary DB is restarted.	<p>To automatically start the service in the primary database when it's restarted, use the following code.</p> <pre data-bbox="597 443 1029 1633">SQL&gt; CREATE OR REPLACE   TRIGGER TrgDgServ   ices after startup on   database   DECLARE   db_role VARCHAR(30);   db_open_mode VARCHAR(30);   BEGIN   SELECT DATABASE_ROLE,     OPEN_MODE INTO db_role,     db_open_mode FROM V   \$DATABASE;   IF db_role = 'PRIMARY'     THEN   DBMS_SERV 2 ICE.START   _SERVICE('orcl_rw');   END IF;   IF db_role = 'PHYSICAL   STANDBY' AND db_open_m   ode LIKE 'READ ONLY%'     THEN   DBMS_SERVICE.START_SER   VICE('orcl_ro');   END IF;   END;   /   Trigger created.   SQL&gt;</pre>	DBA

Task	Description	Skills required
Configure a connection between the read/write and read-only databases.	<p>You can use the following application-configuration example for the read/write and read-only connection.</p> <pre data-bbox="602 443 1029 1845">ORCL_RW = (DESCRIPTION = (CONNECT_TIMEOUT= 120)(RETRY_COUNT=2 0)(RETRY_DELAY=3)( TRANSPORT_CONNECT_ TIMEOUT=3) (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST=devpsftd b.*****.us-west-2 .rds.amazonaws.com) (PORT=1521)) (ADDRESS = (PROTOCOL = TCP)(HOST=psftread .*****.us-west-2. rds.amazonaws.com) (PORT=1521)) ) (CONNECT_DATA=(SERVIC E_NAME = orcl_rw)) ) ORCL_RO = (DESCRIPTION = (CONNECT_TIMEOUT= 120)(RETRY_COUNT=2 0)(RETRY_DELAY=3)( TRANSPORT_CONNECT_ TIMEOUT=3) (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST=devpsftd b.*****.us-west-2 .rds.amazonaws.com) (PORT=1521))</pre>	DBA

Task	Description	Skills required
	<pre>(ADDRESS = (PROTOCOL = TCP)(HOST=psftread .*****.us-west-2. ids.amazonaws.com) (PORT=1521)) ) (CONNECT_DATA=(SERVIC E_NAME = orcl_io)) )</pre>

# Automate AWS resource assessment

Created by Naveen Suthar (AWS), Arun Bagal (AWS), Manish Garg (AWS), and Sandeep Gawande (AWS)

**Code repository:** [infrastructure-assessment-iac-automation](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Infrastructure; Management & governance; Operations; Serverless

**AWS services:** Amazon Athena; AWS CloudTrail; AWS Lambda; Amazon S3; Amazon QuickSight

## Summary

This pattern describes an automated approach for setting up resource assessment capabilities by using the [AWS Cloud Development Kit \(AWS CDK\)](#). By using this pattern, operations teams gather resource auditing details in an automated manner and view the details of all resources deployed in an AWS account on a single dashboard. This is helpful in the following use cases:

- Identifying infrastructure as code (IaC) tools and isolating resources created by different IaC solutions such as [HashiCorp Terraform](#), [AWS CloudFormation](#), AWS CDK, and [AWS Command Line Interface \(AWS CLI\)](#)
- Fetching resource-auditing information

This solution will also help the leadership team obtain insights about the resources and activities in an AWS account from a single dashboard.

**Note:** [Amazon QuickSight](#) is a paid service. Before running it to analyze data and create a dashboard, review the [Amazon QuickSight pricing](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) roles and permissions with access to provision resources
- An [Amazon QuickSight account](#) created with access to [Amazon Simple Storage Service \(Amazon S3\)](#) and [Amazon Athena](#)
- AWS CDK version 2.55.1 or later installed
- [Python](#) version 3.9 or later installed

### Limitations

- This solution is deployed to a single AWS account.
- The solution will not track the events that happened before its deployment unless AWS CloudTrail was already set up and storing data in an S3 bucket.

### Product versions

- AWS CDK version 2.55.1 or later
- Python version 3.9 or later

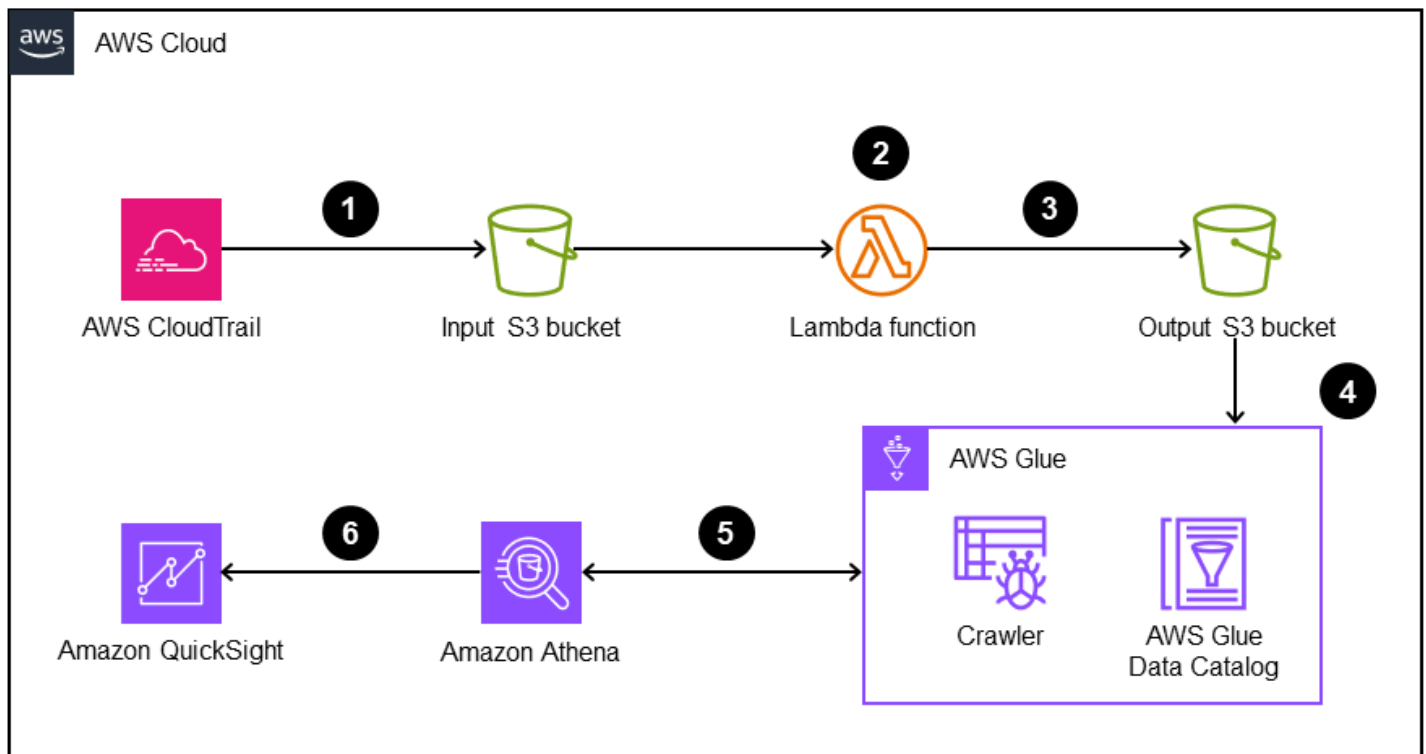

## Architecture

### Target technology stack

- Amazon Athena
- AWS CloudTrail
- AWS Glue
- AWS Lambda
- Amazon QuickSight
- Amazon S3

### Target architecture

The AWS CDK code will deploy all the resources that are required to set up resource-assessment capabilities in an AWS account. The following diagram shows the process of sending CloudTrail logs to AWS Glue, Amazon Athena, and QuickSight.

1. CloudTrail sends logs to an S3 bucket for storage.
2. An event notification invokes a Lambda function that processes the logs and generates filtered data.
3. The filtered data is stored in another S3 bucket.
4. An AWS Glue crawler is set up on the filtered data that is in the S3 bucket to create a schema in the AWS Glue Data Catalog table.
5. The filtered data is ready to be queried by Amazon Athena.
6. The queried data is accessed by QuickSight for visualization.

### Automation and scale

- This solution can be scaled from one AWS account to multiple AWS accounts if there is an organization-wide CloudTrail trail in AWS Organizations. By deploying CloudTrail at the organizational level, you can also use this solution to fetch resource-auditing details for all the required resources.

- This pattern uses AWS serverless resources to deploy the solution.

## Tools

### AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- [AWS CloudTrail](#) helps you audit the governance, compliance, and operational risk of your AWS account.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue crawler and an AWS Glue Data Catalog table.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon QuickSight](#) is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Code repository

The code for this pattern is available in the GitHub [infrastructure-assessment-iac-automation](#) repository.

The code repository contains the following files and folders:

- `lib` folder – The AWS CDK construct Python files used to create AWS resources
- `src/lambda_code` – The Python code that is run in the Lambda function
- `requirements.txt` – The list of all Python dependencies that must be installed

- `cdk.json` – The input file to provide values required to spin up resources

## Best practices

Set up monitoring and alerting for the Lambda function. For more information, see [Monitoring and troubleshooting Lambda functions](#). For general best practices when working with Lambda functions, see the [AWS documentation](#).

## Epics

### Set up your environment

Task	Description	Skills required
Clone the repo on your local machine.	To clone the repository, run the command <code>git clone https://github.com/aws-samples/infrastructure-assessment-iac-automation.git</code> .	AWS DevOps, DevOps engineer
Set up the Python virtual environment and install required dependencies.	<p>To set up the Python virtual environment, run the following commands.</p> <pre>cd infrastructure-assessment-iac-automation python3 -m venv .venv source .venv/bin/activate</pre> <p>To set up the required dependencies, run the command <code>pip install -r requirements.txt</code>.</p>	AWS DevOps, DevOps engineer

Task	Description	Skills required
Set up the AWS CDK environment and synthesize the AWS CDK code.	<ol style="list-style-type: none"> <li>To set up the AWS CDK environment in your AWS account, run the command <code>cdk bootstrap aws://ACCOUNT-NUMBER/REGION</code> .</li> <li>To convert the code to an AWS CloudFormation stack configuration, run the command <code>cdk synth</code>.</li> </ol>	AWS DevOps, DevOps engineer

### Set up AWS credentials on your local machine

Task	Description	Skills required
Export variables for the account and Region where the stack will be deployed.	<p>To provide AWS credentials for AWS CDK by using environment variables, run the following commands.</p> <pre>export CDK_DEFAULT_ACCOUNT=&lt;12 Digit AWS Account Number&gt; export CDK_DEFAULT_REGION=&lt;region&gt;</pre>	AWS DevOps, DevOps engineer
Set up the AWS CLI profile.	To set up the AWS CLI profile for the account, follow the instructions in the <a href="#">AWS documentation</a> .	AWS DevOps, DevOps engineer

## Configure and deploy the resource-assessment tool

Task	Description	Skills required
Deploy resources in the account.	<p>To deploy resources in the AWS account by using AWS CDK, do the following:</p> <ol style="list-style-type: none"><li>1. In the root of the cloned repository, in the <code>cdk.json</code> file, provide inputs for the following parameters:<ul style="list-style-type: none"><li>• <code>s3_context</code></li><li>• <code>ct_context</code></li><li>• <code>kms_context</code></li><li>• <code>lambda_context</code></li><li>• <code>glue_context</code></li><li>• <code>qs_context</code></li></ul></li></ol> <p>These values define resource configurations and nomenclature. Default values are set and can be changed if required.</p> <p><b>Note:</b> To avoid an error saying that the S3 bucket already exists, make sure to provide unique names for <code>s3_context</code> in the <code>ct</code> and <code>output</code> sections.</p> <ol style="list-style-type: none"><li>2. To deploy resources, run the command <code>cdk deploy</code>.</li></ol>	AWS DevOps

Task	Description	Skills required
	<p>The <code>cdk deploy</code> command creates a CloudTrail resource to log events and save the log file in the input S3 bucket. The trail's log files will be processed by the Lambda function. The filtered results are stored in the output S3 bucket and are ready to be consumed by Amazon Athena and Amazon QuickSight.</p>	

Task	Description	Skills required
Run the AWS Glue crawler and create the Data Catalog table.	<p>An <a href="#">AWS Glue crawler</a> is used to keep the data schema dynamic. The solution creates and updates partitions in the <a href="#">AWS Glue Data Catalog table</a> by running the crawler periodically as defined by the AWS Glue crawler scheduler . After the data is available in the output S3 bucket, use the following steps to run the AWS Glue crawler and create the Data Catalog table schema for testing:</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and navigate to the AWS Glue console.</li><li>2. In the navigation pane, under <b>Data Catalog</b>, choose <b>Crawlers</b>.</li><li>3. Select the <code>iac-tool-qa-resource-iac-js-on-crawler</code> crawler.</li><li>4. Run the crawler.</li><li>5. After the crawler runs successfully, it creates an AWS Glue Data Catalog table. AWS QuickSight will use the table to visualize the data.</li></ol>	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<b>Note:</b> The AWS CDK code configures the AWS Glue crawler to run at a particular time, but you can also run it on demand.	
Deploy the QuickSight construct.	<ol style="list-style-type: none"><li>1. To deploy the QuickSight construct, uncomment the code between <code>#QuickSight setup - start</code> and <code>#QuickSight setup - ends in resource_iac_tool_stack.py</code>.</li><li>2. After you uncomment, run the <code>cdk deploy</code> command to create QuickSight DataSource and QuickSight DataSet in the QuickSight account.</li></ol>	AWS DevOps, DevOps engineer

Task	Description	Skills required
Create the QuickSight dashboard.	<p>To create the example QuickSight dashboard and analysis, do the following:</p> <ol style="list-style-type: none"><li>1. Navigate to the QuickSight console and select the AWS Region where resources are deployed.</li><li>2. In the navigation pane, choose <b>Datasets</b>, and validate that a dataset named <code>ct-operations-iac-ds</code> has been created in the Amazon QuickSight dataset.</li></ol> <p>If you don't see the dataset, redeploy the QuickSight construct.</p> <ol style="list-style-type: none"><li>3. Select the <code>ct-operations-iac-ds</code> dataset, and choose <b>USE IN ANALYSIS</b>.</li><li>4. Select the default sheet.</li><li>5. Select the respective columns from the field list on the left side.</li><li>6. After selecting the required columns, select the appropriate visual type to view the data.</li></ol> <p>For more information, see <a href="#">Starting an analysis in</a></p>	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<a href="#">Amazon QuickSight</a> and <a href="#">Visual types in Amazon QuickSight</a> .	

### Clean up all AWS resources in the solution

Task	Description	Skills required
Remove the AWS resources.	<ol style="list-style-type: none"> <li>To remove AWS resources deployed by the solution, run the command <code>cdk destroy</code>.</li> <li>Delete all objects from the two S3 buckets, and then remove the buckets.</li> </ol> <p>For more information, see <a href="#">Deleting a bucket</a>.</p>	AWS DevOps, DevOps engineer

### Set up additional features on top of the AWS resource-assessment tool automation

Task	Description	Skills required
Monitor and clean up manually created resources.	(Optional) If your organization has compliance requirements to create resources using IaC tools, you can achieve compliance by using AWS resource-assessment tool automation to fetch manually provisioned resources. You can also use the tool to import the resources to an IaC tool or to re-create them. To	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<p>monitor manually provisioned resources, perform the following high-level tasks:</p> <ol style="list-style-type: none"><li data-bbox="592 386 1023 514">1. Deploy AWS resource-assessment tool automation.</li><li data-bbox="592 537 1023 905">2. Set up a Lambda function to query the Athena tables on a daily basis, find the relevant data about manually provisioned resources, and export it to a comma-separated values (CSV) file.</li><li data-bbox="592 928 1023 1106">3. After the Lambda function runs, a notification with the required data can be sent to respective stakeholders.</li><li data-bbox="592 1129 1023 1262">4. For longer retention, the .csv file can be stored in the S3 bucket.</li><li data-bbox="592 1285 1023 1507">5. Based on the information in the .csv file, delete the manually created resources or import them to an existing IaC solution.</li></ol>	

## Troubleshooting

Issue	Solution
AWS CDK returns errors.	For help with AWS CDK issues, see <a href="#">Troubleshooting common AWS CDK issues</a> .

## Additional information

### Multiple accounts

To set up the AWS CLI credential for multiple accounts, use AWS profiles. For more information, see the *Configure multiple profiles* section in [Set up the AWS CLI](#).

### AWS CDK commands

When working with AWS CDK, keep in mind the following useful commands:

- Lists all stacks in the app

```
cdk ls
```

- Emits the synthesized AWS CloudFormation template

```
cdk synth
```

- Deploys the stack to your default AWS account and Region

```
cdk deploy
```

- Compares the deployed stack with the current state

```
cdk diff
```

- Opens the AWS CDK documentation

```
cdk docs
```

# Install SAP systems automatically by using open-source tools

Created by Guilherme Sesterheim (AWS)

<b>Code repository:</b> <a href="#">Main repository</a>	<b>Environment:</b> Production	<b>Technologies:</b> DevOps
<b>Workload:</b> SAP	<b>AWS services:</b> Amazon EC2; Amazon S3	

## Summary

This pattern shows how to automate SAP systems installation by using open-source tools to create the following resources:

- An SAP S/4HANA 1909 database
- An SAP ABAP Central Services (ASCS) instance
- An SAP Primary Application Server (PAS) instance

HashiCorp Terraform creates the SAP system's infrastructure and Ansible configures the operating system (OS) and installs SAP applications. Jenkins runs the installation.

This setup turns SAP systems installation into a repeatable process, which can help increase deployment efficiency and quality.

**Note:** The example code provided in this pattern works for both high-availability (HA) systems and non-HA systems.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket that contains all of your SAP media files
- An AWS Identity and Access Management (IAM) principal with an [access key and secret key](#), and that has the following permissions:

- **Read only permissions:** Amazon Route 53, AWS Key Management Service (AWS KMS)
- **Read and write permissions:** Amazon S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS), IAM, Amazon CloudWatch, Amazon DynamoDB
- A Route 53 [private hosted zone](#)
- A subscription to the [Red Hat Enterprise Linux for SAP with HA and Update Services 8.2](#) Amazon Machine Image (AMI) in Amazon Marketplace
- An [AWS KMS customer managed key](#)
- A [Secure Shell \(SSH\) key pair](#)
- An [Amazon EC2 security group](#) that allows SSH connection on port 22 from the hostname where you install Jenkins (the hostname is most likely **localhost**)
- [Vagrant](#) by HashiCorp installed and configured
- [VirtualBox](#) by Oracle installed and configured
- Familiarity with Git, Terraform, Ansible, and Jenkins

## Limitations

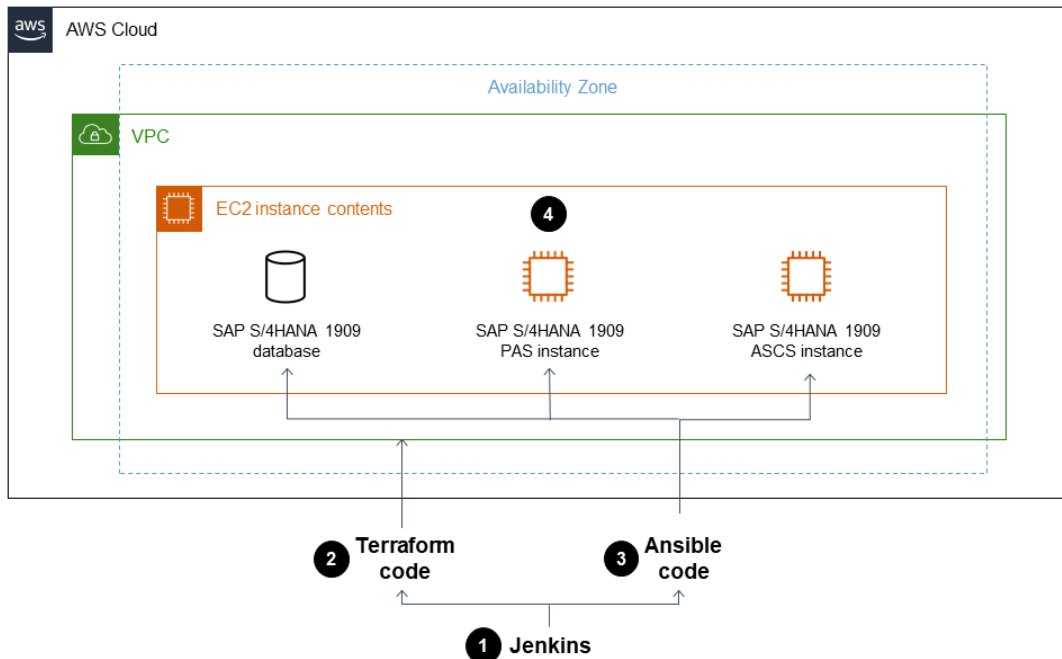

- Only SAP S/4HANA 1909 is fully tested for this specific scenario. The example Ansible code in this pattern requires modification if you use another version of SAP HANA.
- The example procedure in this pattern works for Mac OS and Linux operating systems. Some of the commands can be run only in Unix-based terminals. However, you can achieve a similar result by using different commands and a Windows OS.

## Product versions

- SAP S/4HANA 1909
- Red Hat Enterprise Linux (RHEL) 8.2 or higher versions

## Architecture

The following diagram shows an example workflow that uses open-source tools to automate SAP systems installation in an AWS account:

The diagram shows the following workflow:

1. Jenkins orchestrates running the SAP system installation by running Terraform and Ansible code.
2. Terraform code builds the SAP system's infrastructure.
3. Ansible code configures the OS and installs SAP applications.
4. An SAP S/4HANA 1909 database, an ASCS instance, and PAS instance that include all defined prerequisites are installed on an Amazon EC2 instance.

**Note:** The example setup in this pattern automatically creates an Amazon S3 bucket in your AWS account to store the Terraform state file.

## Technology stack

- Terraform
- Ansible
- Jenkins
- An SAP S/4HANA 1909 database

- An SAP ASCS instance
- An SAP PAS instance
- Amazon EC2

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to protect your data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

### Other tools

- [HashiCorp Terraform](#) is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.
- [Ansible](#) is an open-source configuration as code (CaC) tool that helps automate applications, configurations, and IT infrastructure.
- [Jenkins](#) is an open-source automation server that enables developers to build, test, and deploy their software.

### Code

The code for this pattern is available in the GitHub [aws-install-sap-with-jenkins-ansible](#) repository.

# Epics

## Configure the prerequisites

Task	Description	Skills required
Add your SAP media files to an Amazon S3 bucket.	<p><a href="#">Create an Amazon S3 bucket</a> that contains all of your SAP media files.</p> <p><b>Important:</b> Make sure that you follow the AWS Launch Wizard's folder hierarchy for <b>S/4HANA</b> in the <a href="#">Launch Wizard documentation</a>.</p>	Cloud administrator
Install VirtualBox.	Install and configure <a href="#">VirtualBox</a> by Oracle.	DevOps engineer
Install Vagrant.	Install and configure <a href="#">Vagrant</a> by HashiCorp.	DevOps engineer
Configure your AWS account.	<p>1. Verify that you have an IAM principal with an <a href="#">access key and secret key</a>, and that has the following permissions:</p> <ul style="list-style-type: none"> <li>• <b>Read only permissions:</b> Amazon Route 53, AWS Key Management Service (AWS KMS)</li> <li>• <b>Read and write permissions:</b> Amazon S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS),</li> </ul>	General AWS

Task	Description	Skills required
	<p>IAM, Amazon CloudWatch, Amazon DynamoDB</p> <ol style="list-style-type: none"> <li>2. Save the IAM principal's access key and secret key for reference later.</li> <li>3. Create a Route 53 <a href="#">private hosted zone</a>, if you don't have one already. Save the zone name (for example, <b>sapteam.net</b>) for reference later.</li> <li>4. Subscribe to the <a href="#">Red Hat Enterprise Linux for SAP with HA and Update Services 8.2</a> AMI in Amazon Marketplace. Save the <b>AMI ID</b> (for example, <b>ami-0000000</b>) for reference later.</li> <li>5. Create an <a href="#">AWS KMS customer managed key</a>. Save the KMS key's <a href="#">Amazon Resource Name (ARN)</a> for reference later.</li> </ol> <p><b>Note:</b> The following is an example AWS KMS customer managed key ARN: <b>arn:aws:kms:us-east-1:123412341234:key/uuid</b></p> <ol style="list-style-type: none"> <li>6. Create an <a href="#">SSH key pair</a>. Save the key pair's name</li> </ol>	

Task	Description	Skills required
	<p>and .pem file for reference later.</p> <p>7. Create an <a href="#">Amazon EC2 security group</a> that allows SSH connection on port 22 from the hostname where you install Jenkins. Save the <b>security group ID</b> for reference later.</p> <p><b>Note:</b> The hostname is most likely <b>localhost</b>.</p>	

## Build and run your SAP installation

Task	Description	Skills required
Clone the code repository from GitHub.	Clone the <a href="#">aws-install-sap-with-jenkins-ansible</a> repository on GitHub.	DevOps engineer
Start the Jenkins service.	<p>Open the Linux terminal. Then, navigate to the local folder that contains the cloned code repository folder and run the following command:</p> <pre data-bbox="597 1549 1026 1625">sudo vagrant up</pre> <p><b>Note:</b> The Jenkins startup takes about 20 minutes. The command returns a <b>Service</b></p>	DevOps engineer

Task	Description	Skills required
	<b>is up and running</b> message when successful.	
Open Jenkins in a web browser and log in.	<ol style="list-style-type: none"><li>1. In a web browser, enter <b>http://localhost:5555</b>. Jenkins opens.</li><li>2. Log in to Jenkins by using <b>admin</b> for the username and <b>my_secret_pass_from_vault</b> for the password.</li></ol>	DevOps engineer

Task	Description	Skills required
Configure your SAP system installation parameters.	<ol style="list-style-type: none"><li>1. In Jenkins, choose <b>Manage Jenkins</b>. Then, choose <b>Manage Credentials</b>. A list of credential variables that you can configure appears.</li><li>2. Configure all of the following credential variables:<ul style="list-style-type: none"><li>• For <b>AWS_ACCOUNT_CREDENTIALS</b>, enter your IAM principal's access key ID and secret access key ID.</li><li>• For <b>AMI_ID</b>, enter the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 AMI's AMI ID.</li><li>• For <b>KMS_KEY_ARN</b>, enter your AWS KMS customer managed key's ARN.</li><li>• For <b>SSH_KEYPAIR_NAME</b>, enter the name of your SSH key pair, without entering the <b>.pem</b> file type.</li><li>• For <b>SSH_KEYPAIR_FILE</b>, enter the full name of your key pair's <b>.pem</b> file (for example, <b>mykeypair.pem</b>). Make sure that you also upload the key pairs' <b>.pem</b> file to Jenkins.</li></ul></li></ol>	AWS systems administrator, DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• For <b>S3_ROOT_FOLDER_INSTALL_FILES</b>, enter the name of the Amazon S3 bucket—and folder, if applicable—(for example, <b>s3://my-media-bucket/S4H1909</b>) that contains your SAP media files.</li><li>• For <b>PRIVATE_DNS_ZONE_NAME</b>, enter the name of your Route 53 private hosted zone (for example, <b>myprivatecompanyurl.net</b>).</li><li>• For <b>VPC_ID</b>, enter the VPC ID (for example, <b>vpc-12345</b>) of the Amazon VPC that you're creating the SAP resources in.</li><li>• For <b>SUBNET_IDS</b>, enter two public subnet IDs if you're working in a test environment (for future HA capabilities). If you're working in a production environment, it's a best practice to use two private subnets with a bastion host.</li><li>• For <b>SECURITY_GROUP_ID</b>, enter the ID of the Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you installed Jenkins.</li></ul>	

Task	Description	Skills required
	<p><b>Note:</b> You can configure the other nonrequired parameters as needed, based on your use case. For example, you can change the SAP system ID (SID) of the instances, default password, names, and tags for your SAP system. All of the required variables have <b>(Required)</b> at the beginning of their names.</p>	

Task	Description	Skills required
Run you SAP system installation.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 405">1. In Jenkins, choose <b>Jenkins Home</b>. Then, choose <b>SAP Hana+ASCS+PAS 3 Instances</b>.</li><li data-bbox="592 426 1027 510">2. Choose <b>Spin up and install</b>. Then, choose <b>Main</b>.</li><li data-bbox="592 531 906 573">3. Choose <b>Build now</b>.</li></ol> <p data-bbox="592 646 1027 919">For information on the pipeline steps, see the <b>Understanding the pipeline steps</b> section of <a href="#">Automating SAP installation with open-source tools</a> on the AWS Blog.</p> <p data-bbox="592 961 1027 1329"><b>Note:</b> If an error occurs, move your cursor over the red error box that appears and choose <b>Logs</b>. The logs for the pipeline step that errored out appear. Most errors occur because of incorrect parameter settings.</p>	DevOps engineer, AWS systems administrator

# Automate AWS Service Catalog portfolio and product deployment by using AWS CDK

Created by Sandeep Gawande (AWS), RAJNEESH TYAGI (AWS), and Viyoma Sachdeva (AWS)

**Code repository:** [aws-cdk-servicatalog-automation](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Infrastructure; Management & governance

**Workload:** Open-source

**AWS services:** AWS Service Catalog; AWS CDK

## Summary

AWS Service Catalog helps you centrally manage catalogs of IT services, or *products*, that are approved for use in your organization's AWS environment. A collection of products is called a *portfolio*, and a portfolio also contains configuration information. With AWS Service Catalog, you can create a customized portfolio for each type of user in your organization and then grant access to the appropriate portfolio. Those users can then quickly deploy any product they need from within the portfolio.

If you have a complex networking infrastructure, such as multi-Region and multi-account architectures, it is recommended that you create and manage Service Catalog portfolios in a single, central account. This pattern describes how to use AWS Cloud Development Kit (AWS CDK) to automate creation of Service Catalog portfolios in a central account, grant end users access to them, and then, optionally, provision products in one or more target AWS accounts. This ready-to-use solution creates the Service Catalog portfolios in the source account. It also, optionally, provisions products in target accounts by using AWS CloudFormation stacks and helps you configure TagOptions for the products:

- **AWS CloudFormation StackSets** – You can use StackSets to launch Service Catalog products across multiple AWS Regions and accounts. In this solution, you have the option to automatically provision products when you deploy this solution. For more information, see [Using AWS CloudFormation StackSets](#) (Service Catalog documentation) and [StackSets concepts](#) (CloudFormation documentation).

- **TagOption library** – You can manage tags on provisioned products by using TagOption library. A *TagOption* is a key-value pair managed in AWS Service Catalog. It is not an AWS tag, but it serves as a template for creating an AWS tag based on the TagOption. For more information, see [TagOption library](#) (Service Catalog documentation).

## Prerequisites and limitations

### Prerequisites

- An active AWS account that you want to use as the source account for administering Service Catalog portfolios.
- If you are using this solution to provision products in one or more target accounts, the target account must already exist and be active.
- AWS Identity and Access Management (IAM) permissions to access AWS Service Catalog, AWS CloudFormation, and AWS IAM.

### Product versions

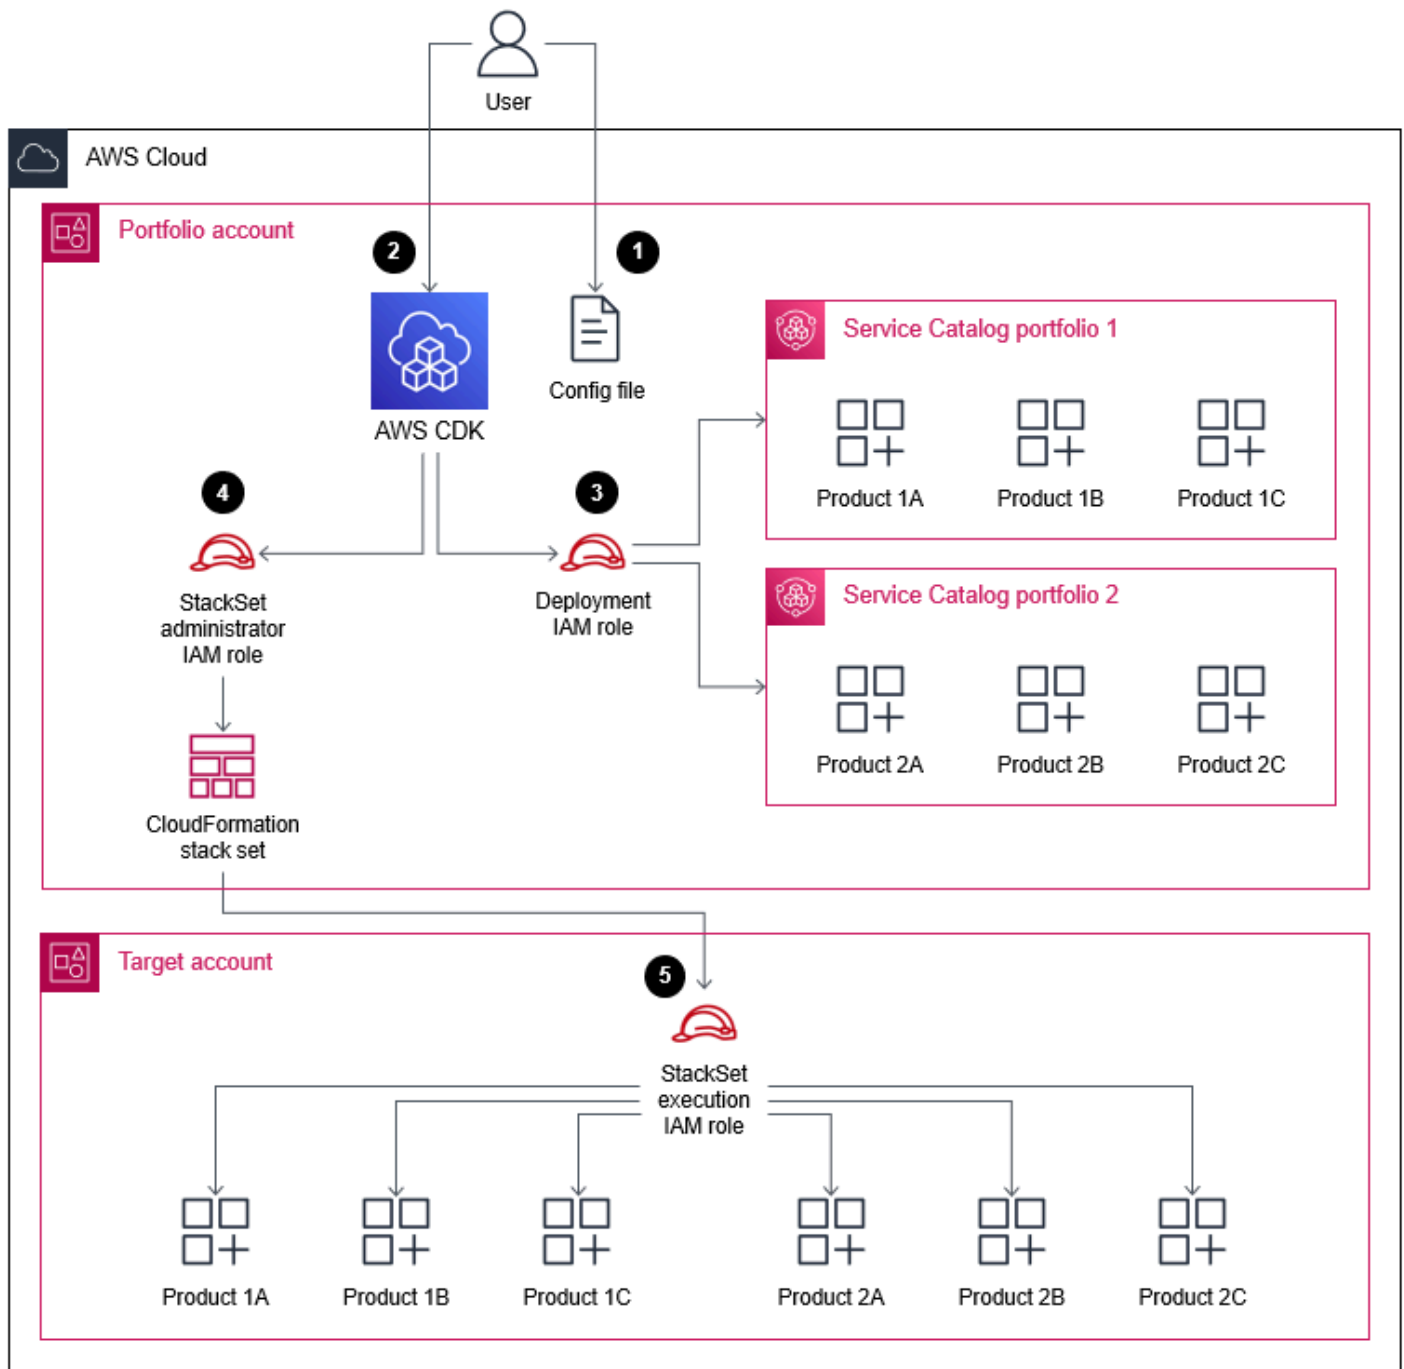

- AWS CDK version 2.27.0

## Architecture

### Target technology stack

- Service Catalog portfolios in a centralized AWS account
- Service Catalog products deployed in target account

### Target architecture

1. In the portfolio (or *source*) account, you update the **config.json** file with the AWS account, AWS Region, IAM role, portfolio, and product information for your use case.
2. You deploy the AWS CDK application.
3. The AWS CDK application assumes the deployment IAM role and creates the Service Catalog portfolios and products defined in the **config.json** file.

If you configured StackSets to deploy products in a target account, the process continues. If you didn't configure StackSets to provision any products, then the process is complete.

4. The AWS CDK application assumes the **StackSet administrator** role and deploys the AWS CloudFormation stack set you defined in the **config.json** file.
5. In the target account, StackSets assumes the **StackSet execution** role and provisions the products.

## Tools

### AWS services

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS CDK Toolkit](#) is a command line cloud development kit that helps you interact with your AWS CDK app.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Service Catalog](#) helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

### Code repository

The code for this pattern is available on GitHub, in the [aws-cdk-servicecatalog-automation](#) repository. The code repository contains the following files and folders:

- **cdk-sevicecatalog-app** – This folder contains the AWS CDK application for this solution.
- **config** – This folder contains the **config.json** file and the CloudFormation template for deploying the products in the Service Catalog portfolio.
- **config/config.json** – This file contains all of the configuration information. You update this file to customize this solution for your use case.
- **config/templates** – This folder contains the CloudFormation templates for the Service Center products.

- **setup.sh** – This script deploys the solution.
- **uninstall.sh** – This script deletes the stack and all of the AWS resources created when deploying this solution.

To use the sample code, follow the instructions in the [Epics](#) section.

## Best practices

- IAM roles used to deploy this solution should adhere to the [principle of least-privilege](#) (IAM documentation).
- Adhere to the [Best practices for developing cloud applications with AWS CDK](#) (AWS blog post).
- Adhere to the [AWS CloudFormation best practices](#) (CloudFormation documentation).

## Epics

### Set up your environment

Task	Description	Skills required
Install the AWS CDK Toolkit.	<p>Make sure you have AWS CDK Toolkit installed. Enter the following command to confirm whether it is installed and check the version.</p> <pre>cdk --version</pre> <p>If AWS CDK Toolkit is not installed, then enter the following command to install it.</p> <pre>npm install -g aws-cdk@2.27.0</pre>	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<p>If AWS CDK Toolkit version is earlier than 2.27.0, then enter the following command to update it to version 2.27.0.</p> <pre data-bbox="597 426 1027 541">npm install -g aws-cdk@2.27.0 --force</pre>	
Clone the repository.	<p>Enter the following command. In <i>Clone the repository</i> in the <a href="#">Additional information</a> section, you can copy the full command containing the URL for the repository. This clones the <a href="#">aws-cdk-servicecatalog-automation</a> repository from GitHub.</p> <pre data-bbox="597 1087 1027 1203">git clone &lt;repository-URL&gt;.git</pre> <p>This creates a <code>cd aws-cdk-servicecatalog-automation</code> folder in the target directory. Enter the following command to navigate into this folder.</p> <pre data-bbox="597 1556 1027 1671">cd aws-cdk-servicecatalog-automation</pre>	AWS DevOps, DevOps engineer

Task	Description	Skills required
Set up AWS credentials.	<p>Enter the following commands. These export the following variables, which define the AWS account and Region where you are deploying the stack.</p> <pre data-bbox="594 537 1027 695">export CDK_DEFAULT_ACCOUNT=&lt;12-digit AWS account number&gt;</pre> <pre data-bbox="594 726 1027 846">export CDK_DEFAULT_REGION=&lt;AWS Region&gt;</pre> <p>AWS credentials for AWS CDK are provided through environment variables.</p>	AWS DevOps, DevOps engineer
Configure permissions for end user IAM roles.	<p>If you are going to use IAM roles to grant access to the portfolio and the products in it, the roles must have permissions to be assumed by the <b>servicecatalog.amazonaws.com</b> service principal. For instructions about how to grant these permissions, see <a href="#">Enabling trusted access with Service Catalog</a> (AWS Organizations documentation).</p>	AWS DevOps, DevOps engineer

Task	Description	Skills required
Configure IAM roles required by StackSets.	<p>If you are using StackSets to automatically provision products in target accounts, you need to configure the IAM roles that administer and run the stack set.</p> <ol style="list-style-type: none"><li data-bbox="592 541 1027 1108">1. In the source account, confirm whether the <code>AWSCloudFormationStackSetAdministrationRole</code> already exists. In the target accounts, confirm whether <code>AWSCloudFormationStackSetExecutionRole</code> already exists. If these roles already exist, you can skip to the next epic.</li><li data-bbox="592 1129 1027 1549">2. Follow the instructions in <a href="#">Grant self-managed permissions</a> (IAM documentation) to create the stack set administration role in the portfolio account and create the execution role in each target account.</li></ol>	AWS DevOps, DevOps engineer

## Customize and deploy the solution

Task	Description	Skills required
Create the CloudFormation templates.	In the config/templates folder, create CloudFormation templates for any products that you want to include in your portfolios. For more information, see <a href="#">Working with AWS CloudFormation templates</a> (CloudFormation documentation).	App developer, AWS DevOps, DevOps engineer
Customize the config file.	In the config folder, open the <b>config.json</b> file and define the parameters as appropriate for your use case. The following parameters are required unless otherwise noted: <ul style="list-style-type: none"><li>• In the <b>portfolios</b> section, define the following parameters to create one or more Service Catalog portfolios:<ul style="list-style-type: none"><li>• <b>portfolioName</b> – The name of the portfolio.</li><li>• <b>providerName</b> – The name of the person, team, or organization that manages the portfolio.</li><li>• <b>description</b> – A brief description of the portfolio.</li></ul></li></ul>	App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>roles</code> – (Optional) Names of any IAM roles that should have access to this portfolio. Users who have this role can access the products in this portfolio.</li><li>• <code>users</code> – (Optional) Names of any IAM users who should have access to this portfolio and its products.</li><li>• <code>groups</code> – (Optional) Names of any IAM user groups that should have access to this portfolio and its products.</li></ul> <p><b>Warning:</b> IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.</p> <p><b>Important:</b> <code>roles</code>, <code>users</code>, and <code>groups</code> are all optional parameters, but if you do not define one of these parameters, then no one</p>	

Task	Description	Skills required
	<p>can view the portfolio products in the Service Catalog console. Define at least one of these parameters. For more information, see <a href="#">Grant permissions to Service Catalog end users</a> (Service Catalog documentation).</p> <ul style="list-style-type: none"><li>• (Optional) In the <code>tagOption</code> section, define TagOptions for the products:<ul style="list-style-type: none"><li>• <code>key</code> – Name of the TagOption key</li><li>• <code>value</code> – Allowed string values for the TagOption</li></ul></li></ul> <p>For more information, see <a href="#">TagOption library</a> (Service Catalog documentation).</p> <ul style="list-style-type: none"><li>• In the <code>products</code> section, define the following parameters for the products:<ul style="list-style-type: none"><li>• <code>portfolioName</code> – The name of the portfolio where you want to add the product. You can specify only one portfolio</li><li>• <code>productName</code> – The name of the product.</li></ul></li></ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <code>owner</code> – The owner of the product.</li> <li>• <code>productVersionName</code> – The name of the product version in string value, such as <code>v1</code>.</li> <li>• <code>templatePath</code> – The file path for the CloudFormation template for the product.</li> <li>• <code>deployWithStackSets</code> – (Optional) Specify one or more accounts and Regions where you want to use StackSets to automatically provision products in the portfolios. If you use this deployment option, all of the following parameters in this section are required: <ul style="list-style-type: none"> <li>• <code>accounts</code> – The target accounts.</li> <li>• <code>regions</code> – The target Regions.</li> <li>• <code>stackSetAdministrationRoleName</code> – The name of the IAM role used to administer the StackSets configuration. Do not change</li> </ul> </li> </ul>	

Task	Description	Skills required
	<p>this value. This role must have this exact name.</p> <ul style="list-style-type: none"> <li>• <code>stackSetExecutionRoleName</code> – The name of the IAM role in the target account that deploys the stack instances. Do not change this value. This role must have this exact name.</li> </ul> <p>For an example of a completed config file, see <i>Sample config file</i> in the <a href="#">Additional information</a> section.</p>	
Deploy the solution.	<p>Enter the following command. This deploys the AWS CDK app and provisions the Service Catalog portfolios and products as specified in the <b>config.json</b> file.</p> <pre>sh +x setup.sh</pre>	App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required
Verify the deployment.	<p>Verify successful deployment by doing the following:</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console with credentials that can access one or more of the portfolios you defined in the config file.</li><li>2. Open the Service Catalog console at <a href="https://console.aws.amazon.com/servicecatalog/">https://console.aws.amazon.com/servicecatalog/</a>.</li><li>3. In the navigation pane, under <b>Provisioning</b>, choose <b>Products</b>. Verify that you see a list of products that you specified for the portfolio.</li><li>4. Follow the instructions in <a href="#">Launching a product</a> (Service Catalog documentation) to launch one of the available products. Confirm that the available product versions and tags match the values you provided in the config file.</li><li>5. If you chose to automatically provision products in one or more target accounts by using</li></ol>	General AWS

Task	Description	Skills required
	<p>StackSets, do the following :</p> <ol style="list-style-type: none"><li data-bbox="630 310 1013 541">a. Sign in with credentials that give you permissions to view the provisioned products in one of the target accounts.</li><li data-bbox="630 562 1013 793">b. In the Service Catalog console, in the navigation pane, under <b>Provisioning</b>, choose <b>Provisioned products</b>.</li><li data-bbox="630 814 1013 940">c. Confirm that the expected products appear in the list.</li></ol>	

Task	Description	Skills required
(Optional) Update the portfolios and products.	<p>If you want to use this solution to update the portfolios or products or to provision new products:</p> <ol style="list-style-type: none"> <li>1. Make the required changes in the <b>config.json</b> file.</li> <li>2. Add or modify any CloudFormation templates as needed in the <code>config/template</code> folder.</li> <li>3. Redeploy the solution.</li> </ol> <p>For example, you can add additional portfolios or provision more resources. The AWS CDK app implements only the changes. If there are no changes to previously deployed portfolios or products, the redeployment doesn't affect them.</p>	App developer, DevOps engineer, General AWS

## Clean up the solution

Task	Description	Skills required
(Optional) Remove AWS resources deployed by this solution.	<p>If you want to delete a provisioned product, follow the instructions in <a href="#">Deleting provisioned products</a> (Service Catalog documentation).</p>	AWS DevOps, DevOps engineer, App developer

Task	Description	Skills required
	<p>If you want to delete all the resources created by this solution, enter the following command.</p> <pre>sh uninstall.sh</pre>

# Automate event-driven backups from CodeCommit to Amazon S3 using CodeBuild and CloudWatch Events

Created by Kirankumar Chandrashekar (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Storage & backup

**Workload:** All other  
workloads

**AWS services:** Amazon S3;  
Amazon CloudWatch; AWS  
CodeBuild; AWS CodeCommit

## Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS CodeCommit to host secure Git-based repositories. CodeCommit is a fully managed source control service. However, if a CodeCommit repository is accidentally deleted, its contents are also deleted and [cannot be restored](#).

This pattern describes how to automatically back up a CodeCommit repository to an Amazon Simple Storage Service (Amazon S3) bucket after a change is made to the repository. If the CodeCommit repository is later deleted, this backup strategy provides you with a point-in-time recovery option.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing CodeCommit repository, with user access configured according to your requirements. For more information, see [Setting up for AWS CodeCommit](#) in the CodeCommit documentation.
- An S3 bucket for uploading the CodeCommit backups.

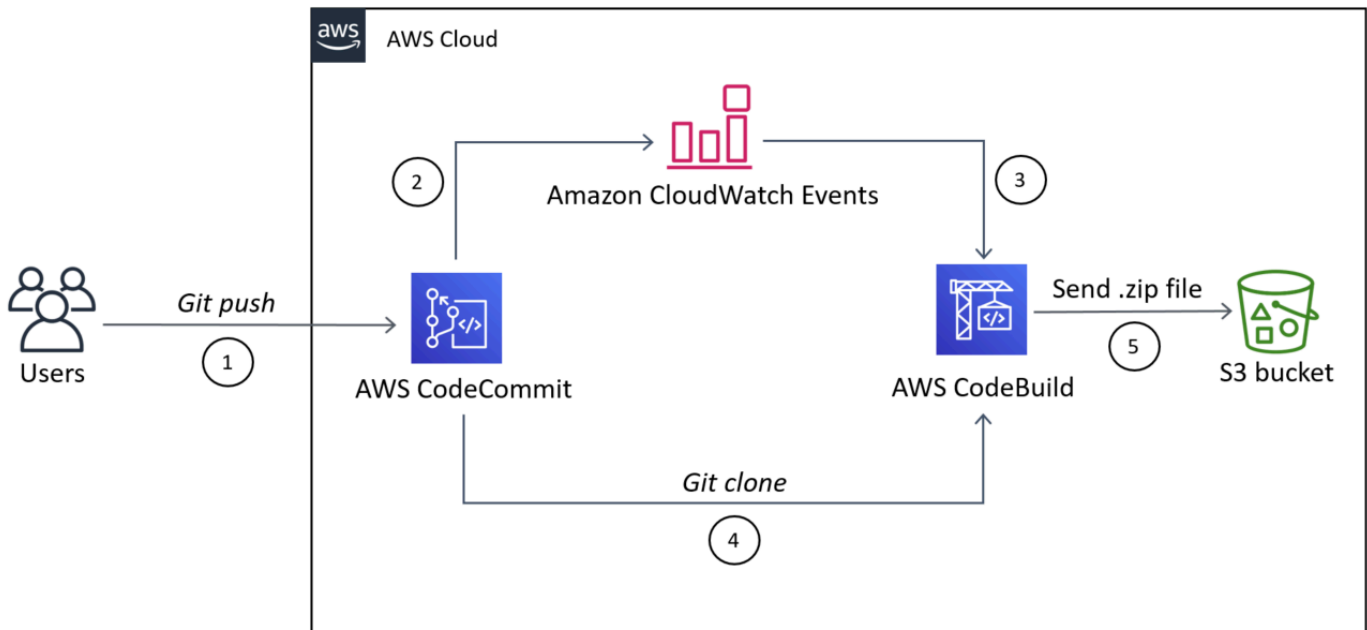

### Limitations

- This pattern automatically backs up all of your CodeCommit repositories. If you want to back up individual CodeCommit repositories, you must modify the Amazon CloudWatch Events rule.

## Architecture

The following diagram illustrates the workflow for this pattern.

The workflow consists of the following steps:

1. Code is pushed to a CodeCommit repository.
2. The CodeCommit repository notifies CloudWatch Events of a repository change (for example, a `git push` command).
3. CloudWatch Events invokes AWS CodeBuild and sends it the CodeCommit repository information.
4. CodeBuild clones the entire CodeCommit repository and packages it into a `.zip` file.
5. CodeBuild uploads the `.zip` file to an S3 bucket.

## Technology stack

- CloudWatch Events
- CodeBuild
- CodeCommit
- Amazon S3

## Tools

- [Amazon CloudWatch Events](#) – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [AWS CodeBuild](#) – CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.
- [AWS CodeCommit](#) – CodeCommit is a fully managed source control service that hosts secure Git-based repositories.
- [AWS Identity and Access Management \(IAM\)](#) – IAM is a web service that helps you securely control access to AWS resources.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

## Epics

### Create a CodeBuild project

Task	Description	Skills required
Create a CodeBuild service role.	Sign in to the AWS Management Console and open the IAM console. Choose <b>Roles</b> , and choose <b>Create role</b> . Create a service role for CodeBuild to clone the CodeCommit repository, upload files to the S3 bucket, and send logs to Amazon CloudWatch. For more	Cloud administrator

Task	Description	Skills required
	information, see <a href="#">Create a CodeBuild service role</a> in the CodeBuild documentation.	
Create a CodeBuild project.	On the CodeBuild console, choose <b>Create CodeBuild project</b> . Create a CodeBuild project by using the <code>buildspec.yml</code> template from the <b>Additional information</b> section. For help with this story, see <a href="#">Create a build project</a> in the CodeBuild documentation.	Cloud administrator

## Create and configure the CloudWatch Events rule

Task	Description	Skills required
Create an IAM role for CloudWatch Events.	On the IAM console, choose <b>Roles</b> and create an IAM role for CloudWatch Events. For more information about this, see <a href="#">CloudWatch Events IAM role</a> in the IAM documentation.  <b>Important:</b> You must add <code>codebuild:StartBuild</code> permissions to the IAM role for CloudWatch Events.	Cloud administrator
Create a CloudWatch Events rule.	1. On the CloudWatch console, choose <b>Events</b> and then choose <b>Rules</b> .	Cloud administrator

Task	Description	Skills required
	<p>Choose <b>Create rule</b>, and use the CloudWatch Events rule from the <i>Additional information</i> section. This creates a rule that listens for event changes (for example, <code>git push</code> or <code>git commit</code> commands) in your CodeCommit repositories. For more information, see <a href="#">Create a CloudWatch Events rule for a CodeCommit source</a> in the AWS CodePipeline documentation.</p> <p>2. Choose <b>Targets</b>, choose <b>Topic</b>, and then choose <b>Configure input</b>. Choose <b>Input transformer</b>, and use the input path and input template from the <i>Additional information</i> section. This ensures that your CodeCommit repository details are parsed and sent as environment variables to the CodeBuild project. For more information, see the <a href="#">input transformer tutorial</a> in the CloudWatch documentation.</p> <p>3. Choose <b>Configure details</b>, and enter a name and</p>	

Task	Description	Skills required
	<p>description for the rule. Choose <b>Create rule</b>.</p> <p><b>Important:</b> This CloudWatch Events rule describes changes in all your CodeCommit repositories. You must modify the CloudWatch Events rule if you want to back up individual CodeCommit repositories or use separate S3 buckets for different repository backups.</p>

}
```

# Automate stack set deployment by using AWS CodePipeline and AWS CodeBuild

Created by *Thiyagarajan Mani (AWS)*, *Mihir Borkar (AWS)*, and *Raghu Gowda (AWS)*

**Code repository:** [automated-code-pipeline-stackset-deployment](#)

**Environment:** Production

**Technologies:** DevOps; DevelopmentAndTesting

**AWS services:** AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; AWS Organizations; AWS CloudFormation

## Summary

In your continuous integration and continuous delivery (CI/CD) processes, you might want to deploy applications automatically into all your existing AWS accounts and into new accounts that you add to your organization in AWS Organizations. When you architect a CI/CD solution for this requirement, the [delegated stack set administrator](#) capability of AWS CloudFormation is useful because it enables a layer of security by restricting access to the management account. However, AWS CodePipeline uses the service-managed permissions model to deploy applications into multiple accounts and Regions. You must use the AWS Organizations management account to deploy with stack sets, because AWS CodePipeline doesn't support the delegated stack set administrator feature.

This pattern describes how you can work around this limitation. The pattern uses AWS CodeBuild and a custom script to automate stack set deployment with AWS CodePipeline. It automates these application deployment activities:

- Deploy an application as stack sets into existing organizational units (OUs)
- Extend the deployment of an application into additional OUs and Regions
- Remove a deployed application from all or specific OUs or Regions

## Prerequisites and limitations

### Prerequisites

Before you follow the steps in this pattern:

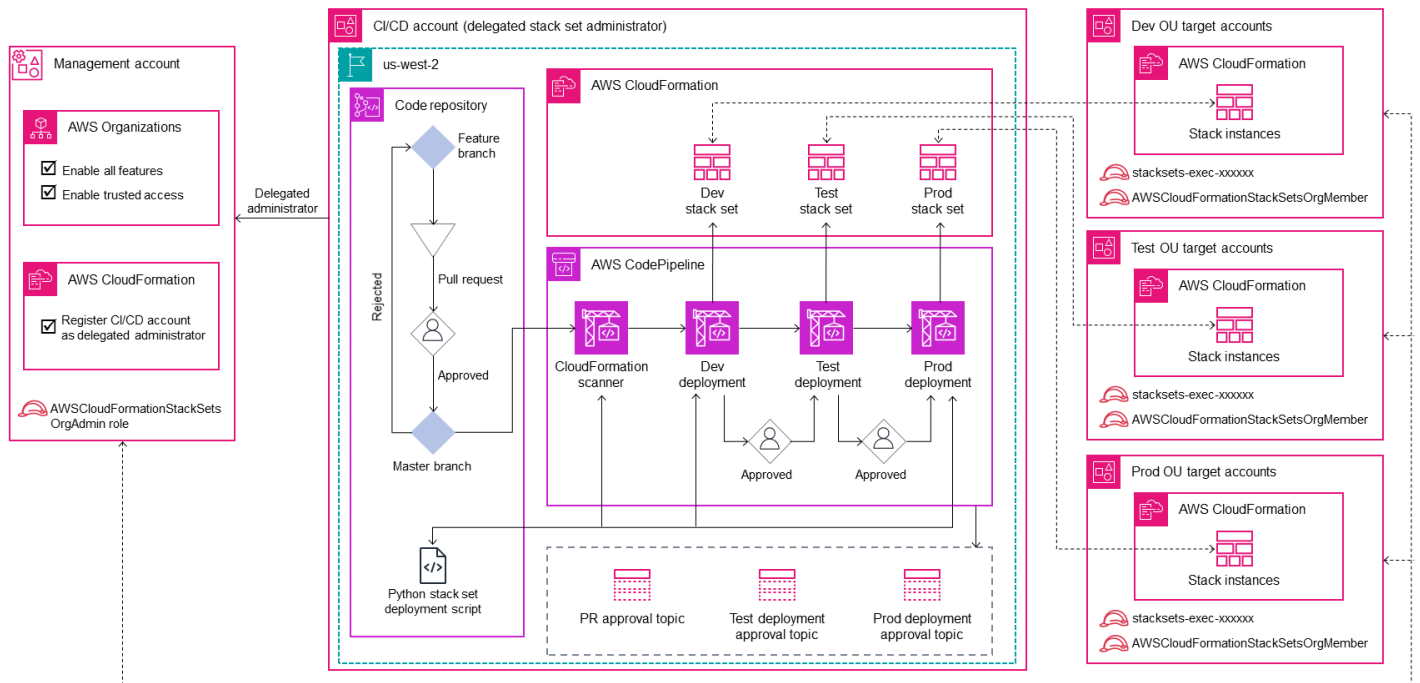

- Create organizations in your AWS Organizations management account. For instructions, see the [AWS Organizations documentation](#).
- Enable trusted access between AWS Organizations and CloudFormation to use service-managed permissions. For instructions, see [Enable trusted access with AWS Organizations](#) in the CloudFormation documentation.

### Limitations

The code that's supplied with this pattern has the following limitations:

- You can deploy only a single CloudFormation template for an application; multiple template deployment isn't currently supported.
- Customizing the current implementation requires DevOps expertise.
- This pattern doesn't use AWS Key Management System (AWS KMS) keys. However, you can enable this functionality by reconfiguring the CloudFormation template included with this pattern.

## Architecture

This architecture for the CI/CD deployment pipeline handles the following:

- Restricts direct access to the management account by delegating stack set deployment responsibility to a dedicated CI/CD account as the stack set administrator for application deployments.
- Uses the service-managed permission model to deploy the application automatically whenever a new account is created and mapped under an OU.
- Ensures application version consistency across all accounts at the environment level.
- Uses multiple approval stages at the repository and pipeline levels to provide additional layers of security and governance for the deployed application.
- Overcomes the current limitation of CodePipeline by using a custom-built deployment script in CodeBuild to automatically deploy or remove stack sets and stack instances. For an illustration of the flow control and hierarchy of API calls implemented by the custom script, see the [Additional information](#) section.
- Creates individual stack sets for the development, testing, and production environments. In addition, you can create stack sets that combine multiple OUs and Regions at every stage. For example, you can combine sandbox and development OUs within a development deployment stage.
- Supports application deployment into, or exclusion from, a subset of accounts or list of OUs.

## Automation and scale

You can use the code provided with this pattern to create a AWS CodeCommit repository and a code pipeline for your application. You can then deploy these as stack sets into multiple accounts at the OU level. The code also automates components such as Amazon Simple Notification Service (Amazon SNS) topics to notify approvers, the required AWS Identity and Access Management (IAM) roles, and the service control policy (SCP) to apply in the management account.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Organizations](#) is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

### Code repository

The code for this pattern is available in the GitHub [automated-code-pipeline-stackset-deployment](#) repository. For the folder structure and other details, see the [readme file](#) for the repository.

## Best practices

This pattern restricts direct access to the management account while deploying the application at the OU level. Adding multiple approval stages to the pipeline and repository process helps provide additional security and governance for the applications and components that you deploy by using this approach.

## Epics

### Configure accounts in AWS Organizations

Task	Description	Skills required
Enable all features in the management account.	Enable all features in the management account for your organization by following the instructions in the <a href="#">AWS Organizations documentation</a> .	AWS administrator, Platform administrator
Create a CI/CD account.	In AWS Organizations, in your organization, create a dedicated CI/CD account, and assign a team to own and control access to the account.	AWS administrator
Add a delegated administrator.	In the management account, register the CI/CD account that you created in the previous step as a delegated stack set administrator. For instructions, see the <a href="#">AWS CloudFormation documentation</a> .	AWS administrator, Platform administrator

## Create an application repository and CI/CD pipeline

Task	Description	Skills required
Clone the code repository.	<ol style="list-style-type: none"> <li>Clone the code repository that's provided with this pattern to your computer:           <pre data-bbox="630 491 1029 730">git clone https://github.com/aws-samples/automated-code-pipeline-stackset-deployment.git</pre> </li> <li>Review the <a href="#">readme file</a> to understand the directory structure and other details.</li> </ol>	AWS DevOps
Create SNS topics.	<p>You can use the <code>sns-template.yaml</code> template that's provided in the GitHub repository to create SNS topics and configure subscriptions for approval requests.</p> <ol style="list-style-type: none"> <li>On the AWS console, sign in to the CI/CD account.</li> <li>Open the CloudFormation console at <a href="https://console.aws.amazon.com/cloudformation">https://console.aws.amazon.com/cloudformation</a>.</li> <li>Create a new stack with new resources (standard option).</li> <li>For <b>Specify template</b>, choose <b>Upload a template file</b>, <b>Choose file</b>, and then select the <code>sns-template</code></li> </ol>	AWS DevOps

Task	Description	Skills required
	<p>ate .yaml file from the templates folder of the cloned GitHub repository. Choose <b>Next</b>.</p> <ol style="list-style-type: none"><li>5. Provide a meaningful application stack name.</li><li>6. Specify a prefix for resources.</li><li>7. Choose <b>Next</b>, <b>Next</b>, and <b>Submit</b>.</li><li>8. When the stack has been created successfully, choose the <b>Outputs</b> tab, and note the Amazon Resource Names (ARNs) of the SNS topics for pull requests, the test environment, and the production environment. You'll use this information in subsequent steps.</li></ol>	

Task	Description	Skills required
Create IAM roles for CI/CD components.	<p>You can use the <code>cicd-role-template.yaml</code> template that's provided in the GitHub repository to create IAM roles and policies required by CI/CD components.</p> <ol style="list-style-type: none"><li>1. On the AWS console, sign in to the CI/CD account.</li><li>2. Open the CloudFormation console at <a href="https://console.aws.amazon.com/cloudformation">https://console.aws.amazon.com/cloudformation</a>.</li><li>3. Create a new stack with new resources (standard option).</li><li>4. For <b>Specify template</b>, choose <b>Upload a template file</b>, <b>Choose file</b>, and then select the <code>cicd-role-template.yaml</code> file from the <code>templates</code> folder of the cloned GitHub repository. Choose <b>Next</b>.</li><li>5. Provide a meaningful application stack name.</li><li>6. Enter values for the following parameters:<ul style="list-style-type: none"><li>• The ARN for the permission boundary policy. You can obtain this ARN from the</li></ul></li></ol>	AWS DevOps

Task	Description	Skills required
	<p><b>Policy details</b> section of your permissions boundary policy on the IAM console.</p> <ul style="list-style-type: none"><li>• The ARN for the SNS production approval topic that you noted previously.</li><li>• The ARN for the SNS test approval topic that you noted previously.</li><li>• A prefix for resources created by the template.</li></ul> <p>7. Choose <b>Next</b>, <b>Next</b>, and <b>Submit</b>.</p> <p>8. When the stack has been created successfully, choose the <b>Outputs</b> tab, and note the ARNs of the IAM roles that were created. You'll use this information in subsequent steps.</p>	

Task	Description	Skills required
Create a CodeCommit repository and a code pipeline for your application.	<p>You can use the <code>cicd-pipeline-template.yaml</code> template that's provided in the GitHub repository to create a CodeCommit repository and a code pipeline for your application.</p> <ol style="list-style-type: none"><li>1. On the AWS console, sign in to the CI/CD account.</li><li>2. Open the CloudFormation console at at <a href="https://console.aws.amazon.com/cloudformation">https://console.aws.amazon.com/cloudformation</a>.</li><li>3. Create a new stack with new resources (standard option).</li><li>4. For <b>Specify template</b>, choose <b>Upload a template file</b>, <b>Choose file</b>, and then select the <code>cicd-pipeline-template.yaml</code> file from the <code>templates</code> folder of the cloned GitHub repository. Choose <b>Next</b>.</li><li>5. Provide a meaningful application stack name.</li><li>6. Enter values for the following parameters:<ul style="list-style-type: none"><li>• <b>AppRepositoryName</b><ul style="list-style-type: none"><li>– The name of the CodeCommit repository</li></ul></li></ul></li></ol>	AWS DevOps

Task	Description	Skills required
	<p>that will be created for the application.</p> <ul style="list-style-type: none"><li>• <b>AppRepositoryDescription</b> – A brief description of the CodeCommit repository that will be created for the application.</li><li>• <b>ApplicationName</b> – The name of your application. This string is used as the name of the CodeCommit repository and as the prefix of the CI/CD pipeline.</li><li>• <b>CloudWatchEventRoleARN</b> – The ARN of the CloudWatch event role from the previous task.</li><li>• <b>CodeBuildProjectRoleARN</b> – The ARN of the CodeBuild project role from the previous task.</li><li>• <b>CodePipelineRoleARN</b> – The ARN of the CodePipeline role from the previous task.</li><li>• <b>DeploymentConfigBucket</b> – The Amazon Simple Storage Service (Amazon S3) bucket name where the deployment configura</li></ul>	

Task	Description	Skills required
	<p>tion files and script .zip file will be stored.</p> <ul style="list-style-type: none"> <li>• <b>DeploymentConfigKey</b> – The path and .zip filename (Amazon S3 key).</li> <li>• <b>PRApprovalSNSARN</b> – The ARN for the SNS topic for pull request notifications.</li> <li>• <b>ProdApprovalSNSARN</b> – The ARN for the SNS topic for production approvals.</li> <li>• <b>TESTApprovalSNSARN</b> – The ARN for the SNS topic for test approvals.</li> <li>• <b>TemplateBucket</b> – The name of the S3 bucket in the CI/CD account where the CI/CD pipeline creation template will be stored.</li> </ul> <p>7. Choose <b>Next, Next</b>, and <b>Submit</b>.</p> <p>8. When the stack completes successfully, it creates a CodeCommit repository that has the specified name and a default directory structure, deployment configuration</p>	

Task	Description	Skills required
	files, scripts, and a code pipeline for the repository.	

## Deploy a stack set

Task	Description	Skills required
Clone the application repository.	<p>The CI/CD pipeline template you used previously creates a sample application repository and code pipeline. To clone and verify the repository:</p> <ol style="list-style-type: none"> <li>1. Sign in to the CI/CD account.</li> <li>2. Find the application repository and CI/CD pipeline that you created in the previous epic.</li> <li>3. Copy the URL for the repository and use the git clone command to clone the repository on your local machine.</li> <li>4. Verify that the directory structure and files match the following:</li> </ol> <pre> root  - deploy_configs      - deployment_config.json  - parameters      - template-parameter-dev.json </pre>	App developer, Data engineer

Task	Description	Skills required
	<pre data-bbox="630 205 1026 541">        - template- parameter-test.json         - template- parameter-prod.json  - templates         - template. yml  - buildspec.yml</pre> <p data-bbox="630 583 1026 1050">where the <code>deploy_configs</code> folder contains the deployment configuration file, and the <code>templates</code> and <code>parameters</code> folders include default files that you'll replace with your own CloudFormation template and parameter files.</p> <p data-bbox="630 1092 1026 1218"><b>Important:</b> Do not customize the folder structure.</p> <p data-bbox="630 1249 1026 1281">5. Create a feature branch.</p>	

Task	Description	Skills required
Add application artifacts.	<p>Update the application repository by using a CloudFormation template.</p> <p><b>Note:</b> This solution supports the deployment of only a single CloudFormation template.</p> <ol style="list-style-type: none"><li>1. Build your CloudFormation template for deploying your application code changes, and name it <code>&lt;application-name&gt;.yaml</code> .</li><li>2. Replace the <code>template.yaml</code> file in the <code>templates</code> folder of the application repository with the CloudFormation template you created in step 1.</li><li>3. Prepare parameter files for each environment (development, testing, and production).</li><li>4. Name the parameter files by using the format <code>&lt;cloudformation-template-name&gt;-parameter-&lt;environment-name&gt;.json</code> .</li><li>5. Replace the default parameter files in the</li></ol>	App developer, Data engineer

Task	Description	Skills required
	parameters folder with your files from step 4.	

Task	Description	Skills required
Update the deployment configuration file.	<p>Update the deployment <code>t_config.json</code> file:</p> <ol style="list-style-type: none"><li>1. In the application repository, navigate to the <code>deploy_configs</code> folder.</li><li>2. Open the file <code>deployment_config.json</code> :</li></ol> <pre data-bbox="630 625 1029 1837">{   "deployment_action":     "&lt;deploy/delete&gt;",   "stack_set_name":     "&lt;stack set name&gt;",   "stack_set_description":     "&lt;stack set description&gt;",   "deployment_targets": {     "dev": {      "org_units": ["list of OUs"],      "regions": ["list of regions"],      "filter_accounts":       ["list of accounts"],      "filter_type":</pre>	App developer, Data engineer

Task	Description	Skills required
	<pre> "&lt;DIFFERENCE/INTER SECTION/UNION&gt;"          },          "test": {              "org_units": ["list of OUs"],              "regions": ["list of regions"],              "filter_accounts": ["list of accounts" ],              "filter_type": "&lt;DIFFERENCE/INTER SECTION/UNION&gt;"          },          "prod": {              "org_units": ["list of OUs"],              "regions": ["list of regions"],              "filter_accounts": ["list of accounts" ], </pre>	

Task	Description	Skills required
	<pre data-bbox="646 289 977 1255"> "filter_type": "&lt;DIFFERENCE/INTER SECTION/UNION&gt;"      }      },     "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],     "auto_deployment": "&lt;True/False&gt;",     "retain_stacks_on_account_removal": "&lt;True/False&gt;",     "region_deployment_concurrency": "&lt;SEQUENTIAL/PARALLEL&gt;"   } </pre> <p data-bbox="592 1276 945 1501">3. Update the values for deployment action, stack set name, stack set description, and deployment targets.</p> <p data-bbox="630 1549 1010 1869">For example, you can set <code>deployment_action</code> to <code>delete</code> to delete the entire stack set and its associated stack instances. Use <code>deploy</code> to create a new stack set, to update</p>	

Task	Description	Skills required
	<p>an existing stack set, or to add or remove stack instances for additional OUs or Regions. For more examples, see the <a href="#">Additional information</a> section.</p> <p>This pattern creates individual stack sets for each environment by adding the environment name to the stack set name you provide in the deployment configuration file.</p>	

Task	Description	Skills required
Commit changes and deploy the stack set.	<p>Commit the changes you specified in your application template, and merge and deploy the stack set into multiple environments stage by stage:</p> <ol style="list-style-type: none"><li>1. Save all your files and commit changes to the feature branch of your local application repository.</li><li>2. Push the feature branch to the remote repository.</li><li>3. Create a pull request to merge the changes to the main branch.</li></ol> <p>When the pull request has been approved and changes have been merged to the main branch, the CI/CD pipeline will be initiated .</p> <ol style="list-style-type: none"><li>4. When the Dev-deployment stage has completed successfully, check the CloudFormation console, <b>StackSets, Service-Managed</b> tab.</li></ol> <p>You'll see a new stack set with the suffix dev.</p> <ol style="list-style-type: none"><li>5. Check the CodeBuild logs for the Dev-deployment stage for any issues.</li></ol>	App developer, Data engineer

Task	Description	Skills required
	<p>6. Deploy the stack set into the testing and production environments by asking your approvers to approve the deployments for those stages and repeating steps 5 and 6. The stack sets for the testing and production environments have the suffixes test and prod.</p>	

## Troubleshooting

Issue	Solution
<p>Deployment fails with the exception:</p> <p><i>Change the Name of Template Parameter file as &lt;application name&gt;-parameter-&lt;env&gt;.json with, default names are not allowed</i></p>	<p>The CloudFormation template parameter files must follow the naming convention specified . Update the parameter file names and try again.</p>
<p>Deployment fails with the exception:</p> <p><i>Change the Name of CloudFormation Template as &lt;application name&gt;.yml, default template.yml or template.yaml are not allowed</i></p>	<p>The CloudFormation template name must follow the naming convention specified. Update the file name and try again.</p>
<p>Deployment fails with the exception:</p> <p><i>No valid CloudFormation Template and its Parameter File found for {environment name} environment</i></p>	<p>Check the file naming conventions for the CloudFormation template and its parameter file for the specified environment.</p>
<p>Deployment fails with the exception:</p>	<p>You specified an invalid value for the <code>deployment_action</code> parameter in the deployment configuration file. The parameter</p>

Issue	Solution
<i>Invalid deployment action provided in deployment config file. Valid options are 'deploy' and 'delete'.</i>	has two valid values: deploy and delete. Use deploy to create and update the stack sets and their associated stack instances. Use delete only when you want to remove the entire stack set and associated stack instances.

## Additional information

### Flow chart

The following flow chart depicts the flow control and hierarchy of API calls implemented by the custom script to automate stack set deployment.

### Sample deployment configuration files

## Creating a new stack set

The following deployment configuration file creates a new stack set called `sample-stack-set` in the AWS Region `us-east-1` in three OUs.

```
{
  "deployment_action": "deploy",
  "stack_set_name": "sample-stack-set",
  "stack_set_description": "this is a sample stack set",
  "deployment_targets": {
    "dev": {
      "org_units": ["dev-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    },
    "test": {
      "org_units": ["test-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    },
    "prod": {
      "org_units": ["prod-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    }
  },
  "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
  "auto_deployment": "True",
  "retain_stacks_on_account_removal": "True",
  "region_deployment_concurrency": "PARALLEL"
}
```

## Deploying an existing stack set to another OU

If you deploy the configuration shown in the previous example and you want to deploy the stack set to an additional OU called `dev-org-unit-2` in the development environment, the deployment configuration file might look like the following.

```
{
  "deployment_action": "deploy",
```

```
"stack_set_name": "sample-stack-set",
"stack_set_description": "this is a sample stack set",
"deployment_targets": {
    "dev": {
        "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
        "regions": ["us-east-1"],
        "filter_accounts": [],
        "filter_type": ""
    },
    "test": {
        "org_units": ["test-org-unit-1"],
        "regions": ["us-east-1"],
        "filter_accounts": [],
        "filter_type": ""
    },
    "prod": {
        "org_units": ["prod-org-unit-1"],
        "regions": ["us-east-1"],
        "filter_accounts": [],
        "filter_type": ""
    }
},
"cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
"auto_deployment": "True",
"retain_stacks_on_account_removal": "True",
"region_deployment_concurrency": "PARALLEL"
}
```

## Deploying an existing stack set to another AWS Region

If you deploy the configuration shown in the previous example and you want to deploy the stack set to an additional AWS Region (us-east-2) in the development environment for two OUs (dev-org-unit-1 and dev-org-unit-2), the deployment configuration file might look like the following.

**Note:** The resources in the CloudFormation template must be valid and Region-specific.

```
{
    "deployment_action": "deploy",
    "stack_set_name": "sample-stack-set",
    "stack_set_description": "this is a sample stack set",
    "deployment_targets": {
```

```

        "dev": {
            "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
            "regions": ["us-east-1", "us-east-2"],
            "filter_accounts": [],
            "filter_type": ""
        },
        "test": {
            "org_units": ["test-org-unit-1"],
            "regions": ["us-east-1"],
            "filter_accounts": [],
            "filter_type": ""
        },
        "prod": {
            "org_units": ["prod-org-unit-1"],
            "regions": ["us-east-1"],
            "filter_accounts": [],
            "filter_type": ""
        }
    },
    "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
    "auto_deployment": "True",
    "retain_stacks_on_account_removal": "True",
    "region_deployment_concurrency": "PARALLEL"
}

```

## Removing a stack instance from an OU or AWS Region

Let's say that the deployment configuration shown in the previous example has been deployed. The following configuration file removes the stack instances from both Regions of the OU dev-org-unit-2.

```

{
    "deployment_action": "deploy",
    "stack_set_name": "sample-stack-set",
    "stack_set_description": "this is a sample stack set",
    "deployment_targets": {
        "dev": {
            "org_units": ["dev-org-unit-1"],
            "regions": ["us-east-1", "us-east-2"],
            "filter_accounts": [],
            "filter_type": ""
        },
    },
}

```

```

        "test": {
            "org_units": ["test-org-unit-1"],
            "regions": ["us-east-1"],
            "filter_accounts": [],
            "filter_type": ""
        },
        "prod": {
            "org_units": ["prod-org-unit-1"],
            "regions": ["us-east-1"],
            "filter_accounts": [],
            "filter_type": ""
        }
    },
    "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
    "auto_deployment": "True",
    "retain_stacks_on_account_removal": "True",
    "region_deployment_concurrency": "PARALLEL"
}

```

The following configuration file removes the stack instance from the AWS Region us-east-1 for both OUs in the development environment.

```

{
    "deployment_action": "deploy",
    "stack_set_name": "sample-stack-set",
    "stack_set_description": "this is a sample stack set",
    "deployment_targets": {
        "dev": {
            "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
            "regions": ["us-east-2"],
            "filter_accounts": [],
            "filter_type": ""
        },
        "test": {
            "org_units": ["test-org-unit-1"],
            "regions": ["us-east-1"],
            "filter_accounts": [],
            "filter_type": ""
        },
        "prod": {
            "org_units": ["prod-org-unit-1"],

```

```

        "regions": ["us-east-1"],
        "filter_accounts": [],
        "filter_type": ""
    },
    },
    "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
    "auto_deployment": "True",
    "retain_stacks_on_account_removal": "True",
    "region_deployment_concurrency": "PARALLEL"
}

```

## Deleting the entire stack set

The following deployment configuration file deletes the entire stack set and all its associated stack instances.

```

{
  "deployment_action": "delete",
  "stack_set_name": "sample-stack-set",
  "stack_set_description": "this is a sample stack set",
  "deployment_targets": {
    "dev": {
      "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
      "regions": ["us-east-2"],
      "filter_accounts": [],
      "filter_type": ""
    },
    "test": {
      "org_units": ["test-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    },
    "prod": {
      "org_units": ["prod-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    }
  },
  "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
  "auto_deployment": "True",
}

```

```
"retain_stacks_on_account_removal": "True",
"region_deployment_concurrency": "PARALLEL"
}
```

## Excluding an account from deployment

The following deployment configuration file excludes the account 111122223333, which is part of the OU dev-org-unit-1, from deployment.

```
{
  "deployment_action": "deploy",
  "stack_set_name": "sample-stack-set",
  "stack_set_description": "this is a sample stack set",
  "deployment_targets": {
    "dev": {
      "org_units": ["dev-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": ["111122223333"],
      "filter_type": "DIFFERENCE"
    },
    "test": {
      "org_units": ["test-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    },
    "prod": {
      "org_units": ["prod-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    }
  },
  "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
  "auto_deployment": "True",
  "retain_stacks_on_account_removal": "True",
  "region_deployment_concurrency": "PARALLEL"
}
```

## Deploying the application to a subset of accounts in an OU

The following deployment configuration file deploys the application to only three accounts (111122223333, 444455556666, and 777788889999) in the OU dev-org-unit-1.

```
{
  "deployment_action": "deploy",
  "stack_set_name": "sample-stack-set",
  "stack_set_description": "this is a sample stack set",
  "deployment_targets": {
    "dev": {
      "org_units": ["dev-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": ["111122223333",
"444455556666", "777788889999"],
      "filter_type": "INTERSECTION"
    },
    "test": {
      "org_units": ["test-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    },
    "prod": {
      "org_units": ["prod-org-unit-1"],
      "regions": ["us-east-1"],
      "filter_accounts": [],
      "filter_type": ""
    }
  },
  "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
  "auto_deployement": "True",
  "retain_stacks_on_account_removal": "True",
  "region_deployment_concurrency": "PARALLEL"
}
```

Infrastructure

**Workload:** Open-source

**AWS services:** Amazon SNS;  
Amazon SQS; AWS CodeBuild  
; AWS CodePipeline; AWS  
Systems Manager; AWS  
CodeCommit

## Summary

You can integrate Amazon Elastic Compute Cloud (Amazon EC2) instances with AWS Systems Manager to automate operational tasks and provide more visibility and control. To integrate with Systems Manager, EC2 instances must have an installed [AWS Systems Manager Agent \(SSM Agent\)](#) and an AmazonSSMManagedInstanceCore AWS Identity and Access Management (IAM) policy attached to their instance profiles.

However, if you want to ensure that all EC2 instance profiles have the AmazonSSMManagedInstanceCore policy attached, you can face challenges updating new EC2 instances that don't have instance profiles or EC2 instances that have an instance profile but don't have the AmazonSSMManagedInstanceCore policy. It can also be difficult to add this policy across multiple Amazon Web Services (AWS) accounts and AWS Regions.

This pattern helps solve these challenges by deploying three [Cloud Custodian](#) policies in your AWS accounts:

- The first Cloud Custodian policy checks for existing EC2 instances that have an instance profile but don't have the `AmazonSSMManagedInstanceCore` policy. The `AmazonSSMManagedInstanceCore` policy is then attached.
- The second Cloud Custodian policy checks for existing EC2 instances without an instance profile and adds a default instance profile that has the `AmazonSSMManagedInstanceCore` policy attached.
- The third Cloud Custodian policy creates [AWS Lambda functions](#) in your accounts to monitor the creation of EC2 instances and instance profiles. This ensures that the `AmazonSSMManagedInstanceCore` policy is automatically attached when an EC2 instance is created.

This pattern uses [AWS DevOps](#) tools to achieve a continuous, at-scale deployment of the Cloud Custodian policies to a multi-account environment, without provisioning a separate compute environment.

## Prerequisites and limitations

### Prerequisites

- Two or more active AWS accounts. One account is the *security account* and the others are *member accounts*.
- Permissions to provision AWS resources in the security account. This pattern uses [administrator permissions](#), but you should grant permissions according to your organization's requirements and policies.
- Ability to assume an IAM role from the security account to member accounts and create the required IAM roles. For more information about this, see [Delegate access across AWS accounts using IAM roles](#) in the IAM documentation.
- AWS Command Line Interface (AWS CLI), installed and configured. For testing purposes, you can configure AWS CLI by using the `aws configure` command or setting environment variables. **Important:** This isn't recommended for production environments and we recommend that this account is only granted least privilege access. For more information about this, see [Grant least privilege](#) in the IAM documentation.
- The `devops-cdk-cloudcustodian.zip` file (attached), downloaded to your local computer.
- Familiarity with Python.

- The required tools (Node.js, AWS Cloud Development Kit (AWS CDK), and Git), installed and configured. You can use the `install-prerequisites.sh` file in the `devops-cdk-cloudcustodian.zip` file to install these tools. Make sure you run this file with root privileges.

## Limitations

- Although this pattern can be used in a production environment, make sure that all IAM roles and policies meet your organization's requirements and policies.

## Package versions

- Cloud Custodian version 0.9 or later
- TypeScript version 3.9.7 or later
- Node.js version 14.15.4 or later
- npm version 7.6.1 or later
- AWS CDK version 1.96.0 or later

## Architecture

The diagram shows the following workflow:

1. Cloud Custodian policies are pushed to an AWS CodeCommit repository in the security account. An Amazon CloudWatch Events rule automatically initiates the AWS CodePipeline pipeline.
2. The pipeline fetches the most recent code from CodeCommit and sends it to the continuous integration part of the continuous integration and continuous delivery (CI/CD) pipeline handled by AWS CodeBuild.
3. CodeBuild performs the complete DevSecOps actions, including policy syntax validation on the Cloud Custodian policies, and runs these policies in `--dryrun` mode to check which resources are identified.
4. If there are no errors, the next task alerts an administrator to review the changes and approve the deployment into the member accounts.

## Technology stack

- AWS CDK

- CodeBuild
- CodeCommit
- CodePipeline
- IAM
- Cloud Custodian

## Automation and scale

The AWS CDK pipelines module provisions a CI/CD pipeline that uses CodePipeline to orchestrate the building and testing of source code with CodeBuild, in addition to the deployment of AWS resources with AWS CloudFormation stacks. You can use this pattern for all member accounts and Regions in your organization. You can also extend the Roles creation stack to deploy other IAM roles in your member accounts.

## Tools

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- [AWS CodeBuild](#) is a fully managed build service in the cloud.
- [AWS CodeCommit](#) is a version control service that you can use to privately store and manage assets.
- [AWS CodePipeline](#) is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- [AWS Identity and Access Management](#) is a web service that helps you securely control access to AWS resources.
- [Cloud Custodian](#) is a tool that unifies the dozens of tools and scripts most organizations use for managing their public cloud accounts into one open-source tool.
- [Node.js](#) is a JavaScript runtime built on Google Chrome's V8 JavaScript engine.

## Code

For a detailed list of modules, account functions, files, and deployment commands used in this pattern, see the README file in the `devops-cdk-cloudcustodian.zip` file (attached).

# Epics

## Set up the pipeline with AWS CDK

Task	Description	Skills required
Set up the CodeCommit repository.	<ol style="list-style-type: none"><li>1. Unzip the <code>devops-cdk-cloudcustodian.zip</code> file (attached) in the working directory on your local computer.</li><li>2. Sign in to the AWS Management Console for your security account, open the CodeCommit console, and then create a new <code>devops-cdk-cloudcustodian</code> repository.</li><li>3. Change into the project directory and set up the CodeCommit repository as the origin, commit the changes, and then push them to the origin branch by running the following commands:<ul style="list-style-type: none"><li>• <code>cd devops-cdk-cloudcustodian</code></li><li>• <code>git init --initial-branch=main</code></li><li>• <code>git add . git commit -m 'initial commit'</code></li><li>• <code>git remote add origin https://git-codeco</code></li></ul></li></ol>	Developer

Task	Description	Skills required
	<pre>commit.us-east-1.amazonaws.com/v1/devops-cdk-cloudcustodian</pre> <ul style="list-style-type: none"><li>• <code>git push origin main</code></li></ul> <p>For more information about this, see <a href="#">Creating a CodeCommit repository</a> in the AWS CodeCommit documentation.</p>	
Install the required tools.	<p>Use the <code>install-prerequisites.sh</code> file to install all the required tools on Amazon Linux. This doesn't include AWS CLI because it comes pre-installed.</p> <p>For more information about this, see the <a href="#">Prerequisites</a> section of <a href="#">Getting started with the AWS CDK</a> in the AWS CDK documentation.</p>	Developer

Task	Description	Skills required
Install the required AWS CDK packages.	<ol style="list-style-type: none"><li>1. Set up your virtual environment by running the following command in AWS CLI: <code>\$ python3 -m venv .env</code></li><li>2. Activate your virtual environment by running the following command: <code>\$ source .env/bin/activate</code></li><li>3. After the virtual environment is activated, install the required dependencies by running the following command: <code>\$ pip install -r requirements.txt</code></li><li>4. To add additional dependencies (for example, other AWS CDK libraries), add them to the <code>requirements.txt</code> file, and then run the following command: <code>pip install -r requirements.txt</code></li></ol> <p>The following packages are required by AWS CDK and are included in the <code>requirements.txt</code> file:</p> <ul style="list-style-type: none"><li>• <code>aws-cdk.aws-cloudwatch</code></li></ul>	Developer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <code>aws-cdk.aws-codebuild</code></li> <li>• <code>aws-cdk.aws-codecommit</code></li> <li>• <code>aws-cdk.aws-codedeploy</code></li> <li>• <code>aws-cdk.aws-codepipeline</code></li> <li>• <code>aws-cdk.aws-codepipeline-actions</code></li> <li>• <code>aws-cdk.aws-events</code></li> <li>• <code>aws-cdk.aws-eventstargets</code></li> <li>• <code>aws-cdk.aws-iam</code></li> <li>• <code>aws-cdk.aws-logs</code></li> <li>• <code>aws-cdk.aws-s3</code></li> <li>• <code>aws-cdk.aws-sns</code></li> <li>• <code>aws-cdk.aws-sns-subscriptions</code></li> <li>• <code>aws-cdk.aws-sqs</code></li> <li>• <code>aws-cdk.core</code></li> </ul>	

## Configure your environment

Task	Description	Skills required
Update the required variables.	Open the <code>vars.py</code> file in the root folder of your CodeCommit repository and update the following variables:	Developer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• Update <code>var_deploy_region = 'us-east-1'</code> with the AWS Region where you want the pipeline to be deployed.</li> <li>• Update <code>var_codecommit_repo_name = "cdk-cloudcustodian"</code> with the name of your CodeCommit repository.</li> <li>• Update <code>var_codecommit_branch_name = "main"</code> with name of the CodeCommit branch.</li> <li>• Update <code>var_admin_email='notifyadmin@email.com'</code> with the email address for the administrator that approves changes.</li> <li>• Update <code>var_slack_webhook_url = https://hooks.slack.com/services/T0000000/B00000000/XXXXXXXXXXXXXXXXXXXXXXX</code> with the Slack webhook used to send Cloud Custodian notifications when changes are made.</li> </ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• Update <code>var_orgId = 'o-yyyyyyyyyyy'</code> with your organization ID.</li><li>• Update <code>security_account = '123456789011'</code> with the AWS account ID for the account where the pipeline is deployed.</li><li>• Update <code>member_accounts = ['111111111111', '111111111112', '111111111113']</code> with the member accounts where you want to bootstrap the AWS CDK stack and deploy the required IAM roles.</li><li>• Set <code>cdk_bootstrap_member_accounts = True</code> to <code>True</code> if you want the pipeline to automatically bootstrap the AWS CDK to your member accounts. If set to <code>True</code> this also requires the name of an existing IAM role in the member accounts that can be assumed from the security account. This IAM role must also have the required permissions to bootstrap the AWS CDK.</li></ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>Update <code>cdk_boots</code> <code>trap_role =</code> <code>'AWSControlTowerEx</code> <code>ecution'</code> with the existing IAM role in the member accounts that can be assumed from the security account. This role must also permission to bootstrap the AWS CDK. <b>Note:</b> This only applies if <code>cdk_bootstrap_member_accounts</code> is set to <code>True</code>.</li></ul>	

Task	Description	Skills required
Update the account.yml file with the member account information.	<p>To run the <a href="#">c7n-org Cloud Custodian</a> tool against multiple accounts, you must place the <code>accounts.yml</code> config file in the root of the repository. The following is a sample Cloud Custodian config file for AWS:</p> <pre data-bbox="597 632 1027 1388">accounts: - account_id: '123123123123'   name: account-1   regions:   - us-east-1   - us-west-2   role: arn:aws:iam::123123123123:role/CloudCustodian   vars:     charge_code: xyz   tags:   - type:prod   - division:some   division   - partition:us   - scope:pci</pre>	Developer

## Bootstrap the AWS accounts

Task	Description	Skills required
Bootstrap the security account.	Bootstrap the <code>deploy_account</code> with the <code>cloudcustodian_stack</code> applicati	Developer

Task	Description	Skills required
	<p>on by running the following command:</p> <pre data-bbox="594 327 1029 531">cdk bootstrap -a python3 cloudcustodian/cl oudcustodian_stack.py</pre>	
<p>Option 1 - Automatically bootstrap the member accounts.</p>	<p>If the <code>cdk_bootstrap_member_accounts</code> variable is set to <code>True</code> in the <code>vars.py</code> file, the accounts specified in the <code>member_accounts</code> variable are automatically bootstrapped by the pipeline.</p> <p>If required, you can update <code>*cdk_bootstrap_role*</code> with an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK.</p> <p>New accounts added to the <code>member_accounts</code> variable are automatically bootstrapped by the pipeline so that the required roles can be deployed.</p>	<p>Developer</p>

Task	Description	Skills required
Option 2 - Manually bootstrap the member accounts.	<p>Although we don't recommend using this approach, you can set the value of <code>cdk_bootstrap_member_accounts</code> to <code>False</code> and perform this step manually by running the following command:</p> <pre data-bbox="594 632 1026 1780">\$ cdk bootstrap -a 'python3 cloudcustodian/member_account_roles_stack.py' \ --trust {security_account_id} \ --context assume-role-credentials:writeIamRoleName={role_name} \ --context assume-role-credentials:readIamRoleName={role_name} \ --mode=ForWriting \ --context bootstrap=true \ --cloudformation-execution-policies arn:aws:iam::aws:policy/AdministratorAccess</pre>	Developer

Task	Description	Skills required
	<p><b>Important:</b> Make sure that you update the <code>{security_account_id}</code> and <code>{role_name}</code> values with the name of an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK.</p> <p>You can also use other approaches to bootstrap the member accounts, for example, with AWS CloudFormation. For more information about this, see <a href="#">Bootstrapping</a> in the AWS CDK documentation.</p>	

## Deploy the AWS CDK stacks

Task	Description	Skills required
<p>Create the IAM roles in the member accounts.</p>	<p>Run the following command to deploy the <code>member_account_roles_stack</code> stack and create the IAM roles in the member accounts:</p> <pre data-bbox="594 1602 1027 1837">cdk deploy --all -a 'python3 cloudcustodian/member_account_roles_stack.py' --require-approval never</pre>	<p>Developer</p>

Task	Description	Skills required
Deploy the Cloud Custodian pipeline stack.	Run the following command to create the Cloud Custodian <code>cloudcustodian_stack.py</code> pipeline that is deployed into the security account:  <pre>cdk deploy -a 'python3 cloudcustodian/cloudcustodian_stack.py'</pre>	Developer

# Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK

Created by Varsha Raju (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps;  
Containers & microservices;  
Modernization; Infrastructure

**AWS services:** AWS  
CodeBuild; AWS CodeCommit;  
AWS CodePipeline; Amazon  
ECS; AWS CDK

## Summary

This pattern describes how to automatically create the continuous integration and continuous delivery (CI/CD) pipelines and underlying infrastructure for building and deploying microservices on Amazon Elastic Container Service (Amazon ECS). You can use this approach if you want to set up proof-of-concept CI/CD pipelines to show your organization the benefits of CI/CD, microservices, and DevOps. You can also use this approach to create initial CI/CD pipelines that you can then customize or change according to your organization's requirements.

The pattern's approach creates a production environment and non-production environment that each have a virtual private cloud (VPC) and an Amazon ECS cluster configured to run in two Availability Zones. These environments are shared by all your microservices and you then create a CI/CD pipeline for each microservice. These CI/CD pipelines pull changes from a source repository in AWS CodeCommit, automatically build the changes, and then deploy them into your production and non-production environments. When a pipeline successfully completes all of its stages, you can use URLs to access the microservice in the production and non-production environments.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket that contains the `starter-code.zip` file (attached).
- AWS Cloud Development Kit (AWS CDK), installed and configured in your account. For more information about this, see [Getting started with the AWS CDK](#) in the AWS CDK documentation.

- Python 3 and pip, installed and configured. For more information about this, see the [Python documentation](#).
- Familiarity with AWS CDK, AWS CodePipeline, AWS CodeBuild, CodeCommit, Amazon Elastic Container Registry (Amazon ECR), Amazon ECS, and AWS Fargate.
- Familiarity with Docker.
- An understanding of CI/CD and DevOps.

### Limitations

- General AWS account limits apply. For more information about this, see [AWS service quotas](#) in the AWS General Reference documentation.

### Product versions

- The code was tested using Node.js version 16.13.0 and AWS CDK version 1.132.0.

## Architecture

The diagram shows the following workflow:

1. An application developer commits code to a CodeCommit repository.
2. A pipeline is initiated.
3. CodeBuild builds and pushes the Docker image to an Amazon ECR repository
4. CodePipeline deploys a new image to an existing Fargate service in a non-production Amazon ECS cluster.
5. Amazon ECS pulls the image from the Amazon ECR repository into a non-production Fargate service.
6. Testing is performed using a non-production URL.
7. The release manager approves the production deployment.
8. CodePipeline deploys the new image to an existing Fargate service in a production Amazon ECS cluster
9. Amazon ECS pulls the image from the Amazon ECR repository into the production Fargate service.
- 10 Production users access your feature by using a production URL.

## Technology stack

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- Amazon ECR
- Amazon ECS
- Amazon VPC

## Automation and scale

You can use this pattern's approach to create pipelines for microservices deployed in a shared AWS CloudFormation stack. The automation can create more than one Amazon ECS cluster in each VPC and also create pipelines for microservices deployed in a shared Amazon ECS cluster. However, this requires that you provide new resource information as inputs to the pipeline stack.

## Tools

- [AWS CDK](#) – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- [AWS CodePipeline](#) – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process. CodePipeline automates the steps required to release your software changes continuously.
- [Amazon ECS](#) – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that is used for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- [Docker](#) – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

## Code

The code for this pattern is available in the `cicdstarter.zip` and `starter-code.zip` files (attached).

## Epics

### Set up your environment

Task	Description	Skills required
Set up the working directory for AWS CDK.	1. Create a directory named <code>cicdproject</code> on your local machine.	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. Download the <code>cicdstarter.zip</code> file (attached) into the <code>cicdproject</code> directory and unzip it. This creates a folder named <code>cicdstarter</code>.</li><li>3. Run the <code>cd &lt;user-home&gt;/cicdproject/cicdstarter</code> command.</li><li>4. Set up the Python virtual environment by running the <code>python3 -m venv .venv</code> command.</li><li>5. Run the <code>source ./venv/bin/activate</code> command.</li><li>6. Configure your AWS environment by running the <code>aws configure</code> command or by using the following environment variables:<ul style="list-style-type: none"><li>• <code>AWS_ACCESS_KEY_ID</code></li><li>• <code>AWS_SECRET_ACCESS_KEY</code></li><li>• <code>AWS_DEFAULT_REGION</code></li></ul></li></ol>	

## Create the shared infrastructure

Task	Description	Skills required
Create the shared infrastructure.	<ol style="list-style-type: none"><li data-bbox="592 331 1027 464">1. In your working directory, run the <code>cd cicdvpc-ecs</code> command.</li><li data-bbox="592 485 1027 716">2. Run the <code>pip3 install -r requirements.txt</code> command to install all required Python dependencies</li><li data-bbox="592 737 1027 911">3. Run the <code>cdk bootstrap</code> command to set the AWS environment for the AWS CDK.</li><li data-bbox="592 932 1027 1213">4. Run the <code>cdk synth --context aws_account=&lt;aws_account_ID&gt; --context aws_region=&lt;aws-region&gt;</code> command.</li><li data-bbox="592 1234 1027 1516">5. Run the <code>cdk deploy --context aws_account=&lt;aws_account_ID&gt; --context aws_region=&lt;aws-region&gt;</code> command.</li><li data-bbox="592 1537 1027 1864">6. The AWS CloudFormation stack creates the following infrastructure:<ul style="list-style-type: none"><li data-bbox="630 1686 990 1864">• A non-production VPC named <code>cicd-vpc-ecs/cicd-vpc-nonprod</code></li></ul></li></ol>	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• A production VPC named <code>cicd-vpc-ecs/cicd-vpc-prod</code></li><li>• A non-production Amazon ECS cluster named <code>cicd-ecs-nonprod</code></li><li>• A production Amazon ECS cluster named <code>cicd-ecs-prod</code></li></ul>	
Monitor the AWS CloudFormation stack.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose the <code>cicd-vpc-ecs</code> stack from the list.</li><li>2. In the stack details pane, choose the <b>Events</b> tab and monitor the progress of your stack creation.</li></ol>	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
Test the AWS CloudFormation stack.	<ol style="list-style-type: none"><li>1. After the <code>cicd-vpc-ecs</code> AWS CloudFormation stack is created, ensure that the <code>cicd-vpc-ecs/cicd-vpc-nonprod</code> and <code>cicd-vpc-ecs/cicd-vpc-prod</code> VPCs are created.</li><li>2. Ensure that the <code>cicd-ecs-nonprod</code> and <code>cicd-ecs-prod</code> Amazon ECS clusters are created.</li></ol> <p><b>Important:</b> Make sure that you record the IDs for the two VPCs and the security group IDs for the default security groups in both VPCs.</p>	AWS DevOps, Cloud infrastructure

## Create a CI/CD pipeline for a microservice

Task	Description	Skills required
Create the infrastructure for the microservice.	<ol style="list-style-type: none"><li>1. Name your microservice. For example, this pattern uses <code>myservice1</code> as the microservice's name.</li><li>2. In your working directory run the <code>cd &lt;working-directory&gt;/cdpipeline</code> command.</li></ol>	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. Run the <code>pip3 install -r requirements.txt</code> command.</li><li>4. Run the full <code>cdk synth</code> command that is available in the <i>Additional information</i> section of this pattern.</li><li>5. Run the full <code>cdk deploy</code> command that is available in the <i>Additional information</i> section of this pattern.</li></ol> <p><b>Note:</b> You can also provide the values for both commands by using the <code>cdk.json</code> file in the directory.</p>	
Monitor the AWS CloudFormation stack.	Open the AWS CloudFormation console and monitor the progress of the <code>myservice-1-cicd-stack</code> stack. Eventually, the status changes to <code>CREATE_COMPLETE</code> .	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
Test the AWS CloudFormation stack.	<ol style="list-style-type: none"><li data-bbox="594 226 1026 457">1. On the AWS CodeCommit console, verify that a repository named <code>myservice1</code> exists and contains the starter code.</li><li data-bbox="594 478 1026 655">2. On the AWS CodeBuild console, verify that a build project named <code>myservice1</code> exists.</li><li data-bbox="594 676 1026 907">3. On the Amazon ECR console, verify that an Amazon ECR repository named <code>myservice1</code> exists.</li><li data-bbox="594 928 1026 1243">4. On the Amazon ECS console, verify that a Fargate service named <code>myservice1</code> exists in both a non-production and production Amazon ECS cluster.</li><li data-bbox="594 1264 1026 1642">5. On the Amazon Elastic Compute Cloud (Amazon EC2) console, verify that the non-production and production Application Load Balancers are created. Record the DNS names of the ALBs.</li><li data-bbox="594 1663 1026 1831">6. On the AWS CodePipeline console, verify that a pipeline named <code>myservice1</code> exists. It</li></ol>	

Task	Description	Skills required
	<p>must have Source, Build, Deploy-NonProd , and Deploy-Prod stages. The pipeline should also have an in progress status.</p> <ol style="list-style-type: none"><li>7. Monitor the pipeline until all stages are complete.</li><li>8. Manually approve it for production.</li><li>9. In a browser window, enter the DNS names of the ALBs.</li><li>10. The application should display Hello World in the non-production and production URLs.</li></ol>	

Task	Description	Skills required
Use the pipeline.	<ol style="list-style-type: none"> <li>1. Open the CodeCommit repository that you created earlier and open the <code>index.js</code> file.</li> <li>2. Replace <code>Hello World</code> with <code>Hello CI/CD</code>.</li> <li>3. Save and commit the changes to the main branch.</li> <li>4. Verify that the pipeline initiates and that the change goes through the <code>Build</code>, <code>Deploy-NonProd</code>, and <code>Deploy-Prod</code> stages.</li> <li>5. Manually approve the production.</li> <li>6. Both production and non-production URLs should now display <code>Hello CI/CD</code>.</li> </ol>	AWS DevOps, Cloud infrastructure
Repeat this epic for each microservice.	Repeat the tasks in this epic to create a CI/CD pipeline for each of your microservices.	AWS DevOps, Cloud infrastructure

it

## Summary

This pattern demonstrates how to develop a typical web application in a serverless architecture, for developers and development leads who are beginning to test DevOps practices on Amazon Web Services (AWS). It builds a sample application that creates a storefront and backend for browsing and purchasing books, and provides a microservice that can be developed independently. The pattern uses AWS Cloud9 as a development environment, an Amazon DynamoDB database as a data store, and AWS services such as AWS CodePipeline and AWS CodeBuild for continuous integration and continuous deployment (CI/CD) functionality.

The pattern guides you through the following development activities:

- Creating a standard AWS Cloud9 development environment
- Using AWS CloudFormation templates to create a web application and a microservice for books
- Using AWS Cloud9 to modify the front-end, commit changes, and test changes
- Creating and testing a CI/CD pipeline to the microservice
- Automating unit tests

The code for this pattern is provided in GitHub, in the [AWS DevOps End-to-End Workshop](#) repository.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Files from the [AWS DevOps End-to-End Workshop](#) downloaded to your computer

**Important:** Building this demo application in your AWS account creates and consumes AWS resources. You are responsible for the cost of the AWS services and resources used to create and run the application. After you finish your work, be sure to remove all resources to avoid ongoing charges. For cleanup instructions, see the *Epics* section.

## Limitations

This walkthrough is intended for demonstration and development purposes only. To use it in a production environment, see [Security best practices](#) in the AWS Identity and Access Management (IAM) documentation, and make the necessary changes to IAM roles, Amazon DynamoDB, and other services used. The web application is derived from the [AWS Bookstore Demo App](#); for additional considerations, see the [Known limitations](#) section of the README file.

## Architecture

The architecture of the bookstore application is illustrated in the [Architecture](#) section of the README file for the [AWS Bookstore Demo App](#).

From a deployment perspective, the Bookstore Demo App uses a single CloudFormation template to deploy all services and objects in one stack. This pattern makes a few changes to demonstrate how a particular developer or team could work in a specific product (Books), and update it independently from the rest of the application. For this reason, the code for this pattern separates the AWS Lambda functions and related objects for the Books microservice into a second CloudFormation template, which creates a Books stack. That makes it possible to see the microservice being updated by using CI/CD practices. In the following diagram, the dashed border identifies the Books microservice.

## Tools

### Tools

- Jest framework for JavaScript testing
- Python 3.9

### Code

The source code and templates for this pattern are available on GitHub, in the [AWS DevOps End-to-End Workshop](#) repository. Before you follow the steps in the *Epics* section, download all the files from the repository to your computer.

**Note:** The *Epics* section provides the high-level steps for this walkthrough, to give you general information about the process. To complete each step, see the [README file](#) in the AWS DevOps End-to-End Workshop repository for detailed instructions.

The [AWS DevOps End-to-End Workshop](#) repository extends the [AWS Bookstore Demo App](#) repository and uses a modified version of the [AWS Cloud9 Bootstrapping](#) code to create the AWS Cloud9 IDE.

## Best practices

Using the Bookstore application is straightforward. Here are some recommended best practices:

- When you install the application, you can use a project name of your choice or use the default name (demobookstore) for convenience.
- After you have the application up and running, it's a good practice to shut down the Amazon Neptune database if you want to keep testing for another day, because the database instance could result in additional charges. However, be aware that the database will automatically be started after seven days.
- For code details, see the documentation for the [AWS Bookstore Demo App](#) repository. It describes each microservice and table.
- For additional best practices, see the *Some challenges if you have time...* section of the [README file](#) in the AWS DevOps End-to-End Workshop repository. We recommend that you review the information to dive deep into additional features for security and to practice decoupling services.

## Epics

### Download the source code

Task	Description	Skills required
Download the source code from GitHub.	The source code and templates for this pattern are available in GitHub, in the <a href="#">AWS DevOps End-to-End Workshop</a> repository. Before you follow the next steps in the <i>Epics</i> section, download all the files from the repository to your computer.	App developer

Task	Description	Skills required
	<p><b>Note:</b> The <i>Epics</i> section provides the high-level steps for this walkthrough, to give you general information about the process. To complete each step, see the <a href="#">README file</a> in the AWS DevOps End-to-End Workshop repository for detailed instructions.</p> <p>The <a href="#">AWS DevOps End-to-End Workshop</a> repository extends the <a href="#">AWS Bookstore Demo App</a> repository and uses a modified version of the <a href="#">AWS Cloud9 Bootstrapping</a> code to create the AWS Cloud9 IDE.</p>	

## Build the Bookstore web application and the Books microservice

Task	Description	Skills required
Create the front-end and Lambda functions for the Bookstore app.	<ol style="list-style-type: none"> <li>Log in to the <a href="#">CloudFormation console</a>, and deploy the <code>DemoBookstoreMainTemplate.yml</code> template to create the <code>DemoBookStoreStack</code> stack. This creates the front-end and Lambda functions that are outside the Books microservice.</li> </ol>	Developer

Task	Description	Skills required
	2. In the <b>Outputs</b> tab of the stack, note the website URL under the <b>WebApplication</b> label.	
Create the Books microservice.	On the <a href="#">CloudFormation console</a> , deploy the DemoBookstoreBooksServiceTemplate.yml template to create the DemoBooksServiceStack stack.	Developer
Test your application.	Use the website URL from the DemoBookStoreStack stack to access the Bookstore application.	Developer

## Use the Cloud9 environment to maintain your application

Task	Description	Skills required
Create an AWS Cloud9 IDE.	On the <a href="#">CloudFormation console</a> , deploy the C9EnvironmentTemplate.yml template to create an AWS Cloud9 environment.	Developer, Developer lead
Create CodeCommit repositories.	1. Log in to the <a href="#">AWS CodeCommit console</a> , and verify that you have a demobookstore-WebAssets repository, which contains the code for the front-end application.	Developer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>2. Create a repository for the Books microservice called <code>demobookstore-BooksService</code> .</li> <li>3. Clone the two repositories in AWS Cloud9 (<code>demobookstore-WebAssets</code> and <code>demobookstore-BooksService</code> ) by using the <code>git clone</code> command.</li> </ol>	
Change the code in the frontend and check the pipeline.	<ol style="list-style-type: none"> <li>1. Use AWS Cloud9 to make some code changes on a webpage. This will update the <code>demobookstore-WebAssets</code> repository.</li> <li>2. On the <a href="#">AWS CodePipeline console</a>, verify that <b>demobookstore-Assets-Pipeline</b> is running.</li> <li>3. Test your web application by refreshing it from the browser (<b>Ctrl+F5</b> on Firefox).</li> </ol>	Developer

## Implement a CI/CD pipeline for the Books microservice

Task	Description	Skills required
Add the YAML files for the build and service update.	<ol style="list-style-type: none"> <li>1. In AWS Cloud9, upload the <code>buildspec.yml</code> and <code>DemoBookstoreBooks</code></li> </ol>	Developer

Task	Description	Skills required
	<p>ServiceUpdateTemplate.yml files.</p> <ul style="list-style-type: none"><li>• buildspec.yml has building instructions, and also includes testing instructions for automated tests. They are commented at this point, and will be used later.</li><li>• DemoBookstoreBooksServiceUpdateTemplate.yml is an updated version of DemoBookstoreBooksServiceTemplate.yml, to be used in the deployment stage of the pipeline.</li></ul> <p>2. Commit and push the files.</p>	

Task	Description	Skills required
Create an S3 bucket for the build pipeline.	<p>To create an S3 bucket, follow the instructions in the <a href="#">Amazon S3 documentation</a>.</p> <ul style="list-style-type: none"><li>The bucket name must be globally unique; for example, demobooks-tore-books-service-pipeline-bucket-YYYYMMDDHHMM .</li><li>Clear the <b>Block all public access</b> check box, and select the <b>I acknowledge...</b> check box.</li></ul>	Developer
Use IAM to create a role for CloudFormation deployment.	Create a demobookstore-CloudFormation-role role and attach the AdministratorAccess policy. In the next epic, you can reconfigure this role for minimum permissions.	Developer
Create a new pipeline to automate building and deploying the Books microservice.	Create a pipeline (for example, <b>demobookstore-BooksService-Pipeline</b> ) with Commit, Build, and Deploy stages, as described in the <a href="#">README file</a> .	Developer
Test your microservice in AWS Cloud9.	Make a change in the <b>ListBooks</b> function and see the pipeline working.	Developer

Task	Description	Skills required
Automate the unit test for the ListBooks Lambda function.	In the AWS Cloud9 IDE, enable the build to run unit tests, and check the test results. For instructions, see the <a href="#">README file</a> .	Developer

### (Optional) Implement additional functionality

Task	Description	Skills required
Make your solution secure.	Configure demobookstore-CloudFormation-role to have minimum permissions, and check other used roles as well.	Developer
Eliminate dependencies in the CloudFormation templates.	The method for exchanging information between the DemoBookstoreMainTemplate.yml template and the DemoBookstoreBooksServiceTemplate.yml template is based on outputs and imports. Passing values between these two templates adds dependencies. To eliminate the dependencies, consider using <a href="#">AWS Systems Manager Parameter Store</a> .	Developer
Create a Cart microservice.	Use the Books microservice as an example for taking shopping cart-rela	Developer

Task	Description	Skills required
	ted functions out of the DemoBookstoreMainTemplate.yml template and creating a Cart microservice.	

## Clean up

Task	Description	Skills required
Delete the S3 buckets.	<p>On the <a href="#">Amazon S3 console</a>, delete the following buckets that are associated with the sample web application:</p> <ul style="list-style-type: none"> <li>Two buckets created for the AWS Bookstore Demo App. The buckets names start with the stack name you provided for AWS CloudFormation when you created the frontend; for example, <b>DemoBookstoreStack</b>.</li> <li>One bucket for the build pipeline; for example, <b>demobookstore-books-service-pipeline-bucket-<code>&lt;YYYYMMDDHHMM&gt;</code></b>.</li> </ul>	Developer
Delete the stacks.	On the <a href="#">CloudFormation console</a> , delete the stacks associated with the sample web applicaton:	Developer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• DemoBooksServiceStack</li> <li>• DemoBookStoreStack</li> </ul> <p>The removal could take more than 90 minutes. If the removal fails, delete them again, and also delete any manual resources (for example, the VPC or network interfaces) based on notifications.</p>	
Delete the IAM roles.	<p>On the <a href="#">IAM console</a>, delete the following roles:</p> <ul style="list-style-type: none"> <li>• demobookstore-Cloudformation-role</li> <li>• demobookstore-BooksService-BuildProject-service-role</li> </ul> <p>For step-by-step instructions, see the <a href="#">IAM documentation</a>.</p>	Developer

## Related resources

- [AWS Bookstore Demo App](#)
- [AWS Cloud9 Bootstrapping example](#)
- [Creating a stack on the AWS CloudFormation console](#) (AWS CloudFormation documentation)
- [Creating a bucket](#) (Amazon S3 documentation)

## Additional information

For detailed, step-by-step instructions, see the [README file](#) in the [AWS DevOps End-to-End Workshop](#) GitHub repository.

**About the May 2023 update:** This pattern was updated to use newer versions of Node and Python. We updated many of the packages in the source code and removed Glyphicon because it's no longer free. We also removed all dependencies on the [AWS Bookstore Demo App](#) repository, so the two repositories can now evolve independently.

# Build and push Docker images to Amazon ECR using GitHub Actions and Terraform

Created by Ruchika Modi (AWS)

<b>Code repository:</b> <a href="#">docker-ecr-actions-workflow</a>	<b>Environment:</b> Production	<b>Technologies:</b> DevOps; Containers & microservices; Infrastructure
<b>Workload:</b> All other workloads	<b>AWS services:</b> Amazon ECR	

## Summary

This pattern explains how you can create reusable GitHub workflows to build your Dockerfile and push the resulting image to Amazon Elastic Container Registry (Amazon ECR). The pattern automates the build process of your Dockerfiles by using Terraform and GitHub Actions. This minimizes the possibility of human error and substantially reduces deployment time.

A GitHub push action to the main branch of your GitHub repository initiates the deployment of resources. The workflow creates a unique Amazon ECR repository based on the combination of the GitHub organization and repository name. It then pushes the Dockerfile image to the Amazon ECR repository.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An active GitHub account.
- A [GitHub repository](#).
- Terraform version 1 or later [installed and configured](#).
- An Amazon Simple Storage Service (Amazon S3) bucket for the [Terraform backend](#).

- An [Amazon DynamoDB](#) table for Terraform state locking and consistency. The table must have a partition key named `LockID` with a type of `String`. If this isn't configured, state locking will be disabled.
- An AWS Identity and Access Management (IAM) role that has permissions to set up the Amazon S3 backend for Terraform. For configuration instructions, see the [Terraform documentation](#).

## Limitations

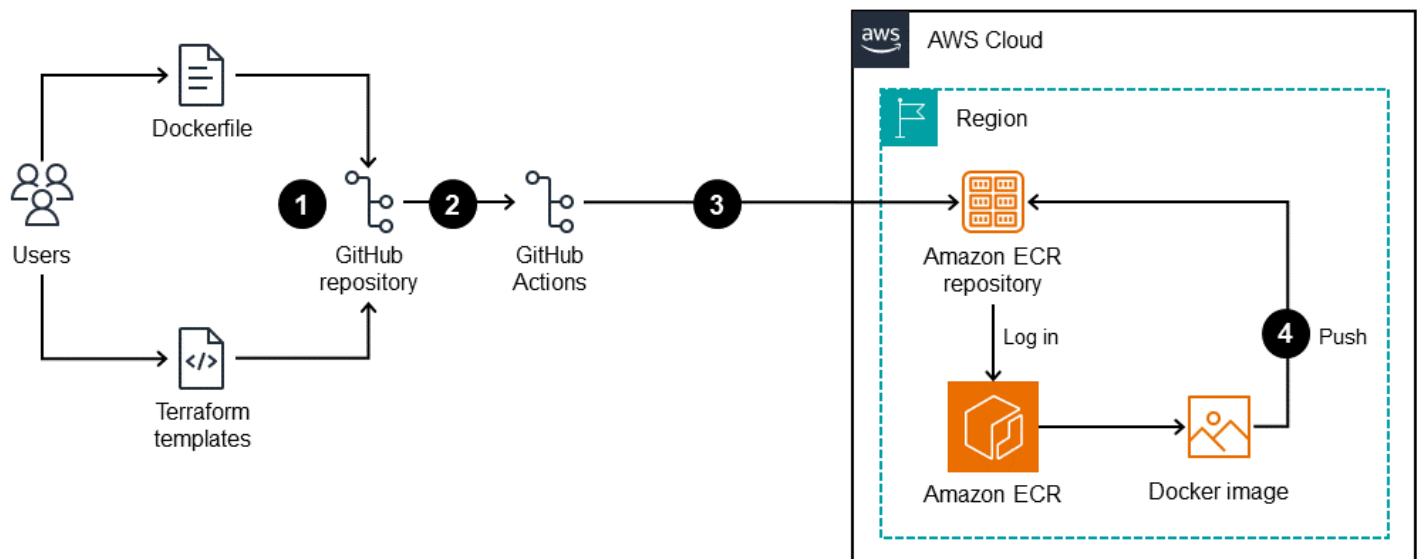

This reusable code has been tested only with GitHub Actions.

## Architecture

### Target technology stack

- Amazon ECR repository
- GitHub Actions
- Terraform

### Target architecture

The diagram illustrates the following:

1. A user adds a Dockerfile and Terraform templates to the GitHub repository.

2. These additions initiate a GitHub Actions workflow.
3. The workflow checks whether an Amazon ECR repository exists. If not, it creates the repository based on the GitHub organization and repository name.
4. The workflow builds the Dockerfile and pushes the image to the Amazon ECR repository.

## Tools

### Amazon services

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container registry service that's secure, scalable, and reliable.

### Other tools

- [GitHub Actions](#) is integrated into the GitHub platform to help you create, share, and run workflows within your GitHub repositories. You can use GitHub Actions to automate tasks such as building, testing, and deploying your code.
- [Terraform](#) is an open source infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises infrastructure.

### Code repository

The code for this pattern is available in the GitHub [Docker ECR Actions Workflow](#) repository.

- When you create GitHub Actions, Docker workflow files are saved in the `/.github/workflows/` folder of this repository. The workflow for this solution is in the [workflow.yaml](#) file.
- The `e2e-test` folder provides a sample Dockerfile for reference and testing.

## Best practices

- For best practices for writing Dockerfiles, see the [Docker documentation](#).
- Use a [VPC endpoint for Amazon ECR](#). VPC endpoints are powered by AWS PrivateLink, a technology that enables you to privately access Amazon ECR APIs through private IP addresses. For Amazon ECS tasks that use the Fargate launch type, the VPC endpoint enables the task to pull private images from Amazon ECR without assigning a public IP address to the task.

## Epics

### Set up the OIDC provider and GitHub repository

Task	Description	Skills required
Configure OpenID Connect.	Create an OpenID Connect (OIDC) provider. You will use the provider in the trust policy for the IAM role used in this action. For instructions, see <a href="#">Configuring OpenID Connect in Amazon Web Services</a> in the GitHub documentation.	AWS administrator, AWS DevOps, General AWS
Clone the GitHub repository.	Clone the GitHub <a href="#">Docker ECR Actions Workflow</a> repository into your local folder: <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>\$git clone https://github.com/aws-samples/docker-ecr-actions-workflow</pre> </div>	DevOps engineer

### Customize the GitHub reusable workflow and deploy the Docker image

Task	Description	Skills required
Customize the event that initiates the Docker workflow.	The workflow for this solution is in <a href="#">workflow.yaml</a> . This script is currently configured to deploy resources when it receives the <code>workflow_dispatch</code> event. You can customize this configuration by changing the event to	DevOps engineer

Task	Description	Skills required
	workflow_call and calling the workflow from another parent workflow.	

Task	Description	Skills required
Customize the workflow.	<p>The <a href="#">workflow.yaml</a> file is configured to create a dynamic, reusable GitHub workflow. You can edit this file to customize the default configuration, or you can pass the input values from the GitHub Actions console if you're using the <code>workflow_dispatch</code> event to initiate deployment manually.</p> <ul style="list-style-type: none"><li>• Make sure to specify the correct AWS account ID and target Region.</li><li>• Create an Amazon ECR lifecycle policy (see <a href="#">sample policy</a>) and update the default path (<code>e2e-test/policy.json</code>) accordingly.</li><li>• The workflow file requires two IAM roles as input:<ul style="list-style-type: none"><li>• An IAM role that has permissions to set up the Amazon S3 backend for Terraform (see the <a href="#">Prerequisites</a> section). You can update the default role name <code>workload-assumable-role</code> in the <code>.yaml</code> file accordingly.</li></ul></li></ul>	DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>An IAM role that has permissions to access GitHub. This role is also used in the Amazon ECR policy to restrict Amazon ECR operations. For more information, see the <a href="#">data.tf file</a>.</li> </ul>	
Deploy the Terraform templates.	The workflow automatically deploys the Terraform templates that create the Amazon ECR repository, based on the GitHub event you configured. These templates are available as .tf files at the <a href="#">root of the Github repository</a> .	AWS DevOps, DevOps engineer

## Troubleshooting

Issue	Solution
Issues or errors when you configure Amazon S3 and DynamoDB as the Terraform remote backend.	Follow the instructions in the <a href="#">Terraform documentation</a> to set up the required permissions on the Amazon S3 and DynamoDB resources for the remote backend configuration.
Unable to run or start the workflow with the <code>workflow_dispatch</code> event.	The workflow that's configured to deploy from the <code>workflow_dispatch</code> event will work only if the workflow is configured on the main branch as well.

# Build and test iOS apps with AWS CodeCommit, AWS CodePipeline, and AWS Device Farm

Created by Abdullahi Olaoye (AWS)

<b>R Type:</b> N/A	<b>Source:</b> On-premises DevOps processes	<b>Target:</b> CI/CD pipeline for iOS apps development on AWS
<b>Created by:</b> AWS	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Web & mobile apps; DevOps
<b>AWS services:</b> AWS CodeCommit; AWS CodePipeline; AWS Device Farm		

## Summary

This pattern outlines the steps for creating a continuous integration and continuous delivery (CI/CD) pipeline that uses AWS CodePipeline to build and test iOS applications on real devices on AWS. The pattern uses AWS CodeCommit to store the application code, the Jenkins open-source tool to build the iOS application, and AWS Device Farm to test the built application on real devices. These three phases are orchestrated together in a pipeline by using AWS CodePipeline.

This pattern is based on the post [Building and testing iOS and iPadOS apps with AWS DevOps and mobile services](#) on the AWS DevOps blog. For detailed instructions, see the blog post.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Apple developer account
- Build server (macOS)
- [Xcode](#) version 11.3 (installed and set up on the build server)

- AWS Command Line Interface (AWS CLI) [installed](#) and [configured](#) on the workstation
- Basic knowledge of [Git](#)

## Limitations

- The application build server must be running macOS.
- The build server must have a public IP address, so CodePipeline can connect to it remotely to initiate builds.

## Architecture

### Source technology stack

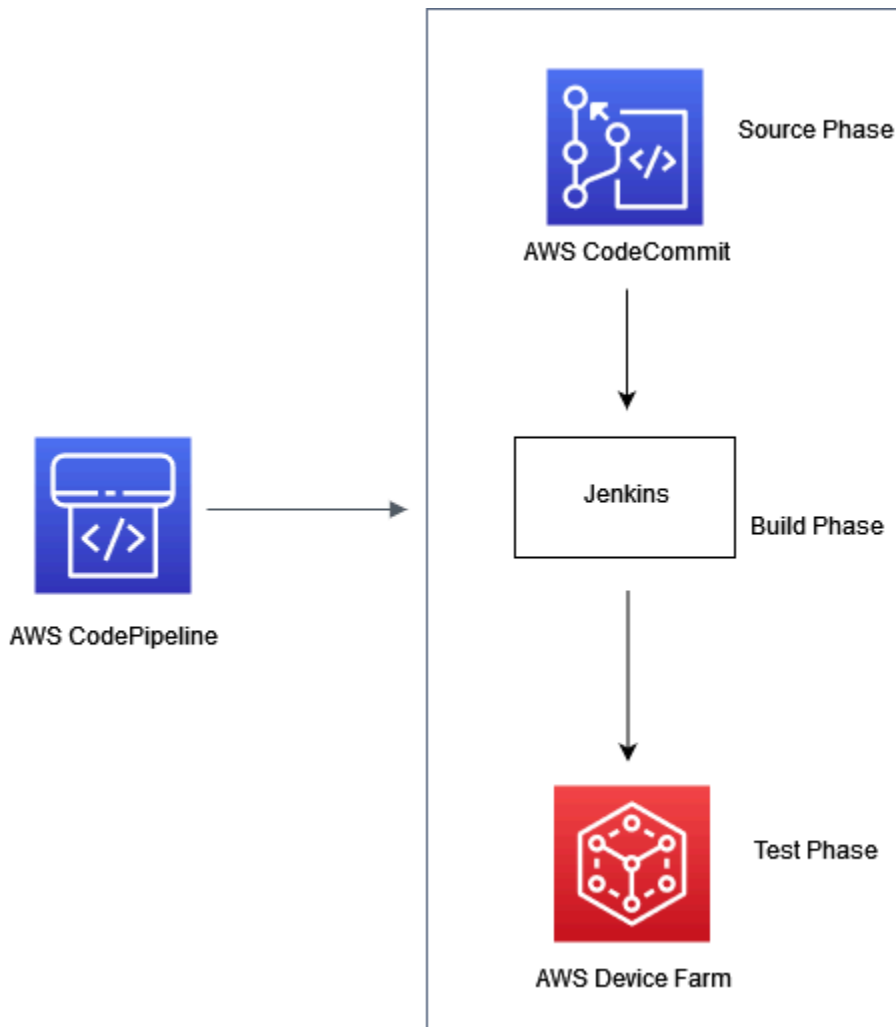

- An on-premises iOS application build process that involves using a simulator or manual test on physical devices

### Target technology stack

- An AWS CodeCommit repository for storing application source code
- A Jenkins server for application builds using Xcode
- An AWS Device Farm device pool for testing applications on real devices

### Target architecture

When a user commits changes to the source repository, the pipeline (AWS CodePipeline) fetches the code from the source repository, initiates a Jenkins build, and passes the application code to Jenkins. After the build, the pipeline retrieves the build artifact and starts an AWS Device Farm job to test the application against a device pool.

## Tools

- [AWS CodePipeline](#) is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deploy phases of your release process every time there is a code change, based on the release model you define.
- [AWS CodeCommit](#) is a fully managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure.
- [AWS Device Farm](#) is an application testing service that lets you improve the quality of your web and mobile apps by testing them across an extensive range of desktop browsers and real mobile devices, without having to provision and manage any testing infrastructure.

- [Jenkins](#) is an open-source automation server that enables developers to build, test, and deploy their software.

## Epics

### Set up the build environment

Task	Description	Skills required
Install Jenkins on the build server that's running macOS.	Jenkins will be used for building the application, so you must first install it on the build server. To get detailed instructions for this and subsequent tasks, see the AWS blog post <a href="#">Building and testing iOS and iPadOS apps with AWS DevOps and mobile services</a> and other resources in the <a href="#">Related resources</a> section at the end of this pattern.	DevOps
Configure Jenkins.	Follow the on-screen instructions to configure Jenkins.	DevOps
Install the AWS CodePipeline plugin for Jenkins.	This plugin must be installed on the Jenkins server in order for Jenkins to interact with the AWS CodePipeline service.	DevOps
Create a Jenkins freestyle project.	In Jenkins, create a freestyle project. Configure the project to specify triggers and other build configuration options.	DevOps

## Configure AWS Device Farm

Task	Description	Skills required
Create a Device Farm project.	Open the AWS Device Farm console. Create a project and a device pool for testing. For instructions, see the blog post.	Developer

## Configure the source repository

Task	Description	Skills required
Create a CodeCommit repository.	Create a repository where the source code will be stored.	DevOps
Commit your application code to the repository.	Connect to the CodeCommit repository you created. Push the code from your local machine to the repository.	DevOps

## Configure the pipeline

Task	Description	Skills required
Create a pipeline in AWS CodePipeline.	Open the AWS CodePipeline console, and create a pipeline. The pipeline orchestrates all the phases of the CI/CD process. For instructions, see the AWS blog post <a href="#">Building and testing iOS and iPadOS apps with AWS DevOps and mobile services</a> .	DevOps

Task	Description	Skills required
Add a test stage to the pipeline.	To add a test stage and integrate it with AWS Device Farm, edit the pipeline.	DevOps
Initiate the pipeline.	To start the pipeline and the CI/CD process, choose <b>Release change</b> .	DevOps

### View application test results

Task	Description	Skills required
Review test results.	In the AWS Device Farm console, select the project you created, and review the results of the tests. The console will show the details of each test.	Developer

# Check AWS CDK applications or CloudFormation templates for best practices by using cdk-nag rule packs

Created by Arun Donti

**Environment:** Production

**Technologies:** DevOps;  
Security, identity, compliance

**Workload:** Open-source

**AWS services:** AWS CDK

## Summary

This pattern explains how you can use the [cdk-nag](#) utility to check [AWS Cloud Development Kit \(AWS CDK\)](#) applications for best practices by using a combination of rule packs. **cdk-nag** is an open-source project that was inspired by [cfn\\_nag](#). It implements rules in evaluation packs such as AWS Solutions Library, Health Insurance Portability and Accountability Act (HIPAA), and National Institute of Standards and Technology (NIST) 800-53 by using [AWS CDK Aspects](#). You can check your AWS CDK applications for best practices by using the rules in these packs, detect and remediate code based on best practices, and suppress the rules that you don't want to use in your evaluations.

You can also use **cdk-nag** to check your AWS CloudFormation templates by using the [cloudformation-include](#) module.

For information about all available packs, see the [Rules](#) section of the [cdk-nag](#) repository. Evaluation packs are available for:

- [AWS Solutions Library](#)
- [HIPAA security](#)
- [NIST 800-53 rev 4](#)
- [NIST 800-53 rev 5](#)
- [Payment Card Industry Data Security Standard \(PCI DSS\) 3.2.1](#)

## Prerequisites and limitations

### Prerequisites

- An application that uses the [AWS CDK](#)

### Tools

- [AWS CDK](#) – Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- [AWS CloudFormation](#) – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and you can launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

### Epics

#### Integrate cdk-nag with your AWS CDK application

Task	Description	Skills required
Learn about cdk-nag.	Navigate to the <a href="#">cdk-nag</a> GitHub repository and read through the documentation.	App developer
Install the cdk-nag package in your AWS CDK application.	To use <b>cdk-nag</b> in your AWS CDK application, you must install it first. <b>cdk-nag</b> is available to download from PyPI, npm, NuGet, and Apache Maven. For the latest information about available versions and download locations, see the <a href="#">Readme file</a> in the repository.	App developer

Task	Description	Skills required
Choose your NagPacks.	<p><b>cdk-nag</b> has different packs of rules called <i>NagPacks</i>. Each NagPack contains rules that conform to a specific standard. For example, the AWS Solutions NagPack contains general best practices, and the NIST 800-53 rev 5 NagPack can help with compliance. You can apply multiple NagPacks to your application, and you can add and remove packs as necessary. For a list of available packs, see the <a href="#">Readme file</a> in the GitHub repository. For information about the individual rules in each pack, see the <a href="#">Rules section</a> of the GitHub repository.</p>	App developer

Task	Description	Skills required
Integrate cdk-nag into your AWS CDK application.	<p>You can integrate <b>cdk-nag</b> into your application on an applicationwide level, or integrate it into individual stages or stacks in your application. For example, to integrate the AWS Solutions and HIPAA security NagPacks into an AWS CDK v2 TypeScript application on an applicationwide level, you can use the following code:</p> <pre data-bbox="597 871 1026 1864">import { App, Aspects }   from 'aws-cdk-lib'; import { CdkTestStack } from '../lib/cdk-test-stack'; import { AwsSolutionsChecks, HIPAASecurityChecks } from   'cdk-nag';  const app = new App(); new CdkTestStack(app,   'CdkNagDemo'); // Simple rule informational messages Aspects.of(app).add(new AwsSolutionsChecks()); // Additional explanations on the purpose of triggered rules Aspects.of(app).add(new HIPAASecurityChecks({ verbose: true }));</pre>	App developer

# Configure cross-account access to Amazon DynamoDB

Created by Shashi Dalmia (AWS) and Jay Enjamoori (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Databases; Security, identity,  
compliance

**AWS services:** Amazon  
DynamoDB; AWS Identity and  
Access Management; AWS  
Lambda

## Summary

This pattern explains the steps for configuring cross-account access to Amazon DynamoDB. Amazon Web Services (AWS) services can access DynamoDB tables that are in the same AWS account if the service has the appropriate AWS Identity and Access Management (IAM) permissions set up in the database. However, access from a different AWS account requires setting up IAM permissions and establishing a trust relationship between the two accounts.

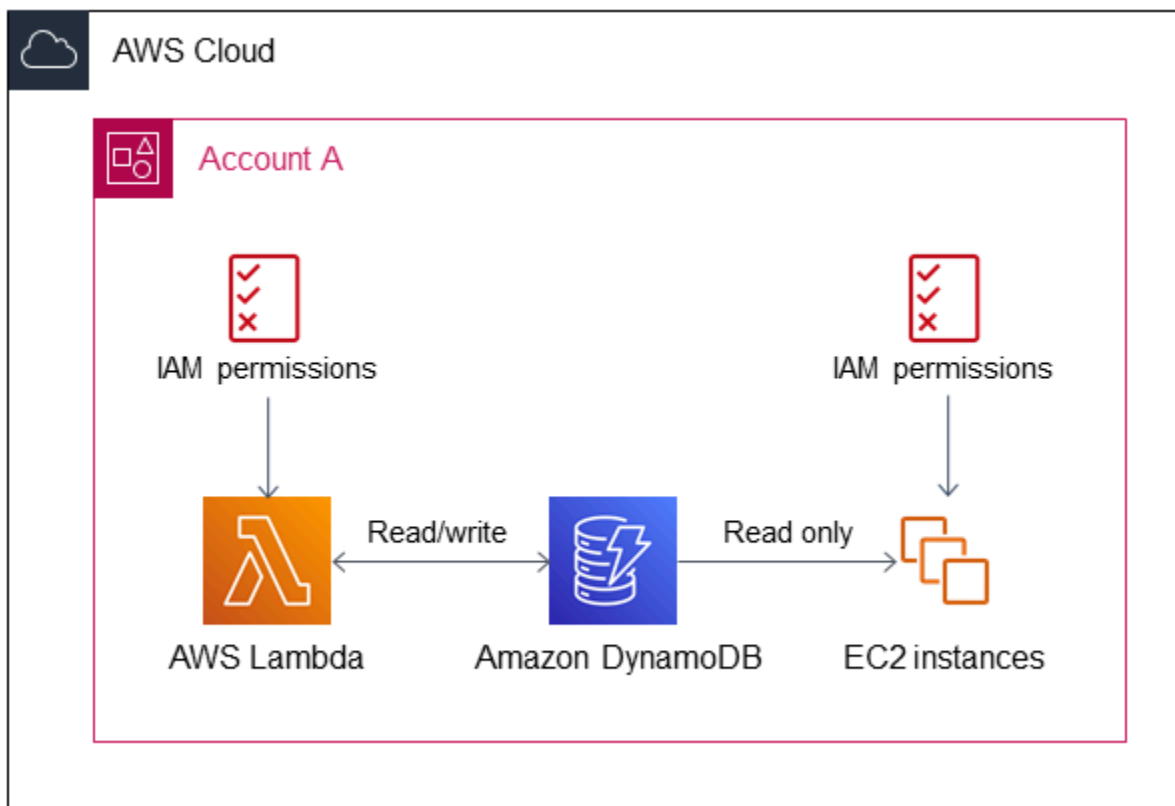

This pattern provides steps and sample code to demonstrate how you can configure AWS Lambda functions in one account to read and write to a DynamoDB table in a different account.

## Prerequisites and limitations

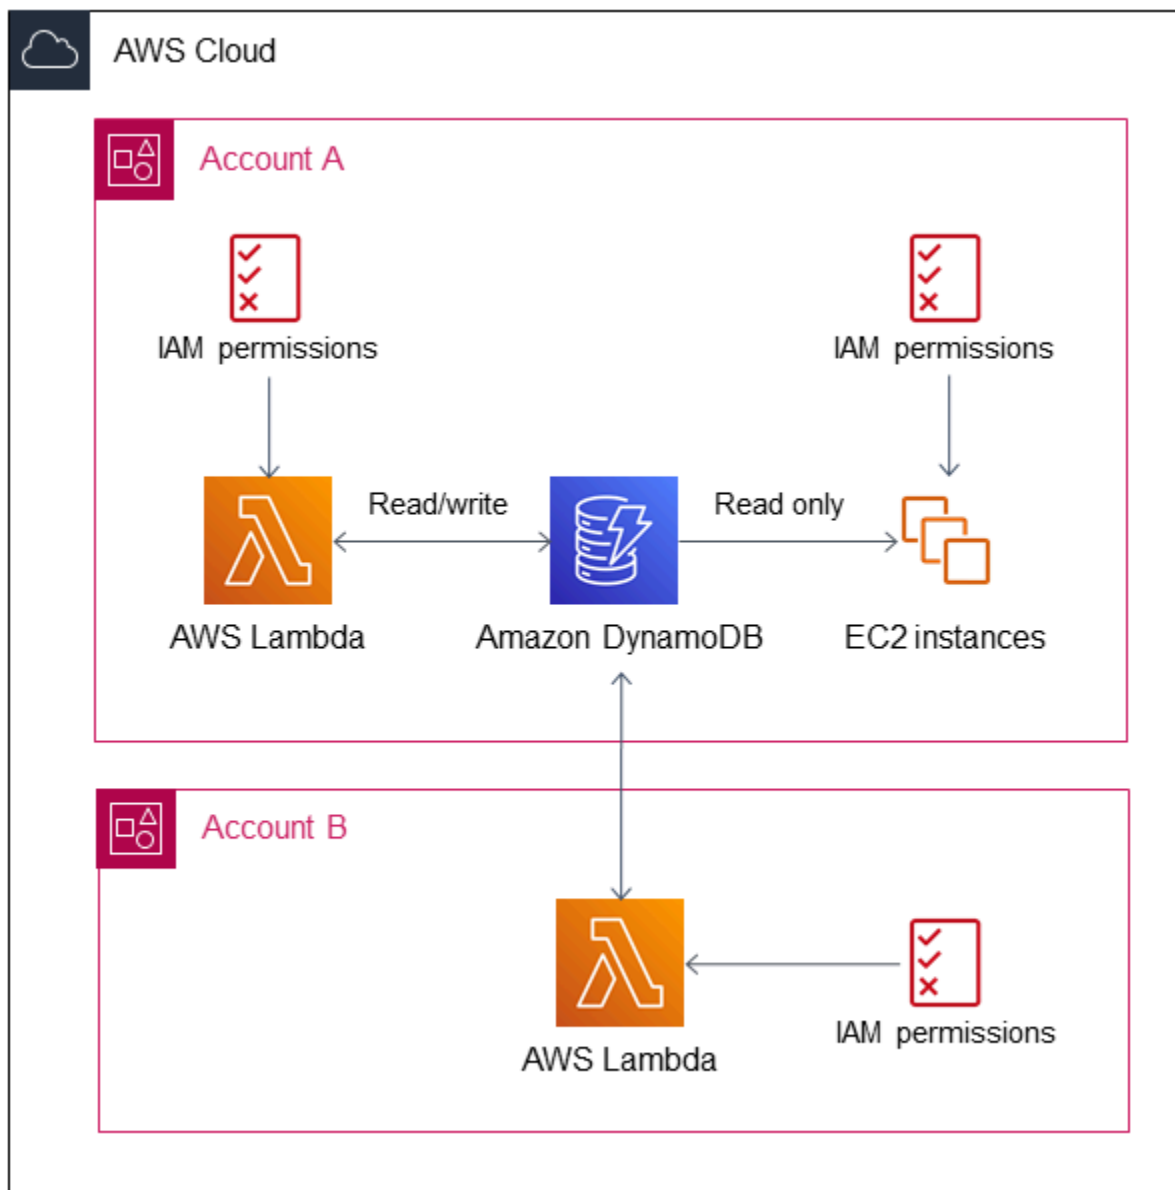

- Two active AWS accounts. This pattern refers to these accounts as *Account A* and *Account B*.
- AWS Command Line Interface (AWS CLI) [installed](#) and [configured](#) to access Account A, to create the DynamoDB database. The other steps in this pattern provide instructions for using the IAM, DynamoDB, and Lambda consoles. If you're planning to use AWS CLI instead, configure it to access both accounts.

## Architecture

In the following diagram, AWS Lambda, Amazon EC2, and DynamoDB are all in the same account. In this scenario, Lambda functions and Amazon Elastic Compute Cloud (Amazon EC2) instances can access DynamoDB.

If resources in a different AWS account try to access DynamoDB, they require setting up cross-account access and a trust relationship. For example, in the following diagram, to enable access between DynamoDB in Account A and the Lambda function in Account B, you must create a trust relationship between the accounts and grant appropriate access to the Lambda service and users, as described in the [Epics](#) section.

## Tools

### AWS services

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- [AWS Lambda](#) is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

## Code

This pattern includes sample code in the [Additional information](#) section to illustrate how you can configure a Lambda function in Account B to write and read from the DynamoDB table in Account A. The code is provided for illustration and testing purposes only. If you're implementing this pattern in a production environment, use the code as a reference and customize it for your own environment.

This pattern illustrates cross-account access with Lambda and DynamoDB. You can use the same steps for other AWS services as well, but make sure that you grant and configure the appropriate permissions in both accounts. For example, if you want to grant access to an Amazon Relational Database Service (Amazon RDS) database in Account A, create a role for that database and bind it with a trust relationship. In Account B, if you want to use Amazon EC2 instead of AWS Lambda, create the respective IAM policy and role, and then attach them to the EC2 instance.

## Epics

### Create a DynamoDB table in Account A

Task	Description	Skills required
Create a DynamoDB table in Account A.	<p>After you configure AWS CLI for Account A, use the following AWS CLI command to create a DynamoDB table:</p> <pre>aws dynamodb create-table \   --table-name Table- Account-A \   --attribute-defini- tions \   Attribute Name=category,Attr- ibuteType=S \</pre>	AWS DevOps

Task	Description	Skills required
	<pre> Attribute Name=item,AttributeType=S \ --key-schema \ Attribute Name=category,KeyType=HASH \ Attribute Name=item,KeyType=RANGE \ --provisioned-throughput \ ReadCapacityUnits=5,WriteCapacityUnits=5 </pre> <p>For more information about creating tables, see the <a href="#">DynamoDB documentation</a>.</p>	

## Create a role in Account A

Task	Description	Skills required
Create a role in Account A.	<p>This role will be used by Account B to gain permissions to access Account A. To create the role:</p> <ol style="list-style-type: none"> <li>1. Sign in to Account A at <a href="https://&lt;account-ID-for-Account-A&gt;.signin.aws.amazon.com/console">https://&lt;account-ID-for-Account-A&gt;.signin.aws.amazon.com/console</a>.</li> <li>2. Open the IAM console at <a href="https://console.aws.amazon.com/iam/">https://console.aws.amazon.com/iam/</a>.</li> </ol>	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. In the navigation pane of the console, choose <b>Roles</b>, and then choose <b>Create role</b>.</li><li>4. For <b>Select trusted entity</b>, choose <b>AWS account</b>, and in the <b>An AWS account</b> section, choose <b>Another AWS account</b>.</li><li>5. For <b>Account ID</b>, enter the ID for Account B.</li><li>6. Choose <b>Next: Permissions</b>.</li><li>7. In the <b>Filter policies</b> box, enter <b>DynamoDB</b>.</li><li>8. In the list of DynamoDB policies, select <b>AmazonDynamoDBFullAccess</b>.  <b>Note:</b> This policy allows all actions on DynamoDB. As a security best practice, you should always grant only required permissions. For a list of other policies you can choose instead, see <a href="#">Example policies</a> in the IAM documentation.</li><li>9. Choose <b>Next: Name, review, and create</b>.</li><li>10. For <b>Role name</b>, enter a unique name for your role (for example, <b>DynamoDB-FullAccess-For-Account-</b></li></ol>	

Task	Description	Skills required
	<p><b>B)</b>, and add an optional role description.</p> <p>11 Review all the sections and (optionally) add metadata to the role by attaching tags as key-value pairs.</p> <p>12 Choose <b>Create role</b>.</p> <p>For more information about creating roles, see the <a href="#">IAM documentation</a>.</p>	
<p>Note the ARN for the role in Account A.</p>	<ol style="list-style-type: none"> <li>1. In the navigation pane of the <a href="#">IAM console</a>, choose <b>Roles</b>.</li> <li>2. In the search box, enter <b>DynamoDB-FullAccess-For-Account-B</b> (or the role name you created in the previous story), and choose the role.</li> <li>3. In the summary page for the role, copy the Amazon Resource Name (ARN). You'll use the ARN when setting up the Lambda code in Account B.</li> </ol>	<p>AWS DevOps</p>

## Configure access to Account A from Account B

Task	Description	Skills required
Create a policy to access Account A.	<ol style="list-style-type: none"><li>1. Sign in to Account B at <a href="https://&lt;account-ID-for-Account-B&gt;.signin.aws.amazon.com/console">https://&lt;account-ID-for-Account-B&gt;.signin.aws.amazon.com/console</a>.</li><li>2. Open the IAM console at <a href="https://console.aws.amazon.com/iam/">https://console.aws.amazon.com/iam/</a>.</li><li>3. In the navigation pane of the console, choose <b>Policies</b>, and then choose <b>Create Policy</b>.</li><li>4. Choose the <b>JSON</b> tab.</li><li>5. Type or paste the following JSON document:</li></ol> <pre>{   "Version":     "2012-10-17",   "Statement": [     {       "Effect":         "Allow",       "Action":         "sts:AssumeRole",       "Resource":         "arn:aws:iam::&lt;Account-A-ID&gt;:role/DynamoDB-FullAccess-For-Account-B"     }   ] }</pre>	AWS DevOps

Task	Description	Skills required
	<p>where the Resource property contains the ARN of the role you created in the previous story in Account A.</p> <ol style="list-style-type: none"><li>6. Choose <b>Next: Tags</b>.</li><li>7. (Optional) Add metadata to the policy by attaching tags as key-value pairs.</li><li>8. Choose <b>Next: Review</b>.</li><li>9. For <b>Policy name</b>, enter a unique name for your policy (for example, <b>DynamoDB-FullAccess-Policy-in-Account-A</b>), and add an optional policy description.</li><li>10. Choose <b>Create policy</b>.</li></ol> <p>For more information about creating policies, see the <a href="#">IAM documentation</a>.</p>	

Task	Description	Skills required
Create a role based on the policy.	<p>This role is used by the Lambda functions in Account B to read from and write to the DynamoDB table in Account A.</p> <ol style="list-style-type: none"><li>1. In Account B, in the navigation pane of the IAM console, choose <b>Roles</b>, and then choose <b>Create role</b>.</li><li>2. For <b>Select type of trusted entity</b>, choose <b>AWS service</b>.</li><li>3. For use case, choose <b>Lambda</b>.</li><li>4. Choose <b>Next: Permissions</b>.</li><li>5. In the <b>Filter policies</b> box, enter <b>DynamoDB</b>.</li><li>6. In the list of DynamoDB policies, select <b>DynamoDB-FullAccess-Policy-in-Account-A</b>, which you created in the previous story.</li><li>7. Choose <b>Next: Name, review, and create</b>.</li><li>8. For <b>Role name</b>, enter a unique name for your role (for example, <b>DynamoDB-FullAccess-in-Account-A</b>), and add an optional role description.</li></ol>	AWS DevOps

Task	Description	Skills required
	<p>9. Review all the sections and (optionally) add metadata to the role by attaching tags as key-value pairs.</p> <p>10 Choose <b>Create role</b>.</p> <p>You can now attach this role to the Lambda functions in the next epic.</p> <p>For more information about creating roles, see the <a href="#">IAM documentation</a>.</p>	

## Create Lambda functions in Account B

Task	Description	Skills required
<p>Create a Lambda function to write data to DynamoDB.</p>	<ol style="list-style-type: none"> <li>1. Sign in to Account B at <a href="https://&lt;account-ID-for-Account-B&gt;.signin.aws.amazon.com/console">https://&lt;account-ID-for-Account-B&gt;.signin.aws.amazon.com/console</a>.</li> <li>2. Open the Lambda console at <a href="https://console.aws.amazon.com/lambda/">https://console.aws.amazon.com/lambda/</a>.</li> <li>3. In the navigation pane of the console, choose <b>Functions</b>, and then choose <b>Create function</b>.</li> <li>4. For <b>Name</b>, enter <b>lambda_write_function</b>.</li> </ol>	<p>AWS DevOps</p>

Task	Description	Skills required
	<p>5. For <b>Runtime</b>, choose <b>Python 3.8</b> or later.</p> <p>6. For <b>Permissions, Change default execution role</b>, choose <b>Use an existing role</b>.</p> <p>7. For <b>Existing role</b>, choose <b>DynamoDB-FullAccess-in-Account-A</b>.</p> <p>8. Choose <b>Create function</b>.</p> <p>9. In the <b>Code</b> tab, paste the <i>Lambda write function</i> sample code provided in the <a href="#">Additional information</a> section in this pattern. Make sure to provide the correct role ARN (from the epic <i>Create a role in Account A</i>) for the <code>RoleArn</code> field, and change <code>region_name</code> to where the DynamoDB table is created in account A (from the epic <i>Create a DynamoDB table in Account A</i>). Failing to do this results in a <code>ResourceNotFoundException</code> error.</p> <p>10. To deploy the code, choose <b>Deploy</b>.</p> <p>11. Run the function by choosing <b>Test</b>. This prompts you to configure</p>	

Task	Description	Skills required
	<p>a test event. Create a new event with your preferred name, such as <b>MyTestEventForWrite</b>, and save the configuration.</p> <p>12 Run the function again by choosing <b>Test</b>. This runs the code with the event name you provided.</p> <p>13 Check the output from the function. It should be similar to the output shown in the <i>Lambda write function</i> section of <a href="#">Additional information</a>. This output indicates that the function accessed the DynamoDB table in Account A and was able to write data to it.</p> <p>For more information about creating Lambda functions, see the <a href="#">Lambda documentation</a>.</p>	

Task	Description	Skills required
Create a Lambda function to read data from DynamoDB.	<ol style="list-style-type: none"><li>1. In the navigation pane of the Lambda console, choose <b>Functions</b>, and then choose <b>Create function</b>.</li><li>2. For <b>Name</b>, enter <b>lambda_read_function</b>.</li><li>3. For <b>Runtime</b>, choose <b>Python 3.8</b> or later.</li><li>4. For <b>Permissions, Change default execution role</b>, choose <b>Use an existing role</b>.</li><li>5. For <b>Existing role</b>, choose <b>DynamoDB-FullAccess-in-Account-A</b>.</li><li>6. Choose <b>Create function</b>.</li><li>7. In the <b>Code</b> tab, paste the <i>Lambda read function</i> sample code provided in <a href="#">Additional information</a> section in this pattern. Make sure to provide the correct role ARN (from the epic <i>Create a role in Account A</i>) for the <code>RoleArn</code> field, and change <code>region_name</code> to where the DynamoDB table is created in account A (from the epic <i>Create a DynamoDB table in Account A</i>). Failing to do</li></ol>	AWS DevOps

Task	Description	Skills required
	<p>this results in a <code>ResourceNotFoundException</code> error.</p> <p>8. To deploy the code, choose <b>Deploy</b>.</p> <p>9. Run the function by choosing <b>Test</b>. This prompts you to configure a test event. Create a new event with your preferred name, such as <b>MyTestEventForRead</b>, and save the configuration.</p> <p>10 Run the function again by choosing <b>Test</b>. This runs the code with the event name you provided.</p> <p>11 Check the output from the function. It should be similar to the output shown in the <i>Lambda read function</i> section of <a href="#">Additional information</a>. This output indicates that the function accessed the DynamoDB table in Account A and was able to read the data you added to the table.</p> <p>For more information about creating Lambda functions,</p>	

Task	Description	Skills required
	see the <a href="#">Lambda documentation</a> .	

## Clean up resources

Task	Description	Skills required
Delete the resources you created.	<p>If you're running this pattern in a testing or proof of concept (PoC) environment, delete the resources you created to avoid incurring costs.</p> <ol style="list-style-type: none"> <li>1. In Account B, delete the two Lambda functions and other resources you created to connect to DynamoDB.</li> <li>2. In Account A, delete the DynamoDB table you created.</li> <li>3. IAM policies do not cost anything, so you can keep them as is. However, for security, we recommend that you delete the following roles and policies you created for this pattern: <ul style="list-style-type: none"> <li>• Account A: <b>DynamoDB-Full-Access-for-Account-A</b> role</li> </ul> </li> </ol>	AWS DevOps

Task	Description	Skills required
	<ul style="list-style-type: none"><li>Account B: <b>DynamoDB-FullAccess-in-Account-A</b> role</li><li>Account B: <b>DynamoDB-FullAccess-Policy-in-Account-A</b> policy</li></ul>

## Additional information

The code in this section is provided for illustration and testing purposes only. If you're implementing this pattern in a production environment, use the code as a reference and customize it for your own environment.

### Lambda write function

#### Sample code

```
import boto3
from datetime import datetime

sts_client = boto3.client('sts')
```

```

sts_session = sts_client.assume_role(RoleArn='arn:aws:iam::<Account-A ID>:role/
DynamoDB-FullAccess-For-Account-B', RoleSessionName='test-dynamodb-session')

KEY_ID = sts_session['Credentials']['AccessKeyId']
ACCESS_KEY = sts_session['Credentials']['SecretAccessKey']
TOKEN = sts_session['Credentials']['SessionToken']

dynamodb_client = boto3.client('dynamodb',
                                region_name='<DynamoDB-table-region-in-account-A',
                                aws_access_key_id=KEY_ID,
                                aws_secret_access_key=ACCESS_KEY,
                                aws_session_token=TOKEN)

def lambda_handler(event, context):
    now = datetime.now()
    date_time = now.strftime("%m/%d/%Y, %H:%M:%S")
    data = dynamodb_client.put_item(TableName='Table-Account-A', Item={"category":
{"S": "Fruit"},"item": {"S": "Apple"},"time": {"S": date_time}})
    return data

```

## Sample output

Test Event Name  
MyTestEventForWrite

Response

```

{
  "ResponseMetadata": {
    "RequestId": "2AUUF03IDSP205GHC187TCKVD7VV4KQNS05AEMVJF66Q9ASUAAJG",

# Configure mutual TLS authentication for applications running on Amazon EKS

Created by Mahendra Siddappa (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps;  
Security, identity, compliance

**AWS services:** Amazon EKS;  
Amazon Route 53

## Summary

Certificate-based mutual Transport Layer Security (TLS) is an optional TLS component that provides two-way peer authentication between servers and clients. With mutual TLS, clients must provide an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client.

Mutual TLS is a common requirement for Internet of Things (IoT) applications and can be used for business-to-business applications or standards such as [Open Banking](#).

This pattern describes how to configure mutual TLS for applications running on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster by using an NGINX ingress controller. You can enable built-in mutual TLS features for the NGINX ingress controller by annotating the ingress resource. For more information about mutual TLS annotations on NGINX controllers, see [Client certificate authentication](#) in the Kubernetes documentation.

**Important:** This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments. If you want to use this pattern in a production environment, you can use [AWS Private Certificate Authority \(AWS Private CA\)](#) or your existing public key infrastructure (PKI) standard to issue private certificates.

## Prerequisites and limitations

### Prerequisites

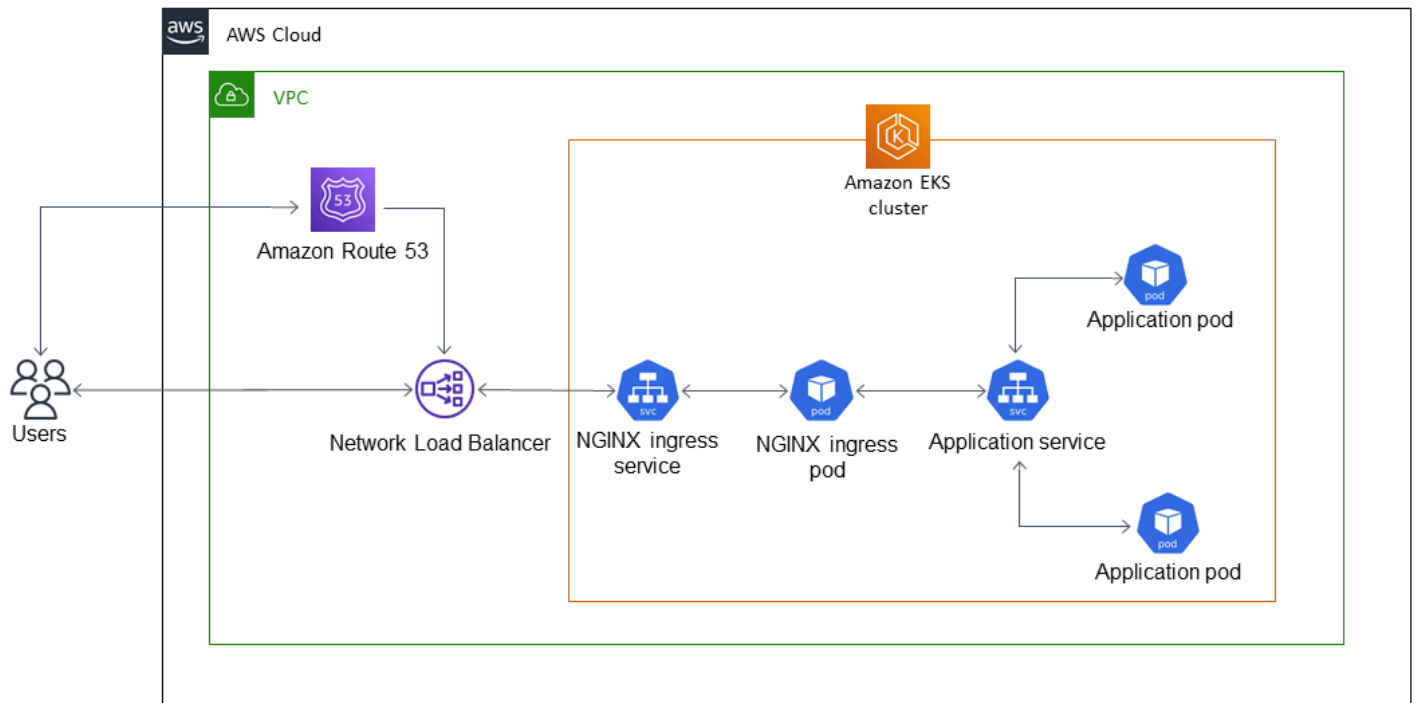

- An active Amazon Web Services (AWS) account.
- An existing Amazon EKS cluster.

- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
- The kubectl command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see [Installing kubectl](#) in the Amazon EKS documentation.
- An existing Domain Name System (DNS) name to test the application.

## Limitations

- This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments.

## Architecture

## Technology stack

- Amazon EKS
- Amazon Route 53
- Kubectl

## Tools

- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.
- [Kubectrl](#) is a command line utility that you use to interact with an Amazon EKS cluster.

## Epics

### Generate the self-signed certificates

Task	Description	Skills required
Generate the CA key and certificate.	Generate the certificate authority (CA) key and certificate by running the following command. <pre>openssl req -x509 -sha256 -newkey rsa:4096 -keyout ca.key -out ca.crt -days 356 -nodes -subj '/CN=Test Cert Authority'</pre>	DevOps engineer
Generate the server key and certificate, and sign with the CA certificate.	Generate the server key and certificate, and sign with the CA certificate by running the following command. <pre>openssl req -new -newkey rsa:4096 -keyout server.key -out server.csr -nodes -subj '/CN= &lt;your_domain_name&gt;' &amp;&amp; openssl x509 -req -sha256 -days 365 -in server.csr -</pre>	DevOps engineer

Task	Description	Skills required
<p>Generate the client key and certificate, and sign with the CA certificate.</p>	<pre data-bbox="594 205 1024 346">CA ca.crt -CAkey ca.key -set_serial 01 -out server.crt</pre> <p data-bbox="594 384 1024 562"><b>Important:</b> Make sure sure that you replace &lt;your_domain_name&gt; with your existing domain name.</p> <pre data-bbox="594 821 1024 1262">openssl req -new - newkey rsa:4096 - keyout client.key - out client.csr -nodes -subj '/CN=Test' &amp;&amp; openssl x509 -req - sha256 -days 365 -in client.csr -CA ca.crt -CAkey ca.key -set_seri al 02 -out client.crt</pre>	<p>DevOps engineer</p>

## Deploy the NGINX ingress controller

Task	Description	Skills required
<p>Deploy the NGINX ingress controller in your Amazon EKS cluster.</p>	<p>Deploy the NGINX ingress controller by using the following command.</p> <pre data-bbox="594 1709 1024 1879">kubectl apply -f https://raw.github usercontent.com/ku bernetes/ingress-n</pre>	<p>DevOps engineer</p>

Task	Description	Skills required
	<pre>ginx/controller-v1 .7.0/deploy/static /provider/aws/depl oy.yaml</pre>	
Verify that the NGINX ingress controller service is running.	<p>Verify that the NGINX ingress controller service is running by using the following command.</p> <pre>kubectl get svc -n ingress-nginx</pre> <p><b>Important:</b> Make sure that the field of service address contains the Network Load Balancer's domain name.</p>	DevOps engineer

## Create a namespace in the Amazon EKS cluster to test mutual TLS

Task	Description	Skills required
Create a namespace in the Amazon EKS cluster.	<p>Create a namespace called <code>mtls</code> in your Amazon EKS cluster by running the following command.</p> <pre>kubectl create ns mtls</pre> <p>This deploys the sample application to test mutual TLS.</p>	DevOps engineer

## Create the deployment and service for the sample application

Task	Description	Skills required
Create the Kubernetes deployment and service in the mtls namespace.	<p>Create a file named <code>mtls.yaml</code> . Paste the following code into the file.</p> <pre data-bbox="597 499 1027 1858">kind: Deployment apiVersion: apps/v1 metadata:   name: mtls-app   labels:     app: mtls spec:   replicas: 1   selector:     matchLabels:       app: mtls   template:     metadata:       labels:         app: mtls     spec:       containers:         - name: mtls-app           image: hashicorp /http-echo           args:             - "-text=mTLS is working"  ---  kind: Service apiVersion: v1 metadata:   name: mtls-service spec:   selector:     app: mtls</pre>	DevOps engineer

Task	Description	Skills required
	<pre>ports:   - port: 5678 #     Default port for image</pre> <p>Create the Kubernetes deployment and service in the <code>mtls</code> namespace by running the following command.</p> <pre>kubectl create -f   mtls.yaml -n mtls</pre>	
Verify that the Kubernetes deployment is created.	<p>Run the following command to verify that the deployment is created and has one pod in available status.</p> <pre>kubectl get deploy -n   mtls</pre>	DevOps engineer
Verify that the Kubernetes service is created.	<p>Verify that the Kubernetes service is created by running the following command.</p> <pre>kubectl get service -n   mtls</pre>	DevOps engineer

### Create a secret in the `mtls` namespace

Task	Description	Skills required
Create a secret for the ingress resource.	Run the following command to create a secret for the NGINX ingress controller by	DevOps engineer

Task	Description	Skills required
	<p>using the certificates that you created earlier.</p> <pre data-bbox="594 331 1029 646">kubect1 create secret   generic mtl5-certs   --from-file=tl5.cr t=server.crt --from- file=tl5.key=server. key --from-file=ca.crt =ca.crt -n mtl5</pre> <p>Your secret has a server certificate for the client to identify the server and a CA certificate for the server to verify the client certificates.</p>	

### Create the ingress resource in the mtl5 namespace

Task	Description	Skills required
<p>Create the ingress resource in the mtl5 namespace.</p>	<p>Create a file named <code>ingress.yaml</code> . Paste the following code into the file (replace <code>&lt;your_domain_name&gt;</code> with your existing domain name).</p> <pre data-bbox="594 1520 1029 1856">apiVersion: networkin g.k8s.io/v1 kind: Ingress metadata:   annotations:     nginx.ingress.kube rnetes.io/auth-tls- verify-client: "on"</pre>	<p>DevOps engineer</p>

Task	Description	Skills required
	<pre>    nginx.ingress.kube netes.io/auth-tls- secret: mtls/mtls-certs   name: mtls-ingress spec:   ingressClassName:   nginx   rules:   - host: ".*.&lt;your_ domain_name&gt;"     http:       paths:       - path: /         pathType: Prefix         backend:           service:             name: mtl- service             port:               number: 2678       tls:       - hosts:         - ".*.&lt;your_ domain_name&gt;"           secretName: mtl- certs</pre> <p>Create the ingress resource in the <code>mtls</code> namespace by running the following command.</p> <pre>kubectl create -f ingress.yaml -n mtl</pre> <p>This means that the NGINX ingress controller can route</p>	

Task	Description	Skills required
	traffic to your sample application.	
Verify that the ingress resource is created.	<p>Verify that the ingress resource is created by running the following command.</p> <pre>kubectl get ing -n mtls</pre> <p><b>Important:</b> Make sure that the address of the ingress resource shows the load balancer created for the NGINX ingress controller.</p>	DevOps engineer

## Configure DNS to point the hostname to the load balancer

Task	Description	Skills required
Create CNAME record that points to the load balancer for the NGINX ingress controller.	<p>Sign in to the AWS Management Console, open the Amazon Route 53 console, and create a Canonical Name (CNAME) record that points <code>mtls.&lt;your_domain_name&gt;</code> to the load balancer for the NGINX ingress controller.</p> <p>For more information, see <a href="#">Creating records by using the Route 53 console</a> in the Route 53 documentation.</p>	DevOps engineer

## Test the application

Task	Description	Skills required
Test mutual TLS setup without certificates.	<p>Run the following command.</p> <pre>curl -k https://m tls.&lt;your_domain_n ame&gt;</pre> <p>You should receive the "400 No required SSL certificate was sent" error response.</p>	DevOps engineer
Test mutual TLS setup with certificates.	<p>Run the following command.</p> <pre>curl -k https://m tls.&lt;your_domain_n ame&gt; --cert client.crt --key client.key</pre> <p>You should receive the "mTLS is working" response.</p>	DevOps engineer

# Create a custom log parser for Amazon ECS using a Firelens log router

Created by Varun Sharma (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Containers & microservices

**Workload:** All other  
workloads

**AWS services:** Amazon ECS

## Summary

Firelens is a log router for Amazon Elastic Container Service (Amazon ECS) and AWS Fargate. You can use Firelens to route container logs from Amazon ECS to Amazon CloudWatch and other destinations (for example, [Splunk](#) or [Sumo Logic](#)). Firelens works with [Fluentd](#) or [Fluent Bit](#) as the logging agent, which means that you can use [Amazon ECS task definition parameters](#) to route logs.

By choosing to parse logs at the source level, you can analyze your logging data and perform queries to more efficiently and effectively respond to operational issues. Because different applications have different logging patterns, you need to use a custom parser that structures the logs and makes searching easier at your end destination.

This pattern uses a Firelens log router with a custom parser to push logs to CloudWatch from a sample Spring Boot application running on Amazon ECS. You can then use Amazon CloudWatch Logs Insights to filter the logs based on custom fields that are generated by the custom parser.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine.
- Docker, installed and configured on your local machine.
- An existing Spring Boot-based containerized application on Amazon Elastic Container Registry (Amazon ECR).

# Architecture

## Technology stack

- CloudWatch
- Amazon ECR
- Amazon ECS
- Fargate
- Docker
- Fluent Bit

## Tools

- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- [Amazon ECS](#) – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster.
- [AWS Identity and Access Management \(IAM\)](#) – IAM is a web service for securely controlling access to AWS services.
- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.

- [Docker](#) – Docker is an open platform for developing, shipping, and running applications.

## Code

The following files are attached to this pattern:

- `customFluentBit.zip` – Contains the files to add the custom parsing and configurations.
- `firelens_policy.json` – Contains the policy document to create an IAM policy.
- `Task.json` – Contains a sample task definition for Amazon ECS.

## Epics

### Create a custom Fluent Bit image

Task	Description	Skills required
Create an Amazon ECR repository.	<p>Sign in to the AWS Management Console, open the Amazon ECR console, and create a repository called <code>fluentbit_custom</code> .</p> <p>For more information about this, see <a href="#">Creating a repository</a> in the Amazon ECR documentation.</p>	Systems administrator, Developer
Unzip the <code>customFluentBit.zip</code> package.	<ol style="list-style-type: none"> <li>1. Download the <code>customFluentBit.zip</code> package (attached) to your local machine.</li> <li>2. Unzip to the <code>customFluentBit</code> directory by running the following command: <code>unzip -d</code></li> </ol>	

Task	Description	Skills required
	<p>customFluentBit.zip</p> <p>3. The directory contains the following files that are required for adding the custom parsing and configurations:</p> <ul style="list-style-type: none"><li>• parsers/springboot_parser.conf – Contains the parser directive and defines the regular expression (regex) pattern for the custom parser. You can add the regex pattern for your specific parser.</li><li>• conf/pars_e_springboot.conf – Contains the filter and the service directive.</li><li>• The Dockerfile</li></ul>	

Task	Description	Skills required
Create the custom Docker image.	<ol style="list-style-type: none"> <li>1. Change the directory to <code>customFluentBit</code> .</li> <li>2. Open the Amazon ECR console, choose the <code>fluentbit_custom</code> repository, and then choose <b>View push commands</b>.</li> <li>3. Upload your project.</li> <li>4. After the upload is complete, copy the build's URL. This URL is required when you create a container in Amazon ECS</li> </ol> <p>For more information about this, see <a href="#">Pushing a Docker image</a> in the Amazon ECR documentation.</p>	Systems administrator, Developer

## Set up the Amazon ECS cluster

Task	Description	Skills required
Create an Amazon ECS cluster.	<p>Create an Amazon ECS cluster by following the instructions from the <i>Networking only template</i> section of <a href="#">Creating a cluster</a> in the Amazon ECS documentation.</p> <p><b>Note:</b> Make sure that you choose <b>Create VPC</b> to create</p>	Systems administrator, Developer

Task	Description	Skills required
	a new virtual private cloud (VPC) for your Amazon ECS cluster.	

## Set up the Amazon ECS task

Task	Description	Skills required
Set up the Amazon ECS task execution IAM role.	<p>Create an Amazon ECS task execution IAM role by using the AmazonECS TaskExecutionRolePolicy managed policy. For more information about this, see <a href="#">Amazon ECS task execution IAM role</a> in the Amazon ECS documentation.</p> <p><b>Note:</b> Make sure that you record the IAM role's Amazon Resource Name (ARN).</p>	Systems administrator, Developer
Attach the IAM policy to the Amazon ECS task execution IAM role.	<ol style="list-style-type: none"> <li>1. Create an IAM policy by using the <code>firelens_policy.json</code> (attached) policy document. For more information about this, see <a href="#">Creating policies on the JSON tab</a> in the IAM documentation.</li> <li>2. Attach this policy to the Amazon ECS task execution IAM role that you created earlier. For more information about this, see <a href="#">Adding</a></li> </ol>	Systems administrator, Developer

Task	Description	Skills required
	<a href="#">IAM policies (AWS CLI)</a> in the IAM documentation.	

Task	Description	Skills required
Set up the Amazon ECS task definition.	<ol style="list-style-type: none"><li>1. Update the following sections in the <code>Task.json</code> sample task definition (attached):<ul style="list-style-type: none"><li>• Update the <code>executionRoleArn</code> and <code>taskRoleArn</code> with the ARN of the task execution IAM role</li><li>• Update the <code>imageInContainerDefinitions</code> with the custom Fluent Bit Docker image that you created earlier</li><li>• Update the <code>imageInContainerDefinitions</code> with your application image's name</li></ul></li><li>2. Open the Amazon ECS console, choose <b>Task Definitions</b>, choose <b>Create new task definition</b>, and then choose <b>Fargate</b> on the <b>Select compatibilities</b> page.</li><li>3. Choose <b>Configure via Json</b>, paste the updated <code>Task.json</code> file into the text area, and then choose <b>Save</b>.</li><li>4. Create the task definition.</li></ol>	Systems administrator, Developer

Task	Description	Skills required
	For more information about this, see <a href="#">Creating a task definition</a> in the Amazon ECS documentation.	

## Run the Amazon ECS task

Task	Description	Skills required
Run the Amazon ECS task.	<p>On the Amazon ECS console, choose <b>Clusters</b>, choose the cluster that you created earlier, and then run the standalone task.</p> <p>For more information about this, see <a href="#">Run a standalone task</a> in the Amazon ECS documentation.</p>	Systems administrator, Developer

## Verify the CloudWatch logs

Task	Description	Skills required
Verify the logs.	<ol style="list-style-type: none"> <li>1. Open the CloudWatch console, choose <b>Log groups</b>, and then choose <code>/aws/ecs/container-insights/{{cluster_ARN}}/firelens/application</code>.</li> <li>2. Verify the logs, particularly the custom fields added by the custom parser.</li> </ol>	Systems administrator, Developer

Task	Description	Skills required
	3. Use CloudWatch to filter logs based on the custom fields.

# Create a pipeline and AMI using CodePipeline and HashiCorp Packer

Created by Akash Kumar (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> DevOps	<b>Target:</b> Amazon Machine Images(AMI)
<b>R Type:</b> Rehost	<b>Workload:</b> All other workloads	<b>Technologies:</b> DevOps; Modernization; Web & mobile apps

## Summary

This pattern provides code samples and steps to create both a pipeline in the Amazon Web Services (AWS) Cloud by using AWS CodePipeline and an Amazon Machine Image (AMI) by using HashiCorp Packer. The pattern is based on the [continuous integration](#) practice, which automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, create a project and configure your source code by using AWS CodeBuild. Finally, create an AMI that gets committed to your repository.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon Linux AMI for launching Amazon Elastic Compute Cloud (Amazon EC2) instances
- [HashiCorp Packer](#) 0.12.3 or later
- Amazon CloudWatch Events (optional)
- Amazon CloudWatch Logs (optional)

## Architecture

The following diagram shows an example of application code that automates the creation of an AMI by using this pattern's architecture.

The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository. Then, CodePipeline uses CodeBuild to initiate the build and add new [artifacts](#) that are ready for deployment to the Amazon Simple Storage Service (Amazon S3) bucket.
2. CodeBuild uses Packer to bundle and package the AMI based on a JSON template. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

### Technology stack

- CodeBuild
- CodeCommit
- CodePipeline
- CloudWatch Events (optional)

## Tools

- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- [AWS CodePipeline](#) – AWS CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software.
- [HashiCorp Packer](#) – HashiCorp Packer is an open-source tool for automating the creation of identical machine images from a single source configuration. Packer is lightweight, runs on every major operating system, and creates machine images for multiple platforms in parallel.

## Code

This pattern includes the following attachments:

- `buildspec.yml` – This file uses CodeBuild to build and create an artifact for deployment.
- `amazon-linux_packer-template.json` – This file uses Packer to create an Amazon Linux AMI.

## Epics

### Set up the code repository

Task	Description	Skills required
Create the repository.	<a href="#">Create a CodeCommit repository.</a>	AWS systems administrator
Clone the repository.	<a href="#">Connect to the CodeCommit repository by cloning the repository.</a>	App developer
Push the source code to the remote repository.	1. <a href="#">Create a commit</a> to add the <code>buildspec.yml</code> and <code>amazon-linux_packer</code>	App developer

Task	Description	Skills required
	<p>r-template.json files to your local repository.</p> <p>2. <a href="#">Push the commit</a> from your local repository to the remote CodeCommit repository.</p>	

## Create a CodeBuild project for the application

Task	Description	Skills required
Create a build project.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management console, open the <a href="#">AWS CodeBuild console</a>, and then choose <b>Create build project</b>.</li> <li>2. For <b>Project name</b>, enter the name of your project.</li> <li>3. For <b>Source provider</b>, choose <b>AWS CodeCommit</b>.</li> <li>4. For <b>Repository</b>, choose the repository where you want to build the code pipeline.</li> <li>5. For <b>Environment image</b>, choose <b>Managed image</b> or <b>Custom image</b>.</li> <li>6. For <b>Operating system</b>, choose <b>Ubuntu</b>.</li> <li>7. For <b>RunTime(s)</b>, choose <b>Standard</b>.</li> <li>8. For <b>Image</b>, choose <b>aws/codebuild/standard:4.0</b>.</li> </ol>	App developer, AWS systems administrator

Task	Description	Skills required
	<p>9. For <b>Image version</b>, choose <b>Always use the latest image for this runtime version</b>.</p> <p>10 For <b>Environment</b>, choose <b>Linux</b>.</p> <p>11 Choose the <b>Privileged</b> check box.</p> <p>12 For <b>Service role</b>, choose <b>New service role</b> or <b>Existing service role</b>.</p> <p>13 For <b>Build specifications</b>, choose <b>Use a buildspec file</b> or <b>Insert build commands</b>.</p> <p>14 (Optional) For <b>Type</b> in the <b>Artifacts</b> section, choose <b>No artifacts</b>.</p> <p>15 (Recommended) To upload build output logs to CloudWatch Logs, choose <b>CloudWatch logs</b>.</p> <p>16 (Optional) To upload build output logs to Amazon S3, choose the <b>S3 logs</b> check box.</p> <p>17 Choose <b>Create build project</b>.</p>	

## Set up the pipeline

Task	Description	Skills required
Pipeline name	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management console, open the <a href="#">AWS CodePipeline console</a>, and then choose <b>Create pipeline</b>.</li><li>2. For <b>Pipeline name</b>, enter a name for the pipeline.</li><li>3. For <b>Service role</b>, choose <b>New service role</b> or <b>Existing service role</b>.</li><li>4. For <b>Role name</b>, enter a name for your role.</li><li>5. In the <b>Advanced settings</b> section, for <b>Artifact store</b>, choose <b>Default location</b> if you want Amazon S3 to create a bucket and store the artifacts in the bucket. To use an existing S3 bucket, choose <b>Custom location</b>. Choose <b>Next</b>.</li><li>6. For <b>Source provider</b>, choose <b>AWS CodeCommit</b>.</li><li>7. For <b>Repository name</b>, choose the repository that you cloned earlier. For <b>Branch name</b>, choose your source code branch.</li><li>8. For <b>Change detection options</b>, choose <b>Amazon CloudWatch Events</b></li></ol>	App developer, AWS systems administrator

Task	Description	Skills required
	<p><b>(recommended)</b> to start the pipeline or <b>AWS CodePipeline</b> to periodically check for changes. Choose <b>Next</b>.</p> <p>9. For <b>Build provider</b>, choose <b>AWS CodeBuild</b>.</p> <p>10 For <b>Project Name</b>, choose the build project that you created in the <i>Create a CodeBuild project for the application</i> epic.</p> <p>11 Choose your build options and then choose <b>Next</b>.</p> <p>12 Choose <b>Skip deploy stage</b>.</p> <p>13 Choose <b>Create pipeline</b>.</p>

# Create a pipeline and deploy artifact updates to on-premises EC2 instances using CodePipeline

Created by Akash Kumar (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> DevOps	<b>Target:</b> Amazon EC2/On-Premises
<b>R Type:</b> Rehost	<b>Technologies:</b> DevOps; Modernization; Web & mobile apps	<b>AWS services:</b> AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS CodePipeline

## Summary

This pattern provides code samples and steps to create a pipeline in the Amazon Web Services (AWS) Cloud and deploy updated [artifacts](#) to on-premises Amazon Elastic Compute Cloud (Amazon EC2) instances in AWS CodePipeline. The pattern is based on the [continuous integration](#) practice. This practice automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, you create a project and configure your source code by using AWS CodeBuild. Finally, you create your application and configure its target environment for on-premises EC2 instances by using AWS CodeDeploy.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [User-defined tags](#) to identify EC2 instances during deployment
- [CodeDeploy agent](#), installed on EC2 instances
- Your required runtime software, installed on EC2 instances
- [Amazon Corretto 8](#) for the Java Development Kit
- [Apache Tomcat](#) web server, installed

- Amazon CloudWatch Events (optional)
- A key pair to log in to the web server (optional)
- An Apache Maven application project for a web application

## Architecture

The following diagram shows an example Java web application that's deployed to on-premises EC2 instances by using this pattern's architecture.

The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository.
2. CodePipeline uses CodeBuild to initiate the build and add new artifacts that are ready for deployment in the Amazon Simple Storage Service (Amazon S3) bucket.
3. CodePipeline uses the CodeDeploy agent to pre-install any dependencies required for the deployment artifact changes.
4. CodePipeline uses the CodeDeploy agent to deploy the artifacts from the S3 bucket to target EC2 instances. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

## Technology stack

- CodeBuild
- CodeCommit
- CodeDeploy
- CodePipeline
- CloudWatch Events (optional)

## Tools

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

## Code

This pattern includes the following attachments:

- `buildspec.yml` – This file specifies the actions that CodeBuild requires to build and create an artifact for deployment.
- `appspec.yml` – This file specifies the actions that CodeDeploy requires to create an application and configure a target environment for on-premises EC2 instances.
- `install_dependencies.sh` – This file installs dependencies for the Apache Tomcat web server.
- `start_server.sh` – This file starts the Apache Tomcat web server.
- `stop_server.sh` – This file stops the Apache Tomcat web server.

## Epics

### Set up the code repository

Task	Description	Skills required
Create the repository.	<a href="#">Create a CodeCommit repository.</a>	AWS systems administrator

# Create dynamic CI pipelines for Java and Python projects automatically

Created by Aromal Raj Jayarajan (AWS), Amarnath Reddy (AWS), MAHESH RAGHUNANDANAN (AWS), and Vijesh Vijayakumaran Nair (AWS)

<b>Code repository:</b> <a href="#">automated-ci-pipeline-creation</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> DevOps; Infrastructure; Serverless; CloudNative
<b>Workload:</b> All other workloads	<b>AWS services:</b> AWS CodeBuild; AWS CodePipeline; AWS Lambda; AWS Step Functions; AWS CodeCommit	

## Summary

This pattern shows how to create dynamic continuous integration (CI) pipelines for Java and Python projects automatically by using AWS developer tools.

As technology stacks diversify and development activities increase, it can become difficult to create and maintain CI pipelines that are consistent across an organization. By automating the process in AWS Step Functions, you can make sure that your CI pipelines are consistent in their usage and approach.

To automate the creation of dynamic CI pipelines, this pattern uses the following variable inputs:

- Programming language (Java or Python only)
- Pipeline name
- Required pipeline stages

**Note:** Step Functions orchestrates pipeline creation by using multiple AWS services. For more information about the AWS services used in this solution, see the **Tools** section of this pattern.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon S3 bucket in the same AWS Region that this solution is being deployed
- An AWS Identity and Access Management (IAM) [principal](#) that has the AWS CloudFormation permissions required to create the resources needed for this solution

### Limitations

- This pattern supports Java and Python projects only.
- The IAM roles provisioned in this pattern follow the principle of least privilege. The IAM roles' permissions must be updated based on the specific resources that your CI pipeline needs to create.

## Architecture

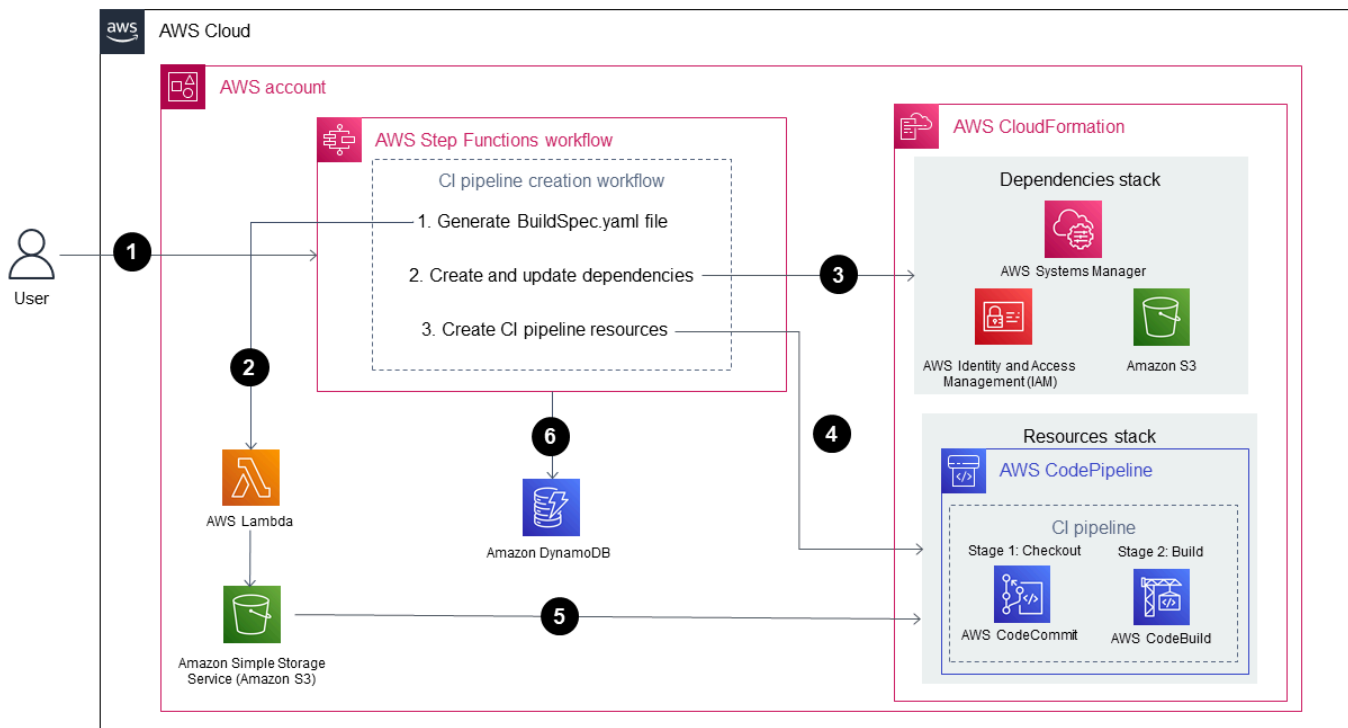

### Target technology stack

- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- IAM
- Amazon Simple Storage Service (Amazon S3)
- AWS Systems Manager
- AWS Step Functions
- AWS Lambda
- Amazon DynamoDB

### Target architecture

The following diagram shows an example workflow for creating dynamic CI pipelines for Java and Python projects automatically by using AWS developer tools.

The diagram shows the following workflow:

1. An AWS user provides the input parameters for CI pipeline creation in JSON format. This input starts a Step Functions workflow (*state machine*) that creates a CI pipeline by using AWS developer tools.
2. A Lambda function reads a folder named **input-reference**, which is stored in an Amazon S3 bucket, and then generates a **buildspec.yml** file. This generated file defines the CI pipeline stages and is stored back in the same Amazon S3 bucket that stores the parameter references.
3. Step Functions checks the CI pipeline creation workflow's dependencies for any changes, and updates the dependencies stack as needed.
4. Step Functions creates the CI pipeline resources in a CloudFormation stack, including a CodeCommit repository, CodeBuild project, and a CodePipeline pipeline.
5. The CloudFormation stack copies the sample source code for the selected technology stack (Java or Python) and the **buildspec.yml** file to the CodeCommit repository.
6. CI pipeline runtime details are stored in a DynamoDB table.

## Automation and scale

- This pattern is for use in a single development environment only. Configuration changes are required for use across multiple development environments.
- To add support for more than one CloudFormation stack, you can create additional CloudFormation templates. For more information, see [Getting started with AWS CloudFormation](#) in the CloudFormation documentation.

## Tools

### Tools

- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [AWS Systems Manager Parameter Store](#) provides secure, hierarchical storage for configuration data management and secrets management.

## Code

The code for this pattern is available in the GitHub [automated-ci-pipeline-creation](#) repository. The repository contains the CloudFormation templates required to create the target architecture outlined in this pattern.

## Best practices

- Don't enter credentials (*secrets*) such as tokens or passwords directly into CloudFormation templates or Step Functions action configurations. If you do, the information will be displayed in the DynamoDB logs. Instead, use AWS Secrets Manager to set up and store secrets. Then, reference the secrets stored in Secrets Manager within the CloudFormation templates and Step Functions action configurations as needed. For more information, see [What is AWS Secrets Manager](#) in the Secrets Manager documentation.
- Configure server-side encryption for CodePipeline artifacts stored in Amazon S3. For more information, see [Configure server-side encryption for artifacts stored in Amazon S3 for CodePipeline](#) in the CodePipeline documentation.
- Apply least-privilege permissions when configuring IAM roles. For more information, see [Apply least-privilege permissions](#) in the IAM documentation.
- Make sure that your Amazon S3 bucket is not publicly accessible. For more information, see [Configuring block public access setting for your S3 buckets](#) in the Amazon S3 documentation.
- Make sure that you activate versioning for your Amazon S3 bucket. For more information, see [Using versioning in S3 buckets](#) in the Amazon S3 documentation.
- Use IAM Access Analyzer when configuring IAM policies. The tool provides actionable recommendations to help you author secure and functional IAM policies. For more information, see [Using AWS Identity and Access Management Access Analyzer](#) in the IAM documentation.
- When possible, define specific access conditions when configuring IAM policies.
- Activate Amazon CloudWatch logging for monitoring and auditing purposes. For more information, see [What is Amazon CloudWatch Logs?](#) in the CloudWatch documentation.

# Epics

## Configure the prerequisites

Task	Description	Skills required
Create an Amazon S3 bucket.	<p>Create an Amazon S3 bucket (or use an existing bucket) to store the required CloudFormation templates, source code, and input files for the solution.</p> <p>For more information, see <a href="#">Step 1: Create your first S3 bucket</a> in the Amazon S3 documentation.</p> <p><b>Note:</b> The Amazon S3 bucket must be in the same AWS Region that you're deploying the solution to.</p>	AWS DevOps
Clone the GitHub repository.	<p>Clone the GitHub <a href="#">automated-ci-pipeline-creation</a> repository by running the following command in a terminal window:</p> <pre data-bbox="597 1461 1027 1661">git clone https://github.com/aws-samples/automated-ci-pipeline-creation.git</pre> <p>For more information, see <a href="#">Cloning a repository</a> in the GitHub documentation.</p>	AWS DevOps

Task	Description	Skills required
Upload the Solution Templates folder from the cloned GitHub repository to your Amazon S3 bucket.	<p>Copy the contents from the cloned <b>Solution-Templates</b> folder and upload them into the Amazon S3 bucket that you created.</p> <p>For more information, see <a href="#">Uploading objects</a> in the Amazon S3 documentation.</p> <p><b>Note:</b> Make sure that you upload the contents of the <b>Solution-Templates</b> folder only. You can upload the files at the Amazon S3 bucket's root level only.</p>	AWS DevOps

## Deploy the solution

Task	Description	Skills required
Create a CloudFormation stack to deploy the solution by using the template.yml file in the cloned GitHub repository.	<ol style="list-style-type: none"> <li>1. Sign into the AWS Management Console and then open the <a href="#">AWS CloudFormation console</a>.</li> <li>2. Choose <b>Create stack</b>. A dropdown list appears.</li> <li>3. In the dropdown list, select <b>With new resources (standard)</b>. The <b>Create stack</b> page opens.</li> <li>4. In the <b>Specify template</b> section, select the</li> </ol>	AWS administrator, AWS DevOps

Task	Description	Skills required
	<p>checkbox next to <b>Upload a template file</b>.</p> <ol style="list-style-type: none"><li data-bbox="592 310 1027 590">5. Select <b>Choose file</b>. Then, navigate to the cloned GitHub repository's root folder and select the <b>template.yml</b> file. Then, choose <b>Open</b>.</li><li data-bbox="592 611 1027 695">6. Choose <b>Next</b>. The <b>Specify stack details</b> page opens.</li><li data-bbox="592 716 1027 1333">7. In the <b>Parameters</b> section, specify the following parameters:<ul style="list-style-type: none"><li data-bbox="630 863 1027 1333">• For <b>S3Templat eBucketName</b>, enter the name of the Amazon S3 bucket that you created earlier, which contains the source code and references for this solution. Make sure that the bucket name parameter is in lowercase .</li><li data-bbox="630 1398 1027 1629">• For <b>DynamoDBTable</b>, enter a name for the DynamoDB table that the CloudFormation stack creates.</li><li data-bbox="630 1650 1027 1831">• For <b>StateMachineName</b>, enter a name for the Step Functions state machine that the</li></ul></li></ol>	

Task	Description	Skills required
	<p>CloudFormation stack creates.</p> <p>8. Choose <b>Next</b>. The <b>Configure stack options</b> page opens.</p> <p>9. On the <b>Configure stack options</b> page, choose <b>Next</b>. Don't change any of the default values. The <b>Review</b> page opens.</p> <p>10 Review the stack creation settings. Then, choose <b>Create stack</b> to launch your stack.</p> <p><b>Note:</b> While your stack is being created, it's listed on the <b>Stacks</b> page with a status of <b>CREATE_IN_PROGRESS</b>. Make sure that you wait for the stack's status to change to <b>CREATE_COMPLETE</b> before completing the remaining steps in this pattern.</p>	

## Test the setup

Task	Description	Skills required
Run the step function that you created.	1. Sign in to the AWS Management Console	AWS administrator, AWS DevOps

Task	Description	Skills required
	<p>and then open the <a href="#">Step Functions console</a>.</p> <ol style="list-style-type: none"><li>2. Open the step function that you created.</li><li>3. Choose <b>Start execution</b>. Then, enter your input values for the workflow in JSON format (see the following example inputs).</li><li>4. Choose <b>Start execution</b>.</li></ol> <p><b>JSON formatting</b></p> <pre data-bbox="597 850 1026 1858">{   "details": {     "tech_stack":       "Name of the Tech Stack       (python/java)",     "project_name":       "Name of the Project       that you want to create       with",     "pre_build":       "Choose the step if       it required in the       buildspec.yml file       i.e., yes/no",     "build": "Choose the       step if it required in       the buildspec.yml file       i.e., yes/no",     "post_build":       "Choose the step if       it required in the       buildspec.yml file       i.e., yes/no",     "reports": "Choose       the step if it required</pre>	

Task	Description	Skills required
	<pre>in the buildspec.yml file i.e., yes/no", } }</pre> <p><b>Java JSON input example</b></p> <pre>{   "details": {     "tech_stack": "java",     "project_name": "pipeline-java-pjt",     "pre_build": "yes",     "build": "yes",     "post_build": "yes",     "reports": "yes"   } }</pre> <p><b>Python JSON input example</b></p> <pre>{   "details": {     "tech_stack": "python",     "project_name": "pipeline-python-p jst",     "pre_build": "yes",     "build": "yes",     "post_build": "yes",     "reports": "yes"   } }</pre>	

Task	Description	Skills required
Confirm that the CodeCommit repository for the CI pipeline was created.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 405">1. Sign in to the AWS Management Console and then open the <a href="#">CodeCommit console</a>.</li><li data-bbox="591 426 1027 846">2. On the <b>Repositories</b> page, verify that the name of the CodeCommit repository that you created appears in the list of repositories. The name of the repository is appended with the following: <b>pipeline-java-pjt-Repo</b></li><li data-bbox="591 867 1027 1140">3. Open the CodeCommit repository and validate that the sample source code along with <b>buildspec.yml</b> files are pushed to the main branch.</li></ol>	AWS DevOps

Task	Description	Skills required
Check the CodeBuild project resources.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and then open the <a href="#">CodeBuild console</a>.</li><li>2. On the <b>Build projects</b> page, verify that the name of the CodeBuild project that you created appears in the list of projects. The name of the project is appended with the following: <b>pipeline-java-pjt-Build</b></li><li>3. Select the name of your CodeBuild project to open the project. Then, review and validate the following configurations:<ul style="list-style-type: none"><li>• <b>Project Configuration</b></li><li>• <b>Source</b></li><li>• <b>Environment</b></li><li>• <b>Buildspec</b></li><li>• <b>Batch Configuration</b></li><li>• <b>Artifacts</b></li></ul></li></ol>	AWS DevOps

Task	Description	Skills required
Validate the CodePipeline stages.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and then open the <a href="#">CodePipeline console</a>.</li><li>2. On the <b>Pipelines</b> page, verify that the name of the pipeline that you created appears in the list of pipelines. The name of the pipeline is appended with the following: <b>pipeline-java-pjt-Pipeline</b></li><li>3. Select the name of your pipeline to open the pipeline. Then, review and validate each stage of the pipeline, including <b>Commit</b> and <b>Deploy</b>.</li></ol>	AWS DevOps
Confirm that the CI pipeline ran successfully.	<ol style="list-style-type: none"><li>1. In the <a href="#">CodePipeline console</a>, on the <b>Pipelines</b> page, select the name of your pipeline to view the pipeline's status.</li><li>2. Verify that each stage of the pipeline has a <b>Succeeded</b> status.</li></ol>	AWS DevOps

## Clean up your resources

Task	Description	Skills required
Delete the resources stack in CloudFormation.	<p>Delete the CI pipeline's resources stack in CloudFormation.</p> <p>For more information, see <a href="#">Deleting a stack on the AWS CloudFormation console</a> in the CloudFormation documentation.</p> <p><b>Note:</b> Make sure that you delete the stack named <b>&lt;project_name&gt;-stack</b>.</p>	AWS DevOps
Delete the CI pipeline's dependencies in Amazon S3 and CloudFormation.	<ol style="list-style-type: none"><li>1. Empty the Amazon S3 bucket named <b>DeploymentArtifactBucket</b>. For more information, see <a href="#">Emptying a bucket</a> in the Amazon S3 documentation.</li><li>2. Delete the CI pipeline's dependency stack in CloudFormation. For more information, see <a href="#">Deleting a stack on the AWS CloudFormation console</a> in the CloudFormation documentation.</li></ol> <p><b>Note:</b> Make sure that you delete the stack named <b>pipeline-creation-dependencies-stack</b>.</p>	AWS DevOps

Task	Description	Skills required
Delete the Amazon S3 template bucket.	Delete the Amazon s3 bucket that you created in the <b>Configure the prerequisites</b> section of this pattern, which stores the templates for this solution.  For more information, see <a href="#">Deleting a bucket</a> in the Amazon S3 documentation.	AWS DevOps

# Deploy CloudWatch Synthetics canaries by using Terraform

Created by Dhrubajyoti Mukherjee (AWS) and Jean-Francois Landreau (AWS)

**Code repository:** [Deploy CloudWatch Synthetics canaries with Terraform](#)

**Environment:** Production

**Technologies:** DevOps; Business productivity; DevelopmentAndTesting; Infrastructure; Web & mobile apps

**AWS services:** Amazon CloudWatch; Amazon S3; Amazon SNS; Amazon VPC; AWS Identity and Access Management

## Summary

It's important to validate the health of a system from a customer perspective and confirm that customers are able to connect. This is more difficult when the customers don't constantly call the endpoint. [Amazon CloudWatch Synthetics](#) supports the creation of canaries, which can test both public and private endpoints. By using canaries, you can know the status of a system even if it isn't in use. These canaries are either Node.js Puppeteer scripts or Python Selenium scripts.

This pattern describes how to use HashiCorp Terraform to deploy canaries that test private endpoints. It embeds a Puppeteer script that tests whether a URL returns 200-OK. The Terraform script can then be integrated with the script that deploys the private endpoint. You can also modify the solution to monitor public endpoints.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account with a virtual private cloud (VPC) and private subnets
- The URL of the endpoint that can be reached from the private subnets

- Terraform installed in the deployment environment

## Limitations

The current solution works for the following CloudWatch Synthetics runtime versions:

- syn-nodejs-puppeteer-3.4
- syn-nodejs-puppeteer-3.5
- syn-nodejs-puppeteer-3.6
- syn-nodejs-puppeteer-3.7

As new runtime versions are released, you might need to update the current solution. You will also need to modify the solution to keep up with security updates.

## Product versions

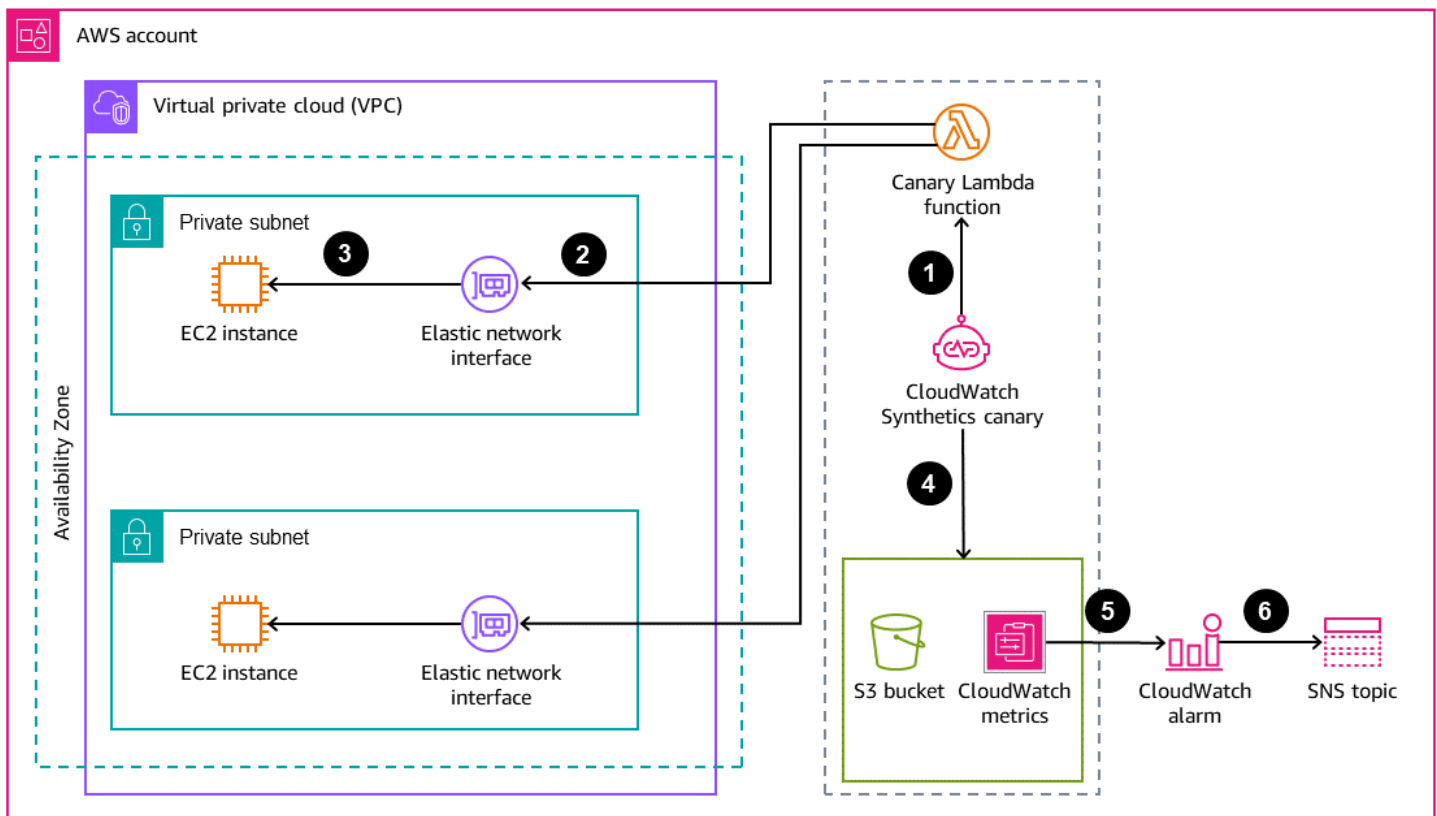

- Terraform 1.3.0

## Architecture

Amazon CloudWatch Synthetics is based on CloudWatch, Lambda, and Amazon Simple Storage Service (Amazon S3). Amazon CloudWatch offers a wizard to create the canaries and a dashboard that displays the status of the canary runs. The Lambda function runs the script. Amazon S3 stores the logs and screenshots from the canary runs.

This pattern simulates a private endpoint through an Amazon Elastic Compute Cloud (Amazon EC2) instance deployed in the targeted subnets. The Lambda function requires elastic network interfaces in the VPC where the private endpoint is deployed.

The diagram shows the following:

1. The Synthetics canary initiates the canary Lambda function.
2. The canary Lambda function connects to the elastic network interface.
3. The canary Lambda function monitors the status of the endpoint.
4. The Synthetics canary pushes run data to the S3 bucket and CloudWatch metrics.
5. A CloudWatch alarm is initiated based on the metrics.
6. The CloudWatch alarm initiates the Amazon Simple Notification Service (Amazon SNS) topic.

## Tools

### AWS services

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses VPC endpoints and elastic network interfaces.

### Other services

- [HashiCorp Terraform](#) is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses Terraform to deploy the infrastructure.
- [Puppeteer](#) is a Node.js library. The CloudWatch Synthetics runtime uses the Puppeteer framework.

### Code

The solution is available in the GitHub [cloud watch-synthetics-canary-terraform](#) repository. For more information, see the *Additional information* section.

## Epics

### Implement the solution for monitoring a private URL

Task	Description	Skills required
Gather requirements for monitoring the private URL.	Gather the full URL definition: domain, parameters, and headers. To communicate privately to Amazon S3 and	Cloud architect, Network administrator

Task	Description	Skills required
	Amazon CloudWatch, use VPC endpoints. Note how the VPC and subnets are accessible to the endpoint. Consider the frequency of canary runs.	

Task	Description	Skills required
Modify the existing solution to monitor the private URL.	<p>Modify the <code>terraform.tfvars</code> file:</p> <ul style="list-style-type: none"><li>• <code>name</code> – The name of your canary.</li><li>• <code>runtime_version</code> – The runtime version of the canary. We recommend using <code>syn-nodejs-puppeteer-3.7</code>.</li><li>• <code>take_screenshot</code> – Whether a screenshot should be taken.</li><li>• <code>api_hostname</code> – The hostname of the endpoint that is monitored.</li><li>• <code>api_path</code> – The path of the endpoint that is monitored.</li><li>• <code>vpc_id</code> – The VPC ID that is used by the canary Lambda function.</li><li>• <code>subnet_ids</code> – The subnet IDs that are used by the canary Lambda function.</li><li>• <code>frequency</code> – The run frequency of the canary in minutes.</li><li>• <code>alert_sns_topic</code> – The SNS topic to which the CloudWatch alarm notification is sent.</li></ul>	Cloud architect

Task	Description	Skills required
Deploy and operate the solution.	<p>To deploy the solution, do the following:</p> <ol style="list-style-type: none"> <li>From the <code>cloudwatch-synthetics-canary-terraform</code> directory in your development environment, initialize Terraform.           <pre>terraform init</pre> </li> <li>Plan and review the changes.           <pre>terraform plan</pre> </li> <li>Deploy the solution.           <pre>terraform apply</pre> </li> </ol>	Cloud architect, DevOps engineer

## Troubleshooting

Issue	Solution
Deletion of the provisioned resources gets stuck.	Manually delete the canary Lambda function, corresponding elastic network interface, and security group, in that order.

## Related resources

- [Using synthetic monitoring](#)
- [Monitor API Gateway endpoints with Amazon CloudWatch Synthetics](#) (blog post)

## Additional information

### Repository artifacts

The repository artifacts are in the following structure.

```
.
### README.md
### main.tf
### modules
#   ### canary
#   ### canary-infra
### terraform.tfvars
### tf.plan
### variable.tf
```

The `main.tf` file contains the core module, and it deploys two submodules:

- `canary-infra` deploys the infrastructure required for the canaries.
- `canary` deploys the canaries.

The input parameters for the solution are located in the `terraform.tfvars` file. You can use the following code example to create one canary.

```
module "canary" {
  source = "./modules/canary"
  name   = var.name
  runtime_version = var.runtime_version
  take_screenshot = var.take_screenshot
  api_hostname = var.api_hostname
  api_path = var.api_path
  reports-bucket = module.canary_infra.reports-bucket
  role = module.canary_infra.role
  security_group_id = module.canary_infra.security_group_id
  subnet_ids = var.subnet_ids
  frequency = var.frequency
  alert_sns_topic = var.alert_sns_topic
}
```

The corresponding `.var` file follows.

```
name      = "my-canary"
runtime_version = "syn-nodejs-puppeteer-3.7"
take_screenshot = false
api_hostname = "mydomain.internal"
api_path = "/path?param=value"
vpc_id = "vpc_id"
subnet_ids = ["subnet_id1"]
frequency = 5
alert_sns_topic = "arn:aws:sns:eu-central-1:111111111111:yyyyy"
```

## Cleaning up the solution

If you are testing this in a development environment, you can clean up the solution to avoid accruing costs.

1. On the AWS Management Console, navigate to the Amazon S3 console. Empty the Amazon S3 bucket that the solution created. Make sure to take a backup of the data, if required.
2. In your development environment, from the `cloudwatch-synthetics-canary-terraform` directory, run the `destroy` command.

```
terraform destroy
```

# Deploy a CI/CD pipeline for Java microservices on Amazon ECS

Created by Vijay Thompson (AWS) and Sankar Sangubotla (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps;  
Containers & microservices

**AWS services:** AWS  
CodeBuild; Amazon EC2  
Container Registry; Amazon  
ECS; AWS Fargate; AWS  
CodePipeline

## Summary

This pattern guides you through the steps for deploying a continuous integration and continuous delivery (CI/CD) pipeline for Java microservices on an existing Amazon Elastic Container Service (Amazon ECS) cluster by using AWS CodeBuild. When the developer commits the changes, the CI/CD pipeline is initiated and the build process starts in CodeBuild. When the build is complete, the artifact is pushed to Amazon Elastic Container Registry (Amazon ECR) and the latest build from Amazon ECR is picked up and pushed to the Amazon ECS service.

## Prerequisites and limitations

### Prerequisites

- An existing Java microservices application running on Amazon ECS
- Familiarity with AWS CodeBuild and AWS CodePipeline

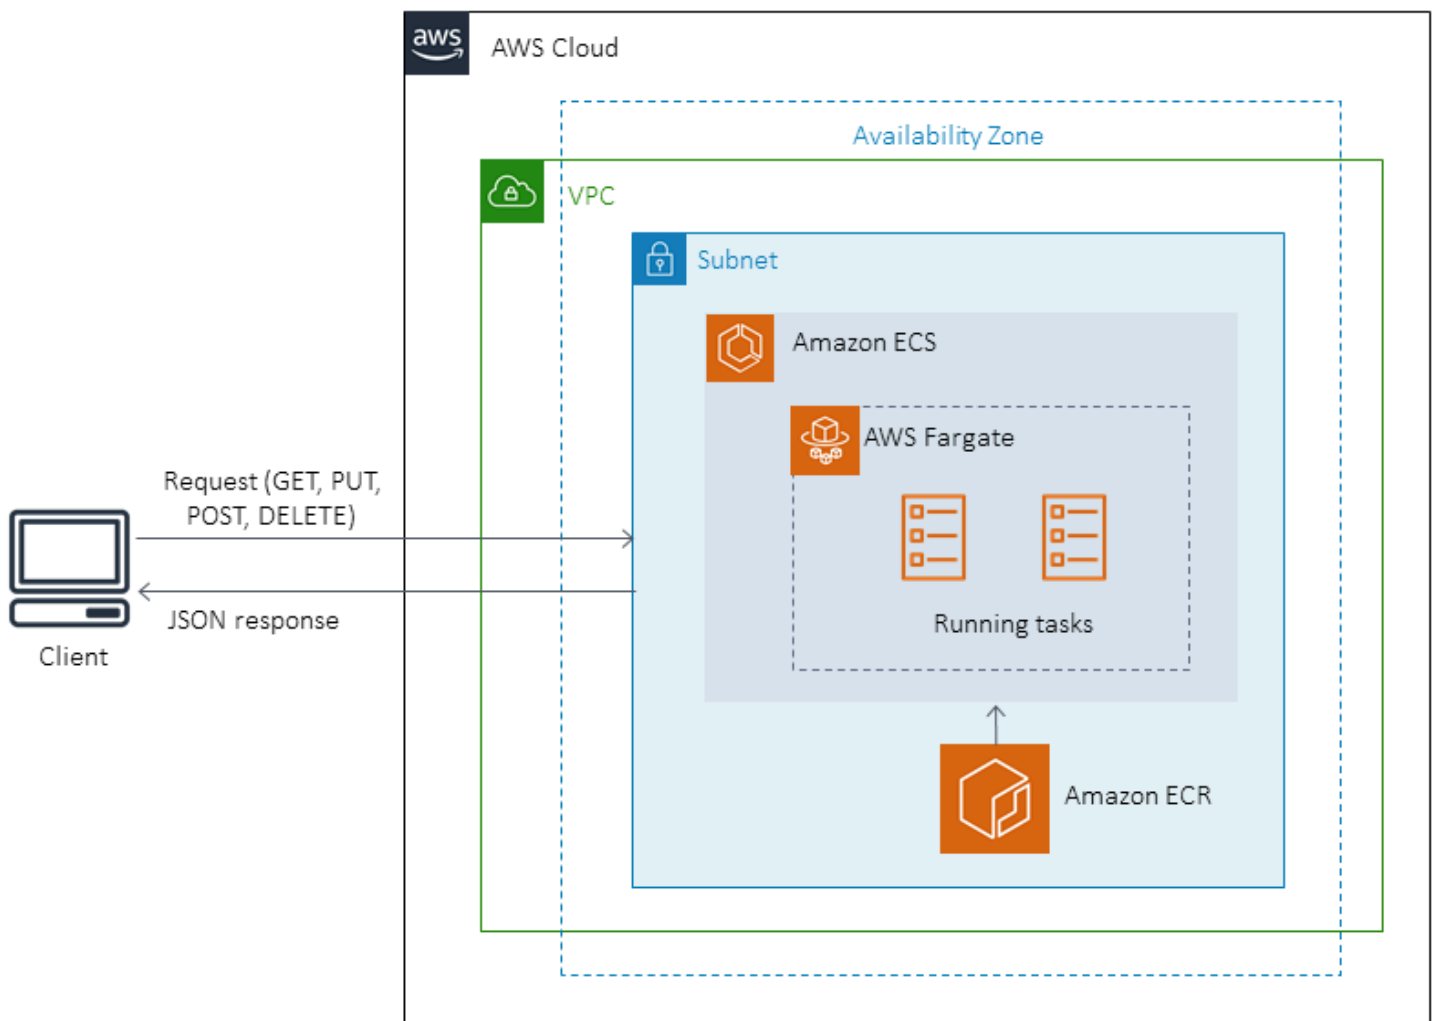

## Architecture

### Source technology stack

- Java microservices running on Amazon ECS
- Code repository in Amazon ECR
- AWS Fargate

### Source architecture

## Target technology stack

- Amazon ECR
- Amazon ECS
- AWS Fargate
- AWS CodePipeline
- AWS CodeBuild

## Target architecture

## Automation and scale

CodeBuild buildspec.yml file:

```
version: 0.2

phases:
  pre_build:
    commands:
      - echo Logging in to Amazon ECR...
      - aws --version
```

```
- $(aws ecr get-login --region $AWS_DEFAULT_REGION --no-include-email)
- REPOSITORY_URI=$AWS_ACCOUNT_ID.dkr.ecr.$AWS_DEFAULT_REGION.amazonaws.com/
$IMAGE_REPO
- COMMIT_HASH=$(echo $CODEBUILD_RESOLVED_SOURCE_VERSION | cut -c 1-7)
- IMAGE_TAG=build-$(echo $CODEBUILD_BUILD_ID | awk -F":" '{print $2}')
build:
  commands:
    - echo Build started on `date`
    - echo building the Jar file
    - mvn clean install
    - echo Building the Docker image...
    - docker build -t $REPOSITORY_URI:$BUILD_TAG .
    - docker tag $REPOSITORY_URI:$BUILD_TAG $REPOSITORY_URI:$IMAGE_TAG
post_build:
  commands:
    - echo Build completed on `date`
    - echo Pushing the Docker images...
    - docker push $REPOSITORY_URI:$BUILD_TAG
    - docker push $REPOSITORY_URI:$IMAGE_TAG
    - echo Writing image definitions file...
    - printf '[{"name":"%s","imageUri":"%s"}]' $DOCKER_CONTAINER_NAME
$REPOSITORY_URI:$IMAGE_TAG > imagedefinitions.json
    - cat imagedefinitions.json
artifacts:
  files:
    - imagedefinitions.json
    - target/DockerDemo.jar
```

## Tools

### AWS services

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. AWS CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left in the queue.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously. You can integrate AWS CodePipeline with third-party services like GitHub, or use an AWS services such as AWS CodeCommit or Amazon ECR.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated

with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can deploy containers for your applications reliably. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

- [Amazon Elastic Container Service \(Amazon ECS\)](#) highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.
- [AWS Fargate](#) is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

## Other tools

- [Docker](#) is a platform that lets you build, test, and deliver applications in packages called *containers*.
- [Git](#) is a distributed version-control system for tracking changes in source code during software development. It is designed for coordinating work among programmers, but it can be used to track changes in any set of files. Its goals include speed, data integrity, and support for distributed, non-linear workflows. You can also use AWS CodeCommit as an alternative to Git.

## Epics

### Set up the build project in AWS CodeBuild

Task	Description	Skills required
Create a CodeBuild build project.	In the <a href="#">AWS CodeBuild console</a> , create a build project, and specify its name.	App developer, AWS systems administrator
Select the source.	This pattern uses Git for the code repository, so choose <b>GitHub</b> from the list of	App developer, AWS systems administrator

Task	Description	Skills required
	available options. Choose a public repository or from your GitHub account.	
Select a repository.	Select the repository from which you want to build the code.	App developer, AWS systems administrator
Select the environment.	You can select from a list of managed images or opt for a custom image using Docker. This pattern uses the following managed image: <ul data-bbox="591 835 894 982" style="list-style-type: none"><li>• Amazon Linux 2</li><li>• Runtime: Standard</li><li>• Image version 1.0</li></ul>	App developer, AWS systems administrator
Choose a service role.	You can create a service role or select from a list of existing roles.	App developer, AWS systems administrator

Task	Description	Skills required
Add environment variables.	<p>In the <b>Additional configuration</b> section, configure the following environment variables:</p> <ul style="list-style-type: none"><li>• <b>AWS_DEFAULT_REGION</b> for the default AWS Region</li><li>• <b>AWS_ACCOUNT_ID</b> for the user account number</li><li>• <b>IMAGE_REPO</b> for the Amazon ECR private repository</li><li>• <b>BUILD_TAG</b> for the version of the build (<b>latest</b> build is the value for this variable)</li><li>• <b>DOCKER_CONTAINER_NAME</b> for the name of the container in the task</li></ul> <p>These variables are placeholders in the <code>buildspec.yml</code> file and will be replaced with their respective values.</p>	App developer, AWS systems administrator

Task	Description	Skills required
Create a buildspec file.	You can create a <code>buildspec.yml</code> file at the same location as <code>pom.xml</code> and add the configuration that is provided in this pattern, or use the online buildspec editor and add the configuration. Configure the environmental variables with the appropriate values by following the steps provided.	App developer, AWS systems administrator
Configure the project for artifacts.	(Optional) Configure the build project for artifacts, if required.	App developer, AWS systems administrator
Configure Amazon CloudWatch Logs.	(Optional) Configure Amazon CloudWatch Logs for the build project, if required. This step is optional but recommended.	App developer, AWS systems administrator
Configure Amazon S3 logs.	(Optional) Configure Amazon Simple Storage Service (Amazon S3) logs for the build project, if you want to store the logs.	App developer, AWS systems administrator

## Configure the pipeline in AWS CodePipeline

Task	Description	Skills required
Create a pipeline.	On the <a href="#">AWS CodePipeline console</a> , create a pipeline and specify its name. For	App developer, AWS systems administrator

Task	Description	Skills required
	more information about creating a pipeline, see the <a href="#">AWS CodePipeline documentation</a> .	
Select a service role.	Create a service role or select from the list of existing service roles. If you are creating a service role, provide a name for the role and select the option for CodePipeline to create the role.	App developer, AWS systems administrator
Choose an artifact store.	In <b>Advanced settings</b> , if you want Amazon S3 to create a bucket and store the artifacts in it, use the default location for the artifact store. Or, select a custom location and specify an existing bucket. You can also choose to encrypt the artifact by using an encryption key.	App developer, AWS systems administrator
Specify the source provider.	For <b>Source provider</b> , choose <b>GitHub (Version 2)</b> .	App developer, AWS systems administrator
Select the repository and branch of the code.	If you are not logged in, provide the connection details to connect to GitHub, and then select the repository name and branch name.	App developer, AWS systems administrator

Task	Description	Skills required
Change detection options.	Choose <b>Start the pipeline on source code change</b> and move to the next page.	App developer, AWS systems administrator
Select a build provider.	For <b>Build provider</b> , choose <b>AWS CodeBuild</b> , and then provide the AWS Region and project name details for the build project.  For <b>Build type</b> , choose <b>Single build</b> .	App developer, AWS systems administrator
Choose a deploy provider.	For <b>Deploy provider</b> , choose Amazon ECS. Choose the cluster name, the service name, the image definitions file, if any, and a deployment timeout value, if required. Choose <b>Create pipeline</b> .	App developer, AWS systems administrator

# Use AWS CodeCommit and AWS CodePipeline to deploy a CI/CD pipeline in multiple AWS accounts

Created by Kirankumar Chandrashekar (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps

**Workload:** All other workloads

**AWS services:** AWS CodeCommit; AWS CodePipeline

## Summary

This pattern shows you how to deploy a continuous integration and continuous delivery (CI/CD) pipeline for your application code workloads in separate Amazon Web Services (AWS) accounts for DevOps, developer, staging, and production workflows.

You can use a [multiple AWS account strategy](#) to provide a high level of [resource or security isolation](#), [optimize costs](#), and separate out your production workflow.

Your application's code remains identical in all these separate AWS accounts and is maintained on a central AWS CodeCommit repository hosted by your DevOps account. Your developer, staging, and production accounts have separate Git branches in this CodeCommit repository.

For example, when code is committed to the developer Git branch in your central CodeCommit repository, Amazon EventBridge in your DevOps account notifies EventBridge in your developer account of the repository changes. In your developer account, AWS CodePipeline and the [source stage](#) go into InProgress status. The source stage is configured from the developer Git branch in the central CodeCommit repository and CodePipeline assumes a [service role](#) for the DevOps account.

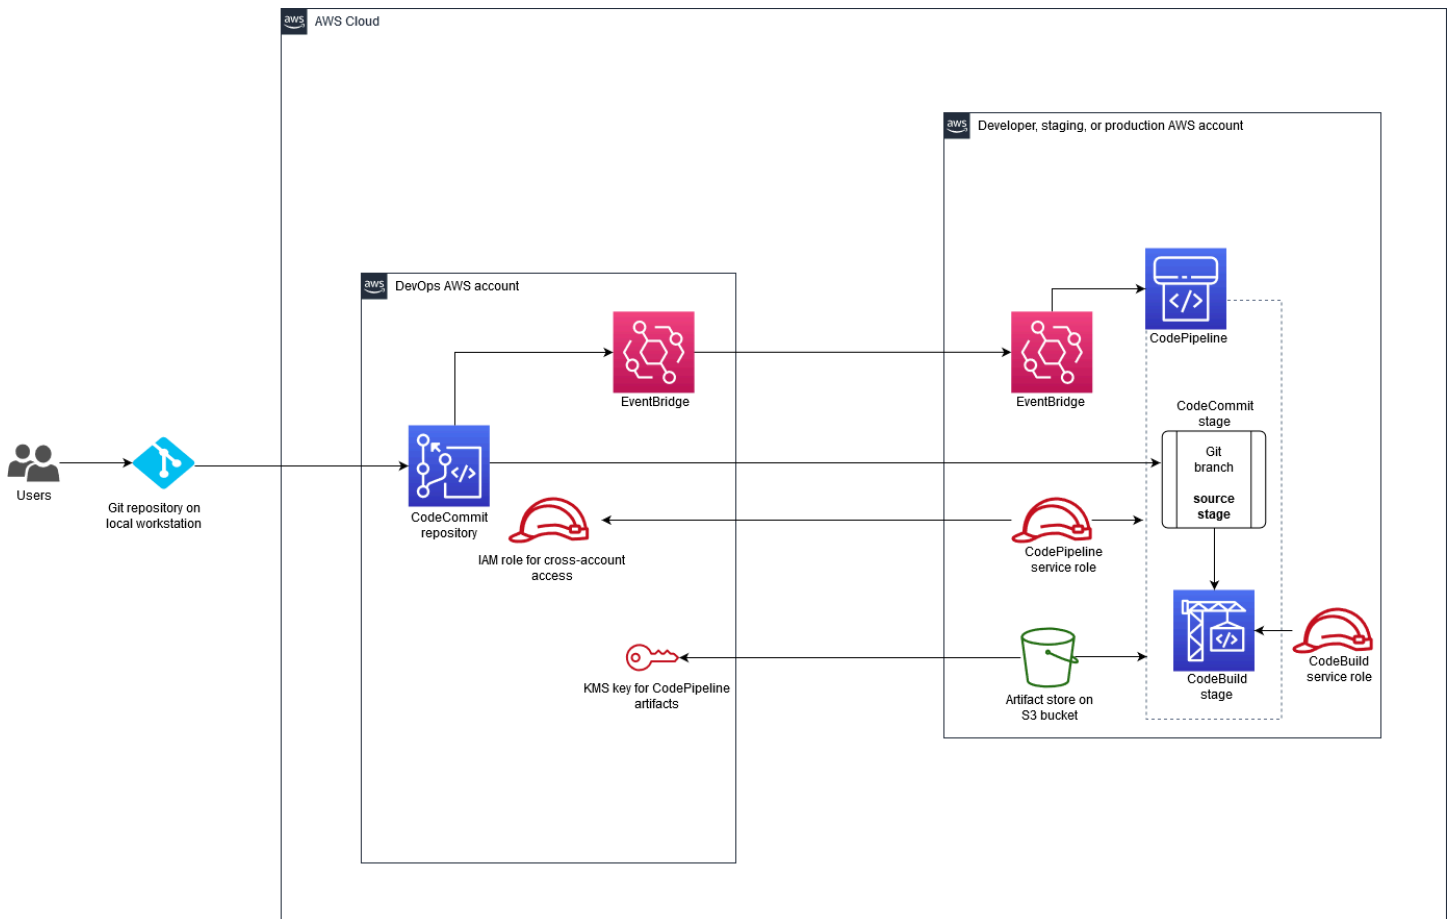

The contents of the CodeCommit repository in the developer branch are uploaded to an artifact store in an Amazon Simple Storage Service (Amazon S3) bucket and encrypted with an AWS Key Management Service (AWS KMS) key. After the source stage's status changes to Succeeded in CodePipeline, the code will be transitioned to the next stage of the [pipeline execution](#).

# Prerequisites and limitations

## Prerequisites

- Existing AWS accounts for each required environment (DevOps, developer, staging, and production). These accounts can be hosted by [AWS Organizations](#).
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#).

## Architecture

## Technology stack

- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- Amazon EventBridge

- AWS Identity and Access Management (IAM)
- AWS KMS
- AWS Organizations
- Amazon S3

## Tools

- [AWS CodeBuild](#) – CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.
- [AWS CodeCommit](#) – CodeCommit is a fully-managed source-control service that hosts secure Git-based repositories
- [AWS CodePipeline](#) – CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- [Amazon EventBridge](#) – EventBridge is a serverless event bus service for connecting your applications with data from a variety of sources.
- [AWS Identity and Access Management \(IAM\)](#) – IAM helps you to manage access to AWS services and resources securely.
- [AWS KMS](#) – AWS Key Management Service (AWS KMS) helps you create and manage cryptographic keys and control their use across a wide range of AWS services and in your applications.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

## Epics

### Create resources in your DevOps AWS account

Task	Description	Skills required
Create a CodeCommit repository.	Sign in to the AWS Management Console for your DevOps account, and open the CodeCommit console. Create a repository and set up all the required Git	DevOps engineer

Task	Description	Skills required
	branches for your developer, staging, and production AWS accounts. For help with this and other stories, see the “Related resources” section.	
Create access credentials for the CodeCommit repository.	On the IAM console, create access credentials to allow application developers to push and pull the application’s code base from the CodeCommit repository.	DevOps engineer
Create an IAM role for CodePipeline service roles.	On the IAM console, create an IAM role that can be used by all your CodePipeline service roles to access the central CodeCommit repository.	Cloud administrator
Set up the EventBridge rules for your other AWS accounts.	On the Amazon EventBridge console, set up rules to send notifications about relevant CodeCommit repository changes to EventBridge in the individual developer, staging, and production AWS accounts.	Cloud administrator
Create an AWS KMS key.	On the AWS KMS console, create a KMS key that allows CodePipeline in your individual developer, staging, and production AWS accounts to encrypt and decrypt artifacts.	Cloud administrator

## Create resources in your other AWS accounts

Task	Description	Skills required
Set up EventBridge to receive events from the DevOps AWS account.	Sign in to the AWS Management Console for one of your individual AWS accounts (developer, staging, or production). On the Amazon EventBridge console, set up EventBridge to receive CodeCommit repository change events from your DevOps account.	Cloud administrator
Create an S3 bucket.	On the Amazon S3 console, create an S3 bucket to store CodePipeline artifacts.	Cloud administrator
Create all required AWS resources for CodePipeline stages.	Create all the other AWS resources that will be required by the CodePipeline stages. These resources will vary depending on the role of each AWS account in your CI/CD pipeline.	Cloud administrator
Create an IAM role.	On the IAM console, create an IAM role for the CodePipeline service role. This service role must be able to assume the IAM role in the DevOps account to access the CodeCommit repository.	Cloud administrator
Create a pipeline in CodePipeline.	On the CodePipeline console, create a pipeline. Then create a source stage that points to	Cloud administrator

Task	Description	Skills required
	the CodeCommit repository in the DevOps account for its individual Git branch.	
Repeat the steps for all your AWS accounts.	Repeat these steps for all the AWS accounts that are required as part of your CI/CD strategy.	Cloud administrator

# Deploy a firewall using AWS Network Firewall and AWS Transit Gateway

Created by Shrikant Patil (AWS)

**Code repository:** [aws-network-firewall-deployment-with-transit-gateway](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Networking; Security, identity, compliance

**AWS services:** AWS Network Firewall; AWS Transit Gateway; Amazon VPC; Amazon CloudWatch

## Summary

This pattern shows you how to deploy a firewall by using AWS Network Firewall and AWS Transit Gateway. The Network Firewall resources are deployed by using an AWS CloudFormation template. Network Firewall automatically scales with your network traffic and can support hundreds of thousands of connections, so that you don't have to worry about building and maintaining your own network security infrastructure. A transit gateway is a network transit hub that you can use to interconnect your virtual private clouds (VPCs) and on-premises networks.

In this pattern, you also learn to include an inspection VPC in your network architecture. Finally, this pattern explains how to use Amazon CloudWatch to provide real-time activity monitoring for your firewall.

**Tip:** It's a best practice to avoid using a Network Firewall subnet to deploy other AWS services. This is because Network Firewall can't inspect traffic from sources or destinations within a firewall's subnet.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) role and policy permissions

- CloudFormation template permissions

## Limitations

You could have issues with domain filtering and a different kind of configuration could be necessary. For more information, see [Stateful domain list rule groups in AWS Network Firewall](#) in the Network Firewall documentation.

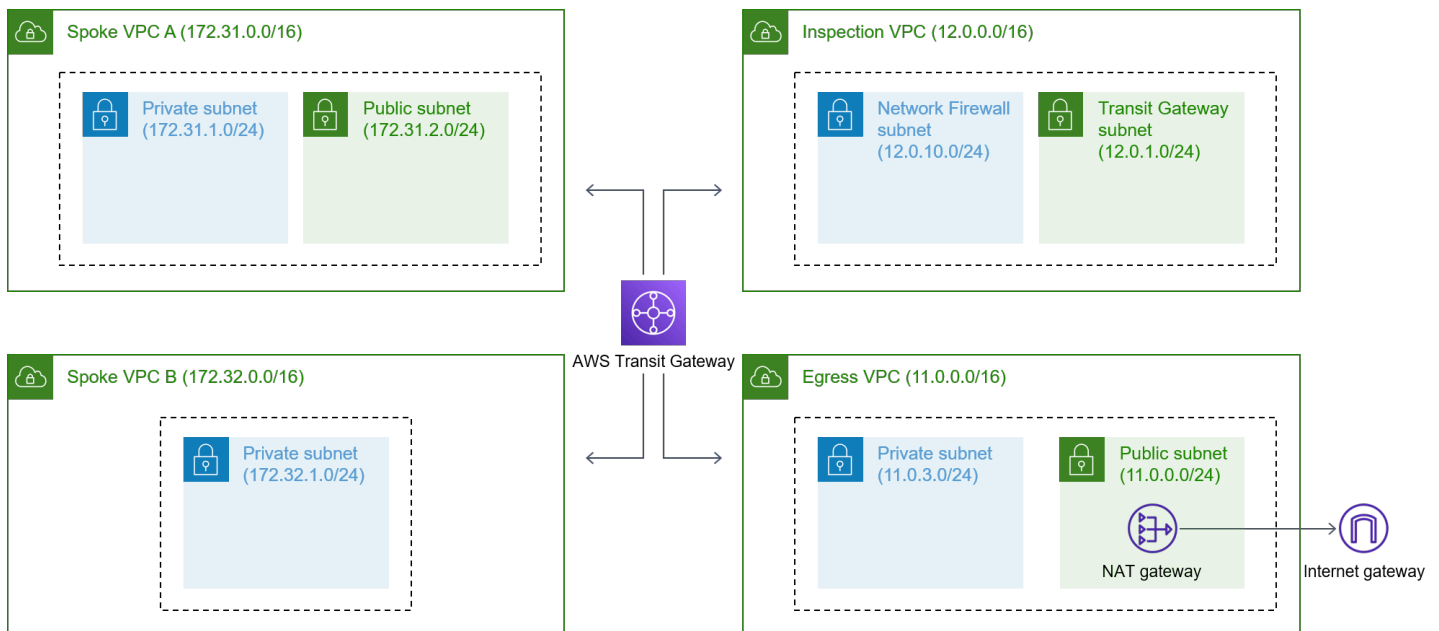

## Architecture

### Technology stack

- Amazon CloudWatch Logs
- Amazon VPC
- AWS Network Firewall
- AWS Transit Gateway

### Target architecture

The following diagram shows how to use Network Firewall and Transit Gateway to inspect your traffic:

The architecture includes the following components:

- Your application is hosted in the two spoke VPCs. The VPCs are monitored by Network Firewall.
- The egress VPC has direct access to the internet gateway but is not protected by Network Firewall.
- The inspection VPC is where Network Firewall is deployed.

## Automation and scale

You can use [CloudFormation](#) to create this pattern by using [infrastructure as code](#).

## Tools

### AWS services

- [Amazon CloudWatch Logs](#) helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- [AWS Network Firewall](#) is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud.
- [AWS Transit Gateway](#) is a central hub that connects VPCs and on-premises networks.

### Code

The code for this pattern is available in the GitHub [AWS Network Firewall deployment with Transit Gateway](#) repository. You can use the CloudFormation template from this repository to deploy a single inspection VPC that uses Network Firewall.

## Epics

### Create the spoke VPC and inspection VPC

Task	Description	Skills required
Prepare and deploy the CloudFormation template.	1. Download the <code>cloudformation/aws_nw_fw.yaml</code>	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>1. template from the GitHub <a href="#">repository</a>.</li> <li>2. Update the template with your values.</li> <li>3. Deploy the template.</li> </ol>	

## Create the transit gateway and routes

Task	Description	Skills required
Create a transit gateway.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the <a href="#">Amazon VPC console</a>.</li> <li>2. On the navigation pane, choose <b>Transit gateways</b>.</li> <li>3. Choose <b>Create transit gateway</b>.</li> <li>4. For <b>Name tag</b>, enter a name for the transit gateway.</li> <li>5. For <b>Description</b>, enter a description for the transit gateway.</li> <li>6. For <b>Amazon side Autonomous System Number (ASN)</b>, leave the default ASN value.</li> <li>7. Select the <b>DNS support</b> option.</li> <li>8. Select the <b>VPN ECMP support</b> option.</li> </ol>	AWS DevOps

Task	Description	Skills required
	<p>9. Select the <b>Default route table association</b> option. This option automatically associates the transit gateway attachments with the default route table for the transit gateway.</p> <p>10 Select the <b>Default route table propagation</b> option. This option automatically propagates the transit gateway attachments to the default route table for the transit gateway.</p> <p>11 Choose <b>Create transit gateway</b>.</p>	
<p>Create transit gateway attachments.</p>	<p><a href="#">Create a transit gateway attachment</a> for the following:</p> <ul style="list-style-type: none"> <li>• An <b>Inspection</b> attachment in the inspection VPC and Transit Gateway subnet</li> <li>• A <b>SpokeVPCA</b> attachment in the spoke VPCA and private subnet</li> <li>• A <b>SpokeVPCB</b> attachment in the spoke VPCB and private subnet</li> <li>• An <b>EgressVPC</b> attachment in the egress VPC and private subnet</li> </ul>	<p>AWS DevOps</p>

Task	Description	Skills required
Create a transit gateway route table.	<ol style="list-style-type: none"><li>1. <a href="#">Create a transit gateway route table</a> for the spoke VPC. This route table must be associated to all the VPCs other than the inspection VPC.</li><li>2. <a href="#">Create a transit gateway route table</a> for the firewall. This route table must be associated to the inspection VPC only.</li><li>3. Add a route to the transit gateway route table for the firewall:<ul style="list-style-type: none"><li>• For <math>0.0.0/0</math>, use the <b>EgressVPC</b> attachment.</li><li>• For the <b>SpokeVPCA</b> CIDR block, use the <b>SpokeVPC1</b> attachment.</li><li>• For the <b>SpokeVPCB</b> CIDR block, use the <b>SpokeVPC2</b> attachment.</li></ul></li><li>4. Add a route to the transit gateway route table for the spoke VPC. For <math>0.0.0/0</math>, use the <b>Inspection VPC</b> attachment.</li></ol>	AWS DevOps

## Create the firewall and routes

Task	Description	Skills required
Create a firewall in the inspection VPC.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">Amazon VPC console</a>.</li><li>2. In the navigation pane, under <b>Network Firewall</b>, choose <b>Firewalls</b>.</li><li>3. Choose <b>Create firewall</b>.</li><li>4. For <b>Name</b>, enter the name that you want to use to identify this firewall. You can't change the name of a firewall after you create it.</li><li>5. For <b>VPC</b>, select your inspection VPC.</li><li>6. For <b>Availability Zone</b> and <b>Subnet</b>, select the zone and firewall subnet that you identified.</li><li>7. In the <b>Associated firewall policy</b> section, choose <b>Associate an existing firewall policy</b>, and then select the firewall policy that you created earlier.</li><li>8. Choose <b>Create firewall</b>.</li></ol>	AWS DevOps
Create a firewall policy.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">Amazon VPC console</a>.</li></ol>	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. In the navigation pane, under <b>Network Firewall</b>, choose <b>Firewall policies</b>.</li><li>3. On the <b>Describe firewall policy</b> page, choose <b>Create firewall policy</b>.</li><li>4. For <b>Name</b>, enter the name that you want to use for the firewall policy. You'll use the name to identify the policy when you associate the policy with your firewall later in this pattern. You can't change the name of a firewall policy after you create it.</li><li>5. Choose <b>Next</b>.</li><li>6. On the <b>Add rule groups</b> page, in the <b>Stateless rule group</b> section, choose <b>Add stateless rule groups</b>.</li><li>7. In the <b>Add from existing rule groups</b> dialog box, select the check box for the stateless rule group that you created earlier. Choose <b>Add rule groups</b>. <b>Note:</b> At the bottom of the page, the firewall policy's capacity counter shows the capacity consumed by adding this rule group next to the maximum capacity</li></ol>	

Task	Description	Skills required
	<p>allowed for a firewall policy.</p> <p>8. Set the stateless default action to <b>Forward to stateful rules</b>.</p> <p>9. In the <b>Stateful rule group</b> section, choose <b>Add stateful rule groups</b>, and then select the check box for the stateful rule group that you created earlier. Choose <b>Add rule groups</b>.</p> <p>10 Choose <b>Next</b> to step through the rest of the setup wizard, and then choose <b>Create firewall policy</b>.</p>	

Task	Description	Skills required
Update your VPC route tables.	<p><b>Inspection VPC route tables</b></p> <ol style="list-style-type: none"><li>1. In the ANF subnet route table (Inspection-ANFRT), add <code>0.0.0/0</code> to the Transit Gateway ID.</li><li>2. In the Transit Gateway subnet route table (Inspection-TGWRT ), add <code>0.0.0/0</code> to the <b>EgressVPC</b>.</li></ol> <p><b>SpokeVPCA route table</b></p> <p>In the private route table, add <code>0.0.0.0/0</code> to the Transit Gateway ID.</p> <p><b>Spoke VPCB route table</b></p> <p>In the private route table, add <code>0.0.0.0/0</code> to the Transit Gateway ID.</p> <p><b>Egress VPC route tables</b></p> <p>In the egress public route table, add the <b>SpokeVPCA</b> and <b>Spoke VPCB</b> CIDR block to the Transit Gateway ID. Repeat the same step for the private subnet.</p>	AWS DevOps

## Set up CloudWatch to perform real-time network inspection

Task	Description	Skills required
Update the firewall's logging configuration.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">Amazon VPC console</a>.</li><li>2. In the navigation pane, under <b>Network Firewall</b>, choose <b>Firewalls</b>.</li><li>3. In the <b>Firewalls</b> page, choose the name of the firewall that you want to edit.</li><li>4. Choose the <b>Firewall details</b> tab. In the <b>Logging</b> section, choose <b>Edit</b>.</li><li>5. Adjust the <b>Log type</b> selections as needed. You can configure logging for alert and flow logs.<ul style="list-style-type: none"><li>• Alert – Sends logs for traffic that matches any stateful rule where the action is set to <b>Alert</b> or <b>Drop</b>. For more information about stateful rules and rule groups, see <a href="#">Rule groups in AWS Network Firewall</a>.</li><li>• Flow – Sends logs for all network traffic that the stateless engine</li></ul></li></ol>	AWS DevOps

Task	Description	Skills required
	<p>forwards to the stateful rules engine.</p> <p>6. For each selected log type, choose the destination type, and then provide the information for the logging destination. For more information, see <a href="#">AWS Network Firewall logging destinations</a> in the Network Firewall documentation.</p> <p>7. Choose <b>Save</b>.</p>	

## Verify the setup

Task	Description	Skills required
Launch an EC2 instance to test the setup.	<a href="#">Launch two Amazon Elastic Compute Cloud (Amazon EC2) instances</a> in the spoke VPC: one for Jumpbox and one for test connectivity.	AWS DevOps
Check the metrics.	Metrics are grouped first by the service namespace and then by the various dimension combinations within each namespace. The CloudWatch namespace for Network Firewall is <code>AWS/NetworkFirewall</code> .	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="594 212 1008 390">1. Sign in to the AWS Management Console and open the <a href="#">CloudWatch console</a>.</li><li data-bbox="594 411 964 493">2. In the navigation pane, choose <b>Metrics</b>.</li><li data-bbox="594 514 1000 690">3. On the <b>All metrics</b> tab, choose the Region, and then choose <b>AWS/NetworkFirewall</b>.</li></ol>

# Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline

Created by Bruno Klein (AWS) and Luis Henrique Massao Yamada (AWS)

**Environment:** Production

**Technologies:** DevOps; Big data

**AWS services:** AWS Glue; AWS CodeCommit; AWS CodePipeline; AWS Lambda

## Summary

This pattern demonstrates how you can integrate Amazon Web Services (AWS) CodeCommit and AWS CodePipeline with AWS Glue, and use AWS Lambda to launch jobs as soon as a developer pushes their changes to a remote AWS CodeCommit repository.

When a developer submits a change to an extract, transform, and load (ETL) repository and pushes the changes to AWS CodeCommit, a new pipeline is invoked. The pipeline initiates a Lambda function that launches an AWS Glue job with these changes. The AWS Glue job performs the ETL task.

This solution is helpful in the situation where businesses, developers, and data engineers want to launch jobs as soon as changes are committed and pushed to the target repositories. It helps achieve a higher level of automation and reproducibility, therefore avoiding errors during the job launch and lifecycle.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [Git](#) installed on the local machine
- [Amazon Cloud Development Kit \(Amazon CDK\)](#) installed on the local machine
- [Python](#) installed on the local machine
- The code in the *Attachments* section

## Limitations

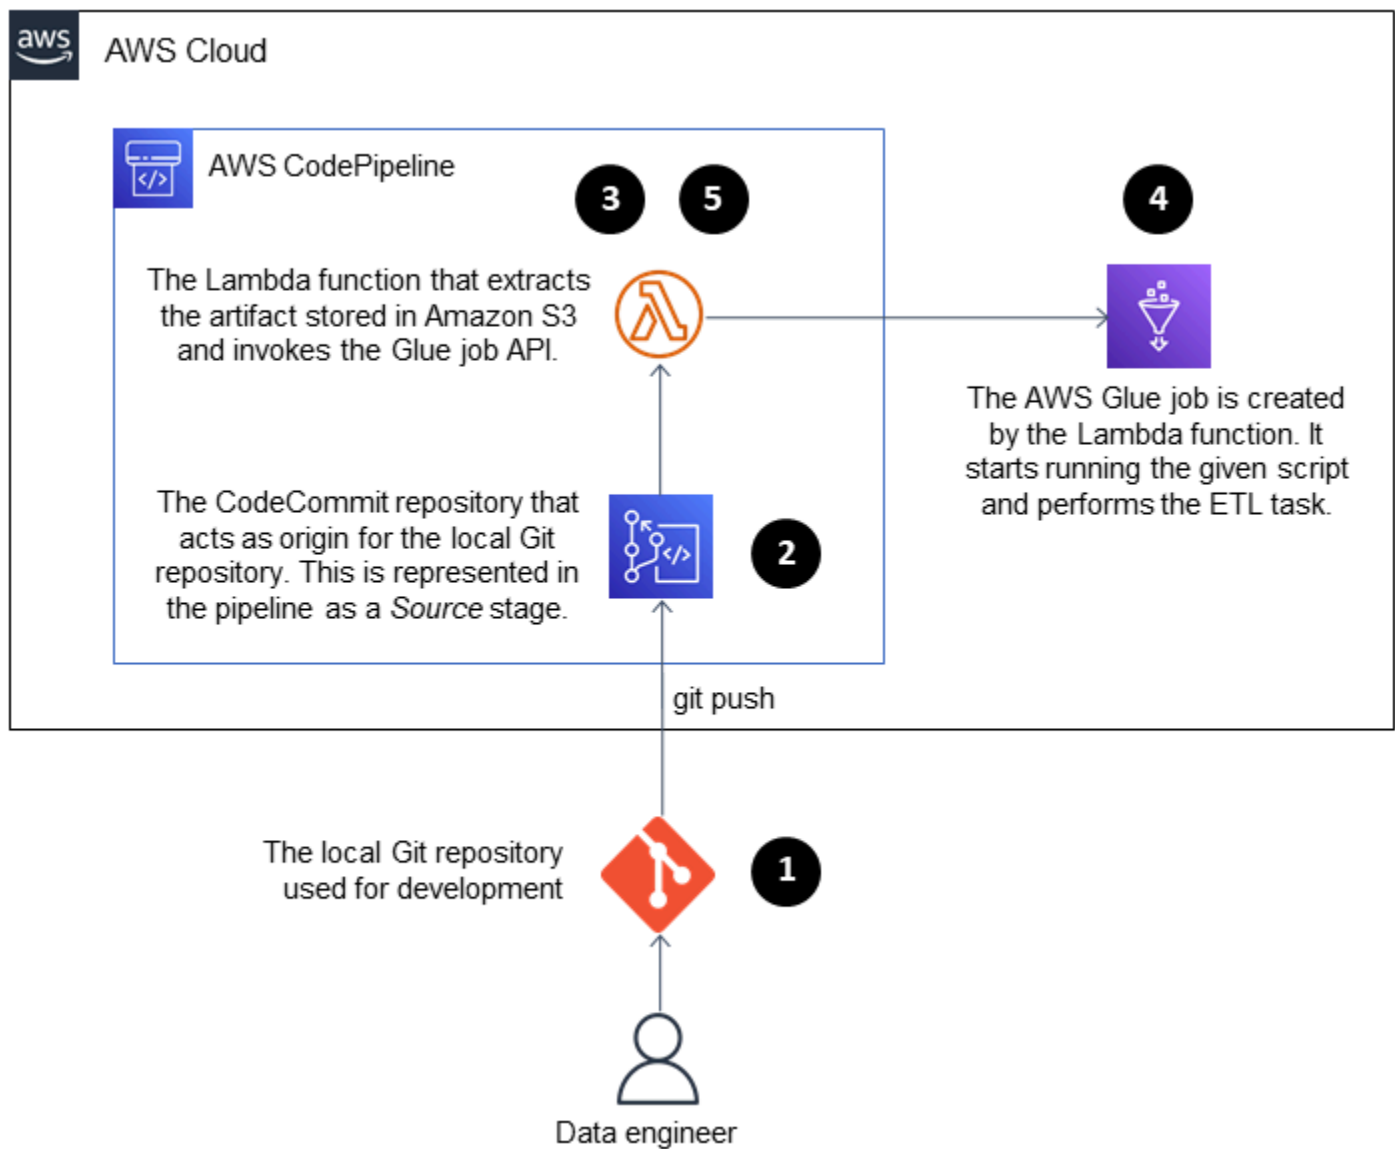

- The pipeline is finished as soon as the AWS Glue job is successfully launched. It does not wait for the conclusion of the job.
- The code provided in the attachment is intended for demo purposes only.

## Architecture

### Target technology stack

- AWS Glue
- AWS Lambda
- AWS CodePipeline
- AWS CodeCommit

### Target architecture

The process consists of these steps:

1. The developer or data engineer makes a modification in the ETL code, commits, and pushes the change to AWS CodeCommit.
2. The push initiates the pipeline.
3. The pipeline initiates a Lambda function, which calls `codecommit:GetFile` on the repository and uploads the file to Amazon Simple Storage Service (Amazon S3).
4. The Lambda function launches a new AWS Glue job with the ETL code.
5. The Lambda function finishes the pipeline.

## Automation and scale

The sample attachment demonstrates how you can integrate AWS Glue with AWS CodePipeline. It provides a baseline example that you can customize or extend for your own use. For details, see the *Epics* section.

## Tools

- [AWS CodePipeline](#) – AWS CodePipeline is a fully managed [continuous delivery](#) service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- [AWS CodeCommit](#) – AWS CodeCommit is a fully managed [source control](#) service that hosts secure, Git-based repositories.
- [AWS Lambda](#) – AWS Lambda is a serverless compute service that lets you run code without provisioning or managing servers.
- [AWS Glue](#) – AWS Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development.
- [Git client](#) – Git provides GUI tools, or you can use the command line or a desktop tool to check out the required artifacts from GitHub.
- [AWS CDK](#) – The AWS CDK is an open source software development framework that helps you define your cloud application resources by using familiar programming languages.

## Epics

### Deploy the sample code

Task	Description	Skills required
Configure the AWS CLI.	Configure the AWS Command Line Interface (AWS CLI) to target and authenticate with your current AWS account. For instructions, see the <a href="#">AWS CLI documentation</a> .	Developer, DevOps engineer
Extract the sample project files.	Extract the files from the attachment to create a folder	Developer, DevOps engineer

Task	Description	Skills required
	that contains the sample project files.	
Deploy the sample code.	<p>After you extract the files, run the following commands from the extract location to create a baseline example:</p> <pre data-bbox="594 554 1029 1031">cdk bootstrap cdk deploy git init git remote add origin &lt;code-commit-repository-url&gt; git stage . git commit -m "adds sample code" git push --set-upstream origin main</pre> <p>After the last command, you can monitor the status of the pipeline and the AWS Glue job.</p>	Developer, DevOps engineer
Customize the code.	Customize the code for the etl.py file in accordance with your business requirements. You can revise the ETL code, modify the pipeline stages, or extend the solution.	Data engineer

# Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile

Created by Sagar Panigrahi (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Containers & microservices

**Workload:** All other  
workloads

**AWS services:** Amazon EKS;  
AWS Cloud9; AWS Identity  
and Access Management;  
AWS CloudFormation

## Summary

This pattern describes how to use AWS Cloud9 and AWS CloudFormation to create an Amazon Elastic Kubernetes Service (Amazon EKS) cluster that can be operated without enabling programmatic access for users in your Amazon Web Services (AWS) account.

AWS Cloud9 is a cloud-based integrated development environment (IDE) that helps you write, run, and debug your code by using a browser. AWS Cloud9 is used as a control center that provisions an Amazon EKS cluster by using Amazon Elastic Compute Cloud (Amazon EC2) instance profiles and AWS CloudFormation templates.

You can use this pattern if you don't want to create AWS Identity and Access Management (IAM) users and want to use IAM roles instead. Role-based access control (RBAC) regulates access to resources based on the roles of individual users. This pattern demonstrates how to update RBAC within an Amazon EKS cluster to allow access to a specific IAM role.

The pattern's setup also helps your DevOps team use AWS Cloud9 features to maintain and develop infrastructure as code (IaC) resources for creating Amazon EKS infrastructure.

## Prerequisites and limitations

### Prerequisites

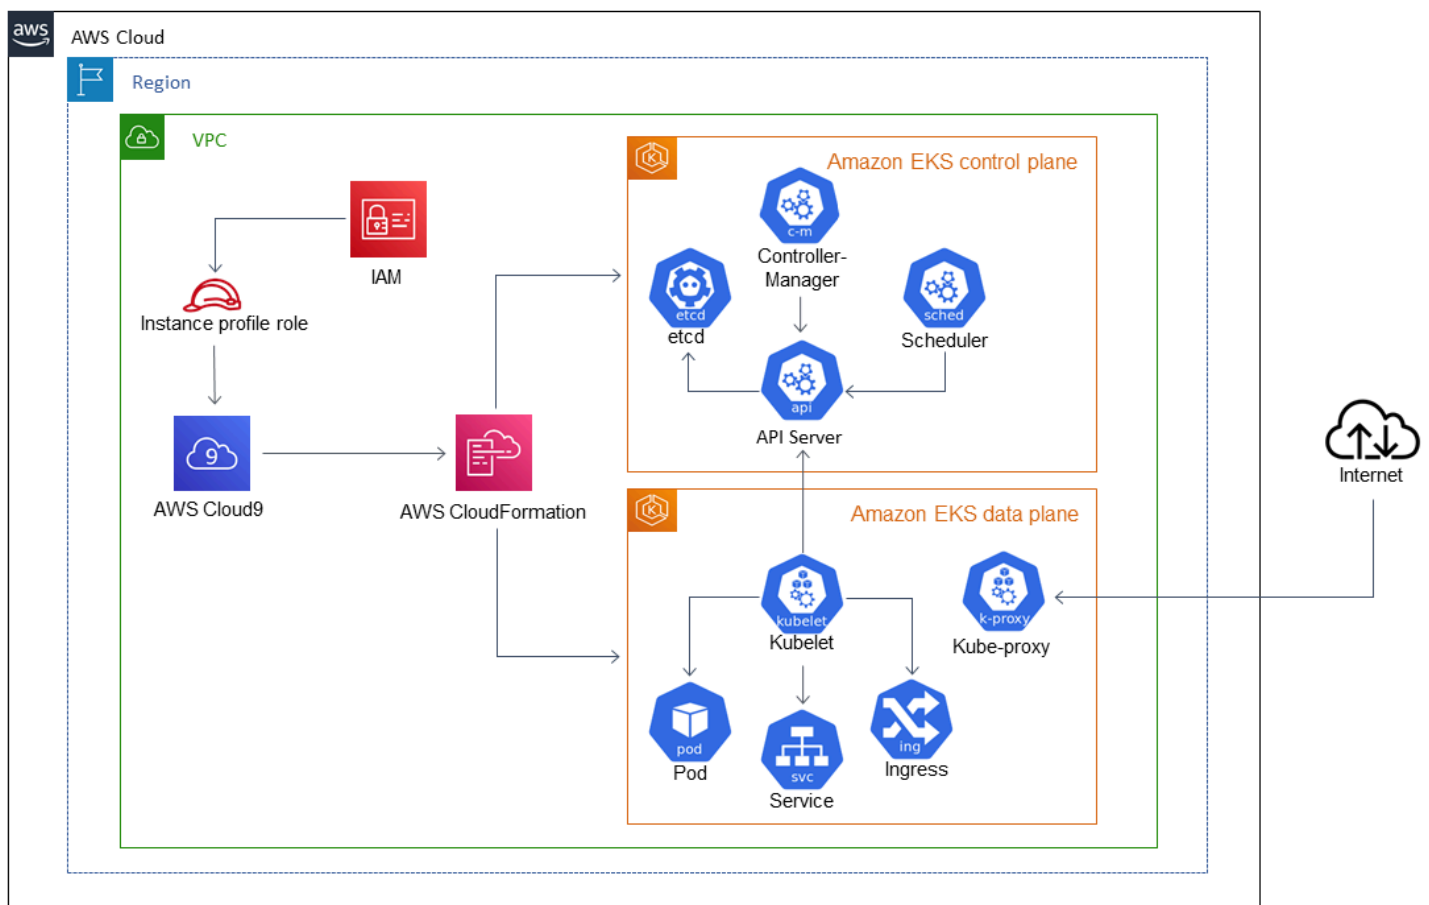

- An active AWS account.

- Permissions to create IAM roles and policies for the account. The IAM role for the user must include the `AWSCloud9Administrator` policy. The `AWSServiceRoleForAmazonEKS` and `eksNodeRoles` roles must also be created because they are required to create an Amazon EKS cluster.
- Knowledge of Kubernetes concepts.

## Limitations

- This pattern describes how to create a basic Amazon EKS cluster. For production clusters, you must update the AWS CloudFormation template.
- The pattern doesn't deploy additional Kubernetes components (for example, [Fluentd](#), [ingress controllers](#), or [storage controllers](#)).

## Architecture

## Technology stack

- AWS Cloud9
- AWS CloudFormation
- Amazon EKS
- IAM

## Automation and scale

You can expand this pattern and incorporate it into continuous integration and continuous deployment (CI/CD) pipelines to automate the complete provisioning of Amazon EKS.

## Tools

- [AWS CloudFormation](#) – AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.
- [AWS Cloud9](#) – AWS Cloud9 offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal.
- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- [Kubect1](#) – `kubect1` is a command line utility that you can use to interact with an Amazon EKS cluster.

## Epics

### Create the IAM roles for the EC2 instance profile

Task	Description	Skills required
Create the IAM policy.	Sign in to the AWS Management Console, open the IAM console, choose <b>Policies</b> , and then choose	Cloud administrator

Task	Description	Skills required
	<p><b>Create policy.</b> Choose the <b>JSON</b> tab and paste the contents from the policy-role-eks-instance-profile-for-cloud9.json file (attached).</p> <p>Resolve any security warnings, errors, or general warnings generated during the policy validation, and then choose <b>Review policy</b>. Enter a <b>Name</b> for the policy. We recommend that you use <code>eks-instance-profile-for-cloud9</code> for the policy name.</p> <p>Review the policy <b>Summary</b> to see the permissions that are granted by your policy. Then choose <b>Create policy</b>.</p>	

Task	Description	Skills required
Create an IAM role using the policy.	<p>On the IAM console, choose <b>Roles</b> and then choose <b>Create role</b>. Choose <b>AWS Service</b> and then choose <b>EC2</b> from the list.</p> <p>Choose <b>Next: Permissions</b> and search for the IAM policy that you created earlier. Choose the appropriate tags for your requirements.</p> <p>In the <b>Review</b> section, enter a name for the role. We recommend that you use <code>role-eks-instance-profile-for-cloud9</code> for the role name. Then choose <b>Create role</b>.</p>	Cloud administrator

### Create an IAM policy and role for the Amazon EKS RBAC

Task	Description	Skills required
Create the IAM policy.	<p>On the IAM console, choose <b>Policies</b> and then choose <b>Create policy</b>. Choose the <b>JSON</b> tab and paste the contents from the <code>policy-for-eks-rbac.json</code> file (attached).</p> <p>Resolve any security warnings, errors, or general warnings generated during the policy validation, and</p>	Cloud administrator

Task	Description	Skills required
	<p>then choose <b>Review policy</b>. Enter a <b>Name</b> for the policy. We recommend that you use <code>policy-for-eks-rbac</code> for the policy name. Review the policy <b>Summary</b> to see the permissions that are granted by your policy. Then choose <b>Create policy</b>.</p>	
<p>Create an IAM role using the policy.</p>	<p>On the IAM console, choose <b>Roles</b> and then choose <b>Create role</b>. Choose <b>AWS Service</b> and then choose <b>EC2</b> from the list. Choose <b>Next: Permissions</b> and search for the IAM policy that you created earlier. Choose the appropriate tags for your requirements.</p> <p>In the <b>Review</b> section, enter a name for the role. We recommend that you use <code>role-eks-admin-for-rbac</code> for the role name. Then choose <b>Create role</b>.</p>	<p>Cloud administrator</p>

## Create the AWS Cloud9 environment

Task	Description	Skills required
<p>Create the AWS Cloud9 environment.</p>	<p>Open the AWS Cloud9 console and choose <b>Create environment</b>. On the <b>Name</b></p>	<p>Cloud administrator</p>

Task	Description	Skills required
	<p><b>environment</b> page, enter a name for your environment. We recommend that you use <code>eks-management-env</code> for the environment name. Configure the remaining settings according to your requirements and then choose <b>Next step</b>.</p> <p>On the <b>Review</b> page, choose <b>Create environment</b>. Wait while AWS Cloud9 creates your environment. This can take several minutes.</p> <p>For more information about the available configuration options, see <a href="#">Creating an EC2 environment</a> in the AWS Cloud9 documentation.</p>	
Remove the temporary IAM credentials for AWS Cloud9.	<p>After your AWS Cloud9 environment is provisioned, choose <b>Settings</b> in the gear icon. Under <b>Preferences</b>, choose <b>AWS settings</b> and then choose <b>Credentials</b>.</p> <p>Turn off <b>AWS managed temporary credentials</b> and close the tab.</p>	Cloud administrator

Task	Description	Skills required
<p>Attach the EC2 instance profile to the underlying EC2 instance.</p>	<p>Open the Amazon EC2 console and choose the EC2 instance that matches your environment in AWS Cloud9. If you used the name that we recommended, the EC2 instance is called <code>aws-cloud9-eks-management-env</code>.</p> <p>Choose the EC2 instance, choose <b>Actions</b>, and then choose <b>Instance settings</b>. Choose <b>Attach/replace IAM role</b>. Search for <code>role-eks-instance-profile-for-cloud9</code> or the name of the IAM role that you created earlier, and then choose <b>Apply</b>.</p>	<p>Cloud administrator</p>

## Create the Amazon EKS cluster

Task	Description	Skills required
<p>Create the Amazon EKS cluster.</p>	<p>Download and open the <code>eks-cfn.yaml</code> (attached) template for AWS CloudFormation. Edit the template according to your requirements.</p> <p>Open the AWS Cloud9 environment and choose <b>New file</b>. Paste the AWS</p>	<p>Cloud administrator</p>

Task	Description	Skills required
	<p>CloudFormation template that you created earlier into the field. We recommend that you use eks-cfn.yaml for the template name.</p> <p>In the AWS Cloud9 terminal, run the following command to create the Amazon EKS cluster:</p> <pre>aws cloudformation create-stack -- stack-name eks-clust er --template-body file://eks-cfn.yam l --region &lt;your_AWS _Region&gt;</pre> <p>If the AWS CloudFormation call is successful, you receive the AWS CloudFormation stack's Amazon Resource Name (ARN) in your output. The stack creation can take between 10 to 20 minutes.</p>	

Task	Description	Skills required
Verify the Amazon EKS cluster's status.	<p>On the AWS CloudFormation console, open the <b>Stacks</b> page and then choose the stack name.</p> <p>The stack is created when the stack status code shows <code>CREATE_COMPLETE</code> . For more information, see <a href="#">Viewing AWS CloudFormation stack data and resources</a> in the AWS CloudFormation documentation.</p>	Cloud administrator

### Access the Kubernetes resources in the Amazon EKS cluster

Task	Description	Skills required
Install kubectl in the AWS Cloud9 environment.	Install kubectl in your AWS Cloud9 environment by following the instructions from <a href="#">Installing kubectl</a> in the Amazon EKS documentation.	Cloud administrator
Update the new Amazon EKS configuration in AWS Cloud9.	<p>Run the following command in the AWS Cloud9 terminal to update the kubeconfig from the Amazon EKS cluster to the AWS Cloud9 environment:</p> <pre>aws eks update-kubeconfig --name EKS-DEV2 --region &lt;your_AWS_Region&gt;</pre>	Cloud administrator

Task	Description	Skills required
	<p><b>Important:</b> EKS-DEV2 is the name of the Amazon EKS cluster in the AWS CloudFormation template that you used to create the cluster.</p> <p>Run the <code>kubectl get all -A</code> command to view all Kubernetes resources.</p>	

Task	Description	Skills required
Add the administrator IAM role to the Kubernetes RBAC.	<p>Run the following command in your AWS Cloud9 terminal to open the RBAC configuration map for Amazon EKS in edit mode:</p> <pre>kubectl edit cm/aws-auth -n kube-system</pre> <p>Append the following lines under the mapRoles section:</p> <pre>- groups: - system:masters rolearn: &lt;ARN_of_IAM_role_from_second_epic&gt; username: eksadmin</pre> <p>Lint the YAML-formatted file to avoid syntax errors. Save the file using <code>vi</code> commands and then exit the file.</p> <p><b>Note:</b> By adding this section, you inform the Kubernetes RBAC that <code>&lt;ARN_of_IAM_role_from_second_epic&gt;</code> is to receive full administrator access on the Amazon EKS cluster. This means that the identified IAM role can carry out administrative actions on the Kubernetes cluster. AWS adds the existing section under</p>	Cloud administrator

Task	Description	Skills required
	mapRoles while the Amazon EKS cluster is provisioned.

# Deploy code in multiple AWS Regions using AWS CodePipeline, AWS CodeCommit, and AWS CodeBuild

Created by Anand Krishna Varanasi (AWS)

**Created by:** AWS

**Environment:** PoC or pilot

**Technologies:** Management & governance; DevOps

**AWS services:** AWS CodeCommit; AWS CodePipeline; AWS CodeBuild

## Summary

This pattern demonstrates how to build infrastructure or architecture across multiple Amazon Web Services (AWS) Regions by using AWS CloudFormation. It includes continuous integration (CI)/continuous deployment (CD) across multiple AWS Regions for faster deployments. The steps in this pattern have been tested for the creation of an AWS CodePipeline job to deploy to three AWS Regions as an example. You can change the number of Regions based on your use case.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Two AWS Identity and Access Management (IAM) roles for AWS CodeBuild and AWS CloudFormation with proper policies for CodeBuild to perform the CI tasks of testing, bundling, packaging the artifacts, and deploying to multiple AWS Regions in parallel. **Note:** Cross-check the policies created by CodePipeline to verify that CodeBuild and AWS CloudFormation have proper permissions in the CI and CD phases.
- A CodeBuild role with the *AmazonS3FullAccess* and *CloudWatchFullAccess* policies. These policies give CodeBuild access to watch events of AWS CodeCommit through Amazon CloudWatch and to use Amazon Simple Storage Service (Amazon S3) as an artifact store.

- An AWS CloudFormation role with the following policies, which give AWS CloudFormation, in the final Build stage, the ability to create or update AWS Lambda functions, push or watch Amazon CloudWatch logs, and to create and update change sets.
  - *AWSLambdaFullAccess*
  - *AWSCodeDeployFullAccess*
  - *CloudWatchFullAccess*
  - *AWSCloudFormationFullAccess*
  - *AWSCodePipelineFullAccess*

## Architecture

This pattern's multiple-Region architecture and workflow comprise the following steps.

1. You send your code to a CodeCommit repository.
2. Upon receiving any code update or commit, CodeCommit invokes a CloudWatch event, which in turn starts a CodePipeline job.
3. CodePipeline engages the CI that is handled by CodeBuild. The following tasks are performed.
  - Testing of the AWS CloudFormation templates (optional)
  - Packaging of the AWS CloudFormation templates for each Region included in the deployment. For example, this pattern deploys in parallel to three AWS Regions, so CodeBuild packages the

AWS CloudFormation templates into three S3 buckets, one in each specified Region. The S3 buckets are used by CodeBuild as artifact repositories only.

4. CodeBuild packages the artifacts as input for next Deploy phase, which runs in parallel in the three AWS Regions. If you specify a different number of Regions, CodePipeline will deploy to those Regions.

## Tools

### Tools

- [AWS CodePipeline](#) – CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software changes continuously.
- [AWS CodeBuild](#) – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) – CodeCommit is a version control service hosted by Amazon Web Services that you can use to privately store and manage assets (such as source code and binary files) in the cloud.
- [AWS CloudFormation](#) – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- [AWS Identity and Access Management](#) – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.

### Code

The following sample code is for the `BuildSpec.yaml` file (Build phase).

```
---
artifacts:
  discard-paths: true
files:
  - packaged-first-region.yaml
  - packaged-second-region.yaml
  - packaged-third-region.yaml
```

```

phases:
build:
commands:
- echo "*****BUILD PHASE - CF PACKAGING*****"
- "aws cloudformation package --template-file sam-template.yaml --s3-bucket
  $S3_FIRST_REGION --output-template-file packaged-first-region.yaml --region
  $FIRST_REGION"
- "aws cloudformation package --template-file sam-template.yaml --s3-bucket
  $S3_SECOND_REGION --output-template-file packaged-second-region.yaml --region
  $SECOND_REGION"
- "aws cloudformation package --template-file sam-template-anand.yaml --s3-bucket
  $S3_THIRD_REGION --output-template-file packaged-third-region.yaml --region
  $THIRD_REGION"
install:
commands:

## Epics

### Prepare the code and the CodeCommit repository

Task	Description	Skills required
Select the primary AWS Region for the deployment.	Sign in to your AWS account and choose the primary Region for the deployment. The CodeCommit repository will be in the primary Region.	DevOps
Create the CodeCommit repository.	Create the CodeCommit repository, and push the	DevOps

Task	Description	Skills required
	required code into it. The code generally includes the AWS CloudFormation or AWS SAM templates, Lambda code if any, and the CodeBuild <code>buildspec.yaml</code> files as input to the AWS CodePipeline.	
Push the code into the CodeCommit repository.	In the <i>Attachments</i> section, download the code for this example, and then push the required code into it. Generally, the code can include AWS CloudFormation or AWS SAM templates, Lambda code and the CodeBuild <code>buildspec.yaml</code> files as input to the pipeline.	DevOps

### Source phase: Create the pipeline

Task	Description	Skills required
Create the CodePipeline job.	On the CodePipeline console, choose <b>Create pipeline</b> .	DevOps
Name the CodePipeline job and choose the service role setting.	Enter a name for the job, and keep the default service role setting so that CodePipeline creates the role with the necessary policies attached.	DevOps

Task	Description	Skills required
Specify the location for the artifact store.	Under <b>Advanced settings</b> , keep the default option so that CodePipeline creates an S3 bucket to use for code artifact storage. If you use an existing S3 bucket instead, the bucket must be in the primary Region that you specified in the first epic.	DevOps
Specify the encryption key.	Keep the default option, <b>Default AWS Managed Key</b> , or choose to use your own AWS Key Management Service (AWS KMS) customer managed key.	DevOps
Specify the source provider.	Under <b>Source provider</b> , choose <b>AWS CodeCommit</b> .	DevOps
Specify the repository.	Choose the CodeCommit repository that you created in the first epic. If you placed the code in a branch, choose the branch.	DevOps
Specify how code changes are detected.	Keep the default, <b>Amazon CloudWatch Events</b> , as the change trigger for CodeCommit to start the CodePipeline job.	DevOps

## Build phase: Configure the pipeline

Task	Description	Skills required
Specify the build provider.	For the build provider, choose <b>AWS CodeBuild</b> .	DevOps
Specify the AWS Region.	Choose the primary Region, which you specified in the first epic.	DevOps

## Build phase: Create and configure the project

Task	Description	Skills required
Create the project	Choose <b>Create project</b> , and enter a name for the project.	DevOps
Specify the environment image.	For this pattern demonstration, use the default CodeBuild managed image. You also have the option to use a custom Docker image if you have one.	DevOps
Specify the operating system.	Choose either Amazon Linux 2 or Ubuntu.	DevOps
Specify the service role.	Choose the role you created for CodeBuild before you started to create the CodePipeline job. (See the <i>Prerequisites</i> section.)	DevOps
Set additional options.	For <b>Timeout</b> and <b>Queued timeout</b> , keep the default values. For certificate, keep the default setting unless you	DevOps

Task	Description	Skills required
	have a custom certificate that you want to use.	
Create the environment variables.	For each AWS Region that you want to deploy to, create environment variables by providing the S3 bucket name and the Region name (for example, us-east-1).	DevOps
Provide the buildspec file name, if it is not buildspec.yml.	Keep this field blank if the file name is the default, <code>buildspec.yaml</code> . If you renamed the buildspec file, enter the name here. Make sure it matches the name of the file that is in the CodeCommit repository.	DevOps
Specify logging.	To see logs for Amazon CloudWatch Events, keep the default setting. Or you can define any specific group or logger names.	DevOps

## Skip the Deploy phase

Task	Description	Skills required
Skip the deploy phase and complete the creation of the pipeline.	When you set up the pipeline, CodePipeline allows you to create only one stage in the Deploy phase. To deploy to multiple AWS Regions, skip this phase. After the	DevOps

Task	Description	Skills required
	pipeline is created, you can add multiple Deploy phase stages.	

### Deploy phase: Configure the pipeline for deployment to the first Region

Task	Description	Skills required
Add a stage to the Deploy phase.	Edit the pipeline and choose <b>Add stage</b> in the Deploy phase. This first stage is for the primary Region.	DevOps
Provide an action name for the stage.	Enter a unique name that reflects the first (primary) stage and Region. For example, enter <b>primary_&lt;region&gt;_deploy</b> .	DevOps
Specify the action provider.	For <b>Action provider</b> , choose AWS CloudFormation.	DevOps
Configure the Region for the first stage.	Choose the first (primary) Region, the same Region where CodePipeline and CodeBuild are set up. This is the primary Region where you want to deploy the stack.	DevOps
Specify the input artifact.	Choose <b>BuildArtifact</b> . This is the output of the build phase.	DevOps
Specify the action to take.	For <b>Action mode</b> , choose <b>Create or update a stack</b> .	DevOps

Task	Description	Skills required
Enter a name for the CloudFormation stack.		DevOps
Specify the template for the first Region.	Select the Region-specific package name that was packaged by CodeBuild and dumped into the S3 bucket for the first (primary) Region.	DevOps
Specify the capabilities.	Capabilities are required if the stack template includes IAM resources or if you create a stack directly from a template that contains macros. For this pattern, use CAPABILITY_IAM, CAPABILITY_NAMED_IAM, CAPABILITY_AUTO_EXPAND.	DevOps

### Deploy phase: Configure the pipeline for deployment to the second Region

Task	Description	Skills required
Add the second stage to the Deploy phase.	To add a stage for the second Region, edit the pipeline and choose <b>Add stage</b> in the Deploy phase. Important: The process of creating the second Region is the same as that of the first Region, except for the following values.	DevOps

Task	Description	Skills required
Provide an action name for the second stage.	Enter a unique name that reflects the second stage and the second Region.	DevOps
Configure the Region for the second stage.	Choose the second Region where you want to deploy the stack.	DevOps
Specify the template for the second Region.	Select the Region-specific package name that was packaged by CodeBuild and dumped into the S3 bucket for the second Region.	DevOps

### Deploy phase: Configure the pipeline for deployment to the third Region

Task	Description	Skills required
Add the third stage to the Deploy phase.	To add a stage for the third Region, edit the pipeline and choose <b>Add stage</b> in the Deploy phase. Important : The process of creating the second Region is the same as that of the previous two Regions, except for the following values.	DevOps
Provide an action name for the third stage.	Enter a unique name that reflects the third stage and the third Region.	DevOps
Configure the Region for the third stage.	Choose the third Region where you want to deploy the stack.	DevOps

Task	Description	Skills required
Specify the template for the third Region.	Select the Region-specific package name that was packaged by CodeBuild and dumped into the S3 bucket for the third Region.	DevOps

## Clean up the deployment

Task	Description	Skills required
Delete the AWS resources.	To clean up the deployment, delete the CloudFormation stacks in each Region. Then delete the CodeCommit, CodeBuild, and CodePipeline resources from the primary Region.	DevOps

# Execute Amazon Redshift SQL queries by using Terraform

Created by Sylvia Qi (AWS) and Aditya Ambati (AWS)

<b>Code repository:</b> <a href="#">terraform-execute-redshift-sql</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> DevOps; Analytics; Big data; Data lakes
<b>Workload:</b> Open-source	<b>AWS services:</b> Amazon Redshift; AWS CLI	

## Summary

Using infrastructure as code (IaC) for the deployment and management of Amazon Redshift is a prevalent practice within DevOps. IaC facilitates the deployment and configuration of various Amazon Redshift resources, such as clusters, snapshots, and parameter groups. However, IaC doesn't extend to the management of database resources like tables, schemas, views, and stored procedures. These database elements are managed through SQL queries and are not directly supported by IaC tools. Although solutions and tools exist for managing these resources, you might prefer not to introduce additional tools into your technology stack.

This pattern outlines a methodology that uses Terraform to deploy Amazon Redshift database resources, including tables, schemas, views, and stored procedures. The pattern distinguishes between two types of SQL queries:

- **Nonrepeatable queries** – These queries are executed once during the initial Amazon Redshift deployment to establish the essential database components.
- **Repeatable queries** – These queries are immutable and can be rerun without impacting the database. The solution uses Terraform to monitor changes in repeatable queries and apply them accordingly.

For more details, see *Solution walkthrough* in [Additional information](#).

## Prerequisites and limitations

### Prerequisites

You must have an active AWS account and install the following on your deployment machine:

- [AWS Command Line Interface](#) (AWS CLI)
- An [AWS CLI profile](#) configured with Amazon Redshift read/write permissions
- [Terraform](#) version 1.6.2 or later
- [Python3](#)
- [Boto3](#)

## Limitations

- This solution supports a single Amazon Redshift database because Terraform only allows for the creation of one database during cluster creation.
- This pattern doesn't include tests to validate changes to the repeatable queries before applying them. We recommend that you incorporate such tests for enhanced reliability.
- To illustrate the solution, this pattern provides a sample `redshift.tf` file that uses a local Terraform state file. However, for production environments, we strongly recommend that you employ a remote state file with a locking mechanism for enhanced stability and collaboration.
- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS services by Region](#). For specific endpoints, see [Service endpoints and quotas](#), and choose the link for the service.

## Product versions

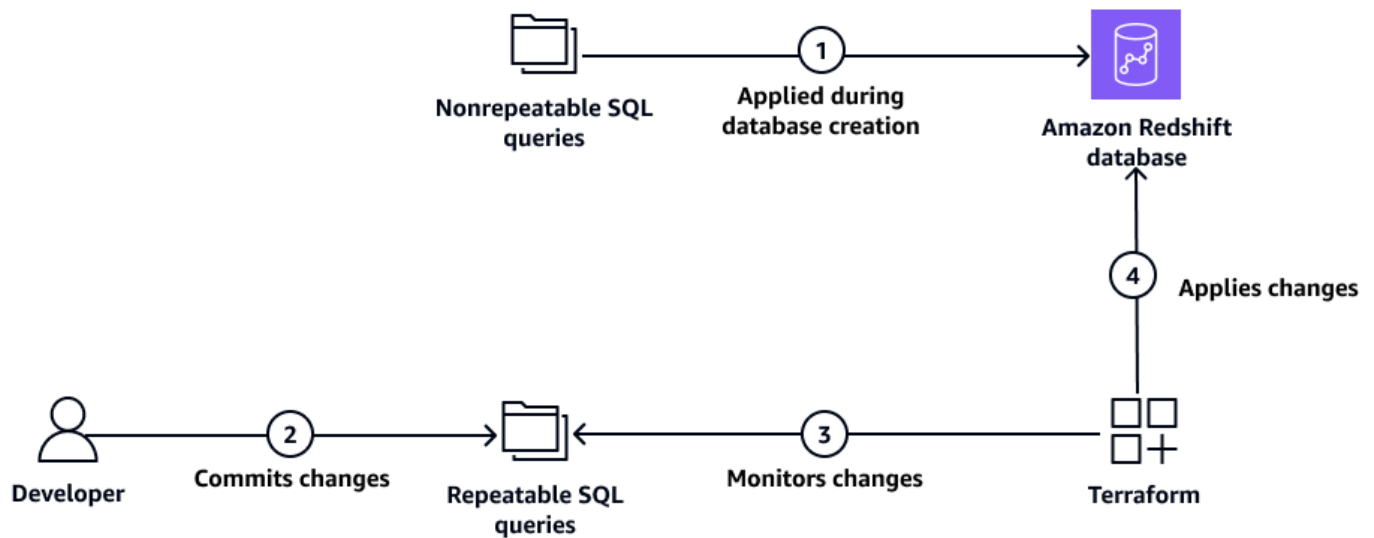

This solution is developed and tested on [Amazon Redshift patch 179](#).

## Code repository

The code for this pattern is available in the GitHub [amazon-redshift-sql-deploy-terraform](#) repository.

## Architecture

The following diagram illustrates how Terraform manages the Amazon Redshift database resources by handling both nonrepeatable and repeatable SQL queries.

The diagram shows the following steps:

1. Terraform applies nonrepeatable SQL queries during the initial Amazon Redshift cluster deployment.
2. The developer commits changes to the repeatable SQL queries.
3. Terraform monitors changes in the repeatable SQL queries.
4. Terraform applies repeatable SQL queries to the Amazon Redshift database.

The solution provided by this pattern is built based on the [Terraform module for Amazon Redshift](#). The Terraform module provisions an Amazon Redshift cluster and database. To enhance the module, we used `terraform_data` resources, which invokes a custom Python script to execute SQL queries using the Amazon Redshift [ExecuteStatement](#) API operation. As a result, the module can do the following:

- Deploy any number of database resources by using SQL queries after the database is provisioned.
- Monitor continuously for changes in the repeatable SQL queries and apply those changes using Terraform.

For more details, see *Solution walkthrough* in [Additional information](#).

## Tools

### AWS services

- [Amazon Redshift](#) is a fully managed petabyte-scale data warehouse service in the AWS Cloud.

## Other tools

- [Terraform](#) is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.
- [Python](#) is a general-purpose programming language that's used in this pattern to execute SQL queries.

## Best practices

- [Amazon Redshift best practices](#)
- [Using the Amazon Redshift Data API to interact with Amazon Redshift clusters](#)

### Other resources

- [Command: apply](#) (Terraform documentation)

## Additional information

### Solution walkthrough

To use the solution, you must organize your Amazon Redshift SQL queries in a specific way. All SQL queries must be stored in files with a `.sql` extension.

In the code example provided with this pattern, the SQL queries are organized in the following folder structure. You can modify the code (`sql-queries.tf` and `sql-queries.py`) to work with any structure that fits your unique use case.

```
/bootstrap
  |- Any # of files
  |- Any # of sub-folders
/nonrepeatable
  |- Any # of files
  |- Any # of sub-folders
/repeatable
  /udf
    |- Any # of files
    |- Any # of sub-folders
  /table
    |- Any # of files
    |- Any # of sub-folders
  /view
    |- Any # of files
    |- Any # of sub-folders
  /stored-procedure
    |- Any # of files
    |- Any # of sub-folders
/finalize
  |- Any # of files
  |- Any # of sub-folders
```

Given the preceding folder structure, during Amazon Redshift cluster deployment, Terraform executes the queries in the following order:

1. `/bootstrap`
2. `/nonrepeatable`
3. `/repeatable`
4. `/finalize`

The `/repeatable` folder contains four subfolders: `/udf`, `/table`, `/view`, and `/stored-procedure`. These subfolders indicate the order in which Terraform executes the SQL queries.

The Python script that executes the SQL queries is `sql-queries.py`. First, the script reads all the files and subfolders of a specific source directory, for example, the `sql_path_bootstrap`

parameter. Then the script executes the queries by calling the Amazon Redshift [ExecuteStatement](#) API operation. You might have one or more SQL queries in a file. The following code snippet shows the Python function that executes SQL statements stored in a file against an Amazon Redshift cluster.

```
def execute_sql_statement(filename, cluster_id, db_name, secret_arn, aws_region):
    """Execute SQL statements in a file"""
    redshift_client = boto3.client(
        'redshift-data', region_name=aws_region)
    contents = get_contents_from_file(filename),
    response = redshift_client.execute_statement(
        Sql=contents[0],
        ClusterIdentifier=cluster_id,
        Database=db_name,
        WithEvent=True,
        StatementName=filename,
        SecretArn=secret_arn
    )
    ...
```

The Terraform script `sql-queries.tf` creates the [terraform\\_data](#) resources that invoke the `sql-queries.py` script. There is a `terraform_data` resource for each of the four folders: `/bootstrap`, `/nonrepeatable`, `/repeatable`, and `/finalize`. The following code snippet shows the `terraform_data` resource that execute the SQL queries in the `/bootstrap` folder.

```
locals {
  program          = "${path.module}/sql-queries.py"
  redshift_cluster_name = try(aws_redshift_cluster.this[0].id, null)
}

resource "terraform_data" "run_bootstrap_queries" {
  count          = var.create && var.run_nonrepeatable_queries && (var.sql_path_bootstrap != "" ) && (var.snapshot_identifier == null) ? 1 : 0
  depends_on    = [aws_redshift_cluster.this[0]]

  provisioner "local-exec" {
    command = "python3 ${local.program} ${var.sql_path_bootstrap}
${local.redshift_cluster_name} ${var.database_name} ${var.redshift_secret_arn}
${local.aws_region}"
  }
}
```

You can control whether to run these queries by using the following variables. If you don't want to run queries in `sql_path_bootstrap`, `sql_path_nonrepeatable`, `sql_path_repeatable`, or `sql_path_finalize`, set their values to `""`.

```
run_nonrepeatable_queries = true
run_repeatable_queries    = true
sql_path_bootstrap        = "src/redshift/bootstrap"
sql_path_nonrepeatable    = "src/redshift/nonrepeatable"
sql_path_repeatable       = "src/redshift/repeatable"
sql_path_finalize         = "src/redshift/finalize"
```

When you run `terraform apply`, Terraform considers the `terraform_data` resource added after the script is completed, regardless of the results of the script. If some SQL queries failed, and you want to rerun them, you can manually remove the resource from the Terraform state, and run `terraform apply` again. For example, the following command removes the `run_bootstrap_queries` resource from the Terraform state.

```
terraform state rm module.redshift.terraform_data.run_bootstrap_queries[0]
```

The following code example shows how the `run_repeatable_queries` resource monitors changes in the `repeatable` folder by using the [sha256 hash](#). If any file within the folder is updated, Terraform marks the entire directory for an update. Then, Terraform runs the queries in the directory again during the next `terraform apply`.

```
resource "terraform_data" "run_repeatable_queries" {
  count          = var.create_redshift && var.run_repeatable_queries &&
    (var.sql_path_repeatable != "") ? 1 : 0
  depends_on    = [terraform_data.run_nonrepeatable_queries]

  # Continuously monitor and apply changes in the repeatable folder
  triggers_replace = {
    dir_sha256 = sha256(join("", [for f in fileset("${var.sql_path_repeatable}",
    "***") : filesha256("${var.sql_path_repeatable}/${f}")]))
  }

  provisioner "local-exec" {
    command = "python3 ${local.sql_queries} ${var.sql_path_repeatable}
    ${local.redshift_cluster_name} ${var.database_name} ${var.redshift_secret_arn}"
  }
}
```

To refine the code, you can implement a mechanism to detect and apply changes only to the files that have been updated within the `repeatable` folder, rather than applying changes to all files indiscriminately.

## Example SQL statements

The following output shows a failed SQL execution, along with an error message.

```
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec): Executing:
["/bin/sh" "-c" "python3 modules/redshift/sql-queries.py src/redshift/nonrepeatable
testcluster-1 db1 arn:aws:secretsmanager:us-east-1:XXXXXXXXXXXX:secret:/redshift/
master_user/password-8RapGH us-east-1"]
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec):
-----
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec): src/redshift/
nonrepeatable/table/admin/admin.application_family.sql
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec):
-----
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec): Status:

# Export AWS Backup reports from across an organization in AWS Organizations as a CSV file

Created by Aromal Raj Jayarajan (AWS) and Purushotham G K (AWS)

**Code repository:** [aws-backup-p-report-generator](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Infrastructure

**AWS services:** AWS Backup; AWS Identity and Access Management; AWS Lambda; Amazon S3; Amazon EventBridge

## Summary

This pattern shows how to export AWS Backup job reports from across an organization in AWS Organizations as a CSV file. The solution uses AWS Lambda and Amazon EventBridge to categorize AWS Backup job reports based on their status, which can help when configuring status-based automations.

AWS Backup helps organizations centrally manage and automate data protection across AWS services, in the cloud, and on premises. However, for AWS Backup jobs configured within AWS Organizations, consolidated reporting is available only in the AWS Management Console of each organization's management account. Bringing this reporting outside of the management account can reduce the effort required for auditing and increase the scope for automations, notifications, and alerting.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An active [organization](#) in AWS Organizations that includes at least a management account and a member account

- AWS Backup configured at the organization level in AWS Organizations (for more information, see [Automate centralized backup at scale across AWS services using AWS Backup](#) on the AWS Blog)
- [Git](#), installed and configured on your local machine

## Limitations

The solution provided in this pattern identifies AWS resources that are configured for AWS Backup jobs only. The report can't identify AWS resources that aren't configured for backup through AWS Backup.

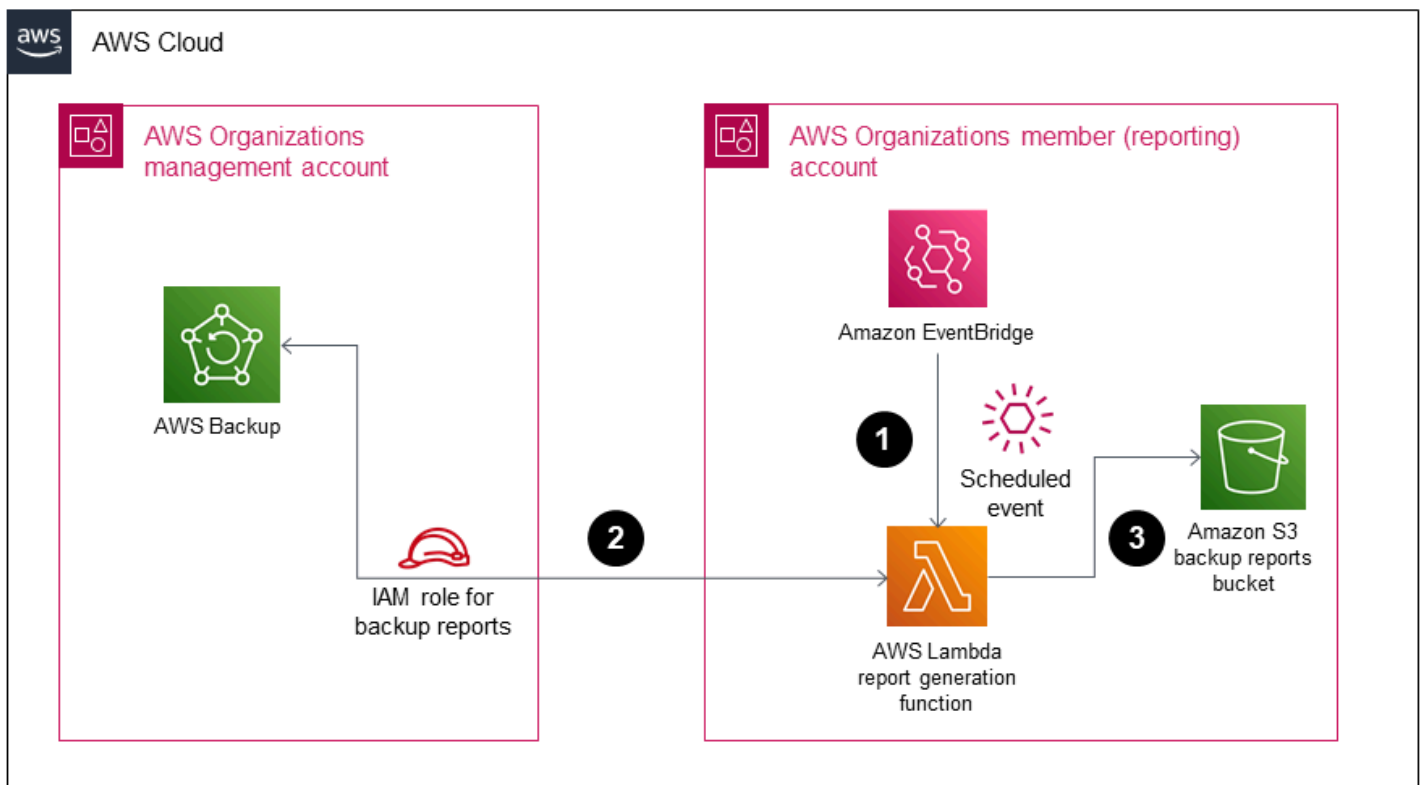

## Architecture

### Target technology stack

- AWS Backup
- AWS CloudFormation
- Amazon EventBridge
- AWS Lambda
- AWS Security Token Service (AWS STS)
- Amazon Simple Storage Service (Amazon S3)
- AWS Identity and Access Management (IAM)

### Target architecture

The following diagram shows an example workflow for exporting AWS Backup job reports from across an organization in AWS Organizations as a CSV file.

The diagram shows the following workflow:

1. A scheduled EventBridge event rule invokes a Lambda function in the member (reporting) AWS account.
2. The Lambda function then uses AWS STS to assume an IAM role that has the permissions required to connect to the management account.
3. The Lambda function then does the following:
  - Requests the consolidated AWS Backup jobs report from the AWS Backup service
  - Categorizes the results based on AWS Backup job status
  - Converts the response to a CSV file
  - Uploads the results to an Amazon S3 bucket in the reporting account within folders that are labeled based on their creation date

## Tools

### Tools

- [AWS Backup](#) is a fully managed service that helps you centralize and automate data protection across AWS services, in the cloud, and on premises.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

## Code

The code for this pattern is available in the GitHub [aws-backup-report-generator](#) repository.

# Export tags for a list of Amazon EC2 instances to a CSV file

Created by Sida Ju (AWS) and Pac Joonhyun (AWS)

**Code repository:** [Search and export EC2 tags](#)

**Environment:** Production

**Technologies:** DevOps

**AWS services:** Amazon EC2

## Summary

This pattern shows how to programmatically export tags for a list of Amazon Elastic Compute Cloud (Amazon EC2) instances to a CSV file.

By using the example Python script provided, you can reduce how long it takes to review and categorize your Amazon EC2 instances by specific tags. For example, you could use the script to quickly identify and categorize a list of instances that your security team has flagged for software updates.

## Prerequisites and limitations

### Prerequisites

- Python 3 installed and configured
- AWS Command Line Interface (AWS CLI) installed and configured

### Limitations

The example Python script provided in this pattern can search Amazon EC2 instances based on the following attributes only:

- Instance IDs
- Private IPv4 addresses
- Public IPv4 addresses

## Tools

- [Python](#) is a general-purpose computer programming language.
- [virtualenv](#) helps you create isolated Python environments.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

## Code repository

The example Python script for this pattern is available in the GitHub [search-ec2-instances-export-tags](#) repository.

## Epics

### Install and configure the prerequisites

# Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere

Created by Lucas Nation (AWS) and Freddie Wilson (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Management & governance;  
Security, identity, compliance

**Workload:** Microsoft; Open-source

**AWS services:** AWS Config;  
AWS CloudFormation

## Summary

Many organizations use [AWS Config managed](#) rules to evaluate the compliance of their Amazon Web Services (AWS) resources against common best practices. However, these rules can be time consuming to maintain and this pattern helps you leverage [Troposphere](#), a Python library, to generate and manage AWS Config managed rules.

The pattern helps you to manage your AWS Config managed rules by using a Python script to convert a Microsoft Excel spreadsheet containing AWS managed rules into an AWS CloudFormation template. Troposphere acts as the infrastructure as code (IaC) and this means that you can update the Excel spreadsheet with managed rules, instead of using a JSON or YAML-formatted file. You then use the template to launch an AWS CloudFormation stack that creates and updates the managed rules in your AWS account.

The AWS CloudFormation template defines each AWS Config managed rule by using the Excel spreadsheet and helps you to avoid manually creating individual rules in the AWS Management Console. The script defaults each managed rule's parameters to an empty dictionary and the scope's `ComplianceResourceTypes` defaults from `THE_RULE_IDENTIFIER.template` file. For more information about the rule identifier, see [Creating AWS Config managed rules with AWS CloudFormation templates](#) in the AWS Config documentation.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Familiarity with using AWS CloudFormation templates to create AWS Config managed rules. For more information about this, see [Creating AWS Config managed rules with AWS CloudFormation templates](#) in the AWS Config documentation.
- Python 3, installed and configured. For more information about this, see the [Python documentation](#).
- An existing integrated development environment (IDE) such as AWS Cloud9. For more information about this, see [What is AWS Cloud9?](#) in the AWS Cloud9 documentation.
- Identify your organizational units (OUs) in a column in the sample `excel_config_rules.xlsx` Excel spreadsheet (attached).

## Epics

### Customize and configure the AWS Config managed rules

Task	Description	Skills required
Update the sample Excel spreadsheet.	<p>Download the sample <code>excel_config_rules.xlsx</code> Excel spreadsheet (attached) and label as Implemented the AWS Config managed rules that you want to use.</p> <p>Rules marked as Implemented will be added to the AWS CloudFormation template.</p>	Developer
(Optional) Update the <code>config_rules_params.json</code> file with AWS Config rule parameters.	Some AWS Config managed rules require parameters and should be passed to the Python script as a JSON file by using the <code>--param-file</code> option. For example, the <code>access-keys-rotate</code>	Developer

Task	Description	Skills required
	<p data-bbox="591 212 967 344">d managed rule uses the following <code>maxAccessKeyAge</code> parameter:</p> <pre data-bbox="591 380 1029 816">{   "access-keys-rotated": {     "InputParameters": {       "maxAccessKeyAge": 90     }   } }</pre> <p data-bbox="591 856 1023 1125">In this sample parameter, the <code>maxAccessKeyAge</code> is set to 90 days. The script reads the parameter file and adds any <code>InputParameters</code> that it finds.</p>	

Task	Description	Skills required
<p>(Optional) Update the <code>config_rules_params.json</code> file with AWS Config ComplianceResourceTypes.</p>	<p>By default, the Python script retrieves the ComplianceResourceTypes from AWS defined templates. If you want to override the scope of a specific AWS Config managed rule, then you need to pass it to the Python script as a JSON file using the <code>--param-file</code> option.</p> <p>For example, the following sample code shows how the ComplianceResourceTypes for <code>ec2-volume-inuse-check</code> is set to the <code>["AWS::EC2::Volume"]</code> list:</p> <pre data-bbox="594 1096 1029 1654">{   "ec2-volume-inuse-check": {     "Scope": {        "ComplianceResourceTypes": [          "AWS::EC2::Volume"       ]     }   } }</pre>	Developer

## Run the Python script

Task	Description	Skills required
Install the pip packages from the requirements.txt file.	<p>Download the requirements.txt file (attached) and run the following command in your IDE to install the Python packages:</p> <pre>pip3 install -r requirements.txt</pre>	Developer
Run the Python script.	<ol style="list-style-type: none"> <li>Download the aws_config_rules.py file (attached) to your local machine.</li> <li>Run the <code>python3 aws_config_rules.py --ou &lt;OU_NAME&gt;</code> command. <b>Note:</b> <code>--ou</code> defines which OU column to choose in the Excel spreadsheet.</li> </ol> <p>You can also add the following optional parameters:</p> <ul style="list-style-type: none"> <li><code>--config-rule-option</code> – Defines the rules to choose from the Excel spreadsheet. The default is the Implemented parameter.</li> <li><code>--excel-file</code> – The path for the Excel</li> </ul>	Developer

Task	Description	Skills required
	<p>spreadsheet. The default is <code>aws_config_rules.xlsx</code>.</p> <ul style="list-style-type: none"> <li>• <code>--param-file</code> – The path of the parameter JSON file. The default is <code>config_rules_params.json</code>.</li> <li>• <code>--max-execution-frequency</code> – Defines how often the AWS Config managed rules are evaluated. The choices are <code>One_Hour</code>, <code>Three_Hours</code>, <code>Six_Hours</code>, <code>Twelve_Hours</code>, or <code>TwentyFour_Hours</code>. The default is <code>TwentyFour_Hours</code>.</li> </ul>	

## Deploy the AWS Config managed rules

Task	Description	Skills required
<p>Launch the AWS CloudFormation stack.</p>	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose <b>Create stack</b>.</li> <li>2. On the <b>Specify template</b> page, choose <b>Upload a template file</b> and</li> </ol>	<p>Developer</p>

Task	Description	Skills required
	<p>then upload your AWS CloudFormation template.</p> <ol style="list-style-type: none"><li>3. Specify a stack name and then choose <b>Next</b>.</li><li>4. Specify tags and then choose <b>Next</b>.</li><li>5. Choose <b>Create stack</b>.</li></ol>

# Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account

Created by Helge Aufderheide (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Analytics; Machine learning &  
AI; Management & governanc  
e

**AWS services:** AWS  
CodeCommit; AWS Identity  
and Access Management;  
Amazon SageMaker

## Summary

This pattern shows how to grant Amazon SageMaker notebook instances and users temporary access to an AWS CodeCommit repository that's in another AWS account. This pattern also shows how you can grant granular permissions for specific actions each entity can perform on each repository.

Organizations often store CodeCommit repositories in a different AWS account than the account that hosts their development environment. This multi-account setup helps control access to the repositories and reduces the risk of their accidental deletion. To grant these cross-account permissions, it's a best practice to use AWS Identity and Access Management (IAM) roles. Then, predefined IAM identities in each AWS account can temporarily assume the roles to create a controlled chain of trust across the accounts.

**Note:** You can apply a similar procedure to grant other IAM identities cross-account access to a CodeCommit repository. For more information, see [Configure cross-account access to an AWS CodeCommit repository using roles](#) in the *AWS CodeCommit User Guide*.

## Prerequisites and limitations

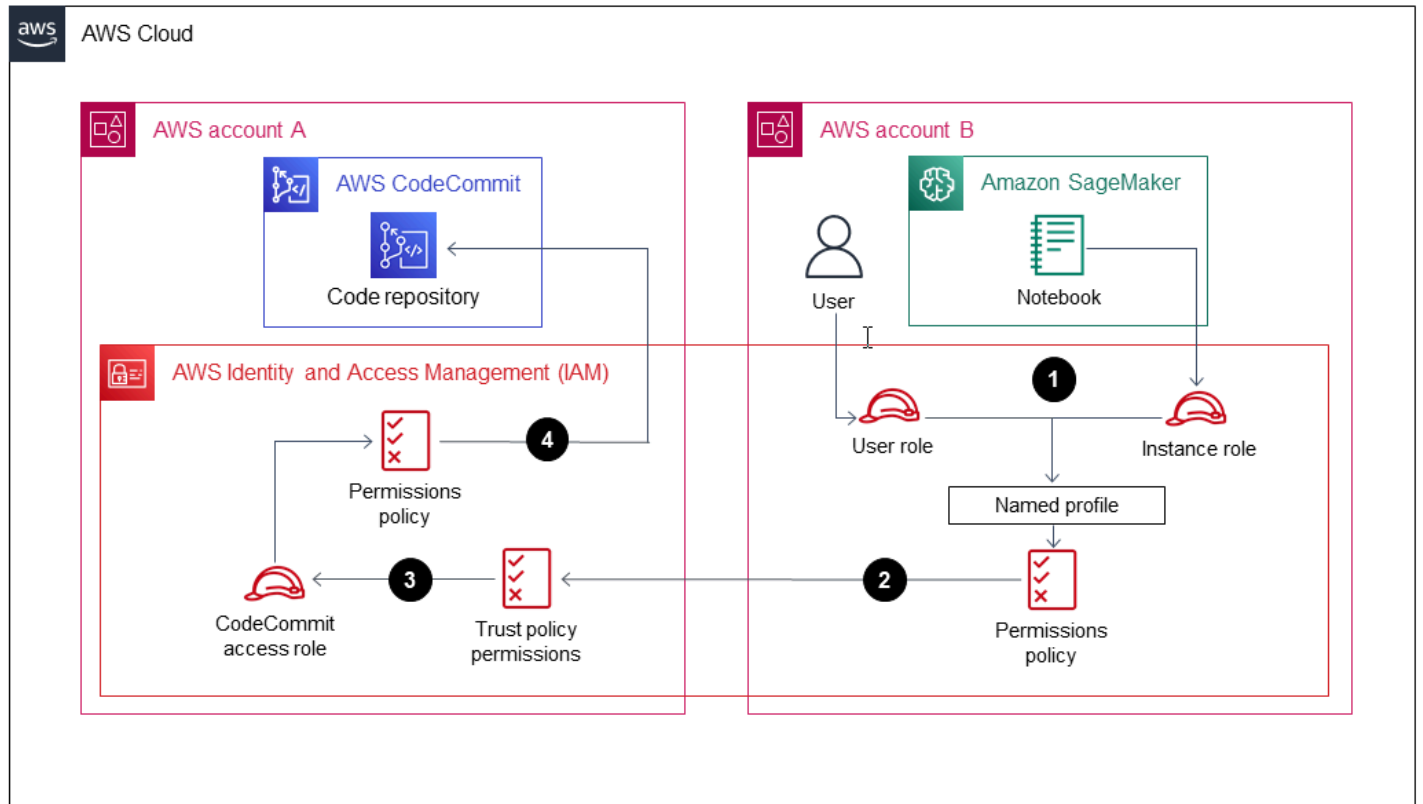

### Prerequisites

- An active AWS account with a CodeCommit repository (*account A*)
- A second active AWS account with a SageMaker notebook instance (*account B*)
- An AWS user with sufficient permissions to create and modify IAM roles in account A

- A second AWS user with sufficient permissions to create and modify IAM roles in account B

## Architecture

The following diagram shows an example workflow for granting a SageMaker notebook instance and users in one AWS account cross-account access to a CodeCommit repository:

The diagram shows the following workflow:

1. The AWS user role and SageMaker notebook instance role in account B assume a [named profile](#).
2. The named profile's permissions policy specifies a CodeCommit access role in account A that the profile then assumes.
3. The CodeCommit access role's trust policy in account A allows the named profile in account B to assume the CodeCommit access role.
4. The CodeCommit repository's IAM permissions policy in account A allows the CodeCommit access role to access the CodeCommit repository.

## Technology stack

- CodeCommit
- Git
- IAM
- pip
- SageMaker

## Tools

- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Git](#) is a distributed version-control system for tracking changes in source code during software development.
- [git-remote-codecommit](#) is a utility that helps you push and pull code from CodeCommit repositories by extending Git.
- [pip](#) is the package installer for Python. You can use pip to install packages from the Python Package Index and other indexes.

## Best practices

When you set permissions with IAM policies, make sure that you grant only the permissions required to perform a task. For more information, see [Apply least-privilege permissions](#) in the IAM documentation.

When implementing this pattern, make sure that you do the following:

- Confirm that IAM principles have only the permissions required to perform specific, needed actions within each repository. For example, it's recommended to allow approved IAM principles to push and merge changes to specific repository branches, but only request merges to protected branches.
- Confirm that IAM principles are assigned different IAM roles based on their respective roles and responsibilities for each project. For example, a developer will have different access permissions than a release manager or AWS Administrator.

# Epics

## Configure the IAM roles

Task	Description	Skills required
Configure the CodeCommit access role and permissions policy.	<p><b>Note:</b> To automate the manual setup process documented in this epic, you can use an <a href="#">AWS CloudFormation template</a>.</p> <p>In the account that contains the CodeCommit repository (<i>account A</i>), do the following:</p> <ol style="list-style-type: none"><li>1. <a href="#">Create an IAM role</a> that can be assumed by the SageMaker notebook instance role in account B.</li><li>2. <a href="#">Create an IAM policy</a> that grants access to the repository and <a href="#">attach the policy to the role</a>. For testing purposes only, choose the <a href="#">AWSCodeCommitPowerUser</a> AWS managed policy. This policy grants all <a href="#">CodeCommit permissions</a> except the ability to delete resources.</li><li>3. <a href="#">Modify the role's trust policy</a> so that account B is listed as a trusted entity.</li></ol> <p><b>Important:</b> Before moving this setup into your productio</p>	General AWS, AWS DevOps

Task	Description	Skills required
	<p>In an environment, it's a best practice to write your own IAM policy that applies <a href="#">least-privilege permissions</a>. For more information, see the <b>Additional information</b> section of this pattern.</p>	

Task	Description	Skills required
<p>Grant the SageMaker notebook instance's role in account B permissions to assume the CodeCommit access role in account A.</p>	<p>In the account that contains the SageMaker notebook instance's IAM role (<i>account B</i>), do the following:</p> <ol style="list-style-type: none"><li>1. Create an IAM policy that allows an IAM role or user to assume the CodeCommit access role in account A.</li></ol> <p><b>Example IAM permissions policy that allows an IAM role or user to assume a cross-account role</b></p> <pre data-bbox="630 884 1029 1562">{   "Version":     "2012-10-17",   "Statement": [     {       "Sid": "VisualEditor0",       "Effect": "Allow",       "Action":         "sts:AssumeRole",       "Resource":         "arn:aws:iam::accountA_ID:role/accountArole_ID"     }   ] }</pre> <ol style="list-style-type: none"><li>2. Attach the policy to your SageMaker notebook instance's role in account B.</li><li>3. Have the SageMaker notebook instance's role in account B assume the</li></ol>	<p>General AWS, AWS DevOps</p>

Task	Description	Skills required
	<p>CodeCommit access role in account A.</p> <p><b>Note:</b> To view your repository's Amazon Resource Name (ARN), see <a href="#">View CodeCommit repository details</a> in the <i>AWS CodeCommit User Guide</i>.</p>	

### Set up your SageMaker notebook instance in account B

Task	Description	Skills required
<p>Set up a user profile on the AWS SageMaker notebook instance to assume the role in account A.</p>	<p><b>Important:</b> <a href="#">Make sure that you have the latest version of the AWS Command Line Interface (AWS CLI) installed.</a></p> <p>In the account that contains the SageMaker notebook instance (<i>account B</i>), do the following:</p> <ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the <a href="#">SageMaker console</a>.</li> <li>2. <a href="#">Access your SageMaker notebook instance</a>. The Jupyter interface opens.</li> <li>3. Choose <b>New</b>, and then choose <b>Terminal</b>. <a href="#">A new terminal window opens in your Jupyter environment.</a></li> </ol>	<p>General AWS, AWS DevOps</p>

Task	Description	Skills required
	<p>4. Navigate to the SageMaker notebook instance's <code>~/.aws/config</code> file. Then, add a user profile to the file by entering the following statement:</p> <pre data-bbox="594 558 1027 1152"> ----- .aws/config- ----- [profile remoterep ouser] role_arn = arn:aws:i am::&lt;ID of Account A&gt;:role/&lt;rolename&gt; role_session_name = remoteaccesssession region = eu-west-1 credential_source = Ec2InstanceMetadata ----- ----- </pre>	
Install the <code>git-remote-codecommit</code> utility.	Follow the instructions in <a href="#">Step 2: Install git-remote-codecommit</a> in the <i>AWS CodeCommit User Guide</i> .	Data scientist

## Access the repository

Task	Description	Skills required
Access the CodeCommit repository by using Git commands or SageMaker.	<p><b>To use Git</b></p> <p>IAM principals that assume the SageMaker notebook instance's role in account B</p>	Git, bash console

Task	Description	Skills required
	<p>can now run Git commands to access the CodeCommit repository in account A. For example, users can run commands such as <code>git clone</code>, <code>git pull</code>, and <code>git push</code>.</p> <p>For instructions, see <a href="#">Connect to an AWS CodeCommit repository</a> in the <i>AWS CodeCommit User Guide</i>.</p> <p>For information about how to use Git with CodeCommit, see <a href="#">Getting started with AWS CodeCommit</a> in the <i>AWS CodeCommit User Guide</i>.</p> <p><b>To use SageMaker</b></p> <p>To use Git from the SageMaker console, you must allow Git to retrieve credentials from your CodeCommit repository. For instructions, see <a href="#">Associate a CodeCommit repository in a different AWS account with a notebook instance</a> in the SageMaker documentation.</p>	

## Related resources

- [Configure cross-account access to an AWS CodeCommit repository using roles](#) (AWS CodeCommit documentation)
- [IAM tutorial: Delegate access across AWS accounts using IAM roles](#) (IAM documentation)

## Additional information

### Restricting CodeCommit permissions to specific actions

To restrict the actions that an IAM principal can take in the CodeCommit repository, modify the actions that are allowed in the CodeCommit access policy.

For more information about CodeCommit API operations, see [CodeCommit permissions reference](#) in the *AWS CodeCommit User Guide*.

**Note:** You can also edit the [AWSCodeCommitPowerUser](#) AWS managed policy to fit your use case.

### Restricting CodeCommit permissions to specific repositories

To create a multitenant environment where more than one code repository is accessible to only specific users, do the following:

1. Create multiple CodeCommit access roles in account A. Then, configure each access role's trust policy to allow specific users in account B to assume the role.
2. Restrict what code repositories that each role can assume by adding a **"Resource"** condition to each CodeCommit access role's policy.

### Example "Resource" condition that restricts an IAM principal's access to a specific CodeCommit repository

```
"Resource" : [ <REPOSITORY_ARN>, <REPOSITORY_ARN> ]
```

**Note:** To help identify and differentiate multiple code repositories in the same AWS account, you can assign different prefixes to the repositories' names. For example, you can name code repositories with prefixes that align to different developer groups, such as **myproject-subproject1-repo1** and **myproject-subproject2-repo1**. Then, you can create an IAM role for each developer group based on their assigned prefixes. For example, you could create a role named **myproject-**

**subproject1-repoaccess** and grant it access to all of the code repositories that include the prefix **myproject-subproject1**.

**Example “Resource” condition that refers to a code repository ARN that includes a specific prefix**

```
"Resource" : arn:aws:codecommit:<region>:<account-id>:myproject-subproject1-*
```

# Implement a GitHub Flow branching strategy for multi-account DevOps environments

Created by Mike Stephens (AWS) and Abhilash Vinod (AWS)

**Code repository:** [git-branching-strategies-for-multi-account-devops](#)

**Environment:** Production

**Technologies:** DevOps; DevelopmentAndTesting; Multi account strategy

**AWS services:** AWS CodeArtifact; AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS CodePipeline

## Summary

When managing a source code repository, different branching strategies affect the software development and release processes that development teams use. Examples of common branching strategies include Trunk, GitHub Flow, and Gitflow. These strategies use different branches, and the activities performed in each environment are different. Organizations that are implementing DevOps processes would benefit from a visual guide to help them understand the differences between these branching strategies. Using this visual in your organization helps development teams align their work and follow organizational standards. This pattern provides this visual and describes the process of implementing a GitHub Flow branching strategy in your organization.

This pattern is part of a documentation series about choosing and implementing DevOps branching strategies for organizations with multiple AWS accounts. This series is designed to help you apply the correct strategy and best practices from the outset, to streamline your experience in the cloud. GitHub Flow is just one possible branching strategy that your organization can use. This documentation series also covers [Trunk](#) and [Gitflow](#) branching models. If you haven't done so already, we recommend that you review [Choosing a Git branching strategy for multi-account DevOps environments](#) prior to implementing the guidance in this pattern. Please use due diligence to choose the right branching strategy for your organization.

This guide provides a diagram that shows how an organization might implement the GitHub Flow strategy. It is recommended that you review the [AWS Well-Architected DevOps Guidance](#) to review best practices. This pattern includes recommended tasks, steps, and restrictions for each step in the DevOps process.

## Prerequisites and limitations

### Prerequisites

- Git, [installed](#). This is used as a source code repository tool.
- Draw.io, [installed](#). This application is used to view and edit the diagram.

## Architecture

### Target architecture

The following diagram can be used like a [Punnett square](#) (Wikipedia). You line up the branches on the vertical axis with the AWS environments on the horizontal axis to determine what actions to perform in each scenario. The numbers indicate the sequence of the actions in the workflow. This example takes you from a feature branch through deployment in production.

For more information about the AWS accounts, environments, and branches in a GitHub Flow approach, see [Choosing a Git branching strategy for multi-account DevOps environments](#).

### Automation and scale

Continuous integration and continuous delivery (CI/CD) is the process of automating the software release lifecycle. It automates much or all of the manual processes traditionally required to get new code from an initial commit into production. A CI/CD pipeline encompasses the sandbox, development, testing, staging, and production environments. In each environment, the CI/CD pipeline provisions any infrastructure that is needed to deploy or test the code. By using CI/CD, development teams can make changes to code that are then automatically tested and deployed.

CI/CD pipelines also provide governance and guardrails for development teams by enforcing consistency, standards, best practices, and minimal acceptance levels for feature acceptance and deployment. For more information, see [Practicing Continuous Integration and Continuous Delivery on AWS](#).

AWS offers a suite of developer services that are designed to help you build CI/CD pipelines. For example, [AWS CodePipeline](#) is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. [AWS CodeCommit](#) is designed to securely host scalable Git repositories, and [AWS CodeBuild](#) compiles source code, runs tests, and produces ready-to-deploy software packages. For more information, see [Developer Tools on AWS](#).

## Tools

### AWS services and tools

AWS provides a suite of developer services that you can use to implement this pattern:

- [AWS CodeArtifact](#) is a highly scalable, managed artifact repository service that helps you store and share software packages for application development.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

### Other tools

- [Draw.io Desktop](#) is an application for making flowcharts and diagrams. The code repository contains templates in .drawio format for Draw.io.
- [Figma](#) is an online design tool designed for collaboration. The code repository contains templates in .fig format for Figma.

## Code repository

This source file for the diagram in this pattern is available in the GitHub [Git Branching Strategy for GitHub Flow](#) repository. It includes files in PNG, draw.io, and Figma formats. You can modify these diagrams to support your organization's processes.

## Best practices

Follow the best practices and recommendations in [AWS Well-Architected DevOps Guidance](#) and [Choosing a Git branching strategy for multi-account DevOps environments](#). These help you effectively implement GitHub Flow-based development, foster collaboration, improve code quality, and streamline the development process.

## Epics

### Reviewing the GitHub Flow workflows

Task	Description	Skills required
Review the standard GitHub Flow process.	<ol style="list-style-type: none"><li>1. In the sandbox environment, the developer creates a feature branch from the main branch and uses the naming pattern <code>feature/&lt;ticket&gt;_&lt;initials&gt;_&lt;short description&gt;</code> .</li><li>2. The developer adds one or more commits to the feature branch, each representing a discrete change or improvement.</li><li>3. The developer opens a merge request (MR) to merge the changes into the main branch. This initiates a review process.</li></ol>	DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 1027 579">4. During the review process, developers discuss the code changes and provide feedback. The goal is to ensure that the changes are of high quality and meet the project's standards.</li><li data-bbox="592 600 1027 919">5. After the developer creates the merge request, an automated build process starts and deploys the changes in the feature branch to the development environment.</li><li data-bbox="592 940 1027 1360">6. Automated tests verify the integrity and quality of the changes encapsulated in the merge request. A successful build, successful deployment, and successful testing are required to complete the merge request.</li><li data-bbox="592 1381 1027 1560">7. When the review process is complete, the changes are merged into the main branch.</li><li data-bbox="592 1581 1027 1759">8. An approver manually approves the deployment of the release artifacts to the testing environment.</li><li data-bbox="592 1780 1027 1871">9. An approver manually approves the deployment</li></ol>	

Task	Description	Skills required
	<p>of the release artifacts to the staging environment.</p> <p>10An approver manually approves the deployment of the release artifacts to the production environment.</p>	

Task	Description	Skills required
Review the bugfix GitHub Flow process.	<ol style="list-style-type: none"><li data-bbox="592 226 1015 556">1. The developer creates a bugfix branch from the main branch and uses the naming pattern <code>bugfix/&lt;ticket number&gt;_&lt;developer initials&gt;_&lt;descriptor&gt;</code> .</li><li data-bbox="592 577 1015 703">2. The developer fixes the issue, commits the fix, and builds the bugfix branch.</li><li data-bbox="592 724 1015 955">3. The developer opens a merge request to merge the bugfix branch into the main branch. This initiates a review process.</li><li data-bbox="592 976 1015 1144">4. During the review process, developers discuss the code changes and provide feedback.</li><li data-bbox="592 1165 1015 1459">5. Upon review completion and approval, the developer completes the merge request of the bugfix branch into the main branch.</li><li data-bbox="592 1480 1015 1648">6. An approver manually approves the deployment of the release artifacts to higher environments.</li></ol>	DevOps engineer

Task	Description	Skills required
Review the hotfix GitHub Flow process.	<p>GitHub Flow is designed to enable continuous delivery, where code changes are frequently and reliably deployed to higher environments. The key is that every feature branch is deployable at any time.</p> <p>Hotfix branches, which are akin to feature or bugfix branches, can follow the same process as either of these other branches. However, given their urgency, hotfixes typically have a higher priority. Depending on the team's policies and the immediacy of the situation, certain steps in the process could be expedited. For instance, code reviews for hotfixes might be fast-tracked. Therefore, while the hotfix process parallels the feature or bugfix process, the urgency surrounding hotfixes may warrant modifications in the procedural adherence. It's crucial to establish guidelines about managing hotfixes to make sure that they are handled efficiently and securely.</p>	DevOps engineer

## Troubleshooting

Issue	Solution
Branch conflicts	A common issue that can occur with the GitHub Flow model is where a hotfix needs to occur in production but a corresponding change needs to occur in a feature, bugfix, or hotfix branch where the same resources are being modified. We recommend that you frequently merge changes from main into lower branches to avoid significant conflicts when you merge to main.
Team maturity	GitHub Flow encourages daily deployments to higher environments, embracing true continuous integration and continuous delivery (CI/CD). It is imperative that the team has the engineering maturity to build features and create automation tests for them. The team must perform an exhaustive merge request review before changes are approved. This fosters a robust engineering culture that promotes quality, accountability, and efficiency in the development process.

## Troubleshooting

Issue	Solution
Branch conflicts	A common issue that can occur with the Gitflow model is where a hotfix needs to occur in production but a corresponding change needs to occur in a lower environment, where another branch is modifying the

Issue	Solution
	same resources. We recommend that you have only a single release branch active at a time. If you have more than one active at a time, the changes in the environments might collide, and you might be unable to move a branch forward to production.
Merging	Releases should be merged back into main and develop as soon as possible to consolidate work back into the primary branches.
Squash merging	Only use a squash merge when you are merging from a feature branch to a develop branch. Using squash merges in higher branches causes difficulty when merging changes back down to lower branches.

## Related resources

# Implement a Trunk branching strategy for multi-account DevOps environments

Created by Mike Stephens (AWS) and Rayjan Wilson (AWS)

**Code repository:** [git-branching-strategies-for-multiaccount-devops](#)

**Environment:** Production

**Technologies:** DevOps; DevelopmentAndTesting; Multi account strategy

**AWS services:** AWS CodeArtifact; AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS CodePipeline

## Summary

When managing a source code repository, different branching strategies affect the software development and release processes that development teams use. Examples of common branching strategies include Trunk, GitHub Flow, and Gitflow. These strategies use different branches, and the activities performed in each environment are different. Organizations that are implementing DevOps processes would benefit from a visual guide to help them understand the differences between these branching strategies. Using this visual in your organization helps development teams align their work and follow organizational standards. This pattern provides this visual and describes the process of implementing a Trunk branching strategy in your organization.

This pattern is part of a documentation series about choosing and implementing DevOps branching strategies for organizations with multiple AWS accounts. This series is designed to help you apply the correct strategy and best practices from the outset, to streamline your experience in the cloud. Trunk is just one possible branching strategy that your organization can use. This documentation series also covers [GitHub Flow](#) and [Gitflow](#) branching models. If you haven't done so already, we recommend that you review [Choosing a Git branching strategy for multi-account DevOps environments](#) prior to implementing the guidance in this pattern. Please use due diligence to choose the right branching strategy for your organization.

This guide provides a diagram that shows how an organization might implement the Trunk strategy. It is recommended that you review the official [AWS Well-Architected DevOps Guidance](#) to review best practices. This pattern includes recommended tasks, steps, and restrictions for each step in the DevOps process.

## Prerequisites and limitations

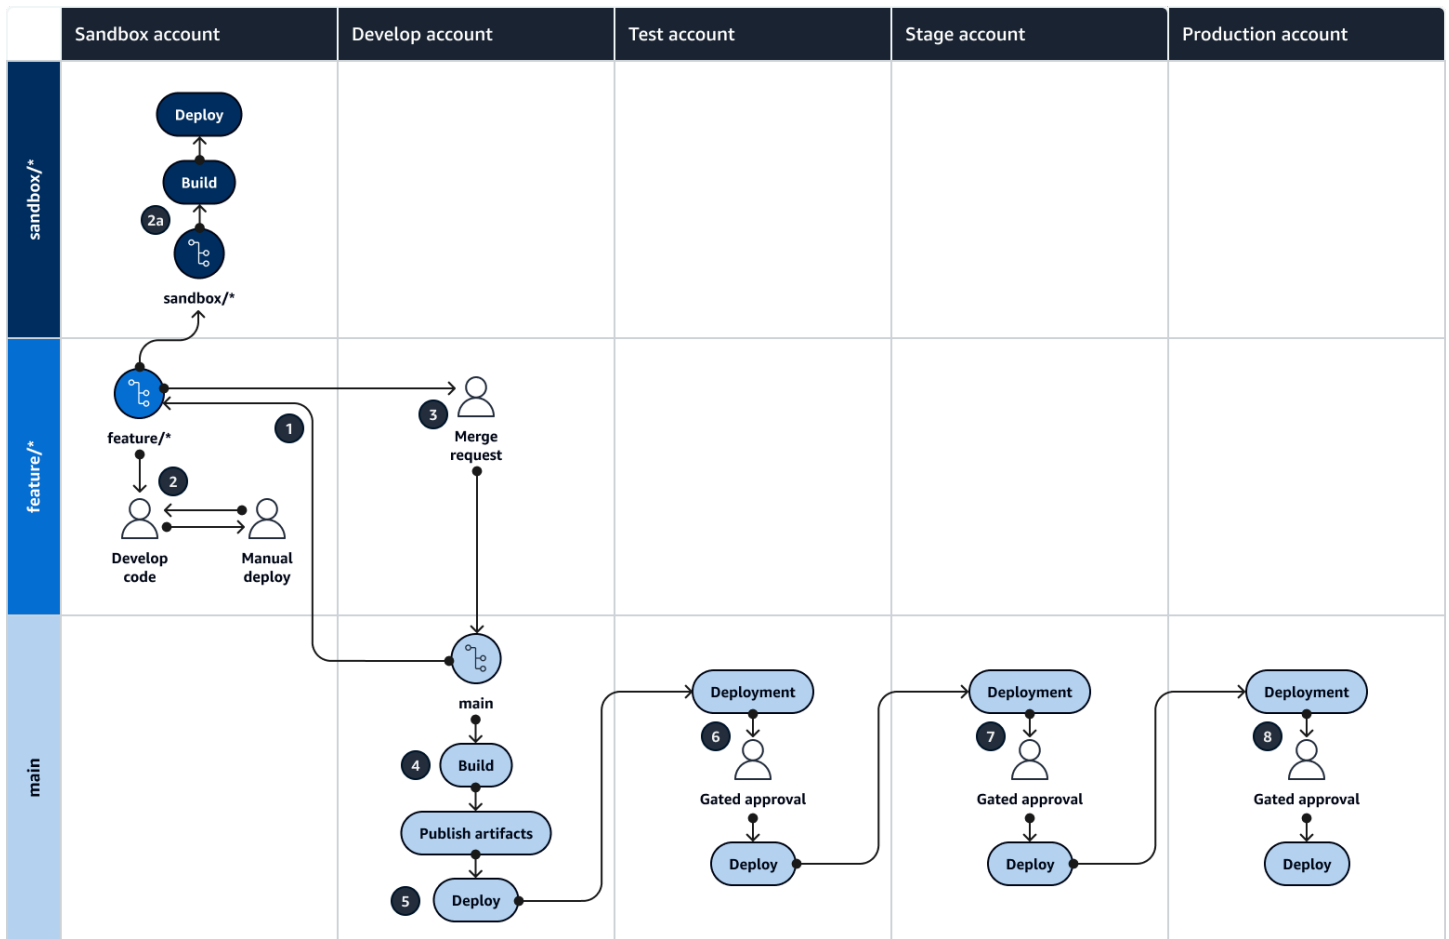

### Prerequisites

- Git, [installed](#). This is used as a source code repository tool.
- Draw.io, [installed](#). This application is used to view and edit the diagram.

## Architecture

### Target architecture

The following diagram can be used like a [Punnett square](#) (Wikipedia). You line up the branches on the vertical axis with the AWS environments on the horizontal axis to determine what actions to perform in each scenario. The numbers indicate the sequence of the actions in the workflow. This example takes you from a feature branch through deployment in production.

For more information about the AWS accounts, environments, and branches in a Trunk approach, see [Choosing a Git branching strategy for multi-account DevOps environments](#).

### Automation and scale

Continuous integration and continuous delivery (CI/CD) is the process of automating the software release lifecycle. It automates much or all of the manual processes traditionally required to get new code from an initial commit into production. A CI/CD pipeline encompasses the sandbox, development, testing, staging, and production environments. In each environment, the CI/CD pipeline provisions any infrastructure that is needed to deploy or test the code. By using CI/CD, development teams can make changes to code that are then automatically tested and deployed. CI/CD pipelines also provide governance and guardrails for development teams by enforcing consistency, standards, best practices, and minimal acceptance levels for feature acceptance and deployment. For more information, see [Practicing Continuous Integration and Continuous Delivery on AWS](#).

AWS offers a suite of developer services that are designed to help you build CI/CD pipelines. For example, [AWS CodePipeline](#) is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. [AWS CodeCommit](#) is designed to securely host scalable Git repositories, and [AWS CodeBuild](#) compiles source code, runs tests, and produces ready-to-deploy software packages. For more information, see [Developer Tools on AWS](#).

## Tools

### AWS services and tools

AWS provides a suite of developer services that you can use to implement this pattern:

- [AWS CodeArtifact](#) is a highly scalable, managed artifact repository service that helps you store and share software packages for application development.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

### Other tools

- [Draw.io Desktop](#) – An application for making flowcharts and diagrams.
- [Figma](#) is an online design tool designed for collaboration. The code repository contains templates in .fig format for Figma.

### Code repository

This source file for the diagram in this pattern is available in the GitHub [Git Branching Strategy for Trunk](#) repository. It includes files in PNG, draw.io, and Figma formats. You can modify these diagrams to support your organization's processes.

## Best practices

Follow the best practices and recommendations in [AWS Well-Architected DevOps Guidance](#) and [Choosing a Git branching strategy for multi-account DevOps environments](#). These help you effectively implement Trunk-based development, foster collaboration, improve code quality, and streamline the development process.

## Epics

### Reviewing the Trunk workflow

Task	Description	Skills required
Review the standard Trunk process.	<ol style="list-style-type: none"><li>1. In the sandbox environment, the developer creates a feature branch from the main branch and uses the naming pattern <code>feature/&lt;ticket&gt;_&lt;initials&gt;_&lt;short description&gt;</code> .</li><li>2. The developer develops code and deploys the code to the sandbox environment iteratively in order to complete the ticket.  <b>Note:</b> The developer can optionally create a sandbox branch to run an automated build or deploy pipeline in the sandbox environment.</li><li>3. The developer creates a merge request from the feature branch into the</li></ol>	DevOps engineer

Task	Description	Skills required
	<p>main branch by using a squash merge.</p> <ol style="list-style-type: none"><li data-bbox="592 317 1027 638">4. A continuous integration and continuous delivery (CI/CD) pipeline automatically builds and publishes the artifacts from the main branch to the development environment.</li><li data-bbox="592 659 992 884">5. An approver manually approves the deployment of the release artifacts to the development environment.</li><li data-bbox="592 905 1003 1087">6. An approver manually approves the deployment of the release artifacts to the testing environment.</li><li data-bbox="592 1108 1003 1291">7. An approver manually approves the deployment of the release artifacts to the staging environment.</li><li data-bbox="592 1312 1008 1537">8. An approver manually approves the deployment of the release artifacts to the production environment.</li></ol>	

# Troubleshooting

Issue	Solution
Branch conflicts	A common issue that can occur with the Trunk model is where a hotfix needs to occur in production but a corresponding change needs to occur in a feature branch, where the same resources are being modified. We recommend that you frequently merge changes from <code>main</code> into lower branches to avoid significant conflicts on merge to <code>main</code> .

## Related resources

This guide doesn't include training for Git; however, there are many high-quality resources available on the internet if you need this training. We recommend that you start with the [Git documentation](#) site.

The following resources can help you with your Trunk branching journey in the AWS Cloud.

### AWS DevOps guidance

# Implement centralized custom Checkov scanning to enforce policy before deploying AWS infrastructure

Created by Benjamin Morris (AWS)

**Code repository:** [Centralized Checkov SAST](#)

**Environment:** Production

**Technologies:** DevOps; Security, identity, compliance

**AWS services:** AWS CloudFormation

## Summary

This pattern provides a GitHub Actions framework for writing custom Checkov policies in one repository that can be reused across a GitHub organization. By following this pattern, an information security team can write, add, and maintain custom policies based on company requirements. The custom policies can be pulled into all pipelines in the GitHub organization automatically. This approach can be used to enforce company standards for resources before the resources are deployed.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A GitHub organization using GitHub Actions
- AWS infrastructure deployed with either HashiCorp Terraform or AWS CloudFormation

### Limitations

- This pattern is written for GitHub Actions. However, it can be adapted to similar continuous integration and continuous delivery (CI/CD) frameworks such as GitLab. No specific paid version of GitHub is required.
- Some AWS services aren't available in all AWS Regions. For Region availability, see [Service endpoints and quotas](#) in the AWS documentation, and choose the link for the service.

## Architecture

This pattern is designed to be deployed as a GitHub repository that contains a GitHub reusable workflow and custom Checkov policies. The reusable workflow can scan both Terraform and CloudFormation infrastructure as code (IaC) repositories.

The following diagram shows the **Reusable GitHub workflows repository** and **Custom Checkov policies repository** as separate icons. However, you can implement these repositories either as separate repositories or a single repository. The example code uses a single repository, with files for workflows (`.github/workflows`) and files for custom policies (`custom_policies` folder and the `.checkov.yml` config file) in the same repository.

The diagram shows the following workflow:

1. A user creates a pull request in a GitHub repository.
2. Pipeline workflows start in GitHub Actions, including a reference to a Checkov reusable workflow.
3. The pipeline workflow downloads the referenced Checkov reusable workflow from an external repository and runs that Checkov workflow by using GitHub Actions.
4. The Checkov reusable workflow downloads the custom policies from an external repository.
5. The Checkov reusable workflow evaluates the IaC in the GitHub repository against both built-in and custom Checkov policies. The Checkov reusable workflow passes or fails based on whether security issues are found.

### Automation and scale

This pattern allows for central management of Checkov configuration, so that policy updates can be applied in one location. However, this pattern does require that each repository use a workflow that contains a reference to the central reusable workflow. You can add this reference manually or use scripts to push the file to the `.github/workflows` folder for each repository.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. Checkov can scan CloudFormation.

### Other tools

- [Checkov](#) is a static code analysis tool that checks IaC for security and compliance misconfigurations.
- [GitHub Actions](#) is integrated into the GitHub platform to help you create, share, and run workflows within your GitHub repositories. You can use GitHub Actions to automate tasks such as building, testing, and deploying your code.
- [Terraform](#) is an IaC tool from HashiCorp that helps you create and manage cloud and on-premises resources. Checkov can scan Terraform.

### Code repository

The code for this pattern is available in the GitHub [centralized-custom-checkov-sast](#) repository.

## Best practices

- To maintain a consistent security posture, align your company's security policies with the Checkov policies.
- In the early phases of implementing Checkov custom policies, you can use the soft-fail option in your Checkov scan to allow IaC with security issues to be merged. As the process matures, switch from the soft-fail option to the hard-fail option.

## Epics

### Create a central Checkov repository for custom policies

Task	Description	Skills required
Create a central Checkov repository.	<p>Create a repository to store custom Checkov policies that will be used within the organization.</p> <p>For a quick start, you can copy the contents of this pattern's GitHub <a href="#">centralized-custom-checkov-sast</a> repository into your central Checkov repository.</p>	DevOps engineer
Create a repository for reusable workflows.	<p>If a repository for reusable workflows already exists, or you plan to include reusable workflow files in the same repository as the custom Checkov policies, you can skip this step.</p> <p>Create a GitHub repository to hold reusable workflows. Other repositories' pipelines will reference this repository.</p>	DevOps engineer

### Create reusable and example Checkov workflows

Task	Description	Skills required
Add a reusable Checkov workflow.	Create a reusable Checkov GitHub Actions workflow	DevOps engineer

Task	Description	Skills required
	<p>(YAML file) in the reusable workflows repository. You can adapt this reusable workflow from the workflow file provided in this pattern.</p> <p>An example of a change that you might want to make is to change the reusable workflow to use the soft-fail option. Setting <code>soft-fail</code> to <code>true</code> allows the job to complete successfully even if there is a failed Checkov scan. For instructions, see <a href="#">Hard and soft fail</a> in the Checkov documentation.</p>	
Add an example workflow.	<p>Add an example Checkov workflow that references the reusable workflow. This will provide a template for how to reuse the reusable workflow. In the example repository, <code>checkov-source.yaml</code> is the reusable workflow and <code>checkov-scan.yaml</code> is the example that consumes <code>checkov-source</code>.</p> <p>For more details about writing an example Checkov workflow, see <a href="#">Additional information</a>.</p>	DevOps engineer

## Associate company policies to Checkov custom policies

Task	Description	Skills required
Determine policies that can be enforced with Checkov.	<ol style="list-style-type: none"><li>1. Review company policies that are related to infrastructure security and which requirements should be in place.</li><li>2. Determine which requirements can be implemented by using Checkov custom policies.</li><li>3. Create a naming convention that maps the policy control to the Checkov custom policy. Typically, Checkov custom policies have an identifier with a Checkov name, the policy source (custom), and a policy number (for example, CKV2_CUSTOM_123 ).</li></ol> <p>For more details about creating Checkov custom policies, see <a href="#">Custom Policies Overview</a> in the Checkov documentation.</p>	Security and Compliance
Add Checkov custom policies.	Convert the identified company policies to custom Checkov policies in the central repository. You can write	Security

Task	Description	Skills required
	simple Checkov policies in either Python or YAML.	

## Implement centralized Checkov custom policies

Task	Description	Skills required
Add the Checkov reusable workflow to all repositories.	At this point, you should have an example Checkov workflow that references the reusable workflow. Copy the sample Checkov workflow that references the reusable workflow to each repository that requires it.	DevOps engineer
Create a mechanism to ensure that Checkov runs before merges.	To ensure that the Checkov workflow gets run for every pull request, create a <a href="#">status check</a> that requires a successful Checkov workflow before pull requests can be merged. GitHub allows you to require that specific workflows run before pull requests can be merged.	DevOps engineer
Create an organization-wide PAT, and share it as a secret.	If your GitHub organization is publicly visible, you can skip this step.  This pattern requires that the Checkov workflow be able to download custom policies from the custom	DevOps engineer

Task	Description	Skills required
	<p>policy repository in your GitHub organization. You must provide permissions such that the Checkov workflow can access those repositories.</p> <p>To do this, <a href="#">create a personal access token (PAT)</a> with permissions to read organization repositories. Share this PAT with repositories, either as an organization-wide secret (if on a paid plan) or a secret in each repository (free version). In the sample code, the default name for the secret is ORG_PAT.</p>	

Task	Description	Skills required
<p>(Optional) Protect the Checkov workflow files from modification.</p>	<p>To protect the Checkov workflow files from unwanted changes, you can use a CODEOWNERS file. The CODEOWNERS file is typically deployed in the root of the directory.</p> <p>For example, to require approvals from your GitHub organization's secEng group when the checkov-scan.yaml file is modified, append the following to a repository's CODEOWNERS file:</p> <pre>[Checkov] .github/workflows /checkov-scan.yaml @myOrg/secEng</pre> <p>A CODEOWNERS file is specific to the repository it lives in. To protect the Checkov workflow used by the repository, you must add (or update) a CODEOWNERS file in each repository.</p> <p>For more information about protecting Checkov workflow files, see <a href="#">Additional information</a>. For more information about CODEOWNERS files, see the official documentation for</p>	DevOps engineer

Task	Description	Skills required
	your CI/CD provider (such as <a href="#">GitHub</a> ).	

## Related resources

- [Checkov Custom Policies Overview](#)
- [CloudFormation Configuration Scanning](#)
- [GitHub Actions Reusable Workflows](#)

## Additional information

### Writing Checkov workflow files

When writing `checkov-scan.yaml`, consider when you want it to run. The top-level `on` key determines when the workflow runs. In the example repository, the workflow will run when there is a pull request targeting the `main` branch (and any time that pull request's source branch is modified). The workflow can also be run as required because of the `workflow_dispatch` key.

You can change the workflow trigger conditions based on how often you want the workflow to run. For example, you could change the workflow to run every time code is pushed to any branch by replacing `pull_request` with `push` and removing the `branches` key.

You can modify the example workflow file that you created within an individual repository. For example, you could adjust the target branch's name from `main` to `production` if a repository is structured around a `production` branch.

### Protecting Checkov workflow files

Checkov scanning provides useful information about potential security misconfiguration. However, some developers might perceive it to be a barrier to their productivity and attempt to remove or disable the scanning workflow.

There are several ways to address this problem, including better messaging about the long-term value of security scanning and clearer documentation about how to deploy secure infrastructure. These are important "soft" approaches to DevSecOps collaboration that can be seen as the solution

to this problem's root cause. However, you can also use technical controls such as a CODEOWNERS file as guardrails to help keep developers on the right path.

### Testing pattern in a sandbox

To test this pattern in a sandbox environment, follow these steps:

1. Create a new GitHub organization. Create a token with read-only access to all repositories in the organization. Because this token is for a sandbox environment, not a paid environment, you will not be able to store this token in an organization-wide secret.
2. Create a checkov repository to hold the Checkov configuration and a github-workflows repository to hold the reusable workflow configuration. Populate the repositories with the contents of the example repository.
3. Create an application repository, and copy and paste the checkov-scan.yaml workflow to its .github/workflows folder. Add a secret to the repository that contains the PAT you created for organization read-only access. The default secret is ORG\_PAT.
4. Create a pull request that adds some Terraform or CloudFormation code to the application repository. Checkov should scan and return a result.

# Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit

Created by Helton Ribeiro (AWS), Petrus Batalha (AWS), and Ricardo Morais (AWS)

**Code repository:** [AWS CodeCommit monorepo multi-pipeline triggers](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Infrastructure; Serverless

**AWS services:** AWS CodeCommit; AWS CodePipeline; AWS Lambda

## Summary

This pattern helps you automatically detect changes to the source code of a monorepo-based application in AWS CodeCommit and then initiate a pipeline in AWS CodePipeline that runs the continuous integration and continuous delivery (CI/CD) automation for each microservice. This approach means that each microservice in your monorepo-based application can have a dedicated CI/CD pipeline, which ensures better visibility, easier sharing of code, and improved collaboration, standardization, and discoverability.

The solution described in this pattern doesn't perform any dependency analysis among the microservices inside the monorepo. It only detects changes in the source code and initiates the matching CI/CD pipeline.

The pattern uses AWS Cloud9 as the integrated development environment (IDE) and AWS Cloud Development Kit (AWS CDK) to define an infrastructure by using two AWS CloudFormation stacks: MonoRepoStack and PipelinesStack. The MonoRepoStack stack creates the monorepo in AWS CodeCommit and the AWS Lambda function that initiates the CI/CD pipelines. The PipelinesStack stack defines your pipeline infrastructure.

**Important:** This pattern's workflow is a proof of concept (PoC). We recommend that you use it only in a test environment. If you want to use this pattern's approach in a production environment, see [Security best practices in IAM](#) in the AWS Identity and Access Management (IAM) documentation and make the required changes to your IAM roles and AWS services.

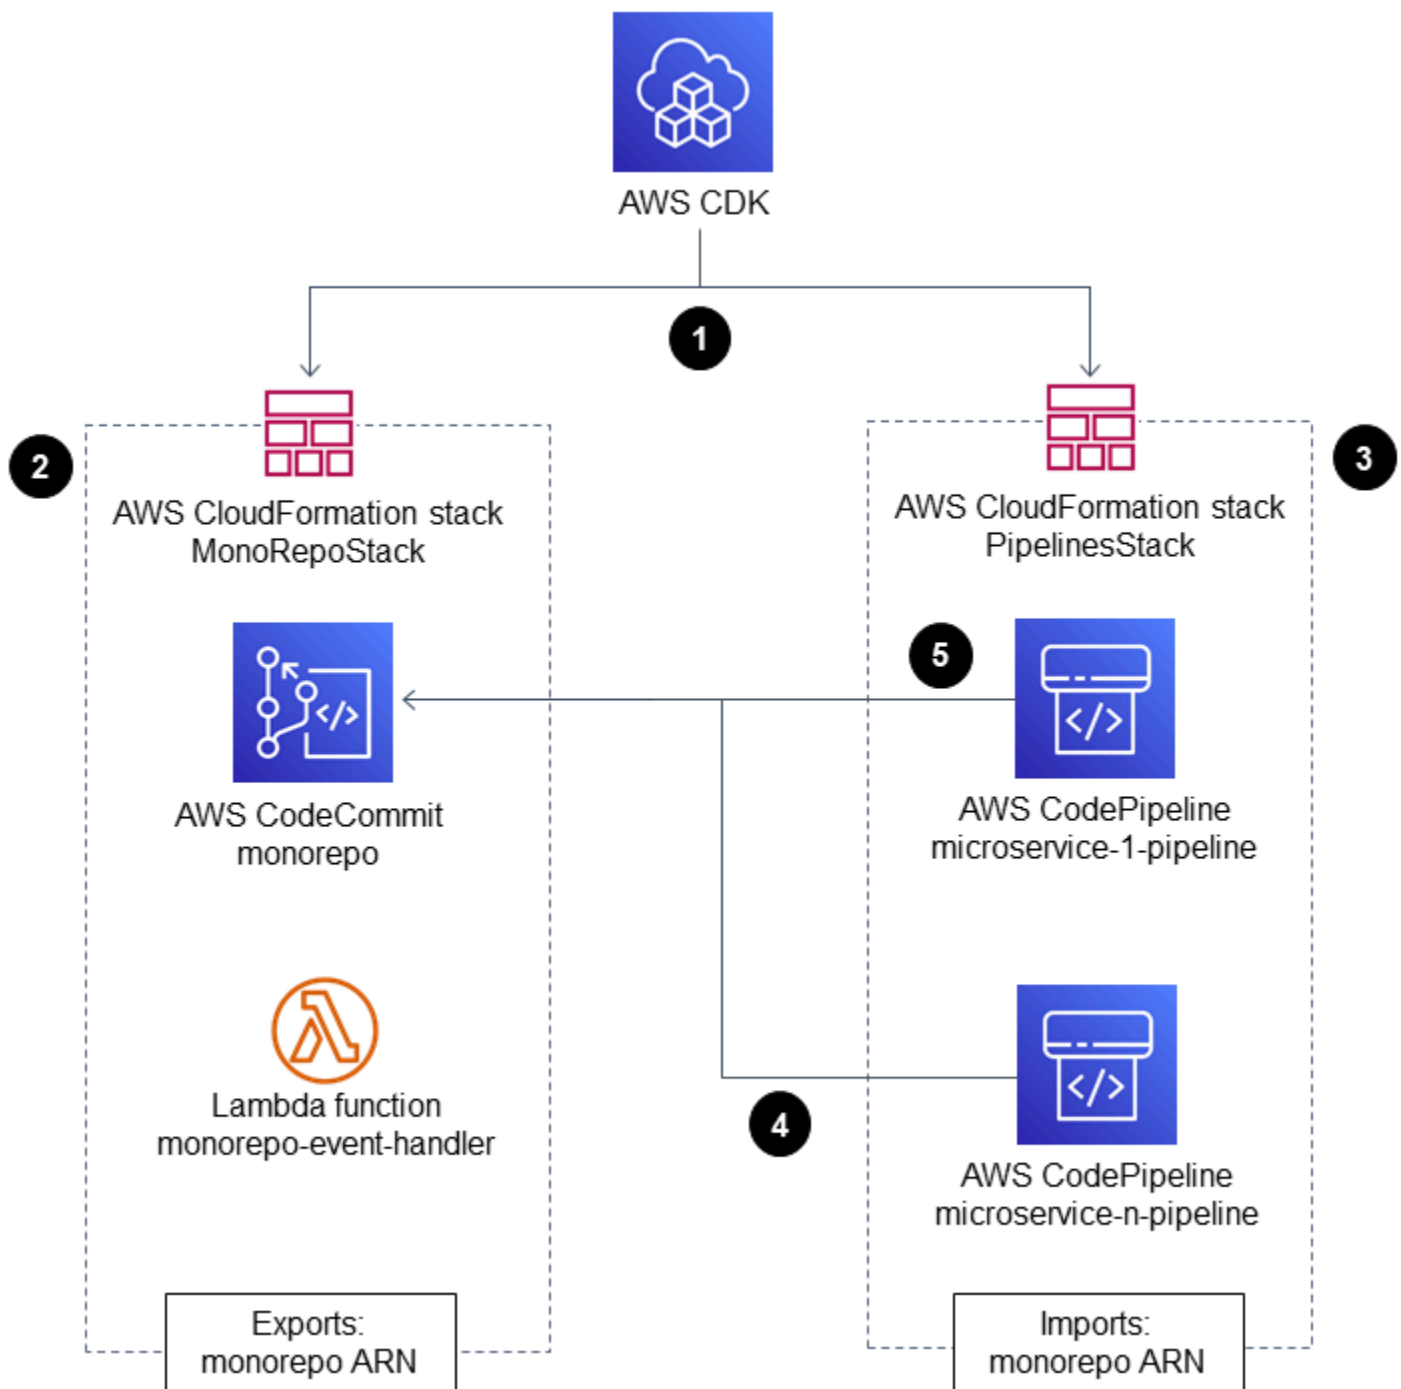

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information, see [Installing, updating, and uninstalling the AWS CLI](#) in the AWS CLI documentation.
- Python 3 and pip, installed on your local machine. For more information, see the [Python documentation](#).
- AWS CDK, installed and configured. For more information, see [Getting started with the AWS CDK](#) in the AWS CDK documentation.
- An AWS Cloud9 IDE, installed and configured. For more information, see [Setting up AWS Cloud9](#) in the AWS Cloud9 documentation.
- The GitHub [AWS CodeCommit monorepo multi-pipeline triggers](#) repository, cloned on your local machine.
- An existing directory containing application code that you want to build and deploy with CodePipeline.
- Familiarity and experience with DevOps best practices on the AWS Cloud. To increase your familiarity with DevOps, you can use the pattern [Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9](#) on the AWS Prescriptive Guidance website.

### Architecture

The following diagram shows how to use the AWS CDK to define an infrastructure with two AWS CloudFormation stacks: MonoRepoStack and PipelinesStack.

The diagram shows the following workflow:

1. The bootstrap process uses the AWS CDK to create the AWS CloudFormation stacks `MonoRepoStack` and `PipelinesStack`.
2. The `MonoRepoStack` stack creates the CodeCommit repository for your application and the `monorepo-event-handler` Lambda function that is initiated after each commit.

3. The PipelinesStack stack creates the pipelines in CodePipeline that are initiated by the Lambda function. Each microservice must have a defined infrastructure pipeline.
4. The pipeline for `microservice-n` is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.
5. The pipeline for `microservice-1` is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.

The following diagram shows the deployment of the AWS CloudFormation stacks MonoRepoStack and PipelinesStack in an account.

1. A user changes code in one of the application's microservices.
2. The user pushes the changes from a local repository to a CodeCommit repository.
3. The push activity initiates the Lambda function that receives all pushes to the CodeCommit repository.
4. The Lambda function reads a parameter in Parameter Store, a capability of AWS Systems Manager, to retrieve the most recent commit ID. The parameter has the naming format: `/MonoRepoTrigger/{repository}/{branch_name}/LastCommit`. If the parameter isn't

found, the Lambda function reads the last commit ID from the CodeCommit repository and saves the returned value in Parameter Store.

5. After identifying the commit ID and the changed files, the Lambda function identifies the pipelines for each microservice directory and initiates the required CodePipeline pipeline.

## Tools

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- [Python](#) is a programming language that lets you work quickly and integrate systems more effectively.

## Code

The source code and templates for this pattern are available in the GitHub [AWS CodeCommit monorepo multi-pipeline triggers](#) repository.

## Best practices

- This sample architecture doesn't include a monitoring solution for the deployed infrastructure. If you want to deploy this solution in a production environment, we recommend that you enable monitoring. For more information, see [Monitor your serverless applications with CloudWatch Application Insights](#) in the AWS Serverless Application Model (AWS SAM) documentation.
- When you edit the sample code provided by this pattern, follow the [best practices for developing and deploying cloud infrastructure](#) in the AWS CDK documentation.
- When you define your microservice pipelines, review the [security best practices](#) in the AWS CodePipeline documentation.
- You can also check your AWS CDK code for best practices by using the [cdk-nag](#) utility. This tool uses a set of rules, grouped by packs, to evaluate your code. The available packs are:
  - [AWS Solutions Library](#)
  - [Health Insurance Portability and Accountability Act \(HIPAA\) security](#)
  - [National Institute of Standards and Technology \(NIST\) 800-53 rev 4](#)
  - [NIST 800-53 rev 5](#)
  - [Payment Card Industry Data Security Standard \(PCI DSS\) 3.2.1](#)

# Epics

## Set up the environment

Task	Description	Skills required
Create a virtual Python environment.	In your AWS Cloud9 IDE, create a virtual Python environment and install the required dependencies by running the following command:  <code>make install</code>	Developer
Bootstrap the AWS account and AWS Region for the AWS CDK.	Bootstrap the required AWS account and Region by running the following command:  <code>make bootstrap account-id=&lt;your-AWS-account-ID&gt; region=&lt;required-region&gt;</code>	Developer

## Add a new pipeline for a microservice

Task	Description	Skills required
Add your sample code to your application directory.	Add the directory that contains your sample application code to the <code>monorepo-sample</code> directory in the cloned GitHub <a href="#">AWS CodeCommi</a>	Developer

Task	Description	Skills required
	<a href="#">t monorepo multi-pipeline triggers</a> repository.	
Edit the monorepo-main.json file.	Add the directory name of your application's code and the pipeline's name to the monorepo-main.json file in the cloned repository .	Developer
Create the pipeline.	<p>In the Pipelines directory for the repository, add the pipeline class for your application. The directory contains two sample files, pipeline_hotsite.py and pipeline_demo.py . Each file has three stages: source, build, and deploy.</p> <p>You can copy one of the files and makes changes to it according to your application's requirements.</p>	Developer

Task	Description	Skills required
Edit the <code>monorepo_config.py</code> file.	<p>In <code>service_map</code>, add the directory name for your application and the class that you created for the pipeline.</p> <p>For example, the following code shows a pipeline definition in the <code>Pipelines</code> directory that uses a file named <code>pipeline_mysample.py</code> with a <code>MySamplePipeline</code> class:</p> <pre data-bbox="597 810 1027 1858">... # Pipeline definition imports from pipelines .pipeline_demo import DemoPipeline from pipelines.pipeline _hotsite import HotsitePipeline from pipelines .pipeline_mysample import MySampleP ipeline  ### Add your pipeline configuration here service_map: Dict[str, ServicePipeline] = {     # folder-name -&gt; pipeline-class     'demo': DemoPipel ine(),     'hotsite': HotsitePipeline(),     'mysample': MySamplePipeline()</pre>	Developer

Task	Description	Skills required
	}	

## Deploy the MonoRepoStack stack

Task	Description	Skills required
Deploy the AWS CloudFormation stack.	<p>Deploy the AWS CloudFormation MonoRepoStack stack with default parameter values in the root directory of the cloned repository by running the <code>make deploy-core</code> command.</p> <p>You can change the repository's name by running the <code>make deploy-core monorepo-name=&lt;repo_name&gt;</code> command.</p> <p><b>Note:</b> You can simultaneously deploy both pipelines by using the <code>make deploy monorepo-name=&lt;repo_name&gt;</code> command.</p>	Developer
Validate the CodeCommit repository.	<p>Validate that your resources were created by running the <code>aws codecommit get-repository --repository-name &lt;repo_name&gt;</code> command.</p> <p><b>Important:</b> Because the AWS CloudFormation stack creates</p>	Developer

Task	Description	Skills required
	<p>the CodeCommit repository where the monorepo is stored, don't run the <code>cdk destroy MonoRepoStack</code> command if you have started to push modifications into it.</p>	
<p>Validate the AWS CloudFormation stack results.</p>	<p>Validate that the AWS CloudFormation <code>MonoRepoStack</code> stack is correctly created and configured by running the following command:</p> <pre data-bbox="594 890 1029 1209">aws cloudformation   list-stacks --   stack-status-filter   CREATE_COMPLETE --   query 'StackSummaries[?   StackName == 'MonoRepo   Stack']'</pre>	<p>Developer</p>

## Deploy the PipelinesStack stack

Task	Description	Skills required
<p>Deploy the AWS CloudFormation stack.</p>	<p>The AWS CloudFormation <code>PipelinesStack</code> stack must be deployed after you deploy the <code>MonoRepoStack</code> stack. The stack increases in size when new microservices are added to the monorepo's code base and is redeploye</p>	<p>Developer</p>

Task	Description	Skills required
	<p>d when a new microservice is onboarded.</p> <p>Deploy the Pipelines Stack stack by running the <code>make deploy-pipelines</code> command.</p> <p><b>Note:</b> You can also deploy simultaneously deploy both pipelines by running the <code>make deploy monorepo-name=&lt;repo_name&gt;</code> command.</p> <p>The following sample output shows how the Pipelines Stacks deployment prints the URLs for the microservices at the end of the implementation:</p> <div data-bbox="594 1192 1029 1472" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"><pre>Outputs: PipelinesStack.dem ourl = .cloudfront.net PipelinesStack.hotsi teurl = .cloudfro nt.net</pre></div>	

Task	Description	Skills required
Validate the AWS CloudFormation stack results.	<p>Validate that the AWS CloudFormation Pipelines Stacks stack is correctly created and configured by running the following command:</p> <pre>aws cloudformation   list-stacks --stack-status-filter CREATE_COMPLETE UPDATE_COMPLETE   --query 'StackSummaries[?StackName == 'PipelinesStack']'</pre>	Developer

## Clean up resources

Task	Description	Skills required
Delete your AWS CloudFormation stacks.	Run the <code>make destroy</code> command.	Developer
Delete the S3 buckets for your pipelines.	<ol style="list-style-type: none"> <li>1. Sign in to the <a href="#">AWS Management Console</a> and open the <a href="#">Amazon Simple Storage Service (Amazon S3) console</a>.</li> <li>2. Delete the S3 buckets that are associated with your pipelines and use the following name: <code>pipelinesstack-cod epipeline*</code></li> </ol>	Developer

# Troubleshooting

Issue	Solution
I encountered AWS CDK issues.	See <a href="#">Troubleshooting common AWS CDK issues</a> in the AWS CDK documentation.
I pushed my microservice code, but the microservice pipeline didn't run.	<b>Setup validation</b> <i>Verify branch configuration:</i> <ul style="list-style-type: none"><li>• Make sure that you are pushing your code to the correct branch. This pipeline is configured to run only when changes are made to the main branch. Pushes to other branches don't initiate the pipeline unless they are configured specifically.</li><li>• After you push your code, check if the commit is visible in AWS CodeCommit to make sure that the push was successful and that the connection between your local environment and the repository is intact. Refresh your credentials if there are issues pushing code.</li></ul> <i>Validate configuration files:</i> <ul style="list-style-type: none"><li>• Confirm that the <code>service_map</code> variable in <code>monorepo_config.py</code> accurately reflects the current directory structure of your microservices. This variable plays a crucial role in mapping your code push to the respective pipeline.</li><li>• Make sure that <code>monorepo-main.json</code> is updated to include the new mapping for your microservice. This file is essential</li></ul>

Issue	Solution
	<p>for the pipeline to recognize and correctly handle changes to your microservice.</p> <p><b>Troubleshooting on the console</b></p> <p><i>AWS CodePipeline checks:</i></p> <ul style="list-style-type: none"><li>• On the <a href="#">AWS Management Console</a>, confirm that you're in the AWS Region where your pipeline is hosted. Open the <a href="#">CodePipeline console</a> and check if the pipeline that corresponds to your microservice has been initiated.</li></ul> <p><b>Error analysis:</b> If the pipeline was initiated but failed, review any error messages or logs provided by CodePipeline to understand what went wrong.</p> <p><i>AWS Lambda troubleshooting:</i></p> <ul style="list-style-type: none"><li>• On the <a href="#">AWS Lambda console</a>, open the <code>monorepo-event-handler</code> Lambda function. Verify that the function was initiated in response to the code push.</li></ul> <p><b>Log analysis:</b> Examine the Lambda function's logs for any issues. The logs can provide detailed insights into what happened when the function ran and help identify whether the function processed the event as expected.</p>

Issue	Solution
I need to redeploy all my microservices.	<p>There are two approaches to force the redeployment of all microservices. Choose the option that fits your requirements.</p> <p><b>Approach 1: Delete a parameter in Parameter Store</b></p> <p>This method involves deleting a specific parameter within Systems Manager Parameter Store that tracks the last commit ID used for deployment. When you remove this parameter, the system is forced to redeploy all microservices upon the next trigger, because it perceives it as a fresh state.</p> <p>Steps:</p> <ol style="list-style-type: none"><li>1. Locate the specific Parameter Store entry that holds the commit ID or a related deployment marker for your monorepo. The parameter name follows the format: <code>"/MonoRepoTrigger/{repository}/{branch_name}/LastCommit"</code></li><li>2. Consider backing up the parameter value if it's critical or if you wish to maintain a record of the deployment state before resetting it.</li><li>3. Use the AWS Management Console, AWS CLI, or SDKs to delete the identified parameter. This action resets the deployment marker.</li><li>4. After deletion, the next push to the repository should cause the system to deploy all microservices, because it looks</li></ol>

Issue	Solution
	<p>for the latest commit to consider for deployment.</p> <p>Pros:</p> <ul style="list-style-type: none"><li>• Simple and quick to implement with minimal steps.</li><li>• Doesn't require making arbitrary code changes to initiate deployments.</li></ul> <p>Cons:</p> <ul style="list-style-type: none"><li>• Less granular control over the deployment process.</li><li>• Potentially risky if the Parameter Store is used for managing other critical configurations.</li></ul> <p><b>Approach 2: Push a commit in each monorepo subfolder</b></p> <p>This method involves making a minor change and pushing it in each microservice subfolder within the monorepo to initiate their individual pipelines.</p> <p>Steps:</p> <ol style="list-style-type: none"><li>1. List all the microservices within the monorepo that need redeployment.</li><li>2. For each microservice, make a minimal, non-impactful change in its subfolder. This might be updating a README file, adding a comment in a configuration file, or any</li></ol>

Issue	Solution
	<p>change that doesn't affect the service's functionality.</p> <ol style="list-style-type: none"><li>3. Commit these changes with a clear message (such as "Initiate redeployment of microservices") and push them to the repository. Make sure that you push the changes to the branch that initiates the deployment.</li><li>4. Monitor the pipelines for each microservice to confirm that they are initiated and complete successfully.</li></ol> <p>Pros:</p> <ul style="list-style-type: none"><li>• Provides granular control over which microservices are redeployed.</li><li>• Safer because it doesn't involve deleting configuration parameters that might be used for other purposes.</li></ul> <p>Cons:</p> <ul style="list-style-type: none"><li>• More time-consuming, especially with a large number of microservices.</li><li>• Requires making unnecessary code changes that could clutter the commit history.</li></ul>

# Integrate a Bitbucket repository with AWS Amplify using AWS CloudFormation

Created by Alwin Abraham (AWS)

**Environment:** Production

**Technologies:** DevOps

**AWS services:** AWS Amplify;  
AWS CloudFormation

## Summary

AWS Amplify helps you to quickly deploy and test static websites without having to set up the infrastructure that is typically required. You can deploy this pattern's approach if your organization wants to use Bitbucket for source control, whether to migrate existing application code or build a new application. By using AWS CloudFormation to automatically set up Amplify, you provide visibility into the configurations that you use.

This pattern describes how to create a front-end continuous integration and continuous deployment (CI/CD) pipeline and deployment environment by using AWS CloudFormation to integrate a Bitbucket repository with AWS Amplify. The pattern's approach means that you can build an Amplify front-end pipeline for repeatable deployments.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account
- An active Bitbucket account with administrator access
- Access to a terminal that uses [cURL](#) or the [Postman](#) application
- Familiarity with Amplify
- Familiarity with AWS CloudFormation
- Familiarity with YAML-formatted files

## Architecture

## Technology stack

- Amplify
- AWS CloudFormation
- Bitbucket

## Tools

- [AWS Amplify](#) – Amplify helps developers to develop and deploy cloud-powered mobile and web apps.
- [AWS CloudFormation](#) – AWS CloudFormation is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- [Bitbucket](#) – Bitbucket is a Git repository management solution designed for professional teams. It gives you a central place to manage Git repositories, collaborate on your source code, and guide you through the development flow.

## Code

The `bitbucket-amplify.yml` file (attached) contains the AWS CloudFormation template for this pattern.

# Epics

## Configure the Bitbucket repository

Task	Description	Skills required
(Optional) Create a Bitbucket repository.	<ol style="list-style-type: none"> <li>1. Sign in to your Bitbucket account and create a new repository. For more information about this, see <a href="#">Create a Git repository</a> in the Bitbucket documentation.</li> <li>2. Record the workspace's name.</li> </ol> <p><b>Note:</b> You can also use an existing Bitbucket repository.</p>	DevOps engineer
Open the workspace settings.	<ol style="list-style-type: none"> <li>1. Open the workspace and choose the <b>Repository</b> tab.</li> <li>2. Choose the repository that you want to integrate with Amplify.</li> <li>3. Choose the name of the workspace that is above the repository's name.</li> <li>4. On the sidebar, choose <b>Settings</b>.</li> </ol>	DevOps engineer
Create an OAuth consumer.	<ol style="list-style-type: none"> <li>1. In the <b>Apps and Features</b> section, choose <b>OAuth consumers</b>, and then choose <b>Add consumer</b>.</li> </ol>	DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. Enter a name for your consumer, for example, Amplify Integration .</li><li>3. Enter a callback URL. Although this field is a required input, it's not used to complete the integration so the value could be <code>http://localhost:3000</code></li><li>4. Check the box for <b>This is a private consumer</b>.</li><li>5. Choose the following permissions:<ul style="list-style-type: none"><li>• <b>Project</b> – Read</li><li>• <b>Repositories</b> – Admin</li><li>• <b>Pull requests</b> – Read</li><li>• <b>Webhooks</b> – Read and Write</li></ul></li><li>6. Leave the default choices for all the other fields and choose <b>Submit</b>.</li><li>7. Record the key and secret that are generated.</li></ol>	

Task	Description	Skills required
Obtain OAuth access token.	<p>1. Open a terminal window and run the following command:</p> <pre>curl -X POST -u "KEY:SECRET" https://bitbucket.org/site/oauth2/access_token -d grant_type=client_credentials</pre> <p><b>Important:</b> Replace KEY and SECRET with the key and secret that you recorded earlier.</p> <p>2. Record the access token without using the quotation marks. The token is only valid for a limited time and the default time is two hours. You must run the AWS CloudFormation template in this timeframe.</p>	DevOps engineer

## Create and deploy the AWS CloudFormation stack

Task	Description	Skills required
Download the AWS CloudFormation template.	Download the bitbucket -amplify.yml AWS CloudFormation template (attached). This template creates the CI/CD pipeline in	

Task	Description	Skills required
	Amplify, in addition to the Amplify project and branch.	

Task	Description	Skills required
Create and deploy the AWS CloudFormation stack.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console in the AWS Region that you want to deploy in and open the AWS CloudFormation console.</li><li>2. Choose <b>Create Stack (with new resources)</b> and then choose <b>Upload a Template File</b>.</li><li>3. Upload the <code>bitbucket-amplify.yml</code> file.</li><li>4. Choose <b>Next</b>, enter a stack name, and then enter the following parameters:<ul style="list-style-type: none"><li>• <b>Access token:</b> Paste the OAuth access token that you created earlier.</li><li>• <b>Repository URL:</b> Add the Bitbucket project repository's URL. The URL is typically in the following format: <code>https://bitbucket.org/&lt;WORKSPACE_NAME&gt;/&lt;REPO_NAME&gt;</code></li><li>• <b>Branch name:</b> This must match the name of a branch in your Bitbucket repository. This branch doesn't need to exist when you run the AWS</li></ul></li></ol>	DevOps engineer

Task	Description	Skills required
	<p>CloudFormation stack but it is required for deploying code to the environment.</p> <ul style="list-style-type: none"> <li>• <b>Project name:</b> This is the name to associate with the Amplify project.</li> </ul> <p>5. Choose <b>Next</b> and then choose <b>Create Stack</b>.</p>	

## Test the CI/CD pipeline

Task	Description	Skills required
<p>Deploy the code to the branch in your repository.</p>	<ol style="list-style-type: none"> <li>1. Clone your Bitbucket repository by running the following command:  <pre>git clone https://bitbucket.org/&lt;WORKSPACE_NAME&gt;/&lt;REPO_NAME&gt;</pre> </li> <li>2. Check out the branch name that was used when running the AWS CloudFormation script. To create and check out a new branch, run the <code>git checkout -b &lt;BRANCH_NAME&gt;</code> command. To check out an existing branch, run the <code>git checkout</code></li> </ol>	<p>App developer</p>

Task	Description	Skills required
	<p data-bbox="630 212 878 289">&lt;BRANCH_NAME&gt; command</p> <ol data-bbox="592 317 1008 646" style="list-style-type: none"><li data-bbox="592 317 1008 541">3. Commit the code into the branch and push it to the remote branch by running the <code>git commit</code> and <code>git push</code> commands.</li><li data-bbox="592 562 1008 646">4. Amplify then builds and deploys the application.</li></ol> <p data-bbox="592 724 1008 898">For more information about this, see <a href="#">Basic Git commands</a> in the Bitbucket documentation.</p>

# Launch a CodeBuild project across AWS accounts using Step Functions and a Lambda proxy function

Created by Richard Milner-Watts (AWS) and Amit Anjarlekar (AWS)

**Code repository:** [Cross-Account CodeBuild Proxy](#)

**Environment:** Production

**Technologies:** DevOps; Management & governance; Operations; Serverless

**AWS services:** AWS CodeBuild; AWS Lambda; AWS Step Functions; AWS X-Ray; AWS CloudFormation

## Summary

This pattern demonstrates how to asynchronously launch an AWS CodeBuild project across multiple AWS accounts by using AWS Step Functions and an AWS Lambda proxy function. You can use the pattern's sample Step Functions state machine to test the success of your CodeBuild project.

CodeBuild helps you launch operational tasks using the AWS Command Line Interface (AWS CLI) from a fully-managed runtime environment. You can change the behavior of your CodeBuild project at runtime by overriding environment variables. Additionally, you can use CodeBuild to manage workflows. For more information, see [Service Catalog Tools](#) on the AWS Workshop website and [Schedule jobs in Amazon RDS for PostgreSQL using AWS CodeBuild and Amazon EventBridge](#) on the AWS Database Blog.

## Prerequisites and limitations

### Prerequisites

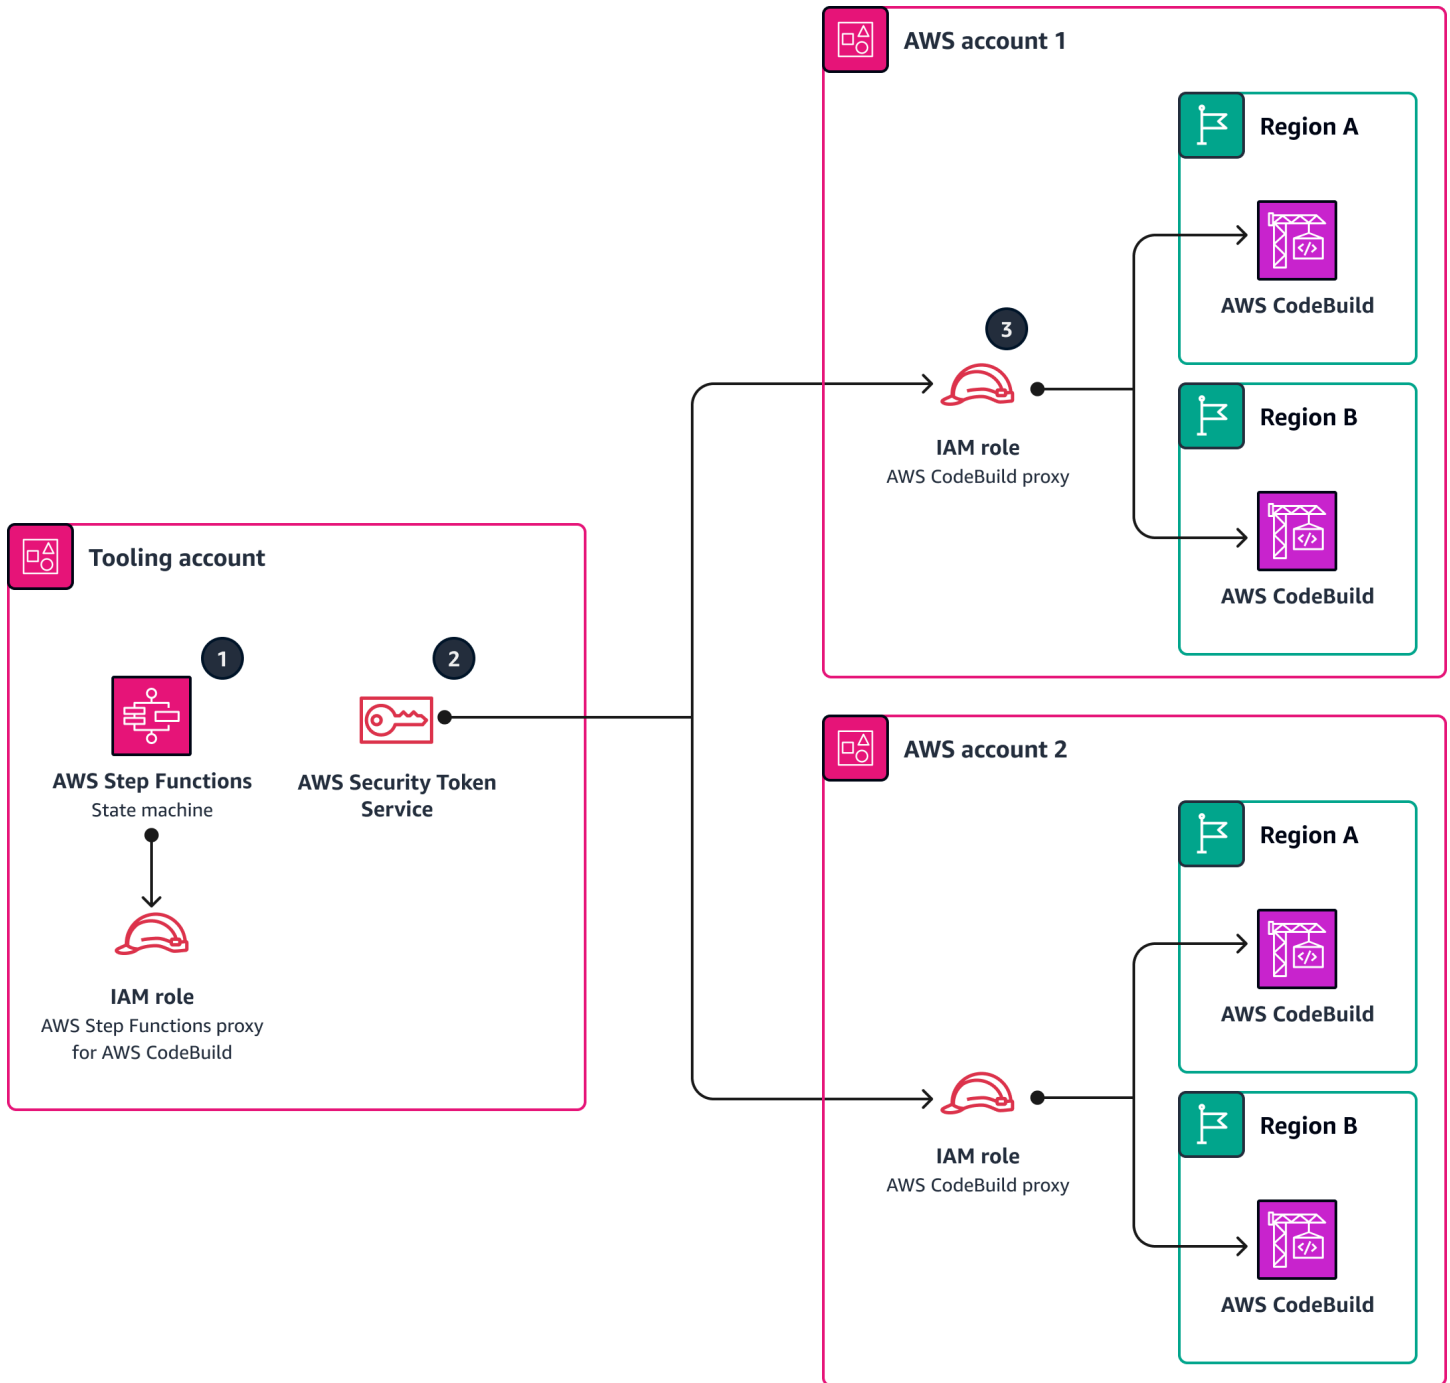

- Two active AWS accounts: a source account for invoking a Lambda proxy function with Step Functions and a target account for building a remote CodeBuild sample project

### Limitations

- This pattern cannot be used to copy [artifacts](#) between accounts.

## Architecture

The following diagram shows the architecture that this pattern builds.

The diagram shows the following workflow:

1. The Step Functions state machine parses the supplied input map and invokes the Lambda proxy function (`codebuild-proxy-lambda`) for each account, Region, and project you defined.
2. The Lambda proxy function uses AWS Security Token Service (AWS STS) to assume an IAM proxy role (`codebuild-proxy-role`), which is associated with an IAM policy (`codebuild-proxy-policy`) in the target account.
3. Using the assumed role, the Lambda function launches the CodeBuild project and returns the CodeBuild job ID. The Step Functions state machine loops and polls the CodeBuild job until receiving a success or failure status.

The state machine logic is shown in the following image.

## Technology stack

- AWS CloudFormation
- CodeBuild
- IAM
- Lambda
- Step Functions
- X-Ray

## Tools

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CloudFormation Designer](#) provides an integrated JSON and YAML editor that helps you view and edit CloudFormation templates.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- [AWS X-Ray](#) helps you collect data about the requests that your application serves, and provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.

## Code

The sample code for this pattern is available in the GitHub [Cross Account CodeBuild Proxy](#) repository. This pattern uses the AWS Lambda Powertools for Python library to provide logging and tracing functionality. For more information on this library and its utilities, see [Powertools for AWS Lambda \(Python\)](#).

## Best practices

1. Adjust the wait time values in the Step Function state machine to minimize polling requests for job status. Use the expected execution time for the CodeBuild project.
2. Adjust the MaxConcurrency property of the map in Step Functions to control how many CodeBuild projects can run in parallel.
3. If required, review the sample code for production readiness. Consider what data might be logged by the solution and whether the default Amazon CloudWatch encryption is sufficient.

## Epics

### Create the Lambda proxy function and associated IAM role in the source account

Task	Description	Skills required
Record the AWS account IDs.	<p>AWS account IDs are required to set up access across accounts.</p> <p>Record the AWS account ID for your source and target accounts. For more information, see <a href="#">Finding your AWS account ID</a> in the IAM documentation.</p>	AWS DevOps
Download the AWS CloudFormation templates.	<ol style="list-style-type: none"> <li>1. Download the sample_target_codebuild_template.yaml AWS CloudFormation template from the <a href="#">GitHub repository</a> for this pattern.</li> <li>2. Download the codebuild_lambda_proxy_template.yaml AWS CloudFormation template</li> </ol>	AWS DevOps

Task	Description	Skills required
	<p>from the <a href="#">GitHub repository</a> for this pattern.</p> <p><b>Note:</b> In the AWS CloudFormation templates, &lt;SourceAccountId&gt; is the AWS account ID for the source account, and &lt;TargetAccountId&gt; is the AWS account ID for the target account.</p>	

Task	Description	Skills required
Create and deploy the AWS CloudFormation stack.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console for your source account, open the <a href="#">AWS CloudFormation console</a>, and then choose <b>Stacks</b>.</li><li>2. Choose <b>Create Stack</b> and then choose <b>With new resources (standard)</b>.</li><li>3. For <b>Template source</b>, choose <b>Upload a template file</b>.</li><li>4. For <b>Upload a template file</b>, choose <b>file</b>, and then choose your downloaded <code>codebuild_lambda_proxy_template.yaml</code> file. Choose <b>Next</b>.</li><li>5. For <b>Stack name</b>, enter a name for the stack (for example, <code>codebuild-lambda-proxy</code> ).</li><li>6. Replace the <code>crossAccountTargetRoleArn</code> parameter with your <code>&lt;TargetAccountId&gt;</code> (for example, <code>&lt;arn:aws:iam::123456789012:role/proxy-lambda-codebuild-role&gt;</code> ). <b>Note:</b> You aren't required to update the default value for the <code>targetCod</code></li></ol>	AWS DevOps

Task	Description	Skills required
	<p>eBuildProject parameter.</p> <ol style="list-style-type: none"><li>7. Choose <b>Next</b>, accept the default stack creation options, and then chose <b>Next</b>.</li><li>8. Choose the <b>I acknowledge that AWS CloudFormation might create IAM resources with custom names</b> check box, and then choose <b>Create stack</b>.</li></ol> <p><b>Note:</b> You must create the AWS CloudFormation stack for the proxy Lambda function before creating any resources in target accounts. When you create a trust policy in a target account, the IAM role is translated from the role name to an internal identifier. This is why the IAM role must already exist.</p>	

Task	Description	Skills required
Confirm the creation of the proxy function and state machine.	<ol style="list-style-type: none"> <li>1. Wait for the AWS CloudFormation stack to reach <b>CREATE_COMPLETE</b> status. This should take less than one minute.</li> <li>2. Open the <a href="#">AWS Lambda console</a>, choose <b>Functions</b>, and then find the <code>lambda-proxy-ProxyLambda-&lt;GUID&gt;</code> function.</li> <li>3. Open the <a href="#">AWS Step Functions console</a>, choose <b>state machines</b>, and then find the <code>sample-crossaccount-codebuild-state-machine</code> state machine.</li> </ol>	AWS DevOps

### Create an IAM role in the target account and launch a sample CodeBuild project

Task	Description	Skills required
Create and deploy the AWS CloudFormation stack.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console for your target account, open the <a href="#">AWS CloudFormation console</a>, and then choose <b>Stacks</b>.</li> <li>2. Choose <b>Create Stack</b> and then choose <b>With new resources (standard)</b>.</li> </ol>	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 1027 338">3. For <b>Template source</b>, choose <b>Upload a template file</b>.</li><li data-bbox="592 363 1027 636">4. For <b>Upload a template file</b>, choose <b>Choose file</b>, and then choose the <code>sample_target_code_build_template.yaml</code> file. Choose <b>Next</b>.</li><li data-bbox="592 661 1027 842">5. For <b>Stack name</b>, enter a name for the stack (for example: <code>sample-codebuild-stack</code> ).</li><li data-bbox="592 867 1027 1236">6. Replace the <code>crossAccountSourceRoleArn</code> parameter with your <code>&lt;SourceAccountId&gt;</code> (for example, <code>&lt;arn:aws:iam::123456789012:role/codebuild-proxy-lambda-role&gt;</code> ).</li><li data-bbox="592 1262 1027 1442">7. Choose <b>Next</b>, accept the default stack creation options, and then choose <b>Next</b>.</li><li data-bbox="592 1467 1027 1740">8. Choose the <b>I acknowledge that AWS CloudFormation might create IAM resources with custom names</b> check box, and then choose <b>Create stack</b>.</li></ol>	

Task	Description	Skills required
Verify the creation of the sample CodeBuild project.	<ol style="list-style-type: none"> <li>1. Wait for the AWS CloudFormation stack to reach <b>CREATE_COMPLETE</b> status. This should take less than one minute.</li> <li>2. Open the <a href="#">AWS CodeBuild console</a> and then find the <code>sample-codebuild-project</code> project.</li> </ol>	AWS DevOps

### Test the cross-account Lambda proxy function

Task	Description	Skills required
Launch the state machine.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console for your source account, open the <a href="#">AWS Step Functions console</a>, and then choose <b>State machines</b>.</li> <li>2. Choose the <code>sample-crossaccount-codebuild-state-machine</code> state machine and then choose <b>Start execution</b>.</li> <li>3. In the <b>Input</b> editor, enter the following JSON, and replace <code>&lt;TargetAccountID&gt;</code> with the AWS account ID of the account that contains the CodeBuild project.</li> </ol>	AWS DevOps

Task	Description	Skills required
	<pre data-bbox="633 210 1023 1081">{   "crossAccountTargetRoleArns": [     {       "arn": "arn:aws:iam::&lt;TargetAccountID&gt;:role/proxy-lambda-codebuild-role",       "region": "eu-west-1",       "codeBuildProject": "sample-codebuild-project",       "SampleValue1": "Value1",       "SampleValue2": "Value2"     }   ] }</pre> <p data-bbox="625 1113 1031 1396"><b>Note:</b> The key-value pairs are passed as environment variables from the function in the source account to the CodeBuild project in the target account.</p> <ol data-bbox="584 1407 1031 1795" style="list-style-type: none"><li>4. Choose <b>Start execution</b>.</li><li>5. On the <b>Details</b> tab of the state machine page, check if <b>Execution Status</b> is set to <b>Succeeded</b>. This confirms that your state machine is running. <b>Note:</b> It can take around 30 seconds for the</li></ol>	

Task	Description	Skills required
	<p>state machine to reach <b>Succeeded</b> status.</p> <p>6. To see the output and input of a step in the state machine, expand that step in the <b>Execution event history</b> section. For example, expand the <b>Lambda - CodeBuild Proxy – Start</b> step. The output includes details on the overridden environment variables, the original payload, and the CodeBuild job ID.</p>	

Task	Description	Skills required
Validate the environment variables.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console for your target account.</li> <li>2. Open the <a href="#">AWS CodeBuild console</a>, expand <b>Build</b>, and then choose <b>Build projects</b>.</li> <li>3. Choose the sample-codebuild-project project, and then choose <b>View details</b>.</li> <li>4. On the <b>Build history</b> tab, choose the most recent build of the project, and then choose <b>View logs</b>.</li> <li>5. In the log output, verify that the environment variables printed to STDOUT match the environment variables from the Step Functions sample state machine.</li> </ol>	AWS DevOps

## Troubleshooting

Issue	Solution
Step Functions execution is taking longer than expected.	Adjust the <code>MaxConcurrency</code> property of the map in the Step Function state machine to control how many CodeBuild projects can run in parallel.

Issue	Solution
<p>The execution of the CodeBuild jobs is taking longer than expected.</p>	<ol style="list-style-type: none"><li data-bbox="831 226 1490 457">1. Adjust the wait time values in the Step Functions state machine to minimize polling requests for job status. Use the expected execution time for the CodeBuild project.</li><li data-bbox="831 478 1490 898">2. Consider whether CodeBuild is the appropriate tool to be using. For example, the time required to initialize a CodeBuild job can be significantly longer than AWS Lambda. If high throughput and fast completion times are a requirement, consider migrating the business logic to AWS Lambda and using a fan-out architecture.</li></ol>

# Manage blue/green deployments of microservices to multiple accounts and Regions by using AWS code services and AWS KMS multi-Region keys

Created by Balaji Vedagiri (AWS), Ashish Kumar (AWS), Faisal Shahdad (AWS), Anand Krishna Varanasi (AWS), Vanitha Dontireddy (AWS), and Vivek Thangamuthu (AWS)

**Code repository:** [ecs-blue-green-global-deployment-with-multiregion-cmk-codepipeline](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Containers & microservices

**AWS services:** AWS CloudFormation; AWS CodeBuild; AWS CodeDeploy; AWS CodePipeline; Amazon ECS

## Summary

This pattern describes how to deploy a global microservices application from a central AWS account to multiple workload accounts and Regions in accordance with a blue/green deployment strategy. The pattern supports the following:

- Software is developed in a central account, whereas workloads and applications are spread across multiple accounts and AWS Regions.
- A single AWS Key Management System (AWS KMS) multi-Region key is used for encryption and decryption to cover disaster recovery.
- The KMS key is Region-specific and has to be maintained or created in three different Regions for pipeline artifacts. A KMS multi-Region key helps retain the same key ID across Regions.
- The Git workflow branching model is implemented with two branches (development and main) and code is merged by using pull requests (PRs). The AWS Lambda function that is deployed from this stack creates a PR from the development branch to the main branch. The PR merge

to the main branch initiates an AWS CodePipeline pipeline, which orchestrates the continuous integration and continuous delivery (CI/CD) flow and deploys the stacks across accounts.

This pattern provides a sample infrastructure as code (IaC) setup through AWS CloudFormation stacks to demonstrate this use case. The blue/green deployment of microservices is implemented by using AWS CodeDeploy.

## Prerequisites and limitations

### Prerequisites

- Four active AWS accounts:
  - A tools account to manage the code pipeline and maintain the AWS CodeCommit repository.
  - Three workload (test) accounts for deploying the microservices workload.
- This pattern uses the following Regions. If you want to use other Regions, you must make the appropriate modifications to the AWS CodeDeploy and AWS KMS multi-Region stacks.
  - Tools (AWS CodeCommit) account: `ap-south-1`
  - Workload (test) account 1: `ap-south-1`
  - Workload (test) account 2: `eu-central-1`
  - Workload (test) account 3: `us-east-1`
- Three Amazon Simple Storage Service (Amazon S3) buckets for the deployment Regions in each workload account. (These are called `S3BUCKETNAMETESTACCOUNT1`, `S3BUCKETNAMETESTACCOUNT2` and `S3BUCKETNAMETESTACCOUNT3` later in this pattern.)

For example, you can create these buckets in specific accounts and Regions with unique bucket names as follows (replace `xxxx` with a random number):

```
##In Test Account 1
aws s3 mb s3://ecs-codepipeline-xxxx-ap-south-1 --region ap-south-1
##In Test Account 2
aws s3 mb s3://ecs-codepipeline-xxxx-eu-central-1 --region eu-central-1
##In Test Account 3
aws s3 mb s3://ecs-codepipeline-xxxx-us-east-1 --region us-east-1

#Example
##In Test Account 1
aws s3 mb s3://ecs-codepipeline-18903-ap-south-1 --region ap-south-1
##In Test Account 2
```

```
aws s3 mb s3://ecs-codepipeline-18903-eu-central-1 --region eu-central-1
##In Test Account 3
aws s3 mb s3://ecs-codepipeline-18903-us-east-1 --region us-east-1
```

## Limitations

The pattern uses AWS CodeBuild and other configuration files to deploy a sample microservice. If you have a different workload type (for example, serverless), you must update all relevant configurations.

## Architecture

### Target technology stack

- AWS CloudFormation
- AWS CodeCommit
- AWS CodeBuild
- AWS CodeDeploy
- AWS CodePipeline

### Target architecture

## Automation and scale

The setup is automated by using AWS CloudFormation stack templates (IaC). It can be easily scaled for multiple environments and accounts.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.

- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Additional tools

- [Git](#) is an open-source, distributed version control system that works with the AWS CodeCommit repository.
- [Docker](#) is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers. This pattern uses Docker to build and test container images locally.
- [cfn-lint](#) and [cfn-nag](#) are open-source tools that help you review CloudFormation stacks for any errors and security issues.

### Code repository
