# Monitor Amazon ECR repositories for wildcard permissions using AWS CloudFormation and AWS Config

Created by Vikrant Telkar (AWS), Sajid Momin (AWS), and Wassim Benhallam (AWS)

**Environment:** Production

**Technologies:** DevOps;  
Containers & microservices

**AWS services:** AWS  
CloudFormation; AWS Config;  
Amazon ECR; Amazon SNS;  
AWS Lambda

## Summary

On the Amazon Web Services (AWS) Cloud, Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that supports private repositories with resource-based permissions using AWS Identity and Access Management (IAM).

IAM supports the "\*" wildcard in both the resource and action attributes, which makes it easier to automatically choose multiple matching items. In your testing environment, you can allow all authenticated AWS users to access an Amazon ECR repository by using the `ecr : *` [wildcard permission](#) in a principal element for your [repository policy statement](#). The `ecr : *` wildcard permission can be useful when developing and testing in development accounts that can't access your production data.

However, you must make sure that the `ecr : *` wildcard permission is not used in your production environments because it can cause serious security vulnerabilities. This pattern's approach helps you to identify Amazon ECR repositories that contain the `ecr : *` wildcard permission in repository policy statements. The pattern provides steps and an AWS CloudFormation template to create a custom rule in AWS Config. An AWS Lambda function then monitors your Amazon ECR repository policy statements for `ecr : *` wildcard permissions. If it finds non-compliant repository policy statements, Lambda notifies AWS Config to send an event to Amazon EventBridge and EventBridge then initiates an Amazon Simple Notification Service (Amazon SNS) topic. The SNS topic notifies you by email about the non-compliant repository policy statements.

## Prerequisites and limitations

### Prerequisites

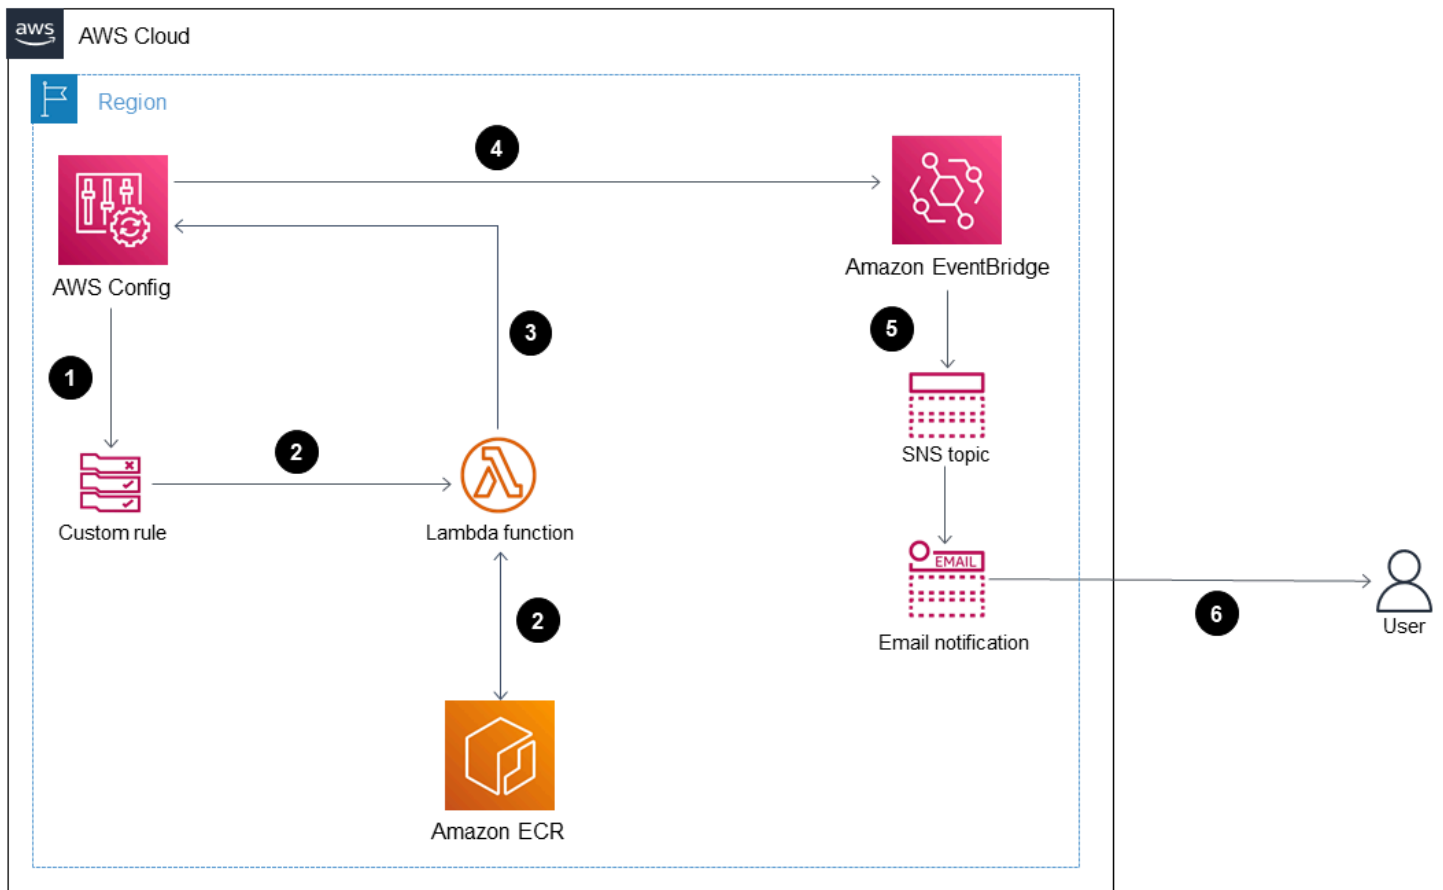

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see [Installing, updating, and uninstalling the AWS CLI](#) in the AWS CLI documentation.
- An existing Amazon ECR repository with an attached policy statement, installed and configured in your testing environment. For more information about this, see [Creating a private repository](#) and [Setting a repository policy statement](#) in the Amazon ECR documentation.
- AWS Config, configured in your preferred AWS Region. For more information about this, see [Getting started with AWS Config](#) in the AWS Config documentation.
- The `aws-config-cloudformation.template` file (attached), downloaded to your local machine.

## Limitations

- This pattern's solution is Regional and your resources must be created in the same Region.

## Architecture

The following diagram shows how AWS Config evaluates Amazon ECR repository policy statements.

The diagram shows the following workflow:

1. AWS Config initiates a custom rule.
2. The custom rule invokes a Lambda function to evaluate the compliance of the Amazon ECR repository policy statements. The Lambda function then identifies non-compliant repository policy statements.
3. The Lambda function sends the non-compliance status to AWS Config.
4. AWS Config sends an event to EventBridge.
5. EventBridge publishes the non-compliance notifications to an SNS topic.
6. Amazon SNS sends an email alert to you or an authorized user.

### Automation and scale

This pattern's solution can monitor any number of Amazon ECR repository policy statements, but all resources that you want to evaluate must be created in the same Region.

## Tools

- [AWS CloudFormation](#) – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- [AWS Config](#) – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.
- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.
- [Amazon EventBridge](#) – Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.
- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

## Code

The code for this pattern is available in the `aws-config-cloudformation.template` file (attached).

## Epics

### Create the AWS CloudFormation stack

Task	Description	Skills required
Create the AWS CloudFormation stack.	<p>Create an AWS CloudFormation stack by running the following command in AWS CLI:</p> <pre> \$ aws cloudformation create-stack --stack-n ame=AWSConfigECR \   --template-body   file://aws-config- cloudformation.tem plate \   --parameters   ParameterKey=&lt;emai l&gt;,ParameterValue= &lt;myemail@example.com&gt; \   --capabilities   CAPABILITY_NAMED_IAM </pre>	AWS DevOps

### Test the AWS Config custom rule

Task	Description	Skills required
Test the AWS Config custom rule.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console, open the AWS Config console, and then choose <b>Resources</b>.</li> <li>2. On the <b>Resource inventory</b> page, you can filter by resource category, resource</li> </ol>	AWS DevOps

Task	Description	Skills required
	<p>type, and compliance status.</p> <p>3. An Amazon ECR repository that contains <code>ecr:*</code> is NON-COMPLIANT? and an Amazon ECR repository that doesn't contain <code>ecr:*</code> is COMPLIANT .</p> <p>4. The email address subscribed to the SNS topic receives notifications if an Amazon ECR repository contains non-compliant policy statements.</p>

# Perform custom actions from AWS CodeCommit events

*Created by Abdullahi Olaoye (AWS)*

**Environment:** PoC or pilot

**Technologies:** DevOps;  
Management & governance

**AWS services:** AWS  
CodeCommit; Amazon SNS

## Summary

When you use an AWS CodeCommit repository to store code, you might want to monitor the repository and initiate a workflow of actions when specific events occur. For example, you might want to send an email notification when a user comments on a line of code in a commit, or initiate an AWS Lambda function to perform security scans on repository contents after a commit. This pattern outlines the steps for configuring a CodeCommit repository for custom actions. The pattern uses AWS CodeCommit notification rules to capture the events of interest, and then sends these events to a configured target.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Familiarity with Git commands.
- AWS CodeCommit, set up. For instructions, see [Setting up for AWS CodeCommit](#).
- (Recommended) AWS Command Line Interface (AWS CLI), installed and configured. For instructions, see [Getting started with the AWS CLI](#).

## Architecture

## Tools

### AWS services

- [AWS CodeCommit](#) is a fully-managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure
- [Amazon Simple Notification Service \(Amazon SNS\)](#) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, AWS Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

# Epics

## Set up a CodeCommit repository

Task	Description	Skills required
Create a CodeCommit repository.	Use the CodeCommit console or the AWS CLI to create a CodeCommit repository. For instructions, see <a href="#">Create a CodeCommit repository</a> .	DevOps engineer
Push content to the CodeCommit repository.	After you create a repository, add content to it by using Git commands. You can migrate the contents of an existing Git repository or local, unversioned content from your computer. For instructions, see <a href="#">Add files to your repository</a> or <a href="#">Migrate to AWS CodeCommit</a> .	DevOps engineer

## Set up Amazon SNS

Task	Description	Skills required
Create an SNS topic.	This SNS topic receives the events from CodeCommit. For instructions, see <a href="#">Creating an Amazon SNS topic</a> .	Cloud architect, DevOps engineer
Create a resource for a custom action.	For the custom action to be performed, you must create the corresponding resource. For example, if your custom action is to run Lambda code	Cloud architect, DevOps engineer

Task	Description	Skills required
	and send messages to an SQS queue, you must create the Lambda function and the SQS queue. Actions such as email and SMS notifications do not require resources. For more information, see the <a href="#">AWS documentation</a> for the type of resource you are creating.	
Subscribe the custom action resource to the SNS topic.	Depending on the custom action, you create a subscription for the appropriate protocol. For example, you subscribe an email address for email notification, a Lambda function to run custom code, or an SQS queue to send events to Amazon SQS. For subscription protocols like email and SMS, you need to confirm the subscription from the link that is sent to the email or telephone number, respectively. For instructions, see <a href="#">Subscribing to an Amazon SNS topic</a> .	Cloud architect, DevOps engineer

## Configure notification rules

Task	Description	Skills required
Create the notification rule for the CodeCommit repository.	When you create the notification rule, you select the Git events that should initiate the	DevOps engineer

Task	Description	Skills required
	<p>notification, select the SNS topic as the target type, and then select the SNS topic you created earlier. You can also configure multiple targets for the repository. For instructions, see <a href="#">Create a notification rule</a>.</p>	
Test custom actions.	<p>Perform one of the events that was configured to initiate the notification. For example, create a pull request if you selected that event as a trigger. You should see your custom action being performed. For example, if you subscribed an email address to the SNS topic, you should receive an email notification.</p>	DevOps engineer

# Publish Amazon CloudWatch metrics to a CSV file

Created by Abdullahi Olaoye (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps

**AWS services:** Amazon  
CloudWatch

## Summary

This pattern uses a Python script to retrieve Amazon CloudWatch metrics and to convert the metrics information into a comma-separated values (CSV) file for improved readability. The script takes the AWS service whose metrics should be retrieved as a required argument. You can specify the AWS Region and AWS credential profile as optional arguments. If you don't specify those arguments, the script uses the default Region and profile that are configured for the workstation where the script is run. After the script runs, it generates and stores a CSV file in the same directory.

See the *Attachments* section for the script and associated files provided with this pattern.

## Prerequisites and limitations

### Prerequisites

- Python 3.x
- AWS Command Line Interface (AWS CLI)

### Limitations

The script currently supports the following AWS services:

- AWS Lambda
- Amazon Elastic Compute Cloud (Amazon EC2)
  - By default, the script doesn't collect Amazon Elastic Block Store (Amazon EBS) volume metrics. To collect Amazon EBS metrics, you must modify the attached `metrics.yaml` file.
- Amazon Relational Database Service (Amazon RDS)
  - However, the script doesn't support Amazon Aurora.

- Application Load Balancer
- Network Load Balancer
- Amazon API Gateway

## Tools

- [Amazon CloudWatch](#) is a monitoring service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides data and actionable insights to help you monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, and provides a unified view of AWS resources, applications, and services that run on AWS and on-premises servers.

## Epics

### Install and configure the prerequisites

Task	Description	Skills required
Install the prerequisites.	Run the following command: <pre>\$ pip3 install -r requirements.txt</pre>	Developer
Configure the AWS CLI.	Run the following command: <pre>\$ aws configure</pre>	Developer

### Configure the Python script

Task	Description	Skills required
Open the script.	To change the default configuration of the script, open <code>metrics.yaml</code> .	Developer

Task	Description	Skills required
Set the period for the script.	<p>This is the time period to fetch. The default period is 5 minutes (300 seconds). You can change the time period, but note the following limitations:</p> <ul style="list-style-type: none"><li>• If the hours value that you specify is between 3 hours and 15 days ago, use a multiple of 60 seconds (1 minute) for the period.</li><li>• If the hours value that you specify is between 15 hours and 63 days ago, use a multiple of 300 seconds (5 minutes) for the period.</li><li>• If the hours value that you specify is greater than 63 days ago, use a multiple of 3,600 seconds (1 hour) for the period.</li></ul> <p>Otherwise, the API operation won't return any data points.</p>	Developer
Set the hours for the script.	<p>This value specifies how many hours of metrics you want to fetch. The default is 1 hour. To retrieve multiple days of metrics, provide the value in hours. For example, for 2 days, specify 48.</p>	Developer

Task	Description	Skills required
Change statistics values for the script.	(Optional) The global statistic s value is Average, which is used when fetching metrics that do not have a specific statistics value assigned. The script supports the statistics values Maximum, SampleCount , and Sum.	Developer

## Run the Python script

Task	Description	Skills required
Run the script.	<p>Use the following command:</p> <pre>\$ python3 cwreport.py &lt;service&gt;</pre> <p>To see a list of service values and the optional region and profile parameters, run the following command:</p> <pre>\$ python3 cwreport.py -h</pre> <p>For more information about the optional parameters, see the <i>Additional information</i> section.</p>	Developer

## Related resources

- [Configuring the AWS CLI](#)

- [Using Amazon CloudWatch metrics](#)
- [Amazon CloudWatch documentation](#)
- [EC2 CloudWatch Metrics](#)
- [AWS Lambda Metrics](#)
- [Amazon RDS Metrics](#)
- [Application Load Balancer Metrics](#)
- [Network Load Balancer Metrics](#)
- [Amazon API Gateway Metrics](#)

## Additional information

### Script usage

```
$ python3 cwreport.py -h
```

### Example syntax

```
python3 cwreport.py <service> <--region=Optional Region> <--profile=Optional credential profile>
```

### Parameters

- **service (required)** – The service you want to run the script against. The script currently supports these services: AWS Lambda, Amazon EC2, Amazon RDS, Application Load Balancer, Network Load Balancer, and API Gateway.
- **region (optional)** – The AWS Region to fetch metrics from. The default Region is ap-southeast-1.
- **profile (optional)** – The AWS CLI named profile to use. If this parameter isn't specified, the default configured credential profile is used.

### Examples

- To use the default Region ap-southeast-1 and default configured credentials to fetch Amazon EC2 metrics: `$ python3 cwreport.py ec2`

- To specify a Region and fetch API Gateway metrics: `$ python3 cwreport.py apigateway --region us-east-1`
- To specify an AWS profile and fetch Amazon EC2 metrics: `$ python3 cwreport.py ec2 --profile testprofile`
- To specify both Region and profile to fetch Amazon EC2 metrics: `$ python3 cwreport.py ec2 --region us-east-1 --profile testprofile`

# Run unit tests for Python ETL jobs in AWS Glue using the pytest framework

**Code repository:** [aws-glue-jobs-unit-testing](#)

**Environment:** Production

**Technologies:** DevOps; Big data; DevelopmentAndTesting

**AWS services:** AWS CloudFormation; AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; AWS Glue

## Summary

You can run unit tests for Python extract, transform, and load (ETL) jobs for AWS Glue in a [local development environment](#), but replicating those tests in a DevOps pipeline can be difficult and time consuming. Unit testing can be especially challenging when you're modernizing mainframe ETL process on AWS technology stacks. This pattern shows you how to simplify unit testing, while keeping existing functionality intact, avoiding disruptions to key application functionality when you release new features, and maintaining high-quality software. You can use the steps and code samples in this pattern to run unit tests for Python ETL jobs in AWS Glue by using the pytest framework in AWS CodePipeline. You can also use this pattern to test and deploy multiple AWS Glue jobs.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon Elastic Container Registry (Amazon ECR) image URI for your AWS Glue library, downloaded from the [Amazon ECR Public Gallery](#)
- Bash terminal (on any operating system) with a profile for the target AWS account and AWS Region
- [Python 3.10](#) or later

- [Pytest](#)
- [Moto](#) Python library for testing AWS services

## Architecture

### Technology stack

- Amazon Elastic Container Registry (Amazon ECR)
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- AWS Glue
- Pytest
- Python
- Python ETL library for AWS Glue

### Target architecture

The following diagram describes how to incorporate unit testing for AWS Glue ETL processes that are based on Python into a typical enterprise-scale AWS DevOps pipeline.

The diagram shows the following workflow:

1. In the source stage, CodePipeline uses a CodeCommit repository for source code, including a sample Python ETL job (`sample.py`), a unit test file (`test_sample.py`), and an AWS CloudFormation template. Then, CodePipeline transfers the most recent code from the main branch to the CodeBuild project for further processing.
2. In the build and publish stage, the most recent code from the previous source stage is unit tested with the help of an AWS Glue public Amazon ECR image. Then, the test report is published to CodeBuild report groups. The container image in the public Amazon ECR repository for AWS Glue libraries includes all the binaries required to run and unit test [PySpark-based](#) ETL tasks in AWS Glue locally. The public container repository has three image tags, one for each version supported by AWS Glue. For demonstration purposes, this pattern uses the `glue_libs_4.0.0_image_01` image tag. To use this container image as a runtime image in CodeBuild, copy the image URI that corresponds to the image tag that you intend to use, and then update the `pipeline.yml` file in the GitHub repository for the TestBuild resource.
3. In the deploy stage, the CodeBuild project is launched and it publishes the code to an Amazon Simple Storage Service (Amazon S3) bucket if all the tests pass.

4. The user deploys the AWS Glue task by using the CloudFormation template in the `deploy` folder.

## Tools

### AWS tools

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Glue](#) is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.

### Other tools

- [Python](#) is a high-level, interpreted general purpose programming language.
- [Moto](#) is a Python library for testing AWS services.
- [Pytest](#) is a framework for writing small unit tests that scale to support complex functional testing for applications and libraries.
- [Python ETL library](#) for AWS Glue is a repository for Python libraries that are used in the local development of PySpark batch jobs for AWS Glue.

### Code

The code for this pattern is available in the GitHub [aws-glue-jobs-unit-testing](#) repository. The repository includes the following resources:

- A sample Python-based AWS Glue job in the `src` folder
- Associated unit test cases (built using the `pytest` framework) in the `tests` folder
- A CloudFormation template (written in YAML) in the `deploy` folder

## Best practices

### Security for CodePipeline resources

It's a best practice to use encryption and authentication for the source repositories that connect to your pipelines in CodePipeline. For more information, see [Security best practices](#) in the CodePipeline documentation.

### Monitoring and logging for CodePipeline resources

It's a best practice to use AWS logging features to determine what actions users take in your account and what resources they use. The log files show the following:

- Time and date of actions
- Source IP address of actions
- Which actions failed due to inadequate permissions

Logging features are available in AWS CloudTrail and Amazon CloudWatch Events. You can use CloudTrail to log AWS API calls and related events made by or on behalf of your AWS account. For more information, see [Logging CodePipeline API calls with AWS CloudTrail](#) in the CodePipeline documentation.

You can use CloudWatch Events to monitor your AWS Cloud resources and applications running on AWS. You can also create alerts in CloudWatch Events. For more information, see [Monitoring CodePipeline events](#) in the CodePipeline documentation.

## Epics

### Deploy the source code

Task	Description	Skills required
Prepare the code archive for deployment.	1. Download code .zip from the GitHub <a href="#">aws-glue-jobs-unit-testing</a> repository, or create the .zip file yourself by using a command-line tool. For example, you	DevOps engineer

Task	Description	Skills required
	<p>can create the .zip file on Linux or Mac by running the following commands in the terminal:</p> <pre data-bbox="630 424 1029 823">git clone https://github.com/aws-samples/aws-glue-jobs-unit-testing.git cd aws-glue-jobs-unit-testing git checkout master zip -r code.zip src/ tests/ deploy/</pre> <ol style="list-style-type: none"><li data-bbox="591 840 1013 1016">2. Sign in to the <a href="#">AWS Management Console</a> and choose the AWS Region of your choice.</li><li data-bbox="591 1041 1029 1268">3. Create an <a href="#">S3 bucket</a>, and then upload the .zip package and code.zip file (downloaded earlier) to the S3 bucket that you created.</li></ol>	

Task	Description	Skills required
Create the CloudFormation stack.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 405">1. Sign in to the AWS Management Console and then open the <a href="#">CloudFormation console</a>.</li><li data-bbox="591 426 1027 604">2. Choose <b>Create stack</b>, and then choose <b>With existing resources (import resources)</b>.</li><li data-bbox="591 625 1027 993">3. In the <b>Specify template</b> section of the <b>Create stack</b> page, choose <b>Upload a template file</b>, and then choose the <b>pipeline.yml</b> template (downloaded from the GitHub repository). Then, choose <b>Next</b>.</li><li data-bbox="591 1014 1027 1192">4. For <b>Stack name</b>, enter <b>glue-unit-testing-pipeline</b>, or choose a stack name of your choice.</li><li data-bbox="591 1213 1027 1539">5. For <b>ApplicationStackName</b>, use the prepopulated <b>glue-codepipeline-app</b> name. This is the name of the CloudFormation stack that's created by the pipeline.</li><li data-bbox="591 1560 1027 1822">6. For <b>BranchName</b>, use the prepopulated <b>master</b> name. This is the name of the branch created in the CodeCommit repository to check in the code from</li></ol>	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<p>the .zip file for the S3 bucket.</p> <p>7. For <b>BucketName</b>, use the prepopulated <b>aws-glue-artifacts-us-east-1</b> bucket name. This is the name of the S3 bucket that contains the .zip file and is used by the pipeline to store code artifacts.</p> <p>8. For <b>CodeZipFile</b>, use the prepopulated <b>code.zip</b> value. This is the key name of the sample code S3 object. The object should be a .zip file.</p> <p>9. For <b>RepositoryName</b>, use the prepopulated <b>aws-glue-unit-testing</b> name. This is the name of the CodeCommit repository that's created by the stack.</p> <p>10 For <b>TestReportGroupName</b>, use the prepopulated <b>glue-unittest-report</b> name. This is the name of the CodeBuild test report group that's created to store the unit test reports.</p> <p>11 Choose <b>Next</b>, and then choose <b>Next</b> again on the <b>Configure stack options</b> page.</p>	

Task	Description	Skills required
	<p>12 On the <b>Review</b> page, under <b>Capabilities</b>, choose the <b>I acknowledge that CloudFormation might create IAM resources with custom names</b> option.</p> <p>13 Choose <b>Submit</b>. After the stack creation is complete, you can see the created resources on the <b>Resources</b> tab. The stack creation takes approximately 5-7 minutes.</p> <p>The stack automatically creates a CodeCommit repository with the initial code that was checked in from the .zip file and uploaded to the S3 bucket. Furthermore, the stack creates a CodePipeline view using the CodeCommit repository as the source. In the steps above, the CodeCommit repository is <b>aws-glue-unit-test</b>, and the pipeline is <b>aws-glue-unit-test-pipeline</b>.</p>	

Task	Description	Skills required
Clean up the resources in your environment.	<p>To avoid additional infrastructure costs, make sure that you delete the stack after experimenting with the examples provided in this pattern.</p> <ol style="list-style-type: none"> <li>1. Open the <a href="#">CloudFormation console</a>, and then select the stack that you created.</li> <li>2. Choose <b>Delete</b>. This deletes all the resources that your stack created, including CodeCommit repositories, AWS Identity and Access Management (IAM) roles or policies, and CodeBuild projects.</li> </ol>	AWS DevOps, DevOps engineer

## Run the unit tests

Task	Description	Skills required
Run the unit tests in the pipeline.	<ol style="list-style-type: none"> <li>1. To test the deployed pipeline, sign in to the AWS Management Console, and then open the <a href="#">CodePipeline console</a>.</li> <li>2. Select the pipeline created by the CloudFormation stack, and then choose <b>Release change</b>. The pipeline starts running (using the most recent</li> </ol>	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<p>code in the CodeCommit repository).</p> <ol style="list-style-type: none"> <li>3. After the <b>Test_and_Build</b> phase is finished, choose the <b>Details</b> tab, and then examine the logs.</li> <li>4. Choose the <b>Reports</b> tab, and then choose the test report from <b>Report history</b> to view the unit test results.</li> <li>5. After the deployment stage is complete, run and monitor the deployed AWS Glue job on the AWS Glue console. For more information, see <a href="#">Monitoring AWS Glue</a> in the AWS Glue documentation.</li> </ol>	

## Troubleshooting

Issue	Solution
<p>A pipeline with an Amazon S3, Amazon ECR, or CodeCommit source no longer starts automatically</p>	<p>If you change any configuration settings for an action that uses event rules in Amazon EventBridge or CloudWatch Events for change detection, the AWS Management Console might not detect a change where source identifiers are similar and have identical initial characters. Because the new event rule is not created by the console, the pipeline no longer starts automatically.</p>

Issue	Solution
	<p>For example, changing a CodeCommit branch name from <code>MyTestBranch-1</code> to <code>MyTestBranch-2</code> is a minor change. Because the change is at the end of the branch name, the event rule for the source action might not update or create a rule for the new source settings.</p> <p>This applies to the following source actions that use events in CloudWatch Events for change detection:</p> <ul style="list-style-type: none"><li>• The S3 bucket name and S3 object key parameters or console identifiers when the source action is in Amazon S3</li><li>• The repository name and image tag parameters or console identifiers when the source action is in Amazon ECR</li><li>• The repository name and branch name parameters or console identifiers when the source action is in CodeCommit</li></ul> <p>To resolve the issue, do one of the following:</p> <ul style="list-style-type: none"><li>• Change the configuration settings in Amazon S3, Amazon ECR, or CodeCommit, so that changes are made to the starting portion of the parameter value. For example, change your branch name from <code>release-branch</code> to <code>2nd-release-branch</code>. Avoid a change at the end of the name, such as <code>release-branch-2</code>.</li><li>• Change the configuration settings in Amazon S3, Amazon ECR, or CodeCommit for each pipeline. For example, change your</li></ul>

Issue	Solution
	<p>branch name from myRepo/myBranch to myDeployRepo/myDeployBranch . Avoid a change at the end of the name, such as myRepo/myBranch2 .</p> <ul style="list-style-type: none"><li>• Instead of using the AWS Management Console, use the AWS Command Line Interface (AWS CLI) or AWS CloudFormation to create and update your change-detection event rules. For instructions on creating event rules for an Amazon S3 source action, see <a href="#">Amazon S3 source actions and CloudWatch Events</a>. For instructions on creating event rules for an Amazon ECR action, see <a href="#">Amazon ECR source actions and CloudWatch Events</a>. For instructions on creating event rules for a CodeCommit action, see <a href="#">CodeCommit source actions and CloudWatch Events</a>. After you edit your action configuration in the console, accept the updated change-detection resources created by the console.</li></ul>

## Additional information

Additionally, you can deploy the AWS CloudFormation templates by using AWS CLI. For more information, see [Quickly deploying templates with transforms](#) in the CloudFormation documentation.

# Set up a Helm v3 chart repository in Amazon S3

Created by Abhishek Sharma (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps;  
Containers & microservices;  
Modernization

**Workload:** All other  
workloads

**AWS services:** Amazon S3

## Summary

This pattern helps you to manage Helm v3 charts efficiently by integrating the Helm v3 repository into Amazon Simple Storage Service (Amazon S3) on the Amazon Web Services (AWS) Cloud. To use this pattern, you must be familiar with Kubernetes and with Helm, which is a Kubernetes package manager. Using Helm repositories to store charts and control chart versions can improve mean time to restore (MTTR) during outages.

This pattern uses AWS CodeCommit for Helm repository creation, and it uses an S3 bucket as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Python version 2.7.12 or later
- pip
- A virtual private cloud (VPC) with subnets and an Amazon Elastic Compute Cloud (Amazon EC2) instance
- Git installed on the EC2 instance
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmable or role) access to Amazon S3 from the client machine

- AWS CodeCommit repository
- AWS Command Line Interface (AWS CLI)

### **Product versions**

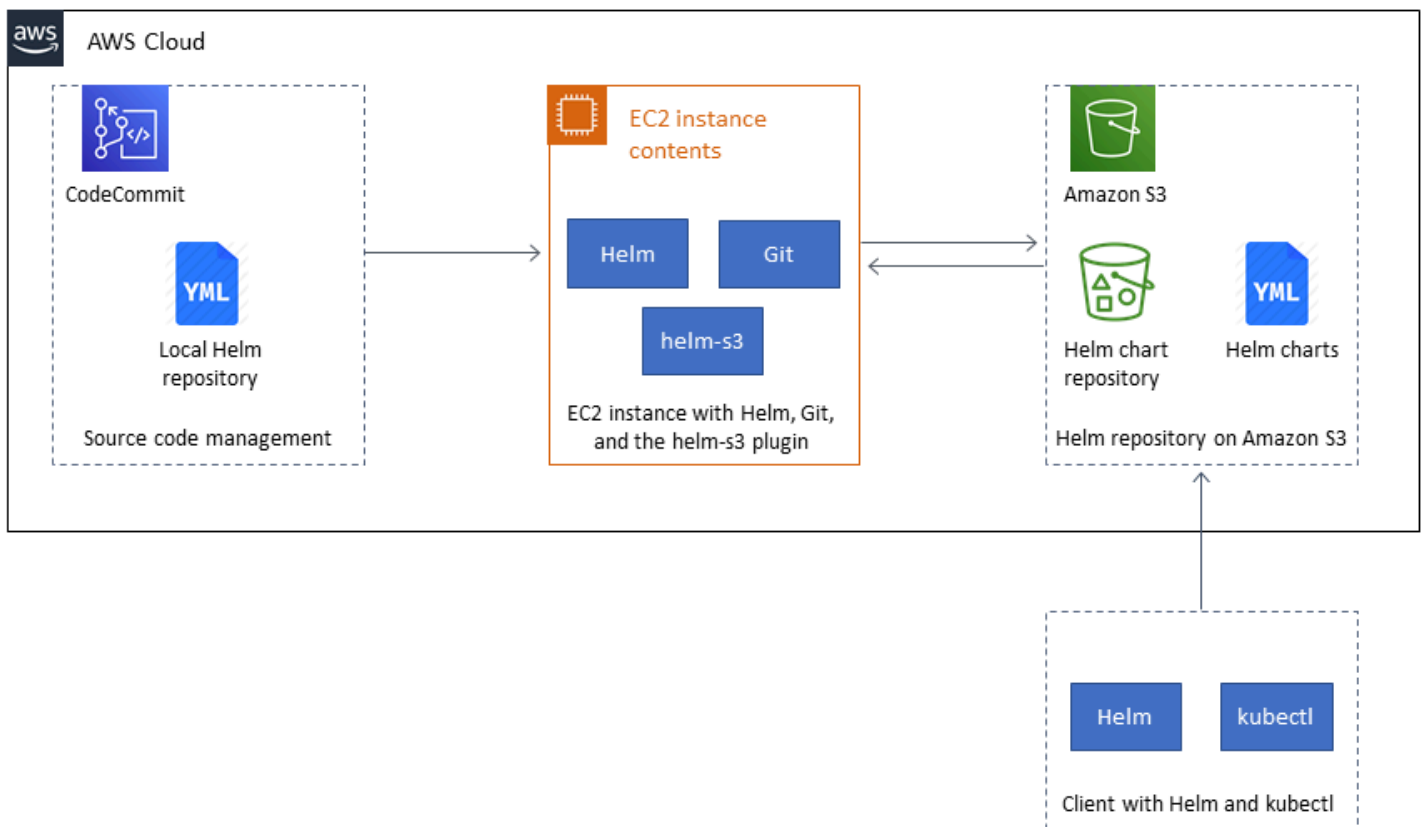

- Helm v3
- Python version 2.7.12 or later

## **Architecture**

### **Target technology stack**

- Amazon S3
- AWS CodeCommit
- Helm
- Kubectl
- Python and pip
- Git
- helm-s3 plugin

### **Target architecture**

## Automation and scale

- You can incorporate Helm into your existing continuous integration/continuous delivery (CI/CD) automation tool to automate the packaging and version control of Helm charts (out of scope for this pattern).
- GitVersion or Jenkins build numbers can be used to automate version control of the charts.

## Tools

- [Helm](#) – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- [helm-s3 plugin](#) – The helm-s3 plugin supports interaction with Amazon S3. It can be used with either Helm v2 or Helm v3.

## Best practices

< **Author remove these notes:** Provide a list of guidelines and recommendations that can help users implement this pattern more effectively.>

## Epics

### Install and validate Helm v3

Task	Description	Skills required
Install the Helm v3 client.	To download and install the Helm client on your local system, run the following command: <pre>sudo curl https://raw.githubusercontent.com/helm/helm/main/scripts/get-helm-3   bash</pre>	Cloud Administrator, DevOps Engineer
Validate the Helm installation.	To validate the Helm client, run the following command: <pre>helm version --short</pre>	Cloud Administrator, DevOps Engineer

### Initialize an S3 bucket as a Helm repository

Task	Description	Skills required
Create an S3 bucket for Helm charts.	Create a unique S3 bucket. In the bucket, create a folder called <code>stable/myapp</code> . The example in this pattern uses <code>s3://my-helm-charts/stable/myapp</code> as the target chart repository.	Cloud Administrator, DevOps Engineer

Task	Description	Skills required
Install the helm-s3 plugin for Amazon S3.	To install the helm-s3 plugin on your client machine, run the following command: <pre>helm plugin install https://github.com/hypnoglow/helm-s3.git</pre>	Cloud Administrator, DevOps Engineer
Initialize the Amazon S3 Helm repository.	To initialize the target folder as a Helm repository, use the following command: <pre>helm s3 init s3://my-helm-charts/stable/myapp</pre> The command creates an <code>index.yaml</code> file in the target to track all the chart information that is stored at that location.	Cloud Administrator, DevOps Engineer
Verify the newly created Helm repository.	To verify that the <code>index.yaml</code> file was created, run the following command: <pre>aws s3 ls s3://my-helm-charts/stable/myapp/</pre>	Cloud Administrator, DevOps Engineer
Add the Amazon S3 repository to Helm on the client machine.	To add the target repository alias to the Helm client machine, use the following command: <pre>helm repo add stable-myapp s3://my-helm-charts/stable/myapp/</pre>	Cloud Administrator, DevOps Engineer

## Package and publish charts in the Amazon S3 Helm repository

Task	Description	Skills required
Clone your Helm charts.	If no local Helm charts are present on in your CodeCommit repository, clone them from your GitHub repo by running the following command: <code>git clone &lt;url_of_your_helm_source_code&gt;.git</code>	Cloud Administrator, DevOps Engineer
Package the local Helm chart.	To package the chart that you created or cloned, use the following command: <code>helm package ./my-app</code>  As an example, this pattern uses the <code>my-app</code> chart. The command packages all the contents of the <code>my-app</code> chart folder into an archive file, which is named using the version number that is mentioned in the <code>Chart.yaml</code> file.	Cloud Administrator, DevOps Engineer
Store the local package in the Amazon S3 Helm repository.	To upload the local package to the Helm repository in Amazon S3, run the following command: <code>helm s3 push ./my-app-0.1.0.tgz stable-my-app</code>  In the command, <code>my-app</code> is your chart folder name,	Cloud Administrator, DevOps Engineer

Task	Description	Skills required
	0.1.0 is the chart version mentioned in <code>Chart.yaml</code> , and <code>stable-myapp</code> is the target repository alias.	
Search for the Helm chart.	To confirm that the chart appears both locally and in the Amazon S3 Helm repository, run the following command: <code>helm search repo stable-myapp</code>	Cloud Administrator, DevOps Engineer

## Upgrade your Helm repository

Task	Description	Skills required
Modify and package the chart.	In <code>values.yaml</code> , set the <code>replicaCount</code> value to 1, and then package the chart, this time changing the version in <code>Chart.yaml</code> to 0.1.1. Version control is ideally achieved through automation by using tools like GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern. To package the chart, run the following command: <code>helm package ./my-app/</code>	Cloud Administrator, DevOps Engineer
Push the new version to the Helm repository in Amazon S3.	To push the new package, version of 0.1.1, to the <code>my-helm-charts</code> Helm repository	Cloud Administrator, DevOps Engineer

Task	Description	Skills required
	<p>y in Amazon S3, run the following command:</p> <pre>helm s3 push ./my-app-0.1.1.tgz stable-myapp</pre>	
Verify the updated Helm chart.	<p>To confirm that the updated chart appears both locally and in the Amazon S3 Helm repository, run the following commands.</p> <pre>helm repo update</pre> <pre>helm search repo stable-myapp</pre>	Cloud Administrator, DevOps Engineer

### Search for and install a chart from the Amazon S3 Helm repository

Task	Description	Skills required
Search for all versions of the my-app chart.	<p>To view all the available versions of a chart, run the following command with the <code>--versions</code> flag:</p> <pre>helm search repo my-app --versions</pre> <p>Without the flag, Helm by default displays the latest uploaded version of a chart.</p>	DevOps Engineer
Install a chart from the Amazon S3 Helm repository.	<p>Automated installation is out of scope for this pattern, but you can manually install. The search results from</p>	DevOps Engineer

Task	Description	Skills required
	<p>the previous task show the multiple versions of the my-app chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command:</p> <pre>helm upgrade --install my-app-release stable-myapp/my-app --version 0.1.1 --namespace dev</pre>	

## Roll back to a previous version by using Helm

Task	Description	Skills required
<p>Review the details for a specific revision.</p>	<p>Automated rollback is out of scope for this pattern, but you can roll back to an earlier version manually. Before you switch or roll back to a working version, and for an additional layer of validation before installing a revision, view which values were passed to each of the revisions by using the following command:</p> <pre>helm get values --revision=2 my-app-release</pre>	<p>DevOps Engineer</p>
<p>Roll back to a previous version.</p>	<p>Automated rollback is out of scope for this pattern. To manually roll back to a</p>	<p>DevOps Engineer</p>

Task	Description	Skills required
	<pre>previous revision, use the following command: helm rollback my-app-re lease 1</pre> <p>This example is rolling back to revision number 1.</p>

# Set up a CI/CD pipeline by using AWS CodePipeline and AWS CDK

Created by Konstantin Zarudaev (AWS), Cizer Pereira (AWS), Lars Kinder (AWS), and Yasha Dabas (AWS)

<b>Code repository:</b> <a href="#">AWS CodePipeline with CI/CD</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> DevOps
<b>Workload:</b> Open-source	<b>AWS services:</b> AWS CodePipeline	

## Home

Automating your software build and release process with continuous integration and continuous delivery (CI/CD) supports repeatable builds and rapid delivery of new features to your users. You can quickly and easily test each code change, and you can catch and fix bugs before releasing your software. By running each change through your staging and release process, you can verify the quality of your application or infrastructure code. CI/CD embodies a culture, a set of operating principles, and a [collection of practices](#) that help application development teams to deliver code changes more frequently and reliably. The implementation is also known as the *CI/CD pipeline*.

This pattern defines a reusable continuous integration and continuous delivery (CI/CD) pipeline on Amazon Web Services (AWS). The AWS CodePipeline pipeline is written using [AWS Cloud Development Kit \(AWS CDK\) v2](#).

Using CodePipeline, you can model the different stages of your software release process through the AWS Management Console interface, the AWS Command Line Interface (AWS CLI), AWS CloudFormation, or the AWS SDKs. This pattern demonstrates the implementation of CodePipeline and its components using AWS CDK. In addition to construct libraries, AWS CDK includes a toolkit (the CLI command `cdk`), which is the primary tool for interacting with your AWS CDK app. Among other functions, the toolkit provides the ability to convert one or more stacks to CloudFormation templates and deploy them to an AWS account.

The pipeline includes tests to validate the security of your third-party libraries, and it helps ensure expedited, automated release in the specified environments. You can increase the overall security of your applications by putting them through a validation process.

The intent of this pattern is to accelerate your use of CI/CD pipelines to deploy your code while ensuring the resources you deploy adhere to DevOps best practices. After you implement the [example code](#), you will have an [AWS CodePipeline](#) with linting, testing, a security check, deployment, and post-deployment processes. This pattern also includes steps for Makefile. Using a Makefile, developers can reproduce CI/CD steps locally and increase the velocity of the development process.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A basic understanding in the following:
  - AWS CDK
  - AWS CloudFormation
  - AWS CodePipeline
  - TypeScript

### Limitations

This pattern uses [AWS CDK](#) for TypeScript only. It doesn't cover other languages supported by AWS CDK.

### Product versions

Use the latest versions of the following tools:

- AWS Command Line Interface (AWS CLI)
- cfn\_nag
- git-remote-codecommit
- Node.js

# Architecture

## Target technology stack

- AWS CDK
- AWS CloudFormation
- AWS CodeCommit
- AWS CodePipeline

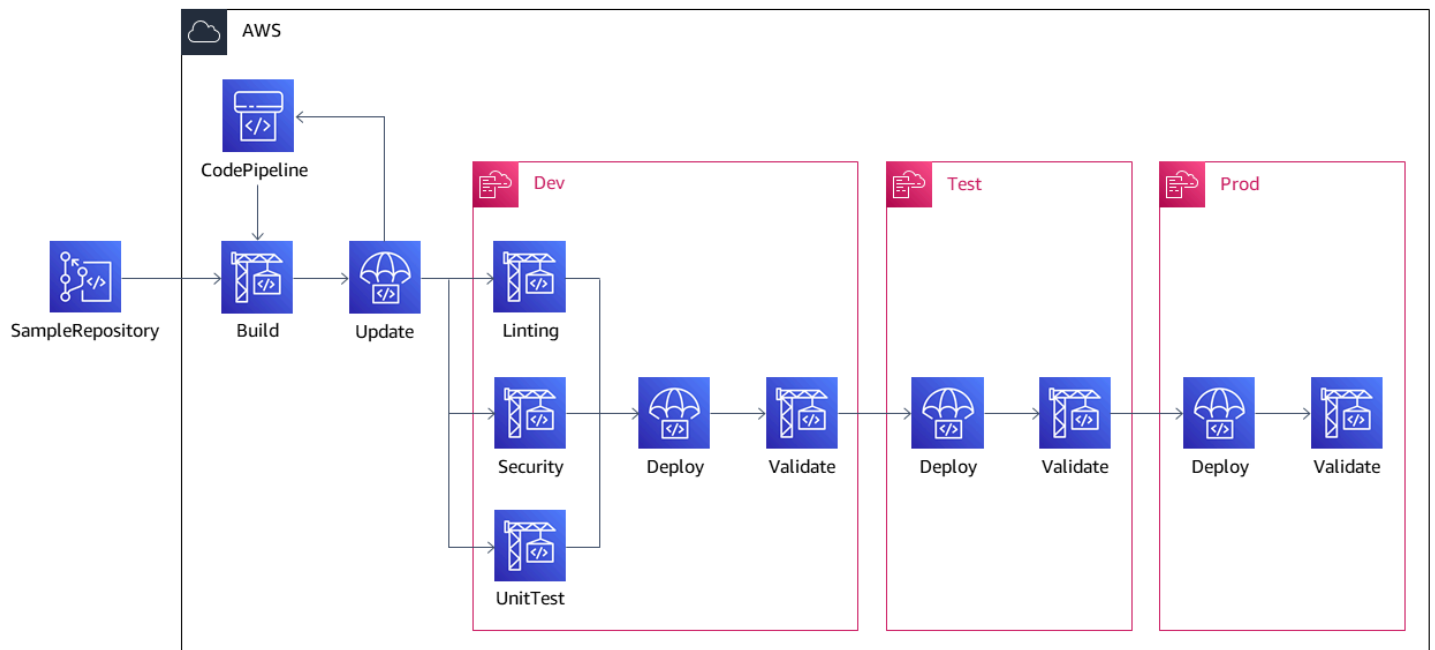

## Target architecture

The pipeline is triggered by a change in the AWS CodeCommit repository (`SampleRepository`). In the beginning, CodePipeline builds artifacts, updates itself, and starts the deployment process. The resulting pipeline deploys a solution to three independent environments:

- Dev – Three-step code check in the active development environment
- Test – Integration and regression test environment
- Prod – Production environment

The three steps included in the Dev stage are linting, security, and unit tests. These steps run in parallel to speed up the process. To ensure that the pipeline provides only working artifacts, it will stop running whenever a step in the process fails. After a Dev stage deployment, the pipeline runs validation tests to verify the results. In the case of success, the pipeline will then deploy the artifacts to the Test environment, which contains post-deployment validation. The final step is to deploy the artifacts to the Prod environment.

The following diagram shows the workflow from the CodeCommit repository to the build and update processes performed by CodePipeline, the three Dev environment steps, and subsequent deployment and validation in each of the three environments.

## Tools

### AWS services

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. In this pattern CloudFormation templates can be used to create a CodeCommit repository and a CodePipeline CI/CD pipeline.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) is a CI/CD service that helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

### Other tools

- [cfn\\_nag](#) is an open-source tool that looks for patterns in CloudFormation templates to identify potential security issues.
- [git-remote-codecommit](#) is a utility for pushing and pulling code from CodeCommit repositories by extending Git.
- [Node.js](#) is an event-driven JavaScript runtime environment designed for building scalable network applications.

## Code

The code for this pattern is available in the GitHub [AWS CodePipeline with CI/CD practices](#) repository.

## Best practices

Review resources, such as AWS Identity and Access Management (IAM) policies, to confirm that they align with your organizational best practices.

## Epics

### Install tools

Task	Description	Skills required
Install tools on macOS or Linux.	<p>If you are using MacOS or Linux, you can install the tools by running the following command in your preferred terminal or using <a href="#">Homebrew for Linux</a>.</p> <pre>brew install brew install git-remot e-codecommit brew install ruby brew- gem brew-gem install cfn- nag</pre>	DevOps engineer

Task	Description	Skills required
Install tools using AWS Cloud9.	<p>If you are using <a href="#">AWS Cloud9</a>, install the tools by running the following command.</p> <pre>gem install cfn-nag</pre> <p><b>Note:</b> AWS Cloud9 should have Node.js and npm installed. To check the installation or version, run the following command.</p> <pre>node -v npm -v</pre>	DevOps engineer
Set up AWS CLI.	<p>To set up AWS CLI, use the instructions for your operating system:</p> <ul style="list-style-type: none"><li>• Windows: <a href="#">Setup steps for HTTPS connections to AWS CodeCommit repositories on Windows with the AWS CLI credential helper</a></li><li>• Linux, macOS, Unix: <a href="#">Setup steps for HTTPS connections to AWS CodeCommit repositories on Linux, macOS, or Unix with the AWS CLI credential helper</a></li></ul>	DevOps engineer

## Set up the initial deployment

Task	Description	Skills required
	<p>Download or clone the code.</p> <p>To get the code that is used by this pattern, do one of the following:</p> <ul style="list-style-type: none"><li>• Download the latest source code from <a href="#">releases</a> in the GitHub repo, and unzip the downloaded file into a folder.</li><li>• Clone the project by running the following command.</li></ul> <pre data-bbox="594 957 1027 1157">git clone --depth 1 https://github.com/aws-samples/aws-codepipeline-cicd.git</pre> <p>Remove the <code>.git</code> directory from the cloned repository.</p> <pre data-bbox="594 1314 1027 1476">cd ./aws-codepipeline-cicd rm -rf ./git</pre> <p>Later, you will use a newly created AWS CodeCommit repository as a remote origin.</p>	DevOps engineer
Connect to the AWS account.	You can connect by using a temporary security token or landing zone authentication. To confirm that you are using	DevOps engineer

Task	Description	Skills required
	<p>the correct account and AWS Region, run the following commands.</p> <pre>AWS_REGION="eu-west-1" ACCOUNT_NUMBER=\$(aws   sts get-caller-identit   y --query Account --   output text) echo "\${ACCOUNT   T_NUMBER}"</pre>	
<p>Bootstrap the environment.</p>	<p>To bootstrap an AWS CDK environment, run the following commands.</p> <pre>npm install npm run cdk bootstrap "aws://\${ACCOUNT_N   UMBER}/\${AWS_REGION}"</pre> <p>After you successfully bootstrap the environment, the following output should be displayed.</p> <pre># Bootstrapping   environment aws://{ac   count}/{region}... # Environment aws://   {account}/{region}   bootstrapped</pre> <p>For more information about AWS CDK bootstrapping, see the <a href="#">AWS CDK documentation</a>.</p>	<p>DevOps engineer</p>

Task	Description	Skills required
Synthesize a template.	<p>To synthesize an AWS CDK app, use the <code>cdk synth</code> command.</p> <pre data-bbox="594 394 1027 474">npm run cdk synth</pre> <p>You should see the following output.</p> <pre data-bbox="594 632 1027 1024">Successfully synthesized to &lt;path-to-directory&gt;/aws-codepipeline-cicd/cdk.out Supply a stack id (CodePipeline, DevMainStack) to display its template.</pre>	DevOps engineer

Task	Description	Skills required
Deploy the CodePipeline stack.	<p>Now that you bootstrapped and synthesized the CloudFormation template, you can deploy it. The deployment will create the CodePipeline pipeline and a CodeCommit repository, which will be the source and trigger of the pipeline.</p> <pre data-bbox="594 680 1029 840">npm run cdk -- deploy CodePipeline --require -approval never</pre> <p>After you run the command, you should see a successful deployment of the CodePipeline stack and output information. The <code>CodePipeline.RepositoryName</code> gives you the name of the CodeCommit repository in the AWS account.</p> <pre data-bbox="594 1331 1029 1860">CodePipeline: deploying ... CodePipeline: creating CloudFormation changeset... # CodePipeline Outputs: CodePipeline.R epositoryName = SampleRepository Stack ARN: arn:aws:cloudformation :REGION:ACCOUNT-ID</pre>	DevOps engineer

Task	Description	Skills required
	<code>:stack/CodePipeline/ STACK-ID</code>	

Task	Description	Skills required
Set up the remote CodeCommit repository and branch.	<p>After a successful deployment, CodePipeline will initiate the first run of the pipeline, which you can find in the <a href="#">AWS CodePipeline console</a>. Because AWS CDK and CodeCommit don't initiate a default branch, this initial pipeline run will fail and return the following error message.</p> <pre data-bbox="597 779 1027 1171">The action failed because no branch named main was found in the selected AWS CodeComm it repository SampleRep ository. Make sure you are using the correct branch name, and then try again. Error: null</pre> <p>To fix this error, set up a remote origin as SampleRepository , and create the required main branch.</p> <pre data-bbox="597 1430 1027 1877">RepoName=\$(aws cloudformation describe-stacks -- stack-name CodePipel ine --query "Stacks[0 ].Outputs[?OutputK ey=='RepositoryNam e'].OutputValue" -- output text) echo "\${RepoName}" #</pre>	DevOps engineer

Task	Description	Skills required
	<pre>git init git branch -m master main git remote add origin codecommit://\${RepoName} git add . git commit -m "Initial commit" git push -u origin main</pre>	

### Test the deployed CodePipeline pipeline

Task	Description	Skills required
Commit a change to activate the pipeline.	<p>After a successful initial deployment, you should have a complete CI/CD pipeline with a main branch for <code>SampleRepository</code> as a source branch. As soon as you commit changes to the main branch, the pipeline will initiate and run the following sequence of actions:</p> <ol style="list-style-type: none"> <li>1. Get your code from the CodeCommit repository.</li> <li>2. Build your code.</li> <li>3. Update the pipeline itself (<code>UpdatePipeline</code> ).</li> <li>4. Run three parallel jobs for linting, security and unit test checks.</li> </ol>	DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>5. In the case of success, the pipeline will deploy the Main stack from <code>./lib/main-stack.ts</code> to the Dev environment.</li> <li>6. Run a post-deployment check for deployed resources. You can follow all CodePipeline steps and results in the CodePipeline console.</li> <li>7. In the case of success, the pipeline will repeat deployment and validation for the Test and Prod environments.</li> </ol>	

### Test locally by using a Makefile

Task	Description	Skills required
<p>Run the development process by using a Makefile.</p>	<p>You can run the whole pipeline locally by using the <code>make</code> command, or you can run an individual step (for example, <code>make linting</code>).</p> <p>To test using <code>make</code>, perform the following actions:</p> <ul style="list-style-type: none"> <li>• Implement the local pipeline: <code>make</code></li> <li>• Run only unit testing: <code>make unittest</code></li> </ul>	<p>App developer, DevOps engineer</p>

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• Deploy to the current account: <code>make deploy</code></li> <li>• Clean up the environment: <code>make clean</code></li> </ul>	

## Clean up resources

Task	Description	Skills required
Delete AWS CDK app resources.	<p>To clean up your AWS CDK app, run the following command.</p> <pre>cdk destroy --all</pre> <p>Be aware that the Amazon Simple Storage Service (Amazon S3) buckets that are created during bootstrapping aren't automatically deleted. They need a retention policy that allows deletion, or you need to delete them manually in your AWS account.</p>	DevOps engineer

## Troubleshooting

Issue	Solution
The template isn't working as expected.	<p>If something goes wrong and template is not working, make sure that you have the following:</p> <ul style="list-style-type: none"> <li>• The proper versions of the tools.</li> </ul>

Issue	Solution
	<ul style="list-style-type: none"><li data-bbox="831 214 1485 296">• Access to the target AWS account (network connectivity).</li><li data-bbox="831 317 1421 399">• Enough permissions to the target AWS account.</li></ul>

# Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let's Encrypt

Created by Mahendra Siddappa (AWS) and Vasanth Jeyaraj (AWS)

**Code repository:** [End-to-end encryption on Amazon EKS](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Containers & microservices; Security, identity, compliance

**Workload:** All other workloads

**AWS services:** Amazon EKS; Amazon Route 53

## Summary

Implementing end-to-end encryption can be complex and you need to manage certificates for each asset in your microservices architecture. Although you can terminate the Transport Layer Security (TLS) connection at the edge of the Amazon Web Services (AWS) network with a Network Load Balancer or Amazon API Gateway, some organizations require end-to-end encryption.

This pattern uses NGINX Ingress Controller for ingress. This is because when you create a Kubernetes ingress, the ingress resource uses a Network Load Balancer. The Network Load Balancer doesn't permit uploads of client certificates. Therefore, you can't achieve mutual TLS with Kubernetes ingress.

This pattern is intended for organizations that require mutual authentication between all microservices in their applications. Mutual TLS reduces the burden of maintaining user names or passwords and can also use the turnkey security framework. This pattern's approach is compatible if your organization has a large number of connected devices or must comply with strict security guidelines.

This pattern helps increase your organization's security posture by implementing end-to-end encryption for applications running on Amazon Elastic Kubernetes Service (Amazon EKS). This pattern provides a sample application and code in the GitHub [End-to-end encryption on Amazon EKS](#) repository to show how a microservice runs with end-to-end encryption on Amazon EKS. The pattern's approach uses [cert-manager](#), an add-on to Kubernetes, with [Let's Encrypt](#) as the

certificate authority (CA). Let's Encrypt is a cost-effective solution to manage certificates and provides free certificates that are valid for 90 days. Cert-manager automates the on-demand provisioning and rotating of certificates when a new microservice is deployed on Amazon EKS.

## Intended audience

This pattern is recommended for users who have experience with Kubernetes, TLS, Amazon Route 53, and Domain Name System (DNS).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing Amazon EKS cluster.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
- The `kubectl` command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see [Installing kubectl](#) in the Amazon EKS documentation.
- An existing DNS name to test the application. For more information about this, see [Registering domain names using Amazon Route 53](#) in the Amazon Route 53 documentation.
- The latest [Helm](#) version, installed on your local machine. For more information about this, see [Using Helm with Amazon EKS](#) in the Amazon EKS documentation and the GitHub [Helm](#) repository.
- The GitHub [End-to-end encryption on Amazon EKS](#) repository, cloned to your local machine.
- Replace the following values in the `policy.json` and `trustpolicy.json` files from the cloned GitHub [End-to-end encryption on Amazon EKS](#) repository:
  - `<account number>` – Replace with the AWS account ID for the account that you want to deploy the solution in.
  - `<zone id>` – Replace with the domain name's Route 53 zone ID.
  - `<node_group_role>` – Replace with the name of the AWS Identity and Access Management (IAM) role associated with the Amazon EKS nodes.
  - `<namespace>` – Replace with the Kubernetes namespace in which you deploy the NGINX Ingress Controller and the sample application.
  - `<application-domain-name>` – Replace with the DNS domain name from Route 53.

## Limitations

- This pattern doesn't describe how to rotate certificates and only demonstrates how to use certificates with microservices on Amazon EKS.

## Architecture

The following diagram shows the workflow and architecture components for this pattern.

The diagram shows the following workflow:

- A client sends a request to access the application to the DNS name.
- The Route 53 record is a CNAME to the Network Load Balancer.
- The Network Load Balancer forwards the request to the NGINX Ingress Controller that is configured with a TLS listener. Communication between the NGINX Ingress Controller and the Network Load Balancer follows HTTPS protocol.
- The NGINX Ingress Controller carries out path-based routing based on the client's request to the application service.
- The application service forwards the request to the application pod. The application is designed to use the same certificate by calling secrets.

6. Pods run the sample application using the cert-manager certificates. The communication between the NGINX Ingress Controller and the pods uses HTTPS.

**Note:** Cert-manager runs in its own namespace. It uses a Kubernetes cluster role to provision certificates as secrets in specific namespaces. You can attach those namespaces to application pods and NGINX Ingress Controller.

## Tools

### AWS services

- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- [Elastic Load Balancing](#) automatically distributes your incoming traffic across multiple targets, containers, and IP addresses.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

### Other tools

- [cert-manager](#) is an add-on to Kubernetes that requests certificates, distributes them to Kubernetes containers, and automates certificate renewal.
- [NGINX Ingress Controller](#) is a traffic management solution for cloud-native apps in Kubernetes and containerized environments.

## Epics

### Create and configure a public hosted zone with Route 53

Task	Description	Skills required
Create a public hosted zone in Route 53.	<p>Sign in to the AWS Management Console, open the Amazon Route 53 console, choose <b>Hosted zones</b>, and then choose <b>Create hosted zone</b>. Create a public hosted zone and record the zone ID. For more information about this, see <a href="#">Creating a public hosted zone</a> in the Amazon Route 53 documentation.</p> <p><b>Note:</b> ACME DNS01 uses the DNS provider to post a challenge for cert-manager to issue the certificate. This challenge asks you to prove that you control the DNS for your domain name by putting a specific value in a TXT record under that domain name. After Let's Encrypt gives your ACME client a token, your client creates a TXT record derived from that token and your account key, and it puts that record at <code>_acme-challenge.&lt;YOURDOMAIN&gt;</code>. Then Let's Encrypt queries the DNS</p>	AWS DevOps

Task	Description	Skills required
	for that record. If it finds a match, you can proceed to issue a certificate.	

## Configure an IAM role to allow cert-manager to access the public hosted zone

Task	Description	Skills required
Create the IAM policy for cert-manager.	<p>An IAM policy is required to provide cert-manager with permission to validate that you own the Route 53 domain. The <code>policy.json</code> sample IAM policy is provided in the <code>1-IAMRole</code> directory in the cloned GitHub <a href="#">End-to-end encryption on Amazon EKS</a> repository.</p> <p>Enter the following command in AWS CLI to create the IAM policy.</p> <pre>aws iam create-policy \   --policy-name   PolicyForCertManager   \   --policy-document   file://policy.json</pre>	AWS DevOps
Create the IAM role for cert-manager.	After you create the IAM policy, you must create an IAM role. The <code>trustpolicy.json</code> sample IAM role is	AWS DevOps

Task	Description	Skills required
	<p>provided in the 1-IAMRole directory.</p> <p>Enter the following command in AWS CLI to create the IAM role.</p> <pre>aws iam create-role \   --role-name RoleForCertManager \   --assume-role-policy-document file://trustpolicy.json</pre>	
Attach the policy to the role.	<p>Enter the following command in AWS CLI to attach the IAM policy to the IAM role. Replace <code>AWS_ACCOUNT_ID</code> with the ID of your AWS account.</p> <pre>aws iam attach-role-policy \   --policy-arn arn:aws:iam::AWS_ACCOUNT_ID:policy/PolicyForCertManager \   --role-name RoleForCertManager</pre>	AWS DevOps

## Set up the NGINX Ingress Controller in Amazon EKS

Task	Description	Skills required
Deploy the NGINX Ingress Controller.	Install the most recent version of <code>nginx-ingress</code>	AWS DevOps

Task	Description	Skills required
	<p>using Helm. You can modify the <code>nginx-ingress</code> configuration according to your requirements before deploying it. This pattern uses an annotated, internal-facing Network Load Balancer and that is available in the <code>5-Nginx-Ingress-Controller</code> directory.</p> <p>Install the NGINX Ingress Controller by running the following Helm command from the <code>5-Nginx-Ingress-Controller</code> directory.</p> <pre>helm install test-nginx nginx-stable/nginx-ingress -f 5-Nginx-Ingress-Controller/values_internal_nlb.yaml</pre>	
Verify that the NGINX Ingress Controller is installed.	Enter the <code>helm list</code> command. The output should show that the NGINX Ingress Controller is installed.	AWS DevOps

Task	Description	Skills required
Create a Route 53 A record.	<p>The A record points to the Network Load Balancer created by NGINX Ingress Controller.</p> <ol style="list-style-type: none"><li>1. Get the DNS name of the Network Load Balancer. For instructions, see <a href="#">Getting the DNS name for an ELB load balancer</a>.</li><li>2. On the Amazon Route 53 console, choose <b>Hosted Zones</b>.</li><li>3. Select the public hosted zone that you want to create the record in, and then choose <b>Create record</b>.</li><li>4. Enter a name for the record.</li><li>5. In <b>Record type</b>, choose <b>A - Routes traffic to IPv4 and some AWS resources</b>.</li><li>6. Enable <b>Alias</b>.</li><li>7. In <b>Route traffic to</b>, do the following:<ol style="list-style-type: none"><li>a. Choose <b>Alias to Network Load Balancer</b>.</li><li>b. Choose the AWS Region in which the Network Load Balancer is deployed.</li></ol></li></ol>	AWS DevOps

Task	Description	Skills required
	<p>c. Enter the DNS name of the Network Load Balancer.</p> <p>8. Choose <b>Create records</b>.</p>	

## Set up NGINX VirtualServer on Amazon EKS

Task	Description	Skills required
Deploy NGINX VirtualServer.	<p>The NGINX VirtualServer resource is a load balancing configuration that is an alternative to the ingress resource. The configuration to create the NGINX VirtualServer resource is available in the <code>nginx_virtualserver.yaml</code> file in the <code>6-Nginx-Virtual-Server</code> directory. Enter the following command in <code>kubectl</code> to create the NGINX VirtualServer resource.</p> <pre>kubectl apply -f   nginx_virtualserver.yaml</pre> <p><b>Important:</b> Make sure that you update the application domain name, certificate secret, and application service name in the <code>nginx_virtualserver.yaml</code> file.</p>	AWS DevOps

Task	Description	Skills required
Verify that NGINX VirtualServer is created.	<p>Enter the following command in <code>kubectl</code> to verify that the NGINX VirtualServer resource was successfully created.</p> <pre>kubectl get virtualserver</pre> <p><b>Note:</b> Verify that the Host column matches your application's domain name.</p>	AWS DevOps
Deploy the NGINX web server with TLS enabled.	<p>This pattern uses a NGINX web server with TLS enabled as the application for testing end-to-end encryption. The configuration files required to deploy the test application are available in the <code>demo-webserver</code> directory.</p> <p>Enter the following command in <code>kubectl</code> to deploy the test application.</p> <pre>kubectl apply -f nginx-tls-ap.yaml</pre>	AWS DevOps

Task	Description	Skills required
Verify that the test application resources are created.	<p>Enter the following commands in <code>kubectl</code> to verify that the required resources are created for the test application:</p> <ul style="list-style-type: none"><li>• <code>kubectl get deployments</code></li></ul> <p><b>Note:</b> Validate the Ready column and Available column.</p> <ul style="list-style-type: none"><li>• <code>kubectl get pods   grep -i example-deploy</code></li></ul> <p><b>Note:</b> Pods should be in running state.</p> <ul style="list-style-type: none"><li>• <code>kubectl get configmap</code></li><li>• <code>kubectl get svc</code></li></ul>	AWS DevOps
Validate the application.	<ol style="list-style-type: none"><li>1. Enter the following command by replacing the <code>&lt;application-domain-name&gt;</code> with the Route53 DNS name that you created earlier.</li></ol> <pre>curl --verbose https://&lt;application-domain-name&gt;</pre> <ol style="list-style-type: none"><li>2. Verify that you can access the application.</li></ol>	AWS DevOps

# Simplify Amazon EKS multi-tenant application deployment by using Flux

Created by Nadeem Rahaman (AWS), Aditya Ambati (AWS), Aniket Dekate (AWS), and Shrikant Patil (AWS)

**Code repository:** [aws-eks-multi-tenancy-deployment](#)

**Environment:** PoC or pilot

**Technologies:** DevOps; Containers & microservices

**AWS services:** AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; Amazon EKS; Amazon VPC

## Summary

Many companies that offer products and services are data-regulated industries that are required to maintain data barriers between their internal business functions. This pattern describes how you can use the multi-tenancy feature in Amazon Elastic Kubernetes Service (Amazon EKS) to build a data platform that achieves logical and physical isolation between tenants or users that share a single Amazon EKS cluster. The pattern provides isolation through the following approaches:

- Kubernetes namespace isolation
- Role-based access control (RBAC)
- Network policies
- Resource quotas
- AWS Identity and Access Management (IAM) roles for service accounts (IRSA)

In addition, this solution uses Flux to keep the tenant configuration immutable when you deploy applications. You can deploy your tenant applications by specifying the tenant repository that contains the Flux `kustomization.yaml` file in your configuration.

This pattern implements the following:

- An AWS CodeCommit repository, AWS CodeBuild projects, and an AWS CodePipeline pipeline, which are created by manually deploying Terraform scripts.
- Network and compute components required for hosting the tenants. These are created through CodePipeline and CodeBuild by using Terraform.
- Tenant namespaces, network policies, and resource quotas, which are configured through a Helm chart.
- Applications that belong to different tenants, deployed by using Flux.

We recommend that you carefully plan and build your own architecture for multi-tenancy based on your unique requirements and security considerations. This pattern provides a starting point for your implementation.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2.11.4 or later, [installed](#) and [configured](#)
- [Terraform](#) version 0.12 or later installed on your local machine
- [Terraform AWS Provider](#) version 3.0.0 or later
- [Kubernetes Provider](#) version 2.10 or later
- [Helm Provider](#) version 2.8.0 or later
- [Kubectl Provider](#) version 1.14 or later

### Limitations

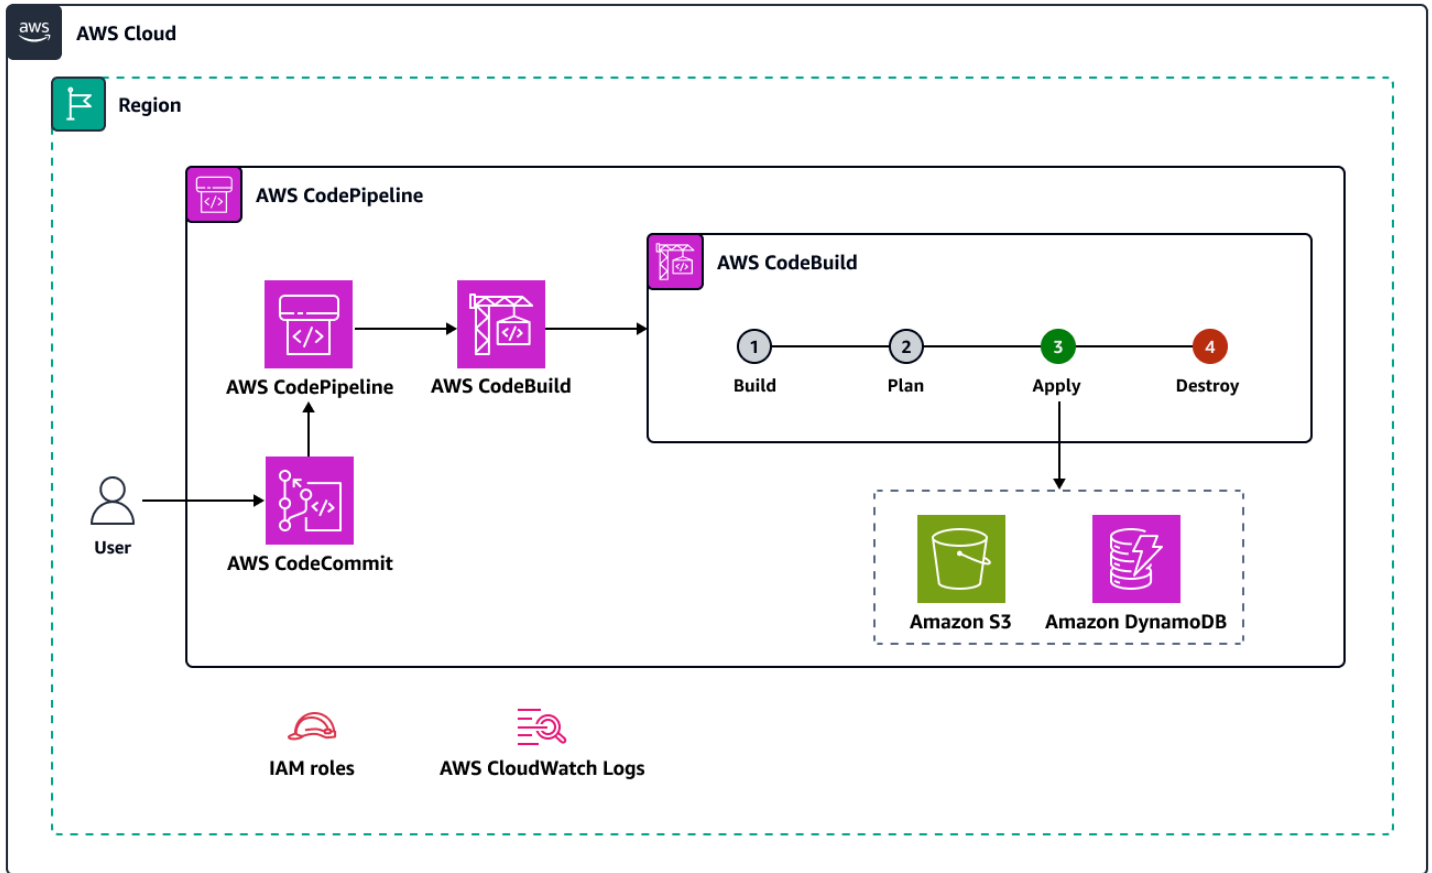

- **Dependency on Terraform manual deployments:** The workflow's initial setup, including creating CodeCommit repositories, CodeBuild projects, and CodePipeline pipelines, relies on manual Terraform deployments. This introduces a potential limitation in terms of automation and scalability, because it requires manual intervention for infrastructure changes.
- **CodeCommit repository dependency:** The workflow relies on CodeCommit repositories as the source code management solution and is tightly coupled with AWS services.

# Architecture

## Target architectures

This pattern deploys three modules to build the pipeline, network, and compute infrastructure for a data platform, as illustrated in the following diagrams.

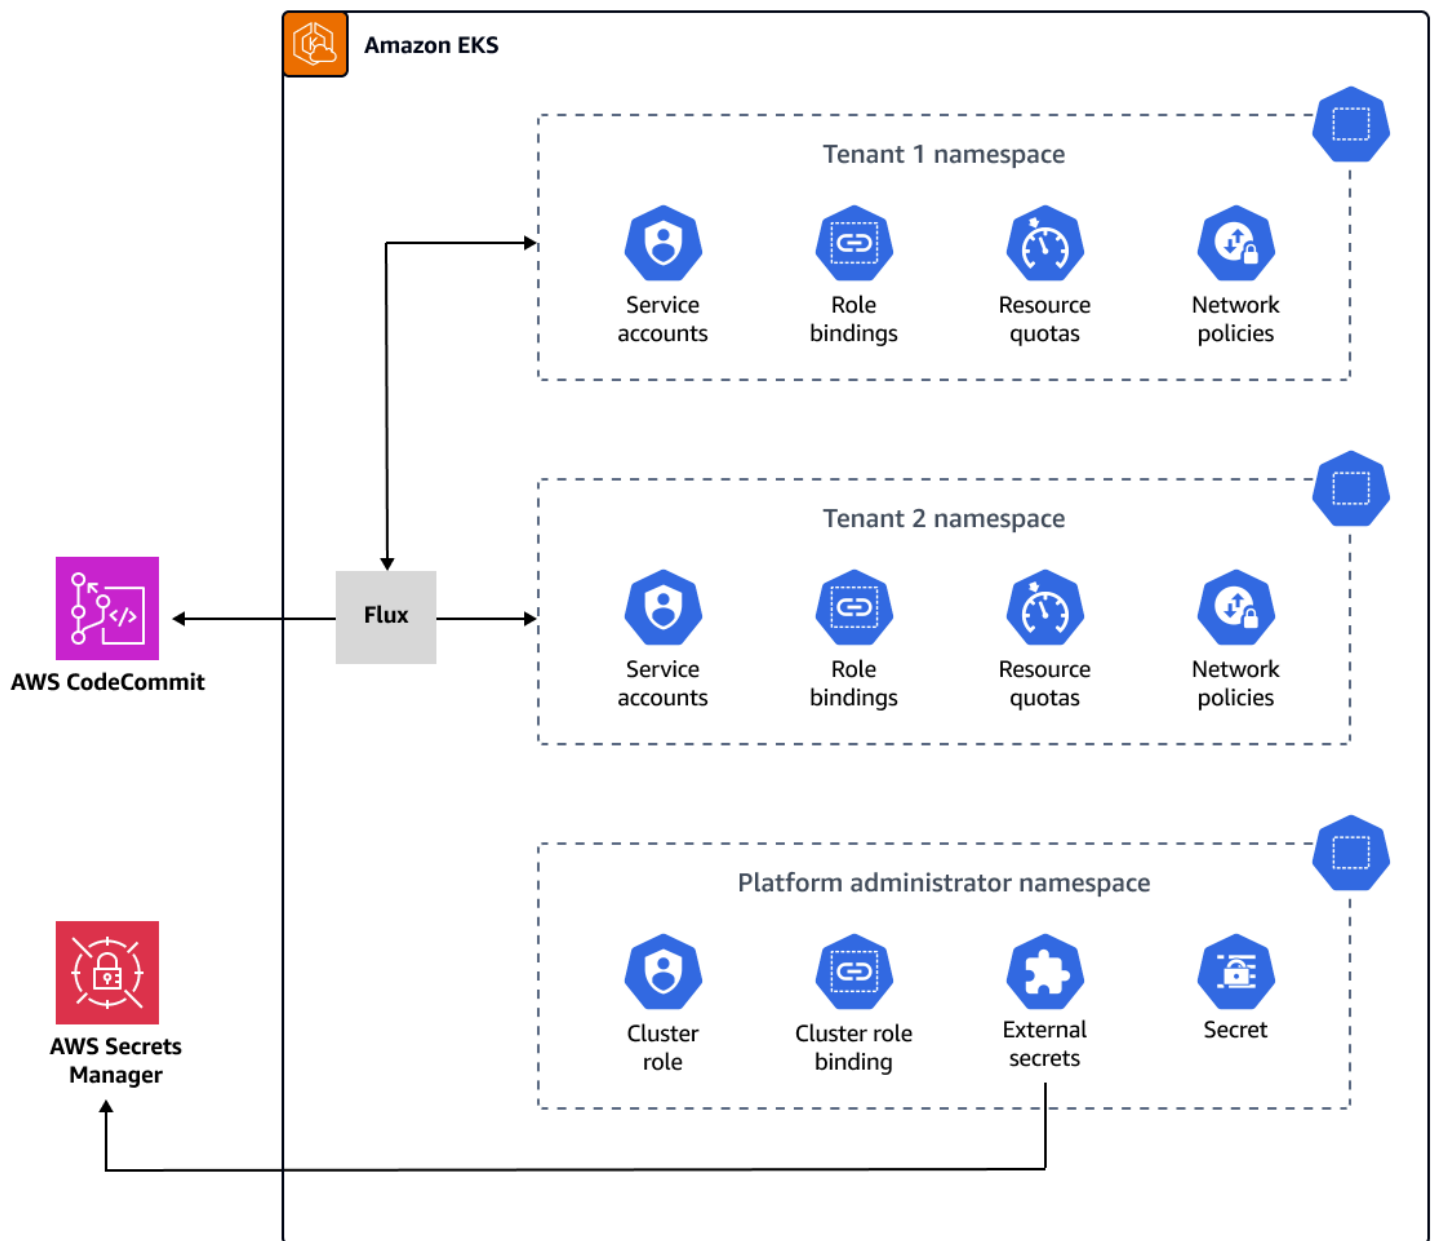

*Pipeline architecture:*

*Network architecture:*

*Compute architecture:*

## Tools

### AWS services

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [AWS Transit Gateway](#) is a central hub that connects virtual private clouds (VPCs) and on-premises networks.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

## Other tools

- [Cilium Network Policies](#) support Kubernetes L3 and L4 networking policies. They can be extended with L7 policies to provide API-level security for HTTP, Kafka, and gRPC, and other similar protocols.
- [Flux](#) is a Git-based continuous delivery (CD) tool that automates application deployments on Kubernetes.
- [Helm](#) is an open source package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- [Terraform](#) is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

## Code repository

The code for this pattern is available in the GitHub [EKS Multi-Tenancy Terraform Solution](#) repository.

## Best practices

For guidelines and best practices for using this implementation, see the following:

- [Flux documentation](#)

# Epics

## Create pipelines for Terraform build, test, and deploy stages

Task	Description	Skills required
Clone the project repository.	<p>Clone the GitHub <a href="#">EKS Multi-Tenancy Terraform Solution</a> repository by running the following command in a terminal window:</p> <pre>git clone https://github.com/aws-samples/aws-eks-multi-tenancy-deployment.git</pre>	AWS DevOps
Bootstrap the Terraform S3 bucket and Amazon DynamoDB.	<ol style="list-style-type: none"><li>1. In the <code>bootstrap</code> folder, open the <code>bootstrap.sh</code> file and update the variable values for the S3 bucket name, DynamoDB table name, and AWS Region:<pre>S3_BUCKET_NAME=" 3_BUCKET_NAME&gt;" DYNAMODB_TABLE_NAME=" ME"&lt;DYNAMODB_NAME &gt;" REGION=" ON&gt;"</pre></li><li>2. Run the <code>bootstrap.sh</code> script. The script requires the AWS CLI, which you installed as part of <a href="#">prerequisites</a>.<pre>cd bootstrap</pre></li></ol>	AWS DevOps

Task	Description	Skills required
	<pre>./bootstrap.sh</pre>	

Task	Description	Skills required
Update the <code>run.sh</code> and <code>locals.tf</code> files.	<ol style="list-style-type: none"><li>1. After the bootstrap process completes successfully, copy the S3 bucket and DynamoDB table name from the <code>variables</code> section of the <code>bootstrap.sh</code> script: <pre data-bbox="630 583 1029 827"># Variables S3_BUCKET_NAME=" S3_BUCKET_NAME&gt;" DYNAMODB_TABLE_NAME =" DYNAMODB_NAME"</pre></li><li>2. Paste those values to the <code>run.sh</code> script, which is in the root directory of the project: <pre data-bbox="630 1058 1029 1331">BACKEND_BUCKET_ID= "&lt;SAME_NAME_AS_S3_ BUCKET_NAME&gt;" DYNAMODB_ID=" &lt;SAME_NAME_AS_DYNA MODB_NAME&gt;"</pre></li><li>3. Upload the project code to a CodeCommit repository. You can automatically create this repository through Terraform by setting the following variable to <code>true</code> in the <code>demo/pipeline/locals.tf</code> file:</li></ol>	AWS DevOps

Task	Description	Skills required
	<pre data-bbox="634 212 1027 327">create_new_repo = true</pre> <p data-bbox="591 344 976 527">4. Update the <code>locals.tf</code> file according to your requirements to create pipeline resources.</p>	
Deploy the pipeline module.	<p data-bbox="591 596 1024 869">To create pipeline resources, run the following Terraform commands manually. There is no orchestration for running these commands automatically.</p> <pre data-bbox="597 905 1027 1304">./run.sh -m pipeline -e demo -r &lt;AWS_REGION&gt; - t init ./run.sh -m pipeline -e demo -r &lt;AWS_REGION&gt; - t plan ./run.sh -m pipeline -e demo -r &lt;AWS_REGION&gt; - t apply</pre>	AWS DevOps

## Create the network infrastructure

Task	Description	Skills required
Start the pipeline.	<p data-bbox="591 1591 1024 1814">1. In the <code>templates</code> folder, make sure that the <code>buildspec</code> files have the following variable set to <code>network</code>:</p>	AWS DevOps

Task	Description	Skills required
	<pre data-bbox="630 212 1029 327">TF_MODULE_TO_BUILD:   "network"</pre> <p data-bbox="591 344 976 569">2. On the <a href="#">CodePipeline console</a>, on the pipeline details page, start the pipeline by choosing <b>Release change</b>.</p> <p data-bbox="591 646 997 871">After this first run, the pipeline starts automatically whenever you commit a change to the CodeCommit repository main branch.</p> <p data-bbox="591 915 954 999">The pipeline includes the following <a href="#">stages</a>:</p> <ul data-bbox="591 1045 1024 1824" style="list-style-type: none"><li>• <code>validate</code> initializes Terraform, runs Terraform security scans by using the <a href="#">checkov</a> and <a href="#">tfsec</a> tools, and uploads the scan reports to the S3 bucket.</li><li>• <code>plan</code> shows the Terraform plan and uploads the plan to the S3 bucket.</li><li>• <code>apply</code> applies the Terraform plan output from the S3 bucket and creates AWS resources.</li><li>• <code>destroy</code> removes the AWS resources created during the <code>apply</code> stage. To enable</li></ul>	

Task	Description	Skills required
	<p>this optional stage, set the following variable to true in the demo/pipeline/locals.tf file:</p> <pre data-bbox="625 428 1029 548">enable_destroy_stage = true</pre>	

Task	Description	Skills required
Validate the resources created through the network module.	<p>Confirm that the following AWS resources were created after the pipeline deployed successfully:</p> <ul style="list-style-type: none"><li>• An egress VPC with three public and three private subnets, internet gateway, and NAT gateway.</li><li>• An Amazon EKS VPC with three private subnets.</li><li>• Tenant 1 and Tenant 2 VPCs with three private subnets each.</li><li>• A transit gateway with all VPC attachments and routes to each private subnet.</li><li>• A static transit gateway route for the Amazon EKS egress VPC with a destination CIDR block of <code>0.0.0.0/0</code> . This is required to enable all VPCs to have outbound internet access through the Amazon EKS egress VPC.</li></ul>	AWS DevOps

## Create the compute infrastructure

Task	Description	Skills required
<p>Update <code>locals.tf</code> to enable the CodeBuild project's access to the VPC.</p>	<p>To deploy the add-ons for the Amazon EKS private cluster, the CodeBuild project must be attached to the Amazon EKS VPC.</p> <ol style="list-style-type: none"> <li>1. In the <code>demo/pipeline</code> folder, open the <code>locals.tf</code> file, and set the <code>vpc_enabled</code> variable to <code>true</code>.</li> <li>2. Run the <code>run.sh</code> script to apply the changes to the pipeline module:</li> </ol> <pre data-bbox="630 1020 1029 1619">demo/pipeline/locals.tf ./run.sh -m pipeline           -env demo -region           &lt;AWS_REGION&gt; -tfcmd           init ./run.sh -m pipeline           -env demo -region           &lt;AWS_REGION&gt; -tfcmd           plan ./run.sh -m pipeline           -env demo -region           &lt;AWS_REGION&gt; -tfcmd           apply</pre>	<p>AWS DevOps</p>
<p>Update the <code>buildspec</code> files to build the compute module.</p>	<p>In the <code>templates</code> folder, in all <code>buildspec</code> YAML files, set the value of the <code>TF_MODULE_TO_BUILD</code></p>	<p>AWS DevOps</p>

Task	Description	Skills required
	<p>variable from network to compute:</p> <pre data-bbox="594 331 1027 449">TF_MODULE_TO_BUILD: "compute"</pre>	

Task	Description	Skills required
Update the values file for the tenant management Helm chart.	<p>1. Open the values.yaml file in the following location:</p> <pre>cd cfg-terraform/demo /compute/cfg-tenant-mgmt</pre> <p>The file looks like this:</p> <pre>--- global:   clusterRoles:     operator:       platform-tenant       flux: flux-tenant-applier       flux:         tenantClusterBaseUrl: \${TEANT_CLUSTER_BASE_URL}         repoSecret:           \${TENANT_REPO_SECRET}   tenants:     tenant-1:       quotas:         limits:           cpu: 1           memory: 1Gi       flux:         path: overlays/tenant-1     tenant-2:       quotas:         limits:           cpu: 1           memory: 2Gi       flux:</pre>	AWS DevOps

Task	Description	Skills required
	<pre>path: overlays/tenant-2</pre> <p>2. In the <code>global</code> and <code>tenants</code> sections, update the configuration based on your requirements:</p> <ul style="list-style-type: none"><li>• <code>tenantCloneBaseUrl</code> – Path to the repository that hosts the code for all tenants (we use the same Git repository for all tenants)</li><li>• <code>repoSecret</code> – Kubernetes secret that holds the SSH keys and known hosts to authenticate to the global tenant Git repository</li><li>• <code>quotas</code> – Kubernetes resources quotas that you want to apply for each tenant</li><li>• <code>flux path</code> – Path to the tenant application YAML files in the global tenant repository</li></ul>	

Task	Description	Skills required
Validate compute resources.	<p>After you update the files in the previous steps, CodePipeline starts automatically. Confirm that it created the following AWS resources for the compute infrastructure:</p> <ul style="list-style-type: none"> <li>• Amazon EKS cluster with private endpoint</li> <li>• Amazon EKS worker nodes</li> <li>• Amazon EKS add-ons: external secrets, aws-loadbalancer-controller, and metrics-server</li> <li>• GitOps module, Flux Helm chart, Cilium Helm chart, and tenant management Helm chart</li> </ul>	AWS DevOps

## Check tenant management and other resources

Task	Description	Skills required
Validate the tenant management resources in Kubernetes.	<p>Run the following commands to check that tenant management resources were created successfully with the help of Helm.</p> <ol style="list-style-type: none"> <li>1. Tenant namespaces were created, as specified in <code>values.yaml</code> :</li> </ol>	AWS DevOps

Task	Description	Skills required
	<pre>kubectl get ns -A</pre> <p>2. Quotas are assigned to each tenant namespace, as specified in values.yaml :</p> <pre>kubectl get quota --namespace=&lt;tenant_namespace&gt;</pre> <p>3. Details of quotas are correct for each tenant namespace:</p> <pre>kubectl describe quota cpu-memory-resource-quota-limit -n &lt;tenant_namespace&gt;</pre> <p>4. Cilium Network Policies were applied to each tenant namespace:</p> <pre>kubectl get CiliumNetworkPolicy -A</pre>	

Task	Description	Skills required
Verify tenant application deployments.	<p>Run the following commands to verify that the tenant applications were deployed.</p> <ol style="list-style-type: none"><li>1. Flux is able to connect to the CodeCommit repository that's specified in the GitOps module: <pre>kubectl get gitrepositories -A</pre></li><li>2. The Flux kustomization controller has deployed the YAML files in the CodeCommit repository: <pre>kubectl get kustomizations -A</pre></li><li>3. All application resources are deployed in their tenant namespaces: <pre>kubectl get all -n &lt;tenant_namespace&gt;</pre></li><li>4. An ingress has been created for each tenant: <pre>kubectl get ingress -n &lt;tenant_namespace&gt;</pre></li></ol>	

# Troubleshooting

Issue	Solution
<p>You encounter an error message that's similar to the following:</p> <pre>Failed to checkout and determine revision: unable to clone unknown error: You have successfully authenticated over SSH. You can use Git to interact with AWS CodeCommit.</pre>	<p>Follow these steps to troubleshoot the issue:</p> <ol style="list-style-type: none"><li>1. Verify the tenant application repository: An empty or misconfigured repository might be causing the error. Make sure that the tenant application repository contains the required code.</li><li>2. Redeploy the <code>tenant_mgmt</code> module: In the <code>tenant_mgmt</code> module configuration file, locate the <code>app</code> block, and then set the <code>deploy</code> parameter to <code>0</code>:<pre>deploy = 0</pre>After you run the Terraform <code>apply</code> command, change the <code>deploy</code> parameter value back to <code>1</code>:<pre>deploy = 1</pre></li><li>3. Recheck the status: After you run the previous steps, use the following command to check whether the issue persists:<pre>kubectl get gitrepositories -A</pre>If it persists, consider diving deeper into the Flux logs for more details or refer to the <a href="#">Flux general troubleshooting guide</a>.</li></ol>

# Subscribe multiple email endpoints to an SNS topic by using a custom resource

Created by Ricardo Morais (AWS)

**Environment:** Production

**Technologies:** DevOps

**AWS services:** Amazon SNS;  
AWS CloudFormation; AWS  
Lambda

## Summary

**Note, August 2022:** AWS CloudFormation now supports the subscription of multiple resources through the **AWS::SNS::Topic** object and its **Subscription** attribute.

This pattern describes how to subscribe multiple email addresses to receive notifications from an Amazon Simple Notification Service (Amazon SNS) topic. It uses an AWS Lambda function as a custom resource in an AWS CloudFormation template. The Lambda function is associated with an input parameter that specifies the email endpoints for the SNS topic.

Currently, you can use the AWS CloudFormation template objects [AWS::SNS::Topic](#) and [AWS::SNS::Subscription](#) to subscribe single endpoints to SNS topics. To subscribe multiple endpoints, you have to invoke the object multiple times. By using the Lambda function as a custom resource, you can subscribe multiple endpoints through an input parameter. You can use this Lambda function as a custom resource in any AWS CloudFormation template.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An AWS profile configured in your local environment with an access key and secret key. You can also run this code from [AWS Cloud9](#).
- Permissions for the following:
  - AWS Identity and Access Management (IAM) role and policy
  - AWS Lambda function
  - Amazon Simple Storage Service (Amazon S3) for uploading the Lambda function

- Amazon SNS topic and policy
- AWS CloudFormation stacks

## Limitations

- The code supports Linux and macOS workstations.

## Product versions

- AWS Command Line Interface (AWS CLI) version 2 or later.

## Architecture

### Target technology stack

- AWS CloudFormation
- Amazon SNS
- AWS Lambda

## Tools

### Tools

- [AWS CLI version 2](#)

### Code

The attachment includes the following files:

- Lambda function: `lambda_function.py`
- AWS CloudFormation template: `template.yaml`
- Two parameter files to handle multiple or single email endpoint subscriptions: `parameters-multiple-values.json` (used as the default) and `parameters-one-value.json`

To deploy the stack, you can use either parameter file. To specify multiple email endpoints:

```
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION>
```

To specify a single email endpoint:

```
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION> -f parameters-one-value.json
```

## Epics

### Option 1 - Deploy an SNS topic with one email subscription

Task	Description	Skills required
Configure the email endpoint for SNS topic subscriptions.	Edit the file <code>parameters-one-value.json</code> (attached), and change the value of the <code>pSNSNotificationsEmail</code> parameter to reflect the email address you want to use, such as <code>someone@example.com</code> .	
Deploy the AWS CloudFormation stack that creates the resources and subscription.	Run the <b>deploy.sh</b> command with your AWS profile name, AWS Region, and the <code>parameters-one-value.json</code> file. <pre>./deploy.sh -p   &lt;YOUR_AWS_PROFILE_NAME&gt; -r &lt;YOUR_AWS_PROFILE_REGION&gt; -f   parameters-one-value.json</pre>	IAM role with proper permissions

## Option 2 - Deploy an SNS topic with two or more email subscriptions

Task	Description	Skills required
Configure the email endpoints for SNS topic subscriptions.	Edit the file parameter <code>s-multiple-values.json</code> (attached), and change the value of the <code>pSNSNotificationsEmail</code> parameter to reflect the email addresses you want to use, separated by commas, as follows: <code>someone1@example.com, someone2@example.com</code> .	
Deploy the AWS CloudFormation stack that creates the resources and subscription.	Run the <b>deploy.sh</b> command with your AWS profile name and AWS Region. You don't have to specify the <code>parameters-multiple-values.json</code> file because it's used by default. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>./deploy.sh -p &lt;YOUR_AWS_PROFILE_ NAME&gt; -r &lt;YOUR_AWS _PROFILE_REGION&gt;</pre> </div>	IAM role with proper permissions

## Option 3 - Deploy an SNS topic through an AWS CloudFormation template

Task	Description	Skills required
Create an SNS topic.	Create an SNS topic through an AWS CloudFormation template, without specifying	IAM role with proper permissions

Task	Description	Skills required
	g subscription endpoints in the <code>AWS::SNS::Topic</code> template object. You can use <code>template.yaml</code> in the attachment as a starting point.	
Create an SNS topic policy.	Create an SNS topic policy in the AWS CloudFormation template.	IAM role with proper permissions
Subscribe the email endpoints list to the SNS topic.	Based on the list of email endpoints (one or more), subscribe the endpoints to the SNS topic you created.	IAM role with proper permissions

# Use Serverspec for test-driven development of infrastructure code

*Created by Sushant Jagdale (AWS)*

**Environment:** PoC or pilot

**Technologies:** DevOps;  
Infrastructure; Hybrid cloud

**AWS services:** Amazon  
EC2; AWS CodeBuild; AWS  
CodeDeploy

## Summary

This pattern shows you how to use [Serverspec](#) to use test-driven development (TDD) when writing infrastructure code on the Amazon Web Services (AWS) Cloud. The pattern also covers automation with AWS CodePipeline. TDD will focus attention on what the infrastructure code must do and sets a clear definition of done. You can use Serverspec to test infrastructure created by tools such as AWS CloudFormation, Terraform by HashiCorp, and Ansible.

Serverspec helps with refactoring infrastructure code. With Serverspec, you can write RSpec tests to check installation of various packages and software, run commands, check for running processes and ports, check file permission settings, and so forth. Serverspec checks whether your servers are configured correctly. You install only Ruby on your servers. You don't need to install any agent software.

Test-driven infrastructure provides the following benefits:

- Cross-platform testing
- Validation of expectations
- Confidence in your automation
- Infrastructure consistency and stability
- Fail early

You can use this pattern to run Serverspec unit tests for Apache software and check file permission settings during Amazon Machine Image (AMI) creation. An AMI will be created only if all the test cases pass. Serverspec will perform following tests:

- Apache process is running.
- Apache port is running.
- Apache configuration files and directories exist at certain locations, and so forth.
- File permissions are correctly configured.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- A virtual private cloud (VPC) with a public subnet
- Installation of AWS Command Line Interface (AWS CLI) and Git

### Product versions

- HashiCorp Packer version: 1.6.6
- Ruby version: 2.5.1 and later
- AWS CLI version: 1.18.185

## Architecture

### Target architecture

1. When you push the code to the CodeCommit repository, an Amazon CloudWatch Events event engages the CodePipeline. In the first stage of the pipeline, the code is fetched from CodeCommit.
2. The second pipeline stage runs CodeBuild, which validates and builds the Packer template.
3. As a part of the Packer build provisioner, Packer installs Apache and Ruby software. Then the provisioner calls a shell script that uses Serverspec to unit test the Apache process, port, files, and directories. The Packer post-processor writes a JavaScript Object Notation (JSON) file with a list of all the artifacts produced by Packer during a run
4. Finally, an Amazon Elastic Compute Cloud (Amazon EC2) instance is created using the AMI ID produced by Packer.

## Tools

- [AWS CLI](#) – Amazon Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services using commands in your command line shell.
- [Amazon CloudWatch Events](#) – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in Amazon Web Services (AWS) resources.
- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) – AWS CodeCommit is a version control service hosted by Amazon Web Services. You can use CodeCommit to privately store and manage assets (such as documents, source code, and binary files) in the cloud.
- [AWS CodePipeline](#) – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process.
- [HashiCorp Packer](#) – HashiCorp Packer is a tool for automating the creation of identical machine images from a single source configuration.
- [Serverspec](#) – Serverspec runs RSpec tests to check server configuration. Serverspec uses Ruby, and you don't need to install agent software.

## Code

The code is attached. The code uses the following structure, with three directories and eight files.

```
### amazon-linux_packer-template.json (Packer template)
```

```

### buildspec.yaml (CodeBuild .yaml file)
### pipeline.yaml (AWS CloudFormation template to automate CodePipeline)
### rspec_tests (RSpec required files and spec)
#   ### Gem-file
#   ### Rakefile
#   ### spec
#       ### apache_spec.rb
#       ### spec_helper.rb
### scripts
    ### rspec.sh (Installation of Ruby and initiation of RSpec)

```

## Epics

### Configure AWS credentials

Task	Description	Skills required
Create an IAM user.	Create an AWS Identity and Access Management (IAM) user with programmatic and console access. For more information, see the <a href="#">AWS documentation</a> .	Developer, Systems administrator, DevOps engineer
Configure AWS credentials.	On your local computer or in your environment, configure AWS credentials for the IAM user. For instructions, see the <a href="#">AWS documentation</a> .	Developer, Systems administrator, DevOps engineer
Test your credentials.	To validate the configured credentials, run the following command. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>aws sts get-caller-identity --profile &lt;profile&gt;</pre> </div>	Developer, Systems administrator, DevOps engineer

## AWS CodePipeline

Task	Description	Skills required
Create a CodeCommit repository.	<p>To create a CodeCommit repository, run the following command.</p> <pre>aws codecommit create-repository --repository-name "&lt;provide repository-name&gt;" --repository-description "repository to unit test the infrastructure code"</pre>	Developer, Systems administrator, DevOps engineer
Write RSpec tests.	<p>Create RSpec test cases for your infrastructure. For more information, see the <i>Additional information</i> section.</p>	Developer, DevOps engineer
Push code to the CodeCommit repository.	<p>To push the attached code to the CodeCommit repository, run the following commands.</p> <pre>git clone &lt;repository url&gt; cp -R /tmp/&lt;code folder&gt;/ &lt;repository_folder&gt;/ git add . git commit -m"initial commit" git push</pre>	Developer, Systems administrator, DevOps engineer
Create the pipeline.	<p>To create the pipeline, run the AWS CLI command that is in</p>	Developer, Systems administrator, DevOps engineer

Task	Description	Skills required
	the <i>Additional information</i> section.	
Start the pipeline.	Commit code to the CodeCommit repository. Any commit to the repository will initiate the pipeline.	Developer, Systems administrator, DevOps engineer
Test the Apache URL.	To test the AMI installation, use the following URL.  <pre>http://&lt;your instance public ip&gt;/hello.html</pre> The page will show a "Hello from Apache" message.	Developer, Systems administrator, DevOps engineer

- [Image creation and testing with HashiCorp Packer and ServerSpec](#) (external article)

## Additional information

### Write RSpec tests

The RSpec test for this pattern is located at `<repository folder>/rspec_tests/spec/apache_spec.rb`.

```
require 'spec_helper'

describe service('httpd') do
  it { should be_enabled }
  it { should be_running }
end

describe port(80) do
  it { should be_listening }
end

describe file('/etc/httpd/conf/httpd.conf') do
  it { should exist }
  it { should be_owned_by 'root' }
  it { should contain 'ServerName www.example.com' }
end

describe file('/etc/httpd/conf/httpd.conf') do
  its(:content) { should match /ServerName www.example.com/ }
end

describe file('/var/www/html/hello.html') do
  it { should exist }
  it { should be_owned_by 'ec2-user' }
end

describe file('/var/log/httpd') do
  it { should be_directory }
end

describe file('/etc/sudoers') do
  it { should be_mode 440 }
end

describe group('root') do
```

```
it { should have_gid 0 }  
end
```

You can add your own tests to the `/spec` directory.

## Create the pipeline

```
aws cloudformation create-stack --stack-name myteststack --template-body file://  
pipeline.yaml --parameters ParameterKey=RepositoryName,ParameterValue=<provide  
repository-name> ParameterKey=ApplicationName,ParameterValue=<provide  
application-name> ParameterKey=SecurityGroupId,ParameterValue=<provide  
SecurityGroupId> ParameterKey=VpcId,ParameterValue=<provide VpcId>  
ParameterKey=SubnetId,ParameterValue=<provide SubnetId> ParameterKey=Region,ParameterValue=<pr  
AccountId> --capabilities CAPABILITY_NAMED_IAM
```

### *Parameter details*

`repository-name` – The name of the AWS CodeCommit repository

`application-name` – The Amazon Resource Name (ARNs) are linked with `ApplicationName`; provide any name

`SecurityGroupId` – Any security group ID from your AWS account that has port 80 open

`VpcId` – The ID of your VPC

`SubnetId` – The ID of a public subnet in your VPC

`Region` – The AWS Region where you are running this pattern

`Keypair` – The Secure Shell (SSH) key name to log in to the EC2 instance

`AccountId` – Your AWS account ID

You can also create a CodePipeline pipeline by using the AWS Management Console and passing the same parameters that are in the previous command line.

# Use third-party Git source repositories in AWS CodePipeline

Created by Kirankumar Chandrashekar (AWS)

**Environment:** PoC or pilot

**Technologies:** DevOps

**Workload:** Open-source

**AWS services:** AWS CodeBuild; AWS CodePipeline; AWS Lambda

## Summary

This pattern describes how to use AWS CodePipeline with third-party Git source repositories.

[AWS CodePipeline](#) is a continuous delivery service that automates tasks for building, testing, and deploying your software. The service currently supports Git repositories managed by GitHub, [AWS CodeCommit](#), and Atlassian Bitbucket. However, some enterprises use third-party Git repositories that are integrated with their single sign-on (SSO) service and Microsoft Active Directory for authentication. You can use these third-party Git repositories as sources for CodePipeline by creating custom actions and webhooks.

A webhook is an HTTP notification that detects events in another tool, such as a GitHub repository, and connects those external events to a pipeline. When you create a webhook in CodePipeline, the service returns a URL that you can use in your Git repository webhook. If you push code to a specific branch of the Git repository, the Git webhook initiates the CodePipeline webhook through this URL, and sets the source stage of the pipeline to **In Progress**. When the pipeline is in this state, a job worker polls CodePipeline for the custom job, runs the job, and sends a success or failure status to CodePipeline. In this case, because the pipeline is in the source stage, the job worker gets the contents of the Git repository, zips the contents, and uploads it to the Amazon Simple Storage Service (Amazon S3) bucket where artifacts for the pipeline are stored, using the object key provided by the polled job. You can also associate a transition for the custom action with an event in Amazon CloudWatch, and initiate the job worker based on the event. This setup enables you to use third-party Git repositories that the service doesn't natively support as sources for CodePipeline.

## Prerequisites and limitations

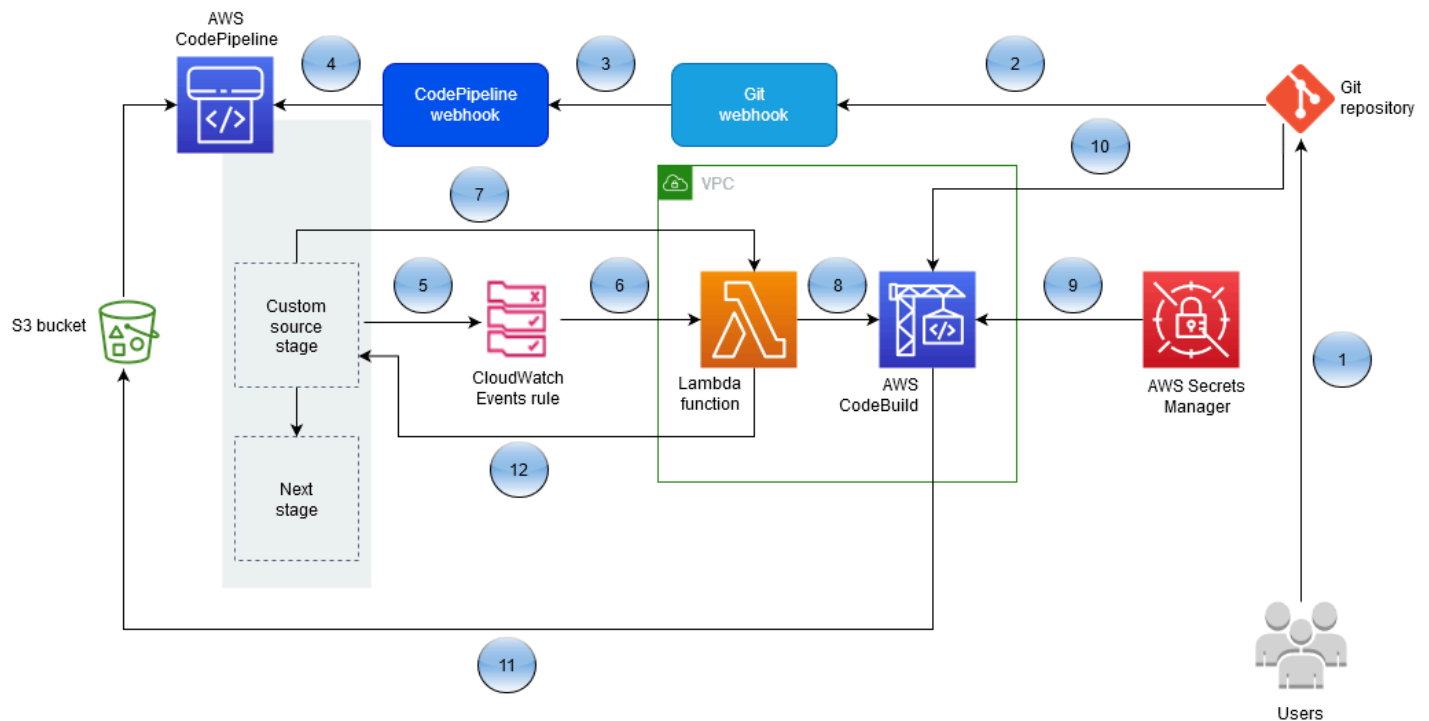

### Prerequisites

- An active AWS account
- A Git repository that supports webhooks and can connect to a CodePipeline webhook URL through the internet
- AWS Command Line Interface (AWS CLI) [installed](#) and [configured](#) to work with the AWS account

### Architecture

The pattern involves these steps:

1. The user commits code to a Git repository.
2. The Git webhook is called.
3. The CodePipeline webhook is called.
4. The pipeline is set to **In Progress**, and the source stage is set to the **In Progress** state.
5. The source stage action initiates a CloudWatch Events rule, indicating that it was started.
6. The CloudWatch event initiates a Lambda function.
7. The Lambda function gets the details of the custom action job.
8. The Lambda function initiates AWS CodeBuild and passes it all the job-related information.
9. CodeBuild gets the public SSH key or user credentials for HTTPS Git access from Secrets Manager.
10. CodeBuild clones the Git repository for a specific branch.
11. CodeBuild zips the archive and uploads it to the S3 bucket that serves as the CodePipeline artifact store.

## Tools

- [AWS CodePipeline](#) – AWS CodePipeline is a fully managed [continuous delivery](#) service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deployment phases of your release process for each code change, based on the release model you define. This enables you to rapidly and reliably deliver features and updates. You can integrate AWS CodePipeline with third-party services such as GitHub or with your own custom plugin.
- [AWS Lambda](#) – AWS Lambda lets you run code without provisioning or managing servers. With Lambda, you can run code for virtually any type of application or backend service with no administration necessary. You upload your code and Lambda takes care of everything required to run and scale your code with high availability. You can set up your code to automatically initiate from other AWS services or call it directly from any web or mobile app.
- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed [continuous integration](#) service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don't need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you can create custom build environments that use your own build tools.

- [AWS Secrets Manager](#) – AWS Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. The service enables you to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, without having to hardcode sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon Relational Database Service (Amazon RDS), Amazon Redshift, and Amazon DocumentDB. The service can be extended to support other types of secrets, including API keys and OAuth tokens. In addition, Secrets Manager lets you control access to secrets by using fine-grained permissions, and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises environments.
- [Amazon CloudWatch](#) – Amazon CloudWatch is a monitoring and observation service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides you with data and actionable insights to monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, providing you with a unified view of AWS resources, applications, and services that run on AWS and on-premises servers. You can use CloudWatch to detect anomalous behavior in your environments, set alarms, visualize logs and metrics side by side, take automated actions, troubleshoot issues, and discover insights to keep your applications running smoothly.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is an object storage service that lets you store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. Amazon S3 provides easy-to-use management features to help you organize your data and configure finely tuned access controls to meet your specific business, organizational, and compliance requirements.

## Epics

### Create a custom action in CodePipeline

Task	Description	Skills required
Create a custom action using AWS CLI or AWS CloudFormation.	This step involves creating a custom source action that can be used in the source	General AWS

Task	Description	Skills required
	<p>stage of a pipeline in your AWS account in a particular region. You must use AWS CLI or AWS CloudFormation (not the console) to create the custom source action. For more information about the commands and steps described in this and other epics, see the "Related resources" section at the end of this pattern. In AWS CLI, use the <code>create-custom-action-type</code> command. Use <code>--configuration-properties</code> to provide all the parameters required for the job worker to process when it polls CodePipeline for a job. Make sure to note the values provided to the <code>--provider</code> and <code>--action-version</code> options, so that you can use the same values when creating the pipeline with this custom source stage. You can also create the custom source action in AWS CloudFormation by using the resource type <code>AWS::CodePipeline::CustomActionType</code>.</p>	

## Set up authentication

Task	Description	Skills required
Create an SSH key pair.	Create a Secure Shell (SSH) key pair. For instructions, see the GitHub documentation.	Systems/DevOps engineer
Create a secret in AWS Secrets Manager.	Copy the contents of the private key from the SSH key pair and create a secret in AWS Secrets Manager. This secret is used for authentication when accessing the Git repository.	General AWS
Add the public key to the Git repository.	Add the public key from the SSH key pair to the Git repository account settings, for authentication against the private key.	Systems/DevOps engineer

## Create a pipeline and webhook

Task	Description	Skills required
Create a pipeline that includes the custom source action.	Create a pipeline in CodePipeline. When you configure the source stage, choose the custom source action that you created previously. You can do this in the AWS CodePipeline console or in AWS CLI. CodePipeline prompts you for the configuration properties that you set on the custom action. This information is	General AWS

Task	Description	Skills required
	<p>required for the job worker to process the job for the custom action. Follow the wizard and create the next stage for the pipeline.</p>	
Create a CodePipeline webhook.	<p>Create a webhook for the pipeline you created with the custom source action. You must use AWS CLI or AWS CloudFormation (not the console) to create the webhook. In AWS CLI, run the <code>put-webhook</code> command and provide the appropriate values for the webhook options. Make a note of the webhook URL that the command returns. If you're using AWS CloudFormation to create the webhook, use the resource type <code>AWS::CodePipeline::Webhook</code>. Make sure to output the webhook URL from the created resource, and make a note of it.</p>	General AWS

Task	Description	Skills required
Create a Lambda function and CodeBuild project.	<p>In this step, you use Lambda and CodeBuild to create a job worker that will poll CodePipeline for job requests for the custom action, run the job, and return the status result to CodePipeline. Create a Lambda function that is initiated by an Amazon CloudWatch Events rule when the custom source action stage of the pipeline transitions to "In Progress." When the Lambda function is initiated, it should get the custom action job details by polling for jobs. You can use the PollForJobs API to return this information. After the polled job information is obtained, the Lambda function should return an acknowledgment, and then process the information with the data it obtains from the configuration properties for the custom action. When the worker is ready to talk to the Git repository, you might initiate a CodeBuild project, because it's convenient to handle Git tasks by using the SSH client.</p>	General AWS, code developer

## Create an event in CloudWatch

Task	Description	Skills required
Create a CloudWatch Events rule.	Create a CloudWatch Events rule that initiates the Lambda function as a target whenever the pipeline's custom action stage transitions to "In Progress."	General AWS

# Create a CI/CD pipeline to validate Terraform configurations by using AWS CodePipeline

Created by Aromal Raj Jayarajan (AWS) and Vijesh Vijayakumaran Nair (AWS)

<b>Code repository:</b> <a href="#">aws-codepipeline-terraform-cicd-samples</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> DevOps
<b>Workload:</b> All other workloads	<b>AWS services:</b> AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; Amazon S3; AWS Identity and Access Management	

## Summary

This pattern shows how to test HashiCorp Terraform configurations by using a continuous integration and continuous delivery (CI/CD) pipeline deployed by AWS CodePipeline.

Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources. The solution provided in this pattern creates a CI/CD pipeline that helps you validate the integrity of your Terraform configurations by running five [CodePipeline stages](#):

1. “checkout” pulls the Terraform configuration that you’re testing from an AWS CodeCommit repository.
2. “validate” runs infrastructure-as-cod (IaC) validation tools, including [tfsec](#), [TFLint](#), and [checkov](#). The stage also runs the following Terraform IaC validation commands: `terraform validate` and `terraform fmt`.
3. “plan” shows what changes will be applied to the infrastructure if the Terraform configuration is applied.
4. “apply” uses the generated plan to provision the required infrastructure in a test environment.
5. “destroy” removes the test infrastructure that was created during the “apply” stage.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- [Git](#), installed and configured on your local machine
- [Terraform](#), installed and configured on your local machine

### Limitations

- This pattern's approach deploys AWS CodePipeline into one AWS account and AWS Region only. Configuration changes are required for multi-account and multi-Region deployments.
- The AWS Identity and Access Management (IAM) role that this pattern provisions (**codepipeline\_iam\_role**) follows the principle of least privilege. This IAM role's permissions must be updated based on the specific resources that your pipeline needs to create.

### Product versions

- AWS CLI version 2.9.15 or later
- Terraform version 1.3.7 or later

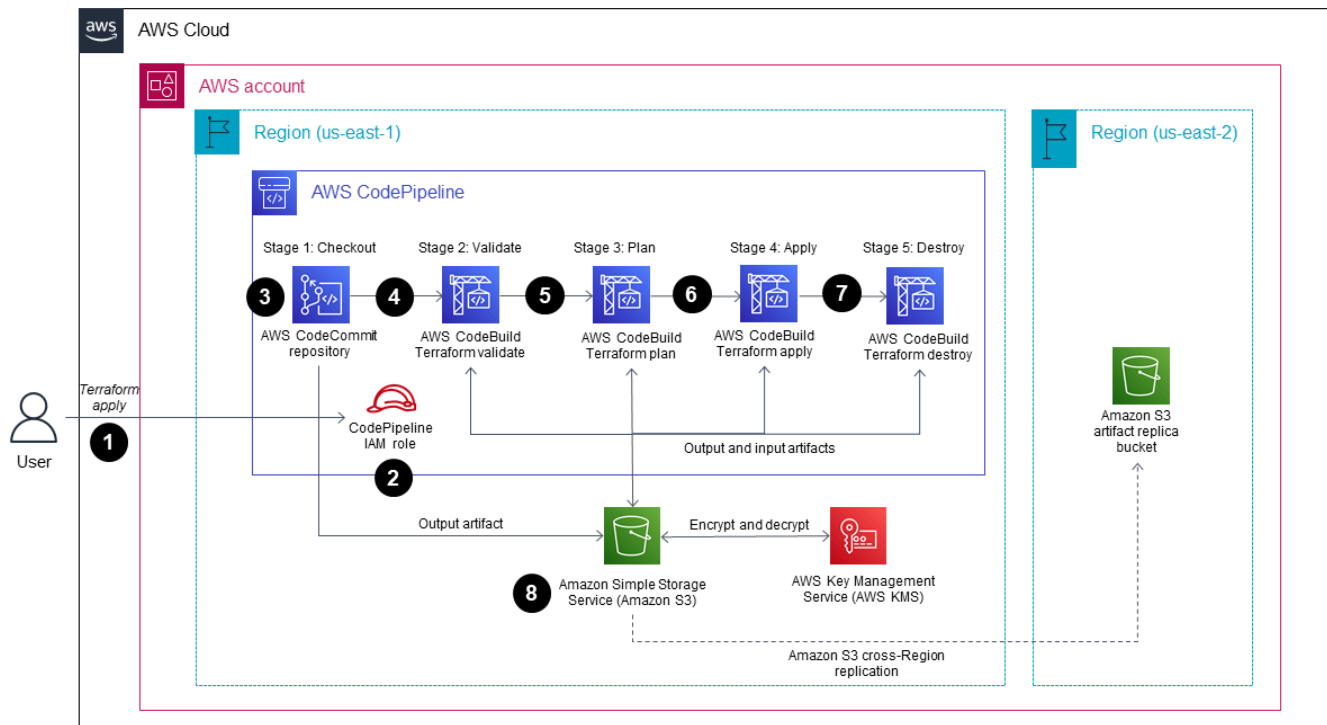

## Architecture

### Target technology stack

- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- AWS IAM
- Amazon Simple Storage Service (Amazon S3)
- AWS Key Management Service (AWS KMS)
- Terraform

### Target architecture

The following diagram shows an example CI/CD pipeline workflow for testing Terraform configurations in CodePipeline.

The diagram shows the following workflow:

1. In CodePipeline, an AWS user initiates the actions proposed in a Terraform plan by running the `terraform apply` command in the AWS CLI.
2. AWS CodePipeline assumes an IAM service role that includes the policies required to access CodeCommit, CodeBuild, AWS KMS, and Amazon S3.
3. CodePipeline runs the “checkout” pipeline stage to pull the Terraform configuration from an AWS CodeCommit repository for testing.
4. CodePipeline runs the “validate” stage to test the Terraform configuration by running IaC validation tools and running Terraform IaC validation commands in a CodeBuild project.
5. CodePipeline runs the “plan” stage to create a plan in the CodeBuild project based on the Terraform configuration. The AWS user can review this plan before the changes are applied to the test environment.
6. Code Pipeline runs the “apply” stage to implement the plan by using the CodeBuild project to provision the required infrastructure in the test environment.

7. CodePipeline runs the “destroy” stage, which uses CodeBuild to remove the test infrastructure that was created during the “apply” stage.
8. An Amazon S3 bucket stores pipeline artifacts, which are encrypted and decrypted by using an AWS KMS [customer managed key](#).

## Tools

### Tools

#### *AWS services*

- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

#### *Other services*

- [HashiCorp Terraform](#) is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.

### Code

The code for this pattern is available in the GitHub [aws-codepipeline-terraform-cicdsamples](#) repository. The repository contains the Terraform configurations required to create the target architecture outlined in this pattern.

# Epics

## Provision the solution components

Task	Description	Skills required
Clone the GitHub repository.	<p>Clone the GitHub <a href="#">aws-codepipeline-terraform-cicdsamples</a> repository by running the following command in a terminal window:</p> <pre data-bbox="594 695 1027 936">git clone https://github.com/aws-samples/aws-codepipeline-terraform-cicdsamples.git</pre> <p>For more information, see <a href="#">Cloning a repository</a> in the GitHub documentation.</p>	DevOps engineer
Create a Terraform variable definitions file.	<p>Create a terraform <code>.tfvars</code> file based on your use case requirements. You can update the variables in the <code>examples/terraform.tfvars</code> file that's in the cloned repository.</p> <p>For more information, see <a href="#">Assigning values to root module variables</a> in the Terraform documentation.</p> <p><b>Note:</b> The repository's <code>Readme.md</code> file includes</p>	DevOps engineer

Task	Description	Skills required
	more information on the required variables.	
Configure AWS as the Terraform provider.	<ol style="list-style-type: none"><li data-bbox="591 338 1027 470">1. In a code editor, open the cloned repository's <code>main.tf</code> file.</li><li data-bbox="591 491 1027 667">2. Add the necessary configurations for establishing connectivity to the target AWS account.</li></ol> <p data-bbox="591 743 976 875">For more information, see <a href="#">AWS provider</a> in the Terraform documentation.</p>	DevOps engineer

Task	Description	Skills required
<p>Update the Terraform provider configuration for creating the Amazon S3 replication bucket.</p>	<ol style="list-style-type: none"><li data-bbox="591 226 1027 359">1. Open the repository's S3 directory by running the following command: <pre data-bbox="630 394 1027 474">cd ./modules/s3</pre></li><li data-bbox="591 489 1027 905">2. Update the Terraform provider configuration for creating the Amazon S3 replication bucket by updating the <code>region</code> value in the <code>tf</code> file. Make sure that you enter the Region that you want Amazon S3 to replicate objects to.</li><li data-bbox="591 926 1027 1440">3. <b>(Optional)</b> By default, Terraform uses local state files for state management. If you want to add Amazon S3 as the remote backend, you must update the Terraform configuration. For more information, see <a href="#">Backend configuration</a> in the Terraform documentation.</li></ol> <p data-bbox="591 1518 1027 1692"><b>Note:</b> Replication activates automatic, asynchronous copying of objects across Amazon S3 buckets.</p>	DevOps engineer

Task	Description	Skills required
Initialize the Terraform configuration.	<p>To initialize your working directory that contains the Terraform configuration files, run the following command in the cloned repository's root folder:</p> <pre data-bbox="594 537 1027 617">terraform init</pre>	DevOps engineer
Create the Terraform plan.	<p>To create a Terraform plan, run the following command in the cloned repository's root folder:</p> <pre data-bbox="594 873 1027 1031">terraform plan --var-file=terraform.tfvars -out=tfplan</pre> <p><b>Note:</b> Terraform evaluates the configuration files to determine the target state for the declared resources. It then compares the target state against the current state and creates a plan.</p>	DevOps engineer
Verify the Terraform plan.	Review the Terraform plan and confirm that it configures the required architecture in your target AWS account.	DevOps engineer

Task	Description	Skills required
Deploy the solution.	<ol style="list-style-type: none"><li>To apply the Terraform plan, run the following command in the cloned repository's root folder: <pre>terraform apply "tfplan"</pre></li><li>Enter <b>yes</b> to confirm that you want to deploy the resources.</li></ol> <p><b>Note:</b> Terraform creates, updates, or destroys infrastructure to achieve the target state declared in the configuration files.</p>	DevOps engineer

## Validate Terraform configurations by running the pipeline

Task	Description	Skills required
Set up the source code repository.	<ol style="list-style-type: none"><li>From the Terraform output, get the <b>source repository</b> details for the repository that contains the Terraform configurations that you want to validate.</li><li>Sign in to the AWS Management Console. Then, open the <a href="#">CodeCommit console</a>.</li><li>Create a new branch in the source repository named</li></ol>	DevOps engineer

Task	Description	Skills required
	<p>main. For instructions, see <a href="#">Create a branch in AWS CodeCommit</a> in the CodeCommit documentation.</p> <p>4. Clone the main branch of the <b>source repository</b> to your local workstation. For instructions, see <a href="#">Setup steps for HTTPS connections to AWS CodeCommit repositories on Windows with the AWS CLI credential helper</a> in the CodeCommit documentation.</p> <p>5. Copy the templates folder from the GitHub <a href="#">aws-codepipeline-terraform-cicdsamples</a> repository by running the following command:</p> <pre data-bbox="630 1255 1029 1417">cp -r templates \$YOUR_CODECOMMIT_REPO_ROOT</pre> <p><b>Note:</b> The templates folder contains the build specification files and the validation script for the root directory of the source repository.</p> <p>6. Add your required Terraform IaC configura</p>	

Task	Description	Skills required
	<p>tions to the root folder of the <b>source repository</b>.</p> <ol style="list-style-type: none"><li data-bbox="594 310 1016 583">7. Add the details for the remote backend in your project's Terraform configuration. For more information, see <a href="#">S3</a> in the Terraform documentation.</li><li data-bbox="594 611 1016 1115">8. <b>(Optional)</b> Update the variables in the <code>templates</code> folder to either activate or deactivate the preconfigured scans, tool change versions, and to specify your directory in custom script files. For more information, see the <i>Additional information</i> section of this pattern.</li><li data-bbox="594 1142 1016 1268">9. Push the changes to the main branch of the <b>source repository</b>.</li></ol>	

Task	Description	Skills required
Validate the pipeline stages.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">CodePipeline console</a>.</li><li>2. In the output generated from the terraform apply "tfplan" command in the previous Epic section, find the name of the generated <b>CodePipeline</b>.</li><li>3. Open the pipeline in the CodePipeline console and choose <b>Release change</b>.</li><li>4. Review each pipeline stage and confirm it's working as expected.</li></ol> <p>For more information, see <a href="#">View pipeline details and history (console)</a> in the <i>AWS CodePipeline User Guide</i>.</p> <p><b>Important:</b> When a change is committed to the main branch of the source repository, the test pipeline is activated automatically.</p>	DevOps engineer

Task	Description	Skills required
Verify the report output.	<ol style="list-style-type: none"><li>1. On the <a href="#">CodePipeline console</a>, in the left navigation pane, choose <b>Build</b>. Then, choose <b>Report history</b>.</li><li>2. Review the tfsec and checkov scan reports that the pipeline generates. These reports can help you identify issues through visualizations and graphical representations.</li></ol> <p><b>Note:</b> The <code>&lt;project_name&gt;-validate</code> CodeBuild project generates vulnerability reports for your code during the “validate” stage.</p>	DevOps engineer

## Clean up your resources

Task	Description	Skills required
Clean up the pipeline and associated resources.	<p>To delete the test resources from your AWS account, run the following command in the cloned repository's root folder:</p> <pre>terraform destroy --var-file=terraform.tfvars</pre>	DevOps engineer

## Troubleshooting

Issue	Solution
You receive an <b>AccessDenied</b> error during the “apply” stage.	<ol style="list-style-type: none"><li>1. Review the execution logs of the CodeBuild project associated with the “apply” stage to identify any missing IAM permissions. For more information, see <a href="#">View build details in AWS CodeBuild</a> in the <i>AWS CodeBuild User Guide</i>.</li><li>2. In a code editor, open the cloned repository's <code>modules</code> folder. Then, navigate to the <code>iam-role</code> folder and open the <code>main.tf</code> file that's in that folder.</li><li>3. In the <code>codepipeline_policy</code> statement, add the IAM policies that are required for provisioning resources in your AWS account.</li></ol>

- [Data protection in AWS CodePipeline](#) (AWS CodePipeline documentation)

## Additional information

### Custom Terraform modules

The following is a list of custom Terraform modules that are used in this pattern:

- `codebuild_terraform` creates the CodeBuild projects that form each stage of the pipeline.
- `codecommit_infrastructure_source_repo` captures and creates the source CodeCommit repository.
- `codepipeline_iam_role` creates the required IAM roles for the pipeline.
- `codepipeline_kms` creates the required AWS KMS key for Amazon S3 object encryption and decryption.
- `codepipeline_terraform` creates the test pipeline for the source CodeCommit repository.
- `s3_artifacts_bucket` creates an Amazon S3 bucket to manage pipeline artifacts.

### Build specification files

The following is a list of build specification (buildspec) files that this pattern uses to run each pipeline stage:

- `buildspec_validate.yml` runs the “validate” stage.
- `buildspec_plan.yml` runs the “plan” stage.
- `buildspec_apply.yml` runs the “apply” stage.
- `buildspec_destroy.yml` runs the “destroy” stage.

### *Build specification file variables*

Each buildspec file uses the following variables to activate different build-specific settings:

Variable	Default value	Description
<code>CODE_SRC_DIR</code>	<code>"."</code>	Defines the source CodeCommit directory
<code>TF_VERSION</code>	<code>"1.3.7"</code>	Defines the Terraform version for the build environment

The `buildspec_validate.yml` file also supports the following variables to activate different build-specific settings:

Variable	Default value	Description
SCRIPT_DIR	"/templates/scripts"	Defines the script directory
ENVIRONMENT	"dev"	Defines the environment name
SKIPVALIDATIONFAILURE	"Y"	Skips validation on failures
ENABLE_TFVALIDATE	"Y"	Activates Terraform validate
ENABLE_TFFORMAT	"Y"	Activates Terraform format
ENABLE_TFCHECKOV	"Y"	Activates checkov scan
ENABLE_TFSEC	"Y"	Activates tfsec scan
TFSEC_VERSION	"v1.28.1"	Defines the tfsec version

# Automatically generate a PynamoDB model and CRUD functions for Amazon DynamoDB by using a Python application

Created by Vijit Vashishtha (AWS), Dheeraj Alimchandani (AWS), and Dhananjay Karanjkar (AWS)

<b>Code repository:</b> <a href="#">amazon-reverse-engineer-dynamodb</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> DevelopmentAndTesting; Databases; DevOps
<b>Workload:</b> Open-source	<b>AWS services:</b> Amazon DynamoDB	

## Summary

It's common to require entities and create, read, update, and delete (CRUD) operations functions to efficiently perform Amazon DynamoDB database operations. PynamoDB is a Python-based interface that supports Python 3. It also provides features such as support for Amazon DynamoDB transactions, automatic attribute value serialization and deserialization, and compatibility with common Python frameworks, such as Flask and Django. This pattern helps developers working with Python and DynamoDB by providing a library that streamlines the automatic creation of PynamoDB models and CRUD operation functions. While it generates essential CRUD functions for database tables, it can also reverse engineer PynamoDB models and CRUD functions from Amazon DynamoDB tables. This pattern is designed to simplify database operations by using a Python-based application.

The following are the key features of this solution:

- **JSON schema to PynamoDB model** – Automatically generate PynamoDB models in Python by importing a JSON schema file.
- **CRUD function generation** – Automatically generate functions to perform CRUD operations on DynamoDB tables.
- **Reverse engineering from DynamoDB** – Use PynamoDB object-relational mapping (ORM) to reverse engineer PynamoDB models and CRUD functions for existing Amazon DynamoDB tables.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Python version 3.8 or later, [downloaded](#) and installed
- Jinja2 version 3.1.2 or later, [downloaded](#) and installed
- Amazon DynamoDB tables for which you want to generate ORM
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- PynamoDB version 5.4.1 or later, [installed](#)

## Architecture

### Target technology stack

- JSON script
- Python application
- PynamoDB model
- Amazon DynamoDB database instance

### Target architecture

1. You create an input JSON schema file. This JSON schema file represents the attributes of the respective DynamoDB tables that you want to create PynamoDB models from and CRUD functions for. It contains the following three important keys:
  - **name** – The name of the target DynamoDB table.
  - **region** – The AWS region where the table is hosted
  - **attributes** – The attributes that are part of the target table, such as the [partition key](#) (also known as a *hash attribute*), [sort key](#), [local secondary indexes](#), [global secondary indexes](#), and any [non-key attributes](#). This tool expects the input schema to only provide the non-key attributes as the application fetches the key attributes directly from the target table. For an example of how to specify attributes in the JSON schema file, see the [Additional information](#) section of this pattern.
2. Run the Python application and provide the JSON schema file as an input.
3. The Python application reads the JSON schema file.

4. The Python application connects to the DynamoDB tables to derive the schema and data types. The application runs the [describe\\_table](#) operation and fetches the key and index attributes for the table.
5. The Python application combines the attributes from the JSON schema file and DynamoDB table. It uses the Jinja template engine to generate a PynamoDB model and corresponding CRUD functions.
6. You access the PynamoDB model to perform CRUD operations on the DynamoDB table.

## Tools

### AWS services

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

### Other tools

- [Jinja](#) is an extensible templating engine that compiles templates into optimized Python code. This pattern uses Jinja to generate dynamic content by embedding placeholders and logic within templates.
- [PynamoDB](#) is a Python-based interface for Amazon DynamoDB.
- [Python](#) is a general-purpose computer programming language.

### Code repository

The code for this pattern is available in the GitHub [Auto-generate PynamoDB models and CRUD functions](#) repository. The repository is divided into two main parts: the controller package and the templates.

#### *Controller package*

The controller Python package contains the main application logic that helps generate the PynamoDB model and the CRUD functions. It contains the following:

- `input_json_validator.py` – This Python script validates the input JSON schema file and creates the Python objects that contain the list of target DynamoDB tables and the required attributes for each.

- `dynamo_connection.py` – This script establishes a connection to the DynamoDB table and uses the `describe_table` operation to extract the attributes that are necessary to create the PynamoDB model.
- `generate_model.py` – This script contains a Python class `GenerateModel` that creates the PynamoDB model based on the input JSON schema file and the `describe_table` operation.
- `generate_crud.py` – For the DynamoDB tables that are defined in the JSON schema file, this script uses the `GenerateCrud` operation to create the Python classes.

## Templates

This Python directory contains the following Jinja templates:

- `model.jinja` – This Jinja template contains the template expression for generating the PynamoDB model script.
- `crud.jinja` – This Jinja template contains the template expression for generating the CRUD functions script.

## Epics

### Set up the environment

Task	Description	Skills required
Clone the repository.	Enter the following command to clone the <a href="#">Auto-generate PynamoDB models and CRUD functions</a> repository. <pre>git clone https://github.com/aws-samples/amazon-reverse-engineer-dynamodb.git</pre>	App developer
Set up the Python environment.	1. Navigate into the top-level directory in the cloned repository.	App developer

Task	Description	Skills required
	<pre data-bbox="634 212 1027 327">cd amazon-reverse-engineer-dynamodb</pre> <p data-bbox="592 342 967 520">2. Enter the following command to install the required libraries and packages.</p> <pre data-bbox="634 562 1027 678">pip install -r requirements.txt</pre>	

### Generate the PynamoDB model and CRUD functions

Task	Description	Skills required
Modify the JSON schema file.	<ol data-bbox="592 993 1023 1123" style="list-style-type: none"> <li>1. Navigate into the top-level directory in the cloned repository.</li> </ol> <pre data-bbox="634 1157 1027 1272">cd amazon-reverse-engineer-dynamodb</pre> <ol data-bbox="592 1293 1023 1854" style="list-style-type: none"> <li>2. Open the <code>test.json</code> file in your preferred editor. You can use this file as a reference to create your own JSON schema file, or you can update the values in this file to match your environment.</li> <li>3. Modify the name, AWS Region, and attributes values for your target DynamoDB tables.</li> </ol>	App developer

Task	Description	Skills required
	<p><b>Note:</b> If you define a table that does not exist in the JSON schema file, this solution does not generate models or CRUD functions for that table.</p> <p>4. Save and close the <code>test.json</code> file. We recommend that you save this file with a new name.</p>	
Run the Python application.	<p>Enter the following command to generate the PynamoDB models and CRUD functions , where <code>&lt;input_schema.json&gt;</code> is the name of your JSON schema file.</p> <pre data-bbox="597 1073 1029 1192">python main.py --file &lt;input_schema.json&gt;</pre>	App developer

## Verify the PynamoDB model and CRUD functions

Task	Description	Skills required
Verify the generated PynamoDB model.	<p>1. In the top-level directory of the cloned repository, enter the following command to navigate into the <code>models</code> repository.</p> <pre data-bbox="630 1745 1029 1822">cd models</pre>	App developer

Task	Description	Skills required
	<p>2. By default, this solution names the PynamoDB model file <code>demo_model_1.py</code>. Validate that this file is present.</p>	
<p>Verify the generated CRUD functions.</p>	<p>1. In the top-level directory of the cloned repository, enter the following command to navigate into the <code>crud</code> repository.</p> <pre data-bbox="630 743 1029 827">cd crud</pre> <p>2. By default, this solution names the script <code>demo_crud.py</code>. Validate that this file is present.</p> <p>3. Use the Python classes in the <code>demo_crud.py</code> file to perform a CRUD operation on the target DynamoDB table. Confirm that the operation completed successfully.</p>	<p>App developer</p>

## Additional information

### Sample attributes for the JSON schema file

```
[
{
  "name": "test_table",
  "region": "ap-south-1",
  "attributes": [
    {
      "name": "id",
      "type": "UnicodeAttribute"
    },
    {
      "name": "name",
      "type": "UnicodeAttribute"
    },
    {
      "name": "age",
      "type": "NumberAttribute"
    }
  ]
}
]
```

# Explore full-stack cloud-native web application development with Green Boost

Created by Ben Stickley (AWS) and Amiin Samatar (AWS)

**Environment:** PoC or pilot

**Technologies:** DevelopmentAndTesting; Web & mobile apps; CloudNative

**Workload:** Open-source

**AWS services:** Amazon Aurora; AWS CDK; Amazon CloudFront; AWS Lambda; AWS WAF

## Summary

In response to the evolving needs of developers, Amazon Web Services (AWS) recognizes the critical demand for an efficient approach to developing cloud-native web applications. The AWS focus is on helping you to overcome common roadblocks associated with deploying web apps on the AWS Cloud. By harnessing the capabilities of modern technologies such as TypeScript, AWS Cloud Development Kit (AWS CDK), React, and Node.js, this pattern aims to streamline and expedite the development process.

Underpinned by the Green Boost (GB) toolkit, the pattern offers a practical guide to constructing web applications that fully use the extensive capabilities of AWS. It acts as a comprehensive roadmap, leading you through the process of deploying a fundamental CRUD (Create, Read, Update, Delete) web application integrated with Amazon Aurora PostgreSQL-Compatible Edition. This is accomplished by using the Green Boost command line interface (Green Boost CLI) and establishing a local development environment.

Following the successful deployment of the application, the pattern delves into key components of the web app, including infrastructure design, backend and frontend development, and essential tools such as cdk-dia for visualization, facilitating efficient project management.

## Prerequisites and limitations

### Prerequisites

- [Git](#) installed
- [Visual Studio Code \(VS Code\)](#) installed
- [AWS Command Line Interface \(AWS CLI\)](#) installed
- [AWS CDK Toolkit](#) installed
- [Node.js 18](#) installed, or [Node.js 18 with pnpm](#) activated
- [pnpm](#) installed, if it isn't part of your Node.js installation
- Basic familiarity with TypeScript, AWS CDK, Node.js, and React
- An [active AWS account](#)
- [An AWS account bootstrapped](#) by using AWS CDK in us-east-1. The us-east-1 AWS Region is required for support of the Amazon CloudFront Lambda@Edge functions.
- [AWS security credentials](#), including `AWS_ACCESS_KEY_ID`, correctly configured in your terminal environment
- For Windows users, a terminal in administrator mode (to accommodate the way pnpm handles node modules)

## Product versions

- AWS SDK for JavaScript version 3
- AWS CDK version 2
- AWS CLI version 2.2
- Node.js version 18
- React version 18

## Architecture

### Target technology stack

- Amazon Aurora PostgreSQL-Compatible Edition
- Amazon CloudFront
- Amazon CloudWatch
- Amazon Elastic Compute Cloud (Amazon EC2)
- AWS Lambda

- AWS Secrets Manager
- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Storage Service (Amazon S3)
- AWS WAF

## Target Architecture

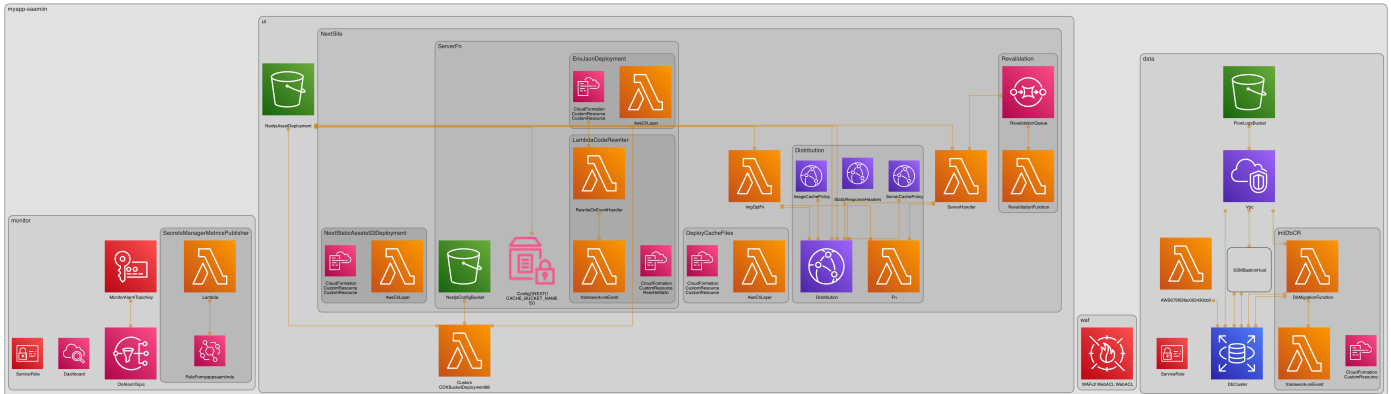

The following diagram shows that user requests pass through Amazon CloudFront, AWS WAF, and AWS Lambda before interacting with an S3 bucket, an Aurora database, an EC2 instance, and ultimately reaching developers. Administrators, on the other hand, use Amazon SNS and Amazon CloudWatch for notifications and monitoring purposes.

To gain a more in-depth look at the application after deployment, you can create diagram by using [cdk-dia](#), as shown in the following example.

These diagrams showcase the web application architecture from two distinct angles. The `cdk-dia` diagram offers a detailed technical view of the AWS CDK infrastructure, highlighting specific AWS services such as Amazon Aurora PostgreSQL-Compatible and AWS Lambda. In contrast, the other

diagram takes a broader perspective, emphasizing the logical flow of data and user interactions. The key distinction lies in the level of detail: The cdk-dia delves into technical intricacies, while the first diagram provides a more user-centric view.

Creation of the cdk-dia diagram is covered in the epic *Understand the app infrastructure by using AWS CDK*.

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon CloudFront](#) speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses AWS Systems Manager Session Manager.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [AWS WAF](#) is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources

## Other tools

- [Git](#) is an open-source, distributed version control system.
- [Green Boost](#) is a toolkit for building web apps on AWS.
- [Next.js](#) is a React framework for adding features and optimizations.
- [Node.js](#) is an event-driven JavaScript runtime environment designed for building scalable network applications.
- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
- [pnpm](#) is a package manager for Node.js project dependencies.

## Best practices

See the [Epics](#) section for more information about the following recommendations:

- Monitor infrastructure by using Amazon CloudWatch Dashboards and alarms.
- Enforce AWS best practices by using cdk-nag to run static infrastructure as code (IaC) analysis.
- Establish DB port forwarding through SSH (Secure Shell) tunneling with Systems Manager Session Manager, which is more secure than having a publicly exposed IP address.
- Manage vulnerabilities by running `pnpm audit`.

- Enforce best practices by using [ESLint](#) to perform static TypeScript code analysis, and [Prettier](#) to standardize code formatting.

## Epics

### Deploy a CRUD web app with Aurora PostgreSQL-Compatible

Task	Description	Skills required
Install the Green Boost CLI.	To install Green Boost CLI, run the following command.  <pre>pnpm add -g gboost</pre>	App developer
Create a GB app.	<ol style="list-style-type: none"> <li>To create an app by using Green Boost, run the command <code>gboost create</code>.</li> <li>Choose the CRUD App with Aurora PostgreSQL template.</li> </ol>	App developer
Install dependencies and deploy the app.	<ol style="list-style-type: none"> <li>Navigate to the project directory: <code>cd &lt;your directory&gt; .</code></li> <li>To install dependencies, run the command <code>pnpm i</code>.</li> <li>Navigate to the infra directory: <code>cd infra</code>.</li> <li>To deploy the app locally, run the command <code>pnpm deploy:local .</code></li> </ol> <p>This is an alias for a <code>cdk deploy ...</code> command</p>	App developer

Task	Description	Skills required
	<p>defined in <code>infra/package.json</code> .</p> <p>Wait for deployment to finish (approximately 20 minutes). While you're waiting, monitor AWS CloudFormation stacks in the CloudFormation console. Notice how the constructs defined in the code map to the resource deployed. Review the <a href="#">CDK Construct tree view</a> in the CloudFormation console.</p>	

Task	Description	Skills required
Access the app.	<p>After deploying your GB app locally, you can access it using the CloudFront URL. The URL is printed in the terminal output, but it can be a bit overwhelming to find. To find it more quickly, use the following steps:</p> <ol style="list-style-type: none"><li>1. Open the terminal where you ran the <code>pnpm deploy:local</code> command.</li><li>2. Look for a section in the terminal output that resembles the following text.</li></ol> <pre data-bbox="630 1056 1027 1293">myapp5stickbui9C39 A55A.CloudFrontDom ainName = d1q16n5po f924c.cloudfront.n et</pre> <p>The URL will be unique to your deployment.</p> <p>Alternatively, you can find the CloudFront URL by accessing the Amazon CloudFront console:</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and</li></ol>	App developer

Task	Description	Skills required
	<p>navigate to the CloudFront service.</p> <p>2. Look for the latest deployed distribution in the list.</p> <p>Copy the <b>Domain Name</b> that is associated with the distribution. It will look similar to <code>your-unique-id.cloudfront.net</code> .</p>	

### Monitor by using Amazon CloudWatch

Task	Description	Skills required
View the CloudWatch Dashboard.	<ol style="list-style-type: none"> <li>1. Open the CloudWatch console and choose <b>Dashboards</b>.</li> <li>2. Select the dashboard that has the name <code>&lt;appId&gt;-&lt;stageName&gt;-dashboard</code>.</li> <li>3. Review the dashboard . What resources are being monitored? What metrics are being recorded? This dashboard is made possible by the open-source construct <a href="#">cdk-monitoring-constructs</a>.</li> </ol>	App developer
Enable alerts.	A CloudWatch Dashboard helps you to actively monitor your web app. To passively	App developer

Task	Description	Skills required
	<p>monitor your web app, you can enable alerting.</p> <ol style="list-style-type: none"><li>1. Navigate to <code>/infra/src/app/stateless/monitor-stack.ts</code>, which defines the monitor stack.</li><li>2. Uncomment the following line, and replace <code>admin@example.com</code> with your email address.</li></ol> <pre data-bbox="634 806 1027 1041">onAlarmTopic.addSubscription(new EmailSubscription("admin@example.com"));</pre> <ol style="list-style-type: none"><li>3. Add the following import information to the top of the file.</li></ol> <pre data-bbox="634 1226 1027 1419">import { EmailSubscription } from "aws-cdk-lib/aws-sns-subscriptions";</pre> <ol style="list-style-type: none"><li>4. Within <code>infra/</code>, run the following command.</li></ol> <pre data-bbox="634 1562 1027 1675">cdk deploy "*/monitor" --exclusively.</pre> <ol style="list-style-type: none"><li>5. To confirm your subscription to the SNS topic that is initiated when a monitoring alarm is initiated, choose</li></ol>	

Task	Description	Skills required
	the link in the email message.	

## Understand the app infrastructure by using AWS CDK

Task	Description	Skills required
Create an architecture diagram.	<p>Generate an architecture diagram of your web app by using <a href="#">cdk-dia</a>. Visualizing the architecture helps improve understanding and communication among team members. It provides a clear overview of the system's components and their relationships.</p> <ol style="list-style-type: none"> <li>1. Install <a href="#">Graphviz</a>.</li> <li>2. Within <code>infra/</code>, run the command <code>pnpm cdk-dia</code>.</li> <li>3. View your <code>infra/diagram.png</code>.</li> </ol>	App developer
Use <code>cdk-nag</code> to enforce best practices.	<p>Use <a href="#">cdk-nag</a> to help you maintain secure and compliant infrastructure by enforcing best practices, reducing the risk of security vulnerabilities and misconfigurations.</p> <ol style="list-style-type: none"> <li>1. Explore <code>cdk-nag</code>'s best practice enforcement through its <a href="#">rules</a> section,</li> </ol>	App developer

Task	Description	Skills required
	<p>including checks from the AWS Solutions Library's Rules Pack.</p> <ol style="list-style-type: none"><li data-bbox="592 363 1027 783">2. To see how cdk-nag enforces rules, make a change in the code. For example, in <code>infra/src/app/stateful/data-stacks.ts</code>, change <code>storageEncrypted: true</code> to <code>storageEncrypted: false</code>.</li><li data-bbox="592 804 1027 1129">3. Within <code>infra/</code>, run the command <code>cdk synth "*/data"</code>. During synthesis, you will encounter a build error that indicates a rule violation.  <code>AwsSolutions-RDS2: The RDS instance or Aurora DB cluster does not have storage encryption enabled.</code>  This error showcases how cdk-nag is a security mechanism for enforcing infrastructure best practices and preventing security misconfigurations.</li><li data-bbox="592 1791 1027 1875">4. If needed, you can also <a href="#">suppress rules</a> at different</li></ol>	

Task	Description	Skills required
	<p>scopes. For example, to suppress AwsSolutions-RDS2, add the following code below the instantiation of <code>DbIamCluster</code> .</p> <pre data-bbox="634 474 1029 1188"> NagSuppressions.addResourceSuppressions(     cluster.node.findChild("Resource"),     [         {             id: "AwsSolutions-RDS2",             reason:                 "Customer requirement necessitates having unencrypted DB storage",         },     ], ); </pre> <p>5. After suppression, run <code>cdk synth "*/data"</code> again. Your AWS CDK app should now synthesize successfully. You can find all suppressed rules in <code>infra/cdk.out/assembly-&lt;appId&gt;-&lt;stageName&gt;/AwsSolutions-&lt;appId&gt;-&lt;stageName&gt;-\${stackId}-NagReport.csv</code> .</p>	

## Evaluate the database configuration and schema

Task	Description	Skills required
Acquire environment variables.	<p>To obtain the required environment variables, use the following steps:</p> <ol style="list-style-type: none"><li>1. To find the DB_BASTION_ID , sign in to the console, and navigate to the EC2 console. Choose <b>Instances (running)</b>, and find the row that contains <b>&lt;stageName&gt;-ssm-db-bastion Name</b>. The instance ID starts with <b>i-</b>.</li><li>2. To find the DB_ENDPOINT , on the Amazon Relational Database Service (Amazon RDS) console, choose <b>DB Instances</b>, and select the regional cluster that has a DB identifier starting with <b>&lt;appId&gt;-&lt;stageName&gt;-data-</b>. Locate the writer instance endpoint, which ends with <b>rds.amazonaws.com</b>.</li></ol>	App developer
Establish port forwarding.	To establish port forwarding, use the following steps:	App developer

Task	Description	Skills required
	<ol style="list-style-type: none"><li>1. Install the AWS Systems Manager <a href="#">Session Manager plugin</a>.</li><li>2. Start port forwarding by running <code>pnpm db:connect</code> within <code>core/</code> to establish a secure connection through the bastion host.</li><li>3. After you see the text <code>Waiting for connections...</code>, in your terminal, an SSH tunnel has been successfully established between your local machine and the Aurora server through the EC2 bastion host.</li></ol>	
Adjust the Systems Manager Session Manager timeout.	(Optional) If the default 20-minute session timeout is too short, you can increase it up to 60 minutes in the Systems Manager console by choosing <b>Session Manager, Preferences, Edit, Idle session timeout</b> .	App developer

Task	Description	Skills required
Visualize the database.	<p>pgAdmin is a user-friendly open-source tool for managing PostgreSQL databases. It simplifies database tasks, allowing you to efficiently create, manage, and optimize databases. This section guides you through <a href="#">installing pgAdmin</a> and using its features for PostgreSQL database management.</p> <ol style="list-style-type: none"><li>1. In the Object Explorer, open the context (right-click) menu for <b>Servers</b>, and then choose <b>Register, Server</b>.</li><li>2. On the <b>General</b> tab, enter <b>&lt;appId&gt;-&lt;stageName&gt;</b> for the <b>Name</b> field.</li><li>3. To fetch the DB password, open the AWS Secrets Manager console, select the secret that has the description <b>Generated by the CDK for the stack: &lt;appId&gt;-&lt;stageName&gt;-data</b>, and choose the <b>Secret Value</b> card. Choose <b>Retrieve Secret Value</b>, and copy the <b>Secret value</b> with a key of <b>password</b>.</li><li>4. On the <b>Connection</b> tab, enter <b>0.0.0</b> for the <b>Host</b></li></ol>	App developer

Task	Description	Skills required
	<p><b>name/address</b> field, and enter <b>&lt;appId&gt;_admin</b> for the <b>Username</b> field. For the <b>Password</b> field, use the secret that you fetched previously. Choose <b>yes</b> for the <b>Save password?</b> field.</p> <p>5. Choose <b>Save</b>.</p> <p>6. To view the tables, navigate to <b>&lt;appId&gt;-&lt;stageName&gt;, Databases, &lt;appId&gt;_db, Schemas, &lt;appId&gt;, Tables</b>.</p> <p>7. Open the context (right-click) menu for the <b>item</b> table, and then select <b>View/Edit Data, All Rows</b>.</p> <p>8. Explore the table.</p>	

## Debug with Node.js

Task	Description	Skills required
<p>Debug the create item use case.</p>	<p>To debug the create item use case, follow these steps:</p> <ol style="list-style-type: none"> <li>1. Open the <code>core/src/modules/item/create-item.use-case.ts</code> file, and insert the following code.</li> </ol>	<p>App developer</p>

Task	Description	Skills required
	<pre data-bbox="633 210 1023 1039">import { fileURLToPath } from "node:url";  // existing create-item.use-case.ts code here  if (process.argv[1] === fileURLToPath(import.meta.url)) {   createItemUseCase(     {       description: "Item 1's Description",       name: "Item 1",     }); }</pre> <ol data-bbox="592 1060 1031 1837" style="list-style-type: none"><li data-bbox="592 1060 1031 1522">2. The code added in the previous step ensures the <code>createItemUseCase</code> function will be called when this module is run directly. Set <a href="#">breakpoints</a> on the lines within this code block where you want to initiate line-by-line debugging.</li><li data-bbox="592 1596 1031 1837">1. Open the <a href="#">VS Code JavaScript Debug Terminal</a>, and then run <code>pnpm tsx core/src/modules/item/create-item.us</code></li></ol>	

Task	Description	Skills required
	<p><code>e-case.ts</code> to run the code with line-by-line debugging. Alternatively, you can use <code>console.log</code> statements, but print statements can be inadequate when you're working with complex business logic. Line-by-line debugging gives you more context.</p>	

## Develop the frontend

Task	Description	Skills required
Set up the development server.	<ol style="list-style-type: none"> <li>1. Navigate to <code>ui/</code>, and run <code>pnpm dev</code> to start the <a href="#">Next.js</a> development server.</li> <li>2. Access your web app locally at <code>http://localhost:3000</code>. The Next.js development server is set up with <a href="#">Fast Refresh</a> instantaneous feedback on edits made to your React components.</li> <li>3. Experiment with customizing the app bar color. Open the <code>ui/src/components/theme/theme.tsx</code> file and locate the section that defines</li> </ol>	App developer

Task	Description	Skills required
	<p>the theme for the app bar. In the <code>colorSchemes.light.palette.primary</code> section, update the main value from <code>colors.lagoon</code> to <code>colors.carrot</code>. After making this change, save the file and observe the update in your browser.</p> <p>4. Experiment by modifying text, components, and adding new pages.</p>	

## Tooling with Green Boost

Task	Description	Skills required
Set up monorepo and the pnpm package manager.	<ol style="list-style-type: none"> <li>Review <code>pnpm-workspace.yaml</code> in the root of your GB repository, and notice how workspaces are defined. For more information about workspaces, see the <a href="#">pnpm documentation</a>.</li> <li>Review <code>ui/package.json</code>, and notice how it references the workspace in <code>core/</code> with the package name <code>"&lt;appId&gt;/core": "workspace:^",</code></li> </ol>	App developer

Task	Description	Skills required
	<p>3. Observe how TypeScript and ESLint configuration is centralized in utility packages defined within packages/. This configuration is then used by application packages such as <code>core/</code>, <code>infra/</code>, and <code>ui/</code>. This is helpful when your app scales and you define more application packages, which can reference the utility packages without duplicating configuration code.</p>	

Task	Description	Skills required
Run pnpm scripts.	<p>Run the following commands in the root of your repository:</p> <ol style="list-style-type: none"><li>1. Run <code>pnpm lint</code>. This command runs static code analysis with <a href="#">ESLint</a>.</li><li>2. Run <code>pnpm typecheck</code>. This command runs the <a href="#">TypeScript compiler</a> to check the types of your code.</li><li>3. Run <code>pnpm test</code>. This command runs <a href="#">Vitest</a> to run unit tests.</li></ol> <p>Notice how these commands are run in all workspaces. The commands are defined in each workspace's <code>package.json#scripts</code> field.</p>	App developer

Task	Description	Skills required
Use ESLint for static code analysis.	<p>To test the static code analysis capability of ESLint, do the following:</p> <ol style="list-style-type: none"><li>1. First, ensure the <a href="#">VS Code ESLint extension</a> (ID: <code>dbaeumer.vscode-eslint</code>) is installed. We recommend also installing <a href="#">VS Code Error Lens</a> (ID: <code>usernamehw.errorlens</code>) to see errors inline.</li><li>2. In your code, purposefully include a line of code that uses the <code>eval()</code> function, as shown in the following example.</li></ol> <pre data-bbox="630 1058 1029 1417">const userInput =   "import('fs').then   ((fs) =&gt; console.l   og(fs.readFileSync   ('/etc/passwd',   { encoding:   'utf8' })))"; eval(userInput);</pre> <p><b>Important:</b> This is for testing purposes only. Using <code>eval()</code> is considered potentially dangerous and should be avoided because of security risks.</p> <ol style="list-style-type: none"><li>3. After you include the <code>eval()</code> line, open your</li></ol>	App developer

Task	Description	Skills required
	<p>code editor to confirm that ESLint indicated the code smell by using red squiggles.</p> <p>4. Review ESLint plugins and configuration at <code>packages/eslint-config-{node,next}/.eslintrc.cjs</code> .</p>	
<p>Manage dependencies and vulnerabilities.</p>	<ol style="list-style-type: none"> <li>1. To identify any Common Vulnerabilities and Exposures (CVEs), run <code>pnpm audit</code> in the root of your repository.</li> </ol> <p>You should see <b>No known vulnerabilities found.</b></p> <ol style="list-style-type: none"> <li>2. Install an intentionally vulnerable package within <code>core/</code> by running <code>pnpm add minimist@0.2.3</code> , and then run <code>pnpm audit</code>. Notice the vulnerability being reported.</li> <li>3. Uninstall the vulnerable package within <code>core/</code> by running <code>pnpm remove minimist</code>.</li> </ol>	<p>App developer</p>

Task	Description	Skills required
Pre-commit hooks with Husky.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 457">1. Make a couple small changes in TypeScript files throughout the repository. The changes can be as basic as adding comments.</li><li data-bbox="592 478 1027 657">2. Stage and commit these changes by using <code>git add -A</code> and then <code>git commit -m "test husky"</code>.  The <a href="#">Husky</a> pre-commit hook trigger, which is defined in <code>.husky/pre-commit</code>, runs the command <code>npm lint-staged</code>.</li><li data-bbox="592 1003 1027 1276">3. Observe how <a href="#">lint-staged</a> runs commands specified in <code>*/.lintstagedrc.js</code> files throughout the repository on files that have been staged by Git.</li></ol> <p data-bbox="592 1350 1027 1528">These tools are mechanisms to help prevent bad code from making its way into your application.</p>	App developer

## Tear down the infrastructure

Task	Description	Skills required
Remove the deployment from your account.	<ol style="list-style-type: none"> <li>To tear down the infrastructure that you provisioned in the first epic, by run <code>pnpm destroy:local</code> in <code>infra/</code>.</li> <li>Wait 15 minutes after <code>pnpm destroy:local</code> is complete, and then delete the retained Lambda@Edge function by searching for your app ID in the Lambda console. Lambda@Edge functions are replicated, which makes them difficult to delete. For more information about deleting Lambda@Edge functions , see the <a href="#">CloudFront documentation</a>.</li> </ol>	App developer

## Troubleshooting

Issue	Solution
Unable to establish port forwarding	<p>Ensure that your AWS credentials are properly configured and have the necessary permissions.</p> <p>Double-check that the bastion host ID (<code>DB_BASTION_ID</code> ) and database endpoint</p>

Issue	Solution
	<p>(DB_ENDPOINT ) environment variables are correctly set.</p> <p>If you still encounter issues, see the AWS documentation for <a href="#">troubleshooting SSH connections and Session Manager</a>.</p>
Website isn't loading on localhost:3000	<p>Confirm that the terminal output indicates successful port forwarding, including the forwarding address.</p> <p>Ensure there are no conflicting processes using port 3000 on your local machine.</p> <p>Verify that the Green Boost application is properly configured and running on the expected port (3000).</p> <p>Check your web browser for any security extensions or settings that might block local connections.</p>
Error messages during local deployment (pnpm deploy:local )	<p>Review the error messages carefully to identify the cause of the issue.</p> <p>Verify that the necessary environment variables and configuration files are correctly set.</p>

# Run unit tests for a Node.js application from GitHub by using AWS CodeBuild

Created by Thomas Scott (AWS) and Jean-Baptiste Guillois (AWS)

**Code repository:** [Node JS Tests Sample](#)

**Environment:** Production

**Technologies:** DevelopmentAndTesting

**AWS services:** AWS CodeBuild

## Summary

This pattern provides sample source code and key unit test components for a Node.js game API. It also includes instructions for running these unit tests from a GitHub repository by using AWS CodeBuild, as part of your continuous integration and continuous delivery (CI/CD) workflow.

Unit testing is a software development process in which different parts of an application, called *units*, are individually and independently tested for correct operation. Tests validate the quality of the code and confirm that it functions as expected. Other developers can also easily gain familiarity with your code base by consulting the tests. Unit tests reduce future refactoring time, help engineers get up to speed on your code base more quickly, and provide confidence in the expected behavior.

Unit testing involves testing individual functions, including AWS Lambda functions. To create unit tests, you need a testing framework and a way of validating tests (assertions). The code examples in this pattern use the [Mocha](#) testing framework and the [Chai assertion library](#).

For more information about unit testing and examples of test components, see the [Additional information](#) section.

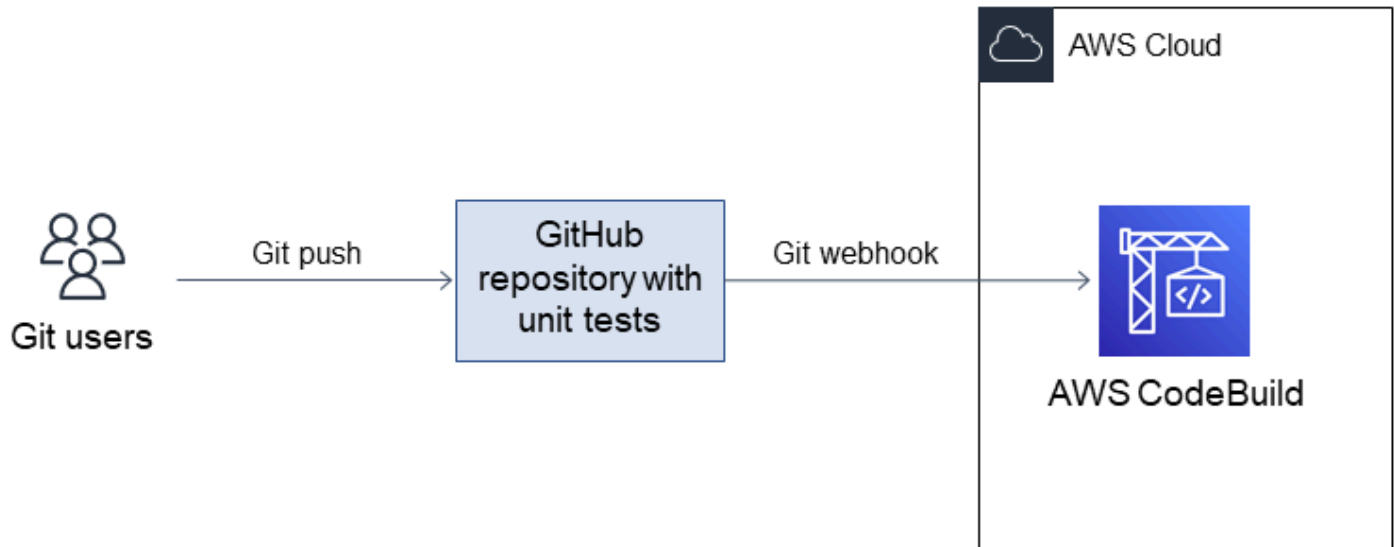

## Prerequisites and limitations

- An active AWS account with correct CodeBuild permissions
- A GitHub account (see [instructions for signing up](#))

- Git (see [installation instructions](#))
- A code editor to make changes and push your code to GitHub (for example, you can use [AWS Cloud9](#))

## Architecture

This pattern implements the architecture that is shown in the following diagram.

## Tools

### Tools

- [Git](#) – Git is a version control system that you can use for code development.
- [AWS Cloud9](#) – AWS Cloud9 is an integrated development environment (IDE) that offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal. It contains a collection of tools that you use to code, build, run, test, and debug software, and helps you release software to the cloud. You access the AWS Cloud9 IDE through a web browser.
- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don't need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you

can create custom build environments that use your own build tools. With CodeBuild, you are charged by the minute for the compute resources you use.

## Code

The source code for this pattern is available on GitHub, in the [Sample game unit test application](#) repository. You can create your own GitHub repository from this sample (option 1) or use the sample repository directly (option 2) for this pattern. Follow the instructions for each option in the next section. The option you follow will depend on your use case.

## Epics

### Option 1 - Run unit tests on your personal GitHub repository with CodeBuild

Task	Description	Skills required
Create your own GitHub repository based on the sample project.	<ol style="list-style-type: none"> <li>1. Log in to GitHub.</li> <li>2. Create a new repository. For instructions, see the <a href="#">GitHub documentation</a>.</li> <li>3. Clone and push the <a href="#">sample repository</a> into the new repository in your account.</li> </ol>	App developer, AWS administrator, AWS DevOps
Create a new CodeBuild project.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the CodeBuild console at <a href="https://console.aws.amazon.com/codesuite/codebuild/home">https://console.aws.amazon.com/codesuite/codebuild/home</a>.</li> <li>2. Choose <b>Create build project</b>.</li> <li>3. In the <b>Project configuration</b> section, for <b>Project name</b>, type <b>aws-tests-sample-node-js</b>.</li> </ol>	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>4. In the <b>Source</b> section, for <b>Source provider</b>, choose <b>GitHub</b>.</li> <li>5. For <b>Repository</b>, choose <b>Repository in my GitHub account</b>, and then paste the URL to your newly created GitHub repository.</li> <li>6. In the <b>Primary source webhook events</b> section, select <b>Rebuild every time a code change is pushed to this repository</b>.</li> <li>7. For event type, choose <b>PUSH</b>.</li> <li>8. In the <b>Environment</b> section, choose <b>Managed image</b>, Amazon Linux 2, and the latest image.</li> <li>9. Leave the default settings for all other options, and then choose <b>Create build project</b>.</li> </ol>	
Start the build.	On the <b>Review</b> page, choose <b>Start build</b> to run the build.	App developer, AWS administrator, AWS DevOps

## Option 2 - Run unit tests on a public repository with CodeBuild

Task	Description	Skills required
Create a new CodeBuild build project.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the CodeBuild console at <a href="https://console.aws.amazon.com/codesuite/codebuild/home">https://console.aws.amazon.com/codesuite/codebuild/home</a>.</li><li>2. Choose <b>Create build project</b>.</li><li>3. In the <b>Project configuration</b> section, for <b>Project name</b>, type <b>aws-tests-sample-node-js</b>.</li><li>4. In the <b>Source</b> section, for <b>Source provider</b>, choose <b>GitHub</b>.</li><li>5. For <b>Repository</b>, choose <b>Public repository</b>, and then paste the URL: <a href="https://github.com/aws-samples/node-js-tests-sample">https://github.com/aws-samples/node-js-tests-sample</a>.</li><li>6. In the <b>Environment</b> section, choose <b>Managed image</b>, Amazon Linux 2, and the latest image.</li><li>7. Leave the default settings for all other options, and then choose <b>Create build project</b>.</li></ol>	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
Start the build.	On the <b>Review</b> page, choose <b>Start build</b> to run the build.	App developer, AWS administrator, AWS DevOps

## Analyze the unit tests

Task	Description	Skills required
View test results.	<p>In the CodeBuild console, review the unit test results from the CodeBuild job. They should match the results shown in the <a href="#">Additional information</a> section.</p> <p>These results validate the GitHub repository integration with CodeBuild.</p>	App developer, AWS administrator, AWS DevOps
Apply a webhook.	You can now apply a webhook, so you can automatically start a build whenever you push code changes to the main branch of your repository. For instructions, see the <a href="#">CodeBuild documentation</a> .	App developer, AWS administrator, AWS DevOps

## Related resources

- [AWS CodeBuild documentation](#)

- [GitHub webhook events](#) (CodeBuild documentation)
- [Creating a new repository](#) (GitHub documentation)

## Additional information

### Unit test results

In the CodeBuild console, you should see the following test results after the project builds successfully.

```
50
51 > node-game-unit-tests@1.0.0 test /codebuild/output/src813991724/src/github.com/aws-samples/node-js-tests-sample
52 > mocha
53
54
55
56 Game Function Group
57   Initialize Game
58     ✓ Check that the game ID is between 0 and 1000
59     ✓ Check that the play date is today
60   Start Game
61     ✓ Check that the game has two competitors
62     ✓ Check that the two competitors have different names
63   End Game
64     ✓ Check that there are no more competitors after the game ends
65   Game ID Stubs and Mocks
66     ✓ Check that an out of range game ID is returned with Stub
67     ✓ Using a mock check that the function was called and returns 9
68
69
70 7 passing (9ms)
71
```

### Example unit test components

This section describes the four types of test components that are used in unit testing: assertions, spies, stubs, and mocks. It includes a brief explanation and code example of each component.

#### Assertions

An assertion is used to verify an expected result. This is an important test component because it validates the expected response from a given function. The following sample assertion validates that the returned ID is between 0 and 1000 when initializing a new game.

```
const { expect } = require('chai');
const { Game } = require('../src/index');

describe('Game Function Group', () => {
  it('Check that the Game ID is between 0 and 1000', function() {
    const game = new Game();
    expect(game.id).is.above(0).but.below(1000)
  })
})
```

```
});  
});
```

## Spies

A spy is used to observe what is happening when a function is running. For example, you might want to validate that the function has been called correctly. The following example shows that start and stop methods are called on a **Game** class object.

```
const { expect } = require('chai');  
const { spy } = require('sinon');  
  
const { Game } = require('../src/index');  
  
describe('Game Function Group', () => {  
  it('should verify that the correct function is called', () => {  
    const spyStart = spy(Game.prototype, "start");  
    const spyStop = spy(Game.prototype, "stop");  
  
    const game = new Game();  
    game.start();  
    game.stop();  
  
    expect(spyStart.called).to.be.true  
    expect(spyStop.called).to.be.true  
  });  
});
```

## Stubs

A stub is used to override a function's default response. This is especially useful when the function makes an external request, because you want to avoid making external requests from unit tests. (External requests are better suited for integration tests, which can physically test requests between different components.) In the following example, a stub forces a return ID from the **getId** function.

```
const { expect } = require('chai');  
const { stub } = require('sinon');  
  
const { Game } = require('../src/index');  
  
describe('Game Function Group', () => {
```

```
it('Check that the Game ID is between 0 and 1000', function() {
  let generateIdStub = stub(Game.prototype, 'getId').returns(999999);

  const game = new Game();

  expect(game.getId).is.equal(999999);

  generateIdStub.restore();
});
});
```

## Mocks

A mock is a fake method that has a pre-programmed behavior for testing different scenarios. A mock can be considered an extended form of a stub and can carry out multiple tasks simultaneously. In the following example, a mock is used to validate three scenarios:

- Function is called
- Function is called with arguments
- Function returns the integer 9

```
const { expect } = require('chai');
const { mock } = require('sinon');

const { Game } = require('../src/index');

describe('Game Function Group', () => {
  it('Check that the Game ID is between 0 and 1000', function() {
    let mock = mock(Game.prototype).expects('getId').withArgs().returns(9);

    const game = new Game();
    const id = game.getId();

    mock.verify();
    expect(id).is.equal(9);
  });
});
```

# Structure a Python project in hexagonal architecture using AWS Lambda

Created by Furkan Oruc (AWS), Dominik Goby (AWS), Darius Kuncce (AWS), and Michal Ploski (AWS)

**Environment:** PoC or pilot

**Technologies:** DevelopmentAndTesting; CloudNative; Containers & microservices; Serverless; Modernization

**AWS services:** Amazon DynamoDB; AWS Lambda; Amazon API Gateway

## Summary

This pattern shows how to structure a Python project in hexagonal architecture by using AWS Lambda. The pattern uses the AWS Cloud Development Kit (AWS CDK) as the infrastructure as code (IaC) tool, Amazon API Gateway as the REST API, and Amazon DynamoDB as the persistence layer. Hexagonal architecture follows domain-driven design principles. In hexagonal architecture, software consists of three components: domain, ports, and adapters. For detailed information about hexagonal architectures and their benefits, see the guide [Building hexagonal architectures on AWS](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Experience in Python
- Familiarity with AWS Lambda, AWS CDK, Amazon API Gateway, and DynamoDB
- A GitHub account (see [instructions for signing up](#))
- Git (see [installation instructions](#))
- A code editor for making changes and pushing your code to GitHub (for example, [AWS Cloud9](#), [Visual Studio Code](#), or [JetBrains PyCharm](#))
- Docker installed, and the Docker daemon up and running

### Product versions

- Git version 2.24.3 or later
- Python version 3.7 or later
- AWS CDK v2
- Poetry version 1.1.13 or later
- AWS Lambda Powertools for Python version 1.25.6 or later
- pytest version 7.1.1 or later
- Moto version 3.1.9 or later
- pydantic version 1.9.0 or later
- Boto3 version 1.22.4 or later
- mypy-boto3-dynamodb version 1.24.0 or later

## Architecture

### Target technology stack

The target technology stack consists of a Python service that uses API Gateway, Lambda, and DynamoDB. The service uses a DynamoDB adapter to persist data. It provides a function that uses Lambda as the entry point. The service uses Amazon API Gateway to expose a REST API. The API uses AWS Identity and Access Management (IAM) for the [authentication of clients](#).

### Target architecture

To illustrate the implementation, this pattern deploys a serverless target architecture. Clients can send requests to an API Gateway endpoint. API Gateway forwards the request to the target Lambda function that implements the hexagonal architecture pattern. The Lambda function performs create, read, update, and delete (CRUD) operations on a DynamoDB table.

**Important:** This pattern was tested in a PoC environment. You must conduct a security review to identify the threat model and create a secure code base before you deploy any architecture to a production environment.

The API supports five operations on a product entity:

- GET `/products` returns all products.
- POST `/products` creates a new product.
- GET `/products/{id}` returns a specific product.
- PUT `/products/{id}` updates a specific product.
- DELETE `/products/{id}` deletes a specific product.

You can use the following folder structure to organize your project to follow the hexagonal architecture pattern:

```

app/ # application code
|--- adapters/ # implementation of the ports defined in the domain
|   |--- tests/ # adapter unit tests
|--- endpoints/ # primary adapters, entry points
|   |--- api/ # api entry point
|       |--- model/ # api model
|       |--- tests/ # end to end api tests
|--- domain/ # domain to implement business logic using hexagonal architecture
|   |--- command_handlers/ # handlers used to execute commands on the domain
|   |--- commands/ # commands on the domain
|   |--- events/ # events triggered via the domain
|   |--- exceptions/ # exceptions defined on the domain
|   |--- model/ # domain model
|   |--- ports/ # abstractions used for external communication
|   |--- tests/ # domain tests
|--- libraries/ # List of 3rd party libraries used by the Lambda function
infra/ # infrastructure code
simple-crud-app.py # AWS CDK v2 app
  
```

## Tools

### AWS services

- [Amazon API Gateway](#) is a fully managed service that makes it easy for developers to create, publish, maintain, monitor, and secure APIs at any scale.
- [Amazon DynamoDB](#) is a fully managed, serverless, key-value NoSQL database that is designed to run high-performance applications at any scale.
- [AWS Lambda](#) is a serverless, event-driven compute service that lets you run code for virtually any type of application or backend service without provisioning or managing servers. You can launch Lambda functions from over 200 AWS services and software as a service (SaaS) applications, and only pay for what you use.

### Tools

- [Git](#) is used as the version control system for code development in this pattern.
- [Python](#) is used as the programming language for this pattern. Python provides high-level data structures and an approach to object-oriented programming. AWS Lambda provides a built-in Python runtime that simplifies the operation of Python services.
- [Visual Studio Code](#) is used as the IDE for development and testing for this pattern. You can use any IDE that supports Python development (for example, [AWS Cloud9](#) or [PyCharm](#)).
- [AWS Cloud Development Kit \(AWS CDK\)](#) is an open-source software development framework that lets you define your cloud application resources by using familiar programming languages. This pattern uses the CDK to write and deploy cloud infrastructure as code.
- [Poetry](#) is used to manage dependencies in the pattern.
- [Docker](#) is used by the AWS CDK to build the Lambda package and layer.

### Code

The code for this pattern is available in the GitHub [Lambda hexagonal architecture sample](#) repository.

## Best practices

To use this pattern in a production environment, follow these best practices:

- Use customer managed keys in AWS Key Management Service (AWS KMS) to encrypt [Amazon CloudWatch log groups](#) and [Amazon DynamoDB tables](#).
- Configure [AWS WAF for Amazon API Gateway](#) to allow access only from your organization's network.
- Consider other options for API Gateway authorization if IAM doesn't meet your needs. For example, you can use [Amazon Cognito user pools](#) or [API Gateway Lambda authorizers](#).
- Use [DynamoDB backups](#).
- Configure Lambda functions with a [virtual private cloud \(VPC\) deployment](#) to keep network traffic inside the cloud.
- Update the allowed origin configuration for [cross-origin resource sharing \(CORS\) preflight](#) to restrict access to the requesting origin domain only.
- Use [cdk-nag](#) to check the AWS CDK code for security best practices.
- Consider using code scanning tools to find common security issues in the code. For example, [Bandit](#) is a tool that's designed to find common security issues in Python code. [Pip-audit](#) scans Python environments for packages that have known vulnerabilities.

This pattern uses [AWS X-Ray](#) to trace requests through the application's entry point, domain, and adapters. AWS X-Ray helps developers identify bottlenecks and determine high latencies to improve application performance.

## Epics

### Initialize the project

Task	Description	Skills required
Create your own repository.	<ol style="list-style-type: none"> <li>1. Log in to GitHub.</li> <li>2. Create a new repository. For instructions, see the <a href="#">GitHub documentation</a>.</li> <li>3. Clone and push the <a href="#">sample repository</a> for this pattern into the new repository in your account.</li> </ol>	App developer

Task	Description	Skills required
Install dependencies.	<ol style="list-style-type: none"><li data-bbox="591 226 1026 264">1. Install Poetry. <pre data-bbox="634 300 1026 373">pip install poetry</pre></li><li data-bbox="591 394 1026 905">2. Install packages from the root directory. The following command installs the application and AWS CDK packages. It also installs development packages that are required for running unit tests. All installed packages are placed in a new virtual environment. <pre data-bbox="634 947 1026 1020">poetry install</pre></li><li data-bbox="591 1041 1026 1220">3. To see a graphical representation of the installed packages, run the following command. <pre data-bbox="634 1262 1026 1335">poetry show --tree</pre></li><li data-bbox="591 1346 1026 1383">4. Update all dependencies. <pre data-bbox="634 1425 1026 1499">poetry update</pre></li><li data-bbox="591 1520 1026 1745">5. Open a new shell within the newly created virtual environment. It contains all installed dependencies. <pre data-bbox="634 1787 1026 1860">poetry shell</pre></li></ol>	App developer

Task	Description	Skills required
Configure your IDE.	<p>We recommend Visual Studio Code, but you can use any IDE of your choice that supports Python. The following steps are for Visual Studio Code.</p> <ol style="list-style-type: none"><li>1. Update the <code>.vscode/settings</code> file.</li></ol> <pre data-bbox="630 617 1029 1493">{   "python.testing.pytestArgs": [     "app/adapters/tests",     "app/entrypoints/api/tests",     "app/domain/tests"   ],   "python.testing.unittestEnabled": false,   "python.testing.pytestEnabled": true,   "python.envFile": "\${workspaceFolder}/.env", }</pre> <ol style="list-style-type: none"><li>2. Create an <code>.env</code> file in the root directory of the project. This ensures that the root directory of the project is included in the <code>PYTHONPATH</code> so that <code>pytest</code> can find it</li></ol>	App developer

Task	Description	Skills required
	<p>and properly discover all packages.</p> <pre>PYTHONPATH=.</pre>	
Run unit tests, option 1: Use Visual Studio Code.	<ol style="list-style-type: none"> <li>1. Choose the Python interpreter of the virtual environment that's managed by Poetry.</li> <li>2. Run tests from Test Explorer.</li> </ol>	App developer
Run unit tests, option 2: Use shell commands.	<ol style="list-style-type: none"> <li>1. Start a new shell within the virtual environment. <pre>poetry shell</pre> </li> <li>2. Run the pytest command from the root directory. <pre>python -m pytest</pre> <p>Alternatively you can run the command directly from Poetry.</p> <pre>poetry run python -m pytest</pre> </li> </ol>	App developer

## Deploy and test the application

Task	Description	Skills required
Request temporary credentials.	To have AWS credentials on the shell when you run cdk	App developer, AWS DevOps

Task	Description	Skills required
	<p>deploy, create temporary credentials by using AWS IAM Identity Center (successor to AWS Single Sign-On). For instructions, see the blog post <a href="#">How to retrieve short-term credentials for CLI use with AWS IAM Identity Center</a>.</p>	
Deploy the application.	<ol style="list-style-type: none"><li>1. Install the AWS CDK v2. <pre>npm install -g aws-cdk</pre><p>For more information, see the <a href="#">AWS CDK documentation</a>.</p></li><li>2. Bootstrap the AWS CDK into your account and Region. <pre>cdk bootstrap aws://12345678900/ us-east-1 --profile aws-profile-name</pre></li><li>3. Deploy the application as an AWS CloudFormation stack by using an AWS profile. <pre>cdk deploy --profile aws-profile-name</pre></li></ol>	App developer, AWS DevOps

Task	Description	Skills required
Test the API, option 1: Use the console.	Use the <a href="#">API Gateway console</a> to test the API. For more information about API operations and request/response messages, see the <a href="#">API usage section of the readme file</a> in the GitHub repository.	App developer, AWS DevOps
Test the API, option 2: Use Postman.	<p>If you want to use a tool such as <a href="#">Postman</a>:</p> <ol style="list-style-type: none"><li>1. <a href="#">Install Postman</a> as a standalone application or browser extension.</li><li>2. Copy the endpoint URL for the API Gateway. It will be in the following format.</li></ol> <div data-bbox="630 1087 1027 1287" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; background-color: #f9f9f9;"><pre>https://{api-id}.execute-api.{region}.amazonaws.com/{stage}/{path}</pre></div> <ol style="list-style-type: none"><li>3. Configure the AWS signature in the authorization tab. For instructions, see the AWS re:Post article on <a href="#">activating IAM authentication for API Gateway REST APIs</a>.</li><li>4. Use Postman to send requests to your API endpoint.</li></ol>	App developer, AWS DevOps

## Develop the service

Task	Description	Skills required
Write unit tests for the business domain.	<ol style="list-style-type: none"><li>1. Create a Python file in the app/domain/tests folder by using the test_ file name prefix.</li><li>2. Create a new test method to test the new business logic by using the following example.</li></ol> <pre data-bbox="630 747 1029 1818">def test_create_product_should_store_in_repository():     # Arrange     command =         create_product_command.CreateProductCommand(             name="Test Product",             description="Test Description",         )     # Act     create_product_command_handler.handle_create_product_command(         command=command, unit_of_work=mock_unit_of_work     )     # Assert</pre>	App developer

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. Create a command class in the <code>app/domain/commands</code> folder.</li><li>4. If the functionality is new, create a stub for the command handler in the <code>app/domain/command_handlers</code> folder.</li><li>5. Run the unit test to see it fail, because there is still no business logic.</li></ol> <pre data-bbox="630 779 1029 863">python -m pytest</pre>	

Task	Description	Skills required
Implement commands and command handlers.	<ol style="list-style-type: none"><li>1. Implement business logic in the newly created command handler file.</li><li>2. For every dependency that interacts with external systems, declare an abstract class in the app/domain/ports folder.</li></ol> <pre data-bbox="630 688 1027 1837">class ProductsRepository(ABC):     @abstractmethod     def add(self,             product: product.Product) -&gt; None:         ...  class UnitOfWork(ABC):     products:         ProductsRepository      @abstractmethod     def commit(self)     -&gt; None:         ...      @abstractmethod     def __enter__( self) -&gt; typing.Any:         ...      @abstractmethod     def __exit__( self, *args) -&gt; None:         ...</pre>	App developer

Task	Description	Skills required
	<p>3. Update the command handler signature to accept the newly declared dependencies by using the abstract port class as type annotation.</p> <pre data-bbox="634 520 1029 995">def handle_create_product_command(     command: create_product_command.CreateProductCommand,     unit_of_work: unit_of_work.UnitOfWork, ) -&gt; str:     ...</pre> <p>4. Update the unit test to simulate the behavior of all declared dependencies for the command handler.</p> <pre data-bbox="634 1230 1029 1877"># Arrange mock_unit_of_work = unittest.mock.create_autospec(     spec=unit_of_work.UnitOfWork, instance=True ) mock_unit_of_work.products = unittest.mock.create_autospec(     spec=unit_of_work.ProductsRepository, instance=True</pre>	

Task	Description	Skills required
	<p data-bbox="630 205 1029 268">)</p> <p data-bbox="591 281 1013 457">5. Update the assertion logic in the test to check for the expected dependency invocations.</p> <pre data-bbox="630 499 1029 1251"># Assert mock_unit _of_work.commit.assert_called_once() product = mock_unit_of_work.products.add.call_args.args[0]  assertpy.assert_that(product.name).is_equal_to("Test Product") assertpy.assert_that(product.description).is_equal_to("Test Description")</pre> <p data-bbox="591 1268 1013 1352">6. Run the unit test to see it succeed.</p> <pre data-bbox="630 1394 1029 1465">python -m pytest</pre>	

Task	Description	Skills required
Write integration tests for secondary adapters.	<ol style="list-style-type: none"><li>1. Create a test file in the <code>app/adapters/tests</code> folder by using <code>test_</code> as a file name prefix.</li><li>2. Use the Moto library to mock AWS services. <pre data-bbox="634 548 1029 905">@pytest.fixture def mock_dynamodb():     with moto.mock_dynamodb():         yield boto3.resource("dynamodb",                                region_name="eu-central-1")</pre></li><li>3. Create a new test method for an integration test of the adapter. <pre data-bbox="634 1087 1029 1816">def test_add_and_commit_should_store_product(mock_dynamodb):     # Arrange     unit_of_work = dynamodb_unit_of_work.DynamoDBUnitOfWork(         table_name=TEST_TABLE_NAME,         dynamodb_client=mock_dynamodb.meta.client     )     current_time = datetime.datetime.now(datetime.timezone</pre></li></ol>	App developer

Task	Description	Skills required
	<pre> one.utc).isoformat ()          new_product_id =         str(uuid.uuid4())         new_product =         product.Product(             id=new_pr         oduct_id,             name="test-         name",             descripti         on="test-descripti         on",             createDat         e=current_time,             lastUpdat         eDate=current_time,         )          # Act         with unit_of_w         ork:             unit_of_w         ork.products.add(n         ew_product)             unit_of_w         ork.commit()          # Assert </pre> <p>4. Create an adapter class in the app/adapters folder. Use the abstract class from the ports folder as a base class.</p> <p>5. Run the unit test to see it fail, because there is still no logic.</p>	

Task	Description	Skills required
	<pre>python -m pytest</pre>	

Task	Description	Skills required
Implement secondary adapters.	<ol style="list-style-type: none"><li>1. Implement logic in the newly created adapter file.</li><li>2. Update test assertions.</li></ol> <pre data-bbox="634 405 1029 1717"># Assert     with unit_of_work_readonly:         product_from_db = unit_of_work_readonly.products.get(new_product_id)          assertpy.assert_that(product_from_db).is_not_none()         assertpy.assert_that(product_from_db.dict()).is_equal_to(             {                 "id": new_product_id,                 "name": "test-name",                 "description": "test-description",                 "createDate": current_time,                 "lastUpdateDate": current_time,             }         )</pre> <ol style="list-style-type: none"><li>3. # Automate the creation of AppStream 2.0 resources using AWS CloudFormation

Created by Ram Kandaswamy (AWS)

**Environment:** Production

**Technologies:** End-user computing; CloudNative; Cost management; DevOps; SaaS

**Workload:** Microsoft

**AWS services:** Amazon AppStream 2.0; AWS CloudFormation

## Summary

This pattern provides code samples and steps to automate the creation of Amazon AppStream 2.0 resources in the Amazon Web Services (AWS) Cloud by using an AWS CloudFormation template. The pattern shows you how to use an AWS CloudFormation stack to automate the creation of your AppStream 2.0 application resources, including an image builder, image, fleet instance, and stack. You can stream your AppStream 2.0 application to end users on an HTML5-compliant browser by using either the desktop or application delivery mode.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An acceptance of AppStream 2.0 terms and conditions
- Basic knowledge of AppStream resources, such as [stacks](#), [fleets](#), and [image builders](#)

### Limitations

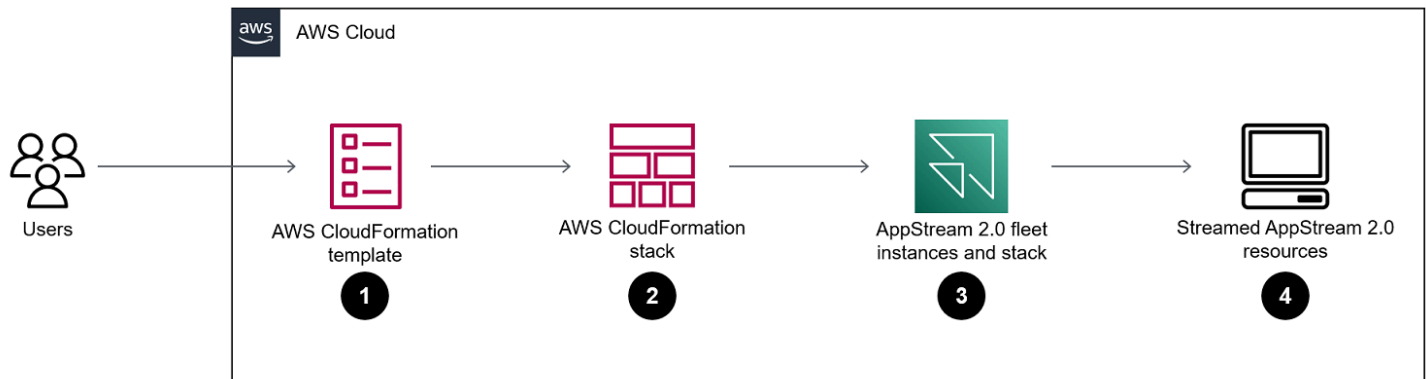

- You can't modify the AWS Identity and Access Management (IAM) role associated with an AppStream 2.0 instance after that instance is created.

- You can't modify properties (such as the subnet or security group) on the AppStream 2.0 image builder instance after that image builder is created.

## Architecture

The following diagram shows you how to automate the creation of AppStream 2.0 resources by using an AWS CloudFormation template.

The diagram shows the following workflow:

1. You create an AWS CloudFormation template based on the YAML code in the *Additional information* section of this pattern.
2. The AWS CloudFormation template creates an AWS CloudFormation test stack.
  - a. (Optional) You create an image builder instance by using AppStream 2.0.
  - b. (Optional) You create a Windows image by using your custom software.
3. The AWS CloudFormation stack creates an AppStream 2.0 fleet instance and stack.
4. You deploy your AppStream 2.0 resources to end users on an HTML5-compliant browser.

### Technology stack

- Amazon AppStream 2.0
- AWS CloudFormation

## Tools

- [Amazon AppStream 2.0](#) is a fully managed application streaming service that provides you with instant access to your desktop applications from anywhere. AppStream 2.0 manages the AWS

resources required to host and run your applications, scales automatically, and provides access to your users on demand.

- [AWS CloudFormation](#) helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

## Epics

### (Optional) Create an AppStream 2.0 image

Task	Description	Skills required
Install custom software and create an image.	<ol style="list-style-type: none"> <li>1. Install the AppStream 2.0 application that you plan to deploy to your users.</li> <li>2. Use the Photon create image agent or a PowerShell script to create a new Windows image for your custom software.</li> </ol> <p><b>Note:</b> Consider using the Windows AppLocker feature to further lock down the image.</p>	AWS DevOps, Cloud architect

### Deploy the AWS CloudFormation template

Task	Description	Skills required
Update the AWS CloudFormation template.	<ol style="list-style-type: none"> <li>1. Save the code in the <i>Additional information</i></li> </ol>	AWS systems administrator, Cloud administrator, Cloud

Task	Description	Skills required
	<p>section of this pattern as a YAML file.</p> <p>2. Update the YAML file with the required values for the parameters in your environment.</p>	<p>architect, General AWS, AWS administrator</p>
<p>Create an AWS CloudFormation stack using the template.</p>	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the <a href="#">AWS CloudFormation console</a>.</li> <li>2. On the navigation pane, choose <b>Stacks</b>.</li> <li>3. Choose <b>Create stack</b> and then choose <b>With new resources (standard)</b>.</li> <li>4. In the <b>Prerequisite – Prepare template</b> section, choose <b>Template is ready</b>.</li> <li>5. In the <b>Specify template</b> section, choose <b>Upload a template file</b>.</li> <li>6. Choose <b>Choose file</b> and then choose your updated AWS CloudFormation template.</li> <li>7. Complete the rest of the steps in the wizard to create your stack.</li> </ol>	<p>App owner, AWS systems administrator, Windows Engineer</p>

## Additional information

The following code is an example of an AWS CloudFormation template that allows you to automatically create AppStream 2.0 resources.

```
AWSTemplateFormatVersion: 2010-09-09
Parameters:
  SubnetIds:
    Type: 'List<AWS::EC2::Subnet::Id>'
  testSecurityGroup:
    Type: 'AWS::EC2::SecurityGroup::Id'
  ImageName:
    Type: String
Resources:

  AppStreamFleet:
    Type: 'AWS::AppStream::Fleet'
    Properties:
      ComputeCapacity:
        DesiredInstances: 5
      InstanceType: stream.standard.medium
      Name: appstream-test-fleet
      DisconnectTimeoutInSeconds: 1200
      FleetType: ON_DEMAND
      IdleDisconnectTimeoutInSeconds: 1200
      ImageName: !Ref ImageName
      MaxUserDurationInSeconds: 345600
      VpcConfig:
        SecurityGroupIds:
          - !Ref testSecurityGroup
```

```
    SubnetIds: !Ref SubnetIds
AppStreamStack:
  Type: 'AWS::AppStream::Stack'
  Properties:
    Description: AppStream stack for test
    DisplayName: AppStream test Stack
    Name: appstream-test-stack
    StorageConnectors:
      - ConnectorType: HOMEFOLDERS
    UserSettings:
      - Action: CLIPBOARD_COPY_FROM_LOCAL_DEVICE
        Permission: ENABLED
      - Action: CLIPBOARD_COPY_TO_LOCAL_DEVICE
        Permission: ENABLED
      - Action: FILE_DOWNLOAD
        Permission: ENABLED
      - Action: PRINTING_TO_LOCAL_DEVICE
        Permission: ENABLED
AppStreamFleetAssociation:
  Type: 'AWS::AppStream::StackFleetAssociation'
  Properties:
    FleetName: appstream-test-fleet
    StackName: appstream-test-stack
  DependsOn:
    - AppStreamFleet
    - AppStreamStack
```

# Set up a Grafana monitoring dashboard for AWS ParallelCluster

Created by Dario La Porta (AWS) and William Lu (AWS)

<b>Code repository:</b> <a href="#">parallecluster-monitoring-dashboard</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> High-performance computing; Analytics ; Management & governance
<b>Workload:</b> Open-source	<b>AWS services:</b> AWS ParallelCluster	

## Summary

AWS ParallelCluster helps you deploy and manage high performance computing (HPC) clusters. It supports AWS Batch and Slurm open source job schedulers. Although AWS ParallelCluster is integrated with Amazon CloudWatch for logging and metrics, it doesn't provide a monitoring dashboard for the workload.

The [Grafana dashboard for AWS ParallelCluster](#) (GitHub) is a monitoring dashboard for AWS ParallelCluster. It provides job scheduler insights and detailed monitoring metrics at the operating system (OS) level. For more information about the dashboards included in this solution, see [Example Dashboards](#) in the GitHub repository. These metrics help you better understand the HPC workload and its performance. However, the dashboard code is not updated for the latest versions of AWS ParallelCluster or the open source packages that are used in solution. This pattern enhances the solution to provide the following benefits:

- Supports AWS ParallelCluster v3
- Uses the latest version of open source packages, including Prometheus, Grafana, Prometheus Slurm Exporter, and NVIDIA DCGM-Exporter
- Increases the number of CPU cores and GPUs that the Slurm jobs use
- Adds a job monitoring dashboard
- Enhances the GPU node monitoring dashboard for nodes with 4 or 8 graphics processing units (GPUs)

This version of the enhanced solution has been implemented and verified in an AWS customer's HPC production environment.

## Prerequisites and limitations

### Prerequisites

- [AWS ParallelCluster CLI](#), installed and configured.
- A supported [network configuration](#) for AWS ParallelCluster. This pattern uses the [AWS ParallelCluster using two subnets](#) configuration, which requires a public subnet, private subnet, internet gateway, and NAT gateway.
- All AWS ParallelCluster cluster nodes must have internet access. This is required so that the installation scripts can download the open source software and Docker images.
- A [key pair](#) in Amazon Elastic Compute Cloud (Amazon EC2). Resources that have this key pair have Secure Shell (SSH) access to the head node.

### Limitations

- This pattern is designed to support Ubuntu 20.04 LTS. If you're using a different version of Ubuntu or if you use Amazon Linux or CentOS, then you need to modify the scripts provided with this solution. These modifications are not included in this pattern.

### Product versions

- Ubuntu 20.04 LTS
- ParallelCluster 3.X

### Billing and cost considerations

- The solution deployed in this pattern is not covered by the free tier. Charges apply for Amazon EC2, Amazon FSx for Lustre, the NAT gateway in Amazon VPC, and Amazon Route 53.

## Architecture

### Target architecture

The following diagram shows how a user can access the monitoring dashboard for AWS ParallelCluster on the head node. The head node runs NICE DCV, Prometheus, Grafana, Prometheus Slurm Exporter, Prometheus Node Exporter, and NGINX Open Source. The compute nodes run Prometheus Node Exporter, and they also run NVIDIA DCGM-Exporter if the node contains GPUs. The head node retrieves information from the compute nodes and displays that data in the Grafana dashboard.

In most cases, the head node is not heavily loaded because the job scheduler doesn't require a significant amount of CPU or memory. Users access the dashboard on the head node by using SSL on port 443.

All authorized viewers can anonymously view the monitoring dashboards. Only the Grafana administrator can modify dashboards. You configure a password for the Grafana administrator in the `aws-parallelcluster-monitoring/docker-compose/docker-compose.head.yml` file.

## Tools

### AWS services

- [NICE DCV](#) is a high-performance remote display protocol that helps you deliver remote desktops and application streaming from any cloud or data center to any device, over varying network conditions.
- [AWS ParallelCluster](#) helps you deploy and manage high performance computing (HPC) clusters. It supports AWS Batch and Slurm open source job schedulers.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined.

### Other tools

- [Docker](#) is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- [Grafana](#) is an open source software that helps you query, visualize, alert on, and explore metrics, logs, and traces.
- [NGINX Open Source](#) is an open source web server and reverse proxy.
- [NVIDIA Data Center GPU Manager \(DCGM\)](#) is a suite of tools for managing and monitoring NVIDIA data center graphics processing units (GPUs) in cluster environments. In this pattern, you use [DCGM-Exporter](#), which helps you export GPU metrics from Prometheus.
- [Prometheus](#) is an open source system-monitoring toolkit that collects and stores its metrics as time-series data with associated key-value pairs, which are called *labels*. In this pattern, you also

use [Prometheus Slurm Exporter](#) to collect and export metrics, and you use [Prometheus Node Exporter](#) to export metrics from the compute nodes.

- [Ubuntu](#) is an open source, Linux-based operating system that is designed for enterprise servers, desktops, cloud environments, and IoT.

## Code repository

The code for this pattern is available in the GitHub [pcluster-monitoring-dashboard](#) repository.

## Epics

### Create the required resources

Task	Description	Skills required
Create an S3 bucket.	Create an Amazon S3 bucket. You use this bucket to store the configuration scripts. For instructions, see <a href="#">Creating a bucket</a> in the Amazon S3 documentation.	General AWS
Clone the repository.	Clone the GitHub <a href="#">pcluster-monitoring-dashboard</a> repo by running the following command. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>git clone https://github.com/aws-samples/parallelcluster-monitoring-dashboard.git</pre> </div>	DevOps engineer
Create an admin password.	1. Choose the <code>aws-parallelcluster-monitoring</code> folder, choose the <code>docker-compose</code> folder,	Linux Shell scripting

Task	Description	Skills required
	<p>and then open the <b>docker-compose.head.yml</b> file.</p> <ol style="list-style-type: none"><li data-bbox="592 317 1027 737">2. In the GF_SECURITY_ADMIN_PASSWORD variable, replace Grafana4PC! with a password of your choice. This is the administrative password that you use to manage the Grafana account.</li><li data-bbox="592 758 1027 842">3. Save and close the <b>docker-compose.head.yml</b> file.</li></ol>	
Copy the required files into the S3 bucket.	Copy the <a href="#">post_install.sh</a> script and the <a href="#">aws-parallelcluster-monitoring</a> folder into the S3 bucket you created. For instructions, see <a href="#">Uploading objects</a> in the Amazon S3 documentation.	General AWS

Task	Description	Skills required
Configure an additional security group for the head node.	<ol style="list-style-type: none"><li>1. Create a security group for the head node. This security group will allow inbound traffic to the monitoring dashboards on the head node. For instructions, see <a href="#">Create a security group</a> in the Amazon VPC documentation.</li><li>2. Add an inbound rule to the security group. For instructions, see <a href="#">Add rules to a security group</a> in the Amazon VPC documentation. Use the following parameters for the rule:<ul style="list-style-type: none"><li>• <b>Type</b> – HTTPS</li><li>• <b>Protocol</b> – TCP</li><li>• <b>Port range</b> – 443</li><li>• <b>Source</b> – Enter your IP address</li><li>• <b>Description</b> – Allow users to access the monitoring dashboard</li></ul></li></ol>	AWS administrator

Task	Description	Skills required
Configure an IAM policy for the head node.	Create an identity-based policy for the head node. This policy allows the node to retrieve metric data from Amazon CloudWatch. The GitHub repo contains an example <a href="#">policy</a> . For instructions, see <a href="#">Creating IAM policies</a> in the AWS Identity and Access Management (IAM) documentation.	AWS administrator
Configure an IAM policy for the compute nodes.	Create an identity-based policy for the compute nodes. This policy allows the node to create the tags that contain the job ID and job owner. The GitHub repo contains an example <a href="#">policy</a> . For instructions, see <a href="#">Creating IAM policies</a> in the IAM documentation.  If you use the provided example file, replace the following values: <ul style="list-style-type: none"><li>• <b>&lt;REGION&gt;</b> – The AWS Region where the cluster is hosted</li><li>• <b>&lt;ACCOUNT_ID&gt;</b> – The AWS account ID</li></ul>	AWS administrator

## Create the cluster

Task	Description	Skills required
Modify the provided cluster template file.	<p>Create the AWS ParallelCluster cluster. Use the provided <a href="#">cluster.yaml</a> AWS CloudFormation template file as a starting point to create the cluster. Replace the following values in the provided template:</p> <ul style="list-style-type: none"><li>• <b>&lt;REGION&gt;</b> – The AWS Region where the cluster is hosted.</li><li>• <b>&lt;HEADNODE_SUBNET&gt;</b> – The public subnet of the VPC.</li><li>• <b>&lt;ADDITIONAL_HEAD_NODE_SG&gt;</b> – The name of the security group that you created for the head node.</li><li>• <b>&lt;KEY_NAME&gt;</b> – Enter the name of an existing Amazon EC2 key pair. Resources that have this key pair have Secure Shell (SSH) access to the head node.</li><li>• <b>&lt;ALLOWED_IPS&gt;</b> --Enter the CIDR-formatted IP address range that is allowed to make SSH connections to the head node.</li></ul>	AWS administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <b>&lt;ADDITIONAL_HEAD_NODE_POLICY&gt;</b> – Enter the name of the IAM policy that you created for the head node.</li> <li>• <b>&lt;BUCKET_NAME&gt;</b> – Enter the name of the S3 bucket you created.</li> <li>• <b>&lt;COMPUTE_SUBNET&gt;</b> – Enter the name of the private subnet in the VPC.</li> <li>• <b>&lt;ADDITIONAL_COMPUTE_NODE_POLICY&gt;</b> – Enter the name of the IAM policy that you created for the compute node.</li> </ul>	
Create the cluster.	<p>In the AWS ParallelCluster CLI, enter the following command. This deploys the CloudFormation template and creates the cluster. For more information about this command, see <a href="#">pcluster create-cluster</a> in the AWS ParallelCluster documentation.</p> <pre>pcluster create-cluster -n &lt;cluster_name&gt; -c cluster.yaml</pre>	AWS administrator

Task	Description	Skills required
Monitor the cluster creation.	<p>Enter the following command to monitor the cluster creation. For more information about this command, see <a href="#">pcluster describe-cluster</a> in the AWS ParallelCluster documentation.</p> <pre data-bbox="594 583 1027 743">pcluster describe-cluster -n &lt;cluster_name&gt;</pre>	AWS administrator

## Using the Grafana dashboards

Task	Description	Skills required
Access to the Grafana portal.	<ol style="list-style-type: none"> <li>Enter the following command to retrieve the public IP address of the head node. <pre data-bbox="630 1247 1027 1486">pcluster describe-cluster -n &lt;cluster_name&gt; --query headNode.publicIpAddress</pre> </li> <li>In a web browser, navigate to the following URL in order to access the Grafana dashboard. <p data-bbox="630 1724 935 1801"><b>https://&lt;head_node_public_ip_address&gt;</b></p> </li> </ol>	AWS administrator

Task	Description	Skills required
	<p>3. On the Grafana front page, choose the 4-square <b>Dashboard</b> icon on the left menu, and then choose <b>General</b>. This shows a list of configured dashboards. The following dashboards are available in Grafana:</p> <ul style="list-style-type: none"><li>• <b>Cluster Cost</b> – Contains information about the cost of the cluster</li><li>• <b>Cluster Logs</b> – Contains information about the logs of the cluster</li><li>• <b>Compute Node Details</b> – Contains information about usage statistics of the compute nodes</li><li>• <b>Compute Node List</b> – Contains the list of the compute nodes of the cluster</li><li>• <b>GPU Nodes</b> – Contains information about usage statistics of the GPU nodes</li><li>• <b>Jobs Details</b> – Contains information about the jobs resources utilization</li><li>• <b>Head Node Details</b> – Contains information about usage statistics of the head node</li></ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <b>ParallelCluster Summary</b> – Contains information about cluster usage</li> </ul>	

## Clean up the solution to stop incurring associated costs

Task	Description	Skills required
Delete the cluster.	<p>Enter the following command to delete the cluster. For more information about this command, see <a href="#">pcluster delete-cluster</a> in the AWS ParallelCluster documentation.</p> <pre>pcluster delete-cluster -n &lt;cluster_name&gt;</pre>	AWS administrator
Delete the IAM policies.	<p>Delete the policies that you created for the head node and compute node. For more information about deleting policies, see <a href="#">Deleting IAM policies</a> in the IAM documentation.</p>	AWS administrator
Delete the security group and rule.	<p>Delete the security group that you created for the head node. For more information, see <a href="#">Delete security group rules</a> and <a href="#">Delete a security</a></p>	AWS administrator

Task	Description	Skills required
	<a href="#">group</a> in the Amazon VPC documentation.	
Delete the S3 bucket.	Delete the S3 bucket that you created to store the configuration scripts. For more information, see <a href="#">Deleting a bucket</a> in the Amazon S3 documentation.	General AWS

## Troubleshooting

Issue	Solution
The head node is not accessible in the browser.	Check the security group and confirm that the inbound port 443 is open.
Grafana doesn't open.	On the head node, check the container log for <code>docker logs Grafana</code> .
Some metrics have no data.	On the head node, check the container logs of all containers.

# Set up an auto scaling virtual desktop infrastructure (VDI) by using NICE EnginFrame and NICE DCV Session Manager

Created by Dario La Porta and Salvatore Maccarone (AWS)

**Code repository:** [elastic-vdi-infrastructure](#)

**Environment:** PoC or pilot

**Technologies:** High-performance computing; Infrastructure

**AWS services:** AWS CDK; AWS CloudFormation; Amazon EC2 Auto Scaling; Elastic Load Balancing (ELB)

## Summary

*NICE DCV* is a high-performance remote display protocol that helps you stream remote desktops and applications from any cloud or data center to any device, over varying network conditions. With *NICE DCV* and Amazon Elastic Compute Cloud (Amazon EC2), you can run graphics-intensive applications remotely on EC2 instances and stream their user interfaces to simpler, remote client machines. This eliminates the need for expensive dedicated workstations and the need to transfer large amounts of data between the cloud and client machines.

This pattern sets up a fully functional, auto scaling Linux and Windows virtual desktop infrastructure (VDI) that is accessible through a web-based user interface. The VDI solution provides research and development (R&D) users with an accessible and performant user interface for submitting graphics-intensive analysis requests and reviewing results remotely.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Administrator permissions and a set of access keys.
- AWS Cloud Development Kit (AWS CDK) Toolkit, installed and configured. For more information, see [Install the AWS CDK](#).

- AWS Command Line Interface (AWS CLI), installed and configured for your AWS account. For more information, see [Installing or updating the latest version of the AWS CLI](#).
- Python, installed and configured. For more information, see [Source releases](#) (Python website).
- One or more virtual private clouds (VPCs) available.
- Two or more Elastic IP address available. For more information about the default limit, see [Elastic IP address limit](#).
- For the Linux EC2 instances, set up a Secure Shell (SSH) key pair. For more information, see [Key pairs and Linux instances](#).

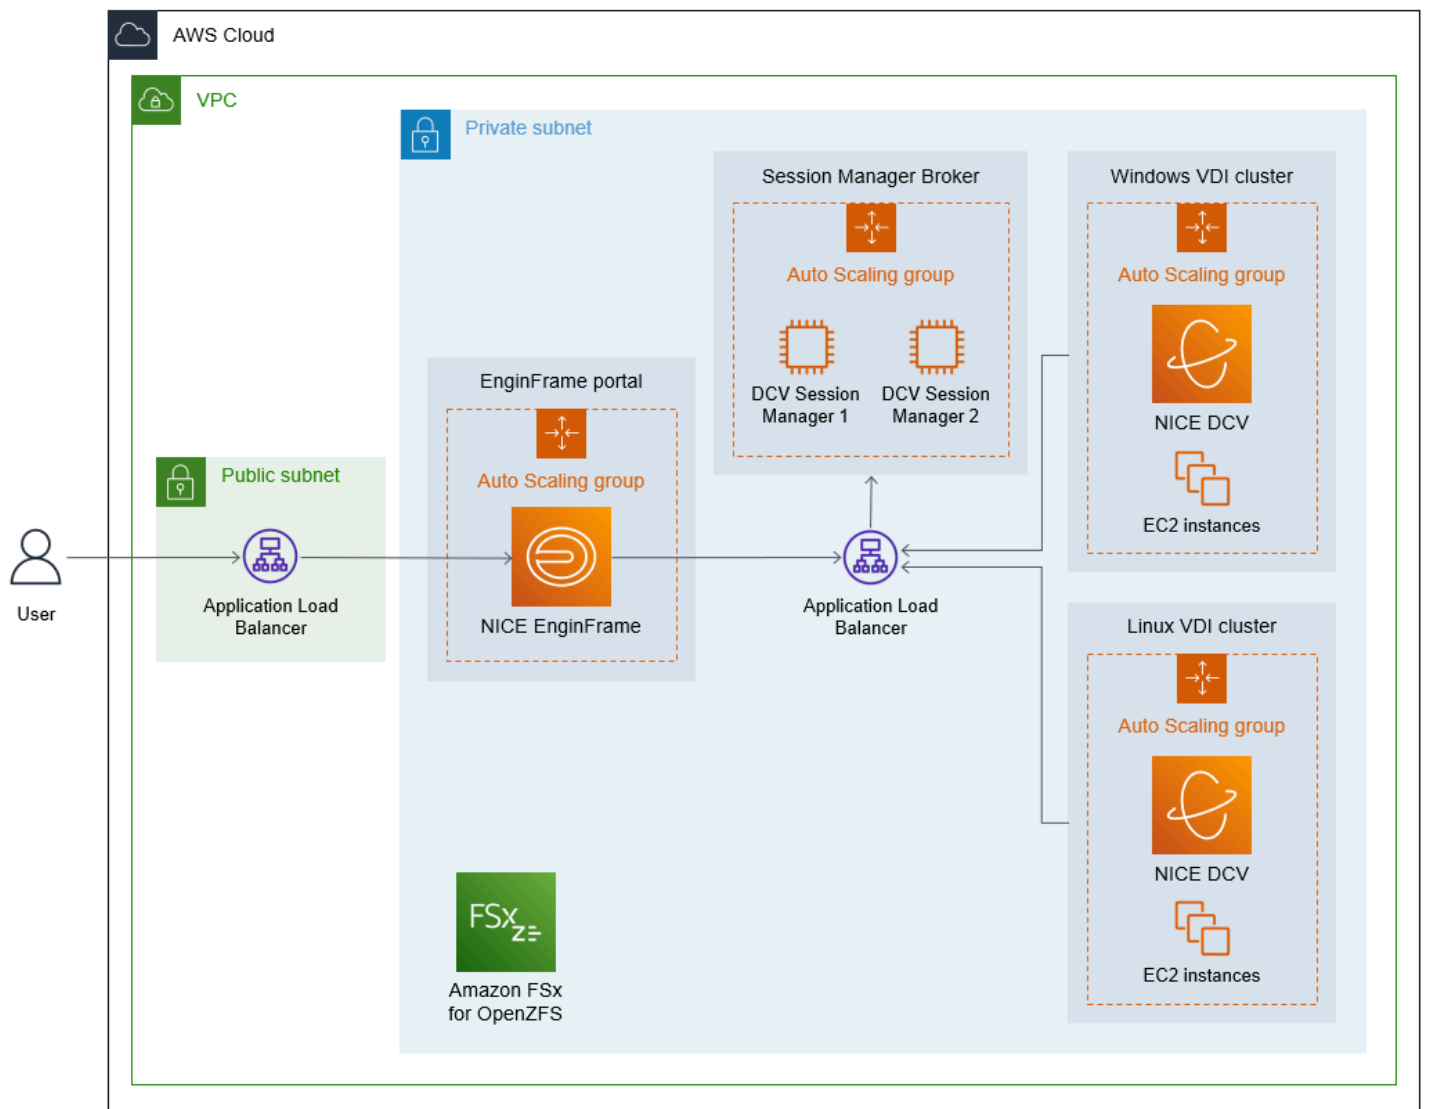

### Product versions

- AWS CDK version 2.26.0 or later
- Python version 3.8 or later

## Architecture

### Target architecture

The following figure shows the different components of this VDI solution. The user interacts with NICE EnginFrame to launch Amazon EC2 instances according to the Amazon EC2 Auto Scaling groups for Windows and Linux NICE DCV instances.

## Automation and scale

The code included with this pattern creates a custom VPC, public and private subnets, an internet gateway, NAT gateway, Application Load Balancer, security groups, and IAM policies. AWS CloudFormation is also used to create the fleet of Linux And Windows NICE DCV servers.

## Tools

### AWS services

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [NICE DCV](#) is a high-performance remote display protocol that helps you deliver remote desktops and application streaming from any cloud or data center to any device, over varying network conditions. In this pattern, it provides a bandwidth-efficient experience that streams high performance computing (HPC) 3D graphics remotely.
- [NICE DCV Session Manager](#) helps you create and manage the lifecycle of NICE DCV sessions across a fleet of NICE DCV servers.
- [NICE EnginFrame](#) is an advanced frontend web interface for accessing technical and scientific applications in the cloud.

## Code repository

The code for this pattern is available in the [Auto scaling VDI solution with NICE EnginFrame and NICE DCV Session Manager](#) repository.

## Epics

### Deploy the virtual desktop infrastructure

Task	Description	Skills required
Clone the repository.	Clone the repository containing the code. <pre>git clone https://github.com/aws-samples/elastic-vdi-infrastructure.git</pre>	Cloud architect
Install the required AWS CDK libraries.	Install the AWS CDK libraries. <pre>cd elastic-vdi-infrastructure python3 -m venv .venv source .venv/bin/activate</pre>	Cloud architect

Task	Description	Skills required
	<pre data-bbox="597 205 1026 310">pip3 install -r requirements.txt</pre>	

Task	Description	Skills required
Update the parameters.	<ol style="list-style-type: none"><li>1. Open the <b>app.py</b> file in your text editor of choice.</li><li>2. Replace the CHANGE_ME value for the following required parameters:<ul style="list-style-type: none"><li>• <code>region</code> – The target AWS Region. For a complete list, see <a href="#">AWS Regions</a>.</li><li>• <code>account</code> – The ID of the target AWS account. For more information, see <a href="#">Finding your AWS account ID</a>.</li><li>• <code>key_name</code> – The key pair used to access the Linux EC2 instances.</li></ul></li><li>3. (Optional) Modify the values for the following parameters to customize the solution for your environment:<ul style="list-style-type: none"><li>• <code>ec2_type_enginframe</code> – The EnginFrame instance type</li><li>• <code>ec2_type_broker</code> – The Session Manager Broker instance type</li><li>• <code>ebs_enginframe_size</code> – The size of the Amazon Elastic Block Store (Amazon</li></ul></li></ol>	Cloud architect

Task	Description	Skills required
	<p>EBS) volume for the EnginFrame instance</p> <ul style="list-style-type: none"><li>• <code>ebs_broker_size</code> – The size of the EBS volume for the Session Manager Broker instance</li><li>• <code>TagName</code> and <code>TagValue</code> – The billing tag for the resources</li><li>• <code>efadmin_uid</code> – The unique identifier of the EnginFrame administrator (<b>efadmin</b>) user</li><li>• <code>linux_shared_storage_size</code> – OpenZFS size in gibibytes (GiB)</li><li>• <code>Shared_Storage_Linux</code> – The mount point of the shared storage</li><li>• <code>Enginframe_installer</code> – The download link for EnginFrame</li><li>• <code>Session_Manager_Broker_Installer</code> – The download link for the Session Manager Broker</li></ul> <p>4. Save and close the <b>app.py</b> file.</p>	

Task	Description	Skills required
Deploy the solution.	<p>Run the following commands in sequence.</p> <pre>cdk bootstrap cdk deploy Assets-Stack Parameters-Stack cdk deploy Elastic-Vdi-Infrastructure</pre> <p>When the deployment is complete, the following two outputs are returned:</p> <ul style="list-style-type: none"><li>• Elastic-Vdi-Infrastructure.EnginFrameURL – The HTTPS address of the EnginFrame portal</li><li>• Elastic-Vdi-Infrastructure.SecretEFadminPassword – The Amazon Resource Name (ARN) of the secret that contains the password for the <b>efadmin</b> user</li></ul> <p>Make note of these values. You use them later in this pattern.</p>	Cloud architect

Task	Description	Skills required
Deploy the fleet of Linux servers.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console, and open the <a href="#">CloudFormation console</a>.</li><li>2. Choose <b>Create stack</b>, and then choose <b>With new resources</b>.</li><li>3. In the <b>cloudformation_files</b> folder, select the <b>dcv-linux-fleet.yaml</b> file.</li><li>4. On the <b>Specify stack details</b> page, define the following parameters:<ul style="list-style-type: none"><li>• <b>Stack name</b> – The name of the stack.</li><li>• <b>DcvFleet</b> – The name of the NICE DCV fleet. Don't leave this value blank or use spaces.</li><li>• <b>InstanceType</b> – The instance type of the fleet.</li><li>• <b>RootVolumeSize</b> – The root volume size of the Linux EC2 instance.</li><li>• <b>MinSize</b> – The minimum number of nodes that should be available and not running any DCV session. For instance, if you enter 2, the solution starts with 2 nodes. When a user creates</li></ul></li></ol>	Cloud architect

Task	Description	Skills required
	<p>a session, the number of available nodes decreases to 1, and the solution creates another node to maintain the minimum.</p> <ul style="list-style-type: none"><li>• <b>MaxSize</b> – The maximum number of nodes in the fleet. Users cannot start new sessions if the maximum has been reached.</li><li>• <b>BillingTagName</b> – The tag name used for billing. This tag name must be different from the one used for the Windows stack.</li><li>• <b>BillingTagValue</b> – The tag value used for billing.</li></ul> <p>5. Complete the stack creation wizard, and then choose <b>Submit</b> to start creating the stack.</p>	

Task	Description	Skills required
Deploy the fleet of Windows servers.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console, and open the <a href="#">CloudFormation console</a>.</li><li>2. Choose <b>Create stack</b>, and then choose <b>With new resources</b>.</li><li>3. In the <b>cloudformation_files</b> folder, select the <b>dcv-windows-fleet.yaml</b> file.</li><li>4. On the <b>Specify stack details</b> page, define the following parameters:<ul style="list-style-type: none"><li>• <b>Stack name</b> – The name of the stack.</li><li>• <b>DcvFleet</b> – The name of the NICE DCV fleet. Don't leave this value blank or use spaces.</li><li>• <b>InstanceType</b> – The instance type of the fleet.</li><li>• <b>RootVolumeSize</b> – The root volume size of the Windows EC2 instance.</li><li>• <b>MinSize</b> – The minimum number of nodes that should be available and not running any DCV session.</li><li>• <b>MaxSize</b> – The maximum number of nodes in the fleet.</li></ul></li></ol>	Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <b>BillingTagName</b> – The tag name used for billing. This tag name must be different from the one used for the Linux stack.</li> <li>• <b>BillingTagValue</b> – The tag value used for billing.</li> </ul> <p>5. Complete the stack creation wizard, and then choose <b>Submit</b> to start creating the stack.</p>	

## Access the deployed environment

Task	Description	Skills required
Retrieve the EnginFrame administrator password.	<p>The EnginFrame administration account is named <b>efadmin</b>, and the password is stored in AWS Secrets Manager as a secret. The ARN of the secret is generated dynamically and is visible in the output of the AWS CDK deployment.</p> <p>1. In the previous epic, in the <i>Deploy the solution story</i>, under the Elastic-VDI-Infrastructure. SecretEFAdminPassword output, find the ARN of the generated secret.</p>	Cloud architect

Task	Description	Skills required
	<p>2. Do one of the following to retrieve the secret:</p> <ul style="list-style-type: none"><li>• Use the <a href="#">Secrets Manager console</a>. For more information, see <a href="#">Retrieve secrets</a>.</li><li>• Enter the <a href="#">get-secret-value</a> command.</li></ul> <pre>aws secretsmanager get-secret-value \   --secret-id   &lt;secret_arn&gt; \   --query SecretStr ing \   --output text</pre>	
Access the EnginFrame portal.	<ol style="list-style-type: none"><li>1. In the previous epic, in the <i>Deploy the solution story</i>, under the Elastic-VDI-Infrastructure. EnginFrameURL output, find the HTTPS address of the EnginFrame portal.</li><li>2. In a web browser, enter the HTTPS address of the portal.</li><li>3. Enter the credentials for the <b>efadmin</b> user.</li></ol>	Cloud architect

Task	Description	Skills required
Start a Windows session.	<ol style="list-style-type: none"> <li>1. In the EnginFrame portal, in the menu, choose <b>Windows Desktop</b>.</li> <li>2. When you are prompted to sign in as a Windows administrator, enter the same password used for the <b>efadmin</b> user.</li> <li>3. Confirm that the Windows session successfully starts.</li> </ol>	Cloud architect
Start a Linux session.	<ol style="list-style-type: none"> <li>1. In the EnginFrame portal, in the menu, choose <b>Linux Desktop</b>.</li> <li>2. When you are prompted to sign in, enter the credentials for the <b>efadmin</b> user.</li> <li>3. Confirm that the Linux session successfully starts.</li> </ol>	Cloud architect

## Clean up

Task	Description	Skills required
Delete the stacks.	In the AWS CloudFormation console, delete the stacks for the Windows and Linux server fleets. For more information, see <a href="#">Deleting a stack</a> .	Cloud architect
Delete the infrastructure.	Delete the deployed infrastructure by using the following AWS CDK command.	Cloud architect

Task	Description	Skills required
	<pre>cdk destroy --all</pre>	

## Troubleshooting

Issue	Solution
The deployment didn't complete because it was interrupted.	Follow the instructions in the <i>Clean up</i> epic and then repeat this pattern to deploy the environment again.

# Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode

Created by Deepak Kumar (AWS)

<b>Environment:</b> Production	<b>Technologies:</b> Hybrid cloud; Infrastructure; Migration	<b>Workload:</b> All other workloads
<b>AWS services:</b> AWS Direct Connect		

## Summary

**Notice:** As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how you can use [Hybrid Linked Mode](#) to view and manage inventories in an on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC) by using a single VMware vSphere Client interface.

By configuring Hybrid Linked Mode, you can migrate your on-premises virtual machines (VMs) and applications to the cloud SDDC. Your IT teams can then manage your cloud-based resources with familiar VMware tools and without requiring any new tools. You can also ensure consistent operations and simplified administration by using the [VMware Cloud Gateway Appliance](#).

This pattern provides two options for configuring Hybrid Linked Mode, but you can only use one option at a time. The first option installs the Cloud Gateway Appliance and uses it to link from the on-premises vCenter Server to the cloud SDDC. The second option configures Hybrid Linked Mode from the cloud SDDC.

## Prerequisites and limitations

### Prerequisites (both options)

- An existing on-premises data center and a cloud SDDC.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN, or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn't exceed 100ms.
- Cloud administrators with access to your on-premises environment.
- The vCenter Server's fully qualified domain name (FQDN) must resolve to a private IP address.

### Prerequisites for Option 1

- The on-premises environment should run on vSphere 6.5.0d or later.
- The Cloud Gateway Appliance and vCenter Server can communicate over AWS Direct Connect, a VPN, or both.
- The Cloud Gateway Appliance meets hardware requirements.
- Firewall ports are open.

### Prerequisites for Option 2

- The on-premises vCenter Server runs on vSphere 6.0 Update 3 or later, or on vSphere 6.5.0d or later .
- Login credentials are available for the on-premises vSphere single sign-on (SSO) domain.
- Users in the on-premises environment have read-only access to the base distinguished name (Base DN).
- The on-premises Domain Name System (DNS) server is configured for VMware Management Gateway.
- Implement network connectivity tests using the VMware Connectivity Validator.
- Firewall ports are open.

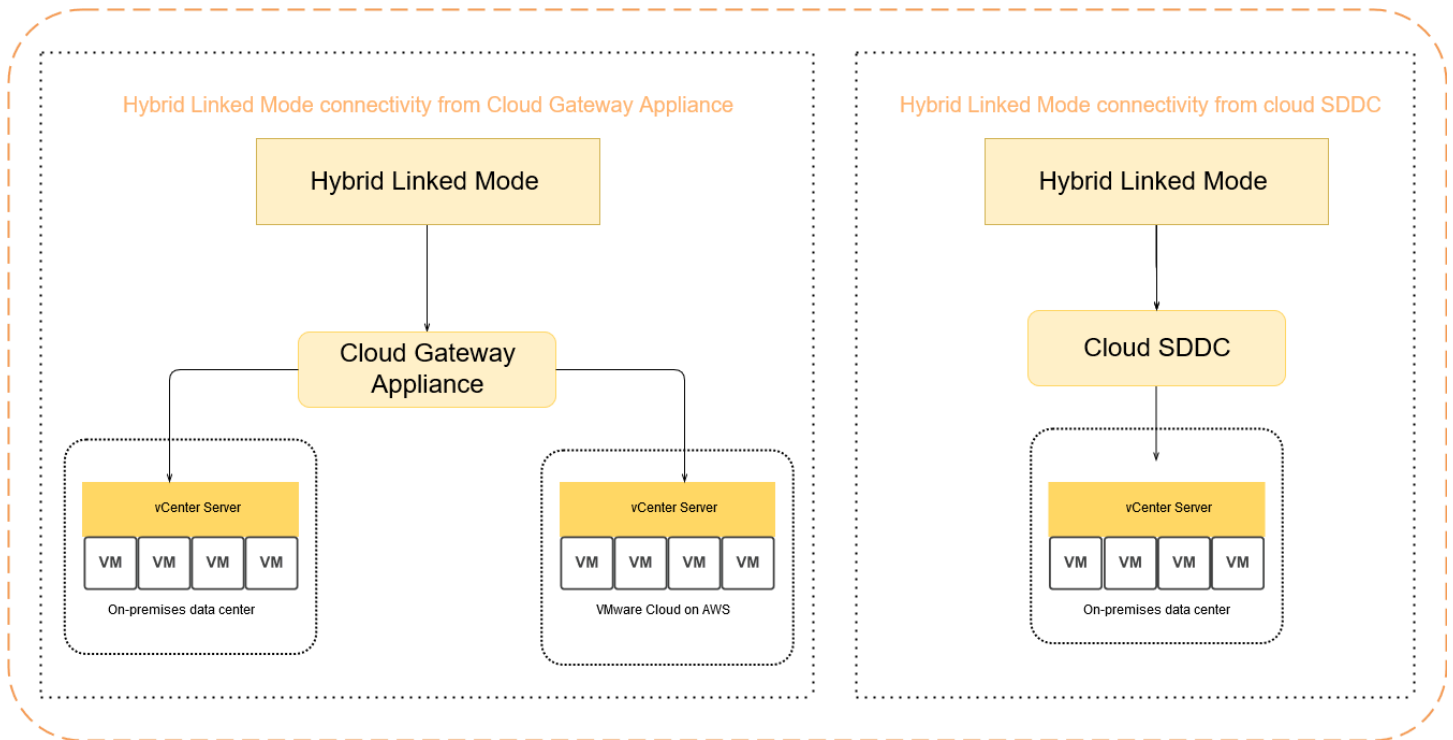

### Limitations

- Hybrid Linked Mode can only connect one on-premises [vCenter Sever Enhanced Linked Mode](#) domain.

- Hybrid Linked Mode only supports on-premises vCenter Server running version 6.7 or later.

## Architecture

The following diagram shows both options for configuring Hybrid Linked Mode.

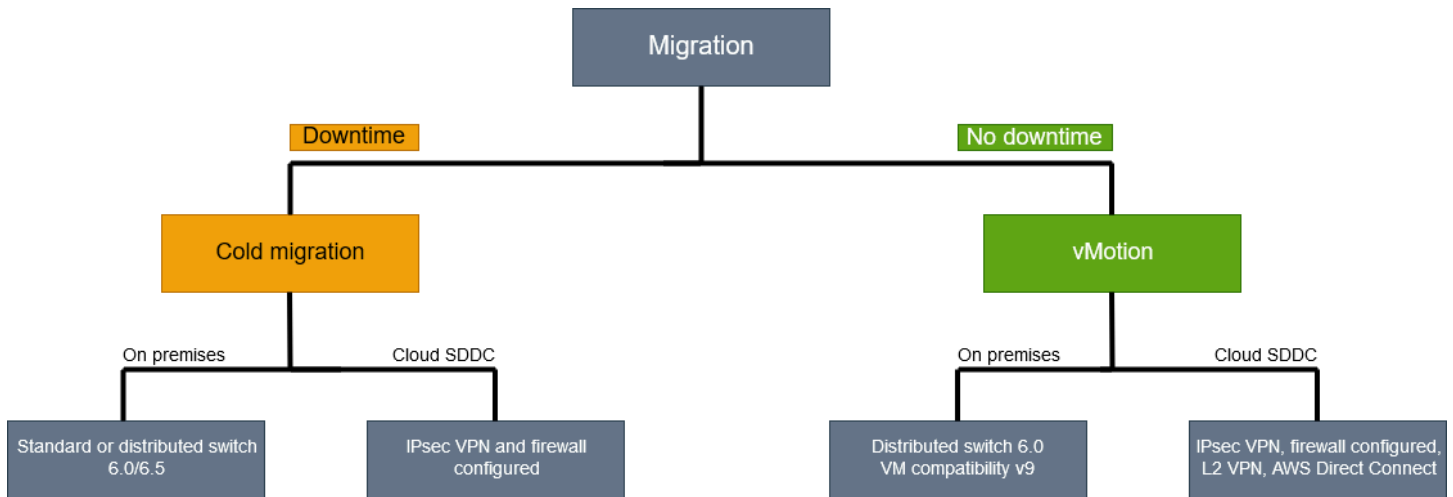

### Migrating different workload types using Hybrid Linked Mode

Hybrid Linked Mode supports migrating workloads between an on-premises data center and a cloud SDDC by using either a [cold migration](#) or a live migration with [VMware vSphere vMotion](#). Factors that must be considered when choosing the migration method include the virtual switch type and version, the connection type to the cloud SDDC, and the virtual hardware version.

A cold migration is appropriate for VMs that experience downtime. You can shut down the VMs, migrate them, and then turn them back on. The migration time is faster because there is no need to copy active memory. We recommend using a cold migration for applications that accept downtime (for example, tier 3 applications or development and testing workloads). If your VMs cannot experience downtime, you should consider a live migration using vMotion for your mission-critical applications.

The following diagram provides an overview of the different workload migration types using Hybrid Linked Mode.

## Tools

- [VMware Cloud on AWS](#) is an integrated cloud offering jointly developed by AWS and VMware.
- [VMware Cloud Gateway Appliance](#) enables a number of hybrid cloud use cases where on-premises resources are connected to cloud resources.
- [VMware vSphere](#) is VMware's virtualization platform, which transforms data centers into aggregated computing infrastructures that include CPU, storage, and networking resources.

## Epics

### Option 1 - Use Hybrid Linked Mode with the Cloud Gateway Appliance

Task	Description	Skills required
Configure the Cloud Gateway Appliance.	<ol style="list-style-type: none"> <li>1. Log in to the VMware Cloud on AWS console and download the Cloud Gateway Appliance.</li> <li>2. Install the Cloud Gateway Appliance in your on-premises environment with the following two steps: <ul style="list-style-type: none"> <li>• Choose <b>Start to configure</b> and then</li> </ul> </li> </ol>	Cloud administrator

Task	Description	Skills required
	<p>deploy the Cloud Gateway Appliance.</p> <ul style="list-style-type: none"> <li>• Configure Hybrid Linked Mode.</li> </ul> <p>For more information and detailed steps, see <a href="#">Configuring Hybrid Linked Mode using the vCenter Cloud Gateway Appliance</a> in the VMware documentation.</p>	

## Option 2 - Use Hybrid Linked Mode from the cloud SDDC

Task	Description	Skills required
Configure Hybrid Linked Mode from the cloud SDDC.	<ol style="list-style-type: none"> <li>1. Log in to the VMware Cloud on AWS console and use the Connectivity Validator to check all required network connectivity. For more information about this, see <a href="#">Validate network connectivity for Hybrid Linked Mode</a> in the VMware documentation.</li> <li>2. Log in to the vSphere Client of the cloud SDDC, choose <b>Menu</b>, choose <b>Administration</b>, and then choose <b>Domains</b>.</li> <li>3. In the <b>Hybrid Cloud</b> section, choose <b>Linked</b></li> </ol>	Cloud administrator

Task	Description	Skills required
	<p><b>Domains</b> and then connect to your on-premises vCenter Server.</p> <p>4. Add an identity source to the cloud SDDC Lightweight Directory Access Protocol (LDAP) domain. For more information about this, see <a href="#">Add an Identity Source to the SDDC LDAP Domain</a> in the VMware documentation.</p>

# Configure VMware vRealize Automation to provision VMs on VMware Cloud on AWS

Created by Deepak Kumar (AWS)

<b>Environment:</b> Production	<b>Technologies:</b> Hybrid cloud; Infrastructure	<b>Workload:</b> All other workloads
<b>AWS services:</b> AWS Direct Connect; AWS Site-to-Site VPN		

## Summary

**Notice:** As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

[VMware vRealize Automation](#) is automation software that you can use to request and manage IT resources. By choosing to configure vRealize Automation with VMware Cloud on AWS, you can automate the delivery of virtual machines (VMs), applications, and IT services across multiple data centers and cloud environments.

Your IT teams can then create catalog items to configure service provisioning and operational capabilities that your users can request and use with their existing vRealize Automation tools. You can also improve your IT agility and efficiency by integrating VMware Cloud on AWS with [vRealize Automation Cloud Assembly](#).

This pattern describes how to configure VMware vRealize Automation to automatically build VMs or application capabilities on VMware Cloud on AWS.

## Prerequisites and limitations

### Prerequisites

- An existing on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC). For more information about the cloud SDCC, see [About Software-Defined Data Centers](#) in the VMware documentation.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN (route or policy-based), or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn't exceed 100ms.
- The vCenter Server's fully qualified domain name (FQDN) must resolve to a private IP address.
- Cloud SDDC users with access to your on-premises environment.
- Organization owner access in the vRealize Automation Cloud Assembly service role.
- End users with permission in vRealize Automation Service Broker to consume service.
- The on-premises data center's Classless Inter-Domain Routing (CIDR) range must be open for the generating of API tokens from the VMware Cloud on AWS console. The following list provides the minimum roles required to generate API tokens:
  - Organization member
  - Organization owner
  - Service Roles - VMware Cloud on AWS
  - Administrator
  - NSX Cloud Administrator
  - NSX Cloud Auditor

For more information about this, see [Connectivity Options for VMware Cloud on AWS SDDCs](#) from the AWS Partner Network Blog.

## Limitations

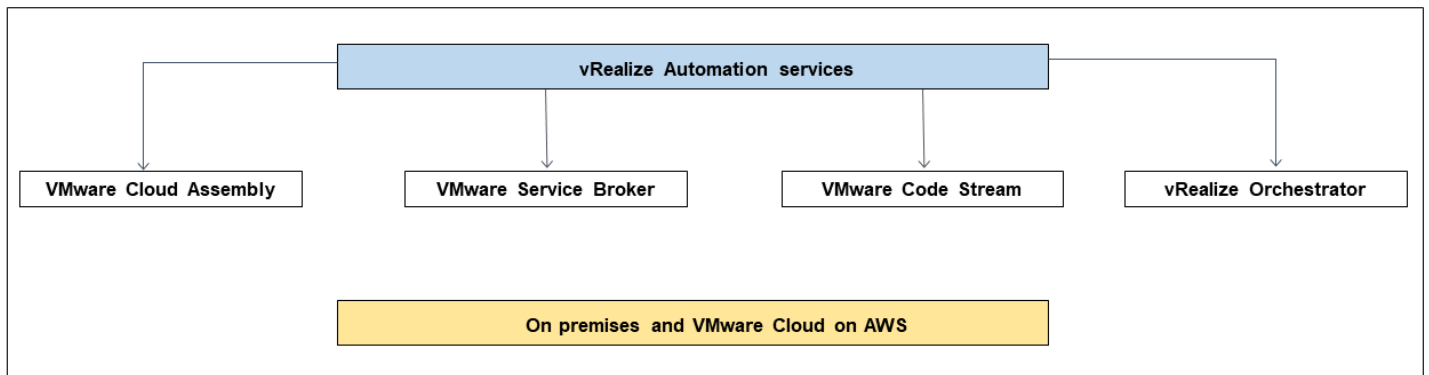

- You can only configure 20 VMware Cloud accounts with public endpoints in one vRealize Automation. For more information about this, see [Scalability and concurrency maximums](#) in the VMware documentation.

## Product versions

- vRealize Automation version 8.x or later
- VMware vRealize Identity Manager version 3.x or later
- VMware vRealize Suite Lifecycle Manager version 8.x or later

## Architecture

The following diagram shows the vRealize Automation services that can use infrastructure from both on-premises and VMware Cloud on AWS environments.

### VMware Cloud Assembly components

VMware Cloud Assembly is a core component of vRealize Automation and you can use it to deploy and provision VMs and compute resources. The following table describes VMware Cloud Assembly components that must be configured for provisioning VMs on VMware Cloud on AWS.

#### Components

##### Cloud Account

#### Definition

The Cloud Account provides connection details (for example, server name, user name and password, access key, and API token). VMware Cloud Assembly uses the Cloud Account to collect an inventory of your resources.

##### Cloud zones

Cloud zones identify resource boundaries in the Cloud Account (for example, AWS Regions and the cloud SDDC). Cloud zones associate compute resources with the Cloud Assembly project.

**Projects**

A project is a logical entity that consists of users and resources such as cloud zones. It also consists of resource quotas and VM naming policies that are used when building the VM.

**Flavor mappings**

Flavor mapping provides information about the VM's capacity (for example, number of CPUs and amount of memory) that are used in the Cloud Template.

**Image mappings**

Image mapping maps the VMware vSphere VM template and Amazon Web Services (AWS) image that are used in the Cloud Template. For more information about this, see [Learn more about image mappings in vRealize Automation](#) in the VMware documentation.

**Network profile**

Network profile controls the placement decision to choose a network during VM provisioning.

**Storage profile**

Storage profile controls the placement decision to choose storage during VM provisioning.

**Cloud Templates**

VMware Cloud Templates are an important component of vRealize Automation because they define cloud infrastructure provisioning and orchestration. The Cloud Templates are specifications for the resources and include the resource type, resource properties, and input to be collected from users.

**Tools**

- [VMware vRealize Automation](#) – vRealize Automation is an infrastructure automation platform with event-driven state management and compliance. It is designed to help organizations

control and secure self-service clouds, multi-cloud automation with governance, and DevOps-based infrastructure delivery.

- [VMware Cloud on AWS](#) – VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.

## Epics

### Generate the API tokens

Task	Description	Skills required
Generate the API tokens from your VMware Cloud on AWS account.	<ol style="list-style-type: none"><li>1. Sign in to the VMware Cloud Console.</li><li>2. On the VMware Cloud Services toolbar, choose <b>My Account</b> and then choose <b>API Token</b>.</li><li>3. Enter a name for your API token, provide the required lifespan, and define the scopes for the token.</li><li>4. Choose the <b>Open ID</b> check box and then choose <b>Generate</b>.</li><li>5. Record the API token's credentials.</li></ol> <p>For more information about this, see <a href="#">How do I generate API tokens</a> in the VMware documentation.</p>	Cloud administrator

## Install vRealize Automation in your on-premises data center

Task	Description	Skills required
Download the required software.	Download the VMware vRealize Suite ISO file from the My VMware Portal. This package contains vRealize Suite Lifecycle Manager, VMware Identity Manager, and vRealize Automation.	Cloud administrator
Install the software.	<p>Install the software and connect to your cloud SDCC by following the instructions from <a href="#">Installing vRealize Suite Lifecycle Manager with Easy Installer for vRealize Automation and VMware Identity Manager</a> in the VMware documentation.</p> <p><b>Important:</b> Make sure that the following are available for your installation:</p> <ul style="list-style-type: none"> <li>• The on-premises VMware vCenter Server setup and login credentials</li> <li>• The network details for the vRealize Automation IP and subnet</li> <li>• The vRealize Automation license key</li> </ul>	Cloud administrator, Cloud architect

## Connect VMware Cloud on AWS with VMware Cloud Assembly

Task	Description	Skills required
Configure your Cloud Accounts.	<ol style="list-style-type: none"><li>1. On the VMware Cloud Console, open the <b>Infrastructure</b> tab, choose <b>Manage – Cloud Accounts</b>, and then choose <b>Add Cloud Accounts</b>.</li><li>2. Choose <b>VMware Cloud on AWS</b> as the type.</li><li>3. Paste the API token information that you recorded earlier. This populates all available cloud SDDCs in your VMware Cloud on AWS organization.</li><li>4. Choose the required cloud SDDC and then provide the vCenter user name and password for the SDDC.</li><li>5. After you are successfully authenticated, you can view the integrated VMware Cloud on AWS account with an <b>OK</b> status.</li></ol> <p>For more information about this, see <a href="#">Create a VMware Cloud on AWS cloud account in vRealize Automation</a> in the VMware documentation.</p>	Cloud architect, Cloud administrator

Task	Description	Skills required
Configure the project.	<ol style="list-style-type: none"><li>1. On the VMware Cloud Console, open the <b>Projects</b> tab and then choose <b>New project</b>.</li><li>2. Enter the name of your project.</li><li>3. Open the <b>Cloud Zones</b> tab and choose <b>default VMware Cloud on AWS Cloud Account</b>.</li></ol>	Cloud administrator
Configure cloud zone.	<ol style="list-style-type: none"><li>1. On the VMware Cloud Console, open <b>Cloud Zones</b> and choose the cloud zone for your SDDC data center.</li><li>2. By default, <code>cloudadmin@vmc.local</code> (this is the default local user ID for the cloud SDDC's vCenter) only has access to provision in the <code>Compute-ResourcePool</code> .</li><li>3. Open the <b>Compute</b> tab under <b>Cloud Zones</b> and then choose <b>Compute-ResourcePool</b>.</li></ol>	Cloud administrator

Task	Description	Skills required
Configure flavor mapping.	<ol style="list-style-type: none"><li>1. Open the <b>Flavor Mappings</b> tab and create a new flavor mapping.</li><li>2. Enter the flavor name, choose the VMware Cloud on AWS account, and then provide the number of vCPUs and amount of memory.</li></ol>	Cloud administrator
Configure image mapping.	<ol style="list-style-type: none"><li>1. Open <b>Image Mappings</b> and create a new image mapping.</li><li>2. Enter the image name.</li><li>3. Choose the VMware Cloud on AWS account and provide the Cloud Account templates that are required.</li></ol>	Cloud administrator
Configure network profile.	<ol style="list-style-type: none"><li>1. Open <b>Network Profile</b> and create a new network profile.</li><li>2. Enter the network profile name.</li><li>3. Open the <b>Network</b> tab and choose the existing network that you want to use for provisioning.</li></ol>	Cloud administrator

Task	Description	Skills required
Configure storage profile.	<ol style="list-style-type: none"><li>1. Open <b>Storage Profile</b> and choose <b>New Storage Profile</b>.</li><li>2. Enter the storage profile's name.</li><li>3. In the <b>Policies</b> section, create a new policy.</li><li>4. Choose <b>Workload Datastore</b>. By default <code>cloudadmin@vmc.local</code> only has access to provision in the workload's datastore.</li></ol>	Cloud administrator

Task	Description	Skills required
Create the Cloud Template.	<ol style="list-style-type: none"><li>1. Open the <b>Design</b> tab, choose <b>Cloud Templates</b> , and then choose <b>New From</b> and <b>Blank Canvas</b>.</li><li>2. Provide the name and description of the Cloud Template.</li><li>3. Choose the project that you created earlier.</li><li>4. From the Cloud Template resources design page, drag components into the blank canvas according to your requirements.</li><li>5. Choose <b>Test</b> to test the template and fix any issues.</li><li>6. Choose <b>Deployment</b> and provide the deployment name to deploy the VMs.</li></ol> <p>For more information about this, see <a href="#">Create a basic cloud template</a> in the VMware documentation.</p>	Cloud administrator

# Deploy a VMware SDDC on AWS by using VMware Cloud on AWS

Created by Deepak Kumar (AWS) and Derek Cox (AWS)

**Environment:** Production

**Technologies:** Hybrid cloud;  
Infrastructure

**Workload:** All other  
workloads

**AWS services:** Amazon VPC

## Summary

**Notice:** As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to create a VMware-based Software-Defined Data Center (SDDC) that's hosted in the Amazon Web Services (AWS) Cloud. You can deploy an SDDC to migrate your VMware vSphere-based workloads to the AWS Cloud and take advantage of AWS services while you use your existing VMware tools and skills. You can use this SDDC to run your production applications across VMware vSphere-based private, public, and hybrid cloud environments, with optimized access to AWS services. For example, you can use the SDDC as a secondary site for disaster recovery or to extend your data center to different geographical locations.

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per SDDC cluster and scale up to 16 hosts per cluster in your production environment. For more information, see the [VMware Cloud on AWS](#) website. To learn more about SDDCs, see [About Software-Defined Data Centers](#) in the VMware documentation.

## Prerequisites and limitations

### Prerequisites

- Sign up for a [MyVMware account](#) and fill out all fields.
- Sign up for an [AWS account](#). For instructions, see the [AWS Knowledge Center](#).
- Sign up for an **MyVMware Cloud on AWS account**. An activation link is sent to the email address you specify when you sign up.

## Limitations

- See [VMware Cloud on AWS configuration limits](#) pages on the VMware website.

## Product versions

- See [VMware Cloud on AWS Release Notes](#) in the VMware documentation.

## Architecture

### Target technology stack

The following diagram shows the VMware software stack, including vSphere, vCenter, vSAN, and NSX-T, running on AWS bare-metal dedicated infrastructure. You can manage your VMware-based resources and tools on AWS with seamless integration with other AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon Simple Storage Service (Amazon S3), Amazon Redshift, AWS Direct Connect, Amazon Relational Database Service (Amazon RDS), and Amazon DynamoDB.

The basic entity of VMware Cloud on AWS is an SDDC, which includes the following components:

- **Compute:** The compute component is the lowest layer of the VMware Cloud on AWS SDDC. VMware Cloud on AWS runs on Amazon EC2 bare metal instance types. These include `i3.metal`, `i3en.metal`, and `i4i.metal`, and provide direct access to physical resources such as processors and memory.  
  
**Important:** The `i3.metal` instance type for VMware Cloud on AWS, including on-demand and subscription options of one-year and three-year terms, is set to reach its end of life and end of support on December 31, 2026. Additionally, new customers are currently not able to request `i3.metal` instances. For more information, see the [announcement on the VMware Cloud Blog](#).
- **Storage:** SDDC clusters support VMware vSAN with an all-flash configuration for storage using non-volatile memory express (NVMe) flash storage, which provides fast and high-performance storage. Starting with SDDC version 1.20, VMware Cloud on AWS offers support for two types of external storage: Amazon FSx for NetApp ONTAP and VMware Cloud Flex Storage.
- **Networking:** Networking capabilities and policies are managed by using VMware NSX-T in the SDDC cluster. Multi-tier virtual networks are created in the SDDC cluster to separate network resources from physical equipment. This enables VMware Cloud on AWS users to create logical, software-defined networks.

## Tools

- [VMware Cloud on AWS](#) is an integrated cloud offering jointly developed by AWS and VMware.

## Epics

### Create a VPC and subnet in your AWS account

Task	Description	Skills required
Sign in to your AWS account.	Sign in to your <a href="#">AWS account</a> with credentials that have administrator permissions.	Cloud administrator
Create a new VPC.	In this step, you define a virtual private cloud (VPC) that links to the SDDC. If you	Cloud administrator

Task	Description	Skills required
	<p>already have a VPC you want to use for the SDDC, skip this step.</p> <ol style="list-style-type: none"><li>1. Choose the AWS Region to deploy your VMware Cloud on AWS SDDC.</li><li>2. Open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>.</li><li>3. In the navigation pane, choose <b>Your VPCs</b>.</li><li>4. Choose <b>Create VPC</b>.</li><li>5. Specify VPC settings such as the VPC <b>name tag</b>, <b>IPv4 CIDR</b> block, <b>Tenancy</b> (keep as <b>Default</b>), and then choose <b>Create VPC</b>.</li><li>6. When the VPC has been created, choose <b>Close</b>.</li></ol> <p>For more information, see <a href="#">Create and configure your VPC</a> in the AWS documentation.</p>	

Task	Description	Skills required
Create a private subnet.	<p>You will now create a private subnet for the elastic network interface (ENI) for each Availability Zone. We recommend that you use a subnet without an internet gateway attached.</p> <ol style="list-style-type: none"><li>1. Open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>.</li><li>2. In the navigation pane, choose <b>Subnets</b>.</li><li>3. Choose <b>Create Subnet</b>.</li><li>4. On the <b>Create Subnet</b> page, choose the VPC that you created earlier.</li><li>5. Complete the settings for the subnet, including a <b>subnet name</b>, <b>Availability Zone</b>, and <b>IPv4 CIDR block</b>.</li><li>6. Choose <b>Create Subnet</b>.</li></ol> <p>Repeat these steps to create subnets for each Availability Zone in the Region.</p>	Cloud administrator

## Activate VMware Cloud on AWS

Task	Description	Skills required
Activate the service.	<p>When you sign up for a MyVMware account, VMware sends you a welcome email and activation link to the email address you specified.</p> <ol style="list-style-type: none"><li>1. Open the <b>Activate Service</b> link from the welcome email in your browser.</li><li>2. Log in with MyVMware credentials.</li><li>3. Review and accept the terms and conditions for the use of services.</li><li>4. Complete the account activation process. You will be redirected to the VMware Cloud on AWS console. (Note: VMware Cloud on AWS accounts are based on an organization, which represents a group or line of business subscribed to the account. This organization has no relationship to AWS Organizations.)</li><li>5. On the <b>Select or Create Organization</b> page, create an organization that is linked to the MyVMware account.</li></ol>	Cloud administrator

Task	Description	Skills required
	<p>6. Enter the <b>Organization Name</b> and <b>Address</b> for logical distinction.</p> <p>7. Select <b>Create Organization</b> to complete the process.</p> <p>For more information about this process, see <a href="#">SDDC Deployment and Best Practices Guide on AWS</a> in the AWS documentation.</p>	
Assign IAM roles.	<p>When the organization has been created, assign privileged access to specific users to access the Cloud Services and SDDC console, SDDC, and NSX components. For instructions, see <a href="#">Assign a VMC Service Role to an Organization Member</a> in the VMware documentation.</p> <p>There are two types of organization roles:</p> <ul style="list-style-type: none"> <li>• Organization owners can add, remove, and modify users and access all cloud resources.</li> <li>• Organization members can access cloud resources only.</li> </ul>	Cloud administrator

## Deploy an SDDC

Task	Description	Skills required
Deploy an SDDC in your VMware Cloud on AWS account.	<p><b>Important:</b> After an AWS account has been associated with a VMware Organization as the seller of record, the AWS account number cannot be updated. There can be only one AWS seller of record per VMware Organization.</p> <p>To deploy an SDDC:</p> <ol style="list-style-type: none"><li>1. Log in to the VMC console at <a href="https://vmc.vmware.com">https://vmc.vmware.com</a>.</li><li>2. Choose <b>VMware Cloud on AWS Service</b> from the available services.</li><li>3. Choose <b>Create SDDC</b>.</li><li>4. Enter SDDC properties such as <b>AWS Region, Deployment (Single Host, Multi-Host, or Stretched Cluster), Host Type, SDDC Name, Number of Hosts, Host Capacity, and Total Capacity</b>, and then choose <b>Next</b>.</li><li>5. Connect to your AWS account, and then choose <b>Next</b>.</li><li>6. Select your previously configured VPC and</li></ol>	Cloud administrator, Cloud architect

Task	Description	Skills required
	<p>subnet, and then choose <b>Next</b>.</p> <p>7. Enter the management subnet CIDR block for the SDDC, and then choose <b>NEXT</b>. For more information, see <a href="#">Selecting IP Subnets and Connectivity for your SDDC</a> on the VMware Cloud Blog.</p> <p>8. Select the two check boxes to acknowledge that you take responsibility for the costs for deploying an SDDC, and then choose <b>Deploy SDDC</b>.</p> <p>You'll be charged when you choose <b>Deploy SDDC</b>. You won't be able to pause or cancel the deployment process, which takes some time to complete.</p> <p>For more information about creating an SDDC, see <a href="#">Deploy an SDDC from the VMC Console</a> in the VMware documentation.</p>

# Integrate VMware vRealize Network Insight with VMware Cloud on AWS

Created by Deepak Kumar (AWS), Piotr Pitera (AWS), and Sachin Trivedi (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> VMware vRealize Network Insight	<b>Target:</b> VMware Cloud on AWS
<b>R Type:</b> Relocate	<b>Workload:</b> All other workloads	<b>Technologies:</b> Hybrid cloud; Infrastructure; Migration
<b>AWS services:</b> VMware Cloud on AWS		

## Summary

**Notice:** As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to integrate VMware vRealize Network Insight with VMware Cloud on AWS and inspect traffic flow from your virtual machines. This integration also helps you plan application migrations to VMware Cloud on AWS.

vRealize Network Insight offers visibility into your network infrastructure. It provides network monitoring and analytics features to improve security, mitigate migration risks, and optimize performance. You can use this tool to monitor traffic flows from your virtual machines and view recommended security rules based on the observed traffic. For more information about vRealize Network Insight, see the [VMware documentation](#).

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per SDDC cluster and scale up to 16 hosts per cluster in your production environment. For more information, see the [VMware Cloud on AWS](#)

website. To learn more about SDDCs, see [About Software-Defined Data Centers](#) in the VMware documentation.

## Prerequisites and limitations

### Prerequisites

- VMware Cloud on AWS SDDC, deployed

### Limitations

- For known limitations, see the [VMware documentation](#).

### Product versions

- vRealize Network Insight version 5.0.0
- VMware Cloud on AWS SDDC version 1.24

## Architecture

### Source technology stack

- vRealize Network Insight

### Target technology stack

- VMware Cloud on AWS

### Target architecture

The following diagram shows the connectivity between VMware Cloud on AWS and vRealize Network Insight on premises.

## Tools

- [VMware Cloud on AWS](#) is an integrated cloud offering jointly developed by AWS and VMware.
- [VMware vRealize Network Insight](#) is a monitoring and analytics tool that provides visibility into the network infrastructure for security planning and troubleshooting.

## Epics

### Set up your environment for vRealize Network Insight

Task	Description	Skills required
Create a VMware user account.	Create a VMware user account or log in to your existing VMware account.	Cloud administrator

Task	Description	Skills required
	<p>To open a new account:</p> <ol style="list-style-type: none"> <li>1. Sign up for a <a href="#">VMware Customer Connect account</a> by completing the registration form.</li> </ol> <p>New users will receive an email to activate their accounts.</p> <ol style="list-style-type: none"> <li>2. Enter the authentication code from the email.</li> <li>3. Log in to <a href="#">Customer Connect</a>.</li> </ol>	
Download the OVA files for vRealize Network Insight.	<p>Download the OVA files for vRealize Network Insight:.</p> <ol style="list-style-type: none"> <li>1. Navigate to the VMware product download page at <a href="https://my.vmware.com/group/vmware/home">https://my.vmware.com/group/vmware/home</a>.</li> <li>2. Search for vRealize Network Insight.</li> <li>3. Download the latest vRealize Network Insight version 5.0.0 platform and collector OVA files.</li> </ol>	Cloud administrator
Deploy vRealize Network Insight.	<p>For deployment instructions, see the <a href="#">VMware documentation</a>.</p>	Cloud administrator

## Add a data source and collector

Task	Description	Skills required
Add a data source.	<ol style="list-style-type: none"> <li>1. Log in to vRealize Network Insight.</li> <li>2. Choose <b>Settings, Accounts and Data Sources, Add Source</b>.</li> <li>3. For <b>Type</b>, choose <b>On-premise vCenter server</b>.</li> </ol> <p>For more information, see the <a href="#">VMware documentation</a>.</p>	Cloud administrator
Set up a collector for the data source.	For instructions, see the <a href="#">VMware documentation</a> .	Cloud administrator

## Analyze application dependencies

Task	Description	Skills required
Create an application.	If you don't have an existing application in vRealize Network Insight, follow the steps in the <a href="#">VMware documentation</a> to create one.	Cloud administrator
Discover and analyze your application.	<ol style="list-style-type: none"> <li>1. Use vRealize Network Insight to discover your application. For instructions, see the <a href="#">VMware documentation</a>.</li> </ol>	Cloud administrator

Task	Description	Skills required
	2. Analyze your application. For instructions, see the <a href="#">VMware documentation</a> .

# Migrate VMs to VMware Cloud on AWS by using HCX OS Assisted Migration

Created by Deepak Kumar (AWS) and Himanshu Gupta (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Non-vSphere environment	<b>Target:</b> VMware Cloud on AWS SDDC
<b>R Type:</b> Relocate	<b>Workload:</b> All other workloads	<b>Technologies:</b> Hybrid cloud; Migration

## Summary

**Notice:** As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to migrate a virtual machine (VM) from a non-vSphere environment to VMware Cloud on Amazon Web Services (AWS) by using OS Assisted Migration (OSAM).

OSAM is part of VMware Hybrid Cloud Extension (HCX), which is included with VMware Cloud on AWS. You can use OSAM to migrate a non-vSphere environment such as VMware KVM or Hyper-V to VMware Cloud on AWS. OSAM uses Sentinel software, which you install on a Windows or Linux guest VM to assist in replicating the VM from your on-premises environment to a Software-Defined Data Center (SDDC) on VMware Cloud on AWS.

This pattern explains how to enable OSAM, install Sentinel software on a Windows VM, connect and register with an HCX Sentinel Gateway (SGW) appliance at the source site, and establish a forwarding connection with an HCX Sentinel Data Receiver (SDR) appliance at the destination site to initiate migration.

For more information about OSAM, see the [VMware documentation](#).

## Prerequisites and limitations

### Prerequisites

- Install HCX in your source and target environments. For HCX prerequisites, see [Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX](#) in the AWS Prescriptive Guidance documentation.
- For OSAM prerequisites, see the [installation checklist](#) in the VMware documentation.
- For OSAM port information, see [VMware HCX port requirements](#) on the VMware Ports and Protocols website.

## Limitations

- [VMware HCX 4.2.0 Configuration Limits](#)
- [Considerations for OSAM Deployment](#)
- [Supported Guest Operating Systems](#)
- [Guest Operating System Considerations](#)

## Product versions

- VMware HCX 4.2.0
- VMware SDDC 1.12

## Architecture

The following diagram shows how HCX OSAM works with the Sentinel software to replicate non-vSphere VMs from your on-premises environment to VMware Cloud on AWS.

OSAM consists of three components:

- The Sentinel Gateway (SGW) appliance, which is used to connect and forward workloads and applications in the source VMware-based environment
- The Sentinel Data Receiver (SDR), which is used in the destination VMware Cloud on AWS environment to receive migrated workloads from the source
- Sentinel software, which must be installed on each guest VM that you want to migrate

OSAM uses the Sentinel software that is installed on Windows or Linux guest VMs to assist in replicating a VM from on premises to a VMware SDDC. The Sentinel software that you install on guest VMs collects the system configurations from the guest VM and assists with the data replication. This information is also used to create the inventory of guest VMs for migration and helps prepare the disks on the replica VM for replication and migration purposes.

## Tools

- VMware HCX 4.2.0
- VMware Cloud on AWS SDDC

## Epics

### Configure HCX

Task	Description	Skills required
Deploy HCX Cloud and HCX Connector.	Follow the instructions in <a href="#">HCX Connector and HCX Cloud Installations</a> in the VMware documentation.	Cloud administrator, Systems administrator

### Configure OSAM and migrate VMs

Task	Description	Skills required
Install HCX Sentinel.	<p>To install Sentinel on Linux:</p> <ol style="list-style-type: none"> <li>1. In the vCenter Server for the HCX Connector, choose <b>Interconnect, Multi-Site Service Mesh, Sentinel Management</b>.</li> <li>2. Choose <b>Download Linux Bundle</b>.</li> <li>3. Install the Sentinel agent on a Linux machine.</li> </ol> <p>For more information, see <a href="#">Downloading and Installing HCX Sentinel Agent software</a> in the VMware documentation.</p>	Cloud administrator
Migrate VMs.	To migrate your VMs in groups (called <i>mobility groups</i> ), follow these steps:	Cloud administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li>1. In the vSphere Client, from the HCX plug-in, choose <b>Services, Migration</b>.</li><li>2. Choose <b>Migrate</b>.</li><li>3. Choose <b>Non vSphere Inventory, Remote connections</b>. This will show the list VMs that you installed HCX Sentinel on.</li><li>4. For <b>Group name</b>, enter the name of the mobility group you want to create for the VMs.</li><li>5. Choose the VMs you want to migrate, and then choose <b>Add</b> to add them to the mobility group.</li><li>6. For each VM:<ol style="list-style-type: none"><li>a. Select the destination compute container.</li><li>b. Select the destination storage.</li><li>c. Select the migration profile.</li><li>d. Select the destination folder.</li></ol></li><li>7. To start the migration process, choose <b>Go</b>.</li></ol> <p>HCX validates your VM selections before migration starts.</p>	

Task	Description	Skills required
	For more information, see <a href="#">Migrating Virtual Machines with Mobility Groups</a> and <a href="#">Monitoring and Estimating Migration with Mobility Groups</a> in the VMware documentation.

# Send logs from VMware Cloud on AWS to Splunk by using VMware Aria Operations for Logs

Created by Deepak Kumar (AWS) and Piotr Pitera (AWS)

<b>Environment:</b> Production	<b>Source:</b> VMware Cloud on AWS logs and events	<b>Target:</b> Splunk on-premises endpoint
<b>R Type:</b> Relocate	<b>Workload:</b> All other workloads	<b>Technologies:</b> Hybrid cloud; Infrastructure; Migration
<b>AWS services:</b> VMware Cloud on AWS		

## Summary

**Notice:** As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to forward VMware Cloud on AWS events or logs to a syslog or an HTTP endpoint such as Splunk by using VMware Aria Operations for Logs.

VMware Aria Operations for Logs is a log analysis tool that offers enhanced visibility and accelerated troubleshooting in the VMware Cloud on AWS environment. You can configure this tool to send either all or a portion of logs or events in VMware Cloud on AWS to a syslog or HTTP endpoint. The endpoint can be either a software as a service (SaaS) endpoint or an on-premises endpoint such as Splunk. (This pattern provides the instructions for Splunk.) To learn more about VMware Aria Operations for Logs, see the [VMware documentation](#).

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per Software-Defined Data Center (SDDC) cluster and scale up to 16 hosts per cluster in your production environment. For more information, see

the [VMware Cloud on AWS](#) website. To learn more about SDDCs, see [About Software-Defined Data Centers](#) in the VMware documentation.

## Prerequisites and limitations

### Prerequisites

- Splunk, configured on premises

### Limitations

You can sign up for a free trial subscription to VMware Aria Operations for Logs. This subscription is valid for 30 days and has the following limitations:

- Maximum size of logs you can forward: 50 GB logs per day
- Maximum number of log forwarding configurations you can create: 10
- Maximum number of log forwarding configurations you can activate: 5

To access all service features, you must upgrade to a premium subscription.

For more information about trial and premium subscriptions, see [VMware Aria Operations for Logs \(SaaS\) Subscriptions and Billing](#) in the VMware documentation. For more information about usage limits, see [Usage Limitations for Features](#) in the VMware documentation.

### Product versions

- VMware Cloud on AWS SDDC version 1.24
- VMware Aria Operations for Logs version 8.10
- On-premises Splunk version 9.x

## Architecture

### Source technology stack

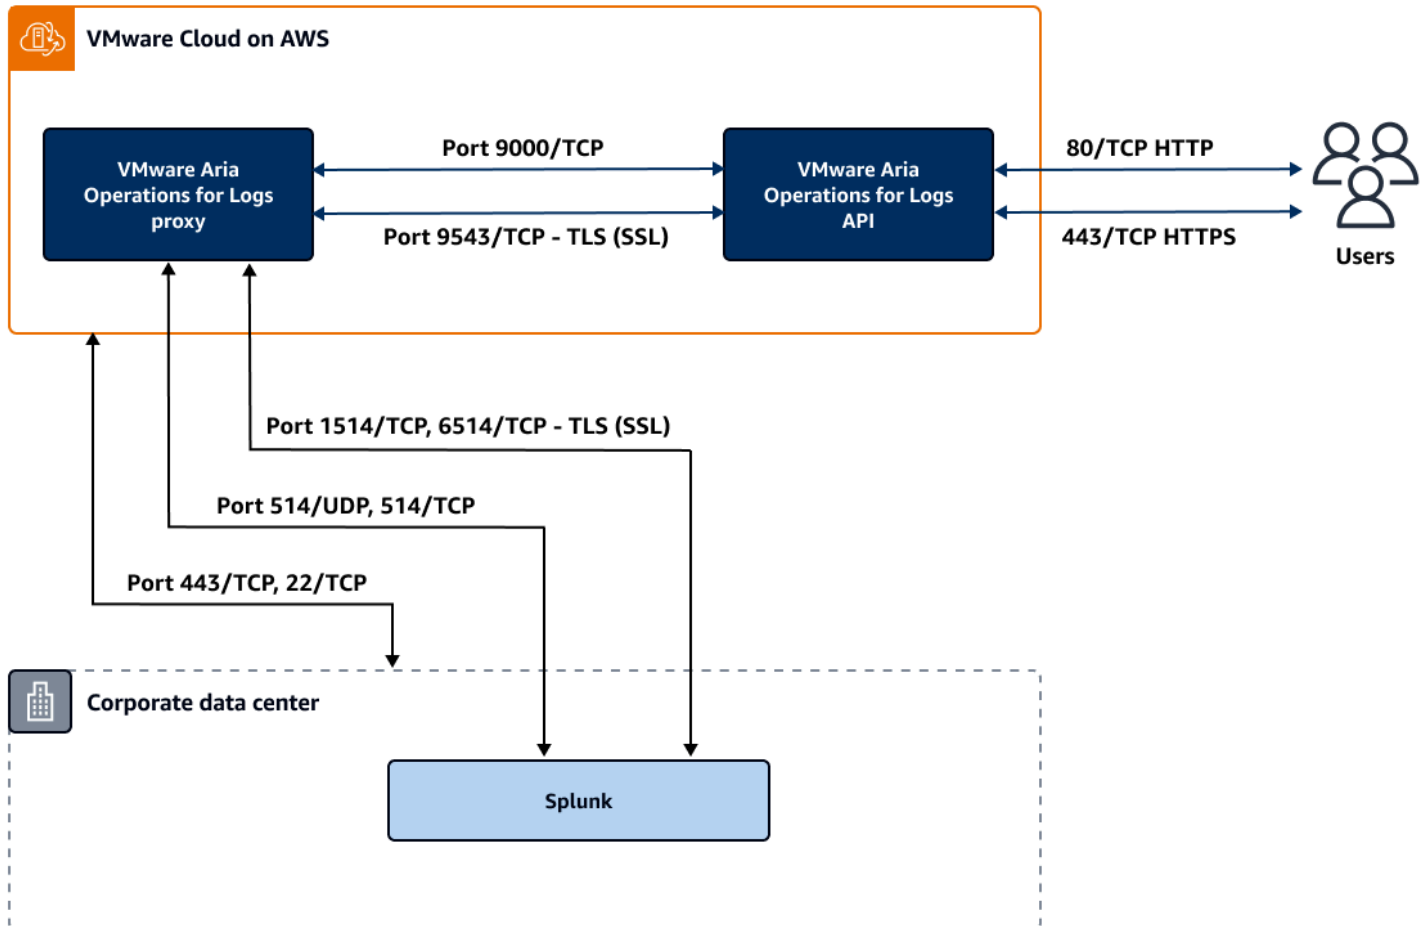

- VMware Cloud on AWS
- VMware Aria Operations for Logs

### Target technology stack

- On-premises Splunk

## Target architecture

The following diagram shows the connectivity between a corporate data center and VMware Aria Operations for Logs in VMware Cloud on AWS.

## Tools

- [VMware Cloud on AWS](#) is an integrated cloud offering jointly developed by AWS and VMware.
- [VMware Aria Operations for Logs](#) is a log analysis and troubleshooting tool for VMware Cloud on AWS.

## Epics

### Deploy an SDDC and enable VMware Aria Operation for Logs

Task	Description	Skills required
Deploy a VMware Cloud on AWS SDDC.	Follow the instructions in <a href="#">Deploy a VMware SDDC on AWS by using VMware Cloud on AWS</a> in AWS Prescriptive Guidance.	Cloud architect, Cloud administrator
Sign up for VMware Aria Operations for Logs.	For instructions, see the <a href="#">VMware documentation</a> .	Cloud architect

### Deploy a cloud proxy

Task	Description	Skills required
Deploy a cloud proxy.	<p>To forward logs to an on-premises instance of Splunk, you must add a cloud proxy for VMware Aria Operations for Logs. This proxy receives information from the on-premises data center and sends it to VMware Aria Operations for Logs for analysis.</p> <p>To download and install the cloud proxy:</p> <ol style="list-style-type: none"> <li>1. Make sure that ports 443, 22, and 514 are open between your on-premises environment and</li> </ol>	Cloud administrator, Cloud architect

Task	Description	Skills required
	<p>VMware Cloud on AWS. For additional ports, you can use 1514/TCP or 6514/TCP. For more information about ports, see <a href="#">VMware Aria Operations for Logs Firewall Recommendations</a> in the VMware documentation.</p> <ol style="list-style-type: none"><li data-bbox="592 646 1031 730">2. Log in to VMware Aria Operations for Logs.</li><li data-bbox="592 751 1031 888">3. On the home page, choose <b>Add Collector</b> in the widget.</li><li data-bbox="592 909 1031 1182">4. On the <b>Cloud Proxy Virtual Appliance</b> screen, copy the token key. You must use this key within 24 hours to finish the following steps.</li><li data-bbox="592 1203 1031 1287">5. Choose the download link for the OVA file.</li><li data-bbox="592 1308 1031 1539">6. Navigate to VMware vSphere web client, choose your cluster, and then select <b>Deploy OVF template</b>.</li><li data-bbox="592 1560 1031 1738">7. When you're prompted for the key, paste the token key that you copied in step 4.</li><li data-bbox="592 1759 1031 1843">8. Choose <b>Finish</b> to install the cloud proxy.</li></ol>	

## Forward logs to an on-premises Splunk endpoint

Task	Description	Skills required
Configure log forwarding.	<p>To forward logs to the Splunk endpoint:</p> <ol style="list-style-type: none"><li>1. Log in to VMware Aria Operations for Logs.</li><li>2. Navigate to <b>Log Management</b>.</li><li>3. Choose <b>Log Forwarding</b>.</li><li>4. Choose <b>New Configuration</b>, and complete the following settings:<ul style="list-style-type: none"><li>• Provide a name for the log forwarding configuration.</li><li>• For <b>Destination</b>, choose <b>On Premises</b>.</li><li>• For <b>Cloud Proxy</b>, select the cloud proxy that you installed earlier.</li><li>• For <b>Endpoint Type</b>, choose <b>TCP</b>.</li><li>• For <b>Endpoint URL</b>, provide your on-premises Splunk URL in the format: <pre>tcp://x.x.x.x (your Splunk IP address):514</pre></li></ul></li><li>• (Optional) For <b>Tags</b>, you can specify tag names</li></ol>	

Task	Description	Skills required
	<p>and values to facilitate querying.</p> <ul style="list-style-type: none"><li>• Choose <b>Apply to all logs</b> or <b>Apply to specific logs</b>. If you want to send all VMware Cloud on AWS logs to Splunk, choose <b>Apply to all logs</b>.</li></ul> <p>5. Choose <b>Verify</b>.</p> <p>6. Choose <b>Save</b>.</p> <p>For more information, see <a href="#">Forward Logs from VMware Aria Operations for Logs</a> in the VMware documentation.</p>

# Set up a CI/CD pipeline for hybrid workloads on Amazon ECS Anywhere by using AWS CDK and GitLab

Created by Dr. Rahul Sharad Gaikwad (AWS)

<b>Code repository:</b> <a href="#">amazon-ec-s-anywhere-cicd-pipeline-cdk-sample</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Hybrid cloud; Containers & microservices; Infrastructure; DevOps
<b>Workload:</b> Open-source	<b>AWS services:</b> AWS CDK; AWS CodePipeline; Amazon ECS; AWS Systems Manager; AWS CodeCommit	

## Summary

Amazon ECS Anywhere is an extension of the Amazon Elastic Container Service (Amazon ECS). It provides support for registering an *external instance*, such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster. This feature helps reduce costs and mitigate complex local container orchestration and operations. You can use ECS Anywhere to deploy and run container applications in both on-premises and cloud environments. It removes the need for your team to learn multiple domains and skill sets, or to manage complex software on their own.

This pattern describes a step-by-step approach to provision an Amazon ECS cluster with Amazon ECS Anywhere instances by using Amazon Web Services (AWS) Cloud Development Kit (AWS CDK) stacks. You then use AWS CodePipeline to set up a continuous integration and continuous deployment (CI/CD) pipeline. Then, you replicate your GitLab code repository to AWS CodeCommit and deploy your containerized application on the Amazon ECS cluster.

This pattern is designed to help those who use on-premises infrastructure to run container applications and use GitLab to manage the application code base. You can manage those workloads by using AWS Cloud services, without disturbing your existing, on-premises infrastructure.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A container application running on on-premises infrastructure.
- A GitLab repository where you manage your application code base. For more information, see [Repository](#) (GitLab).
- AWS Command Line Interface (AWS CLI), installed and configured. For more information, see [Installing or updating the latest version of the AWS CLI](#) (AWS CLI documentation).
- AWS CDK Toolkit, installed and configured globally. For more information, see [Install the AWS CDK](#) (AWS CDK documentation).
- npm, installed and configured for the AWS CDK in TypeScript. For more information, see [Downloading and installing Node.js and npm](#) (npm documentation).

## Limitations

- For limitations and considerations, see [External instances \(Amazon ECS Anywhere\)](#) in the Amazon ECS documentation.

## Product versions

- AWS CDK Toolkit version 2.27.0 or later
- npm version 7.20.3 or later
- Node.js version 16.6.1 or later

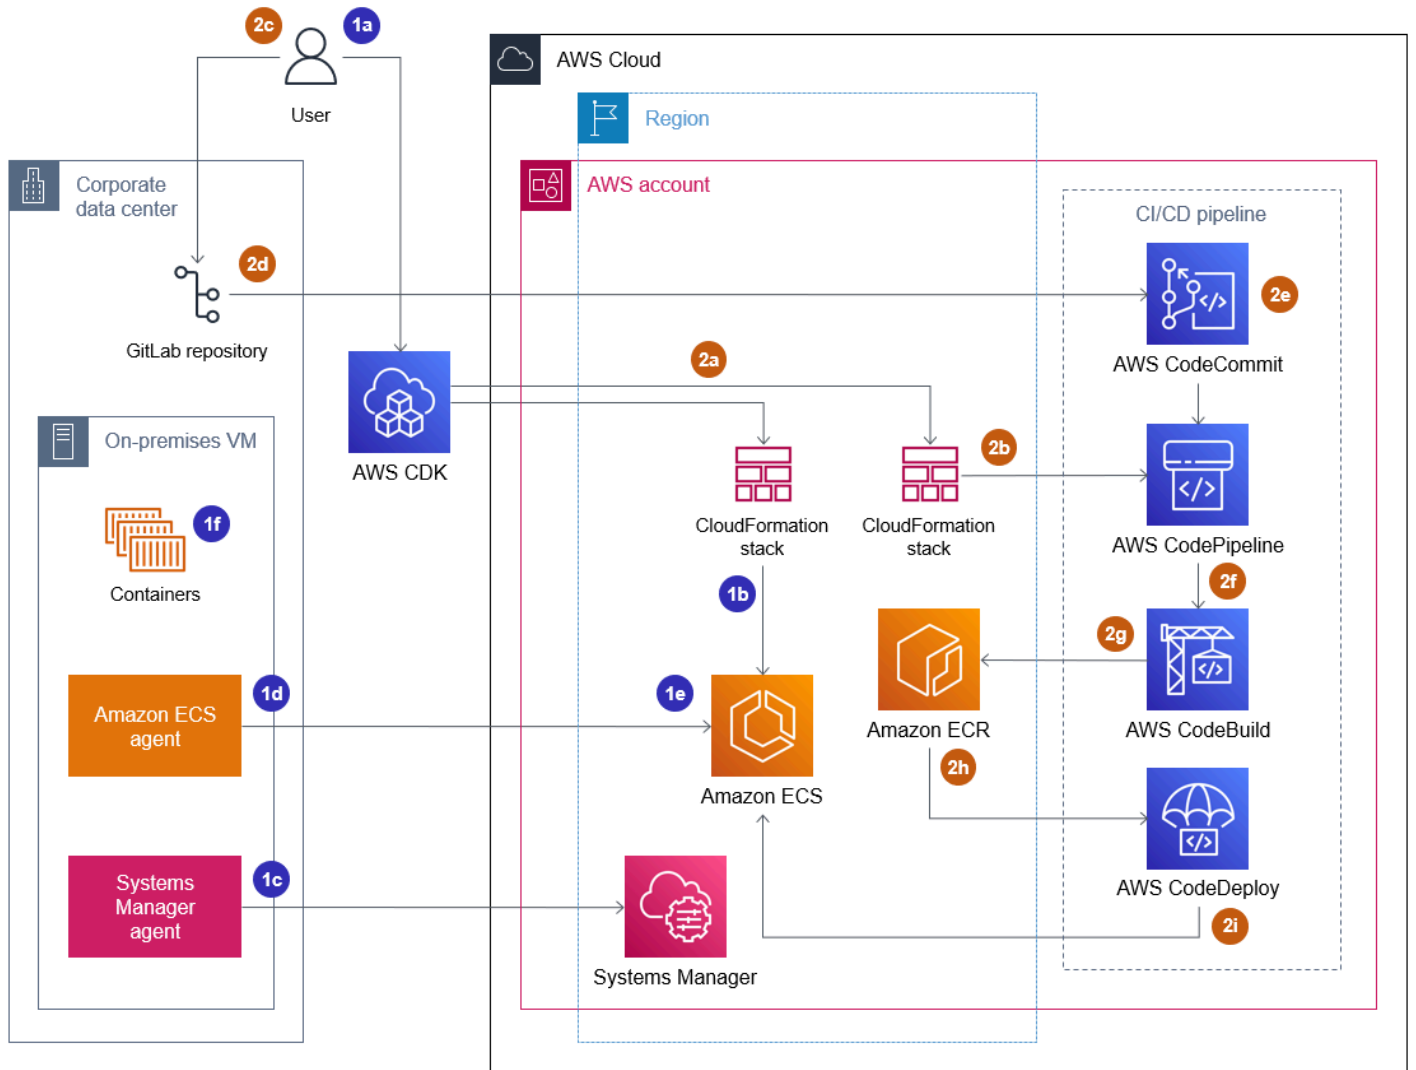

## Architecture

### Target technology stack

- AWS CDK
- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- Amazon ECS Anywhere
- Amazon Elastic Container Registry (Amazon ECR)
- AWS Identity and Access Management (IAM)

- AWS System Manager
- GitLab repository

**Target architecture**

This diagram represents two primary workflows described in this pattern, provisioning the Amazon ECS cluster and setting up the CI/CD pipeline that sets up and deploys the CI/CD pipeline, as follows:

**1. Provisioning the Amazon ECS cluster**

- When you deploy the first AWS CDK stack, it creates a CloudFormation stack on AWS.
- This CloudFormation stack provisions an Amazon ECS cluster and related AWS resources.

- c. To register an external instance with an Amazon ECS cluster, you must install AWS Systems Manager Agent (SSM Agent) on your VM and register the VM as an AWS Systems Manager managed instance.
- d. You must also install the Amazon ECS container agent and Docker on your VM to register it as an external instance with the Amazon ECS cluster.
- e. When the external instance is registered and configured with the Amazon ECS cluster, it can run multiple containers on your VM, which is registered as an external instance.
- f. The Amazon ECS cluster is active and can run the application workloads through containers. The Amazon ECS Anywhere container instance runs in on-premises environment but is associated with the Amazon ECS cluster in the cloud.

## 2. Setting up and deploying the CI/CD pipeline

- a. When you deploy the second AWS CDK stack, it creates another CloudFormation stack on AWS.
- b. This CloudFormation stack provisions a pipeline in CodePipeline and related AWS resources.
- c. You push and merge application code changes to an on-premises GitLab repository.
- d. The GitLab repository is automatically replicated to the CodeCommit repository.
- e. The updates to the CodeCommit repo automatically starts CodePipeline.
- f. CodePipeline copies code from CodeCommit and creates the deployable application build in CodeBuild.
- g. CodePipeline creates a Docker image of the CodeBuild build environment and pushes it to the Amazon ECR repo.
- h. CodePipeline initiates CodeDeploy actions that pull the container image from the Amazon ECR repo.
- i. CodePipeline deploys the container image on the Amazon ECS cluster.

### Automation and scale

This pattern uses the AWS CDK as an infrastructure as code (IaC) tool to configure and deploy this architecture. AWS CDK helps you orchestrate the AWS resources and set up Amazon ECS Anywhere and the CI/CD pipeline.

## Tools

### **AWS services**

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster. This pattern also uses [Amazon ECS Anywhere](#), which provides support for registering an on-premises server or VM to your Amazon ECS cluster.

## Other tools

- [Node.js](#) is an event-driven JavaScript runtime environment designed for building scalable network applications.
- [npm](#) is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- [Vagrant](#) is an open-source utility for building and maintaining portable virtual software development environments. For demonstration purposes, this pattern uses Vagrant to create an on-premises VM.

## Code repository

The code for this pattern is available in the GitHub [CI/CD pipeline for Amazon ECS Anywhere using AWS CDK](#) repository.

## Best practices

Consider the following best practices when deploying this pattern:

- [Best practices for developing and deploying cloud infrastructure with the AWS CDK](#)
- [Best practices for developing cloud applications with AWS CDK](#) (AWS blog post)

# Epics

## Verify the AWS CDK configuration

Task	Description	Skills required
Verify the AWS CDK version.	<p>Verify the version of the AWS CDK Toolkit by entering the following command.</p> <pre>cdk --version</pre> <p>This pattern requires version 2.27.0 or later. If you have an earlier version, follow the instructions in the <a href="#">AWS CDK documentation</a> to update it.</p>	DevOps engineer
Verify the npm version.	<p>Verify the version of npm by entering the following command.</p> <pre>npm --version</pre> <p>This pattern requires version 7.20.3 or later. If you have an earlier version, follow the instructions in the <a href="#">npm documentation</a> to update it.</p>	DevOps engineer
Set up AWS credentials.	<p>Set up AWS credentials by entering the <code>aws configure</code> command and following the prompts.</p> <pre>\$aws configure</pre>	DevOps engineer

Task	Description	Skills required
	<p>AWS Access Key ID [None]: &lt;your-access-key-ID&gt;</p> <p>AWS Secret Access Key [None]: &lt;your-secret-access-key&gt;</p> <p>Default region name [None]: &lt;your-Region-name&gt;</p> <p>Default output format [None]:</p>	

## Bootstrap the AWS CDK environment

Task	Description	Skills required
Clone the AWS CDK code repository.	<ol style="list-style-type: none"> <li>Clone the <a href="#">CI/CD pipeline for Amazon ECS Anywhere using AWS CDK</a> repository for this pattern by entering the following command. <pre>git clone https://github.com/aws-samples/amazon-ecs-anywhere-cicd-pipeline-cdk-sample.git</pre> </li> <li>Navigate into the cloned directory by entering the following command. <pre>cd amazon-ecs-anywhere-cicd-pipeline-cdk-sample</pre> </li> </ol>	DevOps engineer

Task	Description	Skills required
Bootstrap the environment.	<p>Deploy the CloudFormation template to the account and AWS Region that you want to use by entering the following command.</p> <pre>cdk bootstrap &lt;account-number&gt;/&lt;Region&gt;</pre> <p>For more information, see <a href="#">Bootstrapping</a> in the AWS CDK documentation.</p>	DevOps engineer

## Build and deploy the infrastructure for Amazon ECS Anywhere

Task	Description	Skills required
Install the package dependencies and compile the TypeScript files.	<p>Install the package dependencies and compile the TypeScript files by entering the following commands.</p> <pre>\$cd EcsAnywhereCdk \$npm install \$npm fund</pre> <p>These commands install all the packages from the sample repository. For more information, see <a href="#">npm ci</a> and <a href="#">npm install</a> in the npm documentation. If you get any errors about missing packages when</p>	DevOps engineer

Task	Description	Skills required
	you enter these commands, see the <a href="#">Troubleshooting</a> section of this pattern.	
Build the project.	<p>To build the project code, enter the following command.</p> <pre>npm run build</pre> <p>For more information about building and deploying the project, see <a href="#">Your first AWS CDK app</a> in the AWS CDK documentation.</p>	DevOps engineer
Deploy the Amazon ECS Anywhere infrastructure stack.	<ol style="list-style-type: none"><li>1. List the stacks by entering the following command.<pre>\$cdk list</pre></li><li>2. Confirm that the output returns the <code>EcsAnywhereInfraStack</code> and <code>ECSAnywherePipelineStack</code> stacks.</li><li>3. Deploy the <code>EcsAnywhereInfraStack</code> stack by entering the following command.<pre>\$cdk deploy EcsAnywhereInfraStack</pre></li></ol>	DevOps engineer

Task	Description	Skills required
Verify stack creation and output.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the CloudFormation console at <a href="https://console.aws.amazon.com/cloudformation/">https://console.aws.amazon.com/cloudformation/</a>.</li> <li>2. On the <b>Stacks</b> page, select the <code>EcsAnywhereInfraStack</code> stack.</li> <li>3. Confirm that the stack status is either <code>CREATE_IN_PROGRESS</code> or <code>CREATE_COMPLETE</code>.</li> </ol> <p>Setting up the Amazon ECS cluster can take some time. Do not proceed until the stack creation is complete.</p>	DevOps engineer

## Set up an on-premises VM

Task	Description	Skills required
Set up your VM.	Create a Vagrant VM by entering the <code>vagrant up</code> command from the root directory where <code>Vagrantfile</code> is located. For more information, see the <a href="#">Vagrant documentation</a> .	DevOps engineer
Register your VM as an external instance.	<ol style="list-style-type: none"> <li>1. Log in to the Vagrant VM by using the <code>vagrant ssh</code> command. For more</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>information, see the <a href="#">Vagrant documentation</a>.</p> <ol style="list-style-type: none"><li>2. Install AWS CLI on the VM by following <a href="#">AWS CLI installation instructions</a> and entering the following commands.</li></ol> <pre data-bbox="630 579 1027 1451">\$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" \ &gt; -o "awscliv2.zip" \$sudo apt install unzip \$unzip awscliv2.zip \$sudo ./aws/install \$aws configure AWS Access Key ID [None]: &lt;your-access-key-ID&gt; AWS Secret Access Key [None]: &lt;your-secret-access-key&gt; Default region name [None]: &lt;your-Region-name&gt; Default output format [None]:</pre> <ol style="list-style-type: none"><li>1. Create an activation code and ID that you can use to register your VM with AWS Systems Manager and to activate your external instance. The output from this command includes the</li></ol>	

Task	Description	Skills required
	<p>activation ID and activation code values.</p> <pre>aws ssm create-activation \ &gt; --iam-role EcsAnywhereInstanceRole \ &gt;   tee ssm-activation.json</pre> <p>If you receive an error when you run this command, see the <a href="#">Troubleshooting</a> section.</p> <p>2. Export the activation ID and code values.</p> <pre>export ACTIVATION_ID=&lt;activation-ID&gt; export ACTIVATION_CODE=&lt;activation-code&gt;</pre> <p>3. Download the installation script to your VM.</p> <pre>curl --proto "https" -o "ecs-anywhere-install.sh" \ &gt; "https://amazon-ecs-agent.s3.amazonaws.com/ecs-anywhere-install-latest.sh"</pre> <p>4. Run the installation script on your VM.</p>	

Task	Description	Skills required
	<pre data-bbox="634 226 1027 646">sudo bash ecs-anywhere-install.sh \ --cluster EcsAnywhereCluster \ --activation-id \$ACTIVATION_ID \ --activation-code \$ACTIVATION_CODE \ --region &lt;region-name&gt;</pre> <p data-bbox="591 716 1024 1230">This sets up your VM as an Amazon ECS Anywhere external instance and registers the instance in the Amazon ECS cluster. For more information, see <a href="#">Registering an external instance to a cluster</a> in the Amazon ECS documentation. If you experience any issues, see the <a href="#">Troubleshooting</a> section.</p>	
<p data-bbox="115 1297 516 1430">Verify the status of Amazon ECS Anywhere and the external VM.</p>	<p data-bbox="591 1297 1024 1478">To verify whether your VM is connected to the Amazon ECS control plane and running, use the following commands.</p> <pre data-bbox="597 1514 1027 1749">\$aws ssm describe-instance-information \$aws ecs list-container-instances --cluster \$CLUSTER_NAME</pre>	<p data-bbox="1068 1297 1317 1333">DevOps engineer</p>

## Deploy the CI/CD pipeline

Task	Description	Skills required
Create a branch in the CodeCommit repo.	<p>Create a branch named main in the CodeCommit repo by creating the first commit for the repository. You can follow AWS documentation to <a href="#">Create a commit in CodeCommit</a>. The following command is an example.</p> <pre data-bbox="594 730 1027 1329">aws codecommit put-file \   --repository-name EcsAnywhereRepo \   --branch-name main \   --file-path README.md \   --file-content "Test" \   --name "Dev Ops" \   --email "devops@example.com" \   --commit-message "Adding README."</pre>	DevOps engineer
Set up repo mirroring.	<p>You can mirror a GitLab repository to and from external sources. You can select which repository serves as the source. Branches, tags, and commits are synced automatically. Set up a push mirror between the GitLab repository that hosts your application and the CodeCommit repository.</p>	DevOps engineer

Task	Description	Skills required
	<p>For instructions, see <a href="#">Set up a push mirror from GitLab to CodeCommit</a> (GitLab documentation).</p> <p><b>Note:</b> By default, mirroring automatically syncs the repository. If you want to manually update the repositories, see <a href="#">Update a mirror</a> (GitLab documentation).</p>	
Deploy the CI/CD pipeline stack.	<p>Deploy the EcsAnywherePipelineStack stack by entering the following command.</p> <pre data-bbox="594 1016 1029 1136">\$cdk deploy EcsAnywherePipelineStack</pre>	DevOps engineer

Task	Description	Skills required
Test the CI/CD pipeline.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 737">1. Make application code changes and push it to the source, on-premises GitLab repo. For more information, see <a href="#">Push Options</a> (GitLab documentation). For example, edit the <code>../application/index.html</code> file to update the application version value.</li><li data-bbox="591 764 1027 1675">2. When the code is replicated to the CodeCommit repo, this starts the CI/CD pipeline. Do one of the following:<ul style="list-style-type: none"><li data-bbox="630 1010 1027 1325">• If you are using automatic mirroring to synchronize the GitLab repo with the CodeCommit repo, continue to the next step.</li><li data-bbox="630 1352 1027 1675">• If you are using manual mirroring, push the application code changes to the CodeCommit repo by following the instructions in <a href="#">Update a mirror</a> (GitLab documentation).</li></ul></li><li data-bbox="591 1703 1027 1877">3. On your local machine, in a web browser, enter <a href="http://localhost:80">http://localhost:80</a>. This opens the NGINX web</li></ol>	DevOps engineer

Task	Description	Skills required
	<p>page because port 80 is forwarded to localhost in Vagrantfile. Confirm that you can view the updated application version value. This validates the pipeline and image deployment.</p> <p>4. (Optional) If you want to verify the deployment in the AWS Management Console, do the following:</p> <ol style="list-style-type: none"> <li>a. Open the Amazon ECS console at <a href="https://console.aws.amazon.com/ecs/">https://console.aws.amazon.com/ecs/</a>.</li> <li>b. From the navigation bar, select the Region to use.</li> <li>c. In the navigation pane, choose <b>Clusters</b>.</li> <li>d. On the <b>Clusters</b> page, select the <b>EcsAnywhereCluster</b> cluster.</li> <li>e. Choose <b>Task Definitions</b>.</li> <li>f. Confirm the container is running.</li> </ol>	

## Clean up

Task	Description	Skills required
Clean up and delete the resources.	After you walk through this pattern, you should	DevOps engineer

Task	Description	Skills required
	<p>remove the proof-of-concept resources you created. To clean up, enter the following commands.</p> <pre>\$cdk destroy EcsAnywherePipelineStack \$cdk destroy EcsAnywhereInfraStack</pre>	

## Troubleshooting

Issue	Solution
Errors about missing packages when installing package dependencies.	<p>Enter one of the following commands to resolve missing packages.</p> <pre>\$npm ci</pre> <p>or</p> <pre>\$npm install -g @aws-cdk/&lt;package_name&gt;</pre>
<p>When you run the <code>aws ssm create-activation</code> command on the VM, you receive the following error.</p> <pre>An error occurred (ValidationException) when calling the CreateActivation operation: Nonexistent role or missing ssm service principal in trust policy:</pre>	<p>The <code>EcsAnywhereInfraStack</code> stack isn't fully deployed, and the IAM role necessary to run this command hasn't been created yet. Check the stack status in the CloudFormation console. Retry the command after the status changes to <code>CREATE_COMPLETE</code>.</p>

# Access a bastion host by using Session Manager and Amazon EC2 Instance Connect

Created by Piotr Chotkowski (AWS) and Witold Kowalik (AWS)

**Code repository:** [Access a bastion host by using Session Manager and Amazon EC2 Instance Connect](#)

**Environment:** PoC or pilot

**Technologies:** Infrastructure; CloudNative; Security, identity, compliance; Networking

**AWS services:** Amazon EC2; AWS Systems Manager; Amazon VPC

## Summary

A *bastion host*, sometimes called a *jump box*, is a server that provides a single point of access from an external network to the resources located in a private network. A server exposed to an external public network, such as the internet, poses a potential security risk for unauthorized access. It's important to secure and control access to these servers.

This pattern describes how you can use [Session Manager](#) and [Amazon EC2 Instance Connect](#) to securely connect to an Amazon Elastic Compute Cloud (Amazon EC2) bastion host deployed in your AWS account. Session Manager is a capability of AWS Systems Manager. The benefits of this pattern include:

- The deployed bastion host doesn't have any open, inbound ports exposed to the public internet. This reduces the potential attack surface.
- You don't need to store and maintain long-term Secure Shell (SSH) keys in your AWS account. Instead, each user generates a new SSH key pair each time they connect to the bastion host. AWS Identity and Access Management (IAM) policies that are attached to the user's AWS credentials control access to the bastion host.

## Intended audience

This pattern is intended for readers who have experience with basic understanding of Amazon EC2, Amazon Virtual Private Cloud (VPC), and Hashicorp Terraform.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, [installed](#) and [configured](#)
- Session Manager plugin for the AWS CLI, [installed](#)
- Terraform CLI, [installed](#)
- Storage for the Terraform [state](#), such as an Amazon Simple Storage Service (Amazon S3) bucket and an Amazon DynamoDB table that serve as a remote backend to store the Terraform state. For more information on using remote backends for the Terraform state, see [S3 Backends](#) (Terraform documentation). For a code sample that sets up remote state management with an S3 backend, see [remote-state-s3-backend](#) (Terraform Registry). Note the following requirements:
  - The S3 bucket and DynamoDB table must be in the same AWS Region.
  - When creating the DynamoDB table, the partition key must be LockID (case-sensitive), and the partition key type must be String. All other table settings must be at their default values. For more information, see [About primary keys](#) and [Create a table](#) in the DynamoDB documentation.
- An SSH client, installed

### Limitations

- This pattern is intended as a proof of concept (PoC) or as a basis for further development. It should not be used in its current form in production environments. Before deployment, adjust the sample code in the repository to meet your requirements and use case.
- This pattern assumes that the target bastion host uses Amazon Linux 2 as its operating system. While it is possible to use other Amazon Machine Images (AMIs), other operating systems are out of scope for this pattern.
- In this pattern, the bastion host is located in a private subnet without an NAT gateway and internet gateway. This design isolates the EC2 instance from the public internet. You can add a specific network configuration that allows it to communicate with the internet. For more information, see [Connect your virtual private cloud \(VPC\) to other networks](#) in the Amazon VPC

documentation. Similarly, following the [principle of least privilege](#), the bastion host doesn't have access to any other resources in your AWS account unless you explicitly grant permissions. For more information, see [Resource-based policies](#) in the IAM documentation.

## Product versions

- AWS CLI version 2
- Terraform version 1.3.9

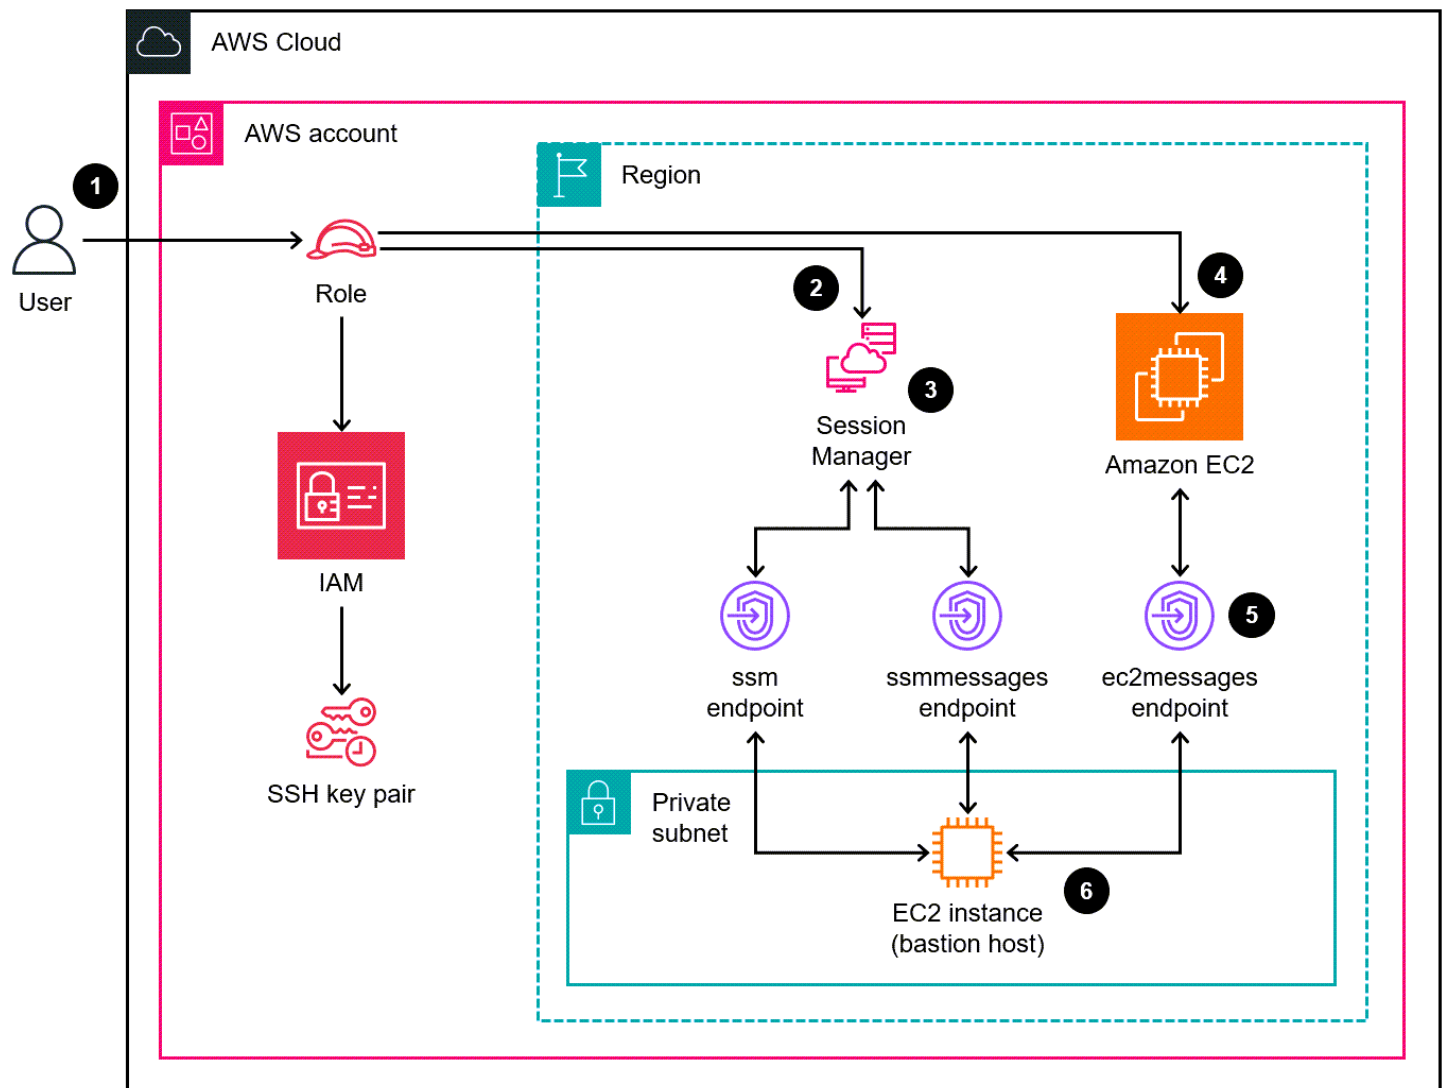

## Architecture

### Target technology stack

- A VPC with a single private subnet
- The following [interface VPC endpoints](#):
  - `amazonaws.<region>.ssm` – The endpoint for the Systems Manager service.
  - `amazonaws.<region>.ec2messages` – Systems Manager uses this endpoint to make calls from SSM Agent to the Systems Manager service.
  - `amazonaws.<region>.ssmmessages` – Session Manager uses this endpoint to connect to your EC2 instance through a secure data channel.
- A `t3.nano` EC2 instance running Amazon Linux 2
- IAM role and instance profile
- Amazon VPC security groups and security group rules for the endpoints and EC2 instance

### Target architecture

The diagram shows the following process:

1. The user assumes an IAM role that has permissions to do the following:
  - Authenticate, authorize, and connect to the EC2 instance
  - Start a session with Session Manager
2. The user initiates an SSH session through Session Manager.
3. Session Manager authenticates the user, verifies the permissions in the associated IAM policies, checks the configuration settings, and sends a message to SSM Agent to open a two-way connection.
4. The user pushes the SSH public key to the bastion host through Amazon EC2 metadata. This must be done before each connection. The SSH public key remains available for 60 seconds.

5. The bastion host communicates with the interface VPC endpoints for Systems Manager and Amazon EC2.
6. The user accesses the bastion host through Session Manager by using a TLS 1.2 encrypted bidirectional communication channel.

## Automation and scale

The following options are available to automate deployment or to scale this architecture:

- You can deploy the architecture through a continuous integration and continuous delivery (CI/CD) pipeline.
- You can modify the code to change the instance type of the bastion host.
- You can modify the code to deploy multiple bastion hosts. In the `bastion-host/main.tf` file, in the `aws_instance` resource block, add the `count` meta-argument. For more information, see the [Terraform documentation](#).

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses [Session Manager](#), a capability of Systems Manager.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

### Other tools

- [HashiCorp Terraform](#) is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses [Terraform CLI](#).

## Code repository

The code for this pattern is available in the GitHub [Access a bastion host by using Session Manager and Amazon EC2 Instance Connect](#) repository.

## Best practices

- We recommend using automated code-scanning tools to improve the security and quality of the code. This pattern was scanned by using [Checkov](#), a static code-analysis tool for IaC. At a minimum, we recommend that you perform basic validation and formatting checks by using the `terraform validate` and `terraform fmt -check -recursive` Terraform commands.
- It's a good practice to add automated tests for IaC. For more information about the different approaches for testing Terraform code, see [Testing HashiCorp Terraform](#) (Terraform blog post).
- During deployment, Terraform uses the replaces the EC2 instance each time a new version of the [Amazon Linux 2 AMI](#) is detected. This deploys the new version of the operating system, including patches and upgrades. If the deployment schedule is infrequent, this can pose a security risk because the instance doesn't have the latest patches. It is important to frequently update and apply security patches to deployed EC2 instances. For more information, see [Update management in Amazon EC2](#).
- Because this pattern is a proof of concept, it uses AWS managed policies, such as `AmazonSSMManagedInstanceCore`. AWS managed policies cover common use cases but don't grant least-privilege permissions. As needed for your use case, we recommend that you create custom policies that grant least-privilege permissions for the resources deployed in this architecture. For more information, see [Get started with AWS managed policies and move toward least-privilege permissions](#).
- Use a password to protect access to SSH keys and store keys in a secure location.
- Set up logging and monitoring for the bastion host. Logging and monitoring are important parts of maintaining systems, from both an operational and security perspective. There are multiple ways to monitor connections and activity in your bastion host. For more information, see the following topics in the Systems Manager documentation:
  - [Monitoring AWS Systems Manager](#)
  - [Logging and monitoring in AWS Systems Manager](#)

- [Auditing session activity](#)
- [Logging session activity](#)

## Epics

### Deploy the resources

Task	Description	Skills required
Clone the code repository.	<ol style="list-style-type: none"> <li>1. In a command-line interface, change your working directory to the location where you want to store the sample files.</li> <li>2. Enter the following command.</li> </ol> <pre>git clone https://github.com/aws-samples/secured-bastion-host-terraform.git</pre>	DevOps engineer, Developer
Initialize the Terraform working directory.	<p>This step is necessary for only the first deployment. If you are redeploying the pattern, skip to the next step.</p> <p>In the root directory of the cloned repository, enter the following command, where:</p> <ul style="list-style-type: none"> <li>• <code>\$S3_STATE_BUCKET</code> is the name of S3 bucket that contains the Terraform state</li> </ul>	DevOps engineer, Developer, Terraform

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>\$PATH_TO_STATE_FILE</code> is the key to the Terraform state file, such as <code>infra/bastion-host/tetfstate</code></li><li>• <code>\$AWS_REGION</code> is the Region where the S3 bucket is deployed</li></ul> <pre data-bbox="597 667 1026 1066">terraform init \     -backend-config="bucket=\$S3_STATE_BUCKET" \     -backend-config="key=\$PATH_TO_STATE_FILE" \     -backend-config="region=\$AWS_REGION</pre> <p data-bbox="597 1100 997 1327"><b>Note:</b> Alternatively, you can open the <code>config.tf</code> file and, in the <code>terraform</code> section, manually provide these values.</p>	

Task	Description	Skills required
Deploy the resources.	<ol style="list-style-type: none"> <li>In the root directory of the cloned repository, enter the following command. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>terraform apply -var-file="dev.tfvars"</pre> </div> </li> <li>Review the list of all changes that will be applied to your AWS account, and then confirm the deployment.</li> <li>Wait until all resources are deployed.</li> </ol>	DevOps engineer, Developer, Terraform

## Set up the local environment

Task	Description	Skills required
Configure the SSH connection.	Update the SSH configuration file to allow SSH connections through Session Manager. For instructions, see <a href="#">Allowing SSH connections for Session Manager</a> . This allows authorized users to enter a proxy command that starts a Session Manager session and transfers all data through a two-way connection.	DevOps engineer
Generate the SSH keys.	Enter the following command to generate a local private and public SSH key pair. You	DevOps engineer, Developer

Task	Description	Skills required
	<p>use this key pair to connect to the bastion host.</p> <pre>ssh-keygen -t rsa -f my_key</pre>	

## Connect to the bastion host by using Session Manager

Task	Description	Skills required
Get the instance ID.	<ol style="list-style-type: none"><li>1. In order to connect to the deployed bastion host, you need the ID of the EC2 instance. Do one of the following to locate the ID:<ul style="list-style-type: none"><li>• Open the Amazon EC2 console at <a href="https://console.aws.amazon.com/ec2/">https://console.aws.amazon.com/ec2/</a>. In the navigation pane, choose <b>Instances</b>. Locate the bastion host instance.</li><li>• In the AWS CLI, enter the following command.<pre>aws ec2 describe-instances</pre></li></ul></li></ol> <p>To filter the results, enter the following command, where <code>\$BASTION_HOST_TAG</code> is the tag you assigned to the bastion host. The default</p>	General AWS

Task	Description	Skills required
	<p>value for this tag is sandbox-dev-bastio n-host .</p> <pre data-bbox="662 380 1029 894">aws ec2 describe- instances \   --filters   "Name=tag:Name,Val ues=\$BASTION_HOST_ TAG" \   --output text \   --query   'Reservations[*].I nstances[*].Instan ceId' \   --output text</pre> <p>2. Copy the ID of the EC2 instance. You use this ID later.</p>	

Task	Description	Skills required
Send the SSH public key.	<p><b>Note:</b> In this section, you upload the public key to the <a href="#">instance metadata</a> of the bastion host. After the key is uploaded, you have 60 seconds to start a connection with the bastion host. After 60 seconds, the public key is removed. For more information, see the <a href="#">Troubleshooting</a> section of this pattern. Complete the next steps quickly to prevent the key from being removed before you connect to the bastion host.</p> <ol style="list-style-type: none"><li>1. Send the SSH key to the bastion host by using EC2 Instance Connect. Enter the following command, where:<ul style="list-style-type: none"><li>• <code>\$INSTANCE_ID</code> is the ID of the EC2 instance</li><li>• <code>\$PUBLIC_KEY_FILE</code> is the path to your public key file, such as <code>my_key.pub</code></li></ul></li></ol> <p><b>Important:</b> Be sure to use the public key and not the private key.</p>	General AWS

Task	Description	Skills required
	<pre data-bbox="634 212 1029 646">aws ec2-instance-connect send-ssh-public-key \   --instance-id \$INSTANCE_ID \   --instance-os-user ec2-user \   --ssh-public-key file://\$PUBLIC_KEY_FILE</pre> <p data-bbox="591 659 1019 890">2. Wait until you receive a message indicating that the key has been successfully uploaded. Continue to the next step immediately.</p>	

Task	Description	Skills required
Connect to the bastion host.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 714">1. Enter the following command to connect to the bastion host through Session Manager, where:<ul style="list-style-type: none"><li data-bbox="630 428 990 604">• <code>\$PRIVATE_KEY_FILE</code> is the path to your private key, such as <code>my_key</code></li><li data-bbox="630 627 990 705">• <code>\$INSTANCE_ID</code> is the ID of the EC2 instance</li></ul></li></ol> <pre data-bbox="630 747 1027 909">ssh -i \$PRIVATE_KEY_FILE ec2-user@\$INSTANCE_ID</pre> <ol style="list-style-type: none"><li data-bbox="592 926 1027 1102">2. Confirm the connection by entering <code>yes</code>. This opens an SSH connection by using Session Manager.</li></ol> <p data-bbox="592 1178 1027 1591"><b>Note:</b> There are other options for opening an SSH connection with the bastion host. For more information, see <i>Alternative approaches to establish an SSH connection with the bastion host</i> in the <a href="#">Additional information</a> section of this pattern.</p>	General AWS

**(Optional) Clean up**

Task	Description	Skills required
Remove the deployed resources.	<ol style="list-style-type: none"> <li>In order to remove all deployed resources, run the following command from the root directory of the cloned repository. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>terraform destroy - var-file="dev.tfvars"</pre> </div> </li> <li>Confirm the removal of the resources.</li> </ol>	DevOps engineer, Developer, Terraform

**Troubleshooting**

Issue	Solution
TargetNotConnected error when trying to connect to the bastion host	<ol style="list-style-type: none"> <li>Reboot the bastion host according to the instructions in <a href="#">Reboot your instance</a> in the Amazon EC2 documentation.</li> <li>After the instance has successfully rebooted, resend the public key to the bastion host and reattempt the connection.</li> </ol>
Permission denied error when trying to connect to the bastion host	After the public key is uploaded to the bastion host, you have only 60 seconds to start the connection. After 60 seconds, the key is automatically removed, and you can't use it to connect to the instance. If this occurs, you can repeat the step to resend the key to the instance.

## Additional information

### Alternative approaches to establish an SSH connection with the bastion host

#### *Port forwarding*

You can use the `-D 8888` option to open an SSH connection with dynamic port forwarding. For more information, see [these instructions](#) at explainshell.com. The following is an example of a command to open an SSH connection by using port forwarding.

```
ssh -i $PRIVATE_KEY_FILE -D 8888 ec2-user@$INSTANCE_ID
```

This kind of connection opens a SOCKS proxy that can forward traffic from your local browser through the bastion host. If you are using Linux or MacOS, to see all options, enter `man ssh`. This displays the SSH reference manual.

### *Using the provided script*

Instead of manually running the steps described in *Connect to the bastion host by using Session Manager* in the [Epics](#) section, you can use the **connect.sh** script included in the code repository. This script generates the SSH key pair, pushes the public key to the EC2 instance, and initiates a connection with the bastion host. When you run the script, you pass the tag and key name as arguments. The following is an example of the command to run the script.

```
./connect.sh sandbox-dev-bastion-host my_key
```

# Centralize DNS resolution by using AWS Managed Microsoft AD and on-premises Microsoft Active Directory

*Created by Brian Westmoreland (AWS)*

**Environment:** Production

**Technologies:** Infrastructure; Networking; DevOps; Security, identity, compliance; Operating systems

**Workload:** Microsoft

**AWS services:** AWS Managed Microsoft AD; Amazon Route 53; AWS RAM; AWS Directory Service; AWS Organizations; AWS Direct Connect; AWS CLI

## Summary

This pattern provides guidance for centralizing Domain Name System (DNS) resolution within an AWS multi-account environment by using AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD). In this pattern the AWS DNS namespace is a subdomain of the on-premises DNS namespace. This pattern also provides guidance on how to configure the on-premises DNS servers to forward queries to AWS when the on-premises DNS solution uses Microsoft Active Directory.

## Prerequisites and limitations

### Prerequisites

- An AWS multi-account environment set up by using AWS Organizations.
- Network connectivity established between AWS accounts.
- Network connectivity established between AWS and the on-premises environment (by using AWS Direct Connect or any type of VPN connection).
- AWS Command Line Interface (AWS CLI) configured on a local workstation.

- AWS Resource Access Manager (AWS RAM) used to share Amazon Route 53 rules between accounts. Therefore, sharing must be enabled within the AWS Organizations environment, as described in the *Epics* section.

### Limitations

- AWS Managed Microsoft AD Standard Edition has a limit of 5 shares.
- AWS Managed Microsoft AD Enterprise Edition has a limit of 125 shares.
- This solution in this pattern is limited to AWS Regions that support sharing through AWS RAM.

### Product versions

- Microsoft Active Directory running on Windows Server 2008, 2012, 2012 R2, or 2016

## Architecture

### Target architecture

In this design, AWS Managed Microsoft AD is installed in the shared services AWS account. Although this is not a requirement, this pattern assumes this configuration. If you configure AWS Managed Microsoft AD in a different AWS account, you might have to modify the steps in the *Epics* section accordingly.

This design uses Route 53 Resolvers to support name resolution through the use of Route 53 rules. If the on-premises DNS solution uses Microsoft DNS, creating a conditional forwarding rule for the AWS namespace (`aws.company.com`), which is a subdomain of the company DNS namespace (`company.com`), is not straightforward. If you try to create a traditional conditional forwarder, it will result in an error. This is because Microsoft Active Directory is already considered authoritative for any subdomain of `company.com`. To get around this error, you must first create a delegation for `aws.company.com` to delegate authority of that namespace. You can then create the conditional forwarder.

The virtual private cloud (VPC) for each spoke account can have its own unique DNS namespace based on the root AWS namespace. In this design, each spoke account appends an abbreviation of the account name to the base AWS namespace. After the private hosted zones in the spoke account have been created, the zones are associated with the VPC in the spoke account as well as with the VPC in the central AWS network account. This enables the central AWS network account to answer DNS queries related to the spoke accounts.

## Automation and scale

This design makes use of Route 53 Resolver endpoints to scale DNS queries between AWS and your on-premises environment. Each Route 53 Resolver endpoint comprises multiple elastic network interfaces (spread across multiple Availability Zones), and each network interface can handle up to 10,000 queries per second. Route 53 Resolver supports up to 6 IP addresses per endpoint, so altogether this design supports up to 60,000 DNS queries per second spread across multiple Availability Zones for high availability.

Additionally, this pattern automatically accounts for future growth within AWS. The DNS forwarding rules configured on premises do not have to be modified to support new VPCs and their associated private hosted zones that are added to AWS.

## Tools

### AWS services

- [AWS Directory Service for Microsoft Active Directory](#) enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.

- [AWS Organizations](#) is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- [AWS Resource Access Manager \(AWS RAM\)](#) helps you securely share your resources across AWS accounts to reduce operational overhead and provide visibility and auditability.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

## Tools

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell. In this pattern, the AWS CLI is used to configure Route 53 authorizations.

## Epics

### Create and share an AWS Managed Microsoft AD directory

Task	Description	Skills required
Deploy AWS Managed Microsoft AD.	<ol style="list-style-type: none"> <li>1. Create and configure a new directory. For detailed steps, see <a href="#">Create your AWS Managed Microsoft AD directory</a> in the <i>AWS Directory Service Administration Guide</i>.</li> <li>2. Record the IP addresses of the AWS Managed Microsoft AD domain controllers. These will be referenced in a later step.</li> </ol>	AWS administrator
Share the directory.	After the directory has been built, share it with other AWS accounts in the AWS organization. For instructions, see <a href="#">Share your directory</a>	AWS administrator

Task	Description	Skills required
	<p>in the <i>AWS Directory Service Administration Guide</i>.</p> <p><b>Note:</b> AWS Managed Microsoft AD Standard Edition has a limit of 5 shares. Enterprise Edition has a limit of 125 shares.</p>	

## Configure Route 53

Task	Description	Skills required
Create Route 53 Resolvers.	<p>Route 53 Resolvers facilitate DNS query resolution between AWS and the on-premises data center.</p> <ol style="list-style-type: none"> <li>1. Install Route 53 Resolvers by following the <a href="#">instructions</a> in the <i>Route 53 Developer Guide</i>.</li> <li>2. Configure Route 53 Resolvers in private subnets in at least two Availability Zones within the central AWS network account VPC for high availability.</li> </ol> <p><b>Note:</b> Although using the central AWS network account VPC isn't a requirement, the</p>	AWS administrator

Task	Description	Skills required
	remaining steps assume this configuration.	

Task	Description	Skills required
Create Route 53 rules.	<p>Your specific use case might require a large number of Route 53 rules, but you will need to configure the following rules as a baseline:</p> <ul style="list-style-type: none"><li>• An outgoing rule for the on-premises namespace (company . com ) by using the outbound Route 53 Resolvers.<ul style="list-style-type: none"><li>• Share this rule with spoke AWS accounts.</li><li>• Associate this rule with spoke account VPCs.</li></ul></li><li>• An outgoing rule for the AWS namespace (aws . company . com ) that points to the central network account Route 53 inbound Resolvers.<ul style="list-style-type: none"><li>• Share this rule with spoke AWS accounts.</li><li>• Associate the rule with spoke account VPCs.</li><li>• <b>Do not</b> associate this rule with the central AWS network account VPC (which houses the Route 53 Resolvers).</li></ul></li><li>• A second outgoing rule for the AWS namespace (aws . company . com )</li></ul>	AWS administrator

Task	Description	Skills required
	<p>that points to the AWS Managed Microsoft AD domain controllers (use the IPs from the previous epic).</p> <ul style="list-style-type: none"> <li>• Associate this rule with the central AWS network account VPC (which houses the Route 53 Resolvers).</li> <li>• <b>Do not</b> share or associate this rule with other AWS accounts.</li> </ul> <p>For more information, see <a href="#">Managing forwarding rules</a> in the <i>Route 53 Developer Guide</i>.</p>	

## Configure on-premises Active Directory DNS

Task	Description	Skills required
Create the delegation.	<p>Use the Microsoft DNS snap-in (dnsmgmt.msc ) to create a new delegation for the company.com namespace within Active Directory. The name of the delegated domain should be aws. This makes the fully qualified domain name (FQDN) of the delegation aws.compa ny.com . For the name servers, use the IP addresses</p>	Active Directory

Task	Description	Skills required
	of the AWS inbound Route 53 Resolvers in the central DNS AWS account for the IP values, and use <code>server.aws.company.com</code> for the name.	
Create the conditional forwarder.	Use the Microsoft DNS snap-in ( <code>dnsmgmt.msc</code> ) to create a new conditional forwarder for <code>aws.company.com</code> . Use the IP addresses of the AWS Managed Microsoft AD domain controllers for the target of the conditional forwarder.	Active Directory

### Create Route 53 private hosted zones for spoke AWS accounts

Task	Description	Skills required
Create the Route 53 private hosted zones.	Create a Route 53 private hosted zone in each spoke account. Associate this private hosted zone with the spoke account VPC. For detailed steps, see <a href="#">Creating a private hosted zone</a> in the <i>Route 53 Developer Guide</i> .	AWS administrator
Create authorizations.	Use the AWS CLI to create an authorization for the central AWS network account VPC. Run this command from the	AWS administrator

Task	Description	Skills required
	<p>context of each spoke AWS account:</p> <pre>aws route53 create-vc-association-authorization --hosted-zone-id &lt;hosted-zone-id&gt; \   --vpc VPCRegion=&lt;region&gt;,VPCId=&lt;vpc-id&gt;</pre> <p>where:</p> <ul style="list-style-type: none"><li>• &lt;hosted-zone-id&gt; is the Route 53 private hosted zone in the spoke account.</li><li>• &lt;region&gt; and &lt;vpc-id&gt; are the AWS Region and VPC ID of the central AWS network account VPC.</li></ul>	

Task	Description	Skills required
Create associations.	<p>Create the Route 53 private hosted zone association for the central AWS network account VPC by using the AWS CLI. Run this command from the context of the central AWS network account:</p> <pre data-bbox="594 583 1026 903">aws route53 associate -vpc-with-hosted-z one --hosted-zone-id &lt;hosted-zone-id&gt; \   --vpc VPCRegion =&lt;region&gt;,VPCId=&lt;vpc- id&gt;</pre> <p>where:</p> <ul data-bbox="594 1024 1026 1348" style="list-style-type: none"><li>• &lt;hosted-zone-id&gt; is the Route 53 private hosted zone in the spoke account.</li><li>• &lt;region&gt; and &lt;vpc-id&gt; are the AWS Region and VPC ID of the central AWS network account.</li></ul>	AWS administrator

# Centralize monitoring by using Amazon CloudWatch Observability Access Manager

Created by Anand Krishna Varanasi (AWS), Jimmy Morgan (AWS), Ashish Kumar (AWS), Balaji Vedagiri (AWS), JAGDISH KOMAKULA (AWS), Sarat Chandra Pothula (AWS), and Vivek Thangamuthu (AWS)

**Code repository:** [cloudwatch-observability-access-manager-terraform](#)

**Environment:** Production

**Technologies:** Infrastructure; Multi account strategy; Operations

**AWS services:** Amazon CloudWatch; Amazon CloudWatch Logs

## Summary

Observability is crucial to monitoring, understanding, and troubleshooting applications. Applications that span multiple accounts, as with AWS Control Tower or landing zone implementations, generate a large number of logs and trace data. To quickly troubleshoot problems or understand user analytics or business analytics, you need a common observability platform across all accounts. The Amazon CloudWatch Observability Access Manager gives you access to, and control over, multiple account logs from a central location.

You can use the Observability Access Manager to view and manage observability data logs generated by source accounts. Source accounts are individual AWS accounts that generate observability data for their resources. Observability data is shared between source accounts and monitoring accounts. The shared observability data can include metrics in Amazon CloudWatch, logs in Amazon CloudWatch Logs, and traces in AWS X-Ray. For more information, see the [Observability Access Manager documentation](#).

This pattern is for users who have applications or infrastructure that run in multiple AWS accounts and need a common place to view logs. It explains how you can set up Observability Access Manager by using Terraform, to monitor the status and health of these applications or infrastructure. You can install this solution in multiple ways:

- As a standalone Terraform module that you set up manually

- By using a continuous integration and continuous delivery (CI/CD) pipeline
- By integrating with other solutions such as [AWS Control Tower Account Factory for Terraform \(AFT\)](#)

The instructions in the [Epics](#) section cover the manual implementation. For AFT installation steps, see the readme file for the GitHub [Observability Access Manager](#) repository.

## Prerequisites and limitations

### Prerequisites

- [Terraform](#) installed or referenced in your system or in automated pipelines. (We recommend that you use the [latest version](#).)
- An account that you can use as a central monitoring account. Other accounts create links to the central monitoring account in order to view logs.
- (Optional) A source code repository such as GitHub, AWS CodeCommit, Atlassian Bitbucket, or similar system. A source code repository isn't necessary if you're using automated CI/CD pipelines.
- (Optional) Permissions to create pull requests (PRs) for code review and code collaboration in GitHub.

### Limitations

Observability Access Manager has the following service quotas, which cannot be changed. Consider these quotas before you deploy this feature. For more information, see [CloudWatch service quotas](#) in the CloudWatch documentation.

- **Source account links:** You can link each source account to a maximum of five monitoring accounts.
- **Sinks:** You can use only one sink per account.

In addition:

- Sinks and links must be created in the same AWS Region; they cannot be cross-Region.

- For cross-Region, cross-account monitoring, you can create [cross-account and cross-region CloudWatch dashboards](#) for alarms and metrics, except for logs and traces. Another option is to [create centralized logging by using Amazon OpenSearch Service](#).

## Architecture

### Components

Amazon CloudWatch Observability Access Manager consists of two major components that enable cross-account observability:

- A *sink* provides the ability for source accounts to send observability data to the central monitoring account. A sink basically provides a gateway junction for source accounts to connect to. There can be only one sink gateway or connection, and multiple accounts can connect to it.
- Each source account has a *link* to the sink gateway junction, and observability data is sent through this link. You must create a sink before you create links from each source account.

### Architecture

The following diagram illustrates Observability Access Manager and its components.

## Tools

### AWS services

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [AWS Organizations](#) is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

## Tools

- [Terraform](#) is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.
- [AWS Control Tower Account Factory for Terraform \(AFT\)](#) sets up a Terraform pipeline to help you provision and customize accounts in AWS Control Tower. You can optionally use AFT to set up Observability Access Manager at scale across multiple accounts.

## Code repository

The code for this pattern is available in the GitHub [Observability Access Manager](#) repository.

## Best practices

- In AWS Control Tower environments, mark the logging account as the central monitoring account (sink).
- If you have multiple organizations with multiple accounts in AWS Organizations, we recommend that you include the organizations instead of individual accounts in the configuration policy. If you have a small number of accounts or if the accounts aren't part of an organization in the sink configuration policy, you might decide to include individual accounts instead.

## Epics

### Set up the sink module

Task	Description	Skills required
Clone the repository.	Clone the GitHub Observability Access Manager repository:  <pre>git clone https://github.com/aws-samples/cloudwatch-observability-access-manager-terraform</pre>	AWS DevOps, Cloud administrator, AWS administrator
Specify property values for the sink module.	In the <code>main.tf</code> file (in the <code>deployments/aft-ac</code>	AWS DevOps, Cloud administrator, AWS administrator

Task	Description	Skills required
	<p>count-customizations/LOGGING/terraform/ folder of the repository), specify values for the following properties:</p> <ul style="list-style-type: none"><li>• <code>sink_name</code> : The name of the Amazon CloudWatch sink.</li><li>• <code>allowed_oam_resource_types</code> : Observability Access Manager currently supports CloudWatch metrics, log groups, and AWS X-Ray traces.</li><li>• <code>allowed_source_accounts</code> : The source accounts that are allowed to send logs to the central CloudWatch sink account.</li><li>• <code>allowed_source_organizations</code> : The source Control Tower organizations that are allowed to send logs to the central CloudWatch sink account.</li></ul> <p>For more information, see <a href="#">AWS::Oam::Sink</a> in the AWS CloudFormation documentation.</p>	

Task	Description	Skills required
Install the sink module.	<p>Export the credentials of the AWS account that you have selected as the monitoring account, and install the Observability Access Manager sink module:</p> <pre>Terraform Init Terraform Plan Terraform Apply</pre>	AWS DevOps, Cloud administrator, AWS administrator

## Set up the link module

Task	Description	Skills required
Specify property values for the link module.	<p>In the <code>main.tf</code> file (in the <code>deployments/aft-account-customizations/LOGGING/terraform/</code> folder of the repository), specify values for the following properties:</p> <ul style="list-style-type: none"> <li><code>account_label</code> : Use one of the following values: <ul style="list-style-type: none"> <li><code>\$AccountName</code> : The name of the account.</li> <li><code>\$AccountEmail</code> : A globally unique email address, which includes the email domain (for example, <code>hello@example.com</code> )</li> </ul> </li> </ul>	AWS DevOps, Cloud administrator, Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <code>\$AccountEmailNoDomain</code> : An email address without the domain name.</li> <li>• <code>allowed_oam_resource_types</code> : Observability Access Manager currently supports CloudWatch metrics, log groups, and AWS X-Ray traces.</li> </ul> <p>For more information, see <a href="#">AWS::Oam::Link</a> in the AWS CloudFormation documentation.</p>	
<p>Install the link module for individual accounts.</p>	<p>Export the credentials of individual accounts and install the Observability Access Manager link module:</p> <div data-bbox="594 1213 1029 1331" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>Terraform Plan Terraform Apply</pre> </div> <p>You can set up the link module individually for each account, or use <a href="#">AFT</a> to automatically install this module across a large number of accounts.</p>	<p>AWS DevOps, Cloud administrator, Cloud architect</p>

## Approve sink-to-link connections

Task	Description	Skills required
<p>Check the status message.</p>	<ol style="list-style-type: none"> <li>1. Sign in to the monitoring account.</li> <li>2. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a>.</li> <li>3. In the left navigation pane, choose <b>Settings</b>.</li> </ol> <p>On the right, you should see the status message <b>Monitoring account enabled</b> with a green checkmark. This means that the monitoring account has an Observability Access Manager sink that the links of other accounts will connect to.</p>	
<p>Approve the link-to-sink connections.</p>	<ol style="list-style-type: none"> <li>1. Choose the <b>Resources to link accounts</b> option below the status message. The information confirms that this is the monitoring account, lists the data that is shared from the tenant source accounts (<b>Logs, Metrics, Traces</b>), and shows the account label as <b>\$AccountName</b>.</li> </ol> <p>This screen provides two options for linking tenant</p>	<p>AWS DevOps, Cloud administrator, Cloud architect</p>

Task	Description	Skills required
	<p>accounts to the monitoring account: organization-level approval or account-level approval. For each option, you can choose to download an AWS CloudFormation template for the approval or approve each account individually.</p> <ol style="list-style-type: none"><li>2. For simplicity, choose <b>Any Account</b> to approve at each account level. This option provides an approval link for the account.</li><li>3. Choose <b>Copy URL</b> to copy the link.</li><li>4. Sign in to each source account.</li><li>5. In a browser window, paste the link, and choose <b>Approve link connect to sink</b>.</li><li>6. Repeat for additional source accounts.</li></ol> <p>For more information, see <a href="#">Link monitoring accounts with source accounts</a> in the Amazon CloudWatch documentation.</p>	

## Verify cross-account observability data

Task	Description	Skills required
View cross-account data.	<ol style="list-style-type: none"><li>1. Sign in to the central monitoring account.</li><li>2. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a>.</li><li>3. In the left navigation pane, choose options to view cross-account logs, metrics, and traces.</li></ol>	AWS DevOps, Cloud administrator, Cloud architect

## (Optional) Enable source accounts to trust monitoring account

Task	Description	Skills required
View metrics, dashboards, logs, widgets, and alarms from other accounts.	<p>As an additional feature, you can share the CloudWatch metrics, dashboards, logs, widgets, and alarms with other accounts. Each account uses an IAM role called <b>CloudWatch-CrossAccountSharingRole</b> to gain access to this data.</p> <p>Source accounts that have a trust relationship with the central monitoring account can assume this role and view data from the monitoring account.</p>	AWS DevOps, Cloud administrator, Cloud architect

Task	Description	Skills required
	<p>CloudWatch provides a sample CloudFormation script to create the role. Choose <b>Manage role in IAM</b> and run this script in the accounts where you want to view data.</p> <pre data-bbox="592 520 1029 1717">{   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Principal": {         "AWS": [           "arn:aws:iam::XXXX           XXXX:root",           "arn:aws:iam::XXXX           XXXX:root",           "arn:aws:iam::XXXX           XXXX:root",           "arn:aws:iam::XXXX           XXXX:root"         ]       },       "Action":       "sts:AssumeRole"     }   ] }</pre> <p>For more information, see <a href="#">Enabling cross-account</a></p>	

Task	Description	Skills required
	<a href="#">functionality in CloudWatch</a> in the CloudWatch documentation	

### (Optional) View cross-account cross-Region from the monitoring account

Task	Description	Skills required
Set up cross-account, cross-Region access.	<p>In the central monitoring account, you can optionally add an account selector to easily switch between accounts and view their data without having to authenticate.</p> <ol style="list-style-type: none"> <li>1. Sign in to the central monitoring account.</li> <li>2. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a>.</li> <li>3. In the left navigation pane, choose <b>Settings</b>.</li> <li>4. In the <b>View cross-account cross-region</b> section, choose <b>Configure</b>.</li> <li>5. Choose <b>Enable</b>, and then select the <b>Show selector in the console</b> check box.</li> <li>6. Choose one of these options:</li> </ol>	AWS DevOps, Cloud administrator, Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <b>Account Id Input:</b> This option prompts you to manually input the account ID whenever you want to change accounts to view cross-account data.</li><li>• <b>AWS Organization account selector:</b> If you have <a href="#">integrated CloudWatch with AWS Organizations</a>, this option provides a dropdown selector with a complete list of accounts in the organization.</li><li>• <b>Custom account selector:</b> This option lets you manually input a list of account IDs to populate the selector.</li></ul> <p>7. Choose <b>Save changes</b>.</p> <p>For more information, see <a href="#">Cross-account cross-Region CloudWatch console</a> in the CloudWatch documentation.</p>

# Check EC2 instances for mandatory tags at launch

**Environment:** Production

**Technologies:** Infrastructure;  
Management & governance;  
Security, identity, compliance;  
CloudNative

**AWS services:** Amazon EC2;  
AWS CloudTrail; Amazon  
CloudWatch; Amazon SNS

## Summary

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster.

You can use tagging to categorize your AWS resources in different ways. EC2 instance tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can assign custom metadata to your EC2 instances by using tags. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor EC2 instances for specific tags. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail **TagResource** or **UntagResource** events, to detect new EC2 instance tagging or tag removal. If a predefined tag is missing, it calls an AWS Lambda function, which sends out a violation message to an email address that you provide, by using Amazon Simple Notification Service (Amazon SNS).

## Prerequisites and limitations

### Prerequisites

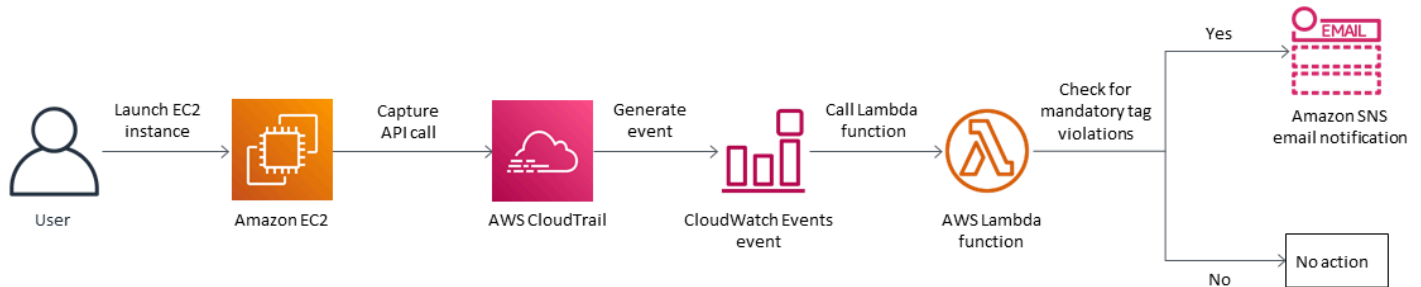

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code.
- An email address where you would like to receive violation notifications.

### Limitations

- This solution supports CloudTrail **TagResource** or **UntagResource** events. It does not create notifications for any other events.
- This solution checks only for tag keys. It does not monitor key values.

## Architecture

### Workflow architecture

### Automation and scale

- You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

## Tools

### AWS services

- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides secure, resizable compute capacity in the cloud. It is designed to make web-scale cloud computing easier for developers.
- [AWS CloudTrail](#) – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or AWS service are recorded as events in CloudTrail.
- [Amazon CloudWatch Events](#) – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.

- [AWS Lambda](#) – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

## Code

This pattern includes an attachment with two files:

- `index.zip` is a compressed file that includes the Lambda code for this pattern.
- `ec2-require-tags.yaml` is a CloudFormation template that deploys the Lambda code.

See the *Epics* section for information about how to use these files.

## Epics

### Deploy the Lambda code

Task	Description	Skills required
Upload the code to an S3 bucket.	Create a new S3 bucket or use an existing S3 bucket to upload the attached <code>index.zip</code> file (Lambda code). This bucket must be in the same AWS Region as the resources (EC2 instances) that you want to monitor.	Cloud architect
Deploy the CloudFormation template.	Open the Cloudformation console in the same AWS Region as the S3 bucket,	Cloud architect

Task	Description	Skills required
	and deploy the <code>ec2-require-tags.yaml</code> file that's provided in the attachment. In the next epic, provide values for the template parameters.	

### Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudFormation template and the EC2 instances that you want to monitor.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, <code>index.zip</code> or <code>controls/index.zip</code> ).	Cloud architect
Provide an email address.	Provide an active email address where you want to receive violation notifications.	Cloud architect
Define a logging level.	Specify the logging level and verbosity. Info designate	Cloud architect

Task	Description	Skills required
	<p>s detailed informational messages on the application's progress and should be used only for debugging. <code>Error</code> designates error events that could still allow the application to continue running. <code>Warning</code> designates potentially harmful situations.</p>	
Enter the required tag keys.	Enter the tag keys that you want to check for. If you want to specify multiple keys, separate them with commas, without spaces. (For example, <code>ApplicationId,CreatedBy,Environment,Organization</code> searches for four keys.) The CloudWatch Events event searches for these tag keys and sends a notification if they are not found.	Cloud architect

## Confirm the subscription

Task	Description	Skills required
Confirm the email subscription.	When the CloudFormation template deploys successfully, it sends a subscription email message to the email address you provided. To	Cloud architect

Task	Description	Skills required
	receive notifications, you must confirm this email subscription.

# Connect to an Amazon EC2 instance by using Session Manager

Created by Jason Cornick (AWS), Abhishek Bastikoppa (AWS), and Yaniv Ron (AWS)

**Environment:** Production

**Technologies:** Infrastructure; CloudNative; End-user computing; Operations

**AWS services:** Amazon CloudWatch Logs; AWS Systems Manager; Amazon EC2

## Summary

This pattern describes how to connect to an Amazon Elastic Compute Cloud (Amazon EC2) instance by using the Session Manager, a capability of AWS Systems Manager. Using this pattern, you can run bash commands on an EC2 instance through a web browser. Session Manager doesn't require that you open inbound ports and doesn't require public IP addresses for EC2 instances. Additionally, it removes the need to maintain bastion hosts with different Secure Shell (SSH) keys. You can govern access to Session Manager with AWS Identity and Access Management (IAM) policies and configure logging, which records important information, such as instance access and actions.

In this pattern, you configure an IAM role and associate it to a Linux EC2 instance that you provision by using an Amazon Machine Image (AMI). You then configure logging in Amazon CloudWatch Logs and use Session Manager to start a session with the instance.

Although this pattern connects to a Linux EC2 instance in the Amazon Web Services (AWS) Cloud, you could use this approach to use Session Manager for connections with other servers, such as on-premises servers or other virtual machines.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Permissions to access the managed node. For instructions, see [Control user session access to managed nodes](#).

- VPC endpoints for ssm, ec2, ec2messages, ssmessages, and s3. For instructions, see [Create VPC endpoints](#) in the Systems Manager documentation.

## Architecture

### Target technology stack

- Session Manager
- Amazon EC2
- CloudWatch Logs

### Target architecture

1. The user authenticates their identity and credentials through IAM.
2. The user initiates an SSH session through Session Manager and sends API calls to the EC2 instance.
3. The AWS Systems Manager SSM Agent, which is installed on the EC2 instance, connects to Session Manager and runs the commands.
4. For auditing and monitoring purposes, Session Manager sends the logging data to CloudWatch Logs. Alternatively, you can send log data to an Amazon Simple Storage Service (Amazon S3) bucket. For more information, see [Logging session data using Amazon S3](#) (Systems Manager documentation).

## Tools

### AWS services

- [Amazon CloudWatch Logs](#) helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down. This pattern uses an Amazon Machine Image (AMI) to provision a Linux EC2 instance.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses [Session Manager](#), a capability of Systems Manager.

## Best practices

We recommend that you read more about the [security pillar](#) of the AWS Well-Architected Framework and explore encryption options and apply the security recommendations in [Setting up Session Manager](#) (Systems Manager documentation).

# Epics

## Set up the infrastructure

Task	Description	Skills required
Create the IAM role.	<p>Create the IAM role for the SSM Agent. Follow the instructions in <a href="#">Creating a role for an AWS service</a> (IAM documentation) and note the following:</p> <ol style="list-style-type: none"><li>1. For the AWS service, choose <b>EC2</b>.</li><li>2. For <b>Permissions Policies</b>, choose AmazonSSMManagedInstanceCore .</li><li>3. In <b>Role Name</b>, enter EC2_SSM_Role .</li></ol>	AWS systems administrator
Create the EC2 instance.	<ol style="list-style-type: none"><li>1. Create the EC2 instance. Follow the instructions in <a href="#">Launch an instance</a> (Amazon EC2 documentation) and note the following:<ol style="list-style-type: none"><li>a. In the <b>Name and tags</b> section, choose <b>Add additional tags</b>. In <b>Key</b>, enter Name, and in <b>Value</b>, enter Production_Server_One .</li><li>b. Choose an Amazon Linux AMI that has the SSM Agent preinstalled.</li></ol></li></ol>	AWS systems administrator

Task	Description	Skills required
	<p>For a complete list, see <a href="#">AMIs with SSM Agent preinstalled</a> (Systems Manager documentation).</p> <p>c. In the <b>Advanced details</b> section, in <b>IAM instance profile</b>, choose <b>EC2_SSM_Role</b>.</p> <p>2. # Create a pipeline in AWS Regions that don't support AWS CodePipeline

Created by Anand Krishna Varanasi (AWS)

**Code repository:** [invisible-codepipeline-unsupported-regions](#)

**Environment:** PoC or pilot

**Technologies:** Infrastructure; DevOps

**AWS services:** AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS CodePipeline

## Summary

AWS CodePipeline is a continuous delivery (CD) orchestration service that's part of a set of DevOps tools from Amazon Web Services (AWS). It integrates with a large variety of sources (such as version control systems and storage solutions), continuous integration (CI) products and services from AWS and AWS Partners, and open-source products to provide an end-to-end workflow service for fast application and infrastructure deployments.

However, CodePipeline isn't supported in all AWS Regions, and it's useful to have an invisible orchestrator that connects AWS CI/CD services. This pattern describes how to implement an end-to-end workflow pipeline in AWS Regions where CodePipeline isn't yet supported by using AWS CI/CD services such as AWS CodeCommit, AWS CodeBuild, and AWS CodeDeploy.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Cloud Development Kit (AWS CDK) CLI version 2.28 or later

# Architecture

## Target technology stack

The following diagram shows a pipeline that was created in a Region that doesn't support CodePipeline, such as the Africa (Cape Town) Region. A developer pushes the CodeDeploy configuration files (also called *deployment lifecycle hook scripts*) to the Git repository that's hosted by CodeCommit. (See the [GitHub repository](#) provided with this pattern.) An Amazon EventBridge rule automatically initiates CodeBuild. (See the [GitHub repository](#) provided with this pattern.)

The CodeDeploy configuration files are fetched from CodeCommit as part of the source stage of the pipeline and transferred to CodeBuild.

In the next phase, CodeBuild performs these tasks:

1. Downloads the application source code TAR file. You can configure the name of this file by using Parameter Store, a capability of AWS Systems Manager.
2. Downloads the CodeDeploy configuration files.
3. Creates a combined archive of application source code and CodeDeploy configuration files that are specific to the application type.
4. Initiates CodeDeploy deployment to an Amazon Elastic Compute Cloud (Amazon EC2) instance by using the combined archive.

## Tools

### AWS services

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon EC2 or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

### Code

The code for this pattern is available in the GitHub [CodePipeline Unsupported Regions](#) repository.

## Epics

### Set up your developer workstation

Task	Description	Skills required
Install the AWS CDK CLI.	For instructions, see the <a href="#">AWS CDK documentation</a> .	AWS DevOps
Install a Git client.	To create commits, you can use a Git client installed on your local computer, and then push your commits to the CodeCommit repository. To set up CodeCommit with your Git client, see the <a href="#">CodeCommit documentation</a> .	AWS DevOps

Task	Description	Skills required
Install npm.	Install the <b>npm</b> package manager. For more information, see the <a href="#">npm documentation</a> .	AWS DevOps

## Set up the pipeline

Task	Description	Skills required
Clone the code repository.	Clone the GitHub <a href="#">CodePipeline Unsupported Regions</a> repository to your local machine by running the following command. <pre>git clone https://github.com/aws-samples/invisible-code-pipeline-unsupported-regions</pre>	DevOps engineer
Set parameters in cdk.json.	Open the <code>cdk.json</code> file and provide values for the following parameters: <pre>"pipeline_account" : "XXXXXXXXXXXX", "pipeline_region": "us-west-2", "repo_name": "app-dev-repo", "ec2_tag_key": "test-vm", "configName" : "cbdeployconfig", "deploymentGroupName": "cbdeploygroup",</pre>	AWS DevOps

Task	Description	Skills required
	<pre data-bbox="594 205 1024 426">"applicationName" :   "cbdeployapplicati on", "projectName" :   "CodeBuildProject"</pre> <p data-bbox="594 464 691 495">where:</p> <ul data-bbox="594 541 1024 1791" style="list-style-type: none"><li data-bbox="594 541 1024 674">• <code>pipeline_account</code> is the AWS account where the pipeline will be built.</li><li data-bbox="594 695 1024 827">• <code>pipeline_region</code> is the AWS Region where the pipeline will be built.</li><li data-bbox="594 848 1024 980">• <code>repo_name</code> is the name of the CodeCommit repository.</li><li data-bbox="594 1001 1024 1182">• <code>ec2_tag_key</code> is the tag attached to the EC2 instance that you want to deploy the code to.</li><li data-bbox="594 1203 1024 1335">• <code>configName</code> is the name of the CodeDeploy configuration file.</li><li data-bbox="594 1356 1024 1537">• <code>deploymentGroupName</code> is the name of the CodeDeploy deployment group.</li><li data-bbox="594 1558 1024 1690">• <code>applicationName</code> is the CodeDeploy application name.</li><li data-bbox="594 1711 1024 1791">• <code>projectName</code> is the CodeBuild project name.</li></ul>	

Task	Description	Skills required
Set up the AWS CDK construct library.	<p>In the cloned GitHub repository, use the following commands to install the AWS CDK construct library, build your application, and synthesize to generate the AWS CloudFormation template for the application.</p> <pre>npm i aws-cdk-lib npm run build cdk synth</pre>	AWS DevOps
Deploy the sample AWS CDK application.	<p>Deploy the code by running the following command in an unsupported Region (such as <code>af-south-1</code> ).</p> <pre>cdk deploy</pre>	AWS DevOps

### Set up the CodeCommit repository for CodeDeploy

Task	Description	Skills required
Set up CI/CD for the application.	<p>Clone the CodeCommit repository that you specified in the <code>cdk.json</code> file (this is called <code>app-dev-repo</code> by default) to set up the CI/CD pipeline for the application.</p> <pre>git clone https://git-codecommit.us-w</pre>	AWS DevOps

Task	Description	Skills required
	<pre>est-2.amazonaws.com/ v1/repos/app-dev-repo</pre> <p>where the repository name and Region depend on the values you provided in the <code>cdk.json</code> file.</p>	

## Test the pipeline

Task	Description	Skills required
<p>Test the pipeline with deployment instructions.</p>	<p>The <code>CodeDeploy_Files</code> folder of the GitHub <a href="#">CodePipeline Unsupported Regions</a> repository includes sample files that instruct CodeDeploy to deploy the application. The <code>appspec.yml</code> file is a CodeDeploy configuration file that contains hooks to control the flow of application deployment. You can use the sample files <code>index.html</code>, <code>start_server.sh</code>, <code>stop_server.sh</code>, and <code>install_dependencies.sh</code> to update a website that's hosted on Apache. These are examples—you can use the code in the GitHub repository to deploy any type of application. When</p>	<p>AWS DevOps</p>

Task	Description	Skills required
	the files are pushed to the CodeCommit repository, the invisible pipeline is initiated automatically. For deployment results, check the results of individual phases in the CodeBuild and CodeDeploy consoles.

# Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing

Created by Dipin Jain (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> On-premises VM	<b>Target:</b> Amazon EC2
<b>R Type:</b> Rehost	<b>Workload:</b> Open-source	<b>Technologies:</b> Infrastructure; Databases; Migration
<b>AWS services:</b> Amazon EC2		

## Summary

The private IP of an Amazon Elastic Compute Cloud (Amazon EC2) instance is retained throughout its lifecycle. However, the private IP might change during a planned or unplanned system crash; for example, during an Amazon Machine Image (AMI) upgrade. In some scenarios, retaining a private static IP can enhance the performance and recovery time of workloads. For example, using a static IP for an Apache Cassandra seed node prevents the cluster from incurring a rebalancing overhead.

This pattern describes how to attach a secondary elastic network interface to EC2 instances to keep the IP static during rehosting. The pattern focuses on Cassandra clusters, but you can use this implementation for any architecture that benefits from private static IPs.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Service (AWS) account

### Product versions

- DataStax version 5.11.1
- Operating system: Ubuntu 16.04.6 LTS

# Architecture

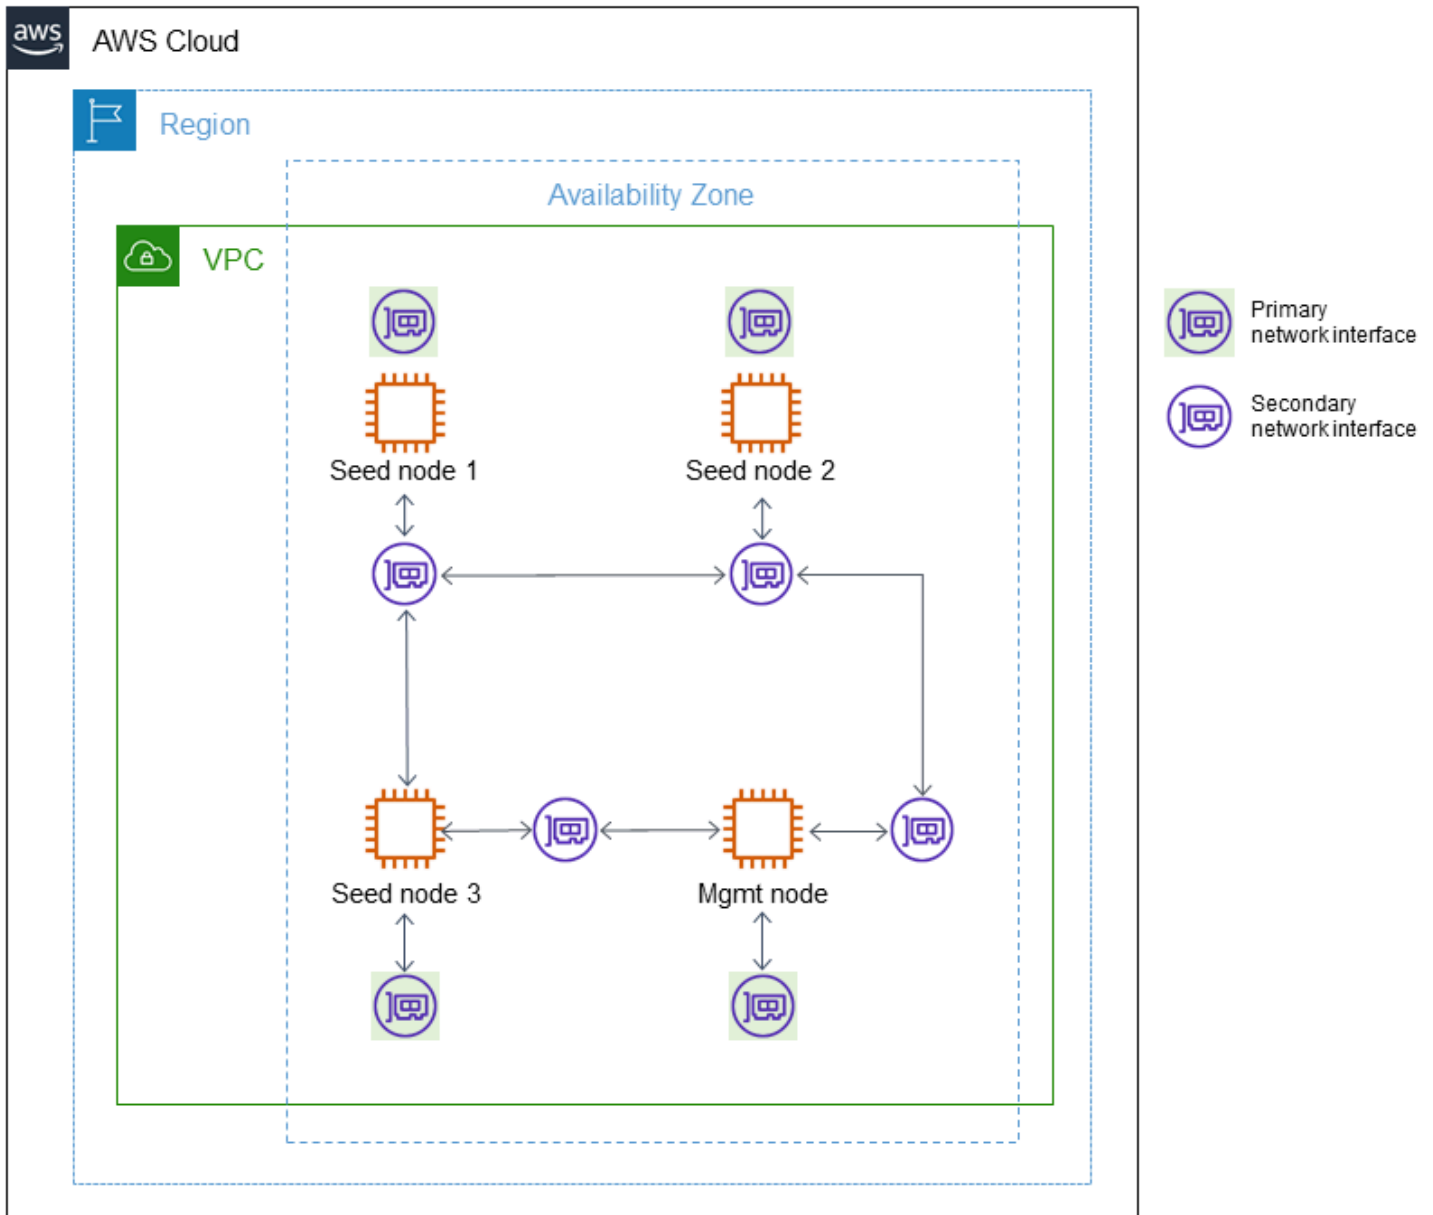

## Source architecture

The source could be a Cassandra cluster on an on-premises virtual machine (VM) or on EC2 instances in the AWS Cloud. The following diagram illustrates the second scenario. This example includes four cluster nodes: three seed nodes and one management node. In the source architecture, each node has a single network interface attached.

## Target architecture

The destination cluster is hosted on EC2 instances with a secondary elastic network interface attached to each node, as illustrated in the following diagram.

## Automation and scale

You can also automate attaching a second elastic network interface to an EC2 Auto Scaling group, as described in an [AWS Knowledge Center video](#).

## Epics

### Configure a Cassandra cluster on Amazon EC2

Task	Description	Skills required
Launch EC2 nodes to host a Cassandra cluster.	On the <a href="#">Amazon EC2 console</a> , launch four EC2 instances for your Ubuntu nodes in your AWS account. Three (seed) nodes are used for the Cassandra cluster, and the fourth node acts as a cluster management node where you will install DataStax Enterprise (DSE) OpsCenter. For instructions, see the <a href="#">Amazon EC2 documentation</a> .	Cloud engineer
Confirm node communications.	Make sure that the four nodes can communicate with one another over the database and cluster management ports.	Network engineer
Install DSE OpsCenter on the management node.	Install DSE OpsCenter 6.1 from the Debian package on the management node. For instructions, see the <a href="#">DataStax documentation</a> .	DBA
Create a secondary network interface.	Cassandra generates a universal unique identifier (UUID) for each node based on the IP address of the EC2 instance for that node. This UUID is used for distributing virtual nodes	Cloud Engineer

Task	Description	Skills required
	<p>(vnodes) on the ring. When Cassandra is deployed on EC2 instances, IP addresses are assigned automatically to the instances as they are created. In the event of a planned or unplanned outage, the IP address for the new EC2 instance changes, the data distribution changes, and the entire ring has to be rebalanced. This is not desirable. To preserve the assigned IP address, use a <a href="#">secondary elastic network interface</a> with a fixed IP address.</p> <ol style="list-style-type: none"><li>1. On the <a href="#">Amazon EC2 console</a>, choose <b>Network Interfaces, Create network interface</b>.</li><li>2. For <b>Subnet</b>, select the subnet that you created the EC2 instance in.</li><li>3. For <b>Private IPv4 address</b>, choose <b>Auto-assign</b>.</li><li>4. For <b>Security groups</b>, select a security group, and then choose <b>Create network interface</b>.</li></ol> <p>For more information about creating a network interface</p>	

Task	Description	Skills required
	, see the <a href="#">Amazon EC2 documentation</a> .	
Attach the secondary network interface to cluster nodes.	<ol style="list-style-type: none"><li>1. On the <a href="#">Amazon EC2 console</a>, choose <b>Instances</b>.</li><li>2. Select the checkbox for the EC2 instance you created earlier.</li><li>3. Choose <b>Actions, Networking, Attach network interface</b>.</li><li>4. Select the network interface you created in the previous step, and then choose <b>Attach</b>.</li></ol> <p>For more information about attaching a network interface, see the <a href="#">Amazon EC2 documentation</a>.</p>	Cloud engineer

Task	Description	Skills required
Add routes in Amazon EC2 to address asymmetric routing.	<p>When you attach the second network interface, the network will very likely perform asymmetric routing. To avoid this, you can add routes for the new network interfaces.</p> <p>For an in-depth explanation and remediation of asymmetric routing, see the <a href="#">AWS Knowledge Center video</a> or <a href="#">Overcoming Asymmetric Routing on Multi-Homed Servers</a> (article in <i>Linux Journal</i> by Patrick McManus, April 5, 2004).</p>	Network engineer
Update DNS entries to point to the secondary network interface IP.	Point the fully qualified domain name (FQDN) of the node to the IP of the secondary network interface.	Network engineer
Install and configure the Cassandra cluster by using DSE OpsCenter.	When the cluster nodes are ready with the secondary network interfaces, you can install and configure the Cassandra cluster.	DBA

## Recover cluster from node failure

Task	Description	Skills required
Create an AMI for the cluster seed node.	Make a backup of the nodes so you can restore them with	Backup administrator

Task	Description	Skills required
	database binaries in case of node failure. For instructions, see <a href="#">Create an AMI</a> in the Amazon EC2 documentation.	
Recover from node failure.	Replace the failed node with a new EC2 instance launched from the AMI, and attach the secondary network interface of the failed node.	Backup administrator
Verify that the Cassandra cluster is healthy.	When the replacement node is up, verify cluster health in DSE OpsCenter.	DBA

# Extend VRFs to AWS by using AWS Transit Gateway Connect

**Environment:** PoC or pilot

**Technologies:** Infrastructure;  
Networking

**AWS services:** AWS Direct  
Connect; AWS Transit  
Gateway

## Summary

Virtual routing and forwarding (VRF) is a feature of traditional networks. It uses isolated logical routing domains, in the form of route tables, to separate network traffic within the same physical infrastructure. You can configure AWS Transit Gateway to support VRF isolation when you connect your on-premises network to AWS. This pattern uses a sample architecture to connect on-premises VRFs to different transit gateway route tables.

This pattern uses transit virtual interfaces (VIFs) in AWS Direct Connect and transit gateway Connect attachments to extend the VRFs. A [transit VIF](#) is used to access one or more Amazon VPC transit gateways that are associated with Direct Connect gateways. A [transit gateway Connect attachment](#) connects a transit gateway with a third-party virtual appliance that is running in a VPC. A transit gateway Connect attachment supports the Generic Routing Encapsulation (GRE) tunnel protocol for high performance, and it supports Border Gateway Protocol (BGP) for dynamic routing.

The approach described in this pattern has the following benefits:

- Using Transit Gateway Connect, you can advertise up to 1,000 routes to the Transit Gateway Connect peer and receive up to 5,000 routes from it. Using the Direct Connect transit VIF feature without Transit Gateway Connect is limited to 20 prefixes per transit gateway.
- You can maintain the traffic isolation and use Transit Gateway Connect to provide hosted services on AWS, regardless of the IP address schemas your customers are using.
- The VRF traffic doesn't need to traverse a public virtual interface. This makes it easier to adhere to compliance and security requirements in many organizations.
- Each GRE tunnel supports up to 5 Gbps, and you can have up to four GRE tunnels per transit gateway Connect attachment. This is faster than many other connection types, such as AWS Site-to-Site VPN connections that support up to 1.25 Gbps.

## Prerequisites and limitations

### Prerequisites

- The required AWS accounts have been created (see the architecture for details)
- Permissions to assume an AWS Identity and Access Management (IAM) role in each account.
- The IAM roles in each account must have permissions to provision AWS Transit Gateway and AWS Direct Connect resources. For more information, see [Authentication and access control for your transit gateways](#) and see [Identity and access management for Direct Connect](#).
- The Direct Connect connections have successfully been created. For more information, see [Create a connection using the Connection wizard](#).

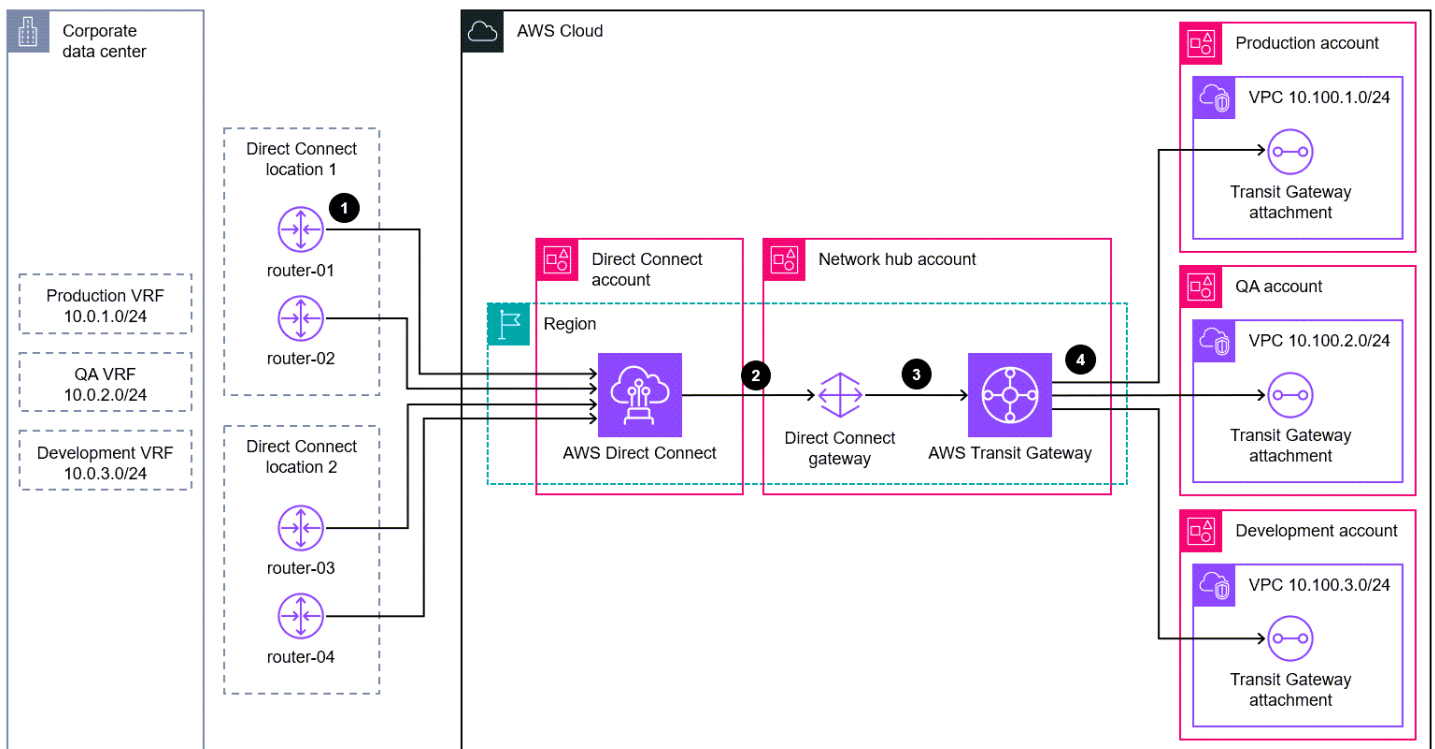

### Limitations

- There are limits for transit gateway attachments to the VPCs in the production, QA, and development accounts. For more information, see [Transit gateway attachments to a VPC](#).
- There are limits for creating and using Direct Connect gateways. For more information, see [AWS Direct Connect quotas](#).

## Architecture

### Target architecture

The following sample architecture provides a reusable solution to deploy transit VIFs with transit gateway Connect attachments. This architecture provides resilience by using multiple Direct Connect locations. For more information, see [Maximum resiliency](#) in the Direct Connect documentation. The on-premises network has production, QA, and development VRFs that are extended to AWS and isolated by using dedicated route tables.

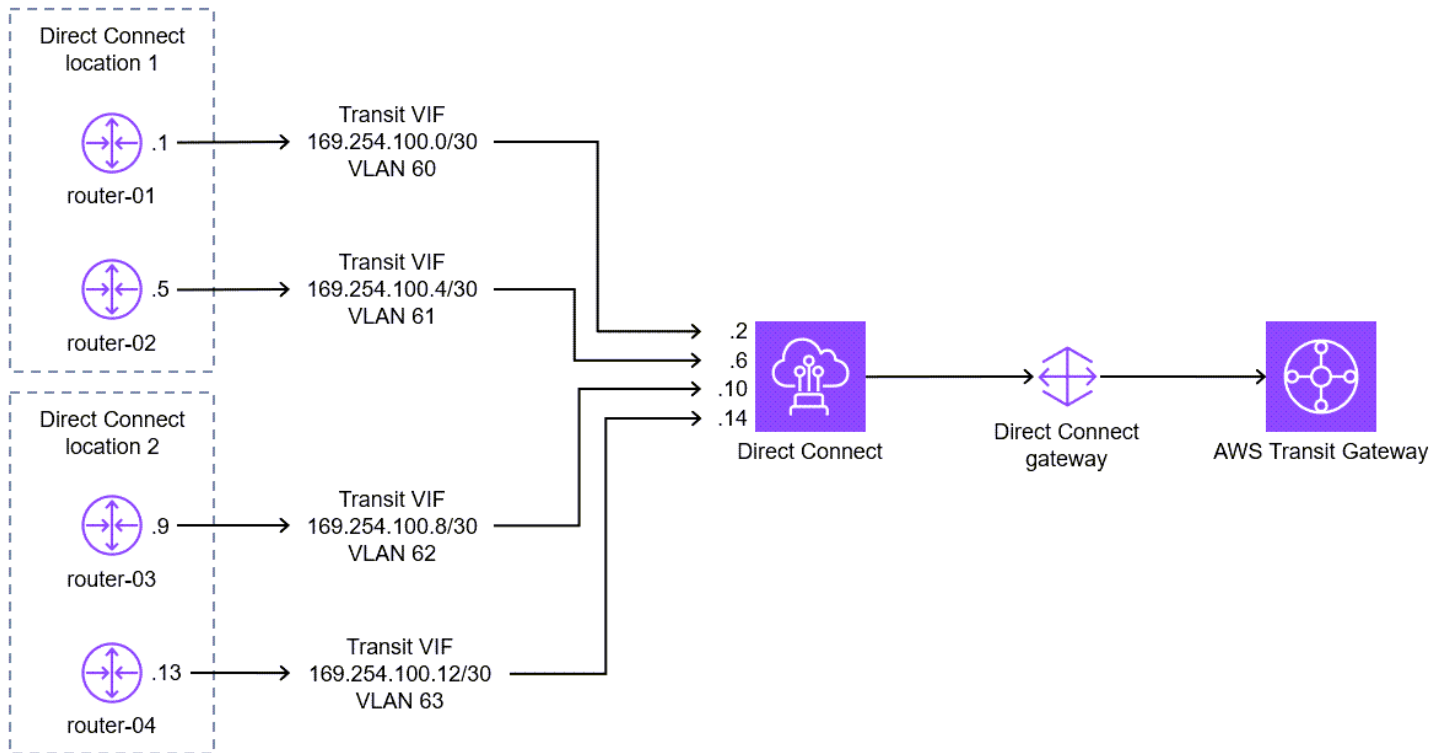

In the AWS environment, two accounts are dedicated to extending the VRFs: a *Direct Connect account* and a *network hub account*. The Direct Connect account contains the connection and the transit VIFs for each router. You create the transit VIFs from the Direct Connect account but deploy them to the network hub account so that you can associate them with the Direct Connect gateway in the network hub account. The network hub account contains the Direct Connect gateway and transit gateway. The AWS resources are connected as follows:

1. Transit VIFs connect the routers in the Direct Connect locations with AWS Direct Connect in the Direct Connect account.
2. A transit VIF connects Direct Connect with the Direct Connect gateway in the network hub account.
3. A [transit gateway association](#) connects the Direct Connect gateway with the transit gateway in the network hub account.
4. [Transit gateway Connect attachments](#) connect the transit gateway with the VPCs in the production, QA, and development accounts.

### *Transit VIF architecture*

The following diagram shows the configuration details for the transit VIFs. This sample architecture uses a VLAN for the tunnel source, but you could also use a loopback.

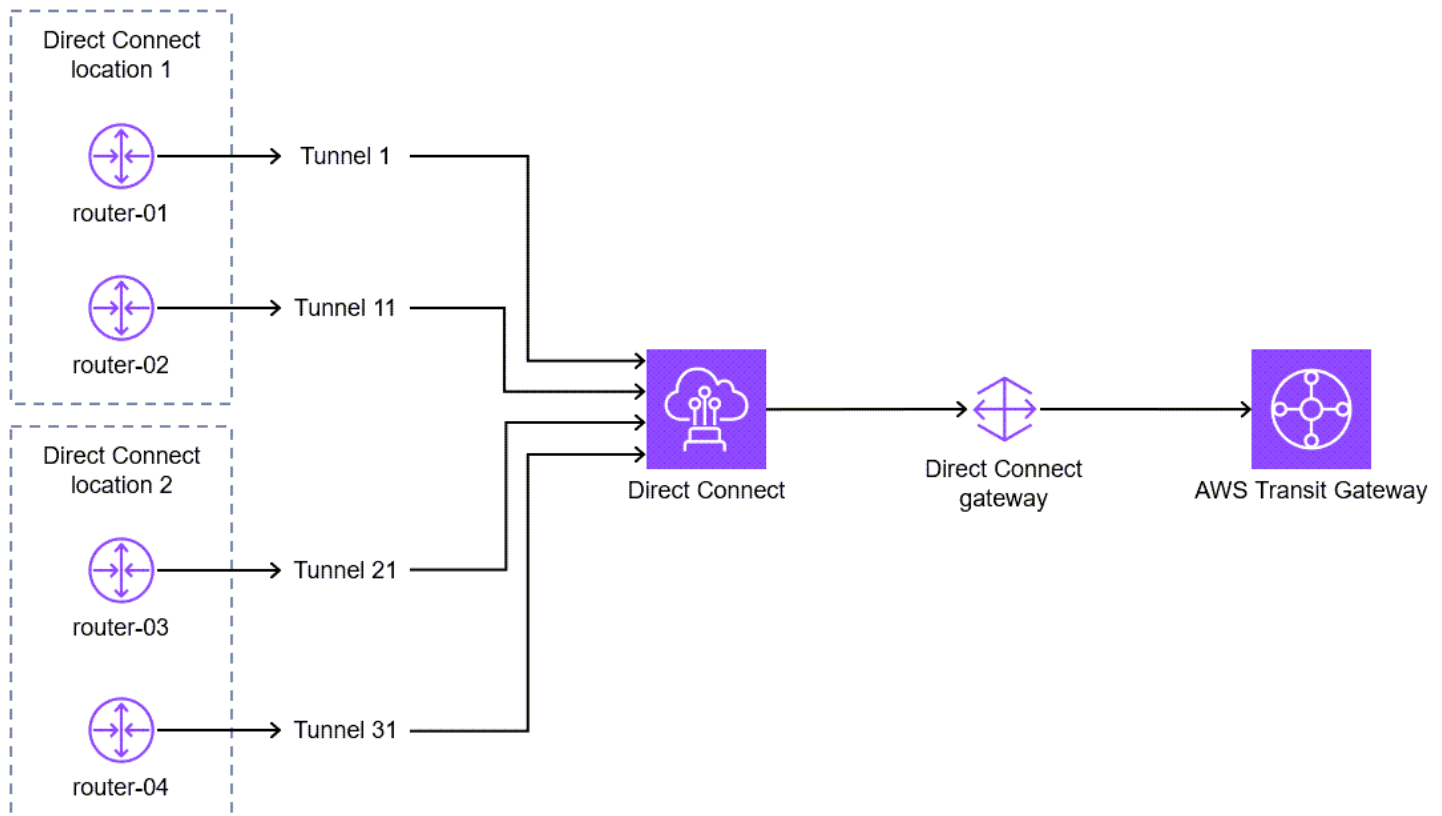

The following are the configuration details, such as autonomous system numbers (ASNs), for the transit VIFs.

Resource	Item	Detail
router-01	ASN	65534
router-02	ASN	65534
router-03	ASN	65534
router-04	ASN	65534
Direct Connect gateway	ASN	64601
Transit gateway	ASN	64600
	CIDR block	10.100.254.0/24

## Transit gateway Connect architecture

The following diagram and tables describe how to configure a single VRF through a transit gateway Connect attachment. For additional VRFs, assign unique tunnel IDs, transit gateway GRE IP addresses, and BGP inside CIDR blocks. The peer GRE IP address matches the router peer IP address from the transit VIF.

The following table contains router configuration details.

Router	Tunnel	IP address	Source	Destination
<i>router-01</i>	Tunnel 1	169.254.101.17	VLAN 60 169.254.100.1	10.100.254.1
<i>router-02</i>	Tunnel 11	169.254.101.81	VLAN 61 169.254.100.5	10.100.254.11
<i>router-03</i>	Tunnel 21	169.254.101.145	VLAN 62	10.100.254.21

			169.254.100.9	
router-04	Tunnel 31	169.254.1 01.209	VLAN 63	10.100.254.31
			169.254.100.13	

The following table contains transit gateway configuration details.

Tunnel	Transit gateway GRE IP address	Peer GRE IP address	BGP inside CIDR blocks
Tunnel 1	10.100.254.1	VLAN 60 169.254.100.1	169.254.101.16/29
Tunnel 11	10.100.254.11	VLAN 61 169.254.100.5	169.254.101.80/29
Tunnel 21	10.100.254.21	VLAN 62 169.254.100.9	169.254.101.144/29
Tunnel 31	10.100.254.31	VLAN 63 169.254.100.13	169.254.101.208/29

## Deployment

The [Epics](#) section describes how to deploy a sample configuration for a single VRF across multiple customer routers. After steps 1–5 are complete, you can create new transit gateway Connect attachments by using steps 6–7 for every new VRF that you’re extending into AWS:

1. Create the transit gateway.
2. Create a Transit Gateway route table for each VRF.
3. Create the transit virtual interfaces.
4. Create the Direct Connect gateway.

5. Create the Direct Connect gateway virtual interface and gateway associations with allowed prefixes.
6. Create the transit gateway Connect attachment.
7. Create the Transit Gateway Connect peers.
8. Associate the transit gateway Connect attachment with the route table.
9. Advertise routes to the routers.

## Tools

### AWS services

- [AWS Direct Connect](#) links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- [AWS Transit Gateway](#) is a central hub that connects virtual private clouds (VPCs) and on-premises networks.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

## Epics

### Plan the architecture

Task	Description	Skills required
Create custom architecture diagrams.	<ol style="list-style-type: none"><li>1. In the <a href="#">Attachments</a> section, download the diagram template.</li><li>2. Open the attached diagram in Microsoft Office PowerPoint.</li><li>3. On the <b>Architecture overview</b> slide, customize</li></ol>	Cloud architect, Network administrator

Task	Description	Skills required
	<p>the architecture diagram for your environment. Identify the on-premises VRFs that need to be extended into your AWS environment.</p> <p>4. On the <b>Transit VIF</b> slide, customize the architecture diagram. Identify the AS numbers of the routers, the Direct Connect gateway, and the transit gateway. Identify the IP addresses at each end of the transit VIF.</p> <p>5. On the <b>Transit Gateway Connect</b> slide, customize an architecture diagram for each VRF. Identify all required IP addresses necessary to configure the routers and the Transit Gateway Connect peers.</p>	

## Create the Transit Gateway resources

Task	Description	Skills required
Create the transit gateway.	<ol style="list-style-type: none"> <li>1. Sign in to the network hub account.</li> <li>2. Follow the instructions in <a href="#">Create a transit gateway</a>. Note the following for this pattern:</li> </ol>	Network administrator, Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• For <b>Amazon side Autonomous System Number (ASN)</b>, enter a unique ASN. For the purposes of this example, the ASN is 64600.</li><li>• Select <b>DNS support</b>.</li><li>• For this sample architecture, <b>VPN ECMP support, Default route table association, Default route table proration, and Multicast support</b> are not required.</li><li>• For <b>Transit gateway CIDR blocks</b>, enter the IPv4 CIDR blocks for your transit gateway. For the purposes of this example, the CIDR block is 10.100.254.0/24 .</li></ul>	

Task	Description	Skills required
Create the transit gateway route table.	<p>Follow the instructions in <a href="#">Create a transit gateway route table</a>. Note the following for this pattern:</p> <ul style="list-style-type: none"> <li>• For <b>Name tag</b>, provide a name for the transit gateway route table. We recommend using a name that corresponds to the VRF, such as <code>routetable-dev-vrf</code>.</li> <li>• For <b>Transit gateway ID</b>, choose the transit gateway that you created previously.</li> </ul>	Cloud architect, Network administrator

## Create the transit virtual interfaces

Task	Description	Skills required
Create the transit virtual interfaces.	<ol style="list-style-type: none"> <li>1. Sign in to the Direct Connect account.</li> <li>2. Follow the instructions in <a href="#">Create a transit virtual interface to the Direct Connect gateway</a>. Note the following for this pattern: <ul style="list-style-type: none"> <li>• For <b>Virtual interface name</b>, enter a name for the transit VIF. We recommend using a name that corresponds to the router, such as</li> </ul> </li> </ol>	Cloud architect, Network administrator

Task	Description	Skills required
	<p>transit-vif-router-01 .</p> <ul style="list-style-type: none"> <li>• For <b>Connection</b>, select the router, such as router-01 .</li> <li>• For <b>Virtual interface owner</b>, enter the account ID of the network hub account. For instructions, see <a href="#">View your AWS account ID</a>.</li> <li>• For <b>Direct Connect gateway</b>, do not make any selection. You attach the Direct Connect gateway in a subsequent step.</li> <li>• For <b>VLAN</b>, enter the VLAN of the router, such as 60.</li> <li>• For <b>BGP ASN</b>, enter the ASN of the router, such as 65534.</li> <li>• Under <b>Additional Settings</b>, do the following: <ul style="list-style-type: none"> <li>• Choose <b>IPv4</b>.</li> <li>• For <b>Your router peer ip</b>, enter the router peer IP address, such as 169.254.100.1 .</li> <li>• For <b>Amazon router peer ip</b>, enter the</li> </ul> </li> </ul>	

Task	Description	Skills required
	<p>Amazon router peer IP, such as 169.254.100.2 .</p> <ul style="list-style-type: none"> <li>For <b>BGP authentication key</b>, a password is required. If this is left blank, AWS creates a key that is only accessible in this account.</li> </ul> <p>3. Repeat these instructions to create all transit VIFs for the VRF.</p>	

### Create the Direct Connect resources

Task	Description	Skills required
Create a Direct Connect gateway.	<ol style="list-style-type: none"> <li>Sign in to the network hub account.</li> <li>Follow the instructions in <a href="#">Creating a Direct Connect gateway</a>. Note the following for this pattern: <ul style="list-style-type: none"> <li>For <b>Amazon side ASN</b>, enter the ASN of the Direct Connect gateway, such as 64601.</li> <li>Do not choose a virtual private gateway.</li> </ul> </li> </ol>	Cloud architect, Network administrator
Attach the Direct Connect gateway to the transit VIFs.	<ol style="list-style-type: none"> <li>In the network hub account, open the AWS Direct Connect console</li> </ol>	Cloud architect, Network administrator

Task	Description	Skills required
	<p>at <a href="https://console.aws.amazon.com/directconnect/v2/">https://console.aws.amazon.com/directconnect/v2/</a>.</p> <ol style="list-style-type: none"> <li>In the navigation pane, choose <b>Virtual Interfaces</b>.</li> <li>Select a new transit VIF, and then choose <b>Accept</b>.</li> <li>Choose the Direct Connect gateway you created.</li> <li>Repeat these instructions for each transit VIF.</li> </ol>	
<p>Create the Direct Connect gateway associations with allowed prefixes.</p>	<p>In the network hub account, follow the instructions in <a href="#">To associate a transit gateway</a>. Note the following for this pattern:</p> <ul style="list-style-type: none"> <li>For <b>Gateways</b>, choose the transit gateway you created previously.</li> <li>For <b>Allowed prefixes</b>, enter the CIDR block assigned to the transit gateway, such as <code>10.100.254.0/24</code>.</li> </ul> <p>Creating this association automatically creates a Transit Gateway attachment that has a Direct Connect Gateway resource type. This attachment does not need to be associated with a transit gateway route table.</p>	<p>Cloud architect, Network administrator</p>

Task	Description	Skills required
Create the transit gateway Connect attachment.	<ol style="list-style-type: none"><li>1. In the network hub account, open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>.</li><li>2. In the navigation pane, choose <b>Transit gateway attachments</b>.</li><li>3. Choose <b>Create transit gateway attachment</b>.</li><li>4. For <b>Name tag</b>, enter a name for the attachment. We recommend using a name that corresponds to the VRF, such as PROD-VRF.</li><li>5. For <b>Transit gateway ID</b>, choose the transit gateway you created previously.</li><li>6. For <b>Attachment type</b>, choose <b>Connect</b>.</li><li>7. For <b>Transport attachment ID</b>, choose the Direct Connect gateway you created previously.</li><li>8. Choose <b>Create transit gateway attachment</b>.</li><li>9. Repeat this step for each VRF that you are extending.</li></ol>	Cloud architect, Network administrator

Task	Description	Skills required
Create the Transit Gateway Connect peers.	<p>1. In the network hub account, follow the instructions in <a href="#">Create a Transit Gateway Connect peer (GRE tunnel)</a>. Note the following for this pattern:</p> <ul style="list-style-type: none"><li>• For <b>Name tag</b>, enter a name for the Transit Gateway Connect peer. We recommending using a name that corresponds with the router, such as <code>connectpeer-router01</code> .</li><li>• For <b>Transit gateway GRE address</b>, enter the assigned IP address from the transit gateway CIDR block, such as <code>10.100.254.1</code> .</li><li>• For <b>Peer GRE address</b>, enter the IP address assigned to the VLAN created on the router for the transit VIF, such as <code>169.254.100.1</code> . Provided that AWS can reach the IP address, you can use any interface, such as VLAN or Loopback, for the peer GRE address.</li><li>• For <b>BGP Inside CIDR Blocks (IPv4)</b>, enter</li></ul>	

Task	Description	Skills required
	<p>the BGP inside CIDR block IP address, such as 169.254.101.16/29 .</p> <ul style="list-style-type: none"> <li>• For <b>Peer ASN</b>, enter the ASN of the router, such as 65534.</li> </ul> <p>2. Repeat these instructions to create a GRE tunnel for each router.</p>	

### Advertise routes to the routers

Task	Description	Skills required
Advertise the routes.	<p>Associate the new transit gateway Connect attachment with the route table you created previously for this VRF. For example, associate the production transit gateway Connect attachment with the Production-VRF route table.</p> <p>Create a static route for the prefix that is advertised to the routers.</p> <ol style="list-style-type: none"> <li>1. Sign in to the network hub account.</li> <li>2. Open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>.</li> </ol>	Network administrator, Cloud architect

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. In the navigation pane, under <b>Transit Gateways</b>, choose <b>Transit gateway route tables</b>.</li><li>4. Select the Production-VRF route table.</li><li>5. On the <b>Actions</b> menu, choose <b>Create static route</b>.</li><li>6. For <b>CIDR</b>, enter the CIDR block for the advertised route to the transit gateway attachment in the target VPC, such as <code>10.100.1.0/24</code>.</li><li>7. For <b>Choose Attachment</b>, choose the relevant transit gateway Connect attachment.</li><li>8. Choose <b>Create static route</b>.</li></ol>

# Get Amazon SNS notifications when the key state of an AWS KMS key changes

Created by Shubham Harsora (AWS), Aromal Raj Jayarajan (AWS), and Navdeep Pareek (AWS)

<b>Code repository:</b> <a href="#">aws-kms-deletion-notification</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Infrastructure; CloudNative; DevOps; Security, identity, compliance
<b>Workload:</b> All other workloads	<b>AWS services:</b> Amazon EventBridge; AWS KMS; Amazon SNS	

## Summary

The data and metadata associated with an AWS Key Management Service (AWS KMS) key is lost when that key is deleted. The deletion is irreversible and you can't recover lost data (including encrypted data). You can prevent data loss by setting up a notification system to alert you of status changes to [key states](#) of your AWS KMS keys.

This pattern shows you how to monitor status changes to AWS KMS keys by using Amazon EventBridge and Amazon Simple Notification Service (Amazon SNS) to issue automated notifications whenever the key state of an AWS KMS key changes to `Disabled` or `PendingDeletion`. For example, if a user tries to disable or delete an AWS KMS key, you will receive an email notification with details about the attempted status change. You can also use this pattern to schedule the deletion of AWS KMS keys.

## Prerequisites and limitations

### Prerequisites

- An active AWS account with an AWS Identity and Access Management (IAM) user
- An [AWS KMS key](#)

# Architecture

## Technology stack

- Amazon EventBridge
- AWS Key Management Service (AWS KMS)
- Amazon Simple Notification Service (Amazon SNS)

## Target architecture

The following diagram shows an architecture for building an automated monitoring and notification process for detecting any changes to the state of an AWS KMS key.

The diagram shows the following workflow:

1. A user disables or schedules the deletion of an AWS KMS key.
2. An EventBridge rule evaluates the scheduled `Disabled` or `PendingDeletion` event.
3. The EventBridge rule invokes the Amazon SNS topic.
4. Amazon SNS sends an email notification message to the users.

**Note:** You can customize the email message to meet your organization's needs. We recommend including information about the entities where the AWS KMS key is used. This can help users

understand the impact of deleting the AWS KMS key. You can also schedule a reminder email notification that's sent one or two days before the AWS KMS key is deleted.

## Automation and scale

The AWS CloudFormation stack deploys all the necessary resources and services for this pattern to work. You can implement the pattern independently in a single account, or by using [AWS CloudFormation StackSets](#) for multiple independent accounts or [organizational units](#) in AWS Organizations.

## Tools

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions. The CloudFormation template for this pattern describes all the AWS resources that you want, and CloudFormation provisions and configures those resources for you.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications and AWS services, and it routes that data to targets such as AWS Lambda. EventBridge simplifies the process of building event-driven architectures.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

## Code

The code for this pattern is available in the GitHub [Monitor AWS KMS keys disable and scheduled deletion](#) repository.

# Epics

## Deploy the CloudFormation template

Task	Description	Skills required
Clone the repository.	<p>Clone the GitHub <a href="#">Monitor AWS KMS keys disable and scheduled deletion</a> repository to your local machine by running the following command:</p> <pre>git clone https://github.com/aws-samples/aws-kms-deletion-notification</pre>	AWS administrator, Cloud architect
Update the template's parameters.	<p>In a code editor, open the <code>Alerting-KMS-Events.yaml</code> CloudFormation template that you cloned from the repository, and then update the following parameters:</p> <ul style="list-style-type: none"> <li>For <code>DestinationEmailAddress</code> , enter an active email address that you plan to use for receiving the SNS notification.</li> <li>For <code>SNSTopicName</code> , enter a name for your SNS topic.</li> </ul>	AWS administrator, Cloud architect
Deploy the CloudFormation template.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and</li> </ol>	AWS administrator, Cloud architect

Task	Description	Skills required
	<p>open the <a href="#">CloudFormation console</a>.</p> <ol style="list-style-type: none"> <li>2. In the navigation pane, choose <b>Create stack</b>, and then choose <b>With new resources (standard)</b>.</li> <li>3. On the <b>Identify resources</b> page, choose <b>Next</b>.</li> <li>4. On the <b>Specify template</b> page, for <b>Template source</b>, select <b>Upload a template file</b>.</li> <li>5. Choose <b>Choose file</b>, select the <code>Alerting-KMS-Events.yaml</code> file from your cloned GitHub repository, and then choose <b>Next</b>.</li> <li>6. For <b>Stack name</b>, enter your stack name.</li> <li>7. Choose <b>Submit</b>.</li> </ol>	

## Confirm the subscription

Task	Description	Skills required
Confirm the subscription email.	After the CloudFormation template successfully deploys, Amazon SNS sends a subscription confirmation message to the email address that you provided in the CloudFormation template.	AWS administrator, Cloud architect

Task	Description	Skills required
	To receive notifications, you must confirm this email subscription. For more information, see <a href="#">Confirm the subscription</a> in the Amazon SNS Developer Guide.	

## Test the subscription notification

Task	Description	Skills required
Disable AWS KMS keys.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">AWS KMS console</a>.</li><li>2. To change the Region, choose the name of the currently displayed Region, and then choose the Region to which you want to switch.</li><li>3. In the navigation pane, choose <b>Customer managed keys</b>.</li><li>4. Select the check box for the AWS KMS key that you want to enable or disable.</li><li>5. To disable the AWS KMS key, choose <b>Key actions</b>, and then choose <b>Disable</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Validate the subscription.	Confirm that you received the Amazon SNS notification email.	AWS administrator

## Clean up resources

Task	Description	Skills required
Delete the CloudFormation stack.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">CloudFormation console</a>.</li><li>2. In the navigation pane, choose <b>Stacks</b>.</li><li>3. Select that stack that you created previously, and then choose <b>Delete</b>.</li></ol>	AWS administrator

## Related resources

- [AWS CloudFormation](#) (AWS documentation)
- [Creating a stack on the AWS CloudFormation console](#) (AWS CloudFormation documentation)
- [Building event-driven architectures on AWS](#) (AWS Workshop Studio documentation)
- [AWS Key Management Service Best Practices](#) (AWS Whitepaper)
- [Security best practices for AWS Key Management Service](#) (AWS KMS Developer Guide)

## Additional information

Amazon SNS provides in-transit encryption by default. To align with security best practices, you can also enable server-side encryption for Amazon SNS by using an AWS KMS customer managed key.

# Mainframe modernization: DevOps on AWS with Micro Focus

Created by Kevin Yung (AWS)

<b>Source:</b> IBM z/OS Mainframe	<b>Target:</b> AWS	<b>R Type:</b> N/A
<b>Environment:</b> PoC or pilot	<b>Technologies:</b> DevOps; Infrastructure	<b>AWS services:</b> Amazon EC2; AWS CloudFormation; AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS Systems Manager; AWS CodePipeline

## Summary

### Customer challenges

Organizations that run core applications on mainframe hardware usually encounter a few challenges when the hardware needs to scale up to meet the demands of digital innovations. These challenges include the following constraints.

- Mainframe development and test environments are unable to scale due to the inflexibility of mainframe hardware components and the high cost of changing.
- Mainframe development is facing skill shortages, because new developers are not familiar and not interested in the traditional mainframe development tools. Modern technology such as containers, continuous integration/continuous delivery (CI/CD) pipelines, and modern test frameworks are not available in mainframe development.

### Pattern outcomes

To address these challenges, Amazon Web Services (AWS) and Micro Focus, an AWS Partner Network (APN) Partner, have collaborated to create this pattern. The solution is designed to help you achieve the following outcomes.

- Improved developer productivity. Developers can be given new mainframe development instances within minutes.

- Use of the AWS Cloud to create new mainframe test environments with virtually unlimited capacity.
- Rapid provisioning of new mainframe CI/CD infrastructure. Provisioning on AWS can be completed within an hour by using AWS CloudFormation and AWS Systems Manager.
- Native use of AWS DevOps tools for mainframe development, including AWS CodeBuild, AWS CodeCommit, AWS CodePipeline, AWS CodeDeploy, and Amazon Elastic Container Registry (Amazon ECR).
- Transform traditional waterfall development to agile development in mainframe projects.

## Technologies summary

In this pattern, the target stack contains the following components.

Logical components	Implementation solutions	Description
Source code repositories	Micro Focus AccuRev Server, CodeCommit, Amazon ECR	<p>Source code management – The solution uses two types of source code.</p> <ul style="list-style-type: none"> <li>• Mainframe source code, for example COBOL, JCL, etc.</li> <li>• AWS infrastructure templates and automation scripts</li> </ul> <p>Both types of source code need version control, but they are managed in different SCMs. Source code deployed into mainframe or Micro Focus Enterprise Servers is managed in Micro Focus AccuRev Server. AWS templates and automation scripts are managed in CodeCommit. Amazon ECR</p>

is used for the Docker image repositories.

Enterprise developer instances

Amazon Elastic Compute Cloud (Amazon EC2), Micro Focus Enterprise Developer for Eclipse

Mainframe developers can develop code in Amazon EC2 by using Micro Focus Enterprise Developer for Eclipse. This eliminates the need to rely on mainframe hardware to write and test code.

Micro Focus license management

Micro Focus License Manager

For centralized Micro Focus license management and governance, the solution uses Micro Focus License Manager to host the required license.

CI/CD pipelines

CodePipeline, CodeBuild, CodeDeploy, Micro Focus Enterprise Developer in a container, Micro Focus Enterprise Test Server in a container, Micro Focus Enterprise Server

Mainframe development teams need CI/CD pipelines to perform code compilation, integration tests, and regression tests. In AWS, CodePipeline and CodeBuild can work with Micro Focus Enterprise Developer and Enterprise Test Server in a container natively.

## Prerequisites and limitations

### Prerequisites

Name

Description

py3270

py3270 is a Python interface to x3270, an IBM 3270 terminal emulator. It provides an API to a x3270 or s3270 subprocess.

x3270	x3270 is an IBM 3270 terminal emulator for the X Window System and Windows. This can be used by developer for unit testing locally.
Robot-Framework-Mainframe-3270-Library	Mainframe3270 is a library for Robot Framework based on py3270 project.
Micro Focus Verastream	Micro Focus Verastream is an integration platform that enables testing mainframe assets the way that mobile apps, web applications, and SOA web services are tested.
Micro Focus Unified Functional Testing (UFT) installer and license	Micro Focus Unified Functional Testing is software that provides functional and regression test automation for software applications and environments.
Micro Focus Enterprise Server installer and license	Enterprise Server provides the runtime environment for mainframe applications.
Micro Focus Enterprise Test Server installer and license	Micro Focus Enterprise Test Server is an IBM mainframe application test environment
Micro Focus AccuRev installer and license for Server, and Micro Focus AccuRev installer and license for Windows and Linux operating systems	AccuRev provides source code management (SCM). The AccuRev system is designed for use by a team of people who are developing a set of files.
Micro Focus Enterprise Developer for Eclipse installer, patch and license	Enterprise Developer provide mainframe developer a platform to develop and maintain the core mainframe online and batch applications.

## Limitations

- Building a Windows Docker image is not supported in CodeBuild. This [reported issue](#) needs support from Windows Kernel/HCS and Docker teams. The work-around is to create a Docker image build runbook by using Systems Manager. This pattern uses the work-around to build

Micro Focus Enterprise Developer for Eclipse and Micro Focus Enterprise Test Server Container images.

- Virtual private cloud (VPC) connectivity from CodeBuild is not supported in Windows yet, so the pattern does not use Micro Focus License Manager to manage licenses in Micro Focus Enterprise Developer and Micro Focus Enterprise Test Server containers.

## Product versions

- Micro Focus Enterprise Developer 5.5 or later
- Micro Focus Enterprise Test Server 5.5 or later
- Micro Focus Enterprise Server 5.5 or later
- Micro Focus AccuRev 7.x or later
- Windows Docker base image for Micro Focus Enterprise Developer and Enterprise Test Server: **microsoft/dotnet-framework-4.7.2-runtime**
- Linux Docker base image for AccuRev client: **amazonlinux:2**

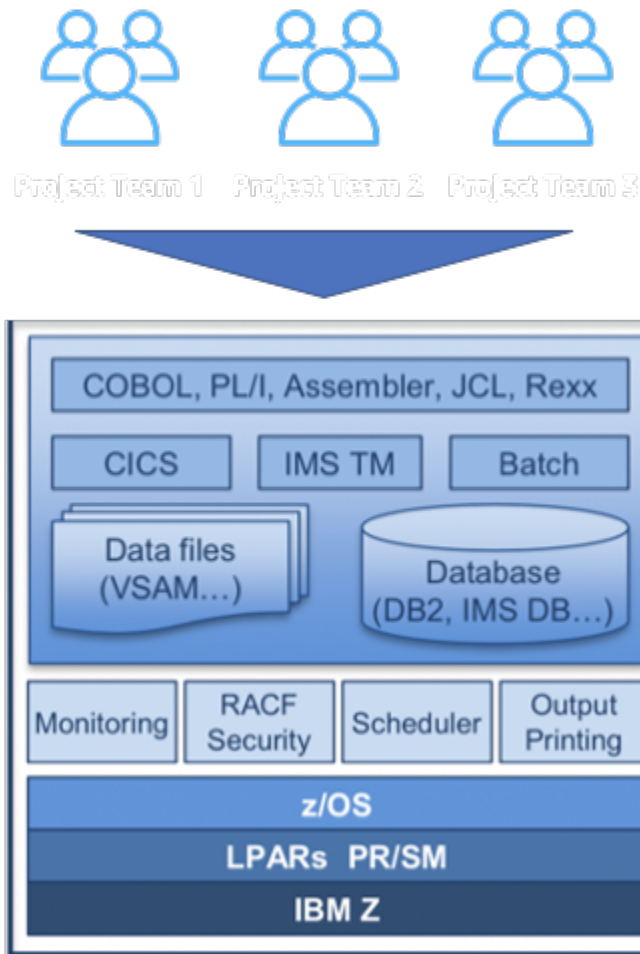

## Architecture

### Mainframe environment

In conventional mainframe development, the developers need to use mainframe hardware to develop and test programs. They face capacity limitations, for example restricted million instructions per second (MIPS) for the dev/test environment, and they must rely on the tools that are available on the mainframe computers.

In many organizations, mainframe development follows the waterfall development methodology, with teams relying on long cycles to release changes. These release cycles are usually longer than digital product development.

The following diagram shows multiple mainframe projects sharing mainframe hardware for their development. In mainframe hardware, it is expensive to scale out a development and test environment for more projects.

## AWS architecture

This pattern extends mainframe development to the AWS Cloud. First, it uses Micro Focus AccuRev SCM to host the mainframe source code on AWS. Then it makes Micro Focus Enterprise Developer and Micro Focus Enterprise Test Server available for building and testing the mainframe code on AWS.

The following sections describe the pattern's three major components.

### 1. SCM

In AWS, the pattern uses Micro Focus AccuRev to create a set of SCM workspaces and version control for the mainframe source code. Its stream-based architecture enables parallel mainframe

development for multiple teams. To merge a change, AccuRev uses the promote concept. To add that change to other workspaces, AccuRev uses the update concept.

At the project level, each team can create one or more streams in AccuRev to track project level changes. These are called project streams. These project streams are inherited from the same parent stream. The parent stream is used to merge the changes from different project streams.

Each project stream can promote code to AccuRev, and a promote post trigger is set up to initiate the AWS CI/CD pipeline. The successful build for a project stream change can be promoted to its parent stream for more regression tests.

Usually, the parent stream is called the system integration stream. When there is a promotion from a project stream to a system integration stream, a post promotion trigger initiates another CI/CD pipeline to run regression tests.

In addition to mainframe code, this pattern includes AWS CloudFormation templates, Systems Manager Automation documents, and scripts. Following infrastructure-as-code best practices, they are version-controlled in AWS CodeCommit.

If you need to synchronize mainframe code back to a mainframe environment for deployment, Micro Focus provides the Enterprise Sync solution, which synchronizes code from the AccuRev SCM back to the mainframe SCM.

## 2. Developer and test environments

In a large organization, scaling more than a hundred or even more than a thousand mainframe developers is challenging. To address this constraint, the pattern uses Amazon EC2 Windows instances for development. On the instances, Micro Focus Enterprise Developer for Eclipse tools are installed. The developer can perform all mainframe code test and debugging locally on the instance.

AWS Systems Manager State Manager and Automation documents are used to automate the developer instance provisioning. The average time to create a developer instance is within 15 minutes. The following software and configurations are prepared.

- AccuRev Windows client for checking out and committing source code into AccuRev
- Micro Focus Enterprise Developers for Eclipse tool, for writing, testing, and debugging mainframe code locally
- Open source testing frameworks Python behavior-driven development (BDD) test framework Behave, py3270, and the x3270 emulator for creating scripts to test applications

- A Docker developer tool for building the Enterprise Test Server Docker image and testing the application in the Enterprise Test Server Docker container

In the development cycle, developers use the EC2 instance to develop and test mainframe code locally. When the local changes are tested successfully, developers promote the change into the AccuRev server.

### 3. CI/CD pipelines

In the pattern, CI/CD pipelines are used for integration tests and regression tests before deployment to the production environment.

As explained in the SCM section, AccuRev uses two types of streams: a project stream and an integration stream. Each stream is hooked up with CI/CD pipelines. To perform the integration between the AccuRev server and AWS CodePipeline, the pattern uses AccuRev post promotion script to create an event to initiate CI/CD.

For example, when a developer promotes a change to a project stream in AccuRev, it initiates a post promotion script to run in AccuRev Server. Then the script uploads the metadata of the change into an Amazon Simple Storage Service (Amazon S3) bucket to create an Amazon S3 event. This event will initiate a CodePipeline configured pipeline to run.

The same event-initiating mechanism is used for the integration stream and its associated pipelines.

In the CI/CD pipeline, CodePipeline uses CodeBuild with the Micro Focus AccuRev Linux client container to check out the latest code from the AccuRev streams. Then the pipeline starts CodeBuild to use the Micro Focus Enterprise Developer Windows container to compile the source code, and to use the Micro Focus Enterprise Test Server Windows container in CodeBuild to test mainframe applications.

The CI/CD pipelines are built using AWS CloudFormation templates, and the blueprint will be used for new projects. By using the templates, it takes less than an hour for a project to create a new CI/CD pipeline in AWS.

To scale your mainframe test capability on AWS, the pattern builds out the Micro Focus DevOps test suite, Micro Focus Verastream and Micro Focus UFT server. By using the modern DevOps tools, you can run as many tests on AWS as you need.

An example mainframe development environment with Micro Focus on AWS is shown in the following diagram.

## Target technology stack

This section provides a closer look at the architecture of each component in the pattern.

### 1. Source code repository – AccuRev SCM

Micro Focus AccuRev SCM is set up to manage mainframe source code versions. For high availability, AccuRev supports primary and replica modes. Operators can fail over to the replica when performing maintenance on the primary node.

To speed up the response of the CI/CD pipeline, the pattern uses Amazon CloudWatch Events to detect source code changes and initiate the start of the pipeline.

1. The CodePipeline is set up to use an Amazon S3 source.
2. A CloudWatch Events rule is set up to capture S3 events from a source S3 bucket.
3. The CloudWatch Events rule sets a target to the pipeline.
4. AccuRev SCM is configured to run a post promotion script locally after promotion is complete.
5. AccuRev SCM generates an XML file that contains the metadata of the promotion, and the script uploads the XML file to the source S3 bucket.

- After the upload, the source S3 bucket sends events to match the CloudWatch Events rule, and the CloudWatch Events rule initiates the CodePipeline to run.

When the pipeline runs, it kicks off a CodeBuild project to use an AccuRev Linux client container to check out the latest mainframe code from an associated AccuRev stream.

The following diagram shows an AccuRev Server setup.

## 2. Enterprise Developer template

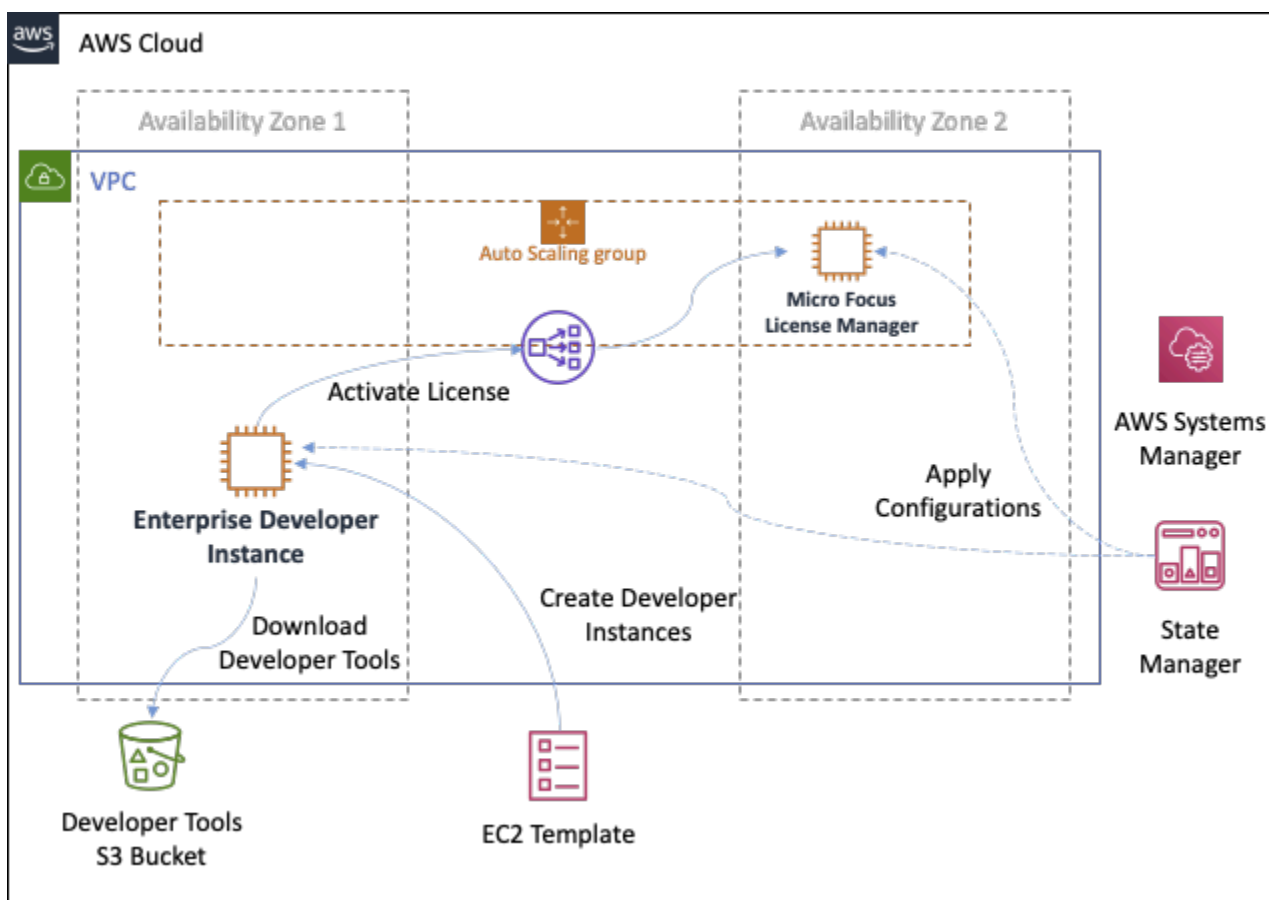

The pattern uses Amazon EC2 templates to simplify creation of the developer instance. By using State Manager, it can apply software and license settings to EC2 instances consistently.

The Amazon EC2 template builds in its VPC context settings and default instance settings, and it follows enterprise tagging requirements. By using a template, a team can create their own new development instances.

When a developer instance starts, by associating with tags, Systems Manager uses State Manager to apply automation. The automation includes the following general steps.

1. Install Micro Focus Enterprise Developer software and install patches.
2. Install the Micro Focus AccuRev client for Windows.
3. Install the pre-configured script for developers to join the AccuRev stream. Initialize Eclipse workspaces.
4. Install development tools, including x3270, py3270, and Docker.
5. Configure license settings to point to a Micro Focus License Manager load balancer.

The following diagram shows an Enterprise developer instance created by the Amazon EC2 template, with software and configuration applied to the instance by State Manager. Enterprise developer instances connect to Micro Focus License Manager to activate their license.

### 3. CI/CD pipelines

As explained in AWS architecture section, in the pattern, there are project-level CI/CD pipelines and system integration pipelines. Each mainframe project team creates a pipeline or multiple CI/

CD pipelines for building the programs that they are developing in a project. These project CI/CD pipelines check out source code from an associated AccuRev stream.

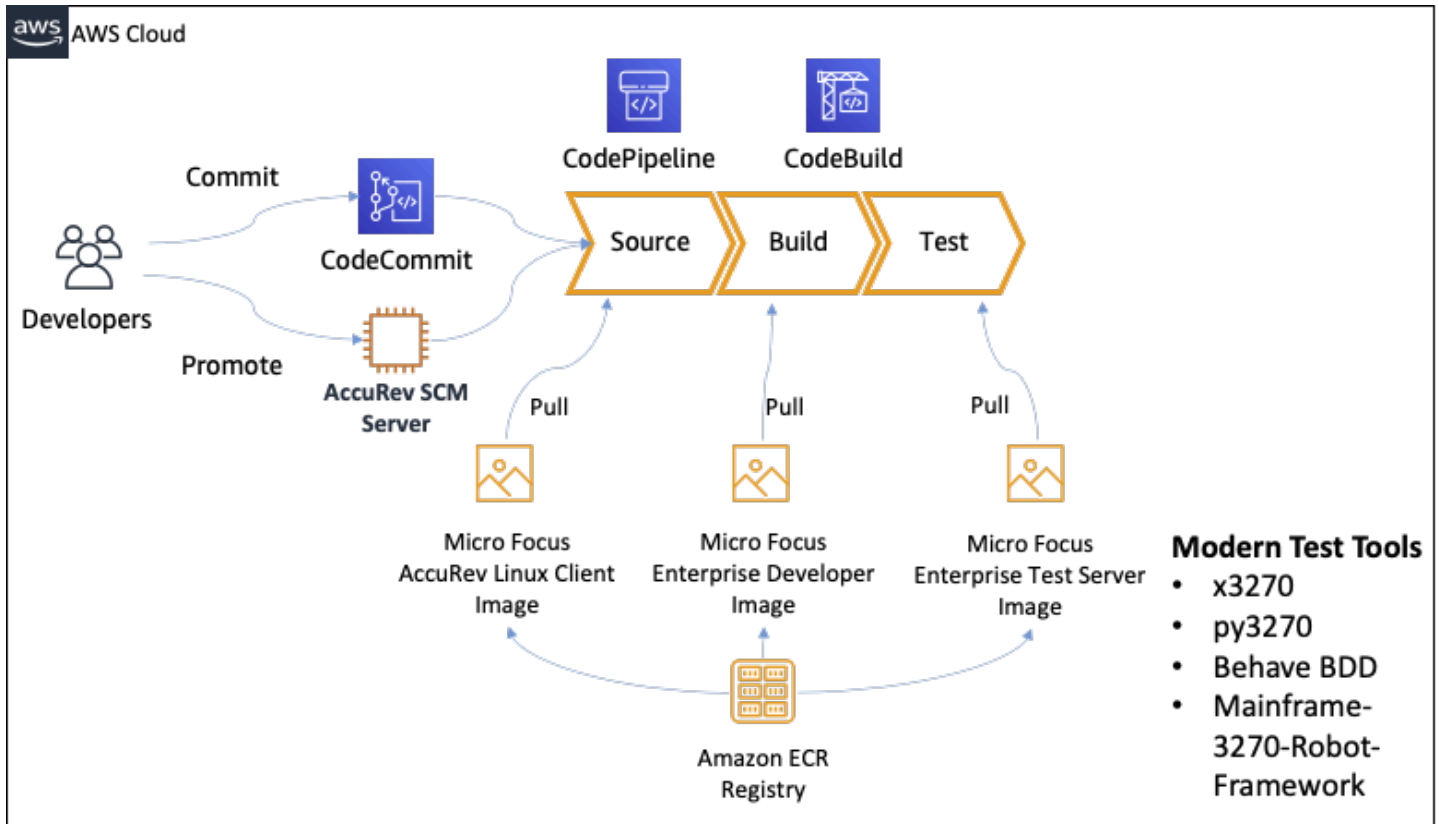

In a project team, developers promote their code in the associated AccuRev stream. Then the promotion initiates the project pipeline to build the code and run and integration tests.

Each project CI/CD pipeline uses CodeBuild projects with the Micro Focus Enterprise Developer tool Amazon ECR image and Micro Focus Enterprise Test Server tool Amazon ECR image.

CodePipeline and CodeBuild are used to create the CI/CDs pipelines. Because CodeBuild and CodePipeline have no upfront fees or commitments, you pay only for what you use. Compared to mainframe hardware, the AWS solution greatly reduces hardware provisioning lead time and lowers the cost of your testing environment.

In modern development, multiple test methodologies are used. For example, test-driven development (TDD), BDD, and Robot Framework. With this pattern, developers can use these modern tools for mainframe testing. For example, by using x3270, py3270 and the Behave python test tool, you can define an online application's behavior. You can also use build mainframe 3270 robot framework in these CI/CD pipelines.

The following diagram shows the team stream CI/CD pipeline.

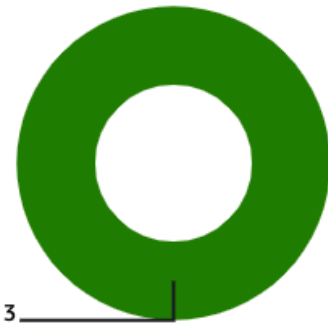

The following diagram shows the project CI/CD test report produced by CodePipeline in Mainframe3270 Robot Framework.

After project level tests are passed successfully, the tested code is manually promoted to the integration stream in AccuRev SCM. You can automate this step after the teams have a confidence on the tests coverage of their project pipeline.

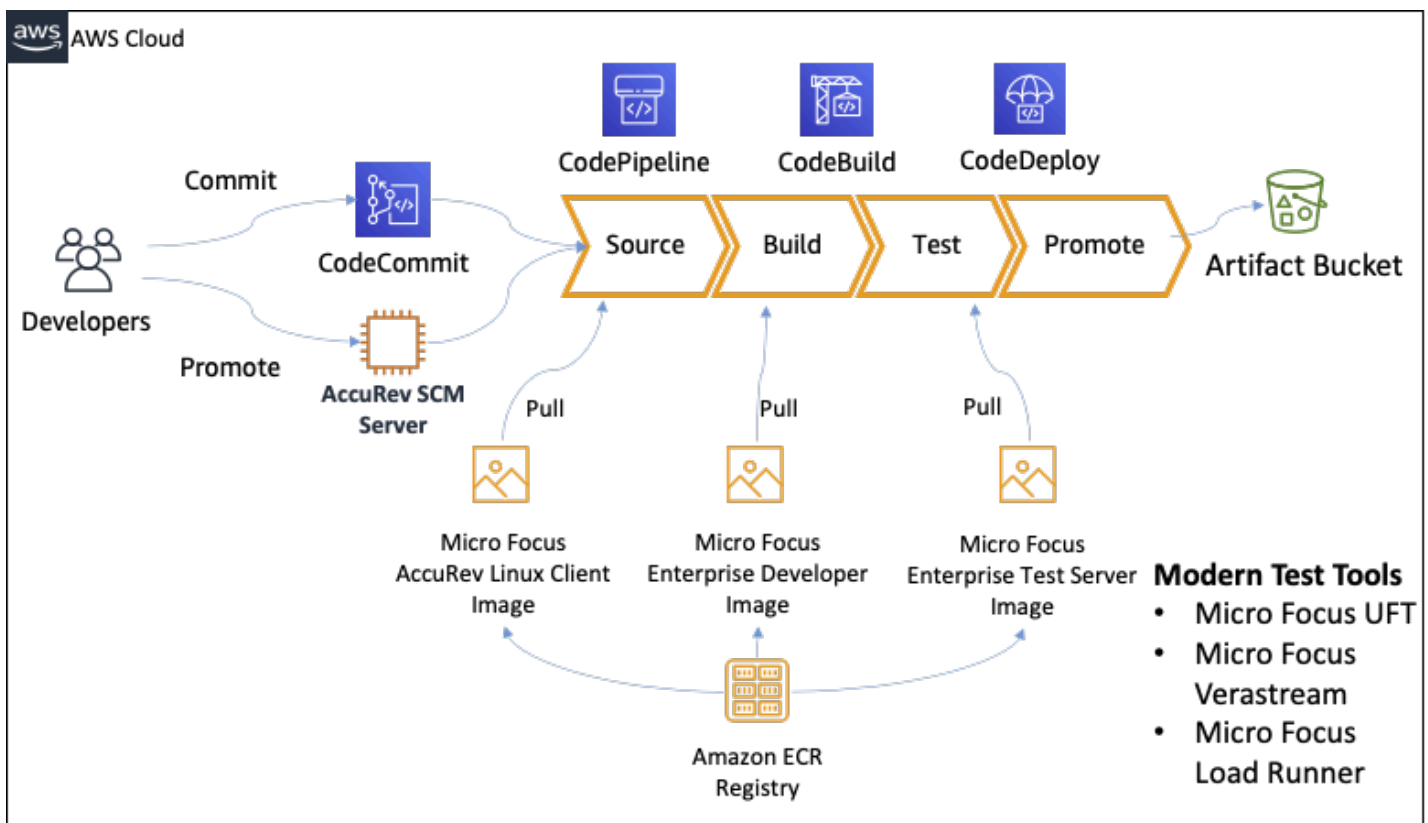

When code is promoted, the system integration CI/CD pipeline checks out the merged code and performs regression tests. The merged code is promoted from all parallel project streams.

Depending on how fine grain the test environment are required, customers can have more system integration CI/CD pipelines in different environment, for example UAT, Pre-Production.

In the pattern, the tools used in the system integration pipeline are Micro Focus Enterprise Test Server, Micro Focus UFT Server, and Micro Focus Verastream. All these tools can be deployed into the Docker container and used with CodeBuild.

After successfully testing of the mainframe programs, the artifact is stored, with version control, in an S3 bucket.

The following diagram shows a system integration CI/CD pipeline.

After the artifact has been successfully tested in the system integration CI/CD pipelines, it can be promoted for production deployment.

If you need to deploy source code back to the mainframe, Micro Focus offers the Enterprise Sync solution to synchronize source code from AccuRev back to Mainframe Endeavour.

The following diagram shows a production CI/CD pipeline deploying the artifact into Micro Focus Enterprise Servers. In this example, CodeDeploy orchestrates the deployment of the tested mainframe artifact into Micro Focus Enterprise Server.

In addition to the architecture walkthrough of the CI/CD pipeline, you can also read the AWS DevOps blog post [Automate thousands of mainframe tests on AWS with the Micro Focus Enterprise Suite](#) for more information on testing mainframe applications in CodeBuild and CodePipeline. Refer to the blog post for the best practices and details of doing mainframe tests on AWS.

# Preserve routable IP space in multi-account VPC designs for non-workload subnets

Created by Adam Spicer (AWS)

**Code repository:** [Non routable secondary CIDRs pattern](#)

**Environment:** Production

**Technologies:** Infrastructure; DevOps; Management & governance; Networking

**AWS services:** AWS Transit Gateway; Amazon VPC; Elastic Load Balancing (ELB)

## Summary

Amazon Web Services (AWS) has published best practices that recommend using dedicated subnets in a virtual private cloud (VPC) for both [transit gateway attachments](#) and [Gateway Load Balancer endpoints](#) (to support [AWS Network Firewall](#) or third-party appliances). These subnets are used to contain elastic network interfaces for these services. If you use both AWS Transit Gateway and a Gateway Load Balancer, two subnets are created in each Availability Zone for the VPC. Because of the way VPCs are designed, these extra subnets [can't be smaller than a /28 mask](#) and can consume precious routable IP space that could otherwise be used for routable workloads. This pattern demonstrates how you can use a secondary, non-routable Classless Inter-Domain Routing (CIDR) range for these dedicated subnets to help preserve routable IP space.

## Prerequisites and limitations

### Prerequisites

- [Multi-VPC strategy](#) for routable IP space
- A non-routable CIDR range for the services you're using ([transit gateway attachments](#) and [Gateway Load Balancer](#) or [Network Firewall endpoints](#))

## Architecture

### Target architecture

This pattern includes two reference architectures: one architecture has subnets for transit gateway (TGW) attachments and a Gateway Load Balancer endpoint (GWLBe), and the second architecture has subnets for TGW attachments only.

### Architecture 1 – TGW-attached VPC with ingress routing to an appliance

The following diagram represents a reference architecture for a VPC that spans two Availability Zones. On ingress, the VPC uses an [ingress routing pattern](#) to direct traffic destined for the public subnet to a [bump-in-the-wire appliance](#) for firewall inspection. A TGW attachment supports egress from the private subnets to a separate VPC.

This pattern uses a non-routable CIDR range for the TGW attachment subnet and the GWLBe subnet. In the TGW routing table, this non-routable CIDR is configured with a blackhole (static) route by using a set of more specific routes. If the routes were to get propagated to the TGW routing table, these more specific blackhole routes would apply.

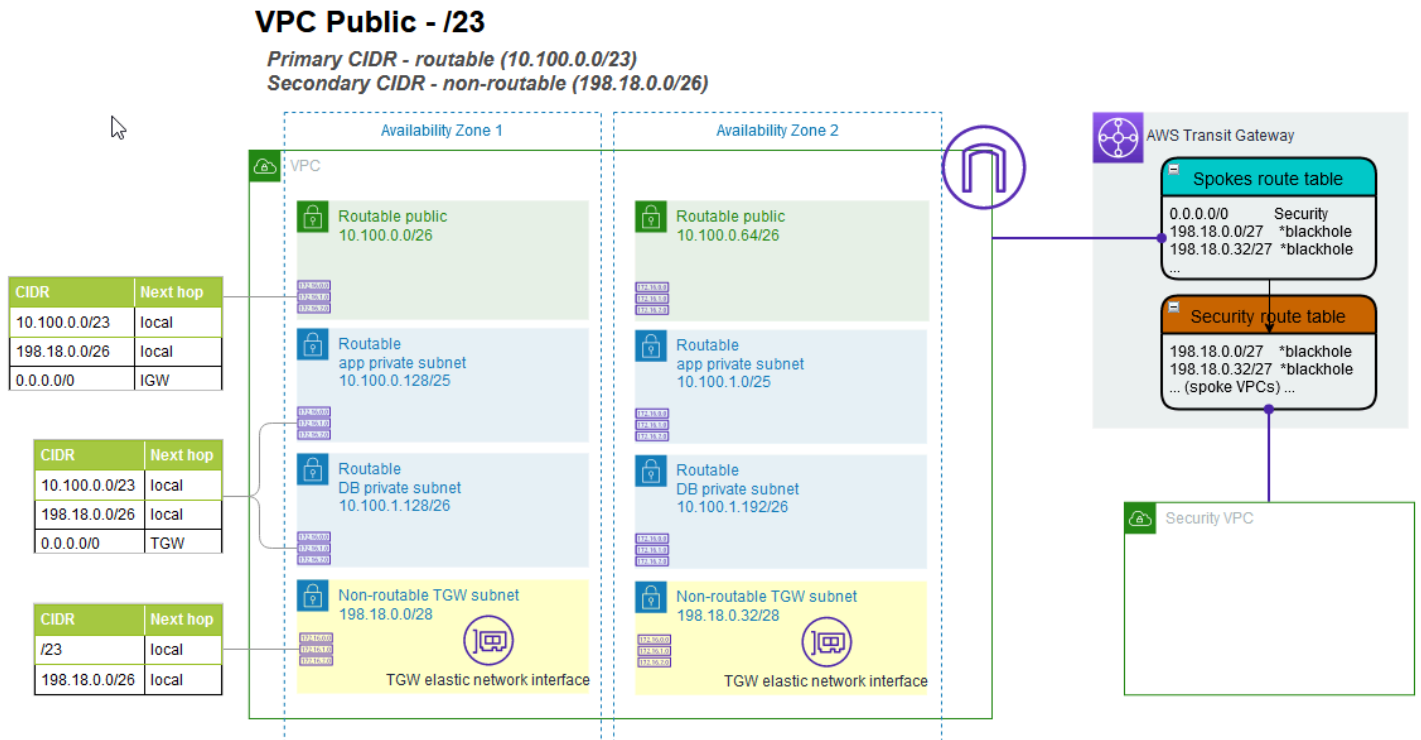

In this example, the /23 routable CIDR is divided up and fully allocated to routable subnets.

### Architecture 2 – TGW-attached VPC

The following diagram represents another reference architecture for a VPC that spans two Availability Zones. A TGW attachment supports outbound traffic (egress) from the private subnets to a separate VPC. It uses a non-routable CIDR range only for the TGW attachments subnet. In the TGW routing table, this non-routable CIDR is configured with a blackhole route by using a set of more specific routes. If the routes were to get propagated to the TGW routing table, these more specific blackhole routes would apply.

In this example, the /23 routable CIDR is divided up and fully allocated to routable subnets.

## Tools

### AWS services and resources

- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. In this pattern, VPC secondary CIDRs are used to preserve routable IP space in workload CIDRs.
- [Internet gateway ingress routing](#) (edge associations) can be used along with Gateway Load Balancer endpoints for dedicated non-routable subnets.

- [AWS Transit Gateway](#) is a central hub that connects VPCs and on-premises networks. In this pattern, VPCs are centrally attached to a transit gateway, and the transit gateway attachments are in a dedicated non-routable subnet.
- [Gateway Load Balancers](#) help you deploy, scale, and manage virtual appliances, such as firewalls, intrusion detection and prevention systems, and deep packet inspection systems. The gateway serves as a single entry and exit point for all traffic. In this pattern, endpoints for a Gateway Load Balancer can be used in a dedicated non-routable subnet.
- [AWS Network Firewall](#) is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud. In this pattern, endpoints for an firewall can be used in a dedicated non-routable subnet.

## Code repository

A runbook and AWS CloudFormation templates for this pattern are available in the GitHub [Non-Routable Secondary CIDR Patterns](#) repository. You can use the sample files to set up a working lab in your environment.

## Best practices

### AWS Transit Gateway

- Use a separate subnet for each transit gateway VPC attachment.
- Allocate a /28 subnet from the secondary non-routable CIDR range for the transit gateway attachment subnets.
- In each transit gateway routing table, add a static, more specific route for the non-routable CIDR range as a blackhole.

### Gateway Load Balancer and ingress routing

- Use ingress routing to direct traffic from the internet to the Gateway Load Balancer endpoints.
- Use a separate subnet for each Gateway Load Balancer endpoint.
- Allocate a /28 subnet from the secondary non-routable CIDR range for the Gateway Load Balancer endpoint subnets.

# Epics

## Create VPCs

Task	Description	Skills required
Determine non-routable CIDR range.	Determine a non-routable CIDR range that will be used for the transit gateway attachment subnet and (optionally) for any Gateway Load Balancer or Network Firewall endpoint subnets. This CIDR range will be used as the secondary CIDR for the VPC. It must <b>not be routable</b> from the VPC's primary CIDR range or the larger network.	Cloud architect
Determine routable CIDR ranges for VPCs.	Determine a set of routable CIDR ranges that will be used for your VPCs. This CIDR range will be used as the primary CIDR for your VPCs.	Cloud architect
Create VPCs.	Create your VPCs and attach them to the transit gateway. Each VPC should have a primary CIDR range that is routable and a secondary CIDR range that is non-routable, based on the ranges you determined in the previous two steps.	Cloud architect

## Configure Transit Gateway blackhole routes

Task	Description	Skills required
Create more specific non-routable CIDRs as blackholes.	Each transit gateway routing table needs to have a set of blackhole routes created for the non-routable CIDRs. These are configured to ensure that any traffic from the secondary VPC CIDR remains non-routable and doesn't leak into the larger network. These routes should be more specific than the non-routable CIDR that is set as the secondary CIDR on the VPC. For example, if the secondary non-routable CIDR is 100.64.0.0/26, the blackhole routes in the transit gateway routing table should be 100.64.0.0/27 and 100.64.0.32/27.	Cloud architect

## Related resources

- [Best practices for deploying Gateway Load Balancer](#)
- [Distributed Inspection Architectures with Gateway Load Balancer](#)
- [Networking Immersion Day – Internet to VPC Firewall Lab](#)
- [Transit gateway design best practices](#)

## Additional information

The non-routable secondary CIDR range can also be useful when working with larger scaled container deployments that require a large set of IP addresses. You can use this pattern with a private NAT Gateway to use a non-routable subnet to host your container deployments. For more information, see the blog post [How to solve Private IP exhaustion with Private NAT Solution](#).

# Provision a Terraform product in AWS Service Catalog by using a code repository

Created by Dr. Rahul Sharad Gaikwad (AWS) and Tamilselvan P (AWS)

<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Infrastructure; DevOps	<b>Workload:</b> All other workloads
<b>AWS services:</b> AWS Service Catalog; Amazon EC2		

## Summary

AWS Service Catalog supports self-service provisioning with governance for your [HashiCorp Terraform](#) configurations. If you use Terraform, you can use Service Catalog as the single tool to organize, govern, and distribute your Terraform configurations within AWS at scale. You can access Service Catalog key features, including cataloging of standardized and pre-approved infrastructure as code (IaC) templates, access control, cloud resources provisioning with least privilege access, versioning, sharing to thousands of AWS accounts, and tagging. End users, such as engineers, database administrators, and data scientists, see a list of products and versions they have access to, and they can deploy them through a single action.

This pattern helps you deploy AWS resources by using Terraform code. The Terraform code in the GitHub repository is accessed through Service Catalog. Using this approach, you integrate the products with your existing Terraform workflows. Administrators can create Service Catalog portfolios and add AWS Launch Wizard products to them by using Terraform.

The following are the benefits of this solution:

- Because of the rollback feature in Service Catalog, if any issues occur during deployment, you can revert the product to a previous version.
- You can easily identify the differences between product versions. This helps you resolve issues during deployment.
- You can configure a repository connection in Service Catalogue, such as to GitHub, GitLab, or AWS CodeCommit. You can make product changes directly through the repository.

For information about the overall benefits of AWS Service Catalog, see [What is Service Catalog](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A GitHub, BitBucket, or other repository that contains Terraform configuration files in ZIP format.
- AWS Serverless Application Model Command Line Interface (AWS SAM CLI), [installed](#).
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#).
- Go, [installed](#).
- Python version 3.9 , [installed](#). AWS SAM CLI requires this version of Python.
- Permissions to write and run AWS Lambda functions and permissions to access and manage Service Catalog products and portfolios.

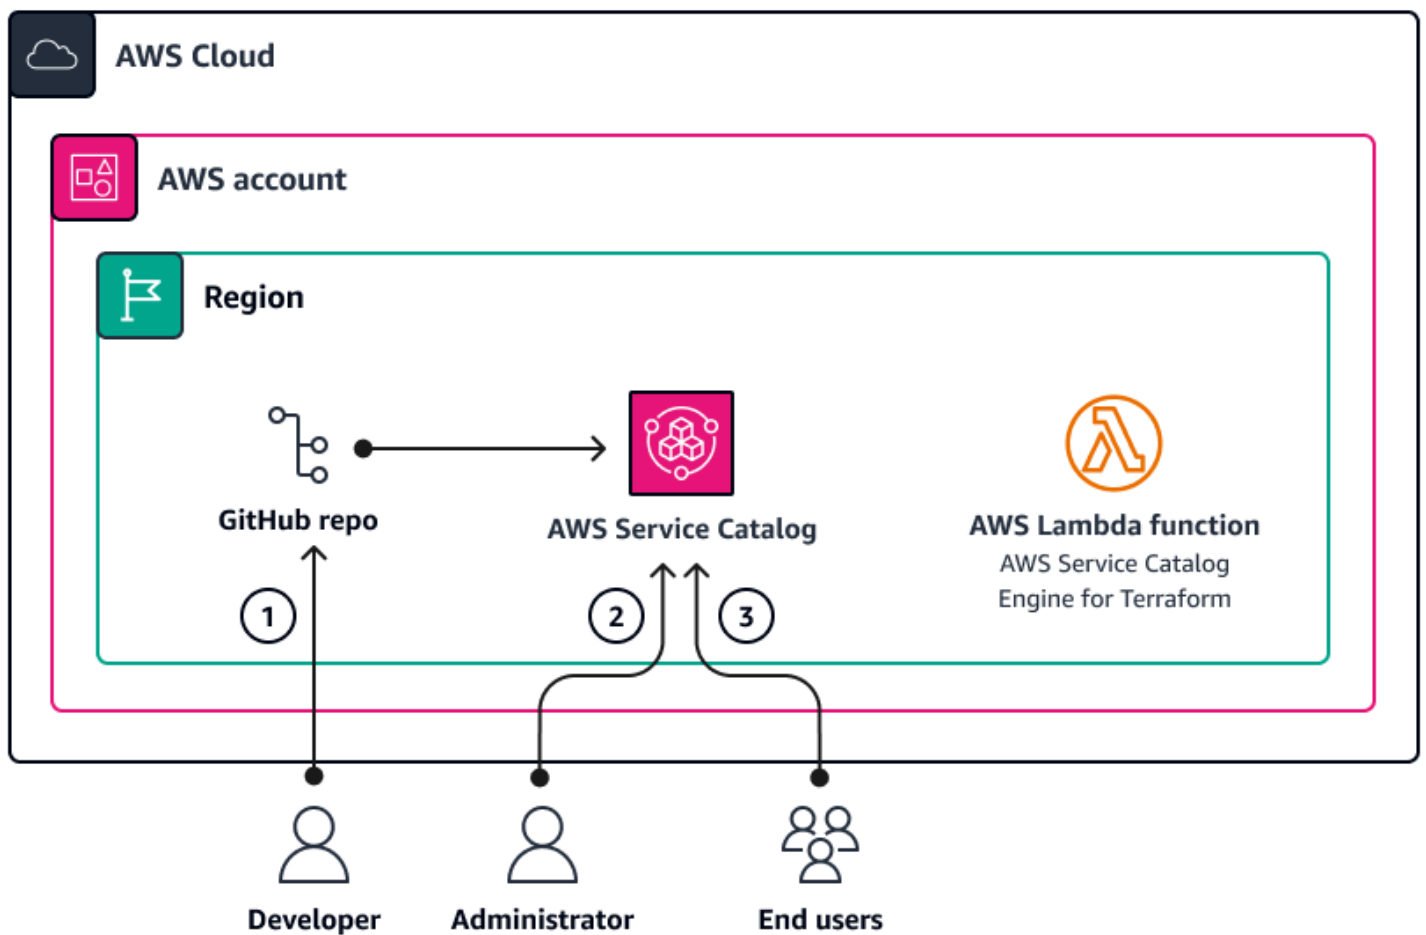

## Architecture

### Target technology stack

- AWS Service Catalog
- AWS Lambda

### Target architecture

The diagram shows the following workflow:

1. When a Terraform configuration is ready, a developer creates a .zip file that contains all of the terraform code. The developer uploads the .zip file into the code repository that is connected to Service Catalog.
2. An administrator associates the Terraform product to a portfolio in Service Catalog. The administrator also creates a launch constraint that allows end users to provision the product.
3. In Service Catalog, end users launch AWS resources by using the Terraform configuration. They can choose which product version to deploy.

## Tools

### AWS services and tools

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Service Catalog](#) helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

## Other services

- [Go](#) is an open source programming language that Google supports.
- [Python](#) is a general-purpose computer programming language.

## Code repository

If you require sample Terraform configurations that you can deploy through Service Catalog, you can use the configurations in the GitHub [Amazon Macie Organization Setup Using Terraform](#) repository. Use of the code samples in this repository is not required.

## Best practices

- Instead of providing the values for variables in the Terraform configuration file (`terraform.tfvars`), configure variable values when launching product through Service Catalog.
- Grant access to the portfolio only to specific users or administrators.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see [Grant least privilege](#) and [Security best practices](#) in the IAM documentation.

## Epics

### Set up your local workstation

Task	Description	Skills required
(Optional) Install Docker.	If you want to run the AWS Lambda functions in your	DevOps engineer

Task	Description	Skills required
	<p>development environment, install Docker. For instructions, see <a href="#">Install Docker Engine</a> in the Docker documentation.</p>	
Install the AWS Service Catalog Engine for Terraform.	<ol style="list-style-type: none"><li>1. Enter the following command to clone the <a href="#">AWS Service Catalog Engine for Terraform</a> repository. <pre>git clone https://github.com/aws-samples/service-catalog-engine-for-terraform-os.git</pre></li><li>2. Navigate to the the root directory of the cloned repository.</li><li>3. Enter the following command. This installs the engine. <pre>run ./bin/bash/deploy-tre.sh -r</pre></li></ol> <p>The AWS Region set in your default profile is not used during the automated installation. Instead, you provide the Region when you run this command.</p>	DevOps engineer, AWS administrator

## Connect the GitHub repository

Task	Description	Skills required
Create a connection to the GitHub repository.	<ol style="list-style-type: none"><li data-bbox="592 331 1027 793">1. Sign in to the AWS Management Console, and then open the <b>Developer Tools</b> console. You can access the Developer Tools console by choosing a service such as AWS CodePipeline, AWS CodeCommit, or AWS CodeDeploy.</li><li data-bbox="592 821 1027 947">2. In the left navigation pane, choose <b>Settings</b>, and then choose <b>Connections</b>.</li><li data-bbox="592 974 1027 1010">3. Choose <b>Create connection</b>.</li><li data-bbox="592 1037 1027 1304">4. Select the repository where you maintain the Terraform source code. For example, you can choose <b>Bitbucket</b>, <b>GitHub</b>, or <b>GitHub Enterprise Server</b>.</li><li data-bbox="592 1331 1027 1457">5. Enter a name for the connection, and then choose <b>Connect</b>.</li><li data-bbox="592 1484 1027 1610">6. When you are prompted, authenticate the repository.</li></ol> <p data-bbox="630 1654 998 1829">After authentication is complete, the connection is created and the status changes to <b>active</b>.</p>	AWS administrator

## Create a Terraform product in Service Catalog

Task	Description	Skills required
Create the Service Catalog product.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Service Catalog console</a>.</li><li>2. Navigate to the <b>Administration</b> section, and then choose <b>Product list</b>.</li><li>3. Choose <b>Create product</b>.</li><li>4. On the <b>Create product</b> page in the <b>Product details</b> section, choose the <b>External</b> product type. Service Catalog uses this product type to support Terraform Community Edition products.</li><li>5. Enter a name and owner for the Service Catalog product.</li><li>6. Select <b>Specify your code repository using a CodeStar provider</b>.</li><li>7. Enter the following information for your repository:<ul style="list-style-type: none"><li>• <b>Connect to your provider using AWS CodeConnections</b> – Select the connection you created previously.</li><li>• <b>Repository</b> – Select the repository.</li></ul></li></ol>	AWS administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• <b>Branch</b> – Select the branch.</li> <li>• <b>Template file path</b> – Choose the path where the code template file is stored. The file name should end with <code>tar.gz</code>.</li> </ul> <p>8. Under <b>Version name and description</b>, provide information about the product version.</p> <p>9. Choose <b>Create product</b>.</p>	
Create a portfolio.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">AWS Service Catalog console</a>.</li> <li>2. Navigate to the <b>Administration</b> section, and then choose, choose <b>Portfolios</b>.</li> <li>3. Choose <b>Create portfolio</b></li> <li>4. Enter the following values: <ul style="list-style-type: none"> <li>• <b>Portfolio name</b> – Sample terraform</li> <li>• <b>Portfolio description</b> – Sample portfolio for Terraform configurations</li> <li>• <b>Owner</b> – Your contact information, such as email</li> </ul> </li> <li>5. Choose <b>Create</b>.</li> </ol>	AWS administrator

Task	Description	Skills required
Add the Terraform product to the portfolio.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Service Catalog console</a>.</li><li>2. Navigate to the <b>Administration</b> section, and then choose <b>Product list</b>.</li><li>3. Select the Terraform product that you created previously.</li><li>4. Choose <b>Actions</b>, and then choose <b>Add product to portfolio</b>.</li><li>5. Choose the Sample terraform portfolio.</li><li>6. Choose <b>Add product to portfolio</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Create the access policy.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Identity and Access Management (IAM) console</a>.</li><li>2. In the navigation pane, choose <b>Policies</b>.</li><li>3. In the content pane, choose <b>Create policy</b>.</li><li>4. Choose the <b>JSON</b> option.</li><li>5. Enter the sample JSON policy in <i>Access policy</i> in the <a href="#">Additional information</a> section of this pattern.</li><li>6. Choose <b>Next</b>.</li><li>7. On the <b>Review and create</b> page, in the <b>Policy name</b> box, enter Terraform ResourceCreationAndArtifactAccessPolicy .</li><li>8. Choose <b>Create policy</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Create a custom trust policy.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Identity and Access Management (IAM) console</a>.</li><li>2. In the navigation pane, choose <b>Roles</b>.</li><li>3. Choose <b>Create role</b>.</li><li>4. Under <b>Trusted entity type</b>, choose <b>Custom trust policy</b>.</li><li>5. In the JSON policy editor, enter the sample JSON policy in <i>Trust policy</i> in the <a href="#">Additional information</a> section of this pattern.</li><li>6. Choose <b>Next</b>.</li><li>7. Under <b>Permissions policies</b>, choose the <code>TerraformResourceCreationAndArtifactAccessPolicy</code> that you previously created.</li><li>8. Choose <b>Next</b>.</li><li>9. Under <b>Role details</b>, in the <b>Role name</b> box, enter <code>SCLaunch-product</code> .  <b>Important:</b> The role name must begin with <code>SCLaunch</code>.</li><li>10. Choose <b>Create role</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Add a launch constraint to the Service Catalog product.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console as a user with administrative permissions.</li><li>2. Open the <a href="#">AWS Service Catalog console</a>.</li><li>3. In the navigation pane, choose <b>Portfolios</b>.</li><li>4. Choose the portfolio that you created previously.</li><li>5. On the <b>Portfolio details</b> page, choose the <b>Constraints</b> tab, and then choose <b>Create constraint</b>.</li><li>6. For <b>Product</b>, select the Terraform product you created previously.</li><li>7. Under <b>Launch constraint</b>, for <b>Method</b>, choose <b>Enter role name</b>.</li><li>8. In the <b>Role name</b> box, enter SCLaunch-product .</li><li>9. Choose <b>Create</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Grant access to the product.	<ol style="list-style-type: none"><li>1. Open the <a href="#">AWS Service Catalog console</a>.</li><li>2. In the navigation pane, choose <b>Portfolios</b>.</li><li>3. Choose the portfolio that you created previously.</li><li>4. Choose the <b>Access</b> tab, and then choose <b>Grant access</b>.</li><li>5. Choose the <b>Roles</b> tab, and then select the role that should have access to deploy this product.</li><li>6. Choose <b>Grant Access</b>.</li></ol>	AWS administrator
Launch the product.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console as a user with permissions to deploy the Service Catalog product.</li><li>2. Open the <a href="#">AWS Service Catalog console</a>.</li><li>3. In the navigation pane, choose <b>Products</b>.</li><li>4. Choose the produce you created previously, and then choose <b>Launch product</b>.</li><li>5. Enter a product name and define any required parameters.</li><li>6. Choose <b>Launch product</b>.</li></ol>	DevOps engineer

## Verify the deployment

Task	Description	Skills required
Validate the deployment.	<p>There are two AWS Step Functions state machines for the Service Catalog provisioning workflow:</p> <ul style="list-style-type: none"><li>• <code>ManageProvisionedProductStateMachine</code><ul style="list-style-type: none"><li>–Service Catalog invokes this state machine when provisioning a new Terraform product and when updating an existing Terraform provisioned product.</li></ul></li><li>• <code>TerminateProvisionedProductStateMachine</code><ul style="list-style-type: none"><li>–Service Catalog invokes this state machine when terminating an existing Terraform provisioned product.</li></ul></li></ul> <p>You check the logs for the <code>ManageProvisionedProductStateMachine</code> state machine to confirm that the product was provisioned.</p> <ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console, and then open the <a href="#">AWS Step Functions console</a>.</li></ol>	DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>2. In the left navigation pane, choose <b>State machines</b>.</li> <li>3. Choose Manage ProvisionedProductStateMachine .</li> <li>4. In the <b>Executions</b> list, enter the provisioned product ID to locate the execution.  <b>Note:</b> The state file backend bucket names start with <code>sc-terraform-engine-state-</code> .</li> <li>5. Validate that all the required resources have been created in the account.</li> </ol>	

## Clean up infrastructure

Task	Description	Skills required
Delete provisioned products.	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console as a user with permissions to deploy the Service Catalog product.</li> <li>2. Open the <a href="#">AWS Service Catalog console</a>.</li> <li>3. In the left navigation, choose <b>Provisioned products</b>.</li> </ol>	DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"><li>4. Select the product you created.</li><li>5. In the <b>Actions</b> list, choose <b>Terminate</b>.</li><li>6. In the confirmation text box, enter <code>terminate</code> , and then choose <b>Terminate provisioned product</b>.</li><li>7. Repeat these steps to terminate all provisioned products.</li></ol>	

Task	Description	Skills required
Remove the AWS Service Catalog Engine for Terraform.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console as a user with administrative permissions.</li><li>2. Open the <a href="#">Amazon S3 console</a>.</li><li>3. In the navigation pane, choose <b>Buckets</b>.</li><li>4. Select the <code>sc-terraform-engine-logging-XXXX</code> bucket.</li><li>5. Choose <b>Empty</b>.</li><li>6. Repeat steps 4–5 for the following buckets:<ul style="list-style-type: none"><li>• <code>sc-terraform-engine-state-XXXX</code></li><li>• <code>terraform-engine-bootstrap-XXXX</code></li></ul></li><li>7. Open the <a href="#">AWS CloudFormation console</a>, and then validate you're in the correct AWS Region.</li><li>8. In the left navigation, choose <b>Stacks</b>.</li><li>9. Select SAM-TRE, and then choose <b>Delete</b>. Wait until the stack has been deleted.</li><li>10. Select Bootstrap-TRE, and then choose <b>Delete</b>. Wait until the stack has been deleted.</li></ol>	AWS administrator

# Register multiple AWS accounts with a single email address by using Amazon SES

Created by Joe Wozniak (AWS) and Shubhangi Vishwakarma (AWS)

**Code repository:** [GitHub aws-account-factory-email](#)

**Environment:** PoC or pilot

**Technologies:** Infrastructure; Management & governance; Messaging & communications

**AWS services:** AWS Lambda; Amazon SES; Amazon DynamoDB

## Summary

This pattern describes how you can decouple real email addresses from the email address that's associated with an AWS account. AWS accounts require a unique email address to be provided at the time of account creation. In some organizations, the team that manages AWS accounts must take on the burden of managing many unique email addresses with their messaging team. This can be difficult for large organizations that manage many AWS accounts.

This pattern provides a unique email address vending solution that enables AWS account owners to associate one email address with multiple AWS accounts. The real email addresses of AWS account owners are then associated with these generated email addresses in a table. The solution handles all incoming email for the unique email accounts, looks up the owner of each account, and then forwards any received messages to the owner.

## Prerequisites and limitations

### Prerequisites

- Administrative access to an AWS account.
- Access to a development environment. We recommend that you use AWS Cloud9 to avoid having to set up the needed tools and access keys yourself.
- (Optional) Familiarity with AWS Cloud Development Kit (AWS CDK) workflows and the Python programming language will help you troubleshoot any issues or make modifications.

## Limitations

- Overall vended email address length of 64 characters. For details, see [CreateAccount](#) in the *AWS Organizations API reference*.

## Product versions

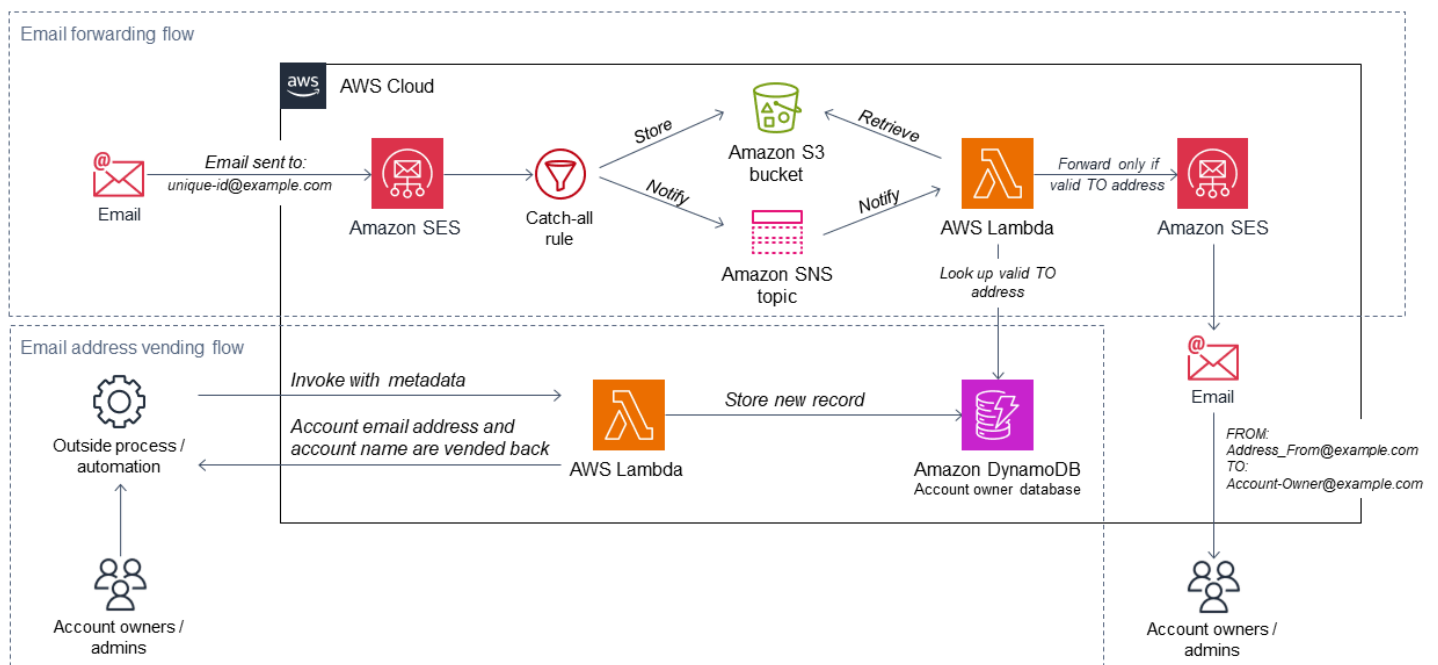

- Node.js version 12.7.0 or later
- Python 3.9 or later
- Python packages **pip** and **virtualenv**
- AWS CDK version 2.23.0 or later
- Docker 20.10.x or later

## Architecture

### Target technology stack

- AWS CloudFormation stack
- AWS Lambda functions
- Amazon Simple Email Address (Amazon SES) rule and rule set
- AWS Identity and Access Management (IAM) roles and policies
- Amazon Simple Storage Service (Amazon S3) bucket and bucket policy
- AWS Key Management Service (AWS KMS) key and key policy
- Amazon Simple Notification Service (Amazon SNS) topic and topic policy
- Amazon DynamoDB table

### Target architecture

This diagram shows two flows:

- Email address vending flow:** In the diagram, the email address vending flow (lower section) begins typically with an account vending solution or outside automation, or is invoked manually. In the request, a Lambda function is called with a payload that contains the needed metadata. The function uses this information to generate a unique account name and email address, stores it in a DynamoDB database, and returns the values to the caller. These values can then be used to create a new AWS account (typically by using AWS Organizations).
- Email forwarding flow:** This flow is illustrated in the upper section of the previous diagram. When an AWS account is created by using the account email generated from the email address vending flow, AWS sends various emails, such as account registration confirmation and periodic notifications, to that email address. By following the steps in this pattern, you configure your AWS account with Amazon SES to receive emails for the entire domain. This solution configures forwarding rules that allow Lambda to process all incoming emails, check to see if the TO address is in the DynamoDB table, and forward the message to the account owner's email address instead. Using this process gives account owners the ability to associate multiple accounts with one email address.

## Automation and scale

This pattern uses the AWS CDK to fully automate the deployment. The solution uses AWS managed services that will (or can be configured to) scale automatically to meet your needs. The Lambda functions might require additional configuration to meet your scaling needs. For more information, see [Lambda function scaling](#) in the Lambda documentation.

## Tools

### AWS services

- [AWS Cloud9](#) is an integrated development environment (IDE) that helps you code, build, run, test, and debug software. It also helps you release software to the AWS Cloud.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Email Service \(Amazon SES\)](#) helps you send and receive emails by using your own email addresses and domains.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Tools needed for deployment

- Development environment with the AWS CLI and IAM access to your AWS account. For details, see the links in the [Related resources](#) section. We recommend that you use AWS Cloud9 to simplify the setup process.
- If you use AWS Cloud9, the following will be configured for you. If you choose not to use AWS Cloud9, you will need to install the following:
  - The AWS CLI to configure access credentials for the AWS CDK. For more information, see the [AWS CLI documentation](#).
  - Python version 3.9 or later
  - Python packages **pip** and **virtualenv**
  - Node.js version 12.7.0 or later
  - AWS CDK version 2.23.0 or later
  - Docker version 20.10.x or later

## Code

The code for this pattern is available in the GitHub [AWS account factory email](#) repository.

## Epics

### Allocate a target deployment environment

Task	Description	Skills required
Identify or create an AWS account.	Identify an existing or new AWS account to which you have full administrative access, to deploy the email solution.	AWS administrator, Cloud administrator
Set up a deployment environment.	Configure an easy to use deployment environment and set up dependencies by following these steps: <ol style="list-style-type: none"> <li>1. Deploy an instance of AWS Cloud9 as a dedicated</li> </ol>	AWS DevOps, App developer

Task	Description	Skills required
	<p>deployment environment. For instructions, see <a href="#">Getting started with AWS Cloud9</a>.</p> <p>2. Clone the GitHub <a href="#">AWS account factory email</a> repository code base to the AWS Cloud9 instance by using the command:</p> <pre data-bbox="634 674 1027 871">git clone https://github.com/aws-samples/aws-account-factory-email</pre> <p>3. In the <code>requirements.txt</code> file (in the root of the repository), update the line that starts with <code>aws-cdk-lib==</code> to match the version of the AWS CDK that's running in your environment. To identify the version, use the <code>cdk --version</code> command.</p>	

## Set up a verified domain

Task	Description	Skills required
Identify and allocate a domain.	The email forwarding functionality requires a dedicated domain. Identify and allocate a domain or	Cloud administrator, Network administrator, DNS administrator

Task	Description	Skills required
	<p>subdomain that you can be verify with Amazon SES. This domain should be available to receive incoming email within the AWS account where the email forwarding solution is deployed.</p> <p>Domain requirements:</p> <ul style="list-style-type: none"><li>• The domain should be a standard domain or subdomain.</li><li>• The domain should be externally DNS resolvable because it will be used to receive emails from outside the organization.</li></ul>	
Verify the domain.	<p>Verify that the identified domain can be used to accept incoming email.</p> <p>Complete the instructions in <a href="#">Verifying your domain for Amazon SES email receiving</a> in the Amazon SES documentation. This will require coordination with the person or team who is responsible for the domain's DNS records.</p>	App developer, AWS DevOps

Task	Description	Skills required
Set up MX records.	Set up your domain with MX records that point to the Amazon SES endpoints in your AWS account and Region. For more information, see <a href="#">Publishing an MX record for Amazon SES email receiving</a> in the Amazon SES documentation.	Cloud administrator, Network administrator, DNS administrator

## Deploy the email vending and forwarding solution

Task	Description	Skills required
Modify the default values in cdk.json.	<p>Edit some of the default values in the <code>cdk.json</code> file (in the root of the repository) so that the solution will operate correctly after it is deployed.</p> <ol style="list-style-type: none"><li>1. Modify the <code>SES_DOMAIN_NAME</code> value to match the domain name you verified previously.</li><li>2. Modify the <code>ADDRESS_FROM</code> value to include the same domain that is in <code>SES_DOMAIN_NAME</code>. The local part of the address should be determined by your cloud team. This address becomes the <code>FROM</code> address for every email</li></ol>	App developer, AWS DevOps

Task	Description	Skills required
	<p>that's forwarded through the solution.</p> <p>3. Modify the ADDRESS_ADMIN value to match the email address that any non-matching incoming messages will be forwarded to. This value must be a valid and operating email address.</p>	

Task	Description	Skills required
Deploy the email vending and forwarding solution.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 426">1. Create a Python virtual environment: <pre data-bbox="634 348 1027 426">python -m venv .venv</pre></li><li data-bbox="591 443 1027 680">2. Activate the Python virtual environment: <pre data-bbox="634 562 1027 680">source .venv/bin/activate</pre><p data-bbox="630 720 919 800">Or, on the Windows platform, use:</p><pre data-bbox="634 842 1027 959">% .venv\Scripts\activate.bat</pre></li><li data-bbox="591 976 1027 1255">3. Install all Python requirements with no errors: <pre data-bbox="634 1142 1027 1255">pip install -r requirements.txt</pre></li><li data-bbox="591 1272 1027 1472">4. Synthesize the CloudFormation template: <pre data-bbox="634 1398 1027 1472">cdk synth</pre><p data-bbox="630 1514 1005 1738">Confirm that there are no errors and that the full CloudFormation template contains the expected output.</p></li><li data-bbox="591 1755 1027 1845">5. (Optional) If you are deploying the AWS CDK</li></ol>	App developer, AWS DevOps

Task	Description	Skills required
	<p>code into the current AWS account or Region for the first time, bootstrap the environment. For more information, see <a href="#">Bootstrap ping</a> in the AWS CDK documentation.</p> <pre>cdk bootstrap aws:// AWS-ACCOUNT-NUMBER/ REGION</pre> <p>Replace <code>AWS-ACCOUNT-NUMBER</code> and <code>REGION</code> with actual values.</p> <p>6. Deploy the solution:</p> <pre>cdk bootstrap cdk deploy</pre> <p>The commands should complete without errors.</p>	

Task	Description	Skills required
Verify that the solution has been deployed.	<p>Verify that the solution deployed successfully before you begin testing:</p> <ol style="list-style-type: none"> <li>1. Open the <a href="#">AWS CloudFormation console</a> and look for a CloudFormation stack that contains the name <code>AwsMailFwdStack</code> .</li> <li>2. Confirm that this <code>AwsMailFwdStack</code> stack has the following resources : <ul style="list-style-type: none"> <li>• Lambda functions</li> <li>• Amazon SES rule and rule set</li> <li>• IAM roles and policies</li> <li>• Amazon S3 bucket and bucket policy</li> <li>• AWS KMS key and key policy</li> <li>• Amazon SNS topic and topic policy</li> <li>• DynamoDB table</li> </ul> </li> </ol>	App developer, AWS DevOps

### Verify that email vending and forwarding operate as expected

Task	Description	Skills required
Verify that the API is working.	In this step, you submit test data to the solution's API and confirm that the solution produces the expected output	App developer, AWS DevOps

Task	Description	Skills required
	<p>and that backend operations have been performed as expected.</p> <p>Manually run the <b>Vend Email</b> Lambda function by using test input. (For an example, see the <a href="#">sample_vend_request.json file</a>.) For <code>OwnerAddress</code>, use a valid email address. The API should return an account name and account email with values as expected.</p>	

Task	Description	Skills required
Verify that email is being forwarded.	<p>In this step, you send a test email through the system and verify that the email is forwarded to the expected recipient.</p> <ol style="list-style-type: none"><li>1. Obtain the account email from the last step.</li><li>2. Send an email to this address with a test subject and body text.</li><li>3. Confirm that you received the email at the account owner's email address.</li><li>4. Confirm that the email you received has a FROM address that matches the ADDRESS_FROM setting in <code>cdk.json</code>.</li><li>5. Confirm that the received email's subject and body are the same as the original sent message.</li></ol>	App developer, AWS DevOps

## Troubleshooting

Issue	Solution
The system doesn't forward email as expected.	<p>Verify that your setup is correct:</p> <ol style="list-style-type: none"><li>1. You should have completed the Amazon SES <a href="#">verification process</a> for your domain.</li></ol>

Issue	Solution
	<ol style="list-style-type: none"><li data-bbox="829 212 1507 485">2. Your domain should be set up properly with MX records pointing to the Amazon SES endpoints in your AWS account and Region. For more information, see <a href="#">Publishing an MX record for Amazon SES email receiving</a> in the Amazon SES documentation.</li></ol> <p data-bbox="829 562 1446 646">After you verify your domain setup, follow these steps:</p> <ol style="list-style-type: none"><li data-bbox="829 688 1490 867">1. Open the <a href="#">AWS CloudWatch console</a> for the account and Region where you deployed the solution, and navigate to CloudWatch log groups in the navigation pane.</li><li data-bbox="829 888 1507 972">2. Search the list of log groups for <code>SesMailForwardLogGroup</code> .</li><li data-bbox="829 993 1474 1129">3. Investigate the logs in this group to see if any errors are generated during the email vending and forwarding process.</li></ol>

Issue	Solution
<p>When you try to deploy the AWS CDK stack, you receive an error similar to:</p> <p>“Template format error: Unrecognized resource types”</p>	<p>In most instances, this error message means that the Region you’re targeting doesn’t have all the available AWS services. If you’re using AWS Cloud9 to deploy the solution, you might be targeting a Region that is different from the Region where the AWS Cloud9 instance is running.</p> <p><b>Note:</b> By default, the AWS CDK deploys to the Region and account that you configured in the AWS CLI.</p> <p>Possible solutions:</p> <ol style="list-style-type: none"><li>1. Investigate if all the services needed for this solution (see the <a href="#">Target technology stack</a> section earlier in this pattern) are in the AWS Region you are targeting by reviewing <a href="#">AWS Services by Region</a>.</li><li>2. If you are using AWS Cloud9 and targeting a Region that’s different from the Region where your AWS Cloud9 instance is running, make sure to set the <code>AWS_DEFAULT_REGION</code> environment variable, or set a Region with the AWS CLI before you deploy the solution. For more information, see the <a href="#">Environment variables to configure the AWS CLI</a> in the AWS CLI documentation. Alternatively, you can modify the <code>app.py</code> file in the root of the repository to include a hard-coded account ID and Region by following the instructions in the <a href="#">AWS CDK documentation for environments</a>.</li></ol>

Issue	Solution
<p>When you deploy the solution, you receive the error message:</p> <pre>“Deployment failed: Error: AwsMailFwdStack: SSM parameter /cdk-bootstrap/hnb659fds/version not found. Has the environment been bootstrapped? Please run 'cdk bootstrap’”</pre>	<p>If you have never deployed any AWS CDK resources to the AWS account and Region you’re targeting, you will have to first run the <code>cdk bootstrap</code> command as the error indicates. If you continue to receive this error after you run the bootstrapping command, you might be trying to deploy the solution to a Region that’s different from the Region where your AWS Cloud9 instance is running.</p> <p>To solve this problem, set the <code>AWS_DEFAULT_REGION</code> environment variable or set a Region with the AWS CLI before you deploy the solution. Alternatively, you can modify the <code>app.py</code> file in the root of the repository to include a hard-coded account ID and Region by following the instructions in the <a href="#">AWS CDK documentation for environments</a>.</p>

# Set up DNS resolution for hybrid networks in a multi-account AWS environment

Created by Amir Durrani

**Environment:** Production

**Technologies:** Infrastructure;  
Networking

**AWS services:** AWS RAM;  
Amazon Route 53; AWS  
Control Tower

## Summary

This pattern describes how you can use on-premises Domain Name System (DNS) services with Amazon Route 53 Resolver rules and outbound Resolver endpoints for name resolution.

DNS is fundamental to establishing and maintaining communications across network environments. If you have a hybrid network connectivity environment, you can share critical network services such as DNS and Active Directory without the operational burden of managing a distributed environment across accounts and virtual private clouds (VPCs). This approach helps you build and support applications that span a large number of accounts. For example, if you have hundreds or thousands of multi-Region accounts with hybrid connectivity requirements, you can share DNS services securely and efficiently across all connected environments within your AWS organization.

DNS is critical to IP networking among all tiers (web, application, and database) of an application. It is best practice to give only the team of DNS experts full access to configure, operate, and support this resource. In a hybrid connectivity environment, you can continue to use your on-premises DNS for name resolution requests originating from resources that reside in different accounts, by using conditional forwarding.

This pattern covers hybrid DNS resolution in an AWS multi-account environment. For single accounts, see the pattern [Set up DNS resolution for hybrid networks in a single-account AWS environment](#).

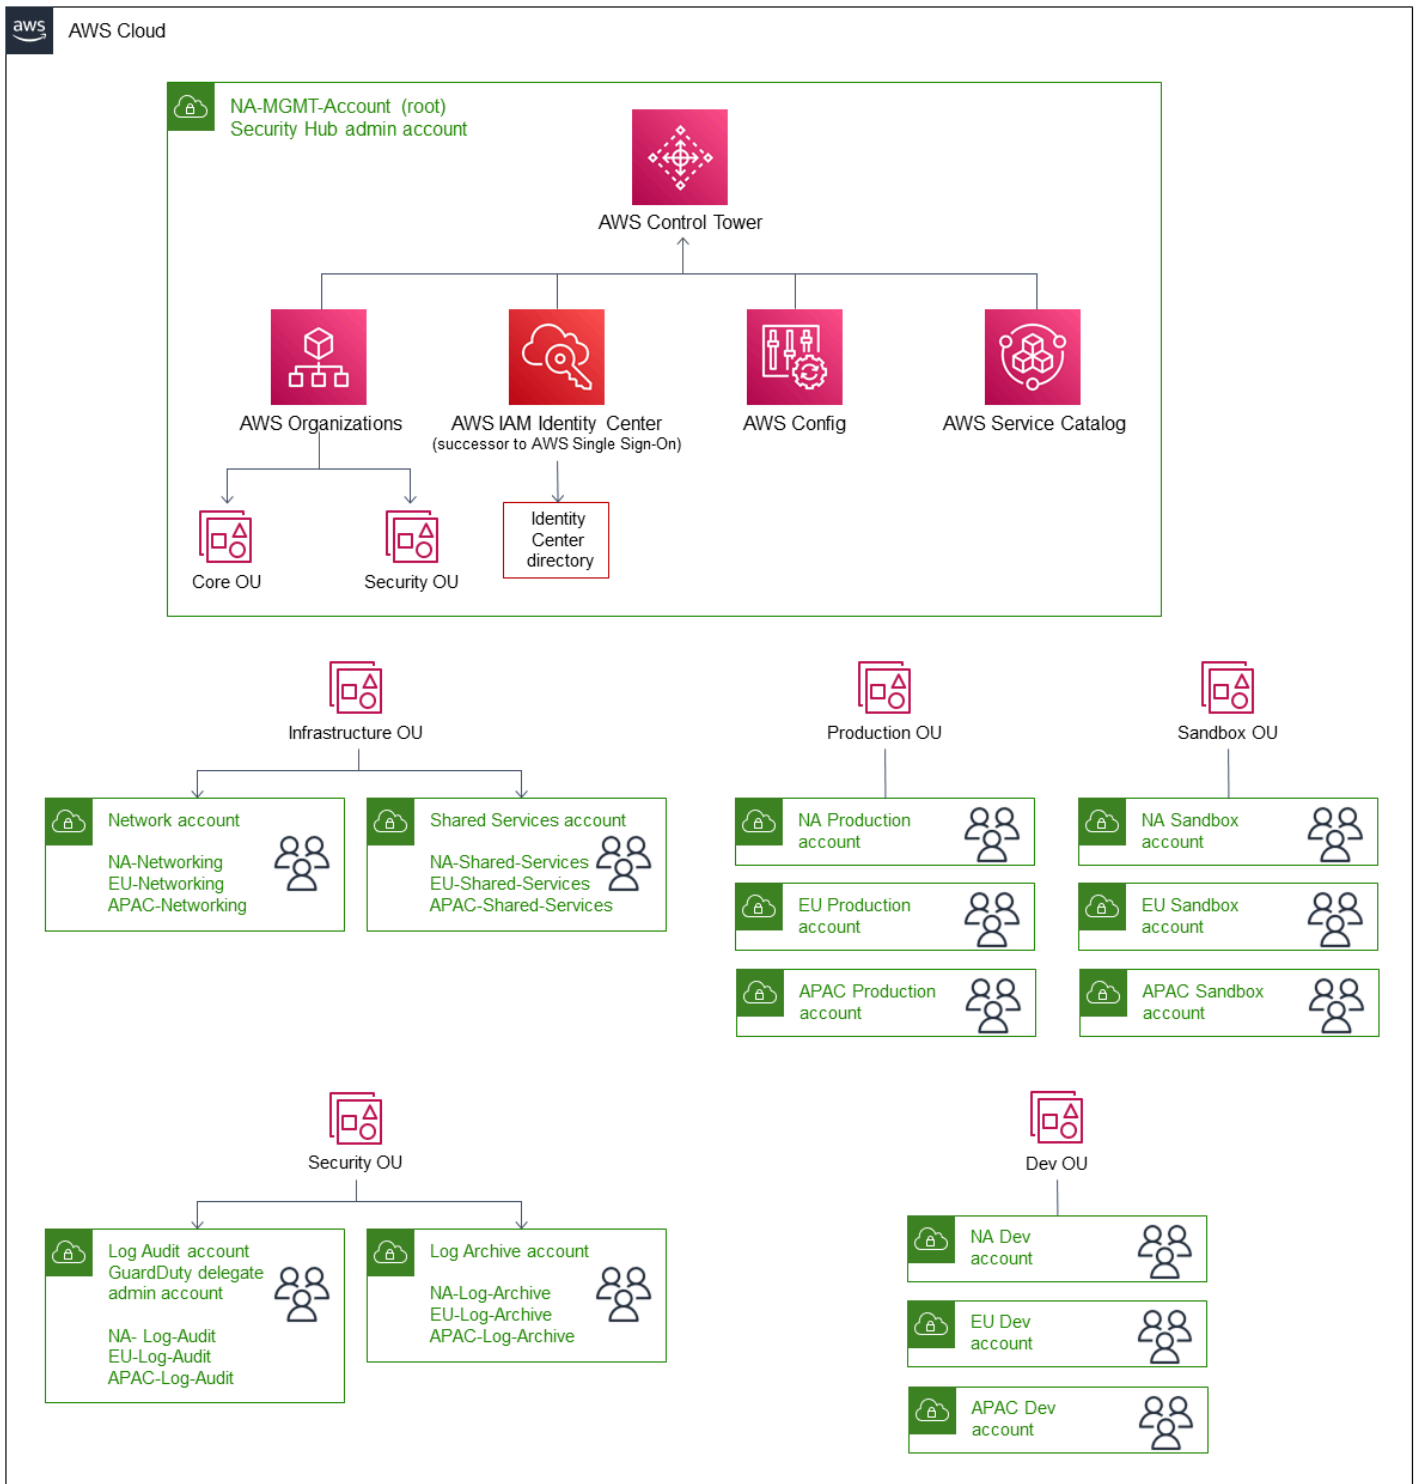

## Prerequisites and limitations

### Prerequisites

- An AWS multi-account environment that is based on best practices and built by using [AWS Control Tower](#). The diagram in the next section shows the typical architecture of such an environment.
- Scalable routing infrastructure between the accounts and VPCs by using [AWS Transit Gateway](#).
- Outbound Resolver endpoints and Resolver rules by using [Amazon Route 53](#).
- Resource shares for outbound Resolver rules by using [AWS Resource Access Manager](#) (AWS RAM).

## Architecture

### AWS multi-account architecture

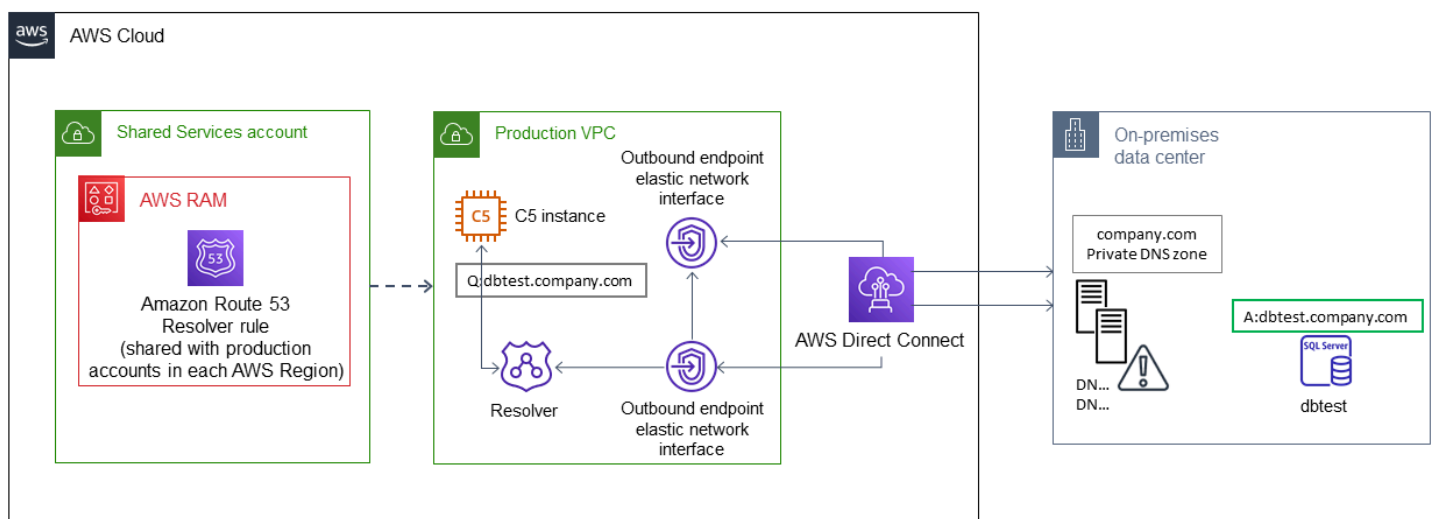

### Target technology stack

- An existing on-premises DNS infrastructure for outbound name resolution across a large number of AWS principals

- Route 53 Resolver rule and outbound Resolver endpoints
- AWS RAM for sharing Route 53 Resolver rules with other AWS principals within and outside the AWS organization

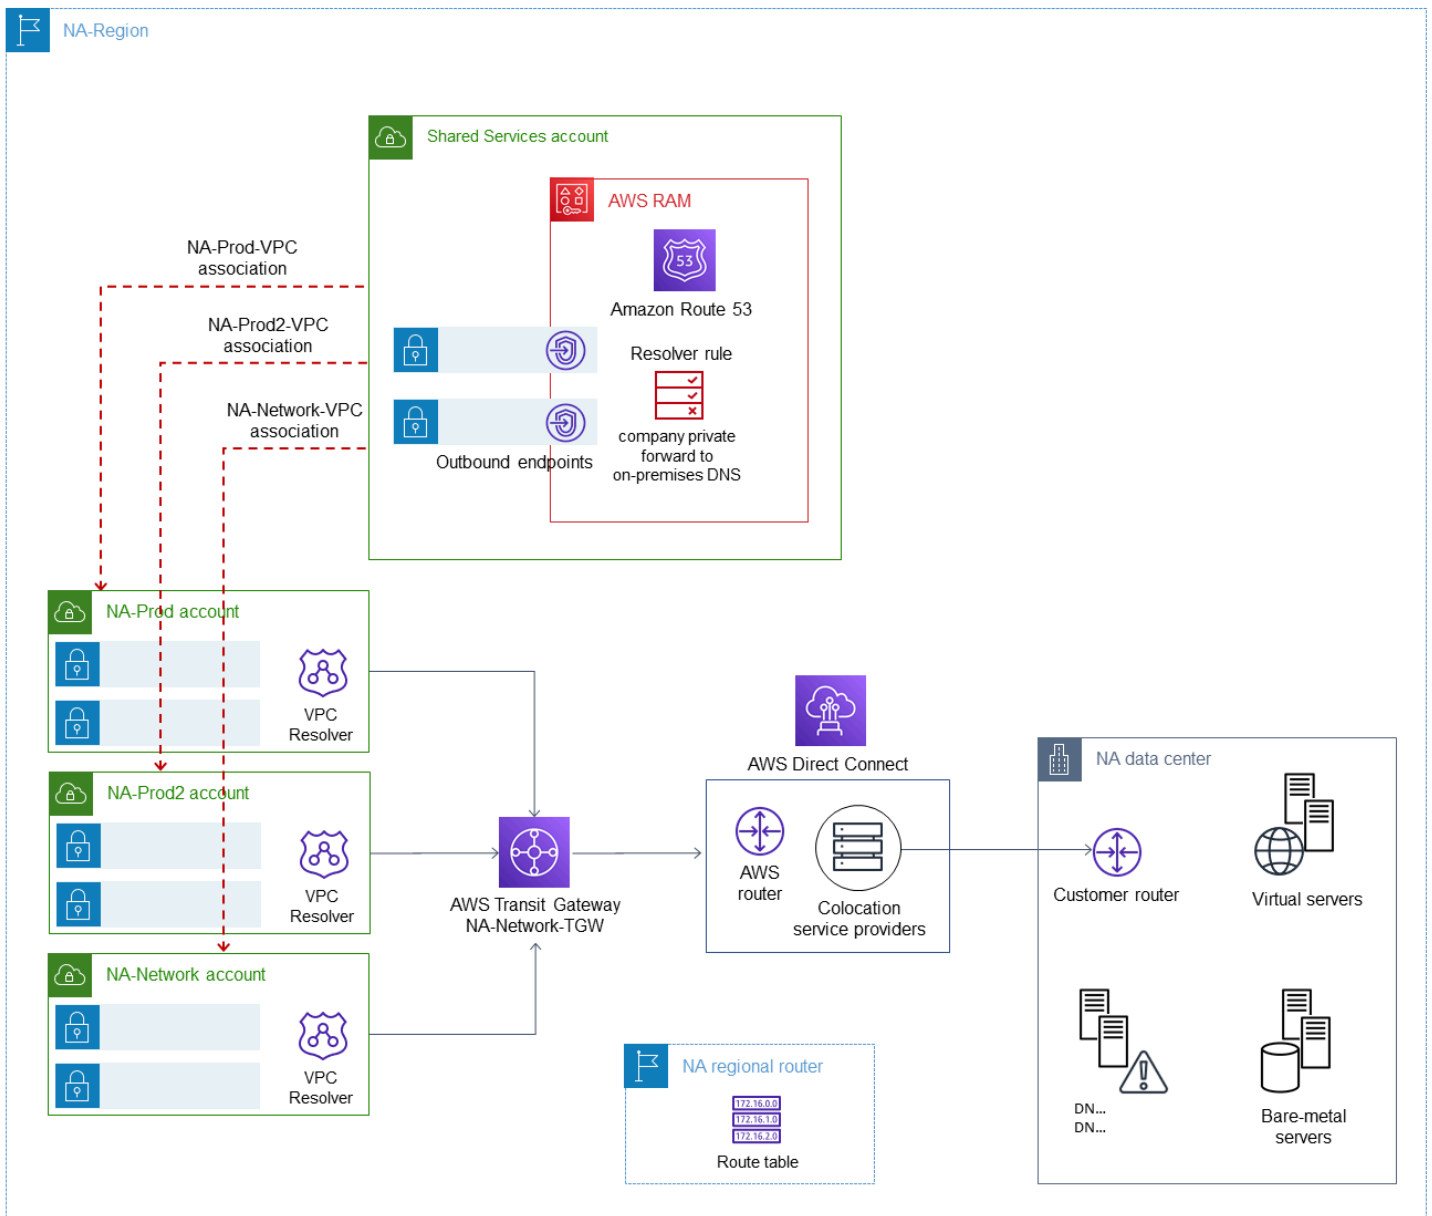

## Target architecture

The following diagram depicts the steps for configuring the end-to-end hybrid DNS resolution. AWS RAM is used to share the Route 53 Resolver rules and Resolver endpoints, which are configured and managed from the central Shared Services account. Route 53 Resolver endpoints are configured for each Availability Zone to receive the outbound name resolution requests for the resources that reside in the on-premises data center, and to then forward these requests to the on-premises DNS resolvers. The on-premises DNS resolvers send the name resolution responses to the outbound endpoints, which then forward the responses to the VPC resolver. These steps establish end-to-end communication by using hostnames instead of IP addresses.

The following diagram shows the architecture in more detail.

## Automation and scale

You can configure and share Route 53 Resolver rules through AWS RAM by using AWS CloudFormation templates.

## Tools

### AWS services

- [AWS Control Tower](#) helps you set up and govern an AWS multi-account environment, following prescriptive best practices.

- [AWS Resource Access Manager \(AWS RAM\)](#) helps you securely share your resources across AWS accounts to reduce operational overhead and provide visibility and auditability.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

## Additional tools

- **nslookup** and **dig** are utilities for querying DNS records.

## Epics

### Configure the Resolver endpoints and rules

Task	Description	Skills required
Configure Route 53 outbound Resolver endpoints and rules.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console for the AWS account that you want to configure and share the Route 53 outbound Resolver rule from.</li><li>2. Open the Route 53 console at <a href="https://console.aws.amazon.com/route53/">https://console.aws.amazon.com/route53/</a>.</li><li>3. On the navigation bar, choose the Region where you want to configure the Resolver endpoint.</li><li>4. In the navigation pane, choose <b>Outbound endpoints</b>, and then choose <b>Configure endpoints</b>.</li><li>5. Provide general settings, IP addresses, and optional</li></ol>	General AWS

Task	Description	Skills required
	<p>tag information, and then choose <b>Next</b>.</p> <p>6. Create one or more rules to specify the domain names of the DNS queries that you want to forward to your network, and then choose <b>Save</b>.</p> <p>For more information, see <a href="#">Forwarding outbound DNS queries to your network</a> in the Route 53 documentation.</p>	

Task	Description	Skills required
Create and share Route 53 outbound Resolver rules with AWS principals.	<ol style="list-style-type: none"><li>1. Open the AWS RAM console at <a href="https://console.aws.amazon.com/ram/">https://console.aws.amazon.com/ram/</a>.</li><li>2. In the navigation pane, choose <b>Resource shares</b>, and then choose <b>Create resource share</b>.</li><li>3. Provide a share name.</li><li>4. For resource type, choose <b>Resolver Rules</b>.</li><li>5. Choose the Resolver rule that you want to share, provide optional tag key and value information, and then choose <b>Next</b>.</li><li>6. Choose the principals that you want to share the Resolver rule resource with. Principals can be internal or external to your AWS organization. For example, you can choose your AWS organization, a specific organizational unit (OU) within the organization, or a specific account.</li><li>7. Review and create the resource share.</li></ol> <p>After the resource is created and shared, it appears in the <b>Shared with me</b> section of the navigatio</p>	General AWS

Task	Description	Skills required
	<p>n pane for the principals it is shared with.</p> <p>8. Associate the VPCs in the (principal) account with the Resolver rule that has been shared by the shared services or networking account.</p> <p>For more information, see <a href="#">Sharing your AWS resources</a> in the AWS RAM documentation.</p>	
<p>Test the outbound DNS name resolution.</p>	<p>Test the name resolution by using the <b>nslookup</b> or <b>dig</b> utility on instances in a VPC in an account that you have shared the Resolver rule with.</p> <p>The query should resolve to the IP address of a resource that resides within your on-premises data center.</p>	<p>General AWS</p>

# Set up DNS resolution for hybrid networks in a single-account AWS environment

Created by Abdullahi Olaoye (AWS)

**Environment:** Production

**Technologies:** Infrastructure

**AWS services:** Amazon Route 53; Amazon VPC

## Summary

This pattern describes how to set up a fully hybrid Domain Name System (DNS) architecture that enables end-to-end DNS resolution of on-premise resources, AWS resources, and internet DNS queries, without administrative overhead. The pattern describes how to set up Amazon Route 53 Resolver forwarding rules that determine where a DNS query that originates from AWS should be sent, based on the domain name. DNS queries for on-premises resources are forwarded to on-premises DNS resolvers. DNS queries for AWS resources and internet DNS queries are resolved by Route 53 Resolver.

This pattern covers hybrid DNS resolution in an AWS single-account environment. For information about setting up outbound DNS queries in an AWS multi-account environment, see the pattern [Set up DNS resolution for hybrid networks in a multi-account AWS environment](#).

## Prerequisites and limitations

### Prerequisites

- An AWS account
- A virtual private cloud (VPC) in your AWS account
- A network connection between the on-premises environment and your VPC, through AWS Virtual Private Network (AWS VPN) or AWS Direct Connect
- IP addresses of your on-premises DNS resolvers (reachable from your VPC)
- Domain/subdomain name to forward to on-premises resolvers (for example, onprem.mydc.com)
- Domain/subdomain name for the AWS private hosted zone (for example, myvpc.cloud.com)

# Architecture

## Target technology stack

- Amazon Route 53 private hosted zone
- Amazon Route 53 Resolver
- Amazon VPC
- AWS VPN or Direct Connect

## Target architecture

## Tools

- [Amazon Route 53 Resolver](#) makes hybrid cloud easier for enterprise customers by enabling seamless DNS query resolution across your entire hybrid cloud. You can create DNS endpoints and conditional forwarding rules to resolve DNS namespaces between your on-premises data center and your VPCs.
- [Amazon Route 53 private hosted zone](#) is a container that holds information about how you want Route 53 to respond to DNS queries for a domain and its subdomains within one or more VPCs that you create with the Amazon VPC service.

## Epics

### Configure a private hosted zone

Task	Description	Skills required
Create a Route 53 private hosted zone for an AWS reserved domain name such as myvpc.cloud.com.	This zone holds the DNS records for AWS resources that should be resolved from the on-premises environment. For instructions, see <a href="#">Creating a private hosted zone</a> in the Route 53 documentation.	Network admin, System admin
Associate the private hosted zone with your VPC.	To enable resources in your VPC to resolve DNS records in this private hosted zone, you must associate your VPC with the hosted zone. For instructions, see <a href="#">Creating a private hosted zone</a> in the Route 53 documentation.	Network admin, System admin

### Set up Route 53 Resolver endpoints

Task	Description	Skills required
Create an inbound endpoint.	Route 53 Resolver uses the inbound endpoint to receive DNS queries from on-premises DNS resolvers. For instructions, see <a href="#">Forwarding inbound DNS queries to your VPCs</a> in the Route 53 documentation. Make a note of the inbound endpoint IP address.	Network admin, System admin

Task	Description	Skills required
Create an outbound endpoint.	Route 53 Resolver uses the outbound endpoint to send DNS queries to on-premises DNS resolvers. For instructions, see <a href="#">Forwarding outbound DNS queries to your network</a> in the Route 53 documentation. Make a note of the output endpoint ID.	Network admin, System admin

### Set up a forwarding rule and associate it with your VPC

Task	Description	Skills required
Create a forwarding rule for the on-premises domain.	This rule will instruct Route 53 Resolver to forward any DNS queries for on-premises domains (such as onprem.mydc.com) to on-premises DNS resolvers. To create this rule, you will need the IP addresses of the on-premises DNS resolvers and the outbound endpoint ID for Route 53 Resolver. For instructions, see <a href="#">Managing forwarding rules</a> in the Route 53 documentation.	Network admin, System admin
Associate the forwarding rule with your VPC.	For the forwarding rule to take effect, you must associate the rule with your VPC. Route 53 Resolver then takes the rule into consideration when resolving	Network admin, System admin

Task	Description	Skills required
	a domain. For instructions, see <a href="#">Managing forwarding rules</a> in the Route 53 documentation.	

## Configure on-premises DNS resolvers

Task	Description	Skills required
Configure conditional forwarding in the on-premise DNS resolvers.	For DNS queries to be sent to the Route 53 private hosted zone from the on-premises environment, you must configure conditional forwarding in the on-premises DNS resolvers. This instructs the DNS resolvers to forward all DNS queries for the AWS domain (for example, for myvpc.cloud.com) to the inbound endpoint IP address for Route 53 Resolver.	Network admin, System admin

## Test end-to-end DNS resolution

Task	Description	Skills required
Test DNS resolution from AWS to the on-premises environment.	From a server in the VPC, perform a DNS query for an on-premises domain (such as server1.onprem.mydc.com).	Network admin, System admin

Task	Description	Skills required
Test DNS resolution from the on-premises environment to AWS.	From an on-premises server, perform DNS resolution for an AWS domain (such as server1.myvpc.cloud.com).	Network admin, System admin

# Set up UiPath RPA bots automatically on Amazon EC2 by using AWS CloudFormation

Created by Dr. Rahul Sharad Gaikwad (AWS) and Tamilselvan P (AWS)

**Environment:** PoC or pilot

**Technologies:** Infrastructure;  
DevOps

**Workload:** All other  
workloads

**AWS services:** Amazon  
CloudWatch; Amazon EC2  
Image Builder; AWS Systems  
Manager; AWS CloudForm  
ation

## Summary

This pattern explains how you can deploy robotic process automation (RPA) bots on Amazon Elastic Compute Cloud (Amazon EC2) instances. It uses an [EC2 Image Builder](#) pipeline to create a custom Amazon Machine Image (AMI). An AMI is a preconfigured virtual machine (VM) image that contains the operating system (OS) and preinstalled software to deploy EC2 instances. This pattern uses AWS CloudFormation templates to install [UiPath Studio Community edition](#) on the custom AMI. UiPath is an RPA tool that helps you set up robots to automate your tasks.

As part of this solution, EC2 Windows instances are launched by using the base AMI, and the UiPath Studio application is installed on the instances. The pattern uses the Microsoft System Preparation (Sysprep) tool to duplicate the customized Windows installation. After that, it removes the host information and creates a final AMI from the instance. You can then launch the instances on demand by using the final AMI with your own naming conventions and monitoring setup.

**Note:** This pattern doesn't provide any information about using RPA bots. For that information, see the [UiPath documentation](#). You can also use this pattern to set up other RPA bot applications by customizing the installation steps based on your requirements.

This pattern provides the following automations and benefits:

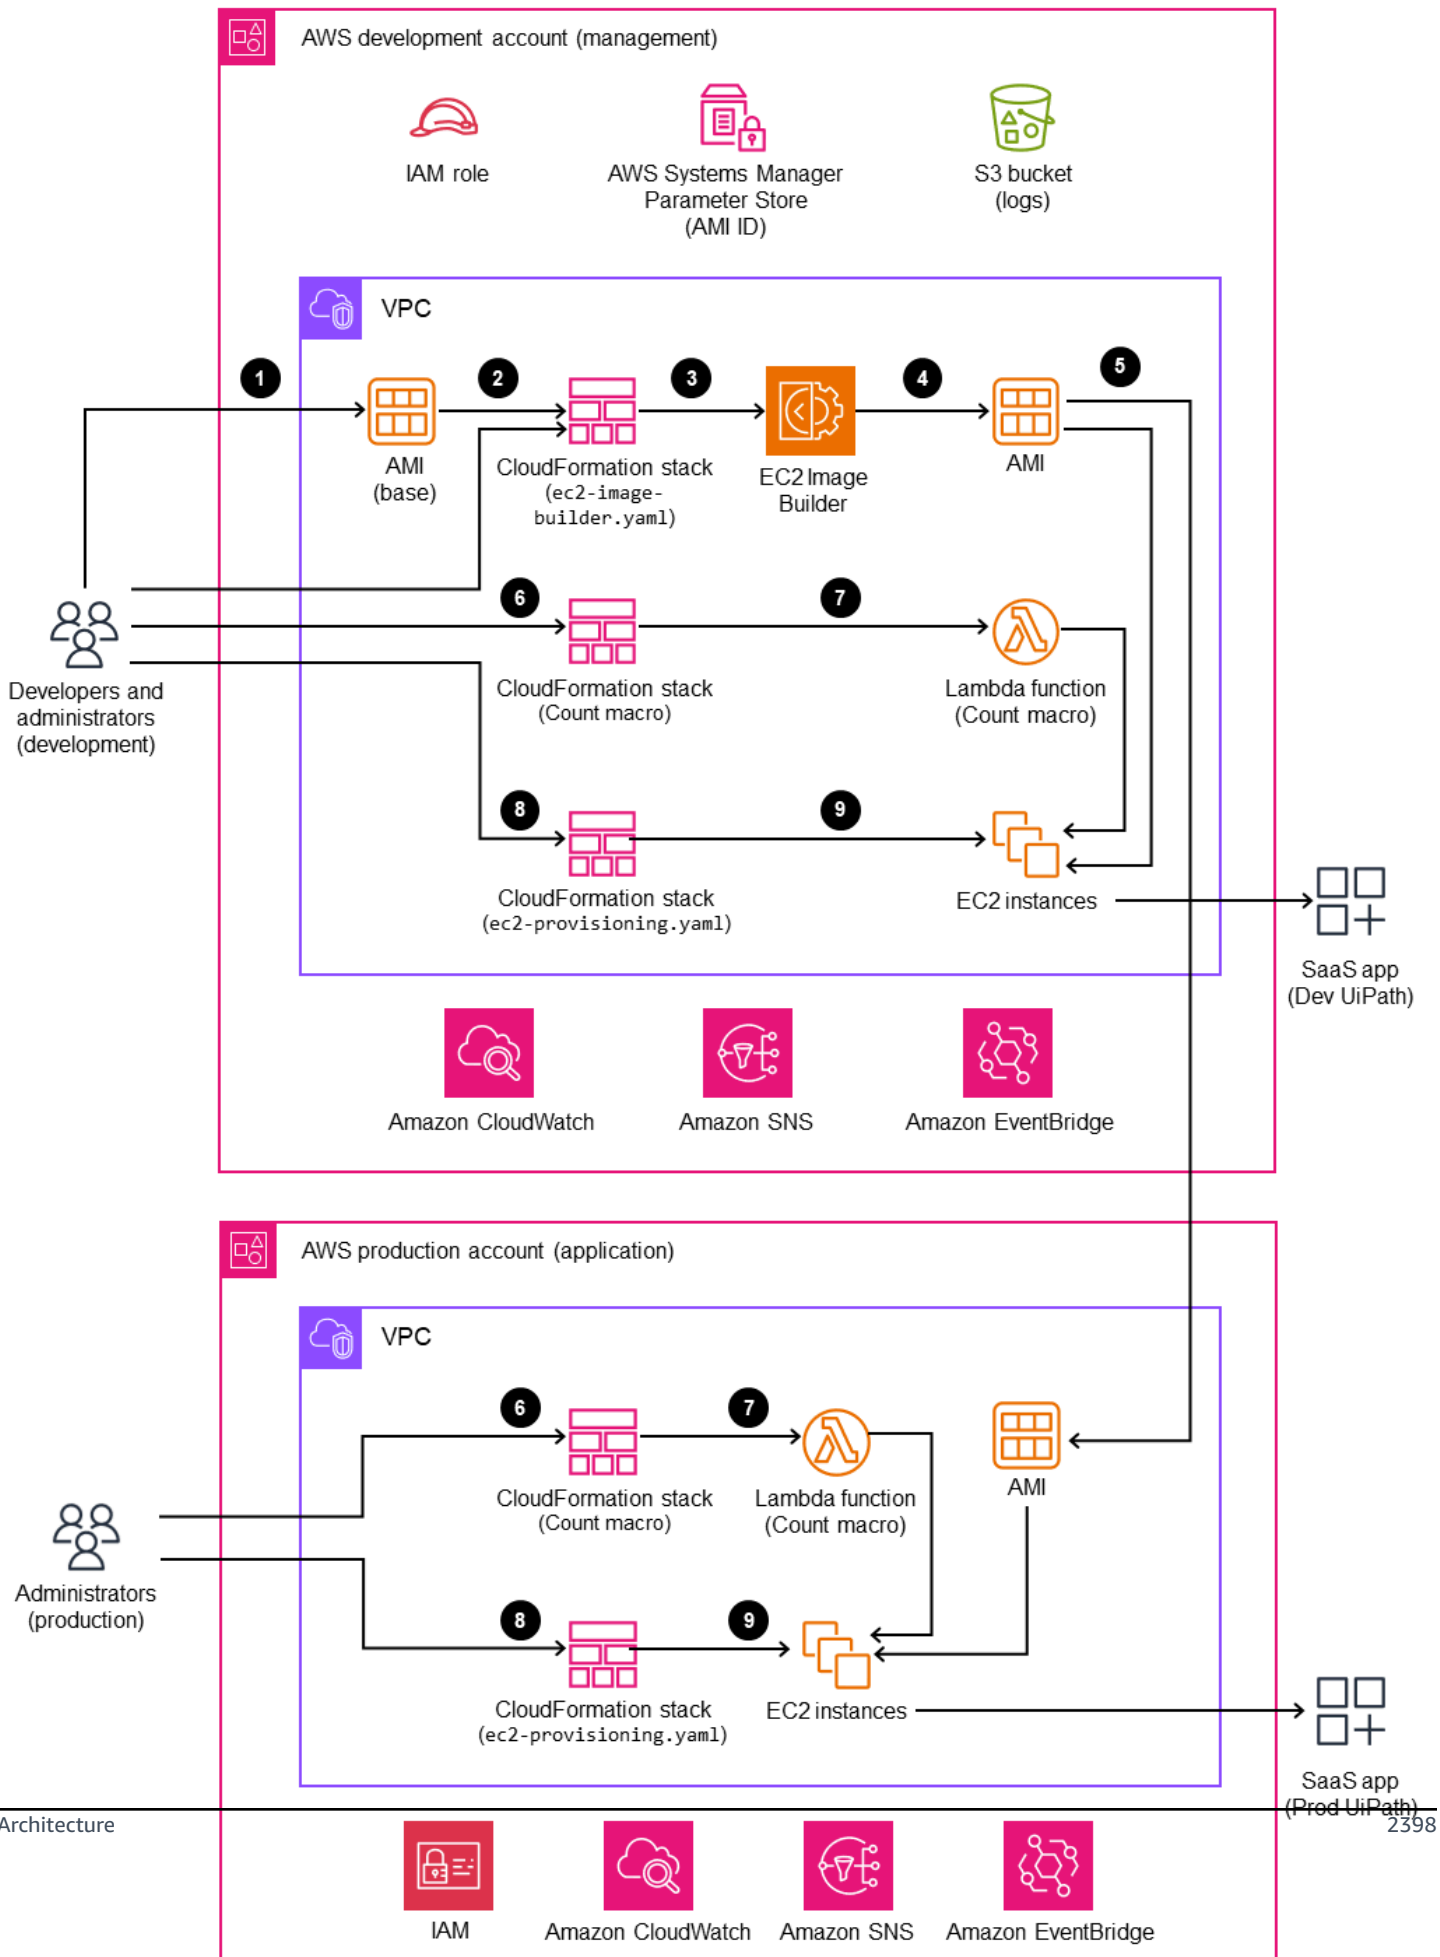

- **Application deployment and sharing:** You can build Amazon EC2 AMIs for application deployment and share them across multiple accounts through an EC2 Image Builder pipeline, which uses AWS CloudFormation templates as infrastructure as code (IaC) scripts.
- **Amazon EC2 provisioning and scaling:** CloudFormation IaC templates provide custom computer name sequences and Active Directory join automation.
- **Observability and monitoring:** The pattern sets up Amazon CloudWatch dashboards to help you monitor Amazon EC2 metrics (such as CPU and disk usage).
- **RPA benefits for your business:** RPA improves accuracy because robots can perform assigned tasks automatically and consistently. RPA also increases speed and productivity because it removes operations that don't add value and handles repetitious activities.

## Prerequisites and limitations

### Prerequisites

- An active [AWS account](#)
- [AWS Identity and Access Management \(IAM\) permissions](#) for deploying CloudFormation templates
- [IAM policies](#) to set up cross-account AMI distribution with EC2 Image Builder

## Architecture

1. The administrator provides the base Windows AMI in the `ec2-image-builder.yaml` file and deploys the stack in the CloudFormation console.
2. The CloudFormation stack deploys the EC2 Image Builder pipeline, which includes the following resources:
  - `Ec2ImageInfraConfiguration`
  - `Ec2ImageComponent`
  - `Ec2ImageRecipe`
  - `Ec2AMI`
3. The EC2 Image Builder pipeline launches a temporary Windows EC2 instance by using the base AMI and installs the required components (in this case, UiPath Studio).
4. The EC2 Image Builder removes all the host information and creates an AMI from Windows Server.
5. You update the `ec2-provisioning.yaml` file with the custom AMI and launch a number of EC2 instances based on your requirements.
6. You deploy the Count macro by using a CloudFormation template. This macro provides a **Count** property for CloudFormation resources so you can specify multiple resources of the same type easily.
7. You update the name of the macro in the CloudFormation `ec2-provisioning.yaml` file and deploy the stack.
8. The administrator updates the `ec2-provisioning.yaml` file based on requirements and launches the stack.
9. The template deploys EC2 instances with the UiPath Studio application.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you model and manage infrastructure resources in an automated and secure manner.
- [Amazon CloudWatch](#) helps you observe and monitor resources and applications on AWS, on premises, and on other clouds.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides secure and resizable compute capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- [EC2 Image Builder](#) simplifies the building, testing, and deployment of virtual machines and container images for use on AWS or on premises.
- [Amazon EventBridge](#) helps you build event-driven applications at scale across AWS, existing systems, or software as a service (SaaS) applications.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely control access to AWS resources. With IAM, you can centrally manage permissions that control which AWS resources users can access. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- [AWS Lambda](#) is a serverless, event-driven compute service that lets you run code for virtually any type of application or backend service without provisioning or managing servers. You can call Lambda functions from over 200 AWS services and SaaS applications, and pay only for what you use.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data..
- [AWS Systems Manager Agent \(SSM Agent\)](#) helps Systems Manager update, manage, and configure EC2 instances, edge devices, on-premises servers, and virtual machines (VMs).

## Code repositories

The code for this pattern is available in the GitHub [UiPath RPA bot setup using CloudFormation](#) repository. The pattern also uses a macro that's available from the [AWS CloudFormation Macros repository](#).

## Best practices

- AWS releases new [Windows AMIs](#) each month. These contain the latest OS patches, drivers, and launch agents. We recommend that you use the latest AMI when you launch new instances or when you build your own custom images.
- Apply all available Windows or Linux security patches during image builds.

# Epics

## Deploy an image pipeline for the base image

Task	Description	Skills required
Set up an EC2 Image Builder pipeline.	<ol style="list-style-type: none"><li>1. Clone the <a href="#">UiPath RPA bot setup using CloudFormation</a> repository, or download the <code>ec2-image-builder.yaml</code> template from the repository.</li><li>2. Sign in to the AWS Management Console, and open the <a href="#">AWS CloudFormation console</a>.</li><li>3. Choose <b>Create stack</b>.</li><li>4. In the <b>Specify template</b> section, choose <b>Upload a template file</b>.</li><li>5. Locate and upload the <code>ec2-image-builder.yaml</code> template from your computer, and then choose <b>Next</b>.</li><li>6. Provide input parameters for your stack or accept the default values. Choose <b>Next</b>.</li></ol> <p><b>Note:</b> The number and values of parameters might vary depending on your input values.</p>	AWS DevOps

Task	Description	Skills required
	<p>7. Optionally, configure stack options, and then choose <b>Next</b>.</p> <p>8. Review your stack details.</p> <p>9. At the end of the screen, select the check box to acknowledge capabilities, and then choose <b>Submit</b>.</p> <p>10 Monitor the stack's progress. When the status is <code>CREATE_COMPLETE</code> , the deployment is ready.</p>	
View EC2 Image Builder settings.	<p>The EC2 Image Builder settings include infrastructure configuration, distribution settings, and security scanning settings. To view the settings:</p> <ol style="list-style-type: none"> <li>1. Open the <a href="#">EC2 Image Builder console</a>.</li> <li>2. From the navigation pane, navigate to various Image Builder settings.</li> </ol> <p><b>Note:</b> As a best practice, you should make any updates to EC2 Image Builder through the CloudFormation template only.</p>	AWS DevOps

Task	Description	Skills required
View the image pipeline.	<p>To view the deployed image pipeline:</p> <ol style="list-style-type: none"><li>1. On the EC2 Image Builder console, choose <b>Image pipelines</b> from the navigation pane.</li><li>2. Select the image pipeline you created.</li><li>3. View the configuration details of the output images, image recipe, infrastructure configuration, distribution settings, Amazon EventBridge rules, and tags.</li></ol>	AWS DevOps

Task	Description	Skills required
View Image Builder logs.	<p>EC2 Image Builder logs are aggregated in CloudWatch log groups. To view the logs in CloudWatch:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">CloudWatch console</a>.</li><li>2. In the navigation pane, choose <b>Logs, Log groups</b>.</li><li>3. Choose the log group name. EC2 Image Builder logs are aggregated in the log group <code>/aws/imagebuilder/XXX</code> .</li><li>4. Check the latest logs in the respective log stream for any errors encountered when running the image pipeline.</li></ol> <p>EC2 Image Builder logs are also stored in an S3 bucket. To view the logs in the bucket:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Amazon S3 console</a>.</li><li>2. In the <b>Buckets</b> list, choose the bucket name. The logs are aggregated in the S3 bucket <code>&lt;stack-name&gt;-XXXXXX</code> .</li></ol>	AWS DevOps

Task	Description	Skills required
Upload the UiPath file to an S3 bucket.	<ol style="list-style-type: none"> <li>1. Download the .msi file for UiPath Studio from the location <a href="https://download.uipath.com/UiPathStudioCommunity.msi">https://download.uipath.com/UiPathStudioCommunity.msi</a>.</li> <li>2. Upload the file to an S3 bucket.</li> <li>3. Update the bucket name and file key in the ec2-image-builder.yaml template, in the user data section, <a href="#">line number 310</a>.</li> </ol>	AWS DevOps

## Deploy and test the Count macro

Task	Description	Skills required
Deploy the Count macro.	<ol style="list-style-type: none"> <li>1. Clone or download the <a href="#">Count CloudFormation macro</a>.</li> <li>2. Navigate to the Count folder.</li> <li>3. You will need an S3 bucket to store the CloudFormation artifacts. If you don't have an S3 bucket already, create one with the name <code>aws_s3_mb_s3://&lt;bucket name&gt;</code>.</li> <li>4. Package the Count macro template. The template uses the <a href="#">AWS Serverless Application Model (SAM)</a>,</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>so it must be transformed before you can deploy it.</p> <pre>aws cloudformation package \   --template-file template.yaml \   --s3-bucket &lt;your bucket name here&gt; \   --output- template-file packaged.yaml</pre> <p>For example:</p> <pre>aws cloudformation package \   --template-file template.yaml \   --s3-bucket count-macro-ec2 \   --output- template-file packaged.yaml</pre> <p>5. Deploy the packaged template to create a CloudFormation stack.</p> <pre>aws cloudformation deploy \   --stack-name Count-macro \   --template-file packaged.yaml \   --capabilities CAPABILITY_IAM</pre>	

Task	Description	Skills required
	<p>If you want to use the console, follow the instructions in the previous epic or in the <a href="#">CloudFormation documentation</a>.</p>	
<p>Test the Count macro.</p>	<p>To test the macro's capabilities, try launching the example template that's provided with the macro.</p> <pre data-bbox="597 695 1027 1056">aws cloudformation   deploy \     --stack-name Count-   test \     --template-file   test.yaml \     --capabilities   CAPABILITY_IAM</pre>	<p>DevOps engineer</p>

## Deploy the CloudFormation stack to provision instances with the custom image

Task	Description	Skills required
<p>Deploy the Amazon EC2 provisioning template.</p>	<p>To deploy EC2 Image Pipeline by using CloudFormation:</p> <ol style="list-style-type: none"> <li>1. Download the <code>ec2-provisioning.yaml</code> template from the <a href="#">GitHub repository</a>, or locate it on your computer if you cloned the repository.</li> <li>2. Open the <a href="#">CloudFormation console</a>.</li> </ol>	<p>AWS DevOps</p>

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. Repeat the steps from the first epic (or follow the instructions in the <a href="#">CloudFormation documentation</a>) to deploy <code>ec2-provisioning.yaml</code>.</li></ol>	
View Amazon EC2 settings.	<p>Amazon EC2 settings include security, networking, storage, status checks, monitoring, and tags configurations. To view these configurations:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Amazon EC2 console</a>.</li><li>2. In the navigation pane, choose <b>Instances</b>, and then select the EC2 instance that was created by the Amazon EC2 provisioning template.</li><li>3. In the instance summary, select the tabs to view the corresponding Amazon EC2 settings.</li></ol>	AWS DevOps

Task	Description	Skills required
View the CloudWatch dashboard.	<ol style="list-style-type: none"><li>1. Open the <a href="#">CloudWatch console</a>.</li><li>2. In the navigation pane, choose <b>Dashboards</b>.</li><li>3. Choose the dashboard that has your stack name.</li></ol> <p><b>Note:</b> After you provision the stack, it takes time to populate the dashboard with metrics.</p> <p>The dashboard provides these metrics: CPUUtilization , DiskUtilization , MemoryUtilization , NetworkIn , NetworkOut , StatusCheckFailed .</p>	AWS DevOps
View custom metrics for memory and disk usage.	<ol style="list-style-type: none"><li>1. On the <a href="#">CloudWatch console</a>, choose <b>Dashboard s</b>.</li><li>2. In the navigation pane, choose <b>Metrics, All metrics</b>.</li><li>3. Choose <b>Custom namespaces, CWAgent</b>.</li></ol>	AWS DevOps
View alarms for memory and disk usage.	<ol style="list-style-type: none"><li>1. On the <a href="#">CloudWatch console</a>, in the navigation pane, choose <b>Dashboards</b>.</li><li>2. Choose <b>All alarms</b>.</li></ol>	AWS DevOps

Task	Description	Skills required
Verify the snapshot lifecycle rule.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Amazon EC2 console</a>.</li><li>2. In the navigation pane, choose <b>Lifecycle Manager</b>.</li><li>3. Verify the settings for the AMI lifecycle.</li></ol>	AWS DevOps

### Delete the environment (optional)

Task	Description	Skills required
Delete the stacks.	<p>When your PoC or pilot project is complete, we recommend that you delete the stacks you created to make sure that you aren't charged for these resources.</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">AWS CloudFormation console</a>.</li><li>2. In the navigation pane, choose <b>Stacks</b>, and then select one or both stacks you created earlier that you want to delete. The stack must be currently running.</li><li>3. In the stack details pane, choose <b>Delete</b>.</li><li>4. When prompted, choose <b>Delete stack</b>.</li></ol> <p><b>Important:</b> The stack deletion operation can't be stopped</p>	AWS DevOps

Task	Description	Skills required
	<p>after it begins. The stack proceeds to the <code>DELETE_IN_PROGRESS</code> state.</p> <p>If the deletion fails, the stack will be in the <code>DELETE_FAILED</code> state. For solutions, see <a href="#">Delete stack fails</a> in the AWS CloudFormation troubleshooting documentation.</p> <p>For information about protecting stacks from being accidentally deleted, see <a href="#">Protecting a stack from being deleted</a> in the AWS CloudFormation documentation.</p>	

## Troubleshooting

Issue	Solution
<p>When you deploy the Amazon EC2 provisioning template, you get the error: <i>Received malformed response from transform 123xxxx:: Count.</i></p>	<p>This is a known issue. (See the custom solution and PR in the <a href="#">AWS CloudFormation macros repository</a>.)</p> <p>To fix this issue, open the AWS Lambda console and update <code>index.py</code> with the content from the <a href="#">GitHub repository</a>.</p>

# Set up disaster recovery for Oracle JD Edwards EnterpriseOne with AWS Elastic Disaster Recovery

Created by Thanigaivel Thirumalai (AWS)

**Environment:** Production

**Technologies:** Infrastructure;  
Migration; Networking

**Workload:** Oracle

**AWS services:** AWS Elastic  
Disaster Recovery; Amazon  
EC2

## Summary

Disasters that are triggered by natural catastrophes, application failures, or disruption of services harm revenue and cause downtime for corporate applications. To reduce the repercussions of such events, planning for disaster recovery (DR) is critical for firms that adopt JD Edwards EnterpriseOne enterprise resource planning (ERP) systems and other mission-critical and business-critical software.

This pattern explains how businesses can use AWS Elastic Disaster Recovery as a DR option for their JD Edwards EnterpriseOne applications. It also outlines the steps for using Elastic Disaster Recovery failover and failback to construct a cross-Region DR strategy for databases hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in the AWS Cloud.

**Note:** This pattern requires the primary and secondary Regions for the cross-Region DR implementation to be hosted on AWS.

[Oracle JD Edwards EnterpriseOne](#) is an integrated ERP software solution for midsize to large companies in a wide range of industries.

AWS Elastic Disaster Recovery minimizes downtime and data loss with fast, reliable recovery of on-premises and cloud-based applications by using affordable storage, minimal compute, and point-in-time recovery.

AWS provides [four core DR architecture patterns](#). This document focuses on setup, configuration, and optimization by using the [pilot light strategy](#). This strategy helps you create a lower-cost DR

environment where you initially provision a replication server for replicating data from the source database, and you provision the actual database server only when you start a DR drill and recovery. This strategy removes the expense of maintaining a database server in the DR Region. Instead, you pay for a smaller EC2 instance that serves as a replication server.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A JD Edwards EnterpriseOne application running on Oracle Database or Microsoft SQL Server with a supported database in a running state on a managed EC2 instance. This application should include all JD Edwards EnterpriseOne base components (Enterprise Server, HTML Server, and Database Server) installed in one AWS Region.
- An AWS Identity and Access Management (IAM) role to set up the Elastic Disaster Recovery service.
- The network for running Elastic Disaster Recovery configured according to the required [connectivity settings](#).

### Limitations

- You can use this pattern to replicate all tiers, unless the database is hosted on Amazon Relational Database Service (Amazon RDS), in which case we recommend that you use the [cross-Region copy functionality](#) of Amazon RDS.
- Elastic Disaster Recovery isn't compatible with CloudEndure Disaster Recovery, but you can upgrade from CloudEndure Disaster Recovery. For more information, see the [FAQ](#) in the Elastic Disaster Recovery documentation.
- Amazon Elastic Block Store (Amazon EBS) limits the rate at which you can take snapshots. You can replicate a maximum number of 300 servers in a single AWS account by using Elastic Disaster Recovery. To replicate more servers, you can use multiple AWS accounts or multiple target AWS Regions. (You will have to set up Elastic Disaster Recovery separately for each account and Region.) For more information, see [Best practices](#) in the Elastic Disaster Recovery documentation.
- The source workloads (the JD Edwards EnterpriseOne application and database) must be hosted on EC2 instances. This pattern doesn't support workloads that are on premises or in other cloud environments.

- This pattern focuses on the JD Edwards EnterpriseOne components. A full DR and business continuity plan (BCP) should include other core services, including:
  - Networking (virtual private cloud, subnets, and security groups)
  - Active Directory
  - Amazon WorkSpaces
  - Elastic Load Balancing
  - A managed database service such as Amazon Relational Database Service (Amazon RDS)

For additional information about prerequisites, configurations, and limitations, see the [Elastic Disaster Recovery documentation](#).

### Product versions

- Oracle JD Edwards EnterpriseOne (Oracle and SQL Server supported versions based on Oracle Minimum Technical Requirements)

## Architecture

### Target technology stack

- A single Region and single virtual private cloud (VPC) for production and non-production, and a second Region for DR
- Single Availability Zones to ensure low latency between servers
- An Application Load Balancer that distributes network traffic to improve the scalability and availability of your applications across multiple Availability Zones
- Amazon Route 53 to provide Domain Name System (DNS) configuration
- Amazon WorkSpaces to provide users with a desktop experience in the cloud
- Amazon Simple Storage Service (Amazon S3) for storing backups, files, and objects
- Amazon CloudWatch for application logging, monitoring, and alarms
- Amazon Elastic Disaster Recovery for disaster recovery

### Target architecture

The following diagram shows the cross-Region disaster recovery architecture for JD Edwards EnterpriseOne using Elastic Disaster Recovery.

## Procedure

Here is a high-level review of the process. For details, see the *Epics* section.

- Elastic Disaster Recovery replication begins with an initial sync. During the initial sync, the AWS Replication Agent replicates all the data from the source disks to the appropriate resource in the staging area subnet.
- Continuous replication continues indefinitely after the initial sync is complete.
- You review the launch parameters, which include service-specific configurations and an Amazon EC2 launch template, after the agent has been installed and replication has started. When the source server is indicated as being ready for recovery, you can start instances.
- When Elastic Disaster Recovery issues a series of API calls to begin the launch operation, the recovery instance is immediately launched on AWS according to your launch settings. The service automatically spins up a conversion server during startup.
- The new instance is spun up on AWS after the conversion is complete and is ready for use. The source server state at the time of launch is represented by the volumes associated with the launched instance. The conversion process involves changes to the drivers, network, and operating system license to ensure that the instance boots natively on AWS.
- After the launch, the newly created volumes are no longer kept in sync with the source servers. The AWS Replication Agent continues to routinely replicate changes made to your source servers to the staging area volumes, but the launched instances do not reflect those changes.
- When you start a new drill or recovery instance, the data is always reflected in the most recent state that has been replicated from the source server to the staging area subnet.

- When the source server is marked as being prepared for recovery, you can start instances.

**Note:** The process works both ways: for failover from a primary AWS Region to a DR Region, and to fail back to the primary site, when it has been recovered. You can prepare for failback by reversing the direction of data replication from the target machine back to the source machine in a fully orchestrated way.

The benefits of this process described in this pattern include:

- **Flexibility:** Replication servers scale out and scale in based on dataset and replication time, so you can perform DR tests without disrupting source workloads or replication.
- **Reliability:** The replication is robust, non-disruptive, and continuous.
- **Automation:** This solution provides a unified, automated process for test, recovery, and failback.
- **Cost optimization:** You can replicate only the needed volumes and pay for them, and pay for compute resources at the DR site only when those resources are activated. You can use a cost-optimized replication instance (we recommend that you use a compute-optimized instance type) for multiple sources or a single source with a large EBS volume.

## Automation and scale

When you perform disaster recovery at scale, the JD Edwards EnterpriseOne servers will have dependencies on other servers in the environment. For example:

- JD Edwards EnterpriseOne application servers that connect to a JD Edwards EnterpriseOne supported database on boot have dependencies on that database.
- JD Edwards EnterpriseOne servers that require authentication and need to connect to a domain controller on boot to start services have dependencies on the domain controller.

For this reason, we recommend that you automate failover tasks. For example, you can use AWS Lambda or AWS Step Functions to automate the JD Edwards EnterpriseOne startup scripts and load balancer changes to automate the end-to-end failover process. For more information, see the blog post [Creating a scalable disaster recovery plan with AWS Elastic Disaster Recovery](#).

## Tools

### AWS services

- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with EC2 instances.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Elastic Disaster Recovery](#) minimizes downtime and data loss with fast, reliable recovery of on-premises and cloud-based applications using affordable storage, minimal compute, and point-in-time recovery.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) gives you full control over your virtual networking environment, including resource placement, connectivity, and security.

## Best practices

### General best practices

- Have a written plan of what to do in the event of a real recovery event.
- After you set up Elastic Disaster Recovery correctly, create an AWS CloudFormation template that can create the configuration on demand, should the need arise. Determine the order in which servers and applications should be launched, and record this in the recovery plan.
- Perform a regular drill (standard Amazon EC2 rates apply).
- Monitor the health of the ongoing replication by using the Elastic Disaster Recovery console or programmatically.
- Protect the point-in-time snapshots and confirm before terminating the instances.
- Create a IAM role for AWS Replication Agent installation.
- Enable termination protection for recovery instances in a real DR scenario.
- Do not use the **Disconnect from AWS** action in the Elastic Disaster Recovery console for servers that you launched recovery instances for, even in the case of a real recovery event. Performing a disconnect terminates all replication resources related to these source servers, including your point-in-time (PIT) recovery points.
- Change the PIT policy to change the number of days for snapshot retention.
- Edit the launch template in Elastic Disaster Recovery launch settings to set the correct subnet, security group, and instance type for your target server.
- Automate the end-to-end failover process by using Lambda or Step Functions to automate JD Edwards EnterpriseOne startup scripts and load balancer changes.

## JD Edwards EnterpriseOne optimization and considerations

- Move **PrintQueue** into the database.
- Move **MediaObjects** into the database.
- Exclude the logs and temp folder from batch and logic servers.
- Exclude the temp folder from Oracle WebLogic.
- Create scripts for startup after the failover.
- Exclude the tempdb for SQL Server.
- Exclude the temp file for Oracle.

## Epics

### Perform initial tasks and configuration

Task	Description	Skills required
Set up the replication network.	Implement your JD Edwards EnterpriseOne system in the primary AWS Region and identify the AWS Region for DR. Follow the steps in the <a href="#">Replication network requirements</a> section of the Elastic Disaster Recovery documentation to plan and set up your replication and DR network.	AWS administrator
Determine RPO and RTO.	Identify the recovery time objective (RTO) and recovery point objective (RPO) for your application servers and database.	Cloud architect, DR architect
Enable replication for Amazon EFS.	If applicable, enable replication from the AWS primary	Cloud administrator

Task	Description	Skills required
	to DR Region for shared file systems such as Amazon Elastic File System (Amazon EFS) by using AWS DataSync, <b>rsync</b> , or another appropriate tool.	
Manage DNS in case of DR.	Identify the process to update the Domain Name System (DNS) during the DR drill or actual DR.	Cloud administrator
Create an IAM role for setup.	Follow the instructions in the <a href="#">Elastic Disaster Recovery initialization and permissions</a> section of the Elastic Disaster Recovery documentation to create an IAM role to initialize and manage the AWS service.	Cloud administrator
Set up VPC peering.	Make sure that the source and target VPCs are peered and accessible to each other. For configuration instructions, see the <a href="#">Amazon VPC documentation</a> .	AWS administrator

## Configure Elastic Disaster Recovery replication settings

Task	Description	Skills required
Initialize Elastic Disaster Recovery.	Open the <a href="#">Elastic Disaster Recovery console</a> , choose the target AWS Region (where you will replicate data and	AWS administrator

Task	Description	Skills required
	launch recovery instances), and then choose <b>Set default replication settings</b> .	
Set up replication servers.	<ol style="list-style-type: none"><li>1. In the <b>Set up replication servers</b> pane, enter the staging area subnet and replication server instance type. The <code>t3.small</code> instance type is selected by default. Configure this setting based on your requirements, and remember to consider instance pricing. For more information, see <a href="#">Amazon EC2 pricing</a>.</li><li>2. In the <b>Service access</b> section, choose <b>View details</b> to review the service linked role and additional policies created during service initialization.</li><li>3. Choose <b>Next</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Configure volumes and security groups.	<ol style="list-style-type: none"><li data-bbox="594 226 1026 499">1. In the <b>Volumes and security groups</b> pane, select the EBS volume type for the replication server and set Amazon EBS encryption to <b>Default</b>.</li><li data-bbox="594 520 1026 844">2. Select <b>Always use AWS Elastic Disaster Recovery security group</b> so that Elastic Disaster Recovery automatically attaches and monitors the default security group.</li><li data-bbox="594 865 1026 898">3. Choose <b>Next</b>.</li></ol>	AWS administrator

Task	Description	Skills required
Configure additional settings.	<ol style="list-style-type: none"><li>In the <b>Additional settings</b> pane, configure data routing and throttling, PIT policy, and tags.<ul style="list-style-type: none"><li>Data routing and throttling control how data flows from the external server to the replication servers. Choose <b>Use private IP for data replication</b>. Otherwise, replication servers will be automatically assigned a public IP, and data will flow over the public internet.</li><li>In the <b>Point in time (PIT) policy</b> section, configure a retention policy that determines the duration after which snapshots are not required. The default retention period is seven days.</li><li>In the <b>Tags</b> section, add custom tags to resources created by Elastic Disaster Recovery in your AWS account.</li></ul></li><li>Choose <b>Next</b>, review the settings in the next pane, and then choose <b>Create</b></li></ol>	AWS administrator

Task	Description	Skills required
	<b>default</b> to create the default template.	

## Install the AWS Replication Agent

Task	Description	Skills required
Create an IAM role.	Create an IAM role that contains the <code>AWSElasticDisasterRecoveryAgentInstallationPolicy</code> policy. In the <b>Select AWS access type</b> section, enable programmatic access. Note the access key ID and secret access key. You will need this information during the installation of the AWS Replication Agent.	AWS administrator
Check requirements.	Check and complete the <a href="#">prerequisites</a> in the Elastic Disaster Recovery documentation for installing the AWS Replication Agent.	AWS administrator
Install the AWS Replication Agent.	Follow the <a href="#">installation instructions</a> for your operating system and install the AWS Replication Agent. <ul style="list-style-type: none"> <li>For Microsoft Windows: Download the setup files and run the .exe file as an administrator. Respond to</li> </ul>	AWS administrator

Task	Description	Skills required
	<p>the prompts to complete the installation.</p> <ul style="list-style-type: none"><li>• For Linux: Copy the following commands (in the order presented) and paste them into your Secure Shell (SSH) session. The first command downloads the installer and the second command runs it.</li></ul> <pre data-bbox="626 720 1029 1119">wget -O ./aws-replication-installer-init.py https://aws-elastic-disaster-recovery-us-west-2.s3.amazonaws.com/latest/linux/aws-replication-installer-init.py</pre> <p><b>Note:</b> Change the URL to reflect your Region.</p> <pre data-bbox="626 1276 1029 1434">sudo python3 aws-replication-installer-init.py</pre> <p>Respond to the prompts to complete the installation.</p> <p>Repeat these steps for the remaining server.</p>	

Task	Description	Skills required
Monitor the replication.	<p>Return to the Elastic Disaster Recovery <b>Source servers</b> pane to monitor the replication status. The initial sync will take some time depending on the size of the data transfer.</p> <p>When the source server is fully synced, the server status will be updated to <b>Ready</b>. This means that a replication server has been created in the staging area, and the EBS volumes have been replicated from the source server to the staging area.</p>	AWS administrator

## Configure launch settings

Task	Description	Skills required
Edit launch settings.	<p>To update the launch settings for the drill and recovery instances, on the <a href="#">Elastic Disaster Recovery console</a>, select the source server, and then choose <b>Actions, Edit launch settings</b>. Or you can choose your replicating source machines from the <b>Source servers</b> page, and then choose the <b>Launch Settings</b> tab. This tab has two sections: <b>General launch</b></p>	AWS administrator

Task	Description	Skills required
	<b>settings and EC2 launch template.</b>	
Configure general launch settings.	<p>Revise the general launch settings according to your requirements.</p> <ul style="list-style-type: none"><li>• <b>Instance type right sizing:</b> If you choose <b>Basic</b>, Elastic Disaster Recovery bypasses the instance type you selected in the Amazon EC2 launch template and automatically chooses the instance type based on the operating system, CPU, and RAM of the source server.</li><li>• <b>Copy private IP:</b> Choose whether you want Elastic Disaster Recovery to ensure that the private IP used by the drill or recovery instance matches the private IP used by the source server. If you chose <b>Yes</b>, make sure that the IP range of the subnet you set in the Amazon EC2 launch template includes the private IP address.</li></ul> <p>For more information, see <a href="#">General launch settings</a> in the Elastic Disaster Recovery documentation.</p>	AWS administrator

Task	Description	Skills required
Configure the Amazon EC2 launch template.	<p>Elastic Disaster Recovery uses Amazon EC2 launch templates to launch drill and recovery instances for each source server. The launch template is created automatically for each source server that you add to Elastic Disaster Recovery after you install the AWS Replication Agent.</p> <p>You must set the Amazon EC2 launch template as the default launch template if you want to use it with Elastic Disaster Recovery.</p> <p>For more information, see <a href="#">EC2 Launch Template</a> in the Elastic Disaster Recovery documentation.</p>	AWS administrator

## Initiate DR drill and failover

Task	Description	Skills required
Initiate Drill	<ol style="list-style-type: none"> <li>1. On the <a href="#">Elastic Disaster Recovery console</a>, open the <b>Source servers</b> page and verify that the status of the source server is <b>Ready</b>.</li> </ol>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 1027 342">2. Select all the source servers that you want to perform the DR drill for.</li><li data-bbox="592 363 1027 827">3. From the <b>Initiate recovery job</b> menu, choose <b>Initiate drill</b> and select the appropriate point-in-time snapshot. This starts a recovery job for the selected source servers. You can monitor the status of the job on the <b>Recovery job history</b> tab.  <b>Note:</b> Further changes to the source server will be synced to the replication server, not to the drill instance.  The launched drill instance also appears on the <b>Recovery instances</b> page.</li><li data-bbox="592 1291 1027 1373">4. Test and verify the DR drill instance.</li><li data-bbox="592 1394 1027 1810">5. On the <b>Recovery instances</b> page, select the drill instance, and then choose <b>Actions, Disconnect from AWS</b>. This deletes the AWS Replication Agent from the recovery instance and removes all resources associated with</li></ol>	

Task	Description	Skills required
	<p>the recovery instance from Elastic Disaster Recovery.</p> <p>6. Choose <b>Delete recovery instances</b>. This deletes the representation of the instance from the Elastic Disaster Recovery console and completely disassociates the instance from the Elastic Disaster Recovery service. It does not delete the underlying EC2 instance.</p> <p>7. Terminate the DR drill instance from the Amazon EC2 console.</p> <p>For more information, see <a href="#">Preparing for failover</a> in the Elastic Disaster Recovery documentation.</p>	

Task	Description	Skills required
Validate the drill.	<p>In the previous step, you launched new target instances in the DR Region. The target instances are replicas of the source servers based on the snapshot taken when you initiated the launch.</p> <p>In this procedure, you connect to your Amazon EC2 target machines to confirm that they're running as expected.</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Amazon EC2 console</a>.</li><li>2. Choose <b>Instances (running)</b>.</li><li>3. Select the target instance and note its private IPv4 address.</li><li>4. Make sure that you can connect to the EC2 instance and that the JD Edwards EnterpriseOne and related components are replicated as expected.</li></ol>	

Task	Description	Skills required
Initiate a failover.	<p>A failover is the redirection of traffic from a primary system to a secondary system. Elastic Disaster Recovery helps you perform a failover by launching recovery instances on AWS. When the recovery instances have been launched, you redirect the traffic from your primary systems to these instances.</p> <ol style="list-style-type: none"><li>1. On the <a href="#">Elastic Disaster Recovery console</a>, open the <b>Source servers</b> page and verify that the <b>Ready for recovery</b> column for the source server shows <b>Ready</b>, and the <b>Data replication status</b> column shows <b>Healthy</b>.</li><li>2. Select the source server. From the <b>Initiate recovery job</b> menu, choose <b>Initiate recovery</b>.</li><li>3. Select the point-in-time snapshot from which to launch the recovery instance, and then choose <b>Initiate recovery</b>.</li></ol> <p>This starts a recovery job. You can monitor the status of the job on the <b>Recovery instances</b> page.</p>	AWS administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="591 210 1013 533">4. Test and verify the recovery instance. If required, adjust the DNS configuration and connect your JD Edwards EnterpriseOne application to the database.</li><li data-bbox="591 554 993 877">5. You can now disconnect and decommission the source JD Edwards EnterpriseOne server, because all changes have been written to the new recovery instance.</li><li data-bbox="591 898 1026 1171">6. Register the recovery instance as the source server in the DR Region by following the process described in the <i>Install the AWS Replication Agent</i> epic.</li></ol> <p data-bbox="591 1247 993 1423">For more information, see <a href="#">Performing a failover</a> in the Elastic Disaster Recovery documentation.</p>	

Task	Description	Skills required
Initiate a failback.	<p>The process for initiating a failback is similar to the process for initiating failover.</p> <ol style="list-style-type: none"><li data-bbox="594 401 1013 814">1. Open the <a href="#">Elastic Disaster Recovery console</a> in the primary Region. Navigate to the <b>Recovery instances</b> page, select the drill instance, and then choose <b>Actions, Disconnect from AWS, Delete recovery instances</b>.</li><li data-bbox="594 842 1024 1350">2. Open the Elastic Disaster Recovery console in the DR Region. Register your new JD Edwards EnterpriseOne server as the source server in the DR Region by installing the AWS Replication Agent. The data will be synced with a new replication server provisioned in the new staging subnet.</li></ol> <p><b>Note:</b> When the new JD Edwards EnterpriseOne server is registered as a source server, you might see two source servers in the Elastic Disaster Recovery console: one server that was created from the primary EC2 instance, and the new</p>	AWS administrator

Task	Description	Skills required
	<p>server that was created from the recovery instance. We recommend that you tag the servers correctly to avoid confusion, and preferably add the new server to the launch template.</p> <p>3. To restart DR replication from the primary Region, disassociate the launched recovery instance from the Elastic Disaster Recovery console in the DR Region, and register the host as a source server in the primary Region.</p> <p>For more information, see <a href="#">Performing a failback</a> in the Elastic Disaster Recovery documentation.</p>	

Task	Description	Skills required
Start JD Edwards EnterpriseOne components.	<ol style="list-style-type: none"><li>1. Start the JD Edwards EnterpriseOne database by logging in to the database server.</li><li>2. When the database is running, start the JD Edwards EnterpriseOne logic and batch servers.</li><li>3. Start WebLogic on the web servers, and start a JAS instance on the JAS servers.</li><li>4. Start WebLogic on the provision server and on the server for the SM console.</li><li>5. Start SM Agent on the servers.</li><li>6. Confirm that the login to JD Edwards EnterpriseOne works correctly.</li></ol> <p>You will need to make incorporate the changes in Route 53 and Application Load Balancer for the JD Edwards EnterpriseOne link to work.</p> <p>You can automate these steps by using Lambda, Step Functions, and Systems Manager (Run Command).</p>	JD Edwards EnterpriseOne CNC

Task	Description	Skills required
	<p><b>Note:</b> Elastic Disaster Recovery performs block-level replication of the source EC2 instance EBS volumes that host the operating system and file systems. Shared file systems that were created by using Amazon EFS aren't part of this replication. You can replicate shared file systems to the DR Region by using AWS DataSync, as noted in the first epic, and then mount these replicated file systems in the DR system.</p>	

## Troubleshooting

Issue	Solution
<p>Source server data replication status is <b>Stalled</b> and replication lags. If you check details, the data replication status displays <b>Agent not seen</b>.</p>	<p>Check to confirm that the stalled source server is running.</p> <p><b>Note:</b> If the source server goes down, the replication server is automatically terminated.</p> <p>For more information about lag issues, see <a href="#">Replication lag issues</a> in the Elastic Disaster Recovery documentation.</p>
<p>Installation of AWS Replication Agent in source EC2 instance fails in RHEL 8.2 after scanning the disks. <code>aws_replication_agent_installer.log</code> reveals that kernel headers are missing.</p>	<p>Before you install the AWS Replication Agent on RHEL 8, CentOS 8, or Oracle Linux 8, run:</p> <pre>sudo yum install elfutils-libelf-devel</pre>

Issue	Solution
<p>On the Elastic Disaster Recovery console, you see the source server as <b>Ready</b> with a lag and data replication status as <b>Stalled</b>.</p> <p>Depending on how long the AWS Replication Agent has been unavailable, the status might indicate high lag, but the issue remains the same.</p>	<p>For more information, see <a href="#">Linux installation requirements</a> in the Elastic Disaster Recovery documentation.</p> <p>Use an operating system command to confirm that the AWS Replication Agent is running in the source EC2 instance, or confirm that the instance is running.</p> <p>After you correct any issues, Elastic Disaster Recovery will restart scanning. Wait until all data has been synced and the replication status is <b>Healthy</b> before you start a DR drill.</p>
<p>Initial replication with high lag. On the Elastic Disaster Recovery console, you can see that the initial sync status is extremely slow for a source server.</p>	<p>Check for the replication lag issues documented in the <a href="#">Replication lag issues</a> section of the Elastic Disaster Recovery documentation.</p> <p>The replication server might be unable to handle the load because of intrinsic compute operations. In that case, try upgrading the instance type after consulting with the <a href="#">AWS Technical Support team</a>.</p>

# Synchronize data between Amazon EFS file systems in different AWS Regions by using AWS DataSync

Created by Sarat Chandra Pothula (AWS) and Aditya Ambati (AWS)

**Code repository:** [aws-efs-c](#)  
[rossregion-datasync](#)

**Environment:** PoC or pilot

**Technologies:** Infrastructure;  
Storage & backup

**AWS services:** AWS CDK;  
AWS DataSync; Amazon EFS

## Summary

This solution provides a robust framework for efficient and secure data synchronization between Amazon Elastic File System (Amazon EFS) instances in different AWS Regions. This approach is scalable and provides controlled, cross-Region data replication. This solution can enhance your disaster recovery and data redundancy strategies.

By using the AWS Cloud Development Kit (AWS CDK), this pattern uses an infrastructure as code (IaC) approach to deploy the solution resources. The AWS CDK application deploys the essential AWS DataSync, Amazon EFS, Amazon Virtual Private Cloud (Amazon VPC), and Amazon Elastic Compute Cloud (Amazon EC2) resources. This IaC provides a repeatable and version-controlled deployment process that is fully aligned with AWS best practices.

## Prerequisites and limitations

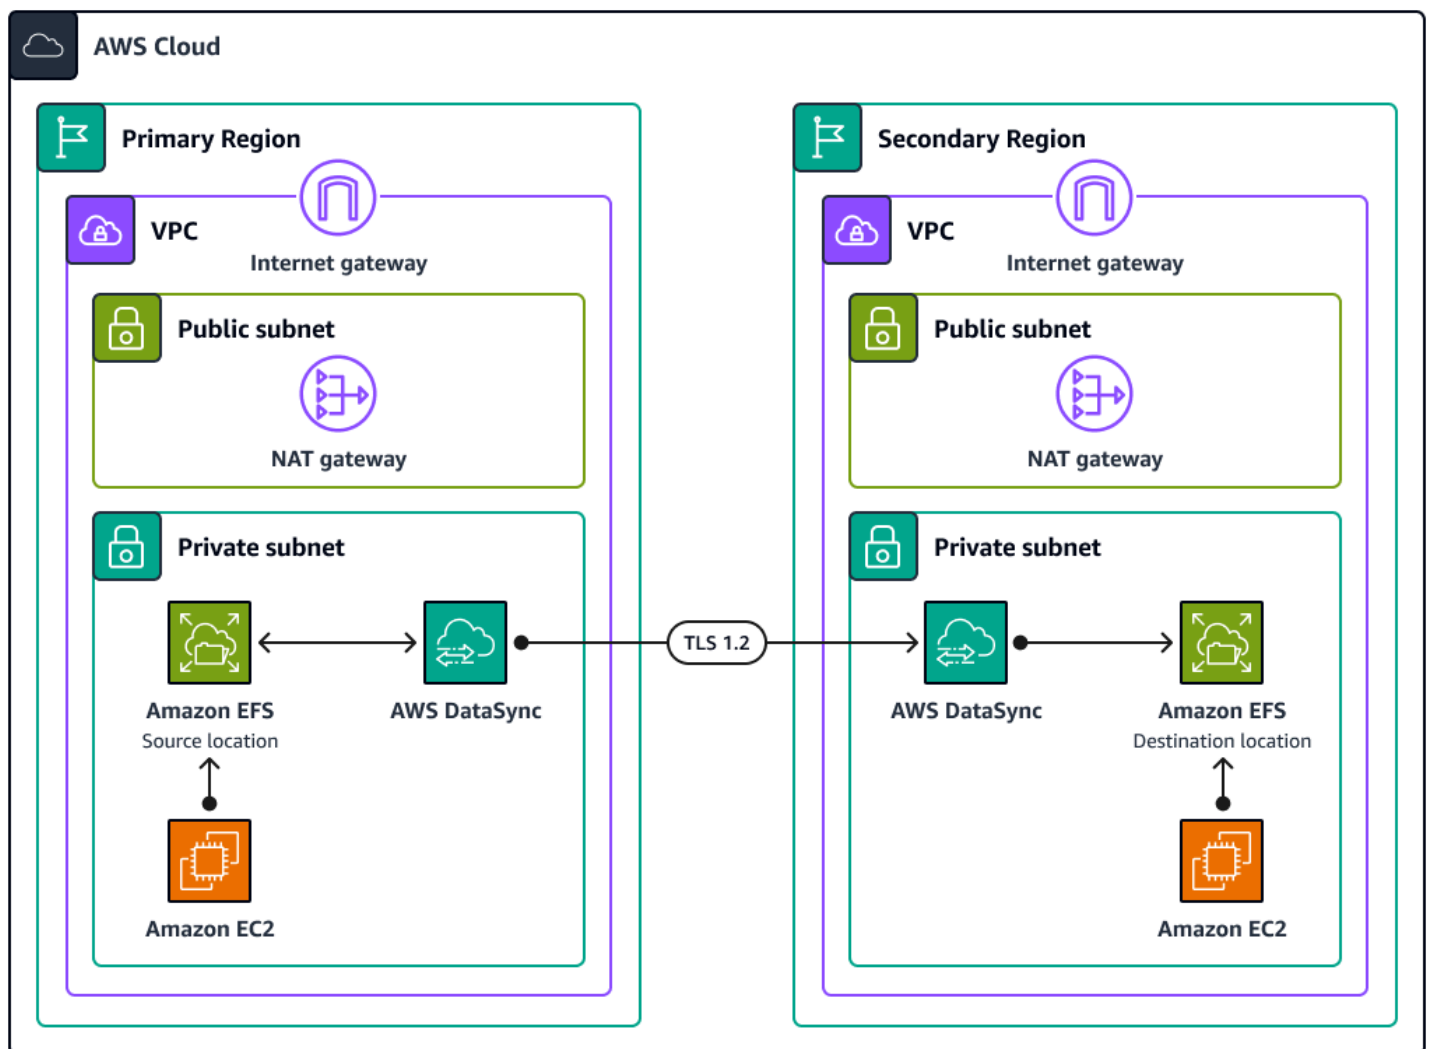

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2.9.11 or later, [installed](#) and [configured](#)
- AWS CDK version 2.114.1 or later, [installed](#) and [bootstrapped](#)
- NodeJS version 20.8.0 or later, [installed](#)

### Limitations

- The solution inherits limitations from DataSync and Amazon EFS, such as data transfer rates, size limitations, and regional availability. For more information, see [AWS DataSync quotas](#) and [Amazon EFS quotas](#).
- This solution supports Amazon EFS only. DataSync supports [other AWS services](#), such as Amazon Simple Storage Service (Amazon S3) and Amazon FSx for Lustre. However, this solution requires modification to synchronize data with these other services.

## Architecture

This solution deploys the following AWS CDK stacks:

- **Amazon VPC stack** – This stack sets up virtual private cloud (VPC) resources, including subnets, an internet gateway, and a NAT gateway in both the primary and secondary AWS Regions.

- **Amazon EFS stack** – This stack deploys Amazon EFS file systems into the primary and secondary Regions and connects them to their respective VPCs.
- **Amazon EC2 stack** – This stack launches EC2 instances in the primary and secondary Regions. These instances are configured to mount the Amazon EFS file system, which allows them to access the shared storage.
- **DataSync location stack** – This stack uses a custom construct called `DataSyncLocationConstruct` to create DataSync location resources in the primary and secondary Regions. These resources define endpoints for data synchronization.
- **DataSync task stack** – This stack uses a custom construct called `DataSyncTaskConstruct` to create a DataSync task in the primary Region. This task is configured to synchronize data between the primary and secondary Regions by using the DataSync source and destination locations.

## Tools

### AWS services

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS DataSync](#) is an online data transfer and discovery service that helps you move files or object data to, from, and between AWS storage services.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

### Code repository

The code for this pattern is available in the GitHub [Amazon EFS Cross-Region DataSync Project](#) repository.

## Best practices

Follow the best practices described in [Best practices for using the AWS CDK in TypeScript to create IaC projects](#).

## Epics

### Deploy the AWS CDK app

Task	Description	Skills required
Clone the project repository.	<p>Enter the following command to clone the <a href="#">Amazon EFS Cross-Region DataSync Project</a> repository.</p> <pre>git clone https://github.com/aws-samples/aws-efs-crossregion-datasync.git</pre>	AWS DevOps
Install the npm dependencies.	<p>Enter the following command.</p> <pre>npm ci</pre>	AWS DevOps
Choose the primary and secondary Regions.	<p>In the cloned repository, navigate to the <code>src/infa</code> directory. In the <code>Launcher.ts</code> file, update the <code>PRIMARY_AWS_REGION</code> and <code>SECONDARY_AWS_REGION</code> values. Use the corresponding <a href="#">Region codes</a>.</p> <pre>const primaryRegion = { account: account,</pre>	AWS DevOps

Task	Description	Skills required
	<pre>region: '&lt;PRIMARY _AWS_REGION&gt;' }; const secondaryRegion = { account: account, region: '&lt;SECONDA RY_AWS_REGION&gt;' };</pre>	
Bootstrap the environment.	<p>Enter the following command to bootstrap the AWS account and AWS Region that you want to use.</p> <pre>cdk bootstrap &lt;aws_accou nt&gt;/&lt;aws_region&gt;</pre> <p>For more information, see <a href="#">Bootstrapping</a> in the AWS CDK documentation.</p>	AWS DevOps
List the AWS CDK stacks.	<p>Enter the following command to view a list of the AWS CDK stacks in the app.</p> <pre>cdk ls</pre>	AWS DevOps
Synthesize the AWS CDK stacks.	<p>Enter the following command to produce an AWS CloudFormation template for each stack defined in the AWS CDK app.</p> <pre>cdk synth</pre>	AWS DevOps

Task	Description	Skills required
Deploy the AWS CDK app.	<p>Enter the following command to deploy all of the stacks to your AWS account, without requiring manual approval for any changes.</p> <pre>cdk deploy --all --require-approval never</pre>	AWS DevOps

## Validate the deployment

Task	Description	Skills required
Log in to the EC2 instance in the primary Region.	<ol style="list-style-type: none"><li>Using Session Manager, a capability of AWS Systems Manager, log in to the EC2 instance in the primary Region. For instructions, see <a href="#">Connect to your Linux instance with AWS Systems Manager Session Manager</a>.</li><li>Change directories to the Amazon EFS mount path.</li></ol> <pre>cd /mnt/efs</pre>	AWS DevOps
Create a temporary file.	<p>Enter the following command to create a temporary file in the Amazon EFS mount path.</p> <pre>sudo dd if=/dev/zero \ of=tmpst.dat \ bs=1G \ seek=5 \</pre>	AWS DevOps

Task	Description	Skills required
	<pre>count=0  ls -lrt tmpst.dat</pre>	
Start the DataSync task.	<p>Enter the following command to replicate the temporary file from the primary Region to the secondary Region, where &lt;ARN-task&gt; is the Amazon Resource Name (ARN) of your DataSync task.</p> <pre>aws datasync start-task-execution \   --task-arn &lt;ARN-task&gt;</pre> <p>The command returns the ARN of the task execution in the following format.</p> <pre>arn:aws:datasync:&lt;region&gt;:&lt;account-ID&gt;:task/task-execution/&lt;exec-ID&gt;</pre>	AWS DevOps

Task	Description	Skills required
<p>Check the status of the data transfer.</p>	<p>Enter the following command to describe the DataSync execution task, where <code>&lt;ARN-task-execution&gt;</code> is the ARN of the task execution.</p> <pre>aws datasync describe-task-execution \   --task-execution-arn &lt;ARN-task-execution&gt;</pre> <p>The DataSync task is complete when <code>PrepareStatus</code>, <code>TransferStatus</code>, and <code>VerifyStatus</code> all have the value <code>SUCCESS</code>.</p>	AWS DevOps
<p>Log in to the EC2 instance in the secondary Region.</p>	<ol style="list-style-type: none"><li>1. Using Session Manager, a capability of AWS Systems Manager, log in to the EC2 instance in the secondary Region. For instructions, see <a href="#">Connect to your Linux instance with AWS Systems Manager Session Manager</a>.</li><li>2. Change directories to the Amazon EFS mount path.</li></ol> <pre>cd /mnt/efs</pre>	AWS DevOps

Task	Description	Skills required
Validate the replication.	<p>Enter the following command to verify that the temporary file exists in the Amazon EFS file system.</p> <pre data-bbox="597 443 1026 562">ls -lrt tmpst.dat</pre>	AWS DevOps

# Upgrade SAP Pacemaker clusters from ENSA1 to ENSA2

Created by Gergely Cserdi (AWS) and Balazs Sandor Skublics (AWS)

<b>Environment:</b> Production	<b>Source:</b> ENSA1-based Pacemaker cluster	<b>Target:</b> ENSA2-based Pacemaker cluster
<b>R Type:</b> Re-architect	<b>Workload:</b> SAP	<b>Technologies:</b> Infrastructure; Modernization
<b>AWS services:</b> Amazon EC2		

## Summary

This pattern explains the steps and considerations for upgrading an SAP Pacemaker cluster that is based on Standalone Enqueue Server (ENSA1) to ENSA2. The information in this pattern applies to both SUSE Linux Enterprise Server (SLES) and Red Hat Enterprise Linux (RHEL) operating systems.

Pacemaker clusters on SAP NetWeaver 7.52 or S/4HANA 1709 and earlier versions run on an ENSA1 architecture and are configured specifically for ENSA1. If you run your SAP workloads on Amazon Web Services (AWS) and you're interested in moving to ENSA2, you might find that the SAP, SUSE, and RHEL documentation doesn't provide comprehensive information. This pattern describes the technical steps required to reconfigure SAP parameters and Pacemaker clusters to upgrade from ENSA1 to ENSA2. It provides examples of SUSE systems, but the concept is the same for RHEL clusters.

**Notes:** ENSA1 and ENSA2 are concepts that pertain to SAP applications only, so the information in this pattern doesn't apply to SAP HANA or other types of clusters.

Technically, ENSA2 can be used with or without Enqueue Replicator 2. However, high availability (HA) and failover automation (through a cluster solution) require Enqueue Replicator 2. This pattern uses the term *ENSA2 clusters* to refer to clusters with Standalone Enqueue Server 2 and Enqueue Replicator 2.

## Prerequisites and limitations

### Prerequisites

- A working ENSA1-based cluster that uses Pacemaker and Corosync on SLES or RHEL.
- At least two Amazon Elastic Compute Cloud (Amazon EC2) instances where the (ABAP) SAP Central Services (ASCS/SCS) and Enqueue Replication Server (ERS) instances are running.
- Knowledge of managing SAP applications and clusters.
- Access to the Linux environment as root user.

### Limitations

- ENSA1-based clusters support a two-node architecture only.
- ENSA2-based clusters cannot be deployed to SAP NetWeaver versions before 7.52.
- EC2 instances in clusters should be in different AWS Availability Zones.

### Product versions

- SAP NetWeaver version 7.52 or later
- Starting with S/4HANA 2020, only ENSA2 clusters are supported
- Kernel 7.53 or later, which supports ENSA2 and Enqueue Replicator 2
- SLES for SAP Applications version 12 or later
- RHEL for SAP with High Availability (HA) version 7.9 or later

## Architecture

### Source technology stack

- SAP NetWeaver 7.52 with SAP Kernel 7.53 or later
- SLES or RHEL operating system

### Target technology stack

- SAP NetWeaver 7.52 with SAP Kernel 7.53 or later, including S/4HANA 2020 with ABAP platform
- SLES or RHEL operating system

## Target architecture

The following diagram shows an HA configuration of ASCS/SCS and ERS instances based on an ENSA2 cluster.

## Comparison of ENSA1 and ENSA2 clusters

SAP introduced ENSA2 as the successor to ENSA1. An ENSA1-based cluster supports a two-node architecture where the ASCS/SCS instance fails over to ERS when an error occurs. This limitation stems from how the ASCS/SCS instance regains the lock table information from the shared memory of the ERS node after failover. ENSA2-based clusters with Enqueue Replicator 2 eliminate this limitation, because the ASCS/SCS instance can collect the lock information from the ERS instance over the network. ENSA2-based clusters can have more than two nodes, because the ASCS/SCS instance is no longer required to fail over to the ERS node. (However, in a two-node ENSA2 cluster environment, the ASCS/SCS instance will still fail over to the ERS node because there are no other nodes in the cluster to fail over to.) ENSA2 is supported starting with SAP Kernel 7.50 with some limitations. For HA setup that supports Enqueue Replicator 2, the minimum requirement is NetWeaver 7.52 (see [SAP OSS Note 2630416](#)). S/4HANA 1809 comes with ENSA2

architecture recommended by default, whereas S/4HANA supports only ENSA2 starting with version 2020.

## Automation and scale

The HA cluster in the target architecture makes ASCS fail over to other nodes automatically.

## Scenarios for moving to ENSA2-based clusters

There are two main scenarios for upgrading to ENSA2-based clusters:

- Scenario 1: You choose to upgrade to ENSA2 without an accompanying SAP upgrade or S/4HANA conversion, assuming that your SAP release and Kernel version support ENSA2.
- Scenario 2: You move to ENSA2 as part of an upgrade or conversion (for example, to S/4HANA 1809 or later) by using SUM.

The [Epics](#) section covers the steps for these two scenarios. The first scenario requires you to manually set up SAP-related parameters before you change the cluster configuration for ENSA2. In the second scenario, the binaries and SAP-related parameters are deployed by SUM, and your only remaining task is to update the cluster configuration for HA. We still recommend that you validate SAP parameters after you use SUM. In most cases, S/4HANA conversion is the main reason for a cluster upgrade.

## Tools

- For OS package managers, we recommend the Zypper (for SLES) or YUM (for RHEL) tools.
- For cluster management, we recommend **crm** (for SLES) or **pcs** (for RHEL) shells.
- SAP instance management tools such as SAPControl.
- (Optional) SUM tool for S/4HANA conversion upgrade.

## Best practices

- For best practices for using SAP workloads on AWS, see the [SAP Lens](#) for the AWS Well-Architected Framework.
- Consider the number of cluster nodes (odd or even) in your ENSA2 multi-node architecture.
- Set up the ENSA2 cluster for SLES 15 in alignment with the SAP S/4-HA-CLU 1.0 certification standard.

- Always save or back up your existing cluster and application state before upgrading to ENSA2.

## Epics

### Configure SAP parameters manually for ENSA2 (scenario 1 only)

Task	Description	Skills required
Configure the parameters in the default profile.	<p>If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the parameters in the default profile (DEFAULT.PFL file) to the following values.</p> <pre>enq/enable=TRUE enq/serverhost=sapas csvirt enq/serverinst=10     (instance number of     ASCS/SCS instance) enque/process_ location=REMOTESA enq/replicatorhost=sap persvirt enq/replicatorinst=11     (instance number of     ERS instance)</pre> <p>where <code>sapascsvirt</code> is the virtual hostname for the ASCS instances, and <code>sapersvirt</code> is the virtual hostname for the ERS instances. You can change</p>	SAP

Task	Description	Skills required
	<p>these to fit your target environment.</p> <p><b>Note:</b> To use this upgrade option, your SAP release and Kernel version must support ENSA2 and Enqueue Replicator 2.</p>	

Task	Description	Skills required
Configure the ASCS/SCS instance profile.	<p>If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the following parameters in the ASCS/SCS instance profile.</p> <p>The section of the profile where ENSA1 is defined looks something like the following.</p> <pre data-bbox="594 758 1027 1633"> #----- ----- ----- ----- Start SAP enqueue server #----- ----- ----- ----- _EN = en.sap\$(S APSYSTEMNAME)\$(INS TANCE_NAME) Execute_04 = local rm - f \$_EN Execute_05 = local ln - s -f \$(DIR_EXECUTABLE)/ enserver\$(FT_EXE) \$_EN Start_Program_01 = local \$_EN pf=\$_PF </pre> <p>To reconfigure this section for ENSA2:</p>	SAP

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>1. Change the <code>_EN</code> program prefix to <code>_ENQ</code> based on the latest information from SAP (OSS Note 2501860; requires an <a href="#">SAP ONE Support Launchpad user account</a>).</li> <li>2. Change the binary for enqueue server from <code>enserver</code> to <code>enq_server</code>.</li> <li>3. Set the new parameter <code>enq/server/replication/enable</code> to <code>TRUE</code>.</li> <li>4. Make sure that <code>Autostart = 0</code>.</li> </ol> <p>This profile section would look something like the following after your changes.</p> <pre data-bbox="597 1241 1027 1808"> #----- ----- ----- ----- Start SAP enqueue server #----- ----- ----- ----- _ENQ = enq.sap\$( SAPSYSTEMNAME)\$(IN STANCE_NAME) Execute_04 = local rm - f \$_ENQ </pre>	

Task	Description	Skills required
	<pre>Execute_05 = local ln - s -f \$(DIR_EXECUTABLE)/ enq_server\$(FT_EXE) \$_ENQ) Start_Program_01 = local \$_ENQ pf= \$_PF) ... enq/server/replic ation/enable = TRUE Autostart = 0</pre> <p><b>Important:</b> _ENQ must not have the restart option enabled. If RestartProgram_01 is set for _ENQ, change it to StartProgram_01 . This prevents SAP from restarting the service or interfering with cluster-managed resources.</p>	

Task	Description	Skills required
Configure the ERS profile.	<p>If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the following parameters in the ERS instance profile.</p> <p>Find the section where the enqueue replicator is defined. It will be similar to the following.</p> <pre data-bbox="594 806 1029 1682"> #----- ----- ----- Start enqueue replicati on server #----- ----- ----- _ER = er.sap\$(S APSYSTEMNAME)\$(INS TANCE_NAME) Execute_03 = local rm - f \$_ER) Execute_04 = local ln - s -f \$(DIR_EXECUTABLE)/ enrepserver\$(FT_EXE) \$_ER) Start_Program_00 = local \$_ER) pf=\$_PF) NR=\$_SCSID) </pre> <p>To reconfigure this section for Enqueue Replicator 2:</p>	SAP

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>1. Change the _ER program prefix to _ENQR based on the latest notes from SAP (OSS Note 2501860; requires an <a href="#">SAP ONE Support Launchpad user account</a>).</li> <li>2. Change the binary for the enqueue replicator to enq_replicator instead of enrepserver .</li> <li>3. Make sure that Autostart = 0.</li> </ol> <p>This profile section should look something like the following after your changes.</p> <pre data-bbox="609 1092 1031 1774"> #----- ----- ----- Start enqueue replicati on server #----- ----- ----- _ENQR = enqr.sap\$ (SAPSYSTEMNAME)\$(I NSTANCE_NAME) Execute_01 = local rm - f \$_ENQR Execute_02 = local ln - s -f \$(DIR_EXECUTABLE)/ enq_replicator\$(FT _EXE) \$_ENQR </pre>	

Task	Description	Skills required
	<pre>Start_Program_00 =   local \$_ENQR pf=   \$_PF) NR=\$(SCSID) ... Autostart = 0</pre> <p><b>Important:</b> <code>_ENQR</code> must not have the restart option enabled. If <code>RestartProgram_01</code> is set for <code>_ENQR</code>, change it to <code>StartProgram_01</code>. This prevents SAP from restarting the service or interfering with cluster-managed services.</p>	
Restart SAP Start Services.	<p>After you change the profiles described previously in this epic, restart SAP Start Services for both ASCS/SCS and ERS.</p> <pre>sapcontrol -nr 10 - function RestartSe vice SCT</pre> <pre>sapcontrol -nr 11 - function RestartSe vice SCT</pre> <p>where SCT refers to the SAP system ID, and assuming that 10 and 11 are the instance numbers for ASCS/SCS and ERS instances, respectively.</p>	SAP

## Reconfigure the cluster for ENSA2 (required for both scenarios)

Task	Description	Skills required
Verify version numbers in SAP resource agents.	<p>When you use SUM to upgrade SAP to S/4HANA 1809 or later, SUM handles the parameter changes in the SAP profiles. Only the cluster requires manual adjustment. However, we recommend that you verify the parameter settings before you make any changes to the cluster.</p> <p><b>Note:</b> The examples in this epic assume that you're using the SUSE operating system. If you're using RHEL, you will need to use tools such as YUM and the <b>pcs</b> shell instead of Zypper and <b>crm</b>.</p> <p>Check both nodes in the architecture to confirm that the <code>resource-agents</code> package matches the minimum version recommended by SAP. For SLES, check SAP OSS Note 2641019. For RHEL, check SAP OSS Note 2641322. (SAP Notes require an <a href="#">SAP ONE Support Launchpad user account</a>.)</p> <pre>sapers:sctadm 23&gt; zypper search -s -i resource-agents</pre>	AWS systems administrator

Task	Description	Skills required
	<pre> Loading repository data... Reading installed packages... S   Name   Type     Version   Arch     Repository --+----- ----+-----+--- ----- -----+--- -----+----- ----- i   resource-agents     package   4.8.0+git 30.d0077df0-150300 .8.28.1   x86_64     SLE-Product-HA15-SP3-   Updates                     </pre> <p>Update the resource-agents version if necessary.</p>	
<p>Back up cluster configuration.</p>	<p>Back up the CRM cluster configuration as follows.</p> <pre> crm configure show &gt; / tmp/cluster_config_backup.txt                     </pre>	<p>AWS systems administrator</p>

# Use consistent Availability Zones in VPCs across different AWS accounts

Created by Adam Spicer (AWS)

**Code repository:** [Multi-account Availability Zone mapping](#)

**Environment:** Production

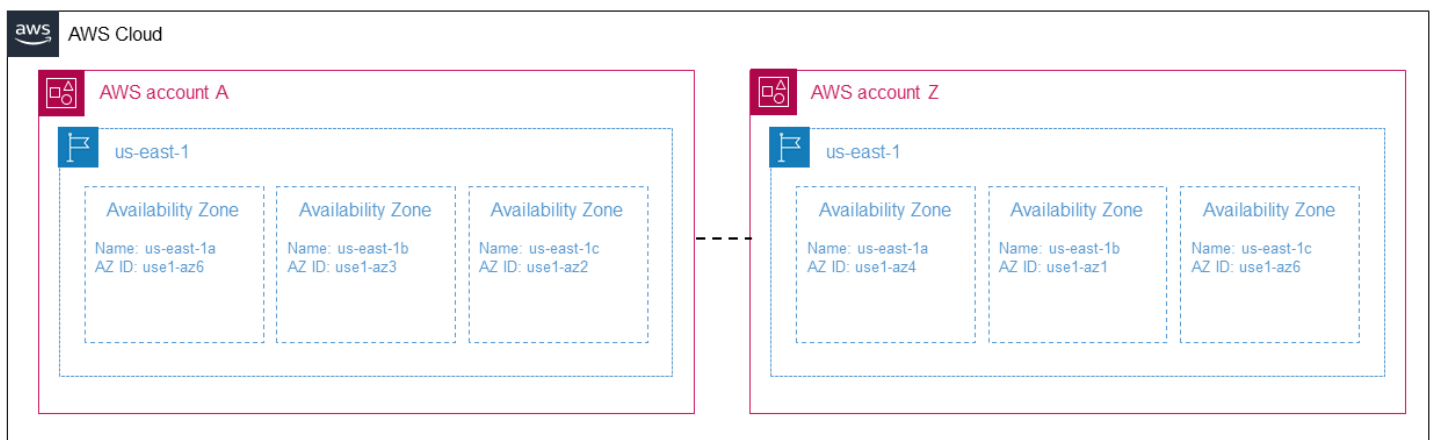

**Technologies:** Infrastructure

**AWS services:** AWS CloudFormation; Amazon VPC; AWS Lambda

## Summary

On the Amazon Web Services (AWS) Cloud, an Availability Zone has a name that can vary between your AWS accounts and an [Availability Zone ID \(AZ ID\)](#) that identifies its location. If you use AWS CloudFormation to create virtual private clouds (VPCs), you must specify the Availability Zone's name or ID when creating the subnets. If you create VPCs in multiple accounts, the Availability Zone name is randomized, which means that subnets use different Availability Zones in each account.

To use the same Availability Zone across your accounts, you must map the Availability Zone name in each account to the same AZ ID. For example, the following diagram shows that the use1-az6 AZ ID is named us-east-1a in AWS account A and us-east-1c in AWS account Z.

This pattern helps ensure zonal consistency by providing a cross-account, scalable solution for using the same Availability Zones in your subnets. Zonal consistency ensures that your cross-account network traffic avoids cross-Availability Zone network paths, which helps reduce data transfer costs and lower network latency between your workloads.

This pattern is an alternative approach to the AWS CloudFormation [AvailabilityZoneId property](#).

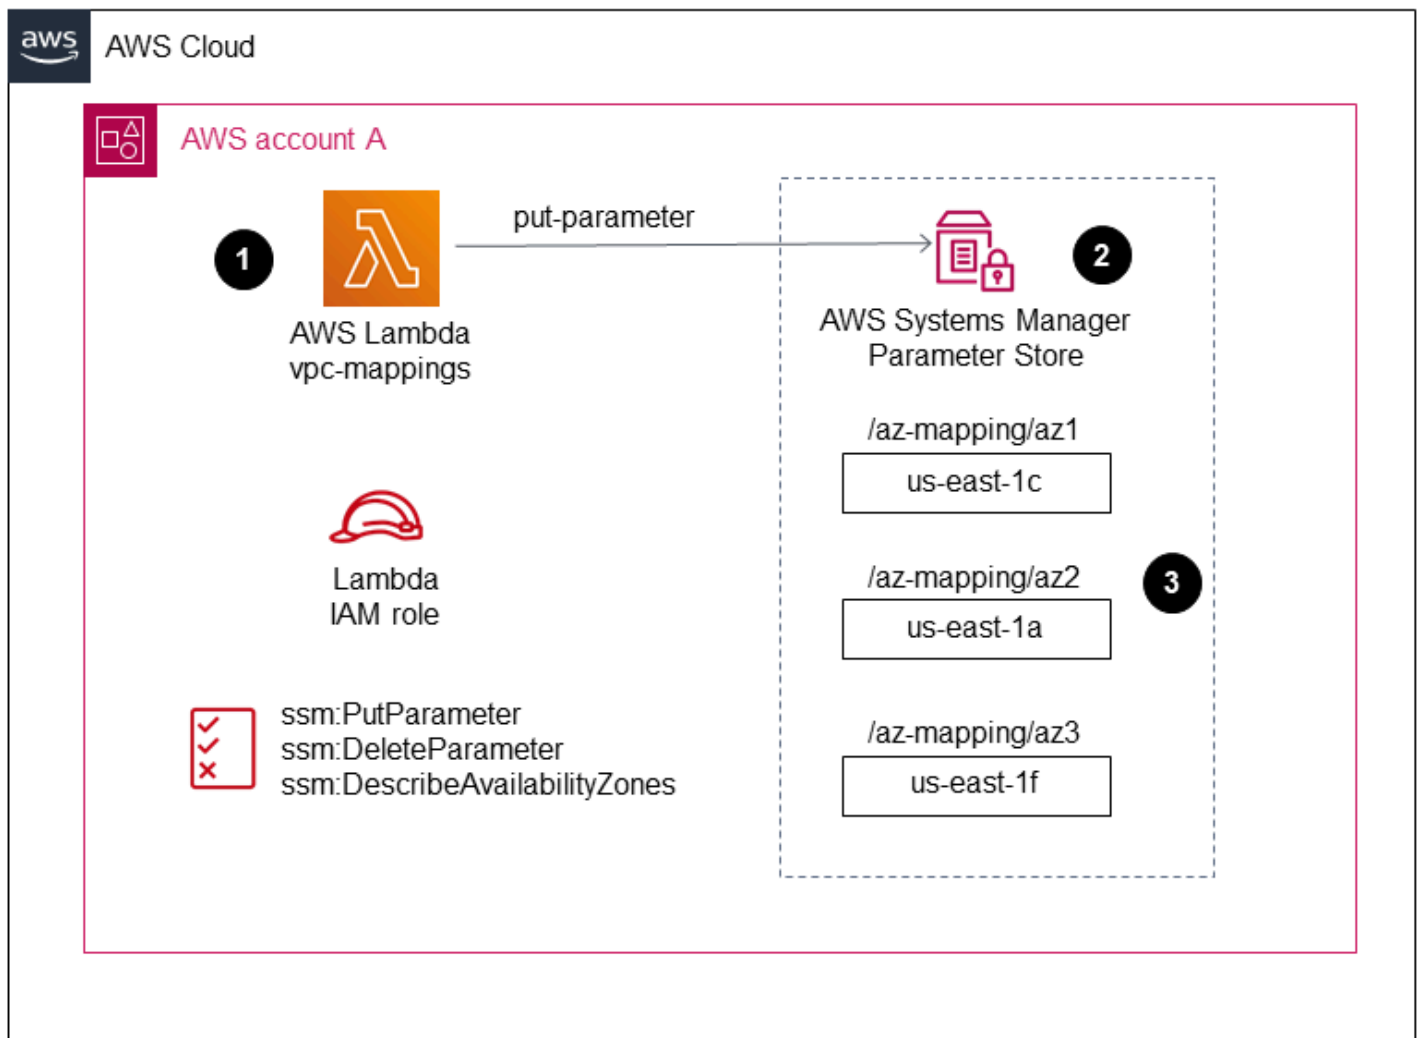

## Prerequisites and limitations

### Prerequisites

- At least two active AWS accounts in the same AWS Region.
- Evaluate how many Availability Zones are needed to support your VPC requirements in the Region.
- Identify and record the AZ ID for each Availability Zone that you need to support. For more information about this, see [Availability Zone IDs for your AWS resources](#) in the AWS Resource Access Manager documentation.
- An ordered, comma-separated list of your AZ IDs. For example, the first Availability Zone on your list is mapped as az1, the second Availability Zone is mapped as az2, and this mapping structure continues until your comma-separated list is fully mapped. There is no maximum number of AZ IDs that can be mapped.
- The az-mapping.yaml file from the GitHub [Multi-account Availability Zone mapping](#) repository, copied to your local machine

## Architecture

The following diagram shows the architecture that is deployed in an account and that creates AWS Systems Manager Parameter Store values. These Parameter Store values are consumed when you create a VPC in the account.

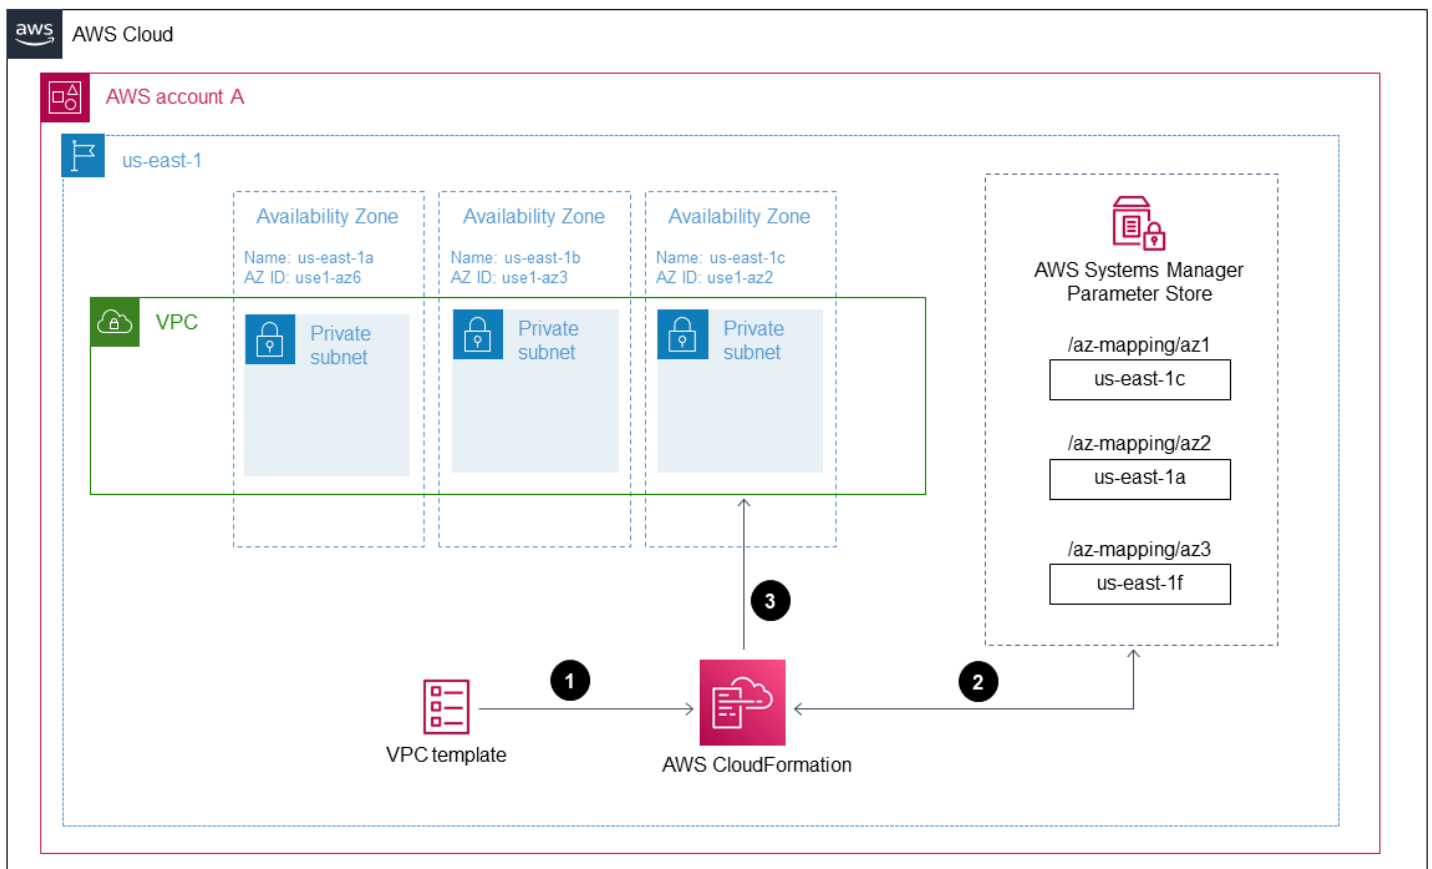

The diagram shows the following workflow:

1. This pattern's solution is deployed to all accounts that require zonal consistency for a VPC.
2. The solution creates Parameter Store values for each AZ ID and stores the new Availability Zone name.
3. The AWS CloudFormation template uses the Availability Zone name stored in each Parameter Store value and this ensures zonal consistency.

The following diagram shows the workflow for creating a VPC with this pattern's solution.

The diagram shows the following workflow:

1. Submit a template for creating a VPC to AWS CloudFormation.
2. AWS CloudFormation resolves the Parameter Store values for each Availability Zone and returns the Availability Zone name for each AZ ID.
3. A VPC is created with the correct AZ IDs required for zonal consistency.

After you deploy this pattern's solution, you can create subnets that reference the Parameter Store values. If you use AWS CloudFormation, you can reference the Availability Zone mapping parameter values from the following YAML-formatted sample code:

```
Resources:
  PrivateSubnet1AZ1:
    Type: AWS::EC2::Subnet
    Properties:
      VpcId: !Ref VPC
      CidrBlock: !Ref PrivateSubnetAZ1CIDR
      AvailabilityZone:
```

```
!Join
- ''
- - '{{resolve:ssm:/az-mapping/az1:1}}'
```

This sample code is contained in the `vpc-example.yaml` file from the GitHub [Multi-account Availability Zone mapping](#) repository. It shows you how to create a VPC and subnets that align to the Parameter Store values for zonal consistency.

## Technology stack

- AWS CloudFormation
- AWS Lambda
- AWS Systems Manager Parameter Store

## Automation and scale

You can deploy this pattern to all your AWS accounts by using AWS CloudFormation StackSets or the Customizations for AWS Control Tower solution. For more information, see [Working with AWS CloudFormation StackSets](#) in the AWS CloudFormation documentation and [Customizations for AWS Control Tower](#) in the AWS Solutions Library.

After you deploy the AWS CloudFormation template, you can update it to use the Parameter Store values and deploy your VPCs in pipelines or according to your requirements.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- [AWS Lambda](#) is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- [AWS Systems Manager Parameter Store](#) is a capability of AWS Systems Manager. It provides secure, hierarchical storage for configuration data management and secrets management.

## Code

The code for this pattern is provided in the GitHub [Multi-account Availability Zone mapping](#) repository.

## Epics

### Deploy the az-mapping.yaml file

Task	Description	Skills required
Determine the required Availability Zones for the Region.	<ol style="list-style-type: none"><li>1. Determine the AZ IDs that must be consistently used in your Region.</li><li>2. Record these AZ IDs in a comma-separated list and in the order that you want them applied in. For example, the first Availability Zone on your list is mapped as az1 and the second is mapped as az2. There is no maximum number of AZ IDs that can be mapped.</li></ol>	Cloud architect
Deploy the az-mapping.yaml file.	Use the az-mapping.yaml file to create an AWS CloudFormation stack in all required AWS accounts. In the AZIDs parameter, use the comma-separated list that you created earlier.	Cloud architect

Task	Description	Skills required
	We recommend that you use <a href="#">AWS CloudFormation StackSets</a> or the <a href="#">Customizations for AWS Control Tower Solution</a> .	

## Deploy the VPCs in your accounts

Task	Description	Skills required
Customize the AWS CloudFormation templates.	<p>When you create the subnets using AWS CloudFormation, customize the templates to use the Parameter Store values that you created earlier.</p> <p>For a sample template, see the <code>vpc-example.yaml</code> file in the GitHub <a href="#">Multi-account Availability Zone mapping</a> repository.</p>	Cloud architect
Deploy the VPCs.	Deploy the customized AWS CloudFormation templates into your accounts. Each VPC in the Region then has zonal consistency in the Availability Zones used for the subnets	Cloud architect

# Validate Account Factory for Terraform (AFT) code locally

Created by Alexandru Pop (AWS) and Michal Gorniak (AWS)

**Environment:** Production

**Technologies:** Infrastructure; DevOps; Modernization; DevelopmentAndTesting

**Workload:** Open-source

**AWS services:** AWS Control Tower

## Summary

This pattern shows how to locally test HashiCorp Terraform code that's managed by AWS Control Tower Account Factory for Terraform (AFT). Terraform is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. AFT sets up a Terraform pipeline that helps you provision and customize multiple AWS accounts in AWS Control Tower.

During code development, it can be helpful to test your Terraform infrastructure as code (IaC) locally, outside of the AFT pipeline. This pattern shows how to do the following:

- Retrieve a local copy of the Terraform code that's stored in the AWS CodeCommit repositories in your AFT management account.
- Simulate the AFT pipeline locally by using the retrieved code.

This procedure can also be used to run Terraform commands that aren't part of the normal AFT pipeline. For example, you can use this method to run commands such as `terraform validate`, `terraform plan`, `terraform destroy`, and `terraform import`.

## Prerequisites and limitations

### Prerequisites

- An active AWS multi-account environment that uses [AWS Control Tower](#)
- A fully deployed of [AFT environment](#)

- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- [AWS CLI credential helper for Code Commit](#), installed and configured
- Python 3.x
- [Git](#), installed and configured on your local machine
- git-remote-commit utility, [installed and configured](#)
- [Terraform](#), installed and configured (the local Terraform package version must match the version that's used in the AFT deployment)

## Limitations

- This pattern doesn't cover the deployment steps required for AWS Control Tower, AFT, or any specific Terraform modules.
- The output that's generated locally during this procedure isn't saved in the AFT pipeline runtime logs.

## Architecture

### Target technology stack

- AFT infrastructure deployed within an AWS Control Tower deployment
- Terraform
- Git
- AWS CLI version 2

### Automation and scale

This pattern shows how to locally invoke Terraform code for AFT global account customizations in a single AFT-managed AWS account. After your Terraform code is validated, you can apply it to the remaining accounts in your multi-account environment. For more information, see [Re-invoke customizations](#) in the AWS Control Tower documentation.

You can also use a similar process to run AFT account customizations in a local terminal. To locally invoke Terraform code from AFT account customizations, clone the **aft-account-customizations repository** instead of **aft-global-account-customizations** repository from CodeCommit in your AFT management account.

## Tools

### AWS services

- [AWS Control Tower](#) helps you set up and govern an AWS multi-account environment, following prescriptive best practices.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

### Other services

- [HashiCorp Terraform](#) is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- [Git](#) is an open-source, distributed version control system.

### Code

The following is an example bash script that can be used to locally run Terraform code that's managed by AFT. To use the script, follow the instructions in the *Epics* section of this pattern.

```
#!/bin/bash
# Version: 1.1 2022-06-24 Unsetting AWS_PROFILE since, when set, it interferes with
script operation
#           1.0 2022-02-02 Initial Version
#
# Purpose: For use with AFT: This script runs the local copy of TF code as if it were
running within AFT pipeline.
#           * Facilitates testing of what the AFT pipeline will do
#           * Provides the ability to run terraform with custom arguments (like 'plan'
or 'move') which are currently not supported within the pipeline.
#
# © 2021 Amazon Web Services, Inc. or its affiliates. All Rights Reserved.
# This AWS Content is provided subject to the terms of the AWS Customer Agreement
# available at http://aws.amazon.com/agreement or other written agreement between
# Customer and either Amazon Web Services, Inc. or Amazon Web Services EMEA SARL or
both.
#
# Note: Arguments to this script are passed directly to 'terraform' without parsing nor
validation by this script.
#
```

```
# Prerequisites:
# 1. local copy of ct GIT repositories
# 2. local backend.tf and aft-providers.tf filled with data for the target account
#    on which terraform is to be run
#    Hint: The contents of above files can be obtain from the logs of a previous
#    execution of the AFT pipeline for the target account.
# 3. 'terraform' binary is available in local PATH
# 4. Recommended: .gitignore file containing 'backend.tf', 'aft_providers.tf' so the
#    local copy of these files are not pushed back to git

readonly credentials=$(aws sts assume-role \
  --role-arn arn:aws:iam::$(aws sts get-caller-identity --query "Account" --output
  text ):role/AWSAFTAdmin \
  --role-session-name AWSAFT-Session \
  --query Credentials )

unset AWS_PROFILE
export AWS_ACCESS_KEY_ID=$(echo $credentials | jq -r '.AccessKeyId')
export AWS_SECRET_ACCESS_KEY=$(echo $credentials | jq -r '.SecretAccessKey')
export AWS_SESSION_TOKEN=$(echo $credentials | jq -r '.SessionToken')
terraform "$@"
```

## Epics

### Save the example code as a local file

Task	Description	Skills required
Save the example code as a local file.	<ol style="list-style-type: none"> <li>Copy the example bash script that's in the <i>Code</i> section of this pattern and paste it into a code editor.</li> <li>Name the file <code>ct_terraform.sh</code> . Then, save the file locally inside a dedicated folder, such as <code>~/scripts</code> or <code>~/bin</code>.</li> </ol>	AWS administrator
Make the example code runnable.	Open a terminal window and authenticate into your AWS	AWS administrator

Task	Description	Skills required
	<p>AFT management account by doing one of the following:</p> <ul style="list-style-type: none"><li>• Use an existing <a href="#">AWS CLI profile</a> that's configured with the permissions required to access the AFT management account. To use the profile, you can run the following command:</li></ul> <pre data-bbox="594 737 1027 852">export AWS_PROFILE=&lt;aft account profile name&gt;</pre> <ul style="list-style-type: none"><li>• If your organization uses SSO to access AWS, enter the credentials for your AFT management account on your organization's SSO page.</li></ul> <p><b>Note:</b> Your organization might also have a custom tool to provide authentication credentials to your AWS environment.</p>	

Task	Description	Skills required
Verify access to AFT management account in the correct AWS Region.	<p><b>Important:</b> Make sure that you use the same terminal session that you authenticated into your AFT management account with.</p> <ol style="list-style-type: none"><li>1. Navigate to your AFT deployment's AWS Region by running the following command: <pre>export AWS_REGION N=&lt;aft_region&gt;</pre></li><li>2. Make sure that you're in the correct account by doing the following:<ul style="list-style-type: none"><li>• Run the following command: <pre>aws code-commit list-repositories</pre></li><li>• Then, verify that the repositories listed in the output match the names of the repositories that are in your AFT management account.</li></ul></li></ol>	AWS administrator
Create a new, local directory to store the AFT repository code.	<p>In the same terminal session, run the following commands:</p> <pre>mkdir my_aft cd my_aft</pre>	AWS administrator

Task	Description	Skills required
Clone the remote AFT repository code.	<ol style="list-style-type: none"> <li data-bbox="592 226 1003 310">1. In your local terminal, run the following command: <div data-bbox="630 344 1029 543" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>git clone codecommit:::\$AWS_REGION://aft-global-customizations</pre> </div> <p data-bbox="630 583 1003 1140"><b>Note:</b> For simplicity, this procedure and AFT use a main code branch only. To use code branching, you can enter code branching commands here as well. However, any applied changes from the non-main branch will be rolled back when AFT automation applies code from the main branch.</p> </li> <li data-bbox="592 1165 1003 1339">2. Then, navigate into the cloned directory by running the following command: <div data-bbox="630 1377 1029 1499" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>cd aft-global-customizations/terraform</pre> </div> </li> </ol>	AWS administrator

### Create the Terraform configuration files required for the AFT pipeline to run locally

Task	Description	Skills required
Open a previously run AFT pipeline and copy the	<b>Note:</b> The <b>backend.tf</b> and <b>aft-providers.tf</b> configuration	AWS administrator

Task	Description	Skills required
Terraform configuration files to a local folder.	<p>files that are created in this epic are needed for the AFT pipeline to run locally. These files are created automatically within the cloud-based AFT pipeline, but must be created manually for the pipeline to run locally. Running the AFT pipeline locally requires one set of files that represents running the pipeline within a single AWS account.</p> <ol style="list-style-type: none"><li>1. Using your AWS Control Tower management account credentials, sign in to the AWS Management Console. Then open the <a href="#">AWS CodePipeline console</a>. Make sure that you're in the same AWS Region where you deployed AFT.</li><li>2. In the left navigation pane, choose <b>Pipelines</b>.</li><li>3. Choose <b>#####-customizations-pipeline</b>. (The <b>#####</b> is the AWS account ID that you're using to run Terraform code locally).</li><li>4. Make sure that <b>Most Recent Execution Marked</b> shows a <b>Succeeded</b> value. If it the value is different</li></ol>	

Task	Description	Skills required
	<p>, you must re-invoke your customizations in the AFT pipeline. For more information, see <a href="#">Re-invoke customizations</a> in the AWS Control Tower documentation.</p> <ol style="list-style-type: none"> <li>5. Choose the most recent runtime to bring up its details.</li> <li>6. In the <b>Apply-AFT-Global-Customizations</b> section, find the <b>Apply-Terraform</b> stage.</li> <li>7. Select the <b>Details</b> section of the <b>Apply-Terraform</b> stage.</li> <li>8. Find the runtime log for the <b>Apply-Terraform</b> stage.</li> <li>9. In the runtime log, look for the section that begins and ends with the following lines: <code>"\n\n aft-providers.tf ... "\n \n backend.tf"</code></li> <li>10. Copy the output between these two labels and save them as a local file named <code>aft-providers.tf</code> within the local Terraform folder (your terminal session's current working directory).</li> </ol>	

Task	Description	Skills required
	<p><b>Example auto generated providers.tf statement</b></p> <pre data-bbox="630 327 1029 1205">## Autogenerated providers.tf ## ## Updated on: 2022-05-31 16:27:45 ## provider "aws" {   region = "us-east-2"   assume_role {     role_arn = "arn:aws:iam::#### #####:role/AWSA FTExecution"   }   default_tags {     tags = {       managed_by         = "AFT"     }   } }</pre>	

11 In the runtime log, look for the section that begins and ends with the following lines: “\n\n tf ... “\n \n **backup.tf**”

12 Copy the output between these two labels and save them as a local file named tf within the local Terraform folder (your terminal session’s current working directory).

Task	Description	Skills required
	<p><b>Example autogenerated backend.tf statement</b></p> <pre data-bbox="592 331 1031 1795"> ## Autogenerated backend.tf ## ## Updated on: 2022-05-3 1 16:27:45 ## terraform {   required_version =   "&gt;= 0.15.0"   backend "s3" {     region          =     "us-east-2"     bucket          =     "aft-backend-##### #####-primary-re gion"     key             =     "#####-aft- global-customizati ons/terraform.tfst ate"     dynamodb_table =     "aft-backend-##### #####"     encrypt         =     "true"     kms_key_id      =     "cbdc21d6-e04d-4c3 7-854f-51e199cfcb7c"     kms_key_id      =     "#####-####-####- ####-#####"     role_arn        =     "arn:aws:iam::#### #####:role/AWS AFTEExecution"   } } </pre>	

Task	Description	Skills required
	<p><b>Note:</b> The <code>backend.tf</code> and <code>aft-providers.tf</code> files are tied to a specific AWS account, AFT deployment, and folder. These files are also different, depending on if they're in the <b>aft-global-customizations</b> repository and <b>aft-account-customizations</b> repository within the same AFT deployment. Make sure that you generate both files from the same runtime listing.</p>	

### Run the AFT pipeline locally by using the example bash script

Task	Description	Skills required
<p>Implement the Terraform configuration changes that you want to validate.</p>	<ol style="list-style-type: none"> <li>Navigate to the cloned <b>aft-global-customizations</b> repository by running the following command: <div data-bbox="630 1377 1029 1499" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>cd aft-global-customizations/terraform</pre> </div> <p><b>Note:</b> The files <code>backend.tf</code> and <code>aft-providers.tf</code> are in this directory. The directory also contains Terraform files from the <b>aft-global-customizations</b> repository.</p> </li> </ol>	<p>AWS administrator</p>

Task	Description	Skills required
	2. Incorporate the Terraform code changes that you want to test locally into the configuration files.	

Task	Description	Skills required
Run the <code>ct_terraform.sh</code> script and review the output.	<ol style="list-style-type: none"><li>1. Navigate to the local folder that contains the <code>sh</code> script.</li><li>2. To validate your modified Terraform code, run the <code>ct_terraform.sh</code> script by running the following command: <pre>~/scripts/ct_terraform.sh apply</pre><p><b>Note:</b> you can run any Terraform command during this step. To see a complete list of Terraform commands, run the following command: <pre>terraform --help</pre></p></li><li>3. Review the command output. Then, debug the code changes locally before committing and pushing the changes back to the AFT repository.</li></ol> <p><b>Important:</b></p> <ul style="list-style-type: none"><li>• Any changes made locally and not pushed back to the remote repository are temporary and may be undone at any time by</li></ul>	AWS administrator

Task	Description	Skills required
	<p>a running AFT pipeline automation.</p> <ul style="list-style-type: none"> <li>• AFT automation can run at any time, because it can be invoked by other users and AFT automation triggers.</li> <li>• AFT will always apply code from the main branch of the repository, undoing any uncommitted changes.</li> </ul>	

### Commit and push your local code changes back to the AFT repository

Task	Description	Skills required
Add references to the backend.tf and aft-providers.tf files to a .gitignore file.	<p>Add the backend.tf and aft-providers.tf files that you created to a .gitignore file by running the following commands:</p> <pre>echo backend.tf &gt;&gt; .gitignore echo aft-providers.tf &gt;&gt;.gitignore</pre> <p><b>Note:</b> Moving the files to the .gitignore file ensures that they don't get committed and pushed back to the remote AFT repository.</p>	AWS administrator
Commit and push your code changes to the remote AFT repository.	<ol style="list-style-type: none"> <li>1. To add any new Terraform configuration files to</li> </ol>	AWS administrator

Task	Description	Skills required
	<p>the repository, run the following command:</p> <pre data-bbox="634 331 1027 411">git add &lt;filename&gt;</pre> <p>2. To commit your changes and push them to the remote AFT repository in AWS CodeCommit, run the following commands:</p> <pre data-bbox="634 688 1027 810">git commit -a git push</pre> <p><b>Important:</b> The code changes that you introduce by following this procedure up until this point are applied to one AWS account only.</p>	

## Roll-out the changes to multiple accounts managed by AFT

Task	Description	Skills required
Roll out the changes to all of your accounts managed by AFT.	To roll out the changes to multiple AWS accounts managed by AFT, follow the instructions in <a href="#">Re-invoke customizations</a> in the AWS Control Tower documentation.	AWS administrator

# Configure logging and monitoring for security events in your AWS IoT environment

Created by Prateek Prakash (AWS)

<b>Environment:</b> Production	<b>Technologies:</b> IoT; Security, identity, compliance; Operations	<b>Workload:</b> All other workloads
<b>AWS services:</b> Amazon CloudWatch; Amazon OpenSearch Service; Amazon GuardDuty; AWS IoT Core; AWS IoT Device Defender; AWS IoT Device Management; Amazon CloudWatch Logs		

## Summary

Ensuring that your Internet of Things (IoT) environments are secure is an important priority, particularly because organizations are connecting billions of devices to their IT environments. This pattern provides a reference architecture that you can use to implement logging and monitoring for security events across your IoT environment on the Amazon Web Services (AWS) Cloud. Typically, an IoT environment on the AWS Cloud has the following three layers:

- IoT devices that generate relevant telemetry data.
- AWS IoT services (for example, [AWS IoT Core](#), [AWS IoT Device Management](#), or [AWS IoT Device Defender](#)) that connect your IoT devices to other devices and AWS services.
- Backend AWS services that help process telemetry data and provide useful insights for your different business use cases.

The best practices provided by the [AWS IoT Lens - AWS Well-Architected Framework](#) whitepaper can help you review and improve your cloud-based architecture and better understand the business impact of your design decisions. An important recommendation is that you analyze

application logs and metrics on your devices and in the AWS Cloud. You can achieve this by leveraging different approaches and techniques (for example, [threat modeling](#)) to identify metrics and events that must be monitored to detect potential security issues.

This pattern describes how to use AWS IoT and security services to design and implement a security logging and monitoring reference architecture for an IoT environment on the AWS Cloud. This architecture builds on existing AWS security best practices and applies them to your IoT environment.

## Prerequisites and limitations

### Prerequisites

- An existing landing zone environment. For more information about this, see the guide [Setting up a secure and scalable multi-account AWS environment](#) on the AWS Prescriptive Guidance website.
- The following accounts must be available in your landing zone:
  - **Log Archive account** – This account is for users that need to access the logging information for accounts in your landing zone’s organizational units (OUs). For more information about this, see the [Security OU – Log Archive account](#) section of the guide [AWS Security Reference Architecture](#) on the AWS Prescriptive Guidance website.
  - **Security account** – Your security and compliance teams use this account for auditing or to perform emergency security operations. This account is also designated as the administrator account for Amazon GuardDuty. Users from the administrator account can configure GuardDuty, in addition to viewing and managing GuardDuty findings for their own account and all member accounts. For more information about this, see [Managing multiple accounts in GuardDuty](#) in the Amazon GuardDuty documentation.
  - **IoT account** – This account is for your IoT environment.

## Architecture

This pattern extends the [Centralized Logging solution](#) from the AWS Solutions Library to collect and process security-related IoT events. The Centralized Logging solution is deployed in the Security account and helps collect, analyze, and display Amazon CloudWatch logs in a single dashboard. This solution consolidates, manages, and analyzes log files from multiple sources. Finally, the Centralized Logging solution also uses Amazon OpenSearch Service and OpenSearch Dashboards to show a unified view of all log events.

The following architecture diagram shows the key components of an IoT security logging and reference architecture on the AWS Cloud.

The diagram shows the following workflow:

1. IoT things are the devices that must be monitored for anomalous security events. These devices run an agent to publish security events or metrics to AWS IoT Core and AWS IoT Device Defender.
2. When AWS IoT logging is enabled, AWS IoT sends progress events about each message as it passes from your devices through the message broker and rules engine to Amazon CloudWatch Logs. You can use CloudWatch Logs subscriptions to push events to a [Centralized Logging solution](#). For more information about this, see [AWS IoT metrics and dimensions](#) in the AWS IoT Core documentation.
3. AWS IoT Device Defender helps monitor insecure configurations and security metrics for your IoT devices. When an anomaly is detected, alarms notify Amazon Simple Notification Service (Amazon SNS), which has an AWS Lambda function as a subscriber. The Lambda function sends the alarm as a message to CloudWatch Logs. You can use CloudWatch Logs subscriptions to push events to your Centralized Logging solution. For more information about this, see [Audit checks](#), [Device-side metrics](#), and [Cloud-side metrics](#) in the AWS IoT Core documentation.

4. AWS CloudTrail logs AWS IoT Core control plane actions that make changes (for example, creating, updating, or attaching APIs). When CloudTrail is set up as part of a landing zone implementation, it sends events to CloudWatch Logs and you can use subscriptions to push events to your Centralized Logging solution
5. AWS Config managed rules or custom rules evaluate resources that are part of your IoT environment. Monitor your [compliance change notifications](#) using CloudWatch Events with CloudWatch Logs as the target. After compliance change notifications are sent to CloudWatch Logs, you can use subscriptions to push events to your Centralized Logging solution.
6. Amazon GuardDuty continuously analyzes CloudTrail management events and helps identify API calls made to AWS IoT Core endpoints from known malicious IP addresses, unusual geolocations, or anonymizing proxies. Monitor GuardDuty notifications using Amazon CloudWatch Events with log groups in CloudWatch Logs as the target. When GuardDuty notifications are sent to CloudWatch Logs, you can use subscriptions to push events to your Centralized Monitoring solution or use the GuardDuty console in your Security account to view the notifications.
7. AWS Security Hub monitors your IoT account by using security best practices. Monitor Security Hub notifications by using CloudWatch Events with log groups in CloudWatch Logs as the target. When Security Hub notifications are sent to CloudWatch Logs, use subscriptions to push events to your Centralized Monitoring solution or use the Security Hub console in your Security account to view the notifications.
8. Amazon Detective evaluates and analyzes information to isolate the root cause and take action on security findings for unusual calls to AWS IoT endpoints or other services in your IoT architecture.
9. Amazon Athena queries logs stored in your Log Archive account to enhance your understanding of security findings and identify trends and malicious activities.

## Tools

- [Amazon Athena](#) is an interactive query service that makes it easy to analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
- [AWS CloudTrail](#) helps you enable governance, compliance, and operational and risk auditing of your AWS account.
- [Amazon CloudWatch](#) monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.

- [Amazon CloudWatch Logs](#) centralizes the logs from all your systems, applications, and AWS services that you use. You can view and monitor the logs, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.
- [AWS Config](#) provides a detailed view of the configuration of AWS resources in your AWS account.
- [Amazon Detective](#) makes it easy to analyze, investigate, and quickly identify the root cause of security findings or suspicious activities.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.
- [Amazon GuardDuty](#) is a continuous security monitoring service.
- [AWS IoT Core](#) provides secure, bi-directional communication for Internet-connected devices (such as sensors, actuators, embedded devices, wireless devices, and smart appliances) to connect to the AWS Cloud over MQTT, HTTPS, and LoRaWAN.
- [AWS IoT Device Defender](#) is a security service that allows you to audit the configuration of your devices, monitor connected devices to detect abnormal behavior, and mitigate security risks.
- [Amazon OpenSearch Service](#) is a managed service that makes it easy to deploy, operate, and scale OpenSearch clusters in the AWS Cloud.
- [AWS Organizations](#) is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.
- [AWS Security Hub](#) provides you with a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

## Epics

### Set up an IoT account in your landing zone environment

Task	Description	Skills required
Validate the security guardrails in the IoT account.	Validate that the guardrails for CloudTrail, AWS Config,	AWS administrator

Task	Description	Skills required
	GuardDuty, and Security Hub are enabled in your IoT account.	
Validate that your IoT account is configured as a member account of your Security account.	<p>Validate that your IoT account is configured and associated as a member account for GuardDuty and Security Hub in your Security account.</p> <p>For more information about this, see <a href="#">Managing GuardDuty accounts with AWS Organizations</a> in the Amazon GuardDuty documentation and <a href="#">Managing administrator and member accounts</a> in the AWS Security Hub documentation.</p>	AWS administrator
Validate log archiving.	Validate that CloudTrail, AWS Config, and VPC Flow Logs are stored in the Log Archive account.	AWS administrator

# Extract and query AWS IoT SiteWise metadata attributes in a data lake

*Created by Ambarish Dongaonkar (AWS)*

**Environment:** Production

**Technologies:** IoT; Analytics;  
Big data

**AWS services:** AWS IoT  
SiteWise; AWS Lambda; AWS  
Glue

## Summary

AWS IoT SiteWise uses asset models and hierarchies to represent your industrial equipment, processes, and facilities. Each model or asset can have multiple attributes that are specific to your environment. Example metadata attributes include the site or physical location of the asset, plant details, and equipment identifiers. These attribute values complement asset measurement data to maximize the business value. Machine learning (ML) can provide additional insights into this metadata and streamline engineering tasks.

However, metadata attributes can't be queried directly from the AWS IoT SiteWise service. To make the attributes queryable, you must extract and ingest them into a data lake. This pattern uses a Python script to extract the attributes for all AWS IoT SiteWise assets and ingest them into a data lake in an Amazon Simple Storage Service (Amazon S3) bucket. When you have completed this process, you can use SQL queries in Amazon Athena to access the AWS IoT SiteWise metadata attributes and other datasets, such as measurement datasets. The metadata attribute information is also useful when working with AWS IoT SiteWise monitors or dashboards. You can also build an AWS QuickSight dashboard by using the extracted attributes in the S3 bucket.

The pattern has reference code, and you can implement the code by using the best compute services for your use case, such as AWS Lambda or AWS Glue.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.

- Permissions to set up AWS Lambda functions or AWS Glue jobs.
- An Amazon S3 bucket.
- The asset models and hierarchies are set up in AWS IoT SiteWise. For more information, see [Creating asset models](#) (AWS IoT SiteWise documentation).

## Architecture

You can use a Lambda function or an AWS Glue job to complete this process. We recommend using Lambda if you have less than 100 models and each model has an average of 15 or fewer attributes. For all other use cases, we recommend using AWS Glue.

The solution architecture and workflow are shown in the following diagram.

1. The scheduled AWS Glue job or Lambda function runs. It extracts the asset metadata attributes from AWS IoT SiteWise and ingests them into an S3 bucket.
2. An AWS Glue crawler crawls the extracted data in the S3 bucket and creates tables in an AWS Glue Data Catalog.
3. Using standard SQL, Amazon Athena queries the tables in the AWS Glue Data Catalog.

### Automation and scale

You can schedule the Lambda function or AWS Glue job to run daily or weekly, according to the update frequency of your AWS IoT SiteWise asset configurations.

There is no limit to the number of AWS IoT SiteWise assets that the sample code can process, but a large number of assets can increase the amount of time required to complete the process.

## Tools

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS IoT SiteWise](#) helps you collect, model, analyze, and visualize data from industrial equipment at scale.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS SDK for Python \(Boto3\)](#) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

## Epics

### Set up the job or function

Task	Description	Skills required
Configure permissions in IAM.	<p>In the IAM console, grant permissions to the IAM role assumed by the Lambda function or AWS Glue job to do the following:</p> <ul style="list-style-type: none"><li>• Read from the AWS IoT SiteWise service</li><li>• Write to the S3 bucket</li></ul>	General AWS

Task	Description	Skills required
	For more information, see <a href="#">Creating a role for an AWS service</a> (IAM documentation).	
Create the Lambda function or AWS Glue job.	<p>If you are using Lambda, create a new Lambda function. For <b>Runtime</b>, choose <b>Python</b>. For more information, see <a href="#">Building Lambda functions with Python</a> (Lambda documentation).</p> <p>If you are using AWS Glue, create a new Python shell job in the AWS Glue console. For more information, see <a href="#">Adding Python shell jobs</a> (AWS Glue documentation).</p>	General AWS
Update the Lambda function or AWS Glue job.	Modify the new Lambda function or AWS Glue job, and enter the code sample in the <a href="#">Additional information</a> section. Modify the code as needed for your use case. For more information, see <a href="#">Edit code using the console editor</a> (Lambda documentation) and <a href="#">Working with scripts</a> (AWS Glue documentation).	General AWS

## Run the job or function

Task	Description	Skills required
Run the Lambda function or AWS Glue job.	Run the Lambda function or AWS Glue job. For more information, see <a href="#">Invoke the Lambda function</a> (Lambda documentation) or <a href="#">Starting jobs using triggers</a> (AWS Glue documentation). This extracts the metadata attributes for the assets and models in the AWS IoT SiteWise hierarchy and stores them in the specified S3 bucket.	General AWS
Set up an AWS Glue crawler.	Set up an AWS Glue crawler with the necessary format classifier for a CSV-formatted file. Use the S3 bucket and prefix details used in the Lambda function or AWS Glue job. For more information, see <a href="#">Defining crawlers</a> (AWS Glue documentation).	General AWS
Run the AWS Glue crawler.	Run the crawler to process the data file created by the Lambda function or AWS Glue job. The crawler creates a table in the specified AWS Glue Data Catalog. For more information, see or <a href="#">Starting crawlers using triggers</a> (AWS Glue documentation).	General AWS

Task	Description	Skills required
Query the metadata attribute s.	Using Amazon Athena, use standard SQL to query the AWS Glue Data Catalog as needed for your use case. You can join the metadata attribute table with other databases and tables. For more information, see <a href="#">Getting Started</a> (Amazon Athena documentation).	General AWS

## Additional information

### Code

The sample code provided is for reference, and you can customize this code as needed for your use case.

```
# Following code can be used in an AWS Lambda function or in an AWS Glue Python shell
job.
# IAM roles used for this job need read access to the AWS IoT SiteWise service and
write access to the S3 bucket.
sw_client = boto3.client('iotsitewise')
s3_client = boto3.client('s3')
output = io.StringIO()

attribute_list=[]
bucket = '{3_bucket name}'
prefix = '{s3_bucket prefix}'
output.write("model_id,model_name,asset_id,asset_name,attribuet_id,attribute_name,attribute_val
\n")

m_resp = sw_client.list_asset_models()
for m_rec in m_resp['assetModelSummaries']:
    model_id = m_rec['id']
    model_name = m_rec['name']

    attribute_list.clear()
    dam_response = sw_client.describe_asset_model(assetModelId=model_id)
    for rec in dam_response['assetModelProperties']:
        if 'attribute' in rec['type']:
            attribute_list.append(rec['name'])

    response = sw_client.list_assets(assetModelId=model_id, filter='ALL')
    for asset in response['assetSummaries']:
        asset_id = asset['id']
        asset_name = asset['name']
        resp = sw_client.describe_asset(assetId=asset_id)
        for rec in resp['assetProperties']:
            if rec['name'] in attribute_list:
                p_resp = sw_client.get_asset_property_value(assetId=asset_id,
propertyId=rec['id'])
                if 'propertyValue' in p_resp:
                    if p_resp['propertyValue']['value']:
                        if 'stringValue' in p_resp['propertyValue']['value']:
                            output.write(model_id + "," + model_name + ","
+ asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
str(p_resp['propertyValue']['value']['stringValue']) + "\n")

                            if 'doubleValue' in p_resp['propertyValue']['value']:
```

```
        output.write(model_id + "," + model_name + ","
+ asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
str(p_resp['propertyValue']['value']['doubleValue']) + "\n")
        if 'integerValue' in p_resp['propertyValue']['value']:
            output.write(model_id + "," + model_name + ","
+ asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
str(p_resp['propertyValue']['value']['integerValue']) + "\n")
        if 'booleanValue' in p_resp['propertyValue']['value']:
            output.write(model_id + "," + model_name + ","
+ asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
str(p_resp['propertyValue']['value']['booleanValue']) + "\n")

output.seek(0)
s3_client.put_object(Bucket=bucket, Key= prefix + '/data.csv', Body=output.getvalue())
output.close()
```

# Set up and troubleshoot AWS IoT Greengrass with client devices

Created by Marouane Sefiani and Akalanka De Silva (AWS)

**Environment:** PoC or pilot

**Technologies:** IoT

**AWS services:** AWS IoT Greengrass; AWS IoT Core

## Summary

AWS IoT Greengrass is an open-source edge runtime and cloud service for building, deploying, and managing Internet of Things (IoT) software on edge devices. Use cases for AWS IoT Greengrass include:

- Smart homes where an AWS IoT Greengrass gateway is used as a hub for home automation
- Smart factories where AWS IoT Greengrass can facilitate ingestion and local processing of data from the shop floor

AWS IoT Greengrass can act as a secure, authenticated, MQTT connection endpoint for other edge devices (also known as *client devices*), which otherwise would typically connect directly to AWS IoT Core. This capability is useful when client devices do not have direct network access to the AWS IoT Core endpoint.

You can set up AWS IoT Greengrass for use with client devices for the following use cases:

- For client devices to send data to AWS IoT Greengrass
- For AWS IoT Greengrass to forward data to AWS IoT Core
- To take advantage of advanced AWS IoT Core rules engine features

These capabilities require installing and configuring the following components on the AWS IoT Greengrass device:

- MQTT broker
- MQTT bridge

- Client device authentication
- IP detector

In addition, published messages from client devices must be in JSON format or [Protocol Buffers \(protobuf\)](#) format.

This pattern describes how to install and configure these required components, and provides troubleshooting tips and best practices.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [AWS Command Line Interface \(AWS CLI\) version 2](#)
- Two client devices running Python 3.7 or later
- One core device running Java Runtime Environment (JRE) version 8 or later, and [Amazon Corretto 11](#) or [OpenJDK 11](#)

### Limitations

- You must choose an AWS Region where AWS IoT Core is available. For the current list of Regions for AWS IoT Core, see [AWS Services by Region](#).
- The core device must have at least 172 MB RAM and 512 MB of disk space.

## Architecture

The following diagram shows the solution architecture for this pattern.

The architecture includes:

- Two client devices. Each device contains a private key, a device certificate, and a root certificate authority (CA) certificate. The AWS IoT Device SDK, which contains an MQTT client, is also installed on each client device.
- A core device that has AWS IoT Greengrass deployed with the following components:
  - MQTT broker
  - MQTT bridge
  - Client device authentication
  - IP detector

This architecture supports the following scenarios:

- Client devices can use their MQTT client to communicate with one another through the core device's MQTT broker.
- Client devices can also communicate with AWS IoT Core in the cloud through the core device's MQTT broker and the MQTT bridge.

- AWS IoT Core in the cloud can send messages to client devices through the MQTT test client and the core device's MQTT bridge and MQTT broker.

For more information about the communications between client devices and the core device, see the [Additional information](#) section.

## Tools

### AWS services

- [AWS IoT Greengrass](#) is an open source Internet of Things (IoT) edge runtime and cloud service that helps you build, deploy, and manage IoT applications on your devices.
- [AWS IoT Core](#) provides secure, bidirectional communication for internet-connected devices to connect to the AWS Cloud.
- [AWS IoT Device SDK](#) is a software development kit that includes open-source libraries, developer guides with samples, and porting guides so that you can build innovative IoT products or solutions on your choice of hardware platforms.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

## Best practices

- The payload of the messages from client devices should be in either JSON or Protobuf format in order to take advantage of the advanced features of the AWS IoT Core rules engine, such as transformation and conditional actions.
- Configure the MQTT bridge to allow bidirectional communication.
- Configure and deploy the IP detector component in AWS IoT Greengrass to ensure that the core device's IP addresses are included in the subject alternative name (SAN) field of the MQTT broker certificate.

# Epics

## Set up the core device

Task	Description	Skills required
Set up AWS IoT Greengrass on your core device.	Install the AWS IoT Greengrass Core software by following the instructions in the <a href="#">developer guide</a> .	AWS IoT Greengrass
Check the status of your installation.	<p>Use the following command to check the status of the AWS IoT Greengrass service on your core device:</p> <pre data-bbox="597 873 1027 989">sudo systemctl status greengrass.service</pre> <p>The expected output of the command is:</p> <pre data-bbox="597 1150 1027 1266">Launched Nucleus successfully</pre>	General AWS
Set up an IAM policy and attach it to the Greengrass service role.	<p>1. Create an IAM policy to allow communications to and from the MQTT bridge. Here's an example policy:</p> <pre data-bbox="630 1524 1027 1856">{   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",</pre>	General AWS

Task	Description	Skills required
	<pre data-bbox="646 205 993 1180">       "Action":     [       "iot:*"     ],     "Resource": "*"   },   {     "Sid": "GreengrassActions",     "Effect": "Allow",     "Action": [       "greengrass:*"     ],     "Resource": "*"   } ] } </pre> <p data-bbox="591 1192 1029 1373">2. Attach the policy to the Greengrass service role. To get the service role, use the command:</p> <pre data-bbox="633 1411 1029 1612"> aws greengrassv2   get-service-role-for-account --region   &lt;region&gt; </pre> <p data-bbox="630 1646 1013 1730">where &lt;region&gt; refers to your AWS Region.</p>	

Task	Description	Skills required
Configure and deploy required components in the AWS IoT Greengrass core device.	<p>Configure and deploy the following components:</p> <ul style="list-style-type: none"><li>• <code>greengrass.clientdevices.mqtt.Moquette</code> (see <a href="#">configuration details</a>)</li><li>• <code>greengrass.clientdevices.mqtt.Bridge</code> (see <a href="#">configuration details</a> and the next task)</li><li>• <code>greengrass.clientdevices.Auth</code> (see <a href="#">configuration details</a> and the task after the next one)</li><li>• <code>aws.greengrass.clientdevices.IPDetector</code> (see <a href="#">configuration details</a>)</li></ul>	AWS IoT Greengrass

Task	Description	Skills required
Confirm that the MQTT bridge allows bidirectional communication.	<p>To relay MQTT messages between client devices and AWS IoT Core, configure and deploy the MQTT bridge component and specify the topics to relay. Here's an example:</p> <pre data-bbox="594 583 1029 1461"> {   "mqttTopicMapping":   {     "ClientDevicesToCloud": {       "topic": "dt/#",       "source":       "LocalMqtt",       "target":       "IotCore"     },     "CloudToClientDevices": {       "topic": "cmd/#",       "source":       "IotCore",       "target":       "LocalMqtt"     }   } }</pre>	AWS IoT Greengrass

Task	Description	Skills required
<p>Confirm that the auth component allows client devices to connect and publish or subscribe to topics.</p>	<p>The following <code>aws.green</code> <code>grass.clientdevices.Auth</code> configuration allows all client devices to connect, publish messages, and subscribe to all topics.</p> <pre data-bbox="597 541 1029 1856"> {   "deviceGroups": {     "formatVersion":       "2021-03-05",     "definitions": {       "MyPermissiveDeviceGroup": {         "selectionRule": "thingName:           *",         "policyName":           "MyPermissivePolicy"       }     },     "policies": {       "MyPermissivePolicy": {         "AllowAll": {           "statementDescription": "Allow             client devices to             perform all actions.",           "operations":             [               "*"             ],           "resources":             [               "*"             ]         }       }     }   } } </pre>	<p>AWS IoT Greengrass</p>

Task	Description	Skills required
	<pre>} }</pre>	

## Set up client devices

Task	Description	Skills required
Install the AWS IoT Device SDK.	<p>Install the AWS IoT Device SDK on client devices. For a full list of supported languages and the associated SDKs, see the <a href="#">AWS IoT Core documentation</a>.</p> <p>For example, the AWS IoT Device SDK for Python SDK is <a href="#">located on GitHub</a>. To install this SDK:</p> <ol style="list-style-type: none"> <li>1. Confirm that Python 3.7 or later is installed, as instructed on the <a href="#">Prerequisites page</a> of the GitHub repository.</li> <li>2. Use the <b>pip</b> command to install the SDK.</li> </ol> <p>For MacOS and Linux::</p> <pre>python3 -m pip install awsiotsdk</pre> <p>For Windows:</p>	General AWS IoT

Task	Description	Skills required
	<pre data-bbox="633 210 1023 325">python -m pip install awscli</pre> <p data-bbox="592 399 998 535">Alternatively, you can install the SDK from the source repository:</p> <pre data-bbox="592 567 1031 1239"># Create a workspace directory to hold all the SDK files mkdir sdk-workspace cd sdk-workspace # Clone the repository git clone https://g ithub.com/aws/aws- iot-device-sdk-pyt hon-v2.git # Install using Pip (use 'python' instead of 'python3' on Windows) python3 -m pip install ./aws-iot- device-sdk-python-v2</pre>	

Task	Description	Skills required
Create a thing.	<ol style="list-style-type: none"><li data-bbox="591 226 1026 499">1. In the <a href="#">AWS IoT console</a>, if a <b>Get started</b> button appears, choose it. Otherwise, in the navigation pane, choose <b>Security, Policies</b>.</li><li data-bbox="591 520 1026 751">2. If the <b>You don't have any policies yet</b> dialog box appears, choose <b>Create a policy</b>. Otherwise, choose <b>Create</b>.</li><li data-bbox="591 772 1026 951">3. Enter a name for the AWS IoT policy (for example, ClientDevicePolicy ).</li><li data-bbox="591 972 1026 1339">4. In the <b>Add statements</b> section, replace the existing policy with the following JSON code. Replace <code>&lt;region&gt;</code> and <code>&lt;account&gt;</code> with your AWS Region and AWS account number. <pre data-bbox="630 1381 1026 1875">{   "Version":     "2012-10-17",   "Statement": [{     "Effect":       "Allow",     "Action":       "iot:Connect",     "Resource":       "arn:aws:iot:region:account:client/*"   }], }</pre></li></ol>	AWS IoT Core

Task	Description	Skills required
	<pre>       {         "Effect": "Allow",         "Action": "iot:Publish",         "Resource": "*"       },       {         "Effect": "Allow",         "Action": "iot:Receive",         "Resource": "*"       },       {         "Effect": "Allow",         "Action": "iot:Subscribe",         "Resource": "*"       },       {         "Effect": "Allow",         "Action": [           "iot:GetT hingShadow",           "iot:Upda teThingShadow",           "iot:Dele teThingShadow"         ],         "Resource": "arn:aws:iot:regio n:account:thing/*"       }     ] </pre>	

Task	Description	Skills required
	<pre data-bbox="630 205 1027 268">}</pre> <ol style="list-style-type: none"> <li data-bbox="591 281 850 315">5. Choose <b>Create</b>.</li> <li data-bbox="591 338 987 470">6. On the <a href="#">AWS IoT console</a>, in the navigation pane, choose <b>Manage, Things</b>.</li> <li data-bbox="591 493 1019 716">7. If the <b>You don't have any things yet</b> dialog box is displayed, choose <b>Register a thing</b>. Otherwise, choose <b>Create</b>.</li> <li data-bbox="591 739 1027 871">8. On the <b>Creating AWS IoT things</b> page, choose <b>Create a single thing</b>.</li> <li data-bbox="591 894 1019 1163">9. On the <b>Add your device to the device registry</b> page, enter a name for your IoT thing (for example, <code>ClientDevice1</code> ), and then choose <b>Next</b>.  <b>Note:</b> You can't change the name of a thing after you create it. To change the name, you must create a new thing, give it the new name, and then delete the old thing.</li> <li data-bbox="591 1556 1003 1688">10 On the <b>Add a certificate for your thing</b> page, choose <b>Create certificate</b>.</li> <li data-bbox="591 1711 1027 1791">11 Choose the <b>Download</b> links to download the certifica</li> </ol>	

Task	Description	Skills required
	<p>te, private key, and root CA certificate.</p> <p><b>Important:</b> This is your only opportunity to download your certificate and private key.</p> <p>12.To activate the certificate, choose <b>Activate</b>. The certificate must be active for a device to connect to AWS IoT.</p> <p>13Choose <b>Attach a policy</b>.</p> <p>14For <b>Add a policy for your thing</b>, choose <b>ClientDevicePolicy, Register Thing</b>.</p>	

Task	Description	Skills required
Download the CA certificate from the Greengrass core device.	<p>If you expect the Greengrass core device to work in offline environments, you have to make the Greengrass core CA certificate available to the client device so it can verify the MQTT broker's certificate (which is issued by the Greengrass core CA). Therefore, it is important to obtain a copy of this certificate. Use one of the following approaches to download the CA certificate:</p> <ul style="list-style-type: none"><li>• If you have network access to the AWS IoT Greengrass device from your PC, enter <code>https://&lt;device IP&gt;:8883</code> in your web browser and view the MQTT broker certificate and the CA certificate. You can also save the CA certificate to the client device.</li><li>• Alternatively, you can use the OpenSSL command line:</li></ul> <pre data-bbox="625 1627 1031 1785">openssl s_client - showcerts -connect &lt;device IP&gt;:8883</pre>	General AWS

<b>Task</b>	<b>Description</b>	<b>Skills required</b>
Copy credentials in the client devices.	Copy the Greengrass core CA certificate, the device certificate, and the private key in the client devices.	General AWS

Task	Description	Skills required
Associate client devices with the core device.	<p>Associate client devices with a core device so that they can discover the core device. The client devices can then use the <a href="#">Greengrass discovery API</a> to retrieve connectivity information and certificates for their associated core devices. For more information, see <a href="#">Associate client devices</a> in the AWS IoT Greengrass documentation.</p> <ol style="list-style-type: none"><li>1. On the <a href="#">AWS IoT Greengrass console</a>, choose <b>Core devices</b>.</li><li>2. Choose the core device to manage.</li><li>3. On the core device's details page, choose the <b>Client devices</b> tab.</li><li>4. In the <b>Associated client devices</b> section, choose <b>Associate client devices</b>.</li><li>5. In the <b>Associate client devices with core device</b> modal, do the following for each client device to associate:<ol style="list-style-type: none"><li>a. Enter the name of the AWS IoT thing to associate as a client device.</li><li>b. Choose <b>Add</b>.</li></ol></li></ol>	AWS IoT Greengrass

Task	Description	Skills required
	<p>6. Choose <b>Associate</b>.</p> <p>The client devices that you associated can now use the Greengrass discovery API to discover this core device.</p>	

## Send and receive data

Task	Description	Skills required
Send data from one client device to another client device.	Use the MQTT client in your device to publish a message on the <code>dt/client1/sensor</code> topic.	General AWS
Send data from the client device to AWS IoT Core.	<p>Use the MQTT client in your device to publish a message on the <code>dt/client1/sensor</code> topic.</p> <p>In the MQTT test client, subscribe to the topic that the device is sending messages on, or subscribe to <code>#</code> for all topics (see <a href="#">details</a>).</p>	General AWS
Send messages from AWS IoT Core to client devices.	On the MQTT test client page, in the <b>Publish to a topic</b> tab, in the <b>Topic name</b> field, enter the topic name of your message. In this example, use <code>cmd/client1</code> for the topic.	General AWS

## Troubleshooting

Issue	Solution
<b>Unable to verify server certificate error</b>	<p>This error occurs when the MQTT client cannot verify the certificate that's presented by the MQTT broker during the TLS handshake. The most common reason is that the MQTT client doesn't have the CA certificate. Follow these steps to make sure that the CA certificate is provided to the MQTT client.</p> <ol style="list-style-type: none"><li>1. If you have network access to the AWS IoT Greengrass device from your PC, enter <code>https://&lt;device IP&gt;:8883</code> in a browser window to view the MQTT broker certificate and the CA certificate. You can also save the CA certificate to the client device.  Alternatively use the OpenSSL command line: <pre>openssl s_client -showcerts -connect &lt;device IP&gt;:8883</pre></li><li>2. Save the contents of the Moquette CA and Greengrass Core CA certificates into files, and then view the decoded contents by using the command: <pre>openssl x509 -in &lt;Name of CA&gt;.pem -text</pre></li></ol> <p>The Moquette CA certificate should show the SAN field as in this example:</p>

Issue	Solution
	<pre>X509v3 Subject Alternative Name:   IP Address:XXX.XXX.XXX.XXX, IP   Address:127.0.0.1, DNS:localhost</pre>
<b>Unable to verify server name error</b>	<p>This error occurs when the MQTT client can't verify that it's connecting to the correct server. The most common reason is that the IP address of the Greengrass device isn't listed in the SAN field of the certificate.</p> <p>Follow the instructions in the previous solution to obtain the MQTT broker certificate and verify that the SAN field contains the IP address of the AWS IoT Greengrass device, as explained in the <a href="#">Additional information</a> section. If not, confirm that the IP detector component is installed correctly and restart the core device.</p>
<b>Unable to verify server name only when connecting from an embedded client device</b>	<p>Mbed TLS, which is a popular TLS library used in embedded devices, currently supports DNS name verification only in the SAN field of the certificate, as shown in the Mbed TLS library code. Because the core device doesn't have its own domain name and depends on the IP address, TLS clients that use Mbed TLS will fail the server name verification during the TLS handshake, causing a connection failure. We recommend that you add the SAN IP address verification to your Mbed TLS library at the <a href="#">x509_cert_check_san function</a>.</p>

## Additional information

This section provides additional information about the communications between the client devices and the core device.

The MQTT broker listens on port 8883 in the core device for a TLS client connection attempt. The following illustration shows an example MQTT broker's server certificate.

## Certificate

aws.greengrass.clientdevices.mqtt.Moquette

Greengrass Core CA

**Subject Name**

Country	US
Organization	Amazon.com Inc.
Organizational Unit	Amazon Web Services
State/Province	Washington
Locality	Seattle
Common Name	aws.greengrass.clientdevices.mqtt.Moquette

**Issuer Name**

Country	US
Organization	Amazon.com Inc.
Organizational Unit	Amazon Web Services
State/Province	Washington
Locality	Seattle
Common Name	Greengrass Core CA

Certificate is issued by Greengrass Core CA (this device)

**Validity**

Not Before	Mon, 10 Apr 2023 00:57:41 GMT
Not After	Mon, 17 Apr 2023 00:57:41 GMT

Valid for only 7 days  
Rotated weekly  
automatically

**Subject Alt Names**

IP Address	192.168.1.12
DNS Name	localhost

TLS clients can connect to this broker on localhost or on the network interface with the IP 192.168.1.12.

The example certificate displays the following details:

- The certificate is issued by the AWS IoT Greengrass Core CA, which is local and specific to the core device; that is, it acts as a local CA.

- This certificate is automatically rotated every week by the client auth component as shown in the following illustration. You can set this interval in the client auth component configuration.

- The subject alternative name (SAN) plays a critical role in the server name verification on the TLS client end. It helps the TLS client ensure that it connects to the correct server and helps avoid man-in-the-middle attacks during TLS session setup. In the example certificate, the SAN field indicates that this server is listening on localhost (the local Unix domain socket), and the network interface has the IP address 192.168.1.12.

The TLS client uses the SAN field in the certificate to verify that it's connecting to a legitimate server during server verification. In contrast, during a typical TLS handshake between an HTTP server and a browser, the domain name in the common name (CN) field or SAN field is used to cross-check the domain that the browser is actually connecting to during the server verification process. If the core device doesn't have a domain name, the IP address included in the SAN field serves the same purpose. For more information, see the [Subject Alternative Name section](#) of *RFC 5280 – Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile*.

The IP detector component in AWS IoT Greengrass ensures that the correct IP addresses are included in the SAN field of the certificate.

The certificate in the example is signed by the AWS IoT Greengrass device acting as a local CA. The TLS client (MQTT client) isn't aware of this CA, so we must provide a CA certificate that looks like the following.

## Certificate

aws.greengrass.clientdevices.mqtt.Moquette

Greengrass Core CA

# Aggregate data in Amazon DynamoDB for ML forecasting in Athena

Created by Sachin Doshi (AWS) and Peter Molnar (AWS)

<b>Code repository:</b> <a href="#">Use ML predictions over Amazon DynamoDB data with Amazon Athena ML</a>	<b>Environment:</b> Production	<b>Technologies:</b> Machine learning & AI; Databases; Serverless
<b>Workload:</b> Open-source	<b>AWS services:</b> Amazon Athena; Amazon DynamoDB; AWS Lambda; Amazon SageMaker; Amazon QuickSight	

## Summary

This pattern shows you how to build complex aggregations of Internet of Things (IoT) data in an Amazon DynamoDB table by using Amazon Athena. You also learn how to enrich the data with machine learning (ML) inference by using Amazon SageMaker and how to query geospatial data by using Athena. You can use this pattern as the basis for creating an ML forecasting solution that meets your organization's requirements.

For demonstration purposes, this pattern uses an example scenario of a business that's operating a scooter rideshare and wants to predict the optimal number of scooters that must be deployed for customers in different urban neighborhoods. The business uses a pre-trained ML model that predicts customer demand for the next hour based on the past four hours. The scenario uses a public dataset from the [Office of Civic Innovation & Technology](#) for the Louisville Metro government. The resources for this scenario are available in a GitHub repository.

## Prerequisites and limitations

- An active AWS account
- Permissions to create an AWS CloudFormation stack with AWS Identity and Access Management (IAM) roles for the following:

- Amazon Simple Storage Service (Amazon S3) bucket
- Athena
- DynamoDB
- SageMaker
- AWS Lambda

## Architecture

### Technology stack

- Amazon QuickSight
- Amazon S3
- Athena
- DynamoDB
- Lambda
- SageMaker

### Target architecture

The following diagram shows an architecture for building complex aggregations of data in DynamoDB by using the querying capabilities of Athena, a Lambda function, Amazon S3 storage, a SageMaker endpoint, and a QuickSight dashboard.

The diagram shows the following workflow:

1. A DynamoDB table ingests IoT data that's transmitted from a fleet of scooters.
2. A Lambda function loads the DynamoDB table with the ingested data.
3. An Athena query creates a new DynamoDB table for the geospatial data that represents the urban neighborhoods.
4. The query location is saved in an S3 bucket.
5. An Athena function queries the ML inference from the SageMaker endpoint that hosts the pre-trained ML model.
6. Athena queries data directly from the DynamoDB tables and aggregates the data for analysis.
7. A user views the output of the analyzed data in a QuickSight dashboard.

## Tools

### AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [Amazon SageMaker](#) is a managed ML service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon QuickSight](#) is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

## Code repository

The code for this pattern is available in the GitHub [Use ML predictions over Amazon DynamoDB data with Amazon Athena ML](#) repository. You can use the CloudFormation template from the repository to create the following resources used in the example scenario:

- A DynamoDB table
- A Lambda function to load the table with relevant data
- A SageMaker endpoint for inference requests, with the pre-trained XGBoost model that's stored in Amazon S3
- An Athena workgroup named V2EngineWorkGroup
- Named Athena queries to look up the geospatial shapefiles and predict scooter demand
- A prebuilt [Amazon Athena DynamoDB connector](#) that enables Athena to communicate with DynamoDB and uses [AWS Serverless Application Model \(AWS SAM\)](#) to build the application in reference to the DynamoDB connector

# Epics

## Get the example dataset

Task	Description	Skills required
Download the dataset and resources.	<ol style="list-style-type: none"><li>1. Download a <a href="#">public dataset of dockless vehicle rentals</a>. For demo purposes, this data is prepopulated in DynamoDB as part of the use case, but in a production environment you send this data to DynamoDB through various mechanisms such as IoT devices or <a href="#">Amazon Kinesis</a> consumers. These mechanisms use Lambda to insert data into DynamoDB.</li><li>2. Download the <a href="#">GIS shapefiles</a> that represent the boundaries of historical and cultural neighborhoods within the city of Louisville, KY. The public dataset is provided by the <a href="#">Louisville and Jefferson County, KY Information Consortium</a>. The original shapefiles are already converted into a text file that you can query with Athena, but you can find the Python code for transforming shapefiles</li></ol>	App developer, Data scientist

Task	Description	Skills required
	<p>in the Jupyter notebook at <a href="#">Geo-Spatial processing of GIS shapefiles with Amazon Athena</a> in GitHub.</p> <ol style="list-style-type: none"> <li data-bbox="592 411 1027 636">3. Download the pretrained <a href="#">Python code</a> that trains the ML model for hourly forecasts by using SageMaker and Athena.</li> <li data-bbox="592 659 1027 884">4. Get the SQL query in Athena that brings everything together for live predictions from the data stored in DynamoDB.</li> <li data-bbox="592 907 1027 1087">5. (Optionally) Use QuickSight to <a href="#">visualize geospatial data over a map of Louisville, Kentucky</a>.</li> </ol>	

### Use a CloudFormation template to deploy the required resources

Task	Description	Skills required
Create a CloudFormation stack.	<ol style="list-style-type: none"> <li data-bbox="592 1381 1027 1514">1. Download the CloudFormation template from the GitHub <a href="#">repository</a>.</li> <li data-bbox="592 1537 1027 1850">2. Sign in to the AWS Management Console, and then choose us-east-1 . <b>Note:</b> The ML model is stored in the Amazon Elastic Container Registry (Amazon ECR) for the us-</li> </ol>	AWS DevOps

Task	Description	Skills required
	<p>east-1 AWS Region, but the pattern is Region agnostic. You can replicate the pattern in any Region where the AWS services used in this pattern are supported.</p> <ol style="list-style-type: none"><li data-bbox="592 556 1015 735">3. Open the <a href="#">CloudFormation console</a>, and then choose <b>Stacks</b> on the navigation pane.</li><li data-bbox="592 756 1023 934">4. Choose <b>Create stack</b>, and then choose <b>With existing resources (import resources)</b>.</li><li data-bbox="592 955 1006 1039">5. On the <b>Identify resources</b> page, choose <b>Next</b>.</li><li data-bbox="592 1060 982 1239">6. In the <b>Specify template</b> section, for <b>Template source</b>, select <b>Upload a template file</b>.</li><li data-bbox="592 1260 974 1438">7. Choose <b>File</b>, and then choose the CloudFormation template that you downloaded earlier.</li><li data-bbox="592 1459 998 1690">8. Choose <b>Next</b>, accept the default parameter values, and choose <b>Next</b> to step through the rest of the setup wizard.</li><li data-bbox="592 1711 990 1837">9. Select the <b>I acknowledge that AWS CloudFormation might create IAM</b></li></ol>	

Task	Description	Skills required
	<p><b>resources with custom names</b> check box.</p> <p>10Choose <b>Create stack</b>.</p> <p><b>Note:</b> It can take 15–20 minutes for the CloudFormation stack to create these resources.</p>	

Task	Description	Skills required
Verify the CloudFormation deployment.	<p>To verify that the sample data from the CloudFormation template is loaded into DynamoDB, do the following:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">DynamoDB console</a>, and then choose <b>Tables</b> from the navigation pane.</li><li>2. In the <b>Tables</b> section, check for the DynamoDBT ableDocklessVehicles table.</li><li>3. After resource creation is complete, open the <a href="#">Athena console</a>, and then choose <b>Workgroups</b> from the navigation pane.</li><li>4. Choose the V2EngineWorkGroup workgroup , and then choose <b>Switch workgroup</b>.</li><li>5. If you get a prompt to save the query result location, choose an Amazon S3 location where you have write permissions.</li><li>6. Choose <b>Save</b>.</li><li>7. In the navigation pane, choose <b>Query editor</b>, and then select the athena-ml-db-<code>&lt;your-AWS-account-number&gt;</code> database.</li></ol>	App developer

## Load geolocation files into Athena

Task	Description	Skills required
Create an Athena table with geospatial data.	<p>To load the geolocation files into Athena, do the following:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Athena console</a>, and then choose <b>Query editor</b> from the navigation pane.</li><li>2. Choose the <b>Saved queries</b> tab.</li><li>3. Search for and select <b>Q1: Neighborhoods</b>.</li><li>4. To return to the query editor, choose the <b>Editor</b> tab.</li><li>5. Choose <b>Run</b>. This creates a table named <code>louisville_ky_neighborhoods</code> in your database. Make sure the table is created in the <code>athena-ml-db- &lt;your-AWS-account-number&gt;</code> database.</li></ol> <p>The query creates a new table for the geospatial data that represents the urban neighborhoods. The data table is created from GIS shapefiles. The CREATE EXTERNAL TABLE statement defines the schema of the table and the location and</p>	Data engineer

Task	Description	Skills required
	<p>format of the underlying data file.</p> <p>For the Python code to process shapefiles and produce this table, see <a href="#">Geo-Spatial processing of GIS shapefiles with Amazon Athena</a> in AWS Samples. For detailed SQL code, see <a href="#">create_neighborhood_table.sql</a> on GitHub.</p>	

## Predict demand for scooters by neighborhood from the aggregated DynamoDB data

Task	Description	Skills required
Declare a function in Athena to query SageMaker.	<ol style="list-style-type: none"> <li>Open the <a href="#">Athena console</a>, choose <b>Query editor</b> from the navigation pane, and then choose the <b>Editor</b> tab.</li> <li>Copy and paste the following SQL statement into the query editor.</li> </ol> <pre> USING EXTERNAL   FUNCTION predict_d   emand   ( location_id     BIGINT,     hr BIGINT ,     dow BIGINT,     n_pickup_1 BIGINT,     n_pickup_2 BIGINT,     n_pickup_3 BIGINT,     n_pickup_4 BIGINT, </pre>	Data scientist, Data engineer

Task	Description	Skills required
	<pre data-bbox="630 205 1026 508">n_dropoff_1 BIGINT, n_dropoff_2 BIGINT, n_dropoff_3 BIGINT, n_dropoff_4 BIGINT ) RETURNS DOUBLE SAGEMAKER '&lt;Your SageMaker endpoint&gt;'</pre> <p data-bbox="630 541 1013 865">The first part of the SQL statement declares the external function to query ML inferences from the SageMaker endpoint that hosts the pre-trained model.</p> <ol data-bbox="591 886 1013 1117" style="list-style-type: none"><li>3. Define the order and type of the input parameters and the type of the return values.</li><li>4. Choose <b>Run</b>.</li></ol>	

Task	Description	Skills required
Predict demand for scooters by neighborhood from the aggregated DynamoDB data.	<p>Now you can use Athena to query transactional data directly from DynamoDB, and then aggregate the data for analysis and forecasting. This isn't easily achieved by directly querying a DynamoDB NoSQL database.</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Athena console</a>, and then choose the <b>Query editor</b> from the navigation pane.</li><li>2. Choose the <b>Saved queries</b> tab.</li><li>3. Search for and select <b>Q2: DynamoDBAthenaMLScooterPredict</b>.</li><li>4. To return to the query editor, choose the <b>Editor</b> tab.</li><li>5. Choose <b>Run</b>.</li></ol> <p>The SQL statement does the following:</p> <ul style="list-style-type: none"><li>• Uses an <a href="#">Athena Federated Query</a> to query the DynamoDB table with the raw trip data</li><li>• Places geographic coordinates into neighborhoods by using the geospatial functions of Athena</li></ul>	App developer, Data scientist

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>Enriches data with ML inference by using SageMaker</li> </ul> <p>For information about using SQL to aggregate DynamoDB data and SageMaker inference data in Athena, see <a href="#">athena_loading.sql</a> in GitHub.</p>	
Verify the output.	<p>The output table includes the neighborhood, longitude, and latitude of the centroid of the neighborhood. It also includes the number of vehicles that are predicted for the next hour.</p> <p>The query produces the predictions for a selected point in time. You can make predictions for any other time by changing the expression <code>on TIMESTAMP '2019-09-07 15:00'</code> everywhere in the statement.</p> <p>If you have a real-time data feed in your DynamoDB table, change the timestamp to <code>NOW()</code>.</p>	App developer, Data scientist

## Clean up the environment

Task	Description	Skills required
Delete resources.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Athena console</a> and <a href="#">empty the bucket</a> that you created as part of the CloudFormation stack.</li><li>2. Open the <a href="#">CloudFormation console</a>, and then <a href="#">delete the stack</a> named <code>bdb-1462-athena-dynamodb-ml-stack</code> .</li><li>3. Open the <a href="#">Amazon CloudWatch console</a>, and then <a href="#">delete the log group</a> named <code>/aws/sagemaker/Endpoints/Sg-athena-ml-dynamodb-model-endpoint</code> .</li></ol>	App developer, AWS DevOps

# Associate an AWS CodeCommit repository in one AWS account with SageMaker Studio in another account

Created by Laurens van der Maas (AWS) and Aubrey Oosthuizen (AWS)

**Environment:** Production

**Technologies:** Machine learning & AI; DevOps; Security, identity, compliance; CloudNative

**AWS services:** AWS CodeCommit; Amazon SageMaker; AWS Identity and Access Management

## Summary

This pattern provides instructions and code on how to associate an AWS CodeCommit repository in one AWS account (Account A) with Amazon SageMaker Studio in another AWS account (Account B). To set up the association, you must create an AWS Identity and Access Management (IAM) policy and role in Account A and an IAM inline policy in Account B. Then, you use a shell script to clone the CodeCommit repository from Account A to SageMaker Studio in Account B.

## Prerequisites and limitations

### Prerequisites

- Two [AWS accounts](#), one containing the CodeCommit repository and the other containing a SageMaker Domain with a user
- Provisioned [SageMaker Domain and user](#), with internet access or access to CodeCommit and AWS Security Token Service (AWS STS) through virtual private network (VPC) endpoints
- A basic understanding of [IAM](#)
- A basic understanding of [SageMaker Studio](#)
- A basic understanding of [Git](#) and [CodeCommit](#)

### Limitations

This pattern applies to SageMaker Studio only, not to RStudio on Amazon SageMaker.

# Architecture

## Technology stack

- Amazon SageMaker
- Amazon SageMaker Studio
- AWS CodeCommit
- AWS Identity and Access Management (IAM)
- Git

## Target architecture

The following diagram shows an architecture that associates a CodeCommit repository from Account A to SageMaker Studio in Account B.

The diagram shows the following workflow:

1. A user assumes the `MyCrossAccountRepositoryContributorRole` role in Account A through the `sts:AssumeRole` role, while using the SageMaker execution role in SageMaker Studio in Account B. The assumed role includes the CodeCommit permissions to clone and interact with the specified repository.
2. The user performs Git commands from the system terminal in SageMaker Studio.

## Automation and scale

This pattern consists of manual steps that can be automated by using the [AWS Cloud Development Kit \(AWS CDK\)](#), [AWS CloudFormation](#), or [Terraform](#).

## Tools

### AWS tools

- [Amazon SageMaker](#) is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- [Amazon SageMaker Studio](#) is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

### Other tools

- [Git](#) is a distributed version-control system for tracking changes in source code during software development.

## Epics

### Create an IAM policy and IAM role in Account A

Task	Description	Skills required
Create an IAM policy for repository access in Account A.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">IAM console</a>.</li><li>2. In the navigation pane, choose <b>Policies</b>, and then choose <b>Create policy</b>.</li><li>3. Choose the <b>JSON</b> tab.</li></ol>	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"><li>4. Copy the policy statement from <i>Example IAM policy</i> in the <a href="#">Additional information</a> section of this pattern, and then paste the statement into the JSON editor. Make sure to replace all placeholder values in the policy.</li><li>5. Choose <b>Next:Tags</b>, and then choose <b>Next:Review</b>.</li><li>6. For <b>Name</b>, enter a name for the policy. <b>Note:</b> In this pattern, the IAM policy is referred to as <code>CrossAccountAccessForMySharedDemoRepo</code>, but you can choose whatever policy name that you prefer.</li><li>7. Choose <b>Create policy</b>.</li></ol> <p><b>Tip:</b> It's a best practice to restrict the scope of your IAM policies to the minimum required permissions for your use case.</p>	

Task	Description	Skills required
Create an IAM role for repository access in Account A.	<ol style="list-style-type: none"><li>1. In the navigation pane of the <a href="#">IAM console</a>, choose <b>Roles</b>, and then choose <b>Create role</b>.</li><li>2. For <b>Trusted entity type</b>, select <b>AWS account</b>.</li><li>3. In the <b>AWS account</b> section, select <b>Another AWS account</b>.</li><li>4. For <b>Account ID</b>, enter the account ID for Account B.</li><li>5. On the <b>Add permissions</b> page, search for and choose the <code>CrossAccountAccessForMySharedDemoRepo</code> policy that you created earlier.</li><li>6. Choose <b>Next</b>.</li><li>7. For <b>Role name</b>, enter a name. <b>Note:</b> In this pattern, the IAM role name is referred to as <code>MyCrossAccountRepositoryContributorRole</code>, but you can choose whatever role name that you prefer.</li><li>8. Choose <b>Create role</b>, and then copy the Amazon Resource Name (ARN) of the new role.</li></ol>	AWS DevOps

## Create an IAM inline policy in Account B

Task	Description	Skills required
<p>Attach an inline policy to the execution role that's attached to your SageMaker Domain user in Account B.</p>	<ol style="list-style-type: none"><li>1. In the navigation pane of the <a href="#">IAM console</a>, choose <b>Roles</b>.</li><li>2. Search for and choose the execution role that's attached to your SageMaker Domain user in Account B.</li><li>3. Choose <b>Add permissions</b>, and then choose <b>Create inline policy</b>.</li><li>4. Choose the <b>JSON</b> tab.</li><li>5. Copy the following policy statement, and then paste it into the JSON editor.</li></ol> <pre data-bbox="630 1087 1029 1885">{   "Version":     "2012-10-17",   "Statement": [     {       "Sid":         "VisualEditor0",       "Effect":         "Allow",       "Action":         "sts:AssumeRole",       "Resource":         ": "arn:aws: iam::&lt;Account_A_ID &gt;:role/&lt;Account_A_ Role_Name&gt;"     }   ] }</pre>	AWS DevOps

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>6. Replace &lt;Account_A_ID&gt; with the account ID for Account A. Replace &lt;Account_A_Role_Name&gt; with the name of the IAM role that you created earlier.</li> <li>7. Choose <b>Review policy</b>.</li> <li>8. For <b>Name</b>, enter a name for your inline policy.</li> <li>9. Choose <b>Create policy</b>.</li> </ol>	

### Clone the repository in SageMaker Studio for Account B

Task	Description	Skills required
Create the shell script in SageMaker Studio in Account B.	<ol style="list-style-type: none"> <li>1. In the navigation pane of the <a href="#">SageMaker console</a>, choose <b>Studio</b>.</li> <li>2. Select your user profile and then choose <b>Open Studio</b>.</li> <li>3. In the <b>Home</b> section, choose <b>Open Launcher</b>.</li> <li>4. In the <b>Utilities and files</b> section, choose <b>Text file</b>.</li> <li>5. Copy the script from <i>Example SageMaker shell script</i> in the <a href="#">Additional information</a> section of this pattern, and then paste the statement into the new file. Make sure to replace</li> </ol>	AWS DevOps

Task	Description	Skills required
	<p>all placeholder values in the script.</p> <p>6. Right-click the <b>untitled.txt</b> tab of your new file, and then choose <b>Rename Text</b>. For <b>New Name</b>, enter <b>cross_account_git_clone.sh</b>, and then choose <b>Rename</b>.</p>	
<p>Invoke the shell script from the system terminal.</p>	<ol style="list-style-type: none"> <li>1. In the <b>Home</b> section of the <a href="#">SageMaker console</a>, choose <b>Open Launcher</b>.</li> <li>2. In the <b>Utilities and files</b> section, choose <b>System terminal</b>.</li> <li>3. In the terminal, run the following command: <div data-bbox="630 1108 1029 1306" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>chmod u+x ./cross_a ccount_git_clone.s h &amp;&amp; ./cross_a ccount_git_clone.sh</pre> </div> </li> </ol> <p>You have cloned your CodeCommit repository in a SageMaker Studio cross-account. You can now perform all Git commands from the system terminal.</p>	<p>AWS DevOps</p>

## Additional information

### Example IAM policy

If you use this example policy, do the following:

- Replace <CodeCommit\_Repository\_Region> with the AWS Region for the repository.
- Replace <Account\_A\_ID> with the account ID for Account A.
- Replace <CodeCommit\_Repository\_Name> with the name of your CodeCommit repository in Account A.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "codecommit:BatchGet*",
        "codecommit:Create*",
        "codecommit>DeleteBranch",
        "codecommit:Get*",
        "codecommit:List*",
        "codecommit:Describe*",
        "codecommit:Put*",
        "codecommit:Post*",
        "codecommit:Merge*",
        "codecommit:Test*",
        "codecommit:Update*",
        "codecommit:GitPull",
        "codecommit:GitPush"
      ],
      "Resource": [
        "arn:aws:codecommit:<CodeCommit_Repository_Region>:<Account_A_ID>:<CodeCommit_Repository_Name>"
      ]
    }
  ]
}
```

### Example SageMaker shell script

If you use this example script, do the following:

- Replace <Account\_A\_ID> with the account ID for Account A.
- Replace <Account\_A\_Role\_Name> with the name of the IAM role that you created earlier.

- Replace `<CodeCommit_Repository_Region>` with the AWS Region for the repository.
- Replace `<CodeCommit_Repository_Name>` with the name of your CodeCommit repository in Account A.

```
#!/usr/bin/env bash
#Launch from system terminal
pip install --quiet git-remote-codecommit

mkdir -p ~/.aws
touch ~/.aws/config

echo "[profile CrossAccountAccessProfile]
region = <CodeCommit_Repository_Region>
credential_source=EcsContainer
role_arn = arn:aws:iam::<Account_A_ID>:role/<Account_A_Role_Name>
output = json" > ~/.aws/config

echo '[credential "https://git-
codecommit.<CodeCommit_Repository_Region>.amazonaws.com"]
    helper = !aws codecommit credential-helper $@ --profile
CrossAccountAccessProfile
    UseHttpPath = true' > ~/.gitconfig

git clone codecommit::<CodeCommit_Repository_Region>://
CrossAccountAccessProfile@<CodeCommit_Repository_Name>
```

# Automate Amazon Lookout for Vision training and deployment for anomaly detection

Created by Michael Wallner (AWS), Gabriel Rodriguez Garcia (AWS), Kangkang Wang (AWS), Shukhrat Khodjaev (AWS), Sanjay Ashok (AWS), Yassine Zaafouri (AWS), and Gabriel Zylka (AWS)

**Code repository:** [automated-silicon-wafer-anomaly-detection-using-amazon-lookout-for-vision](#)

**Environment:** Production

**Technologies:** Machine learning & AI; CloudNative; DevOps

**AWS services:** AWS CloudFormation; AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; AWS Lambda; Amazon Lookout for Vision

## Summary

This pattern helps you automate the training and deployment of [Amazon Lookout for Vision](#) machine learning models for visual inspection. Although this pattern concentrates on anomaly detection for silicon wafers, you can adapt the solution for use in a wide range of products and industries.

In 2020, the annual capacity of one of the largest semiconductor manufacturers in the world exceeded 12 million 12-inch equivalent wafers. To ensure the quality and reliability of these wafers, visual inspection is an essential step in the production process. The traditional methods of visual inspection, such as manual sampling or the use of outdated, legacy tools that rely on statistical measures, can be time-consuming and inefficient. Given the scale of this process and its importance to the broader semiconductor industry, there is a significant opportunity to optimize and automate visual inspection by using advanced artificial intelligence (AI) technologies.

Lookout for Vision helps streamline the image and object inspection process, reducing the need for costly and inconsistent manual inspection. This solution improves quality control, facilitates

accurate defect and damage assessment, and ensures compliance with industry standards. Additionally, you can automate the Lookout for Vision inspection process, without specialized machine learning expertise.

Using this solution, you can integrate your computer vision model into any system. For instance, you might integrate a model into a website where users upload images and analyze them for defects. The following image shows an example of a silicon wafer with scratch defects from a chemical mechanical polishing (CMP) process. You can use Lookout for Vision to detect these anomalies. For example, Lookout for Vision detected anomalies in this image with 99.04% confidence.

This solution is based on the code and the use case described in the [Build an event-based tracking solution using Amazon Lookout for Vision blog post](#). This solution modifies the original code to enable CI/CD pipeline automation and to integrate the open source [Amazon Lookout for Vision Python SDK](#) (GitHub). For more information about the Python SDK, see the [Build, train, and deploy Amazon Lookout for Vision models using the Python SDK](#) blog post.

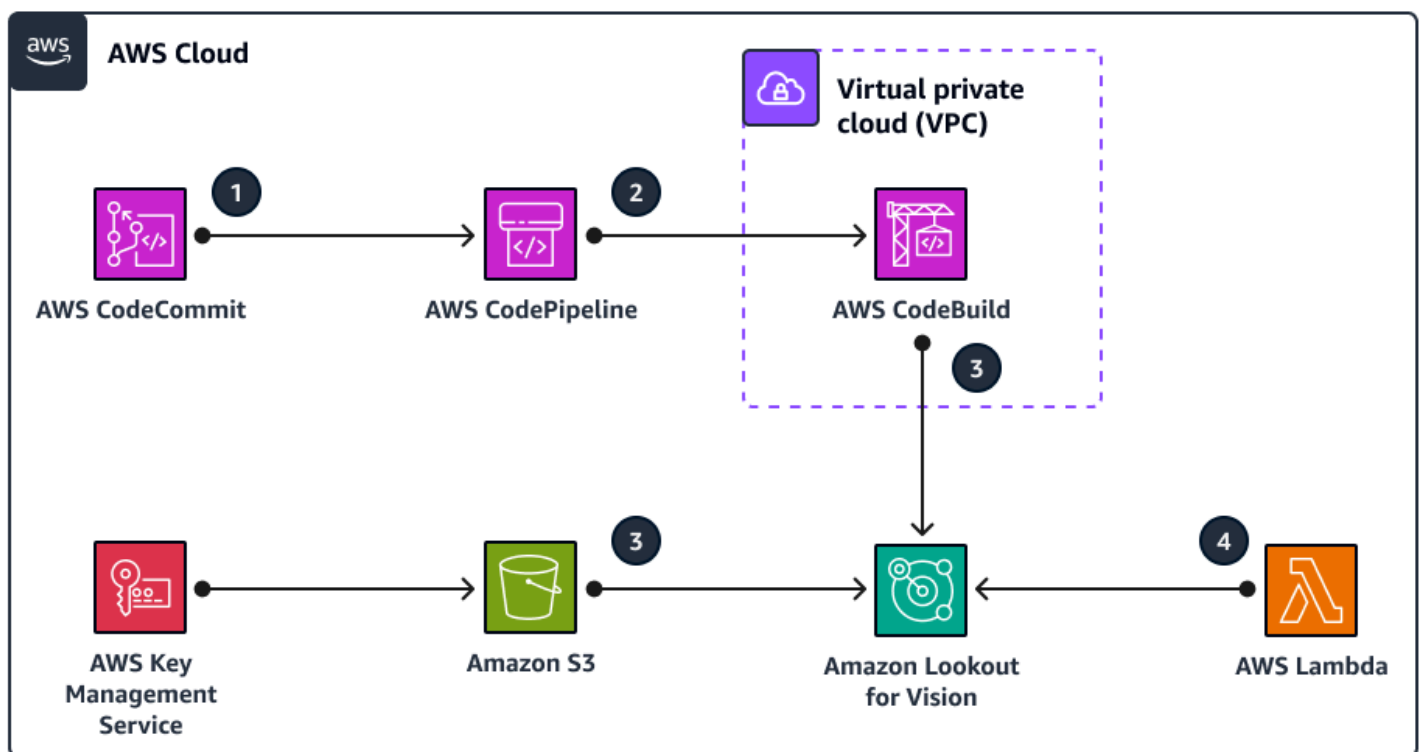

# Prerequisites and limitations

## Prerequisites

- An active AWS account
- Administrative permissions in the AWS account
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- AWS CDK, [installed and configured](#)
- Python version 3.10, [installed](#)

## Architecture

### Target architecture

This architecture illustrates automation of build, train and deployment of Amazon Lookout for Vision models through a CI/CD pipeline. The diagram shows the following workflow:

1. The code is stored in an Amazon CodeCommit repository. Developers can modify the code, change input images, or add other steps to the automation pipeline.

2. After deploying the solution or updating the main branch of the CodeCommit repository, Amazon CodePipeline automatically pushes the code into Amazon CodeBuild.
3. CodeBuild uses the Lookout for Vision Python SDK to train and deploy the images classification model. The images used for training are stored in an Amazon Simple Storage Service (Amazon S3) bucket. CodeBuild automatically downloads these images and stores them. To customize the solution to your needs, you can import your own images.
4. The Lookout for Vision model is exposed to end users through AWS Lambda. However, you are not limited to this approach. You can also deploy Lookout for Vision at the edge on IoT devices, or you can run it as batch process on a scheduled basis to generate predictions.

## Tools

### AWS services

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Lookout for Vision](#) uses computer vision to find visual defects in industrial products, accurately and at scale.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Code repository

The code for this pattern is available in the GitHub [Automate Amazon Lookout for Vision training and deployment for Silicon Wafer Anomaly Detection](#) repository.

## Best practices

When running the code as an experiment, make sure to [stop your Amazon Lookout for Vision endpoint](#).

## Epics

### Deploy the solution

Task	Description	Skills required
Clone the GitHub repository.	<p>Clone the GitHub <a href="#">Automate Amazon Lookout for Vision training and deployment for Silicon Wafer Anomaly Detection</a> repository to your local workstation.</p> <pre>git clone https://github.com/aws-samples/automated-silicon-wafer-anomaly-detection-using-amazon-lookout-for-vision.git</pre>	Bash
Create a virtual environment.	<p>Enter the following command to create a virtual environment on your local workstation.</p> <pre>python3 -m venv .venv</pre>	Python
Install dependencies.	<p>After the virtual environment is created, enter the following command to install the required dependencies.</p>	Python

Task	Description	Skills required
	<pre>pip install -r requirements.txt</pre>	
(Linux users only) Activate the virtual environment.	<p>After the initialization is completed and the virtual environment is created, use the following command to activate the virtual environment.</p> <pre>source .venv/bin/activate</pre>	Bash
(Windows users only) Activate the virtual environment.	<p>After the initialization is completed and the virtual environment is created, use the following command to activate the virtual environment.</p> <pre>.venv\Scripts\activate.bat</pre>	PowerShell

Task	Description	Skills required
Deploy the stack.	<ol style="list-style-type: none"> <li data-bbox="591 226 1015 405">1. In the AWS CDK CLI, enter the following command to synthesize the AWS CloudFormation template.</li> </ol> <pre data-bbox="634 443 1029 520">cdk synth</pre> <ol style="list-style-type: none"> <li data-bbox="591 537 976 667">2. Enter the following command to deploy the CloudFormation stack.</li> </ol> <pre data-bbox="634 705 1029 863">cdk deploy --all -- require-approval never</pre> <p data-bbox="630 905 1003 1224">The <code>--all</code> flag ensures that all components are installed at once. <code>--require-approval never</code> eliminates the need to approve each component deployment.</p>	AWS administrator

## Test the solution

Task	Description	Skills required
Enter an example test event.	<ol style="list-style-type: none"> <li data-bbox="591 1518 995 1598">1. Open the <a href="#">Functions page</a> of the Lambda console.</li> <li data-bbox="591 1623 971 1801">2. Choose the <code>amazon-lookout-for-vision-project-lambda</code> function.</li> <li data-bbox="591 1827 927 1862">3. Choose the <b>Test</b> tab.</li> </ol>	General AWS

Task	Description	Skills required
	<p>4. Under <b>Test event</b>, choose <b>Create new event</b>.</p> <p>5. Enter the following.</p> <p>6. Choose <b>Test</b>.</p> <pre data-bbox="630 443 1029 604">{   "tbd": "tbd" }</pre> <p>7. To review the test results, under <b>Execution result</b>, expand <b>Details</b>.</p>

# Automatically extract content from PDF files using Amazon Textract

*Created by Tianxia Jia (AWS)*

**Environment:** Production

**Technologies:** Machine learning & AI; Analytics; Big data

**AWS services:** Amazon S3; Amazon Textract; Amazon SageMaker

## Summary

Many organizations need to extract information from PDF files that are uploaded to their business applications. For example, an organization could need to accurately extract information from tax or medical PDF files for tax analysis or medical claim processing.

On the Amazon Web Services (AWS) Cloud, Amazon Textract automatically extracts information (for example, printed text, forms, and tables) from PDF files and produces a JSON-formatted file that contains information from the original PDF file. You can use Amazon Textract in the AWS Management Console or by implementing API calls. We recommend that you use [programmatic API calls](#) to scale and automatically process large numbers of PDF files.

When Amazon Textract processes a file, it creates the following list of Block objects: pages, lines and words of text, forms (key-value pairs), tables and cells, and selection elements. Other object information is also included, for example, [bounding boxes](#), confidence intervals, IDs, and relationships. Amazon Textract extracts the content information as strings. Correctly identified and transformed data values are required because they can be more easily used by your downstream applications.

This pattern describes a step-by-step workflow for using Amazon Textract to automatically extract content from PDF files and process it into a clean output. The pattern uses a template matching technique to correctly identify the required field, key name, and tables, and then applies post-processing corrections to each data type. You can use this pattern to process different types of PDF files and you can then scale and automate this workflow to process PDF files that have an identical format.

## Prerequisites and limitations

### Prerequisites

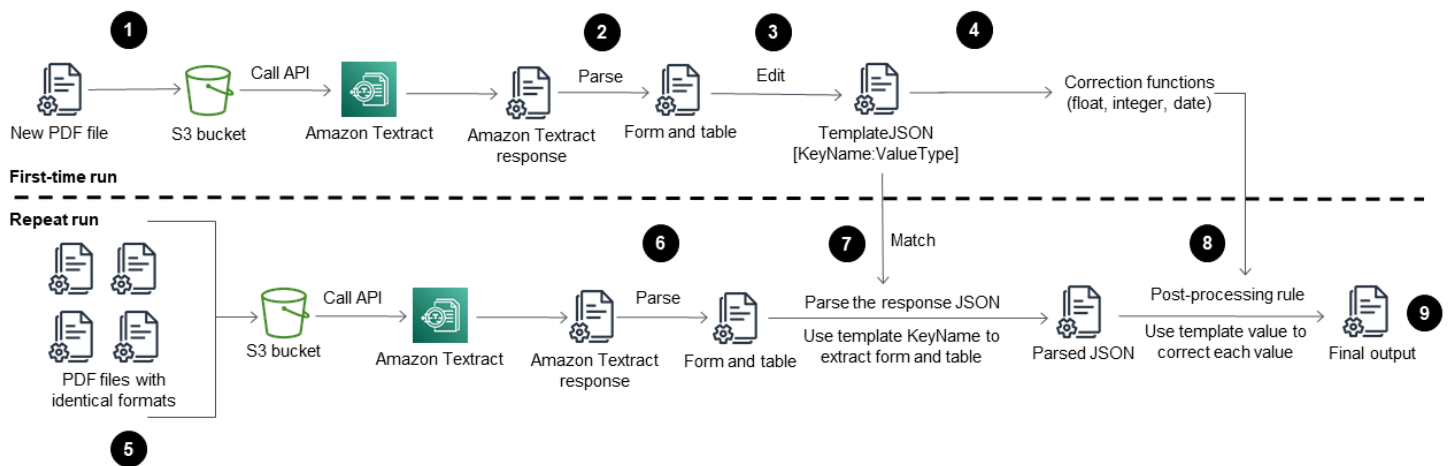

- An active AWS account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket to store the PDF files after they are converted to JPEG format for processing by Amazon Textract. For more information about S3 buckets, see [Buckets overview](#) in the Amazon S3 documentation.
- The `Textract_PostProcessing.ipynb` Jupyter notebook (attached), installed and configured. For more information about Jupyter notebooks, see [Create a Jupyter notebook](#) in the Amazon SageMaker documentation.
- Existing PDF files that have an identical format.
- An understanding of Python.

### Limitations

- Your PDF files must be of good quality and clearly readable. Native PDF files are recommended, but you can use scanned documents that are converted to a PDF format if all the individual words are clear. For more information about this, see [PDF document preprocessing with Amazon Textract: Visuals detection and removal](#) on the AWS Machine Learning Blog.
- For multipage files, you can use an asynchronous operation or split the PDF files into a single page and use a synchronous operation. For more information about these two options, see [Detecting and analyzing text in multipage documents](#) and [Detecting and analyzing text in single-page documents](#) in the Amazon Textract documentation.

## Architecture

This pattern's workflow first runs Amazon Textract on a sample PDF file (*First-time run*) and then runs it on PDF files that have an identical format to the first PDF (*Repeat run*). The following diagram shows the combined *First-time run* and *Repeat run* workflow that automatically and repeatedly extracts content from PDF files with identical formats.

The diagram shows the following workflow for this pattern:

1. Convert a PDF file into JPEG format and store it in an S3 bucket.
2. Call the Amazon Textract API and parse the Amazon Textract response JSON file.
3. Edit the JSON file by adding the correct `KeyName:DataType` pair for each required field. Create a `TemplateJSON` file for the *Repeat run* stage.
4. Define the post-processing correction functions for each data type (for example, float, integer, and date).
5. Prepare the PDF files that have an identical format to your first PDF file.
6. Call the Amazon Textract API and parse the Amazon Textract response JSON.
7. Match the parsed JSON file with the `TemplateJSON` file.
8. Implement post-processing corrections.

The final JSON output file has the correct `KeyName` and `Value` for each required field.

### Target technology stack

- Amazon SageMaker
- Amazon S3
- Amazon Textract

### Automation and scale

You can automate the *Repeat run* workflow by using an AWS Lambda function that initiates Amazon Textract when a new PDF file is added to Amazon S3. Amazon Textract then runs the

processing scripts and the final output can be saved to a storage location. For more information about this, see [Using an Amazon S3 trigger to invoke a Lambda function](#) in the Lambda documentation.

## Tools

- [Amazon SageMaker](#) is a fully managed ML service that helps you to quickly and easily build and train ML models, and then directly deploy them into a production-ready hosted environment.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Textract](#) makes it easy to add document text detection and analysis to your applications.

## Epics

### First-time run

Task	Description	Skills required
Convert the PDF file.	<p>Prepare the PDF file for your first-time run by splitting it into a single page and converting it into JPEG format for the Amazon Textract <a href="#">synchronous operation</a> (Syn API).</p> <p><b>Note:</b> You can also use the Amazon Textract <a href="#">asynchronous operation</a> (Asyn API) for multipage PDF files.</p>	Data scientist, Developer
Parse the Amazon Textract response JSON.	<p>Open the <code>Texttract_PostProcessing.ipynb</code> Jupyter notebook (attached) and call the Amazon Textract API by using the following code:</p>	Data scientist, Developer

# Build an MLOps workflow by using Amazon SageMaker and Azure DevOps

*Created by Deepika Kumar (AWS) and Sara van de Moosdijk (AWS)*

**Environment:** Production

**Technologies:** Machine learning & AI; DevOps; Operations

**Workload:** Microsoft

**AWS services:** Amazon API Gateway; Amazon ECR; Amazon EventBridge; AWS Lambda; Amazon SageMaker

## Summary

Machine learning operations (MLOps) is a set of practices that automate and simplify machine learning (ML) workflows and deployments. MLOps focuses on automating the ML lifecycle. It helps ensure that models are not just developed but also deployed, monitored, and retrained systematically and repeatedly. It brings DevOps principles to ML. MLOps results in faster deployment of ML models, better accuracy over time, and stronger assurance that they provide real business value.

Organizations often have existing DevOps tools and data storage solutions before starting their MLOps journey. This pattern showcases how to harness the strengths of both Microsoft Azure and AWS. It helps you integrate Azure DevOps with Amazon SageMaker to create an MLOps workflow.

The solution simplifies working between Azure and AWS. You can use Azure for development and AWS for machine learning. It promotes an effective process for making machine learning models from start to finish, including data handling, training, and deployment on AWS. For efficiency, you manage these processes through Azure DevOps pipelines.

## Prerequisites and limitations

### Prerequisites

- **Azure subscription** – Access to Azure services, such as Azure DevOps, for setting up the continuous integration and continuous deployment (CI/CD) pipelines.
- **Active AWS account** – Permissions to use the AWS services used in this pattern.
- **Data** – Access to historical data for training the machine learning model.
- **Familiarity with ML concepts** – Understanding of Python, Jupyter Notebooks, and machine learning model development.
- **Security configuration** – Proper configuration of roles, policies, and permissions across both Azure and AWS to ensure secure data transfer and access.

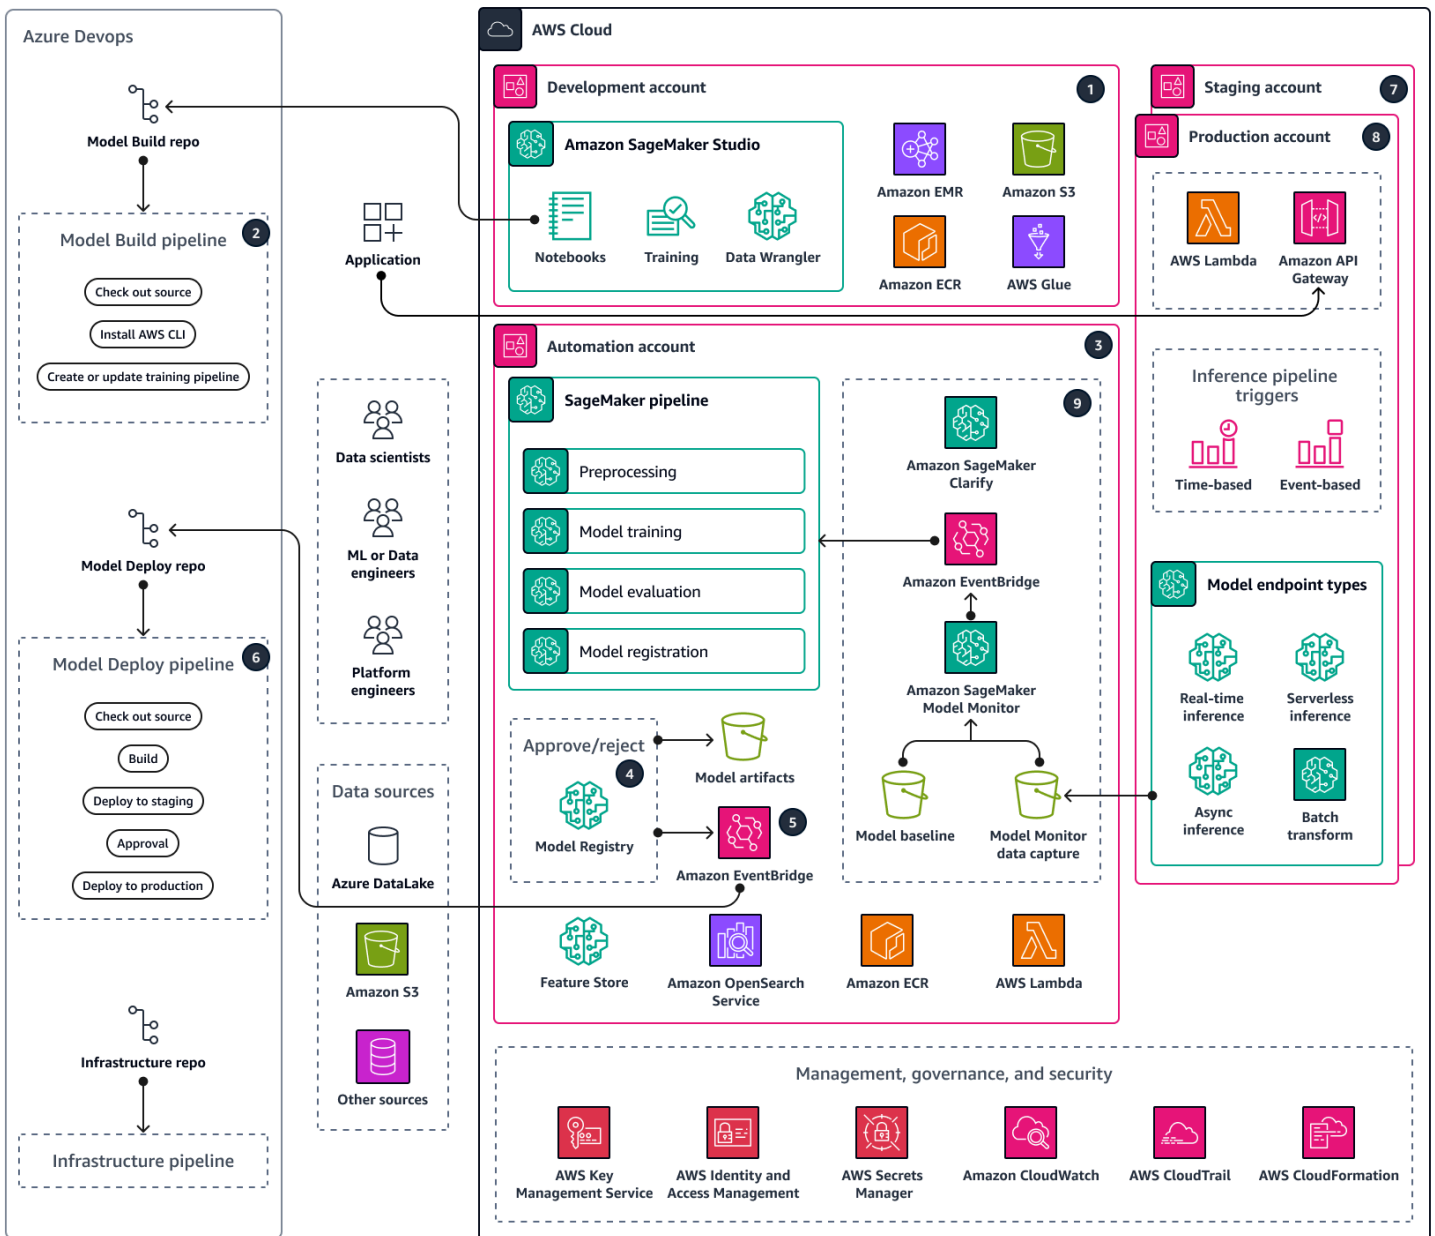

## Limitations

- This guidance does not provide guidance on secure cross-cloud data transfers. For more information about cross-cloud data transfers, see [AWS Solutions for Hybrid and Multicloud](#).
- Multicloud solutions may increase latency for real-time data processing and model inference.
- This guidance provides one example of a multi-account MLOps architecture. Adjustments are necessary based on your machine learning and AWS strategy.

## Architecture

### Target architecture

The target architecture integrates Azure DevOps with Amazon SageMaker, creating a cross-cloud ML workflow. It uses Azure for CI/CD processes and SageMaker for ML model training and deployment. It outlines the process of obtaining data (from sources such as Amazon S3, Snowflake, and Azure Data Lake) through model building and deployment. Key components include CI/CD pipelines for model building and deployment, data preparation, infrastructure management, and Amazon SageMaker for training, evaluation, and deployment of ML models. This architecture is designed to provide efficient, automated, and scalable ML workflows across cloud platforms.

The architecture consists of the following components:

1. Data scientists perform ML experiments in the development account to explore different approaches for ML use cases by using various data sources. Data scientists perform unit tests and trials. Following model evaluation, Data scientists push and merge the code to the Model Build repository, which is hosted on Azure DevOps. This repository contains code for a multi-step model building pipeline.
2. On Azure DevOps, the Model Build Pipeline, which provides continuous integration (CI), can be activated automatically or manually upon code merge to the main branch. In the Automation

- account, this activates the SageMaker pipeline for data preprocessing, model training and evaluation, and conditional model registration based on accuracy.
3. The Automation account is a central account across ML platforms that hosts ML environments (Amazon ECR), models (Amazon S3), model metadata (SageMaker Model Registry), features (SageMaker Feature Store), automated pipelines (SageMaker Pipelines), and ML log insights (CloudWatch and OpenSearch Service). This account allows reusability of ML assets and enforces best practices to accelerate delivery of ML use cases.
  4. The latest model version is added to SageMaker Model Registry for review. It tracks model versions and respective artifacts (lineage and metadata). It also manages the status of the model (approve, reject, or pending), and it manages the version for downstream deployment.
  5. After a trained model in Model Registry is approved through the studio interface or an API call, an event can be dispatched to Amazon EventBridge. EventBridge starts the Model Deploy pipeline on Azure DevOps.
  6. The Model Deploy pipeline, which provides continuous deployment (CD), checks out the source from the Model Deploy repository. The source contains code, the configuration for the model deployment, and test scripts for quality benchmarks. The Model Deploy pipeline can be tailored to your inference type.
  7. After quality control checks, the Model Deploy pipeline deploys the model to the Staging account. The Staging account is a copy of the Production account, and it is used for integration testing and evaluation. For a batch transformation, the Model Deploy pipeline can automatically update the batch inference process to use the latest approved model version. For a real-time, serverless, or asynchronous inference, it sets up or updates the respective model endpoint.
  8. After successful testing in the Staging account, a model can be deployed to the Production account by manual approval through the Model Deploy pipeline. This pipeline provisions a production endpoint in the **Deploy to production** step, including model monitoring and a data feedback mechanism.
  9. After the model is in production, use tools such as SageMaker Model Monitor and SageMaker Clarify to identify bias, detect drift, and continuously monitor the model's performance.

## Automation and scale

Use infrastructure as code (IaC) to automatically deploy to multiple accounts and environments. By automating the process of setting up an MLOps workflow, it is possible to separate the environments used by ML teams working on different projects. [AWS CloudFormation](#) helps you model, provision, and manage AWS resources by treating infrastructure as code.

# Tools

## AWS services

- [Amazon SageMaker](#) is a managed ML service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. In this pattern, Amazon S3 is used for data storage and integrated with SageMaker for model training and model objects.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, Lambda is used for data pre-processing and post-processing tasks.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable. In this pattern, it stores Docker containers that SageMaker uses as training and deployment environments.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. In this pattern, EventBridge orchestrates event-driven or time-based workflows that initiate automatic model retraining or deployment.
- [Amazon API Gateway](#) helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale. In this pattern, it is used to create an external-facing, single point of entry for Amazon SageMaker endpoints.

## Other tools

- [Azure DevOps](#) helps you manage CI/CD pipelines and facilitate code builds, tests, and deployment.
- [Azure Data Lake Storage](#) or [Snowflake](#) are possible third-party sources of training data for ML models.

## Best practices

Before implementing any component of this multicloud MLOps workflow, complete the following activities:

- Define and understand the machine learning workflow and the tools required to support it. Different use cases require different workflows and components. For example, a feature store might be required for feature reuse and low latency inference in a personalization use case, but it may not be required for other use cases. Understanding the target workflow, use case requirements, and preferred collaboration methods of the data science team is needed to successfully customize the architecture.
- Create a clear separation of responsibility for each component of the architecture. Spreading data storage across Azure Data Lake Storage, Snowflake, and Amazon S3 can increase complexity and cost. If possible, choose a consistent storage mechanism. Similarly, avoid using a combination of Azure and AWS DevOps services, or a combination of Azure and AWS ML services.
- Choose one or more existing models and datasets to perform end-to-end testing of the MLOps workflow. The test artifacts should reflect real use cases that the data science teams develop when the platform enters production.

## Epics

### Design your MLOps architecture

Task	Description	Skills required
Identify data sources.	Based on current and future use cases, available data sources, and types of data (such as confidential data), document the data sources that need to be integrated with the MLOps platform. Data can be stored in Amazon S3, Azure Data Lake Storage, Snowflake, or other sources. Create a plan for integrati	Data engineer, Data scientist, Cloud architect

Task	Description	Skills required
	ng these sources with your platform and securing access to the correct resources.	
Choose applicable services.	Customize the architecture by adding or removing services based on the desired workflow of the data science team, applicable data sources, and existing cloud architecture. For example, data engineers and data scientists may perform data preprocessing and feature engineering in SageMaker, AWS Glue, or Amazon EMR. It is unlikely that all three services would be required.	AWS administrator, Data engineer, Data scientist, ML engineer

Task	Description	Skills required
Analyze security requirements.	<p>Gather and document security requirements. This includes determining:</p> <ul style="list-style-type: none"><li>• Which teams or engineers can access specific data sources</li><li>• Whether teams are allowed to access the code and models of other teams</li><li>• Which permissions (if any) team members should have for non-development accounts</li><li>• Which security measures need to be implemented for cross-cloud data transfer</li></ul>	AWS administrator, Cloud architect

## Set up AWS Organizations

Task	Description	Skills required
Set up AWS Organizations.	<p>Set up AWS Organizations on the root AWS account. This helps you manage the subsequent accounts that you create as part of a multi-account MLOps strategy. For more information, see the <a href="#">AWS Organizations documentation</a>.</p>	AWS administrator

## Set up the development environment and versioning

Task	Description	Skills required
Create an AWS development account.	Create an AWS account where data engineers and data scientists have permissions to experiment and create ML models. For instructions, see <a href="#">Creating a member account in your organization</a> in the AWS Organizations documentation.	AWS administrator
Create a Model Build repository.	Create a Git repository in Azure where data scientists can push their model build and deployment code after the experimentation phase is complete. For instructions, see <a href="#">Set up a Git repository</a> in the Azure DevOps documentation.	DevOps engineer, ML engineer
Create a Model Deploy repository.	Create a Git repository in Azure that stores standard deployment code and templates. It should include code for every deployment option that the organization uses, as identified in the design phase. For example, it should include real-time endpoints, asynchronous endpoints, serverless inference, or batch transforms. For instructions, see <a href="#">Set up</a>	DevOps engineer, ML engineer

Task	Description	Skills required
	<a href="#">a Git repository</a> in the Azure DevOps documentation.	
Create an Amazon ECR repository.	Set up an Amazon ECR repository that stores the approved ML environments as Docker images. Allow data scientists and ML engineers to define new environments. For instructions, see <a href="#">Creating a private repository</a> in the Amazon ECR documentation.	ML engineer
Set up SageMaker Studio.	Set up SageMaker Studio on the development account according to the previously defined security requirements and preferred data science tools, such as your choice of integrated development environment (IDE). Use lifecycle configurations to automate the installation of key functionality and create a uniform development environment for data scientists. For more information, see <a href="#">Amazon SageMaker Studio</a> in the SageMaker documentation.	ML engineer, Data scientist

## Integrate CI/CD pipelines

Task	Description	Skills required
Create an Automation account.	Create an AWS account where automated pipelines and jobs run. You can give data science teams read access to this account. For instructions, see <a href="#">Creating a member account in your organization</a> in the AWS Organizations documentation.	AWS administrator
Set up a model registry.	Set up SageMaker Model Registry in the Automation account. This registry stores the metadata for ML models and helps certain data scientists or team leads to approve or reject models. For more information, see <a href="#">Register and deploy models with Model Registry</a> in the SageMaker documentation.	ML engineer
Create a Model Build pipeline.	Create a CI/CD pipeline in Azure that starts manually or automatically when code is pushed to the Model Build repository. The pipeline should check out the source code and create or update a SageMaker pipeline in the Automation account. The pipeline should add a new model to the model registry.	DevOps engineer, ML engineer

Task	Description	Skills required
	For more information about creating a pipeline, see the <a href="#">Azure Pipelines documentation</a> .	

## Build the deployment stack

Task	Description	Skills required
Create AWS staging and deployment accounts.	Create AWS accounts for staging and deployment of ML models. These accounts should be identical to allow for accurate testing of the models in staging before moving to production. You can give data science teams read access to the staging account. For instructions, see <a href="#">Creating a member account in your organization</a> in the AWS Organizations documentation.	AWS administrator
Set up S3 buckets for model monitoring.	Complete this step if you want to enable model monitoring for the deployed models that are created by the Model Deploy pipeline. Create Amazon S3 buckets for storing the input and output data. For more information about creating S3 buckets, see <a href="#">Creating a bucket</a> in the Amazon	ML engineer

Task	Description	Skills required
	<p>S3 documentation. Set up cross-account permissions so that the automated model monitoring jobs run in the Automation account. For more information, see <a href="#">Monitor data and model quality</a> in the SageMaker documentation.</p>	
<p>Create a Model Deploy pipeline.</p>	<p>Create a CI/CD pipeline in Azure that starts when a model is approved in the model registry. The pipeline should check out the source code and model artifact, build the infrastructure templates for deploying the model in the staging and production accounts, deploy the model in the staging account, run automated tests, wait for manual approval, and deploy the approved model into the production account. For more information about creating a pipeline, see the <a href="#">Azure Pipelines documentation</a>.</p>	<p>DevOps engineer, ML engineer</p>

### (Optional) Automate ML environment infrastructure

Task	Description	Skills required
<p>Build AWS CDK or CloudFormation templates.</p>	<p>Define AWS Cloud Development Kit (AWS CDK) or AWS</p>	<p>AWS DevOps</p>

Task	Description	Skills required
	CloudFormation templates for all environments that need to be deployed automatically. This might include the development environment, automation environment, and staging and deployment environments. For more information, see the <a href="#">AWS CDK</a> and <a href="#">CloudFormation</a> documentation.	
Create an Infrastructure pipeline.	Create a CI/CD pipeline in Azure for infrastructure deployment. An administrator can initiate this pipeline to create new AWS accounts and set up the environments that the ML team requires.	DevOps engineer

## Troubleshooting

Issue	Solution
<b>Insufficient monitoring and drift detection</b> – Inadequate monitoring can lead to missed detection of model performance issues or data drift.	Strengthen monitoring frameworks with tools such as Amazon CloudWatch, SageMaker Model Monitor, and SageMaker Clarify. Configure alerts for immediate action on identified issues.
<b>CI pipeline trigger errors</b> – The CI pipeline in Azure DevOps might not be triggered upon code merge due to misconfiguration.	Check the Azure DevOps project settings to ensure that the webhooks are properly set up and pointing to the correct SageMaker endpoints.

Issue	Solution
<b>Governance</b> – The central Automation account might not enforce best practices across ML platforms, leading to inconsistent workflows.	Audit the Automation account settings, ensuring that all ML environments and models conform to predefined best practices and policies.
<b>Model registry approval delays</b> – This happens when there's a delay in checking and approving the model, either because people take time to review it or because of technical issues.	Implement a notification system to alert stakeholders of models that are pending approval, and streamline the review process.
<b>Model deployment event failures</b> – Events dispatched to start model deployment pipelines might fail, causing deployment delays.	Confirm that Amazon EventBridge has the correct permissions and event patterns to invoke Azure DevOps pipelines successfully.
<b>Production deployment bottlenecks</b> – Manual approval processes can create bottlenecks, delaying the production deployment of models.	Optimize the approval workflow within the model deploy pipeline, promoting timely reviews and clear communication channels.

# Create a custom Docker container image for SageMaker and use it for model training in AWS Step Functions

Created by Julia Bluszcz (AWS), Neha Sharma (AWS), Aubrey Oosthuizen (AWS), Mohan Gowda Purushothama (AWS), and Mateusz Zaremba (AWS)

**Environment:** Production

**Technologies:** Machine learning & AI; DevOps

**AWS services:** Amazon ECR; Amazon SageMaker; AWS Step Functions

## Summary

This pattern shows how to create a Docker container image for [Amazon SageMaker](#) and use it for a training model in [AWS Step Functions](#). By packaging custom algorithms in a container, you can run almost any code in the SageMaker environment, regardless of programming language, framework, or dependencies.

In the example [SageMaker notebook](#) provided, the custom Docker container image is stored in [Amazon Elastic Container Registry \(Amazon ECR\)](#). Step Functions then uses the container that's stored in Amazon ECR to run a Python processing script for SageMaker. Then, the container exports the model to [Amazon Simple Storage Service \(Amazon S3\)](#).

## Prerequisites and limitations

### Prerequisites

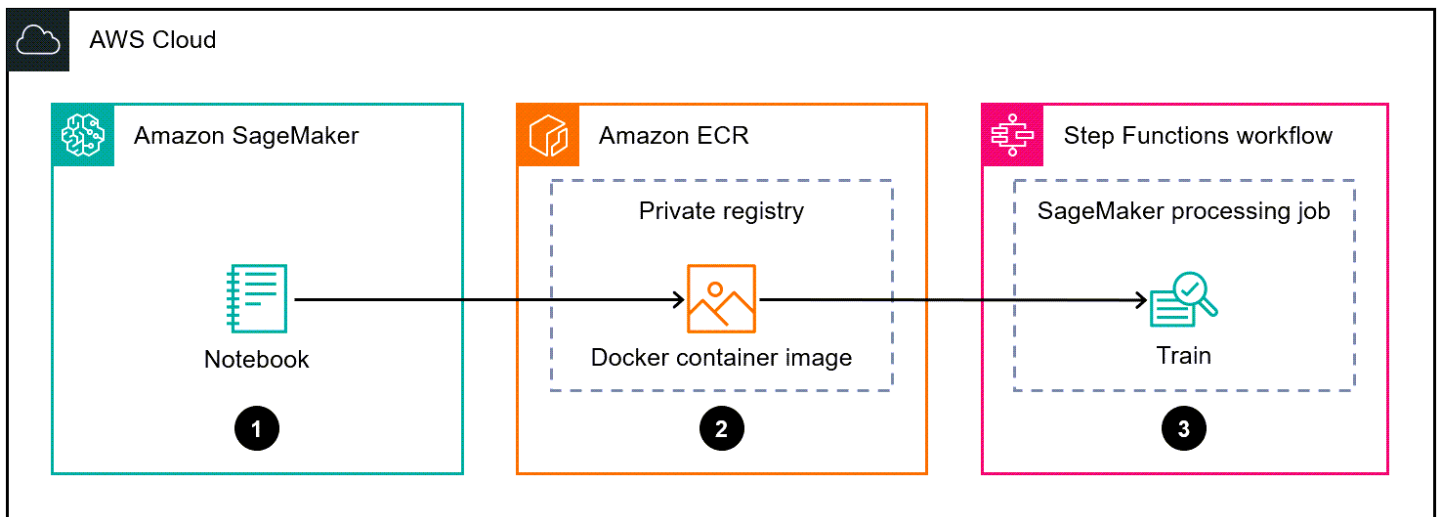

- An active AWS account
- An [AWS Identity and Access Management \(IAM\) role for SageMaker](#) with Amazon S3 permissions
- An [IAM role for Step Functions](#)
- Familiarity with Python
- Familiarity with the Amazon SageMaker Python SDK
- Familiarity with the AWS Command Line Interface (AWS CLI)
- Familiarity with AWS SDK for Python (Boto3)
- Familiarity with Amazon ECR
- Familiarity with Docker

## Product versions

- AWS Step Functions Data Science SDK version 2.3.0
- Amazon SageMaker Python SDK version 2.78.0

## Architecture

The following diagram shows an example workflow for creating a Docker container image for SageMaker, then using it for a training model in Step Functions:

The diagram shows the following workflow:

1. A data scientist or DevOps engineer uses a Amazon SageMaker notebook to create a custom Docker container image.
2. A data scientist or DevOps engineer stores the Docker container image in an Amazon ECR private repository that's in a private registry.
3. A data scientist or DevOps engineer uses the Docker container to run a Python SageMaker processing job in a Step Functions workflow.

## Automation and scale

The example SageMaker notebook in this pattern uses an `m1.m5.xlarge` notebook instance type. You can change the instance type to fit your use case. For more information about SageMaker notebook instance types, see [Amazon SageMaker Pricing](#).

## Tools

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon SageMaker](#) is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- [Amazon SageMaker Python SDK](#) is an open source library for training and deploying machine-learning models on SageMaker.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- [AWS Step Functions Data Science Python SDK](#) is an open source library that helps you create Step Functions workflows that process and publish machine learning models.

# Deploy preprocessing logic into an ML model in a single endpoint using an inference pipeline in Amazon SageMaker

Created by Mohan Gowda Purushothama (AWS), Gabriel Rodriguez Garcia (AWS), and Mateusz Zaremba (AWS)

**Environment:** Production

**Technologies:** Machine learning & AI; Containers & microservices

**AWS services:** Amazon SageMaker; Amazon ECR

## Summary

This pattern explains how to deploy multiple pipeline model objects in a single endpoint by using an [inference pipeline](#) in Amazon SageMaker. The pipeline model object represents different machine learning (ML) workflow stages, such as preprocessing, model inference, and postprocessing. To illustrate the deployment of serially connected pipeline model objects, this pattern shows you how to deploy a preprocessing [Scikit-learn](#) container and a regression model based on the [linear learner algorithm](#) built into SageMaker. The deployment is hosted behind a single endpoint in SageMaker.

**Note:** The deployment in this pattern uses the ml.m4.2xlarge instance type. We recommend using an instance type that aligns with your data size requirements and the complexity of your workflow. For more information, see [Amazon SageMaker Pricing](#). This pattern uses [prebuilt Docker images for Scikit-learn](#), but you can use your own Docker containers and integrate them into your workflow.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- [Python 3.9](#)
- [Amazon SageMaker Python SDK](#) and [Boto3 library](#)
- AWS Identity and Access Management (AWS IAM) [role](#) with basic SageMaker [permissions](#) and Amazon Simple Storage Service (Amazon S3) [permissions](#)

## Product versions

- [Amazon SageMaker Python SDK 2.49.2](#)

## Architecture

### Target technology stack

- Amazon Elastic Container Registry (Amazon ECR)
- Amazon SageMaker
- Amazon SageMaker Studio
- Amazon Simple Storage Service (Amazon S3)
- [Real-time inference](#) endpoint for Amazon SageMaker

### Target architecture

The following diagram shows the architecture for the deployment of an Amazon SageMaker pipeline model object.

The diagram shows the following workflow:

1. A SageMaker notebook deploys a pipeline model.
2. An S3 bucket stores the model artifacts.
3. Amazon ECR gets the source container images from the S3 bucket.

## Tools

### AWS tools

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.

- [Amazon SageMaker](#) is a managed ML service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- [Amazon SageMaker Studio](#) is a web-based, integrated development environment (IDE) for ML that lets you build, train, debug, deploy, and monitor your ML models.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

## Code

The code for this pattern is available in the GitHub [Inference Pipeline with Scikit-learn and Linear Learner](#) repository.

## Epics

### Prepare the dataset

Task	Description	Skills required
Prepare the dataset for your regression task.	<p><a href="#">Open a notebook</a> in Amazon SageMaker Studio.</p> <p>To import all necessary libraries and initialize your working environment, use the following example code in your notebook:</p> <pre>import sagemaker from sagemaker import get_execution_role  sagemaker_session = sagemaker.Session()  # Get a SageMaker- compatible role used by this Notebook Instance.</pre>	Data scientist

Task	Description	Skills required
	<pre>role = get_execution_role()  # S3 prefix bucket = sagemaker_session.default_bucket() prefix = "Scikit-LearnLearner-pipeline-abalone-example"</pre> <p>To download a sample dataset, add the following code to your notebook:</p> <pre>! mkdir abalone_data ! aws s3 cp s3://sagemaker-sample-files/datasets/tabular/uci_abalone/abalone.csv ./abalone_data</pre> <p><b>Note:</b> The example in this pattern uses the <a href="#">Abalone Data Set</a> from the UCI Machine Learning Repository.</p>	

Task	Description	Skills required
Upload the dataset to an S3 bucket.	<p>In the notebook where you prepared your dataset earlier, add the following code to upload your sample data to an S3 bucket:</p> <pre> WORK_DIRECTORY =   "abalone_data"  train_input = sagemaker _session.upload_data(   path="{}/{}".forma t(WORK_DIRECTORY,   "abalone.csv"),   bucket=bucket,   key_prefix="{}/ {}".format(prefix,   "train"),   ) </pre>	Data scientist

## Create the data preprocessor using SKLearn

Task	Description	Skills required
Prepare the preprocessor.py script.	<ol style="list-style-type: none"> <li>Copy the preprocessing logic from the Python file in the GitHub <a href="#">sklearn_abalone_featurizer.py</a> repository, and then paste the code into a separate Python file called <code>sklearn_abalone_featurizer.py</code>. You can modify the code to fit your custom dataset and custom workflow.</li> </ol>	Data scientist

Task	Description	Skills required
	2. Save the <code>sklearn_balone_featurizer.py</code> file in the root directory of your project (that is, in the same location where you run your SageMaker notebook).	

Task	Description	Skills required
Create the SKLearn preprocessor object.	<p>To create an SKLearn preprocessor object (called SKLearn Estimator) that you can incorporate into your final inference pipeline, run the following code in your SageMaker notebook:</p> <pre data-bbox="594 583 1027 1619">from sagemaker.sklearn. estimator import SKLearn  FRAMEWORK_VERSION = "0.23-1" script_path = "sklearn_abalone_f eaturizer.py"  sklearn_preprocessor = SKLearn(     entry_point=script _path,     role=role,     framework_version= FRAMEWORK_VERSION,     instance_type="ml. c4.xlarge",     sagemaker_session= sagemaker_session, ) sklearn_preproc essor.fit({"train": train_input})</pre>	Data scientist

Task	Description	Skills required
Test the preprocessor's inference.	<p>To confirm that your preprocessor is defined correctly, launch a <a href="#">batch transform job</a> by entering the following code in your SageMaker notebook:</p> <pre data-bbox="597 535 1029 1770"># Define a SKLearn Transformer from the trained SKLearn Estimator transformer = sklearn_preprocessor.transformer(     instance_count=1,     instance_type="ml.m5.xlarge",     assemble_with="Line",     accept="text/csv" )  # Preprocess training input transformer.transform(train_input,     content_type="text/csv") print("Waiting for transform job: " +     transformer.latest_transform_job.job_name) transformer.wait() preprocessed_train = transformer.output_path</pre>	

## Create a machine learning model

Task	Description	Skills required
Create a model object.	<p>To create a model object based on the linear learner algorithm, enter the following code in your SageMaker notebook:</p> <pre data-bbox="594 596 1026 1831">import boto3 from sagemaker .image_uris import retrieve  ll_image = retrieve( "linear-learner", boto3.Session().re gion_name) s3_ll_output_key _prefix = "ll_train ing_output" s3_ll_output_location = "s3://{}/{}/{}/{}" .format(     bucket, prefix,     s3_ll_output_key_p refix, "ll_model" )  ll_estimator = sagemaker.estimato r.Estimator(     ll_image,     role,     instance_count=1,     instance_type="ml. m4.2xlarge",     volume_size=20,     max_run=3600,     input_mode="File",</pre>	Data scientist

Task	Description	Skills required
	<pre> output_path=s3_ll_ output_location, sagemaker_session= sagemaker_session, )  ll_estimator.s et_hyperparameters (feature_dim=10, predictor_type="re gressor", mini_batch_size=32)  ll_train_data = sagemaker.inputs.TrainingInput( preprocessed_train , distribution="FullyReplicated", content_type="text/csv", s3_data_type="S3Prefix", )  data_channels = {"train": ll_train_data} ll_estimator.fit(inputs=data_channels, logs=True) </pre> <p>The preceding code retrieves the relevant Amazon ECR Docker image from the public Amazon ECR Registry for the model, creates an estimator object, and then uses that</p>	

Task	Description	Skills required
	object to train the regression model.	

## Deploy the final pipeline

Task	Description	Skills required
Deploy the pipeline model.	<p>To create a pipeline model object (that is, a preprocessor object) and deploy the object, enter the following code in your SageMaker notebook:</p> <pre>from sagemaker.model import Model from sagemaker .pipeline import PipelineModel import boto3 from time import gmtime, strftime  timestamp_prefix =     strftime("%Y-%m-%d- %H-%M-%S", gmtime())  scikit_learn_inf erencee_model =     sklearn_preprocess or.create_model() linear_learner_model = ll_estimator.creat e_model()  model_name = "inferenc e-pipeline-" +     timestamp_prefix</pre>	Data scientist

Task	Description	Skills required
	<pre>endpoint_name =     "inference-pipeline-     ep-" + timestamp_prefix sm_model = PipelineM odel(     name=model_name,     role=role, models=     [scikit_learn_infe     rencee_model,     linear_learner_model] )  sm_model.deploy(init ial_instance_count =1, instance_type="ml. c4.xlarge", endpoint_ name=endpoint_name)</pre> <p><b>Note:</b> You can adjust the instance type used in the model object to meet your needs.</p>	

Task	Description	Skills required
Test the inference.	<p>To confirm the endpoint is working correctly, run the following sample inference code in your SageMaker notebook:</p> <pre data-bbox="597 489 1024 1325">from sagemaker.predictor import Predictor from sagemaker.serializers import CSVSerializer  payload = "M, 0.44, 0.365, 0.125, 0.516, 0.2155, 0.114, 0.155" actual_rings = 10 predictor = Predictor(endpoint_name=endpoint_name, sagemaker_session=sagemaker_session, serializer=CSVSerializer())  print(predictor.predict(payload))</pre>	Data scientist

# Develop advanced generative AI chat-based assistants by using RAG and ReAct prompting

Created by Praveen Kumar Jeyarajan (AWS), Jundong Qiao (AWS), Kara Yang (AWS), Kiowa Jackson (AWS), Noah Hamilton (AWS), and Shuai Cao (AWS)

**Code repository:** [genai-bedrock-chatbot](#)

**Environment:** PoC or pilot

**Technologies:** Machine learning & AI; Databases; DevOps; Serverless

**AWS services:** Amazon Bedrock; Amazon ECS; Amazon Kendra; AWS Lambda

## Summary

A typical corporation has 70 percent of its data trapped in siloed systems. You can use generative AI-powered chat-based assistants to unlock insights and relationships between these data silos through natural language interactions. To get the most out of generative AI, the outputs must be trustworthy, accurate, and inclusive of the available corporate data. Successful chat-based assistants depend on the following:

- Generative AI models (such as Anthropic Claude 2)
- Data source vectorization
- Advanced reasoning techniques, such as the [ReAct framework](#), for prompting the model

This pattern provides data-retrieval approaches from data sources such as Amazon Simple Storage Service (Amazon S3) buckets, AWS Glue, and Amazon Relational Database Service (Amazon RDS). Value is gained from that data by interleaving [Retrieval Augmented Generation \(RAG\)](#) with chain-of-thought methods. The results support complex chat-based assistant conversations that draw on the entirety of your corporation's stored data.

This pattern uses Amazon SageMaker manuals and pricing data tables as an example to explore the capabilities of a generative AI chat-based assistant. You will build a chat-based assistant that helps

customers evaluate the SageMaker service by answering questions about pricing and the service's capabilities. The solution uses a Streamlit library for building the frontend application and the LangChain framework for developing the application backend powered by a large language model (LLM).

Inquiries to the chat-based assistant are met with an initial intent classification for routing to one of three possible workflows. The most sophisticated workflow combines general advisory guidance with complex pricing analysis. You can adapt the pattern to suit enterprise, corporate, and industrial use cases.

## Prerequisites and limitations

### Prerequisites

- [AWS Command Line Interface \(AWS CLI\)](#) installed and configured
- [AWS Cloud Development Kit \(AWS CDK\) Toolkit 2.114.1 or later](#) installed and configured
- Basic familiarity with Python and AWS CDK
- [Git](#) installed
- [Docker](#) installed
- [Python 3.11 or later](#) installed and configured (for more information, see the [Tools](#) section)
- An [active AWS account](#) bootstrapped by using [AWS CDK](#)
- Amazon Titan and Anthropic Claude [model access](#) enabled in the Amazon Bedrock service
- [AWS security credentials](#), including `AWS_ACCESS_KEY_ID`, correctly configured in your terminal environment

### Limitations

- LangChain doesn't support every LLM for streaming. The Anthropic Claude models are supported, but models from AI21 Labs are not.
- This solution is deployed to a single AWS account.
- This solution can be deployed only in AWS Regions where Amazon Bedrock and Amazon Kendra are available. For information about availability, see the documentation for [Amazon Bedrock](#) and [Amazon Kendra](#).

### Product versions

- Python version 3.11 or later
- Streamlit version 1.30.0 or later
- Streamlit-chat version 0.1.1 or later
- LangChain version 0.1.12 or later
- AWS CDK version 2.132.1 or later

## Architecture

### Target technology stack

- Amazon Athena
- Amazon Bedrock
- Amazon Elastic Container Service (Amazon ECS)
- AWS Glue
- AWS Lambda
- Amazon S3
- Amazon Kendra
- Elastic Load Balancing

### Target architecture

The AWS CDK code will deploy all the resources that are required to set up the chat-based assistant application in an AWS account. The chat-based assistant application shown in the following diagram is designed to answer SageMaker related queries from users. Users connect through an Application Load Balancer to a VPC that contains an Amazon ECS cluster hosting the Streamlit application. An orchestration Lambda function connects to the application. S3 bucket data sources provide data to the Lambda function through Amazon Kendra and AWS Glue. The Lambda function connects to Amazon Bedrock for answering queries (questions) from chat-based assistant users.

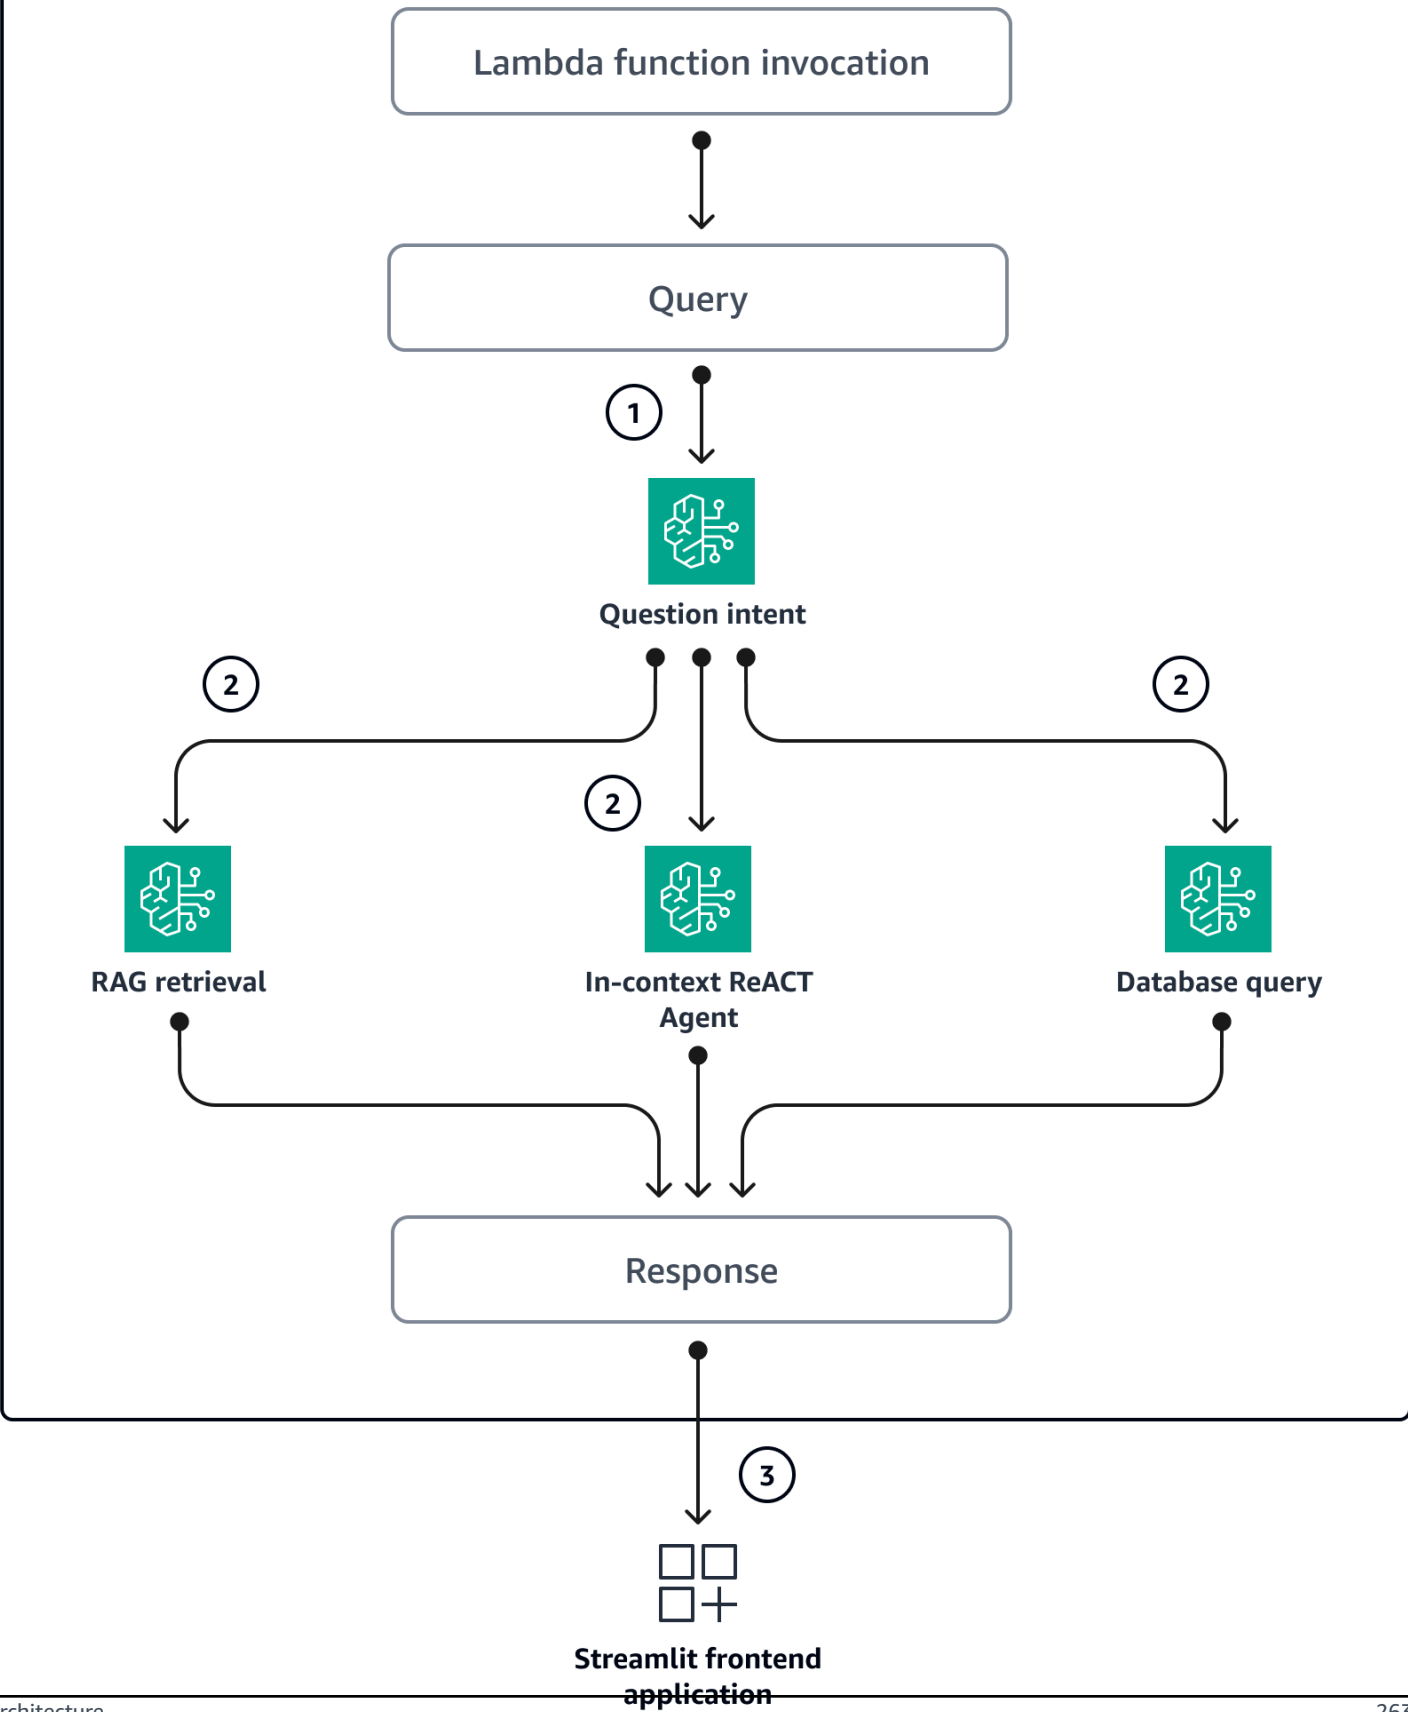

1. The orchestration Lambda function sends the LLM prompt request to the Amazon Bedrock model (Claude 2).
2. Amazon Bedrock sends the LLM response back to the orchestration Lambda function.

**Logic flow within the orchestration Lambda function**

When users ask a question through the Streamlit application, it invokes the orchestration Lambda function directly. The following diagram shows the logic flow when the Lambda function is invoked.

### Response orchestration Lambda function

- Step 1 – The input query (question) is classified into one of the three intents:
  - General SageMaker guidance questions
  - General SageMaker pricing (training/inference) questions
  - Complex questions related to SageMaker and pricing
- Step 2 – The input query initiates one of the three services:
  - RAG Retrieval service, which retrieves relevant context from the [Amazon Kendra](#) vector database and calls the LLM through [Amazon Bedrock](#) to summarize the retrieved context as the response.
  - Database Query service, which uses- the LLM, database metadata, and sample rows from relevant tables to convert the input query into a SQL query. Database Query service runs the SQL query against the SageMaker pricing database through [Amazon Athena](#) and summarizes the query results as the response.
  - In-context ReACT Agent service, which breaks down the input query into multiple steps before providing a response. The agent uses RAG Retrieval service and Database Query service as tools to retrieve relevant information during the reasoning process. After the reasoning and actions processes are complete, the agent generates the final answer as the response.
- Step 3 – The response from the orchestration Lambda function is sent to the Streamlit application as output.

## Tools

### AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- [Amazon Bedrock](#) is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.

- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue crawler and an AWS Glue Data Catalog table.
- [Amazon Kendra](#) is an intelligent search service that uses natural language processing and advanced machine learning algorithms to return specific answers to search questions from your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

## Code repository

The code for this pattern is available in the GitHub [genai-bedrock-chatbot](#) repository.

The code repository contains the following files and folders:

- `assets` folder – The static assets the architecture diagram and the public dataset
- `code/lambda-container` folder – The Python code that is run in the Lambda function
- `code/streamlit-app` folder – The Python code that is run as the container image in Amazon ECS
- `tests` folder – The Python files that are run to unit test the AWS CDK constructs
- `code/code_stack.py` – The AWS CDK construct Python files used to create AWS resources
- `app.py` – The AWS CDK stack Python files used to deploy AWS resources in the target AWS account
- `requirements.txt` – The list of all Python dependencies that must be installed for AWS CDK
- `requirements-dev.txt` – The list of all Python dependencies that must be installed for AWS CDK to run the unit-test suite
- `cdk.json` – The input file to provide values required to spin up resources

**Note:** The AWS CDK code uses [L3 \(layer 3\) constructs](#) and [AWS Identity and Access Management \(IAM\) policies managed by AWS](#) for deploying the solution.

## Best practices

- The code example provided here is for a proof-of-concept (PoC) or pilot demo only. If you want to take the code to Production, be sure to use the following best practices:
  - [Amazon S3 access logging is enabled.](#)
  - [VPC Flow Logs is enabled.](#)
  - The [Amazon Kendra Enterprise Edition index](#) is enabled.
- Set up monitoring and alerting for the Lambda function. For more information, see [Monitoring and troubleshooting Lambda functions](#). For general best practices when working with Lambda functions, see the [AWS documentation](#).

## Epics

### Set up AWS credentials on your local machine

Task	Description	Skills required
Export variables for the account and AWS Region where the stack will be deployed.	To provide AWS credentials for AWS CDK by using environment variables, run the following commands. <pre>export CDK_DEFAULT_ACCOUNT=&lt;12 Digit AWS Account Number&gt; export CDK_DEFAULT_REGION=&lt;region&gt;</pre>	DevOps engineer, AWS DevOps
Set up the AWS CLI profile.	To set up the AWS CLI profile for the account, follow the instructions in the <a href="#">AWS documentation</a> .	DevOps engineer, AWS DevOps

## Set up your environment

Task	Description	Skills required
Clone the repo on your local machine.	<p>To clone the repository, run the following command in your terminal.</p> <pre>git clone https://github.com/aws-labs/genai-bedrock-chat-bot.git</pre>	DevOps engineer, AWS DevOps
Set up the Python virtual environment and install required dependencies.	<p>To set up the Python virtual environment, run the following commands.</p> <pre>cd genai-bedrock-chat-bot python3 -m venv .venv source .venv/bin/activate</pre> <p>To set up the required dependencies, run the following command.</p> <pre>pip3 install -r requirements.txt</pre>	DevOps engineer, AWS DevOps
Set up the AWS CDK environment and synthesize the AWS CDK code.	<p>1. To set up the AWS CDK environment in your AWS account, run the following command.</p> <pre>cdk bootstrap aws://ACCOUNT-NUMBER/REGION</pre>	DevOps engineer, AWS DevOps

Task	Description	Skills required
	2. To convert the code to an AWS CloudFormation stack configuration, run the command <code>cdk synth</code> .	

## Configure and deploy the chat-based assistant application

Task	Description	Skills required
Provision Claude model access.	To enable Anthropic Claude model access for your AWS account, follow the instructions in the <a href="#">Amazon Bedrock documentation</a> .	AWS DevOps
Deploy resources in the account.	To deploy resources in the AWS account by using the AWS CDK, do the following: <ol style="list-style-type: none"> <li>1. In the root of the cloned repository, in the <code>cdk.json</code> file, provide inputs for the logging parameters. Example values are INFO, DEBUG, WARN, and ERROR. <p>These values define log-level messages for the Lambda function and the Streamlit application.</p> </li> <li>2. The <code>app.py</code> file in the root of the cloned repository contains the AWS CloudFormation stack</li> </ol>	AWS DevOps, DevOps engineer

Task	Description	Skills required
	<p>name used for deployment. The default stack name is <code>chatbot-stack</code>.</p> <p>3. To deploy resources, run the command <code>cdk deploy</code>.</p> <p>The <code>cdk deploy</code> command uses <code>L3</code> constructs to create multiple Lambda functions for copying documents and CSV dataset files to S3 buckets.</p> <p>4. After the command is complete, sign in to the AWS Management Console, open the CloudFormation console, and <a href="#">review that the stack deployed successfully</a>.</p> <p>Upon successful deployment, you can access the chat-based assistant application by using the URL provided in the CloudFormation <b>Outputs</b> section.</p>	

Task	Description	Skills required
Run the AWS Glue crawler and create the Data Catalog table.	<p>An <a href="#">AWS Glue crawler</a> is used to keep the data schema dynamic. The solution creates and updates partitions in the <a href="#">AWS Glue Data Catalog table</a> by running the crawler on demand. After the CSV dataset files are copied into the S3 bucket, run the AWS Glue crawler and create the Data Catalog table schema for testing:</p> <ol style="list-style-type: none"><li>1. Navigate to the AWS Glue console.</li><li>2. In the navigation pane, under <b>Data Catalog</b>, choose <b>Crawlers</b>.</li><li>3. Select the crawler with suffix <code>sagemaker-pricing-crawler</code> .</li><li>4. Run the crawler.</li><li>5. After the crawler runs successfully, it creates an AWS Glue Data Catalog table.</li></ol> <p><b>Note:</b> The AWS CDK code configures the AWS Glue crawler to run on demand, but you can also <a href="#">schedule</a> it to run periodically.</p>	DevOps engineer, AWS DevOps

Task	Description	Skills required
Initiate document indexing.	<p>After the files are copied into the S3 bucket, use Amazon Kendra to crawl and index them:</p> <ol style="list-style-type: none"> <li>1. Navigate to the Amazon Kendra console.</li> <li>2. Select the index with the suffix chatbot-index .</li> <li>3. In the navigation pane, choose <b>Data sources</b>, and select the data source connector with the suffix chatbot-index .</li> <li>4. Choose <b>Sync Now</b> to initiate the indexing process.</li> </ol> <p><b>Note:</b> The AWS CDK code configures the Amazon Kendra index sync to run on demand, but you can also run periodically by using the <a href="#">Schedule parameter</a>.</p>	AWS DevOps, DevOps engineer

## Clean up all AWS resources in the solution

Task	Description	Skills required
Remove the AWS resources.	<p>After you test the solution, clean up the resources:</p> <ol style="list-style-type: none"> <li>1. To remove AWS resources deployed by the solution,</li> </ol>	DevOps engineer, AWS DevOps

Task	Description	Skills required
	<p>run the command <code>cdk destroy</code>.</p> <p>2. Delete all objects from the two S3 buckets, and then remove the buckets.</p> <p>For more information, see <a href="#">Deleting a bucket</a>.</p>	

## Troubleshooting

Issue	Solution
AWS CDK returns errors.	For help with AWS CDK issues, see <a href="#">Troubleshooting common AWS CDK issues</a> .

### AWS CDK commands

When working with AWS CDK, keep in mind the following useful commands:

- Lists all stacks in the app

```
cdk ls
```

- Emits the synthesized AWS CloudFormation template

```
cdk synth
```

- Deploys the stack to your default AWS account and Region

```
cdk deploy
```

- Compares the deployed stack with the current state

```
cdk diff
```

- Opens the AWS CDK documentation

```
cdk docs
```

- Deletes the CloudFormation stack and removes AWS deployed resources

```
cdk destroy
```

# Develop a fully automated chat-based assistant by using Amazon Bedrock agents and knowledge bases

Created by Jundong Qiao (AWS), Kara Yang (AWS), Kiowa Jackson (AWS), Noah Hamilton (AWS), Praveen Kumar Jeyarajan (AWS), and Shuai Cao (AWS)

**Code repository:** [genai-bedrock-agent-chatbot](#)

**Environment:** PoC or pilot

**Technologies:** Machine learning & AI; Serverless

**AWS services:** Amazon Bedrock; AWS CDK; AWS Lambda

## Summary

Many organizations face challenges when creating a chat-based assistant that is capable of orchestrating diverse data sources to offer comprehensive answers. This pattern presents a solution for developing a chat-based assistant that is capable of answering queries from both documentation and databases, with a straightforward deployment.

Starting with [Amazon Bedrock](#), this fully managed generative artificial intelligence (AI) service provides a wide array of advanced foundation models (FMs). This facilitates the efficient creation of generative AI applications with a strong focus on privacy and security. In the context of documentation retrieval, the [Retrieval Augmented Generation \(RAG\)](#) is a pivotal feature. It uses [knowledge bases](#) to augment FM prompts with contextually relevant information from external sources. An [Amazon OpenSearch Serverless](#) index serves as the vector database behind the knowledge bases for Amazon Bedrock. This integration is enhanced through careful prompt engineering to minimize inaccuracies and make sure that responses are anchored in factual documentation. For database queries, the FMs of Amazon Bedrock transform textual inquiries into structured SQL queries, incorporating specific parameters. This enables the precise retrieval of data from databases managed by [AWS Glue databases](#). [Amazon Athena](#) is used for these queries.

For handling more intricate queries, achieving comprehensive answers demands information sourced from both documentation and databases. [Agents for Amazon Bedrock](#) is a generative AI feature that helps you build autonomous agents that can understand complex tasks and break

them down into simpler tasks for orchestration. The combination of insights retrieved from the simplified tasks, facilitated by Amazon Bedrock autonomous agents, enhances the synthesis of information, leading to more thorough and exhaustive answers. This pattern demonstrates how to build a chat-based assistant by using Amazon Bedrock and the related generative AI services and features within an automated solution.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Docker, [installed](#)
- AWS Cloud Development Kit (AWS CDK), [installed](#) and [bootstrapped](#) to the us-east-1 or us-west-2 AWS Regions
- AWS CDK Toolkit version 2.114.1 or later, [installed](#)
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- Python version 3.11 or later, [installed](#)
- In Amazon Bedrock, [enable access](#) to Claude 2, Claude 2.1, Claude Instant, and Titan Embeddings G1 – Text

### Limitations

- This solution is deployed to a single AWS account.
- This solution can be deployed only in AWS Regions where Amazon Bedrock and Amazon OpenSearch Serverless are supported. For more information, see the documentation for [Amazon Bedrock](#) and [Amazon OpenSearch Serverless](#).

### Product versions

- Llama-index version 0.10.6 or later
- SQLAlchemy version 2.0.23 or later
- Opensearch-py version 2.4.2 or later
- Requests\_aws4auth version 1.2.3 or later
- AWS SDK for Python (Boto3) version 1.34.57 or later

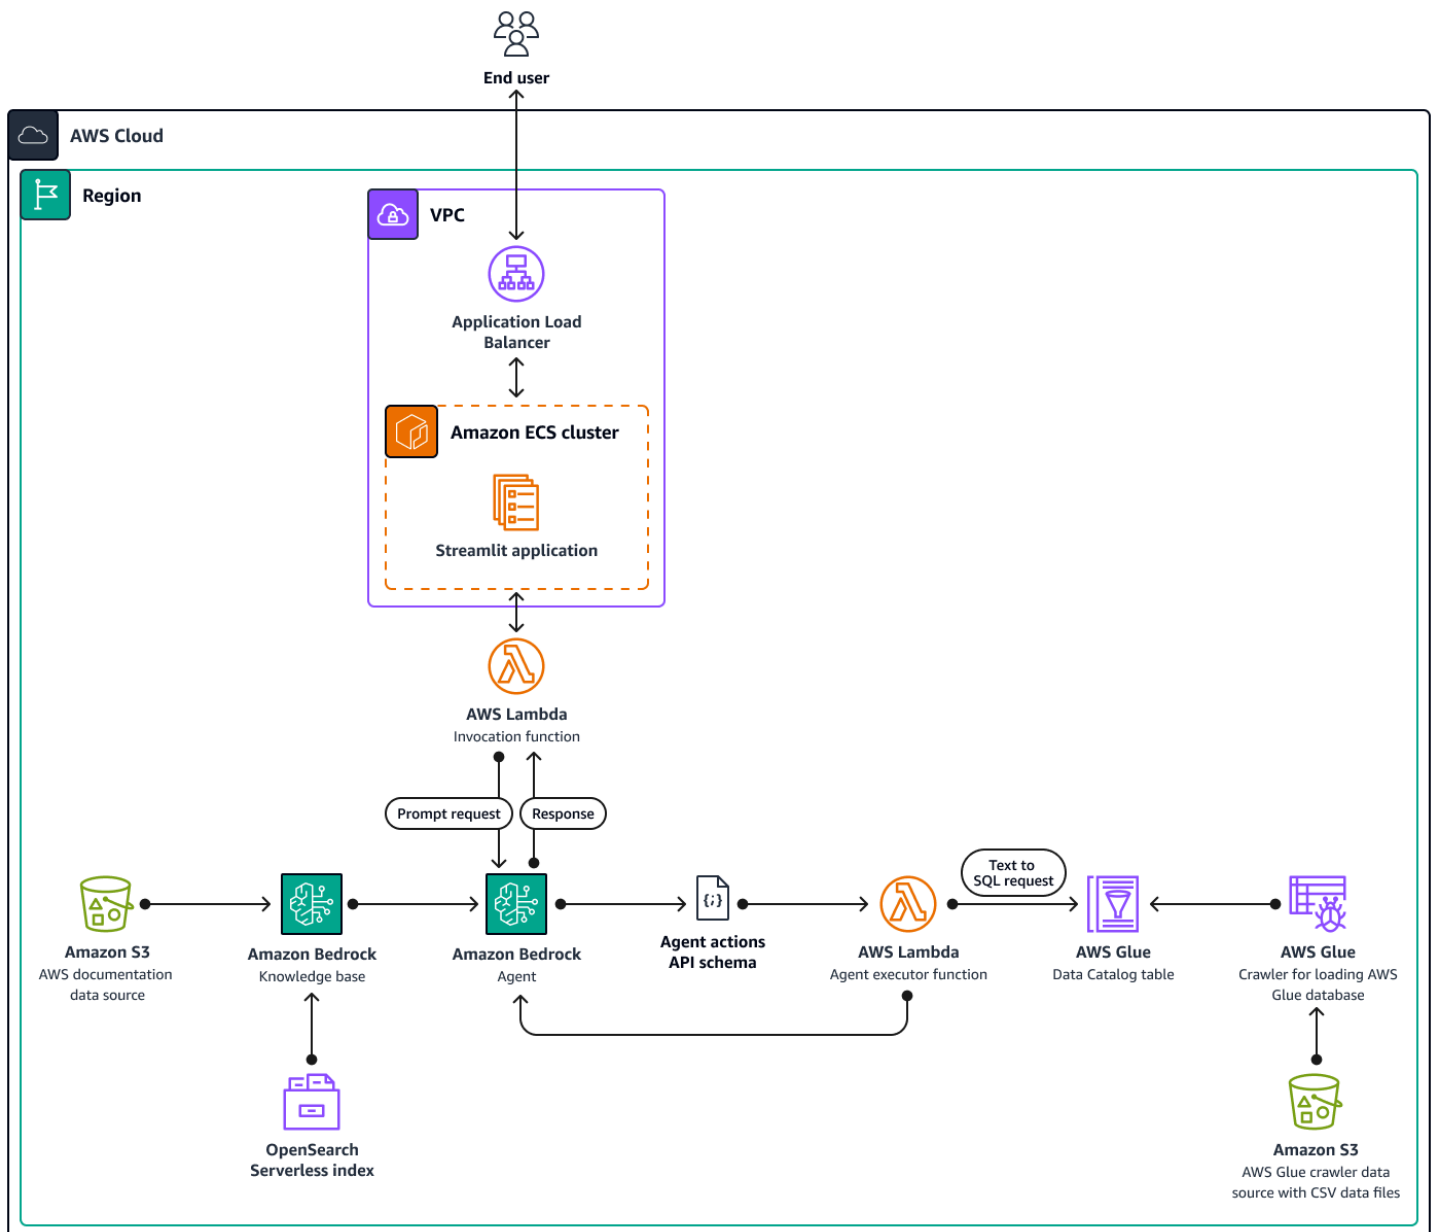

# Architecture

## Target technology stack

The [AWS Cloud Development Kit \(AWS CDK\)](#) is an open source software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation. The AWS CDK stack used in this pattern deploys the following AWS resources:

- AWS Key Management Service (AWS KMS)
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue Data Catalog, for the AWS Glue database component
- AWS Lambda
- AWS Identity and Access Management (IAM)
- Amazon OpenSearch Serverless
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon Elastic Container Service (Amazon ECS)
- AWS Fargate
- Amazon Virtual Private Cloud (Amazon VPC)
- [Application Load Balancer](#)

## Target architecture

The diagram shows a comprehensive AWS cloud-native setup within a single AWS Region, using multiple AWS services. The primary interface for the chat-based assistant is a [Streamlit](#) application hosted on an Amazon ECS cluster. An [Application Load Balancer](#) manages accessibility. Queries made through this interface activate the Invocation Lambda function, which then interfaces with agents for Amazon Bedrock. This agent responds to user inquiries by either consulting the knowledge bases for Amazon Bedrock or by invoking an Agent executor Lambda function. This function triggers a set of actions associated with the agent, following a predefined API schema. The knowledge bases for Amazon Bedrock use an OpenSearch Serverless index as their vector

database foundation. Additionally, the Agent executor function generates SQL queries that are executed against the AWS Glue database through Amazon Athena.

## Tools

### AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- [Amazon Bedrock](#) is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue crawler and an AWS Glue Data Catalog table.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon OpenSearch Serverless](#) is an on-demand serverless configuration for Amazon OpenSearch Service. In this pattern, an OpenSearch Serverless index serves as a vector database for the knowledge bases for Amazon Bedrock.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

### Other tools

- [Streamlit](#) is an open source Python framework to create data applications.

## Code repository

The code for this pattern is available in the GitHub [genai-bedrock-agent-chatbot](#) repository. The code repository contains the following files and folders:

- `assets` folder – The static assets, such as the architecture diagram and the public dataset.
- `code/lambda/action-lambda` folder – The Python code for the Lambda function that acts as an action for the Amazon Bedrock agent.
- `code/lambda/create-index-lambda` folder – The Python code for the Lambda function that creates the OpenSearch Serverless index.
- `code/lambda/invoke-lambda` folder – The Python code for the Lambda function that invokes the Amazon Bedrock agent, which is called directly from the Streamlit application.
- `code/lambda/update-lambda` folder – The Python code for the Lambda function that updates or deletes resources after the AWS resources are deployed through the AWS CDK.
- `code/layer/boto3_layer` folder – The AWS CDK stack that creates a Boto3 layer that is shared across all Lambda functions.
- `code/layer/opensearch_layer` folder – The AWS CDK stack that creates an OpenSearch Serverless layer that installs all dependencies to create the index.
- `code/streamlit-app` folder – The Python code that is run as the container image in Amazon ECS
- `code/code_stack.py` – The AWS CDK construct Python files that create AWS resources.
- `app.py` – The AWS CDK stack Python files that deploy AWS resources in the target AWS account.
- `requirements.txt` – The list of all Python dependencies that must be installed for the AWS CDK.
- `cdk.json` – The input file to provide the values that are required to create resources. Also, in the `context/config` fields, you can customize the solution accordingly. For more information about customization, see the [Additional information](#) section.

## Best practices

- The code example provided here is for proof-of-concept (PoC) or pilot purposes only. If you want to take the code to production, be sure to use the following best practices:
  - Enable [Amazon S3 access logging](#)
  - Enable [VPC Flow Logs](#)

- Set up monitoring and alerting for the Lambda functions. For more information, see [Monitoring and troubleshooting Lambda functions](#). For best practices, see the [Best practices for working with AWS Lambda functions](#).

## Epics

### Set up AWS credentials on your local workstation

Task	Description	Skills required
Export variables for the account and Region.	To provide AWS credentials for the AWS CDK by using environment variables, run the following commands. <pre>export CDK_DEFAULT_ACCOUNT=&lt;12-digit AWS account number&gt; export CDK_DEFAULT_REGION=&lt;Region&gt;</pre>	AWS DevOps, DevOps engineer
Set up the AWS CLI named profile.	To set up the AWS CLI named profile for the account, follow the instructions in <a href="#">Configuration and credential file settings</a> .	AWS DevOps, DevOps engineer

### Set up your environment

Task	Description	Skills required
Clone the repo to your local workstation.	To clone the repository, run the following command in your terminal. <pre>git clone https://github.com/aws-labs/</pre>	DevOps engineer, AWS DevOps

Task	Description	Skills required
	<pre>genai-bedrock-agent- chatbot.git</pre>	
Set up the Python virtual environment.	<p>To set up the Python virtual environment, run the following commands.</p> <pre>cd genai-bedrock-agen t-chatbot python3 -m venv .venv source .venv/bin/ activate</pre> <p>To set up the required dependencies, run the following command.</p> <pre>pip3 install -r requirements.txt</pre>	DevOps engineer, AWS DevOps
Set up the AWS CDK environment.	To convert the code to an AWS CloudFormation template, run the command <code>cdk synth</code> .	AWS DevOps, DevOps engineer

## Configure and deploy the application

Task	Description	Skills required
Deploy resources in the account.	<p>To deploy resources in the AWS account by using the AWS CDK, do the following:</p> <ol style="list-style-type: none"> <li>1. In the root of the cloned repository, in the <code>cdk.json</code> file, provide</li> </ol>	DevOps engineer, AWS DevOps

Task	Description	Skills required
	<p>inputs for the logging parameters. ## Additional information

### Customize the chat-based assistant with your own data

To integrate your custom data for deploying the solution, follow these structured guidelines. These steps are designed to ensure a seamless and efficient integration process, enabling you to deploy the solution effectively with your bespoke data.

*For knowledge base data integration*

### Data preparation

1. Locate the `assets/knowledgebase_data_source/` directory.
2. Place your dataset within this folder.

## Configuration adjustments

1. Open the `cdk.json` file.
2. Navigate to the `context/configure/paths/knowledgebase_file_name` field, and then update it accordingly.
3. Navigate to the `bedrock_instructions/knowledgebase_instruction` field, and then update it to accurately reflect the nuances and context of your new dataset.

### *For structural data integration*

## Data organization

1. Within the `assets/data_query_data_source/` directory, create a subdirectory, such as `tabular_data`.
2. Put your structured dataset (acceptable formats include CSV, JSON, ORC, and Parquet) into this newly created subfolder.
3. If you are connecting to an existing database, update the function `create_sql_engine()` in `code/lambda/action-lambda/build_query_engine.py` to connect to your database.

## Configuration and code updates

1. In the `cdk.json` file, update the `context/configure/paths/athena_table_data_prefix` field to align with the new data path.
2. Revise `code/lambda/action-lambda/dynamic_examples.csv` by incorporating new text-to-SQL examples that correspond with your dataset.
3. Revise `code/lambda/action-lambda/prompt_templates.py` to mirror the attributes of your structured dataset.
4. In the `cdk.json` file, update the `context/configure/bedrock_instructions/action_group_description` field to explain the purpose and functionality of the Action group Lambda function.
5. In the `assets/agent_api_schema/artifacts_schema.json` file, explain the new functionalities of your Action group Lambda function.

### *General update*

In the `cdk.json` file, in the `context/configure/bedrock_instructions/agent_instruction` section, provide a comprehensive description of the Amazon Bedrock agent's intended functionality and design purpose, taking into account the newly integrated data.

# Document institutional knowledge from voice inputs by using Amazon Bedrock and Amazon Transcribe

Created by Praveen Kumar Jeyarajan (AWS), Jundong Qiao (AWS), Megan Wu (AWS), and Rajiv Upadhyay (AWS)

**Code repository:** [genai-knowledge-capture](#)

**Environment:** PoC or pilot

**Technologies:** Machine learning & AI; Business productivity; CloudNative

**AWS services:** Amazon Bedrock; AWS CDK; AWS Lambda; Amazon SNS; AWS Step Functions; Amazon Transcribe

## Summary

Capturing institutional knowledge is paramount for ensuring organizational success and resilience. Institutional knowledge represents the collective wisdom, insights, and experiences accumulated by employees over time, often tacit in nature and passed down informally. This wealth of information encompasses unique approaches, best practices, and solutions to intricate problems that might not be documented elsewhere. By formalizing and documenting this knowledge, companies can preserve institutional memory, foster innovation, enhance decision-making processes, and accelerate learning curves for new employees. Additionally, it promotes collaboration, empowers individuals, and cultivates a culture of continuous improvement. Ultimately, harnessing institutional knowledge helps companies use their most valuable asset—the collective intelligence of their workforce—to navigate challenges, drive growth, and maintain competitive advantage in dynamic business environments.

This pattern explains how to capture institutional knowledge through voice recordings from senior employees. It uses [Amazon Transcribe](#) and [Amazon Bedrock](#) for systematic documentation and verification. By documenting this informal knowledge, you can preserve it and share it with subsequent cohorts of employees. This endeavor supports operational excellence and improves

the effectiveness of training programs through the incorporation of practical knowledge acquired through direct experience.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Docker, [installed](#)
- AWS Cloud Development Kit (AWS CDK) version 2.114.1 or later, [installed](#) and [bootstrapped](#) to the us-east-1 or us-west-2 AWS Regions
- AWS CDK Toolkit version 2.114.1 or later, [installed](#)
- AWS Command Line Interface (AWS CLI), [installed](#) and [configured](#)
- Python version 3.12 or later, [installed](#)
- Permissions to create Amazon Transcribe, Amazon Bedrock, Amazon Simple Storage Service (Amazon S3), and AWS Lambda resources

### Limitations

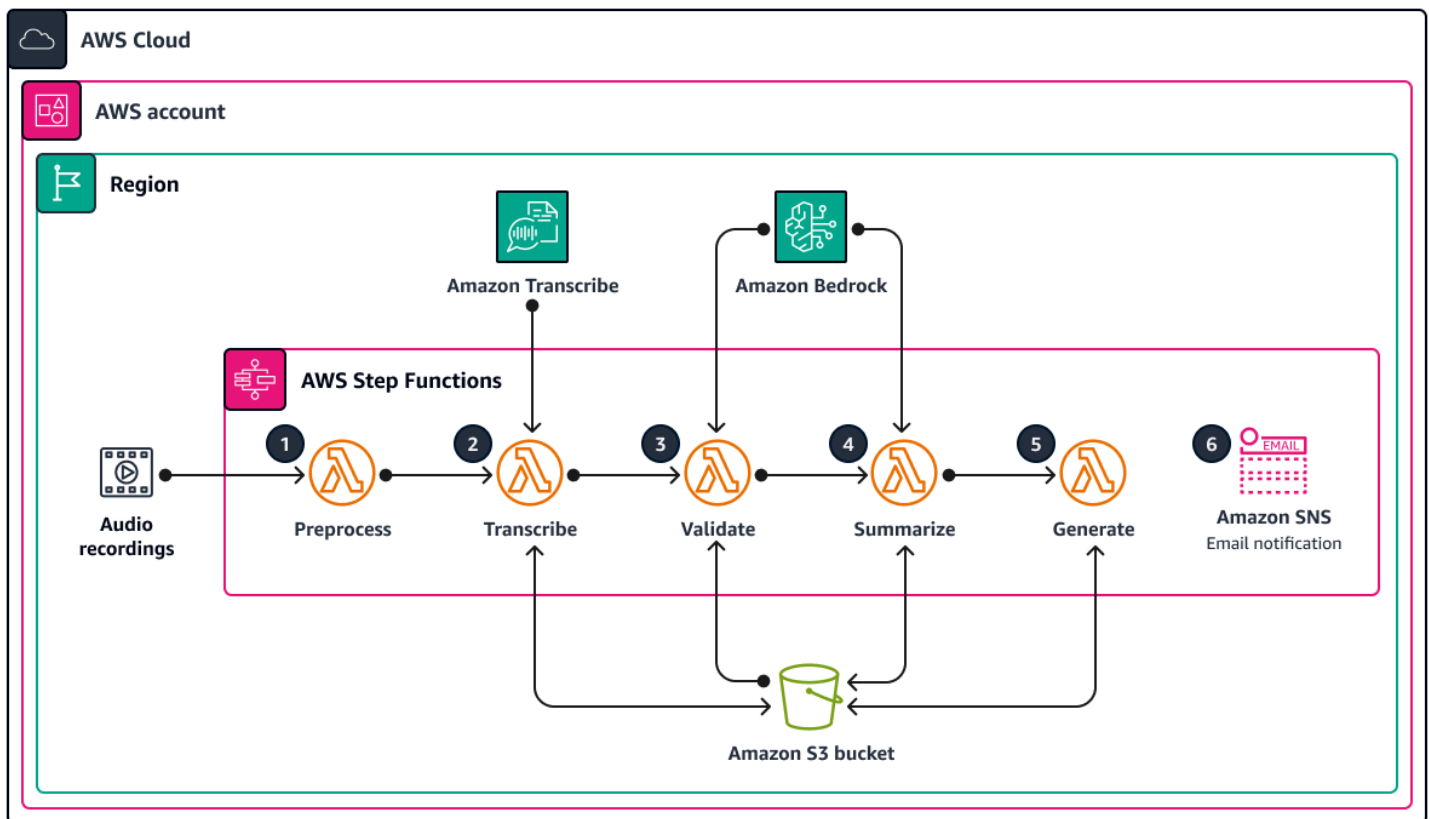

- This solution is deployed to a single AWS account.
- This solution can be deployed only in AWS Regions where Amazon Bedrock and Amazon Transcribe are available. For information about availability, see the documentation for [Amazon Bedrock](#) and [Amazon Transcribe](#).
- The audio files must be in a format that Amazon Transcribe supports. For a list of supported formats, see [Media formats](#) in the Transcribe documentation.

### Product versions

- AWS SDK for Python (Boto3) version 1.34.57 or later
- LangChain version 0.1.12 or later

## Architecture

The architecture represents a serverless workflow on AWS. [AWS Step Functions](#) orchestrates Lambda functions for audio processing, text analysis, and document generation. The following diagram shows the Step Functions workflow, also known as a *state machine*.

Each step in the state machine is handled by a distinct Lambda function. The following are the steps in the document generation process:

1. The `preprocess` Lambda function validates the input passed to Step Functions and lists all of the audio files present in the provided Amazon S3 URI folder path. Downstream Lambda functions in the workflow use the file list to validate, summarize, and generate the document.
2. The `transcribe` Lambda function uses Amazon Transcribe to convert audio files into text transcripts. This Lambda function is responsible for initiating the transcription process and accurately transforming speech into text, which is then stored for subsequent processing.
3. The `validate` Lambda function analyzes the text transcripts, determining the relevance of the responses to the initial questions. By using a large language model (LLM) through Amazon Bedrock, it identifies and separates on-topic answers from off-topic responses.

4. The `summarize` Lambda function uses Amazon Bedrock to generate a coherent and concise summary of the on-topic answers.
5. The `generate` Lambda function assembles the summaries into a well-structured document. It can format the document according to predefined templates and include any additional necessary content or data.
6. If any of the Lambda functions fail, you receive an email notification through Amazon Simple Notification Service (Amazon SNS).

Throughout this process, AWS Step Functions makes sure that each Lambda function is initiated in the correct sequence. This state machine has the capacity for parallel processing to enhance efficiency. An Amazon S3 bucket acts as the central storage repository, supporting the workflow by managing the various media and document formats involved.

## Tools

### AWS services

- [Amazon Bedrock](#) is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- [Amazon Transcribe](#) is an automatic speech recognition service that uses machine learning models to convert audio to text.

### Other tools

- [LangChain](#) is a framework for developing applications that are powered by large language models (LLMs).

## Code repository

The code for this pattern is available in the GitHub [genai-knowledge-capture](#) repository.

The code repository contains the following files and folders:

- `assets` folder – The static assets for the solution, such as the architecture diagram and the public dataset
- `code/lambda`s folder – The Python code for all Lambda functions
  - `code/lambda`s/`generate` folder - The Python code that generates a document from the summarized data in the S3 bucket
  - `code/lambda`s/`preprocess` folder - The Python code that processes the inputs for the Step Functions state machine
  - `code/lambda`s/`summarize` folder - The Python code that summarizes the transcribed data by using Amazon Bedrock service
  - `code/lambda`s/`transcribe` folder - The Python code that converts speech data (audio file) into text by using Amazon Transcribe
  - `code/lambda`s/`validate` folder - The Python code that validates whether all answers pertain to the same topic
- `code/code_stack.py` – The AWS CDK construct Python file that is used to create AWS resources
- `app.py` – The AWS CDK app Python file that is used to deploy AWS resources in the target AWS account
- `requirements.txt` – The list of all Python dependencies that must be installed for the AWS CDK
- `cdk.json` – The input file to provide values that are required to create resources

## Best practices

The code example provided is for proof-of-concept (PoC) or pilot purposes only. If you want to take the solution to production, use the following best practices:

- Enable [Amazon S3 access logging](#)
- Enable [VPC Flow Logs](#)

## Epics

### Set up AWS credentials on your local workstation

Task	Description	Skills required
Export variables for the account and AWS Region.	To provide AWS credentials for the AWS CDK by using environment variables, run the following commands. <pre>export CDK_DEFAULT_ACCOUNT= LT_ACCOUNT=&lt;12-digit AWS account number&gt; export CDK_DEFAULT_REGION= LT_REGION=&lt;Region&gt;</pre>	AWS DevOps, DevOps engineer
Set up the AWS CLI named profile.	To set up the AWS CLI named profile for the account, follow the instructions in <a href="#">Configuration and credential file settings</a> .	AWS DevOps, DevOps engineer

### Set up your environment

Task	Description	Skills required
Clone the repo to your local workstation.	To clone the <a href="#">genai-knowledge-capture</a> repository, run the following command in your terminal. <pre>git clone https://github.com/aws-samples/genai-knowledge-capture</pre>	AWS DevOps, DevOps engineer

Task	Description	Skills required
(Optional) Replace the audio files.	<p>To customize the sample application to incorporate your own data, do the following:</p> <ol style="list-style-type: none"><li>1. Navigate to the <code>assets/audio_samples</code> folder in the cloned repository.</li><li>2. Delete the folders containing the sample audio files.</li><li>3. Create a folder for each topic you want to analyze.</li><li>4. Transfer your audio files to their respective folders.</li></ol>	AWS DevOps, DevOps engineer
Set up the Python virtual environment.	<p>To set up the Python virtual environment, run the following commands.</p> <pre>cd genai-knowledge-capture python3 -m venv .venv source .venv/bin/activate pip install -r requirements.txt</pre>	AWS DevOps, DevOps engineer
Synthesize the AWS CDK code.	<p>To convert the code to an AWS CloudFormation stack configuration, run the following command.</p> <pre>cdk synth</pre>	AWS DevOps, DevOps engineer

## Configure and deploy the solution

Task	Description	Skills required
Provision foundation model access.	Enable access to the Anthropic Claude 3 Sonnet model for your AWS account. For instructions, see <a href="#">Add model access</a> in the Bedrock documentation.	AWS DevOps
Deploy resources in the account.	<p>To deploy resources in the AWS account by using the AWS CDK, do the following:</p> <ol style="list-style-type: none"><li>1. # Generate personalized and re-ranked recommendations using Amazon Personalize

Created by Mason Cahill (AWS), Matthew Chasse (AWS), and Tayo Olajide (AWS)

<b>Code repository:</b> <a href="#">personalize-pet-recommendations</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Machine learning & AI; CloudNative; DevOps; Infrastructure; Serverless
<b>Workload:</b> Open-source	<b>AWS services:</b> AWS CloudFormation; Amazon Kinesis Data Firehose; AWS Lambda; Amazon Personalize; AWS Step Functions	

## Summary

This pattern shows you how to use Amazon Personalize to generate personalized recommendations—including re-ranked recommendations—for your users based on the ingestion of real-time user-interaction data from those users. The example scenario used in this pattern is based on a pet adoption website that generates recommendations for its users based on their interactions (for example, what pets a user visits). By following the example scenario, you learn to use Amazon Kinesis Data Streams to ingest interaction data, AWS Lambda to generate recommendations and re-rank the recommendations, and Amazon Data Firehose to store the data in an Amazon Simple Storage Service (Amazon S3) bucket. You also learn to use AWS Step Functions to build a state machine that manages the solution version (that is, a trained model) that generates your recommendations.

## Prerequisites and limitations

### Prerequisites

- An active [AWS account](#) with a [bootstrapped](#) AWS Cloud Development Kit (AWS CDK)
- [AWS Command Line Interface \(AWS CLI\)](#) with configured credentials

- [Python 3.9](#)

## Product versions

- Python 3.9
- AWS CDK 2.23.0 or later
- AWS CLI 2.7.27 or later

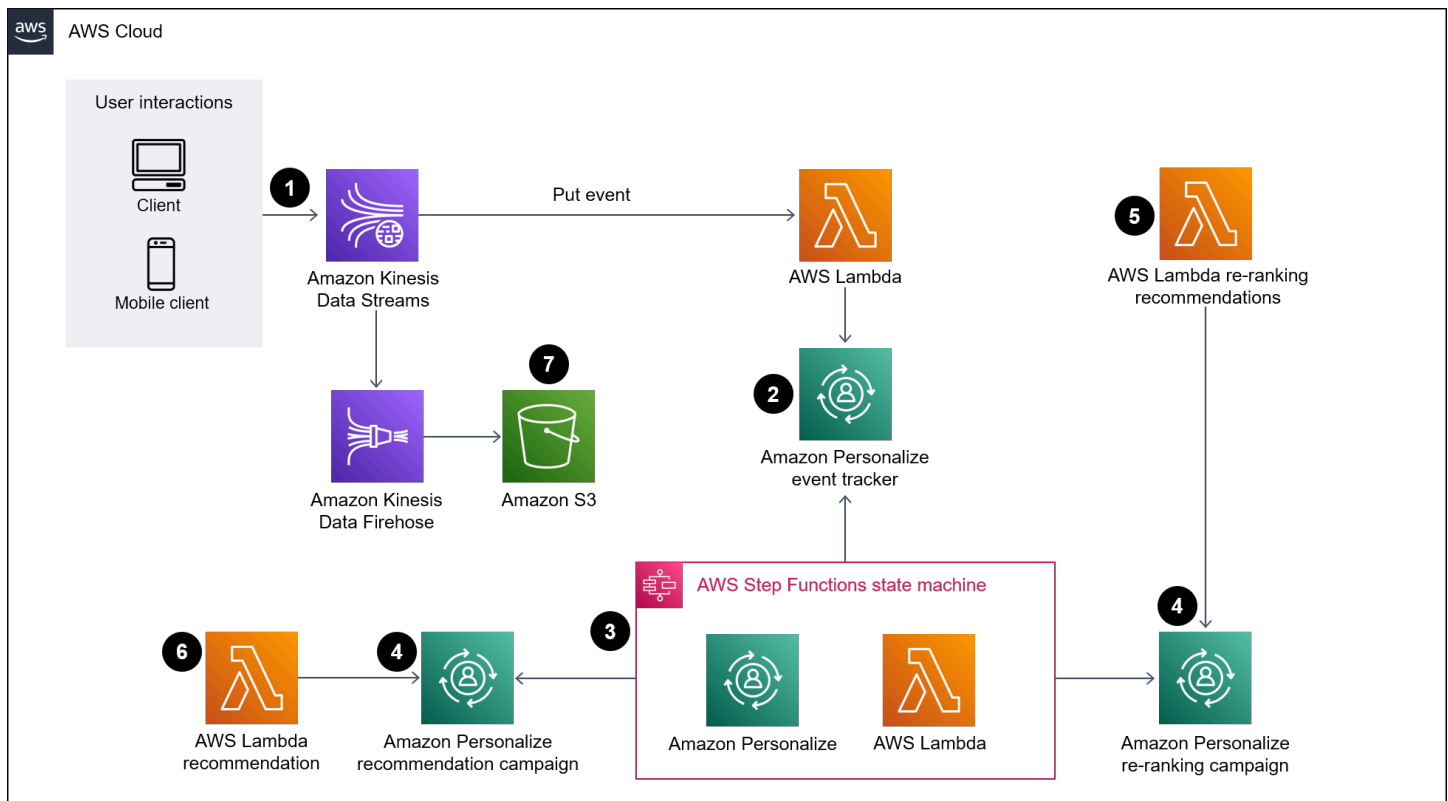

## Architecture

### Technology stack

- Amazon Data Firehose
- Amazon Kinesis Data Streams
- Amazon Personalize
- Amazon Simple Storage Service (Amazon S3)
- AWS Cloud Development Kit (AWS CDK)
- AWS Command Line Interface (AWS CLI)
- AWS Lambda
- AWS Step Functions

### Target architecture

The following diagram illustrates a pipeline for ingesting real-time data into Amazon Personalize. The pipeline then uses that data to generate personalized and re-ranked recommendations for users.

The diagram shows the following workflow:

1. Kinesis Data Streams ingests real-time user data (for example, events like visited pets) for processing by Lambda and Firehose.
2. A Lambda function processes the records from Kinesis Data Streams and makes an API call to add the user-interaction in the record to an event tracker in Amazon Personalize.
3. A time-based rule invokes a Step Functions state machine and generates new solution versions for the recommendation and re-ranking models by using the events from the event tracker in Amazon Personalize.
4. Amazon Personalize [campaigns](#) are updated by the state machine to use the new [solution version](#).
5. Lambda re-ranks the list of recommended items by calling the Amazon Personalize re-ranking campaign.
6. Lambda retrieves the list of recommended items by calling the Amazon Personalize recommendations campaign.
7. Firehose saves the events to an S3 bucket where they can be accessed as historical data.

# Tools

## AWS tools

- [AWS Cloud Development Kit \(AWS CDK\)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Data Firehose](#) helps you deliver real-time [streaming data](#) to other AWS services, custom HTTP endpoints, and HTTP endpoints owned by supported third-party service providers.
- [Amazon Kinesis Data Streams](#) helps you collect and process large streams of data records in real time.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Personalize](#) is a fully managed machine learning (ML) service that helps you generate item recommendations for your users based on your data.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications.

## Other tools

- [pytest](#) is a Python framework for writing small, readable tests.
- [Python](#) is a general-purpose computer programming language.

## Code

The code for this pattern is available in the GitHub [Animal Recommender](#) repository. You can use the AWS CloudFormation template from this repository to deploy the resources for the example solution.

**Note:** The Amazon Personalize solution versions, event tracker, and campaigns are backed by [custom resources](#) (within the infrastructure) that expand on native CloudFormation resources.

# Epics

## Create the infrastructure

Task	Description	Skills required
Create an isolated Python environment.	<p><b>Mac/Linux setup</b></p> <ol style="list-style-type: none"><li>1. To manually create a virtual environment, run the <code>\$ python3 -m venv .venv</code> command from your terminal.</li><li>2. After the init process completes, run the <code>\$ source .venv/bin/activate</code> command to activate the virtual environment.</li></ol> <p><b>Windows setup</b></p> <p>To manually create a virtual environment, run the <code>% .venv\Scripts\activate.bat</code> command from your terminal.</p>	DevOps engineer
Synthesize the CloudFormation template.	<ol style="list-style-type: none"><li>1. To install the required dependencies, run the <code>\$ pip install -r requirements.txt</code> command from your terminal.</li><li>2. In the AWS CLI, set the following environment variables:</li></ol>	DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>export ACCOUNT_ID=123456789</code></li><li>• <code>export CDK_DEPLOY_REGION=us-east-1</code></li><li>• <code>export CDK_ENVIRONMENT=dev</code></li></ul> <ol style="list-style-type: none"><li>3. In the <code>config/{env}.yaml</code> file, update <code>vpcId</code> to match your virtual private cloud (VPC) ID.</li><li>4. To synthesize the CloudFormation template for this code, run the <code>\$ cdk synth</code> command.</li></ol> <p><b>Note:</b> In step 2, <code>CDK_ENVIRONMENT</code> refers to the <code>config/{env}.yaml</code> file.</p>	

Task	Description	Skills required
Deploy resources and create infrastructure.	<p>To deploy the solution resources, run the <code>./deploy.sh</code> command from your terminal.</p> <p>This command installs the required Python dependencies. A Python script creates an S3 bucket and an AWS Key Management Service (AWS KMS) key, and then adds the seed data for the initial model creations. Finally, the script runs <code>cdk deploy</code> to create the remaining infrastructure.</p> <p><b>Note:</b> The initial model training happens during stack creation. It can take up to two hours for the stack to finish getting created.</p>	DevOps engineer

## Additional information

### Example payloads and responses

## Recommendation Lambda function

To retrieve recommendations, submit a request to the recommendation Lambda function with a payload in the following format:

```
{
  "userId": "3578196281679609099",
  "limit": 6
}
```

The following example response contains a list of animal groups:

```
[{"id": "1-domestic short hair-1-1"},
{"id": "1-domestic short hair-3-3"},
{"id": "1-domestic short hair-3-2"},
{"id": "1-domestic short hair-1-2"},
{"id": "1-domestic short hair-3-1"},
{"id": "2-beagle-3-3"},
```

If you leave out the `userId` field, the function returns general recommendations.

## Re-ranking Lambda function

To use re-ranking, submit a request to the re-ranking Lambda function. The payload contains the `userId` of all the item IDs to be re-ranked and their metadata. The following example data uses the Oxford Pets classes for `animal_species_id` (1=cat, 2=dog) and integers 1-5 for `animal_age_id` and `animal_size_id`:

```
{
  "userId":"12345",
  "itemMetadataList":[
    {
      "itemId":"1",
      "animalMetadata":{"
        "animal_species_id":"2",
        "animal_primary_breed_id":"Saint_Bernard",
        "animal_size_id":"3",
        "animal_age_id":"2"
      }
    },
    {
      "itemId":"2",
```

```

    "animalMetadata":{
      "animal_species_id":"1",
      "animal_primary_breed_id":"Egyptian_Mau",
      "animal_size_id":"1",
      "animal_age_id":"1"
    }
  },
  {
    "itemId":"3",
    "animalMetadata":{
      "animal_species_id":"2",
      "animal_primary_breed_id":"Saint_Bernard",
      "animal_size_id":"3",
      "animal_age_id":"2"
    }
  }
]
}

```

The Lambda function re-ranks these items, and then returns an ordered list that includes the item IDs and the direct response from Amazon Personalize. This is a ranked list of the animal groups that the items are in and their score. Amazon Personalize uses [User-Personalization](#) and [Personalized-Ranking](#) recipes to include a score for each item in the recommendations. These scores represent the relative certainty that Amazon Personalize has about which item the user will choose next. Higher scores represent greater certainty.

```

{
  "ranking":[
    "1",
    "3",
    "2"
  ],
  "personalizeResponse":{
    "ResponseMetadata":{
      "RequestId":"a2ec0417-9dcd-4986-8341-a3b3d26cd694",
      "HTTPStatusCode":200,
      "HTTPHeaders":{
        "date":"Thu, 16 Jun 2022 22:23:33 GMT",
        "content-type":"application/json",
        "content-length":"243",
        "connection":"keep-alive",
        "x-amzn-requestid":"a2ec0417-9dcd-4986-8341-a3b3d26cd694"
      }
    }
  }
}

```

```
    },
    "RetryAttempts":0
  },
  "personalizedRanking":[
    {
      "itemId":"2-Saint_Bernard-3-2",
      "score":0.8947961
    },
    {
      "itemId":"1-Siamese-1-1",
      "score":0.105204
    }
  ],
  "recommendationId":"RID-d97c7a87-bd4e-47b5-a89b-ac1d19386aec"
}
}
```

### *Amazon Kinesis payload*

The payload to send to Amazon Kinesis has the following format:

```
{
  "Partitionkey": "randomstring",
  "Data": {
    "userId": "12345",
    "sessionId": "sessionId4545454",
    "eventType": "DetailView",
    "animalMetadata": {
      "animal_species_id": "1",
      "animal_primary_breed_id": "Russian_Blue",
      "animal_size_id": "1",
      "animal_age_id": "2"
    },
    "animal_id": "98765"
  }
}
```

**Note:** The `userId` field is removed for an unauthenticated user.

# Train and deploy a custom GPU-supported ML model on Amazon SageMaker

*Created by Ankur Shukla (AWS)*

**Environment:** PoC or pilot

**Technologies:** Machine learning & AI; Containers & microservices

**AWS services:** Amazon ECS; Amazon SageMaker

## Summary

Training and deploying a graphics processing unit (GPU)-supported machine learning (ML) model requires an initial setup and initialization of certain environment variables to fully unlock the benefits of NVIDIA GPUs. However, it can be time-consuming to set up the environment and make it compatible with Amazon SageMaker architecture on the Amazon Web Services (AWS) Cloud.

This pattern helps you train and build a custom GPU-supported ML model using Amazon SageMaker. It provides steps to train and deploy a custom CatBoost model built on an open-source Amazon reviews dataset. You can then benchmark its performance on a p3.16xlarge Amazon Elastic Compute Cloud (Amazon EC2) instance.

This pattern is useful if your organization wants to deploy existing GPU-supported ML models on SageMaker. Your data scientists can follow the steps in this pattern to create NVIDIA GPU-supported containers and deploy ML models on those containers.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) source bucket to store the model artifacts and predictions.
- An understanding of SageMaker notebook instances and Jupyter notebooks.
- An understanding of how to create an AWS Identity and Access Management (IAM) role with basic SageMaker role permissions, S3 bucket access and update permissions, and additional permissions for Amazon Elastic Container Registry (Amazon ECR).

## Limitations

- This pattern is intended for supervised ML workloads with a train and deploy code written in Python.

## Architecture

## Technology stack

- SageMaker
- Amazon ECR

## Tools

### Tools

- [Amazon ECR](#) – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- [Amazon SageMaker](#) – SageMaker is a fully managed ML service.
- [Docker](#) – Docker is a software platform for building, testing, and deploying applications quickly.
- [Python](#) – Python is a programming language.

### Code

The code for this pattern is available on the GitHub [Implementing a review classification model with Catboost and SageMaker](#) repository.

## Epics

### Prepare the data

Task	Description	Skills required
Create an IAM role and attach the required policies.	<p>Sign in to the AWS Management Console, open the IAM console, and create a new IAM role. Attach the following policies to the IAM role:</p> <ul style="list-style-type: none"><li>• AmazonEC2ContainerRegistryFullAccess</li><li>• AmazonS3FullAccess</li><li>• AmazonSageMakerFullAccess</li></ul> <p>For more information about this, see <a href="#">Create a notebook</a></p>	Data scientist

Task	Description	Skills required
	<p><a href="#">instance</a> in the Amazon SageMaker documentation.</p>	
Create the SageMaker notebook instance.	<p>Open the SageMaker console, choose <b>Notebook instances</b>, and then choose <b>Create notebook instance</b>. For <b>IAM role</b>, choose the IAM role that you created earlier. Configure the notebook instance according to your requirements and then choose <b>Create notebook instance</b>.</p> <p>For detailed steps and instructions, see <a href="#">Create a notebook instance</a> in the Amazon SageMaker documentation.</p>	Data scientist
Clone the repository.	<p>Open the terminal in the SageMaker notebook instance and clone the GitHub <a href="#">Implementing a review classification model with Catboost and SageMaker</a> repository by running the following command:</p> <pre data-bbox="594 1570 1029 1810">git clone https://github.com/aws-samples/review-classification-using-catboost-sagemaker.git</pre>	

Task	Description	Skills required
Start the Jupyter notebook.	Start the Review classification model with Catboost and SageMaker.ipynb Jupyter notebook, which contains the predefined steps.	Data scientist

## Feature engineering

Task	Description	Skills required
Run commands in Jupyter notebook.	Open the Jupyter notebook and run the commands from the following stories to prepare the data to train your ML model.	Data scientist
Read the data from the S3 bucket.	<pre>import pandas as pd import csv fname = 's3://amazon-reviews-pds/tsv/amazon_reviews_us_Digital_Video_Download_v1_00.tsv.gz' df = pd.read_csv(fname, sep='\t', delimiter='\t', error_bad_lines=False)</pre>	Data scientist
Preprocess the data.	<pre>import numpy as np def pre_process(df):      df.fillna(value={'review_body': '', 'review_headline': ''}, inplace=True)</pre>	Data scientist

Task	Description	Skills required
	<pre>df.fillna( value={'verified_purchase': 'Unk'}, inplace=True)  df.fillna(0, inplace=True) return df df = pre_process(df) df.review_date = pd.to_datetime(df. review_date) df['target'] = np.where(df['star_ rating']&gt;=4,1,0)</pre> <p><b>Note:</b> This code replaces null values in the 'review_body' with an empty string and replaces the 'verified_purchase' column with 'Unk', which means "unknown."</p>	

Task	Description	Skills required
Split the data into training, validation, and test datasets.	<p>To keep the distribution of the target label identical across the split sets, you must stratify the sampling by using the <a href="#">scikit-learn library</a>.</p> <pre data-bbox="597 491 1024 1845">from sklearn.model_selection import StratifiedShuffleSplit sss = StratifiedShuffleSplit(n_splits=2, test_size=0.10, random_state=0) sss.get_n_splits(df, df['target']) for train_index, test_index in sss.split(df, df['target']):     X_train_val, X_test = df.iloc[train_index], df.iloc[test_index]  sss.get_n_splits(X_train_val, X_train_val['target']) for train_index, test_index in sss.split(X_train_val, X_train_val['target']):     X_train, X_val = X_train_val.iloc[train_index], X_train_val.iloc[test_index]</pre>	Data scientist

## Build, run, and push the Docker image to Amazon ECR

Task	Description	Skills required
Prepare and push the Docker image.	In the Jupyter notebook, run the commands from the following stories to prepare the Docker image and push it to Amazon ECR.	ML engineer
Create a repository in Amazon ECR.	<pre> %%sh  algorithm_name=s agemaker-catboost- github-gpu-img  chmod +x code/train chmod +x code/serve  account=\$(aws sts get- caller-identity -- query Account --output text)  # Get the region defined in the current configuration (default to us-west-2 if none defined) region=\$(aws configure get region) region=\${region:-us- east-1}  fullname="\${accou nt}.dkr.ecr.\${regi on}.amazonaws.com/ \${algorithm_name}: latest"  aws ecr create-re pository --repository- </pre>	ML engineer

Task	Description	Skills required
	<pre>name "\${algorithm_name} " &gt; /dev/nul</pre>	
Build a Docker image locally.	<pre>docker build -t "\${algorithm_name}" . docker tag \${algorit hm_name} \${fullname}</pre>	ML engineer
Run the Docker image and push it to Amazon ECR.	<pre>docker push \${fullname}</pre>	ML engineer

## Training

Task	Description	Skills required
Create a SageMaker hyperparameter tuning job.	In the Jupyter notebook, run the commands from the following stories to create a SageMaker hyperparameter tuning job using your Docker image.	Data scientist
Create a SageMaker estimator .	Create a <a href="#">SageMaker estimator</a> by using the Docker image's name. <pre>import sagemaker as sage from time import gmtime, strftime sess = sage.Session() from sagemaker.tuner import IntegerPa rameter, Categori alParameter, Continuou sParameter, Hyperpara meterTuner</pre>	Data scientist

Task	Description	Skills required
	<pre>account = sess.boto _session.client('s ts').get_caller_id entity()['Account'] region = sess.boto _session.region_name image = '{}.dkr.e cr.{}.amazonaws.co m/sagemaker-catboo st-github-gpu-img: latest'.format(acc ount, region) tree_hpo = sage.esti mator.Estimator(im age,  role, 1,  'ml.p3.16xlarge',  train_volume_size = 100,  output_path="s3:// {}/sagemaker/DEMO- GPU-Catboost/outputs".format(bucket),  sagemaker_session= sess)</pre>	

Task	Description	Skills required
Create an HPO job.	<p>Create a hyperparameter optimization (HPO) tuning job with parameter ranges and pass the train and validation sets as parameters to the function.</p> <pre data-bbox="592 535 1031 1822">hyperparameter_ranges = {'iterations': IntegerParameter(80000, 130000),      'max_depth': IntegerParameter(6, 10),      'max_ctr_complexity': IntegerParameter(4, 10),      'learning_rate': ContinuousParameter(0.01, 0.5)}  objective_metric_name = 'auc' metric_definitions = [{'Name': 'auc',      'Regex': 'auc: ([0-9\\.]+'}]  tuner = HyperparameterTuner(tree_hpo,      objective_metric_name,      hyperparameter_ranges,</pre>	Data scientist

Task	Description	Skills required
	<pre>metric_definitions , objective_type='Ma ximize', max_jobs=50, max_parallel_jobs= 2)</pre>	
Run the HPO job.	<pre>train_location = 's3://' + bucket + '/s agemaker/DEMO-GPU- Catboost/data/train/' valid_location = 's3://' + bucket + '/s agemaker/DEMO-GPU- Catboost/data/valid/'  tuner.fit({'train': train_location, 'validati on': valid_location })</pre>	Data scientist
Receive the best performing training job.	<pre>import sagemaker as sage from time import gmtime, strftime sess = sage.Session()  best_job =tuner.be st_training_job()</pre>	Data scientist

## Batch transform

Task	Description	Skills required
Create a SageMaker batch transform job on test data for model prediction.	In the Jupyter notebook, run the commands from the following stories to create the model from your SageMaker hyperparameter tuning job and submit a SageMaker batch transform job on the test data for model prediction.	Data scientist
Create the SageMaker model.	Create a model in SageMaker model using the best training job. <pre data-bbox="594 953 1026 1881">attached_estimator =     sage.estimator.Estimator.attach(best_job)  output_path = 's3://' +     bucket + '/sagemaker/     DEMO-GPU-Catboost/     data/test-predictions/' input_path = 's3://' +     bucket + '/sagemaker/     DEMO-GPU-Catboost/     data/test/'  transformer = attached_estimator.transformer(instance_count=1,  instance_type='ml.p3.16xlarge',</pre>	Data scientist

Task	Description	Skills required
	<pre> assemble_with='Line',  accept='text/csv',  max_payload=1,  output_path=output_path,  env = {'SAGEMAKER_MODEL_SERVER_TIMEOUT' : '3600' }) </pre>	
Create batch transform job.	<p>Create batch transform job on the test data set.</p> <pre> transformer.transform(input_path,  content_type='text/csv',  split_type='Line') </pre>	Data scientist

## Analyze the results

Task	Description	Skills required
Read the results and evaluate the model's performance.	In the Jupyter notebook, run the commands from the following stories to read	Data scientist

Task	Description	Skills required
	<p>the results and evaluate the performance of the model on Area Under the ROC Curve (ROC-AUC) and Area Under the Precision Recall Curve (PR-AUC) model metrics.</p> <p>For more information about this, see <a href="#">Amazon Machine Learning key concepts</a> in the Amazon Machine Learning (Amazon ML) documentation.</p>	
Read the batch transform job results.	<p>Read the batch transform job results into a data frame.</p> <pre data-bbox="597 919 1027 1675">file_name = 's3://' + bucket + '/sagemaker/DEMO-GPU-Catboost/data/test-predictions/file_1.out'  results =     pd.read_csv(file_name, names=['review_id', 'target', 'score'], sep='\t', escapechar='\\', quoting=csv.QUOTE_NONE,      lineterminator='\n', quotechar='').dropna()</pre>	Data scientist

Task	Description	Skills required
Evaluate the performance metrics.	<p>Evaluate the performance of the model on ROC-AUC and PR-AUC.</p> <pre data-bbox="592 394 1027 1877">from sklearn import metrics import matplotlib import pandas as pd matplotlib.use('agg', warn=False, force=True) from matplotlib import pyplot as plt  %matplotlib inline  def analyze_results(labels, predictions):     precision, recall,     thresholds = metrics.p recision_recall_cu rve(labels, predictio ns)     auc = metrics.a uc(recall, precision)      fpr, tpr, _ = metrics.roc_curve( labels, predictions)     roc_auc_score = metrics.roc_auc_sc ore(labels, predictio ns)      print('Neural- Nets: ROC auc=%.3f' % ( roc_auc_score))      plt.plot(fpr, tpr, label="data 1, auc=" + str(roc_auc_score))</pre>	Data scientist

## Additional information

The following list shows the different elements of the Dockerfile that is run in the *Build, run, and push the Docker image into Amazon ECR* epic.

### Install Python with aws-cli.

```
FROM amazonlinux:1

RUN yum update -y && yum install -y python36 python36-devel python36-libs python36-
tools python36-pip && \
yum install gcc tar make wget util-linux kmod man sudo git -y && \
yum install wget -y && \
yum install aws-cli -y && \
yum install nginx -y && \
yum install gcc-c++.noarch -y && yum clean all
```

### Install the Python packages

```
RUN pip-3.6 install --no-cache-dir --upgrade pip && \pip3 install --no-cache-dir --
upgrade setuptools && \
pip3 install Cython && \
```

```
pip3 install --no-cache-dir numpy==1.16.0 scipy==1.4.1 scikit-learn==0.20.3
pandas==0.24.2 \
flask gevent unicorn boto3 s3fs matplotlib joblib catboost==0.20.2
```

## Install CUDA and CuDNN

```
RUN wget https://developer.nvidia.com/compute/cuda/9.0/Prod/local_installers/
cuda_9.0.176_384.81_linux-run \
&& chmod u+x cuda_9.0.176_384.81_linux-run \
&& ./cuda_9.0.176_384.81_linux-run --tmpdir=/data --silent --toolkit --override \
&& wget https://custom-gpu-sagemaker-image.s3.amazonaws.com/installation/cudnn-9.0-
linux-x64-v7.tgz \
&& tar -xvzf cudnn-9.0-linux-x64-v7.tgz \
&& cp /data/cuda/include/cudnn.h /usr/local/cuda/include \
&& cp /data/cuda/lib64/libcudnn* /usr/local/cuda/lib64 \

&& chmod a+r /usr/local/cuda/include/cudnn.h /usr/local/cuda/lib64/libcudnn* \
&& rm -rf /data/*
```

## Create the required directory structure for SageMaker

```
RUN mkdir /opt/ml /opt/ml/input /opt/ml/input/config /opt/ml/input/data /opt/ml/input/
data/training /opt/ml/model /opt/ml/output /opt/program
```

## Set the NVIDIA environment variables

```
ENV PYTHONPATH=/opt/program
ENV PYTHONUNBUFFERED=TRUE
ENV PYTHONDONTWRITEBYTECODE=TRUE
ENV PATH="/opt/program:${PATH}"

# Set NVIDIA mount environments
ENV LD_LIBRARY_PATH=/usr/local/nvidia/lib:/usr/local/nvidia/lib64:$LD_LIBRARY_PATH
ENV NVIDIA_VISIBLE_DEVICES="all"
ENV NVIDIA_DRIVER_CAPABILITIES="compute,utility"
ENV NVIDIA_REQUIRE_CUDA "cuda>=9.0"
```

## Copy training and inference files into the Docker image

```
COPY code/* /opt/program/
WORKDIR /opt/program
```

# Use SageMaker Processing for distributed feature engineering of terabyte-scale ML datasets

Created by Chris Boomhower (AWS)

**Environment:** Production

**Technologies:** Machine learning & AI; Big data

**AWS services:** Amazon SageMaker

## Summary

Many terabyte-scale or larger datasets often consist of a hierarchical folder structure, and the files in the dataset sometimes share interdependencies. For this reason, machine learning (ML) engineers and data scientists must make thoughtful design decisions to prepare such data for model training and inference. This pattern demonstrates how you can use manual macrosharding and microsharding techniques in combination with Amazon SageMaker Processing and virtual CPU (vCPU) parallelization to efficiently scale feature engineering processes for complicated big data ML datasets.

This pattern defines *macrosharding* as the splitting of data directories across multiple machines for processing, and *microsharding* as the splitting of data on each machine across multiple processing threads. The pattern demonstrates these techniques by using Amazon SageMaker with sample time-series waveform records from the [PhysioNet MIMIC-III](#) dataset. By implementing the techniques in this pattern, you can minimize the processing time and costs for feature engineering while maximizing resource utilization and throughput efficiency. These optimizations rely on distributed SageMaker Processing on Amazon Elastic Compute Cloud (Amazon EC2) instances and vCPUs for similar, large datasets, regardless of data type.

## Prerequisites and limitations

### Prerequisites

- Access to SageMaker notebook instances or SageMaker Studio, if you want to implement this pattern for your own dataset. If you are using Amazon SageMaker for the first time, see [Get started with Amazon SageMaker](#) in the AWS documentation.
- SageMaker Studio, if you want to implement this pattern with the [PhysioNet MIMIC-III](#) sample data.

- The pattern uses SageMaker Processing, but doesn't require any experience running SageMaker Processing jobs.

## Limitations

- This pattern is well suited to ML datasets that include interdependent files. These interdependencies benefit the most from manual macrosharding and running multiple, single-instance SageMaker Processing jobs in parallel. For datasets where such interdependencies do not exist, the `ShardedByS3Key` feature in SageMaker Processing might be a better alternative to macrosharding, because it sends sharded data to multiple instances that are managed by the same Processing job. However, you can implement this pattern's microsharding strategy in both scenarios to best utilize instance vCPUs.

## Product versions

- Amazon SageMaker Python SDK version 2

## Architecture

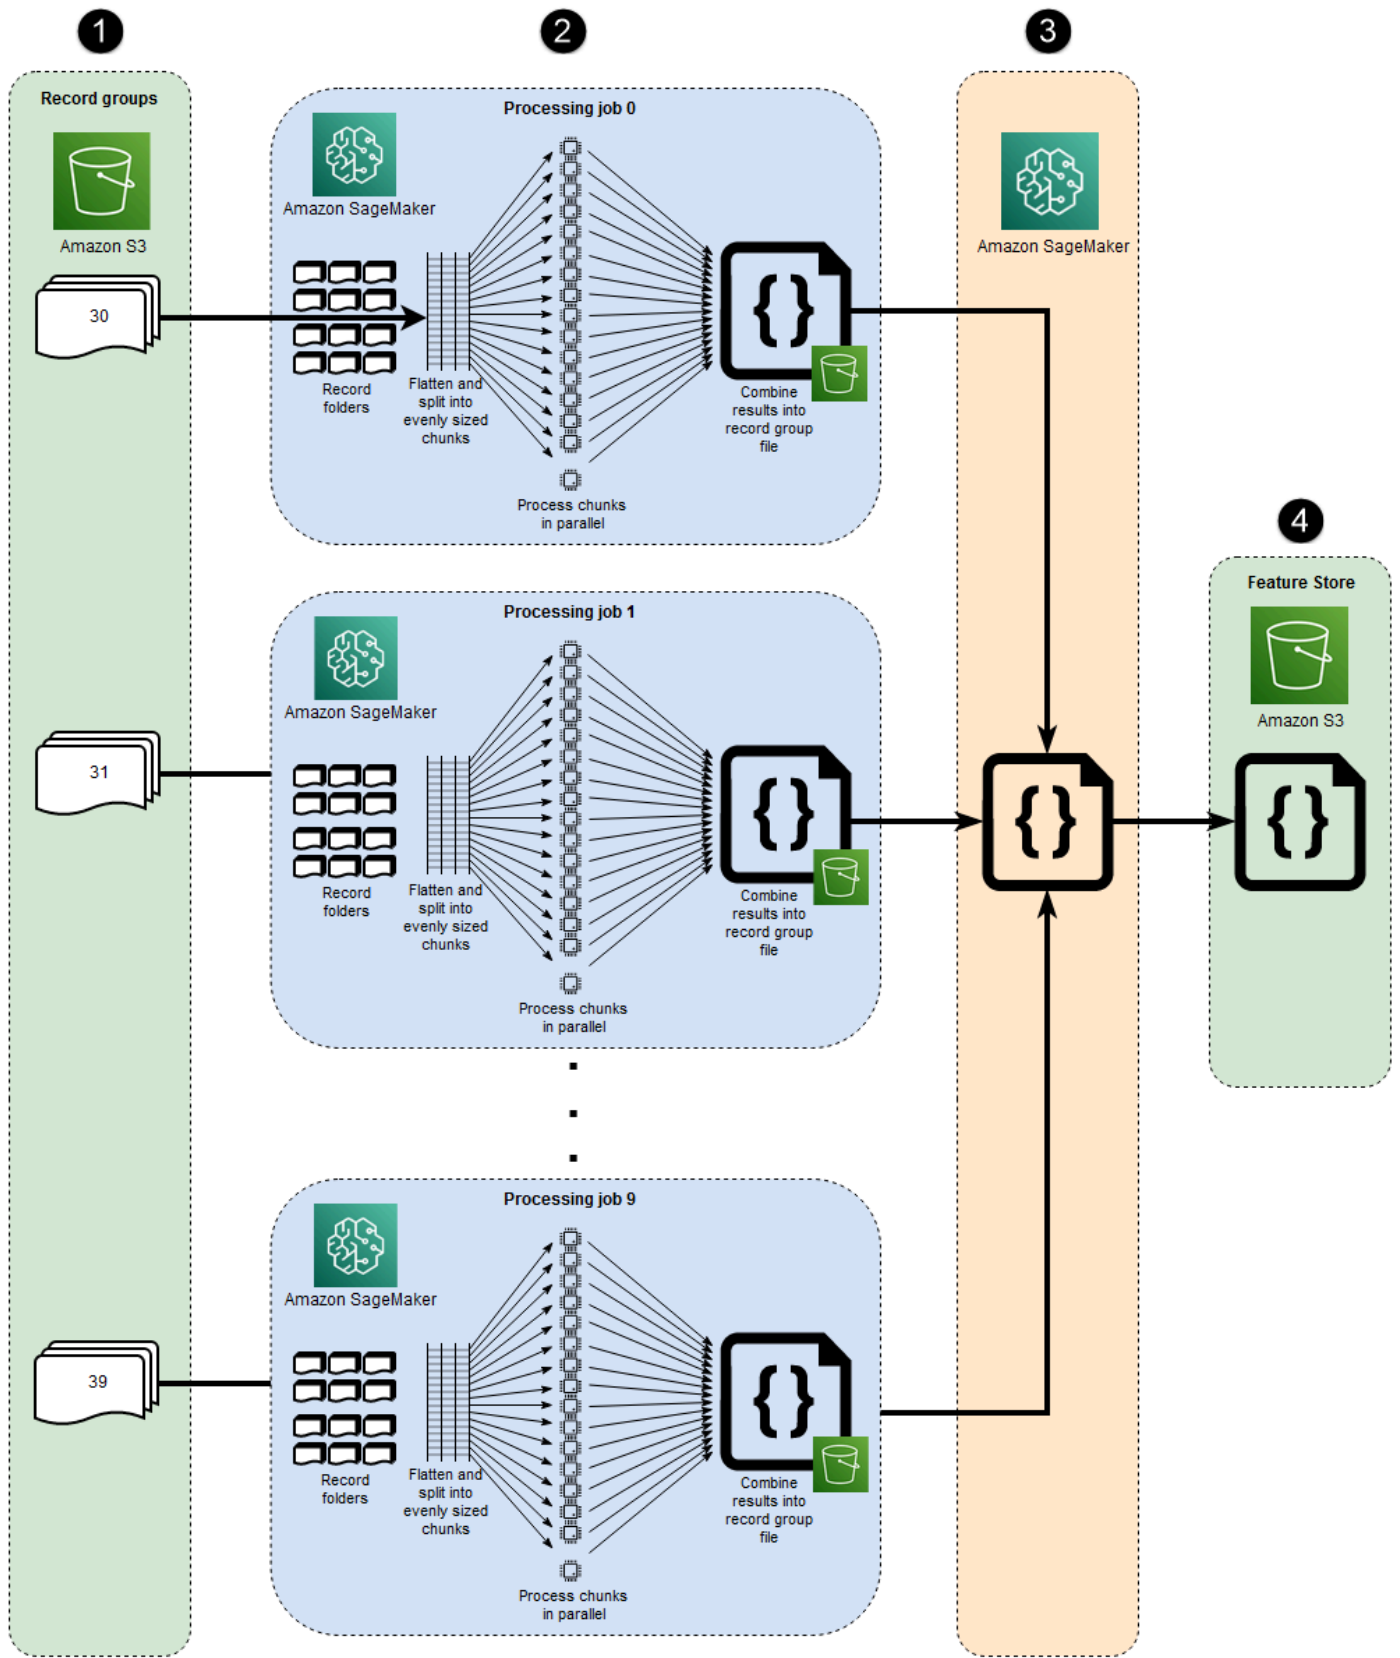

### Target technology stack

- Amazon Simple Storage Service (Amazon S3)
- Amazon SageMaker

### Target architecture

#### *Macrosharding and distributed EC2 instances*

The 10 parallel processes represented in this architecture reflect the structure of the MIMIC-III dataset. (Processes are represented by ellipses for diagram simplification.) A similar architecture applies to any dataset when you use manual macrosharding. In the case of MIMIC-III, you can use the dataset's raw structure to your advantage by processing each patient group folder separately, with minimal effort. In the following diagram, the record groups block appears on the left (1). Given the distributed nature of the data, it makes sense to shard by patient group.

However, manually sharding by patient group means that a separate Processing job is required for each patient group folder, as you can see in the middle section of the diagram (2), instead of a single Processing job with multiple EC2 instances. Because MIMIC-III's data includes both binary waveform files and matching text-based header files, and there is a required dependency on the [wfdb library](#) for binary data extraction, all the records for a specific patient must be made available on the same instance. The only way to be certain that each binary waveform file's associated header file is also present is to implement manual sharding to run each shard within its own Processing job, and to specify `s3_data_distribution_type='FullyReplicated'` when you define the Processing job input. Alternatively, if all data were available in a single directory and no dependencies existed between files, a more suitable option might be to launch a single Processing job with multiple EC2 instances and `s3_data_distribution_type='ShardedByS3Key'` specified. Specifying `ShardedByS3Key` as the Amazon S3 data distribution type directs SageMaker to manage data sharding automatically across instances.

Launching a Processing job for each folder is a cost-efficient way to preprocess the data, because running multiple instances concurrently saves time. For additional cost and time savings, you can use microsharding within each Processing job.

### *Microsharding and parallel vCPUs*

Within each Processing job, the grouped data is further divided to maximize use of all available vCPUs on the SageMaker fully managed EC2 instance. The blocks in the middle section of the diagram (2) depict what happens within each primary Processing job. The contents of the patient record folders are flattened and divided evenly based on the number of available vCPUs on the instance. After the folder contents are divided, the evenly sized set of files are distributed across all vCPUs for processing. When processing is complete, the results from each vCPU are combined into a single data file for each Processing job.

In the attached code, these concepts are represented in the following section of the `src/feature-engineering-pass1/preprocessing.py` file.

```
def chunks(lst, n):
    """
    Yield successive n-sized chunks from lst.

    :param lst: list of elements to be divided
    :param n: number of elements per chunk
    :type lst: list
    :type n: int
```

```
:return: generator comprising evenly sized chunks
:rtype: class 'generator'
"""
for i in range(0, len(lst), n):
    yield lst[i:i + n]

# Generate list of data files on machine
data_dir = input_dir
d_subs = next(os.walk(os.path.join(data_dir, '.')))[1]
file_list = []
for ds in d_subs:
    file_list.extend(os.listdir(os.path.join(data_dir, ds, '.')))
dat_list = [os.path.join(re.split('_|\.', f)[0].replace('n', ''), f[:-4]) for f in
    file_list if f[-4:] == '.dat']

# Split list of files into sub-lists
cpu_count = multiprocessing.cpu_count()
splits = int(len(dat_list) / cpu_count)
if splits == 0: splits = 1
dat_chunks = list(chunks(dat_list, splits))

# Parallelize processing of sub-lists across CPUs
ws_df_list = Parallel(n_jobs=-1, verbose=0)(delayed(run_process)(dc) for dc in
    dat_chunks)

# Compile and pickle patient group dataframe
ws_df_group = pd.concat(ws_df_list)
ws_df_group = ws_df_group.reset_index().rename(columns={'index': 'signal'})
ws_df_group.to_json(os.path.join(output_dir, group_data_out))
```

A function, `chunks`, is first defined to consume a given list by dividing it into evenly sized chunks of length `n` and by returning these results as a generator. Next, the data is flattened across patient folders by compiling a list of all binary waveform files that are present. After this is done, the number of vCPUs available on the EC2 instance is obtained. The list of binary waveform files is evenly divided across these vCPUs by calling `chunks`, and then each waveform sublist is processed on its own vCPU by using [joblib's Parallel class](#). Results are automatically combined into a single list of dataframes by the Processing job, which SageMaker then processes further before writing it to Amazon S3 upon job completion. In this example, there are 10 files written to Amazon S3 by the Processing jobs (one for each job).

When all the initial Processing jobs are complete, a secondary Processing job, which is shown in the block to the right of the diagram (3) combines the output files produced by each primary Processing job and writes the combined output to Amazon S3 (4).

## Tools

### Tools

- [Python](#) – The sample code used for this pattern is Python (version 3).
- [SageMaker Studio](#) – Amazon SageMaker Studio is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models. You run SageMaker Processing jobs by using Jupyter notebooks inside SageMaker Studio.
- [SageMaker Processing](#) – Amazon SageMaker Processing provides a simplified way to run your data processing workloads. In this pattern, the feature engineering code is implemented at scale by using SageMaker Processing jobs.

### Code

The attached .zip file provides the complete code for this pattern. The following section describes the steps to build the architecture for this pattern. Each step is illustrated by sample code from the attachment.

## Epics

### Set up your SageMaker Studio environment

Task	Description	Skills required
Access Amazon SageMaker Studio.	Onboard to SageMaker Studio in your AWS account by following the directions provided in the <a href="#">Amazon SageMaker documentation</a> .	Data scientist, ML engineer
Install the wget utility.	Install <i>wget</i> if you onboarded with a new SageMaker Studio configuration or if you've	Data scientist, ML engineer

Task	Description	Skills required
	<p>never used these utilities in SageMaker Studio before.</p> <p>To install, open a terminal window in the SageMaker Studio console and run the following command:</p> <pre>sudo yum install wget</pre>	
Download and unzip the sample code.	<p>Download the attachments.zip file in the <i>Attachments</i> section. In a terminal window, navigate to the folder where you downloaded the file and extract its contents:</p> <pre>unzip attachment.zip</pre> <p>Navigate to the folder where you extracted the .zip file, and extract the contents of the Scaled-Processing.zip file.</p> <pre>unzip Scaled-Processing.zip</pre>	Data scientist, ML engineer

Task	Description	Skills required
Download the sample dataset from <a href="https://physionet.org">physionet.org</a> and upload it to Amazon S3.	Run the <code>get_data.ipynb</code> Jupyter notebook within the folder that contains the <code>Scaled-Processing</code> files. This notebook downloads a sample MIMIC-III dataset from <a href="https://physionet.org">physionet.org</a> and uploads it to your SageMaker Studio session bucket in Amazon S3.	Data scientist, ML engineer

### Configure the first preprocessing script

Task	Description	Skills required
Flatten the file hierarchy across all subdirectories.	<p>In large datasets such as MIMIC-III, files are often distributed across multiple subdirectories even within a logical parent group. Your script should be configured to flatten all group files across all subdirectories, as the following code demonstrates.</p> <pre># Generate list of .dat files on machine data_dir = input_dir d_subs = next(os.walk(os.path.join(data_dir, '.')))[1] file_list = [] for ds in d_subs:     file_list.extend(os.listdir(os.path.</pre>	Data scientist, ML engineer

Task	Description	Skills required
	<pre> join(data_dir, ds,       '.')) dat_list = [os.path. join(re.split('_ \ .', f)[0].replace('n', '), f[:-4]) for f in file_list if f[-4:] == '.dat'] </pre> <p><b>Note</b> The example code snippets in this epic are from the <code>src/feature-engineering-pass1/preprocessing.py</code> file, which is provided in the attachment.</p>	
<p>Divide files into subgroups based on vCPU count.</p>	<p>Files should be divided into evenly sized subgroups, or chunks, depending on the number of vCPUs present on the instance that runs the script. For this step, you can implement code similar to the following.</p> <pre> # Split list of files into sub-lists cpu_count = multiprocessing. cpu_count() splits = int(len(d at_list) / cpu_count) if splits == 0: splits = 1 dat_chunks = list(chun ks(dat_list, splits)) </pre>	<p>Data scientist, ML engineer</p>

Task	Description	Skills required
Parallelize processing of subgroups across vCPUs.	<p>Script logic should be configured to process all subgroups in parallel. To do this, use the Joblib library's <code>Parallel</code> class and <code>delayed</code> method as follows.</p> <pre data-bbox="597 537 1026 894"># Parallelize processing of sub-lists across CPUs ws_df_list = Parallel( n_jobs=-1, verbose=0) (delayed(run_process) (dc) for dc in dat_chunks)</pre>	Data scientist, ML engineer

Task	Description	Skills required
Save single file group output to Amazon S3.	<p>When parallel vCPU processing is complete, the results from each vCPU should be combined and uploaded to the file group's S3 bucket path. For this step, you can use code similar to the following.</p> <pre data-bbox="597 632 1027 1192"> # Compile and pickle patient group dataframe ws_df_group = pd.concat (ws_df_list) ws_df_group = ws_df_group. reset_index().re name(columns={'index': 'signal'}) ws_df_group.to_j son(os.path.join(o utput_dir, group_dat a_out)) </pre>	Data scientist, ML engineer

## Configure the second preprocessing script

Task	Description	Skills required
Combine data files produced across all Processing jobs that ran the first script.	The previous script outputs a single file for each SageMaker Processing job that processes a group of files from the dataset. Next, you need to combine these output files into a single object and write a single output dataset to Amazon S3. This is demonstra	Data scientist, ML engineer

Task	Description	Skills required
	<p>ted in the src/feature-engineering-pass1p5/preprocessing.py file, which is provided in the attachment, as follows.</p> <pre data-bbox="592 472 1031 1877">def write_parquet(wavs_df, path):     """     Write waveform summary dataframe to S3 in parquet format.      :param wavs_df:     waveform summary dataframe     :param path: S3 directory prefix     :type wavs_df:     pandas dataframe     :type path: str     :return: None     """     extra_args = {"ServerSideEncryption": "aws:kms"}     wr.s3.to_parquet(df=wavs_df, path=path, compression='snappy', s3_additional_kwargs=extra_args)  def combine_data():     """     Get combined data and write to parquet.</pre>	

Task	Description	Skills required
	<pre>         :return: waveform         summary dataframe         :rtype: pandas         dataframe         """         wavs_df = get_data(         )         wavs_df = normalize         _signal_names(wavs         _df)         write_parquet(wavs         _df, "s3://{}/{}/"         {}.format(buck         et_xform, dataset_p         refix, pass1p5ou         t_data))          return wavs_df  wavs_df = combine_d ata() </pre>	

## Run Processing jobs

Task	Description	Skills required
Run the first Processing job.	To perform macrosharding, run a separate Processing job for each file group. Microsharding is performed inside each Processing job, because each job runs your first script. The following code demonstrates how to launch a Processing job for each file group directory in the	Data scientist, ML engineer

Task	Description	Skills required
	<p>following snippet (included in notebooks/FeatExtract_Pass1.ipynb ).</p> <pre data-bbox="592 380 1031 1824"> pat_groups = list(range(30,40)) ts = str(int(time.time()))  for group in pat_groups:     sklearn_processor = SKLearnProcessor(         framework_version='0.20.0',         role=role,         instance_type='ml.m5.4xlarge',         instance_count=1,         volume_size_in_gb=5)     sklearn_processor.run(         code='../src/feature-engineering-pass1/preprocessing.py',         job_name='-'.join(['scaled-processing-p1', str(group), ts]),         arguments=["input_path", "/opt/ml/processing/input", </pre>	

Task	Description	Skills required
	<pre>                 "output_path", "/opt/ml/processing/output",                 "group_data_out", "ws_df_group.json"             ],             inputs=             [                 ProcessingInput(                     source=f's3://{sess.default_bucket()}/data_inputs/{group}',                     destination='/opt/ml/processing/input',                     s3_data_distribution_type='FullyReplicated'                 )             ],             outputs=             [                 ProcessingOutput(                     source='/opt/ml/processing/output',                     destination=f's3://{sess.default_bucket()}/data_outputs/{group}'                 )             ],             wait=False         ) </pre>	

Task	Description	Skills required
Run the second Processing job.	<p>To combine the outputs generated by the first set of processing jobs and perform any additional computations for preprocessing, you run your second script by using a single SageMaker Processing job. The following code demonstrates this (included in notebooks/FeatExtract_Pass1p5.ipynb ).</p> <pre data-bbox="597 779 1029 1785">ts = str(int(time.time( ))) bucket = sess.default_bucket()  sklearn_processor =     SKLearnProcessor(         framework_version=' 0.20.0',          role=role,          instance_ type='ml.t3.2xlarge',          instance_ count=1,          volume_si ze_in_gb=5) sklearn_processor.run(     code='../src/featu re-engineering-pas s1p5/preprocessing .py',</pre>	Data scientist, ML engineer

Task	Description	Skills required
	<pre> job_name='-'.join( ['scaled-processing', 'p1p5', ts]), arguments=['bucket ', bucket,           'passlout _prefix', 'data_out puts',           'passlout _data', 'ws_df_gr oup.json',           'pass1p5o ut_data', 'waveform _summary.parquet',           'statsdat a_name', 'signal_s tats.csv'], wait=True ) </pre>

# Visualize AI/ML model results using Flask and AWS Elastic Beanstalk

Created by Chris Caudill (AWS) and Durga Sury

**Environment:** PoC or pilot

**Technologies:** Machine learning & AI; Analytics; DevOps; Web & mobile apps

**Workload:** Open-source

**AWS services:** Amazon Comprehend; AWS Elastic Beanstalk

## Summary

Visualizing output from artificial intelligence and machine learning (AI/ML) services often requires complex API calls that must be customized by your developers and engineers. This can be a drawback if your analysts want to quickly explore a new dataset.

You can enhance the accessibility of your services and provide a more interactive form of data analysis by using a web-based user interface (UI) that enables users to upload their own data and visualize the model results in a dashboard.

This pattern uses [Flask](#) and [Plotly](#) to integrate Amazon Comprehend with a custom web application and visualize sentiments and entities from user-provided data. The pattern also provides the steps to deploy an application by using AWS Elastic Beanstalk. You can adapt the application by using [Amazon Web Services \(AWS\) AI services](#) or with a custom trained model hosted on an endpoint (for example, an [Amazon SageMaker endpoint](#)).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine. For more information about this, see [Configuration basics](#) in the AWS CLI documentation. You can

also use an AWS Cloud9 integrated development environment (IDE); for more information about this, see [Python tutorial for AWS Cloud9](#) and [Previewing running applications in the AWS Cloud9 IDE](#) in the AWS Cloud9 documentation.

- An understanding of Flask's web application framework. For more information about Flask, see the [Quickstart](#) in the Flask documentation.
- Python version 3.6 or later, installed and configured. You can install Python by following the instructions from [Setting up your Python development environment](#) in the AWS Elastic Beanstalk documentation.
- Elastic Beanstalk Command Line Interface (EB CLI), installed and configured. For more information about this, see [Install the EB CLI](#) and [Configure the EB CLI](#) from the AWS Elastic Beanstalk documentation.

## Limitations

- This pattern's Flask application is designed to work with .csv files that use a single text column and are restricted to 200 rows. The application code can be adapted to handle other file types and data volumes.
- The application doesn't consider data retention and continues to aggregate uploaded user files until they are manually deleted. You can integrate the application with Amazon Simple Storage Service (Amazon S3) for persistent object storage or use a database such as Amazon DynamoDB for serverless key-value storage.
- The application only considers documents in the English language. However, you can use Amazon Comprehend to detect a document's primary language. For more information about the supported languages for each action, see [API reference](#) in the Amazon Comprehend documentation.
- A troubleshooting list that contains common errors and their solutions is available in the *Additional information* section.

## Architecture

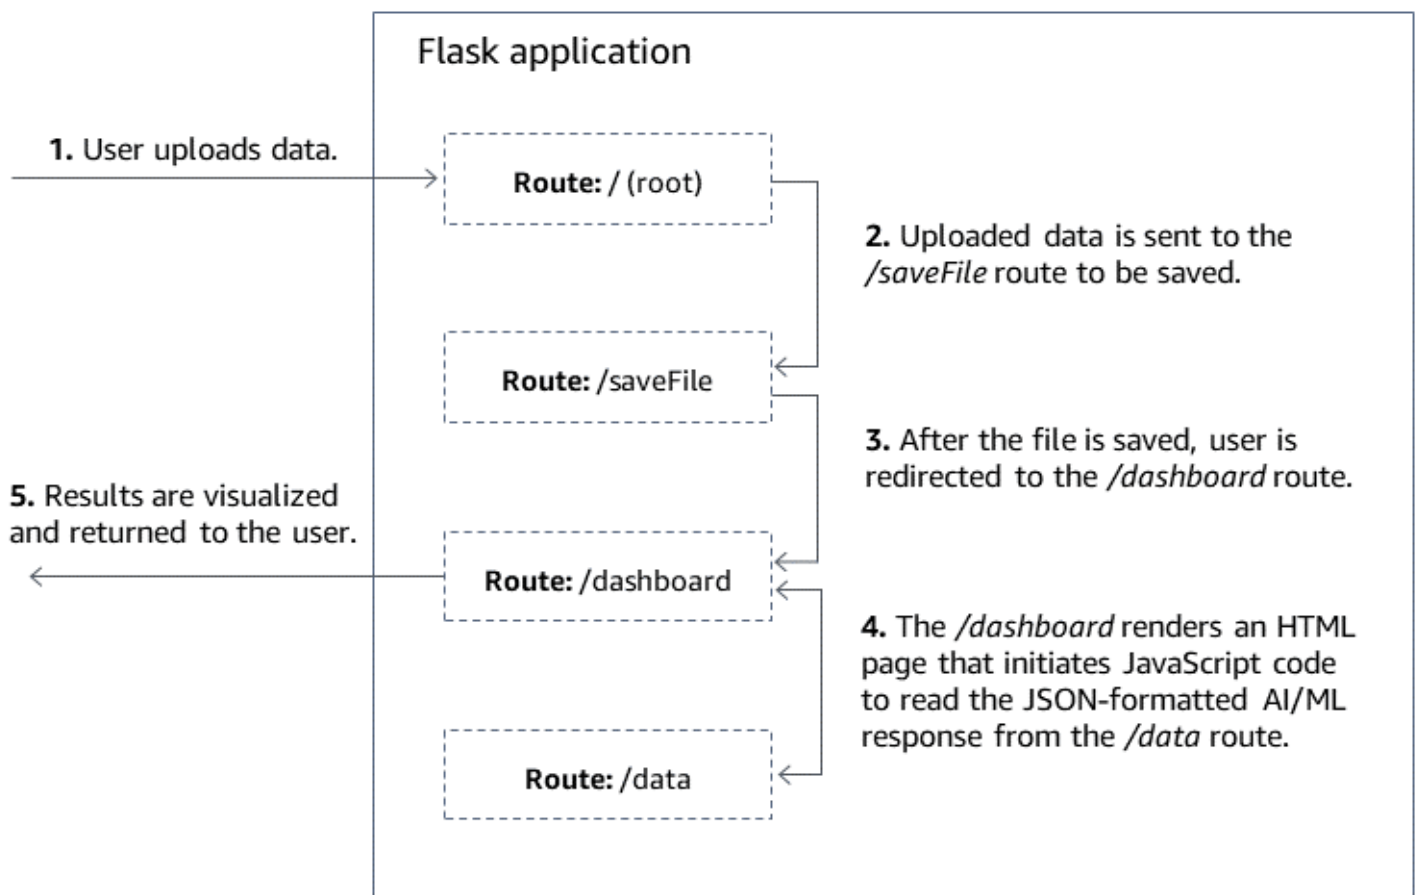

### Flask application architecture

Flask is a lightweight framework for developing web applications in Python. It is designed to combine Python's powerful data processing with a rich web UI. The pattern's Flask application shows you how to build a web application that enables users to upload data, sends the data to

Amazon Comprehend for inference, and then visualizes the results. The application has the following structure:

- `static` – Contains all the static files that support the web UI (for example, JavaScript, CSS, and images)
- `templates` – Contains all of the application's HTML pages
- `userData` – Stores uploaded user data
- `application.py` – The Flask application file
- `comprehend_helper.py` – Functions to make API calls to Amazon Comprehend
- `config.py` – The application configuration file
- `requirements.txt` – The Python dependencies required by the application

The `application.py` script contains the web application's core functionality, which consists of four Flask routes. The following diagram shows these Flask routes.

- `/` is the application's root and directs users to the `upload.html` page (stored in the `templates` directory).
- `/saveFile` is a route that is invoked after a user uploads a file. This route receives a POST request via an HTML form, which contains the file uploaded by the user. The file is saved in the `userData` directory and the route redirects users to the `/dashboard` route.
- `/dashboard` sends users to the `dashboard.html` page. Within this page's HTML, it runs the JavaScript code in `static/js/core.js` that reads data from the `/data` route and then builds visualizations for the page.
- `/data` is a JSON API that presents the data to be visualized in the dashboard. This route reads the user-provided data and uses the functions in `comprehend_helper.py` to send the user data to Amazon Comprehend for sentiment analysis and named entity recognition (NER). Amazon Comprehend's response is formatted and returned as a JSON object.

## Deployment architecture

For more information about design considerations for applications deployed using Elastic Beanstalk on the AWS Cloud, see in the [AWS Elastic Beanstalk documentation](#).

## [Design considerations](#)

## Technology stack

- Amazon Comprehend
- Elastic Beanstalk
- Flask

## Automation and scale

Elastic Beanstalk deployments are automatically set up with load balancers and auto scaling groups. For more configuration options, see [Configuring Elastic Beanstalk environments](#) in the AWS Elastic Beanstalk documentation.

## Tools

- [AWS Command Line Interface \(AWS CLI\)](#) is a unified tool that provides a consistent interface for interacting with all parts of AWS.
- [Amazon Comprehend](#) uses natural language processing (NLP) to extract insights about the content of documents without requiring special preprocessing.
- [AWS Elastic Beanstalk](#) helps you quickly deploy and manage applications in the AWS Cloud without having to learn about the infrastructure that runs those applications.
- [Elastic Beanstalk CLI \(EB CLI\)](#) is a command line interface for AWS Elastic Beanstalk that provides interactive commands to simplify creating, updating, and monitoring environments from a local repository.
- The [Flask](#) framework performs data processing and API calls using Python and offers interactive web visualization with Plotly.

## Code

The code for this pattern is available in the GitHub [Visualize AI/ML model results using Flask and AWS Elastic Beanstalk](#) repository.

## Epics

### Set up the Flask application

Task	Description	Skills required
Clone the GitHub repository.	Pull the application code from the GitHub <a href="#">Visualize AI/ML</a>	Developer

Task	Description	Skills required
	<p><a href="#">model results using Flask and AWS Elastic Beanstalk</a> repository by running the following command:</p> <pre>git clone git@github.com:aws-samples/aws-comprehend-elasticbeanstalk-for-flask.git</pre> <p><b>Note:</b> Make sure that you configure your SSH keys with GitHub.</p>	
Install the Python modules.	<p>After you clone the repository, a new local <code>aws-comprehend-elasticbeanstalk-for-flask</code> directory is created. In that directory, the <code>requirements.txt</code> file contains the Python modules and versions that run the application. Use the following commands to install the modules:</p> <pre>cd aws-comprehend-elasticbeanstalk-for-flask</pre> <pre>pip install -r requirements.txt</pre>	Python developer

Task	Description	Skills required
Test the application locally.	<p>Start the Flask server by running the following command:</p> <pre>python application.py</pre> <p>This returns information about the running server. You should be able to access the application by opening a browser and visiting <code>http://localhost:5000</code></p> <p><b>Note:</b> If you're running the application in an AWS Cloud9 IDE, you need to replace the <code>application.run()</code> command in the <code>application.py</code> file with the following line:</p> <pre>application.run(host=os.getenv('IP', '0.0.0.0'),port=int(os.getenv('PORT', 8080)))</pre> <p>You must revert this change before deployment.</p>	Python developer

## Deploy the application to Elastic Beanstalk

Task	Description	Skills required
Launch the Elastic Beanstalk application.	<p>To launch your project as an Elastic Beanstalk application, run the following command from your application's root directory:</p> <pre>eb init -p python-3.6 comprehend_flask --region us-east-1</pre> <p><b>Important:</b></p> <ul style="list-style-type: none"><li>• <code>comprehend_flask</code> is the name of the Elastic Beanstalk application and can be changed according to your requirements.</li><li>• You can replace the AWS Region with a Region of your choice. The default Region in AWS CLI is used if you don't specify a Region.</li><li>• The application was built with Python version 3.6. You might encounter errors if you use other Python versions.</li></ul> <p>Run the <code>eb init -i</code> command for more deployment configuration options.</p>	Architect, Developer

Task	Description	Skills required
Deploy the Elastic Beanstalk environment.	<p>Run the following command from the application's root directory:</p> <pre>eb create comprehend-flask-env</pre> <p><b>Note:</b> <code>comprehend-flask-env</code> is the name of the Elastic Beanstalk environment and can be changed according to your requirements. The name can only contain letters, numbers, and dashes.</p>	Architect, Developer

Task	Description	Skills required
Authorize your deployment to use Amazon Comprehend.	<p>Although your application might be successfully deployed, you should also provide your deployment with access to Amazon Comprehend. <code>ComprehendFullAccess</code> is an AWS managed policy that provides the deployed application with permissions to make API calls to Amazon Comprehend.</p> <p>Attach the <code>ComprehendFullAccess</code> policy to <code>aws-elasticbeanstalk-ec2-role</code> (this role is automatically created for your deployment's Amazon Elastic Compute Cloud (Amazon EC2) instances) by running the following command:</p> <pre>aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/ComprehendFullAccess --role-name aws-elasticbeanstalk-ec2-role</pre> <p><b>Important:</b> <code>aws-elasticbeanstalk-ec2-role</code> is created when your application deploys. You must</p>	Developer, Security architect

Task	Description	Skills required
	complete the deployment process before you can attach the AWS Identity and Access Management (IAM) policy.	
Visit your deployed application.	<p>After your application successfully deploys, you can visit it by running the <code>eb open</code> command.</p> <p>You can also run the <code>eb status</code> command to receive details about your deployment. The deployment URL is listed under <code>CNAME</code>.</p>	Architect, Developer

### (Optional) Customize the application to your ML model

Task	Description	Skills required
Authorize Elastic Beanstalk to access the new model.	<p>Make sure that Elastic Beanstalk has the required access permissions for your new model endpoint. For example, if you use an Amazon SageMaker endpoint, your deployment needs to have permission to invoke the endpoint.</p> <p>For more information about this, see <a href="#">InvokeEndpoint</a> in the Amazon SageMaker documentation.</p>	Developer, Security architect

Task	Description	Skills required
Send the user data to a new model.	<p>To change the underlying ML model in this application, you must change the following files:</p> <ul style="list-style-type: none"><li>• <code>comprehend_helper.py</code> – This is the Python script that connects with Amazon Comprehend, processes the response, and returns the final result to the application. In this script, you can either route the data to another AI service on the AWS Cloud or you can send the data to a custom model endpoint. We recommend that you also format the results in this script for logical separation and the reusability of this pattern.</li><li>• <code>application.py</code> – If you change the name of the <code>comprehend_helper.py</code> script or functions, you need to update the <code>application.py</code> script to reflect those changes.</li></ul>	Data scientist

Task	Description	Skills required
Update the dashboard visualizations.	<p>Typically, incorporating a new ML model means that visualizations must be updated to reflect the new results. These changes are made in the following files:</p> <ul style="list-style-type: none"><li>• <code>templates/dashboard.html</code> – The prebuilt application only accounts for two basic visualizations. The entire layout of the page can be adjusted in this file.</li><li>• <code>static/js/core.js</code> – This script captures the formatted output of the Flask server's <code>/data</code> route and uses Plotly to create visualizations. You can add or update the page's charts.</li></ul>	Web developer

### (Optional) Deploy the updated application

Task	Description	Skills required
Update your application's requirements file.	<p>Before sending changes to Elastic Beanstalk, update the <code>requirements.txt</code> file to reflect any new Python modules by running the following command in your application's root directory:</p>	Python developer

Task	Description	Skills required
	<pre>pip freeze &gt; requirements.txt</pre>	
Redeploy the Elastic Beanstalk environment.	<p>To ensure that your application changes are reflected in your Elastic Beanstalk deployment, navigate to your application's root directory and run the following command:</p> <pre>eb deploy</pre> <p>This sends the most recent version of the application's code to your existing Elastic Beanstalk deployment.</p>	Systems administrator, Architect

## Additional information

### Troubleshooting list

The following are six common errors and their solutions.

#### **Error 1**

```
Unable to assume role "arn:aws:iam:xxxxxxxxxx:role/aws-elasticbeanstalk-ec2-role".  
Verify that the role exists and is configured correctly.
```

**Solution:** If this error occurs when you run `eb create`, create a sample application on the Elastic Beanstalk console to create the default instance profile. For more information about this, see [Creating an Elastic Beanstalk environment](#) in the AWS Elastic Beanstalk documentation.

### Error 2

```
Your WSGIPath refers to a file that does not exist.
```

**Solution:** This error occurs in deployment logs because Elastic Beanstalk expects the Flask code to be named `application.py`. If you chose a different name, run `eb config` and edit the `WSGIPath` as shown in the following code sample:

```
aws:elasticbeanstalk:container:python:
  NumProcesses: '1'
  NumThreads: '15'
  StaticFiles: /static/=static/
  WSGIPath: application.py
```

Make sure that you replace `application.py` with your file name.

You can also leverage Gunicorn and a Procfile. For more information about this approach, see [Configuring the WSGI server with a Procfile](#) in the AWS Elastic Beanstalk documentation.

### Error 3

```
Target WSGI script '/opt/python/current/app/application.py' does not contain WSGI
application 'application'.
```

**Solution:** Elastic Beanstalk expects the variable that represents your Flask application to be named `application`. Make sure that the `application.py` file uses `application` as the variable name:

```
application = Flask(__name__)
```

### Error 4

```
The EB CLI cannot find your SSH key file for keyname
```

**Solution:** Use the EB CLI to specify which key pair to use or to create a key pair for your deployment's EC2 instances. To resolve the error, run `eb init -i` and one of the options will ask:

Do you want to set up SSH for your instances?

Respond with Y to either create a key pair or specify an existing key pair.

### **Error 5**

*I've updated my code and redeployed but my deployment is not reflecting my changes.*

**Solution:** If you're using a Git repository with your deployment, make sure that you add and commit your changes before redeploying.

### **Error 6**

*You are previewing the Flask application from an AWS Cloud9 IDE and run into errors.*

**Solution:** For more information about this, see [Previewing running applications in the AWS Cloud9 IDE](#) in the AWS Cloud9 documentation.

## **Natural language processing using Amazon Comprehend**

By choosing to use Amazon Comprehend, you can detect custom entities in individual text documents by running real-time analysis or asynchronous batch jobs. Amazon Comprehend also enables you to train custom entity recognition and text classification models that can be used in real time by creating an endpoint.

This pattern uses asynchronous batch jobs to detect sentiments and entities from an input file that contains multiple documents. The sample application provided by this pattern is designed for users to upload a .csv file containing a single column with one text document per row. The `comprehend_helper.py` file in the GitHub [Visualize AI/ML model results using Flask and AWS Elastic Beanstalk](#) repository reads the input file and sends the input to Amazon Comprehend for processing.

### *BatchDetectEntities*

Amazon Comprehend inspects the text of a batch of documents for named entities and returns the detected entity, location, [type of entity](#), and a score that indicates Amazon Comprehend's level of confidence. A maximum of 25 documents can be sent in one API call, with each document smaller than 5,000 bytes in size. You can filter the results to show only certain entities based on the use case. For example, you could skip the 'quantity' entity type and set a threshold

score for the detected entity (for example, 0.75). We recommend that you explore the results for your specific use case before choosing a threshold value. For more information about this, see [BatchDetectEntities](#) in the Amazon Comprehend documentation.

### *BatchDetectSentiment*

Amazon Comprehend inspects a batch of incoming documents and returns the prevailing sentiment for each document (POSITIVE, NEUTRAL, MIXED, or NEGATIVE). A maximum of 25 documents can be sent in one API call, with each document smaller than 5,000 bytes in size. Analyzing the sentiment is straightforward and you choose the sentiment with the highest score to be displayed in the final results. For more information about this, see [BatchDetectSentiment](#) in the Amazon Comprehend documentation.

## Flask configuration handling

Flask servers use a series of [configuration variables](#) to control how the server runs. These variables can contain debug output, session tokens, or other application settings. You can also define custom variables that can be accessed while the application is running. There are multiple approaches for setting configuration variables.

In this pattern, the configuration is defined in `config.py` and inherited within `application.py`.

- `config.py` contains the configuration variables that are set up on the application's startup. In this application, a `DEBUG` variable is defined to tell the application to run the server in [debug mode](#). **Note:** Debug mode should not be used when running an application in a production environment. `UPLOAD_FOLDER` is a custom variable that is defined to be referenced later in the application and inform it where uploaded user data should be stored.
- `application.py` initiates the Flask application and inherits the configuration settings defined in `config.py`. This is performed by the following code:

```
application = Flask(__name__)
application.config.from_pyfile('config.py')
```

# Access AWS services from IBM z/OS by installing the AWS CLI

Created by Souma Ghosh (AWS), Phil de Valence (AWS), and Paulo Vitor Pereira (AWS)

**Environment:** Production

**Technologies:** Mainframe;  
Migration; Storage & backup

**Workload:** IBM

**AWS services:** AWS CLI; AWS  
Mainframe Modernization;  
Amazon S3

## Summary

The [AWS Command Line Interface \(AWS CLI\)](#) is an open source tool for managing multiple AWS services by using commands in a command line shell. With minimal configuration, you can run commands from command line sessions such as the command prompt, terminal, and bash shell to implement functionality that's equivalent to that provided by the browser-based AWS Management Console.

All AWS infrastructure as a service (IaaS) administration, management, and access functions in the AWS Management Console are available in the AWS API and AWS CLI. You can install the AWS CLI on an IBM z/OS mainframe to directly access, manage, and interact with AWS services from z/OS. The AWS CLI enables users and applications to perform various tasks, such as:

- Transferring files or datasets between z/OS and Amazon Simple Storage Service (Amazon S3) object storage and viewing content of buckets
- Starting and stopping different AWS resources; for example, starting a batch job in an AWS Mainframe Modernization environment
- Calling an AWS Lambda function to implement common business logic
- Integrating with artificial intelligence and machine learning (AI/ML) and analytics services

This pattern describes how to install, configure, and use the AWS CLI on z/OS. You can install it globally, so it's available to all z/OS users, or at a user level. The pattern also details how to use the AWS CLI in an interactive command line session from z/OS Unix System Services (USS) or as a batch job.

## Prerequisites and limitations

### Prerequisites

- **Network communication from z/OS to AWS**

By default, the AWS CLI sends requests to AWS services by using HTTPS on TCP port 443. To use the AWS CLI successfully, you must be able to make outbound connections on TCP port 443. You can use any of the following z/OS USS commands (some of these might not be installed in your environment) to test network connectivity from z/OS to AWS:

```
ping amazonaws.com
dig amazonaws.com
traceroute amazonaws.com
curl -k https://docs.aws.amazon.com/cli/v1/userguide/cli-chap-welcome.html
```

- **AWS credentials**

In order to communicate with AWS Cloud services from z/OS, the AWS CLI requires you to configure some credentials with privileges to access the target AWS account. For programmatic commands to AWS, you can use access keys, which consist of an access key ID and secret access key. If you don't have access keys, you can create them from the AWS Management Console. As a best practice, do not use the access keys for the AWS account root user for any task unless the root user is required. Instead, [create a new administrator IAM user](#) and [prepare for least-privilege permissions](#) to set up the user with access keys. After you create the user, you can [create an access key ID and secret access key](#) for this user.

**Warning:** AWS Identity and Access Management (IAM) users have long-term credentials that present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

- **IBM Python for z/OS**

The AWS CLI requires Python 3.8 or later. IBM has enabled Python to run on z/OS with [IBM Open Enterprise Python for z/OS](#). IBM Open Enterprise Python is available at no charge through Shopz SMP/E, or you can download the PAX file from the [IBM website](#). For instructions, see the [installation and configuration documentation](#) for IBM Open Enterprise Python for z/OS.

## Limitations

- The installation instructions provided in this pattern are applicable to **AWS CLI version 1 only**. The latest version of the AWS CLI is version 2. However, this pattern uses the older version because the installation methods are different for version 2, and the binary executables available for version 2 aren't compatible with the z/OS system.

## Product versions

- AWS CLI version 1
- Python 3.8 or later

## Architecture

### Technology stack

- Mainframe running z/OS
- Mainframe z/OS UNIX System Services (USS)
- Mainframe Open MVS (OMVS) – z/OS UNIX shell environment command interface
- Mainframe disk, such as a direct-access storage device (DASD)
- AWS CLI

### Target architecture

The following diagram shows an AWS CLI deployment on IBM z/OS. You can invoke the AWS CLI from an interactive user session, such as SSH, and telnet sessions. You can also invoke it from a batch job by using job control language (JCL), or from any program that can call a z/OS Unix shell command.

The AWS CLI communicates with AWS service endpoints over a TCP/IP network. This network connection can happen over the internet or through a private AWS Direct Connect connection from the customer data center to AWS Cloud data centers. The communication is authenticated with AWS credentials and encrypted.

## Automation and scale

You can explore the capabilities of an AWS service with the AWS CLI and develop USS shell scripts to manage your AWS resources from z/OS. You can also run AWS CLI commands and shell scripts from the z/OS batch environment, and you can automate batch jobs to run on a specific schedule by integrating with mainframe schedulers. AWS CLI commands or scripts can be coded inside parameters (PARMs) and procedures (PROCs), and can be scaled by following the standard approach of calling the PARM or PROC from different batch jobs with different parameters.

## Tools

- [AWS Command Line Interface \(AWS CLI\)](#) is an open source tool that helps you interact with AWS services through commands in your command-line shell.

## Best practices

- For security reasons, restrict the access permissions to the USS directory where the AWS access key details are stored. Allow access to only the users or programs that use the AWS CLI.
- Do not use the AWS account root user access keys for any task. Instead, [create a new administrator IAM user](#) for yourself and set it up with access keys.

**Warning:** IAM users have long-term credentials that present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

## Epics

### Install AWS CLI version 1 on z/OS USS

Task	Description	Skills required
Install Python 3.8 or later.	<ol style="list-style-type: none"> <li>1. Log in to the z/OS USS command prompt interface by using one of these methods: <ul style="list-style-type: none"> <li>• Use a <a href="#">Time Sharing Option (TSO) OMVS</a> command from the <a href="#">Interactive System Productivity Facility (ISPF)</a> panel, or</li> <li>• Use SSH or telnet to connect to the IP of the mainframe logical partition (LPAR).</li> </ul> <p>This pattern assumes that <code>cliuser</code> is the userid used to log in to</p> </li> </ol>	Mainframe z/OS administrator

Task	Description	Skills required
	<p>the USS environment and <code>/u/cliuser/</code> is the home directory for the user. You can set the user home directory differently in your z/OS environment depending on your installation requirements.</p> <p>2. Follow the installation guide for <a href="#">IBM Open Enterprise Python for z/OS</a> to install Python 3.8 or later if it isn't already installed.</p>	

Task	Description	Skills required
Set USS environment variables.	<p>Add environment variables to the profile. You can add these either to the <code>/u/cliuser/.profile</code> file for an individual user (<code>cliuser</code>) or to the <code>/etc/profile</code> file for all users.</p> <p><b>Note:</b> This pattern assumes that Python has been installed in the <code>/u/awsccli/python</code> directory. If your installation directory is different, update the code accordingly.</p> <pre data-bbox="594 953 1027 1749"># Python configuration export BPXKAUTO VT='ON' export CEERUNOPT S='FILETAG(AUTOCVT ,AUTOTAG) POSIX(ON)' export TAGREDIR_ERR=txt export TAGREDIR_IN=txt export TAGREDIR_ OUT=txt  # AWS CLI configura tion export PATH=/u/c liuser/python/bin: \$PATH export PYTHONPATH=/u/ cliuser/python:\$PYTHON PATH</pre>	Mainframe z/OS administr ator

Task	Description	Skills required
Test the Python installation.	<p>Run the <b>python</b> command:</p> <pre>python --version</pre> <p>The output should confirm that you have Python 3.8 or later installed correctly.</p>	Mainframe z/OS administrator
Verify or install <b>pip</b> .	<ol style="list-style-type: none"><li>1. The <b>pip</b> command is usually installed automatically when you install Python from the IBM website. To verify, run the command:<pre>pip --version</pre><p>If <b>pip</b> is installed, this command should show the installed version.</p></li><li>2. If the <b>pip</b> command isn't found, install <b>pip</b> by running the following command:<pre>python -m ensurepip --upgrade</pre><p>For more installation options, see the <a href="#">pip documentation</a>.</p></li></ol>	Mainframe z/OS administrator

Task	Description	Skills required
Install AWS CLI version 1.	<p>1. To install the AWS CLI, run the command:</p> <pre>python -m pip install awscli</pre> <p>The output should be similar to the following.</p> <pre>Successfully installed PyYAML-6. 0.1 awscli-1.32.23 botocore-1.34.23 colorama-0.4.4 docutils-0.16 jmespath-1.0.1 pyasn1-0.5.1 python- dateutil-2.8.2 rsa-4.7.2 s3transfe r-0.10.0 urllib3-2 .0.7</pre> <p>2. Change the permission of the <b>aws</b> executable by running the following command. Make sure to update the placeholder directory <code>&lt;python_installation_dir&gt;</code> with your Python installation path.</p> <pre>chmod 744 &lt;python_installation_dir&gt;/bin/aws</pre>	Mainframe z/OS administrator

Task	Description	Skills required
	<p>3. Run the following command to test the AWS CLI installation:</p> <pre data-bbox="630 373 1029 457">aws --version</pre> <p>The output should show the versions of the AWS CLI, Python, and botocore, similar to the following.</p> <pre data-bbox="630 709 1029 911">aws-cli/1.32.3 Python/3.9.5 OS/390/27.00 botocore/1.34.3</pre>	

## Configure AWS CLI access from z/OS

Task	Description	Skills required
<p>Configure the AWS access keys, default Region, and output.</p>	<p>The <a href="#">AWS CLI documentation</a> describes different options for setting up AWS access. You can choose a configuration according to your organization's standards. This example uses the short-term credential configuration.</p> <p>1. <a href="#">Configure the AWS CLI</a> with the following command:</p> <pre data-bbox="630 1728 1029 1812">aws configure</pre>	<p>AWS administrator, Mainframe z/OS administrator, Mainframe z/OS developer</p>

Task	Description	Skills required
	<p>2. Provide the details for the following items when prompted. The access key ID and secret access key values are from the keys you obtained when you set AWS credentials in the <a href="#">Prerequisites</a> steps.</p> <pre data-bbox="634 617 1029 1371">AWS Access Key ID [None]: ASIAIOSFO DNN7EXAMPLE AWS Secret Access Key [None]: wJalrXUtn FEMI/K7MDENG/bPxRf iCYEXAMPLEKEY Default region name [None]: us-east-1 Default output format [None]: aws configure set aws_session_token IQoJb3JpZ21uX2IQoJ b3JpZ21uX2IQoJb3Jp Z21uX2IQoJb3JpZ21u X2IQoJb3JpZVERYLON GSTRINGEXAMPLE</pre> <p>This configuration, including access keys, is stored in the <code>/u/cliuser/.aws</code> folder. For security reasons, restrict this folder to allow access only to the users or programs that use the AWS CLI.</p>	

Task	Description	Skills required
Test the AWS CLI.	<ol style="list-style-type: none"><li>1. Run the following command at the command prompt to test the AWS CLI with a simple command: <pre>aws s3 ls</pre><p>The output should list all the S3 buckets for the configured AWS account without any errors.</p></li><li>2. Follow the instructions in the next two epics to transfer data from USS to Amazon S3. You can choose one of these two options:<ul style="list-style-type: none"><li>• Option 1 (next epic): Interactively transfer an EBCDIC comma-separated value (CSV) file to Amazon S3 and query the file from Amazon Athena.</li><li>• Option 2: Transfer an EBCDIC fixed-length dataset to Amazon S3 as a batch job.</li></ul></li></ol>	Mainframe z/OS administrator, Mainframe z/OS developer

## Option 1 – Transfer data from USS to Amazon S3 interactively from a USS session

Task	Description	Skills required
Download and transfer the sample CSV file.	<ol style="list-style-type: none"> <li>1. Download sales-records.csv from the <a href="#">Attachments</a> section. This file provides a sample CSV file with sales records.</li> <li>2. Transfer the file to z/OS USS.</li> <li>3. Verify that the /u/cliuser/sales-records.csv file is readable in EBCDIC format in USS by using a text editor of your choice.</li> </ol>	App developer, Mainframe z/OS developer
Create an S3 bucket and upload the CSV file.	<ol style="list-style-type: none"> <li>1. Create an S3 bucket to store the CSV file.           <pre>aws s3 mb s3://&lt;s3_bucket_name&gt;</pre> <p>where &lt;s3_bucket_name&gt; is the unique name for a bucket; for example:</p> <pre>aws s3 mb s3://DOC-EXAMPLE-BUCKET1</pre> </li> <li>2. Upload the CSV file from z/OS USS to the S3 bucket:</li> </ol>	App developer, Mainframe z/OS developer

Task	Description	Skills required
	<pre>aws s3 cp &lt;csv_file_path&gt; s3://&lt;s3_bucket_name&gt;</pre> <p>For example:</p> <pre>aws s3 cp /u/cliuser/sales-records.csv s3://DOC-EXAMPLE-BUCKET1</pre> <p>3. List the contents of the S3 bucket and confirm that they include the uploaded file:</p> <pre>aws s3 ls s3://&lt;s3_bucket_name&gt;</pre> <p>For example:</p> <pre>aws s3 ls s3://DOC-EXAMPLE-BUCKET1</pre>	

Task	Description	Skills required
View the S3 bucket and uploaded file.	<ol style="list-style-type: none"><li data-bbox="591 226 1029 407">1. Sign in to the AWS Management Console and open the <a href="#">Amazon S3 console</a>.</li><li data-bbox="591 428 1029 554">2. Navigate to see the new S3 bucket and the uploaded object.</li></ol> <p data-bbox="591 638 1029 856">For more information about uploading objects, see <a href="#">Getting started with Amazon S3</a> in the Amazon S3 documentation.</p>	General AWS

Task	Description	Skills required
Run a SQL query on an Amazon Athena table.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">Amazon Athena console</a>.</li> <li>2. Create a new table (for example, DOC-EXAMPLE-BUCKET ) by using the CSV data from Amazon S3. For more information, see <a href="#">Querying Amazon S3 Inventory with Amazon Athena</a> in the Amazon S3 documentation.</li> <li>3. Run the SELECT query against the table to view the data.</li> </ol> <pre data-bbox="634 940 1027 1058">SELECT * FROM &lt;table_name&gt;;</pre> <p data-bbox="634 1094 818 1129">For example:</p> <pre data-bbox="634 1171 1027 1289">SELECT * FROM DOC- EXAMPLE-BUCKET;</pre> <p data-bbox="591 1356 1008 1486">The output of the SQL query will display the contents of your CSV file.</p>	General AWS, App developer

## Option 2 – Transfer data from USS to Amazon S3 by using batch JCL

Task	Description	Skills required
Upload the sample file.	<ol style="list-style-type: none"> <li>1. Download sales-records-fixed.txt from</li> </ol>	Mainframe z/OS developer

Task	Description	Skills required
	<p>the <a href="#">Attachments</a> section.</p> <p>This is a sample file with sales records. Rename the text file; for example, to <code>USER.DATA.FIXED</code>.</p> <ol style="list-style-type: none"><li>2. Transfer the file to z/OS as a fixed-blocked (FB), 256 record length (LRECL), physical sequential (PS) dataset.</li><li>3. Use the dataset list utility to verify that the <code>USER.DATA.FIXED</code> dataset is readable in EBCDIC format under ISPF option 3.4. See the <a href="#">Additional information</a> section for example output.</li></ol>	

Task	Description	Skills required
Create batch JCL.	<p>Code the batch JCL as follows to create the destination S3 bucket, upload the dataset, and list the bucket content. Make sure to replace the directory name, file names, and bucket name to your own values.</p> <pre data-bbox="597 636 1026 1837"> //AWSCLICP JOB   ACTINFO1, 'IBMUSER'   ,CLASS=A,MSGCLASS= H,MSGLLEVEL=(1,1), // NOTIFY=&amp;SYSUID,TIM E=1440 //*----- ----- ----- //* Sample job for AWS   CLI //*----- ----- ----- //USSCMD EXEC PGM=BPXBAT TCH //STDERR DD SYSOUT=* //STDOUT DD SYSOUT=* //STDENV DD *   export PATH=/u/c liuser/python/bin: \$PATH //STDPARM DD * SH   export _BPXK_AUT OCVT=ON;   aws s3 mb s3://DOC- EXAMPLE-BUCKET2; </pre>	Mainframe z/OS developer

Task	Description	Skills required
	<pre>cp "'/'USER.DATA.FIXE D'" /tmp/tmpfile; aws s3 cp /tmp/tmpf ile s3://DOC-EXAMPLE- BUCKET2/USER.DATA.F IXED; rm /tmp/tmpfile; aws s3 ls s3://DOC- EXAMPLE-BUCKET2; /*</pre>	
Submit the batch JCL job.	<ol style="list-style-type: none"> <li>1. Submit the JCL job that you coded in the previous step.</li> <li>2. Check the status of the job in System Display and Search Facility (SDSF). If successful, the job should end with return code 0.</li> <li>3. The standard output (STDOUT) from the job log shows the successful bucket creation, dataset upload, and list of bucket contents. For a sample screen illustration, see the <a href="#">Additional information</a> section.</li> </ol>	Mainframe z/OS developer

Task	Description	Skills required
View the dataset uploaded to the S3 bucket.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console and open the <a href="#">Amazon S3 console</a>.</li><li>2. Navigate to see the uploaded file in the test bucket.</li><li>3. You can further process the USER.DATA.FIXED file or analyze it by using analytics services such as Amazon Redshift.</li></ol>	General AWS

# Back up and archive mainframe data to Amazon S3 using BMC AMI Cloud Data

Created by Santosh Kumar Singh (AWS), Mikhael Liberman (Model9 Mainframe Software), Gilberto Biondo (AWS), and Maggie Li (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Mainframe	<b>Target:</b> Amazon S3
<b>R Type:</b> N/A	<b>Technologies:</b> Mainframe; Storage & backup; Modernization	<b>AWS services:</b> Amazon EC2; Amazon EFS; Amazon S3; AWS Direct Connect

## Summary

This pattern demonstrates how to back up and archive mainframe data directly to Amazon Simple Storage Service (Amazon S3), and then recall and restore that data to the mainframe by using BMC AMI Cloud Data (previously known as Model9 Manager). If you are looking for a way to modernize your backup and archive solution as part of a mainframe modernization project or to meet compliance requirements, this pattern can help meet those goals.

Typically, organizations that run core business applications on mainframes use a virtual tape library (VTL) to back up data stores such as files and logs. This method can be expensive because it consumes billable MIPS, and the data stored on tapes outside the mainframe is inaccessible. To avoid these issues, you can use BMC AMI Cloud Data to quickly and cost-effectively transfer operational and historical mainframe data directly to Amazon S3. You can use BMC AMI Cloud Data to back up and archive data over TCP/IP to AWS while taking advantage of IBM z Integrated Information Processor (zIIP) engines to reduce cost, parallelism, and transfer times.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- BMC AMI Cloud Data with a valid license key
- TCP/IP connectivity between the mainframe and AWS

- An AWS Identity and Access Management (IAM) role for read/write access to an S3 bucket
- Mainframe security product (RACF) access in place to run BMC AMI Cloud processes
- A BMC AMI Cloud z/OS agent (Java version 8 64-bit SR5 FP16 or later) that has available network ports, firewall rules permitting access to S3 buckets, and a dedicated z/FS file system
- [Requirements](#) met for the BMC AMI Cloud management server

## Limitations

- BMC AMI Cloud Data stores its operational data in a PostgreSQL database that runs as a Docker container on the same Amazon Elastic Compute Cloud (Amazon EC2) instance as the management server. Amazon Relational Database Service (Amazon RDS) is not currently supported as a backend for BMC AMI Cloud Data. For more information about the latest product updates, see [What's New?](#) in the BMC documentation.
- This pattern backs up and archives z/OS mainframe data only. BMC AMI Cloud Data backs up and archives only mainframe files.
- This pattern doesn't convert data into standard open formats such as JSON or CSV. Use an additional transformation service such as [BMC AMI Cloud Analytics](#) (previously known as Model9 Gravity) to convert the data into standard open formats. Cloud-native applications and data analytics tools can access the data after it's written to the cloud.

## Product versions

- BMC AMI Cloud Data version 2.x

## Architecture

### Source technology stack

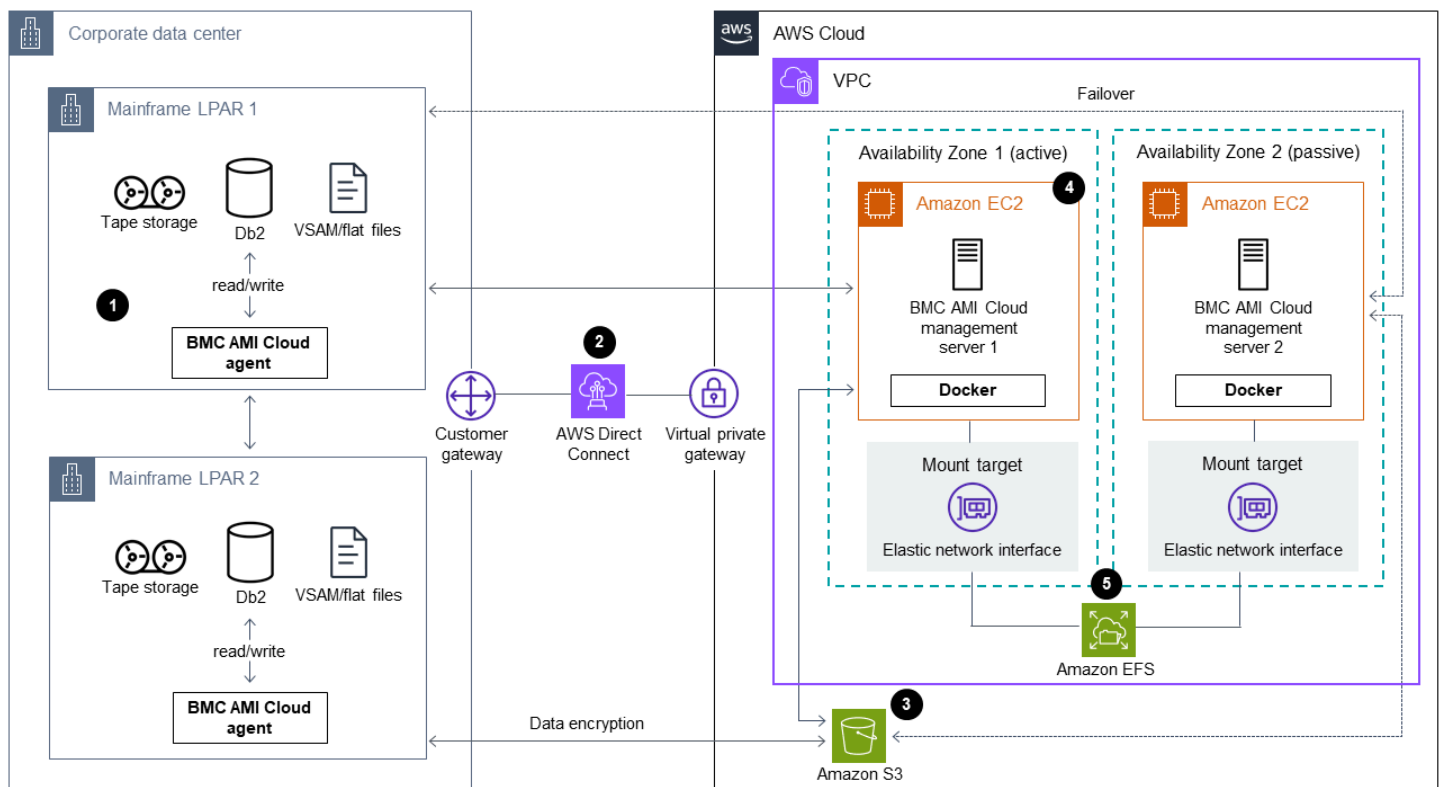

- Mainframe running z/OS
- Mainframe files such as datasets and z/OS UNIX System Services (USS) files
- Mainframe disk, such as a direct-access storage device (DASD)
- Mainframe tape (virtual or physical tape library)

### Target technology stack

- Amazon S3
- Amazon EC2 instance in a virtual private cloud (VPC)
- AWS Direct Connect
- Amazon Elastic File System (Amazon EFS)

## Target architecture

The following diagram shows a reference architecture where BMC AMI Cloud Data software agents on a mainframe drive the legacy data backup and archive processes that store the data in Amazon S3.

The diagram shows the following workflow:

1. BMC AMI Cloud Data software agents run on mainframe logical partitions (LPARs). The software agents read and write mainframe data from DASD or tape directly to Amazon S3 over TCP/IP.
2. AWS Direct Connect sets up a physical, isolated connection between the on-premises network and AWS. For enhanced security, run a site-to-site VPN on top of AWS Direct Connect to encrypt data in transit.

3. The S3 bucket stores mainframe files as object storage data, and BMC AMI Cloud Data agents directly communicate with the S3 buckets. Certificates are used for HTTPS encryption of all communications between the agent and Amazon S3. Amazon S3 data encryption is used to encrypt and protect the data at rest.
4. BMC AMI Cloud Data management servers run as Docker containers on EC2 instances. The instances communicate with agents running on mainframe LPARs and S3 buckets.
5. Amazon EFS is mounted on both active and passive EC2 instances to share the Network File System (NFS) storage. This is to make sure that metadata related to a policy created on the management server isn't lost in the event of a failover. In the event of a failover by the active server, the passive server can be accessed without any data loss. If the passive server fails, the active server can be accessed without any data loss.

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve nearly any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- [AWS Direct Connect](#) links your internal network to a AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

### BMC tools

- [BMC AMI Cloud management server](#) is a GUI application that runs as a Docker container on an Amazon Linux Amazon Machine Image (AMI) for Amazon EC2. The management server provides

the functionality to manage BMC AMI Cloud activities such as reporting, creating and managing policies, running archives, and performing backups, recalls, and restores.

- [BMC AMI Cloud agent](#) runs on an on-premises mainframe LPAR that reads and writes files directly to object storage by using TCP/IP. A started task runs on a mainframe LPAR and is responsible for reading and writing backup and archive data to and from Amazon S3.
- [BMC AMI Cloud Mainframe Command Line Interface \(M9CLI\)](#) provides you with a set of commands to perform BMC AMI Cloud actions directly from TSO/E or in batch operations, without the dependency on the management server.

## Epics

### Create an S3 bucket and IAM policy

Task	Description	Skills required
Create an S3 bucket.	<a href="#">Create an S3 bucket</a> to store the files and volumes that you want to back up and archive from your mainframe environment.	General AWS
Create an IAM policy.	<p>All BMC AMI Cloud management servers and agents require access to the S3 bucket that you created in the previous step.</p> <p>To grant the required access, create the following IAM policy:</p> <pre>{   "Version":     "2012-10-17",   "Statement": [     {       "Sid":         "Listfolder",</pre>	General AWS

Task	Description	Skills required
	<pre>                 "Action": [                     "s3:ListBucket",                     "s3:GetBucketLocat ion",                     "s3:ListBucketVers ions"                 ],                 "Effect":                 "Allow",                 "Resource":                 [                     "arn:aws:s3:::&lt;Bucket Name&gt;"                 ]             },             {                 "Sid":                 "Objectaccess",                 "Effect":                 "Allow",                 "Action": [                     "s3:PutObject",                     "s3:GetObjectAcl",                     "s3:GetObject",                     "s3&gt;DeleteObjectVe rsion",                     "s3&gt;DeleteObject",                     "s3:PutObjectAcl",                     "s3:GetObjectVersion"                 ],             } </pre>	

Task	Description	Skills required
	<pre>                 "Resource":             [                 "arn:aws:s3:::&lt;Bucket                 Name&gt;/*"             ]         }     ] } </pre>	

## Get the BMC AMI Cloud software license and download the software

Task	Description	Skills required
Get a BMC AMI Cloud software license.	To get a software license key, contact the <a href="#">BMC AMI Cloud team</a> . The output of the z/OS D M=CPU command is required for generating a license.	Build lead
Download the BMC AMI Cloud software and license key.	Obtain the installation files and license key by following the instructions in the <a href="#">BMC documentation</a> .	Mainframe infrastructure administrator

## Install the BMC AMI Cloud software agent on the mainframe

Task	Description	Skills required
Install the BMC AMI Cloud software agent.	1. Before you start the installation process, verify that <a href="#">minimum software and hardware requireme</a>	Mainframe infrastructure administrator

Task	Description	Skills required
	<p><a href="#">nts</a> for the agent have been met.</p> <p>2. To install the agent, follow the instructions in the <a href="#">BMC documentation</a>.</p> <p>3. After the agent starts running on the mainframe LPAR, check for the ZM91000I MODEL9 BACKUP AGENT INITIALIZED message in the spool. Verify that the connectivity is successfully established between the agent and the S3 bucket by looking for the Object store connectivity has been established successfully message in the agent's STDOUT.</p>	

### Set up a BMC AMI Cloud management server on an EC2 instance

Task	Description	Skills required
Create Amazon EC2 Linux 2 instances.	Launch two Amazon EC2 Linux 2 instances in different Availability Zones by following the instructions from <a href="#">Step 1: Launch an instance</a> in the Amazon EC2 documentation.	Cloud architect, Cloud administrator

Task	Description	Skills required
	<p>The instance must meet the following recommended hardware and software requirements:</p> <ul style="list-style-type: none"><li>• CPU – Minimum 4 cores</li><li>• RAM – Minimum 8 GB</li><li>• Drive – 40 GB</li><li>• Recommended EC2 instance – C5.xlarge</li><li>• OS – Linux</li><li>• Software – Docker, unzip, vi/VIM</li><li>• Network bandwidth – Minimum 1 GB</li></ul> <p>For more information, see the <a href="#">BMC documentation</a>.</p>	
Create an Amazon EFS file system.	<p>Create an Amazon EFS file system by following the instructions from <a href="#">Step 1: Create your Amazon EFS file system</a> in the Amazon EFS documentation.</p> <p>When creating the file system, do the following:</p> <ul style="list-style-type: none"><li>• Choose the Standard storage class.</li><li>• Choose the same VPC that you used to launch your EC2 instances.</li></ul>	Cloud administrator, Cloud architect

Task	Description	Skills required
Install Docker and configure the management server.	<p><b>Connect to your EC2 instances:</b></p> <p>Connect to your EC2 instances by following the instructions from <a href="#">Connect to your Linux instance</a> in the Amazon EC2 documentation.</p> <p><b>Configure your EC2 instances :</b></p> <p>For each EC2 instance, do the following:</p> <ol style="list-style-type: none"><li>1. To install Docker, run the command: <pre>sudo yum install docker</pre></li><li>2. To start Docker, run the command: <pre>sudo service docker start</pre></li><li>3. To validate the status of Docker, run the command: <pre>sudo service docker status</pre></li><li>4. In the <code>/etc/selinux</code> folder, change the config file to <code>SELINUX=permissive</code>.</li></ol>	Cloud architect, Cloud administrator

Task	Description	Skills required
	<p>5. Upload the model9-v2 .x.y_build_build-id-server.zip and VerificationScripts.zip files (that you downloaded earlier) to a temporary folder in one of the EC2 instances (for example, into the /var/tmp folder in your instance)</p> <p>6. To go to the tmp folder, run the command:</p> <pre>cd/var/tmp</pre> <p>7. To unzip the verification script, run the command:</p> <pre>unzip VerificationScripts.zip</pre> <p>8. To change the directory, run the command:</p> <pre>cd /var/tmp/sysutils/PrereqsScripts</pre> <p>9. To run the verification script, run the command:</p> <pre>./M9VerifyPrereqs.sh</pre> <p>10 After the verification script prompts for the input,</p>	

Task	Description	Skills required
	<p>enter the Amazon S3 URL and port number. Then, enter the z/OS IP/DNS and port number.</p> <p><b>Note:</b> The script runs a check to confirm that EC2 instance can connect with the S3 bucket and agent that's running on the mainframe. If a connection is established, a success message is displayed.</p>	

Task	Description	Skills required
Install the management server software.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 499">1. Create a folder and subfolder in the root directory (for example, / data/model9 ) in the EC2 instance that you plan to make the active server.</li><li data-bbox="591 520 1027 751">2. To install the amazon-efs-utils package and to mount the Amazon EFS file system created earlier, run the following commands: <pre data-bbox="634 789 1027 1024">sudo yum install -y amazon-efs-utils sudo mount -t efs -o tls &lt;File System ID&gt;:/ /data/model9</pre></li><li data-bbox="591 1045 1027 1465">3. To update the EC2 instance's /etc/fstab file with an entry for the Amazon EFS file system (so that Amazon EFS is automatically remounted when Amazon EC2 reboots), run the command: <pre data-bbox="634 1503 1027 1696">&lt;Amazon-EFS-file-system-id&gt;:/ /data/ model9 efs defaults, _netdev 0 0</pre></li><li data-bbox="591 1717 1027 1843">4. To define the path to the BMC AMI Cloud installation files and the target</li></ol>	Cloud architect, Cloud administrator

Task	Description	Skills required
	<p>installation location, run the following commands to export variables:</p> <pre data-bbox="634 380 1027 575">export MODEL9_HOME=/data/model9 export M9INSTALL=/var/tmp</pre> <p><b>Note:</b> We recommend that you add these EXPORT commands to your .bashrc script.</p> <p>5. To change the directory , run the cd \$MODEL9_HOME command, and then create another subdirectory by running the mkdir diag command.</p> <p>6. To unzip the installation file, run the command:</p> <pre data-bbox="634 1234 1027 1430">unzip \$M9INSTALL/model9-&lt;v2.x.y&gt;_build_&lt;build-id&gt;-server.zip</pre> <p><b>Note:</b> Replace x.y (the version) and build-id with your values.</p> <p>7. To deploy the application, run the following commands:</p>	

Task	Description	Skills required
	<pre data-bbox="634 212 1027 562">docker load -i   \$MODEL9_HOME/model 9-&lt;v2.x.y&gt;_build_&lt; build-id&gt;.docker docker load -i   \$MODEL9_HOME/postg res-12.10-x86.dock er.gz</pre> <p data-bbox="630 604 1024 737"><b>Note:</b> Replace <code>v2.x.y</code> (the version) and <code>build-id</code> with your values.</p> <p data-bbox="591 758 992 932">8. In the <code>\$MODEL9_HOME/conf</code> folder, update the <code>model9-local.yml</code> file.</p> <p data-bbox="630 982 1019 1304"><b>Note:</b> Some of the parameters have default values and others can be updated as necessary. For more information, see the instructions in the <code>model9-local.yml</code> file.</p> <p data-bbox="591 1325 980 1549">9. Create a file called <code>\$MODEL9_HOME/conf</code>, and then add the following parameters to the file:</p> <pre data-bbox="634 1591 1027 1745">TZ=America/New_York EXTRA_JVM_ARGS=- Xmx2048m</pre> <p data-bbox="591 1766 1024 1843">10.To create a Docker network bridge, run the command:</p>	

Task	Description	Skills required
	<pre data-bbox="634 212 1027 365">docker network create -d bridge model9net work</pre> <p data-bbox="594 384 984 562"><b>11</b>To start the PostgreSQL database container for BMC AMI Cloud, run the following command:</p> <pre data-bbox="634 600 1027 1234">docker run -p 127.0.0.1:5432:5432 \ -v \$MODEL9_HOME/db/da ta:/var/lib/postgr esql/data:z \ --name model9db -- restart unless-st opped \ --network model9net work \ -e POSTGRES_PASSWORD= model9 -e POSTGRES_ DB=model9 -d postgres:12.10</pre> <p data-bbox="594 1253 984 1476"><b>12</b>After the PostgreSQL container starts running, run the following command to start the application server:</p> <pre data-bbox="634 1514 1027 1772">docker run -d -p 0.0.0.0:443:443 -p 0.0.0.0:80:80 \ --sysctl net.ipv4. tcp_keepalive_time =600 \</pre>

Task	Description	Skills required
	on, see the <a href="#">BMC documentation</a> .	

## Add an agent and define a backup or archive policy on the BMC AMI Cloud management server

Task	Description	Skills required
Add a new agent.	<p>Before you add a new agent, confirm the following:</p> <ul style="list-style-type: none"> <li>• A BMC AMI Cloud agent is running on the mainframe LPAR and has been initialized completely. Identify the agent by looking for the ZM91000I MODEL9 BACKUP AGENT INITIALIZED initialization message in the spool.</li> <li>• A Docker container for the management server is fully initialized and running.</li> </ul> <p>You must create an agent on the management server before you define any backup and archive policies. To create the agent, do the following:</p> <ol style="list-style-type: none"> <li>1. Use a web browser to access the management server that's deployed on your Amazon EC2 machine,</li> </ol>	Mainframe storage administrator or developer

Task	Description	Skills required
	<p>and then log in with your mainframe credentials.</p> <ol style="list-style-type: none"><li>2. Choose the <b>AGENTS</b> tab, and then choose <b>ADD NEW AGENT</b>.</li><li>3. For <b>Name</b>, enter the agent name.</li><li>4. For <b>Hostname/IP Address</b>, enter the host name or IP address of your mainframe.</li><li>5. For <b>Port</b>, enter your port number.</li><li>6. Choose <b>TEST CONNECTION</b>. You can see a <b>success</b> message if the connectivity is successfully established.</li><li>7. Choose <b>CREATE</b>.</li></ol> <p>After the agent is created, you'll see the <b>connected</b> status against the object storage and mainframe agent in a new window that appears in the table.</p>	

Task	Description	Skills required
Create a backup or archive policy.	<ol style="list-style-type: none"> <li>1. Choose <b>POLICIES</b>.</li> <li>2. Choose <b>CREATE POLICY</b>.</li> <li>3. On the <b>CREATE A NEW POLICY</b> page, enter your policy specifications.</li> </ol> <p><b>Note:</b> For more information about the available specifications, see <a href="#">Creating a new policy</a> in the BMC documentation.</p> <ol style="list-style-type: none"> <li>4. Choose <b>FINISH</b>.</li> <li>5. The new policy is now listed as a table. To see this table, choose the <b>POLICIES</b> tab.</li> </ol>	Mainframe storage administrator or developer

### Run the backup or archive policy from the management server

Task	Description	Skills required
Run the backup or archive policy.	<p>Run the data backup or archive policy that you created earlier from the management server either manually or automatically (based on a schedule). To run the policy manually:</p> <ol style="list-style-type: none"> <li>1. Choose the <b>POLICIES</b> tab from the navigation menu.</li> <li>2. On the right side of the table for the policy that</li> </ol>	Mainframe storage administrator or developer

Task	Description	Skills required
	<p>you want to run, choose the three-dot menu.</p> <ol style="list-style-type: none"><li data-bbox="591 310 889 352">3. Choose <b>Run Now</b>.</li><li data-bbox="591 373 1026 508">4. In the pop-up confirmation window, choose <b>YES, RUN POLICY NOW</b>.</li><li data-bbox="591 529 1026 663">5. After the policy runs, verify the run status in the policy activity section.</li><li data-bbox="591 684 987 907">6. For the policy that ran, choose the three-dot menu, and then choose <b>View Run Log</b> to see the logs.</li><li data-bbox="591 928 1003 1062">7. To verify that the backup was created, check the S3 bucket.</li></ol>	

Task	Description	Skills required
Restore the backup or archive policy.	<ol style="list-style-type: none"><li data-bbox="591 226 1026 308">1. On the navigation menu, choose the <b>POLICIES</b> tab.</li><li data-bbox="591 329 1026 604">2. Choose the policy to run your restore process on. This will list all the backup or archive activities that ran in the past for that specific policy.</li><li data-bbox="591 625 1026 947">3. To select the backups that you want to restore, choose the <b>Date-time</b> column. The file/Volume/Storage group name shows the run details of the policy.</li><li data-bbox="591 968 1026 1150">4. On the right side of the table, choose the three-dot menu, and then choose <b>RESTORE</b>.</li><li data-bbox="591 1171 1026 1354">5. In the pop-up window, enter your target name, volume, and storage group, and then choose <b>RESTORE</b>.</li><li data-bbox="591 1375 1026 1507">6. Enter your mainframe credentials, and then choose <b>RESTORE</b> again.</li><li data-bbox="591 1528 1026 1654">7. To verify that the restore was successful, check the logs or the mainframe.</li></ol>	Mainframe storage administrator or developer

## Run the backup or archive policy from the mainframe

Task	Description	Skills required
<p>Run the backup or archive policy by using M9CLI.</p>	<p>Use the M9CLI to perform backup and restore processes from TSO/E, REXX, or through JCLs without setting up rules on the BMC AMI Cloud management server.</p> <p><b>Using TSO/E:</b></p> <p>If you use TSO/E, make sure that M9CLI REXX is concatenated to TSO. To back up a dataset through TSO/E, use the TSO M9CLI BACKDSN &lt;DSNAME&gt; command.</p> <p><b>Note:</b> For more information about M9CLI commands, see <a href="#">CLI reference</a> in the BMC documentation.</p> <p><b>Using JCLs:</b></p> <p>To run the backup and archive policy by using JCLs, run the M9CLI command.</p> <p><b>Using batch operations:</b></p> <p>The following example shows you how to archive a dataset by running the M9CLI command in batch:</p>	<p>Mainframe storage administrator or developer</p>

Task	Description	Skills required
	<pre>//JOBNAME JOB ... //M9CLI EXEC PGM=IKJEF T01 //STEPLIB DD DISP=SHR, DSN=&lt;MODEL9 LOADLIB&gt; //SYSEXEC DD DISP=SHR, DSN=&lt;MODEL9 EXEC LIB&gt; //SYSTSPRT DD SYSOUT=* //SYSPRINT DD SYSOUT=* //SYSTSIN DD TSO M9CLI ARCHIVE M9CLI ARCHIVE &lt;DSNNAME OR DSN PATTERN&gt; /</pre>	

Task	Description	Skills required
Run the backup or archive policy in JCL batch.	<p>BMC AMI Cloud provides a sample JCL routine called <b>M9SAPIJ</b>. You can customize <b>M9SAPIJ</b> to run a specific policy created on the management server with a JCL. This job can also be part of a batch scheduler for running backup and restore processes automatically.</p> <p>The batch job expects the following mandatory values:</p> <ul style="list-style-type: none"><li>• Management server IP address/host name</li><li>• Port number</li><li>• Policy ID or policy name (which is created on the management server)</li></ul> <p><b>Note:</b> You can also change other values by following the instructions on the sample job.</p>	Mainframe storage administrator or developer

# Build an advanced mainframe file viewer in the AWS Cloud

Created by Boopathy GOPALSAMY (AWS) and Jeremiah O'Connor (AWS)

**Environment:** PoC or pilot

**Technologies:** Mainframe;  
Migration; Serverless

**Workload:** IBM

**AWS services:** Amazon  
Athena; AWS Lambda;  
Amazon OpenSearch Service;  
AWS Step Functions

## Summary

This pattern provides code samples and steps to help you build an advanced tool for browsing and reviewing your mainframe fixed-format files by using AWS serverless services. The pattern provides an example of how to convert a mainframe input file to an Amazon OpenSearch Service document for browsing and searching. The file viewer tool can help you achieve the following:

- Retain the same mainframe file structure and layout for consistency in your AWS target migration environment (for example, you can maintain the same layout for files in a batch application that transmits files to external parties)
- Speed up development and testing during your mainframe migration
- Support maintenance activities after the migration

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a subnet that's reachable by your legacy platform
- An input file and its corresponding common business-oriented language (COBOL) copybook (**Note:** For input file and COBOL copybook examples, see [gfs-mainframe-solutions](#) on the GitHub repository. For more information about COBOL copybooks, see the [Enterprise COBOL for z/OS 6.3 Programming Guide](#) on the IBM website.)

## Limitations

- Copybook parsing is limited to no more than two nested levels (OCCURS)

## Architecture

### Source technology stack

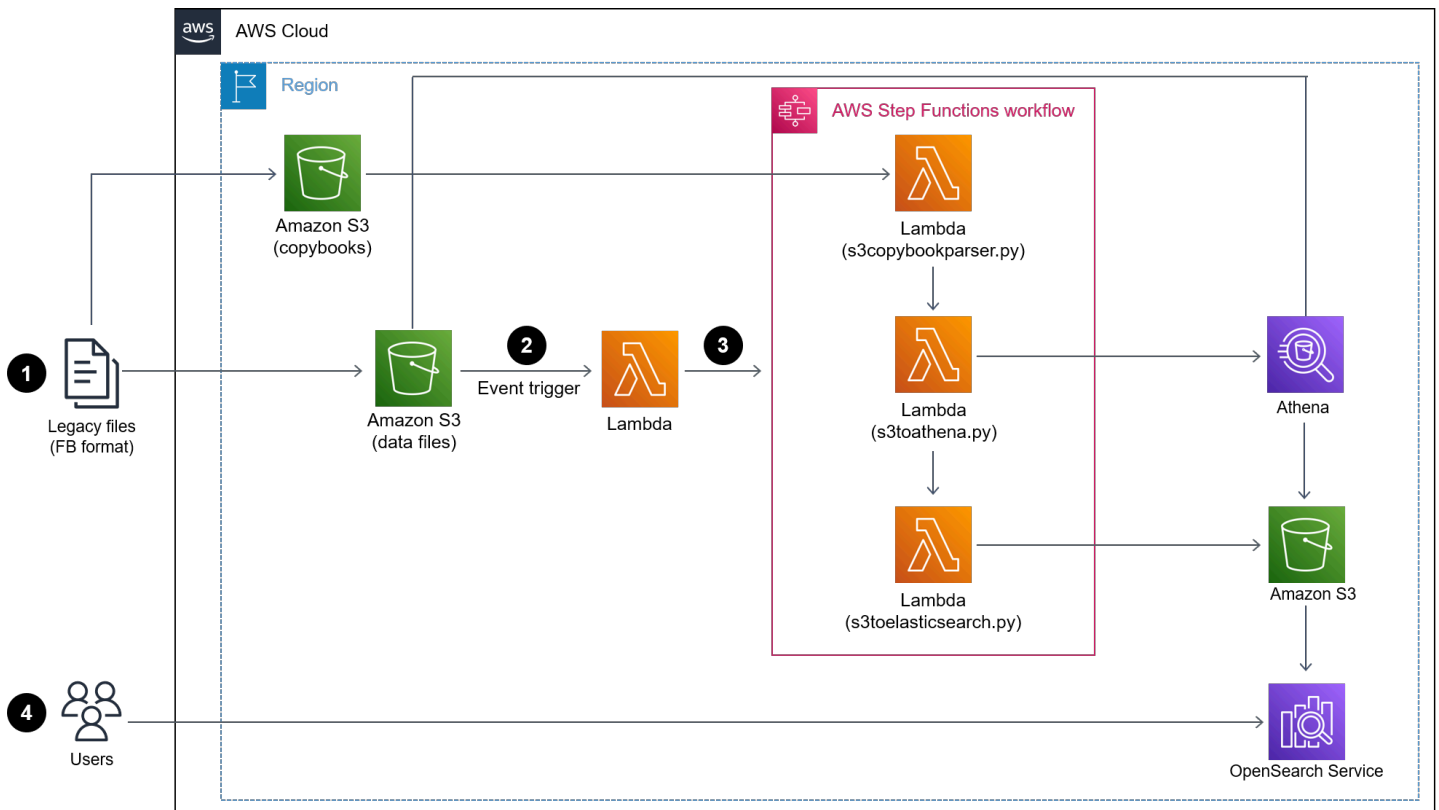

- Input files in [FB \(Fixed Blocked\)](#) format
- COBOL copybook layout

### Target technology stack

- Amazon Athena
- Amazon OpenSearch Service
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS Step Functions

### Target architecture

The following diagram shows the process of parsing and converting a mainframe input file to an OpenSearch Service document for browsing and searching.

The diagram shows the following workflow:

1. An admin user or application pushes input files to one S3 bucket and COBOL copybooks to another S3 bucket.
2. The S3 bucket with the input files invokes a Lambda function that kicks off a serverless Step Functions workflow. **Note:** The use of an S3 event trigger and Lambda function to drive the Step Functions workflow in this pattern is optional. The GitHub code samples in this pattern don't include the use of these services, but you can use these services based on your requirements.
3. The Step Functions workflow coordinates all the batch processes from the following Lambda functions:
  - The `s3copybookparser.py` function parses the copybook layout and extracts field attributes, data types, and offsets (required for input data processing).
  - The `s3toathena.py` function creates an Athena table layout. Athena parses the input data that's processed by the `s3toathena.py` function and converts the data to a CSV file.
  - The `s3toelasticsearch.py` function ingests the results file from the S3 bucket and pushes the file to OpenSearch Service.
4. Users access OpenSearch Dashboards with OpenSearch Service to retrieve the data in various table and column formats and then run queries against the indexed data.

# Tools

## AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, you use Lambda to implement core logic, such as parsing files, converting data, and loading data into OpenSearch Service for interactive file access.
- [Amazon OpenSearch Service](#) is a managed service that helps you deploy, operate, and scale OpenSearch Service clusters in the AWS Cloud. In this pattern, you use OpenSearch Service to index the converted files and provide interactive search capabilities for users.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications. In this pattern, you use Step Functions to orchestrate Lambda functions.

## Other tools

- [GitHub](#) is a code-hosting service that provides collaboration tools and version control.
- [Python](#) is a high-level programming language.

## Code

The code for this pattern is available in the GitHub [gfs-mainframe-patterns](#) repository.

# Epics

## Prepare the target environment

Task	Description	Skills required
Create the S3 bucket.	<p><a href="#">Create an S3 bucket</a> for storing the copybooks, input files, and output files. We recommend the following folder structure for your S3 bucket:</p> <ul style="list-style-type: none"> <li>• copybook/</li> <li>• input/</li> <li>• output/</li> <li>• query/</li> <li>• results/</li> </ul>	General AWS
Create the s3copybookparser function.	<ol style="list-style-type: none"> <li>1. <a href="#">Create a Lambda function</a> called <code>s3copybookparser</code> and upload the source code (<code>s3copybookparser.py</code> and <code>copybook.py</code>) from the <a href="#">GitHub</a> repository.</li> <li>2. <a href="#">Attach the IAM policy</a> <code>S3ReadOnly</code> to the Lambda function.</li> </ol>	General AWS
Create the s3toathena function.	<ol style="list-style-type: none"> <li>1. Create a Lambda function called <code>s3toathena</code> and upload the source code (<code>s3toathena.py</code>) from the <a href="#">GitHub</a> repository. Configure the Lambda timeout to &gt; 60 seconds.</li> </ol>	General AWS

Task	Description	Skills required
	2. To provide access to the required resources, attach the IAM policies <code>AmazonAthenaFullAccess</code> and <code>S3FullAccess</code> to the Lambda function.	

Task	Description	Skills required
Create the <code>s3toelasticsearch</code> function.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 793">1. <a href="#">Add a Python dependency to your Lambda environment</a>. <b>Important:</b> To use the <code>s3toelasticsearch</code> function, you must add the Python dependency because the Lambda function uses Python Elasticsearch client dependencies (<code>Elasticsearch==7.9.0</code> and <code>requests_aws4auth</code> ).</li><li data-bbox="591 814 1027 1140">2. Create a Lambda function called <code>s3toelasticsearch</code> and upload the source code (<code>s3toelasticsearch.py</code> ) from the <a href="#">GitHub</a> repository.</li><li data-bbox="591 1161 1027 1287">3. Import the Python dependency as a Lambda layer.</li><li data-bbox="591 1308 1027 1539">4. Attach the IAM policies <code>S3ReadOnly</code> and <code>AmazonOpenSearchServiceReadOnlyAccess</code> to the Lambda function.</li></ol>	General AWS

Task	Description	Skills required
<p>Create the OpenSearch Service cluster.</p>	<p><b>Create the cluster</b></p> <ol style="list-style-type: none"> <li>1. <a href="#">Create an OpenSearch Service cluster</a>. When you create the cluster, do the following: <ul style="list-style-type: none"> <li>• <a href="#">Create a master user and password</a> for the cluster that you can use for signing in to <a href="#">OpenSearch Dashboards</a>. <b>Note:</b> This step is not required if you use authentication through Amazon Cognito.</li> <li>• Choose fine-grained access control. This gives you additional ways of controlling access to your data in OpenSearch Service.</li> </ul> </li> <li>2. Copy the domain URL and pass it as the environment variable <b>'HOST'</b> to the Lambda function <code>s3toelasticsearch</code>.</li> </ol> <p><b>Grant access to the IAM role</b></p> <p>To provide fine-grained access to the Lambda function's IAM role (<code>arn:aws:iam::**:role/service-role/s3toelasticsearch</code></p>	<p>General AWS</p>

Task	Description	Skills required
	<p>search-role-** ), do the following:</p> <ol style="list-style-type: none"><li>1. Sign in to OpenSearch Dashboards as the master user.</li><li>2. Choose the <b>Security</b> tab, and then choose <b>Roles</b>, <b>all_access</b>, <b>Map user</b>, <b>Backend roles</b>.</li><li>3. Add the Amazon Resource Name (ARN) of the Lambda function's IAM role, and then choose <b>Save</b>. For more information, see <a href="#">Mapping roles to users</a> in the OpenSearch Service documentation.</li></ol>	
Create Step Functions for orchestration.	<ol style="list-style-type: none"><li>1. <a href="#">Create a Step Functions state machine</a> with the standard flow. The definition is included in the <a href="#">GitHub</a> repository.</li><li>2. In the JSON script, replace the Lambda function's ARNs with the ARNs from the Lambda function in your environment.</li></ol>	General AWS

## Deploy and run

Task	Description	Skills required
<p>Upload the input files and copybooks to the S3 bucket.</p>	<p>Download sample files from the <a href="#">GitHub</a> repository sample folder and upload the files to the S3 bucket that you created earlier.</p> <ol style="list-style-type: none"> <li>1. Upload Mockedcopy.cpy and acctix.cpy to the &lt;S3_Bucket&gt;/copybook folder.</li> <li>2. Upload the Modeduplicate.txt and acctindex.cpy sample input files to the &lt;S3_Bucket&gt;/input folder.</li> </ol>	<p>General AWS</p>
<p>Invoke the Step Functions.</p>	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console and open the <a href="#">Step Functions console</a>.</li> <li>2. In the navigation pane, choose <b>State machines</b>.</li> <li>3. Choose your state machine, and then choose <b>Start execution</b>.</li> <li>4. In the <b>Input</b> box, enter the following copybook/file path as a JSON variable to the S3 bucket, and then choose <b>Start execution</b>.</li> </ol> <pre data-bbox="597 1829 1027 1885">{</pre>	<p>General AWS</p>

Task	Description	Skills required
	<pre data-bbox="609 210 1015 661">"s3_copybook_bucket_name": "&lt;BUCKET NAME&gt;", "s3_copybook_bucket_key": "&lt;COPYBOOK PATH&gt;", "s3_source_bucket_name": "&lt;BUCKET NAME", "s3_source_bucket_key": "INPUT FILE PATH" }</pre> <p data-bbox="592 703 779 735">For example:</p> <pre data-bbox="609 777 1015 1312">{ "s3_copybook_bucket_name": "fileaidtest", "s3_copybook_bucket_key": "copybook/acctix.cpy", "s3_source_bucket_name": "fileaidtest", "s3_source_bucket_key": "input/acctindex" }</pre>	

Task	Description	Skills required
Validate the workflow execution in Step Functions.	<p>In the <a href="#">Step Functions console</a>, review the workflow execution in the <b>Graph inspector</b>. The execution run states are color coded to represent execution status. For example, blue indicates <b>In Progress</b>, green indicates <b>Succeeded</b>, and red indicates <b>Failed</b>. You can also review the table in the <b>Execution event history</b> section for more detailed information about the execution events.</p> <p>For an example of a graphical workflow execution, see <i>Step Functions graph</i> in the <i>Additional information</i> section of this pattern.</p>	General AWS

Task	Description	Skills required
Validate the delivery logs in Amazon CloudWatch.	<ol style="list-style-type: none"><li data-bbox="589 226 1008 405">1. Sign in to the AWS Management Console and open the <a href="#">CloudWatch console</a>.</li><li data-bbox="589 426 959 562">2. In the navigation pane, expand <b>Logs</b>, and then choose <b>Log groups</b>.</li><li data-bbox="589 583 1008 762">3. In the search box, search for the <code>s3toelast icsearch</code> function's log group.</li></ol> <p data-bbox="589 835 1021 1056">For an example of successful delivery logs, see <i>CloudWatch delivery logs</i> in the <i>Additional information</i> section of this pattern.</p>	General AWS

Task	Description	Skills required
Validate the formatted file in OpenSearch Dashboards and perform file operations.	<ol style="list-style-type: none"><li>1. Sign in to the AWS Management Console. Under <b>Analytics</b>, choose <b>Amazon OpenSearch Service</b>.</li><li>2. In the navigation pane, choose <b>Domains</b>.</li><li>3. In the search box, enter the URL for your domain in <a href="#">OpenSearch Dashboards</a>.</li><li>4. Choose your dashboard , and then <a href="#">sign in as the master user</a>.</li><li>5. Browse the indexed data in table format.</li><li>6. Compare the input file against the formatted output file (indexed document) in OpenSearch Dashboards. The dashboard view shows the added column headers for your formatted files. Confirm that the source data from your unformatted input files matches the target data in the dashboard view.</li><li>7. Perform actions such as search (for example, by using field names, values, or expressions), filter, and <a href="#">DQL</a> (Dashboard Query</li></ol>	General AWS

Task	Description	Skills required
	Language) operations against the indexed file.

# Containerize mainframe workloads that have been modernized by Blu Age

Created by Richard Milner-Watts (AWS)

<b>Code repository:</b> <a href="#">Blu Age Application Container Example</a>	<b>Environment:</b> Production	<b>Source:</b> Mainframe workloads
<b>Target:</b> Containers	<b>R Type:</b> Re-architect	<b>Workload:</b> IBM; All other workloads
<b>Technologies:</b> Mainframe; Containers & microservices; Migration; Modernization	<b>AWS services:</b> Amazon ECS; Amazon ECR	

## Summary

This pattern provides a sample container environment for running mainframe workloads that have been modernized by using the [Blu Age](#) tool. Blu Age converts legacy mainframe workloads into modern Java code. This pattern provides a wrapper around the Java application so you can run it by using container orchestration services such as [Amazon Elastic Container Service \(Amazon ECS\)](#) or [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#).

For more information about modernizing your workloads by using Blu Age and AWS services, see these AWS Prescriptive Guidance publications:

- [Running modernized Blu Age mainframe workloads on serverless AWS infrastructure](#)
- [Deploy an environment for containerized Blu Age applications by using Terraform](#)

For assistance with using Blu Age to modernize your mainframe workloads, contact the Blu Age team by choosing **Contact our experts** on the [Blu Age website](#). For assistance with migrating your modernized workloads to AWS, integrating them with AWS services, and moving them into production, contact your AWS account manager or fill out the [AWS Professional Services form](#).

## Prerequisites and limitations

### Prerequisites

- A modernized Java application that was created by Blu Age. For testing purposes, this pattern provides a sample Java application that you can use as a proof of concept.
- A [Docker](#) environment that you can use to build the container.

### Limitations

Depending on the container orchestration platform that you use, the resources that can be made available to the container (such as CPU, RAM, and storage) might be limited. For example, if you're using Amazon ECS with AWS Fargate, see the [Amazon ECS documentation](#) for limits and considerations.

## Architecture

### Source technology stack

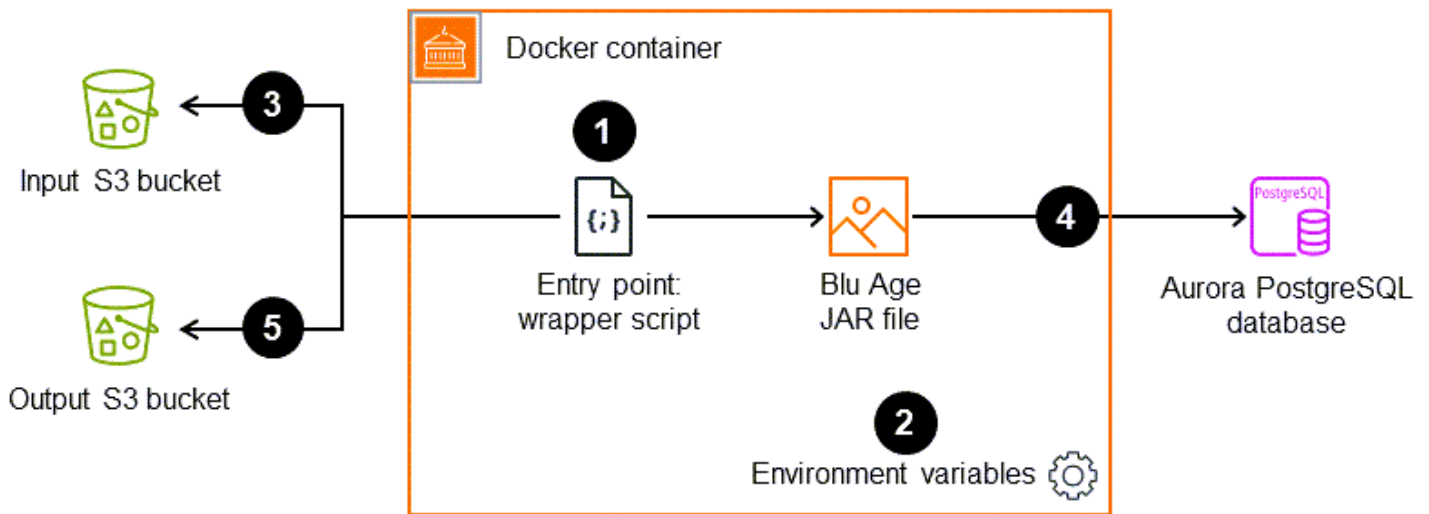

- Blu Age
- Java

### Target technology stack

- Docker

### Target architecture

The following diagram shows the architecture of the Blu Age application within a Docker container.

1. The entry point for the container is the wrapper script. This bash script is responsible for preparing the runtime environment for the Blu Age application and processing outputs.
2. Environment variables within the container are used to configure variables in the wrapper script, such as the Amazon Simple Storage Service (Amazon S3) bucket names and database credentials. Environment variables are supplied by either AWS Secrets Manager or Parameter Store, a capability of AWS Systems Manager. If you're using Amazon ECS as your container orchestration service, you can also hardcode the environment variables in the Amazon ECS task definition.
3. The wrapper script is responsible for pulling any input files from the S3 bucket into the container before you run the Blu Age application. The AWS Command Line Interface (AWS CLI) is installed within the container. This provides a mechanism for accessing objects that are stored in Amazon S3 through the gateway virtual private cloud (VPC) endpoint.
4. The Java Archive (JAR) file for the Blu Age application might need to communicate with other data sources, such as Amazon Aurora.
5. After completion, the wrapper script delivers the resulting output files into an S3 bucket for further processing (for example, by Amazon CloudWatch logging services). The pattern also supports delivering zipped log files to Amazon S3, if you're using an alternative to standard CloudWatch logging.

## Tools

### AWS services

- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.

## Tools

- [Docker](#) is a software platform for building, testing, and deploying applications. Docker packages software into standardized units called [containers](#), which have everything the software needs to run, including libraries, system tools, code, and runtime. You can use Docker to deploy and scale applications into any environment.
- [Bash](#) is a command language interface (shell) for the GNU operating system.
- [Java](#) is the programming language and development environment used in this pattern.
- [Blu Age](#) is an AWS mainframe modernization tool that converts legacy mainframe workloads, including application code, dependencies, and infrastructure, into modern workloads for the cloud.

## Code repository

The code for this pattern is available in the GitHub [Blu Age sample container repository](#).

## Best practices

- Externalize the variables for altering your application's behavior by using environment variables. These variables enable the container orchestration solution to alter the runtime environment without rebuilding the container. This pattern includes examples of environment variables that can be useful for Blu Age applications.
- Validate any application dependencies before you run your Blu Age application. For example, verify that the database is available and credentials are valid. Write tests in the wrapper script to verify dependencies, and fail early if they are not met.
- Use verbose logging within the wrapper script. Interacting directly with a running container can be challenging, depending on the orchestration platform and how long the job takes. Make sure that useful output is written to STDOUT to help diagnose any issues. For example, output might include the contents of the application's working directory both before and after you run the application.

## Epics

### Obtain a Blu Age application JAR file

Task	Description	Skills required
Option 1 - Work with Blu Age to obtain your application's JAR file.	<p>The container in this pattern requires a Blu Age application. Alternatively, you can use the sample Java application that's provided with this pattern for a prototype.</p> <p>Work with the Blu Age team to obtain a JAR file for your application that can be baked into the container. If the JAR file isn't available, see the next task to use the sample application instead.</p>	Cloud architect
Option 2 - Build or use the supplied sample application JAR file.	<p>This pattern provides a prebuilt sample JAR file. This file outputs the application's environment variables to STDOUT before sleeping for 30 seconds and exiting.</p> <p>This file is named <code>bluAgeSample.jar</code> and is located in the <a href="#">docker folder</a> of the GitHub repository.</p> <p>If you want to alter the code and build your own version of the JAR file, use the source code located at <a href="#">./java_sample/src/sample_java_app.jar</a></p>	App developer

Task	Description	Skills required
	<p><a href="#">va</a> in the GitHub repository. You can use the build script at <a href="#">./java_sample/build.sh</a> to compile the Java source and build a new JAR file.</p>	

## Build the Blu Age container

Task	Description	Skills required
Clone the GitHub repository.	<p>Clone the sample code repository by using the command:</p> <pre>git clone https://github.com/aws-samples/aws-blu-age-sample-container</pre>	AWS DevOps
Use Docker to build the container.	<p>Use Docker to build the container before you push it to a Docker registry such as Amazon ECR:</p> <ol style="list-style-type: none"> <li>1. From your chosen terminal, navigate to the <code>docker</code> folder within your local GitHub repository.</li> <li>2. Use this command to build the container:</li> </ol> <pre>docker build -t &lt;tag&gt; .</pre>	AWS DevOps

Task	Description	Skills required
	where <tag> is the container name you want to use.	
Test the Blu Age container.	<p>(Optional) If necessary, test the container locally by using the command:</p> <pre data-bbox="594 583 1029 705">docker run -it &lt;tag&gt; /bin/bash</pre>	AWS DevOps

Task	Description	Skills required
Authenticate to your Docker repository.	<p>If you plan to use Amazon ECR, follow the instructions in the <a href="#">Amazon ECR documentation</a> to install and configure the AWS CLI and authenticate the Docker CLI to your default registry.</p> <p>We recommend that you use the <a href="#">get-login-password command</a> for authentication.</p> <p><b>Note:</b> The <a href="#">Amazon ECR console</a> provides a pre-populated version of this command if you use the <b>View push commands</b> button. For more information, see the <a href="#">Amazon ECR documentation</a>.</p> <pre>aws ecr get-login -password --region &lt;region&gt;   docker login --username AWS --password-stdin &lt;account&gt;.dkr.ecr. &lt;region&gt;.amazonaws .com</pre> <p>If you don't plan to use Amazon ECR, follow the instructions provided for your container registry system.</p>	AWS DevOps

Task	Description	Skills required
Create a container repository.	<p>Create a repository in Amazon ECR. For instructions, see the pattern <a href="#">Deploy an environment for containerized Blue applications by using Terraform</a>.</p> <p>If you're using another container registry system, follow the instructions provided for that system.</p>	AWS DevOps

Task	Description	Skills required
Tag and push your container to the target repository.	<p>If you're using Amazon ECR:</p> <ol style="list-style-type: none"><li>1. Tag the local Docker image with the Amazon ECR registry and repository, so you can push it to your remote repository:</li></ol> <pre data-bbox="634 569 1027 846">docker tag &lt;tag&gt;:latest &lt;account&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/&lt;repository&gt;:&lt;versionNumber&gt;</pre> <ol style="list-style-type: none"><li>2. Push the image to the remote repository:</li></ol> <pre data-bbox="634 982 1027 1220">docker push &lt;account&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/&lt;repository&gt;:&lt;versionNumber&gt;</pre> <p>For more information, see <a href="#">Pushing a Docker image</a> in the <i>Amazon ECR User Guide</i>.</p>	AWS DevOps

# Convert and unpack EBCDIC data to ASCII on AWS by using Python

Created by Luis Gustavo Dantas (AWS)

<b>Code repository:</b> <a href="#">Mainframe Data Utilities</a>	<b>Environment:</b> PoC or pilot	<b>Source:</b> Mainframe EBCDIC data
<b>Target:</b> Distributed or cloud modernized ASCII data	<b>R Type:</b> Replatform	<b>Workload:</b> IBM
<b>Technologies:</b> Mainframe; Databases; Storage & backup; Modernization	<b>AWS services:</b> Amazon EBS; Amazon EC2	

## Summary

Because mainframes typically host critical business data, modernizing data is one of the most important tasks when migrating data to the Amazon Web Services (AWS) Cloud or other American Standard Code for Information Interchange (ASCII) environment. On mainframes, data is typically encoded in extended binary-coded decimal interchange code (EBCDIC) format. Exporting database, Virtual Storage Access Method (VSAM), or flat files generally produces packed, binary EBCDIC files, which are more complex to migrate. The most commonly used database migration solution is change data capture (CDC), which, in most cases, automatically converts data encoding. However, CDC mechanisms might not be available for these database, VSAM, or flat files. For these files, an alternative approach is required to modernize the data.

This pattern describes how to modernize EBCDIC data by converting it to ASCII format. After conversion, you can load the data into distributed databases or have applications in the cloud process the data directly. The pattern uses the conversion script and sample files in the [mainframe-data-utilities](#) GitHub repository.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An EBCDIC input file and its corresponding common business-oriented language (COBOL) copybook. A sample EBCDIC file and COBOL copybook are included in the [mainframe-data-utilities](#) GitHub repository. For more information about COBOL copybooks, see [Enterprise COBOL for z/OS 6.4 Programming Guide](#) on the IBM website.

## Limitations

- File layouts defined inside COBOL programs are not supported. They must be made available separately.

## Product versions

- Python version 3.8 or later

## Architecture

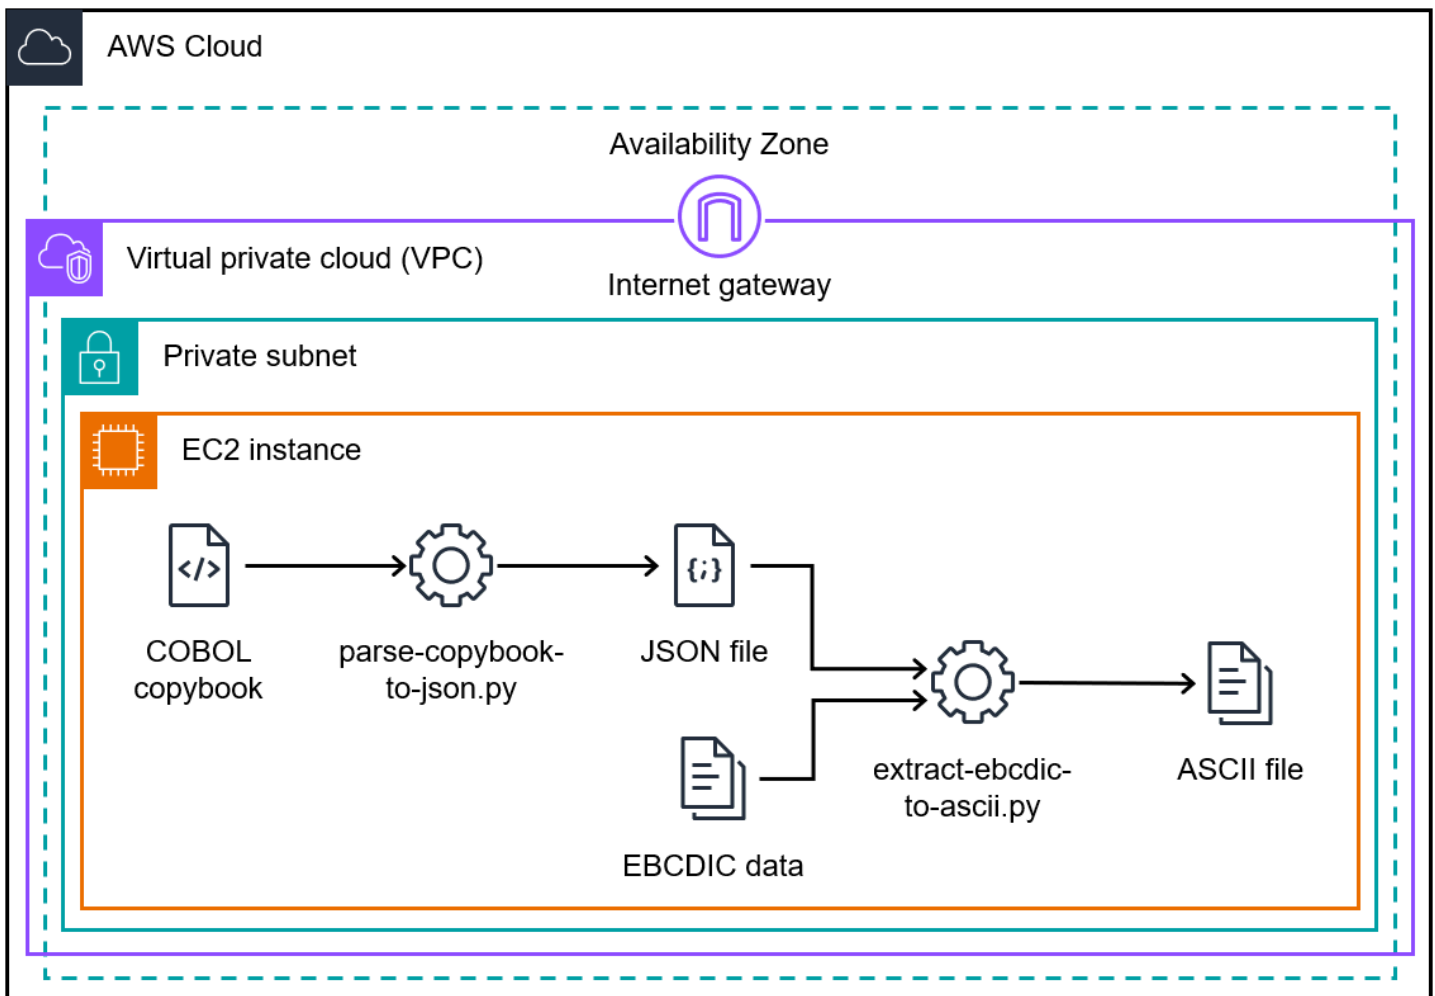

### Source technology stack

- EBCDIC data on a mainframe
- COBOL copybook

### Target technology stack

- Amazon Elastic Compute Cloud (Amazon EC2) instance in a virtual private cloud (VPC)
- Amazon Elastic Block Store (Amazon EBS)
- Python and its required packages, JavaScript Object Notation (JSON), sys, and datetime
- ASCII flat file ready to be read by a modern application or loaded in a relational database table

### Target architecture

The architecture diagram shows the process of converting an EBCDIC file to an ASCII file on an EC2 instance:

1. Using the `parse_copybook_to_json.py` script, you convert the COBOL copybook to a JSON file.
2. Using the JSON file and the `extract_ebcdic_to_ascii.py` script, you convert the EBCDIC data to an ASCII file.

### Automation and scale

After the resources needed for the first manual file conversions are in place, you can automate file conversion. This pattern doesn't include instructions for automation. There are multiple ways to automate the conversion. The following is an overview of one possible approach:

1. Encapsulate the AWS Command Line Interface (AWS CLI) and Python script commands into a shell script.

2. Create an AWS Lambda function that asynchronously submits the shell script job into an EC2 instance. For more information, see [Scheduling SSH jobs using AWS Lambda](#).
3. Create an Amazon Simple Storage Service (Amazon S3) trigger that invokes the Lambda function every time a legacy file is uploaded. For more information, see [Using an Amazon S3 trigger to invoke a Lambda function](#).

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

### Other tools

- [GitHub](#) is a code-hosting service that provides collaboration tools and version control.
- [Python](#) is a high-level programming language.

### Code repository

The code for this pattern is available in the [mainframe-data-utilities](#) GitHub repository.

## Epics

### Prepare the EC2 instance

Task	Description	Skills required
Launch an EC2 instance.	The EC2 instance must have outbound internet access.	General AWS

Task	Description	Skills required
	<p>This allows the instance to access the Python source code available on GitHub. To create the instance:</p> <ol style="list-style-type: none"><li>1. Open the Amazon EC2 console at <a href="https://console.aws.amazon.com/ec2">https://console.aws.amazon.com/ec2</a>.</li><li>2. Launch an EC2 Linux instance. Use a public IP address and allow inbound access through port 22. Ensure that the storage size of the instance is at least twice the size of the EBCDIC data file. For instructions, see the <a href="#">Amazon EC2 documentation</a>.</li></ol>	

Task	Description	Skills required
Install Git.	<ol style="list-style-type: none"><li data-bbox="592 226 1026 499">1. Using a secure shell (SSH) client, connect to the EC2 instance you just launched. For more information, see <a href="#">Connect to your Linux instance</a>.</li><li data-bbox="592 520 1026 699">2. In the Amazon EC2 console, run the following command. # Convert mainframe files from EBCDIC format to character-delimited ASCII format in Amazon S3 using AWS Lambda

Created by Luis Gustavo Dantas (AWS)

<b>Code repository:</b> <a href="#">Mainframe Data Utilities</a>	<b>Environment:</b> PoC or pilot	<b>Source:</b> IBM EBCDIC files
<b>Target:</b> Delimited ASCII files	<b>R Type:</b> Replatform	<b>Workload:</b> IBM
<b>Technologies:</b> Mainframe	<b>AWS services:</b> AWS CloudShell; AWS Lambda; Amazon S3; Amazon CloudWatch	

## Summary

This pattern shows you how to launch an AWS Lambda function that automatically converts mainframe EBCDIC (Extended Binary Coded Decimal Interchange Code) files to character-delimited ASCII (American Standard Code for Information Interchange) files. The Lambda function runs after the ASCII files are uploaded to an Amazon Simple Storage Service (Amazon S3) bucket. After the file conversion, you can read the ASCII files on x86-based workloads or load the files into modern databases.

The file conversion approach demonstrated in this pattern can help you overcome the challenges of working with EBCDIC files on modern environments. Files encoded in EBCDIC often contain data represented in a binary or packed decimal format, and fields are fixed-length. These characteristics create obstacles because modern x86-based workloads or distributed environments generally work with ASCII-encoded data and can't process EBCDIC files.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An S3 bucket

- An AWS Identity and Access Management (IAM) user with administrative permissions
- AWS CloudShell
- [Python 3.8.0](#) or later
- A flat file encoded in EBCDIC and its corresponding data structure in a common business-oriented language (COBOL) copybook

**Note:** This pattern uses a sample EBCDIC file ([CLIENT.EBCDIC.txt](#)) and its corresponding COBOL copybook ([COBKS05.cpy](#)). Both files are available in the GitHub [mainframe-data-utilities](#) repository.

## Limitations

- COBOL copybooks usually hold multiple layout definitions. The [mainframe-data-utilities](#) project can parse this kind of copybook but can't infer which layout to consider on data conversion. This is because copybooks don't hold this logic (which remains on COBOL programs instead). Consequently, you must manually configure the rules for selecting layouts after you parse the copybook.
- This pattern is subject to [Lambda quotas](#).

## Architecture

### Source technology stack

- IBM z/OS, IBM i, and other EBCDIC systems
- Sequential files with data encoded in EBCDIC (such as IBM Db2 unloads)
- COBOL copybook

### Target technology stack

- Amazon S3
- Amazon S3 event notification
- IAM
- Lambda function
- Python 3.8 or later
- Mainframe Data Utilities

- JSON metadata
- Character-delimited ASCII files

## Target architecture

The following diagram shows an architecture for converting mainframe EBCDIC files to ASCII files.

The diagram shows the following workflow:

1. The user runs the copybook parser script to convert the COBOL copybook into a JSON file.
2. The user uploads the JSON metadata to an S3 bucket. This makes the metadata readable by the data conversion Lambda function.
3. The user or an automated process uploads the EBCDIC file to the S3 bucket.
4. The S3 notification event triggers the data conversion Lambda function.
5. AWS verifies the S3 bucket read-write permissions for the Lambda function.
6. Lambda reads the file from the S3 bucket and locally converts the file from EBCDIC to ASCII.
7. Lambda logs the process status in Amazon CloudWatch.
8. Lambda writes the ASCII file back to Amazon S3.

**Note:** The copybook parser script runs only once, after it converts the metadata to JSON and then uploads that data to an S3 bucket. After the initial conversion, any EBCDIC file that uses the same JSON file that's uploaded to the S3 bucket will use the same metadata.

## Tools

### AWS tools

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS CloudShell](#) is a browser-based shell that you can use to manage AWS services by using the AWS Command Line Interface (AWS CLI) and a range of preinstalled development tools.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

### Other tools

- [GitHub](#) is a code-hosting service that provides collaboration tools and version control.
- [Python](#) is a high-level programming language.

### Code

The code for this pattern is available in the GitHub [mainframe-data-utilities](#) repository.

## Best practices

Consider the following best practices:

- Set the required permissions at the Amazon Resource Name (ARN) level.
- Always grant least-privilege permissions for IAM policies. For more information, see [Security best practices in IAM](#) in the IAM documentation.

# Epics

## Create environment variables and a working folder

Task	Description	Skills required
Create the environment variables.	<p>Copy the following environment variables to a text editor, and then replace the &lt;placeholder&gt; values in the following example with your resource values:</p> <pre data-bbox="594 716 1027 995">bucket=&lt;your_bucket_name&gt; account=&lt;your_account_number&gt; region=&lt;your_region_code&gt;</pre> <p><b>Note:</b> You will create references to your S3 bucket, AWS account, and AWS Region later.</p> <p>To define environment variables, open the <a href="#">CloudShell console</a>, and then copy and paste your updated environment variables onto the command line.</p> <p><b>Note:</b> You must repeat this step every time the CloudShell session restarts.</p>	General AWS
Create a working folder.	To simplify the resource clean-up process later on, create a working folder in	General AWS

Task	Description	Skills required
	<p>CloudShell by running the following command:</p> <pre data-bbox="594 327 1027 449">mkdir workdir; cd workdir</pre> <p><b>Note:</b> You must change the directory to the working directory (<code>workdir</code>) every time you lose a connection to your CloudShell session.</p>	

## Define an IAM role and policy

Task	Description	Skills required
<p>Create a trust policy for the Lambda function.</p>	<p>The EBCDIC converter runs in a Lambda function. The function must have an IAM role. Before you create the IAM role, you must define a trust policy document that enables resources to assume that policy.</p> <p>From the CloudShell working folder, create a policy document by running the following command:</p> <pre data-bbox="594 1629 1027 1885">E2ATrustPol=\$(cat &lt;&lt;EOF {   "Version":   "2012-10-17",   "Statement": [     {</pre>	<p>General AWS</p>

Task	Description	Skills required
	<pre>                 "Effect":                 "Allow",                 "Principa                 l": {                  "Service": "lambda.a                 mazonaws.com"                 },                 "Action":                 "sts:AssumeRole"                 }             ]         }     EOF ) printf "\$E2ATrustPol" &gt;     E2ATrustPol.json </pre>	
<p>Create the IAM role for Lambda conversion.</p>	<p>To create an IAM role, run the following AWS CLI command from the CloudShell working folder:</p> <pre> aws iam create-role   --role-name E2AConvLa   mbdaRole --assume-   role-policy-docume   nt file://E2ATrustPol   .json </pre>	<p>General AWS</p>

Task	Description	Skills required
Create the IAM policy document for the Lambda function.	<p>The Lambda function must have read-write access to the S3 bucket and write permissions for Amazon CloudWatch Logs.</p> <p>To create an IAM policy, run the following command from the CloudShell working folder:</p> <pre>E2APolicy=\$(cat &lt;&lt;EOF {   "Version":   "2012-10-17",   "Statement": [     {       "Sid":       "Logs",       "Effect":       "Allow",       "Action": [         "logs:PutLogEvents",         "logs:CreateLogStream",         "logs:CreateLogGroup"       ],       "Resource":       [         "arn:aws:logs:*:*:log-group:*",         "arn:aws:logs:*:*:log-group:*:log-stream:*"       ]     }   ] }</pre>	General AWS

Task	Description	Skills required
	<pre>        },         {             "Sid": "S3",             "Effect":                 "Allow",             "Action": [                 "s3:GetObject",                 "s3:PutObject",                 "s3:GetObjectVersion"             ],             "Resource":                 [                     "arn:aws:s3:::%s/*",                     "arn:aws:s3:::%s"                 ]         }     ] } EOF ) printf "\$E2APolicy" "\$bucket" "\$bucket" &gt; E2AConvLambdaPolicy.json</pre>	

Task	Description	Skills required
Attach the IAM policy document to the IAM role.	<p>To attach the IAM policy to the IAM role, run the following command from your CloudShell working folder:</p> <pre>aws iam put-role-policy --role-name E2AConvLambdaRole --policy-name E2AConvLambdaPolicy --policy-document file://E2AConvLambdaPolicy.json</pre>	General AWS

## Create the Lambda function for EBCDIC conversion

Task	Description	Skills required
Download the EBCDIC conversion source code.	<p>From the CloudShell working folder, run the following command to download the mainframe-data-utilities source code from GitHub:</p> <pre>git clone https://github.com/aws-samples/mainframe-data-utilities.git mdu</pre>	General AWS
Create the ZIP package.	<p>From the CloudShell working folder, run the following command to create the ZIP package that creates the Lambda function for EBCDIC conversion:</p>	General AWS

Task	Description	Skills required
	<pre>cd mdu; zip ../mdu.zip *.py; cd ..</pre>	
Create the Lambda function.	<p>From the CloudShell working folder, run the following command to create the Lambda function for EBCDIC conversion:</p> <pre>aws lambda create-function \ --function-name E2A \ --runtime python3.9 \ --zip-file fileb://mdu.zip \ --handler extract_ebcdic_to_ascii.lambda_handler \ --role arn:aws:iam::\$account:role/E2AConvLambdaRole \ --timeout 10 \ --environment "Variables={layout=\$bucket/layout/}"</pre> <p><b>Note:</b> The environment variable layout tells the Lambda function where the JSON metadata resides.</p>	General AWS

Task	Description	Skills required
<p>Create the resource-based policy for the Lambda function.</p>	<p>From the CloudShell working folder, run the following command to allow your Amazon S3 event notification to trigger the Lambda function for EBCDIC conversion:</p> <pre data-bbox="597 583 1027 1100">aws lambda add-permission \ --function-name E2A \ --action lambda:InvokeFunction \ --principal s3.amazonaws.com \ --source-arn arn:aws:s3:::\$bucket \ --source-account \$account \ --statement-id 1</pre>	<p>General AWS</p>

## Create the Amazon S3 event notification

Task	Description	Skills required
<p>Create the configuration document for the Amazon S3 event notification.</p>	<p>The Amazon S3 event notification initiates the EBCDIC conversion Lambda function when files are placed in the input folder.</p> <p>From the CloudShell working folder, run the following command to create the JSON document for the Amazon S3 event notification:</p>	<p>General AWS</p>

Task	Description	Skills required
	<pre>{   "LambdaFunctionConfigurations": [     {       "Id": "E2A",       "LambdaFunctionArn": "arn:aws:lambda:%s:%s:function:E2A",       "Events": [         "s3:ObjectCreated:Put" ],       "Filter": {         "Key": {           "FilterRules": [             {               "Name": "prefix",               "Value": "input/"             }           ]         }       }     }   ] } EOF ) printf "\$S3E2AEvent" "\$region" "\$account" &gt; S3E2AEvent.json</pre>	

Task	Description	Skills required
Create the Amazon S3 event notification.	<p>From the CloudShell working folder, run the following command to create the Amazon S3 event notification:</p> <pre>aws s3api put-bucket-notification-configuration --bucket \$bucket --notification-configuration file://S3E2AEvent.json</pre>	General AWS

## Create and upload the JSON metadata

Task	Description	Skills required
Parse the COBOL copybook.	<p>From the CloudShell working folder, run the following command to parse a sample COBOL copybook into a JSON file (which defines how to read and slice the data file properly):</p> <pre>python3 mdu/parse_copybook_to_json.py \ -copybook mdu/LegacyReference/COBKS05.cpy \ -output CLIENT.json \ -output-s3key CLIENT.ASCII.txt \ -output-s3bkt \$bucket \ -output-type s3 \</pre>	General AWS

Task	Description	Skills required
	<pre>-print          25</pre>	
Add the transformation rule.	<p>The sample data file and its corresponding COBOL copybook is a multi-layout file. This means that the conversion must slice data based on certain rules. In this case, bytes on position 3 and 4 in each row define the layout.</p> <p>From the CloudShell working folder, edit the <code>CLIENT.js</code> on file and change the contents from <code>"transf-rule": []</code>, to the following:</p> <pre>"transf-rule": [   {     "offset": 4,     "size": 2,     "hex": "0002",     "transf": "transf1"   },   {     "offset": 4,     "size": 2,     "hex": "0000",     "transf": "transf2"   } ],</pre>	General AWS, IBM Mainframe , Cobol

Task	Description	Skills required
Upload the JSON metadata to the S3 bucket.	<p>From the CloudShell working folder, run the following AWS CLI command to upload the JSON metadata to your S3 bucket:</p> <pre>aws s3 cp CLIENT.json s3://\$bucket/layout/ CLIENT.json</pre>	General AWS

## Convert the EBCDIC file

Task	Description	Skills required
Send the EBCDIC file to the S3 bucket.	<p>From the CloudShell working folder, run the following command to send the EBCDIC file to the S3 bucket:</p> <pre>aws s3 cp mdu/sample- data/CLIENT.EBCDIC.txt s3://\$bucket/input/</pre> <p><b>Note:</b> We recommend that you set different folders for input (EBCDIC) and output (ASCII) files to avoid calling the Lambda conversion function again when the ASCII file is uploaded to the S3 bucket.</p>	General AWS
Check the output.	<p>From the CloudShell working folder, run the following command to check if the</p>	General AWS

Task	Description	Skills required
	<p>ASCII file is generated in your S3 bucket:</p> <pre data-bbox="597 331 1026 411">awss3 ls s3://\$bucket/</pre> <p><b>Note:</b> The data conversion can take several seconds to happen. We recommend that you check for the ASCII file a few times.</p> <p>After the ASCII file is available , run the following command to download the file from the S3 bucket to the current folder:</p> <pre data-bbox="597 982 1026 1100">aws s3 cp s3://\$bucket/CLIENT.ASCII.txt .</pre> <p>Check the ASCII file content:</p> <pre data-bbox="597 1213 1026 1293">head CLIENT.ASCII.txt</pre>	

## Clean the environment

Task	Description	Skills required
(Optional) Prepare the variables and folder.	If you lose connection with CloudShell, reconnect and then run the following command to change the directory to the working folder:	General AWS

Task	Description	Skills required
	<pre>cd workdir</pre> <p>Ensure that the environment variables are defined:</p> <pre>bucket=&lt;your_bucket_name&gt; account=&lt;your_account_number&gt; region=&lt;your_region_code&gt;</pre>	
Remove the notification configuration for the bucket.	<p>From the CloudShell working folder, run the following command to remove the Amazon S3 event notification configuration:</p> <pre>aws s3api put-bucket-notification-configuration \ --bucket=\$bucket \ --notification-configuration="{}</pre>	General AWS
Delete the Lambda function.	<p>From the CloudShell working folder, run the following command to delete the Lambda function for the EBCDIC converter:</p> <pre>aws lambda delete-function --function-name E2A</pre>	General AWS

Task	Description	Skills required
Delete the IAM role and policy.	<p>From the CloudShell working folder, run the following command to remove the EBCDIC converter role and policy:</p> <pre>aws iam delete-role-policy --role-name E2AConvLambdaRole --policy-name E2AConvLambdaPolicy  aws iam delete-role --role-name E2AConvLambdaRole</pre>	General AWS
Delete the files generated in the S3 bucket.	<p>From the CloudShell working folder, run the following command to delete the files generated in the S3 bucket:</p> <pre>aws s3 rm s3://\$bucket/layout --recursive aws s3 rm s3://\$bucket/input --recursive aws s3 rm s3://\$bucket/CLIENT.ASCII.txt</pre>	General AWS
Delete the working folder.	<p>From the CloudShell working folder, run the following command to remove <code>workdir</code> and its contents:</p> <pre>cd ..; rm -Rf workdir</pre>	General AWS

# Convert mainframe data files with complex record layouts using Micro Focus

Created by Peter West

<b>Environment:</b> Production	<b>Source:</b> Mainframe EBCDIC Data Files	<b>Target:</b> Micro Focus ASCII Data Files
<b>R Type:</b> Rehost	<b>Workload:</b> All other workloads	<b>Technologies:</b> Mainframe; Modernization
<b>AWS services:</b> AWS Mainframe Modernization		

## Summary

This pattern shows you how to convert mainframe data files with non-text data and complex record layouts from EBCDIC (Extended Binary Coded Decimal Interchange Code) character encoding to ASCII (American Standard Code for Information Interchange) character encoding by using a Micro Focus structure file. To complete the file conversion, you must do the following:

1. Prepare a single source file that describes all the data items and record layouts in your mainframe environment.
2. Create a structure file that contains the record layout of the data by using the Micro Focus Data File Editor as part of the Micro Focus Classic Data File Tools or Data File Tools. The structure file identifies the non-text data so that you can correctly convert your mainframe files from EBCDIC to ASCII.
3. Test the structure file by using the Classic Data File Tools or Data File Tools.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Micro Focus Enterprise Developer for Windows, available through [AWS Mainframe Modernization](#)

## Product versions

- Micro Focus Enterprise Server 7.0 and later

## Tools

- [Micro Focus Enterprise Developer](#) provides the run environment for applications created with any integrated development environment (IDE) variant of Enterprise Developer.
- Micro Focus [Classic Data File Tools](#) help you convert, navigate, edit, and create data files. The Classic Data File Tools include [Data File Converter](#), [Record Layout Editor](#), and [Data File Editor](#).
- Micro Focus [Data File Tools](#) help you create, edit, and move data files. The Data File Tools include [Data File Editor](#), [File Conversion Utilities](#), and the [Data File Structure Command Line Utility](#).

## Epics

### Prepare the source file

Task	Description	Skills required
Identify source components.	<p>Identify all possible record layouts for the file, including any redefinitions that contain non-text data.</p> <p>If you have layouts that contain redefinitions, you must factor these layouts down to unique layouts that describe each possible permutation of the data structure. Typically, a data file's record layouts can be described by the following archetypes:</p> <ul style="list-style-type: none"> <li>• Record layout with only text data</li> </ul>	App developer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>Record layout with non-text data</li><li>Record layout with non-text data subordinate to a REDEFINES clause</li></ul> <p>For more information on creating flattened record layouts for files that contain complex record layouts, see <a href="#">Rehosting EBCDIC applications on ASCII environments for mainframe migrations</a>.</p>	

Task	Description	Skills required
Identify record layout conditions.	<p>For files with multiple record layouts or files that contain complex layouts with a REDEFINES clause, identify the data and conditions within a record that you can use to define which layout to use during conversion. We recommend that you discuss this task with a subject matter expert (SME) who understands the programs that process these files.</p> <p>For example, a file might contain two record types that contain non-text data. You can inspect the source and possibly find code similar to the following:</p> <pre data-bbox="594 1188 1027 1465">MOVE "M" TO PART-TYPE MOVE "MAIN ASSEMBLY" TO PART-NAME MOVE "S" TO PART-TYPE MOVE "SUB ASSEMBLY 1" TO PART-NAME</pre> <p>The code helps you identify the following:</p> <ul data-bbox="594 1633 982 1864" style="list-style-type: none"><li>• The "PART-TYPE" field is used to determine the record type</li><li>• The value "M" is used for the "M-PART-RECORD"</li></ul>	App developer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>The value "S" is used for the "S-PART-RECORD"</li></ul> <p>You can document the values that are used by this field to associate the record layouts with the correct data records in the file.</p>	
Build the source file.	<p>If the file is described over multiple source files or if the record layout contains non-text data that's subordinate to a REDEFINES clause, then create a new source file that contains the record layouts. The new program doesn't need to describe the file using SELECT and FD statements. The program can simply contain the record descriptions as 01 levels within Working-Storage.</p> <p><b>Note:</b> You can create a source file for each data file or create a master source file that describes all the data files.</p>	App developer

Task	Description	Skills required
Compile the source file.	<p>Compile the source file to build the data dictionary. We recommend that you compile the source file by using the EBCDIC character set. If the IBMCOMP directive or ODOSLIDE directives are being used, then you must use these directives in the source file too.</p> <p><b>Note:</b> IBMCOMP affects the byte storage of COMP fields and ODOSLIDE affects padding on OCCURS VARYING structures. If these directives are set incorrectly, then the conversion tool won't read the data record correctly. This results in bad data in the converted file.</p>	App developer

### (Option A) Create the structure file using Classic Data File Tools

Task	Description	Skills required
Start the tool and load the dictionary.	<ol style="list-style-type: none"> <li>1. Choose the Windows Start menu icon, search for and choose <b>Micro Focus Enterprise Developer</b>, and then choose <b>Classic Data File Tools</b>.</li> <li>2. Choose <b>File</b>, and then choose <b>Record Layout</b>.</li> </ol>	App developer

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="591 210 1029 533">3. In the <b>Select a file to construct the layouts from</b> dialog box, for <b>File name</b>, select the IDY (.idy) file that was created when you compiled the source file earlier. Then, choose <b>Open</b>.</li><li data-bbox="591 554 1029 877">4. To confirm that Classic Data File Tools is using EBCDIC, in the <b>Data File Tools</b> dialog box, choose <b>YES</b> if the IDY file is set to <b>EBCDIC</b> and <b>Datatools</b> is set to <b>ANSI</b>.</li></ol>	

Task	Description	Skills required
Create the default record layout.	<p>Use the default record layout for all records that don't match any conditional layouts.</p> <ol style="list-style-type: none"><li>1. In the <b>Layout</b> window, expand the data structure , and then locate the 01 level used for the default layout.</li><li>2. Right-click the 01 item, and then choose <b>New Layout</b>.</li><li>3. In the <b>New Record Layout Wizard</b> dialog box, choose <b>Default Layout</b>, and then choose <b>Next</b>.</li><li>4. Choose <b>Finish</b>.</li></ol> <p>The default layout appears in the <b>Layouts</b> pane and can be identified by the red folder icon.</p>	App developer

Task	Description	Skills required
Create a conditional record layout.	<p>Use the conditional record layout when there is more than one record layout in a file.</p> <ol style="list-style-type: none"><li>1. In the <b>Layouts</b> pane, expand the data structure , and then locate the 01 level used for the conditional layout.</li><li>2. Right-click the 01 item, and then choose <b>New Layout</b>.</li><li>3. In the <b>New Record Layout Wizard</b> dialog box, choose <b>Conditional Layout</b>, and then choose <b>Next</b>.</li><li>4. Choose <b>Finish</b>. The conditional layout appears in the <b>Layouts</b> pane and can be identified by the yellow folder icon.</li><li>5. Expand the conditional layout, right-click the field where you must place a condition, and then choose <b>Properties</b>.</li><li>6. In the <b>Field Properties</b> dialog box, enter the condition. Confirm that the character set is set to <b>EBCDIC</b>, and then choose <b>OK</b>. A checkmark appears</li></ol>	App developer

Task	Description	Skills required
	<p>next to the field that has a condition set.</p> <ol style="list-style-type: none"> <li>7. Repeat steps 5–6 for any other fields that require conditions for this layout.</li> <li>8. Repeat steps 1–6 for any other conditional layouts that must be added.</li> <li>9. Choose <b>File</b>, choose <b>Save As</b>, and then save the structure file to disk.</li> </ol>	

### (Option B) Create the structure file using Data File Tools

Task	Description	Skills required
<p>Start the tool and load the dictionary.</p>	<ol style="list-style-type: none"> <li>1. Choose the Windows Start menu icon, search for and choose <b>Micro Focus Enterprise Developer</b>, and then choose <b>Data File Tools</b>.</li> <li>2. Choose <b>File, New, Structure File</b>.</li> <li>3. In the <b>Open</b> dialog box, for <b>File name</b>, select the IDY (.idy) file that was created when you compiled the source file earlier. Then, choose <b>Open</b>.</li> <li>4. To confirm that Data File Tools is using EBCDIC, confirm that the drop-</li> </ol>	<p>App developer</p>

Task	Description	Skills required
	down menu in the <b>Debug File</b> section is set to <b>EBCDIC</b> .	
Create the default record layout.	<p>Use the default record layout for all records that do not match any conditional layouts.</p> <ol style="list-style-type: none"><li>1. In the <b>Available Layouts</b> section on the left pane, expand the data structure , and then locate the 01 level used for the default layout.</li><li>2. Right-click the 01 item, and then choose <b>Create Default Layout</b>.</li></ol> <p>The default layout appears in the <b>Layouts</b> pane and can be identified by the blue “D” icon.</p>	App developer

Task	Description	Skills required
Create a conditional record layout.	<p>Use the conditional record layout when there is more than one record layout in a file.</p> <ol style="list-style-type: none"><li>1. In the <b>Selected Layouts</b> section on the right pane, expand the data structure , and then locate the 01 level used for the conditional layout.</li><li>2. Right-click the 01 item, and then choose <b>Create Conditional Layout</b>. The conditional layout appears in the <b>Layouts</b> pane on the right side and can be identified by the green "C" icon.</li><li>3. Expand the conditional layout, right-click the field where you must place a condition, and then choose <b>Properties</b>.</li><li>4. In the <b>Field Properties</b> dialog box, enter the condition. Confirm that the character set is set to <b>EBCDIC</b>, and then choose <b>OK</b>. A red "IF" icon appears next to the field that has a condition set.</li></ol>	App developer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>5. Repeat steps 3–4 for any other fields that require conditions for this layout.</li> <li>6. Repeat steps 1–4 for any other conditional layouts that must be added.</li> <li>7. Choose <b>File</b>, choose <b>Save As</b>, and then save the structure file to disk.</li> </ol>	

### (Option A) Test the structure file using Classic Data File Tools

Task	Description	Skills required
Test an EBCDIC data file.	<p>Confirm that you can use your structure file to view an EBCDIC test data file correctly</p> <ul style="list-style-type: none"> <li>•</li> <li>1. Choose the Windows Start menu icon, find and choose <b>Micro Focus Enterprise Developer</b>, and then choose <b>Classic Data Tools</b>.</li> <li>2. Choose <b>File</b>, and then choose <b>Open</b>.</li> <li>3. In the <b>Open</b> dialog box, for <b>File name</b>, select the EBCDIC dataset, and then choose <b>Open</b>.</li> <li>4. Choose <b>File, Data File Editor, Load Record Layouts</b>.</li> </ul>	App developer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>5. In the <b>Open</b> dialog box, for <b>File name</b>, select the structure file, and then choose <b>Open</b>.</li> <li>6. To confirm that the character set mode is set to EBCDIC, confirm that the drop-down menu is set to <b>EBCDIC</b>. You can see the raw record data in the left pane and the formatted data in the right pane.</li> <li>7. Choose various records to ensure that all formats are rendered with the correct layout.</li> </ol>	

### (Option B) Test the structure file using Data File Tools

Task	Description	Skills required
Test an EBCDIC data file.	<p>Confirm that you can use your structure file to view an EBCDIC test data file correctly</p> <ul style="list-style-type: none"> <li>•</li> <li>1. Choose the Windows Start menu icon, find and select <b>Micro Focus Enterprise Developer</b>, and then choose <b>Data File Tools</b>.</li> <li>2. Choose <b>File, Open, Data File</b>.</li> </ul>	App developer

Task	Description	Skills required
	<ol style="list-style-type: none"><li>3. In the <b>Open Data File</b> dialog box, on the <b>Local</b> tab, for <b>Filename</b>, choose <b>Browse</b> to find the location of the EBCDIC test file.</li><li>4. For <b>Structure File (optional)</b>, choose <b>Browse</b> to find the location of the structure file.</li><li>5. In the <b>File Details</b> section, enter the details of the file and confirm that <b>Encoding</b> is set to <b>EBCDIC</b>.</li><li>6. Choose either <b>Open Shared</b> or <b>Open Exclusive</b> mode depending on your requirements.</li><li>7. Confirm that the drop-down menu in the <b>Appearance</b> section of the toolbar is set to <b>EBCDIC</b>. You will see the raw record data in the left pane and the formatted data in the right pane.</li><li>8. Choose various records to ensure that all formats are rendered with the correct layout.</li></ol>	

## Test data file conversion

Task	Description	Skills required
Test the conversion of an EBCDIC file.	<ol style="list-style-type: none"><li>1. Choose the Windows Start menu icon, find and select <b>Micro Focus Enterprise Developer</b>, and then choose <b>Classic Data Tools</b>.</li><li>2. Choose <b>Tools</b>, and then choose <b>Convert</b>.</li><li>3. In the <b>Data File Convert</b> dialog box, in the <b>Input file</b> section, for <b>Filename</b>, choose <b>Browse</b> to find and select the EBCDIC input file. Confirm that <b>Character set</b> is set to <b>EBCDIC</b>.</li><li>4. In the <b>Character Set Conversion</b> section, select the <b>Convert character set</b> and <b>Records contain non-text data items</b> check boxes. Choose <b>Select layout for conversion</b>, and then choose <b>Browse</b> to find and select the structure file.</li><li>5. In the <b>New file</b> section, for <b>Filename</b>, enter the path and file name of the ASCII output file that you want to create. By default, the conversion tool defaults to the same format as the</li></ol>	App developer

Task	Description	Skills required
	<p>input file. For testing, leave the options set to their default values.</p> <ol style="list-style-type: none"><li>6. Choose <b>Convert</b>.</li><li>7. Follow the steps in either the <i>(Option A) Test the structure file using Classic Data File Tools</i> or <i>(Option B) Test the structure file using Data File Tools</i> section, but load the ASCII output file instead of the EBCDIC file.</li><li>8. Load both the EBCDIC and ASCII files into the Data File Editor, and then compare the files side by side to check the accuracy of the conversion.</li></ol>

# Deploy an environment for containerized Blu Age applications by using Terraform

Created by Richard Milner-Watts (AWS)

<b>Code repository:</b> <a href="#">Blu Age Sample ECS Infrastructure (Terraform)</a>	<b>Environment:</b> Production	<b>Source:</b> Mainframe
<b>Target:</b> Containers	<b>R Type:</b> Replatform	<b>Workload:</b> IBM; All other workloads
<b>Technologies:</b> Mainframe; Containers & microservices	<b>AWS services:</b> Amazon ECS; AWS Step Functions; Amazon VPC; Amazon Aurora	

## Summary

Migrating legacy mainframe workloads into modern cloud architectures can eliminate the costs of maintaining a mainframe—costs that only increase as the environment ages. However, migrating jobs from a mainframe can pose unique challenges. Internal resources might not be familiar with the job logic, and the high performance of mainframes at these specialized tasks can be difficult to replicate when compared to commodity, generalized CPUs. Rewriting these jobs can be a large undertaking and require significant effort.

Blu Age converts legacy mainframe workloads into modern Java code, which you can then run as a container.

This pattern provides a sample serverless architecture for running a containerized application that has been modernized with the Blu Age tool. The included HashiCorp Terraform files will build a secure architecture for the orchestration of Blu Age containers, supporting both batch tasks and real-time services.

For more information about modernizing your workloads by using Blu Age and AWS services, see these AWS Prescriptive Guidance publications:

- [Running mainframe workloads that have been modernized with Blu Age on AWS serverless infrastructure](#)
- [Containerize mainframe workloads that have been modernized by Blu Age](#)

For assistance with using Blu Age to modernize your mainframe workloads, contact the Blu Age team by choosing **Contact our experts** on the [Blu Age website](#). For assistance with migrating your modernized workloads to AWS, integrating them with AWS services, and moving them into production, contact your AWS account manager or fill out the [AWS Professional Services form](#).

## Prerequisites and limitations

### Prerequisites

- The sample containerized Blu Age application provided by the [Containerize mainframe workloads that have been modernized by Blu Age](#) pattern. The sample application provides the logic to handle the processing of input and output for the modernized application, and it can integrate with this architecture.
- Terraform is required to deploy these resources.

### Limitations

- Amazon Elastic Container Service (Amazon ECS) places limits on the task resources that can be made available to the container. These resources include CPU, RAM, and storage. For example, when using Amazon ECS with AWS Fargate, the [task resource limits apply](#).

### Product versions

This solution was tested with the following versions:

- Terraform 1.3.6
- Terraform AWS Provider 4.46.0

## Architecture

### Source technology stack

- Blu Age

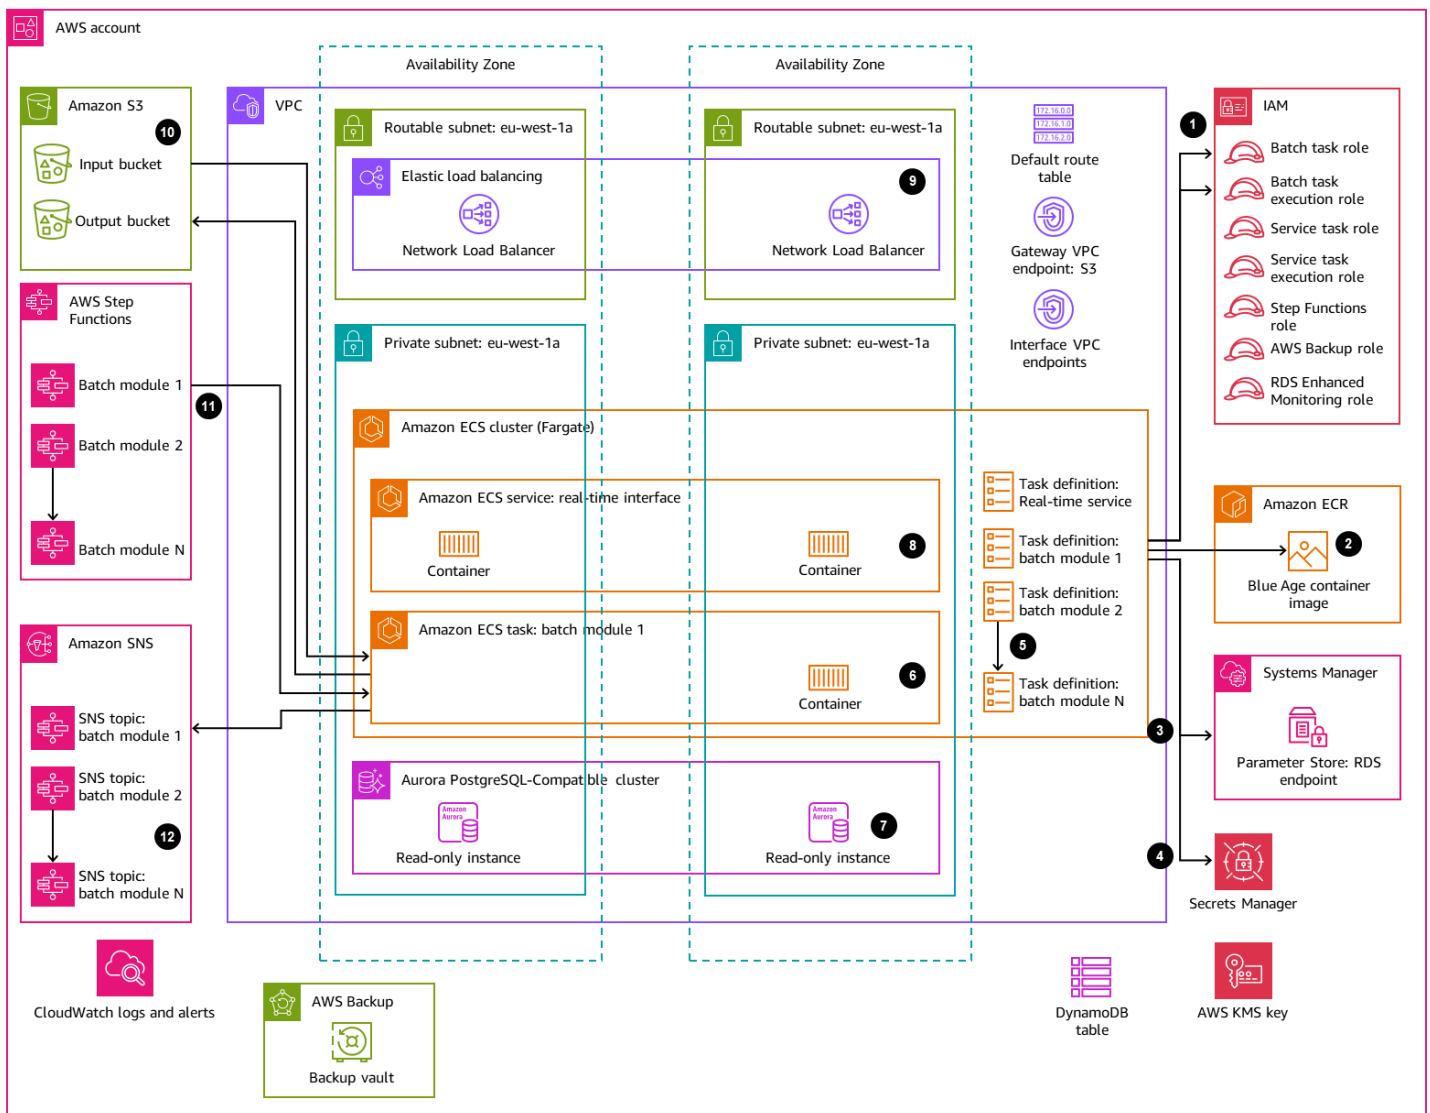

- Terraform

### **Target technology stack**

- Amazon Aurora PostgreSQL-Compatible Edition
- AWS Backup
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- AWS Identity and Access Management Service (IAM)
- AWS Key Management Server (AWS KMS)
- AWS Secrets Manager
- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Storage Service (Amazon S3)
- AWS Step Functions
- AWS Systems Manager

### **Target architecture**

The following diagram shows the solution architecture.

1. The solution deploys the following IAM roles:

- Batch task role
- Batch task execution role
- Service task role
- Service task execution role
- Step Functions role
- AWS Backup role
- RDS Enhanced Monitoring role.

The roles conform to least-privileged access principles.

2. Amazon ECR is used to store the container image that is orchestrated by this pattern.
3. AWS Systems Manager Parameter Store provides configuration data about each environment to the Amazon ECS task definition at runtime.
4. AWS Secrets Manager provides sensitive configuration data about the environment to the Amazon ECS task definition at runtime. The data has been encrypted by AWS KMS.
5. The Terraform modules create Amazon ECS task definitions for all real-time and batch tasks.
6. Amazon ECS runs a batch task by using AWS Fargate as the compute engine. This is a short-lived task, initiated as required by AWS Step Functions.
7. Amazon Aurora PostgreSQL-Compatible provides a database to support the modernized application. This replaces mainframe databases such as IBM Db2 or IBM IMS DB.
8. Amazon ECS runs a long-lived service to deliver a modernized real-time workload. These stateless applications run permanently with containers spread across Availability Zones.
9. A Network Load Balancer is used to grant access to the real-time workload. The Network Load Balancer supports earlier protocols, such as IBM CICS. Alternatively, you can use an Application Load Balancer with HTTP-based workloads.
10. Amazon S3 provides object storage for job inputs and outputs. The container should handle pull and push operations into Amazon S3 to prepare the working directory for the Blu Age application.
11. The AWS Step Functions service is used to orchestrate running the Amazon ECS tasks to process batch workloads.
12. SNS topics for each batch workload are used to integrate the modernized application with other systems, such as email, or to initiate additional actions, such as delivering output objects from Amazon S3 into FTP.

**Note:** By default, the solution has no access to the internet. This pattern assumes that the virtual private cloud (VPC) will be connected to other networks using a service such as [AWS Transit Gateway](#). As such, multiple interface VPC endpoints are deployed to grant access to the AWS services used by the solution. To turn on direct internet access, you can use the toggle in the Terraform module to replace the VPC endpoints with an internet gateway and the associated resources.

## Automation and scale

The use of serverless resources throughout this pattern helps to ensure that, by scaling out, there are few limits on the scale of this design. This reduces *noisy neighbor concerns*, such as the

competition for compute resources that might be experienced on the original mainframe. Batch tasks can be scheduled to run simultaneously as needed.

Individual containers are limited by the maximum sizes supported by Fargate. For more information, see the [Task CPU and memory](#) section in the Amazon ECS documentation.

To [scale real-time workloads horizontally](#), you can add containers.

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [AWS Backup](#) is a fully managed service that helps you centralize and automate data protection across AWS services, in the cloud, and on premises.
- [Amazon Elastic Container Registry \(Amazon ECR\)](#) is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service \(AWS KMS\)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- [AWS Systems Manager Parameter Store](#) provides secure, hierarchical storage for configuration data management and secrets management.

## Other services

- [HashiCorp Terraform](#) is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses Terraform to create the sample architecture.

## Code repository

The source code for this pattern is available in the GitHub [Blu Age Sample ECS Infrastructure \(Terraform\)](#) repository.

## Best practices

- For test environments, use features such as the `forceDate` option to configure the modernized application to generate consistent test results by always running for a known time period.
- Tune each task individually to consume the optimal amount of resources. You can use [Amazon CloudWatch Container Insights](#) to obtain guidance on potential bottlenecks.

## Epics

### Prepare the environment for deployment

Task	Description	Skills required
Clone the solution source code.	Clone the solution code from the <a href="#">GitHub project</a> .	DevOps engineer
Bootstrap the environment by deploying resources to store the Terraform state.	<ol style="list-style-type: none"> <li>1. Open a terminal window, and confirm that Terraform is installed and that AWS credentials are available.</li> <li>2. Navigate to the <code>bootstrap-terraform</code> folder.</li> <li>3. Edit the file <code>main.tf</code> if you want to change the names of the S3 bucket</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>(<code>&lt;accountId&gt;-terraform-backend</code> ) and Amazon DynamoDB table (<code>terraform-lock</code> ).</p> <p>4. Run the <code>terraform apply</code> command to deploy the resources. Make a note of the S3 bucket and DynamoDB table names.</p>	

## Deploy the solution infrastructure

Task	Description	Skills required
<p>Review and update the Terraform configuration.</p>	<p>In the root directory, open the file <code>main.tf</code>, review the contents, and consider making the following updates:</p> <ol style="list-style-type: none"> <li>1. Update the AWS Region by searching for and replacing the string <code>eu-west-1</code> with desired Region that you want to use.</li> <li>2. Update the bucket name in the Terraform Backend block if the default was altered in the previous epic.</li> <li>3. Update the <code>dynamodb_table</code> value if the default was altered in the previous epic.</li> </ol>	<p>DevOps engineer</p>

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 1008 533">4. Update the value of the <code>stack_prefix</code> variable to the string that you want. This string will be prepended to the names of all resources created by this pattern.</li><li data-bbox="592 554 992 737">5. Update the value of the <code>vpc_cidr</code>. This should be at least a /24 address range.</li><li data-bbox="592 758 1024 1703">6. Review the <code>Locals</code> section. This is used to define the Blu Age tasks that will be deployed. The solution will iterate over the list object <code>bluage_batch_modules</code>, creating the associated resources (Step Functions state machine, task definition, and SNS topic) for each element of the list. In some cases, you might want to adjust variables for different environments. For example, to force the runtime in test environments, you can change value of the <code>force_execution_time</code> variable.</li><li data-bbox="592 1724 1008 1850">7. To turn on internet access, change the value for <code>direct_internet_ac</code></li></ol>	

Task	Description	Skills required
	<p>cess_required from false to true. This will deploy an internet gateway, along with the NAT gateways and route tables that turn on public internet access for the infrastructure. By default, the solution will deploy interface VPC endpoints into a VPC without direct internet access.</p> <p>8. To grant access to any client-server workloads that are served through Elastic Load Balancing , update the values of additional_nlb_igress_cidrs with the CIDR networks that should be allowed.</p>	
Deploy the Terraform file.	<p>From your terminal, run the terraform apply command to deploy all resources. Review the changes generated by Terraform, and enter <b>yes</b> to initiate the build.</p> <p>Note that it can take over 15 minutes to deploy this infrastructure.</p>	DevOps engineer

## (Optional) Deploy a valid Blu Age containerized application

Task	Description	Skills required
Push the Blu Age container image to Amazon ECR.	<p>Push the container into the Amazon ECR repository that you created in the previous epic. For instructions, see the <a href="#">Amazon ECR documentation</a>.</p> <p>Make a note of the container image URI.</p>	DevOps engineer
Update the Terraform to reference the Blu Age container image.	Update the file <code>main.tf</code> to reference the container image that you uploaded.	DevOps engineer
Redeploy the Terraform file.	From your terminal, run <code>terraform apply</code> to deploy all resources. Review the suggested updates from Terraform, and then enter <b>yes</b> to proceed with the deployment.	DevOps engineer

# Generate data insights by using AWS Mainframe Modernization and Amazon Q in QuickSight

**Environment:** PoC or pilot

**Technologies:** Mainframe  
; Analytics; Migration;  
Modernization; Machine  
learning & AI

**Workload:** IBM

**AWS services:** AWS Lambda;  
AWS Mainframe Moderniza  
tion; Amazon QuickSight;  
Amazon S3

## Summary

If your organization is hosting business-critical data in a mainframe environment, gaining insights from that data is crucial for driving growth and innovation. By unlocking mainframe data, you can build faster, secure, and scalable business intelligence to accelerate data-driven decision-making, growth, and innovation in the Amazon Web Services (AWS) Cloud.

This pattern presents a solution for generating business insights and creating sharable narratives from mainframe data by using [AWS Mainframe Modernization File Transfer](#) with BMC and [Amazon Q in QuickSight](#). Mainframe datasets are transferred to [Amazon Simple Storage Service \(Amazon S3\)](#) by using AWS Mainframe Modernization File Transfer with BMC. An AWS Lambda function formats and prepares mainframe data file for loading into Amazon QuickSight.

After the data is available in Amazon QuickSight, you can use natural language prompts with Amazon Q in QuickSight to create summaries of the data, ask questions, and generate data stories. You don't have to write SQL queries or learn a business intelligence (BI) tool.

## Business context

This pattern presents a solution for mainframe data analytics and data insights use cases. Using the pattern, you build a visual dashboard for your company's data. To demonstrate the solution, this pattern uses a health care company that provides medical, dental, and vision plans to its

members in the US. In this example, member demographics and plan information are stored in the mainframe datasets. The visual dashboard shows the following:

- Member distribution by region
- Member distribution by gender
- Member distribution by age
- Member distribution by plan type
- Members who have not completed preventive immunization

After you create the dashboard, you generate a data story that explains the insights from the previous analysis. The data story provides recommendations for increasing the number of members who have completed preventive immunizations.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Mainframe datasets with business data
- Access to install a file transfer agent on the mainframe

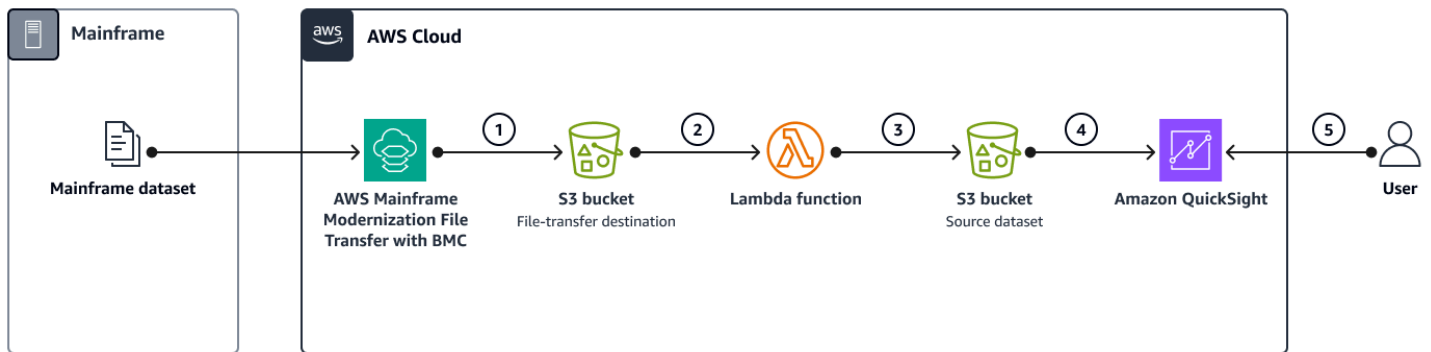

### Limitations

- Your mainframe data file should be in one of the file formats supported by Amazon QuickSight. For a list supported file formats, see the [Amazon QuickSight documentation](#).

This pattern uses a Lambda function to convert the mainframe file into a format supported by Amazon QuickSight.

## Architecture

The following diagram shows an architecture for generating business insights from mainframe data by using AWS Mainframe Modernization File Transfer with BMC and Amazon Q in QuickSight.

The diagram shows the following workflow:

1. A mainframe dataset containing business data is transferred to Amazon S3 by using AWS Mainframe Modernization File Transfer with BMC.
2. The Lambda function converts the file that's in the file-transfer destination S3 bucket to comma-separated values (CSV) format.
3. The Lambda function sends the converted file to the source dataset S3 bucket.
4. The data in the file is ingested by Amazon QuickSight.
5. Users access the data in Amazon QuickSight. You can use Amazon Q in QuickSight to interact with the data by using natural language prompts.

## Tools

### AWS services

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Mainframe Modernization File Transfer with BMC](#) converts and transfers mainframe datasets to Amazon S3 for mainframe modernization, migration, and augmentation use cases.
- [Amazon QuickSight](#) is a cloud-scale BI service that helps you visualize, analyze, and report your data in a single dashboard. This pattern uses the generative BI capabilities of [Amazon Q in QuickSight](#).
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

## Best practices

- When you create the AWS Identity and Access Management (IAM) roles for AWS Mainframe Modernization File Transfer with BMC and the Lambda function, follow the principle of [least privilege](#).
- Ensure that your source dataset has [supported data types](#) for Amazon QuickSight. If your source dataset contains unsupported data types, convert them to supported data types. For information about unsupported mainframe data types and how to convert them to data types supported by Amazon Q in QuickSight, see the [Related resources](#) section.

## Epics

### Set up AWS Mainframe Modernization File Transfer with BMC

Task	Description	Skills required
Install the file transfer agent.	To install AWS Mainframe Modernization File Transfer Agent on your mainframe, follow the instructions in the <a href="#">AWS documentation</a> .	Mainframe system administrator
Create an S3 bucket for mainframe file transfer.	<a href="#">Create an S3 bucket</a> to store the output file from AWS Mainframe Modernization File Transfer with BMC. In the architecture diagram, this is the file-transfer destination bucket.	Migration engineer
Create the data transfer endpoint.	<ol style="list-style-type: none"> <li>1. Create an S3 bucket to stage the input mainframe file for AWS Mainframe Modernization File Transfer with BMC.</li> <li>2. To create the mainframe data transfer endpoint,</li> </ol>	AWS Mainframe Modernization specialist

Task	Description	Skills required
	follow the instructions in the <a href="#">AWS documentation</a> .	

## Convert the mainframe file name extension for Amazon QuickSight integration

Task	Description	Skills required
Create an S3 bucket.	<a href="#">Create an S3 bucket</a> for the Lambda function to copy the converted mainframe file from the source to the final destination bucket.	Migration engineer
Create a Lambda function.	To create a Lambda function that changes the file extension and copies the mainframe file to the destination bucket, do the following: <ol style="list-style-type: none"> <li>1. Sign in to the AWS Management Console, and navigate to the AWS Lambda console.</li> <li>2. Choose <b>Create function</b>, and then choose <b>Author from scratch</b>.</li> <li>3. For <b>Function name</b>, enter a name for your function.</li> <li>4. In the <b>Runtime</b> dropdown list, choose <b>Python.3.X</b>.</li> <li>5. Expand <b>Change default execution role</b>, and then choose <b>Create a new</b></li> </ol>	Migration engineer

Task	Description	Skills required
	<p><b>role with basic Lambda permissions.</b></p> <ol style="list-style-type: none"><li>6. Choose <b>Create function</b>.</li><li>7. Choose the <b>Code</b> tab, and then paste the <code>S3CopyLambda.py</code> Python code that's provided in the <a href="#">Additional information</a> section. The Python code was generated by using <a href="#">Amazon Q Developer</a> in the Microsoft Visual Studio integrated development environment (IDE).</li><li>8. Edit the <code>destination_bucket_name</code> to the name of the S3 bucket that you created previously, and change <code>destination_file_key</code> to the mainframe file name.</li><li>9. Deploy the Lambda function.</li></ol>	

Task	Description	Skills required
Create an Amazon S3 trigger to invoke the Lambda function.	<p>To configure a trigger that invokes the Lambda function, do the following:</p> <ol style="list-style-type: none"><li>1. On the Lambda console, open the <b>Functions</b> page.</li><li>2. Choose the Lambda function.</li><li>3. In <b>Function overview</b>, choose <b>Add trigger</b>.</li><li>4. In the <b>Trigger configuration</b> dropdown list, choose <b>S3</b>.</li><li>5. In the <b>Bucket</b> field, enter the name of your source bucket.</li><li>6. In the <b>Event type</b> dropdown list, choose <b>All object create events</b>.</li><li>7. Select the <b>I acknowledge that using the same S3 bucket for both input and output is not recommended</b> check box, and then choose <b>Add</b>.</li></ol> <p>For more information, see <a href="#">Tutorial: Using an Amazon S3 trigger to invoke a Lambda function</a>.</p>	Migration lead

Task	Description	Skills required
Provide IAM permissions for the Lambda function.	<p>IAM permissions are required for the Lambda function to access the file-transfer destination and source dataset S3 buckets. Update the policy associated with the Lambda function execution role by allowing <code>s3:GetObject</code> and <code>s3:DeleteObject</code> permissions for the file-transfer destination S3 bucket and <code>s3:PutObject</code> access for the source dataset S3 bucket.</p> <p>For more information, see the <a href="#">Create a permissions policy</a> section in <i>Tutorial: Using an Amazon S3 trigger to invoke a Lambda function</i>.</p>	Migration lead

## Define a mainframe data transfer task

Task	Description	Skills required
Create a transfer task to copy the mainframe file to the S3 bucket.	<p>To create a mainframe file transfer task, follow the instructions in the <a href="#">AWS Mainframe Modernization documentation</a>.</p> <p><b>Note:</b> Specify <b>Source code page</b> encoding as <b>IBM1047</b></p>	Migration engineer

Task	Description	Skills required
	and <b>Target code page</b> encoding as <b>UTF-8</b> .	
Verify the transfer task.	To verify that the data transfer is successful, follow the instructions in the <a href="#">AWS Mainframe Modernization documentation</a> . Confirm that the mainframe file is in the file-transfer destination S3 bucket.	Migration lead
Verify the Lambda copy function.	<p>Verify that the Lambda function is initiated and that the file is copied with a .csv extension to the source dataset S3 bucket.</p> <p>The .csv file created by the Lambda function is the input data file for Amazon QuickSight. For example data, see the Sample-data-member-healthcare-APG file in the <a href="#">Attachments</a> section.</p>	Migration lead

## Connect Amazon QuickSight to the mainframe data

Task	Description	Skills required
Set up Amazon QuickSight.	To set up Amazon QuickSight, follow the instructions in the <a href="#">AWS documentation</a> .	Migration lead

Task	Description	Skills required
Create a dataset for Amazon QuickSight.	To create a dataset for Amazon QuickSight, follow the instructions in the <a href="#">AWS documentation</a> . The input data file is the converted mainframe file that was created when you defined the mainframe data transfer task.	Migration lead

### Get business insights from the mainframe data by using Amazon Q in QuickSight

Task	Description	Skills required
Set up Amazon Q in QuickSight.	<p>This capability requires Enterprise Edition. To set up Amazon Q in QuickSight, do the following:</p> <ol style="list-style-type: none"> <li>1. To get the Amazon Q add-on, follow the instructions Step 1: Get the Q add-on in the <a href="#">AWS documentation</a>.</li> <li>2. To use the generative BI capabilities in Amazon Q, upgrade your users' accounts. Follow the instructions in the <a href="#">AWS documentation</a>.</li> <li>3. Create an Amazon Q topic by using the dataset that you created previously. Follow the instructions in the <a href="#">AWS documentation</a>.</li> </ol>	Migration lead

Task	Description	Skills required
	4. To configure the topic metadata so that it's natural language–friendly, follow the instructions in the <a href="#">AWS documentation</a> .	

Task	Description	Skills required
Analyze mainframe data and build a visual dashboard.	<p>To analyze and visualize your data in Amazon QuickSight, do the following:</p> <ol style="list-style-type: none"><li>1. To create the mainframe data analysis, follow the instructions in the <a href="#">AWS documentation</a>. For the dataset, choose the dataset created in the previous step.</li><li>2. On the analysis page choose <b>Build visual</b>.</li><li>3. In the <b>Create topic for analysis</b> window, choose <b>Update existing topic</b>.</li><li>4. In the <b>Select a topic</b> dropdown list, choose the topic that you created previously.</li><li>5. Choose <b>Topic linking</b>.</li><li>6. After you link the topic, choose <b>Build visual</b> to open the Amazon Q <b>Build a Visual</b> window.</li><li>7. In the prompt bar. write your analysis questions . The example questions used for this pattern are the following:<ul style="list-style-type: none"><li>• Show member distribution by region</li></ul></li></ol>	Migration engineer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• Show members distribution by age</li> <li>• Show member distribution by gender</li> <li>• Show member distribution by plan type</li> <li>• Show member not completed preventive immunization</li> </ul> <p>After you enter your questions, choose <b>Build</b>. Amazon Q in QuickSight creates the visuals.</p> <p>8. To add the visuals to your visual dashboard, choose <b>ADD TO ANALYSIS</b>.</p> <p>When you're finished, you can publish your dashboard to share with others in your organization. For examples, see <i>Mainframe visual dashboard</i> in the <a href="#">Additional information</a> section.</p>	

### Create a data story with Amazon Q in QuickSight from the mainframe data

Task	Description	Skills required
Create a data story.	Create a data story to explain insights from the previous	Migration engineer

Task	Description	Skills required
	<p>analysis, and generate a recommendation to increase preventive immunization for members:</p> <ol style="list-style-type: none"><li>1. To create the data story, follow the instructions in the <a href="#">AWS documentation</a>.</li><li>2. For the data story prompt, use the following:  Build a data story about Region with most numbers of members. Also show the member distribution by medical plan, vision plan, dental plan. Recommend how to motivate members to complete immunization. Include 4 points of supporting data for this pattern.  You can also build your own prompt to generate data stories for other business insights.</li><li>3. Choose <b>Add visuals</b>, and add the visuals that are relevant to the data story. For this pattern, use the</li></ol>	

Task	Description	Skills required
	<p>visuals that you created previously.</p> <p>4. Choose <b>Build</b>.</p> <p>5. For example data story output, see <i>Data story output</i> in the <a href="#">Additional information</a> section.</p>	
View the generated data story.	To view the generated data story, follow the instructions in the <a href="#">AWS documentation</a> .	Migration lead
Edit a generated data story.	To change the formatting, layout, or visuals in a data story, follow the instructions in the <a href="#">AWS documentation</a> .	Migration lead
Share a data story.	To share a data story, follow the instructions in the <a href="#">AWS documentation</a> .	Migration engineer

## Troubleshooting

Issue	Solution
Unable to discover the mainframe files or datasets entered in <b>Data sets search criteria</b> for <b>Create transfer task</b> in AWS Mainframe Modernization File Transfer with BMC.	<ol style="list-style-type: none"> <li>1. First, check the connection by choosing <b>Data transfer endpoints</b> on the AWS Mainframe Modernization Transfer with BMC console. If the last heartbeat time is greater than two minutes, the connection for file transfer hasn't been established. If the last heartbeat time is less than 2 minutes for the agent running on the</li> </ol>

Issue	Solution
	<p>mainframe, the connection to the agent is successful. Proceed to step 2.</p> <ol style="list-style-type: none"><li>2. Check the AWS Secrets Manager setup. A secret key must be configured in Secrets Manager with a <b>key</b> of <code>userId</code> (uppercase I) with a <b>value</b> of the mainframe's user ID and a <b>key</b> of <code>password</code> with the <b>value</b> of the mainframe password. The <code>userId</code> and <code>password</code> secret keys are case-sensitive and must be entered as is.</li></ol>

## Related resources

To convert mainframe data types such as [PACKED-DECIMAL \(COMP-3\)](#) or [BINARY \(COMP or COMP-4\)](#) to a [data type](#) supported by Amazon QuickSight, see the following patterns:

- [Convert and unpack EBCDIC data to ASCII on AWS by using Python](#)
- [Convert mainframe files from EBCDIC format to character-delimited ASCII format in Amazon S3 using AWS Lambda](#)

## Additional information

### S3CopyLambda.py

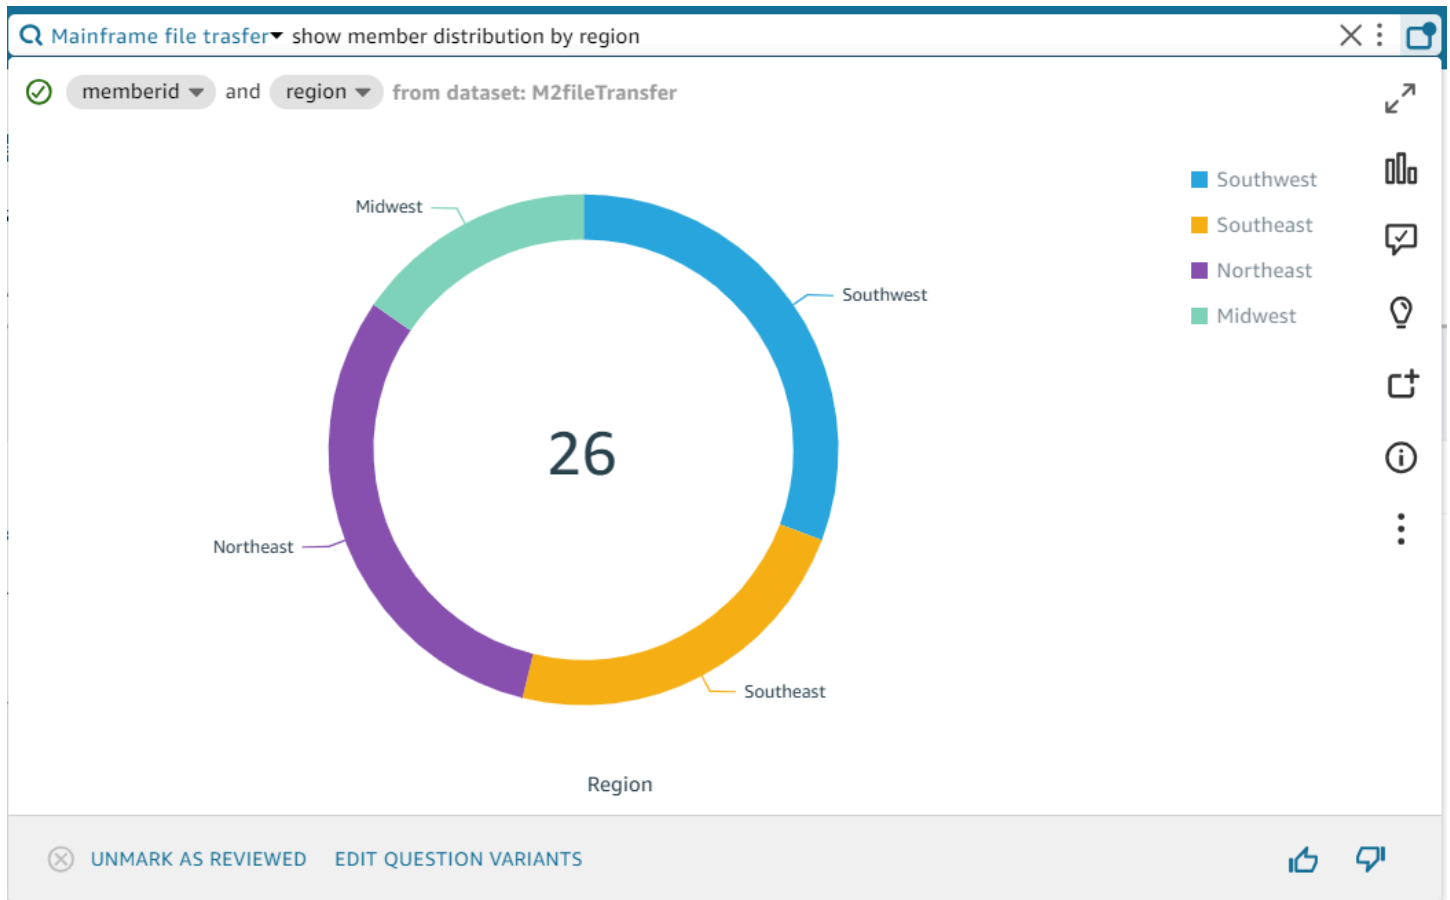

The following Python code was generated by using a prompt with Amazon Q Developer in an IDE:

```
#Create a lambda function triggered by S3. display the S3 bucket name and key
import boto3
s3 = boto3.client('s3')
def lambda_handler(event, context):
    print(event)
    bucket = event['Records'][0]['s3']['bucket']['name']
    key = event['Records'][0]['s3']['object']['key']
    print(bucket, key)
    #If key starts with object_created, skip copy, print "copy skipped". Return lambda with
    key value.
```

```
if key.startswith('object_created'):
    print("copy skipped")
    return {
        'statusCode': 200,
        'body': key
    }
# Copy the file from the source bucket to the destination bucket.
Destination_bucket_name = 'm2-filetransfer-final-opt-bkt'. Destination_file_key =
'healthdata.csv'
copy_source = {'Bucket': bucket, 'Key': key}
s3.copy_object(Bucket='m2-filetransfer-final-opt-bkt', Key='healthdata.csv',
    CopySource=copy_source)
print("file copied")
#Delete the file from the source bucket.
s3.delete_object(Bucket=bucket, Key=key)
return {
    'statusCode': 200,
    'body': 'Copy Successful'
}
```

## Mainframe visual dashboard

The following data visual was created by Amazon Q in QuickSight for the analysis question show member distribution by region.

The following data visual was created by Amazon Q in QuickSight for the question show member distribution by Region who have not completed preventive immunization, in pie chart.

## Data story output

The following screenshots show sections of the data story created by Amazon Q in QuickSight for the prompt Build a data story about Region with most numbers of members. Also show the member distribution by medical plan, vision plan, dental plan. Recommend how to motivate members to complete immunization. Include 4 points of supporting data.

In the introduction, the data story recommends choosing the region with the most members to gain the greatest impact from immunization efforts.

QuickSight | Leveraging Data to Strengthen Community Health: ...

BACK TO EDITOR | SHARE

# Leveraging Data to Strengthen Community Health: A Story of Immunization Rates

Prepared by [Name]

## Introduction

This presentation will focus on immunization completion rates among members of one health insurance provider. Understanding differences in rates across various regions served and demographic groups can point to areas that would most benefit from targeted efforts to increase immunizations. With insights drawn from member data, recommendations will be suggested for improving collaboration with at-risk communities.

## Member Distribution by Region

The data story provides an analysis of member numbers for the top three regions, and names the Southwest as the leading region for focusing on immunization efforts.

QuickSight | Increasing Immunization Rates: A Data-Driven Appr...

SCROLLABLE PAGE | Publish Changes | BACK TO EDITOR | SHARE

## Region with Most Members

Region	Number of Members	Percentage
Southwest	8	31%
Northeast	8	31%
Southeast	6	23%
Midwest	4	15%
<b>Total</b>	<b>26</b>	

According to the graph, the Southwest region has the highest number of enrolled members at 8. This is followed closely by the Northeast region also with 8 members. The Southeast region comes in third for total enrollment with 6 members. Given that the objective is to identify the region with the highest number of enrolled members, and based on the data insights from the graph showing the Southwest region in the lead, the Southwest region currently has the most health plan members enrolled of any region.

**Note:** The Southwest and Northeast regions each have eight members. However, the Southwest has more members that aren't fully vaccinated, so it has more potential to benefit from initiatives to increase immunization rates.

# Integrate Stonebranch Universal Controller with AWS Mainframe Modernization

Created by Vaidy Sankaran (AWS), Robert Lemieux (Stonebranch), Huseyin Gomleksizoglu (Stonebranch), and Pablo Alonso Prieto (AWS)

<b>Code repository:</b> <a href="#">aws-mainframe-modernization-stonebranch-integration</a>	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Mainframe ; DevOps; Modernization; Operations; SaaS
<b>Workload:</b> Open-source; Microsoft	<b>AWS services:</b> AWS Mainframe Modernization; Amazon RDS; Amazon S3	

## Summary

This pattern explains how to integrate [Stonebranch Universal Automation Center \(UAC\) workload orchestration](#) with [Amazon Web Services \(AWS\) Mainframe Modernization service](#). AWS Mainframe Modernization service migrates and modernizes mainframe applications to the AWS Cloud. It offers two patterns: [AWS Mainframe Modernization Replatform](#) with Micro Focus Enterprise Technology and [AWS Mainframe Modernization Automated Refactor](#) with AWS Blu Age.

Stonebranch UAC is a real-time IT automation and orchestration platform. UAC is designed to automate and orchestrate jobs, activities, and workflows across hybrid IT systems, from on-premises to AWS. Enterprise clients using mainframe systems are transitioning to cloud-centric modernized infrastructures and applications. Stonebranch's tools and professional services facilitate the migration of existing schedulers and automation capabilities to the AWS Cloud.

When you migrate or modernize your mainframe programs to the AWS Cloud using AWS Mainframe Modernization service, you can use this integration to automate batch scheduling, increase agility, improve maintenance, and decrease costs.

This pattern provides instructions for integrating [Stonebranch scheduler](#) with mainframe applications migrated to the [AWS Mainframe Modernization service Micro Focus Enterprise runtime](#). This pattern is for solutions architects, developers, consultants, migration specialists, and others working in migrations, modernizations, operations, or DevOps.

## Targeted outcome

This pattern focuses on providing the following target outcomes:

- The ability to schedule, automate, and run mainframe batch jobs running in [AWS Mainframe Modernization service \(Microfocus runtime\)](#) from [Stonebranch Universal Controller](#).
- Monitor the application's batch processes from the Stonebranch Universal Controller.
- Start/Restart/Rerun/Stop batch processes automatically or manually from the Stonebranch Universal Controller.
- Retrieve the results of the AWS Mainframe Modernization batch processes.
- Capture the [AWS CloudWatch](#) logs of the batch jobs in Stonebranch Universal Controller.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Micro Focus [Bankdemo](#) application with job control language (JCL) files, and a batch process deployed in a [AWS Mainframe Modernization service \(Micro Focus runtime\)](#) environment
- Basic knowledge of how to build and deploy a mainframe application that runs on Micro Focus [Enterprise Server](#)
- Basic knowledge of [Stonebranch Universal Controller](#)
- Stonebranch trial license (contact [Stonebranch](#))
- Windows or Linux Amazon Elastic Compute Cloud (Amazon EC2) instances (for example, xlarge) with a minimum of four cores, 8 GB memory, and 2 GB disk space
- Apache Tomcat version 8.5.x or 9.0.x
- Oracle Java Runtime Environment (JRE) or OpenJDK version 8 or 11
- [Amazon Aurora MySQL-Compatible Edition](#)
- [Amazon Simple Storage Service \(Amazon S3\)](#) bucket for export repository
- [Amazon Elastic File System \(Amazon EFS\)](#) for agent Stonebranch Universal Message Service (OMS) connections for high availability (HA)
- Stonebranch Universal Controller 7.2 Universal Agent 7.2 Installation Files
- AWS Mainframe Modernization [task scheduling template](#) (latest released version of the .zip file)

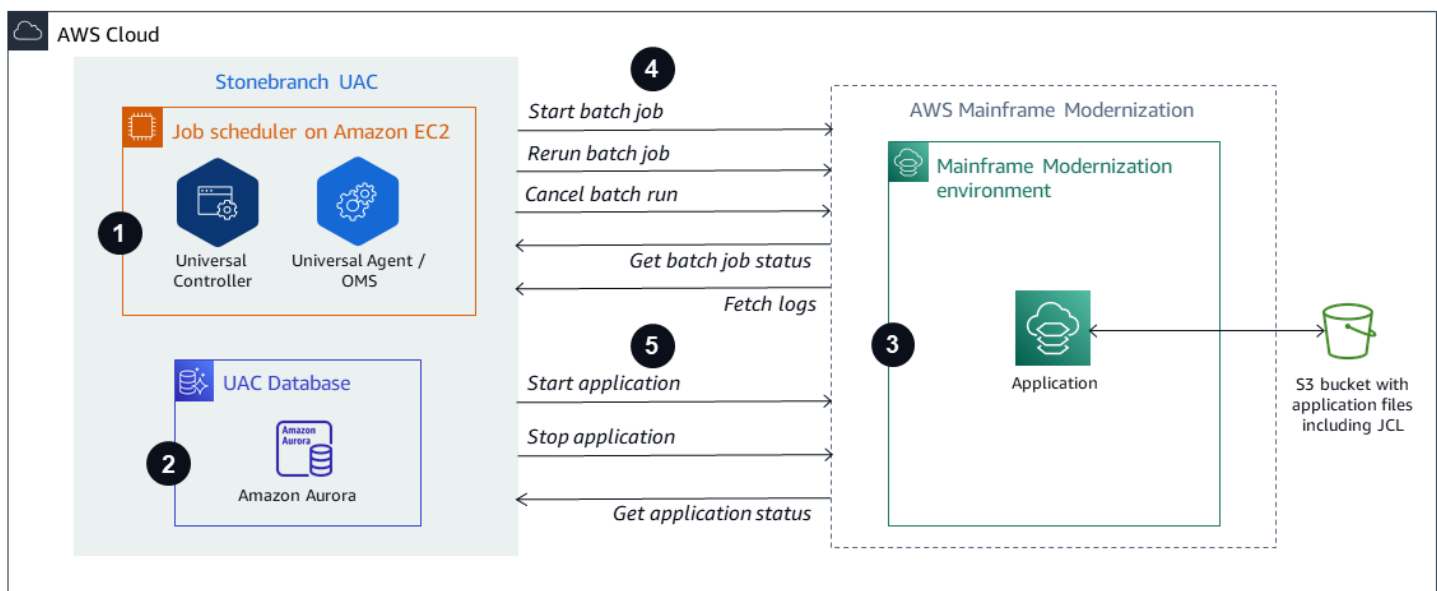

## Limitations

- The product and solution has been tested and compatibility validated only with OpenJDK 8 and 11.
- The [aws-mainframe-modernization-stonebranch-integration](#) task scheduling template will work only with AWS Mainframe Modernization service.
- This task scheduling template will work on only a Unix, Linux, or Windows edition of Stonebranch agents.

## Architecture

### Target state architecture

The following diagram shows the example AWS environment that is required for this pilot.

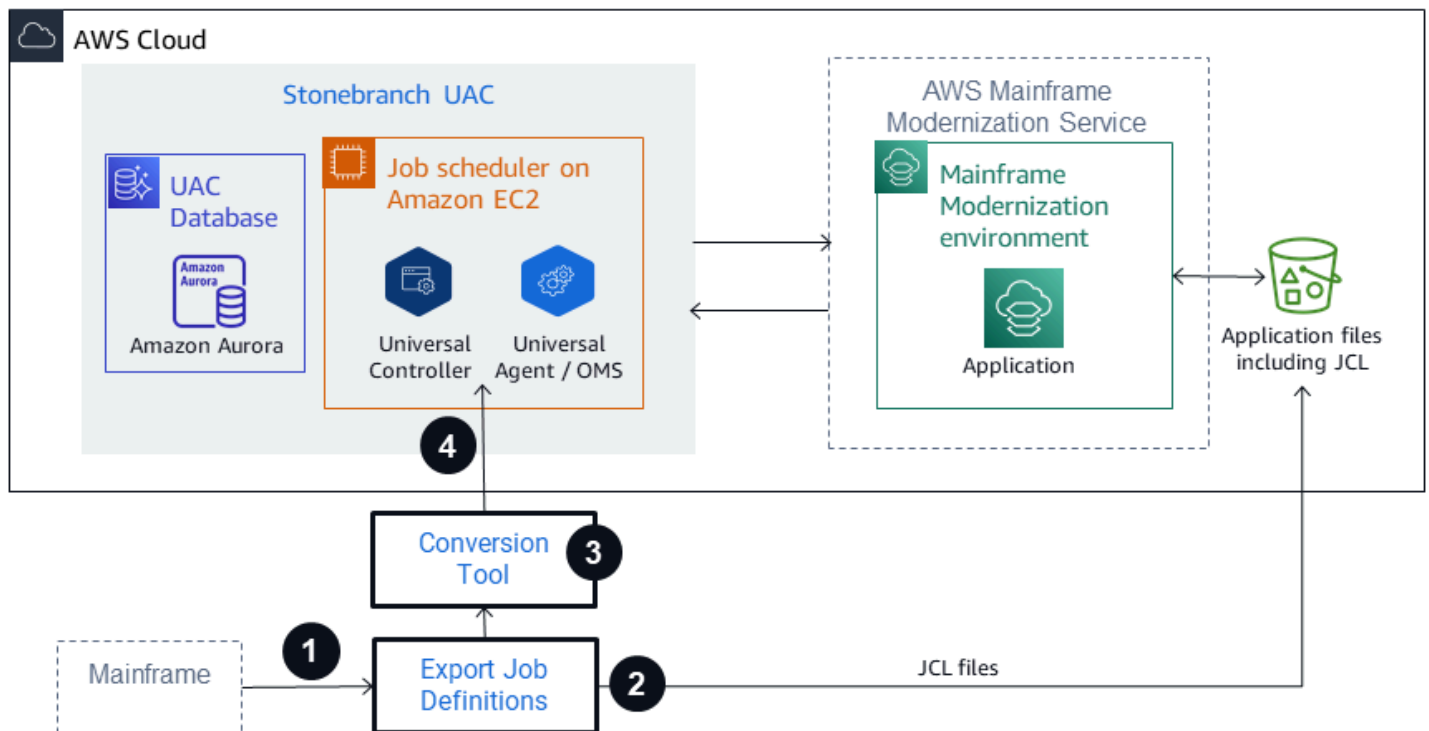

1. Stonebranch Universal Automation Center (UAC) includes two main components: Universal Controller and Universal Agents. Stonebranch OMS is used as a message bus between the controller and individual agents.
2. Stonebranch UAC Database is used by Universal Controller. The database can be MySQL, Microsoft SQL Server, Oracle, or Aurora MySQL–Compatible.
3. AWS Mainframe Modernization service – Micro Focus runtime environment with the [BankDemo application deployed](#). The BankDemo application files will be stored in an S3 bucket. This bucket also contains the mainframe JCL files.

4. Stonebranch UAC can run the following functions for the batch run:
  - a. Start a batch job using the JCL file name that exists in the S3 bucket linked to the AWS mainframe modernization service.
  - b. Get the status of the batch job run.
  - c. Wait until the batch job run is completed.
  - d. Fetch logs of the batch job run.
  - e. Rerun the failed batch jobs.
  - f. Cancel the batch job while the job is running.
5. Stonebranch UAC can run the following functions for the application:
  - a. Start Application
  - b. Get Status of the Application
  - c. Wait until the Application is started or stopped
  - d. Stop Application
  - e. Fetch Logs of Application operation

### **Stonebranch jobs conversion**

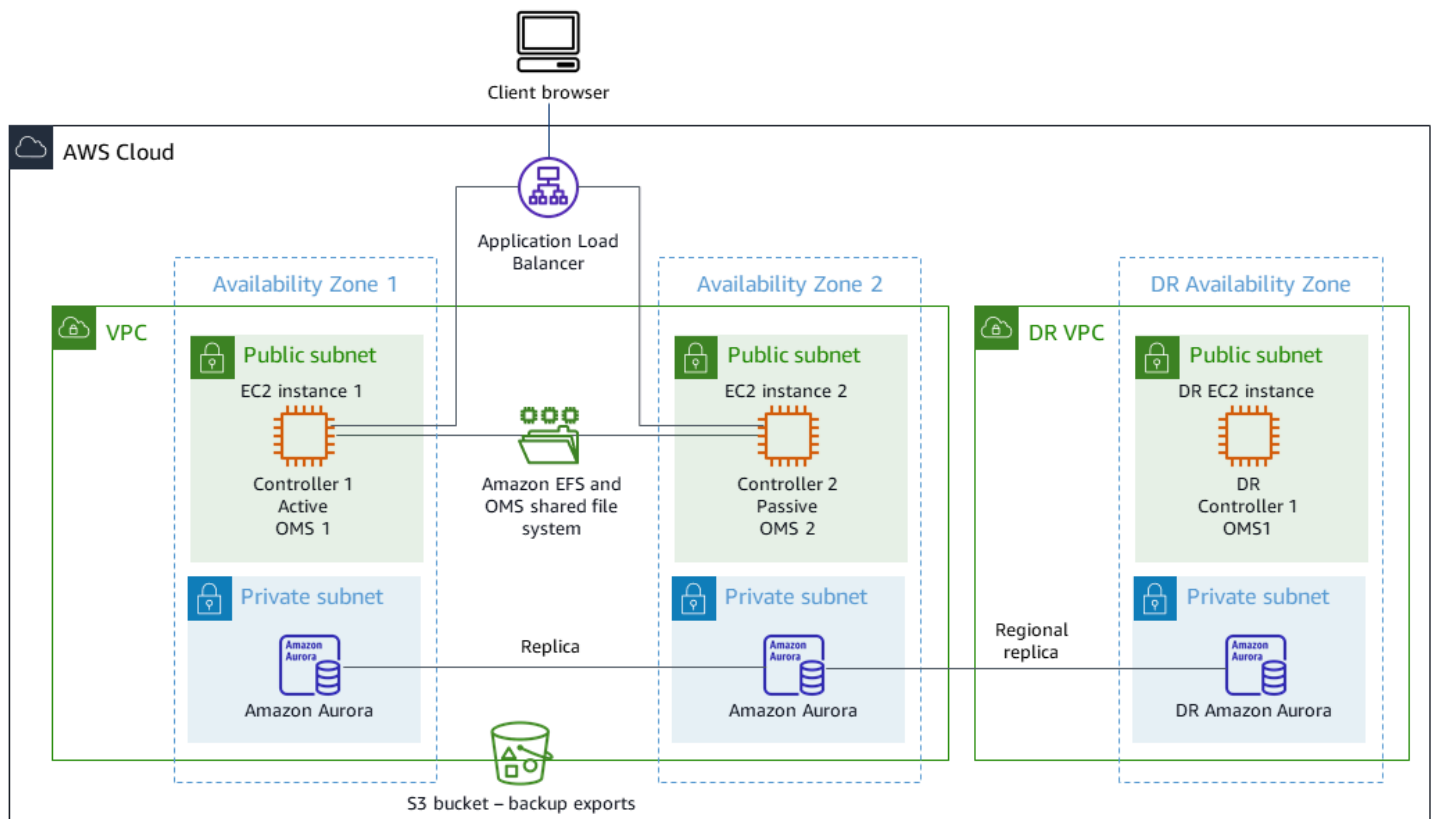

The following diagram represents Stonebranch's job conversion process during the modernization journey. It describes how the job schedules and tasks definitions are converted into a compatible format that can run AWS Mainframe Modernization batch tasks.

1. For the conversion process, the job definitions are exported from the existing mainframe system.
2. JCL files can be uploaded to the S3 bucket for the Mainframe Modernization application so that these JCL files can be deployed by the AWS Mainframe Modernization service.
3. The conversion tool converts the exported job definitions to UAC tasks.
4. After all the task definitions and job schedules are created, these objects will be imported to the Universal Controller. The converted tasks then run the processes in the AWS Mainframe Modernization service instead of running them on the mainframe.

## Stonebranch UAC architecture

The following architecture diagram represents an active-active-passive model of high availability (HA) Universal Controller. Stonebranch UAC is deployed in multiple Availability Zones to provide high availability and support disaster recovery (DR).

## Universal Controller

Two Linux servers are provisioned as Universal Controllers. Both connect to the same database endpoint. Each server houses a Universal Controller application and OMS. The most recent version of Universal Controller is used at the time it is provisioned.

The Universal Controllers are deployed in the Tomcat webapp as the document ROOT and are served on port 80. This deployment eases the configuration of the frontend load balancer.

HTTP over TLS or HTTPS is enabled using the Stonebranch wildcard certificate (for example, <https://customer.stonebranch.cloud>). This secures communication between the browser and the application.

## OMS

A Universal Agent and OMS (Opwise Message Service) reside on each Universal Controller server. All deployed Universal Agents from the customer end are set up to connect to both OMS services. OMS acts as a common messaging service between the Universal Agents and the Universal Controller.

Amazon EFS mounts a spool directory on each server. OMS uses this shared spool directory to keep the connection and task information from controllers and agents. OMS works in a high-availability mode. If the active OMS goes down, the passive OMS has access to all the data, and it resumes active operations automatically. Universal Agents detect this change and automatically connect to the new active OMS.

### *Database*

Amazon Relational Database Service (Amazon RDS) houses the UAC database, with Amazon Aurora MySQL–Compatible as its engine. Amazon RDS helps in managing and offering scheduled backups at regular intervals. Both Universal Controller instances connect to the same database endpoint.

### *Load balancer*

An Application Load Balancer is set-up for each instance. The load balancer directs traffic to the active controller at any given moment. Your instance domain names point to the respective load balancer endpoints.

### *URLs*

Each of your instances has a URL, as shown in the following example.

<b>Environment</b>	<b>Instance</b>
<b>Production</b>	<a href="https://customer.stonebranch.cloud">customer.stonebranch.cloud</a>
<b>Development (non-production)</b>	<a href="https://customerdev.stonebranch.cloud">customerdev.stonebranch.cloud</a>
<b>Testing (non-production)</b>	<a href="https://customertest.stonebranch.cloud">customertest.stonebranch.cloud</a>

**Note:** Non-production instance names can be set based on your needs.

### *High availability*

High availability (HA) is the ability of a system to operate continuously without failure for a designated period of time. Such failures include, but are not limited to, storage, server communication response delays caused by CPU or memory issues, and networking connectivity.

To meet HA requirements:

- All EC2 instances, databases, and other configurations are mirrored across two separate Availability Zones within the same AWS Region.
- The controller is provisioned through an Amazon Machine Image (AMI) on two Linux servers in the two Availability Zones. For example, if you are provisioned in the Europe eu-west-1 Region, you have a Universal Controller in Availability Zone eu-west-1a and Availability Zone eu-west-1c.
- No jobs are allowed to run directly on the application servers and no data is allowed to be stored on these servers.
- The Application Load Balancer runs health checks on each Universal Controller to identify the active one and direct traffic to it. In the event that one server incurs issues, the load balancer automatically promotes the passive Universal Controller to an active state. The load balancer then identifies the new active Universal Controller instance from the health checks and starts directing traffic. The failover happens within four minutes with no job loss, and the frontend URL remains the same.
- The Aurora MySQL–Compatible database service stores Universal Controller data. For production environments, a database cluster is built with two database instances in two different Availability Zones within a single AWS Region. Both Universal Controllers use a Java Database Connectivity (JDBC) interface that points to a single database cluster endpoint. In the event that one database instance incurs issues, the database cluster endpoint dynamically points to the healthy instance. No manual intervention is required.

### *Backup and purge*

Stonebranch Universal Controller is set to back up and purge old data following the schedule shown in the table.

<b>Type</b>	<b>Schedule</b>
<b>Activity</b>	7 days
<b>Audit</b>	90 days
<b>History</b>	60 days

Backup data older than the dates shown is exported to .xml format and stored in the file system. After the backup process is complete, older data is purged from the database and archived in an S3 bucket for up to one year for production instances.

You can adjust this schedule in your Universal Controller interface. However, increasing these time-frames might cause a longer downtime during maintenance.

## Tools

### AWS services

- [AWS Mainframe Modernization](#) is an AWS cloud-native platform that helps you modernize your mainframe applications to AWS managed runtime environments. It provides tools and resources to help you plan and implement migration and modernization.
- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with Amazon EC2 instances.
- [Amazon Elastic File System \(Amazon EFS\)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon Aurora MySQL-Compatible Edition.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon EC2 instances, containers, and IP addresses in one or more Availability Zones. This pattern uses an Application Load Balancer.

### Stonebranch

- [Universal Automation Center \(UAC\)](#) is a system of enterprise workload automation products. This pattern uses the following UAC components:
  - [Universal Controller](#), a Java web application running in a Tomcat web container, is the enterprise job scheduler and workload automation broker solution of [Universal Automation Center](#). The Controller presents a user interface for creating, monitoring, and configuring Controller information; handles the scheduling logic; processes all messages to and from [Universal Agents](#); and synchronizes much of the [high availability](#) operation of Universal Automation Center.
  - [Universal Agent](#) is a vendor-independent scheduling agent that collaborates with existing job scheduler on all major computing platforms, both legacy and distributed. All schedulers that run on z/Series, i/Series, Unix, Linux, or Windows are supported.

- [Universal Agent](#) is a vendor-independent scheduling agent that collaborates with existing job scheduler on all major computing platforms, both legacy and distributed. All schedulers that run on z/Series, i/Series, Unix, Linux, or Windows are supported.
- [Stonebranch aws-mainframe-modernization-stonebranch-integration AWS Mainframe Modernization Universal Extension](#) is the integration template to run, monitor and rerun batch jobs in AWS Mainframe Modernization platform.

## Code

The code for this pattern is available in the [aws-mainframe-modernization-stonebranch-integration](#) GitHub repository.

## Epics

### Install Universal Controller and Universal Agent on Amazon EC2

Task	Description	Skills required
Download the installation files.	Download the installation from Stonebranch servers. To get the installation files, contact with Stonebranch.	Cloud architect
Launch the EC2 instance.	You will need about 3 GB of extra space for the Universal Controller and Universal Agent installations. So provide at least 30 GB of disk space for the instance.  Add port 8080 to the security group so that it's accessible.	Cloud architect
Check prerequisites.	Before the installation, do the following:	Cloud administrator, Linux administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 1031 982">1. Install Java as described in <a href="#">Downloading Java Runtime Environment</a>. <pre data-bbox="630 380 1031 575">\$ sudo yum -y update \$ sudo yum install   java-11-amazon-cor   retto</pre><p data-bbox="630 617 1031 982">Be sure to use one of the supported JAVA versions. The previous command should install java-11. Check the Java version and be sure you are using version 11 before continuing.</p></li><li data-bbox="592 1010 1031 1182">2. As described in <a href="#">Installing Apache Tomcat</a> document, run the following commands. <pre data-bbox="630 1224 1031 1539">\$ sudo yum install   tomcat tomcat-admin-   webapps \$ sudo systemctl   enable tomcat \$ sudo systemctl start   tomcat</pre></li><li data-bbox="592 1556 1031 1871">3. Create an Amazon Aurora database as described in <a href="#">Creating an Aurora MySQL DB cluster and connecting to it</a>. Use Amazon Aurora MySQL-Compatible Edition.</li></ol>	

Task	Description	Skills required
	Choose a Master username and Master password. Keep the default values for the rest of the settings.	

Task	Description	Skills required
Install Universal Controller.	<ol style="list-style-type: none"><li data-bbox="591 226 1024 407">1. Upload the universal-controller-7.2.0.0.tar installation file to the EC2 instance.</li><li data-bbox="591 428 1024 512">2. Unarchive the installation files to a temp folder. <pre data-bbox="634 548 1029 705">\$ tar -xvf universal-controller-7.2.0.0.tar</pre></li><li data-bbox="591 722 1024 806">3. Give the installation script run permission. <pre data-bbox="634 842 1029 957">\$ chmod a+x install-controller.sh</pre></li><li data-bbox="591 974 1024 1394">4. Install the controller. This example uses the following command to install Universal Controller under /usr/share/tomcat. Use the Amazon Aurora database that you created in the previous steps. <pre data-bbox="634 1430 1029 1843">\$ sudo ./install-controller.sh --tomcat-dir /usr/share/tomcat/ --controller-file universal-controller-7.2.0.0-build.145.war --dbuser admin --dbpass "*****" --dbname uc --rdbms mysql --dburl</pre></li></ol>	Cloud architect, Linux administrator

Task	Description	Skills required
	<pre data-bbox="634 205 1027 426">jdbc:mysql://database-2-instance-1.ci63miincgy.us-east-1.rds.amazonaws.com:3306/</pre> <p data-bbox="630 464 1011 594">The last line of the output of the script should be "Installation complete."</p> <p data-bbox="592 617 1000 695">5. Navigate to the following URL in the EC2 instance.</p> <pre data-bbox="634 737 1027 852">http://&lt;public_ip&gt;:8080/uc</pre> <p data-bbox="592 871 980 1098">6. On the login screen, enter <b>ops.admin</b> in the <b>Username</b> section, and keep the <b>Password</b> field empty.</p> <p data-bbox="592 1119 1024 1197">7. Set a new password for the <code>ops.admin</code> user.</p>	

Task	Description	Skills required
Install Universal Agent.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 405">1. Upload the <code>sb-7.2.0.1-linux-3.10-x86_64.tar.Z</code> installation file to the EC2 instance.</li><li data-bbox="592 430 1015 464">2. Log in to the EC2 instance.</li><li data-bbox="592 489 1024 569">3. Task	Description	Skills required
Add OMS to Universal Controller.	<ol style="list-style-type: none"> <li>1. Log in to Universal Controller with the <code>ops.admin</code> user.</li> <li>2. Choose the <b>Services</b> menu at the top left corner of the screen, and then choose the <b>OMS Servers</b> menu in the <b>System</b></li> <li>3. In the OMS Server Address field, type <a href="#">localhost</a>, and then save.</li> <li>4. You will see the status of the OMS server as <b>Connected</b> and the <b>Session Status</b> as <b>Operational</b>.</li> </ol>	Universal Controller administrator

### Import AWS Mainframe Modernization Universal Extension and create a task

Task	Description	Skills required
Import Integration Template.	<p>For this step, you need the <a href="#">AWS Mainframe Modernization Universal Extension</a>. Ensure the latest released version of the .zip file is downloaded.</p> <ol style="list-style-type: none"> <li>1. Log in to the Universal Controller with the <code>ops.admin</code> user.</li> </ol>	Universal Controller administrator

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="591 212 938 342">2. Navigate to <b>Services</b>, <b>Import Integration Template</b>.</li><li data-bbox="591 365 1013 638">3. Select the Integration Template .zip file (aws_mainframe_modernization_stonebranch_extension.zip ), and choose <b>Import</b>.</li></ol> <p data-bbox="591 716 997 940">After the Integration Template is imported, you will see <b>AWS Mainframe Modernization Tasks</b> under <b>Available Services</b>.</p>	

Task	Description	Skills required
Enable resolvable credentials.	<ol style="list-style-type: none"> <li>Navigate to <b>Services, AWS Mainframe Modernization Tasks</b>.</li> <li>On the right panel, fill in the required fields: <ul style="list-style-type: none"> <li><b>Name:</b> New Mainframe Modernization Task</li> <li><b>Agent:</b> Select the only agent (AGNT0001).</li> </ul> <p>Under <b>AWS Mainframe Modernization Details:</b></p> <ul style="list-style-type: none"> <li><b>Action:</b> List Environments</li> <li><b>AWS Credentials:</b> If you have an AWS Identity and Access Management (IAM) role added to the EC2 instance, you can keep this field empty. If you will use <code>AWSAccessKeyID</code> and <code>AWSSecretKey</code>, choose the icon <b>( )</b> next to the field.</li> </ul> <p>In the <b>Credential Details</b> window that opens, enter the following information and then save.</p> <ul style="list-style-type: none"> <li><b>Name:</b> AWS Mainframe Modernization Credentials</li> </ul> </li> </ol>	Universal Controller administrator

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <b>Runtime User:</b> Write the AWS access key ID in this field.</li><li>• <b>Runtime Password:</b> Write the AWS secret key in this field.</li><li>• <b>End Point:</b> Be sure that the endpoint has the correct AWS Region. The default is <a href="https://m2.us-east-1.amazonaws.com">https://m2.us-east-1.amazonaws.com</a>.</li><li>• <b>Region:</b> Enter the Region of the AWS Mainframe Modernization service. The default is us-east-1 .</li></ul> <p>3. Keep the default values in the rest of the fields, and save the task.</p>	

Task	Description	Skills required
Launch the task.	<ol style="list-style-type: none"><li>1. At the top of the right panel, choose <b>Launch Task</b>.</li><li>2. In the <b>Confirm</b> window, choose <b>Launch</b>. After that, the Universal Controller Console will display a message similar to the following message.  <i>2022-08-24 10:11:49 AM</i>  <i>Successfully launched the Universal task "New Mainframe Modernization Task" with task instance sys_id 1661291493634146313NC8E38DB8OZJY.</i></li><li>3. Navigate to the <b>Instances</b> If you don't see the <b>Instances</b> tab, choose the right arrow to scroll right.</li><li>4. Open the context (right-click) menu for the task instance in the list, choose <b>Retrieve Output</b>, and then choose <b>Submit</b> in the <b>Retrieve Output</b></li><li>5. In the <b>Retrieve Output</b> window, you will see the list of environments in <b>STDOUT</b>.</li></ol>	Universal Controller administrator

## Test starting a batch job

Task	Description	Skills required
Create a task for the batch job.	<ol style="list-style-type: none"><li>1. Navigate to <b>Services, AWS Mainframe Modernization Tasks</b>.</li><li>2. On the right panel, fill in the required fields:<ul style="list-style-type: none"><li>• <b>Name:</b> New Mainframe Modernization Task</li><li>• <b>Agent:</b> Select the only agent (AGNT0001).</li></ul></li></ol> <p>Under <b>AWS Mainframe Modernization Details:</b></p> <ul style="list-style-type: none"><li>• <b>Action:</b> Start Batch (or Start Batch and Wait to run the batch job and wait until the task completes in AWS)</li><li>• <b>AWS Credentials:</b> If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use <code>AWSAccessKeyId</code> and <code>AWSSecretKey</code>, choose the icon <b>( )</b> next to the field.</li><li>• <b>End Point:</b> Be sure that the endpoint has the correct AWS Region. The default is <a href="https://m2.us-east-1.amazonaws.com">https://m2.us-east-1.amazonaws.com</a>.</li></ul>	Universal Controller administrator

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <b>Region:</b> Enter the Region of the AWS Mainframe Modernization service. The default is us-east-1 .</li><li>• <b>Application:</b> Choose the icon next to the field (<b> </b>), and choose <b>Submit</b> in the <b>Refresh Application Choices</b>. This will connect to the AWS Mainframe Modernization service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job.</li><li>• <b>JCL File Name:</b> RUNHELLO.jcl</li><li>• <b>Wait for Success or Failure:</b> If this option is selected, the task will wait until the status of the batch job is success or failure.</li><li>• <b>Polling Interval:</b> This is the amount of time between each polling.</li><li>• <b>Fetch Execution Logs:</b> If selected, logs will be fetched automatically</li></ul>	

Task	Description	Skills required
	<p>when the batch job has completed.</p> <ul style="list-style-type: none"><li>• <b>Log Format:</b> This is the format of the logs to be printed out. It can be Text or JSON format.</li></ul> <p>3. Keep the default values in the rest of the fields, and save the task.</p>	

Task	Description	Skills required
Launch the task.	<ol style="list-style-type: none"><li>1. At the top of the right panel, choose <b>Launch Task</b>.</li><li>2. In the <b>Confirm</b> window, choose <b>Launch</b>. After that, the Universal Controller Console will display a message similar to the following message.  <i>2022-08-24 11:11:59 AM</i>  <i>Successfully launched the Universal task "Mainframe Modernization Start Batch" with task instance sys_id &lt;sys id&gt;.</i></li><li>3. Navigate to the <b>Instances</b> If you don't see the <b>Instances</b> tab, choose the right arrow to scroll right.</li><li>4. Open the context (right-click) menu for the task instance in the list, choose <b>Retrieve Output</b>, and then choose <b>Submit</b> in the <b>Retrieve Output</b></li><li>5. In the <b>Retrieve Output</b> window, you will see the list of environments in STDOUT.</li></ol>	Universal Controller administrator

## Create a workflow for multiple tasks

Task	Description	Skills required
Copy the tasks.	<ol style="list-style-type: none"> <li>1. Open the context (right click) menu for the task that you want to create copies of, and choose <b>Copy</b>.</li> <li>2. In the <b>Copy AWS Mainframe Modernization Task</b> window enter the following new name for the new task: Mainframe Modernization Start Batch - <i>RUNAWS2</i>.</li> <li>3. Copy the task again, using the following name: Mainframe Modernization Start Batch - <i>RUNAWS3</i>.</li> <li>4. Copy with the task again, using the following name: Mainframe Modernization Start Batch - <i>RUNAWS4</i>.</li> <li>5. Copy the task a final time, using the following name: Mainframe Modernization Start Batch - <i>FOOBAR</i>.</li> </ol>	Universal Controller administrator
Update tasks.	<ol style="list-style-type: none"> <li>1. Open (double-click) the Mainframe Modernization Start Batch - <i>RUNAWS2</i> task, change the <b>JCL File Name</b> field to <i>RUNAWS2.jcl</i> , and save.</li> <li>2. Open (double-click) the Mainframe Modernization</li> </ol>	Universal Controller administrator

Task	Description	Skills required
	<p>Start Batch - RUNAWS3 task, change the <b>JCL File Name</b> field to RUNAWS3.jc1 , and save.</p> <p>3. Open (double-click) the Mainframe Modernization Start Batch - RUNAWS4 task, change the <b>JCL File Name</b> field to RUNAWS4.jc1 , and save.</p> <p>4. Open (double-click) the Mainframe Modernization Start Batch - FOOBAR task, change the <b>JCL File Name</b> field to MISSING.jc1 , and save. <b>This task will fail because the JCL File Name value is incorrect.</b></p>	

Task	Description	Skills required
Create a workflow.	<ol style="list-style-type: none"><li>1. Navigate to <b>Services, Workflows</b>.</li><li>2. On the right panel, enter <b>Mainframe Modernization Workflow</b> in the <b>Name</b> field, and save.</li><li>3. In the right panel, choose <b>Edit Workflow</b>.</li><li>4. On the <b>Workflow Editor Tab</b>, the <b>Add Task</b> button <b>(+)</b>.</li><li>5. In the <b>Task Find</b> window, choose <b>Search</b> to see all the tasks in the Universal Controller.</li><li>6. Click the icon next to <b>Mainframe Modernization Start Batch Task</b>, and drag the icon into an empty place in the <b>Workflow Editor</b>.</li><li>7. Repeat the same action for the other <b>Mainframe Modernization</b> tasks and place them as shown in the <i>Additional information</i> section.</li><li>8. Choose the <b>Connect</b> button <b>()</b>, and connect the tasks together. To connect a task with another, click in the middle of a task, and drag it to the target task.</li></ol>	Universal Controller administrator

Task	Description	Skills required
	<p>9. Connect the tasks as shown in the <i>Additional information</i> section, and save the workflow.</p> <p>10 Right-click an empty place in the Workflow Editor, choose <b>Launch Workflow</b>, and then choose <b>OK</b>.</p>	
<p>Check the status of the workflow.</p>	<ol style="list-style-type: none"> <li>1. On the left menu, choose the <b>Activity</b></li> <li>2. In the middle of the window, choose <b>Start</b>.  You will see the list of task instances in the list.</li> <li>3. Open (double-click) Mainframe Modernization Workflow in the list, or open the context (right-click) menu and choose <b>Workflow Task Commands, View Workflow</b>.  You will see the tasks as shown in the Additional information section. The second task was expected to fail because you used a missing JCL file.</li> </ol>	<p>Universal Controller administrator</p>

## Troubleshoot failed batch jobs and rerun

Task	Description	Skills required
Fix the failed task and rerun.	<ol style="list-style-type: none"><li>1. Open (double-click) the failed task to see the error for the task.</li><li>2. You have two options for fixing the failed task.<ul style="list-style-type: none"><li>• Fix the JCL file name, and set it to <code>FOOBAR.jcl</code>.</li><li>• Add the correct JCL file name to the <b>JCL File Name (Temp)</b>. This field will overwrite the <b>JCL File Name</b> field.</li></ul><p>For this pilot, choose the second option, and save the task instance.</p></li><li>3. In the <b>Workflow Monitor</b>, open the context (right-click) menu for the failed task, and choose <b>Commands, Re-run</b>.</li><li>4. After that, all the tasks will complete successfully.</li></ol>	Universal Controller administrator

## Create Start Application and Stop Application tasks

Task	Description	Skills required
<p>Create the Start Application action.</p>	<ol style="list-style-type: none"> <li>1. Navigate to <b>Services, AWS Mainframe Modernization Tasks</b>.</li> <li>2. On the right panel, fill in the required fields. <ul style="list-style-type: none"> <li>• <b>Name:</b> Mainframe Modernization Start Application</li> <li>• <b>Agent:</b> Select the only agent (AGNT0001)</li> </ul> <p>Under <b>AWS Mainframe Modernization Details:</b></p> <ul style="list-style-type: none"> <li>• <b>Action:</b> Start Application</li> <li>• <b>AWS Credentials:</b> If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use <code>AWSAccessKeyId</code> and <code>AWSSecretKey</code>, select the credential that you created before.</li> <li>• <b>End Point:</b> Be sure that the endpoint has the correct Region. The default is <a href="https://m2.us-east-1.amazonaws.com">https://m2.us-east-1.amazonaws.com</a>.</li> <li>• <b>Region:</b> Enter the Region of the AWS Mainframe Modernization service.</li> </ul> </li> </ol>	<p>Universal Controller administrator</p>

Task	Description	Skills required
	<p>The default is us-east-1 .</p> <ul style="list-style-type: none"><li>• <b>Application:</b> Choose the icon next to the field (<b>○</b>), and choose <b>Submit</b> in the <b>Refresh Application Choices</b>. This will connect to the AWS Mainframe Modernization service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job.</li><li>• <b>Wait for Success or Failure:</b> If this option is selected, the task will wait until the status of the batch job is success or failure.</li><li>• <b>Polling Interval:</b> This is the amount of time between each polling.</li><li>• <b>Fetch Execution Logs:</b> If selected, logs will be fetched automatically when the batch job has completed.</li><li>• <b>Log Format:</b> This is the format of the logs to be printed out. It can be Text or JSON format.</li></ul>	

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>3. Keep the default values in the rest of the fields, and save the task.</li> <li>4. Now copy this task and create a task for Stop Application. Change the name to <b>Mainframe Modernization Stop Application</b>, and change the action to <b>Stop Application</b>.</li> </ol>	

### Create a Cancel Batch Execution task

Task	Description	Skills required
<p>Create the Cancel Batch action.</p>	<ol style="list-style-type: none"> <li>1. Navigate to <b>Services, AWS Mainframe Modernization Tasks</b>.</li> <li>2. On the right panel, fill in the required fields. <ul style="list-style-type: none"> <li>• <b>Name:</b> Mainframe Modernization Cancel Batch Execution</li> <li>• <b>Agent:</b> Select the only agent (AGNT0001)</li> </ul> <p>Under <b>AWS Mainframe Modernization Details:</b></p> <ul style="list-style-type: none"> <li>• <b>Action:</b> Cancel Batch Execution</li> <li>• <b>AWS Credentials:</b> If you have an IAM role added</li> </ul> </li> </ol>	

Task	Description	Skills required
	<p>to the EC2 instance, you can keep this field empty. If you will use <code>AWSAccessKeyID</code> and <code>AWSSecretKey</code>, select the credential that you created before.</p> <ul style="list-style-type: none"><li>• <b>End Point:</b> Be sure that the endpoint has the correct Region. The default is <a href="https://m2.us-east-1.amazonaws.com">https://m2.us-east-1.amazonaws.com</a>.</li><li>• <b>Region:</b> Enter the Region of the AWS Mainframe Modernization service. The default is <code>us-east-1</code>.</li><li>• <b>Application:</b> Choose the icon next to the field <b>( )</b>, and choose <b>Submit</b> in the <b>Refresh Application Choices</b>. This will connect to the AWS Mainframe Modernization service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job.</li><li>• <b>Wait for Success or Failure:</b> If this option is selected, the task will</li></ul>	

Task	Description	Skills required
	<p>wait until the status of the batch job is success or failure.</p> <ul style="list-style-type: none"><li>• <b>Polling Interval:</b> This is the amount of time between each polling.</li><li>• <b>Fetch Execution Logs:</b> If selected, logs will be fetched automatically when the batch job has completed.</li><li>• <b>Log Format:</b> This is the format of the logs to be printed out. It can be Text or JSON format.</li></ul> <p>3. Keep the default values in the rest of the fields, and save the task.</p>

# Migrate and replicate VSAM files to Amazon RDS or Amazon MSK using Connect from Precisely

Created by Prachi Khanna (AWS) and Boopathy GOPALSAMY (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> VSAM	<b>Target:</b> Database
<b>R Type:</b> Re-architect	<b>Workload:</b> IBM	<b>Technologies:</b> Mainframe; Modernization
<b>AWS services:</b> Amazon MSK; Amazon RDS; AWS Mainframe Modernization		

## Summary

This pattern shows you how to migrate and replicate Virtual Storage Access Method (VSAM) files from a mainframe to a target environment in the AWS Cloud by using [Connect](#) from Precisely. The target environments covered in this pattern include Amazon Relational Database Service (Amazon RDS) and Amazon Managed Streaming for Apache Kafka (Amazon MSK). Connect uses [change data capture \(CDC\)](#) to continuously monitor updates to your source VSAM files and then transfer these updates to one or more of your AWS target environments. You can use this pattern to meet your application modernization or data analytics goals. For example, you can use Connect to migrate your VSAM application files to the AWS Cloud with low latency, or migrate your VSAM data to an AWS data warehouse or data lake for analytics that can tolerate synchronization latencies that are higher than required for application modernization.

## Prerequisites and limitations

### Prerequisites

- [IBM z/OS V2R1](#) or later
- [CICS Transaction Server for z/OS \(CICS TS\) V5.1](#) or later (CICS/VSAM data capture)
- [IBM MQ 8.0](#) or later
- Compliance with [z/OS security requirements](#) (for example, APF authorization for SQData load libraries)

- VSAM recovery logs turned on
- (Optional) [CICS VSAM Recovery Version \(CICS VR\)](#) to automatically capture CDC logs
- An active AWS account
- An [Amazon Virtual Private Cloud \(VPC\)](#) with a subnet that's reachable by your legacy platform
- A VSAM Connect license from Precisely

## Limitations

- Connect doesn't support automatic target table creation based on source VSAM schemas or copybooks. You must define the target table structure for the first time.
- For non-streaming targets such as Amazon RDS, you must specify the conversion source to target mapping in the Apply Engine configuration script.
- Logging, monitoring, and alerting functions are implemented through APIs and require external components (such as Amazon CloudWatch) to be fully operational.

## Product versions

- SQData 40134 for z/OS
- SQData 4.0.43 for the Amazon Linux Amazon Machine Image (AMI) on Amazon Elastic Compute Cloud (Amazon EC2)

## Architecture

### Source technology stack

- Job Control Language (JCL)
- z/OS Unix shell and Interactive System Productivity Facility (ISPF)
- VSAM utilities (IDCAMS)

### Target technology stack

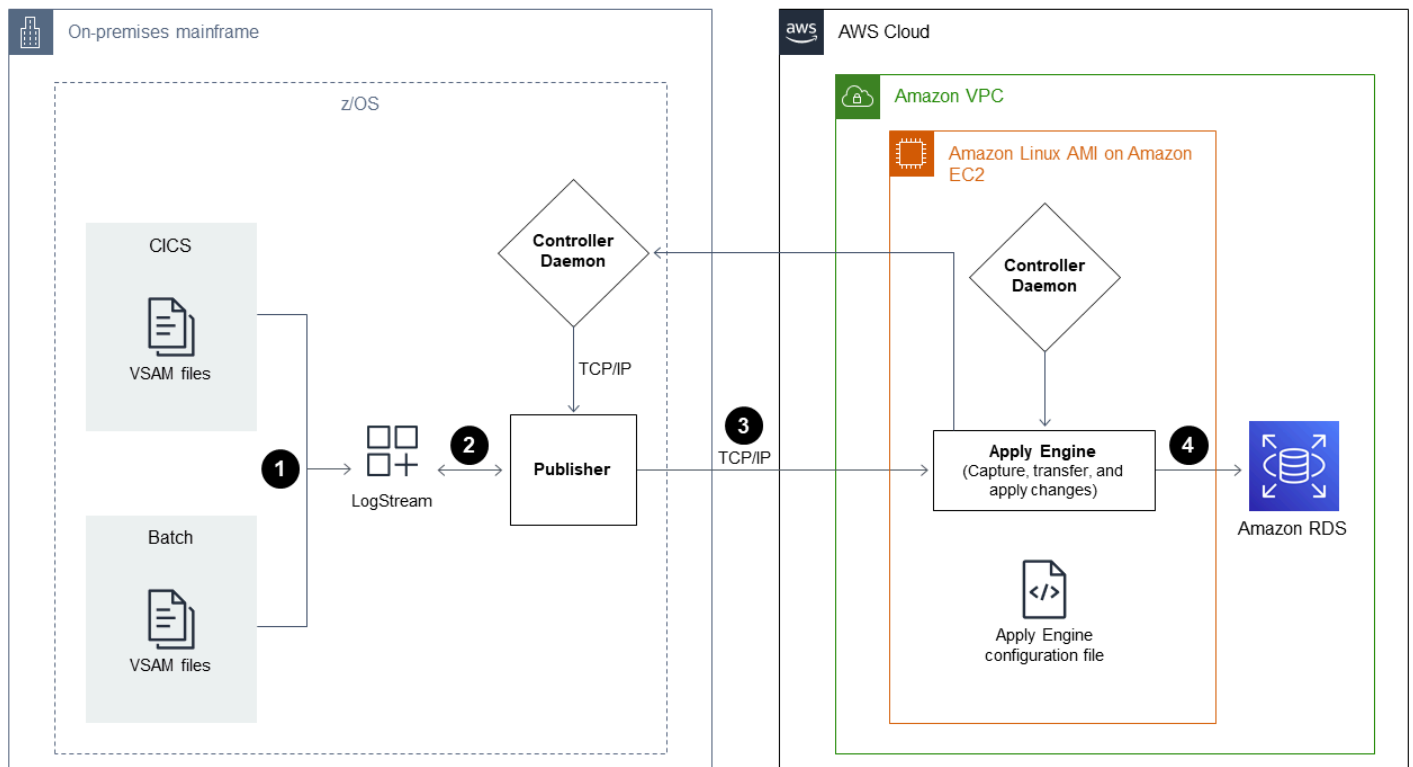

- Amazon EC2
- Amazon MSK
- Amazon RDS

- Amazon VPC

## Target architecture

### Migrating VSAM files to Amazon RDS

The following diagram shows how to migrate VSAM files to a relational database, such as Amazon RDS, in real time or near real time by using the CDC agent/publisher in the source environment (on-premises mainframe) and the [Apply Engine](#) in the target environment (AWS Cloud).

The diagram shows the following batch workflow:

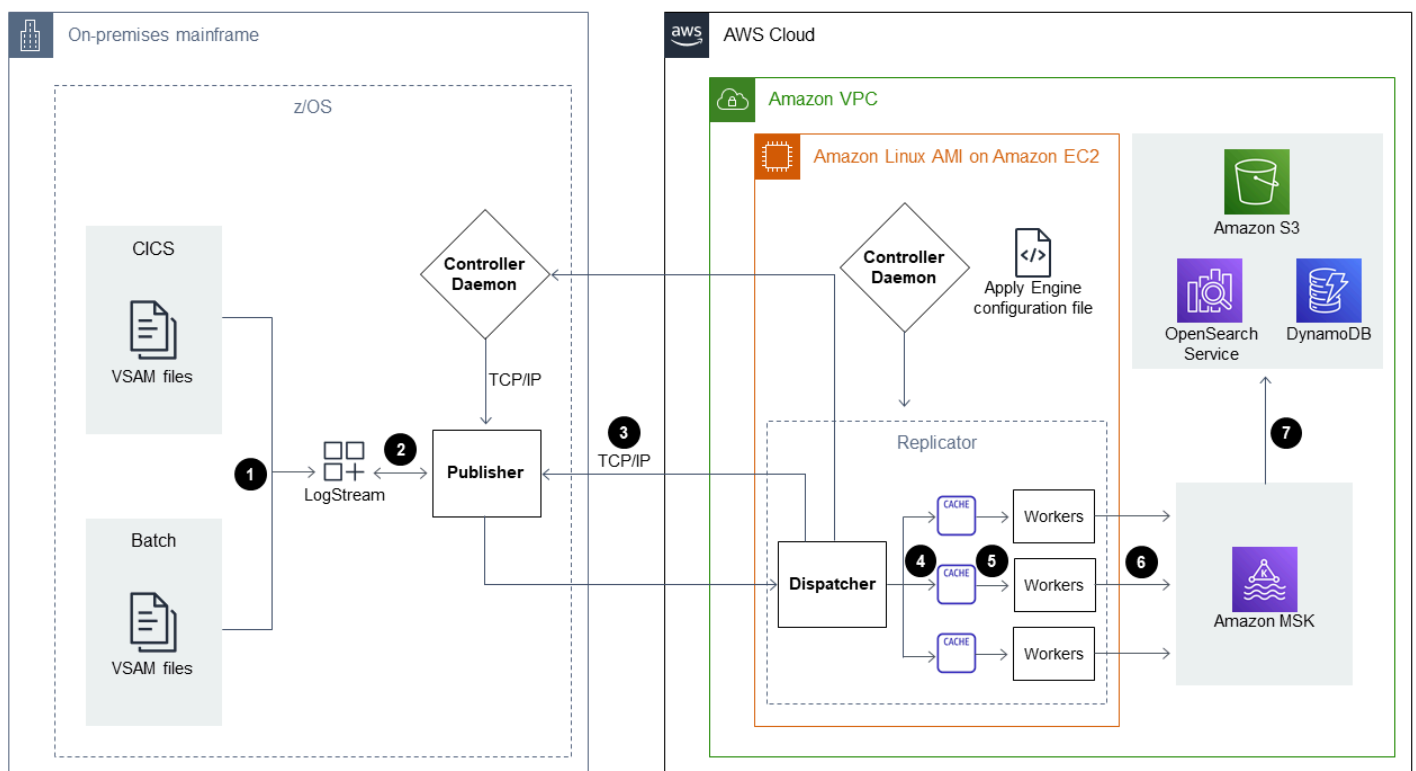

1. Connect captures changes to a file by comparing VSAM files from backup files to identify changes and then sends the changes to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to a target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Apply Engine in the target environment receives the changes from the Publisher agent and applies them to a relational or non-relational database.

The diagram shows the following online workflow:

1. Connect captures changes in the online file by using a log replicate and then streams captured changes to a logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Apply Engine in the target environment receives the changes from the Publisher agent and then applies them to a relational or non-relational database.

### Migrating VSAM files to Amazon MSK

The following diagram shows how to stream VSAM data structures from a mainframe to Amazon MSK in high-performance mode and automatically generate JSON or AVRO schema conversions that integrate with Amazon MSK.

The diagram shows the following batch workflow:

1. Connect captures changes to a file by using CICS VR or by comparing VSAM files from backup files to identify changes. Captured changes are sent to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Replicator Engine that's operating in parallel processing mode splits the data to a unit of work cache.
5. Worker threads capture the data from the cache.
6. Data is published to Amazon MSK topics from the worker threads.
7. Users apply changes from Amazon MSK to targets such as Amazon DynamoDB, Amazon Simple Storage Service (Amazon S3), or Amazon OpenSearch Service by using [connectors](#).

The diagram shows the following online workflow:

1. Changes in the online file are captured by using a log replicate. Captured changes are streamed to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Replicator Engine that's operating in parallel processing mode splits the data to a unit of work cache.
5. Worker threads capture the data from the cache.
6. Data is published to Amazon MSK topics from the worker threads.
7. Users apply changes from Amazon MSK to targets such as DynamoDB, Amazon S3, or OpenSearch Service by using [connectors](#).

## Tools

- [Amazon Managed Streaming for Apache Kafka \(Amazon MSK\)](#) is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.

## Epics

### Prepare the source environment (mainframe)

Task	Description	Skills required
Install Connect CDC 4.1.	<ol style="list-style-type: none"> <li>1. <a href="#">Contact the Precisely Support team</a> to obtain a license and installation packages.</li> <li>2. Use example JCLs to install Connect CDC 4.1. For instructions, see <a href="#">Install Connect CDC (SQData) using JCL</a> in the Precisely documentation.</li> <li>3. Run the SETPROG APF command to authorize the Connect load libraries SQDATA.V4nnn.LOADLIB.</li> </ol>	IBM Mainframe Developer/Admin
Set up the zFS directory.	<p>To set up a zFS directory, follow the instructions from <a href="#">zFS variable directories</a> in the Precisely documentation.</p> <p><b>Note:</b> Controller Daemon and Capture/Publisher agent configurations are stored in the z/OS UNIX Systems Services file system (referred to as zFS). The Controller Daemon, Capture, Storage, and Publisher agents require a predefined zFS directory structure for storing a small number of files.</p>	IBM Mainframe Developer/Admin

Task	Description	Skills required
Configure TCP/IP ports.	<p>To configure TCP/IP ports, follow the instructions from <a href="#">TCP/IP ports</a> in the Precisely documentation.</p> <p><b>Note:</b> The Controller Daemon requires TCP/IP ports on source systems. The ports are referenced by the engines on the target systems (where captured change data is processed).</p>	IBM Mainframe Developer/Admin
Create a z/OS logstream.	<p>To create a <a href="#">z/OS logstream</a>, follow the instructions from <a href="#">Create z/OS system logStreams</a> in the Precisely documentation.</p> <p><b>Note:</b> Connect uses the logstream to capture and stream data between your source environment and target environment during migration.</p> <p>For an example JCL that creates a z/OS LogStream, see <a href="#">Create z/OS system logStreams</a> in the Precisely documentation.</p>	IBM Mainframe Developer

Task	Description	Skills required
Identify and authorize IDs for zFS users and started tasks.	Use RACF to grant access to the OMVS zFS file system. For an example JCL, see <a href="#">Identify and authorize zFS user and started task IDs</a> in the Precisely documentation.	IBM Mainframe Developer/Admin
Generate z/OS public/private keys and the authorized key file.	Run the JCL to generate the key pair. For an example, see <i>Key pair example</i> in the <i>Additional information</i> section of this pattern.  For instructions, see <a href="#">Generate z/OS public and private keys and authorized key file</a> in the Precisely documentation.	IBM Mainframe Developer/Admin
Activate the CICS VSAM Log Replicate and attach it to the logstream.	Run the following JCL script: <pre data-bbox="594 1108 1029 1509">//STEP1 EXEC PGM=IDCAM S //SYSPRINT DD SYSOUT=* //SYSIN DD *   ALTER SQDATA.CI CS.FILEA -   LOGSTREAMID(SQDATA .VSAMCDC.LOG1) -   LOGREPLICATE</pre>	IBM Mainframe Developer/Admin

Task	Description	Skills required
<p>Activate the VSAM File Recovery Log through an FCT.</p>	<p>Modify the File Control Table (FCT) to reflect the following parameter changes:</p> <pre data-bbox="597 394 1027 1150"> Configure FCT Params   CEDA ALT FILE(name)   GROUP(groupname)   DSNAME(data set   name)   RECOVERY(NONE BACK   OUTONLY ALL)   FWDRECOVLOG(NO 1-9   9)   BACKUPTYPE(STATIC    DYNAMIC)   RECOVERY PARAMETERS   RECOVry : None     Backoutonly   All   Fwdrecovlog : No     1-99   BAckuptype : Static     Dynamic </pre>	<p>IBM Mainframe Developer/ Admin</p>
<p>Set up CDCzLog for the Publisher agent.</p>	<ol style="list-style-type: none"> <li>1. Create the CDCzLog Publisher CAB file.</li> <li>2. Encrypt the published data.</li> <li>3. Prepare the CDCzLog Publisher Runtime JCL.</li> </ol>	<p>IBM Mainframe Developer/ Admin</p>

Task	Description	Skills required
Activate the Controller Daemon.	<ol style="list-style-type: none"><li data-bbox="592 226 1026 552">1. Open the ISPF panel and run the following command to open the Precisely menu: EXEC 'SQDATA.V4nnnnn.IS PFLIB(SQDC\$STA) ' 'SQDATA.V4nnnnn '</li><li data-bbox="592 573 1026 699">2. To set up the Controller Daemon, choose option 2 from the menu.</li></ol>	IBM Mainframe Developer/ Admin
Activate the publisher.	<ol style="list-style-type: none"><li data-bbox="592 747 1026 1073">1. Open the ISPF panel and run the following command to open the Precisely menu: EXEC 'SQDATA.V4nnnnn.IS PFLIB(SQDC\$STA) ' 'SQDATA.V4nnnnn '</li><li data-bbox="592 1094 1026 1220">2. To set up the publisher, choose option 3 from the menu and I for insert.</li></ol>	IBM Mainframe Developer/ Admin

Task	Description	Skills required
Activate the logstream.	<ol style="list-style-type: none"> <li>1. Open the ISPF panel and run the following command to open the Precisely menu: EXEC 'SQDATA.V4nnnnn.IS PFLIB(SQDC\$STA)' 'SQDATA.V4nnnnn'</li> <li>2. To set up the logstream , choose option 4 from the menu and I for insert. Then, enter the name of the logstream created in the preceding steps.</li> </ol>	IBM Mainframe Developer/ Admin

### Prepare the target environment (AWS)

Task	Description	Skills required
Install Precisely on an EC2 instance.	To install Connect from Precisely on the Amazon Linux AMI for Amazon EC2, follow the instructions from <a href="#">Install Connect CDC (SQData) on UNIX</a> in the Precisely documentation.	General AWS
Open TCP/IP ports.	To modify the security group to include the Controller Daemon ports for inbound and outbound access, follow the instructions from <a href="#">TCP/IP</a> in the Precisely documentation.	General AWS

Task	Description	Skills required
Create file directories.	To create file directories, follow the instructions from <a href="#">Prepare target apply environment</a> in the Precisely documentation.	General AWS
Create the Apply Engine configuration file.	<p>Create the Apply Engine configuration file in the working directory of the Apply Engine. The following example configuration file shows Apache Kafka as the target:</p> <pre data-bbox="597 856 1026 1293">builtin.features=S ASL_SCRAM   security.protocol= SASL_SSL   sasl.mechanism=SCR AM-SHA-512   sasl.username=   sasl.password=   metadata.broker.li st=</pre> <p><b>Note:</b> For more information, see <a href="#">Security</a> in the Apache Kafka documentation.</p>	General AWS
Create scripts for Apply Engine processing.	Create the scripts for the Apply Engine to process source data and replicate source data to the target. For more information, see <a href="#">Create an apply engine script</a> in the Precisely documentation.	General AWS

Task	Description	Skills required
Run the scripts.	Use the SQDPARSE and SQDENG commands to run the script. For more information, see <a href="#">Parse a script for zOS</a> in the Precisely documentation.	General AWS

## Validate the environment

Task	Description	Skills required
Validate the list of VSAM files and target tables for CDC processing.	<ol style="list-style-type: none"> <li>1. Validate VSAM files, including replication logs, recovery logs, FCT parameters, and the logstream.</li> <li>2. Validate target database tables, including whether the tables are created as per the required schema definition, table access, and other criteria.</li> </ol>	General AWS, Mainframe
Verify that the Connect CDC SQData product is linked.	<p>Run a testing job and verify that the return code from this job is 0 (Successful).</p> <p><b>Note:</b> Connect CDC SQData Apply Engine status messages should show active connection messages.</p>	General AWS, Mainframe

## Run and validate test cases (Batch)

Task	Description	Skills required
Run the batch job in the mainframe.	<p>Run the batch application job using a modified JCL. Include steps in the modified JCL that do the following:</p> <ol style="list-style-type: none"> <li>1. Take a backup of the data files.</li> <li>2. Compare the backup file with the modified data files, generate the delta file, and then note the delta record count from the messages.</li> <li>3. Push the delta file to the z/OS logstream.</li> <li>4. Run the JCL. For an example JCL, see <a href="#">Prepare file compare capture JCL</a> in the Precisely documentation.</li> </ol>	General AWS, Mainframe
Check the logstream.	Check the logstream to confirm that you can see the change data for the completed mainframe batch job.	General AWS, Mainframe
Validate the counts for the source delta changes and target table.	<p>To confirm the records are tallied, do the following:</p> <ol style="list-style-type: none"> <li>1. Gather the source delta count from the batch JCL messages.</li> </ol>	General AWS, Mainframe

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>2. Monitor the Apply Engine for record level counts of the number of records inserted, updated, or deleted in the VSAM file.</li> <li>3. Query the target table for record counts.</li> <li>4. Compare and tally all the different record counts.</li> </ol>	

### Run and validate test cases (Online)

Task	Description	Skills required
Run the online transaction in a CICS region.	<ol style="list-style-type: none"> <li>1. Run the online transaction to validate the test case.</li> <li>2. Validate the transaction execution code (RC=0 – Success).</li> </ol>	IBM Mainframe Developer
Check the logstream.	Confirm that the logstream is populated with specific record level changes.	AWS Mainframe Developer
Validate the count in the target database.	Monitor the Apply Engine for record level counts.	Precisely, Linux
Validate the record counts and data records in the target database.	Query the target database to validate the record counts and data records.	General AWS

- [VSAM z/OS](#) (Precisely documentation)

- [Apply engine](#) (Precisely documentation)
- [Replicator engine](#) (Precisely documentation)
- [The log stream](#) (IBM documentation)

## Additional information

### Configuration file example

This is an example configuration file for a logstream where the source environment is a mainframe and the target environment is Amazon MSK:

```
-- JOBNAME -- PASS THE SUBSCRIBER NAME
-- REPORT progress report will be produced after "n" (number) of Source records
processed.

JOBNAME VSMTOKFK;
--REPORT EVERY 100;
-- Change Op has been 'I' for insert, 'D' for delete , and 'R' for Replace. For RDS
it is 'U' for update
-- Character Encoding on z/OS is Code Page 1047, on Linux and UNIX it is Code Page
819 and on Windows, Code Page 1252
OPTIONS
CDCOP('I', 'U', 'D'),
PSEUDO NULL = NO,
USE AVRO COMPATIBLE NAMES,
APPLICATION ENCODING SCHEME = 1208;

-- SOURCE DESCRIPTIONS

BEGIN GROUP VSAM_SRC;
DESCRIPTION COBOL ../copybk/ACCOUNT AS account_file;
END GROUP;

-- TARGET DESCRIPTIONS

BEGIN GROUP VSAM_TGT;
DESCRIPTION COBOL ../copybk/ACCOUNT AS account_file;
END GROUP;

-- SOURCE DATASTORE (IP & Publisher name)
```

```

DATASTORE cdc://10.81.148.4:2626/vsmcdct/VSMTOKFK
OF VSAMCDC
AS CDCIN
DESCRIBED BY GROUP VSAM_SRC ACCEPT ALL;

--      TARGET DATASTORE(s) - Kafka and topic name

DATASTORE 'kafka:///MSKTutorialTopic/key'
OF JSON
AS CDCOUT
DESCRIBED BY GROUP VSAM_TGT FOR INSERT;

--      MAIN SECTION

PROCESS INTO
CDCOUT
SELECT
{
SETURL(CDCOUT, 'kafka:///MSKTutorialTopic/key')
REMAP(CDCIN, account_file, GET_RAW_RECORD(CDCIN, AFTER), GET_RAW_RECORD(CDCIN,
BEFORE))
REPLICATE(CDCOUT, account_file)
}
FROM CDCIN;

```

## Key pair example

This an example of how to run the JCL to generate the key pair:

```

//SQDUTIL EXEC PGM=SQDUTIL //SQDPUBL DD DSN=&USER..NACL.PUBLIC, //
DCB=(RECFM=FB,LRECL=80,BLKSIZE=21200), // DISP=(,CATLG,DELETE),UNIT=SYSDA, //
SPACE=(TRK,(1,1)) //SQDPKEY DD DSN=&USER..NACL.PRIVATE, //
DCB=(RECFM=FB,LRECL=80,BLKSIZE=21200), // DISP=(,CATLG,DELETE),UNIT=SYSDA, //
SPACE=(TRK,(1,1)) //SQDPARMS DD keygen //SYSPRINT DD SYSOUT= //SYSOUT DD SYSOUT=* //
SQDLOG DD SYSOUT=* //*SQDLOG8 DD DUMMY

```

# Modernize mainframe output management on AWS by using OpenText Micro Focus Enterprise Server and LRS PageCenterX

Created by Shubham Roy (AWS), Abraham Rondon (Micro Focus), and Guy Tucker (Levi, Ray and Shoup Inc)

<b>Environment:</b> PoC or pilot	<b>Source:</b> IBM mainframe	<b>Target:</b> AWS
<b>R Type:</b> Replatform	<b>Workload:</b> IBM	<b>Technologies:</b> Mainframe; Migration; Modernization
<b>AWS services:</b> AWS Managed Microsoft AD; Amazon EC2; Amazon FSx for Windows File Server; Amazon RDS; AWS Mainframe Modernization		

## Summary

By modernizing your mainframe output management, you can achieve cost savings, mitigate the technical debt of maintaining legacy systems, and improve resiliency and agility through DevOps and Amazon Web Services (AWS) cloud-native technologies. This pattern shows you how to modernize your business-critical mainframe output-management workloads on the AWS Cloud. The pattern uses [OpenText Micro Focus Enterprise Server](#) as a runtime for a modernized mainframe application, with Levi, Ray & Shoup, Inc. (LRS) VPSX/MFI (Micro Focus Interface) as a print server and LRS PageCenterX as an archive server. LRS PageCenterX provides output-management solutions for viewing, indexing, searching, archiving, and securing access to business outputs.

The pattern is based on the [replatform](#) mainframe modernization approach. Mainframe applications are migrated by [AWS Mainframe Modernization](#) on Amazon Elastic Compute Cloud (Amazon EC2). Mainframe output-management workloads are migrated to Amazon EC2, and a mainframe database, such as IBM Db2 for z/OS, is migrated to Amazon Relational Database Service (Amazon RDS). The LRS Directory Integration Server (LRS/DIS) works with AWS Directory Service for Microsoft Active Directory for output-management workflow authentication and authorization.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A mainframe output-management workload.
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on OpenText Micro Focus Enterprise Server. For more information, see the [Enterprise Server](#) data sheet in the OpenText Micro Focus documentation.
- Basic knowledge of LRS cloud printing solutions and concepts. For more information, see *Output Modernization* in the LRS documentation.
- Micro Focus Enterprise Server software and license. For more information, contact OpenText [Micro Focus sales](#).
- LRS VPSX/MFI, LRS PageCenterX, LRS/Queue, and LRS/DIS software and licenses. For more information, [contact LRS](#). You must provide the hostnames of the EC2 instances where the LRS products will be installed.

**Note:** For more information about configuration considerations for mainframe output-management workloads, see *Considerations* in the [Additional information](#) section of this pattern.

### Product versions

- [OpenText Micro Focus Enterprise Server](#) 8.0 or later
- [LRS VPSX/MFI](#)
- [LRS PageCenterX](#) V1R3 or later

## Architecture

### Source technology stack

- Operating system – IBM z/OS
- Programming language – Common business-oriented language (COBOL), job control language (JCL), and Customer Information Control System (CICS)

- Database – IBM Db2 for z/OS, IBM Information Management System (IMS) database, and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Print and archive solutions – IBM mainframe z/OS output and printing products (IBM Infoprint Server for z/OS, LRS, and CA Deliver) and archiving solutions (CA Deliver, ASG Mobius, or CA Bundle)

## Source architecture

The following diagram shows a typical current state architecture for a mainframe output-management workload.

The diagram shows the following workflow:

1. Users perform business transactions on a system of engagement (SoE) that's built on an IBM CICS application written in COBOL.

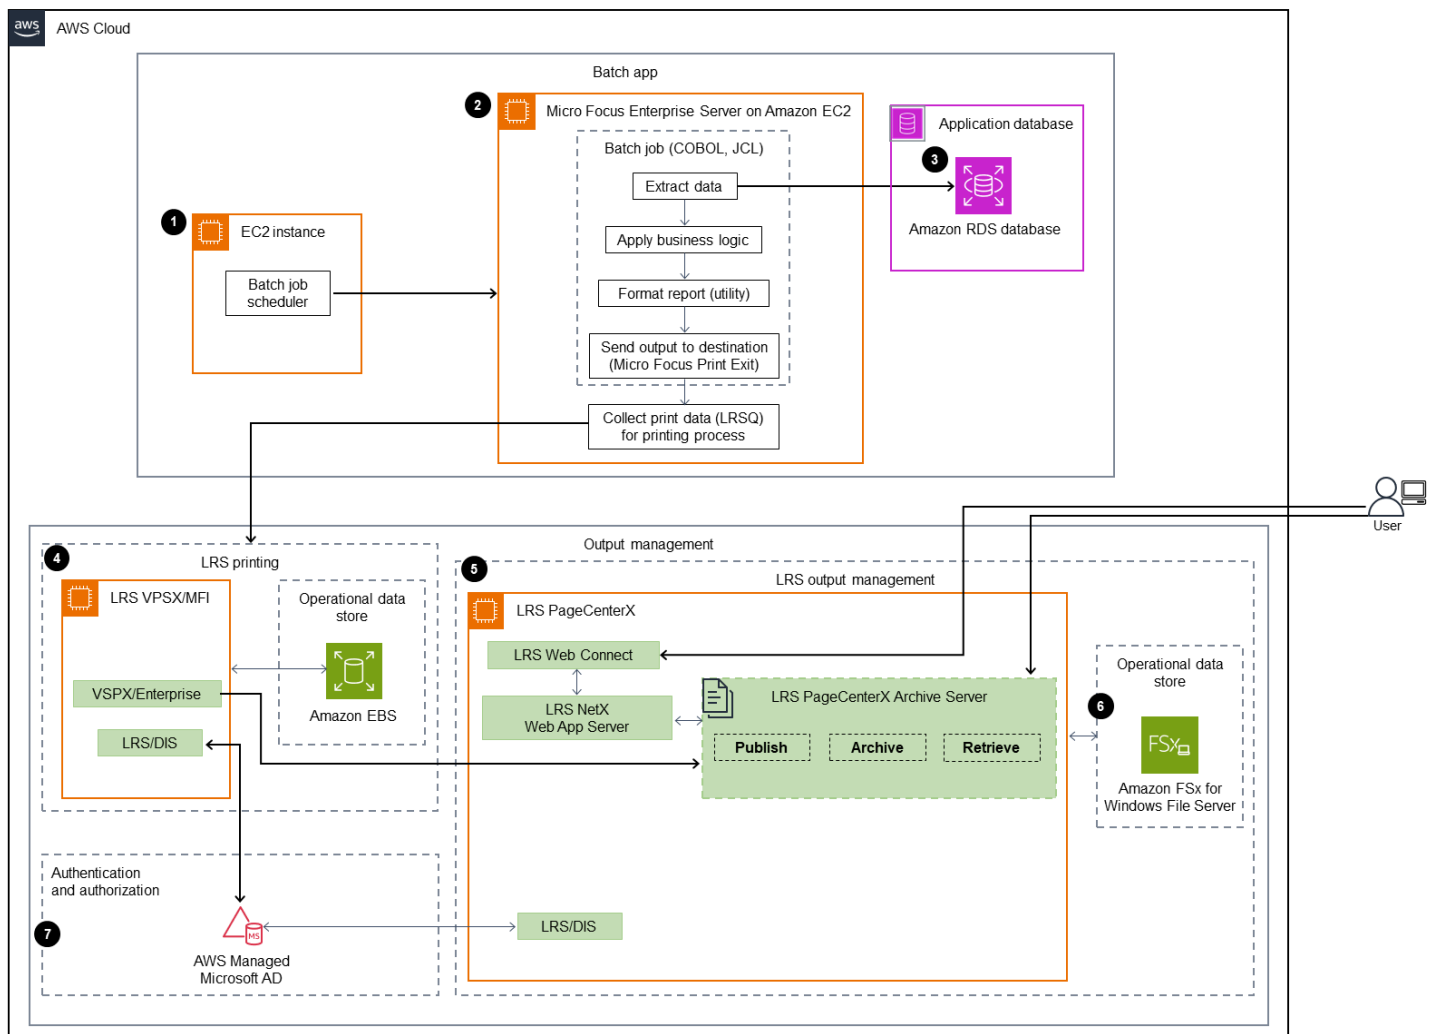

2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM Db2 for z/OS.
3. The SoR persists the business data from the SoE.
4. The batch job scheduler initiates a batch job to generate print output.
5. The batch job extracts data from the database. It formats the data according to business requirements, and then it generates business output such as billing statements, ID cards, or loan statements. Finally, the batch job routes the output to output management for format, publish, and storage of the output based on the business requirements.
6. Output management receives output from the batch job. Output management indexes, arranges, and publishes the output to a specified destination in the output-management system, such as LRS PageCenterX solutions (as demonstrated in this pattern) or CA View.
7. Users can view, search, and retrieve the output.

### Target technology stack

- Operating system – Windows Server running on Amazon EC2
- Compute – Amazon EC2
- Storage – Amazon Elastic Block Store (Amazon EBS) and Amazon FSx for Windows File Server
- Programming language – COBOL, JCL, and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD
- Printing and archiving – LRS printing (VPSX) and archiving (PageCenterX) solution on AWS
- Mainframe runtime environment – OpenText Micro Focus Enterprise Server

### Target architecture

The following diagram shows an architecture for a mainframe output-management workload that's deployed in the AWS Cloud.

The diagram shows the following workflow:

1. The batch job scheduler initiates a batch job to create output, such as billing statements, ID cards, or loan statements.
2. The mainframe batch job ([replatformed to Amazon EC2](#)) uses the OpenText Micro Focus Enterprise Server runtime to extract data from the application database, apply business logic to the data, and format the data. It then sends the data to an output destination by using [OpenText Micro Focus printer exit module](#) (OpenText Micro Focus documentation).
3. The application database (an SoR that runs on Amazon RDS) persists data for print output.
4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2, and its operational data is stored in Amazon EBS. LRS VPSX/MFI uses the TCP/IP-based LRS/Queue transmission agent to collect output data through the OpenText Micro Focus JES Print Exit API.

LRS VPSX/MFI does data preprocessing, such as EBCDIC to ASCII translation. It also does more complex tasks, including converting mainframe-exclusive data streams such as IBM Advanced Function Presentation (AFP) and Xerox Line Conditioned Data Stream (LCDS) into more common viewing and printing data streams such as Printer Command Language (PCL) and PDF.

During the maintenance window of LRS PageCenterX, LRS VPSX/MFI persists the output queue and serves as backup for the output queue. LRS VPSX/MFI connects and sends output to LRS PageCenterX by using the LRS/Queue protocol. LRS/Queue performs an exchange of both readiness and completion for the jobs to help ensure that the data transfer occurs.

**Notes:**

For more information on print data passed from OpenText Micro Focus Print Exit to LRS/Queue and LRS VPSX/MFI supported mainframe batch mechanisms, see *Print data capture* in the [Additional information](#) section.

LRS VPSX/MFI can perform health checks at the printer-fleet level. For more information, see *Printer-fleet health checks* in the [Additional information](#) section of this pattern.

5. The LRS PageCenterX output-management solution is deployed on Amazon EC2, and its operational data is stored in Amazon FSx for Windows File Server. LRS PageCenterX provides a central report management system of all files imported into LRS PageCenterX along with all users able to access the files. Users can view specific file content or perform searches across multiple files for matching criteria.

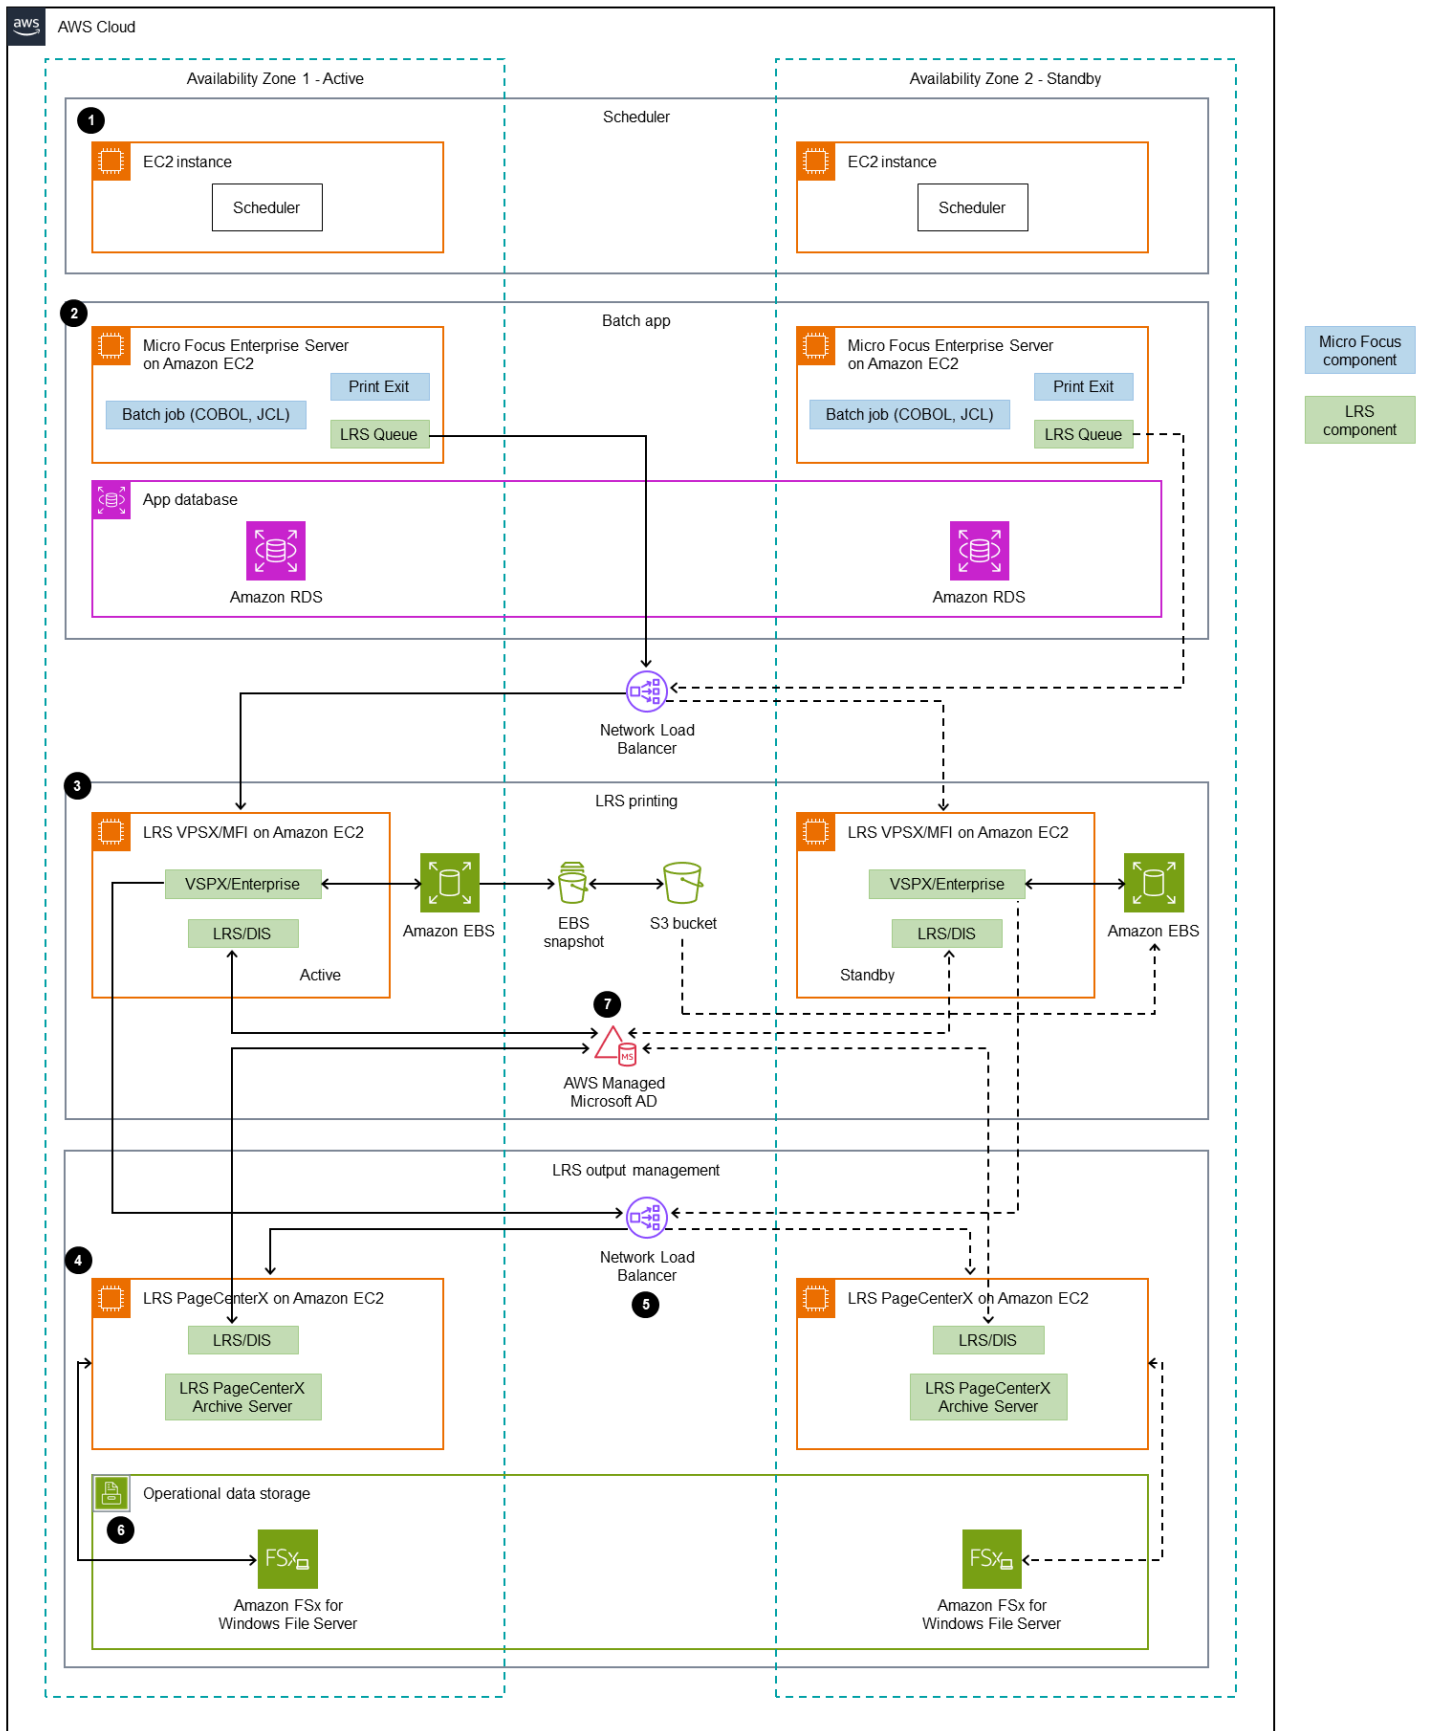

The LRS/NetX component is a multi-threaded web application server that provides a common runtime environment for the LRS PageCenterX application and other LRS applications. The LRS/Web Connect component is installed on your web server and provides a connector from the web server to the LRS/NetX web application server.

6. LRS PageCenterX provides storage for file system objects. The operational data of LRS PageCenterX is stored in Amazon FSx for Windows File Server.
7. Output-management authentication and authorization are performed by AWS Managed Microsoft AD with LRS/DIS.

**Note:** The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM AFP or Xerox LCDS.

## **AWS infrastructure architecture**

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe output-management workload.

The diagram shows the following workflow:

1. The batch scheduler initiates the batch process and is deployed on Amazon EC2 across multiple [Availability Zones](#) for high availability (HA).

**Note:** This pattern doesn't cover the implementation of the batch scheduler. For more information about implementation, see the software vendor documentation for your scheduler.

2. The mainframe batch job (written in a programming language such as JCL or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The batch job is deployed on Amazon EC2 across two Availability Zones for HA. It uses the OpenText Micro Focus Print Exit API to route print output to LRS VPSX/MFI for data preprocessing.
3. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA (active-standby redundant pair). It uses [Amazon EBS](#) as an operational data store. The Network Load Balancer performs a health check on the LRS VPSX/MFI EC2 instances. If an active instance is in an unhealthy state, the load balancer routes traffic to hot standby instances in the other Availability Zone. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of a failure, a failed instance must be restarted before the LRS services can resume processing the print request.

**Note:** LRS VPSX/MFI can also perform health checks at the printer-fleet level. For more information, see *Printer-fleet health checks* in the [Additional information](#) section of this pattern.

4. LRS PageCenterX output management is deployed on Amazon EC2 across two Availability Zones for HA (active-standby redundant pair). It uses [Amazon FSx for Windows File Server](#) as an operational data store. If an active instance is in an unhealthy state, the load balancer performs a health check on the LRS PageCenterX EC2 instances and routes traffic to standby instances in the other Availability Zone.
5. A [Network Load Balancer](#) provides a DNS name to integrate the LRS VPSX/MFI Server with LRS PageCenterX.

**Note:** LRS PageCenterX supports a Layer 4 load balancer.

6. LRS PageCenterX uses Amazon FSx for Windows File Server as an operational data store deployed across two Availability Zones for HA. LRS PageCenterX understands only files that are in the file share, not in an external database.
7. [AWS Managed Microsoft AD](#) is used with LRS/DIS to perform output-management workflow authentication and authorization. For more information, see *Print output authentication and authorization* in the [Additional information](#) section.

## Tools

### AWS services

- [AWS Directory Service for Microsoft Active Directory](#) enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Elastic Load Balancing \(ELB\)](#) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon EC2 instances, containers, and IP addresses in one or more Availability Zones. This pattern uses a Network Load Balancer.
- [Amazon FSx](#) provides file systems that support industry-standard connectivity protocols and offer high availability and replication across AWS Regions. This pattern uses Amazon FSx for Windows File Server.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.

### Other tools

- [LRS PageCenterX](#) software provides a scalable document and report content management solution that helps users obtain maximum value from information through automated indexing, encryption, and advanced search features.
- [LRS VPSX/MFI \(Micro Focus Interface\)](#), codeveloped by LRS and OpenText Micro Focus, captures output from an OpenText Micro Focus Enterprise Server JES spool and reliably delivers it to a specified print destination.

- LRS/Queue is a transmission agent that's TCP/IP based. LRS VPSX/MFI uses LRS/Queue to collect or capture print data through the OpenText Micro Focus JES Print Exit programming interface.
- LRS Directory Integration Server (LRS/DIS) is used for authentication and authorization during the print workflow.
- [OpenText Micro Focus Enterprise Server](#) is an application deployment environment for mainframe applications. It provides the runtime environment for mainframe applications that are migrated or created by using any version of OpenText Micro Focus Enterprise Developer.

## Epics

### Set up the OpenText Micro Focus runtime and deploy a mainframe batch application

Task	Description	Skills required
Set up the runtime and deploy a demo application.	<p>To set up OpenText Micro Focus Enterprise Server on Amazon EC2 and deploy the OpenText Micro Focus BankDemo demonstration application, follow the instructions in <a href="#">AWS Mainframe Modernization user-guide</a>.</p> <p>The BankDemo application is a mainframe batch application that creates and then initiates print output.</p>	Cloud architect

### Set up an LRS print server on Amazon EC2

Task	Description	Skills required
Create an Amazon EC2 Windows instance.	To launch an Amazon EC2 Windows instance, follow the instructions in <a href="#">Step 1: Launch</a>	Cloud architect

Task	Description	Skills required
	<p><a href="#">an instance</a> in the Amazon EC2 documentation. Use the same hostname that you used for your LRS product license.</p> <p>Your instance must meet the following hardware and software requirements for LRS VPSX/MFI:</p> <ul style="list-style-type: none"><li>• CPU – Dual Core</li><li>• RAM – 16 GB</li><li>• Drive – 500 GB</li><li>• Minimum EC2 instance – m5.xlarge</li><li>• OS – Windows</li><li>• Software – Internet Information Services (IIS) or Apache</li></ul> <p><b>Note:</b> The preceding hardware and software requirements are intended for a small printer fleet (around 500-1000). To get the full requirements, consult with your LRS and AWS contacts.</p> <ol style="list-style-type: none"><li>1. When you create your Windows instance, confirm that the EC2 hostname is the same hostname used for the LRS product license.</li></ol>	

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>3. On the Windows <b>Start</b> menu, find and open <b>Server Manager</b>.</li><li>4. In Server Manager, choose <b>Dashboard, Quick Start, Add roles and features</b>, and then choose <b>Server roles</b>.</li><li>5. In Server roles, choose <b>WebServer (IIS)</b>, and then choose <b>Application Development</b>.</li><li>6. In Application Development, select the <b>CGI</b> check box.</li><li>7. To install CGI, follow the instructions in the Windows Server Manager <b>Add roles and features</b> wizard.</li><li>8. Open port 5500 in the Windows firewall of the EC2 instance for LRS/ Queue communication.</li></ol>	

Task	Description	Skills required
Install LRS VPSX/MFI on the EC2 instance.	<ol style="list-style-type: none"><li>1. Connect to your EC2 instance.</li><li>2. Open the link to the product download page from the LRS email message that you should have received.  <b>Note:</b> LRS products are distributed by electronic file transfer (EFT).</li><li>3. Download LRS VPSX/MFI, and unzip the file (default folder: c:\LRS).</li><li>4. To install LRS VPSX/MFI, launch the LRS Product Installer from the unzipped folder.</li><li>5. On the <b>Select Features</b> menu, select <b>VPSX® Server</b>, and then choose <b>Next</b> to start the installation process. You will receive a success message when installation is complete.</li></ol>	Cloud architect

Task	Description	Skills required
Install LRS/Queue.	<ol style="list-style-type: none"><li data-bbox="594 226 1026 357">1. Connect to your OpenText Micro Focus Enterprise Server EC2 instance.</li><li data-bbox="594 378 1026 697">2. Open the link to the LRS product download page from the LRS email message that you should have received, download LRS/Queue, and then unzip the file.</li><li data-bbox="594 718 1026 949">3. Navigate to the location where you downloaded the files, and then launch the LRS Product Installer to install LRS/Queue.</li><li data-bbox="594 970 1026 1150">4. Follow the instructions in the LRS Product Installer to complete the installation process.</li></ol>	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	<p>The LRS/DIS product often is included in LRS VPSX installation. However, if LRS/DIS wasn't installed along with LRS VPSX, use the following steps to install it:</p> <ol style="list-style-type: none"><li>1. Connect to your LRS VPSX/MFI EC2 instance.</li><li>2. Open the link to the LRS product download page from the LRS email message that you should have received, download LRS/DIS, and then unzip the file.</li><li>3. Navigate to the location where you downloaded the files, and then launch the LRS Product Installer.</li><li>4. In the LRS Product Installer, expand <b>LRS Misc Tools</b>, select <b>LRS DIS</b>, and then choose <b>Next</b>.</li><li>5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.</li></ol>	Cloud architect

Task	Description	Skills required
Create a target group.	<p>Create a target group by following the instructions in <a href="#">Create a target group for your Network Load Balancer</a>. When you create the target group, register the LRS VPSX/MFI EC2 instance as the target:</p> <ol style="list-style-type: none"><li>1. On the <b>Specify group details</b> page, for <b>Choose a Target Type</b>, choose <b>Instances</b>.</li><li>2. For <b>Protocol</b>, choose <b>TCP</b>.</li><li>3. For <b>Port</b>, choose <b>5500</b>.</li><li>4. On the <b>Register targets</b> page, in the <b>Available instances</b> section, select the LRS VPSX/MFI EC2 instance.</li></ol>	Cloud architect

Task	Description	Skills required
Create a Network Load Balancer.	<p>To create the Network Load Balancer, follow the instructions in the <a href="#">Elastic Load Balancing documentation</a>.</p> <p>Your Network Load Balancer routes traffic from OpenText Micro Focus Enterprise Server to the LRS VPSX/MFI EC2 instance.</p> <p>When you create the Network Load Balancer, choose the following values on the <b>Listeners and Routing</b> page:</p> <ol style="list-style-type: none"> <li>1. For <b>Protocol</b>, choose <b>TCP</b>.</li> <li>2. For <b>Port</b>, choose <b>5500</b>.</li> <li>3. For <b>Default action</b>, choose <b>Forward to</b> for the target group that you created earlier.</li> </ol>	Cloud architect

## Integrate OpenText Micro Focus Enterprise Server with LRS/Queue and LRS VPSX/MFI

Task	Description	Skills required
Configure Micro Focus Enterprise Server for LRS/Queue integration.	<ol style="list-style-type: none"> <li>1. Connect to your OpenText Micro Focus Enterprise Server EC2 instance by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</li> <li>2. On the Windows <b>Start</b> menu, open the OpenText</li> </ol>	Cloud architect

Task	Description	Skills required
	<p>Micro Focus Enterprise Server Administration UI.</p> <ol style="list-style-type: none"> <li>3. In the menu bar, choose <b>NATIVE</b>.</li> <li>4. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b> for your Enterprise Server region.</li> <li>5. From <b>General</b> in the left navigation pane, scroll down to the <b>Additional</b> section to configure the environment variables (LRSQ_ADDRESS , LRSQ_PORT , LRSQ_COMMAND ) to point to LRSQ. <ul style="list-style-type: none"> <li>• For <b>LRSQ_ADDRESS</b>, enter the IP address or DNS name of the Network Load Balancer that you created earlier.</li> <li>• For <b>LRSQ_PORT</b>, enter <b>VPSX LRSQ Listener Port (5500)</b>.</li> <li>• For <b>LRSQ_COMMAND</b>, enter the path location of the LRSQ executable.</li> </ul> </li> </ol> <p><b>Note:</b> LRS currently supports a maximum character limit of 50 for DNS names. If your DNS name is longer than 50</p>	

Task	Description	Skills required
	<p>characters, you can use the IP address of the Network Load Balancer as an alternative.</p>	
<p>Configure OpenText Micro Focus Enterprise Server for LRS VPSX/MFI integration.</p>	<ol style="list-style-type: none"> <li>1. Copy the VPSX_MFI_R2 folder from the LRS VPSX/MFI installer to the Micro Focus Enterprise Server location at C:\BANKDEMO\print.</li> <li>2. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</li> <li>3. On the Windows <b>Start</b> menu, open the Micro Focus Enterprise Server Administration UI.</li> <li>4. On the menu bar, choose <b>NATIVE</b>.</li> <li>5. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b>.</li> <li>6. Under BANKDEMO, choose <b>JES</b>.</li> <li>7. Under <b>JES Program Path</b>, add the DLL (VPSX_MFI_R2) path from C:\BANKDEMO\print .</li> </ol>	<p>Cloud architect</p>

## Set up the print queue and the print users

Task	Description	Skills required
<p>Associate the OpenText Micro Focus Print Exit module with the Micro Focus Enterprise Server batch printer Server Execution Process.</p>	<ol style="list-style-type: none"> <li>1. Connect to your OpenText Micro Focus Enterprise Server EC2 instance by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</li> <li>2. On the Windows <b>Start</b> menu, open the OpenText Micro Focus Enterprise Server Administration UI.</li> <li>3. On the menu bar, choose <b>NATIVE</b>.</li> <li>4. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b>.</li> <li>5. Under BANKDEMO, choose <b>JES</b>, and scroll down to <b>Printers</b>.</li> <li>6. In Printers, associate the OpenText Micro Focus Print Exit module (<b>LRSRTE6 for Batch</b>) to the OpenText Micro Focus Enterprise Server batch printer <b>Server Execution Process (SEP)</b>. This enables print output routing to LRS VPSX/MFI.</li> </ol> <p>For more information about configuration, see <a href="#">Using the Exit</a> in the</p>	<p>Cloud architect</p>

Task	Description	Skills required
	<p>OpenText Micro Focus documentation.</p>	
<p>Create a print output queue in LRS VPSX/MFI and integrate it with LRS PageCenterX.</p>	<ol style="list-style-type: none"> <li>1. Connect to your LRS VPSX/MFI EC2 instance.</li> <li>2. On the Windows <b>Start</b> menu, open <b>VPSX Web Interface</b>.</li> <li>3. In the navigation pane, choose <b>Printers</b>.</li> <li>4. Choose <b>Add</b>, and then choose <b>Add Printer</b>.</li> <li>5. On the <b>Printer Configuration</b> page, for <b>Printer Name</b>, enter <b>Local</b>.</li> <li>6. For <b>VPSX ID</b>, enter <b>VPS1</b>.</li> <li>7. For <b>CommType</b>, select <b>TCPIP/LRSQ</b>.</li> <li>8. For <b>Host/IP Address</b>, enter the IP address of the Network Load Balancer fronting the LRS PageCenterX EC2 instances .</li> <li>9. For <b>Remote port</b>, enter 5800.</li> <li>10 For <b>Remote queue</b>, enter the name of the LRS PageCenterX document folder where output will be stored.</li> <li>11 Choose <b>Add</b>.</li> </ol>	<p>Cloud architect</p>

Task	Description	Skills required
<p>Create a print user in LRS VPSX/MFI.</p>	<ol style="list-style-type: none"> <li>1. Connect to your LRS VPSX/MFI EC2 instance.</li> <li>2. On the Windows <b>Start</b> menu, open <b>VPSX Web Interface</b>.</li> <li>3. In the navigation pane, choose <b>Security</b>, and then choose <b>Users</b>.</li> <li>4. In the <b>User Name</b> column, choose <b>admin</b>, and then choose <b>Copy</b>.</li> <li>5. In the <b>User Profile Maintenance</b> window, for <b>User Name</b>, enter a username (for example, <b>PrintUser</b>).</li> <li>6. For <b>Description</b>, enter a brief description (for example, <b>User for test print</b>).</li> <li>7. Choose <b>Update</b>. This creates a print user (for example, <b>PrintUser</b>).</li> <li>8. In the navigation pane, under <b>User</b>, choose the new user that you created.</li> <li>9. On the <b>Command</b> menu, choose <b>Security</b>.</li> <li>10 On the <b>Security Rules</b> page, choose all the applicable printer security and job security options, and then choose <b>Save</b>.</li> </ol>	<p>Cloud architect</p>

Task	Description	Skills required
	<p>11.To add your new print user to the <b>Administrator</b> group, on the navigation pane, choose <b>Security</b>, and then choose <b>Configure</b>.</p> <p>12In the <b>Security configuration</b> window, add your new print user to the <b>Administrator</b> column.</p>	

### Set up an LRS PageCenterX server on Amazon EC2

Task	Description	Skills required
Create an Amazon EC2 Windows instance.	<p>Launch an Amazon EC2 Windows instance by following the instructions from <a href="#">Step 1: Launch an instance</a> in the Amazon EC2 documentation. Use the same hostname that you used for your LRS product license.</p> <p>Your instance must meet the following hardware and software requirements for LRS PageCenterX:</p> <ul style="list-style-type: none"> <li>• CPU – Dual Core</li> <li>• RAM – 16 GB</li> <li>• Drive – 500 GB</li> <li>• Minimum EC2 instance – m5.xlarge</li> <li>• OS – Windows</li> </ul>	Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• Software –IIS or Apache</li></ul> <p><b>Note:</b> The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts.</p> <ol style="list-style-type: none"><li>1. When you create your Windows instance, confirm that the EC2 hostname is the same hostname used for the LRS product license.</li><li>2. Connect to your EC2 instance by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</li><li>3. On the Windows <b>Start</b> menu, find and open <b>Server Manager</b>.</li><li>4. In Server Manager, choose <b>Dashboard, Quick Start, Add roles and features</b>, then choose <b>Server roles</b>.</li><li>5. In Server roles, choose <b>WebServer (IIS)</b>, and then choose <b>Application Development</b>.</li><li>6. In Application Development, select the <b>CGI</b> check box.</li></ol>	

Task	Description	Skills required
	<p>7. To install CGI, follow the instructions in the Windows Server Manger <b>Add roles and features</b> wizard.</p> <p>8. Open port 5800 for inbound TCP/IP traffic in the Windows firewall of the EC2 instance. LRS VPSX uses the TCPIP/LRS Q protocol on 5800 port to communicate to LRS PageCenterX.</p>	

Task	Description	Skills required
Install LRS PageCenterX on the EC2 instance.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 308">1. Connect to your EC2 instance.</li><li data-bbox="591 329 1027 558">2. Open the link to the product download page from the LRS email message that you should have received.  <b>Note:</b> LRS products are distributed by electronic file transfer (EFT).</li><li data-bbox="591 751 1027 884">3. Download LRS PageCenterX, and unzip the file (default folder: c:\LRS).</li><li data-bbox="591 905 1027 1079">4. To install LRS PageCenterX, launch the LRS Product Installer from the unzipped folder.</li><li data-bbox="591 1100 1027 1430">5. On the <b>Select Features</b> menu, select <b>PageCenterX</b>, and then choose <b>Next</b> to start the installation process. You will receive a success message when installation is complete.</li></ol>	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	<p>The LRS/DIS product often is included in LRS VPSX installation. However, if LRS/DIS wasn't installed along with LRS VPSX, use the following steps to install it:</p> <ol style="list-style-type: none"><li data-bbox="592 541 1027 632">1. Connect to your LRS PageCenterX EC2 instance.</li><li data-bbox="592 646 1027 926">2. Open the link to the LRS product download page from the LRS email that you should have received, download LRS/DIS, and then unzip the file.</li><li data-bbox="592 940 1027 1121">3. Navigate to the location where you downloaded the files, and then launch the LRS Product Installer.</li><li data-bbox="592 1136 1027 1325">4. In the LRS Product Installer, expand <b>LRS Misc Tools</b>, select <b>LRS DIS</b>, and then choose <b>Next</b>.</li><li data-bbox="592 1339 1027 1570">5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.</li></ol>	Cloud architect

Task	Description	Skills required
Create a target group.	<p>Create a target group by following the instructions in <a href="#">Create a target group for your Network Load Balancer</a>. When you create the target group, register the LRS PageCenterX EC2 instance as the target:</p> <ol style="list-style-type: none"><li>1. On the <b>Specify group details</b> page, for <b>Choose a Target Type</b>, choose <b>Instances</b>.</li><li>2. For <b>Protocol</b>, choose <b>TCP</b>.</li><li>3. For <b>Port</b>, choose <b>5800</b>.</li><li>4. On the <b>Register targets</b> page, in the <b>Available instances</b> section, select the LRS PageCenterX EC2 instance.</li></ol>	Cloud architect

Task	Description	Skills required
<p>Create a Network Load Balancer.</p>	<p>To create the Network Load Balancer, follow the instructions in the <a href="#">Elastic Load Balancing documentation</a>. Your Network Load Balancer routes traffic from LRS VPSX/MFI to the LRS PageCenterX EC2 instance.</p> <p>When you create the Network Load Balancer, choose the following values on the <b>Listeners and Routing</b> page:</p> <ol style="list-style-type: none"> <li>1. For <b>Protocol</b>, choose <b>TCP</b>.</li> <li>2. For <b>Port</b>, choose <b>5800</b>.</li> <li>3. For <b>Default action</b>, choose <b>Forward to</b> for the target group that you created earlier.</li> </ol>	<p>Cloud architect</p>

### Set up output-management features in LRS PageCenterX

Task	Description	Skills required
<p>Enable the Import function in LRS PageCenterX.</p>	<p>You can use the LRS PageCenterX Import function to recognize the outputs landing on LRS PageCenterX by criteria such as Job name or Form ID. You can then route the outputs to specific folders in LRS PageCenterX.</p>	<p>Cloud architect</p>

Task	Description	Skills required
	<p>To enable the Import function, do the following:</p> <ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</li><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin</b>.</li><li>4. On the <b>Configuration</b> page, choose <b>Advanced, Import parameter</b>.</li><li>5. In the <b>Import parameter section</b>, select the <b>Advanced Import</b> check box.</li><li>6. To commit the changes, choose <b>Update</b>.</li></ol>	

Task	Description	Skills required
Configure the document retention policy.	<p>LRS PageCenterX uses a document retention policy to decide how long to keep a document in LRS PageCenterX.</p> <p>To configure the document retention policy, do the following:</p> <ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance.</li><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin</b>.</li><li>4. On the Admin page, choose <b>Archive Group List/General admin</b>, and then choose <b>Retention policy</b>.</li><li>5. In the Retention policy section, choose <b>Add</b> to create a retention policy.</li><li>6. On the <b>Retention Policy Information</b> page, enter a <b>Retention policy name</b>, <b>Description</b>, and <b>Document retention period</b>.</li><li>7. To save your changes and create the policy, choose <b>Ok</b>.</li></ol>	Cloud architect

Task	Description	Skills required
Create a rule to route the output document to a specific folder in LRS PageCenterX.	<p>In LRS PageCenterX, <b>Destination</b> determines the folder path where output will be sent when this destination is invoked by <b>Report Definition</b>. For this example, create a folder based on the <b>Form ID</b> folder in the report definition, and save the output to that folder.</p> <ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance.</li><li>2. On the Windows Start menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin, Advance Import, Destination</b>.</li><li>4. In the Destination section, choose <b>Add</b> to open the <b>Destination Maintenance</b> form.</li><li>5. On the Destination Maintenance form, enter the following values:<ul style="list-style-type: none"><li>• <b>Destination name</b> – Form</li><li>• <b>Description</b> – Description of the destination, such as <b>Form-based folder structure</b></li></ul></li></ol>	Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <b>Destination type</b> – Folder</li><li>• <b>Folder Parameters</b> – Import folder path (the folder path that will be created in PageCenterX when the document arrives; for example, the path /Test/&amp;FORM/&amp;IMPORTDATE/&amp;IMPORTTIME will create a base Test folder, a subfolder based on <b>Form-Id</b> named STD, a subfolder based on <b>Import date</b>, and then a subfolder based on <b>Import time</b>)</li><li>• <b>Document name</b> – Dynamic name assigned to a document when it's stored in the folder.</li></ul> <p>6. In the dropdown list, choose a retention policy. For example, choose <b>Year1</b> to retain the document for 1 year.</p> <p>7. To save the changes, choose <b>Ok</b>.</p>	

Task	Description	Skills required
Create a report definition.	<ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance.</li><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin, Advance Import, Report Definition</b>, and then choose <b>Add</b>.</li><li>4. On the <b>Report definition maintenance</b> page, on the <b>General</b> tab, enter the <b>Report Definition name</b>.</li><li>5. On the <b>General</b> tab, under <b>Fields</b>, you can specify selection criteria such as <b>Job Name, Form, Class</b>, and <b>Author</b>. For example, you could enter a <b>Job Name</b> of <b>MFIDEMO</b>. The <b>Job Name</b> value will be the name of the batch job that will generate print output.</li><li>6. On the <b>Destination</b> tab, under <b>Available Destination</b>, choose the previously created destination (<b>Form</b>).</li><li>7. Choose <b>Add</b> to add the <b>Form</b> destination as <b>Assigned destination</b>.</li></ol> <p><b>Note:</b> This example includes a report definition where an output generated</p>	Cloud architect

Task	Description	Skills required
	by the MFIDEMO and routed to LRS PageCenterX is saved in the folder structure defined in the destination definition.	

## Set up authentication and authorization for output management

Task	Description	Skills required
Create an AWS Managed Microsoft AD domain with users and groups.	<ol style="list-style-type: none"> <li>1. To create a directory on AWS Managed Microsoft AD, follow the instructions in <a href="#">Create your AWS Managed Microsoft AD directory</a>.</li> <li>2. To deploy an EC2 instance (Active Directory manager) and install Active Directory tools to manage your AWS Managed Microsoft AD, follow the instructions in <a href="#">Step 3: Deploy an EC2 instance to manage your AWS Managed Microsoft AD</a>.</li> <li>3. To connect to your EC2 instance, follow the instructions in the <a href="#">Amazon EC2 documentation</a>.</li> </ol> <p><b>Note:</b> When you connect to the EC2 instance, in the <b>Windows Security</b> window,</p>	Cloud architect

Task	Description	Skills required
	<p>enter the administrator credentials for the directory that you created in step 1.</p> <p>4. On the Windows <b>Start</b> menu, under <b>Windows Administrative Tools</b>, choose <b>Active Directory Users and Computers</b>.</p> <p>5. To create a print user in the Active Directory domain, follow the instructions in <a href="#">Create a user</a>.</p>	
Join the EC2 instances to an AWS Managed Microsoft AD domain.	Join the LRS VPSX/MFI and LRS PageCenterX EC2 instances to your AWS Managed Microsoft AD domain <a href="#">automatically</a> (AWS Knowledge Center documentation) or <a href="#">manually</a> (AWS Directory Service documentation).	Cloud architect

Task	Description	Skills required
Configure and integrate LRS/DIS with AWS Managed Microsoft AD for the LRS PageCenterX EC2 instance.	<ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance.</li><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin</b>.</li><li>4. On the <b>Configuration</b> page, in the <b>Security Parameters</b> section, for <b>Security Type</b>, select <b>LRS/DIS</b>.</li><li>5. Enter your preferences for the rest of the options in the Security Parameters section.</li><li>6. On the Windows <b>Start</b> menu, open the <b>PageCenterX</b> folder, choose <b>Server Start</b>, and then choose <b>Server Stop</b>.</li><li>7. Log in to LRS PageCenterX with your Active Directory username and password.</li></ol>	Cloud architect

Task	Description	Skills required
Configure an Import group to import output from LRS VPSX to LRS PageCenterX.	<ol style="list-style-type: none"> <li>1. Connect to your LRS PageCenterX EC2 instance.</li> <li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li> <li>3. In <b>Folder Explorer</b>, choose <b>Admin, Security admin, Groups</b>.</li> <li>4. In the Groups section, choose <b>Add</b> to open the <b>Group preference</b> form.</li> <li>5. In the Group preference form, enter values for <b>Group name</b> and <b>Description</b>.</li> <li>6. Expand <b>General options</b>, and then select the <b>Import</b> check box.</li> <li>7. To save the changes, choose <b>Ok</b>.</li> </ol>	Cloud architect
Add a security rule to the Import group.	<ol style="list-style-type: none"> <li>1. Open the context (right-click) menu for <b>Import group</b>.</li> <li>2. Choose <b>Advance</b>, and then choose <b>Security</b>.</li> <li>3. In the Security section, choose <b>Import</b>, and select the <b>Subfolder</b> check box.</li> <li>4. To save the changes, choose <b>Apply</b>.</li> </ol>	Cloud architect

Task	Description	Skills required
Create a user in LRS PageCenterX to perform output import from LRS VPSX/MFI.	<p>When you create a user in LRS PageCenterX to perform output import, the username should be the same as the <b>VPSX ID</b> of the print output queue in LRS VPSX/MFI. In this example, the VPSX ID is <b>VPS1</b>.</p> <ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance.</li><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin, Security admin, User</b>.</li><li>4. Choose <b>Add</b> to open the <b>User profile maintenance</b> form.</li><li>5. In User profile maintenance, for <b>User name</b>, enter <b>VPS1</b>.</li></ol>	Cloud architect

Task	Description	Skills required
Add the LRS PageCenterX Import user to the Import only group.	<p>To provide necessary permission for document import from LRS VPSX to LRS PageCenterX, do the following:</p> <ol style="list-style-type: none"><li>1. Connect to your LRS PageCenterX EC2 instance.</li><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In <b>Folder Explorer</b>, choose <b>Admin, Security admin, Groups</b>.</li><li>4. In the Groups section, open the context (right-click) menu for the <b>Import only</b> group, and then choose <b>Advance, Security</b>.</li><li>5. On the <b>Folder Security Records (ImportOnly)</b> page, choose the <b>User</b> tab.</li><li>6. On the User tab, under <b>Name</b>, select user <b>VPS1</b> from the dropdown list, and choose <b>Apply</b>.</li></ol>	Cloud architect

Task	Description	Skills required
Configure LRS/DIS with AWS Managed Microsoft AD for the LRS VPSX/MFI EC2 instance.	<ol style="list-style-type: none"><li>1. Connect to your LRS VPSX/MFI EC2 instance.</li><li>2. On the Windows <b>Start</b> menu, open <b>VPSX Web Interface</b>.</li><li>3. In the navigation pane, choose <b>Security</b>, and then choose <b>Configure</b>.</li><li>4. On the <b>Security Configuration</b> page, in the <b>Security Parameters</b> section, for <b>Security Type</b>, select <b>LRS/DIS (External)</b>.</li><li>5. Enter your preferences for the rest of the options in the Security Parameters section.</li><li>6. On the Windows <b>Start</b> menu, open the <b>LRS Output Management</b> folder, choose <b>Server Start</b>, and then choose <b>Server Stop</b>.</li><li>7. Log in to LRS VPSX/MFI with your Active Directory username and password.</li></ol>	Cloud architect

## Configure Amazon FSx for Windows File Server as the operational data store for LRS PageCenterX

Task	Description	Skills required
Create a file system for LRS PageCenterX.	To use Amazon FSx for Windows File Server as an operational data store for LRS PageCenterX in a Multi-AZ environment, follow the instructions in <a href="#">Step 1: Create your file system</a> .	Cloud architect
Map the file share to the LRS PageCenterX EC2 instance.	To map the file share created in previous step to the LRS PageCenterX EC2 instance, follow the instructions in <a href="#">Step 2: Map your file share to an EC2 instance running Windows Server</a> .	Cloud architect
Map LRS PageCenterX Control Directory and Master Folder Directory to the Amazon FSx network share drive.	<ol style="list-style-type: none"> <li>1. Connect to your LRS PageCenterX EC2 instance by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</li> <li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li> <li>3. In <b>Folder Explorer</b>, choose <b>Admin, Configuration</b>.</li> <li>4. On the Configuration page, choose <b>Directories</b>, and then choose <b>Control Directory</b>.</li> </ol>	Cloud architect

Task	Description	Skills required
	<p>5. In <b>Control Directories</b>, enter <code>\\FSx file share DNS name\share\cntl</code> .</p> <p>6. In <b>Master Folder Directory</b>, enter <code>\\FSx file share DNS name\share\mstr</code> .</p>	

### Test an output-management workflow

Task	Description	Skills required
Initiate a batch print request from the OpenText Micro Focus BankDemo app.	<ol style="list-style-type: none"> <li>1. Open the 3270-terminal emulator in your OpenText Micro Focus Enterprise Server EC2 instance.</li> <li>2. Connect to the BankDemo app by running the command <code>connect 127.0.0.1:9278</code> .</li> <li>3. On the BankDemo command line interface, for <b>User id</b>, enter <b>B0001</b>. For <b>Password</b>, enter a non-blank key.</li> <li>4. For the <b>Request printed statement(s)</b> option, enter <b>X</b> on the blank line.</li> <li>5. In the <b>Send statement by</b> section, for <b>Mail</b>, enter <b>Y</b>, and then press F10.</li> </ol>	Test engineer
Check the print output in LRS PageCenterX.	1. Connect to your LRS PageCenterX EC2 instance	Test engineer

Task	Description	Skills required
	<p>by following the instructions in the <a href="#">Amazon EC2 documentation</a>.</p> <ol style="list-style-type: none"><li>2. On the Windows <b>Start</b> menu, open <b>PCX Web Interface</b>.</li><li>3. In the navigation pane, open the <b>Test</b> folder, open the <b>STD</b> folder, and then open the folder with the job run date, such as 08-03-2023 (MM-DD-YY YY).</li></ol> <p><b>Note:</b> This is the same folder structure as defined in the story <i>Create a rule to route the output document to a specific folder in LRS PageCenterX</i>.</p> <ol style="list-style-type: none"><li>4. Open the formtest-STD.txt file.</li></ol> <p>You can now see the print output of an account statement with columns for <b>Account No.</b>, <b>Description</b>, <b>Date</b>, <b>Amount</b>, and <b>Balance</b>. For an example, see the batch_print_output attachment for this pattern.</p>

## Additional information

### Considerations

During your modernization journey, you might consider a wide variety of configurations for mainframe batch and online processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform might incorporate the IBM AFP data stream or Xerox LCDS into the current workflow. Additionally, [mainframe carriage control characters](#) and [channel command words](#) can affect the look of the printed page and might need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

### Print data capture

OpenText Micro Focus Print Exit passes the necessary information for LRS VPSX/MFI to effectively process the spool file. The information consists of fields passed in the relevant control blocks, such as the following:

- JOBNAME
- OWNER (USERID)
- DESTINATION
- FORM
- FILENAME
- WRITER

LRS VPSX/MFI supports the following mainframe batch mechanisms for capturing data from OpenText Micro Focus Enterprise Server:

- BATCH COBOL print/spool processing using standard z/OS JCL SYSOUT DD/OUTPUT statements.
- BATCH COBOL print/spool processing using standard z/OS JCL CA-SPOOL SUBSYS DD statements.
- IMS/COBOL print/spool processing using the CBLTDLI interface. For a full list of supported methods and programming examples, see the LRS documentation that's included with your product license.

## Printer-fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep-dive health checks for printer fleets, see the LRS documentation that's included with your product license.

## Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or a Lightweight Directory Access Protocol (LDAP) server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks—for example, command-level security such as hold or release, purge, modify, copy, and reroute. Security can be set up by either the user-ID or the group, similar to an Active Directory security group or an LDAP group.

# Modernize mainframe batch printing workloads on AWS by using Micro Focus Enterprise Server and LRS VPSX/MFI

Created by Shubham Roy (AWS), Abraham Rondon (Micro Focus), Guy Tucker (Levi, Ray and Shoup Inc), and Kevin Yung (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> IBM Mainframe	<b>Target:</b> AWS
<b>R Type:</b> Replatform	<b>Workload:</b> IBM	<b>Technologies:</b> Mainframe; Modernization
<b>AWS services:</b> AWS Managed Microsoft AD; Amazon EC2; Amazon S3; Amazon EBS		

## Summary

This pattern shows you how to modernize your business-critical mainframe batch printing workloads on the Amazon Web Services (AWS) Cloud by using Micro Focus Enterprise Server as a runtime for a modernized mainframe application and LRS VPSX/MFI (Micro Focus Interface) as a print server. The pattern is based on the [replatform](#) mainframe modernization approach. In this approach, you migrate your mainframe batch jobs to Amazon Elastic Compute Cloud (Amazon EC2) and migrate your mainframe database, such as IBM DB2 for z/OS, to Amazon Relational Database Service (Amazon RDS). The authentication and authorization for the modernized print workflow is performed by AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. The LRS Directory Information Server (LRS/DIS) is integrated with AWS Managed Microsoft AD. By modernizing your batch printing workloads, you can reduce IT infrastructure costs, mitigate the technical debt of maintaining legacy systems, remove data silos, increase agility and efficiency with a DevOps model, and take advantage of on-demand resources and automation in the AWS Cloud.

## Prerequisites and limitations

### Prerequisites

- An active AWS account

- A mainframe printing or output management workload
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on Micro Focus Enterprise Server (For more information, see the [Enterprise Server](#) data sheet in the Micro Focus documentation.)
- Basic knowledge of LRS cloud printing solutions and concepts (For more information, see [Output Modernization](#) in the LRS documentation.)
- Micro Focus Enterprise Server software and license (For more information, contact [Micro Focus sales](#).)
- LRS VPSX/MFI, LRS/Queue, and LRS/DIS software and licenses (For more information, contact [LRS sales](#).)

**Note:** For more information about configuration considerations for mainframe batch printing workloads, see *Considerations* in the *Additional information* section of this pattern.

### Product versions

- [Micro Focus Enterprise Server](#) 6.0 (product update 7)
- [LRS VPSX/MFI](#) V1R3 or higher

## Architecture

### Source technology stack

- Operating system – IBM z/OS
- Programming language – Common Business-Oriented Language (COBOL), job control language (JCL), and Customer Information Control System (CICS)
- Database – IBM DB2 for z/OS and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Printing and output management – IBM mainframe z/OS printing products (IBM Tivoli Output Manager for z/OS, LRS, and CA View)

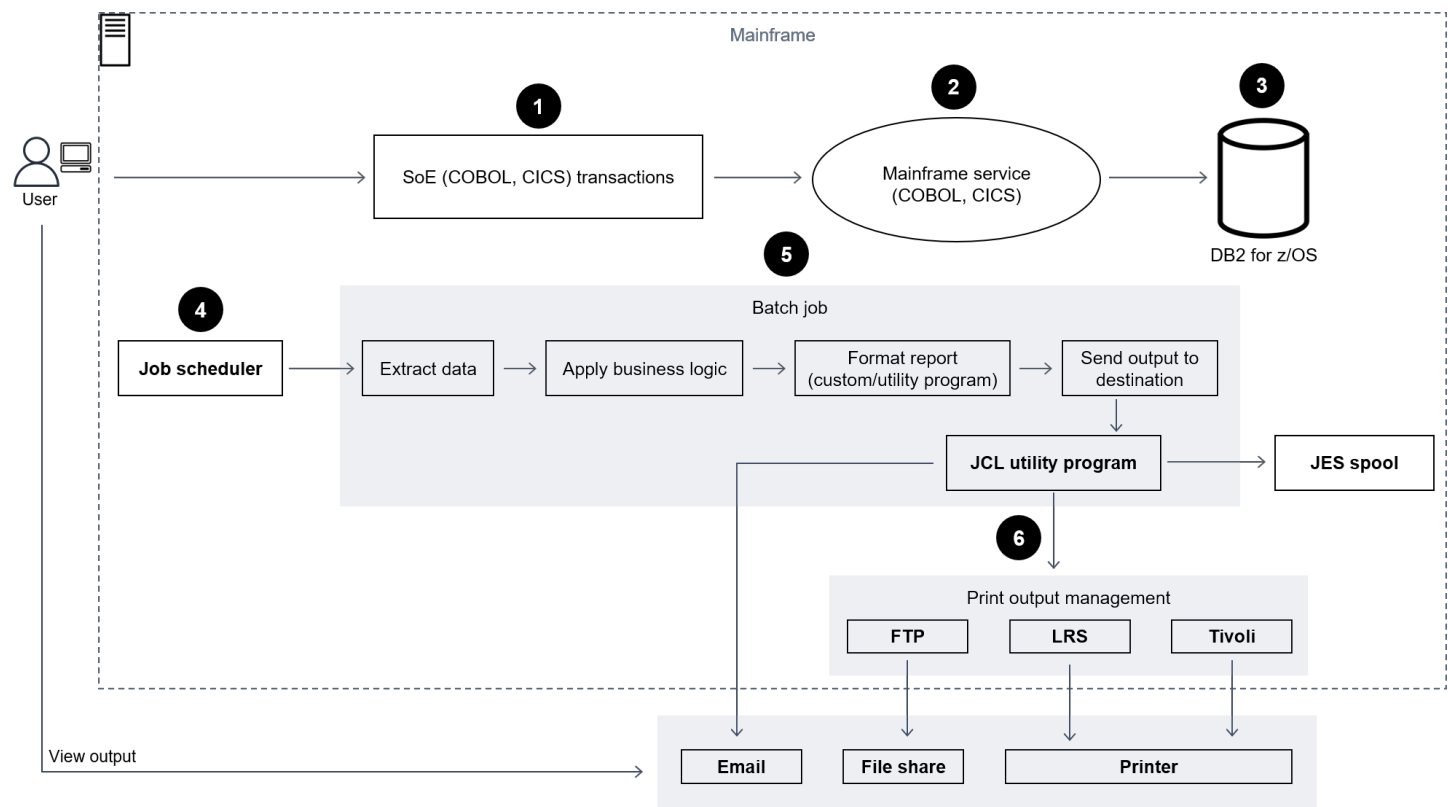

### Target technology stack

- Operating system – Microsoft Windows Server running on Amazon EC2

- Compute – Amazon EC2
- Programming language – COBOL, JCL, and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD
- Printing and output management – LRS printing solution on AWS
- Mainframe runtime environment – Micro Focus Enterprise Server

## Source architecture

The following diagram shows a typical current state architecture for a mainframe batch printing workload:

The diagram shows the following workflow:

1. Users perform business transactions on a system of engagement (SoE) that's built on an IBM CICS application written in COBOL.
2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM DB2 for z/OS.

3. The SoR persists the business data from the SoE.
4. The batch job scheduler initiates a batch job to generate print output.
5. The batch job extracts data from the database, formats the data according to business requirements, and then generates business output such as billing statements, ID cards, or loan statements. Finally, the batch job routes the output to printing output management for processing and output delivery, based on the business requirements.
6. Printing output management receives print output from the batch job, and then delivers that output to a specified destination, such as email, a file share that uses secure FTP, a physical printer that uses LRS printing solutions (as demonstrated in this pattern), or IBM Tivoli.

## Target architecture

The following diagram shows an architecture for a mainframe batch printing workload that's deployed in the AWS Cloud:

The diagram shows the following workflow:

1. The batch job scheduler initiates a batch job to create print output, such as billing statements, ID cards, or loan statements.

2. The mainframe batch job ([replatformed to Amazon EC2](#)) uses the Micro Focus Enterprise Server runtime to extract data from the application database, apply business logic to the data, format the data, and then send the data to a print destination by using [Micro Focus Print Exit](#) (Micro Focus documentation).
3. The application database (an SoR that runs on Amazon RDS) persists data for print output.
4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2 and its operational data is stored in Amazon Elastic Block Store (Amazon EBS). LRS VPSX/MFI uses the TCP/IP-based LRS/Queue transmission agent to collect print data through the Micro Focus JES Print Exit API and deliver the data to a specified printer destination.

**Note:** The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM Advanced Function Presentation (AFP) or Xerox Line Condition Data Stream (LCDS). For more information about using Micro Focus for mainframe application migration and modernization on AWS, see [Empowering Enterprise Mainframe Workloads on AWS with Micro Focus](#) in the AWS documentation.

### **AWS infrastructure architecture**

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe batch printing workload:

The diagram shows the following workflow:

1. The batch scheduler initiates the batch process and is deployed on Amazon EC2 across multiple [Availability Zones](#) for high availability (HA). **Note:** This pattern doesn't cover the implementation of the batch scheduler. For more information about implementation, see the software vendor documentation for your scheduler.
2. The mainframe batch job (written on a programming language such as JCL or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The job is deployed on Amazon EC2 across two Availability Zones for HA and uses Micro Focus Print Exit to route print output to LRS VPSX/MFI for end-user printing.
3. LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data from the Micro Focus JES Print Exit programming interface. Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the spool file and dynamically build LRS/Queue commands. The commands are then run using a standard built-in function from Micro Focus. **Note:** For more information on print data passed from Micro Focus Print Exit to LRS/Queue and LRS VPSX/MFI supported mainframe batch mechanisms, see *Print data capture* in the *Additional information* section of this pattern.
4. A [Network Load Balancer](#) provides a DNS name to integrate Micro Focus Enterprise Server with LRS VPSX/MFI. **Note:** LRS VPSX/MFI supports a Layer 4 load balancer. The Network Load

Balancer also does a basic health check on LRS VPSX/MFI and routes traffic to the registered targets that are healthy.

5. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA and uses [Amazon EBS](#) as an operational data store. LRS VPSX/MFI supports both the active-active and active-passive service modes. This architecture uses multiple AZs in an active-passive pair as an active and hot standby. The Network Load Balancer performs a health check on LRS VPSX/MFI EC2 instances and routes traffic to hot standby instances in the other AZ if an active instance is in an unhealthy state. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of recovery, a failed instance has to be restarted for the LRS services to resume processing the print request. **Note:** LRS VPSX/MFI can also perform health checks at the printer fleet level. For more information, see *Printer fleet health checks* in the *Additional information* section of this pattern.
6. [AWS Managed Microsoft AD](#) integrates with LRS/DIS to perform print workflow authentication and authorization. For more information, see *Print authentication and authorization* in the *Additional information* section of this pattern.
7. LRS VPSX/MFI uses Amazon EBS for block storage. You can back up Amazon EBS data from active EC2 instances to Amazon S3 as point-in-time snapshots and restore them to hot standby EBS volumes. To automate the creation, retention, and deletion of Amazon EBS volume snapshots, you can use [Amazon Data Lifecycle Manager](#) to set the frequency of automated snapshots and restore them based on your [RTO/RPO requirements](#).

## Tools

### AWS services

- [Amazon EBS](#) – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.
- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- [Amazon RDS](#) – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks.

- [AWS Managed Microsoft AD](#) – AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft Active Directory, enables your directory-aware workloads and AWS resources to use managed Active Directory in AWS.

## Other tools

- [LRS VPSX/MFI \(Micro Focus Interface\)](#) – VPSX/MFI, co-developed by LRS and Micro Focus, captures output from a Micro Focus Enterprise Server JES spool and reliably delivers it to a specified print destination.
- LRS Directory Information Server (LRS/DIS) – LRS/DIS is used for authentication and authorization during the print workflow.
- LRS/Queue – LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data through the Micro Focus JES Print Exit programming interface.
- [Micro Focus Enterprise Server](#) – Micro Focus Enterprise Server is an application deployment environment for mainframe applications. It provides the execution environment for mainframe applications that are migrated or created by using any version of Micro Focus Enterprise Developer.

## Epics

### Set up Micro Focus Enterprise Server on Amazon EC2 and deploy a mainframe batch application

Task	Description	Skills required
Set up Micro Focus Enterprise Server and deploy a demo application.	Set up Micro Focus Enterprise Server on Amazon EC2, and then deploy the Micro Focus BankDemo demonstration application on Amazon EC2 by following the instructions in the <a href="#">Micro Focus Enterprise Server on AWS</a> Quick Start deployment guide.  The BankDemo application is a mainframe batch applicati	Cloud architect

Task	Description	Skills required
	on that creates and then initiates print output.	

## Set up an LRS print server on Amazon EC2

Task	Description	Skills required
Get an LRS product license for printing.	To get an LRS product license for LRS VPSX/MFI, LRS/Queue, and LRS/DIS, contact the <a href="#">LRS Output Management team</a> . You must provide the host names of the EC2 instances where the LRS products will be installed.	Build lead
Create an Amazon EC2 Windows instance to install LRS VPSX/MFI.	Launch an Amazon EC2 Windows instance by following the instructions from <a href="#">Step 1: Launch an instance</a> in the Amazon EC2 documentation. Your instance must meet the following hardware and software requirements for LRS VPSX/MFI: <ul style="list-style-type: none"> <li>• CPU – Dual Core</li> <li>• RAM – 16 GB</li> <li>• Drive – 500 GB</li> <li>• Minimum EC2 instance – m5.xlarge</li> <li>• OS – Windows/Linux</li> </ul>	Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• Software – Internet Information Service (IIS) or Apache</li></ul> <p><b>Note:</b> The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts.</p> <p>When you create your Windows instance, do the following:</p> <ol style="list-style-type: none"><li>1. Confirm that the EC2 host name is the same host name used for the LRS product license.</li><li>2. Enable CGI in Amazon EC2 by completing the following:<ol style="list-style-type: none"><li>a. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>b. In the Windows Start menu, find and open Server Manager.</li><li>c. In Server Manager, choose <b>Dashboard</b>,</li></ol></li></ol>	

Task	Description	Skills required
	<p><b>Quick Start, Add roles and features.</b> Then, choose <b>Server roles</b>.</p> <p>d. In <b>Server roles</b>, choose <b>WebServer (IIS)</b>, and then choose <b>Application Development</b>.</p> <p>e. In <b>Application Development</b>, select the <b>CGI</b> check box.</p> <p>f. Follow the instructions on the Windows Server Manger <b>Add roles and features</b> wizard to install CGI.</p> <p>g. Open port 5500 in the Windows firewall of the EC2 instance for LRS/ Queue communication.</p>	

Task	Description	Skills required
Install LRS VPSX/MFI on the EC2 instance.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 499">1. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li data-bbox="592 520 1027 846">2. Open the link to the product download page from the LRS email that you should receive. <b>Note:</b> LRS products are distributed by electronic file transfer (EFT).</li><li data-bbox="592 867 1027 993">3. Download LRS VPSX/MFI and unzip the file (default folder: c:\LRS).</li><li data-bbox="592 1014 1027 1192">4. Launch the LRS Product Installer from the unzipped folder to install LRS VPSX/MFI.</li><li data-bbox="592 1213 1027 1591">5. In the <b>Select Features</b> menu, select <b>VPSX® Server (V1R3.022)</b>, and then choose <b>Next</b> to start the installation process. You will receive a success message when installation is complete.</li></ol>	Cloud architect

Task	Description	Skills required
Install LRS/Queue.	<ol style="list-style-type: none"><li data-bbox="592 226 1026 548">1. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.</li></ol>	Cloud architect

Task	Description	Skills required
<p>Create a target group and register LRS VPSX/MFI EC2 as the target.</p>	<p>Create a target group by following the instructions from <a href="#">Create a target group for your Network Load Balancer</a> in the Elastic Load Balancing documentation.</p> <p>When you create the target group, do the following:</p> <ol style="list-style-type: none"><li>1. On the <b>Specify group details</b> page, for <b>Choose a Target Type</b>, choose <b>Instances</b>.</li><li>2. For <b>Protocol</b>, choose <b>TCP</b>.</li><li>3. For <b>Port</b>, choose <b>5500</b>.</li><li>4. On the <b>Register targets</b> page, in the <b>Available instances</b> section, select the LRS VPSX/MFI EC2 instances.</li></ol>	<p>Cloud architect</p>

Task	Description	Skills required
<p>Create a Network Load Balancer.</p>	<p>Follow the instructions from <a href="#">Create a Network Load Balancer</a> in the Elastic Load Balancing documentation. Your Network Load Balancer routes traffic from Micro Focus Enterprise Server to LRS VPSX/MFI EC2.</p> <p>When you create the Network Load Balancer, do the following on the <b>Listeners and Routing</b> page:</p> <ol style="list-style-type: none"> <li>1. For <b>Protocol</b>, choose <b>TCP</b>.</li> <li>2. For <b>Port</b>, choose <b>5500</b>.</li> <li>3. For <b>Default action</b>, choose <b>Forward to</b> for the target group that you created earlier.</li> </ol>	<p>Cloud architect</p>

### Integrate Micro Focus Enterprise Server with LRS VPSX/MFI and LRS/Queue

Task	Description	Skills required
<p>Configure Micro Focus Enterprise Server for LRS/Queue integration.</p>	<ol style="list-style-type: none"> <li>1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li> <li>2. In the Windows Start menu, open the Micro</li> </ol>	<p>Cloud architect</p>

Task	Description	Skills required
	<p>Focus Enterprise Server Administration UI.</p> <ol style="list-style-type: none"><li>3. In the menu bar, choose <b>NATIVE</b>.</li><li>4. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b>.</li><li>5. From <b>General</b> in the left navigation pane, scroll down to the <b>Additional</b> section to configure the environment variables (LRSQ_ADDRESS, LRSQ_PORT, LRSQ_COMMAND) to point to LRSQ.</li><li>6. For <b>LRSQ_ADDRESS</b>, enter the IP address or DNS name of the Network Load Balancer that you created earlier.</li><li>7. For <b>LRSQ_PORT</b>, enter <b>VPSX LRSQ Listener Port (5500)</b>.</li><li>8. For <b>LRSQ_COMMAND</b>, enter the path location of the LRSQ executable.</li></ol> <p><b>Note:</b> LRS currently supports a maximum character limit of 50 for DNS names, but this is subject to change in the future. If your DNS name</p>	

Task	Description	Skills required
	is greater than 50, then you can use the IP address of the Network Load Balancer as an alternative.	

Task	Description	Skills required
Configure Micro Focus Enterprise Server for LRS VPSX/MFI integration.	<ol style="list-style-type: none"><li>1. Copy the VPSX_MFI_R2 folder from the LRS VPSX/MFI installer to the Micro Focus Enterprise Server location at C:\BANKDEMO\print.</li><li>2. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>3. In the Windows Start menu, open the Micro Focus Enterprise Server Administration UI.</li><li>4. In the menu bar, choose <b>NATIVE</b>.</li><li>5. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b>.</li><li>6. Under <b>BANKDEMO</b>, choose <b>JES</b>.</li><li>7. Under <b>JES Program Path</b>, add the DLL (VPSX_MFI_R2) path from the C:\BANKDEMO\print location.</li></ol>	Cloud architect

## Set up printers and print users in Micro Focus Enterprise Server and LRS VPSX/MFI

Task	Description	Skills required
Associate the Micro Focus Print Exit module to the Micro Focus Enterprise Server batch printer Server Execution Process.	<ol style="list-style-type: none"><li>1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>2. In the Windows Start menu, open the Micro Focus Enterprise Server Administration UI.</li><li>3. In the menu bar, choose <b>NATIVE</b>.</li><li>4. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b>.</li><li>5. Under <b>BANKDEMO</b>, choose <b>JES</b>, and scroll down to <b>Printers</b>.</li><li>6. In <b>Printers</b>, associate the Micro Focus Print Exit module (LRSPRTE6 for Batch) to the Micro Focus Enterprise Server batch printer Server Execution Process (SEP). This allows print output routing to LRS VPSX/MFI.</li><li>7. Sign in to the Enterprise Server Administration UI.</li></ol>	Cloud architect

Task	Description	Skills required
	For more information about configuration, see <a href="#">Using the Exit</a> in the Micro Focus documentation.	

Task	Description	Skills required
Add a printer in LRS VPSX/MFI.	<ol style="list-style-type: none"><li>1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>2. Open the VPSX Web Interface from the Windows Start menu.</li><li>3. In the navigation pane, choose <b>Printers</b>.</li><li>4. Choose <b>Add</b>, and then choose <b>Add Printer</b>.</li><li>5. On the <b>Printer Configuration</b> page, for <b>Printer Name</b>, enter <b>Local</b>.</li><li>6. For <b>VPSX ID</b>, enter <b>VPS1</b>.</li><li>7. For <b>CommType</b>, select <b>TCPIP/LRSQ</b>.</li><li>8. For <b>Host/IP Address</b>, enter the IP address of the physical printer that you want to add.</li><li>9. For <b>Device</b>, enter the name of your device.</li><li>10 Choose either <b>Windows Driver</b> or <b>Linux/Mac Driver</b>.</li><li>11 Choose <b>Add</b>.</li></ol>	Cloud architect

Task	Description	Skills required
Create a print user in LRS VPSX/MFI.	<ol style="list-style-type: none"><li>1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>2. Open the VPSX Web Interface from the Windows Start menu.</li><li>3. In the navigation pane, choose <b>Security</b>, and then choose <b>Users</b>.</li><li>4. In the <b>User Name</b> column, choose <b>admin</b>, and then choose <b>Copy</b>.</li><li>5. In the <b>User Profile Maintenance</b> window, for <b>User Name</b>, enter a user name (for example, <b>PrintUser</b>).</li><li>6. For <b>Description</b>, enter a brief description (for example, <b>User for test print</b>).</li><li>7. Choose <b>Update</b>. This creates a print user (for example, <b>PrintUser</b>).</li><li>8. In the navigation pane, under <b>User</b>, choose the new user that you created.</li><li>9. From the <b>Command</b> menu, choose <b>Security</b>.</li></ol>	Cloud architect

Task	Description	Skills required
	<p>10 On the <b>Security Rules</b> page, choose all the applicable printer security and job security options, and then choose <b>Save</b>.</p> <p>11 To add your new print user to the <b>Administrator</b> group, go to the navigation pane, choose <b>Security</b>, and then choose <b>Configure</b>.</p> <p>12 In the <b>Security configuration</b> window, add your new print user to the <b>Administrator</b> column.</p>	

## Set up print authentication and authorization

Task	Description	Skills required
<p>Create an AWS Managed Microsoft AD domain with users and groups.</p>	<ol style="list-style-type: none"> <li>1. Create an Active Directory on AWS Managed Microsoft AD by following the instructions from <a href="#">Create your AWS Managed Microsoft AD directory</a> in the AWS Directory Service documentation.</li> <li>2. Deploy an EC2 instance (Active Directory manager) and install Active Directory tools to manage your AWS Managed Microsoft AD by following the instructions from <a href="#">Step 3: Deploy an EC2</a></li> </ol>	<p>Cloud architect</p>

Task	Description	Skills required
	<p><a href="#">instance to manage your AWS Managed Microsoft AD</a> in the AWS Directory Service documentation.</p> <ol style="list-style-type: none"><li>3. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation. <b>Note:</b> When you connect to the EC2 instance, enter your administrator credentials (for the directory that you created in step one) in the Windows Security window.</li><li>4. In the Windows Start menu, under <b>Windows Administrative Tools</b>, choose <b>Active Directory Users and Computers</b>.</li><li>5. Create a print user in the Active Directory domain by following the steps from <a href="#">Create a user</a> in the AWS Directory service documentation.</li></ol>	

Task	Description	Skills required
Join LRS VPSX/MFI EC2 to an AWS Managed Microsoft AD domain.	Join LRS VPSX/MFI EC2 to your AWS Managed Microsoft AD domain <a href="#">automatically</a> (AWS Knowledge Center documentation) or <a href="#">manually</a> (AWS Directory Service documentation).	Cloud architect

Task	Description	Skills required
Configure and integrate LRS/DIS with AWS Managed Microsoft AD.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 548">1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li data-bbox="592 569 1027 699">2. In the Windows Start menu, open the VPSX Web Interface.</li><li data-bbox="592 720 1027 850">3. In the navigation pane, choose <b>Security</b>, and then choose <b>Configure</b>.</li><li data-bbox="592 871 1027 1098">4. On the <b>Security Configuration</b> page, in the <b>Security Parameters</b> section, for <b>Security Type</b>, select <b>Internal</b>.</li><li data-bbox="592 1119 1027 1295">5. Enter your preferences for the rest of the options in the <b>Security Parameters</b> section.</li><li data-bbox="592 1316 1027 1598">6. Open the <b>LRS Output Management</b> folder from the Microsoft Windows Start menu, choose <b>Server Start</b>, and then choose <b>Server Stop</b>.</li><li data-bbox="592 1619 1027 1749">7. Log in to LRS VPSX/MFI with your Active Directory user name and password.</li></ol>	Cloud architect

## Test a print workflow

Task	Description	Skills required
<p>Initiate a batch print request from the Micro Focus BankDemo app.</p>	<ol style="list-style-type: none"> <li>1. Open the 3270 terminal emulator in your Micro Focus Enterprise Server EC2 instance.</li> <li>2. Connect to the BankDemo app by running the following command: connect 127.0.0.1 :9278</li> <li>3. On the BankDemo command line interface, for <b>User id</b>, enter <b>B0001</b>. For <b>Password</b>, enter a non-blank key.</li> <li>4. For the <b>Request printed statement(s)</b> option, enter <b>X</b> on the blank line.</li> <li>5. In the <b>Send statement by</b> section, for <b>Mail</b>, enter <b>Y</b>, and then press F10.</li> </ol>	<p>Test engineer</p>
<p>Check the print output in LRS VPSX/MFI.</p>	<ol style="list-style-type: none"> <li>1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li> <li>2. In Windows Start menu, open the VPSX Web Interface.</li> </ol>	<p>Test engineer</p>

Task	Description	Skills required
	<p>3. In the navigation pane, choose <b>Printers</b>, and then choose <b>Output Queue</b>.</p> <p>4. In the <b>Spool ID</b> column, choose the spool ID for the request in the printer queue.</p> <p>5. On the <b>Actions</b> tab, in the <b>COMMAND</b> column, choose <b>Browse</b>.</p> <p>You can now see the print output of an account statement with columns for <b>Account No.</b>, <b>Description</b>, <b>Date</b>, <b>Amount</b>, and <b>Balance</b>. For an example, see the <b>batch_print_output</b> attachment for this pattern.</p>	

## Related resources

- [LRS Output Modernization](#) (LRS documentation)
- [ANSI and machine carriage controls](#) (IBM documentation)
- [Channel command words](#) (IBM documentation)
- [Empowering Enterprise Mainframe Workloads on AWS with Micro Focus](#) (AWS Partner Network Blog)

- [Line Conditioned Data Stream \(LCDS\)](#) (Compart documentation)
- [Micro Focus Enterprise Server on AWS](#) (AWS Quick Starts)

## Additional information

### Considerations

During your modernization journey, you may consider a wide variety of configurations for both mainframe batch processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform may incorporate the IBM Advanced Function Presentation (AFP) or the Xerox Line Condition Data Stream (LCDS) into the current workflow. Additionally, [mainframe carriage control characters](#) and [channel command words](#) can affect the look of the printed page and may need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

### Print data capture

Micro Focus Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the spool file. The information consists of fields passed in the relevant control blocks, such as:

- JOBNAME
- OWNER (USERID)
- DESTINATION
- FORM
- FILENAME
- WRITER

LRS VPSX/MFI supports the following mainframe batch mechanisms for capturing data from Micro Focus Enterprise Server.

- BATCH COBOL print/spool processing using standard z/OS JCL SYSOUT DD/OUTPUT statements
- BATCH COBOL print/spool processing using standard z/OS JCL CA-SPOOL SUBSYS DD statements
- IMS/COBOL print/spool processing using the CBLTDLI interface (For a full list of supported methods and programming examples, see the LRS documentation that's included with your product license.)

## Printer fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep dive health checks for printer fleets, see the LRS documentation that's included with your product license.

## Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or an LDAP server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks. For example, command-level security such as hold/release, purge, modify, copy, and reroute. Security can be set up by either the User-ID or Group (similar to AD group or LDAP group).

# Modernize mainframe online printing workloads on AWS by using Micro Focus Enterprise Server and LRS VPSX/MFI

Created by Shubham Roy (AWS), Abraham Rondon (Micro Focus), Guy Tucker (Levi, Ray and Shoup Inc), and Kevin Yung (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Mainframe	<b>Target:</b> AWS
<b>R Type:</b> Replatform	<b>Workload:</b> IBM	<b>Technologies:</b> Mainframe; Migration; Modernization

**AWS services:** AWS Managed Microsoft AD; Amazon EC2; Amazon RDS; Amazon EBS

## Summary

This pattern shows you how to modernize your business-critical mainframe online printing workloads on the Amazon Web Services (AWS) Cloud by using Micro Focus Enterprise Server as a runtime for a modernized mainframe application and LRS VPSX/MFI (Micro Focus Interface) as a print server. The pattern is based on the [replatform](#) mainframe modernization approach. In this approach, you migrate your mainframe online application to Amazon Elastic Compute Cloud (Amazon EC2) and migrate your mainframe database, such as IBM DB2 for z/OS, to Amazon Relational Database Service (Amazon RDS). The authentication and authorization for the modernized print workflow is performed by AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. The LRS Directory Information Server (LRS/DIS) is integrated with AWS Managed Microsoft AD for print workflow authentication and authorization. By modernizing your online printing workloads, you can reduce IT infrastructure costs, mitigate the technical debt of maintaining legacy systems, remove data silos, increase agility and efficiency with a DevOps model, and take advantage of on-demand resources and automation in the AWS Cloud.

## Prerequisites and limitations

### Prerequisites

- An active AWS account

- A mainframe online printing or output management workload
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on Micro Focus Enterprise Server (For more information, see the [Enterprise Server](#) data sheet in the Micro Focus documentation.)
- Basic knowledge of LRS cloud printing solutions and concepts (For more information, see [Output Modernization](#) in the LRS documentation.)
- Micro Focus Enterprise Server software and license (For more information, contact [Micro Focus sales](#).)
- LRS VPSX/MFI, LRS/Queue, and LRS/DIS software and licenses (For more information, contact [LRS sales](#).)

**Note:** For more information about configuration considerations for mainframe online printing workloads, see *Considerations* in the *Additional information* section of this pattern.

### Product versions

- [Micro Focus Enterprise Server](#) 8.0 or later
- [LRS VPSX/MFI](#) V1R3 or later

## Architecture

### Source technology stack

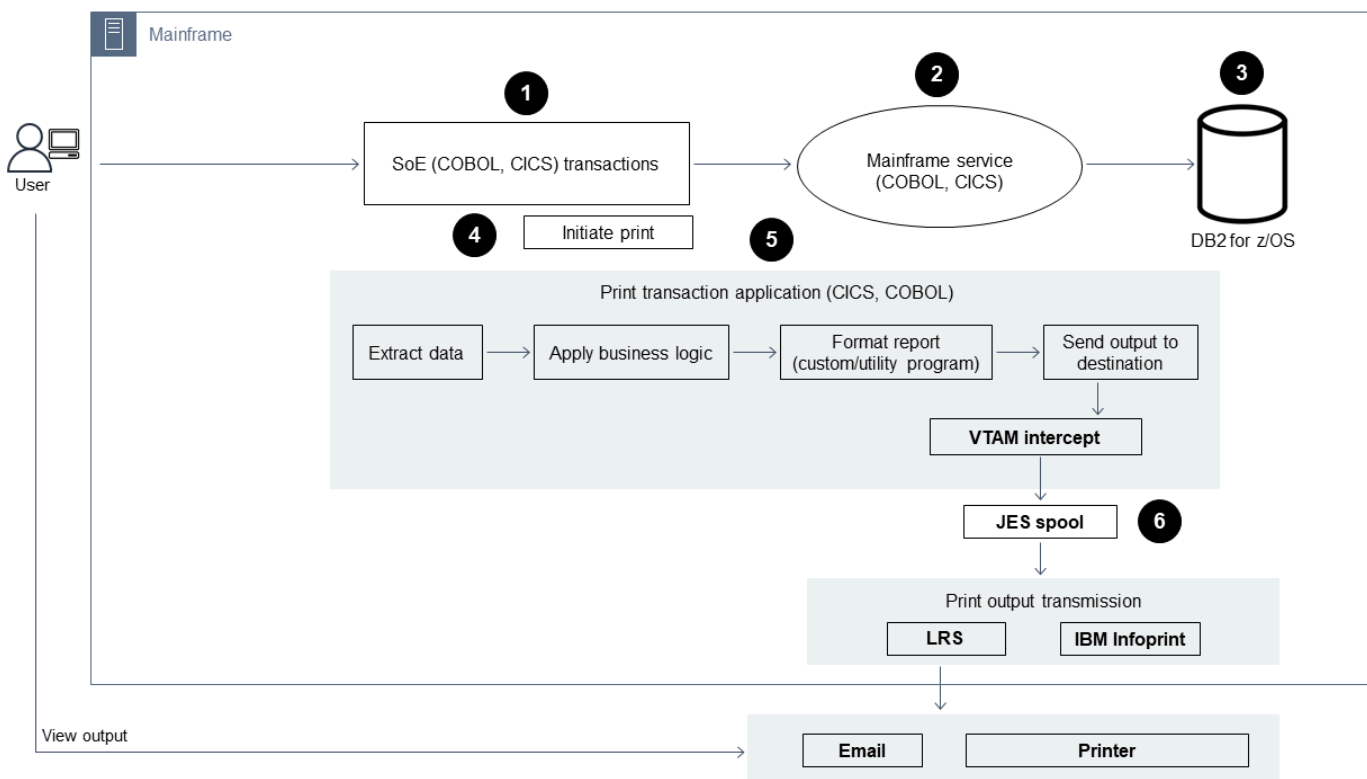

- Operating system – IBM z/OS
- Programming language – Common Business-Oriented Language (COBOL) and Customer Information Control System (CICS)
- Database – IBM DB2 for z/OS IBM Information Management System (IMS) and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Printing and output management – IBM mainframe z/OS printing products (IBM Infoprint Server for z/OS, LRS, and CA View)

### Target technology stack

- Operating system – Microsoft Windows Server running on Amazon EC2
- Compute – Amazon EC2
- Programming language – COBOL and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD
- Printing and output management – LRS printing solution on AWS
- Mainframe runtime environment – Micro Focus Enterprise Server

## Source architecture

The following diagram shows a typical current state architecture for a mainframe online printing workload.

The diagram shows the following workflow:

1. Users perform business transactions on a system of engagement (SoE) that's built on an IBM CICS application written in COBOL.

2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM DB2 for z/OS.
3. The SoR persists the business data from the SoE.
4. A user initiates a request to generate print output from the CICS SoE, which initiates a print transaction application to process the print request.
5. The print transaction application (such as a CICS and COBOL program) extracts data from the database, formats the data according to business requirements, and generates business output (print data) such as billing statements, ID cards, or loan statements. Then, the application sends a print request by using Virtual Telecommunications Access Method (VTAM). A z/OS print server (such as IBM Infoprint Server) uses NetSpool or a similar VTAM component to intercept the print requests, and then creates print output datasets on the JES spool by using JES output parameters. The JES output parameters specify routing information that the print server uses to transmit the output to a particular network printer. The term *VTAM* refers to the z/OS Communications Server and the System Network Architecture (SNA) services element of z/OS.
6. The printing output transmission component transmits the output print datasets from the JES spool to remote printers or print servers, such as LRS (as demonstrated in this pattern), IBM Infoprint Server, or email destinations.

## Target architecture

The following diagram shows an architecture for a mainframe online printing workload that's deployed in the AWS Cloud:

The diagram shows the following workflow:

1. A user initiates a print request from an online (CICS) user-interface to create print output, such as billing statements, ID cards, or loan statements.
2. The mainframe online application ([replatformed to Amazon EC2](#)) uses the Micro Focus Enterprise Server runtime to extract data from the application database, apply business logic to the data, format the data, and then send the data to a print destination by using [Micro Focus CICS Print Exit](#) (DFHUPRNT).
3. The application database (an SoR that runs on Amazon RDS) persists data for print output.
4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2, and its operational data is stored in Amazon Elastic Block Store (Amazon EBS). LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect print data through the Micro Focus CICS Print Exit API (DFHUPRNT) and deliver the data to a specified printer destination. The original TERMID (TERM) that's used in the modernized CICS application is used as the VPSX/MFI Queue name.

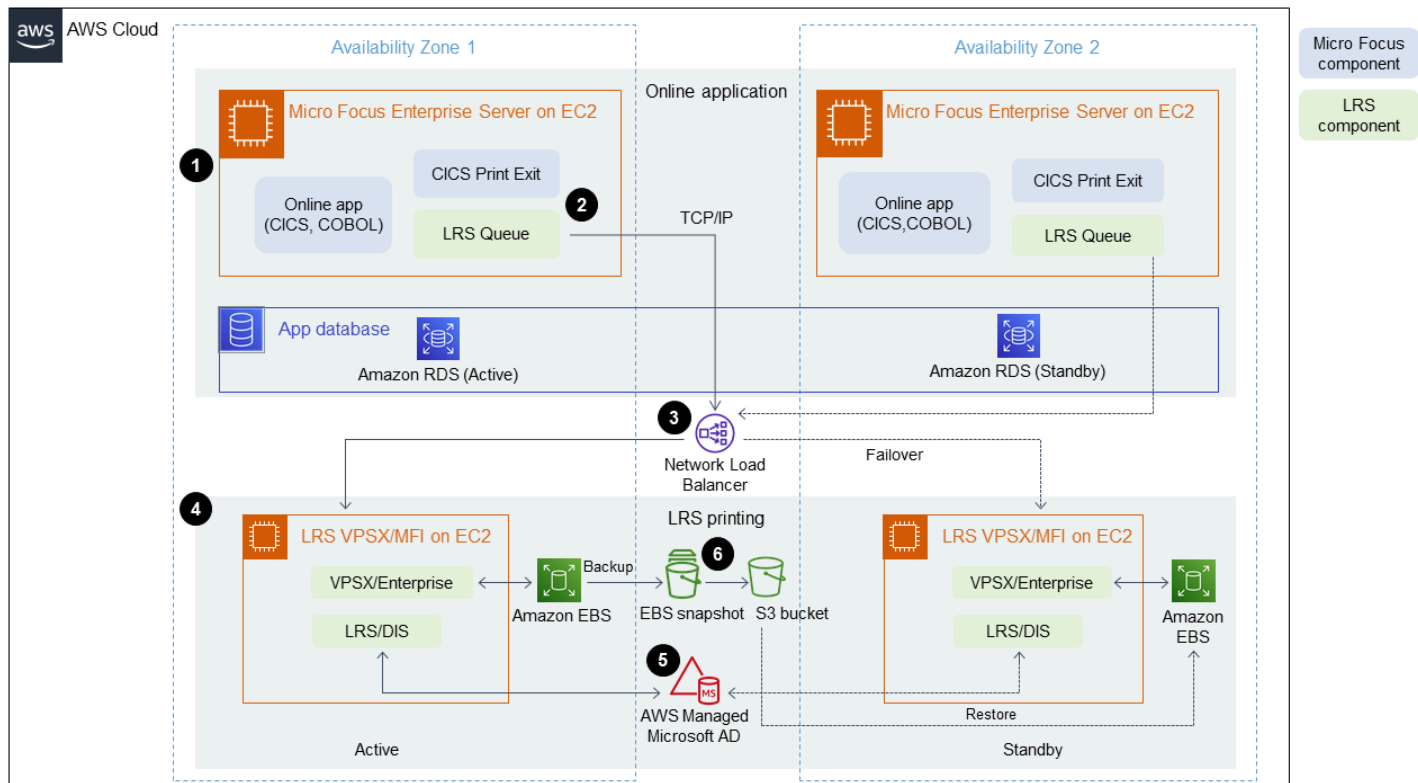

**Note:** The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM Advanced Function Presentation (AFP) or Xerox Line Condition Data Stream (LCDS). For more information about using Micro Focus for mainframe application

migration and modernization on AWS, see [Empowering Enterprise Mainframe Workloads on AWS with Micro Focus](#) in the AWS documentation.

## AWS infrastructure architecture

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe online printing workload:

The diagram shows the following workflow:

1. The mainframe online application (written on a programming language such as CICS or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The online application is deployed on Amazon EC2 across two [Availability Zones](#) (AZ) for high availability (HA) and uses Micro Focus CICS Print Exit to route print output to LRS VPSX/MFI for end-user printing.
2. LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data from the Micro Focus online Print Exit programming interface. Online Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the print file and dynamically build LRS/Queue commands.

**Note:** For more information on various CICS application programming methods for print and how they are supported in Micro Focus Enterprise server and LRS VPSX/MFI, see *Print data capture* in the *Additional information* section of this pattern.

3. A [Network Load Balancer](#) provides a DNS name to integrate Micro Focus Enterprise Server with LRS VPSX/MFI. **Note:** LRS VPSX/MFI supports a Layer 4 load balancer. The Network Load Balancer also does a basic health check on LRS VPSX/MFI and routes traffic to the registered targets that are healthy.
4. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA and uses [Amazon EBS](#) as an operational data store. LRS VPSX/MFI supports both the active-active and active-passive service modes. This architecture uses multiple Availability Zones in an active-passive pair as an active and hot standby. The Network Load Balancer performs a health check on LRS VPSX/MFI EC2 instances and routes traffic to hot standby instances in another Availability Zone if an active instance is in an unhealthy state. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of recovery, a failed instance has to be restarted for the LRS services to resume processing the print request.

**Note:** LRS VPSX/MFI can also perform health checks at the printer fleet level. For more information, see *Printer fleet health checks* in the *Additional information* section of this pattern.

5. [AWS Managed Microsoft AD](#) integrates with LRS/DIS to perform print workflow authentication and authorization. For more information, see *Print authentication and authorization* in the *Additional information* section of this pattern.
6. LRS VPSX/MFI uses Amazon EBS for block storage. You can back up Amazon EBS data from active EC2 instances to Amazon S3 as point-in-time snapshots and restore them to hot standby EBS volumes. To automate the creation, retention, and deletion of Amazon EBS volume snapshots, you can use [Amazon Data Lifecycle Manager](#) to set the frequency of automated snapshots and restore them based on your [RTO/RPO requirements](#).

## Tools

### AWS services

- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with Amazon EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [AWS Directory Service for Microsoft Active Directory \(AD\)](#), also known as AWS Managed Microsoft Active Directory, enables your directory-aware workloads and AWS resources to use managed Active Directory in AWS.

## Other tools

- [LRS VPSX/MFI \(Micro Focus Interface\)](#), co-developed by LRS and Micro Focus, captures output from a Micro Focus Enterprise Server JES spool and reliably delivers it to a specified print destination.
- LRS Directory Information Server (LRS/DIS) is used for authentication and authorization during the print workflow.
- LRS/Queue is a TCP/IP-based LRS/Queue transmission agent, used by LRS VPSX/MFI, to collect or capture print data through the Micro Focus online Print Exit programming interface.
- [Micro Focus Enterprise Server](#) is an application deployment environment for mainframe applications. It provides the execution environment for mainframe applications that are migrated or created by using any version of Micro Focus Enterprise Developer.

## Epics

### Set up Micro Focus Enterprise Server on Amazon EC2 and deploy a mainframe online application

Task	Description	Skills required
Set up Micro Focus Enterprise Server and deploy a demo online application.	Set up Micro Focus Enterprise Server on Amazon EC2, and then deploy the Micro Focus Account Demo application (ACCT Demo) on Amazon EC2 by following the instructions from <a href="#">Tutorial: CICS Support</a>	Cloud architect

Task	Description	Skills required
	<p>in the Micro Focus documentation.</p> <p>The ACCT Demo application is a mainframe online (CICS) application that creates and then initiates print output.</p>	

## Set up an LRS print server on Amazon EC2

Task	Description	Skills required
Get an LRS product license for printing.	To get an LRS product license for LRS VPSX/MFI, LRS/Queue, and LRS/DIS, contact the <a href="#">LRS Output Management team</a> . You must provide the host names of the EC2 instances where the LRS products will be installed.	Build lead
Create an Amazon EC2 Windows instance to install LRS VPSX/MFI.	<p>Launch an Amazon EC2 Windows instance by following the instructions from <a href="#">Step 1: Launch an instance</a> in the Amazon EC2 documentation. Your instance must meet the following hardware and software requirements for LRS VPSX/MFI:</p> <ul style="list-style-type: none"> <li>• CPU – Dual Core</li> <li>• RAM – 16 GB</li> <li>• Drive – 500 GB</li> </ul>	Cloud architect

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• Minimum EC2 instance – m5.xlarge</li><li>• OS – Windows/Linux</li><li>• Software – Internet Information Service (IIS) or Apache</li></ul> <p><b>Note:</b> The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts.</p> <p>When you create your Windows instance, do the following:</p> <ol style="list-style-type: none"><li>1. Confirm that the EC2 host name is the same host name used for the LRS product license.</li><li>2. Enable CGI in Amazon EC2 by completing the following:<ol style="list-style-type: none"><li>a. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li></ol></li></ol>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>b. In the Windows Start menu, find and open Server Manager.</li><li>c. In Server Manager, choose <b>Dashboard, Quick Start, Add roles and features</b>. Then, choose <b>Server roles</b>.</li><li>d. In <b>Server roles</b>, choose <b>WebServer (IIS)</b>, and then choose <b>Application Development</b>.</li><li>e. In <b>Application Development</b>, select the <b>CGI</b> check box.</li><li>f. Follow the instructions on the Windows Server Manager <b>Add roles and features</b> wizard to install CGI.</li><li>g. Open port 5500 in the Windows firewall of the EC2 instance for LRS/ Queue communication.</li></ul>	

Task	Description	Skills required
Install LRS VPSX/MFI on the EC2 instance.	<ol style="list-style-type: none"><li>1. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>2. Open the link to the product download page from the LRS email that you should receive. <b>Note:</b> LRS products are distributed by electronic file transfer (EFT).</li><li>3. Download LRS VPSX/MFI and unzip the file (default folder: c:\LRS).</li><li>4. Launch the LRS Product Installer from the unzipped folder to install LRS VPSX/MFI.</li><li>5. In the <b>Select Features</b> menu, select <b>VPSX® Server (V1R3.022)</b>, and then choose <b>Next</b> to start the installation process. You will receive a success message when installation is complete.</li></ol>	Cloud architect

Task	Description	Skills required
Install LRS/Queue.	<ol style="list-style-type: none"><li data-bbox="594 226 1024 548">1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li data-bbox="594 569 1024 842">2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/Queue, and then unzip the file.</li><li data-bbox="594 863 1024 1094">3. Go to the location where you downloaded the files, and then launch the LRS product installer to install LRS/Queue.</li></ol>	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	<ol style="list-style-type: none"><li data-bbox="592 226 998 548">1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li data-bbox="592 569 998 842">2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/DIS, and then unzip the file.</li><li data-bbox="592 863 998 1041">3. Go to the location where you downloaded the files, and then launch the LRS Product Installer.</li><li data-bbox="592 1062 998 1241">4. In the LRS Product Installer , expand <b>LRS Misc Tools</b>, select <b>LRS DIS</b>, and then choose <b>Next</b>.</li><li data-bbox="592 1262 998 1482">5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.</li></ol>	Cloud architect

Task	Description	Skills required
Create a target group and register LRS VPSX/MFI EC2 as the target.	<p>Create a target group by following the instructions from <a href="#">Create a target group for your Network Load Balancer</a> in the Elastic Load Balancing documentation.</p> <p>When you create the target group, do the following:</p> <ol style="list-style-type: none"><li>1. On the <b>Specify group details</b> page, for <b>Choose a Target Type</b>, choose <b>Instances</b>.</li><li>2. For <b>Protocol</b>, choose <b>TCP</b>.</li><li>3. For <b>Port</b>, choose <b>5500</b>.</li><li>4. On the <b>Register targets</b> page, in the <b>Available instances</b> section, select the LRS VPSX/MFI EC2 instances.</li></ol>	Cloud architect

Task	Description	Skills required
<p>Create a Network Load Balancer.</p>	<p>Follow the instructions from <a href="#">Create a Network Load Balancer</a> in the Elastic Load Balancing documentation. Your Network Load Balancer routes traffic from Micro Focus Enterprise Server to LRS VPSX/MFI EC2.</p> <p>When you create the Network Load Balancer, do the following on the <b>Listeners and Routing</b> page:</p> <ol style="list-style-type: none"> <li>1. For <b>Protocol</b>, choose <b>TCP</b>.</li> <li>2. For <b>Port</b>, choose <b>5500</b>.</li> <li>3. For <b>Default action</b>, choose <b>Forward to</b> for the target group that you created earlier.</li> </ol>	<p>Cloud architect</p>

### Integrate Micro Focus Enterprise Server with LRS VPSX/MFI and LRS/Queue

Task	Description	Skills required
<p>Configure Micro Focus Enterprise Server for LRS/Queue integration.</p>	<ol style="list-style-type: none"> <li>1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li> <li>2. In the Windows Start menu, open the Micro</li> </ol>	<p>Cloud architect</p>

Task	Description	Skills required
	<p>Focus Enterprise Server Administration UI.</p> <ol style="list-style-type: none"><li data-bbox="592 310 982 394">3. In the menu bar, choose <b>NATIVE</b>.</li><li data-bbox="592 415 982 646">4. In the navigation pane, choose <b>Directory Server</b>, and then choose <b>BANKDEMO</b> or your Enterprise server region.</li><li data-bbox="592 667 1019 1035">5. From <b>General</b> in the left navigation pane, scroll down to the <b>Additional</b> section to configure the environment variables (<b>LRSQ_ADDRESS</b>, <b>LRSQ_PORT</b>, <b>LRSQ_COMMAND</b>) to point to LRSQ.</li><li data-bbox="592 1056 1019 1287">6. For <b>LRSQ_ADDRESS</b>, enter the IP address or DNS name of the Network Load Balancer that you created earlier.</li><li data-bbox="592 1308 1003 1434">7. For <b>LRSQ_PORT</b>, enter <b>VPSX LRSQ Listener Port (5500)</b>.</li><li data-bbox="592 1455 1003 1581">8. ## Set up printers and print users in Micro Focus Enterprise Server and LRS VPSX/MFI

Task	Description	Skills required
Create a print queue in the LRS VPSX.	<ol style="list-style-type: none"> <li>1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li> </ol>	Cloud architect

Task	Description	Skills required
	<ol style="list-style-type: none"><li>2. Open the VPSX Web Interface from the Windows Start menu.</li><li>3. In the navigation pane, choose <b>Printers</b>.</li><li>4. Choose <b>Add</b>, and then choose <b>Add Printer</b>.</li><li>5. On the <b>Printer Configuration</b> page, for <b>Printer Name</b>, enter <b>P275</b>.</li><li>6. For <b>VPSX ID</b>, enter <b>VPS1</b>.</li><li>7. For <b>CommType</b>, select <b>TCPIP/LRSQ</b>.</li><li>8. For <b>Host/IP Address</b>, enter the IP address of the physical printer that you want to add.</li><li>9. For <b>Device</b>, enter the name of your device.</li><li>10 Choose either <b>Windows Driver</b> or <b>Linux/Mac Driver</b>.</li><li>11 Choose <b>Add</b>.</li></ol> <p><b>Note:</b> The print queue must be equivalent to the Print TERMIDs created in Micro Focus Enterprise Server.</p>	

Task	Description	Skills required
Create a print user in LRS VPSX/MFI.	<ol style="list-style-type: none"><li>1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>2. Open the VPSX Web Interface from the Windows Start menu.</li><li>3. In the navigation pane, choose <b>Security</b>, and then choose <b>Users</b>.</li><li>4. In the <b>User Name</b> column, choose <b>admin</b>, and then choose <b>Copy</b>.</li><li>5. In the <b>User Profile Maintenance</b> window, for <b>User Name</b>, enter a user name (for example, <b>PrintUser</b>).</li><li>6. For <b>Description</b>, enter a brief description (for example, <b>User for test print</b>).</li><li>7. Choose <b>Update</b>. This creates a print user (for example, <b>PrintUser</b>).</li><li>8. In the navigation pane, under <b>User</b>, choose the new user that you created.</li><li>9. From the <b>Command</b> menu, choose <b>Security</b>.</li></ol>	Cloud architect

Task	Description	Skills required
	<p>10 On the <b>Security Rules</b> page, choose all the applicable printer security and job security options, and then choose <b>Save</b>.</p> <p>11 To add your new print user to the <b>Administrator</b> group, go to the navigation pane, choose <b>Security</b>, and then choose <b>Configure</b>.</p> <p>12 In the <b>Security configuration</b> window, add your new print user to the <b>Administrator</b> column.</p>	

## Set up print authentication and authorization

Task	Description	Skills required
<p>Create an AWS Managed Microsoft AD domain with users and groups.</p>	<ol style="list-style-type: none"> <li>1. Create an Active Directory on AWS Managed Microsoft AD by following the instructions from <a href="#">Create your AWS Managed Microsoft AD directory</a> in the AWS Directory Service documentation.</li> <li>2. Deploy an EC2 instance (Active Directory manager) and install Active Directory tools to manage your AWS Managed Microsoft AD by following the instructions from <a href="#">Step 3: Deploy an EC2</a></li> </ol>	<p>Cloud architect</p>

Task	Description	Skills required
	<p><a href="#">instance to manage your AWS Managed Microsoft AD</a> in the AWS Directory Service documentation.</p> <ol style="list-style-type: none"><li>3. Connect to your EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation. <b>Note:</b> When you connect to the EC2 instance, enter your administrator credentials (for the directory that you created in step one) in the Windows Security window.</li><li>4. In the Windows Start menu, under <b>Windows Administrative Tools</b>, choose <b>Active Directory Users and Computers</b>.</li><li>5. Create a print user in the Active Directory domain by following the steps from <a href="#">Create a user</a> in the AWS Directory service documentation.</li></ol>	

Task	Description	Skills required
Join LRS VPSX/MFI EC2 to an AWS Managed Microsoft AD domain.	Join LRS VPSX/MFI EC2 to your AWS Managed Microsoft AD domain <a href="#">automatically</a> (AWS Knowledge Center documentation) or <a href="#">manually</a> (AWS Directory Service documentation).	Cloud architect

Task	Description	Skills required
Configure and integrate LRS/DIS with AWS Managed Microsoft AD.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 548">1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li data-bbox="592 569 1027 699">2. In the Windows Start menu, open the <b>VPSX Web Interface</b>.</li><li data-bbox="592 720 1027 850">3. In the navigation pane, choose <b>Security</b>, and then choose <b>Configure</b>.</li><li data-bbox="592 871 1027 1098">4. On the <b>Security Configuration</b> page, in the <b>Security Parameters</b> section, for <b>Security Type</b>, select <b>Internal</b>.</li><li data-bbox="592 1119 1027 1295">5. Enter your preferences for the rest of the options in the <b>Security Parameters</b> section.</li><li data-bbox="592 1316 1027 1598">6. Open the <b>LRS Output Management</b> folder from the Microsoft Windows Start menu, choose <b>Server Start</b>, and then choose <b>Server Stop</b>.</li><li data-bbox="592 1619 1027 1749">7. Log in to LRS VPSX/MFI with your Active Directory user name and password.</li></ol>	Cloud architect

## Test an online print workflow

Task	Description	Skills required
Initiate an online print request from the Micro Focus ACCT Demo app.	<ol style="list-style-type: none"><li data-bbox="591 323 1026 600">1. Open the TN3270 terminal emulator in your Micro Focus Enterprise Server EC2 instance. (<b>Note:</b> This pattern uses 3270 terminal emulators.)</li><li data-bbox="591 621 1026 848">2. Connect to the TN3270 terminal emulator (Rumba). For <b>Host name address</b>, use <b>127.0.0.1</b>. For <b>Telnet Port</b>, use <b>9270</b>.</li><li data-bbox="591 869 1026 1045">3. After connecting to the 3270 screen, press CTL +SHIFT+Z to clear the screen.</li><li data-bbox="591 1066 1026 1583">4. To start the ACCT Demo application, in clear screen, enter <b>ACCT</b>. This opens the ACCT Demo online (CICS) application main screen. <b>Note:</b> The main screen includes menu options such as <b>Account file</b>, <b>To search by name</b>, <b>enter</b>, <b>Request type</b>, <b>Account</b>, and <b>Printer</b>.</li><li data-bbox="591 1604 1026 1873">5. To submit a print request from the ACCT Demo online (CICS) application, enter <b>P</b> in the <b>request type</b> field, <b>11111</b> in the <b>account</b> field, and <b>P275</b> in</li></ol>	Cloud architect

Task	Description	Skills required
	<p>the <b>printer</b> field. Be sure to set the value in the <b>printer</b> field to the value of the CICS printer's terminal ID.</p> <p>6. Press <b>Enter</b>.</p> <p>The "Print Request Scheduled" message appears at the bottom of the screen. This confirms that an online print request was generated from the ACCT Demo application and sent to LRS VPS/MFI for print processing.</p>	

Task	Description	Skills required
Check the print output in LRS VPSX/MFI.	<ol style="list-style-type: none"><li>1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from <a href="#">Step 2: Connect to your instance</a> in the Amazon EC2 documentation.</li><li>2. In the Windows Start menu, open the <b>VPSX Web Interface</b>.</li><li>3. In the navigation pane, choose <b>Printers</b>, and then choose <b>Output Queue</b>. Find the <b>P275</b> print queue that you created for online printing earlier.</li><li>4. For the print queue (<b>P275</b>), in the <b>Spool ID</b> column, choose the spool ID for the request in the printer queue.</li><li>5. On the <b>Actions</b> tab, in the <b>COMMAND</b> column, choose <b>Browse</b>.</li></ol> <p>You can now see the print output of an account statement with columns for Account No., SURNAME, FIRST, ADDRESS, TELEPHONE, No. Cards Issued, Date issued, Amount, and Balance.</p>	Test engineer

Task	Description	Skills required
	For an example, see the <b>online_print_output</b> attachment for this pattern.

- [Advanced Function Presentation \(AFP\) data stream](#) (IBM documentation)
- [Line Conditioned Data Stream \(LCDS\)](#) (Compart documentation)

## Additional information

### Considerations

During your modernization journey, you may consider a wide variety of configurations for mainframe online processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform may incorporate the IBM Advanced Function Presentation (AFP) or the Xerox Line Condition Data Stream (LCDS) into the current workflow. Additionally, [mainframe carriage control characters](#) and [channel command words](#) can affect the look of the printed page and may need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

### Print data capture

This section summarizes the CICS application programming methods that you can use in an IBM mainframe environment for printing. LRS VPSX/MFI components provide techniques to allow the same application programs to create data in the same way. The following table describes how each application programming method is supported in a modernized CICS application running in AWS and Micro Focus Enterprise Server with an LRS VPSX/MFI print server.

Method	Description	Support for the method in a modernized environment
EXEC CICS SEND TEXT.. or EXEC CICS SEND MAP..	These CICS and VTAM methods are responsible for creating and delivering 3270/SCS print data streams to LUTYPE0, LUTYPE1, and LUTYPE3 print devices.	A Micro Focus online Print Exit (DFHUPRNT) application program interface (API) enables print data to be processed by VPSX/MFI when 3270/SCS print data streams are created by using either of these methods.
EXEC CICS SEND TEXT.. or EXEC CICS SEND MAP.. (with third-party IBM mainframe software)	The CICS and VTAM methods are responsible for creating and delivering 3270/SCS print data streams to LUTYPE0, LUTYPE1, and LUTYPE3 print devices. Third-party software products intercept the print data, convert the data to standard print format data with an ASA/MCH control character, and place the data on the JES spool to be processed by mainframe-based printing systems that use JES.	A Micro Focus online Print Exit (DFHUPRNT) API enables print data to be processed by VPSX/MFI when 3270/SCS print data streams are created by using either of these methods.
EXEC CICS SPOOLOPEN	This method is used by CICS application programs to write data directly to the JES	Micro Focus Enterprise Server spools the data to the Enterprise Server spool where

	spool. The data then becomes available to be processed by mainframe-based printing systems that use JES.	it can be processed by the VPSX/MFI Batch Print Exit (LRSPRTE6) that spools the data to VPSX.
DRS/API	An LRS-supplied programmatic interface is used for writing print data to JES.	VPSX/MFI supplies a replacement interface that spools the print data directly to VPSX.

## Printer fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep dive health checks for printer fleets, see the LRS documentation that's included with your product license.

## Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or an LDAP server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks. For example, command-level security such as hold/release, purge, modify, copy, and reroute. Security can be set up by either the User-ID or Group (similar to AD group or LDAP group).

# Move mainframe files directly to Amazon S3 using Transfer Family

Created by Luis Gustavo Dantas (AWS)

<b>Environment:</b> Production	<b>Source:</b> Mainframe	<b>Target:</b> Amazon S3
<b>R Type:</b> N/A	<b>Workload:</b> IBM	<b>Technologies:</b> Mainframe; Storage & backup; Modernization
<b>AWS services:</b> AWS Transfer Family; Amazon S3		

## Summary

As part of the modernization journey, you can face the challenge of transferring files between your on-premises servers and the Amazon Web Services (AWS) Cloud. Transferring data from mainframes can be a significant challenge because mainframes typically can't access modern data stores like Amazon Simple Storage Service (Amazon S3), Amazon Elastic Block Store (Amazon EBS), or Amazon Elastic File System (Amazon EFS).

Many customers use intermediate staging resources, such as on-premises Linux, Unix, or Windows servers, to transfer files to the AWS Cloud. You can avoid this indirect method by using AWS Transfer Family with the Secure Shell (SSH) File Transfer Protocol (SFTP) to upload mainframe files directly to Amazon S3.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a subnet that's reachable by your legacy platform
- A Transfer Family endpoint for your VPC
- Mainframe Virtual Storage Access Method (VSAM) files converted to sequential, [fixed-length files](#) (IBM documentation)

## Limitations

- SFTP transfers files in binary mode by default, which means that files are uploaded to Amazon S3 with EBCDIC encoding preserved. If your file doesn't contain binary or packed data, then you can use the `sftp` [ascii subcommand](#) (IBM documentation) to convert your files to text during the transfer.
- You must [unpack mainframe files](#) (AWS Prescriptive Guidance) that contain packed and binary content to use these files in your target environment.
- Amazon S3 objects can range in size from a minimum of 0 bytes to a maximum of 5 TB. For more information about Amazon S3 capabilities, see [Amazon S3 FAQs](#).

## Architecture

### Source technology stack

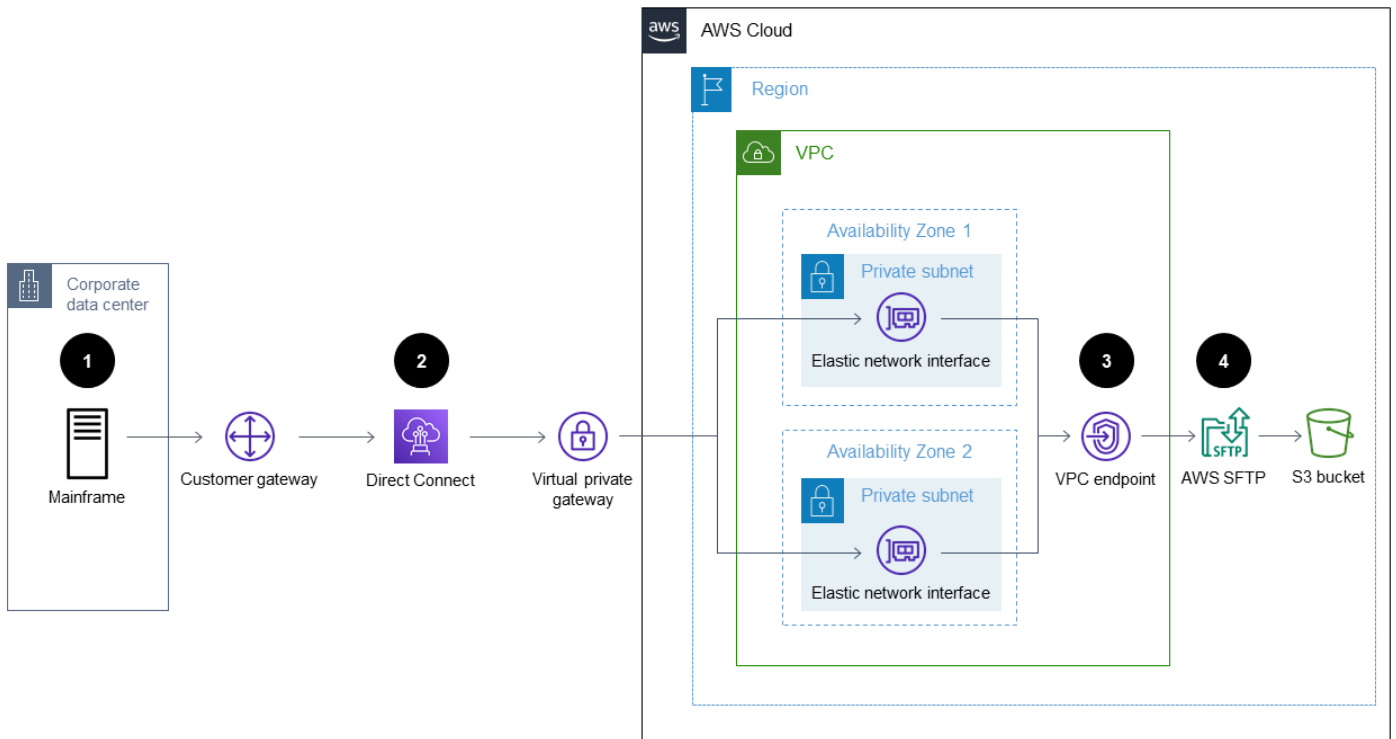

- Job control language (JCL)
- z/OS Unix shell and ISPF
- SFTP
- VSAM and flat files

### Target technology stack

- Transfer Family
- Amazon S3
- Amazon Virtual Private Cloud (Amazon VPC)

### Target architecture

The following diagram shows a reference architecture for using Transfer Family with SFTP to upload mainframe files directly to an S3 bucket.

The diagram shows the following workflow:

1. You use a JCL job to transfer your mainframe files from the legacy mainframe to the AWS Cloud through Direct Connect.
2. Direct Connect enables your network traffic to remain on the AWS global network and bypass the public internet. Direct Connect also enhances the network speed, starting at 50 Mbps and scaling up to 100 Gbps.
3. The VPC endpoint enables connections between your VPC resources and the supported services without using the public internet. Access to Transfer Family and Amazon S3 achieves high availability by taking place through the elastic network interfaces located in two private subnets and Availability Zones.
4. Transfer Family authenticates users and uses SFTP to receive your files from the legacy environment and move them to an S3 bucket.

## Automation and scale

After the Transfer Family service is in place, you can transfer an unlimited number of files from the mainframe to Amazon S3 by using a JCL job as the SFTP client. You can also automate the

file transfer by using a mainframe batch job scheduler to run the SFTP jobs when you're ready to transfer the mainframe files.

## Tools

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- [AWS Transfer Family](#) enables you to securely scale your recurring business-to-business file transfers to Amazon S3 and Amazon EFS by using SFTP, FTPS, and FTP protocols.

## Epics

### Create the S3 bucket and the access policy

Task	Description	Skills required
Create the S3 bucket.	<a href="#">Create an S3 bucket</a> to host the files that you transfer from your legacy environment.	General AWS
Create the IAM role and policy.	Transfer Family uses your AWS Identity and Access Management (IAM) role to grant access to the S3 bucket that you created earlier.  <a href="#">Create an IAM role</a> that includes the following <a href="#">IAM policy</a> :  <pre>{   "Version":     "2012-10-17",   "Statement": [</pre>	General AWS

Task	Description	Skills required
	<pre> {   "Sid":   "UserFolderListing",   "Action": [      "s3:ListBucket",      "s3:GetBucketLocat ion"   ],   "Effect":   "Allow",   "Resource":   [      "arn:aws:s3:::&lt;your- bucket-name&gt;"   ] }, {   "Sid":   "HomeDirObjectAcce ss",   "Effect":   "Allow",   "Action": [      "s3:PutObject",      "s3:GetObjectAcl",      "s3:GetObject",      "s3:DeleteObjectVe rsion",      "s3:DeleteObject",      "s3:PutObjectAcl",      "s3:GetObjectVersion"   ], </pre>	

Task	Description	Skills required
	<pre data-bbox="597 205 1024 464">           "Resource":             "arn:aws:s3:::&lt;your-             bucket-name&gt;/*"           }         ]       } </pre> <p data-bbox="597 499 1024 632"><b>Note:</b> You must choose the Transfer use case when you create the IAM role.</p>	

## Define the transfer service

Task	Description	Skills required
Create the SFTP server.	<ol data-bbox="597 926 1024 1864" style="list-style-type: none"> <li>1. Sign in to the AWS Management console, open the <a href="#">Transfer Family console</a>, and then choose <b>Create server</b>.</li> <li>2. Choose only <b>SFTP (SSH File Transfer Protocol) - file transfer over Secure Shell protocol</b> and then choose <b>Next</b>.</li> <li>3. For <b>Identity provider</b>, choose <b>Service managed</b> and then choose <b>Next</b>.</li> <li>4. For <b>Endpoint type</b>, choose <b>VPC hosted</b>.</li> <li>5. For <b>Access</b>, choose <b>Internal</b>.</li> <li>6. For <b>VPC</b>, choose your VPC.</li> </ol>	General AWS

Task	Description	Skills required
	<p>7. In the <b>Availability Zones</b> section, choose your Availability Zones and subnets.</p> <p>8. In the <b>Security Groups</b> section, choose your security group, and then choose <b>Next</b>.</p> <p>9. For <b>Domain</b>, choose <b>Amazon S3</b> and then choose <b>Next</b>.</p> <p>10 Leave the default options on the <b>Configure additional details</b> page and then choose <b>Next</b>.</p> <p>11 Choose <b>Create server</b>.</p> <p><b>Note:</b> For more information about how to set up an SFTP server, see <a href="#">Create an SFTP-enabled server</a> (AWS Transfer Family User Guide).</p>	

Task	Description	Skills required
Get the server address.	<ol style="list-style-type: none"><li>1. Open the <a href="#">Transfer Family console</a> and choose your server ID in the <b>Server ID</b> column.</li><li>2. In the <b>Endpoint details</b> section, for <b>Endpoint type</b>, choose the endpoint ID. This takes you to the Amazon VPC console.</li><li>3. On the <b>Details</b> tab of the Amazon VPC console, find the DNS names next to <b>DNS names</b>.</li></ol>	General AWS
Create the SFTP client key pair.	Create an SSH key pair for either <a href="#">Microsoft Windows</a> or <a href="#">macOS/Linux/UNIX</a> .	General AWS, SSH

Task	Description	Skills required
Create the SFTP user.	<ol style="list-style-type: none"> <li>1. Open the <a href="#">Transfer Family console</a>, choose <b>Servers</b> from the navigation pane, and then select your server.</li> <li>2. In the <b>Server ID</b> column, choose the server ID for your server and then choose <b>Add user</b>.</li> <li>3. For <b>Username</b>, enter a user name that matches your SSH key pair user name.</li> <li>4. For <b>Role</b>, choose the IAM role that you created earlier.</li> <li>5. For <b>Home directory</b>, choose the S3 bucket that you created earlier.</li> <li>6. For <b>SSH public keys</b>, enter the key pair that you created earlier.</li> <li>7. Choose <b>Add</b>.</li> </ol>	General AWS

## Transfer the mainframe file

Task	Description	Skills required
Send the SSH private key to the mainframe.	<p>Use SFTP or SCP to send the SSH private key to the legacy environment.</p> <p>SFTP example:</p>	Mainframe, z/OS Unix shell, FTP, SCP

Task	Description	Skills required
	<pre>sftp [USERNAME@mainframeIP] [password] cd [/u/USERNAME] put [your-key-pair-file]</pre> <p>SCP example:</p> <pre>scp [your-key-pair-file] [USERNAME@MainframeIP]:/[u/USERNAME]</pre> <p>Next, store the SSH key in the z/OS Unix file system under the user name that will later run the file transfer batch job (for example, /u/CONTROLM ).</p> <p><b>Note:</b> For more information about z/OS Unix shell, see <a href="#">An introduction to the z/OS shells</a> (IBM documentation).</p>	

Task	Description	Skills required
<p>Create the JCL SFTP client.</p>	<p>Because mainframes don't have a native SFTP client, you must use the BPXBATCH utility to run the SFTP client from the z/OS Unix shell.</p> <p>In the ISPF editor, create the JCL SFTP client. For example:</p> <pre data-bbox="594 617 1027 1570"> //JOBNAM JOB ... //***** ***** ***** ***** **** //SFTP EXEC PGM=BPXBA TCH,REGION=0M //STDPARM DD * SH cp '//MAINFRAME.FILE.NAME' filename.txt; echo 'put filename.txt' &gt; uplcmd; sftp -b uplcmd -i ssh_private_key_file ssh_username@transfer service ip or DNS&gt;; //SYSPRINT DD SYSOUT=* //STDOUT DD SYSOUT=* //STDENV DD * //STDERR DD SYSOUT=* </pre> <p><b>Note:</b> For more information about how to run a command in the z/OS Unix shell, see <a href="#">The BPXBATCH utility</a> (IBM documentation). For more</p>	<p>JCL, Mainframe, z/OS Unix shell</p>

Task	Description	Skills required
	<p>information about how to create or edit JCL jobs in z/OS, see <a href="#">What is ISPF?</a> and <a href="#">The ISPF editor</a> (IBM documentation).</p>	
<p>Run the JCL SFTP client.</p>	<ol style="list-style-type: none"> <li>1. In the ISPF editor, enter <b>SUB</b>, and then press the ENTER key after the JCL job is created.</li> <li>2. Monitor the mainframe's file transfer batch job activity in SDSF.</li> </ol> <p><b>Note:</b> For more information about how to check the activity of batch jobs, see <a href="#">z/OS SDSF User's Guide</a> (IBM documentation).</p>	<p>Mainframe, JCL, ISPF</p>
<p>Validate the file transfer.</p>	<ol style="list-style-type: none"> <li>1. Sign in to the AWS Management console, open the <a href="#">Amazon S3 console</a>, and then choose <b>Buckets</b> from the navigation pane.</li> <li>2. Choose the bucket that's associated with your Transfer Family.</li> <li>3. In the <b>Objects</b> section of the <b>Objects</b> tab, find the file that you transferred from the mainframe.</li> </ol>	<p>General AWS</p>

Task	Description	Skills required
Automate the JCL SFTP client.	<p>Use job scheduler to automatically trigger the JCL SFTP client.</p> <p><b>Note:</b> You can use mainframe job schedulers, such as <a href="#">BMC Control-M</a> or <a href="#">CA Workload Automation</a>, to automate batch jobs for file transfers based on time and other batch job dependencies.</p>	Job scheduler

# Transfer large-scale Db2 z/OS data to Amazon S3 in CSV files

Created by Bruno Sahinoglu (AWS), Ivan Schuster (AWS), and Abhijit Kshirsagar (AWS)

<b>Code repository:</b> <a href="#">Unload DB2 z/OS to S3</a>	<b>Environment:</b> Production	<b>Source:</b> Db2
<b>Target:</b> Amazon S3	<b>R Type:</b> Replatform	<b>Workload:</b> IBM
<b>Technologies:</b> Mainframe ; Data lakes; Databases; DevelopmentAndTesting; Migration	<b>AWS services:</b> Amazon Aurora; AWS Glue; Amazon S3; AWS Transfer Family; Amazon Athena	

## Summary

A mainframe is still a system of record in many enterprises, containing a massive amount of data including master data entities with records of current as well as the historical business transactions. It is often siloed and not easily accessed by the distributed systems within the same enterprise. With the emergence of cloud technology and big data democratization, enterprises are interested in using the insights hidden in the mainframe data to develop new business capabilities.

With that objective, enterprises are looking to open their mainframe Db2 data to their Amazon Web Services (AWS) Cloud environment. The business reasons are several and the transfer methods differ from case to case. You might prefer to connect your application directly to the mainframe, or you might prefer to replicate your data in near real time. If the use case is to feed a data warehouse or a data lake, having an up-to-date copy is no longer a concern, and the procedure described in this pattern might suffice, especially if you want to avoid any third-party product licensing costs. Another use case might be the mainframe data transfer for a migration project. In a migration scenario, data is required for performing the functional equivalence testing. The approach described in this post is a cost effective way to transfer the Db2 data to the AWS Cloud environment.

Because Amazon Simple Storage Service (Amazon S3) is one of the most integrated AWS services, you can access the data from there and gather insights directly by using other AWS services such as Amazon Athena, AWS Lambda functions, or Amazon QuickSight . You can also load the data

to Amazon Aurora or Amazon DynamoDB by using AWS Glue or AWS Database Migration Service (AWS DMS). With that aim in mind, this describes how to unload Db2 data in CSV files in ASCII format on the mainframe and transfer the files to Amazon S3.

For this purpose, [mainframe scripts](#) have been developed to help to generate job control languages (JCLs) to unload and transfer as many Db2 tables as you need.

## Prerequisites and limitations

### Prerequisites

- An IBM z/OS operating system user with authorization to run Restructured Extended Executor (REXX) and JCL scripts.
- Access to z/OS Unix System Services (USS) to generate SSH (Secure Shell) private and public keys.
- A writable S3 bucket. For more information, see [Create your first S3 bucket](#) in the Amazon S3 documentation.
- An AWS Transfer Family SSH File Transfer Protocol (SFTP)-enabled server using **Service managed** as the identity provider and Amazon S3 as the AWS storage service. For more information, see [Create an SFTP-enabled server](#) in the AWS Transfer Family documentation.

### Limitations

- This approach isn't suitable for near real-time or real-time data synchronization.
- Data can be moved only from Db2 z/OS to Amazon S3, not the other way around.

## Architecture

### Source technology stack

- Mainframe running Db2 on z/OS

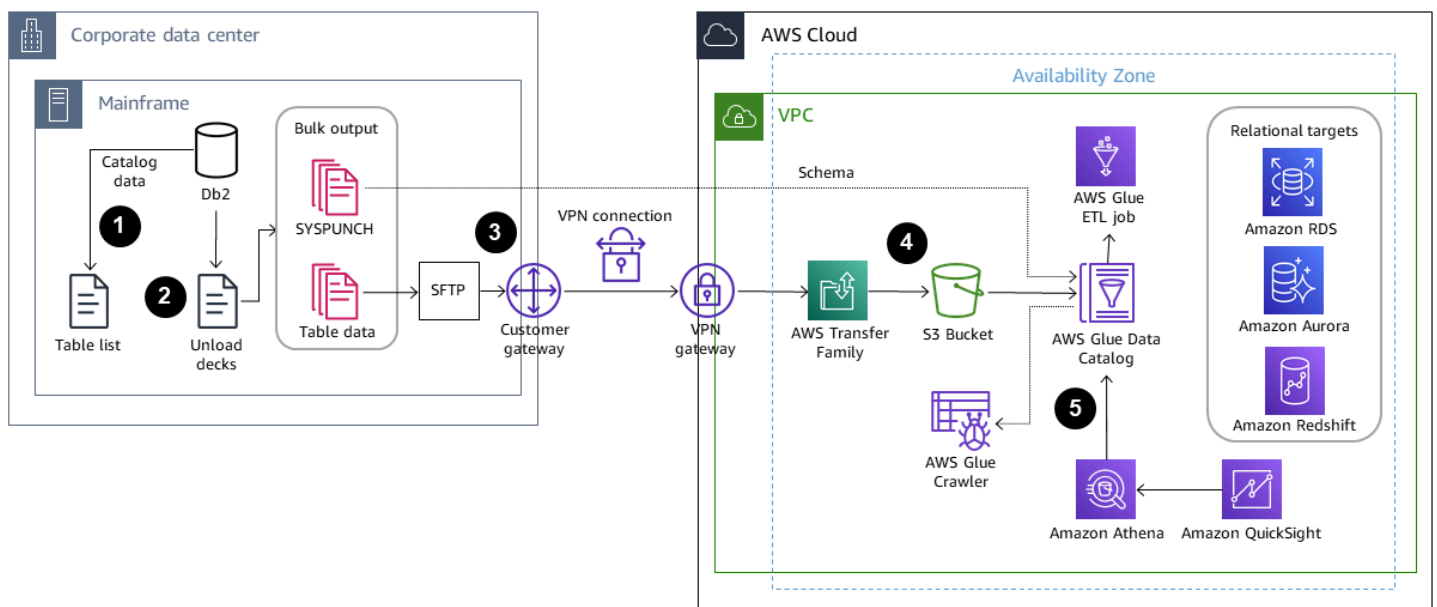

### Target technology stack

- AWS Transfer Family
- Amazon S3

- Amazon Athena
- Amazon QuickSight
- AWS Glue
- Amazon Relational Database Service (Amazon RDS)
- Amazon Aurora
- Amazon Redshift

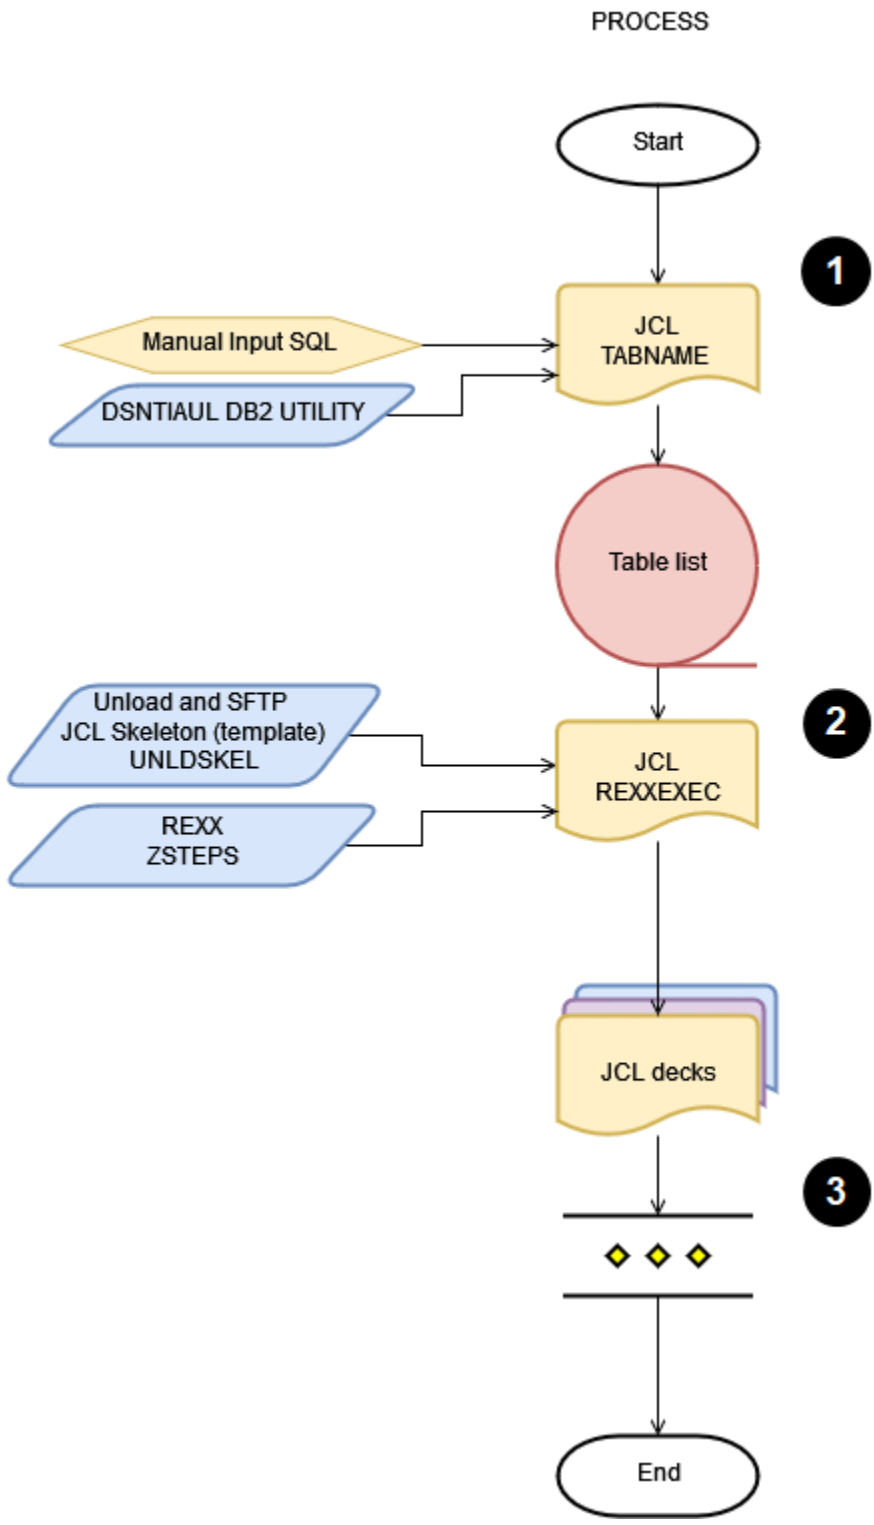

## Source and target architecture

The following diagram shows the process for generating, extracting, and transferring Db2 z/OS data in ASCII CSV format to an S3 bucket.

1. A list of tables is selected for data migration from the Db2 catalog.
2. The list is used to drive the generation of unload jobs with the numeric and data columns in the external format.
3. The data is then transferred over to Amazon S3 by using AWS Transfer Family.
4. An AWS Glue extract, transform, and load (ETL) job can transform the data and load it to a processed bucket in the specified format, or AWS Glue can feed the data directly into the database.
5. Amazon Athena and Amazon QuickSight can be used to query and render the data to drive analytics.

The following diagram shows a logical flow of the entire process.

1. The first JCL, called TABNAME, will use the Db2 utility DSNTIAUL to extract and generate the list of tables that you plan to unload from Db2. To choose your tables, you must manually adapt the SQL input to select and add filter criteria to include one or more Db2 schemas.
2. The second JCL, called REXXEXEC, will use the a JCL skeleton and the REXX program that is provided to process the Table list created by the JCL TABNAME and generate one JCL per table name. Each JCL will contain one step for unloading the table and another step for sending the file to the S3 bucket by using the SFTP protocol.
3. The last step consists of running the JCL to unload the table and transferring the file to AWS. The entire process can be automated using a scheduler on premises or on AWS.

## Tools

### AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- [Amazon Aurora](#) is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- [AWS Glue](#) is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- [Amazon QuickSight](#) is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- [Amazon Redshift](#) is a managed petabyte-scale data warehouse service in the AWS Cloud.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Transfer Family](#) is a secure transfer service that enables you to transfer files into and out of AWS storage services.

### Mainframe tools

- [SSH File Transfer Protocol \(SFTP\)](#) is a secure file transfer protocol that allows remote login to and file transfer between servers. SSH provides security by encrypting all traffic.

- [DSNTIAUL](#) is a sample program provided by IBM for unloading data.
- [DSNUTILB](#) is a utilities batch program provided by IBM for unloading data with different options from DSNTIAUL.
- [z/OS OpenSSH](#) is a port of Open Source Software SSH running on the Unix System Service under the IBM operating system z/OS. SSH is a secure, encrypted connection program between two computers running on a TCP/IP network. It provides multiple utilities, including ssh-keygen.
- [REXX \(Restructured Extended Executor\)](#) script is used to automate JCL generation with the Db2 Unload and SFTP steps.

## Code

The code for this pattern is available in the GitHub [unloaddb2](#) repository.

## Best practices

For the first unload, the generated JCLs should unload the entire table data.

After the first full unload, perform incremental unloads for better performance and cost savings. Update the SQL query in the template JCL deck to accommodate any changes to the unload process.

You can convert the schema manually or by using a script on Lambda with the Db2 SYSPUNCH as an input. For an industrial process, [AWS Schema Conversion Tool \(SCT\)](#) is the preferred option.

Finally, use a mainframe-based scheduler or a scheduler on AWS with an agent on the mainframe to help manage and automate the entire process.

## Epics

### Set up the S3 bucket

Task	Description	Skills required
Create the S3 bucket.	For instructions, see <a href="#">Create your first S3 bucket</a> .	General AWS

## Set up the Transfer Family server

Task	Description	Skills required
<p>Create an SFTP-enabled server.</p>	<p>To open and create an SFTP server on the <a href="#">AWS Transfer Family console</a>, do the following:</p> <ol style="list-style-type: none"> <li>1. On the Choose protocols, page, select the <b>SFTP (SSH File Transfer Protocol) – file transfer over Secure Shell</b> check box.</li> <li>2. For the identity provider, choose <b>Service managed</b>.</li> <li>3. For the endpoint, choose <b>Publicly accessible</b>.</li> <li>4. For the domain, choose <b>Amazon S3</b>.</li> <li>5. On the <b>Configure additional details</b> page, keep the default settings.</li> <li>6. Create the server.</li> </ol>	<p>General AWS</p>
<p>Create an IAM role for Transfer Family.</p>	<p>To create an AWS Identity and Access Management (IAM) role for Transfer Family to access Amazon S3, follow the instructions in <a href="#">Create an IAM role and policy</a>.</p>	<p>AWS administrator</p>
<p>Add an Amazon S3 service-managed user.</p>	<p>To add the Amazon S3 service-managed user, follow the instructions in the <a href="#">AWS</a></p>	<p>General AWS</p>

Task	Description	Skills required
	<a href="#">documentation</a> , and use your mainframe user ID.	

## Secure the communication protocol

Task	Description	Skills required
Create the SSH key.	<p>Under your mainframe USS environment, run the following command.</p> <pre>ssh-keygen -t rsa</pre> <p><b>Note:</b> When prompted for a passphrase, keep it empty.</p>	Mainframe developer
Give the right authorization levels to the SSH folder and key files.	<p>By default, the public and private keys will be stored in the user directory <code>/u/home/u sername/.ssh</code> .</p> <p>You must give the authorization 644 to the key files and 700 to the folder.</p> <pre>chmod 644 .ssh/id_rsa chmod 700 .ssh</pre>	Mainframe developer
Copy the public key content to your Amazon S3 service-managed user.	<p>To copy the USS-generated public key content, open the <a href="#">AWS Transfer Family console</a>.</p> <ol style="list-style-type: none"> <li>1. In the navigation pane, choose <b>Servers</b>.</li> </ol>	Mainframe developer

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>2. Choose the identifier in the <b>Server ID</b> column to see the <b>Server details</b></li> <li>3. Under <b>Users</b>, choose a user name to see the <b>User details</b></li> <li>4. Under <b>SSH public keys</b>, choose <b>Add SSH public key</b> to add the public key to a user. For the SSH public key, enter your public key. Your key is validated by the service before you can add your new user.</li> <li>5. Choose <b>Add key</b>.</li> </ol>	

## Generate the JCLs

Task	Description	Skills required
Generate the in-scope Db2 table list.	<p>Provide input SQL to create a list of the tables that are scoped for data migration . This step requires you to specify selection criteria querying the Db2 catalog table SYSIBM.SYSTABLES using a SQL where clause. Filters can be customized to include a specific schema or table names that start with a particular prefix or based on a timestamp for incremental</p>	Mainframe developer

Task	Description	Skills required
	<p>unload. Output is captured in a physical sequential (PS) dataset on the mainframe. This dataset will act as input for the next phase of JCL generation.</p> <p>Before you use the JCL TABNAME (You can rename it if necessary), make the following changes:</p> <ol style="list-style-type: none"><li>1. Substitute &lt;Jobcard&gt; with a job class and a user that is authorized to run Db2 utilities.</li><li>2. Substitute &lt;HLQ1&gt; or customize the output dataset names to meet your site standards.</li><li>3. Update the STEPLIB stack of PDSEs (partitioned data set extended) according to your site standards. The example in this pattern uses the IBM defaults.</li><li>4. Substitute the PLAN name and LIB with your installation-specific values.</li><li>5. Substitute &lt;Schema&gt; and &lt;Prefix&gt; with your selection criteria for the Db2 catalog.</li></ol>	

Task	Description	Skills required
	<p>6. Save the resultant JCL in a PDS (partitioned data set) library.</p> <p>7. Submit the JCL.</p> <p><b>Db2 table list extraction job</b></p> <pre data-bbox="592 548 1027 1837"> &lt;Jobcard&gt; //* //* UNLOAD ALL THE TABLE   NAMES FOR A PARTICULAR   SCHEMA //* //STEP01 EXEC PGM=IEFBR 14 //* //DD1      DD  DISP=(MOD ,DELETE,DELETE), //          UNIT=SYSDA, //          SPACE=(1000, (1,1)), //          DSN=&lt;HLQ1 &gt;.DSN81210.TABLIST //* //DD2      DD  DISP=(MOD ,DELETE,DELETE), //          UNIT=SYSDA, //          SPACE=(1000, (1,1)), //          DSN=&lt;HLQ1 &gt;.DSN81210.SYSPUNCH //* //UNLOAD  EXEC PGM=IKJEF T01,DYNAMNBR=20 //SYSTSPRT DD   SYSOUT=* //STEPLIB DD   DISP=SHR,DSN=DSNC1 0.DBCG.SDSNEXIT </pre>	

Task	Description	Skills required
	<pre>//          DD  DISP=SHR, DSN=DSNC10.SDSNLOAD //          DD  DISP=SHR, DSN=CEE.SCEERUN //          DD  DISP=SHR, DSN=DSNC10.DBCG.RU NLIB.LOAD //SYSTSIN DD *           DSN SYSTEM(DBCG)           RUN PROGRAM(D SNTIAUL) PLAN(DSNT IB12) PARS('SQL') -           LIB('DSNC 10.DBCG.RUNLIB.LOAD')           END //SYSPRINT DD SYSOUT=* //* //SYSUDUMP DD SYSOUT=* //* //SYSRECOO DD DISP=(NEW ,CATLG,DELETE), //          UNIT=SYSD A,SPACE=(32760,(10 00,500)), //          DSN=&lt;HLQ1 &gt;.DSN81210.TABLST //* //SYSPUNCH DD DISP=(NEW ,CATLG,DELETE), //          UNIT=SYSD A,SPACE=(32760,(10 00,500)), //          VOL=SER=S CR03,RECFM=FB,LREC L=120,BLKSIZE=12 //          DSN=&lt;HLQ1 &gt;.DSN81210.SYSPUNCH //* //SYSIN    DD *           SELECT CHAR(CREA TOR), CHAR(NAME)</pre>	

Task	Description	Skills required
	<pre>FROM SYSIBM.SY STABLES WHERE OWNER = '&lt;Schema&gt;' AND NAME LIKE '&lt;Prefix&gt;%' AND TYPE = 'T'; /*</pre>	

Task	Description	Skills required
Modify the JCL templates.	<p>The JCL templates that are provided with this pattern contain a generic job card and library names. However, most mainframe sites will have their own naming standards for dataset names, library names, and job cards. For example, a specific job class might be required to run Db2 jobs. The Job Entry Subsystem implementations JES2 and JES3 can impose additional changes. Standard load libraries might have a different first qualifier than SYS1, which is IBM default. Therefore, customize the templates to account for your site-specific standards before you run them.</p> <p>Make the following changes in the skeleton JCL UNLDSKEL:</p> <ol style="list-style-type: none"><li>1. Modify the job card with a job class and user that is authorized to run Db2 utilities.</li><li>2. Customize output dataset names to meet your site standards.</li><li>3. Update the STEPLIB stack of PDSEs according to</li></ol>	Mainframe developer

Task	Description	Skills required
	<p>your site standards. The example in this pattern uses the IBM defaults.</p> <ol style="list-style-type: none"> <li>4. Substitute &lt;DSN&gt; with your Db2 subsystem name and correlation ID.</li> <li>5. Save the resultant JCL in a PDS library that is part of your ISPSLIB stack, which is the standard skeleton template library for ISPF.</li> </ol> <p><b>Unload and SFTP JCL skeleton</b></p> <pre data-bbox="594 940 1026 1827"> //&amp;USRPFX.U JOB   (DB2UNLOAD), 'JOB',   CLASS=A,MSGCLASS=A,   //          TIME=1440   ,NOTIFY=&amp;USRPFX //* DELETE DATASETS //STEP01 EXEC   PGM=IEFBR14 //DD01 DD DISP=(MOD   ,DELETE,DELETE), //          UNIT=SYSD A, //          SPACE=(TR K,(1,1)), // DSN=&amp;USRPFX..DB2.P UNCH.&amp;JOBNAME //DD02 DD DISP=(MOD   ,DELETE,DELETE), //          UNIT=SYSD A, //          SPACE=(TR K,(1,1)), </pre>

## Additional information

After you have your Db2 data on Amazon S3, you have many ways to develop new insights. Because Amazon S3 integrates with AWS data analytics services, you can freely consume or expose this data on the distributed side. For example, you can do the following:

- Build a [data lake on Amazon S3](#), and extract valuable insights by using query-in-place, analytics, and machine learning tools without moving the data.
- Initiate a [Lambda function](#) by setting up a post-upload processing workflow that is integrated with AWS Transfer Family.

- Develop new microservices for accessing the data in Amazon S3 or in [fully managed database](#) by using [AWS Glue](#), which is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development.

In a migration use case, because you can transfer any data from the mainframe to S3, you can do the following:

- Retire physical infrastructure, and create a cost-effective data archival strategy with Amazon S3 Glacier and S3 Glacier Deep Archive.
- Build scalable, durable, and secure backup and restore solutions with Amazon S3 and other AWS services, such as S3 Glacier and Amazon Elastic File System (Amazon EFS), to augment or replace existing on-premises capabilities.

# Identify and alert when Amazon Data Firehose resources are not encrypted with an AWS KMS key

Created by Ram Kandaswamy (AWS)

**Environment:** Production

**Technologies:** Management & governance; Analytics; Big data; CloudNative; Infrastructure; Security, identity, compliance

**AWS services:** AWS CloudTrail; Amazon CloudWatch; AWS Identity and Access Management; Amazon Kinesis; AWS Lambda; Amazon SNS

## Summary

For compliance, some organizations must have encryption enabled on data delivery resources such as Amazon Data Firehose. This pattern shows a way to monitor, detect, and notify when resources are out of compliance.

To maintain the encryption requirement, this pattern can be used on Amazon Web Services (AWS) to provide automated monitoring and detection of Firehose delivery resources that are not encrypted with AWS Key Management Service (AWS KMS) key. The solution sends alert notifications, and it can be extended to perform automatic remediation. This solution can be applied to an individual account or a multiple-account environment, such as an environment using AWS Landing Zone or AWS Control Tower.

## Prerequisites and limitations

### Prerequisites

- Firehose delivery stream
- Sufficient permissions and familiarity with AWS CloudFormation, which is used in this infrastructure automation

### Limitations

The solution is not real time because it uses AWS CloudTrail events for detection, and there is a delay between the time an unencrypted resource is created and the notification is sent.

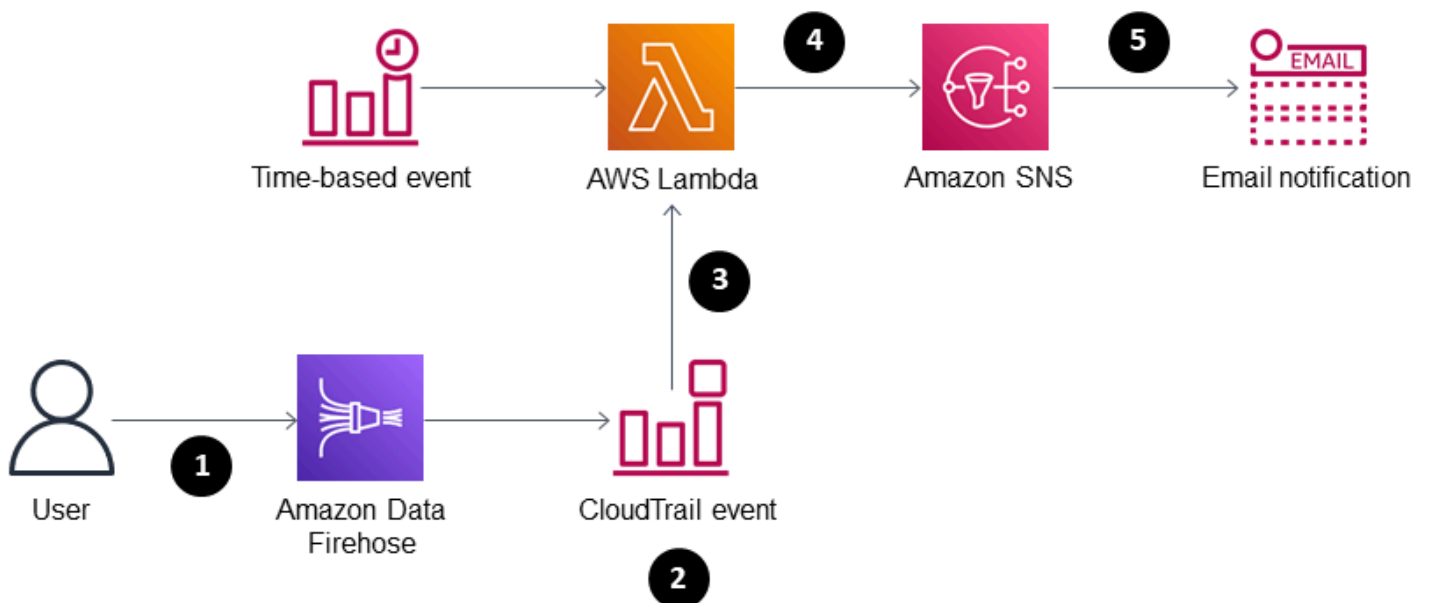

## Architecture

### Target technology stack

The solution uses serverless technology and the following services:

- AWS CloudTrail
- Amazon CloudWatch
- AWS Command Line Interface (AWS CLI)
- AWS Identity and Access Management (IAM)
- Amazon Data Firehose
- AWS Lambda
- Amazon Simple Notification Service (Amazon SNS)

### Target architecture

1. A user creates or modifies Firehose.
2. A CloudTrail event is detected and matched.

3. Lambda is invoked.
4. Noncompliant resources are identified.
5. Email notification is sent.

## Automation and scale

Using AWS CloudFormation StackSets, you can apply this solution to multiple AWS Regions or accounts with a single command.

## Tools

- [AWS CloudTrail](#) – AWS CloudTrail is an AWS service that helps you enable governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS Command Line Interface, and AWS SDKs and API operations.
- [Amazon CloudWatch Events](#) – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is an open source tool that enables you to interact with AWS services using commands in your command line shell.
- [IAM](#) – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- [Amazon Data Firehose](#) – Amazon Data Firehose is a fully managed service for delivering real-time streaming data. With Firehose, you don't need to write applications or manage resources. You configure your data producers to send data to Firehose, and it automatically delivers the data to the destination that you specified.
- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).

# Epics

## Enforce encryption for compliance

Task	Description	Skills required
Deploy AWS CloudFormation StackSets.	<p>In the AWS CLI, use the <code>firehose-encryption-checker.yaml</code> template (attached) to create the stack set by running the following command. Provide a valid Amazon SNS topic Amazon Resource Name (ARN) for the parameter. The deployment should successfully create CloudWatch Events rules, the Lambda function, and an IAM role with the necessary permissions as described in the template.</p> <pre>aws cloudformation create-stack-set   --stack-set-name my-stack-set -- template-body file:// firehose-encryption- checker.yaml</pre>	Cloud architect, Systems administrator
Create stack instances.	<p>Stacks need to be created in the AWS Regions of your choice as well as in one or more accounts. To create stack instances, run the following command, replacing the stack name,</p>	Cloud architect, Systems administrator

Task	Description	Skills required
	<p>account numbers, and Regions with your own.</p> <pre>aws cloudformation create-stack-insta nces --stack-s et-name my-stack- set --account s 123456789012 223456789012 -- regions us-east-1 us- east-2 us-west-1 us- west-2 --operati on-preferences FailureToleranceCo unt=1</pre>	

## Related resources

- [Working with AWS CloudFormation StackSets](#)
- [What is Amazon CloudWatch Events?](#)

## Additional information

AWS Config does not support the Firehose delivery stream resource type, so an AWS Config rule cannot be used in the solution.

# Automate adding or updating Windows registry entries using AWS Systems Manager

Created by Appasaheb Bagali (AWS)

**Environment:** PoC or pilot

**Technologies:** Management & governance; CloudNative; DevOps; Infrastructure; Modernization; Security, identity, compliance

**Workload:** Microsoft

**AWS services:** AWS Systems Manager

## Summary

AWS Systems Manager is a remote management tool for Amazon Elastic Compute Cloud (Amazon EC2) instances. Systems Manager provides visibility and control over your infrastructure on Amazon Web Services. This versatile tool can be used to fix Windows registry changes that are identified as vulnerabilities by the security vulnerability scan report.

This pattern covers the steps to keep your EC2 instances that are running Windows operating system secure by automating registry changes that are recommended for the safety of your environment. The pattern uses the Run command to run a Command document. The code is attached, and a portion of it is included in the *Code* section.

## Prerequisites and limitations

- An active AWS account
- Permissions to access the EC2 instance and Systems Manager

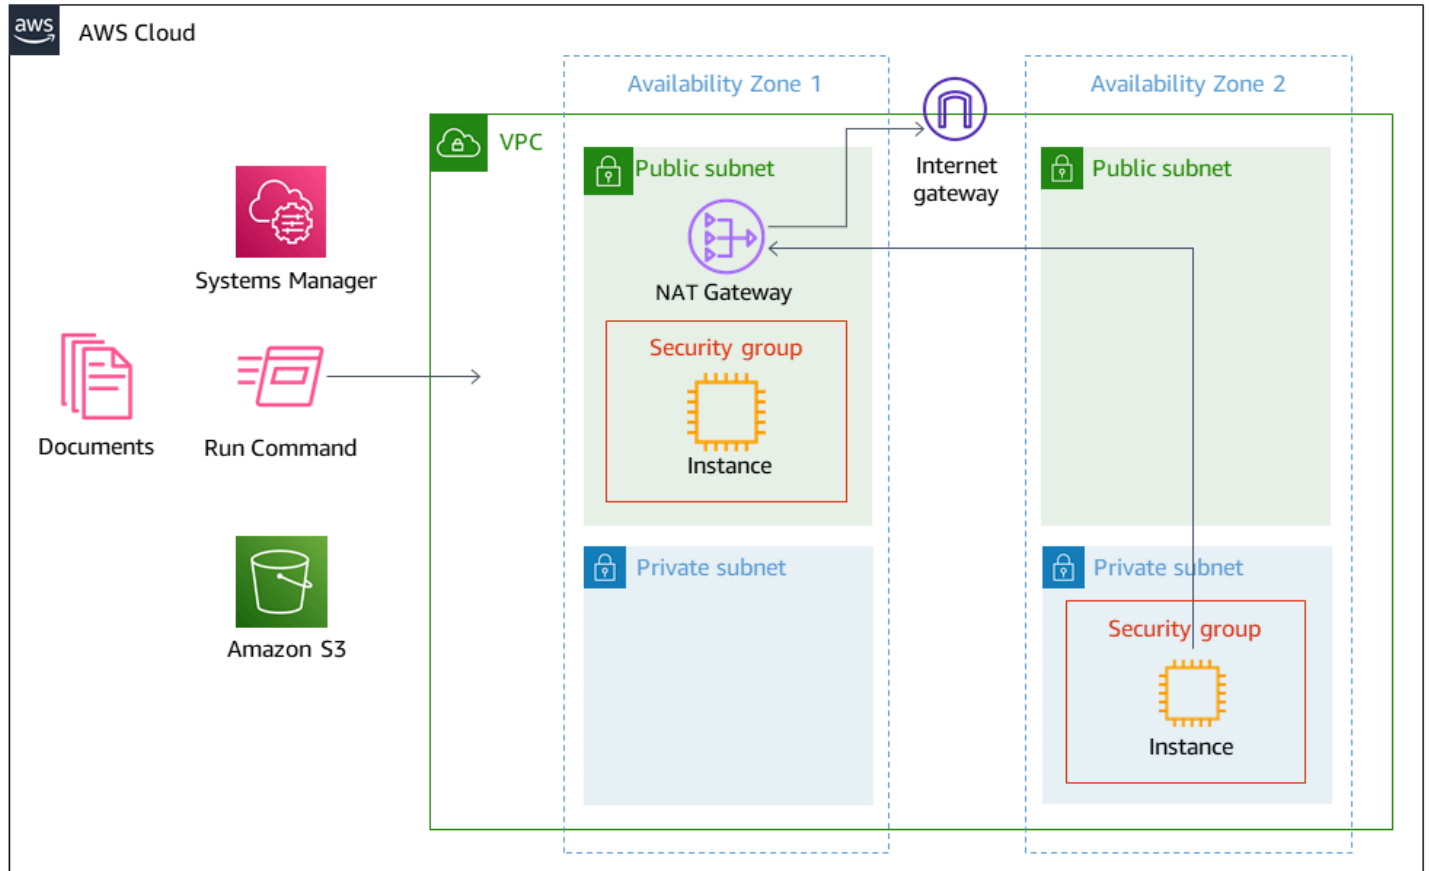

## Architecture

### Target technology stack

- A virtual private cloud (VPC), with two subnets and a network address translation (NAT) gateway

- A Systems Manager Command document to add or update the registry name and value
- Systems Manager Run Command to run the Command document on the specified EC2 instances

## Target architecture

## Tools

### Tools

- [IAM policies and roles](#) – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- [Amazon Simple Storage Service](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers. In this pattern, an S3 bucket is used to store the Systems Manager logs.
- [AWS Systems Manager](#) – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Systems Manager helps you maintain security and

compliance by scanning your *managed instances* and reporting (or taking corrective action on) any policy violations it detects.

- [AWS Systems Manager Command document](#) – AWS Systems Manager Command documents are used by Run Command. Most Command documents are supported on all Linux and Windows Server operating systems supported by Systems Manager.
- [AWS Systems Manager Run Command](#) – AWS Systems Manager Run Command gives you a way to manage the configuration of your managed instances remotely and securely. Using Run Command, you can automate common administrative tasks and perform one-time configuration changes at scale.

## Code

You can use the following example code to add or update a Microsoft Windows registry name to Version, registry path to HKCU:\Software\ScriptingGuys\Scripts, and value to 2.

```
#Windows registry path which needs to add/update
$registryPath = 'HKCU:\\Software\\ScriptingGuys\\Scripts'
#Windows registry Name which needs to add/update
$Name = 'Version'
#Windows registry value which needs to add/update
$value = 2
# Test-Path cmdlet to see if the registry key exists.
IF(!(Test-Path $registryPath))
{
    New-Item -Path $registryPath -Force | Out-Null
    New-ItemProperty -Path $registryPath -Name $name -Value $value ` -
PropertyType DWORD - Force | Out- Null
} ELSE {
    New-ItemProperty -Path $registryPath -Name $name -Value $value `
-PropertyType DWORD -Force | Out-Null
}
echo 'Registry Path:$registryPath
echo 'Registry Name:$registryPath
echo 'Registry Value: '(Get-ItemProperty -Path $registryPath -Name $Name).version
```

The full Systems Manager Command document JavaScript Object Notation (JSON) code example is attached.

## Epics

### Set up a VPC

Task	Description	Skills required
Create a VPC.	On the AWS Management Console, create a VPC that has public and private subnets and a NAT gateway. For more information, see the <a href="#">AWS documentation</a> .	Cloud administrator
Create security groups.	Ensure that each security group allows access for Remote Desktop Protocol (RDP) from the source IP address.	Cloud administrator

### Create an IAM policy and an IAM role

Task	Description	Skills required
Create an IAM policy.	Create an IAM policy that provides access to Amazon S3, Amazon EC2, and Systems Manager.	Cloud administrator
Create an IAM role.	Create an IAM role, and attach the IAM policy that provides access to Amazon S3, Amazon EC2, and Systems Manager.	Cloud administrator

## Run the automation

Task	Description	Skills required
Create the Systems Manager Command document.	Create a Systems Manager Command document that will deploy the Microsoft Windows registry changes to add or update.	Cloud administrator
Run the Systems Manager Run Command.	Run the Systems Manager Run Command, selecting the Command document and the Systems Manager target instances. This pushes the Microsoft Windows registry change in the selected Command document to the target instances.	Cloud administrator

# Automatically stop and start an Amazon RDS DB instance using AWS Systems Manager Maintenance Windows

Created by Ashita Dsilva (AWS)

**Environment:** Production

**Technologies:** Management & governance; Cost management; Databases; CloudNative

**AWS services:** AWS Systems Manager; Amazon RDS

## Summary

This pattern demonstrates how to automatically stop and start an Amazon Relational Database Service (Amazon RDS) DB instance on a specific schedule (for example, shutting down a DB instance outside of business hours to reduce costs) by using AWS Systems Manager Maintenance Windows.

AWS Systems Manager Automation provides the `AWS-StopRdsInstance` and `AWS-StartRdsInstance` runbooks to stop and start Amazon RDS DB instances. This means that you don't need to write custom logic with AWS Lambda functions or create an Amazon CloudWatch Events rule.

AWS Systems Manager provides two capabilities for scheduling tasks: [State Manager](#) and [Maintenance Windows](#). State Manager sets and maintains the required state configuration for resources in your Amazon Web Services (AWS) account one time or on a specific schedule. Maintenance Windows runs tasks on the resources in your account during a specific time window. Although you can use this pattern's approach with State Manager or Maintenance Windows, we recommend that you use Maintenance Windows because it can run one or more tasks based on assigned priority and can also run AWS Lambda functions and AWS Step Functions tasks. For more information about State Manager and Maintenance Windows, see [Choosing between State Manager and Maintenance Windows](#) in the AWS Systems Manager documentation.

This pattern provides detailed steps to configure two separate maintenance windows that use cron expressions to stop and then start an Amazon RDS DB instance.

## Prerequisites and limitations

### Prerequisites

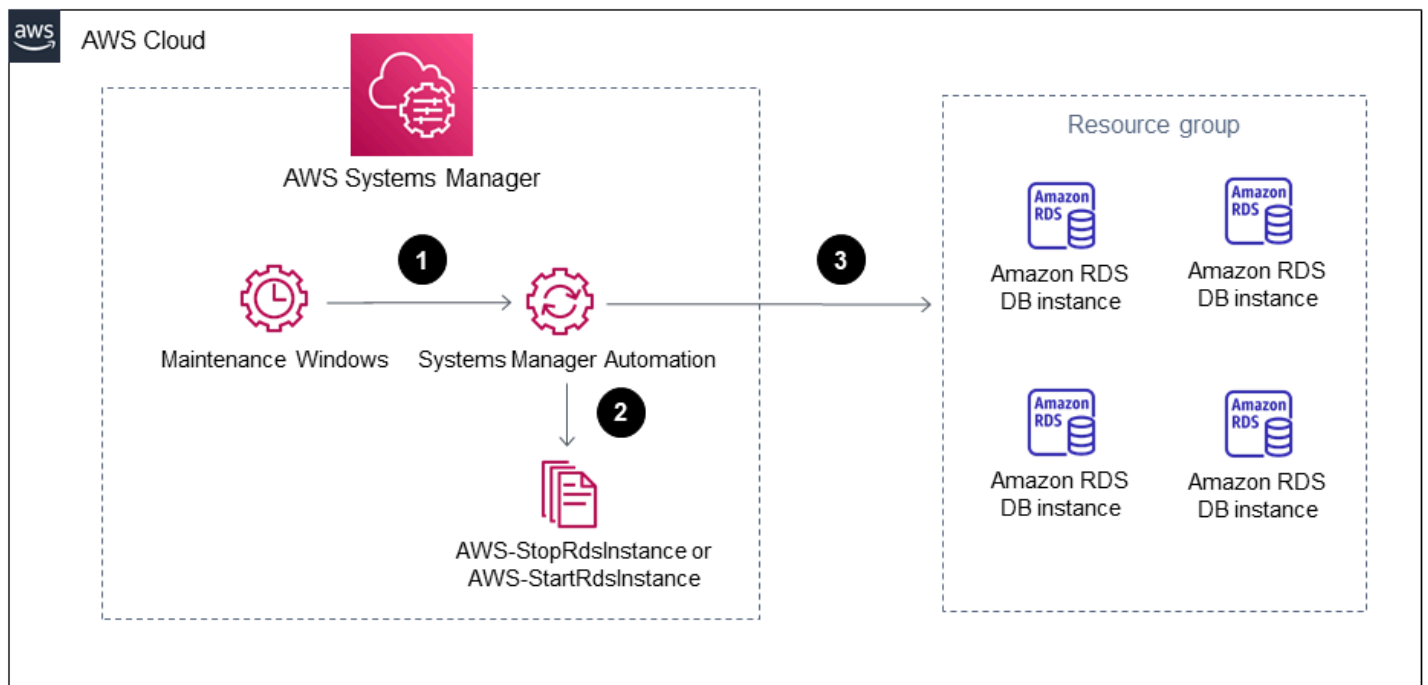

- An active AWS account.
- An existing Amazon RDS DB instance that you want to stop and start on a specific schedule.
- Cron expressions for your required schedule. For example, the (0 9 \* \* 1-5) cron expression runs in the morning at 09:00 on Monday through Friday.
- Familiarity with Systems Manager.

### Limitations

- An Amazon RDS DB instance can be stopped for up to seven days at one time. After seven days, the DB instance automatically restarts to ensure that it receives any required maintenance updates.
- You can't stop a DB instance that is a read replica or that has a read replica.
- You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.
- Service quotas apply to Maintenance Windows and Systems Manager Automation. For more information about service quotas, see [AWS Systems Manager endpoints and quotas](#) in the AWS General Reference documentation.

## Architecture

The following diagram shows the workflow to automatically stop and start an Amazon RDS DB instance.

The workflow has the following steps:

1. Create a maintenance window and use cron expressions to define the stop and start schedule for your Amazon RDS DB instances.
2. Register a Systems Manager Automation task to the maintenance window by using the `AWS-StopRdsInstance` or `AWS-StartRdsInstance` runbook.
3. Register a target with the maintenance window by using a tag-based resource group for your Amazon RDS DB instances.

### Technology stack

- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- Amazon RDS
- Systems Manager

### Automation and scale

You can stop and start multiple Amazon RDS DB instances at the same time by tagging the required Amazon RDS DB instances, creating a resource group that includes all the tagged DB instances, and registering this resource group as a target for the maintenance window.

## Tools

- [AWS CloudFormation](#) is a service that helps you model and set up your AWS resources.
- [AWS Identity and Access Management \(IAM\)](#) is a web service that helps you securely control access to AWS resources.
- [Amazon Relational Database Service \(Amazon RDS\)](#) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- [AWS Resource Groups](#) helps you organize AWS resources into groups, tag resources, and manage, monitor, and automate tasks on grouped resources.
- [AWS Systems Manager](#) is an AWS service that you can use to view and control your infrastructure on AWS.
- [AWS Systems Manager Automation](#) simplifies common maintenance and deployment tasks of Amazon Elastic Compute Cloud (Amazon EC2) instances and other AWS resources.
- [AWS Systems Manager Maintenance Windows](#) helps you define a schedule for when to perform potentially disruptive actions on your instances.

## Epics

### Create and configure the IAM service role for Systems Manager Automation

Task	Description	Skills required
Configure the IAM service role for Systems Manager Automation.	Sign in to the AWS Management Console and create a service role for Systems Manager Automation. You can use one of the following two methods to create this service role: <ul style="list-style-type: none"><li>• <a href="#">Use AWS CloudFormation to configure a service role for Systems Manager Automation</a></li></ul>	AWS administrator

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <a href="#">Use IAM to configure roles for Systems Manager Automation</a></li></ul> <p>The Systems Manager Automation workflow invokes Amazon RDS by using a service role to perform start and stop actions on the Amazon RDS DB instance.</p> <p>The service role must be configured with the following <a href="#">inline policy</a> that has permissions to start and stop the Amazon RDS DB instance:</p> <pre data-bbox="592 1045 1031 1854">{   "Version":   "2012-10-17",   "Statement": [     {       "Sid":       "RdsStartStop",       "Effect":       "Allow",       "Action": [         "rds:StopDBInstance",         "rds:StartDBInstance"       ],       "Resource":       "&lt;RDS_Instance_Arn&gt;"     }   ],   {</pre>	

Task	Description	Skills required
	<pre data-bbox="597 205 1026 703">           "Sid":             "RdsDescribe",             "Effect":               "Allow",               "Action":                 "rds:DescribeDBIns                 tances",                 "Resource":                   "*"               }             ]           }         </pre> <p data-bbox="597 739 998 966">Make sure that you replace &lt;RDS_Instance_ARN&gt; with your Amazon RDS DB instance's Amazon Resource Name (ARN).</p> <p data-bbox="597 1012 998 1144"><b>Important:</b> Make sure that you record the service role's ARN.</p>	

## Create a resource group

Task	Description	Skills required
Tag the Amazon RDS DB instances.	Open the <a href="#">Amazon RDS console</a> and tag the Amazon RDS DB instances that you want to add to the resource group. A tag is metadata assigned to an AWS resource and consists of a key-value pair. We recommend that you	AWS administrator

Task	Description	Skills required
	<p>use <i>Action</i> as the <b>Tag key</b> and <i>StartStop</i> as the <b>Value</b>.</p> <p>For more information about this, see <a href="#">Adding, listing, and removing tags</a> in the Amazon RDS documentation.</p>	
<p>Create a resource group for your tagged Amazon RDS DB instances.</p>	<p>Open the <a href="#">AWS Resource Groups console</a> and create a resource group based on the tag that you created for your Amazon RDS DB instances.</p> <p>Under <b>Grouping Criteria</b>, make sure that you choose <b>AWS::RDS::DBInstance</b> for the resource type and then provide the tag's key-value pair (for example, "Action-StartStop"). This ensures that the service only checks for Amazon RDS DB instances and not other resources that have this tag. Make sure that you record the resource group's name.</p> <p>For more information and detailed steps, see <a href="#">Build a tag-based query and create a group</a> in the AWS Resource Groups documentation.</p>	<p>AWS administrator</p>

## Configure a maintenance window to stop the Amazon RDS DB instances

Task	Description	Skills required
Create a maintenance window.	<ol style="list-style-type: none"><li data-bbox="591 331 1019 890">1. Open the <a href="#">AWS Systems Manager console</a>, choose <b>Maintenance Windows</b>, and then choose <b>Create a maintenance window</b>. Provide a name for your maintenance window (for example, "StopRdsInstance"), enter a description, and then uncheck <b>Allow unregistered targets</b>.</li><li data-bbox="591 915 1019 1619">2. Choose <b>CRON/Rate expression</b> and provide the schedule expression to define when the Amazon RDS DB instances should be stopped. Enter <b>1</b> for the <b>Duration</b> and <b>0</b> for <b>Stop initiating tasks</b>. By default, the <b>Time zone</b> shows UTC. You can change the time zone to initiate the maintenance window based on the timestamp defined in your cron expression.</li><li data-bbox="591 1644 1019 1862">3. Choose <b>Create maintenance window</b>. The system returns you to the maintenance window page and the state of your</li></ol>	AWS administrator

Task	Description	Skills required
	<p data-bbox="630 212 971 289">maintenance window is <b>Enabled</b>.</p> <p data-bbox="591 373 1029 877"><b>Important:</b> The task to stop the DB instance runs almost instantly when initiated and doesn't span the entire duration of the maintenance window. This pattern provides the minimum values for <b>Duration</b> and <b>Stop initiating tasks</b> because they are the required parameters for a maintenance window.</p> <p data-bbox="591 926 1019 1150">For more information and detailed steps, see <a href="#">Create a maintenance window (console)</a> in the AWS Systems Manager documentation.</p>	

Task	Description	Skills required
Assign a target to the maintenance window.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 457">1. On the <a href="#">AWS Systems Manager console</a>, choose <b>Maintenance Windows</b>, choose <b>Actions</b>, and then choose <b>Register targets</b>.</li><li data-bbox="591 478 1027 751">2. In the <b>Targets</b> area, specify <b>Choose a resource group</b> and then choose the name of an existing resource group in your account.</li><li data-bbox="591 772 1027 961">3. For <b>Resource types</b>, choose <b>AWS::RDS::DBInstance</b> and then choose <b>Register target</b>.</li></ol> <p data-bbox="591 1024 1027 1297">For more information and detailed steps, see <a href="#">Assign targets to a maintenance window (console)</a> in the AWS Systems Manager documentation.</p>	AWS administrator

Task	Description	Skills required
Assign a task to the maintenance window.	<ol style="list-style-type: none"><li>1. On the <a href="#">AWS Systems Manager console</a>, choose <b>Maintenance Windows</b> and then choose your maintenance window. Choose <b>Actions</b> and then choose <b>Register Automation task</b>.</li><li>2. For <b>Document</b>, choose <b>AWS-StopRdsInstance</b>.</li><li>3. In the <b>Targets</b> section, choose <b>Selecting registered target groups</b> and then choose the maintenance window target that you registered with the current maintenance window.</li><li>4. For <b>Rate control</b>, specify 100 percent for <b>Concurrency</b> and <b>Error threshold</b>. You can change the <b>Rate control</b> values according to your requirements for task concurrency and error threshold. For more information about this, see <a href="#">About concurrency and error thresholds</a> in the AWS Systems Manager documentation.</li><li>5. In the <b>IAM service role</b> section, for <b>Service role</b>, leave this box blank or create your own custom</li></ol>	AWS administrator

Task	Description	Skills required
	<p>role. If you leave the box blank, Systems Manager automatically creates the service-linked role <b>AWSServiceRoleForAmazonSSM</b> and then associates the role with the task. To create your own custom role, see <a href="#">Create a custom service role for maintenance windows (console)</a>, and then associate that custom role with the task.</p> <p>6. In the <b>Input Parameters</b> section, specify the following parameters for the runbook:</p> <ul style="list-style-type: none"><li>• <b>InstanceID</b>: <code>{{RESOURCE_ID}}</code></li><li>• <b>AutomationAssumeRole</b>: Provide the ARN of the service role that you created for Systems Manager Automation.</li><li>• <b>Note</b>: For <b>InstanceID</b>, a pseudo parameter is used to extract the Amazon RDS DB resource ID from the ARN. To learn more about pseudo parameters, see <a href="#">About pseudo parameters</a></li></ul>	

Task	Description	Skills required
	<p>in the AWS Systems Manager documentation.</p> <p>7. Choose <b>Register Automation task</b>.</p> <p><b>Important:</b> The <b>Service role</b> option defines the service role required for the maintenance window to run tasks. However, this role is not identical to the service role that you created earlier for Systems Manager Automation.</p> <p>For more information and detailed steps, see <a href="#">Assign tasks to a maintenance window (console)</a> in the AWS Systems Manager documentation.</p>	

## Configure a maintenance window to start the Amazon RDS DB instances

Task	Description	Skills required
Configure a maintenance window to start the Amazon RDS DB instances.	Repeat the steps from the <i>Configure a maintenance window to stop the Amazon RDS DB instances</i> epic to configure another maintenance window to start the Amazon RDS DB instances at a scheduled time.	AWS administrator

Task	Description	Skills required
	<p><b>Important:</b> You must make the following changes when you configure the maintenance window to start the DB instances:</p> <ul style="list-style-type: none"><li>• Use a new name for the maintenance window (for example, "StartRdsInstance").</li><li>• Replace the cron expression with the cron expression that you want to use to start the DB instances.</li><li>• Replace the AWS-StopRdsInstance runbook with AWS-StartRdsInstance in <b>Task</b>.</li></ul>	

## Related resources

# Centralize software package distribution in AWS Organizations by using Terraform

Created by Pradip kumar Pandey (AWS), Aarti Rajput (AWS), Chintamani Aphale (AWS), T.V.R.L.Phani Kumar Dadi (AWS), Mayuri Shinde (AWS), and Pratap Kumar Nanda (AWS)

**Environment:** Production

**Technologies:** Management & governance; Infrastructure

**AWS services:** AWS Organizations; AWS Systems Manager

## Summary

Enterprises often maintain multiple AWS accounts that are spread across multiple AWS Regions in order to create a strong isolation barrier between workloads. To stay secure and compliant, their administration teams install agent-based tools such as [CrowdStrike](#), [SentinelOne](#), or [TrendMicro](#) tools for security scanning, and the [Amazon CloudWatch agent](#), [Datadog Agent](#), or [AppDynamics agents](#) for monitoring. These teams often face challenges when they want to centrally automate software package management and distribution across this large landscape.

[Distributor](#), a capability of [AWS Systems Manager](#), automates the process of packaging and publishing software to managed Microsoft Windows and Linux instances across the cloud and on-premises servers through a single simplified interface. This pattern demonstrates how you can use Terraform to further simplify the process of managing the installation of software and to run scripts across a large number of instances and member accounts within AWS Organizations with minimal effort.

This solution works for Amazon, Linux, and Windows instances that are managed by Systems Manager.

## Prerequisites and limitations

- A [Distributor package](#) that has the software to be installed
- [Terraform](#) version 0.15.0 or later
- Amazon Elastic Compute Cloud (Amazon EC2) instances that are [managed by Systems Manager](#) and have basic [permissions to access Amazon Simple Storage Service \(Amazon S3\)](#) in the target account

- A landing zone for your organization that's set up by using [AWS Control Tower](#)
- (Optional) [Account Factory for Terraform \(AFT\)](#)

## Architecture

### Resource details

This pattern uses [Account Factory for Terraform \(AFT\)](#) to create all required AWS resources and the code pipeline to deploy the resources in a deployment account. The code pipeline runs in two repositories:

- **Global customization** contains Terraform code that will run across all accounts registered with AFT.
- **Account customizations** contains Terraform code that will run in the deployment account.

You can also deploy this solution without using AFT, by running [Terraform](#) commands in the account customizations folder.

The Terraform code deploys the following resources:

- AWS Identity and Access Management (IAM) role and policies
  - [SystemsManager-AutomationExecutionRole](#) grants the user permissions to run automations in the target accounts.
  - [SystemsManager-AutomationAdministrationRole](#) grants the user permissions to run automations in multiple accounts and organizational units (OUs).
- Compressed files and manifest.json for the package
  - In Systems Manager, a [package](#) includes at least one .zip file of software or installable assets.
  - The JSON manifest includes pointers to your package code files.
- S3 bucket
  - The distributed package that is shared across the organization is securely stored in an Amazon S3 bucket.
- AWS Systems Manager documents (SSM documents)
  - `DistributeSoftwarePackage` contains the logic to distribute the software package to every target instance in the member accounts.

- `AddSoftwarePackageToDistributor` contains the logic to package the installable software assets and add it to Automation, a capability of AWS Systems Manager.
- Systems Manager association
- A Systems Manager association is used to deploy the solution.

## Architecture and workflow

The diagram illustrates the following steps:

1. To run the solution from a centralized account, you upload your packages or software along with deployment steps to an S3 bucket.
2. Your customized package becomes available in the Systems Manager console [Documents](#) section, in the **Owned by me** tab.
3. State Manager, a capability of Systems Manager, creates, schedules, and runs an association for the package across the organization. The association specifies that the software package must be installed and running on a managed node before it can be installed on the target node.
4. The association instructs Systems Manager to install the package on the target node.
5. For any subsequent installations or changes, users can run the same association periodically or manually from a single location to perform deployments across accounts.
6. In member accounts, Automation sends deployment commands to Distributor.
7. Distributor distributes software packages across instances.

This solution uses the management account within AWS Organizations, but you can also designate an account (delegated administrator) to manage this on behalf of the organization.

## Tools

### AWS services

- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. This pattern uses Amazon S3 to centralize and securely store the distributed package.
- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses the following Systems Manager capabilities:
  - [Distributor](#) helps you package and publish software to Systems Manager managed instances.
  - [Automation](#) simplifies common maintenance, deployment, and remediation tasks for many AWS services.
  - [Documents](#) performs actions on your Systems Manager managed instances across your organization and accounts.
- [AWS Organizations](#) is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

### Other tools

- [Terraform](#) is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

### Code repository

The instructions and code for this pattern are available in the GitHub [Centralized package distribution](#) repository.

## Best practices

- To assign tags to an association, use the [AWS Command Line Interface \(AWS CLI\)](#) or the [AWS Tools for PowerShell](#). Adding tags to an association by using the Systems Manager console

isn't supported. For more information, see [Tagging Systems Manager resources](#) in the Systems Manager documentation.

- To run an association by using a new version of a document shared from another account, set the document version to default.
- To tag only the target node, use one tag key. If you want to target your nodes by using multiple tag keys, use the resource group option.

## Epics

### Configure source files and accounts

Task	Description	Skills required
Clone the repository.	<ol style="list-style-type: none"> <li>1. Clone the GitHub <a href="#">Centralized package distribution</a> repository:           <pre>git clone https://github.com/aws-samples/aws-organization-centralised-package-distribution</pre> </li> <li>2. The Terraform code repository requires two customization folders that are managed by AFT. Confirm that your local copy of the repository contains these folders:           <pre>\$ cd centralised-package-distribution \$ ls global-customization account-customization</pre> </li> </ol>	DevOps engineer

Task	Description	Skills required
Update global variables.	<p>Update the following input parameters in the <code>global-customization/variables.tf</code> file. These variables apply to all accounts that are created and managed by AFT.</p> <ul style="list-style-type: none"><li>• <code>account_id</code> : The ID of the account where the Distributor solution will be deployed.</li><li>• <code>aws_region</code> : The AWS Region where the association will be deployed.</li></ul>	DevOps engineer
Update account variables.	<p>Update the following input parameters in the <code>account-customization/variables.tf</code> file. These variables apply only to specific accounts that are created and managed by AFT.</p> <ul style="list-style-type: none"><li>• <code>package_bucket_name</code> : The name of the S3 bucket that contains the package distribution file.</li><li>• <code>package_name</code> : The name of the package distribution file.</li><li>• <code>package_version</code> : The package version of the installer.</li></ul>	DevOps engineer

## Customize parameters and deployment files

Task	Description	Skills required
Update input parameters for the State Manager association.	<p>Update the following input parameters in the <code>account-customization/association.tf</code> file to define the state you want to maintain on your instances. You can use the default parameter values if they support your use case.</p> <ul style="list-style-type: none"><li>• <code>targetAccounts</code> : The organizational unit (OU) IDs within AWS Organizations that represent accounts with the target instances for distribution. OU IDs start with "ou".</li><li>• <code>targetRegions</code> : The AWS Regions (for example, "us-east-1" or "ap-south-east-2") where the target instances are running.</li><li>• <code>action</code>: Specify whether to install or uninstall the package.</li><li>• <code>installationType</code> : One of the following installation types:<ul style="list-style-type: none"><li>• <code>uninstall</code> : The package is uninstalled.</li><li>• <code>reinstall</code> : The application is taken</li></ul></li></ul>	DevOps engineer

Task	Description	Skills required
	<p>offline until the reinstallation process is complete.</p> <ul style="list-style-type: none"><li>• <b>In-place update:</b> The application is available while new or updated files are added to the installation.</li><li>• <b>name:</b> The name of the package to install or uninstall.</li><li>• <b>version:</b> The version of the package to install or uninstall. If no version of the package is installed, the system returns an error.</li><li>• <b>bucketName :</b> The S3 bucket name the package has been deployed to. This bucket should consist of the packages and the manifest file only.</li><li>• <b>bucketPrefix :</b> The S3 prefix where the package assets are stored.</li><li>• <b>AutomationAssumeRole :</b> The Amazon Resource Name (ARN) of <code>SystemsManager-AutomationAdministrationRole</code> .</li></ul>	

Task	Description	Skills required
Prepare compressed files and the <code>manifest.json</code> file for the package.	<p>This pattern provides sample PowerShell installable files (.msi for Windows and .rpm for Linux) with install and uninstall scripts in the <code>account-customization/package</code> folder.</p> <ol style="list-style-type: none"> <li>1. Replace the PowerShell installable files with your own files, or provide your installable file, install and uninstall scripts, and manifest file to create a package in the <code>account-customization</code> folder in your account.</li> <li>2. Customize the default <code>manifest.json</code> file that Terraform generates in the <code>account-customization</code> folder according to your requirements.</li> </ol>	DevOps engineer

### Run Terraform commands to provision resources

Task	Description	Skills required
Initialize the Terraform configuration.	<p>To deploy the solution automatically with AFT, push the code to AWS CodeCommit:</p> <pre>\$ git add *</pre>	DevOps engineer

Task	Description	Skills required
	<pre>\$ git commit -m "message" \$ git push</pre> <p>You can also deploy this solution without using AFT by running a Terraform command from the <code>account-customization</code> folder. To initialize the working directory that contains the Terraform files, run:</p> <pre>\$ terraform init</pre>	
Preview changes.	<p>To preview the changes that Terraform will make to the infrastructure, run the command:</p> <pre>\$ terraform plan</pre> <p>This command evaluates the Terraform configuration to determine the desired state of the resources that have been declared. It also compares the desired state with the actual infrastructure to provision within the workspace.</p>	DevOps engineer

Task	Description	Skills required
Apply changes.	<p>Run the following command to implement the changes that you made to the <code>variables.tf</code> files:</p> <pre>\$ terraform apply</pre>	DevOps engineer

## Validate resources

Task	Description	Skills required
Validate the creation of SSM documents.	<ol style="list-style-type: none"> <li>On the <a href="#">Systems Manager console</a>, in the left navigation pane, choose <b>Documents</b>.</li> <li>Choose the <b>Owned by me</b> tab.</li> </ol> <p>You should see the <code>DistributeSoftwarePackage</code> and <code>AddSoftwarePackageToDistributor</code> packages.</p>	DevOps engineer
Validate the successful deployment of automations.	<ol style="list-style-type: none"> <li>On the Systems Manager console, in the left navigation pane, choose <b>Automation</b>.</li> <li>In the <b>Automation executions</b> list, you should see the most recent <code>DistributeSoftwarePackage</code> and <code>AddSoftware</code></li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>rePackageToDistributor deployments.</p> <p>3. Choose <b>Execution ID</b> to validate that they completed successfully.</p>	
<p>Validate that the package deployed to the targeted member account instances.</p>	<ol style="list-style-type: none"> <li>1. On the Systems Manager console, in the navigation pane, choose <b>Run Command</b>.</li> <li>2. In <b>Command history</b>, you will see each invocation and its status.</li> <li>3. Choose any <b>Command ID</b> to see the deployment history for each target instance.</li> <li>4. Choose the <b>Instance ID</b> and check the <b>Output</b> section for the distribution.</li> </ol>	<p>DevOps engineer</p>

## Troubleshooting

Issue	Solution
<p>The State Manager association failed or is stuck in pending status.</p>	<p>See the <a href="#">troubleshooting information</a> in the AWS Knowledge Center.</p>
<p>A scheduled association failed to run.</p>	<p>Your schedule specification might be invalid. State Manager doesn't currently support specifying months in cron expressions for associations. Use <a href="#">cron or rate expressions</a> to confirm the schedule.</p>

# Configure VPC Flow Logs for centralization across AWS accounts

Created by Benjamin Morris (AWS) and Aman Kaur Gandhi (AWS)

**Environment:** Production

**Technologies:** Management & governance

**AWS services:** Amazon VPC; Amazon S3

## Summary

In an Amazon Web Services (AWS) virtual private cloud (VPC), the VPC Flow Logs feature can provide useful data for operational and security troubleshooting. However, there are limitations on using VPC Flow Logs in a multi-account environment. Specifically, cross-account flow logs from Amazon CloudWatch Logs are not supported. Instead, you can centralize the logs by configuring an Amazon Simple Storage Service (Amazon S3) bucket with the appropriate bucket policy.

**Note:** This pattern discusses the requirements for sending flow logs to a centralized location. However, if you also want logs to be available locally in member accounts, you can create multiple flow logs for each VPC. Users without access to the Log Archive account can see traffic logs for troubleshooting. Alternatively, you can configure a single flow log for each VPC that sends logs to CloudWatch Logs. You can then use an Amazon Data Firehose subscription filter to forward the logs to an S3 bucket. For more information, see the [Related resources](#) section.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An AWS Organizations organization with an account that is used to centralize logs (for example, Log Archive)

### Limitations

If you use the AWS Key Management Service (AWS KMS) managed key `aws/s3` to encrypt your central bucket, it won't receive logs from a different account. Instead, you will see an error that looks like the following.

```
"Unsuccessful": [  
  {  
    "Error": {  
      "Code": "400",  
      "Message": "LogDestination: <bucketName> is undeliverable"  
    },  
    "ResourceId": "vpc-1234567890123456"  
  }  
]
```

This is because an account's AWS managed keys can't be shared across accounts.

The solution is to use either Amazon S3 managed encryption (SSE-S3) or an AWS KMS customer managed key that you can share with member accounts.

## Architecture

### Target technology stack

In the following diagram, two flow logs are deployed for each VPC. One sends logs to a local CloudWatch Logs group. The other sends logs to an S3 bucket in a centralized logging account. The bucket policy permits the log delivery service to write logs to the bucket.

**Important:** Understand the risks associated with the bucket policy required for this solution. Because the principal that is writing to this bucket is a service principal, and not an AWS Identity and Access Management (IAM) principal, the `aws:PrincipalOrgID` condition will not be a valid condition. This means that there is currently no way to restrict writes based on the account's parent organization.

To secure the bucket, use a hard-to-guess bucket name, and treat the bucket name as a sensitive value that should not be exposed outside of the organization. Make sure that you are using least-privilege permissions in the bucket policy, granting no more than `s3:putObject` and `s3:GetBucketAcl` permissions. If you are working in an environment that has a static set of accounts, you can use a Deny effect to block access except from specific accounts, although this is not operationally feasible for most organizations.

### Target architecture

## Automation and scale

Each VPC is configured to send logs to the S3 bucket in the central logging account. Use one of the following automation solutions to help ensure that flow logs are configured appropriately:

- [AWS CloudFormation StackSets](#)
- [AWS Control Tower Account Factory for Terraform \(AFT\)](#)
- [An AWS Config rule with remediation](#)

## Tools

### Tools

- [Amazon CloudWatch Logs](#) helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

- [Amazon Virtual Private Cloud \(Amazon VPC\)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses the [VPC Flow Logs](#) feature to capture information about the IP traffic going to and from network interfaces in your VPC.

## Best practices

Using infrastructure as code (IaC) can greatly simplify the VPC Flow Logs deployment process. Abstracting your VPC deployment definitions to include a flow log resource construct will deploy your VPCs with flow logs automatically. This is demonstrated in the next section.

### Centralized flow logs

*Example syntax for adding centralized flow logs to a VPC module in HashiCorp Terraform*

This code creates a flow log that sends logs from a VPC to a centralized S3 bucket. Note that this pattern doesn't cover creation of the S3 bucket.

For recommended bucket policy statements, see the [Additional information](#) section.

```
variable "vpc_id" {
  type          = string
  description = "ID of the VPC for which you want to create a Flow Log"
}

locals {
  # For more details: https://docs.aws.amazon.com/vpc/latest/userguide/flow-logs.html#flow-logs-custom
  custom_log_format_v5 = "${version} ${account-id} ${interface-id} ${srcaddr} ${dstaddr} ${srcport} ${dstport} ${protocol} ${packets} ${bytes} ${start} ${end} ${action} ${log-status} ${vpc-id} ${subnet-id} ${instance-id} ${tcp-flags} ${type} ${pkt-srcaddr} ${pkt-dstaddr} ${region} ${az-id} ${sublocation-type} ${sublocation-id} ${pkt-src-aws-service} ${pkt-dst-aws-service} ${flow-direction} ${traffic-path}"
}

resource "aws_flow_log" "centralized" {
  log_destination          = "arn:aws:s3:::centralized-vpc-flow-logs-
<log_archive_account_id>" # Optionally, a prefix can be added after the ARN.
  log_destination_type    = "s3"
  traffic_type             = "ALL"
}
```

```
vpc_id          = var.vpc_id
log_format      = local.custom_log_format_v5 # If you want fields from VPC Flow
Logs v3+, you will need to create a custom log format.
tags           = {
  Name = "centralized_flow_log"
}
}
```

## Local flow logs

*Example syntax for adding local flow logs to a VPC module in Terraform with required permissions*

This code creates a flow log that sends logs from a VPC to a local CloudWatch Logs group.

```
data "aws_region" "current" {}

variable "vpc_id" {
  type        = string
  description = "ID of the VPC for which you want to create a Flow Log"
}

resource "aws_iam_role" "local_flow_log_role" {
  name = "flow-logs-policy-${var.vpc_id}"

  assume_role_policy = <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "vpc-flow-logs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
EOF
}

resource "aws_iam_role_policy" "logs_permissions" {
  name = "flow-logs-policy-${var.vpc_id}"
}
```

```
role = aws_iam_role.local_flow_log_role.id

policy = <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:DescribeLogGroups",
        "logs:DescribeLogStreams",
        "logs:CreateLogDelivery",
        "logs>DeleteLogDelivery"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:logs:${data.aws_region.current.name}:*:log-group:vpc-flow-logs*"
    }
  ]
}
EOF
}

resource "aws_cloudwatch_log_group" "local_flow_logs" {
  # checkov:skip=CKV_AWS_338:local retention is set to 30, centralized S3 bucket can
  # retain for long-term
  name           = "vpc-flow-logs/${var.vpc_id}"
  retention_in_days = 30
}

resource "aws_flow_log" "local" {
  iam_role_arn      = aws_iam_role.local_flow_log_role.arn
  log_destination   = aws_cloudwatch_log_group.local_flow_logs.arn
  traffic_type      = "ALL"
  vpc_id            = var.vpc_id
  tags              = {
    Name = "local_flow_log"
  }
}
}
```

## Epics

### Deploy VPC Flow Logs infrastructure

Task	Description	Skills required
Determine the encryption strategy and create the policy for the central S3 bucket.	The central bucket does not support the aws/s3 AWS KMS key, so you must use either SSE-S3 or an AWS KMS customer managed key. If you use an AWS KMS key, the key policy must allow member accounts to use the key.	Compliance
Create the central flow log bucket.	<p>Create the central bucket to which flow logs will be sent, and apply the encryption strategy that you chose in the previous step. This should be in a Log Archive or similarly purposed account.</p> <p>Obtain the bucket policy from the <a href="#">Additional information</a> section, and apply it to your central bucket after updating placeholders with your environment specific values.</p>	General AWS
Configure VPC Flow Logs to send logs to the central flow log bucket.	Add flow logs to each VPC that you want to gather data from. The most scalable way to do this is to use IaC tools such as AFT or AWS Cloud Development Kit (AWS CDK). For example, you can create	Network administrator

Task	Description	Skills required
	a Terraform module that deploys a VPC alongside a flow log. If necessary, you add the flow logs manually.	
Configure VPC Flow Logs to send to local CloudWatch Logs.	(Optional) If you want flow logs to be visible in the accounts where the logs are being generated, create another flow log to send data to CloudWatch Logs in the local account. Alternatively, you can send the data to an account-specific S3 bucket in the local account.	General AWS

## Additional information

### Bucket policy

This example of a bucket policy can be applied to your central S3 bucket for flow logs, after you add values for placeholder names.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AWSLogDeliveryWrite",
      "Effect": "Allow",
      "Principal": {
```

```

        "Service": "delivery.logs.amazonaws.com"
    },
    "Action": "s3:PutObject",
    "Resource": "arn:aws:s3:::<BUCKET_NAME>/**",
    "Condition": {
        "StringEquals": {
            "s3:x-amz-acl": "bucket-owner-full-control"
        }
    }
},
{
    "Sid": "AWSLogDeliveryCheck",
    "Effect": "Allow",
    "Principal": {
        "Service": "delivery.logs.amazonaws.com"
    },
    "Action": "s3:GetBucketAcl",
    "Resource": "arn:aws:s3:::<BUCKET_NAME>"
},
{
    "Sid": "DenyUnencryptedTraffic",
    "Effect": "Deny",
    "Principal": {
        "AWS": "*"
    },
    "Action": "s3:*",
    "Resource": [
        "arn:aws:s3:::<BUCKET_NAME>/**",
        "arn:aws:s3:::<BUCKET_NAME>"
    ],
    "Condition": {
        "Bool": {
            "aws:SecureTransport": "false"
        }
    }
}
]
}

```

If you have a static list of accounts, you can add the following statement to deny any accounts outside of that list.

```
{
```

```

    "Sid": "AccountDenyList",
    "Effect": "Deny",
    "Principal": "*",
    "Action": "s3:PutObject",
    "NotResource": [
      "arn:aws:s3:::<BUCKET_NAME>/<OPTIONAL_PREFIX>/AWSLogs/<ACCOUNT_ID1>/*",
      "arn:aws:s3:::<BUCKET_NAME>/<OPTIONAL_PREFIX>/AWSLogs/<ACCOUNT_ID2>/*",
      "arn:aws:s3:::<BUCKET_NAME>/<OPTIONAL_PREFIX>/AWSLogs/<ACCOUNT_ID3>/*",
    ]
  }
}

```

As an alternative to the previous NotResource-Deny pattern, you can instead add conditions to each of your Allow statements to specify approved accounts.

```

"Condition": {
  "StringEquals": {
    "aws:SourceAccount": [
      "111111111111",
      "222222222222"
    ]
  }
}
}

```

### *Adding a prefix*

You can also restrict writes to a known prefix within the bucket, if you are concerned about unwanted external writes to the bucket in a scenario where the bucket name becomes exposed publicly. If you implement this, update the `log_destination` in the `aws_flow_log` resource to include the prefix following the bucket Amazon Resource Name (ARN). For example, the following statement restricts writes to a specific prefix.

```

{
  "Sid": "PrefixAllowList",
  "Effect": "Deny",
  "Principal": "*",
  "Action": "s3:PutObject",
  "NotResource": [
    "arn:aws:s3:::<BUCKET_NAME>/<PREFIX>/*"
  ]
}

```

# Configure logging for .NET applications in Amazon CloudWatch Logs by using NLog

Created by Bibhuti Sahu (AWS) and Rob Hill (AWS) (AWS)

**Environment:** Production

**Technologies:** Management & governance; DevOps; Web & mobile apps

**Workload:** Microsoft

**AWS services:** Amazon CloudWatch Logs

## Summary

This pattern describes how to use the NLog open-source logging framework to log .NET application usage and events in [Amazon CloudWatch Logs](#). In the CloudWatch console, you can view the application's log messages in near real time. You can also set up [metrics](#) and configure [alarms](#) to notify you if a metric threshold is exceeded. Using CloudWatch Application Insights, you can view automated or custom dashboards that show potential problems for the monitored applications. CloudWatch Application Insights is designed to help you quickly isolate ongoing issues with your applications and infrastructure.

To write log messages to CloudWatch Logs, you add the AWS.Logger.NLog NuGet package to the .NET project. Then, you update the NLog.config file to use CloudWatch Logs as a target.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A .NET web or console application that:
  - Uses supported .NET Framework or .NET Core versions. For more information, see *Product versions*.
  - Uses NLog to send log data to Application Insights.
- Permissions to create an IAM role for an AWS service. For more information, see [Service role permissions](#).

- Permissions to pass a role to an AWS service. For more information, see [Granting a user permissions to pass a role to an AWS service](#).

## Product versions

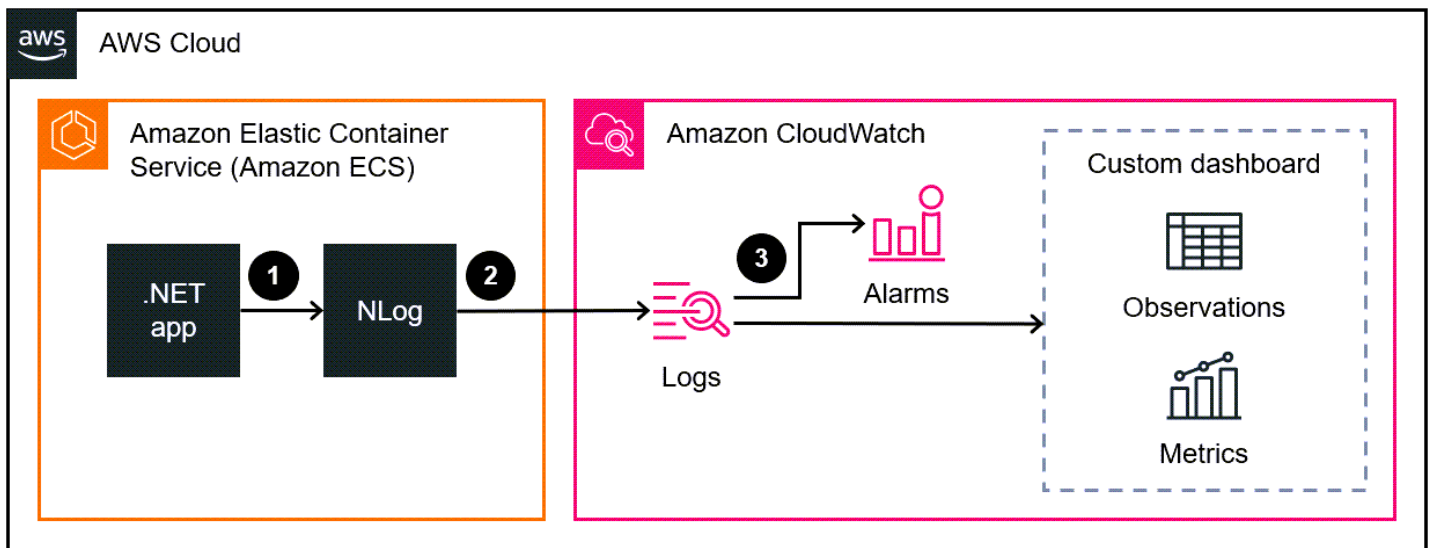

- .NET Framework version 3.5 or later
- .NET Core versions 1.0.1, 2.0.0, or later

## Architecture

### Target technology stack

- NLog
- Amazon CloudWatch Logs

### Target architecture

1. The .NET application writes log data to the NLog logging framework.
2. NLog writes the log data to CloudWatch Logs.
3. You use CloudWatch alarms and custom dashboards to monitor the .NET application.

# Tools

## AWS services

- [Amazon CloudWatch Application Insights](#) helps you observe the health of your applications and underlying AWS resources.
- [Amazon CloudWatch Logs](#) helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Tools for PowerShell](#) are a set of PowerShell modules that help you script operations on your AWS resources from the PowerShell command line.

## Other tools

- [Logger.NLog](#) is an NLog target that records log data to CloudWatch Logs.
- [NLog](#) is an open-source logging framework for .NET platforms that helps you write log data to targets, such as databases, log files, or consoles.
- [PowerShell](#) is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.
- [Visual Studio](#) is an integrated development environment (IDE) that includes compilers, code completion tools, graphical designers, and other features that support software development.

## Best practices

- Set a [retention policy](#) for the target log group. This must be done outside of the NLog configuration. By default, log data is stored in CloudWatch Logs indefinitely.
- Adhere to the [Best practices for managing AWS access keys](#).

# Epics

## Set up access and tools

Task	Description	Skills required
Create an IAM policy.	<p>Follow the instructions in <a href="#">Creating policies using the JSON editor</a> in the IAM documentation. Enter the following JSON policy, which has the least-privilege permissions necessary to allow CloudWatch Logs to read and write logs.</p> <pre data-bbox="591 884 1029 1858">{   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Action": [          "logs:CreateLogGroup",         "logs:CreateLogStream",         "logs:GetLogEvents",         "logs:PutLogEvents",         "logs:DescribeLogGroups",         "logs:DescribeLogStreams",</pre>	AWS administrator, AWS DevOps

Task	Description	Skills required
	<pre> "logs:PutRetention Policy"     ],     "Resource":     [         "*"     ] } ] } </pre>	
Create an IAM role.	<p>Follow the instructions in <a href="#">Creating a role to delegate permissions to an AWS service</a> in the IAM documentation. Select the policy that you created previously. This is the role CloudWatch Logs assumes to perform logging actions.</p>	AWS administrator, AWS DevOps
Set up AWS Tools for PowerShell.	<ol style="list-style-type: none"> <li>1. Follow the instructions for your operating system in <a href="#">Installing the AWS Tools for PowerShell</a>.</li> <li>2. Use the AWS Tools for PowerShell cmdlets to store your access key and secret key in a profile. For instructions, see <a href="#">Managing Profiles</a> in the AWS Tools for PowerShell documentation.</li> </ol>	General AWS

## Configure NLog

Task	Description	Skills required
Install the NuGet package.	<ol style="list-style-type: none"><li>1. In Visual Studio, choose <b>File</b>, and then choose <b>Open a project or solution</b>.</li><li>2. Choose the project where you want to install NLog.</li><li>3. In Visual Studio, choose <b>Tools, NuGet Package Manager, Package Manager Console</b>.</li><li>4. Install the <code>AWS.Logger.NLog</code> NuGet package by entering the following command.<div data-bbox="630 1052 1029 1213" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>Install-Package   AWS.Logger.NLog -   Version 3.1.0</pre></div></li></ol>	App developer
Configure the logging target.	<ol style="list-style-type: none"><li>1. Open the <code>NLog.config</code> file.</li><li>2. For the target type, enter <code>AWSTarget</code>.</li><li>3. For the target <code>logGroup</code>, enter the name of the <a href="#">log group</a> that you want to use. If the log group doesn't already exist, a new log group with the provided name is automatically created.</li></ol>	App developer

Task	Description	Skills required
	<p>4. For the target region, enter the AWS Region where CloudWatch Logs is configured.</p> <p>5. For the target profile, enter the name of the profile that you created previously to store to store the access key and secret key.</p> <p>6. Save and close the NLog.config file.</p> <p>For a sample configuration file, see the <a href="#">Additional information</a> section of this pattern. When you run your application, NLog will write the log messages and send them to CloudWatch Logs.</p>	

## Validate and monitor logs

Task	Description	Skills required
Validate logging.	<p>Follow the instructions in <a href="#">View log data sent to CloudWatch Logs</a> in the CloudWatch Logs documentation. Validate that log events are being recorded for the .NET application. If log events are not being</p>	General AWS

Task	Description	Skills required
	recorded, see the <a href="#">Troubleshooting</a> section in this pattern.	
Monitor the .NET application stack.	Configure monitoring in CloudWatch as needed for your use case. You can use <a href="#">CloudWatch Logs Insights</a> , <a href="#">CloudWatch Metrics Insights</a> , and <a href="#">CloudWatch Application Insights</a> to monitor your .NET workload. You can also configure <a href="#">alarms</a> so that you can receive alerts, and you can create a custom <a href="#">dashboard</a> for monitoring the workload from a single view.	General AWS

## Troubleshooting

Issue	Solution
Log data doesn't appear in CloudWatch Logs.	Make sure that the IAM policy is attached to the IAM role that CloudWatch Logs assumes. For instructions, see the <i>Set up access and tools</i> section in the <a href="#">Epics</a> section.

profile="demo"/>
    </targets>
    <rules>
      <logger name="*" minlevel="Info" writeTo="aws" />
    </rules>
  </nlog>
</configuration>
```

# Copy AWS Service Catalog products across different AWS accounts and AWS Regions

Created by Sachin Vighe (AWS) and Santosh Kale (AWS)

**Environment:** Production

**Technologies:** Management & governance; Serverless

**Workload:** All other workloads

**AWS services:** AWS Service Catalog; AWS Lambda

## Summary

AWS Service Catalog is a Regional service and this means that AWS Service Catalog [portfolios and products](#) are only visible in the AWS Region where they are created. If you set up an [AWS Service Catalog hub](#) in a new Region, you must recreate your existing products and this can be a time-consuming process.

This pattern's approach helps simplify this process by describing how to copy products from an AWS Service Catalog hub in a source AWS account or Region to a new hub in a destination account or Region. For more information about the AWS Service Catalog hub and spoke model, see [AWS Service Catalog hub and spoke model: How to automate the deployment and management of AWS Service Catalog to many accounts](#) on the AWS Management and Governance Blog.

The pattern also provides the separate code packages required to copy AWS Service Catalog products across accounts or to other Regions. By using this pattern, your organization can save time, make existing and previous product versions available in a new AWS Service Catalog hub, minimize the risk of manual errors, and scale the approach across multiple accounts or Regions.

**Note:** This pattern's *Epics* section provides two options for copying products. You can use Option 1 to copy products across accounts or choose Option 2 to copy products across Regions.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.

- Existing AWS Service Catalog products in a source account or Region.
- An existing AWS Service Catalog hub in a destination account or Region.
- If you want to copy products across accounts, you must share and then import the AWS Service Catalog portfolio containing the products into your destination account. For more information about this, see [Sharing and importing portfolios](#) in the AWS Service Catalog documentation.

## Limitations

- AWS Service Catalog products that you want to copy across Regions or accounts cannot belong to more than one portfolio.

## Architecture

The following diagram shows the copying of AWS Service Catalog products from a source account to a destination account.

The following diagram shows the copying of AWS Service Catalog products from a source Region to a destination Region.

## Technology stack

- Amazon CloudWatch
- AWS Identity and Access Management (IAM)
- AWS Lambda
- AWS Service Catalog

## Automation and scale

You can scale this pattern's approach by using a Lambda function that can be scaled depending on the number of requests received or how many AWS Service Catalog products you need to copy. For more information about this, see [Lambda function scaling](#) in the AWS Lambda documentation.

## Tools

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Service Catalog](#) helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

## Code

You can use the `cross-account-copy` package (attached) to copy AWS Service Catalog products across accounts or the `cross-region-copy` package (attached) to copy products across Regions.

The `cross-account-copy` package contains the following files:

- `copyconf.properties` – The configuration file that contains the Region and AWS account ID parameters for copying products across accounts.
- `scProductCopyLambda.py` – The Python function for copying products across accounts.
- `createDestAccountRole.sh` – The script to create an IAM role in the destination account.
- `createSrcAccountRole.sh` – The script to create an IAM role in the source account.
- `copyProduct.sh` – The script to create and invoke the Lambda function for copying products across accounts.

The `cross-region-copy` package contains the following files:

- `copyconf.properties` – The configuration file that contains the Region and AWS account ID parameters for copying products across Regions.
- `scProductCopyLambda.py` – The Python function for copying products across Regions.
- `copyProduct.sh` – The script to create an IAM role and create and invoke the Lambda function for copying products across Regions.

# Epics

## Option 1 – Copy AWS Service Catalog products across accounts

Task	Description	Skills required
Update the configuration file.	<ol style="list-style-type: none"> <li>1. Download the <code>cross-account-copy</code> package (attached) to your local machine.</li> <li>2. Update the <code>copyconf.properties</code> configuration file with the following values: <ul style="list-style-type: none"> <li>• <code>srcRegion</code> – Provide the source Region that contains the products.</li> <li>• <code>destRegion</code> – Provide the destination Region for the products.</li> <li>• <code>sourceAccountId</code> – Provide the AWS account ID for your source account.</li> <li>• <code>destAccountId</code> – Provide the AWS account ID for your destination account.</li> </ul> </li> </ol>	AWS administrator, AWS systems administrator, Cloud administrator
Configure your credentials for AWS CLI in the destination account.	Configure your credentials to access AWS CLI in your destination account by running the <code>aws configure</code> command and providing the following values :	AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required
	<pre data-bbox="597 226 1026 684">\$aws configure AWS Access Key ID [None]: &lt;your_access_key_id&gt; AWS Secret Access Key [None]: &lt;your_secret_access_key&gt; Default region name [None]: Region Default output format [None]:</pre> <p data-bbox="597 726 1013 898">For more information about this, see <a href="#">Configuration basics</a> in the AWS Command Line Interface documentation.</p>	

Task	Description	Skills required
<p>Configure your credentials for AWS CLI in the source account.</p>	<p>Configure your credentials to access AWS CLI in your source account by running the <code>aws configure</code> command and providing the following values:</p> <pre data-bbox="594 537 1029 1016">\$aws configure AWS Access Key ID [None]: &lt;your_access_key_id&gt; AWS Secret Access Key [None]: &lt;your_secret_access_key&gt; Default region name [None]: Region Default output format [None]:</pre> <p>For more information about this, see <a href="#">Configuration basics</a> in the AWS Command Line Interface documentation.</p>	<p>AWS administrator, AWS systems administrator, Cloud administrator</p>
<p>Create a Lambda execution role in your destination account.</p>	<p>Run the <code>createDestAccountRole.sh</code> script in your destination account. The script implements the following actions:</p> <ul style="list-style-type: none"><li>• Creates a Lambda execution role in your destination account</li><li>• Creates and attaches the IAM policy for the Lambda execution role</li></ul>	<p>AWS administrator, AWS systems administrator, Cloud administrator</p>

Task	Description	Skills required
Create the cross-account IAM role in your source account.	<p>Run the <code>createSrcAccountRole.sh</code> script in your source account. The script implements the following actions:</p> <ul style="list-style-type: none"><li>• Creates a cross-account IAM role in your source account that is assumed by the Lambda execution role in the destination account to copy products</li><li>• Creates and attaches an IAM policy for the cross-account role in your source account</li></ul>	AWS administrator, AWS systems administrator, Cloud administrator
Run the <code>copyProduct</code> script in the destination account.	<p>Run the <code>copyProduct.sh</code> script in your destination account. The script implements the following actions:</p> <ul style="list-style-type: none"><li>• Creates and invokes the Lambda function to copy products from the source account to the destination account</li></ul>	AWS administrator, AWS systems administrator, Cloud administrator

## Option 2 – Copy AWS Service Catalog products from a source Region to a destination Region

Task	Description	Skills required
Update the configuration file.	<ol style="list-style-type: none"> <li>1. Download the <code>cross-region-copy</code> package (attached) to your local machine.</li> <li>2. Update the <code>copyconf.properties</code> configuration file with the following values: <ul style="list-style-type: none"> <li>• <code>srcRegion</code> – Provide the source Region that contains the products.</li> <li>• <code>destRegion</code> – Provide the destination Region for the products.</li> <li>• <code>accountId</code> – Provide your AWS account ID.</li> </ul> </li> </ol>	AWS systems administrator, Cloud administrator, AWS administrator
Configure your credentials for AWS CLI.	<p>Configure your credentials to access AWS CLI in your environment by running the <code>aws configure</code> command and providing the following values:</p> <pre data-bbox="594 1482 1027 1854"> \$aws configure AWS Access Key ID [None]: &lt;your_access_key_id&gt; AWS Secret Access Key [None]: &lt;your_secret_access_key&gt; Default region name [None]: Region </pre>	AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required
	<p>Default output format [None]:</p> <p>For more information about this, see <a href="#">Configuration basics</a> in the AWS Command Line Interface documentation.</p>	
Run the copyProduct script.	<p>Run the copyProduct .sh script in your destination Region. The script implements the following actions:</p> <ul style="list-style-type: none"> <li>• Creates a Lambda execution role</li> <li>• Creates and attaches the IAM policy for the Lambda execution role</li> <li>• Creates and invokes the Lambda function to copy products from the source Region to the destination Region</li> </ul>	AWS administrator, AWS systems administrator, Cloud administrator

# Create alarms for custom metrics using Amazon CloudWatch anomaly detection

Created by Ram Kandaswamy (AWS) and Raheem Jiwani (AWS)

**Environment:** Production

**Technologies:** Management & governance; DevOps; Operations; CloudNative

**AWS services:** Amazon CloudWatch

## Summary

On the Amazon Web Services (AWS) Cloud, you can use Amazon CloudWatch to create alarms that monitor metrics and send notifications or automatically make changes if a threshold is breached.

To avoid being limited by [static thresholds](#), you can create alarms based on past patterns and that notify you if specific metrics are outside the normal operating window. For example, you could monitor your API's response times from Amazon API Gateway and receive notifications about anomalies that prevent you from meeting a service-level agreement (SLA).

This pattern describes how to use CloudWatch anomaly detection for custom metrics. The pattern shows you how to create a custom metric in Amazon CloudWatch Logs Insights or publish a custom metric with an AWS Lambda function, and then set up anomaly detection and create notifications using Amazon Simple Notification Service (Amazon SNS).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing SNS topic, configured to send email notifications. For more information about this, see [Getting started with Amazon SNS](#) in the Amazon SNS documentation.
- An existing application, configured with [CloudWatch Logs](#).

### Limitations

- CloudWatch metrics don't support millisecond time intervals. For more information about the granularity of regular and custom metrics, see the [Amazon CloudWatch FAQs](#).

## Architecture

The diagram shows the following workflow:

1. Logs that use metrics created and updated by CloudWatch Logs are streamed to CloudWatch.
2. An alarm initiates based on thresholds and sends an alert to an SNS topic.
3. Amazon SNS sends you an email notification.

### Technology stack

- CloudWatch
- AWS Lambda
- Amazon SNS

## Tools

- [Amazon CloudWatch](#) provides a reliable, scalable, and flexible monitoring solution.

- [AWS Lambda](#) is a compute service that helps you run code without provisioning or managing servers.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) is a managed service that provides message delivery from publishers to subscribers.

## Epics

### Set up anomaly detection for a custom metric

Task	Description	Skills required
Option 1 - Create a custom metric with a Lambda function.	<p>Download the <code>lambda_function.py</code> file (attached ) and then replace the sample <code>lambda_function.py</code> file in the <a href="#">aws-lambda-developer-guide</a> repository on the AWS Documentation GitHub. This provides you with a sample Lambda function that sends custom metrics to CloudWatch Logs. The Lambda function uses the Boto3 API to integrate with CloudWatch.</p> <p>After you run the Lambda function, you can sign in to the AWS Management Console, open the CloudWatch console, and the published metric is available under your published namespace.</p>	DevOps engineer, AWS DevOps
Option 2 – Create custom metrics from CloudWatch log groups.	Sign in to the AWS Management Console, open the CloudWatch console, and	DevOps engineer, AWS DevOps

Task	Description	Skills required
	<p>then choose <b>Log groups</b>. Choose the log group that you want to create a metric for.</p> <p>Choose <b>Actions</b> and then choose <b>Create metric filter</b>. For <b>Filter pattern</b>, enter the filter pattern that you want to use. For more information, see <a href="#">Filter and pattern syntax</a> in the CloudWatch documentation.</p> <p>To test your filter pattern, enter one or more log events under <b>Test Pattern</b>. Each log event must be within one line, because line breaks are used to separate log events in the <b>Log event</b> messages box. After you test the pattern, you can enter a name and value for your metric under <b>Metric details</b>.</p> <p>For more information and steps to create a custom metric, see <a href="#">Create a metric filter for a log group</a> in the CloudWatch documentation.</p>	

Task	Description	Skills required
Create an alarm for your custom metric.	<p>On the CloudWatch console, choose <b>Alarms</b> and then choose <b>Create Alarm</b>. Choose <b>Select metric</b> and enter the name of the metric that you created earlier into the search box. Choose the <b>Graphed metrics</b> tab and configure the options according to your requirements.</p> <p>Under <b>Conditions</b>, choose <b>Anomaly detection</b> instead of <b>Static thresholds</b>. This shows you a band based on two standard default deviations. You can set up thresholds and adjust them according to your requirements.</p> <p>Choose <b>Next</b>.</p> <p><b>Note:</b> The band is dynamic and depends on the quality of the datapoints. When you begin aggregating more data, the band and thresholds are automatically updated.</p>	DevOps engineer, AWS DevOps

Task	Description	Skills required
Set up SNS notifications.	<p>Under <b>Notification</b>, choose the SNS topic to notify when the alarm is in ALARM state, OK state, or INSUFFICIENT_DATA state.</p> <p>To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose <b>Add notification</b>. Choose <b>Next</b>. Enter a name and description for the alarm. The name must only contain ASCII characters. Then choose <b>Next</b>.</p> <p>Under <b>Preview and create</b>, confirm that the information and conditions are correct, and then choose <b>Create alarm</b>.</p>	DevOps engineer, AWS DevOps

# Document your AWS landing zone design

Created by Michael Daehnert (AWS), Florian Langer (AWS), and Michael Lodemann (AWS)

**Environment:** Production

**Technologies:** Management & governance; Infrastructure; Security, identity, compliance

**AWS services:** AWS Control Tower

## Summary

A *landing zone* is a well-architected, multi-account environment that's based on security and compliance best practices. It is the enterprise-wide container that holds all of your organizational units (OUs), AWS accounts, users, and other resources. A landing zone can scale to fit the needs of an enterprise of any size. AWS has two options for creating your landing zone: a service-based landing zone using [AWS Control Tower](#) or a customized landing zone that you build. Each option requires a different level of AWS knowledge.

AWS created AWS Control Tower to help you save time by automating the setup of a landing zone. AWS Control Tower is managed by AWS and uses best practices and guidelines to help you create your foundational environment. AWS Control Tower uses integrated services, such as [AWS Service Catalog](#) and [AWS Organizations](#), to provision accounts in your landing zone and manage access to those accounts.

AWS landing zone projects vary in requirements, implementation details, and operational action items. There are customization aspects that need to be handled with every landing zone implementation. This includes (but is not limited to) how access management is handled, which technology stack is used, and what the monitoring requirements are for operational excellence. This pattern provides a template that helps you document your landing zone project. By using the template, you can document your project more quickly and help your development and operations teams understand your landing zone.

## Prerequisites and limitations

### Limitations

This pattern does not describe what a landing zone is or how to implement one. For more information about these topics, see the [Related resources](#) section.

# Epics

## Create the design document

Task	Description	Skills required
Identify key stakeholders.	Identify key service and team managers that are linked to your landing zone.	Project manager
Customize the template.	Download the template in the <a href="#">Attachments</a> section, and then update the template as follows:  <ol style="list-style-type: none"><li>1. Remove any sections that don't apply to your organization's landing zone or processes.</li><li>2. Add any sections that are unique to your organization.</li></ol>	Project manager
Complete the template.	In meetings with the stakeholders or by using a write-and-review process, complete the template as follows:  <ol style="list-style-type: none"><li>1. Use the guidance and information in the blue boxes to complete each section.</li><li>2. Replace or remove any yellow fields with custom values for your organization.</li></ol>	Project manager

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>3. Replace or remove any image fields with your custom architecture or flow diagrams.</li> <li>4. Complete the <i>Revision history</i> and <i>Contributors</i> section of the template.</li> </ol>	
Share the design document.	When your landing zone design documentation is complete, save it in a shared repository or central location where all stakeholders can access it. We recommend that you use standard document control processes to record and approve revisions to the design document.	Project manager

# Set up AWS CloudFormation drift detection in a multi-Region, multi-account organization

Created by Ram Kandaswamy (AWS)

<b>Environment:</b> Production	<b>Technologies:</b> Management & governance; CloudNative; Infrastructure; Operations; Modernization	<b>Workload:</b> All other workloads
<b>AWS services:</b> Amazon SNS; AWS Config; AWS Lambda; AWS CloudFormation		

## Summary

Customers on Amazon Web Services (AWS) are often looking for an efficient way to detect resource configuration mismatches, including drift in AWS CloudFormation stacks, and fix them as soon as possible. This is especially the case when AWS Control Tower or AWS Landing Zone solutions are used.

This pattern provides a prescriptive solution that efficiently solves the problem by using consolidated resource configuration changes and acting on those changes to generate results. The solution is designed for scenarios where there are several CloudFormation stacks created in more than one Region or more than one account or a combination of both. The goals of the solution are the following:

- Simplify the drift detection process
- Set up notification and alerting
- Set up consolidated reporting

## Prerequisites and limitations

### Prerequisites

- AWS Config enabled in all the Regions and accounts that must be monitored

## Limitations

- The report generated supports only the .csv or .json output formats.

## Architecture

### Target technology stack

The current guidance will help organizations achieve the goal by using a combination of the following services:

- AWS Config rule
- Amazon CloudWatch rule
- AWS Identity and Access Management (IAM)
- AWS Lambda
- Amazon Simple Notification Service (Amazon SNS)

1. The AWS Config rule detects drift.

2. Drift detection results in other accounts are sent to the management account.
3. The CloudWatch rule calls Lambda.
4. Lambda queries the AWS Config rule for aggregated results.
5. Lambda notifies Amazon SNS, which sends email notification of the drift.

## Automation and scale

The solution presented here can scale for both additional Regions and accounts.

## Tools

[AWS Config](#) – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time. With AWS Config, you can assess, audit, and evaluate the configurations of your AWS resources.

[Amazon CloudWatch](#) – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.

[AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

[Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).

## Best practices

< **Author remove these notes:** Provide a list of guidelines and recommendations that can help users implement this pattern more effectively.>

# Epics

## Automate drift detection for CloudFormation

Task	Description	Skills required
Create the aggregator.	On the AWS Config console, create an aggregator in the management account. Ensure that data replication is turned on so that AWS Config can fetch data from the source accounts. Also, select all applicable Regions and accounts. You can select accounts based on organizations. This is the recommended approach because new accounts in the organization are automatically part of the aggregator.	Cloud architect
Create an AWS managed rule.	Add the <code>cloudformation-stack-drift-detection-check</code> AWS managed rule. The rule needs one parameter value: <code>cloudformationArn</code> . Enter the IAM role Amazon Resource Name (ARN) that has permissions to detect stack drift. In addition, the role must have a trust policy that enables AWS Config to assume the role.	Cloud architect

Task	Description	Skills required
<p>Create the advanced query section of the aggregator.</p>	<p>To fetch drifted stacks from multiple sources, create the following query:</p> <pre>SELECT resourceId, configuration.driftInformation.stackDriftStatus WHERE resourceType = 'AWS::CloudFormation::Stack' AND configuration.driftInformation.stackDriftStatus IN ('DRIFTED')</pre>	<p>Cloud architect, Developer</p>
<p>Automate running the query and publish.</p>	<p>Create a Lambda function using the code that is attached. Lambda will publish the results to an Amazon SNS topic that is provided as an environment variable in the Lambda function. Also, to receive alerts, create an email subscription to an existing Amazon SNS topic.</p>	<p>Cloud architect, Developer</p>
<p>Create a CloudWatch rule.</p>	<p>Create a schedule-based CloudWatch rule to call the Lambda function, which is responsible for alerting.</p>	<p>Cloud architect</p>

## Related resources

### Resources

- [What Is AWS Config?](#)
- [Concepts: multi-account multi-Region data aggregation](#)
- [Multi-account multi-Region data aggregation](#)
- [Detecting unmanaged configuration changes to stacks and resources](#)
- [IAM: Pass an IAM role to a specific AWS service](#)
- [What is Amazon SNS?](#)

## Additional information

### Considerations

Using custom solutions that involve API calls at specific intervals to initiate drift detection on each CloudFormation stack or on stack sets is not optimal. It leads to a large number API calls and affects the performance. Because of the number of API calls, throttling can happen. Another potential issue is a delay in detection if resource changes are identified based on schedule only.

### FAQ

Q. Should I use an add-on based solution with AWS Landing Zone?

A. With the availability of the advanced queries feature in AWS Config, along with the aggregator, the recommendation is to use AWS Config instead of an add-on.

Q. How does this solution address CloudFormation StackSets?

A. Because stack sets are made of stacks, you can use this solution. Stack instance details are also available as part of the solution.

[attachment.zip](#)

# Improve operational performance by enabling Amazon DevOps Guru across multiple AWS Regions, accounts, and OUs with the AWS CDK

Created by Dr. Rahul Sharad Gaikwad (AWS)

**Code repository:** [Amazon DevOps Guru sample code](#)

**Environment:** PoC or pilot

**Technologies:** Management & governance; CloudNative; DevOps; Operations; Security, identity, compliance; Serverless

**AWS services:** Amazon API Gateway; AWS CDK; Amazon DevOps Guru; Amazon DynamoDB; AWS Organizations

## Summary

This pattern demonstrates the steps to enable the Amazon DevOps Guru service across multiple Amazon Web Services (AWS) Regions, accounts, and organizational units (OUs) by using the AWS Cloud Development Kit (AWS CDK) in TypeScript. You can use AWS CDK stacks to deploy AWS CloudFormation StackSets from the administrator (primary) AWS account to enable Amazon DevOps Guru across multiple accounts, instead of logging into each account and enabling DevOps Guru individually for each account.

Amazon DevOps Guru provides artificial intelligence operations (AIOps) features to help you improve the availability of your applications and resolve operational issues faster. DevOps Guru reduces your manual effort by applying machine learning (ML) powered recommendations, without requiring any ML expertise. DevOps Guru analyzes your resources and operational data. If it detects any anomalies, it provides metrics, events, and recommendations to help you address the issue.

This pattern describes three deployment options for enabling Amazon DevOps Guru:

- For all stack resources across multiple accounts and Regions

- For all stack resources across OUs
- For specific stack resources across multiple accounts and Regions

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. (See [Installing, updating, and uninstalling the AWS CLI](#) in the AWS CLI documentation.)
- AWS CDK Toolkit, installed and configured. (See [AWS CDK Toolkit](#) in the AWS CDK documentation.)
- Node Package Manager (npm), installed and configured for the AWS CDK in TypeScript. (See [Downloading and installing Node.js and npm](#) in the npm documentation.)
- Python3 installed and configured, for running a Python script to inject traffic into the sample serverless application. (See [Python Setup and Usage](#) in the Python documentation.)
- Pip, installed and configured to install the Python requests library. (See the [pip installation instructions](#) on the PyPI website.)

### Product versions

- AWS CDK Toolkit version 1.107.0 or later
- npm version 7.9.0 or later
- Node.js version 15.3.0 or later

## Architecture

### Technologies

The architecture for this pattern includes the following services:

- [Amazon DevOps Guru](#)
- [AWS CloudFormation](#)
- [Amazon API Gateway](#)

- [AWS Lambda](#)
- [Amazon DynamoDB](#)
- [Amazon CloudWatch](#)
- [AWS CloudTrail](#)

## AWS CDK stacks

The pattern uses the following AWS CDK stacks:

- `CdkStackSetAdminRole` – Creates an AWS Identity and Access management (IAM) administrator role to establish a trust relationship between the administrator and target accounts.
- `CdkStackSetExecRole` – Creates an IAM role to trust the administrator account.
- `CdkDevopsGuruStackMultiAccReg` – Enables DevOps Guru across multiple AWS Regions and accounts for all stacks, and sets up Amazon Simple Notification Service (Amazon SNS) notifications.
- `CdkDevopsGuruStackMultiAccRegSpecStacks` – Enables DevOps Guru across multiple AWS Regions and accounts for specific stacks, and sets up Amazon SNS notifications.
- `CdkDevopsGuruStackOrgUnit` – Enables DevOps Guru across OUs, and sets up Amazon SNS notifications.
- `CdkInfrastructureStack` – Deploys sample serverless application components such as API Gateway, Lambda, and DynamoDB in the administrator account to demonstrate fault injection and insights generation.

## Sample application architecture

The following diagram illustrates the architecture of a sample serverless application that has been deployed across multiple accounts and Regions. The pattern uses the administrator account to deploy all the AWS CDK stacks. It also uses the administrator account as one of the target accounts for setting up DevOps Guru.

1. When DevOps Guru is enabled, it first baselines each resource's behavior and then ingests operational data from CloudWatch vended metrics.
2. If it detects an anomaly, it correlates it with the events from CloudTrail, and generates an insight.

- The insight provides a correlated sequence of events along with prescribed recommendations to enable the operator to identify the culprit resource.
- Amazon SNS sends notification messages to the operator.

## Automation and scale

The [GitHub repository](#) provided with this pattern uses the AWS CDK as an infrastructure as code (IaC) tool to create the configuration for this architecture. AWS CDK helps you orchestrate resources and enable DevOps Guru across multiple AWS accounts, Regions, and OUs.

## Tools

### AWS services

- [AWS CDK](#) – AWS Cloud Development Kit (AWS CDK) helps you define your cloud infrastructure as code in one of five supported programming languages: TypeScript, JavaScript, Python, Java, and C#.

- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is a unified tool that provides a consistent command-line interface for interacting with AWS services and resources.

## Code

The source code for this pattern is available on GitHub, in the [Amazon DevOps Guru CDK Samples](#) repository. The AWS CDK code is written in TypeScript. To clone and use the repository, follow the instructions in the next section.

**Important:** Some of the stories in this pattern include AWS CDK and AWS CLI command examples that are formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) continuation character at the end of each line with a caret (^).

## Epics

### Prepare the AWS resources for deployment

Task	Description	Skills required
Configure AWS named profiles.	<p>Set up your AWS named profiles as follows to deploy stacks in a multi-account environment.</p> <p>For the administrator account:</p> <pre>\$aws configure --profile administrator AWS Access Key ID [****]: &lt;your-administrator-access- key-ID&gt; AWS Secret Access Key [****]: &lt;your-administrator-secret- access-key&gt; Default region name [None]: &lt;your-administrator-region&gt;</pre>	DevOps engineer

Task	Description	Skills required
	<p>Default output format [None]: json</p> <p>For the target account:</p> <pre>\$aws configure --profile target AWS Access Key ID [****: &lt;your-target- access-key-ID&gt; AWS Secret Access Key [****]: &lt;your-target- secret-access-key&gt; Default region name [None]: &lt;your-target- region&gt; Default output format [None]: json</pre> <p>For more information, see <a href="#">Using named profiles</a> in the AWS CLI documentation.</p>	
Verify AWS profile configurations.	(Optional) You can verify your AWS profile configurations in the <code>credentials</code> and <code>config</code> files by following the instructions in <a href="#">Set and view configuration settings</a> in the AWS CLI documentation.	DevOps engineer

Task	Description	Skills required
Verify the AWS CDK version.	<p>Verify the version of the AWS CDK Toolkit by running the following command:</p> <pre data-bbox="594 394 1026 474">\$cdk --version</pre> <p>This pattern requires version 1.107.0 or later. If you have an earlier version of the AWS CDK, follow the instructions in the <a href="#">AWS CDK documentation</a> to update it.</p>	DevOps engineer
Clone the project code.	<p>Clone the GitHub repository for this pattern by using the command:</p> <pre data-bbox="594 999 1026 1192">\$git clone https://github.com/aws-samples/amazon-devops-guru-cdk-samples.git</pre>	DevOps engineer

Task	Description	Skills required
Install package dependencies and compile the TypeScript files.	<p>Install the package dependencies and compile the TypeScript files by running the following commands:</p> <pre data-bbox="594 489 1027 688">\$cd amazon-devopsguru-cdk-samples \$npm install \$npm fund</pre> <p>These commands install all the packages from the sample repository.</p> <p><b>Important:</b> If you get any errors about missing packages, use one of the following commands:</p> <pre data-bbox="594 1115 1027 1194">\$npm ci</pre> <p>—or—</p> <pre data-bbox="594 1304 1027 1423">\$npm install -g @aws-cdk/&lt;package-name&gt;</pre> <p>You can find the list of package names and versions in the <code>Dependencies</code> section of the <code>/amazon-devopsguru-cdk-samples/package.json</code> file. For more information, see</p>	DevOps engineer

	<a href="#">npm ci</a> and <a href="#">npm install</a> in the npm documentation.	

### Build (synthesize) the AWS CDK stacks

Task	Description	Skills required
Configure an email address for Amazon SNS notifications.	<p>Follow these steps to provide an email address for Amazon SNS notifications:</p> <ol style="list-style-type: none"> <li>1. Edit the files <code>/amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-multi-account-reg-stack.ts</code> and <code>/amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-org-unit-stack.ts</code>.</li> <li>2. In the <code>DevOpsGuruTopic</code>, <code>Subscription</code> section, update the <code>Endpoint</code> parameter with your email address.</li> <li>3. Save and close the files.</li> </ol>	DevOps engineer
Build the project code.	<p>Build the project code and synthesize the stacks by running the command:</p> <pre>npm run build &amp;&amp; cdk synth</pre>	DevOps engineer

Task	Description	Skills required
	<p>You should see output similar to the following:</p> <pre data-bbox="597 331 1026 1205">\$npm run build &amp;&amp; cdk synth &gt; cdk-devopsguru@0.1.0 build &gt; tsc Successfully synthesized to ~/amazon-devopsguru-cdk-samples/cdk.out Supply a stack id (CdkDevopsGuruStackMultiAccReg, CdkDevopsGuruStackMultiAccRegSpecStacks, CdkDevopsguruStackOrgUnit, CdkInfrastructureStack, CdkStackSetAdminRole, CdkStackSetExecRole) to display its template.</pre> <p>For more information and steps, see <a href="#">Your first AWS CDK app</a> in the AWS CDK documentation.</p>	

Task	Description	Skills required
List the AWS CDK stacks.	<p>Run the following command to list all AWS CDK stacks:</p> <pre>\$cdk list</pre> <p>The command displays the following list:</p> <pre>CdkDevopsGuruStack MultiAccReg CdkDevopsGuruStack ackMultiAccRegSpec Stacks CdkDevopsguruStackOr gUnit CdkInfrastructureStack CdkStackSetAdminRole CdkStackSetExecRole</pre>	DevOps engineer

### Option 1 - Enable DevOps Guru for all stack resources across multiple accounts

Task	Description	Skills required
Deploy the AWS CDK stacks for creating IAM roles.	<p>This pattern uses <a href="#">AWS CloudFormation StackSets</a> to perform stack operations across multiple accounts. If you are creating your first stack set, you must create the following IAM roles to get the required permissions set up in your AWS accounts:</p>	DevOps engineer

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• <code>AWSCloudFormationStackSetAdministrationRole</code></li><li>• <code>AWSCloudFormationStackSetExecutionRole</code></li></ul> <p><b>Note:</b> The roles must have these exact names.</p> <ol style="list-style-type: none"><li>1. Create the IAM <code>AWSCloudFormationStackSetAdministrationRole</code> role in the administrator (primary) account by running the following CLI command: <pre>\$cdk deploy CdkStackSetAdminRole --profile administrator</pre></li><li>2. Create the IAM <code>AWSCloudFormationStackSetExecutionRole</code> role in all target accounts where you want to run the stack instances. To create this role, run these CLI commands: <pre>\$cdk deploy CdkStackSetExecRole \ --parameters AdministratorAccou</pre></li></ol>	

Task	Description	Skills required
	<pre>ntId=&lt;administrato r-account-ID&gt; \   --profile administr ator  \$cdk deploy CdkStackS etExecRole \   --parameters   AdministratorAccou ntId=&lt;administrato r-account-ID&gt; \   --profile target</pre> <p>For more information, see <a href="#">Grant self-managed permissions</a> in the AWS CloudFormation documentation.</p>	

Task	Description	Skills required
Deploy the AWS CDK stack for enabling DevOps Guru across multiple accounts.	<p>The AWS CDK <code>CdkDevopsGuruStackMultiAccReg</code> stack creates stack sets to deploy stack instances across multiple accounts and Regions. To deploy the stack, run the following CLI command with the specified parameters:</p> <pre data-bbox="597 684 1026 1318">\$cdk deploy CdkDevopsGuruStackMultiAccReg \   --profile administrator \   --parameters AdministratorAccountId=&lt;administrator-account-ID&gt; \   --parameters TargetAccountId=&lt;target-account-ID&gt; \   --parameters RegionIds="&lt;region-1&gt;,&lt;region-2&gt;"</pre> <p>Currently Amazon DevOps Guru is available in the AWS Regions listed in the <a href="#">DevOps Guru FAQ</a>.</p>	DevOps engineer

## Option 2 - Enable DevOps Guru for all stack resources across OUs

Task	Description	Skills required
Extract OU IDs.	On the <a href="#">AWS Organizations</a> console, identify the IDs of the organizational units where you want to enable DevOps Guru.	DevOps engineer
Enable service-managed permissions for OUs.	If you're using AWS Organizations for account management, you must grant service-managed permissions to enable DevOps Guru. Instead of creating the IAM roles manually, use <a href="#">organization-based trusted access and service-linked roles (SLRs)</a> .	DevOps engineer
Deploy the AWS CDK stack for enabling DevOps Guru across OUs.	<p>The AWS CDK <code>CdkDevops guruStackOrgUnit</code> stack enables DevOps Guru service across OUs. To deploy the stack, run the following command with the specified parameters:</p> <pre data-bbox="597 1423 1029 1864"> \$cdk deploy CdkDevops guruStackOrgUnit \   --profile administrator \   --parameters   RegionIds="&lt;region-1&gt;,&lt;region-2&gt;" \   --parameters   OrganizationalUnit   Ids="&lt;OU-1&gt;,&lt;OU-2&gt;" </pre>	DevOps engineer

### Option 3 - Enable DevOps Guru for specific stack resources across multiple accounts

Task	Description	Skills required
Deploy the AWS CDK stacks for creating IAM roles.	<p>If you haven't already created the required IAM roles shown in the first option, do that first:</p> <ol style="list-style-type: none"><li>1. Create the IAM <code>AWSCloudFormationStackSetAdministrationRole</code> role in the administrator (primary) account by running the following CLI command: <pre>\$cdk deploy CdkStackSetAdminRole --profile administrator</pre></li><li>2. Create the IAM <code>AWSCloudFormationStackSetExecutionRole</code> role in all target accounts where you want to run the stack instances. To create this role, run the CLI commands: <pre>\$cdk deploy CdkStackSetExecRole \   --parameters AdministratorAccountId=&lt;administrator-account-ID&gt; \   --profile administrator</pre></li></ol>	DevOps engineer

Task	Description	Skills required
	<pre data-bbox="630 205 1026 506">\$cdk deploy CdkStackSetExecRole \   --parameters   AdministratorAccountID=&lt;administrator-account-ID&gt; \   --profile target</pre> <p data-bbox="591 575 1029 751">For more information, see <a href="#">Grant self-managed permissions</a> in the AWS CloudFormation documentation.</p>	
Delete existing stacks.	<p data-bbox="591 800 997 1066">If you already used the first option to enable DevOps Guru for all stack resources , you can delete the old stack by using the following command:</p> <pre data-bbox="597 1108 1026 1304">\$cdk destroy CdkDevopsGuruStackMultiAccount --profile administrator</pre> <p data-bbox="591 1346 1023 1570">Or, you can change the <code>RegionIds</code> parameter when you redeploy the stack to avoid a <i>Stacks already exist</i> error.</p>	DevOps engineer

Task	Description	Skills required
Update the AWS CDK stack with a stack list.	<ol style="list-style-type: none"><li data-bbox="594 226 1026 457">1. Edit the file <code>/amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-multi-acc-reg-spec-stack.ts</code> .</li><li data-bbox="594 478 1026 1045">2. Under <code>Resources</code> , <code>CloudFormation</code> , <code>StackNames</code> , list the stacks for which you want to enable DevOps Guru. For demonstration purposes, the parameter specifies the <code>CdkInfrastructureStack</code> stack, but you can edit this entry based on your requirements.</li><li data-bbox="594 1066 1026 1108">3. Save and close the file.</li><li data-bbox="594 1129 1026 1213">4. To synthesize and update the stack template, run: <div data-bbox="630 1239 1026 1318" style="border: 1px solid #ccc; border-radius: 10px; padding: 5px; text-align: center; margin-top: 10px;"><code>\$cdk synth</code></div></li></ol>	Data engineer

Task	Description	Skills required
<p>Deploy the AWS CDK stack for enabling DevOps Guru for specific stack resources across multiple accounts.</p>	<p>The AWS CDK CdkDevopsGuruStackMultiAccRegSpecStacks stack enables DevOps Guru for specific stack resources across multiple accounts. To deploy the stack, run the following command:</p> <pre data-bbox="597 636 1027 1270">\$cdk deploy CdkDevopsGuruStackMultiAccRegSpecStacks \   --profile administrator \   --parameters AdministratorAccountId=&lt;administrator-account-ID&gt; \   --parameters TargetAccountId=&lt;target-account-ID&gt; \   --parameters RegionIds="&lt;region-1&gt;,&lt;region-2&gt;"</pre> <p><b>Note:</b> If you previously deployed this stack for option 1, change the RegionIds parameter (making sure to choose from <a href="#">available Regions</a>) to avoid a <i>Stacks already exist</i> error.</p>	<p>DevOps engineer</p>

## Deploy the AWS CDK infrastructure stack

Task	Description	Skills required
Deploy the sample serverless infrastructure stack.	<p>The AWS CDK <code>CdkInfrastructureStack</code> stack deploys serverless components such as API Gateway, Lambda, and a DynamoDB table to demonstrate DevOps Guru insights. To deploy the stack, run the following command:</p> <pre data-bbox="594 785 1027 947">\$cdk deploy CdkInfrastructureStack --profile administrator</pre>	DevOps engineer
Insert sample records in DynamoDB.	<p>Run the following command to populate the DynamoDB table with sample records. Provide the correct path for the <code>populate-shops-dynamodb-table.json</code> script.</p> <pre data-bbox="594 1346 1027 1703">\$aws dynamodb batch-write-item \   --request-items   file://scripts/populate-shops-dynamodb-table.json \   --profile administrator</pre> <p>The command displays the following output:</p>	DevOps engineer

Task	Description	Skills required
	<pre data-bbox="594 214 1026 411">{   "UnprocessedItems" : {} }</pre>	

Task	Description	Skills required
Verify inserted records in DynamoDB.	<p>To verify that the DynamoDB table includes the sample records from the <code>populate-shops-dynamodb-table.json</code> file, access the URL for the <code>ListRestApiEndpointMonitorOperator</code> API, which is published as an output of the AWS CDK stack. You can also find this URL in the <b>Outputs</b> tab of the AWS CloudFormation console for the <code>CdkInfrastructureStack</code> stack. The AWS CDK output would look similar to the following:</p> <pre data-bbox="594 1066 1029 1780">CdkInfrastructureStack.CreateRestApiMonitorOperatorEndpointD1D00045 =   https://oure17c5vob.execute-api.&lt;your-region&gt;.amazonaws.com/prod/  CdkInfrastructureStack.ListRestApiMonitorOperatorEndpointABBDB8D8 =   https://cdff8icfrn4.execute-api.&lt;your-region&gt;.amazonaws.com/prod/</pre>	DevOps engineer

Task	Description	Skills required
Wait for resources to complete baselining.	This serverless stack has a few resources. We recommend that you wait for 2 hours before you carry out the next steps. If you deployed this stack in a production environment, it might take up to 24 hours to complete baselining, depending on the number of resources you selected to monitor in DevOps Guru.	DevOps engineer

## Generate DevOps Guru insights

Task	Description	Skills required
Update the AWS CDK infrastructure stack.	<p>To try out DevOps Guru insights, you can make some configuration changes to reproduce a typical operational issue.</p> <ol style="list-style-type: none"> <li>1. Edit the file <code>/amazon-devopsguru-cdk-samples/lib/infrastructure-stack.ts</code>.</li> <li>2. In the <code>DDB Table</code> section, change the read capacity for the DynamoDB table from 5 to 1.</li> <li>3. Save and close the file.</li> <li>4. Run the following commands to synthesize</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>and deploy the updated AWS CDK infrastructure stack:</p> <pre data-bbox="630 380 1029 575">\$cdk synth \$cdk deploy CdkInfrastructureStack -- profile administrator</pre>	

Task	Description	Skills required
Inject HTTP requests on the API.	<p>Inject ingress traffic in the form of HTTP requests on the <code>ListRestApiMonitorOperatorEndpointxx</code> API:</p> <ol style="list-style-type: none"><li>1. Edit the Python script <code>/amazon-devopsguru-cdk-samples/scripts/sendAPIRequest.py</code>.</li><li>2. Update the <code>url</code> variable with the API link for <code>ListRestApiMonitorOperatorEndpointxx</code>. You can find this URL in the output of the AWS CDK <b>deploy</b> command or on the AWS Cloudformation console, in the <b>Outputs</b> tab for the stack.</li><li>3. Save and close the file.</li><li>4. Run the Python script by using the command: <pre>\$python sendAPIRequest.py</pre></li><li>5. Make sure that you get a 200 status code.</li><li>6. You might need to run the script through multiple (preferably four) terminals</li></ol>	DevOps engineer

Task	Description	Skills required
	<p>to inject traffic at a high rate.</p> <p>7. After the script runs approximately 10 minutes in a loop, you can see an operational insight on the <a href="#">DevOps Guru console</a>.</p>	
Review DevOps Guru insights.	<p>Under standard conditions, the DevOps Guru dashboard displays zero in the ongoing insights counter. If it detects an anomaly, it raises an alert in the form of an insight. In the navigation pane, choose <b>Insights</b> to see the details of the anomaly, including an overview, aggregated metrics, relevant events, and recommendations. For more information about reviewing insights, see the <a href="#">Gaining operational insights with AIOps using Amazon DevOps Guru</a> blog post.</p>	DevOps engineer

## Clean up

Task	Description	Skills required
Clean up and delete resources .	After you walk through this pattern, you should remove the resources you created to avoid incurring any	DevOps engineer

Task	Description	Skills required
	<p>further charges. Run these commands:</p> <pre data-bbox="594 327 1026 1283">\$cdk destroy CdkDevops GuruStackMultiAccR eg --profile administr ator \$cdk destroy CdkDevops guruStackOrgUnit -- profile administrator \$cdk destroy CdkDevops GuruStackMultiAccR egSpecStacks --profile administrator \$cdk destroy CdkInfras tructureStack -- profile administrator \$cdk destroy CdkStackS etAdminRole --profile administrator \$cdk destroy CdkStackS etExecRole --profile administrator \$cdk destroy CdkStackS etExecRole --profile target</pre>

# Implement Account Factory for Terraform (AFT) by using a bootstrap pipeline

Created by Vinicius Elias (AWS) and Edgar Costa Filho (AWS)

<b>Code repository:</b> <a href="#">aft-boots-trap-pipeline</a>	<b>Environment:</b> Production	<b>Technologies:</b> Management & governance; Infrastructure
<b>Workload:</b> Open-source	<b>AWS services:</b> AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; AWS Control Tower; AWS Organizations	

## Summary

This pattern provides a simple and secure method for deploying AWS Control Tower Account Factory for Terraform (AFT) from the management account of AWS Organizations. The core of the solution is an AWS CloudFormation template that automates the AFT configuration by creating a Terraform pipeline, which is structured to be easily adaptable for initial deployment or subsequent updates.

Security and data integrity are top priorities at AWS, so the Terraform state file, which is a critical component that tracks the state of the managed infrastructure and configurations, is securely stored in an Amazon Simple Storage Service (Amazon S3) bucket. This bucket is configured with several security measures, including server-side encryption and policies to block public access, to help ensure that your Terraform state is safeguarded against unauthorized access and data breaches.

The management account orchestrates and oversees the entire environment, so it is a critical resource in AWS Control Tower. This pattern follows AWS best practices and ensures that the deployment process is not only efficient but also aligns with security and governance standards, to offer a comprehensive, secure, and efficient way to deploy AFT in your AWS environment.

For more information about AFT, see the [AWS Control Tower documentation](#).

# Prerequisites and limitations

## Prerequisites

- A basic AWS multi-account environment with the following accounts at the minimum: management account, Log Archive account, Audit account, and one additional account for AFT management.
- An established AWS Control Tower environment. The management account should be properly configured, because the CloudFormation template will be deployed within it.
- The necessary permissions in the AWS management account. You'll need sufficient permissions to create and manage resources such as S3 buckets, AWS Lambda functions, AWS Identity and Access Management (IAM) roles, and AWS CodePipeline projects.
- Familiarity with Terraform. Understanding Terraform's core concepts and workflow is important because the deployment involves generating and managing Terraform configurations.

## Limitations

- Be aware of the [AWS resource quotas](#) in your account. The deployment might create multiple resources, and encountering service quotas could impede the deployment process.
- The template is designed for specific versions of Terraform and AWS services. Upgrading or changing versions might require template modifications.

## Product versions

- Terraform version 1.5.7 or later
- AFT version 1.11.1 or later

## Architecture

### Target technology stack

- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline

- Amazon EventBridge
- IAM
- AWS Lambda
- Amazon S3

## Target architecture

The following diagram illustrates the implementation discussed in this pattern.

The workflow consists of three main tasks: creating the resources, generating the content, and running the pipeline.

### Creating the resources

The [CloudFormation template that's provided with this pattern](#) creates and sets up all required resources, depending on the parameters you select when you deploy the template. At the minimum, the template creates the following resources:

- A CodeCommit repository to store the AFT Terraform bootstrap code
- An S3 bucket to store the Terraform state file that's associated with the AFT implementation
- A CodePipeline pipeline

- Two CodeBuild projects to implement the Terraform plan and apply commands in different stages of the pipeline
- IAM roles for CodeBuild and CodePipeline services
- A second S3 bucket to store pipeline runtime artifacts
- An EventBridge rule to capture CodeCommit repository changes on the main branch
- Another IAM role for the EventBridge rule

Additionally, if you set the `Generate AFT Files` parameter in the CloudFormation template to `true`, the template creates these additional resources to generate the content:

- An S3 bucket to store the generated content and to be used as the source of the CodeCommit repository
- A Lambda function to process the given parameters and generate the appropriate content
- An IAM function to run the Lambda function
- A CloudFormation custom resource that runs the Lambda function when the template is deployed

### *Generating the content*

To generate the AFT bootstrap files and their content, the solution uses a Lambda function and an S3 bucket. The function creates a folder in the bucket, and then creates two files inside the folder: `main.tf` and `backend.tf`. The function also processes the provided CloudFormation parameters and populates these files with predefined code, replacing the respective parameter values.

To view the code that's used as a template to generate the files, see the solution's [GitHub repository](#). Basically, the files are generated as follows.

#### **main.tf**

```
module "aft" {
  source = "github.com/aws-ia/terraform-aws-control_tower_account_factory?
ref=<aft_version>"

  # Required variables
  ct_management_account_id = "<ct_management_account_id>"
  log_archive_account_id   = "<log_archive_account_id>"
  audit_account_id        = "<audit_account_id>"
  aft_management_account_id = "<aft_management_account_id>"
}
```

```
ct_home_region          = "<ct_home_region>"

# Optional variables
tf_backend_secondary_region = "<tf_backend_secondary_region>"
aft_metrics_reporting      = "<false|true>"

# AFT Feature flags
aft_feature_cloudtrail_data_events      = "<false|true>"
aft_feature_enterprise_support          = "<false|true>"
aft_feature_delete_default_vpcs_enabled = "<false|true>"

# Terraform variables
terraform_version      = "<terraform_version>"
terraform_distribution = "<terraform_distribution>"

}
```

## backend.tf

```
terraform {
  backend "s3" {
    region = "<aft-main-region>"
    bucket = "<s3-bucket-name>"
    key    = "aft-setup.tfstate"
  }
}
```

During the CodeCommit repository creation, if you set the `Generate AFT Files` parameter to `true`, the template uses the S3 bucket with the generated content as the source of the main branch to automatically populate the repository.

### *Running the pipeline*

After the resources have been created and the bootstrap files have been configured, the pipeline runs. The first stage (*Source*) fetches the source code from the main branch of the repository, and the second stage (*Build*) runs the Terraform plan command and generates the results to be reviewed. In the third stage (*Approval*), the pipeline waits for a manual action to approve or reject the last stage (*Deploy*). At the last stage, the pipeline runs the Terraform apply command by using the result of the previous Terraform plan command as input. Finally, a cross-account role and the permissions in the management account are used to create the AFT resources in the AFT management account.

# Tools

## AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS Lambda](#) is a compute service that runs your code in response to events and automatically manages compute resources, providing a fast way to create a modern, serverless application for production.
- [AWS SDK for Python \(Boto3\)](#) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

## Other tools

- [Terraform](#) is an infrastructure as code (IaC) tool that lets you build, change, and version infrastructure safely and efficiently. This includes low-level components such as compute instances, storage, and networking; and high-level components such as DNS entries and SaaS features.
- [Python](#) is an easy to learn, powerful programming language. It has efficient high-level data structures and provides a simple but effective approach to object-oriented programming.

## Code repository

The code for this pattern is available in the GitHub [AFT bootstrap pipeline repository](#).

For the official AFT repository, see [AWS Control Tower Account Factory for Terraform](#) in GitHub.

## Best practices

When you deploy AFT by using the provided CloudFormation template, we recommend that you follow best practices to help ensure a secure, efficient, and successful implementation. Key guidelines and recommendations for implementing and operating the AFT include the following.

- **Thorough review of parameters:** Carefully review and understand each parameter in the CloudFormation template. Accurate parameter configuration is crucial for the correct setup and functioning of AFT.
- **Regular template updates:** Keep the template updated with the latest AWS features and Terraform versions. Regular updates help you take advantage of new functionality and maintain security.
- **Versioning:** Pin your AFT module version and use a separate AFT deployment for testing if possible.
- **Scope:** Use AFT only to deploy infrastructure guardrails and customizations. Do not use it to deploy your application.
- **Linting and validation:** The AFT pipeline requires a linted and validated Terraform configuration. Run lint, validate, and test before pushing the configuration to AFT repositories.
- **Terraform modules:** Build reusable Terraform code as modules, and always specify the Terraform and AWS provider versions to match your organization's requirements.

## Epics

### Set up and configure the AWS environment

Task	Description	Skills required
Prepare the AWS Control Tower environment.	Set up and configure AWS Control Tower in your AWS environment to ensure centralized management and governance for your AWS accounts. For more information, see <a href="#">Getting started with AWS Control</a>	Cloud administrator

Task	Description	Skills required
	<a href="#">Tower</a> in the AWS Control Tower documentation.	
Launch the AFT management account.	Use the AWS Control Tower Account Factory to launch a new AWS account to serve as your AFT management account. For more information, see <a href="#">Provision accounts with AWS Service Catalog Account Factory</a> in the AWS Control Tower documentation.	Cloud administrator

## Deploy the CloudFormation template in the management account

Task	Description	Skills required
Launch the CloudFormation template.	<p>In this epic, you deploy the CloudFormation template provided with this solution to set up the AFT bootstrap pipeline in your AWS management account. The pipeline deploys the AFT solution in the AFT management account that you set up in the previous epic.</p> <p><b>Step 1: Open the AWS CloudFormation console</b></p> <ul style="list-style-type: none"> <li>• Sign in to the AWS Management Console and</li> </ul>	Cloud administrator

Task	Description	Skills required
	<p>open the <a href="#">AWS CloudFormation console</a>. Make sure that you are operating within the correct AWS Control Tower main Region.</p> <p><b>Step 2: Create a new stack</b></p> <ol style="list-style-type: none"><li>1. Choose to create a new stack.</li><li>2. Select the option to upload a template file, and upload the <a href="#">CloudFormation template</a> that's provided with this pattern.</li></ol> <p><b>Step 3: Configure stack parameters</b></p> <ul style="list-style-type: none"><li>• Repository Name : Specify the repository name for storing the AFT bootstrap module.</li><li>• Branch Name: Specify the source repository branch.</li><li>• CodeBuild Docker Image: Choose the file to use as the CodeBuild Docker base image.</li></ul> <p><b>Step 4: Decide on file generation</b></p>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• The <code>Generate AFT Files</code> parameter controls whether to generate default AFT deployment files. Set this parameter to:<ul style="list-style-type: none"><li>• <code>true</code> to automatically create and store AFT deployment files in the specified repository.</li><li>• <code>false</code> if you want to manually handle the file creation or already have the files in place.</li></ul></li></ul> <p>If you selected <code>false</code>, go to step 8; otherwise, follow steps 5–7 first.</p> <p><b>Step 5: Fill in AWS Control Tower and AFT account details</b></p> <ul style="list-style-type: none"><li>• Input AWS Control Tower and AFT account-specific information:<ul style="list-style-type: none"><li>• <code>Log Archive Account ID</code>: The ID of the Log Archive account ID in AWS Control Tower.</li><li>• <code>Audit Account ID</code>: The ID of the Audit account in AWS Control Tower.</li></ul></li></ul>	

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• AFT Management Account ID: The ID of the AFT management account that you created in the first epic.</li><li>• AFT Main Region and AFT Secondary Region: The main and secondary AWS Regions for AFT deployment.</li></ul> <p><b>Step 6: Configure AFT options</b></p> <ul style="list-style-type: none"><li>• Set up metrics reporting:<ul style="list-style-type: none"><li>• AFT Enable Metrics Reporting : Enable or disable AFT metrics reporting. For more information, see <a href="#">Operational metrics</a> in the AWS Control Tower documentation.</li></ul></li><li>• Set AFT feature options:<ul style="list-style-type: none"><li>• Enable AFT CloudTrail Data Events: Enable CloudTrail data events in all AFT managed accounts. For more information, see <a href="#">AWS CloudTrail data events</a> in</li></ul></li></ul>	

Task	Description	Skills required
	<p>the AWS Control Tower documentation.</p> <ul style="list-style-type: none"><li>• Enable AFT Enterprise Support : Enable Enterprise Support in all AFT managed accounts. For more information, see <a href="#">AWS Enterprise Support plan</a> in the AWS Control Tower documentation.</li><li>• Enable AFT Delete Default VPC: Delete all VPCs in the AFT management account only. For more information, see <a href="#">Delete the AWS default VPC</a> in the AWS Control Tower documentation.</li></ul> <p><b>Step 7: Specify versions</b></p> <ul style="list-style-type: none"><li>• AFT Terraform Version: Choose the version of Terraform to use in AFT pipelines.</li><li>• AFT Version: Define the AFT version for deployment. Keep the default setting (latest) to use the most current AFT version.</li></ul>	

Task	Description	Skills required
	<p><b>Step 8: Review and create the stack</b></p> <ul style="list-style-type: none"><li>Review all the parameters and settings. If everything is in order, proceed to create the stack.</li></ul> <p><b>Step 9: Monitor stack creation</b></p> <ul style="list-style-type: none"><li>AWS CloudFormation provisions and configures the resources you defined. Monitor the stack creation process on the CloudFormation console. This process might take several minutes.</li></ul> <p><b>Step 10: Verify the deployment</b></p> <ul style="list-style-type: none"><li>When the stack status shows <b>CREATE_COMPLETE</b>, verify that all resources have been correctly created.</li><li>In the <b>Outputs</b> section, note the Terraform BackendBucketName value.</li></ul>	

## Populate and validate the AFT bootstrap repository and pipeline

Task	Description	Skills required
Populate the AFT bootstrap repository.	<p>(Optional) After you deploy the CloudFormation template, you can populate or validate the content in the newly created AFT bootstrap repository, and test whether the pipeline has run successfully.</p> <p>If you set the <code>Generate AFT Files</code> parameter to <code>true</code>, skip to the next story (validating the pipeline).</p> <p><b>Step 1: Populate the repository</b></p> <ol style="list-style-type: none"><li>1. Open the <a href="#">AWS CodeCommit console</a> and select the newly created repository. If you kept the default name, the repository will be called <code>aft-setup</code>.</li><li>2. Clone the repository to your local machine by using SSH, HTTPS, or HTTPS (GRC), and open it in an editor.</li><li>3. Create a folder called <code>terraform</code> and two empty files inside it: <code>backend.tf</code> and <code>main.tf</code>.</li></ol>	Cloud administrator

Task	Description	Skills required
	<p>4. Open the backend.tf file and add this code snippet:</p> <pre data-bbox="630 380 1029 816">terraform {   backend "s3" {     region = "&lt;aft-main-region&gt;"     bucket = "&lt;s3-bucket-name&gt;"     key    = "aft-setup"   } }</pre> <p>In the file:</p> <ul style="list-style-type: none"><li>• Replace &lt;aft-main-region&gt; with the main AFT Region. This should match the AWS Control Tower main Region.</li><li>• Replace &lt;s3-bucket-name&gt; with the name of the Terraform backend bucket. You can find this in the Terraform BackendBucketName output generated by the CloudFormation template you deployed earlier.</li></ul> <p>5. Open the main.tf file and use one of the examples available in the <a href="#">AFT repository</a> to deploy AFT. For example, you can</p>	

Task	Description	Skills required
	<p>work with your preferred version control system (VCS) provider (CodeCommit, GitHub, or Bitbucket) or customize the AFT VPC. For more AFT input options, see the <a href="#">README file</a> in the AFT repository.</p> <p><b>Step 2: Commit and push your changes</b></p> <ul style="list-style-type: none"><li>• After you have created and populated the folder and files, confirm your changes, and upload the code to the repository. The pipeline starts automatically, runs through the Source and Build stages, and then waits for an Approval action before the Deploy stage.</li></ul>	

Task	Description	Skills required
Validate the AFT bootstrap pipeline.	<p><b>Step 1: View the pipeline</b></p> <ul style="list-style-type: none"><li>• Open the <a href="#">CodePipeline console</a> and check whether the <code>aft-bootstrap-pipeline</code> pipeline was started successfully. It should be running a Terraform plan or waiting for a manual approval action.</li></ul> <p><b>Step 2: Approve the Terraform plan results</b></p> <ul style="list-style-type: none"><li>• You can review the results of the Terraform plan by looking at the execution logs of the Build stage, and then approve or reject the execution on the Approval stage. If you approve, the pipeline starts deploying AFT resources in the provided AFT management account.</li></ul> <p><b>Step 3: Wait for the deployment</b></p> <ul style="list-style-type: none"><li>• Wait for the pipeline to run successfully. This should take around 30 minutes. Any failures you might encounter are often caused</li></ul>	Cloud administrator

Task	Description	Skills required
	<p>by API quotas. In these cases, you can rerun the pipeline to continue the deployment.</p> <p><b>Step 4: Check created resources</b></p> <ul style="list-style-type: none"> <li>• Access the AFT management account and confirm that the resources have been created.</li> </ul>	

## Troubleshooting

Issue	Solution
<p>The custom Lambda function included in the CloudFormation template fails during deployment.</p>	<p>Check the Amazon CloudWatch logs for the Lambda function to identify the error. The logs provide detailed information and can help pinpoint the specific issue. Confirm that the Lambda function has the necessary permissions and that the environment variables have been set correctly.</p>
<p>You encounter failures in resource creation or management caused by inadequate permissions.</p>	<p>Review the IAM roles and policies that are attached to the Lambda function, CodeBuild, and other services involved in the deployment. Confirm that they have the necessary permissions. If there are permission issues, adjust the IAM policies to grant the required access.</p>

Issue	Solution
You're using an outdated version of the CloudFormation template with newer AWS services or Terraform versions.	Regularly update the CloudFormation template to be compatible with the latest AWS and Terraform releases. Check the release notes or documentation for any version-specific changes or requirements.
You reach AWS service quotas during deployment.	Before you deploy the pipeline, check AWS service quotas for resources such as S3 buckets, IAM roles, and Lambda functions . Request increases if necessary. For more information, see <a href="#">AWS service quotas</a> on the AWS website.
You encounter errors due to incorrect input parameters in the CloudFormation template.	Double-check all input parameters for typos or incorrect values. Confirm that resource identifiers, such as account IDs and Region names, are accurate.

# Manage AWS Service Catalog products in multiple AWS accounts and AWS Regions

Created by Ram Kandaswamy (AWS)

**Environment:** Production

**Technologies:** Management & governance; Infrastructure; Modernization

**Workload:** All other workloads

**AWS services:** AWS Service Catalog; AWS CloudFormation

## Summary

Amazon Web Services (AWS) Service Catalog simplifies and accelerates the governance and distribution of infrastructure as code (IaC) templates for enterprises. You use AWS CloudFormation templates to define a collection of AWS resources (*stacks*) required for a product. AWS CloudFormation StackSets extends this functionality by enabling you to create, update, or delete stacks across multiple accounts and AWS Regions with a single operation.

AWS Service Catalog administrators create products by using CloudFormation templates that are authored by developers, and publish them. These products are then associated with a portfolio, and constraints are applied for governance. To make your products available to users in other AWS accounts or organizational units (OUs), you typically [share your portfolio](#) with them. This pattern describes an alternative approach for managing AWS Service Catalog product offerings that is based on AWS CloudFormation StackSets. Instead of sharing portfolios, you use stack set constraints to set AWS Regions and accounts where your product can be deployed and used. By using this approach, you can provision your AWS Service Catalog products in multiple accounts, OUs, and AWS Regions, and manage them from a central location, while meeting your governance requirements.

Benefits of this approach:

- The product is provisioned and managed from the primary account, and not shared with other accounts.

- This approach provides a consolidated view of all provisioned products (stacks) that are based on a specific product.
- Configuration with AWS Service Management Connector is easier, because it targets only one account.
- It's easier to query and use products from AWS Service Catalog.

## Prerequisites and limitations

### Prerequisites

- AWS CloudFormation templates for IaC and versioning
- Multi-account setup and AWS Service Catalog for provisioning and managing AWS resources

### Limitations

- This approach uses AWS CloudFormation StackSets, and the limitations of StackSets apply:
  - StackSets doesn't support CloudFormation template deployment through macros. If you're using a macro to preprocess the template, you won't be able to use a StackSets-based deployment.
  - StackSets provides the ability to disassociate a stack from the stack set, so you can target a specific stack to fix an issue. However, a disassociated stack cannot be re-associated with the stack set.
- AWS Service Catalog autogenerates StackSet names. Customization isn't currently supported.

## Architecture

### Target architecture

1. The user creates an AWS CloudFormation template to provision AWS resources, in JSON or YAML format.
2. The CloudFormation template creates a product in AWS Service Catalog, which is added to a portfolio.
3. The user creates a provisioned product, which creates CloudFormation stacks in the target accounts.
4. Each stack provisions the resources specified in the CloudFormation templates.

## Tools

### AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Service Catalog](#) helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

## Epics

### Provision products across accounts

Task	Description	Skills required
Create a portfolio.	A portfolio is a container that includes one or more products that are grouped together based on specific criteria. Using a portfolio for your products helps you apply	AWS Service Catalog, IAM

Task	Description	Skills required
	<p>common constraints across your product set.</p> <p>To create a portfolio, follow the instructions in the <a href="#">AWS Service Catalog documentation</a>. If you're using the AWS CLI, here's an example command:</p> <pre data-bbox="594 646 1029 888">aws servicecatalog   create-portfolio --   provider-name my-provid   er --display-name my-   portfolio</pre> <p>For more information, see the <a href="#">AWS CLI documentation</a>.</p>	
Create a CloudFormation template.	Create a CloudFormation template that describes the resources. Resource property values should be parameterized where applicable.	AWS CloudFormation, JSON/YAML

Task	Description	Skills required
Create a product with version information.	<p>The CloudFormation template becomes a product when you publish it in the AWS Service Catalog. Provide values for the optional version detail parameters, such as version title and description; this will be helpful for querying for the product later.</p> <p>To create a product, follow the instructions in the <a href="#">AWS Service Catalog documentation</a>. If you're using the AWS CLI, an example command is:</p> <pre>aws servicecatalog   create-product --cli-   input-json file://cr   eate-product-input   .json</pre> <p>where <code>create-product-input.json</code> is the file that passes the parameters for the product. For an example of this file, see the <i>Additional information</i> section. For more information, see the <a href="#">AWS CLI documentation</a>.</p>	AWS Service Catalog

Task	Description	Skills required
Apply constraints.	Apply stack set constraints to the portfolio, to configure product deployment options such as multiple AWS accounts, Regions, and permissions. For instructions, see the <a href="#">AWS Service Catalog documentation</a> .	AWS Service Catalog
Add permissions.	<p>Provide permissions to users so that they can launch the products in the portfolio . For console instructions, see the <a href="#">AWS Service Catalog documentation</a>. If you're using the AWS CLI, here's an example command:</p> <pre data-bbox="594 1045 1029 1486">aws servicecatalog   associate-principal-   with-portfolio \     --portfolio-id     port-2s6abcdefwdh4 \     --principal-arn     arn:aws:iam::44445     5556666:role/Admin \     --principal-type     IAM</pre> <p>For more information, see the <a href="#">AWS CLI documentation</a>.</p>	AWS Service Catalog, IAM

Task	Description	Skills required
Provision the product.	<p>A provisioned product is a resourced instance of a product. Provisioning a product based on a CloudFormation template launches a CloudFormation stack and its underlying resources.</p> <p>Provision the product by targeting the applicable AWS Regions and accounts, based on stack set constraints. In the AWS CLI, here's an example command:</p> <pre data-bbox="597 951 1027 1388">aws servicecatalog   provision-product \     --product-id prod-   abcdfz3syn2rg \     --provisioning-   artifact-id pa-abc347   pcscfm \     --provisioned-prod   uct-name "mytestpp   name3"</pre> <p>For more information, see the <a href="#">AWS CLI documentation</a>.</p>	AWS Service Catalog

## Additional information

When you use the `create-product` command, the `cli-input-json` parameter points to a file that specifies information such as product owner, support email, and CloudFormation template details. Here's an example of such a file:

```
{
  "Owner": "Test admin",
  "SupportDescription": "Testing",
  "Name": "SNS",
  "SupportEmail": "example@example.com",
  "ProductType": "CLOUD_FORMATION_TEMPLATE",
  "AcceptLanguage": "en",
  "ProvisioningArtifactParameters": {
    "Description": "SNS product",
    "DisableTemplateValidation": true,
    "Info": {
      "LoadTemplateFromURL": "<url>"
    }
  },
  "Name": "version 1"
}
```

# Migrate an AWS member account from AWS Organizations to AWS Control Tower

Created by Rodolfo Jr. Cerrada (AWS)

**Environment:** Production

**Technologies:** Management & governance; Modernization

**AWS services:** AWS Organizations; AWS Control Tower

## Summary

This pattern describes how to migrate an Amazon Web Services (AWS) account from AWS Organizations, where it is a member account that's governed by a management account, to AWS Control Tower. By enrolling the account in AWS Control Tower, you can take advantage of preventive and detective guardrails and features that streamline your account governance. You might also want to migrate your member account if your AWS Organizations management account has been compromised, and you want to move member accounts to a new organization that is governed by AWS Control Tower.

AWS Control Tower provides a framework that combines and integrates the capabilities of several other AWS services, including AWS Organizations, and ensures consistent compliance and governance across your multi-account environment. With AWS Control Tower, you can follow a set of prescribed rules and definitions that extend the capabilities of AWS Organizations. For example, you can use guardrails to ensure that security logs and necessary cross-account access permissions are created, and not altered.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Control Tower set up in your target organization in AWS Organizations (for instructions, see [Setting up](#) in the AWS Control Tower documentation)
- Administrator credentials for AWS Control Tower (member of the **AWSControlTowerAdmins** group)

- Administrator credentials for the source AWS account

## Limitations

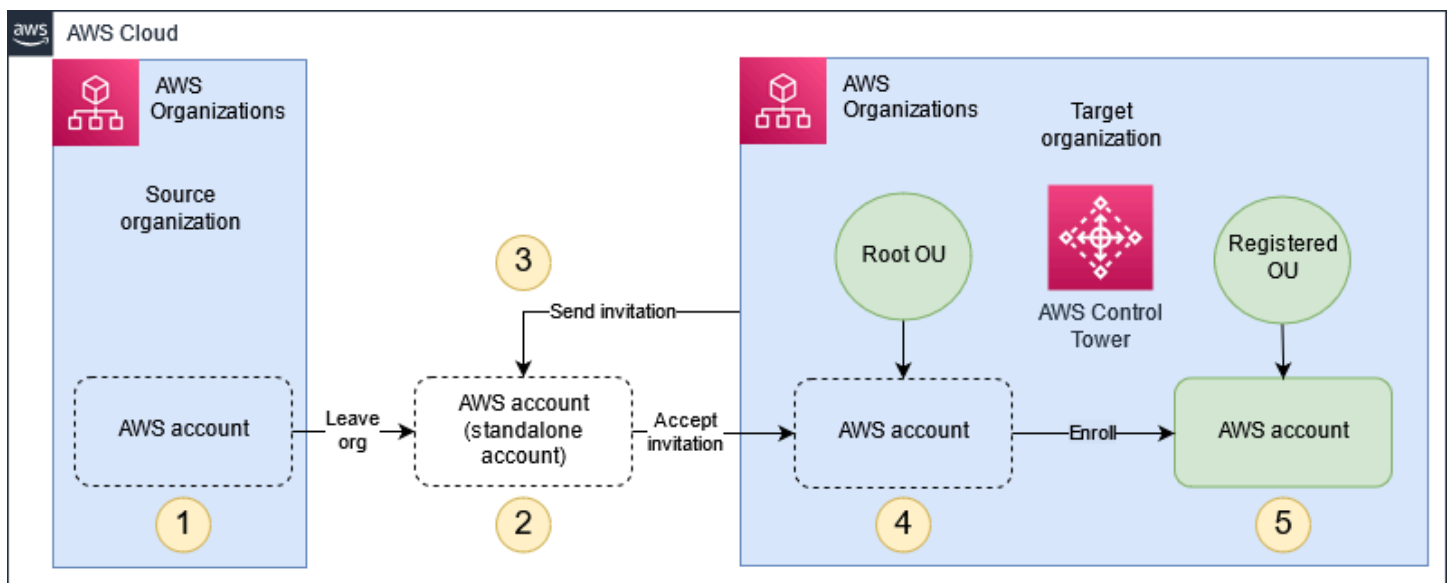

- The source management account in AWS Organizations must be different from the target management account in AWS Control Tower.

## Product versions

- AWS Control Tower version 2.3 (February 2020) or later (see [release notes](#))

## Architecture

The following diagram illustrates the migration process and reference architecture. This pattern migrates the AWS account from the source organization to a target organization that is governed by AWS Control Tower.

The enrollment process consists of these steps:

1. The account leaves the source organization in AWS Organizations.
2. The account becomes a standalone account. This means that it doesn't belong to any organization, so governance and billing are managed independently by account administrators.
3. The target organization sends an invitation for the account to join the organization.

4. The standalone account accepts the invitation and becomes a member of the target organization.
5. The account is enrolled in AWS Control Tower and moved to a registered organizational unit (OU). (We recommend that you check the AWS Control Tower dashboard to confirm the enrollment.) At this point, all guardrails that are enabled in the registered OU take effect.

## Tools

### AWS services

- [AWS Organizations](#) is an account management service that enables you to consolidate multiple AWS accounts into a single entity (an *organization*) that you create and centrally manage.
- [AWS Control Tower](#) integrates the capabilities of other services, including AWS Organizations, AWS IAM Identity Center (successor to AWS Single Sign-On), and AWS Service Catalog, to help you enforce and manage governance rules for security, operations, and compliance at scale across all your organizations and accounts in the AWS Cloud.

## Epics

### Remove the member account from the source organization

Task	Description	Skills required
Verify that the member account can run as a standalone account.	Confirm that the member account that will leave the source organization has the information that is required for it to operate as a standalone account. For example, if the member account doesn't have billing information, it can't operate as a standalone account, because AWS uses the payment information to charge for any billable AWS	Account administrator

Task	Description	Skills required
	<p>activity that occurs while the account isn't attached to an organization.</p> <p>Typically, if you created the member account by using the AWS Organizations console, API, or AWS Command Line Interface (CLI) commands, the information required of standalone accounts isn't automatically collected. To add this information, sign in to the account, and specify a support plan, contact information, and a payment method.</p> <p>For more information about what you need to know before removing an account from an organization, see <a href="#">Before removing an account from organization</a> in the AWS Organizations documentation.</p>	

Task	Description	Skills required
Remove the member account from its source organization.	<p>Follow the instructions in the AWS Organizations documentation to remove a member account from an organization. You can sign in to the organization's management account and <a href="#">remove the member account</a>, or sign in to the member account and <a href="#">leave the organization</a>.</p> <p>If you don't have administrator-level credentials to remove or leave the account, ask for assistance from your organization's administrator.</p> <p>If the member account is missing a support plan, contact information, or payment information, you will be prompted to provide and verify that information.</p> <p>When you leave the organization, you are redirected to the <b>Getting Started</b> page of the AWS Organizations console, where you can view invitations for your account to join other organizations.</p> <p><b>Important:</b> At this point, your account is a standalone account. If you are running</p>	Management account administrator or account administrator

Task	Description	Skills required
	workloads that aren't covered by AWS Free Tier, you will be charged according to the payment and billing information you provided for the account.	
Verify that the member account is no longer part of the source organization.	In the AWS Organizations console, you should no longer see the <b>Leave organization</b> button. Instead, you should see pending invitations, if any, from other organizations.	Account administrator

Task	Description	Skills required
Remove the IAM roles that grant access to your account from the organization you left.	<p>When you remove the account from the source organization, AWS Identity and Access Management (IAM) roles created by AWS Organizations or by administrators aren't automatically deleted. To terminate access from the source organization's management account, you must manually delete the IAM roles. For more information, see <a href="#">Deleting roles or instance profiles</a> in the IAM documentation.</p> <p>When a member account leaves an organization, all tags that were attached to the account are deleted. Standalone accounts do not support tags.</p>	Account administrator

### Invite the account to join the new organization with AWS Control Tower

Task	Description	Skills required
Sign in to AWS Control Tower.	<p>Sign in to the AWS Control Tower console as an administrator.</p> <p>Currently, there is no direct way to move an AWS account from a source organization to an organization in an</p>	AWS Control Tower administrator

Task	Description	Skills required
	<p>OU that's governed by AWS Control Tower. However, you can extend AWS Control Tower governance to an existing AWS account when you enroll it into an OU that's already governed by AWS Control Tower. That's why you have to log in to AWS Control Tower for this step.</p>	

Task	Description	Skills required
Invite the member account.	<ol style="list-style-type: none"><li data-bbox="591 226 1027 405">1. Sign in to the AWS Organizations console, and navigate to the <b>AWS Accounts</b> page.</li><li data-bbox="591 426 1027 604">2. On the <b>Add an AWS account</b> page, choose <b>Invite an existing AWS account</b>.</li><li data-bbox="591 625 1027 951">3. Complete the account information, including the 12-digit account number (without dashes) and the optional description and tags, and then choose <b>Send invitation</b>.</li></ol> <p data-bbox="591 1024 1027 1203"><b>Important:</b> Verify that no applications or network connectivity will be affected by the account transfer.</p> <p data-bbox="591 1245 1027 1854">This action sends an invitation email with a link to the member account. When the account administrator follows the link and accepts the invitation, the member account appears in the <b>AWS accounts</b> page. For more information, see <a href="#">Inviting an AWS account to join your organization</a> in the AWS Organizations documentation.</p>	AWS Control Tower administrator

Task	Description	Skills required
Test applications and connectivity.	<p>When the member account has been registered into the new organization, it appears in the OU within a root. It also appears in the AWS Control Tower console, flagged as not enrolled in accounts, because it hasn't yet been enrolled in the AWS Control Tower registered OU.</p> <p>Verify the following:</p> <ul style="list-style-type: none"><li>• Check the AWS Control Tower dashboard to see if there are any guardrail violations.</li><li>• Check network connectivity (VPN or AWS Direct Connect) to make sure it wasn't affected by the transfer.</li><li>• (Application owners) Test the applications that are associated with this account to verify that they run as expected, and that dependencies weren't affected by the account transfer.</li></ul>	AWS Control Tower administrator, Member account administrator, Application owners

## Prepare the account for enrollment

Task	Description	Skills required
Review guardrails and fix any violations.	<p>Review the guardrails that are defined in the target OU, especially the preventive guardrails, and fix any violations.</p> <p>A number of <a href="#">mandatory, preventive guardrails</a> are enabled by default when you set up your AWS Control Tower landing zone. These can't be disabled. You must review these mandatory guardrails and fix the member account (manually or by using a script) before you enroll the account.</p> <p><b>Note:</b> Preventive guardrails keep AWS Control Tower registered accounts compliant and prevent policy violations. Any violation of preventive guardrails might affect enrollment. Detective guardrail violations appear in the AWS Control Tower dashboard, if detected, after successful enrollment. They do not affect the enrollment process. For more information, see <a href="#">Guardrails in AWS</a></p>	AWS Control Tower administrator, Member account administrator

Task	Description	Skills required
	<a href="#">Control Tower</a> in the AWS documentation.	
Check for connectivity issues after fixing guardrail violations.	In some cases, you might have to close specific ports or disable services to fix guardrail violations. Make sure that applications that use those ports and services are remediated before you enroll the account.	Application owner

## Enroll the account into AWS Control Tower

Task	Description	Skills required
Sign in to the AWS Control Tower console.	Use sign-in credentials that have administrative permissions for AWS Control Tower. Do not use the root user (management account) credentials to enroll an AWS Organizations account. This will display an error message.	AWS Control Tower administrator
Enroll the account.	<ol style="list-style-type: none"> <li>From the Account Factory page in AWS Control Tower, choose <b>Enroll account</b>.</li> <li>Fill in the details, including the email address associated with the account you want to enroll, the display name that will appear in AWS Control Tower,</li> </ol>	AWS Control Tower administrator

Task	Description	Skills required
	<p>the IAM Identity Center email address, the first and last name of the account owner, and the OU in which you would like to enroll the account. The IAM Identity Center email address is your preferred user email address. You can use the same email address as the account email.</p> <p>3. Choose <b>Enroll account</b>.</p> <p>For more information, see <a href="#">Enroll an existing account</a> in the AWS Control Tower documentation.</p>	

## Verify the account after enrollment

Task	Description	Skills required
Verify the account.	<p>From AWS Control Tower, choose <b>Accounts</b>. The account that you just enrolled has an initial state of <b>Enrolling</b>. When enrollment is complete, its state changes to <b>Enrolled</b>.</p>	AWS Control Tower administrator, Member account administrator
Check for guardrail violations.	<p>Guardrails defined in the OU will automatically apply to the enrolled member account. Monitor the AWS Control Tower dashboard for violation</p>	AWS Control Tower administrator, Member account administrator

Task	Description	Skills required
	s and fix them accordingly. For more information, see <a href="#">Guardrails in AWS Control Tower</a> in the AWS documentation.	

## Troubleshooting

Issue	Solution
You receive the error message: <b>An unknown error occurred. Try again later, or contact AWS Support.</b>	This error occurs when you use root user credentials (management account) in AWS Control Tower to enroll a new account. AWS Service Catalog can't map the Account Factory Portfolio or product to the root user, which results in the error message. To remediate this error, use non-root, full-access user (administrator) credentials to enroll the new account. For more information about how to assign administrative access to an administrative user, see <a href="#">Getting started</a> in the AWS IAM Identity Center (successor to AWS Single Sign-On) documentation.
The AWS Control Tower <b>Activities</b> page displays a <b>Get Catastrophic Drift</b> action.	This action reflects a drift check of the service and does not indicate any issues with the AWS Control Tower setup. No action is required.

# Monitor use of a shared Amazon Machine Image across multiple AWS accounts

Created by Naveen Suthar (AWS) and Sandeep Gawande (AWS)

**Code repository:** [cross-account-ami-auditing-terraform-samples](#)

**Environment:** PoC or pilot

**Technologies:** Management & governance; DevOps; Serverless; Operations

**AWS services:** Amazon DynamoDB; AWS Lambda; Amazon EventBridge

## Summary

[Amazon Machine Images \(AMIs\)](#) are used to create Amazon Elastic Compute Cloud (Amazon EC2) instances in your Amazon Web Services (AWS) environment. You can create AMIs in a separate, centralized AWS account, which is called a *creator account* in this pattern. You can then share the AMI across multiple AWS accounts that are in the same AWS Region, which are called *consumer accounts* in this pattern. Managing AMIs from a single account provides scalability and simplifies governance. In the consumer accounts, you can reference the shared AMI in Amazon EC2 Auto Scaling [launch templates](#) and Amazon Elastic Kubernetes Service (Amazon EKS) [node groups](#).

When a shared AMI is [deprecated](#), [deregistered](#), or [unshared](#), AWS services that refer to the AMI in the consumer accounts cannot use this AMI to launch new instances. Any auto scaling event or relaunch of the same instance fails. This can lead to issues in the production environment, such as application downtime or performance degradation. When AMI sharing and usage events occur in multiple AWS accounts, it can be difficult to monitor this activity.

This pattern helps you monitor shared AMI usage and status across accounts in the same Region. It uses serverless AWS services, such as Amazon EventBridge, Amazon DynamoDB, AWS Lambda, and Amazon Simple Email Service (Amazon SES). You provision the infrastructure as code (IaC) by using HashiCorp Terraform. This solution provides alerts when a service in a consumer account references a deregistered or unshared AMI.

## Prerequisites and limitations

### Prerequisites

- Two or more active AWS accounts: one creator account and one or more consumer accounts
- One or more AMIs that are shared from the creator account to a consumer account
- Terraform CLI, [installed](#) (Terraform documentation)
- Terraform AWS Provider, [configured](#) (Terraform documentation)
- (Optional, but recommended) Terraform backend, [configured](#) (Terraform documentation)
- Git, [installed](#)

### Limitations

- This pattern monitors AMIs that have been shared to specific accounts by using the account ID. This pattern does not monitor AMIs that have been shared to an organization by using the organization ID.
- AMIs can only be shared to accounts that are within the same AWS Region. This pattern monitors AMIs within a single, target Region. To monitor use of AMIs in multiple Regions, you deploy this solution in each Region.
- This pattern doesn't monitor any AMIs that were shared before this solution was deployed. If you want to monitor previously shared AMIs, you can unshare the AMI and then reshare it with the consumer accounts.

### Product versions

- Terraform version 1.2.0 or later
- Terraform AWS Provider version 4.20 or later

## Architecture

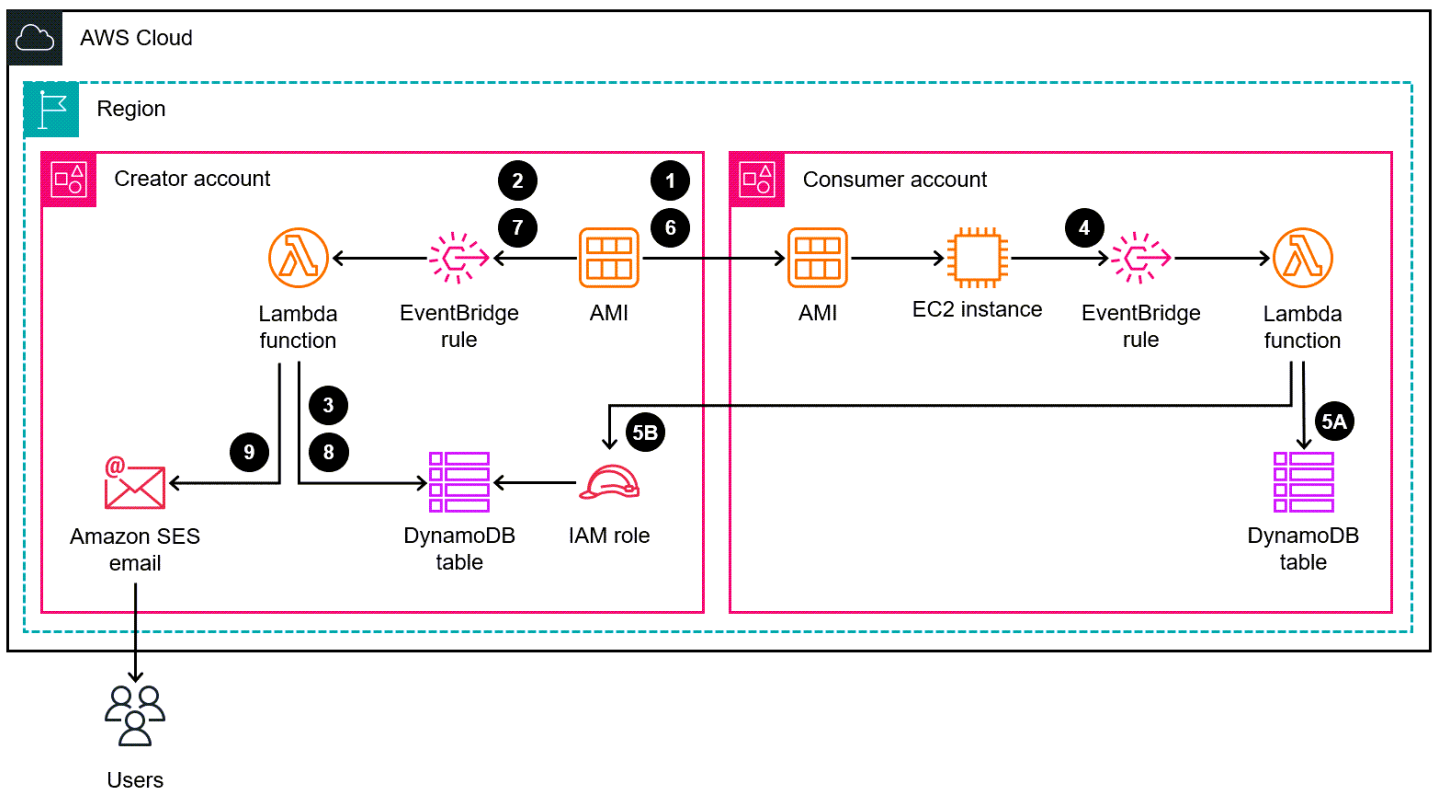

### Target technology stack

The following resources are provisioned as IaC through Terraform:

- Amazon DynamoDB tables

- Amazon EventBridge rules
- AWS Identity and Access Management (IAM) role
- AWS Lambda functions
- Amazon SES

## Target architecture

The diagram shows the following workflow:

1. An AMI in the creator account is shared with a consumer account in the same AWS Region.
2. When the AMI is shared, an Amazon EventBridge rule in the creator account captures the `ModifyImageAttribute` event and initiates a Lambda function in the creator account.
3. The Lambda function stores data related to the AMI in a DynamoDB table in the creator account.
4. When an AWS service in the consumer account uses the shared AMI to launch an Amazon EC2 instance or when the shared AMI is associated with a launch template, an EventBridge rule in the consumer account captures use of the shared AMI.
5. The EventBridge rule initiates a Lambda function in the consumer account. The Lambda function does the following:
  - 5A. The Lambda function in the consumer account reads data from the DynamoDB table in the creator account.
  - 5B. The Lambda function in the consumer account sends an email via Amazon SES.

- a. The Lambda function updates the AMI-related data in a DynamoDB table in the consumer account.
  - b. The Lambda function assumes an IAM role in the creator account and updates the DynamoDB table in the creator account. In the Mapping table, it creates an item that maps the instance ID or launch template ID to its respective AMI ID.
6. The AMI that is centrally managed in the creator account is deprecated, deregistered, or unshared.
  7. The EventBridge rule in the creator account captures the `ModifyImageAttribute` or `DeregisterImage` event with the `remove` action and initiates the Lambda function.
  8. The Lambda function checks the DynamoDB table to determine whether the AMI is used in any of the consumer accounts. If there are no instance IDs or launch template IDs associated with the AMI in the Mapping table, then the process is complete.
  9. If any instance IDs or launch template IDs are associated with the AMI in the Mapping table, then the Lambda function uses Amazon SES to send an email notification to the configured subscribers.

## Tools

### AWS services

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Simple Email Service \(Amazon SES\)](#) helps you send and receive emails by using your own email addresses and domains.

### Other tools

- [HashiCorp Terraform](#) is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- [Python](#) is a general-purpose computer programming language.

## Code repository

The code for this pattern is available in the GitHub [cross-account-ami-monitoring-terraform-samples](#) repository.

## Best practices

- Follow the [Best practices for working with AWS Lambda functions](#).
- Follow the [Best practices for building AMIs](#).
- When creating the IAM role, follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see [Grant least privilege](#) and [Security best practices](#) in the IAM documentation.
- Set up monitoring and alerting for the AWS Lambda functions. For more information, see [Monitoring and troubleshooting Lambda functions](#).

## Epics

### Customize the Terraform configuration files

Task	Description	Skills required
Create the AWS CLI named profiles.	For the creator account and each consumer account, create an AWS Command Line Interface (AWS CLI) named profile. For instructions, see <a href="#">Set Up the AWS CLI</a> in the AWS Getting Started Resources Center.	DevOps engineer
Clone the repository.	Enter the following command. This clones	DevOps engineer

Task	Description	Skills required
	<p>the <a href="#">cross-account-ami-monitoring-terraform-sample</a> repository from GitHub by using SSH.</p> <pre data-bbox="597 428 1026 665">git clone git@github.com:aws-samples/cross-account-ami-monitoring-terraform-samples.git</pre>	

Task	Description	Skills required
Update the provider.tf file.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 405">1. Enter the following command to navigate into the terraform folder in the cloned repository. <pre data-bbox="630 443 1027 604">cd cross-account-ami-monitoring/terrafo rm</pre></li><li data-bbox="592 621 1027 695">2. Open the provider.tf file.</li><li data-bbox="592 720 1027 1503">3. Update the Terraform AWS Provider configurations for the creator account and consumer account as follows:<ul style="list-style-type: none"><li data-bbox="630 972 1027 1104">• For <code>alias</code>, enter a name for the provider configuration.</li><li data-bbox="630 1129 1027 1308">• For <code>region</code>, enter the target AWS Region where you want to deploy this solution.</li><li data-bbox="630 1333 1027 1503">• For <code>profile</code>, enter the AWS CLI named profile for accessing the account.</li></ul></li><li data-bbox="592 1528 1027 1749">4. If you are configuring more than one consumer account, create a profile for each additional consumer account.</li><li data-bbox="592 1774 1027 1858">5. Save and close the provider.tf file.</li></ol>	DevOps engineer

Task	Description	Skills required
	<p>For more information about configuring the providers, see <a href="#">Multiple provider configurations</a> in the Terraform documentation.</p>	
Update the terraform.tfvars file.	<ol style="list-style-type: none"><li>1. Open the terraform.tfvars file.</li><li>2. In the account_email_mapping parameter, configure alerts for the creator account and consumer account as follows:<ul style="list-style-type: none"><li>• For account, enter the account ID.</li><li>• For email, enter the email address where you want to send alerts. You can enter only one email address for each account.</li></ul></li><li>3. If you are configuring more than one consumer account, enter an account and email address for each additional consumer account.</li><li>4. Save and close the terraform.tfvars file.</li></ol>	DevOps engineer

Task	Description	Skills required
Update the main.tf file.	<p>Complete these steps only if you are deploying this solution to more than one consumer account. If you are deploying this solution to only one consumer account, no modification of this file is necessary.</p> <ol style="list-style-type: none"><li>1. Open the <code>main.tf</code> file.</li><li>2. For each additional consumer account, create a new module that is based off the <code>consumer_account_A</code> module in the template. For each consumer account, for <code>provider</code>, the value should match the alias you entered in the <code>provider.tf</code> file.</li><li>3. Save and close the <code>main.tf</code> file.</li></ol>	DevOps engineer

## Deploy the solution by using Terraform

Task	Description	Skills required
Deploy the solution.	In the Terraform CLI, enter the following commands to deploy the AWS resources in the creator and consumer accounts:	DevOps engineer

Task	Description	Skills required
	<ol style="list-style-type: none"><li data-bbox="592 212 945 338">1. Enter the following command to initialize Terraform. <pre data-bbox="634 380 1029 457">terraform init</pre></li><li data-bbox="592 474 1000 600">2. Enter the following command to validate the Terraform configurations. <pre data-bbox="634 642 1029 720">terraform validate</pre></li><li data-bbox="592 737 1003 863">3. Enter the following command to create a Terraform execution plan. <pre data-bbox="634 905 1029 982">terraform plan</pre></li><li data-bbox="592 999 1008 1220">4. Review the configuration changes in the Terraform plan and confirm that you want to implement these changes.</li><li data-bbox="592 1245 979 1371">5. Enter the following command to deploy the resources. <pre data-bbox="634 1413 1029 1491">terraform apply</pre></li></ol>	

Task	Description	Skills required
Verify the email address identity.	When you deployed the Terraform plan, Terraform created an email address identity for each consumer account in Amazon SES. Before notifications can be sent to that email address, you must verify the email address. For instructions, see <a href="#">Verifying an email address identity</a> in the Amazon SES documentation.	General AWS

## Validate resource deployment

Task	Description	Skills required
Validate deployment in the creator account.	<ol style="list-style-type: none"><li>1. Sign in to the creator account.</li><li>2. In the navigation bar, confirm that you are viewing the target Region. If you're in a different Region, choose the name of the currently displayed Region, and then choose the target Region.</li><li>3. Open the DynamoDB console at <a href="https://console.aws.amazon.com/dynamodb/">https://console.aws.amazon.com/dynamodb/</a>.</li><li>4. In the navigation pane, choose <b>Tables</b>.</li></ol>	DevOps engineer

Task	Description	Skills required
	<p>5. In the list of tables, validate that the AmiShare table is present.</p> <p>6. Open the Lambda console at <a href="https://console.aws.amazon.com/lambda">https://console.aws.amazon.com/lambda</a>.</p> <p>7. In the navigation pane, choose <b>Functions</b>.</p> <p>8. In the list of functions, validate that the ami-share function is present.</p> <p>9. Open the IAM console at <a href="https://console.aws.amazon.com/iamv2/">https://console.aws.amazon.com/iamv2/</a>.</p> <p>10. In the navigation pane, choose <b>Roles</b>.</p> <p>11. In the list of roles, validate that the external-ddb-role role is present.</p> <p>12. Open the EventBridge console at <a href="https://console.aws.amazon.com/events/">https://console.aws.amazon.com/events/</a>.</p> <p>13. In the navigation pane, choose <b>Rules</b>.</p> <p>14. In the list of rules, validate that the modify_image_attribute_event rule is present.</p> <p>15. Open the Amazon SES console at <a href="https://console.aws.amazon.com/SES/">https://console.aws.amazon.com/SES/</a>.</p>	

Task	Description	Skills required
	<p><a href="https://console.aws.amazon.com/iam/home#verified-identities">console.aws.amazon.com/iam/home#verified-identities/</a>.</p> <p>16 In the navigation pane, choose <b>Verified Identities</b>.</p> <p>17 In the list of identities, validate that an email address identity has been registered and verified for each consumer account.</p>	

Task	Description	Skills required
Validate deployment in the consumer account.	<ol style="list-style-type: none"><li data-bbox="591 226 976 308">1. Sign in to the consumer account.</li><li data-bbox="591 329 1024 699">2. In the navigation bar, confirm that are viewing the target Region. If you're in a different Region, choose the name of the currently displayed Region, and then choose the target Region.</li><li data-bbox="591 720 1013 905">3. Open the DynamoDB console at <a href="https://console.aws.amazon.com/dynamodb/">https://console.aws.amazon.com/dynamodb/</a>.</li><li data-bbox="591 926 964 1008">4. In the navigation pane, choose <b>Tables</b>.</li><li data-bbox="591 1029 1013 1161">5. In the list of tables, validate that the Mapping table is present.</li><li data-bbox="591 1182 1013 1314">6. Open the Lambda console at <a href="https://console.aws.amazon.com/lambda">https://console.aws.amazon.com/lambda</a>.</li><li data-bbox="591 1335 964 1417">7. In the navigation pane, choose <b>Functions</b>.</li><li data-bbox="591 1438 1000 1717">8. In the list of functions , validate that the <code>ami-usage-function</code> and <code>ami-deregister-function</code> functions are present.</li><li data-bbox="591 1738 943 1820">9. Open the EventBridge console at <a href="https://">https://</a></li></ol>	DevOps engineer

Task	Description	Skills required
	<p><a href="https://console.aws.amazon.com/events/">console.aws.amazon.com/events/</a>.</p> <p>10 In the navigation pane, choose <b>Rules</b>.</p> <p>11 In the list of rules, validate that the <code>ami_usage_events</code> and <code>ami_deregister_events</code> rules are present.</p>	

## Validate monitoring

Task	Description	Skills required
Create an AMI in the creator account.	<ol style="list-style-type: none"> <li>1. In the creator account, create a private AMI. For instructions, see <a href="#">Create an AMI from an Amazon EC2 Instance</a>.</li> <li>2. Share the new AMI with one of the consumer accounts. For instructions, see <a href="#">Share an AMI with specific AWS accounts</a>.</li> </ol>	DevOps engineer
Use the AMI in the consumer account.	In the consumer account, use the shared AMI to create an EC2 instance or launch template. For instructions, see <a href="#">How do I launch an EC2 instance from a custom AMI</a> (AWS re:Post Knowledge Center) or How to create	DevOps engineer

Task	Description	Skills required
	launch template (Amazon EC2 Auto Scaling documentation).	
Validate monitoring and alerting.	<ol style="list-style-type: none"> <li>1. Sign in to the creator account.</li> <li>2. Open the Amazon EC2 console at <a href="https://console.aws.amazon.com/ec2/">https://console.aws.amazon.com/ec2/</a>.</li> <li>3. In the navigation pane, choose <b>AMIs</b>.</li> <li>4. Select the AMI in the list, and then choose <b>Actions</b>, <b>Edit AMI permissions</b>.</li> <li>5. In the <b>Shared accounts</b> section, select the consumer account, and then choose <b>Remove selected</b>.</li> <li>6. Choose <b>Save changes</b>.</li> <li>7. Validate that the target email address you defined for the consumer account receives a notification that the sharing was canceled for the AMI.</li> </ol>	DevOps engineer

### (Optional) Stop monitoring shared AMIs

Task	Description	Skills required
Delete the resources.	<ol style="list-style-type: none"> <li>1. Enter the following command to remove the</li> </ol>	DevOps engineer

Task	Description	Skills required
	<p>resources deployed by this pattern and stop monitoring shared AMIs.</p> <div data-bbox="630 380 1029 457" style="border: 1px solid #ccc; border-radius: 10px; padding: 5px; margin: 10px 0;"> <pre>terraform destroy</pre> </div> <p>2. Confirm the destroy command by entering yes.</p>	

## Troubleshooting

Issue	Solution
<p>I did not receive an email alert.</p>	<p>There could be multiple reasons why the Amazon SES email was not sent. Check the following:</p> <ol style="list-style-type: none"> <li>1. In the <a href="#">Epics</a> section, use the <i>Validate resource deployment</i> epic to confirm that the infrastructure was provisioned properly in all AWS accounts.</li> <li>2. Validate the Lambda function events in Amazon CloudWatch Logs. For instructions, see <a href="#">Using the CloudWatch console</a> in the Lambda documentation. Confirm that there are no permissions issues, such as an explicit deny in any identity-based or resource-based policies. For more information, see <a href="#">Policy evaluation logic</a> in the IAM documentation.</li> <li>3. In Amazon SES, validate that the status of the email address identity is <b>Verified</b>. For more information, see <a href="#">Verifying an email address identity</a>.</li> </ol>

# Set up alerts for programmatic account closures in AWS Organizations

Created by Richard Milner-Watts (AWS), Debojit Bhadra (AWS), and Manav Yadav (AWS)

**Code repository:** [AWS Account Closure Notifier](#)

**Environment:** Production

**Technologies:** Management & governance

**AWS services:** AWS CloudTrail; Amazon EventBridge; AWS Lambda; AWS Organizations; Amazon SNS

## Summary

The [CloseAccount API](#) for [AWS Organizations](#) enables you to close member accounts within an organization programmatically, without having to log in to the account with root credentials. The [RemoveAccountFromOrganization API](#) pulls an account out from an organization in AWS Organizations, so it becomes a standalone account.

These APIs potentially increase the number of operators who can close or remove an AWS account. All users who have access to the organization through AWS Identity and Access Management (IAM) in the AWS Organizations management account can call these APIs, so access isn't limited to the owner of the account's root email with any associated multi-factor authentication (MFA) device.

This pattern implements alerts when the `CloseAccount` and `RemoveAccountFromOrganization` APIs are called, so you can monitor these activities. For alerts, it uses an [Amazon Simple Notification Service](#) (Amazon SNS) topic. You can also set up Slack notifications through a [webhook](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An organization in AWS Organizations

- Access to the organization management account, under the organization's root, to create the required resources

## Limitations

- As described in the [AWS Organizations API reference](#), the `CloseAccount` API allows only 10 percent of active member accounts to be closed within a rolling 30-day period.
- When an AWS account is closed, its status is changed to `SUSPENDED`. For 90 days after this status transition, AWS Support can reopen the account. After 90 days the account is permanently deleted.
- Users who have access to the AWS Organizations management account and APIs might also have permissions to disable these alerts. If the primary concern is malicious behavior instead of accidental deletion, consider protecting the resources created by this pattern with an [IAM permissions boundary](#).
- The API calls for `CloseAccount` and `RemoveAccountFromOrganization` are processed in the US East (N. Virginia) Region (`us-east-1`). Therefore, you must deploy this solution in `us-east-1` in order to observe the events.

## Architecture

### Target technology stack

- AWS Organizations
- AWS CloudTrail
- Amazon EventBridge
- AWS Lambda
- Amazon SNS

### Target architecture

The following diagram shows the solution architecture for this pattern.

1. AWS Organizations processes a `CloseAccount` or `RemoveAccountFromOrganization` request.
2. Amazon EventBridge is integrated with AWS CloudTrail to deliver these events to the default event bus.
3. A custom Amazon EventBridge rule matches the AWS Organizations requests and calls an AWS Lambda function.
4. The Lambda function delivers a message to an SNS topic, which users can subscribe to for email alerts or further processing.
5. If Slack notifications are enabled, the Lambda function delivers a message to a Slack webhook.

# Tools

## AWS services

- [AWS CloudFormation](#) provides a way to model a collection of related AWS and third-party resources, provision them quickly and consistently, and manage them throughout their lifecycles, by treating infrastructure as code.
- [Amazon EventBridge](#) is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge receives an event, an indicator of a change in environment, and applies a rule to route the event to a target. Rules match events to targets based on either the structure of the event, called an *event pattern*, or on a schedule.
- [AWS Lambda](#) is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests each day to thousands each second. You pay only for the compute time that you consume. There is no charge when your code is not running.
- [AWS Organizations](#) helps you centrally manage and govern your environment as you grow and scale your AWS resources. Using AWS Organizations, you can programmatically create new AWS accounts and allocate resources, group accounts to organize your workflows, apply policies to accounts or groups for governance, and simplify billing by using a single payment method for all your accounts.
- [AWS CloudTrail](#) monitors and records account activity across your AWS infrastructure, and gives you control over storage, analysis, and remediation actions.
- [Amazon Simple Notification Service \(Amazon SNS\)](#) is a fully managed messaging service for both application-to-application (A2A) and application-to-person (A2P) communication.

## Other tools

- [AWS Lambda Powertools for Python library](#) is a set of utilities that provide tracing, logging, metrics, and event handling features for Lambda functions.

## Code

The code for this pattern is located in the GitHub [AWS Account Closer Notifier](#) repository.

The solution includes a CloudFormation template that deploys the architecture for this pattern. It uses the [AWS Lambda Powertools for Python library](#) to provide logging and tracing.

# Epics

## Deploy the architecture

Task	Description	Skills required
Launch the CloudFormation template for the solution stack.	<p>The CloudFormation template for this pattern is in the main branch of the <a href="#">GitHub repository</a>. It deploys the IAM roles, EventBridge rules, Lambda functions, and the SNS topic.</p> <p>To launch the template:</p> <ol style="list-style-type: none"><li>1. Clone the <a href="#">GitHub repository</a> to obtain a copy of the solution code.</li><li>2. Open the AWS Management Console for the AWS Organizations management account.</li><li>3. Choose the US East (N. Virginia) Region (us-east-1), and then open the <a href="#">CloudFormation console</a>.</li><li>4. Create the stack by using the <code>account-closure-notifier.yml</code> template and specifying the following values:<ul style="list-style-type: none"><li>• Stack name: <code>aws-account-closure-notifier-stack</code></li></ul></li></ol>	AWS administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• ResourcePrefix parameter: aws-account-closure-notifier</li> <li>• SlackNotification parameter: If Slack notifications are required, change this setting to true.</li> <li>• SlackWebhookEndpoint parameter: If Slack notifications are required, specify the webhook URL.</li> </ul> <p>For more information about launching a CloudFormation stack, see the <a href="#">AWS documentation</a>.</p>	
Verify that the solution has launched successfully.	<ol style="list-style-type: none"> <li>1. Wait for the CloudFormation stack to reach a status of CREATE_COMPLETE.</li> <li>2. Open the <a href="#">EventBridge console</a> in us-east-1 .</li> <li>3. Verify that a new rule has been created with the name aws-account-closure-notifier-event-rule .</li> </ol>	AWS administrator

Task	Description	Skills required
Subscribe to the SNS topic.	<p>(Optional) If you want to subscribe to the SNS topic:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Amazon SNS console</a> in us-east-1 , and find the topic named <code>aws-account-closure-notifier-sns-topic</code> .</li><li>2. Choose the topic name, and then choose <b>Create subscription</b>.</li><li>3. For <b>Protocol</b>, choose <b>Email</b>.</li><li>4. For <b>Endpoint</b>, specify the email address that should receive the notification, and then choose <b>Create subscription</b>.</li><li>5. Check your email inbox for a message from AWS Notifications. Use the link in this email to confirm the subscription.</li></ol> <p>For more information about setting up SNS notifications, see the <a href="#">Amazon SNS documentation</a>.</p>	AWS administrator

## Verify the solution

Task	Description	Skills required
Send a test event to the default event bus.	<p>The <a href="#">GitHub repository</a> provides a sample event that you can send to the EventBridge default event bus for testing. The EventBridge rule also reacts to events that use the custom event source <code>account.closure.notifier</code>.</p> <p><b>Note:</b> You can't use the CloudTrail event source to send this event, because it's not possible to send an event as an AWS service.</p> <p>To send a test event:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">EventBridge console</a> in <code>us-east-1</code>.</li><li>2. In the navigation pane, under <b>Buses</b>, choose <b>Event buses</b>, and then select the default event bus.</li><li>3. Choose <b>Send events</b>.</li><li>4. For <b>Event source</b>, enter <code>account.closure.notifier</code>.</li><li>5. For <b>Detail type</b>, enter <code>AWS API Call via CloudTrail</code>.</li><li>6. For <b>Event detail</b>, copy and paste the contents of</li></ol>	AWS administrator

Task	Description	Skills required
	<p>tests/dummy-event.json from the GitHub repository into the text box.</p> <p>7. Choose <b>Send</b> to initiate the notification workflow.</p>	
Verify that the email notification was received.	Check the mailbox that subscribed to the SNS topic for notifications. You should receive an email with details of the account that was closed and the principal that performed the API call.	AWS administrator
Verify that the Slack notification was received.	(Optional) If you specified a webhook URL for the <code>SlackWebhookEndpoint</code> parameter when you deployed the CloudFormation template, check the Slack channel that is mapped to the webhook. It should display a message with details of the account that was closed and the principal that performed the API call.	AWS administrator

- [Automate RabbitMQ configuration in Amazon MQ](#)
- [Improve call quality on agent workstations in Amazon Connect contact centers](#)
- [More patterns](#)

# Automate RabbitMQ configuration in Amazon MQ

Created by Yogesh Bhatia (AWS) and Afroz Khan (AWS)

**Environment:** PoC or pilot

**Technologies:** Messaging & communications; DevOps; Infrastructure

**AWS services:** Amazon MQ; AWS CloudFormation

## Summary

[Amazon MQ](#) is a managed message broker service that provides compatibility with many popular message brokers. Using Amazon MQ with RabbitMQ provides a robust RabbitMQ cluster managed in the Amazon Web Services (AWS) Cloud with multiple brokers and configuration options. Amazon MQ provides a highly available, secure, and scalable infrastructure, and can process a large number of messages per second with ease. Multiple applications can use the infrastructure with different virtual hosts, queues, and exchanges. However, managing these configuration options or creating the infrastructure manually can require time and effort. This pattern describes a way to manage configurations for RabbitMQ in one step, through a single file. You can embed the code provided with this pattern within any continuous integration (CI) tool such as Jenkins or Bamboo.

You can use this pattern to configure any RabbitMQ cluster. All it requires is connectivity to the cluster. Although there are many other ways to manage RabbitMQ configurations, this solution creates entire application configurations in one step, so you can manage queues and other details easily.

## Prerequisites and limitations

### Prerequisites

- AWS Command Line Interface (AWS CLI) installed and configured to point to your AWS account (for instructions, see [AWS CLI documentation](#))
- Ansible installed, so you can run playbooks to create the configuration
- **rabbitmqadmin** installed (for instructions, see the [RabbitMQ documentation](#))
- A RabbitMQ cluster in Amazon MQ, created with healthy Amazon CloudWatch metrics

### Additional requirements

- Make sure to create the configurations for virtual hosts and users separately and not as part of JSON.
- Make sure that the configuration JSON is part of the repository and is version-controlled.
- The version of the **rabbitmqadmin** CLI must be the same as the version of the RabbitMQ server, so the best option is to download the CLI from the RabbitMQ console.
- As part of the pipeline, make sure that JSON syntax is validated before each run.

### Product versions

- AWS CLI version 2.0
- Ansible version 2.9.13
- **rabbitmqadmin** version 3.9.13 (must be the same as the RabbitMQ server version)

## Architecture

### Source technology stack

- An RabbitMQ cluster running on an existing on-premises virtual machine (VM) or a Kubernetes cluster (on premises or in the cloud)

### Target technology stack

- Automated RabbitMQ configurations on Amazon MQ for RabbitMQ

### Target architecture

There are many ways to configure RabbitMQ. This pattern uses the import configuration functionality, where a single JSON file contains all the configurations. This file applies all settings and can be managed by a version-control system such as Bitbucket or Git. This pattern uses Ansible to implement the configuration through the **rabbitmqadmin** CLI.

## Tools

### Tools

- [rabbitmqadmin](#) is a command-line tool for the RabbitMQ HTTP-based API. It is used to manage and monitor RabbitMQ nodes and clusters.
- [Ansible](#) is an open-source tool for automating applications and IT infrastructure.
- [AWS CLI](#) enables you to interact with AWS services by using commands in a command-line shell.

### AWS services

- [Amazon MQ](#) is a managed message broker service that makes it easy to set up and operate message brokers in the cloud.
- [AWS CloudFormation](#) helps you set up your AWS infrastructure and speed up cloud provisioning with infrastructure as code.

### Code

The JSON configuration file used in this pattern and a sample Ansible playbook are provided in the attachment.

# Epics

## Create your AWS infrastructure

Task	Description	Skills required
Create a RabbitMQ cluster on AWS.	If you don't already have a RabbitMQ cluster, you can use <a href="#">AWS CloudFormation</a> to create the stack on AWS. Or, you can use the <a href="#">Cloudformation module in Ansible</a> to create the stack. With the latter approach, you can use Ansible for both tasks: to create the RabbitMQ infrastructure and to manage configurations.	AWS CloudFormation, Ansible

## Create the Amazon MQ for RabbitMQ configuration

Task	Description	Skills required
Create a properties file.	Download the JSON configuration file ( <code>rabbitmqconfig.json</code> ) in the attachment, or export it from the RabbitMQ console. Modify it to configure queues, exchanges, and bindings. This configuration file demonstrates the following: <ul style="list-style-type: none"><li>- Creates two queues: <code>sample-queue1</code> and <code>sample-queue2</code></li></ul>	JSON

Task	Description	Skills required
	<ul style="list-style-type: none"><li>- Creates two exchanges: <code>sample-exchange1</code> and <code>sample-exchange2</code></li><li>- Implements the binding between the queues and exchanges</li></ul> <p>These configurations are performed under the root (/) virtual host, as required by <b>rabbitmqadmin</b>.</p>	

Task	Description	Skills required
Retrieve the details of the Amazon MQ for RabbitMQ infrastructure.	<p>Retrieve the following details for the RabbitMQ infrastructure on AWS:</p> <ul style="list-style-type: none"><li>• Broker name</li><li>• RabbitMQ host</li><li>• RabbitMQ user name (the administrator user created during cluster creation)</li><li>• RabbitMQ password</li></ul> <p>You can use the AWS Management Console or the AWS CLI to retrieve this information. These details enable the Ansible playbook to connect to your AWS account and use the RabbitMQ cluster to run commands.</p> <p><b>Important:</b> The computer that runs the Ansible playbook must be able to access your AWS account, and AWS CLI must already be configured, as described in the <i>Prerequisites</i> section.</p>	AWS CLI, Amazon MQ

Task	Description	Skills required
Create the <code>hosts_var</code> file.	<p>Create the <code>hosts_var</code> file for Ansible and make sure that all the variables are defined in the file. Consider using Ansible Vault to store the password. You can configure the <code>hosts_var</code> file as follows (replace the asterisks with your information):</p> <pre data-bbox="594 730 1026 1087">RABBITMQ_HOST:   "*****.mq.us- east-2.amazonaws.com" RABBITMQ_VHOST: "/" RABBITMQ_USERNAME:   "admin" RABBITMQ_PASSWORD:   "*****"</pre>	Ansible

Task	Description	Skills required
Create an Ansible playbook.	<p>For a sample playbook, see <code>ansible-rabbit-config.yaml</code> in the attachment. Download and save this file. The Ansible playbook imports and manages all RabbitMQ configurations, such as queues, exchanges, and bindings, that applications require.</p> <p>Follow best practices for Ansible playbooks, such as securing passwords. Use Ansible Vault for password encryption, and retrieve the RabbitMQ password from the encrypted file.</p>	Ansible

## Deploy the configuration

Task	Description	Skills required
Run the playbook.	<p>Run the Ansible playbook that you created in the previous epic.</p> <pre data-bbox="594 1520 1029 1682">ansible-playbook   ansible-rabbit-config.yaml</pre> <p>You can verify the new configurations on the RabbitMQ console.</p>	RabbitMQ, Amazon MQ, Ansible

# Improve call quality on agent workstations in Amazon Connect contact centers

*Created by Ernest Ozdoba (AWS)*

**Environment:** Production

**Technologies:** Messaging & communications; End-user computing

**AWS services:** Amazon Connect

## Summary

Call quality issues are some of the most difficult problems to troubleshoot in contact centers. To avoid voice quality issues and complex troubleshooting procedures, you must optimize your agents' work environment and workstation settings. This pattern describes voice quality optimization techniques for agent workstations in Amazon Connect contact centers. It provides recommendations in the following areas:

- Work environment adjustments. Agents' surroundings don't affect how voice is transmitted over the network, but they do have an effect on call quality.
- Agent workstation settings. Hardware and network configurations for contact center workstations have significant effects on call quality.
- Browser settings. Agents use a web browser to access the Amazon Connect Contact Control Panel (CCP) website and communicate with customers, so browser settings can affect call quality.

The following components can also affect call quality, but they fall outside the scope of the workstation and aren't covered in this pattern:

- Traffic flows to the Amazon Web Services (AWS) Cloud over AWS Direct Connect, a full-tunnel VPN, or a split-tunnel VPN
- Network conditions when working in or outside the corporate office
- Public switched telephone network (PSTN) connectivity
- The customer's device and telephony carrier
- Virtual desktop infrastructure (VDI) setup

For more information relating to these areas, see [Common Contact Control Panel \(CCP\) Issues](#) and [Use the Endpoint Test Utility](#) in the Amazon Connect documentation.

## Prerequisites and limitations

### Prerequisites

- Headsets and workstations must comply with the requirements specified in the [Amazon Connect Administrator Guide](#).

### Limitations

- The optimization techniques in this pattern apply to soft phone voice quality. They do not apply when you configure the Amazon Connect CCP in desk phone mode. However, you can use desk phone mode if your soft phone setup doesn't provide acceptable voice quality for the call.

### Product versions

- For supported browsers and versions, see the [Amazon Connect Administrator Guide](#).

## Architecture

This pattern is architecture-agnostic because it targets agent workstation settings. As the following diagram shows, the voice path from the agent to the customer is affected by the agent's headset, browser, operating system, workstation hardware, and network.

In Amazon Connect contact centers, the user's audio connectivity is established with WebRTC. Voice is encoded with the [Opus interactive audio codec](#) and encrypted with the Secure Real-time Transport Protocol (SRTP) in transit. Other network architectures are possible, including VPN, private WAN/LAN, and ISP networks.

## Tools

- [Amazon Connect Endpoint Test Utility](#) – This utility checks network connectivity and browser settings.
- Browser configuration editors for WebRTC settings:
  - For Firefox: **about:config**
  - For Chrome: **chrome://flags**
- [CCP Log Parser](#) – This tool helps you analyze CCP logs for troubleshooting purposes.

## Epics

### Adjust the work environment

Task	Description	Skills required
Reduce background noise.	<p>Avoid noisy environments. If this is not possible, optimize the environment with these soundproofing tips:</p> <ul style="list-style-type: none"> <li>• Absorb noise by using sound-dissipating surfaces such as curtains, carpets, and soft furnishings.</li> <li>• Block noise by putting barriers between desks.</li> <li>• Consider an active noise cancellation (ANC) solution such as a white noise generator to help concentration and ensure privacy,</li> </ul>	Agent, Manager

Task	Description	Skills required
	<p>or use noise-canceling headsets.</p> <ul style="list-style-type: none"> <li>Prevent echo on your calls. Big, empty spaces might create echo effects or amplify noises. Covering surfaces that can bounce sounds will help reduce echoes.</li> </ul>	

### Optimize agent workstation settings

Task	Description	Skills required
Choose the right headset.	<ul style="list-style-type: none"> <li>If the environment is noisy, choose a stereo headset. Directing sound to both ears helps agents focus and hear the customer better, and reduces the overall noise by making it less likely for agents to raise their voices.</li> <li>Avoid using loud speakers or built-in computer audio. For best quality, use a wired headset that's dedicated to contact center use. Wireless headsets are convenient, but they might be a source of additional audio delay and reduced audio quality</li> </ul>	Agent, Manager

Task	Description	Skills required
	because of radio interference and transcoding.	

Task	Description	Skills required
Use the headset as intended.	<ul style="list-style-type: none"><li>• Enable the active noise canceling and speech enhancement features of your headset if they are available. Look for settings such as ANC or ANR. For instructions on activating these settings, see the user manual for your headset.</li><li>• Adjust your microphone so you can speak directly into it. The best position for your microphone is just below your chin. Correct placement can make a difference of 10 decibels (dB) in the sound level. Most headsets allow you to rotate or bend the microphone arm (boom), so it is important to keep it in the right place when you are talking.</li><li>• Some headsets are equipped with multiple microphones and advanced features such as voice beamforming, which helps capture speech without a boom. To make sure that you're using the main microphone as intended by the manufacturer, see</li></ul>	Agent

Task	Description	Skills required
	the user manual for your device.	
Check workstation resources.	Make sure that your agents' computers are performing. If they use third-party applications that consume resources, their computers might not meet the minimum <a href="#">hardware requirements</a> to run CCP. If agents experience call quality issues, make sure that they have enough processing power (CPU), disk space, network bandwidth, and memory available for CCP. Agents should close any unnecessary applications and tabs to improve CCP performance and call quality.	Administrator

Task	Description	Skills required
Configure the operating system's sound settings.	<p>The default settings for microphone level and boost usually work fine. If you find that outbound voice is quiet or the microphone is picking up too much, it might help to adjust these settings. Microphone settings can be found in your computer's system sound configuration (<b>Sound, Input</b> on <a href="#">MacOS</a>, <b>Microphone Properties</b> in <a href="#">Windows</a>). You can access advanced settings that might affect voice quality through system tools or third-party applications. Here are some of the settings you can check:</p> <ul style="list-style-type: none"><li>• <b>Sample rate</b> – This value determines how many times the sound is probed per second. The default setting is usually 44 or 48 kilohertz (kHz). The optimal value for Amazon Connect is 48 kHz. You can use your browser settings to override the default value. For more information, see the <a href="#">troubleshooting section</a> of the <i>Amazon Connect Administrator Guide</i>.</li><li>• <b>Gain</b> – This value determines how much the microphone</li></ul>	Agent, Administrator

Task	Description	Skills required
	<p>e amplifies the sound. If you turn the gain up, your microphone might pick up more background noise.</p> <ul style="list-style-type: none"><li>• Bit depth – This digital resolution value describes how many levels of sound amplitude are being recognized. The higher the bit depth, the smoother the voice sounds. However, many traditional telephony networks use the pulse-code modulation (PCM) standard, which supports only 8-bit resolution.</li><li>• Open threshold – This is the minimal sound amplitude that a microphone picks up.</li></ul> <p>If you're experiencing voice quality issues, try restoring these values to their default settings before investigating further.</p> <p>For more information about these and other adjustable settings, see your device manual.</p>	

Task	Description	Skills required
Use a wired network.	<p>Typically, wired ethernet has lower latency, so it is easier to provide the consistent transmission quality required for voice data transmission. We recommend 100 KB bandwidth per call at the minimum.</p> <ul style="list-style-type: none"><li>• If agents are working from home, we recommend wired over wireless connections. It shouldn't take more than 150 milliseconds to hear the customer. You can access Amazon Connect's latency test from the <a href="#">Amazon Connect Endpoint Test Utility</a>. However, this utility measures the delay from the browser to Amazon Connect Regions, not to customers. The 150-millisecond one-way delay recommendation prevents the agent and customer from talking over each other. The value is measured from end to end, and each element adds a delay, including the part of the call between the Amazon Connect Region and the customer.</li></ul>	Network administrator, Agent

Task	Description	Skills required
	<ul style="list-style-type: none"><li>If agents are working from the office, corporate Wi-Fi is acceptable as long as parameters are in the recommended range, and Real-time Transport Protocol (RTP) traffic is prioritized.</li></ul>	
Update hardware drivers.	<p>When you use a USB or other type of headset that has its own firmware, we recommend that you keep it updated with the latest version. Simple headsets that use an auxiliary port use the computer's built-in audio device, so make sure that the operating system hardware driver is up to date. In rare cases, an audio driver update can cause audio issues, and you might need to roll it back. For more information about changing firmware and driver versions, see your device manual.</p>	Administrator

Task	Description	Skills required
Avoid USB hubs and dongles.	<p>When you connect your headset, avoid additional devices such as dongles, port type converters, hubs, and extension cables.</p> <p>These devices might affect call quality. Connect your device directly to the port in your computer instead.</p>	Agent

Task	Description	Skills required
Check CCP logs.	<p>The CCP Log Parser provides an easy way to check application logs.</p> <ol style="list-style-type: none"><li>1. <a href="#">Download the CCP logs</a> after a call.</li><li>2. Open the <a href="#">CCP Log Parser</a>.</li><li>3. Drag and drop the log file to upload the log for analysis.</li><li>4. When the log has been analyzed, the <b>Snapshots &amp; Logs</b> tab will be selected by default. Choose the <b>Metrics</b> tab next to it to check insights.</li><li>5. In the <b>WebRTC Metrics - audio_input</b> section, check the following:<ul style="list-style-type: none"><li>• The <b>Audio Level</b> graph, to see if your received audio level is above 0. This indicates that audio was received from your caller.</li><li>• The <b>Packets</b> graph for any lost packets. If this chart shows significant increases, contact your IT support team.</li></ul></li><li>6. In the <b>WebRTC Metrics - audio_output</b> section, check the following:</li></ol>	Agent (advanced skills)

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>• The <b>Audio Level</b> graph, to confirm that audio was sent out from your device.</li> <li>• The <b>Packets</b> graph. If you see a packet loss spike, report it to your IT support team.</li> <li>• The <b>Jitter Buffer &amp; RTT</b> graph. Round trip time (RTT) values above 300 will affect the call experience. Report these to your IT support team.</li> </ul>	

## Optimize browser settings

Task	Description	Skills required
Restore default WebRTC settings.	<p>WebRTC has to be enabled to make soft phone calls with CCP. We recommend that you keep the default settings for WebRTC-related features.</p> <ul style="list-style-type: none"> <li>• In Chrome, you can set flags by navigating to the URL <b>chrome://flags</b>. Type <b>WebRTC</b> in the search box to find settings that can interfere with CCP, and set these to <b>Default</b>.</li> <li>• In Firefox, type <b>about:config</b> in the address bar, and</li> </ul>	Administrator

Task	Description	Skills required
	then type <b>WebRTC</b> in the search box on the configuration page. Non-default settings appear in bold text and can be changed to <b>Default</b> .	
Disable browser extensions when troubleshooting.	Some browser extensions might affect call quality or even prevent calls from connecting properly. Use the incognito window or private mode in your browser, and disable all extensions. If that solves the problem, review your browser extensions and look for suspicious add-ons, or disable them individually.	Agent, Administrator
Check the browser sample rate.	Confirm that your microphone input is set to the optimal 48 kHz sample rate. For instructions, see the <a href="#">Amazon Connect Administrator Guide</a> .	Agent, Administrator

## Related resources

If you've followed the steps in this pattern but you're still encountering problems with call quality, see the following resources for troubleshooting tips.

- Review [common Contact Control Panel \(CCP\) issues](#).
- Check the connection with the [Endpoint Test Utility](#).
- Follow the [troubleshooting guide](#) for any other issues.

If your troubleshooting and adjustments don't solve the call quality issue, the root cause might be external to your workstation. For further troubleshooting, contact your IT support team.

# Automate migration strategy identification and planning using AppScore

<b>Environment:</b> Production	<b>Source:</b> All workloads	<b>Target:</b> AWS Cloud
<b>R Type:</b> N/A	<b>Workload:</b> All other workloads	<b>Technologies:</b> Migration; Modernization; Web & mobile apps; SaaS
<b>AWS services:</b> AWS Application Discovery Service; AWS Migration Hub		

## Summary

On-premises applications require a transformative approach to help unlock the benefits of the Amazon Web Services (AWS) Cloud. The [seven common migration strategies \(7 Rs\)](#) provide you with transformation options, which vary from making technology changes in on-premises database servers to rebuilding an application by using a cloud-native microservices architecture.

Choosing to use the full 7 Rs model means that you operate at the application and business level instead of only evaluating and preparing the servers for migration. Although you can obtain server data by using tools such as [AWS Migration Evaluator](#), other application information is often not recorded (for example, roadmap status, required recovery time objective (RTO) and recovery point objective (RPO), or data privacy requirements).

This pattern describes how to use [AppScore](#) to avoid these challenges by using an application-centric view of your portfolio. This includes a recommended transformation route to the AWS Cloud for each application against the full 7 Rs model. AppScore helps you capture application information, determine the ideal transformation route, identify the risk, complexity and benefits of cloud adoption, and quickly define the migration scopes, move groups, and schedules.

This pattern was created by AWS and [AppScore Technology Limited](#), an AWS Partner.

## Prerequisites and limitations

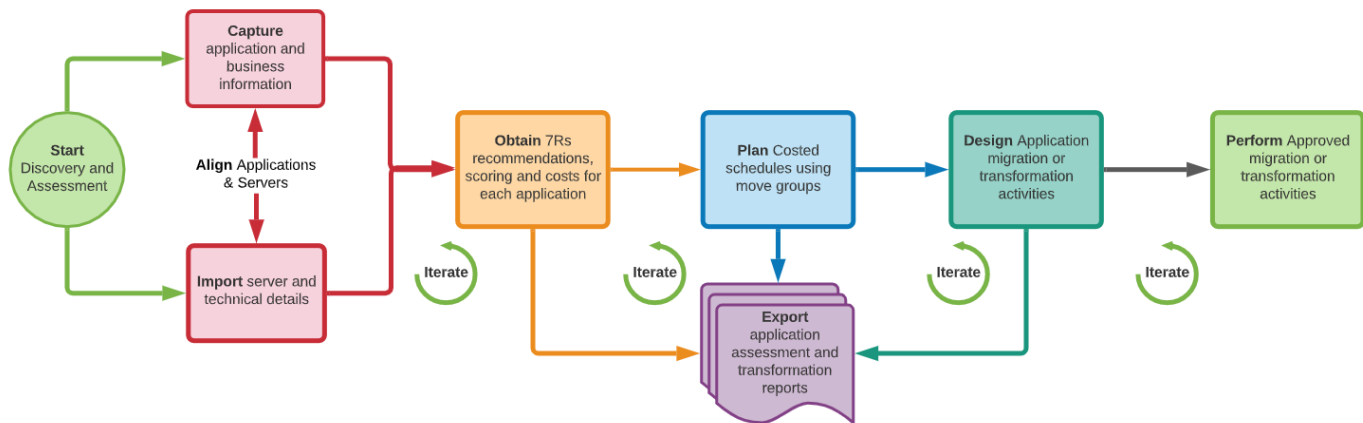

### Prerequisites

- Existing applications that you want to migrate to the AWS Cloud.
- Existing server inventory information from a tool such as [AWS Migration Evaluator](#). You can also import this data at a later stage in your migration.
- An existing AppScore account with **Power User** privileges. For more information about AppScore user accounts, see [How do I assign role-based access control \(RBAC\) to users?](#) in the AppScore documentation
- An understanding of how to assign RBAC roles in AppScore. AppScore provides three subject matter expert (SME) roles that align to the questions asked in the **Scoring** stage. This means that an SME only answers questions relevant to their expertise and role. For more information about this, see [How do I assign role-based access control \(RBAC\) to users?](#) in the AppScore documentation.
- An understanding of AppScore's recommendations, which are based on the following three categories of application attributes:
  - **Risk** – The business criticality of the application, whether it contains confidential data, data sovereignty requirements, and the number of application users or interfaces
  - **Complexity** – The application's development language (for example, COBOL has a higher score than .NET or PHP), age, UI, or number of interfaces
  - **Benefit** – The batch processing demand, application profile, disaster recovery model, development and test environment use
- An understanding of AppScore's four phases of iterative data capture:
  - **Signposting** – Questions that are combined with server data to produce the 7 Rs assessments. For more information, see [How to signpost and score applications](#) in the AppScore documentation.
  - **Scoring** – Questions that produce scores for risk, benefit, and complexity.
  - **Current State Assessment** – Questions that provide a current state assessment of the application.
  - **Transformation** – Questions that comprehensively evaluate the application for future state design.

**Important:** Only the *Signposting* and *Scoring* stages are required to receive application scores, 7 Rs assessments, and enable group planning. After you group applications and form scopes, you can complete the *Current State Assessment* and *Transformation* stages to build a more detailed overview of your application.

# Architecture

The following diagram shows the AppScore workflow that uses application and server data to create a recommendation for your migration strategy and transformation plan .

## Tools

- [AppScore](#) – AppScore helps you bridge the gap between discovery and migration implementation by providing an application-centric view of your portfolio with a recommended route to the cloud for each application against the full 7 Rs model.
- [AWS Migration Evaluator](#) – AWS Migration Evaluator is a migration assessment service that helps you create a directional business case for planning and migration.

## Epics

### Create and load the initial application list

Task	Description	Skills required
Prepare the list of applications.	Log in to the AppScore portal with your user credentials. Download the Import Template from the <b>Application</b> page and then update the Import Template with your application’s non-techn	Migration engineer

Task	Description	Skills required
	<p>ical attributes (for example, data classification or a list of attributes that can be customized).</p> <p>For more information about this, see <a href="#">How do I alter the AppScore application and business questionnaires</a> in the AppScore documentation.</p> <p><b>Note:</b> You can also manually add an application by choosing <b>New Application</b> on the <b>Application</b> page. You can then enter the non-technical attributes of the application.</p>	
Import the application data.	On the <b>Application</b> page, choose <b>Import Applications</b> to import your application data.	Migration engineer

### Capture the application and business data

Task	Description	Skills required
Review and answer Signposting and Scoring questions.	<p>Open the <b>Servers</b> page and choose <b>Import Servers</b>. Choose the .csv file that contains your server data.</p> <p>The file can include attributes such as name, data center, operating system, virtual or</p>	App owner

Task	Description	Skills required
	<p>physical, application name, role, database technology, environment, CPU core count and utilization, RAM size and utilization, disk size and utilization, matched machine type, and current and projected monthly costs.</p> <p>Confirm column mapping and choose <b>Confirm and Import</b>. Missing information in the imported data is highlighted on the <b>Server</b> page. You can resolve these gaps on this page or by using the <b>Bulk Edit</b> option. Servers are associated with the relevant application. However, if applications don't exist in AppScore, they are automatically created and the servers are then associated.</p> <p>You can also use an API connection to retrieve the data with AWS Migration Hub. For more information about this, see <a href="#">How do I import servers from AWS Migration Hub via API?</a> In the AppScore documentation.</p> <p><b>Note:</b> If you used a discovery tool (for example, AWS Migration Evaluator) to</p>	

Task	Description	Skills required
	<p>capture performance over time, you must load an early extract of the server data as soon as possible and refresh the data when performance metrics are fully captured. AppScore uses the server names, operating system and database versions, data centers, and environments to provide scores and 7 Rs recommendations.</p>	
Check the application scores.	<p>Open the <b>Applications</b> page to see the score and 7 Rs assessment for your applications. Your current run costs are also calculated. These calculations are updated when new information is imported to the <b>Applications</b> or <b>Servers</b> pages.</p>	App owner
Analyze individual applications.	<p>Choose an application on the <b>Applications</b> page to review detailed recommendations. You can choose <b>Application Assessment Report</b> to generate a .pdf or .docx file with the detailed assessment data for specific applications.</p>	App owner

## Create the migration schedule

Task	Description	Skills required
Choose the applications for the move group.	<p>Open the <b>Planning</b> page, choose <b>Group Builder</b>, and then create application move groups according to your requirements.</p> <p>You can add or remove attributes from the application list in the <b>Columns</b> section. You can also use application attributes in the <b>Filters</b> section to choose specific applications, which includes filtering out all applications that are already part of existing move groups.</p>	Migration engineer
Create the move group.	Choose <b>Group Selected</b> , enter a name for your move group, choose the applications that you want to include in your move group, and then choose <b>Add to Group</b> .	Migration engineer
Schedule the migration.	On the <b>Transformation Schedules</b> page, AppScore provides an estimated transformation duration, effort, and cost for your move group. The move group is automatically added into the overall transformation schedule.	Migration engineer

Task	Description	Skills required
	<p><b>Note:</b> You can customize the assumptions behind the effort estimation in the <b>Planning Settings</b> page. This helps align them with your organization's requirements. For more information about this, see <a href="#">How do I configure the planning settings</a> in the AppScore documentation.</p>	
Generate the complete transformation report.	<p>Open the <b>Group Manager</b> page and choose <b>Create Application Transformation Report Doc</b>. Choose the move groups and then choose <b>Export</b>. This generates a .docx file that summarizes the transformation, including the details for each move group.</p> <p>For a sample application transformation report, see <a href="#">Sample application transformation report</a> from the AppScore website.</p>	Migration engineer

# Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python

Created by Venkata Naveen Koppula (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Automation	<b>Target:</b> Database in AWS Cloud
<b>R Type:</b> N/A	<b>Workload:</b> Microsoft	<b>Technologies:</b> Migration; Databases

## Summary

This pattern outlines steps for automatically creating AWS CloudFormation templates for [AWS Database Migration Service](#) (AWS DMS) using Microsoft Excel and Python.

Migrating databases using AWS DMS often involves creation of AWS CloudFormation templates to provision AWS DMS tasks. Previously, creating AWS CloudFormation templates required knowledge of the JSON or YAML programming language. With this tool, you only need basic knowledge of Excel and how to run a Python script using a terminal or command window.

As input, the tool takes an Excel workbook that includes the names of the tables to be migrated, Amazon Resource Names (ARNs) of AWS DMS endpoints, and AWS DMS replication instances. The tool then generates AWS CloudFormation templates for the required AWS DMS tasks.

For detailed steps and background information, see the blog post [Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel](#) in the AWS Database blog.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Microsoft Excel version 2016 or later
- Python version 2.7 or later
- The **xlrd** Python module (installed at a command prompt with the command: **pip install xlrd**)
- AWS DMS source and target endpoints and AWS DMS replication instance

## Limitations

- The names of schemas, tables, and associated columns are transformed into lowercase characters at the destination endpoints.
- This tool doesn't address the creation of AWS DMS endpoints and replication instances.
- Currently, the tool supports only one schema for each AWS DMS task.

## Architecture

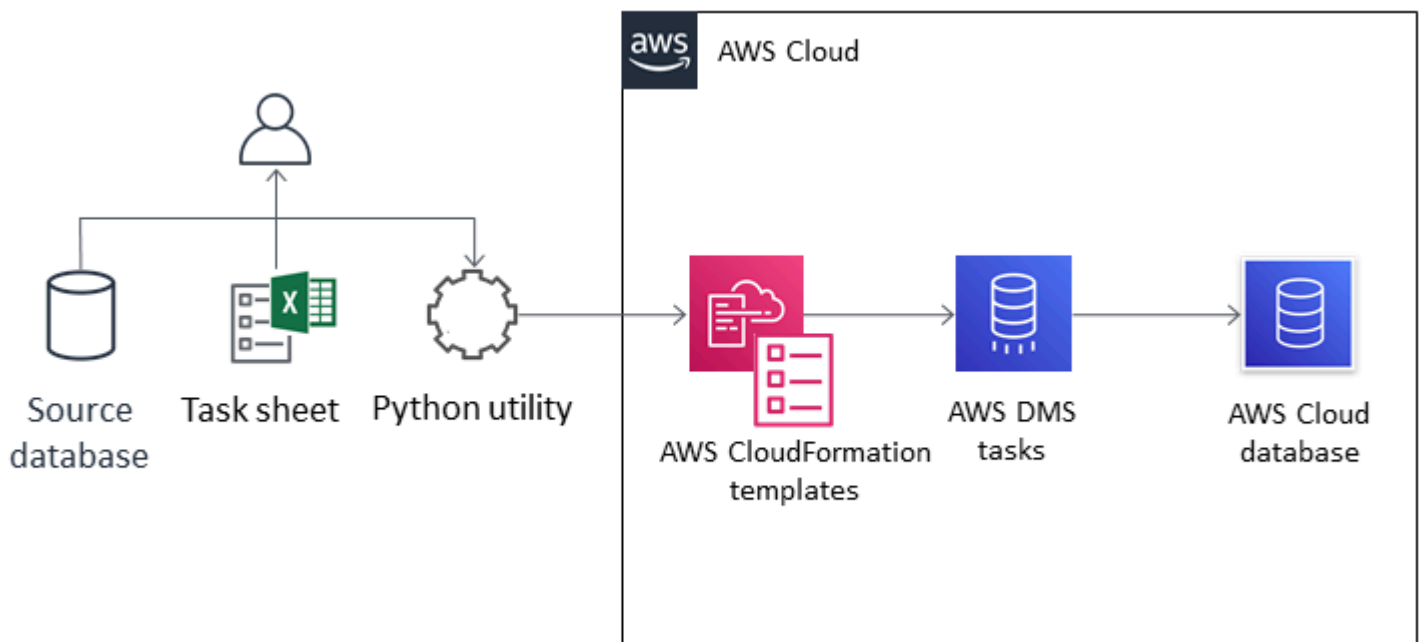

### Source technology stack

- An on-premises database
- Microsoft Excel

### Target technology stack

- AWS CloudFormation templates
- A database in the AWS Cloud

### Architecture

## Tools

- [Pycharm IDE](#), or any integrated development environment (IDE) that supports Python version 3.6
- Microsoft Office 2016 (for Microsoft Excel)

## Epics

### Configure the network, AWS DMS replication instance, and endpoints

Task	Description	Skills required
If necessary, request a service quota increase.	Request a service quota increase for the AWS DMS tasks if needed.	General AWS
Configure the AWS Region, virtual private clouds (VPCs), CIDR ranges, Availability Zones, and subnets.		General AWS
Configure the AWS DMS replication instance.	The AWS DMS replication instance can connect to both on-premises and AWS databases.	General AWS
Configure AWS DMS endpoints.	Configure endpoints for both the source and target databases.	General AWS

### Prepare the worksheets for AWS DMS tasks and tags

Task	Description	Skills required
Configure the tables list.	List all tables involved in the migration.	Database

Task	Description	Skills required
Prepare the tasks worksheet.	Prepare the Excel worksheet using the tables list you configured.	General AWS, Microsoft Excel
Prepare the tags worksheet.	Detail the AWS resource tags to attach to the AWS DMS tasks.	General AWS, Microsoft Excel

## Download and run the tool

Task	Description	Skills required
Download and extract the template generation tool from the GitHub repository.	GitHub repository: <a href="https://github.com/aws-samples/dms-cloudformation-templates-generator/">https://github.com/aws-samples/dms-cloudformation-templates-generator/</a>	
Run the tool.	Follow the detailed instructions in the blog post listed under "References and help."	

## Related resources

# Get started with automated portfolio discovery

Created by Pratik Chunawala (AWS) and Rodolfo Jr. Cerrada (AWS)

<b>Environment:</b> Production	<b>Source:</b> On-premises	<b>Target:</b> On-premises
<b>R Type:</b> N/A	<b>Workload:</b> All other workloads	<b>Technologies:</b> Migration

## Summary

Assessing the portfolio and collecting metadata is a critical challenge when migrating applications and servers to the Amazon Web Services (AWS) Cloud, especially for large migrations that have more than 300 servers. Using an automated portfolio discovery tool can help you collect information about your applications, such as the number of users, frequency of use, dependencies, and information about the application's infrastructure. This information is essential when planning migration waves so that you can properly prioritize and group applications with similar traits. Using a discovery tool streamlines communication between the portfolio team and the application owners because the portfolio team can validate the results of the discovery tool rather than manually collecting the metadata. This pattern discusses key considerations for selecting an automated discovery tool and information about how to deploy and test one in your environment.

This pattern includes a template, which is a starting point for building your own checklist of high-level activities. Next to the checklist is template for a responsible, accountable, consulted, informed (RACI) matrix. You can use this RACI matrix to determine who is responsible for each task in your checklist.

## Epics

### Select a discovery tool

Task	Description	Skills required
Determine whether a discovery tool is appropriate for your use case.	A discovery tool might not be the best solution for your use case. Consider the	Migration lead, Migration engineer

Task	Description	Skills required
	<p>amount of time required to select, procure, prepare, and deploy a discovery tool. It can take 4–8 weeks to set up the scanning appliance for an agentless discovery tool in your environment or to install agents to all in-scope workloads. Once deployed, you must allow 4–12 weeks for the discovery tool to collect metadata by scanning the application workloads and performing application stack analysis. If you are migrating fewer than 100 servers, you might be able to manually collect the metadata and analyze dependencies faster than the time required to deploy and collect metadata with an automated discovery tool.</p>	

Task	Description	Skills required
Select a discovery tool.	Review the <b>Considerations for selecting an automated discovery tool</b> in the <a href="#">Additional information</a> section. Determine the appropriate criteria for selecting a discovery tool for your use case, and then evaluate each tool against those criteria. For a comprehensive list of automated discovery tools, see <a href="#">Discovery, Planning, and Recommendation migration tools</a> .	Migration lead, Migration engineer

## Prepare for installation

Task	Description	Skills required
Prepare the pre-deployment checklist.	Create a checklist of the tasks you must complete before deploying the tool. For an example, see <a href="#">Predeployment Checklist</a> on the Flexera documentation website.	Build lead, Migration engineer, Migration lead, Network administrator
Prepare the network requirements.	Provision the ports, protocols, IP addresses, and routing necessary for the tool to run and access the target servers. For more information, see the installation guide for your discovery tool. For an	Migration engineer, Network administrator, Cloud architect

Task	Description	Skills required
	example, see <a href="#">Deployment Requirements</a> on the Flexera documentation website.	
Prepare the account and credential requirements.	Identify the credentials you need to access the target servers and to install all of the tool's components.	Cloud administrator, General AWS, Migration engineer, Migration lead, Network administrator, AWS administrator
Prepare the appliances on which you will install the tool.	Ensure that the appliances on which you will install the tool components meet the specifications and platform requirements for the tool.	Migration engineer, Migration lead, Network administrator
Prepare the change orders.	According to the change management process in your organization, prepare the any change orders needed, and ensure these change orders are approved.	Build lead, Migration lead
Send requirements to stakeholders.	Send the pre-deployment checklist and network requirements to the stakeholders. Stakeholders should review, evaluate, and prepare the necessary requirements before proceeding with the deployment.	Build lead, Migration lead

## Deploy the tool

Task	Description	Skills required
Download the installer.	Download the installer or the virtual machine image. Virtual machine images typically come in Open Virtualization Format (OVF).	Build lead, Migration lead
Extract the files.	If you are using an installer, you must download and run the installer on an on-premises server.	Build lead, Migration lead
Deploy the tool on the servers.	<p>Deploy the discovery tool on the target, on-premises servers as follows:</p> <ul style="list-style-type: none"> <li>• If your source file is a virtual machine image, deploy it into your virtual machine environment, such as VMware.</li> <li>• If your source file is an installer, run the installer to install and set up the tool.</li> </ul>	Build lead, Migration lead, Network administrator
Log in to the discovery tool.	Follow the on-screen prompts, and log in to get started with the tool.	Migration lead, Build lead
Activate the product.	Enter your license key.	Build lead, Migration lead
Configure the tool.	Enter any credentials necessary to access the target servers, such as credentials for Windows, VMware,	Build lead, Migration lead

Task	Description	Skills required
	Simple Network Management Protocol (SNMP), and Secure Shell Protocol (SSH), or databases.	

## Test the tool

Task	Description	Skills required
Select test servers.	Identify a small set of non-production subnets or IP addresses that you can use to test the discovery tool. This helps you validate the scans quickly, identify and troubleshoot any errors quickly, and isolate your tests from production environments.	Build lead, Migration lead, Network administrator
Start scanning the selected test servers.	<p>For an agentless discovery tool, enter the subnets or IP addresses for the selected test servers in the discovery tool console, and start the scan.</p> <p>For an agent-based discovery tool, install the agent on the selected test servers.</p>	Build lead, Migration lead, Network administrator
Review the scan results.	Review the scan results for the test servers. If any errors are found, troubleshoot and fix the errors. Document the	Build lead, Migration lead, Network administrator

Task	Description	Skills required
	errors and solutions. You reference this information in the future, and you can add this information to your portfolio runbook.	
Rescan the test servers.	Once the rescan is complete, repeat the scan until there are no errors.	Build lead, Migration lead, Network administrator

## Additional information

### Considerations for selecting an automated discovery tool

Each discovery tool has benefits and limitations. When selecting the appropriate tool for your use case, consider the following:

- Select a discovery tool that can collect most, if not all, of the metadata you need to achieve your portfolio assessment goal.
- Identify any metadata you need to gather manually because the tool doesn't support it.

- Provide the discovery tool requirements to stakeholders so they can review and assess the tool based on their internal security and compliance requirements, such as server, network, and credential requirements.
  - Does the tool require that you install an agent in the in-scope workload?
  - Does the tool require that you set up a virtual appliance in your environment?
- Determine your data residency requirements. Some organizations don't want to store their data outside of their environment. To address this, you might need to install some components of the tool in the on-premises environment.
- Make sure the tool supports the operating system (OS) and OS version of the in-scope workload.
- Determine whether your portfolio includes mainframe, mid-range, and legacy servers. Most of the discovery tools can detect these workloads as dependencies, but some tools might not be able to get device details, such as utilization and server dependencies. Device42 and modernizeIT discovery tools both support mainframe and mid-range servers.

# Migrate on-premises Cloudera workloads to Cloudera Data Platform on AWS

<b>Environment:</b> PoC or pilot	<b>Source:</b> Cloudera workloads	<b>Target:</b> Cloudera Data Platform (CDP) Public Cloud
<b>R Type:</b> N/A	<b>Workload:</b> All other workloads	<b>Technologies:</b> Migration; Big data; Databases; Analytics

**AWS services:** Amazon EC2; Amazon EKS; AWS Identity and Access Management; Amazon S3; Amazon RDS

## Summary

This pattern describes the high-level steps for migrating your on-premises Cloudera Distributed Hadoop (CDH), Hortonworks Data Platform (HDP), and Cloudera Data Platform (CDP) workloads to CDP Public Cloud on AWS. We recommend that you partner with Cloudera Professional Services and a systems integrator (SI) to implement these steps.

There are many reasons Cloudera customers want to move their on-premises CDH, HDP, and CDP workloads to the cloud. Some typical reasons include:

- Streamline adoption of new data platform paradigms such as data lakehouse or data mesh
- Increase business agility, democratize access and inference on existing data assets
- Lower the total cost of ownership (TCO)
- Enhance workload elasticity
- Enable greater scalability; drastically reduce time to provision data services compared with legacy, on-premises install base
- Retire legacy hardware; significantly reduce hardware refresh cycles
- Take advantage of pay-as-you-go pricing, which is extended to Cloudera workloads on AWS with the Cloudera licensing model (CCU)

- Take advantage of faster deployment and improved integration with continuous integration and continuous delivery (CI/CD) platforms
- Use a single unified platform (CDP) for multiple workloads

Cloudera supports all major workloads, including Machine Learning, Data Engineering, Data Warehouse, Operational Database, Stream Processing (CSP), and data security and governance. Cloudera has offered these workloads for many years on premises, and you can migrate these workloads to the AWS Cloud by using CDP Public Cloud with Workload Manager and Replication Manager.

Cloudera Shared Data Experience (SDX) provides a shared metadata catalog across these workloads to facilitate consistent data management and operations. SDX also includes comprehensive, granular security to protect against threats, and unified governance for audit and search capabilities for compliance with standards such as Payment Card Industry Data Security Standard (PCI DSS) and GDPR.

### CDP migration at a glance

	Source workload	CDH, HDP, and CDP Private Cloud
	Source environment	<ul style="list-style-type: none"> <li>• Windows, Linux</li> <li>• On-premises, colocation, or any non-AWS environment</li> </ul>
<b>Workload</b>	Destination workload	CDP Public Cloud on AWS
	Destination environment	<ul style="list-style-type: none"> <li>• Deployment model: customer account</li> <li>• Operating model: customer/Cloudera control plane</li> </ul>
	Migration strategy (7Rs)	Rehost, replatform, or refactor
<b>Migration</b>	Is this an upgrade in the workload version?	Yes

## Migration duration

- **Deployment:** About 1 week to create customer account, virtual private cloud (VPC), and CDP Public Cloud customer-managed environment.
- **Migration duration:** 1-4 months, depending on the complexity and size of the workload.

**Cost**

## Cost of running the workload on AWS

- At a high level, the cost of a CDH workload migration to AWS assumes that you will establish a new environment on AWS. It includes accounting for personnel time and effort as well as provisioning computing resources and licensing software for the new environment.
- The Cloudera cloud consumption-based pricing model gives you the flexibility to take advantage of bursting and automatic scaling capabilities. For more information, see [CDP Public Cloud service rates](#) on the Cloudera website.
- Cloudera Enterprise [Data Hub](#) is based on Amazon Elastic Compute Cloud (Amazon EC2) and closely models traditional clusters. Data Hub can be [customized](#), but this will affect costs.
- [CDP Public Cloud Data Warehouse](#), [Cloudera Machine Learning](#), and [Cloudera Data Engineering \(CDE\)](#) are container-based and can be configured to scale automatically.

	System requirements	See the <a href="#">Prerequisites</a> section.
<b>Infrastructure agreements and framework</b>	SLA	See <a href="#">Cloudera Service Level Agreement for CDP Public Cloud</a> .
	DR	See <a href="#">Disaster Recovery</a> in the Cloudera documentation.
<b>Compliance</b>	Licensing and operating model (for target AWS account)	Bring Your Own License (BYOL) model
	Security requirements	See <a href="#">Cloudera Security Overview</a> in the Cloudera documentation.
	Other <a href="#">compliance certifications</a>	See the information on the Cloudera website about <a href="#">General Data Protection Regulation (GDPR)</a> compliance and the <a href="#">CDP Trust Center</a> .

## Prerequisites and limitations

### Prerequisites

- [AWS account requirements](#), including accounts, resources, services, and permissions, such as AWS Identity and Access Management (IAM) roles and policies setup
- [Prerequisites for deploying CDP](#) from the Cloudera website

The migration requires the following roles and expertise:

Role	Skills and responsibilities
Migration lead	Ensures executive support, team collaboration, planning, implementation, and assessment

Cloudera SME	Expert skills in CDH, HDP, and CDP administration, system administration, and architecture
AWS architect	Skills in AWS services, networking, security, and architectures

## Architecture

Building to the appropriate architecture is a critical step to ensure that migration and performance meet your expectations. For your migration effort to meet this playbook's assumptions, your target data environment in the AWS Cloud, either on virtual private cloud (VPC) hosted instances or CDP, must be an equivalent match to your source environment in terms of operating system and software versions as well as major machine specifications.

The following diagram (reproduced with permission from the [Cloudera Shared Data Experience data sheet](#)) shows the infrastructure components for the CDP environment and how the tiers or infrastructure components interact.

The architecture includes the following CDP components:

- Data Hub is a service for launching and managing workload clusters powered by Cloudera Runtime. You can use the cluster definitions in Data Hub to provision and access workload clusters for custom use cases and define custom cluster configurations. For more information, see the [Cloudera website](#).

- Data Flow and Streaming addresses the key challenges enterprises face with data in motion. It manages the following:
  - Processing real-time data streaming at high volume and high scale
  - Tracking data provenance and lineage of streaming data
  - Managing and monitoring edge applications and streaming sources

For more information, see [Cloudera DataFlow](#) and [CSP](#) on the Cloudera website.

- Data Engineering includes data integration, data quality, and data governance, which help organizations build and maintain data pipelines and workflows. For more information, see the [Cloudera website](#). Learn about [support for spot instances to facilitate cost savings on AWS](#) for Cloudera Data Engineering workloads.
- Data Warehouse enables you to create independent data warehouses and data marts that automatically scale to meet workload demands. This service provides isolated compute instances and automated optimization for each data warehouse and data mart, and helps you save costs while meeting SLAs. For more information, see the [Cloudera website](#). Learn about [managing costs](#) and [auto-scaling](#) for Cloudera Data Warehouse on AWS.
- Operational Database in CDP provides a reliable and flexible foundation for scalable, high-performance applications. It delivers a real-time, always available, scalable database that serves traditional structured data alongside new, unstructured data within a unified operational and warehousing platform. For more information, see the [Cloudera website](#).
- Machine Learning is a cloud-native machine learning platform that merges self-service data science and data engineering capabilities into a single, portable service within an enterprise data cloud. It enables scalable deployment of machine learning and artificial intelligence (AI) on data anywhere. For more information, see the [Cloudera website](#).

## CDP on AWS

The following diagram (adapted with permission from the Cloudera website) shows the high-level architecture of CDP on AWS. CDP implements its [own security model](#) to manage both accounts and data flow. These are integrated with [IAM](#) through the use of [cross-account roles](#).

# CDP on AWS

## High-level architecture

The CDP control plane resides in a Cloudera master account in its own VPC. Each customer account has its own sub-account and unique VPC. Cross-account IAM roles and SSL technologies route management traffic to and from the control plane to customer services that reside on internet-routable public subnets within each customer VPC. On the customer's VPC, the Cloudera Shared Data Experience (SDX) provides enterprise-strength security with unified governance and compliance so you can get insights from your data faster. SDX is a design philosophy incorporated into all Cloudera products. For more information about [SDX](#) and the [CDP Public Cloud network architecture for AWS](#), see the Cloudera documentation.

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

## Automation and tooling

- For additional tooling, you can use [Cloudera Backup Data Recovery \(BDR\)](#), [AWS Snowball](#), and [AWS Snowmobile](#) to help migrate data from on-premises CDH, HDP, and CDP to AWS-hosted CDP.
- For new deployments, we recommend that you use the [AWS Partner Solution for CDP](#).

## Epics

### Prepare for migration

Task	Description	Skills required
Engage the Cloudera team.	<p>Cloudera pursues a standardized engagement model with its customers and can work with your systems integrator (SI) to promote the same approach. Contact the Cloudera customer team so they can provide guidance and the necessary technical resources to get the project started. Contacting the Cloudera team ensures that all necessary teams can prepare for the migration as its date approaches.</p> <p>You can contact Cloudera Professio</p>	Migration lead

Task	Description	Skills required
	nal Services to move your Cloudera deployment from pilot to production quickly, at lower cost, and with peak performance. For a complete list of offerings, see the <a href="#">Cloudera website</a> .	
Create a CDP Public Cloud environment on AWS for your VPC.	Work with Cloudera Professional Services or your SI to plan and deploy CDP Public Cloud into a VPC on AWS.	Cloud architect, Cloudera SME

Task	Description	Skills required
Prioritize and assess workloads for migration.	<p>Evaluate all your on-premises workloads to determine the workloads that are the easiest to migrate. Applications that aren't mission-critical are the best to move first, because they will have minimal impact on your customers. Save the mission-critical workloads for last, after you successfully migrate other workloads.</p> <p><b>Note:</b> Transient (CDP Data Engineering) workloads are easier to migrate than persistent (CDP Data Warehouse) workloads. It's also important to consider data volume and locations when migrating. Challenges can include replicating data continuously from an on-premises environment to the cloud, and changing the data ingestion pipelines to import data directly to the cloud.</p>	Migration lead

Task	Description	Skills required
Discuss CDH, HDP, CDP, and legacy application migration activities.	<p>Consider and start planning for the following activities with Cloudera Workload Manager:</p> <ul style="list-style-type: none"><li>• Data and workloads to copy to your AWS environment</li><li>• Cloud-ready data</li><li>• Noisy neighbors, which use up resources and create issues for other tenants</li><li>• Elastic workloads</li><li>• Small clusters with high operational overhead</li></ul>	Migration lead

Task	Description	Skills required
Complete the Cloudera Replication Manager requirements and recommendations.	<p>Work with Cloudera Professional Services and your SI to prepare to migrate workloads to your CDP Public Cloud environment on AWS. Understanding the following requirements and recommendations can help you avoid common issues during and after you install the Replication Manager service.</p> <ul style="list-style-type: none"><li>• Review Replication Manager supporting documents to confirm that you meet the environment and system requirements. For more information, see <a href="#">Support matrix for CDP Public Cloud Replication Manager</a> on the Cloudera website.</li><li>• You don't need root access to the nodes on which the Replication Manager App and Data Lifecycle Manager (DLM) engine will be installed.</li><li>• Install Apache Hive during the initial installation of Replication Manager, unless you are certain that you won't use Hive replication</li></ul>	Migration lead

Task	Description	Skills required
	<p>in the future. If you decide to install Hive after creating HDFS replication policies in Replication Manager, you have to delete and then recreate all HDFS replication policies after you add Hive.</p> <ul style="list-style-type: none"><li>• Clusters used in Replication Manager must have symmetrical configurations. Each cluster in a replication relationship must be configured exactly the same for security (Kerberos), user management (LDAP/AD), and Knox Proxy. Cluster services such as Hadoop Distributed File System (HDFS), Apache Hive, Apache Knox, Apache Ranger, and Apache Atlas can have different configurations for high availability (HA). For example, source and target clusters might have separate HA and non-HA configurations.</li></ul>	

## Migrate CDP to AWS

Task	Description	Skills required
<p>Migrate the first workload for dev/test environments by using Cloudera Workload Manager.</p>	<p>Your SI can help you migrate your first workload to the AWS Cloud. This should be an application that isn't customer-facing or mission-critical. Ideal candidates for dev/test migration are applications that have data that the cloud can easily ingest, such as CDP Data Engineering workloads. This is a transient workload that usually has fewer users accessing it, compared with a persistent workload such as a CDP Data Warehouse workload that could have many users who need uninterrupted access. Data Engineering workloads aren't persistent, which minimizes the business impact if something goes wrong. However, these jobs could be critical for production reporting, so prioritize low-impact Data Engineering workloads first.</p>	<p>Migration lead</p>
<p>Repeat migration steps as necessary.</p>	<p>Cloudera Workload Manager helps identify workloads that are best suited for the cloud. It provides metrics</p>	<p>Cloudera SME</p>

Task	Description	Skills required
	<p>such as cloud performance ratings, sizing/capacity plans for the target environment, and replication plans. The best candidates for migration are seasonal workloads, ad hoc reporting, and intermittent jobs that don't consume many resources.</p> <p>Cloudera Replication Manager moves data from on premises to the cloud, and from the cloud to on premises.</p> <p>Proactively optimize workloads, applications, performance, and infrastructure capacity for data warehousing, data engineering, and machine learning by using Workload Manager. For a complete guide on how to modernize a data warehouse, see the <a href="#">Cloudera website</a>.</p>

# Restart the AWS Replication Agent automatically without disabling SELinux after rebooting a RHEL source server

Created by Anil Kunapareddy (AWS), Shanmugam Shanker (AWS), and Venkatramana Chintha (AWS)

**Environment:** Production

**Technologies:** Migration;  
Operating systems

**Workload:** Open-source

**AWS services:** AWS Application Migration Service

## Summary

AWS Application Migration Service helps simplify, expedite, and automate the migration of your Red Hat Enterprise Linux (RHEL) workload to the Amazon Web Services (AWS) Cloud. To add source servers to Application Migration Service, you install the AWS Replication Agent on the servers.

Application Migration Service provides real-time, asynchronous, block-level replication. This means that you can continue normal IT operations during the entire replication process. These IT operations might require that you reboot or restart your RHEL source server during the migration. If this happens, the AWS Replication Agent will not restart automatically, and your data replication will stop. Typically, you can set Security-Enhanced Linux (SELinux) to **disabled** or **permissive** mode to automatically restart AWS Replication Agent. However, your organization's security policies might prohibit disabling SELinux, and you might also have to [relabel your files](#).

This pattern describes how to automatically restart the AWS Replication Agent without turning off SELinux when your RHEL source server reboots or restarts during a migration.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An on-premises RHEL workload that you want to migrate to the AWS Cloud.

- Application Migration Service initialized from the Application Migration Service console. Initialization is required only the first time you use this service. For instructions, see the [Application Migration Service documentation](#).
- An existing [AWS Identity and Access Management \(IAM\) policy](#) for Application Migration Service. For more information, see the [Application Migration Service documentation](#).

## Versions

- RHEL version 7 or later

## Tools

### AWS services

- [AWS Application Migration Service](#) is a highly automated lift-and-shift (rehost) solution that simplifies, expedites, and reduces the cost of migrating applications to AWS.

### Linux commands

The following table provides a list of Linux commands that you will run on your RHEL source server. These are also described in the epics and stories for this pattern.

Command	Description
<code>#systemctl -version</code>	Identifies the system version.
<code>#systemctl list-units --type=service</code>	Lists all active services that are available on the RHEL server.
<code>#systemctl list-units --type=service   grep running</code>	Lists all services that are currently running on the RHEL server.
<code>#systemctl list-units --type=service   grep failed</code>	Lists all services that failed to load after the RHEL server rebooted or restarted.
<code>restorecon -Rv /etc/rc.d/init.d/aws-replication-service</code>	Changes the context to <code>aws-replication-service</code> .

<code>yum install policycoreutils*</code>	Installs the policy core utilities that are required for the operation of the SELinux system.
<code>ausearch -c "insmod" --raw   audit2allow -M my-modprobe</code>	Searches the audit log and creates a module for policies.
<code>semodule -i my-modprobe.pp</code>	Activates the policy.
<code>cat my-modprobe.te</code>	Displays the contents of the <code>my-modprobe.te</code> file.
<code>semodule -l   grep my-modprobe</code>	Checks whether the policy has been loaded to the SELinux module.

## Epics

### Install the AWS Replication Agent and reboot the RHEL source server

Task	Description	Skills required
Create an Application Migration Service user with an access key and a secret access key.	To install the AWS Replication Agent, you must create an Application Migration Service user with the required AWS credentials. For instructions, see the <a href="#">Application Migration Service documentation</a> .	Migration engineer
Install the AWS Replication Agent.	<ol style="list-style-type: none"> <li>Sign in to the AWS Management Console and open the AWS Migration Service console at <a href="https://console.aws.amazon.com/mgn/home">https://console.aws.amazon.com/mgn/home</a>.</li> <li>Configure replication settings by following the</li> </ol>	Migration engineer

Task	Description	Skills required
	<p>instructions in the <a href="#">Application Migration Service documentation</a>.</p> <p>3. Install the AWS Replication Agent by following the instructions in the <a href="#">Application Migration Service documentation</a>.</p> <p>4. On the <b>Source Servers</b> page, choose the RHEL source server, and then choose <b>Replication</b> to start the initial replication. For more information, see the <a href="#">Application Migration Service documentation</a>.</p>	
Restart or reboot the RHEL source server.	Restart or reboot your RHEL source server when its <b>Data replication status</b> displays <b>Healthy</b> on the <a href="#">Migration dashboard</a> .	Migration engineer
Check data replication status.	Wait for one hour and then check the <b>Data replication status</b> again on the Migration dashboard. It should be in the <b>Stalled</b> state.	Migration engineer

## Check AWS Replication Agent status on the RHEL source server

Task	Description	Skills required
Identify the system version.	Open the command line interface for your RHEL source server and run the following command to identify the system version:  <code>#systemctl -version</code>	Migration engineer
List all active services.	To list all active services available on the RHEL server, run the command:  <code>#systemctl list-units --type=service</code>	Migration engineer
List all running services.	To list all services that are currently running on the RHEL server, use the command:  <code>#systemctl list-units --type=service   grep running</code>	Migration engineer
List all services that failed to load.	To list all services that failed to load after the RHEL server rebooted or restarted, run the command:  <code>#systemctl list-units --type=service   grep failed</code>	Migration engineer

## Create and run the SELinux module

Task	Description	Skills required
Change the security context.	<p>In the command line interface for your RHEL source server, run the following command to change the security context to the AWS replication service:</p> <pre>restorecon -Rv /etc/rc.d/init.d/aws-replication-service</pre>	Migration engineer
Install core utilities.	<p>To install the core utilities required for the operation of the SELinux system and its policies, run the command:</p> <pre>yum install policycoreutils*</pre>	Migration engineer
Search the audit log and create a module for policies.	<p>Run the command:</p> <pre>ausearch -c "insmod" --raw   audit2allow -M my-modprobe</pre>	Migration engineer
Display the contents of the my-modprobe-te file.	<p>The my-modprobe.te file is generated by the <b>audit2allow</b> command. It includes the SELinux domains, policy source directory, and subdirectories, and specifies the access vector rules and transitions associated with the domains. To display the</p>	Migration engineer

Task	Description	Skills required
	<p>contents of the file, run the command:</p> <pre>cat my modprobe.te</pre>	
<p>Activate the policy.</p>	<p>To insert the module and make the policy package active, run the command:</p> <pre>semodule -i my-modprobe.pp</pre>	<p>Migration engineer</p>
<p>Check whether the module has been loaded.</p>	<p>Run the command:</p> <pre>semodule -l   grep my-modprobe</pre> <p>After the SELinux module is loaded, you will no longer have to set SELinux to <b>disabled</b> or <b>permissive</b> mode during your migration.</p>	<p>Migration engineer</p>
<p>Reboot or restart the RHEL source server and verify the data replication status.</p>	<p>Open the AWS Migration Service console, navigate to <b>Data replication progress</b>, and then reboot or restart your RHEL source server. Data replication should now resume automatically after the RHEL source server reboots.</p>	<p>Migration engineer</p>

# Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL

Created by Naresh Damera (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> Amazon Aurora PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration ; DevelopmentAndTesting; Storage & backup; Databases
<b>AWS services:</b> Amazon Aurora; AWS DMS; Amazon RDS; AWS SCT		

## Summary

During a migration from Amazon Relational Database Service (Amazon RDS) for Oracle to Amazon Aurora PostgreSQL-Compatible Edition, you might encounter a data mismatch when validating the migration in Amazon Web Services (AWS) Database Migration Service (AWS DMS). To prevent this mismatch, you can convert VARCHAR2(1) data type to Boolean data type.

VARCHAR2 data type stores variable-length text strings, and VARCHAR2(1) indicates that the string is 1 character in length or 1 byte. For more information about VARCHAR2, see [Oracle built-in data types](#) (Oracle documentation).

In this pattern, in the sample source data table column, the VARCHAR2(1) data is either a **Y**, for *Yes*, or **N**, for *No*. This pattern includes instructions for using AWS DMS and AWS Schema Conversion Tool (AWS SCT) to convert this data type from the **Y** and **N** values in VARCHAR2(1) to **true** or **false** values in Boolean.

## Target audience

This pattern is recommended for those who have experience migrating Oracle databases to Aurora PostgreSQL-Compatible by using AWS DMS. As you complete the migration, adhere to the recommendations in [Converting Oracle to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL](#) (AWS SCT documentation).

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- Confirm that your environment is prepared for Aurora, including setting up credentials, permissions, and a security group. For more information, see [Setting up your environment for Amazon Aurora](#) (Aurora documentation).
- A source Amazon RDS for Oracle database that contains a table column with VARCHAR2(1) data.
- A target Amazon Aurora PostgreSQL-Compatible database instance. For more information, see [Creating a database cluster and connecting to a database on an Aurora PostgreSQL database cluster](#) (Aurora documentation).

### Product versions

- Amazon RDS for Oracle version 12.1.0.2 or later.
- AWS DMS version 3.1.4 or later. For more information, see [Using an Oracle database as a source for AWS DMS](#) and [Using a PostgreSQL database as a target for AWS DMS](#) (AWS DMS documentation). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- AWS Schema Conversion Tool (AWS SCT) version 1.0.632 or later. We recommend that you use the latest version of AWS SCT for the most comprehensive version and feature support.
- Aurora supports the PostgreSQL versions listed in [Database Engine Versions for Aurora PostgreSQL-Compatible](#) (Aurora documentation).

## Architecture

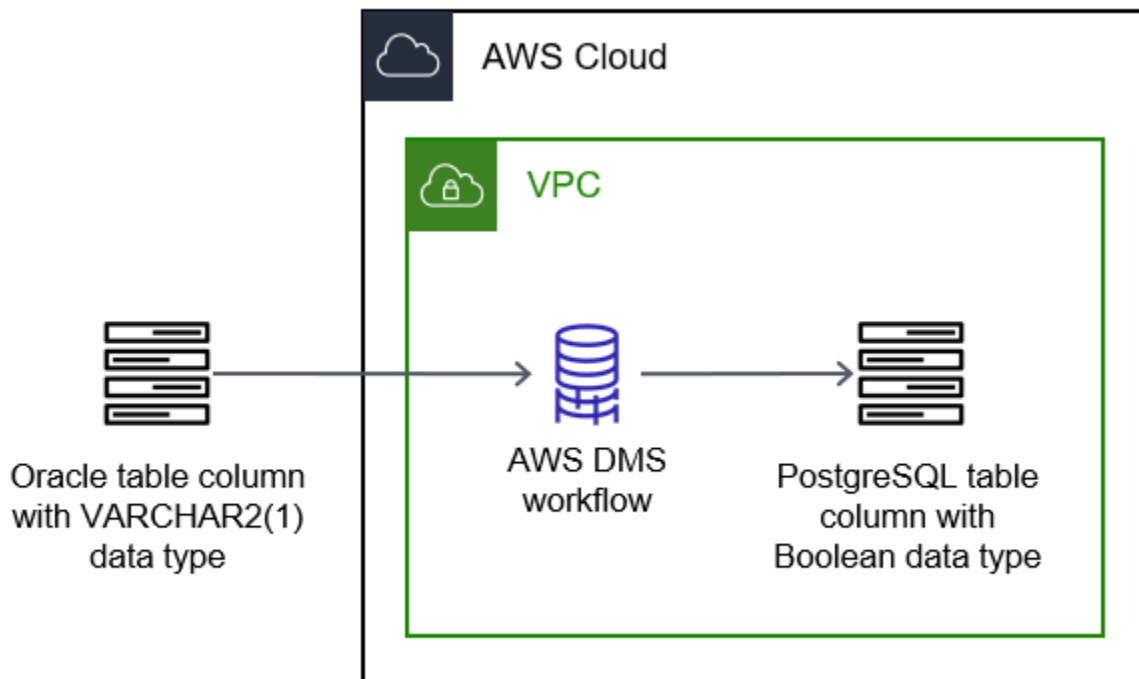

### Source technology stack

Amazon RDS for Oracle database instance

### Target technology stack

Amazon Aurora PostgreSQL-Compatible database instance

### Source and target architecture

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Relational Database Service \(Amazon RDS\) for Oracle](#) helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

### Other services

- [Oracle SQL Developer](#) is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.. In this pattern, you use this tool to connect to the Amazon RDS for Oracle database instance and query the data.

- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. In this pattern, you use this tool to connect to the Aurora database instance and query the data.

## Epics

### Prepare for the migration

Task	Description	Skills required
Create database migration report.	<ol style="list-style-type: none"> <li>1. In AWS SCT, create a database migration assessment report. For more information, see <a href="#">Creating migration assessment reports</a>.</li> <li>2. Review and perform the action items in the migration assessment report. For more information, see <a href="#">Assessment report action items</a>.</li> </ol>	DBA, Developer
Disable foreign key constraints on the target database.	<p>In PostgreSQL, foreign keys are implemented by using triggers. During the full load phase, AWS DMS loads each table one at a time. We strongly recommend that you disable foreign key constraints during a full load by using one of the following methods:</p> <ul style="list-style-type: none"> <li>• Temporarily disable all triggers from the instance, and finish the full load.</li> </ul>	DBA, Developer

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>Use the <code>session_replication_role</code> parameter in PostgreSQL.</li> </ul> <p>If disabling foreign key constraints is not feasible, create an AWS DMS migration task for the primary data that is specific to the parent table and child table.</p>	
<p>Disable the primary keys and unique keys on the target database.</p>	<p>Using the following commands, disable the primary keys and constraints on the target database. This helps improve the performance of the initial load task.</p> <pre>ALTER TABLE &lt;table&gt; DISABLE PRIMARY KEY;</pre> <pre>ALTER TABLE &lt;table&gt; DISABLE CONSTRAINT &lt;constraint_name&gt;;</pre>	DBA, Developer
<p>Create the initial load task.</p>	<p>In AWS DMS, create the migration task for the initial load. For instructions, see <a href="#">Creating a task</a>. For the migration method, choose <b>Migrate existing data</b>. This migration method is called Full Load in the API. Do not start this task yet.</p>	DBA, Developer

Task	Description	Skills required
Edit task settings for the initial load task.	<p>Edit the task settings to add data validation. These validation settings must be created in a JSON file. For instructions and examples, see <a href="#">Specifying task settings</a>. Add the following validations:</p> <ul style="list-style-type: none"><li>• To validate that the VARCHAR2(1) data is accurately converted to Boolean in the target database, add the code in <i>Data validation script</i> in the <a href="#">Additional information</a> section of this pattern. The validation script converts the Boolean values of <b>1</b> to <b>Y</b> and <b>0</b> to <b>N</b> in the target table, and then it compares the values in the target table to the source table.</li></ul> <p>To validate the rest of the data migration, enable data validation in the task. For more information, see <a href="#">Data validation task settings</a>.</p>	AWS administrator, DBA

Task	Description	Skills required
Create the ongoing replication task.	In AWS DMS, create the migration task that keeps the target database in sync with the source database. For instructions, see <a href="#">Creating a task</a> . For the migration method, choose <b>Replicate data changes only</b> . Do not start this task yet.	DBA

## Test the migration tasks

Task	Description	Skills required
Create sample data for testing.	In the source database, create a sample table with data for testing purposes.	Developer
Confirm there are no conflicting activities.	Use the <code>pg_stat_activity</code> to check for any activity on the server that might affect the migration. For more information, see <a href="#">The Statistics Collector</a> (PostgreSQL documentation).	AWS administrator
Start the AWS DMS migration tasks.	In the AWS DMS console, on the <b>Dashboard</b> page, start the initial load and ongoing replication tasks that you created in the previous epic.	AWS administrator
Monitor the tasks and table load states.	During the migration, monitor the <a href="#">task status</a> and the <a href="#">table states</a> . When the initial load	AWS administrator

Task	Description	Skills required
	<p>task is complete, on the <b>Table statistics</b> tab:</p> <ul style="list-style-type: none"> <li>The <b>Load state</b> should be <b>Table completed</b>.</li> <li>The <b>Validation state</b> should be <b>Validated</b>.</li> </ul>	
Verify the migration results.	Using pgAdmin, query the table on target database. A successful query indicates that the data was migrated successfully.	Developer
Add primary keys and foreign keys on the target database.	Create the primary key and foreign key on the target database. For more information, see <a href="#">ALTER TABLE</a> (PostgreSQL website).	DBA
Clean up the test data.	On the source and target databases, clean up data that was created for unit testing.	Developer

## Cut over

Task	Description	Skills required
Complete the migration.	Repeat the previous epic, <i>Test the migration tasks</i> , using the real source data. This migrates the data from the source to the target database.	Developer
Validate that the source and target databases are in sync.	Validate that the source and target databases are in sync.	Developer

Task	Description	Skills required
	For more information and instructions, see <a href="#">AWS DMS data validation</a> .	
Stop the source database.	Stop the Amazon RDS for Oracle database. For instructions, see <a href="#">Stopping an Amazon RDS DB instance temporarily</a> . When you stop the source database, the initial load and ongoing replication tasks in AWS DMS are automatically stopped. No additional action is required to stop these tasks.	Developer

## Additional information

### Data validation script

The following data validation script converts **1** to **Y** and **0** to **N**. This helps the AWS DMS task successfully complete and pass the table validation.

```
{
  "rule-type": "validation",
  "rule-id": "5",
  "rule-name": "5",
  "rule-target": "column",
  "object-locator": {
    "schema-name": "ADMIN",
    "table-name": "TEMP_CHRA_BOOL",
    "column-name": "GRADE"
  },
  "rule-action": "override-validation-function",
  "target-function": "case grade when '1' then 'Y' else 'N' end"
}
```

The case statement in the script performs the validation. If validation fails, AWS DMS inserts a record in the **public.awsdms\_validation\_failures\_v1** table on the target database instance. This record includes the table name, error time, and details about the mismatched values in the source and target tables.

If you do not add this data validation script to the AWS DMS task and the data is inserted in the target table, the AWS DMS task shows validation state as **Mismatched Records**.

During AWS SCT conversion, the AWS DMS migration task changes the data type of VARCHAR2(1) data type to Boolean and adds a primary key constraint on the "NO" column.

# Create application users and roles in Aurora PostgreSQL-Compatible

Created by Abhishek Verma (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Any database	<b>Target:</b> PostgreSQL database
<b>R Type:</b> Re-architect	<b>Workload:</b> Open-source	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS; Amazon Aurora		

## Summary

When you migrate to Amazon Aurora PostgreSQL-Compatible Edition, the database users and roles that exist on the source database must be created in the Aurora PostgreSQL-Compatible database. You can create the users and roles in Aurora PostgreSQL-Compatible by using two different approaches:

- Use similar users and roles in the target as in the source database. In this approach, the data definition languages (DDLs) are extracted for users and roles from the source database. Then they are transformed and applied to the target Aurora PostgreSQL-Compatible database. For example, the blog post [Use SQL to map users, roles, and grants from Oracle to PostgreSQL](#) covers using extraction from an Oracle source database engine.
- Use standardized users and roles that are commonly used during development, administration, and for performing other related operations in the database. This includes read-only, read/write, development, administration, and deployment operations performed by the respective users.

This pattern contains the grants required for users and roles creation in Aurora PostgreSQL-Compatible required for the standardized users and roles approach. The user and role creation steps are aligned to the security policy of granting least privilege to the database users. The following table lists the users, their corresponding roles, and their details on the database.

Users	Roles	Purpose
-------	-------	---------

APP_read	APP_RO	Used for read-only access on the schema APP
APP_WRITE	APP_RW	Used for the write and read operations on the schema APP
APP_dev_user	APP_DEV	Used for the development purpose on the schema APP_DEV, with read-only access on the schema APP
Admin_User	rds_superuser	Used for performing administrator operations on the database
APP	APP_DEP	Used for creating the objects under the APP schema and for deployment of objects in the APP schema

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account
- A PostgreSQL database, Amazon Aurora PostgreSQL-Compatible Edition database, or Amazon Relational Database Service (Amazon RDS) for PostgreSQL database

### Product versions

- All versions of PostgreSQL

## Architecture

### Source technology stack

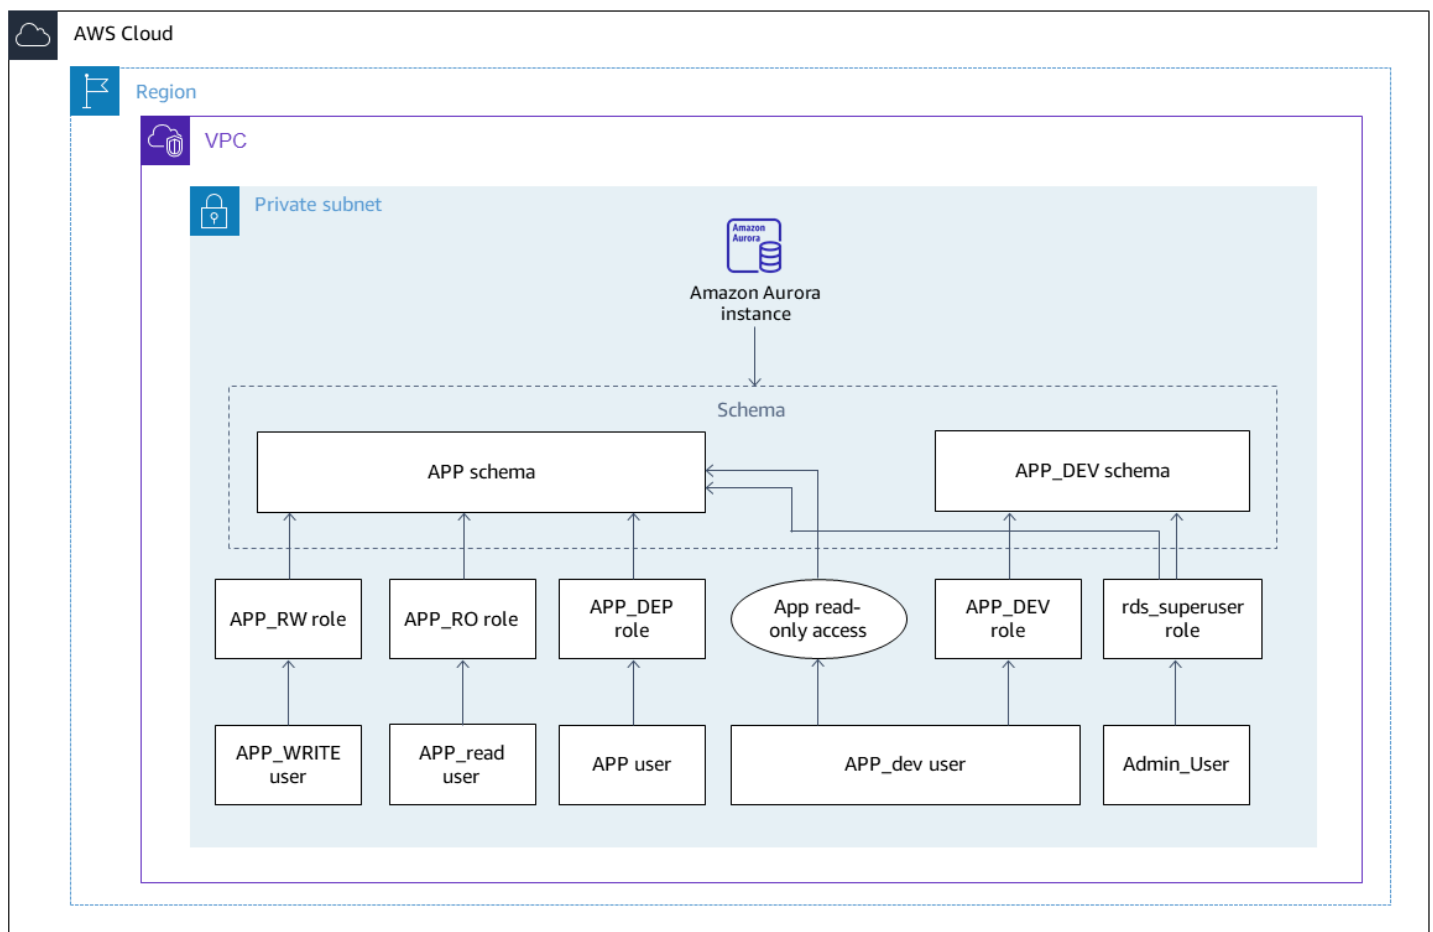

- Any database

## Target technology stack

- Amazon Aurora PostgreSQL-Compatible

## Target architecture

The following diagram shows user roles and the schema architecture in the Aurora PostgreSQL-Compatible database.

## Automation and scale

This pattern contains the users, roles, and schema creation script, which you can run multiple times without any impact to existing users of the source or target database.

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

### Other services

- [psql](#) is a terminal-based front-end tool that is installed with every PostgreSQL Database installation. It has a command line interface for running SQL, PL-PGSQL, and operating system commands.
- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Epics

### Create the users and roles

Task	Description	Skills required
Create the deployment user.	<p>The deployment user APP will be used to create and modify the database objects during deployments. Use the following scripts to create the deployment user role APP_DEP in the schema APP. Validate access rights to make sure this user has only the privilege to create objects in the required schema APP.</p> <ol style="list-style-type: none"><li>1. Connect to the admin user, and create the schema.</li></ol> <pre>CREATE SCHEMA APP;</pre>	DBA

Task	Description	Skills required
	<p>2. Create the user.</p> <pre>CREATE USER APP WITH PASSWORD &lt;password &gt; ;</pre> <p>3. Create the role.</p> <pre>CREATE ROLE APP_DEP ; GRANT all on schema APP to APP_DEP ; GRANT USAGE ON SCHEMA APP to APP_DEP ; GRANT connect on database &lt;db_name&gt; to APP_DEP ; GRANT APP_DEP to APP;</pre> <p>4. To test the privileges, connect to APP and create the tables.</p> <pre>set search_path to APP; SET CREATE TABLE test(id integer ) ; CREATE TABLE</pre> <p>5. Check the privileges.</p> <pre>select schemaname , tablename , tableowner r from pg_tables where tablename like 'test' ; schemaname   tablename   tableowner</pre>	

Task	Description	Skills required
	<pre>APP   test   APP</pre>	

Task	Description	Skills required
Create the read-only user.	<p>The read-only user APP_read will be used for performing the read-only operation in the schema APP. Use the following scripts to create the read-only user. Validate access rights to make sure that this user has privilege only to read the objects in the schema APP and for automatically granting read access for any new objects created in the schema APP.</p> <ol style="list-style-type: none"><li>1. Create the user APP_read.</li></ol> <pre data-bbox="634 953 1029 1150">create user APP_read ; alter user APP_read with password 'your_password' ;</pre> <ol style="list-style-type: none"><li>2. Create the role.</li></ol> <pre data-bbox="634 1241 1029 1717">CREATE ROLE APP_ro ; GRANT SELECT ON ALL TABLES IN SCHEMA APP TO APP_RO ; GRANT USAGE ON SCHEMA APP TO APP_RO GRANT CONNECT ON DATABASE testdb TO APP_RO ; GRANT APP_RO TO APP_read;</pre> <ol style="list-style-type: none"><li>3. To test the privileges, log in using the APP_read user.</li></ol>	DBA

Task	Description	Skills required
	<pre>set search_path to APP ; create table test1( id integer) ; ERROR: permission denied for schema APP LINE 1: create table test1( id integer) ; insert into test values (34) ; ERROR: permission denied for table test SQL state: 42501 select from test no rows selected</pre>	

Task	Description	Skills required
Create the read/write user.	<p>The read/write user <code>APP_WRITE</code> will be used to perform read and write operations on the schema <code>APP</code>. Use the following scripts to create the read/write user and grant it the <code>APP_RW</code> role. Validate access rights to make sure that this user has read and write privileges only on the objects in the schema <code>APP</code> and for automatically granting read and write access for any new object created in schema <code>APP</code>.</p> <ol style="list-style-type: none"><li>1. Create the user.</li></ol> <pre data-bbox="630 1045 1029 1289">CREATE USER APP_WRITE ; alter user APP_WRITE with password 'your_password' ;</pre> <ol style="list-style-type: none"><li>2. Create the role.</li></ol> <pre data-bbox="630 1373 1029 1787">CREATE ROLE APP_RW; GRANT SELECT, INSERT, UPDATE, DELETE ON ALL TABLES IN SCHEMA APP TO APP_RW ; GRANT CONNECT ON DATABASE postgres to APP_RW ; GRANT USAGE ON SCHEMA APP to APP_RW ;</pre>	

Task	Description	Skills required
	<pre>ALTER DEFAULT PRIVILEGES IN SCHEMA APP GRANT SELECT, INSERT, UPDATE, DELETE ON TABLES TO APP_RW ; GRANT APP_RW to APP_WRITE</pre> <p data-bbox="591 558 993 688">3. To test the privileges, log in using the APP_WRITE user.</p> <pre>SET SEARCH_PATH to APP; CREATE TABLE test1( id integer) ; ERROR: permission denied for schema APP LINE 1: create table test1( id integer) ; SELECT * FROM test ; id ---- 12 INSERT INTO test values (31) ; INSERT 0 1</pre>	

Task	Description	Skills required
Create the admin user.	<p>The admin user <code>Admin_User</code> will be used to perform admin operations on the database. Examples of these operations are <code>CREATE ROLE</code> and <code>CREATE DATABASE</code>. <code>Admin_User</code> uses the built-in role <code>rds_superuser</code> to perform admin operations on the database. Use the following scripts to create and test the privilege for the admin user <code>Admin_User</code> in the database.</p> <ol style="list-style-type: none"><li>1. Create the user and grant the role.</li></ol> <pre data-bbox="634 1052 1027 1367">create user Admin_User WITH PASSWORD 'Your password' ALTER user Admin_user CREATEDB; ALTER user Admin_user CREATEROLE;</pre> <ol style="list-style-type: none"><li>2. To test the privilege, log in from the <code>Admin_User</code> user.</li></ol> <pre data-bbox="634 1556 1027 1803">SELECT * FROM APP.test ; id ---- 31 CREATE ROLE TEST ;</pre>	DBA

Task	Description	Skills required
	<pre>CREATE DATABASE test123 ;</pre>	

Task	Description	Skills required
Create the development user.	<p>The development user <code>APP_dev_user</code> will have rights to create the objects in its local schema <code>APP_DEV</code> and read access in the schema <code>APP</code>. Use the following scripts to create and test the privileges of the user <code>APP_dev_user</code> in the database.</p> <ol style="list-style-type: none"><li>1. Create the user.</li></ol> <pre data-bbox="630 810 1029 968">CREATE USER APP1_dev_user with password 'your password';</pre> <ol style="list-style-type: none"><li>2. Create the <code>APP_DEV</code> schema for the <code>App_dev_user</code>.</li></ol> <pre data-bbox="630 1157 1029 1272">CREATE SCHEMA APP1_DEV ;</pre> <ol style="list-style-type: none"><li>3. Create the <code>APP_DEV</code> role.</li></ol> <pre data-bbox="630 1367 1029 1877">CREATE ROLE APP1_DEV ; GRANT APP1_R0 to APP1_DEV ; GRANT SELECT ON ALL TABLES IN SCHEMA APP1_DEV to APP1_dev_user GRANT USAGE, CREATE ON SCHEMA APP1_DEV to APP1_DEV_USER GRANT APP1_DEV to APP1_DEV_USER ;</pre>	DBA

Task	Description	Skills required
	<p>4. To test the privileges, log in from APP_dev_user .</p> <pre data-bbox="633 331 1031 970">CREATE TABLE APP1_dev.test1( id integer ); CREATE TABLE INSERT into APP1_dev.test1 ( select * from APP1.test ); INSERT 0 1 CREATE TABLE APP1.test4 ( id int) ; ERROR: permission denied for schema APP1 LINE 1: create table APP1.test4 ( id int) ;</pre>	

## Related resources

### PostgreSQL documentation

- [CREATE ROLE](#)
- [CREATE USER](#)
- [Predefined Roles](#)

## Additional information

### PostgreSQL 14 enhancement

PostgreSQL 14 provides a set of predefined roles that give access to certain commonly needed, privileged capabilities and information. Administrators (including roles that have the CREATE ROLE privilege) can grant these roles or other roles in their environment to users, providing them with access to the specified capabilities and information.

Administrators can grant users access to these roles using the GRANT command. For example, to grant the `pg_signal_backend` role to `Admin_User1`, you can run the following command.

```
GRANT pg_signal_backend TO Admin_User1;
```

The `pg_signal_backend` role is intended to allow administrators to enable trusted, non-superuser roles to send signals to other backends. For more information, see [PostgreSQL 14 enhancement](#).

### **Fine-tuning access**

In some cases, it might be necessary to provide more granular access to the users (for example, table-based access or column-based access). In such cases, additional roles can be created to grant those privileges to the users. For more information, see [PostgreSQL Grants](#).

# Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database

Created by HariKrishna Boorgadda (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> Aurora PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Modernization; Databases
<b>AWS services:</b> Amazon Aurora		

## Summary

Best practices for Enterprise disaster recovery (DR) basically consist of designing and implementing fault-tolerant hardware and software systems that can survive a disaster (*business continuance*) and resume normal operations (*business resumption*), with minimal intervention and, ideally, with no data loss. Building fault-tolerant environments to satisfy Enterprise DR objectives can be expensive and time consuming and requires a strong commitment by the business.

Oracle Database provides three different approaches to DR that provide the highest level of data protection and availability compared to any other approach for protecting Oracle data.

- Oracle Zero Data Loss Recovery Appliance
- Oracle Active Data Guard
- Oracle GoldenGate

This pattern provides a way to emulate the Oracle GoldenGate DR by using an Amazon Aurora global database. The reference architecture uses Oracle GoldenGate for DR across three AWS Regions. The pattern walks through the replatforming of the source architecture to the cloud-native Aurora global database based on Amazon Aurora PostgreSQL–Compatible Edition.

Aurora global databases are designed for applications with a global footprint. A single Aurora database spans multiple AWS Regions with as many as five secondary Regions. Aurora global databases provide the following features:

- Physical storage-level replication
- Low-latency global reads
- Fast disaster recovery from Region-wide outages
- Fast cross-Region migrations
- Low replication lag across Regions
- Little-to-no performance impact on your database

For more information about Aurora global database features and advantages, see [Using Amazon Aurora global databases](#). For more information about unplanned and managed failovers, see [Using failover in an Amazon Aurora global database](#).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Java Database Connectivity (JDBC) PostgreSQL driver for application connectivity
- An Aurora global database based on Amazon Aurora PostgreSQL-Compatible Edition
- An Oracle Real Application Clusters (RAC) database migrated to the Aurora global database based on Aurora PostgreSQL-Compatible

### Limitations of Aurora global databases

- Aurora global databases aren't available in all AWS Regions. For a list of supported Regions, see [Aurora global databases with Aurora PostgreSQL](#).
- For information about features that aren't supported and other limitations of Aurora global databases, see the [Limitations of Amazon Aurora global databases](#).

### Product versions

- Amazon Aurora PostgreSQL-Compatible Edition version 10.14 or later

## Architecture

### Source technology stack

- Oracle RAC four-node database
- Oracle GoldenGate

## Source architecture

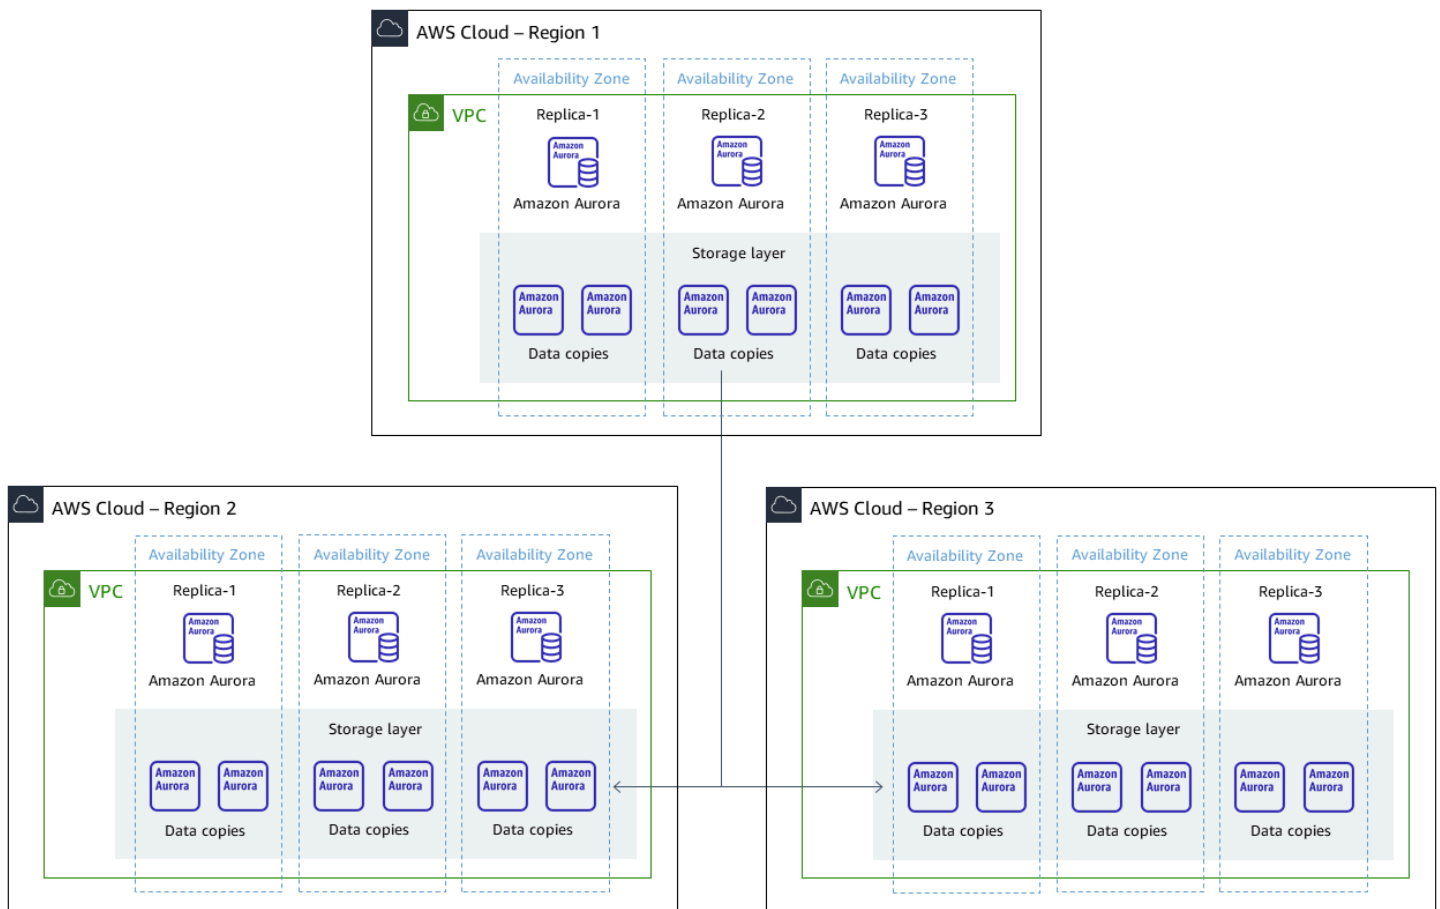

The following diagram shows three clusters with four-node Oracle RAC in different AWS Regions replicated using Oracle GoldenGate.

## Target technology stack

- A three-cluster Amazon Aurora global database based on Aurora PostgreSQL-Compatible, with one cluster in the primary Region, two clusters in different secondary Regions

## Target architecture

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Aurora global databases](#) span multiple AWS Regions, providing low latency global reads and fast recovery from the rare outage that might affect an entire AWS Region.

## Epics

### Add Regions with reader DB instances

Task	Description	Skills required
Attach one or more secondary Aurora clusters.	On the AWS Management Console, choose Amazon	DBA

Task	Description	Skills required
	Aurora. Select the primary cluster, choose <b>Actions</b> , and choose <b>Add region</b> from the dropdown list.	
Select the instance class.	You can change the instance class of the secondary cluster. However, we recommend keeping it the same as the primary cluster instance class.	DBA
Add the third Region.	Repeat the steps in this epic to add a cluster in the third Region.	DBA

## Fail over the Aurora global database

Task	Description	Skills required
Remove the primary cluster from the Aurora global database.	<ol style="list-style-type: none"> <li>On the Databases page, choose the primary cluster.</li> <li>Choose <b>Remove from Global</b> to fail over to a secondary cluster.</li> </ol>	DBA
Reconfigure your application to divert write traffic to the newly promoted cluster.	Modify the endpoint in the application with that of the newly promoted cluster.	DBA
Stop issuing any write operations to the unavailable cluster.	Stop the application and any data manipulation language (DML) activity to the cluster that you removed.	DBA
Create a new Aurora global database.	Now you can create an Aurora global database with the	DBA

Task	Description	Skills required
	newly promoted cluster as the primary cluster.	

## Start the primary cluster

Task	Description	Skills required
Select the primary cluster to be started from the global database.	On the Amazon Aurora console, in the Global Database setup, choose the primary cluster.	DBA
Start the cluster.	On the <b>Actions</b> dropdown list, choose <b>Start</b> . This process might take some time. Refresh the screen to see the status, or check the <b>Status</b> column for the current state of the cluster after the operation is completed.	DBA

## Clean up the resources

Task	Description	Skills required
Delete the remaining secondary clusters.	After the failover pilot is completed, remove the secondary clusters from the global database.	DBA
Delete the primary cluster.	Remove the cluster.	DBA

# Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT

*Created by Pinesh Singal (AWS)*

<b>Environment:</b> PoC or pilot	<b>Source:</b> Amazon RDS for Oracle	<b>Target:</b> Amazon RDS for PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases; Modernization
<b>AWS services:</b> Amazon EC2; Amazon RDS		

## Summary

Many migration strategies and approaches run in multiple phases that can last from a few weeks to several months. During this time, you can experience delays because of patching or upgrades in the source Oracle DB instances that you want to migrate to PostgreSQL DB instances. To avoid this situation, we recommend that you incrementally migrate the remaining Oracle database code to PostgreSQL database code.

This pattern provides an incremental migration strategy with no downtime for a multi-terabyte Oracle DB instance that has a high number of transactions performed after your initial migration and that must be migrated to a PostgreSQL database. You can use this pattern's step-by-step approach to incrementally migrate an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance without signing in to the Amazon Web Services (AWS) Management Console.

The pattern uses [Oracle SQL Developer](#) to find the differences between two schemas in the source Oracle database. You then use AWS Schema Conversion Tool (AWS SCT) to convert the Amazon RDS for Oracle database schema objects to Amazon RDS for PostgreSQL database schema objects. You can then run a Python script in the Windows Command Prompt to create AWS SCT objects for the incremental changes to the source database objects.

**Note:** Before you migrate your production workloads, we recommend that you run a proof of concept (PoC) for this pattern's approach in a testing or non-production environment.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing Amazon RDS for Oracle DB instance.
- An existing Amazon RDS for PostgreSQL DB instance.
- AWS SCT, installed and configured with JDBC drivers for Oracle and PostgreSQL database engines. For more information about this, see [Installing AWS SCT](#) and [Installing the required database drivers](#) in the AWS SCT documentation.
- Oracle SQL Developer, installed and configured. For more information about this, see the [Oracle SQL Developer](#) documentation.
- The `incremental-migration-sct-sql.zip` file (attached), downloaded to your local computer.

### Limitations

- The minimum requirements for your source Amazon RDS for Oracle DB instance are:
  - Oracle versions 10.2 and later (for versions 10.x), 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c for the Enterprise, Standard, Standard One, and Standard Two editions
- The minimum requirements for your target Amazon RDS for PostgreSQL DB instance are:
  - PostgreSQL versions 9.4 and later (for versions 9.x), 10.x, and 11.x
- This pattern uses Oracle SQL Developer. Your results might vary if you use other tools to find and export schema differences.
- The [SQL scripts](#) generated by Oracle SQL Developer can raise transformation errors, which means that you need to perform a manual migration.
- If the AWS SCT source and target test connections fail, make sure that you configure the JDBC driver versions and inbound rules for the virtual private cloud (VPC) security group to accept incoming traffic.

### Product versions

- Amazon RDS for Oracle DB instance version 12.1.0.2 (version 10.2 and later)
- Amazon RDS for PostgreSQL DB instance version 11.5 (version 9.4 and later)

- Oracle SQL Developer version 19.1 and later
- AWS SCT version 1.0.632 and later

## Architecture

### Source technology stack

- Amazon RDS for Oracle DB instance

### Target technology stack

- Amazon RDS for PostgreSQL DB instance

### Source and target architecture

The following diagram shows the migration of an Amazon RDS for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance.

The diagram shows the following migration workflow:

1. Open Oracle SQL Developer and connect to the source and target databases.
2. Generate a [diff report](#) and then generate the SQL scripts file for the schema difference objects. For more information about diff reports, see [Detailed diff reports](#) in the Oracle documentation.

3. Configure AWS SCT and run the Python code.
4. The SQL scripts file converts from Oracle to PostgreSQL.
5. Run the SQL scripts file on the target PostgreSQL DB instance.

## Automation and scale

You can automate this migration by adding additional parameters and security-related changes for multiple functionalities in a single program to your Python script.

## Tools

- [AWS SCT](#) – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another.
- [Oracle SQL Developer](#) – Oracle SQL Developer is an integrated development environment (IDE) that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.

## Code

The `incremental-migration-sct-sql.zip` file (attached) contains the complete source code for this pattern.

## Epics

### Create the SQL scripts file for the source database schema differences

Task	Description	Skills required
Run Database Diff in Oracle SQL Developer.	<ol style="list-style-type: none"><li>1. Sign in to your source Oracle DB instance, choose <b>Tools</b>, and then choose <b>Database Diff</b>.</li><li>2. Choose your source database in <b>Source Connection</b>.</li></ol>	DBA

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>Choose the updated or patched source database in <b>Destination Connection</b>.</li> <li>Configure the remaining options according to your requirements, choose <b>Next</b>, and then choose <b>Finish</b> to generate the diff report.</li> </ol>	
Generate the SQL scripts file.	<p>Choose <b>Generate Script</b> to generate the differences in the SQL files.</p> <p>This generates the SQL scripts file that AWS SCT uses to convert your database from Oracle to PostgreSQL.</p>	DBA

### Use the Python script to create the target DB objects in AWS SCT

Task	Description	Skills required
Configure AWS SCT with the Windows Command Prompt.	<ol style="list-style-type: none"> <li>Copy the <code>AWSSchemaConversionToolBatch.jar</code> file from your pre-installed AWS SCT folder and paste it into your working directory.</li> <li>Deploy the Python code from the <code>run_aws_sct_sql.py</code> file from the <code>incremental-migration-sct-sql.zip</code> folder (attached</li> </ol>	DBA

Task	Description	Skills required
	<p>           ). This creates .xml files and .sct files in the projects directory with your source and target database environment configuration details. It also reads the SQL scripts file that you generated in Oracle SQL Developer . Finally, it creates .sql file objects in the output directory.         </p> <p>           3. Configure the source and target environment configuration details in the database_migration .txt file by using the following format:         </p> <pre data-bbox="609 1144 1031 1871"> #source_vendor,source_hostname,source_dbname,source_user,source_pwd,source_schema,source_port,source_sid,target_vendor,target_hostname,target_user,target_pwd,target_dbname,target_port  ORACLE,myoracledb.cokmvis0v46q.us-east-1.rds.amazonaws.com,ORCL,orcl,orcl1234,orcl,1521,ORCL,POSTGRESQL,mypgdbinstance.cokmvis0v46 </pre>	

Task	Description	Skills required
	<pre>q.us-east-1.rds.amazonaws.com,pguser,pgpassword,pgdb,5432</pre> <p>4. Modify the AWS SCT configuration parameters according to your requirements and then copy the SQL scripts file into your working directory in the input subdirectory.</p>	
Run the Python script.	<ol style="list-style-type: none"> <li>1. Run the Python script by using the following command: <code>\$ python run_aws_sct_sql.py database_migration.txt</code></li> <li>2. This creates the DB objects SQL file. Non-converted codes with transformation errors can be manually converted.</li> </ol>	DBA
Create the objects in Amazon RDS for PostgreSQL	Run the SQL files and create objects in your Amazon RDS for PostgreSQL DB instance.	DBA

# Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible

Created by *Bhanu Ganesh Gudivada (AWS)* and *Jeevan Shetty (AWS)*

<b>Environment:</b> Production	<b>Source:</b> On-premises Oracle Database	<b>Target:</b> Aurora PostgreSQL-Compatible
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle; Open-source	<b>Technologies:</b> Migration; Databases

**AWS services:** Amazon Aurora

## Summary

Often during migration, there are cases where you have to process unstructured and structured data that is loaded from files on a local file system. The data might also be in a character set that differs from the database character set.

These files hold the following types of data:

- **Metadata** – This data describes the file structure.
- **Semi-structured data** – These are textual strings in a specific format, such as JSON or XML. You might be able to make assertions about such data, such as "will always start with '<' " or "does not contain any newline characters."
- **Full text** – This data usually contains all types of characters, including newline and quote characters. It might also consist of multibyte characters in UTF-8.
- **Binary data** – This data might contain bytes or combinations of bytes including, nulls and end-of-file markers.

Loading a mixture of these types of data can be a challenge.

The pattern can be used with on-premises Oracle databases , Oracle databases that are on Amazon Elastic Compute Cloud (Amazon EC2) instances on the Amazon Web Services (AWS) Cloud, and

Amazon Relational Database Service (Amazon RDS) for Oracle databases. As an example, this pattern is using Amazon Aurora PostgreSQL-Compatible Edition.

In Oracle Database, with the help of a BFILE (binary file) pointer, the DBMS\_LOB package, and Oracle system functions, you can load from file and convert to CLOB with character encoding. Because PostgreSQL does not support the BLOB data type when migrating to an Amazon Aurora PostgreSQL-Compatible Edition database, these functions must be converted to PostgreSQL-compatible scripts.

This pattern provides two approaches for loading a file into a single database column in an Amazon Aurora PostgreSQL-Compatible database:

- Approach 1 – You import data from your Amazon Simple Storage Service (Amazon S3) bucket by using the `table_import_from_s3` function of the `aws_s3` extension with the `encode` option.
- Approach 2 – You encode to hexadecimal outside of the database, and then you decode to view TEXT inside the database.

We recommend using Approach 1 because Aurora PostgreSQL-Compatible has direct integration with the `aws_s3` extension.

This pattern uses the example of loading a flat file that contains an email template, which has multibyte characters and distinct formatting, into an Amazon Aurora PostgreSQL-Compatible database.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon RDS instance or an Aurora PostgreSQL-Compatible instance
- A basic understanding of SQL and Relational Database Management System (RDBMS)
- An Amazon Simple Storage Service (Amazon S3) bucket.
- Knowledge of system functions in Oracle and PostgreSQL
- RPM Package HexDump-XXD-0.1.1 (included with Amazon Linux 2)

### Limitations

- For the TEXT data type, the longest possible character string that can be stored is about 1 GB.

## Product versions

- Aurora supports the PostgreSQL versions listed in [Amazon Aurora PostgreSQL updates](#).

## Architecture

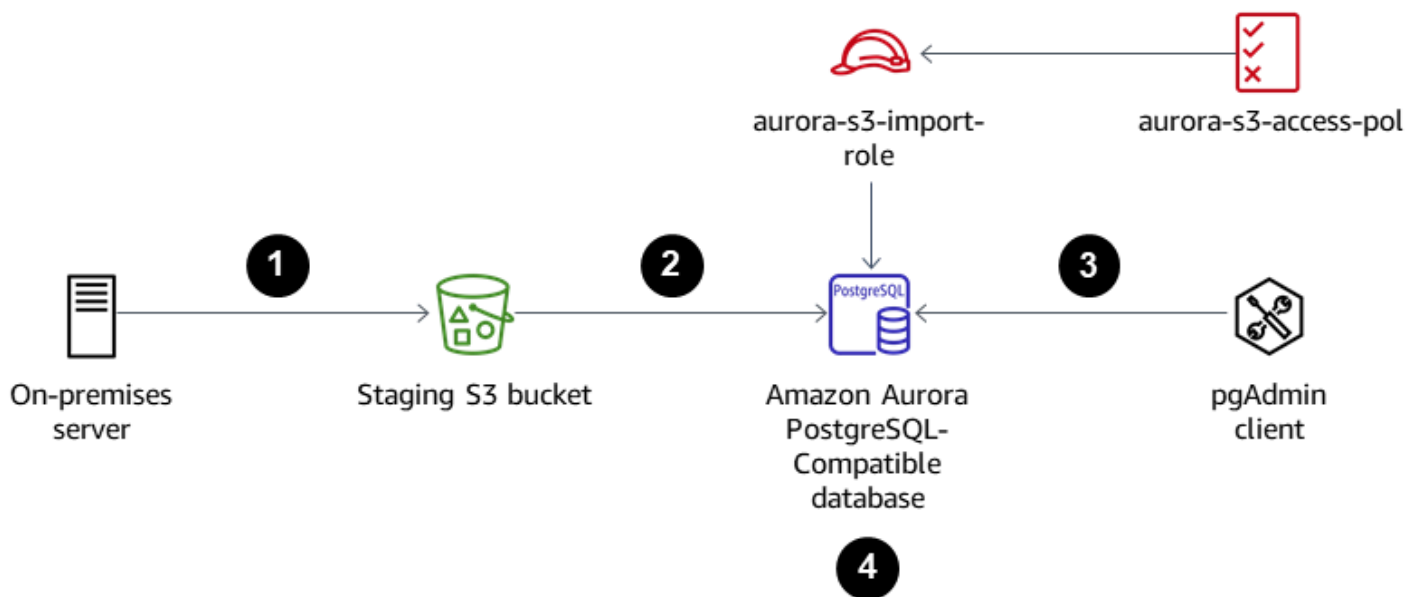

### Target technology stack

- Aurora PostgreSQL-Compatible

### Target architecture

#### Approach 1 – Using `aws_s3.table_import_from_s3`

From an on-premises server, a file containing an email template with multibyte characters and custom formatting is transferred to Amazon S3. The custom database function provided by this pattern uses the `aws_s3.table_import_from_s3` function with `file_encoding` to load files into the database and return query results as the TEXT data type.

1. Files are transferred to the staging S3 bucket.
2. Files are uploaded to the Amazon Aurora PostgreSQL-Compatible database.
3. Using the pgAdmin client, the custom function `load_file_into_clob` is deployed to the Aurora database.

- The custom function internally uses `table_import_from_s3` with `file_encoding`. The output from the function is obtained by using `array_to_string` and `array_agg` as TEXT output.

*Approach 2 – Encoding to hexadecimal outside of the database and decoding to view TEXT inside the database*

A file from an on-premises server or a local file system is converted into a hex dump. Then the file is imported into PostgreSQL as a TEXT field.

- Convert the file to a hex dump in the command line by using the `xxd -p` option.
- Upload the hex dump files into Aurora PostgreSQL-Compatible by using the `\copy` option, and then decode the hex dump files to binary.
- Encode the binary data to return as TEXT.

## Tools

### AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

## Other tools

- [pgAdmin4](#) is an open source administration and development platform for PostgreSQL. pgAdmin4 can be used on Linux, Unix, mac OS, and Windows to manage PostgreSQL.

## Epics

### Approach 1: Import data from Amazon S3 to Aurora PostgreSQL-Compatible

Task	Description	Skills required
Launch an EC2 instance.	For instructions on launching an instance, see <a href="#">Launch your instance</a> .	DBA
Install the PostgreSQL client pgAdmin tool.	Download and install <a href="#">pgAdmin</a> .	DBA
Create an IAM policy.	<p>Create an AWS Identity and Access Management (IAM) policy named <code>aurora-s3-access-pol</code> that grants access to the S3 bucket where the files will be stored. Use the following code, replacing <code>&lt;bucket-name&gt;</code> with the name of your S3 bucket.</p> <pre> {   "Version":   "2012-10-17",   "Statement": [     {       "Effect":       "Allow",       "Action": [         "s3:GetObject", </pre>	DBA

Task	Description	Skills required
	<pre>"s3:AbortMultipart Upload",  "s3:DeleteObject",  "s3:ListMultipartU ploadParts",  "s3:PutObject",  "s3:ListBucket"     ],     "Resource":   [      "arn:aws:s3:::&lt;buc ket-name&gt;/*",      "arn:aws:s3:::&lt;buc ket-name&gt;"       ]     }   ] }</pre>	

Task	Description	Skills required
Create an IAM role for object import from Amazon S3 to Aurora PostgreSQL-Compatible.	<p>Use the following code to create an IAM role named <code>aurora-s3-import-role</code> with the <a href="#">AssumeRole</a> trust relationship. <code>AssumeRole</code> allows Aurora to access other AWS services on your behalf.</p> <pre data-bbox="597 636 1026 1272">{   "Version": "2012-10-17",   "Statement": [     {       "Effect": "Allow", "Principal": {       "Service": "rds.amazonaws.com"     }, "Action": "sts:AssumeRole"   } ]</pre>	DBA

Task	Description	Skills required
Associate the IAM role to the cluster.	<p>To associate the IAM role with the Aurora PostgreSQL-Compatible database cluster, run the following AWS CLI command. Change <code>&lt;Account-ID&gt;</code> to the ID of the AWS account that hosts the Aurora PostgreSQL-Compatible database. This enables the Aurora PostgreSQL-Compatible database to access the S3 bucket.</p> <pre data-bbox="594 825 1027 1220">aws rds add-role-to-db-cluster --db-cluster-identifier aurora-postgres-cl --feature-name s3Import --role-arn arn:aws:iam::<account-id>:role/aurora-s3-import-role</account-id></pre>	DBA
Upload the example to Amazon S3.	<ol style="list-style-type: none"> <li>In the <i>Additional information</i> section of this pattern, copy the email template code into a file named <code>salary.event.notification.email.vm</code>.</li> <li>Upload the file to the S3 bucket.</li> </ol>	DBA, App owner

Task	Description	Skills required
Deploy the custom function.	<ol style="list-style-type: none"><li data-bbox="594 226 1026 499">1. From the <i>Additional information</i> section, copy the custom function <code>load_file_into_clob</code> SQL file content into a temporary table.</li><li data-bbox="594 525 1026 751">2. Log in to the Aurora PostgreSQL-Compatible database and deploy it into the database schema by using the pgAdmin client.</li></ol>	App owner, DBA

Task	Description	Skills required
Run the custom function for importing the data into the database.	<p>Run the following SQL command, replacing the items in angle brackets with the appropriate values.</p> <pre data-bbox="597 443 1027 758">select load_file _into_clob('aws-s3 -import-test'::text, 'us-west-1'::text, 'employee.salary .event.notification .email.vm'::text);</pre> <p>Replace the items in angle brackets with the appropriate values, as shown in the following example, before running the command.</p> <pre data-bbox="597 1062 1027 1377">Select load_file _into_clob('aws-s3 -import-test'::text, 'us-west-1'::text, 'employee.salary .event.notification .email.vm'::text);</pre> <p>The command loads the file from Amazon S3 and returns the output as TEXT.</p>	App owner, DBA

## Approach 2: Convert the template file into a hex dump in a local Linux system

Task	Description	Skills required
Convert the template file into a hex dump.	<p>The Hexdump utility displays the contents of binary files in hexadecimal, decimal, octal, or ASCII. The hexdump command is part of the <code>util-linux</code> package and comes pre-installed in Linux distributions. The Hexdump RPM package is part of Amazon Linux 2 as well.</p> <p>To convert the file contents into a hex dump, run the following shell command.</p> <pre>xxd -p &lt;/path/file.vm&gt;   tr -d '\n' &gt; &lt;/path/ file.hex&gt;</pre> <p>Replace the path and file with the appropriate values, as shown in the following example.</p> <pre>xxd -p employee. salary.event.notif ication.email.vm   tr -d '\n' &gt; employee. salary.event.notif ication.email.vm.hex</pre>	DBA
Load the hexdump file into the database schema.	Use the following commands to load the hexdump file	DBA

Task	Description	Skills required
	<p>into the Aurora PostgreSQL-Compatible database.</p> <ol style="list-style-type: none"><li data-bbox="592 338 1027 520">1. Log in to Aurora PostgreSQL database, and create a new table called <code>email_template_hex</code> .</li></ol> <pre data-bbox="634 554 1027 709">CREATE TABLE email_template_hex(hex_data TEXT);</pre> <ol style="list-style-type: none"><li data-bbox="592 730 1027 913">2. Load the files from the local file system into the DB schema by using the following command.</li></ol> <pre data-bbox="634 947 1027 1102">\copy email_template_hex FROM '/path/file.hex';</pre> <p data-bbox="630 1142 1000 1272">Replace the path with the location on your local file system.</p> <pre data-bbox="634 1306 1027 1545">\copy email_template_hex FROM '/tmp/employee.salary.event.notification.email.vm.hex';</pre> <ol style="list-style-type: none"><li data-bbox="592 1566 1027 1694">3. Create one more table called <code>email_template_bytea</code> .</li></ol>	

Task	Description	Skills required
	<pre data-bbox="634 212 1027 365">CREATE TABLE email_template_bytea(hex_data bytea);</pre> <p data-bbox="591 384 976 562">4. Insert the data from <code>email_template_hex</code> into <code>email_template_bytea</code> .</p> <pre data-bbox="634 600 1027 953">INSERT INTO email_template_bytea (hex_data) (SELECT decode(hex_data, 'hex') FROM email_template_hex limit 1);</pre> <p data-bbox="591 972 976 1104">5. To return hex bytea code as TEXT data, run the following command.</p> <pre data-bbox="634 1142 1027 1377">SELECT encode(hex_data::bytea, 'escape') FROM email_template_bytea;</pre>

# Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS

Created by Pinesh Singal (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Amazon RDS for Oracle	<b>Target:</b> Amazon RDS PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle; Open-source	<b>Technologies:</b> Migration; Security, identity, compliance; Databases; Analytics; Data lakes
<b>AWS services:</b> AWS DMS; Amazon RDS; AWS SCT; AWS Management Console; Amazon Connect; Amazon CloudWatch Logs; Amazon CloudWatch		

## Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database instance to an Amazon RDS for PostgreSQL database on the Amazon Web Services (AWS) Cloud. To encrypt connections between the databases, the pattern uses certificate authority (CA) and SSL mode in Amazon RDS and AWS Database Migration Service (AWS DMS).

The pattern describes an online migration strategy with little or no downtime for a multi-terabyte Oracle source database with a high number of transactions. For data security, the pattern uses SSL when transferring the data.

This pattern uses AWS Schema Conversion Tool (AWS SCT) to convert the Amazon RDS for Oracle database schema to an Amazon RDS for PostgreSQL schema. Then the pattern uses AWS DMS to migrate data from the Amazon RDS for Oracle database to the Amazon RDS for PostgreSQL database.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Amazon RDS database certificate authority (CA) configured with *rds-ca-rsa2048-g1* only
  - The rds-ca-2019 certificate is set to expire in August 2024
  - The rds-ca-2015 certificate expired on March 5, 2020
- AWS SCT
- AWS DMS
- pgAdmin
- SQL tools (for example, SQL Developer or SQL\*Plus)

### Limitations

- Amazon RDS for Oracle database – The minimum requirement is for Oracle versions 19c for the Enterprise and Standard Two editions.
- Amazon RDS for PostgreSQL database – The minimum requirement is for PostgreSQL version 12 and later (for versions 9.x and later).

### Product versions

- Amazon RDS for Oracle database version 12.1.0.2 instance
- Amazon RDS for PostgreSQL database version 11.5 instance

## Architecture

### Source technology stack

- An Amazon RDS for Oracle database instance with version 12.1.0.2.v18.

### Target technology stack

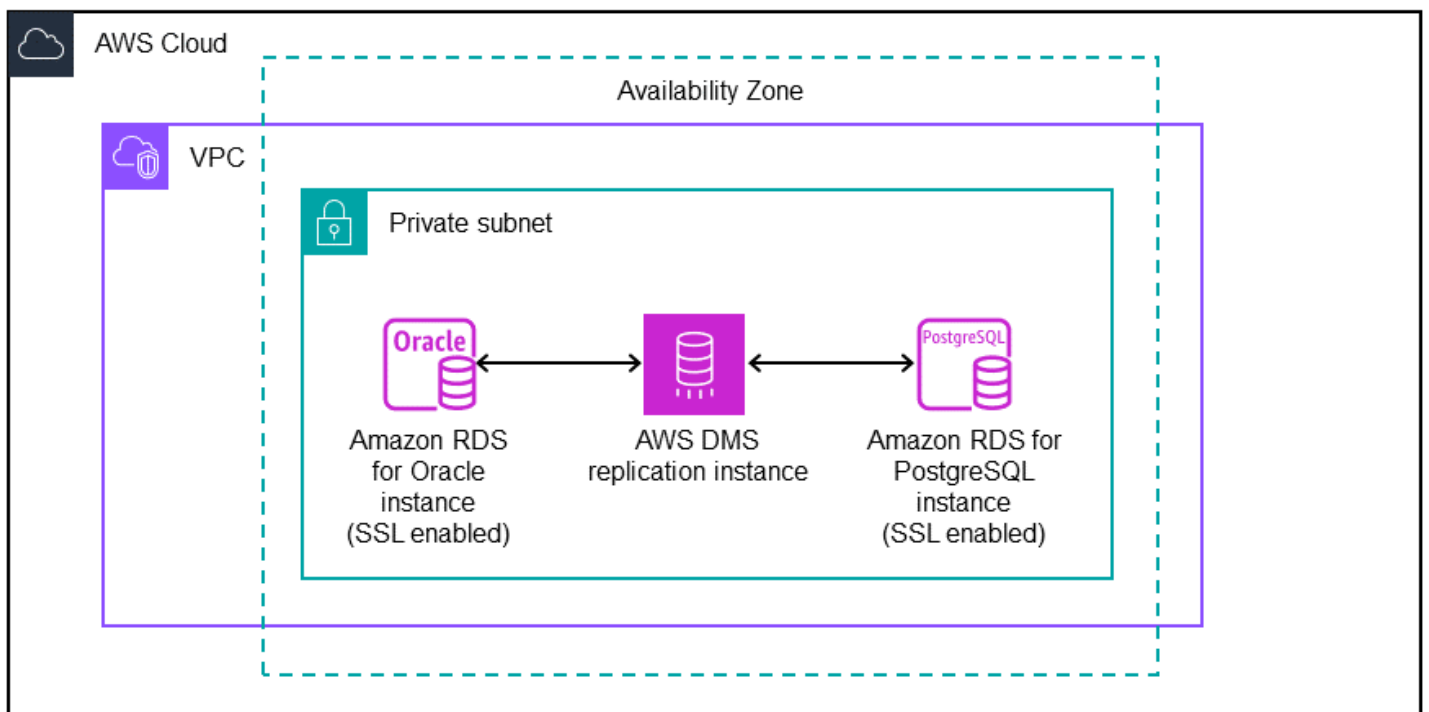

- AWS DMS
- An Amazon RDS for PostgreSQL database instance with version 11.5.

## Target architecture

The following diagram shows the architecture for data migration architecture between Oracle (source) and PostgreSQL (target) databases. The architecture includes the following:

- A virtual private cloud (VPC)
- An Availability Zone
- A private subnet
- An Amazon RDS for Oracle database
- An AWS DMS replication instance
- An RDS for PostgreSQL database

To encrypt connections for source and target databases, CA and SSL mode must be enabled in Amazon RDS and AWS DMS.

## Tools

### AWS services

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

- [Amazon Relational Database Service \(Amazon RDS\) for Oracle](#) helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

## Other services

- [pgAdmin](#) is an open source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Best practices

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

If your RDS instance is currently on CA certificate `rds-ca-2019`, and you want to upgrade to `rds-ca-rsa2048-g1`, follow the instructions in [Updating your CA certificate by modifying your DB instance or cluster](#) or [Updating your CA certificate by applying maintenance](#).

## Epics

### Configure the Amazon RDS for Oracle instance

Task	Description	Skills required
Create the Oracle database instance.	Sign in to your AWS account, open the AWS Management Console, and navigate to the Amazon RDS console. On the console, choose <b>Create database</b> , and then choose <b>Oracle</b> .	General AWS, DBA

Task	Description	Skills required
Configure security groups.	Configure inbound and outbound security groups.	General AWS
Create an option group.	Create an option group in the same VPC and security group as the Amazon RDS for Oracle database. For <b>Option</b> , choose <b>SSL</b> . For <b>Port</b> , choose <b>2484</b> (for SSL connections).	General AWS
Configure the option settings.	Use the following settings: <ul style="list-style-type: none"><li>• <code>SQLNET.CIPHER_SUITE : SSL_RSA_WITH_AES_256_CBC_SHA</code></li><li>• <code>SQLNET.SSL_VERSION : 1.2 or 1.0</code></li></ul>	General AWS
Modify the RDS for Oracle DB instance.	Set the CA certificate as <b>rds-ca-rsa2048-g1</b> .  Under <b>Option group</b> , attach the previously created option group.	DBA, General AWS

Task	Description	Skills required
Confirm that the RDS for Oracle DB instance is available.	<p>Make sure that the Amazon RDS for Oracle database instance is up and running and that the database schema is accessible.</p> <p>To connect to the RDS for Oracle DB, use the <code>sqlplus</code> command from the command line.</p> <pre data-bbox="597 716 1026 1787">\$ sqlplus orcl/**** @myoracledb.cokmvi s0v46q.us-east-1.r ds.amazonaws.com:1 521/ORCL SQL*Plus: Release 12.1.0.2.0 Production on Tue Oct 15 18:11:07 2019 Copyright (c) 1982, 2016, Oracle. All rights reserved. Last Successful login time: Mon Dec 16 2019 23:17:31 +05:30 Connected to: Oracle Database 12c Enterprise Edition Release 12.1.0.2.0 - 64bit Production With the Partition ing, OLAP, Advanced Analytics and Real Application Testing options SQL&gt;</pre>	DBA

Task	Description	Skills required
Create objects and data in the RDS for Oracle database.	Create objects and insert data in the schema.	DBA

## Configure the Amazon RDS for PostgreSQL instance

Task	Description	Skills required
Create the RDS for PostgreSQL database.	On the Amazon RDS console <b>Create database</b> page, choose <b>PostgreSQL</b> to create an Amazon RDS for PostgreSQL database instance.	DBA, General AWS
Configure security groups.	Configure inbound and outbound security groups.	General AWS
Create a parameter group.	If you are using PostgreSQL version 11.x, create a parameter group to set SSL parameters. In PostgreSQL version 12, the SSL parameter group is enabled by default.	General AWS
Edit parameters.	Change the <code>rds.force_ssl</code> parameter to 1 (on).  By default, the <code>ssl</code> parameter is 1 (on). By setting the <code>rds.force_ssl</code> parameter to 1, you force all connections to connect through SSL mode only.	General AWS

Task	Description	Skills required
Modify the RDS for PostgreSQL DB instance.	<p>Set the CA certificate as <b>rds-ca-rsa2048-g1</b>.</p> <p>Attach the default parameter group or the previously created parameter group, depending on your PostgreSQL version.</p>	DBA, General AWS

Task	Description	Skills required
Confirm that the RDS for PostgreSQL DB instance is available.	<p>Make sure that the Amazon RDS for PostgreSQL database is up and running.</p> <p>The <code>psql</code> command establishes an SSL connection with <code>sslmode</code> set from the command line.</p> <p>One option is to set <code>sslmode=1</code> in the parameter group and use a <code>psql</code> connection without including the <code>sslmode</code> parameter in the command.</p> <p>The following output shows that the SSL connection is established.</p> <pre data-bbox="602 1115 1027 1856">\$ psql -h mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com -p 5432 "dbname=pgdb user=pguser" Password for user pguser: psql (11.3, server 11.5) SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256, compression: off) Type "help" for help. pgdb=&gt;</pre>	DBA

Task	Description	Skills required
	<p>A second option is to set <code>sslmode=1</code> in the parameter group and to include the <code>sslmode</code> parameter in the <code>psql</code> command.</p> <p>The following output shows that the SSL connection is established.</p> <pre data-bbox="602 695 1027 1413"> \$ psql -h mypgdbins tance.cokmvis0v46q .us-east-1.rds.ama zonaws.com -p 5432 "dbname=pgdb user=pgus er sslmode=require" Password for user pguser: psql (11.3, server 11.5) SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA- AES256-GCM-SHA384, bits: 256, compressi on: off) Type "help" for help. pgdb=&gt;</pre>	

## Configure and run AWS SCT

Task	Description	Skills required
Install AWS SCT.	Install the latest version of the AWS SCT application.	General AWS

Task	Description	Skills required
Configure AWS SCT with JDBC drivers.	<p>Download the Java Database Connectivity (JDBC) drivers for Oracle (<a href="#">ojdbc8.jar</a>) and PostgreSQL (<a href="#">postgresql-42.2.5.jar</a>).</p> <p>To configure the drivers in AWS SCT, choose <b>Settings, Global settings, Drivers</b>.</p>	General AWS

Task	Description	Skills required
Create the AWS SCT project.	<p>Create the AWS SCT project and report, using Oracle as the source DB engine and Amazon RDS for PostgreSQL as the target DB engine:</p> <ol style="list-style-type: none"><li>1. Test connections to the source Oracle database and target Amazon RDS for PostgreSQL database by providing connection details.</li></ol> <p>For the source Oracle database, the following permissions or privileges are required:</p> <ul style="list-style-type: none"><li>• CONNECT</li><li>• SELECT_CATALOG_ROLE</li><li>• SELECT ANY DICTIONARY</li><li>• SELECT on SYS.USER\$ TO &lt;sct_user&gt;</li></ul> <p>For more information, see <a href="#">Using Oracle Database as a source for AWS SCT</a>.</p> <p>Both source and target connections must be successful before AWS SCT can start the migration report.</p>	General AWS

Task	Description	Skills required
	<ol style="list-style-type: none"> <li>After the report, enter the schema to be converted, and choose <b>Finish</b>.</li> </ol>	
Validate database objects.	<ol style="list-style-type: none"> <li>Choose <b>Load schema</b>.  AWS SCT displays the source and the converted target objects, including objects that have errors. Update any incorrect objects on the target database.</li> <li>Review the errors, and clear them by using manual intervention.</li> <li>After all errors are cleared, choose <b>Load schema</b> again.</li> <li>Choose <b>Apply to database</b>.</li> <li>Connect to pgAdmin, or any tool that supports a PostgreSQL DB connection, and check the schema and objects.</li> </ol>	DBA, General AWS

## Configure and run AWS DMS

Task	Description	Skills required
Create a replication instance.	<ol style="list-style-type: none"> <li>Sign in to your account, open the AWS Management Console, and navigate to the AWS DMS console.</li> </ol>	General AWS

Task	Description	Skills required
	2. Create a replication instance with valid settings for the VPC, security group, Availability Zone, and extra connection attributes.	
Import the certificate.	<p>Download the <a href="#">certificate bundle (PEM)</a> for your AWS Region.</p> <p>The bundle contains both the <code>rds-ca-2019</code> intermediate and root certificates. The bundle also contains the <code>rds-ca-rsa2048-g1</code>, <code>rds-ca-rsa4096-g1</code>, and <code>rds-ca-ecc384-g1</code> root CA certificates. Your application trust store needs to register only the root CA certificate.</p>	General AWS

Task	Description	Skills required
Create the source endpoint.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 688">1. Create a source endpoint for Amazon RDS for Oracle by choosing <b>Select RDS DB instance</b> and then selecting the RDS for Oracle DB instance that you created. The endpoint configuration details will be automatically populated .</li><li data-bbox="592 716 1027 890">2. Choose <b>Provide access information manually</b>. For <b>Port</b>, make sure that you enter <b>2484</b>.</li><li data-bbox="592 917 1027 1188">3. Under <b>Secure Socket Layer (SSL) mode</b>, choose <code>verify-ca</code> , and then choose the CA certificate that you created previously.</li><li data-bbox="592 1215 1027 1486">4. Under <b>Endpoint settings</b>, add the extra connection attribute <code>NumberDataTypesScale=-2</code> to support the NUMBER data type with no size.</li></ol> <p data-bbox="592 1562 1027 1736">For more information, see <a href="#">Using an Oracle database as a source for AWS Database Migration Service</a>.</p>	General AWS

Task	Description	Skills required
Create the target endpoint.	<ol style="list-style-type: none"><li>1. Create a target endpoint for Amazon RDS for PostgreSQL by choosing <b>Select RDS DB instance</b> and then selecting your RDS for PostgreSQL DB instance. The endpoint configuration details will be automatically populated .</li><li>2. Choose <b>Provide access information manually</b>. For <b>Port</b>, make sure that you enter <b>2484</b>.</li></ol> <p>For more information, see <a href="#">Using a PostgreSQL database as a target for AWS Database Migration Service</a>.</p>	General AWS
Test the endpoints.	<ol style="list-style-type: none"><li>1. Test the source and target endpoints to confirm that both are successful and available.</li><li>2. If a test fails, make sure that the security group inbound rules are valid.</li></ol>	General AWS

Task	Description	Skills required
Create migration tasks.	<p>To create a migration task for full load and change data capture (CDC) or for data validation, do the following:</p> <ol style="list-style-type: none"><li>1. To create a database migration task, choose the replication instance, source database endpoint, target database endpoint. Specify the migration type as one of the following:<ul style="list-style-type: none"><li>• <b>Migrate existing data</b> (full load)</li><li>• <b>Replicate data changes only (CDC)</b></li><li>• <b>Migrate existing data and replicate ongoing changes</b> (full load and CDC)</li></ul></li><li>2. Under <b>Table mappings</b>, you can configure selection rules and transformation rules in GUI or JSON formats:<ul style="list-style-type: none"><li>• Under <b>Selection rules</b>, select the schema, enter the table name, and select the action (Include or Exclude) to be configured; for example, Schema ORCL, Table name %, Action Include.</li></ul></li></ol>	General AWS

Task	Description	Skills required
	<ul style="list-style-type: none"><li>• Under <b>Transformation rules</b>, do one of the following:<ul style="list-style-type: none"><li>• Select the schema and choose the action (case, prefix, suffix); for example, Target Schema ORCL, Action Make lowercase.</li><li>• Select the schema, enter the table name, and choose the action (case, prefix, suffix); for example, Target Schema ORCL, Table %, Action Make lowercase.</li></ul></li></ul> <ol style="list-style-type: none"><li>3. Turn on Amazon CloudWatch Logs monitoring.</li><li>4. For the mapping rules, add the following JSON code.</li></ol> <pre data-bbox="634 1325 1029 1814">{   "rules": [     {       "rule-type": "transfor mation",       "rule-id" : "1",       "rule-nam e": "1",       "rule-tar get": "table",</pre>	

Task	Description	Skills required
	<pre>                 "object-l ocator": {                  "schema-name": "%",                  "table-name": "%"                 },                 "rule- action": "convert- lowercase",                 "value":                 null,                 "old-valu e": null                 },                 {                 "rule- type": "transfor mation",                 "rule-id" : "2",                 "rule-nam e": "2",                 "rule-tar get": "schema",                 "object-l ocator": {                  "schema-name":                 "ORCL",                  "table-name": "%"                 },                 "rule- action": "convert- lowercase",                 "value":                 null,                 "old-valu e": null                 },                 { </pre>	

Task	Description	Skills required
	<pre>                     "rule-type": "selection",                     "rule-id": "3",                     "rule-name": "3",                     "object-locator": {                         "schema-name": "ORCL",                         "table-name": "DEPT"                     },                     "rule-action": "include",                     "filters": []                 }             ]         }             </pre>	
<p>Plan the production run.</p>	<p>Confirm downtime with stakeholders such as application owners to run AWS DMS in production systems.</p>	<p>Migration lead</p>

Task	Description	Skills required
Run the migration task.	<p>1. Start the AWS DMS task that has a status of <b>Ready</b>, and monitor the migration task logs in Amazon CloudWatch for any errors.</p> <p>If you chose <b>Migrate existing data and replicate ongoing changes</b> as the migration type, and the status is <b>Load complete ongoing replication</b>, the full load with CDC data migration is completed and validation is ongoing.</p> <p>2. After you start the migration, you can obtain additional SSL-connection information in CloudWatch. For Oracle, CloudWatch shows the following connection string.</p> <pre>2019-12-17T09:15:11 [SOURCE_UNLOAD ]I: Connecting to Oracle: Beginning session (oracle_endpoint_connection.c:834)</pre> <p>The PostgreSQL connection string will be similar to the following example.</p>	General AWS

Task	Description	Skills required
	<pre>2019-12-17T09:15:11 [TARGET_LOAD ]I: Going to connect to ODBC connection string: PROTOCOL=7.4-0;DRIVER={PostgreSQL};SERVER=mypgsqlinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com;DATABASE=pgdb;PORT=5432;sslmode=require;UID=pguser; (odbc_endpoint_imp.c:2218)</pre>	
Validate the data.	<p>Review migration task results and data in the source Oracle and target PostgreSQL databases:</p> <ol style="list-style-type: none"> <li>1. Connect to pgAdmin and check the data in your PostgreSQL database with schema ORCL.</li> <li>2. For CDC, check the ongoing changes by inserting or updating data in the source Oracle database.</li> </ol>	DBA
Stop the migration task.	After you successfully complete the data validation, stop the migration task.	General AWS

## Clean up the resources

Task	Description	Skills required
Delete the AWS DMS tasks.	<ol style="list-style-type: none"><li>1. On the AWS DMS console, navigate to <b>Database migration tasks</b>, and stop any ongoing or running AWS DMS task.</li><li>2. Select the task or tasks, choose <b>Actions</b>, and choose <b>Delete</b>.</li></ol>	General AWS
Delete the AWS DMS endpoints.	Select the source and target endpoints that you created, choose <b>Actions</b> , and choose <b>Delete</b> .	General AWS
Delete the AWS DMS replication instance.	Choose the replication instance, choose <b>Actions</b> , and then choose <b>Delete</b> .	General AWS
Delete the PostgreSQL database.	<ol style="list-style-type: none"><li>1. On the Amazon RDS console, choose <b>Databases</b>.</li><li>2. Select the PostgreSQL database instance that you created, choose <b>Actions</b>, and then choose <b>Delete</b>.</li></ol>	General AWS
Delete the Oracle database.	On the Amazon RDS console, select the Oracle database instance, choose <b>Actions</b> , and then choose <b>Delete</b> .	General AWS

## Troubleshooting

Issue	Solution
AWS SCT source and target test connections are failing.	Configure JDBC driver versions and VPC security group inbound rules to accept the incoming traffic.
The Oracle source endpoint test run fails.	Check the endpoint settings and whether the replication instance is available.
The AWS DMS task full-load run fails.	Check whether the source and target databases have matching data types and sizes.
The AWS DMS validation migration task returns errors.	<ol style="list-style-type: none"><li>1. Check whether the table has a primary key. Tables without a primary key are not validated.</li><li>2. If the table has a primary key but returns errors, check the extra connection attribute in the source endpoint. The extra connection attribute must have <code>numberData typeScale=-2</code> to support the NUMBER data type with no size dynamically based on data available in table.</li></ol>

## Additional information

Amazon RDS Certificate Authority certificates `rds-ca-2019` are set to expire in August 2024. If you use or plan to use SSL or TLS with certificate verification to connect to your RDS DB instances

or Multi-AZ DB clusters, consider using one of the new CA certificates: `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, or `rds-ca-ecc384-g1`.

# Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation

Created by Pinesh Singal (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Amazon RDS for Oracle	<b>Target:</b> Amazon RDS for PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle; Open-source	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> AWS DMS; Amazon RDS; AWS SCT		

## Summary

This pattern shows how to migrate a multi-terabyte [Amazon Relational Database Service \(Amazon RDS\) for Oracle](#) DB instance to an [Amazon RDS for PostgreSQL](#) DB instance by using the AWS Command Line Interface (AWS CLI). The approach provides minimal downtime and doesn't require signing in to the AWS Management Console.

This pattern helps avoid manual configurations and individual migrations by using the AWS Schema Conversion Tool (AWS SCT) and AWS Database Migration Service (AWS DMS) consoles. The solution sets up a one-time configuration for multiple databases and performs the migrations by using AWS SCT and AWS DMS on the AWS CLI.

The pattern uses AWS SCT to convert database schema objects from Amazon RDS for Oracle to Amazon RDS for PostgreSQL and then uses AWS DMS to migrate the data. Using Python scripts in AWS CLI, you create AWS SCT objects and AWS DMS tasks with an AWS CloudFormation template.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing Amazon RDS for Oracle DB instance.
- An existing Amazon RDS for PostgreSQL DB instance.

- An Amazon EC2 instance or local machine with Windows or Linux OS for running scripts.
- An understanding of the following AWS DMS migration task types: full-load, cdc, full-load-and-cdc. For more information, see [Creating a task](#) in the AWS DMS documentation.
- AWS SCT, installed and configured with Java Database Connectivity (JDBC) drivers for Oracle and PostgreSQL database engines. For more information, see [Installing AWS SCT](#) and [Installing the required database drivers](#) in the AWS SCT documentation.
- The `AWSSchemaConversionToolBatch.jar` file from the installed AWS SCT folder, copied to your working directory.
- The `cli-sct-dms-cft.zip` file (attached), downloaded and extracted in your working directory.
- The most recent AWS DMS replication instance engine version. For more information, see [How do I create an AWS DMS replication instance](#) in the AWS Support documentation and [AWS DMS 3.4.4 release notes](#) in the AWS DMS documentation.
- AWS CLI version 2, installed and configured with your access key ID, secret access key, and default AWS Region name for the Amazon Elastic Compute Cloud (Amazon EC2) instance or operating system (OS) where the scripts are run. For more information, see [Installing, updating, and uninstalling the AWS CLI version 2](#) and [Configuring the AWS CLI](#) in the AWS CLI documentation.
- Familiarity with AWS CloudFormation templates. For more information, see [AWS CloudFormation concepts](#) in the AWS CloudFormation documentation.
- Python version 3, installed and configured on the Amazon EC2 instance or OS where the scripts are run. For more information, see the [Python documentation](#).

## Limitations

- The minimum requirements for your source Amazon RDS for Oracle DB instance are:
  - Oracle versions 12c (v12.1.0.2, v12.2.0.1), 18c (v18.0.0.0) and 19c (v19.0.0.0) for the Enterprise, Standard, Standard One, and Standard Two editions.
  - Although Amazon RDS supports Oracle 18c (v18.0.0.0), this version is on a deprecation path because Oracle no longer provide patches for 18c after the end-of-support date. For more information, see [Oracle on Amazon RDS](#) in the Amazon RDS documentation.
  - Amazon RDS for Oracle 11g is no longer supported.

- The minimum requirements for your target Amazon RDS for PostgreSQL DB instance are:
  - PostgreSQL versions 9 (versions 9.5 and 9.6), 10.x, 11.x, 12.x, and 13.x

### **Product versions**

- Amazon RDS for Oracle DB instance version 12.1.0.2 and later
- Amazon RDS for PostgreSQL DB instance version 11.5 and later
- AWS CLI version 2
- The latest version of AWS SCT
- The latest version of Python 3

### **Architecture**

#### **Source technology stack**

- Amazon RDS for Oracle

#### **Target technology stack**

- Amazon RDS for PostgreSQL

#### **Source and target architecture**

The following diagram shows the migration of an Amazon RDS for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance using AWS DMS and Python scripts.

The diagram shows the following migration workflow:

1. The Python script uses AWS SCT to connect to the source and target DB instances.
2. The user starts AWS SCT with the Python script, converts the Oracle code to PostgreSQL code, and runs it on the target DB instance.
3. The Python script creates AWS DMS replication tasks for the source and target DB instances.
4. The user deploys Python scripts to start the AWS DMS tasks and then stops the tasks after the data migration is complete.

## Automation and scale

You can automate this migration by adding additional parameters and security-related changes for multiple functionalities in a single program to your Python script.

## Tools

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. This pattern converts the .csv input file to a .json input file using a Python script. The .json file is used in AWS CLI commands to create an AWS CloudFormation stack that creates multiple AWS DMS replication tasks with Amazon Resource Names (ARNs), migration types, task settings, and table mappings.
- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups. This pattern uses AWS DMS to create, start, and stop tasks with a Python script run over the command-line and create the AWS CloudFormation template.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. This patterns requires the `AWSSchemaConversionToolBatch.jar` file from the installed AWS SCT directory.

## Code

The `cli-sct-dms-cft.zip` file (attached) contains the complete source code for this pattern.

## Epics

### Configure AWS SCT and create database objects in AWS CLI

Task	Description	Skills required
Configure AWS SCT to run from the AWS CLI.	1. Configure the source and target environment configuration details in the <code>database_migration.txt</code> file by using the following format:	DBA

Task	Description	Skills required
	<pre data-bbox="609 226 1015 1081">#source_vendor, source_hostname, source_dbname, source_user, source_pwd, source_schema, source_port, source_sid, target_vendor, target_hostname, target_user, target_pwd, target_dbname, target_port ORACLE, myoracleb.cokmvis0v46q.us-east-1.rds.amazonaws.com, ORCL, orcl, orcl1234, orcl, 1521, ORCL, POSTGRESQL, mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com, pguser, pgpassword, pgdb, 5432</pre> <p data-bbox="592 1123 1031 1543">2. Modify the AWS SCT configuration parameters according to your requirements in the following files: <code>project_settings.xml</code> , <code>Oracle_PG_Test_Batch.xml</code> , and <code>ORACLE-orcl-to-POSTGRESQL.xml</code> .</p>	

Task	Description	Skills required
Run the run_aws_sct.py Python script.	<p>Run the run_aws_sct.py Python script by using the following command:</p> <pre>\$ python run_aws_sct.py database_migration.txt</pre> <p>The Python script converts the database objects from Oracle to PostgreSQL and creates SQL files in PostgreSQL format. The script also creates the Database migration assessment report .pdf file that provides you with detailed recommendations and conversion statistics for database objects.</p>	DBA
Create objects in Amazon RDS for PostgreSQL.	<ol style="list-style-type: none"> <li>1. Manually modify the SQL files generated by AWS SCT, if required.</li> <li>2. Run the SQL files and create objects in your Amazon RDS for PostgreSQL DB instance.</li> </ol>	DBA

### Configure and create AWS DMS tasks by using the AWS CLI and AWS CloudFormation

Task	Description	Skills required
Create an AWS DMS replication instance.	Sign in to the AWS Management Console, open the AWS DMS console, and	DBA

Task	Description	Skills required
	<p>create a replication instance that is configured according to your requirements.</p> <p>For more information, see <a href="#">Creating a replication instance</a> in the AWS DMS documentation and <a href="#">How do I create an AWS DMS replication instance</a> in the AWS Support documentation.</p>	
Create the source endpoint.	<p>On the AWS DMS console, choose <b>Endpoints</b> and then create a source endpoint for the Oracle database according to your requirements.</p> <p><b>Note:</b> The extra connection attribute must be <code>numberDataTypesScale</code> with a -2 value.</p> <p>For more information, see <a href="#">Creating source and target endpoints</a> in the AWS DMS documentation.</p>	DBA

Task	Description	Skills required
Create the target endpoint.	<p>On the AWS DMS console, choose <b>Endpoints</b> and then create a target endpoint for the PostgreSQL database according to your requirements.</p> <p>For more information, see <a href="#">Creating source and target endpoints</a> in the AWS DMS documentation.</p>	DevOps engineer
Configure the AWS DMS replication details to run from the AWS CLI.	<p>Configure the AWS DMS source and target endpoints and replication details in the <code>dms-arn-list.txt</code> file with the source endpoint ARN, target endpoint ARN, and the replication instance ARN by using following format:</p> <pre data-bbox="594 1226 1026 1860"> #sourceARN,targetARN,repARN arn:aws:dms:us-east-1:123456789012: endpoint:EH7AINRUDZ5GOYIY6HVMXECMCQ arn:aws:dms:us-east-1:123456789012: endpoint:HHJVUV57N703CQF4PJZKGIOYY5 arn:aws:dms:us-east-1:123456789012: rep:LL57N77AQQAHHJF4PJFHNEZ5G </pre>	DBA

Task	Description	Skills required
Run the <code>dms-create-task.py</code> Python script to create the AWS DMS tasks.	<p>1. Run the <code>dms-create-task.py</code> Python script by using the following command:</p> <pre>\$ python dms-create-task.py database_migration.txt dms-arn-list.txt &lt;cft-stack-name&gt; &lt;migration-type&gt;</pre> <ul style="list-style-type: none"><li>• <code>database_migration.txt</code> is the database migration text file</li><li>• <code>dms-arn-list.txt</code> is the ARN list for AWS DMS</li><li>• <code>&lt;cft-stack-name&gt;</code> is the user-defined AWS CloudFormation stack name</li><li>• <code>&lt;migration-type&gt;</code> is the migration type (<b>full-load</b>, <b>cdc</b>, or <b>full-load-and-cdc</b>)</li></ul> <p>2. Depending on your migration type, you can use the following commands to create three types of AWS DMS tasks:</p> <ul style="list-style-type: none"><li>• <code>\$ python dms-create-task.py database_</code></li></ul>	DBA

Task	Description	Skills required
	<pre>migration.txt dms-arn-list.txt dms-cli-cft-stack full-load</pre> <ul style="list-style-type: none"> <li>• <code>\$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack cdc</code></li> <li>• <code>\$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack full-load-and-cdc</code></li> </ul> <p>3. The AWS CloudFormation stack and AWS DMS tasks are created</p>	
Check that AWS DMS tasks are ready.	In the AWS console, check that your AWS DMS tasks are in Ready status in the <b>Status</b> section.	DBA

### Start and stop the AWS DMS tasks by using the AWS CLI

Task	Description	Skills required
Start the AWS DMS tasks.	Run the <code>dms-start-task.py</code> Python script	DBA

Task	Description	Skills required
	<p>by using the following command:</p> <pre data-bbox="591 338 976 470">\$ python dms-start-task.py start '&lt;cdc-start-datetime&gt;'</pre> <p><b>Note:</b> The start date and time must be in the 'DD-MON-YYYY' or 'YYYY-MM-DDTHH:MI:SS' timestamp data type formats (for example, '01-Dec-2019' or '2018-03-08T12:12:12' )</p> <p>You can review the AWS DMS task status in the <b>Table statistics</b> tab of your migration tasks on the <b>Tasks</b> page of the AWS DMS console.</p>	

Task	Description	Skills required
Validate the data.	<ol style="list-style-type: none"><li data-bbox="592 226 1027 457">1. After the full-load migration is complete, the task is continuously kept running for continuous data change (CDC).</li><li data-bbox="592 478 1027 793">2. When CDC is complete or no more changes need to be migrated, review and validate the migration task results and data in your Oracle and PostgreSQL databases.</li><li data-bbox="592 814 1027 1423">3. You can validate your data by checking status and count columns (Validation state, Validation pending, Validation failed , Validation suspended , and Validation details ) in the <b>Table statistics</b> tab of your database migration task on the <b>Tasks</b> page of the AWS DMS console.</li></ol> <p data-bbox="592 1507 1027 1633">For more information, see <a href="#">AWS DMS data validation</a> in the AWS DMS documentation.</p>	DBA

Task	Description	Skills required
Stop the AWS DMS tasks.	<p>Run the Python script by using the following command:</p> <pre>\$ python dms-start-task.py stop</pre> <p><b>Note:</b> AWS DMS tasks might stop with a failedstatus, depending on the validation status. For more information, see the troubleshooting table in the <i>Additional information</i> section.</p>	DBA

## Troubleshooting

Issue	Solution
AWS SCT source and target test connections fail	Configure the JDBC driver versions and VPC security group inbound rules to accept the incoming traffic.
Source or target endpoint test run fails	<p>Check if the endpoint settings and replication instance is in Available status. Check if the endpoint connection status is Successful .</p> <p>For more information, see <a href="#">How can I troubleshoot AWS DMS endpoint connectivity failures</a> in the AWS Support documentation.</p>
Full-load run fails	Check if the source and target databases have matching data types and sizes.

Issue	Solution
	<p>For more information, see <a href="#">Troubleshooting migration tasks in AWS DMS</a> in the AWS DMS documentation.</p>
Validation run errors	<p>Check if the table has a primary key because non-primary key tables are not validated.</p> <p>If the table has a primary key and errors, check that the extra connection attribute in the source endpoint has <code>numberDataTypeScale=-2</code>.</p> <p>For more information, see <a href="#">Extra connection attributes when using Oracle as a source for AWS DMS</a>, <a href="#">OracleSettings</a>, and <a href="#">Troubleshooting</a> in the AWS DMS documentation.</p>

# Migrate Oracle `SERIALLY_REUSABLE` pragma packages into PostgreSQL

Created by Vinay Paladi (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle Database	<b>Target:</b> PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle; Open-source	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> AWS SCT; Amazon Aurora		

## Summary

This pattern provides a step-by-step approach for migrating Oracle packages that are defined as `SERIALLY_REUSABLE` pragma to PostgreSQL on Amazon Web Services (AWS). This approach maintains the functionality of the `SERIALLY_REUSABLE` pragma.

PostgreSQL doesn't support the concept of packages and the `SERIALLY_REUSABLE` pragma. To get similar functionality in PostgreSQL, you can create schemas for packages and deploy all the related objects (such as functions, procedures, and types) inside the schemas. To achieve the functionality of the `SERIALLY_REUSABLE` pragma, the example wrapper function script that's provided in this pattern uses an [AWS Schema Conversion Tool \(AWS SCT\) extension pack](#).

For more information, see [SERIALLY\\_REUSABLE Pragma](#) in the Oracle documentation.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- The latest version of AWS SCT and the required drivers
- An Amazon Aurora PostgreSQL-Compatible Edition database or an Amazon Relational Database Service (Amazon RDS) for PostgreSQL database

### Product versions

- Oracle Database version 10g and later

## Architecture

### Source technology stack

- Oracle Database on premises

### Target technology stack

- [Aurora PostgreSQL-Compatible](#) or Amazon RDS for PostgreSQL
- AWS SCT

### Migration architecture

## Tools

### AWS services

- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.
- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.

## Other tools

- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Epics

### Migrate the Oracle package by using AWS SCT

Task	Description	Skills required
Set up AWS SCT.	Configure AWS SCT connectivity to the source database. For more information, see <a href="#">Using Oracle Database as a source for AWS SCT</a> .	DBA, Developer
Convert the script.	Use AWS SCT to convert the Oracle package by selecting the target database as Aurora PostgreSQL-Compatible.	DBA, Developer
Save the .sql files.	Before you save the .sql file, modify the <b>Project Settings</b> option in AWS SCT to <b>Single file per stage</b> . AWS SCT will separate the .sql file into multiple .sql files based on object type.	DBA, Developer
Change the code.	Open the <code>init</code> function generated by AWS SCT, and change it as shown in the example in the <i>Additional information</i> section. It will add a variable to achieve the	DBA, Developer

Task	Description	Skills required
	functionality <code>pg_serial</code> <code>ize = 0</code> .	
Test the conversion.	Deploy the <code>init</code> function to the Aurora PostgreSQL-Compatible database, and test the results.	DBA, Developer

## Additional information

Source Oracle Code:

```
CREATE OR REPLACE PACKAGE test_pkg_var
IS
PRAGMA SERIALLY_REUSABLE;
PROCEDURE function_1
(test_id number);
PROCEDURE function_2
(test_id number
);
END;

CREATE OR REPLACE PACKAGE BODY test_pkg_var
IS
PRAGMA SERIALLY_REUSABLE;
v_char VARCHAR2(20) := 'shared.airline';
v_num number := 123;

PROCEDURE function_1(test_id number)
IS
```

```
begin
dbms_output.put_line( 'v_char-'|| v_char);
dbms_output.put_line( 'v_num-'||v_num);
v_char:='test1';
function_2(0);
END;
```

```
PROCEDURE function_2(test_id number)
is
begin
dbms_output.put_line( 'v_char-'|| v_char);
dbms_output.put_line( 'v_num-'||v_num);
END;
END test_pkg_var;
```

Calling the above functions

```
set serveroutput on
```

```
EXEC test_pkg_var.function_1(1);
```

```
EXEC test_pkg_var.function_2(1);
```

Target Postgresql Code:

```
CREATE SCHEMA test_pkg_var;
```

```
CREATE OR REPLACE FUNCTION test_pkg_var.init(pg_serialize IN INTEGER DEFAULT 0)
```

```
RETURNS void
```

```
AS
```

```
$BODY$
```

```
DECLARE
```

```
BEGIN
```

```
if aws_oracle_ext.is_package_initialized( 'test_pkg_var' ) AND pg_serialize = 0
```

```
then
```

```
return;

end if;

PERFORM aws_oracle_ext.set_package_initialized( 'test_pkg_var' );

PERFORM aws_oracle_ext.set_package_variable( 'test_pkg_var', 'v_char',
  'shared.airline.basecurrency'::CHARACTER

VARYING(100));

PERFORM aws_oracle_ext.set_package_variable('test_pkg_var', 'v_num', 123::integer);

END;

$BODY$

LANGUAGE plpgsql;

CREATE OR REPLACE FUNCTION test_pkg_var.function_1(pg_serialize int default 1)

RETURNS void
AS

$BODY$
DECLARE

BEGIN

PERFORM test_pkg_var.init(pg_serialize);

raise notice 'v_char%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_char');

raise notice 'v_num%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_num');

PERFORM aws_oracle_ext.set_package_variable( 'test_pkg_var', 'v_char',
  'test1'::varchar);

PERFORM test_pkg_var.function_2(0);
END;

$BODY$
```

```
LANGUAGE plpgsql;

CREATE OR REPLACE FUNCTION test_pkg_var.function_2(IN pg_serialize integer default 1)

RETURNS void

AS

$BODY$

DECLARE

BEGIN

PERFORM test_pkg_var.init(pg_serialize);

raise notice 'v_char%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_char');

raise notice 'v_num%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_num');

END;
$BODY$
LANGUAGE plpgsql;
```

Calling the above functions

```
select test_pkg_var.function_1()

select test_pkg_var.function_2()
```

# Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible

Created by anuradha chintha (AWS) and Rakesh Raghav (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> Aurora PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Open-source	<b>Technologies:</b> Migration; Databases; Modernization
<b>AWS services:</b> AWS Identity and Access Management; AWS Lambda; Amazon S3; Amazon SNS; Amazon Aurora		

## Summary

External tables give Oracle the ability to query data that is stored outside the database in flat files. You can use the ORACLE\_LOADER driver to access any data stored in any format that can be loaded by the SQL\*Loader utility. You can't use Data Manipulation Language (DML) on external tables, but you can use external tables for query, join, and sort operations.

Amazon Aurora PostgreSQL-Compatible Edition doesn't provide functionality similar to external tables in Oracle. Instead, you must use modernization to develop a scalable solution that meets functional requirements and is frugal.

This pattern provides steps for migrating different types of Oracle external tables to Aurora PostgreSQL-Compatible Edition on the Amazon Web Services (AWS) Cloud by using the `aws_s3` extension.

We recommend thoroughly testing this solution before implementing it in a production environment.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI)
- An available Aurora PostgreSQL-Compatible database instance.
- An on-premises Oracle database with an external table
- pg.Client API
- Data files

## Limitations

- This pattern doesn't provide the functionality to act as a replacement for Oracle external tables. However, the steps and sample code can be enhanced further to achieve your database modernization goals.
- Files should not contain the character that is passing as a delimiter in `aws_s3` export and import functions.

## Product versions

- To import from Amazon S3 into RDS for PostgreSQL the database must be running PostgreSQL version 10.7 or later.

## Architecture

### Source technology stack

- Oracle

### Source architecture

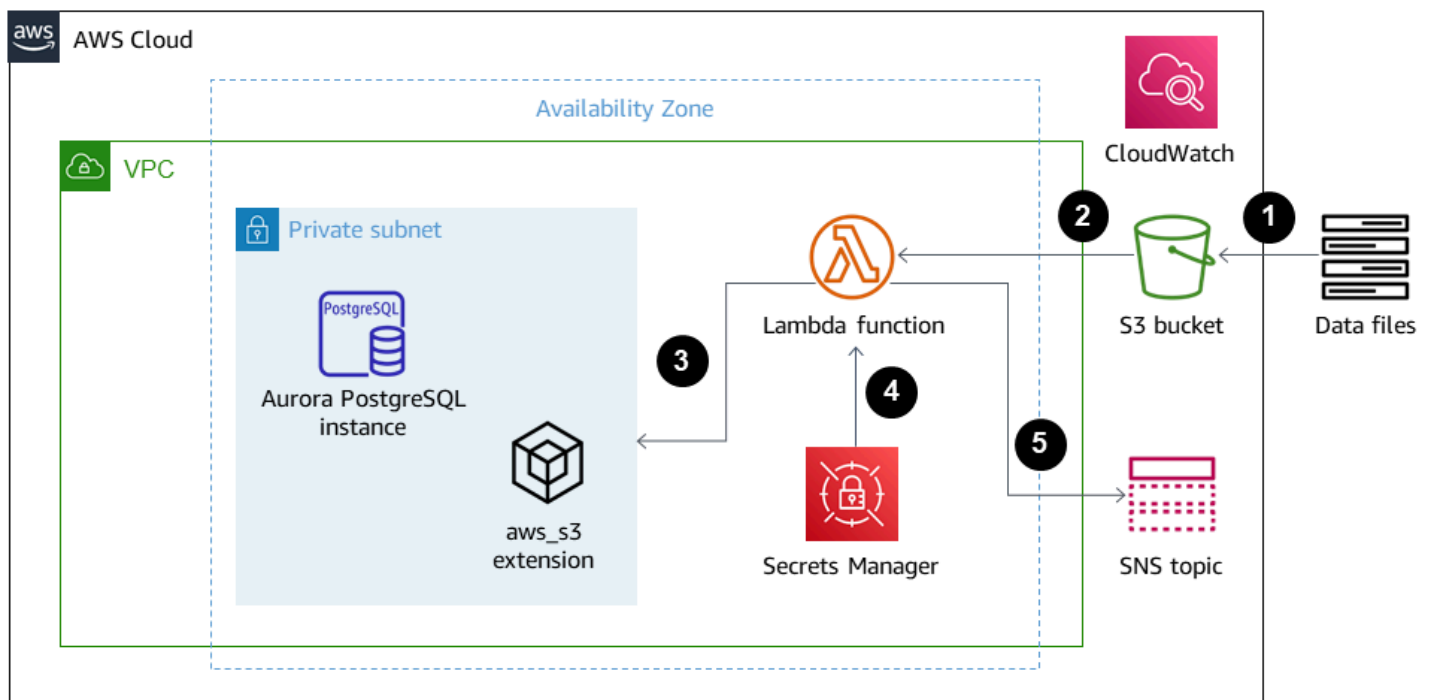

### Target technology stack

- Amazon Aurora PostgreSQL-Compatible
- Amazon CloudWatch
- AWS Lambda
- AWS Secrets Manager
- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Storage Service (Amazon S3)

### Target architecture

The following diagram shows a high-level representation of the solution.

1. Files are uploaded to the S3 bucket.
2. The Lambda function is initiated.
3. The Lambda function initiates the DB function call.
4. Secrets Manager provides the credentials for database access.
5. Depending on the DB function, an SNS alarm is created.

## Automation and scale

Any additions or changes to the external tables can be handled with metadata maintenance.

## Tools

- [Amazon Aurora PostgreSQL-Compatible](#) – Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases.
- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With only one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts.
- [Amazon CloudWatch](#) – Amazon CloudWatch monitors Amazon S3 resources and utilization.

- [AWS Lambda](#) – AWS Lambda is a serverless compute service that supports running code without provisioning or managing servers, creating workload-aware cluster scaling logic, maintaining event integrations, or managing runtimes. In this pattern, Lambda runs the database function whenever a file is uploaded to Amazon S3.
- [AWS Secrets Manager](#) – AWS Secrets Manager is a service for credential storage and retrieval. Using Secrets Manager, you can replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) provides a storage layer to receive and store files for consumption and transmission to and from the Aurora PostgreSQL-Compatible cluster.
- [aws\\_s3](#) – The `aws_s3` extension integrates Amazon S3 and Aurora PostgreSQL-Compatible.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients. In this pattern, Amazon SNS is used to send notifications.

## Code

Whenever a file is placed in the S3 bucket, a DB function must be created and called from the processing application or the Lambda function. For details, see the code (attached).

## Epics

### Create an external file

Task	Description	Skills required
Add an external file to the source database.	Create an external file, and move it to the <code>oracle</code> directory.	DBA

## Configure the target (Aurora PostgreSQL-Compatible)

Task	Description	Skills required
Create an Aurora PostgreSQL database.	Create a DB instance in your Amazon Aurora PostgreSQL-Compatible cluster.	DBA
Create a schema, <code>aws_s3</code> extension, and tables.	Use the code under <code>ext_tbl_scripts</code> in the <i>Additional information</i> section. The tables include actual tables, staging tables, error and log tables, and a metatable.	DBA, Developer
Create the DB function.	To create the DB function, use the code under <code>load_external_table_latest</code> function in the <i>Additional information</i> section.	DBA, Developer

## Create and configure the Lambda function

Task	Description	Skills required
Create a role.	Create a role with permissions to access Amazon S3 and Amazon Relational Database Service (Amazon RDS). This role will be assigned to Lambda for running the pattern.	DBA
Create the Lambda function.	Create a Lambda function that reads the file name from Amazon S3 (for example,	DBA

Task	Description	Skills required
	<p><code>file_key = info.get('object', {}).get('key') )</code> and calls the DB function (for example, <code>cursor.callproc("load_external_tables", [file_key])</code> ) with the file name as the input parameter.</p> <p>Depending on the function call result, an SNS notification will be initiated (for example, <code>client.publish(TopicArn='arn:', Message='fileloadsuccess', Subject='fileloadsuccess')</code> ).</p> <p>Based on your business needs, you can create a Lambda function with extra code if required. For more information, see the <a href="#">Lambda documentation</a>.</p>	
Configure an S3 bucket event trigger.	Configure a mechanism to call the Lambda function for all object creation events in the S3 bucket.	DBA
Create a secret.	Create a secret name for the database credentials by using Secrets Manager. Pass the secret in the Lambda function.	DBA

Task	Description	Skills required
Upload the Lambda supporting files.	Upload a .zip file that contains the Lambda support packages and the attached Python script for connecting to Aurora PostgreSQL-Compatible. The Python code calls the function that you created in the database.	DBA
Create an SNS topic.	Create an SNS topic to send mail for the success or failure of the data load.	DBA

### Add integration with Amazon S3

Task	Description	Skills required
Create an S3 bucket.	On the Amazon S3 console, create an S3 bucket with a unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts.	DBA
Create IAM policies.	To create the AWS Identity and Access Management (IAM) policies, use the code under <code>s3bucketpolicy_for_import</code> in the <i>Additional information</i> section.	DBA
Create roles.	Create two roles for Aurora PostgreSQL-Compatible,	DBA

Task	Description	Skills required
	one role for Import and one role for Export. Assign the corresponding policies to the roles.	
Attach the roles to the Aurora PostgreSQL-Compatible cluster.	Under <b>Manage roles</b> , attach the Import and Export roles to the Aurora PostgreSQL cluster.	DBA
Create supporting objects for Aurora PostgreSQL-Compatible.	<p>For the table scripts, use the code under <code>ext_tbl_scripts</code> in the <i>Additional information</i> section.</p> <p>For the custom function, use the code under <code>load_external_Table_latest</code> in the <i>Additional information</i> section.</p>	DBA

## Process a test file

Task	Description	Skills required
Upload a file into the S3 bucket.	<p>To upload a test file into the S3 bucket, use the console or the following command in AWS CLI.</p> <pre>aws s3 cp /Users/Desktop/ukpost/exttbl/"testing files"/aps s3://s3importtest/inputtext/aps</pre>	DBA

Task	Description	Skills required
	As soon as the file is uploaded, a bucket event initiates the Lambda function, which runs the Aurora PostgreSQL-Compatible function.	
Check the data and the log and error files.	The Aurora PostgreSQL-Compatible function loads the files into the main table, and it creates .log and .bad files in the S3 bucket.	DBA
Monitor the solution.	In the Amazon CloudWatch console, monitor the Lambda function.	DBA

# Migrate function-based indexes from Oracle to PostgreSQL

Created by Veeranjanyulu Grandhi (AWS) and Navakanth Talluri (AWS)

<b>Environment:</b> Production	<b>Source:</b> Oracle	<b>Target:</b> PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases

## Summary

Indexes are a common way to enhance database performance. An index allows the database server to find and retrieve specific rows much faster than it could without an index. But indexes also add overhead to the database system as a whole, so they should be used sensibly. Function-based indexes, which are based on a function or expression, can involve multiple columns and mathematical expressions. A function-based index improves the performance of queries that use the index expression.

Natively, PostgreSQL doesn't support creating function-based indexes using functions that have volatility defined as stable. However, you can create similar functions with volatility as IMMUTABLE and use them in index creation.

An IMMUTABLE function cannot modify the database, and it's guaranteed to return the same results given the same arguments forever. This category allows the optimizer to pre-evaluate the function when a query calls it with constant arguments.

This pattern helps in migrating the Oracle function-based indexes when used with functions such as `to_char`, `to_date`, and `to_number` to the PostgreSQL equivalent.

## Prerequisites and limitations

### Prerequisites

- An active Amazon Web Services (AWS) account
- A source Oracle database instance with the listener service set up and running
- Familiarity with PostgreSQL databases

### Limitations

- Database size limit is 64 TB.
- Functions used in index creation must be IMMUTABLE.

## Product versions

- All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c
- PostgreSQL versions 9.6 and later

## Architecture

### Source technology stack

- An Oracle database on premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance, or an Amazon RDS for Oracle DB instance

### Target technology stack

- Any PostgreSQL engine

## Tools

- **pgAdmin 4** is an open source management tool for Postgres. The pgAdmin 4 tool provides a graphical interface for creating, maintaining, and using database objects.
- **Oracle SQL Developer** is an integrated development environment (IDE) for developing and managing Oracle Database in both traditional and cloud deployments.

## Epics

### Create a function-based index using a default function

Task	Description	Skills required
Create a function-based index on a column using the to_char function.	Use the following code to create the function-based index.	DBA, App developer

Task	Description	Skills required
	<pre> postgres=# create table funcindex( col1 timestamp without time zone); CREATE TABLE postgres=# insert into funcindex values (now()); INSERT 0 1 postgres=# select * from funcindex;           col1 ----- ----- 2022-08-09 16:00:57. 77414 (1 rows)  postgres=# create index funcindex_idx on funcindex(to_char( col1, 'DD-MM-YYYY HH24:MI:SS')); ERROR:  functions in index expression must be marked IMMUTABLE </pre> <p><b>Note:</b> PostgreSQL doesn't allow creating a function-based index without the IMMUTABLE clause.</p>	
Check the volatility of the function.	To check the function volatility, use the code in the <i>Additional information</i> section.	DBA

## Create function-based indexes using a wrapper function

Task	Description	Skills required
Create a wrapper function.	To create a wrapper function, use the code in the <i>Additional information section</i> .	PostgreSQL developer
Create an index by using the wrapper function.	<p>Use the code in the <i>Additional information section</i> to create a user-defined function with the keyword IMMUTABLE in the same schema as the application, and refer to it in the index-creation script.</p> <p>If a user-defined function is created in a common schema (from the previous example), update the <code>search_path</code> as shown.</p> <pre>ALTER ROLE &lt;ROLENAME&gt; set search_path=\$user, COMMON;</pre>	DBA, PostgreSQL developer

## Validate index creation

Task	Description	Skills required
Validate index creation.	Validate that the index needs to be created, based on query access patterns.	DBA
Validate that the index can be used.	To check whether the function-based index is picked up by the PostgreSQL	DBA

Task	Description	Skills required
	<p>L Optimizer, run an SQL statement using explain or explain analyze. Use the code in the <i>Additional information</i> section. If possible, gather the table statistics as well.</p> <p><b>Note:</b> If you notice the explain plan, PostgreSQL optimizer has chosen a function-based index because of the predicate condition.</p>

## Additional information

### Create a wrapper function

```
CREATE OR REPLACE FUNCTION myschema.to_char(var1 timestamp without time zone, var2
varchar) RETURNS varchar AS $BODY$ select to_char(var1, 'YYYYMMDD'); $BODY$ LANGUAGE
sql IMMUTABLE;
```

### Create an index by using the wrapper function

```
postgres=# create function common.to_char(var1 timestamp without time zone, var2
varchar) RETURNS varchar AS $BODY$ select to_char(var1, 'YYYYMMDD'); $BODY$ LANGUAGE
sql IMMUTABLE;
CREATE FUNCTION
```

```
postgres=# create index funcindex_idx on funcindex(common.to_char(col1,'DD-MM-YYYY
HH24:MI:SS'));
CREATE INDEX
```

## Check the volatility of the function

```
SELECT DISTINCT p.proname as "Name",p.provolatile as "volatility" FROM
pg_catalog.pg_proc p
LEFT JOIN pg_catalog.pg_namespace n ON n.oid = p.pronamespace
LEFT JOIN pg_catalog.pg_language l ON l.oid = p.prolang
WHERE n.nspname OPERATOR(pg_catalog.~) '^(pg_catalog)$' COLLATE pg_catalog.default AND
p.proname='to_char'GROUP BY p.proname,p.provolatile
ORDER BY 1;
```

## Validate that the index can be used

```
explain analyze <SQL>
```

```
postgres=# explain select col1 from funcindex where common.to_char(col1,'DD-MM-YYYY
HH24:MI:SS') = '09-08-2022 16:00:57';
```

QUERY PLAN

```
-----
Index Scan using funcindex_idx on funcindex (cost=0.42..8.44 rows=1 width=8)
  Index Cond: ((common.to_char(col1, 'DD-MM-YYYY HH24:MI:SS'::character
varying))::text = '09-08-2022 16:00:57'::text)
(2 rows)
```

# Migrate Oracle native functions to PostgreSQL using extensions

Created by Pinesh Singal (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle; Open-source	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon EC2; Amazon RDS		

## Summary

This migration pattern provides step-by-step guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database instance to an Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition database by modifying the `aws_oracle_ext` and `orafce` extensions to PostgreSQL (`psql`) native built-in code. This will save processing time.

The pattern describes an offline manual migration strategy with no downtime for a multi-terabyte Oracle source database with a high number of transactions.

The migration process uses AWS Schema Conversion Tool (AWS SCT) with the `aws_oracle_ext` and `orafce` extensions to convert an Amazon RDS for Oracle database schema to an Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database schema. Then the code is manually changed to PostgreSQL supported native `psql` built-in code. This is because the extension calls impact code processing on the PostgreSQL database server, and not all the extension code is fully complaint or compatible with PostgreSQL code.

This pattern primarily focuses on manually migrating SQL codes using AWS SCT and the extensions `aws_oracle_ext` and `orafce`. You convert the already used extensions into native PostgreSQL (`psql`) built-ins. Then you remove all references to the extensions and convert the codes accordingly.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Operating system (Windows or Mac) or Amazon EC2 instance (up and running)
- Orafce

## Limitations

Not all Oracle functions using `aws_oracle_ext` or `orafce` extensions can be converted to native PostgreSQL functions. It might need manual rework so as to compile it with PostgreSQL libraries.

One drawback of using AWS SCT extensions is its slow performance in running and fetching the results. Its cost can be understood from simple [PostgreSQL EXPLAIN plan](#) (execution plan of a statement) on the Oracle `SYSDATE` function migration to the PostgreSQL `NOW( )` function between all three codes (`aws_oracle_ext`, `orafce`, and `psql` default), as explained in the *Performance comparison check* section in the attached document.

## Product versions

- **Source:** Amazon RDS for Oracle database 10.2 and later (for 10.x), 11g (11.2.0.3.v1 and later) and up to 12.2, 18c, and 19c (and later) for Enterprise Edition, Standard Edition, Standard Edition 1, and Standard Edition 2
- **Target:** Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database 9.4 and later (for 9.x), 10.x, 11.x, 12.x, 13.x, and 14.x (and later)
- **AWS SCT:** Latest version (this pattern was tested with 1.0.632)
- **Orafce:** Latest version (this pattern was tested with 3.9.0)

## Architecture

### Source technology stack

- An Amazon RDS for Oracle database instance with version 12.1.0.2.v18

### Target technology stack

- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database instance with version 11.5

## Database migration architecture

The following diagram represents the database migration architecture between the source Oracle and target PostgreSQL databases. The architecture involves AWS Cloud, a virtual private cloud (VPC), Availability Zones, a private subnet, an Amazon RDS for Oracle database, AWS SCT, an Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database, extensions for Oracle (`aws_oracle_ext` and `orafce`), and structured query language (SQL) files.

1. Launch Amazon RDS for Oracle DB instance (source DB).
2. Use AWS SCT with the `aws_oracle_ext` and `orafce` extension packs to convert the source code from Oracle to PostgreSQL.
3. The conversion produces PostgreSQL-supported migrated `.sql` files.
4. Manually convert the non-converted Oracle extension codes to PostgreSQL (`psql`) codes.
5. The manual conversion produces PostgreSQL-supported converted `.sql` files.
6. Run these `.sql` files on your Amazon RDS for PostgreSQL DB instance (target DB).

## Tools

### Tools

#### *AWS services*

- [AWS SCT](#) - AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another. You can convert relational Online Transactional Processing (OLTP) schema, or data warehouse schema. Your converted schema is suitable for an Amazon RDS for MySQL DB instance, an Amazon Aurora DB cluster, an Amazon RDS for PostgreSQL DB

instance, or an Amazon Redshift cluster. The converted schema can also be used with a database on an Amazon EC2 instance or stored as data in an Amazon S3 bucket.

AWS SCT provides a project-based user interface to automatically convert the database schema of your source database into a format compatible with your target Amazon RDS instance.

You can use AWS SCT to do migration from an Oracle source database to any of the targets listed preceding. Using AWS SCT, you can export the source database object definitions such as schema, views, stored procedures, and functions.

You can use AWS SCT to convert data from Oracle to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition.

In this pattern, you use AWS SCT to convert and migrate Oracle code into PostgreSQL using the extensions `aws_oracle_ext` and `orafce`, and manually migrating the extension codes into `psql` default or native built-in code.

- The [AWS SCT](#) extension pack is an add-on module that emulates functions present in the source database that are required when converting objects to the target database. Before you can install the AWS SCT extension pack, you need to convert your database schema.

When you convert your database or data warehouse schema, AWS SCT adds an additional schema to your target database. This schema implements SQL system functions of the source database that are required when writing your converted schema to your target database. This additional schema is called the extension pack schema.

The extension pack schema for OLTP databases is named according to the source database. For Oracle databases, the extension pack schema is `AWS_ORACLE_EXT`.

### *Other tools*

- [Orafce](#) – Orafce is a module that implements Oracle compatible functions, data types, and packages. It's an open-source tool with a Berkeley Source Distribution (BSD) license so that anyone can use it. The `orafce` module is useful for migrating from Oracle to PostgreSQL because it has many Oracle functions implemented in PostgreSQL.

## Code

For a list of all commonly used and migrated code from Oracle to PostgreSQL to avoid AWS SCT extension code usage, see the attached document.

## Epics

### Configure the Amazon RDS for Oracle source database

Task	Description	Skills required
Create the Oracle database instance.	Create an Amazon RDS for Oracle or Aurora PostgreSQL-Compatible database instance from the Amazon RDS console.	General AWS, DBA
Configure the security groups.	Configure inbound and outbound security groups.	General AWS
Create the database.	Create the Oracle database with needed users and schemas.	General AWS, DBA
Create the objects.	Create objects and insert data in schema.	DBA

### Configure the Amazon RDS for PostgreSQL target database

Task	Description	Skills required
Create the PostgreSQL database instance.	Create an Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL database instance from the Amazon RDS console.	General AWS, DBA
Configure the security groups.	Configure inbound and outbound security groups.	General AWS

Task	Description	Skills required
Create the database.	Create the PostgreSQL database with needed users and schemas.	General AWS, DBA
Validate the extensions.	Make sure that <code>aws_oracle_ext</code> and <code>orafce</code> are installed and configured correctly in the PostgreSQL database.	DBA
Verify that the PostgreSQL database is available.	Make sure that the PostgreSQL database is up and running.	DBA

### Migrate the Oracle schema into PostgreSQL using AWS SCT and the extensions

Task	Description	Skills required
Install AWS SCT.	Install the latest version of AWS SCT.	DBA
Configure AWS SCT.	Configure AWS SCT with Java Database Connectivity (JDBC) drivers for Oracle ( <code>ojdbc8.jar</code> ) and PostgreSQL ( <code>postgresql-42.2.5.jar</code> ).	DBA
Enable the AWS SCT extension pack or template.	Under AWS SCT <b>Project Settings</b> , enable built-in function implementation with the <code>aws_oracle_ext</code> and <code>orafce</code> extensions for the Oracle database schema.	DBA

Task	Description	Skills required
Convert the schema.	In AWS SCT, choose <b>Convert Schema</b> to convert the schema from Oracle to PostgreSQL and generate the .sql files.	DBA

## Convert AWS SCT extension code to psql code

Task	Description	Skills required
Manually convert the code.	Manually convert each line of extension-supported code into psql default built-in code, as detailed in the attached document. For example, change <code>AWS_ORACLE_EXT.SYSDATE()</code> or <code>ORACLE.SYSDATE()</code> to <code>NOW()</code> .	DBA
Validate the code	(Optional) Validate each line of code by temporarily running it in the PostgreSQL database.	DBA
Create objects in the PostgreSQL database.	To create objects in the PostgreSQL database, run the .sql files that were generated by AWS SCT and modified in the previous two steps.	DBA

# Migrate a Db2 database from Amazon EC2 to Aurora MySQL-Compatible by using AWS DMS

Created by Pinesh Singal (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> IBM Db2 on Amazon EC2	<b>Target:</b> Amazon Aurora MySQL-Compatible Edition
<b>R Type:</b> Re-architect	<b>Workload:</b> IBM	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> AWS DMS; Amazon EC2; AWS SCT; Amazon Aurora		

## Summary

After you migrate your [IBM Db2 for LUW database](#) to [Amazon Elastic Compute Cloud \(Amazon EC2\)](#), consider re-architecting the database by moving to an Amazon Web Services (AWS) cloud-native database. This pattern covers migrating an IBM [Db2](#) for LUW database running on an [Amazon EC2](#) instance to an [Amazon Aurora MySQL-Compatible Edition](#) database on AWS.

The pattern describes an online migration strategy with minimal downtime for a multi-terabyte Db2 source database with a high number of transactions.

This pattern uses [AWS Schema Conversion Tool \(AWS SCT\)](#) to convert the Db2 database schema to an Aurora MySQL-Compatible schema. Then the pattern uses [AWS Database Migration Service \(AWS DMS\)](#) to migrate data from the Db2 database to the Aurora MySQL-Compatible database. Manual conversions will be required for the code that isn't converted by AWS SCT.

## Prerequisites and limitations

### Prerequisites

- An active AWS account with a virtual private cloud (VPC)
- AWS SCT

- AWS DMS

## Product versions

- AWS SCT latest version
- Db2 for Linux version 11.1.4.4 and later

## Architecture

### Source technology stack

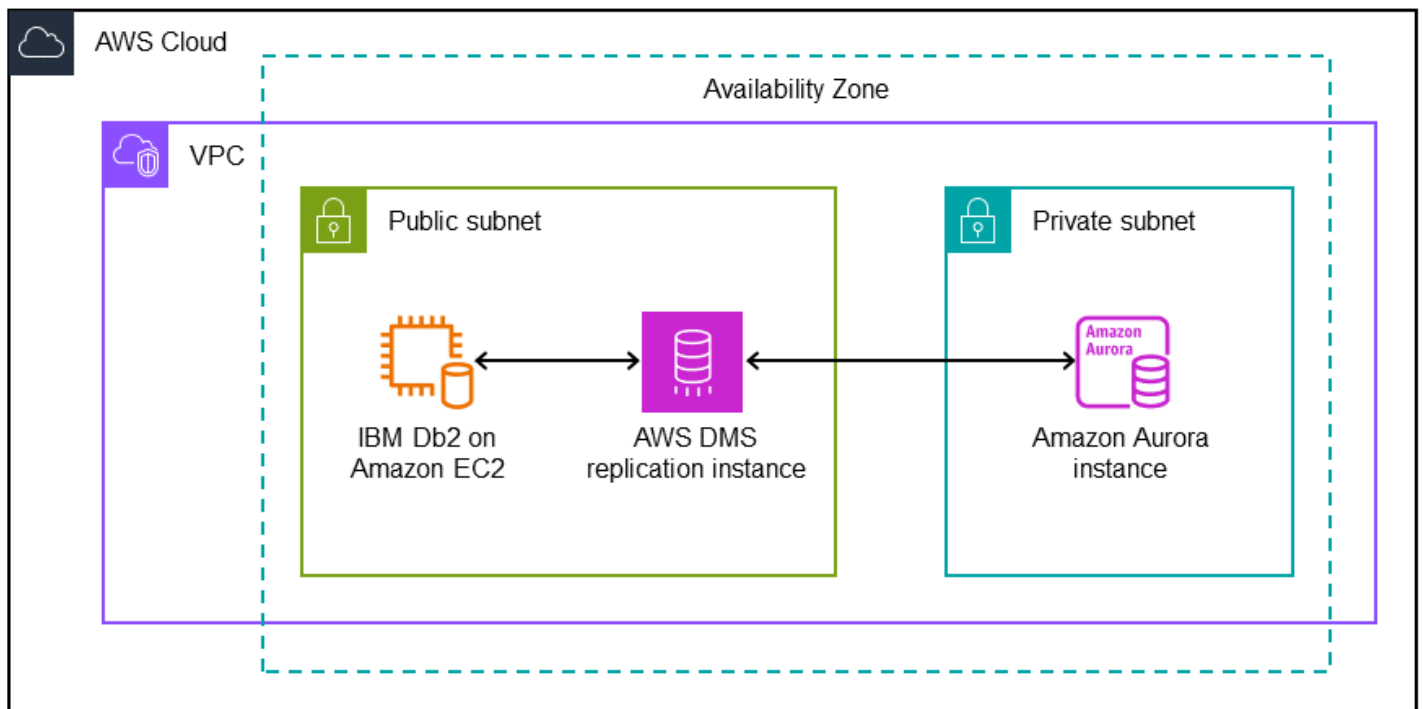

- DB2/Linux x86-64 bit mounted on an EC2 instance

### Target technology stack

- An Amazon Aurora MySQL-Compatible Edition database instance

### Source and target architecture

The following diagram shows the data migration architecture between the source Db2 and target Aurora MySQL-Compatible databases. The architecture on the AWS Cloud includes a virtual private cloud (VPC) (Virtual Private Cloud), an Availability Zone, a public subnet for the Db2 instance and the AWS DMS replication instance, and a private subnet for the Aurora MySQL-Compatible database.

## Tools

### AWS services

- [Amazon Aurora](#) is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. AWS SCT supports as a source IBM Db2 for LUW versions 9.1, 9.5, 9.7, 10.1, 10.5, 11.1, and 11.5.

### Best practices

For best practices, see [Best practices for AWS Database Migration Service](#).

## Epics

### Configure the source IBM Db2 database

Task	Description	Skills required
Create the IBM Db2 database on Amazon EC2.	<p>You can create an IBM Db2 database on an EC2 instance by using an Amazon Machine Image (AMI) from AWS Marketplace or by installing Db2 software on an EC2 instance.</p> <p>Launch an EC2 instance by selecting an AMI for IBM Db2 (for example, <a href="#">IBM Db2 v11.5.7 RHEL 7.9</a>), which is similar to an on-premises database.</p>	DBA, General AWS
Configure security groups.	Configure the VPC security group inbound rules for SSH (Secure Shell) and TCP with port 22 and 50000, respectively.	General AWS
Create the database instance.	<p>Create a new instance (user) and database (schema), or use the default db2inst1 instance and sample database.</p> <ol style="list-style-type: none"> <li>1. Connect to the EC2 instance by using the terminal to connect to the Db2 database. Alternatively, you can install any</li> </ol>	DBA

Task	Description	Skills required
	<p>DB client software that will connect to the Db2 database.</p> <ol style="list-style-type: none"><li data-bbox="592 363 1027 541">2. To set the password of the db2inst1 user, run the command <code>sudo passwd db2inst1</code>.</li><li data-bbox="592 562 1027 695">3. To connect to the db2inst1 instance, run the command <code>sudo su - db2inst1</code>.</li><li data-bbox="592 716 1027 848">4. To connect to the Db2 database, run the command <code>db2</code>.</li><li data-bbox="592 869 1027 1146">5. To connect to the sample database, use the command <code>connect to sample</code>. Alternatively, connect to the database that you created.</li><li data-bbox="592 1167 1027 1392">6. After you connect to the database instance, create objects and insert data into these objects by using Db2 SQL statements.</li></ol>	
Confirm that the Db2 DB instance is available.	To confirm that the Db2 database instance is up and running, use the <code>Db2pd -</code> command.	DBA

## Configure the target Aurora MySQL-Compatible database

Task	Description	Skills required
Create the Aurora MySQL-Compatible database.	<p>Create an Amazon Aurora with MySQL compatibility Database from AWS RDS service</p> <ul style="list-style-type: none"><li>• Create a database on Amazon Aurora with MySQL compatibility and version of your choice, e.g. Aurora (MySQL)–5.6.10a</li><li>• Install MySQL Workbench application or your preferred DB client software which allows you to connect to MySQL database</li></ul>	DBA, General AWS
Configure security groups.	Configure the VPC security group inbound rules for SSH and TCP connections.	General AWS
Confirm that the Aurora database is available.	<p>To make sure that the Aurora MySQL-Compatible database is up and running, do the following:</p> <ol style="list-style-type: none"><li>1. Connect to the EC2 instance through SSH.</li><li>2. Configure and connect to the Aurora MySQL-Compatible instance from MySQL Workbench . Use the endpoint as the</li></ol>	DBA

Task	Description	Skills required
	<p>hostname, as shown in the following example.</p> <pre>mysql-cluster-instance-1.cokmvis0v46q.us-east-1.rds.amazonaws.com</pre> <ol style="list-style-type: none"> <li>3. Create and connect to the new schema (for example, <code>mysql-sample-db2</code> ).</li> <li>4. Run the MySQL statements to check the schemas and objects in the database.</li> </ol>	

## Configure and run AWS SCT

Task	Description	Skills required
Install AWS SCT.	Download and install the latest version of <a href="#">AWS SCT</a> (the current latest version 1.0.628).	General AWS
Configure AWS SCT.	<ol style="list-style-type: none"> <li>1. Download the Java Database Connectivity (JDBC) drivers for IBM Db2 (4.22.X version) and MySQL (8.x).</li> <li>2. To configure the drivers in AWS SCT, choose <b>Settings, Global settings, Drivers</b>.</li> </ol>	General AWS
Create an AWS SCT project.	Create an AWS SCT project and report that uses Db2	General AWS

Task	Description	Skills required
	<p>for LUW as the source DB engine and Aurora MySQL-Compatible for the target DB engine.</p> <p>To identify the privileges needed to connect to a Db2 for LUW database, see <a href="#">Using Db2 LUW as a source for AWS SCT</a>.</p>	

Task	Description	Skills required
Validate the objects.	<p>Choose <b>Load schema</b>, validate the objects. Update any incorrect objects on the target database:</p> <ol style="list-style-type: none"><li>1. Connect to the Amazon Aurora MySQL-Compatible server by providing the connection details, and choose <b>Test connection</b>.</li></ol> <p>Both source and target connections must be successful before AWS SCT can start the migration report.</p> <ol style="list-style-type: none"><li>2. After the report is completed, enter the schema to be converted, and choose <b>Finish</b>.</li></ol> <p>AWS SCT lists any source and target objects that are converted and have errors.</p> <ol style="list-style-type: none"><li>3. Review the errors, and clear them manually.</li><li>4. After all errors are cleared, open the context (right-click) menu for the schema, and choose <b>Load schema</b>.</li><li>5. Choose <b>Apply to database</b>.</li><li>6. In MySQL Workbench , connect to the Aurora MySQL-Compatible</li></ol>	DBA, General AWS

Task	Description	Skills required
	database, and check the schema and objects.	

## Configure and run AWS DMS

Task	Description	Skills required
Create a replication instance.	Sign in to the AWS Management Console, navigate to the AWS DMS service, and create a replication instance with valid settings for the VPC security group that you configured for the source and target databases.	General AWS
Create endpoints.	<p>Create the source endpoint for the Db2 database, and create the target endpoint for the Aurora MySQL-Compatible database:</p> <ol style="list-style-type: none"> <li>1. Create an endpoint for IBM Db2 as the source by choosing <b>Select RDS DB instance</b> and then choosing the Db2 instance that you created. The endpoint configuration details will be automatically populated.</li> <li>2. In the endpoint-specific settings, add the following</li> </ol>	General AWS

Task	Description	Skills required
	<p>extra connection attributes.</p> <pre>CurrentLSN=&lt;scan&gt;; MaxKBytesPerRead=64; SetDataCaptureChanges=true</pre> <p>If you don't mention these attributes, the source endpoint test connection will not be successful. For more information, see <a href="#">Using IBM Db2 LUW as a source for AWS DMS</a>.</p> <p>3. Create an endpoint for Aurora MySQL-Compatible as the target by choosing <b>Select RDS DB instance</b> and then choosing the Aurora MySQL-Compatible instance that you created. The endpoint configuration details will be automatically populated. For more information, see <a href="#">Using a MySQL-compatible database as a target for AWS Database Migration Service</a>.</p> <p>4. Test the source and target endpoints. Confirm that both are successful and available</p>	

Task	Description	Skills required
	5. If the test fails, make sure that the security group inbound rules are valid.	

Task	Description	Skills required
Create migration tasks.	<p>Create a single migration task or multiple migration tasks for full load and CDC or Data validation:</p> <ol style="list-style-type: none"><li>1. To create a database migration task, choose the replication instance, source database endpoint, target database endpoint. Specify the migration type as <b>Migrate existing data (full load)</b>, <b>Replicate data changes only (CDC)</b>, or <b>Migrate existing data and replicate ongoing changes (full load and CDC)</b>.</li><li>2. Under <b>Table mappings</b>, you can configure selection rules and transformation rules in GUI or JSON formats.</li><li>3. Under <b>Selection rules</b>, select the schema, enter table name, and select Action (Include/Exclude) to be configured (for example, Schema: SAMPLE; Table name: %, Action: Include).</li><li>4. Under <b>Transformation rules</b>, select the target (Schema, Table, or Column). Select the schema name, and choose</li></ol>	General AWS

Task	Description	Skills required
	<p>the action (case, prefix, suffix); for example, Target: Schema; mysql-sample-db; Action: Make lowercase.</p> <p>5. Turn on Amazon CloudWatch Logs monitoring.</p>	
Plan the production run.	Confirm downtime with stakeholders such as application owners to run AWS DMS in production systems.	Migration lead
Run the migration tasks.	<ol style="list-style-type: none"><li>1. Start the AWS DMS task that has a status of <b>Ready</b>.</li><li>2. Monitor the migration task logs in Amazon CloudWatch Logs for any errors.</li></ol>	General AWS

Task	Description	Skills required
Validate the data.	<p>Review migration task results and data in the source Db2 and target MySQL databases:</p> <ol style="list-style-type: none"> <li>1. If the status is <b>Load complete ongoing replication</b>, the full load with CDC data migration is completed, and validation is ongoing.</li> <li>2. Connect to the Aurora MySQL-Compatible database, and check the data.</li> <li>3. Check the ongoing changes by inserting or updating data in the Db2 database.</li> </ol>	DBA
Stop migration tasks.	After data validation is successfully completed, stop the validation migration tasks.	General AWS

## Troubleshooting

Issue	Solution
AWS SCT source and target test connections are failing.	Configure JDBC driver versions and VPC security group inbound rules to accept the incoming traffic.
The Db2 source endpoint test run fails.	Configure the extra connection setting <code>CurrentLSN=&lt;scan&gt;</code> ; .

Issue	Solution
<p>The AWS DMS task fails to connect to the Db2 source, and the following error is returned.</p> <pre>database is recoverable if either or both of the database configuration parameters LOGARCHMETH1 and LOGARCHMETH2 are set to ON</pre>	<p>To avoid the error, run the following commands:</p> <ol style="list-style-type: none"><li>1. <code>\$ db2 update db cfg for sample using LOGARCHMETH1 DISK:/home/db2inst1/logs</code></li><li>2. <code>\$ db2stop</code></li><li>3. <code>\$ db2start</code></li><li>4. <code>\$ db2 connect to sample</code></li></ol> <div data-bbox="868 695 1507 894" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>SQL1116N A connection to or activation of database "SAMPLE" cannot be made because of BACKUP PENDING.  SQLSTATE=57019</pre></div> <ol style="list-style-type: none"><li>5. <code>\$ db2 backup database sample to ../logs</code></li></ol> <div data-bbox="868 1031 1507 1150" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>SQL2036N The path for the file or device "../logs" is not valid</pre></div> <ol style="list-style-type: none"><li>6. <code>\$ cd</code></li><li>7. <code>\$ pwd</code></li></ol> <div data-bbox="868 1297 1507 1377" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>/home/db2inst1</pre></div> <ol style="list-style-type: none"><li>8. <code>\$ mkdir /tmp/backup</code></li><li>9. <code>\$ db2 backup database sample to /tmp/backup</code></li></ol> <div data-bbox="868 1570 1507 1730" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>Backup successful. # Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS

**Source:** Microsoft SQL Server on Amazon EC2     **Target:** Amazon DocumentDB     **R Type:** Re-architect

**Environment:** PoC or pilot     **Technologies:** CloudNative; Databases; Migration     **Workload:** Microsoft

**AWS services:** Amazon EC2; Amazon DocumentDB

## Summary

This pattern describes how to use AWS Database Migration Service (AWS DMS) to migrate a Microsoft SQL Server database hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon DocumentDB (with MongoDB compatibility) database.

The AWS DMS replication task reads the table structure of the SQL Server database, creates the corresponding collection in Amazon DocumentDB, and performs a full-load migration.

You can also use this pattern to migrate an on-premises SQL Server or an Amazon Relational Database Service (Amazon RDS) for SQL Server DB instance to Amazon DocumentDB. For more information, see the guide [Migrating Microsoft SQL Server databases to the AWS Cloud](#) on the AWS Prescriptive Guidance website.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An existing SQL Server database on an EC2 instance.
- Fixed database (**db\_owner**) role assigned to AWS DMS in the SQL Server database. For more information, see [Database-level roles](#) in the SQL Server documentation.
- Familiarity with using the `mongodump`, `mongorestore`, `mongoexport`, and `mongoimport` utilities to [move data in and out of an Amazon DocumentDB cluster](#).
- [Microsoft SQL Server Management Studio](#), installed and configured.

## Limitations

- The cluster size limit in Amazon DocumentDB is 64 TB. For more information, see [Cluster limits](#) in the Amazon DocumentDB documentation.
- AWS DMS doesn't support the merging of multiple source tables into a single Amazon DocumentDB collection.
- If AWS DMS processes any changes from a source table without a primary key, it will ignore large object (LOB) columns in the source table.

## Architecture

### Source technology stack

- Amazon EC2

### Target architecture

### Target technology stack

- Amazon DocumentDB

## Tools

- [AWS DMS](#) – AWS Database Migration Service (AWS DMS) helps you migrate databases easily and securely.
- [Amazon DocumentDB](#) – Amazon DocumentDB (with MongoDB compatibility) is a fast, reliable, and fully managed database service.
- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- [Microsoft SQL Server](#) – SQL Server is a relational database management system.
- [SQL Server Management Studio \(SSMS\)](#) – SSMS is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

## Epics

### Create and configure a VPC

Task	Description	Skills required
Create a VPC.	Sign in to the AWS Management Console and open the Amazon VPC console. Create a virtual private cloud (VPC) with an IPv4 CIDR block range.	System administrator
Create security groups and network ACLs.	On the Amazon VPC console, create security groups and network access control lists (network ACLs) for your VPC, according to your requirements. You can also use the default settings for these configurations. For more information about this and	System administrator

Task	Description	Skills required
	other stories, see the “Related resources” section.	

## Create and configure the Amazon DocumentDB cluster

Task	Description	Skills required
Create an Amazon DocumentDB cluster.	Open the Amazon DocumentDB console and choose “Clusters.” Choose “Create,” and create an Amazon DocumentDB cluster with one instance. Important : Make sure you configure this cluster with your VPC’s security groups.	System administrator
Install the mongo shell.	The mongo shell is a command-line utility that you use to connect to and query your Amazon DocumentDB cluster. To install it, run the “/etc/yum.repos.d/mongodb-org-3.6.repo” command to create the repository file. Run the “sudo yum install -y mongodb-org-shell” command to install the mongo shell. To encrypt data in transit, download the public key for Amazon DocumentDB, and then connect to your Amazon DocumentDB instance. For more information about	System administrator

Task	Description	Skills required
	these steps, see the “Related resources” section.	
Create a database in the Amazon DocumentDB cluster.	Run the "use" command with the name of your database to create a database in your Amazon DocumentDB cluster.	System administrator

## Create and configure the AWS DMS replication instance

Task	Description	Skills required
Create the AWS DMS replication instance.	Open the AWS DMS console and choose “Create replication instance.” Enter a name and description for your replication task. Choose the instance class, engine version, storage, VPC, Multi-AZ, and make it publicly accessible. Choose the “Advanced” tab to set the network and encryption settings. Specify the maintenance settings, and then choose “Create replication instance.”	System administrator
Configure the SQL Server database.	Log in to Microsoft SQL Server and add an inbound rule for communication between the source endpoint and the AWS DMS replication instance. Use the replication instance’s private IP address as the source. Important	System administrator

Task	Description	Skills required
	: The replication instance and target endpoint should be on the same VPC. Use an alternative source in the security group if the VPCs are different for the source and replication instances.	

## Create and test the source and target endpoints in AWS DMS

Task	Description	Skills required
Create the source and target database endpoints.	Open the AWS DMS console and choose "Connect source and target database endpoints." Specify the connection information for the source and target databases. If required, choose the "Advanced" tab to set values for "Extra connection attributes." Download and use the certificate bundle in your endpoint configuration.	System administrator
Test the endpoint connection.	Choose "Run test" to test the connection. Troubleshoot any error messages by verifying the security group settings and the connections to the AWS DMS replication instance from both the source and target database instances.	System administrator

## Migrate data

Task	Description	Skills required
Create the AWS DMS migration task.	On the AWS DMS console, choose "Tasks," "Create task." Specify the task options, including the source and destination endpoint names, and replication instance names. Under "Migration type" choose "Migrate existing data," and "Replicate data changes only." Choose "Start task."	System administrator
Run the AWS DMS migration task.	Under "Task settings," specify the settings for the table preparation mode, such as "Do nothing," "Drop tables on target," "Truncate," and "Include LOB columns in replication." Set a maximum LOB size that AWS DMS will accept and choose "Enable logging." Leave the "Advanced settings" at their default values and choose "Create task."	System administrator
Monitor the migration.	On the AWS DMS console, choose "Tasks" and choose your migration task. Choose "Task monitoring" to monitor your task. The task stops when the full-load migration	System administrator

Task	Description	Skills required
	is complete and cached changes are applied.	

## Test and verify the migration

Task	Description	Skills required
Connect to the Amazon DocumentDB cluster by using the mongo shell.	Open the Amazon DocumentDB console, choose your cluster under "Clusters." In the "Connectivity and Security" tab, choose "Connect to this cluster with the mongo shell."	System administrator
Verify the results of your migration.	Run the "use" command with the name of your database and then run the "show collections" command. Run the "db. .count();" command with the name of your database. If the results match your source database, then your migration was successful.	System administrator

# Migrate an on-premises ThoughtSpot Falcon database to Amazon Redshift

Created by Battulga Purevragchaa (AWS) and Antony Prasad Thevaraj (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> On-premises ThoughtSpot Falcon database	<b>Target:</b> Amazon Redshift
<b>R Type:</b> Re-architect	<b>Workload:</b> All other workloads	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> AWS DMS; Amazon Redshift		

## Summary

On-premises data warehouses require significant administration time and resources, particularly for large datasets. The financial cost of building, maintaining, and growing these warehouses is also very high. To help manage costs, keep extract, transform, and load (ETL) complexity low, and deliver performance as your data grows, you must constantly choose which data to load and which data to archive.

By migrating your on-premises [ThoughtSpot Falcon databases](#) to the Amazon Web Services (AWS) Cloud, you can access cloud-based data lakes and data warehouses that increase your business agility, security, and application reliability, in addition to reducing your overall infrastructure costs. Amazon Redshift helps to significantly lower the cost and operational overhead of a data warehouse. You can also use Amazon Redshift Spectrum to analyze large amounts of data in its native format without data loading.

This pattern describes the steps and process for migrating a ThoughtSpot Falcon database from an on-premises data center to an Amazon Redshift database on the AWS Cloud.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A ThoughtSpot Falcon database hosted in an on-premises data center

## Product versions

- ThoughtSpot version 7.0.1

## Architecture

The diagram shows the following workflow:

1. Data is hosted in an on-premises relational database.
2. AWS Schema Conversion Tool (AWS SCT) converts the data definition language (DDL) that is compatible with Amazon Redshift.
3. After the tables are created, you can migrate the data by using AWS Database Migration Service (AWS DMS).
4. The data is loaded into Amazon Redshift.
5. The data is stored in Amazon Simple Storage Service (Amazon S3) if you use Redshift Spectrum or already host the data in Amazon S3.

## Tools

- [AWS DMS](#) – AWS Data Migration Service (AWS DMS) helps you quickly and securely migrate databases to AWS.

- [Amazon Redshift](#) – Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.
- [AWS SCT](#) – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another.

## Epics

### Prepare for the migration

Task	Description	Skills required
Identify the appropriate Amazon Redshift configuration.	Identify the appropriate Amazon Redshift cluster configuration based on your requirements and data volume.  For more information, see <a href="#">Amazon Redshift clusters</a> in the Amazon Redshift documentation.	DBA
Research Amazon Redshift to evaluate if it meets your requirements.	Use the <a href="#">Amazon Redshift FAQs</a> to understand and evaluate whether Amazon Redshift meets your requirements.	DBA

### Prepare the target Amazon Redshift cluster

Task	Description	Skills required
Create an Amazon Redshift cluster.	Sign in to the AWS Management Console, open the Amazon Redshift console, and then create an Amazon	DBA

Task	Description	Skills required
	<p>Redshift cluster in a virtual private cloud (VPC).</p> <p>For more information, see <a href="#">Creating a cluster in a VPC</a> in the Amazon Redshift documentation.</p>	
Conduct a PoC for your Amazon Redshift database design.	<p>Follow Amazon Redshift best practices by conducting a proof of concept (PoC) for your database design.</p> <p>For more information, see <a href="#">Conducting a proof of concept for Amazon Redshift</a> in the Amazon Redshift documentation.</p>	DBA
Create database users.	<p>Create the users in your Amazon Redshift database and grant the appropriate roles for access to the schema and tables.</p> <p>For more information, see <a href="#">Grant access privileges for a user or user group</a> in the Amazon Redshift documentation.</p>	DBA

Task	Description	Skills required
Apply configuration settings to the target database.	<p>Apply configuration settings to the Amazon Redshift database according to your requirements.</p> <p>For more information about enabling database, session, and server-level parameters, see the <a href="#">Configuration reference</a> in the Amazon Redshift documentation.</p>	DBA

## Create objects in the Amazon Redshift cluster

Task	Description	Skills required
Manually create tables with DDL in Amazon Redshift.	(Optional) If you use AWS SCT, the tables are automatically created. However, if there are failures when replicating DDLs, you have to manually create the tables	DBA
Create external tables for Redshift Spectrum.	<p>Create an external table with an external schema for Amazon Redshift Spectrum. To create external tables, you must be the owner of the external schema or a <a href="#">database superuser</a>.</p> <p>For more information, see <a href="#">Creating external tables for Amazon Redshift Spectrum</a></p>	DBA

Task	Description	Skills required
	in the Amazon Redshift documentation.	

## Migrate data using AWS DMS

Task	Description	Skills required
Use AWS DMS to migrate the data.	<p>After you create the DDL of the tables in the Amazon Redshift database, migrate your data to Amazon Redshift by using AWS DMS.</p> <p>For detailed steps and instructions, see <a href="#">Using an Amazon Redshift database as a target for AWS DMS</a> in the AWS DMS documentation.</p>	DBA
Use the COPY command to load the data.	<p>Use the Amazon Redshift COPY command to load the data from Amazon S3 to Amazon Redshift.</p> <p>For more information, see <a href="#">Using the COPY command to load from Amazon S3</a> in the Amazon Redshift documentation.</p>	DBA

## Validate the Amazon Redshift cluster

Task	Description	Skills required
Validate the source and target records.	Validate the table count for the source and target records that were loaded from your source system.	DBA
Implement Amazon Redshift best practices for performance tuning.	Implement Amazon Redshift best practices for table and database design.  For more information, see the blog post <a href="#">Top 10 performance tuning techniques for Amazon Redshift</a> .	DBA
Optimize query performance.	Amazon Redshift uses SQL-based queries to interact with data and objects in the system. Data manipulation language (DML) is the subset of SQL that you can use to view, add, change, and delete data. DDL is the subset of SQL that you use to add, change, and delete database objects such as tables and views.  For more information, see <a href="#">Tuning query performance</a> in the Amazon Redshift documentation.	DBA
Implement WLM.	You can use workload management (WLM) to define multiple query queues and	DBA

Task	Description	Skills required
	<p>route queries to appropriate queues at runtime.</p> <p>For more information, see <a href="#">Implementing workload management</a> in the Amazon Redshift documentation.</p>	
Work with concurrency scaling.	<p>By using the Concurrency Scaling feature, you can support virtually unlimited concurrent users and concurrent queries, with consistently fast query performance.</p> <p>For more information, see <a href="#">Working with concurrency scaling</a> in the Amazon Redshift documentation.</p>	DBA
Use Amazon Redshift best practices for table design.	<p>When you plan your database, certain important table design decisions can strongly influence overall query performance.</p> <p>For more information about choosing the most appropriate table design option, see <a href="#">Amazon Redshift best practices for designing tables</a> in the Amazon Redshift documentation.</p>	DBA

Task	Description	Skills required
<p>Create materialized views in Amazon Redshift.</p>	<p>A materialized view contains a precomputed results set based on an SQL query over one or more base tables. You can issue SELECT statements to query a materialized view in the same way that you query other tables or views in the database.</p> <p>For more information, see <a href="#">Creating materialized views in Amazon Redshift</a> in the Amazon Redshift documentation.</p>	DBA
<p>Define joins between the tables.</p>	<p>To search more than one table at the same time in ThoughtSpot, you must define joins between the tables by specifying columns that contain matching data across two tables. These columns represent the primary key and foreign key of the join.</p> <p>You can define them by using the ALTER TABLE command in Amazon Redshift or ThoughtSpot. For more information, see <a href="#">ALTER TABLE</a> in the Amazon Redshift documentation.</p>	DBA

## Set up ThoughtSpot connection to Amazon Redshift

Task	Description	Skills required
Add an Amazon Redshift connection.	<p>Add an Amazon Redshift connection to your on-premises ThoughtSpot Falcon database.</p> <p>For more information, see <a href="#">Add an Amazon Redshift connection</a> in the ThoughtSpot documentation.</p>	DBA
Edit the Amazon Redshift connection.	<p>You can edit the Amazon Redshift connection to add tables and columns.</p> <p>For more information, see <a href="#">Edit an Amazon Redshift connection</a> in the ThoughtSpot documentation.</p>	DBA
Remap the Amazon Redshift connection.	<p>Modify the connection parameters by editing the source mapping .yaml file that was created when you added the Amazon Redshift connection.</p> <p>For example, you can remap the existing table or column to a different table or column in an existing database connection. ThoughtSpot recommends that you check the dependencies before and after you remap a table or</p>	DBA

Task	Description	Skills required
	<p>column in a connection to ensure that they display as required.</p> <p>For more information, see <a href="#">Remap an Amazon Redshift connection</a> in the ThoughtSpot documentation.</p>	
Delete a table from the Amazon Redshift connection.	<p>(Optional) If you attempt to remove a table in an Amazon Redshift connection, ThoughtSpot checks for dependencies and shows a list of dependent objects. You can choose the listed objects to delete them or remove the dependency. You can then remove the table.</p> <p>For more information, see <a href="#">Delete a table from an Amazon Redshift connection</a> in the ThoughtSpot documentation.</p>	DBA

Task	Description	Skills required
Delete a table with dependent objects from an Amazon Redshift connection.	<p>(Optional) If you try to delete a table with dependent objects, the operation is blocked. A Cannot delete window appears, with a list of links to dependent objects. When all the dependencies are removed, you can then delete the table</p> <p>For more information, see <a href="#">Delete a table with dependent objects from an Amazon Redshift connection</a> in the ThoughtSpot documentation.</p>	DBA
Delete an Amazon Redshift connection.	<p>(Optional) Because a connection can be used in multiple data sources or visualizations, you must delete all of the sources and tasks that use that connection before you can delete the Amazon Redshift connection.</p> <p>For more information, see <a href="#">Delete an Amazon Redshift connection</a> in the ThoughtSpot documentation.</p>	DBA

Task	Description	Skills required
Check connection reference for Amazon Redshift.	Make sure that you provide the required information for your Amazon Redshift connection by using the <a href="#">Connection reference</a> in the ThoughtSpot documentation.	DBA

# Migrate an Oracle database to Amazon DynamoDB using AWS DMS

Created by Rambabu Karnena (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon DynamoDB
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon DynamoDB		

## Summary

This pattern walks you through the steps for migrating an Oracle database to [Amazon DynamoDB](#) using AWS Database Migration Service ([AWS DMS](#)). It covers three types of source databases:

- On-premises Oracle databases
- Oracle databases on Amazon Elastic Compute Cloud ([Amazon EC2](#))
- Amazon Relational Database Service ([Amazon RDS](#)) for Oracle DB instances

In this proof of concept, this pattern focuses on migrating from an Amazon RDS for Oracle DB instance.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An application connecting to an Amazon RDS for Oracle database
- A table created in the source Amazon RDS for Oracle database with a primary key and sample data

### Limitations

- Oracle database objects, such as procedures, functions, packages, and triggers, are not considered for migration because Amazon DynamoDB does not support these database objects.

## Product versions

- This pattern applies to all editions and versions of Oracle databases that are supported by AWS DMS. For more information, see using an [Oracle database as a source for AWS DMS](#) and using an [Amazon DynamoDB database as a target for AWS DMS](#). We recommend that you use the latest versions of AWS DMS for the most comprehensive version and feature support.

## Architecture

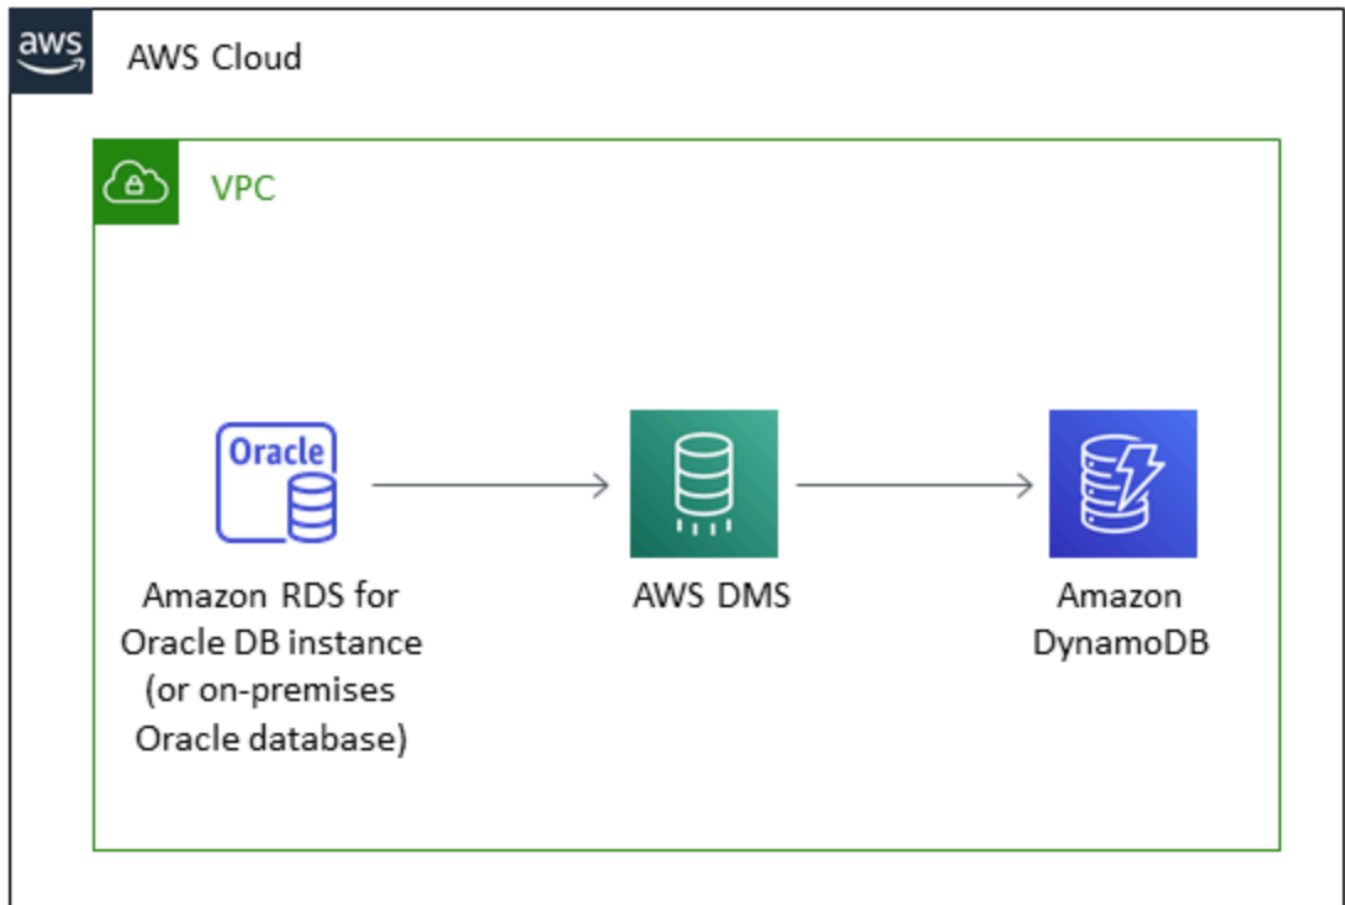

### Source technology stack

- Amazon RDS for Oracle DB instances, Oracle on Amazon EC2, or on-premises Oracle databases

### Target technology stack

- Amazon DynamoDB

### AWS data migration architecture

## Tools

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.

## Epics

### Plan the migration

Task	Description	Skills required
Create a VPC.	In your AWS account, create a virtual private cloud (VPC) and a private subnet.	Systems administrator
Create security groups and network access control lists.	For more information, see the <a href="#">AWS documentation</a> .	Systems administrator
Configure and start the Amazon RDS for Oracle DB instance.	For more information, see the <a href="#">AWS documentation</a> .	DBA, Systems administrator

### Migrate data

Task	Description	Skills required
Create an IAM role to access DynamoDB.	In the AWS Identity and Access Management (IAM) console, create the role, attach the policy AmazonDynamoDBFullAccess to it, and select AWS DMS as the service.	Systems administrator
Create an AWS DMS replication instance for migration.	The replication instance should be in the same Availability Zone and VPC as the source database.	Systems administrator
Create source and target endpoints in AWS DMS.	To create the source database endpoint, you have two options:	Systems administrator

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>On the Amazon RDS console, choose <b>Databases, DB identifier, Connectivity &amp; Security</b>, and choose the endpoint.</li> <li>On the AWS DMS console, choose <b>Select RDS DB instance</b>.</li> </ul> <p>To create the target database endpoint, choose the role Amazon Resource Name (ARN) from the previous task to access DynamoDB.</p>	
Create an AWS DMS task to load the source Oracle database tables to DynamoDB.	Choose the source and destination endpoint names and the replication instance from the previous steps. The type can be full load. Choose the Oracle schema and specify % to select all tables.	Systems administrator
Validate the tables in DynamoDB.	To view the migration results, choose <b>Tables</b> from the left navigation pane in the DynamoDB console.	DBA

## Migrate the application

Task	Description	Skills required
Modify the application code.	To connect to and retrieve data from DynamoDB, update the application code.	App owner, DBA, Systems administrator

## Cut over

Task	Description	Skills required
Switch the application clients to use DynamoDB.		DBA, App owner, Systems administrator

## Close the project

Task	Description	Skills required
Shut down AWS resources.	For example, the shut down the Amazon RDS for Oracle instance, DynamoDB, and the AWS DMS replication instance.	DBA, Systems administrator
Gather metrics.	Metrics include the time to migrate, the percentages of manual work and work performed by the tool, and cost savings.	DBA, App owner, Systems administrator

# Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS

Created by Saurav Mishra (AWS) and Eduardo Valentim (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle database	<b>Target:</b> PostgreSQL 9.0
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases; Storage & backup
<b>AWS services:</b> AWS DMS		

## Summary

This pattern describes how to speed up loading a partitioned table from Oracle to PostgreSQL by using AWS Database Migration Service (AWS DMS), which doesn't support native partitioning. The target PostgreSQL database can be installed on Amazon Elastic Compute Cloud (Amazon EC2), or it can be an Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition DB instance.

Uploading a partitioned table includes the following steps:

1. Create a parent table similar to the Oracle partition table, but don't include any partition.
2. Create child tables that will inherit from the parent table that you created in step 1.
3. Create a procedure function and trigger to handle the inserts in the parent table.

However, because the trigger is fired for every insert, the initial load using AWS DMS can be very slow.

To speed up initial loads from Oracle to PostgreSQL 9.0, this pattern creates a separate AWS DMS task for each partition and loads the corresponding child tables. You then create a trigger during cutover.

PostgreSQL version 10 supports native partitioning. However, you might decide to use inherited partitioning in some cases. For more information, see the [Additional information](#) section.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Oracle database with a partitioned table
- A PostgreSQL database on AWS

## Product versions

- PostgreSQL 9.0

## Architecture

### Source technology stack

- A partitioned table in Oracle

### Target technology stack

- A partitioned table in PostgreSQL (on Amazon EC2, Amazon RDS for PostgreSQL, or Aurora PostgreSQL)

### Target architecture

## Tools

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

## Epics

### Set up AWS DMS

Task	Description	Skills required
Create the tables in PostgreSQL.	Create the parent and corresponding child tables in PostgreSQL with the required check conditions for partitions.	DBA
Create the AWS DMS task for each partition.	Include the filter condition of the partition in the AWS DMS task. Map the partitions to the corresponding PostgreSQL child tables.	DBA
Run the AWS DMS tasks using full load and change data capture (CDC).	Make sure that the <code>StopTaskCachedChangesApplied</code> parameter is set to <code>true</code> and the <code>StopTaskCachedChangesNotApplied</code> parameter is set to <code>false</code> .	DBA

## Cut over

Task	Description	Skills required
Stop the replication tasks.	Before you stop the tasks, confirm that the source and destination are in sync.	DBA
Create a trigger on the parent table.	Because the parent table will receive all insert and update commands, create a trigger that will route these commands to the respective child tables based on the partitioning condition.	DBA

## Related resources

- [AWS DMS](#)
- [Table Partitioning \(PostgreSQL documentation\)](#)

## Additional information

Although PostgreSQL version 10 supports native partitioning, you might decide to use inherited partitioning for the following use cases:

- Partitioning enforces a rule that all partitions must have the same set of columns as the parent, but table inheritance supports children having extra columns.
- Table inheritance supports multiple inheritances.
- Declarative partitioning supports only list and range partitioning. With table inheritance, you can divide the data as you want. However, if the constraint exclusion can't prune partitions effectively, query performance will suffer.
- Some operations need a stronger lock when using declarative partitioning than when using table inheritance. For example, adding or removing a partition to or from a partitioned table requires an `ACCESS EXCLUSIVE` lock on the parent table, whereas a `SHARE UPDATE EXCLUSIVE` lock is enough for regular inheritance.

When you use separate job partitions, you can also reload partitions if there are any AWS DMS validation issues. For better performance and replication control, run tasks on separate replication instances.

# Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL

Created by Jitender Kumar (AWS), Neha Sharma (AWS), and Srinu Ramaswamy (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Amazon RDS for Oracle	<b>Target:</b> Amazon RDS for MySQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS		

## Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for MySQL DB instance on Amazon Web Services (AWS). The pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT).

The pattern provides best practices for handling the migration of stored procedures. It also covers and code changes to support the application layer.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An Amazon RDS for Oracle source database.
- An Amazon RDS for MySQL target database. Source and target databases should be in the same virtual private cloud (VPC). If you're using multiple VPCs, or you must have the required access permissions.
- Security groups that allow connectivity between the source and target databases, AWS SCT, the application server, and AWS DMS.
- A user account with the required privilege to run AWS SCT on the source database.
- Supplemental logging enabled for running AWS DMS on the source database.

## Limitations

- The source and target Amazon RDS database size limit is 64 TB. For Amazon RDS size information, see the [AWS documentation](#).
- Oracle is case-insensitive for database objects, but MySQL is not. AWS SCT can handle this issue while creating an object. However, some manual work is required to support full case insensitivity.
- This migration doesn't use MySQL extensions to enable Oracle-native functions. AWS SCT handles most of the conversion, but some work is required to change code manually.
- Java Database Connectivity (JDBC) driver changes are required in the application.

## Product versions

- Amazon RDS for Oracle 12.2.0.1 and later. For currently supported RDS for Oracle versions, see the [AWS documentation](#).
- Amazon RDS for MySQL 8.0.15 and later. For currently supported RDS for MySQL versions, see the [AWS documentation](#).
- AWS DMS version 3.3.0 and later. See the AWS documentation for more information about AWS DMS supported [source endpoints](#) and [target endpoints](#).
- AWS SCT version 1.0.628 and later. See the [AWS SCT source and target endpoint support matrix](#) in the AWS documentation.

## Architecture

### Source technology stack

- Amazon RDS for Oracle. For more information, see [Using an Oracle database as a source for AWS DMS](#).

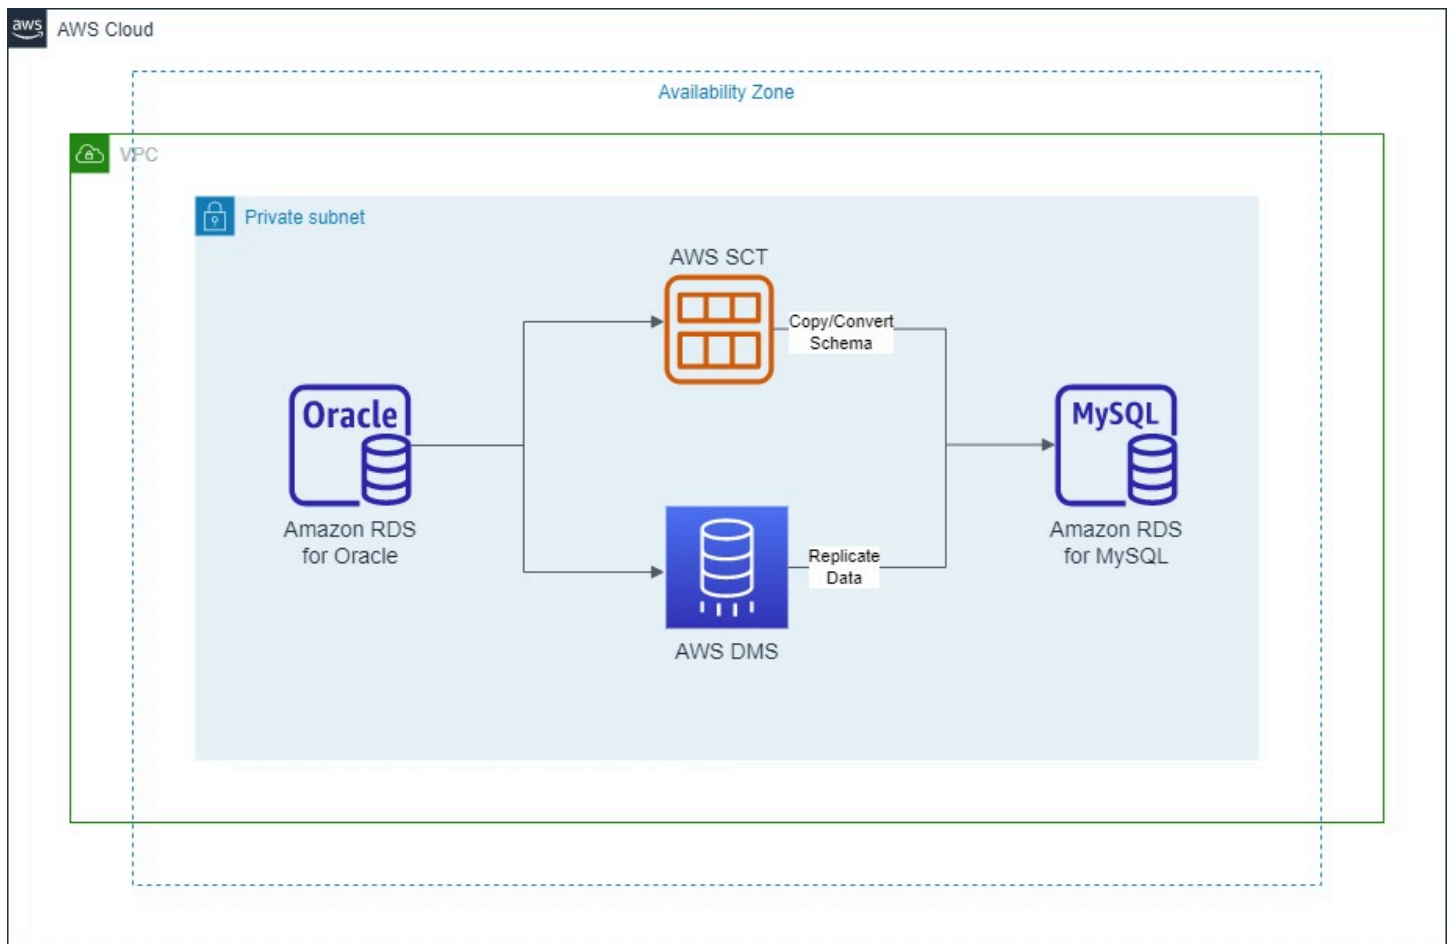

### Target technology stack

- Amazon RDS for MySQL. For more information, see [Using a MySQL-Compatible database as a target for AWS DMS](#).

### Migration architecture

In the following diagram, AWS SCT copies and converts schema objects from the Amazon RDS for Oracle source database and sends the objects to the Amazon RDS for MySQL target database. AWS DMS replicates data from the source database and sends it to the Amazon RDS for MySQL instance.

## Tools

- [AWS Data Migration Service](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses [Amazon RDS for Oracle](#) and [Amazon RDS for MySQL](#).
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

## Epics

### Prepare for migration

Task	Description	Skills required
Validate the source and target database versions and engines.		DBA
Identify hardware requirements for the target server instance.		DBA, SysAdmin
Identify storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type (capacity, storage features, network features).		DBA, SysAdmin
Identify network-access security requirements for the source and target databases.		DBA, SysAdmin
Choose an application migration strategy.	Consider whether you want full downtime or partial downtime for cutover activities.	DBA, SysAdmin, App owner

### Configure infrastructure

Task	Description	Skills required
Create a VPC and subnets.		SysAdmin

Task	Description	Skills required
Create security groups and network access control lists (ACLs).		SysAdmin
Configure and start the Amazon RDS for Oracle instance.		DBA, SysAdmin
Configure and start the Amazon RDS for MySQL instance.		DBA, SysAdmin
Prepare a test case for validation of code conversion.	This will help in unit-testing for the converted code.	DBA, Developer
Configure the AWS DMS instance.		
Configure source and target endpoints in AWS DMS.		

## Migrate data

Task	Description	Skills required
Generate the target database script using AWS SCT.	Check the accuracy of the code that was converted by AWS SCT. Some manual work will be required.	DBA, Developer
In AWS SCT, choose the "Case Insensitive" setting.	In AWS SCT, choose Project Settings, Target Case Sensitivity, Case Insensitive.	DBA, Developer

Task	Description	Skills required
In AWS SCT, choose not to use the Oracle native function.	In Project Settings, check the functions TO_CHAR/T O_NUMBER/TO_DATE.	DBA, Developer
Make changes for "sql%notfound" code.	You might have to convert the code manually.	
Query on tables and objects in stored procedures (use lowercase queries).		DBA, Developer
Create the primary script after all changes are made, and then deploy the primary script on the target database.		DBA, Developer
Unit-test stored procedures and application calls using sample data.		
Clean up data that was created during unit testing.		DBA, Developer
Drop foreign key constraints on the target database.	This step is required to load initial data. If you don't want to drop the foreign key constraints, you must create a migration task for data specific to the primary and secondary tables.	DBA, Developer
Drop primary keys and unique keys on the target database.	This step results in better performance for the initial load.	DBA, Developer
Enable supplemental logging on the source database.		DBA

Task	Description	Skills required
Create a migration task for the initial load in AWS DMS, and then run it.	Choose the option to migrate existing data.	DBA
Add the primary keys and foreign keys to the target database.	Constraints need to be added after the initial load.	DBA, Developer
Create a migration task for ongoing replication.	Ongoing replication keeps the target database synchronized with the source database.	DBA

## Migrate applications

Task	Description	Skills required
Replace Oracle native functions with MySQL native functions.		App owner
Make sure that only lowercase names are used for database objects in SQL queries.		DBA, SysAdmin, App owner

## Cut over to the target database

Task	Description	Skills required
Shut down the application server.		App owner
Validate that the source and target databases are in sync.		DBA, App owner

Task	Description	Skills required
Stop the Amazon RDS for Oracle DB instance.		DBA
Stop the migration task.	This will stop automatically after you complete the previous step.	DBA
Change the JDBC connection from Oracle to MySQL.		App owner, DBA
Start the application.		DBA, SysAdmin, App owner

## Close the project

Task	Description	Skills required
Review and validate the project documents.		DBA, SysAdmin
Gather metrics about time to migrate, percentage of manual versus tool tasks, cost savings, etc.		DBA, SysAdmin
Stop and delete AWS DMS instances.		DBA
Remove the source and target endpoints.		DBA
Remove migration tasks.		DBA
Take a snapshot of the Amazon RDS for Oracle DB instance.		DBA

Task	Description	Skills required
Delete the Amazon RDS for Oracle DB instance.		DBA
Shut down and delete any other temporary AWS resources you used.		DBA, SysAdmin
Close the project and provide any feedback.		DBA

# Migrate from IBM Db2 on Amazon EC2 to Aurora PostgreSQL-Compatible using AWS DMS and AWS SCT

Created by *Sirsendu Halder (AWS)* and *Abhimanyu Chhabra (AWS)*

<b>Environment:</b> PoC or pilot	<b>Source:</b> IBM Db2	<b>Target:</b> Aurora PostgreSQL-Compatible
<b>R Type:</b> Re-architect	<b>Workload:</b> IBM	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon Aurora; AWS DMS; AWS SCT		

## Summary

This pattern provides guidance for migrating an IBM Db2 database on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon Aurora PostgreSQL-Compatible Edition DB instance. This pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT) for data migration and schema conversion.

The pattern targets an online migration strategy with little or no downtime for a multi-terabyte IBM Db2 database that has a high number of transactions. We recommend that you convert the columns in primary keys (PKs) and foreign keys (FKs) with the data type NUMERIC to INT or BIGINT in PostgreSQL for better performance.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source IBM Db2 database on an EC2 instance

### Product versions

- DB2/LINUX8664 version 11.1.4.4 and later

## Architecture

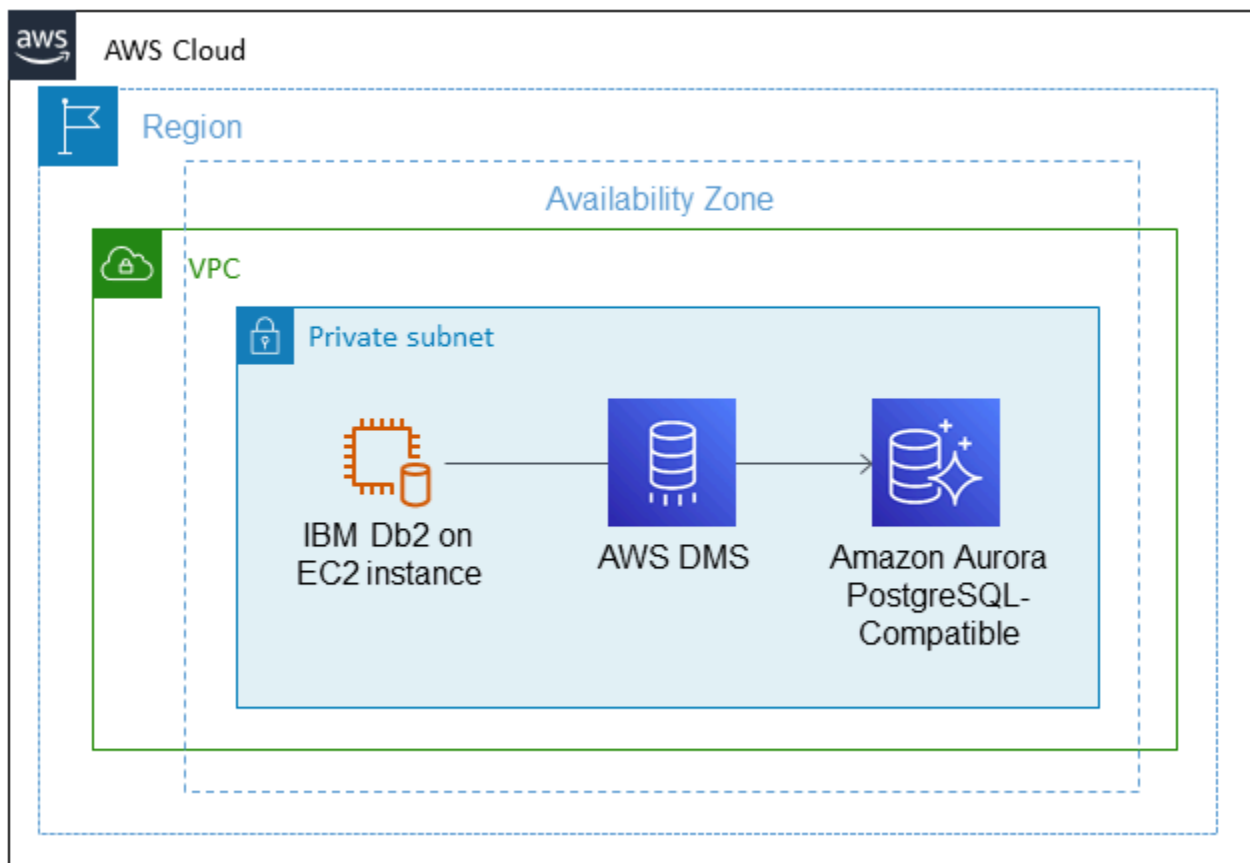

### Source technology stack

- A Db2 database on an EC2 instance

### Target technology stack

- An Aurora PostgreSQL-Compatible version 10.18 or later DB instance

### Database migration architecture

## Tools

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate databases into the AWS Cloud or between combinations of cloud and on-premises setups. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. You can use AWS DMS to migrate your data to and from the most widely used

commercial and open-source databases. AWS DMS supports heterogeneous migrations between different database platforms, such as IBM Db2 to Aurora PostgreSQL-Compatible version 10.18 or higher. For details, see [Sources for Data Migration](#) and [Targets for Data Migration](#) in the AWS DMS documentation.

- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format that's compatible with the target database. Any objects that are not automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan the application source code for embedded SQL statements and convert them.

## Epics

### Set up the environment

Task	Description	Skills required
Create an Aurora PostgreSQL-Compatible DB instance.	<p>To create the DB instance, follow the instructions in the <a href="#">AWS documentation</a>. For engine type, choose <b>Amazon Aurora</b>. For edition, choose <b>Amazon Aurora PostgreSQL-Compatible Edition</b>.</p> <p>The Aurora PostgreSQL-Compatible version 10.18 or later DB instance should be in the same virtual private cloud (VPC) as the source IBM Db2 database.</p>	Amazon RDS

## Convert your database schema

Task	Description	Skills required
Install and verify AWS SCT.	<ol style="list-style-type: none"><li>1. Install AWS SCT by following the steps in the <a href="#">AWS SCT documentation</a>.</li><li>2. Verify the installation by following the procedures in the <a href="#">AWS SCT documentation</a>.</li></ol>	AWS administrator, DBA, Migration engineer
Start AWS SCT and create a project.	To start the AWS SCT tool and create a new project to run a database migration assessment report, follow the instructions in the <a href="#">AWS SCT documentation</a> .	Migration engineer
Add database servers and create a mapping rule.	<ol style="list-style-type: none"><li>1. Add source and target database servers by following the instructions in the <a href="#">AWS SCT documentation</a>.</li><li>2. Create a mapping rule to define the target database platform for your source database. For instructions, see the <a href="#">AWS SCT documentation</a>.</li></ol>	Migration engineer
Create a database migration assessment report.	Create the database migration assessment report by following the steps in the <a href="#">AWS SCT documentation</a> .	Migration engineer

Task	Description	Skills required
View the assessment report.	Use the <b>Summary</b> tab of the database migration assessment report to view the report and analyze the data. This analysis will help you determine the complexity of the migration. For more information, see the <a href="#">AWS SCT documentation</a> .	Migration engineer
Convert the schema.	To convert your source database schemas:  <ol style="list-style-type: none"><li>1. On the AWS SCT console, choose <b>View</b>, and then <b>Main view</b>.</li><li>2. Select the object or parent node from your source schema, open the context (right-click) menu, and then choose <b>Convert schema</b>.</li></ol> For more information, see the <a href="#">AWS SCT documentation</a> .	Migration engineer

Task	Description	Skills required
Apply the converted database schema to the target DB instance.	<ol style="list-style-type: none"><li>1. Choose the schema element in the right panel of your project that displays the planned schema for your target DB instance.</li><li>2. Open the context (right-click) menu for the schema element, and then choose <b>Apply to database</b>.</li></ol> <p>For more information, see the <a href="#">AWS SCT documentation</a>.</p>	Migration engineer

## Migrate your data

Task	Description	Skills required
Set up a VPC and DB parameter groups.	<p>Set up a VPC and DB parameter groups, and configure the inbound rules and parameters required for migration. For instructions, see the <a href="#">AWS DMS documentation</a>.</p> <p>For the VPC security group, select both the EC2 instance for Db2 and the Aurora PostgreSQL-Compatible DB instance. This replication instance must be in the same</p>	Migration engineer

Task	Description	Skills required
	VPC as the source and target DB instances.	
Prepare source and target DB instances.	<p>Prepare the source and target DB instances for migration . In a production environment, the source database will already exist.</p> <p>For the source database, the server name must be the public Domain Name System (DNS) of the EC2 instance where Db2 is running. For user name, you can use db2inst1 followed by the port, which will be 5000 for IBM Db2.</p>	Migration engineer

Task	Description	Skills required
Create an Amazon EC2 client and endpoints.	<ol style="list-style-type: none"><li>1. Create an Amazon EC2 client. You use this client to populate your source database with data to replicate. You also use this client to verify replication by running queries on the target database.</li><li>2. Create endpoints for the source database and target DB instance to use for the next steps. For instructions, see the <a href="#">AWS DMS documentation</a>. You must create separate endpoints for the source and target databases. For Aurora PostgreSQL-Compatible version 10.18 or later, the port will be 5432, and you can get the server name from the DB instance's endpoint.</li></ol>	Migration engineer
Create a replication instance.	Create a replication instance by using the AWS DMS console and specify the source and target endpoints . The replication instance performs the data migration between the endpoints. For more information, see the <a href="#">AWS DMS documentation</a> .	Migration engineer

Task	Description	Skills required
Create an AWS DMS task to migrate the data.	<p>Create a task to load the source IBM Db2 tables to the target PostgreSQL DB instance by following the steps in the <a href="#">AWS DMS documentation</a>.</p> <ul style="list-style-type: none"><li>• For source and target, use the source and destination endpoint names.</li><li>• The migration type can be full load.</li><li>• For the schema rule, you can use the <code>inst1</code> schema from the Db2 database.</li><li>• For the table name, specify <code>%</code> to migrate all tables. When the load is complete, you'll see the Db2 tables of the <code>inst1</code> schema appearing in the Aurora PostgreSQL-Compatible database.</li></ul>	Migration engineer

# Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS

*Created by Kumar Babu P G (AWS)*

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for PostgreSQL/Amazon Aurora PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS; Amazon Aurora		

## Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL. AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source, so Quest SharePlex replicates data from an on-premises 8i or 9i database to an intermediate Oracle database (Oracle 10g or 11g), which is compatible with AWS DMS.

From the intermediate Oracle instance, the schema and data are migrated to the PostgreSQL database on AWS by using AWS Schema Conversion Tool (AWS SCT) and AWS DMS. This method helps achieve continuous streaming of data from the source Oracle database to the target PostgreSQL DB instance with minimum replication lag. In this implementation, the downtime is limited to the length of time it takes to create or validate all the foreign keys, triggers, and sequences on the target PostgreSQL database.

The migration uses an Amazon Elastic Compute Cloud (Amazon EC2) instance with Oracle 10g or 11g installed to host the changes from the source Oracle database. AWS DMS uses this intermediate Oracle instance as the source to stream the data to Amazon RDS for PostgreSQL or Aurora PostgreSQL. Data replication can be paused and resumed from the on-premises Oracle database to the intermediate Oracle instance. It can also be paused and resumed from the intermediate Oracle instance to the target PostgreSQL database so you can validate the data by using either AWS DMS data validation or a custom data validation tool.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises data center
- AWS Direct Connect configured between the on-premises data center and AWS
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors installed either on a local machine or on the EC2 instance where AWS SCT is installed
- Familiarity with [using an Oracle database as an AWS DMS source](#)
- Familiarity with [using a PostgreSQL database as an AWS DMS target](#)
- Familiarity with Quest SharePlex data replication

### Limitations

- The database size limit is 64 TB
- The on-premises Oracle database must be Enterprise Edition

### Product versions

- Oracle 8i or 9i for the source database
- Oracle 10g or 11g for the intermediate database
- PostgreSQL 9.6 or later

## Architecture

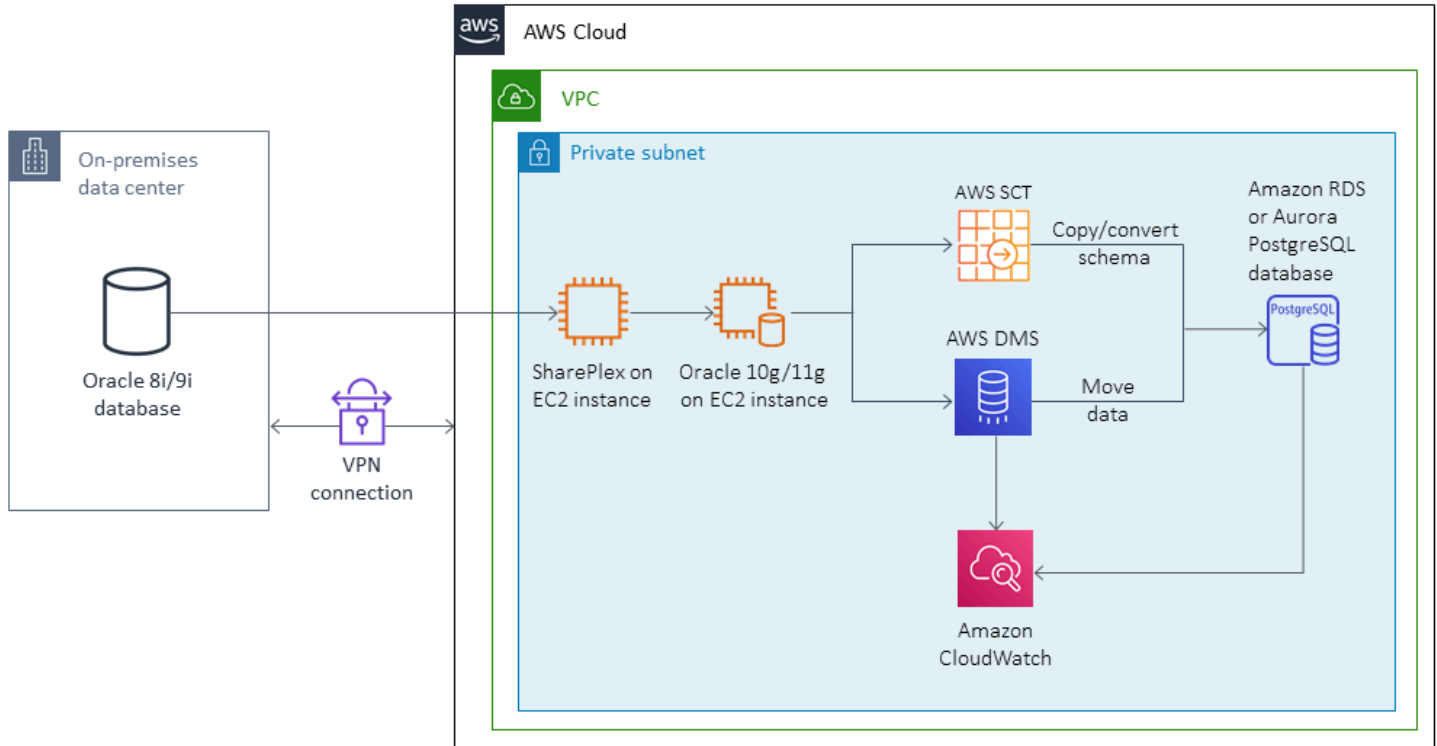

### Source technology stack

- Oracle 8i or 9i database
- Quest SharePlex

### Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL

## Source and target architecture

## Tools

- **AWS DMS** – [AWS Database Migration Service](#) (AWS DMS) helps you migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.
- **AWS SCT** – [AWS Schema Conversion Tool](#) (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.

- **Quest SharePlex** – [Quest SharePlex](#) is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.

## Epics

### Create the EC2 instance and install Oracle

Task	Description	Skills required
Set up the network for Amazon EC2.	Create the virtual private cloud (VPC), subnets, internet gateway, route tables, and security groups.	AWS SysAdmin
Create the new EC2 instance.	Select the Amazon Machine Image (AMI) for the EC2 instance. Choose the instance size and configure instance details: the number of instances (1), the VPC and subnet from the previous step, auto-assign public IP, and other options. Add storage, configure security groups, and launch the instance. When prompted, create and save a key pair for the next step.	AWS SysAdmin
Install Oracle on the EC2 instance.	Acquire the licenses and the required Oracle binaries, and install Oracle 10g or 11g on the EC2 instance.	DBA

## Set up SharePlex on an EC2 instance and configure data replication

Task	Description	Skills required
Set up SharePlex.	Create an Amazon EC2 instance and install the SharePlex binaries that are compatible with Oracle 8i or 9i.	AWS SysAdmin, DBA
Configure data replication.	Follow SharePlex best practices to configure data replication from an on-premises Oracle 8i/9i database to an Oracle 10g/11g instance.	DBA

## Convert the Oracle database schema to PostgreSQL

Task	Description	Skills required
Set up AWS SCT.	Create a new report, and then connect to Oracle as the source and PostgreSQL as the target. In project settings, open the SQL Scripting tab and change the target SQL script to Multiple Files.	DBA
Convert the Oracle database schema.	In the Action tab, choose Generate Report, Convert Schema, and then Save as SQL.	DBA
Modify the SQL scripts generated by AWS SCT.		DBA

## Create and configure the Amazon RDS DB instance

Task	Description	Skills required
Create the Amazon RDS DB instance.	In the Amazon RDS console, create a new PostgreSQL DB instance.	AWS SysAdmin, DBA
Configure the DB instance.	Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a master user name, and a master password.	AWS SysAdmin, DBA
Configure network and security.	Specify the VPC, subnet group, public accessibility, Availability Zone preference, and security groups.	AWS SysAdmin, DBA
Configure database options.	Specify the database name, port, parameter group, encryption, and master key.	AWS SysAdmin, DBA
Configure backups.	Specify the backup retention period, backup window, start time, duration, and whether to copy tags to snapshots.	AWS SysAdmin, DBA
Configure monitoring options.	Enable or disable enhanced monitoring and performance insights.	AWS SysAdmin, DBA
Configure maintenance options.	Specify auto minor version upgrade, maintenance	AWS SysAdmin, DBA

Task	Description	Skills required
	window, and the start day, time, and duration.	
Run the pre-migration scripts from AWS SCT.	On the Amazon RDS instance, run these scripts: create_database.sql, create_sequence.sql, create_table.sql, create_view.sql, and create_function.sql.	AWS SysAdmin, DBA

### Migrate data by using AWS DMS

Task	Description	Skills required
Create a replication instance in AWS DMS.	Complete the fields for the name, instance class, VPC (same as for the EC2 instance), Multi-AZ, and public accessibility. In the advanced configuration section, specify allocated storage, subnet group, Availability Zone, VPC security groups, and AWS Key Management Service (AWS KMS) root key.	AWS SysAdmin, DBA
Create the source database endpoint.	Specify the endpoint name, type, source engine (Oracle), server name (Amazon EC2 private DNS name), port, SSL mode, user name, password, SID, VPC (specify the VPC that has the replication instance), and replication instance. To test the connection, choose	AWS SysAdmin, DBA

Task	Description	Skills required
	Run Test, and then create the endpoint. You can also configure the following advanced settings: maxFileSize and numberDataTypeScale.	
Create the AWS DMS replication task.	Specify the task name, replication instance, source and target endpoints, and replication instance. For migration type, choose "Migrate existing data and replicate ongoing changes." Clear the "Start task on create" check box.	AWS SysAdmin, DBA
Configure the AWS DMS replication task settings.	For target table preparation mode, choose "Do nothing." Stop the task after the full load completes to create primary keys. Specify limited or full LOB mode, and enable control tables. Optionally, you can configure the CommitRate advanced setting.	DBA

Task	Description	Skills required
Configure the table mappings.	In the table mappings section, create an Include rule for all tables in all schemas included in the migration, and then create an Exclude rule. Add three transformation rules to convert the schema, table, and column names to lowercase, and add any other rules needed for this specific migration.	DBA
Start the task.	Start the replication task. Make sure that the full load is running. Run ALTER SYSTEM SWITCH LOGFILE on the primary Oracle database to kick-start the task.	DBA
Run the mid-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run these scripts: create_index.sql and create_constraint.sql.	DBA
Restart the task to continue change data capture (CDC).	In the Amazon RDS for PostgreSQL DB instance, run VACUUM, and restart the AWS DMS task to apply the cached CDC changes.	DBA

## Cut over to the PostgreSQL database

Task	Description	Skills required
Check the AWS DMS logs and metadata tables.	Validate any errors and fix if required.	DBA
Stop all Oracle dependencies.	Shut down listeners on the Oracle database and run ALTER SYSTEM SWITCH LOGFILE. Stop the AWS DMS task when it shows no activity.	DBA
Run the post-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run these scripts: create_foreign_key_constraint.sql and create_triggers.sql.	DBA
Complete any additional Amazon RDS for PostgreSQL steps.	Increment sequences to match Oracle if needed, run VACUUM and ANALYZE, and take a snapshot for compliance.	DBA
Open the connections to Amazon RDS for PostgreSQL.	Remove the AWS DMS security groups from Amazon RDS for PostgreSQL, add production security groups, and point your applications to the new database.	DBA
Clean up AWS DMS resources.	Remove the endpoints, replication tasks, replication instances, and the EC2 instance.	SysAdmin, DBA

# Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS

Created by Kumar Babu P G (AWS) and Pragnesh Patel (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle 8i or 9i	<b>Target:</b> Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS; Amazon Aurora		

## Summary

This pattern describes how to migrate an on-premises legacy Oracle 8i or 9i database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition.

AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source, so this pattern uses an intermediate Oracle database instance that's compatible with AWS DMS, such as Oracle 10g or 11g. It also uses the materialized views feature to migrate data from the source Oracle 8i/9i instance to the intermediate Oracle 10g/11g instance.

AWS Schema Conversion Tool (AWS SCT) converts the database schema, and AWS DMS migrates the data to the target PostgreSQL database.

This pattern helps users who want to migrate from legacy Oracle databases with minimum database downtime. In this implementation, the downtime would be limited to the length of time it takes to create or validate all the foreign keys, triggers, and sequences on the target database.

The pattern uses Amazon Elastic Compute Cloud (Amazon EC2) instances with an Oracle 10g/11g database installed to help AWS DMS stream the data. You can temporarily pause streaming replication from the on-premises Oracle database to the intermediate Oracle instance to enable AWS DMS to catch up on data validation or to use another data validation tool. The PostgreSQL DB

instance and intermediate Oracle database will have the same data when AWS DMS has finished migrating current changes.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises data center
- AWS Direct Connect configured between the on-premises data center and AWS
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors installed either on a local machine or on the EC2 instance where AWS SCT is installed
- Familiarity with [using an Oracle database as an AWS DMS source](#)
- Familiarity with [using a PostgreSQL database as an AWS DMS target](#)

### Limitations

- The database size limit is 64 TB

### Product versions

- Oracle 8i or 9i for the source database
- Oracle 10g or 11g for the intermediate database
- PostgreSQL 10.17 or later

## Architecture

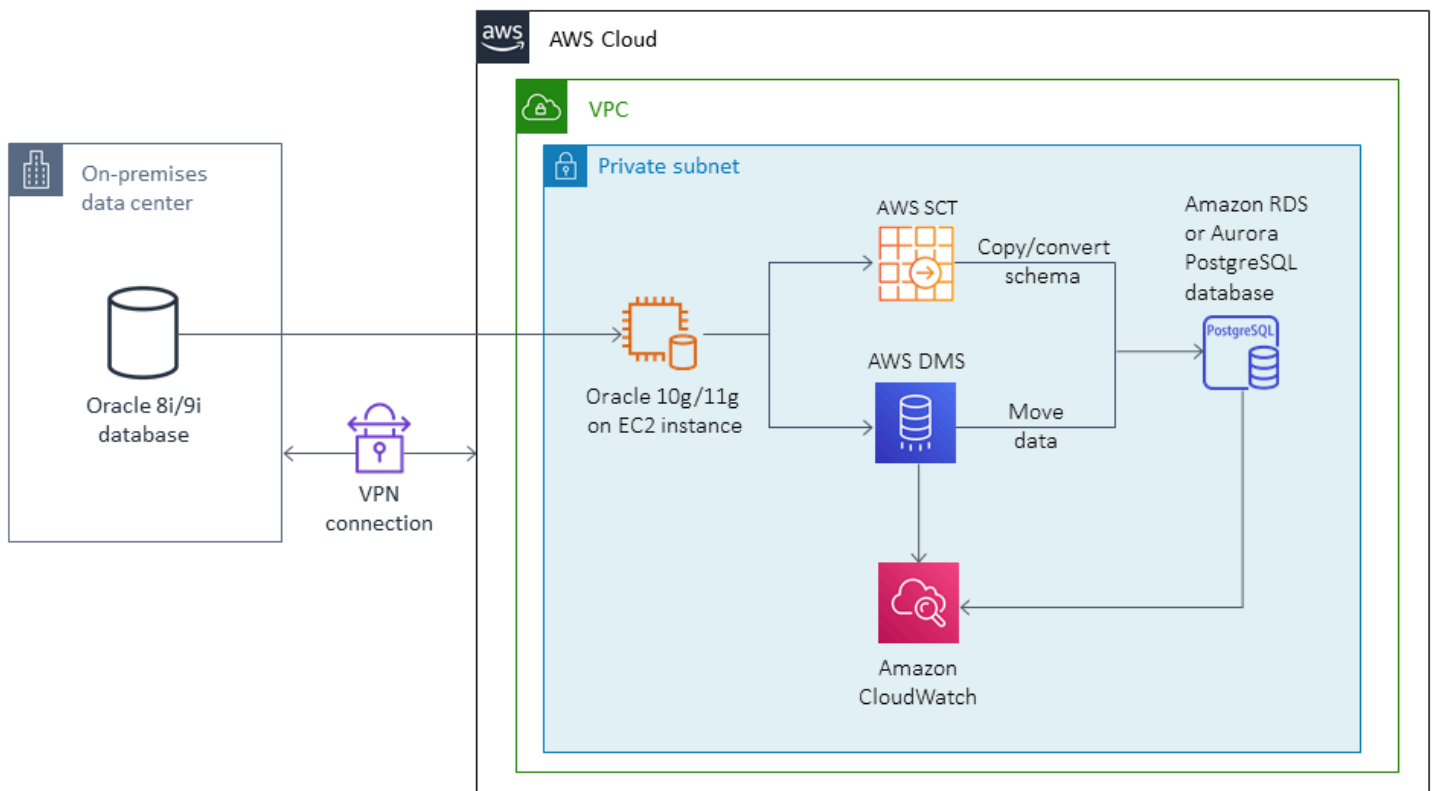

### Source technology stack

- Oracle 8i or 9i database

### Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible

### Target architecture

## Tools

- [AWS DMS](#) helps migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.
- [AWS SCT](#) automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.

## Best practices

For best practices for refreshing materialized views, see the following Oracle documentation:

- [Refreshing materialized views](#)
- [Fast refresh for materialized views](#)

## Epics

### Install Oracle on an EC2 instance and create materialized views

Task	Description	Skills required
Set up the network for the EC2 instance.	Create the virtual private cloud (VPC), subnets, internet gateway, route tables, and security groups.	AWS SysAdmin
Create the EC2 instance.	Select the Amazon Machine Image (AMI) for the EC2 instance. Choose the instance size and configure instance details: the number of instances (1), the VPC and subnet from the previous step, auto-assign public IP, and other options. Add storage, configure security groups, and launch the instance. When prompted, create and save a key pair for the next step.	AWS SysAdmin
Install Oracle on the EC2 instance.	Acquire the licenses and the required Oracle binaries, and install Oracle 10g or 11g on the EC2 instance.	DBA

Task	Description	Skills required
Configure Oracle networking.	Modify or add entries in <code>listener.ora</code> to connect to the on-premises source Oracle 8i/9i database, and then create the database links.	DBA
Create materialized views.	Identify the database objects to replicate in the source Oracle 8i/9i database, and then create materialized views for all the objects by using the database link.	DBA
Deploy scripts to refresh materialized views at required intervals.	Develop and deploy scripts to refresh materialized views at required intervals on the Amazon EC2 Oracle 10g/11g instance. Use the incremental refresh option to refresh materialized views.	DBA

## Convert the Oracle database schema to PostgreSQL

Task	Description	Skills required
Set up AWS SCT.	Create a new report, and then connect to Oracle as the source and PostgreSQL as the target. In project settings, open the <b>SQL Scripting</b> tab. Change the target SQL script to <b>Multiple Files</b> . (AWS SCT doesn't support Oracle 8i/9i databases, so you have to	DBA

Task	Description	Skills required
	restore the schema-only dump on the intermediate Oracle 10g/11g instance and use it as a source for AWS SCT.)	
Convert the Oracle database schema.	On the <b>Action</b> tab, choose <b>Generate Report, Convert Schema</b> , and then <b>Save as SQL</b> .	DBA
Modify the SQL scripts.	Make modifications based on best practices. For example, switch to suitable data types and develop PostgreSQL equivalents for Oracle-specific functions.	DBA, DevDBA

### Create and configure the Amazon RDS DB instance to host the converted database

Task	Description	Skills required
Create the Amazon RDS DB instance.	In the Amazon RDS console, create a new PostgreSQL DB instance.	AWS SysAdmin, DBA
Configure the DB instance.	Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a master user name, and a master password.	AWS SysAdmin, DBA

Task	Description	Skills required
Configure network and security.	Specify the VPC, subnet group, public accessibility, Availability Zone preference, and security groups.	DBA, SysAdmin
Configure database options.	Specify the database name, port, parameter group, encryption, and master key.	DBA, AWS SysAdmin
Configure backups.	Specify the backup retention period, backup window, start time, duration, and whether to copy tags to snapshots.	AWS SysAdmin, DBA
Configure monitoring options.	Enable or disable enhanced monitoring and performance insights.	AWS SysAdmin, DBA
Configure maintenance options.	Specify auto minor version upgrade, maintenance window, and the start day, time, and duration.	AWS SysAdmin, DBA
Run the pre-migration scripts from AWS SCT.	On the target Amazon RDS for PostgreSQL instance, create the database schema by using the SQL scripts from AWS SCT with other modifications. These might include running multiple scripts and including user creation, database creation, schema creation, tables, views, functions, and other code objects.	AWS SysAdmin, DBA

## Migrate data by using AWS DMS

Task	Description	Skills required
Create a replication instance in AWS DMS.	Complete the fields for the name, instance class, VPC (same as for the EC2 instance), Multi-AZ, and public accessibility. In the advanced configuration section, specify allocated storage, subnet group, Availability Zone, VPC security groups, and AWS Key Management Service (AWS KMS) key.	AWS SysAdmin, DBA
Create the source database endpoint.	Specify the endpoint name, type, source engine (Oracle), server name (the EC2 instance's private DNS name), port, SSL mode, user name, password, SID, VPC (specify the VPC that has the replication instance), and replication instance. To test the connection, choose <b>Run Test</b> , and then create the endpoint. You can also configure the following advanced settings: <b>maxFileSize</b> and <b>numberDataTypesScale</b> .	AWS SysAdmin, DBA
Connect AWS DMS to Amazon RDS for PostgreSQL.	Create a migration security group for connections across VPCs, if your PostgreSQL database is in another VPC.	AWS SysAdmin, DBA

Task	Description	Skills required
Create the target database endpoint.	Specify the endpoint name, type, source engine (PostgreSQL), server name (Amazon RDS endpoint), port, SSL mode, user name, password, database name, VPC (specify the VPC that has the replication instance), and replication instance. To test the connection, choose <b>Run Test</b> , and then create the endpoint. You can also configure the following advanced settings: <b>maxFileSize</b> and <b>numberDataTypes</b> .	AWS SysAdmin, DBA
Create the AWS DMS replication task.	Specify the task name, replication instance, source and target endpoints, and replication instance. For migration type, choose <b>Migrate existing data and replicate ongoing changes</b> . Clear the <b>Start task on create</b> check box.	AWS SysAdmin, DBA
Configure the AWS DMS replication task settings.	For target table preparation mode, choose <b>Do nothing</b> . Stop the task after full load completes (to create primary keys). Specify limited or full LOB mode, and enable control tables. Optionally, you can configure the <b>CommitRate</b> advanced setting.	DBA

Task	Description	Skills required
Configure the table mappings.	In the <b>Table mappings</b> section, create an Include rule for all tables in all schemas included in the migration, and then create an Exclude rule. Add three transformation rules to convert the schema, table, and column names to lowercase, and add any other rules you need for this specific migration.	DBA
Start the task.	Start the replication task. Make sure that the full load is running. Run <code>ALTER SYSTEM SWITCH LOGFILE</code> on the primary Oracle database to start the task.	DBA
Run the mid-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run the following scripts: <code>create_index.sql</code> and <code>create_constraint.sql</code> (if the complete schema wasn't initially created).	DBA
Resume the task to continue change data capture (CDC).	Run <code>VACUUM</code> on the Amazon RDS for PostgreSQL DB instance, and restart the AWS DMS task to apply cached CDC changes.	DBA

## Cut over to the PostgreSQL database

Task	Description	Skills required
Check the AWS DMS logs and validation tables.	Check and fix any replication or validation errors.	DBA
Stop using the on-premises Oracle database and its dependencies.	Stop all Oracle dependencies, shut down listeners on the Oracle database, and run <code>ALTER SYSTEM SWITCH LOGFILE</code> . Stop the AWS DMS task when it shows no activity.	DBA
Run the post-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run these scripts: <code>create_foreign_key_constraint.sql</code> and <code>create_triggers.sql</code> . Make sure that the sequences are up to date.	DBA
Complete additional Amazon RDS for PostgreSQL steps.	Increment sequences to match Oracle if needed, run <code>VACUUM</code> and <code>ANALYZE</code> , and take a snapshot for compliance.	DBA
Open the connections to Amazon RDS for PostgreSQL.	Remove the AWS DMS security groups from Amazon RDS for PostgreSQL, add production security groups, and point your applications to the new database.	DBA
Clean up the AWS DMS objects.	Remove the endpoints, replication tasks, replicati	SysAdmin, DBA

Task	Description	Skills required
	on instances, and the EC2 instance.

# Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT

*Created by Anil Kunapareddy (AWS) and Harshad Gohil*

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for MySQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS		

## Summary

Managing Oracle databases on Amazon Elastic Compute Cloud (Amazon EC2) instances requires resources and can be costly. Moving these databases to an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance will ease your job by optimizing the overall IT budget. Amazon RDS for MySQL also provides features like Multi-AZ, scalability, and automatic backups.

This pattern walks you through the migration of a source Oracle database on Amazon EC2 to a target Amazon RDS for MySQL DB instance. It uses AWS Database Migration Service (AWS DMS) to migrate the data, and AWS Schema Conversion Tool (AWS SCT) to convert the source database schema and objects to a format that's compatible with Amazon RDS for MySQL.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source database with instance and listener services running, in ARCHIVELOG mode
- A target Amazon RDS for MySQL database, with sufficient storage for data migration

### Limitations

- AWS DMS does not create a schema on the target database; you have to do that. The schema name must already exist for the target. Tables from the source schema are imported to user/

schema, which AWS DMS uses to connect to the target instance. You must create multiple replication tasks if you have to migrate multiple schemas.

## Product versions

- All Oracle database editions for versions 10.2 and later, 11g and up to 12.2, and 18c. For the latest list of supported versions, see [Using an Oracle Database as a Source for AWS DMS](#) and [Using a MySQL-Compatible Database as a Target for AWS DMS](#). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the [AWS SCT documentation](#).
- AWS DMS supports versions 5.5, 5.6, and 5.7 of MySQL.

## Architecture

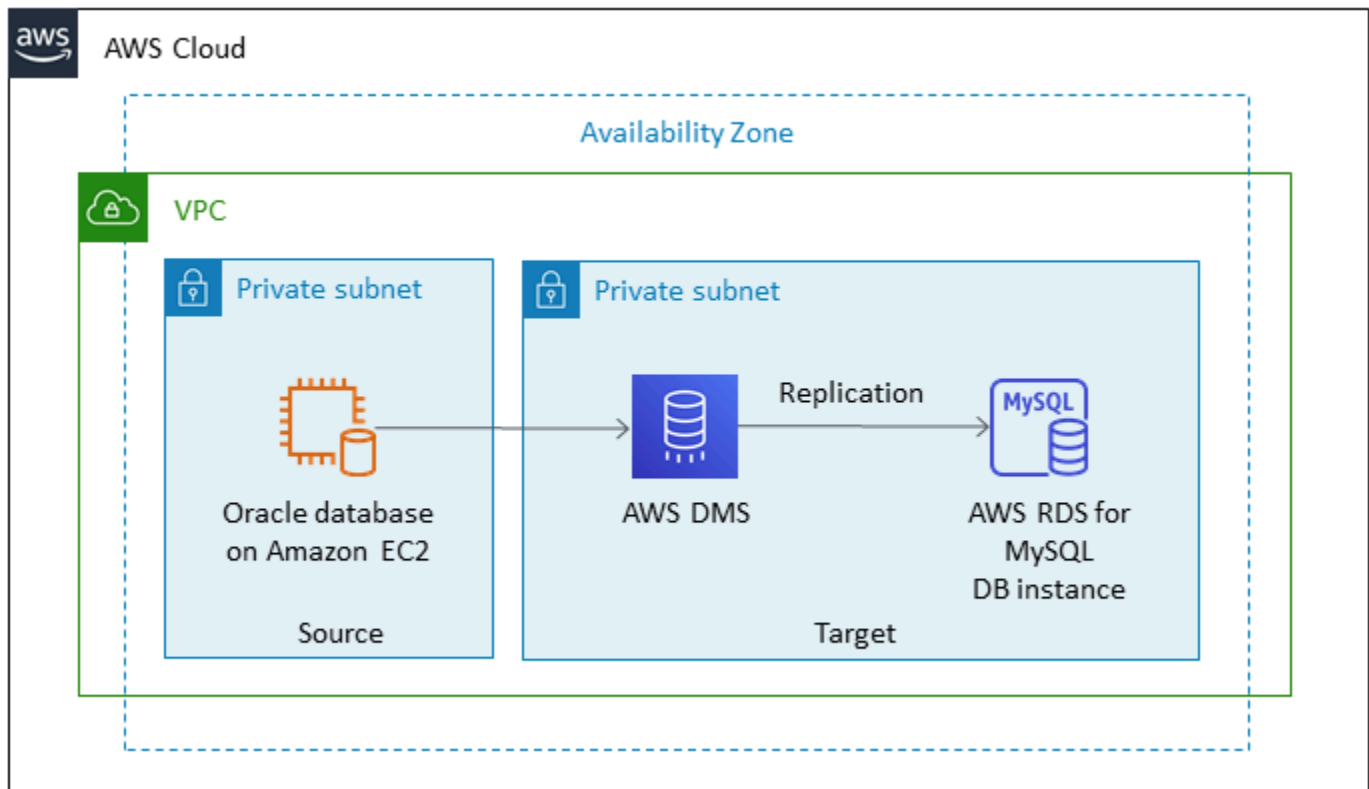

### Source technology stack

- An Oracle database on an EC2 instance

### Target technology stack

- Amazon RDS for MySQL DB instance

### Data migration architecture

### Source and target architecture

### Tools

- **AWS DMS** - [AWS Database Migration Service](#) (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for MySQL or an EC2

instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogeneous database engines.

- **AWS SCT** - [AWS Schema Conversion Tool](#) (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format that's compatible with the target database. After converting your database schema and code objects using AWS SCT, you can use AWS DMS to migrate data from the source database to the target database to complete your migration projects.

## Epics

### Plan the migration

Task	Description	Skills required
Identify the source and target database versions and engines.		DBA/Developer
Identify the DMS replication instance.		DBA/Developer
Identify storage requirements such as storage type and capacity.		DBA/Developer
Identify network requirements such as latency and bandwidth.		DBA/Developer
Identify hardware requirements for the source and target server instances (based on Oracle compatibility list and capacity requirements).		DBA/Developer

Task	Description	Skills required
Identify network access security requirements for source and target databases.		DBA/Developer
Install AWS SCT and Oracle drivers.		DBA/Developer
Determine a backup strategy.		DBA/Developer
Determine availability requirements.		DBA/Developer
Identify application migration and switch-over strategy.		DBA/Developer
Select the proper DB instance type based on capacity, storage, and network features.		DBA/Developer

## Configure the environment

Task	Description	Skills required
Create a virtual private cloud (VPC). The source, target, and replication instance should be in the same VPC. It is also good to have these in the same Availability Zone.		Developer
Create the necessary security groups for database access.		Developer
Generate and configure a key pair.		Developer

Task	Description	Skills required
Configure subnets, Availability Zones, and CIDR blocks.		Developer

### Configure the source: Oracle database on EC2 instance

Task	Description	Skills required
Install Oracle Database on Amazon EC2 with required users and roles.		DBA
Perform the three steps in the next column to access Oracle from outside the EC2 instance.	<ol style="list-style-type: none"> <li>1. Change the local host in <code>tnsnames</code> to the Amazon EC2 public DNS.</li> <li>2. Change the local host in <code>listener</code> to the Amazon EC2 public DNS.</li> <li>3. Stop and restart the listener.</li> </ol>	DBA
When Amazon EC2 is restarted, the public DNS changes. Make sure to update Amazon EC2 public DNS in 'tnsnames' and 'listener' or use an Elastic IP address.		DBA/Developer
Configure the EC2 instance security group so that the replication instance and required clients can access the source database.		DBA/Developer

## Configure the target: Amazon RDS for MySQL

Task	Description	Skills required
Configure and start the Amazon RDS for MySQL DB instance.		Developer
Create the necessary tablespace in the Amazon RDS for MySQL DB instance.		DBA
Configure the security group so that the replication instance and required clients can access the target database.		Developer

## Configure AWS SCT and create a schema in the target database

Task	Description	Skills required
Install AWS SCT and Oracle drivers.		Developer
Enter the appropriate parameters and connect to the source and target.		Developer
Generate a schema conversion report.		Developer
Correct the code and schema as necessary, especially tablespaces and quotes, and run on the target database.		Developer

Task	Description	Skills required
Validate the schema on source vs. target before migrating data.		Developer

## Migrate data using AWS DMS

Task	Description	Skills required
For full-load and change data capture (CDC) or just CDC, you must set an extra connection attribute.		Developer
The user specified in the AWS DMS source Oracle database definitions must be granted all the required privileges. For a complete list, see <a href="https://docs.aws.amazon.com/dms/latest/userguide/CHAP_Source.Oracle.html#CHAP_Source.Oracle.Self-Managed">https://docs.aws.amazon.com/dms/latest/userguide/CHAP_Source.Oracle.html#CHAP_Source.Oracle.Self-Managed</a> .		DBA/Developer
Enable supplemental logging in the source database.		DBA/Developer
For full-load and change data capture (CDC) or just CDC, enable ARCHIVELOG mode in the source database.		DBA
Create source and target endpoints, and test the connections.		Developer

Task	Description	Skills required
When the endpoints are connected successfully, create a replication task.		Developer
Select CDC only (or) full load plus CDC in the task to capture changes for continuous replication only (or) full load plus ongoing changes, respectively.		Developer
Run the replication task and monitor Amazon CloudWatch logs.		Developer
Validate the data in the source and target databases.		Developer

### Migrate your application and cut over

Task	Description	Skills required
Follow the steps for your application migration strategy.		DBA, Developer, App owner
Follow the steps for your application cutover/switch-over strategy.		DBA, Developer, App owner

## Close the project

Task	Description	Skills required
Validate the schema and data in source vs. target databases.		DBA/Developer
Gather metrics around time to migrate, percent of manual vs. tool, cost savings, etc.		DBA/Developer/AppOwner
Review the project documents and artifacts.		DBA/Developer/AppOwner
Shut down temporary AWS resources.		DBA/Developer
Close out the project and provide feedback.		DBA/Developer/AppOwner

# Migrate from Oracle to Amazon DocumentDB using AWS DMS

<b>R Type:</b> Re-architect	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon DocumentDB
<b>Created by:</b> AWS	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Databases; Migration
<b>Workload:</b> Oracle	<b>AWS services:</b> Amazon DocumentDB	

## Summary

This pattern provides guidance for migrating an Oracle database to an Amazon DocumentDB (with MongoDB compatibility) database by using AWS Database Migration Service (AWS DMS). This approach can be applied to an on-premises Oracle source database as well as an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance. This pattern uses an Amazon RDS Oracle DB source instance as an example.

Amazon DocumentDB (with MongoDB compatibility) is a fully managed, MongoDB-compatible document database service that makes it easy to store, query, and index JSON data.

The use case for this pattern is one-to-one replication of an Oracle database table to an Amazon DocumentDB collection. The pattern uses AWS DMS replication tasks to read the table structure of the Oracle database, create the corresponding collection in Amazon DocumentDB, and perform a full load migration. You can view and query your data in Amazon DocumentDB, the same as you would in MongoDB.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- Familiarity with using Oracle databases
- Familiarity with using Amazon DocumentDB
- For the Oracle user, SELECT ANY TABLE privilege

- For the Amazon DocumentDB use, the privilege required to dump data

## Limitations

The following limitations apply when using Amazon DocumentDB as a target for AWS DMS:

- In Amazon DocumentDB, collection names can't contain the dollar symbol (\$). In addition, database names can't contain any Unicode characters.
- AWS DMS doesn't support merging of multiple source tables into a single Amazon DocumentDB collection.
- When AWS DMS processes changes from a source table that doesn't have a primary key, any large binary object (LOB) columns in that table are ignored.
- If the **Change table** option is enabled and AWS DMS encounters a source column named "\_id", that column appears as "\_\_id" (two underscores) in the change table.
- If you choose Oracle as a source endpoint, the Oracle source must have full supplemental logging enabled. Otherwise, if there are columns at the source that weren't changed, the data is loaded into Amazon DocumentDB as null values.

## Product versions

- Amazon RDS for Oracle version 11.2.0.3 or later
- AWS DMS version 3.1.3 or later (for the latest version information, see [Using Amazon DocumentDB as a Target for AWS DMS](#) in the AWS DMS documentation)

## Architecture

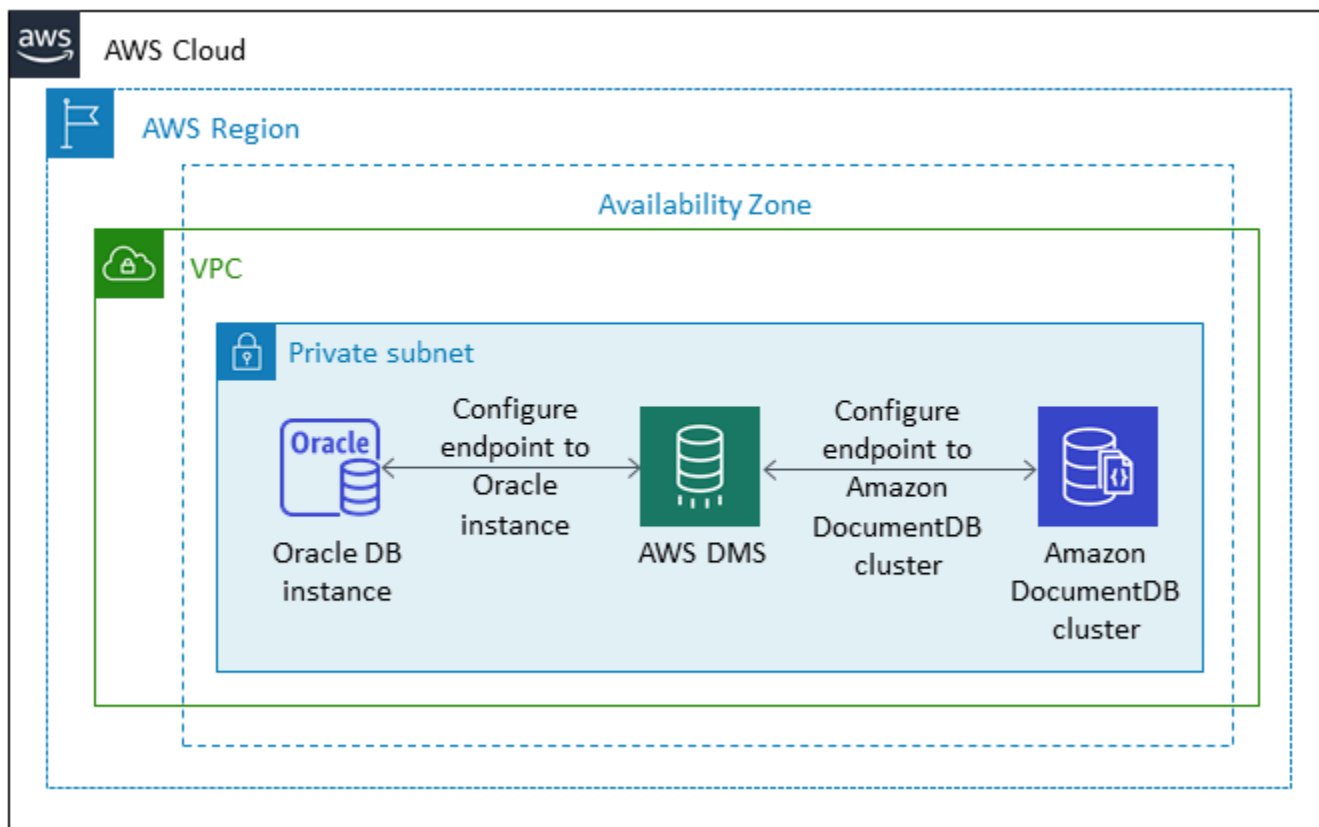

### Source technology stack

- Amazon RDS for Oracle DB instance

### Target technology stack

- Amazon DocumentDB

### Source and target architecture

## Tools

- **AWS DMS** – [AWS Database Migration Service](#) (AWS DMS) is a web service that you can use to migrate data from a source data store to a target data store. The [AWS DMS User Guide](#) specifies the Oracle source database versions and editions that are supported for use with AWS DMS. For additional information relevant to this pattern, see [Using Amazon DocumentDB as a Target for AWS DMS](#).
- **Amazon EC2** – [Amazon Elastic Compute Cloud](#) (Amazon EC2) provides scalable computing capacity in the AWS cloud. Your Amazon DocumentDB cluster should be running in your default virtual private cloud (VPC). To interact with your Amazon DocumentDB cluster, you must launch an EC2 instance into your default VPC, in the same AWS Region where you created your Amazon DocumentDB cluster. For details, refer to [Launch an Amazon EC2 instance](#) in the Amazon DocumentDB documentation.

## Epics

### Plan the migration

Task	Description	Skills required
Validate the source and target database versions and engines.		AWS Admin
Choose the proper instance type (capacity, storage features, network features).		AWS Admin
Identify network/host access security requirements for the source and target databases.		AWS Admin
Create an outbound security group to the source and target databases.		AWS Admin
Create and configure an EC2 instance for Amazon DocumentDB.		AWS Admin

### Configure infrastructure

Task	Description	Skills required
Create a VPC and subnets.		AWS Admin
Create security groups and network access control lists (ACLs).		AWS Admin

Task	Description	Skills required
Configure and start the source Amazon RDS for Oracle instance.		AWS Admin
Configure and start the Amazon DocumentDB instance.		AWS Admin

### Prepare the source database

Task	Description	Skills required
Verify that the Oracle database can be connected using the connection details.		AWS Admin
Verify that the Oracle user has the SELECT ANY TABLE privilege.		AWS Admin

### Prepare the target database

Task	Description	Skills required
Create the Amazon DocumentDB cluster by choosing the proper instance class and number of instances .		AWS Admin

## Configure Amazon EC2

Task	Description	Skills required
Configure the EC2 instance.	To interact with your Amazon DocumentDB cluster, you must launch an EC2 instance into your default VPC, in the same AWS Region where you created your Amazon DocumentDB cluster. Configure the AWS Region, VPCs, Availability Zones, and subnets for the EC2 instance.	AWS Admin
Configure the key pair.	A public/private key pair allows you to connect securely to the EC2 instance after it launches.	AWS Admin
Set the bastion host CIDR ranges (optional).	Set the CIDR IP range that is allowed for external Secure Shell (SSH) access to the bastion host instances.	AWS Admin

## Migrate data – full load

Task	Description	Skills required
Create an AWS DMS replication instance.		AWS Admin
Create source and target endpoints.		AWS Admin
Create AWS DMS replication tasks for a full load.		AWS Admin

## Test the migration

Task	Description	Skills required
Connect to the Amazon DocumentDB cluster through the EC2 instance.		AWS Admin
Connect to the cluster using the mongo shell.	For instructions, see the Amazon DocumentDB links in the References and Help section.	AWS Admin
Verify the results of the migration.		AWS Admin

# Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT

Created by Veeranjanyulu Grandhi (AWS) and vinod kumar (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for MariaDB
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS		

## Summary

This pattern walks you through the steps for migrating an Oracle database on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon Relational Database Service (Amazon RDS) for MariaDB DB instance. The pattern uses AWS Data Migration Service (AWS DMS) for data migration and AWS Schema Conversion Tool (AWS SCT) for schema conversion.

Managing Oracle databases on EC2 instances requires more resources and is more costly than using a database on Amazon RDS. Amazon RDS makes it easy to set up, operate, and scale a relational database in the cloud. Amazon RDS provides cost-efficient and resizable capacity while automating time-consuming administration tasks such as hardware provisioning, database setup, patching, and backups.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- A source Oracle database with instance and listener services up and running. This database should be in ARCHIVELOG mode.
- Familiarity with [Using an Oracle Database as a Source for AWS DMS](#).
- Familiarity with [Using Oracle as a Source for AWS SCT](#).

## Limitations

- Database size limit: 64 TB

## Product versions

- All Oracle database editions for versions 10.2 and later, 11g and up to 12.2, and 18c. For the latest list of supported versions, see [Using an Oracle Database as a Source for AWS DMS](#) and the [AWS SCT version table](#) in the AWS documentation.
- Amazon RDS supports MariaDB Server Community Server versions 10.3, 10.4, 10.5, and 10.6. For the latest list of supported versions, see the [Amazon RDS documentation](#).

## Architecture

### Source technology stack

- An Oracle database on an EC2 instance

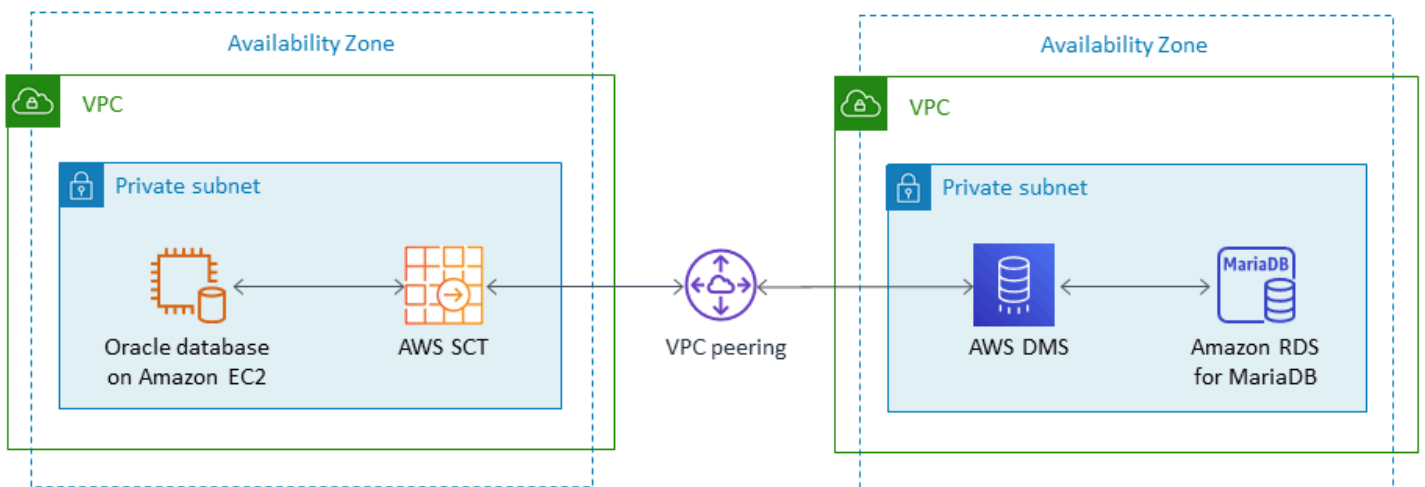

### Target technology stack

- Amazon RDS for MariaDB

### Data migration architecture

### Target architecture

### Tools

- [AWS Schema Conversion Tool \(AWS SCT\)](#) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects—including views, stored procedures, and functions—to a format compatible with the

target database. After converting your database schema and code objects using AWS SCT, you can use AWS DMS to migrate data from the source database to the target database to complete your migration projects. For more information, see [Using Oracle as a Source for AWS SCT](#) in the AWS SCT documentation.

- [AWS Database Migration Service](#) (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases. AWS DMS supports homogeneous migrations such as Oracle to Oracle, as well as heterogeneous migrations between different database platforms, such as Oracle or Microsoft SQL Server to Amazon Aurora. To learn more about migrating Oracle databases, see [Using an Oracle Database as a Source for AWS DMS](#) in the AWS DMS documentation.

## Epics

### Plan for the migration

Task	Description	Skills required
Identify versions and database engines.	Identify the source and target database versions and engines.	DBA, Developer
Identify the replication instance.	Identify the AWS DMS replication instance.	DBA, Developer
Identify storage requirements.	Identify storage type and capacity.	DBA, Developer
Identify network requirements.	Identify network latency and bandwidth.	DBA, Developer
Identify hardware requirements.	Identify hardware requirements for the source and target server instances (based on the Oracle compatibility list and capacity requirements).	DBA, Developer

Task	Description	Skills required
Identify security requirements.	Identify network-access security requirements for the source and target databases.	DBA, Developer
Install drivers.	Install the latest AWS SCT and Oracle drivers.	DBA, Developer
Determine a backup strategy.		DBA, Developer
Determine availability requirements.		DBA, Developer
Choose an application migration/switchover strategy.		DBA, Developer
Select the instance type.	Select the proper instance type based on capacity, storage, and network features.	DBA, Developer

## Configure the environment

Task	Description	Skills required
Create a virtual private cloud (VPC).	The source, target, and replication instances should be in the same VPC and in the same Availability Zone (recommended).	Developer
Create security groups.	Create the necessary security groups for database access.	Developer
Generate a key pair.	Generate and configure a key pair.	Developer

Task	Description	Skills required
Configure other resources.	Configure subnets, Availability Zones, and CIDR blocks.	Developer

## Configure the source

Task	Description	Skills required
Launch the EC2 instance.	For instructions, see the <a href="#">Amazon EC2 documentation</a> .	Developer
Install the Oracle database.	Install the Oracle database on the EC2 instance, with required users and roles.	DBA
Follow the steps in the task description to access Oracle from outside of the EC2 instance.	<ol style="list-style-type: none"> <li>1. Change the local host in <code>tnsnames</code> to the Amazon EC2 public DNS.</li> <li>2. Change the local host in <code>listener</code> to the Amazon EC2 public DNS.</li> <li>3. Stop and restart the listener.</li> </ol>	DBA
Update the Amazon EC2 public DNS.	After the EC2 instance restarts, the public DNS changes. Make sure to update the Amazon EC2 public DNS in <code>tnsnames</code> and <code>listener</code> , or use an Elastic IP address.	DBA, Developer
Configure the EC2 instance security group.	Configure the EC2 instance security group so the replication instance and required	DBA, Developer

Task	Description	Skills required
	clients can access the source database.	

### Configure the target Amazon RDS for MariaDB environment

Task	Description	Skills required
Start the RDS DB instance.	Configure and start the Amazon RDS for MariaDB DB instance.	Developer
Create tablespaces.	Create any necessary tablespaces in the Amazon RDS MariaDB database.	DBA
Configure a security group.	Configure a security group so the replication instance and required clients can access the target database.	Developer

### Configure AWS SCT

Task	Description	Skills required
Install drivers.	Install the latest AWS SCT and Oracle drivers.	Developer
Connect.	Enter appropriate parameters and then connect to the source and target.	Developer
Generate a schema conversion report.	Generate an AWS SCT schema conversion report.	Developer

Task	Description	Skills required
Correct the code and schema as necessary.	Make any necessary corrections to the code and schema (especially tablespaces and quotation marks).	DBA, Developer
Validate the schema.	Validate the schema on the source versus the target before loading data.	Developer

### Migrate data using AWS DMS

Task	Description	Skills required
Set a connection attribute.	For full-load and change data capture (CDC) or just for CDC, set an extra connection attribute. For more information, see the <a href="#">Amazon RDS documentation</a> .	Developer
Enable supplemental logging.	Enable supplemental logging on the source database.	DBA, Developer
Enable archive log mode.	For full-load and CDC (or just for CDC), enable archive log mode on the source database.	DBA
Create and test endpoints.	Create source and target endpoints and test the connections. For more information, see the <a href="#">Amazon DMS documentation</a> .	Developer
Create a replication task.	When the endpoints are connected successfully, create	Developer

Task	Description	Skills required
	a replication task. For more information, see the <a href="#">Amazon DMS documentation</a> .	
Choose replication type.	Choose <b>CDC only</b> or <b>Full load plus CDC</b> in the task to capture changes for continuous replication only, or for full load and ongoing changes, respectively.	Developer
Start and monitor the task.	Start the replication task and monitor Amazon CloudWatch logs. For more information, see the <a href="#">Amazon DMS documentation</a> .	Developer
Validate the data.	Validate the data in the source and target databases.	Developer

## Migrate applications and cut over to the target database

Task	Description	Skills required
Follow the chosen application migration strategy.		DBA, App owner, Developer
Follow the chosen application cutover/switchover strategy.		DBA, App owner, Developer

## Close the project

Task	Description	Skills required
Validate the schema and data.	Ensure that the schema and data are validated successfully in the source versus the target before project closure.	DBA, Developer
Gather metrics.	Gather metrics for time to migrate, percentage of manual versus tool tasks, cost savings, and similar criteria.	DBA, App owner, Developer
Review documentation.	Review the project documents and artifacts.	DBA, App owner, Developer
Shut down resources.	Shut down temporary AWS resources.	DBA, Developer
Close the project.	Close the migration project and provide any feedback.	DBA, App owner, Developer

# Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT

<b>R Type:</b> Re-architect	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for MySQL
<b>Created by:</b> AWS	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Databases; Migration
<b>Workload:</b> Oracle	<b>AWS services:</b> Amazon RDS	

## Summary

This pattern walks you through the migration of an on-premises Oracle database to an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance. It uses AWS Database Migration Service (AWS DMS) to migrate the data, and AWS Schema Conversion Tool (AWS SCT) to convert the source database schema and objects to a format that's compatible with Amazon RDS for MySQL.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Oracle database in an on-premises data center

### Limitations

- Database size limit: 64 TB

### Product versions

- All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c. For the latest list of supported versions, see [Using an Oracle Database as a Source for AWS DMS](#). We recommend that you use the latest version of AWS DMS for the most comprehensive

version and feature support. For information about Oracle database versions supported by AWS SCT, see the [AWS SCT documentation](#).

- AWS DMS currently supports MySQL versions 5.5, 5.6, and 5.7. For the latest list of supported versions, see [Using a MySQL-Compatible Database as a Target for AWS DMS](#) in the AWS documentation.

## Architecture

### Source technology stack

- On-premises Oracle database

### Target technology stack

- Amazon RDS for MySQL DB instance

### Data migration architecture

## Tools

- **AWS DMS** - [AWS Database Migration Services](#) (AWS DMS) helps you migrate relational databases, data warehouses, NoSQL databases, and other types of data stores. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.
- **AWS SCT** - [AWS Schema Conversion Tool](#) (AWS SCT) is used to convert your database schema from one database engine to another. The custom code that the tool converts includes views, stored procedures, and functions. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.

## Epics

### Plan the migration

Task	Description	Skills required
Validate the source and target database version and engine.		DBA
Identify the hardware requirements for the target server instance.		DBA, SysAdmin
Identify the storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type based on capacity, storage features, and network features.		DBA, SysAdmin

# Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL by using an Oracle bystander and AWS DMS

Created by Cady Motyka (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for PostgreSQL/Amazon Aurora PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS		

## Summary

This pattern describes how you can migrate an on-premises Oracle database to either of the following PostgreSQL-compatible AWS database services with minimal downtime:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

The solution uses AWS Database Migration Service (AWS DMS) to migrate the data, AWS Schema Conversion Tool (AWS SCT) to convert the database schema, and an Oracle bystander database to help manage the migration. In this implementation, the downtime is restricted to however long it takes to create or validate all of the foreign keys on the database.

The solution also uses Amazon Elastic Compute Cloud (Amazon EC2) instances with an Oracle bystander database to help control the stream of data through AWS DMS. You can temporarily pause streaming replication from the on-premises Oracle database to the Oracle bystander to activate AWS DMS to catch up on data validation, or to use another data validation tool. The Amazon RDS for PostgreSQL DB instance or Aurora PostgreSQL-Compatible DB instance and the bystander database will have the same data when AWS DMS finishes migrating current changes.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Oracle database in an on-premises data center with an Active Data Guard standby database configured
- AWS Direct Connect configured between the on-premises data center and AWS Secrets Manager for storing the database secrets
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed either on a local machine or on the EC2 instance where AWS SCT is installed
- Familiarity with [using an Oracle database as a source for AWS DMS](#)
- Familiarity with [using a PostgreSQL database as a target for AWS DMS](#)

## Limitations

- Database size limit: 64 TB

## Product versions

- AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For the latest list of supported versions, see [Using an Oracle Database as a Source for AWS DMS](#). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the [AWS SCT documentation](#).
- AWS DMS supports PostgreSQL versions 9.4 and later (for versions 9.x), 10.x, 11.x, 12.x, and 13.x. For the latest information, see [Using a PostgreSQL Database as a Target for AWS DMS](#) in the AWS documentation.

## Architecture

### Source technology stack

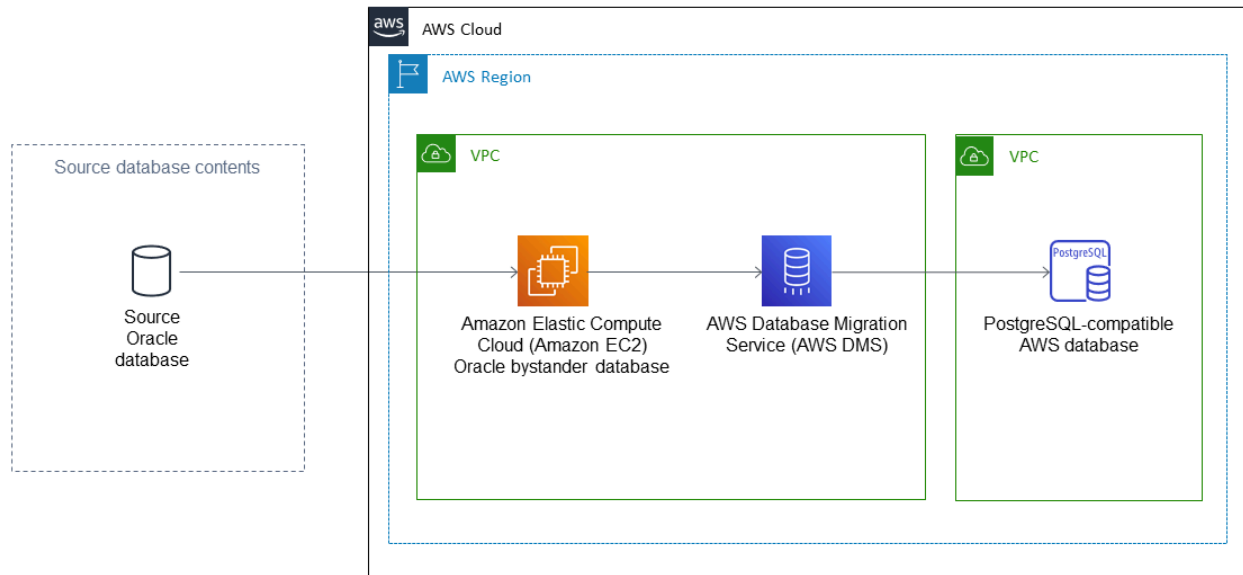

- An on-premises Oracle database
- An EC2 instance that holds a bystander for the Oracle database

### Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL instance, PostgreSQL 9.3 and later

## Target architecture

The following diagram shows an example workflow for migrating an Oracle database to a PostgreSQL-compatible AWS database by using AWS DMS and an Oracle bystander:

## Tools

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.
- [Amazon Relational Database Service \(Amazon RDS\)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.

## Epics

### Convert the Oracle database schema to PostgreSQL

Task	Description	Skills required
Set up AWS SCT.	<p>Create a new report, and connect to Oracle as the source and PostgreSQL as the target. In <b>Project Settings</b>, go to the <b>SQL Scripting</b> tab. Change the <b>Target SQL Script</b> to <b>Multiple Files</b>. These files will be used later and named the following:</p> <ul style="list-style-type: none"><li>• create_database.sql</li><li>• create_sequence.sql</li><li>• create_table.sql</li><li>• create_view.sql</li><li>• create_function.sql</li></ul>	DBA
Convert the Oracle database schema.	<p>In the <b>Action</b> tab, choose <b>Generate Report</b>. Then, choose <b>Convert Schema</b> and choose <b>Save as SQL</b>.</p>	DBA
Modify the scripts.	<p>For example, you might want to modify the script if a number in the source schema has been converted to numeric format in PostgreSQL, but you want to use <b>BIGINT</b> instead for better performance.</p>	DBA

## Create and configure the Amazon RDS DB instance

Task	Description	Skills required
Create the Amazon RDS DB instance.	In the correct AWS Region, create a new PostgreSQL DB instance. For more information, see <a href="#">Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance</a> in the Amazon RDS documentation.	AWS SysAdmin, DBA
Configure DB instance specifications.	Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a primary user name, and a primary password.	AWS SysAdmin, DBA
Configure network and security.	Specify the virtual private cloud (VPC), subnet group, public accessibility, Availability Zone preference, and security groups.	DBA, SysAdmin
Configure database options.	Specify the database name, port, parameter group, encryption, and KMS key.	AWS SysAdmin, DBA
Configure backups.	Specify the backup retention period, backup window, start time, duration, and whether to copy tags to snapshots.	AWS SysAdmin, DBA

Task	Description	Skills required
Configure monitoring options.	Activate or deactivate enhanced monitoring and performance insights.	AWS SysAdmin, DBA
Configure maintenance options.	Specify auto minor version upgrade, maintenance window, and start day, time, and duration.	AWS SysAdmin, DBA
Run the pre-migration scripts from AWS SCT.	On the Amazon RDS instance, run the following scripts generated by AWS SCT: <ul style="list-style-type: none"> <li>• create_database.sql</li> <li>• create_sequence.sql</li> <li>• create_table.sql</li> <li>• create_view.sql</li> <li>• create_function.sql</li> </ul>	AWS SysAdmin, DBA

## Configure the Oracle bystander in Amazon EC2

Task	Description	Skills required
Set up the network for Amazon EC2.	Create the new VPC, subnets, internet gateway, route tables, and security groups.	AWS SysAdmin
Create the EC2 instance.	In the appropriate AWS Region, create a new EC2 instance. Select the Amazon Machine Image (AMI), choose the instance size, and configure instance details: number of instances (1),	AWS SysAdmin

Task	Description	Skills required
	<p>the VPC and subnet you created in the previous task, auto-assign public IP, and other options. Add storage, configure security groups, and launch. When prompted, create and save a key pair for the next step.</p>	
<p>Connect the Oracle source database to the EC2 instance.</p>	<p>Copy the IPv4 public IP address and DNS to a text file and connect by using SSH as follows: <b>ssh -i "your_file.pem" ec2-user@&lt;your-IP-address-or-public-DNS&gt;</b>.</p>	<p>AWS SysAdmin</p>
<p>Set up the initial host for a bystander in Amazon EC2.</p>	<p>Set up SSH keys, bash profile, ORATAB, and symbolic links. Create Oracle directories.</p>	<p>AWS SysAdmin, Linux Admin</p>
<p>Set up the database copy for a bystander in Amazon EC2</p>	<p>Use RMAN to create a database copy, enable supplemental logging, and create the standby control file. After copying is complete, place the database in recovery mode.</p>	<p>AWS SysAdmin, DBA</p>

Task	Description	Skills required
Set up Oracle Data Guard.	Modify your <b>listener.ora</b> file and start the listener. Set up a new archive destination. Place the bystander in recovery mode, replace temporary files to avoid future corruption, install a crontab if necessary to prevent the archive directory from running out of space, and edit the <b>manage-trclog-files-oracle.cfg</b> file for the source and standby.	AWS SysAdmin, DBA
Prep the Oracle database to sync shipping.	Add the standby log files and change the recovery mode. Change the log shipping to <b>SYNC AFFIRM</b> on both the source primary and the source standby. Switch logs on primary, confirm via the Amazon EC2 bystander alert log that you are using the standby log files, and confirm that the redo stream is flowing in SYNC.	AWS SysAdmin, DBA

## Migrate data with AWS DMS

Task	Description	Skills required
Create a replication instance in AWS DMS.	Complete the fields for the name, instance class, VPC (same as the Amazon	AWS SysAdmin, DBA

Task	Description	Skills required
	<p>EC2 instance), Multi-AZ, and public accessibility. Under <b>Advance</b>, specify allocated storage, subnet group, Availability Zone, VPC security groups, and AWS Key Management Service (AWS KMS) key.</p>	
Create the source database endpoint.	<p>Specify the endpoint name, type, source engine (Oracle), server name (Amazon EC2 private DNS name), port, SSL mode, user name, password, SID, VPC (specify the VPC that has the replication instance) , and replication instance. To test the connection, choose <b>Run Test</b>, and then create the endpoint. You can also configure the following advanced settings: <b>maxFileSize</b> and <b>numberDataTypeScale</b>.</p>	AWS SysAdmin, DBA
Connect AWS DMS to Amazon RDS for PostgreSQL.	Create a migration security group for connections across VPCs.	AWS SysAdmin, DBA

Task	Description	Skills required
Create the target database endpoint.	Specify the endpoint name, type, source engine (PostgreSQL), server name (Amazon RDS endpoint), port, SSL mode, user name, password, database name, VPC (specify the VPC that has the replication instance), and replication instance. To test the connection, choose <b>Run Test</b> , and then create the endpoint. You can also configure the following advanced settings: <b>maxFileSize</b> and <b>numberDataTypes</b> .	AWS SysAdmin, DBA
Create the AWS DMS replication task.	Specify the task name, replication instance, source and target endpoints, and replication instance. For migration type, choose <b>Migrate existing data and replicate ongoing changes</b> . Clear the <b>Start task on create</b> checkbox.	AWS SysAdmin, DBA
Configure the AWS DMS replication task settings.	For target table preparation mode, choose <b>Do nothing</b> . Stop task after full load completes (to create primary keys). Specify limited or full LOB mode, and activate control tables. Optionally, you can configure the <b>CommitRate</b> advance setting.	DBA

Task	Description	Skills required
Configure table mappings.	In the <b>Table mappings</b> section, create an <b>Include</b> rule for all tables in all schemas included in the migration, and then create an <b>Exclude</b> rule. Add three transformation rules to convert the schema, table, and column names to lowercase, and add any other rules needed for this specific migration.	DBA
Start the task.	Start the replication task. Make sure that the full load is running. Run <b>ALTER SYSTEM SWITCH LOGFILE</b> on the primary Oracle database to kick-start the task.	DBA
Run the mid-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run the following scripts generated by AWS SCT: <ul style="list-style-type: none"><li>• create_index.sql</li><li>• create_constraint.sql</li></ul>	DBA
Restart the task to continue change data capture (CDC).	Run <b>VACUUM</b> on the Amazon RDS for PostgreSQL DB instance, and restart the AWS DMS task to apply cached CDC changes.	DBA

## Cut over to the PostgreSQL database

Task	Description	Skills required
Review the AWS DMS logs and validation tables for any errors.	Check and fix any replication or validation errors.	DBA
Stop all Oracle dependencies.	Stop all Oracle dependencies, shut down listeners on the Oracle database, and run <b>ALTER SYSTEM SWITCH LOGFILE</b> . Stop the AWS DMS task when it shows no activity.	DBA
Run the post-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run the following scripts generated by AWS SCT: <ul style="list-style-type: none"> <li>• create_foreign_key_constraint.sql</li> <li>• create_triggers.sql</li> </ul>	DBA
Complete additional Amazon RDS for PostgreSQL steps.	Increment sequences to match Oracle if needed, run <b>VACUUM</b> and <b>ANALYZE</b> , and take a snapshot for compliance.	DBA
Open the connections to Amazon RDS for PostgreSQL.	Remove the AWS DMS security groups from Amazon RDS for PostgreSQL, add production security groups, and point your applications to the new database.	DBA

Task	Description	Skills required
Clean up AWS DMS objects.	Remove the endpoints, replication tasks, replication instances, and the EC2 instance.	SysAdmin, DBA

# Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate

Created by Dhairya Jindani (AWS), Rajeshkumar Sabankar (AWS), and Sindhusha Paturu (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon RDS for PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon RDS		

## Summary

This pattern shows how to migrate an Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL by using Oracle Cloud Infrastructure (OCI) GoldenGate.

By using Oracle GoldenGate, you can replicate data between your source database and one or more destination databases with minimal downtime.

**Note:** The source Oracle database can be either on-premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. You can use a similar procedure when using on-premises replication tools.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Oracle GoldenGate license
- Java Database Connectivity (JDBC) driver to connect to the PostgreSQL database
- Schema and tables created with the [AWS Schema Conversion Tool \(AWS SCT\)](#) on the target Amazon RDS for PostgreSQL database

### Limitations

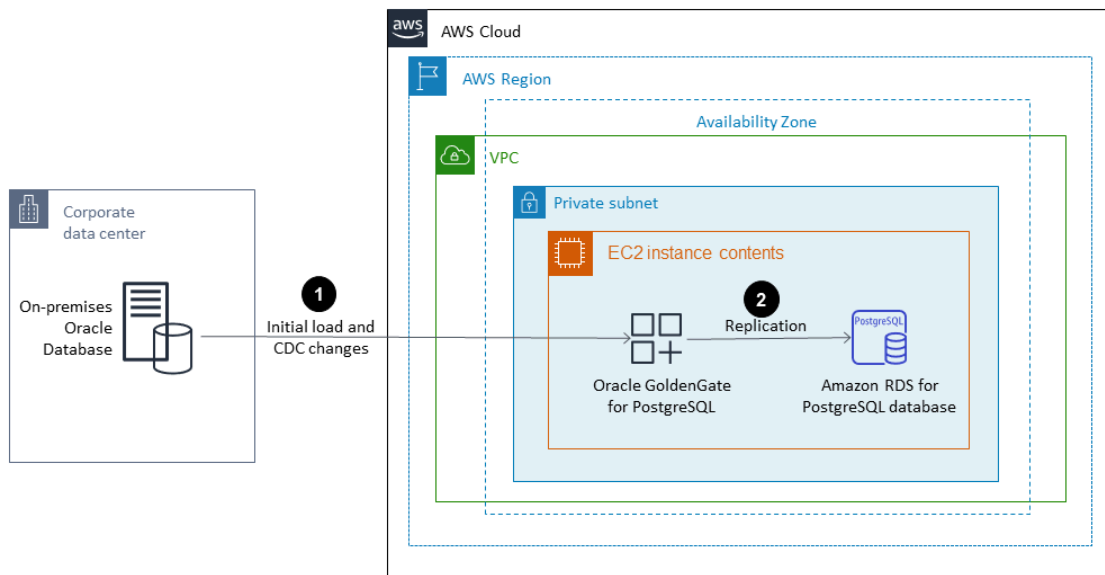

- Oracle GoldenGate can replicate existing table data (initial load) and ongoing changes (change data capture) only

## Product versions

- Oracle Database Enterprise Edition 10g or newer versions
- Oracle GoldenGate 12.2.0.1.1 for Oracle or newer versions
- Oracle GoldenGate 12.2.0.1.1 for PostgreSQL or newer versions

## Architecture

The following diagram shows an example workflow for migrating an Oracle database to Amazon RDS for PostgreSQL by using Oracle GoldenGate:

The diagram shows the following workflow:

1. The Oracle GoldenGate [Extract process](#) runs against the source database to extract data.
2. The Oracle GoldenGate [Replicat process](#) delivers the extracted data to the target Amazon RDS for PostgreSQL database.

## Tools

- [Oracle GoldenGate](#) helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.
- [Amazon Relational Database Service \(Amazon RDS\) for PostgreSQL](#) helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.

## Epics

### Download and install Oracle GoldenGate

Task	Description	Skills required
Download Oracle GoldenGate.	<p>Download the following versions of Oracle GoldenGate:</p> <ul style="list-style-type: none"> <li>• Oracle GoldenGate 12.2.0.1.1 for Oracle or a newer version</li> <li>• Oracle GoldenGate 12.2.0.1.1 for PostgreSQL or a newer version</li> </ul> <p>To download the software, see <a href="#">Oracle GoldenGate Downloads</a> on the Oracle website.</p>	DBA
Install Oracle GoldenGate for Oracle on the source Oracle Database server.	For instructions, see the <a href="#">Oracle GoldenGate documentation</a> .	DBA
Install Oracle GoldenGate for PostgreSQL database on the Amazon EC2 instance.	For instructions, see the <a href="#">Oracle GoldenGate documentation</a> .	DBA

## Configure Oracle GoldenGate on the source and target databases

Task	Description	Skills required
Set up Oracle GoldenGate for Oracle Database on the source database.	<p>For instructions, see the <a href="#">Oracle GoldenGate documentation</a>.</p> <p>Make sure that you configure the following:</p> <ul style="list-style-type: none"><li>• Supplemental logging</li><li>• Oracle GoldenGate users</li><li>• Any required grants and permissions</li><li>• Parameter files</li><li>• Manager process</li><li>• Directory</li><li>• <b>GLOBALS</b> files</li><li>• Oracle Wallet</li></ul>	DBA
Set up Oracle GoldenGate for PostgreSQL on the target database.	<p>For instructions, see <a href="#">Part VI Using Oracle GoldenGate for PostgreSQL</a> on the Oracle website.</p> <p>Make sure that you configure the following:</p> <ul style="list-style-type: none"><li>• Manager process</li><li>• <b>GLOBALS</b> files</li><li>• Oracle Wallet</li></ul>	DBA

## Configure the data capture

Task	Description	Skills required
Set up the Extract process in the source database.	<p>In the source Oracle Database, create an extract file to extract data.</p> <p>For instructions, see <a href="#">ADD EXTRACT</a> in the Oracle documentation.</p> <p><b>Note:</b> The extract file includes the creation of the extract parameter file and trail file directory.</p>	DBA
Set up a data pump to transfer the trail file from the source to the target database.	<p>Create an EXTRACT parameter file and trail file directory by following the instructions in <a href="#">PARFILE</a> in <i>Database Utilities</i> on the Oracle website.</p> <p>For more information, see <a href="#">What is a Trail?</a> in <i>Fusion Middleware Understanding Oracle GoldenGate</i> on the Oracle website.</p>	DBA
Set up replication on the Amazon EC2 instance.	<p>Create a replication parameter file and trail file directory.</p> <p>For more information about creating replication parameter files, see section <a href="#">3.5 Validating a parameter</a></p>	DBA

Task	Description	Skills required
	<p><a href="#">file</a> in the Oracle Database documentation.</p> <p>For more information about creating a trail file directory , see <a href="#">Creating a trail</a> in the Oracle Cloud documentation.</p> <p><b>Important:</b> Make sure that you add a checkpoint table entry in the GLOBALS file at the target.</p> <p>For more information, see <a href="#">What is a Replicat?</a> in <i>Fusion Middleware Understanding Oracle GoldenGate</i> on the Oracle website.</p>	

## Configure the data replication

Task	Description	Skills required
In the source database, create a parameter file to extract data for the initial load.	<p>Follow the instructions in <a href="#">Creating a parameter file in GGSCI</a> in the Oracle Cloud documentation.</p> <p><b>Important:</b> Make sure that the Manager is running on the target.</p>	DBA
In the target database, create a parameter file to replicate data for the initial load.	<p>Follow the instructions in <a href="#">Creating a parameter file in GGSCI</a> in the Oracle Cloud documentation.</p>	DBA

Task	Description	Skills required
	<b>Important:</b> Make sure that you add and start the Replicat process.	

## Cut over to the Amazon RDS for PostgreSQL database

Task	Description	Skills required
Stop the Replicat process and make sure that the source and target databases are in sync.	Compare row counts between the source and target databases to make sure that the data replication was successful.	DBA
Configure data definition language (DDL) support.	Run the DDL script for creating triggers, sequence, synonyms, and referential keys on PostgreSQL.  <b>Note:</b> You can use any standard SQL client application to connect to a database in your DB cluster. For example, you can use <a href="#">pgAdmin</a> to connect to your DB instance.	DBA

# Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT

*Created by Piyush Goyal (AWS) and Brian motzer (AWS)*

<b>Source:</b> Oracle	<b>Target:</b> Redshift	<b>R Type:</b> Re-architect
<b>Environment:</b> Production	<b>Technologies:</b> Migration; Analytics; Databases	<b>Workload:</b> Oracle
<b>AWS services:</b> Amazon Redshift; AWS DMS		

## Summary

This pattern provides guidance for migrating Oracle databases to an Amazon Redshift cloud data warehouse in the Amazon Web Services (AWS) Cloud by using AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT). The pattern covers source Oracle databases that are on premises or installed on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It also covers Amazon Relational Database Service (Amazon RDS) for Oracle databases.

## Prerequisites and limitations

### Prerequisites

- An Oracle database that is running in an on-premises data center or in the AWS Cloud
- An active AWS account
- Familiarity with [using an Oracle database as a source for AWS DMS](#)
- Familiarity with [using an Amazon Redshift database as a target for AWS DMS](#)
- Knowledge of Amazon RDS, Amazon Redshift, the applicable database technologies, and SQL
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, where AWS SCT is installed

### Product versions

- For self-managed Oracle databases, AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For Amazon RDS for Oracle

databases that AWS manages, AWS DMS supports all Oracle database editions for versions 11g (versions 11.2.0.4 and later) and up to 12.2, 18c, and 19c. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

## Architecture

### Source technology stack

One of the following:

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

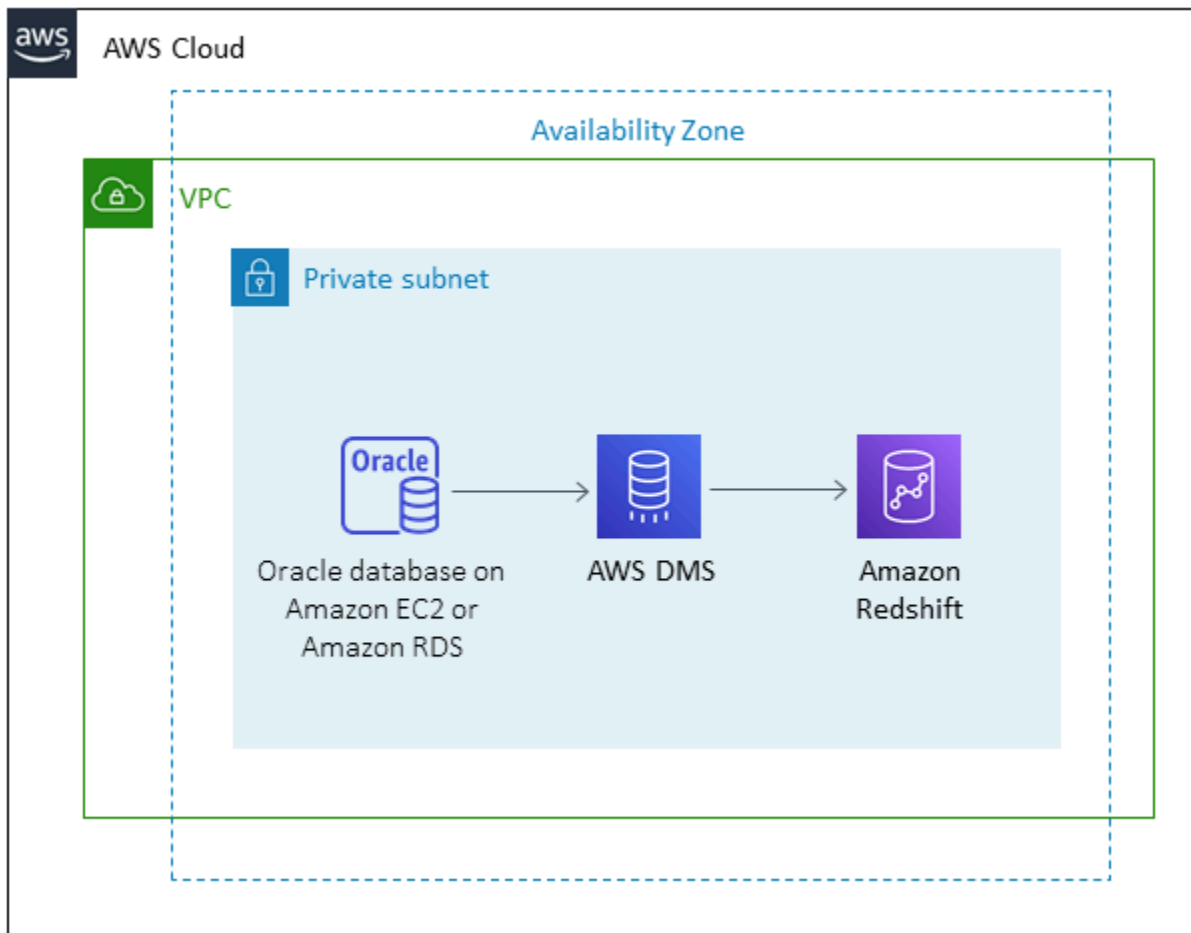

### Target technology stack

- Amazon Redshift

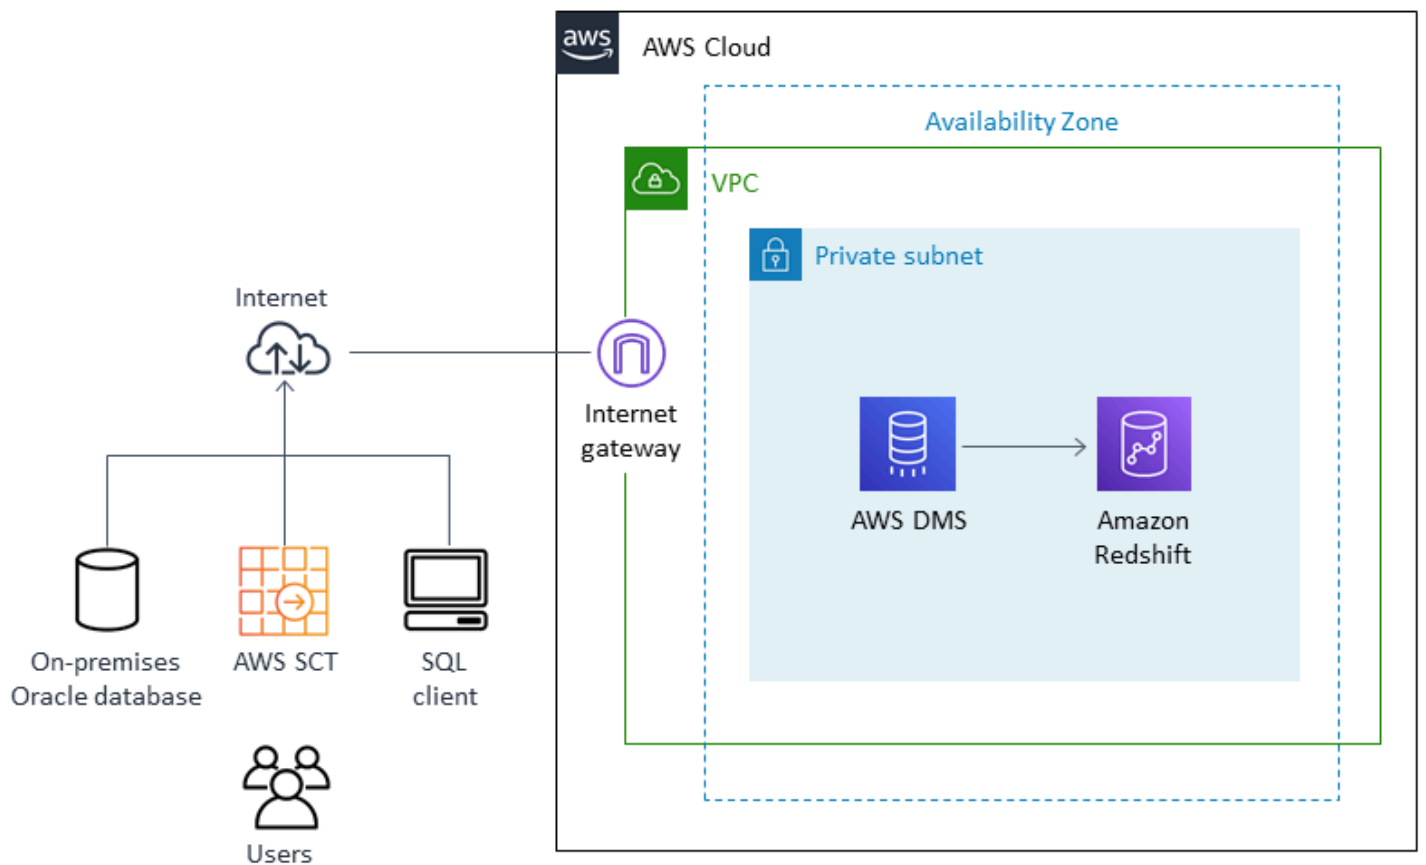

### Target architecture

*From an Oracle database running in the AWS Cloud to Amazon Redshift:*

*From an Oracle database running in an on-premises data center to Amazon Redshift:*

## Tools

- [AWS DMS](#) - AWS Data Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from most widely used commercial and open-source databases.
- [AWS SCT](#) - AWS Schema Conversion Tool (AWS SCT) can be used to convert your existing database schema from one database engine to another. It supports various database engines, including Oracle, SQL Server, and PostgreSQL, as sources.

## Epics

### Prepare for the migration

Task	Description	Skills required
Validate the database versions.	Validate the source and target database versions and make sure they are supported by AWS DMS. For information about supported Oracle Database versions, see <a href="#">Using an Oracle database as a source for AWS DMS</a> . For information about using Amazon Redshift as a target, see <a href="#">Using an Amazon Redshift database as a target for AWS DMS</a> .	DBA
Create a VPC and security group.	In your AWS account, create a virtual private cloud (VPC), if it doesn't exist. Create a security group for outbound traffic to source and target databases. For more information, see the <a href="#">Amazon Virtual Private Cloud (Amazon VPC) documentation</a> .	Systems administrator
Install AWS SCT.	Download and install the latest version of AWS SCT and its corresponding drivers. For more information, see <a href="#">Installing, verifying, and updating the AWS SCT</a> .	DBA

Task	Description	Skills required
Create a user for the AWS DMS task.	Create an AWS DMS user in the source database and grant it READ privileges. This user will be used by both AWS SCT and AWS DMS.	DBA
Test the DB connectivity.	Test the connectivity to the Oracle DB instance.	DBA
Create a new project in AWS SCT.	Open the AWS SCT tool and create a new project.	DBA
Analyze the Oracle schema to be migrated.	Use AWS SCT to analyze the schema to be migrated, and generate a database migration assessment report. For more information, see <a href="#">Creating a database migration assessment report</a> in the AWS SCT documentation.	DBA
Review the assessment report.	Review the report for migration feasibility. Some DB objects might require manual conversion. For more information about the report, see <a href="#">Viewing the assessment report</a> in the AWS SCT documentation.	DBA

## Prepare the target database

Task	Description	Skills required
Create an Amazon Redshift cluster.	Create an Amazon Redshift cluster within the VPC that you created previously. For more information, see <a href="#">Amazon Redshift clusters</a> in the Amazon Redshift documentation.	DBA
Create database users.	Extract the list of users, roles, and grants from the Oracle source database. Create users in the target Amazon Redshift database and apply the roles from the previous step.	DBA
Evaluate database parameters.	Review the database options, parameters, network files, and database links from the Oracle source database, and evaluate their applicability to the target.	DBA
Apply any relevant settings to the target.	For more information about this step, see <a href="#">Configuration reference</a> in the Amazon Redshift documentation.	DBA

## Create objects in the target database

Task	Description	Skills required
Create an AWS DMS user in the target database.	Create an AWS DMS user in the target database and grant	DBA

Task	Description	Skills required
	it read and write privileges. Validate the connectivity from AWS SCT.	
Convert the schema, review the SQL report, and save any errors or warnings.	For more information, see <a href="#">Converting database schemas using the AWS SCT</a> in the AWS SCT documentation.	DBA
Apply the schema changes to the target database or save them as a .sql file.	For instructions, see <a href="#">Saving and applying your converted schema in the AWS SCT</a> in the AWS SCT documentation.	DBA
Validate the objects in the target database.	Validate the objects that were created in the previous step in the target database. Rewrite or redesign any objects that weren't successfully converted.	DBA
Disable foreign keys and triggers.	Disable any foreign key and triggers. These can cause data loading issues during the full load process when running AWS DMS.	DBA

## Migrate data using AWS DMS

Task	Description	Skills required
Create an AWS DMS replication instance.	Sign in to the AWS Management Console, and open the AWS DMS console. In the navigation pane,	DBA

Task	Description	Skills required
	choose <b>Replication instances</b> , <b>Create replication instance</b> . For detailed instructions, see <a href="#">step 1</a> in <i>Getting started with AWS DMS</i> in the AWS DMS documentation.	
Create source and target endpoints.	Create source and target endpoints, Test the connection from the replication instance to both source and target endpoints. For detailed instructions, see <a href="#">step 2</a> in <i>Getting started with AWS DMS</i> in the AWS DMS documentation.	DBA
Create a replication task.	Create a replication task and select the appropriate migration method. For detailed instructions, see <a href="#">step 3</a> in <i>Getting started with AWS DMS</i> in the AWS DMS documentation.	DBA
Start the data replication.	Start the replication task and monitor the logs for any errors.	DBA

## Migrate your application

Task	Description	Skills required
Create application servers.	Create the new application servers on AWS.	Application owner

Task	Description	Skills required
Migrate the application code.	Migrate the application code to the new servers.	Application owner
Configure the application server.	Configure the application server for the target database and drivers.	Application owner
Optimize the application code.	Optimize the application code for the target engine.	Application owner

### Cut over to the target database

Task	Description	Skills required
Validate users.	In the target Amazon Redshift database, validate users and grant them roles and privileges.	DBA
Validate that the application is locked.	Make sure that the application is locked, to prevent further changes.	Application owner
Validate the data.	Validate the data in the target Amazon Redshift database.	DBA
Enable foreign keys and triggers.	Enable foreign keys and triggers in the target Amazon Redshift database.	DBA
Connect to the new database.	Configure the application to connect to the new Amazon Redshift database.	Application owner

Task	Description	Skills required
Perform final checks.	Perform a final, comprehensive system check before going live.	DBA, Application owner
Go live.	Go live with the target Amazon Redshift database.	DBA

## Close the migration project

Task	Description	Skills required
Shut down temporary AWS resources.	Shut down temporary AWS resources such as the AWS DMS replication instance and the EC2 instance used for AWS SCT.	DBA, Systems administrator
Review documents.	Review and validate the migration project documents.	DBA, Systems administrator
Gather metrics.	Collect information about the migration project, such as the time to migrate, the percentage of manual versus tool tasks, and total cost savings.	DBA, Systems administrator
Close out the project.	Close out the project and provide feedback.	DBA, Systems administrator

# Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT

Created by Senthil Ramasamy (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle Database	<b>Target:</b> Amazon Aurora PostgreSQL-Compatible
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon Aurora		

## Summary

This pattern describes how to migrate an Oracle database to Amazon Aurora PostgreSQL-Compatible Edition by using AWS Data Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT).

The pattern covers source Oracle databases that are on premises, Oracle databases that are installed on Amazon Elastic Compute Cloud (Amazon EC2) instances, and Amazon Relational Database Service (Amazon RDS) for Oracle databases. The pattern converts these databases to Aurora PostgreSQL-Compatible.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- An Oracle database in an on-premises data center or in the AWS Cloud.
- SQL clients installed either on a local machine or on an EC2 instance.
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed on either a local machine or an EC2 instance where AWS SCT is installed.

### Limitations

- Database size limit: 128 TB
- If the source database supports a commercial off-the-shelf (COTS) application or is vendor-specific, you might not be able to convert it to another database engine. Before using this pattern, confirm that the application supports Aurora PostgreSQL-Compatible.

## Product versions

- For self-managed Oracle databases, AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g, and up to 12.2, 18c, and 19c. For the latest list of supported Oracle database versions (both self-managed and Amazon RDS for Oracle), see [Using an Oracle database as a source for AWS DMS](#) and [Using a PostgreSQL database as a target for AWS DMS](#).
- We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the [AWS SCT documentation](#).
- Aurora supports the PostgreSQL versions listed in [Amazon Aurora PostgreSQL releases and engine versions](#).

## Architecture

### Source technology stack

One of the following:

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

### Target technology stack

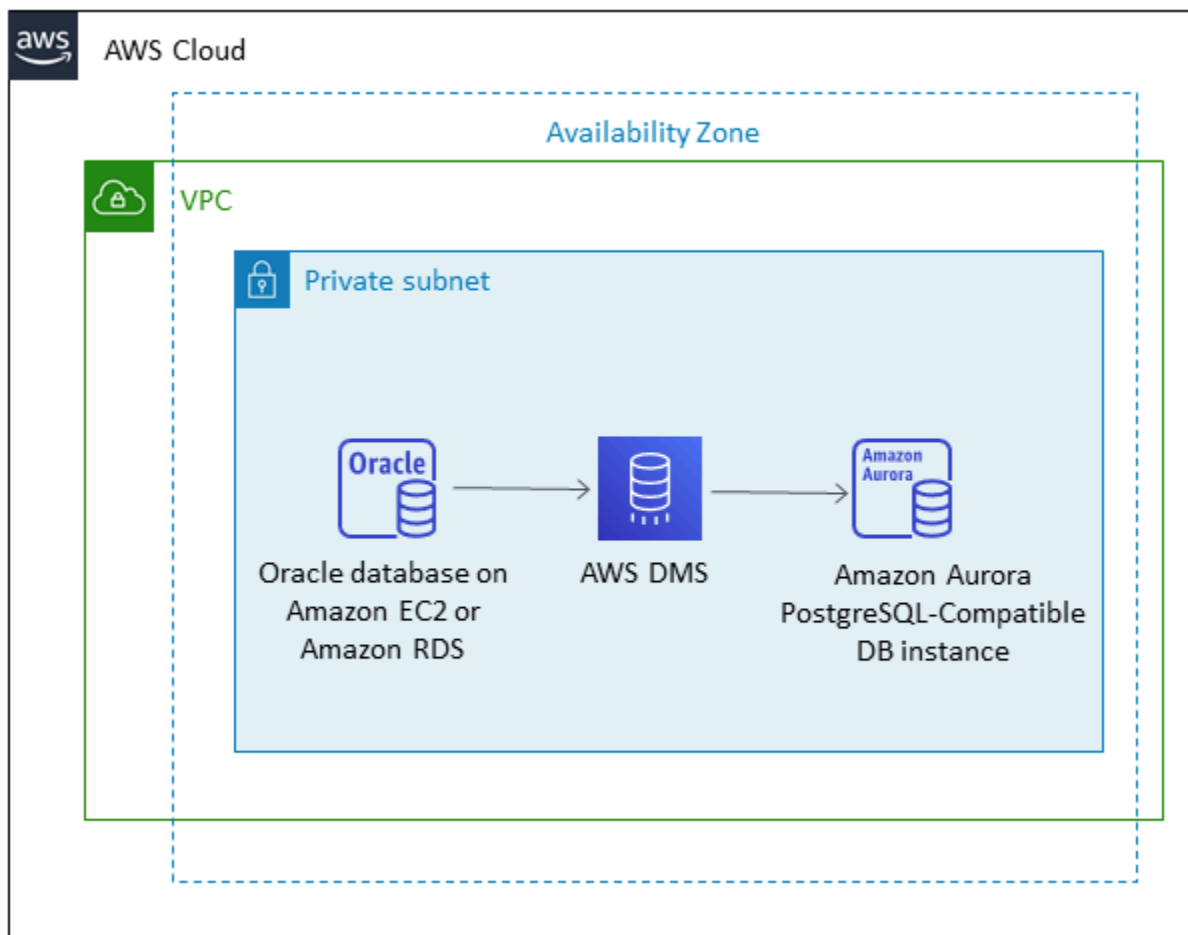

- Aurora PostgreSQL-Compatible

### Target architecture

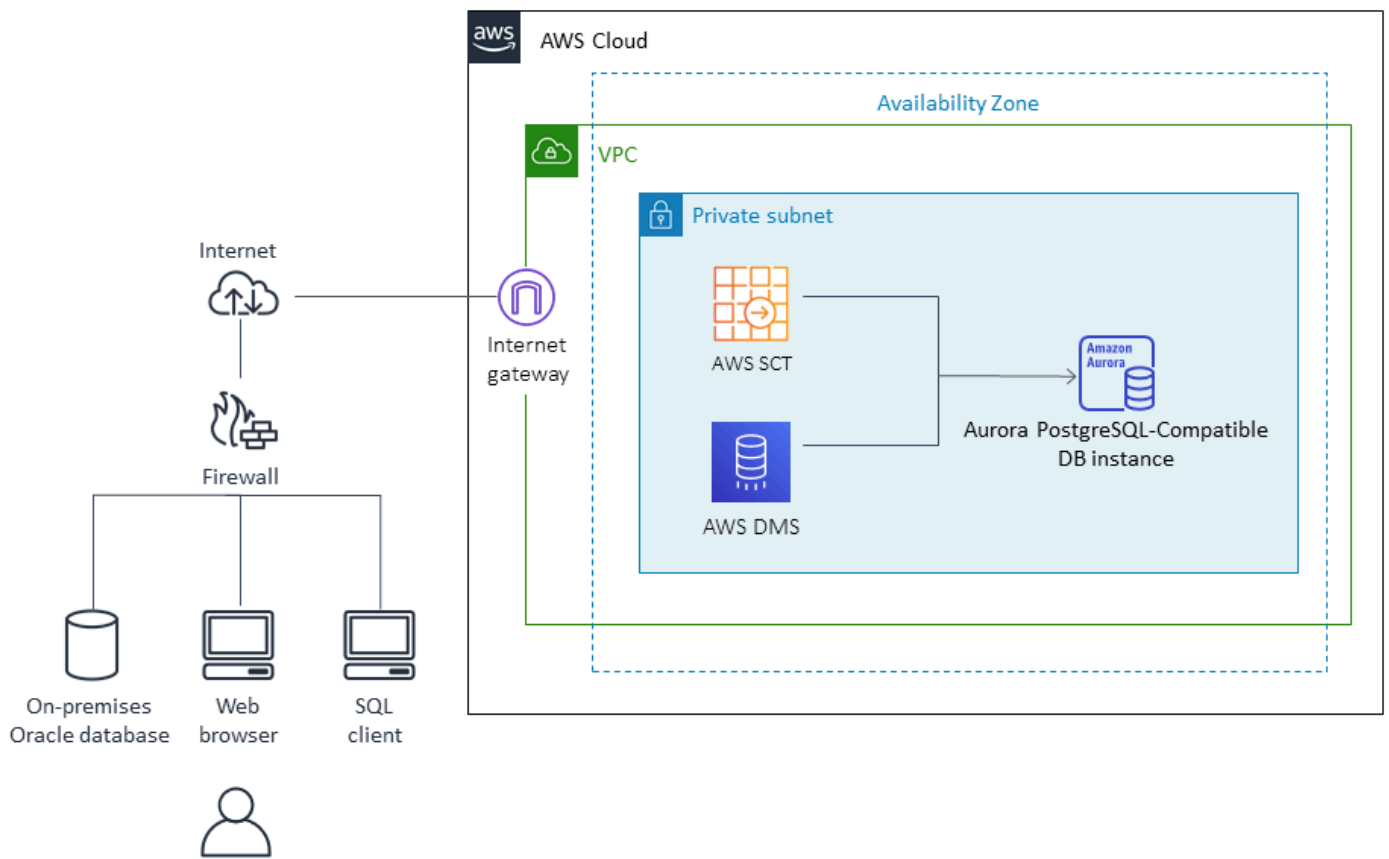

## Data migration architecture

- From an Oracle database running in the AWS Cloud

- From an Oracle database running in an on-premises data center

## Tools

- [AWS Database Migration Service \(AWS DMS\)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [AWS Schema Conversion Tool \(AWS SCT\)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

## Epics

### Prepare for the migration

Task	Description	Skills required
Prepare the source database.	To prepare the source database, see <a href="#">Using Oracle</a>	DBA

Task	Description	Skills required
	<a href="#">Database as a source for AWS SCT</a> in the AWS SCT documentation.	
Create an EC2 instance for AWS SCT.	Create and configure an EC2 instance for AWS SCT, if required.	DBA
Download AWS SCT.	Download the latest version of AWS SCT and associated drivers. For more information, see <a href="#">Installing, verifying, and updating AWS SCT</a> in the AWS SCT documentation.	DBA
Add users and permissions.	Add and validate the prerequisite users and permissions in the source database.	DBA
Create an AWS SCT project.	Create an AWS SCT project for the workload, and connect to the source database. For instructions, see <a href="#">Creating an AWS SCT project</a> and <a href="#">Adding database servers</a> in the AWS SCT documentation.	DBA

Task	Description	Skills required
Evaluate feasibility.	Generate an assessment report, which summarizes action items for schemas that can't be converted automatically and provides estimates for manual conversion efforts. For more information, see <a href="#">Creating and reviewing the database migration assessment report</a> in the AWS SCT documentation.	DBA

## Prepare the target database

Task	Description	Skills required
Create a target Amazon RDS DB instance.	Create a target Amazon RDS DB instance, using Amazon Aurora as the database engine. For instructions, see <a href="#">Creating an Amazon RDS DB instance</a> in the Amazon RDS documentation.	DBA
Extract users, roles, and permissions.	Extract the list of users, roles, and permissions from the source database.	DBA
Map users.	Map the existing database users to the new database users.	App owner
Create users.	Create users in the target database.	DBA, App owner

Task	Description	Skills required
Apply roles.	Apply roles from the previous step to the target database.	DBA
Check options, parameters, network files, and database links.	Review the source database for options, parameters, network files, and database links, and then evaluate their applicability to the target database.	DBA
Apply settings.	Apply any relevant settings to the target database.	DBA

## Transfer objects

Task	Description	Skills required
Configure AWS SCT connectivity.	Configure AWS SCT connectivity to the target database.	DBA
Convert the schema using AWS SCT.	AWS SCT automatically converts the source database schema and most of the custom code to a format that is compatible with the target database. Any code that the tool cannot convert automatically is clearly marked so that you can convert it manually.	DBA
Review the report.	Review the generated SQL report and save any errors and warnings.	DBA

Task	Description	Skills required
Apply automated schema changes.	Apply automated schema changes to the target database or save them as a .sql file.	DBA
Validate objects.	Validate that AWS SCT created the objects on the target.	DBA
Handle items that weren't converted.	Manually rewrite, reject, or redesign any items that failed to convert automatically.	DBA, App owner
Apply role and user permissions.	Apply the generated role and user permissions and review any exceptions.	DBA

## Migrate the data

Task	Description	Skills required
Determine the method.	Determine the method for migrating data.	DBA
Create a replication instance.	Create a replication instance from the AWS DMS console. For more information, see <a href="#">Working with an AWS DMS replication instance</a> in the AWS DMS documentation.	DBA
Create the source and target endpoints.	To create endpoints, follow the instructions in <a href="#">Creating source and target endpoints</a>	DBA

Task	Description	Skills required
	<a href="#">in the AWS DMS</a> documentation.	
Create a replication task.	To create a task, see <a href="#">Working with AWS DMS tasks</a> in the AWS DMS documentation.	DBA
Start the replication task and monitor the logs.	For more information about this step, see <a href="#">Monitoring AWS DMS tasks</a> in the AWS DMS documentation.	DBA

## Migrate the application

Task	Description	Skills required
Analyze and convert SQL items in the application code.	Use AWS SCT to analyze and convert the SQL items in the application code. When you convert your database schema from one engine to another, you also need to update the SQL code in your applications to interact with the new database engine instead of the old one. You can view, analyze, edit, and save the converted SQL code.	App owner
Create application servers.	Create the new application servers on AWS.	App owner
Migrate the application code.	Migrate the application code to the new servers.	App owner

Task	Description	Skills required
Configure the application servers.	Configure the application servers for the target database and drivers.	App owner
Fix code.	Fix any code that's specific to the source database engine in your application.	App owner
Optimize code.	Optimize your application code for the target database engine.	App owner

## Cut over

Task	Description	Skills required
Cut over to the target database.	Perform the cutover to the new database.	DBA
Lock the application.	Lock the application from any further changes.	App owner
Validate changes.	Validate that all changes were propagated to the target database.	DBA
Redirect to the target database.	Point the new application servers to the target database.	App owner
Check everything.	Perform a final, comprehensive system check.	App owner
Go live.	Complete final cutover tasks.	App owner

## Close the project

Task	Description	Skills required
Shut down temporary resources.	Shut down the temporary AWS resources such as the AWS DMS replication instance and the EC2 instance used for AWS SCT.	DBA, App owner
Update feedback.	Update feedback on the AWS DMS process for internal teams.	DBA, App owner
Revise process and templates.	Revise the AWS DMS process and improve the template if necessary.	DBA, App owner
Validate documents.	Review and validate the project documents.	DBA, App owner
Gather metrics.	Gather metrics to evaluate the time to migrate, percent of manual versus tool cost savings, and so on.	DBA, App owner
Close the project.	Close the migration project and provide feedback to stakeholders.	DBA, App owner

# Migrate data from an on-premises Oracle database to Aurora PostgreSQL

Created by Michelle Deng (AWS) and Shunan Xiang (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> Aurora PostgreSQL-Compatible
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon Aurora; AWS DMS; AWS SCT		

## Summary

This pattern provides guidance for data migration from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition. It targets an online data migration strategy with a minimal amount of downtime for multi-terabyte Oracle databases that contain large tables with high data manipulation language (DML) activities. An Oracle Active Data Guard standby database is used as the source to offload data migration from the primary database. The replication from the Oracle primary database to standby can be suspended during the full load to avoid ORA-01555 errors.

Table columns in primary keys (PKs) or foreign keys (FKs), with data type NUMBER, are commonly used to store integers in Oracle. We recommend that you convert these to INT or BIGINT in PostgreSQL for better performance. You can use the AWS Schema Conversion Tool (AWS SCT) to change the default data type mapping for PK and FK columns. (For more information, see the AWS blog post [Convert the NUMBER data type from Oracle to PostgreSQL](#).) The data migration in this pattern uses AWS Database Migration Service (AWS DMS) for both full load and change data capture (CDC).

You can also use this pattern to migrate an on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL, or an Oracle database that's hosted on Amazon Elastic Compute Cloud (Amazon EC2) to either Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Oracle source database in an on-premises data center with Active Data Guard standby configured
- AWS Direct Connect configured between the on-premises data center and the AWS Cloud
- Familiarity with [using an Oracle database as a source for AWS DMS](#)
- Familiarity with [using a PostgreSQL database as a target for AWS DMS](#)

### Limitations

- Amazon Aurora database clusters can be created with up to 128 TiB of storage. Amazon RDS for PostgreSQL database instances can be created with up to 64 TiB of storage. For the latest storage information, see [Amazon Aurora storage and reliability](#) and [Amazon RDS DB instance storage](#) in the AWS documentation.

### Product versions

- AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For the latest list of supported versions, see [Using an Oracle Database as a Source for AWS DMS](#) in the AWS documentation.

## Architecture

### Source technology stack

- On-premises Oracle databases with Oracle Active Data Guard standby configured

### Target technology stack

- Aurora PostgreSQL-Compatible

### Data migration architecture

## Tools

- AWS DMS** - [AWS Database Migration Service](#) (AWS DMS) supports several source and target databases. See [Using an Oracle Database as a Source for AWS DMS](#) in the AWS DMS documentation for a list of supported Oracle source and target database versions and editions. If the source database is not supported by AWS DMS, you must select another method for migrating the data in Phase 6 (in the *Epics* section). **Important note:** Because this is a heterogeneous migration, you must first check to see whether the database supports a commercial off-the-shelf (COTS) application. If the application is COTS, consult the vendor to confirm that Aurora PostgreSQL-Compatible is supported before proceeding. For more information, see [AWS DMS Step-by-Step Migration Walkthroughs](#) in the AWS documentation.
- AWS SCT** - The [AWS Schema Conversion Tool](#) (AWS SCT) facilitates heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. The custom code that the tool converts includes views, stored procedures, and functions. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.

## Epics

### Plan the migration

Task	Description	Skills required
Validate the source and target database versions.		DBA
Install AWS SCT and drivers.		DBA
Add and validate the AWS SCT prerequisite users and grants-source database.		DBA
Create an AWS SCT project for the workload, and connect to the source database.		DBA
Generate an assessment report and evaluate feasibility.		DBA, App owner

### Prepare the target database

Task	Description	Skills required
Create an Aurora PostgreSQL-Compatible target database.		DBA
Extract users, roles, and grants list from the source database.		DBA
Map the existing database users to the new database users.		App owner

Task	Description	Skills required
Create users in the target database.		DBA
Apply roles from the previous step to the target Aurora PostgreSQL-Compatible database.		DBA
Review database options, parameters, network files, and database links from the source database, and evaluate their applicability to the target database.		DBA, App owner
Apply any relevant settings to the target database.		DBA

### Prepare for database object code conversion

Task	Description	Skills required
Configure AWS SCT connectivity to the target database.		DBA
Convert the schema in AWS SCT, and save the converted code as a .sql file.		DBA, App owner
Manually convert any database objects that failed to convert automatically.		DBA, App owner
Optimize the database code conversion.		DBA, App owner

Task	Description	Skills required
Separate the .sql file into multiple .sql files based on the object type.		DBA, App owner
Validate the SQL scripts in the target database.		DBA, App owner

## Prepare for data migration

Task	Description	Skills required
Create an AWS DMS replication instance.		DBA
Create the source and target endpoints.	If the data type of the PKs and FKs is converted from NUMBER in Oracle to BIGINT in PostgreSQL, consider specifying the connection attribute <code>numberDataTypeScale=-2</code> when you create the source endpoint.	DBA

## Migrate data – full load

Task	Description	Skills required
Create the schema and tables in the target database.		DBA
Create AWS DMS full-load tasks by either grouping tables or splitting a big table based on the table size.		DBA

Task	Description	Skills required
Stop the applications on the source Oracle databases for a short period.		App owner
Verify that the Oracle standby database is synchronous with the primary database, and stop the replication from the primary database to the standby database.		DBA, App owner
Start applications on the source Oracle database.		App owner
Start the AWS DMS full-load tasks in parallel from the Oracle standby database to the Aurora PostgreSQL-Compatible database.		DBA
Create PKs and secondary indexes after the full load is complete.		DBA
Validate the data.		DBA

### Migrate data – CDC

Task	Description	Skills required
Create AWS DMS ongoing replication tasks by specifying a custom CDC start time or system change number (SCN) when the Oracle		DBA

Task	Description	Skills required
standby was synchronized with the primary database, and before the applications were restarted in the previous task.		
Start AWS DMS tasks in parallel to replicate ongoing changes from the Oracle standby database to the Aurora PostgreSQL-Compatible database.		DBA
Re-establish the replication from the Oracle primary database to the standby database.		DBA
Monitor the logs and stop the applications on the Oracle database when the target Aurora PostgreSQL-Compatible database is almost synchronous with the source Oracle database.		DBA, App owner
Stop the AWS DMS tasks when the target is fully synchronized with the source Oracle database.		DBA
Create FKs and validate the data in the target database.		DBA

Task	Description	Skills required
Create functions, views, triggers, sequences, and other object types in the target database.		DBA
Apply role grants in the target database.		DBA

## Migrate the application

Task	Description	Skills required
Use AWS SCT to analyze and convert the SQL statements inside the application code.		App owner
Create new application servers on AWS.		App owner
Migrate the application code to the new servers.		App owner
Configure the application server for the target database and drivers.		App owner
Fix any code that's specific to the source database engine in the application.		App owner
Optimize the application code for the target database.		App owner

## Cut over

Task	Description	Skills required
Point the new application server to the target database.		DBA, App owner
Perform sanity checks.		DBA, App owner
Go live.		DBA, App owner

## Close the project

Task	Description	Skills required
Shut down temporary AWS resources.		DBA, Systems administrator
Review and validate the project documents.		DBA, App owner
Gather metrics for time to migrate, percentage of manual versus tool use, cost savings, and similar data.		DBA, App owner
Close out the project and provide feedback.		DBA, App owner

# Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS

*Created by Amit Kumar (AWS)*

<b>Environment:</b> PoC or pilot	<b>Source:</b> SAP ASE	<b>Target:</b> Amazon RDS for SQL Server
<b>R Type:</b> Re-architect	<b>Workload:</b> SAP	<b>Technologies:</b> Migration; Databases; Modernization
<b>AWS services:</b> Amazon RDS; AWS DMS		

## Summary

This pattern provides guidance for migrating an SAP Adaptive Server Enterprise (ASE) database to an Amazon Relational Database Service (Amazon RDS) DB instance that's running Microsoft SQL Server. The source database can be located in an on-premises data center or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern uses AWS Database Migration Service (AWS DMS) to migrate data and (optionally) computer-aided software engineering (CASE) tools to convert the database schema.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An SAP ASE database in an on-premises data center or on an EC2 instance
- A target Amazon RDS for SQL Server database that's up and running

### Limitations

- Database size limit: 64 TB

### Product versions

- SAP ASE version 15.7 or 16.x only. For the latest information, see [Using an SAP Database as a Source for AWS DMS](#).
- For Amazon RDS target databases, AWS DMS supports [Microsoft SQL Server versions on Amazon RDS](#) for the Enterprise, Standard, Web, and Express editions. For the latest information about supported versions, see the [AWS DMS documentation](#). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

## Architecture

### Source technology stack

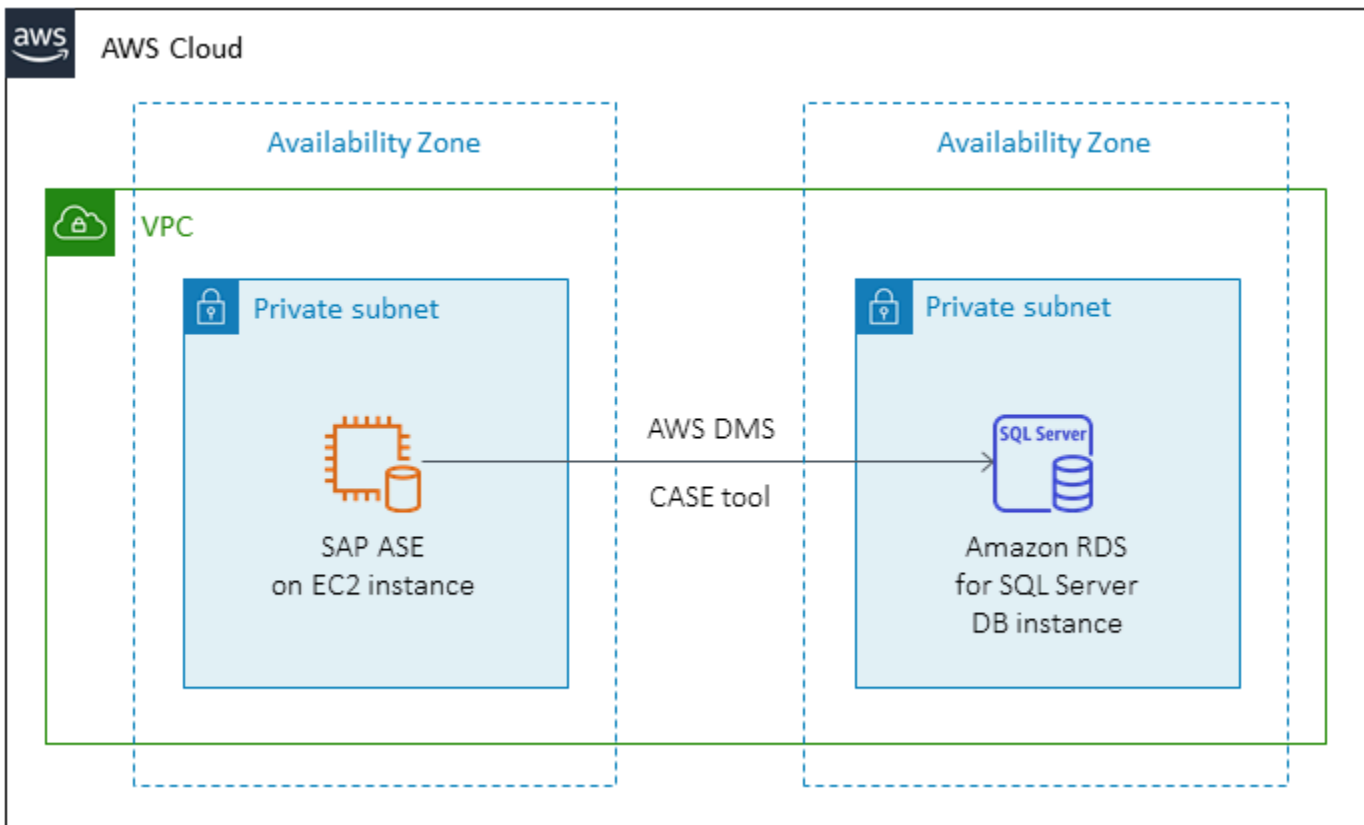

- An SAP ASE database that's on premises or on an Amazon EC2 instance

### Target technology stack

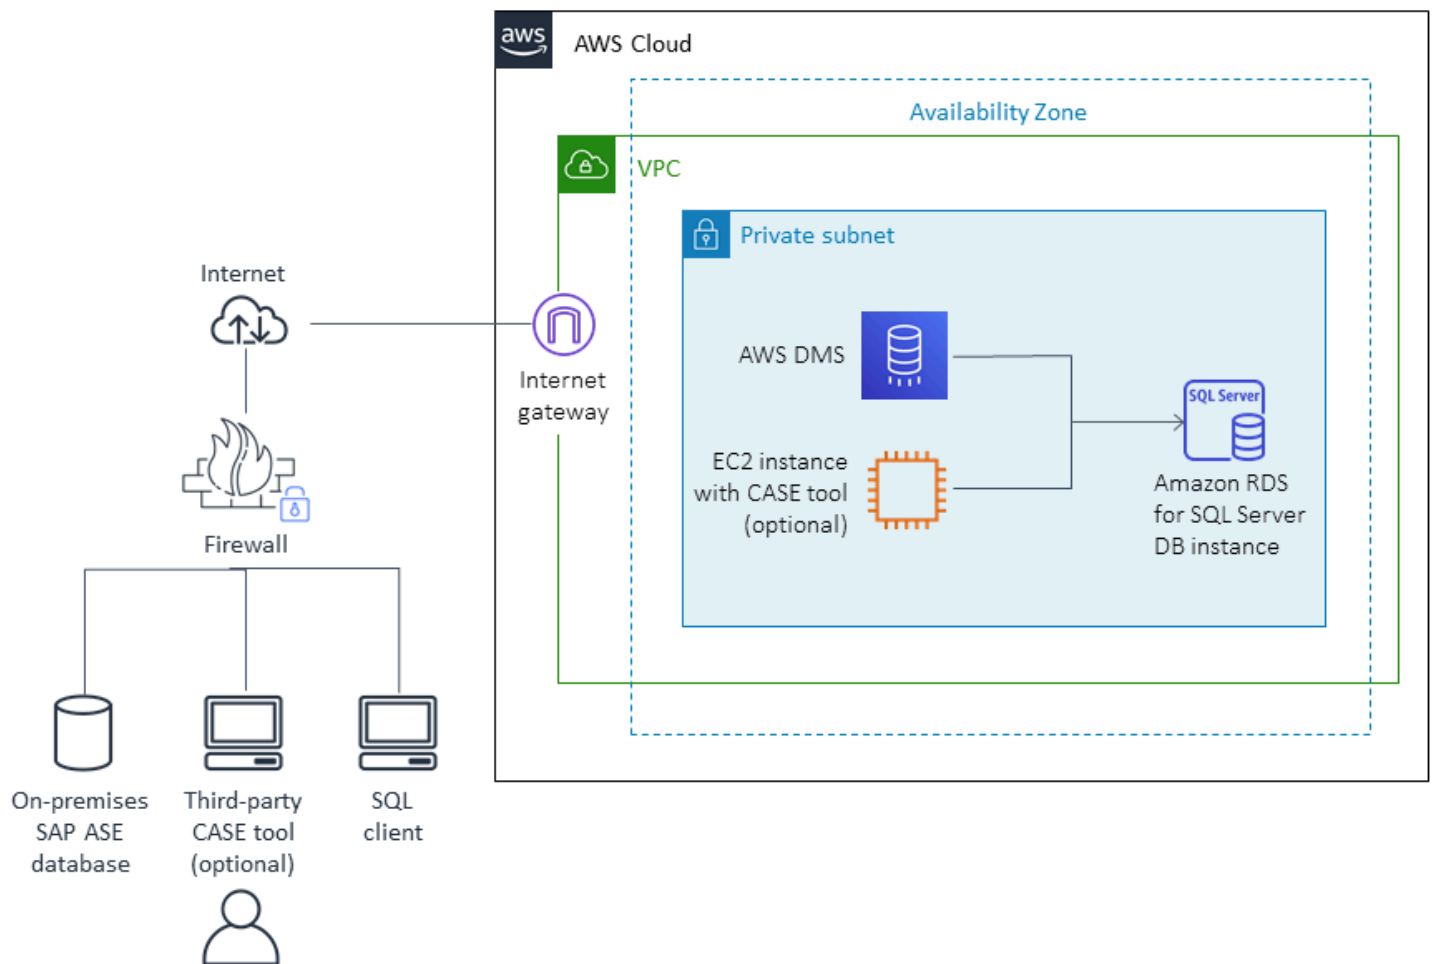

- An Amazon RDS for SQL Server DB instance

### Source and target architecture

*From an SAP ASE database on Amazon EC2 to an Amazon RDS for SQL Server DB instance:*

*From an on-premises SAP ASE database to an Amazon RDS for SQL Server DB instance:*

## Tools

- [AWS Database Migration Service](#) (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for SQL Server or an EC2 instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogeneous database engines.
- For schema conversions, you can optionally use [erwin Data Modeler](#) or [SAP PowerDesigner](#).

## Epics

### Plan the migration

Task	Description	Skills required
Validate the source and target database versions.		DBA
Identify the storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type based on capacity, storage features, and network features.		DBA, SysAdmin
Identify the network access security requirements for the source and target databases.		DBA, SysAdmin
Identify the application migration strategy.		DBA, SysAdmin, App owner

### Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		SysAdmin
Create security groups and network access control lists (ACLs).		SysAdmin
Configure and start an Amazon RDS DB instance.		SysAdmin

## Migrate data - option 1

Task	Description	Skills required
Migrate the database schema manually or use a CASE tool such as erwin Data Modeler or SAP PowerDesigner.		DBA

## Migrate data - option 2

Task	Description	Skills required
Migrate data using AWS DMS.		DBA

## Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, SysAdmin, App owner

## Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastructure.		DBA, SysAdmin, App owner

## Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.		DBA, SysAdmin
Review and validate the project documents.		DBA, SysAdmin, App owner
Gather metrics such as time to migrate, percentage of manual versus automated tasks, and cost savings.		DBA, SysAdmin, App owner
Close out the project and provide feedback.		DBA, SysAdmin, App owner

# Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS

Created by Marcelo Fernandes (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Microsoft SQL Server	<b>Target:</b> Amazon Redshift
<b>R Type:</b> Re-architect	<b>Workload:</b> Microsoft	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon Redshift		

## Summary

This pattern provides guidance for migrating an on-premises Microsoft SQL Server database to Amazon Redshift by using AWS Data Migration Service (AWS DMS).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Microsoft SQL Server database in an on-premises data center
- Completed prerequisites for using an Amazon Redshift database as a target for AWS DMS, as discussed in the [AWS DMS documentation](#)

### Product versions

- SQL Server 2005-2019, Enterprise, Standard, Workgroup, Developer, and Web editions. For the latest list of supported versions, see [Using a Microsoft SQL Server Database as a Source for AWS DMS](#) in the AWS documentation.

## Architecture

### Source technology stack

- An on-premises Microsoft SQL Server database

## Target technology stack

- Amazon Redshift

## Data migration architecture

## Tools

- [AWS DMS](#) is a data migration service that supports several types of source and target databases. For information about the Microsoft SQL Server database versions and editions that are supported for use with AWS DMS, see [Using a Microsoft SQL Server Database as a Source for AWS DMS](#) in the AWS DMS documentation. If AWS DMS doesn't support your source database, you must select an alternative method for data migration.

## Epics

### Plan the migration

Task	Description	Skills required
Validate the source and target database version and engine.		DBA
Identify the hardware requirements for the target server instance.		DBA, Systems administrator
Identify the storage requirements (storage type and capacity).		DBA, Systems administrator
Choose the proper instance type based on capacity, storage features, and network features.		DBA, Systems administrator
Identify the network access security requirements for the source and target databases.		DBA, Systems administrator
Identify the application migration strategy.		DBA, App owner, Systems administrator

### Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).	For more information, see <a href="#">Working with a DB instance in a VPC</a> in the AWS documentation.	Systems administrator

Task	Description	Skills required
Create security groups.		Systems administrator
Configure and start an Amazon Redshift cluster.	For more information, see <a href="#">Create a sample Amazon Redshift cluster</a> in the Amazon Redshift documentation.	DBA, Systems administrator

## Migrate data

Task	Description	Skills required
Migrate the data from the Microsoft SQL Server database by using AWS DMS.		DBA

## Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, App owner, Systems administrator

## Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastructure.		DBA, App owner, Systems administrator

## Close the project

Task	Description	Skills required
Shut down the temporary resources.		DBA, Systems administrator
Review and validate the project documents.		DBA, App owner, Systems administrator
Gather metrics such as time to migrate, percentage of manual versus automated tasks, and cost savings.		DBA, App owner, Systems administrator
Close out the project and provide feedback.		DBA, App owner, Systems administrator

# Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents

Created by Neha Thakur (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Microsoft SQL Server	<b>Target:</b> Amazon Redshift
<b>R Type:</b> Re-architect	<b>Workload:</b> Microsoft	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon Redshift; AWS SCT		

## Summary

This pattern outlines steps for migrating an on-premises Microsoft SQL Server source database to an Amazon Redshift target database by using AWS Schema Conversion Tool (AWS SCT) data extraction agents. An agent is an external program that is integrated with AWS SCT but performs data transformation elsewhere and interacts with other AWS services on your behalf.

## Prerequisites and limitations

### Prerequisites

- A Microsoft SQL Server source database used for the data warehouse workload in an on-premises data center
- An active AWS account

### Product versions

- Microsoft SQL Server version 2008 or later. For the latest list of supported versions, see [AWS SCT documentation](#).

## Architecture

### technology stackSource

- An on-premises Microsoft SQL Server database

## technology stackTarget

- Amazon Redshift

## Data migration architecture

## Tools

- [AWS Schema Conversion Tool](#) (AWS SCT) handles heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. When the source and target databases are very different, you can use an AWS SCT agent to perform additional data transformation. For more information, see [Migrating Data from an On-Premises Data Warehouse to Amazon Redshift](#) in the AWS documentation.

# Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents

Created by Sergey Dmitriev (AWS)

<b>R Type:</b> Re-architect	<b>Source:</b> Databases: Relational	<b>Target:</b> Amazon Redshift
<b>Created by:</b> AWS	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Databases; Migration
<b>AWS services:</b> Amazon Redshift		

## Summary

This pattern walks you through the steps for migrating a Teradata database, used as a data warehouse in an on-premises data center, to an Amazon Redshift database. The pattern uses AWS Schema Conversion Tool (AWS SCT) data extraction agents. An agent is an external program that is integrated with AWS SCT but performs data transformation elsewhere and interacts with other AWS services on your behalf.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Teradata source database in an on-premises data center

### Product versions

- Teradata version 13 and later. For the latest list of supported versions, see the [AWS SCT documentation](#).

## Architecture

### Source technology stack

- On-premises Teradata database

## Target technology stack

- Amazon Redshift cluster

## Data migration architecture

## Tools

- **AWS SCT** – [AWS Schema Conversion Tool](#) (AWS SCT) handles heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. When the source and target databases are very different from one another, you can use an AWS SCT agent to perform additional data transformation. For more information, see [Migrating Data from an On-Premises Data Warehouse to Amazon Redshift](#) in the AWS documentation.

## Epics

### Prepare for migration

Task	Description	Skills required
Validate the source and target database versions and engines.		DBA
Identify hardware requirements for the target server instance.		DBA, SysAdmin
Identify storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type (capacity, storage features, network features).		DBA, SysAdmin
Identify network-access security requirements for the source and target databases.		DBA, SysAdmin
Choose an application migration strategy.		DBA, SysAdmin, App owner

### Configure infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		SysAdmin
Create security groups.		SysAdmin

Task	Description	Skills required
Configure and start the Amazon Redshift cluster.		SysAdmin

## Migrate data

Task	Description	Skills required
Migrate data by using AWS SCT data extraction agents.	For detailed information on using AWS SCT data extraction agents, see the links in the References and Help section.	DBA

## Migrate applications

Task	Description	Skills required
Follow the chosen application migration strategy.		DBA, SysAdmin, App owner

## Cut over to the target Amazon Redshift database

Task	Description	Skills required
Switch over application clients to the new infrastructure.		DBA, SysAdmin, App owner

## Close the project

Task	Description	Skills required
Shut down temporary AWS resources.		DBA, SysAdmin
Review and validate the project documents.		DBA, SysAdmin, App owner
Gather metrics about time to migrate, percentage of manual versus tool tasks, cost savings, etc.		DBA, SysAdmin, App owner
Close the project and provide any feedback.

# Migrate legacy applications from Oracle Pro\*C to ECPG

Created by Sai Parthasaradhi (AWS) and Mahesh Balumuri (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases

## Summary

Most legacy applications that have embedded SQL code use the Oracle Pro\*C precompiler to access the database. When you migrate these Oracle databases to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition, you have to convert your application code to a format that's compatible with the precompiler in PostgreSQL, which is called ECPG. This pattern describes how to convert Oracle Pro\*C code to its equivalent in PostgreSQL ECPG.

For more information about Pro\*C, see the [Oracle documentation](#). For a brief introduction to ECPG, see the [Additional information](#) section.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database
- An Oracle database running on premises

## Tools

- The PostgreSQL packages listed in the next section.
- [AWS CLI](#) – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

## Epics

### Set the build environment on CentOS or RHEL

Task	Description	Skills required
Install PostgreSQL packages.	<p>Install the required PostgreSQL packages by using the following commands.</p> <pre data-bbox="594 590 1027 1068">yum update -y yum install -y yum- utils rpm -ivh https://d ownload.postgresql .org/pub/repos/yum /repopms/EL-8-x86 _64/pgdg-redhat-repo- latest.noarch.rpm dnf -qy module disable postgresql</pre>	App developer, DevOps engineer
Install the header files and libraries.	<p>Install the postgresql112-devel package, which contains header files and libraries, by using the following commands. Install the package in both the development and the runtime environments to avoid errors in the runtime environment.</p> <pre data-bbox="594 1566 1027 1797">dnf -y install postgresq l112-devel yum install ncompress zip ghostscript jq unzip wget git -y</pre>	App developer, DevOps engineer

Task	Description	Skills required
	<p>For the development environment only, also run the following commands.</p> <pre>yum install zlib-devel make -y ln -s /usr/pgsql-12/ bin/ecpg /usr/bin/</pre>	
Configure the environment path variable.	<p>Set the environment path for PostgreSQL client libraries.</p> <pre>export PATH=\$PATH:/usr/ pgsql-12/bin</pre>	App developer, DevOps engineer

Task	Description	Skills required
Install additional software as necessary.	<p>If required, install <b>pgLoader</b> as a replacement for <b>SQL*Loader</b> in Oracle.</p> <pre>wget -O /etc/yum.repos.d/pgloader-ccl.repo https://d1.packager.io/srv/opf/pgloader-ccl/master/installer/el/7.repo yum install pgloader-ccl -y ln -s /opt/pgloader-ccl/bin/pgloader /usr/bin/</pre> <p>If you're calling any Java applications from Pro*C modules, install Java.</p> <pre>yum install java -y</pre> <p>Install <b>ant</b> to compile the Java code.</p> <pre>yum install ant -y</pre>	App developer, DevOps engineer

Task	Description	Skills required
Install the AWS CLI.	<p>Install the AWS CLI to run commands to interact with AWS services such as AWS Secrets Manager and Amazon Simple Storage Service (Amazon S3) from your applications.</p> <pre>cd /tmp/ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip" unzip awscliv2.zip ./aws/install -i /usr/local/aws-cli -b /usr/local/bin --update</pre>	App developer, DevOps engineer
Identify the programs to be converted.	Identify the applications that you want to convert from Pro*C to ECPG.	App developer, App owner

## Convert Pro\*C code to ECPG

Task	Description	Skills required
Remove unwanted headers.	Remove the include headers that are not required in PostgreSQL, such as <code>oci.h</code> , <code>oratypes</code> , and <code>sqllda</code> .	App owner, App developer
Update variable declarations.	Add EXEC SQL statements for all variable declarations	App developer, App owner

Task	Description	Skills required
	<p>that are used as host variables</p> <ul style="list-style-type: none"><li>•</li></ul> <p>Remove the EXEC SQL VAR declarations such as the following from your application.</p> <pre>EXEC SQL VAR query IS STRING(2048);</pre>	

Task	Description	Skills required
Update ROWNUM functionality.	<p>The ROWNUM function isn't available in PostgreSQL. Replace this with the ROW_NUMBER window function in SQL queries.</p> <p>Pro*C code:</p> <pre data-bbox="594 569 1029 1125">SELECT SUBSTR(RTRIM(FILE_NAME, '.txt'),12) INTO :gcplFileSeq FROM (SELECT FILE_NAME FROM DEMO_FILES_TABLE WHERE FILE_NAME LIKE '%POC%' ORDER BY FILE_NAME DESC) FL2 WHERE ROWNUM &lt;=1 ORDER BY ROWNUM;</pre> <p>ECPG code:</p> <pre data-bbox="594 1236 1029 1845">SELECT SUBSTR(RTRIM(FILE_NAME, '.txt'),12) INTO :gcplFileSeq FROM (SELECT FILE_NAME , ROW_NUMBER() OVER (ORDER BY FILE_NAME DESC) AS ROWNUM FROM demo_schema.DEMO_FILES_TABLE WHERE FILE_NAME LIKE '%POC%' ORDER BY FILE_NAME DESC) FL2</pre>	App developer, App owner

Task	Description	Skills required
	<pre>WHERE ROWNUM &lt;=1 ORDER BY ROWNUM;</pre>	
Update function parameters to use alias variables.	<p>In PostgreSQL, function parameters can't be used as host variables. Overwrite them by using an alias variable.</p> <p>Pro*C code:</p> <pre>int processData(int referenceId){     EXEC SQL char     col_val[100];     EXEC SQL select     column_name     INTO :col_val from     table_name where     col=:referenceId; }</pre> <p>ECPG code:</p> <pre>int processData(int referenceIdParam){     EXEC SQL int reference     Id = referenceIdParam;     EXEC SQL char     col_val[100];     EXEC SQL select     column_name     INTO :col_val from     table_name where     col=:referenceId; }</pre>	App developer, App owner

Task	Description	Skills required
Update struct types.	<p>Define struct types in EXEC SQL BEGIN and END blocks with typedef if the struct type variables are used as host variables. If the struct types are defined in header (.h) files, include the files with EXEC SQL include statements.</p> <p>Pro*C code:</p> <p>Header file (demo.h)</p> <pre data-bbox="594 842 1027 1682">struct s_partiti on_ranges {     char    sc_table_ group[31];     char    sc_table_ name[31];     char    sc_range_ value[10]; }; struct s_partiti on_ranges_ind {     short    ss_table_ group;     short    ss_table_ name;     short    ss_range_ value; };</pre> <p>ECPG code:</p> <p>Header file (demo.h)</p>	App developer, App owner

Task	Description	Skills required

<p>Modify logic to fetch from cursors.</p>	<p>To fetch multiple rows from cursors by using array variables, change the code to use FETCH FORWARD.</p> <p>Pro*C code:</p> <pre>EXEC SQL char aPoeFiles [MAX_FILES][FILENA ME_LENGTH]; EXEC SQL FETCH filename_ cursor into :aPoeFile s;</pre> <p>ECPG code:</p> <pre>EXEC SQL char aPoeFiles [MAX_FILES][FILENA ME_LENGTH]; EXEC SQL int fetchSize = MAX_FILES; EXEC SQL FETCH FORWARD :fetchSiz e filename_cursor into :aPoeFiles;</pre>	<p>App developer, App owner</p>

Task	Description	Skills required
Modify package calls that don't have return values.	<p>Oracle package functions that don't have return values should be called with an indicator variable. If your application includes multiple functions that have the same name or if the unknown type functions generate runtime errors, typecast the values to the data types.</p> <p>Pro*C code:</p> <pre data-bbox="594 806 1029 1402">void ProcessData (char  *data , int id) {     EXEC SQL EXECUTE         BEGIN          pkg_demo. process_data (:data, :id);          END;     END-EXEC; }</pre> <p>ECPG code:</p> <pre data-bbox="594 1514 1029 1843">void ProcessData (char *dataParam, int idParam ) {     EXEC SQL char  *data = dataParam;     EXEC SQL int id  = idParam;</pre>	App developer, App owner

Task	Description	Skills required
	<pre>EXEC SQL short rowInd; EXEC SQL short rowInd = 0; EXEC SQL SELECT pkg_demo.process_data ( inp_data =&gt; :data::te xt, inp_id =&gt; :id ) INTO :rowInd; }</pre>	

Task	Description	Skills required
Rewrite SQL_CURSOR variables.	<p>Rewrite the SQL_CURSOR variable and its implementation.</p> <p>Pro*C code:</p> <pre data-bbox="597 474 1027 1071"> /* SQL Cursor */ SQL_CURSOR demo_cursor; EXEC SQL   ALLOCATE :demo_cursor; EXEC SQL EXECUTE   BEGIN     pkg_demo. get_cursor(   demo_cur= &gt;:demo_cursor   );   END; END-EXEC; </pre> <p>ECPG code:</p> <pre data-bbox="597 1182 1027 1875"> EXEC SQL DECLARE   demo_cursor CURSOR FOR   SELECT     * from     pkg_demo.open_file name_rc(   demo_cur= &gt;refcursor   ); EXEC SQL char open_file name_rcInd[100]; # As the below function returns cursor_name as # return we need to use char[] type as indicator. </pre>	App developer, App owner

Task	Description	Skills required
	<pre>EXEC SQL SELECT   pkg_demo.get_cursor (     demo_cur= &gt;'demo_cursor'   ) INTO :open_fil ename_rcInd;</pre>	
<p>Apply common migration patterns.</p>	<ul style="list-style-type: none"> <li>• Change SQL queries so they're compatible with PostgreSQL.</li> <li>• Move anonymous blocks, when they aren't supported in ECPG, to the database.</li> <li>• Remove dbms_application_info logic, which isn't supported by PostgreSQL.</li> <li>• Move EXEC SQL COMMIT statements after the cursor close. If you commit queries while in the loop to fetch the records from the cursor, the cursor is closed and a cursor doesn't exist error is displayed.</li> <li>• For information about handling exceptions in ECPG and error codes, see <a href="#">Error Handling</a> in the PostgreSQL documentation.</li> </ul>	<p>App developer, App owner</p>

Task	Description	Skills required
Enable debugging, if required.	To run the ECPG program in debug mode, add the following command inside the main function block.  <pre>ECPGdebug(1, stderr);</pre>	App developer, App owner

## Compile ECPG programs

Task	Description	Skills required
Create an executable file for ECPG.	If you have an embedded SQL C source file named <code>prog1.pgc</code> , you can create an executable program by using the following sequence of commands.  <pre>ecpg prog1.pgc cc -I/usr/local/pgsql/ include -c prog1.c cc -o prog1 prog1.o -L/ usr/local/pgsql/lib - lecpg</pre>	App developer, App owner
Create a make file for compilation.	Create a make file to compile the ECPG program, as shown in the following sample file.  <pre>CFLAGS ::= \$(CFLAGS) -I/ usr/pgsql-12/include - g -Wall LDFLAGS ::= \$(LDFLAGS ) -L/usr/pgsql-12/li b -Wl,-rpath,/usr/pg sql-12/lib</pre>	App developer, App owner

Task	Description	Skills required
	<pre>LDLIBS ::= \$(LDLIBS) - lecpg PROGRAMS = test .PHONY: all clean %.c: %.pgc     ecpg \$&lt; all: \$(PROGRAMS) clean:     rm -f \$(PROGRAM S) \$(PROGRAMS:%=%.c)     \$(PROGRAMS:%=%.o)</pre>	

## Test the application

Task	Description	Skills required
Test the code.	Test the converted application code to make sure that it functions correctly.	App developer, App owner, Test engineer

## Related resources

- [ECPG - Embedded SQL in C](#) (PostgreSQL documentation)
- [Error Handling](#) (PostgreSQL documentation)
- [Why Use the Oracle Pro\\*C/C++ Precompiler](#) (Oracle documentation)

## Additional information

PostgreSQL has an embedded SQL precompiler, ECPG, which is equivalent to the Oracle Pro\*C precompiler. ECPG converts C programs that have embedded SQL statements to standard C code by replacing the SQL calls with special function calls. The output files can then be processed with any C compiler tool chain.

## Input and output files

ECPG converts each input file you specify on the command line to the corresponding C output file. If an input file name doesn't have a file extension, .pgc is assumed. The file's extension is replaced by .c to construct the output file name. However, you can override the default output file name by using the `-o` option.

If you use a dash (-) as the input file name, ECPG reads the program from standard input and writes to standard output, unless you override that by using the `-o` option.

## Header files

When the PostgreSQL compiler compiles the pre-processed C code files, it looks for the ECPG header files in the PostgreSQL `include` directory. Therefore, you might have to use the `-I` option to point the compiler to the correct directory (for example, `-I/usr/local/pgsql/include`).

## Libraries

Programs that use C code with embedded SQL have to be linked against the `libecpg` library. For example, you can use the linker options `-L/usr/local/pgsql/lib -lecpg`.

Converted ECPG applications call functions in the `libpq` library through the embedded SQL library (`ecpglib`), and communicate with the PostgreSQL server by using the standard frontend/backend protocol.

# Migrate virtual generated columns from Oracle to PostgreSQL

Created by Veeranjanyulu Grandhi (AWS), Rajesh Madiwale (AWS), and Ramesh Pathuri (AWS)

<b>Environment:</b> Production	<b>Source:</b> Oracle Database	<b>Target:</b> Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> Amazon Aurora; Amazon RDS; AWS DMS		

## Summary

In version 11 and earlier, PostgreSQL doesn't provide a feature that is directly equivalent to an Oracle virtual column. Handling virtual generated columns while migrating from Oracle Database to PostgreSQL version 11 or earlier is difficult for two reasons:

- Virtual columns aren't visible during migration.
- PostgreSQL doesn't support the `generate` expression before version 12.

However, there are workarounds to emulate similar functionality. When you use AWS Database Migration Service (AWS DMS) to migrate data from Oracle Database to PostgreSQL version 11 and earlier, you can use trigger functions to populate the values in virtual generated columns. This pattern provides examples of Oracle Database and PostgreSQL code that you can use for this purpose. On AWS, you can use Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition for your PostgreSQL database.

Starting with PostgreSQL version 12, generated columns are supported. Generated columns can either be calculated from other column values on the fly, or calculated and stored. [PostgreSQL generated columns](#) are similar to Oracle virtual columns.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A source Oracle database
- Target PostgreSQL databases (on Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible)
- [PL/pgSQL](#) coding expertise

### Limitations

- Applies only to PostgreSQL versions before version 12.
- Applies to Oracle Database version 11g or later.
- Virtual columns are not supported in data migration tools.
- Applies only to columns defined in the same table.
- If a virtual generated column refers to a deterministic user-defined function, it cannot be used as a partitioning key column.
- The output of the expression must be a scalar value. It cannot return an Oracle supplied datatype, a user-defined type, LOB, or LONG RAW.
- Indexes that are defined against virtual columns are equivalent to function-based indexes in PostgreSQL.
- Table statistics must be gathered.

### Tools

- [pgAdmin 4](#) is an open source management tool for PostgreSQL. This tool provides a graphical interface that simplifies the creation, maintenance, and use of database objects.
- [Oracle SQL Developer](#) is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.

## Epics

### Create source and target database tables

Task	Description	Skills required
Create a source Oracle Database table.	<p>In Oracle Database, create a table with virtual generated columns by using the following statement.</p> <pre data-bbox="594 642 1027 1157">CREATE TABLE test.generated_column ( CODE NUMBER,   STATUS VARCHAR2(12)   DEFAULT 'PreOpen',   FLAG CHAR(1) GENERATED   ALWAYS AS (CASE   UPPER(STATUS) WHEN   'OPEN' THEN 'N' ELSE   'Y' END) VIRTUAL   VISIBLE );</pre> <p>In this source table, the data in the STATUS column is migrated through AWS DMS to the target database. The FLAG column, however, is populated by using <code>generate</code> by functionality, so this column isn't visible to AWS DMS during migration. To implement the functionality of <code>generated by</code>, you must use triggers and functions in the target database to populate the</p>	DBA, App developer

Task	Description	Skills required
	values in the FLAG column, as shown in the next epic.	
Create a target PostgreSQL table on AWS.	<p>Create a PostgreSQL table on AWS by using the following statement.</p> <pre>CREATE TABLE test.generated_column (   code integer not null,   status character varying(12) not null ,   flag character(1) );</pre> <p>In this table, the status column is a standard column. The flag column will be a generated column based on the data in the status column.</p>	DBA, App developer

## Create a trigger function to handle the virtual column in PostgreSQL

Task	Description	Skills required
Create a PostgreSQL trigger.	<p>In PostgreSQL, create a trigger.</p> <pre>CREATE TRIGGER tgr_gen_column AFTER INSERT OR UPDATE OF status ON test.generated_column FOR EACH ROW</pre>	DBA, App developer

Task	Description	Skills required
	<pre>EXECUTE FUNCTION test.tgf_gen_colu m();</pre>	

Task	Description	Skills required
Create a PostgreSQL trigger function.	<p>In PostgreSQL, create a function for the trigger. This function populates a virtual column that is inserted or updated by the application or AWS DMS, and validates the data.</p> <pre data-bbox="597 590 1027 1875">CREATE OR REPLACE FUNCTION test.tgf_ gen_column() RETURNS trigger AS \$VIRTUAL_ COL\$ BEGIN IF (TG_OP = 'INSERT') THEN IF (NEW.flag IS NOT NULL) THEN RAISE EXCEPTION 'ERROR: cannot insert into column "flag" USING DETAIL = 'Column "flag" is a generated column.'; END IF; END IF; IF (TG_OP = 'UPDATE') THEN IF (NEW.flag::VARCHAR ! = OLD.flag::varchar) THEN RAISE EXCEPTION 'ERROR: cannot update column "flag" USING DETAIL = 'Column "flag" is a generated column.'; END IF; END IF; IF TG_OP IN ('INSERT' , 'UPDATE') THEN</pre>	DBA, App developer

Task	Description	Skills required
	<pre> IF (old.flag is NULL)   OR (coalesce(old.stat us, '') != coalesce( new.status, '')) THEN UPDATE test.gene rated_column SET flag = (CASE   UPPER(status) WHEN   'OPEN' THEN 'N' ELSE   'Y' END) WHERE code = new.code; END IF; END IF; RETURN NEW; END \$VIRTUAL_COL\$ LANGUAGE plpgsql; </pre>	

## Test data migration by using AWS DMS

Task	Description	Skills required
Create a replication instance.	To create a replication instance, follow the <a href="#">instructions</a> in the AWS DMS documentation. The replication instance should be in the same virtual private cloud (VPC) as your source and target databases.	DBA, App developer
Create source and target endpoints.	To create the endpoints, follow the <a href="#">instructions</a> in the AWS DMS documentation.	DBA, App developer
Test the endpoint connections.	You can test the endpoint connections by specifying the	DBA, App developer

Task	Description	Skills required
	VPC and replication instance and choosing <b>Run test</b> .	
Create and start a full load task.	For instructions, see <a href="#">Creating a Task</a> and <a href="#">Full-load task settings</a> in the AWS DMS documentation.	DBA, App developer
Validate the data for the virtual column.	Compare the data in the virtual column in the source and target databases. You can validate the data manually or write a script for this step.	DBA, App developer

# Set up Oracle UTL\_FILE functionality on Aurora PostgreSQL-Compatible

Created by Rakesh Raghav (AWS) and anuradha chintha (AWS)

<b>Environment:</b> PoC or pilot	<b>Source:</b> Oracle	<b>Target:</b> Aurora PostgreSQL
<b>R Type:</b> Re-architect	<b>Workload:</b> Oracle	<b>Technologies:</b> Migration; Infrastructure; Databases
<b>AWS services:</b> Amazon S3; Amazon Aurora		

## Summary

As part of your migration journey from Oracle to Amazon Aurora PostgreSQL-Compatible Edition on the Amazon Web Services (AWS) Cloud, you might encounter multiple challenges. For example, migrating code that relies on the Oracle UTL\_FILE utility is always a challenge. In Oracle PL/SQL, the UTL\_FILE package is used for file operations, such as read and write, in conjunction with the underlying operating system. The UTL\_FILE utility works for both server and client machine systems.

Amazon Aurora PostgreSQL-Compatible is a managed database offering. Because of this, it isn't possible to access files on the database server. This pattern walks you through the integration of Amazon Simple Storage Service (Amazon S3) and Amazon Aurora PostgreSQL-Compatible to achieve a subset of UTL\_FILE functionality. Using this integration, we can create and consume files without using third-party extract, transform, and load (ETL) tools or services.

Optionally, you can set up Amazon CloudWatch monitoring and Amazon SNS notifications.

We recommend thoroughly testing this solution before implementing it in a production environment.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- AWS Database Migration Service (AWS DMS) expertise
- Expertise in PL/pgSQL coding
- An Amazon Aurora PostgreSQL-Compatible cluster
- An S3 bucket

## Limitations

This pattern doesn't provide the functionality to act as a replacement for the Oracle UTL\_FILE utility. However, the steps and sample code can be enhanced further to achieve your database modernization goals.

## Product versions

- Amazon Aurora PostgreSQL-Compatible Edition 11.9

## Architecture

### Target technology stack

- Amazon Aurora PostgreSQL-Compatible
- Amazon CloudWatch
- Amazon Simple Notification Service (Amazon SNS)
- Amazon S3

### Target architecture

The following diagram shows a high-level representation of the solution.

1. Files are uploaded from the application into the S3 bucket.
2. The aws\_s3 extension accesses the data, using PL/pgSQL, and uploads the data to Aurora PostgreSQL-Compatible.

## Tools

- [Amazon Aurora PostgreSQL-Compatible](#) – Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine. It combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases.
- [AWS CLI](#) – The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With only one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts.
- [Amazon CloudWatch](#) – Amazon CloudWatch monitors Amazon S3 resources and use.

- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. In this pattern, Amazon S3 provides a storage layer to receive and store files for consumption and transmission to and from the Aurora PostgreSQL-Compatible cluster.
- [aws\\_s3](#) – The `aws_s3` extension integrates Amazon S3 and Aurora PostgreSQL-Compatible.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients. In this pattern, Amazon SNS is used to send notifications.
- [pgAdmin](#) – pgAdmin is an open-source management tool for Postgres. pgAdmin 4 provides a graphical interface for creating, maintaining, and using database objects.

## Code

To achieve the required functionality, the pattern creates multiple functions with naming similar to `UTL_FILE`. The *Additional information* section contains the code base for these functions.

In the code, replace `testaurorabucket` with the name of your test S3 bucket. Replace `us-east-1` with the AWS Region where your test S3 bucket is located.

## Epics

### Integrate Amazon S3 and Aurora PostgreSQL-Compatible

Task	Description	Skills required
Set up IAM policies.	Create AWS Identity and Access Management (IAM) policies that grant access to the S3 bucket and objects in it. For the code, see the <i>Additional information</i> section.	AWS administrator, DBA
Add Amazon S3 access roles to Aurora PostgreSQL.	Create two IAM roles: one role for read and one role for write access to Amazon S3. Attach the two roles to the Aurora PostgreSQL-Compatible cluster:	AWS administrator, DBA

Task	Description	Skills required
	<ul style="list-style-type: none"> <li>One role for the S3Export feature</li> <li>One role for the S3Import feature</li> </ul> <p>For more information, see the Aurora PostgreSQL-Compatible documentation on <a href="#">importing</a> and <a href="#">exporting</a> data to Amazon S3.</p>	

### Set up the extensions in Aurora PostgreSQL-Compatible

Task	Description	Skills required
Create the aws_commons extension.	The aws_commons extension is a dependency of the aws_s3 extension.	DBA, Developer
Create the aws_s3 extension.	The aws_s3 extension interacts with Amazon S3.	DBA, Developer

### Validate Amazon S3 and Aurora PostgreSQL-Compatible integration

Task	Description	Skills required
Test importing files from Amazon S3 into Aurora PostgreSQL.	To test importing files into Aurora PostgreSQL-Compatible, create a sample CSV file and upload it into the S3 bucket. Create a table definition based on the CSV file, and load the file	DBA, Developer

Task	Description	Skills required
	into the table by using the <code>aws_s3.table_import_from_s3</code> function.	
Test exporting files from Aurora PostgreSQL to Amazon S3.	To test exporting files from Aurora PostgreSQL-Compatible, create a test table, populate it with data, and then export the data by using the <code>aws_s3.query_export_to_s3</code> function.	DBA, Developer

### To mimic the UTL\_FILE utility, create wrapper functions

Task	Description	Skills required
Create the <code>utl_file_utility</code> schema.	The schema keeps the wrapper functions together. To create the schema, run the following command.  <pre>CREATE SCHEMA utl_file_utility;</pre>	DBA, Developer
Create the <code>file_type</code> type.	To create the <code>file_type</code> type, use the following code.  <pre>CREATE TYPE utl_file_utility.file_type AS (   p_path character varying(30),   p_file_name character varying);</pre>	DBA/Developer

Task	Description	Skills required
Create the init function.	The <code>init</code> function initializes common variables such as <code>bucket</code> or <code>region</code> . For the code, see the <i>Additional information</i> section.	DBA/Developer
Create the wrapper functions.	Create the wrapper functions <code>fopen</code> , <code>put_line</code> , and <code>fclose</code> . For code, see the <i>Additional information</i> section.	DBA, Developer

### Test the wrapper functions

Task	Description	Skills required
Test the wrapper functions in write mode.	To test the wrapper functions in write mode, use the code provided in the <i>Additional information</i> section.	DBA, Developer
Test the wrapper functions in append mode.	To test the wrapper functions in append mode, use the code provided in the <i>Additional information</i> section.	DBA, Developer

```

## Test your setup and wrapper functions

Use the following anonymous code blocks to test your setup.

### *Test the write mode*

The following code writes a file named `s3inttest` in the S3 bucket.

```
do $$
declare
l_file_name varchar := 's3inttest' ;
l_path varchar := 'integration_test' ;
l_mode char(1) := 'W';
l_fs utl_file_utility.file_type ;
l_status boolean;

begin
select * from
utl_file_utility.fopen( l_file_name, l_path , l_mode ) into l_fs ;
raise notice 'fopen : l_fs : %', l_fs;

select * from
utl_file_utility.put_line( l_file_name, l_path , 'this is test file:in s3bucket: for
test purpose', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;

select * from utl_file_utility.fclose( l_file_name , l_path ) into l_status ;
raise notice 'fclose : l_status %', l_status;

end;
$$
```

### *Test the append mode*

The following code appends lines onto the `s3inttest` file that was created in the previous test.

```
do $$
```

```
declare
l_file_name varchar := 's3intttest' ;
l_path varchar := 'integration_test' ;
l_mode char(1) := 'A';
l_fs utl_file_utility.file_type ;
l_status boolean;

begin
select * from
utl_file_utility.fopen( l_file_name, l_path , l_mode ) into l_fs ;
raise notice 'fopen : l_fs : %', l_fs;

select * from
utl_file_utility.put_line( l_file_name, l_path , 'this is test file:in s3bucket: for
test purpose : append 1', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;

select * from
utl_file_utility.put_line( l_file_name, l_path , 'this is test file:in s3bucket : for
test purpose : append 2', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;

select * from utl_file_utility.fclose( l_file_name , l_path ) into l_status ;
raise notice 'fclose : l_status %', l_status;

end;
$$
```

## Amazon SNS notifications

Optionally, you can set up Amazon CloudWatch monitoring and Amazon SNS notifications on the S3 bucket. For more information, see [Monitoring Amazon S3](#) and [Setting up Amazon SNS Notifications](#).

# Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL

Created by Venkatramana Chintha (AWS) and Eduardo Valentim (AWS)

<b>R Type:</b> Re-architect	<b>Source:</b> Relational	<b>Target:</b> Amazon Aurora PostgreSQL, Amazon RDS for PostgreSQL
<b>Created by:</b> AWS	<b>Environment:</b> PoC or pilot	<b>Technologies:</b> Databases; Migration
<b>Workload:</b> Oracle	<b>AWS services:</b> Amazon Aurora	

## Summary

This pattern describes a step-by-step approach to validate objects after migrating an Oracle database to Amazon Aurora PostgreSQL-Compatible Edition.

This pattern outlines usage scenarios and steps for database object validation; for more detailed information, see [Validating database objects after migration using AWS SCT and AWS DMS](#) on the [AWS Database blog](#).

## Prerequisites and limitations

### Prerequisites

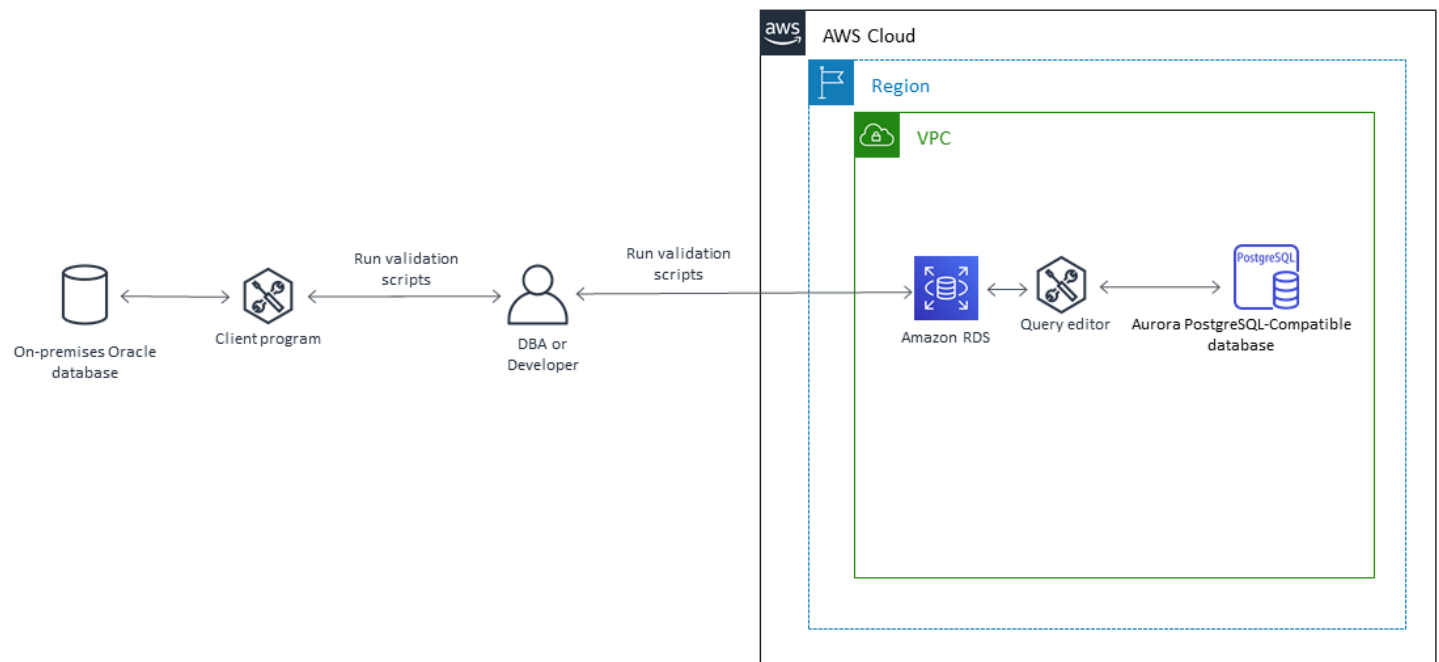

- An active AWS account.
- An on-premises Oracle database that was migrated to an Aurora PostgreSQL-Compatible database.
- Sign-in credentials that have the [AmazonRDSDDataFullAccess](#) policy applied, for the Aurora PostgreSQL-Compatible database.
- This pattern uses the [query editor for Aurora Serverless DB clusters](#), which is available in the Amazon Relational Database Service (Amazon RDS) console. However, you can use this pattern with any other query editor.

## Limitations

- Oracle SYNONYM objects are not available in PostgreSQL but can be partially validated through **views** or SET search\_path queries.
- The Amazon RDS query editor is available only in [certain AWS Regions and for certain MySQL and PostgreSQL versions](#).

## Architecture

## Tools

### Tools

- [Amazon Aurora PostgreSQL-Compatible Edition](#) – Aurora PostgreSQL-Compatible is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases.
- [Amazon RDS](#) – Amazon Relational Database Service (Amazon RDS) makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

- [Query Editor for Aurora Serverless](#) – Query editor helps you run SQL queries in the Amazon RDS console. You can run any valid SQL statement on the Aurora Serverless DB cluster, including data manipulation and data definition statements.

To validate the objects, use the full scripts in the "Object validation scripts" file in the "Attachments" section. Use the following table for reference.

<b>Oracle object</b>	<b>Script to use</b>
Packages	Query 1
Tables	Query 3
Views	Query 5
Sequences	Query 7
Triggers	Query 9
Primary keys	Query 11
Indexes	Query 13
Check constraints	Query 15
Foreign keys	Query 17
<b>PostgreSQL object</b>	<b>Script to use</b>
Packages	Query 2
Tables	Query 4
Views	Query 6
Sequences	Query 8
Triggers	Query 10

Primary keys	Query 12
Indexes	Query 14
Check constraints	Query 16
Foreign keys	Query 18

## Epics

### Validate objects in the source Oracle database

Task	Description	Skills required
Run the “packages” validation query in the source Oracle database.	Download and open the “Object validation scripts” file from the “Attachments” section. Connect to the source Oracle database through your client program. Run the “Query 1” validations script from the “Object validation scripts” file. Important: Enter your Oracle user name instead of “your_schema” in the queries. Make sure you record your query results.	Developer, DBA
Run the “tables” validation query.	Run the “Query 3” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “views” validation query.	Run the “Query 5” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA

Task	Description	Skills required
Run the “sequences” count validation.	Run the “Query 7” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “triggers” validation query.	Run the “Query 9” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “primary keys” validation query.	Run the “Query 11” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “indexes” validation query.	Run the “Query 13” validation script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “check constraints” validation query.	Run the “Query 15” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “foreign keys” validation query.	Run the “Query 17” validation script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA

## Validate objects in the target Aurora PostgreSQL-Compatible database

Task	Description	Skills required
Connect to the target Aurora PostgreSQL-Compatible database by using the query editor.	Sign in to the AWS Management Console and open the Amazon RDS console. In the upper-right corner, choose the AWS Region in which you created the Aurora PostgreSQL-Compatible database. In the navigation pane, choose "Databases," and choose the target Aurora PostgreSQL-Compatible database. In "Actions," choose "Query." Important: If you haven't connected to the database before, the "Connect to database" page opens. You then need to enter your database information, such as user name and password.	Developer, DBA
Run the "packages" validation query.	Run the "Query 2" script from the "Object validation scripts" file in the "Attachments" section. Make sure you record your query results.	Developer, DBA
Run the "tables" validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 4" script from the "Object validation scripts"	Developer, DBA

Task	Description	Skills required
	file. Make sure you record your query results.	
Run the “views” validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the “Query 6” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “sequences” count validation.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the “Query 8” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “triggers” validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the “Query 10” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “primary keys” validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the “Query 12” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA

Task	Description	Skills required
Run the “indexes” validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the “Query 14” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “check constraints” validation query.	Run the “Query 16” script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA
Run the “foreign keys” validation query.	Run the “Query 18” validation script from the “Object validation scripts” file. Make sure you record your query results.	Developer, DBA

### Compare source and target database validation records

Task	Description	Skills required
Compare and validate both query results.	Compare the query results of the Oracle and Aurora PostgreSQL-Compatible databases to validate all objects. If they all match, then all objects have been successfully validated.	Developer, DBA

# Accelerate the discovery and migration of Microsoft workloads to AWS

*Created by Ali Alzand*

<b>Environment:</b> Production	<b>Source:</b> Microsoft workload running either on-premises or other cloud service providers	<b>Target:</b> Amazon EC2 Windows
<b>R Type:</b> Rehost	<b>Workload:</b> Microsoft	<b>Technologies:</b> Migration
<b>AWS services:</b> Amazon EC2		

## Summary

This pattern shows you how to use the [Migration Validator Toolkit PowerShell module](#) to discover and migrate your Microsoft workloads to AWS. The module works by performing multiple checks and validations for common tasks associated with any Microsoft workload. For example, the module checks for instances that might have multiple disks attached to it or instances that use many IP addresses. For a full list of checks that the module can perform, see the [Checks](#) section on the module's GitHub page.

The Migration Validator Toolkit PowerShell module can help your organization reduce the time and effort involved in discovering what applications and services are running on your Microsoft workloads. The module can also help you identify the configurations of your workloads so that you can find out if your configurations are supported on AWS. The module also provides recommendations for next steps and mitigation actions, so that you can avoid any misconfigurations before, during, or after your migration.

## Prerequisites and limitations

### Prerequisites

- Local administrator account
- PowerShell 4.0

### Limitations

- Works only on Microsoft Windows Server 2012 R2 or later

## Tools

### Tools

- PowerShell 4.0

### Code repository

The Migration Validator Toolkit PowerShell module for this pattern is available in the GitHub [migration-validator-toolkit-for-microsoft-workloads](#) repository.

## Epics

### Run the Migration Validator Toolkit PowerShell module on a single target

Task	Description	Skills required
Download, extract, import, and invoke the module.	<p>Choose one of the following methods to download and deploy the module:</p> <ul style="list-style-type: none"><li>• Run the PowerShell script</li><li>• Download and extract the .zip file</li><li>• Clone the GitHub repository</li></ul> <p><b>Run the PowerShell script</b></p> <p>In PowerShell, run the following example code:</p> <pre>#MigrationValidato rToolkit \$uri = 'https:// github.com/aws-sam ples/migration-val</pre>	System Administrator

Task	Description	Skills required
	<pre> idator-toolkit-for- microsoft-workloads/ archive/refs/heads/ main.zip' \$destination = (Get- Location).Path if ((Test-Path -Path "\$destination\Migr ationValidatorTool kit.zip" -PathType Leaf) -or (Test-Path - Path "\$destination\Migr ationValidatorTool kit")) {     write-host "File \$destination\Migra tionValidatorToolk it.zip or folder \$destination\Migra tionValidatorToolkit found, exiting" }else {     Write-host "Enable TLS 1.2 for this PowerShell session only."     [Net.ServicePointM anager]::SecurityP rotocol = [Net.Secu rityProtocolType]: :Tls12     \$webClient = New-Object System.Ne t.WebClient     Write-host "Downloading Migration ValidatorToolkit.zip"     \$webClient.Downloa dFile(\$uri, "\$destina tion\MigrationVali datorToolkit.zip") </pre>	

Task	Description	Skills required
	<pre data-bbox="609 212 1015 1417"> Write-host "MigrationValidatorToolkit.zip download successfully" Add-Type -Assembly "system.io.compression.filesystem" [System.IO.Compression.ZipFile]::ExtractToDirectory("\$destination\MigrationValidatorToolkit.zip", "\$destination\MigrationValidatorToolkit") Write-host "Extracting MigrationValidatorToolkit.zip complete successfully" Import-Module "\$destination\MigrationValidatorToolkit\migration-validator-toolkit-for-microsoft-workloads-main\MigrationValidatorToolkit.psm1"; Invoke-MigrationValidatorToolkit } </pre> <p data-bbox="592 1459 1015 1627">The code downloads the module from a .zip file. Then, the code extracts, imports, and invokes the module.</p> <p data-bbox="592 1680 925 1753"><b>Download and extract the .zip file</b></p>	

Task	Description	Skills required
	<ol style="list-style-type: none"><li>1. Download the <a href="#">.zip file</a> (download).</li><li>2. Extract the .zip file.</li><li>3. Follow the steps in the <i>Invoke the module manually</i> story of this guide.</li></ol> <p><b>Clone the GitHub repository</b></p> <ol style="list-style-type: none"><li>1. To clone the GitHub <a href="#">migration-validator-toolkit-for-microsoft-workloads</a> repository, run the following Git command in a terminal window:</li></ol> <pre data-bbox="630 1016 1029 1297">git clone https://github.com/aws-samples/migration-validator-toolkit-for-microsoft-workloads.git</pre> <ol style="list-style-type: none"><li>2. Follow the steps in the <i>Invoke the module manually</i> story of this guide.</li></ol>	

Task	Description	Skills required
Invoke the module manually.	<ol style="list-style-type: none"><li>1. Go to the directory where the downloaded module is stored.</li><li>2. To generate the output of your choice, run one of the following commands as an administrator in PowerShell:</li></ol> <p><a href="#">Format-Table</a> format:</p> <pre>Import-Module .\MigrationValidatorToolkit.psm1;Invoke-MigrationValidatorToolkit</pre> <p><a href="#">Format-List</a> format:</p> <pre>Import-Module .\MigrationValidatorToolkit.psm1;Invoke-MigrationValidatorToolkit -List</pre> <p><a href="#">Out-GridView</a> format:</p> <pre>Import-Module .\MigrationValidatorToolkit.psm1;Invoke-MigrationValidatorToolkit -GridView</pre> <p><a href="#">ConvertTo-Csv</a> format:</p> <pre>Import-Module .\MigrationValidatorToolkit</pre>	System Administrator

Task	Description	Skills required
	<pre>.psm1; Invoke-MigrationValidatorToolkit -csv</pre>	

## Run the Migration Validator Toolkit PowerShell module on multiple targets

Task	Description	Skills required
Download the .zip file or clone the GitHub repository.	<p>Choose one of the following options:</p> <ul style="list-style-type: none"> <li>Download the <a href="#">zip file</a>. (download).</li> <li>To clone the GitHub <a href="#">migration-validator-toolkit-for-microsoft-workloads</a> repository, run the following Git command in a terminal window:</li> </ul> <pre>git clone https://github.com/aws-samples/migration-validator-toolkit-for-microsoft-workloads.git</pre>	System Administrator
Update the server.csv list.	<p>If you downloaded the .zip file, follow these steps:</p> <ol style="list-style-type: none"> <li>Extract the .zip file.</li> <li>Go to the MigrationValidatorToolkit\Inputs\ directory.</li> </ol>	System Administrator

Task	Description	Skills required
Invoke the module.	<p>3. Update <code>serverlist.csv</code> with the host name of your target computers.</p> <p>You can use any computer within the domain that uses a domain user that has administrator access to target computers.</p> <ol style="list-style-type: none"><li>1. Download the source code as a .zip file and extract the file.</li><li>2. As an administrator in PowerShell, run the following command:</li></ol> <pre>Import-Module .\MigrationValidatorToolkit.psm1; Invoke-DomainComputers</pre> <p>The output .csv file is saved in <code>MigrationValidatorToolkit\Outputs\folder</code> with the prefix name <code>DomainComputers_MigrationAutomations_YYYY-MM-DDTHH-MM-SS</code>.</p>	System Administrator

## Troubleshooting

Issue	Solution
MigrationValidatorToolkit writes information about executions, commands, and errors to log files on the running host.	<p>You can view log files manually in the following location:</p> <ol style="list-style-type: none"><li>1. Go to the MigrationValidatorToolkit\logs\ directory.</li><li>2. Locate the log file. The format of the log file name is: ComputerName_MigrationValidatorToolkit_YYYY-MM-SSTHH-MM-SS.log</li></ol>

- [Options, tools, and best practices for migrating Microsoft workloads to AWS](#) (AWS Prescriptive Guidance)
- [Microsoft migration patterns](#) (AWS Prescriptive Guidance)
- [Free Cloud Migration Services on AWS](#) (AWS documentation)
- [Predefined post-launch actions](#) (Application marketing documentation)

### Additional information

#### Frequently asked questions

*Where can I run the Migration Validator Toolkit PowerShell module?*

You can run the module on Microsoft Windows Server 2012 R2 or later.

*When do I run this module?*

We recommend that you run the module during the [assess phase](#) of the migration journey.

*Does the module modify my existing servers?*

No. All actions in this module are read-only.

### *How long does it take to run the module?*

It typically takes 1–5 minutes to run the module, but it depends on the resource allocation of your server.

### *What permissions does the module need to run?*

You must run the module from a local administrator account.

### *Can I run the module on physical servers?*

Yes, as long as the operating system is Microsoft Windows Server 2012 R2 or later.

### *How do I run the module at scale for multiple servers?*

To run the module on multiple domain-joined computers at scale, follow the steps in the *Run the Migration Validator Toolkit PowerShell module on multiple targets* epic of this guide. For non domain-joined computers, use a remote invocation or run the module locally by following the steps in the *Run the Migration Validator Toolkit PowerShell module on a single target* epic of this guide.

# Automate pre-workload ingestion activities for AWS Managed Services on Windows

Created by Jacob Zhang (AWS), Calvin Yeh (AWS), and Dwayne Bordelon (AWS)

<b>Code repository:</b> <a href="#">GitHub</a>	<b>Environment:</b> Production	<b>Source:</b> Windows Servers
<b>Target:</b> AWS Managed Services	<b>R Type:</b> Rehost	<b>Technologies:</b> Migration

**AWS services:** AWS CloudFormation; AWS Managed Services; AWS Systems Manager; Amazon S3

## Summary

On the Amazon Web Services (AWS) Cloud, AWS Managed Services (AMS) uses AMS workload ingest (WIGS) to move existing workloads into an AMS managed VPC. This pattern describes a solution to automate common pre-workload ingestion activities, such as upgrading .NET and Windows PowerShell and running Windows WIGS pre-ingestion validation maintained by AMS. The pattern also provides a unified user interface for the run results. It packages an AWS Systems Manager Command document, which performs the pre-ingestion activities, into an AWS CloudFormation template. The template can be deployed repeatedly without requiring access to Systems Manager itself or conflicting with automations from AMS.

## Business background

Migrations to AMS require the provision of new Amazon Elastic Compute Cloud (Amazon EC2) instances using AMS managed Amazon Machine Images (AMIs) that include AMS components. Any workloads or applications running in existing data centers must be redeployed to fresh EC2 instances launched from these AMS AMIs. To avoid the potentially massive amount of manual work during the process, the AMS team built the AMS workload ingest (WIGS) workflow to onboard your custom images to AMS.

Windows instances must satisfy a few prerequisites before the WIGS process takes place. Windows PowerShell scripts are usually used to perform the necessary preparations (WIGS prep) and check if

the instances are ready for WIGs (WIGS pre-ingestion validation). The prep and validation processes require an engineer to spend 15–30 minutes on each server, manually logging in and running the scripts one by one.

## Business driver

Traditionally, using Systems Manager, you can automate operational tasks such as running Windows PowerShell scripts. However, because of elevated risks and frequent conflicts between automations from AMS and those from the users, AMS does not usually grant its users access to Systems Manager.

For mass migrations using AWS Application Migration Service (AWS MGN), Windows PowerShell scripts in the `C:\Program Files (x86)\AWS Replication Agent\post_launch` folder usually run automatically when a test or cutover instance is launched. However, these scripts, if run immediately during an instance launch, frequently conflict with automations from AMS. As a result, the launch might fail without providing the run results that you need to troubleshoot the failure.

This pattern tackles these problems and provides a working automated solution.

## Prerequisites and limitations

### Prerequisites

- An active AWS account with AMS onboarding completed.
- An Amazon Simple Storage Service (Amazon S3) bucket in the AWS account. If there is no S3 bucket over which you have control in the account, use a request for change (RFC) to create one.
- The PreWIGs\_CFN.json template downloaded from the [ams-auto-prewigs-windows](#) repository.
- A server to which you apply this pattern must meet the following requirements:
  - Run Windows Server 2012 or later.
  - Be launched or ready to launch in the sandbox VPC migration subnet.
  - Have an AWS Systems Manager Agent (SSM Agent) installed.
  - Have an AWS Identity and Access Management (IAM) instance profile attached. The instance profile must have permissions to download files from S3 buckets in the same AWS account. An instance profile that satisfies the above-mentioned requirement is usually already established during earlier setups of a migration.
- Be viewable from AWS Systems Manager Fleet Manager.

## Limitations

- Pre-WIGS activities vary depending on your environment and business requirements. You might need to make minor modifications to this pattern to suit your specific needs.

## Product versions

- The pattern is tested with Windows Server 2012, 2012 R2, 2016, and 2019. It theoretically works with later Windows versions. It does not work with earlier Windows versions.

## Architecture

The architecture diagram shows the following:

1. A sandbox VPC with a migration subnet containing servers that have not been prepped.
2. The S3 bucket that stores scripts that are used by the CloudFormation template.
3. The CloudFormation template deploys the Systems Manager Command document. The process iterates until the steps complete.
4. The instances are prepped and RFCs for WIGS are made.
5. In the AMS managed VPC, the AMS managed subnet contains the servers after workload ingestion.

## How it works

- This pattern is packaged into an AWS CloudFormation template that allows infrastructure as code (IaC) repeatable deployments. You need to deploy this template only one time for each AWS account that requires this automation.
- The automation is applied to all EC2 instances with a tag key **AutoPreWIGs** in the AWS account where this pattern is deployed. The first time an Amazon EC2 Windows instance with the tag key **AutoPreWIGs** starts, the automation performs the following tasks.
  1. Upgrades Windows PowerShell to version 5.1 and .NET to version 4.5.2. The instance might reboot several times, depending on its existing Windows PowerShell and .NET versions. After each reboot, the upgrades continue until they are complete. This step uses embedded code in the CloudFormation template modified from a [Windows PowerShell script](#), as well as specific Systems Manager guidance on server reboots.
  2. Downloads from Amazon S3 and runs a Windows PowerShell script that you have customized to prepare the Amazon EC2 Windows instance for WIGS. For more information see the *Epics* section.
  3. Installs the Windows WIGS pre-ingestion validation PowerShell module from AWS.

4. Runs the Windows WIGS pre-ingestion validation and makes the results viewable in Systems Manager State Manager.

## Tools

- [AWS CloudFormation](#) – AWS CloudFormation is a service that helps you model and set up your AWS resources. You can use a `template` that describes all the AWS resources that you want and their dependencies, so that you can launch and configure those resources as a stack. This pattern uses a CloudFormation template to automate deployment of the resources in this pattern.
- [AWS Managed Services](#) – AWS Managed Services (AMS) is an enterprise service that provides ongoing management of your AWS infrastructure. Changes made to the infrastructure in an AMS environment must be made through an RFC.
- [AWS Systems Manager](#) – AWS Systems Manager (formerly known as SSM) is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources. This pattern uses Systems Manager to run and view the run results of the pre-WIGS activities.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance. This pattern uses Amazon S3 to store the CloudFormation template and a Windows PowerShell script that is downloaded.

## Best practices

< **Author remove these notes:** Provide a list of guidelines and recommendations that can help users implement this pattern more effectively.>

## Epics

### Create a custom Windows PowerShell script to automate additional tasks

Task	Description	Skills required
Perform necessary changes to the servers based on business needs.	If you need changes automatically applied to your servers before their	PowerShell scripting

Task	Description	Skills required
	<p>ingestions, create a Windows PowerShell script named <code>ingestion-prep.ps1</code> .</p> <p><b>Important:</b> The script must not contain instructions to reboot the server, and it must not require administrator privileges.</p>	
Remove software that isn't supported by AMS.	AMS requires certain software, such as antivirus applications and VMware Tools removed before WIGS runs. Include the uninstallation in the <code>ingestion-prep.ps1</code> script. For more information about software that isn't supported, see the <a href="#">AWS documentation</a> .	PowerShell scripting

### Upload the CloudFormation template and the optional Windows PowerShell script to Amazon S3

Task	Description	Skills required
Create a folder in S3.	In an S3 bucket in the same AWS account where you deploy this pattern, create a folder.	General AWS
Upload the scripts.	Upload the <code>PreWIGs_CFN.json</code> CloudFormation template and the <code>ingestion-prep.ps1</code>	General AWS

Task	Description	Skills required
	Windows PowerShell script, which you created in the previous epic, to the Amazon S3 folder.	

## Deploy the CloudFormation stack

Task	Description	Skills required
Select the change type.	Navigate to the AMS console to create an RFC. Use the <b>Create Stack from CloudFormation (CFN) Template</b> change type.	General AMS
Set run parameters for the path to the CloudFormation template.	In the <b>Execution configuration</b> section, expand <b>Additional configuration</b> . In the <b>CloudFormation template S3 endpoint</b> box, paste the URL to the CloudFormation template.	General AMS
Specify the path to the Amazon S3 folder.	Under <b>Parameters</b> , use <b>ScriptSource</b> as the <b>Name</b> . For <b>Value</b> , enter the path to the S3 folder that contains the Windows PowerShell scripts. Make sure that you use the <code>https://xxx</code> URL instead of the <code>s3://xxx</code> URI, and include the <code>/</code> at the end.	General AMS
Deploy the stack.	To deploy the stack, choose <b>Create</b> .	General AMS

Task	Description	Skills required
Escalate the RFC to AMS Ops.	The RFC must be implemented manually by the AMS Ops team because it uses Systems Manager to deploy resources with and requires a security review. As soon as you create the RFC, it will be automatically rejected by the system. Choose the RFC, and add a correspondence to the RFC stating <b>Please execute manually</b> . Note the RFC ID, and escalate it with a service request.	General AMS

### Apply the automation to the instances

Task	Description	Skills required
Add the AutoPreWIGs tag to instances.	<p>Note IDs of all instances to which you want to apply this automation and wait at least 30 minutes for the instance to finish the automations implemented by AMS. Submit an automated RFC to add the tag with <b>AutoPreWIGs</b> as the key and any string, such as <b>1</b>, as the value.</p> <p>The automation will be applied a few minutes after you add the tag.</p>	General AMS

Task	Description	Skills required
Verify the automation results.	Open the Systems Manager console, and choose <b>State Manager</b> . Choose the <b>Association ID</b> with the name <b>AMS-PreWIG-Prep-and-Validation-Association</b> . On the <b>Execution history</b> tab, you can see the results of the automation.	General AMS
Fix any errors.	If the automation fails, choose its <b>Execution ID</b> . You can see the run results for each EC2 instance. To see the details for each step of the automation, choose <b>Output</b> . If a particular step fails, use the information in the <b>Output</b> and the <b>Error</b> sections to diagnose the problem.	Migration engineer
Remove the AutoPreWIGs tag.	<b>Important:</b> After you fix the errors, if any, submit an automated RFC to remove the <b>AutoPreWIGs</b> tag. WIGS will fail if you don't remove the tag.	General AMS

## Ingest the prepared instances

Task	Description	Skills required
Submit RFCs for WIGS.	Now that the instances are ready for workload ingestion, submit the RFCs for WIGS.	General AMS

# Create an approval process for firewall requests during a rehost migration to AWS

Created by Srikanth Rangavajhala (AWS)

<b>R Type:</b> Rehost	<b>Environment:</b> Production	<b>Technologies:</b> Migration
<b>Source:</b> On premises	<b>Target:</b> AWS Cloud	

## Summary

If you want to use [AWS Application Migration Service](#) or [Cloud Migration Factory on AWS](#) for a rehost migration to the Amazon Web Services (AWS) Cloud, one of the prerequisites is that you must keep TCP ports 443 and 1500 open. Typically, opening these firewall ports requires approval from your information security (InfoSec) team.

This pattern outlines the process to obtain a firewall request approval from an InfoSec team during a rehost migration to the AWS Cloud. You can use this process to avoid rejections of your firewall request by the InfoSec team, which can become expensive and time consuming. The firewall request process has two review and approval steps between AWS migration consultants and leads who work with your InfoSec and application teams to open the firewall ports.

This pattern assumes that you are planning a rehost migration with AWS consultants or migration specialists from your organization. You can use this pattern if your organization doesn't have a firewall approval process or firewall request blanket approval form. For more information about this, see the *Limitations* section of this pattern. For more information on network requirements for Application Migration Service, see [Network requirements](#) in the Application Migration Service documentation.

## Prerequisites and limitations

### Prerequisites

- A planned rehost migration with AWS consultants or migration specialists from your organization
- The required port and IP information to migrate the stack
- Existing and future state architecture diagrams

- Firewall information about the on-premises and destination infrastructure, ports, and zone-to-zone traffic flow
- A firewall request review checklist (attached)
- A firewall request document, configured according to your organization's requirements
- A contact list for the firewall reviewers and approvers, including the following roles:
  - **Firewall request submitter** – AWS migration specialist or consultant. The firewall request submitter can also be a migration specialist from your organization.
  - **Firewall request reviewer** – Typically, this is the single point of contact (SPOC) from AWS.
  - **Firewall request approver** – An InfoSec team member.

## Limitations

- This pattern describes a generic firewall request approval process. Requirements can vary for individual organizations.
- Make sure that you track changes to your firewall request document.

The following table shows the use cases for this pattern.

Does your organization have an existing firewall approval process?	Does your organization have an existing firewall request form?	Suggested action
Yes	Yes	Collaborate with AWS consultants or your migration specialists to implement your organization's process.
No	Yes	Use this pattern's firewall approval process. Use either an AWS consultant or a migration specialist from your organization to submit the firewall request blanket approval form.

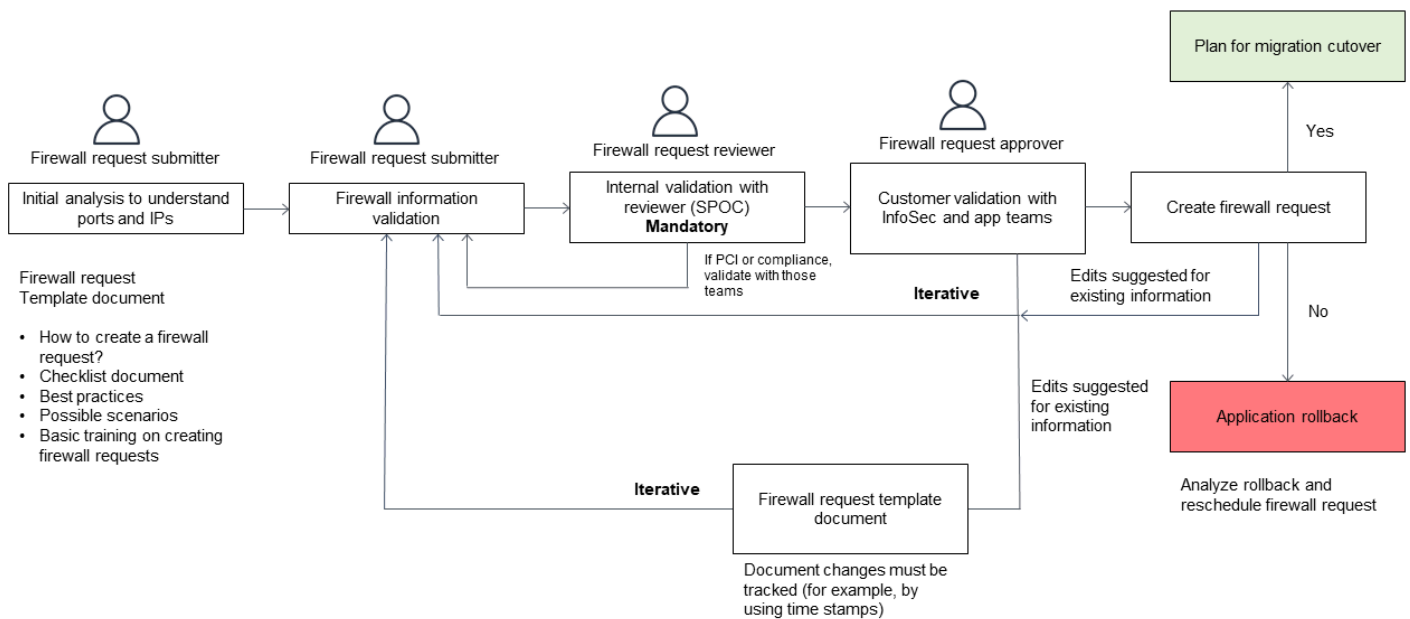

No

No

Use this pattern's firewall approval process. Use either an AWS consultant or a migration specialist from your organization to submit the firewall request blanket approval form.

## Architecture

The following diagram shows the steps for the firewall request approval process.

## Tools

You can use scanner tools such as [Palo Alto Networks](#) or [SolarWinds](#) to analyze and validate firewalls and IP addresses.

## Epics

### Analyze the firewall request

Task	Description	Skills required
Analyze the ports and IP addresses.	The firewall request submitter completes an initial analysis to understand the required firewall ports and IP addresses. After this is complete, they request that your InfoSec team opens the required ports and maps the IP addresses.	AWS Cloud engineer, migration specialist

### Validate the firewall request

Task	Description	Skills required
Validate the firewall information.	<p>The AWS Cloud engineer schedules a meeting with your InfoSec team. During this meeting, the engineer examines and validates the firewall request information.</p> <p>Typically, the firewall request submitter is the same person as the firewall requester. This validation phase can become iterative based on the feedback given by the approver if anything is observed or recommended.</p>	AWS Cloud engineer, migration specialist

Task	Description	Skills required
Update the firewall request document.	<p>After the InfoSec team shares their feedback, the firewall request document is edited, saved, and re-uploaded. This document is updated after each iteration.</p> <p>We recommend that you store this document in a version-controlled storage folder. This means that all changes are tracked and correctly applied.</p>	AWS Cloud engineer, migration specialist

## Submit the firewall request

Task	Description	Skills required
Submit the firewall request.	<p>After the firewall request approver has approved the firewall blanket approval request, the AWS Cloud engineer submits the firewall request. The request specifies the ports that must be open and IP addresses that are required to map and update the AWS account.</p> <p>You can make suggestions or provide feedback after the firewall request is submitted . We recommend that you automate this feedback process and send any edits</p>	AWS Cloud engineer, migration specialist

Task	Description	Skills required
	through a defined workflow mechanism.

# Ingest and migrate EC2 Windows instances into an AWS Managed Services account

Created by Anil Kunapareddy (AWS) and Venkatramana Chintha (AWS)

<b>Environment:</b> Production	<b>Source:</b> VPC in AWS Cloud	<b>Target:</b> VPC Managed by AWS Managed Services
<b>R Type:</b> Rehost	<b>Workload:</b> Microsoft	<b>Technologies:</b> Migration; Operations; Security, identity, compliance; CloudNative
<b>AWS services:</b> AWS Managed Services		

## Summary

This pattern explains the step-by-step process of migrating and ingesting Amazon Elastic Compute Cloud (Amazon EC2) Windows instances into an Amazon Web Services (AWS) Managed Services (AMS) account. AMS can help you manage the instance more efficiently and securely. AMS provides operational flexibility, enhances security and compliance, and helps you optimize capacity and reduce costs.

This pattern starts with an EC2 Windows instance that you have migrated to a staging subnet in your AMS account. A variety of migration services and tools are available to perform this task, such as AWS Application Migration Service.

To make a change to your AMS-managed environment, you create and submit a request for change (RFC) for a particular operation or action. Using an AMS workload ingest (WIGS) RFC, you ingest the instance into the AMS account and create a custom Amazon Machine Image (AMI). You then create the AMS-managed EC2 instance by submitting another RFC to create an EC2 stack. For more information, see [AMS Workload Ingest](#) in the AMS documentation.

## Prerequisites and limitations

### Prerequisites

- An active, AMS-managed AWS account
- An existing landing zone
- Permissions to make changes in the AMS-managed VPC
- An Amazon EC2 Windows instance in a staging subnet in your AMS account
- Completion of the [general prerequisites](#) for migrating workloads using AMS WIGS
- Completion of the [Windows prerequisites](#) for migrating workloads using AMS WIGS

## Limitations

- This pattern is for EC2 instances operating Windows Server. This pattern doesn't apply to instances running other operating systems, such as Linux.

## Architecture

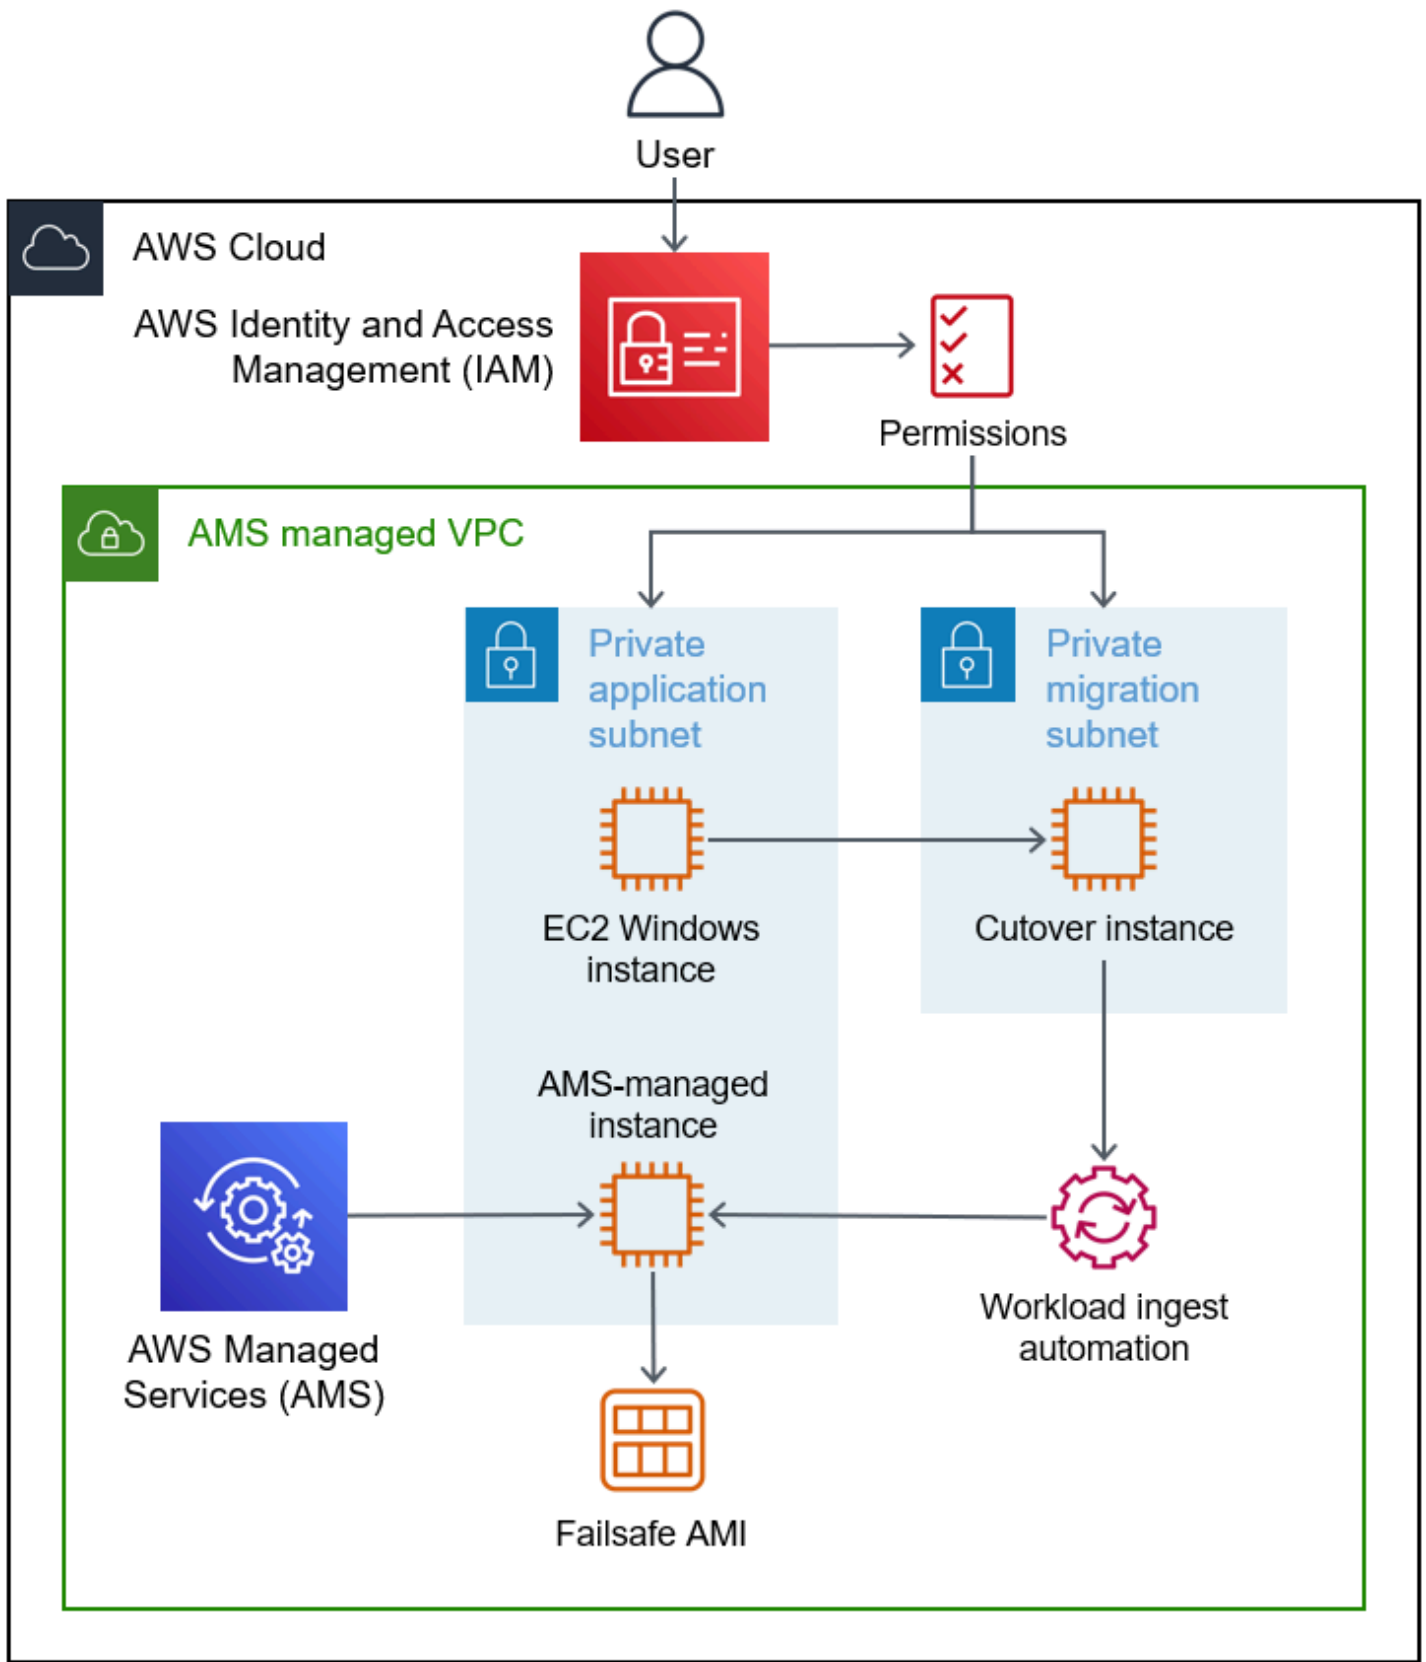

### Source technology stack

Amazon EC2 Windows instance in a staging subnet in your AMS account

### Target technology stack

Amazon EC2 Windows instance managed by AWS Managed Services (AMS)

### Target architecture

## Tools

### AWS services

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Managed Services \(AMS\)](#) helps you operate more efficiently and securely by providing ongoing management of your AWS infrastructure, including monitoring, incident management, security guidance, patch support, and backup for AWS workloads.

### Other services

- [PowerShell](#) is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.

## Epics

### Configure settings on the instance

Task	Description	Skills required
Change the DNS Client settings.	<ol style="list-style-type: none"><li>1. On the source EC2 instance, open Command Prompt as an administrator, type <code>gpedit.msc</code> , and then press <b>Enter</b>.</li><li>2. In the Local Group Policy Editor, navigate to <b>Computer Configuration, Administrative Templates, Network, DNS Client</b>.</li><li>3. For <b>Primary DNS suffix</b>, choose <b>Not configured</b>.</li></ol>	Migration engineer

Task	Description	Skills required
	4. For <b>Primary DNS suffix devolution</b> , choose <b>Not configured</b> .	
Change the Windows Update settings.	<ol style="list-style-type: none"> <li>1. In the Local Group Policy Editor, navigate to <b>Computer Configuration, Administrative Templates, Windows Components, Windows Update</b>.</li> <li>2. For <b>Specify intranet Microsoft update service location</b>, choose <b>Not configured</b>.</li> <li>3. For <b>Configure Automatic Updates</b>, choose <b>Not configured</b>.</li> <li>4. For <b>Automatic Updates detection frequency</b>, choose <b>Not configured</b>.</li> <li>5. Close the Local Group Policy Editor.</li> </ol>	Migration engineer
Enable the firewall.	<ol style="list-style-type: none"> <li>1. On the source EC2 instance, open Command Prompt as an administrator, type <code>services.msc</code>, and then press <b>Enter</b>.</li> <li>2. In Windows Services, enable <b>Firewall</b>.</li> <li>3. Close Windows Services.</li> </ol>	Migration engineer

## Prepare the instance for AMS WIGS

Task	Description	Skills required
Clean up and prepare the instance.	<ol style="list-style-type: none"> <li>Using a bastion host and local credentials, create a Remote Desktop Protocol (RDP) connection to the EC2 instance in the staging subnet.</li> <li>Remove all legacy software, antivirus software, and backup solutions that aren't required in AMS.</li> </ol>	Migration engineer
Repair the sppnp.dll file.	<ol style="list-style-type: none"> <li>Go to C:\Windows\System32\sppnp.dll .</li> <li>Rename sppnp.dll to sppnp_old.dll .</li> <li>Using PowerShell and administrator credentials, enter the following commands: <div data-bbox="630 1373 1029 1535" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>dism /online /cleanup-image /restorehealth sfc /scannow</pre> </div> </li> <li>Restart the EC2 Windows instance.</li> </ol>	Migration engineer
Run the pre-WIG validation script.	<ol style="list-style-type: none"> <li>Download the Windows WIGS Pre-ingestion Validation zip file (windows-prewings-</li> </ol>	Migration engineer

Task	Description	Skills required
	<p>validation.zip )            from <a href="#">Migrating workloads : Windows pre-ingestion validation</a> in the AMS documentation.</p> <ol style="list-style-type: none"> <li>Run the Windows pre-WIG validation script and verify the results.</li> <li>If the validation fails, fix the issue, and rerun the validation script until the validation succeeds.</li> </ol>	
<p>Create the failsafe AMI.</p>	<p>After the pre-WIG validation passes, create a pre-ingestion AMI as follows:</p> <ol style="list-style-type: none"> <li>Choose <b>Deployment, Advanced stack components, AMI, Create</b>.</li> <li>During creation, add a tag Key=Name, Value=APPLICATION-ID_Ingest Ready .</li> <li>Wait until AMI is created before proceeding.</li> </ol> <p>For more information, see <a href="#">AMI   Create</a> in the AMS documentation.</p>	<p>Migration engineer</p>

## Ingest and validate the instance

Task	Description	Skills required
Submit the RFC to create the workload ingest stack.	Submit a request for change (RFC) to start the AMS WIGS. For instructions, see <a href="#">Workload Ingest Stack: Creating</a> in the AMS documentation. This starts the workload ingestion and installs all the software required by AMS, including backup tools, Amazon EC2 management software, and antivirus software.	Migration engineer
Validate successful migration.	After the workload ingestion is complete, you can see the AMS-managed instance and AMS-ingested AMI.  <ol style="list-style-type: none"><li>1. Log in to the AMS-managed instance with domain credentials.</li><li>2. Validate the domain joining as follows:<ol style="list-style-type: none"><li>a. In Windows Explorer, right-click <b>This PC</b>, and then choose <b>Properties</b>.</li><li>b. In the Device Specification section, confirm that the domain appears in the <b>Full device name</b>.</li></ol></li><li>3. Validate the source and target disk drives.</li></ol>	Migration engineer

## Launch the instance in the target AMS account

Task	Description	Skills required
Submit the RFC to create an EC2 stack.	<ol style="list-style-type: none"><li>Using the AMS-ingested AMI of the Windows instance, prepare an RFC for an EC2 stack according to the instructions in <a href="#">Create EC2 stack instance</a> in AMS documentation. In the EC2 stack RFC, provide all the parameters, including the server name, tags, target VPC, target subnet, instance type, target security groups, ingestion AMI, and role.</li><li>Submit the RFC for the EC2 stack, and then wait for the instance to be successfully created.</li></ol>	Migration engineer

# Migrate Db2 for LUW to Amazon EC2 by using log shipping to reduce outage time

Created by Feng Cai (AWS), Ambarish Satarkar (AWS), and Saurabh Sharma (AWS)

<b>Environment:</b> Production	<b>Source:</b> On-premises Db2 for Linux	<b>Target:</b> Db2 on Amazon EC2
<b>R Type:</b> Rehost	<b>Workload:</b> IBM	<b>Technologies:</b> Migration; Databases
<b>AWS services:</b> AWS Direct Connect; Amazon EBS; Amazon EC2; Amazon S3; AWS Site-to-Site VPN		

## Summary

When customers migrate their IBM Db2 for LUW (Linux, UNIX, and Windows) workloads to Amazon Web Services (AWS), using Amazon Elastic Compute Cloud (Amazon EC2) with the Bring Your Own License (BYOL) model is the fastest way. However, migrating large amounts of data from on-premises Db2 into AWS can be a challenge, especially when the outage window is short. Many customers try to set the outage window to less than 30 minutes, which leaves little time for the database itself.

This pattern covers how to accomplish a Db2 migration with a short outage window by using transaction log shipping. This approach applies to Db2 on a little-endian Linux platform.

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Db2 instance running on EC2 instance that matches the on-premises file system layouts
- An Amazon Simple Storage Service (Amazon S3) bucket accessible to the EC2 instance
- An AWS Identity and Access Management (IAM) policy and role to make programmatic calls to Amazon S3

- Synchronized time zone and system clocks on Amazon EC2 and the on-premises server
- The on-premises network connected to AWS through [AWS Site-to-Site VPN](#) or [AWS Direct Connect](#)

## Limitations

- The Db2 on-premises instance and Amazon EC2 must be on the same [platform family](#).
- The Db2 on-premises workload must be logged. To block any unlogged transaction, set `blocknonlogged=yes` in the database configuration.

## Product versions

- Db2 for LUW version 11.5.9 and later

## Architecture

### Source technology stack

- Db2 on Linux x86\_64

### Target technology stack

- Amazon EBS
- Amazon EC2
- AWS Identity and Access Management (IAM)
- Amazon S3
- AWS Site-to-Site VPN or Direct Connect

### Target architecture

The following diagram shows one Db2 instance running on-premises with a virtual private network (VPN) connection to Db2 on Amazon EC2. The dotted lines represent the VPN tunnel between your data center and the AWS Cloud.

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Direct Connect](#) links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- [Amazon Elastic Block Store \(Amazon EBS\)](#) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Site-to-Site VPN](#) helps you pass traffic between instances that you launch on AWS and your own remote network.

## Other tools

- [db2cli](#) is the Db2 interactive CLI command.

## Best practices

- On the target database, use [gateway endpoints for Amazon S3](#) to access the database backup image and log files in Amazon S3.
- On the source database, use [AWS PrivateLink for Amazon S3](#) to send the database backup image and log files to Amazon S3.

## Epics

### Set environment variables

Task	Description	Skills required
Set environment variables.	<p>This pattern uses the following names:</p> <ul style="list-style-type: none"> <li>• Instance name: db2inst1</li> <li>• Database name: SAMPLE</li> </ul> <p>You can change them to fit your environment.</p>	DBA

### Configure the on-premises Db2 server

Task	Description	Skills required
Set up the AWS CLI.	<p>To download and install the latest version of the AWS CLI, run the following commands:</p> <pre>\$ curl "https://awscli.amazonaws.c</pre>	Linux administrator

Task	Description	Skills required
	<pre>om/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip" unzip awscliv2.zip sudo ./aws/install</pre>	
Set up a local destination for Db2 archive logs.	<p>To keep the target database on Amazon EC2 in sync with the on-premises source database, the latest transaction logs need be retrieved from the source.</p> <p>In this setup, /db2logs is set by LOGARCHMETH2 on the source as a staging area. The archived logs in this directory will be synced into Amazon S3 and accessed by Db2 on Amazon EC2. The pattern uses LOGARCHMETH2 because LOGARCHMETH1 might have been configured to use a third-party vendor tool that AWS CLI command cannot access. To retrieve the logs, run the following command:</p> <pre>db2 connect to sample db2 update db cfg for SAMPLE using LOGARCHMETH2 disk:/db2logs</pre>	DBA

Task	Description	Skills required
Run an online database backup.	Run an online database backup, and save it to the local backup file system:  <pre>db2 backup db sample online to /backup</pre>	DBA

## Set up the S3 bucket and IAM policy

Task	Description	Skills required
Create an S3 bucket.	Create an S3 bucket for the on-premises server to send the backup Db2 images and log files to on AWS. The bucket will also be accessed by Amazon EC2:  <pre>aws s3api create-bucket --bucket logshipmig- db2 --region us-east-1</pre>	AWS systems administrator
Create an IAM policy.	The <code>db2bucket.json</code> file contains the IAM policy to access the Amazon S3 bucket:  <pre>{   "Version":     "2012-10-17",   "Statement": [     {       "Effect":         "Allow",       "Action": [</pre>	AWS administrator, AWS systems administrator

Task	Description	Skills required
	<pre> "kms:GenerateDataKey", "kms:Decrypt", "s3:PutObject", "s3:GetObject", "s3:AbortMultipartUpload", "s3:ListBucket", "s3:DeleteObject", "s3:GetObjectVersion", "s3:ListMultipartUploadParts" ], "Resource": [ "arn:aws:s3:::logshippmig-db2/*", "arn:aws:s3:::logshippmig-db2" ] ] } </pre> <p>To create the policy, use the following AWS CLI command:</p> <pre>aws iam create-policy \</pre>	

Task	Description	Skills required
	<pre data-bbox="597 205 1023 424">--policy-name db2s3policy \ --policy-document file://db2bucket.j son</pre> <p data-bbox="597 466 1023 684">The JSON output shows the Amazon Resource Name (ARN) for the policy, where <code>aws_account_id</code> represents your account ID:</p> <pre data-bbox="597 726 1023 886">"Arn": "arn:aws: iam::aws_account_i d:policy/db2s3policy"</pre>	

Task	Description	Skills required
<p>Attach the IAM policy to the IAM role used by the EC2 instance.</p>	<p>In most AWS environments, a running EC2 instance has an IAM Role set by your systems administrator. If the IAM role is not set, create the role and choose <b>Modify IAM role</b> on the EC2 console to associate the role with the EC2 instance that hosts the Db2 database. Attach the IAM policy to the IAM role with the policy ARN:</p> <pre data-bbox="594 772 1029 1136">aws iam attach-role-policy \   --policy-arn   "arn:aws:iam::aws_   account_id:policy/   db2s3policy" \   --role-name   db2s3role</pre> <p>After the policy is attached, any EC2 instance associated with the IAM role can access the S3 bucket.</p>	<p>AWS administrator, AWS systems administrator</p>

### Send the source database backup image and log files to Amazon S3

Task	Description	Skills required
<p>Configure the AWS CLI on the on-premises Db2 server.</p>	<p>Configure the AWS CLI with the Access Key ID and Secret Access Key generated in the earlier step:</p>	<p>AWS administrator, AWS systems administrator</p>

Task	Description	Skills required
	<pre>\$ aws configure AWS Access Key ID [None]: ***** AWS Secret Access Key [None]: ***** ***** Default region name [None]: us-east-1 Default output format [None]: json</pre>	
Send the backup image to Amazon S3.	<p>Earlier, an online database backup was saved to the /backup local directory. To send that backup image to the S3 bucket, run the following command:</p> <pre>aws s3 sync /backup s3://logshipmig-db2/ SAMPLE_backup</pre>	AWS administrator, Migration engineer

Task	Description	Skills required
Send the Db2 archive logs to Amazon S3.	<p>Sync the on-premises Db2 archive logs with the S3 bucket that can be accessed by the target Db2 instance on Amazon EC2:</p> <pre>aws s3 sync /db2logs s3://logshipmig-db2/ SAMPLE_LOG</pre> <p>Run this command periodically by using cron or other scheduling tools. The frequency depends on how often the source database archives transaction log files.</p>	AWS administrator, Migration engineer

### Connect Db2 on Amazon EC2 to Amazon S3 and start the database sync

Task	Description	Skills required
Create a PKCS12 keystore.	<p>Db2 uses a Public-Key Cryptography Standards (PKCS) encryption keystore to keep the AWS access key secure. Create a keystore and configure the source Db2 instance to use it:</p> <pre>gsk8capicmd_64 -keydb -create -db "/home/db 2inst1/.keystore/d b2s3.p12" -pw "&lt;password&gt;" -type pkcs12 - stash</pre>	DBA

Task	Description	Skills required
	<pre>db2 "update dbm cfg using keystore_ location /home/db2 inst1/.keystore/db 2s3.p12 keystore_type pkcs12"</pre>	
<p>Create the Db2 storage access alias.</p>	<p>To create the <a href="#">storage access alias</a>, use the following script syntax:</p> <pre>db2 "catalog storage access alias &lt;alias_na me&gt; vendor S3 server &lt;S3 endpoint&gt; container '&lt;bucket_ name&gt;'"</pre> <p>For example, your script might look like the following:</p> <pre>db2 "catalog storage access alias DB2AWSS3 vendor S3 server s3.us-east-1.amazo naws.com container 'logshipmig-db2'"</pre>	DBA

Task	Description	Skills required
Set the staging area.	<p>By default, Db2 uses <code>DB2_OBJECT_STORAGE_LOCAL_STAGING_PATH</code> as the staging area to upload and download files to and from Amazon S3. The default path is <code>sqllib/tmp/RemoteStorage.xx</code> under the instance home directory, with <code>xxxx</code> referring to the Db2 partition number. Note that the staging area must have enough capacity to hold the backup images and log files. You can use the registry to point the staging area into a different directory.</p> <p>We also recommend using <code>DB2_ENABLE_COS_SDK=ON</code>, <code>DB2_OBJECT_STORAGE_SETTINGS=EnableStreamingRestore</code>, and the link to the <code>awssdk</code> library to bypass the Amazon S3 staging area for database backup and restore:</p> <pre>#By root: cp -rp /home/db2inst1/ sqllib/lib64/awssdk/ RHEL/7.6/* /home/db2 inst1/sqllib/lib64/  #By db2 instance owner:</pre>	DBA

Task	Description	Skills required
	<pre>db2set DB2_OBJECS T_STORAGE_LOCAL_ST AGING_PATH=/db2stage db2set DB2_ENABL E_COS_SDK=ON Db2set DB2_OBJECS T_STORAGE_SETTINGS =EnableStreamingRe store db2stop db2start</pre>	
Restore the database from the backup image.	<p>Restore the target database on Amazon EC2 from the backup image in the S3 bucket:</p> <pre>db2 restore db sample from DB2REMOTE:// DB2AWSS3/logshipmig- db2/SAMPLE_backup replace existing</pre>	DBA

Task	Description	Skills required
Roll forward the database.	<p>After the restore is complete, the target database will be put into rollforward pending state. Configure LOGARCHMETH1 and LOGARCHMETH2 so that Db2 knows where to get the transaction log files:</p> <pre data-bbox="594 583 1029 905">db2 update db cfg for SAMPLE using LOGARCHME TH1 'DB2REMOTE://DB2AW SS3//SAMPLE_LOGS/' db2 update db cfg for SAMPLE using LOGARCHME TH2 OFF</pre> <p>Start database rollforward:</p> <pre data-bbox="594 1014 1029 1171">db2 ROLLFORWARD DATABASE sample to END OF LOGS</pre> <p>This command processes all log files that have been transferred to the S3 bucket. Run it periodically based on the frequency of the s3 sync command on the on-premises Db2 servers. For example, if s3 sync runs at each hour, and it takes 10 minutes to sync all the log files, set the command to run at 10 minutes after each hour.</p>	DBA

## Bring Db2 on Amazon EC2 online during the cutover window

Task	Description	Skills required
Bring the target database online.	<p>During the cutover window, do one of the following:</p> <ul style="list-style-type: none"> <li>Put the on-premises database in ADMIN MODE, and run the <code>s3 sync</code> command to force the last transaction log to be archived.</li> <li>Shut down the database.</li> </ul> <p>After the last transaction log is synced into Amazon S3, run the <code>ROLLFORWARD</code> command for the final time:</p> <pre> db2 rollforward DB   sample to END OF LOGS db2 rollforward DB   sample complete                Rollforward Status .... Rollforward status                         = not pending .... DB20000I The ROLLFORWA RD command completed successfully.  db2 activate db sample DB20000I The ACTIVATE DATABASE command </pre>	DBA

Task	Description	Skills required
	<p>completed successfully.</p> <p>Bring the target database online, and point the application connections to Db2 on Amazon EC2.</p>	

## Troubleshooting

Issue	Solution
If multiple databases have the same instance name and database name on different hosts (DEV, QA, PROD), backups and logs might go to the same subdirectory.	Use different S3 buckets for DEV, QA, and PROD, and add the hostname as subdirectory prefix to avoid confusion.
<p>If there are multiple backup images in the same location, you will get the following error when you restore:</p> <p>SQL2522N More than one backup file matches the time stamp value provided for the backed up database image.</p>	<p>In the <code>restore</code> command, add the timestamp of the backup:</p> <pre>db2 restore db sample from DB2REMOTE://DB2AWSS3/logshimig-db2/SAMPLE_backup taken at 20230628164042 replace existing</pre>

# Migrate Db2 for LUW to Amazon EC2 with high availability disaster recovery

Created by Feng Cai (AWS), Aruna Gangireddy (AWS), and Venkatesan Govindan (AWS)

<b>Environment:</b> Production	<b>Source:</b> IBM Db2 for LUW on premises	<b>Target:</b> Db2 on Amazon EC2
<b>R Type:</b> Rehost	<b>Workload:</b> IBM	<b>Technologies:</b> Migration; Databases; Operating systems
<b>AWS services:</b> AWS Direct Connect; Amazon EC2; Amazon S3; AWS Site-to-Site VPN		

## Summary

When customers migrate their IBM Db2 LUW (Linux, UNIX, and Windows) workload to Amazon Web Services (AWS), using Amazon Elastic Compute Cloud (Amazon EC2) with the Bring Your Own License (BYOL) model is the fastest way. However, migrating large amounts of data from on-premises Db2 into AWS can be a challenge, especially when the outage window is short. Many customers try to set the outage window to less than 30 minutes, which leaves little time for the database itself.

This pattern covers how to accomplish a Db2 migration with a short outage window by using Db2 high availability disaster recovery (HADR). This approach applies to Db2 databases that are on the little-endian Linux platform and are not using Data Partitioning Feature (DPF).

## Prerequisites and limitations

### Prerequisites

- An active AWS account
- A Db2 instance running on an Amazon EC2 instance that matches the on-premises file system layouts

- An Amazon Simple Storage Service (Amazon S3) bucket accessible to the EC2 instance
- An AWS Identity and Access Management (IAM) policy and role to make programmatic calls to Amazon S3
- Synchronized time zone and system clocks on Amazon EC2 and the on-premises server
- The on-premises network connected to AWS through [AWS Site-to-Site VPN](#) or [AWS Direct Connect](#)
- Communication between the on-premises server and Amazon EC2 on HADR ports

## Limitations

- The Db2 on-premises instance and Amazon EC2 must be on the same [platform family](#).
- HADR is not supported in a partitioned database environment.
- HADR doesn't support the use of raw I/O (direct disk access) for database log files.
- HADR doesn't support infinite logging.
- LOGINDEXBUILD must be set to YES, which will increase the log usage for rebuilding the index.
- The Db2 on-premises workload must be logged. Set `blocknonlogged=yes` in the database configuration to block any unlogged transactions.

## Product versions

- Db2 for LUW version 11.5.9 and later

## Architecture

### Source technology stack

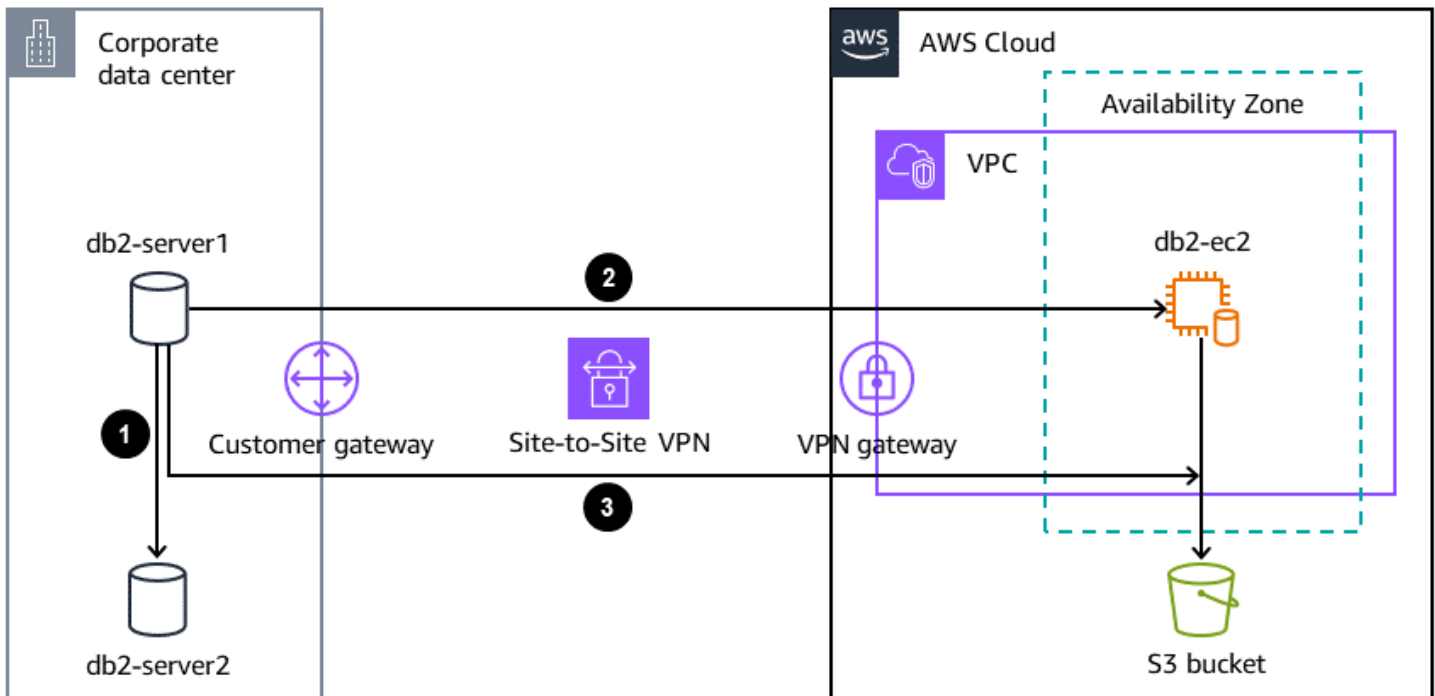

- Db2 on Linux x86\_64

### Target technology stack

- Amazon EC2
- AWS Identity and Access Management (IAM)
- Amazon S3
- AWS Site-to-Site VPN

## Target architecture

In the following diagram, Db2 on premises is running on `db2-server1` as the primary. It has two HADR standby targets. One standby target is on premises and is optional. The other standby target, `db2-ec2`, is on Amazon EC2. After the database is cut over to AWS, `db2-ec2` becomes the primary.

1. Logs are streamed from the primary on-premises database to the standby on-premises database.
2. Using Db2 HADR, logs are streamed from the primary on-premises database through Site-to-Site VPN to Db2 on Amazon EC2.
3. Db2 backup and archive logs are sent from the primary on-premises database to the S3 bucket on AWS.

## Tools

### AWS services

- [AWS Command Line Interface \(AWS CLI\)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

- [AWS Direct Connect](#) links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Identity and Access Management \(IAM\)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Simple Storage Service \(Amazon S3\)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Site-to-Site VPN](#) helps you pass traffic between instances that you launch on AWS and your own remote network.

## Other tools

- [db2cli](#) is the Db2 interactive CLI command.

## Best practices

- On the target database, use [gateway endpoints for Amazon S3](#) to access the database backup image and log files in Amazon S3.
- On the source database, use [AWS PrivateLink for Amazon S3](#) to send the database backup image and log files to Amazon S3.

## Epics

### Set environment variables

Task	Description	Skills required
Set environment variables.	This pattern uses the following names and ports:  1. Db2 on-premises hostname: db2-server1  2. HADR standby hostname: db2-server2 (if HADR	DBA

Task	Description	Skills required
	<p>is currently running on premises)</p> <ol style="list-style-type: none"> <li>Amazon EC2 hostname: db2-ec2</li> <li>Instance name: db2inst1</li> <li>Database name: SAMPLE</li> <li>HADR ports: <ul style="list-style-type: none"> <li>db2-server1: 50010</li> <li>db2-server2: 50011</li> <li>db2-ec2: 50012</li> </ul> </li> </ol> <p>You can change them to fit your environment.</p>	

### Configure the on-premises Db2 server

Task	Description	Skills required
Set up AWS CLI.	<p>To download and install the latest version of AWS CLI, run the following commands:</p> <pre>\$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip" unzip awscliv2.zip sudo ./aws/install</pre>	Linux administrator
Set up a local destination for Db2 archive logs.	Conditions such as heavy update batch jobs and network slowdowns can cause	DBA

Task	Description	Skills required
	<p>the HADR standby server to have a lag. To catch up, the standby server needs the transaction logs from the primary server. The sequence of places to request logs is the following:</p> <ul style="list-style-type: none"><li>• The active log directory on the primary server</li><li>• The LOGARCHMETH1 or LOGARCHMETH2 location on the standby server</li><li>• The LOGARCHMETH1 or LOGARCHMETH2 location on the primary server</li></ul> <p>In this setup, /db2logs is set by LOGARCHMETH2 on the source as a staging area. The archived logs in this directory will be synced into Amazon S3 and accessed by Db2 on Amazon EC2. The pattern uses LOGARCHMETH2 because LOGARCHMETH1 might have been configured to use a third-party vendor tool that the AWS CLI command cannot access:</p> <pre>db2 connect to sample</pre>	

Task	Description	Skills required
	<pre>db2 update db cfg for SAMPLE using LOGARCHME TH2 disk:/db2logs</pre>	
Run an online database backup.	<p>Run an online database backup, and save it to the local backup file system:</p> <pre>db2 backup db sample online to /backup</pre>	DBA

### Set up the S3 bucket and IAM policy

Task	Description	Skills required
Create an S3 bucket.	<p>Create an S3 bucket for the on-premises server to send the backup Db2 images and log files to on AWS. The bucket will be accessed by Amazon EC2:</p> <pre>aws s3api create-bucket --bucket hadrmig-db2 --region us-east-1</pre>	AWS administrator
Create an IAM policy.	<p>The db2bucket.json file contains the IAM policy for accessing the S3 bucket:</p> <pre>{   "Version":   "2012-10-17",   "Statement": [     {</pre>	AWS administrator, AWS systems administrator

Task	Description	Skills required
	<pre>       "Effect":         "Allow",       "Action": [         "kms:GenerateDataKey",         "kms:Decrypt",         "s3:PutObject",         "s3:GetObject",         "s3:AbortMultipartUpload",         "s3:ListBucket",         "s3:DeleteObject",         "s3:GetObjectVersion",         "s3:ListMultipartUploadParts"       ],       "Resource": [         "arn:aws:s3:::hadr-mig-db2/*",         "arn:aws:s3:::hadr-mig-db2"       ]     ]   } } </pre> <p>To create the policy, use the following AWS CLI command:</p>	

Task	Description	Skills required
	<pre>aws iam create-policy \   --policy-name   db2s3hapolicy \   --policy-document   file://db2bucket.j son</pre> <p>The JSON output shows the Amazon Resource Name (ARN) for the policy, where <code>aws_account_id</code> represents your account ID:</p> <pre>"Arn": "arn:aws: iam::aws_account_i d:policy/db2s3hapo licy"</pre>	

Task	Description	Skills required
<p>Attach the IAM policy to the IAM role.</p>	<p>Usually, the EC2 instance with Db2 running would have an IAM role assigned by the systems administrator. If no IAM role is assigned, you can choose <b>Modify IAM role</b> on the Amazon EC2 console.</p> <p>Attach the IAM policy to the IAM role associated with the EC2 instance. After the policy is attached, the EC2 instance can access the S3 bucket:</p> <pre data-bbox="597 856 1029 1129">aws iam attach-role-policy --policy-arn "arn:aws:iam::aws_account_id:policy/db2s3hapolicy" --role-name db2s3harole</pre>	

### Send the source database backup image and log files to Amazon S3

Task	Description	Skills required
<p>Configure AWS CLI on the on-premises Db2 server.</p>	<p>Configure AWS CLI with the Access Key ID and Secret Access Key that you generated earlier:</p> <pre data-bbox="597 1629 1029 1885">\$ aws configure AWS Access Key ID [None]: ***** AWS Secret Access Key [None]: ***** *****</pre>	<p>AWS administrator, AWS systems administrator</p>

Task	Description	Skills required
	<pre>Default region name [None]: us-east-1 Default output format [None]: json</pre>	
<p>Send the backup image to Amazon S3.</p>	<p>Earlier, an online database backup was saved to the /backup local directory. To send that backup image to the S3 bucket, run the following command:</p> <pre>aws s3 sync /backup s3://hadrmig-db2/S AMPLE_backup</pre>	<p>AWS administrator, AWS systems administrator</p>
<p>Send the Db2 archive logs to Amazon S3.</p>	<p>Sync the on-premises Db2 archive logs with the Amazon S3 bucket that can be accessed by the target Db2 instance on Amazon EC2:</p> <pre>aws s3 sync /db2logs s3://hadrmig-db2/S AMPLE_LOGS</pre> <p>Run this command periodically by using cron or other scheduling tools. The frequency depends on how often the source database archives transaction log files.</p>	

## Connect Db2 on Amazon EC2 to Amazon S3 and start the initial database sync

Task	Description	Skills required
Create a PKCS12 keystore.	<p>Db2 uses a Public-Key Cryptography Standards (PKCS) encryption keystore to keep the AWS access key secure. Create a keystore, and configure the source Db2 to use it:</p> <pre data-bbox="597 688 1027 1247">gsk8capicmd_64 -keydb   -create -db "/home/db   2inst1/.keystore/d   b2s3.p12" -pw "&lt;password&gt;" -type pkcs12 -   stash  db2 "update dbm cfg   using keystore_   location /home/db2   inst1/.keystore/db   2s3.p12 keystore_type   pkcs12"</pre>	DBA
Create the Db2 storage access alias.	<p>Db2 uses a storage access alias to access Amazon S3 directly with the <code>INGEST</code>, <code>LOAD</code>, <code>BACKUP DATABASE</code>, or <code>RESTORE DATABASE</code> commands.</p> <p>Because you assigned an IAM role to the EC2 instance, <code>USER</code> and <code>PASSWORD</code> are not required:</p>	DBA

Task	Description	Skills required
	<pre>db2 "catalog storage access alias &lt;alias_name&gt; vendor S3 server &lt;S3 endpoint&gt; container '&lt;bucket_name&gt;' "</pre> <p>For example, your script might look like the following:</p> <pre>db2 "catalog storage access alias DB2AWSS3 vendor S3 server s3.us-east-1.amazonaws.com container 'hadrmig-db2' "</pre>	

Task	Description	Skills required
Set the staging area.	<p>We recommend using DB2_ENABLE_COS_SDK=ON , DB2_OBJEC T_STORAGE_SETTINGS=EnableStreamingRe store , and the link to the awssdk library to bypass the Amazon S3 staging area for database backup and restore:</p> <pre data-bbox="594 684 1029 1398">#By root: cp -rp /home/db2inst1/ sqllib/lib64/awssdk/ RHEL/7.6/* /home/db2 inst1/sqllib/lib64/  #By db2 instance owner: db2set DB2_OBJEC T_STORAGE_LOCAL_ST AGING_PATH=/db2stage db2set DB2_ENABL E_COS_SDK=ON db2set DB2_OBJEC T_STORAGE_LOCAL_ST AGING_PATH=/db2stage db2stop db2start</pre>	DBA

Task	Description	Skills required
Restore the database from the backup image.	<p>Restore the target database on Amazon EC2 from the backup image in the S3 bucket:</p> <pre>db2 create db sample on /data1 db2 restore db sample from DB2REMOTE:// DB2AWSS3/hadrmig-db2/ SAMPLE_backup replace existing</pre>	DBA

### Set up HADR with no HADR on premises

Task	Description	Skills required
Configure the on-premises Db2 server as the primary.	<p>Update the database configuration settings for HADR on db2-server1 (the on-premises source) as the primary. Set HADR_SYNC MODE to SUPERASYNC mode, which has the shortest transaction response time:</p> <pre>db2 update db cfg for sample using HADR_LOCA L_HOST db2-server1 HADR_LOCAL_SVC 50010 HADR_REMOTE_HOST db2- ec2 HADR_REMOTE_SVC 50012 HADR_REMO TE_INST db2inst1 HADR_SYNCMODE</pre>	DBA

Task	Description	Skills required
	<p>SUPERASYNC DB20000 I The UPDATE DATABASE CONFIGURATION command completed successfully</p> <p>Some network delays between the on-premises data center and AWS are expected. (You can set a different HADR_SYNCMODE value based on network reliability. For more information, see the <a href="#">Related resources</a> section).</p>	
<p>Change the target database log archive destination.</p>	<p>Change the target database log archive destination to match the Amazon EC2 environment:</p> <pre data-bbox="594 1163 1027 1556"> db2 update db cfg for SAMPLE using LOGARCHME TH1 'DB2REMOTE://DB2AW SS3//SAMPLE_LOGS/' LOGARCHMETH2 OFF DB20000I The UPDATE DATABASE CONFIGURA TION command completed successfully </pre>	<p>DBA</p>

Task	Description	Skills required
Configure HADR for Db2 on the Amazon EC2 server.	<p>Update database configuration for HADR on db2-ec2 as standby:</p> <pre>db2 update db cfg for sample using HADR_LOCAL_HOST db2-ec2 HADR_LOCA L_SVC 50012 HADR_REMO TE_HOST db2-server1 HADR_REMOTE_SVC 50010 HADR_REMOTE_INST db2inst1 HADR_SYNC MODE SUPERASYN C DB20000I The UPDATE DATABASE CONFIGURATION command completed successfu lly</pre>	DBA

Task	Description	Skills required
Verify HADR setup.	<p>Verify the HADR parameters on the source and target Db2 servers.</p> <p>To verify the setup on db2-server1 , run the following command:</p> <pre data-bbox="597 569 1027 1816"> db2 get db cfg for sample grep HADR HADR database role                  = PRIMARY HADR local host name                 (HADR_LOCAL_HOST) = db2-server1 HADR local service name (HADR_LOCAL_SVC) = 50010 HADR remote host name                 (HADR_REMOTE_HOST) = db2-ec2 HADR remote service name (HADR_REMOTE_SVC) = 50012 HADR instance name of remote server (HADR_REMOTE_INST) = db2inst1 HADR timeout value  (HADR_TIMEOUT) = 120 HADR target list                 (HADR_TARGET_LIST) = HADR log write synchronization mode </pre>	DBA

Task	Description	Skills required
	<pre> (HADR_SYNCMODE) = NEARSYNC HADR spool log data limit (4KB) (HADR_SPOOL_LIMIT) = AUTOMATIC(52000) HADR log replay delay (seconds) (HADR_REP LAY_DELAY) = 0 HADR peer window duration (seconds) (HADR_PEER_WINDOW) = 0 HADR SSL certifica te label (HADR_SSL_LABEL) = HADR SSL Hostname Validation (HADR_SSL_HOST_VAL) = OFF </pre> <p>To verify the setup on db2-ec2, run the following command:</p> <pre> db2 get db cfg for sample grep HADR HADR database role  = STANDBY HADR local host name (HADR_LOCAL_HOST) = db2-ec2 HADR local service name (HADR_LOCAL_SVC) = 50012 HADR remote host name (HADR_REMOTE_HOST) = db2-server1 </pre>	

Task	Description	Skills required
	<pre> HADR remote service name (HADR_REMOTE_SVC) = 50010 HADR instance name of remote server (HADR_REMOTE_INST) = db2inst1 HADR timeout value  (HADR_TIMEOUT) = 120 HADR target list       (HADR_TAR GET_LIST) = HADR log write synchronization mode       (HADR_SYNCMODE) = SUPERASYNC HADR spool log data limit (4KB) (HADR_SPOOL_LIMIT) = AUTOMATIC(52000) HADR log replay delay (seconds)      (HADR_REP LAY_DELAY) = 0 HADR peer window duration (seconds) (HADR_PEER_WINDOW) = 0 HADR SSL certifica te label (HADR_SSL_LABEL) = HADR SSL Hostname Validation (HADR_SSL_HOST_VAL) = OFF </pre> <p>The HADR_LOCAL_HOST , HADR_LOCAL_SVC , HADR_REMOTE_HOST , and HADR_REMOTE_SVC</p>	

Task	Description	Skills required
<p>Start up the Db2 HADR instance.</p>	<p>parameters indicate the one primary and one standby HADR setup.</p> <p>Start the Db2 HADR instance on the standby server db2-ec2 first:</p> <pre data-bbox="594 554 1029 835">db2 start hadr on db sample as standby DB20000I The START HADR ON DATABASE command completed successfully.</pre> <p>Start Db2 HADR on the primary (source) server db2-server1 :</p> <pre data-bbox="594 1041 1029 1323">db2 start hadr on db sample as primary DB20000I The START HADR ON DATABASE command completed successfully.</pre> <p>The HADR connection between Db2 on premises and on Amazon EC2 has now been successfully established. The Db2 primary server db2-server1 starts streaming transaction log records to db2-ec2 in real time.</p>	<p>DBA</p>

## Set up HADR when HADR exists on premises

Task	Description	Skills required
<p>Add Db2 on Amazon EC2 as an auxiliary standby.</p>	<p>If HADR is running on the on-premises Db2 instance, you can add Db2 on Amazon EC2 as an auxiliary standby using HADR_TARGET_LIST by running the following commands on db2-ec2:</p> <pre>db2 update db cfg for sample using HADR_LOCAL_HOST db2-ec2 HADR_LOCA L_SVC 50012 HADR_REMO TE_HOST db2-server1 HADR_REMOTE_SVC 50010 HADR_REMOTE_INST db2inst1 HADR_SYNC MODE SUPERASYN C DB20000I The UPDATE DATABASE CONFIGURATION command completed successfu lly. db2 update db cfg for sample using HADR_TARGET_LIST "db2-server1:50010  db2-server2:50011 " DB20000I The UPDATE DATABASE CONFIGURATION command completed successfu lly.</pre>	<p>DBA</p>

Task	Description	Skills required
Add the auxiliary standby information to the on-premises servers.	<p>Update HADR_TARG ET_LIST on the two on-premises servers (primary and standby).</p> <p>On db2-server1 , run the following code:</p> <pre>db2 update db cfg for sample using HADR_TARG ET_LIST "db2-server2:50011 db2-ec2:50012" DB20000I</pre> <p>The UPDATE DATABASE CONFIGURATION command completed successfully. SQL1363W One or more of the parameters submitted for immediate modification were not changed dynamically. For these configuration parameters, the database must be shutdown and reactivated before the configuration parameter changes become effective.</p> <p>On db2-server2 , run the following code:</p>	DBA

Task	Description	Skills required
	<pre>db2 update db cfg for sample using HADR_TARG ET_LIST "db2-serv er1:50010 db2-ec2: 50012" DB2000I The UPDATE DATABASE CONFIGURATION command completed successfu lly. SQL1363W One or more of the parameter s submitted for immediate modificat ion were not changed dynamically. For these configura tion parameters, the database must be shutdown and reactivated before the configuration parameter changes become effective.</pre>	

Task	Description	Skills required
Verify HADR setup.	<p>Verify the HADR parameters on the source and target Db2 servers.</p> <p>On db2-server1 , run the following code:</p> <pre data-bbox="594 520 1029 1806"> db2 get db cfg for sample grep HADR HADR database role                  = PRIMARY HADR local host name                 (HADR_LOCAL_HOST) = db2-server1 HADR local service name (HADR_LOCAL_SVC) = 50010 HADR remote host name                 (HADR_REMOTE_HOST) = db2-server2 HADR remote service name (HADR_REMOTE_SVC) = 50011 HADR instance name of remote server (HADR_REMOTE_INST) = db2inst1 HADR timeout value  (HADR_TIMEOUT) = 120 HADR target list                 (HADR_TARGET_LIST) = db2-server2:50011 db2-ec2:50012 </pre>	

Task	Description	Skills required
	<pre> HADR log write synchronization mode     (HADR_SYNCMODE) = NEARSYNC HADR spool log data limit (4KB) (HADR_SPOOL_LIMIT) = AUTOMATIC(52000) HADR log replay delay (seconds)    (HADR_REP LAY_DELAY) = 0 HADR peer window duration (seconds) (HADR_PEER_WINDOW) = 0 HADR SSL certifica te label (HADR_SSL_LABEL) = HADR SSL Hostname Validation (HADR_SSL_HOST_VAL) = OFF </pre> <p>On db2-server2 , run the following code:</p> <pre> db2 get db cfg for sample grep HADR HADR database role          = STANDBY HADR local host name         (HADR_LOCA AL_HOST) = db2-server2 HADR local service name (HADR_LOCAL_SVC) = 50011 HADR remote host name         (HADR_REM OTE_HOST) = db2-serve r1 </pre>

Task	Description	Skills required
	<pre>HADR log replay delay (seconds) (HADR_REP LAY_DELAY) = 0 HADR peer window duration (seconds) (HADR_PEER_WINDOW) = 0 HADR SSL certifica te label (HADR_SSL_LABEL) = HADR SSL Hostname Validation (HADR_SSL_HOST_VAL) = OFF</pre> <p>The HADR_LOCAL_HOST , HADR_LOCAL_SVC , HADR_REMOTE_HOST , HADR_REMOTE_SVC , and HADR_TARGET_LIST parameters indicate the one primary and two standby HADR setup.</p>	

Task	Description	Skills required
Stop and start Db2 HADR.	<p>HADR_TARGET_LIST is now set up on all three servers. Each Db2 server is aware of the other two. Stop and restart HADR (brief outage) to take advantage of the new configuration.</p> <p>On db2-server1 , run the following commands:</p> <pre>db2 stop hadr on db sample db2 deactivate db sample db2 activate db sample</pre> <p>On db2-server2 , run the following commands:</p> <pre>db2 deactivate db sample db2 start hadr on db sample as standby SQL1766W The command completed successfully</pre> <p>On db2-ec2, run the following commands:</p> <pre>db2 start hadr on db sample as standby SQL1766W The command completed successfully</pre> <p>On db2-server1 , run the following commands:</p>	DBA

Task	Description	Skills required
	<pre data-bbox="597 212 1027 407">db2 start hadr on db sample as primary SQL1766W The command completed successfully</pre> <p data-bbox="597 443 1027 863">The HADR connection between Db2 on premises and on Amazon EC2 is now successfully established. The Db2 primary server db2-server1 starts streaming transaction log records to both db2-server2 and db2-ec2 in real time.</p>	

### Make Db2 on Amazon EC2 as primary during the cutover window

Task	Description	Skills required
<p data-bbox="110 1146 553 1272">Make sure that there is no HADR lag on the standby server.</p>	<p data-bbox="597 1146 1027 1713">Check HADR status from the primary server db2-server1 . Don't be alarmed when HADR_STATE is in REMOTE_CATCHUP status, which is normal when HADR_SYNCMODE is set to SUPERASYNC . The PRIMARY_LOG_TIME and STANDBY_REPLAY_LOG_TIME show that they are in sync:</p> <pre data-bbox="597 1749 1027 1885">db2pd -hadr -db sample  HADR_ROLE = PRIMARY</pre>	<p data-bbox="1065 1146 1508 1178">DBA</p>

Task	Description	Skills required
	<pre>REPLAY_TYPE = PHYSICAL  HADR_SYNCMODE = SUPERASYNC  STANDBY_ID = 2  LOG_STREAM_ID = 0  HADR_STATE = REMOTE_CATCHUP .....  PRIMARY_LOG_TIME = 10/26/2022 02:11:32. 000000 (1666750292)  STANDBY_LOG_TIME = 10/26/2022 02:11:32. 000000 (1666750292) STANDBY_R EPLAY_LOG_TIME = 10/26/2022 02:11:32. 000000 (1666750292)</pre>	

Task	Description	Skills required
Run HADR takeover.	<p>To complete the migration, make db2-ec2 the primary database by running the HADR takeover command. Use the command db2pd to verify the HADR_ROLE value:</p> <pre data-bbox="594 537 1027 1373">db2 TAKEOVER HADR ON   DATABASE sample DB20000I The TAKEOVER   HADR ON DATABASE   command completed   successfully.  db2pd -hadr -db sample Database Member 0 -- Database SAMPLE -- Active -- Up 0   days 00:03:25 -- Date   2022-10-26-02.46.4   5.048988        HADR_ROLE = PRIMARY        REPLAY_TYPE =   PHYSICAL</pre> <p>To complete the migration to AWS, point the application connections to Db2 on Amazon EC2.</p>	

## Troubleshooting

Issue	Solution
<p>If you use NAT for firewall and security reasons, the host can have two IP addresses (one internal and one external), which can cause an HADR IP address check failure. The <code>START HADR ON DATABASE</code> command will return the following message:</p> <pre>HADR_LOCAL_HOST:HADR_LOCAL_SVC (-xx-xx-xx-xx.:50011 (xx.xx.xx .xx:50011)) on remote database is different from HADR_REMOTE_HOST:H ADR_REMOTE_SVC (xx-xx-xx- xx.:50011 (x.x.x.x:50011)) on local database.</pre>	<p>To <a href="#">support HADR in a NAT environment</a>, you can configure the <code>HADR_LOCAL_HOST</code> with both the internal and external address. For example, if the Db2 server has the internal name <code>host1</code> and the external name <code>host1E</code>, <code>HADR_LOCAL_HOST</code> can be <code>HADR_LOCAL_HOST: "host1   host1E"</code>.</p>
