Given the same arguments, the function can return different results on successive calls, even for the rows in a single statement. The query optimizer cannot make assumptions about the behavior of a volatile function. A query that uses a volatile function must reevaluate the function for every input.

STABLE

Given the same arguments, the function is guaranteed to return the same results on successive calls processed within a single statement. The function can return different results when called in different statements. This category makes it so the optimizer can reduce the number of times the function is called within a single statement.

Note that if the chosen strictness is not valid for the function, there is a risk that the optimizer might skip some calls based on this strictness. This can result in an incorrect result set.

The IMMUTABLE clause isn't currently supported for Lambda UDFs.

LAMBDA '*lambda_fn_name*'

The name of the function that Amazon Redshift calls.

For steps to create an AWS Lambda function, see [Create a Lambda function with the console](#) in the *AWS Lambda Developer Guide*.

For information regarding permissions required for the Lambda function, see [AWS Lambda permissions](#) in the *AWS Lambda Developer Guide*.

```
IAM_ROLE { default | 'arn:aws:iam::<AWS account-id>:role/<role-name>'
```

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE EXTERNAL FUNCTION command runs.

Use the Amazon Resource Name (ARN) for an IAM role that your cluster uses for authentication and authorization. The CREATE EXTERNAL FUNCTION command is authorized to invoke Lambda functions through this IAM role. If your cluster has an existing IAM role with permissions to invoke Lambda functions attached, you can substitute your role's ARN. For more information, see [Configuring the authorization parameter for Lambda UDFs](#).

The following shows the syntax for the IAM_ROLE parameter.

```
IAM_ROLE 'arn:aws:iam::aws-account-id:role/role-name'
```

RETRY_TIMEOUT *milliseconds*

The amount of total time in milliseconds that Amazon Redshift uses for the delays in retry backoffs.

Instead of retrying immediately for any failed queries, Amazon Redshift performs backoffs and waits for a certain amount of time between retries. Then Amazon Redshift retries the request to rerun the failed query until the sum of all the delays is equal to or exceeds the RETRY_TIMEOUT value that you specified. The default value is 20,000 milliseconds.

When a Lambda function is invoked, Amazon Redshift retries for queries that receive errors such as TooManyRequestsException, EC2ThrottledException, and ServiceException.

You can set the RETRY_TIMEOUT parameter to 0 milliseconds to prevent any retries for a Lambda UDF.

MAX_BATCH_ROWS *count*

The maximum number of rows that Amazon Redshift sends in a single batch request for a single lambda invocation.

This parameter's minimum value is 1. The maximum value is INT_MAX, or 2,147,483,647.

This parameter is optional. The default value is INT_MAX, or 2,147,483,647.

MAX_BATCH_SIZE *size* [KB | MB]

The maximum size of the data payload that Amazon Redshift sends in a single batch request for a single lambda invocation.

This parameter's minimum value is 1 KB. The maximum value is 5 MB.

This parameter's default value is 5 MB.

KB and MB are optional. If you don't set the unit of measurement, Amazon Redshift defaults to using KB.

Usage notes

Consider the following when you create Lambda UDFs:

- The order of Lambda function calls on the input arguments isn't fixed or guaranteed. It might vary between instances of running queries, depending on the cluster configuration.
- The functions are not guaranteed to be applied to each input argument once and only once. The interaction between Amazon Redshift and AWS Lambda might lead to repetitive calls with the same inputs.

Examples

Following are examples of using scalar Lambda user-defined functions (UDFs).

Scalar Lambda UDF example using a Node.js Lambda function

The following example creates an external function called `exfunc_sum` that takes two integers as input arguments. This function returns the sum as an integer output. The name of the Lambda function to be called is `lambda_sum`. The language used for this Lambda function is Node.js 12.x. Make sure to specify the IAM role. The example uses `'arn:aws:iam::123456789012:user/johndoe'` as the IAM role.

```
CREATE EXTERNAL FUNCTION exfunc_sum(INT,INT)
RETURNS INT
VOLATILE
```

```
LAMBDA 'lambda_sum'  
IAM_ROLE 'arn:aws:iam::123456789012:role/Redshift-Exfunc-Test';
```

The Lambda function takes in the request payload and iterates over each row. All the values in a single row are added to calculate the sum for that row, which is saved in the response array. The number of rows in the results array is similar to the number of rows received in the request payload.

The JSON response payload must have the result data in the 'results' field for it to be recognized by the external function. The arguments field in the request sent to the Lambda function contains the data payload. There can be multiple rows in the data payload in case of a batch request. The following Lambda function iterates over all the rows in the request data payload. It also individually iterates over all the values within a single row.

```
exports.handler = async (event) => {  
  // The 'arguments' field in the request sent to the Lambda function contains the  
  // data payload.  
  var t1 = event['arguments'];  
  
  // 'len(t1)' represents the number of rows in the request payload.  
  // The number of results in the response payload should be the same as the number  
  // of rows received.  
  const resp = new Array(t1.length);  
  
  // Iterating over all the rows in the request payload.  
  for (const [i, x] of t1.entries())  
  {  
    var sum = 0;  
    // Iterating over all the values in a single row.  
    for (const y of x) {  
      sum = sum + y;  
    }  
    resp[i] = sum;  
  }  
  // The 'results' field should contain the results of the lambda call.  
  const response = {  
    results: resp  
  };  
  return JSON.stringify(response);  
};
```

The following example calls the external function with literal values.

```
select exfunc_sum(1,2);
exfunc_sum
-----
3
(1 row)
```

The following example creates a table called `t_sum` with two columns, `c1` and `c2`, of the integer data type and inserts two rows of data. Then the external function is called by passing the column names of this table. The two table rows are sent in a batch request in request payload as a single Lambda invocation.

```
CREATE TABLE t_sum(c1 int, c2 int);
INSERT INTO t_sum VALUES (4,5), (6,7);
SELECT exfunc_sum(c1,c2) FROM t_sum;
exfunc_sum
-----
9
13
(2 rows)
```

Scalar Lambda UDF example using the `RETRY_TIMEOUT` attribute

In the following section, you can find an example of how to use the `RETRY_TIMEOUT` attribute in Lambda UDFs.

AWS Lambda functions have concurrency limits that you can set for each function. For more information on concurrency limits, see [Managing concurrency for a Lambda function](#) in the *AWS Lambda Developer Guide* and the post [Managing AWS Lambda Function Concurrency](#) on the AWS Compute Blog.

When the number of requests being served by a Lambda UDF exceeds the concurrency limits, the new requests receive the `TooManyRequestsException` error. The Lambda UDF retries on this error until the sum of all the delays between the requests sent to the Lambda function is equal to or exceeds the `RETRY_TIMEOUT` value that you set. The default `RETRY_TIMEOUT` value is 20,000 milliseconds.

The following example uses a Lambda function named `exfunc_sleep_3`. This function takes in the request payload, iterates over each row, and converts the input to uppercase. It then sleeps for 3 seconds and returns the result. The language used for this Lambda function is Python 3.8.

The number of rows in the results array is similar to the number of rows received in the request payload. The JSON response payload must have the result data in the `results` field for it to be recognized by the external function. The `arguments` field in the request sent to the Lambda function contains the data payload. In the case of a batch request, multiple rows can appear in the data payload.

The concurrency limit for this function is specifically set to 1 in reserved concurrency to demonstrate the use of the `RETRY_TIMEOUT` attribute. When the attribute is set to 1, the Lambda function can only serve one request at a time.

```
import json
import time
def lambda_handler(event, context):
    t1 = event['arguments']
    # 'len(t1)' represents the number of rows in the request payload.
    # The number of results in the response payload should be the same as the number of
    rows received.
    resp = [None]*len(t1)

    # Iterating over all rows in the request payload.
    for i, x in enumerate(t1):
        # Iterating over all the values in a single row.
        for j, y in enumerate(x):
            resp[i] = y.upper()

    time.sleep(3)
    ret = dict()
    ret['results'] = resp
    ret_json = json.dumps(ret)
    return ret_json
```

Following, two additional examples illustrate the `RETRY_TIMEOUT` attribute. They each invoke a single Lambda UDF. While invoking the Lambda UDF, each example runs the same SQL query to invoke the Lambda UDF from two concurrent database sessions at the same time. When first query that invokes the Lambda UDF is being served by the UDF, the second query receives the `TooManyRequestsException` error. This result occurs because you specifically set the reserved concurrency in the UDF to 1. For information on how to set reserved concurrency for Lambda functions, see [Configuring reserved concurrency](#).

The first example, following, sets the `RETRY_TIMEOUT` attribute for the Lambda UDF to 0 milliseconds. If the Lambda request receives any exceptions from the Lambda function, Amazon

Redshift doesn't make any retries. This result occurs because the `RETRY_TIMEOUT` attribute is set to 0.

```
CREATE OR REPLACE EXTERNAL FUNCTION exfunc_upper(varchar)
RETURNS varchar
VOLATILE
LAMBDA 'exfunc_sleep_3'
IAM_ROLE 'arn:aws:iam::123456789012:role/Redshift-Exfunc-Test'
RETRY_TIMEOUT 0;
```

With the `RETRY_TIMEOUT` set to 0, you can run the following two queries from separate database sessions to see different results.

The first SQL query that uses the Lambda UDF runs successfully.

```
select exfunc_upper('Varchar');
 exfunc_upper
-----
 VARCHAR
(1 row)
```

The second query, which is run from a separate database session at the same time, receives the `TooManyRequestsException` error.

```
select exfunc_upper('Varchar');
ERROR:  Rate Exceeded.; Exception: TooManyRequestsException; ShouldRetry: 1
DETAIL:
-----
error:  Rate Exceeded.; Exception: TooManyRequestsException; ShouldRetry: 1
code:      32103
context:query:      0
location:  exfunc_client.cpp:102
process:   padbmaster [pid=26384]
-----
```

The second example, following, sets the `RETRY_TIMEOUT` attribute for the Lambda UDF to 3,000 milliseconds. Even if the second query is run concurrently, the Lambda UDF retries until the total delays is 3,000 milliseconds. Thus, both queries run successfully.

```
CREATE OR REPLACE EXTERNAL FUNCTION exfunc_upper(varchar)
RETURNS varchar
```

```
VOLATILE
LAMBDA 'exfunc_sleep_3'
IAM_ROLE 'arn:aws:iam::123456789012:role/Redshift-Exfunc-Test'
RETRY_TIMEOUT 3000;
```

With the `RETRY_TIMEOUT` set to 3,000 milliseconds, you can run the following two queries from separate database sessions to see the same results.

The first SQL query that runs the Lambda UDF runs successfully.

```
select exfunc_upper('Varchar');
 exfunc_upper
-----
 VARCHAR
(1 row)
```

The second query runs concurrently, and the Lambda UDF retries until the total delay is 3,000 milliseconds.

```
select exfunc_upper('Varchar');
 exfunc_upper
-----
 VARCHAR
(1 row)
```

Scalar Lambda UDF example using a Python Lambda function

The following example creates an external function that is named `exfunc_multiplication` and that multiplies numbers and returns an integer. This example incorporates the `success` and `error_msg` fields in the Lambda response. The `success` field is set to `false` when there is an integer overflow in the multiplication result, and the `error_msg` message is set to `Integer multiplication overflow`. The `exfunc_multiplication` function takes three integers as input arguments and returns the sum as an integer output.

The name of the Lambda function that is called is `lambda_multiplication`. The language used for this Lambda function is Python 3.8. Make sure to specify the IAM role.

```
CREATE EXTERNAL FUNCTION exfunc_multiplication(int, int, int)
RETURNS INT
VOLATILE
```

```
LAMBDA 'lambda_multiplication'  
IAM_ROLE 'arn:aws:iam::123456789012:role/Redshift-Exfunc-Test';
```

The Lambda function takes in the request payload and iterates over each row. All the values in a single row are multiplied to calculate the result for that row, which is saved in the response list. This example uses a Boolean success value that is set to true by default. If the multiplication result for a row has an integer overflow, then the success value is set to false. Then the iteration loop breaks.

While creating the response payload, if the success value is false, the following Lambda function adds the `error_msg` field in the payload. It also sets the error message to `Integer multiplication overflow`. If the success value is true, then the result data is added in the `results` field. The number of rows in the results array, if any, is similar to the number of rows received in the request payload.

The `arguments` field in the request sent to the Lambda function contains the data payload. There can be multiple rows in the data payload in case of a batch request. The following Lambda function iterates over all the rows in the request data payload and individually iterates over all the values within a single row.

```
import json  
def lambda_handler(event, context):  
    t1 = event['arguments']  
    # 'len(t1)' represents the number of rows in the request payload.  
    # The number of results in the response payload should be the same as the number of  
    rows received.  
    resp = [None]*len(t1)  
  
    # By default success is set to 'True'.  
    success = True  
    # Iterating over all rows in the request payload.  
    for i, x in enumerate(t1):  
        mul = 1  
        # Iterating over all the values in a single row.  
        for j, y in enumerate(x):  
            mul = mul*y  
  
        # Check integer overflow.  
        if (mul >= 9223372036854775807 or mul <= -9223372036854775808):  
            success = False  
            break
```

```

        else:
            resp[i] = mul
    ret = dict()
    ret['success'] = success
    if not success:
        ret['error_msg'] = "Integer multiplication overflow"
    else:
        ret['results'] = resp
    ret_json = json.dumps(ret)

    return ret_json

```

The following example calls the external function with literal values.

```

SELECT exfunc_multiplication(8, 9, 2);
   exfunc_multiplication
-----
                144
(1 row)

```

The following example creates a table named `t_multi` with three columns, `c1`, `c2`, and `c3`, of the integer data type. The external function is called by passing the column names of this table. The data is inserted in such a way to cause integer overflow to show how the error is propagated.

```

CREATE TABLE t_multi (c1 int, c2 int, c3 int);
INSERT INTO t_multi VALUES (2147483647, 2147483647, 4);
SELECT exfunc_multiplication(c1, c2, c3) FROM t_multi;
DETAIL:
-----
error: Integer multiplication overflow
code:      32004context:
context:
query:     38
location:  exfunc_data.cpp:276
process:   query2_16_38 [pid=30494]
-----

```

CREATE EXTERNAL SCHEMA

Creates a new external schema in the current database. You can use this external schema to connect to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition

databases. You can also create an external schema that references a database in an external data catalog such as AWS Glue, Athena, or a database in an Apache Hive metastore, such as Amazon EMR.

The owner of this schema is the issuer of the CREATE EXTERNAL SCHEMA command. To transfer ownership of an external schema, use [ALTER SCHEMA](#) to change the owner. To grant access to the schema to other users or user groups, use the [GRANT](#) command.

You can't use the GRANT or REVOKE commands for permissions on an external table. Instead, grant or revoke the permissions on the external schema.

Note

If you currently have Redshift Spectrum external tables in the Amazon Athena data catalog, you can migrate your Athena data catalog to an AWS Glue Data Catalog. To use the AWS Glue Data Catalog with Redshift Spectrum, you might need to change your AWS Identity and Access Management (IAM) policies. For more information, see [Upgrading to the AWS Glue Data Catalog](#) in the *Athena User Guide*.

To view details for external schemas, query the [SVV_EXTERNAL_SCHEMAS](#) system view.

Syntax

The following syntax describes the CREATE EXTERNAL SCHEMA command used to reference data using an external data catalog. For more information, see [Amazon Redshift Spectrum](#).

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] local_schema_name
FROM [ [ DATA CATALOG ] | HIVE METASTORE | POSTGRES | MYSQL | KINESIS | MSK |
      REDSHIFT ]
[ DATABASE 'database_name' ]
[ SCHEMA 'schema_name' ]
[ REGION 'aws-region' ]
[ IAM_ROLE [ default | 'SESSION' | 'arn:aws:iam::<AWS account-id>:role/<role-name>' ] ]
[ AUTHENTICATION [ none | iam | mtls ] ]
[ AUTHENTICATION_ARN 'acm-certificate-arn' | SECRET_ARN 'ssm-secret- arn' ]
[ URI ['hive_metastore_uri' [ PORT port_number ] | 'hostname' [ PORT port_number ] |
      'msk bootstrap URL' ] ]
[ CLUSTER_ARN 'arn:aws:kafka:<region>:<AWS account-id>:cluster/msk/<cluster uuid>' ]
[ CATALOG_ROLE [ 'SESSION' | 'catalog-role-arn-string' ] ]
[ CREATE EXTERNAL DATABASE IF NOT EXISTS ]
```

```
[ CATALOG_ID 'Amazon Web Services account ID containing Glue or Lake Formation
  database' ]
```

The following syntax describes the CREATE EXTERNAL SCHEMA command used to reference data using a federated query to RDS POSTGRES or Aurora PostgreSQL. You can also create an external schema that references streaming sources, such as Kinesis Data Streams. For more information, see [Querying data with federated queries in Amazon Redshift](#).

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] local_schema_name
FROM POSTGRES
DATABASE 'federated_database_name' [SCHEMA 'schema_name']
URI 'hostname' [ PORT port_number ]
IAM_ROLE [ default | 'arn:aws:iam::<AWS account-id>:role/<role-name>' ]
SECRET_ARN 'ssm-secret-arn'
```

The following syntax describes the CREATE EXTERNAL SCHEMA command used to reference data using a federated query to RDS MySQL or Aurora MySQL. For more information, see [Querying data with federated queries in Amazon Redshift](#).

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] local_schema_name
FROM MYSQL
DATABASE 'federated_database_name'
URI 'hostname' [ PORT port_number ]
IAM_ROLE [ default | 'arn:aws:iam::<AWS account-id>:role/<role-name>' ]
SECRET_ARN 'ssm-secret-arn'
```

The following syntax describes the CREATE EXTERNAL SCHEMA command used to reference data in a Kinesis stream. For more information, see [Streaming ingestion to a materialized view](#).

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] schema_name
FROM KINESIS
IAM_ROLE [ default | 'arn:aws:iam::<AWS account-id>:role/<role-name>' ]
```

The following syntax describes the CREATE EXTERNAL SCHEMA command used to reference the Amazon Managed Streaming for Apache Kafka cluster and its topics to ingest from. To connect, you provide the broker URI. For more information, see [Streaming ingestion to a materialized view](#).

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] schema_name
FROM MSK
[ IAM_ROLE [ default | 'arn:aws:iam::<AWS account-id>:role/<role-name>' ] ]
```

```
URI 'msk_bootstrap_URL'  
AUTHENTICATION [ none | iam | mtls ]  
[ AUTHENTICATION_ARN 'acm-certificate-arn' | SECRET_ARN 'ssm-secret-arn' ];
```

The following syntax describes the CREATE EXTERNAL SCHEMA command used to reference data using a cross-database query.

```
CREATE EXTERNAL SCHEMA local_schema_name  
FROM REDSHIFT  
DATABASE 'redshift_database_name' SCHEMA 'redshift_schema_name'
```

Parameters

IF NOT EXISTS

A clause that indicates that if the specified schema already exists, the command should make no changes and return a message that the schema exists, rather than terminating with an error. This clause is useful when scripting, so the script doesn't fail if CREATE EXTERNAL SCHEMA tries to create a schema that already exists.

local_schema_name

The name of the new external schema. For more information about valid names, see [Names and identifiers](#).

FROM [DATA CATALOG] | HIVE METASTORE | POSTGRES | MYSQL | KINESIS | MSK | REDSHIFT

A keyword that indicates where the external database is located.

DATA CATALOG indicates that the external database is defined in the Athena data catalog or the AWS Glue Data Catalog.

If the external database is defined in an external Data Catalog in a different AWS Region, the REGION parameter is required. DATA CATALOG is the default.

HIVE METASTORE indicates that the external database is defined in an Apache Hive metastore. If HIVE METASTORE, is specified, URI is required.

POSTGRES indicates that the external database is defined in RDS PostgreSQL or Aurora PostgreSQL.

MYSQL indicates that the external database is defined in RDS MySQL or Aurora MySQL.

KINESIS indicates that the data source is a stream from Kinesis Data Streams.

MSK indicates that the data source is an Amazon MSK provisioned or serverless cluster.

FROM REDSHIFT

A keyword that indicates that the database is located in Amazon Redshift.

DATABASE '*redshift_database_name*' SCHEMA '*redshift_schema_name*'

The name of the Amazon Redshift database.

The *redshift_schema_name* indicates the schema in Amazon Redshift. The default *redshift_schema_name* is `public`.

DATABASE '*federated_database_name*'

A keyword that indicates the name of the external database in a supported PostgreSQL or MySQL database engine.

[SCHEMA '*schema_name*']

The *schema_name* indicates the schema in a supported PostgreSQL database engine. The default *schema_name* is `public`.

You can't specify a SCHEMA when you set up a federated query to a supported MySQL database engine.

REGION '*aws-region*'

If the external database is defined in an Athena data catalog or the AWS Glue Data Catalog, the AWS Region in which the database is located. This parameter is required if the database is defined in an external Data Catalog.

URI ['*hive_metastore_uri*' [PORT *port_number*] | '*hostname*' [PORT *port_number*] | '*msk bootstrap URL*']

The hostname URI and *port_number* of a supported PostgreSQL or MySQL database engine. The *hostname* is the head node of the replica set. The endpoint must be reachable (routable) from the Amazon Redshift cluster. The default PostgreSQL *port_number* is 5432. The default MySQL *port_number* is 3306.

Note

The supported PostgreSQL or MySQL database engine must be in the same VPC as your Amazon Redshift cluster with a security group linking Amazon Redshift and RDS url-

rsPostgreSQL or Aurora PostgreSQL. Additionally, you can use enhanced VPC routing to configure a cross-VPC use case. For more information, see [Redshift-managed VPC endpoints](#).

Specifying a hive metastore URI

If the database is in a Hive metastore, specify the URI and optionally the port number for the metastore. The default port number is 9083.

A URI doesn't contain a protocol specification ("http://"). An example valid URI: `uri '172.10.10.10'`.

Specifying a broker URI for streaming ingestion

Including the bootstrap-broker URI provides the ability to connect to an Amazon MSK cluster and receive streamed data. For more information and to see an example, see [Getting started with streaming ingestion from Amazon Managed Streaming for Apache Kafka](#).

```
IAM_ROLE [ default | 'SESSION' | 'arn:aws:iam::aws account-id:role/role-name' ]
```

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE EXTERNAL SCHEMA command runs.

Use 'SESSION' if you connect to your Amazon Redshift cluster using a federated identity and access the tables from the external schema created using this command. For more information, see [Using a federated identity to manage Amazon Redshift access to local resources and Amazon Redshift Spectrum external tables](#), which explains how to configure federated identity. Note that this configuration, using 'SESSION' in place of the ARN, can be used only if the schema is created using DATA CATALOG.

Use the Amazon Resource Name (ARN) for an IAM role that your cluster uses for authentication and authorization. As a minimum, the IAM role must have permission to perform a LIST operation on the Amazon S3 bucket to be accessed and a GET operation on the Amazon S3 objects the bucket contains.

The following shows the syntax for the IAM_ROLE parameter string for a single ARN.

```
IAM_ROLE 'arn:aws:iam::aws-account-id:role/role-name'
```

You can chain roles so that your cluster can assume another IAM role, possibly belonging to another account. You can chain up to 10 roles. For an example of chaining roles, see [Chaining IAM roles in Amazon Redshift Spectrum](#).

To this IAM role, attach an IAM permissions policy similar to the following.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessSecret",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetResourcePolicy",
        "secretsmanager:GetSecretValue",
        "secretsmanager:DescribeSecret",
        "secretsmanager:ListSecretVersionIds"
      ],
      "Resource": "arn:aws:secretsmanager:us-west-2:123456789012:secret:my-
rds-secret-VNenFy"
    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetRandomPassword",
        "secretsmanager:ListSecrets"
      ],
      "Resource": "*"
    }
  ]
}
```

For the steps to create an IAM role to use with federated query, see [Creating a secret and an IAM role to use federated queries](#).

Note

Don't include spaces in the list of chained roles.

The following shows the syntax for chaining three roles.

```
IAM_ROLE 'arn:aws:iam::<aws-account-id>:role/<role-1-name>,arn:aws:iam::<aws-account-id>:role/<role-2-name>,arn:aws:iam::<aws-account-id>:role/<role-3-name>'
```

```
SECRET_ARN 'ssm-secret-arn'
```

The Amazon Resource Name (ARN) of a supported PostgreSQL or MySQL database engine secret created using AWS Secrets Manager. For information about how to create and retrieve an ARN for a secret, see [Creating a Basic Secret](#) and [Retrieving the Secret Value Secret](#) in the *AWS Secrets Manager User Guide*.

```
CATALOG_ROLE [ 'SESSION' | catalog-role-arn-string]
```

Use 'SESSION' to connect to your Amazon Redshift cluster using a federated identity for authentication and authorization to the data catalog. For more information about completing the steps for federated identity, see [Using a federated identity to manage Amazon Redshift access to local resources and Amazon Redshift Spectrum external tables](#). Note that the 'SESSION' role can be used only if the schema is created in DATA CATALOG.

Use the Amazon Resource Name ARN for an IAM role that your cluster uses for authentication and authorization for the data catalog.

If CATALOG_ROLE isn't specified, Amazon Redshift uses the specified IAM_ROLE. The catalog role must have permission to access the Data Catalog in AWS Glue or Athena. For more information, see [IAM policies for Amazon Redshift Spectrum](#).

The following shows the syntax for the CATALOG_ROLE parameter string for a single ARN.

```
CATALOG_ROLE 'arn:aws:iam::<aws-account-id>:role/<catalog-role>'
```

You can chain roles so that your cluster can assume another IAM role, possibly belonging to another account. You can chain up to 10 roles. For more information, see [Chaining IAM roles in Amazon Redshift Spectrum](#).

Note

The list of chained roles must not include spaces.

The following shows the syntax for chaining three roles.

```
CATALOG_ROLE 'arn:aws:iam::<aws-account-id>:role/<catalog-role-1-name>,arn:aws:iam::<aws-account-id>:role/<catalog-role-2-name>,arn:aws:iam::<aws-account-id>:role/<catalog-role-3-name>'
```

CREATE EXTERNAL DATABASE IF NOT EXISTS

A clause that creates an external database with the name specified by the DATABASE argument, if the specified external database doesn't exist. If the specified external database exists, the command makes no changes. In this case, the command returns a message that the external database exists, rather than terminating with an error.

Note

You can't use CREATE EXTERNAL DATABASE IF NOT EXISTS with HIVE METASTORE. To use CREATE EXTERNAL DATABASE IF NOT EXISTS with a Data Catalog enabled for AWS Lake Formation, you need CREATE_DATABASE permission on the Data Catalog.

CATALOG_ID '*Amazon Web Services account ID containing Glue or Lake Formation database*'

The account id where the data catalog database is stored.

CATALOG_ID can be specified only if you plan to connect to your Amazon Redshift cluster or to Amazon Redshift Serverless using a federated identity for authentication and authorization to the data catalog by setting either of the following:

- CATALOG_ROLE to 'SESSION'
- IAM_ROLE to 'SESSION' and 'CATALOG_ROLE' set to its default

For more information about completing the steps for federated identity, see [Using a federated identity to manage Amazon Redshift access to local resources and Amazon Redshift Spectrum external tables](#).

AUTHENTICATION

The authentication type defined for streaming ingestion. Streaming ingestion with authentication types works with Amazon Managed Streaming for Apache Kafka. The AUTHENTICATION types are the following:

- **none** – Specifies that there is no authentication required. This corresponds to Unauthenticated access on MSK.

- **iam** – Specifies IAM authentication. When you choose this, make sure that the IAM role has permissions for IAM authentication. For more information about defining the external schema, see [Getting started with streaming ingestion from Amazon Managed Streaming for Apache Kafka \(Amazon MSK\)](#).
- **mtls** – Specifies that mutual transport layer security provides secure communication by facilitating authentication between a client and server. In this case, the client is Redshift and the server is Amazon MSK. For more information about configuring streaming ingestion with mTLS, see [Authentication with mTLS for Redshift streaming ingestion from Amazon MSK](#).

AUTHENTICATION_ARN

The ARN of the AWS Certificate Manager certificate used by Amazon Redshift for mTLS authentication with Amazon MSK. The ARN is available in the ACM console when you choose the issued certificate.

CLUSTER_ARN

For streaming ingestion, the CLUSTER_ARN is the cluster identifier for the Amazon Managed Streaming for Apache Kafka cluster you're streaming from. When using CLUSTER_ARN, it requires an IAM role policy that includes the `kafka:GetBootstrapBrokers` permission. This option is provided for backward compatibility. Currently, we recommend using the bootstrap-broker URI option to connect to Amazon Managed Streaming for Apache Kafka clusters. For more information, see [Streaming ingestion](#).

Usage notes

For limits when using the Athena data catalog, see [Athena Limits](#) in the AWS General Reference.

For limits when using the AWS Glue Data Catalog, see [AWS Glue Limits](#) in the AWS General Reference.

These limits don't apply to a Hive metastore.

There is a maximum of 9,900 schemas per database. For more information, see [Quotas and limits](#) in the *Amazon Redshift Management Guide*.

To unregister the schema, use the [DROP SCHEMA](#) command.

To view details for external schemas, query the following system views:

- [SVV_EXTERNAL_SCHEMAS](#)
- [SVV_EXTERNAL_TABLES](#)
- [SVV_EXTERNAL_COLUMNS](#)

Examples

The following example creates an external schema using a database in a data catalog named `sampledb` in the US West (Oregon) Region. Use this example with an Athena or AWS Glue data catalog.

```
create external schema spectrum_schema
from data catalog
database 'sampledb'
region 'us-west-2'
iam_role 'arn:aws:iam::123456789012:role/MySpectrumRole';
```

The following example creates an external schema and creates a new external database named `spectrum_db`.

```
create external schema spectrum_schema
from data catalog
database 'spectrum_db'
iam_role 'arn:aws:iam::123456789012:role/MySpectrumRole'
create external database if not exists;
```

The following example creates an external schema using a Hive metastore database named `hive_db`.

```
create external schema hive_schema
from hive metastore
database 'hive_db'
uri '172.10.10.10' port 99
iam_role 'arn:aws:iam::123456789012:role/MySpectrumRole';
```

The following example chains roles to use the role `myS3Role` for accessing Amazon S3 and uses `myAthenaRole` for data catalog access. For more information, see [Chaining IAM roles in Amazon Redshift Spectrum](#).

```
create external schema spectrum_schema
```

```
from data catalog
database 'spectrum_db'
iam_role 'arn:aws:iam::123456789012:role/myRedshiftRole,arn:aws:iam::123456789012:role/
myS3Role'
catalog_role 'arn:aws:iam::123456789012:role/myAthenaRole'
create external database if not exists;
```

The following example creates an external schema that references an Aurora PostgreSQL database.

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] myRedshiftSchema
FROM POSTGRES
DATABASE 'my_aurora_db' SCHEMA 'my_aurora_schema'
URI 'endpoint to aurora hostname' PORT 5432
IAM_ROLE 'arn:aws:iam::123456789012:role/MyAuroraRole'
SECRET_ARN 'arn:aws:secretsmanager:us-east-2:123456789012:secret:development/
MyTestDatabase-AbCdEf'
```

The following example creates an external schema to refer to the sales_db imported on the consumer cluster.

```
CREATE EXTERNAL SCHEMA sales_schema FROM REDSHIFT DATABASE 'sales_db' SCHEMA 'public';
```

The following example creates an external schema that references an Aurora MySQL database.

```
CREATE EXTERNAL SCHEMA [IF NOT EXISTS] myRedshiftSchema
FROM MYSQL
DATABASE 'my_aurora_db'
URI 'endpoint to aurora hostname'
IAM_ROLE 'arn:aws:iam::123456789012:role/MyAuroraRole'
SECRET_ARN 'arn:aws:secretsmanager:us-east-2:123456789012:secret:development/
MyTestDatabase-AbCdEf'
```

CREATE EXTERNAL TABLE

Creates a new external table in the specified schema. All external tables must be created in an external schema. Search path isn't supported for external schemas and external tables. For more information, see [CREATE EXTERNAL SCHEMA](#).

In addition to external tables created using the CREATE EXTERNAL TABLE command, Amazon Redshift can reference external tables defined in an AWS Glue or AWS Lake Formation catalog or

an Apache Hive metastore. Use the [CREATE EXTERNAL SCHEMA](#) command to register an external database defined in the external catalog and make the external tables available for use in Amazon Redshift. If the external table exists in an AWS Glue or AWS Lake Formation catalog or Hive metastore, you don't need to create the table using CREATE EXTERNAL TABLE. To view external tables, query the [SVV_EXTERNAL_TABLES](#) system view.

By running the CREATE EXTERNAL TABLE AS command, you can create an external table based on the column definition from a query and write the results of that query into Amazon S3. The results are in Apache Parquet or delimited text format. If the external table has a partition key or keys, Amazon Redshift partitions new files according to those partition keys and registers new partitions into the external catalog automatically. For more information about CREATE EXTERNAL TABLE AS, see [Usage notes](#).

You can query an external table using the same SELECT syntax you use with other Amazon Redshift tables. You can also use the INSERT syntax to write new files into the location of external table on Amazon S3. For more information, see [INSERT \(external table\)](#).

To create a view with an external table, include the WITH NO SCHEMA BINDING clause in the [CREATE VIEW](#) statement.

You can't run CREATE EXTERNAL TABLE inside a transaction (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).

Required privileges

To create external tables, you must be the owner of the external schema or a superuser. To transfer ownership of an external schema, use ALTER SCHEMA to change the owner. Access to external tables is controlled by access to the external schema. You can't [GRANT](#) or [REVOKE](#) permissions on an external table. Instead, grant or revoke USAGE on the external schema.

The [Usage notes](#) have additional information about specific permissions for external tables.

Syntax

```
CREATE EXTERNAL TABLE
  external_schema.table_name
  (column_name data_type [, ...] )
  [ PARTITIONED BY (col_name data_type [, ... ] ) ]
  [ { ROW FORMAT DELIMITED row_format |
    ROW FORMAT SERDE 'serde_name'
```

```
[ WITH SERDEPROPERTIES ( 'property_name' = 'property_value' [, ...] ) ] } ]
STORED AS file_format
LOCATION { 's3://bucket/folder/' | 's3://bucket/manifest_file' }
[ TABLE PROPERTIES ( 'property_name'='property_value' [, ...] ) ]
```

The following is the syntax for CREATE EXTERNAL TABLE AS.

```
CREATE EXTERNAL TABLE
external_schema.table_name
[ PARTITIONED BY (col_name [, ...] ) ]
[ ROW FORMAT DELIMITED row_format ]
STORED AS file_format
LOCATION { 's3://bucket/folder/' }
[ TABLE PROPERTIES ( 'property_name'='property_value' [, ...] ) ]
AS
{ select_statement }
```

Parameters

external_schema.table_name

The name of the table to be created, qualified by an external schema name. External tables must be created in an external schema. For more information, see [CREATE EXTERNAL SCHEMA](#).

The maximum length for the table name is 127 bytes; longer names are truncated to 127 bytes. You can use UTF-8 multibyte characters up to a maximum of four bytes. Amazon Redshift enforces a limit of 9,900 tables per cluster, including user-defined temporary tables and temporary tables created by Amazon Redshift during query processing or system maintenance. Optionally, you can qualify the table name with the database name. In the following example, the database name is `spectrum_db`, the external schema name is `spectrum_schema`, and the table name is `test`.

```
create external table spectrum_db.spectrum_schema.test (c1 int)
stored as parquet
location 's3://amzn-s3-demo-bucket/myfolder/';
```

If the database or schema specified doesn't exist, the table isn't created, and the statement returns an error. You can't create tables or views in the system databases `template0`, `template1`, `padb_harvest`, or `sys:internal`.

The table name must be a unique name for the specified schema.

For more information about valid names, see [Names and identifiers](#).

(*column_name data_type*)

The name and data type of each column being created.

The maximum length for the column name is 127 bytes; longer names are truncated to 127 bytes. You can use UTF-8 multibyte characters up to a maximum of four bytes. You can't specify column names "\$path" or "\$size". For more information about valid names, see [Names and identifiers](#).

By default, Amazon Redshift creates external tables with the pseudocolumns \$path and \$size. You can disable creation of pseudocolumns for a session by setting the spectrum_enable_pseudo_columns configuration parameter to false. For more information, see [Pseudocolumns](#).

If pseudocolumns are enabled, the maximum number of columns you can define in a single table is 1,598. If pseudocolumns aren't enabled, the maximum number of columns you can define in a single table is 1,600.

If you are creating a "wide table," make sure that your list of columns doesn't exceed row-width boundaries for intermediate results during loads and query processing. For more information, see [Usage notes](#).

For a CREATE EXTERNAL TABLE AS command, a column list is not required, because columns are derived from the query.

data_type

The following [Data types](#) are supported:

- SMALLINT (INT2)
- INTEGER (INT, INT4)
- BIGINT (INT8)
- DECIMAL (NUMERIC)
- REAL (FLOAT4)
- DOUBLE PRECISION (FLOAT8)
- BOOLEAN (BOOL)
- CHAR (CHARACTER)

- VARCHAR (CHARACTER VARYING)
- VARBYTE (CHARACTER VARYING) – can be used with Parquet and ORC data files, and only with non-partitioned tables.
- DATE – can be used only with text, Parquet, or ORC data files, or as a partition column.
- TIMESTAMP

For DATE, you can use the formats as described following. For month values represented using digits, the following formats are supported:

- mm-dd-yyyy For example, 05-01-2017. This is the default.
- yyyy-mm-dd, where the year is represented by more than 2 digits. For example, 2017-05-01.

For month values represented using the three letter abbreviation, the following formats are supported:

- mmm-dd-yyyy For example, may-01-2017. This is the default.
- dd-mmm-yyyy, where the year is represented by more than 2 digits. For example, 01-may-2017.
- yyyy-mmm-dd, where the year is represented by more than 2 digits. For example, 2017-may-01.

For year values that are consistently less than 100, the year is calculated in the following manner:

- If year is less than 70, the year is calculated as the year plus 2000. For example, the date 05-01-17 in the mm-dd-yyyy format is converted into 05-01-2017.
- If year is less than 100 and greater than 69, the year is calculated as the year plus 1900. For example the date 05-01-89 in the mm-dd-yyyy format is converted into 05-01-1989.
- For year values represented by two digits, add leading zeroes to represent the year in 4 digits.

Timestamp values in text files must be in the format yyyy-mm-dd HH:mm:ss.SSSSSS, as the following timestamp value shows: 2017-05-01 11:30:59.000000.

The length of a VARCHAR column is defined in bytes, not characters. For example, a VARCHAR(12) column can contain 12 single-byte characters or 6 two-byte characters. When you query an external table, results are truncated to fit the defined column size without returning an error. For more information, see [Storage and ranges](#).

For best performance, we recommend specifying the smallest column size that fits your data. To find the maximum size in bytes for values in a column, use the [OCTET_LENGTH](#) function. The following example returns the maximum size of values in the email column.

```
select max(octet_length(email)) from users;
```

```
max
---
62
```

PARTITIONED BY (*col_name data_type* [, ...])

A clause that defines a partitioned table with one or more partition columns. A separate data directory is used for each specified combination, which can improve query performance in some circumstances. Partitioned columns don't exist within the table data itself. If you use a value for *col_name* that is the same as a table column, you get an error.

After creating a partitioned table, alter the table using an [ALTER TABLE ... ADD PARTITION](#) statement to register new partitions to the external catalog. When you add a partition, you define the location of the subfolder on Amazon S3 that contains the partition data.

For example, if the table `spectrum.lineitem_part` is defined with `PARTITIONED BY (l_shipdate date)`, run the following `ALTER TABLE` command to add a partition.

```
ALTER TABLE spectrum.lineitem_part ADD PARTITION (l_shipdate='1992-01-29')
LOCATION 's3://spectrum-public/lineitem_partition/l_shipdate=1992-01-29';
```

If you are using `CREATE EXTERNAL TABLE AS`, you don't need to run `ALTER TABLE...ADD PARTITION`. Amazon Redshift automatically registers new partitions in the external catalog. Amazon Redshift also automatically writes corresponding data to partitions in Amazon S3 based on the partition key or keys defined in the table.

To view partitions, query the [SVV_EXTERNAL_PARTITIONS](#) system view.

Note

For a `CREATE EXTERNAL TABLE AS` command, you don't need to specify the data type of the partition column because this column is derived from the query.

ROW FORMAT DELIMITED *rowformat*

A clause that specifies the format of the underlying data. Possible values for *rowformat* are as follows:

- LINES TERMINATED BY '*delimiter*'
- FIELDS TERMINATED BY '*delimiter*'

Specify a single ASCII character for '*delimiter*'. You can specify non-printing ASCII characters using octal, in the format '*\ddd*' where *d* is an octal digit (0–7) up to '*\177*'. The following example specifies the BEL (bell) character using octal.

```
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\007'
```

If ROW FORMAT is omitted, the default format is DELIMITED FIELDS TERMINATED BY '\A' (start of heading) and LINES TERMINATED BY '\n' (newline).

ROW FORMAT SERDE '*serde_name*', [WITH SERDEPROPERTIES ('*property_name*' = '*property_value*' [, ...])]

A clause that specifies the SERDE format for the underlying data.

'serde_name'

The name of the SerDe. You can specify the following formats:

- org.apache.hadoop.hive.serde2.RegexSerDe
- com.amazonaws.glue.serde.GrokSerDe
- org.apache.hadoop.hive.serde2.OpenCSVSerde

This parameter supports the following SerDe property for OpenCSVSerde:

```
'wholeFile' = 'true'
```

Set the `wholeFile` property to `true` to properly parse new line characters (`\n`) within quoted strings for OpenCSV requests.

- org.openx.data.jsonserde.JsonSerDe
 - The JSON SERDE also supports Ion files.
 - The JSON must be well-formed.
 - Timestamps in Ion and JSON must use ISO8601 format.

- This parameter supports the following SerDe property for JsonSerDe:

```
'strip.outer.array'='true'
```

Processes Ion/JSON files containing one very large array enclosed in outer brackets ([...]) as if it contains multiple JSON records within the array.

- `com.amazon.ionhiveserde.IonHiveSerDe`

The Amazon ION format provides text and binary formats, in addition to data types. For an external table that references data in ION format, you map each column in the external table to the corresponding element in the ION format data. For more information, see [Amazon Ion](#). You also need to specify the input and output formats.

WITH SERDEPROPERTIES ('*property_name*' = '*property_value*' [, ...])]

Optionally, specify property names and values, separated by commas.

If ROW FORMAT is omitted, the default format is DELIMITED FIELDS TERMINATED BY '\A' (start of heading) and LINES TERMINATED BY '\n' (newline).

STORED AS *file_format*

The file format for data files.

Valid formats are as follows:

- PARQUET
- RCFILE (for data using ColumnarSerDe only, not LazyBinaryColumnarSerDe)
- SEQUENCEFILE
- TEXTFILE (for text files, including JSON files).
- ORC
- AVRO
- INPUTFORMAT '*input_format_classname*' OUTPUTFORMAT '*output_format_classname*'

The CREATE EXTERNAL TABLE AS command only supports two file formats, TEXTFILE and PARQUET.

For INPUTFORMAT and OUTPUTFORMAT, specify a class name, as the following example shows.

```
'org.apache.hadoop.mapred.TextInputFormat'
```

```
LOCATION { 's3://bucket/folder/' | 's3://bucket/manifest_file' }
```

The path to the Amazon S3 bucket or folder that contains the data files or a manifest file that contains a list of Amazon S3 object paths. The buckets must be in the same AWS Region as the Amazon Redshift cluster. For a list of supported AWS Regions, see [Amazon Redshift Spectrum limitations](#).

If the path specifies a bucket or folder, for example 's3://amzn-s3-demo-bucket/custdata/', Redshift Spectrum scans the files in the specified bucket or folder and any subfolders. Redshift Spectrum ignores hidden files and files that begin with a period or underscore.

If the path specifies a manifest file, the 's3://bucket/manifest_file' argument must explicitly reference a single file—for example, 's3://amzn-s3-demo-bucket/manifest.txt'. It can't reference a key prefix.

The manifest is a text file in JSON format that lists the URL of each file that is to be loaded from Amazon S3 and the size of the file, in bytes. The URL includes the bucket name and full object path for the file. The files that are specified in the manifest can be in different buckets, but all the buckets must be in the same AWS Region as the Amazon Redshift cluster. If a file is listed twice, the file is loaded twice. The following example shows the JSON for a manifest that loads three files.

```
{
  "entries": [
    {"url": "s3://amzn-s3-demo-bucket1/custdata.1", "meta": { "content_length":
5956875 } },
    {"url": "s3://amzn-s3-demo-bucket1/custdata.2", "meta": { "content_length":
5997091 } },
    {"url": "s3://amzn-s3-demo-bucket2/custdata.1", "meta": { "content_length":
5978675 } }
  ]
}
```

You can make the inclusion of a particular file mandatory. To do this, include a mandatory option at the file level in the manifest. When you query an external table with a mandatory file that is missing, the SELECT statement fails. Ensure that all files included in the definition of the external table are present. If they aren't all present, an error appears showing the first mandatory file that isn't found. The following example shows the JSON for a manifest with the mandatory option set to true.

```
{
  "entries": [
    {"url": "s3://amzn-s3-demo-bucket1/custdata.1", "mandatory": true, "meta":
  { "content_length": 5956875 } },
    {"url": "s3://amzn-s3-demo-bucket1/custdata.2", "mandatory": false, "meta":
  { "content_length": 5997091 } },
    {"url": "s3://amzn-s3-demo-bucket2/custdata.1", "meta": { "content_length":
  5978675 } }
  ]
}
```

To reference files created using UNLOAD, you can use the manifest created using [UNLOAD](#) with the MANIFEST parameter. The manifest file is compatible with a manifest file for [COPY from Amazon S3](#), but uses different keys. Keys that aren't used are ignored.

TABLE PROPERTIES ('*property_name*'=*property_value* [, ...])

A clause that sets the table definition for table properties.

 **Note**

Table properties are case-sensitive.

'compression_type'=*value*

A property that sets the type of compression to use if the file name doesn't contain an extension. If you set this property and there is a file extension, the extension is ignored and the value set by the property is used. Valid values for compression type are as follows:

- bzip2
- gzip
- none
- snappy

'data_cleansing_enabled'='true / false'

This property sets whether data handling is on for the table. When 'data_cleansing_enabled' is set to true, data handling is on for the table. When 'data_cleansing_enabled' is set to false, data handling is off for the table. Following is a list of the table-level data handling properties controlled by this property:

- `column_count_mismatch_handling`
- `invalid_char_handling`
- `numeric_overflow_handling`
- `replacement_char`
- `surplus_char_handling`

For examples, see [Data handling examples](#).

`'invalid_char_handling'='value'`

Specifies the action to perform when query results contain invalid UTF-8 character values. You can specify the following actions:

DISABLED

Doesn't perform invalid character handling.

FAIL

Cancels queries that return data containing invalid UTF-8 values.

SET_TO_NULL

Replaces invalid UTF-8 values with null.

DROP_ROW

Replaces each value in the row with null.

REPLACE

Replaces the invalid character with the replacement character you specify using `replacement_char`.

`'replacement_char'='character'`

Specifies the replacement character to use when you set `invalid_char_handling` to **REPLACE**.

`'numeric_overflow_handling'='value'`

Specifies the action to perform when ORC data contains an integer (for example, `BIGINT` or `int64`) that is larger than the column definition (for example, `SMALLINT` or `int16`). You can specify the following actions:

DISABLED

Invalid character handling is turned off.

FAIL

Cancel the query when the data includes invalid characters.

SET_TO_NULL

Set invalid characters to null.

DROP_ROW

Set each value in the row to null.

`'surplus_bytes_handling'='value'`

Specifies how to handle data being loaded that exceeds the length of the data type defined for columns containing VARBYTE data. By default, Redshift Spectrum sets the value to null for data that exceeds the width of the column.

You can specify the following actions to perform when the query returns data that exceeds the length of the data type:

SET_TO_NULL

Replaces data that exceeds the column width with null.

DISABLED

Doesn't perform surplus byte handling.

FAIL

Cancel queries that return data exceeding the column width.

DROP_ROW

Drop all rows that contain data exceeding column width.

TRUNCATE

Removes the characters that exceed the maximum number of characters defined for the column.

`'surplus_char_handling'='value'`

Specifies how to handle data being loaded that exceeds the length of the data type defined for columns containing VARCHAR, CHAR, or string data. By default, Redshift Spectrum sets the value to null for data that exceeds the width of the column.

You can specify the following actions to perform when the query returns data that exceeds the column width:

SET_TO_NULL

Replaces data that exceeds the column width with null.

DISABLED

Doesn't perform surplus character handling.

FAIL

Cancels queries that return data exceeding the column width.

DROP_ROW

Replaces each value in the row with null.

TRUNCATE

Removes the characters that exceed the maximum number of characters defined for the column.

`'column_count_mismatch_handling'='value'`

Identifies if the file contains less or more values for a row than the number of columns specified in the external table definition. This property is only available for an uncompressed text file format. You can specify the following actions:

DISABLED

Column count mismatch handling is turned off.

FAIL

Fail the query if the column count mismatch is detected.

SET_TO_NULL

Fill missing values with NULL and ignore the additional values in each row.

DROP_ROW

Drop all rows that contain column count mismatch error from the scan.

```
'numRows'='row_count'
```

A property that sets the `numRows` value for the table definition. To explicitly update an external table's statistics, set the `numRows` property to indicate the size of the table. Amazon Redshift doesn't analyze external tables to generate the table statistics that the query optimizer uses to generate a query plan. If table statistics aren't set for an external table, Amazon Redshift generates a query execution plan based on an assumption that external tables are the larger tables and local tables are the smaller tables.

```
'skip.header.line.count'='line_count'
```

A property that sets number of rows to skip at the beginning of each source file.

```
'serialization.null.format'=' '
```

A property that specifies Spectrum should return a NULL value when there is an exact match with the text supplied in a field.

```
'orc.schema.resolution'='mapping_type'
```

A property that sets the column mapping type for tables that use ORC data format. This property is ignored for other data formats.

Valid values for column mapping type are as follows:

- name
- position

If the `orc.schema.resolution` property is omitted, columns are mapped by name by default. If `orc.schema.resolution` is set to any value other than `'name'` or `'position'`, columns are mapped by position. For more information about column mapping, see [Mapping external table columns to ORC columns](#).

Note

The COPY command maps to ORC data files only by position. The `orc.schema.resolution` table property has no effect on COPY command behavior.

`'write.parallel'='on / off'`

A property that sets whether CREATE EXTERNAL TABLE AS should write data in parallel. By default, CREATE EXTERNAL TABLE AS writes data in parallel to multiple files, according to the number of slices in the cluster. The default option is on. When 'write.parallel' is set to off, CREATE EXTERNAL TABLE AS writes to one or more data files serially onto Amazon S3. This table property also applies to any subsequent INSERT statement into the same external table.

`'write.maxfilesize.mb'='size'`

A property that sets the maximum size (in MB) of each file written to Amazon S3 by CREATE EXTERNAL TABLE AS. The size must be a valid integer between 5 and 6200. The default maximum file size is 6,200 MB. This table property also applies to any subsequent INSERT statement into the same external table.

`'write.kms.key.id'='value'`

You can specify an AWS Key Management Service key to enable Server-Side Encryption (SSE) for Amazon S3 objects, where *value* is one of the following:

- `auto` to use the default AWS KMS key stored in the Amazon S3 bucket.
- `kms-key` that you specify to encrypt data.

select_statement

A statement that inserts one or more rows into the external table by defining any query. All rows that the query produces are written to Amazon S3 in either text or Parquet format based on the table definition.

Examples

A collection of examples is available at [Examples](#).

Usage notes

This topic contains usage notes for [CREATE EXTERNAL TABLE](#). You can't view details for Amazon Redshift Spectrum tables using the same resources that you use for standard Amazon Redshift tables, such as [PG_TABLE_DEF](#), [STV_TBL_PERM](#), `PG_CLASS`, or `information_schema`. If your business intelligence or analytics tool doesn't recognize Redshift Spectrum external tables, configure your application to query [SVV_EXTERNAL_TABLES](#) and [SVV_EXTERNAL_COLUMNS](#).

CREATE EXTERNAL TABLE AS

In some cases, you might run the CREATE EXTERNAL TABLE AS command on an AWS Glue Data Catalog, AWS Lake Formation external catalog, or Apache Hive metastore. In such cases, you use an AWS Identity and Access Management (IAM) role to create the external schema. This IAM role must have both read and write permissions on Amazon S3.

If you use a Lake Formation catalog, the IAM role must have the permission to create table in the catalog. In this case, it must also have the data lake location permission on the target Amazon S3 path. This IAM role becomes the owner of the new AWS Lake Formation table.

To ensure that file names are unique, Amazon Redshift uses the following format for the name of each file uploaded to Amazon S3 by default.

```
<date>_<time>_<microseconds>_<query_id>_<slice-number>_part_<part-number>.<format>.
```

An example is 20200303_004509_810669_1007_0001_part_00.parquet.

Consider the following when running the CREATE EXTERNAL TABLE AS command:

- The Amazon S3 location must be empty.
- Amazon Redshift only supports PARQUET and TEXTFILE formats when using the STORED AS clause.
- You don't need to define a column definition list. Column names and column data types of the new external table are derived directly from the SELECT query.
- You don't need to define the data type of the partition column in the PARTITIONED BY clause. If you specify a partition key, the name of this column must exist in the SELECT query result. When having multiple partition columns, their order in the SELECT query doesn't matter. Amazon Redshift uses their order defined in the PARTITIONED BY clause to create the external table.
- Amazon Redshift automatically partitions output files into partition folders based on the partition key values. By default, Amazon Redshift removes partition columns from the output files.
- The LINES TERMINATED BY 'delimiter' clause isn't supported.
- The ROW FORMAT SERDE 'serde_name' clause isn't supported.
- The use of manifest files isn't supported. Thus, you can't define the LOCATION clause to a manifest file on Amazon S3.

- Amazon Redshift automatically updates the 'numRows' table property at the end of the command.
- The 'compression_type' table property only accepts 'none' or 'snappy' for the PARQUET file format.
- Amazon Redshift doesn't allow the LIMIT clause in the outer SELECT query. Instead, you can use a nested LIMIT clause.
- You can use STL_UNLOAD_LOG to track the files that are written to Amazon S3 by each CREATE EXTERNAL TABLE AS operation.

Permissions to create and query external tables

To create external tables, make sure that you're the owner of the external schema or a superuser. To transfer ownership of an external schema, use [ALTER SCHEMA](#). The following example changes the owner of the spectrum_schema schema to newowner.

```
alter schema spectrum_schema owner to newowner;
```

To run a Redshift Spectrum query, you need the following permissions:

- Usage permission on the schema
- Permission to create temporary tables in the current database

The following example grants usage permission on the schema spectrum_schema to the spectrumusers user group.

```
grant usage on schema spectrum_schema to group spectrumusers;
```

The following example grants temporary permission on the database spectrumdb to the spectrumusers user group.

```
grant temp on database spectrumdb to group spectrumusers;
```

Pseudocolumns

By default, Amazon Redshift creates external tables with the pseudocolumns *\$path* and *\$size*. Select these columns to view the path to the data files on Amazon S3 and the size of the data

files for each row returned by a query. The *\$path* and *\$size* column names must be delimited with double quotation marks. A *SELECT ** clause doesn't return the pseudocolumns. You must explicitly include the *\$path* and *\$size* column names in your query, as the following example shows.

```
select "$path", "$size"
from spectrum.sales_part
where saledate = '2008-12-01';
```

You can disable creation of pseudocolumns for a session by setting the *spectrum_enable_pseudo_columns* configuration parameter to *false*.

Important

Selecting *\$size* or *\$path* incurs charges because Redshift Spectrum scans the data files in Amazon S3 to determine the size of the result set. For more information, see [Amazon Redshift Pricing](#).

Setting data handling options

You can set table parameters to specify input handling for data being queried in external tables, including:

- Surplus characters in columns containing VARCHAR, CHAR, and string data. For more information, see the external table property *surplus_char_handling*.
- Invalid characters in columns containing VARCHAR, CHAR, and string data. For more information, see the external table property *invalid_char_handling*.
- Replacement character to use when you specify REPLACE for the external table property *invalid_char_handling*.
- Cast overflow handling in columns containing integer and decimal data. For more information, see the external table property *numeric_overflow_handling*.
- *Surplus_bytes_handling* to specify input handling for surplus bytes in columns containing varbyte data. For more information, see the external table property *surplus_bytes_handling*.

Examples

The following example creates a table named SALES in the Amazon Redshift external schema named spectrum. The data is in tab-delimited text files. The TABLE PROPERTIES clause sets the numRows property to 170,000 rows.

Depending on the identity you use to run CREATE EXTERNAL TABLE, there may be IAM permissions that you have to configure. As a best practice, we recommend attaching permissions policies to an IAM role and then assigning it to users and groups as needed. For more information, see [Identity and access management in Amazon Redshift](#).

```
create external table spectrum.sales(  
  salesid integer,  
  listid integer,  
  sellerid integer,  
  buyerid integer,  
  eventid integer,  
  saledate date,  
  qty sold smallint,  
  pricepaid decimal(8,2),  
  commission decimal(8,2),  
  saletime timestamp)  
row format delimited  
fields terminated by '\t'  
stored as textfile  
location 's3://redshift-downloads/ticket/spectrum/sales/'  
table properties ('numRows'='170000');
```

The following example creates a table that uses the JsonSerDe to reference data in JSON format.

```
create external table spectrum.cloudtrail_json (  
  event_version int,  
  event_id bigint,  
  event_time timestamp,  
  event_type varchar(10),  
  awsregion varchar(20),  
  event_name varchar(max),  
  event_source varchar(max),  
  requesttime timestamp,  
  useragent varchar(max),  
  recipientaccountid bigint)  
row format serde 'org.openx.data.jsonserde.JsonSerDe'
```

```
with serdeproperties (
'dots.in.keys' = 'true',
'mapping.requesttime' = 'requesttimestamp'
) location 's3://amzn-s3-demo-bucket/json/cloudtrail';
```

The following CREATE EXTERNAL TABLE AS example creates a nonpartitioned external table. Then it writes the result of the SELECT query as Apache Parquet to the target Amazon S3 location.

```
CREATE EXTERNAL TABLE spectrum.lineitem
STORED AS parquet
LOCATION 'S3://amzn-s3-demo-bucket/cetas/lineitem/'
AS SELECT * FROM local_lineitem;
```

The following example creates a partitioned external table and includes the partition columns in the SELECT query.

```
CREATE EXTERNAL TABLE spectrum.partitioned_lineitem
PARTITIONED BY (l_shipdate, l_shipmode)
STORED AS parquet
LOCATION 'S3://amzn-s3-demo-bucket/cetas/partitioned_lineitem/'
AS SELECT l_orderkey, l_shipmode, l_shipdate, l_partkey FROM local_table;
```

For a list of existing databases in the external data catalog, query the [SVV_EXTERNAL_DATABASES](#) system view.

```
select eskind,databasename,esoptions from svv_external_databases order by databasename;
```

```
eskind | databasename | esoptions
-----+-----
+-----+-----
      1 | default      | {"REGION":"us-
west-2","IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
      1 | sampledb     | {"REGION":"us-
west-2","IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
      1 | spectrumdb   | {"REGION":"us-
west-2","IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
```

To view details of external tables, query the [SVV_EXTERNAL_TABLES](#) and [SVV_EXTERNAL_COLUMNS](#) system views.

The following example queries the SVV_EXTERNAL_TABLES view.

```
select schemaname, tablename, location from svv_external_tables;
```

schemaname	tablename	location
spectrum	sales	s3://redshift-downloads/ticket/spectrum/sales
spectrum	sales_part	s3://redshift-downloads/ticket/spectrum/
	sales_partition	

The following example queries the SVV_EXTERNAL_COLUMNS view.

```
select * from svv_external_columns where schemaname like 'spectrum%' and tablename = 'sales';
```

schemaname	tablename	columnname	external_type	columnnum	part_key
spectrum	sales	salesid	int	1	0
spectrum	sales	listid	int	2	0
spectrum	sales	sellerid	int	3	0
spectrum	sales	buyerid	int	4	0
spectrum	sales	eventid	int	5	0
spectrum	sales	saledate	date	6	0
spectrum	sales	qtysold	smallint	7	0
spectrum	sales	pricepaid	decimal(8,2)	8	0
spectrum	sales	commission	decimal(8,2)	9	0
spectrum	sales	saletime	timestamp	10	0

To view table partitions, use the following query.

```
select schemaname, tablename, values, location
from svv_external_partitions
where tablename = 'sales_part';
```

schemaname	tablename	values	location
spectrum	sales_part	["2008-01-01"]	s3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-01
spectrum	sales_part	["2008-02-01"]	s3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-02

```
spectrum | sales_part | ["2008-03-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-03
spectrum | sales_part | ["2008-04-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-04
spectrum | sales_part | ["2008-05-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-05
spectrum | sales_part | ["2008-06-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-06
spectrum | sales_part | ["2008-07-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-07
spectrum | sales_part | ["2008-08-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-08
spectrum | sales_part | ["2008-09-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-09
spectrum | sales_part | ["2008-10-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-10
spectrum | sales_part | ["2008-11-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-11
spectrum | sales_part | ["2008-12-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-12
```

The following example returns the total size of related data files for an external table.

```
select distinct "$path", "$size"
  from spectrum.sales_part;
```

\$path	\$size
s3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-01/	1616
s3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-02/	1444
s3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-02/	1444

Partitioning examples

To create an external table partitioned by date, run the following command.

```
create external table spectrum.sales_part(
  salesid integer,
  listid integer,
  sellerid integer,
  buyerid integer,
  eventid integer,
  dateid smallint,
```

```
qtysold smallint,  
pricepaid decimal(8,2),  
commission decimal(8,2),  
saletime timestamp)  
partitioned by (saledate date)  
row format delimited  
fields terminated by '|'   
stored as textfile  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/'  
table properties ('numRows'='170000');
```

To add the partitions, run the following ALTER TABLE commands.

```
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-01-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-01/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-02-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-02/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-03-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-03/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-04-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-04/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-05-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-05/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-06-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-06/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-07-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-07/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-08-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-08/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-09-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-09/';  
alter table spectrum.sales_part  
add if not exists partition (saledate='2008-10-01')  
location 's3://redshift-downloads/tickit/spectrum/sales_partition/saledate=2008-10/';
```

```
alter table spectrum.sales_part
add if not exists partition (saledate='2008-11-01')
location 's3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-11/';
alter table spectrum.sales_part
add if not exists partition (saledate='2008-12-01')
location 's3://redshift-downloads/ticket/spectrum/sales_partition/saledate=2008-12/';
```

To select data from the partitioned table, run the following query.

```
select top 10 spectrum.sales_part.eventid, sum(spectrum.sales_part.pricepaid)
from spectrum.sales_part, event
where spectrum.sales_part.eventid = event.eventid
and spectrum.sales_part.pricepaid > 30
and saledate = '2008-12-01'
group by spectrum.sales_part.eventid
order by 2 desc;
```

```
eventid | sum
-----+-----
    914 | 36173.00
   5478 | 27303.00
   5061 | 26383.00
   4406 | 26252.00
   5324 | 24015.00
   1829 | 23911.00
   3601 | 23616.00
   3665 | 23214.00
   6069 | 22869.00
   5638 | 22551.00
```

To view external table partitions, query the [SVV_EXTERNAL_PARTITIONS](#) system view.

```
select schemaname, tablename, values, location from svv_external_partitions
where tablename = 'sales_part';
```

```
schemaname | tablename | values          | location
-----+-----+-----
+-----
spectrum   | sales_part | ["2008-01-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-01
spectrum   | sales_part | ["2008-02-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-02
```

```
spectrum | sales_part | ["2008-03-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-03
spectrum | sales_part | ["2008-04-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-04
spectrum | sales_part | ["2008-05-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-05
spectrum | sales_part | ["2008-06-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-06
spectrum | sales_part | ["2008-07-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-07
spectrum | sales_part | ["2008-08-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-08
spectrum | sales_part | ["2008-09-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-09
spectrum | sales_part | ["2008-10-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-10
spectrum | sales_part | ["2008-11-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-11
spectrum | sales_part | ["2008-12-01"] | s3://redshift-downloads/ticket/spectrum/
sales_partition/saledate=2008-12
```

Row format examples

The following shows an example of specifying the ROW FORMAT SERDE parameters for data files stored in AVRO format.

```
create external table spectrum.sales(salesid int, listid int, sellerid int,
  buyerid int, eventid int, dateid int, qtysold int, pricepaid decimal(8,2), comment
  VARCHAR(255))
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.avro.AvroSerDe'
WITH SERDEPROPERTIES ('avro.schema.literal'='{\"namespace\": \"dory.sample\", \"name\":
  \"dory_avro\", \"type\": \"record\", \"fields\": [{\"name\": \"salesid\", \"type\": \"int
  \"},
  {\"name\": \"listid\", \"type\": \"int\"},
  {\"name\": \"sellerid\", \"type\": \"int\"},
  {\"name\": \"buyerid\", \"type\": \"int\"},
  {\"name\": \"eventid\", \"type\": \"int\"},
  {\"name\": \"dateid\", \"type\": \"int\"},
  {\"name\": \"qtysold\", \"type\": \"int\"},
  {\"name\": \"pricepaid\", \"type\": {\"type\": \"bytes\", \"logicalType\": \"decimal\",
  \"precision\": 8, \"scale\": 2}}, {\"name\": \"comment\", \"type\": \"string\"}}}')
STORED AS AVRO
location 's3://amzn-s3-demo-bucket/avro/sales' ;
```

The following shows an example of specifying the ROW FORMAT SERDE parameters using RegEx.

```
create external table spectrum.types(
  cbigint bigint,
  cbigint_null bigint,
  cint int,
  cint_null int)
row format serde 'org.apache.hadoop.hive.serde2.RegexSerDe'
with serdeproperties ('input.regex'='([^\x01]+)\x01([^\x01]+)\x01([^\x01]+)\x01([^\x01]+)')
stored as textfile
location 's3://amzn-s3-demo-bucket/regex/types';
```

The following shows an example of specifying the ROW FORMAT SERDE parameters using Grok.

```
create external table spectrum.grok_log(
  timestamp varchar(255),
  pid varchar(255),
  loglevel varchar(255),
  progname varchar(255),
  message varchar(255))
row format serde 'com.amazonaws.glue.serde.GrokSerDe'
with serdeproperties ('input.format'='[DFEWI], \\[%{TIMESTAMP_ISO8601:timestamp} #
%{POSINT:pid:int}\\.\\] *(?<loglevel>:DEBUG|FATAL|ERROR|WARN|INFO) -- +%{DATA:progname}:
%{GREEDYDATA:message}')
```

```
stored as textfile
location 's3://DOC-EXAMPLE-BUCKET/grok/logs';
```

The following shows an example of defining an Amazon S3 server access log in an S3 bucket. You can use Redshift Spectrum to query Amazon S3 access logs.

```
CREATE EXTERNAL TABLE spectrum.mybucket_s3_logs(
  bucketowner varchar(255),
  bucket varchar(255),
  requestdatetime varchar(2000),
  remoteip varchar(255),
  requester varchar(255),
  requested varchar(255),
  operation varchar(255),
  key varchar(255),
  requesturi_operation varchar(255),
  requesturi_key varchar(255),
```

```

requesturi_httpprotoversion varchar(255),
httpstatus varchar(255),
errorcode varchar(255),
bytessent bigint,
objectsize bigint,
totaltime varchar(255),
turnaroundtime varchar(255),
referrer varchar(255),
useragent varchar(255),
versionid varchar(255)
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
'input.regex' = '([^ ]*) ([^ ]*) \\[(.??)\\] ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
\\([^ ]*)\\s*([ ]*)\\s*([ ]*)\\" (- |[^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
([ ]*) (\\"[^\"]*"\\") ([^ ]*).*$')
LOCATION 's3://amzn-s3-demo-bucket/s3logs';

```

The following shows an example of specifying the ROW FORMAT SERDE parameters for ION format data.

```

CREATE EXTERNAL TABLE tbl_name (columns)
ROW FORMAT SERDE 'com.amazon.ionhiveserde.IonHiveSerDe'
STORED AS
INPUTFORMAT 'com.amazon.ionhiveserde.formats.IonInputFormat'
OUTPUTFORMAT 'com.amazon.ionhiveserde.formats.IonOutputFormat'
LOCATION 's3://amzn-s3-demo-bucket/prefix'

```

Data handling examples

The following examples access the file: [spi_global_rankings.csv](#). You can upload the `spi_global_rankings.csv` file to an Amazon S3 bucket to try these examples.

The following example creates the external schema `schema_spectrum_uddh` and database `spectrum_db_uddh`. For `aws-account-id`, enter your AWS account ID and for `role-name` enter your Redshift Spectrum role name.

```

create external schema schema_spectrum_uddh
from data catalog
database 'spectrum_db_uddh'
iam_role 'arn:aws:iam::aws-account-id:role/role-name'

```

```
create external database if not exists;
```

The following example creates the external table `soccer_league` in the external schema `schema_spectrum_uddh`.

```
CREATE EXTERNAL TABLE schema_spectrum_uddh.soccer_league
(
  league_rank smallint,
  prev_rank   smallint,
  club_name   varchar(15),
  league_name varchar(20),
  league_off  decimal(6,2),
  league_def  decimal(6,2),
  league_spi  decimal(6,2),
  league_nspi integer
)
ROW FORMAT DELIMITED
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n\\1'
stored as textfile
LOCATION 's3://spectrum-uddh/league/'
table properties ('skip.header.line.count'='1');
```

Check the number of rows in the `soccer_league` table.

```
select count(*) from schema_spectrum_uddh.soccer_league;
```

The numbers of rows displays.

```
count
645
```

The following query displays the top 10 clubs. Because club Barcelona has an invalid character in the string, a NULL is displayed for the name.

```
select league_rank, club_name, league_name, league_nspi
from schema_spectrum_uddh.soccer_league
where league_rank between 1 and 10;
```

```
league_rank club_name league_name league_nspi
1 Manchester City Barclays Premier Lea 34595
```

```

2 Bayern Munich German Bundesliga 34151
3 Liverpool Barclays Premier Lea 33223
4 Chelsea Barclays Premier Lea 32808
5 Ajax Dutch Eredivisie 32790
6 Atletico Madrid Spanish Primera Divi 31517
7 Real Madrid Spanish Primera Divi 31469
8 NULL Spanish Primera Divi 31321
9 RB Leipzig German Bundesliga 31014
10 Paris Saint-Ger French Ligue 1 30929

```

The following example alters the `soccer_league` table to specify the `invalid_char_handling`, `replacement_char`, and `data_cleansing_enabled` external table properties to insert a question mark (?) as a substitute for unexpected characters.

```

alter table schema_spectrum_uddh.soccer_league
set table properties
('invalid_char_handling'='REPLACE','replacement_char'='?','data_cleansing_enabled'='true');

```

The following example queries the table `soccer_league` for teams with a rank from 1 to 10.

```

select league_rank,club_name,league_name,league_nspi
from schema_spectrum_uddh.soccer_league
where league_rank between 1 and 10;

```

Because the table properties were altered, the results show the top 10 clubs, with the question mark (?) replacement character in the eighth row for club Barcelona.

```

league_rank club_name league_name league_nspi
1 Manchester City Barclays Premier Lea 34595
2 Bayern Munich German Bundesliga 34151
3 Liverpool Barclays Premier Lea 33223
4 Chelsea Barclays Premier Lea 32808
5 Ajax Dutch Eredivisie 32790
6 Atletico Madrid Spanish Primera Divi 31517
7 Real Madrid Spanish Primera Divi 31469
8 Barcel?na Spanish Primera Divi 31321
9 RB Leipzig German Bundesliga 31014
10 Paris Saint-Ger French Ligue 1 30929

```

The following example alters the `soccer_league` table to specify the `invalid_char_handling` external table properties to drop rows with unexpected characters.

```
alter table schema_spectrum_uddh.soccer_league
set table properties
('invalid_char_handling'='DROP_ROW', 'data_cleansing_enabled'='true');
```

The following example queries the table `soccer_league` for teams with a rank from 1 to 10.

```
select league_rank, club_name, league_name, league_nspi
from schema_spectrum_uddh.soccer_league
where league_rank between 1 and 10;
```

The results display the top clubs, not including the eighth row for club Barcelona.

league_rank	club_name	league_name	league_nspi
1	Manchester City	Barclays Premier Lea	34595
2	Bayern Munich	German Bundesliga	34151
3	Liverpool	Barclays Premier Lea	33223
4	Chelsea	Barclays Premier Lea	32808
5	Ajax	Dutch Eredivisie	32790
6	Atletico Madrid	Spanish Primera Divi	31517
7	Real Madrid	Spanish Primera Divi	31469
9	RB Leipzig	German Bundesliga	31014
10	Paris Saint-Ger	French Ligue 1	30929

CREATE EXTERNAL VIEW

The Data Catalog views preview feature is available only in the following Regions.

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Europe (Ireland) (eu-west-1)
- Europe (Stockholm) (eu-north-1)

Creates a view in the Data Catalog. Data Catalog views are a single view schema that works with other SQL engines such as Amazon Athena and Amazon EMR. You can query the view from your choice of engine. For more information about Data Catalog views, see [Creating Data Catalog views](#).

Syntax

```
CREATE EXTERNAL VIEW schema_name.view_name [ IF NOT EXISTS ]
{catalog_name.schema_name.view_name | awsdatalog.dbname.view_name |
 external_schema_name.view_name}
AS query_definition;
```

Parameters

schema_name.view_name

The schema that's attached to your AWS Glue database, followed by the name of the view.

PROTECTED

Specifies that the CREATE EXTERNAL VIEW command should only complete if the query within the query_definition can successfully complete.

IF NOT EXISTS

Creates the view if the view doesn't already exist.

catalog_name.schema_name.view_name | awsdatalog.dbname.view_name |
external_schema_name.view_name

The notation of the schema to use when creating the view. You can specify to use the AWS Glue Data Catalog, a Glue database that you created, or an external schema that you created. See [CREATE DATABASE](#) and [CREATE EXTERNAL SCHEMA](#) for more information.

query_definition

The definition of the SQL query that Amazon Redshift runs to alter the view.

Examples

The following example creates a Data Catalog view named sample_schema.glue_data_catalog_view.

```
CREATE EXTERNAL PROTECTED VIEW sample_schema.glue_data_catalog_view IF NOT EXISTS
AS SELECT * FROM sample_database.remote_table "remote-table-name";
```

CREATE FUNCTION

Creates a new scalar user-defined function (UDF) using either a SQL SELECT clause or a Python program.

For more information and examples, see [User-defined functions](#).

Required privileges

You must have permission by one of the following ways to run CREATE OR REPLACE FUNCTION:

- For CREATE FUNCTION:
 - Superuser can use both trusted and untrusted languages to create functions.
 - Users with the CREATE [OR REPLACE] FUNCTION privilege can create functions with trusted languages.
- For REPLACE FUNCTION:
 - Superuser
 - Users with the CREATE [OR REPLACE] FUNCTION privilege
 - Function owner

Syntax

```
CREATE [ OR REPLACE ] FUNCTION f_function_name
( { [py_arg_name py_arg_data_type |
sql_arg_data_type } [ , ... ] ] )
RETURNS data_type
{ VOLATILE | STABLE | IMMUTABLE }
AS $$
  { python_program | SELECT_clause }
$$ LANGUAGE { plpythonu | sql }
```

Parameters

OR REPLACE

Specifies that if a function with the same name and input argument data types, or *signature*, as this one already exists, the existing function is replaced. You can only replace a function with a new function that defines an identical set of data types. You must be a superuser to replace a function.

If you define a function with the same name as an existing function but a different signature, you create a new function. In other words, the function name is overloaded. For more information, see [Overloading function names](#).

f_function_name

The name of the function. If you specify a schema name (such as `myschema.myfunction`), the function is created using the specified schema. Otherwise, the function is created in the current schema. For more information about valid names, see [Names and identifiers](#).

We recommend that you prefix all UDF names with `f_`. Amazon Redshift reserves the `f_` prefix for UDF names, so by using the `f_` prefix, you ensure that your UDF name will not conflict with any existing or future Amazon Redshift built-in SQL function names. For more information, see [Preventing UDF naming conflicts](#).

You can define more than one function with the same function name if the data types for the input arguments are different. In other words, the function name is overloaded. For more information, see [Overloading function names](#).

py_arg_name py_arg_data_type | sql_arg_data_type

For a Python UDF, a list of input argument names and data types. For a SQL UDF, a list of data types, without argument names. In a Python UDF, refer to arguments using the argument names. In a SQL UDF, refer to arguments using `$1`, `$2`, and so on, based on the order of the arguments in the argument list.

For a SQL UDF, the input and return data types can be any standard Amazon Redshift data type. For a Python UDF, the input and return data types can be `SMALLINT`, `INTEGER`, `BIGINT`, `DECIMAL`, `REAL`, `DOUBLE PRECISION`, `BOOLEAN`, `CHAR`, `VARCHAR`, `DATE`, or `TIMESTAMP`. In addition, Python user-defined functions (UDFs) support a data type of `ANYELEMENT`. This is automatically converted to a standard data type based on the data type of the corresponding argument supplied at runtime. If multiple arguments use `ANYELEMENT`, they all resolve to the same data type at runtime, based on the first `ANYELEMENT` argument in the list. For more information, see [Python UDF data types](#) and [Data types](#).

You can specify a maximum of 32 arguments.

RETURNS *data_type*

The data type of the value returned by the function. The `RETURNS` data type can be any standard Amazon Redshift data type. In addition, Python UDFs can use a data type of `ANYELEMENT`, which is automatically converted to a standard data type based on the argument

supplied at runtime. If you specify ANYELEMENT for the return data type, at least one argument must use ANYELEMENT. The actual return data type matches the data type supplied for the ANYELEMENT argument when the function is called. For more information, see [Python UDF data types](#).

VOLATILE | STABLE | IMMUTABLE

Informs the query optimizer about the volatility of the function.

You will get the best optimization if you label your function with the strictest volatility category that is valid for it. However, if the category is too strict, there is a risk that the optimizer will erroneously skip some calls, resulting in an incorrect result set. In order of strictness, beginning with the least strict, the volatility categories are as follows:

- VOLATILE
- STABLE
- IMMUTABLE

VOLATILE

Given the same arguments, the function can return different results on successive calls, even for the rows in a single statement. The query optimizer can't make any assumptions about the behavior of a volatile function, so a query that uses a volatile function must reevaluate the function for every input row.

STABLE

Given the same arguments, the function is guaranteed to return the same results for all rows processed within a single statement. The function can return different results when called in different statements. This category allows the optimizer to optimize multiple calls of the function within a single statement to a single call for the statement.

IMMUTABLE

Given the same arguments, the function always returns the same result, forever. When a query calls an IMMUTABLE function with constant arguments, the optimizer pre-evaluates the function.

AS \$\$ *statement* \$\$

A construct that encloses the statement to be run. The literal keywords AS \$\$ and \$\$ are required.

Amazon Redshift requires you to enclose the statement in your function by using a format called dollar quoting. Anything within the enclosure is passed exactly as is. You don't need to escape any special characters because the contents of the string are written literally.

With *dollar quoting*, you use a pair of dollar signs (\$\$) to signify the start and the end of the statement to run, as shown in the following example.

```
$$ my statement $$
```

Optionally, between the dollar signs in each pair, you can specify a string to help identify the statement. The string that you use must be the same in both the start and the end of the enclosure pairs. This string is case-sensitive, and it follows the same constraints as an unquoted identifier except that it can't contain dollar signs. The following example uses the string `test`.

```
$test$ my statement $test$
```

For more information about dollar quoting, see "Dollar-quoted String Constants" under [Lexical Structure](#) in the PostgreSQL documentation.

python_program

A valid executable Python program that returns a value. The statement that you pass in with the function must conform to indentation requirements as specified in the [Style Guide for Python Code](#) on the Python website. For more information, see [Python language support for UDFs](#).

SQL_clause

A SQL SELECT clause.

The SELECT clause can't include any of the following types of clauses:

- FROM
- INTO
- WHERE
- GROUP BY
- ORDER BY
- LIMIT

LANGUAGE { plpythonu | sql }

For Python, specify `plpythonu`. For SQL, specify `sql`. You must have permission for usage on language for SQL or `plpythonu`. For more information, see [UDF security and permissions](#).

Usage notes

Nested functions

You can call another SQL user-defined function (UDF) from within a SQL UDF. The nested function must exist when you run the `CREATE FUNCTION` command. Amazon Redshift doesn't track dependencies for UDFs, so if you drop the nested function, Amazon Redshift doesn't return an error. However, the UDF will fail if the nested function doesn't exist. For example, the following function calls the `f_sql_greater` function in the `SELECT` clause.

```
create function f_sql_commission (float, float )
  returns float
  stable
  as $$
  select f_sql_greater ($1, $2)
  $$ language sql;
```

UDF security and privileges

To create a UDF, you must have permission for usage on language for SQL or `plpythonu` (Python). By default, `USAGE ON LANGUAGE SQL` is granted to `PUBLIC`. However, you must explicitly grant `USAGE ON LANGUAGE PLPYTHONU` to specific users or groups.

To revoke usage for SQL, first revoke usage from `PUBLIC`. Then grant usage on SQL only to the specific users or groups permitted to create SQL UDFs. The following example revokes usage on SQL from `PUBLIC` then grants usage to the user group `udf_devs`.

```
revoke usage on language sql from PUBLIC;
grant usage on language sql to group udf_devs;
```

To run a UDF, you must have execute permission for each function. By default, execute permission for new UDFs is granted to `PUBLIC`. To restrict usage, revoke execute permission from `PUBLIC` for the function. Then grant the privilege to specific individuals or groups.

The following example revokes execute permission on function `f_py_greater` from PUBLIC then grants usage to the user group `udf_devs`.

```
revoke execute on function f_py_greater(a float, b float) from PUBLIC;
grant execute on function f_py_greater(a float, b float) to group udf_devs;
```

Superusers have all privileges by default.

For more information, see [GRANT](#) and [REVOKE](#).

Examples

Scalar Python UDF example

The following example creates a Python UDF that compares two integers and returns the larger value.

```
create function f_py_greater (a float, b float)
  returns float
  stable
  as $$
  if a > b:
    return a
  return b
  $$ language plpythonu;
```

The following example queries the SALES table and calls the new `f_py_greater` function to return either COMMISSION or 20 percent of PRICEPAID, whichever is greater.

```
select f_py_greater (commission, pricepaid*0.20) from sales;
```

Scalar SQL UDF example

The following example creates a function that compares two numbers and returns the larger value.

```
create function f_sql_greater (float, float)
  returns float
  stable
  as $$
  select case when $1 > $2 then $1
    else $2
```

```
end  
$$ language sql;
```

The following query calls the new `f_sql_greater` function to query the SALES table and returns either COMMISSION or 20 percent of PRICEPAID, whichever is greater.

```
select f_sql_greater (commission, pricepaid*0.20) from sales;
```

CREATE GROUP

Defines a new user group. Only a superuser can create a group.

Syntax

```
CREATE GROUP group_name  
[ [ WITH ] [ USER username ] [, ...] ]
```

Parameters

group_name

Name of the new user group. Group names beginning with two underscores are reserved for Amazon Redshift internal use. For more information about valid names, see [Names and identifiers](#).

WITH

Optional syntax to indicate additional parameters for CREATE GROUP.

USER

Add one or more users to the group.

username

Name of the user to add to the group.

Examples

The following example creates a user group named ADMIN_GROUP with a two users, ADMIN1 and ADMIN2.

```
create group admin_group with user admin1, admin2;
```

CREATE IDENTITY PROVIDER

Defines a new identity provider. Only a superuser can create an identity provider.

Syntax

```
CREATE IDENTITY PROVIDER identity_provider_name TYPE type_name  
NAMESPACE namespace_name  
[PARAMETERS parameter_string]  
[APPLICATION_ARN arn]  
[IAM_ROLE iam_role]
```

Parameters

identity_provider_name

Name of the new identity provider. For more information about valid names, see [Names and identifiers](#).

type_name

The identity provider to interface with. Azure is currently the only supported identity provider.

namespace_name

The namespace. This is a unique, shorthand identifier for the identity provider directory.

parameter_string

A string containing a properly formatted JSON object that contains parameters and values required for the identity provider.

arn

The Amazon resource name (ARN) for an IAM Identity Center managed application. This parameter is applicable only when the identity-provider type is AWSIDC.

iam_role

The IAM role that provides permissions to make the connection to IAM Identity Center. This parameter is applicable only when the identity-provider type is AWSIDC.

Examples

The following example creates an identity provider named *oauth_standard*, with a TYPE *azure*, to establish communication with Microsoft Azure Active Directory (AD).

```
CREATE IDENTITY PROVIDER oauth_standard TYPE azure
NAMESPACE 'aad'
PARAMETERS '{"issuer":"https://sts.windows.net/2sdfdsf-d475-420d-b5ac-667adad7c702/",
"client_id":"87f4aa26-78b7-410e-bf29-57b39929ef9a",
"client_secret":"BUAH~ewrqewrqwerUUY^%tHe1oNZShoiU7",
"audience":["https://analysis.windows.net/powerbi/connector/AmazonRedshift"]}
}'
```

You can connect an IAM Identity Center managed application with an existing provisioned cluster or Amazon Redshift Serverless workgroup. This gives you the ability to manage access to a Redshift database through IAM Identity Center. To do so, run a SQL command like the following sample. You have to be a database administrator.

```
CREATE IDENTITY PROVIDER "redshift-idc-app" TYPE AWSIDC
NAMESPACE 'awsidc'
APPLICATION_ARN 'arn:aws:sso::123456789012:application/ssoins-12345f67fe123d4/ap1-
a0b0a12dc123b1a4'
IAM_ROLE 'arn:aws:iam::123456789012:role/MyRedshiftRole';
```

The application ARN in this case identifies the managed application to connect to. You can find it by running `SELECT * FROM SVV_IDENTITY_PROVIDERS;`

For more information about using `CREATE IDENTITY PROVIDER`, including additional examples, see [Native identity provider \(IdP\) federation for Amazon Redshift](#). For more information about setting up a connection to IAM Identity Center from Redshift, see [Connect Redshift with IAM Identity Center to give users a single sign-on experience](#).

CREATE LIBRARY

Installs a Python library, which is available for users to incorporate when creating a user-defined function (UDF) with the [CREATE FUNCTION](#) command. The total size of user-installed libraries can't exceed 100 MB.

`CREATE LIBRARY` can't be run inside a transaction block (`BEGIN ... END`). For more information about transactions, see [Serializable isolation](#).

Amazon Redshift supports Python version 2.7. For more information, see www.python.org.

For more information, see [Example: Importing custom Python library modules](#).

Required privileges

Following are required privileges for CREATE LIBRARY:

- Superuser
- Users with the CREATE LIBRARY privilege or with the privilege of the specified language

Syntax

```
CREATE [ OR REPLACE ] LIBRARY library_name LANGUAGE plpythonu
FROM
{ 'https://file_url'
| 's3://bucketname/file_name'
authorization
  [ REGION [AS] 'aws_region' ]
  IAM_ROLE { default | 'arn:aws:iam::<AWS account-id>:role/<role-name>' }
}
```

Parameters

OR REPLACE

Specifies that if a library with the same name as this one already exists, the existing library is replaced. REPLACE commits immediately. If a UDF that depends on the library is running concurrently, the UDF might fail or return unexpected results, even if the UDF is running within a transaction. You must be the owner or a superuser to replace a library.

library_name

The name of the library to be installed. You can't create a library that contains a module with the same name as a Python Standard Library module or an Amazon Redshift preinstalled Python module. If an existing user-installed library uses the same Python package as the library to be installed, you must drop the existing library before installing the new library. For more information, see [Python language support for UDFs](#).

LANGUAGE plpythonu

The language to use. Python (plpythonu) is the only supported language. Amazon Redshift supports Python version 2.7. For more information, see www.python.org.

FROM

The location of the library file. You can specify an Amazon S3 bucket and object name, or you can specify a URL to download the file from a public website. The library must be packaged in the form of a .zip file. For more information, see [Building and Installing Python Modules](#) in the Python documentation.

https://file_url

The URL to download the file from a public website. The URL can contain up to three redirects. The following is an example of a file URL.

```
'https://www.example.com/pylib.zip'
```

s3://bucket_name/file_name

The path to a single Amazon S3 object that contains the library file. The following is an example of an Amazon S3 object path.

```
's3://amzn-s3-demo-bucket/my-pylib.zip'
```

If you specify an Amazon S3 bucket, you must also provide credentials for an AWS user that has permission to download the file.

Important

If the Amazon S3 bucket doesn't reside in the same AWS Region as your Amazon Redshift cluster, you must use the `REGION` option to specify the AWS Region in which the data is located. The value for `aws_region` must match an AWS Region listed in the table in the [REGION](#) parameter description for the `COPY` command.

authorization

A clause that indicates the method your cluster uses for authentication and authorization to access the Amazon S3 bucket that contains the library file. Your cluster must have permission to access the Amazon S3 with the `LIST` and `GET` actions.

The syntax for authorization is the same as for the COPY command authorization. For more information, see [Authorization parameters](#).

```
IAM_ROLE { default | 'arn:aws:iam::<AWS account-id>:role/<role-name>' }
```

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE LIBRARY command runs.

Use the Amazon Resource Name (ARN) for an IAM role that your cluster uses for authentication and authorization. If you specify IAM_ROLE, you can't use ACCESS_KEY_ID and SECRET_ACCESS_KEY, SESSION_TOKEN, or CREDENTIALS.

Optionally, if the Amazon S3 bucket uses server-side encryption, provide the encryption key in the credentials-args string. If you use temporary security credentials, provide the temporary token in the *credentials-args* string.

For more information, see [Temporary security credentials](#).

REGION [AS] *aws_region*

The AWS Region where the Amazon S3 bucket is located. REGION is required when the Amazon S3 bucket isn't in the same AWS Region as the Amazon Redshift cluster. The value for *aws_region* must match an AWS Region listed in the table in the [REGION](#) parameter description for the COPY command.

By default, CREATE LIBRARY assumes that the Amazon S3 bucket is located in the same AWS Region as the Amazon Redshift cluster.

Examples

The following two examples install the [urlparse](#) Python module, which is packaged in a file named `urlparse3-1.0.3.zip`.

The following command installs a UDF library named `f_urlparse` from a package that has been uploaded to an Amazon S3 bucket located in the US East Region.

```
create library f_urlparse
language plpythonu
from 's3://amzn-s3-demo-bucket/urlparse3-1.0.3.zip'
credentials 'aws_iam_role=arn:aws:iam::<aws-account-id>:role/<role-name>'
```

```
region as 'us-east-1';
```

The following example installs a library named `f_urlparse` from a library file on a website.

```
create library f_urlparse
language plpythonu
from 'https://example.com/packages/urlparse3-1.0.3.zip';
```

CREATE MASKING POLICY

Creates a new dynamic data masking policy to obfuscate data of a given format. For more information on dynamic data masking, see [Dynamic data masking](#).

Superusers and users or roles that have the `sys:secadmin` role can create a masking policy.

Syntax

```
CREATE MASKING POLICY
  policy_name [IF NOT EXISTS]
  WITH (input_columns)
  USING (masking_expression);
```

Parameters

policy_name

The name of the masking policy. The masking policy can't have the same name as another masking policy that already exists in the database.

input_columns

A tuple of column names in the format (col1 type, col2 type ...).

Column names are used as the input for the masking expression. Column names don't have to match the names of the columns being masked, but the input and output data types must match.

masking_expression

The SQL expression used to transform the target columns. It can be written using data manipulation functions such as String manipulation functions, or in conjunction with user-

defined functions written in SQL, Python, or with AWS Lambda. You can include a tuple of column expressions for masking policies that have multiple outputs. If you use a constant as your masking expression, you must explicitly cast it to a type that matches the input type.

You must have the `USAGE` permission on any user-defined functions that you use in the masking expression.

CREATE MATERIALIZED VIEW

Creates a materialized view based on one or more Amazon Redshift tables. You can also base materialized views on external tables created using Spectrum or federated query. For information about Spectrum, see [Amazon Redshift Spectrum](#). For information about federated query, see [Querying data with federated queries in Amazon Redshift](#).

Syntax

```
CREATE MATERIALIZED VIEW mv_name
[ BACKUP { YES | NO } ]
[ table_attributes ]
[ AUTO REFRESH { YES | NO } ]
AS query
```

Parameters

BACKUP

A clause that specifies whether the materialized view should be included in automated and manual cluster snapshots.

For materialized views that don't contain critical data, specify `BACKUP NO` to save processing time when creating snapshots and restoring from snapshots and to reduce storage space on Amazon Simple Storage Service. The `BACKUP NO` setting has no effect on automatic replication of data to other nodes within the cluster, so materialized views with `BACKUP NO` specified are restored in the event of a node failure. The default is `BACKUP YES`.

table_attributes

A clause that specifies how the data in the materialized view is distributed, including the following:

- The distribution style for the materialized view, in the format `DISTSTYLE { EVEN | ALL | KEY }`. If you omit this clause, the distribution style is `EVEN`. For more information, see [Distribution styles](#).
- The distribution key for the materialized view, in the format `DISTKEY (distkey_identifier)`. For more information, see [Designating distribution styles](#).
- The sort key for the materialized view, in the format `SORTKEY (column_name [, ...])`. For more information, see [Sort keys](#).

AS query

A valid `SELECT` statement that defines the materialized view and its content. The result set from the query defines the columns and rows of the materialized view. For information about limitations when creating materialized views, see [Limitations](#).

Furthermore, specific SQL language constructs used in the query determines whether the materialized view can be incrementally or fully refreshed. For information about the refresh method, see [REFRESH MATERIALIZED VIEW](#). For information about the limitations for incremental refresh, see [Limitations for incremental refresh](#).

If the query contains an SQL command that doesn't support incremental refresh, Amazon Redshift displays a message indicating that the materialized view will use a full refresh. The message may or may not be displayed, depending on the SQL client application. Check the state column of the [STV_MV_INFO](#) to see the refresh type used by a materialized view.

AUTO REFRESH

A clause that defines whether the materialized view should be automatically refreshed with latest changes from its base tables. The default value is `NO`. For more information, see [Refreshing a materialized view](#).

Usage notes

To create a materialized view, you must have the following privileges:

- `CREATE` privileges for a schema.
- Table-level or column-level `SELECT` privilege on the base tables to create a materialized view. If you have column-level privileges on specific columns, you can create a materialized view on only those columns.

Incremental refresh for materialized views in a datashare

Amazon Redshift supports automatic and incremental refresh for materialized views in a consumer datashare when the base tables are shared. Incremental refresh is an operation where Amazon Redshift identifies changes in the base table or tables that happened after the previous refresh and updates only the corresponding records in the materialized view. This runs more quickly than a full refresh and improves workload performance. You don't have to change your materialized-view definition to take advantage of incremental refresh.

There are a couple limitations to note for taking advantage of incremental refresh with a materialized view:

- The materialized view must reference only one database, either local or remote.
- Incremental refresh is available only on new materialized views. Therefore, you must drop existing materialized views and recreate them for incremental refresh to occur.

For more information about creating materialized views in a datashare, see [Working with views in Amazon Redshift data sharing](#), which contains several query examples.

DDL updates to materialized views or base tables

When using materialized views in Amazon Redshift, follow these usage notes for data definition language (DDL) updates to materialized views or base tables.

- You can add columns to a base table without affecting any materialized views that reference the base table.
- Some operations can leave the materialized view in a state that can't be refreshed at all. Examples are operations such as renaming or dropping a column, changing the type of a column, and changing the name of a schema. Such materialized views can be queried but can't be refreshed. In this case, you must drop and recreate the materialized view.
- In general, you can't alter a materialized view's definition (its SQL statement).
- You can't rename a materialized view.

Limitations

You can't define a materialized view that references or includes any of the following:

- Standard views, or system tables and views.

- Temporary tables.
- User-defined functions.
- The ORDER BY, LIMIT, or OFFSET clause.
- late-binding references to base tables. In other words, any base tables or related columns referenced in the defining SQL query of the materialized view must exist and must be valid.
- Leader node-only functions: CURRENT_SCHEMA, CURRENT_SCHEMAS, HAS_DATABASE_PRIVILEGE, HAS_SCHEMA_PRIVILEGE, HAS_TABLE_PRIVILEGE.
- You can't use the AUTO REFRESH YES option when the materialized view definition includes mutable functions or external schemas. You also can't use it when you define a materialized view on another materialized view.
- You don't have to manually run [ANALYZE](#) on materialized views. This happens currently only via AUTO ANALYZE. For more information, see [Analyzing tables](#).

Examples

The following example creates a materialized view from three base tables that are joined and aggregated. Each row represents a category with the number of tickets sold. When you query the tickets_mv materialized view, you directly access the precomputed data in the tickets_mv materialized view.

```
CREATE MATERIALIZED VIEW tickets_mv AS
  select  catgroup,
         sum(qtysold) as sold
  from    category c, event e, sales s
  where   c.catid = e.catid
  and     e.eventid = s.eventid
  group by catgroup;
```

The following example creates a materialized view similar to the previous example and uses the aggregate function MAX().

```
CREATE MATERIALIZED VIEW tickets_mv_max AS
  select  catgroup,
         max(qtysold) as sold
  from    category c, event e, sales s
  where   c.catid = e.catid
  and     e.eventid = s.eventid
  group by catgroup;
```

```
SELECT name, state FROM STV_MV_INFO;
```

The following example uses a UNION ALL clause to join the Amazon Redshift `public_sales` table and the Redshift Spectrum `spectrum.sales` table to create a material view `mv_sales_vw`. For information about the CREATE EXTERNAL TABLE command for Amazon Redshift Spectrum, see [CREATE EXTERNAL TABLE](#). The Redshift Spectrum external table references the data on Amazon S3.

```
CREATE MATERIALIZED VIEW mv_sales_vw as
select salesid, qtysold, pricepaid, commission, saletime from public.sales
union all
select salesid, qtysold, pricepaid, commission, saletime from spectrum.sales
```

The following example creates a materialized view `mv_fq` based on a federated query external table. For information about federated query, see [CREATE EXTERNAL SCHEMA](#).

```
CREATE MATERIALIZED VIEW mv_fq as select firstname, lastname from apg.mv_fq_example;

select firstname, lastname from mv_fq;
  firstname | lastname
-----+-----
   John     | Day
   Jane     | Doe
(2 rows)
```

The following example shows the definition of a materialized view.

```
SELECT pg_catalog.pg_get_viewdef('mv_sales_vw'::regclass::oid, true);

pg_get_viewdef
-----
create materialized view mv_sales_vw as select a from t;
```

The following sample shows how to set AUTO REFRESH in the materialized view definition and also specifies a DISTSTYLE. First, create a simple base table.

```
CREATE TABLE baseball_table (ball int, bat int);
```

Then, create a materialized view.

```
CREATE MATERIALIZED VIEW mv_baseball DISTSTYLE ALL AUTO REFRESH YES AS SELECT ball AS
baseball FROM baseball_table;
```

Now you can query the `mv_baseball` materialized view. To check if `AUTO REFRESH` is turned on for a materialized view, see [STV_MV_INFO](#).

The following sample creates a materialized view that references a source table in another database. It assumes that the database containing the source table, `database_A`, is in the same cluster or workgroup as your materialized view, which you create in `database_B`. (You can substitute your own databases for the sample.) First, create a table in `database_A` called `cities`, with a `cityname` column. Make the column's data type a `VARCHAR`. After you create the source table, run the following command in `database_B` to create a materialized view whose source is your `cities` table. Make sure to specify the source table's database and schema in the `FROM` clause:

```
CREATE MATERIALIZED VIEW cities_mv AS
SELECT  cityname
FROM    database_A.public.cities;
```

Query the materialized view you created. The query retrieves records whose original source is the `cities` table in `database_A`:

```
select * from cities_mv;
```

When you run the `SELECT` statement, `cities_mv` returns the records. Records are refreshed from the source table only when a `REFRESH` statement is run. Also, note that you can't update records directly in the materialized view. For information about refreshing the data in a materialized view, see [REFRESH MATERIALIZED VIEW](#).

For details about materialized view overview and SQL commands used to refresh and drop materialized views, see the following topics:

- [Materialized views in Amazon Redshift](#)
- [REFRESH MATERIALIZED VIEW](#)
- [DROP MATERIALIZED VIEW](#)

CREATE MODEL

Topics

- [Prerequisites](#)
- [Required privileges](#)
- [Cost control](#)
- [Full CREATE MODEL](#)
- [Parameters](#)
- [Usage notes](#)
- [Use cases](#)

Prerequisites

Before you use the CREATE MODEL statement, complete the prerequisites in [Cluster setup for using Amazon Redshift ML](#). The following is a high-level summary of the prerequisites.

- Create an Amazon Redshift cluster with the AWS Management Console or the AWS Command Line Interface (AWS CLI).
- Attach the AWS Identity and Access Management (IAM) policy while creating the cluster.
- To allow Amazon Redshift and SageMaker to assume the role to interact with other services, add the appropriate trust policy to the IAM role.

For details for the IAM role, trust policy, and other prerequisites, see [Cluster setup for using Amazon Redshift ML](#).

Following, you can find different use cases for the CREATE MODEL statement.

- [Simple CREATE MODEL](#)
- [CREATE MODEL with user guidance](#)
- [CREATE XGBoost models with AUTO OFF](#)
- [Bring your own model \(BYOM\) - local inference](#)
- [Bring your own model \(BYOM\) - remote inference](#)
- [CREATE MODEL with K-MEANS](#)
- [Full CREATE MODEL](#)

Required privileges

Following are required privileges for CREATE MODEL:

- Superuser
- Users with the CREATE MODEL privilege
- Roles with the GRANT CREATE MODEL privilege

Cost control

Amazon Redshift ML uses existing cluster resources to create prediction models, so you don't have to pay additional costs. However, you might have additional costs if you need to resize your cluster or want to train your models. Amazon Redshift ML uses Amazon SageMaker to train models, which does have an additional associated cost. There are ways to control additional costs, such as limiting the maximum amount of time training can take or by limiting the number of training examples used to train your model. For more information, see [Costs for using Amazon Redshift ML](#).

Full CREATE MODEL

The following summarizes the basic options of the full CREATE MODEL syntax.

Full CREATE MODEL syntax

The following is the full syntax of the CREATE MODEL statement.

Important

When creating a model using the CREATE MODEL statement, follow the order of the keywords in the syntax following.

```
CREATE MODEL model_name
FROM { table_name | ( select_statement ) | 'job_name' }
[ TARGET column_name ]
FUNCTION function_name [ ( data_type [, ...] ) ]
[ RETURNS data_type ]
  -- supported only for BYOM
[ SAGEMAKER 'endpoint_name'[:'model_name']]
  -- supported only for BYOM remote inference
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
```

```

[ AUTO ON / OFF ]
  -- default is AUTO ON
[ MODEL_TYPE { XGBOOST | MLP | LINEAR_LEARNER | KMEANS | FORECAST } ]
  -- not required for non AUTO OFF case, default is the list of all supported types
  -- required for AUTO OFF
[ PROBLEM_TYPE ( REGRESSION | BINARY_CLASSIFICATION | MULTICLASS_CLASSIFICATION ) ]
  -- not supported when AUTO OFF
[ OBJECTIVE ( 'MSE' | 'Accuracy' | 'F1' | 'F1_Macro' | 'AUC' |
             'reg:squarederror' | 'reg:squaredlogerror' | 'reg:logistic' |
             'reg:pseudohubererror' | 'reg:tweedie' | 'binary:logistic' |
             'binary:hinge',
             'multi:softmax' | 'RMSE' | 'WAPE' | 'MAPE' | 'MASE' |
             'AverageWeightedQuantileLoss' ) ]
  -- for AUTO ON: first 5 are valid
  -- for AUTO OFF: 6-13 are valid
  -- for FORECAST: 14-18 are valid
[ PREPROCESSORS 'string' ]
  -- required for AUTO OFF, when it has to be 'none'
  -- optional for AUTO ON
[ HYPERPARAMETERS { DEFAULT | DEFAULT EXCEPT ( Key 'value' (, ...) ) } ]
  -- support XGBoost hyperparameters, except OBJECTIVE
  -- required and only allowed for AUTO OFF
  -- default NUM_ROUND is 100
  -- NUM_CLASS is required if objective is multi:softmax (only possible for AUTO OFF)
[ SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket', |
    -- required
  TAGS 'string', |
    -- optional
  KMS_KEY_ID 'kms_string', |
    -- optional
  S3_GARBAGE_COLLECT on / off, |
    -- optional, default is on.
  MAX_CELLS integer, |
    -- optional, default is 1,000,000
  MAX_RUNTIME integer (, ...) |
    -- optional, default is 5400 (1.5 hours)
  HORIZON integer, |
    -- required if creating a forecast model
  FREQUENCY integer, |
    -- required if creating a forecast model
  PERCENTILES string, |
    -- optional if creating a forecast model
  MAX_BATCH_ROWS integer -- optional for BYOM remote inference

```

```
) ]
```

Parameters

`model_name`

The name of the model. The model name in a schema must be unique.

```
FROM { table_name | ( select_query ) | 'job_name' }
```

The `table_name` or the query that specifies the training data. They can either be an existing table in the system, or an Amazon Redshift-compatible SELECT query enclosed with parentheses, that is (). There must be at least two columns in the query result.

`TARGET column_name`

The name of the column that becomes the prediction target. The column must exist in the FROM clause.

```
FUNCTION function_name ( data_type [, ...] )
```

The name of the function to be created and the data types of the input arguments. You can provide the schema name of a schema in your database instead of a function name.

`RETURNS data_type`

The data type to be returned from the model's function. The returned SUPER data type is applicable only to BYOM with remote inference.

```
SAGEMAKER 'endpoint_name'[:'model_name']
```

The name of the Amazon SageMaker endpoint. If the endpoint name points to a multimodel endpoint, add the name of the model to use. The endpoint must be hosted in the same AWS Region as the Amazon Redshift cluster.

```
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
```

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE MODEL command runs. Alternatively, you can specify an ARN of an IAM role to use that role.

[AUTO ON / OFF]

Turns on or off CREATE MODEL automatic discovery of preprocessor, algorithm, and hyper-parameters selection. Specifying on when creating a Forecast model indicates to use an

AutoPredictor, where Amazon Forecast applies the optimal combinations of algorithms to each time series in your dataset.

MODEL_TYPE { XGBOOST | MLP | LINEAR_LEARNER | KMEANS | FORECAST }

(Optional) Specifies the model type. You can specify if you want to train a model of a specific model type, such as XGBoost, multilayer perceptron (MLP), KMEANS, or Linear Learner, which are all algorithms that Amazon SageMaker Autopilot supports. If you don't specify the parameter, then all supported model types are searched during training for the best model. You can also create a forecast model in Redshift ML to create accurate time-series forecasts.

PROBLEM_TYPE (REGRESSION | BINARY_CLASSIFICATION | MULTICLASS_CLASSIFICATION)

(Optional) Specifies the problem type. If you know the problem type, you can restrict Amazon Redshift to only search of the best model of that specific model type. If you don't specify this parameter, a problem type is discovered during the training, based on your data.

OBJECTIVE ('MSE' | 'Accuracy' | 'F1' | 'F1Macro' | 'AUC' | 'reg:squarederror' | 'reg:squaredlogerror' | 'reg:logistic' | 'reg:pseudohubererror' | 'reg:tweedie' | 'binary:logistic' | 'binary:hinge' | 'multi:softmax' | 'RMSE' | 'WAPE' | 'MAPE' | 'MASE' | 'AverageWeightedQuantileLoss')

(Optional) Specifies the name of the objective metric used to measure the predictive quality of a machine learning system. This metric is optimized during training to provide the best estimate for model parameter values from data. If you don't specify a metric explicitly, the default behavior is to automatically use MSE: for regression, F1: for binary classification, Accuracy: for multiclass classification. For more information about objectives, see [AutoMLJobObjective](#) in the *Amazon SageMaker API Reference* and [Learning task parameters](#) in the XGBOOST documentation. The values RMSE, WAPE, MAPE, MASE, and AverageWeightedQuantileLoss are only applicable to Forecast models. For more information, see the [CreateAutoPredictor](#) API operation.

PREPROCESSORS 'string'

(Optional) Specifies certain combinations of preprocessors to certain sets of columns. The format is a list of columnSets, and the appropriate transforms to be applied to each set of columns. Amazon Redshift applies all the transformers in a specific transformers list to all columns in the corresponding ColumnSet. For example, to apply OneHotEncoder with Imputer to columns t1 and t2, use the sample command following.

```
CREATE MODEL customer_churn
FROM customer_data
```

```

TARGET 'Churn'
FUNCTION predict_churn
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
PROBLEM_TYPE BINARY_CLASSIFICATION
OBJECTIVE 'F1'
PREPROCESSORS '['
...
  {"ColumnSet": [
    "t1",
    "t2"
  ],
  "Transformers": [
    "OneHotEncoder",
    "Imputer"
  ]
},
  {"ColumnSet": [
    "t3"
  ],
  "Transformers": [
    "OneHotEncoder"
  ]
},
  {"ColumnSet": [
    "temp"
  ],
  "Transformers": [
    "Imputer",
    "NumericPassthrough"
  ]
}
]'
SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket'
)

```

HYPERPARAMETERS { DEFAULT | DEFAULT EXCEPT (key 'value' (..)) }

Specifies whether the default XGBoost parameters are used or overridden by user-specified values. The values must be enclosed with single quotes. Following are examples of parameters for XGBoost and their defaults.

Parameter name	Parameter value	Default value	Notes
num_class	Integer	Requires for Multiple classes classification.	N/A
num_round	Integer	100	N/A
tree_method	String	Auto	N/A
max_depth	Integer	6	[0 , 10]
min_child_weight	Float	1	MinValue: 0, MaxValue: 120
subsample	Float	1	MinValue: 0.5, MaxValue: 1
gamma	Float	0	MinValue: 0, MaxValue: 5
alpha	Float	0	MinValue: 0, MaxValue: 1000
eta	Float	0.3	MinValue: 0.1, MaxValue: 0.5
colsample_bylevel	Float	1	MinValue: 0.1, MaxValue: 1
colsample_bynode	Float	1	MinValue: 0.1, MaxValue: 1
colsample_bytree	Float	1	MinValue: 0.5, MaxValue: 1
lambda	Float	1	MinValue: 0, MaxValue: 1000

Parameter name	Parameter value	Default value	Notes
max_delta_step	Integer	0	[0, 10]

SETTINGS (S3_BUCKET 'amzn-s3-demo-bucket', | TAGS 'string', | KMS_KEY_ID 'kms_string' , | S3_GARBAGE_COLLECT on / off, | MAX_CELLS integer , | MAX_RUNTIME (,...) , | HORIZON integer, | FREQUENCY forecast_frequency, | PERCENTILES array of strings)

S3_BUCKET clause specifies the Amazon S3 location that is used to store intermediate results.

(Optional) The TAGS parameter is a comma-separated list of key-value pairs that you can use to tag resources created in Amazon SageMaker; and Amazon Forecast. Tags help you organize resources and allocate costs. Values in the pair are optional, so you can create tags by using the format `key=value` or just by creating a key. For more information about tags in Amazon Redshift, see [Tagging overview](#).

(Optional) KMS_KEY_ID specifies if Amazon Redshift uses server-side encryption with an AWS KMS key to protect data at rest. Data in transit is protected with Secure Sockets Layer (SSL).

(Optional) S3_GARBAGE_COLLECT { ON | OFF } specifies whether Amazon Redshift performs garbage collection on the resulting datasets used to train models and the models. If set to OFF, the resulting datasets used to train models and the models remains in Amazon S3 and can be used for other purposes. If set to ON, Amazon Redshift deletes the artifacts in Amazon S3 after the training completes. The default is ON.

(Optional) MAX_CELLS specifies the number of cells in the training data. This value is the product of the number of records (in the training query or table) times the number of columns. The default is 1,000,000.

(Optional) MAX_RUNTIME specifies the maximum amount of time to train. Training jobs often complete sooner depending on dataset size. This specifies the maximum amount of time the training should take. The default is 5,400 (90 minutes).

HORIZON specifies the maximum number of predictions the forecast model can return. Once the model is trained, you can't change this integer. This parameter is required if training a forecast model.

FREQUENCY specifies how granular in time units you want the forecasts to be. Available options are Y | M | W | D | H | 30min | 15min | 10min | 5min | 1min. This parameter is required if training a forecast model.

(Optional) PERCENTILES is a comma-delimited string that specifies the forecast types used to train a predictor. Forecast types can be quantiles from 0.01 to 0.99, in increments of 0.01 or higher. You can also specify the mean forecast with mean. You can specify a maximum of five forecast types.

MAX_BATCH_ROWS *integer*

(Optional) The maximum number of rows that Amazon Redshift sends in a single batch request for a single SageMaker invocation. It is supported only for BYOM with remote inference. This parameter's minimum value is 1. The maximum value is INT_MAX, or 2,147,483,647. This parameter is required only when both input and returned data types are *SUPER*. The default value is INT_MAX, or 2,147,483,647.

Usage notes

When using CREATE MODEL, consider the following:

- The CREATE MODEL statement operates in an asynchronous mode and returns upon the export of training data to Amazon S3. The remaining steps of training in Amazon SageMaker occur in the background. While training is in progress, the corresponding inference function is visible but can't be run. You can query [STV_ML_MODEL_INFO](#) to see the state of training.
- The training can run for up to 90 minutes in the background, by default in the Auto model and can be extended. To cancel the training, simply run the [DROP MODEL](#) command.
- The Amazon Redshift cluster that you use to create the model and the Amazon S3 bucket that is used to stage the training data and model artifacts must be in the same AWS Region.
- During the model training, Amazon Redshift and SageMaker store intermediate artifacts in the Amazon S3 bucket that you provide. By default, Amazon Redshift performs garbage collection at the end of the CREATE MODEL operation. Amazon Redshift removes those objects from Amazon S3. To retain those artifacts on Amazon S3, set the S3_GARBAGE COLLECT OFF option.
- You must use at least 500 rows in the training data provided in the FROM clause.
- You can only specify up to 256 feature (input) columns in the FROM { table_name | (select_query) } clause when using the CREATE MODEL statement.

- For AUTO ON, the column types that you can use as the training set are SMALLINT, INTEGER, BIGINT, DECIMAL, REAL, DOUBLE, BOOLEAN, CHAR, VARCHAR, DATE, TIME, TIMETZ, TIMESTAMP, and TIMESTAMPTZ. For AUTO OFF, the column types that you can use as the training set are SMALLINT, INTEGER, BIGINT, DECIMAL, REAL, DOUBLE, and BOOLEAN.
- You can't use DECIMAL, DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, GEOMETRY, GEOGRAPHY, HLLSKETCH, SUPER, or VARBYTE as the target column type.
- To improve model accuracy, do one of the following:
 - Add as many relevant columns in the CREATE MODEL command as possible when you specify the training data in the FROM clause.
 - Use a larger value for MAX_RUNTIME and MAX_CELLS. Larger values for this parameter increase the cost of training a model.
- The CREATE MODEL statement execution returns as soon as the training data is computed and exported to the Amazon S3 bucket. After that point, you can check the status of the training using the SHOW MODEL command. When a model being trained in the background fails, you can check the error using SHOW MODEL. You can't retry a failed model. Use DROP MODEL to remove a failed model and recreate a new model. For more information about SHOW MODEL, see [SHOW MODEL](#).
- Local BYOM supports the same kind of models that Amazon Redshift ML supports for non-BYOM cases. Amazon Redshift supports plain XGBoost (using XGBoost version 1.0 or later), KMEANS models without preprocessors, and XGBOOST/MLP/Linear Learner models trained by trained by Amazon SageMaker Autopilot. It supports the latter with preprocessors that Autopilot has specified that are also supported by Amazon SageMaker Neo.
- If your Amazon Redshift cluster has enhanced routing enabled for your virtual private cloud (VPC), make sure to create an Amazon S3 VPC endpoint and an SageMaker VPC endpoint for the VPC that your cluster is in. Doing this enables the traffic to run through your VPC between these services during CREATE MODEL. For more information, see [SageMaker Clarify Job Amazon VPC Subnets and Security Groups](#).

Use cases

The following use cases demonstrate how to use CREATE MODEL to suit your needs.

Simple CREATE MODEL

The following summarizes the basic options of the CREATE MODEL syntax.

Simple CREATE MODEL syntax

```
CREATE MODEL model_name
FROM { table_name | ( select_query ) }
TARGET column_name
FUNCTION prediction_function_name
IAM_ROLE { default }
SETTINGS (
    S3_BUCKET 'amzn-s3-demo-bucket',
    [ MAX_CELLS integer ]
)
```

Simple CREATE MODEL parameters

model_name

The name of the model. The model name in a schema must be unique.

FROM { *table_name* | (*select_query*) }

The *table_name* or the query that specifies the training data. They can either be an existing table in the system, or an Amazon Redshift-compatible SELECT query enclosed with parentheses, that is (). There must be at least two columns in the query result.

TARGET *column_name*

The name of the column that becomes the prediction target. The column must exist in the FROM clause.

FUNCTION *prediction_function_name*

A value that specifies the name of the Amazon Redshift machine learning function to be generated by the CREATE MODEL and used to make predictions using this model. The function is created in the same schema as the model object and can be overloaded.

Amazon Redshift machine learning supports models, such as Xtreme Gradient Boosted tree (XGBoost) models for regression and classification.

IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE MODEL command runs. Alternatively, you can specify the ARN of an IAM role to use that role.

`S3_BUCKET 'amzn-s3-demo-bucket'`

The name of the Amazon S3 bucket that you previously created used to share training data and artifacts between Amazon Redshift and SageMaker. Amazon Redshift creates a subfolder in this bucket prior to unload of the training data. When training is complete, Amazon Redshift deletes the created subfolder and its contents.

`MAX_CELLS` integer

The maximum number of cells to export from the FROM clause. The default is 1,000,000.

The number of cells is the product of the number of rows in the training data (produced by the FROM clause table or query) times the number of columns. If the number of cells in the training data are more than that specified by the `max_cells` parameter, CREATE MODEL downsamples the FROM clause training data to reduce the size of the training set below MAX_CELLS. Allowing larger training datasets can produce higher accuracy but also can mean the model takes longer to train and costs more.

For information about costs of using Amazon Redshift, see [Costs for using Amazon Redshift ML](#).

For more information about costs associated with various cell numbers and free trial details, see [Amazon Redshift pricing](#).

CREATE MODEL with user guidance

Following, you can find a description of options for CREATE MODEL in addition to the options described in [Simple CREATE MODEL](#).

By default, CREATE MODEL searches for the best combination of preprocessing and model for your specific dataset. You might want additional control or introduce additional domain knowledge (such as problem type or objective) over your model. In a customer churn scenario, if the outcome “customer is not active” is rare, then the F1 objective is often preferred to the accuracy objective. Because high accuracy models might predict “customer is active” all the time, this results in high accuracy but little business value. For information about F1 objective, see [AutoMLJobObjective](#) in the *Amazon SageMaker API Reference*.

Then the CREATE MODEL follows your suggestions on the specified aspects, such as the objective. At the same time, the CREATE MODEL automatically discovers the best preprocessors and the best hyperparameters.

CREATE MODEL with user guidance syntax

CREATE MODEL offers more flexibility on the aspects that you can specify and the aspects that Amazon Redshift automatically discovers.

```
CREATE MODEL model_name
FROM { table_name | ( select_statement ) }
TARGET column_name
FUNCTION function_name
IAM_ROLE { default }
[ MODEL_TYPE { XGBOOST | MLP | LINEAR_LEARNER } ]
[ PROBLEM_TYPE ( REGRESSION | BINARY_CLASSIFICATION | MULTICLASS_CLASSIFICATION ) ]
[ OBJECTIVE ( 'MSE' | 'Accuracy' | 'F1' | 'F1Macro' | 'AUC' ) ]
SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket', |
  S3_GARBAGE_COLLECT { ON | OFF }, |
  KMS_KEY_ID 'kms_key_id', |
  MAX_CELLS integer, |
  MAX_RUNTIME integer (, ...)
)
```

CREATE MODEL with user guidance parameters

MODEL_TYPE { *XGBOOST* | *MLP* | *LINEAR_LEARNER* }

(Optional) Specifies the model type. You can specify if you want to train a model of a specific model type, such as XGBoost, multilayer perceptron (MLP), or Linear Learner, which are all algorithms that Amazon SageMaker Autopilot supports. If you don't specify the parameter, then all supported model types are searched during training for the best model.

PROBLEM_TYPE (*REGRESSION* | *BINARY_CLASSIFICATION* | *MULTICLASS_CLASSIFICATION*)

(Optional) Specifies the problem type. If you know the problem type, you can restrict Amazon Redshift to only search of the best model of that specific model type. If you don't specify this parameter, a problem type is discovered during the training, based on your data.

OBJECTIVE ('MSE' | 'Accuracy' | 'F1' | 'F1Macro' | 'AUC')

(Optional) Specifies the name of the objective metric used to measure the predictive quality of a machine learning system. This metric is optimized during training to provide the best estimate for model parameter values from data. If you don't specify a metric explicitly, the default behavior is to automatically use MSE: for regression, F1: for binary classification, Accuracy: for

multiclass classification. For more information about objectives, see [AutoMLJobObjective](#) in the *Amazon SageMaker API Reference*.

MAX_CELLS integer

(Optional) Specifies the number of cells in the training data. This value is the product of the number of records (in the training query or table) times the number of columns. The default is 1,000,000.

MAX_RUNTIME integer

(Optional) Specifies the maximum amount of time to train. Training jobs often complete sooner depending on dataset size. This specifies the maximum amount of time the training should take. The default is 5,400 (90 minutes).

S3_GARBAGE_COLLECT { ON | OFF }

(Optional) Specifies whether Amazon Redshift performs garbage collection on the resulting datasets used to train models and the models. If set to OFF, the resulting datasets used to train models and the models remains in Amazon S3 and can be used for other purposes. If set to ON, Amazon Redshift deletes the artifacts in Amazon S3 after the training completes. The default is ON.

KMS_KEY_ID 'kms_key_id'

(Optional) Specifies if Amazon Redshift uses server-side encryption with an AWS KMS key to protect data at rest. Data in transit is protected with Secure Sockets Layer (SSL).

PREPROCESSORS 'string'

(Optional) Specifies certain combinations of preprocessors to certain sets of columns. The format is a list of columnSets, and the appropriate transforms to be applied to each set of columns. Amazon Redshift applies all the transformers in a specific transformers list to all columns in the corresponding ColumnSet. For example, to apply OneHotEncoder with Imputer to columns t1 and t2, use the sample command following.

```
CREATE MODEL customer_churn
FROM customer_data
TARGET 'Churn'
FUNCTION predict_churn
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
PROBLEM_TYPE BINARY_CLASSIFICATION
OBJECTIVE 'F1'
PREPROCESSORS '['
```

```
...
{"ColumnSet": [
  "t1",
  "t2"
],
"Transformers": [
  "OneHotEncoder",
  "Imputer"
]
},
{"ColumnSet": [
  "t3"
],
"Transformers": [
  "OneHotEncoder"
]
},
{"ColumnSet": [
  "temp"
],
"Transformers": [
  "Imputer",
  "NumericPassthrough"
]
}
]'
SETTINGS (
S3_BUCKET 'amzn-s3-demo-bucket'
)
```

Amazon Redshift supports the following transformers:

- **OneHotEncoder** – Typically used to encode a discrete value into a binary vector with one nonzero value. This transformer is suitable for many machine learning models.
- **OrdinalEncoder** – Encodes discrete values into a single integer. This transformer is suitable for certain machine learning models, such as MLP and Linear Learner.
- **NumericPassthrough** – Passes input as is into the model.
- **Imputer** – Fills in missing values and not a number (NaN) values.
- **ImputerWithIndicator** – Fills in missing values and NaN values. This transformer also creates an indicator of whether any values were missing and filled in.

- Normalizer – Normalizes values, which can improve the performance of many machine learning algorithms.
- DateTimeVectorizer – Creates a vector embedding, representing a column of datetime data type that can be used in machine learning models.
- PCA – Projects the data into a lower dimensional space to reduce the number of features while keeping as much information as possible.
- StandardScaler – Standardizes features by removing the mean and scaling to unit variance.
- MinMax – Transforms features by scaling each feature to a given range.

Amazon Redshift ML stores the trained transformers, and automatically applies them as part of the prediction query. You don't need to specify them when generating predictions from your model.

CREATE XGBoost models with AUTO OFF

The AUTO OFF CREATE MODEL has generally different objectives from the default CREATE MODEL.

As an advanced user who already knows the model type that you want and hyperparameters to use when training these models, you can use CREATE MODEL with AUTO OFF to turn off the CREATE MODEL automatic discovery of preprocessors and hyperparameters. To do so, you explicitly specify the model type. XGBoost is currently the only model type supported when AUTO is set to OFF. You can specify hyperparameters. Amazon Redshift uses default values for any hyperparameters that you specified.

CREATE XGBoost models with AUTO OFF syntax

```
CREATE MODEL model_name
FROM { table_name | (select_statement ) }
TARGET column_name
FUNCTION function_name
IAM_ROLE { default }
AUTO OFF
MODEL_TYPE XGBOOST
OBJECTIVE { 'reg:squarederror' | 'reg:squaredlogerror' | 'reg:logistic' |
           'reg:pseudohubererror' | 'reg:tweedie' | 'binary:logistic' | 'binary:hinge'
           |
           'multi:softmax' | 'rank:pairwise' | 'rank:ndcg' }
HYPERPARAMETERS DEFAULT EXCEPT (
  NUM_ROUND '10',
  ETA '0.2',
  NUM_CLASS '10',
```

```

    (, ...)
)
PREPROCESSORS 'none'
SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket', |
  S3_GARBAGE_COLLECT { ON | OFF }, |
  KMS_KEY_ID 'kms_key_id', |
  MAX_CELLS integer, |
  MAX_RUNTIME integer (, ...)
)

```

CREATE XGBoost models with AUTO OFF parameters

AUTO OFF

Turns off CREATE MODEL automatic discovery of preprocessor, algorithm, and hyperparameters selection.

MODEL_TYPE XGBOOST

Specifies to use XGBOOST to train the model.

OBJECTIVE str

Specifies an objective recognized by the algorithm. Amazon Redshift supports reg:squarederror, reg:squaredlogerror, reg:logistic, reg:pseudohubererror, reg:tweedie, binary:logistic, binary:hinge, multi:softmax. For more information about these objectives, see [Learning task parameters](#) in the XGBoost documentation.

HYPERPARAMETERS { DEFAULT | DEFAULT EXCEPT (key 'value' (,..)) }

Specifies whether the default XGBoost parameters are used or overridden by user-specified values. The values must be enclosed with single quotes. Following are examples of parameters for XGBoost and their defaults.

Parameter name	Parameter value	Default value	Notes
num_class	Integer	Requires for Multiclass	N/A

Parameter name	Parameter value	Default value	Notes
			classification.
num_round	Integer	100	N/A
tree_method	String	Auto	N/A
max_depth	Integer	6	[0 , 10]
min_child_weight	Float	1	MinValue: 0, MaxValue: 120
subsample	Float	1	MinValue: 0.5, MaxValue: 1
gamma	Float	0	MinValue: 0, MaxValue: 5
alpha	Float	0	MinValue: 0, MaxValue: 1000
eta	Float	0.3	MinValue: 0.1, MaxValue: 0.5
colsample_bylevel	Float	1	MinValue: 0.1, MaxValue: 1
colsample_bynode	Float	1	MinValue: 0.1, MaxValue: 1
colsample_bytree	Float	1	MinValue: 0.5, MaxValue: 1
lambda	Float	1	MinValue: 0, MaxValue: 1000
max_delta_step	Integer	0	[0, 10]

The following example prepares data for XGBoost.

```
DROP TABLE IF EXISTS abalone_xgb;

CREATE TABLE abalone_xgb (
length_val float,
diameter float,
height float,
whole_weight float,
shucked_weight float,
viscera_weight float,
shell_weight float,
rings int,
record_number int);

COPY abalone_xgb
FROM 's3://redshift-downloads/redshift-ml/abalone_xg/'
REGION 'us-east-1'
IAM_ROLE default
IGNOREHEADER 1 CSV;
```

The following example creates an XGBoost model with specified advanced options, such as `MODEL_TYPE`, `OBJECTIVE`, and `PREPROCESSORS`.

```
DROP MODEL abalone_xgboost_multi_predict_age;

CREATE MODEL abalone_xgboost_multi_predict_age
FROM ( SELECT length_val,
             diameter,
             height,
             whole_weight,
             shucked_weight,
             viscera_weight,
             shell_weight,
             rings
       FROM abalone_xgb WHERE record_number < 2500 )
TARGET rings FUNCTION ml_fn_abalone_xgboost_multi_predict_age
IAM_ROLE default
AUTO OFF
MODEL_TYPE XGBOOST
OBJECTIVE 'multi:softmax'
PREPROCESSORS 'none'
HYPERPARAMETERS DEFAULT EXCEPT (NUM_ROUND '100', NUM_CLASS '30')
SETTINGS (S3_BUCKET 'amzn-s3-demo-bucket');
```

The following example uses an inference query to predict the age of the fish with a record number greater than 2500. It uses the function `ml_fn_abalone_xgboost_multi_predict_age` created from the above command.

```
select ml_fn_abalone_xgboost_multi_predict_age(length_val,
                                              diameter,
                                              height,
                                              whole_weight,
                                              shucked_weight,
                                              viscera_weight,
                                              shell_weight)+1.5 as age
from abalone_xgb where record_number > 2500;
```

Bring your own model (BYOM) - local inference

Amazon Redshift ML supports using bring your own model (BYOM) for local inference.

The following summarizes the options for the CREATE MODEL syntax for BYOM. You can use a model trained outside of Amazon Redshift with Amazon SageMaker for in-database inference locally in Amazon Redshift.

CREATE MODEL syntax for local inference

The following describes the CREATE MODEL syntax for local inference.

```
CREATE MODEL model_name
FROM ('job_name' | 's3_path' )
FUNCTION function_name ( data_type [, ...] )
RETURNS data_type
IAM_ROLE { default }
[ SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket', | --required
  KMS_KEY_ID 'kms_string') --optional
];
```

Amazon Redshift currently only supports pretrained XGBoost, MLP, and Linear Learner models for BYOM. You can import SageMaker Autopilot and models directly trained in Amazon SageMaker for local inference using this path.

CREATE MODEL parameters for local inference

model_name

The name of the model. The model name in a schema must be unique.

FROM (*job_name* | *s3_path*)

The *job_name* uses an Amazon SageMaker job name as the input. The job name can either be an Amazon SageMaker training job name or an Amazon SageMaker Autopilot job name. The job must be created in the same AWS account that owns the Amazon Redshift cluster. To find the job name, launch Amazon SageMaker. In the **Training** dropdown menu, choose **Training jobs**.

The *s3_path* specifies the S3 location of the .tar.gz model artifacts file that is to be used when creating the model.

FUNCTION *function_name* (*data_type* [, ...])

The name of the function to be created and the data types of the input arguments. You can provide a schema name.

RETURNS *data_type*

The data type of the value returned by the function.

IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE MODEL command runs.

Use the Amazon Resource Name (ARN) for an IAM role that your cluster uses for authentication and authorization.

SETTINGS (S3_BUCKET '*amzn-s3-demo-bucket*', | KMS_KEY_ID '*kms_string*')

The S3_BUCKET clause specifies the Amazon S3 location that is used to store intermediate results.

(Optional) The KMS_KEY_ID clause specifies if Amazon Redshift uses server-side encryption with an AWS KMS key to protect data at rest. Data in transit is protected with Secure Sockets Layer (SSL).

For more information, see [CREATE MODEL with user guidance](#).

CREATE MODEL for local inference example

The following example creates a model that has been previously trained in Amazon SageMaker, outside of Amazon Redshift. Because the model type is supported by Amazon Redshift ML for local inference, the following CREATE MODEL creates a function that can be used locally in Amazon Redshift. You can provide a SageMaker training job name.

```
CREATE MODEL customer_churn
FROM 'training-job-customer-churn-v4'
FUNCTION customer_churn_predict (varchar, int, float, float)
RETURNS int
IAM_ROLE default
SETTINGS (S3_BUCKET 'amzn-s3-demo-bucket');
```

After the model is created, you can use the function *customer_churn_predict* with the specified argument types to make predictions.

Bring your own model (BYOM) - remote inference

Amazon Redshift ML also supports using bring your own model (BYOM) for remote inference.

The following summarizes the options for the CREATE MODEL syntax for BYOM.

CREATE MODEL syntax for remote inference

The following describes the CREATE MODEL syntax for remote inference.

```
CREATE MODEL model_name
FUNCTION function_name ( data_type [, ...] )
RETURNS data_type
SAGEMAKER 'endpoint_name'[:'model_name']
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
[SETTINGS (MAX_BATCH_ROWS integer)];
```

CREATE MODEL parameters for remote inference

model_name

The name of the model. The model name in a schema must be unique.

FUNCTION *fn_name* ([*data_type*] [, ...])

The name of the function and the data types of the input arguments. See [Data types](#) for all of the supported data types. Geography, geometry, and hllsketch aren't supported.

You can also provide a function name inside a schema using two-part notation, such as `myschema.myfunction`.

RETURNS *data_type*

The data type of the value returned by the function. See [Data types](#) for all of the supported data types. Geography, geometry, and hllsketch aren't supported.

SAGEMAKER '*endpoint_name*'[:'*model_name*']

The name of the Amazon SageMaker endpoint. If the endpoint name points to a multimodel endpoint, add the name of the model to use. The endpoint must be hosted in the same AWS Region as the Amazon Redshift cluster. To find your endpoint, launch Amazon SageMaker. In the **Inference** dropdown menu, choose **Endpoints**.

IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>'}

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE MODEL command runs. Alternatively, you can specify the ARN of an IAM role to use that role.

MAX_BATCH_ROWS *integer*

The maximum number of rows that Amazon Redshift sends in a single batch request for a single SageMaker invocation. It is supported only for BYOM with remote inference. The actual number of rows in a batch also depends on the input size, but is less than or equal to this value. This parameter's minimum value is 1. The maximum value is INT_MAX, or 2,147,483,647. This parameter is required only when both input and returned data types are SUPER. The default value is INT_MAX, or 2,147,483,647.

When the model is deployed to a SageMaker endpoint, SageMaker creates the information of the model in Amazon Redshift. It then performs inference through the external function. You can use the SHOW MODEL command to view the model information on your Amazon Redshift cluster.

CREATE MODEL for remote inference usage notes

Before using CREATE MODEL for remote inference, consider the following:

- The endpoint must be hosted by the same AWS account that owns the Amazon Redshift cluster.
- Make sure either that the Amazon SageMaker endpoint has enough resources to accommodate inference calls from Amazon Redshift or that the Amazon SageMaker endpoint can be automatically scaled.

- If you're not using the SUPER data type as input, the model only accepts inputs in the format of comma-separated values (CSV) which corresponds to a content type of `text/CSV` in SageMaker.
- If you're not using the SUPER data type as input, the output of models is a single value of the type specified when you create the function. The output is in the format of comma-separated values (CSV) through a content type of `text/CSV` in SageMaker. VARCHAR data types cannot be in quotes and cannot contain new lines, and each output must be in a new line.
- Models accept nulls as empty strings.
- When the input data type is SUPER, only one input argument is supported.
- When the input data type is SUPER, the returned data type must also be SUPER.
- MAX_BATCH_ROWS is required when both input and returned data types are SUPER.
- When the input data type is SUPER the content type of the endpoint invocation is either `application/json` when MAX_BATCH_ROWS is 1 or `application/jsonlines` in all other cases.
- When the returned data type is SUPER the accept type of the endpoint invocation is either `application/json` when MAX_BATCH_ROWS is 1 or `application/jsonlines` in all other cases.

CREATE MODEL for remote inference example

The following example creates a model that uses a SageMaker endpoint to make predictions. Make sure that the endpoint is running to make predictions and specify its name in the CREATE MODEL command.

```
CREATE MODEL remote_customer_churn
FUNCTION remote_fn_customer_churn_predict (varchar, int, float, float)
RETURNS int
SAGEMAKER 'customer-churn-endpoint'
IAM_ROLE default;
```

The following example creates a BYOM with remote inference with a large language model model (LLM). LLMs hosted on Amazon SageMaker Jumpstart accept and return the `application/json` content type and they support a single JSON per invocation. The input and returned data types must be SUPER and MAX_BATCH_ROWS must be set to 1.

```
CREATE MODEL sample_super_data_model
FUNCTION sample_super_data_model_predict(super)
```

```

RETURNS super
SAGEMAKER 'sample_super_data_model_endpoint'
IAM_ROLE default
SETTINGS (MAX_BATCH_ROWS 1);

```

CREATE MODEL with K-MEANS

Amazon Redshift supports the K-Means algorithm that groups data that isn't labeled. This algorithm solves clustering problems where you want to discover groupings in the data. Unclassified data is grouped and partitioned based on its similarities and differences.

CREATE MODEL with K-MEANS syntax

```

CREATE MODEL model_name
FROM { table_name | ( select_statement ) }
FUNCTION function_name
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
AUTO OFF
MODEL_TYPE KMEANS
PREPROCESSORS 'string'
HYPERPARAMETERS DEFAULT EXCEPT ( K 'val' [, ...] )
SETTINGS (
    S3_BUCKET 'amzn-s3-demo-bucket',
    KMS_KEY_ID 'kms_string', |
    -- optional
    S3_GARBAGE_COLLECT on / off, |
    -- optional
    MAX_CELLS integer, |
    -- optional
    MAX_RUNTIME integer
    -- optional);

```

CREATE MODEL with K-MEANS parameters

AUTO OFF

Turns off CREATE MODEL automatic discovery of preprocessor, algorithm, and hyper-parameters selection.

MODEL_TYPE KMEANS

Specifies to use KMEANS to train the model.

PREPROCESSORS 'string'

Specifies certain combinations of preprocessors to certain sets of columns. The format is a list of columnSets, and the appropriate transforms to be applied to each set of columns. Amazon Redshift supports 3 K-Means preprocessors, namely StandardScaler, MinMax, and NumericPassthrough. If you don't want to apply any preprocessing for K-Means, choose NumericPassthrough explicitly as a transformer. For more information about supported transformers, see [CREATE MODEL with user guidance parameters](#).

The K-Means algorithm uses Euclidean distance to calculate similarity. Preprocessing the data ensures that the features of the model stay on the same scale and produce reliable results.

HYPERPARAMETERS DEFAULT EXCEPT (K 'val' [, ...])

Specifies whether the K-Means parameters are used. You must specify the K parameter when using the K-Means algorithm. For more information, see [K-Means Hyperparameters](#) in the *Amazon SageMaker Developer Guide*

The following example prepares data for K-Means.

```
CREATE MODEL customers_clusters
FROM customers
FUNCTION customers_cluster
IAM_ROLE default
AUTO OFF
MODEL_TYPE KMEANS
PREPROCESSORS '[
{
  "ColumnSet": [ "*" ],
  "Transformers": [ "NumericPassthrough" ]
}
]'
HYPERPARAMETERS DEFAULT EXCEPT ( K '5' )
SETTINGS (S3_BUCKET 'amzn-s3-demo-bucket');

select customer_id, customers_cluster(...) from customers;
customer_id | customers_cluster
-----
12345          1
12346          2
12347          4
12348
```

CREATE MODEL with Forecast

Forecast models in Redshift ML use Amazon Forecast to create accurate time-series forecasts. Doing so lets you use historical data over a time period to make predictions about future events. Common use cases of Amazon Forecast include using retail product data to decide how to price inventory, manufacturing quantity data to predict how much of one item to order, and web traffic data to forecast how much traffic a web server might receive.

[Quota limits from Amazon Forecast](#) are enforced in Amazon Redshift forecast models. For example, the maximum number of forecasts is 100, but it's adjustable. Dropping a forecast model doesn't automatically delete the associated resources in Amazon Forecast. If you delete a Redshift cluster, all associated models are dropped as well.

Note that Forecast models are currently only available in the following Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (Oregon) (us-west-2)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)

CREATE MODEL with Forecast syntax

```
CREATE [ OR REPLACE ] MODEL forecast_model_name
FROM { table_name | ( select_query ) }
TARGET column_name
IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }
AUTO ON
MODEL_TYPE FORECAST
SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket',
  HORIZON integer,
```

```
FREQUENCY forecast_frequency  
[PERCENTILES '0.1', '0.5', '0.9']  
)
```

CREATE MODEL with Forecast parameters

forecast_model_name

The name of the model. The model name must be unique.

FROM { table_name | (select_query) }

The table_name or the query that specifies the training data. This can either be an existing table in the system, or an Amazon Redshift compatible SELECT query enclosed with parentheses. The table or query result must have at least three columns: (1) a varchar column that specifies the name of the time-series. Each dataset can have multiple time-series; (2) a datetime column; and (3) the target column to predict. This target column must be either an int or a float. If you supply a dataset that has more than three columns, Amazon Redshift assumes that all additional columns are part of a related time series. Note that related time series must be of type int or float. For more information about related time series, see [Using Related Time Series Datasets](#).

TARGET column_name

The name of the column that becomes the prediction target. The column must exist in the FROM clause.

IAM_ROLE { default | 'arn:aws:iam::<account-id>:role/<role-name>' }

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the CREATE MODEL command runs. Alternatively, you can specify an ARN of an IAM role to use that role.

AUTO ON

Turns on the CREATE MODEL automatic discovery of algorithm and hyper-parameters selection. Specifying on when creating a Forecast model indicates to use a Forecast AutoPredictor, where Amazon Forecast applies the optimal combinations of algorithms to each time series in your dataset.

MODEL_TYPE FORECAST

Specifies to use FORECAST to train the model.

S3_BUCKET 'amzn-s3-demo-bucket'

The name of the Amazon Simple Storage Service bucket that you previously created and that's used to share training data and artifacts between Amazon Redshift and Amazon Forecast. Amazon Redshift creates a subfolder in this bucket before unloading the training data. When training is complete, Amazon Redshift deletes the created subfolder and its contents.

HORIZON integer

The maximum number of predictions the forecast model can return. Once the model is trained, you can't change this integer.

FREQUENCY forecast_frequency

Specifies how granular you want the forecasts to be. Available options are Y | M | W | D | H | 30min | 15min | 10min | 5min | 1min. Required if you're training a forecast model.

PERCENTILES string

A comma-delimited string that specifies the forecast types used to train a predictor. Forecast types can be quantiles from 0.01 to 0.99, by increments of 0.01 or higher. You can also specify the mean forecast with mean. You can specify a maximum of five forecast types.

The following example demonstrates how to create a simple forecast model.

```
CREATE MODEL forecast_example
FROM forecast_electricity_
TARGET target
IAM_ROLE 'arn:aws:iam::<account-id>:role/<role-name>'
AUTO ON
MODEL_TYPE FORECAST
SETTINGS (S3_BUCKET 'amzn-s3-demo-bucket',
          HORIZON 24,
          FREQUENCY 'H',
          PERCENTILES '0.25,0.50,0.75,mean',
          S3_GARBAGE_COLLECT OFF);
```

After you create the forecast model, you can create a new table with the prediction data.

```
CREATE TABLE forecast_model_results as SELECT Forecast(forecast_example)
```

You can then query the new table to get predictions.

```
SELECT * FROM forecast_model_results
```

CREATE PROCEDURE

Creates a new stored procedure or replaces an existing procedure for the current database.

For more information and examples, see [Creating stored procedures in Amazon Redshift](#).

Required privileges

You must have permission by one of the following ways to run CREATE OR REPLACE PROCEDURE:

- For CREATE PROCEDURE:
 - Superuser
 - Users with CREATE and USAGE privilege on the schema where the stored procedure is created
- For REPLACE PROCEDURE:
 - Superuser
 - Procedure owner

Syntax

```
CREATE [ OR REPLACE ] PROCEDURE sp_procedure_name
  ( [ [ argname ] [ argmode ] argtype [, ...] ] )
  [ NONATOMIC ]
  AS $$
  procedure_body
  $$ LANGUAGE plpgsql
  [ { SECURITY INVOKER | SECURITY DEFINER } ]
  [ SET configuration_parameter { TO value | = value } ]
```

Parameters

OR REPLACE

A clause that specifies that if a procedure with the same name and input argument data types, or signature, as this one already exists, the existing procedure is replaced. You can only replace a procedure with a new procedure that defines an identical set of data types.

If you define a procedure with the same name as an existing procedure, but a different signature, you create a new procedure. In other words, the procedure name is overloaded. For more information, see [Overloading procedure names](#).

sp_procedure_name

The name of the procedure. If you specify a schema name (such as **myschema.myprocedure**), the procedure is created in the specified schema. Otherwise, the procedure is created in the current schema. For more information about valid names, see [Names and identifiers](#).

We recommend that you prefix all stored procedure names with `sp_`. Amazon Redshift reserves the `sp_` prefix for stored procedure names. By using the `sp_` prefix, you ensure that your stored procedure name doesn't conflict with any existing or future Amazon Redshift built-in stored procedure or function names. For more information, see [Naming stored procedures](#).

You can define more than one procedure with the same name if the data types for the input arguments, or signatures, are different. In other words, in this case the procedure name is overloaded. For more information, see [Overloading procedure names](#)

[argname] [argmode] argtype

A list of argument names, argument modes, and data types. Only the data type is required. Name and mode are optional and their position can be switched.

The argument mode can be IN, OUT, or INOUT. The default is IN.

You can use OUT and INOUT arguments to return one or more values from a procedure call. When there are OUT or INOUT arguments, the procedure call returns one result row containing *n* columns, where *n* is the total number of OUT or INOUT arguments.

INOUT arguments are input and output arguments at the same time. *Input arguments* include both IN and INOUT arguments, and *output arguments* include both OUT and INOUT arguments.

OUT arguments aren't specified as part of the CALL statement. Specify INOUT arguments in the stored procedure CALL statement. INOUT arguments can be useful when passing and returning values from a nested call, and also when returning a `refcursor`. For more information on `refcursor` types, see [Cursors](#).

The argument data types can be any standard Amazon Redshift data type. In addition, an argument data type can be `refcursor`.

You can specify a maximum of 32 input arguments and 32 output arguments.

AS \$\$ *procedure_body* \$\$

A construct that encloses the procedure to be run. The literal keywords AS \$\$ and \$\$ are required.

Amazon Redshift requires you to enclose the statement in your procedure by using a format called dollar quoting. Anything within the enclosure is passed exactly as is. You don't need to escape any special characters because the contents of the string are written literally.

With *dollar quoting*, you use a pair of dollar signs (\$\$) to signify the start and the end of the statement to run, as shown in the following example.

```
$$ my statement $$
```

Optionally, between the dollar signs in each pair, you can specify a string to help identify the statement. The string that you use must be the same in both the start and the end of the enclosure pairs. This string is case-sensitive, and it follows the same constraints as an unquoted identifier except that it can't contain dollar signs. The following example uses the string test.

```
$test$ my statement $test$
```

This syntax is also useful for nested dollar quoting. For more information about dollar quoting, see "Dollar-quoted String Constants" under [Lexical Structure](#) in the PostgreSQL documentation.

procedure_body

A set of valid PL/pgSQL statements. PL/pgSQL statements augment SQL commands with procedural constructs, including looping and conditional expressions, to control logical flow. Most SQL commands can be used in the procedure body, including data modification language (DML) such as COPY, UNLOAD and INSERT, and data definition language (DDL) such as CREATE TABLE. For more information, see [PL/pgSQL language reference](#).

LANGUAGE *plpgsql*

A language value. Specify plpgsql. You must have permission for usage on language to use plpgsql. For more information, see [GRANT](#).

NONATOMIC

Creates the stored procedure in a nonatomic transaction mode. NONATOMIC mode automatically commits the statements inside the procedure. Additionally, when an error occurs

inside the NONATOMIC procedure, the error is not re-thrown if it is handled by an exception block. For more information, see [Managing transactions](#) and [RAISE](#).

When you define a stored procedure as NONATOMIC, consider the following:

- When you nest stored procedure calls, all the procedures must be created in the same transaction mode.
- The SECURITY DEFINER option and SET configuration_parameter option are not supported when creating a procedure in NONATOMIC mode.
- Any cursor that is opened (explicitly or implicitly) is closed automatically when an implicit commit is processed. Therefore, you must open an explicit transaction before beginning a cursor loop to ensure that any SQL within the loop's iteration is not implicitly committed.

SECURITY INVOKER | SECURITY DEFINER

The SECURITY DEFINER option is not supported when NONATOMIC is specified.

The security mode for the procedure determines the procedure's access privileges at runtime. The procedure must have permission to access the underlying database objects.

For SECURITY INVOKER mode, the procedure uses the privileges of the user calling the procedure. The user must have explicit permissions on the underlying database objects. The default is SECURITY INVOKER.

For SECURITY DEFINER mode, the procedure uses the privileges of the procedure owner. The procedure owner is defined as the user that owns the procedure at run time, not necessarily the user that initially defined the procedure. The user calling the procedure needs execute privilege on the procedure, but doesn't need any privileges on the underlying objects.

SET configuration_parameter { TO value | = value }

These options are not supported when NONATOMIC is specified.

The SET clause causes the specified configuration_parameter to be set to the specified value when the procedure is entered. This clause then restores configuration_parameter to its earlier value when the procedure exits.

Usage notes

If a stored procedure was created using the SECURITY DEFINER option, when invoking the CURRENT_USER function from within the stored procedure, Amazon Redshift returns the user name of the owner of the stored procedure.

Examples

Note

If when running these examples you encounter an error similar to:

```
ERROR: 42601: [Amazon](500310) unterminated dollar-quoted string at or near "$$
```

See [Overview of stored procedures in Amazon Redshift](#).

The following example creates a procedure with two input parameters.

```
CREATE OR REPLACE PROCEDURE test_sp1(f1 int, f2 varchar(20))
AS $$
DECLARE
    min_val int;
BEGIN
    DROP TABLE IF EXISTS tmp_tbl;
    CREATE TEMP TABLE tmp_tbl(id int);
    INSERT INTO tmp_tbl values (f1),(10001),(10002);
    SELECT INTO min_val MIN(id) FROM tmp_tbl;
    RAISE INFO 'min_val = %, f2 = %', min_val, f2;
END;
$$ LANGUAGE plpgsql;
```

Note

When you write stored procedures, we recommend a best practice for securing sensitive values:

Don't hard code any sensitive information in stored procedure logic. For example, don't assign a user password in a CREATE USER statement in the body of a stored procedure. This poses a security risk, because hard-coded values can be recorded as schema metadata in catalog tables. Instead, pass sensitive values, such as passwords, as arguments to the stored procedure, by means of parameters.

For more information about stored procedures, see [CREATE PROCEDURE](#) and [Creating stored procedures in Amazon Redshift](#). For more information about catalog tables, see [System catalog tables](#).

The following example creates a procedure with one IN parameter, one OUT parameter, and one INOUT parameter.

```
CREATE OR REPLACE PROCEDURE test_sp2(f1 IN int, f2 INOUT varchar(256), out_var OUT
  varchar(256))
AS $$
DECLARE
  loop_var int;
BEGIN
  IF f1 is null OR f2 is null THEN
    RAISE EXCEPTION 'input cannot be null';
  END IF;
  DROP TABLE if exists my_etl;
  CREATE TEMP TABLE my_etl(a int, b varchar);
  FOR loop_var IN 1..f1 LOOP
    insert into my_etl values (loop_var, f2);
    f2 := f2 || '+' || f2;
  END LOOP;
  SELECT INTO out_var count(*) from my_etl;
END;
$$ LANGUAGE plpgsql;
```

CREATE RLS POLICY

Creates a new row-level security policy to provide granular access to database objects.

Superusers and users or roles that have the sys:secadmin role can create a policy.

Syntax

```
CREATE RLS POLICY policy_name
[ WITH (column_name data_type [, ...]) [ [AS] relation_alias ] ]
USING ( using_predicate_exp )
```

Parameters

policy_name

The name of the policy.

WITH (*column_name data_type* [, ...])

Specifies the *column_name* and *data_type* referenced to the columns of tables to which the policy is attached.

You can omit the WITH clause only when the RLS policy doesn't reference any columns of tables to which the policy is attached.

AS *relation_alias*

Specifies an optional alias for the table that the RLS policy will be attached to.

USING (*using_predicate_exp*)

Specifies a filter that is applied to the WHERE clause of the query. Amazon Redshift applies a policy predicate before the query-level user predicates. For example, **current_user = 'joe' and price > 10** limits Joe to see only records with the price greater than \$10.

Usage notes

When working with the CREATE RLS POLICY statement, observe the following:

- Amazon Redshift supports filters that can be part of a WHERE clause of a query.
- All policies being attached to a table must have been created with the same table alias.
- You don't require SELECT permission on lookup tables. When you create a policy, Amazon Redshift grants the SELECT permission on the lookup table for the respective policy. A lookup table is a table object used inside a policy definition.
- Amazon Redshift row-level security doesn't support the following object types inside a policy definition: catalog tables, cross-database relations, external tables, regular views, late-binding views, tables with RLS policies turned on, and temporary tables.

Examples

The following SQL statements create the tables, users, and roles for the CREATE RLS POLICY example.

```
-- Create users and roles reference in the policy statements.  
CREATE ROLE analyst;  
  
CREATE ROLE consumer;
```

```
CREATE USER bob WITH PASSWORD 'Name_is_bob_1';

CREATE USER alice WITH PASSWORD 'Name_is_alice_1';

CREATE USER joe WITH PASSWORD 'Name_is_joe_1';

GRANT ROLE sys:secadmin TO bob;

GRANT ROLE analyst TO alice;

GRANT ROLE consumer TO joe;

GRANT ALL ON TABLE tickit_category_redshift TO PUBLIC;
```

The following example creates a policy called `policy_concerts`.

```
CREATE RLS POLICY policy_concerts
WITH (catgroup VARCHAR(10))
USING (catgroup = 'Concerts');
```

CREATE ROLE

Creates a new custom role that is a collection of permissions. For a list of Amazon Redshift system-defined roles, see [the section called “Amazon Redshift system-defined roles”](#). Query [SVV_ROLES](#) to view the currently created roles in your cluster or workgroup.

There is a quota of the number of roles that can be created. For more information, see [Quotas and limits in Amazon Redshift](#) in the *Amazon Redshift Management Guide*.

Required permissions

Following are the required privileges for CREATE ROLE.

- Superuser
- Users with the CREATE ROLE privilege

Syntax

```
CREATE ROLE role_name
```

```
[ EXTERNALID external_id ]
```

Parameters

role_name

The name of the role. The role name must be unique and can't be the same as any user names. A role name can't be a reserved word.

A superuser or regular user with the CREATE ROLE privilege can create roles. A user that is not a superuser but that has been granted USAGE to the role WITH GRANT OPTION and ALTER privilege can grant this role to anyone.

EXTERNALID *external_id*

The identifier for the role, which is associated with an identity provider. For more information, see [Native identity provider \(IdP\) federation for Amazon Redshift](#).

Examples

The following example creates a role `sample_role1`.

```
CREATE ROLE sample_role1;
```

The following example creates a role `sample_role1`, with an external ID that is associated with an identity provider.

```
CREATE ROLE sample_role1 EXTERNALID "ABC123";
```

CREATE SCHEMA

Defines a new schema for the current database.

Required privileges

Following are required privileges for CREATE SCHEMA:

- Superuser
- Users with the CREATE SCHEMA privilege

Syntax

```
CREATE SCHEMA [ IF NOT EXISTS ] schema_name [ AUTHORIZATION username ]  
           [ QUOTA {quota [MB | GB | TB] | UNLIMITED} ] [ schema_element [ ... ] ]  
  
CREATE SCHEMA AUTHORIZATION username[ QUOTA {quota [MB | GB | TB] | UNLIMITED} ]  
 [ schema_element [ ... ] ]
```

Parameters

IF NOT EXISTS

Clause that indicates that if the specified schema already exists, the command should make no changes and return a message that the schema exists, rather than terminating with an error.

This clause is useful when scripting, so the script doesn't fail if CREATE SCHEMA tries to create a schema that already exists.

schema_name

Name of the new schema. The schema name can't be PUBLIC. For more information about valid names, see [Names and identifiers](#).

Note

The list of schemas in the [search_path](#) configuration parameter determines the precedence of identically named objects when they are referenced without schema names.

AUTHORIZATION

Clause that gives ownership to a specified user.

username

Name of the schema owner.

schema_element

Definition for one or more objects to be created within the schema.

QUOTA

The maximum amount of disk space that the specified schema can use. This space is the collective disk usage. It includes all permanent tables, materialized views under the specified schema, and duplicate copies of all tables with ALL distribution on each compute node. The schema quota doesn't take into account temporary tables created as part of a temporary namespace or schema.

To view the configured schema quotas, see [SVV_SCHEMA_QUOTA_STATE](#).

To view the records where schema quotas were exceeded, see [STL_SCHEMA_QUOTA_VIOLATIONS](#).

Amazon Redshift converts the selected value to megabytes. Gigabytes is the default unit of measurement when you don't specify a value.

You must be a database superuser to set and change a schema quota. A user that is not a superuser but that has CREATE SCHEMA permission can create a schema with a defined quota. When you create a schema without defining a quota, the schema has an unlimited quota. When you set the quota below the current value used by the schema, Amazon Redshift doesn't allow further ingestion until you free disk space. A DELETE statement deletes data from a table and disk space is freed up only when VACUUM runs.

Amazon Redshift checks each transaction for quota violations before committing the transaction. Amazon Redshift checks the size (the disk space used by all tables in a schema) of each modified schema against the set quota. Because the quota violation check occurs at the end of a transaction, the size limit can exceed the quota temporarily within a transaction before it's committed. When a transaction exceeds the quota, Amazon Redshift stops the transaction, prohibits subsequent ingestions, and reverts all the changes until you free disk space. Due to background VACUUM and internal cleanup, it is possible that a schema isn't full by the time that you check the schema after a canceled transaction.

As an exception, Amazon Redshift disregards the quota violation and commits transactions in certain cases. Amazon Redshift does this for transactions that consist solely of one or more of the following statements where there isn't an INSERT or COPY ingestion statement in the same transaction:

- DELETE
- TRUNCATE
- VACUUM

- DROP TABLE
- ALTER TABLE APPEND only when moving data from the full schema to another non-full schema

UNLIMITED

Amazon Redshift imposes no limit to the growth of the total size of the schema.

Limits

Amazon Redshift enforces the following limits for schemas.

- There is a maximum of 9900 schemas per database.

Examples

The following example creates a schema named US_SALES and gives ownership to the user DWUSER.

```
create schema us_sales authorization dwuser;
```

The following example creates a schema named US_SALES, gives ownership to the user DWUSER, and sets the quota to 50 GB.

```
create schema us_sales authorization dwuser QUOTA 50 GB;
```

To view the new schema, query the PG_NAMESPACE catalog table as shown following.

```
select nspname as schema, username as owner
from pg_namespace, pg_user
where pg_namespace.nspowner = pg_user.usesysid
and pg_user.username = 'dwuser';
```

```
   schema | owner
-----+-----
 us_sales | dwuser
(1 row)
```

The following example either creates the US_SALES schema, or does nothing and returns a message if it already exists.

```
create schema if not exists us_sales;
```

CREATE TABLE

Creates a new table in the current database. You define a list of columns, which each hold data of a distinct type. The owner of the table is the issuer of the CREATE TABLE command.

Required privileges

Following are required privileges for CREATE TABLE:

- Superuser
- Users with the CREATE TABLE privilege

Syntax

```
CREATE [ [LOCAL ] { TEMPORARY | TEMP } ] TABLE
[ IF NOT EXISTS ] table_name
( { column_name data_type [column_attributes] [ column_constraints ]
  | table_constraints
  | LIKE parent_table [ { INCLUDING | EXCLUDING } DEFAULTS ] }
[ , ... ] )
[ BACKUP { YES | NO } ]
[table_attributes]
```

where *column_attributes* are:

```
[ DEFAULT default_expr ]
[ IDENTITY ( seed, step ) ]
[ GENERATED BY DEFAULT AS IDENTITY ( seed, step ) ]
[ ENCODE encoding ]
[ DISTKEY ]
[ SORTKEY ]
[ COLLATE CASE_SENSITIVE | COLLATE CASE_INSENSITIVE ]
```

and *column_constraints* are:

```
[ { NOT NULL | NULL } ]
[ { UNIQUE | PRIMARY KEY } ]
[ REFERENCES reftable [ ( refcolumn ) ] ]
```

and *table_constraints* are:

```
[ UNIQUE ( column_name [, ... ] ) ]
[ PRIMARY KEY ( column_name [, ... ] ) ]
[ FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn ) ]
```

and *table_attributes* are:

```
[ DISTSTYLE { AUTO | EVEN | KEY | ALL } ]
[ DISTKEY ( column_name ) ]
[ [COMPOUND | INTERLEAVED ] SORTKEY ( column_name [,...]) | [ SORTKEY AUTO ] ]
[ ENCODE AUTO ]
```

Parameters

LOCAL

Optional. Although this keyword is accepted in the statement, it has no effect in Amazon Redshift.

TEMPORARY | TEMP

Keyword that creates a temporary table that is visible only within the current session. The table is automatically dropped at the end of the session in which it is created. The temporary table can have the same name as a permanent table. The temporary table is created in a separate, session-specific schema. (You can't specify a name for this schema.) This temporary schema becomes the first schema in the search path, so the temporary table takes precedence over the permanent table unless you qualify the table name with the schema name to access the permanent table. For more information about schemas and precedence, see [search_path](#).

Note

By default, database users have permission to create temporary tables by their automatic membership in the PUBLIC group. To deny this privilege to a user, revoke the TEMP privilege from the PUBLIC group, and then explicitly grant the TEMP privilege only to specific users or groups of users.

IF NOT EXISTS

Clause that indicates that if the specified table already exists, the command should make no changes and return a message that the table exists, rather than stopping with an error. Note

that the existing table might be nothing like the one that would have been created; only the table name is compared.

This clause is useful when scripting, so the script doesn't fail if CREATE TABLE tries to create a table that already exists.

table_name

Name of the table to be created.

Important

If you specify a table name that begins with '#', the table is created as a temporary table. The following is an example:

```
create table #newtable (id int);
```

You also reference the table with the '#'. For example:

```
select * from #newtable;
```

The maximum length for the table name is 127 bytes; longer names are truncated to 127 bytes. You can use UTF-8 multibyte characters up to a maximum of four bytes. Amazon Redshift enforces a quota of the number of tables per cluster by node type, including user-defined temporary tables and temporary tables created by Amazon Redshift during query processing or system maintenance. Optionally, the table name can be qualified with the database and schema name. In the following example, the database name is `tickit`, the schema name is `public`, and the table name is `test`.

```
create table tickit.public.test (c1 int);
```

If the database or schema doesn't exist, the table isn't created, and the statement returns an error. You can't create tables or views in the system databases `template0`, `template1`, `padb_harvest`, or `sys:internal`.

If a schema name is given, the new table is created in that schema (assuming the creator has access to the schema). The table name must be a unique name for that schema. If no schema

is specified, the table is created by using the current database schema. If you are creating a temporary table, you can't specify a schema name, because temporary tables exist in a special schema.

Multiple temporary tables with the same name can exist at the same time in the same database if they are created in separate sessions because the tables are assigned to different schemas.

For more information about valid names, see [Names and identifiers](#).

column_name

Name of a column to be created in the new table. The maximum length for the column name is 127 bytes; longer names are truncated to 127 bytes. You can use UTF-8 multibyte characters up to a maximum of four bytes. The maximum number of columns you can define in a single table is 1,600. For more information about valid names, see [Names and identifiers](#).

Note

If you are creating a "wide table," take care that your list of columns doesn't exceed row-width boundaries for intermediate results during loads and query processing. For more information, see [Usage notes](#).

data_type

Data type of the column being created. For CHAR and VARCHAR columns, you can use the MAX keyword instead of declaring a maximum length. MAX sets the maximum length to 4,096 bytes for CHAR or 65535 bytes for VARCHAR. The maximum size of a GEOMETRY object is 1,048,447 bytes.

For information about the data types that Amazon Redshift supports, see [Data types](#).

DEFAULT *default_expr*

Clause that assigns a default data value for the column. The data type of *default_expr* must match the data type of the column. The DEFAULT value must be a variable-free expression. Subqueries, cross-references to other columns in the current table, and user-defined functions aren't allowed.

The *default_expr* expression is used in any INSERT operation that doesn't specify a value for the column. If no default value is specified, the default value for the column is null.

If a COPY operation with a defined column list omits a column that has a DEFAULT value, the COPY command inserts the value of *default_expr*.

IDENTITY(*seed*, *step*)

Clause that specifies that the column is an IDENTITY column. An IDENTITY column contains unique autogenerated values. The data type for an IDENTITY column must be either INT or BIGINT.

When you add rows using an INSERT or INSERT INTO [tablename] VALUES() statement, these values start with the value specified as *seed* and increment by the number specified as *step*.

When you load the table using an INSERT INTO [tablename] SELECT * FROM or COPY statement, the data is loaded in parallel and distributed to the node slices. To be sure that the identity values are unique, Amazon Redshift skips a number of values when creating the identity values. Identity values are unique, but the order might not match the order in the source files.

GENERATED BY DEFAULT AS IDENTITY(*seed*, *step*)

Clause that specifies that the column is a default IDENTITY column and enables you to automatically assign a unique value to the column. The data type for an IDENTITY column must be either INT or BIGINT. When you add rows without values, these values start with the value specified as *seed* and increment by the number specified as *step*. For information about how values are generated, see [IDENTITY](#).

Also, during INSERT, UPDATE, or COPY you can provide a value without EXPLICIT_IDS. Amazon Redshift uses that value to insert into the identity column instead of using the system-generated value. The value can be a duplicate, a value less than the seed, or a value between step values. Amazon Redshift doesn't check the uniqueness of values in the column. Providing a value doesn't affect the next system-generated value.

Note

If you require uniqueness in the column, don't add a duplicate value. Instead, add a unique value that is less than the seed or between step values.

Keep in mind the following about default identity columns:

- Default identity columns are NOT NULL. NULL can't be inserted.
- To insert a generated value into a default identity column, use the keyword DEFAULT.

```
INSERT INTO tablename (identity-column-name) VALUES (DEFAULT);
```

- Overriding values of a default identity column doesn't affect the next generated value.
- You can't add a default identity column with the ALTER TABLE ADD COLUMN statement.
- You can append a default identity column with the ALTER TABLE APPEND statement.

ENCODE *encoding*

The compression encoding for a column. ENCODE AUTO is the default for tables. Amazon Redshift automatically manages compression encoding for all columns in the table. If you specify compression encoding for any column in the table, the table is no longer set to ENCODE AUTO. Amazon Redshift no longer automatically manages compression encoding for all columns in the table. You can specify the ENCODE AUTO option for the table to enable Amazon Redshift to automatically manage compression encoding for all columns in the table.

Amazon Redshift automatically assigns an initial compression encoding to columns for which you don't specify compression encoding as follows:

- All columns in temporary tables are assigned RAW compression by default.
- Columns that are defined as sort keys are assigned RAW compression.
- Columns that are defined as BOOLEAN, REAL, DOUBLE PRECISION, GEOMETRY, or GEOGRAPHY data type are assigned RAW compression.
- Columns that are defined as SMALLINT, INTEGER, BIGINT, DECIMAL, DATE, TIME, TIMETZ, TIMESTAMP, or TIMESTAMPTZ are assigned AZ64 compression.
- Columns that are defined as CHAR, VARCHAR, or VARBYTE are assigned LZ0 compression.

Note

If you don't want a column to be compressed, explicitly specify RAW encoding.

The following [compression encodings \(p. 63\)](#) are supported:

- AZ64

- BYTEDICT
- DELTA
- DELTA32K
- LZO
- MOSTLY8
- MOSTLY16
- MOSTLY32
- RAW (no compression)
- RUNLENGTH
- TEXT255
- TEXT32K
- ZSTD

DISTKEY

Keyword that specifies that the column is the distribution key for the table. Only one column in a table can be the distribution key. You can use the DISTKEY keyword after a column name or as part of the table definition by using the DISTKEY (*column_name*) syntax. Either method has the same effect. For more information, see the DISTSTYLE parameter later in this topic.

The data type of a distribution key column can be: BOOLEAN, REAL, DOUBLE PRECISION, SMALLINT, INTEGER, BIGINT, DECIMAL, DATE, TIME, TIMETZ, TIMESTAMP, or TIMESTAMPTZ, CHAR, or VARCHAR.

SORTKEY

Keyword that specifies that the column is the sort key for the table. When data is loaded into the table, the data is sorted by one or more columns that are designated as sort keys. You can use the SORTKEY keyword after a column name to specify a single-column sort key, or you can specify one or more columns as sort key columns for the table by using the SORTKEY (*column_name* [, ...]) syntax. Only compound sort keys are created with this syntax.

You can define a maximum of 400 SORTKEY columns per table.

The data type of a sort key column can be: BOOLEAN, REAL, DOUBLE PRECISION, SMALLINT, INTEGER, BIGINT, DECIMAL, DATE, TIME, TIMETZ, TIMESTAMP, or TIMESTAMPTZ, CHAR, or VARCHAR.

COLLATE CASE_SENSITIVE | COLLATE CASE_INSENSITIVE

A clause that specifies whether string search or comparison on the column is `CASE_SENSITIVE` or `CASE_INSENSITIVE`. The default value is the same as the current case sensitivity configuration of the database.

To find the database collation information, use the following command:

```
SELECT db_collation();

db_collation
-----
case_sensitive
(1 row)
```

NOT NULL | NULL

`NOT NULL` specifies that the column isn't allowed to contain null values. `NULL`, the default, specifies that the column accepts null values. `IDENTITY` columns are declared `NOT NULL` by default.

UNIQUE

Keyword that specifies that the column can contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns. To define a unique table constraint, use the `UNIQUE (column_name [, ...])` syntax.

Important

Unique constraints are informational and aren't enforced by the system.

PRIMARY KEY

Keyword that specifies that the column is the primary key for the table. Only one column can be defined as the primary key by using a column definition. To define a table constraint with a multiple-column primary key, use the `PRIMARY KEY (column_name [, ...])` syntax.

Identifying a column as the primary key provides metadata about the design of the schema. A primary key implies that other tables can rely on this set of columns as a unique identifier for rows. One primary key can be specified for a table, whether as a column constraint or a table

constraint. The primary key constraint should name a set of columns that is different from other sets of columns named by any unique constraint defined for the same table.

PRIMARY KEY columns are also defined as NOT NULL.

 **Important**

Primary key constraints are informational only. They aren't enforced by the system, but they are used by the planner.

References *reftable* [(*refcolumn*)]

Clause that specifies a foreign key constraint, which implies that the column must contain only values that match values in the referenced column of some row of the referenced table. The referenced columns should be the columns of a unique or primary key constraint in the referenced table.

 **Important**

Foreign key constraints are informational only. They aren't enforced by the system, but they are used by the planner.

LIKE *parent_table* [{ INCLUDING | EXCLUDING } DEFAULTS]

A clause that specifies an existing table from which the new table automatically copies column names, data types, and NOT NULL constraints. The new table and the parent table are decoupled, and any changes made to the parent table aren't applied to the new table. Default expressions for the copied column definitions are copied only if INCLUDING DEFAULTS is specified. The default behavior is to exclude default expressions, so that all columns of the new table have null defaults.

Tables created with the LIKE option don't inherit primary and foreign key constraints. Distribution style, sort keys, BACKUP, and NULL properties are inherited by LIKE tables, but you can't explicitly set them in the CREATE TABLE ... LIKE statement.

BACKUP { YES | NO }

A clause that specifies whether the table should be included in automated and manual cluster snapshots.

For tables, such as staging tables, that don't contain critical data, specify `BACKUP NO` to save processing time when creating snapshots and restoring from snapshots and to reduce storage space on Amazon Simple Storage Service. The `BACKUP NO` setting has no effect on automatic replication of data to other nodes within the cluster, so tables with `BACKUP NO` specified are restored in the event of a node failure. The default is `BACKUP YES`.

`DISTSTYLE { AUTO | EVEN | KEY | ALL }`

Keyword that defines the data distribution style for the whole table. Amazon Redshift distributes the rows of a table to the compute nodes according to the distribution style specified for the table. The default is `AUTO`.

The distribution style that you select for tables affects the overall performance of your database. For more information, see [Data distribution for query optimization](#). Possible distribution styles are as follows:

- **AUTO:** Amazon Redshift assigns an optimal distribution style based on the table data. For example, if `AUTO` distribution style is specified, Amazon Redshift initially assigns the `ALL` distribution style to a small table. When the table grows larger, Amazon Redshift might change the distribution style to `KEY`, choosing the primary key (or a column of the composite primary key) as the `DISTKEY`. If the table grows larger and none of the columns are suitable to be the `DISTKEY`, Amazon Redshift changes the distribution style to `EVEN`. The change in distribution style occurs in the background with minimal impact to user queries.

To view the distribution style applied to a table, query the `PG_CLASS` system catalog table. For more information, see [Viewing distribution styles](#).

- **EVEN:** The data in the table is spread evenly across the nodes in a cluster in a round-robin distribution. Row IDs are used to determine the distribution, and roughly the same number of rows are distributed to each node.
- **KEY:** The data is distributed by the values in the `DISTKEY` column. When you set the joining columns of joining tables as distribution keys, the joining rows from both tables are collocated on the compute nodes. When data is collocated, the optimizer can perform joins more efficiently. If you specify `DISTSTYLE KEY`, you must name a `DISTKEY` column, either for the table or as part of the column definition. For more information, see the `DISTKEY` parameter earlier in this topic.
- **ALL:** A copy of the entire table is distributed to every node. This distribution style ensures that all the rows required for any join are available on every node, but it multiplies storage requirements and increases the load and maintenance times for the table. `ALL` distribution can improve execution time when used with certain dimension tables where `KEY` distribution

isn't appropriate, but performance improvements must be weighed against maintenance costs.

DISTKEY (*column_name*)

Constraint that specifies the column to be used as the distribution key for the table. You can use the DISTKEY keyword after a column name or as part of the table definition, by using the DISTKEY (*column_name*) syntax. Either method has the same effect. For more information, see the DISTSTYLE parameter earlier in this topic.

[COMPOUND | INTERLEAVED] SORTKEY (*column_name* [,...]) | [SORTKEY AUTO]

Specifies one or more sort keys for the table. When data is loaded into the table, the data is sorted by the columns that are designated as sort keys. You can use the SORTKEY keyword after a column name to specify a single-column sort key, or you can specify one or more columns as sort key columns for the table by using the SORTKEY (*column_name* [, . . .]) syntax.

You can optionally specify COMPOUND or INTERLEAVED sort style. If you specify SORTKEY with columns the default is COMPOUND. For more information, see [Sort keys](#).

If you don't specify any sort keys options, the default is AUTO.

You can define a maximum of 400 COMPOUND SORTKEY columns or 8 INTERLEAVED SORTKEY columns per table.

AUTO

Specifies that Amazon Redshift assigns an optimal sort key based on the table data. For example, if AUTO sort key is specified, Amazon Redshift initially assigns no sort key to a table. If Amazon Redshift determines that a sort key will improve the performance of queries, then Amazon Redshift might change the sort key of your table. The actual sorting of the table is done by automatic table sort. For more information, see [Automatic table sort](#).

Amazon Redshift doesn't modify tables that have existing sort or distribution keys. With one exception, if a table has a distribution key that has never been used in a JOIN, then the key might be changed if Amazon Redshift determines there is a better key.

To view the sort key of a table, query the SVV_TABLE_INFO system catalog view. For more information, see [SVV_TABLE_INFO](#). To view the Amazon Redshift Advisor recommendations for tables, query the SVV_ALTER_TABLE_RECOMMENDATIONS system catalog view. For more information, see [SVV_ALTER_TABLE_RECOMMENDATIONS](#). To view the actions taken

by Amazon Redshift, query the `SVL_AUTO_WORKER_ACTION` system catalog view. For more information, see [SVL_AUTO_WORKER_ACTION](#).

COMPOUND

Specifies that the data is sorted using a compound key made up of all of the listed columns, in the order they are listed. A compound sort key is most useful when a query scans rows according to the order of the sort columns. The performance benefits of sorting with a compound key decrease when queries rely on secondary sort columns. You can define a maximum of 400 `COMPOUND SORTKEY` columns per table.

INTERLEAVED

Specifies that the data is sorted using an interleaved sort key. A maximum of eight columns can be specified for an interleaved sort key.

An interleaved sort gives equal weight to each column, or subset of columns, in the sort key, so queries don't depend on the order of the columns in the sort key. When a query uses one or more secondary sort columns, interleaved sorting significantly improves query performance. Interleaved sorting carries a small overhead cost for data loading and vacuuming operations.

Important

Don't use an interleaved sort key on columns with monotonically increasing attributes, such as identity columns, dates, or timestamps.

ENCODE AUTO

Enables Amazon Redshift to automatically adjust the encoding type for all columns in the table to optimize query performance. `ENCODE AUTO` preserves the initial encode types that you specify in creating the table. Then, if Amazon Redshift determines that a new encoding type can improve query performance, Amazon Redshift can change the encoding type of the table columns. `ENCODE AUTO` is the default if you don't specify an encoding type on any column in the table.

UNIQUE (*column_name* [,...])

Constraint that specifies that a group of one or more columns of a table can contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns. In the context of unique

constraints, null values aren't considered equal. Each unique table constraint must name a set of columns that is different from the set of columns named by any other unique or primary key constraint defined for the table.

 **Important**

Unique constraints are informational and aren't enforced by the system.

PRIMARY KEY (*column_name* [,...])

Constraint that specifies that a column or a number of columns of a table can contain only unique (nonduplicate) non-null values. Identifying a set of columns as the primary key also provides metadata about the design of the schema. A primary key implies that other tables can rely on this set of columns as a unique identifier for rows. One primary key can be specified for a table, whether as a single column constraint or a table constraint. The primary key constraint should name a set of columns that is different from other sets of columns named by any unique constraint defined for the same table.

 **Important**

Primary key constraints are informational only. They aren't enforced by the system, but they are used by the planner.

FOREIGN KEY (*column_name* [, ...]) REFERENCES *reftable* [(*refcolumn*)]

Constraint that specifies a foreign key constraint, which requires that a group of one or more columns of the new table must only contain values that match values in the referenced column or columns of some row of the referenced table. If *refcolumn* is omitted, the primary key of *reftable* is used. The referenced columns must be the columns of a unique or primary key constraint in the referenced table.

 **Important**

Foreign key constraints are informational only. They aren't enforced by the system, but they are used by the planner.

Usage notes

Uniqueness, primary key, and foreign key constraints are informational only; *they are not enforced by Amazon Redshift* when you populate a table. For example, if you insert data into a table with dependencies, the insert can succeed even if it violates the constraint. Nonetheless, primary keys and foreign keys are used as planning hints and they should be declared if your ETL process or some other process in your application enforces their integrity. For information about how to drop a table with dependencies, see [DROP TABLE](#).

Limits and quotas

Consider the following limits when you create a table.

- There is a limit for the maximum number of tables in a cluster by node type. For more information, see [Limits](#) in the *Amazon Redshift Management Guide*.
- The maximum number of characters for a table name is 127.
- The maximum number of columns you can define in a single table is 1,600.
- The maximum number of SORTKEY columns you can define in a single table is 400.

Summary of column-level settings and table-level settings

Several attributes and settings can be set at the column level or at the table level. In some cases, setting an attribute or constraint at the column level or at the table level has the same effect. In other cases, they produce different results.

The following list summarizes column-level and table-level settings:

DISTKEY

There is no difference in effect whether set at the column level or at the table level.

If DISTKEY is set, either at the column level or at the table level, DISTSTYLE must be set to KEY or not set at all. DISTSTYLE can be set only at the table level.

SORTKEY

If set at the column level, SORTKEY must be a single column. If SORTKEY is set at the table level, one or more columns can make up a compound or interleaved composite sort key.

COLLATE CASE_SENSITIVE | COLLATE CASE_INSENSITIVE

Amazon Redshift doesn't support altering case-sensitivity configuration for a column. When you append a new column to the table, Amazon Redshift uses the default value for case-sensitivity. Amazon Redshift doesn't support the COLLATE key word when appending a new column.

For information on how to create databases using database collation, see [CREATE DATABASE](#).

For information on the COLLATE function, see [COLLATE function](#).

UNIQUE

At the column level, one or more keys can be set to UNIQUE; the UNIQUE constraint applies to each column individually. If UNIQUE is set at the table level, one or more columns can make up a composite UNIQUE constraint.

PRIMARY KEY

If set at the column level, PRIMARY KEY must be a single column. If PRIMARY KEY is set at the table level, one or more columns can make up a composite primary key .

FOREIGN KEY

There is no difference in effect whether FOREIGN KEY is set at the column level or at the table level. At the column level, the syntax is simply REFERENCES *reftable* [(*refcolumn*)].

Distribution of incoming data

When the hash distribution scheme of the incoming data matches that of the target table, no physical distribution of the data is actually necessary when the data is loaded. For example, if a distribution key is set for the new table and the data is being inserted from another table that is distributed on the same key column, the data is loaded in place, using the same nodes and slices. However, if the source and target tables are both set to EVEN distribution, data is redistributed into the target table.

Wide tables

You might be able to create a very wide table but be unable to perform query processing, such as INSERT or SELECT statements, on the table. The maximum width of a table with fixed width columns, such as CHAR, is 64KB - 1 (or 65535 bytes). If a table includes VARCHAR columns, the table can have a larger declared width without returning an error because VARCHARS columns

don't contribute their full declared width to the calculated query-processing limit. The effective query-processing limit with VARCHAR columns will vary based on a number of factors.

If a table is too wide for inserting or selecting, you receive the following error.

```
ERROR: 8001
DETAIL: The combined length of columns processed in the SQL statement
exceeded the query-processing limit of 65535 characters (pid:7627)
```

Examples

For examples that show how to use the CREATE TABLE command, see the [Examples](#) topic.

Examples

The following examples demonstrate various column and table attributes in Amazon Redshift CREATE TABLE statements. For more information about CREATE TABLE, including parameter definitions, see [CREATE TABLE](#).

Many of the examples use tables and data from the *TICKIT* sample data set. For more information, see [Sample database](#).

You can prefix the table name with the database name and schema name in a CREATE TABLE command. For instance, `dev_database.public.sales`. The database name must be the database you are connected to. Any attempt to create database objects in another database fails with an invalid-operation error.

Create a table with a distribution key, a compound sort key, and compression

The following example creates a SALES table in the TICKIT database with compression defined for several columns. LISTID is declared as the distribution key, and LISTID and SELLERID are declared as a multicolumn compound sort key. Primary key and foreign key constraints are also defined for the table. Prior to creating the table in the example, you might need to add a UNIQUE constraint to each column referenced by a foreign key, if constraints don't exist.

```
create table sales(
salesid integer not null,
listid integer not null,
sellerid integer not null,
```

```

buyerid integer not null,
eventid integer not null encode mostly16,
dateid smallint not null,
qtysold smallint not null encode mostly8,
pricepaid decimal(8,2) encode delta32k,
commission decimal(8,2) encode delta32k,
saletime timestamp,
primary key(salesid),
foreign key(listid) references listing(listid),
foreign key(sellerid) references users(userid),
foreign key(buyerid) references users(userid),
foreign key(dateid) references date(dateid))
distkey(listid)
compound sortkey(listid,sellerid);

```

The results follow:

schemaname	tablename	column	type	encoding	distkey
	sortkey	notnull			
public	0	true	integer	lzo	false
public	1	true	integer	none	true
public	2	true	integer	none	false
public	0	true	integer	lzo	false
public	0	true	integer	mostly16	false
public	0	true	smallint	lzo	false
public	0	true	smallint	mostly8	false
public	0	false	numeric(8,2)	delta32k	false
public	0	false	numeric(8,2)	delta32k	false
public	0	false	timestamp without time zone	lzo	false

The following example creates table t1 with a case-insensitive column col1.

```
create table T1 (  
  col1 Varchar(20) collate case_insensitive  
);  
  
insert into T1 values ('bob'), ('john'), ('Tom'), ('JOHN'), ('Bob');
```

Query the table:

```
select * from T1 where col1 = 'John';  
  
col1  
-----  
john  
JOHN  
(2 rows)
```

Create a table using an interleaved sort key

The following example creates the CUSTOMER table with an interleaved sort key.

```
create table customer_interleaved (  
  c_custkey      integer      not null,  
  c_name         varchar(25)   not null,  
  c_address      varchar(25)   not null,  
  c_city         varchar(10)   not null,  
  c_nation       varchar(15)   not null,  
  c_region       varchar(12)   not null,  
  c_phone        varchar(15)   not null,  
  c_mktsegment   varchar(10)   not null)  
diststyle all  
interleaved sortkey (c_custkey, c_city, c_mktsegment);
```

Create a table using IF NOT EXISTS

The following example either creates the CITIES table, or does nothing and returns a message if it already exists:

```
create table if not exists cities(  
  cityid integer not null,  
  city varchar(100) not null,  
  state char(2) not null);
```

Create a table with ALL distribution

The following example creates the VENUE table with ALL distribution.

```
create table venue(
venueid smallint not null,
venueid varchar(100),
venuecity varchar(30),
venuestate char(2),
venuestate integer,
primary key(venueid))
diststyle all;
```

Create a Table with EVEN distribution

The following example creates a table called MYEVENT with three columns.

```
create table myevent(
eventid int,
eventname varchar(200),
eventcity varchar(30))
diststyle even;
```

The table is distributed evenly and isn't sorted. The table has no declared DISTKEY or SORTKEY columns.

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 'myevent';
```

column	type	encoding	distkey	sortkey
eventid	integer	lzo	f	0
eventname	character varying(200)	lzo	f	0
eventcity	character varying(30)	lzo	f	0

(3 rows)

Create a temporary table that is LIKE another table

The following example creates a temporary table called TEMPEVENT, which inherits its columns from the EVENT table.

```
create temp table tempevent(like event);
```

This table also inherits the DISTKEY and SORTKEY attributes of its parent table:

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 'tempevent';
```

column	type	encoding	distkey	sortkey
eventid	integer	none	t	1
venueid	smallint	none	f	0
catid	smallint	none	f	0
dateid	smallint	none	f	0
eventname	character varying(200)	lzo	f	0
starttime	timestamp without time zone	bytedict	f	0

(6 rows)

Create a table with an IDENTITY column

The following example creates a table named VENUE_IDENT, which has an IDENTITY column named VENUEID. This column starts with 0 and increments by 1 for each record. VENUEID is also declared as the primary key of the table.

```
create table venue_ident(venueid bigint identity(0, 1),
venueid varchar(100),
venuecity varchar(30),
venuestate char(2),
venuestate integer,
primary key(venueid));
```

Create a table with a default IDENTITY column

The following example creates a table named t1. This table has an IDENTITY column named hist_id and a default IDENTITY column named base_id.

```
CREATE TABLE t1(
  hist_id BIGINT IDENTITY NOT NULL, /* Cannot be overridden */
  base_id BIGINT GENERATED BY DEFAULT AS IDENTITY NOT NULL, /* Can be overridden */
  business_key varchar(10) ,
  some_field varchar(10)
);
```

Inserting a row into the table shows that both hist_id and base_id values are generated.

```
INSERT INTO T1 (business_key, some_field) values ('A','MM');
```

```
SELECT * FROM t1;
```

hist_id	base_id	business_key	some_field
1	1	A	MM

Inserting a second row shows that the default value for base_id is generated.

```
INSERT INTO T1 (base_id, business_key, some_field) values (DEFAULT, 'B','MNOP');
```

```
SELECT * FROM t1;
```

hist_id	base_id	business_key	some_field
1	1	A	MM
2	2	B	MNOP

Inserting a third row shows that the value for base_id doesn't need to be unique.

```
INSERT INTO T1 (base_id, business_key, some_field) values (2,'B','MNNN');
```

```
SELECT * FROM t1;
```

hist_id	base_id	business_key	some_field
1	1	A	MM
2	2	B	MNOP
3	2	B	MNNN

Create a table with DEFAULT column values

The following example creates a CATEGORYDEF table that declares default values for each column:

```
create table categorydef(
  catid smallint not null default 0,
  catgroup varchar(10) default 'Special',
  catname varchar(10) default 'Other',
```

```
catdesc varchar(50) default 'Special events',
primary key(catid));

insert into categorydef values(default,default,default,default);
```

```
select * from categorydef;
```

```
 catid | catgroup | catname |   catdesc
-----+-----+-----+-----
      0 | Special  | Other   | Special events
(1 row)
```

DISTSTYLE, DISTKEY, and SORTKEY options

The following example shows how the DISTKEY, SORTKEY, and DISTSTYLE options work. In this example, COL1 is the distribution key; therefore, the distribution style must be either set to KEY or not set. By default, the table has no sort key and so isn't sorted:

```
create table t1(col1 int distkey, col2 int) diststyle key;
```

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 't1';
```

```
column | type   | encoding | distkey | sortkey
-----+-----+-----+-----+-----
col1   | integer | az64     | t       | 0
col2   | integer | az64     | f       | 0
```

In the following example, the same column is defined as the distribution key and the sort key. Again, the distribution style must be either set to KEY or not set.

```
create table t2(col1 int distkey sortkey, col2 int);
```

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 't2';
```

```
column | type   | encoding | distkey | sortkey
-----+-----+-----+-----+-----
col1   | integer | none     | t       | 1
```

```
col2 | integer | az64 | f | 0
```

In the following example, no column is set as the distribution key, COL2 is set as the sort key, and the distribution style is set to ALL:

```
create table t3(col1 int, col2 int sortkey) diststyle all;
```

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 't3';
```

Column	Type	Encoding	DistKey	SortKey
col1	integer	az64	f	0
col2	integer	none	f	1

In the following example, the distribution style is set to EVEN and no sort key is defined explicitly; therefore the table is distributed evenly but isn't sorted.

```
create table t4(col1 int, col2 int) diststyle even;
```

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 't4';
```

column	type	encoding	distkey	sortkey
col1	integer	az64	f	0
col2	integer	az64	f	0

Create a table with the ENCODE AUTO option

The following example creates the table t1 with automatic compression encoding. ENCODE AUTO is the default for tables when you don't specify an encoding type for any column.

```
create table t1(c0 int, c1 varchar);
```

The following example creates the table t2 with automatic compression encoding by specifying ENCODE AUTO.

```
create table t2(c0 int, c1 varchar) encode auto;
```

The following example creates the table `t3` with automatic compression encoding by specifying `ENCODE AUTO`. Column `c0` is defined with an initial encoding type of `DELTA`. Amazon Redshift can change the encoding if another encoding provides better query performance.

```
create table t3(c0 int encode delta, c1 varchar) encode auto;
```

The following example creates the table `t4` with automatic compression encoding by specifying `ENCODE AUTO`. Column `c0` is defined with an initial encoding of `DELTA`, and column `c1` is defined with an initial encoding of `LZO`. Amazon Redshift can change these encodings if other encodings provide better query performance.

```
create table t4(c0 int encode delta, c1 varchar encode lzo) encode auto;
```

CREATE TABLE AS

Topics

- [Syntax](#)
- [Parameters](#)
- [CTAS usage notes](#)
- [CTAS examples](#)

Creates a new table based on a query. The owner of this table is the user that issues the command.

The new table is loaded with data defined by the query in the command. The table columns have names and data types associated with the output columns of the query. The `CREATE TABLE AS` (`CTAS`) command creates a new table and evaluates the query to load the new table.

Syntax

```
CREATE [ [ LOCAL ] { TEMPORARY | TEMP } ]  
TABLE table_name  
[ ( column_name [, ... ] ) ]  
[ BACKUP { YES | NO } ]  
[ table_attributes ]  
AS query
```

where *table_attributes* are:

```
[ DISTSTYLE { AUTO | EVEN | ALL | KEY } ]  
[ DISTKEY( distkey_identifier ) ]  
[ [ COMPOUND | INTERLEAVED ] SORTKEY( column_name [, ...] ) ]
```

Parameters

LOCAL

Although this optional keyword is accepted in the statement, it has no effect in Amazon Redshift.

TEMPORARY | TEMP

Creates a temporary table. A temporary table is automatically dropped at the end of the session in which it was created.

table_name

The name of the table to be created.

Important

If you specify a table name that begins with '#', the table is created as a temporary table. For example:

```
create table #newtable (id) as select * from oldtable;
```

The maximum table name length is 127 bytes; longer names are truncated to 127 bytes. Amazon Redshift enforces a quota of the number of tables per cluster by node type. The table name can be qualified with the database and schema name, as the following table shows.

```
create table tickit.public.test (c1) as select * from oldtable;
```

In this example, `tickit` is the database name and `public` is the schema name. If the database or schema doesn't exist, the statement returns an error.

If a schema name is given, the new table is created in that schema (assuming the creator has access to the schema). The table name must be a unique name for that schema. If no schema is specified, the table is created using the current database schema. If you are creating a

temporary table, you can't specify a schema name, since temporary tables exist in a special schema.

Multiple temporary tables with the same name are allowed to exist at the same time in the same database if they are created in separate sessions. These tables are assigned to different schemas.

column_name

The name of a column in the new table. If no column names are provided, the column names are taken from the output column names of the query. Default column names are used for expressions. For more information about valid names, see [Names and identifiers](#).

BACKUP { YES | NO }

A clause that specifies whether the table should be included in automated and manual cluster snapshots.

For tables, such as staging tables, that don't contain critical data, specify BACKUP NO to save processing time when creating snapshots and restoring from snapshots and to reduce storage space on Amazon Simple Storage Service. The BACKUP NO setting has no effect on automatic replication of data to other nodes within the cluster, so tables with BACKUP NO specified are restored in the event of a node failure. The default is BACKUP YES.

DISTSTYLE { AUTO | EVEN | KEY | ALL }

Keyword that defines the data distribution style for the whole table. Amazon Redshift distributes the rows of a table to the compute nodes according to the distribution style specified for the table. The default is DISTSTYLE AUTO.

The distribution style that you select for tables affects the overall performance of your database. For more information, see [Data distribution for query optimization](#).

- **AUTO:** Amazon Redshift assigns an optimal distribution style based on the table data. To view the distribution style applied to a table, query the PG_CLASS system catalog table. For more information, see [Viewing distribution styles](#).
- **EVEN:** The data in the table is spread evenly across the nodes in a cluster in a round-robin distribution. Row IDs are used to determine the distribution, and roughly the same number of rows are distributed to each node. This is the default distribution method.
- **KEY:** The data is distributed by the values in the DISTKEY column. When you set the joining columns of joining tables as distribution keys, the joining rows from both tables are

collocated on the compute nodes. When data is collocated, the optimizer can perform joins more efficiently. If you specify `DISTSTYLE KEY`, you must name a `DISTKEY` column.

- **ALL:** A copy of the entire table is distributed to every node. This distribution style ensures that all the rows required for any join are available on every node, but it multiplies storage requirements and increases the load and maintenance times for the table. `ALL` distribution can improve execution time when used with certain dimension tables where `KEY` distribution isn't appropriate, but performance improvements must be weighed against maintenance costs.

`DISTKEY` (*column*)

Specifies a column name or positional number for the distribution key. Use the name specified in either the optional column list for the table or the select list of the query. Alternatively, use a positional number, where the first column selected is 1, the second is 2, and so on. Only one column in a table can be the distribution key:

- If you declare a column as the `DISTKEY` column, `DISTSTYLE` must be set to `KEY` or not set at all.
- If you don't declare a `DISTKEY` column, you can set `DISTSTYLE` to `EVEN`.
- If you don't specify `DISTKEY` or `DISTSTYLE`, CTAS determines the distribution style for the new table based on the query plan for the `SELECT` clause. For more information, see [Inheritance of column and table attributes](#).

You can define the same column as the distribution key and the sort key; this approach tends to accelerate joins when the column in question is a joining column in the query.

[`COMPOUND` | `INTERLEAVED`] `SORTKEY` (*column_name* [, ...])

Specifies one or more sort keys for the table. When data is loaded into the table, the data is sorted by the columns that are designated as sort keys.

You can optionally specify `COMPOUND` or `INTERLEAVED` sort style. The default is `COMPOUND`. For more information, see [Sort keys](#).

You can define a maximum of 400 `COMPOUND SORTKEY` columns or 8 `INTERLEAVED SORTKEY` columns per table.

If you don't specify `SORTKEY`, CTAS determines the sort keys for the new table based on the query plan for the `SELECT` clause. For more information, see [Inheritance of column and table attributes](#).

COMPOUND

Specifies that the data is sorted using a compound key made up of all of the listed columns, in the order they are listed. A compound sort key is most useful when a query scans rows according to the order of the sort columns. The performance benefits of sorting with a compound key decrease when queries rely on secondary sort columns. You can define a maximum of 400 COMPOUND SORTKEY columns per table.

INTERLEAVED

Specifies that the data is sorted using an interleaved sort key. A maximum of eight columns can be specified for an interleaved sort key.

An interleaved sort gives equal weight to each column, or subset of columns, in the sort key, so queries don't depend on the order of the columns in the sort key. When a query uses one or more secondary sort columns, interleaved sorting significantly improves query performance. Interleaved sorting carries a small overhead cost for data loading and vacuuming operations.

AS query

Any query (SELECT statement) that Amazon Redshift supports.

CTAS usage notes

Limits

Amazon Redshift enforces a quota of the number of tables per cluster by node type.

The maximum number of characters for a table name is 127.

The maximum number of columns you can define in a single table is 1,600.

Inheritance of column and table attributes

CREATE TABLE AS (CTAS) tables don't inherit constraints, identity columns, default column values, or the primary key from the table that they were created from.

You can't specify column compression encodings for CTAS tables. Amazon Redshift automatically assigns compression encoding as follows:

- Columns that are defined as sort keys are assigned RAW compression.

- Columns that are defined as `BOOLEAN`, `REAL`, `DOUBLE PRECISION`, `GEOMETRY`, or `GEOGRAPHY` data type are assigned RAW compression.
- Columns that are defined as `SMALLINT`, `INTEGER`, `BIGINT`, `DECIMAL`, `DATE`, `TIME`, `TIMETZ`, `TIMESTAMP`, or `TIMESTAMPTZ` are assigned AZ64 compression.
- Columns that are defined as `CHAR`, `VARCHAR`, or `VARBYTE` are assigned LZ0 compression.

For more information, see [Compression encodings](#) and [Data types](#).

To explicitly assign column encodings, use [CREATE TABLE](#).

CTAS determines distribution style and sort key for the new table based on the query plan for the `SELECT` clause.

For complex queries, such as queries that include joins, aggregations, an order by clause, or a limit clause, CTAS makes a best effort to choose the optimal distribution style and sort key based on the query plan.

 **Note**

For best performance with large datasets or complex queries, we recommend testing using typical datasets.

You can often predict which distribution key and sort key CTAS chooses by examining the query plan to see which columns, if any, the query optimizer chooses for sorting and distributing data. If the top node of the query plan is a simple sequential scan from a single table (XN Seq Scan), then CTAS generally uses the source table's distribution style and sort key. If the top node of the query plan is anything other a sequential scan (such as XN Limit, XN Sort, XN HashAggregate, and so on), CTAS makes a best effort to choose the optimal distribution style and sort key based on the query plan.

For example, suppose you create five tables using the following types of `SELECT` clauses:

- A simple select statement
- A limit clause
- An order by clause using `LISTID`
- An order by clause using `QTYSOLD`
- A `SUM` aggregate function with a group by clause.

The following examples show the query plan for each CTAS statement.

```
explain create table sales1_simple as select listid, dateid, qtysold from sales;
          QUERY PLAN
```

```
-----
XN Seq Scan on sales (cost=0.00..1724.56 rows=172456 width=8)
(1 row)
```

```
explain create table sales2_limit as select listid, dateid, qtysold from sales limit
100;
```

```
          QUERY PLAN
```

```
-----
XN Limit (cost=0.00..1.00 rows=100 width=8)
-> XN Seq Scan on sales (cost=0.00..1724.56 rows=172456 width=8)
(2 rows)
```

```
explain create table sales3_orderbylistid as select listid, dateid, qtysold from sales
order by listid;
```

```
          QUERY PLAN
```

```
-----
XN Sort (cost=1000000016724.67..1000000017155.81 rows=172456 width=8)
Sort Key: listid
-> XN Seq Scan on sales (cost=0.00..1724.56 rows=172456 width=8)
(3 rows)
```

```
explain create table sales4_orderbyqty as select listid, dateid, qtysold from sales
order by qtysold;
```

```
          QUERY PLAN
```

```
-----
XN Sort (cost=1000000016724.67..1000000017155.81 rows=172456 width=8)
Sort Key: qtysold
-> XN Seq Scan on sales (cost=0.00..1724.56 rows=172456 width=8)
(3 rows)
```

```
explain create table sales5_groupby as select listid, dateid, sum(qtysold) from sales
group by listid, dateid;
```

```
          QUERY PLAN
```

```
-----
XN HashAggregate (cost=3017.98..3226.75 rows=83509 width=8)
-> XN Seq Scan on sales (cost=0.00..1724.56 rows=172456 width=8)
```

(2 rows)

To view the distribution key and sort key for each table, query the PG_TABLE_DEF system catalog table, as shown following.

```
select * from pg_table_def where tablename like 'sales%';
```

tablename	column	distkey	sortkey
sales	salesid	f	0
sales	listid	t	0
sales	sellerid	f	0
sales	buyerid	f	0
sales	eventid	f	0
sales	dateid	f	1
sales	qtysold	f	0
sales	pricepaid	f	0
sales	commission	f	0
sales	saletime	f	0
sales1_simple	listid	t	0
sales1_simple	dateid	f	1
sales1_simple	qtysold	f	0
sales2_limit	listid	f	0
sales2_limit	dateid	f	0
sales2_limit	qtysold	f	0
sales3_orderbylistid	listid	t	1
sales3_orderbylistid	dateid	f	0
sales3_orderbylistid	qtysold	f	0
sales4_orderbyqty	listid	t	0
sales4_orderbyqty	dateid	f	0
sales4_orderbyqty	qtysold	f	1
sales5_groupby	listid	f	0
sales5_groupby	dateid	f	0
sales5_groupby	sum	f	0

The following table summarizes the results. For simplicity, we omit cost, rows, and width details from the explain plan.

Table	CTAS SELECT statement	Explain plan top node	Dist key	Sort key
S1_SIMPLE	<code>select listid, dateid, qtysold from sales</code>	XN Seq Scan on sales ...	LISTID	DATEID
S2_LIMIT	<code>select listid, dateid, qtysold from sales limit 100</code>	XN Limit ...	None (EVEN)	None
S3_ORDER_BY_LISTID	<code>select listid, dateid, qtysold from sales order by listid</code>	XN Sort ... Sort Key: listid	LISTID	LISTID
S4_ORDER_BY_QTY	<code>select listid, dateid, qtysold from sales order by qtysold</code>	XN Sort ... Sort Key: qtysold	LISTID	QTYSOLD
S5_GROUP_BY	<code>select listid, dateid, sum(qtysold) from sales group by listid, dateid</code>	XN HashAggregate ...	None (EVEN)	None

You can explicitly specify distribution style and sort key in the CTAS statement. For example, the following statement creates a table using EVEN distribution and specifies SALESID as the sort key.

```
create table sales_disteven
diststyle even
sortkey (salesid)
as
select eventid, venueid, dateid, eventname
from event;
```

Compression encoding

ENCODE AUTO is used as the default for tables. Amazon Redshift automatically manages compression encoding for all columns in the table.

Distribution of incoming data

When the hash distribution scheme of the incoming data matches that of the target table, no physical distribution of the data is actually necessary when the data is loaded. For example, if a distribution key is set for the new table and the data is being inserted from another table that is distributed on the same key column, the data is loaded in place, using the same nodes and slices. However, if the source and target tables are both set to EVEN distribution, data is redistributed into the target table.

Automatic ANALYZE operations

Amazon Redshift automatically analyzes tables that you create with CTAS commands. You do not need to run the ANALYZE command on these tables when they are first created. If you modify them, you should analyze them in the same way as other tables.

CTAS examples

The following example creates a table called EVENT_BACKUP for the EVENT table:

```
create table event_backup as select * from event;
```

The resulting table inherits the distribution and sort keys from the EVENT table.

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 'event_backup';
```

column	type	encoding	distkey	sortkey
catid	smallint	none	false	0
dateid	smallint	none	false	1
eventid	integer	none	true	0
eventname	character varying(200)	none	false	0
starttime	timestamp without time zone	none	false	0
venueid	smallint	none	false	0

The following command creates a new table called EVENTDISTSORT by selecting four columns from the EVENT table. The new table is distributed by EVENTID and sorted by EVENTID and DATEID:

```
create table eventdistsort
distkey (1)
sortkey (1,3)
as
select eventid, venueid, dateid, eventname
from event;
```

The result is as follows:

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 'eventdistsort';
```

column	type	encoding	distkey	sortkey
eventid	integer	none	t	1
venueid	smallint	none	f	0
dateid	smallint	none	f	2
eventname	character varying(200)	none	f	0

You could create exactly the same table by using column names for the distribution and sort keys. For example:

```
create table eventdistsort1
distkey (eventid)
sortkey (eventid, dateid)
as
select eventid, venueid, dateid, eventname
from event;
```

The following statement applies even distribution to the table but doesn't define an explicit sort key.

```
create table eventdisteven
diststyle even
as
select eventid, venueid, dateid, eventname
from event;
```

The table doesn't inherit the sort key from the EVENT table (EVENTID) because EVEN distribution is specified for the new table. The new table has no sort key and no distribution key.

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 'eventdisteven';
```

column	type	encoding	distkey	sortkey
eventid	integer	none	f	0
venueid	smallint	none	f	0
dateid	smallint	none	f	0
eventname	character varying(200)	none	f	0

The following statement applies even distribution and defines a sort key:

```
create table eventdistevensort diststyle even sortkey (venueid)
as select eventid, venueid, dateid, eventname from event;
```

The resulting table has a sort key but no distribution key.

```
select "column", type, encoding, distkey, sortkey
from pg_table_def where tablename = 'eventdistevensort';
```

column	type	encoding	distkey	sortkey
eventid	integer	none	f	0
venueid	smallint	none	f	1
dateid	smallint	none	f	0
eventname	character varying(200)	none	f	0

The following statement redistributes the EVENT table on a different key column from the incoming data, which is sorted on the EVENTID column, and defines no SORTKEY column; therefore the table isn't sorted.

```
create table venuedistevent distkey(venueid)
as select * from event;
```

The result is as follows:

```
select "column", type, encoding, distkey, sortkey
```

```
from pg_table_def where tablename = 'venuedistevent';
```

column	type	encoding	distkey	sortkey
eventid	integer	none	f	0
venueid	smallint	none	t	0
catid	smallint	none	f	0
dateid	smallint	none	f	0
eventname	character varying(200)	none	f	0
starttime	timestamp without time zone	none	f	0

CREATE USER

Creates a new database user. Database users can retrieve data, run commands, and perform other actions in a database, depending on their privileges and roles. You must be a database superuser to run this command.

Required privileges

Following are required privileges for CREATE USER:

- Superuser
- Users with the CREATE USER privilege

Syntax

```
CREATE USER name [ WITH ]
PASSWORD { 'password' | 'md5hash' | 'sha256hash' | DISABLE }
[ option [ ... ] ]
```

where *option* can be:

```
CREATEDB | NOCREATEDB
| CREATEUSER | NOCREATEUSER
| SYSLOG ACCESS { RESTRICTED | UNRESTRICTED }
| IN GROUP groupname [, ... ]
| VALID UNTIL 'abstime'
| CONNECTION LIMIT { limit | UNLIMITED }
| SESSION TIMEOUT limit
| EXTERNALID external_id
```

Parameters

name

The name of the user to create. The user name can't be PUBLIC. For more information about valid names, see [Names and identifiers](#).

WITH

Optional keyword. WITH is ignored by Amazon Redshift

PASSWORD { 'password' | 'md5hash' | 'sha256hash' | DISABLE }

Sets the user's password.

By default, users can change their own passwords, unless the password is disabled. To disable a user's password, specify DISABLE. When a user's password is disabled, the password is deleted from the system and the user can log on only using temporary AWS Identity and Access Management (IAM) user credentials. For more information, see [Using IAM Authentication to Generate Database User Credentials](#). Only a superuser can enable or disable passwords. You can't disable a superuser's password. To enable a password, run [ALTER USER](#) and specify a password.

You can specify the password in clear text, as an MD5 hash string, or as a SHA256 hash string.

Note

When you launch a new cluster using the AWS Management Console, AWS CLI, or Amazon Redshift API, you must supply a clear text password for the initial database user. You can change the password later by using [ALTER USER](#).

For clear text, the password must meet the following constraints:

- It must be 8 to 64 characters in length.
- It must contain at least one uppercase letter, one lowercase letter, and one number.
- It can use any ASCII characters with ASCII codes 33–126, except ' (single quotation mark), " (double quotation mark), \, /, or @.

As a more secure alternative to passing the CREATE USER password parameter as clear text, you can specify an MD5 hash of a string that includes the password and user name.

Note

When you specify an MD5 hash string, the CREATE USER command checks for a valid MD5 hash string, but it doesn't validate the password portion of the string. It is possible in this case to create a password, such as an empty string, that you can't use to log on to the database.

To specify an MD5 password, follow these steps:

1. Concatenate the password and user name.

For example, for password `ez` and user `user1`, the concatenated string is `ezuser1`.

2. Convert the concatenated string into a 32-character MD5 hash string. You can use any MD5 utility to create the hash string. The following example uses the Amazon Redshift [MD5 function](#) and the concatenation operator (`||`) to return a 32-character MD5-hash string.

```
select md5('ez' || 'user1');  
  
md5  
-----  
153c434b4b77c89e6b94f12c5393af5b
```

3. Concatenate 'md5' in front of the MD5 hash string and provide the concatenated string as the `md5hash` argument.

```
create user user1 password 'md5153c434b4b77c89e6b94f12c5393af5b';
```

4. Log on to the database using the sign-in credentials.

For this example, log on as `user1` with password `ez`.

Another secure alternative is to specify an SHA-256 hash of a password string; or you can provide your own valid SHA-256 digest and 256-bit salt that was used to create the digest.

- Digest – The output of a hashing function.
- Salt – Randomly generated data that is combined with the password to help reduce patterns in the hashing function output.

```
'sha256|Mypassword'
```

```
'sha256|digest|256-bit-salt'
```

In the following example, Amazon Redshift generates and manages the salt.

```
CREATE USER admin PASSWORD 'sha256|Mypassword1';
```

In the following example, a valid SHA-256 digest and 256-bit salt that was used to create the digest are supplied.

To specify a password and hash it with your own salt, follow these steps:

1. Create a 256-bit salt. You can obtain a salt by using any hexadecimal string generator to generate a string 64 characters long. For this example, the salt is `c721bff5d9042cf541ff7b9d48fa8a6e545c19a763e3710151f9513038b0f6c6`.
2. Use the `FROM_HEX` function to convert your salt to binary. This is because the SHA2 function requires the binary representation of the salt. See the following statement.

```
SELECT  
FROM_HEX('c721bff5d9042cf541ff7b9d48fa8a6e545c19a763e3710151f9513038b0f6c6');
```

3. Use the `CONCAT` function to append your salt to your password. For this example, the password is `Mypassword1`. See the following statement.

```
SELECT  
CONCAT('Mypassword1', FROM_HEX('c721bff5d9042cf541ff7b9d48fa8a6e545c19a763e3710151f9513038b0f6c6'));
```

4. Use the `SHA2` function to create a digest from your password and salt combination. See the following statement.

```
SELECT  
SHA2(CONCAT('Mypassword1', FROM_HEX('c721bff5d9042cf541ff7b9d48fa8a6e545c19a763e3710151f9513038b0f6c6')),  
0);
```

5. Using the digest and salt from the previous steps, create the user. See the following statement.

```
CREATE USER admin PASSWORD 'sha256|  
821708135fcc42eb3afda85286dee0ed15c2c461d000291609f77eb113073ec2|  
c721bff5d9042cf541ff7b9d48fa8a6e545c19a763e3710151f9513038b0f6c6';
```

6. Log on to the database using the sign-in credentials.

For this example, log on as admin with password Mypassword1.

If you set a password in plain text without specifying the hashing function, then an MD5 digest is generated using the username as the salt.

CREATEDB | NOCREATEDB

The CREATEDB option allows the new user to create databases. The default is NOCREATEDB.

CREATEUSER | NOCREATEUSER

The CREATEUSER option creates a superuser with all database privileges, including CREATE USER. The default is NOCREATEUSER. For more information, see [superuser](#).

SYSLOG ACCESS { RESTRICTED | UNRESTRICTED }

A clause that specifies the level of access the user has to the Amazon Redshift system tables and views.

Regular users who have the SYSLOG ACCESS RESTRICTED permission can see only the rows generated by that user in user-visible system tables and views. The default is RESTRICTED.

Regular users who have the SYSLOG ACCESS UNRESTRICTED permission can see all rows in user-visible system tables and views, including rows generated by another user. UNRESTRICTED doesn't give a regular user access to superuser-visible tables. Only superusers can see superuser-visible tables.

Note

Giving a user unrestricted access to system tables gives the user visibility to data generated by other users. For example, STL_QUERY and STL_QUERYTEXT contain the full text of INSERT, UPDATE, and DELETE statements, which might contain sensitive user-generated data.

All rows in SVV_TRANSACTIONS are visible to all users.

For more information, see [Visibility of data in system tables and views](#).

IN GROUP *groupname*

Specifies the name of an existing group that the user belongs to. Multiple group names may be listed.

VALID UNTIL *abstime*

The VALID UNTIL option sets an absolute time after which the user's password is no longer valid. By default the password has no time limit.

CONNECTION LIMIT { *limit* | UNLIMITED }

The maximum number of database connections the user is permitted to have open concurrently. The limit isn't enforced for superusers. Use the UNLIMITED keyword to permit the maximum number of concurrent connections. A limit on the number of connections for each database might also apply. For more information, see [CREATE DATABASE](#). The default is UNLIMITED. To view current connections, query the [STV_SESSIONS](#) system view.

 **Note**

If both user and database connection limits apply, an unused connection slot must be available that is within both limits when a user attempts to connect.

SESSION TIMEOUT *limit*

The maximum time in seconds that a session remains inactive or idle. The range is 60 seconds (one minute) to 1,728,000 seconds (20 days). If no session timeout is set for the user, the cluster setting applies. For more information, see [Quotas and limits in Amazon Redshift](#) in the *Amazon Redshift Management Guide*.

When you set the session timeout, it's applied to new sessions only.

To view information about active user sessions, including the start time, user name, and session timeout, query the [STV_SESSIONS](#) system view. To view information about user-session history, query the [STL_SESSIONS](#) view. To retrieve information about database users, including session-timeout values, query the [SVL_USER_INFO](#) view.

EXTERNALID *external_id*

The identifier for the user, which is associated with an identity provider. The user must have their password disabled. For more information, see [Native identity provider \(IdP\) federation for Amazon Redshift](#).

Usage notes

By default, all users have CREATE and USAGE privileges on the PUBLIC schema. To disallow users from creating objects in the PUBLIC schema of a database, use the REVOKE command to remove that privilege.

When using IAM authentication to create database user credentials, you might want to create a superuser that is able to log on only using temporary credentials. You can't disable a superuser's password, but you can create an unknown password using a randomly generated MD5 hash string.

```
create user iam_superuser password 'md5A1234567890123456780123456789012' createuser;
```

The case of a *username* enclosed in double quotation marks is always preserved regardless of the setting of the `enable_case_sensitive_identifier` configuration option. For more information, see [enable_case_sensitive_identifier](#).

Examples

The following command creates a user named `dbuser`, with the password "abcD1234", database creation privileges, and a connection limit of 30.

```
create user dbuser with password 'abcD1234' createdb connection limit 30;
```

Query the `PG_USER_INFO` catalog table to view details about a database user.

```
select * from pg_user_info;
```

username	usesysid	usecreatedb	usesuper	usecatupd	passwd	valuntil
rdsdb	1	true	true	true	*****	infinity
adminuser	100	true	true	false	*****	UNLIMITED

```
dbuser | 102 | true | false | false | ***** | |
| 30
```

In the following example, the account password is valid until June 10, 2017.

```
create user dbuser with password 'abcD1234' valid until '2017-06-10';
```

The following example creates a user with a case-sensitive password that contains special characters.

```
create user newman with password '@AbC4321!';
```

To use a backslash ('\') in your MD5 password, escape the backslash with a backslash in your source string. The following example creates a user named slashpass with a single backslash ('\') as the password.

```
select md5('\\'||'slashpass');

md5
-----
0c983d1a624280812631c5389e60d48c
```

Create a user with the md5 password.

```
create user slashpass password 'md50c983d1a624280812631c5389e60d48c';
```

The following example creates a user named dbuser with an idle-session timeout set to 120 seconds.

```
CREATE USER dbuser password 'abcD1234' SESSION TIMEOUT 120;
```

The following example creates a user named bob. The namespace is myco_aad. This is only a sample. To run the command successfully, you must have a registered identity provider. For more information, see [Native identity provider \(IdP\) federation for Amazon Redshift](#).

```
CREATE USER myco_aad:bob EXTERNALID "ABC123" PASSWORD DISABLE;
```

CREATE VIEW

Creates a view in a database. The view isn't physically materialized; the query that defines the view is run every time the view is referenced in a query. To create a view with an external table, include the `WITH NO SCHEMA BINDING` clause.

To create a standard view, you need access to the underlying tables, or to underlying views. To query a standard view, you need select permissions for the view itself, but you don't need select permissions for the underlying tables. In a case where you create a view that references a table or view in another schema, or if you create a view that references a materialized view, you need usage permissions. To query a late binding view, you need select permissions for the late binding view itself. You should also make sure the owner of the late binding view has select permissions for the referenced objects (tables, views, or user-defined functions). For more information about late-binding Views, see [Usage notes](#).

Required permissions

To use `CREATE VIEW`, one of the following permissions is required.

- To create a view using `CREATE [OR REPLACE] VIEW`:
 - Superuser
 - Users with the `CREATE [REPLACE] VIEW` permission
- To replace an existing view using `CREATE OR REPLACE VIEW`:
 - Superuser
 - Users with the `CREATE [OR REPLACE] VIEW` permission
 - View owner

If a user wants to access a view that incorporates a user-defined function, the user must have the `EXECUTE` permission on that function.

Syntax

```
CREATE [ OR REPLACE ] VIEW name [ ( column_name [, ...] ) ] AS query  
[ WITH NO SCHEMA BINDING ]
```

Parameters

OR REPLACE

If a view of the same name already exists, the view is replaced. You can only replace a view with a new query that generates the identical set of columns, using the same column names and data types. CREATE OR REPLACE VIEW locks the view for reads and writes until the operation completes.

When a view is replaced, its other properties such as ownership and granted privileges are preserved.

name

The name of the view. If a schema name is given (such as `myschema.myview`) the view is created using the specified schema. Otherwise, the view is created in the current schema. The view name must be different from the name of any other view or table in the same schema.

If you specify a view name that begins with '# ', the view is created as a temporary view that is visible only in the current session.

For more information about valid names, see [Names and identifiers](#). You can't create tables or views in the system databases `template0`, `template1`, `padb_harvest`, or `sys:internal`.

column_name

Optional list of names to be used for the columns in the view. If no column names are given, the column names are derived from the query. The maximum number of columns you can define in a single view is 1,600.

query

A query (in the form of a SELECT statement) that evaluates to a table. This table defines the columns and rows in the view.

WITH NO SCHEMA BINDING

Clause that specifies that the view isn't bound to the underlying database objects, such as tables and user-defined functions. As a result, there is no dependency between the view and the objects it references. You can create a view even if the referenced objects don't exist. Because there is no dependency, you can drop or alter a referenced object without affecting the view. Amazon Redshift doesn't check for dependencies until the view is queried. To view details about late-binding views, run the [PG_GET_LATE_BINDING_VIEW_COLS](#) function.

When you include the `WITH NO SCHEMA BINDING` clause, tables and views referenced in the `SELECT` statement must be qualified with a schema name. The schema must exist when the view is created, even if the referenced table doesn't exist. For example, the following statement returns an error.

```
create view myevent as select eventname from event
with no schema binding;
```

The following statement runs successfully.

```
create view myevent as select eventname from public.event
with no schema binding;
```

Note

You can't update, insert into, or delete from a view.

Usage notes

Late-binding views

A late-binding view doesn't check the underlying database objects, such as tables and other views, until the view is queried. As a result, you can alter or drop the underlying objects without dropping and recreating the view. If you drop underlying objects, queries to the late-binding view will fail. If the query to the late-binding view references columns in the underlying object that aren't present, the query will fail.

If you drop and then re-create a late-binding view's underlying table or view, the new object is created with default access permissions. You might need to grant permissions to the underlying objects for users who will query the view.

To create a late-binding view, include the `WITH NO SCHEMA BINDING` clause. The following example creates a view with no schema binding.

```
create view event_vw as select * from public.event
with no schema binding;
```

```
select * from event_vw limit 1;
```

eventid	venueid	catid	dateid	eventname	starttime
2	306	8	2114	Boris Godunov	2008-10-15 20:00:00

The following example shows that you can alter an underlying table without recreating the view.

```
alter table event rename column eventname to title;
```

```
select * from event_vw limit 1;
```

eventid	venueid	catid	dateid	title	starttime
2	306	8	2114	Boris Godunov	2008-10-15 20:00:00

You can reference Amazon Redshift Spectrum external tables only in a late-binding view. One application of late-binding views is to query both Amazon Redshift and Redshift Spectrum tables. For example, you can use the [UNLOAD](#) command to archive older data to Amazon S3. Then, create a Redshift Spectrum external table that references the data on Amazon S3 and create a view that queries both tables. The following example uses a UNION ALL clause to join the Amazon Redshift SALES table and the Redshift Spectrum SPECTRUM.SALES table.

```
create view sales_vw as
select * from public.sales
union all
select * from spectrum.sales
with no schema binding;
```

For more information about creating Redshift Spectrum external tables, including the SPECTRUM.SALES table, see [Getting started with Amazon Redshift Spectrum](#).

When you create a standard view from a late-binding view, the standard view's definition contains the definition of the late-binding view at the time the standard view was made. The late-binding view's dependency isn't tracked, so changes to the late-binding view aren't tracked in the standard view.

To update the standard view to refer to the latest definition of the late-binding view, run CREATE OR REPLACE VIEW with the initial view definition you used to create the standard view.

See the following example of creating a standard view from a late-binding view.

```
create view sales_vw_lbv as
select * from public.sales
with no schema binding;

show view sales_vw_lbv;
                                Show View DDL statement
-----
create view sales_vw_lbv as select * from public.sales with no schema binding;
(1 row)

create view sales_vw as
select * from sales_vw_lbv;

show view sales_vw;
                                Show View DDL statement
-----
SELECT sales_vw_lbv.price, sales_vw_lbv."region" FROM (SELECT sales.price,
sales."region" FROM sales) sales_vw_lbv;
(1 row)
```

Note that the late-binding view as shown in the DDL statement for the standard view is defined when the standard view is created, and won't update with any changes you make to the late-binding view afterward.

Examples

The example commands use a sample set of objects and data called the *TICKIT* database. For more information, see [Sample database](#).

The following command creates a view called *myevent* from a table called *EVENT*.

```
create view myevent as select eventname from event
where eventname = 'LeAnn Rimes';
```

The following command creates a view called *myuser* from a table called *USERS*.

```
create view myuser as select lastname from users;
```

The following command creates or replaces a view called *myuser* from a table called *USERS*.

```
create or replace view myuser as select lastname from users;
```

The following example creates a view with no schema binding.

```
create view myevent as select eventname from public.event  
with no schema binding;
```

DEALLOCATE

Deallocates a prepared statement.

Syntax

```
DEALLOCATE [PREPARE] plan_name
```

Parameters

PREPARE

This keyword is optional and is ignored.

plan_name

The name of the prepared statement to deallocate.

Usage Notes

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you don't explicitly deallocate a prepared statement, it is deallocated when the current session ends. For more information on prepared statements, see [PREPARE](#).

See Also

[EXECUTE](#), [PREPARE](#)

DECLARE

Defines a new cursor. Use a cursor to retrieve a few rows at a time from the result set of a larger query.

When the first row of a cursor is fetched, the entire result set is materialized on the leader node, in memory or on disk, if needed. Because of the potential negative performance impact of using cursors with large result sets, we recommend using alternative approaches whenever possible. For more information, see [Performance considerations when using cursors](#).

You must declare a cursor within a transaction block. Only one cursor at a time can be open per session.

For more information, see [FETCH](#), [CLOSE](#).

Syntax

```
DECLARE cursor_name CURSOR FOR query
```

Parameters

cursor_name

Name of the new cursor.

query

A SELECT statement that populates the cursor.

DECLARE CURSOR usage notes

If your client application uses an ODBC connection and your query creates a result set that is too large to fit in memory, you can stream the result set to your client application by using a cursor. When you use a cursor, the entire result set is materialized on the leader node, and then your client can fetch the results incrementally.

Note

To enable cursors in ODBC for Microsoft Windows, enable the **Use Declare/Fetch** option in the ODBC DSN you use for Amazon Redshift. We recommend setting the ODBC cache size, using the **Cache Size** field in the ODBC DSN options dialog, to 4,000 or greater on multi-node clusters to minimize round trips. On a single-node cluster, set Cache Size to 1,000.

Because of the potential negative performance impact of using cursors, we recommend using alternative approaches whenever possible. For more information, see [Performance considerations when using cursors](#).

Amazon Redshift cursors are supported with the following limitations:

- Only one cursor at a time can be open per session.
- Cursors must be used within a transaction (BEGIN ... END).
- The maximum cumulative result set size for all cursors is constrained based on the cluster node type. If you need larger result sets, you can resize to an XL or 8XL node configuration.

For more information, see [Cursor constraints](#).

Cursor constraints

When the first row of a cursor is fetched, the entire result set is materialized on the leader node. If the result set doesn't fit in memory, it is written to disk as needed. To protect the integrity of the leader node, Amazon Redshift enforces constraints on the size of all cursor result sets, based on the cluster's node type.

The following table shows the maximum total result set size for each cluster node type. Maximum result set sizes are in megabytes.

Node type	Maximum result set per cluster (MB)
RA3 16XL multiple nodes	14400000
DC2 Large single node	8000
DC2 Large multiple nodes	192000
DC2 8XL multiple nodes	3200000
RA3 4XL multiple nodes	3200000
RA3 XLPLUS multiple nodes	1000000
RA3 XLPLUS single node	64000
Amazon Redshift Serverless	150000

To view the active cursor configuration for a cluster, query the [STV_CURSOR_CONFIGURATION](#) system table as a superuser. To view the state of active cursors, query the [STV_ACTIVE_CURSORS](#) system table. Only the rows for a user's own cursors are visible to the user, but a superuser can view all cursors.

Performance considerations when using cursors

Because cursors materialize the entire result set on the leader node before beginning to return results to the client, using cursors with very large result sets can have a negative impact on performance. We strongly recommend against using cursors with very large result sets. In some cases, such as when your application uses an ODBC connection, cursors might be the only feasible solution. If possible, we recommend using these alternatives:

- Use [UNLOAD](#) to export a large table. When you use UNLOAD, the compute nodes work in parallel to transfer the data directly to data files on Amazon Simple Storage Service. For more information, see [Unloading data in Amazon Redshift](#).
- Set the JDBC fetch size parameter in your client application. If you use a JDBC connection and you are encountering client-side out-of-memory errors, you can enable your client to retrieve result sets in smaller batches by setting the JDBC fetch size parameter. For more information, see [Setting the JDBC fetch size parameter](#).

DECLARE CURSOR examples

The following example declares a cursor named LOLLAPALOOZA to select sales information for the Lollapalooza event, and then fetches rows from the result set using the cursor:

```
-- Begin a transaction

begin;

-- Declare a cursor

declare lollapalooza cursor for
select eventname, starttime, pricepaid/qtysold as costperticket, qtysold
from sales, event
where sales.eventid = event.eventid
and eventname='Lollapalooza';

-- Fetch the first 5 rows in the cursor lollapalooza:
```

```
fetch forward 5 from lollapalooza;
```

eventname	starttime	costperticket	qtysold
Lollapalooza	2008-05-01 19:00:00	92.00000000	3
Lollapalooza	2008-11-15 15:00:00	222.00000000	2
Lollapalooza	2008-04-17 15:00:00	239.00000000	3
Lollapalooza	2008-04-17 15:00:00	239.00000000	4
Lollapalooza	2008-04-17 15:00:00	239.00000000	1

(5 rows)

```
-- Fetch the next row:
```

```
fetch next from lollapalooza;
```

eventname	starttime	costperticket	qtysold
Lollapalooza	2008-10-06 14:00:00	114.00000000	2

```
-- Close the cursor and end the transaction:
```

```
close lollapalooza;
commit;
```

The following example loops over a refcursor with all the results from a table:

```
CREATE TABLE tbl_1 (a int, b int);
INSERT INTO tbl_1 values (1, 2),(3, 4);

CREATE OR REPLACE PROCEDURE sp_cursor_loop() AS $$
DECLARE
    target record;
    curs1 cursor for select * from tbl_1;
BEGIN
    OPEN curs1;
    LOOP
        fetch curs1 into target;
        exit when not found;
        RAISE INFO 'a %', target.a;
    END LOOP;
    CLOSE curs1;
END;
$$ LANGUAGE plpgsql;
```

```
CALL sp_cursor_loop();

SELECT message
  from svl_stored_proc_messages
  where querytxt like 'CALL sp_cursor_loop()%';

message
-----
  a 1
  a 3
```

DELETE

Deletes rows from tables.

Note

The maximum size for a single SQL statement is 16 MB.

Syntax

```
[ WITH [RECURSIVE] common_table_expression [, common_table_expression , ...] ]
DELETE [ FROM ] { table_name | materialized_view_name }
  [ { USING } table_name, ... ]
  [ WHERE condition ]
```

Parameters

WITH clause

Optional clause that specifies one or more *common-table-expressions*. See [WITH clause](#).

FROM

The FROM keyword is optional, except when the USING clause is specified. The statements `delete from event;` and `delete event;` are equivalent operations that remove all of the rows from the EVENT table.

Note

To delete all the rows from a table, [TRUNCATE](#) the table. TRUNCATE is much more efficient than DELETE and doesn't require a VACUUM and ANALYZE. However, be aware that TRUNCATE commits the transaction in which it is run.

table_name

A temporary or persistent table. Only the owner of the table or a user with DELETE privilege on the table may delete rows from the table.

Consider using the TRUNCATE command for fast unqualified delete operations on large tables; see [TRUNCATE](#).

Note

After deleting a large number of rows from a table:

- Vacuum the table to reclaim storage space and re-sort rows.
- Analyze the table to update statistics for the query planner.

materialized_view_name

A materialized view. The DELETE statement works on a materialized view used for [Streaming ingestion to a materialized view](#). Only the owner of the materialized view or a user with DELETE privilege on the materialized view may delete rows from it.

You can't run DELETE on a materialized view for streaming ingestion with a row-level security (RLS) policy that doesn't have the IGNORE RLS permission granted to the user. There is an exception to this: If the user performing the DELETE has IGNORE RLS granted, it runs successfully. For more information, see [RLS policy ownership and management](#).

USING table_name, ...

The USING keyword is used to introduce a table list when additional tables are referenced in the WHERE clause condition. For example, the following statement deletes all of the rows from the EVENT table that satisfy the join condition over the EVENT and SALES tables. The SALES table must be explicitly named in the FROM list:

```
delete from event using sales where event.eventid=sales.eventid;
```

If you repeat the target table name in the USING clause, the DELETE operation runs a self-join. You can use a subquery in the WHERE clause instead of the USING syntax as an alternative way to write the same query.

WHERE *condition*

Optional clause that limits the deletion of rows to those that match the condition. For example, the condition can be a restriction on a column, a join condition, or a condition based on the result of a query. The query can reference tables other than the target of the DELETE command. For example:

```
delete from t1
where col1 in(select col2 from t2);
```

If no condition is specified, all of the rows in the table are deleted.

Examples

Delete all of the rows from the CATEGORY table:

```
delete from category;
```

Delete rows with CATID values between 0 and 9 from the CATEGORY table:

```
delete from category
where catid between 0 and 9;
```

Delete rows from the LISTING table whose SELLERID values don't exist in the SALES table:

```
delete from listing
where listing.sellerid not in(select sales.sellerid from sales);
```

The following two queries both delete one row from the CATEGORY table, based on a join to the EVENT table and an additional restriction on the CATID column:

```
delete from category
```

```
using event
where event.catid=category.catid and category.catid=9;
```

```
delete from category
where catid in
(select category.catid from category, event
where category.catid=event.catid and category.catid=9);
```

The following query deletes all rows from the `mv_cities` materialized view. The materialized view name in this example is a sample:

```
delete from mv_cities;
```

DESC DATASHARE

Displays a list of the database objects within a datashare that are added to it using ALTER DATASHARE. Amazon Redshift displays the names, databases, schemas, and types of tables, views, and functions.

Additional information about datashare objects can be found by using system views. For more information, see [SVV_DATASHARE_OBJECTS](#) and [SVV_DATASHARES](#).

Syntax

```
DESC DATASHARE datashare_name [ OF [ ACCOUNT account_id ] NAMESPACE namespace_guid ]
```

Parameters

datashare_name

The name of the datashare .

NAMESPACE *namespace_guid*

A value that specifies the namespace that the datashare uses. When you run DESC DATAHSARE as a consumer cluster administrator, specify the NAMESPACE parameter to view inbound datashares.

ACCOUNT *account_id*

A value that specifies the account that the datashare belongs to.

Usage Notes

As a consumer account administrator, when you run `DESC DATASHARE` to see inbound datashares within the AWS account, specify the `NAMESPACE` option. When you run `DESC DATASHARE` to see inbound datashares across AWS accounts, specify the `ACCOUNT` and `NAMESPACE` options.

Examples

The following example displays the information for outbound datashares on a producer cluster.

```
DESC DATASHARE salesshare;
```

producer_account	producer_namespace	share_type	share_name
object_type	object_name	include_new	
123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d	OUTBOUND	salesshare
TABLE	public.tickit_sales_redshift		
123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d	OUTBOUND	salesshare
SCHEMA	public	t	

The following example displays the information for inbound datashares on a consumer cluster.

```
DESC DATASHARE salesshare of ACCOUNT '123456789012' NAMESPACE
'13b8833d-17c6-4f16-8fe4-1a018f5ed00d';
```

producer_account	producer_namespace	share_type	share_name
object_type	object_name	include_new	
123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d	INBOUND	salesshare
table	public.tickit_sales_redshift		
123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d	INBOUND	salesshare
schema	public		

(2 rows)

DESC IDENTITY PROVIDER

Displays information about an identity provider. Only a superuser can describe an identity provider.

Syntax

```
DESC IDENTITY PROVIDER identity_provider_name
```

Parameters

identity_provider_name

The name of the identity provider.

Example

The following example displays information about the identity provider.

```
DESC IDENTITY PROVIDER azure_idp;
```

Sample output.

```
uid | name | type | instanceid | namespace |
      |      |      |      | params |
      |      |      |      |      | enabled |
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
+-----+
126692 | azure_idp | azure | e40d4bb2-7670-44ae-bfb8-5db013221d73 | aad |
{"issuer":"https://login.microsoftonline.com/e40d4bb2-7670-44ae-bfb8-5db013221d73/
v2.0", "client_id":"871c010f-5e61-4fb1-83ac-98610a7e9110", "client_secret":'',
 "audience":["https://analysis.windows.net/powerbi/connector/AmazonRedshift", "https://
analysis.windows.net/powerbi/connector/AWSRDS"]} | t
(1 row)
```

DETACH MASKING POLICY

Detaches an already attached dynamic data masking policy from a column. For more information on dynamic data masking, see [Dynamic data masking](#).

Superusers and users or roles that have the sys:secadmin role can detach a masking policy.

Syntax

```
DETACH MASKING POLICY policy_name
  ON { table_name }
  ( output_column_names )
  FROM { user_name | ROLE role_name | PUBLIC };
```

Parameters

policy_name

The name of the masking policy to detach.

table_name

The name of the table to detach the masking policy from.

output_column_names

The names of the columns to which the masking policy was attached.

user_name

The name of the user to whom the masking policy was attached.

You can only set one of `user_name`, `role_name`, and `PUBLIC` in a single `DETACH MASKING POLICY` statement.

role_name

The name of the role to which the masking policy was attached.

You can only set one of `user_name`, `role_name`, and `PUBLIC` in a single `DETACH MASKING POLICY` statement.

PUBLIC

Shows that the policy was attached to all users in the table.

You can only set one of `user_name`, `role_name`, and `PUBLIC` in a single `DETACH MASKING POLICY` statement.

DETACH RLS POLICY

Detach a row-level security policy on a table from one or more users or roles.

Superusers and users or roles that have the `sys:secadmin` role can detach a policy.

Syntax

```
DETACH RLS POLICY policy_name ON [TABLE] table_name [, ...]
FROM { user_name | ROLE role_name | PUBLIC } [, ...]
```

Parameters

policy_name

The name of the policy.

ON [TABLE] *table_name* [, ...]

The table or view that the row-level security policy is detached from.

FROM { *user_name* | ROLE *role_name* | PUBLIC } [, ...]

Specifies whether the policy is detached from one or more specified users or roles.

Usage notes

When working with the DETACH RLS POLICY statement, observe the following:

- You can detach a policy from a relation, user, role, or public.

Examples

The following example detaches a policy on a table from a role.

```
DETACH RLS POLICY policy_concerts ON tickit_category_redshift FROM ROLE analyst, ROLE
dbadmin;
```

DROP DATABASE

Drops a database.

You can't run DROP DATABASE within a transaction block (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).

Syntax

```
DROP DATABASE database_name
```

Parameters

database_name

Name of the database to be dropped. You can't drop the dev, padb_harvest, template0, template1, or sys:internal databases, and you can't drop the current database.

To drop an external database, drop the external schema. For more information, see [DROP SCHEMA](#).

DROP DATABASE usage notes

When using the DROP DATABASE statement, consider the following:

- In general, we recommend that you don't drop a database that contains an AWS Data Exchange datashare using the DROP DATABASE statement. If you do, the AWS accounts that have access to the datashare lose access. Performing this type of alteration can breach data product terms in AWS Data Exchange.

The following example shows an error when a database that contains an AWS Data Exchange datashare is dropped.

```
DROP DATABASE test_db;  
ERROR: Drop of database test_db that contains ADX-managed datashare(s)  
requires session variable datashare_break_glass_session_var to be set to value  
'ce8d280c10ad41'
```

To allow dropping the database, set the following variable and run the DROP DATABASE statement again.

```
SET datashare_break_glass_session_var to 'ce8d280c10ad41';
```

```
DROP DATABASE test_db;
```

In this case, Amazon Redshift generates a random one-time value to set the session variable to allow DROP DATABASE for a database that contains an AWS Data Exchange datashare.

Examples

The following example drops a database named TICKIT_TEST:

```
drop database tickit_test;
```

DROP DATASHARE

Drops a datashare. This command isn't reversible.

Only a superuser or the datashare owner can drop a datashare.

Required privileges

Following are required privileges for DROP DATASHARE:

- Superuser
- Users with the DROP DATASHARE privilege
- Datashare owner

Syntax

```
DROP DATASHARE datashare_name;
```

Parameters

datashare_name

The name of the datashare to be dropped.

DROP DATASHARE usage notes

When using the DROP DATASHARE statement, consider the following:

- In general, we recommend that you don't drop an AWS Data Exchange datashare using the DROP DATASHARE statement. If you do, the AWS accounts that have access to the datashare lose access. Performing this type of alteration can breach data product terms in AWS Data Exchange.

The following example shows an error when an AWS Data Exchange datashare is dropped.

```
DROP DATASHARE salesshare;  
ERROR: Drop of ADX-managed datashare salesshare requires session variable  
datashare_break_glass_session_var to be set to value '620c871f890c49'
```

To allow dropping an AWS Data Exchange datashare, set the following variable and run the DROP DATASHARE statement again.

```
SET datashare_break_glass_session_var to '620c871f890c49';
```

```
DROP DATASHARE salesshare;
```

In this case, Amazon Redshift generates a random one-time value to set the session variable to allow DROP DATASHARE for an AWS Data Exchange datashare.

Examples

The following example drops a datashare named salesshare.

```
DROP DATASHARE salesshare;
```

DROP EXTERNAL VIEW (preview)

This is prerelease documentation views in Data Catalog for Amazon Redshift, which is in preview release. The documentation and the feature are both subject to change. We recommend that you use this feature only with test clusters, and not in production environments. For preview terms and conditions, see Beta and Previews in [AWS Service Terms](#).

You can create an Amazon Redshift cluster in **Preview** to test new features of Amazon Redshift. You can't use those features in production or move your **Preview** cluster to a production cluster or

a cluster on another track. For preview terms and conditions, see *Beta and Previews* in [AWS Service Terms](#).

To create a cluster in Preview

1. Sign in to the AWS Management Console and open the Amazon Redshift console at <https://console.aws.amazon.com/redshiftv2/>.
2. On the navigation menu, choose **Provisioned clusters dashboard**, and choose **Clusters**. The clusters for your account in the current AWS Region are listed. A subset of properties of each cluster is displayed in columns in the list.
3. A banner displays on the **Clusters** list page that introduces preview. Choose the button **Create preview cluster** to open the create cluster page.
4. Enter properties for your cluster. Choose the **Preview track** that contains the features you want to test. We recommend entering a name for the cluster that indicates that it is on a preview track. Choose options for your cluster, including options labeled as **-preview**, for the features you want to test. For general information about creating clusters, see [Creating a cluster](#) in the *Amazon Redshift Management Guide*.
5. Choose **Create cluster** to create a cluster in preview.

Note

The `preview_2023` track is the most recent preview track available. This track supports creating clusters with RA3 node types only. Node type DC2 and any older node type is not supported.

6. When your preview cluster is available, use your SQL client to load and query data.

The Data Catalog views preview feature is available only in the following Regions.

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Europe (Ireland) (eu-west-1)
- Europe (Stockholm) (eu-north-1)

You can also create a preview workgroup to test Data Catalog views. You can't use those features in production or move your workgroup to another workgroup. For preview terms and conditions, see Beta and Previews in [AWS Service Terms](#). For instructions on how to create a preview workgroup, see <https://docs.aws.amazon.com/redshift/latest/mgmt/serverless-workgroup-preview.html>.

Drops an external view from the database. Dropping an external view removes it from all SQL engines the view is associated with, such as Amazon Athena and Amazon EMR Spark. This command can't be reversed. For more information about Data Catalog views, see [Creating Data Catalog views \(preview\)](#).

Syntax

```
DROP EXTERNAL VIEW schema_name.view_name [ IF EXISTS ]  
{catalog_name.schema_name.view_name | awsdatacatalog.dbname.view_name |  
external_schema_name.view_name}
```

Parameters

schema_name.view_name

The schema that's attached to your AWS Glue database, followed by the name of the view.

IF EXISTS

Drops the view only if it exists.

catalog_name.schema_name.view_name | *awsdatacatalog.dbname.view_name* |
external_schema_name.view_name

The notation of the schema to use when dropping the view. You can specify to use the AWS Glue Data Catalog, a Glue database that you created, or an external schema that you created.

See [CREATE DATABASE](#) and [CREATE EXTERNAL SCHEMA](#) for more information.

query_definition

The definition of the SQL query that Amazon Redshift runs to alter the view.

Examples

The following example drops a Data Catalog view named `sample_schema.glue_data_catalog_view`.

```
DROP EXTERNAL VIEW sample_schema.glue_data_catalog_view IF EXISTS
```

DROP FUNCTION

Removes a user-defined function (UDF) from the database. The function's signature, or list of argument data types, must be specified because multiple functions can exist with the same name but different signatures. You can't drop an Amazon Redshift built-in function.

This command isn't reversible.

Required privileges

Following are required privileges for DROP FUNCTION:

- Superuser
- Users with the DROP FUNCTION privilege
- Function owner

Syntax

```
DROP FUNCTION name
( [arg_name] arg_type [, ...] )
[ CASCADE | RESTRICT ]
```

Parameters

name

The name of the function to be removed.

arg_name

The name of an input argument. DROP FUNCTION ignores argument names, because only the argument data types are needed to determine the function's identity.

arg_type

The data type of the input argument. You can supply a comma-separated list with a maximum of 32 data types.

CASCADE

Keyword specifying to automatically drop objects that depend on the function, such as views.

To create a view that isn't dependent on a function, include the `WITH NO SCHEMA BINDING` clause in the view definition. For more information, see [CREATE VIEW](#).

RESTRICT

Keyword specifying that if any objects depend on the function, do not drop the function and return a message. This action is the default.

Examples

The following example drops the function named `f_sqrt`:

```
drop function f_sqrt(int);
```

To remove a function that has dependencies, use the `CASCADE` option, as shown in the following example:

```
drop function f_sqrt(int)cascade;
```

DROP GROUP

Deletes a user group. This command isn't reversible. This command doesn't delete the individual users in a group.

See `DROP USER` to delete an individual user.

Syntax

```
DROP GROUP name
```

Parameter

name

Name of the user group to delete.

Example

The following example deletes the `guests` user group:

```
DROP GROUP guests;
```

You can't drop a group if the group has any privileges on an object. If you attempt to drop such a group, you will receive the following error.

```
ERROR: group "guests" can't be dropped because the group has a privilege on some object
```

If the group has privileges for an object, you must revoke the privileges before dropping the group. To find the objects that the `guests` group has privileges for, use the following example. For more information about the metadata view used in the example, see [SVV_RELATION_PRIVILEGES](#).

```
SELECT DISTINCT namespace_name, relation_name, identity_name, identity_type
FROM svv_relation_privileges
WHERE identity_type='group' AND identity_name='guests';
```

namespace_name	relation_name	identity_name	identity_type
public	table1	guests	group
public	table2	guests	group

The following example revokes all privileges on all tables in the `public` schema from the `guests` user group, and then drops the group.

```
REVOKE ALL ON ALL TABLES IN SCHEMA public FROM GROUP guests;
DROP GROUP guests;
```

DROP IDENTITY PROVIDER

Deletes an identity provider. This command isn't reversible. Only a superuser can drop an identity provider.

Syntax

```
DROP IDENTITY PROVIDER identity_provider_name [ CASCADE ]
```

Parameters

identity_provider_name

Name of the identity provider to delete.

CASCADE

Deletes users and roles attached to the identity provider, when it is deleted.

Example

The following example deletes the *oauth_provider* identity provider.

```
DROP IDENTITY PROVIDER oauth_provider;
```

If you drop the identity provider, some users may not be able to log in or use client tools configured to use the identity provider.

DROP LIBRARY

Removes a custom Python library from the database. Only the library owner or a superuser can drop a library.

DROP LIBRARY can't be run inside a transaction block (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).

This command isn't reversible. The DROP LIBRARY command commits immediately. If a UDF that depends on the library is running concurrently, the UDF might fail, even if the UDF is running within a transaction.

For more information, see [CREATE LIBRARY](#).

Required privileges

Following are required privileges for DROPLIBRARY:

- Superuser
- Users with the DROP LIBRARY privilege

- Library owner

Syntax

```
DROP LIBRARY library_name
```

Parameters

library_name

The name of the library.

DROP MASKING POLICY

Drops a dynamic data masking policy from all databases. You can't drop a masking policy that's still attached to one or more tables. For more information on dynamic data masking, see [Dynamic data masking](#).

Superusers and users or roles that have the sys:secadmin role can drop a masking policy.

Syntax

```
DROP MASKING POLICY policy_name;
```

Parameters

policy_name

The name of the masking policy to drop.

DROP MODEL

Removes a model from the database. Only the model owner or a superuser can drop a model.

DROP MODEL also deletes all the associated prediction function that is derived from this model, all Amazon Redshift artifacts related to the model, and all Amazon S3 data related to the model. While the model is still being trained in Amazon SageMaker, DROP MODEL will cancel those operations.

This command isn't reversible. The DROP MODEL command commits immediately.

Required permissions

Following are required permissions for DROP MODEL:

- Superuser
- Users with the DROP MODEL permission
- Model owner
- Schema owner

Syntax

```
DROP MODEL [ IF EXISTS ] model_name
```

Parameters

IF EXISTS

A clause that indicates that if the specified schema already exists, the command should make no changes and return a message that the schema exists.

model_name

The name of the model. The model name in a schema must be unique.

Examples

The following example drops the model demo_ml.customer_churn.

```
DROP MODEL demo_ml.customer_churn
```

DROP MATERIALIZED VIEW

Removes a materialized view.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

Syntax

```
DROP MATERIALIZED VIEW [ IF EXISTS ] mv_name [ CASCADE | RESTRICT ]
```

Parameters

IF EXISTS

A clause that specifies to check if the named materialized view exists. If the materialized view doesn't exist, then the `DROP MATERIALIZED VIEW` command returns an error message. This clause is useful when scripting, to keep the script from failing if you drop a nonexistent materialized view.

mv_name

The name of the materialized view to be dropped.

CASCADE

A clause that indicates to automatically drop objects that the materialized view depends on, such as other views.

RESTRICT

A clause that indicates to not drop the materialized view if any objects depend on it. This is the default.

Usage Notes

Only the owner of a materialized view can use `DROP MATERIALIZED VIEW` on that view. A superuser or a user who has specifically been granted `DROP` privileges can be exceptions to this.

When you write a drop statement for a materialized view and a view with a matching name exists, it results in an error that instructs you to use `DROP VIEW`. An error occurs even in a case where you use `DROP MATERIALIZED VIEW IF EXISTS`.

Example

The following example drops the `tickets_mv` materialized view.

```
DROP MATERIALIZED VIEW tickets_mv;
```

DROP PROCEDURE

Drops a procedure. To drop a procedure, both the procedure name and input argument data types (signature), are required. Optionally, you can include the full argument data types, including OUT arguments. To find the signature for a procedure, use the [SHOW PROCEDURE](#) command. For more information about procedure signatures, see [PG_PROC_INFO](#).

Required privileges

Following are required privileges for DROP PROCEDURE:

- Superuser
- Users with the DROP PROCEDURE privilege
- Procedure owner

Syntax

```
DROP PROCEDURE sp_name ( [ [ argname ] [ argmode ] argtype [, ...] ] )
```

Parameters

sp_name

The name of the procedure to be removed.

argname

The name of an input argument. DROP PROCEDURE ignores argument names, because only the argument data types are needed to determine the procedure's identity.

argmode

The mode of an argument, which can be IN, OUT, or INOUT. OUT arguments are optional because they aren't used to identify a stored procedure.

argtype

The data type of the input argument. For a list of the supported data types, see [Data types](#).

Examples

The following example drops a stored procedure named `quarterly_revenue`.

```
DROP PROCEDURE quarterly_revenue(volume INOUT bigint, at_price IN numeric,result OUT int);
```

DROP RLS POLICY

Drops a row-level security policy for all tables in all databases.

Superusers and users or roles that have the `sys:secadmin` role can drop a policy.

Syntax

```
DROP RLS POLICY [ IF EXISTS ] policy_name [ CASCADE | RESTRICT ]
```

Parameters

IF EXISTS

A clause that indicates if the specified policy already exists.

policy_name

The name of the policy.

CASCADE

A clause that indicates to automatically detach the policy from all attached tables before dropping the policy.

RESTRICT

A clause that indicates not to drop the policy when it is attached to some tables. This is the default.

Examples

The following example drops the row-level security policy.

```
DROP RLS POLICY policy_concerts;
```

DROP ROLE

Removes a role from a database. Only the role owner who either created the role, a user with the WITH ADMIN option, or a superuser can drop a role.

You can't drop a role that is granted to a user or another role that is dependent on this role.

Required privileges

Following are the required privileges for DROP ROLE:

- Superuser
- Role owner who is either the user that created the role or a user that has been granted the role with the WITH ADMIN OPTION privilege.

Syntax

```
DROP ROLE role_name [ FORCE | RESTRICT ]
```

Parameters

role_name

The name of the role.

[FORCE | RESTRICT]

The default setting is RESTRICT. Amazon Redshift throws an error when you try to drop a role that has inherited another role. Use FORCE to remove all role assignments, if any exists.

Examples

The following example drops the role `sample_role`.

```
DROP ROLE sample_role FORCE;
```

The following example attempts to drop the role `sample_role1` that has been granted to a user with the default `RESTRICT` option.

```
CREATE ROLE sample_role1;
GRANT sample_role1 TO user1;
DROP ROLE sample_role1;
ERROR: cannot drop this role since it has been granted on a user
```

To successfully drop the `sample_role1` that has been granted to a user, use the `FORCE` option.

```
DROP ROLE sample_role1 FORCE;
```

The following example attempts to drop the role `sample_role2` that has another role dependent on it with the default `RESTRICT` option.

```
CREATE ROLE sample_role1;
CREATE ROLE sample_role2;
GRANT sample_role1 TO sample_role2;
DROP ROLE sample_role2;
ERROR: cannot drop this role since it depends on another role
```

To successfully drop the `sample_role2` that has another role dependent on it, use the `FORCE` option.

```
DROP ROLE sample_role2 FORCE;
```

DROP SCHEMA

Deletes a schema. For an external schema, you can also drop the external database associated with the schema. This command isn't reversible.

Required privileges

Following are required privileges for `DROP SCHEMA`:

- Superuser
- Schema owner
- Users with the `DROP SCHEMA` privilege

Syntax

```
DROP SCHEMA [ IF EXISTS ] name [, ...]  
[ DROP EXTERNAL DATABASE ]  
[ CASCADE | RESTRICT ]
```

Parameters

IF EXISTS

Clause that indicates that if the specified schema doesn't exist, the command should make no changes and return a message that the schema doesn't exist, rather than terminating with an error.

This clause is useful when scripting, so the script doesn't fail if DROP SCHEMA runs against a nonexistent schema.

name

Names of the schemas to drop. You can specify multiple schema names separated by commas.

DROP EXTERNAL DATABASE

Clause that indicates that if an external schema is dropped, drop the external database associated with the external schema, if one exists. If no external database exists, the command returns a message stating that no external database exists. If multiple external schemas are dropped, all databases associated with the specified schemas are dropped.

If an external database contains dependent objects such as tables, include the CASCADE option to drop the dependent objects as well.

When you drop an external database, the database is also dropped for any other external schemas associated with the database. Tables defined in other external schemas using the database are also dropped.

DROP EXTERNAL DATABASE doesn't support external databases stored in a HIVE metastore.

CASCADE

Keyword that indicates to automatically drop all objects in the schema. If DROP EXTERNAL DATABASE is specified, all objects in the external database are also dropped.

RESTRICT

Keyword that indicates not to drop a schema or external database if it contains any objects. This action is the default.

Example

The following example deletes a schema named S_SALES. This example uses RESTRICT as a safety mechanism so that the schema isn't deleted if it contains any objects. In this case, you need to delete the schema objects before deleting the schema.

```
drop schema s_sales restrict;
```

The following example deletes a schema named S_SALES and all objects that depend on that schema.

```
drop schema s_sales cascade;
```

The following example either drops the S_SALES schema if it exists, or does nothing and returns a message if it doesn't.

```
drop schema if exists s_sales;
```

The following example deletes an external schema named S_SPECTRUM and the external database associated with it. This example uses RESTRICT so that the schema and database aren't deleted if they contain any objects. In this case, you need to delete the dependent objects before deleting the schema and the database.

```
drop schema s_spectrum drop external database restrict;
```

The following example deletes multiple schemas and the external databases associated with them, along with any dependent objects.

```
drop schema s_sales, s_profit, s_revenue drop external database cascade;
```

DROP TABLE

Removes a table from a database.

If you are trying to empty a table of rows, without removing the table, use the DELETE or TRUNCATE command.

DROP TABLE removes constraints that exist on the target table. Multiple tables can be removed with a single DROP TABLE command.

DROP TABLE with an external table can't be run inside a transaction (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).

To find an example where the DROP privilege is granted to a group, see GRANT [Examples](#).

Required privileges

Following are required privileges for DROP TABLE:

- Superuser
- Users with the DROP TABLE privilege
- Table owner with the USAGE privilege on the schema

Syntax

```
DROP TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Parameters

IF EXISTS

Clause that indicates that if the specified table doesn't exist, the command should make no changes and return a message that the table doesn't exist, rather than terminating with an error.

This clause is useful when scripting, so the script doesn't fail if DROP TABLE runs against a nonexistent table.

name

Name of the table to drop.

CASCADE

Clause that indicates to automatically drop objects that depend on the table, such as views.

To create a view that isn't dependent on other database objects, such as views and tables, include the `WITH NO SCHEMA BINDING` clause in the view definition. For more information, see [CREATE VIEW](#).

RESTRICT

Clause that indicates not to drop the table if any objects depend on it. This action is the default.

Examples

Dropping a table with no dependencies

The following example creates and drops a table called `FEEDBACK` that has no dependencies:

```
create table feedback(a int);  
  
drop table feedback;
```

If a table contains columns that are referenced by views or other tables, Amazon Redshift displays a message such as the following.

```
Invalid operation: cannot drop table feedback because other objects depend on it
```

Dropping two tables simultaneously

The following command set creates a `FEEDBACK` table and a `BUYERS` table and then drops both tables with a single command:

```
create table feedback(a int);  
  
create table buyers(a int);  
  
drop table feedback, buyers;
```

Dropping a table with a dependency

The following steps show how to drop a table called `FEEDBACK` using the `CASCADE` switch.

First, create a simple table called `FEEDBACK` using the `CREATE TABLE` command:

```
create table feedback(a int);
```

Next, use the CREATE VIEW command to create a view called FEEDBACK_VIEW that relies on the table FEEDBACK:

```
create view feedback_view as select * from feedback;
```

The following example drops the table FEEDBACK and also drops the view FEEDBACK_VIEW, because FEEDBACK_VIEW is dependent on the table FEEDBACK:

```
drop table feedback cascade;
```

Viewing the dependencies for a table

To return the dependencies for your table, use the following example. Replace *my_schema* and *my_table* with your own schema and table.

```
SELECT dependent_ns.nspname as dependent_schema
, dependent_view.relname as dependent_view
, source_ns.nspname as source_schema
, source_table.relname as source_table
, pg_attribute.attname as column_name
FROM pg_depend
JOIN pg_rewrite ON pg_depend.objid = pg_rewrite.oid
JOIN pg_class as dependent_view ON pg_rewrite.ev_class = dependent_view.oid
JOIN pg_class as source_table ON pg_depend.refobjid = source_table.oid
JOIN pg_attribute ON pg_depend.refobjid = pg_attribute.attrelid
    AND pg_depend.refobjsubid = pg_attribute.attnum
JOIN pg_namespace dependent_ns ON dependent_ns.oid = dependent_view.relnamespace
JOIN pg_namespace source_ns ON source_ns.oid = source_table.relnamespace
WHERE
source_ns.nspname = 'my_schema'
AND source_table.relname = 'my_table'
AND pg_attribute.attnum > 0
ORDER BY 1,2
LIMIT 10;
```

To drop *my_table* and its dependencies, use the following example. This example also returns all dependencies for the table that has been dropped.

```

DROP TABLE my_table CASCADE;

SELECT dependent_ns.nspname as dependent_schema
, dependent_view.relname as dependent_view
, source_ns.nspname as source_schema
, source_table.relname as source_table
, pg_attribute.attname as column_name
FROM pg_depend
JOIN pg_rewrite ON pg_depend.objid = pg_rewrite.oid
JOIN pg_class as dependent_view ON pg_rewrite.ev_class = dependent_view.oid
JOIN pg_class as source_table ON pg_depend.refobjid = source_table.oid
JOIN pg_attribute ON pg_depend.refobjid = pg_attribute.attrelid
    AND pg_depend.refobjsubid = pg_attribute.attnum
JOIN pg_namespace dependent_ns ON dependent_ns.oid = dependent_view.relnamespace
JOIN pg_namespace source_ns ON source_ns.oid = source_table.relnamespace
WHERE
source_ns.nspname = 'my_schema'
AND source_table.relname = 'my_table'
AND pg_attribute.attnum > 0
ORDER BY 1,2
LIMIT 10;

```

```

+-----+-----+-----+-----+-----+
| dependent_schema | dependent_view | source_schema | source_table | column_name |
+-----+-----+-----+-----+-----+

```

Dropping a table Using IF EXISTS

The following example either drops the FEEDBACK table if it exists, or does nothing and returns a message if it doesn't:

```
drop table if exists feedback;
```

DROP USER

Drops a user from a database. Multiple users can be dropped with a single DROP USER command. You must be a database superuser or have the DROP USER permission to run this command.

Syntax

```
DROP USER [ IF EXISTS ] name [, ... ]
```

Parameters

IF EXISTS

Clause that indicates that if the specified user doesn't exist, the command should make no changes and return a message that the user doesn't exist, rather than terminating with an error.

This clause is useful when scripting, so the script doesn't fail if DROP USER runs against a nonexistent user.

name

Name of the user to remove. You can specify multiple users, with a comma separating each user name from the next.

Usage notes

You can't drop the user named `rdscdb` or the administrator user of the database which is typically named `awsuser` or `admin`.

You can't drop a user if the user owns any database object, such as a schema, database, table, or view, or if the user has any privileges on a database, table, column, or group. If you attempt to drop such a user, you receive one of the following errors.

```
ERROR: user "username" can't be dropped because the user owns some object [SQL
State=55006]
```

```
ERROR: user "username" can't be dropped because the user has a privilege on some object
[SQL State=55006]
```

For detailed instructions on how to find the objects owned by a database user, see [How do I resolve the "user cannot be dropped" error in Amazon Redshift?](#) in *Knowledge Center*.

Note

Amazon Redshift checks only the current database before dropping a user. DROP USER doesn't return an error if the user owns database objects or has any privileges on objects in another database. If you drop a user that owns objects in another database, the owner for those objects is changed to 'unknown'.

If a user owns an object, first drop the object or change its ownership to another user before dropping the original user. If the user has privileges for an object, first revoke the privileges before dropping the user. The following example shows dropping an object, changing ownership, and revoking privileges before dropping the user.

```
drop database dwdatabase;  
alter schema dw owner to dwadmin;  
revoke all on table dwtable from dwuser;  
drop user dwuser;
```

Examples

The following example drops a user called paulo:

```
drop user paulo;
```

The following example drops two users, paulo and martha:

```
drop user paulo, martha;
```

The following example drops the user paulo if it exists, or does nothing and returns a message if it doesn't:

```
drop user if exists paulo;
```

DROP VIEW

Removes a view from the database. Multiple views can be dropped with a single DROP VIEW command. This command isn't reversible.

Required privileges

Following are required privileges for DROP VIEW:

- Superuser
- Users with the DROP VIEW privilege
- View owner

Syntax

```
DROP VIEW [ IF EXISTS ] name [, ... ] [ CASCADE | RESTRICT ]
```

Parameters

IF EXISTS

Clause that indicates that if the specified view doesn't exist, the command should make no changes and return a message that the view doesn't exist, rather than terminating with an error.

This clause is useful when scripting, so the script doesn't fail if DROP VIEW runs against a nonexistent view.

name

Name of the view to be removed.

CASCADE

Clause that indicates to automatically drop objects that depend on the view, such as other views.

To create a view that isn't dependent on other database objects, such as views and tables, include the WITH NO SCHEMA BINDING clause in the view definition. For more information, see [CREATE VIEW](#).

Note that if you include CASCADE and the count of database objects dropped runs to ten or more, it's possible that your database client won't list all of the dropped objects in the summary results. This is typically because SQL client tools have default limitations on the results returned.

RESTRICT

Clause that indicates not to drop the view if any objects depend on it. This action is the default.

Examples

The following example drops the view called *event*:

```
drop view event;
```

To remove a view that has dependencies, use the `CASCADE` option. For example, say we start with a table called `EVENT`. We then create the `eventview` view of the `EVENT` table, using the `CREATE VIEW` command, as shown in the following example:

```
create view eventview as
select dateid, eventname, catid
from event where catid = 1;
```

Now, we create a second view called `myeventview`, that is based on the first view `eventview`:

```
create view myeventview as
select eventname, catid
from eventview where eventname <> ' ';
```

At this point, two views have been created: `eventview` and `myeventview`.

The `myeventview` view is a child view with `eventview` as its parent.

To delete the `eventview` view, the obvious command to use is the following:

```
drop view eventview;
```

Notice that if you run this command in this case, you get the following error:

```
drop view eventview;
ERROR: can't drop view eventview because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too.
```

To remedy this, run the following command (as suggested in the error message):

```
drop view eventview cascade;
```

Both `eventview` and `myeventview` have now been dropped successfully.

The following example either drops the `eventview` view if it exists, or does nothing and returns a message if it doesn't:

```
drop view if exists eventview;
```

END

Commits the current transaction. Performs exactly the same function as the COMMIT command.

See [COMMIT](#) for more detailed documentation.

Syntax

```
END [ WORK | TRANSACTION ]
```

Parameters

WORK

Optional keyword.

TRANSACTION

Optional keyword; WORK and TRANSACTION are synonyms.

Examples

The following examples all end the transaction block and commit the transaction:

```
end;
```

```
end work;
```

```
end transaction;
```

After any of these commands, Amazon Redshift ends the transaction block and commits the changes.

EXECUTE

Runs a previously prepared statement.

Syntax

```
EXECUTE plan_name [ (parameter [, ...]) ]
```

Parameters

plan_name

Name of the prepared statement to be run.

parameter

The actual value of a parameter to the prepared statement. This must be an expression yielding a value of a type compatible with the data type specified for this parameter position in the PREPARE command that created the prepared statement.

Usage notes

EXECUTE is used to run a previously prepared statement. Because prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement run earlier in the current session.

If the previous PREPARE statement specified some parameters, a compatible set of parameters must be passed to the EXECUTE statement, or else Amazon Redshift returns an error. Unlike functions, prepared statements aren't overloaded based on the type or number of specified parameters; the name of a prepared statement must be unique within a database session.

When an EXECUTE command is issued for the prepared statement, Amazon Redshift may optionally revise the query execution plan (to improve performance based on the specified parameter values) before running the prepared statement. Also, for each new execution of a prepared statement, Amazon Redshift may revise the query execution plan again based on the different parameter values specified with the EXECUTE statement. To examine the query execution plan that Amazon Redshift has chosen for any given EXECUTE statements, use the [EXPLAIN](#) command.

For examples and more information on the creation and usage of prepared statements, see [PREPARE](#).

See also

[DEALLOCATE](#), [PREPARE](#)

EXPLAIN

Displays the execution plan for a query statement without running the query. For information about the query analysis workflow, see [Query analysis workflow](#).

Syntax

```
EXPLAIN [ VERBOSE ] query
```

Parameters

VERBOSE

Displays the full query plan instead of just a summary.

query

Query statement to explain. The query can be a SELECT, INSERT, CREATE TABLE AS, UPDATE, or DELETE statement.

Usage notes

EXPLAIN performance is sometimes influenced by the time it takes to create temporary tables. For example, a query that uses the common subexpression optimization requires temporary tables to be created and analyzed in order to return the EXPLAIN output. The query plan depends on the schema and statistics of the temporary tables. Therefore, the EXPLAIN command for this type of query might take longer to run than expected.

You can use EXPLAIN only for the following commands:

- SELECT
- SELECT INTO
- CREATE TABLE AS
- INSERT
- UPDATE
- DELETE

The EXPLAIN command will fail if you use it for other SQL commands, such as data definition language (DDL) or database operations.

The EXPLAIN output relative unit costs are used by Amazon Redshift to choose a query plan. Amazon Redshift compares the sizes of various resource estimates to determine the plan.

Query planning and execution steps

The execution plan for a specific Amazon Redshift query statement breaks down execution and calculation of a query into a discrete sequence of steps and table operations that eventually produce a final result set for the query. For information about query planning, see [Query processing](#).

The following table provides a summary of steps that Amazon Redshift can use in developing an execution plan for any query a user submits for execution.

EXPLAIN operators	Query execution steps	Description
SCAN:		
Sequential Scan	scan	Amazon Redshift relation scan or table scan operator or step. Scans whole table sequentially from beginning to end; also evaluates query constraints for every row (Filter) if specified with WHERE clause. Also used to run INSERT, UPDATE, and DELETE statements.
JOINS: Amazon Redshift uses different join operators based on the physical design of the tables being joined, the location of the data required for the join, and specific attributes of the query itself. Subquery Scan -- Subquery scan and append are used to run UNION queries.		
Nested Loop	nloop	Least optimal join; mainly used for cross-joins (Cartesian products; without a join condition) and some inequality joins.
Hash Join	hjoin	Also used for inner joins and left and right outer joins and typically faster than a nested loop join. Hash Join reads the outer table, hashes the joining column, and finds matches

EXPLAIN operators	Query execution steps	Description
		in the inner hash table. Step can spill to disk. (Inner input of hjoin is hash step which can be disk-based.)
Merge Join	mjoin	Also used for inner joins and outer joins (for join tables that are both distributed and sorted on the joining columns). Typically the fastest Amazon Redshift join algorithm, not including other cost considerations.

AGGREGATION: Operators and steps used for queries that involve aggregate functions and GROUP BY operations.

Aggregate	aggr	Operator/step for scalar aggregate functions.
HashAggregate	aggr	Operator/step for grouped aggregate functions. Can operate from disk by virtue of hash table spilling to disk.
GroupAggregate	aggr	Operator sometimes chosen for grouped aggregate queries if the Amazon Redshift configuration setting for force_hash_grouping setting is off.

SORT: Operators and steps used when queries have to sort or merge result sets.

Sort	sort	Sort performs the sorting specified by the ORDER BY clause as well as other operations such as UNIONS and joins. Can operate from disk.
Merge	merge	Produces final sorted results of a query based on intermediate sorted results derived from operations performed in parallel.

EXCEPT, INTERSECT, and UNION operations:

EXPLAIN operators	Query execution steps	Description
SetOp Except [Distinct]	hjoin	Used for EXCEPT queries. Can operate from disk based on virtue of fact that input hash can be disk-based.
Hash Intersect [Distinct]	hjoin	Used for INTERSECT queries. Can operate from disk based on virtue of fact that input hash can be disk-based.
Append [All Distinct]	save	Append used with Subquery Scan to implement UNION and UNION ALL queries. Can operate from disk based on virtue of "save".
Miscellaneous/Other:		
Hash	hash	Used for inner joins and left and right outer joins (provides input to a hash join). The Hash operator creates the hash table for the inner table of a join. (The inner table is the table that is checked for matches and, in a join of two tables, is usually the smaller of the two.)
Limit	limit	Evaluates the LIMIT clause.
Materialize	save	Materialize rows for input to nested loop joins and some merge joins. Can operate from disk.
--	parse	Used to parse textual input data during a load.
--	project	Used to rearrange columns and compute expressions, that is, project data.
Result	--	Run scalar functions that don't involve any table access.

EXPLAIN operators	Query execution steps	Description
--	return	Return rows to the leader or client.
Subplan	--	Used for certain subqueries.
Unique	unique	Eliminates duplicates from SELECT DISTINCT and UNION queries.
Window	window	Compute aggregate and ranking window functions. Can operate from disk.

Network Operations:

Network (Broadcast)	bcast	Broadcast is also an attribute of Join Explain operators and steps.
Network (Distribute)	dist	Distribute rows to compute nodes for parallel processing by data warehouse cluster.
Network (Send to Leader)	return	Sends results back to the leader for further processing.

DML Operations (operators that modify data):

Insert (using Result)	insert	Inserts data.
Delete (Scan + Filter)	delete	Deletes data. Can operate from disk.
Update (Scan + Filter)	delete, insert	Implemented as delete and Insert.

Using EXPLAIN for RLS

If a query contains a table that is subject to row-level security (RLS) policies, EXPLAIN displays a special RLS SecureScan node. Amazon Redshift also logs the same node type to the STL_EXPLAIN system table. EXPLAIN doesn't reveal the RLS predicate that applies to dim_tbl. The RLS SecureScan node type serves as an indicator that the execution plan contains additional operations that are invisible to the current user.

The following example illustrates an RLS SecureScan node.

```
EXPLAIN
SELECT D.cint
FROM fact_tbl F INNER JOIN dim_tbl D ON F.k_dim = D.k
WHERE F.k_dim / 10 > 0;

                        QUERY PLAN
-----
XN Hash Join DS_DIST_ALL_NONE (cost=0.08..0.25 rows=1 width=4)
  Hash Cond: ("outer".k_dim = "inner"."k")
    -> *XN* *RLS SecureScan f (cost=0.00..0.14 rows=2 width=4)*
        Filter: ((k_dim / 10) > 0)
    -> XN Hash (cost=0.07..0.07 rows=2 width=8)
        -> XN Seq Scan on dim_tbl d (cost=0.00..0.07 rows=2 width=8)
            Filter: (("k" / 10) > 0)
```

To enable full investigation of query plans that are subject to RLS, Amazon Redshift offers the EXPLAIN RLS system permissions. Users that have been granted this permission can inspect complete query plans that also include RLS predicates.

The following example illustrates an additional Seq Scan below the RLS SecureScan node also includes the RLS policy predicate ($k_dim > 1$).

```
EXPLAIN SELECT D.cint
FROM fact_tbl F INNER JOIN dim_tbl D ON F.k_dim = D.k
WHERE F.k_dim / 10 > 0;

                        QUERY PLAN
-----
XN Hash Join DS_DIST_ALL_NONE (cost=0.08..0.25 rows=1 width=4)
  Hash Cond: ("outer".k_dim = "inner"."k")
    *-> XN RLS SecureScan f (cost=0.00..0.14 rows=2 width=4)
        Filter: ((k_dim / 10) > 0)*
        -> *XN* *Seq Scan on fact_tbl rls_table (cost=0.00..0.06 rows=5 width=8)
            Filter: (k_dim > 1)*
    -> XN Hash (cost=0.07..0.07 rows=2 width=8)
        -> XN Seq Scan on dim_tbl d (cost=0.00..0.07 rows=2 width=8)
            Filter: (("k" / 10) > 0)
```

While the EXPLAIN RLS permission is granted to a user, Amazon Redshift logs the full query plan including RLS predicates in the STL_EXPLAIN system table. Queries that are run while this permission is not granted will be logged without RLS internals. Granting or removing the EXPLAIN

RLS permission won't change what Amazon Redshift has logged to STL_EXPLAIN for previous queries.

AWS Lake Formation-RLS protected Redshift relations

The following example illustrates an LF SecureScan node, which you can use to view Lake Formation-RLS relations.

```
EXPLAIN
SELECT *
FROM lf_db.public.t_share
WHERE a > 1;
QUERY PLAN
-----
XN LF SecureScan t_share (cost=0.00..0.02 rows=2 width=11)
(2 rows)
```

Examples

Note

For these examples, the sample output might vary depending on Amazon Redshift configuration.

The following example returns the query plan for a query that selects the EVENTID, EVENTNAME, VENUEID, and VENUENAME from the EVENT and VENUE tables:

```
explain
select eventid, eventname, event.venueid, venueid
from event, venue
where event.venueid = venue.venueid;
```

QUERY PLAN

```
-----
XN Hash Join DS_DIST_OUTER (cost=2.52..58653620.93 rows=8712 width=43)
Hash Cond: ("outer".venueid = "inner".venueid)
-> XN Seq Scan on event (cost=0.00..87.98 rows=8798 width=23)
-> XN Hash (cost=2.02..2.02 rows=202 width=22)
-> XN Seq Scan on venue (cost=0.00..2.02 rows=202 width=22)
```

```
(5 rows)
```

The following example returns the query plan for the same query with verbose output:

```
explain verbose
select eventid, eventname, event.venueid, venueid
from event, venue
where event.venueid = venue.venueid;
```

QUERY PLAN

```
-----
{HASHJOIN
:startup_cost 2.52
:total_cost 58653620.93
:plan_rows 8712
:plan_width 43
:best_pathkeys <>
:dist_info DS_DIST_OUTER
:dist_info.dist_keys (
TARGETENTRY
{
VAR
:varno 2
:varattno 1
...

XN Hash Join DS_DIST_OUTER (cost=2.52..58653620.93 rows=8712 width=43)
Hash Cond: ("outer".venueid = "inner".venueid)
-> XN Seq Scan on event (cost=0.00..87.98 rows=8798 width=23)
-> XN Hash (cost=2.02..2.02 rows=202 width=22)
-> XN Seq Scan on venue (cost=0.00..2.02 rows=202 width=22)
(519 rows)
```

The following example returns the query plan for a CREATE TABLE AS (CTAS) statement:

```
explain create table venue_nonulls as
select * from venue
where venueseats is not null;
```

QUERY PLAN

```
-----
XN Seq Scan on venue (cost=0.00..2.02 rows=187 width=45)
```

```
Filter: (venue seats IS NOT NULL)
(2 rows)
```

FETCH

Retrieves rows using a cursor. For information about declaring a cursor, see [DECLARE](#).

FETCH retrieves rows based on the current position within the cursor. When a cursor is created, it is positioned before the first row. After a FETCH, the cursor is positioned on the last row retrieved. If FETCH runs off the end of the available rows, such as following a FETCH ALL, the cursor is left positioned after the last row.

FORWARD 0 fetches the current row without moving the cursor; that is, it fetches the most recently fetched row. If the cursor is positioned before the first row or after the last row, no row is returned.

When the first row of a cursor is fetched, the entire result set is materialized on the leader node, in memory or on disk, if needed. Because of the potential negative performance impact of using cursors with large result sets, we recommend using alternative approaches whenever possible. For more information, see [Performance considerations when using cursors](#).

For more information, see [DECLARE](#), [CLOSE](#).

Syntax

```
FETCH [ NEXT | ALL | { FORWARD [ count | ALL ] } ] FROM cursor
```

Parameters

NEXT

Fetches the next row. This is the default.

ALL

Fetches all remaining rows. (Same as FORWARD ALL.) ALL isn't supported for single-node clusters.

FORWARD [*count* | ALL]

Fetches the next *count* rows, or all remaining rows. FORWARD 0 fetches the current row. For single-node clusters, the maximum value for count is 1000. FORWARD ALL isn't supported for single-node clusters.

cursor

Name of the new cursor.

FETCH example

The following example declares a cursor named LOLLAPALOOZA to select sales information for the Lollapalooza event, and then fetches rows from the result set using the cursor:

```
-- Begin a transaction

begin;

-- Declare a cursor

declare lollapalooza cursor for
select eventname, starttime, pricepaid/qtysold as costperticket, qtysold
from sales, event
where sales.eventid = event.eventid
and eventname='Lollapalooza';

-- Fetch the first 5 rows in the cursor lollapalooza:

fetch forward 5 from lollapalooza;

 eventname |          starttime          | costperticket | qtysold
-----+-----+-----+-----
Lollapalooza | 2008-05-01 19:00:00 | 92.00000000 | 3
Lollapalooza | 2008-11-15 15:00:00 | 222.00000000 | 2
Lollapalooza | 2008-04-17 15:00:00 | 239.00000000 | 3
Lollapalooza | 2008-04-17 15:00:00 | 239.00000000 | 4
Lollapalooza | 2008-04-17 15:00:00 | 239.00000000 | 1
(5 rows)

-- Fetch the next row:

fetch next from lollapalooza;

 eventname |          starttime          | costperticket | qtysold
-----+-----+-----+-----
Lollapalooza | 2008-10-06 14:00:00 | 114.00000000 | 2

-- Close the cursor and end the transaction:
```

```
close lollapalooza;  
commit;
```

GRANT

Defines access permissions for a user or role.

Permissions include access options such as being able to read data in tables and views, write data, create tables, and drop tables. Use this command to give specific permissions for a table, database, schema, function, procedure, language, or column. To revoke permissions from a database object, use the [REVOKE](#) command.

Permissions also include the following datashare producer access options:

- Granting datashare access to consumer namespaces and accounts.
- Granting permission to alter a datashare by adding or removing objects from the datashare.
- Granting permission to share a datashare by adding or removing consumer namespaces from the datashare.

Datashare consumer access options are as follows:

- Granting users full access to databases created from a datashare or to external schemas that point to such databases.
- Granting users object-level permissions on databases created from a datashare like you can for local database objects. To grant this level of permission, you must use the WITH PERMISSIONS clause when creating a database from the datashare. For more information, see [CREATE DATABASE](#).

For more information about datashare permissions, see [Data sharing within and between clusters](#).

You can also grant roles to manage database permissions and control what users can do relative to your data. By defining roles and assigning roles to users, you can limit the the actions those users can take, such as limiting users to only the CREATE TABLE and INSERT commands. For more information about the CREATE ROLE command, see [the section called "CREATE ROLE"](#). Amazon Redshift has some system-defined roles that you can also use to grant specific permissions to your users. For more information, see [the section called "Amazon Redshift system-defined roles"](#).

You can only GRANT or REVOKE USAGE permissions on an external schema to database users and user groups that use the ON SCHEMA syntax. When using ON EXTERNAL SCHEMA with AWS Lake Formation, you can only GRANT and REVOKE permissions to an AWS Identity and Access Management (IAM) role. For the list of permissions, see the syntax.

For stored procedures, the only permission that you can grant is EXECUTE.

You can't run GRANT (on an external resource) within a transaction block (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).

To see which permissions users have been granted for a database, use [HAS_DATABASE_PRIVILEGE](#). To see which permissions users have been granted for a schema, use [HAS_SCHEMA_PRIVILEGE](#). To see which permissions users have been granted for a table, use [HAS_TABLE_PRIVILEGE](#).

Syntax

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | DROP | REFERENCES | ALTER | TRUNCATE }
  [, ...] | ALL [ PRIVILEGES ] }
  ON { [ TABLE ] table_name [, ...] | ALL TABLES IN SCHEMA schema_name [, ...] }
  TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
  [, ...]

GRANT { { CREATE | TEMPORARY | TEMP | ALTER } [, ...] | ALL [ PRIVILEGES ] }
  ON DATABASE db_name [, ...]
  TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
  [, ...]

GRANT { { CREATE | USAGE | ALTER } [, ...] | ALL [ PRIVILEGES ] }
  ON SCHEMA schema_name [, ...]
  TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
  [, ...]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
  ON { FUNCTION function_name ( [ [ argname ] argtype [, ...] ] ) [, ...] | ALL
  FUNCTIONS IN SCHEMA schema_name [, ...] }
  TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
  [, ...]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
  ON { PROCEDURE procedure_name ( [ [ argname ] argtype [, ...] ] ) [, ...] | ALL
  PROCEDURES IN SCHEMA schema_name [, ...] }
```

```

    TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
    [, ...]

GRANT USAGE
    ON LANGUAGE language_name [, ...]
    TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
    [, ...]

```

Granting column-level permissions for tables

The following is the syntax for column-level permissions on Amazon Redshift tables and views.

```

GRANT { { SELECT | UPDATE } ( column_name [, ...] ) [, ...] | ALL [ PRIVILEGES ]
      ( column_name [, ...] ) }
    ON { [ TABLE ] table_name [, ...] }

    TO { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]

```

Granting ASSUMEROLE permissions

The following is the syntax for the ASSUMEROLE permissions granted to users and groups with a specified role. To begin using the ASSUMEROLE privilege, see [Usage notes for granting the ASSUMEROLE permission](#).

```

GRANT ASSUMEROLE
    ON { 'iam_role' [, ...] | default | ALL }
    TO { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
    FOR { ALL | COPY | UNLOAD | EXTERNAL FUNCTION | CREATE MODEL } [, ...]

```

Granting permissions for Redshift Spectrum integration with Lake Formation

The following is the syntax for Redshift Spectrum integration with Lake Formation.

```

GRANT { SELECT | ALL [ PRIVILEGES ] } ( column_list )
    ON EXTERNAL TABLE schema_name.table_name
    TO { IAM_ROLE iam_role } [, ...] [ WITH GRANT OPTION ]

GRANT { { SELECT | ALTER | DROP | DELETE | INSERT } [, ...] | ALL [ PRIVILEGES ] }
    ON EXTERNAL TABLE schema_name.table_name [, ...]
    TO { { IAM_ROLE iam_role } [, ...] | PUBLIC } [ WITH GRANT OPTION ]

GRANT { { CREATE | ALTER | DROP } [, ...] | ALL [ PRIVILEGES ] }

```

```
ON EXTERNAL SCHEMA schema_name [, ...]
TO { IAM_ROLE iam_role } [, ...] [ WITH GRANT OPTION ]
```

Granting datashare permissions

Producer-side datashare permissions

The following is the syntax for using GRANT to grant ALTER or SHARE permissions to a user or role. The user can alter the datashare with the ALTER permission, or grant usage to a consumer with the SHARE permission. ALTER and SHARE are the only permissions that you can grant on a datashare to users and roles.

```
GRANT { ALTER | SHARE } ON DATASHARE datashare_name
      TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
      [, ...]
```

The following is the syntax for using GRANT for datashare usage permissions on Amazon Redshift. You grant access to a datashare to a consumer using the USAGE permission. You can't grant this permission to users or user groups. This permission also doesn't support the WITH GRANT OPTION for the GRANT statement. Only users or user groups with the SHARE permission previously granted to them FOR the datashare can run this type of GRANT statement.

```
GRANT USAGE
      ON DATASHARE datashare_name
      TO NAMESPACE 'namespaceGUID' | ACCOUNT 'accountnumber' [ VIA DATA CATALOG ]
```

The following is an example of how to grant usage of a datashare to a Lake Formation account.

```
GRANT USAGE ON DATASHARE salesshare TO ACCOUNT '123456789012' VIA DATA CATALOG;
```

Consumer-side datashare permissions

The following is the syntax for GRANT data-sharing usage permissions on a specific database or schema created from a datashare.

Further permissions required for consumers to access a database created from a datashare vary depending on whether or not the CREATE DATABASE command used to create the database from the datashare used the WITH PERMISSIONS clause. For more information about the CREATE DATABASE command and WITH PERMISSIONS clause, see [CREATE DATABASE](#).

Databases created without using the WITH PERMISSIONS clause

When you grant USAGE on a database created from a datashare without the WITH PERMISSIONS clause, you don't need to grant permissions separately on the objects in the shared database. Entities granted usage on databases created from datashares without the WITH PERMISSIONS clause automatically have access to all objects in the database.

Databases created using the WITH PERMISSIONS clause

When you grant USAGE on a database where the shared database was created from a datashare with the WITH PERMISSIONS clause, consumer-side identities must still be granted the relevant permissions for database objects in the shared database in order to access them, just as you would grant permissions for local database objects. To grant permissions to objects in a database created from a datashare, use the three-part syntax `database_name.schema_name.object_name`. To grant permissions to objects in an external schema pointing to a shared schema within the shared database, use the two-part syntax `schema_name.object_name`.

```
GRANT USAGE ON { DATABASE shared_database_name [, ...] | SCHEMA shared_schema }
TO { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
```

Granting scoped permissions

Scoped permissions let you grant permissions to a user or role on all objects of a type within a database or schema. Users and roles with scoped permissions have the specified permissions on all current and future objects within the database or schema.

You can view the scope of database-level scoped permissions in [SVV_DATABASE_PRIVILEGES](#). You can view the scope of schema-level scoped permissions in [SVV_SCHEMA_PRIVILEGES](#).

The following is the syntax for granting scoped permissions to users and roles. For more information about scoped permissions, see [Scoped permissions](#).

```
GRANT { CREATE | USAGE | ALTER } [,...] | ALL [ PRIVILEGES ] }
FOR SCHEMAS IN
DATABASE db_name
TO { username [ WITH GRANT OPTION ] | ROLE role_name } [, ...]

GRANT
{ { SELECT | INSERT | UPDATE | DELETE | DROP | ALTER | TRUNCATE | REFERENCES }
  [, ...] } | ALL [PRIVILEGES] } }
FOR TABLES IN
{SCHEMA schema_name [DATABASE db_name ] | DATABASE db_name }
TO { username [ WITH GRANT OPTION ] | ROLE role_name } [, ...]
```

```

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
FOR FUNCTIONS IN
{SCHEMA schema_name [DATABASE db_name ] | DATABASE db_name }
TO { username [ WITH GRANT OPTION ] | ROLE role_name | } [, ...]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
FOR PROCEDURES IN
{SCHEMA schema_name [DATABASE db_name ] | DATABASE db_name }
TO { username [ WITH GRANT OPTION ] | ROLE role_name | } [, ...]

GRANT USAGE
FOR LANGUAGES IN
{DATABASE db_name}
TO { username [ WITH GRANT OPTION ] | ROLE role_name } [, ...]

```

Note that scoped permissions don't distinguish between permissions for functions and for procedures. For example, the following statement grants bob the EXECUTE permission for both functions and procedures in the schema Sales_schema.

```
GRANT EXECUTE FOR FUNCTIONS IN SCHEMA Sales_schema TO bob;
```

Granting machine learning permissions

The following is the syntax for machine learning model permissions on Amazon Redshift.

```

GRANT CREATE MODEL
    TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
    [, ...]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
    ON MODEL model_name [, ...]

    TO { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
    [, ...]

```

Granting role permissions

The following is the syntax for granting role permissions on Amazon Redshift.

```
GRANT { ROLE role_name } [, ...] TO { { user_name [ WITH ADMIN OPTION ] } |
    ROLE role_name }[, ...]
```

The following is the syntax for granting system permissions to roles on Amazon Redshift.

```
GRANT
{
  { CREATE USER | DROP USER | ALTER USER |
  CREATE SCHEMA | DROP SCHEMA |
  ALTER DEFAULT PRIVILEGES |
  ACCESS CATALOG |
  CREATE TABLE | DROP TABLE | ALTER TABLE |
  CREATE OR REPLACE FUNCTION | CREATE OR REPLACE EXTERNAL FUNCTION |
  DROP FUNCTION |
  CREATE OR REPLACE PROCEDURE | DROP PROCEDURE |
  CREATE OR REPLACE VIEW | DROP VIEW |
  CREATE MODEL | DROP MODEL |
  CREATE DATASHARE | ALTER DATASHARE | DROP DATASHARE |
  CREATE LIBRARY | DROP LIBRARY |
  CREATE ROLE | DROP ROLE |
  TRUNCATE TABLE
  VACUUM | ANALYZE | CANCEL }[, ...]
}
| { ALL [ PRIVILEGES ] }
TO { ROLE role_name } [, ...]
```

Granting explain permissions for row-level security policy filters

The following is the syntax for granting permissions to explain the row-level security policy filters of a query in the EXPLAIN plan. You can revoke the privilege using the REVOKE statement.

```
GRANT EXPLAIN RLS TO ROLE rolename
```

The following is the syntax for granting permissions to bypass row-level security policies for a query.

```
GRANT IGNORE RLS TO ROLE rolename
```

Granting permissions for RLS lookup tables to a policy object

The following is the syntax for granting permissions to the specified row-level security policy.

```
GRANT SELECT ON [ TABLE ] table_name [, ...]
TO RLS POLICY policy_name [, ...]
```

Parameters

SELECT

Grants permission to select data from a table or view using a SELECT statement. The SELECT permission is also required to reference existing column values for UPDATE or DELETE operations.

INSERT

Grants permission to load data into a table using an INSERT statement or a COPY statement.

UPDATE

Grants permission to update a table column using an UPDATE statement. UPDATE operations also require the SELECT permission, because they must reference table columns to determine which rows to update, or to compute new values for columns.

DELETE

Grants permission to delete a data row from a table. DELETE operations also require the SELECT permission, because they must reference table columns to determine which rows to delete.

DROP

Grants permission to drop a table. This permission applies in Amazon Redshift and in an AWS Glue Data Catalog that is enabled for Lake Formation.

REFERENCES

Grants permission to create a foreign key constraint. You need to grant this permission on both the referenced table and the referencing table; otherwise, the user can't create the constraint.

ALTER

Depending on the database object, grants the following permissions to the user or user group:

- For tables, ALTER grants permission to alter a table or view. For more information, see [ALTER TABLE](#).
- For databases, ALTER grants permission to alter a database. For more information, see [ALTER DATABASE](#).
- For schemas, ALTER grants permission to alter a schema. For more information, see [ALTER SCHEMA](#).
- For external tables, ALTER grants permission to alter a table in an AWS Glue Data Catalog that is enabled for Lake Formation. This permission only applies when using Lake Formation.

TRUNCATE

Grants permission to truncate a table. Without this permission, only the owner of a table or a superuser can truncate a table. For more information about the TRUNCATE command, see [the section called “TRUNCATE”](#).

ALL [PRIVILEGES]

Grants all available permissions at once to the specified user or role. The PRIVILEGES keyword is optional.

GRANT ALL ON SCHEMA doesn't grant CREATE permissions for external schemas.

You can grant the ALL permission to a table in an AWS Glue Data Catalog that is enabled for Lake Formation. In this case, individual permissions (such as SELECT, ALTER, and so on) are recorded in the Data Catalog.

Note

Amazon Redshift doesn't support the RULE and TRIGGER permissions. For more information, go to [Unsupported PostgreSQL features](#).

ASSUMEROLE

Grants permission to run COPY, UNLOAD, EXTERNAL FUNCTION, and CREATE MODEL commands to users, roles, or groups with a specified role. The user, role, or group assumes that role when running the specified command. To begin using the ASSUMEROLE permission, see [Usage notes for granting the ASSUMEROLE permission](#).

ON [TABLE] *table_name*

Grants the specified permissions on a table or a view. The TABLE keyword is optional. You can list multiple tables and views in one statement.

ON ALL TABLES IN SCHEMA *schema_name*

Grants the specified permissions on all tables and views in the referenced schema.

(*column_name* [,...]) ON TABLE *table_name*

Grants the specified permissions to users, groups, or PUBLIC on the specified columns of the Amazon Redshift table or view.

(*column_list*) ON EXTERNAL TABLE *schema_name.table_name*

Grants the specified permissions to an IAM role on the specified columns of the Lake Formation table in the referenced schema.

ON EXTERNAL TABLE *schema_name.table_name*

Grants the specified permissions to an IAM role on the specified Lake Formation tables in the referenced schema.

ON EXTERNAL SCHEMA *schema_name*

Grants the specified permissions to an IAM role on the referenced schema.

ON *iam_role*

Grants the specified permissions to an IAM role.

TO *username*

Indicates the user receiving the permissions.

TO IAM_ROLE *iam_role*

Indicates the IAM role receiving the permissions.

WITH GRANT OPTION

Indicates that the user receiving the permissions can in turn grant the same permissions to others. WITH GRANT OPTION can't be granted to a group or to PUBLIC.

ROLE *role_name*

Grants the permissions to a role.

GROUP *group_name*

Grants the permissions to a user group. Can be a comma-separated list to specify multiple user groups.

PUBLIC

Grants the specified permissions to all users, including users created later. PUBLIC represents a group that always includes all users. An individual user's permissions consist of the sum of permissions granted to PUBLIC, permissions granted to any groups that the user belongs to, and any permissions granted to the user individually.

Granting PUBLIC to a Lake Formation EXTERNAL TABLE results in granting the permission to the Lake Formation *everyone* group.

CREATE

Depending on the database object, grants the following permissions to the user or user group:

- For databases, CREATE allows users to create schemas within the database.
- For schemas, CREATE allows users to create objects within a schema. To rename an object, the user must have the CREATE permission and own the object to be renamed.
- CREATE ON SCHEMA isn't supported for Amazon Redshift Spectrum external schemas. To grant usage of external tables in an external schema, grant USAGE ON SCHEMA to the users that need access. Only the owner of an external schema or a superuser is permitted to create external tables in the external schema. To transfer ownership of an external schema, use [ALTER SCHEMA](#) to change the owner.

TEMPORARY | TEMP

Grants the permission to create temporary tables in the specified database. To run Amazon Redshift Spectrum queries, the database user must have permission to create temporary tables in the database.

Note

By default, users are granted permission to create temporary tables by their automatic membership in the PUBLIC group. To remove the permission for any users to create temporary tables, revoke the TEMP permission from the PUBLIC group. Then explicitly grant the permission to create temporary tables to specific users or groups of users.

ON DATABASE *db_name*

Grants the specified permissions on a database.

USAGE

Grants USAGE permission on a specific schema, which makes objects in that schema accessible to users. Specific actions on these objects must be granted separately (for example, SELECT or UPDATE permission on tables) for local Amazon Redshift schemas. By default, all users have CREATE and USAGE permission on the PUBLIC schema.

When you grant USAGE to external schemas using ON SCHEMA syntax, you don't need to grant actions separately on the objects in the external schema. The corresponding catalog permissions control granular permissions on the external schema objects.

ON SCHEMA *schema_name*

Grants the specified permissions on a schema.

GRANT CREATE ON SCHEMA and the CREATE permission in GRANT ALL ON SCHEMA aren't supported for Amazon Redshift Spectrum external schemas. To grant usage of external tables in an external schema, grant USAGE ON SCHEMA to the users that need access. Only the owner of an external schema or a superuser is permitted to create external tables in the external schema. To transfer ownership of an external schema, use [ALTER SCHEMA](#) to change the owner.

EXECUTE ON ALL FUNCTIONS IN SCHEMA *schema_name*

Grants the specified permissions on all functions in the referenced schema.

Amazon Redshift doesn't support GRANT or REVOKE statements for pg_proc builtin entries defined in pg_catalog namespace.

EXECUTE ON PROCEDURE *procedure_name*

Grants the EXECUTE permission on a specific stored procedure. Because stored procedure names can be overloaded, you must include the argument list for the procedure. For more information, see [Naming stored procedures](#).

EXECUTE ON ALL PROCEDURES IN SCHEMA *schema_name*

Grants the specified permissions on all stored procedures in the referenced schema.

USAGE ON LANGUAGE *language_name*

Grants the USAGE permission on a language.

The USAGE ON LANGUAGE permission is required to create user-defined functions (UDFs) by running the [CREATE FUNCTION](#) command. For more information, see [UDF security and permissions](#).

The USAGE ON LANGUAGE permission is required to create stored procedures by running the [CREATE PROCEDURE](#) command. For more information, see [Security and privileges for stored procedures](#).

For Python UDFs, use plpythonu. For SQL UDFs, use sql. For stored procedures, use plpgsql.

FOR { ALL | COPY | UNLOAD | EXTERNAL FUNCTION | CREATE MODEL } [, ...]

Specifies the SQL command for which the permission is granted. You can specify ALL to grant the permission on the COPY, UNLOAD, EXTERNAL FUNCTION, and CREATE MODEL statements. This clause applies only to granting the ASSUMEROLE permission.

ALTER

Grants the ALTER permission to users to add or remove objects from a datashare, or to set the property PUBLICACCESSIBLE. For more information, see [ALTER DATASHARE](#).

SHARE

Grants permissions to users and user groups to add data consumers to a datashare. This permission is required to enable the particular consumer (account or namespace) to access the datashare from their clusters. The consumer can be the same or a different AWS account, with the same or a different cluster namespace as specified by a globally unique identifier (GUID).

ON DATASHARE *datashare_name*

Grants the specified permissions on the referenced datashare. For information about consumer access control granularity, see [Data sharing at different levels in Amazon Redshift](#).

USAGE

When USAGE is granted to a consumer account or namespace within the same account, the specific consumer account or namespace within the account can access the datashare and the objects of the datashare in read-only fashion.

TO NAMESPACE 'clusternamespace GUID'

Indicates a namespace in the same account where consumers can receive the specified permissions to the datashare. Namespaces use a 128-bit alphanumeric GUID.

TO ACCOUNT 'accountnumber' [VIA DATA CATALOG]

Indicates the number of another account whose consumers can receive the specified permissions to the datashare. Specifying 'VIA DATA CATALOG' indicates that you are granting usage of the datashare to a Lake Formation account. Omitting this parameter means you're granting usage to an account that owns the cluster.

ON DATABASE *shared_database_name*> [, ...]

Grants the specified usage permissions on the specified database that is created in the specified datashare.

ON SCHEMA *shared_schema*

Grants the specified permissions on the specified schema that is created in the specified datashare.

FOR { SCHEMAS | TABLES | FUNCTIONS | PROCEDURES | LANGUAGES } **IN**

Specifies the database objects to grant permission to. The parameters following **IN** define the scope of the granted permission.

CREATE MODEL

Grants the **CREATE MODEL** permission to specific users or user groups.

ON MODEL *model_name*

Grants the **EXECUTE** permission on a specific model.

ACCESS CATALOG

Grants the permission to view relevant metadata of objects that the role has access to.

{ role } [, ...]

The role to be granted to another role, a user, or **PUBLIC**.

PUBLIC represents a group that always includes all users. An individual user's permissions consist of the sum of permissions granted to **PUBLIC**, permissions granted to any groups that the user belongs to, and any permissions granted to the user individually.

TO { { *user_name* [**WITH ADMIN OPTION**] } | role }[, ...]

Grants the specified role to a specified user with the **WITH ADMIN OPTION**, another role, or **PUBLIC**.

The **WITH ADMIN OPTION** clause provides the administration options for all the granted roles to all the grantees.

EXPLAIN RLS TO ROLE *rolename*

Grants the permission to explain the row-level security policy filters of a query in the **EXPLAIN** plan to a role.

IGNORE RLS TO ROLE *rolename*

Grants the permission to bypass row-level security policies for a query to a role.

Usage notes

To learn more about the usage notes for GRANT, see [the section called “Usage notes”](#).

Examples

For examples of how to use GRANT, see [the section called “Examples”](#).

Usage notes

To grant privileges on an object, you must meet one of the following criteria:

- Be the object owner.
- Be a superuser.
- Have a grant privilege for that object and privilege.

For example, the following command enables the user HR both to perform SELECT commands on the employees table and to grant and revoke the same privilege for other users.

```
grant select on table employees to HR with grant option;
```

HR can't grant privileges for any operation other than SELECT, or on any other table than employees.

As another example, the following command enables the user HR both to perform ALTER commands on the employees table and to grant and revoke the same privilege for other users.

```
grant ALTER on table employees to HR with grant option;
```

HR can't grant privileges for any operation other than ALTER, or on any other table than employees.

Having privileges granted on a view doesn't imply having privileges on the underlying tables. Similarly, having privileges granted on a schema doesn't imply having privileges on the tables in the schema. Instead, grant access to the underlying tables explicitly.

To grant privileges to an AWS Lake Formation table, the IAM role associated with the table's external schema must have permission to grant privileges to the external table. The following

example creates an external schema with an associated IAM role `myGrantor`. The IAM role `myGrantor` has the permission to grant permissions to others. The `GRANT` command uses the permission of the IAM role `myGrantor` that is associated with the external schema to grant permission to the IAM role `myGrantee`.

```
create external schema mySchema
from data catalog
database 'spectrum_db'
iam_role 'arn:aws:iam::123456789012:role/myGrantor'
create external database if not exists;
```

```
grant select
on external table mySchema.mytable
to iam_role 'arn:aws:iam::123456789012:role/myGrantee';
```

If you `GRANT ALL` privileges to an IAM role, individual privileges are granted in the related Lake Formation–enabled Data Catalog. For example, the following `GRANT ALL` results in the granted individual privileges (`SELECT`, `ALTER`, `DROP`, `DELETE`, and `INSERT`) showing in the Lake Formation console.

```
grant all
on external table mySchema.mytable
to iam_role 'arn:aws:iam::123456789012:role/myGrantee';
```

Superusers can access all objects regardless of `GRANT` and `REVOKE` commands that set object privileges.

Usage notes for column-level access control

The following usage notes apply to column-level privileges on Amazon Redshift tables and views. These notes describe tables; the same notes apply to views unless we explicitly note an exception.

- For an Amazon Redshift table, you can grant only the `SELECT` and `UPDATE` privileges at the column level. For an Amazon Redshift view, you can grant only the `SELECT` privilege at the column level.
- The `ALL` keyword is a synonym for `SELECT` and `UPDATE` privileges combined when used in the context of a column-level `GRANT` on a table.
- If you don't have the `SELECT` privilege on all columns in a table, performing a `SELECT *` operation returns only those columns that you have access to. When using a view, a `SELECT *` operation

attempts to access all columns in the view. If you do not have permission to access all columns, these queries fail with a permission denied error.

- `SELECT *` doesn't expand to only accessible columns in the following cases:
 - You can't create a regular view with only accessible columns using `SELECT *`.
 - You can't create a materialized view with only accessible columns using `SELECT *`.
- If you have `SELECT` or `UPDATE` privilege on a table or view and add a column, you still have the same privileges on the table or view and thus all its columns.
- Only a table's owner or a superuser can grant column-level privileges.
- The `WITH GRANT OPTION` clause isn't supported for column-level privileges.
- You can't hold the same privilege at both the table level and the column level. For example, the user `data_scientist` can't have both `SELECT` privilege on the table `employee` and `SELECT` privilege on the column `employee.department`. Consider the following results when granting the same privilege to a table and a column within the table:
 - If a user has a table-level privilege on a table, then granting the same privilege at the column level has no effect.
 - If a user has a table-level privilege on a table, then revoking the same privilege for one or more columns of the table returns an error. Instead, revoke the privilege at the table level.
 - If a user has a column-level privilege, then granting the same privilege at the table level returns an error.
 - If a user has a column-level privilege, then revoking the same privilege at the table level revokes both column and table privileges for all columns on the table.
- You can't grant column-level privileges on late-binding views.
- To create a materialized view, you must have table-level `SELECT` privilege on the base tables. Even if you have column-level privileges on specific columns, you can't create a materialized view on only those columns. However, you can grant `SELECT` privilege to columns of a materialized view, similar to regular views.
- To look up grants of column-level privileges, use the [PG_ATTRIBUTE_INFO](#) view.

Usage notes for granting the `ASSUMEROLE` permission

The following usage notes apply to granting the `ASSUMEROLE` permission in Amazon Redshift.

You use the `ASSUMEROLE` permission to control IAM role access permissions for database users, roles, or groups on commands such as `COPY`, `UNLOAD`, `EXTERNAL FUNCTION`, or `CREATE MODEL`.

After you grant the ASSUMEROLE permission to a user, role, or group for an IAM role, the user, role, or group can assume that role when running the command. The ASSUMEROLE permission enables you to grant access to the appropriate commands as required.

Only a database superuser can grant or revoke the ASSUMEROLE permission for users, roles, and groups. A superuser always retains the ASSUMEROLE permission.

To enable the use of the ASSUMEROLE permission for users, roles, and groups, a superuser performs the following two actions:

- Run the following statement once on the cluster:

```
revoke assumeroles on all from public for all;
```

- Grant the ASSUMEROLE permission to users, roles, and groups for the appropriate commands.

You can specify role chaining in the ON clause when granting the ASSUMEROLE permission. You use commas to separate roles in a role chain, for example, Role1, Role2, Role3. If role chaining was specified when granting the ASSUMEROLE permission, you must specify the role chain when performing operations granted by the ASSUMEROLE permission. You can't specify individual roles within the role chain when performing operations granted by the ASSUMEROLE permission. For example, if a user, role, or group is granted the role chain Role1, Role2, Role3, you can't specify only Role1 to perform operations.

If a user attempts to perform a COPY, UNLOAD, EXTERNAL FUNCTION, or CREATE MODEL operation and hasn't been granted the ASSUMEROLE permission, a message similar to the following appears.

```
ERROR: User awsuser does not have ASSUMEROLE permission on IAM role
"arn:aws:iam::123456789012:role/RoleA" for COPY
```

To list users that have been granted access to IAM roles and commands through the ASSUMEROLE permission, see [HAS_ASSUMEROLE_PRIVILEGE](#). To list IAM roles and command permissions that have been granted to a user that you specify, see [PG_GET_IAM_ROLE_BY_USER](#). To list users, roles, and groups that have been granted access to an IAM role that you specify, see [PG_GET GRANTEE BY IAM_ROLE](#).

Usage notes for granting machine learning permissions

You can't directly grant or revoke permissions related to an ML function. An ML function belongs to an ML model and permissions are controlled through the model. Instead, you can grant permissions related to the ML model. The following example demonstrates how to grant permissions to all users to run the ML function associated with the model `customer_churn`.

```
GRANT EXECUTE ON MODEL customer_churn TO PUBLIC;
```

You can also grant all permissions to a user for the ML model `customer_churn`.

```
GRANT ALL on MODEL customer_churn TO ml_user;
```

Granting the EXECUTE permission related to an ML function will fail if there is an ML function in the schema, even if that ML function already has the EXECUTE permission through GRANT EXECUTE ON MODEL. We recommend using a separate schema when using the CREATE MODEL command to keep the ML functions in a separate schema by themselves. The following example demonstrates how to do so.

```
CREATE MODEL ml_schema.customer_churn
FROM customer_data
TARGET churn
FUNCTION ml_schema.customer_churn_prediction
IAM_ROLE default
SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket'
);
```

Examples

The following example grants the SELECT privilege on the SALES table to the user `fred`.

```
grant select on table sales to fred;
```

The following example grants the SELECT privilege on all tables in the QA_TICKIT schema to the user `fred`.

```
grant select on all tables in schema qa_tickit to fred;
```

The following example grants all schema privileges on the schema QA_TICKIT to the user group QA_USERS. Schema privileges are CREATE and USAGE. USAGE grants users access to the objects in the schema, but doesn't grant privileges such as INSERT or SELECT on those objects. Grant privileges on each object separately.

```
create group qa_users;  
grant all on schema qa_tickit to group qa_users;
```

The following example grants all privileges on the SALES table in the QA_TICKIT schema to all users in the group QA_USERS.

```
grant all on table qa_tickit.sales to group qa_users;
```

The following example grants all privileges on the SALES table in the QA_TICKIT schema to all users in the groups QA_USERS and RO_USERS.

```
grant all on table qa_tickit.sales to group qa_users, group ro_users;
```

The following example grants the DROP privilege on the SALES table in the QA_TICKIT schema to all users in the group QA_USERS.

```
grant drop on table qa_tickit.sales to group qa_users;>
```

The following sequence of commands shows how access to a schema doesn't grant privileges on a table in the schema.

```
create user schema_user in group qa_users password 'Abcd1234';  
create schema qa_tickit;  
create table qa_tickit.test (col1 int);  
grant all on schema qa_tickit to schema_user;
```

```
set session authorization schema_user;  
select current_user;
```

```
current_user  
-----  
schema_user  
(1 row)
```

```
select count(*) from qa_tickit.test;
```

```
ERROR: permission denied for relation test [SQL State=42501]
```

```
set session authorization dw_user;
grant select on table qa_tickit.test to schema_user;
set session authorization schema_user;
select count(*) from qa_tickit.test;
```

```
count
-----
0
(1 row)
```

The following sequence of commands shows how access to a view doesn't imply access to its underlying tables. The user called VIEW_USER can't select from the DATE table, although this user has been granted all privileges on VIEW_DATE.

```
create user view_user password 'Abcd1234';
create view view_date as select * from date;
grant all on view_date to view_user;
set session authorization view_user;
select current_user;
```

```
current_user
-----
view_user
(1 row)
```

```
select count(*) from view_date;
```

```
count
-----
365
(1 row)
```

```
select count(*) from date;
```

```
ERROR: permission denied for relation date
```

The following example grants SELECT privilege on the `cust_name` and `cust_phone` columns of the `cust_profile` table to the user `user1`.

```
grant select(cust_name, cust_phone) on cust_profile to user1;
```

The following example grants SELECT privilege on the `cust_name` and `cust_phone` columns and UPDATE privilege on the `cust_contact_preference` column of the `cust_profile` table to the `sales_group` group.

```
grant select(cust_name, cust_phone), update(cust_contact_preference) on cust_profile to group sales_group;
```

The following example shows the usage of the ALL keyword to grant both SELECT and UPDATE privileges on three columns of the table `cust_profile` to the `sales_admin` group.

```
grant ALL(cust_name, cust_phone, cust_contact_preference) on cust_profile to group sales_admin;
```

The following example grants the SELECT privilege on the `cust_name` column of the `cust_profile_vw` view to the `user2` user.

```
grant select(cust_name) on cust_profile_vw to user2;
```

Examples of granting access to datashares

The following examples show GRANT datasharing usage permissions on a specific database or schema created from a datashare.

In the following example, a producer-side admin grants the USAGE permission on the `salesshare` datashare to the specified namespace.

```
GRANT USAGE ON DATASHARE salesshare TO NAMESPACE  
'13b8833d-17c6-4f16-8fe4-1a018f5ed00d';
```

In the following example, a consumer-side admin grants the USAGE permission on the `sales_db` to Bob.

```
GRANT USAGE ON DATABASE sales_db TO Bob;
```

In the following example, a consumer-side admin grants the GRANT USAGE permission on the `sales_schema` schema to the `Analyst_role` role. `sales_schema` is an external schema that points to `sales_db`.

```
GRANT USAGE ON SCHEMA sales_schema TO ROLE Analyst_role;
```

At this point, Bob and `Analyst_role` can access all database objects in `sales_schema` and `sales_db`.

The following example shows granting additional object-level permission for objects in a shared database. These extra permissions are only necessary if the CREATE DATABASE command that was used to create the shared database used the WITH PERMISSIONS clause. If the CREATE DATABASE command didn't use WITH PERMISSIONS, granting USAGE on the shared database grants full access to all objects in that database.

```
GRANT SELECT ON sales_db.sales_schema.tickit_sales_redshift to Bob;
```

Examples of granting scoped permissions

The following example grants usage for all current and future schemas in the `Sales_db` database to the `Sales` role.

```
GRANT USAGE FOR SCHEMAS IN DATABASE Sales_db TO ROLE Sales;
```

The following example grants the SELECT permission for all current and future tables in the `Sales_db` database to the user `alice`, and also gives `alice` the permission to grant scoped permissions on tables in `Sales_db` to other users.

```
GRANT SELECT FOR TABLES IN DATABASE Sales_db TO alice WITH GRANT OPTION;
```

The following example grants the EXECUTE permission for functions in the `Sales_schema` schema to the user `bob`.

```
GRANT EXECUTE FOR FUNCTIONS IN SCHEMA Sales_schema TO bob;
```

The following example grants all permissions for all tables in the ShareDb database's ShareSchema schema to the Sales role. When specifying the schema, you can specify the schema's database using the two-part format `database.schema`.

```
GRANT ALL FOR TABLES IN SCHEMA ShareDb.ShareSchema TO ROLE Sales;
```

The following example is the same as the preceding one. You can specify the database using the `DATABASE` keyword instead of using a two-part format.

```
GRANT ALL FOR TABLES IN SCHEMA ShareSchema DATABASE ShareDb TO ROLE Sales;
```

Examples of granting the ASSUMEROLE privilege

The following are examples of granting the ASSUMEROLE privilege.

The following example shows the `REVOKE` statement that a superuser runs once on the cluster to enable the use of the ASSUMEROLE privilege for users and groups. Then, the superuser grants the ASSUMEROLE privilege to users and groups for the appropriate commands. For information on enabling the use of the ASSUMEROLE privilege for users and groups, see [Usage notes for granting the ASSUMEROLE permission](#).

```
revoke assumerole on all from public for all;
```

The following example grants the ASSUMEROLE privilege to the user `reg_user1` for the IAM role `Redshift-S3-Read` to perform `COPY` operations.

```
grant assumerole on 'arn:aws:iam::123456789012:role/Redshift-S3-Read'  
to reg_user1 for copy;
```

The following example grants the ASSUMEROLE privilege to the user `reg_user1` for the IAM role `chain RoleA, RoleB` to perform `UNLOAD` operations.

```
grant assumerole  
on 'arn:aws:iam::123456789012:role/RoleA,arn:aws:iam::210987654321:role/RoleB'  
to reg_user1  
for unload;
```

The following is an example of the UNLOAD command using the IAM role chain RoleA, RoleB.

```
unload ('select * from venue limit 10')
to 's3://companyb/redshift/venue_pipe_'
iam_role 'arn:aws:iam::123456789012:role/RoleA,arn:aws:iam::210987654321:role/RoleB';
```

The following example grants the ASSUMEROLE privilege to the user reg_user1 for the IAM role Redshift-Exfunc to create external functions.

```
grant assumerole on 'arn:aws:iam::123456789012:role/Redshift-Exfunc'
to reg_user1 for external function;
```

The following example grants the ASSUMEROLE privilege to the user reg_user1 for the IAM role Redshift-model to create machine learning models.

```
grant assumerole on 'arn:aws:iam::123456789012:role/Redshift-ML'
to reg_user1 for create model;
```

Examples of granting the ROLE privileges

The following example grants sample_role1 to user1.

```
CREATE ROLE sample_role1;
GRANT ROLE sample_role1 TO user1;
```

The following example grants sample_role1 to user1 with the WITH ADMIN OPTION, sets the current session for user1, and user1 grants sample_role1 to user2.

```
GRANT ROLE sample_role1 TO user1 WITH ADMIN OPTION;
SET SESSION AUTHORIZATION user1;
GRANT ROLE sample_role1 TO user2;
```

The following example grants sample_role1 to sample_role2.

```
GRANT ROLE sample_role1 TO ROLE sample_role2;
```

The following example grants sample_role2 to sample_role3 and sample_role4. Then it attempts to grants sample_role3 to sample_role1.

```
GRANT ROLE sample_role2 TO ROLE sample_role3;
GRANT ROLE sample_role3 TO ROLE sample_role2;
ERROR: cannot grant this role, a circular dependency was detected between these roles
```

The following example grants the CREATE USER system privileges to sample_role1.

```
GRANT CREATE USER TO ROLE sample_role1;
```

The following example grants the system-defined role sys:dba to user1.

```
GRANT ROLE sys:dba TO user1;
```

The following example attempts to grant sample_role3 in a circular dependency to sample_role2.

```
CREATE ROLE sample_role3;
GRANT ROLE sample_role2 TO ROLE sample_role3;
GRANT ROLE sample_role3 TO ROLE sample_role2; -- fail
ERROR: cannot grant this role, a circular dependency was detected between these roles
```

INSERT

Topics

- [Syntax](#)
- [Parameters](#)
- [Usage notes](#)
- [INSERT examples](#)

Inserts new rows into a table. You can insert a single row with the VALUES syntax, multiple rows with the VALUES syntax, or one or more rows defined by the results of a query (INSERT INTO...SELECT).

Note

We strongly encourage you to use the [COPY](#) command to load large amounts of data. Using individual INSERT statements to populate a table might be prohibitively slow. Alternatively, if your data already exists in other Amazon Redshift database tables, use

INSERT INTO SELECT or [CREATE TABLE AS](#) to improve performance. For more information about using the COPY command to load tables, see [Loading data in Amazon Redshift](#).

Note

The maximum size for a single SQL statement is 16 MB.

Syntax

```
INSERT INTO table_name [ ( column [, ...] ) ]  
{DEFAULT VALUES |  
VALUES ( { expression | DEFAULT } [, ...] )  
[, ( { expression | DEFAULT } [, ...] )  
[, ...] ] |  
query }
```

Parameters

table_name

A temporary or persistent table. Only the owner of the table or a user with INSERT privilege on the table can insert rows. If you use the *query* clause to insert rows, you must have SELECT privilege on the tables named in the query.

Note

Use INSERT (external table) to insert results of a SELECT query into existing tables on external catalog. For more information, see [INSERT \(external table\)](#).

column

You can insert values into one or more columns of the table. You can list the target column names in any order. If you don't specify a column list, the values to be inserted must correspond to the table columns in the order in which they were declared in the CREATE TABLE statement. If the number of values to be inserted is less than the number of columns in the table, the first *n* columns are loaded.

Either the declared default value or a null value is loaded into any column that isn't listed (implicitly or explicitly) in the INSERT statement.

DEFAULT VALUES

If the columns in the table were assigned default values when the table was created, use these keywords to insert a row that consists entirely of default values. If any of the columns don't have default values, nulls are inserted into those columns. If any of the columns are declared NOT NULL, the INSERT statement returns an error.

VALUES

Use this keyword to insert one or more rows, each row consisting of one or more values. The VALUES list for each row must align with the column list. To insert multiple rows, use a comma delimiter between each list of expressions. Do not repeat the VALUES keyword. All VALUES lists for a multiple-row INSERT statement must contain the same number of values.

expression

A single value or an expression that evaluates to a single value. Each value must be compatible with the data type of the column where it is being inserted. If possible, a value whose data type doesn't match the column's declared data type is automatically converted to a compatible data type. For example:

- A decimal value 1.1 is inserted into an INT column as 1.
- A decimal value 100.8976 is inserted into a DEC(5,2) column as 100.90.

You can explicitly convert a value to a compatible data type by including type cast syntax in the expression. For example, if column COL1 in table T1 is a CHAR(3) column:

```
insert into t1(col1) values('Incomplete'::char(3));
```

This statement inserts the value Inc into the column.

For a single-row INSERT VALUES statement, you can use a scalar subquery as an expression. The result of the subquery is inserted into the appropriate column.

Note

Subqueries aren't supported as expressions for multiple-row INSERT VALUES statements.

DEFAULT

Use this keyword to insert the default value for a column, as defined when the table was created. If no default value exists for a column, a null is inserted. You can't insert a default value into a column that has a NOT NULL constraint if that column doesn't have an explicit default value assigned to it in the CREATE TABLE statement.

query

Insert one or more rows into the table by defining any query. All of the rows that the query produces are inserted into the table. The query must return a column list that is compatible with the columns in the table, but the column names don't have to match.

Usage notes

Note

We strongly encourage you to use the [COPY](#) command to load large amounts of data. Using individual INSERT statements to populate a table might be prohibitively slow. Alternatively, if your data already exists in other Amazon Redshift database tables, use INSERT INTO SELECT or [CREATE TABLE AS](#) to improve performance. For more information about using the COPY command to load tables, see [Loading data in Amazon Redshift](#).

The data format for the inserted values must match the data format specified by the CREATE TABLE definition.

After inserting a large number of new rows into a table:

- Vacuum the table to reclaim storage space and re-sort rows.
- Analyze the table to update statistics for the query planner.

When values are inserted into DECIMAL columns and they exceed the specified scale, the loaded values are rounded up as appropriate. For example, when a value of 20.259 is inserted into a DECIMAL(8,2) column, the value that is stored is 20.26.

You can insert into a GENERATED BY DEFAULT AS IDENTITY column. You can update columns defined as GENERATED BY DEFAULT AS IDENTITY with values that you supply. For more information, see [GENERATED BY DEFAULT AS IDENTITY](#).

INSERT examples

The CATEGORY table in the TICKIT database contains the following rows:

```

catid | catgroup | catname | catdesc
-----+-----+-----+-----
  1 | Sports  | MLB     | Major League Baseball
  2 | Sports  | NHL     | National Hockey League
  3 | Sports  | NFL     | National Football League
  4 | Sports  | NBA     | National Basketball Association
  5 | Sports  | MLS     | Major League Soccer
  6 | Shows   | Musicals | Musical theatre
  7 | Shows   | Plays   | All non-musical theatre
  8 | Shows   | Opera   | All opera and light opera
  9 | Concerts | Pop     | All rock and pop music concerts
 10 | Concerts | Jazz    | All jazz singers and bands
 11 | Concerts | Classical | All symphony, concerto, and choir concerts
(11 rows)

```

Create a CATEGORY_STAGE table with a similar schema to the CATEGORY table but define default values for the columns:

```

create table category_stage
(catid smallint default 0,
catgroup varchar(10) default 'General',
catname varchar(10) default 'General',
catdesc varchar(50) default 'General');

```

The following INSERT statement selects all of the rows from the CATEGORY table and inserts them into the CATEGORY_STAGE table.

```

insert into category_stage
(select * from category);

```

The parentheses around the query are optional.

This command inserts a new row into the CATEGORY_STAGE table with a value specified for each column in order:

```

insert into category_stage values
(12, 'Concerts', 'Comedy', 'All stand-up comedy performances');

```

You can also insert a new row that combines specific values and default values:

```
insert into category_stage values
(13, 'Concerts', 'Other', default);
```

Run the following query to return the inserted rows:

```
select * from category_stage
where catid in(12,13) order by 1;
```

catid	catgroup	catname	catdesc
12	Concerts	Comedy	All stand-up comedy performances
13	Concerts	Other	General

(2 rows)

The following examples show some multiple-row INSERT VALUES statements. The first example inserts specific CATID values for two rows and default values for the other columns in both rows.

```
insert into category_stage values
(14, default, default, default),
(15, default, default, default);
```

```
select * from category_stage where catid in(14,15) order by 1;
```

catid	catgroup	catname	catdesc
14	General	General	General
15	General	General	General

(2 rows)

The next example inserts three rows with various combinations of specific and default values:

```
insert into category_stage values
(default, default, default, default),
(20, default, 'Country', default),
(21, 'Concerts', 'Rock', default);
```

```
select * from category_stage where catid in(0,20,21) order by 1;
```

catid	catgroup	catname	catdesc
0	General	General	General

```

20 | General | Country | General
21 | Concerts | Rock    | General
(3 rows)

```

The first set of VALUES in this example produces the same results as specifying DEFAULT VALUES for a single-row INSERT statement.

The following examples show INSERT behavior when a table has an IDENTITY column. First, create a new version of the CATEGORY table, then insert rows into it from CATEGORY:

```

create table category_ident
(catid int identity not null,
catgroup varchar(10) default 'General',
catname varchar(10) default 'General',
catdesc varchar(50) default 'General');

insert into category_ident(catgroup,catname,catdesc)
select catgroup,catname,catdesc from category;

```

Note that you can't insert specific integer values into the CATID IDENTITY column. IDENTITY column values are automatically generated.

The following example demonstrates that subqueries can't be used as expressions in multiple-row INSERT VALUES statements:

```

insert into category(catid) values
((select max(catid)+1 from category)),
((select max(catid)+2 from category));

ERROR: can't use subqueries in multi-row VALUES

```

The following example shows an insert into a temporary table populated with data from the venue table using the WITH SELECT clause. For more information about the venue table, see [Sample database](#).

First, create the temporary table #venuetemp.

```
CREATE TABLE #venuetemp AS SELECT * FROM venue;
```

List the rows in the #venuetemp table.

```
SELECT * FROM #venuetemp ORDER BY venueid;
```

venueid	venue name	venue city	venue state	venue seats
1	Toyota Park	Bridgeview	IL	0
2	Columbus Crew Stadium	Columbus	OH	0
3	RFK Stadium	Washington	DC	0
4	CommunityAmerica Ballpark	Kansas City	KS	0
5	Gillette Stadium	Foxborough	MA	68756
...				

Insert 10 duplicate rows in the #venuetemp table using the WITH SELECT clause.

```
INSERT INTO #venuetemp (WITH venuecopy AS (SELECT * FROM venue) SELECT * FROM venuecopy
ORDER BY 1 LIMIT 10);
```

List the rows in the #venuetemp table.

```
SELECT * FROM #venuetemp ORDER BY venueid;
```

venueid	venue name	venue city	venue state	venue seats
1	Toyota Park	Bridgeview	IL	0
1	Toyota Park	Bridgeview	IL	0
2	Columbus Crew Stadium	Columbus	OH	0
2	Columbus Crew Stadium	Columbus	OH	0
3	RFK Stadium	Washington	DC	0
3	RFK Stadium	Washington	DC	0
4	CommunityAmerica Ballpark	Kansas City	KS	0
4	CommunityAmerica Ballpark	Kansas City	KS	0
5	Gillette Stadium	Foxborough	MA	68756
5	Gillette Stadium	Foxborough	MA	68756
...				

INSERT (external table)

Inserts the results of a SELECT query into existing external tables on external catalog such as for AWS Glue, AWS Lake Formation, or an Apache Hive metastore. Use the same AWS Identity and Access Management (IAM) role used for the CREATE EXTERNAL SCHEMA command to interact with external catalogs and Amazon S3.

For nonpartitioned tables, the INSERT (external table) command writes data to the Amazon S3 location defined in the table, based on the specified table properties and file format.

For partitioned tables, INSERT (external table) writes data to the Amazon S3 location according to the partition key specified in the table. It also automatically registers new partitions in the external catalog after the INSERT operation completes.

You can't run INSERT (external table) within a transaction block (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).

Syntax

```
INSERT INTO external_schema.table_name
{ select_statement }
```

Parameters

external_schema.table_name

The name of an existing external schema and a target external table to insert into.

select_statement

A statement that inserts one or more rows into the external table by defining any query. All of the rows that the query produces are written to Amazon S3 in either text or Parquet format based on the table definition. The query must return a column list that is compatible with the column data types in the external table. However, the column names don't have to match.

Usage notes

The number of columns in the SELECT query must be the same as the sum of data columns and partition columns. The location and the data type of each data column must match that of the external table. The location of partition columns must be at the end of the SELECT query, in the same order they were defined in CREATE EXTERNAL TABLE command. The column names don't have to match.

In some cases, you might want to run the INSERT (external table) command on an AWS Glue Data Catalog or a Hive metastore. In the case of AWS Glue, the IAM role used to create the external schema must have both read and write permissions on Amazon S3 and AWS Glue. If you use an

AWS Lake Formation catalog, this IAM role becomes the owner of the new Lake Formation table. This IAM role must at least have the following permissions:

- SELECT, INSERT, UPDATE permission on the external table
- Data location permission on the Amazon S3 path of the external table

To ensure that file names are unique, Amazon Redshift uses the following format for the name of each file uploaded to Amazon S3 by default.

<date>_<time>_<microseconds>_<query_id>_<slice-number>_part_<part-number>.<format>.

An example is `20200303_004509_810669_1007_0001_part_00.parquet`.

Consider the following when running the INSERT (external table) command:

- External tables that have a format other than PARQUET or TEXTFILE aren't supported.
- This command supports existing table properties such as 'write.parallel', 'write.maxfilesize.mb', 'compression_type', and 'serialization.null.format'. To update those values, run the ALTER TABLE SET TABLE PROPERTIES command.
- The 'numRows' table property is automatically updated toward the end of the INSERT operation. The table property must be defined or added to the table already if it wasn't created by CREATE EXTERNAL TABLE AS operation.
- The LIMIT clause isn't supported in the outer SELECT query. Instead, use a nested LIMIT clause.
- You can use the [STL_UNLOAD_LOG](#) table to track the files that got written to Amazon S3 by each INSERT (external table) operation.
- Amazon Redshift supports only Amazon S3 standard encryption for INSERT (external table).

INSERT (external table) examples

The following example inserts the results of the SELECT statement into the external table.

```
INSERT INTO spectrum.lineitem
SELECT * FROM local_lineitem;
```

The following example inserts the results of the SELECT statement into a partitioned external table using static partitioning. The partition columns are hardcoded in the SELECT statement. The partition columns must be at the end of the query.

```
INSERT INTO spectrum.customer
SELECT name, age, gender, 'May', 28 FROM local_customer;
```

The following example inserts the results of the SELECT statement into a partitioned external table using dynamic partitioning. The partition columns aren't hardcoded. Data is automatically added to the existing partition folders, or to new folders if a new partition is added.

```
INSERT INTO spectrum.customer
SELECT name, age, gender, month, day FROM local_customer;
```

LOCK

Restricts access to a database table. This command is only meaningful when it is run inside a transaction block.

The LOCK command obtains a table-level lock in "ACCESS EXCLUSIVE" mode, waiting if necessary for any conflicting locks to be released. Explicitly locking a table in this way causes reads and writes on the table to wait when they are attempted from other transactions or sessions. An explicit table lock created by one user temporarily prevents another user from selecting data from that table or loading data into it. The lock is released when the transaction that contains the LOCK command completes.

Less restrictive table locks are acquired implicitly by commands that refer to tables, such as write operations. For example, if a user tries to read data from a table while another user is updating the table, the data that is read will be a snapshot of the data that has already been committed. (In some cases, queries will stop if they violate serializable isolation rules.) See [Managing concurrent write operations](#).

Some DDL operations, such as DROP TABLE and TRUNCATE, create exclusive locks. These operations prevent data reads.

If a lock conflict occurs, Amazon Redshift displays an error message to alert the user who started the transaction in conflict. The transaction that received the lock conflict is stopped. Every time a lock conflict occurs, Amazon Redshift writes an entry to the [STL_TR_CONFLICT](#) table.

Syntax

```
LOCK [ TABLE ] table_name [, ...]
```

Parameters

TABLE

Optional keyword.

table_name

Name of the table to lock. You can lock more than one table by using a comma-delimited list of table names. You can't lock views.

Example

```
begin;  
  
lock event, sales;  
  
...
```

MERGE

Conditionally merges rows from a source table into a target table. Traditionally, this can only be achieved by using multiple insert, update or delete statements separately. For more information on the operations that MERGE lets you combine, see [UPDATE](#), [DELETE](#), and [INSERT](#).

Syntax

```
MERGE INTO target_table  
USING source_table [ [ AS ] alias ]  
ON match_condition  
[ WHEN MATCHED THEN { UPDATE SET col_name = { expr } [,...] | DELETE }  
WHEN NOT MATCHED THEN INSERT [ ( col_name [,...] ) ] VALUES ( { expr } [, ...] ) |  
REMOVE DUPLICATES ]
```

Parameters

target_table

The temporary or permanent table that the MERGE statement merges into.

source_table

The temporary or permanent table supplying the rows to merge into *target_table*. *source_table* can also be a Spectrum table.

alias

The temporary alternative name for *source_table*.

This parameter is optional. Preceding *alias* with AS is also optional.

match_condition

Specifies equal predicates between the source table column and target table column that are used to determine whether the rows in *source_table* can be matched with rows in *target_table*. If the condition is met, MERGE runs *matched_clause* for that row. Otherwise MERGE runs *not_matched_clause* for that row.

WHEN MATCHED

Specifies the action to be run when the match condition between a source row and a target row evaluates to True. You can specify either an UPDATE action or a DELETE action.

UPDATE

Updates the matched row in *target_table*. Only values in the *col_name* you specify are updated.

DELETE

Deletes the matched row in *target_table*.

WHEN NOT MATCHED

Specifies the action to be run when the match condition is evaluated to False or Unknown. You can only specify the INSERT insert action for this clause.

INSERT

Inserts into *target_table* rows from *source_table* that don't match any rows in *target_table*, according to *match_condition*. The target *col_name* can be listed in any order. If you don't provide any *col_name* values, the default order is all the table's columns in their declared order.

col_name

One or more column names that you want to modify. Don't include the table name when specifying the target column.

expr

The expression defining the new value for *col_name*.

REMOVE DUPLICATES

Specifies that the MERGE command runs in simplified mode. Simplified mode has the following requirements:

- *target_table* and *source_table* must have the same number of columns and compatible column types.
- Omit the WHEN clause and the UPDATE and INSERT clauses from your MERGE command.
- Use the REMOVE DUPLICATES clause in your MERGE command.

In simplified mode, MERGE does the following:

- Rows in *target_table* that have a match in *source_table* are updated to match the values in *source_table*.
- Rows in *source_table* that don't have a match in *target_table* are inserted into *target_table*.
- When multiple rows in *target_table* match the same row in *source_table*, the duplicate rows are removed. Amazon Redshift keeps one row and updates it. Duplicate rows that don't match a row in *source_table* remain unchanged.

Using REMOVE DUPLICATES gives better performance than using WHEN MATCHED and WHEN NOT MATCHED. We recommend using REMOVE DUPLICATES if *target_table* and *source_table* are compatible and you don't need to preserve duplicate rows in *target_table*.

Usage notes

- To run MERGE statements, you must be the owner of both *source_table* and *target_table*, or have the SELECT permission for those tables. Additionally, you must have UPDATE, DELETE, and INSERT permissions for *target_table* depending on the operations included in your MERGE statement.
- *target_table* can't be a system table, catalog table, or external table.
- *source_table* and *target_table* can't be the same table.

- You can't use the WITH clause in a MERGE statement.
- Rows in *target_table* can't match multiple rows in *source_table*.

Consider the following example:

```
CREATE TABLE target (id INT, name CHAR(10));
CREATE TABLE source (id INT, name CHAR(10));

INSERT INTO target VALUES (1, 'Bob'), (2, 'John');
INSERT INTO source VALUES (1, 'Tony'), (1, 'Alice'), (3, 'Bill');

MERGE INTO target USING source ON target.id = source.id
WHEN MATCHED THEN UPDATE SET id = source.id, name = source.name
WHEN NOT MATCHED THEN INSERT VALUES (source.id, source.name);
ERROR: Found multiple matches to update the same tuple.

MERGE INTO target USING source ON target.id = source.id
WHEN MATCHED THEN DELETE
WHEN NOT MATCHED THEN INSERT VALUES (source.id, source.name);
ERROR: Found multiple matches to update the same tuple.
```

In both MERGE statements, the operation fails because there are multiple rows in the source table with an ID value of 1.

- *match_condition* and *expr* can't partially reference SUPER type columns. For example, if your SUPER type object is an array or a structure, you can't use individual elements of that column for *match_condition* or *expr*, but you can use the entire column.

Consider the following example:

```
CREATE TABLE IF NOT EXISTS target (key INT, value SUPER);
CREATE TABLE IF NOT EXISTS source (key INT, value SUPER);

INSERT INTO target VALUES (1, JSON_PARSE('{"key": 88}'));
INSERT INTO source VALUES (1, ARRAY(1, 'John')), (2, ARRAY(2, 'Bill'));

MERGE INTO target USING source ON target.key = source.key
WHEN matched THEN UPDATE SET value = source.value[0]
WHEN NOT matched THEN INSERT VALUES (source.key, source.value[0]);
ERROR: Partial reference of SUPER column is not supported in MERGE statement.
```

For more information on the SUPER type, see [SUPER type](#).

- If *source_table* is large, defining the join columns from both *target_table* and *source_table* as the distribution keys can improve performance.
- To use the REMOVE DUPLICATES clause, you need SELECT, INSERT, and DELETE permissions for *target_table*.
- *source_table* can be a view or subquery. Following is an example of a MERGE statement where *source_table* is a subquery that removes duplicate rows.

```
MERGE INTO target
USING (SELECT id, name FROM source GROUP BY 1, 2) as my_source
ON target.id = my_source.id
WHEN MATCHED THEN UPDATE SET id = my_source.id, name = my_source.name
WHEN NOT MATCHED THEN INSERT VALUES (my_source.id, my_source.name);
```

Examples

The following example creates two tables, then runs a MERGE operation on them, updating matching rows in the target table and inserting rows that don't match. Then it inserts another value into the source table and runs another MERGE operation, this time deleting matching rows and inserting the new row from the source table.

First create and populate the source and target tables.

```
CREATE TABLE target (id INT, name CHAR(10));
CREATE TABLE source (id INT, name CHAR(10));

INSERT INTO target VALUES (101, 'Bob'), (102, 'John'), (103, 'Susan');
INSERT INTO source VALUES (102, 'Tony'), (103, 'Alice'), (104, 'Bill');

SELECT * FROM target;
 id | name
-----+-----
 101 | Bob
 102 | John
 103 | Susan
(3 rows)

SELECT * FROM source;
 id | name
-----+-----
 102 | Tony
```

```
103 | Alice
104 | Bill
(3 rows)
```

Next, merge the source table into the target table, updating the target table with matching rows and insert rows from the source table that have no match.

```
MERGE INTO target USING source ON target.id = source.id
WHEN MATCHED THEN UPDATE SET id = source.id, name = source.name
WHEN NOT MATCHED THEN INSERT VALUES (source.id, source.name);

SELECT * FROM target;
 id | name
-----+-----
 101 | Bob
 102 | Tony
 103 | Alice
 104 | Bill
(4 rows)
```

Note that the rows with id values of 102 and 103 are updated to match the name values from the target table. Also, a new row with an id value of 104 and name value of Bill is inserted into the target table.

Next, insert a new row into the source table.

```
INSERT INTO source VALUES (105, 'David');

SELECT * FROM source;
 id | name
-----+-----
 102 | Tony
 103 | Alice
 104 | Bill
 105 | David
(4 rows)
```

Finally, run a merge operation deleting matching rows in the target table, and inserting rows that don't match.

```
MERGE INTO target USING source ON target.id = source.id
WHEN MATCHED THEN DELETE
```

```

WHEN NOT MATCHED THEN INSERT VALUES (source.id, source.name);

SELECT * FROM target;
 id |   name
-----+-----
 101 | Bob
 105 | David
(2 rows)

```

The rows with id values 102, 103, and 104 are deleted from the target table, and a new row with an id value of 105 and name value of David is inserted into the target table.

The following example shows the simplified syntax of a MERGE command that uses the REMOVE DUPLICATES clause.

```

CREATE TABLE target (id INT, name CHAR(10));
CREATE TABLE source (id INT, name CHAR(10));

INSERT INTO target VALUES (30, 'Tony'), (11, 'Alice'), (23, 'Bill');
INSERT INTO source VALUES (23, 'David'), (22, 'Clarence');

MERGE INTO target USING source ON target.id = source.id REMOVE DUPLICATES;

SELECT * FROM target;
 id | name
----+-----
 30 | Tony
 11 | Alice
 23 | David
 22 | Clarence
(4 rows)

```

The following example shows the simplified syntax of a MERGE command that uses the REMOVE DUPLICATES clause, removing duplicate rows from *target_table* if they have matching rows in *source_table*.

```

CREATE TABLE target (id INT, name CHAR(10));
CREATE TABLE source (id INT, name CHAR(10));

INSERT INTO target VALUES (30, 'Tony'), (30, 'Daisy'), (11, 'Alice'), (23, 'Bill'),
(23, 'Nikki');
INSERT INTO source VALUES (23, 'David'), (22, 'Clarence');

```

```
MERGE INTO target USING source ON target.id = source.id REMOVE DUPLICATES;

SELECT * FROM target;
id | name
---+-----
30 | Tony
30 | Daisy
11 | Alice
23 | David
22 | Clarence
(5 rows)
```

After MERGE runs, there's only one row with an ID value of 23 in *target_table*. Because there was no row in *source_table* with the ID value 30, the two duplicate rows with ID values of 30 remain in *target_table*.

PREPARE

Prepare a statement for execution.

PREPARE creates a prepared statement. When the PREPARE statement is run, the specified statement (SELECT, INSERT, UPDATE, or DELETE) is parsed, rewritten, and planned. When an EXECUTE command is then issued for the prepared statement, Amazon Redshift may optionally revise the query execution plan (to improve performance based on the specified parameter values) before running the prepared statement.

Syntax

```
PREPARE plan_name [ (datatype [, ...] ) ] AS statement
```

Parameters

plan_name

An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to run or deallocate a previously prepared statement.

datatype

The data type of a parameter to the prepared statement. To refer to the parameters in the prepared statement itself, use \$1, \$2, and so on.

statement

Any SELECT, INSERT, UPDATE, or DELETE statement.

Usage notes

Prepared statements can take parameters: values that are substituted into the statement when it is run. To include parameters in a prepared statement, supply a list of data types in the PREPARE statement, and, in the statement to be prepared itself, refer to the parameters by position using the notation \$1, \$2, ... When running the statement, specify the actual values for these parameters in the EXECUTE statement. For more details, see [EXECUTE](#).

Prepared statements only last for the duration of the current session. When the session ends, the prepared statement is discarded, so it must be re-created before being used again. This also means that a single prepared statement can't be used by multiple simultaneous database clients; however, each client can create its own prepared statement to use. The prepared statement can be manually removed using the DEALLOCATE command.

Prepared statements have the largest performance advantage when a single session is being used to run a large number of similar statements. As mentioned, for each new execution of a prepared statement, Amazon Redshift may revise the query execution plan to improve performance based on the specified parameter values. To examine the query execution plan that Amazon Redshift has chosen for any specific EXECUTE statements, use the [EXPLAIN](#) command.

For more information on query planning and the statistics collected by Amazon Redshift for query optimization, see the [ANALYZE](#) command.

Examples

Create a temporary table, prepare INSERT statement and then run it:

```
DROP TABLE IF EXISTS prep1;
CREATE TABLE prep1 (c1 int, c2 char(20));
PREPARE prep_insert_plan (int, char)
AS insert into prep1 values ($1, $2);
```

```
EXECUTE prep_insert_plan (1, 'one');
EXECUTE prep_insert_plan (2, 'two');
EXECUTE prep_insert_plan (3, 'three');
DEALLOCATE prep_insert_plan;
```

Prepare a SELECT statement and then run it:

```
PREPARE prep_select_plan (int)
AS select * from prep1 where c1 = $1;
EXECUTE prep_select_plan (2);
EXECUTE prep_select_plan (3);
DEALLOCATE prep_select_plan;
```

[DEALLOCATE](#), [EXECUTE](#)

REFRESH MATERIALIZED VIEW

Refreshes a materialized view.

When you create a materialized view, its contents reflect the state of the underlying database table or tables at that time. The data in the materialized view remains unchanged, even when applications make changes to the data in the underlying tables. To update the data in a materialized view, you can use the `REFRESH MATERIALIZED VIEW` statement at any time. When you use this statement, Amazon Redshift identifies changes that have taken place in the base table or tables, and then applies those changes to the materialized view.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

Syntax

```
REFRESH MATERIALIZED VIEW mv_name
```

Parameters

mv_name

The name of the materialized view to be refreshed.

Usage notes

Only the owner of a materialized view can perform a `REFRESH MATERIALIZED VIEW` operation on that materialized view. Furthermore, the owner must have `SELECT` privilege on the underlying base tables to successfully run `REFRESH MATERIALIZED VIEW`.

The `REFRESH MATERIALIZED VIEW` command runs as a transaction of its own. Amazon Redshift transaction semantics are followed to determine what data from base tables is visible to the `REFRESH` command, or when the changes made by the `REFRESH` command are made visible to other transactions running in Amazon Redshift.

- For incremental materialized views, `REFRESH MATERIALIZED VIEW` uses only those base table rows that are already committed. Therefore, if the refresh operation runs after a data manipulation language (DML) statement in the same transaction, then changes of that DML statement aren't visible to refresh.
- For a full refresh of a materialized view, `REFRESH MATERIALIZED VIEW` sees all base table rows visible to the refresh transaction, according to usual Amazon Redshift transaction semantics.
- Depending on the input argument type, Amazon Redshift still supports incremental refresh for materialized views for the following functions with specific input argument types: `DATE` (timestamp), `DATE_PART` (date, time, interval, time-tz), `DATE_TRUNC` (timestamp, interval).
- Incremental refresh is supported on a materialized view where the base table is in a datashare.

Some operations in Amazon Redshift interact with materialized views. Some of these operations might force a `REFRESH MATERIALIZED VIEW` operation to fully recompute the materialized view even though the query defining the materialized view only uses the SQL features eligible for incremental refresh. For example:

- Background vacuum operations might be blocked if materialized views aren't refreshed. After an internally defined threshold period, a vacuum operation is allowed to run. When this vacuum operation happens, any dependent materialized views are marked for recomputation upon the next refresh (even if they are incremental). For information about `VACUUM`, see [VACUUM](#). For more information about events and state changes, see [STL_MV_STATE](#).
- Some user-initiated operations on base tables force a materialized view to be fully recomputed next time that a `REFRESH` operation is run. Examples of such operations are a manually invoked `VACUUM`, a classic resize, an `ALTER DISTKEY` operation, an `ALTER SORTKEY` operation, and a truncate operation. Automatic operations in some cases can also result in a materialized view being fully recomputed the next time a `REFRESH` operation is run. For example, an auto-vacuum

delete operation can cause a full recompute. For more information about events and state changes, see [STL_MV_STATE](#).

Incremental refresh for materialized views in a datashare

Amazon Redshift supports automatic and incremental refresh for materialized views in a consumer datashare when the base tables are shared. Incremental refresh is an operation where Amazon Redshift identifies changes in the base table or tables that happened after the previous refresh and updates only the corresponding records in the materialized view. For more information about this behavior, see [CREATE MATERIALIZED VIEW](#).

Limitations for incremental refresh

Amazon Redshift currently doesn't support incremental refresh for materialized views that are defined with a query using any of the following SQL elements:

- OUTER JOIN (RIGHT, LEFT, or FULL).
- Set operations: UNION, INTERSECT, EXCEPT, MINUS.
- UNION ALL when it occurs in a subquery and an aggregate function or a GROUP BY clause is present in the query.
- Aggregate functions: MEDIAN, PERCENTILE_CONT, LISTAGG, STDDEV_SAMP, STDDEV_POP, APPROXIMATE COUNT, APPROXIMATE PERCENTILE, and bitwise aggregate functions.

Note

The COUNT, SUM, MIN, MAX, and AVG aggregate functions are supported.

- DISTINCT aggregate functions, such as DISTINCT COUNT, DISTINCT SUM, and so on.
- Window functions.
- A query that uses temporary tables for query optimization, such as optimizing common subexpressions.
- Subqueries
- External tables referencing the following formats in the query that defines the materialized view.
 - Delta Lake
 - Hudi

Incremental refresh is supported for materialized views defined using external tables referencing other formats on the preview track. For more information about setting up Preview clusters, see [Creating a preview cluster](#) in the *Amazon Redshift Management Guide*. For information about setting up Preview workgroups, see [Creating a preview workgroup](#) in the *Amazon Redshift Management Guide*.

- Mutable functions, such as date-time functions, RANDOM and non-STABLE user-defined functions.
- For limitations regarding incremental refresh for zero-ETL integrations, see [Considerations when using zero-ETL integrations with Amazon Redshift](#).

For more information about materialized-view limitations, including the effect of background operations like VACUUM on materialized-view refresh operations, see [Usage notes](#).

Examples

The following example refreshes the `tickets_mv` materialized view.

```
REFRESH MATERIALIZED VIEW tickets_mv;
```

RESET

Restores the value of a configuration parameter to its default value.

You can reset either a single specified parameter or all parameters at once. To set a parameter to a specific value, use the [SET](#) command. To display the current value of a parameter, use the [SHOW](#) command.

Syntax

```
RESET { parameter_name | ALL }
```

The following statement sets the value of a session context variable to NULL.

```
RESET { variable_name | ALL }
```

Parameters

parameter_name

Name of the parameter to reset. See [Modifying the server configuration](#) for more documentation about parameters.

ALL

Resets all runtime parameters, including all the session context variables.

variable

The name of the variable to reset. If the value to RESET is a session context variable, Amazon Redshift sets it to NULL.

Examples

The following example resets the `query_group` parameter to its default value:

```
reset query_group;
```

The following example resets all runtime parameters to their default values.

```
reset all;
```

The following example resets the context variable.

```
RESET app_context.user_id;
```

REVOKE

Removes access permissions, such as permissions to create, drop, or update tables, from a user or role.

You can only GRANT or REVOKE USAGE permissions on an external schema to database users and roles using the ON SCHEMA syntax. When using ON EXTERNAL SCHEMA with AWS Lake Formation, you can only GRANT and REVOKE permissions to an AWS Identity and Access Management (IAM) role. For the list of permissions, see the syntax.

For stored procedures, USAGE ON LANGUAGE plpgsql permissions are granted to PUBLIC by default. EXECUTE ON PROCEDURE permission is granted only to the owner and superusers by default.

Specify in the REVOKE command the permissions that you want to remove. To give permissions, use the [GRANT](#) command.

Syntax

```
REVOKE [ GRANT OPTION FOR ]
{ { SELECT | INSERT | UPDATE | DELETE | DROP | REFERENCES | ALTER | TRUNCATE } [,...] |
  ALL [ PRIVILEGES ] }
ON { [ TABLE ] table_name [, ...] | ALL TABLES IN SCHEMA schema_name [, ...] }
FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
{ { CREATE | TEMPORARY | TEMP | ALTER } [,...] | ALL [ PRIVILEGES ] }
ON DATABASE db_name [, ...]
FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
{ { CREATE | USAGE | ALTER } [,...] | ALL [ PRIVILEGES ] }
ON SCHEMA schema_name [, ...]
FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
EXECUTE
  ON FUNCTION function_name ( [ [ argname ] argtype [, ...] ] ) [, ...]
  FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
{ { EXECUTE } [,...] | ALL [ PRIVILEGES ] }
  ON PROCEDURE procedure_name ( [ [ argname ] argtype [, ...] ] ) [, ...]
  FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]
```

```

REVOKE [ GRANT OPTION FOR ]
USAGE
    ON LANGUAGE language_name [, ...]
    FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]

```

Revoking column-level permissions for tables

The following is the syntax for column-level permissions on Amazon Redshift tables and views.

```

REVOKE { { SELECT | UPDATE } ( column_name [, ...] ) [, ...] | ALL [ PRIVILEGES ]
( column_name [, ...] ) }
    ON { [ TABLE ] table_name [, ...] }
    FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
[ RESTRICT ]

```

Revoking ASSUMEROLE permissions

The following is the syntax to revoke the ASSUMEROLE permission from users and groups with a specified role.

```

REVOKE ASSUMEROLE
    ON { 'iam_role' [, ...] | default | ALL }
    FROM { user_name | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
    FOR { ALL | COPY | UNLOAD | EXTERNAL FUNCTION | CREATE MODEL }

```

Revoking permissions for Redshift Spectrum for Lake Formation

The following is the syntax for Redshift Spectrum integration with Lake Formation.

```

REVOKE [ GRANT OPTION FOR ]
{ SELECT | ALL [ PRIVILEGES ] } ( column_list )
    ON EXTERNAL TABLE schema_name.table_name
    FROM { IAM_ROLE iam_role } [, ...]

REVOKE [ GRANT OPTION FOR ]
{ { SELECT | ALTER | DROP | DELETE | INSERT } [, ...] | ALL [ PRIVILEGES ] }
    ON EXTERNAL TABLE schema_name.table_name [, ...]
    FROM { { IAM_ROLE iam_role } [, ...] | PUBLIC }

```

```
REVOKE [ GRANT OPTION FOR ]
{ { CREATE | ALTER | DROP } [, ...] | ALL [ PRIVILEGES ] }
  ON EXTERNAL SCHEMA schema_name [, ...]
  FROM { IAM_ROLE iam_role } [, ...]
```

Revoking datashare permissions

Producer-side datashare permissions

The following is the syntax for using REVOKE to remove ALTER or SHARE permissions from a user or role. The user whose permissions have been revoked can no longer alter the datashare, or grant usage to a consumer.

```
REVOKE { ALTER | SHARE } ON DATASHARE datashare_name
  FROM { username [ WITH GRANT OPTION ] | ROLE role_name | GROUP group_name | PUBLIC }
  [, ...]
```

The following is the syntax for using REVOKE to remove a consumer's access to a datashare.

```
REVOKE USAGE
  ON DATASHARE datashare_name
  FROM NAMESPACE 'namespaceGUID' [, ...] | ACCOUNT 'accountnumber' [ VIA DATA CATALOG ]
  [, ...]
```

The following is an example of revoking usage of a datashare from a Lake Formation account.

```
REVOKE USAGE ON DATASHARE salesshare FROM ACCOUNT '123456789012' VIA DATA CATALOG;
```

Consumer-side datashare permissions

The following is the REVOKE syntax for data-sharing usage permissions on a specific database or schema created from a datashare. Revoking usage permission from a database created with the WITH PERMISSIONS clause doesn't revoke any additional permissions you granted a user or role, including object-level permissions granted for underlying objects. If you re-grant usage permission to that user or role, they will retain all additional permissions that they had before you revoked usage.

```
REVOKE USAGE ON { DATABASE shared_database_name [, ...] | SCHEMA shared_schema }
  FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
```

Revoking scoped permissions

Scoped permissions let you grant permissions to a user or role on all objects of a type within a database or schema. Users and roles with scoped permissions have the specified permissions on all current and future objects within the database or schema.

You can view the scope of database-level scoped permissions in [SVV_DATABASE_PRIVILEGES](#). You can view the scope of schema-level scoped permissions in [SVV_SCHEMA_PRIVILEGES](#).

The following is the syntax for revoking scoped permissions from users and roles. For more information about scoped permissions, see [Scoped permissions](#).

```

REVOKE [ GRANT OPTION ]
{ CREATE | USAGE | ALTER } [,...] | ALL [ PRIVILEGES ] }
FOR SCHEMAS IN
DATABASE db_name
FROM { username | ROLE role_name } [, ...]

REVOKE [ GRANT OPTION ]
{ { SELECT | INSERT | UPDATE | DELETE | DROP | ALTER | TRUNCATE | REFERENCES }
  [, ...] } | ALL [PRIVILEGES] } }
FOR TABLES IN
{SCHEMA schema_name [DATABASE db_name ] | DATABASE db_name }
FROM { username | ROLE role_name} [, ...]

REVOKE [ GRANT OPTION ] { EXECUTE | ALL [ PRIVILEGES ] }
FOR FUNCTIONS IN
{SCHEMA schema_name [DATABASE db_name ] | DATABASE db_name }
FROM { username | ROLE role_name | } [, ...]

REVOKE [ GRANT OPTION ] { EXECUTE | ALL [ PRIVILEGES ] }
FOR PROCEDURES IN
{SCHEMA schema_name [DATABASE db_name ] | DATABASE db_name }
FROM { username | ROLE role_name | } [, ...]

REVOKE [ GRANT OPTION ] USAGE
FOR LANGUAGES IN
{DATABASE db_name}
FROM { username | ROLE role_name } [, ...]

```

Note that scoped permissions don't distinguish between permissions for functions and for procedures. For example, the following statement revokes EXECUTE permissions for both functions and procedures from bob in the schema Sales_schema.

```
REVOKE EXECUTE FOR FUNCTIONS IN SCHEMA Sales_schema FROM bob;
```

Revoking machine learning permissions

The following is the syntax for machine learning model permissions on Amazon Redshift.

```
REVOKE [ GRANT OPTION FOR ]
  CREATE MODEL FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
  [ RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { EXECUTE | ALL [ PRIVILEGES ] }
  ON MODEL model_name [, ...]

  FROM { username | ROLE role_name | GROUP group_name | PUBLIC } [, ...]
  [ RESTRICT ]
```

Revoking role permissions

The following is the syntax for revoking role permissions on Amazon Redshift.

```
REVOKE [ ADMIN OPTION FOR ] { ROLE role_name } [, ...] FROM { user_name } [, ...]
```

```
REVOKE { ROLE role_name } [, ...] FROM { ROLE role_name } [, ...]
```

The following is the syntax for revoking system permissions to roles on Amazon Redshift.

```
REVOKE
  {
  { CREATE USER | DROP USER | ALTER USER |
  CREATE SCHEMA | DROP SCHEMA |
  ALTER DEFAULT PRIVILEGES |
  ACCESS CATALOG |
  CREATE TABLE | DROP TABLE | ALTER TABLE |
  CREATE OR REPLACE FUNCTION | CREATE OR REPLACE EXTERNAL FUNCTION |
  DROP FUNCTION |
  CREATE OR REPLACE PROCEDURE | DROP PROCEDURE |
```

```

CREATE OR REPLACE VIEW | DROP VIEW |
CREATE MODEL | DROP MODEL |
CREATE DATASHARE | ALTER DATASHARE | DROP DATASHARE |
CREATE LIBRARY | DROP LIBRARY |
CREATE ROLE | DROP ROLE
TRUNCATE TABLE
VACUUM | ANALYZE | CANCEL }[, ...]
}
| { ALL [ PRIVILEGES ] }
FROM { ROLE role_name } [, ...]

```

Revoking explain permissions for row-level security policy filters

The following is the syntax for revoking permissions to explain the row-level security policy filters of a query in the EXPLAIN plan. You can revoke the privilege using the REVOKE statement.

```
REVOKE EXPLAIN RLS FROM ROLE rolename
```

The following is the syntax for granting permissions to bypass row-level security policies for a query.

```
REVOKE IGNORE RLS FROM ROLE rolename
```

The following is the syntax for revoking permissions from the specified row-level security policy.

```
REVOKE SELECT ON [ TABLE ] table_name [, ...]
      FROM RLS POLICY policy_name [, ...]
```

Parameters

GRANT OPTION FOR

Revokes only the option to grant a specified permission to other users and doesn't revoke the permission itself. You can't revoke GRANT OPTION from a group or from PUBLIC.

SELECT

Revokes the permission to select data from a table or a view using a SELECT statement.

INSERT

Revokes the permission to load data into a table using an INSERT statement or a COPY statement.

UPDATE

Revokes the permission to update a table column using an UPDATE statement.

DELETE

Revokes the permission to delete a data row from a table.

REFERENCES

Revokes the permission to create a foreign key constraint. You should revoke this permission on both the referenced table and the referencing table.

TRUNCATE

Revokes the permission to truncate a table. Without this permission, only the owner of a table or a superuser can truncate a table. For more information about the TRUNCATE command, see [the section called "TRUNCATE"](#).

ALL [PRIVILEGES]

Revokes all available permissions at once from the specified user or group. The PRIVILEGES keyword is optional.

Note

Amazon Redshift doesn't support the RULE and TRIGGER permissions. For more information, go to [Unsupported PostgreSQL features](#).

ALTER

Depending on the database object, revokes the following permissions from the user or user group:

- For tables, ALTER revokes permission to alter a table or view. For more information, see [ALTER TABLE](#).
- For databases, ALTER revokes permission to alter a database. For more information, see [ALTER DATABASE](#).
- For schemas, ALTER grants revokes to alter a schema. For more information, see [ALTER SCHEMA](#).
- For external tables, ALTER revokes permission to alter a table in an AWS Glue Data Catalog that is enabled for Lake Formation. This permission only applies when using Lake Formation.

DROP

Revokes permission to drop a table. This permission applies in Amazon Redshift and in an AWS Glue Data Catalog that is enabled for Lake Formation.

ASSUMEROLE

Revokes the permission to run COPY, UNLOAD, EXTERNAL FUNCTION, or CREATE MODEL commands from users, roles, or groups with a specified role.

ON [TABLE] *table_name*

Revokes the specified permissions on a table or a view. The TABLE keyword is optional.

ON ALL TABLES IN SCHEMA *schema_name*

Revokes the specified permissions on all tables in the referenced schema.

(*column_name* [...]) ON TABLE *table_name*

Revokes the specified permissions from users, groups, or PUBLIC on the specified columns of the Amazon Redshift table or view.

(*column_list*) ON EXTERNAL TABLE *schema_name.table_name*

Revokes the specified permissions from an IAM role on the specified columns of the Lake Formation table in the referenced schema.

ON EXTERNAL TABLE *schema_name.table_name*

Revokes the specified permissions from an IAM role on the specified Lake Formation tables in the referenced schema.

ON EXTERNAL SCHEMA *schema_name*

Revokes the specified permissions from an IAM role on the referenced schema.

FROM IAM_ROLE *iam_role*

Indicates the IAM role losing the permissions.

ROLE *role_name*

Revokes the permissions from the specified role.

GROUP *group_name*

Revokes the permissions from the specified user group.

PUBLIC

Revokes the specified permissions from all users. PUBLIC represents a group that always includes all users. An individual user's permissions consist of the sum of permissions granted to PUBLIC, permissions granted to any groups that the user belongs to, and any permissions granted to the user individually.

Revoking PUBLIC from a Lake Formation external table results in revoking the permission from the Lake Formation *everyone* group.

CREATE

Depending on the database object, revokes the following permissions from the user or group:

- For databases, using the CREATE clause for REVOKE prevents users from creating schemas within the database.
- For schemas, using the CREATE clause for REVOKE prevents users from creating objects within a schema. To rename an object, the user must have the CREATE permission and own the object to be renamed.

Note

By default, all users have CREATE and USAGE permissions on the PUBLIC schema.

TEMPORARY | TEMP

Revokes the permission to create temporary tables in the specified database.

Note

By default, users are granted permission to create temporary tables by their automatic membership in the PUBLIC group. To remove the permission for any users to create temporary tables, revoke the TEMP permission from the PUBLIC group and then explicitly grant the permission to create temporary tables to specific users or groups of users.

ON DATABASE *db_name*

Revokes the permissions on the specified database.

USAGE

Revokes USAGE permissions on objects within a specific schema, which makes these objects inaccessible to users. Specific actions on these objects must be revoked separately (such as the EXECUTE permission on functions).

Note

By default, all users have CREATE and USAGE permissions on the PUBLIC schema.

ON SCHEMA *schema_name*

Revokes the permissions on the specified schema. You can use schema permissions to control the creation of tables; the CREATE permission for a database only controls the creation of schemas.

RESTRICT

Revokes only those permissions that the user directly granted. This behavior is the default.

EXECUTE ON PROCEDURE *procedure_name*

Revokes the EXECUTE permission on a specific stored procedure. Because stored procedure names can be overloaded, you must include the argument list for the procedure. For more information, see [Naming stored procedures](#).

EXECUTE ON ALL PROCEDURES IN SCHEMA *procedure_name*

Revokes the specified permissions on all procedures in the referenced schema.

USAGE ON LANGUAGE *language_name*

Revokes the USAGE permission on a language. For Python user-defined functions (UDFs), use `plpythonu`. For SQL UDFs, use `sql`. For stored procedures, use `plpgsql`.

To create a UDF, you must have permission for usage on language for SQL or `plpythonu` (Python). By default, USAGE ON LANGUAGE SQL is granted to PUBLIC. However, you must explicitly grant USAGE ON LANGUAGE PLPYTHONU to specific users or groups.

To revoke usage for SQL, first revoke usage from PUBLIC. Then grant usage on SQL only to the specific users or groups permitted to create SQL UDFs. The following example revokes usage on SQL from PUBLIC then grants usage to the user group `udf_devs`.

```
revoke usage on language sql from PUBLIC;  
grant usage on language sql to group udf_devs;
```

For more information, see [UDF security and permissions](#).

To revoke usage for stored procedures, first revoke usage from PUBLIC. Then grant usage on `plpgsql` only to the specific users or groups permitted to create stored procedures. For more information, see [Security and privileges for stored procedures](#).

FOR { ALL | COPY | UNLOAD | EXTERNAL FUNCTION | CREATE MODEL } [, ...]

Specifies the SQL command for which the permission is revoked. You can specify ALL to revoke the permission on the COPY, UNLOAD, EXTERNAL FUNCTION, and CREATE MODEL statements. This clause applies only to revoking the ASSUMEROLE permission.

ALTER

Revokes the ALTER permission for users or user groups that allows those that don't own a datashare to alter the datashare. This permission is required to add or remove objects from a datashare, or to set the property PUBLICACCESSIBLE. For more information, see [ALTER DATASHARE](#).

SHARE

Revokes permissions for users and user groups to add consumers to a datashare. Revoking this permission is required to stop the particular consumer from accessing the datashare from its clusters.

ON DATASHARE *datashare_name*

Grants the specified permissions on the referenced datashare.

FROM username

Indicates the user losing the permissions.

FROM GROUP *group_name*

Indicates the user group losing the permissions.

WITH GRANT OPTION

Indicates that the user losing the permissions can in turn revoke the same permissions for others. You can't revoke WITH GRANT OPTION for a group or for PUBLIC.

USAGE

When USAGE is revoked for a consumer account or namespace within the same account, the specified consumer account or namespace within an account can't access the datashare and the objects of the datashare in read-only fashion.

Revoking the USAGE permission revokes the access to a datashare from consumers.

FROM NAMESPACE 'clusternamespace GUID'

Indicates the namespace in the same account that has consumers losing the permissions to the datashare. Namespaces use a 128-bit alphanumeric globally unique identifier (GUID).

FROM ACCOUNT 'accountnumber' [VIA DATA CATALOG]

Indicates the account number of another account that has the consumers losing the permissions to the datashare. Specifying 'VIA DATA CATALOG' indicates that you are revoking usage of the datashare from a Lake Formation account. Omitting the account number means that you're revoking from the account that owns the cluster.

ON DATABASE *shared_database_name*> [, ...]

Revokes the specified usage permissions on the specified database that was created in the specified datashare.

ON SCHEMA *shared_schema*

Revokes the specified permissions on the specified schema that was created in the specified datashare.

FOR { SCHEMAS | TABLES | FUNCTIONS | PROCEDURES | LANGUAGES } IN

Specifies the database objects to revoke permission from. The parameters following IN define the scope of the revoked permission.

CREATE MODEL

Revokes the CREATE MODEL permission to create machine learning models in the specified database.

ON MODEL *model_name*

Revokes the EXECUTE permission for a specific model.

ACCESS CATALOG

Revokes the permission to view relevant metadata of objects that the role has access to.

```
[ ADMIN OPTION FOR ] { role } [, ...]
```

The role that you revoke from a specified user that has the WITH ADMIN OPTION.

```
FROM { role } [, ...]
```

The role that you revoke the specified role from.

Usage notes

To learn more about the usage notes for REVOKE, see [the section called "Usage notes"](#).

Examples

For examples of how to use REVOKE, see [the section called "Examples"](#).

Usage notes

To revoke privileges from an object, you must meet one of the following criteria:

- Be the object owner.
- Be a superuser.
- Have a grant privilege for that object and privilege.

For example, the following command enables the user HR both to perform SELECT commands on the employees table and to grant and revoke the same privilege for other users.

```
grant select on table employees to HR with grant option;
```

HR can't revoke privileges for any operation other than SELECT, or on any other table than employees.

Superusers can access all objects regardless of GRANT and REVOKE commands that set object privileges.

PUBLIC represents a group that always includes all users. By default all members of PUBLIC have CREATE and USAGE privileges on the PUBLIC schema. To restrict any user's permissions on the PUBLIC schema, you must first revoke all permissions from PUBLIC on the PUBLIC schema, then grant privileges to specific users or groups. The following example controls table creation privileges in the PUBLIC schema.

```
revoke create on schema public from public;
```

To revoke privileges from a Lake Formation table, the IAM role associated with the table's external schema must have permission to revoke privileges to the external table. The following example creates an external schema with an associated IAM role `myGrantor`. IAM role `myGrantor` has the permission to revoke permissions from others. The `REVOKE` command uses the permission of the IAM role `myGrantor` that is associated with the external schema to revoke permission to the IAM role `myGrantee`.

```
create external schema mySchema
from data catalog
database 'spectrum_db'
iam_role 'arn:aws:iam::123456789012:role/myGrantor'
create external database if not exists;
```

```
revoke select
on external table mySchema.mytable
from iam_role 'arn:aws:iam::123456789012:role/myGrantee';
```

Note

If the IAM role also has the `ALL` permission in an AWS Glue Data Catalog that is enabled for Lake Formation, the `ALL` permission isn't revoked. Only the `SELECT` permission is revoked. You can view the Lake Formation permissions in the Lake Formation console.

Usage notes for revoking the `ASSUMEROLE` permission

The following usage notes apply to revoking the `ASSUMEROLE` privilege in Amazon Redshift.

Only a database superuser can revoke the `ASSUMEROLE` privilege for users and groups. A superuser always retains the `ASSUMEROLE` privilege.

To enable the use of the `ASSUMEROLE` privilege for users and groups, a superuser runs the following statement once on the cluster. Before granting the `ASSUMEROLE` privilege to users and groups, a superuser must run the following statement once on the cluster.

```
revoke assumerole on all from public for all;
```

Usage notes for revoking machine learning permissions

You can't directly grant or revoke permissions related to an ML function. An ML function belongs to an ML model and permissions are controlled through the model. Instead, you can revoke permissions related to the ML model. The following example demonstrates how to revoke the run permission from all users associated with the model `customer_churn`.

```
REVOKE EXECUTE ON MODEL customer_churn FROM PUBLIC;
```

You can also revoke all permissions from a user for the ML model `customer_churn`.

```
REVOKE ALL on MODEL customer_churn FROM ml_user;
```

Granting or revoking the EXECUTE permission related to an ML function will fail if there is an ML function in the schema, even if that ML function already has the EXECUTE permission through `GRANT EXECUTE ON MODEL`. We recommend using a separate schema when using the `CREATE MODEL` command to keep the ML functions in a separate schema by themselves. The following example demonstrates how to do so.

```
CREATE MODEL ml_schema.customer_churn
FROM customer_data
TARGET churn
FUNCTION ml_schema.customer_churn_prediction
IAM_ROLE default
SETTINGS (
  S3_BUCKET 'amzn-s3-demo-bucket'
);
```

Examples

The following example revokes INSERT privileges on the SALES table from the GUESTS user group. This command prevents members of GUESTS from being able to load data into the SALES table by using the INSERT command.

```
revoke insert on table sales from group guests;
```

The following example revokes the SELECT privilege on all tables in the QA_TICKIT schema from the user fred.

```
revoke select on all tables in schema qa_tickit from fred;
```

The following example revokes the privilege to select from a view for user bobr.

```
revoke select on table eventview from bobr;
```

The following example revokes the privilege to create temporary tables in the TICKIT database from all users.

```
revoke temporary on database tickit from public;
```

The following example revokes SELECT privilege on the cust_name and cust_phone columns of the cust_profile table from the user user1.

```
revoke select(cust_name, cust_phone) on cust_profile from user1;
```

The following example revokes SELECT privilege on the cust_name and cust_phone columns and UPDATE privilege on the cust_contact_preference column of the cust_profile table from the sales_group group.

```
revoke select(cust_name, cust_phone), update(cust_contact_preference) on cust_profile  
from group sales_group;
```

The following example shows the usage of the ALL keyword to revoke both SELECT and UPDATE privileges on three columns of the table cust_profile from the sales_admin group.

```
revoke ALL(cust_name, cust_phone, cust_contact_preference) on cust_profile from group  
sales_admin;
```

The following example revokes the SELECT privilege on the cust_name column of the cust_profile_vw view from the user2 user.

```
revoke select(cust_name) on cust_profile_vw from user2;
```

Examples of revoking the USAGE permission from databases created from datashares

The following example revokes access to the salesshare datashare from the from the 13b8833d-17c6-4f16-8fe4-1a018f5ed00d namespace.

```
REVOKE USAGE ON DATASHARE salesshare FROM NAMESPACE  
'13b8833d-17c6-4f16-8fe4-1a018f5ed00d';
```

The following example revokes the USAGE permission on the sales_db from Bob.

```
REVOKE USAGE ON DATABASE sales_db FROM Bob;
```

The following example REVOKE USAGE permission on the sales_schema from the Analyst_role.

```
REVOKE USAGE ON SCHEMA sales_schema FROM ROLE Analyst_role;
```

Examples of revoking scoped permissions

The following example revokes usage for all current and future schemas in the Sales_db database from the Sales role.

```
REVOKE USAGE FOR SCHEMAS IN DATABASE Sales_db FROM ROLE Sales;
```

The following example revokes the ability to grant the SELECT permission for all current and future tables in the Sales_db database from the user alice. alice retains access to all tables in Sales_db.

```
REVOKE GRANT OPTION SELECT FOR TABLES IN DATABASE Sales_db FROM alice;
```

The following example revokes the EXECUTE permission for functions in the Sales_schema schema from the user bob.

```
REVOKE EXECUTE FOR FUNCTIONS IN SCHEMA Sales_schema FROM bob;
```

The following example revokes all permissions for all tables in the ShareDb database's ShareSchema schema from the Sales role. When specifying the schema, you can also specify the schema's database using the two-part format database.schema.

```
REVOKE ALL FOR TABLES IN SCHEMA ShareDb.ShareSchema FROM ROLE Sales;
```

The following example is the same as the preceding one. You can specify the schema's database using the DATABASE keyword instead of using a two-part format.

```
REVOKE ALL FOR TABLES IN SCHEMA ShareSchema DATABASE ShareDb FROM ROLE Sales;
```

Examples of revoking the ASSUMEROLE privilege

The following are examples of revoking the ASSUMEROLE privilege.

A superuser must enable the use of the ASSUMEROLE privilege for users and groups by running the following statement once on the cluster:

```
revoke assumeroles on all from public for all;
```

The following statement revokes the ASSUMEROLE privilege from user reg_user1 on all roles for all operations.

```
revoke assumeroles on all from reg_user1 for all;
```

Examples of revoking the ROLE privilege

The following example revokes the sample_role1 from to sample_role2.

```
CREATE ROLE sample_role2;  
GRANT ROLE sample_role1 TO ROLE sample_role2;  
REVOKE ROLE sample_role1 FROM ROLE sample_role2;
```

The following example revokes system privileges from user1.

```
GRANT ROLE sys:DBA TO user1;  
REVOKE ROLE sys:DBA FROM user1;
```

The following example revokes sample_role1 and sample_role2 from user1.

```
CREATE ROLE sample_role1;  
CREATE ROLE sample_role2;  
GRANT ROLE sample_role1, ROLE sample_role2 TO user1;  
REVOKE ROLE sample_role1, ROLE sample_role2 FROM user1;
```

The following example revokes sample_role2 with the ADMIN OPTION from user1.

```
GRANT ROLE sample_role2 TO user1 WITH ADMIN OPTION;  
REVOKE ADMIN OPTION FOR ROLE sample_role2 FROM user1;
```

```
REVOKE ROLE sample_role2 FROM user1;
```

The following example revokes `sample_role1` and `sample_role2` from `sample_role5`.

```
CREATE ROLE sample_role5;  
GRANT ROLE sample_role1, ROLE sample_role2 TO ROLE sample_role5;  
REVOKE ROLE sample_role1, ROLE sample_role2 FROM ROLE sample_role5;
```

The following example revokes the `CREATE SCHEMA` and `DROP SCHEMA` system privileges to `sample_role1`.

```
GRANT CREATE SCHEMA, DROP SCHEMA TO ROLE sample_role1;  
REVOKE CREATE SCHEMA, DROP SCHEMA FROM ROLE sample_role1;
```

ROLLBACK

Stops the current transaction and discards all updates made by that transaction.

This command performs the same function as the [ABORT](#) command.

Syntax

```
ROLLBACK [ WORK | TRANSACTION ]
```

Parameters

WORK

Optional keyword. This keyword isn't supported within a stored procedure.

TRANSACTION

Optional keyword. `WORK` and `TRANSACTION` are synonyms. Neither is supported within a stored procedure.

For information about using `ROLLBACK` within a stored procedure, see [Managing transactions](#).

Example

The following example creates a table then starts a transaction where data is inserted into the table. The `ROLLBACK` command then rolls back the data insertion to leave the table empty.

The following command creates an example table called MOVIE_GROSS:

```
create table movie_gross( name varchar(30), gross bigint );
```

The next set of commands starts a transaction that inserts two data rows into the table:

```
begin;

insert into movie_gross values ( 'Raiders of the Lost Ark', 234000000);

insert into movie_gross values ( 'Star Wars', 100000000 );
```

Next, the following command selects the data from the table to show that it was successfully inserted:

```
select * from movie_gross;
```

The command output shows that both rows successfully inserted:

```
name          | gross
-----+-----
Raiders of the Lost Ark | 234000000
Star Wars      | 100000000
(2 rows)
```

This command now rolls back the data changes to where the transaction began:

```
rollback;
```

Selecting data from the table now shows an empty table:

```
select * from movie_gross;

name | gross
-----+-----
(0 rows)
```

SELECT

Returns rows from tables, views, and user-defined functions.

Note

The maximum size for a single SQL statement is 16 MB.

Syntax

```
[ WITH with_subquery [, ...] ]  
SELECT  
[ TOP number | [ ALL | DISTINCT ]  
* | expression [ AS output_name ] [, ...] ]  
[ FROM table_reference [, ...] ]  
[ WHERE condition ]  
[ [ START WITH expression ] CONNECT BY expression ]  
[ GROUP BY expression [, ...] ]  
[ HAVING condition ]  
[ QUALIFY condition ]  
[ { UNION | ALL | INTERSECT | EXCEPT | MINUS } query ]  
[ ORDER BY expression [ ASC | DESC ] ]  
[ LIMIT { number | ALL } ]  
[ OFFSET start ]
```

WITH clause

A WITH clause is an optional clause that precedes the SELECT list in a query. The WITH clause defines one or more *common_table_expressions*. Each common table expression (CTE) defines a temporary table, which is similar to a view definition. You can reference these temporary tables in the FROM clause. They're used only while the query they belong to runs. Each CTE in the WITH clause specifies a table name, an optional list of column names, and a query expression that evaluates to a table (a SELECT statement). When you reference the temporary table name in the FROM clause of the same query expression that defines it, the CTE is recursive.

WITH clause subqueries are an efficient way of defining tables that can be used throughout the execution of a single query. In all cases, the same results can be achieved by using subqueries in the main body of the SELECT statement, but WITH clause subqueries may be simpler to write and read. Where possible, WITH clause subqueries that are referenced multiple times are optimized as common subexpressions; that is, it may be possible to evaluate a WITH subquery once and reuse its results. (Note that common subexpressions aren't limited to those defined in the WITH clause.)

Syntax

```
[ WITH [RECURSIVE] common_table_expression [, common_table_expression , ...] ]
```

where *common_table_expression* can be either non-recursive or recursive. Following is the non-recursive form:

```
CTE_table_name [ ( column_name [, ...] ) ] AS ( query )
```

Following is the recursive form of *common_table_expression*:

```
CTE_table_name ( column_name [, ...] ) AS ( recursive_query )
```

Parameters

RECURSIVE

Keyword that identifies the query as a recursive CTE. This keyword is required if any *common_table_expression* defined in the WITH clause is recursive. You can only specify the RECURSIVE keyword once, immediately following the WITH keyword, even when the WITH clause contains multiple recursive CTEs. In general, a recursive CTE is a UNION ALL subquery with two parts.

common_table_expression

Defines a temporary table that you can reference in the [FROM clause](#) and is used only during the execution of the query to which it belongs.

CTE_table_name

A unique name for a temporary table that defines the results of a WITH clause subquery. You can't use duplicate names within a single WITH clause. Each subquery must be given a table name that can be referenced in the [FROM clause](#).

column_name

A list of output column names for the WITH clause subquery, separated by commas. The number of column names specified must be equal to or less than the number of columns defined by the subquery. For a CTE that is non-recursive, the *column_name* clause is optional. For a recursive CTE, the *column_name* list is required.

query

Any SELECT query that Amazon Redshift supports. See [SELECT](#).

recursive_query

A UNION ALL query that consists of two SELECT subqueries:

- The first SELECT subquery doesn't have a recursive reference to the same *CTE_table_name*. It returns a result set that is the initial seed of the recursion. This part is called the initial member or seed member.
- The second SELECT subquery references the same *CTE_table_name* in its FROM clause. This is called the recursive member. The *recursive_query* contains a WHERE condition to end the *recursive_query*.

Usage notes

You can use a WITH clause in the following SQL statements:

- SELECT
- SELECT INTO
- CREATE TABLE AS
- CREATE VIEW
- DECLARE

- EXPLAIN
- INSERT INTO...SELECT
- PREPARE
- UPDATE (within a WHERE clause subquery. You can't define a recursive CTE in the subquery. The recursive CTE must precede the UPDATE clause.)
- DELETE

If the FROM clause of a query that contains a WITH clause doesn't reference any of the tables defined by the WITH clause, the WITH clause is ignored and the query runs as normal.

A table defined by a WITH clause subquery can be referenced only in the scope of the SELECT query that the WITH clause begins. For example, you can reference such a table in the FROM clause of a subquery in the SELECT list, WHERE clause, or HAVING clause. You can't use a WITH clause in a subquery and reference its table in the FROM clause of the main query or another subquery. This query pattern results in an error message of the form `relation table_name doesn't exist for the WITH clause table`.

You can't specify another WITH clause inside a WITH clause subquery.

You can't make forward references to tables defined by WITH clause subqueries. For example, the following query returns an error because of the forward reference to table W2 in the definition of table W1:

```
with w1 as (select * from w2), w2 as (select * from w1)
select * from sales;
ERROR:  relation "w2" does not exist
```

A WITH clause subquery may not consist of a SELECT INTO statement; however, you can use a WITH clause in a SELECT INTO statement.

Recursive common table expressions

A recursive *common table expression* (CTE) is a CTE that references itself. A recursive CTE is useful in querying hierarchical data, such as organization charts that show reporting relationships between employees and managers. See [Example: Recursive CTE](#).

Another common use is a multilevel bill of materials, when a product consists of many components and each component itself also consists of other components or subassemblies.

Be sure to limit the depth of recursion by including a WHERE clause in the second SELECT subquery of the recursive query. For an example, see [Example: Recursive CTE](#). Otherwise, an error can occur similar to the following:

- Recursive CTE out of working buffers.
- Exceeded recursive CTE max rows limit, please add correct CTE termination predicates or change the `max_recursion_rows` parameter.

Note

`max_recursion_rows` is a parameter setting the maximum number of rows a recursive CTE can return in order to prevent infinite recursion loops. We recommend against changing this to a larger value than the default. This prevents infinite recursion problems in your queries from taking up excessive space in your cluster.

You can specify a sort order and limit on the result of the recursive CTE. You can include group by and distinct options on the final result of the recursive CTE.

You can't specify a WITH RECURSIVE clause inside a subquery. The *recursive_query* member can't include an order by or limit clause.

Examples

The following example shows the simplest possible case of a query that contains a WITH clause. The WITH query named VENUECOPY selects all of the rows from the VENUE table. The main query in turn selects all of the rows from VENUECOPY. The VENUECOPY table exists only for the duration of this query.

```
with venuecopy as (select * from venue)
select * from venuecopy order by 1 limit 10;
```

venueid	venue name	venue city	venue state	venue seats
1	Toyota Park	Bridgeview	IL	0
2	Columbus Crew Stadium	Columbus	OH	0
3	RFK Stadium	Washington	DC	0
4	CommunityAmerica Ballpark	Kansas City	KS	0
5	Gillette Stadium	Foxborough	MA	68756

```

6 | New York Giants Stadium | East Rutherford | NJ | 80242
7 | BMO Field | Toronto | ON | 0
8 | The Home Depot Center | Carson | CA | 0
9 | Dick's Sporting Goods Park | Commerce City | CO | 0
v 10 | Pizza Hut Park | Frisco | TX | 0
(10 rows)

```

The following example shows a WITH clause that produces two tables, named VENUE_SALES and TOP_VENUES. The second WITH query table selects from the first. In turn, the WHERE clause of the main query block contains a subquery that constrains the TOP_VENUES table.

```

with venue_sales as
(select venuename, venuecity, sum(pricepaid) as venue_name_sales
from sales, venue, event
where venue.venueid=event.venueid and event.eventid=sales.eventid
group by venue_name_sales, venuecity),

top_venues as
(select venue_name_sales
from venue_sales
where venue_name_sales > 800000)

select venue_name_sales, venuecity, venuestate,
sum(qtysold) as venue_qty,
sum(pricepaid) as venue_sales
from sales, venue, event
where venue.venueid=event.venueid and event.eventid=sales.eventid
and venue_name_sales in(select venue_name_sales from top_venues)
group by venue_name_sales, venuecity, venuestate
order by venue_name_sales;

```

venue_name_sales	venuecity	venuestate	venue_qty	venue_sales
August Wilson Theatre	New York City	NY	3187	1032156.00
Biltmore Theatre	New York City	NY	2629	828981.00
Charles Playhouse	Boston	MA	2502	857031.00
Ethel Barrymore Theatre	New York City	NY	2828	891172.00
Eugene O'Neill Theatre	New York City	NY	2488	828950.00
Greek Theatre	Los Angeles	CA	2445	838918.00
Helen Hayes Theatre	New York City	NY	2948	978765.00
Hilton Theatre	New York City	NY	2999	885686.00
Imperial Theatre	New York City	NY	2702	877993.00

Lunt-Fontanne Theatre	New York City	NY	3326	1115182.00
Majestic Theatre	New York City	NY	2549	894275.00
Nederlander Theatre	New York City	NY	2934	936312.00
Pasadena Playhouse	Pasadena	CA	2739	820435.00
Winter Garden Theatre	New York City	NY	2838	939257.00

(14 rows)

The following two examples demonstrate the rules for the scope of table references based on WITH clause subqueries. The first query runs, but the second fails with an expected error. The first query has WITH clause subquery inside the SELECT list of the main query. The table defined by the WITH clause (HOLIDAYS) is referenced in the FROM clause of the subquery in the SELECT list:

```
select caldate, sum(pricepaid) as daysales,
(with holidays as (select * from date where holiday ='t'))
select sum(pricepaid)
from sales join holidays on sales.dateid=holidays.dateid
where caldate='2008-12-25') as dec25sales
from sales join date on sales.dateid=date.dateid
where caldate in('2008-12-25','2008-12-31')
group by caldate
order by caldate;
```

caldate	daysales	dec25sales
2008-12-25	70402.00	70402.00
2008-12-31	12678.00	70402.00

(2 rows)

The second query fails because it attempts to reference the HOLIDAYS table in the main query as well as in the SELECT list subquery. The main query references are out of scope.

```
select caldate, sum(pricepaid) as daysales,
(with holidays as (select * from date where holiday ='t'))
select sum(pricepaid)
from sales join holidays on sales.dateid=holidays.dateid
where caldate='2008-12-25') as dec25sales
from sales join holidays on sales.dateid=holidays.dateid
where caldate in('2008-12-25','2008-12-31')
group by caldate
order by caldate;
```

```
ERROR: relation "holidays" does not exist
```

Example: Recursive CTE

The following is an example of a recursive CTE that returns the employees who report directly or indirectly to John. The recursive query contains a WHERE clause to limit the depth of recursion to less than 4 levels.

```
--create and populate the sample table
create table employee (
  id int,
  name varchar (20),
  manager_id int
);

insert into employee(id, name, manager_id) values
(100, 'Carlos', null),
(101, 'John', 100),
(102, 'Jorge', 101),
(103, 'Kwaku', 101),
(110, 'Liu', 101),
(106, 'Mateo', 102),
(110, 'Nikki', 103),
(104, 'Paulo', 103),
(105, 'Richard', 103),
(120, 'Saanvi', 104),
(200, 'Shirley', 104),
(201, 'Sofia', 102),
(205, 'Zhang', 104);

--run the recursive query
with recursive john_org(id, name, manager_id, level) as
( select id, name, manager_id, 1 as level
  from employee
  where name = 'John'
  union all
  select e.id, e.name, e.manager_id, level + 1 as next_level
  from employee e, john_org j
  where e.manager_id = j.id and level < 4
  )
select distinct id, name, manager_id from john_org order by manager_id;
```

Following is the result of the query.

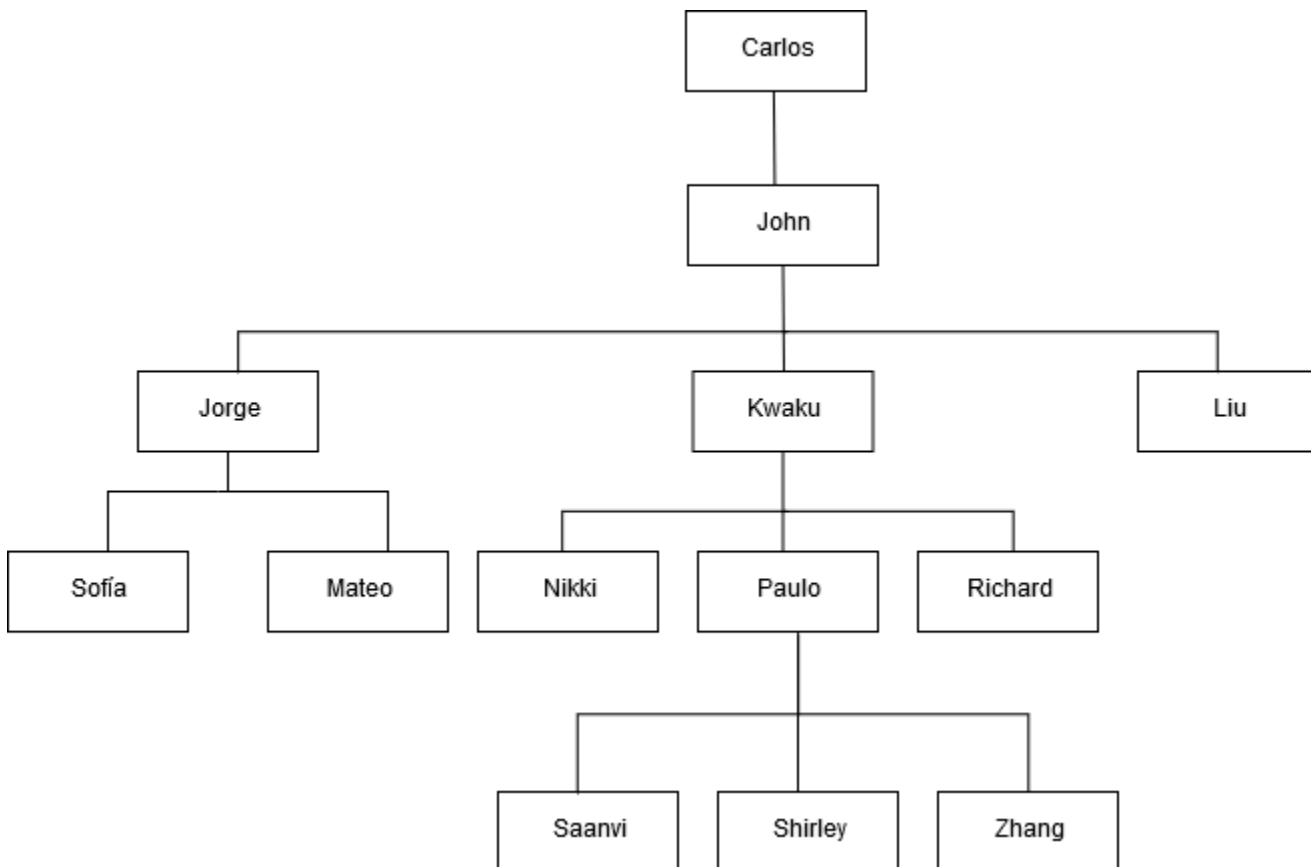

id	name	manager_id
----	------	------------

```

-----+-----+-----
101   John      100
102   Jorge     101
103   Kwaku     101
110   Liu       101
201   Sofia     102
106   Mateo     102
110   Nikki     103
104   Paulo     103
105   Richard   103
120   Saanvi    104
200   Shirley   104
205   Zhang     104

```

Following is an organization chart for John's department.

SELECT list

Topics

- [Syntax](#)

- [Parameters](#)
- [Usage notes](#)
- [Examples](#)

The SELECT list names the columns, functions, and expressions that you want the query to return. The list represents the output of the query.

For more information about SQL functions, see [SQL functions reference](#). For more information about expressions, see [Conditional expressions](#).

Syntax

```
SELECT
[ TOP number ]
[ ALL | DISTINCT ] * | expression [ AS column_alias ] [, ...]
```

Parameters

TOP *number*

TOP takes a positive integer as its argument, which defines the number of rows that are returned to the client. The behavior with the TOP clause is the same as the behavior with the LIMIT clause. The number of rows that is returned is fixed, but the set of rows isn't. To return a consistent set of rows, use TOP or LIMIT in conjunction with an ORDER BY clause.

ALL

A redundant keyword that defines the default behavior if you don't specify DISTINCT. SELECT ALL * means the same as SELECT * (select all rows for all columns and retain duplicates).

DISTINCT

Option that eliminates duplicate rows from the result set, based on matching values in one or more columns.

Note

If your application allows invalid foreign keys or primary keys, it can cause queries to return incorrect results. For example, a SELECT DISTINCT query might return duplicate

rows if the primary key column doesn't contain all unique values. For more information, see [Defining table constraints](#).

* (asterisk)

Returns the entire contents of the table (all columns and all rows).

expression

An expression formed from one or more columns that exist in the tables referenced by the query. An expression can contain SQL functions. For example:

```
avg(datediff(day, listtime, saletime))
```

AS column_alias

A temporary name for the column that is used in the final result set. The AS keyword is optional. For example:

```
avg(datediff(day, listtime, saletime)) as avgwait
```

If you don't specify an alias for an expression that isn't a simple column name, the result set applies a default name to that column.

Note

The alias is recognized right after it is defined in the target list. You can use an alias in other expressions defined after it in the same target list. The following example illustrates this.

```
select clicks / impressions as probability, round(100 * probability, 1) as percentage from raw_data;
```

The benefit of the lateral alias reference is you don't need to repeat the aliased expression when building more complex expressions in the same target list. When Amazon Redshift parses this type of reference, it just inlines the previously defined

aliases. If there is a column with the same name defined in the FROM clause as the previously aliased expression, the column in the FROM clause takes priority. For example, in the above query if there is a column named 'probability' in table raw_data, the 'probability' in the second expression in the target list refers to that column instead of the alias name 'probability'.

Usage notes

TOP is a SQL extension; it provides an alternative to the LIMIT behavior. You can't use TOP and LIMIT in the same query.

Examples

The following example returns 10 rows from the SALES table. Though the query uses the TOP clause, it still returns an unpredictable set of rows because no ORDER BY clause is specified,

```
select top 10 *
from sales;
```

The following query is functionally equivalent, but uses a LIMIT clause instead of a TOP clause:

```
select *
from sales
limit 10;
```

The following example returns the first 10 rows from the SALES table using the TOP clause, ordered by the QTYSOLD column in descending order.

```
select top 10 qtysold, sellerid
from sales
order by qtysold desc, sellerid;
```

```
qtysold | sellerid
-----+-----
8 |      518
8 |      520
8 |      574
8 |      718
8 |      868
```

```

8 |      2663
8 |      3396
8 |      3726
8 |      5250
8 |      6216
(10 rows)

```

The following example returns the first two QTYSOLD and SELLERID values from the SALES table, ordered by the QTYSOLD column:

```

select top 2 qtysold, sellerid
from sales
order by qtysold desc, sellerid;

qtysold | sellerid
-----+-----
8 |      518
8 |      520
(2 rows)

```

The following example shows the list of distinct category groups from the CATEGORY table:

```

select distinct catgroup from category
order by 1;

catgroup
-----
Concerts
Shows

The following example returns the distinct set of week numbers for December 2008. Without the `DISTINCT` clause, the statement would return 31 rows, or one for each day of the month.

```
select distinct week, month, year
from date
where month='DEC' and year=2008
order by 1, 2, 3;
```

```
week | month | year
-----+-----+-----
49 | DEC   | 2008
50 | DEC   | 2008
51 | DEC   | 2008
52 | DEC   | 2008
53 | DEC   | 2008
(5 rows)
```

FROM clause

The `FROM` clause in a query lists the table references (tables, views, and subqueries) that data is selected from. If multiple table references are listed, the tables must be joined, using appropriate syntax in either the `FROM` clause or the `WHERE` clause. If no join criteria are specified, the system processes the query as a cross-join (Cartesian product).

Topics

- [Syntax](#)
- [Parameters](#)
- [Usage notes](#)
- [PIVOT and UNPIVOT examples](#)
- [JOIN examples](#)

Syntax

```
FROM table_reference [, ...]
```

where *table_reference* is one of the following:

```
with_subquery_table_name [ table_alias ]
 [ * ] [ table_alias ]
( subquery ) [ table_alias ]
 [ NATURAL ] join_type table_reference
  [ ON join_condition | USING ( join_column [, ...] ) ]
 PIVOT (
  aggregate(expr) [ [ AS ] aggregate_alias ]
  FOR column_name IN ( expression [ AS ] in_alias [, ...] )
) [ table_alias ]
 UNPIVOT [ INCLUDE NULLS | EXCLUDE NULLS ] (
  value_column_name
  FOR name_column_name IN ( column_reference [ [ AS ]
  in_alias ] [, ...] )
) [ table_alias ]
UNPIVOT expression AS value_alias [ AT attribute_alias ]
```

The optional *table_alias* can be used to give temporary names to tables and complex table references and, if desired, their columns as well, like the following:

```
[ AS ] alias [ ( column_alias [, ...] ) ]
```

Parameters

with_subquery_table_name

A table defined by a subquery in the [WITH clause](#).

table_name

Name of a table or view.

alias

Temporary alternative name for a table or view. An alias must be supplied for a table derived from a subquery. In other table references, aliases are optional. The AS keyword is always optional. Table aliases provide a convenient shortcut for identifying tables in other parts of a query, such as the WHERE clause. For example:

```
select * from sales s, listing l
where s.listid=l.listid
```

column_alias

Temporary alternative name for a column in a table or view.

subquery

A query expression that evaluates to a table. The table exists only for the duration of the query and is typically given a name or *alias*. However, an alias isn't required. You can also define column names for tables that derive from subqueries. Naming column aliases is important when you want to join the results of subqueries to other tables and when you want to select or constrain those columns elsewhere in the query.

A subquery may contain an ORDER BY clause, but this clause may have no effect if a LIMIT or OFFSET clause isn't also specified.

NATURAL

Defines a join that automatically uses all pairs of identically named columns in the two tables as the joining columns. No explicit join condition is required. For example, if the CATEGORY and EVENT tables both have columns named CATID, a natural join of those tables is a join over their CATID columns.

Note

If a NATURAL join is specified but no identically named pairs of columns exist in the tables to be joined, the query defaults to a cross-join.

join_type

Specify one of the following types of join:

- [INNER] JOIN
- LEFT [OUTER] JOIN
- RIGHT [OUTER] JOIN
- FULL [OUTER] JOIN
- CROSS JOIN

Cross-joins are unqualified joins; they return the Cartesian product of the two tables.

Inner and outer joins are qualified joins. They are qualified either implicitly (in natural joins); with the ON or USING syntax in the FROM clause; or with a WHERE clause condition.

An inner join returns matching rows only, based on the join condition or list of joining columns. An outer join returns all of the rows that the equivalent inner join would return plus non-matching rows from the "left" table, "right" table, or both tables. The left table is the first-listed table, and the right table is the second-listed table. The non-matching rows contain NULL values to fill the gaps in the output columns.

ON *join_condition*

Type of join specification where the joining columns are stated as a condition that follows the ON keyword. For example:

```
sales join listing
on sales.listid=listing.listid and sales.eventid=listing.eventid
```

USING (*join_column* [, ...])

Type of join specification where the joining columns are listed in parentheses. If multiple joining columns are specified, they are delimited by commas. The USING keyword must precede the list. For example:

```
sales join listing
using (listid,eventid)
```

PIVOT

Rotates output from rows to columns, for the purpose of representing tabular data in a format that is easy to read. Output is represented horizontally across multiple columns. PIVOT is similar to a GROUP BY query with an aggregation, using an aggregate expression to specify an output format. However, in contrast to GROUP BY, the results are returned in columns instead of rows.

For examples that show how to query with PIVOT and UNPIVOT, see [PIVOT and UNPIVOT examples](#).

UNPIVOT

Rotating columns into rows with UNPIVOT – The operator transforms result columns, from an input table or query results, into rows, to make the output easier to read. UNPIVOT combines

the data of its input columns into two result columns: a name column and a value column. The name column contains column names from the input, as row entries. The value column contains values from the input columns, such as results of an aggregation. For example, the counts of items in various categories.

Object unpivoting with UNPIVOT (SUPER) – You can perform object unpivoting, where *expression* is a SUPER expression referring to another FROM clause item. For more information, see [Object unpivoting](#). It also has examples that show how to query semistructured data, such as data that's JSON-formatted.

Usage notes

Joining columns must have comparable data types.

A NATURAL or USING join retains only one of each pair of joining columns in the intermediate result set.

A join with the ON syntax retains both joining columns in its intermediate result set.

See also [WITH clause](#).

PIVOT and UNPIVOT examples

PIVOT and UNPIVOT are parameters in the FROM clause that rotate query output from rows to columns and columns to rows, respectively. They represent tabular query results in a format that's easy to read. The following examples use test data and queries to show how to use them.

For more information about these and other parameters, see [FROM clause](#).

PIVOT examples

Set up the sample table and data and use them to run the subsequent example queries.

```
CREATE TABLE part (  
    partname varchar,  
    manufacturer varchar,  
    quality int,  
    price decimal(12, 2)  
);  
  
INSERT INTO part VALUES ('prop', 'local parts co', 2, 10.00);
```

```

INSERT INTO part VALUES ('prop', 'big parts co', NULL, 9.00);
INSERT INTO part VALUES ('prop', 'small parts co', 1, 12.00);

INSERT INTO part VALUES ('rudder', 'local parts co', 1, 2.50);
INSERT INTO part VALUES ('rudder', 'big parts co', 2, 3.75);
INSERT INTO part VALUES ('rudder', 'small parts co', NULL, 1.90);

INSERT INTO part VALUES ('wing', 'local parts co', NULL, 7.50);
INSERT INTO part VALUES ('wing', 'big parts co', 1, 15.20);
INSERT INTO part VALUES ('wing', 'small parts co', NULL, 11.80);

```

PIVOT on partname with an AVG aggregation on price.

```

SELECT *
FROM (SELECT partname, price FROM part) PIVOT (
    AVG(price) FOR partname IN ('prop', 'rudder', 'wing')
);

```

The query results in the following output.

prop	rudder	wing
10.33	2.71	11.50

In the previous example, the results are transformed into columns. The following example shows a GROUP BY query that returns the average prices in rows, rather than in columns.

```

SELECT partname, avg(price)
FROM (SELECT partname, price FROM part)
WHERE partname IN ('prop', 'rudder', 'wing')
GROUP BY partname;

```

The query results in the following output.

partname	avg
prop	10.33
rudder	2.71
wing	11.50

A PIVOT example with manufacturer as an implicit column.

```
SELECT *
FROM (SELECT quality, manufacturer FROM part) PIVOT (
    count(*) FOR quality IN (1, 2, NULL)
);
```

The query results in the following output.

manufacturer	1	2	null
local parts co	1	1	1
big parts co	1	1	1
small parts co	1	0	2

Input table columns that are not referenced in the PIVOT definition are added implicitly to the result table. This is the case for the `manufacturer` column in the previous example. The example also shows that `NULL` is a valid value for the `IN` operator.

PIVOT in the above example returns similar information as the following query, which includes `GROUP BY`. The difference is that PIVOT returns the value `0` for column 2 and the manufacturer `small parts co`. The `GROUP BY` query does not contain a corresponding row. In most cases, PIVOT inserts `NULL` if a row doesn't have input data for a given column. However, the count aggregate doesn't return `NULL` and `0` is the default value.

```
SELECT manufacturer, quality, count(*)
FROM (SELECT quality, manufacturer FROM part)
WHERE quality IN (1, 2) OR quality IS NULL
GROUP BY manufacturer, quality
ORDER BY manufacturer;
```

The query results in the following output.

manufacturer	quality	count
big parts co		1
big parts co	2	1
big parts co	1	1
local parts co	2	1
local parts co	1	1
local parts co		1
small parts co	1	1

```
small parts co | | 2
```

The PIVOT operator accepts optional aliases on the aggregate expression and on each value for the IN operator. Use aliases to customize the column names. If there is no aggregate alias, only the IN list aliases are used. Otherwise, the aggregate alias is appended to the column name with an underscore to separate the names.

```
SELECT *
FROM (SELECT quality, manufacturer FROM part) PIVOT (
    count(*) AS count FOR quality IN (1 AS high, 2 AS low, NULL AS na)
);
```

The query results in the following output.

manufacturer	high_count	low_count	na_count
local parts co	1	1	1
big parts co	1	1	1
small parts co	1	0	2

Set up the following sample table and data and use them to run the subsequent example queries. The data represents booking dates for a collection of hotels.

```
CREATE TABLE bookings (
    booking_id int,
    hotel_code char(8),
    booking_date date,
    price decimal(12, 2)
);

INSERT INTO bookings VALUES (1, 'FOREST_L', '02/01/2023', 75.12);
INSERT INTO bookings VALUES (2, 'FOREST_L', '02/02/2023', 75.00);
INSERT INTO bookings VALUES (3, 'FOREST_L', '02/04/2023', 85.54);

INSERT INTO bookings VALUES (4, 'FOREST_L', '02/08/2023', 75.00);
INSERT INTO bookings VALUES (5, 'FOREST_L', '02/11/2023', 75.00);
INSERT INTO bookings VALUES (6, 'FOREST_L', '02/14/2023', 90.00);

INSERT INTO bookings VALUES (7, 'FOREST_L', '02/21/2023', 60.00);
INSERT INTO bookings VALUES (8, 'FOREST_L', '02/22/2023', 85.00);
INSERT INTO bookings VALUES (9, 'FOREST_L', '02/27/2023', 90.00);
```

```
INSERT INTO bookings VALUES (10, 'DESERT_S', '02/01/2023', 98.00);
INSERT INTO bookings VALUES (11, 'DESERT_S', '02/02/2023', 75.00);
INSERT INTO bookings VALUES (12, 'DESERT_S', '02/04/2023', 85.00);

INSERT INTO bookings VALUES (13, 'DESERT_S', '02/05/2023', 75.00);
INSERT INTO bookings VALUES (14, 'DESERT_S', '02/06/2023', 34.00);
INSERT INTO bookings VALUES (15, 'DESERT_S', '02/09/2023', 85.00);

INSERT INTO bookings VALUES (16, 'DESERT_S', '02/12/2023', 23.00);
INSERT INTO bookings VALUES (17, 'DESERT_S', '02/13/2023', 76.00);
INSERT INTO bookings VALUES (18, 'DESERT_S', '02/14/2023', 85.00);

INSERT INTO bookings VALUES (19, 'OCEAN_WV', '02/01/2023', 98.00);
INSERT INTO bookings VALUES (20, 'OCEAN_WV', '02/02/2023', 75.00);
INSERT INTO bookings VALUES (21, 'OCEAN_WV', '02/04/2023', 85.00);

INSERT INTO bookings VALUES (22, 'OCEAN_WV', '02/06/2023', 75.00);
INSERT INTO bookings VALUES (23, 'OCEAN_WV', '02/09/2023', 34.00);
INSERT INTO bookings VALUES (24, 'OCEAN_WV', '02/12/2023', 85.00);

INSERT INTO bookings VALUES (25, 'OCEAN_WV', '02/13/2023', 23.00);
INSERT INTO bookings VALUES (26, 'OCEAN_WV', '02/14/2023', 76.00);
INSERT INTO bookings VALUES (27, 'OCEAN_WV', '02/16/2023', 85.00);

INSERT INTO bookings VALUES (28, 'CITY_BLD', '02/01/2023', 98.00);
INSERT INTO bookings VALUES (29, 'CITY_BLD', '02/02/2023', 75.00);
INSERT INTO bookings VALUES (30, 'CITY_BLD', '02/04/2023', 85.00);

INSERT INTO bookings VALUES (31, 'CITY_BLD', '02/12/2023', 75.00);
INSERT INTO bookings VALUES (32, 'CITY_BLD', '02/13/2023', 34.00);
INSERT INTO bookings VALUES (33, 'CITY_BLD', '02/17/2023', 85.00);

INSERT INTO bookings VALUES (34, 'CITY_BLD', '02/22/2023', 23.00);
INSERT INTO bookings VALUES (35, 'CITY_BLD', '02/23/2023', 76.00);
INSERT INTO bookings VALUES (36, 'CITY_BLD', '02/24/2023', 85.00);
```

In this sample query, booking records are tallied to give a total for each week. The end date for each week becomes a column name.

```
SELECT * FROM
  (SELECT
    booking_id,
```

```

        (date_trunc('week', booking_date::date) + '5 days'::interval)::date as enddate,
        hotel_code AS "hotel code"
FROM bookings
) PIVOT (
    count(booking_id) FOR enddate IN ('2023-02-04', '2023-02-11', '2023-02-18')
);

```

The query results in the following output.

hotel code	2023-02-04	2023-02-11	2023-02-18
FOREST_L	3	2	1
DESERT_S	4	3	2
OCEAN_WV	3	3	3
CITY_BLD	3	1	2

Amazon Redshift doesn't support CROSSTAB to pivot on multiple columns. But you can change row data to columns, in a similar manner to an aggregation with PIVOT, with a query like the following. This uses the same booking sample data as the previous example.

```

SELECT
    booking_date,
    MAX(CASE WHEN hotel_code = 'FOREST_L' THEN 'forest is booked' ELSE '' END) AS
    FOREST_L,
    MAX(CASE WHEN hotel_code = 'DESERT_S' THEN 'desert is booked' ELSE '' END) AS
    DESERT_S,
    MAX(CASE WHEN hotel_code = 'OCEAN_WV' THEN 'ocean is booked' ELSE '' END) AS
    OCEAN_WV
FROM bookings
GROUP BY booking_date
ORDER BY booking_date asc;

```

The sample query results in booking dates listed next to short phrases that indicate which hotels are booked.

booking_date	forest_l	desert_s	ocean_wv
2023-02-01	forest is booked	desert is booked	ocean is booked
2023-02-02	forest is booked	desert is booked	ocean is booked
2023-02-04	forest is booked	desert is booked	ocean is booked
2023-02-05		desert is booked	

```
2023-02-06 | | desert is booked |
```

The following are usage notes for PIVOT:

- PIVOT can be applied to tables, sub-queries, and common table expressions (CTEs). PIVOT cannot be applied to any JOIN expressions, recursive CTEs, PIVOT, or UNPIVOT expressions. Also not supported are SUPER unnested expressions and Redshift Spectrum nested tables.
- PIVOT supports the COUNT, SUM, MIN, MAX, and AVG aggregate functions.
- The PIVOT aggregate expression has to be a call of a supported aggregate function. Complex expressions on top of the aggregate are not supported. The aggregate arguments cannot contain references to tables other than the PIVOT input table. Correlated references to a parent query are also not supported. The aggregate argument may contain sub-queries. These can be correlated internally or on the PIVOT input table.
- The PIVOT IN list values cannot be column references or sub-queries. Each value must be type compatible with the FOR column reference.
- If the IN list values do not have aliases, PIVOT generates default column names. For constant IN values such as 'abc' or 5 the default column name is the constant itself. For any complex expression, the column name is a standard Amazon Redshift default name such as ?column?.

UNPIVOT examples

Set up the sample data and use it to run the subsequent examples.

```
CREATE TABLE count_by_color (quality varchar, red int, green int, blue int);

INSERT INTO count_by_color VALUES ('high', 15, 20, 7);
INSERT INTO count_by_color VALUES ('normal', 35, NULL, 40);
INSERT INTO count_by_color VALUES ('low', 10, 23, NULL);
```

UNPIVOT on input columns red, green, and blue.

```
SELECT *
FROM (SELECT red, green, blue FROM count_by_color) UNPIVOT (
    cnt FOR color IN (red, green, blue)
);
```

The query results in the following output.

```

color | cnt
-----+-----
red   | 15
red   | 35
red   | 10
green | 20
green | 23
blue  | 7
blue  | 40

```

By default, NULL values in the input column are skipped and do not yield a result row.

The following example shows UNPIVOT with INCLUDE NULLS.

```

SELECT *
FROM (
    SELECT red, green, blue
    FROM count_by_color
) UNPIVOT INCLUDE NULLS (
    cnt FOR color IN (red, green, blue)
);

```

The following is the resulting output.

```

color | cnt
-----+-----
red   | 15
red   | 35
red   | 10
green | 20
green |
green | 23
blue  | 7
blue  | 40
blue  |

```

If the INCLUDING NULLS parameter is set, NULL input values generate result rows.

The following query shows UNPIVOT with quality as an implicit column.

```

SELECT *
FROM count_by_color UNPIVOT (

```

```
cnt FOR color IN (red, green, blue)
);
```

The query results in the following output.

quality	color	cnt
high	red	15
normal	red	35
low	red	10
high	green	20
low	green	23
high	blue	7
normal	blue	40

Columns of the input table that are not referenced in the UNPIVOT definition are added implicitly to the result table. In the example, this is the case for the quality column.

The following example shows UNPIVOT with aliases for values in the IN list.

```
SELECT *
FROM count_by_color UNPIVOT (
    cnt FOR color IN (red AS r, green AS g, blue AS b)
);
```

The previous query results in the following output.

quality	color	cnt
high	r	15
normal	r	35
low	r	10
high	g	20
low	g	23
high	b	7
normal	b	40

The UNPIVOT operator accepts optional aliases on each IN list value. Each alias provides customization of the data in each value column.

The following are usage notes for UNPIVOT.

- UNPIVOT can be applied to tables, sub-queries, and common table expressions (CTEs). UNPIVOT cannot be applied to any JOIN expressions, recursive CTEs, PIVOT, or UNPIVOT expressions. Also not supported are SUPER unnested expressions and Redshift Spectrum nested tables.
- The UNPIVOT IN list must contain only input table column references. The IN list columns must have a common type that they are all compatible with. The UNPIVOT value column has this common type. The UNPIVOT name column is of type VARCHAR.
- If an IN list value does not have an alias, UNPIVOT uses the column name as a default value.

JOIN examples

A SQL JOIN clause is used to combine the data from two or more tables based on common fields. The results might or might not change depending on the join method specified. For more information about the syntax of a JOIN clause, see [Parameters](#).

The following examples use data from the TICKIT sample data. For more information about the database schema, see [Sample database](#). To learn how to load sample data, see [Loading data](#) in the *Amazon Redshift Getting Started Guide*.

The following query is an inner join (without the JOIN keyword) between the LISTING table and SALES table, where the LISTID from the LISTING table is between 1 and 5. This query matches LISTID column values in the LISTING table (the left table) and SALES table (the right table). The results show that LISTID 1, 4, and 5 match the criteria.

```
select listing.listid, sum(pricepaid) as price, sum(commission) as comm
from listing, sales
where listing.listid = sales.listid
and listing.listid between 1 and 5
group by 1
order by 1;
```

listid	price	comm
1	728.00	109.20
4	76.00	11.40
5	525.00	78.75

The following query is a left outer join. Left and right outer joins retain values from one of the joined tables when no match is found in the other table. The left and right tables are the first and second tables listed in the syntax. NULL values are used to fill the "gaps" in the result set. This

query matches LISTID column values in the LISTING table (the left table) and the SALES table (the right table). The results show that LISTIDs 2 and 3 did not result in any sales.

```
select listing.listid, sum(pricepaid) as price, sum(commission) as comm
from listing left outer join sales on sales.listid = listing.listid
where listing.listid between 1 and 5
group by 1
order by 1;
```

listid	price	comm
1	728.00	109.20
2	NULL	NULL
3	NULL	NULL
4	76.00	11.40
5	525.00	78.75

The following query is a right outer join. This query matches LISTID column values in the LISTING table (the left table) and the SALES table (the right table). The results show that LISTIDs 1, 4, and 5 match the criteria.

```
select listing.listid, sum(pricepaid) as price, sum(commission) as comm
from listing right outer join sales on sales.listid = listing.listid
where listing.listid between 1 and 5
group by 1
order by 1;
```

listid	price	comm
1	728.00	109.20
4	76.00	11.40
5	525.00	78.75

The following query is a full join. Full joins retain values from the joined tables when no match is found in the other table. The left and right tables are the first and second tables listed in the syntax. NULL values are used to fill the "gaps" in the result set. This query matches LISTID column values in the LISTING table (the left table) and the SALES table (the right table). The results show that LISTIDs 2 and 3 did not result in any sales.

```
select listing.listid, sum(pricepaid) as price, sum(commission) as comm
from listing full join sales on sales.listid = listing.listid
```

```

where listing.listid between 1 and 5
group by 1
order by 1;

```

listid	price	comm
1	728.00	109.20
2	NULL	NULL
3	NULL	NULL
4	76.00	11.40
5	525.00	78.75

The following query is a full join. This query matches LISTID column values in the LISTING table (the left table) and the SALES table (the right table). Only rows that do not result in any sales (LISTIDs 2 and 3) are in the results.

```

select listing.listid, sum(pricepaid) as price, sum(commission) as comm
from listing full join sales on sales.listid = listing.listid
where listing.listid between 1 and 5
and (listing.listid IS NULL or sales.listid IS NULL)
group by 1
order by 1;

```

listid	price	comm
2	NULL	NULL
3	NULL	NULL

The following example is an inner join with the ON clause. In this case, NULL rows are not returned.

```

select listing.listid, sum(pricepaid) as price, sum(commission) as comm
from sales join listing
on sales.listid=listing.listid and sales.eventid=listing.eventid
where listing.listid between 1 and 5
group by 1
order by 1;

```

listid	price	comm
1	728.00	109.20
4	76.00	11.40
5	525.00	78.75

The following query is a cross join or Cartesian join of the LISTING table and the SALES table with a predicate to limit the results. This query matches LISTID column values in the SALES table and the LISTING table for LISTIDs 1, 2, 3, 4, and 5 in both tables. The results show that 20 rows match the criteria.

```
select sales.listid as sales_listid, listing.listid as listing_listid
from sales cross join listing
where sales.listid between 1 and 5
and listing.listid between 1 and 5
order by 1,2;
```

sales_listid	listing_listid
1	1
1	2
1	3
1	4
1	5
4	1
4	2
4	3
4	4
4	5
5	1
5	1
5	2
5	2
5	3
5	3
5	4
5	4
5	5
5	5

The following example is a natural join between two tables. In this case, the columns listid, sellerid, eventid, and dateid have identical names and data types in both tables and so are used as the join columns. The results are limited to five rows.

```
select listid, sellerid, eventid, dateid, numtickets
from listing natural join sales
order by 1
limit 5;
```

listid	sellerid	eventid	dateid	numtickets
113	29704	4699	2075	22
115	39115	3513	2062	14
116	43314	8675	1910	28
118	6079	1611	1862	9
163	24880	8253	1888	14

The following example is a join between two tables with the USING clause. In this case, the columns listid and eventid are used as the join columns. The results are limited to five rows.

```
select listid, listing.sellerid, eventid, listing.dateid, numtickets
from listing join sales
using (listid, eventid)
order by 1
limit 5;
```

listid	sellerid	eventid	dateid	numtickets
1	36861	7872	1850	10
4	8117	4337	1970	8
5	1616	8647	1963	4
5	1616	8647	1963	4
6	47402	8240	2053	18

The following query is an inner join of two subqueries in the FROM clause. The query finds the number of sold and unsold tickets for different categories of events (concerts and shows). The FROM clause subqueries are *table* subqueries; they can return multiple columns and rows.

```
select catgroup1, sold, unsold
from
(select catgroup, sum(qtysold) as sold
from category c, event e, sales s
where c.catid = e.catid and e.eventid = s.eventid
group by catgroup) as a(catgroup1, sold)
join
(select catgroup, sum(numtickets)-sum(qtysold) as unsold
from category c, event e, sales s, listing l
where c.catid = e.catid and e.eventid = s.eventid
and s.listid = l.listid
group by catgroup) as b(catgroup2, unsold)
```

```
on a.catgroup1 = b.catgroup2
order by 1;
```

```
catgroup1 | sold | unsold
-----+-----+-----
Concerts  | 195444 | 1067199
Shows     | 149905 | 817736
```

WHERE clause

The WHERE clause contains conditions that either join tables or apply predicates to columns in tables. Tables can be inner-joined by using appropriate syntax in either the WHERE clause or the FROM clause. Outer join criteria must be specified in the FROM clause.

Syntax

```
[ WHERE condition ]
```

condition

Any search condition with a Boolean result, such as a join condition or a predicate on a table column. The following examples are valid join conditions:

```
sales.listid=listing.listid
sales.listid<>listing.listid
```

The following examples are valid conditions on columns in tables:

```
catgroup like 'S%'
venue seats between 20000 and 50000
eventname in('Jersey Boys','Spamalot')
year=2008
length(catdesc)>25
date_part(month, caldate)=6
```

Conditions can be simple or complex; for complex conditions, you can use parentheses to isolate logical units. In the following example, the join condition is enclosed by parentheses.

```
where (category.catid=event.catid) and category.catid in(6,7,8)
```

Usage notes

You can use aliases in the WHERE clause to reference select list expressions.

You can't restrict the results of aggregate functions in the WHERE clause; use the HAVING clause for this purpose.

Columns that are restricted in the WHERE clause must derive from table references in the FROM clause.

Example

The following query uses a combination of different WHERE clause restrictions, including a join condition for the SALES and EVENT tables, a predicate on the EVENTNAME column, and two predicates on the STARTTIME column.

```
select eventname, starttime, pricepaid/qtysold as costperticket, qtysold
from sales, event
where sales.eventid = event.eventid
and eventname='Hannah Montana'
and date_part(quarter, starttime) in(1,2)
and date_part(year, starttime) = 2008
order by 3 desc, 4, 2, 1 limit 10;
```

eventname	starttime	costperticket	qtysold
Hannah Montana	2008-06-07 14:00:00	1706.00000000	2
Hannah Montana	2008-05-01 19:00:00	1658.00000000	2
Hannah Montana	2008-06-07 14:00:00	1479.00000000	1
Hannah Montana	2008-06-07 14:00:00	1479.00000000	3
Hannah Montana	2008-06-07 14:00:00	1163.00000000	1
Hannah Montana	2008-06-07 14:00:00	1163.00000000	2
Hannah Montana	2008-06-07 14:00:00	1163.00000000	4
Hannah Montana	2008-05-01 19:00:00	497.00000000	1
Hannah Montana	2008-05-01 19:00:00	497.00000000	2
Hannah Montana	2008-05-01 19:00:00	497.00000000	4

(10 rows)

Oracle-Style outer joins in the WHERE clause

For Oracle compatibility, Amazon Redshift supports the Oracle outer-join operator (+) in WHERE clause join conditions. This operator is intended for use only in defining outer-join conditions; don't try to use it in other contexts. Other uses of this operator are silently ignored in most cases.

An outer join returns all of the rows that the equivalent inner join would return, plus non-matching rows from one or both tables. In the FROM clause, you can specify left, right, and full outer joins. In the WHERE clause, you can specify left and right outer joins only.

To outer join tables TABLE1 and TABLE2 and return non-matching rows from TABLE1 (a left outer join), specify TABLE1 LEFT OUTER JOIN TABLE2 in the FROM clause or apply the (+) operator to all joining columns from TABLE2 in the WHERE clause. For all rows in TABLE1 that have no matching rows in TABLE2, the result of the query contains nulls for any select list expressions that contain columns from TABLE2.

To produce the same behavior for all rows in TABLE2 that have no matching rows in TABLE1, specify TABLE1 RIGHT OUTER JOIN TABLE2 in the FROM clause or apply the (+) operator to all joining columns from TABLE1 in the WHERE clause.

Basic syntax

```
[ WHERE {  
[ table1.column1 = table2.column1(+ ) ]  
[ table1.column1(+ ) = table2.column1 ]  
}
```

The first condition is equivalent to:

```
from table1 left outer join table2  
on table1.column1=table2.column1
```

The second condition is equivalent to:

```
from table1 right outer join table2  
on table1.column1=table2.column1
```

Note

The syntax shown here covers the simple case of an equijoin over one pair of joining columns. However, other types of comparison conditions and multiple pairs of joining columns are also valid.

For example, the following WHERE clause defines an outer join over two pairs of columns. The (+) operator must be attached to the same table in both conditions:

```
where table1.col1 > table2.col1(+)  
and table1.col2 = table2.col2(+)
```

Usage notes

Where possible, use the standard FROM clause OUTER JOIN syntax instead of the (+) operator in the WHERE clause. Queries that contain the (+) operator are subject to the following rules:

- You can only use the (+) operator in the WHERE clause, and only in reference to columns from tables or views.
- You can't apply the (+) operator to expressions. However, an expression can contain columns that use the (+) operator. For example, the following join condition returns a syntax error:

```
event.eventid*10(+)=category.catid
```

However, the following join condition is valid:

```
event.eventid(+)*10=category.catid
```

- You can't use the (+) operator in a query block that also contains FROM clause join syntax.
- If two tables are joined over multiple join conditions, you must use the (+) operator in all or none of these conditions. A join with mixed syntax styles runs as an inner join, without warning.
- The (+) operator doesn't produce an outer join if you join a table in the outer query with a table that results from an inner query.
- To use the (+) operator to outer-join a table to itself, you must define table aliases in the FROM clause and reference them in the join condition:

```
select count(*)  
from event a, event b  
where a.eventid(+)=b.catid;
```

```
count  
-----  
8798  
(1 row)
```

- You can't combine a join condition that contains the (+) operator with an OR condition or an IN condition. For example:

```
select count(*) from sales, listing
where sales.listid(+)=listing.listid or sales.salesid=0;
ERROR: Outer join operator (+) not allowed in operand of OR or IN.
```

- In a WHERE clause that outer-joins more than two tables, the (+) operator can be applied only once to a given table. In the following example, the SALES table can't be referenced with the (+) operator in two successive joins.

```
select count(*) from sales, listing, event
where sales.listid(+)=listing.listid and sales.dateid(+)=date.dateid;
ERROR: A table may be outer joined to at most one other table.
```

- If the WHERE clause outer-join condition compares a column from TABLE2 with a constant, apply the (+) operator to the column. If you don't include the operator, the outer-joined rows from TABLE1, which contain nulls for the restricted column, are eliminated. See the Examples section below.

Examples

The following join query specifies a left outer join of the SALES and LISTING tables over their LISTID columns:

```
select count(*)
from sales, listing
where sales.listid = listing.listid(+);

count
-----
172456
(1 row)
```

The following equivalent query produces the same result but uses FROM clause join syntax:

```
select count(*)
from sales left outer join listing on sales.listid = listing.listid;

count
-----
172456
(1 row)
```

The SALES table doesn't contain records for all listings in the LISTING table because not all listings result in sales. The following query outer-joins SALES and LISTING and returns rows from LISTING even when the SALES table reports no sales for a given list ID. The PRICE and COMM columns, derived from the SALES table, contain nulls in the result set for those non-matching rows.

```
select listing.listid, sum(pricepaid) as price,
sum(commission) as comm
from listing, sales
where sales.listid(+) = listing.listid and listing.listid between 1 and 5
group by 1 order by 1;
```

```
listid | price  | comm
-----+-----+-----
1 | 728.00 | 109.20
2 |        |
3 |        |
4 | 76.00  | 11.40
5 | 525.00 | 78.75
(5 rows)
```

Note that when the WHERE clause join operator is used, the order of the tables in the FROM clause doesn't matter.

An example of a more complex outer join condition in the WHERE clause is the case where the condition consists of a comparison between two table columns *and* a comparison with a constant:

```
where category.catid=event.catid(+) and eventid(+)=796;
```

Note that the (+) operator is used in two places: first in the equality comparison between the tables and second in the comparison condition for the EVENTID column. The result of this syntax is the preservation of the outer-joined rows when the restriction on EVENTID is evaluated. If you remove the (+) operator from the EVENTID restriction, the query treats this restriction as a filter, not as part of the outer-join condition. In turn, the outer-joined rows that contain nulls for EVENTID are eliminated from the result set.

Here is a complete query that illustrates this behavior:

```
select catname, catgroup, eventid
from category, event
where category.catid=event.catid(+) and eventid(+)=796;
```

```

catname | catgroup | eventid
-----+-----+-----
Classical | Concerts |
Jazz | Concerts |
MLB | Sports |
MLS | Sports |
Musicals | Shows | 796
NBA | Sports |
NFL | Sports |
NHL | Sports |
Opera | Shows |
Plays | Shows |
Pop | Concerts |
(11 rows)

```

The equivalent query using FROM clause syntax is as follows:

```

select catname, catgroup, eventid
from category left join event
on category.catid=event.catid and eventid=796;

```

If you remove the second (+) operator from the WHERE clause version of this query, it returns only 1 row (the row where eventid=796).

```

select catname, catgroup, eventid
from category, event
where category.catid=event.catid(+) and eventid=796;

catname | catgroup | eventid
-----+-----+-----
Musicals | Shows | 796
(1 row)

```

GROUP BY clause

The GROUP BY clause identifies the grouping columns for the query. Grouping columns must be declared when the query computes aggregates with standard functions such as SUM, AVG, and COUNT. For more information, see [Aggregate functions](#).

Syntax

```

GROUP BY group_by_clause [, ...]

```

```
group_by_clause := {
  expr |
  GROUPING SETS ( ( ) | group_by_clause [, ...] ) |
  ROLLUP ( expr [, ...] ) |
  CUBE ( expr [, ...] )
}
```

Parameters

expr

The list of columns or expressions must match the list of non-aggregate expressions in the select list of the query. For example, consider the following simple query.

```
select listid, eventid, sum(pricepaid) as revenue,
count(qtysold) as numtix
from sales
group by listid, eventid
order by 3, 4, 2, 1
limit 5;
```

listid	eventid	revenue	numtix
89397	47	20.00	1
106590	76	20.00	1
124683	393	20.00	1
103037	403	20.00	1
147685	429	20.00	1

(5 rows)

In this query, the select list consists of two aggregate expressions. The first uses the SUM function and the second uses the COUNT function. The remaining two columns, LISTID and EVENTID, must be declared as grouping columns.

Expressions in the GROUP BY clause can also reference the select list by using ordinal numbers. For example, the previous example could be abbreviated as follows.

```
select listid, eventid, sum(pricepaid) as revenue,
count(qtysold) as numtix
from sales
group by 1,2
```

```
order by 3, 4, 2, 1
limit 5;
```

listid	eventid	revenue	numtix
89397	47	20.00	1
106590	76	20.00	1
124683	393	20.00	1
103037	403	20.00	1
147685	429	20.00	1

(5 rows)

GROUPING SETS/ROLLUP/CUBE

You can use the aggregation extensions GROUPING SETS, ROLLUP, and CUBE to perform the work of multiple GROUP BY operations in a single statement. For more information on aggregation extensions and related functions, see [Aggregation extensions](#).

Aggregation extensions

Amazon Redshift supports aggregation extensions to do the work of multiple GROUP BY operations in a single statement.

The examples for aggregation extensions use the orders table, which holds sales data for an electronics company. You can create orders with the following.

```
CREATE TABLE ORDERS (
  ID INT,
  PRODUCT CHAR(20),
  CATEGORY CHAR(20),
  PRE_OWNED CHAR(1),
  COST DECIMAL
);

INSERT INTO ORDERS VALUES
(0, 'laptop',      'computers',    'T', 1000),
(1, 'smartphone', 'cellphones',   'T', 800),
(2, 'smartphone', 'cellphones',   'T', 810),
(3, 'laptop',     'computers',    'F', 1050),
(4, 'mouse',     'computers',    'F', 50);
```

GROUPING SETS

Computes one or more grouping sets in a single statement. A grouping set is the set of a single GROUP BY clause, a set of 0 or more columns by which you can group a query's result set. GROUP BY GROUPING SETS is equivalent to running a UNION ALL query on one result set grouped by different columns. For example, GROUP BY GROUPING SETS((a), (b)) is equivalent to GROUP BY a UNION ALL GROUP BY b.

The following example returns the cost of the order table's products grouped according to both the products' categories and the kind of products sold.

```
SELECT category, product, sum(cost) as total
FROM orders
GROUP BY GROUPING SETS(category, product);
```

category	product	total
computers		2100
cellphones		1610
	laptop	2050
	smartphone	1610
	mouse	50

(5 rows)

ROLLUP

Assumes a hierarchy where preceding columns are considered the parents of subsequent columns. ROLLUP groups data by the provided columns, returning extra subtotal rows representing the totals throughout all levels of grouping columns, in addition to the grouped rows. For example, you can use GROUP BY ROLLUP((a), (b)) to return a result set grouped first by a, then by b while assuming that b is a subsection of a. ROLLUP also returns a row with the whole result set without grouping columns.

GROUP BY ROLLUP((a), (b)) is equivalent to GROUP BY GROUPING SETS((a,b), (a), ()).

The following example returns the cost of the order table's products grouped first by category and then product, with product as a subdivision of category.

```
SELECT category, product, sum(cost) as total
```

```
FROM orders
GROUP BY ROLLUP(category, product) ORDER BY 1,2;
```

category	product	total
cellphones	smartphone	1610
cellphones		1610
computers	laptop	2050
computers	mouse	50
computers		2100
		3710

(6 rows)

CUBE

Groups data by the provided columns, returning extra subtotal rows representing the totals throughout all levels of grouping columns, in addition to the grouped rows. CUBE returns the same rows as ROLLUP, while adding additional subtotal rows for every combination of grouping column not covered by ROLLUP. For example, you can use `GROUP BY CUBE ((a), (b))` to return a result set grouped first by a, then by b while assuming that b is a subsection of a, then by b alone. CUBE also returns a row with the whole result set without grouping columns.

`GROUP BY CUBE((a), (b))` is equivalent to `GROUP BY GROUPING SETS((a, b), (a), (b), ())`.

The following example returns the cost of the order table's products grouped first by category and then product, with product as a subdivision of category. Unlike the preceding example for ROLLUP, the statement returns results for every combination of grouping column.

```
SELECT category, product, sum(cost) as total
FROM orders
GROUP BY CUBE(category, product) ORDER BY 1,2;
```

category	product	total
cellphones	smartphone	1610
cellphones		1610
computers	laptop	2050
computers	mouse	50
computers		2100
	laptop	2050
	mouse	50
	smartphone	1610

(9 rows)

3710

GROUPING/GROUPING_ID functions

ROLLUP and CUBE add NULL values to the result set to indicate subtotal rows. For example, GROUP BY ROLLUP((a), (b)) returns one or more rows that have a value of NULL in the b grouping column to indicate they are subtotals of fields in the a grouping column. These NULL values serve only to satisfy the format of returning tuples.

When you run GROUP BY operations with ROLLUP and CUBE on relations that store NULL values themselves, this can produce result sets with rows that appear to have identical grouping columns. Returning to the previous example, if the b grouping column contains a stored NULL value, GROUP BY ROLLUP((a), (b)) returns a row with a value of NULL in the b grouping column that isn't a subtotal.

To distinguish between NULL values created by ROLLUP and CUBE, and the NULL values stored in the tables themselves, you can use the GROUPING function, or its alias GROUPING_ID. GROUPING takes a single grouping set as its argument, and for each row in the result set returns a 0 or 1 bit value corresponding to the grouping column in that position, and then converts that value into an integer. If the value in that position is a NULL value created by an aggregation extension, GROUPING returns 1. It returns 0 for all other values, including stored NULL values.

For example, GROUPING(category, product) can return the following values for a given row, depending on the grouping column values for that row. For the purposes of this example, all NULL values in the table are NULL values created by an aggregation extension.

category column	product column	GROUPING function bit value	Decimal value
not NULL	not NULL	00	0
not NULL	NULL	01	1
NULL	not NULL	10	2
NULL	NULL	11	3

GROUPING functions appear in the SELECT list portion of the query in the following format.

```
SELECT ... [GROUPING( expr )...] ...
GROUP BY ... {CUBE | ROLLUP| GROUPING SETS} ( expr ) ...
```

The following example is the same as the preceding example for CUBE, but with the addition of GROUPING functions for its grouping sets.

```
SELECT category, product,
       GROUPING(category) as grouping0,
       GROUPING(product) as grouping1,
       GROUPING(category, product) as grouping2,
       sum(cost) as total
FROM orders
GROUP BY CUBE(category, product) ORDER BY 3,1,2;
```

category	product	grouping0	grouping1	grouping2	total
cellphones	smartphone	0	0	0	1610
cellphones		0	1	1	1610
computers	laptop	0	0	0	2050
computers	mouse	0	0	0	50
computers		0	1	1	2100
	laptop	1	0	2	2050
	mouse	1	0	2	50
	smartphone	1	0	2	1610
		1	1	3	3710

(9 rows)

Partial ROLLUP and CUBE

You can run ROLLUP and CUBE operations with only a portion of the subtotals.

The syntax for partial ROLLUP and CUBE operations is as follows.

```
GROUP BY expr1, { ROLLUP | CUBE }( expr2, [, ...] )
```

Here, the GROUP BY clause only creates subtotal rows at the level of *expr2* and onwards.

The following examples show partial ROLLUP and CUBE operations on the orders table, grouping first by whether a product is pre-owned and then running ROLLUP and CUBE on the category and product columns.

```
SELECT pre_owned, category, product,
       GROUPING(category, product, pre_owned) as group_id,
       sum(cost) as total
FROM orders
GROUP BY pre_owned, ROLLUP(category, product) ORDER BY 4,1,2,3;
```

pre_owned	category	product	group_id	total
F	computers	laptop	0	1050
F	computers	mouse	0	50
T	cellphones	smartphone	0	1610
T	computers	laptop	0	1000
F	computers		2	1100
T	cellphones		2	1610
T	computers		2	1000
F			6	1100
T			6	2610

(9 rows)

```
SELECT pre_owned, category, product,
       GROUPING(category, product, pre_owned) as group_id,
       sum(cost) as total
FROM orders
GROUP BY pre_owned, CUBE(category, product) ORDER BY 4,1,2,3;
```

pre_owned	category	product	group_id	total
F	computers	laptop	0	1050
F	computers	mouse	0	50
T	cellphones	smartphone	0	1610
T	computers	laptop	0	1000
F	computers		2	1100
T	cellphones		2	1610

T	computers		2	1000
F		laptop	4	1050
F		mouse	4	50
T		laptop	4	1000
T		smartphone	4	1610
F			6	1100
T			6	2610

(13 rows)

Since the pre-owned column isn't included in the ROLLUP and CUBE operations, there's no grand total row that includes all other rows.

Concatenated grouping

You can concatenate multiple GROUPING SETS/ROLLUP/CUBE clauses to calculate different levels of subtotals. Concatenated groupings return the Cartesian product of the provided grouping sets.

The syntax for concatenating GROUPING SETS/ROLLUP/CUBE clauses is as follows.

```
GROUP BY {ROLLUP|CUBE|GROUPING SETS}(expr1[, ...]),
        {ROLLUP|CUBE|GROUPING SETS}(expr1[, ...])[, ...]
```

Consider the following example to see how a small concatenated grouping can produce a large final result set.

```
SELECT pre_owned, category, product,
       GROUPING(category, product, pre_owned) as group_id,
       sum(cost) as total
FROM orders
GROUP BY CUBE(category, product), GROUPING SETS(pre_owned, ())
ORDER BY 4,1,2,3;
```

pre_owned	category	product	group_id	total
F	computers	laptop	0	1050
F	computers	mouse	0	50
T	cellphones	smartphone	0	1610
T	computers	laptop	0	1000
	cellphones	smartphone	1	1610
	computers	laptop	1	2050
	computers	mouse	1	50
F	computers		2	1100
T	cellphones		2	1610

T	computers		2	1000
	cellphones		3	1610
	computers		3	2100
F		laptop	4	1050
F		mouse	4	50
T		laptop	4	1000
T		smartphone	4	1610
		laptop	5	2050
		mouse	5	50
		smartphone	5	1610
F			6	1100
T			6	2610
			7	3710

(22 rows)

Nested grouping

You can use GROUPING SETS/ROLLUP/CUBE operations as your GROUPING SETS *expr* to form a nested grouping. The sub grouping inside nested GROUPING SETS is flattened.

The syntax for nested grouping is as follows.

```
GROUP BY GROUPING SETS({ROLLUP|CUBE|GROUPING SETS}(expr[, ...])[, ...])
```

Consider the following example.

```
SELECT category, product, pre_owned,
       GROUPING(category, product, pre_owned) as group_id,
       sum(cost) as total
FROM orders
GROUP BY GROUPING SETS(ROLLUP(category), CUBE(product, pre_owned))
ORDER BY 4,1,2,3;
```

category	product	pre_owned	group_id	total
cellphones			3	1610
computers			3	2100
	laptop	F	4	1050
	laptop	T	4	1000
	mouse	F	4	50
	smartphone	T	4	1610
	laptop		5	2050
	mouse		5	50

	smartphone		5	1610
		F	6	1100
		T	6	2610
			7	3710
			7	3710

(13 rows)

Note that because both `ROLLUP(category)` and `CUBE(product, pre_owned)` contain the grouping set `()`, the row representing the grand total is duplicated.

Usage notes

- The `GROUP BY` clause supports up to 64 grouping sets. In the case of `ROLLUP` and `CUBE`, or some combination of `GROUPING SETS`, `ROLLUP`, and `CUBE`, this limitation applies to the implied number of grouping sets. For example, `GROUP BY CUBE((a), (b))` counts as 4 grouping sets, not 2.
- You can't use constants as grouping columns when using aggregation extensions.
- You can't make a grouping set that contains duplicate columns.

HAVING clause

The `HAVING` clause applies a condition to the intermediate grouped result set that a query returns.

Syntax

```
[ HAVING condition ]
```

For example, you can restrict the results of a `SUM` function:

```
having sum(pricepaid) >10000
```

The `HAVING` condition is applied after all `WHERE` clause conditions are applied and `GROUP BY` operations are completed.

The condition itself takes the same form as any `WHERE` clause condition.

Usage notes

- Any column that is referenced in a `HAVING` clause condition must be either a grouping column or a column that refers to the result of an aggregate function.
- In a `HAVING` clause, you can't specify:

- An ordinal number that refers to a select list item. Only the GROUP BY and ORDER BY clauses accept ordinal numbers.

Examples

The following query calculates total ticket sales for all events by name, then eliminates events where the total sales were less than \$800,000. The HAVING condition is applied to the results of the aggregate function in the select list: `sum(pricepaid)`.

```
select eventname, sum(pricepaid)
from sales join event on sales.eventid = event.eventid
group by 1
having sum(pricepaid) > 800000
order by 2 desc, 1;
```

eventname	sum
Mamma Mia!	1135454.00
Spring Awakening	972855.00
The Country Girl	910563.00
Macbeth	862580.00
Jersey Boys	811877.00
Legally Blonde	804583.00

The following query calculates a similar result set. In this case, however, the HAVING condition is applied to an aggregate that isn't specified in the select list: `sum(qtysold)`. Events that did not sell more than 2,000 tickets are eliminated from the final result.

```
select eventname, sum(pricepaid)
from sales join event on sales.eventid = event.eventid
group by 1
having sum(qtysold) >2000
order by 2 desc, 1;
```

eventname	sum
Mamma Mia!	1135454.00
Spring Awakening	972855.00
The Country Girl	910563.00
Macbeth	862580.00
Jersey Boys	811877.00

Legally Blonde		804583.00
Chicago		790993.00
Spamalot		714307.00

The following query calculates total ticket sales for all events by name, then eliminates events where the total sales were less than \$800,000. The HAVING condition is applied to the results of the aggregate function in the select list using the alias pp for sum(pricepaid).

```
select eventname, sum(pricepaid) as pp
from sales join event on sales.eventid = event.eventid
group by 1
having pp > 800000
order by 2 desc, 1;
```

eventname		pp
-----+-----		
Mamma Mia!		1135454.00
Spring Awakening		972855.00
The Country Girl		910563.00
Macbeth		862580.00
Jersey Boys		811877.00
Legally Blonde		804583.00

QUALIFY clause

The QUALIFY clause filters results of a previously computed window function according to user-specified search conditions. You can use the clause to apply filtering conditions to the result of a window function without using a subquery.

It is similar to the [HAVING clause](#), which applies a condition to further filters rows from a WHERE clause. The difference between QUALIFY and HAVING is that filtered results from the QUALIFY clause could be based on the result of running window functions on the data. You can use both the QUALIFY and HAVING clauses in one query.

Syntax

```
QUALIFY condition
```

Note

If you're using the QUALIFY clause directly after the FROM clause, the FROM relation name must have an alias specified before the QUALIFY clause.

Examples

The examples in this section use the sample data below.

```
create table store_sales (ss_sold_date date, ss_sold_time time,
                        ss_item text, ss_sales_price float);
insert into store_sales values ('2022-01-01', '09:00:00', 'Product 1', 100.0),
                              ('2022-01-01', '11:00:00', 'Product 2', 500.0),
                              ('2022-01-01', '15:00:00', 'Product 3', 20.0),
                              ('2022-01-01', '17:00:00', 'Product 4', 1000.0),
                              ('2022-01-01', '18:00:00', 'Product 5', 30.0),
                              ('2022-01-02', '10:00:00', 'Product 6', 5000.0),
                              ('2022-01-02', '16:00:00', 'Product 7', 5.0);
```

The following example demonstrates how to find the two most expensive items sold after 12:00 each day.

```
SELECT *
FROM store_sales ss
WHERE ss_sold_time > time '12:00:00'
QUALIFY row_number()
OVER (PARTITION BY ss_sold_date ORDER BY ss_sales_price DESC) <= 2
```

ss_sold_date	ss_sold_time	ss_item	ss_sales_price
2022-01-01	17:00:00	Product 4	1000
2022-01-01	18:00:00	Product 5	30
2022-01-02	16:00:00	Product 7	5

You can then find the last item sold each day.

```
SELECT *
FROM store_sales ss
QUALIFY last_value(ss_item)
OVER (PARTITION BY ss_sold_date ORDER BY ss_sold_time ASC
```

```
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) = ss_item;
```

ss_sold_date	ss_sold_time	ss_item	ss_sales_price
2022-01-01	18:00:00	Product 5	30
2022-01-02	16:00:00	Product 7	5

The following example returns the same records as the previous query, the last item sold each day, but it doesn't use the QUALIFY clause.

```
SELECT * FROM (
  SELECT *,
  last_value(ss_item)
  OVER (PARTITION BY ss_sold_date ORDER BY ss_sold_time ASC
        ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) ss_last_item
  FROM store_sales ss
)
WHERE ss_last_item = ss_item;
```

ss_sold_date	ss_sold_time	ss_item	ss_sales_price	ss_last_item
2022-01-02	16:00:00	Product 7	5	Product 7
2022-01-01	18:00:00	Product 5	30	Product 5

UNION, INTERSECT, and EXCEPT

Topics

- [Syntax](#)
- [Parameters](#)
- [Order of evaluation for set operators](#)
- [Usage notes](#)
- [Example UNION queries](#)
- [Example UNION ALL query](#)
- [Example INTERSECT queries](#)
- [Example EXCEPT query](#)

The UNION, INTERSECT, and EXCEPT *set operators* are used to compare and merge the results of two separate query expressions. For example, if you want to know which users of a website are

both buyers and sellers but their user names are stored in separate columns or tables, you can find the *intersection* of these two types of users. If you want to know which website users are buyers but not sellers, you can use the EXCEPT operator to find the *difference* between the two lists of users. If you want to build a list of all users, regardless of role, you can use the UNION operator.

Syntax

```
query  
{ UNION [ ALL ] | INTERSECT | EXCEPT | MINUS }  
query
```

Parameters

query

A query expression that corresponds, in the form of its select list, to a second query expression that follows the UNION, INTERSECT, or EXCEPT operator. The two expressions must contain the same number of output columns with compatible data types; otherwise, the two result sets can't be compared and merged. Set operations don't allow implicit conversion between different categories of data types; for more information, see [Type compatibility and conversion](#).

You can build queries that contain an unlimited number of query expressions and link them with UNION, INTERSECT, and EXCEPT operators in any combination. For example, the following query structure is valid, assuming that the tables T1, T2, and T3 contain compatible sets of columns:

```
select * from t1  
union  
select * from t2  
except  
select * from t3  
order by c1;
```

UNION

Set operation that returns rows from two query expressions, regardless of whether the rows derive from one or both expressions.

INTERSECT

Set operation that returns rows that derive from two query expressions. Rows that aren't returned by both expressions are discarded.

EXCEPT | MINUS

Set operation that returns rows that derive from one of two query expressions. To qualify for the result, rows must exist in the first result table but not the second. MINUS and EXCEPT are exact synonyms.

ALL

The ALL keyword retains any duplicate rows that are produced by UNION. The default behavior when the ALL keyword isn't used is to discard these duplicates. INTERSECT ALL, EXCEPT ALL, and MINUS ALL aren't supported.

Order of evaluation for set operators

The UNION and EXCEPT set operators are left-associative. If parentheses aren't specified to influence the order of precedence, a combination of these set operators is evaluated from left to right. For example, in the following query, the UNION of T1 and T2 is evaluated first, then the EXCEPT operation is performed on the UNION result:

```
select * from t1
union
select * from t2
except
select * from t3
order by c1;
```

The INTERSECT operator takes precedence over the UNION and EXCEPT operators when a combination of operators is used in the same query. For example, the following query evaluates the intersection of T2 and T3, then union the result with T1:

```
select * from t1
union
select * from t2
intersect
select * from t3
order by c1;
```

By adding parentheses, you can enforce a different order of evaluation. In the following case, the result of the union of T1 and T2 is intersected with T3, and the query is likely to produce a different result.

```
(select * from t1
 union
 select * from t2)
 intersect
 (select * from t3)
 order by c1;
```

Usage notes

- The column names returned in the result of a set operation query are the column names (or aliases) from the tables in the first query expression. Because these column names are potentially misleading, in that the values in the column derive from tables on either side of the set operator, you might want to provide meaningful aliases for the result set.
- A query expression that precedes a set operator should not contain an ORDER BY clause. An ORDER BY clause produces meaningful sorted results only when it is used at the end of a query that contains set operators. In this case, the ORDER BY clause applies to the final results of all of the set operations. The outermost query can also contain standard LIMIT and OFFSET clauses.
- When set operator queries return decimal results, the corresponding result columns are promoted to return the same precision and scale. For example, in the following query, where T1.REVENUE is a DECIMAL(10,2) column and T2.REVENUE is a DECIMAL(8,4) column, the decimal result is promoted to DECIMAL(12,4):

```
select t1.revenue union select t2.revenue;
```

The scale is 4 because that is the maximum scale of the two columns. The precision is 12 because T1.REVENUE requires 8 digits to the left of the decimal point ($12 - 4 = 8$). This type promotion ensures that all values from both sides of the UNION fit in the result. For 64-bit values, the maximum result precision is 19 and the maximum result scale is 18. For 128-bit values, the maximum result precision is 38 and the maximum result scale is 37.

If the resulting data type exceeds Amazon Redshift precision and scale limits, the query returns an error.

- For set operations, two rows are treated as identical if, for each corresponding pair of columns, the two data values are either *equal* or *both NULL*. For example, if tables T1 and T2 both contain

one column and one row, and that row is NULL in both tables, an INTERSECT operation over those tables returns that row.

Example UNION queries

In the following UNION query, rows in the SALES table are merged with rows in the LISTING table. Three compatible columns are selected from each table; in this case, the corresponding columns have the same names and data types.

The final result set is ordered by the first column in the LISTING table and limited to the 5 rows with the highest LISTID value.

```
select listid, sellerid, eventid from listing
union select listid, sellerid, eventid from sales
order by listid, sellerid, eventid desc limit 5;
```

```
listid | sellerid | eventid
-----+-----+-----
 1 |    36861 |    7872
 2 |    16002 |    4806
 3 |    21461 |    4256
 4 |     8117 |    4337
 5 |     1616 |    8647
(5 rows)
```

The following example shows how you can add a literal value to the output of a UNION query so you can see which query expression produced each row in the result set. The query identifies rows from the first query expression as "B" (for buyers) and rows from the second query expression as "S" (for sellers).

The query identifies buyers and sellers for ticket transactions that cost \$10,000 or more. The only difference between the two query expressions on either side of the UNION operator is the joining column for the SALES table.

```
select listid, lastname, firstname, username,
pricepaid as price, 'S' as buyorsell
from sales, users
where sales.sellerid=users.userid
and pricepaid >=10000
union
select listid, lastname, firstname, username, pricepaid,
```

```
'B' as buyorsell
from sales, users
where sales.buyerid=users.userid
and pricepaid >=10000
order by 1, 2, 3, 4, 5;
```

listid	lastname	firstname	username	price	buyorsell
209658	Lamb	Colette	VOR15LYI	10000.00	B
209658	West	Kato	ELU81XAA	10000.00	S
212395	Greer	Harlan	GX071KOC	12624.00	S
212395	Perry	Cora	YWR73YNZ	12624.00	B
215156	Banks	Patrick	ZNQ69CLT	10000.00	S
215156	Hayden	Malachi	BBG56AKU	10000.00	B

(6 rows)

The following example uses a UNION ALL operator because duplicate rows, if found, need to be retained in the result. For a specific series of event IDs, the query returns 0 or more rows for each sale associated with each event, and 0 or 1 row for each listing of that event. Event IDs are unique to each row in the LISTING and EVENT tables, but there might be multiple sales for the same combination of event and listing IDs in the SALES table.

The third column in the result set identifies the source of the row. If it comes from the SALES table, it is marked "Yes" in the SALESROW column. (SALESROW is an alias for SALES.LISTID.) If the row comes from the LISTING table, it is marked "No" in the SALESROW column.

In this case, the result set consists of three sales rows for listing 500, event 7787. In other words, three different transactions took place for this listing and event combination. The other two listings, 501 and 502, did not produce any sales, so the only row that the query produces for these list IDs comes from the LISTING table (SALESROW = 'No').

```
select eventid, listid, 'Yes' as salesrow
from sales
where listid in(500,501,502)
union all
select eventid, listid, 'No'
from listing
where listid in(500,501,502)
order by listid asc;
```

eventid	listid	salesrow
---------	--------	----------

```

7787 |    500 | No
7787 |    500 | Yes
7787 |    500 | Yes
7787 |    500 | Yes
6473 |    501 | No
5108 |    502 | No
(6 rows)

```

If you run the same query without the ALL keyword, the result retains only one of the sales transactions.

```

select eventid, listid, 'Yes' as salesrow
from sales
where listid in(500,501,502)
union
select eventid, listid, 'No'
from listing
where listid in(500,501,502)
order by listid asc;

```

```

eventid | listid | salesrow
-----+-----+-----
7787 |    500 | No
7787 |    500 | Yes
6473 |    501 | No
5108 |    502 | No
(4 rows)

```

Example UNION ALL query

The following example uses a UNION ALL operator because duplicate rows, if found, need to be retained in the result. For a specific series of event IDs, the query returns 0 or more rows for each sale associated with each event, and 0 or 1 row for each listing of that event. Event IDs are unique to each row in the LISTING and EVENT tables, but there might be multiple sales for the same combination of event and listing IDs in the SALES table.

The third column in the result set identifies the source of the row. If it comes from the SALES table, it is marked "Yes" in the SALESROW column. (SALESROW is an alias for SALES.LISTID.) If the row comes from the LISTING table, it is marked "No" in the SALESROW column.

In this case, the result set consists of three sales rows for listing 500, event 7787. In other words, three different transactions took place for this listing and event combination. The other two

listings, 501 and 502, did not produce any sales, so the only row that the query produces for these list IDs comes from the LISTING table (SALESROW = 'No').

```
select eventid, listid, 'Yes' as salesrow
from sales
where listid in(500,501,502)
union all
select eventid, listid, 'No'
from listing
where listid in(500,501,502)
order by listid asc;
```

```
eventid | listid | salesrow
-----+-----+-----
7787 | 500 | No
7787 | 500 | Yes
7787 | 500 | Yes
7787 | 500 | Yes
6473 | 501 | No
5108 | 502 | No
(6 rows)
```

If you run the same query without the ALL keyword, the result retains only one of the sales transactions.

```
select eventid, listid, 'Yes' as salesrow
from sales
where listid in(500,501,502)
union
select eventid, listid, 'No'
from listing
where listid in(500,501,502)
order by listid asc;
```

```
eventid | listid | salesrow
-----+-----+-----
7787 | 500 | No
7787 | 500 | Yes
6473 | 501 | No
5108 | 502 | No
(4 rows)
```

Example INTERSECT queries

Compare the following example with the first UNION example. The only difference between the two examples is the set operator that is used, but the results are very different. Only one of the rows is the same:

```
235494 | 23875 | 8771
```

This is the only row in the limited result of 5 rows that was found in both tables.

```
select listid, sellerid, eventid from listing
intersect
select listid, sellerid, eventid from sales
order by listid desc, sellerid, eventid
limit 5;
```

```
listid | sellerid | eventid
-----+-----+-----
235494 | 23875 | 8771
235482 | 1067 | 2667
235479 | 1589 | 7303
235476 | 15550 | 793
235475 | 22306 | 7848
(5 rows)
```

The following query finds events (for which tickets were sold) that occurred at venues in both New York City and Los Angeles in March. The difference between the two query expressions is the constraint on the VENUECITY column.

```
select distinct eventname from event, sales, venue
where event.eventid=sales.eventid and event.venueid=venue.venueid
and date_part(month,starttime)=3 and venuecity='Los Angeles'
intersect
select distinct eventname from event, sales, venue
where event.eventid=sales.eventid and event.venueid=venue.venueid
and date_part(month,starttime)=3 and venuecity='New York City'
order by eventname asc;

eventname
-----
A Streetcar Named Desire
Dirty Dancing
```

```

Electra
Running with Annalise
Hairspray
Mary Poppins
November
Oliver!
Return To Forever
Rhinoceros
South Pacific
The 39 Steps
The Bacchae
The Caucasian Chalk Circle
The Country Girl
Wicked
Woyzeck
(16 rows)

```

Example EXCEPT query

The CATEGORY table in the TICKIT database contains the following 11 rows:

catid	catgroup	catname	catdesc
1	Sports	MLB	Major League Baseball
2	Sports	NHL	National Hockey League
3	Sports	NFL	National Football League
4	Sports	NBA	National Basketball Association
5	Sports	MLS	Major League Soccer
6	Shows	Musicals	Musical theatre
7	Shows	Plays	All non-musical theatre
8	Shows	Opera	All opera and light opera
9	Concerts	Pop	All rock and pop music concerts
10	Concerts	Jazz	All jazz singers and bands
11	Concerts	Classical	All symphony, concerto, and choir concerts

(11 rows)

Assume that a CATEGORY_STAGE table (a staging table) contains one additional row:

catid	catgroup	catname	catdesc
1	Sports	MLB	Major League Baseball
2	Sports	NHL	National Hockey League
3	Sports	NFL	National Football League

```

4 | Sports | NBA | National Basketball Association
5 | Sports | MLS | Major League Soccer
6 | Shows | Musicals | Musical theatre
7 | Shows | Plays | All non-musical theatre
8 | Shows | Opera | All opera and light opera
9 | Concerts | Pop | All rock and pop music concerts
10 | Concerts | Jazz | All jazz singers and bands
11 | Concerts | Classical | All symphony, concerto, and choir concerts
12 | Concerts | Comedy | All stand up comedy performances
(12 rows)

```

Return the difference between the two tables. In other words, return rows that are in the CATEGORY_STAGE table but not in the CATEGORY table:

```

select * from category_stage
except
select * from category;

catid | catgroup | catname | catdesc
-----+-----+-----+-----
12 | Concerts | Comedy | All stand up comedy performances
(1 row)

```

The following equivalent query uses the synonym MINUS.

```

select * from category_stage
minus
select * from category;

catid | catgroup | catname | catdesc
-----+-----+-----+-----
12 | Concerts | Comedy | All stand up comedy performances
(1 row)

```

If you reverse the order of the SELECT expressions, the query returns no rows.

ORDER BY clause

Topics

- [Syntax](#)
- [Parameters](#)

- [Usage notes](#)
- [Examples with ORDER BY](#)

The ORDER BY clause sorts the result set of a query.

Syntax

```
[ ORDER BY expression [ ASC | DESC ] ]  
[ NULLS FIRST | NULLS LAST ]  
[ LIMIT { count | ALL } ]  
[ OFFSET start ]
```

Parameters

expression

Expression that defines the sort order of the query result set, typically by specifying one or more columns in the select list. Results are returned based on binary UTF-8 ordering. You can also specify the following:

- Columns that aren't in the select list
- Expressions formed from one or more columns that exist in the tables referenced by the query
- Ordinal numbers that represent the position of select list entries (or the position of columns in the table if no select list exists)
- Aliases that define select list entries

When the ORDER BY clause contains multiple expressions, the result set is sorted according to the first expression, then the second expression is applied to rows that have matching values from the first expression, and so on.

ASC | DESC

Option that defines the sort order for the expression, as follows:

- ASC: ascending (for example, low to high for numeric values and 'A' to 'Z' for character strings). If no option is specified, data is sorted in ascending order by default.
- DESC: descending (high to low for numeric values; 'Z' to 'A' for strings).

NULLS FIRST | NULLS LAST

Option that specifies whether NULL values should be ordered first, before non-null values, or last, after non-null values. By default, NULL values are sorted and ranked last in ASC ordering, and sorted and ranked first in DESC ordering.

LIMIT *number* | ALL

Option that controls the number of sorted rows that the query returns. The LIMIT number must be a positive integer; the maximum value is 2147483647.

LIMIT 0 returns no rows. You can use this syntax for testing purposes: to check that a query runs (without displaying any rows) or to return a column list from a table. An ORDER BY clause is redundant if you are using LIMIT 0 to return a column list. The default is LIMIT ALL.

OFFSET *start*

Option that specifies to skip the number of rows before *start* before beginning to return rows. The OFFSET number must be a positive integer; the maximum value is 2147483647. When used with the LIMIT option, OFFSET rows are skipped before starting to count the LIMIT rows that are returned. If the LIMIT option isn't used, the number of rows in the result set is reduced by the number of rows that are skipped. The rows skipped by an OFFSET clause still have to be scanned, so it might be inefficient to use a large OFFSET value.

Usage notes

Note the following expected behavior with ORDER BY clauses:

- NULL values are considered "higher" than all other values. With the default ascending sort order, NULL values sort at the end. To change this behavior, use the NULLS FIRST option.
- When a query doesn't contain an ORDER BY clause, the system returns result sets with no predictable ordering of the rows. The same query run twice might return the result set in a different order.
- The LIMIT and OFFSET options can be used without an ORDER BY clause; however, to return a consistent set of rows, use these options in conjunction with ORDER BY.
- In any parallel system like Amazon Redshift, when ORDER BY doesn't produce a unique ordering, the order of the rows is nondeterministic. That is, if the ORDER BY expression produces duplicate values, the return order of those rows might vary from other systems or from one run of Amazon Redshift to the next.

- Amazon Redshift doesn't support string literals in ORDER BY clauses.

Examples with ORDER BY

Return all 11 rows from the CATEGORY table, ordered by the second column, CATGROUP. For results that have the same CATGROUP value, order the CATDESC column values by the length of the character string. Then order by columns CATID and CATNAME.

```
select * from category order by 2, length(catdesc), 1, 3;
```

catid	catgroup	catname	catdesc
10	Concerts	Jazz	All jazz singers and bands
9	Concerts	Pop	All rock and pop music concerts
11	Concerts	Classical	All symphony, concerto, and choir conce
6	Shows	Musicals	Musical theatre
7	Shows	Plays	All non-musical theatre
8	Shows	Opera	All opera and light opera
5	Sports	MLS	Major League Soccer
1	Sports	MLB	Major League Baseball
2	Sports	NHL	National Hockey League
3	Sports	NFL	National Football League
4	Sports	NBA	National Basketball Association

(11 rows)

Return selected columns from the SALES table, ordered by the highest QTYSOLD values. Limit the result to the top 10 rows:

```
select salesid, qtysold, pricepaid, commission, saletime from sales
order by qtysold, pricepaid, commission, salesid, saletime desc
limit 10;
```

salesid	qtysold	pricepaid	commission	saletime
15401	8	272.00	40.80	2008-03-18 06:54:56
61683	8	296.00	44.40	2008-11-26 04:00:23
90528	8	328.00	49.20	2008-06-11 02:38:09
74549	8	336.00	50.40	2008-01-19 12:01:21
130232	8	352.00	52.80	2008-05-02 05:52:31
55243	8	384.00	57.60	2008-07-12 02:19:53
16004	8	440.00	66.00	2008-11-04 07:22:31
489	8	496.00	74.40	2008-08-03 05:48:55

```
4197 |      8 |   512.00 |    76.80 | 2008-03-23 11:35:33
16929 |      8 |   568.00 |    85.20 | 2008-12-19 02:59:33
(10 rows)
```

Return a column list and no rows by using LIMIT 0 syntax:

```
select * from venue limit 0;
venueid | venuename | venuecity | venuestate | venueseats
-----+-----+-----+-----+-----
(0 rows)
```

CONNECT BY clause

The CONNECT BY clause specifies the relationship between rows in a hierarchy. You can use CONNECT BY to select rows in a hierarchical order by joining the table to itself and processing the hierarchical data. For example, you can use it to recursively loop through an organization chart and list data.

Hierarchical queries process in the following order:

1. If the FROM clause has a join, it is processed first.
2. The CONNECT BY clause is evaluated.
3. The WHERE clause is evaluated.

Syntax

```
[START WITH start_with_conditions]
CONNECT BY connect_by_conditions
```

Note

While START and CONNECT are not reserved words, use delimited identifiers (double quotation marks) or AS if you're using START and CONNECT as table aliases in your query to avoid failure at runtime.

```
SELECT COUNT(*)
FROM Employee "start"
CONNECT BY PRIOR id = manager_id
```

```
START WITH name = 'John'
```

```
SELECT COUNT(*)  
FROM Employee AS start  
CONNECT BY PRIOR id = manager_id  
START WITH name = 'John'
```

Parameters

start_with_conditions

Conditions that specify the root row(s) of the hierarchy

connect_by_conditions

Conditions that specify the relationship between parent rows and child rows of the hierarchy. At least one condition must be qualified with the unary operator used to refer to the parent row.

```
PRIOR column = expression  
-- or  
expression > PRIOR column
```

Operators

You can use the following operators in a CONNECT BY query.

LEVEL

Pseudocolumn that returns the current row level in the hierarchy. Returns 1 for the root row, 2 for the child of the root row, and so on.

PRIOR

Unary operator that evaluates the expression for the parent row of the current row in the hierarchy.

Examples

The following example is a CONNECT BY query that returns the number of employees that report directly or indirectly to John, no deeper than 4 levels.

```
SELECT id, name, manager_id
```

```
FROM employee
WHERE LEVEL < 4
START WITH name = 'John'
CONNECT BY PRIOR id = manager_id;
```

Following is the result of the query.

id	name	manager_id
101	John	100
102	Jorge	101
103	Kwaku	101
110	Liu	101
201	Sofía	102
106	Mateo	102
110	Nikki	103
104	Paulo	103
105	Richard	103
120	Saanvi	104
200	Shirley	104
205	Zhang	104

Table definition for this example:

```
CREATE TABLE employee (
  id INT,
  name VARCHAR(20),
  manager_id INT
);
```

Following are the rows inserted into the table.

```
INSERT INTO employee(id, name, manager_id) VALUES
(100, 'Carlos', null),
(101, 'John', 100),
(102, 'Jorge', 101),
(103, 'Kwaku', 101),
(110, 'Liu', 101),
(106, 'Mateo', 102),
(110, 'Nikki', 103),
(104, 'Paulo', 103),
(105, 'Richard', 103),
```

```
(120, 'Saanvi', 104),
(200, 'Shirley', 104),
(201, 'Sofia', 102),
(205, 'Zhang', 104);
```

Following is an organization chart for John's department.

Subquery examples

The following examples show different ways in which subqueries fit into SELECT queries. See [JOIN examples](#) for another example of the use of subqueries.

SELECT list subquery

The following example contains a subquery in the SELECT list. This subquery is *scalar*: it returns only one column and one value, which is repeated in the result for each row that is returned from the outer query. The query compares the Q1SALES value that the subquery computes with sales values for two other quarters (2 and 3) in 2008, as defined by the outer query.

```
select qtr, sum(pricepaid) as qtrsales,
(select sum(pricepaid)
```

```

from sales join date on sales.dateid=date.dateid
where qtr='1' and year=2008) as q1sales
from sales join date on sales.dateid=date.dateid
where qtr in('2','3') and year=2008
group by qtr
order by qtr;

```

```

qtr | qtrsales | q1sales
-----+-----+-----
2   | 30560050.00 | 24742065.00
3   | 31170237.00 | 24742065.00
(2 rows)

```

WHERE clause subquery

The following example contains a table subquery in the WHERE clause. This subquery produces multiple rows. In this case, the rows contain only one column, but table subqueries can contain multiple columns and rows, just like any other table.

The query finds the top 10 sellers in terms of maximum tickets sold. The top 10 list is restricted by the subquery, which removes users who live in cities where there are ticket venues. This query can be written in different ways; for example, the subquery could be rewritten as a join within the main query.

```

select firstname, lastname, city, max(qtysold) as maxsold
from users join sales on users.userid=sales.sellerid
where users.city not in(select venuecity from venue)
group by firstname, lastname, city
order by maxsold desc, city desc
limit 10;

```

```

firstname | lastname | city | maxsold
-----+-----+-----+-----
Noah      | Guerrero | Worcester | 8
Isadora   | Moss     | Winooski | 8
Kieran    | Harrison | Westminster | 8
Heidi     | Davis    | Warwick   | 8
Sara      | Anthony  | Waco      | 8
Bree      | Buck     | Valdez    | 8
Evangeline | Sampson  | Trenton   | 8
Kendall   | Keith    | Stillwater | 8
Bertha    | Bishop   | Stevens Point | 8
Patricia  | Anderson | South Portland | 8

```

`(10 rows)`

WITH clause subqueries

See [WITH clause](#).

Correlated subqueries

The following example contains a *correlated subquery* in the WHERE clause; this kind of subquery contains one or more correlations between its columns and the columns produced by the outer query. In this case, the correlation is where `s.listid=l.listid`. For each row that the outer query produces, the subquery is run to qualify or disqualify the row.

```
select salesid, listid, sum(pricepaid) from sales s
where qtysold=
(select max(numtickets) from listing l
where s.listid=l.listid)
group by 1,2
order by 1,2
limit 5;
```

salesid	listid	sum
27	28	111.00
81	103	181.00
142	149	240.00
146	152	231.00
194	210	144.00

`(5 rows)`

Correlated subquery patterns that are not supported

The query planner uses a query rewrite method called subquery decorrelation to optimize several patterns of correlated subqueries for execution in an MPP environment. A few types of correlated subqueries follow patterns that Amazon Redshift can't decorrelate and doesn't support. Queries that contain the following correlation references return errors:

- Correlation references that skip a query block, also known as "skip-level correlation references." For example, in the following query, the block containing the correlation reference and the skipped block are connected by a NOT EXISTS predicate:

```
select event.eventname from event
```

```
where not exists
(select * from listing
where not exists
(select * from sales where event.eventid=sales.eventid));
```

The skipped block in this case is the subquery against the LISTING table. The correlation reference correlates the EVENT and SALES tables.

- Correlation references from a subquery that is part of an ON clause in an outer query:

```
select * from category
left join event
on category.catid=event.catid and eventid =
(select max(eventid) from sales where sales.eventid=event.eventid);
```

The ON clause contains a correlation reference from SALES in the subquery to EVENT in the outer query.

- Null-sensitive correlation references to an Amazon Redshift system table. For example:

```
select attrelid
from stv_locks sl, pg_attribute
where sl.table_id=pg_attribute.attrelid and 1 not in
(select 1 from pg_opclass where sl.lock_owner = opowner);
```

- Correlation references from within a subquery that contains a window function.

```
select listid, qtysold
from sales s
where qtysold not in
(select sum(numtickets) over() from listing l where s.listid=l.listid);
```

- References in a GROUP BY column to the results of a correlated subquery. For example:

```
select listing.listid,
(select count (sales.listid) from sales where sales.listid=listing.listid) as list
from listing
group by list, listing.listid;
```

- Correlation references from a subquery with an aggregate function and a GROUP BY clause, connected to the outer query by an IN predicate. (This restriction doesn't apply to MIN and MAX aggregate functions.) For example:

```
select * from listing where listid in
(select sum(qtysold)
from sales
where numtickets>4
group by salesid);
```

SELECT INTO

Selects rows defined by any query and inserts them into a new table. You can specify whether to create a temporary or a persistent table.

Syntax

```
[ WITH with_subquery [, ...] ]
SELECT
[ TOP number ] [ ALL | DISTINCT ]
* | expression [ AS output_name ] [, ...]
INTO [ TEMPORARY | TEMP ] [ TABLE ] new_table
[ FROM table_reference [, ...] ]
[ WHERE condition ]
[ GROUP BY expression [, ...] ]
[ HAVING condition [, ...] ]
[ { UNION | INTERSECT | { EXCEPT | MINUS } } [ ALL ] query ]
[ ORDER BY expression
[ ASC | DESC ]
[ LIMIT { number | ALL } ]
[ OFFSET start ]
```

For details about the parameters of this command, see [SELECT](#).

Examples

Select all of the rows from the EVENT table and create a NEWEVENT table:

```
select * into newevent from event;
```

Select the result of an aggregate query into a temporary table called PROFITS:

```
select username, lastname, sum(pricepaid-commission) as profit
into temp table profits
```

```
from sales, users
where sales.sellerid=users.userid
group by 1, 2
order by 3 desc;
```

SET

Sets the value of a server configuration parameter. Use the SET command to override a setting for the duration of the current session or transaction only.

Use the [RESET](#) command to return a parameter to its default value.

You can change the server configuration parameters in several ways. For more information, see [Modifying the server configuration](#).

Syntax

```
SET { [ SESSION | LOCAL ]
{ SEED | parameter_name } { TO | = }
{ value | 'value' | DEFAULT } |
SEED TO value }
```

The following statement sets the value of a session context variable.

```
SET { [ SESSION | LOCAL ]
variable_name { TO | = }
{ value | 'value' }
```

Parameters

SESSION

Specifies that the setting is valid for the current session. Default value.

variable_name

Specifies the name of the context variable set for the session.

The naming convention is a two-part name separated by a dot, for example *identifier.identifier*. Only one dot separator is allowed. Use an *identifier* that follows the standard identifier rules for Amazon Redshift. For more information, see [Names and identifiers](#). Delimited identifiers aren't allowed.

LOCAL

Specifies that the setting is valid for the current transaction.

SEED TO *value*

Sets an internal seed to be used by the RANDOM function for random number generation.

SET SEED takes a numeric *value* between 0 and 1, and multiplies this number by $(2^{31} - 1)$ for use with the [RANDOM function](#) function. If you use SET SEED before making multiple RANDOM calls, RANDOM generates numbers in a predictable sequence.

parameter_name

Name of the parameter to set. See [Modifying the server configuration](#) for information about parameters.

value

New parameter value. Use single quotation marks to set the value to a specific string. If using SET SEED, this parameter contains the SEED value.

DEFAULT

Sets the parameter to the default value.

Examples

Changing a parameter for the current session

The following example sets the datestyle:

```
set datestyle to 'SQL,DMY';
```

Setting a query group for workload management

If query groups are listed in a queue definition as part of the cluster's WLM configuration, you can set the QUERY_GROUP parameter to a listed query group name. Subsequent queries are assigned to the associated query queue. The QUERY_GROUP setting remains in effect for the duration of the session or until a RESET QUERY_GROUP command is encountered.

This example runs two queries as part of the query group 'priority', then resets the query group.

```
set query_group to 'priority';
```

```
select tbl, count(*)from stv_blocklist;
select query, elapsed, substring from svl_qlog order by query desc limit 5;
reset query_group;
```

For more information, see [Workload management](#).

Change the default identity namespace for the session

A database user can set `default_identity_namespace`. This sample shows how to use `SET SESSION` to override the setting for the duration of the current session and then show the new identity provider value. This is used most commonly when you are using an identity provider with Redshift and IAM Identity Center. For more information about using an identity provider with Redshift, see [Connect Redshift with IAM Identity Center to give users a single sign-on experience](#).

```
SET SESSION default_identity_namespace = 'MYCO';

SHOW default_identity_namespace;
```

After running the command, you can run a `GRANT` statement or a `CREATE` statement like the following:

```
GRANT SELECT ON TABLE mytable TO alice;

GRANT UPDATE ON TABLE mytable TO salesrole;

CREATE USER bob password 'md50c983d1a624280812631c5389e60d48c';
```

In this instance, the effect of setting the default identity namespace is equivalent to prefixing each identity with the namespace. In this example, `alice` is replaced with `MYCO:alice`. For more information about settings that pertain to Redshift configuration with IAM Identity Center, see [ALTER SYSTEM](#) and [ALTER IDENTITY PROVIDER](#).

Setting a label for a group of queries

The `QUERY_GROUP` parameter defines a label for one or more queries that are run in the same session after a `SET` command. In turn, this label is logged when queries are run and can be used to constrain results returned from the `STL_QUERY` and `STV_INFLIGHT` system tables and the `SVL_QLOG` view.

```
show query_group;
```

```

query_group
-----
unset
(1 row)

set query_group to '6 p.m.';

show query_group;
query_group
-----
6 p.m.
(1 row)

select * from sales where salesid=500;
salesid | listid | sellerid | buyerid | eventid | dateid | ...
-----+-----+-----+-----+-----+-----+-----
500 | 504 | 3858 | 2123 | 5871 | 2052 | ...
(1 row)

reset query_group;

select query, trim(label) querygroup, pid, trim(querytxt) sql
from stl_query
where label = '6 p.m.';
query | querygroup | pid | sql
-----+-----+-----+-----
57 | 6 p.m. | 30711 | select * from sales where salesid=500;
(1 row)

```

Query group labels are a useful mechanism for isolating individual queries or groups of queries that are run as part of scripts. You don't need to identify and track queries by their IDs; you can track them by their labels.

Setting a seed value for random number generation

The following example uses the SEED option with SET to cause the RANDOM function to generate numbers in a predictable sequence.

First, return three RANDOM integers without setting the SEED value first:

```

select cast (random() * 100 as int);
int4

```

```
-----  
6  
(1 row)  
  
select cast (random() * 100 as int);  
int4  
-----  
68  
(1 row)  
  
select cast (random() * 100 as int);  
int4  
-----  
56  
(1 row)
```

Now, set the SEED value to .25, and return three more RANDOM numbers:

```
set seed to .25;  
  
select cast (random() * 100 as int);  
int4  
-----  
21  
(1 row)  
  
select cast (random() * 100 as int);  
int4  
-----  
79  
(1 row)  
  
select cast (random() * 100 as int);  
int4  
-----  
12  
(1 row)
```

Finally, reset the SEED value to .25, and verify that RANDOM returns the same results as the previous three calls:

```
set seed to .25;
```

```
select cast (random() * 100 as int);
int4
-----
21
(1 row)

select cast (random() * 100 as int);
int4
-----
79
(1 row)

select cast (random() * 100 as int);
int4
-----
12
(1 row)
```

The following example sets a customized context variable.

```
SET app_context.user_id TO 123;
SET app_context.user_id TO 'sample_variable_value';
```

SET SESSION AUTHORIZATION

Sets the user name for the current session.

You can use the SET SESSION AUTHORIZATION command, for example, to test database access by temporarily running a session or transaction as an unprivileged user. You must be a database superuser to run this command.

Syntax

```
SET [ LOCAL ] SESSION AUTHORIZATION { user_name | DEFAULT }
```

Parameters

LOCAL

Specifies that the setting is valid for the current transaction. Omitting this parameter specifies that the setting is valid for the current session.

user_name

Name of the user to set. The user name may be written as an identifier or a string literal.

DEFAULT

Sets the session user name to the default value.

Examples

The following example sets the user name for the current session to `dwuser`:

```
SET SESSION AUTHORIZATION 'dwuser';
```

The following example sets the user name for the current transaction to `dwuser`:

```
SET LOCAL SESSION AUTHORIZATION 'dwuser';
```

This example sets the user name for the current session to the default user name:

```
SET SESSION AUTHORIZATION DEFAULT;
```

SET SESSION CHARACTERISTICS

This command is deprecated.

SHOW

Displays the current value of a server configuration parameter. This value may be specific to the current session if a SET command is in effect. For a list of configuration parameters, see [Configuration reference](#).

Syntax

```
SHOW { parameter_name | ALL }
```

The following statement displays the current value of a session context variable. If the variable doesn't exist, Amazon Redshift throws an error.

```
SHOW variable_name
```

Parameters

parameter_name

Displays the current value of the specified parameter.

ALL

Displays the current values of all of the parameters.

variable_name

Displays the current value of the specified variable.

Examples

The following example displays the value for the `query_group` parameter:

```
show query_group;

query_group

unset
(1 row)
```

The following example displays a list of all parameters and their values:

```
show all;
name          | setting
-----+-----
datestyle     | ISO, MDY
extra_float_digits | 0
query_group   | unset
search_path   | $user,public
statement_timeout | 0
```

The following example displays the current value of the specified variable.

```
SHOW app_context.user_id;
```

SHOW COLUMNS

Shows a list of columns in a table, along with some column attributes.

Each output row consists of a comma-separated list of database name, schema name, table name, column name, ordinal position, column default, is nullable, data type, character maximum length, numeric precision, and remarks. For more information about these attributes, see [SVV_ALL_COLUMNS](#).

If more than 10,000 columns would result from the SHOW COLUMNS command, then an error is returned.

Syntax

```
SHOW COLUMNS FROM TABLE database_name.schema_name.table_name [LIKE 'filter_pattern']  
[LIMIT row_limit ]
```

Parameters

database_name

The name of the database that contains the tables to list.

To show tables in an AWS Glue Data Catalog, specify (awsdatacatalog) as the database name, and ensure the system configuration `data_catalog_auto_mount` is set to `true`. For more information, see [ALTER SYSTEM](#).

schema_name

The name of the schema that contains the tables to list.

To show AWS Glue Data Catalog tables, provide the AWS Glue database name as the schema name.

table_name

The name of the table that contains the columns to list.

filter_pattern

A valid UTF-8 character expression with a pattern to match table names. The LIKE option performs a case-sensitive match that supports the following pattern-matching metacharacters:

Metacharacter	Description
%	Matches any sequence of zero or more characters.
_	Matches any single character.

If *filter_pattern* does not contain metacharacters, then the pattern only represents the string itself; in that case LIKE acts the same as the equals operator.

row_limit

The maximum number of rows to return. The *row_limit* can be 0–10,000.

Examples

Following example shows the columns in the Amazon Redshift database named `dev` that are in schema `public` and table `tb`.

```
SHOW COLUMNS FROM TABLE dev.public.tb;
```

```

database_name | schema_name | table_name | column_name | ordinal_position
| column_default | is_nullable | data_type | character_maximum_length |
numeric_precision | remarks
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----
dev          | public      | tb         | col         | 1 |
| YES        | integer    |             |    | 32 |

```

Following example shows the tables in the AWS Glue Data Catalog database named `awsdatacatalog` that are in schema `batman` and table `nation`. Output is limited to 2 rows.

```
SHOW COLUMNS FROM TABLE awsdatacatalog.batman.nation LIMIT 2;
```

```

database_name | schema_name | table_name | column_name | ordinal_position
| column_default | is_nullable | data_type | character_maximum_length |
numeric_precision | remarks
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----

```

```

awsdatacatalog | batman      | nation      | n_nationkey |          | 1 |
|              | integer    |             |             |          |   |
awsdatacatalog | batman      | nation      | n_name       |          | 2 |
|              | character  |             |             |          |   |

```

SHOW EXTERNAL TABLE

Shows the definition of an external table, including table attributes and column attributes. You can use the output of the SHOW EXTERNAL TABLE statement to recreate the table.

For more information about external table creation, see [CREATE EXTERNAL TABLE](#).

Syntax

```
SHOW EXTERNAL TABLE [external_database].external_schema.table_name [ PARTITION ]
```

Parameters

external_database

The name of the associated external database. This parameter is optional.

external_schema

The name of the associated external schema.

table_name

The name of the table to show.

PARTITION

Displays ALTER TABLE statements to add partitions to the table definition.

Examples

The following examples are based on an external table defined as follows:

```

CREATE EXTERNAL TABLE my_schema.alldatatypes_parquet_test_partitioned (
  csmallint smallint,
  cint int,
  cbigint bigint,

```

```

cfloat float4,
cdouble float8,
cchar char(10),
cvarchar varchar(255),
cdecimal_small decimal(18,9),
cdecimal_big decimal(30,15),
ctimestamp TIMESTAMP,
cboolean boolean,
cstring varchar(16383)
)
PARTITIONED BY (cdate date, ctime TIMESTAMP)
STORED AS PARQUET
LOCATION 's3://amzn-s3-demo-bucket/alldatatypes_parquet_partitioned';

```

Following is an example of the SHOW EXTERNAL TABLE command and output for the table `my_schema.alldatatypes_parquet_test_partitioned`.

```
SHOW EXTERNAL TABLE my_schema.alldatatypes_parquet_test_partitioned;
```

```

"CREATE EXTERNAL TABLE my_schema.alldatatypes_parquet_test_partitioned (
  csmallint smallint,
  cint int,
  cbigint bigint,
  cfloat float4,
  cdouble float8,
  cchar char(10),
  cvarchar varchar(255),
  cdecimal_small decimal(18,9),
  cdecimal_big decimal(30,15),
  ctimestamp timestamp,
  cboolean boolean,
  cstring varchar(16383)
)
PARTITIONED BY (cdate date, ctime timestamp)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.parquet.MapredParquetInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.parquet.MapredParquetOutputFormat'
LOCATION 's3://amzn-s3-demo-bucket/alldatatypes_parquet_partitioned';"

```

Following is an example of the SHOW EXTERNAL TABLE command and output for the same table, but with the database also specified in the parameter.

```
SHOW EXTERNAL TABLE my_database.my_schema.alldatatypes_parquet_test_partitioned;
```

```
"CREATE EXTERNAL TABLE my_database.my_schema.alldatatypes_parquet_test_partitioned (
  csmallint smallint,
  cint int,
  cbigint bigint,
  cfloat float4,
  cdouble float8,
  cchar char(10),
  cvarchar varchar(255),
  cdecimal_small decimal(18,9),
  cdecimal_big decimal(30,15),
  ctimestamp timestamp,
  cboolean boolean,
  cstring varchar(16383)
)
PARTITIONED BY (cdate date, ctime timestamp)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.parquet.MapredParquetInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.parquet.MapredParquetOutputFormat'
LOCATION 's3://amzn-s3-demo-bucket/alldatatypes_parquet_test_partitioned';"
```

Following is an example of the SHOW EXTERNAL TABLE command and output when using the PARTITION parameter. The output contains ALTER TABLE statements to add partitions to the table definition.

```
SHOW EXTERNAL TABLE my_schema.alldatatypes_parquet_test_partitioned PARTITION;
```

```
"CREATE EXTERNAL TABLE my_schema.alldatatypes_parquet_test_partitioned (
  csmallint smallint,
  cint int,
  cbigint bigint,
  cfloat float4,
  cdouble float8,
  cchar char(10),
  cvarchar varchar(255),
  cdecimal_small decimal(18,9),
  cdecimal_big decimal(30,15),
  ctimestamp timestamp,
  cboolean boolean,
  cstring varchar(16383)
```

```

)
PARTITIONED BY (cdate date)
ROW FORMAT SERDE 'org.apache.hadoop.hive.q1.io.parquet.serde.ParquetHiveSerDe'
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.q1.io.parquet.MapredParquetInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive.q1.io.parquet.MapredParquetOutputFormat'
LOCATION 's3://amzn-s3-demo-bucket/alldatatypes_parquet_partitioned';
ALTER TABLE my_schema.alldatatypes_parquet_test_partitioned ADD IF NOT
  EXISTS PARTITION (cdate='2021-01-01') LOCATION 's3://amzn-s3-demo-bucket/

ALTER TABLE my_schema.alldatatypes_parquet_test_partitioned ADD IF NOT
  EXISTS PARTITION (cdate='2021-01-02') LOCATION 's3://amzn-s3-demo-bucket/
alldatatypes_parquet_partitioned2/cdate=2021-01-02';"

```

SHOW DATABASES

Displays databases from a specified account ID.

Syntax

```

SHOW DATABASES FROM
DATA CATALOG [ ACCOUNT '<id1>', '<id2>', ... ]
[ LIKE '<expression>' ]
[ IAM_ROLE default | 'SESSION' | 'arn:aws:iam::<account-id>:role/<role-name>' ]

```

Parameters

ACCOUNT '<id1>', '<id2>', ...

The AWS Glue Data Catalog accounts from which to list databases. Omitting this parameter indicates that Amazon Redshift should show the databases from the account that owns the cluster.

LIKE '<expression>'

Filters the list of databases to those that match the expression that you specify. This parameter supports patterns that use the wildcard characters % (percent) and _ (underscore).

IAM_ROLE default | 'SESSION' | 'arn:aws:iam::<account-id>:role/<role-name>'

If you specify an IAM role that is associated with the cluster when running the SHOW DATABASES command, Amazon Redshift will use the role's credentials when you run queries on the database.

Specifying the default keyword means to use the IAM role that's set as the default and associated with the cluster.

Use 'SESSION' if you connect to your Amazon Redshift cluster using a federated identity and access the tables from the external database created using the [the section called "CREATE DATABASE"](#) command. For an example of using a federated identity, see [Using a federated identity to manage Amazon Redshift access to local resources and Amazon Redshift Spectrum external tables](#), which explains how to configure federated identity.

Use the Amazon Resource Name (ARN) for an IAM role that your cluster uses for authentication and authorization. As a minimum, the IAM role must have permission to perform a LIST operation on the Amazon S3 bucket to be accessed and a GET operation on the Amazon S3 objects the bucket contains. To learn more about databases created from the AWS Glue Data Catalog for datashares and using IAM_ROLE, see [Working with Lake Formation-managed datashares as a consumer](#).

The following shows the syntax for the IAM_ROLE parameter string for a single ARN.

```
IAM_ROLE 'arn:aws:iam::<aws-account-id>:role/<role-name>'
```

You can chain roles so that your cluster can assume another IAM role, possibly belonging to another account. You can chain up to 10 roles. For more information, see [Chaining IAM roles in Amazon Redshift Spectrum](#).

To this IAM role, attach an IAM permissions policy similar to the following.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessSecret",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetResourcePolicy",
        "secretsmanager:GetSecretValue",
        "secretsmanager:DescribeSecret",
        "secretsmanager:ListSecretVersionIds"
      ],
      "Resource": "arn:aws:secretsmanager:us-west-2:123456789012:secret:my-rds-secret-VNenFy"
    }
  ]
}
```

```

    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetRandomPassword",
        "secretsmanager:ListSecrets"
      ],
      "Resource": "*"
    }
  ]
}

```

For the steps to create an IAM role to use with federated query, see [Creating a secret and an IAM role to use federated queries](#).

Note

Don't include spaces in the list of chained roles.

The following shows the syntax for chaining three roles.

```

IAM_ROLE 'arn:aws:iam::<aws-account-id>:role/<role-1-name>,arn:aws:iam::<aws-account-id>:role/<role-2-name>,arn:aws:iam::<aws-account-id>:role/<role-3-name>'

```

Examples

The following example displays all of the Data Catalog databases from the account ID 123456789012.

```
SHOW DATABASES FROM DATA CATALOG ACCOUNT '123456789012'
```

catalog_id	database_name	database_arn
type	location	target_database
	parameters	
-----+-----+-----		
+-----		
+-----		
+-----+-----		

```

123456789012 | database1 | arn:aws:glue:us-east-1:123456789012:database/database1
| Data Catalog |
|
123456789012 | database2 | arn:aws:glue:us-east-1:123456789012:database/database2
| Data Catalog | arn:aws:redshift:us-
east-1:123456789012:datashare:035c45ea-61ce-86f0-8b75-19ac6102c3b7/database2 |
|

```

The following are examples that demonstrate how to display all of the Data Catalog databases from the account ID 123456789012 while using an IAM role's credentials.

```
SHOW DATABASES FROM DATA CATALOG ACCOUNT '123456789012' IAM_ROLE default;
```

```
SHOW DATABASES FROM DATA CATALOG ACCOUNT '123456789012' IAM_ROLE <iam-role-arn>;
```

SHOW MODEL

Shows useful information about a machine learning model, including its status, the parameters used to create it and the prediction function with its input argument types. You can use the information from the `SHOW MODEL` to recreate the model. If base tables have changed, running `CREATE MODEL` with the same SQL statement results in a different model. The information returned by the `SHOW MODEL` is different for the model owner and a user with the `EXECUTE` privilege. `SHOW MODEL` shows different outputs when a model is trained from Amazon Redshift or when the model is a BYOM model.

Syntax

```
SHOW MODEL ( ALL | model_name )
```

Parameters

ALL

Returns all the models that the user can use and their schemas.

model_name

The name of the model. The model name in a schema must be unique.

Usage notes

The SHOW MODEL command returns the following:

- The model name.
- The schema where the model was created.
- The owner of the model.
- The model creation time.
- The status of the model, such as READY, TRAINING, or FAILED.
- The reason message for a failed model.
- The validation error if model has finished training.
- The estimated cost needed to derive the model for a non-BYOM approach. Only the owner of the model can view this information.
- A list of user-specified parameters and their values, specifically the following:
 - The specified TARGET column.
 - The model type, AUTO or XGBoost.
 - The problem type, such as REGRESSION, BINARY_CLASSIFICATION, MULTICLASS_CLASSIFICATION. This parameter is specific to AUTO.
 - The name of the Amazon SageMaker training job or the Amazon SageMaker Autopilot job that created the model. You can use this job name to find more information about the model on Amazon SageMaker.
 - The objective, such as MSE, F1, Accuracy. This parameter is specific to AUTO.
 - The name of the created function.
 - The type of inference, local or remote.
 - The prediction function input arguments.
 - The prediction function input argument types for models that aren't bring your own model (BYOM).
 - The return type of the prediction function. This parameter is specific to BYOM.
 - The name of the Amazon SageMaker endpoint for a BYOM model with remote inference.
 - The IAM role. Only the owner of the model can see this.
 - The S3 bucket used. Only the owner of the model can see this.
 - The AWS KMS key, if one was provided. Only the owner of the model can see this.
 - The maximum time that the model can run.

- If the model type is not AUTO, then Amazon Redshift also shows the list of hyperparameters provided and their values.

You can also view some of the information provided by SHOW MODEL in other catalog tables, such as pg_proc. Amazon Redshift returns information about the prediction function that is registered in pg_proc catalog table. This information includes the input argument names and their types for the prediction function. Amazon Redshift returns the same information in the SHOW MODEL command.

```
SELECT * FROM pg_proc WHERE proname ILIKE '%<function_name>%';
```

Examples

The following example shows the show model output.

```
SHOW MODEL ALL;
```

Schema Name	Model Name
public	customer_churn

The owner of the customer_churn can see the following output. A user with only the EXECUTE privilege can't see the IAM role, the Amazon S3 bucket, and the estimated cost of the mode.

```
SHOW MODEL customer_churn;
```

Key	Value
Model Name	customer_churn
Schema Name	public
Owner	'owner'
Creation Time	Sat, 15.01.2000 14:45:20
Model State	READY
validation:F1	0.855
Estimated Cost	5.7
TRAINING DATA:	
Table	customer_data
Target Column	CHURN
PARAMETERS:	

Model Type	auto
Problem Type	binary_classification
Objective	f1
Function Name	predict_churn
Function Parameters	age zip average_daily_spend average_daily_cases
Function Parameter Types	int int float float
IAM Role	'iam_role'
KMS Key	'kms_key'
Max Runtime	36000

SHOW DATASHARES

Displays the inbound and outbound shares in a cluster either from the same account or across accounts. If you don't specify a datashare name, then Amazon Redshift displays all datashares in all databases in the cluster. Users who have the ALTER and SHARE privileges can see the shares that they have privileges for.

Syntax

```
SHOW DATASHARES [ LIKE 'namepattern' ]
```

Parameters

LIKE

An optional clause that compares the specified name pattern to the description of the datashare. When this clause is used, Amazon Redshift displays only the datashares with names that match the specified name pattern.

namepattern

The name of the datashare requested or part of the name to be matched using wildcard characters.

Examples

The following example displays the inbound and outbound shares in a cluster.

```
SHOW DATASHARES;  
SHOW DATASHARES LIKE 'sales%';
```

```

share_name | share_owner | source_database | consumer_database | share_type |
createdate | is_publicaccessible | share_acl | producer_account |
producer_namespace
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
'salesshare' | 100 | dev | | outbound
| 2020-12-09 01:22:54. | False | | 123456789012 |
13b8833d-17c6-4f16-8fe4-1a018f5ed00d

```

SHOW PROCEDURE

Shows the definition of a given stored procedure, including its signature. You can use the output of a SHOW PROCEDURE to recreate the stored procedure.

Syntax

```
SHOW PROCEDURE sp_name [( [ [ argname ] [ argmode ] argtype [, ...] ] )]
```

Parameters

sp_name

The name of the procedure to show.

[argname] [argmode] argtype

Input argument types to identify the stored procedure. Optionally, you can include the full argument data types, including OUT arguments. This part is optional if the name of the stored procedure is unique (that is, not overloaded).

Examples

The following example shows the definition of the procedure test_sp12.

```

show procedure test_sp2(int, varchar);
                                Stored Procedure Definition
-----
CREATE OR REPLACE PROCEDURE public.test_sp2(f1 integer, INOUT f2 character varying, OUT
character varying)
LANGUAGE plpgsql
AS $$

```

```
DECLARE
out_var alias for $3;
loop_var int;
BEGIN
IF f1 is null OR f2 is null THEN
RAISE EXCEPTION 'input cannot be null';
END IF;
CREATE TEMP TABLE etl(a int, b varchar);
FOR loop_var IN 1..f1 LOOP
insert into etl values (loop_var, f2);
f2 := f2 || '+' || f2;
END LOOP;
SELECT INTO out_var count(*) from etl;
END;
$_$

(1 row)
```

SHOW SCHEMAS

Shows a list of schemas in a database, along with some schema attributes.

Each output row consists of database name, schema name, schema owner, schema type, schema ACL, source database, and schema option. For more information about these attributes, see [SVV_ALL_SCHEMAS](#).

If more than 10,000 schemas can result from the SHOW SCHEMAS command, then an error is returned.

Syntax

```
SHOW SCHEMAS FROM DATABASE database_name [LIKE 'filter_pattern'] [LIMIT row_limit ]
```

Parameters

database_name

The name of the database that contains the tables to list.

To show tables in an AWS Glue Data Catalog, specify (awsdatacatalog) as the database name, and ensure the system configuration `data_catalog_auto_mount` is set to `true`. For more information, see [ALTER SYSTEM](#).

filter_pattern

A valid UTF-8 character expression with a pattern to match schema names. The LIKE option performs a case-sensitive match that supports the following pattern-matching metacharacters:

Metacharacter	Description
%	Matches any sequence of zero or more characters.
_	Matches any single character.

If *filter_pattern* does not contain metacharacters, then the pattern only represents the string itself; in that case LIKE acts the same as the equals operator.

row_limit

The maximum number of rows to return. The *row_limit* can be 0–10,000.

Examples

Following example shows the schemas from the Amazon Redshift database named `dev`.

```
SHOW SCHEMAS FROM DATABASE dev;
```

```

database_name |      schema_name      | schema_owner | schema_type |      schema_acl
              | source_database | schema_option
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
dev          | pg_automv           |              | 1 | local          |
              |                    |              |   |                |
dev          | pg_catalog          |              | 1 | local          | jpuser=UC/
jpuser~=U/jpuser |                    |              |   |                |
dev          | public              |              | 1 | local          | jpuser=UC/
jpuser~=UC/jpuser |                    |              |   |                |
dev          | information_schema  |              | 1 | local          | jpuser=UC/
jpuser~=U/jpuser |                    |              |   |                |
dev          | schemad79cd6d93bf043 |              | 1 | local          |
              |                    |              |   |                |

```

Following example shows the schemas in the AWS Glue Data Catalog database named `awsdatacatalog`. The maximum number of output rows is 5.

```
SHOW SCHEMAS FROM DATABASE awsdatalog LIMIT 5;
```

database_name	schema_name	schema_owner	schema_type	schema_acl
source_database	schema_option			
awsdatacatalog	000_too_many_glue_db		EXTERNAL	
awsdatacatalog	123_default		EXTERNAL	
awsdatacatalog	adhoc		EXTERNAL	
awsdatacatalog	all_shapes_10mb		EXTERNAL	
awsdatacatalog	all_shapes_1g		EXTERNAL	

SHOW TABLE

Shows the definition of a table, including table attributes, table constraints, column attributes, and column constraints. You can use the output of the SHOW TABLE statement to recreate the table.

For more information on table creation, see [CREATE TABLE](#).

Syntax

```
SHOW TABLE [schema_name.]table_name
```

Parameters

schema_name

(Optional) The name of the related schema.

table_name

The name of the table to show.

Examples

Following is an example of the SHOW TABLE output for the table sales.

```
show table sales;
```

```
CREATE TABLE public.sales (  
  salesid integer NOT NULL ENCODE az64,  
  listid integer NOT NULL ENCODE az64 distkey,  
  sellerid integer NOT NULL ENCODE az64,  
  buyerid integer NOT NULL ENCODE az64,  
  eventid integer NOT NULL ENCODE az64,  
  dateid smallint NOT NULL,  
  qtysold smallint NOT NULL ENCODE az64,  
  pricepaid numeric(8,2) ENCODE az64,  
  commission numeric(8,2) ENCODE az64,  
  saletime timestamp without time zone ENCODE az64  
)  
DISTSTYLE KEY SORTKEY ( dateid );
```

Following is an example of the SHOW TABLE output for the table category in the schema public.

```
show table public.category;
```

```
CREATE TABLE public.category (  
  catid smallint NOT NULL distkey,  
  catgroup character varying(10) ENCODE lzo,  
  catname character varying(10) ENCODE lzo,  
  catdesc character varying(50) ENCODE lzo  
) DISTSTYLE KEY SORTKEY ( catid );
```

The following example creates table foo with a primary key.

```
create table foo(a int PRIMARY KEY, b int);
```

The SHOW TABLE results display the create statement with all properties of the foo table.

```
show table foo;
```

```
CREATE TABLE public.foo ( a integer NOT NULL ENCODE az64, b integer ENCODE az64,  
  PRIMARY KEY (a) ) DISTSTYLE AUTO;
```

SHOW TABLES

Shows a list of tables in a schema, along with some table attributes.

Each output row consists of database name, schema name, table name, table type, table ACL, and remarks. For more information about these attributes, see [SVV_ALL_TABLES](#).

If more than 10,000 tables would result from the SHOW TABLES command, then an error is returned.

Syntax

```
SHOW TABLES FROM SCHEMA database_name.schema_name [LIKE 'filter_pattern']  
[LIMIT row_limit ]
```

Parameters

database_name

The name of the database that contains the tables to list.

To show tables in an AWS Glue Data Catalog, specify (awsdatacatalog) as the database name, and ensure the system configuration `data_catalog_auto_mount` is set to `true`. For more information, see [ALTER SYSTEM](#).

schema_name

The name of the schema that contains the tables to list.

To show AWS Glue Data Catalog tables, provide the AWS Glue database name as the schema name.

filter_pattern

A valid UTF-8 character expression with a pattern to match table names. The LIKE option performs a case-sensitive match that supports the following pattern-matching metacharacters:

Metacharacter	Description
%	Matches any sequence of zero or more characters.
_	Matches any single character.

If *filter_pattern* does not contain metacharacters, then the pattern only represents the string itself; in that case LIKE acts the same as the equals operator.

row_limit

The maximum number of rows to return. The *row_limit* can be 0–10,000.

Examples

Following example shows the tables in the Amazon Redshift database named `dev` that are in schema `public`.

```
SHOW TABLES FROM SCHEMA dev.public;
```

database_name	schema_name	table_name	table_type	table_acl	remarks
dev	public	tb	TABLE		
dev	public	tb2	TABLE		
dev	public	tb3	TABLE		

Following example shows the tables in the AWS Glue Data Catalog database named `awsdatacatalog` that are in schema `batman`.

```
SHOW TABLES FROM SCHEMA awsdatacatalog.batman;
```

database_name	schema_name	table_name	table_type	table_acl	remarks
awsdatacatalog	batman	nation	EXTERNAL		
awsdatacatalog	batman	part	EXTERNAL		
awsdatacatalog	batman	partsupp	EXTERNAL		
awsdatacatalog	batman	region	EXTERNAL		
awsdatacatalog	batman	supplier	EXTERNAL		
awsdatacatalog	batman	automount_nation	EXTERNAL		

SHOW VIEW

Shows the definition of a view, including for materialized views and late-binding views. You can use the output of the `SHOW VIEW` statement to recreate the view.

Syntax

```
SHOW VIEW [schema_name.]view_name
```

Parameters

schema_name

(Optional) The name of the related schema.

view_name

The name of the view to show.

Examples

Following is the view definition for the view LA_Venues_v.

```
create view LA_Venues_v as select * from venue where venuecity='Los Angeles';
```

Following is an example of the SHOW VIEW command and output for the view defined preceding.

```
show view LA_Venues_v;
```

```
SELECT venue.venueid,  
venue.venuename,  
venue.venuecity,  
venue.venuestate,  
venue.venueseats  
FROM venue WHERE ((venue.venuecity)::text = 'Los Angeles'::text);
```

Following is the view definition for the view public.Sports_v in the schema public.

```
create view public.Sports_v as select * from category where catgroup='Sports';
```

Following is an example of the SHOW VIEW command and output for the view defined preceding.

```
show view public.Sports_v;
```

```
SELECT category.catid,  
       category.catgroup,  
       category.catname,  
       category.catdesc  
FROM category WHERE ((category.catgroup)::text = 'Sports'::text);
```

START TRANSACTION

Synonym of the `BEGIN` function.

See [BEGIN](#).

TRUNCATE

Deletes all of the rows from a table without doing a table scan: this operation is a faster alternative to an unqualified `DELETE` operation. To run a `TRUNCATE` command, you must have the `TRUNCATE TABLE` permission, be the owner of the table, or a superuser. To grant permissions to truncate a table, use the [GRANT](#) command.

`TRUNCATE` is much more efficient than `DELETE` and doesn't require a `VACUUM` and `ANALYZE`. However, be aware that `TRUNCATE` commits the transaction in which it is run.

Syntax

```
TRUNCATE [ TABLE ] table_name
```

The command also works on a materialized view.

```
TRUNCATE materialized_view_name
```

Parameters

TABLE

Optional keyword.

table_name

A temporary or persistent table. Only the owner of the table or a superuser may truncate it.

You can truncate any table, including tables that are referenced in foreign-key constraints.

You don't need to vacuum a table after truncating it.

materialized_view_name

A materialized view.

You can truncate a materialized view that is used for [Streaming ingestion to a materialized view](#).

Usage notes

The TRUNCATE command commits the transaction in which it is run; therefore, you can't roll back a TRUNCATE operation, and a TRUNCATE command may commit other operations when it commits itself.

Examples

Use the TRUNCATE command to delete all of the rows from the CATEGORY table:

```
truncate category;
```

Attempt to roll back a TRUNCATE operation:

```
begin;

truncate date;

rollback;

select count(*) from date;
count
-----
0
(1 row)
```

The DATE table remains empty after the ROLLBACK command because the TRUNCATE command committed automatically.

The following example uses the TRUNCATE command to delete all of the rows from a materialized view.

```
truncate my_materialized_view;
```

It deletes all records in the materialized view and leaves the materialized view and its schema intact. In the query, the materialized view name is a sample.

UNLOAD

Unloads the result of a query to one or more text, JSON, or Apache Parquet files on Amazon S3, using Amazon S3 server-side encryption (SSE-S3). You can also specify server-side encryption with an AWS Key Management Service key (SSE-KMS) or client-side encryption with a customer managed key.

By default, the format of the unloaded file is pipe-delimited (|) text.

You can manage the size of files on Amazon S3, and by extension the number of files, by setting the MAXFILESIZE parameter. Ensure that the S3 IP ranges are added to your allow list. To learn more about the required S3 IP ranges, see [Network isolation](#).

You can unload the result of an Amazon Redshift query to your Amazon S3 data lake in Apache Parquet, an efficient open columnar storage format for analytics. Parquet format is up to 2x faster to unload and consumes up to 6x less storage in Amazon S3, compared with text formats. This enables you to save data transformation and enrichment you have done in Amazon S3 into your Amazon S3 data lake in an open format. You can then analyze your data with Redshift Spectrum and other AWS services such as Amazon Athena, Amazon EMR, and Amazon SageMaker.

For more information and example scenarios about using the UNLOAD command, see [Unloading data in Amazon Redshift](#).

Required privileges and permissions

For the UNLOAD command to succeed, at least SELECT privilege on the data in the database is needed, along with permission to write to the Amazon S3 location. The permissions needed are similar to the COPY command. For information about COPY command permissions, see [Permissions to access other AWS Resources](#).

Syntax

```
UNLOAD ('select-statement')
```

```

TO 's3://object-path/name-prefix'
authorization
[ option, ...]

where authorization is
IAM_ROLE { default | 'arn:aws:iam::<AWS account-id-1>:role/<role-
name>[,arn:aws:iam::<AWS account-id-2>:role/<role-name>][,...]' }

where option is
| [ FORMAT [ AS ] ] CSV | PARQUET | JSON
| PARTITION BY ( column_name [, ... ] ) [ INCLUDE ]
| MANIFEST [ VERBOSE ]
| HEADER
| DELIMITER [ AS ] 'delimiter-char'
| FIXEDWIDTH [ AS ] 'fixedwidth-spec'
| ENCRYPTED [ AUTO ]
| BZIP2
| GZIP
| ZSTD
| ADDQUOTES
| NULL [ AS ] 'null-string'
| ESCAPE
| ALLOWOVERWRITE
| CLEANPATH
| PARALLEL [ { ON | TRUE } | { OFF | FALSE } ]
| MAXFILESIZE [AS] max-size [ MB | GB ]
| ROWGROUPSIZE [AS] size [ MB | GB ]
| REGION [AS] 'aws-region' }
| EXTENSION 'extension-name'

```

Parameters

('select-statement')

A SELECT query. The results of the query are unloaded. In most cases, it is worthwhile to unload data in sorted order by specifying an ORDER BY clause in the query. This approach saves the time required to sort the data when it is reloaded.

The query must be enclosed in single quotation marks as shown following:

```
('select * from venue order by venueid')
```

Note

If your query contains quotation marks (for example to enclose literal values), put the literal between two sets of single quotation marks—you must also enclose the query between single quotation marks:

```
('select * from venue where venuestate='NV''')
```

TO 's3://*object-path/name-prefix*'

The full path, including bucket name, to the location on Amazon S3 where Amazon Redshift writes the output file objects, including the manifest file if MANIFEST is specified. The object names are prefixed with *name-prefix*. If you use PARTITION BY, a forward slash (/) is automatically added to the end of the *name-prefix* value if needed. For added security, UNLOAD connects to Amazon S3 using an HTTPS connection. By default, UNLOAD writes one or more files per slice. UNLOAD appends a slice number and part number to the specified name prefix as follows:

<object-path>/<name-prefix><slice-number>_part_<part-number>.

If MANIFEST is specified, the manifest file is written as follows:

<object_path>/<name_prefix>manifest.

If PARALLEL is specified OFF, the data files are written as follows:

<object_path>/<name_prefix><part-number>.

UNLOAD automatically creates encrypted files using Amazon S3 server-side encryption (SSE), including the manifest file if MANIFEST is used. The COPY command automatically reads server-side encrypted files during the load operation. You can transparently download server-side encrypted files from your bucket using either the Amazon S3 console or API. For more information, see [Protecting Data Using Server-Side Encryption](#).

To use Amazon S3 client-side encryption, specify the ENCRYPTED option.

⚠ Important

REGION is required when the Amazon S3 bucket isn't in the same AWS Region as the Amazon Redshift database.

authorization

The UNLOAD command needs authorization to write data to Amazon S3. The UNLOAD command uses the same parameters the COPY command uses for authorization. For more information, see [Authorization parameters](#) in the COPY command syntax reference.

IAM_ROLE { default | 'arn:aws:iam::<AWS account-id-1>:role/<role-name>'

Use the default keyword to have Amazon Redshift use the IAM role that is set as default and associated with the cluster when the UNLOAD command runs.

Use the Amazon Resource Name (ARN) for an IAM role that your cluster uses for authentication and authorization. If you specify IAM_ROLE, you can't use ACCESS_KEY_ID and SECRET_ACCESS_KEY, SESSION_TOKEN, or CREDENTIALS. The IAM_ROLE can be chained. For more information, see [Chaining IAM roles](#) in the *Amazon Redshift Management Guide*.

[FORMAT [AS]] CSV | PARQUET | JSON

Keywords to specify the unload format to override the default format.

When CSV, unloads to a text file in CSV format using a comma (,) character as the default delimiter. If a field contains delimiters, double quotation marks, newline characters, or carriage returns, then the field in the unloaded file is enclosed in double quotation marks. A double quotation mark within a data field is escaped by an additional double quotation mark. When zero rows are unloaded, Amazon Redshift might write empty Amazon S3 objects.

When PARQUET, unloads to a file in Apache Parquet version 1.0 format. By default, each row group is compressed using SNAPPY compression. For more information about Apache Parquet format, see [Parquet](#).

When JSON, unloads to a JSON file with each line containing a JSON object, representing a full record in the query result. Amazon Redshift supports writing nested JSON when the query result contains SUPER columns. To create a valid JSON object, the name of each column in the query must be unique. In the JSON file, boolean values are unloaded as t or f, and NULL values

are unloaded as null. When zero rows are unloaded, Amazon Redshift does not write Amazon S3 objects.

The `FORMAT` and `AS` keywords are optional. You can't use `CSV` with `FIXEDWIDTH` or `ADDQUOTES`. You can't use `PARQUET` with `DELIMITER`, `FIXEDWIDTH`, `ADDQUOTES`, `ESCAPE`, `NULL AS`, `HEADER`, `GZIP`, `BZIP2`, or `ZSTD`. `PARQUET` with `ENCRYPTED` is only supported with server-side encryption with an AWS Key Management Service key (SSE-KMS). You can't use `JSON` with `DELIMITER`, `HEADER`, `FIXEDWIDTH`, `ADDQUOTES`, `ESCAPE`, or `NULL AS`.

`PARTITION BY (column_name [, ...]) [INCLUDE]`

Specifies the partition keys for the unload operation. `UNLOAD` automatically partitions output files into partition folders based on the partition key values, following the Apache Hive convention. For example, a Parquet file that belongs to the partition year 2019 and the month September has the following prefix: `s3://amzn-s3-demo-bucket/my_prefix/year=2019/month=September/000.parquet`.

The value for *column_name* must be a column in the query results being unloaded.

If you specify `PARTITION BY` with the `INCLUDE` option, partition columns aren't removed from the unloaded files.

Amazon Redshift doesn't support string literals in `PARTITION BY` clauses.

`MANIFEST [VERBOSE]`

Creates a manifest file that explicitly lists details for the data files that are created by the `UNLOAD` process. The manifest is a text file in JSON format that lists the URL of each file that was written to Amazon S3.

If `MANIFEST` is specified with the `VERBOSE` option, the manifest includes the following details:

- The column names and data types, and for `CHAR`, `VARCHAR`, or `NUMERIC` data types, dimensions for each column. For `CHAR` and `VARCHAR` data types, the dimension is the length. For a `DECIMAL` or `NUMERIC` data type, the dimensions are precision and scale.
- The row count unloaded to each file. If the `HEADER` option is specified, the row count includes the header line.
- The total file size of all files unloaded and the total row count unloaded to all files. If the `HEADER` option is specified, the row count includes the header lines.
- The author. Author is always "Amazon Redshift".

You can specify VERBOSE only following MANIFEST.

The manifest file is written to the same Amazon S3 path prefix as the unload files in the format `<object_path_prefix>manifest`. For example, if UNLOAD specifies the Amazon S3 path prefix `'s3://amzn-s3-demo-bucket/venue_'`, the manifest file location is `'s3://amzn-s3-demo-bucket/venue_manifest'`.

HEADER

Adds a header line containing column names at the top of each output file. Text transformation options, such as CSV, DELIMITER, ADDQUOTES, and ESCAPE, also apply to the header line. You can't use HEADER with FIXEDWIDTH.

DELIMITER AS '*delimiter_character*'

Specifies a single ASCII character that is used to separate fields in the output file, such as a pipe character (|), a comma (,), or a tab (\t). The default delimiter for text files is a pipe character. The default delimiter for CSV files is a comma character. The AS keyword is optional. You can't use DELIMITER with FIXEDWIDTH. If the data contains the delimiter character, you need to specify the ESCAPE option to escape the delimiter, or use ADDQUOTES to enclose the data in double quotation marks. Alternatively, specify a delimiter that isn't contained in the data.

FIXEDWIDTH '*fixedwidth_spec*'

Unloads the data to a file where each column width is a fixed length, rather than separated by a delimiter. The *fixedwidth_spec* is a string that specifies the number of columns and the width of the columns. The AS keyword is optional. Because FIXEDWIDTH doesn't truncate data, the specification for each column in the UNLOAD statement needs to be at least as long as the length of the longest entry for that column. The format for *fixedwidth_spec* is shown below:

```
'colID1:colWidth1,colID2:colWidth2, ...'
```

You can't use FIXEDWIDTH with DELIMITER or HEADER.

ENCRYPTED [AUTO]

Specifies that the output files on Amazon S3 are encrypted using Amazon S3 server-side encryption or client-side encryption. If MANIFEST is specified, the manifest file is also encrypted. For more information, see [Unloading encrypted data files](#). If you don't specify the ENCRYPTED parameter, UNLOAD automatically creates encrypted files using Amazon S3 server-side encryption with AWS-managed encryption keys (SSE-S3).

For ENCRYPTED, you might want to unload to Amazon S3 using server-side encryption with an AWS KMS key (SSE-KMS). If so, use the [KMS_KEY_ID](#) parameter to provide the key ID. You can't use the [CREDENTIALS](#) parameter with the KMS_KEY_ID parameter. If you run an UNLOAD command for data using KMS_KEY_ID, you can then do a COPY operation for the same data without specifying a key.

To unload to Amazon S3 using client-side encryption with a customer-supplied symmetric key, provide the key in one of two ways. To provide the key, use the [MASTER_SYMMETRIC_KEY](#) parameter or the `master_symmetric_key` portion of a [CREDENTIALS](#) credential string. If you unload data using a root symmetric key, make sure that you supply the same key when you perform a COPY operation for the encrypted data.

UNLOAD doesn't support Amazon S3 server-side encryption with a customer-supplied key (SSE-C).

If ENCRYPTED AUTO is used, the UNLOAD command fetches the default AWS KMS encryption key on the target Amazon S3 bucket property and encrypts the files written to Amazon S3 with the AWS KMS key. If the bucket doesn't have the default AWS KMS encryption key, UNLOAD automatically creates encrypted files using Amazon Redshift server-side encryption with AWS-managed encryption keys (SSE-S3). You can't use this option with KMS_KEY_ID, MASTER_SYMMETRIC_KEY, or CREDENTIALS that contains `master_symmetric_key`.

`KMS_KEY_ID 'key-id'`

Specifies the key ID for an AWS Key Management Service (AWS KMS) key to be used to encrypt data files on Amazon S3. For more information, see [What is AWS Key Management Service?](#) If you specify KMS_KEY_ID, you must specify the [ENCRYPTED](#) parameter also. If you specify KMS_KEY_ID, you can't authenticate using the CREDENTIALS parameter. Instead, use either [IAM_ROLE](#) or [ACCESS_KEY_ID](#) and [SECRET_ACCESS_KEY](#).

`MASTER_SYMMETRIC_KEY 'root_key'`

Specifies the root symmetric key to be used to encrypt data files on Amazon S3. If you specify MASTER_SYMMETRIC_KEY, you must specify the [ENCRYPTED](#) parameter also. You can't use MASTER_SYMMETRIC_KEY with the CREDENTIALS parameter. For more information, see [Loading encrypted data files from Amazon S3](#).

`BZIP2`

Unloads data to one or more bzip2-compressed files per slice. Each resulting file is appended with a `.bz2` extension.

GZIP

Unloads data to one or more gzip-compressed files per slice. Each resulting file is appended with a `.gz` extension.

ZSTD

Unloads data to one or more Zstandard-compressed files per slice. Each resulting file is appended with a `.zst` extension.

ADDQUOTES

Places quotation marks around each unloaded data field, so that Amazon Redshift can unload data values that contain the delimiter itself. For example, if the delimiter is a comma, you could unload and reload the following data successfully:

```
"1","Hello, World"
```

Without the added quotation marks, the string `Hello, World` would be parsed as two separate fields.

Some output formats do not support `ADDQUOTES`.

If you use `ADDQUOTES`, you must specify `REMOVEQUOTES` in the `COPY` if you reload the data.

NULL AS '*null-string*'

Specifies a string that represents a null value in unload files. If this option is used, all output files contain the specified string in place of any null values found in the selected data. If this option isn't specified, null values are unloaded as:

- Zero-length strings for delimited output
- Whitespace strings for fixed-width output

If a null string is specified for a fixed-width unload and the width of an output column is less than the width of the null string, the following behavior occurs:

- An empty field is output for non-character columns
- An error is reported for character columns

Unlike other data types where a user-defined string represents a null value, Amazon Redshift exports the `SUPER` data columns using the JSON format and represents it as null as determined by the JSON format. As a result, `SUPER` data columns ignore the `NULL [AS]` option used in `UNLOAD` commands.

ESCAPE

For CHAR and VARCHAR columns in delimited unload files, an escape character (\) is placed before every occurrence of the following characters:

- Linefeed: \n
- Carriage return: \r
- The delimiter character specified for the unloaded data.
- The escape character: \
- A quotation mark character: " or ' (if both ESCAPE and ADDQUOTES are specified in the UNLOAD command).

Important

If you loaded your data using a COPY with the ESCAPE option, you must also specify the ESCAPE option with your UNLOAD command to generate the reciprocal output file. Similarly, if you UNLOAD using the ESCAPE option, you need to use ESCAPE when you COPY the same data.

ALLOWOVERWRITE

By default, UNLOAD fails if it finds files that it would possibly overwrite. If ALLOWOVERWRITE is specified, UNLOAD overwrites existing files, including the manifest file.

CLEANPATH

The CLEANPATH option removes existing files located in the Amazon S3 path specified in the TO clause before unloading files to the specified location.

If you include the PARTITION BY clause, existing files are removed only from the partition folders to receive new files generated by the UNLOAD operation.

You must have the `s3:DeleteObject` permission on the Amazon S3 bucket. For information, see [Policies and Permissions in Amazon S3](#) in the *Amazon Simple Storage Service User Guide*. Files that you remove by using the CLEANPATH option are permanently deleted and can't be recovered. If the target Amazon S3 bucket has versioning enabled, UNLOAD with the CLEANPATH option does not remove previous versions of the files.

You can't specify the CLEANPATH option if you specify the ALLOWOVERWRITE option.

PARALLEL

By default, UNLOAD writes data in parallel to multiple files, according to the number of slices in the cluster. The default option is ON or TRUE. If PARALLEL is OFF or FALSE, UNLOAD writes to one or more data files serially, sorted absolutely according to the ORDER BY clause, if one is used. The maximum size for a data file is 6.2 GB. So, for example, if you unload 13.4 GB of data, UNLOAD creates the following three files.

```
s3://amzn-s3-demo-bucket/key000    6.2 GB
s3://amzn-s3-demo-bucket/key001    6.2 GB
s3://amzn-s3-demo-bucket/key002    1.0 GB
```

Note

The UNLOAD command is designed to use parallel processing. We recommend leaving PARALLEL enabled for most cases, especially if the files are used to load tables using a COPY command.

MAXFILESIZE [AS] max-size [MB | GB]

Specifies the maximum size of files that UNLOAD creates in Amazon S3. Specify a decimal value between 5 MB and 6.2 GB. The AS keyword is optional. The default unit is MB. If MAXFILESIZE isn't specified, the default maximum file size is 6.2 GB. The size of the manifest file, if one is used, isn't affected by MAXFILESIZE.

ROWGROUPSIZE [AS] size [MB | GB]

Specifies the size of row groups. Choosing a larger size can reduce the number of row groups, reducing the amount of network communication. Specify an integer value between 32 MB and 128 MB. The AS keyword is optional. The default unit is MB.

If ROWGROUPSIZE isn't specified, the default size is 32 MB. To use this parameter, the storage format must be Parquet and the node type must be ra3.4xlarge, ra3.16xlarge, or dc2.8xlarge.

REGION [AS] '*aws-region*'

Specifies the AWS Region where the target Amazon S3 bucket is located. REGION is required for UNLOAD to an Amazon S3 bucket that isn't in the same AWS Region as the Amazon Redshift database.

The value for `aws_region` must match an AWS Region listed in the [Amazon Redshift regions and endpoints](#) table in the *AWS General Reference*.

By default, UNLOAD assumes that the target Amazon S3 bucket is located in the same AWS Region as the Amazon Redshift database.

EXTENSION '*extension-name*'

Specifies the file extension to append to the names of the unloaded files. Amazon Redshift doesn't run any validation, so you must verify that the specified file extension is correct. If you're using a compression method such as GZIP, you still have to specify `.gz` in the extension parameter. If you don't provide any extension, Amazon Redshift doesn't add anything to the filename. If you specify a compression method without providing an extension, Amazon Redshift only adds the compression method's extension to the filename.

Usage notes

Using ESCAPE for all delimited text UNLOAD operations

When you UNLOAD using a delimiter, your data can include that delimiter or any of the characters listed in the ESCAPE option description. In this case, you must use the ESCAPE option with the UNLOAD statement. If you don't use the ESCAPE option with the UNLOAD, subsequent COPY operations using the unloaded data might fail.

Important

We strongly recommend that you always use ESCAPE with both UNLOAD and COPY statements. The exception is if you are certain that your data doesn't contain any delimiters or other characters that might need to be escaped.

Loss of floating-point precision

You might encounter loss of precision for floating-point data that is successively unloaded and reloaded.

Limit clause

The SELECT query can't use a LIMIT clause in the outer SELECT. For example, the following UNLOAD statement fails.

```
unload ('select * from venue limit 10')
to 's3://amzn-s3-demo-bucket/venue_pipe_' iam_role 'arn:aws:iam::0123456789012:role/
MyRedshiftRole';
```

Instead, use a nested LIMIT clause, as in the following example.

```
unload ('select * from venue where venueid in
(select venueid from venue order by venueid desc limit 10)')
to 's3://amzn-s3-demo-bucket/venue_pipe_' iam_role 'arn:aws:iam::0123456789012:role/
MyRedshiftRole';
```

You can also populate a table using SELECT...INTO or CREATE TABLE AS using a LIMIT clause, then unload from that table.

Unloading a column of the GEOMETRY data type

You can only unload GEOMETRY columns to text or CSV format. You can't unload GEOMETRY data with the FIXEDWIDTH option. The data is unloaded in the hexadecimal form of the extended well-known binary (EWKB) format. If the size of the EWKB data is more than 4 MB, then a warning occurs because the data can't later be loaded into a table.

Unloading the HLLSKETCH data type

You can only unload HLLSKETCH columns to text or CSV format. You can't unload HLLSKETCH data with the FIXEDWIDTH option. The data is unloaded in the Base64 format for dense HyperLogLog sketches or in the JSON format for sparse HyperLogLog sketches. For more information, see [HyperLogLog functions](#).

The following example exports a table containing HLLSKETCH columns into a file.

```
CREATE TABLE a_table(an_int INT, b_int INT);
INSERT INTO a_table VALUES (1,1), (2,1), (3,1), (4,1), (1,2), (2,2), (3,2), (4,2),
(5,2), (6,2);

CREATE TABLE hll_table (sketch HLLSKETCH);
INSERT INTO hll_table select hll_create_sketch(an_int) from a_table group by b_int;

UNLOAD ('select * from hll_table') TO 's3://amzn-s3-demo-bucket/unload/'
IAM_ROLE 'arn:aws:iam::0123456789012:role/MyRedshiftRole' NULL AS 'null' ALLOWOVERWRITE
CSV;
```

Unloading a column of the VARBYTE data type

You can only unload VARBYTE columns to text or CSV format. The data is unloaded in the hexadecimal form. You can't unload VARBYTE data with the FIXEDWIDTH option. The ADDQUOTES option of UNLOAD to a CSV is not supported. A VARBYTE column can't be a PARTITIONED BY column.

FORMAT AS PARQUET clause

Be aware of these considerations when using FORMAT AS PARQUET:

- Unload to Parquet doesn't use file level compression. Each row group is compressed with SNAPPY.
- If MAXFILESIZE isn't specified, the default maximum file size is 6.2 GB. You can use MAXFILESIZE to specify a file size of 5 MB–6.2 GB. The actual file size is approximated when the file is being written, so it might not be exactly equal to the number you specify.

To maximize scan performance, Amazon Redshift tries to create Parquet files that contain equally sized 32-MB row groups. The MAXFILESIZE value that you specify is automatically rounded down to the nearest multiple of 32 MB. For example, if you specify MAXFILESIZE 200 MB, then each Parquet file unloaded is approximately 192 MB (32 MB row group x 6 = 192 MB).

- If a column uses TIMESTAMPTZ data format, only the timestamp values are unloaded. The time zone information isn't unloaded.
- Don't specify file name prefixes that begin with underscore (_) or period (.) characters. Redshift Spectrum treats files that begin with these characters as hidden files and ignores them.

PARTITION BY clause

Be aware of these considerations when using PARTITION BY:

- Partition columns aren't included in the output file.
- Make sure to include partition columns in the SELECT query used in the UNLOAD statement. You can specify any number of partition columns in the UNLOAD command. However, there is a limitation that there should be at least one nonpartition column to be part of the file.
- If the partition key value is null, Amazon Redshift automatically unloads that data into a default partition called `partition_column=__HIVE_DEFAULT_PARTITION__`.
- The UNLOAD command doesn't make any calls to an external catalog. To register your new partitions to be part of your existing external table, use a separate ALTER TABLE ... ADD

PARTITION ... command. Or you can run a CREATE EXTERNAL TABLE command to register the unloaded data as a new external table. You can also use an AWS Glue crawler to populate your Data Catalog. For more information, see [Defining Crawlers](#) in the *AWS Glue Developer Guide*.

- If you use the MANIFEST option, Amazon Redshift generates only one manifest file in the root Amazon S3 folder.
- The column data types that you can use as the partition key are SMALLINT, INTEGER, BIGINT, DECIMAL, REAL, BOOLEAN, CHAR, VARCHAR, DATE, and TIMESTAMP.

Using the ASSUMEROLE privilege to grant access to an IAM role for UNLOAD operations

To provide access for specific users and groups to an IAM role for UNLOAD operations, a superuser can grant the ASSUMEROLE privilege on an IAM role to users and groups. For information, see [GRANT](#).

UNLOAD doesn't support Amazon S3 access point aliases

You can't use Amazon S3 access point aliases with the UNLOAD command.

Examples

For examples that show how to use the UNLOAD command, see [UNLOAD examples](#).

UNLOAD examples

These examples demonstrate various parameters of the UNLOAD command. The TICKIT sample data is used in many of the examples. For more information, see [Sample database](#).

Note

These examples contain line breaks for readability. Do not include line breaks or spaces in your *credentials-args* string.

Unload VENUE to a pipe-delimited file (default delimiter)

The following example unloads the VENUE table and writes the data to `s3://amzn-s3-demo-bucket/unload/`:

```
unload ('select * from venue')
```

```
to 's3://amzn-s3-demo-bucket/unload/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole';
```

By default, UNLOAD writes one or more files per slice. Assuming a two-node cluster with two slices per node, the previous example creates these files in `amzn-s3-demo-bucket`:

```
unload/0000_part_00
unload/0001_part_00
unload/0002_part_00
unload/0003_part_00
```

To better differentiate the output files, you can include a prefix in the location. The following example unloads the `VENUE` table and writes the data to `s3://amzn-s3-demo-bucket/unload/venue_pipe_`:

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/venue_pipe_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole';
```

The result is these four files in the `unload` folder, again assuming four slices.

```
venue_pipe_0000_part_00
venue_pipe_0001_part_00
venue_pipe_0002_part_00
venue_pipe_0003_part_00
```

Unload `LINEITEM` table to partitioned Parquet files

The following example unloads the `LINEITEM` table in Parquet format, partitioned by the `l_shipdate` column.

```
unload ('select * from lineitem')
to 's3://amzn-s3-demo-bucket/lineitem/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
PARQUET
PARTITION BY (l_shipdate);
```

Assuming four slices, the resulting Parquet files are dynamically partitioned into various folders.

```
s3://amzn-s3-demo-bucket/lineitem/l_shipdate=1992-01-02/0000_part_00.parquet
                                0001_part_00.parquet
                                0002_part_00.parquet
                                0003_part_00.parquet
s3://amzn-s3-demo-bucket/lineitem/l_shipdate=1992-01-03/0000_part_00.parquet
                                0001_part_00.parquet
                                0002_part_00.parquet
                                0003_part_00.parquet
s3://amzn-s3-demo-bucket/lineitem/l_shipdate=1992-01-04/0000_part_00.parquet
                                0001_part_00.parquet
                                0002_part_00.parquet
                                0003_part_00.parquet
...
```

Note

In some cases, the UNLOAD command used the INCLUDE option as shown in the following SQL statement.

```
unload ('select * from lineitem')
to 's3://amzn-s3-demo-bucket/lineitem/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
PARQUET
PARTITION BY (l_shipdate) INCLUDE;
```

In these cases, the `l_shipdate` column is also in the data in the Parquet files. Otherwise, the `l_shipdate` column data isn't in the Parquet files.

Unload the VENUE table to a JSON file

The following example unloads the VENUE table and writes the data in JSON format to `s3://amzn-s3-demo-bucket/unload/`.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
JSON;
```

Following are sample rows from the VENUE table.

venueid	venue name	venue city	venue state	venue seats
1	Pinewood Racetrack	Akron	OH	0
2	Columbus "Crew" Stadium	Columbus	OH	0
4	Community, Ballpark, Arena	Kansas City	KS	0

After unloading to JSON, the format of the file is similar to the following.

```
{
  "venueid":1,"venue name":"Pinewood
  Racetrack","venue city":"Akron","venue state":"OH","venue seats":0}
{"venueid":2,"venue name":"Columbus \"Crew\" Stadium
","venue city":"Columbus","venue state":"OH","venue seats":0}
{"venueid":4,"venue name":"Community, Ballpark, Arena","venue city":"Kansas
  City","venue state":"KS","venue seats":0}
```

Unload VENUE to a CSV file

The following example unloads the VENUE table and writes the data in CSV format to `s3://amzn-s3-demo-bucket/unload/`.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
CSV;
```

Suppose that the VENUE table contains the following rows.

venueid	venue name	venue city	venue state	venue seats
1	Pinewood Racetrack	Akron	OH	0
2	Columbus "Crew" Stadium	Columbus	OH	0
4	Community, Ballpark, Arena	Kansas City	KS	0

The unload file looks similar to the following.

```
1,Pinewood Racetrack,Akron,OH,0
2,"Columbus ""Crew"" Stadium",Columbus,OH,0
4,"Community, Ballpark, Arena",Kansas City,KS,0
```

Unload VENUE to a CSV file using a delimiter

The following example unloads the VENUE table and writes the data in CSV format using the pipe character (|) as the delimiter. The unloaded file is written to `s3://amzn-s3-demo-bucket/unload/`. The VENUE table in this example contains the pipe character in the value of the first row (Pinewood Race|track). It does this to show that the value in the result is enclosed in double quotation marks. A double quotation mark is escaped by a double quotation mark, and the entire field is enclosed in double quotation marks.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
CSV DELIMITER AS '|';
```

Suppose that the VENUE table contains the following rows.

venueid	venue name	venue city	venue state	venue seats
1	Pinewood Race track	Akron	OH	0
2	Columbus "Crew" Stadium	Columbus	OH	0
4	Community, Ballpark, Arena	Kansas City	KS	0

The unload file looks similar to the following.

```
1|"Pinewood Race|track"|Akron|OH|0
2|"Columbus ""Crew"" Stadium"|Columbus|OH|0
4|Community, Ballpark, Arena|Kansas City|KS|0
```

Unload VENUE with a manifest file

To create a manifest file, include the MANIFEST option. The following example unloads the VENUE table and writes a manifest file along with the data files to `s3://amzn-s3-demo-bucket/venue_pipe_:`

Important

If you unload files with the MANIFEST option, you should use the MANIFEST option with the COPY command when you load the files. If you use the same prefix to load the files

and don't specify the MANIFEST option, COPY fails because it assumes the manifest file is a data file.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_pipe_' iam_role 'arn:aws:iam::0123456789012:role/
MyRedshiftRole'
manifest;
```

The result is these five files:

```
s3://amzn-s3-demo-bucket/venue_pipe_0000_part_00
s3://amzn-s3-demo-bucket/venue_pipe_0001_part_00
s3://amzn-s3-demo-bucket/venue_pipe_0002_part_00
s3://amzn-s3-demo-bucket/venue_pipe_0003_part_00
s3://amzn-s3-demo-bucket/venue_pipe_manifest
```

The following shows the contents of the manifest file.

```
{
  "entries": [
    {"url":"s3://amzn-s3-demo-bucket/ticket/venue_0000_part_00"},
    {"url":"s3://amzn-s3-demo-bucket/ticket/venue_0001_part_00"},
    {"url":"s3://amzn-s3-demo-bucket/ticket/venue_0002_part_00"},
    {"url":"s3://amzn-s3-demo-bucket/ticket/venue_0003_part_00"}
  ]
}
```

Unload VENUE with MANIFEST VERBOSE

When you specify the MANIFEST VERBOSE option, the manifest file includes the following sections:

- The `entries` section lists Amazon S3 path, file size, and row count for each file.
- The `schema` section lists the column names, data types, and dimension for each column.
- The `meta` section shows the total file size and row count for all files.

The following example unloads the VENUE table using the MANIFEST VERBOSE option.

```
unload ('select * from venue')
```

```
to 's3://amzn-s3-demo-bucket/unload_venue_folder/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
manifest verbose;
```

The following shows the contents of the manifest file.

```
{
  "entries": [
    {"url": "s3://amzn-s3-demo-bucket/venue_pipe_0000_part_00", "meta":
    { "content_length": 32295, "record_count": 10 }},
    {"url": "s3://amzn-s3-demo-bucket/venue_pipe_0001_part_00", "meta":
    { "content_length": 32771, "record_count": 20 }},
    {"url": "s3://amzn-s3-demo-bucket/venue_pipe_0002_part_00", "meta":
    { "content_length": 32302, "record_count": 10 }},
    {"url": "s3://amzn-s3-demo-bucket/venue_pipe_0003_part_00", "meta":
    { "content_length": 31810, "record_count": 15 }}
  ],
  "schema": {
    "elements": [
      {"name": "venueid", "type": { "base": "integer" }},
      {"name": "venue name", "type": { "base": "character varying", 25 }},
      {"name": "venue city", "type": { "base": "character varying", 25 }},
      {"name": "venue state", "type": { "base": "character varying", 25 }},
      {"name": "venue seats", "type": { "base": "character varying", 25 }}
    ]
  },
  "meta": {
    "content_length": 129178,
    "record_count": 55
  },
  "author": {
    "name": "Amazon Redshift",
    "version": "1.0.0"
  }
}
```

Unload VENUE with a header

The following example unloads VENUE with a header row.

```
unload ('select * from venue where venuesseats > 75000')
to 's3://amzn-s3-demo-bucket/unload/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
```

```
header
parallel off;
```

The following shows the contents of the output file with a header row.

```
venueid|venueName|venueCity|venueState|venueSeats
6|New York Giants Stadium|East Rutherford|NJ|80242
78|INVESCO Field|Denver|CO|76125
83|FedExField|Landover|MD|91704
79|Arrowhead Stadium|Kansas City|MO|79451
```

Unload VENUE to smaller files

By default, the maximum file size is 6.2 GB. If the unload data is larger than 6.2 GB, UNLOAD creates a new file for each 6.2 GB data segment. To create smaller files, include the MAXFILESIZE parameter. Assuming the size of the data in the previous example was 20 GB, the following UNLOAD command creates 20 files, each 1 GB in size.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
maxfilesize 1 gb;
```

Unload VENUE serially

To unload serially, specify PARALLEL OFF. UNLOAD then writes one file at a time, up to a maximum of 6.2 GB per file.

The following example unloads the VENUE table and writes the data serially to `s3://amzn-s3-demo-bucket/unload/`.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/venue_serial_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
parallel off;
```

The result is one file named `venue_serial_000`.

If the unload data is larger than 6.2 GB, UNLOAD creates a new file for each 6.2 GB data segment. The following example unloads the LINEORDER table and writes the data serially to `s3://amzn-s3-demo-bucket/unload/`.

```
unload ('select * from lineorder')
to 's3://amzn-s3-demo-bucket/unload/lineorder_serial_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
parallel off gzip;
```

The result is the following series of files.

```
lineorder_serial_0000.gz
lineorder_serial_0001.gz
lineorder_serial_0002.gz
lineorder_serial_0003.gz
```

To better differentiate the output files, you can include a prefix in the location. The following example unloads the VENUE table and writes the data to `s3://amzn-s3-demo-bucket/venue_pipe_`:

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/unload/venue_pipe_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole';
```

The result is these four files in the `unload` folder, again assuming four slices.

```
venue_pipe_0000_part_00
venue_pipe_0001_part_00
venue_pipe_0002_part_00
venue_pipe_0003_part_00
```

Load VENUE from unload files

To load a table from a set of unload files, simply reverse the process by using a `COPY` command. The following example creates a new table, `LOADVENUE`, and loads the table from the data files created in the previous example.

```
create table loadvenue (like venue);

copy loadvenue from 's3://amzn-s3-demo-bucket/venue_pipe_' iam_role
'arn:aws:iam::0123456789012:role/MyRedshiftRole';
```

If you used the MANIFEST option to create a manifest file with your unload files, you can load the data using the same manifest file. You do so with a COPY command with the MANIFEST option. The following example loads data using a manifest file.

```
copy loadvenue
from 's3://amzn-s3-demo-bucket/venue_pipe_manifest' iam_role
  'arn:aws:iam::0123456789012:role/MyRedshiftRole'
manifest;
```

Unload VENUE to encrypted files

The following example unloads the VENUE table to a set of encrypted files using an AWS KMS key. If you specify a manifest file with the ENCRYPTED option, the manifest file is also encrypted. For more information, see [Unloading encrypted data files](#).

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_encrypt_kms'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
kms_key_id '1234abcd-12ab-34cd-56ef-1234567890ab'
manifest
encrypted;
```

The following example unloads the VENUE table to a set of encrypted files using a root symmetric key.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_encrypt_cmk'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
master_symmetric_key 'EXAMPLEMASTERKEYtkbjk/OpCwtYSx/M4/t7DMCDIK722'
encrypted;
```

Load VENUE from encrypted files

To load tables from a set of files that were created by using UNLOAD with the ENCRYPT option, reverse the process by using a COPY command. With that command, use the ENCRYPTED option and specify the same root symmetric key that was used for the UNLOAD command. The following example loads the LOADVENUE table from the encrypted data files created in the previous example.

```
create table loadvenue (like venue);
```

```
copy loadvenue
from 's3://amzn-s3-demo-bucket/venue_encrypt_manifest'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
master_symmetric_key 'EXAMPLEMASTERKEYtkbjk/OpCwtYSx/M4/t7DMCDIK722'
manifest
encrypted;
```

Unload VENUE data to a tab-delimited file

```
unload ('select venueid, venueName, venueSeats from venue')
to 's3://amzn-s3-demo-bucket/venue_tab_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
delimiter as '\t';
```

The output data files look like this:

```
1 Toyota Park Bridgeview IL 0
2 Columbus Crew Stadium Columbus OH 0
3 RFK Stadium Washington DC 0
4 CommunityAmerica Ballpark Kansas City KS 0
5 Gillette Stadium Foxborough MA 68756
...
```

Unload VENUE to a fixed-width data file

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_fw_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
fixedwidth as 'venueid:3,venueName:39,venueCity:16,venueState:2,venueSeats:6';
```

The output data files look like the following.

```
1 Toyota Park           Bridgeview  IL0
2 Columbus Crew Stadium Columbus    OH0
3 RFK Stadium           Washington  DC0
4 CommunityAmerica BallparkKansas City  KS0
5 Gillette Stadium      Foxborough MA68756
...
```

Unload VENUE to a set of tab-delimited GZIP-compressed files

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_tab_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
delimiter as '\t'
gzip;
```

Unload VENUE to a GZIP-compressed text file

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_tab_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
extension 'txt.gz'
gzip;
```

Unload data that contains a delimiter

This example uses the ADDQUOTES option to unload comma-delimited data where some of the actual data fields contain a comma.

First, create a table that contains quotation marks.

```
create table location (id int, location char(64));

insert into location values (1,'Phoenix, AZ'),(2,'San Diego, CA'),(3,'Chicago, IL');
```

Then, unload the data using the ADDQUOTES option.

```
unload ('select id, location from location')
to 's3://amzn-s3-demo-bucket/location_'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
delimiter ',' addquotes;
```

The unloaded data files look like this:

```
1,"Phoenix, AZ"
2,"San Diego, CA"
3,"Chicago, IL"
...
```

Unload the results of a join query

The following example unloads the results of a join query that contains a window function.

```
unload ('select venuecity, venuestate, caldate, pricepaid,
sum(pricepaid) over(partition by venuecity, venuestate
order by caldate rows between 3 preceding and 3 following) as winsum
from sales join date on sales.dateid=date.dateid
join event on event.eventid=sales.eventid
join venue on event.venueid=venue.venueid
order by 1,2')
to 's3://amzn-s3-demo-bucket/ticket/winsum'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole';
```

The output files look like this:

```
Atlanta|GA|2008-01-04|363.00|1362.00
Atlanta|GA|2008-01-05|233.00|2030.00
Atlanta|GA|2008-01-06|310.00|3135.00
Atlanta|GA|2008-01-08|166.00|8338.00
Atlanta|GA|2008-01-11|268.00|7630.00
...
```

Unload using NULL AS

UNLOAD outputs null values as empty strings by default. The following examples show how to use NULL AS to substitute a text string for nulls.

For these examples, we add some null values to the VENUE table.

```
update venue set venuestate = NULL
where venuecity = 'Cleveland';
```

Select from VENUE where VENUESTATE is null to verify that the columns contain NULL.

```
select * from venue where venuestate is null;
```

venueid	venue name	venuecity	venuestate	venueseats
22	Quicken Loans Arena	Cleveland		0

101	Progressive Field	Cleveland	43345
72	Cleveland Browns Stadium	Cleveland	73200

Now, **UNLOAD** the **VENUE** table using the **NULL AS** option to replace null values with the character string 'fred'.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/nulls/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
null as 'fred';
```

The following sample from the unload file shows that null values were replaced with `fred`. It turns out that some values for **VENUESEATS** were also null and were replaced with `fred`. Even though the data type for **VENUESEATS** is integer, **UNLOAD** converts the values to text in the unload files, and then **COPY** converts them back to integer. If you are unloading to a fixed-width file, the **NULL AS** string must not be larger than the field width.

```
248|Charles Playhouse|Boston|MA|0
251|Paris Hotel|Las Vegas|NV|fred
258|Tropicana Hotel|Las Vegas|NV|fred
300|Kennedy Center Opera House|Washington|DC|0
306|Lyric Opera House|Baltimore|MD|0
308|Metropolitan Opera|New York City|NY|0
  5|Gillette Stadium|Foxborough|MA|5
  22|Quicken Loans Arena|Cleveland|fred|0
101|Progressive Field|Cleveland|fred|43345
...
```

To load a table from the unload files, use a **COPY** command with the same **NULL AS** option.

Note

If you attempt to load nulls into a column defined as **NOT NULL**, the **COPY** command fails.

```
create table loadvenueNULLs (like venue);

copy loadvenueNULLs from 's3://amzn-s3-demo-bucket/nulls/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
```

```
null as 'fred';
```

To verify that the columns contain null, not just empty strings, select from `LOADVENUENULLS` and filter for null.

```
select * from loadvenuenuLLs where venuestate is null or venueseats is null;
```

venueid	venueName	venueCity	venueState	venueSeats
72	Cleveland Browns Stadium	Cleveland		73200
253	Mirage Hotel	Las Vegas	NV	
255	Venetian Hotel	Las Vegas	NV	
22	Quicken Loans Arena	Cleveland		0
101	Progressive Field	Cleveland		43345
251	Paris Hotel	Las Vegas	NV	

...

You can `UNLOAD` a table that contains nulls using the default `NULL AS` behavior and then `COPY` the data back into a table using the default `NULL AS` behavior; however, any non-numeric fields in the target table contain empty strings, not nulls. By default `UNLOAD` converts nulls to empty strings (white space or zero-length). `COPY` converts empty strings to `NULL` for numeric columns, but inserts empty strings into non-numeric columns. The following example shows how to perform an `UNLOAD` followed by a `COPY` using the default `NULL AS` behavior.

```
unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/nulls/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole' allowoverwrite;

truncate loadvenuenuLLs;
copy loadvenuenuLLs from 's3://amzn-s3-demo-bucket/nulls/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole';
```

In this case, when you filter for nulls, only the rows where `VENUESEATS` contained nulls. Where `VENUESTATE` contained nulls in the table (`VENUE`), `VENUESTATE` in the target table (`LOADVENUENULLS`) contains empty strings.

```
select * from loadvenuenuLLs where venuestate is null or venueseats is null;
```

venueid	venueName	venueCity	venueState	venueSeats
---------	-----------	-----------	------------	------------

```

-----+-----+-----+-----+-----
253 | Mirage Hotel          | Las Vegas | NV      |
255 | Venetian Hotel        | Las Vegas | NV      |
251 | Paris Hotel           | Las Vegas | NV      |
...

```

To load empty strings to non-numeric columns as NULL, include the `EMPTYASNULL` or `BLANKSASNULL` options. It's OK to use both.

```

unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/nulls/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole' allowoverwrite;

truncate loadvenuenuLLS;
copy loadvenuenuLLS from 's3://amzn-s3-demo-bucket/nulls/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole' EMPTYASNULL;

```

To verify that the columns contain NULL, not just whitespace or empty strings, select from `LOADVENUENUALLS` and filter for null.

```
select * from loadvenuenuLLS where venuestate is null or venueseats is null;
```

```

venueid |          venueName          | venueCity | venuestate | venueseats
-----+-----+-----+-----+-----
  72 | Cleveland Browns Stadium | Cleveland |           |      73200
253 | Mirage Hotel              | Las Vegas | NV        |
255 | Venetian Hotel            | Las Vegas | NV        |
  22 | Quicken Loans Arena       | Cleveland |           |           0
101 | Progressive Field         | Cleveland |           |      43345
251 | Paris Hotel               | Las Vegas | NV        |
...

```

Unload using `ALLOWOVERWRITE` parameter

By default, `UNLOAD` doesn't overwrite existing files in the destination bucket. For example, if you run the same `UNLOAD` statement twice without modifying the files in the destination bucket, the second `UNLOAD` fails. To overwrite the existing files, including the manifest file, specify the `ALLOWOVERWRITE` option.

```

unload ('select * from venue')
to 's3://amzn-s3-demo-bucket/venue_pipe_'

```

```
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
manifest allowoverwrite;
```

Unload EVENT table using PARALLEL and MANIFEST parameters

You can UNLOAD a table in parallel and generate a manifest file. The Amazon S3 data files are all created at the same level and names are suffixed with the pattern `0000_part_00`. The manifest file is at the same folder level as the data files and suffixed with the text `manifest`. The following SQL unloads the EVENT table and creates files with the base name `parallel`

```
unload ('select * from myticket1.event')
to 's3://amzn-s3-demo-bucket/parallel'
iam_role 'arn:aws:iam::123456789012:role/MyRedshiftRole'
parallel on
manifest;
```

The Amazon S3 files listing is similar to the following.

Name	Last modified	Size
parallel0000_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	52.1 KB
parallel0001_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	53.4 KB
parallel0002_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	52.1 KB
parallel0003_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	51.1 KB
parallel0004_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	54.6 KB
parallel0005_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	53.4 KB
parallel0006_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	54.1 KB
parallel0007_part_00	August 2, 2023, 14:54:39 (UTC-07:00)	55.9 KB
parallelmanifest	August 2, 2023, 14:54:39 (UTC-07:00)	886.0 B

The `parallelmanifest` file content is similar to the following.

```
{
  "entries": [
    {"url": "s3://amzn-s3-demo-bucket/parallel0000_part_00", "meta": { "content_length": 53316 }},
    {"url": "s3://amzn-s3-demo-bucket/parallel0001_part_00", "meta": { "content_length": 54704 }},
    {"url": "s3://amzn-s3-demo-bucket/parallel0002_part_00", "meta": { "content_length": 53326 }},
```

```

    {"url":"s3://amzn-s3-demo-bucket/parallel0003_part_00", "meta": { "content_length":
52356 }},
    {"url":"s3://amzn-s3-demo-bucket/parallel0004_part_00", "meta": { "content_length":
55933 }},
    {"url":"s3://amzn-s3-demo-bucket/parallel0005_part_00", "meta": { "content_length":
54648 }},
    {"url":"s3://amzn-s3-demo-bucket/parallel0006_part_00", "meta": { "content_length":
55436 }},
    {"url":"s3://amzn-s3-demo-bucket/parallel0007_part_00", "meta": { "content_length":
57272 }}
  ]
}

```

Unload EVENT table using PARALLEL OFF and MANIFEST parameters

You can UNLOAD a table serially (PARALLEL OFF) and generate a manifest file. The Amazon S3 data files are all created at the same level and names are suffixed with the pattern 0000. The manifest file is at the same folder level as the data files and suffixed with the text manifest.

```

unload ('select * from myticket1.event')
to 's3://amzn-s3-demo-bucket/serial'
iam_role 'arn:aws:iam::123456789012:role/MyRedshiftRole'
parallel off
manifest;

```

The Amazon S3 files listing is similar to the following.

Name	Last modified	Size
serial0000	- August 2, 2023, 15:54:39 (UTC-07:00)	426.7 KB
serialmanifest	- August 2, 2023, 15:54:39 (UTC-07:00)	120.0 B

The serialmanifest file content is similar to the following.

```

{
  "entries": [
    {"url":"s3://amzn-s3-demo-bucket/serial000", "meta": { "content_length": 436991 }}
  ]
}

```

Unload EVENT table using PARTITION BY and MANIFEST parameters

You can UNLOAD a table by partition and generate a manifest file. A new folder is created in Amazon S3 with child partition folders, and the data files in the child folders with a name pattern similar to `0000_par_00`. The manifest file is at the same folder level as the child folders with the name `manifest`.

```
unload ('select * from myticket1.event')
to 's3://amzn-s3-demo-bucket/partition'
iam_role 'arn:aws:iam::123456789012:role/MyRedshiftRole'
partition by (eventname)
manifest;
```

The Amazon S3 files listing is similar to the following.

Name	Type	Last modified	Size
partition	Folder		

In the `partition` folder are child folders with the partition name and the manifest file. Shown following is the bottom of the list of folders in the `partition` folder, similar to the following.

Name	Type	Last modified	Size
...			
eventname=Zucchero/	Folder		
eventname=Zumanity/	Folder		
eventname=ZZ Top/	Folder		
manifest	-	August 2, 2023, 15:54:39 (UTC-07:00)	467.6 KB

In the `eventname=Zucchero/` folder are the data files similar to the following.

Name	Last modified	Size
0000_part_00 -	August 2, 2023, 15:59:19 (UTC-07:00)	70.0 B
0001_part_00 -	August 2, 2023, 15:59:16 (UTC-07:00)	106.0 B
0002_part_00 -	August 2, 2023, 15:59:15 (UTC-07:00)	70.0 B

```
0004_part_00 - August 2, 2023, 15:59:17 (UTC-07:00) 141.0 B
0006_part_00 - August 2, 2023, 15:59:16 (UTC-07:00) 35.0 B
0007_part_00 - August 2, 2023, 15:59:19 (UTC-07:00) 108.0 B
```

The bottom of the manifest file content is similar to the following.

```
{
  "entries": [
    ...
    {"url":"s3://amzn-s3-demo-bucket/partition/eventname=Zucchero/007_part_00", "meta":
  { "content_length": 108 }},
    {"url":"s3://amzn-s3-demo-bucket/partition/eventname=Zumanity/007_part_00", "meta":
  { "content_length": 72 }}
  ]
}
```

Unload EVENT table using MAXFILESIZE, ROWGROUPSIZE, and MANIFEST parameters

You can UNLOAD a table in parallel and generate a manifest file. The Amazon S3 data files are all created at the same level and names are suffixed with the pattern `0000_part_00`. The generated Parquet data files are limited to 256 MB and row group size 128 MB. The manifest file is at the same folder level as the data files and suffixed with `manifest`.

```
unload ('select * from myticket1.event')
to 's3://amzn-s3-demo-bucket/eventsize'
iam_role 'arn:aws:iam::123456789012:role/MyRedshiftRole'
maxfilesize 256 MB
rowgroupsize 128 MB
parallel on
parquet
manifest;
```

The Amazon S3 files listing is similar to the following.

Name	Type	Last modified	Size
eventsiz0000_part_00.parquet	parquet	August 2, 2023, 17:35:21 (UTC-07:00)	24.5 KB
eventsiz0001_part_00.parquet	parquet	August 2, 2023, 17:35:21 (UTC-07:00)	24.8 KB
eventsiz0002_part_00.parquet	parquet	August 2, 2023, 17:35:21 (UTC-07:00)	24.4 KB
eventsiz0003_part_00.parquet	parquet	August 2, 2023, 17:35:21 (UTC-07:00)	24.0 KB

```

UPDATE

Topics

- [Syntax](#)
- [Parameters](#)
- [Usage notes](#)
- [Examples of UPDATE statements](#)

Updates values in one or more table columns when a condition is satisfied.

Note

The maximum size for a single SQL statement is 16 MB.

Syntax

```
[ WITH [RECURSIVE] common_table_expression [, common_table_expression , ...] ]
    UPDATE table_name [ [ AS ] alias ] SET column = { expression | DEFAULT }
[ ,... ]

[ FROM fromlist ]
[ WHERE condition ]
```

Parameters

WITH clause

Optional clause that specifies one or more *common-table-expressions*. See [WITH clause](#).

table_name

A temporary or persistent table. Only the owner of the table or a user with UPDATE privilege on the table may update rows. If you use the FROM clause or select from tables in an expression or condition, you must have SELECT privilege on those tables. You can't give the table an alias here; however, you can specify an alias in the FROM clause.

Note

Amazon Redshift Spectrum external tables are read-only. You can't UPDATE an external table.

alias

Temporary alternative name for a target table. Aliases are optional. The AS keyword is always optional.

SET *column* =

One or more columns that you want to modify. Columns that aren't listed retain their current values. Do not include the table name in the specification of a target column. For example, `UPDATE tab SET tab.col = 1` is invalid.

expression

An expression that defines the new value for the specified column.

DEFAULT

Updates the column with the default value that was assigned to the column in the `CREATE TABLE` statement.

FROM *tablelist*

You can update a table by referencing information in other tables. List these other tables in the `FROM` clause or use a subquery as part of the `WHERE` condition. Tables listed in the `FROM` clause can have aliases. If you need to include the target table of the `UPDATE` statement in the list, use an alias.

WHERE *condition*

Optional clause that restricts updates to rows that match a condition. When the condition returns `true`, the specified `SET` columns are updated. The condition can be a simple predicate on a column or a condition based on the result of a subquery.

You can name any table in the subquery, including the target table for the `UPDATE`.

Usage notes

After updating a large number of rows in a table:

- Vacuum the table to reclaim storage space and re-sort rows.
- Analyze the table to update statistics for the query planner.

Left, right, and full outer joins aren't supported in the `FROM` clause of an `UPDATE` statement; they return the following error:

```
ERROR: Target table must be part of an equijoin predicate
```

If you need to specify an outer join, use a subquery in the WHERE clause of the UPDATE statement.

If your UPDATE statement requires a self-join to the target table, you need to specify the join condition, as well as the WHERE clause criteria that qualify rows for the update operation. In general, when the target table is joined to itself or another table, a best practice is to use a subquery that clearly separates the join conditions from the criteria that qualify rows for updates.

UPDATE queries with multiple matches per row throw an error when the configuration parameter `error_on_nondeterministic_update` is set to `true`. For more information, see [error_on_nondeterministic_update](#).

You can update a GENERATED BY DEFAULT AS IDENTITY column. Columns defined as GENERATED BY DEFAULT AS IDENTITY can be updated with values you supply. For more information, see [GENERATED BY DEFAULT AS IDENTITY](#).

Examples of UPDATE statements

For more information about the tables used in the following examples, see [Sample database](#).

The CATEGORY table in the TICKIT database contains the following rows:

```
+-----+-----+-----+-----+
| catid | catgroup | catname |          catdesc          |
+-----+-----+-----+-----+
| 5     | Sports  | MLS     | Major League Soccer      |
| 11    | Concerts | Classical | All symphony, concerto, and choir concerts |
| 1     | Sports  | MLB     | Major League Baseball    |
| 6     | Shows   | Musicals | Musical theatre          |
| 3     | Sports  | NFL     | National Football League |
| 8     | Shows   | Opera   | All opera and light opera |
| 2     | Sports  | NHL     | National Hockey League   |
| 9     | Concerts | Pop     | All rock and pop music concerts |
| 4     | Sports  | NBA     | National Basketball Association |
| 7     | Shows   | Plays   | All non-musical theatre  |
| 10    | Concerts | Jazz    | All jazz singers and bands |
+-----+-----+-----+-----+
```

Updating a table based on a range of values

Update the CATGROUP column based on a range of values in the CATID column.

```
UPDATE category
SET catgroup='Theatre'
```

```
WHERE catid BETWEEN 6 AND 8;
```

```
SELECT * FROM category
WHERE catid BETWEEN 6 AND 8;
```

```
+-----+-----+-----+-----+
| catid | catgroup | catname |          catdesc          |
+-----+-----+-----+-----+
| 6     | Theatre | Musicals | Musical theatre          |
| 7     | Theatre | Plays   | All non-musical theatre  |
| 8     | Theatre | Opera   | All opera and light opera |
+-----+-----+-----+-----+
```

Updating a table based on a current value

Update the CATNAME and CATDESC columns based on their current CATGROUP value:

```
UPDATE category
SET catdesc=default, catname='Shows'
WHERE catgroup='Theatre';
```

```
SELECT * FROM category
WHERE catname='Shows';
```

```
+-----+-----+-----+-----+
| catid | catgroup | catname | catdesc |
+-----+-----+-----+-----+
| 6     | Theatre | Shows   | NULL    |
| 7     | Theatre | Shows   | NULL    |
| 8     | Theatre | Shows   | NULL    |
+-----+-----+-----+-----+)
```

In this case, the CATDESC column was set to null because no default value was defined when the table was created.

Run the following commands to set the CATEGORY table data back to the original values:

```
TRUNCATE category;
```

```
COPY category
FROM 's3://redshift-downloads/tickit/category_pipe.txt'
DELIMITER '|'
IGNOREHEADER 1
```

```
REGION 'us-east-1'
IAM_ROLE default;
```

Updating a table based on the result of a WHERE clause subquery

Update the CATEGORY table based on the result of a subquery in the WHERE clause:

```
UPDATE category
SET catdesc='Broadway Musical'
WHERE category.catid IN
(SELECT category.catid FROM category
JOIN event ON category.catid = event.catid
JOIN venue ON venue.venueid = event.venueid
JOIN sales ON sales.eventid = event.eventid
WHERE venuecity='New York City' AND catname='Musicals');
```

View the updated table:

```
SELECT * FROM category ORDER BY catid;
```

catid	catgroup	catname	catdesc
2	Sports	NHL	National Hockey League
3	Sports	NFL	National Football League
4	Sports	NBA	National Basketball Association
5	Sports	MLS	Major League Soccer
6	Shows	Musicals	Broadway Musical
7	Shows	Plays	All non-musical theatre
8	Shows	Opera	All opera and light opera
9	Concerts	Pop	All rock and pop music concerts
10	Concerts	Jazz	All jazz singers and bands
11	Concerts	Classical	All symphony, concerto, and choir concerts

Updating a table based on the result of a WITH clause subquery

To update the CATEGORY table based on the result of a subquery using the WITH clause, use the following example.

```
WITH u1 as (SELECT catid FROM event ORDER BY catid DESC LIMIT 1)
UPDATE category SET catid='200' FROM u1 WHERE u1.catid=category.catid;
```

```
SELECT * FROM category ORDER BY catid DESC LIMIT 1;
```

```
+-----+-----+-----+-----+
| catid | catgroup | catname |          catdesc          |
+-----+-----+-----+-----+
| 200   | Concerts | Pop     | All rock and pop music concerts |
+-----+-----+-----+-----+
```

Updating a table based on the result of a join condition

Update the original 11 rows in the CATEGORY table based on matching CATID rows in the EVENT table:

```
UPDATE category SET catid=100
FROM event
WHERE event.catid=category.catid;
```

```
SELECT * FROM category ORDER BY catid;
```

```
+-----+-----+-----+-----+
| catid | catgroup | catname |          catdesc          |
+-----+-----+-----+-----+
| 2     | Sports   | NHL     | National Hockey League   |
| 3     | Sports   | NFL     | National Football League |
| 4     | Sports   | NBA     | National Basketball Association |
| 5     | Sports   | MLS     | Major League Soccer      |
| 10    | Concerts | Jazz    | All jazz singers and bands |
| 11    | Concerts | Classical | All symphony, concerto, and choir concerts |
| 100   | Concerts | Pop     | All rock and pop music concerts |
| 100   | Shows    | Plays   | All non-musical theatre   |
| 100   | Shows    | Opera   | All opera and light opera |
| 100   | Shows    | Musicals | Broadway Musical         |
+-----+-----+-----+-----+
```

Note that the EVENT table is listed in the FROM clause and the join condition to the target table is defined in the WHERE clause. Only four rows qualified for the update. These four rows are the rows whose CATID values were originally 6, 7, 8, and 9; only those four categories are represented in the EVENT table:

```
SELECT DISTINCT catid FROM event;
```

```
+-----+
```

```

| catid |
+-----+
| 6     |
| 7     |
| 8     |
| 9     |
+-----+

```

Update the original 11 rows in the CATEGORY table by extending the previous example and adding another condition to the WHERE clause. Because of the restriction on the CATGROUP column, only one row qualifies for the update (although four rows qualify for the join).

```

UPDATE category SET catid=100
FROM event
WHERE event.catid=category.catid
AND catgroup='Concerts';

SELECT * FROM category WHERE catid=100;

```

```

+-----+-----+-----+-----+
| catid | catgroup | catname |          catdesc          |
+-----+-----+-----+-----+
| 100   | Concerts | Pop     | All rock and pop music concerts |
+-----+-----+-----+-----+

```

An alternative way to write this example is as follows:

```

UPDATE category SET catid=100
FROM event JOIN category cat ON event.catid=cat.catid
WHERE cat.catgroup='Concerts';

```

The advantage to this approach is that the join criteria are clearly separated from any other criteria that qualify rows for the update. Note the use of the alias CAT for the CATEGORY table in the FROM clause.

Updates with outer joins in the FROM clause

The previous example showed an inner join specified in the FROM clause of an UPDATE statement. The following example returns an error because the FROM clause does not support outer joins to the target table:

```

UPDATE category SET catid=100

```

```
FROM event LEFT JOIN category cat ON event.catid=cat.catid
WHERE cat.catgroup='Concerts';
ERROR: Target table must be part of an equijoin predicate
```

If the outer join is required for the UPDATE statement, you can move the outer join syntax into a subquery:

```
UPDATE category SET catid=100
FROM
(SELECT event.catid FROM event LEFT JOIN category cat ON event.catid=cat.catid)
  eventcat
WHERE category.catid=eventcat.catid
AND catgroup='Concerts';
```

Updates with columns from another table in the SET clause

To update the listing table in the TICKIT sample database with values from the sales table, use the following example.

```
SELECT listid, numtickets FROM listing WHERE sellerid = 1 ORDER BY 1 ASC LIMIT 5;
```

```
+-----+-----+
| listid | numtickets |
+-----+-----+
| 100423 | 4          |
| 108334 | 24         |
| 117150 | 4          |
| 135915 | 20         |
| 205927 | 6          |
+-----+-----+
```

```
UPDATE listing
SET numtickets = sales.sellerid
FROM sales
WHERE sales.sellerid = 1 AND listing.sellerid = sales.sellerid;
```

```
SELECT listid, numtickets FROM listing WHERE sellerid = 1 ORDER BY 1 ASC LIMIT 5;
```

```
+-----+-----+
| listid | numtickets |
+-----+-----+
| 100423 | 1          |
| 108334 | 1          |
```

```

| 117150 | 1 |
| 135915 | 1 |
| 205927 | 1 |
+-----+-----+

```

VACUUM

Re-sorts rows and reclaims space in either a specified table or all tables in the current database.

Note

Only users with the necessary table permissions can effectively vacuum a table. If `VACUUM` is run without the necessary table permissions, the operation completes successfully but has no effect. For a list of valid table permissions to effectively run `VACUUM`, see the following [Required privileges](#) section.

Amazon Redshift automatically sorts data and runs `VACUUM DELETE` in the background. This lessens the need to run the `VACUUM` command. For more information, see [Vacuuming tables](#).

By default, `VACUUM` skips the sort phase for any table where more than 95 percent of the table's rows are already sorted. Skipping the sort phase can significantly improve `VACUUM` performance. To change the default sort or delete threshold for a single table, include the table name and the `TO threshold PERCENT` parameter when you run `VACUUM`.

Users can access tables while they are being vacuumed. You can perform queries and write operations while a table is being vacuumed, but when data manipulation language (DML) commands and a vacuum run concurrently, both might take longer. If you run `UPDATE` and `DELETE` statements during a vacuum, system performance might be reduced. `VACUUM DELETE` temporarily blocks update and delete operations.

Amazon Redshift automatically performs a `DELETE ONLY` vacuum in the background. Automatic vacuum operation pauses when users run data definition language (DDL) operations, such as `ALTER TABLE`.

Note

The Amazon Redshift `VACUUM` command syntax and behavior are substantially different from the PostgreSQL `VACUUM` operation. For example, the default `VACUUM` operation in Amazon Redshift is `VACUUM FULL`, which reclaims disk space and re-sorts all rows. In

contrast, the default VACUUM operation in PostgreSQL simply reclaims space and makes it available for reuse.

For more information, see [Vacuuming tables](#).

Required privileges

Following are required privileges for VACUUM:

- Superuser
- Users with the VACUUM privilege
- Table owner
- Database owner whom the table is shared to

Syntax

```
VACUUM [ FULL | SORT ONLY | DELETE ONLY | REINDEX | RECLUSTER ]  
[ [ table_name ] [ TO threshold PERCENT ] [ BOOST ] ]
```

Parameters

FULL

Sorts the specified table (or all tables in the current database) and reclaims disk space occupied by rows that were marked for deletion by previous UPDATE and DELETE operations. VACUUM FULL is the default.

A full vacuum doesn't perform a reindex for interleaved tables. To reindex interleaved tables followed by a full vacuum, use the [VACUUM REINDEX](#) option.

By default, VACUUM FULL skips the sort phase for any table that is already at least 95 percent sorted. If VACUUM is able to skip the sort phase, it performs a DELETE ONLY and reclaims space in the delete phase such that at least 95 percent of the remaining rows aren't marked for deletion.

If the sort threshold isn't met (for example, if 90 percent of rows are sorted) and VACUUM performs a full sort, then it also performs a complete delete operation, recovering space from 100 percent of deleted rows.

You can change the default vacuum threshold only for a single table. To change the default vacuum threshold for a single table, include the table name and the `TO threshold PERCENT` parameter.

SORT ONLY

Sorts the specified table (or all tables in the current database) without reclaiming space freed by deleted rows. This option is useful when reclaiming disk space isn't important but re-sorting new rows is important. A `SORT ONLY` vacuum reduces the elapsed time for vacuum operations when the unsorted region doesn't contain a large number of deleted rows and doesn't span the entire sorted region. Applications that don't have disk space constraints but do depend on query optimizations associated with keeping table rows sorted can benefit from this kind of vacuum.

By default, `VACUUM SORT ONLY` skips any table that is already at least 95 percent sorted. To change the default sort threshold for a single table, include the table name and the `TO threshold PERCENT` parameter when you run `VACUUM`.

DELETE ONLY

Amazon Redshift automatically performs a `DELETE ONLY` vacuum in the background, so you rarely, if ever, need to run a `DELETE ONLY` vacuum.

A `VACUUM DELETE` reclaims disk space occupied by rows that were marked for deletion by previous `UPDATE` and `DELETE` operations, and compacts the table to free up the consumed space. A `DELETE ONLY` vacuum operation doesn't sort table data.

This option reduces the elapsed time for vacuum operations when reclaiming disk space is important but re-sorting new rows isn't important. This option can also be useful when your query performance is already optimal, and re-sorting rows to optimize query performance isn't a requirement.

By default, `VACUUM DELETE ONLY` reclaims space such that at least 95 percent of the remaining rows aren't marked for deletion. To change the default delete threshold for a single table, include the table name and the `TO threshold PERCENT` parameter when you run `VACUUM`.

Some operations, such as `ALTER TABLE APPEND`, can cause tables to be fragmented. When you use the `DELETE ONLY` clause the vacuum operation reclaims space from fragmented tables. The same threshold value of 95 percent applies to the defragmentation operation.

REINDEX *tablename*

Analyzes the distribution of the values in interleaved sort key columns, then performs a full VACUUM operation. If REINDEX is used, a table name is required.

VACUUM REINDEX takes significantly longer than VACUUM FULL because it makes an additional pass to analyze the interleaved sort keys. The sort and merge operation can take longer for interleaved tables because the interleaved sort might need to rearrange more rows than a compound sort.

If a VACUUM REINDEX operation terminates before it completes, the next VACUUM resumes the reindex operation before performing the full vacuum operation.

VACUUM REINDEX isn't supported with TO *threshold* PERCENT.

table_name

The name of a table to vacuum. If you don't specify a table name, the vacuum operation applies to all tables in the current database. You can specify any permanent or temporary user-created table. The command isn't meaningful for other objects, such as views and system tables.

If you include the TO *threshold* PERCENT parameter, a table name is required.

RECLUSTER *tablename*

Sorts the portions of the table that are unsorted. Portions of the table that are already sorted by automatic table sort are left intact. This command doesn't merge the newly sorted data with the sorted region. It also doesn't reclaim all space that is marked for deletion. When this command completes, the table might not appear fully sorted, as indicated by the `unsorted` field in `SVV_TABLE_INFO`.

We recommend that you use VACUUM RECLUSTER for large tables with frequent ingestion and queries that access only the most recent data.

VACUUM RECLUSTER isn't supported with TO *threshold* PERCENT. If RECLUSTER is used, a table name is required.

VACUUM RECLUSTER isn't supported on tables with interleaved sort keys and tables with ALL distribution style.

table_name

The name of a table to vacuum. You can specify any permanent or temporary user-created table. The command isn't meaningful for other objects, such as views and system tables.

TO *threshold* PERCENT

A clause that specifies the threshold above which VACUUM skips the sort phase and the target threshold for reclaiming space in the delete phase. The *sort threshold* is the percentage of total rows that are already in sort order for the specified table prior to vacuuming. The *delete threshold* is the minimum percentage of total rows not marked for deletion after vacuuming.

Because VACUUM re-sorts the rows only when the percent of sorted rows in a table is less than the sort threshold, Amazon Redshift can often reduce VACUUM times significantly. Similarly, when VACUUM isn't constrained to reclaim space from 100 percent of rows marked for deletion, it is often able to skip rewriting blocks that contain only a few deleted rows.

For example, if you specify 75 for *threshold*, VACUUM skips the sort phase if 75 percent or more of the table's rows are already in sort order. For the delete phase, VACUUMS sets a target of reclaiming disk space such that at least 75 percent of the table's rows aren't marked for deletion following the vacuum. The *threshold* value must be an integer between 0 and 100. The default is 95. If you specify a value of 100, VACUUM always sorts the table unless it's already fully sorted and reclaims space from all rows marked for deletion. If you specify a value of 0, VACUUM never sorts the table and never reclaims space.

If you include the TO *threshold* PERCENT parameter, you must also specify a table name. If a table name is omitted, VACUUM fails.

You can't use the TO *threshold* PERCENT parameter with REINDEX.

BOOST

Runs the VACUUM command with additional resources, such as memory and disk space, as they're available. With the BOOST option, VACUUM operates in one window and blocks concurrent deletes and updates for the duration of the VACUUM operation. Running with the BOOST option contends for system resources, which might affect query performance. Run the VACUUM BOOST when the load on the system is light, such as during maintenance operations.

Consider the following when using the BOOST option:

- When BOOST is specified, the *table_name* value is required.
- BOOST isn't supported with REINDEX.
- BOOST is ignored with DELETE ONLY.

Usage notes

For most Amazon Redshift applications, a full vacuum is recommended. For more information, see [Vacuuming tables](#).

Before running a vacuum operation, note the following behavior:

- You can't run VACUUM within a transaction block (BEGIN ... END). For more information about transactions, see [Serializable isolation](#).
- You can run only one VACUUM command on a cluster at any given time. If you attempt to run multiple vacuum operations concurrently, Amazon Redshift returns an error.
- Some amount of table growth might occur when tables are vacuumed. This behavior is expected when there are no deleted rows to reclaim or the new sort order of the table results in a lower ratio of data compression.
- During vacuum operations, some degree of query performance degradation is expected. Normal performance resumes as soon as the vacuum operation is complete.
- Concurrent write operations proceed during vacuum operations, but we don't recommend performing write operations while vacuuming. It's more efficient to complete write operations before running the vacuum. Also, any data that is written after a vacuum operation has been started can't be vacuumed by that operation. In this case, a second vacuum operation is necessary.
- A vacuum operation might not be able to start if a load or insert operation is already in progress. Vacuum operations temporarily require exclusive access to tables in order to start. This exclusive access is required briefly, so vacuum operations don't block concurrent loads and inserts for any significant period of time.
- Vacuum operations are skipped when there is no work to do for a particular table; however, there is some overhead associated with discovering that the operation can be skipped. If you know that a table is pristine or doesn't meet the vacuum threshold, don't run a vacuum operation against it.
- A DELETE ONLY vacuum operation on a small table might not reduce the number of blocks used to store the data, especially when the table has a large number of columns or the cluster uses a large number of slices per node. These vacuum operations add one block per column per slice to account for concurrent inserts into the table, and there is potential for this overhead to outweigh the reduction in block count from the reclaimed disk space. For example, if a 10-column table on an 8-node cluster occupies 1000 blocks before a vacuum, the vacuum doesn't reduce the actual block count unless more than 80 blocks of disk space are reclaimed because of deleted rows. (Each data block uses 1 MB.)

Automatic vacuum operations pause if any of the following conditions are met:

- A user runs a data definition language (DDL) operation, such as ALTER TABLE, that requires an exclusive lock on a table that automatic vacuum is currently working on.
- A user triggers VACUUM on any table in the cluster (only one VACUUM can run at a time).
- A period of high cluster load.

Examples

Reclaim space and database and re-sort rows in all tables based on the default 95 percent vacuum threshold.

```
vacuum;
```

Reclaim space and re-sort rows in the SALES table based on the default 95 percent threshold.

```
vacuum sales;
```

Always reclaim space and re-sort rows in the SALES table.

```
vacuum sales to 100 percent;
```

Re-sort rows in the SALES table only if fewer than 75 percent of rows are already sorted.

```
vacuum sort only sales to 75 percent;
```

Reclaim space in the SALES table such that at least 75 percent of the remaining rows aren't marked for deletion following the vacuum.

```
vacuum delete only sales to 75 percent;
```

Reindex and then vacuum the LISTING table.

```
vacuum reindex listing;
```

The following command returns an error.

```
vacuum reindex listing to 75 percent;
```

Recluster and then vacuum the LISTING table.

```
vacuum recluster listing;
```

Recluster and then vacuum the LISTING table with the BOOST option.

```
vacuum recluster listing boost;
```

Amazon Redshift supports a number of functions that are extensions to the SQL standard, as well as standard aggregate functions, scalar functions, and window functions.

Note

Amazon Redshift is based on PostgreSQL. Amazon Redshift and PostgreSQL have a number of very important differences that you must be aware of as you design and develop your data warehouse applications. For more information about how Amazon Redshift SQL differs from PostgreSQL, see [Amazon Redshift and PostgreSQL](#).

Leader node–only functions

Some Amazon Redshift queries are distributed and run on the compute nodes; other queries run exclusively on the leader node.

The leader node distributes SQL to the compute nodes when a query references user-created tables or system tables (tables with an STL or STV prefix and system views with an SVL or SVV prefix). A query that references only catalog tables (tables with a PG prefix, such as PG_TABLE_DEF) or that does not reference any tables, runs exclusively on the leader node.

Some Amazon Redshift SQL functions are supported only on the leader node and are not supported on the compute nodes. A query that uses a leader-node function must run exclusively on the leader node, not on the compute nodes, or it will return an error.

The documentation for each leader-node only function includes a note stating that the function will return an error if it references user-defined tables or Amazon Redshift system tables.

For more information, see [SQL functions supported on the leader node](#).

The following SQL functions are leader-node only functions and are not supported on the compute nodes:

System information functions

- CURRENT_SCHEMA
- CURRENT_SCHEMAS

- HAS_DATABASE_PRIVILEGE
- HAS_SCHEMA_PRIVILEGE
- HAS_TABLE_PRIVILEGE

String functions

- SUBSTR

Math functions

- FACTORIAL()

The following leader-node only functions are deprecated and are no longer supported:

Date functions

- AGE
- CURRENT_TIME
- CURRENT_TIMESTAMP
- LOCALTIME
- ISFINITE
- NOW

String functions

- GETBIT
- GET_BYTE
- SET_BIT
- SET_BYTE
- TO_ASCII

Aggregate functions

Topics

- [ANY_VALUE function](#)
- [APPROXIMATE PERCENTILE_DISC function](#)
- [AVG function](#)
- [COUNT function](#)
- [LISTAGG function](#)
- [MAX function](#)
- [MEDIAN function](#)
- [MIN function](#)
- [PERCENTILE_CONT function](#)
- [STDDEV_SAMP and STDDEV_POP functions](#)
- [SUM function](#)
- [VAR_SAMP and VAR_POP functions](#)

Aggregate functions compute a single result value from a set of input values.

SELECT statements using aggregate functions can include two optional clauses: GROUP BY and HAVING. The syntax for these clauses is as follows (using the COUNT function as an example):

```
SELECT count (*) expression FROM table_reference
WHERE condition [GROUP BY expression ] [ HAVING condition]
```

The GROUP BY clause aggregates and groups results by the unique values in a specified column or columns. The HAVING clause restricts the results returned to rows where a particular aggregate condition is true, such as count (*) > 1. The HAVING clause is used in the same way as WHERE to restrict rows based on the value of a column. For an example of these additional clauses, see the [COUNT](#).

Aggregate functions don't accept nested aggregate functions or window functions as arguments.

ANY_VALUE function

The ANY_VALUE function returns any value from the input expression values nondeterministically. This function returns NULL if the input expression doesn't result in any rows being returned. The function can also return NULL if there are NULL values in the input expression.

Syntax

```
ANY_VALUE( [ DISTINCT | ALL ] expression )
```

Arguments

DISTINCT | ALL

Specify either DISTINCT or ALL to return any value from the input expression values. The DISTINCT argument has no effect and is ignored.

expression

The target column or expression on which the function operates. The *expression* is one of the following data types:

- SMALLINT
- INTEGER
- BIGINT
- DECIMAL
- REAL
- DOUBLE PRECISION
- BOOLEAN
- CHAR
- VARCHAR
- DATE
- TIMESTAMP
- TIMESTAMPTZ
- TIME
- TIMETZ
- INTERVAL YEAR TO MONTH
- INTERVAL DAY TO SECOND
- VARBYTE
- SUPER
- HLLSKETCH
- GEOMETRY

- GEOGRAPHY

Returns

Returns the same data type as *expression*.

Usage notes

If a statement that specifies the ANY_VALUE function for a column also includes a second column reference, the second column must appear in a GROUP BY clause or be included in an aggregate function.

Examples

The examples use the event table that is created in [Step 4: Load sample data from Amazon S3](#) in the *Amazon Redshift Getting Started Guide*. The following example returns an instance of any dateid where the eventname is Eagles.

```
select any_value(dateid) as dateid, eventname from event where eventname = 'Eagles'
group by eventname;
```

Following are the results.

```
dateid | eventname
-----+-----
 1878  | Eagles
```

The following example returns an instance of any dateid where the eventname is Eagles or Cold War Kids.

```
select any_value(dateid) as dateid, eventname from event where eventname in('Eagles',
'Cold War Kids') group by eventname;
```

Following are the results.

```
dateid | eventname
-----+-----
 1922  | Cold War Kids
 1878  | Eagles
```

APPROXIMATE PERCENTILE_DISC function

APPROXIMATE PERCENTILE_DISC is an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the given set. Approximation enables the function to run much faster, with a low relative error of around 0.5 percent.

For a given *percentile* value, APPROXIMATE PERCENTILE_DISC uses a quantile summary algorithm to approximate the discrete percentile of the expression in the ORDER BY clause. APPROXIMATE PERCENTILE_DISC returns the value with the smallest cumulative distribution value (with respect to the same sort specification) that is greater than or equal to *percentile*.

Syntax

```
APPROXIMATE PERCENTILE_DISC ( percentile )  
WITHIN GROUP (ORDER BY expr)
```

Arguments

percentile

Numeric constant between 0 and 1. Nulls are ignored in the calculation.

WITHIN GROUP (ORDER BY *expr*)

Clause that specifies numeric or date/time values to sort and compute the percentile over.

Returns

The same data type as the ORDER BY expression in the WITHIN GROUP clause.

Usage notes

If the APPROXIMATE PERCENTILE_DISC statement includes a GROUP BY clause, the result set is limited. The limit varies based on node type and the number of nodes. If the limit is exceeded, the function fails and returns the following error.

```
GROUP BY limit for approximate percentile_disc exceeded.
```

If you need to evaluate more groups than the limit permits, consider using [PERCENTILE_CONT function](#).

Examples

The following example returns the number of sales, total sales, and fiftieth percentile value for the top 10 dates.

```
select top 10 date.caldate,
count(totalprice), sum(totalprice),
approximate percentile_disc(0.5)
within group (order by totalprice)
from listing
join date on listing.dateid = date.dateid
group by date.caldate
order by 3 desc;
```

caldate	count	sum	percentile_disc
2008-01-07	658	2081400.00	2020.00
2008-01-02	614	2064840.00	2178.00
2008-07-22	593	1994256.00	2214.00
2008-01-26	595	1993188.00	2272.00
2008-02-24	655	1975345.00	2070.00
2008-02-04	616	1972491.00	1995.00
2008-02-14	628	1971759.00	2184.00
2008-09-01	600	1944976.00	2100.00
2008-07-29	597	1944488.00	2106.00
2008-07-23	592	1943265.00	1974.00

AVG function

The AVG function returns the average (arithmetic mean) of the input expression values. The AVG function works with numeric values and ignores NULL values.

Syntax

```
AVG ( [ DISTINCT | ALL ] expression )
```

Arguments

expression

The target column or expression that the function operates on. The *expression* is one of the following data types:

- SMALLINT
- INTEGER
- BIGINT
- NUMERIC
- DECIMAL
- REAL
- DOUBLE PRECISION
- SUPER

DISTINCT | ALL

With the argument `DISTINCT`, the function eliminates all duplicate values from the specified expression before calculating the average. With the argument `ALL`, the function retains all duplicate values from the expression for calculating the average. `ALL` is the default.

Data types

The argument types supported by the `AVG` function are `SMALLINT`, `INTEGER`, `BIGINT`, `NUMERIC`, `DECIMAL`, `REAL`, `DOUBLE PRECISION`, and `SUPER`.

The return types supported by the `AVG` function are:

- `BIGINT` for any integer type argument
- `DOUBLE PRECISION` for a floating point argument
- Returns the same data type as expression for any other argument type.

The default precision for an `AVG` function result with a `NUMERIC` or `DECIMAL` argument is 38. The scale of the result is the same as the scale of the argument. For example, an `AVG` of a `DEC(5,2)` column returns a `DEC(38,2)` data type.

Examples

Find the average quantity sold per transaction from the `SALES` table:

```
select avg(qtysold)from sales;  
  
avg
```

```

-----
2
(1 row)

```

Find the average total price listed for all listings:

```

select avg(numtickets*priceperticket) as avg_total_price from listing;

avg_total_price
-----
3034.41
(1 row)

```

Find the average price paid, grouped by month in descending order:

```

select avg(pricepaid) as avg_price, month
from sales, date
where sales.dateid = date.dateid
group by month
order by avg_price desc;

avg_price | month
-----+-----
659.34 | MAR
655.06 | APR
645.82 | JAN
643.10 | MAY
642.72 | JUN
642.37 | SEP
640.72 | OCT
640.57 | DEC
635.34 | JUL
635.24 | FEB
634.24 | NOV
632.78 | AUG
(12 rows)

```

COUNT function

The COUNT function counts the rows defined by the expression.

The COUNT function has the following variations.

- `COUNT (*)` counts all the rows in the target table whether they include nulls or not.
- `COUNT (expression)` computes the number of rows with non-NULL values in a specific column or expression.
- `COUNT (DISTINCT expression)` computes the number of distinct non-NULL values in a column or expression.
- `APPROXIMATE COUNT DISTINCT` approximates the number of distinct non-NULL values in a column or expression.

Syntax

```
COUNT( * | expression )
```

```
COUNT ( [ DISTINCT | ALL ] expression )
```

```
APPROXIMATE COUNT ( DISTINCT expression )
```

Arguments

expression

The target column or expression that the function operates on. The `COUNT` function supports all argument data types.

DISTINCT | ALL

With the argument `DISTINCT`, the function eliminates all duplicate values from the specified expression before doing the count. With the argument `ALL`, the function retains all duplicate values from the expression for counting. `ALL` is the default.

APPROXIMATE

When used with `APPROXIMATE`, a `COUNT DISTINCT` function uses a HyperLogLog algorithm to approximate the number of distinct non-NULL values in a column or expression. Queries that use the `APPROXIMATE` keyword run much faster, with a low relative error of around 2%. Approximation is warranted for queries that return a large number of distinct values, in the millions or more per query, or per group, if there is a group by clause. For smaller sets of distinct values, in the thousands, approximation might be slower than a precise count. `APPROXIMATE` can only be used with `COUNT DISTINCT`.

Return type

The COUNT function returns BIGINT.

Examples

Count all of the users from the state of Florida:

```
select count(*) from users where state='FL';
```

```
count
-----
510
```

Count all of the event names from the EVENT table:

```
select count(eventname) from event;
```

```
count
-----
8798
```

Count all of the event names from the EVENT table:

```
select count(all eventname) from event;
```

```
count
-----
8798
```

Count all of the unique venue IDs from the EVENT table:

```
select count(distinct venueid) as venues from event;
```

```
venues
-----
204
```

Count the number of times each seller listed batches of more than four tickets for sale. Group the results by seller ID:

```
select count(*), sellerid from listing
```

```
where numtickets > 4
group by sellerid
order by 1 desc, 2;
```

```
count | sellerid
-----+-----
12    |    6386
11    |   17304
11    |   20123
11    |   25428
...   |
```

The following examples compare the return values and execution times for COUNT and APPROXIMATE COUNT.

```
select count(distinct pricepaid) from sales;
```

```
count
-----
 4528
```

Time: 48.048 ms

```
select approximate count(distinct pricepaid) from sales;
```

```
count
-----
 4553
```

Time: 21.728 ms

LISTAGG function

For each group in a query, the LISTAGG aggregate function orders the rows for that group according to the ORDER BY expression, then concatenates the values into a single string.

Syntax

```
LISTAGG( [DISTINCT] aggregate_expression [, 'delimiter' ] )
```

```
[ WITHIN GROUP (ORDER BY order_list) ]
```

Arguments

DISTINCT

A clause that eliminates duplicate values from the specified expression before concatenating. Trailing spaces are ignored. For example, the strings ' a ' and ' a ' are treated as duplicates. LISTAGG uses the first value encountered. For more information, see [Significance of trailing blanks](#).

aggregate_expression

Any valid expression, such as a column name, that provides the values to aggregate. NULL values and empty strings are ignored.

delimiter

The string constant to separate the concatenated values. The default is NULL.

WITHIN GROUP (ORDER BY order_list)

A clause that specifies the sort order of the aggregated values.

Returns

VARCHAR(MAX). If the result set is larger than the maximum VARCHAR size, LISTAGG returns the following error:

```
Invalid operation: Result size exceeds LISTAGG limit
```

Usage notes

- If a statement includes multiple LISTAGG functions that use WITHIN GROUP clauses, each WITHIN GROUP clause must use the same ORDER BY values.

For example, the following statement returns an error.

```
SELECT LISTAGG(sellerid)
WITHIN GROUP (ORDER BY dateid) AS sellers,
LISTAGG(dateid)
WITHIN GROUP (ORDER BY sellerid) AS dates
FROM sales;
```

The following statements runs successfully.

```
SELECT LISTAGG(sellerid)
WITHIN GROUP (ORDER BY dateid) AS sellers,
LISTAGG(dateid)
WITHIN GROUP (ORDER BY dateid) AS dates
FROM sales;

SELECT LISTAGG(sellerid)
WITHIN GROUP (ORDER BY dateid) AS sellers,
LISTAGG(dateid) AS dates
FROM sales;
```

Examples

The following example aggregates seller IDs, ordered by seller ID.

```
SELECT LISTAGG(sellerid, ', ')
WITHIN GROUP (ORDER BY sellerid)
FROM sales
WHERE eventid = 4337;
```

listagg

380, 380, 1178, 1178, 1178, 2731, 8117, 12905, 32043, 32043, 32043, 32432, 32432,
38669, 38750, 41498, 45676, 46324, 47188, 47188, 48294

The following example uses DISTINCT to return a list of unique seller IDs.

```
SELECT LISTAGG(DISTINCT sellerid, ', ')
WITHIN GROUP (ORDER BY sellerid)
FROM sales
WHERE eventid = 4337;
```

listagg

380, 1178, 2731, 8117, 12905, 32043, 32432, 38669, 38750, 41498, 45676, 46324, 47188,
48294

The following example aggregates seller IDs in date order.

```
SELECT LISTAGG(sellerid, ', ')
WITHIN GROUP (ORDER BY dateid)
FROM sales
WHERE eventid = 4337;
```

listagg

```
41498, 47188, 47188, 1178, 1178, 1178, 380, 45676, 46324, 48294, 32043, 32043, 32432,
12905, 8117, 38750, 2731, 32432, 32043, 380, 38669
```

The following example returns a pipe-separated list of sales dates for the buyer with an ID of 660.

```
SELECT LISTAGG(
    (SELECT caldate FROM date WHERE date.dateid=sales.dateid), ' | '
)
WITHIN GROUP (ORDER BY sellerid DESC, salesid ASC)
FROM sales
WHERE buyerid = 660;
```

listagg

```
2008-07-16 | 2008-07-09 | 2008-01-01 | 2008-10-26
```

The following example returns a comma-separated list of sales IDs for the buyer IDs 660, 661, and 662.

```
SELECT buyerid,
LISTAGG(salesid,', ')
WITHIN GROUP (ORDER BY salesid) AS sales_id
FROM sales
WHERE buyerid BETWEEN 660 AND 662
GROUP BY buyerid
ORDER BY buyerid;
```

buyerid	sales_id
660	32872, 33095, 33514, 34548
661	19951, 20517, 21695, 21931
662	3318, 3823, 4215, 51980, 53202, 55908, 57832, 171603

MAX function

The MAX function returns the maximum value in a set of rows. DISTINCT or ALL might be used but do not affect the result.

Syntax

```
MAX ( [ DISTINCT | ALL ] expression )
```

Arguments

expression

The target column or expression that the function operates on. The *expression* is one of the following data types:

- SMALLINT
- INTEGER
- BIGINT
- DECIMAL
- REAL
- DOUBLE PRECISION
- CHAR
- VARCHAR
- DATE
- TIMESTAMP
- TIMESTAMPTZ
- TIME
- TIMETZ
- VARBYTE
- SUPER

DISTINCT | ALL

With the argument DISTINCT, the function eliminates all duplicate values from the specified expression before calculating the maximum. With the argument ALL, the function retains all duplicate values from the expression for calculating the maximum. ALL is the default.

Data types

Returns the same data type as *expression*. The Boolean equivalent of the MIN function is the [BOOL_AND function](#), and the Boolean equivalent of MAX is the [BOOL_OR function](#).

Examples

Find the highest price paid from all sales:

```
select max(pricepaid) from sales;
```

```
max
-----
12624.00
(1 row)
```

Find the highest price paid per ticket from all sales:

```
select max(pricepaid/qtysold) as max_ticket_price
from sales;
```

```
max_ticket_price
-----
2500.000000000
(1 row)
```

MEDIAN function

Calculates the median value for the range of values. NULL values in the range are ignored.

MEDIAN is an inverse distribution function that assumes a continuous distribution model.

MEDIAN is a special case of [PERCENTILE_CONT](#).

Syntax

```
MEDIAN(median_expression)
```

Arguments

median_expression

The target column or expression that the function operates on.

Data types

The return type is determined by the data type of *median_expression*. The following table shows the return type for each *median_expression* data type.

Input type	Return type
INT2, INT4, INT8, NUMERIC, DECIMAL	DECIMAL
FLOAT, DOUBLE	DOUBLE
DATE	DATE
TIMESTAMP	TIMESTAMP
TIMESTAMPTZ	TIMESTAMPTZ

Usage notes

If the *median_expression* argument is a DECIMAL data type defined with the maximum precision of 38 digits, it is possible that MEDIAN will return either an inaccurate result or an error. If the return value of the MEDIAN function exceeds 38 digits, the result is truncated to fit, which causes a loss of precision. If, during interpolation, an intermediate result exceeds the maximum precision, a numeric overflow occurs and the function returns an error. To avoid these conditions, we recommend either using a data type with lower precision or casting the *median_expression* argument to a lower precision.

If a statement includes multiple calls to sort-based aggregate functions (LISTAGG, PERCENTILE_CONT, or MEDIAN), they must all use the same ORDER BY values. Note that MEDIAN applies an implicit order by on the expression value.

For example, the following statement returns an error.

```
SELECT TOP 10 salesid, SUM(pricepaid),
PERCENTILE_CONT(0.6) WITHIN GROUP(ORDER BY salesid),
MEDIAN(pricepaid)
FROM sales
GROUP BY salesid, pricepaid;
```

An error occurred when executing the SQL command:

```
SELECT TOP 10 salesid, SUM(pricepaid),
PERCENTILE_CONT(0.6) WITHIN GROUP(ORDER BY salesid),
MEDIAN(pricepaid)
FROM sales
GROUP BY salesid, pricepaid;
```

ERROR: within group ORDER BY clauses for aggregate functions must be the same

The following statement runs successfully.

```
SELECT TOP 10 salesid, SUM(pricepaid),
PERCENTILE_CONT(0.6) WITHIN GROUP(ORDER BY salesid),
MEDIAN(salesid)
FROM sales
GROUP BY salesid, pricepaid;
```

Examples

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

The following example shows that MEDIAN produces the same results as PERCENTILE_CONT(0.5).

```
SELECT TOP 10 DISTINCT sellerid, qtysold,
PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY qtysold),
MEDIAN(qtysold)
FROM sales
GROUP BY sellerid, qtysold;
```

sellerid	qtysold	percentile_cont	median
2	2	2	2
26	1	1	1
33	1	1	1
38	1	1	1
43	1	1	1
48	2	2	2
48	3	3	3
77	4	4	4
85	4	4	4
95	2	2	2

```
+-----+-----+-----+-----+
```

The following example finds the median quantity sold for each sellerid.

```
SELECT sellerid,
MEDIAN(qtysold)
FROM sales
GROUP BY sellerid
ORDER BY sellerid
LIMIT 10;
```

```
+-----+-----+
| sellerid | median |
+-----+-----+
|         1 |     1.5 |
|         2 |         2 |
|         3 |         2 |
|         4 |         2 |
|         5 |         1 |
|         6 |         1 |
|         7 |     1.5 |
|         8 |         1 |
|         9 |         4 |
|        12 |         2 |
+-----+-----+
```

To verify the results of the previous query for the first sellerid, use the following example.

```
SELECT qtysold
FROM sales
WHERE sellerid=1;
```

```
+-----+
| qtysold |
+-----+
|         2 |
|         1 |
+-----+
```

MIN function

The MIN function returns the minimum value in a set of rows. DISTINCT or ALL might be used but do not affect the result.

Syntax

```
MIN ( [ DISTINCT | ALL ] expression )
```

Arguments

expression

The target column or expression that the function operates on. The *expression* is one of the following data types:

- SMALLINT
- INTEGER
- BIGINT
- DECIMAL
- REAL
- DOUBLE PRECISION
- CHAR
- VARCHAR
- DATE
- TIMESTAMP
- TIMESTAMPTZ
- TIME
- TIMETZ
- VARBYTE
- SUPER

DISTINCT | ALL

With the argument DISTINCT, the function eliminates all duplicate values from the specified expression before calculating the minimum. With the argument ALL, the function retains all duplicate values from the expression for calculating the minimum. ALL is the default.

Data types

Returns the same data type as *expression*. The Boolean equivalent of the MIN function is [BOOL_AND function](#), and the Boolean equivalent of MAX is [BOOL_OR function](#).

Examples

Find the lowest price paid from all sales:

```
select min(pricepaid) from sales;
```

```
min
-----
20.00
(1 row)
```

Find the lowest price paid per ticket from all sales:

```
select min(pricepaid/qtysold)as min_ticket_price
from sales;
```

```
min_ticket_price
-----
20.000000000
(1 row)
```

PERCENTILE_CONT function

PERCENTILE_CONT is an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification, and returns an interpolated value that would fall into the given percentile value with respect to the sort specification.

PERCENTILE_CONT computes a linear interpolation between values after ordering them. Using the percentile value (P) and the number of not null rows (N) in the aggregation group, the function computes the row number after ordering the rows according to the sort specification. This row number (RN) is computed according to the formula $RN = (1 + (P * (N - 1)))$. The final result of the aggregate function is computed by linear interpolation between the values from rows at row numbers $CRN = \text{CEILING}(RN)$ and $FRN = \text{FLOOR}(RN)$.

The final result will be as follows.

If ($CRN = FRN = RN$) then the result is (value of expression from row at RN)

Otherwise the result is as follows:

$$(CRN - RN) * (\text{value of expression for row at FRN}) + (RN - FRN) * (\text{value of expression for row at CRN}).$$

Syntax

```
PERCENTILE_CONT(percentile)
WITHIN GROUP(ORDER BY expr)
```

Arguments

percentile

Numeric constant between 0 and 1. NULL values are ignored in the calculation.

expr

Specifies numeric or date/time values to sort and compute the percentile over.

Returns

The return type is determined by the data type of the ORDER BY expression in the WITHIN GROUP clause. The following table shows the return type for each ORDER BY expression data type.

Input type	Return type
INT2, INT4, INT8, NUMERIC, DECIMAL	DECIMAL
FLOAT, DOUBLE	DOUBLE
DATE	DATE
TIMESTAMP	TIMESTAMP
TIMESTAMPTZ	TIMESTAMPTZ

Usage notes

If the ORDER BY expression is a DECIMAL data type defined with the maximum precision of 38 digits, it is possible that PERCENTILE_CONT will return either an inaccurate result or an error. If

the return value of the PERCENTILE_CONT function exceeds 38 digits, the result is truncated to fit, which causes a loss of precision.. If, during interpolation, an intermediate result exceeds the maximum precision, a numeric overflow occurs and the function returns an error. To avoid these conditions, we recommend either using a data type with lower precision or casting the ORDER BY expression to a lower precision.

If a statement includes multiple calls to sort-based aggregate functions (LISTAGG, PERCENTILE_CONT, or MEDIAN), they must all use the same ORDER BY values. Note that MEDIAN applies an implicit order by on the expression value.

For example, the following statement returns an error.

```
SELECT TOP 10 salesid, SUM(pricepaid),  
PERCENTILE_CONT(0.6) WITHIN GROUP(ORDER BY salesid),  
MEDIAN(pricepaid)  
FROM sales  
GROUP BY salesid, pricepaid;
```

An error occurred when executing the SQL command:

```
SELECT TOP 10 salesid, SUM(pricepaid),  
PERCENTILE_CONT(0.6) WITHIN GROUP(ORDER BY salesid),  
MEDIAN(pricepaid)  
FROM sales  
GROUP BY salesid, pricepaid;
```

ERROR: within group ORDER BY clauses for aggregate functions must be the same

The following statement runs successfully.

```
SELECT TOP 10 salesid, SUM(pricepaid),  
PERCENTILE_CONT(0.6) WITHIN GROUP(ORDER BY salesid),  
MEDIAN(salesid)  
FROM sales  
GROUP BY salesid, pricepaid;
```

Examples

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

The following example shows that PERCENTILE_CONT(0.5) produces the same results as MEDIAN.

```

SELECT TOP 10 DISTINCT sellerid, qtysold,
PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY qtysold),
MEDIAN(qtysold)
FROM sales
GROUP BY sellerid, qtysold;

```

sellerid	qtysold	percentile_cont	median
2	2	2	2
26	1	1	1
33	1	1	1
38	1	1	1
43	1	1	1
48	2	2	2
48	3	3	3
77	4	4	4
85	4	4	4
95	2	2	2

The following example finds PERCENTILE_CONT(0.5) and PERCENTILE_CONT(0.75) for the quantity sold for each sellerid in the SALES table.

```

SELECT sellerid,
PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY qtysold) as pct_05,
PERCENTILE_CONT(0.75) WITHIN GROUP(ORDER BY qtysold) as pct_075
FROM sales
GROUP BY sellerid
ORDER BY sellerid
LIMIT 10;

```

sellerid	pct_05	pct_075
1	1.5	1.75
2	2	2.25
3	2	3
4	2	2
5	1	1.5
6	1	1
7	1.5	1.75
8	1	1

```

|          9 |          4 |          4 |
|         12 |          2 |         3.25 |
+-----+-----+-----+

```

To verify the results of the previous query for the first sellerid, use the following example.

```

SELECT qty sold
FROM sales
WHERE sellerid=1;

```

```

+-----+
| qty sold |
+-----+
|          2 |
|          1 |
+-----+

```

STDDEV_SAMP and STDDEV_POP functions

The STDDEV_SAMP and STDDEV_POP functions return the sample and population standard deviation of a set of numeric values (integer, decimal, or floating-point). The result of the STDDEV_SAMP function is equivalent to the square root of the sample variance of the same set of values.

STDDEV_SAMP and STDDEV are synonyms for the same function.

Syntax

```

STDDEV_SAMP | STDDEV ( [ DISTINCT | ALL ] expression)
STDDEV_POP ( [ DISTINCT | ALL ] expression)

```

The expression must have an integer, decimal, or floating point data type. Regardless of the data type of the expression, the return type of this function is a double precision number.

Note

Standard deviation is calculated using floating point arithmetic, which might result in slight imprecision.

Usage notes

When the sample standard deviation (STDDEV or STDDEV_SAMP) is calculated for an expression that consists of a single value, the result of the function is NULL not 0.

Examples

The following query returns the average of the values in the VENUESEATS column of the VENUE table, followed by the sample standard deviation and population standard deviation of the same set of values. VENUESEATS is an INTEGER column. The scale of the result is reduced to 2 digits.

```
select avg(venueseats),
       cast(stddev_samp(venueseats) as dec(14,2)) stddevsamp,
       cast(stddev_pop(venueseats) as dec(14,2)) stddevpop
from venue;
```

```
avg | stddevsamp | stddevpop
-----+-----+-----
17503 | 27847.76 | 27773.20
(1 row)
```

The following query returns the sample standard deviation for the COMMISSION column in the SALES table. COMMISSION is a DECIMAL column. The scale of the result is reduced to 10 digits.

```
select cast(stddev(commission) as dec(18,10))
from sales;
```

```
stddev
-----
130.3912659086
(1 row)
```

The following query casts the sample standard deviation for the COMMISSION column as an integer.

```
select cast(stddev(commission) as integer)
from sales;
```

```
stddev
-----
130
```

```
(1 row)
```

The following query returns both the sample standard deviation and the square root of the sample variance for the COMMISSION column. The results of these calculations are the same.

```
select
cast(stddev_samp(commission) as dec(18,10)) stddevsamp,
cast(sqrt(var_samp(commission)) as dec(18,10)) sqrtvarsamp
from sales;
```

```
stddevsamp   | sqrtvarsamp
-----+-----
130.3912659086 | 130.3912659086
(1 row)
```

SUM function

The SUM function returns the sum of the input column or expression values. The SUM function works with numeric values and ignores NULL values.

Syntax

```
SUM ( [ DISTINCT | ALL ] expression )
```

Arguments

expression

The target column or expression that the function operates on. The *expression* is one of the following data types:

- SMALLINT
- INTEGER
- BIGINT
- NUMERIC
- DECIMAL
- REAL
- DOUBLE PRECISION
- SUPER

DISTINCT | ALL

With the argument `DISTINCT`, the function eliminates all duplicate values from the specified expression before calculating the sum. With the argument `ALL`, the function retains all duplicate values from the expression for calculating the sum. `ALL` is the default.

Data types

The argument types supported by the `SUM` function are `SMALLINT`, `INTEGER`, `BIGINT`, `NUMERIC`, `DECIMAL`, `REAL`, `DOUBLE PRECISION`, and `SUPER`.

The return types supported by the `SUM` function are

- `BIGINT` for `BIGINT`, `SMALLINT`, and `INTEGER` arguments
- `NUMERIC` for `NUMERIC` arguments
- `DOUBLE PRECISION` for floating point arguments
- Returns the same data type as expression for any other argument type.

The default precision for a `SUM` function result with a `NUMERIC` or `DECIMAL` argument is 38. The scale of the result is the same as the scale of the argument. For example, a `SUM` of a `DEC(5,2)` column returns a `DEC(38,2)` data type.

Examples

Find the sum of all commissions paid from the `SALES` table:

```
select sum(commission) from sales;
```

```
sum
-----
16614814.65
(1 row)
```

Find the number of seats in all venues in the state of Florida:

```
select sum(venueseats) from venue
where venuestate = 'FL';
```

```
sum
```

```
-----  
250411  
(1 row)
```

Find the number of seats sold in May:

```
select sum(qtysold) from sales, date  
where sales.dateid = date.dateid and date.month = 'MAY';  
  
sum  
-----  
32291  
(1 row)
```

VAR_SAMP and VAR_POP functions

The VAR_SAMP and VAR_POP functions return the sample and population variance of a set of numeric values (integer, decimal, or floating-point). The result of the VAR_SAMP function is equivalent to the squared sample standard deviation of the same set of values.

VAR_SAMP and VARIANCE are synonyms for the same function.

Syntax

```
VAR_SAMP | VARIANCE ( [ DISTINCT | ALL ] expression)  
VAR_POP ( [ DISTINCT | ALL ] expression)
```

The expression must have an integer, decimal, or floating-point data type. Regardless of the data type of the expression, the return type of this function is a double precision number.

Note

The results of these functions might vary across data warehouse clusters, depending on the configuration of the cluster in each case.

Usage notes

When the sample variance (VARIANCE or VAR_SAMP) is calculated for an expression that consists of a single value, the result of the function is NULL not 0.

Examples

The following query returns the rounded sample and population variance of the NUMTICKETS column in the LISTING table.

```
select avg(numtickets),
round(var_samp(numtickets)) varsamp,
round(var_pop(numtickets)) varpop
from listing;
```

```
avg | varsamp | varpop
-----+-----+-----
10 |      54 |      54
(1 row)
```

The following query runs the same calculations but casts the results to decimal values.

```
select avg(numtickets),
cast(var_samp(numtickets) as dec(10,4)) varsamp,
cast(var_pop(numtickets) as dec(10,4)) varpop
from listing;
```

```
avg | varsamp | varpop
-----+-----+-----
10 | 53.6291 | 53.6288
(1 row)
```

Array functions

Following, you can find a description for the array functions for SQL that Amazon Redshift supports to access and manipulate arrays.

Topics

- [array function](#)
- [array_concat function](#)
- [array_flatten function](#)
- [get_array_length function](#)
- [split_to_array function](#)
- [subarray function](#)

array function

Creates an array of the SUPER data type.

Syntax

```
ARRAY( [ expr1 ] [ , expr2 [ , ... ] ] )
```

Argument

expr1, expr2

Expressions of any Amazon Redshift data type except date and time types, since Amazon Redshift doesn't cast the date and time types to the SUPER data type. The arguments don't need to be of the same data type.

Return type

The array function returns the SUPER data type.

Example

The following examples show an array of numeric values and an array of different data types.

```
--an array of numeric values
select array(1,50,null,100);
      array
-----
 [1,50,null,100]
(1 row)

--an array of different data types
select array(1,'abc',true,3.14);
      array
-----
 [1,"abc",true,3.14]
(1 row)
```

array_concat function

The `array_concat` function concatenates two arrays to create an array that contains all the elements in the first array followed by all the elements in the second array. The two arguments must be valid arrays.

Syntax

```
array_concat( super_expr1, super_expr2 )
```

Arguments

super_expr1

The value that specifies the first of the two arrays to concatenate.

super_expr2

The value that specifies the second of the two arrays to concatenate.

Return type

The `array_concat` function returns a SUPER data value.

Example

The following examples shows concatenation of two arrays of the same type and concatenation of two arrays of different types.

```
-- concatenating two arrays
SELECT ARRAY_CONCAT(ARRAY(10001,10002),ARRAY(10003,10004));
           array_concat
-----
 [10001,10002,10003,10004]
(1 row)

-- concatenating two arrays of different types
SELECT ARRAY_CONCAT(ARRAY(10001,10002),ARRAY('ab','cd'));
           array_concat
-----
 [10001,10002,"ab","cd"]
```

```
(1 row)
```

array_flatten function

Merges multiple arrays into a single array of SUPER type.

Syntax

```
array_flatten( super_expr1, super_expr2, .. )
```

Arguments

super_expr1, *super_expr2*

A valid SUPER expression of array form.

Return type

The array_flatten function returns a SUPER data value.

Example

The following example shows an array_flatten function.

```
SELECT ARRAY_FLATTEN(ARRAY(ARRAY(1,2,3,4),ARRAY(5,6,7,8),ARRAY(9,10)));
      array_flatten
-----
 [1,2,3,4,5,6,7,8,9,10]
(1 row)
```

get_array_length function

Returns the length of the specified array. The GET_ARRAY_LENGTH function returns the length of a SUPER array given an object or array path.

Syntax

```
get_array_length( super_expr )
```

Arguments

super_expr

A valid SUPER expression of array form.

Return type

The `get_array_length` function returns a BIGINT.

Example

The following example shows a `get_array_length` function.

```
SELECT GET_ARRAY_LENGTH(ARRAY(1,2,3,4,5,6,7,8,9,10));
get_array_length
-----
                10
(1 row)
```

split_to_array function

Uses a delimiter as an optional parameter. If no delimiter is present, then the default is a comma.

Syntax

```
split_to_array( string, delimiter )
```

Arguments

string

The input string to be split.

delimiter

An optional value on which the input string will be split. The default is a comma.

Return type

The `split_to_array` function returns a SUPER data value.

Example

The following example show a `split_to_array` function.

```
SELECT SPLIT_TO_ARRAY('12|345|6789', '|');
      split_to_array
-----
["12","345","6789"]
(1 row)
```

subarray function

Manipulates arrays to return a subset of the input arrays.

Syntax

```
SUBARRAY( super_expr, start_position, length )
```

Arguments

super_expr

A valid SUPER expression in array form.

start_position

The position within the array to begin the extraction, starting at index position 0. A negative position counts backward from the end of the array.

length

The number of elements to extract (the length of the substring).

Return type

The subarray function returns a SUPER data value.

Examples

The following is an example of a subarray function.

```
SELECT SUBARRAY(ARRAY('a', 'b', 'c', 'd', 'e', 'f'), 2, 3);
      subarray
-----
```

```
["c", "d", "e"]
(1 row)
```

Bit-wise aggregate functions

Bit-wise aggregate functions compute bit operations to perform aggregation of integer columns and columns that can be converted or rounded to integer values.

Topics

- [Using NULLs in bit-wise aggregations](#)
- [DISTINCT support for bit-wise aggregations](#)
- [Overview examples for bit-wise functions](#)
- [BIT_AND function](#)
- [BIT_OR function](#)
- [BOOL_AND function](#)
- [BOOL_OR function](#)

Using NULLs in bit-wise aggregations

When you apply a bit-wise function to a column that is nullable, any NULL values are eliminated before the function result is calculated. If no rows qualify for aggregation, the bit-wise function returns NULL. The same behavior applies to regular aggregate functions. Following is an example.

```
select sum(venueSeats), bit_and(venueSeats) from venue
where venueSeats is null;
```

```
sum | bit_and
-----+-----
null |      null
(1 row)
```

DISTINCT support for bit-wise aggregations

As other aggregate functions do, bit-wise functions support the DISTINCT keyword.

However, using DISTINCT with these functions has no impact on the results. The first instance of a value is sufficient to satisfy bit-wise AND or OR operations. It makes no difference if duplicate values are present in the expression being evaluated.

Because the `DISTINCT` processing is likely to incur some query execution overhead, we recommend that you don't use `DISTINCT` with bit-wise functions.

Overview examples for bit-wise functions

Following, you can find some overview examples demonstrating how to work with the bit-wise functions. You can also find specific code examples with each function description.

Examples for the bit-wise functions are based on the TICKIT sample database. The `USERS` table in the TICKIT sample database contains several Boolean columns that indicate whether each user is known to like different types of events, such as sports, theatre, opera, and so on. An example follows.

```
select userid, username, lastname, city, state,
likesports, liketheatre
from users limit 10;
```

```
userid | username | lastname | city | state | likesports | liketheatre
-----+-----+-----+-----+-----+-----+-----
1 | JSG99FHE | Taylor | Kent | WA | t | t
9 | MSD36KVR | Watkins | Port Orford | MD | t | f
```

Assume that a new version of the `USERS` table is built in a different way. In this new version, a single integer column that defines (in binary form) eight types of events that each user likes or dislikes. In this design, each bit position represents a type of event. A user who likes all eight types has all eight bits set to 1 (as in the first row of the following table). A user who doesn't like any of these events has all eight bits set to 0 (see the second row). A user who likes only sports and jazz is represented in the third row following.

USER	SPORTS	THEATRE	JAZZ	OPERA	ROCK	VEGAS	BROADW.	CLASSICAL
User 1	1	1	1	1	1	1	1	1
User 2	0	0	0	0	0	0	0	0
User 3	1	0	1	0	0	0	0	0

In the database table, these binary values can be stored in a single `LIKES` column as integers, as shown following.

User	Binary value	Stored value (integer)
User 1	11111111	255
User 2	00000000	0
User 3	10100000	160

BIT_AND function

The BIT_AND function runs bit-wise AND operations on all of the values in a single integer column or expression. This function aggregates each bit of each binary value that corresponds to each integer value in the expression.

The BIT_AND function returns a result of 0 if none of the bits is set to 1 across all of the values. If one or more bits is set to 1 across all values, the function returns an integer value. This integer is the number that corresponds to the binary value for the those bits.

For example, a table contains four integer values in a column: 3, 7, 10, and 22. These integers are represented in binary form as follows:

Integer	Binary value
3	11
7	111
10	1010
22	10110

A BIT_AND operation on this dataset finds that all bits are set to 1 in the second-to-last position only. The result is a binary value of 00000010, which represents the integer value 2. Therefore, the BIT_AND function returns 2.

Syntax

```
BIT_AND ( [DISTINCT | ALL] expression )
```

Arguments

expression

The target column or expression that the function operates on. This expression must have an INT, INT2, or INT8 data type. The function returns an equivalent INT, INT2, or INT8 data type.

DISTINCT | ALL

With the argument DISTINCT, the function eliminates all duplicate values for the specified expression before calculating the result. With the argument ALL, the function retains all duplicate values. ALL is the default. For more information, see [DISTINCT support for bit-wise aggregations](#).

Examples

Given that meaningful business information is stored in integer columns, you can use bit-wise functions to extract and aggregate that information. The following query applies the BIT_AND function to the LIKES column in a table called USERLIKES and groups the results by the CITY column.

```
select city, bit_and(likes) from userlikes group by city
order by city;
city          | bit_and
-----+-----
Los Angeles  |      0
Sacramento   |      0
San Francisco |      0
San Jose     |     64
Santa Barbara |    192
(5 rows)
```

You can interpret these results as follows:

- The integer value 192 for Santa Barbara translates to the binary value 11000000. In other words, all users in this city like sports and theatre, but not all users like any other type of event.
- The integer 64 translates to 01000000. So, for users in San Jose, the only type of event that they all like is theatre.
- The values of 0 for the other three cities indicate that no "likes" are shared by all users in those cities.

BIT_OR function

The BIT_OR function runs bit-wise OR operations on all of the values in a single integer column or expression. This function aggregates each bit of each binary value that corresponds to each integer value in the expression.

For example, suppose that your table contains four integer values in a column: 3, 7, 10, and 22. These integers are represented in binary form as follows.

Integer	Binary value
3	11
7	111
10	1010
22	10110

If you apply the BIT_OR function to the set of integer values, the operation looks for any value in which a 1 is found in each position. In this case, a 1 exists in the last five positions for at least one of the values, yielding a binary result of 00011111; therefore, the function returns 31 (or $16 + 8 + 4 + 2 + 1$).

Syntax

```
BIT_OR ( [DISTINCT | ALL] expression )
```

Arguments

expression

The target column or expression that the function operates on. This expression must have an INT, INT2, or INT8 data type. The function returns an equivalent INT, INT2, or INT8 data type.

DISTINCT | ALL

With the argument DISTINCT, the function eliminates all duplicate values for the specified expression before calculating the result. With the argument ALL, the function retains all

duplicate values. ALL is the default. For more information, see [DISTINCT support for bit-wise aggregations](#).

Example

The following query applies the BIT_OR function to the LIKES column in a table called USERLIKES and groups the results by the CITY column.

```
select city, bit_or(likes) from userlikes group by city
order by city;
city          | bit_or
-----+-----
Los Angeles  |    127
Sacramento   |    255
San Francisco |    255
San Jose     |    255
Santa Barbara |    255
(5 rows)
```

For four of the cities listed, all of the event types are liked by at least one user (255=11111111). For Los Angeles, all of the event types except sports are liked by at least one user (127=01111111).

BOOL_AND function

The BOOL_AND function operates on a single Boolean or integer column or expression. This function applies similar logic to the BIT_AND and BIT_OR functions. For this function, the return type is a Boolean value (true or false).

If all values in a set are true, the BOOL_AND function returns true (t). If any value is false, the function returns false (f).

Syntax

```
BOOL_AND ( [DISTINCT | ALL] expression )
```

Arguments

expression

The target column or expression that the function operates on. This expression must have a `BOOLEAN` or integer data type. The return type of the function is `BOOLEAN`.

DISTINCT | ALL

With the argument `DISTINCT`, the function eliminates all duplicate values for the specified expression before calculating the result. With the argument `ALL`, the function retains all duplicate values. `ALL` is the default. For more information, see [DISTINCT support for bit-wise aggregations](#).

Examples

You can use the Boolean functions against either Boolean expressions or integer expressions. For example, the following query return results from the standard `USERS` table in the `TICKIT` database, which has several Boolean columns.

The `BOOL_AND` function returns `false` for all five rows. Not all users in each of those states likes sports.

```
select state, bool_and(likesports) from users
group by state order by state limit 5;
```

```
state | bool_and
-----+-----
AB    | f
AK    | f
AL    | f
AZ    | f
BC    | f
(5 rows)
```

BOOL_OR function

The `BOOL_OR` function operates on a single Boolean or integer column or expression. This function applies similar logic to the `BIT_AND` and `BIT_OR` functions. For this function, the return type is a Boolean value (`true`, `false`, or `NULL`).

If one or more values in a set is `true`, the `BOOL_OR` function returns `true (t)`. If all values in a set are `false`, the function returns `false (f)`. `NULL` can be returned if the value is unknown.

Syntax

```
BOOL_OR ( [DISTINCT | ALL] expression )
```

Arguments

expression

The target column or expression that the function operates on. This expression must have a `BOOLEAN` or integer data type. The return type of the function is `BOOLEAN`.

DISTINCT | ALL

With the argument `DISTINCT`, the function eliminates all duplicate values for the specified expression before calculating the result. With the argument `ALL`, the function retains all duplicate values. `ALL` is the default. See [DISTINCT support for bit-wise aggregations](#).

Examples

You can use the Boolean functions with either Boolean expressions or integer expressions. For example, the following query return results from the standard `USERS` table in the `TICKIT` database, which has several Boolean columns.

The `BOOL_OR` function returns `true` for all five rows. At least one user in each of those states likes sports.

```
select state, bool_or(likesports) from users
group by state order by state limit 5;
```

```
state | bool_or
-----+-----
AB    | t
AK    | t
AL    | t
AZ    | t
BC    | t
(5 rows)
```

The following example returns NULL.

```
SELECT BOOL_OR(NULL = '123')
           bool_or
-----
NULL
```

Conditional expressions

Topics

- [CASE conditional expression](#)
- [DECODE function](#)
- [GREATEST and LEAST functions](#)
- [NVL and COALESCE functions](#)
- [NVL2 function](#)
- [NULLIF function](#)

Amazon Redshift supports some conditional expressions that are extensions to the SQL standard.

CASE conditional expression

The CASE expression is a conditional expression, similar to if/then/else statements found in other languages. CASE is used to specify a result when there are multiple conditions. Use CASE where a SQL expression is valid, such as in a SELECT command.

There are two types of CASE expressions: simple and searched.

- In simple CASE expressions, an expression is compared with a value. When a match is found, the specified action in the THEN clause is applied. If no match is found, the action in the ELSE clause is applied.
- In searched CASE expressions, each CASE is evaluated based on a Boolean expression, and the CASE statement returns the first matching CASE. If no match is found among the WHEN clauses, the action in the ELSE clause is returned.

Syntax

Simple CASE statement used to match conditions:

```
CASE expression
  WHEN value THEN result
  [WHEN...]
  [ELSE result]
END
```

Searched CASE statement used to evaluate each condition:

```
CASE
  WHEN condition THEN result
  [WHEN ...]
  [ELSE result]
END
```

Arguments

expression

A column name or any valid expression.

value

Value that the expression is compared with, such as a numeric constant or a character string.

result

The target value or expression that is returned when an expression or Boolean condition is evaluated. The data types of all the result expressions must be convertible to a single output type.

condition

A Boolean expression that evaluates to true or false. If *condition* is true, the value of the CASE expression is the result that follows the condition, and the remainder of the CASE expression is not processed. If *condition* is false, any subsequent WHEN clauses are evaluated. If no WHEN condition results are true, the value of the CASE expression is the result of the ELSE clause. If the ELSE clause is omitted and no condition is true, the result is null.

Examples

The following examples use the VENUE table and SALES table from the sample TICKIT data. For more information, see [Sample database](#).

Use a simple CASE expression to replace New York City with Big Apple in a query against the VENUE table. Replace all other city names with other.

```
select venuecity,
       case venuecity
         when 'New York City'
          then 'Big Apple' else 'other'
        end
from venue
order by venueid desc;
```

venuecity	case
Los Angeles	other
New York City	Big Apple
San Francisco	other
Baltimore	other
...	

Use a searched CASE expression to assign group numbers based on the PRICEPAID value for individual ticket sales:

```
select pricepaid,
       case when pricepaid <10000 then 'group 1'
            when pricepaid >10000 then 'group 2'
            else 'group 3'
        end
from sales
order by 1 desc;
```

pricepaid	case
12624	group 2
10000	group 3
10000	group 3
9996	group 1
9988	group 1
...	

DECODE function

A DECODE expression replaces a specific value with either another specific value or a default value, depending on the result of an equality condition. This operation is equivalent to the operation of a simple CASE expression or an IF-THEN-ELSE statement.

Syntax

```
DECODE ( expression, search, result [, search, result ]... [ ,default ] )
```

This type of expression is useful for replacing abbreviations or codes that are stored in tables with meaningful business values that are needed for reports.

Parameters

expression

The source of the value that you want to compare, such as a column in a table.

search

The target value that is compared against the source expression, such as a numeric value or a character string. The search expression must evaluate to a single fixed value. You cannot specify an expression that evaluates to a range of values, such as `age between 20 and 29`; you need to specify separate search/result pairs for each value that you want to replace.

The data type of all instances of the search expression must be the same or compatible. The *expression* and *search* parameters must also be compatible.

result

The replacement value that query returns when the expression matches the search value. You must include at least one search/result pair in the DECODE expression.

The data types of all instances of the result expression must be the same or compatible. The *result* and *default* parameters must also be compatible.

default

An optional default value that is used for cases when the search condition fails. If you do not specify a default value, the DECODE expression returns NULL.

Usage notes

If the *expression* value and the *search* value are both NULL, the DECODE result is the corresponding *result* value. For an illustration of this use of the function, see the Examples section.

When used this way, DECODE is similar to [NVL2 function](#), but there are some differences. For a description of these differences, see the NVL2 usage notes.

Examples

When the value 2008-06-01 exists in the caldate column of datetable, the following example replaces it with June 1st, 2008. The example replaces all other caldate values with NULL.

```
select decode(caldate, '2008-06-01', 'June 1st, 2008')
from datetable where month='JUN' order by caldate;

case
-----
June 1st, 2008

...
(30 rows)
```

The following example uses a DECODE expression to convert the five abbreviated CATNAME columns in the CATEGORY table to full names and convert other values in the column to Unknown.

```
select catid, decode(catname,
'NHL', 'National Hockey League',
'MLB', 'Major League Baseball',
'MLS', 'Major League Soccer',
'NFL', 'National Football League',
'NBA', 'National Basketball Association',
'Unknown')
from category
order by catid;

catid | case
-----+-----
1     | Major League Baseball
2     | National Hockey League
3     | National Football League
4     | National Basketball Association
```

```

5      | Major League Soccer
6      | Unknown
7      | Unknown
8      | Unknown
9      | Unknown
10     | Unknown
11     | Unknown
(11 rows)

```

Use a `DECODE` expression to find venues in Colorado and Nevada with `NULL` in the `VENUESEATS` column; convert the `NULL`s to zeroes. If the `VENUESEATS` column is not `NULL`, return 1 as the result.

```

select venuename, venuestate, decode(venueSeats,null,0,1)
from venue
where venuestate in('NV','CO')
order by 2,3,1;

```

venueName	venuestate	case
Coors Field	CO	1
Dick's Sporting Goods Park	CO	1
Ellie Caulkins Opera House	CO	1
INVESCO Field	CO	1
Pepsi Center	CO	1
Ballys Hotel	NV	0
Bellagio Hotel	NV	0
Caesars Palace	NV	0
Harrahs Hotel	NV	0
Hilton Hotel	NV	0
...		

(20 rows)

GREATEST and LEAST functions

Returns the largest or smallest value from a list of any number of expressions.

Syntax

```

GREATEST (value [, ...])
LEAST (value [, ...])

```

Parameters

expression_list

A comma-separated list of expressions, such as column names. The expressions must all be convertible to a common data type. NULL values in the list are ignored. If all of the expressions evaluate to NULL, the result is NULL.

Returns

Returns the greatest (for GREATEST) or least (for LEAST) value from the provided list of expressions.

Example

The following example returns the highest value alphabetically for `firstname` or `lastname`.

```
select firstname, lastname, greatest(firstname,lastname) from users
where userid < 10
order by 3;
```

firstname	lastname	greatest
Lars	Ratliff	Ratliff
Reagan	Hodge	Reagan
Colton	Roy	Roy
Barry	Roy	Roy
Tamekah	Juarez	Tamekah
Rafael	Taylor	Taylor
Victor	Hernandez	Victor
Vladimir	Humphrey	Vladimir
Mufutau	Watkins	Watkins

(9 rows)

NVL and COALESCE functions

Returns the value of the first expression that isn't null in a series of expressions. When a non-null value is found, the remaining expressions in the list aren't evaluated.

NVL is identical to COALESCE. They are synonyms. This topic explains the syntax and contains examples for both.

Syntax

```
NVL( expression, expression, ... )
```

The syntax for COALESCE is the same:

```
COALESCE( expression, expression, ... )
```

If all expressions are null, the result is null.

These functions are useful when you want to return a secondary value when a primary value is missing or null. For example, a query might return the first of three available phone numbers: cell, home, or work. The order of the expressions in the function determines the order of evaluation.

Arguments

expression

An expression, such as a column name, to be evaluated for null status.

Return type

Amazon Redshift determines the data type of the returned value based on the input expressions. If the data types of the input expressions don't have a common type, then an error is returned.

Examples

If the list contains integer expressions, the function returns an integer.

```
SELECT COALESCE(NULL, 12, NULL);
```

```
coalesce  
-----  
12
```

This example, which is the same as the previous example, except that it uses NVL, returns the same result.

```
SELECT NVL(NULL, 12, NULL);
```

```
coalesce  
-----
```

12

The following example returns a string type.

```
SELECT COALESCE(NULL, 'Amazon Redshift', NULL);
```

```
coalesce
-----
Amazon Redshift
```

The following example results in an error because the data types vary in the expression list. In this case, there is both a string type and a number type in the list.

```
SELECT COALESCE(NULL, 'Amazon Redshift', 12);
ERROR: invalid input syntax for integer: "Amazon Redshift"
```

For this example, you create a table with `START_DATE` and `END_DATE` columns, insert rows that include null values, then apply an `NVL` expression to the two columns.

```
create table datetable (start_date date, end_date date);
insert into datetable values ('2008-06-01','2008-12-31');
insert into datetable values (null,'2008-12-31');
insert into datetable values ('2008-12-31',null);
```

```
select nvl(start_date, end_date)
from datetable
order by 1;
```

```
coalesce
-----
2008-06-01
2008-12-31
2008-12-31
```

The default column name for an `NVL` expression is `COALESCE`. The following query returns the same results:

```
select coalesce(start_date, end_date)
from datetable
order by 1;
```

For the following example queries, you create a table with sample hotel-booking information and insert several rows. Some records contain null values.

```
create table booking_info (booking_id int, booking_code character(8), check_in date,
  check_out date, funds_collected numeric(12,2));
```

Insert the following sample data. Some records don't have a check_out date or funds_collected amount.

```
insert into booking_info values (1, 'OCEAN_WV', '2023-02-01', '2023-02-03', 100.00);
insert into booking_info values (2, 'OCEAN_WV', '2023-04-22', '2023-04-26', 120.00);
insert into booking_info values (3, 'DSRT_SUN', '2023-03-13', '2023-03-16', 125.00);
insert into booking_info values (4, 'DSRT_SUN', '2023-06-01', '2023-06-03', 140.00);
insert into booking_info values (5, 'DSRT_SUN', '2023-07-10', null, null);
insert into booking_info values (6, 'OCEAN_WV', '2023-08-15', null, null);
```

The following query returns a list of dates. If the check_out date isn't available, it lists the check_in date.

```
select coalesce(check_out, check_in)
from booking_info
order by booking_id;
```

The results are the following. Note that the last two records show the check_in date.

```
coalesce
-----
2023-02-03
2023-04-26
2023-03-16
2023-06-03
2023-07-10
2023-08-15
```

If you expect a query to return null values for certain functions or columns, you can use an NVL expression to replace the nulls with some other value. For example, aggregate functions, such as SUM, return null values instead of zeroes when they have no rows to evaluate. You can use an NVL expression to replace these null values with 700.0. Instead of 485, the result of summing the funds_collected is 1885 because two rows that have null are replaced with 700.

```
select sum(nvl(funds_collected, 700.0)) as sumresult from booking_info;
```

```
sumresult
```

```
-----
```

```
1885
```

NVL2 function

Returns one of two values based on whether a specified expression evaluates to NULL or NOT NULL.

Syntax

```
NVL2 ( expression, not_null_return_value, null_return_value )
```

Arguments

expression

An expression, such as a column name, to be evaluated for null status.

not_null_return_value

The value returned if *expression* evaluates to NOT NULL. The *not_null_return_value* value must either have the same data type as *expression* or be implicitly convertible to that data type.

null_return_value

The value returned if *expression* evaluates to NULL. The *null_return_value* value must either have the same data type as *expression* or be implicitly convertible to that data type.

Return type

The NVL2 return type is determined as follows:

- If either *not_null_return_value* or *null_return_value* is null, the data type of the not-null expression is returned.

If both *not_null_return_value* and *null_return_value* are not null:

- If *not_null_return_value* and *null_return_value* have the same data type, that data type is returned.

- If *not_null_return_value* and *null_return_value* have different numeric data types, the smallest compatible numeric data type is returned.
- If *not_null_return_value* and *null_return_value* have different datetime data types, a timestamp data type is returned.
- If *not_null_return_value* and *null_return_value* have different character data types, the data type of *not_null_return_value* is returned.
- If *not_null_return_value* and *null_return_value* have mixed numeric and non-numeric data types, the data type of *not_null_return_value* is returned.

Important

In the last two cases where the data type of *not_null_return_value* is returned, *null_return_value* is implicitly cast to that data type. If the data types are incompatible, the function fails.

Usage notes

[DECODE function](#) can be used in a similar way to NVL2 when the *expression* and *search* parameters are both null. The difference is that for DECODE, the return will have both the value and the data type of the *result* parameter. In contrast, for NVL2, the return will have the value of either the *not_null_return_value* or *null_return_value* parameter, whichever is selected by the function, but will have the data type of *not_null_return_value*.

For example, assuming *column1* is NULL, the following queries will return the same value. However, the DECODE return value data type will be INTEGER and the NVL2 return value data type will be VARCHAR.

```
select decode(column1, null, 1234, '2345');
select nvl2(column1, '2345', 1234);
```

Example

The following example modifies some sample data, then evaluates two fields to provide appropriate contact information for users:

```
update users set email = null where firstname = 'Aphrodite' and lastname = 'Acevedo';
```

```

select (firstname + ' ' + lastname) as name,
nvl2(email, email, phone) AS contact_info
from users
where state = 'WA'
and lastname like 'A%'
order by lastname, firstname;

name          contact_info

```

NULLIF function

Syntax

The NULLIF expression compares two arguments and returns null if the arguments are equal. If they are not equal, the first argument is returned. This expression is the inverse of the NVL or COALESCE expression.

```
NULLIF ( expression1, expression2 )
```

Arguments

expression1, *expression2*

The target columns or expressions that are compared. The return type is the same as the type of the first expression. The default column name of the NULLIF result is the column name of the first expression.

Examples

In the following example, the query returns the string `first` because the arguments are not equal.

```
SELECT NULLIF('first', 'second');
```

```
case
-----
first
```

In the following example, the query returns `NULL` because the string literal arguments are equal.

```
SELECT NULLIF('first', 'first');
```

```
case
-----
NULL
```

In the following example, the query returns `1` because the integer arguments are not equal.

```
SELECT NULLIF(1, 2);
```

```
case
-----
1
```

In the following example, the query returns `NULL` because the integer arguments are equal.

```
SELECT NULLIF(1, 1);
```

```
case
-----
NULL
```

In the following example, the query returns null when the `LISTID` and `SALESID` values match:

```
select nullif(listid,salesid), salesid
from sales where salesid<10 order by 1, 2 desc;
```

```
listid | salesid
```

```

-----+-----
  4 |      2
  5 |      4
  5 |      3
  6 |      5
 10 |      9
 10 |      8
 10 |      7
 10 |      6
    |      1
(9 rows)

```

You can use `NULLIF` to ensure that empty strings are always returned as nulls. In the example below, the `NULLIF` expression returns either a null value or a string that contains at least one character.

```

insert into category
values(0, '', 'Special', 'Special');

select nullif(catgroup, '') from category
where catdesc='Special';

catgroup
-----
null
(1 row)

```

`NULLIF` ignores trailing blanks. If a string is not empty but contains blanks, `NULLIF` still returns null:

```

create table nulliftest(c1 char(2), c2 char(2));

insert into nulliftest values ('a','a ');

insert into nulliftest values ('b','b');

select nullif(c1,c2) from nulliftest;
c1
-----
null
null
(2 rows)

```

Data type formatting functions

Topics

- [CAST function](#)
- [CONVERT function](#)
- [TO_CHAR](#)
- [TO_DATE function](#)
- [TO_NUMBER](#)
- [TEXT_TO_INT_ALT](#)
- [TEXT_TO_NUMERIC_ALT](#)
- [Datetime format strings](#)
- [Numeric format strings](#)
- [Teradata-style formatting characters for numeric data](#)

Data type formatting functions provide an easy way to convert values from one data type to another. For each of these functions, the first argument is always the value to be formatted and the second argument contains the template for the new format. Amazon Redshift supports several data type formatting functions.

CAST function

The CAST function converts one data type to another compatible data type. For instance, you can convert a string to a date, or a numeric type to a string. CAST performs a runtime conversion, which means that the conversion doesn't change a value's data type in a source table. It's changed only in the context of the query.

The CAST function is very similar to [the section called "CONVERT"](#), in that they both convert one data type to another, but they are called differently.

Certain data types require an explicit conversion to other data types using the CAST or CONVERT function. Other data types can be converted implicitly, as part of another command, without using CAST or CONVERT. See [Type compatibility and conversion](#).

Syntax

Use either of these two equivalent syntax forms to cast expressions from one data type to another.

```
CAST ( expression AS type )  
expression :: type
```

Arguments

expression

An expression that evaluates to one or more values, such as a column name or a literal. Converting null values returns nulls. The expression cannot contain blank or empty strings.

type

One of the supported [Data types](#).

Return type

CAST returns the data type specified by the *type* argument.

Note

Amazon Redshift returns an error if you try to perform a problematic conversion, such as a DECIMAL conversion that loses precision, like the following:

```
select 123.456::decimal(2,1);
```

or an INTEGER conversion that causes an overflow:

```
select 12345678::smallint;
```

Examples

Some of the examples use the sample [TICKIT database](#). For more information about setting up sample data, see [Load data](#).

The following two queries are equivalent. They both cast a decimal value to an integer:

```
select cast(pricepaid as integer)  
from sales where salesid=100;
```

```
pricepaid
-----
162
(1 row)
```

```
select pricepaid::integer
from sales where salesid=100;
```

```
pricepaid
-----
162
(1 row)
```

The following produces a similar result. It doesn't require sample data to run:

```
select cast(162.00 as integer) as pricepaid;
```

```
pricepaid
-----
162
(1 row)
```

In this example, the values in a timestamp column are cast as dates, which results in removing the time from each result:

```
select cast(saletime as date), salesid
from sales order by salesid limit 10;
```

```
 saletime | salesid
-----+-----
2008-02-18 |      1
2008-06-06 |      2
2008-06-06 |      3
2008-06-09 |      4
2008-08-31 |      5
2008-07-16 |      6
2008-06-26 |      7
2008-07-10 |      8
2008-07-22 |      9
2008-08-06 |     10
(10 rows)
```

If you didn't use CAST as illustrated in the previous sample, the results would include the time:
2008-02-18 02:36:48.

The following query casts variable character data to a date. It doesn't require sample data to run.

```
select cast('2008-02-18 02:36:48' as date) as mysaletime;
```

```
mysaletime
```

```
-----
```

```
2008-02-18
```

```
(1 row)
```

In this example, the values in a date column are cast as timestamps:

```
select cast(caldate as timestamp), dateid
from date order by dateid limit 10;
```

caldate		dateid
2008-01-01 00:00:00		1827
2008-01-02 00:00:00		1828
2008-01-03 00:00:00		1829
2008-01-04 00:00:00		1830
2008-01-05 00:00:00		1831
2008-01-06 00:00:00		1832
2008-01-07 00:00:00		1833
2008-01-08 00:00:00		1834
2008-01-09 00:00:00		1835
2008-01-10 00:00:00		1836

(10 rows)

In a case like the previous sample, you can gain additional control over output formatting by using [TO_CHAR](#).

In this example, an integer is cast as a character string:

```
select cast(2008 as char(4));
```

```
bpchar
```

```
-----
```

```
2008
```

In this example, a DECIMAL(6,3) value is cast as a DECIMAL(4,1) value:

```
select cast(109.652 as decimal(4,1));

numeric
-----
109.7
```

This example shows a more complex expression. The PRICEPAID column (a DECIMAL(8,2) column) in the SALES table is converted to a DECIMAL(38,2) column and the values are multiplied by 100000000000000000000:

```
select salesid, pricepaid::decimal(38,2)*100000000000000000000
as value from sales where salesid<10 order by salesid;
```

```
salesid | value
-----+-----
       1 | 72800000000000000000.00
       2 | 76000000000000000000.00
       3 | 35000000000000000000.00
       4 | 17500000000000000000.00
       5 | 15400000000000000000.00
       6 | 39400000000000000000.00
       7 | 78800000000000000000.00
       8 | 19700000000000000000.00
       9 | 59100000000000000000.00
(9 rows)
```

Note

You can't perform a CAST or CONVERT operation on the GEOMETRY data type to change it to another data type. However, you can provide a hexadecimal representation of a string literal in extended well-known binary (EWKB) format as input to functions that accept a GEOMETRY argument. For example, the ST_AsText function following expects a GEOMETRY data type.

```
SELECT ST_AsText('01010000000000000000000001C40000000000002040');
```

```
st_astext
```

```
-----  
POINT(7 8)
```

You can also explicitly specify the GEOMETRY data type.

```
SELECT ST_AsText('010100000000000000000014400000000000001840'::geometry);
```

```
st_astext  
-----  
POINT(5 6)
```

CONVERT function

Like the [CAST function](#), the CONVERT function converts one data type to another compatible data type. For instance, you can convert a string to a date, or a numeric type to a string. CONVERT performs a runtime conversion, which means that the conversion doesn't change a value's data type in a source table. It's changed only in the context of the query.

Certain data types require an explicit conversion to other data types using the CONVERT function. Other data types can be converted implicitly, as part of another command, without using CAST or CONVERT. See [Type compatibility and conversion](#).

Syntax

```
CONVERT ( type, expression )
```

Arguments

type

One of the supported [Data types](#).

expression

An expression that evaluates to one or more values, such as a column name or a literal. Converting null values returns nulls. The expression cannot contain blank or empty strings.

Return type

CONVERT returns the data type specified by the *type* argument.

Note

Amazon Redshift returns an error if you try to perform a problematic conversion, such as a DECIMAL conversion that loses precision, like the following:

```
SELECT CONVERT(decimal(2,1), 123.456);
```

or an INTEGER conversion that causes an overflow:

```
SELECT CONVERT(smallint, 12345678);
```

Examples

Some of the examples use the sample [TICKIT database](#). For more information about setting up sample data, see [Load data](#).

The following query uses the CONVERT function to convert a column of decimals into integers

```
SELECT CONVERT(integer, pricepaid)
FROM sales WHERE salesid=100;
```

This example converts an integer into a character string.

```
SELECT CONVERT(char(4), 2008);
```

In this example, the current date and time is converted to a variable character data type:

```
SELECT CONVERT(VARCHAR(30), GETDATE());
```

```
getdate
-----
2023-02-02 04:31:16
```

This example converts the saletime column into just the time, removing the dates from each row.

```
SELECT CONVERT(time, saletime), salesid
FROM sales order by salesid limit 10;
```

For information about converting a timestamp from one time zone to another, see the [CONVERT_TIMEZONE function](#). For additional date and time functions, see [Date and time functions](#).

The following example converts variable character data into a datetime object.

```
SELECT CONVERT(datetime, '2008-02-18 02:36:48') as mysaletime;
```

Note

You can't perform a CAST or CONVERT operation on the GEOMETRY data type to change it to another data type. However, you can provide a hexadecimal representation of a string literal in extended well-known binary (EWKB) format as input to functions that accept a GEOMETRY argument. For example, the ST_AsText function following expects a GEOMETRY data type.

```
SELECT ST_AsText('0101000000000000000000000001C400000000000002040');
```

```
st_astext
-----
POINT(7 8)
```

You can also explicitly specify the GEOMETRY data type.

```
SELECT ST_AsText('0101000000000000000000000014400000000000001840'::geometry);
```

```
st_astext
-----
POINT(5 6)
```

TO_CHAR

TO_CHAR converts a timestamp or numeric expression to a character-string data format.

Syntax

```
TO_CHAR (timestamp_expression | numeric_expression , 'format')
```

Arguments

timestamp_expression

An expression that results in a `TIMESTAMP` or `TIMESTAMPTZ` type value or a value that can implicitly be coerced to a timestamp.

numeric_expression

An expression that results in a numeric data type value or a value that can implicitly be coerced to a numeric type. For more information, see [Numeric types](#). `TO_CHAR` inserts a space to the left of the numeral string.

Note

`TO_CHAR` does not support 128-bit `DECIMAL` values.

format

The format for the new value. For valid formats, see [Datetime format strings](#) and [Numeric format strings](#).

Return type

`VARCHAR`

Examples

The following example converts a timestamp to a value with the date and time in a format with the name of the month padded to nine characters, the name of the day of the week, and the day number of the month.

```
select to_char(timestamp '2009-12-31 23:15:59', 'MONTH-DY-DD-YYYY HH12:MIPM');  
  
to_char
```

```
-----  
DECEMBER -THU-31-2009 11:15PM
```

The following example converts a timestamp to a value with day number of the year.

```
select to_char(timestamp '2009-12-31 23:15:59', 'DDD');  
  
to_char  
-----  
365
```

The following example converts a timestamp to an ISO day number of the week.

```
select to_char(timestamp '2022-05-16 23:15:59', 'ID');  
  
to_char  
-----  
1
```

The following example extracts the month name from a date.

```
select to_char(date '2009-12-31', 'MONTH');  
  
to_char  
-----  
DECEMBER
```

The following example converts each STARTTIME value in the EVENT table to a string that consists of hours, minutes, and seconds.

```
select to_char(starttime, 'HH12:MI:SS')  
from event where eventid between 1 and 5  
order by eventid;  
  
to_char  
-----  
02:30:00  
08:00:00  
02:30:00  
02:30:00  
07:00:00
```

The following example converts an entire timestamp value into a different format.

```
select starttime, to_char(starttime, 'MON-DD-YYYY HH12:MIPM')
from event where eventid=1;
```

starttime		to_char
-----+-----		
2008-01-25 14:30:00		JAN-25-2008 02:30PM

The following example converts a timestamp literal to a character string.

```
select to_char(timestamp '2009-12-31 23:15:59', 'HH24:MI:SS');
```

to_char

23:15:59

The following example converts a decimal number to a character string.

```
select to_char(125.8, '999.99');
```

to_char

125.80

The following example converts a decimal number to a character string.

```
select to_char(125.8, '999D99');
```

to_char

125.80

The following example converts a number to a character string with a leading zero.

```
select to_char(125.8, '0999D99');
```

to_char

0125.80

The following example converts a number to a character string with the negative sign at the end.

```
select to_char(-125.8, '999D99S');
```

```
to_char
-----
125.80-
```

The following example converts a number to a character string with the positive or negative sign at the specified position.

```
select to_char(125.8, '999D99SG');
```

```
to_char
-----
125.80+
```

The following example converts a number to a character string with the positive sign at the specified position.

```
select to_char(125.8, 'PL999D99');
```

```
to_char
-----
+ 125.80
```

The following example converts a number to a character string with the currency symbol.

```
select to_char(-125.88, '$S999D99');
```

```
to_char
-----
$-125.88
```

The following example converts a number to a character string with the currency symbol in the specified position.

```
select to_char(-125.88, 'S999D99L');
```

```
to_char
```

```
-----
-125.88$
```

The following example converts a number to a character string using a thousands (comma) separator.

```
select to_char(1125.8, '9,999.99');

to_char
-----
1,125.80
```

The following example converts a number to a character string using angle brackets for negative numbers.

```
select to_char(-125.88, '$999D99PR');

to_char
-----
$<125.88>
```

The following example converts a number to a Roman numeral string.

```
select to_char(125, 'RN');

to_char
-----
CXXV
```

The following example converts a date to a century code.

```
select to_char(date '2020-12-31', 'CC');

to_char
-----
21
```

The following example displays the day of the week.

```
SELECT to_char(current_timestamp, 'FMDay, FMDD HH12:MI:SS');
```

```
to_char
-----
Wednesday, 31 09:34:26
```

The following example displays the ordinal number suffix for a number.

```
SELECT to_char(482, '999th');
```

```
to_char
-----
482nd
```

The following example subtracts the commission from the price paid in the sales table. The difference is then rounded up and converted to a roman numeral, shown in the to_char column:

```
select salesid, pricepaid, commission, (pricepaid - commission)
as difference, to_char(pricepaid - commission, 'rn') from sales
group by sales.pricepaid, sales.commission, salesid
order by salesid limit 10;
```

salesid	pricepaid	commission	difference	to_char
1	728.00	109.20	618.80	dcxix
2	76.00	11.40	64.60	lxv
3	350.00	52.50	297.50	ccxcviii
4	175.00	26.25	148.75	cxlix
5	154.00	23.10	130.90	cxxxix
6	394.00	59.10	334.90	cccxxxv
7	788.00	118.20	669.80	dclxx
8	197.00	29.55	167.45	clxvii
9	591.00	88.65	502.35	dii
10	65.00	9.75	55.25	lv

The following example adds the currency symbol to the difference values shown in the to_char column:

```
select salesid, pricepaid, commission, (pricepaid - commission)
as difference, to_char(pricepaid - commission, 'l99999D99') from sales
group by sales.pricepaid, sales.commission, salesid
order by salesid limit 10;
```

salesid	pricepaid	commission	difference	to_char
1	728.00	109.20	618.80	\$ 618.80
2	76.00	11.40	64.60	\$ 64.60
3	350.00	52.50	297.50	\$ 297.50
4	175.00	26.25	148.75	\$ 148.75
5	154.00	23.10	130.90	\$ 130.90
6	394.00	59.10	334.90	\$ 334.90
7	788.00	118.20	669.80	\$ 669.80
8	197.00	29.55	167.45	\$ 167.45
9	591.00	88.65	502.35	\$ 502.35
10	65.00	9.75	55.25	\$ 55.25

The following example lists the century in which each sale was made.

```
select salesid, saletime, to_char(saletime, 'cc') from sales
order by salesid limit 10;
```

salesid	saletime	to_char
1	2008-02-18 02:36:48	21
2	2008-06-06 05:00:16	21
3	2008-06-06 08:26:17	21
4	2008-06-09 08:38:52	21
5	2008-08-31 09:17:02	21
6	2008-07-16 11:59:24	21
7	2008-06-26 12:56:06	21
8	2008-07-10 02:12:36	21
9	2008-07-22 02:23:17	21
10	2008-08-06 02:51:55	21

The following example converts each STARTTIME value in the EVENT table to a string that consists of hours, minutes, seconds, and time zone.

```
select to_char(starttime, 'HH12:MI:SS TZ')
from event where eventid between 1 and 5
order by eventid;
```

to_char
02:30:00 UTC
08:00:00 UTC

```
02:30:00 UTC
02:30:00 UTC
07:00:00 UTC
```

The following example shows formatting for seconds, milliseconds, and microseconds.

```
select sysdate,
to_char(sysdate, 'HH24:MI:SS') as seconds,
to_char(sysdate, 'HH24:MI:SS.MS') as milliseconds,
to_char(sysdate, 'HH24:MI:SS.US') as microseconds;
```

timestamp	seconds	milliseconds	microseconds
2015-04-10 18:45:09	18:45:09	18:45:09.325	18:45:09.325143

TO_DATE function

TO_DATE converts a date represented by a character string to a DATE data type.

Note

TO_DATE doesn't support format strings with Q (Quarter number).

Syntax

```
TO_DATE(string, format)
```

```
TO_DATE(string, format, is_strict)
```

Arguments

string

A string to be converted.

format

A string literal that defines the format of the input *string*, in terms of its date parts. For a list of valid day, month, and year formats, see [Datetime format strings](#).

is_strict

An optional Boolean value that specifies whether an error is returned if an input date value is out of range. When *is_strict* is set to TRUE, an error is returned if there is an out of range value. When *is_strict* is set to FALSE, which is the default, then overflow values are accepted.

Return type

TO_DATE returns a DATE, depending on the *format* value.

If the conversion to *format* fails, then an error is returned.

Examples

The following SQL statement converts the date 02 Oct 2001 into a date data type.

```
select to_date('02 Oct 2001', 'DD Mon YYYY');

to_date
-----
2001-10-02
(1 row)
```

The following SQL statement converts the string 20010631 to a date.

```
select to_date('20010631', 'YYYYMMDD', FALSE);
```

The result is July 1, 2001, because there are only 30 days in June.

```
to_date
-----
2001-07-01
```

The following SQL statement converts the string 20010631 to a date:

```
to_date('20010631', 'YYYYMMDD', TRUE);
```

The result is an error because there are only 30 days in June.

```
ERROR:  date/time field date value out of range: 2001-6-31
```

TO_NUMBER

TO_NUMBER converts a string to a numeric (decimal) value.

Note

We recommend that you use FM in your format string to suppress padding blanks and zeroes. For a list of valid formats, see [Numeric format strings](#).

Syntax

```
to_number(string, format)
```

Arguments

string

String to be converted. The format must be a literal value.

format

The second argument is a format string that indicates how the character string should be parsed to create the numeric value. For example, the format 'FM99D999' specifies that the string to be converted consists of five digits with the decimal point in the third position. For example, `to_number('12.345', 'FM99D999')` returns 12.345 as a numeric value. For a list of valid formats, see [Numeric format strings](#).

Return type

TO_NUMBER returns a DECIMAL number.

If the conversion to *format* fails, then an error is returned.

Examples

The following example converts the string 12,454.8- to a number:

```
select to_number('12,454.8-', 'FM99G999D9S');  
  
to_number
```

```
-----  
-12454.8
```

The following example converts the string \$ 12,454.88 to a number:

```
select to_number('$ 12,454.88', 'FML99G999D99');  
  
to_number  
-----  
12454.88
```

The following example converts the string \$ 2,012,454.88 to a number:

```
select to_number('$ 2,012,454.88', 'FML9,999,999.99');  
  
to_number  
-----  
2012454.88
```

TEXT_TO_INT_ALT

TEXT_TO_INT_ALT converts a character string to an integer using Teradata-style formatting. Fraction digits in the result are truncated.

Syntax

```
TEXT_TO_INT_ALT (expression [ , 'format'] )
```

Arguments

expression

An expression that results in one or more CHAR or VARCHAR values, such as a column name or literal string. Converting null values returns nulls. The function converts blank or empty strings to 0.

format

A string literal that defines the format of the input expression. For more information about the formatting characters you can specify, see [Teradata-style formatting characters for numeric data](#).

Return type

TEXT_TO_INT_ALT returns an INTEGER value.

The fractional portion of the cast result is truncated.

Amazon Redshift returns an error if the conversion to the *format* phrase that you specify isn't successful.

Examples

The following example converts the input *expression* string '123-' to the integer -123.

```
select text_to_int_alt('123-');
```

```
text_to_int_alt
-----
          -123
```

The following example converts the input *expression* string '2147483647+' to the integer 2147483647.

```
select text_to_int_alt('2147483647');
```

```
text_to_int_alt
-----
2147483647
```

The following example converts the exponential input *expression* string '-123E-2' to the integer -1.

```
select text_to_int_alt('-123E-2');
```

```
text_to_int_alt
-----
          -1
```

The following example converts the input *expression* string '2147483647+' to the integer 2147483647.

```
select text_to_int_alt('2147483647');
```

```
text_to_int_alt
-----
2147483647
```

The following example converts the input *expression* string '123{' with the *format* phrase '999S' to the integer 1230. The S character indicates a Signed Zoned Decimal. For more information, see [Teradata-style formatting characters for numeric data](#).

```
select text_to_int_alt('123{', '999S');
```

```
text_to_int_alt
-----
      1230
```

The following example converts the input *expression* string 'USD123' with the *format* phrase 'C9(I)' to the integer 123. See [Teradata-style formatting characters for numeric data](#).

```
select text_to_int_alt('USD123', 'C9(I)');
```

```
text_to_int_alt
-----
      123
```

The following example specifies a table column as the input *expression*.

```
select text_to_int_alt(a), text_to_int_alt(b) from t_text2int order by 1;
```

```
text_to_int_alt | text_to_int_alt
-----+-----
      -123 |          -123
      -123 |          -123
       123 |           123
       123 |           123
```

Following is the table definition and the insert statement for this example.

```
create table t_text2int (a varchar(200), b char(200));
```

```
insert into t_text2int VALUES('123', '123'),('123.123', '123.123'), ('-123', '-123'),  
('123-', '123-');
```

TEXT_TO_NUMERIC_ALT

TEXT_TO_NUMERIC_ALT performs a Teradata-style cast operation to convert a character string to a numeric data format.

Syntax

```
TEXT_TO_NUMERIC_ALT (expression [, 'format'] [, precision, scale])
```

Arguments

expression

An expression that evaluates to one or more CHAR or VARCHAR values, such as a column name or a literal. Converting null values returns nulls. Blank or empty strings are converted to 0.

format

A string literal that defines the format of the input expression. For more information, see [Teradata-style formatting characters for numeric data](#).

precision

The number of digits in the numeric result. The default is 38.

scale

The number of digits to the right of the decimal point in the numeric result. The default is 0.

Return type

TEXT_TO_NUMERIC_ALT returns a DECIMAL number.

Amazon Redshift returns an error if the conversion to the *format* phrase that you specify isn't successful.

Amazon Redshift casts the input *expression* string to the numeric type with the highest precision that you specify for that type in the *precision* option. If the length of the numeric value exceeds the value that you specify for *precision*, Amazon Redshift rounds the numeric value according to the following rules:

- If the length of the cast result exceeds the length that you specify in the *format* phrase, Amazon Redshift returns an error.
- If the result is cast to a numeric value, the result is rounded to the closest value. If the fractional portion is exactly midway between the upper and lower cast result, the result is rounded to the nearest even value.

Examples

The following example converts the input *expression* string '1.5' to the numeric value '2'. Because the statement doesn't specify *scale*, the *scale* defaults to 0 and the cast result doesn't include a fraction result. Because .5 is midway between 1 and 2, the cast result is rounded to the even value of 2.

```
select text_to_numeric_alt('1.5');
```

```
text_to_numeric_alt
-----
                    2
```

The following example converts the input *expression* string '2.51' to the numeric value 3. Because the statement doesn't specify a *scale* value, the *scale* defaults to 0 and the cast result doesn't include a fraction result. Because .51 is closer to 3 than 2, the cast result is rounded to the value of 3.

```
select text_to_numeric_alt('2.51');
```

```
text_to_numeric_alt
-----
                    3
```

The following example converts the input *expression* string 123.52501 with a *precision* of 10 and a *scale* of 2 to the numeric value 123.53.

```
select text_to_numeric_alt('123.52501', 10, 2);
```

```
text_to_numeric_alt
-----
```

```
( '+123.456' , '+123.456' ),
( '-' || repeat('9', 38), '-' || repeat('9', 38)),
( repeat('9', 38) || '+', repeat('9', 38) || '+'),
( '-123E2', '-123E2');
```

Datetime format strings

You can find a reference for datetime format strings following.

The following format strings apply to functions such as TO_CHAR. These strings can contain datetime separators (such as '-', '/', or ':') and the following "dateparts" and "timeparts".

Datepart or timepart	Meaning
BC or B.C., AD or A.D., b.c. or bc, ad or a.d.	Upper and lowercase era indicators
CC	Two-digit century number
YYYY, YYY, YY, Y	4-digit, 3-digit, 2-digit, 1-digit year number
Y,YYY	4-digit year number with comma
IYYY, IYY, IY, I	4-digit, 3-digit, 2-digit, 1-digit International Organization for Standardization (ISO) year number
Q	Quarter number (1 to 4)
MONTH, Month, month	Month name (uppercase, mixed-case, lowercase, blank-padded to 9 characters)
MON, Mon, mon	Abbreviated month name (uppercase, mixed-case, lowercase, blank-padded to 3 characters)
MM	Month number (01-12)
RM, rm	Month number in Roman numerals (I–XII, with I being January, uppercase or lowercase)
W	Week of month (1–5; the first week starts on the first day of the month.)

Datepart or timepart	Meaning
WW	Week number of year (1–53; the first week starts on the first day of the year.)
IW	ISO week number of year (the first Thursday of the new year is in week 1.)
DAY, Day, day	Day name (uppercase, mixed-case, lowercase, blank-padded to 9 characters)
DY, Dy, dy	Abbreviated day name (uppercase, mixed-case, lowercase, blank-padded to 3 characters)
DDD	Day of year (001–366)
IDDD	Day of ISO 8601 week-numbering year (001–371; day 1 of the year is Monday of the first ISO week)
DD	Day of month as a number (01–31)
D	Day of week (1–7; Sunday is 1) <div data-bbox="829 1157 1508 1612" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p>Note</p> <p>The D datepart behaves differently from the day of week (DOW) datepart used for the datetime functions DATE_PART and EXTRACT. DOW is based on integers 0–6, where Sunday is 0. For more information, see Date parts for date or timestamp functions.</p> </div>
ID	ISO 8601 day of the week, Monday (1) to Sunday (7)
J	Julian day (days since January 1, 4712 BC)

Datepart or timepart	Meaning
HH24	Hour (24-hour clock, 00–23)
HH or HH12	Hour (12-hour clock, 01–12)
MI	Minutes (00–59)
SS	Seconds (00–59)
MS	Milliseconds (.000)
US	Microseconds (.000000)
AM or PM, A.M. or P.M., a.m. or p.m., am or pm	Upper and lowercase meridian indicators (for 12-hour clock)
TZ, tz	Upper and lowercase time zone abbreviation; valid for TIMESTAMPTZ only
OF	Offset from UTC; valid for TIMESTAMPTZ only

Note

You must surround datetime separators (such as '-', '/' or ':') with single quotation marks, but you must surround the "dateparts" and "timeparts" listed in the preceding table with double quotation marks.

Examples

For examples of formatting dates as strings, see [TO_CHAR](#).

Numeric format strings

Following, you can find a reference for numeric format strings.

The following format strings apply to functions such as TO_NUMBER and TO_CHAR.

- For examples of formatting strings as numbers, see [TO_NUMBER](#).

- For examples of formatting numbers as strings, see [TO_CHAR](#).

Format	Description
9	Numeric value with the specified number of digits.
0	Numeric value with leading zeros.
. (period), D	Decimal point.
, (comma)	Thousands separator.
CC	Century code. For example, the 21st century started on 2001-01-01 (supported for TO_CHAR only).
FM	Fill mode. Suppress padding blanks and zeroes.
PR	Negative value in angle brackets.
S	Sign anchored to a number.
L	Currency symbol in the specified position.
G	Group separator.
MI	Minus sign in the specified position for numbers that are less than 0.
PL	Plus sign in the specified position for numbers that are greater than 0.
SG	Plus or minus sign in the specified position.
RN	Roman numeral between 1 and 3999 (supported for TO_CHAR only).

Format	Description
TH or th	Ordinal number suffix. Does not convert fractional numbers or values that are less than zero.

Teradata-style formatting characters for numeric data

Following, you can find how the `TEXT_TO_INT_ALT` and `TEXT_TO_NUMERIC_ALT` functions interpret the characters in the input *expression* string. You can also find a list of the characters that you can specify in the *format* phrase. In addition, you can find a description of the differences between Teradata-style formatting and Amazon Redshift for the *format* option.

Format	Description
G	Not supported as a group separator in the input <i>expression</i> string. You can't specify this character in the <i>format</i> phrase.
D	<p>Radix symbol. You can specify this character in the <i>format</i> phrase. This character is equivalent to the . (period).</p> <p>The Radix symbol can't appear in a <i>format</i> phrase that contains any of the following characters:</p> <ul style="list-style-type: none"> • . (period) • S (uppercase 's') • V (uppercase 'v')
/, : %	<p>Insertion characters / (forward slash), comma (,), : (colon), and % (percent sign).</p> <p>You can't include these characters in the <i>format</i> phrase.</p>

Format	Description
	Amazon Redshift ignores these characters in the input <i>expression</i> string.
.	<p>Period as a radix character, that is a decimal point.</p> <p>This character can't appear in a <i>format</i> phrase that contains any of the following characters:</p> <ul style="list-style-type: none"> • D (uppercase 'd') • S (uppercase 's') • V (uppercase 'v')
B	You can't include the blank space character (B) in the <i>format</i> phrase. In the input <i>expression</i> string, leading and trailing spaces are ignored and spaces between digits aren't allowed.
+ -	You can't include the plus sign (+) or minus sign (-) in the <i>format</i> phrase. However, the plus sign (+) and minus sign (-) are parsed implicitly as part of numeric value if they appear in the input <i>expression</i> string.
V	<p>Decimal point position indicator.</p> <p>This character can't appear in a <i>format</i> phrase that contains any of the following characters:</p> <ul style="list-style-type: none"> • D (uppercase 'd') • . (period)
Z	Zero-suppressed decimal digit. Amazon Redshift trims leading zeros. The Z character can't follow a 9 character. The Z character must be to the left of the radix character if the fraction part contains the 9 character.

Format	Description
9	Decimal digit.
CHAR(<i>n</i>)	<p>For this format, you can specify the following:</p> <ul style="list-style-type: none">• CHAR consists of Z or 9 characters. Amazon Redshift doesn't support a + (plus) or - (minus) in the CHAR value.• <i>n</i> is an integer constant, I, or F. For I, this is the number of characters necessary to display the integer portion of numeric or integer data. For F, this is the number of characters necessary to display the fractional portion of numeric data.
-	<p>Hyphen (-) character.</p> <p>You can't include this character in the <i>format</i> phrase.</p> <p>Amazon Redshift ignores this character in the input <i>expression</i> string.</p>

Format	Description
S	<p>Signed Zoned Decimal. The S character must follow the last decimal digit in the <i>format</i> phrase. The last character of the input <i>expression</i> string and the corresponding numeric conversion are listed in Data formatting characters for Signed Zone Decimal, Teradata-style numeric data formatting.</p> <p>The S character can't appear in a <i>format</i> phrase that contains any of the following characters:</p> <ul style="list-style-type: none">• + (plus sign)• . (period)• D (uppercase 'd')• Z (uppercase 'z')• F (uppercase 'f')• E (uppercase 'e')
E	<p>Exponential notation. The input <i>expression</i> string can include the exponent character. You can't specify E as an exponent character in <i>format</i> phrase.</p>
FN9	Not supported in Amazon Redshift.
FNE	Not supported in Amazon Redshift.

Format	Description
\$, USD, US Dollars	<p>Dollar sign (\$), ISO currency symbol (USD), and the currency name US Dollars.</p> <p>The ISO currency symbol USD and the currency name US Dollars are case-sensitive. Amazon Redshift supports only the USD currency. The input <i>expression</i> string can include spaces between the USD currency symbol and the numeric value, for example '\$ 123E2' or '123E2 \$'.</p>
L	<p>Currency symbol. This currency symbol character can only appear once in the <i>format</i> phrase. You can't specify repeated currency symbol characters.</p>
C	<p>ISO currency symbol. This currency symbol character can only appear once in the <i>format</i> phrase. You can't specify repeated currency symbol characters.</p>
N	<p>Full currency name. This currency symbol character can only appear once in the <i>format</i> phrase. You can't specify repeated currency symbol characters.</p>
O	<p>Dual currency symbol. You can't specify this character in the <i>format</i> phrase.</p>
U	<p>Dual ISO currency symbol. You can't specify this character in the <i>format</i> phrase.</p>
A	<p>Full dual currency name. You can't specify this character in the <i>format</i> phrase.</p>

Data formatting characters for Signed Zone Decimal, Teradata–style numeric data formatting

You can use the following characters in the *format* phrase of the `TEXT_TO_INT_ALT` and `TEXT_TO_NUMERIC_ALT` functions for a signed zoned decimal value.

Last character of the input string	Numeric conversion
{ or 0	$n \dots 0$
A or 1	$n \dots 1$
B or 2	$n \dots 2$
C or 3	$n \dots 3$
D or 4	$n \dots 4$
E or 5	$n \dots 5$
F or 6	$n \dots 6$
G or 7	$n \dots 7$
H or 8	$n \dots 8$
I or 9	$n \dots 9$
}	$-n \dots 0$
J	$-n \dots 1$
K	$-n \dots 2$
L	$-n \dots 3$
M	$-n \dots 4$
N	$-n \dots 5$
O	$-n \dots 6$
P	$-n \dots 7$

Last character of the input string	Numeric conversion
Q	$-n \dots 8$
R	$-n \dots 9$

Date and time functions

In this section, you can find information about the date and time scalar functions that Amazon Redshift supports.

Summary of date and time functions

Function	Syntax	Returns
<p>+ (Concatenation) operator</p> <p>Concatenates a date to a time on either side of the + symbol and returns a TIMESTAMP or TIMESTAMPTZ.</p>	<i>date + time</i>	TIMESTAMP or TIMESTAMPTZ
<p>ADD_MONTHS</p> <p>Adds the specified number of months to a date or timestamp.</p>	ADD_MONTHS (<i>{date timestamp}, integer</i>)	TIMESTAMP
<p>AT TIME ZONE</p> <p>Specifies which time zone to use with a TIMESTAMP or TIMESTAMPTZ expression.</p>	AT TIME ZONE ' <i>timezone</i> '	TIMESTAMP or TIMESTAMPTZ

Function	Syntax	Returns
<p>CONVERT_TIMEZONE</p> <p>Converts a timestamp from one time zone to another.</p>	<p>CONVERT_TIMEZONE (['timezone'], 'timezone', timestamp)</p>	TIMESTAMP
<p>CURRENT_DATE</p> <p>Returns a date in the current session time zone (UTC by default) for the start of the current transaction.</p>	CURRENT_DATE	DATE
<p>DATE_CMP</p> <p>Compares two dates and returns 0 if the dates are identical, 1 if <i>date1</i> is greater, and -1 if <i>date2</i> is greater.</p>	DATE_CMP (<i>date1</i> , <i>date2</i>)	INTEGER
<p>DATE_CMP_TIMESTAMP</p> <p>Compares a date to a time and returns 0 if the values are identical, 1 if <i>date</i> is greater and -1 if <i>timestamp</i> is greater.</p>	DATE_CMP_TIMESTAMP (<i>date</i> , <i>timestamp</i>)	INTEGER
<p>DATE_CMP_TIMESTAMPPTZ</p> <p>Compares a date and a timestamp with time zone and returns 0 if the values are identical , 1 if <i>date</i> is greater and -1 if <i>timestampptz</i> is greater.</p>	DATE_CMP_TIMESTAMPPTZ (<i>date</i> , <i>timestampptz</i>)	INTEGER
<p>DATE_PART_YEAR</p> <p>Extracts the year from a date.</p>	DATE_PART_YEAR (<i>date</i>)	INTEGER
<p>DATEADD</p> <p>Increments a date or time by a specified interval.</p>	DATEADD (<i>datepart</i> , <i>interval</i> , { <i>date</i> <i>time</i> <i>timetz</i> <i>timestamp</i> })	TIMESTAMP or TIME or TIMETZ

Function	Syntax	Returns
<p>DATEDIFF</p> <p>Returns the difference between two dates or times for a given date part, such as a day or month.</p>	<p>DATEDIFF (<i>datepart</i>, {<i>date time timetz timestamp</i> }, {<i>date time timetz timestamp</i>})</p>	BIGINT
<p>DATE_PART</p> <p>Extracts a date part value from a date or time.</p>	<p>DATE_PART (<i>datepart</i>, {<i>date timestamp</i>})</p>	DOUBLE
<p>DATE_TRUNC</p> <p>Truncates a timestamp based on a date part.</p>	<p>DATE_TRUNC ('<i>datepart</i>', <i>timestamp</i>)</p>	TIMESTAMP
<p>EXTRACT</p> <p>Extracts a date or time part from a timestamp, timestamptz, time, or timetz.</p>	<p>EXTRACT (<i>datepart</i> FROM <i>source</i>)</p>	INTEGER or DOUBLE
<p>GETDATE</p> <p>Returns the current date and time in the current session time zone (UTC by default). The parentheses are required.</p>	<p>GETDATE()</p>	TIMESTAMP
<p>INTERVAL_CMP</p> <p>Compares two intervals and returns 0 if the intervals are equal, 1 if <i>interval1</i> is greater, and -1 if <i>interval2</i> is greater.</p>	<p>INTERVAL_CMP (<i>interval1</i>, <i>interval2</i>)</p>	INTEGER
<p>LAST_DAY</p> <p>Returns the date of the last day of the month that contains <i>date</i>.</p>	<p>LAST_DAY(<i>date</i>)</p>	DATE

Function	Syntax	Returns
<p>MONTHS_BETWEEN</p> <p>Returns the number of months between two dates.</p>	<p>MONTHS_BETWEEN (<i>date</i>, <i>date</i>)</p>	<p>FLOAT8</p>
<p>NEXT_DAY</p> <p>Returns the date of the first instance of <i>day</i> that is later than <i>date</i>.</p>	<p>NEXT_DAY (<i>date</i>, <i>day</i>)</p>	<p>DATE</p>
<p>SYSDATE</p> <p>Returns the date and time in UTC for the start of the current transaction.</p>	<p>SYSDATE</p>	<p>TIMESTAMP</p>
<p>TIMEOFDAY</p> <p>Returns the current weekday, date, and time in the current session time zone (UTC by default) as a string value.</p>	<p>TIMEOFDAY()</p>	<p>VARCHAR</p>
<p>TIMESTAMP_CMP</p> <p>Compares two timestamps and returns 0 if the timestamps are equal, 1 if <i>timestamp1</i> is greater, and -1 if <i>timestamp2</i> is greater.</p>	<p>TIMESTAMP_CMP (<i>timestamp</i> <i>1</i>, <i>timestamp2</i>)</p>	<p>INTEGER</p>
<p>TIMESTAMP_CMP_DATE</p> <p>Compares a timestamp to a date and returns 0 if the values are identical, 1 if <i>timestamp</i> is greater, and -1 if <i>date</i> is greater.</p>	<p>TIMESTAMP_CMP_DATE (<i>timestamp</i>, <i>date</i>)</p>	<p>INTEGER</p>

Function	Syntax	Returns
<p>TIMESTAMP_CMP_TIMESTAMPTZ</p> <p>Compares a timestamp with a timestamp with time zone and returns 0 if the values are equal, 1 if <i>timestamp</i> is greater, and -1 if <i>timestamptz</i> is greater.</p>	<p>TIMESTAMP_CMP_TIME STAMPTZ (<i>timestamp</i>, <i>timestamptz</i>)</p>	INTEGER
<p>TIMESTAMPTZ_CMP</p> <p>Compares two timestamp with time zone values and returns 0 if the values are equal, 1 if <i>timestamptz1</i> is greater, and -1 if <i>timestamp tz2</i> is greater.</p>	<p>TIMESTAMPTZ_CMP (<i>timestamptz1</i>, <i>timestamptz2</i>)</p>	INTEGER
<p>TIMESTAMPTZ_CMP_DATE</p> <p>Compares the value of a timestamp with time zone and a date and returns 0 if the values are equal, 1 if <i>timestamptz</i> is greater, and -1 if <i>date</i> is greater.</p>	<p>TIMESTAMPTZ_CMP_DATE (<i>timestamptz</i>, <i>date</i>)</p>	INTEGER
<p>TIMESTAMPTZ_CMP_TIMESTAMP</p> <p>Compares a timestamp with time zone with a timestamp and returns 0 if the values are equal, 1 if <i>timestamptz</i> is greater, and -1 if <i>timestamp</i> is greater.</p>	<p>TIMESTAMPTZ_CMP_TIMESTAMP (<i>timestamptz</i>, <i>timestamp</i>)</p>	INTEGER
<p>TIMEZONE</p> <p>Returns a timestamp for the specified time zone and timestamp value.</p>	<p>TIMEZONE ('<i>timezone</i>' { <i>timestamp</i> <i>timestamptz</i> })</p>	TIMESTAMP or TIMESTAMP TZ
<p>TO_TIMESTAMP</p> <p>Returns a timestamp with time zone for the specified timestamp and time zone format.</p>	<p>TO_TIMESTAMP ('<i>timestamp</i>', '<i>format</i>')</p>	TIMESTAMP TZ

Function	Syntax	Returns
TRUNC Truncates a timestamp and returns a date.	TRUNC(<i>timestamp</i>)	DATE

Note

Leap seconds are not considered in elapsed-time calculations.

Date and time functions in transactions

When you run the following functions within a transaction block (BEGIN ... END), the function returns the start date or time of the current transaction, not the start of the current statement.

- SYSDATE
- TIMESTAMP
- CURRENT_DATE

The following functions always return the start date or time of the current statement, even when they are within a transaction block.

- GETDATE
- TIMEOFDAY

Deprecated leader node-only functions

The following date functions are deprecated because they run only on the leader node. For more information, see [Leader node-only functions](#).

- AGE. Use [DATEDIFF function](#) instead.
- CURRENT_TIME. Use [GETDATE function](#) or [SYSDATE](#) instead.
- CURRENT_TIMESTAMP. Use [GETDATE function](#) or [SYSDATE](#) instead.
- LOCALTIME. Use [GETDATE function](#) or [SYSDATE](#) instead.
- LOCALTIMESTAMP. Use [GETDATE function](#) or [SYSDATE](#) instead.

- ISFINITE
- NOW. Use [GETDATE function](#) or [SYSDATE](#) instead.

+ (Concatenation) operator

Concatenates a DATE to a TIME or TIMETZ on either side of the + symbol and returns a TIMESTAMP or TIMESTAMPTZ.

Syntax

```
date + {time | timetz}
```

The order of the arguments can be reversed. For example, *time* + *date*.

Arguments

date

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

time

A column of data type TIME or an expression that implicitly evaluates to a TIME type.

timetz

A column of data type TIMETZ or an expression that implicitly evaluates to a TIMETZ type.

Return type

TIMESTAMP if input is *date* + *time*.

TIMESTAMPTZ if input is *date* + *timetz*.

Examples

Example setup

To set up the TIME_TEST and TIMETZ_TEST tables used in the examples, use the following command.

```
create table time_test(time_val time);
```

```

insert into time_test values
('20:00:00'),
('00:00:00.5550'),
('00:58:00');

create table timetz_test(timetz_val timetz);

insert into timetz_test values
('04:00:00+00'),
('00:00:00.5550+00'),
('05:58:00+00');

```

Examples with a time column

The following example table TIME_TEST has a column TIME_VAL (type TIME) with three values inserted.

```
select time_val from time_test;
```

```

time_val
-----
20:00:00
00:00:00.5550
00:58:00

```

The following example concatenates a date literal and a TIME_VAL column.

```
select date '2000-01-02' + time_val as ts from time_test;
```

```

ts
-----
2000-01-02 20:00:00
2000-01-02 00:00:00.5550
2000-01-02 00:58:00

```

The following example concatenates a date literal and a time literal.

```
select date '2000-01-01' + time '20:00:00' as ts;
```

```

      ts
-----

```

```
2000-01-01 20:00:00
```

The following example concatenates a time literal and a date literal.

```
select time '20:00:00' + date '2000-01-01' as ts;
```

```
      ts
-----
2000-01-01 20:00:00
```

Examples with a TIMETZ column

The following example table TIMETZ_TEST has a column TIMETZ_VAL (type TIMETZ) with three values inserted.

```
select timetz_val from timetz_test;
```

```
timetz_val
-----
04:00:00+00
00:00:00.5550+00
05:58:00+00
```

The following example concatenates a date literal and a TIMETZ_VAL column.

```
select date '2000-01-01' + timetz_val as ts from timetz_test;
```

```
ts
-----
2000-01-01 04:00:00+00
2000-01-01 00:00:00.5550+00
2000-01-01 05:58:00+00
```

The following example concatenates a TIMETZ_VAL column and a date literal.

```
select timetz_val + date '2000-01-01' as ts from timetz_test;
```

```
ts
-----
2000-01-01 04:00:00+00
2000-01-01 00:00:00.5550+00
2000-01-01 05:58:00+00
```

The following example concatenates a DATE literal and a TIMETZ literal. The example returns a TIMESTAMPTZ which is in the time zone UTC by default. UTC is 8 hours ahead of PST, so the result is 8 hours ahead of the input time.

```
select date '2000-01-01' + timetz '20:00:00 PST' as ts;
```

```
      ts
-----
2000-01-02 04:00:00+00
```

ADD_MONTHS function

ADD_MONTHS adds the specified number of months to a date or timestamp value or expression. The [DATEADD](#) function provides similar functionality.

Syntax

```
ADD_MONTHS( {date | timestamp}, integer)
```

Arguments

date | timestamp

A column of data type DATE or TIMESTAMP or an expression that implicitly evaluates to a DATE or TIMESTAMP type. If the date is the last day of the month, or if the resulting month is shorter, the function returns the last day of the month in the result. For other dates, the result contains the same day number as the date expression.

integer

A value of data type INTEGER. Use a negative number to subtract months from dates.

Return type

TIMESTAMP

Examples

The following query uses the ADD_MONTHS function inside a TRUNC function. The TRUNC function removes the time of day from the result of ADD_MONTHS. The ADD_MONTHS function

adds 12 months to each value from the CALDATE column. The values in the CALDATE column are dates.

```
select distinct trunc(add_months(caldate, 12)) as calplus12,
trunc(caldate) as cal
from date
order by 1 asc;
```

```
calplus12 | cal
-----+-----
2009-01-01 | 2008-01-01
2009-01-02 | 2008-01-02
2009-01-03 | 2008-01-03
...
(365 rows)
```

The following example uses the ADD_MONTHS function to add 1 month to a *timestamp*.

```
select add_months('2008-01-01 05:07:30', 1);
```

```
add_months
-----
2008-02-01 05:07:30
```

The following examples demonstrate the behavior when the ADD_MONTHS function operates on dates with months that have different numbers of days. This example shows how the function handles adding 1 month to March 31 and adding 1 month to April 30. April has 30 days, so adding 1 month to March 31 results in April 30. May has 31 days, so adding 1 month to April 30 results in May 31.

```
select add_months('2008-03-31',1);
```

```
add_months
-----
2008-04-30 00:00:00
```

```
select add_months('2008-04-30',1);
```

```
add_months
-----
2008-05-31 00:00:00
```

AT TIME ZONE function

AT TIME ZONE specifies which time zone to use with a `TIMESTAMP` or `TIMESTAMPTZ` expression.

Syntax

```
AT TIME ZONE 'timezone'
```

Arguments

timezone

The `TIMEZONE` for the return value. The time zone can be specified as a time zone name (such as `'Africa/Kampala'` or `'Singapore'`) or as a time zone abbreviation (such as `'UTC'` or `'PDT'`).

To view a list of supported time zone names, run the following command.

```
select pg_timezone_names();
```

To view a list of supported time zone abbreviations, run the following command.

```
select pg_timezone_abbrevs();
```

For more information and examples, see [Time zone usage notes](#).

Return type

`TIMESTAMPTZ` when used with a `TIMESTAMP` expression. `TIMESTAMP` when used with a `TIMESTAMPTZ` expression.

Examples

The following example converts a timestamp value without time zone and interprets it as MST time (UTC+7 in POSIX). The example returns a value of data type `TIMESTAMPTZ` for the UTC timezone. If you configure your default timezone to a timezone other than UTC, you might see a different result.

```
SELECT TIMESTAMP '2001-02-16 20:38:40' AT TIME ZONE 'MST';
```

```
timezone
-----
2001-02-17 03:38:40+00
```

The following example takes an input timestamp with a time zone value where the specified time zone is EST (UTC+5 in POSIX) and converts it to MST (UTC+7 in POSIX). The example returns a value of data type `TIMESTAMP`.

```
SELECT TIMESTAMPTZ '2001-02-16 20:38:40-05' AT TIME ZONE 'MST';
```

```
timezone
-----
2001-02-16 18:38:40
```

CONVERT_TIMEZONE function

`CONVERT_TIMEZONE` converts a timestamp from one time zone to another. The function automatically adjusts for daylight saving time.

Syntax

```
CONVERT_TIMEZONE( [source_timezone'], [target_timezone'], timestamp)
```

Arguments

source_timezone

(Optional) The time zone of the current timestamp. The default is UTC. For more information, see [Time zone usage notes](#).

target_timezone

The time zone for the new timestamp. For more information, see [Time zone usage notes](#).

timestamp

A timestamp column or an expression that implicitly converts to a timestamp.

Return type

`TIMESTAMP`

Time zone usage notes

source_timezone or *target_timezone* can be specified as a time zone name (such as 'Africa/Kampala' or 'Singapore') or as a time zone abbreviation (such as 'UTC' or 'PDT'). You don't have to convert time zone names to names or abbreviations to abbreviations. For example, you can choose a timestamp from the source time zone name 'Singapore' and convert it to a timestamp in the time zone abbreviation 'PDT'.

Note

The results of using a time zone name or a time zone abbreviation can be different due to local seasonal time, such as daylight saving time.

Using a time zone name

To view a current and complete list of time zone names, run the following command.

```
select pg_timezone_names();
```

Each row contains a comma-separated string with the time zone name, abbreviation, UTC offset, and indicator if the time zone observes daylight-savings (t or f). For example, the following snippet shows two resulting rows. The first row is the time zone Europe/Paris, abbreviation CET, with 01:00:00 offset from UTC, and f to indicate it doesn't observe daylight-savings time. The second row is the time zone Israel, abbreviation IST, with 02:00:00 offset from UTC, and f to indicate it doesn't observe daylight-savings time.

```
pg_timezone_names
-----
(Europe/Paris,CET,01:00:00,f)
(Israel,IST,02:00:00,f)
```

Run the SQL statement to obtain the entire list and find a time zone name. Approximately 600 rows are returned. Even though some of the returned time zone names are capitalized initialisms or acronyms (for example; GB, PRC, ROK), the CONVERT_TIMEZONE function treats them as time zone names, not time zone abbreviations.

If you specify a time zone using a time zone name, CONVERT_TIMEZONE automatically adjusts for daylight saving time (DST), or any other local seasonal protocol, such as Summer Time, Standard

Time, or Winter Time, that is in force for that time zone during the date and time specified by *'timestamp'*. For example, 'Europe/London' represents UTC in the winter and adds one hour in the summer.

Using a time zone abbreviation

To view a current and complete list of time zone abbreviations, run the following command.

```
select pg_timezone_abbrevs();
```

The results contain a comma-separated string with the time zone abbreviation, UTC offset, and indicator if the time zone observes daylight-savings (t or f). For example, the following snippet shows two resulting rows. The first row contains the abbreviation for Pacific Daylight Time PDT, with a `-07:00:00` offset from UTC, and t to indicate it observes daylight-savings time. The second row contains the abbreviation for Pacific Standard Time PST, with a `-08:00:00` offset from UTC, and f to indicate it doesn't observe daylight-savings time.

```
pg_timezone_abbrevs
-----
(PDT, -07:00:00, t)
(PST, -08:00:00, f)
```

Run the SQL statement to obtain the entire list and find an abbreviation based on its offset and daylight-savings indicator. Approximately 200 rows are returned.

Time zone abbreviations represent a fixed offset from UTC. If you specify a time zone using a time zone abbreviation, `CONVERT_TIMEZONE` uses the fixed offset from UTC and doesn't adjust for any local seasonal protocol.

Using POSIX-style format

A POSIX-style time zone specification is in the form *STDoffset* or *STDoffsetDST*, where *STD* is a time zone abbreviation, *offset* is the numeric offset in hours west from UTC, and *DST* is an optional daylight-savings zone abbreviation. Daylight savings time is assumed to be one hour ahead of the given offset.

POSIX-style time zone formats use positive offsets west of Greenwich, in contrast to the ISO-8601 convention, which uses positive offsets east of Greenwich.

The following are examples of POSIX-style time zones:

- PST8
- PST8PDT
- EST5
- EST5EDT

Note

Amazon Redshift doesn't validate POSIX-style time zone specifications, so it is possible to set the time zone to an invalid value. For example, the following command doesn't return an error, even though it sets the time zone to an invalid value.

```
set timezone to 'xxx36';
```

Examples

Many of the examples use the TICKIT sample data set. For more information, see [Sample database](#).

The following example converts the timestamp value from the default UTC time zone to PST.

```
select convert_timezone('PST', '2008-08-21 07:23:54');
```

```
convert_timezone
-----
2008-08-20 23:23:54
```

The following example converts the timestamp value in the LISTTIME column from the default UTC time zone to PST. Though the timestamp is within the daylight time period, it's converted to standard time because the target time zone is specified as an abbreviation (PST).

```
select listtime, convert_timezone('PST', listtime) from listing
where listid = 16;
```

```
listtime      | convert_timezone
-----+-----
2008-08-24 09:36:12    2008-08-24 01:36:12
```

The following example converts a timestamp LISTTIME column from the default UTC time zone to US/Pacific time zone. The target time zone uses a time zone name, and the timestamp is within the daylight time period, so the function returns the daylight time.

```
select listtime, convert_timezone('US/Pacific', listtime) from listing
where listid = 16;
```

```
listtime      | convert_timezone
-----+-----
2008-08-24 09:36:12 | 2008-08-24 02:36:12
```

The following example converts a timestamp string from EST to PST:

```
select convert_timezone('EST', 'PST', '20080305 12:25:29');
```

```
convert_timezone
-----
2008-03-05 09:25:29
```

The following example converts a timestamp to US Eastern Standard Time because the target time zone uses a time zone name (America/New_York) and the timestamp is within the standard time period.

```
select convert_timezone('America/New_York', '2013-02-01 08:00:00');
```

```
convert_timezone
-----
2013-02-01 03:00:00
(1 row)
```

The following example converts the timestamp to US Eastern Daylight Time because the target time zone uses a time zone name (America/New_York) and the timestamp is within the daylight time period.

```
select convert_timezone('America/New_York', '2013-06-01 08:00:00');
```

```
convert_timezone
-----
2013-06-01 04:00:00
(1 row)
```

The following example demonstrates the use of offsets.

```
SELECT CONVERT_TIMEZONE('GMT', 'NEWZONE +2', '2014-05-17 12:00:00') as newzone_plus_2,
CONVERT_TIMEZONE('GMT', 'NEWZONE-2:15', '2014-05-17 12:00:00') as newzone_minus_2_15,
CONVERT_TIMEZONE('GMT', 'America/Los_Angeles+2', '2014-05-17 12:00:00') as la_plus_2,
CONVERT_TIMEZONE('GMT', 'GMT+2', '2014-05-17 12:00:00') as gmt_plus_2;
```

newzone_plus_2	newzone_minus_2_15	la_plus_2	gmt_plus_2
2014-05-17 10:00:00	2014-05-17 14:15:00	2014-05-17 10:00:00	2014-05-17 10:00:00

(1 row)

CURRENT_DATE function

CURRENT_DATE returns a date in the current session time zone (UTC by default) in the default format: YYYY-MM-DD.

Note

CURRENT_DATE returns the start date for the current transaction, not for the start of the current statement. Consider the scenario where you start a transaction containing multiple statements on 10/01/08 23:59, and the statement containing CURRENT_DATE runs at 10/02/08 00:00. CURRENT_DATE returns 10/01/08, not 10/02/08.

Syntax

```
CURRENT_DATE
```

Return type

DATE

Examples

The following example returns the current date (in the AWS Region where the function runs).

```
select current_date;
```

```
date
-----
```

```
2008-10-01
```

The following example creates a table, inserts a row where the default of column `today's_date` is `CURRENT_DATE`, and then selects all the rows in the table.

```
CREATE TABLE insert_dates(  
    label varchar(128) NOT NULL,  
    today's_date DATE DEFAULT CURRENT_DATE);
```

```
INSERT INTO insert_dates(label)  
VALUES('Date row inserted');
```

```
SELECT * FROM insert_dates;
```

```
label          | today's_date  
-----+-----  
Date row inserted | 2023-05-10
```

DATE_CMP function

`DATE_CMP` compares two dates. The function returns 0 if the dates are identical, 1 if *date1* is greater, and -1 if *date2* is greater.

Syntax

```
DATE_CMP(date1, date2)
```

Arguments

date1

A column of data type `DATE` or an expression that evaluates to a `DATE` type.

date2

A column of data type `DATE` or an expression that evaluates to a `DATE` type.

Return type

`INTEGER`

Examples

The following query compares the DATE values in the CALDATE column to the date January 4, 2008 and returns whether the value in CALDATE is before (-1), equal to (0), or after (1) January 4, 2008:

```
select caldate, '2008-01-04',
       date_cmp(caldate, '2008-01-04')
from date
order by dateid
limit 10;
```

caldate	?column?	date_cmp
2008-01-01	2008-01-04	-1
2008-01-02	2008-01-04	-1
2008-01-03	2008-01-04	-1
2008-01-04	2008-01-04	0
2008-01-05	2008-01-04	1
2008-01-06	2008-01-04	1
2008-01-07	2008-01-04	1
2008-01-08	2008-01-04	1
2008-01-09	2008-01-04	1
2008-01-10	2008-01-04	1

(10 rows)

DATE_CMP_TIMESTAMP function

DATE_CMP_TIMESTAMP compares a date to a timestamp and returns 0 if the values are identical, 1 if *date* is greater chronologically and -1 if *timestamp* is greater.

Syntax

```
DATE_CMP_TIMESTAMP(date, timestamp)
```

Arguments

date

A column of data type DATE or an expression that evaluates to a DATE type.

timestamp

A column of data type TIMESTAMP or an expression that evaluates to a TIMESTAMP type.

Return type

INTEGER

Examples

The following example compares the date 2008-06-18 to LISTTIME. The values of the column LISTTIME are timestamps. Listings made before this date return 1; listings made after this date return -1.

```
select listid, '2008-06-18', listtime,
       date_cmp_timestamp('2008-06-18', listtime)
from listing
order by 1, 2, 3, 4
limit 10;
```

listid	?column?	listtime	date_cmp_timestamp
1	2008-06-18	2008-01-24 06:43:29	1
2	2008-06-18	2008-03-05 12:25:29	1
3	2008-06-18	2008-11-01 07:35:33	-1
4	2008-06-18	2008-05-24 01:18:37	1
5	2008-06-18	2008-05-17 02:29:11	1
6	2008-06-18	2008-08-15 02:08:13	-1
7	2008-06-18	2008-11-15 09:38:15	-1
8	2008-06-18	2008-11-09 05:07:30	-1
9	2008-06-18	2008-09-09 08:03:36	-1
10	2008-06-18	2008-06-17 09:44:54	1

(10 rows)

DATE_CMP_TIMESTAMPTZ function

DATE_CMP_TIMESTAMPTZ compares a date to a timestamp with time zone and returns 0 if the values are identical, 1 if *date* is greater chronologically and -1 if *timestamptz* is greater.

Syntax

```
DATE_CMP_TIMESTAMPTZ(date, timestamptz)
```

Arguments

date

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

timestamptz

A column of data type TIMESTAMPTZ or an expression that implicitly evaluates to a TIMESTAMPTZ type.

Return type

INTEGER

Examples

The following example compares the date 2008-06-18 to LISTTIME. Listings made before this date return 1; listings made after this date return -1.

```
select listid, '2008-06-18', CAST(listtime AS timestamptz),
       date_cmp_timestamptz('2008-06-18', CAST(listtime AS timestamptz))
from listing
order by 1, 2, 3, 4
limit 10;
```

listid	?column?	timestamptz	date_cmp_timestamptz
1	2008-06-18	2008-01-24 06:43:29+00	1
2	2008-06-18	2008-03-05 12:25:29+00	1
3	2008-06-18	2008-11-01 07:35:33+00	-1
4	2008-06-18	2008-05-24 01:18:37+00	1
5	2008-06-18	2008-05-17 02:29:11+00	1
6	2008-06-18	2008-08-15 02:08:13+00	-1
7	2008-06-18	2008-11-15 09:38:15+00	-1
8	2008-06-18	2008-11-09 05:07:30+00	-1
9	2008-06-18	2008-09-09 08:03:36+00	-1
10	2008-06-18	2008-06-17 09:44:54+00	1

(10 rows)

DATEADD function

Increments a DATE, TIME, TIMETZ, or TIMESTAMP value by a specified interval.

Syntax

```
DATEADD( datepart, interval, {date|time|timetz|timestamp} )
```

Arguments

datepart

The date part (year, month, day, or hour, for example) that the function operates on. For more information, see [Date parts for date or timestamp functions](#).

interval

An integer that specified the interval (number of days, for example) to add to the target expression. A negative integer subtracts the interval.

date|time|timetz|timestamp

A DATE, TIME, TIMETZ, or TIMESTAMP column or an expression that implicitly converts to a DATE, TIME, TIMETZ, or TIMESTAMP. The DATE, TIME, TIMETZ, or TIMESTAMP expression must contain the specified date part.

Return type

TIMESTAMP or TIME or TIMETZ depending on the input data type.

Examples with a DATE column

The following example adds 30 days to each date in November that exists in the DATE table.

```
select dateadd(day,30,caldate) as novplus30
from date
where month='NOV'
order by dateid;

novplus30
-----
2008-12-01 00:00:00
2008-12-02 00:00:00
2008-12-03 00:00:00
...
(30 rows)
```

The following example adds 18 months to a literal date value.

```
select dateadd(month,18,'2008-02-28');
```

date_add
2009-08-28 00:00:00

(1 row)

The default column name for a DATEADD function is DATE_ADD. The default timestamp for a date value is 00:00:00.

The following example adds 30 minutes to a date value that doesn't specify a timestamp.

```
select dateadd(m,30,'2008-02-28');
```

date_add
2008-02-28 00:30:00

(1 row)

You can name date parts in full or abbreviate them. In this case, *m* stands for minutes, not months.

Examples with a TIME column

The following example table TIME_TEST has a column TIME_VAL (type TIME) with three values inserted.

```
select time_val from time_test;
```

time_val
20:00:00
00:00:00.5550
00:58:00

The following example adds 5 minutes to each TIME_VAL in the TIME_TEST table.

```
select dateadd(minute,5,time_val) as minplus5 from time_test;
```

```
minplus5
-----
20:05:00
00:05:00.5550
01:03:00
```

The following example adds 8 hours to a literal time value.

```
select dateadd(hour, 8, time '13:24:55');

date_add
-----
21:24:55
```

The following example shows when a time goes over 24:00:00 or under 00:00:00.

```
select dateadd(hour, 12, time '13:24:55');

date_add
-----
01:24:55
```

Examples with a TIMETZ column

The output values in these examples are in UTC which is the default timezone.

The following example table TIMETZ_TEST has a column TIMETZ_VAL (type TIMETZ) with three values inserted.

```
select timetz_val from timetz_test;

timetz_val
-----
04:00:00+00
00:00:00.5550+00
05:58:00+00
```

The following example adds 5 minutes to each TIMETZ_VAL in TIMETZ_TEST table.

```
select dateadd(minute,5,timetz_val) as minplus5_tz from timetz_test;
```

```
minplus5_tz
-----
04:05:00+00
00:05:00.5550+00
06:03:00+00
```

The following example adds 2 hours to a literal timetz value.

```
select dateadd(hour, 2, timetz '13:24:55 PST');

date_add
-----
23:24:55+00
```

Examples with a TIMESTAMP column

The output values in these examples are in UTC which is the default timezone.

The following example table `TIMESTAMP_TEST` has a column `TIMESTAMP_VAL` (type `TIMESTAMP`) with three values inserted.

```
SELECT timestamp_val FROM timestamp_test;

timestamp_val
-----
1988-05-15 10:23:31
2021-03-18 17:20:41
2023-06-02 18:11:12
```

The following example adds 20 years only to the `TIMESTAMP_VAL` values in `TIMESTAMP_TEST` from before the year 2000.

```
SELECT dateadd(year,20,timestamp_val)
FROM timestamp_test
WHERE timestamp_val < to_timestamp('2000-01-01 00:00:00', 'YYYY-MM-DD HH:MI:SS');

date_add
-----
2008-05-15 10:23:31
```

The following example adds 5 seconds to a literal timestamp value written without a seconds indicator.

```
SELECT dateadd(second, 5, timestamp '2001-06-06');

date_add
-----
2001-06-06 00:00:05
```

Usage notes

The DATEADD(month, ...) and ADD_MONTHS functions handle dates that fall at the ends of months differently:

- **ADD_MONTHS:** If the date you are adding to is the last day of the month, the result is always the last day of the result month, regardless of the length of the month. For example, April 30 + 1 month is May 31.

```
select add_months('2008-04-30',1);

add_months
-----
2008-05-31 00:00:00
(1 row)
```

- **DATEADD:** If there are fewer days in the date you are adding to than in the result month, the result is the corresponding day of the result month, not the last day of that month. For example, April 30 + 1 month is May 30.

```
select dateadd(month,1,'2008-04-30');

date_add
-----
2008-05-30 00:00:00
(1 row)
```

The DATEADD function handles the leap year date 02-29 differently when using dateadd(month, 12,...) or dateadd(year, 1, ...).

```
select dateadd(month,12,'2016-02-29');
```

```
date_add
-----
2017-02-28 00:00:00

select dateadd(year, 1, '2016-02-29');

date_add
-----
2017-03-01 00:00:00
```

DATEDIFF function

DATEDIFF returns the difference between the date parts of two date or time expressions.

Syntax

```
DATEDIFF( datepart, {date|time|timetz|timestamp}, {date|time|timetz|timestamp} )
```

Arguments

datepart

The specific part of the date or time value (year, month, or day, hour, minute, second, millisecond, or microsecond) that the function operates on. For more information, see [Date parts for date or timestamp functions](#).

Specifically, DATEDIFF determines the number of date part boundaries that are crossed between two expressions. For example, suppose that you're calculating the difference in years between two dates, 12-31-2008 and 01-01-2009. In this case, the function returns 1 year despite the fact that these dates are only one day apart. If you are finding the difference in hours between two timestamps, 01-01-2009 8:30:00 and 01-01-2009 10:00:00, the result is 2 hours. If you are finding the difference in hours between two timestamps, 8:30:00 and 10:00:00, the result is 2 hours.

date|time|timetz|timestamp

A DATE, TIME, TIMETZ, or TIMESTAMP column or expressions that implicitly convert to a DATE, TIME, TIMETZ, or TIMESTAMP. The expressions must both contain the specified date or time part. If the second date or time is later than the first date or time, the result is positive. If the second date or time is earlier than the first date or time, the result is negative.

Return type

BIGINT

Examples with a DATE column

The following example finds the difference, in number of weeks, between two literal date values.

```
select datediff(week, '2009-01-01', '2009-12-31') as numweeks;
```

```
numweeks
-----
52
(1 row)
```

The following example finds the difference, in hours, between two literal date values. When you don't provide the time value for a date, it defaults to 00:00:00.

```
select datediff(hour, '2023-01-01', '2023-01-03 05:04:03');
```

```
date_diff
-----
53
(1 row)
```

The following example finds the difference, in days, between two literal TIMESTAMETZ values.

```
Select datediff(days, 'Jun 1,2008 09:59:59 EST', 'Jul 4,2008 09:59:59 EST')
```

```
date_diff
-----
33
```

The following example finds the difference, in days, between two dates in the same row of a table.

```
select * from date_table;
```

```
start_date | end_date
-----+-----
2009-01-01 | 2009-03-23
```

```
2023-01-04 | 2024-05-04
```

```
(2 rows)
```

```
select datediff(day, start_date, end_date) as duration from date_table;
```

```
duration
```

```
-----
```

```
81
```

```
486
```

```
(2 rows)
```

The following example finds the difference, in number of quarters, between a literal value in the past and today's date. This example assumes that the current date is June 5, 2008. You can name date parts in full or abbreviate them. The default column name for the DATEDIFF function is DATE_DIFF.

```
select datediff(qtr, '1998-07-01', current_date);
```

```
date_diff
```

```
-----
```

```
40
```

```
(1 row)
```

The following example joins the SALES and LISTING tables to calculate how many days after they were listed any tickets were sold for listings 1000 through 1005. The longest wait for sales of these listings was 15 days, and the shortest was less than one day (0 days).

```
select priceperticket,
datediff(day, listtime, saletime) as wait
from sales, listing where sales.listid = listing.listid
and sales.listid between 1000 and 1005
order by wait desc, priceperticket desc;
```

```
priceperticket | wait
```

```
-----+-----
```

```
96.00          | 15
```

```
123.00         | 11
```

```
131.00         | 9
```

```
123.00         | 6
```

```
129.00         | 4
```

```
96.00          | 4
```

```
96.00          | 0
```

```
(7 rows)
```

This example calculates the average number of hours sellers waited for all ticket sales.

```
select avg(datediff(hours, listtime, saletime)) as avgwait
from sales, listing
where sales.listid = listing.listid;
```

```
avgwait
-----
465
(1 row)
```

Examples with a TIME column

The following example table TIME_TEST has a column TIME_VAL (type TIME) with three values inserted.

```
select time_val from time_test;
```

```
time_val
-----
20:00:00
00:00:00.5550
00:58:00
```

The following example finds the difference in number of hours between the TIME_VAL column and a time literal.

```
select datediff(hour, time_val, time '15:24:45') from time_test;
```

```
date_diff
-----
-5
15
15
```

The following example finds the difference in number of minutes between two literal time values.

```
select datediff(minute, time '20:00:00', time '21:00:00') as nummins;
```

```
nummins
-----
60
```

Examples with a TIMETZ column

The following example table TIMETZ_TEST has a column TIMETZ_VAL (type TIMETZ) with three values inserted.

```
select timetz_val from timetz_test;
```

```
timetz_val
-----
04:00:00+00
00:00:00.5550+00
05:58:00+00
```

The following example finds the differences in number of hours, between a TIMETZ literal and timetz_val.

```
select datediff(hours, timetz '20:00:00 PST', timetz_val) as numhours from timetz_test;
```

```
numhours
-----
0
-4
1
```

The following example finds the difference in number of hours, between two literal TIMETZ values.

```
select datediff(hours, timetz '20:00:00 PST', timetz '00:58:00 EST') as numhours;
```

```
numhours
-----
1
```

DATE_PART function

DATE_PART extracts date part values from an expression. DATE_PART is a synonym of the PGDATE_PART function.

Syntax

```
DATE_PART(datepart, {date|timestamp})
```

Arguments

datepart

An identifier literal or string of the specific part of the date value (for example, year, month, or day) that the function operates on. For more information, see [Date parts for date or timestamp functions](#).

{*date*|*timestamp*}

A date column, timestamp column, or an expression that implicitly converts to a date or timestamp. The column or expression in *date* or *timestamp* must contain the date part specified in *datepart*.

Return type

DOUBLE

Examples

The default column name for the DATE_PART function is pgdate_part.

For more information about the data used in some of these examples, see [Sample database](#).

The following example finds the minute from a timestamp literal.

```
SELECT DATE_PART(minute, timestamp '20230104 04:05:06.789');
```

```
pgdate_part
-----
           5
```

The following example finds the week number from a timestamp literal. The week number calculation follows the ISO 8601 standard. For more information, see [ISO 8601](#) in Wikipedia.

```
SELECT DATE_PART(week, timestamp '20220502 04:05:06.789');
```

```
pgdate_part
```

```
-----  
18
```

The following example finds the day of the month from a timestamp literal.

```
SELECT DATE_PART(day, timestamp '20220502 04:05:06.789');  
  
pgdate_part  
-----  
2
```

The following example finds the day of the week from a timestamp literal. The day of week number calculation is an integer from 0-6, starting with Sunday.

```
SELECT DATE_PART(dayofweek, timestamp '20220502 04:05:06.789');  
  
pgdate_part  
-----  
1
```

The following example finds the century from a timestamp literal. The century calculation follows the ISO 8601 standard. For more information, see [ISO 8601](#) in Wikipedia.

```
SELECT DATE_PART(century, timestamp '20220502 04:05:06.789');  
  
pgdate_part  
-----  
21
```

The following example finds the millennium from a timestamp literal. The millennium calculation follows the ISO 8601 standard. For more information, see [ISO 8601](#) in Wikipedia.

```
SELECT DATE_PART(millennium, timestamp '20220502 04:05:06.789');  
  
pgdate_part  
-----  
3
```

The following example finds the microseconds from a timestamp literal. The microseconds calculation follows the ISO 8601 standard. For more information, see [ISO 8601](#) in Wikipedia.

```
SELECT DATE_PART(microsecond, timestamp '20220502 04:05:06.789');
```

```
pgdate_part
-----
      789000
```

The following example finds the month from a date literal.

```
SELECT DATE_PART(month, date '20220502');
```

```
pgdate_part
-----
           5
```

The following example applies the DATE_PART function to a column in a table.

```
SELECT date_part(w, listtime) AS weeks, listtime
FROM listing
WHERE listid=10
```

```
weeks |      listtime
-----+-----
    25 | 2008-06-17 09:44:54
(1 row)
```

You can name date parts in full or abbreviate them; in this case, *w* stands for weeks.

The day of week date part returns an integer from 0-6, starting with Sunday. Use DATE_PART with *dow* (DAYOFWEEK) to view events on a Saturday.

```
SELECT date_part(dow, starttime) AS dow, starttime
FROM event
WHERE date_part(dow, starttime)=6
ORDER BY 2,1;
```

```
dow |      starttime
-----+-----
    6 | 2008-01-05 14:00:00
    6 | 2008-01-05 14:00:00

```

DATE_PART_YEAR function

The DATE_PART_YEAR function extracts the year from a date.

Syntax

```
DATE_PART_YEAR(date)
```

Argument

date

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

Return type

INTEGER

Examples

The following example finds the year from a date literal.

```
SELECT DATE_PART_YEAR(date '20220502 04:05:06.789');
```

```
date_part_year
-----
2022
```

The following example extracts the year from the CALDATE column. The values in the CALDATE column are dates. For more information about the data used in this example, see [Sample database](#).

```
select caldate, date_part_year(caldate)
from date
order by
dateid limit 10;
```

```
caldate | date_part_year
-----+-----
2008-01-01 | 2008
```

```
2008-01-02 |          2008
2008-01-03 |          2008
2008-01-04 |          2008
2008-01-05 |          2008
2008-01-06 |          2008
2008-01-07 |          2008
2008-01-08 |          2008
2008-01-09 |          2008
2008-01-10 |          2008
(10 rows)
```

DATE_TRUNC function

The DATE_TRUNC function truncates a timestamp expression or literal based on the date part that you specify, such as hour, day, or month.

Syntax

```
DATE_TRUNC('datepart', timestamp)
```

Arguments

datepart

The date part to which to truncate the timestamp value. The input *timestamp* is truncated to the precision of the input *datepart*. For example, month truncates to the first day of the month. Valid formats are as follows:

- microsecond, microseconds
- millisecond, milliseconds
- second, seconds
- minute, minutes
- hour, hours
- day, days
- week, weeks
- month, months
- quarter, quarters
- year, years
- decade, decades

- century, centuries
- millennium, millennia

For more information about abbreviations of some formats, see [Date parts for date or timestamp functions](#)

timestamp

A timestamp column or an expression that implicitly converts to a timestamp.

Return type

TIMESTAMP

Examples

Truncate the input timestamp to the second.

```
SELECT DATE_TRUNC('second', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-04-30 04:05:06
```

Truncate the input timestamp to the minute.

```
SELECT DATE_TRUNC('minute', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-04-30 04:05:00
```

Truncate the input timestamp to the hour.

```
SELECT DATE_TRUNC('hour', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-04-30 04:00:00
```

Truncate the input timestamp to the day.

```
SELECT DATE_TRUNC('day', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-04-30 00:00:00
```

Truncate the input timestamp to the first day of a month.

```
SELECT DATE_TRUNC('month', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-04-01 00:00:00
```

Truncate the input timestamp to the first day of a quarter.

```
SELECT DATE_TRUNC('quarter', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-04-01 00:00:00
```

Truncate the input timestamp to the first day of a year.

```
SELECT DATE_TRUNC('year', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2020-01-01 00:00:00
```

Truncate the input timestamp to the first day of a century.

```
SELECT DATE_TRUNC('millennium', TIMESTAMP '20200430 04:05:06.789');
date_trunc
2001-01-01 00:00:00
```

Truncate the input timestamp to the Monday of a week.

```
select date_trunc('week', TIMESTAMP '20220430 04:05:06.789');
date_trunc
2022-04-25 00:00:00
```

In the following example, the DATE_TRUNC function uses the 'week' date part to return the date for the Monday of each week.

```
select date_trunc('week', saletime), sum(pricepaid) from sales where
saletime like '2008-09%' group by date_trunc('week', saletime) order by 1;
```

date_trunc	sum
2008-09-01	2474899
2008-09-08	2412354
2008-09-15	2364707
2008-09-22	2359351

`2008-09-29 | 705249`

EXTRACT function

The EXTRACT function returns a date or time part from a `TIMESTAMP`, `TIMESTAMPTZ`, `TIME`, `TIMETZ`, `INTERVAL YEAR TO MONTH`, or `INTERVAL DAY TO SECOND` value. Examples include a day, month, year, hour, minute, second, millisecond, or microsecond from a timestamp.

Syntax

```
EXTRACT(datepart FROM source)
```

Arguments

datepart

The subfield of a date or time to extract, such as a day, month, year, hour, minute, second, millisecond, or microsecond. For possible values, see [Date parts for date or timestamp functions](#).

source

A column or expression that evaluates to a data type of `TIMESTAMP`, `TIMESTAMPTZ`, `TIME`, `TIMETZ`, `INTERVAL YEAR TO MONTH`, or `INTERVAL DAY TO SECOND`.

Return type

`INTEGER` if the *source* value evaluates to data type `TIMESTAMP`, `TIME`, `TIMETZ`, `INTERVAL YEAR TO MONTH`, or `INTERVAL DAY TO SECOND`.

`DOUBLE PRECISION` if the *source* value evaluates to data type `TIMESTAMPTZ`.

Examples with `TIMESTAMP`

The following example determines the week numbers for sales in which the price paid was \$10,000 or more. This example uses the TICKIT data. For more information, see [Sample database](#).

```
select salesid, extract(week from saletime) as weeknum
from sales
where pricepaid > 9999
order by 2;
```

```

salesid | weeknum
-----+-----
159073 |      6
160318 |      8
161723 |     26

```

The following example returns the minute value from a literal timestamp value.

```

select extract(minute from timestamp '2009-09-09 12:08:43');

date_part
-----
8

```

The following example returns the millisecond value from a literal timestamp value.

```

select extract(ms from timestamp '2009-09-09 12:08:43.101');

date_part
-----
101

```

Examples with TIMESTAMPTZ

The following example returns the year value from a literal timestamptz value.

```

select extract(year from timestamptz '1.12.1997 07:37:16.00 PST');

date_part
-----
1997

```

Examples with TIME

The following example table TIME_TEST has a column TIME_VAL (type TIME) with three values inserted.

```

select time_val from time_test;

time_val
-----
20:00:00

```

```
00:00:00.5550
00:58:00
```

The following example extracts the minutes from each `time_val`.

```
select extract(minute from time_val) as minutes from time_test;
```

```
minutes
-----
      0
      0
     58
```

The following example extracts the hours from each `time_val`.

```
select extract(hour from time_val) as hours from time_test;
```

```
hours
-----
    20
     0
     0
```

The following example extracts milliseconds from a literal value.

```
select extract(ms from time '18:25:33.123456');
```

```
date_part
-----
    123
```

Examples with TIMETZ

The following example table `TIMETZ_TEST` has a column `TIMETZ_VAL` (type `TIMETZ`) with three values inserted.

```
select timetz_val from timetz_test;
```

```
timetz_val
-----
04:00:00+00
```

```
00:00:00.5550+00
05:58:00+00
```

The following example extracts the hours from each `timetz_val`.

```
select extract(hour from timetz_val) as hours from time_test;
```

```
hours
-----
      4
      0
      5
```

The following example extracts milliseconds from a literal value. Literals aren't converted to UTC before the extraction is processed.

```
select extract(ms from timetz '18:25:33.123456 EST');
```

```
date_part
-----
      123
```

The following example returns the timezone offset hour from UTC from a literal `timetz` value.

```
select extract(timezone_hour from timetz '1.12.1997 07:37:16.00 PDT');
```

```
date_part
-----
      -7
```

Examples with INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND

The following example extracts the day part of 1 from the `INTERVAL DAY TO SECOND` that defines 36 hours, which is 1 day 12 hours.

```
select EXTRACT('days' from INTERVAL '36 hours' DAY TO SECOND)
```

```
date_part
-----
      1
```

The following example extracts the month part of 3 from the YEAR TO MONTH that defines 15 months, which is 1 year 3 months.

```
select EXTRACT('month' from INTERVAL '15 months' YEAR TO MONTH)
```

```
date_part
```

```
-----
```

```
3
```

The following example extracts the month part of 6 from 30 months which is 2 years 6 months.

```
select EXTRACT('month' from INTERVAL '30' MONTH)
```

```
date_part
```

```
-----
```

```
6
```

The following example extracts the hour part of 2 from 50 hours which is 2 days 2 hours.

```
select EXTRACT('hours' from INTERVAL '50' HOUR)
```

```
date_part
```

```
-----
```

```
2
```

The following example extracts the minute part of 11 from 1 hour 11 minutes 11.123 seconds.

```
select EXTRACT('minute' from INTERVAL '70 minutes 70.123 seconds' MINUTE TO SECOND)
```

```
date_part
```

```
-----
```

```
11
```

The following example extracts the seconds part of 1.11 from 1 day 1 hour 1 minute 1.11 seconds.

```
select EXTRACT('seconds' from INTERVAL '1 day 1:1:1.11' DAY TO SECOND)
```

```
date_part
```

```
-----
```

```
1.11
```

The following example extracts the total number of hours in an INTERVAL. Each part is extracted and added to a total.

```
select EXTRACT('days' from INTERVAL '50' HOUR) * 24 + EXTRACT('hours' from INTERVAL '50' HOUR)
```

?column?

50

The following example extracts the total number of seconds in an INTERVAL. Each part is extracted and added to a total.

```
select EXTRACT('days' from INTERVAL '1 day 1:1:1.11' DAY TO SECOND) * 86400 +  
       EXTRACT('hours' from INTERVAL '1 day 1:1:1.11' DAY TO SECOND) * 3600 +  
       EXTRACT('minutes' from INTERVAL '1 day 1:1:1.11' DAY TO SECOND) * 60 +  
       EXTRACT('seconds' from INTERVAL '1 day 1:1:1.11' DAY TO SECOND)
```

?column?

90061.11

GETDATE function

GETDATE returns the current date and time in the current session time zone (UTC by default). It returns the start date or time of the current statement, even when it is within a transaction block.

Syntax

```
GETDATE()
```

The parentheses are required.

Return type

TIMESTAMP

Examples

The following example uses the GETDATE function to return the full timestamp for the current date.

```
select getdate();
```

```
timestamp
```

```
-----
```

```
2008-12-04 16:10:43
```

The following example uses the GETDATE function inside the TRUNC function to return the current date without the time.

```
select trunc(getdate());
```

```
trunc
```

```
-----
```

```
2008-12-04
```

INTERVAL_CMP function

INTERVAL_CMP compares two intervals and returns 1 if the first interval is greater, -1 if the second interval is greater, and 0 if the intervals are equal. For more information, see [Examples of interval literals without qualifier syntax](#).

Syntax

```
INTERVAL_CMP(interval1, interval2)
```

Arguments

interval1

An interval literal value.

interval2

An interval literal value.

Return type

INTEGER

Examples

The following example compares the value of 3 days to 1 year.

```
select interval_cmp('3 days','1 year');
```

```
interval_cmp  
-----  
-1
```

This example compares the value 7 days to 1 week.

```
select interval_cmp('7 days','1 week');
```

```
interval_cmp  
-----  
0
```

The following example compares the value of 1 year to 3 days.

```
select interval_cmp('1 year','3 days');
```

```
interval_cmp  
-----  
1
```

LAST_DAY function

LAST_DAY returns the date of the last day of the month that contains *date*. The return type is always DATE, regardless of the data type of the *date* argument.

For more information about retrieving specific date parts, see [DATE_TRUNC function](#).

Syntax

```
LAST_DAY( { date | timestamp } )
```

Arguments

date | *timestamp*

A column of data type DATE or TIMESTAMP or an expression that implicitly evaluates to a DATE or TIMESTAMP type.

Return type

DATE

Examples

The following example returns the date of the last day in the current month.

```
select last_day(sysdate);
```

```
  last_day
-----
2014-01-31
```

The following example returns the number of tickets sold for each of the last 7 days of the month. The values in the SALETIME column are timestamps.

```
select datediff(day, saletime, last_day(saletime)) as "Days Remaining", sum(qtysold)
from sales
where datediff(day, saletime, last_day(saletime)) < 7
group by 1
order by 1;
```

```
days remaining | sum
-----+-----
              0 | 10140
              1 | 11187
              2 | 11515
              3 | 11217
              4 | 11446
              5 | 11708
              6 | 10988
```

(7 rows)

MONTHS_BETWEEN function

MONTHS_BETWEEN determines the number of months between two dates.

If the first date is later than the second date, the result is positive; otherwise, the result is negative.

If either argument is null, the result is NULL.

Syntax

```
MONTHS_BETWEEN( date1, date2 )
```

Arguments

date1

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

date2

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

Return type

FLOAT8

The whole number portion of the result is based on the difference between the year and month values of the dates. The fractional portion of the result is calculated from the day and timestamp values of the dates and assumes a 31-day month.

If *date1* and *date2* both contain the same date within a month (for example, 1/15/14 and 2/15/14) or the last day of the month (for example, 8/31/14 and 9/30/14), then the result is a whole number based on the year and month values of the dates, regardless of whether the timestamp portion matches, if present.

Examples

The following example returns the months between 1/18/1969 and 3/18/1969.

```
select months_between('1969-01-18', '1969-03-18')
as months;

months
-----
-2
```

The following example returns the months between 1/18/1969 and 1/18/1969.

```
select months_between('1969-01-18', '1969-01-18')
as months;
```

```
months
-----
0
```

The following example returns the months between the first and last showings of an event.

```
select eventname,
min(starttime) as first_show,
max(starttime) as last_show,
months_between(max(starttime),min(starttime)) as month_diff
from event
group by eventname
order by eventname
limit 5;
```

eventname	first_show	last_show	month_diff
.38 Special	2008-01-21 19:30:00.0	2008-12-25 15:00:00.0	11.12
3 Doors Down	2008-01-03 15:00:00.0	2008-12-01 19:30:00.0	10.94
70s Soul Jam	2008-01-16 19:30:00.0	2008-12-07 14:00:00.0	10.7

A Catered Affair	2008-01-08 19:30:00.0	2008-12-19 19:00:00.0	11.35

NEXT_DAY function

NEXT_DAY returns the date of the first instance of the specified day that is later than the given date.

If the *day* value is the same day of the week as the given date, the next occurrence of that day is returned.

Syntax

```
NEXT_DAY( { date | timestamp }, day )
```

Arguments

date | *timestamp*

A column of data type DATE or TIMESTAMP or an expression that implicitly evaluates to a DATE or TIMESTAMP type.

day

A string containing the name of any day. Capitalization doesn't matter.

Valid values are as follows.

Day	Values
Sunday	Su, Sun, Sunday
Monday	M, Mo, Mon, Monday
Tuesday	Tu, Tue, Tues, Tuesday
Wednesday	W, We, Wed, Wednesday
Thursday	Th, Thu, Thurs, Thursday
Friday	F, Fr, Fri, Friday
Saturday	Sa, Sat, Saturday

Return type

DATE

Examples

The following example returns the date of the first Tuesday after 8/20/2014.

```
select next_day('2014-08-20', 'Tuesday');
```

```
next_day
-----
2014-08-26
```

The following example returns the date of the first Tuesday after 1/1/2008 at 5:54:44.

```
select listtime, next_day(listtime, 'Tue') from listing limit 1;
```

```
listtime          | next_day
-----+-----
```

2008-01-01 05:54:44 | 2008-01-08

The following example gets target marketing dates for the third quarter.

```
select username, (firstname ||' '|| lastname) as name,
eventname, caldate, next_day (caldate, 'Monday') as marketing_target
from sales, date, users, event
where sales.buyerid = users.userid
and sales.eventid = event.eventid
and event.dateid = date.dateid
and date.qtr = 3
order by marketing_target, eventname, name;
```

URY81YWF	Wilma Anthony	Britney Spears	2008-07-02	2008-07-07

SYSDATE function

SYSDATE returns the current date and time in the current session time zone (UTC by default).

Note

SYSDATE returns the start date and time for the current transaction, not for the start of the current statement.

Syntax

```
SYSDATE
```

This function requires no arguments.

Return type

TIMESTAMP

Examples

The following example uses the SYSDATE function to return the full timestamp for the current date.

```
select sysdate;

timestamp
-----
2008-12-04 16:10:43.976353
```

The following example uses the SYSDATE function inside the TRUNC function to return the current date without the time.

```
select trunc(sysdate);

trunc
-----
2008-12-04
```

The following query returns sales information for dates that fall between the date when the query is issued and whatever date is 120 days earlier.

```
select salesid, pricepaid, trunc(saletime) as saletime, trunc(sysdate) as now
from sales
where saletime between trunc(sysdate)-120 and trunc(sysdate)
order by saletime asc;
```

salesid	pricepaid	saletime	now
91535	670.00	2008-08-07	2008-12-05
91635	365.00	2008-08-07	2008-12-05
91901	1002.00	2008-08-07	2008-12-05
...			

TIMEOFDAY function

TIMEOFDAY is a special alias used to return the weekday, date, and time as a string value. It returns the time of day string for the current statement, even when it is within a transaction block.

Syntax

```
TIMEOFDAY()
```

Return type

VARCHAR

Examples

The following example returns the current date and time by using the TIMEOFDAY function.

```
select timeofday();

timeofday
-----
Thu Sep 19 22:53:50.333525 2013 UTC
```

TIMESTAMP_CMP function

Compares the value of two timestamps and returns an integer. If the timestamps are identical, the function returns 0. If the first timestamp is greater, the function returns 1. If the second timestamp is greater, the function returns -1.

Syntax

```
TIMESTAMP_CMP(timestamp1, timestamp2)
```

Arguments

timestamp1

A column of data type TIMESTAMP or an expression that implicitly evaluates to a TIMESTAMP type.

timestamp2

A column of data type `TIMESTAMP` or an expression that implicitly evaluates to a `TIMESTAMP` type.

Return type

`INTEGER`

Examples

The following example compares timestamps and shows the results of the comparison.

```
SELECT TIMESTAMP_CMP('2008-01-24 06:43:29', '2008-01-24 06:43:29'),
       TIMESTAMP_CMP('2008-01-24 06:43:29', '2008-02-18 02:36:48'), TIMESTAMP_CMP('2008-02-18
       02:36:48', '2008-01-24 06:43:29');
```

timestamp_cmp	timestamp_cmp	timestamp_cmp
0	-1	1

The following example compares the `LISTTIME` and `SALETIME` for a listing. The value for `TIMESTAMP_CMP` is `-1` for all listings because the timestamp for the sale is after the timestamp for the listing.

```
select listing.listid, listing.listtime,
       sales.saletime, timestamp_cmp(listing.listtime, sales.saletime)
from listing, sales
where listing.listid=sales.listid
order by 1, 2, 3, 4
limit 10;
```

listid	listtime	saletime	timestamp_cmp
1	2008-01-24 06:43:29	2008-02-18 02:36:48	-1
4	2008-05-24 01:18:37	2008-06-06 05:00:16	-1
5	2008-05-17 02:29:11	2008-06-06 08:26:17	-1
5	2008-05-17 02:29:11	2008-06-09 08:38:52	-1
6	2008-08-15 02:08:13	2008-08-31 09:17:02	-1
10	2008-06-17 09:44:54	2008-06-26 12:56:06	-1
10	2008-06-17 09:44:54	2008-07-10 02:12:36	-1
10	2008-06-17 09:44:54	2008-07-16 11:59:24	-1

```

10 | 2008-06-17 09:44:54 | 2008-07-22 02:23:17 | -1
12 | 2008-07-25 01:45:49 | 2008-08-04 03:06:36 | -1
(10 rows)

```

This example shows that `TIMESTAMP_CMP` returns a 0 for identical timestamps:

```

select listid, timestamp_cmp(listtime, listtime)
from listing
order by 1 , 2
limit 10;

```

listid	timestamp_cmp
1	0
2	0
3	0
4	0
5	0
6	0
7	0
8	0
9	0
10	0

(10 rows)

TIMESTAMP_CMP_DATE function

`TIMESTAMP_CMP_DATE` compares the value of a timestamp and a date. If the timestamp and date values are identical, the function returns 0. If the timestamp is greater chronologically, the function returns 1. If the date is greater, the function returns -1.

Syntax

```
TIMESTAMP_CMP_DATE(timestamp, date)
```

Arguments

timestamp

A column of data type `TIMESTAMP` or an expression that implicitly evaluates to a `TIMESTAMP` type.

date

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

Return type

INTEGER

Examples

The following example compares LISTTIME to the date 2008-06-18. Listings made after this date return 1; listings made before this date return -1. LISTTIME values are timestamps.

```
select listid, listtime,
timestamp_cmp_date(listtime, '2008-06-18')
from listing
order by 1, 2, 3
limit 10;
```

listid	listtime	timestamp_cmp_date
1	2008-01-24 06:43:29	-1
2	2008-03-05 12:25:29	-1
3	2008-11-01 07:35:33	1
4	2008-05-24 01:18:37	-1
5	2008-05-17 02:29:11	-1
6	2008-08-15 02:08:13	1
7	2008-11-15 09:38:15	1
8	2008-11-09 05:07:30	1
9	2008-09-09 08:03:36	1
10	2008-06-17 09:44:54	-1

(10 rows)

TIMESTAMP_CMP_TIMESTAMPTZ function

TIMESTAMP_CMP_TIMESTAMPTZ compares the value of a timestamp expression with a timestamp with time zone expression. If the timestamp and timestamp with time zone values are identical, the function returns 0. If the timestamp is greater chronologically, the function returns 1. If the timestamp with time zone is greater, the function returns -1.

Syntax

```
TIMESTAMP_CMP_TIMESTAMPTZ(timestamp, timestamptz)
```

Arguments

timestamp

A column of data type `TIMESTAMP` or an expression that implicitly evaluates to a `TIMESTAMP` type.

timestamptz

A column of data type `TIMESTAMPTZ` or an expression that implicitly evaluates to a `TIMESTAMPTZ` type.

Return type

INTEGER

Examples

The following example compares timestamps to timestamps with time zones and shows the results of the comparison.

```
SELECT TIMESTAMP_CMP_TIMESTAMPTZ('2008-01-24 06:43:29', '2008-01-24 06:43:29+00'),
       TIMESTAMP_CMP_TIMESTAMPTZ('2008-01-24 06:43:29', '2008-02-18 02:36:48+00'),
       TIMESTAMP_CMP_TIMESTAMPTZ('2008-02-18 02:36:48', '2008-01-24 06:43:29+00');
```

timestamp_cmp_timestamptz	timestamp_cmp_timestamptz	timestamp_cmp_timestamptz
0	-1	1

TIMESTAMPTZ_CMP function

`TIMESTAMPTZ_CMP` compares the value of two timestamp with time zone values and returns an integer. If the timestamps are identical, the function returns 0. If the first timestamp is greater chronologically, the function returns 1. If the second timestamp is greater, the function returns -1.

Syntax

```
TIMESTAMPTZ_CMP(timestamptz1, timestamptz2)
```

Arguments

timestampz1

A column of data type TIMESTAMPTZ or an expression that implicitly evaluates to a TIMESTAMPTZ type.

timestampz2

A column of data type TIMESTAMPTZ or an expression that implicitly evaluates to a TIMESTAMPTZ type.

Return type

INTEGER

Examples

The following example compares timestamps with time zones and shows the results of the comparison.

```
SELECT TIMESTAMPTZ_CMP('2008-01-24 06:43:29+00', '2008-01-24 06:43:29+00'),
       TIMESTAMPTZ_CMP('2008-01-24 06:43:29+00', '2008-02-18 02:36:48+00'),
       TIMESTAMPTZ_CMP('2008-02-18 02:36:48+00', '2008-01-24 06:43:29+00');
```

timestampz_cmp	timestampz_cmp	timestampz_cmp
0	-1	1

TIMESTAMPTZ_CMP_DATE function

TIMESTAMPTZ_CMP_DATE compares the value of a timestamp and a date. If the timestamp and date values are identical, the function returns 0. If the timestamp is greater chronologically, the function returns 1. If the date is greater, the function returns -1.

Syntax

```
TIMESTAMPTZ_CMP_DATE(timestampz, date)
```

Arguments

timestamptz

A column of data type TIMESTAMPTZ or an expression that implicitly evaluates to a TIMESTAMPTZ type.

date

A column of data type DATE or an expression that implicitly evaluates to a DATE type.

Return type

INTEGER

Examples

The following example compares LISTTIME as a timestamp with time zone to the date 2008-06-18. Listings made after this date return 1; listings made before this date return -1.

```
select listid, CAST(listtime as timestamptz) as tstz,
timestamp_cmp_date(tstz, '2008-06-18')
from listing
order by 1, 2, 3
limit 10;
```

listid	tstz	timestamptz_cmp_date
1	2008-01-24 06:43:29+00	-1
2	2008-03-05 12:25:29+00	-1
3	2008-11-01 07:35:33+00	1
4	2008-05-24 01:18:37+00	-1
5	2008-05-17 02:29:11+00	-1
6	2008-08-15 02:08:13+00	1
7	2008-11-15 09:38:15+00	1
8	2008-11-09 05:07:30+00	1
9	2008-09-09 08:03:36+00	1
10	2008-06-17 09:44:54+00	-1

(10 rows)

TIMESTAMPTZ_CMP_TIMESTAMP function

TIMESTAMPTZ_CMP_TIMESTAMP compares the value of a timestamp with time zone expression with a timestamp expression. If the timestamp with time zone and timestamp values are identical, the function returns 0. If the timestamp with time zone is greater chronologically, the function returns 1. If the timestamp is greater, the function returns -1.

Syntax

```
TIMESTAMPTZ_CMP_TIMESTAMP(timestamptz, timestamp)
```

Arguments

timestamptz

A column of data type TIMESTAMPTZ or an expression that implicitly evaluates to a TIMESTAMPTZ type.

timestamp

A column of data type TIMESTAMP or an expression that implicitly evaluates to a TIMESTAMP type.

Return type

INTEGER

Examples

The following example compares timestamps with time zones to timestamps and shows the results of the comparison.

```
SELECT TIMESTAMPTZ_CMP_TIMESTAMP('2008-01-24 06:43:29+00', '2008-01-24 06:43:29'),
       TIMESTAMPTZ_CMP_TIMESTAMP('2008-01-24 06:43:29+00', '2008-02-18 02:36:48'),
       TIMESTAMPTZ_CMP_TIMESTAMP('2008-02-18 02:36:48+00', '2008-01-24 06:43:29');
```

timestamptz_cmp_timestamp	timestamptz_cmp_timestamp	timestamptz_cmp_timestamp
0	-1	1

TIMEZONE function

TIMEZONE returns a timestamp for the specified time zone and timestamp value.

For information and examples about how to set time zone, see [timezone](#).

For information and examples about how to convert time zone, see [CONVERT_TIMEZONE](#).

Syntax

```
TIMEZONE('timezone', { timestamp | timestampz })
```

Arguments

timezone

The time zone for the return value. The time zone can be specified as a time zone name (such as **'Africa/Kampala'** or **'Singapore'**) or as a time zone abbreviation (such as **'UTC'** or **'PDT'**). To view a list of supported time zone names, run the following command.

```
select pg_timezone_names();
```

To view a list of supported time zone abbreviations, run the following command.

```
select pg_timezone_abbrevs();
```

For more information and examples, see [Time zone usage notes](#).

timestamp | timestampz

An expression that results in a **TIMESTAMP** or **TIMESTAMPTZ** type, or a value that can implicitly be coerced to a timestamp or a timestamp with time zone.

Return type

TIMESTAMPTZ when used with a **TIMESTAMP** expression.

TIMESTAMP when used with a **TIMESTAMPTZ** expression.

Examples

The following returns a timestamp for the UTC time zone using the timestamp **2008-06-17 09:44:54** from the PST time zone.

```
SELECT TIMEZONE('PST', '2008-06-17 09:44:54');
```

```
timezone
```

```
-----  
2008-06-17 17:44:54+00
```

The following returns a timestamp for the PST time zone using the timestamp with UTC time zone `2008-06-17 09:44:54+00`.

```
SELECT TIMEZONE('PST', timestampz('2008-06-17 09:44:54+00'));
```

```
timezone
```

```
-----  
2008-06-17 01:44:54
```

TO_TIMESTAMP function

TO_TIMESTAMP converts a TIMESTAMP string to TIMESTAMPTZ. For a list of additional date and time functions for Amazon Redshift, see [Date and time functions](#).

Syntax

```
to_timestamp(timestamp, format)
```

```
to_timestamp (timestamp, format, is_strict)
```

Arguments

timestamp

A string that represents a timestamp value in the format specified by *format*. If this argument is left as empty, the timestamp value defaults to `0001-01-01 00:00:00`.

format

A string literal that defines the format of the *timestamp* value. Formats that include a time zone (**TZ**, **tz**, or **OF**) are not supported as input. For valid timestamp formats, see [Datetime format strings](#).

is_strict

An optional Boolean value that specifies whether an error is returned if an input timestamp value is out of range. When *is_strict* is set to TRUE, an error is returned if there is an out of range value. When *is_strict* is set to FALSE, which is the default, then overflow values are accepted.

Return type

TIMESTAMPTZ

Examples

The following example demonstrates using the TO_TIMESTAMP function to convert a TIMESTAMP string to a TIMESTAMPTZ.

```
select sysdate, to_timestamp(sysdate, 'YYYY-MM-DD HH24:MI:SS') as second;
```

```
timestamp                | second
-----|-----
2021-04-05 19:27:53.281812 | 2021-04-05 19:27:53+00
```

It's possible to pass TO_TIMESTAMP part of a date. The remaining date parts are set to default values. The time is included in the output:

```
SELECT TO_TIMESTAMP('2017', 'YYYY');
```

```
to_timestamp
-----
2017-01-01 00:00:00+00
```

The following SQL statement converts the string '2011-12-18 24:38:15' to a TIMESTAMPTZ. The result is a TIMESTAMPTZ that falls on the next day because the number of hours is more than 24 hours:

```
SELECT TO_TIMESTAMP('2011-12-18 24:38:15', 'YYYY-MM-DD HH24:MI:SS');
```

```
to_timestamp
-----
```

```
2011-12-19 00:38:15+00
```

The following SQL statement converts the string '2011-12-18 24:38:15' to a TIMESTAMPTZ. The result is an error because the time value in the timestamp is more than 24 hours:

```
SELECT TO_TIMESTAMP('2011-12-18 24:38:15', 'YYYY-MM-DD HH24:MI:SS', TRUE);
```

```
ERROR: date/time field time value out of range: 24:38:15.0
```

TRUNC function

Truncates a TIMESTAMP and returns a DATE.

This function can also truncate a number. For more information, see [TRUNC function](#).

Syntax

```
TRUNC(timestamp)
```

Arguments

timestamp

A column of data type TIMESTAMP or an expression that implicitly evaluates to a TIMESTAMP type.

To return a timestamp value with 00:00:00 as the time, cast the function result to a TIMESTAMP.

Return type

DATE

Examples

The following example returns the date portion from the result of the SYSDATE function (which returns a timestamp).

```
SELECT SYSDATE;
```

```
+-----+
|      timestamp      |
+-----+
| 2011-07-21 10:32:38.248109 |
+-----+
```

```
SELECT TRUNC(SYSDATE);
```

```
+-----+
|   trunc   |
+-----+
| 2011-07-21 |
+-----+
```

The following example applies the TRUNC function to a TIMESTAMP column. The return type is a date.

```
SELECT TRUNC(starttime) FROM event
ORDER BY eventid LIMIT 1;
```

```
+-----+
|   trunc   |
+-----+
| 2008-01-25 |
+-----+
```

The following example returns a timestamp value with 00:00:00 as the time by casting the TRUNC function result to a TIMESTAMP.

```
SELECT CAST((TRUNC(SYSDATE)) AS TIMESTAMP);
```

```
+-----+
|      trunc      |
+-----+
| 2011-07-21 00:00:00 |
+-----+
```

Date parts for date or timestamp functions

The following table identifies the date part and time part names and abbreviations that are accepted as arguments to the following functions:

- DATEADD
- DATEDIFF
- DATE_PART
- EXTRACT

Date part or time part	Abbreviations
millennium, millennia	mil, mils
century, centuries	c, cent, cents
decade, decades	dec, decs
epoch	epoch (supported by the EXTRACT)
year, years	y, yr, yrs
quarter, quarters	qtr, qtrs
month, months	mon, mons
week, weeks	w
day of week	<p>dayofweek, dow, dw, weekday (supported by the DATE_PART and the EXTRACT function)</p> <p>Returns an integer from 0–6, starting with Sunday.</p> <div data-bbox="597 1430 636 1465" style="float: left; margin-right: 5px;">  </div> <div data-bbox="646 1430 724 1465" style="float: left; margin-right: 5px;"> Note </div> <div data-bbox="641 1482 1461 1667" style="clear: both;"> <p>The DOW date part behaves differently from the day of week (D) date part used for datetime format strings. D is based on integers 1–7, where Sunday is 1. For more information, see Datetime format strings.</p> </div>
day of year	dayofyear, doy, dy, yearday (supported by the EXTRACT)
day, days	d

Date part or time part	Abbreviations
hour, hours	h, hr, hrs
minute, minutes	m, min, mins
second, seconds	s, sec, secs
millisecond, milliseconds	ms, msec, msecs, msecond, mseconds, millisec, millisecs, millisecon
microsecond, microseconds	microsec, microsecs, microsecond, usecond, useconds, us, usec, usecs
timezone, timezone_hour, timezone_minute	Supported by the EXTRACT for timestamp with time zone (TIMESTAMPTZ) only.

Variations in results with seconds, milliseconds, and microseconds

Minor differences in query results occur when different date functions specify seconds, milliseconds, or microseconds as date parts:

- The `EXTRACT` function return integers for the specified date part only, ignoring higher- and lower-level date parts. If the specified date part is seconds, milliseconds and microseconds are not included in the result. If the specified date part is milliseconds, seconds and microseconds are not included. If the specified date part is microseconds, seconds and milliseconds are not included.
- The `DATE_PART` function returns the complete seconds portion of the timestamp, regardless of the specified date part, returning either a decimal value or an integer as required.

For example, compare the results of the following queries:

```
create table seconds(micro timestamp);

insert into seconds values('2009-09-21 11:10:03.189717');

select extract(sec from micro) from seconds;

date_part
```

```

-----
3

select date_part(sec, micro) from seconds;

pgdate_part
-----
3.189717

```

CENTURY, EPOCH, DECADE, and MIL notes

CENTURY or CENTURIES

Amazon Redshift interprets a CENTURY to start with year *###1* and end with year *###0*:

```

select extract (century from timestamp '2000-12-16 12:21:13');
date_part
-----
20

select extract (century from timestamp '2001-12-16 12:21:13');
date_part
-----
21

```

EPOCH

The Amazon Redshift implementation of EPOCH is relative to 1970-01-01 00:00:00.000000 independent of the time zone where the cluster resides. You might need to offset the results by the difference in hours depending on the time zone where the cluster is located.

The following example demonstrates the following:

1. Creates a table called EVENT_EXAMPLE based on the EVENT table. This CREATE AS command uses the DATE_PART function to create a date column (called PGDATE_PART by default) to store the epoch value for each event.
2. Selects the column and data type of EVENT_EXAMPLE from PG_TABLE_DEF.
3. Selects EVENTNAME, STARTTIME, and PGDATE_PART from the EVENT_EXAMPLE table to view the different date and time formats.

4. Selects EVENTNAME and STARTTIME from EVENT EXAMPLE as is. Converts epoch values in PGDATE_PART using a 1 second interval to a timestamp without time zone, and returns the results in a column called CONVERTED_TIMESTAMP.

```
create table event_example
as select eventname, starttime, date_part(epoch, starttime) from event;

select "column", type from pg_table_def where tablename='event_example';
```

column	type
eventname	character varying(200)
starttime	timestamp without time zone
pgdate_part	double precision

(3 rows)

```
select eventname, starttime, pgdate_part from event_example;
```

eventname	starttime	pgdate_part

...		

DECADE or DECADES

Amazon Redshift interprets the DECADE or DECADES DATEPART based on the common calendar. For example, because the common calendar starts from the year 1, the first decade (decade 1) is 0001-01-01 through 0009-12-31, and the second decade (decade 2) is 0010-01-01 through 0019-12-31. For example, decade 201 spans from 2000-01-01 to 2009-12-31:

```
select extract(decade from timestamp '1999-02-16 20:38:40');
date_part
-----
200

select extract(decade from timestamp '2000-02-16 20:38:40');
date_part
-----
201

select extract(decade from timestamp '2010-02-16 20:38:40');
date_part
-----
202
```

MIL or MILS

Amazon Redshift interprets a MIL to start with the first day of year #001 and end with the last day of year #000:

```
select extract (mil from timestamp '2000-12-16 12:21:13');
date_part
-----
2
```

```
select extract (mil from timestamp '2001-12-16 12:21:13');
date_part
-----
3
```

Hash functions

Topics

- [CHECKSUM function](#)
- [farmFingerprint64 function](#)
- [FUNC_SHA1 function](#)
- [FNV_HASH function](#)
- [MD5 function](#)
- [SHA function](#)
- [SHA1 function](#)
- [SHA2 function](#)
- [MURMUR3_32_HASH](#)

A hash function is a mathematical function that converts a numerical input value into another value.

CHECKSUM function

Computes a checksum value for building a hash index.

Syntax

```
CHECKSUM(expression)
```

Argument

expression

The input expression must be a VARCHAR, INTEGER, or DECIMAL data type.

Return type

The CHECKSUM function returns an integer.

Example

The following example computes a checksum value for the COMMISSION column:

```
select checksum(commission)
from sales
order by salesid
limit 10;

checksum
-----
10920
1140
5250
2625
2310
5910
11820
2955
8865
975
(10 rows)
```

farmFingerprint64 function

Computes the farmhash value of the input argument using the Fingerprint64 function.

Syntax

```
farmFingerprint64(expression)
```

Argument

expression

The input expression must be a VARCHAR or VARBYTE data type.

Return type

The `farmFingerprint64` function returns a `BIGINT`.

Example

The following example returns the `farmFingerprint64` value of Amazon Redshift that is input as a `VARCHAR` data type.

```
SELECT farmFingerprint64('Amazon Redshift');
```

```
farmfingerprint64
-----
8085098817162212970
```

The following example returns the `farmFingerprint64` value of Amazon Redshift that is input as a `VARBYTE` data type.

```
SELECT farmFingerprint64('Amazon Redshift'::varbyte);
```

```
farmfingerprint64
-----
8085098817162212970
```

FUNC_SHA1 function

Synonym of `SHA1` function.

See [SHA1 function](#).

FNV_HASH function

Computes the 64-bit FNV-1a non-cryptographic hash function for all basic data types.

Syntax

```
FNV_HASH(value [, seed])
```

Arguments

value

The input value to be hashed. Amazon Redshift uses the binary representation of the value to hash the input value; for instance, INTEGER values are hashed using 4 bytes and BIGINT values are hashed using 8 bytes. Also, hashing CHAR and VARCHAR inputs does not ignore trailing spaces.

seed

The BIGINT seed of the hash function is optional. If not given, Amazon Redshift uses the default FNV seed. This enables combining the hash of multiple columns without any conversions or concatenations.

Return type

BIGINT

Example

The following examples return the FNV hash of a number, the string 'Amazon Redshift', and the concatenation of the two.

```
select fnv_hash(1);
       fnv_hash
-----
-5968735742475085980
(1 row)
```

```
select fnv_hash('Amazon Redshift');
       fnv_hash
-----
7783490368944507294
(1 row)
```

```
select fnv_hash('Amazon Redshift', fnv_hash(1));
       fnv_hash
-----
-2202602717770968555
```

```
(1 row)
```

Usage notes

- To compute the hash of a table with multiple columns, you can compute the FNV hash of the first column and pass it as a seed to the hash of the second column. Then, it passes the FNV hash of the second column as a seed to the hash of the third column.

The following example creates seeds to hash a table with multiple columns.

```
select fnv_hash(column_3, fnv_hash(column_2, fnv_hash(column_1))) from sample_table;
```

- The same property can be used to compute the hash of a concatenation of strings.

```
select fnv_hash('abcd');
       fnv_hash
-----
-281581062704388899
(1 row)
```

```
select fnv_hash('cd', fnv_hash('ab'));
       fnv_hash
-----
-281581062704388899
(1 row)
```

- The hash function uses the type of the input to determine the number of bytes to hash. Use casting to enforce a specific type, if necessary.

The following examples use different types of input to produce different results.

```
select fnv_hash(1::smallint);
       fnv_hash
-----
589727492704079044
(1 row)
```

```
select fnv_hash(1);
       fnv_hash
-----
```

```
-5968735742475085980  
(1 row)
```

```
select fnv_hash(1::bigint);  
       fnv_hash  
-----  
-8517097267634966620  
(1 row)
```

MD5 function

Uses the MD5 cryptographic hash function to convert a variable-length string into a 32-character string that is a text representation of the hexadecimal value of a 128-bit checksum.

Syntax

```
MD5(string)
```

Arguments

string

A variable-length string.

Return type

The MD5 function returns a 32-character string that is a text representation of the hexadecimal value of a 128-bit checksum.

Examples

The following example shows the 128-bit value for the string 'Amazon Redshift':

```
select md5('Amazon Redshift');  
md5  
-----  
f7415e33f972c03abd4f3fed36748f7a  
(1 row)
```

SHA function

Synonym of SHA1 function.

See [SHA1 function](#).

SHA1 function

The SHA1 function uses the SHA1 cryptographic hash function to convert a variable-length string into a 40-character string that is a text representation of the hexadecimal value of a 160-bit checksum.

Syntax

SHA1 is a synonym of [SHA function](#) and [FUNC_SHA1 function](#).

```
SHA1(string)
```

Arguments

string

A variable-length string.

Return type

The SHA1 function returns a 40-character string that is a text representation of the hexadecimal value of a 160-bit checksum.

Example

The following example returns the 160-bit value for the word 'Amazon Redshift':

```
select sha1('Amazon Redshift');
```

SHA2 function

The SHA2 function uses the SHA2 cryptographic hash function to convert a variable-length string into a character string. The character string is a text representation of the hexadecimal value of the checksum with the specified number of bits.

Syntax

```
SHA2(string, bits)
```

Arguments

string

A variable-length string.

integer

The number of bits in the hash functions. Valid values are 0 (same as 256), 224, 256, 384, and 512.

Return type

The SHA2 function returns a character string that is a text representation of the hexadecimal value of the checksum or an empty string if the number of bits is invalid.

Example

The following example returns the 256-bit value for the word 'Amazon Redshift':

```
select sha2('Amazon Redshift', 256);
```

MURMUR3_32_HASH

The MURMUR3_32_HASH function computes the 32-bit Murmur3A non-cryptographic hash for all common data types including numeric and string types.

Syntax

```
MURMUR3_32_HASH(value [, seed])
```

Arguments

value

The input value to hash. Amazon Redshift hashes the binary representation of the input value. This behavior is similar to [FNV_HASH function](#), but the value is converted to the binary representation specified by the [Apache Iceberg 32-bit Murmur3 hash specification](#).

seed

The INT seed of the hash function. This argument is optional. If not given, Amazon Redshift uses the default seed of 0. This enables combining the hash of multiple columns without any conversions or concatenations.

Return type

The function returns an INT.

Example

The following examples return the Murmur3 hash of a number, the string 'Amazon Redshift', and the concatenation of the two.

```
select MURMUR3_32_HASH(1);
```

```
      MURMUR3_32_HASH  
-----  
      1392991556  
(1 row)
```

```
select MURMUR3_32_HASH('Amazon Redshift');
```

```
      MURMUR3_32_HASH  
-----  
     -1563580564  
(1 row)
```

```
select MURMUR3_32_HASH('Amazon Redshift', MURMUR3_32_HASH(1));
```

```
      MURMUR3_32_HASH  
-----  
     -1346554171  
(1 row)
```

Usage notes

To compute the hash of a table with multiple columns, you can compute the Murmur3 hash of the first column and pass it as a seed to the hash of the second column. Then, it passes the Murmur3 hash of the second column as a seed to the hash of the third column.

The following example creates seeds to hash a table with multiple columns.

```
select MURMUR3_32_HASH(column_3, MURMUR3_32_HASH(column_2, MURMUR3_32_HASH(column_1)))
from sample_table;
```

The same property can be used to compute the hash of a concatenation of strings.

```
select MURMUR3_32_HASH('abcd');
```

```
      MURMUR3_32_HASH
-----
1139631978
(1 row)
```

```
select MURMUR3_32_HASH('cd', MURMUR3_32_HASH('ab'));
```

```
      MURMUR3_32_HASH
-----
1711522338
(1 row)
```

The hash function uses the type of the input to determine the number of bytes to hash. Use casting to enforce a specific type, if necessary.

The following examples use different input types to produce different results.

```
select MURMUR3_32_HASH(1, MURMUR3_32_HASH(1));
```

```
      MURMUR3_32_HASH
-----
-1193428387
(1 row)
```

```
select MURMUR3_32_HASH(1);
```

```
      MURMUR3_32_HASH
-----
1392991556
(1 row)
```

```
select MURMUR3_32_HASH(1, MURMUR3_32_HASH(2));

      MURMUR3_32_HASH
-----
1179621905
(1 row)
```

HyperLogLog functions

Following, you can find descriptions for the HyperLogLog functions for SQL that Amazon Redshift supports.

Topics

- [HLL function](#)
- [HLL_CREATE_SKETCH function](#)
- [HLL_CARDINALITY function](#)
- [HLL_COMBINE function](#)
- [HLL_COMBINE_SKETCHES function](#)

HLL function

The HLL function returns the HyperLogLog cardinality of the input expression values. The HLL function works with any data types except the HLLSKETCH data type. The HLL function ignores NULL values. When there are no rows in a table or all rows are NULL, the resulting cardinality is 0.

Syntax

```
HLL (aggregate_expression)
```

Argument

aggregate_expression

Any valid expression that provides the value to an aggregate, such as a column name. This function supports any data type as input except HLLSKETCH, GEOMETRY, GEOGRAPHY, and VARBYTE.

Return type

The HLL function returns a BIGINT or INT8 value.

Examples

The following example returns the cardinality of column `an_int` in table `a_table`.

```
CREATE TABLE a_table(an_int INT);
INSERT INTO a_table VALUES (1), (2), (3), (4);

SELECT hll(an_int) AS cardinality FROM a_table;
cardinality
-----
4
```

HLL_CREATE_SKETCH function

The `HLL_CREATE_SKETCH` function returns an `HLLSKETCH` data type that encapsulates the input expression values. The `HLL_CREATE_SKETCH` function works with any data type and ignores `NULL` values. When there are no rows in a table or all rows are `NULL`, the resulting sketch has no index-value pairs such as `{"version":1, "logm":15, "sparse":{"indices":[], "values":[]}}`.

Syntax

```
HLL_CREATE_SKETCH (aggregate_expression)
```

Argument

aggregate_expression

Any valid expression that provides the value to an aggregate, such as a column name.

`NULL` values are ignored. This function supports any data type as input except `HLLSKETCH`, `GEOMETRY`, `GEOGRAPHY`, and `VARBYTE`.

Return type

The `HLL_CREATE_SKETCH` function returns an `HLLSKETCH` value.

Examples

The following example returns the HLLSKETCH type for column `an_int` in table `a_table`. A JSON object is used to represent a sparse HyperLogLog sketch when importing, exporting, or printing sketches. A string representation (in Base64 format) is used to represent a dense HyperLogLog sketch.

```
CREATE TABLE a_table(an_int INT);
INSERT INTO a_table VALUES (1), (2), (3), (4);

SELECT hll_create_sketch(an_int) AS sketch FROM a_table;
sketch
-----
{"version":1,"logm":15,"sparse":{"indices":
[20812342,20850007,22362299,47158030],"values":[1,2,1,1]}}
(1 row)
```

HLL_CARDINALITY function

The `HLL_CARDINALITY` function returns the cardinality of the input HLLSKETCH data type.

Syntax

```
HLL_CARDINALITY (hllsketch_expression)
```

Argument

hllsketch_expression

Any valid expression that evaluates to an HLLSKETCH type, such as a column name. The input value is the HLLSKETCH data type.

Return type

The `HLL_CARDINALITY` function returns a BIGINT or INT8 value.

Examples

The following example returns the cardinality of column `sketch` in table `hll_table`.

```
CREATE TABLE a_table(an_int INT, b_int INT);
```

```
INSERT INTO a_table VALUES (1,1), (2,1), (3,1), (4,1), (1,2), (2,2), (3,2), (4,2),
(5,2), (6,2);

CREATE TABLE hll_table (sketch HLLSKETCH);
INSERT INTO hll_table select hll_create_sketch(an_int) from a_table group by b_int;

SELECT hll_cardinality(sketch) AS cardinality FROM hll_table;
cardinality
-----
6
4
(2 rows)
```

HLL_COMBINE function

The HLL_COMBINE aggregate function returns an HLLSKETCH data type that combines all input HLLSKETCH values.

The combination of two or more HyperLogLog sketches is a new HLLSKETCH that encapsulates information about the union of the distinct values that each input sketch represents. After combining sketches, Amazon Redshift extracts the cardinality of the union of two or more datasets. For more information on how to combine multiple sketches, see [Example: Return a HyperLogLog sketch from combining multiple sketches](#).

Syntax

```
HLL_COMBINE (hllsketch_expression)
```

Argument

hllsketch_expression

Any valid expression that evaluates to an HLLSKETCH type, such as a column name. The input value is the HLLSKETCH data type.

Return type

The HLL_COMBINE function returns an HLLSKETCH type.

Examples

The following example returns the combined HLLSKETCH values in the table `hll_table`.

```

CREATE TABLE a_table(an_int INT, b_int INT);
INSERT INTO a_table VALUES (1,1), (2,1), (3,1), (4,1), (1,2), (2,2), (3,2), (4,2),
(5,2), (6,2);

CREATE TABLE hll_table (sketch HLLSKETCH);
INSERT INTO hll_table select hll_create_sketch(an_int) from a_table group by b_int;

SELECT hll_combine(sketch) AS sketches FROM hll_table;
sketches
-----
{"version":1,"logm":15,"sparse":{"indices":
[20812342,20850007,22362299,40314817,42650774,47158030],"values":[1,2,1,3,2,1]}}
(1 row)

```

HLL_COMBINE_SKETCHES function

The HLL_COMBINE_SKETCHES is a scalar function that takes as input two HLLSKETCH values and combines them into a single HLLSKETCH.

The combination of two or more HyperLogLog sketches is a new HLLSKETCH that encapsulates information about the union of the distinct values that each input sketch represents.

Syntax

```
HLL_COMBINE_SKETCHES (hllsketch_expression1, hllsketch_expression2)
```

Argument

hllsketch_expression1 and *hllsketch_expression2*

Any valid expression that evaluates to an HLLSKETCH type, such as a column name.

Return type

The HLL_COMBINE_SKETCHES function returns an HLLSKETCH type.

Examples

The following example returns the combined HLLSKETCH values in the table `hll_table`.

```

WITH tbl1(x, y)
  AS (SELECT Hll_create_sketch(1),

```

```
        H11_create_sketch(2)
    UNION ALL
    SELECT H11_create_sketch(3),
           H11_create_sketch(4)
    UNION ALL
    SELECT H11_create_sketch(5),
           H11_create_sketch(6)
    UNION ALL
    SELECT H11_create_sketch(7),
           H11_create_sketch(8)),
tbl2(x, y)
AS (SELECT H11_create_sketch(9),
           H11_create_sketch(10)
    UNION ALL
    SELECT H11_create_sketch(11),
           H11_create_sketch(12)
    UNION ALL
    SELECT H11_create_sketch(13),
           H11_create_sketch(14)
    UNION ALL
    SELECT H11_create_sketch(15),
           H11_create_sketch(16)
    UNION ALL
    SELECT H11_create_sketch(NULL),
           H11_create_sketch(NULL)),
tbl3(x, y)
AS (SELECT *
    FROM tbl1
    UNION ALL
    SELECT *
    FROM tbl2)
SELECT H11_combine_sketches(x, y)
FROM tbl3;
```

JSON functions

Topics

- [JSON_PARSE function](#)
- [CAN_JSON_PARSE function](#)
- [JSON_SERIALIZE function](#)
- [JSON_SERIALIZE_TO_VARBYTE function](#)

- [Text-based JSON functions](#)

Note

We recommend that you use the following functions for working with JSON:

- [JSON_PARSE function](#)
- [CAN_JSON_PARSE function](#)
- [JSON_SERIALIZE function](#)
- [JSON_SERIALIZE_TO_VARBYTE function](#)

With `JSON_PARSE`, you only need to convert JSON text to a `SUPER` type value once at ingestion, after which you can operate on the `SUPER` values. Amazon Redshift parses `SUPER` values more efficiently than `VARCHAR`, which is the output for the text-based JSON functions. For more information on working with the `SUPER` data type, go to [Semistructured data in Amazon Redshift](#).

When you need to store a relatively small set of key-value pairs, you might save space by storing the data in JSON format. Because JSON strings can be stored in a single column, using JSON might be more efficient than storing your data in tabular format. For example, suppose you have a sparse table, where you need to have many columns to fully represent all possible attributes, but most of the column values are `NULL` for any given row or any given column. By using JSON for storage, you might be able to store the data for a row in key:value pairs in a single JSON string and eliminate the sparsely-populated table columns.

In addition, you can easily modify JSON strings to store additional key:value pairs when your JSON schema changes without needing to add columns to a table.

We recommend using JSON sparingly. JSON isn't a good choice for storing larger datasets because, by storing disparate data in a single column, JSON doesn't use the Amazon Redshift column store architecture. Though Amazon Redshift supports JSON functions over `CHAR` and `VARCHAR` columns, we recommend using `SUPER` for processing data in JSON serialization format. `SUPER` uses a post-parse schemaless representation that can efficiently query hierarchical data. For more information about the `SUPER` data type, see [Semistructured data in Amazon Redshift](#).

JSON uses UTF-8 encoded text strings, so JSON strings can be stored as CHAR or VARCHAR data types.

JSON strings must be properly formatted JSON, according to the following rules:

- The root level JSON can either be a JSON object or a JSON array. A JSON object is an unordered set of comma-separated key:value pairs enclosed by curly braces.

For example, `{"one":1, "two":2}`

- A JSON array is an ordered set of comma-separated values enclosed by brackets.

An example is the following: `["first", {"one":1}, "second", 3, null]`

- JSON arrays use a zero-based index; the first element in an array is at position 0. In a JSON key:value pair, the key is a string in double quotation marks.
- A JSON value can be any of the following:
 - JSON object
 - array
 - string
 - Represented using double quotation marks
 - number
 - Includes integers, decimals, and floats
 - boolean
 - null
- Empty objects and empty arrays are valid JSON values.
- JSON fields are case-sensitive.
- White space between JSON structural elements (such as `{ }`, `[]`) is ignored.

The Amazon Redshift JSON functions and the Amazon Redshift COPY command use the same methods to work with JSON-formatted data. For more information about working with JSON, see [COPY from JSON format](#)

JSON_PARSE function

The JSON_PARSE function parses data in JSON format and converts it into the SUPER representation.

To ingest into SUPER data type using the INSERT or UPDATE command, use the JSON_PARSE function. When you use JSON_PARSE() to parse JSON strings into SUPER values, certain restrictions apply. For additional information, see [Parsing options for SUPER](#).

Syntax

```
JSON_PARSE( {json_string | binary_value} )
```

Arguments

json_string

An expression that returns serialized JSON as a VARBYTE or VARCHAR type.

binary_value

A VARBYTE type binary value.

Return type

SUPER

Examples

To convert the JSON array [10001,10002,"abc"] into the SUPER data type, use the following example.

```
SELECT JSON_PARSE(' [10001,10002,"abc"] ');
```

```
+-----+
|  json_parse  |
+-----+
| [10001,10002,"abc"] |
+-----+
```

To make sure that the function converted the JSON array into the SUPER data type, use the following example. For more information, see [JSON_TYPEOF function](#)

```
SELECT JSON_TYPEOF(JSON_PARSE(' [10001,10002,"abc"] '));
```

```
+-----+
```

```
| json_typeof |  
+-----+  
| array      |  
+-----+
```

CAN_JSON_PARSE function

The CAN_JSON_PARSE function parses data in JSON format and returns `true` if the result can be converted to a SUPER value using the JSON_PARSE function.

Syntax

```
CAN_JSON_PARSE( {json_string | binary_value} )
```

Arguments

json_string

An expression that returns serialized JSON in VARCHAR form.

binary_value

A VARBYTE type binary value.

Return type

BOOLEAN

Usage notes

- CAN_JSON_PARSE returns `false` for empty strings. It returns `NULL` when the input argument is `null`.

Examples

The following example shows CAN_JSON_PARSE running on a properly formed JSON array using a CASE condition. It returns `true`, so Amazon Redshift runs the JSON_PARSE function on the example value.

```
SELECT CASE  
        WHEN CAN_JSON_PARSE(' [10001,10002,"abc"]' )
```

```

        THEN JSON_PARSE(' [10001,10002,"abc"]')
    END;

```

```

case
-----

```

```

'[10001,10002,"abc"]'

```

The following example shows `CAN_JSON_PARSE` running on a value that isn't JSON format using a CASE condition. It returns false, so Amazon Redshift returns the segment in the ELSE clause of the CASE condition instead.

```

SELECT CASE
    WHEN CAN_JSON_PARSE('This is a string.')
    THEN JSON_PARSE('This is a string.')
    ELSE 'This is not JSON.'
END;

```

```

case
-----

```

```

"This is not JSON."

```

JSON_SERIALIZE function

The `JSON_SERIALIZE` function serializes a SUPER expression into textual JSON representation to follow RFC 8259. For more information on that RFC, see [The JavaScript Object Notation \(JSON\) Data Interchange Format](#).

The SUPER size limit is approximately the same as the block limit, and the VARCHAR limit is smaller than the SUPER size limit. Therefore, the `JSON_SERIALIZE` function returns an error when the JSON format exceeds the varchar limit of the system. To check the size of a SUPER expression, see the [JSON_SIZE](#) function.

Syntax

```

JSON_SERIALIZE(super_expression)

```

Arguments

super_expression

A SUPER expression or column.

Return type

VARCHAR

Examples

To serialize a SUPER value to a string, use the following example.

```
SELECT JSON_SERIALIZE(JSON_PARSE(' [10001,10002,"abc"] '));
```

```
+-----+
| json_serialize |
+-----+
| [10001,10002,"abc"] |
+-----+
```

JSON_SERIALIZE_TO_VARBYTE function

The JSON_SERIALIZE_TO_VARBYTE function converts a SUPER value to a JSON string similar to JSON_SERIALIZE(), but stored in a VARBYTE value instead.

Syntax

```
JSON_SERIALIZE_TO_VARBYTE(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

VARBYTE

Examples

To serialize a SUPER value and returns the result in VARBYTE format, use the following example.

```
SELECT JSON_SERIALIZE_TO_VARBYTE(JSON_PARSE(' [10001,10002,"abc"] '));
```

```

+-----+
|      json_serialize_to_varbyte      |
+-----+
| 5b31303030312c31303030322c22616263225d |
+-----+

```

To serialize a SUPER value and casts the result to VARCHAR format, use the following example. For more information, see [CAST function](#).

```
SELECT CAST((JSON_SERIALIZE_TO_VARBYTE(JSON_PARSE('[10001,10002,"abc"]'))) AS VARCHAR);
```

```

+-----+
| json_serialize_to_varbyte |
+-----+
| [10001,10002,"abc"]      |
+-----+

```

Text-based JSON functions

The following functions parse JSON values as VARCHAR. For parsing JSON, we recommend you instead use the following functions, which parse JSON values as SUPER. Amazon Redshift parses SUPER values more efficiently than VARCHAR.

- [JSON_PARSE function](#)
- [CAN_JSON_PARSE function](#)
- [JSON_SERIALIZE function](#)
- [JSON_SERIALIZE_TO_VARBYTE function](#)

Topics

- [IS_VALID_JSON function](#)
- [IS_VALID_JSON_ARRAY function](#)
- [JSON_ARRAY_LENGTH function](#)
- [JSON_EXTRACT_ARRAY_ELEMENT_TEXT function](#)
- [JSON_EXTRACT_PATH_TEXT function](#)

IS_VALID_JSON function

Note

CAN_JSON_PARSE and its associated functions parse JSON values as SUPER, which Amazon Redshift parses more efficiently than VARCHAR.

Instead of using IS_VALID_JSON, we recommend that you validate your JSON strings using the [CAN_JSON_PARSE function](#).

The IS_VALID_JSON function validates a JSON string. The function returns Boolean `true` if the string is properly formed JSON or `false` if the string is malformed. To validate a JSON array, use [IS_VALID_JSON_ARRAY function](#)

For more information, see [JSON functions](#).

Syntax

```
IS_VALID_JSON('json_string')
```

Arguments

json_string

A string or expression that evaluates to a JSON string.

Return type

BOOLEAN

Examples

To create a table and insert JSON strings for testing, use the following example.

```
CREATE TABLE test_json(id int IDENTITY(0,1), json_strings VARCHAR);

-- Insert valid JSON strings --
INSERT INTO test_json(json_strings) VALUES
('{"a":2}'),
('{"a":{"b":{"c":1}}'),
```

```

({'"a": [1,2,"b"]}');

-- Insert invalid JSON strings --
INSERT INTO test_json(json_strings) VALUES
('{{}}'),
('{1:"a"}'),
('[1,2,3]');

```

To validate the strings in the preceding example, use the following example.

```

SELECT id, json_strings, IS_VALID_JSON(json_strings)
FROM test_json
ORDER BY id;

```

```

+----+-----+-----+
| id | json_strings | is_valid_json |
+----+-----+-----+
| 0  | {"a":2}      | true          |
| 4  | {"a":{"b":{"c":1}}} | true          |
| 8  | {"a": [1,2,"b"]} | true          |
| 12 | {{}}         | false         |
| 16 | {1:"a"}     | false         |
| 20 | [1,2,3]     | false         |
+----+-----+-----+

```

IS_VALID_JSON_ARRAY function

Note

JSON_PARSE and its associated functions parse JSON values as SUPER, which Amazon Redshift parses more efficiently than VARCHAR.

Instead of using IS_VALID_JSON_ARRAY, we recommend that you parse your JSON strings using the [JSON_PARSE function](#) to get a SUPER value. Then, use the [IS_ARRAY function](#) to confirm that the array is properly formed.

The IS_VALID_JSON_ARRAY function validates a JSON array. The function returns Boolean true if the array is properly formed JSON or false if the array is malformed. To validate a JSON string, use [IS_VALID_JSON function](#)

For more information, see [JSON functions](#).

Syntax

```
IS_VALID_JSON_ARRAY('json_array')
```

Arguments

json_array

A string or expression that evaluates to a JSON array.

Return type

BOOLEAN

Examples

To create a table and insert JSON strings for testing, use the following example.

```
CREATE TABLE test_json_arrays(id int IDENTITY(0,1), json_arrays VARCHAR);

-- Insert valid JSON array strings --
INSERT INTO test_json_arrays(json_arrays)
VALUES('[]'),
('["a","b"]'),
('["a",["b",1,["c",2,3,null]]]');

-- Insert invalid JSON array strings --
INSERT INTO test_json_arrays(json_arrays)
VALUES('{ "a":1 }'),
('a'),
('1,2,');
```

To validate the strings in the preceding example, use the following example.

```
SELECT json_arrays, IS_VALID_JSON_ARRAY(json_arrays)
FROM test_json_arrays ORDER BY id;
```

json_arrays	is_valid_json_array
[]	true

["a", "b"]	true	
["a", ["b", 1, ["c", 2, 3, null]]]	true	
{"a":1}	false	
a	false	
[1, 2,]	false	
+-----+	+-----+	+-----+

JSON_ARRAY_LENGTH function

Note

JSON_PARSE and its associated functions parse JSON values as SUPER, which Amazon Redshift parses more efficiently than VARCHAR.

Instead of using JSON_ARRAY_LENGTH, we recommend that you parse your JSON strings using the [JSON_PARSE function](#) to get a SUPER value. Then, use the [get_array_length function](#) to get the length of your array.

The JSON_ARRAY_LENGTH function returns the number of elements in the outer array of a JSON string. If the *null_if_invalid* argument is set to `true` and the JSON string is invalid, the function returns NULL instead of returning an error.

For more information, see [JSON functions](#).

Syntax

```
JSON_ARRAY_LENGTH('json_array' [, null_if_invalid ] )
```

Arguments

json_array

A properly formatted JSON array.

null_if_invalid

(Optional) A BOOLEAN value that specifies whether to return NULL if the input JSON string is invalid instead of returning an error. To return NULL if the JSON is invalid, specify `true` (t). To return an error if the JSON is invalid, specify `false` (f). The default is `false`.

Return type

INTEGER

Examples

To return the number of elements in the array, use the following example.

```
SELECT JSON_ARRAY_LENGTH(' [11,12,13,{"f1":21,"f2":[25,26]},14]');
```

```
+-----+
| json_array_length |
+-----+
|                   5 |
+-----+
```

To return an error because the JSON is invalid, use the following example.

```
SELECT JSON_ARRAY_LENGTH(' [11,12,13,{"f1":21,"f2":[25,26]},14]');
```

```
ERROR: invalid json array object [11,12,13,{"f1":21,"f2":[25,26]},14
```

To set *null_if_invalid* to *true*, so the statement returns NULL instead of returning an error for invalid JSON, use the following example.

```
SELECT JSON_ARRAY_LENGTH(' [11,12,13,{"f1":21,"f2":[25,26]},14', true);
```

```
+-----+
| json_array_length |
+-----+
| NULL              |
+-----+
```

JSON_EXTRACT_ARRAY_ELEMENT_TEXT function

Note

JSON_PARSE and its associated functions parse JSON values as SUPER, which Amazon Redshift parses more efficiently than VARCHAR.

Instead of using JSON_EXTRACT_ARRAY_ELEMENT_TEXT, we recommend that you parse your JSON strings using the [JSON_PARSE function](#) to get a SUPER value. Then, query

the element you want using its array index, using the `value[element position]` syntax. For more information on querying array elements in SUPER values, go to [Querying semistructured data](#).

The `JSON_EXTRACT_ARRAY_ELEMENT_TEXT` function returns a JSON array element in the outermost array of a JSON string, using a zero-based index. The first element in an array is at position 0. If the index is negative or out of bound, `JSON_EXTRACT_ARRAY_ELEMENT_TEXT` returns empty string. If the *null_if_invalid* argument is set to `true` and the JSON string is invalid, the function returns NULL instead of returning an error.

For more information, see [JSON functions](#).

Syntax

```
JSON_EXTRACT_ARRAY_ELEMENT_TEXT('json string', pos [, null_if_invalid ] )
```

Arguments

json_string

A properly formatted JSON string.

pos

An INTEGER representing the index of the array element to be returned, using a zero-based array index.

null_if_invalid

(Optional) A BOOLEAN value that specifies whether to return NULL if the input JSON string is invalid instead of returning an error. To return NULL if the JSON is invalid, specify `true` (t). To return an error if the JSON is invalid, specify `false` (f). The default is `false`.

Return type

VARCHAR

A VARCHAR string representing the JSON array element referenced by *pos*.

Examples

To return array element at position 2, which is the third element of a zero-based array index, use the following example.

```
SELECT JSON_EXTRACT_ARRAY_ELEMENT_TEXT(' [111,112,113]', 2);
```

```
+-----+
| json_extract_array_element_text |
+-----+
|                               113 |
+-----+
```

To return an error because the JSON is invalid, use the following example.

```
SELECT JSON_EXTRACT_ARRAY_ELEMENT_TEXT(' ["a", ["b", 1, ["c", 2, 3, null, ]]]', 1);
```

```
ERROR: invalid json array object ["a", ["b", 1, ["c", 2, 3, null, ]]]
```

To set *null_if_invalid* to *true*, so the statement returns NULL instead of returning an error for invalid JSON, use the following example.

```
SELECT JSON_EXTRACT_ARRAY_ELEMENT_TEXT(' ["a", ["b", 1, ["c", 2, 3, null, ]]]', 1, true);
```

```
+-----+
| json_extract_array_element_text |
+-----+
| NULL                            |
+-----+
```

JSON_EXTRACT_PATH_TEXT function

Note

JSON_PARSE and its associated functions parse JSON values as SUPER, which Amazon Redshift parses more efficiently than VARCHAR.

Instead of using JSON_EXTRACT_PATH_TEXT, we recommend that you parse your JSON strings using the [JSON_PARSE function](#) to get a SUPER value. Then, query the element you want using the `value.attribute` syntax. For more information on querying array elements in SUPER values, go to [Querying semistructured data](#).

The `JSON_EXTRACT_PATH_TEXT` function returns the value for the key-value pair referenced by a series of path elements in a JSON string. The JSON path can be nested up to five levels deep. Path elements are case-sensitive. If a path element does not exist in the JSON string, `JSON_EXTRACT_PATH_TEXT` returns `NULL`.

If the `null_if_invalid` argument is set to `true` and the JSON string is invalid, the function returns `NULL` instead of returning an error.

`JSON_EXTRACT_PATH_TEXT` has a 64KB data-size maximum. Thus, if any JSON record is larger than 64KB, processing it with `JSON_EXTRACT_PATH_TEXT` results in an error.

For information about additional JSON functions, see [JSON functions](#). For more information about working with JSON, see [COPY from JSON format](#).

Syntax

```
JSON_EXTRACT_PATH_TEXT('json_string', 'path_elem' [, 'path_elem'[, ...] ]  
[, null_if_invalid ] )
```

Arguments

json_string

A properly formatted JSON string.

path_elem

A path element in a JSON string. One path element is required. Additional path elements can be specified, up to five levels deep.

null_if_invalid

(Optional) A `BOOLEAN` value that specifies whether to return `NULL` if the input JSON string is invalid instead of returning an error. To return `NULL` if the JSON is invalid, specify `true` (`t`). To return an error if the JSON is invalid, specify `false` (`f`). The default is `false`.

In a JSON string, Amazon Redshift recognizes `\n` as a newline character and `\t` as a tab character. To load a backslash, escape it with a backslash (`\\`). For more information, see [Escape characters in JSON](#).

Return type

VARCHAR

A VARCHAR string representing the JSON value referenced by the path elements.

Examples

To return the value for the path 'f4', 'f6', use the following example.

```
SELECT JSON_EXTRACT_PATH_TEXT('{"f2":{"f3":1},"f4":{"f5":99,"f6":"star"}}', 'f4', 'f6');
```

```
+-----+
| json_extract_path_text |
+-----+
| star                    |
+-----+
```

To return an error because the JSON is invalid, use the following example.

```
SELECT JSON_EXTRACT_PATH_TEXT('{"f2":{"f3":1},"f4":{"f5":99,"f6":"star"}}', 'f4', 'f6');
```

```
ERROR: invalid json object {"f2":{"f3":1},"f4":{"f5":99,"f6":"star"}}
```

To set *null_if_invalid* to *true*, so the statement returns NULL for invalid JSON instead of returning an error, use the following example.

```
SELECT JSON_EXTRACT_PATH_TEXT('{"f2":{"f3":1},"f4":{"f5":99,"f6":"star"}}', 'f4',
'f6', true);
```

```
+-----+
| json_extract_path_text |
+-----+
| NULL                    |
+-----+
```

To return the value for the path 'farm', 'barn', 'color', where the value retrieved is at the third level, use the following example. This sample is formatted with a JSON lint tool, to make it easier to read.

```
SELECT JSON_EXTRACT_PATH_TEXT('{
```

```

    "farm": {
      "barn": {
        "color": "red",
        "feed stocked": true
      }
    }
  }, 'farm', 'barn', 'color');
+-----+
| json_extract_path_text |
+-----+
| red                    |
+-----+

```

To return NULL because the 'color' element is missing, use the following example. This sample is formatted with a JSON lint tool.

```

SELECT JSON_EXTRACT_PATH_TEXT('{
  "farm": {
    "barn": {}
  }
}', 'farm', 'barn', 'color');
+-----+
| json_extract_path_text |
+-----+
| NULL                   |
+-----+

```

If the JSON is valid, trying to extract an element that's missing returns NULL.

To return the value for the path 'house', 'appliances', 'washing machine', 'brand', use the following example.

```

SELECT JSON_EXTRACT_PATH_TEXT('{
  "house": {
    "address": {
      "street": "123 Any St.",
      "city": "Any Town",
      "state": "FL",
      "zip": "32830"
    },
    "bathroom": {

```

```

    "color": "green",
    "shower": true
  },
  "appliances": {
    "washing machine": {
      "brand": "Any Brand",
      "color": "beige"
    },
    "dryer": {
      "brand": "Any Brand",
      "color": "white"
    }
  }
}
}', 'house', 'appliances', 'washing machine', 'brand');

```

```

+-----+
| json_extract_path_text |
+-----+
| Any Brand              |
+-----+

```

The following example creates a sample table and populates it with SUPER values, then returns the value for the path 'f2' for both rows.

```

CREATE TABLE json_example(id INT, json_text SUPER);

INSERT INTO json_example VALUES
(1, JSON_PARSE('{"f2":{"f3":1},"f4":{"f5":99,"f6":"star"}}')),
(2, JSON_PARSE('{
  "farm": {
    "barn": {
      "color": "red",
      "feed stocked": true
    }
  }
}')));

SELECT * FROM json_example;
id      | json_text
-----+-----
1       | {"f2":{"f3":1},"f4":{"f5":99,"f6":"star"}}
2       | {"farm":{"barn":{"color":"red","feed stocked":true}}}

```

```
SELECT id, JSON_EXTRACT_PATH_TEXT(JSON_SERIALIZE(json_text), 'f2') FROM json_example;
```

id	json_text
1	{"f3":1}
2	

Machine learning functions

By using Amazon Redshift machine learning (ML), you can train ML models using SQL statements and invoke them in SQL queries for prediction. Amazon Redshift model explainability includes feature-importance values to help you understand how each attribute in your training data contributes to the predicted result.

Following, you can find descriptions for the machine learning functions for SQL that Amazon Redshift supports.

Topics

- [EXPLAIN_MODEL function](#)

EXPLAIN_MODEL function

The EXPLAIN_MODEL function returns a SUPER data type that contains a model explainability report in a JSON format. The explainability report contains information about the Shapley value for all model features.

The EXPLAIN_MODEL function currently supports only the AUTO ON or AUTO OFF XGBoost models.

When the explainability report isn't available, the function returns statuses showing on the progress of the model. These include Waiting for training job to complete, Waiting for processing job to complete, and Processing job failed.

When you run the CREATE MODEL statement, the explanation state becomes Waiting for training job to complete. When the model has been trained and an explanation request is sent, the explanation state becomes Waiting for processing job to complete. When the

model explanation completes successfully, the full explainability report is available. Otherwise, the state becomes `Processing job failed`.

When you run the `CREATE MODEL` statement, you can use the optional `MAX_RUNTIME` parameter to specify the maximum amount of time the training should take. Once model creation reaches that amount of time, Amazon Redshift stops creating the model. If you reach that time limit while creating an autopilot model, Amazon Redshift will return the best model so far. Model explainability becomes available once the model training finishes, so if `MAX_RUNTIME` is set to a low amount of time, the explainability report might not be available. Training time varies and depends on model complexity, data size, and other factors.

Syntax

```
EXPLAIN_MODEL ('schema_name.model_name')
```

Argument

schema_name

The name of the schema. If no `schema_name` is specified, then the current schema is selected.

model_name

The name of the model. The model name in a schema must be unique.

Return type

The `EXPLAIN_MODEL` function returns a `SUPER` data type, as shown following.

```
{"version":"1.0","explanations":{"kernel_shap":{"label0":{"global_shap_values":{"x0":0.05,"x1":0.10,"x2":0.30,"x3":0.15},"expected_value":0.50}}}}
```

Examples

The following example returns the explanation state waiting for training job to complete.

```
select explain_model('customer_churn_auto_model');
           explain_model
-----
{"explanations":"waiting for training job to complete"}
```

```
(1 row)
```

When the model explanation completes successfully, the full explainability report is available as follows.

```
select explain_model('customer_churn_auto_model');
           explain_model
-----
{"version":"1.0","explanations":{"kernel_shap":{"label0":{"global_shap_values":
{"x0":0.05386043365892927,"x1":0.10801289723274592,"x2":0.23227865827017378,"x3":0.067668513394
(1 row)
```

Because the EXPLAIN_MODEL function returns the SUPER data type, you can query the explainability report. By doing this, you can extract `global_shap_values`, `expected_value`, or feature-specific Shapley values.

The following example extracts `global_shap_values` for the model.

```
select json_table.report.explanations.kernel_shap.label0.global_shap_values from
(select explain_model('customer_churn_auto_model') as report) as json_table;
           global_shap_values
-----
{"state":0.10983770427197151,"account_length":0.1772441398408543,"area_code":0.0862682396863959
(1 row)
```

The following example extracts `global_shap_values` for the feature `x0`.

```
select json_table.report.explanations.kernel_shap.label0.global_shap_values.x0 from
(select explain_model('customer_churn_auto_model') as report) as json_table;
           x0
-----
0.05386043365892927
(1 row)
```

If the model is created in a specific schema and you have access to the created model, then you can query the model explanation as shown following.

```
-- Check the current schema
SHOW search_path;
      search_path
```

```
-----  
  $user, public  
(1 row)  
-- If you have the privilege to access the model explanation  
-- in `test_schema`  
SELECT explain_model('test_schema.test_model_name');  
          explain_model  
-----  
{"explanations":"waiting for training job to complete"}  
(1 row)
```

This section describes the mathematical operators and functions supported in Amazon Redshift.

Mathematical operator symbols

The following table lists the supported mathematical operators.

Supported operators

Operator	Description	Example	Result
+	addition	2 + 3	5
-	subtraction	2 - 3	-1
*	multiplication	2 * 3	6
/	division	4 / 2	2
%	modulo	5 % 4	1
^	exponentiation	2.0 ^ 3.0	8
/	square root	/ 25.0	5
/	cube root	/ 27.0	3

Operator	Description	Example	Result
@	absolute value	@ -5.0	5
<<	bitwise shift left	1 << 4	16
>>	bitwise shift right	8 >> 2	2
&	bitwise and	8 & 2	0

Examples

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

To calculate the commission paid plus a \$2.00 handling for a given transaction, use the following example.

```
SELECT
  commission,
  (commission + 2.00) AS comm
FROM
  sales
WHERE
  salesid = 10000;
```

```
+-----+-----+
| commission | comm |
+-----+-----+
|      28.05 | 30.05 |
+-----+-----+
```

To calculate 20 percent of the sales price for a given transaction, use the following example.

```
SELECT pricepaid, (pricepaid * .20) as twentypct
FROM sales
WHERE salesid=10000;
```

```

+-----+-----+
| pricepaid | twentypct |
+-----+-----+
|      187 |      37.4 |
+-----+-----+

```

To forecast ticket sales based on a continuous growth pattern, use the following example. In this example, the subquery returns the number of tickets sold in 2008. That result is multiplied exponentially by a continuous growth rate of 5% over 10 years.

```

SELECT (SELECT SUM(qtysold) FROM sales, date
WHERE sales.dateid=date.dateid AND year=2008)^(5::float/100)*10) AS qty10years;

```

```

+-----+
| qty10years |
+-----+
| 587.664019657491 |
+-----+

```

To find the total price paid and commission for sales with a date ID that is greater than or equal to 2000, use the following example. Then subtract the total commission from the total price paid.

```

SELECT SUM(pricepaid) AS sum_price, dateid,
SUM(commission) AS sum_comm, (SUM(pricepaid) - SUM(commission)) AS value
FROM sales
WHERE dateid >= 2000
GROUP BY dateid
ORDER BY dateid
LIMIT 10;

```

```

+-----+-----+-----+-----+
| sum_price | dateid | sum_comm | value |
+-----+-----+-----+-----+
| 305885 | 2000 | 45882.75 | 260002.25 |
| 316037 | 2001 | 47405.55 | 268631.45 |
| 358571 | 2002 | 53785.65 | 304785.35 |
| 366033 | 2003 | 54904.95 | 311128.05 |
| 307592 | 2004 | 46138.8 | 261453.2 |
| 333484 | 2005 | 50022.6 | 283461.4 |
| 317670 | 2006 | 47650.5 | 270019.5 |
| 351031 | 2007 | 52654.65 | 298376.35 |

```

```
| 313359 | 2008 | 47003.85 | 266355.15 |
| 323675 | 2009 | 48551.25 | 275123.75 |
+-----+-----+-----+-----+
```

ABS function

ABS calculates the absolute value of a number, where that number can be a literal or an expression that evaluates to a number.

Syntax

```
ABS(number)
```

Arguments

number

Number or expression that evaluates to a number. It can be the SMALLINT, INTEGER, BIGINT, DECIMAL, FLOAT4, FLOAT8, or SUPER type.

Return type

ABS returns the same data type as its argument.

Examples

To calculate the absolute value of -38, use the following example.

```
SELECT ABS(-38);
```

```
+-----+
| abs |
+-----+
| 38 |
+-----+
```

To calculate the absolute value of (14-76), use the following example.

```
SELECT ABS(14-76);
```

```
+-----+
| abs |
+-----+
| 62 |
+-----+
```

ACOS function

ACOS is a trigonometric function that returns the arc cosine of a number. The return value is in radians and is between 0 and PI.

Syntax

```
ACOS(number)
```

Arguments

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the arc cosine of -1, use the following example.

```
SELECT ACOS(-1);
```

```
+-----+
|      acos      |
+-----+
| 3.141592653589793 |
+-----+
```

To convert the arc cosine of .5 to the equivalent number of degrees, use the following example.

```
SELECT (ACOS(.5) * 180/(SELECT PI())) AS degrees;
```

```
+-----+
|      degrees      |
+-----+
| 60.00000000000001 |
+-----+
```

ASIN function

ASIN is a trigonometric function that returns the arc sine of a number. The return value is in radians and is between $\text{PI}/2$ and $-\text{PI}/2$.

Syntax

```
ASIN(number)
```

Arguments

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the arc sine of 1, use the following example.

```
SELECT ASIN(1) AS halfpi;
```

```
+-----+
|      halfpi      |
+-----+
| 1.5707963267948966 |
+-----+
```

To convert the arc sine of .5 to the equivalent number of degrees, use the following example.

```
SELECT (ASIN(.5) * 180/(SELECT PI())) AS degrees;
```

```
+-----+
|      degrees      |
+-----+
| 30.000000000000004 |
+-----+
```

ATAN function

ATAN is a trigonometric function that returns the arc tangent of a number. The return value is in radians and is between $-\pi$ and π .

Syntax

```
ATAN(number)
```

Arguments

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the arc tangent of 1 and multiply it by 4, use the following example.

```
SELECT ATAN(1) * 4 AS pi;
```

```
+-----+
|      pi      |
+-----+
| 3.141592653589793 |
+-----+
```

To convert the arc tangent of 1 to the equivalent number of degrees, use the following example.

```
SELECT (ATAN(1) * 180/(SELECT PI())) AS degrees;
```

```
+-----+
| degrees |
+-----+
|      45 |
+-----+
```

ATAN2 function

ATAN2 is a trigonometric function that returns the arc tangent of one number divided by another number. The return value is in radians and is between $\text{PI}/2$ and $-\text{PI}/2$.

Syntax

```
ATAN2(number1, number2)
```

Arguments

number1

A DOUBLE PRECISION number.

number2

A DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the arc tangent of $2/2$ and multiply it by 4, use the following example.

```
SELECT ATAN2(2,2) * 4 AS PI;
```

```
+-----+
|      pi      |
+-----+
| 3.141592653589793 |
+-----+
```

To convert the arc tangent of $1/0$ (which evaluates to 0) to the equivalent number of degrees, use the following example.

```
SELECT (ATAN2(1,0) * 180/(SELECT PI())) AS degrees;
```

```
+-----+
| degrees |
+-----+
|      90 |
+-----+
```

CBRT function

The CBRT function is a mathematical function that calculates the cube root of a given number.

Syntax

```
CBRT(number)
```

Arguments

CBRT takes a DOUBLE PRECISION number as an argument.

Return type

DOUBLE PRECISION

Examples

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

To calculate the cube root of the commission paid for a given transaction, use the following example.

```
SELECT CBRT(commission) FROM sales WHERE salesid=10000;
```

```
+-----+
|      cbrt      |
+-----+
| 3.0383953904884344 |
+-----+
```

```
+-----+
```

CEILING (or CEIL) function

The CEILING or CEIL function is used to round a number up to the next whole number. (The [FLOOR function](#) rounds a number down to the next whole number.)

Syntax

```
{CEIL | CEILING}(number)
```

Arguments

number

The number or expression that evaluates to a number. It can be the SMALLINT, INTEGER, BIGINT, DECIMAL, FLOAT4, FLOAT8, or SUPER type.

Return type

CEILING and CEIL return the same data type as its argument.

When the input is of the SUPER type, the output retains the same dynamic type as the input while the static type remains the SUPER type. When the dynamic type of SUPER isn't a number, Amazon Redshift returns a null.

Examples

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

To calculate the ceiling of the commission paid for a given sales transaction, use the following example.

```
SELECT CEILING(commission) FROM sales
WHERE salesid=10000;
```

```
+-----+
| ceiling |
+-----+
|      29 |
```

```
+-----+
```

COS function

COS is a trigonometric function that returns the cosine of a number. The return value is in radians and is between -1 and 1, inclusive.

Syntax

```
COS(double_precision)
```

Arguments

number

The input parameter is a DOUBLE PRECISION number.

Return type

The COS function returns a DOUBLE PRECISION number.

Examples

To return the cosine of 0, use the following example.

```
SELECT COS(0);
```

```
+-----+
|  cos  |
+-----+
|   1   |
+-----+
```

To return the cosine of π , use the following example.

```
SELECT COS(PI());
```

```
+-----+
|  cos  |
+-----+
|  -1   |
```

```
+-----+
```

COT function

COT is a trigonometric function that returns the cotangent of a number. The input parameter must be nonzero.

Syntax

```
COT(number)
```

Argument

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the cotangent of 1, use the following example.

```
SELECT COT(1);
```

```
+-----+
|      cot      |
+-----+
| 0.6420926159343306 |
+-----+
```

DEGREES function

Converts an angle in radians to its equivalent in degrees.

Syntax

```
DEGREES(number)
```

Argument

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the degree equivalent of .5 radians, use the following example.

```
SELECT DEGREES(.5);

+-----+
| degrees |
+-----+
| 28.64788975654116 |
+-----+
```

To convert PI radians to degrees, use the following example.

```
SELECT DEGREES(pi());

+-----+
| degrees |
+-----+
| 180 |
+-----+
```

DEXP function

The DEXP function returns the exponential value in scientific notation for a double precision number. The only difference between the DEXP and EXP functions is that the parameter for DEXP must be a DOUBLE PRECISION.

Syntax

```
DEXP(number)
```

Argument

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Example

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

Use the DEXP function to forecast ticket sales based on a continuous growth pattern. In this example, the subquery returns the number of tickets sold in 2008. That result is multiplied by the result of the DEXP function, which specifies a continuous growth rate of 7% over 10 years.

```
SELECT (SELECT SUM(qtysold)
FROM sales, date
WHERE sales.dateid=date.dateid
AND year=2008) * DEXP((7::FLOAT/100)*10) qty2010;
```

```
+-----+
|      qty2010      |
+-----+
| 695447.4837722216 |
+-----+
```

DLOG1 function

The DLOG1 function returns the natural logarithm of the input parameter. Synonym of [LN function](#).

DLOG10 function

The DLOG10 returns the base 10 logarithm of the input parameter.

Synonym of [LOG function](#).

Syntax

```
DLOG10(number)
```

Argument

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Example

To return the base 10 logarithm of the number 100, use the following example.

```
SELECT DLOG10(100);
```

```
+-----+
| dlog10 |
+-----+
|      2 |
+-----+
```

EXP function

The EXP function implements the exponential function for a numeric expression, or the base of the natural logarithm, e, raised to the power of expression. The EXP function is the inverse of [LN function](#).

Syntax

```
EXP(expression)
```

Argument

expression

The expression must be an INTEGER, DECIMAL, or DOUBLE PRECISION data type.

Return type

DOUBLE PRECISION

Example

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

Use the EXP function to forecast ticket sales based on a continuous growth pattern. In this example, the subquery returns the number of tickets sold in 2008. That result is multiplied by the result of the EXP function, which specifies a continuous growth rate of 7% over 10 years.

```
SELECT (SELECT SUM(qtysold)
FROM sales, date
WHERE sales.dateid=date.dateid
AND year=2008) * EXP((7::FLOAT/100)*10) qty2018;
```

```
+-----+
|      qty2018      |
+-----+
| 695447.4837722216 |
+-----+
```

FLOOR function

The FLOOR function rounds a number down to the next whole number.

Syntax

```
FLOOR(number)
```

Argument

number

The number or expression that evaluates to a number. It can be the SMALLINT, INTEGER, BIGINT, DECIMAL, FLOAT4, FLOAT8, or SUPER type.

Return type

FLOOR returns the same data type as its argument.

When the input is of the SUPER type, the output retains the same dynamic type as the input while the static type remains the SUPER type. When the dynamic type of SUPER isn't a number, Amazon Redshift returns NULL.

Examples

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

To show the value of the commission paid for a given sales transaction before and after using the FLOOR function, use the following example.

```
SELECT commission
FROM sales
WHERE salesid=10000;

+-----+
| commission |
+-----+
|      28.05 |
+-----+

SELECT FLOOR(commission)
FROM sales
WHERE salesid=10000;

+-----+
| floor |
+-----+
|    28 |
+-----+
```

LN function

Returns the natural logarithm of the input parameter.

Synonym of [DLOG1 function](#).

Syntax

```
LN(expression)
```

Argument

expression

The target column or expression that the function operates on.

Note

This function returns an error for some data types if the expression references an Amazon Redshift user-created table or an Amazon Redshift STL or STV system table.

Expressions with the following data types produce an error if they reference a user-created or system table. Expressions with these data types run exclusively on the leader node:

- BOOLEAN
- CHAR
- DATE
- DECIMAL or NUMERIC
- TIMESTAMP
- VARCHAR

Expressions with the following data types run successfully on user-created tables and STL or STV system tables:

- BIGINT
- DOUBLE PRECISION
- INTEGER
- REAL
- SMALLINT

Return type

The LN function returns the same type as the input *expression*.

Examples

To return the natural logarithm or base e logarithm of the number 2.718281828, use the following example.

```
SELECT LN(2.718281828);
```

```
+-----+
|          ln          |
+-----+
| 0.9999999998311267 |
+-----+
```

Note that the answer is nearly equal to 1.

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

To return the natural logarithm of the values in the userid column in the USERS table, use the following example.

```
SELECT username, LN(userid) FROM users ORDER BY userid LIMIT 10;
```

```
+-----+-----+
| username |          ln          |
+-----+-----+
| JSG99FHE |                   0 |
| PGL08LJI | 0.6931471805599453 |
| IFT66TXU | 1.0986122886681098 |
| XDZ38RDD | 1.3862943611198906 |
| AEB55QTM | 1.6094379124341003 |
| NDQ15VBM | 1.791759469228055 |
| OWY35QYB | 1.9459101490553132 |
| AZG78YIP | 2.0794415416798357 |
| MSD36KVR | 2.1972245773362196 |
| WKW41AIW | 2.302585092994046 |
+-----+-----+
```

LOG function

Returns logarithm of a number.

If you're using this function to calculate the base 10 logarithm, you can also use [DLOG10 function](#).

Syntax

```
LOG([base, ]argument)
```

Parameters

base

(Optional) The base of the logarithm function. This number must be positive and can't equal 1. If this parameter is omitted, Amazon Redshift computes the base 10 logarithm of the *argument*.

argument

The argument of the logarithm function. This number must be positive. If the *argument* value is 1, the function returns 0.

Return type

The LOG function returns a DOUBLE PRECISION number.

Examples

To find the base 2 logarithm of 100, use the following example.

```
SELECT LOG(2, 100);
+-----+
|      log      |
+-----+
| 6.643856189774725 |
+-----+
```

To find the base 10 logarithm of 100, use the following example. Note that if you omit the base parameter, Amazon Redshift assumes a base of 10.

```
SELECT LOG(100);
+-----+
| log |
+-----+
|  2  |
+-----+
```

MOD function

Returns the remainder of two numbers, otherwise known as a *modulo* operation. To calculate the result, the first parameter is divided by the second.

Syntax

```
MOD(number1, number2)
```

Arguments

number1

The first input parameter is an INTEGER, SMALLINT, BIGINT, or DECIMAL number. If either parameter is a DECIMAL type, the other parameter must also be a DECIMAL type. If either parameter is an INTEGER, the other parameter can be an INTEGER, SMALLINT, or BIGINT. Both parameters can also be SMALLINT or BIGINT, but one parameter cannot be a SMALLINT if the other is a BIGINT.

number2

The second parameter is an INTEGER, SMALLINT, BIGINT, or DECIMAL number. The same data type rules apply to *number2* as to *number1*.

Return type

The return type of the MOD function is the same numeric type as the input parameters, if both input parameters are the same type. If either input parameter is an INTEGER, however, the return type will also be an INTEGER. Valid return types are DECIMAL, INT, SMALLINT, and BIGINT.

Usage notes

You can use % as a modulo operator.

Examples

To return the remainder when a number is divided by another, use the following example.

```
SELECT MOD(10, 4);
```

```
+-----+
| mod |
+-----+
|  2  |
+-----+
```

To return a DECIMAL result when using the MOD function, use the following example.

```
SELECT MOD(10.5, 4);
```

```
+-----+
| mod   |
+-----+
| 2.5   |
+-----+
```

To cast a number before running the MOD function, use the following example. For more information, see [CAST function](#).

```
SELECT MOD(CAST(16.4 AS INTEGER), 5);
```

```
+-----+
| mod   |
+-----+
| 1     |
+-----+
```

To check if the first parameter is even by dividing it by 2, use the following example.

```
SELECT mod(5,2) = 0 AS is_even;
```

```
+-----+
| is_even |
+-----+
| false   |
+-----+
```

To use % as a modulo operator, use the following example.

```
SELECT 11 % 4 as remainder;
```

```
+-----+
| remainder |
+-----+
|          3 |
+-----+
```

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

To return information for odd-numbered categories in the CATEGORY table, use the following example.

```
SELECT catid, catname
FROM category
WHERE MOD(catid,2)=1
ORDER BY 1,2;
```

```
+-----+-----+
| catid | catname |
+-----+-----+
|    1  | MLB    |
|    3  | NFL    |
|    5  | MLS    |
|    7  | Plays  |
|    9  | Pop    |
|   11  | Classical |
+-----+-----+
```

PI function

The PI function returns the value of pi to 14 decimal places.

Syntax

```
PI()
```

Return type

DOUBLE PRECISION

Examples

To return the value of pi, use the following example.

```
SELECT PI();
```

```
+-----+
|      pi      |
+-----+
| 3.141592653589793 |
+-----+
```

POWER function

The POWER function is an exponential function that raises a numeric expression to the power of a second numeric expression. For example, 2 to the third power is calculated as POWER(2, 3), with a result of 8.

Syntax

```
{POW | POWER}(expression1, expression2)
```

Arguments

expression1

Numeric expression to be raised. Must be an INTEGER, DECIMAL, or FLOAT data type.

expression2

Power to raise *expression1*. Must be an INTEGER, DECIMAL, or FLOAT data type.

Return type

DOUBLE PRECISION

Examples

The following examples use the TICKET sample database. For more information, see [Sample database](#).

In the following example, the POWER function is used to forecast what ticket sales will look like in the next 10 years, based on the number of tickets sold in 2008 (the result of the subquery). The growth rate is set at 7% per year in this example.

```
SELECT (SELECT SUM(qtysold) FROM sales, date
WHERE sales.dateid=date.dateid
AND year=2008) * POW((1+7::FLOAT/100),10) qty2010;
```

```
+-----+
|      qty2010      |
+-----+
| 679353.7540885945 |
+-----+
```

The following example is a variation on the previous example, with the growth rate at 7% per year but the interval is set to months (120 months over 10 years).

```
SELECT (SELECT SUM(qtysold) FROM sales, date
WHERE sales.dateid=date.dateid
AND year=2008) * POW((1+7::FLOAT/100/12),120) qty2010;
```

```
+-----+
|      qty2010      |
+-----+
| 694034.54678046 |
+-----+
```

RADIANS function

The RADIANS function converts an angle in degrees to its equivalent in radians.

Syntax

```
RADIANS(number)
```

Argument

number

The input parameter is a DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the radian equivalent of 180 degrees, use the following example.

```
SELECT RADIANS(180);
```

```
+-----+
|      radians      |
+-----+
| 3.141592653589793 |
+-----+
```

RANDOM function

The RANDOM function generates a random value between 0.0 (inclusive) and 1.0 (exclusive).

Syntax

```
RANDOM()
```

Return type

DOUBLE PRECISION

Usage notes

Call RANDOM after setting a seed value with the [SET](#) command to cause RANDOM to generate numbers in a predictable sequence.

Examples

To compute a random value between 0 and 99, use the following example. If the random number is 0 to 1, this query produces a random number from 0 to 100.

```
SELECT CAST(RANDOM() * 100 AS INT);
```

```
+-----+  
| int4 |  
+-----+  
|   59 |  
+-----+
```

This example uses the [SET](#) command to set a SEED value so that RANDOM generates a predictable sequence of numbers.

To return three RANDOM integers without setting the SEED value, use the following example.

```
SELECT CAST(RANDOM() * 100 AS INT);
```

```
+-----+  
| int4 |  
+-----+  
|    6 |  
+-----+
```

```
SELECT CAST(RANDOM() * 100 AS INT);
```

```
+-----+
| int4 |
+-----+
|  68 |
+-----+

SELECT CAST(RANDOM() * 100 AS INT);

+-----+
| int4 |
+-----+
|  56 |
+-----+
```

To set the SEED value to .25, and return three more RANDOM numbers, use the following example.

```
SET SEED TO .25;
SELECT CAST(RANDOM() * 100 AS INT);
+-----+
| int4 |
+-----+
|  21 |
+-----+

SELECT CAST(RANDOM() * 100 AS INT);
+-----+
| int4 |
+-----+
|  79 |
+-----+

SELECT CAST(RANDOM() * 100 AS INT);
+-----+
| int4 |
+-----+
|  12 |
+-----+
```

To reset the SEED value to .25, and verify that RANDOM returns the same results as the previous three calls, use the following example.

```
SET SEED TO .25;
```

```
SELECT CAST(RANDOM() * 100 AS INT);
```

```
+-----+
| int4 |
+-----+
|  21 |
+-----+
```

```
SELECT CAST(RANDOM() * 100 AS INT);
```

```
+-----+
| int4 |
+-----+
|  79 |
+-----+
```

```
SELECT CAST(RANDOM() * 100 AS INT);
```

```
+-----+
| int4 |
+-----+
|  12 |
+-----+
```

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

To retrieve a uniform random sample of 10 items from the SALES table, use the following example.

```
SELECT *
FROM sales
ORDER BY RANDOM()
LIMIT 10;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
| salesid | listid | sellerid | buyerid | eventid | dateid | qtysold | pricepaid |
commission | saletime |
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+

46.95 | 2008-10-18 05:43:11 |
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+

```

To retrieve a random sample of 10 items, but choose the items in proportion to their prices, use the following example. For example, an item that is twice the price of another would be twice as likely to appear in the query results.

```

SELECT *
FROM sales
ORDER BY -LOG(RANDOM()) / pricepaid
LIMIT 10;

+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+

```

ROUND function

The ROUND function rounds numbers to the nearest integer or decimal.

The ROUND function can optionally include a second argument as an INTEGER to indicate the number of decimal places for rounding, in either direction. When you don't provide the second argument, the function rounds to the nearest whole number. When the second argument *integer* is specified, the function rounds to the nearest number with *integer* decimal places of precision.

Syntax

```
ROUND(number [ , integer ] )
```

Arguments

number

A number or expression that evaluates to a number. It can be the DECIMAL, FLOAT8 or SUPER type. Amazon Redshift can implicitly convert other numeric data types.

integer

(Optional) An INTEGER that indicates the number of decimal places for rounding in either direction. The SUPER data type isn't supported for this argument.

Return type

ROUND returns the same numeric data type as the input *number*.

When the input is of the SUPER type, the output retains the same dynamic type as the input while the static type remains the SUPER type. When the dynamic type of SUPER isn't a number, Amazon Redshift returns NULL.

Examples

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

To round the commission paid for a given transaction to the nearest whole number, use the following example.

```
SELECT commission, ROUND(commission)
FROM sales WHERE salesid=10000;
```

```
+-----+-----+
| commission | round |
+-----+-----+
|      28.05 |    28 |
+-----+-----+
```

To round the commission paid for a given transaction to the first decimal place, use the following example.

```
SELECT commission, ROUND(commission, 1)
FROM sales WHERE salesid=10000;
```

```
+-----+-----+
| commission | round |
+-----+-----+
|      28.05 |   28.1 |
+-----+-----+
```

To extend the precision in the opposite direction as the previous example, use the following example.

```
SELECT commission, ROUND(commission, -1)
FROM sales WHERE salesid=10000;
```

```
+-----+-----+
| commission | round |
```

```
+-----+-----+
|      28.05 |      30 |
+-----+-----+
```

SIN function

SIN is a trigonometric function that returns the sine of a number. The return value is between -1 and 1.

Syntax

```
SIN(number)
```

Argument

number

A DOUBLE PRECISION number in radians.

Return type

DOUBLE PRECISION

Examples

To return the sine of $-\pi$, use the following example.

```
SELECT SIN(-PI());
```

```
+-----+
|      sin      |
+-----+
| -0.00000000000000012246 |
+-----+
```

SIGN function

The SIGN function returns the sign (positive or negative) of a number. The result of the SIGN function is 1 if the argument is positive, -1 if the argument is negative, or 0 if the argument is 0.

Syntax

```
SIGN(number)
```

Argument

number

Number or expression that evaluates to a number. It can be a DECIMAL, FLOAT8, or SUPER type. Amazon Redshift can convert other data types per the implicit conversion rules.

Return type

SIGN returns the same numeric data type as the input argument. If the input is DECIMAL, the output is DECIMAL(1,0).

When the input is of the SUPER type, the output retains the same dynamic type as the input while the static type remains the SUPER type. When the dynamic type of SUPER isn't a number, Amazon Redshift returns a NULL.

Examples

The following example shows that column d in table t2 has DOUBLE PRECISION as its type since the input is DOUBLE PRECISION and that column n in table t2 has NUMERIC(1,0) as the output since the input is NUMERIC.

```
CREATE TABLE t1(d DOUBLE PRECISION, n NUMERIC(12, 2));
INSERT INTO t1 VALUES (4.25, 4.25), (-4.25, -4.25);
CREATE TABLE t2 AS SELECT SIGN(d) AS d, SIGN(n) AS n FROM t1;
SELECT table_name, column_name, data_type FROM SVV_REDSHIFT_COLUMNS WHERE
  table_name='t1' OR table_name='t2';
```

table_name	column_name	data_type
t1	d	double precision
t1	n	numeric(12,2)
t2	d	double precision
t2	n	numeric(1,0)
t1	col1	character varying(20)

```
+-----+-----+-----+
```

The following example uses the TICKIT sample database. For more information, see [Sample database](#).

To determine the sign of the commission paid for a given transaction from the SALES table, use the following example.

```
SELECT commission, SIGN(commission)
FROM sales WHERE salesid=10000;
```

```
+-----+-----+
| commission | sign |
+-----+-----+
|      28.05 |    1 |
+-----+-----+
```

SQRT function

The SQRT function returns the square root of a NUMERIC value. The square root is a number multiplied by itself to get the given value.

Syntax

```
SQRT(expression)
```

Argument

expression

The expression must have an INTEGER, DECIMAL, or FLOAT data type, or a data type that implicitly converts to those data types. The *expression* can include functions.

Return type

DOUBLE PRECISION

Examples

To return the square root of 16, use the following example.

```
SELECT SQRT(16);
```

```
+-----+
|  sqrt  |
+-----+
|    4   |
+-----+
```

To return the square root of the string 16 using an implicit type conversion, use the following example.

```
SELECT SQRT('16');
```

```
+-----+
|  sqrt  |
+-----+
|    4   |
+-----+
```

To return the square root of 16.4 after using the ROUND function, use the following example.

```
SELECT SQRT(ROUND(16.4));
```

```
+-----+
|  sqrt  |
+-----+
|    4   |
+-----+
```

To return the length of the radius when given the area of a circle, use the following example. It calculates the radius in inches, for instance, when given the area in square inches. The area in the sample is 20.

```
SELECT SQRT(20/PI()) AS radius;
```

```
+-----+
|      radius      |
+-----+
| 2.5231325220201604 |
+-----+
```

The following examples use the TICKIT sample database. For more information, see [Sample database](#).

To return the square root for COMMISSION values from the SALES table, use the following example. The COMMISSION column is a DECIMAL column. This example shows how you can use the function in a query with more complex conditional logic.

```
SELECT SQRT(commission)
FROM sales WHERE salesid < 10 ORDER BY salesid;
```

```
+-----+
|      sqrt      |
+-----+
| 10.449880382090505 |
| 3.3763886032268267 |
| 7.245688373094719 |
| 5.123475382979799 |
| 4.806245936279167 |
| 7.687652437513028 |
| 10.871982339941507 |
| 5.4359911699707535 |
| 9.41541289588513 |
+-----+
```

To return the rounded square root for the same set of COMMISSION values, use the following example.

```
SELECT ROUND(SQRT(commission))
FROM sales WHERE salesid < 10 ORDER BY salesid;
```

```
+-----+
| round |
+-----+
| 10 |
| 3 |
| 7 |
| 5 |
| 5 |
| 8 |
| 11 |
| 5 |
| 9 |
```

```
+-----+
```

TAN function

TAN is a trigonometric function that returns the tangent of a number. The input argument is a number (in radians).

Syntax

```
TAN(number)
```

Argument

number

A DOUBLE PRECISION number.

Return type

DOUBLE PRECISION

Examples

To return the tangent of zero, use the following example.

```
SELECT TAN(0);
```

```
+-----+  
| tan |  
+-----+  
|  0  |  
+-----+
```

TRUNC function

The TRUNC function truncates numbers to the previous integer or decimal.

The TRUNC function can optionally include a second argument as an INTEGER to indicate the number of decimal places for rounding, in either direction. When you don't provide the second

argument, the function rounds to the nearest whole number. When the second argument *integer* is specified, the function rounds to the nearest number with *integer* decimal places of precision.

This function can also truncate a `TIMESTAMP` and return a `DATE`. For more information, see [TRUNC function](#).

Syntax

```
TRUNC(number [ , integer ])
```

Arguments

number

A number or an expression that evaluates to a number. It can be the `DECIMAL`, `FLOAT8` or `SUPER` type. Amazon Redshift can convert other data types per the implicit conversion rules.

integer

(Optional) An `INTEGER` that indicates the number of decimal places of precision, in either direction. If no *integer* is provided, the number is truncated as a whole number; if an *integer* is specified, the number is truncated to the specified decimal place. This isn't supported for the `SUPER` data type.

Return type

`TRUNC` returns the same data type as the input *number*.

When the input is of the `SUPER` type, the output retains the same dynamic type as the input while the static type remains the `SUPER` type. When the dynamic type of `SUPER` isn't a number, Amazon Redshift returns `NULL`.

Examples

Some of the following examples use the `TICKIT` sample database. For more information, see [Sample database](#).

To truncate the commission paid for a given sales transaction, use the following example.

```
SELECT commission, TRUNC(commission)
FROM sales WHERE salesid=784;
```

```

+-----+-----+
| commission | trunc |
+-----+-----+
|    111.15 |   111 |
+-----+-----+

```

To truncate the same commission value to the first decimal place, use the following example.

```

SELECT commission, TRUNC(commission,1)
FROM sales WHERE salesid=784;

```

```

+-----+-----+
| commission | trunc |
+-----+-----+
|    111.15 | 111.1 |
+-----+-----+

```

To truncate the commission with a negative value for the second argument, use the following example. Note that 111.15 is rounded down to 110.

```

SELECT commission, TRUNC(commission,-1)
FROM sales WHERE salesid=784;

```

```

+-----+-----+
| commission | trunc |
+-----+-----+
|    111.15 |   110 |
+-----+-----+

```

Object functions

Following are the SQL object functions that Amazon Redshift supports to create SUPER type objects:

Topics

- [LOWER_ATTRIBUTE_NAMES function](#)
- [OBJECT function](#)
- [OBJECT_TRANSFORM function](#)
- [UPPER_ATTRIBUTE_NAMES function](#)

LOWER_ATTRIBUTE_NAMES function

Converts all applicable attribute names in a SUPER value to lowercase, using the same case conversion routine as the [LOWER function](#). LOWER_ATTRIBUTE_NAMES supports UTF-8 multibyte characters, up to a maximum of four bytes per character.

To convert SUPER attribute names to uppercase, use the [UPPER_ATTRIBUTE_NAMES function](#).

Syntax

```
LOWER_ATTRIBUTE_NAMES(super_expression)
```

Arguments

super_expression

A SUPER expression.

Return type

SUPER

Usage notes

In Amazon Redshift, column identifiers are traditionally case-insensitive and converted to lowercase. If you ingest data from case-sensitive data formats such as JSON, the data might contain mixed-case attribute names.

Consider the following example.

```
CREATE TABLE t1 (s) AS SELECT JSON_PARSE('{"AttributeName": "Value"}');

SELECT s.AttributeName FROM t1;

attributename
-----
NULL

SELECT s."AttributeName" FROM t1;
```

```

attributename
-----
NULL

```

Amazon Redshift returns NULL for both queries. To query `AttributeName`, use `LOWER_ATTRIBUTE_NAMES` to convert the data's attribute names to lowercase. Consider the following example.

```
CREATE TABLE t2 (s) AS SELECT LOWER_ATTRIBUTE_NAMES(s) FROM t1;
```

```
SELECT s.attributename FROM t2;
```

```

attributename
-----
"Value"

```

```
SELECT s.AttributeName FROM t2;
```

```

attributename
-----
"Value"

```

```
SELECT s."attributename" FROM t2;
```

```

attributename
-----
"Value"

```

```
SELECT s."AttributeName" FROM t2;
```

```

attributename
-----
"Value"

```

A related option for working with mixed-case object attribute names is the `enable_case_sensitive_super_attribute` configuration option, which lets Amazon Redshift recognize case in SUPER attribute names. This can be an

alternative solution to using `LOWER_ATTRIBUTE_NAMES`. For more information about `enable_case_sensitive_super_attribute`, go to [enable_case_sensitive_super_attribute](#).

Examples

Converting SUPER attribute names to lowercase

The following example uses `LOWER_ATTRIBUTE_NAMES` to convert the attribute names of all SUPER values in a table.

```
-- Create a table and insert several SUPER values.
CREATE TABLE t (i INT, s SUPER);

INSERT INTO t VALUES
  (1, NULL),
  (2, 'A'::SUPER),
  (3, JSON_PARSE('{"AttributeName": "B"}')),
  (4, JSON_PARSE(
    '[{"Subobject": {"C": "C"},
      "Subarray": [{"D": "D"}, "E"]}'));

-- Convert all attribute names to lowercase.
UPDATE t SET s = LOWER_ATTRIBUTE_NAMES(s);

SELECT i, s FROM t ORDER BY i;
```

i	s
1	NULL
2	"A"
3	{"attributename": "B"}
4	[{"subobject": {"c": "C"}, "subarray": [{"d": "D"}, "E"]}]

Observe how `LOWER_ATTRIBUTE_NAMES` functions.

- NULL values and scalar SUPER values such as "A" are unchanged.
- In a SUPER object, all attribute names are changed to lowercase, but attribute values such as "B" remain unchanged.
- `LOWER_ATTRIBUTE_NAMES` applies recursively to any SUPER object that is nested inside a SUPER array or inside another object.

Using LOWER_ATTRIBUTE_NAMES on a SUPER object with duplicate attribute names

If a SUPER object contains attributes whose names differ only in their case, LOWER_ATTRIBUTE_NAMES will raise an error. Consider the following example.

```
SELECT LOWER_ATTRIBUTE_NAMES(JSON_PARSE('{ "A": "A", "a": "a" }'));
```

```
error:   Invalid input
```

```
code:    8001
```

```
context: SUPER value has duplicate attributes after case conversion.
```

OBJECT function

Creates an object of the SUPER data type.

Syntax

```
OBJECT ( [ key1, value1 ], [ key2, value2 ...] )
```

Arguments

key1, key2

Expressions that evaluate to VARCHAR type strings.

value1, value2

Expressions of any Amazon Redshift data type except datetime types, since Amazon Redshift doesn't cast datetime types to the SUPER data type. For more information on datetime types, see [Datetime types](#).

value expressions in an object don't need to be of the same data type.

Return type

SUPER

Example

```
-- Creates an empty object.  
select object();  
  
object
```

```

-----
{}
(1 row)

-- Creates objects with different keys and values.
select object('a', 1, 'b', true, 'c', 3.14);

object
-----
{"a":1,"b":true,"c":3.14}
(1 row)

select object('a', object('aa', 1), 'b', array(2,3), 'c', json_parse('{}'));

object
-----
{"a":{"aa":1},"b":[2,3],"c":{}}
(1 row)

-- Creates objects using columns from a table.
create table bar (k varchar, v super);
insert into bar values ('k1', json_parse('[1]')), ('k2', json_parse('{}'));
select object(k, v) from bar;

object
-----
{"k1":[1]}
{"k2":{}}
(2 rows)

-- Errors out because DATE type values can't be converted to SUPER type.
select object('k', '2008-12-31'::date);

ERROR:  OBJECT could not convert type date to super

```

OBJECT_TRANSFORM function

Transforms a SUPER object.

Syntax

```

OBJECT_TRANSFORM(
  input

```

```
[KEEP path1, ...]  
[SET  
  path1, value1,  
  ..., ...  
]  
)
```

Arguments

input

An expression that resolves to a SUPER type object.

KEEP

All *path* values specified in this clause are kept and carried over to the output object.

This clause is optional.

path1, path2, ...

Constant string literals, in the format of double-quoted path components delimited by periods. For example, `'"a"."b"."c"'` is a valid path value. This applies to the path parameter in both the KEEP and SET clauses.

SET

path and *value* pairs to modify an existing path or add a new path, and set the value of that path in the output object.

This clause is optional.

value1, value2, ...

Expressions that resolve to SUPER type values. Note that numeric, text, and Boolean types are resolvable to SUPER.

Return type

SUPER

Usage notes

OBJECT_TRANSFORM returns a SUPER type object containing the path values from *input* that were specified in KEEP and the *path* and *value* pairs that were specified in SET.

If both KEEP and SET are empty, OBJECT_TRANSFORM returns *input*.

If *input* isn't a SUPER type *object*, OBJECT_TRANSFORM returns *input*, regardless of any KEEP or SET values.

Example

The following example transforms a SUPER object into another SUPER object.

```
CREATE TABLE employees (  
    col_person SUPER  
);  
  
INSERT INTO employees  
VALUES  
    (  
        json_parse('  
            {  
                "name": {  
                    "first": "John",  
                    "last": "Doe"  
                },  
                "age": 25,  
                "ssn": "111-22-3333",  
                "company": "Company Inc.",  
                "country": "U.S."  
            }  
        ')  
    ),  
    (  
        json_parse('  
            {  
                "name": {  
                    "first": "Jane",  
                    "last": "Appleseed"  
                },  
                "age": 34,  
                "ssn": "444-55-7777",  
                "company": "Organization Org.",  
                "country": "Ukraine"  
            }  
        ')  
    )  
;
```

```
SELECT
  OBJECT_TRANSFORM(
    col_person
    KEEP
      '"name"."first"',
      '"age"',
      '"company"',
      '"country"'
    SET
      '"name"."first"', UPPER(col_person.name.first::TEXT),
      '"age"', col_person.age + 5,
      '"company"', 'Amazon'
  ) AS col_person_transformed
FROM employees;
```

--This result is formatted for ease of reading.

```
          col_person_transformed
-----
{
  "name": {
    "first": "JOHN"
  },
  "age": 30,
  "company": "Amazon",
  "country": "U.S."
}
{
  "name": {
    "first": "JANE"
  },
  "age": 39,
  "company": "Amazon",
  "country": "Ukraine"
}
```

UPPER_ATTRIBUTE_NAMES function

Converts all applicable attribute names in a SUPER value to uppercase, using the same case conversion routine as the [UPPER function](#). UPPER_ATTRIBUTE_NAMES supports UTF-8 multibyte characters, up to a maximum of four bytes per character.

To convert SUPER attribute names to lowercase, use the [LOWER_ATTRIBUTE_NAMES function](#).

Syntax

```
UPPER_ATTRIBUTE_NAMES(super_expression)
```

Arguments

super_expression

A SUPER expression.

Return type

SUPER

Examples

Converting SUPER attribute names to uppercase

The following example uses UPPER_ATTRIBUTE_NAMES to convert the attribute names of all SUPER values in a table.

```
-- Create a table and insert several SUPER values.
CREATE TABLE t (i INT, s SUPER);

INSERT INTO t VALUES
  (1, NULL),
  (2, 'a'::SUPER),
  (3, JSON_PARSE('{"AttributeName": "b"}')),
  (4, JSON_PARSE(
    '[{"Subobject": {"c": "c"},
      "Subarray": [{"d": "d"}, "e"]}'));

-- Convert all attribute names to uppercase.
UPDATE t SET s = UPPER_ATTRIBUTE_NAMES(s);

SELECT i, s FROM t ORDER BY i;
```

i	s
1	NULL
2	"a"
3	{"ATTRIBUTENAME": "B"}

```
4 | [{"SUBOBJECT":{"C":"c"},"SUBARRAY":[{"D":"d"}, "e"]}]
```

Observe how UPPER_ATTRIBUTE_NAMES functions.

- NULL values and scalar SUPER values such as "a" are unchanged.
- In a SUPER object, all attribute names are changed to uppercase, but attribute values such as "b" remain unchanged.
- UPPER_ATTRIBUTE_NAMES applies recursively to any SUPER object that is nested inside a SUPER array or inside another object.

Using UPPER_ATTRIBUTE_NAMES on a SUPER object with duplicate attribute names

If a SUPER object contains attributes whose names differ only in their case, UPPER_ATTRIBUTE_NAMES will raise an error. Consider the following example.

```
SELECT UPPER_ATTRIBUTE_NAMES(JSON_PARSE('{"A": "A", "a": "a"}'));
```

```
error:   Invalid input
code:    8001
context: SUPER value has duplicate attributes after case conversion.
```

Spatial functions

Relationships between geometry objects are based on the Dimensionally Extended nine-Intersection Model (DE-9IM). This model defines predicates such as equals, contains, and covers. For more information about the definition of spatial relationships, see [DE-9IM](#) in Wikipedia.

For more information about how to use spatial data with Amazon Redshift, see [Querying spatial data in Amazon Redshift](#).

Amazon Redshift provides spatial functions that work with GEOMETRY and GEOGRAPHY data types. The following lists the functions that support the GEOGRAPHY data type:

- [ST_Area](#)
- [ST_AsEWKT](#)
- [ST_AsGeoJSON](#)
- [ST_AsHexEWKB](#)
- [ST_AsHexWKB](#)

- [ST_AsText](#)
- [ST_Distance](#)
- [ST_GeogFromText](#)
- [ST_GeogFromWKB](#)
- [ST_Length](#)
- [ST_NPoints](#)
- [ST_Perimeter](#)

AddBBox

AddBBox returns a copy of the input geometry that supports encoding with a precomputed bounding box. For more information about support for bounding boxes, see [Bounding box](#).

Syntax

```
AddBBox(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

If *geom* is null, then null is returned.

Examples

The following SQL returns a copy of an input polygon geometry that supports being encoded with a bounding box.

```
SELECT ST_AsText(AddBBox(ST_GeomFromText('POLYGON((0 0,1 0,0 1,0 0))')));
```

```
st_astext
-----
POLYGON((0 0,1 0,0 1,0 0))
```

DropBBox

DropBBox returns a copy of the input geometry that doesn't support encoding with a precomputed bounding box. For more information about support for bounding boxes, see [Bounding box](#).

Syntax

```
DropBBox(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

If *geom* is null, then null is returned.

Examples

The following SQL returns a copy of an input polygon geometry that doesn't support being encoded with a bounding box.

```
SELECT ST_AsText(DropBBox(ST_GeomFromText('POLYGON((0 0,1 0,0 1,0 0))')));
```

```
st_astext
-----
POLYGON((0 0,1 0,0 1,0 0))
```

GeometryType

GeometryType returns the subtype of an input geometry as a string.

Syntax

```
GeometryType(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

VARCHAR representing the subtype of *geom*.

If *geom* is null, then null is returned.

The values returned are as follows.

Returned string value for 2D, 3DZ, 4D geometries	Returned string value for 3DM geometries	Geometry subtype
POINT	POINTM	Returned if <i>geom</i> is a POINT subtype
LINestring	LINestringM	Returned if <i>geom</i> is a LINestring subtype
POLYGON	POLYGONM	Returned if <i>geom</i> is a POLYGON subtype
MULTIPOINT	MULTIPOINTM	Returned if <i>geom</i> is a MULTIPOINT subtype
MULTILINestring	MULTILINestringM	Returned if <i>geom</i> is a MULTILINestring subtype
MULTIPOLYGON	MULTIPOLYGONM	Returned if <i>geom</i> is a MULTIPOLYGON subtype
GEOMETRYCOLLECTION	GEOMETRYCOLLECTIONM	Returned if <i>geom</i> is a GEOMETRYCOLLECTION subtype

Examples

The following SQL converts a well-known text (WKT) representation of a polygon and returns the GEOMETRY subtype as a string.

```
SELECT GeometryType(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'));
```

```
geometrytype
```

```
-----
```

```
POLYGON
```

H3_FromLongLat

H3_FromLongLat returns the corresponding H3 cell ID from an input longitude, latitude, and resolution. For information about H3 indexing, see [H3](#).

Syntax

```
H3_FromLongLat(longitude, latitude, resolution)
```

Arguments

longitude

A value of data type DOUBLE PRECISION or an expression that evaluates to a DOUBLE PRECISION type.

latitude

A value of data type DOUBLE PRECISION or an expression that evaluates to a DOUBLE PRECISION type.

resolution

A value of data type INTEGER or an expression that evaluates to an INTEGER type. The value represents the resolution of the H3 grid system. The value must be an integer between 0–15, inclusive. With 0 being the coarsest and 15 being the finest.

Return type

BIGINT – represents the H3 cell ID.

If *resolution* is out of bounds, then an error is returned.

Examples

The following SQL returns the H3 cell ID from longitude 0, latitude 0, and resolution 10.

```
SELECT H3_FromLongLat(0, 0, 10);
```

```
h3_fromlonglat  
-----  
623560421467684863
```

H3_FromPoint

H3_FromPoint returns the corresponding H3 cell ID from an input geometry point and resolution. For information about H3 indexing, see [H3](#).

Syntax

```
H3_FromPoint(geom, resolution)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The *geom* must be a POINT.

resolution

A value of data type INTEGER or an expression that evaluates to an INTEGER type. The value represents the resolution of the H3 grid system. The value must be an integer between 0–15, inclusive. With 0 being the coarsest and 15 being the finest.

Return type

BIGINT – represents the H3 cell ID.

If *geom* is not a POINT, then an error is returned.

If *resolution* is out of bounds, then an error is returned.

If *geom* is empty, then NULL is returned.

Examples

The following SQL returns the H3 cell ID from point 0, 0, and resolution 10.

```
SELECT H3_FromPoint(ST_GeomFromText('POINT(0 0)'), 10);
```

```
h3_frompoint  
-----  
623560421467684863
```

H3_Polyfill

H3_Polyfill returns the corresponding H3 cell IDs that correspond to the hexagons and pentagons that are contained in the input polygon of the given resolution. For information about H3 indexing, see [H3](#).

Syntax

```
H3_Polyfill(geom, resolution)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The *geom* must be a POLYGON.

resolution

A value of data type INTEGER or an expression that evaluates to an INTEGER type. The value represents the resolution of the H3 grid system. The value must be an integer between 0–15, inclusive. With 0 being the coarsest and 15 being the finest.

Return type

SUPER – represents a list of H3 cell IDs.

If *geom* is not a POLYGON, then an error is returned.

If *resolution* is out of bounds, then an error is returned.

If *geom* is empty, then NULL is returned.

Examples

The following SQL returns a SUPER data type array of H3 cell IDs from a polygon and resolution 4.

```
SELECT H3_Polyfill(ST_GeomFromText('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'), 4);
```

```
h3_polyfill
```

```
-----  
[596538848238895103,596538805289222143,596538856828829695,596538813879156735,59653792052595916
```

ST_AddPoint

ST_AddPoint returns a linestring geometry that is the same as the input geometry with a point added. If an index is provided, then the point is added at the index position. If the index is -1 or not provided, then the point is appended to the linestring.

The index is zero-based. The spatial reference system identifier (SRID) of the result is the same as that of the input geometry.

The dimension of the returned geometry is the same as that of the *geom1* value. If *geom1* and *geom2* have different dimensions, *geom2* is projected to the dimension of *geom1*.

Syntax

```
ST_AddPoint(geom1, geom2)
```

```
ST_AddPoint(geom1, geom2, index)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT. The point can be the empty point.

index

A value of data type INTEGER that represents the position of a zero-based index.

Return type

GEOMETRY

If *geom1*, *geom2*, or *index* is null, then null is returned.

If *geom2* is the empty point, then a copy of *geom1* is returned.

If *geom1* is not a LINESTRING, then an error is returned.

If *geom2* is not a POINT, then an error is returned.

If *index* is out of range, then an error is returned. Valid values for the index position are -1 or a value between 0 and ST_NumPoints(*geom1*).

Examples

The following SQL adds a point to a linestring to make it a closed linestring.

```
WITH tmp(g) AS (SELECT ST_GeomFromText('LINESTRING(0 0,10 0,10 10,5 5,0 5)',4326))
SELECT ST_AsEWKT(ST_AddPoint(g, ST_StartPoint(g))) FROM tmp;
```

```
st_asewkt
```

```
-----
SRID=4326;LINESTRING(0 0,10 0,10 10,5 5,0 5,0 0)
```

The following SQL adds a point to a specific position in a linestring.

```
WITH tmp(g) AS (SELECT ST_GeomFromText('LINESTRING(0 0,10 0,10 10,5 5,0 5)',4326))
SELECT ST_AsEWKT(ST_AddPoint(g, ST_SetSRID(ST_Point(5, 10), 4326), 3)) FROM tmp;
```

```
st_asewkt
```

```
-----
SRID=4326;LINESTRING(0 0,10 0,10 10,5 10,5 5,0 5)
```

ST_Angle

ST_Angle returns the angle in radians between points measured clockwise as follows:

- If three points are input, then the returned angle P1-P2-P3 is measured as if the angle was obtained by rotating from P1 to P3 around P2 clockwise.
- If four points are input, then the returned clockwise angle formed by the directed lines P1-P2 and P3-P4 is returned. If the input is a degenerate case (that is, P1 equals P2, or P3 equals P4), then null is returned.

The return value is in radians and in the range $[0, 2\pi)$.

ST_Angle operates on 2D projections of the input geometries.

Syntax

```
ST_Angle(geom1, geom2, geom3)
```

```
ST_Angle(geom1, geom2, geom3, geom4)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT.

geom3

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT.

geom4

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT.

Return type

DOUBLE PRECISION.

If *geom1* equals *geom2*, or *geom2* equals *geom3*, then a null is returned.

If *geom1*, *geom2*, *geom3*, or *geom4* is null, then a null is returned.

If any of *geom1*, *geom2*, *geom3*, or *geom4* is the empty point, then an error is returned.

If *geom1*, *geom2*, *geom3*, and *geom4* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

Examples

The following SQL returns the angle converted to degrees of three input points.

```
SELECT ST_Angle(ST_Point(1,1), ST_Point(0,0), ST_Point(1,0)) / Pi() * 180.0 AS angle;
```

```
angle
```

```
-----  
45
```

The following SQL returns the angle converted to degrees of four input points.

```
SELECT ST_Angle(ST_Point(1,1), ST_Point(0,0), ST_Point(1,0), ST_Point(2,0)) / Pi() *  
180.0 AS angle;
```

```
angle
```

```
-----  
225
```

ST_Area

For an input geometry, `ST_Area` returns the Cartesian area of the 2D projection. The area units are the same as the units in which the coordinates of the input geometry are expressed. For points, linestrings, multipoints, and multilinestrings, the function returns 0. For geometry collections, it returns the sum of the areas of the geometries in the collection.

For an input geography, `ST_Area` returns the geodesic area of the 2D projection of an input areal geography computed on the spheroid determined by the SRID. The unit of length is in square meters. The function returns zero (0) for points, multipoints, and linear geographies. When the input is a geometry collection, the function returns the sum of the areas of the areal geographies in the collection.

Syntax

```
ST_Area(geo)
```

Arguments

geo

A value of data type `GEOMETRY` or `GEOGRAPHY`, or an expression that evaluates to a `GEOMETRY` or `GEOGRAPHY` type.

Return type

`DOUBLE PRECISION`

If *geo* is null, then null is returned.

Examples

The following SQL returns the Cartesian area of a multipolygon.

```
SELECT ST_Area(ST_GeomFromText('MULTIPOLYGON(((0 0,10 0,0 10,0 0)),((10 0,20 0,20 10,10 0)))'));
```

```
st_area
-----
      100
```

The following SQL returns the area of a polygon in a geography.

```
SELECT ST_Area(ST_GeogFromText('polygon((34 35, 28 30, 25 34, 34 35))'));
```

```
st_area
-----
201824655743.383
```

The following SQL returns zero for a linear geography.

```
SELECT ST_Area(ST_GeogFromText('multipoint(0 0, 1 1, -21.32 121.2)'));
```

```
st_area
-----
0
```

ST_AsBinary

ST_AsBinary returns the hexadecimal well-known binary (WKB) representation of an input geometry. For 3DZ, 3DM, and 4D geometries, ST_AsBinary uses the Open Geospatial Consortium (OGC) standard value for the geometry type.

Syntax

```
ST_AsBinary(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

VARBYTE

If *geom* is null, then null is returned.

Examples

The following SQL returns the hexadecimal WKB representation of a polygon.

ST_AsEWKT

ST_AsEWKT returns the extended well-known text (EWKT) representation of an input geometry or geography. For 3DZ, 3DM, and 4D geometries, ST_AsEWKT appends Z, M, or ZM to the WKT value for the geometry type.

Syntax

```
ST_AsEWKT(geo)
```

```
ST_AsEWKT(geo, precision)
```

Arguments

geo

A value of data type GEOMETRY or GEOGRAPHY, or an expression that evaluates to a GEOMETRY or GEOGRAPHY type.

precision

A value of data type INTEGER. For geometries, the coordinates of *geo* are displayed using the specified precision 1–20. If *precision* is not specified, the default is 15. For geographies, the coordinates of *geo* are displayed using the specified precision. If *precision* is not specified, the default is 15.

Return type

VARCHAR

If *geo* is null, then null is returned.

If *precision* is null, then null is returned.

If the result is larger than a 64-KB VARCHAR, then an error is returned.

Examples

The following SQL returns the EWKT representation of a linestring.

```
SELECT ST_AsEWKT(ST_GeomFromText('LINESTRING(3.141592653589793  
-6.283185307179586,2.718281828459045 -1.414213562373095)', 4326));
```

```

st_asewkt
-----
SRID=4326;LINESTRING(3.14159265358979 -6.28318530717959,2.71828182845905
-1.41421356237309)

```

The following SQL returns the EWKT representation of a linestring. The coordinates of the geometries are displayed with six digits of precision.

```

SELECT ST_AsEWKT(ST_GeomFromText('LINESTRING(3.141592653589793
-6.283185307179586,2.718281828459045 -1.414213562373095)', 4326), 6);

```

```

st_asewkt
-----
SRID=4326;LINESTRING(3.14159 -6.28319,2.71828 -1.41421)

```

The following SQL returns the EWKT representation of a geography.

```

SELECT ST_AsEWKT(ST_GeogFromText('LINESTRING(110 40, 2 3, -10 80, -7 9)'));

```

```

          st_asewkt
-----
SRID=4326;LINESTRING(110 40,2 3,-10 80,-7 9)

```

ST_AsGeoJSON

ST_AsGeoJSON returns the GeoJSON representation of an input geometry or geography. For more information about GeoJSON, see [GeoJSON](#) in Wikipedia.

For 3DZ and 4D geometries, the output geometry is a 3DZ projection of the input 3DZ or 4D geometry. That is, the x, y, and z coordinates are present in the output. For 3DM geometries, the output geometry is a 2D projection of the input 3DM geometry. That is, only x and y coordinates are present in the output.

For input geographies, ST_AsGeoJSON returns the GeoJSON representation of an input geography. The coordinates of the geography are displayed using the specified precision.

Syntax

```
ST_AsGeoJSON(geo)
```

```
ST_AsGeoJSON(geo, precision)
```

Arguments

geo

A value of data type GEOMETRY or GEOGRAPHY, or an expression that evaluates to a GEOMETRY or GEOGRAPHY type.

precision

A value of data type INTEGER. For geometries, the coordinates of *geo* are displayed using the specified precision 1–20. If *precision* is not specified, the default is 15. For geographies, the coordinates of *geo* are displayed using the specified precision. If *precision* is not specified, the default is 15.

Return type

VARCHAR

If *geo* is null, then null is returned.

If *precision* is null, then null is returned.

If the result is larger than a 64-KB VARCHAR, then an error is returned.

Examples

The following SQL returns the GeoJSON representation of a linestring.

```
SELECT ST_AsGeoJSON(ST_GeomFromText('LINESTRING(3.141592653589793  
-6.283185307179586,2.718281828459045 -1.414213562373095)'));
```

```
st_asgeojson  
-----
```

```
{"type":"LineString","coordinates":[[[3.14159265358979,-6.28318530717959],
[2.71828182845905,-1.41421356237309]]]}
```

The following SQL returns the GeoJSON representation of a linestring. The coordinates of the geometries are displayed with six digits of precision.

```
SELECT ST_AsGeoJSON(ST_GeomFromText('LINESTRING(3.141592653589793
-6.283185307179586,2.718281828459045 -1.414213562373095)'), 6);
```

```
st_asgeojson
```

```
-----
{"type":"LineString","coordinates":[[[3.14159,-6.28319],[2.71828,-1.41421]]]}
```

The following SQL returns the GeoJSON representation of a geography.

```
SELECT ST_AsGeoJSON(ST_GeogFromText('LINESTRING(110 40, 2 3, -10 80, -7 9)'));
```

```
st_asgeojson
```

```
-----
{"type":"LineString","coordinates":[[[110,40],[2,3],[-10,80],[-7,9]]]}
```

ST_AsHexWKB

ST_AsHexWKB returns the hexadecimal well-known binary (WKB) representation of an input geometry or geography using ASCII hexadecimal characters (0–9, A–F). For 3DZ, 3DM, and 4D geometries or geographies, ST_AsHexWKB uses the Open Geospatial Consortium (OGC) standard value for the geometry or geography type.

Syntax

```
ST_AsHexWKB(geo)
```

Arguments

geo

A value of data type GEOMETRY or GEOGRAPHY, or an expression that evaluates to a GEOMETRY or GEOGRAPHY type.

Syntax

```
ST_AsText(geo)
```

```
ST_AsText(geo, precision)
```

Arguments

geo

A value of data type GEOMETRY or GEOGRAPHY, or an expression that evaluates to a GEOMETRY or GEOGRAPHY type.

precision

A value of data type INTEGER. For geometries, the coordinates of *geo* are displayed using the specified precision 1–20. If *precision* is not specified, the default is 15. For geographies, the coordinates of *geo* are displayed using the specified precision. If *precision* is not specified, the default is 15.

Return type

VARCHAR

If *geo* is null, then null is returned.

If *precision* is null, then null is returned.

If the result is larger than a 64-KB VARCHAR, then an error is returned.

Examples

The following SQL returns the WKT representation of a linestring.

```
SELECT ST_AsText(ST_GeomFromText('LINESTRING(3.141592653589793  
-6.283185307179586,2.718281828459045 -1.414213562373095)', 4326));
```

```
st_astext  
-----  
LINESTRING(3.14159265358979 -6.28318530717959,2.71828182845905 -1.41421356237309)
```

The following SQL returns the WKT representation of a linestring. The coordinates of the geometries are displayed with six digits of precision.

```
SELECT ST_AsText(ST_GeomFromText('LINESTRING(3.141592653589793
-6.283185307179586,2.718281828459045 -1.414213562373095)', 4326), 6);
```

```
st_astext
-----
LINESTRING(3.14159 -6.28319,2.71828 -1.41421)
```

The following SQL returns the WKT representation of a geography.

```
SELECT ST_AsText(ST_GeogFromText('LINESTRING(110 40, 2 3, -10 80, -7 9)'));
```

```
st_astext
-----
LINESTRING(110 40,2 3,-10 80,-7 9)
```

ST_Azimuth

ST_Azimuth returns the north-based Cartesian azimuth using the 2D projections of the two input points.

Syntax

```
ST_Azimuth(point1, point2)
```

Arguments

point1

A POINT value of data type GEOMETRY. The spatial reference system identifier (SRID) of *point1* must match the SRID of *point2*.

point2

A POINT value of data type GEOMETRY. The SRID of *point2* must match the SRID of *point1*.

Return type

A number that is an angle in radians of DOUBLE PRECISION data type. Values range from 0 (inclusive) to 2 pi (exclusive).

If *point1* or *point2* is the empty point, then an error is returned.

If either *point1* or *point2* is null, then null is returned.

If *point1* and *point2* are equal, then null is returned.

If *point1* or *point2* is not a point, then an error is returned.

If *point1* and *point2* don't have the value for the spatial reference system identifier (SRID), then an error is returned.

Examples

The following SQL returns the azimuth of the input points.

```
SELECT ST_Azimuth(ST_Point(1,2), ST_Point(5,6));
```

```
st_azimuth
-----
0.7853981633974483
```

ST_Boundary

ST_Boundary returns the boundary of an input geometry as follows:

- If the input geometry is empty (that is, it contains no points) it is returned as is.
- If the input geometry is a point or nonempty multipoint, an empty geometry collection is returned.
- If the input is a linestring or a multilinestring, then a multipoint containing all the points on the boundary is returned. The multipoint might be empty).
- If the input is a polygon that does not have any interior rings, then a closed linestring representing its boundary is returned.
- If the input is a polygon that has interior rings, or is a multipolygon, then a multilinestring is returned. The multilinestring contains all the boundaries of all the rings in the areal geometry as closed linestrings.

To determine point equality, `ST_Boundary` operates on the 2D projection of the input geometry. If the input geometry is empty, a copy of it is returned in the same dimension as the input. For nonempty 3DM and 4D geometries, their *m* coordinates are dropped. In the special case of 3DZ and 4D multilinestrings, the *z* coordinates of the multilinestring's boundary points are computed as the averages of the distinct *z*-values of the linestring boundary points with the same 2D projection.

Syntax

```
ST_Boundary(geom)
```

Arguments

geom

A value of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type.

Return type

`GEOMETRY`

If *geom* is null, then null is returned.

If *geom* is a `GEOMETRYCOLLECTION`, then an error is returned.

Examples

The following SQL returns the boundary of the input polygon as a multilinestring.

```
SELECT ST_AsEWKT(ST_Boundary(ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(1 1,1 2,2 1,1 1)'))));
```

```
st_asewkt
-----
MULTILINESTRING((0 0,10 0,10 10,0 10,0 0),(1 1,1 2,2 1,1 1))
```

ST_Buffer

`ST_Buffer` returns 2D geometry that represents all points whose distance from the input geometry projected on the *xy*-Cartesian plane is less than or equal to the input distance.

Syntax

```
ST_Buffer(geom, distance)
```

```
ST_Buffer(geom, distance, number_of_segments_per_quarter_circle)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

distance

A value of data type DOUBLE PRECISION that represents distance (or radius) of the buffer.

number_of_segments_per_quarter_circle

A value of data type INTEGER. This value determines the number of points to approximate a quarter circle around each vertex of the input geometry. Negative values default to zero. The default is 8.

Return type

GEOMETRY

The ST_Buffer function returns two-dimensional (2D) geometry in the xy-Cartesian plane.

If *geom* is a GEOMETRYCOLLECTION, then an error is returned.

Examples

The following SQL returns the buffer of the input linestring.

```
SELECT ST_AsEwkt(ST_Buffer(ST_GeomFromText('LINESTRING(1 2,5 2,5 8)'), 2));
```

```

      st_asewkt

```

ST_Centroid

ST_Centroid returns a point that represents a centroid of a geometry as follows:

- For POINT geometries, it returns the point whose coordinates are the average of the coordinates of the points in the geometry.
- For LINESTRING geometries, it returns the point whose coordinates are the weighted average of the midpoints of the segments of the geometry, where the weights are the lengths of the segments of the geometry.
- For POLYGON geometries, it returns the point whose coordinates are the weighted average of the centroids of a triangulation of the areal geometry where the weights are the areas of the triangles in the triangulation.
- For geometry collections, it returns the weighted average of the centroids of the geometries of maximum topological dimension in the geometry collection.

Syntax

```
ST_Centroid(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

If *geom* is null, then null is returned.

If *geom* is empty, then null is returned.

Examples

The following SQL returns central point of an input linestring.

```
SELECT ST_AsEWKT(ST_Centroid(ST_GeomFromText('LINESTRING(110 40, 2 3, -10 80, -7 9, -22 -33)', 4326)))
```

```
st_asewkt
```

```
-----  
SRID=4326;POINT(15.6965103455214 27.0206782881905)
```

ST_Collect

ST_Collect has two variants. One accepts two geometries, and one accepts an aggregate expression.

The first variant of ST_Collect creates a geometry from the input geometries. The order of the input geometries is preserved. This variant works as follows:

- If both input geometries are points, then a MULTIPOINT with two points is returned.
- If both input geometries are linestrings, then a MULTILINESTRING with two linestrings is returned.
- If both input geometries are polygons, then a MULTIPOLYGON with two polygons is returned.
- Otherwise, a GEOMETRYCOLLECTION with two input geometries is returned.

The second variant of ST_Collect creates a geometry from geometries in a geometry column. There isn't a determined return order of the geometries. Specify the WITHIN GROUP (ORDER BY ...) clause to specify the order of the returned geometries. This variant works as follows:

- If all non-NULL rows in the input aggregate expression are points, then a multipoint containing all the points in the aggregate expression is returned.
- If all non-NULL rows in the aggregate expression are linestrings, then a multilinestring containing all the linestrings in the aggregate expression is returned.
- If all non-NULL rows in the aggregate expression are polygons, the result is a multipolygon containing all the polygons in the aggregate expression is returned.
- Otherwise, a GEOMETRYCOLLECTION containing all the geometries in the aggregate expression is returned.

The `ST_Collect` returns the geometry of the same dimension as the input geometries. All input geometries must be of the same dimension.

Syntax

```
ST_Collect(geom1, geom2)
```

```
ST_Collect(aggregate_expression) [WITHIN GROUP (ORDER BY sort_expression1 [ASC | DESC]  
[, sort_expression2 [ASC | DESC] ...])]
```

Arguments

geom1

A value of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type.

geom2

A value of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type.

aggregate_expression

A column of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type.

[WITHIN GROUP (ORDER BY *sort_expression1* [ASC | DESC] [, *sort_expression2* [ASC | DESC] ...])]

An optional clause that specifies the sort order of the aggregated values. The `ORDER BY` clause contains a list of sort expressions. Sort expressions are expressions similar to valid sort expressions in a query select list, such as a column name. You can specify ascending (ASC) or descending (DESC) order. The default is ASC.

Return type

`GEOMETRY` of subtype `MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, or `GEOMETRYCOLLECTION`.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometries.

If both *geom1* or *geom2* are null, then null is returned.

If all rows of *aggregate_expression* are null, then null is returned.

If *geom1* is null, then a copy of *geom2* is returned. Likewise, if *geom2* is null, then a copy of *geom1* is returned.

If *geom1* and *geom2* have different SRID values, then an error is returned.

If two geometries in *aggregate_expression* have different SRID values, then an error is returned.

If the returned geometry is larger than the maximum size of a GEOMETRY, then an error is returned.

If *geom1* and *geom2* are of different dimensions, then an error is returned.

If two geometries in *aggregate_expression* are of different dimensions, then an error is returned.

Examples

The following SQL returns a geometry collection that contains the two input geometries.

```
SELECT ST_AsText(ST_Collect(ST_GeomFromText('LINESTRING(0 0,1 1)'),
  ST_GeomFromText('POLYGON((10 10,20 10,10 20,10 10))')));
```

```
st_astext
```

```
-----
```

```
GEOMETRYCOLLECTION(LINESTRING(0 0,1 1),POLYGON((10 10,20 10,10 20,10 10)))
```

The following SQL collects all the geometries from a table into a geometry collection.

```
WITH tbl(g) AS (SELECT ST_GeomFromText('POINT(1 2)', 4326) UNION ALL
  SELECT ST_GeomFromText('LINESTRING(0 0,10 0)', 4326) UNION ALL
  SELECT ST_GeomFromText('MULTIPOINT(13 4,8 5,4 4)', 4326) UNION ALL
  SELECT NULL::geometry UNION ALL
  SELECT ST_GeomFromText('POLYGON((0 0,10 0,0 10,0 0))', 4326))
SELECT ST_AsEWKT(ST_Collect(g)) FROM tbl;
```

```
st_astext
```

```
-----
```

```
SRID=4326;GEOMETRYCOLLECTION(POINT(1 2),LINESTRING(0 0,10 0),MULTIPOINT((13 4),(8 5),
(4 4)),POLYGON((0 0,10 0,0 10,0 0)))
```

The following SQL collects all geometries in the table grouped by the id column and ordered by this ID. In this example, resulting geometries are grouped by ID as follows:

- id 1 – points in a multipoint.
- id 2 – linestrings in a multilinestring.
- id 3 – mixed subtypes in a geometry collection.
- id 4 – polygons in a multipolygon.
- id 5 – null and the result is null.

```
WITH tbl(id, g) AS (SELECT 1, ST_GeomFromText('POINT(1 2)', 4326) UNION ALL
SELECT 1, ST_GeomFromText('POINT(4 5)', 4326) UNION ALL
SELECT 2, ST_GeomFromText('LINESTRING(0 0,10 0)', 4326) UNION ALL
SELECT 2, ST_GeomFromText('LINESTRING(10 0,20 -5)', 4326) UNION ALL
SELECT 3, ST_GeomFromText('MULTIPOINT(13 4,8 5,4 4)', 4326) UNION ALL
SELECT 3, ST_GeomFromText('MULTILINESTRING((-1 -1,-2 -2),(-3 -3,-5 -5))', 4326) UNION
  ALL
SELECT 4, ST_GeomFromText('POLYGON((0 0,10 0,0 10,0 0))', 4326) UNION ALL
SELECT 4, ST_GeomFromText('POLYGON((20 20,20 30,30 20,20 20))', 4326) UNION ALL
SELECT 1, NULL::geometry UNION ALL SELECT 2, NULL::geometry UNION ALL
SELECT 5, NULL::geometry UNION ALL SELECT 5, NULL::geometry)
SELECT id, ST_AsEWKT(ST_Collect(g)) FROM tbl GROUP BY id ORDER BY id;
```

id	st_asewkt
1	SRID=4326;MULTIPOINT((1 2),(4 5))
2	SRID=4326;MULTILINESTRING((0 0,10 0),(10 0,20 -5))
3	SRID=4326;GEOMETRYCOLLECTION(MULTIPOINT((13 4),(8 5),(4 4)),MULTILINESTRING((-1 -1,-2 -2),(-3 -3,-5 -5)))
4	SRID=4326;MULTIPOLYGON(((0 0,10 0,0 10,0 0)),((20 20,20 30,30 20,20 20)))
5	

The following SQL collects all geometries from a table in a geometry collection. Results are ordered in descending order by `id`, and then lexicographically based on their minimum and maximum x-coordinates.

```
WITH tbl(id, g) AS (
SELECT 1, ST_GeomFromText('POINT(4 5)', 4326) UNION ALL
SELECT 1, ST_GeomFromText('POINT(1 2)', 4326) UNION ALL
SELECT 2, ST_GeomFromText('LINESTRING(10 0,20 -5)', 4326) UNION ALL
```

```

SELECT 2, ST_GeomFromText('LINESTRING(0 0,10 0)', 4326) UNION ALL
SELECT 3, ST_GeomFromText('MULTIPOINT(13 4,8 5,4 4)', 4326) UNION ALL
SELECT 3, ST_GeomFromText('MULTILINESTRING((-1 -1,-2 -2),(-3 -3,-5 -5))', 4326) UNION
  ALL
SELECT 4, ST_GeomFromText('POLYGON((20 20,20 30,30 20,20 20))', 4326) UNION ALL
SELECT 4, ST_GeomFromText('POLYGON((0 0,10 0,0 10,0 0))', 4326) UNION ALL
SELECT 1, NULL::geometry UNION ALL SELECT 2, NULL::geometry UNION ALL
SELECT 5, NULL::geometry UNION ALL SELECT 5, NULL::geometry)
SELECT ST_AsEWKT(ST_Collect(g) WITHIN GROUP (ORDER BY id DESC, ST_XMin(g), ST_XMax(g)))
FROM tbl;

```

st_asewkt

```

SRID=4326;GEOMETRYCOLLECTION(POLYGON((0 0,10 0,0 10,0 0)),POLYGON((20 20,20 30,30
20,20 20)),MULTILINESTRING((-1 -1,-2 -2),(-3 -3,-5 -5)),MULTIPOINT((13 4),(8 5),(4
4)),LINESTRING(0 0,10 0),LINESTRING(10 0,20 -5),POINT(1 2),POINT(4 5)

```

ST_Contains

ST_Contains returns true if the 2D projection of the first input geometry contains the 2D projection of the second input geometry. Geometry A contains geometry B if every point in B is a point in A, and their interiors have nonempty intersection.

ST_Contains(A, B) is equivalent to ST_Within(B, A).

Syntax

```
ST_Contains(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. This value is compared with *geom1* to determine if it is contained within *geom1*.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the first polygon contains the second polygon.

```
SELECT ST_Contains(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))');
```

```
st_contains
-----
false
```

ST_ContainsProperly

ST_ContainsProperly returns true if both input geometries are nonempty, and all points of the 2D projection of the second geometry are interior points of the 2D projection of the first geometry.

Syntax

```
ST_ContainsProperly(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype can't be GEOMETRYCOLLECTION.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype can't be GEOMETRYCOLLECTION. This value is compared with *geom1* to determine if all its points are interior points of *geom1*.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL returns the values of ST_Contains and ST_ContainsProperly where the input linestring intersects the interior and the boundary of the input polygon (but not its exterior). The polygon contains the linestring but doesn't properly contain the linestring.

```
WITH tmp(g1, g2)
AS (SELECT ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0))'),
      ST_GeomFromText('LINESTRING(5 5,10 5,10 6,5 5)')) SELECT ST_Contains(g1, g2),
      ST_ContainsProperly(g1, g2)
FROM tmp;
```

```
st_contains | st_containsproperly
-----+-----
t          | f
```

ST_ConvexHull

ST_ConvexHull returns a geometry that represents the convex hull of the nonempty points contained in the input geometry.

For empty input, the resulting geometry is the same as the input geometry. For all nonempty input, the function operates on the 2D projection of the input geometry. However, the dimension

of the output geometry depends on the dimension of the input geometry. More specifically, when the input geometry is a nonempty 3DM or 3D geometry, *m* coordinates are dropped. That is, the dimension of the returned geometry is 2D or 3DZ, respectively. If the input is a nonempty 2D or 3DZ geometry, the resulting geometry has the same dimension.

Syntax

```
ST_ConvexHull(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* is null, then null is returned.

The values returned are as follows.

Number of points on the convex hull	Geometry subtype
0	A copy of <i>geom</i> is returned.
1	A POINT subtype is returned.
2	A LINESTRING subtype is returned. The two points of the returned linestring are lexicographically ordered.
3 or greater	A POLYGON subtype with no interior rings is returned. The polygon is clockwise oriented, and the first point of the exterior ring is the lexicographically smallest point of the ring.

Examples

The following SQL returns the extended well-known text (EWKT) representation of a linestring. In this case, the convex hull returned is a polygon.

```
SELECT ST_AsEWKT(ST_ConvexHull(ST_GeomFromText('LINESTRING(0 0,1 0,0 1,1 1,0.5 0.5)')))
as output;
```

```
output
-----
POLYGON((0 0,0 1,1 1,0 0 0))
```

The following SQL returns the EWKT representation of a linestring. In this case, the convex hull returned is a linestring.

```
SELECT ST_AsEWKT(ST_ConvexHull(ST_GeomFromText('LINESTRING(0 0,1 1,0.2 0.2,0.6 0.6,0.5
0.5)'))) as output;
```

```
output
-----
LINESTRING(0 0,1 1)
```

The following SQL returns the EWKT representation of a multipoint. In this case, the convex hull returned is a point.

```
SELECT ST_AsEWKT(ST_ConvexHull(ST_GeomFromText('MULTIPOINT(0 0,0 0,0 0)'))) as output;
```

```
output
-----
POINT(0 0)
```

ST_CoveredBy

`ST_CoveredBy` returns true if the 2D projection of the first input geometry is covered by the 2D projection of the second input geometry. Geometry A is covered by geometry B if both are nonempty and every point in A is a point in B.

`ST_CoveredBy(A, B)` is equivalent to `ST_Covers(B, A)`.

Syntax

```
ST_CoveredBy(geom1, geom2)
```

Arguments

geom1

A value of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type. This value is compared with *geom2* to determine if it's covered by *geom2*.

geom2

A value of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type.

Return type

`BOOLEAN`

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the first polygon is covered by the second polygon.

```
SELECT ST_CoveredBy(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))');
```

```
st_coveredby
-----
true
```

ST_Covers

ST_Covers returns true if the 2D projection of the first input geometry covers the 2D projection of the second input geometry. Geometry A covers geometry B if both are nonempty and every point in B is a point in A.

ST_Covers(A, B) is equivalent to ST_CoveredBy(B, A).

Syntax

```
ST_Covers(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. This value is compared with *geom1* to determine if it covers *geom1*.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the first polygon covers the second polygon.

```
SELECT ST_Covers(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),  
ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'));
```

```
st_covers
```

```
-----  
false
```

ST_Crosses

ST_Crosses returns true if the 2D projections of the two input geometries cross each other.

Syntax

```
ST_Crosses(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

Examples

The following SQL checks if the first polygon crosses the second multipoint. In this example, the multipoint intersects both the interior and exterior of the polygon, which is why ST_Crosses returns true.

```
SELECT ST_Crosses (ST_GeomFromText('polygon((0 0,10 0,10 10,0 10,0 0))'),  
ST_GeomFromText('multipoint(5 5,0 0,-1 -1)'));
```

```
st_crosses
-----
true
```

The following SQL checks if the first polygon crosses the second multipoint. In this example, the multipoint intersects the exterior of the polygon but not its interior, which is why `ST_Crosses` returns false.

```
SELECT ST_Crosses (ST_GeomFromText('polygon((0 0,10 0,10 10,0 10,0 0))'),
  ST_GeomFromText('multipoint(0 0,-1 -1)));
```

```
st_crosses
-----
false
```

ST_Dimension

`ST_Dimension` returns the inherent dimension of an input geometry. The *inherent dimension* is the dimension value of the subtype that is defined in the geometry.

For 3DM, 3DZ, and 4D geometry inputs, `ST_Dimension` returns the same result as for 2D geometry inputs.

Syntax

```
ST_Dimension(geom)
```

Arguments

geom

A value of data type `GEOMETRY` or an expression that evaluates to a `GEOMETRY` type.

Return type

`INTEGER` representing the inherent dimension of *geom*.

If *geom* is null, then null is returned.

The values returned are as follows.

Returned value	Geometry subtype
0	Returned if <i>geom</i> is a POINT or MULTIPOINT subtype
1	Returned if <i>geom</i> is a LINESTRING or MULTILINESTRING subtype.
2	Returned if <i>geom</i> is a POLYGON or MULTIPOLYGON subtype
0	Returned if <i>geom</i> is an empty GEOMETRYCOLLECTION subtype
Largest dimension of the components of the collection	Returned if <i>geom</i> is a GEOMETRYCOLLECTION subtype

Examples

The following SQL converts a well-known text (WKT) representation of a four-point LINESTRING to a GEOMETRY object and returns the dimension of the linestring.

```
SELECT ST_Dimension(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27
29.31,77.29 29.07)'));
```

```
st_dimension
-----
1
```

ST_Disjoint

ST_Disjoint returns true if the 2D projections of the two input geometries have no points in common.

Syntax

```
ST_Disjoint(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the first polygon is disjoint from the second polygon.

```
SELECT ST_Disjoint(ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(2 2,2 5,5 5,5 2,2 2)'), ST_Point(4, 4));
```

```
st_disjoint
-----
true
```

ST_Distance

For input geometries, ST_Distance returns the minimum Euclidean distance between the 2D projections of the two input geometry values.

For 3DM, 3DZ, 4D geometries, ST_Distance returns the Euclidean distance between the 2D projections of two input geometry values.

For input geographies, `ST_Distance` returns the geodesic distance of the two 2D points. The unit of distance is in meters. For geographies other than points and empty points an error is returned.

Syntax

```
ST_Distance(geo1, geo2)
```

Arguments

geo1

A value of data type `GEOMETRY` or `GEOGRAPHY`, or an expression that evaluates to a `GEOMETRY` or `GEOGRAPHY` type. The data type of *geo1* must be the same as *geo2*.

geo2

A value of data type `GEOMETRY` or `GEOGRAPHY`, or an expression that evaluates to a `GEOMETRY` or `GEOGRAPHY` type. The data type of *geo2* must be the same as *geo1*.

Return type

`DOUBLE PRECISION` in the same units as the input geometries or geographies.

If *geo1* or *geo2* is null or empty, then null is returned.

If *geo1* and *geo2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geo1* or *geo2* is a geometry collection, then an error is returned.

Examples

The following SQL returns the distance between two polygons.

```
SELECT ST_Distance(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 -3,-2 -1,0 -3,-1 -3))');
```

```
  st_distance
-----
1.4142135623731
```

The following SQL returns the distance (in meters) between the Brandenburg Gate and the Reichstag building in Berlin using a GEOGRAPHY data type.

```
SELECT ST_Distance(ST_GeogFromText('POINT(13.37761826722198 52.516411678282445)'),
  ST_GeogFromText('POINT(13.377950831464005 52.51705102546893)'));
```

```
  st_distance
-----
74.64129172609631
```

ST_DistanceSphere

ST_DistanceSphere returns the distance between two point geometries lying on a sphere.

Syntax

```
ST_DistanceSphere(geom1, geom2)
```

```
ST_DistanceSphere(geom1, geom2, radius)
```

Arguments

geom1

A point value in degrees of data type GEOMETRY lying on a sphere. The first coordinate of the point is the longitude value. The second coordinate of the point is the latitude value. For 3DZ, 3DM, or 4D geometries, only the first two coordinates are used.

geom2

A point value in degrees of data type GEOMETRY lying on a sphere. The first coordinate of the point is the longitude value. The second coordinate of the point is the latitude value. For 3DZ, 3DM, or 4D geometries, only the first two coordinates are used.

radius

The radius of a sphere of data type DOUBLE PRECISION. If no *radius* is provided, the sphere defaults to Earth and the radius is computed from the World Geodetic System (WGS) 84 representation of the ellipsoid.

Return type

DOUBLE PRECISION in the same units as the radius. If no radius is provided, the distance is in meters.

If *geom1* or *geom2* is null or empty, then null is returned.

If no *radius* is provided, then the result is in meters along the Earth's surface.

If *radius* is a negative number, then an error is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is not a point, then an error is returned.

Examples

The following example SQL computes the distance in kilometers between two points on Earth.

```
SELECT ROUND(ST_DistanceSphere(ST_Point(-122, 47), ST_Point(-122.1, 47.1))/ 1000, 0);
```

```
round
```

```
-----
```

```
13
```

The following example SQL computes the distances in kilometers between three airport locations in Germany: Berlin Tegel (TXL), Munich International (MUC), and Frankfurt International (FRA).

```
WITH airports_raw(code,lon,lat) AS (
  (SELECT 'MUC', 11.786111, 48.353889) UNION
  (SELECT 'FRA', 8.570556, 50.033333) UNION
  (SELECT 'TXL', 13.287778, 52.559722)),
airports1(code,location) AS (SELECT code, ST_Point(lon, lat) FROM airports_raw),
airports2(code,location) AS (SELECT * from airports1)
SELECT (airports1.code || ' <-> ' || airports2.code) AS airports,
round(ST_DistanceSphere(airports1.location, airports2.location) / 1000, 0) AS
  distance_in_km
FROM airports1, airports2 WHERE airports1.code < airports2.code ORDER BY 1;
```

airports	distance_in_km
FRA <-> MUC	299
FRA <-> TXL	432
MUC <-> TXL	480

ST_DWithin

ST_DWithin returns true if the Euclidean distance between the 2D projections of the two input geometry values is not larger than a threshold value.

Syntax

```
ST_DWithin(geom1, geom2, threshold)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

threshold

A value of data type DOUBLE PRECISION. This value is in the units of the input arguments.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *threshold* is negative, then an error is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the distance between two polygons is within five units.

```
SELECT ST_DWithin(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),  
ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'),5);
```

```
st_dwithin  
-----  
true
```

ST_EndPoint

ST_EndPoint returns the last point of an input linestring. The spatial reference system identifier (SRID) value of the result is the same as that of the input geometry. The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_EndPoint(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING.

Return type

GEOMETRY

If *geom* is null, then null is returned.

If *geom* is empty, then null is returned.

If *geom* isn't a LINESTRING, then null is returned.

Examples

The following SQL returns an extended well-known text (EWKT) representation of a four-point LINESTRING to a GEOMETRY object and returns the end point of the linestring.

```
SELECT ST_AsEWKT(ST_EndPoint(ST_GeomFromText('LINESTRING(0 0,10 0,10 10,5 5,0
5)',4326)));
```

```
st_asewkt
-----
SRID=4326;POINT(0 5)
```

ST_Envelope

ST_Envelope returns the minimum bounding box of the input geometry, as follows:

- If the input geometry is empty, the returned geometry is a copy of the input geometry.
- If the minimum bounding box of the input geometry degenerates to a point, the returned geometry is a point.
- If the minimum bounding box of the input geometry is one-dimensional, a two-point linestring is returned.
- If none of the preceding is true, the function returns a clockwise-oriented polygon whose vertices are the corners of the minimum bounding box.

The spatial reference system identifier (SRID) of the returned geometry is the same as that of the input geometry.

For all nonempty input, the function operates on the 2D projection of the input geometry.

Syntax

```
ST_Envelope(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

If *geom* is null, then null is returned.

Examples

The following SQL converts a well-known text (WKT) representation of a four-point LINESTRING to a GEOMETRY object and returns a polygon whose vertices whose corners are the minimum bounding box.

```
SELECT ST_AsText(ST_Envelope(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((0 0,10 0,0
10,0 0)),LINESTRING(20 10,20 0,10 0))')));
```

```
st_astext
```

```
-----
POLYGON((0 0,0 10,20 10,20 0,0 0))
```

ST_Equals

ST_Equals returns true if the 2D projections of the input geometries are geometrically equal. Geometries are considered geometrically equal if they have equal point sets and their interiors have a nonempty intersection.

Syntax

```
ST_Equals(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. This value is compared with *geom1* to determine if it is equal to *geom1*.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then an error is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the two polygons are geometrically equal.

```
SELECT ST_Equals(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))');
```

```
st_equals
-----
false
```

The following SQL checks if the two linestrings are geometrically equal.

```
SELECT ST_Equals(ST_GeomFromText('LINESTRING(1 0,10 0)'), ST_GeomFromText('LINESTRING(1
  0,5 0,10 0)');
```

```
st_equals
-----
true
```

ST_ExteriorRing

`ST_ExteriorRing` returns a closed linestring that represents the exterior ring of an input polygon. The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_ExteriorRing(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY of subtype LINESTRING.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* is null, then null is returned.

If *geom* is not a polygon, then null is returned.

If *geom* is empty, then an empty polygon is returned.

Examples

The following SQL returns the exterior ring of a polygon as a closed linestring.

```
SELECT ST_AsEWKT(ST_ExteriorRing(ST_GeomFromText('POLYGON((7 9,8 7,11 6,15 8,16 6,17
7,17 10,18 12,17 14,15 15,11 15,10 13,9 12,7 9),(9 9,10 10,11 11,11 10,10 8,9 9),(12
14,15 14,13 11,12 14))'))));
```

```
st_asewkt
-----
LINESTRING(7 9,8 7,11 6,15 8,16 6,17 7,17 10,18 12,17 14,15 15,11 15,10 13,9 12,7 9)
```

ST_Force2D

ST_Force2D returns a 2D geometry of the input geometry. For 2D geometries, a copy of the input is returned. For 3DZ, 3DM, and 4D geometries, ST_Force2D projects the geometry to the xy-Cartesian plane. Empty points in the input geometry remain empty points in the output geometry.

Syntax

```
ST_Force2D(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* is null, then null is returned.

If *geom* is empty, then an empty geometry is returned.

Examples

The following SQL returns a 2D geometry from a 3DZ geometry.

```
SELECT ST_AsEWKT(ST_Force2D(ST_GeomFromText('MULTIPOINT Z(0 1 2, EMPTY, 2 3 4, 5 6 7)')));
```

```
st_asewkt
-----
MULTIPOINT((0 1),EMPTY,(2 3),(5 6))
```

ST_Force3D

ST_Force3D is an alias for ST_Force3DZ. For more information, see [ST_Force3DZ](#).

ST_Force3DM

ST_Force3DM returns a 3DM geometry of the input geometry. For 2D geometries, the *m* coordinates of the nonempty points in the output geometry are all set to 0. For 3DM geometries, a copy of the input geometry is returned. For 3DZ geometries, the geometry is projected to the *xy*-Cartesian plane, and the *m* coordinates of the nonempty points in the output geometry are all set to 0. For 4D geometries, the geometry is projected to the *xym*-Cartesian space. Empty points in the input geometry remain empty points in the output geometry.

Syntax

```
ST_Force3DM(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* is null, then null is returned.

If *geom* is empty, then an empty geometry is returned.

Examples

The following SQL returns a 3DM geometry from a 3DZ geometry.

```
SELECT ST_AsEWKT(ST_Force3DM(ST_GeomFromText('MULTIPOINT Z(0 1 2, EMPTY, 2 3 4, 5 6 7)')));
```

```
st_asewkt
-----
MULTIPOINT M ((0 1 0),EMPTY,(2 3 0),(5 6 0))
```

ST_Force3DZ

ST_Force3DZ returns a 3DZ geometry from the input geometry. For 2D geometries, the z coordinates of the nonempty points in the output geometry are all set to 0. For 3DM geometries, the geometry is projected on the xy-Cartesian plane, and the z coordinates of the nonempty points in the output geometry are all set to 0. For 3DZ geometries, a copy of the input geometry is returned. For 4D geometries, the geometry is projected to the xyz-Cartesian space. Empty points in the input geometry remain empty points in the output geometry.

Syntax

```
ST_Force3DZ(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* is null, then null is returned.

If *geom* is empty, then an empty geometry is returned.

Examples

The following SQL returns a 3DZ geometry from a 3DM geometry.

```
SELECT ST_AsEWKT(ST_Force3DZ(ST_GeomFromText('MULTIPOINT M(0 1 2, EMPTY, 2 3 4, 5 6 7)')));
```

```
st_asewkt
-----
MULTIPOINT Z ((0 1 0),EMPTY,(2 3 0),(5 6 0))
```

ST_Force4D

ST_Force4D returns a 4D geometry of the input geometry. For 2D geometries, the z and m coordinates of the nonempty points in the output geometry are all set to 0. For 3DM geometries, the z coordinates of the nonempty points in the output geometry are all set to 0. For 3DZ geometries, the m coordinates of the nonempty points in the output geometry are all set to 0.

For 4D geometries, a copy of the input geometry is returned. Empty points in the input geometry remain empty points in the output geometry.

Syntax

```
ST_Force4D(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* is null, then null is returned.

If *geom* is empty, then an empty geometry is returned.

Examples

The following SQL returns a 4D geometry from a 3DM geometry.

```
SELECT ST_AsEWKT(ST_Force4D(ST_GeomFromText('MULTIPOINT M(0 1 2, EMPTY, 2 3 4, 5 6 7)')));
```

```
st_asewkt
-----
MULTIPOINT ZM ((0 1 0 2),EMPTY,(2 3 0 4),(5 6 0 7))
```

ST_GeoHash

ST_GeoHash returns the geohash representation of the input point with the specified precision. The default precision value is 20. For more information about the definition of geohash, see [Geohash](#) in Wikipedia.

Syntax

```
ST_GeoHash(geom)
```

```
ST_GeoHash(geom, precision)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

precision

A value of data type INTEGER. The default is 20.

Return type

GEOMETRY

The function returns the geohash representation of the input point.

If the input point is empty, the function returns null.

If the input geometry is not a point, the function returns an error.

Examples

The following SQL returns the geohash representation of the input point.

```
SELECT ST_GeoHash(ST_GeomFromText('POINT(45 -45)'), 25) AS geohash;
```

```
      geohash
-----
m000000000000000000000000gzz
```

The following SQL returns null because the input point is empty.

```
SELECT ST_GeoHash(ST_GeomFromText('POINT EMPTY'), 10) IS NULL AS result;
```

```
result
-----
true
```

ST_GeogFromText

ST_GeogFromText constructs a geography object from a well-known text (WKT) or extended well-known text (EWKT) representation of an input geography.

Syntax

```
ST_GeogFromText(wkt_string)
```

Arguments

wkt_string

A value of data type VARCHAR that is a WKT or EWKT representation of a geography.

Return type

GEOGRAPHY

If the SRID value is set to the provided value in the input. If SRID is not provided, it is set to 4326.

If *wkt_string* is null, then null is returned.

If *wkt_string* is not valid, then an error is returned.

Examples

The following SQL constructs a polygon from a geography object with an SRID value.

```
SELECT ST_AsEWKT(ST_GeogFromText('SRID=4324;POLYGON((0 0,0 1,1 1,10 10,1 0,0 0))'));
```

```
st_asewkt
-----
SRID=4324;POLYGON((0 0,0 1,1 1,10 10,1 0,0 0))
```

The following SQL constructs a polygon from a geography object. The SRID value is set to 4326.

```
SELECT ST_AsEWKT(ST_GeogFromText('POLYGON((0 0,0 1,1 1,10 10,1 0,0 0))'));
```

```
st_asewkt
```

```
-----  
SRID=4326;POLYGON((0 0,0 1,1 1,10 10,1 0,0 0))
```

ST_GeogFromWKB

ST_GeogFromWKB constructs a geography object from a hexadecimal well-known binary (WKB) representation of an input geography.

Syntax

```
ST_GeogFromWKB(wkb_string)
```

Arguments

wkb_string

A value of data type VARCHAR that is a hexadecimal WKB representation of a geography.

Return type

GEOGRAPHY

If the SRID value is provided it is set to the provided value. If SRID is not provided, it is set to 4326.

If *wkb_string* is null, then null is returned.

If *wkb_string* is not valid, then an error is returned.

Examples

The following SQL constructs a geography from a hexadecimal WKB value.

If *geom* or *index* is null, then null is returned.

If *index* is out of range, then an error is returned.

Examples

The following SQL returns the geometries in a geometry collection.

```
WITH tmp1(idx) AS (SELECT 1 UNION SELECT 2),
tmp2(g) AS (SELECT ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((0 0,10 0,0 10,0
0)),LINESTRING(20 10,20 0,10 0))'))
SELECT idx, ST_AsEWKT(ST_GeometryN(g, idx)) FROM tmp1, tmp2 ORDER BY idx;
```

idx	st_asewkt
1	POLYGON((0 0,10 0,0 10,0 0))
2	LINESTRING(20 10,20 0,10 0)

ST_GeometryType

ST_GeometryType returns the subtype of an input geometry as a string.

For 3DM, 3DZ, and 4D geometry inputs, ST_GeometryType returns the same result as for 2D geometry inputs.

Syntax

```
ST_GeometryType(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

VARCHAR representing the subtype of *geom*.

If *geom* is null, then null is returned.

The values returned are as follows.

Returned string value	Geometry subtype
ST_Point	Returned if <i>geom</i> is a POINT subtype
ST_LineString	Returned if <i>geom</i> is a LINESTRING subtype
ST_Polygon	Returned if <i>geom</i> is a POLYGON subtype
ST_MultiPoint	Returned if <i>geom</i> is a MULTIPOINT subtype
ST_MultiLineString	Returned if <i>geom</i> is a MULTILINESTRING subtype
ST_MultiPolygon	Returned if <i>geom</i> is a MULTIPOLYGON subtype
ST_GeometryCollection	Returned if <i>geom</i> is a GEOMETRYCOLLECTION subtype

Examples

The following SQL returns the subtype of the input linestring geometry.

```
SELECT ST_GeometryType(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27
29.31,77.29 29.07)'));
```

```
st_geometrytype
-----
ST_LineString
```

ST_GeomFromEWKB

ST_GeomFromEWKB constructs a geometry object from the extended well-known binary (EWKB) representation of an input geometry.

Syntax

```
ST_GeomFromEWKT(ewkt_string)
```

Arguments

ewkt_string

A value of data type VARCHAR or an expression that evaluates to a VARCHAR type, that is an EWKT representation of a geometry.

You can use the WKT keyword EMPTY to designate an empty point, a multipoint with an empty point, or a geometry collection with an empty point. The following example creates an empty point.

```
ST_GeomFromEWKT('SRID=4326;POINT EMPTY');
```

Return type

GEOMETRY

If *ewkt_string* is null, then null is returned.

If *ewkt_string* is not valid, then an error is returned.

Examples

The following SQL constructs a multilinestring from an EWKT value and returns a geometry. It also returns the ST_AsEWKT result of the geometry.

```
SELECT ST_GeomFromEWKT('SRID=4326;MULTILINESTRING((1 0,1 0),(2 0,3 0),(4 0,5 0,6 0))')
as geom, ST_AsEWKT(geom);
```

	geom	st_asewkt
-----+-----		

```
SELECT ST_AsText(ST_GeomFromGeoHash('9qqj7nmxcggy4d0dbxqz0'));
```

```
st_asewkt
```

```
-----
POLYGON((-115.172816 36.114646,-115.172816 36.114646,-115.172816 36.114646,-115.172816
36.114646,-115.172816 36.114646))
```

The following SQL returns a point with high precision.

```
SELECT ST_AsText(ST_GeomFromGeoHash('9qqj7nmxcggy4d0dbxqz00'));
```

```
st_asewkt
```

```
-----
POINT(-115.172816 36.114646)
```

The following SQL returns a polygon with low precision.

```
SELECT ST_AsText(ST_GeomFromGeoHash('9qq'));
```

```
st_asewkt
```

```
-----
POLYGON((-115.3125 35.15625,-115.3125 36.5625,-113.90625 36.5625,-113.90625
35.15625,-115.3125 35.15625))
```

The following SQL returns a polygon with precision 3.

```
SELECT ST_AsText(ST_GeomFromGeoHash('9qqj7nmxcggy4d0dbxqz0', 3));
```

```
st_asewkt
```

```
-----
POLYGON((-115.3125 35.15625,-115.3125 36.5625,-113.90625 36.5625,-113.90625
35.15625,-115.3125 35.15625))
```

ST_GeomFromGeoJSON

ST_GeomFromGeoJSON constructs a geometry object from the GeoJSON representation of an input geometry. For more information about the GeoJSON format, see [GeoJSON](#) in Wikipedia.

If there is at least one point with three or more coordinates, the resulting geometry is 3DZ, where the Z component is zero for the points that have only two coordinates. If all points in the input GeoJSON contain two coordinates or are empty, ST_GeomFromGeoJSON returns a 2D geometry. The returned geometry always has the spatial reference identifier (SRID) of 4326.

Syntax

```
ST_GeomFromGeoJSON(geojson_string)
```

Arguments

geojson_string

A value of data type VARCHAR or an expression that evaluates to a VARCHAR type, that is a GeoJSON representation of a geometry.

Return type

GEOMETRY

If *geojson_string* is null, then null is returned.

If *geojson_string* is not valid, then an error is returned.

Examples

The following SQL returns a 2D geometry represented in the input GeoJSON.

```
SELECT ST_AsEWKT(ST_GeomFromGeoJSON('{"type":"Point","coordinates":[1,2]}'));
```

```
st_asewkt
```

```
-----
SRID=4326;POINT(1 2)
```

The following SQL returns a 3DZ geometry represented in the input GeoJSON.

```
SELECT ST_AsEWKT(ST_GeomFromGeoJSON('{"type":"LineString","coordinates":[[[1,2,3],
[4,5,6],[7,8,9]]}'));
```

```
st_asewkt
-----
SRID=4326;LINESTRING Z (1 2 3,4 5 6,7 8 9)
```

The following SQL returns 3DZ geometry when only one point has three coordinates while all other points have two coordinates in the input GeoJSON.

```
SELECT ST_AsEWKT(ST_GeomFromGeoJSON('{"type":"Polygon","coordinates":[[[0, 0],[0, 1,
8],[1, 0],[0, 0]]}'));
```

```
st_asewkt
-----
SRID=4326;POLYGON Z ((0 0 0,0 1 8,1 0 0,0 0 0))
```

ST_GeomFromGeoSquare

`ST_GeomFromGeoSquare` returns a geometry that covers the area that is represented by an input geosquare value. The returned geometry is always two-dimensional. To calculate a geosquare value, see [ST_GeoSquare](#).

Syntax

```
ST_GeomFromGeoSquare(geosquare)
```

```
ST_GeomFromGeoSquare(geosquare, max_depth)
```

Arguments

geosquare

A value of data type BIGINT or an expression that evaluates to a BIGINT type that is a geosquare value that describes the sequence of subdivisions made on the initial domain to reach the desired square. This value is calculated by [ST_GeoSquare](#).

max_depth

A value of data type INTEGER that represents the maximum number of domain subdivisions made on the initial domain. The value must be greater than or equal to 1.

Return type

GEOMETRY

If *geosquare* is not valid, the function returns an error.

If the input *max_depth* is not within range, the function returns an error.

Examples

The following SQL returns a geometry from a geosquare value.

```
SELECT ST_AsText(ST_GeomFromGeoSquare(797852));
```

```
st_astext
```

```
-----
POLYGON((13.359375 52.3828125,13.359375 52.734375,13.7109375 52.734375,13.7109375
52.3828125,13.359375 52.3828125))
```

The following SQL returns a geometry from a geosquare value and a maximum depth of 3.

```
SELECT ST_AsText(ST_GeomFromGeoSquare(797852, 3));
```

```
st_astext
```

```
-----
POLYGON((0 45,0 90,45 90,45 45,0 45))
```

The following SQL first calculates the geosquare value for Seattle by specifying the x coordinate as longitude and the y coordinate as latitude (-122.3, 47.6). Then it returns the polygon for the geosquare. Although the output is a two-dimensional geometry, it can be used to calculate spatial data in terms of longitude and latitude.

```
SELECT ST_AsText(ST_GeomFromGeoSquare(ST_GeoSquare(ST_Point(-122.3, 47.6))));
```

```
st_astext
```

```
-----  
POLYGON((-122.335167014971 47.6080129947513,-122.335167014971  
47.6080130785704,-122.335166931152 47.6080130785704,-122.335166931152  
47.6080129947513,-122.335167014971 47.6080129947513))
```

ST_GeomFromText

ST_GeomFromText constructs a geometry object from a well-known text (WKT) representation of an input geometry.

ST_GeomFromText accepts 3DZ, 3DM, and 4D where the geometry type is prefixed with Z, M, or ZM, respectively.

Syntax

```
ST_GeomFromText(wkt_string)
```

```
ST_GeomFromText(wkt_string, srid)
```

Arguments

wkt_string

A value of data type VARCHAR that is a WKT representation of a geometry.

You can use the WKT keyword EMPTY to designate an empty point, a multipoint with an empty point, or a geometry collection with an empty point. The following example creates a multipoint with one empty and one nonempty point.

ST_GeoSquare

ST_GeoSquare recursively subdivides the domain ([-180, 180], [-90, 90]) into equal square regions called *geosquares* to a specified depth. The subdivision is based on the location of a provided point. One of the geosquares containing the point is subdivided at each step until reaching the maximum depth. The selection of this geosquare is stable, that is, the function result depends on the input arguments only. The function returns a unique value that identifies the final geosquare in which the point is located.

The ST_GeoSquare accepts a POINT where the x coordinate is representing the longitude, and the y coordinate is representing the latitude. The longitude and latitude are limited to [-180, 180] and [-90, 90], respectively. The output of ST_GeoSquare can be used as input to the [ST_GeomFromGeoSquare](#) function.

There are 360° around the arc of the equatorial circumference of the Earth that are divided into two hemispheres (Eastern and Western), each with 180° of longitudinal lines (Meridians) from the 0° Meridian. By convention, the eastern longitudes are "+" (positive) coordinates when projected to an x-axis on a Cartesian plane and the western longitudes are "-" (negative) coordinates when projected to an x-axis on a Cartesian plane. There are 90° of latitudinal lines north and south of the 0° equatorial circumference of the Earth, each parallel to the 0° equatorial circumference of the Earth. By convention, the northern latitudinal lines intersect the "+" (positive) y-axis when projected to a Cartesian plane, and the southern latitudinal lines intersect the "-" (negative) y-axis when projected to a Cartesian plane. The spherical grid formed by the intersection of longitudinal lines and latitudinal lines is converted to a grid projected onto a Cartesian plane with standard positive and negative x-coordinates and positive and negative y-coordinates on the Cartesian plane.

The purpose of ST_GeoSquare is to tag or mark close points with equal code values. Points that are located in the same geosquare receive the same code value. A geosquare is used to encode geographic coordinates (latitude and longitude) into an integer. A larger region is divided into grids to delineate an area on a map with varying resolutions. A geosquare can be used for spatial indexing, spatial binning, proximity searches, location searching, and creating unique place identifiers. The [ST_GeoHash](#) function follows a similar process of dividing a region into grids, but has a different encoding.

Syntax

```
ST_GeoSquare(geom)
```

```
ST_GeoSquare(geom, max_depth)
```

Arguments

geom

A POINT value of data type GEOMETRY or an expression that evaluates to a POINT subtype. The x coordinate (longitude) of the point must be within the range: -180 – 180. The y coordinate (latitude) of the point must be within the range: -90 – 90.

max_depth

A value of data type INTEGER. The maximum number of times the domain containing the point is subdivided recursively. The value must be an integer from 1 – 32. The default is 32. The actual final number of the subdivisions is less than or equal to the specified *max_depth*.

Return type

BIGINT

The function returns a unique value that identifies the final geosquare in which the input point is located.

If the input *geom* is not a point, the function returns an error.

If the input point is empty, the return value is not a valid input to the [ST_GeomFromGeoSquare](#) function. Use the [ST_IsEmpty](#) function to prevent calls to ST_GeoSquare with an empty point.

If the input point is not within range, the function returns an error.

If the input *max_depth* is out of range, the function returns an error.

Examples

The following SQL returns a geosquare from an input point.

```
SELECT ST_GeoSquare(ST_Point(13.5, 52.5));
```

```
st_geosquare
```

```
-----  
-4410772491521635895
```

The following SQL returns a geosquare from an input point with a maximum depth of 10.

```
SELECT ST_GeoSquare(ST_Point(13.5, 52.5), 10);
```

```
st_geosquare
-----
797852
```

ST_InteriorRingN

ST_InteriorRingN returns a closed linestring corresponding to the interior ring of an input polygon at the index position. The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_InteriorRingN(geom, index)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

index

A value of data type INTEGER that represents the position of a ring of a one-based index.

Return type

GEOMETRY of subtype LINESTRING.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *geom* or *index* is null, then null is returned.

If *index* is out of range, then null is returned.

If *geom* is not a polygon, then null is returned.

If *geom* is an empty polygon, then null is returned.

Examples

The following SQL returns the second ring of the polygon as a closed linestring.

```
SELECT ST_AsEWKT(ST_InteriorRingN(ST_GeomFromText('POLYGON((7 9,8 7,11 6,15 8,16 6,17
7,17 10,18 12,17 14,15 15,11 15,10 13,9 12,7 9),(9 9,10 10,11 11,11 10,10 8,9 9),(12
14,15 14,13 11,12 14))'),2));
```

```
st_asewkt
-----
LINESTRING(12 14,15 14,13 11,12 14)
```

ST_Intersects

ST_Intersects returns true if the 2D projections of the two input geometries have at least one point in common.

Syntax

```
ST_Intersects(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the first polygon intersects the second polygon.

```
SELECT ST_Intersects(ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0)),(2 2,2 5,5 5,5 2,2 2)'), ST_GeomFromText('MULTIPOINT((4 4),(6 6))'));
```

```
st_intersects
-----
true
```

ST_Intersection

ST_Intersection returns a geometry representing the point-set intersection of two geometries. That is, it returns the portion of the two input geometries that is shared between them.

Syntax

```
ST_Intersection(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

If *geom1* and *geom2* don't share any space (they are disjoint), then an empty geometry is returned.

If *geom1* or *geom2* are empty, then an empty geometry is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

If *geom1* or *geom2* is not a two-dimensional (2D) geometry, then an error is returned.

Examples

The following SQL returns the non-empty geometry representing the intersection of two input geometries.

```
SELECT ST_AsEWKT(ST_Intersection(ST_GeomFromText('polygon((0 0,100 100,0 200,0 0))'),
  ST_GeomFromText('polygon((0 0,10 0,0 10,0 0))')));
```

```
      st_asewkt
-----
POLYGON((0 0,0 10,5 5,0 0))
```

The following SQL returns an empty geometry when passed disjoint (non-intersecting) input geometries.

```
SELECT ST_AsEWKT(ST_Intersection(ST_GeomFromText('linestring(0 100,0 0)'),
  ST_GeomFromText('polygon((1 0,10 0,1 10,1 0))')));
```

```
      st_asewkt
-----
LINESTRING EMPTY
```

ST_IsPolygonCCW

`ST_IsPolygonCCW` returns true if the 2D projection of the input polygon or multipolygon is counterclockwise. If the input geometry is a point, linestring, multipoint, or multilinestring, then true is returned. For geometry collections, `ST_IsPolygonCCW` returns true if all the geometries in the collection are counterclockwise.

Syntax

```
ST_IsPolygonCCW(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL checks if the polygon is counterclockwise.

```
SELECT ST_IsPolygonCCW(ST_GeomFromText('POLYGON((7 9,8 7,11 6,15 8,16 6,17 7,17 10,18
12,17 14,15 15,11 15,10 13,9 12,7 9),(9 9,10 10,11 11,11 10,10 8,9 9),(12 14,15 14,13
11,12 14))'));
```

```
st_isplaygonccw
-----
true
```

ST_IsPolygonCW

ST_IsPolygonCW returns true if the 2D projection of the input polygon or multipolygon is clockwise. If the input geometry is a point, linestring, multipoint, or multilinestring, then true is returned. For geometry collections, ST_IsPolygonCW returns true if all the geometries in the collection are clockwise.

Syntax

```
ST_IsPolygonCW(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL checks if the polygon is clockwise.

```
SELECT ST_IsPolygonCW(ST_GeomFromText('POLYGON((7 9,8 7,11 6,15 8,16 6,17 7,17 10,18
12,17 14,15 15,11 15,10 13,9 12,7 9),(9 9,10 10,11 11,11 10,10 8,9 9),(12 14,15 14,13
11,12 14))'));
```

```
st_ispolygonccw
-----
true
```

ST_IsClosed

ST_IsClosed returns true if the 2D projection of the input geometry is closed. The following rules define a closed geometry:

- The input geometry is a point or a multipoint.
- The input geometry is a linestring, and the start and end points of the linestring coincide.
- The input geometry is a nonempty multilinestring and all its linestrings are closed.
- The input geometry is a nonempty polygon, all polygon's rings are nonempty, and the start and end points of all its rings coincide.
- The input geometry is a nonempty multipolygon and all its polygons are closed.
- The input geometry is a nonempty geometry collection and all its components are closed.

Syntax

```
ST_IsClosed(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is an empty point, then false is returned.

If *geom* is null, then null is returned.

Examples

The following SQL checks if the polygon is closed.

```
SELECT ST_IsClosed(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'));
```

```
st_isclosed  
-----  
true
```

ST_IsCollection

ST_IsCollection returns true if the input geometry is one of the following subtypes: GEOMETRYCOLLECTION, MULTIPOINT, MULTILINESTRING, or MULTIPOLYGON.

Syntax

```
ST_IsCollection(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL checks if the polygon is a collection.

```
SELECT ST_IsCollection(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'));
```

```
st_iscollection
-----
false
```

ST_IsEmpty

ST_IsEmpty returns true if the input geometry is empty. A geometry is not empty if it contains at least one nonempty point.

ST_IsEmpty returns true if the input geometry has at least one nonempty point.

Syntax

```
ST_IsEmpty(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL checks if the specified polygon is empty.

```
SELECT ST_IsEmpty(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'));
```

```
st_isempty
-----
false
```

ST_IsRing

ST_IsRing returns true if the input linestring is a ring. A linestring is a ring if it is closed and simple.

Syntax

```
ST_IsRing(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The geometry must be a LINESTRING.

Return type

BOOLEAN

If *geom* is not a LINESTRING, then an error is returned.

Examples

The following SQL checks if the specified linestring is a ring.

```
SELECT ST_IsRing(ST_GeomFromText('linestring(0 0, 1 1, 1 2, 0 0)'));
```

```
st_isring
-----
true
```

ST_IsSimple

ST_IsSimple returns true if the 2D projection of the input geometry is simple. For more information about the definition of a simple geometry, see [Geometric simplicity](#).

Syntax

```
ST_IsSimple(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL checks if the specified linestring is simple. In this example, it isn't simple because it has self-intersection.

```
SELECT ST_IsSimple(ST_GeomFromText('LINESTRING(0 0,10 0,5 5,5 -5)'));
```

```
st_issimple
-----
false
```

ST_IsValid

ST_IsValid returns true if the 2D projection of the input geometry is valid. For more information about the definition of a valid geometry, see [Geometric validity](#).

Syntax

```
ST_IsValid(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL checks if the specified polygon is valid. In this example, the polygon is invalid because the interior of the polygon isn't simply connected.

```
SELECT ST_IsValid(ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 0,10 5,5 10,0 5,5 0))'));
```

```
st_isvalid
-----
false
```

ST_Length

For a linear geometry, ST_Length returns the Cartesian length of a 2D projection. The length units are the same as the units in which the coordinates of the input geometry are expressed. The function returns zero (0) for points, multipoints, and areal geometries. When the input is a geometry collection, the function returns the sum of the lengths of the geometries in the collection.

For a geography, `ST_Length` returns the geodesic length of the 2D projection of an input linear geography computed on the spheroid determined by the SRID. The unit of length is in meters. The function returns zero (0) for points, multipoints, and areal geographies. When the input is a geometry collection, the function returns the sum of the lengths of the geographies in the collection.

Syntax

```
ST_Length(geo)
```

Arguments

geo

A value of data type `GEOMETRY` or `GEOGRAPHY`, or an expression that evaluates to a `GEOMETRY` or `GEOGRAPHY` type.

Return type

`DOUBLE PRECISION`

If *geo* is null, then null is returned.

If the SRID value is not found, then an error is returned.

Examples

The following SQL returns the Cartesian length of a multilinestring.

```
SELECT ST_Length(ST_GeomFromText('MULTILINESTRING((0 0,10 0,0 10),(10 0,20 0,20 10))'));
```

```
st_length
-----
44.142135623731
```

The following SQL returns the length of a linestring in a geography.

```
SELECT ST_Length(ST_GeogFromText('SRID=4326;LINESTRING(5 0,6 0,4 0)'));
```

```
st_length
-----
333958.472379804
```

The following SQL returns the length of a point in a geography.

```
SELECT ST_Length(ST_GeogFromText('SRID=4326;POINT(4 5)'));
```

```
st_length
-----
0
```

ST_LengthSphere

ST_LengthSphere returns the length of a linear geometry in meters. For point, multipoint, and areal geometries, ST_LengthSphere returns 0. For geometry collections, ST_LengthSphere returns the total length of the linear geometries in the collection in meters.

ST_LengthSphere interprets the coordinates of each point of the input geometry as longitude and latitude in degrees. For 3DZ, 3DM, or 4D geometries, only the first two coordinates are used.

Syntax

```
ST_LengthSphere(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION length in meters. The length computation is based on the spherical model of the Earth whose radius is Earth's mean radius of the World Geodetic System (WGS) 84 ellipsoidal model of the Earth.

If *geom* is null, then null is returned.

Examples

The following example SQL computes the length of a linestring in meters.

```
SELECT ST_LengthSphere(ST_GeomFromText('LINESTRING(10 10,45 45)'));
```

```
st_lengthsphere
-----
5127736.08292556
```

ST_Length2D

ST_Length2D is an alias for ST_Length. For more information, see [ST_Length](#).

ST_LineFromMultiPoint

ST_LineFromMultiPoint returns a linestring from an input multipoint geometry. The order of the points is preserved. The spatial reference system identifier (SRID) of the returned geometry is the same as that of the input geometry. The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_LineFromMultiPoint(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be MULTIPOINT.

Return type

GEOMETRY

If *geom* is null, then null is returned.

If *geom* is empty, then an empty LINESTRING is returned.

If *geom* contains empty points, then these empty points are ignored.

If *geom* isn't a MULTIPOINT, then error is returned.

Examples

The following SQL creates a linestring from a multipoint.

```
SELECT ST_AsEWKT(ST_LineFromMultiPoint(ST_GeomFromText('MULTIPOINT(0 0,10 0,10 10,5 5,0 5)',4326)));
```

```
st_asewkt
```

```
-----  
SRID=4326;LINESTRING(0 0,10 0,10 10,5 5,0 5)
```

ST_LineInterpolatePoint

ST_LineInterpolatePoint returns a point along a line at a fractional distance from the start of the line.

To determine point equality, ST_LineInterpolatePoint operates on the 2D projection of the input geometry. If the input geometry is empty, a copy of it is returned in the same dimension as the input. For 3DZ, 3DM, and 4D geometries, the z or m coordinate is the average of the z or m coordinates of the segment where the point lies.

Syntax

```
ST_LineInterpolatePoint(geom, fraction)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype is LINESTRING.

fraction

A value of data type `DOUBLE PRECISION` that represents the position of a point along the linestring for the line. The value is a fraction in the range 0–1, inclusive.

Return type

`GEOMETRY` of subtype `POINT`.

If *geom* or *fraction* is null, then null is returned.

If *geom* is empty, then the empty point is returned.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

If *fraction* is out of range, then an error is returned.

If *geom* is not a linestring, then an error is returned.

Examples

The following SQL returns a point halfway along a linestring.

```
SELECT ST_AsEWKT(ST_LineInterpolatePoint(ST_GeomFromText('LINESTRING(0 0, 5 5, 7 7, 10 10)'), 0.50));
```

```
st_asewkt
-----
POINT(5 5)
```

The following SQL returns a point 90 percent of the way along a linestring.

```
SELECT ST_AsEWKT(ST_LineInterpolatePoint(ST_GeomFromText('LINESTRING(0 0, 5 5, 7 7, 10 10)'), 0.90));
```

```
st_asewkt
-----
POINT(9 9)
```

ST_M

ST_M returns the m coordinate of an input point.

Syntax

```
ST_M(point)
```

Arguments

point

A POINT value of data type GEOMETRY.

Return type

DOUBLE PRECISION value of the m coordinate.

If *point* is null, then null is returned.

If *point* is a 2D or 3DZ point, then null is returned.

If *point* is the empty point, then null is returned.

If *point* is not a POINT, then an error is returned.

Examples

The following SQL returns the m coordinate of a point in a 3DM geometry.

```
SELECT ST_M(ST_GeomFromEWKT('POINT M (1 2 3)'));
```

```
st_m
-----
3
```

The following SQL returns the m coordinate of a point in a 4D geometry.

```
SELECT ST_M(ST_GeomFromEWKT('POINT ZM (1 2 3 4)'));
```

```
st_m
-----
4
```

ST_MakeEnvelope

ST_MakeEnvelope returns a geometry as follows:

- If the input coordinates specify a point, then the returned geometry is a point.
- If the input coordinates specify a line, then the returned geometry is a linestring.
- Otherwise, the returned geometry is a polygon, where the input coordinates specify the lower-left and upper-right corners of a box.

If provided, the spatial reference system identifier (SRID) value of the returned geometry is set to the input SRID value.

Syntax

```
ST_MakeEnvelope(xmin, ymin, xmax, ymax)
```

```
ST_MakeEnvelope(xmin, ymin, xmax, ymax, srid)
```

Arguments

xmin

A value of data type DOUBLE PRECISION. This value is the first coordinate of the lower-left corner of a box.

ymin

A value of data type DOUBLE PRECISION. This value is the second coordinate of the lower-left corner of a box.

xmax

A value of data type DOUBLE PRECISION. This value is the first coordinate of the upper-right corner of a box.

*y*max

A value of data type DOUBLE PRECISION. This value is the second coordinate of the upper-right corner of a box.

srid

A value of data type INTEGER that represents a spatial reference system identifier (SRID). If the SRID value is not provided, then it is set to zero.

Return type

GEOMETRY of subtype POINT, LINESTRING, or POLYGON.

The SRID of the returned geometry is set to *srid* or zero if *srid* isn't set.

If *xmin*, *ymin*, *xmax*, *ymin*, or *srid* is null, then null is returned.

If *srid* is negative, then an error is returned.

Examples

The following SQL returns a polygon representing an envelope defined by the four input coordinate values.

```
SELECT ST_AsEWKT(ST_MakeEnvelope(2,4,5,7));
```

```
st_astext
-----
POLYGON((2 4,2 7,5 7,5 4,2 4))
```

The following SQL returns a polygon representing an envelope defined by the four input coordinate values and an SRID value.

```
SELECT ST_AsEWKT(ST_MakeEnvelope(2,4,5,7,4326));
```

```
st_astext
-----
```

```
SRID=4326;POLYGON((2 4,2 7,5 7,5 4,2 4))
```

ST_MakeLine

ST_MakeLine creates a linestring from the input geometries.

The dimension of the returned geometry is the same as that of the input geometries. Both input geometries must be of the same dimension.

Syntax

```
ST_MakeLine(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT, LINESTRING, or MULTIPOINT.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT, LINESTRING, or MULTIPOINT.

Return type

GEOMETRY of subtype LINESTRING.

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* is the empty point or contains empty points, then these empty points are ignored.

If *geom1* and *geom2* are empty, then the empty LINESTRING is returned.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometries.

If *geom1* and *geom2* have different SRID values, then an error is returned.

If *geom1* or *geom2* is not a POINT, LINESTRING, or MULTIPOINT, then an error is returned.

If *geom1* and *geom2* have different dimensions, then an error is returned.

Examples

The following SQL constructs a linestring from two input linestrings.

```
SELECT ST_MakeLine(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27
29.31,77.29 29.07)'), ST_GeomFromText('LINESTRING(88.29 39.07,88.42 39.26,88.27
39.31,88.29 39.07)'));
```

```
st_makeline
```

```
-----
```

```

```

ST_MakePoint

ST_MakePoint returns a point geometry whose coordinate values are the input values.

Syntax

```
ST_MakePoint(x, y)
```

```
ST_MakePoint(x, y, z)
```

```
ST_MakePoint(x, y, z, m)
```

Arguments

x

A value of data type DOUBLE PRECISION representing the first coordinate.

y

A value of data type DOUBLE PRECISION representing the second coordinate.

z

A value of data type DOUBLE PRECISION representing the third coordinate.

m

A value of data type `DOUBLE PRECISION` representing the fourth coordinate.

Return type

`GEOMETRY` of subtype `POINT`.

The spatial reference system identifier (SRID) value of the returned geometry is set to 0.

If *x*, *y*, *z*, or *m* is null, then null is returned.

Examples

The following SQL returns a `GEOMETRY` type of subtype `POINT` with the provided coordinates.

```
SELECT ST_AsText(ST_MakePoint(1,3));
```

```
st_astext
-----
POINT(1 3)
```

The following SQL returns a `GEOMETRY` type of subtype `POINT` with the provided coordinates.

```
SELECT ST_AsEWKT(ST_MakePoint(1, 2, 3));
```

```
st_asewkt
-----
POINT Z (1 2 3)
```

The following SQL returns a `GEOMETRY` type of subtype `POINT` with the provided coordinates.

```
SELECT ST_AsEWKT(ST_MakePoint(1, 2, 3, 4));
```

```
st_asewkt
-----
POINT ZM (1 2 3 4)
```

ST_MakePolygon

ST_MakePolygon has two variants that return a polygon. One takes a single geometry, and another takes two geometries.

- The input of the first variant is a linestring that defines the outer ring of the output polygon.
- The input of the second variant is a linestring and a multilinestring. Both of these are empty or closed.

The boundary of the exterior ring of the output polygon is the input linestring, and the boundaries of the interior rings of the polygon are the linestrings in the input multilinestring. If the input linestring is empty, an empty polygon is returned. Empty linestrings in the multilinestring are disregarded. The spatial reference system identifier (SRID) of the resulting geometry is the common SRID of the two input geometries.

The dimension of the returned geometry is the same as that of the input geometries. The exterior ring and interior rings must be of the same dimension.

Syntax

```
ST_MakePolygon(geom1)
```

```
ST_MakePolygon(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING. The *linestring* value must be closed or empty.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be MULTILINESTRING.

Return type

GEOMETRY of subtype POLYGON.

The spatial reference system identifier (SRID) of the returned geometry is equal to the SRID of the inputs.

If *geom1*, or *geom2* is null, then null is returned.

If *geom1* is not a linestring, then an error is returned.

If *geom2* is not a multilinestring, then an error is returned.

If *geom1* is not closed, then an error is returned.

If *geom1* is a single point or is not closed, then an error is returned.

If *geom2* contains at least one linestring that has a single point or is not closed, then an error is returned.

If *geom1* and *geom2* have different SRID values, then an error is returned.

If *geom1* and *geom2* have different dimensions, then an error is returned.

Examples

The following SQL returns a polygon from an input linestring.

```
SELECT ST_AsText(ST_MakePolygon(ST_GeomFromText('LINESTRING(77.29 29.07,77.42
29.26,77.27 29.31,77.29 29.07)')));
```

```
st_astext
-----
POLYGON((77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07))
```

The following SQL creates a polygon from a closed linestring and a closed multilinestring. The linestring is used for the exterior ring of the polygon. The linestrings in the multilinestrings are used for the interior rings of the polygon.

```
SELECT ST_AsEWKT(ST_MakePolygon(ST_GeomFromText('LINESTRING(0 0,10 0,10 10,0 10,0 0)'),
ST_GeomFromText('MULTILINESTRING((1 1,1 2,2 1,1 1),(3 3,3 4,4 3,3 3)'))));
```

```
st_astext
-----
```

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(1 1,1 2,2 1,1 1),(3 3,3 4,4 3,3 3))
```

ST_MemSize

ST_MemSize returns the amount of memory space (in bytes) used by the input geometry. This size depends on the Amazon Redshift internal representation of the geometry and thus can change if the internal representation changes. You can use this size as an indication of the relative size of geometry objects in Amazon Redshift.

Syntax

```
ST_MemSize(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER representing the inherent dimension of *geom*.

If *geom* is null, then null is returned.

Examples

The following SQL returns the memory size of a geometry collection.

```
SELECT ST_MemSize(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((0 0,10 0,0 10,0 0)),LINESTRING(20 10,20 0,10 0))'))::varchar + ' bytes';
```

```
?column?
```

```
-----  
172 bytes
```

ST_MMax

ST_MMax returns the maximum m coordinate of an input geometry.

Syntax

```
ST_MMax(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the maximum m coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

If *geom* is a 2D or 3DZ geometry, then null is returned.

Examples

The following SQL returns the largest m coordinate of a linestring in a 3DM geometry.

```
SELECT ST_MMax(ST_GeomFromEWKT('LINESTRING M (0 1 2, 3 4 5, 6 7 8)'));
```

```
st_mmax
-----
      8
```

The following SQL returns the largest m coordinate of a linestring in a 4D geometry.

```
SELECT ST_MMax(ST_GeomFromEWKT('LINESTRING ZM (0 1 2 3, 4 5 6 7, 8 9 10 11)'));
```

```
st_mmax
-----
     11
```

ST_MMin

ST_MMin returns the minimum m coordinate of an input geometry.

Syntax

```
ST_MMin(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the minimum m coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

If *geom* is a 2D or 3DZ geometry, then null is returned.

Examples

The following SQL returns the smallest m coordinate of a linestring in a 3DM geometry.

```
SELECT ST_MMin(ST_GeomFromEWKT('LINESTRING M (0 1 2, 3 4 5, 6 7 8)'));
```

```
st_mmin  
-----  
2
```

The following SQL returns the smallest m coordinate of a linestring in a 4D geometry.

```
SELECT ST_MMin(ST_GeomFromEWKT('LINESTRING ZM (0 1 2 3, 4 5 6 7, 8 9 10 11)'));
```

```
st_mmin
```

3

ST_Multi

ST_Multi converts a geometry to the corresponding multitype. If the input geometry is already a multitype or a geometry collection, a copy of it is returned. If the input geometry is a point, linestring, or polygon, then a multipoint, multilinestring, or multipolygon, respectively, that contains the input geometry is returned.

Syntax

```
ST_Multi(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY with subtype MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, or GEOMETRYCOLLECTION.

The spatial reference system identifier (SRID) of the returned geometry is the same as that of the input geometry.

If *geom* is null, then null is returned.

Examples

The following SQL returns a multipoint from an input multipoint.

```
SELECT ST_AsEWKT(ST_Multi(ST_GeomFromText('MULTIPOINT((1 2),(3 4))', 4326)));
```

```
st_asewkt
```

```
-----  
SRID=4326;MULTIPOINT((1 2),(3 4))
```

The following SQL returns a multipoint from an input point.

```
SELECT ST_AsEWKT(ST_Multi(ST_GeomFromText('POINT(1 2)', 4326)));
```

```
st_asewkt
```

```
-----  
SRID=4326;MULTIPOINT((1 2))
```

The following SQL returns a geometry collection from an input geometry collection.

```
SELECT ST_AsEWKT(ST_Multi(ST_GeomFromText('GEOMETRYCOLLECTION(POINT(1 2),MULTIPOINT((1 2),(3 4)))', 4326)));
```

```
st_asewkt
```

```
-----  
SRID=4326;GEOMETRYCOLLECTION(POINT(1 2),MULTIPOINT((1 2),(3 4)))
```

ST_NDims

ST_NDims returns the coordinate dimension of a geometry. ST_NDims doesn't consider the topological dimension of a geometry. Instead, it returns a constant value depending on the dimension of the geometry.

Syntax

```
ST_NDims(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER representing the inherent dimension of *geom*.

If *geom* is null, then null is returned.

The values returned are as follows.

Returned value	Dimension of input geometry
2	2D
3	3DZ or 3DM
4	4D

Examples

The following SQL returns the number of dimensions of a 2D linestring.

```
SELECT ST_NDims(ST_GeomFromText('LINESTRING(0 0,1 1,2 2,0 0)'));
```

```
st_ndims
-----
2
```

The following SQL returns the number of dimensions of a 3DZ linestring.

```
SELECT ST_NDims(ST_GeomFromText('LINESTRING Z(0 0 3,1 1 3,2 2 3,0 0 3)'));
```

```
st_ndims
-----
3
```

The following SQL returns the number of dimensions of a 3DM linestring.

```
SELECT ST_NDims(ST_GeomFromText('LINESTRING M(0 0 4,1 1 4,2 2 4,0 0 4)'));
```

```
st_ndims
-----
3
```

The following SQL returns the number of dimensions of a 4D linestring.

```
SELECT ST_NDims(ST_GeomFromText('LINESTRING ZM(0 0 3 4,1 1 3 4,2 2 3 4,0 0 3 4)'));
```

```
st_ndims
-----
4
```

ST_NPoints

ST_NPoints returns the number of nonempty points in an input geometry or geography.

Syntax

```
ST_NPoints(geo)
```

Arguments

geo

A value of data type GEOMETRY or GEOGRAPHY, or an expression that evaluates to a GEOMETRY or GEOGRAPHY type.

Return type

INTEGER

If *geo* is an empty point, then 0 is returned.

If *geo* is null, then null is returned.

Examples

The following SQL returns the number of points in a linestring.

```
SELECT ST_NPoints(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07)'));
```

```
st_npoints
-----
4
```

The following SQL returns the number of points in a linestring in a geography.

```
SELECT ST_NPoints(ST_GeogFromText('LINESTRING(110 40, 2 3, -10 80, -7 9)'));
```

```
st_npoints
-----
4
```

ST_NRings

ST_NRings returns the number of rings in an input geometry.

Syntax

```
ST_NRings(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER

If *geom* is null, then null is returned.

The values returned are as follows.

Returned value	Geometry subtype
0	Returned if <i>geom</i> is a POINT, LINESTRING, MULTIPOINT, or MULTILINESTRING subtype

Returned value	Geometry subtype
The number of rings.	Returned if <i>geom</i> is a POLYGON or MULTIPOLYGON subtype
The number of rings in all components	Returned if <i>geom</i> is a GEOMETRYCOLLECTION subtype

Examples

The following SQL returns the number of rings in a multipolygon.

```
SELECT ST_NRings(ST_GeomFromText('MULTIPOLYGON(((0 0,10 0,0 10,0 0)),((0 0,-10 0,0
-10,0 0)))'));
```

```
st_nrings
-----
2
```

ST_NumGeometries

ST_NumGeometries returns the number of geometries in an input geometry.

Syntax

```
ST_NumGeometries(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER representing the number of geometries in *geom*.

If *geom* is null, then null is returned.

If *geom* is a single empty geometry, then 0 is returned.

If *geom* is a single nonempty geometry, then 1 is returned.

If *geom* is a GEOMETRYCOLLECTION or a MULTI subtype, then the number of geometries is returned.

Examples

The following SQL returns the number of geometries in the input multilinestring.

```
SELECT ST_NumGeometries(ST_GeomFromText('MULTILINESTRING((0 0,1 0,0 5),(3 4,13 26))'));
```

```
st_numgeometries
-----
2
```

ST_NumInteriorRings

ST_NumInteriorRings returns the number of rings in an input polygon geometry.

Syntax

```
ST_NumInteriorRings(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER

If *geom* is null, then null is returned.

If *geom* is not a polygon, then null is returned.

Examples

The following SQL returns the number of interior rings in the input polygon.

```
SELECT ST_NumInteriorRings(ST_GeomFromText('POLYGON((0 0,100 0,100 100,0 100,0 0),(1
1,1 5,5 1,1 1),(7 7,7 8,8 7,7 7))'));
```

```
st_numinteriorrings
```

```
-----
```

```
2
```

ST_NumPoints

ST_NumPoints returns the number of points in an input geometry.

Syntax

```
ST_NumPoints(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER

If *geom* is null, then null is returned.

If *geom* is not of subtype LINESTRING, then null is returned.

Examples

The following SQL returns the number of points in the input linestring.

```
SELECT ST_NumPoints(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27
29.31,77.29 29.07)'));)
```

```
st_numpoints
```

```
-----
```

4

The following SQL returns null because the input *geom* is not of subtype LINESTRING.

```
SELECT ST_NumPoints(ST_GeomFromText('MULTIPOINT(1 2,3 4)'));
```

```
st_numpoints  
-----
```

ST_Perimeter

For an input areal geometry, *ST_Perimeter* returns the Cartesian perimeter (length of the boundary) of the 2D projection. The perimeter units are the same as the units in which the coordinates of the input geometry are expressed. The function returns zero (0) for points, multipoints, and linear geometries. When the input is a geometry collection, the function returns the sum of the perimeters of the geometries in the collection.

For an input geography, *ST_Perimeter* returns the geodesic perimeter (length of the boundary) of the 2D projection of an input areal geography computed on the spheroid determined by the SRID. The unit of perimeter is in meters. The function returns zero (0) for points, multipoints, and linear geographies. When the input is a geometry collection, the function returns the sum of the perimeters of the geographies in the collection.

Syntax

```
ST_Perimeter(geo)
```

Arguments

geo

A value of data type GEOMETRY or GEOGRAPHY, or an expression that evaluates to a GEOMETRY or GEOGRAPHY type.

Return type

DOUBLE PRECISION

If *geo* is null, then null is returned.

If the SRID value is not found, then an error is returned.

Examples

The following SQL returns the Cartesian perimeter of a multipolygon.

```
SELECT ST_Perimeter(ST_GeomFromText('MULTIPOLYGON(((0 0,10 0,0 10,0 0)),((10 0,20 0,20
10,10 0)))'));;
```

```
st_perimeter
-----
```

```
68.2842712474619
```

The following SQL returns the Cartesian perimeter of a multipolygon.

```
SELECT ST_Perimeter(ST_GeomFromText('MULTIPOLYGON(((0 0,10 0,0 10,0 0)),((10 0,20 0,20
10,10 0)))'));;
```

```
st_perimeter
-----
```

```
68.2842712474619
```

The following SQL returns the perimeter of a polygon in a geography.

```
SELECT ST_Perimeter(ST_GeogFromText('SRID=4326;POLYGON((0 0,1 0,0 1,0 0))'));;
```

```
st_perimeter
-----
```

```
378790.428393693
```

The following SQL returns the perimeter of a linestring in a geography.

```
SELECT ST_Perimeter(ST_GeogFromText('SRID=4326;LINESTRING(5 0,10 0))');;
```

```
st_perimeter
-----
0
```

ST_Perimeter2D

ST_Perimeter2D is an alias for ST_Perimeter. For more information, see [ST_Perimeter](#).

ST_Point

ST_Point returns a point geometry from the input coordinate values.

Syntax

```
ST_Point(x, y)
```

Arguments

x

A value of data type DOUBLE PRECISION that represents a first coordinate.

y

A value of data type DOUBLE PRECISION that represents a second coordinate.

Return type

GEOMETRY of subtype POINT.

The spatial reference system identifier (SRID) value of the returned geometry is set to 0.

If *x* or *y* is null, then null is returned.

Examples

The following SQL constructs a point geometry from the input coordinates.

```
SELECT ST_AsText(ST_Point(5.0, 7.0));
```

```
st_astext
```

```
-----  
POINT(5 7)
```

ST_PointN

ST_PointN returns a point in a linestring as specified by an index value. Negative index values are counted backward from the end of the linestring, so that -1 is the last point.

The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_PointN(geom, index)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING.

index

A value of data type INTEGER that represents the index of a point in a linestring.

Return type

GEOMETRY of subtype POINT.

The spatial reference system identifier (SRID) value of the returned geometry is set to 0.

If *geom* or *index* is null, then null is returned.

If *index* is out of range, then null is returned.

If *geom* is empty, then null is returned.

If *geom* is not a LINESTRING, then null is returned.

Examples

The following SQL returns an extended well-known text (EWKT) representation of a six-point LINESTRING to a GEOMETRY object and returns the point at index 5 of the linestring.

```
SELECT ST_AsEWKT(ST_PointN(ST_GeomFromText('LINESTRING(0 0,10 0,10 10,5 5,0 5,0 0)',4326), 5));
```

```
st_asewkt  
-----  
SRID=4326;POINT(0 5)
```

ST_Points

ST_Points returns a multipoint geometry containing all nonempty points in the input geometry. ST_Points doesn't remove points that are duplicated in the input, including the start and end points of ring geometries.

Syntax

```
ST_Points(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY of subtype MULTIPOINT.

The spatial reference system identifier (SRID) value of the returned geometry is the same as *geom*.

If *geom* is null, then null is returned.

If *geom* is empty, then the empty multipoint is returned.

Examples

The following SQL examples construct a multipoint geometry from the input geometry. The result is a multipoint geometry containing the nonempty points in the input geometry.

```
SELECT ST_AsEWKT(ST_Points(ST_SetSRID(ST_GeomFromText('LINESTRING(1 0,2 0,3 0)'),  
4326)));
```

```
st_asewkt
-----
SRID=4326;MULTIPOINT((1 0),(2 0),(3 0))
```

```
SELECT ST_AsEWKT(ST_Points(ST_SetSRID(ST_GeomFromText('MULTIPOLYGON(((0 0,1 0,0 1,0
0)))'), 4326)));
```

```
st_asewkt
-----
SRID=4326;MULTIPOINT((0 0),(1 0),(0 1),(0 0))
```

ST_Polygon

ST_Polygon returns a polygon geometry whose outer ring is the input linestring with the value that was input for the spatial reference system identifier (SRID).

The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_Polygon(linestring, srid)
```

Arguments

linestring

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING that represents a linestring. The *linestring* value must be closed.

srid

A value of data type INTEGER that represents a SRID.

Return type

GEOMETRY of subtype POLYGON.

The SRID value of the returned geometry is set to *srid*.

If *linestring* or *srid* is null, then null is returned.

If *linestring* is not a linestring, then an error is returned.

If *linestring* is not closed, then an error is returned.

If *srid* is negative, then an error is returned.

Examples

The following SQL constructs a polygon with an SRID value.

```
SELECT ST_AsEWKT(ST_Polygon(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27
29.31,77.29 29.07)'),4356));
```

```
st_asewkt
-----
SRID=4356;POLYGON((77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07))
```

ST_RemovePoint

ST_RemovePoint returns a linestring geometry that has the point of the input geometry at an index position removed.

The index is zero-based. The spatial reference system identifier (SRID) of the result is the same as the input geometry. The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_RemovePoint(geom, index)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING.

index

A value of data type INTEGER that represents the position of a zero-based index.

Return type

GEOMETRY

If *geom* or *index* is null, then null is returned.

If *geom* is not subtype LINESTRING, then an error is returned.

If *index* is out of range, then an error is returned. Valid values for the index position are between 0 and ST_NumPoints(*geom*) minus 1.

Examples

The following SQL removes the last point in a linestring.

```
WITH tmp(g) AS (SELECT ST_GeomFromText('LINESTRING(0 0,10 0,10 10,5 5,0 5)',4326))
SELECT ST_AsEWKT(ST_RemovePoint(g, ST_NumPoints(g) - 1)) FROM tmp;
```

```
st_asewkt
-----
SRID=4326;LINESTRING(0 0,10 0,10 10,5 5)
```

ST_Reverse

ST_Reverse reverses the order of the vertices for linear and areal geometries. For point or multipoint geometries, a copy of the original geometry is returned. For geometry collections, ST_Reverse reverses the order of the vertices for each of the geometries in the collection.

The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_Reverse(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

The spatial reference system identifier (SRID) of the returned geometry is the same as that of the input geometry.

If *geom* is null, then null is returned.

Examples

The following SQL reverses the order of the points in a linestring.

```
SELECT ST_AsEWKT(ST_Reverse(ST_GeomFromText('LINESTRING(1 0,2 0,3 0,4 0)', 4326)));
```

```
st_asewkt
```

```
-----  
SRID=4326;LINESTRING(4 0,3 0,2 0,1 0)
```

ST_SetPoint

ST_SetPoint returns a linestring with updated coordinates with respect to the input linestring's position as specified by the index. The new coordinates are the coordinates of the input point.

The dimension of the returned geometry is the same as that of the *geom1* value. If *geom1* and *geom2* have different dimensions, *geom2* is projected to the dimension of *geom1*.

Syntax

```
ST_SetPoint(geom1, index, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING.

index

A value of data type INTEGER that represents the position of an index. A 0 refers to the first point of the linestring from the left, 1 refers to the second point, and so on. The index can be

a negative value. A -1 refers to the first point of the linestring from the right, -2 refers to the second point of the linestring from the right, and so on.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be POINT.

Return type

GEOMETRY

If *geom2* is the empty point, then *geom1* is returned.

If *geom1*, *geom2*, or *index* is null, then null is returned.

If *geom1* is not a linestring, then an error is returned.

If *index* is not within a valid index range, then an error is returned.

If *geom2* is not a point, then an error is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

Examples

The following SQL returns a new linestring where we set the second point of the input linestring with the specified point.

```
SELECT ST_AsText(ST_SetPoint(ST_GeomFromText('LINESTRING(1 2, 3 2, 5 2, 1 2)'), 2,  
ST_GeomFromText('POINT(7 9)')));
```

```
st_astext  
-----  
LINESTRING(1 2,3 2,7 9,1 2)
```

The following SQL example returns a new linestring where we set the third point from the right (the index is negative) of the linestring with the specified point.

```
SELECT ST_AsText(ST_SetPoint(ST_GeomFromText('LINESTRING(1 2, 3 2, 5 2, 1 2)'), -3,  
ST_GeomFromText('POINT(7 9)')));
```

```
st_astext
```

```
-----
```

```
LINESTRING(1 2,7 9,5 2,1 2)
```

ST_SetSRID

ST_SetSRID returns a geometry that is the same as input geometry, except updated with the value input for the spatial reference system identifier (SRID).

Syntax

```
ST_SetSRID(geom, srid)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

srid

A value of data type INTEGER that represents a SRID.

Return type

GEOMETRY

The SRID value of the returned geometry is set to *srid*.

If *geom* or *srid* is null, then null is returned.

If *srid* is negative, then an error is returned.

Examples

The following SQL sets the SRID value of a linestring.

```
SELECT ST_AsEWKT(ST_SetSRID(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27
29.31,77.29 29.07)'),50));
```

```
st_asewkt
```

```
-----
```

```
SRID=50;LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07)
```

ST_Simplify

ST_Simplify returns a simplified copy of the input geometry using the Ramer-Douglas-Peucker algorithm with the given tolerance. The topology of the input geometry might not be preserved. For more information about the algorithm, see [Ramer–Douglas–Peucker algorithm](#) in Wikipedia.

When ST_Simplify calculates distances to simplify a geometry, ST_Simplify operates on the 2D projection of the input geometry.

Syntax

```
ST_Simplify(geom, tolerance)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

tolerance

A value of data type DOUBLE PRECISION that represents the tolerance level of the Ramer-Douglas-Peucker algorithm. If *tolerance* is a negative number, then zero is used.

Return type

GEOMETRY.

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometry.

The dimension of the returned geometry is the same as that of the input geometry.

If *geom* is null, then null is returned.

Examples

The following SQL simplifies the input linestring using a Euclidean distance tolerance of 1 with the Ramer-Douglas-Peucker algorithm. The units of the distance are the same as those of the coordinates of the geometry.

```
SELECT ST_AsEWKT(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,1 2,1 1,2 2,2 1)'), 1));
```

```
st_asewkt
-----
LINESTRING(0 0,1 2,2 1)
```

ST_SRID

ST_SRID returns the spatial reference system identifier (SRID) of an input geometry. For more information about an SRID, see [Querying spatial data in Amazon Redshift](#).

Syntax

```
ST_SRID(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

INTEGER representing the SRID value of *geom*.

If *geom* is null, then null is returned.

Examples

The following SQL returns an SRID value of a linestring that is set to SRID 4326.

```
SELECT ST_SRID(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07)', 4326));
```

```
st_srid
-----
4326
```

The following SQL returns an SRID value of a linestring that is not set when constructed. This results in 0 for the SRID value.

```
SELECT ST_SRID(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29
29.07)'));
```

```
st_srid
-----
0
```

ST_StartPoint

ST_StartPoint returns the first point of an input linestring. The spatial reference system identifier (SRID) value of the result is the same as that of the input geometry. The dimension of the returned geometry is the same as that of the input geometry.

Syntax

```
ST_StartPoint(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. The subtype must be LINESTRING.

Return type

GEOMETRY

If *geom* is null, then null is returned.

If *geom* is empty, then null is returned.

If *geom* isn't a LINESTRING, then null is returned.

Examples

The following SQL returns an extended well-known text (EWKT) representation of a four-point LINESTRING to a GEOMETRY object and returns the start point of the linestring.

```
SELECT ST_AsEWKT(ST_StartPoint(ST_GeomFromText('LINESTRING(0 0,10 0,10 10,5 5,0
5)',4326)));
```

```
st_asewkt
-----
SRID=4326;POINT(0 0)
```

ST_Touches

ST_Touches returns true if the 2D projections of the two input geometries touch. The two geometries touch if they are nonempty, intersect, and have no interior points in common.

Syntax

```
ST_Touches(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if a polygon touches a linestring.

```
SELECT ST_Touches(ST_GeomFromText('POLYGON((0 0,10 0,0 10,0 0))'),
  ST_GeomFromText('LINESTRING(20 10,20 0,10 0)');
```

```
st_touches
-----
t
```

ST_Transform

ST_Transform returns a new geometry with coordinates that are transformed in a spatial reference system defined by the input spatial reference system identifier (SRID).

Syntax

```
ST_Transform(geom, srid)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

srid

A value of data type INTEGER that represents an SRID.

Return type

GEOMETRY.

The SRID value of the returned geometry is set to *srid*.

If *geom* or *srid* is null, then null is returned.

If the SRID value associated with the input *geom* does not exist, then an error is returned.

If *srid* does not exist, then an error is returned.

Examples

The following SQL transforms the SRID of an empty geometry collection.

```
SELECT ST_AsEWKT(ST_Transform(ST_GeomFromText('GEOMETRYCOLLECTION EMPTY', 3857),
4326));
```

```
st_asewkt
```

```
-----
SRID=4326;GEOMETRYCOLLECTION EMPTY
```

The following SQL transforms the SRID of a linestring.

```
SELECT ST_AsEWKT(ST_Transform(ST_GeomFromText('LINESTRING(110 40, 2 3, -10 80, -7 9,
-22 -33)', 4326), 26918));
```

```
st_asewkt
```

```
-----
SRID=26918;LINESTRING(73106.6977300955 15556182.9688576,14347201.5059964
1545178.32934967,1515090.41262989 9522193.25115316,10491250.83295
2575457.28410878,5672303.72135968 -5233682.61176205)
```

The following SQL transforms the SRID of a polygon.

```
SELECT ST_AsEWKT(ST_Transform(ST_GeomFromText('POLYGON Z ((-10 10 -7, -65 10 -6, -10 64
-5, -10 10 -7), (-11 11 5, -11 12 6, -12 11 7, -11 11 5))', 6989), 6317));
```

```
st_asewkt
```

```
-----
SRID=6317;POLYGON Z ((6186430.2771091 -1090834.57212608
1100247.33216237,2654831.67853801 -5693304.90741276 1100247.50581055,2760987.41750022

1209007.49312929,6146675.25029258 -1194792.63532103 1209007.1115113))
```

ST_Union

ST_Union returns a geometry representing the union of two geometries. That is, it merges the input geometries to produce a resulting geometry with no overlaps.

Syntax

```
ST_Union(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

GEOMETRY

The spatial reference system identifier (SRID) value of the returned geometry is the SRID value of the input geometries.

If *geom1* or *geom2* is null, then null is returned.

If *geom1* or *geom2* are empty, then an empty geometry is returned.

If *geom1* and *geom2* don't have the same value for the spatial reference system identifier (SRID), then an error is returned.

If *geom1* or *geom2* is a geometry collection, linestring, or multilinestring, then an error is returned.

If *geom1* or *geom2* is not a two-dimensional (2D) geometry, then an error is returned.

Examples

The following SQL returns the non-empty geometry representing the union of two input geometries.

```
SELECT ST_AsEWKT(ST_Union(ST_GeomFromText('POLYGON((0 0,100 100,0 200,0 0))'),
  ST_GeomFromText('POLYGON((0 0,10 0,0 10,0 0))')));
```

```
st_asewkt
```

```
-----  
POLYGON((0 0,0 200,100 100,5 5,10 0,0 0))
```

ST_Within

ST_Within returns true if the 2D projection of the first input geometry is within the 2D projection of the second input geometry.

For example, geometry A is within geometry B if every point in A is a point in B and their interiors have nonempty intersection.

ST_Within(A, B) is equivalent to ST_Contains(B, A).

Syntax

```
ST_Within(geom1, geom2)
```

Arguments

geom1

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type. This value is compared with *geom2* to determine if it is within *geom2*.

geom2

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom1* or *geom2* is null, then null is returned.

If *geom1* and *geom2* don't have the same spatial reference system identifier (SRID) value, then an error is returned.

If *geom1* or *geom2* is a geometry collection, then an error is returned.

Examples

The following SQL checks if the first polygon is within the second polygon.

```
SELECT ST_Within(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'));
```

```
st_within
-----
true
```

ST_X

ST_X returns the first coordinate of an input point.

Syntax

```
ST_X(point)
```

Arguments

point

A POINT value of data type GEOMETRY.

Return type

DOUBLE PRECISION value of the first coordinate.

If *point* is null, then null is returned.

If *point* is the empty point, then null is returned.

If *point* is not a POINT, then an error is returned.

Examples

The following SQL returns the first coordinate of a point.

```
SELECT ST_X(ST_Point(1,2));
```

```
st_x  
-----  
1.0
```

ST_XMax

ST_XMax returns the maximum first coordinate of an input geometry.

Syntax

```
ST_XMax(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the maximum first coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

Examples

The following SQL returns the largest first coordinate of a linestring.

```
SELECT ST_XMax(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29  
29.07)'));
```

```
st_xmax  
-----  
77.42
```

ST_XMin

ST_XMin returns the minimum first coordinate of an input geometry.

Syntax

```
ST_XMin(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the minimum first coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

Examples

The following SQL returns the smallest first coordinate of a linestring.

```
SELECT ST_XMin(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07)'));
```

```
st_xmin
-----
77.27
```

ST_Y

ST_Y returns the second coordinate of an input point.

Syntax

```
ST_Y(point)
```

Arguments

point

A POINT value of data type GEOMETRY.

Return type

DOUBLE PRECISION value of the second coordinate.

If *point* is null, then null is returned.

If *point* is the empty point, then null is returned.

If *point* is not a POINT, then an error is returned.

Examples

The following SQL returns the second coordinate of a point.

```
SELECT ST_Y(ST_Point(1,2));
```

```
st_y  
-----  
2.0
```

ST_YMax

ST_YMax returns the maximum second coordinate of an input geometry.

Syntax

```
ST_YMax(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the maximum second coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

Examples

The following SQL returns the largest second coordinate of a linestring.

```
SELECT ST_YMax(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29
29.07)'));
```

```
st_ymax
-----
29.31
```

ST_YMin

ST_YMin returns the minimum second coordinate of an input geometry.

Syntax

```
ST_YMin(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the minimum second coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

Examples

The following SQL returns the smallest second coordinate of a linestring.

```
SELECT ST_YMin(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29
29.07)'));
```

```
st_ymin
-----
29.07
```

ST_Z

ST_Z returns the z coordinate of an input point.

Syntax

```
ST_Z(point)
```

Arguments

point

A POINT value of data type GEOMETRY.

Return type

DOUBLE PRECISION value of the m coordinate.

If *point* is null, then null is returned.

If *point* is a 2D or 3DM point, then null is returned.

If *point* is the empty point, then null is returned.

If *point* is not a POINT, then an error is returned.

Examples

The following SQL returns the z coordinate of a point in a 3DZ geometry.

```
SELECT ST_Z(ST_GeomFromEWKT('POINT Z (1 2 3)'));
```

```
st_z  
-----  
3
```

The following SQL returns the z coordinate of a point in a 4D geometry.

```
SELECT ST_Z(ST_GeomFromEWKT('POINT ZM (1 2 3 4)'));
```

```
st_z  
-----  
3
```

ST_ZMax

ST_ZMax returns the maximum z coordinate of an input geometry.

Syntax

```
ST_ZMax(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the maximum z coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

If *geom* is a 2D or 3DM geometry, then null is returned.

Examples

The following SQL returns the largest z coordinate of a linestring in a 3DZ geometry.

```
SELECT ST_ZMax(ST_GeomFromEWKT('LINESTRING Z (0 1 2, 3 4 5, 6 7 8)'));
```

```
st_zmax
-----
      8
```

The following SQL returns the largest z coordinate of a linestring in a 4D geometry.

```
SELECT ST_ZMax(ST_GeomFromEWKT('LINESTRING ZM (0 1 2 3, 4 5 6 7, 8 9 10 11)'));
```

```
st_zmax
-----
     10
```

ST_ZMin

ST_ZMin returns the minimum z coordinate of an input geometry.

Syntax

```
ST_ZMin(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

DOUBLE PRECISION value of the minimum z coordinate.

If *geom* is empty, then null is returned.

If *geom* is null, then null is returned.

If *geom* is a 2D or 3DM geometry, then null is returned.

Examples

The following SQL returns the smallest z coordinate of a linestring in a 3DZ geometry.

```
SELECT ST_ZMin(ST_GeomFromEWKT('LINESTRING Z (0 1 2, 3 4 5, 6 7 8)'));
```

```
st_zmin
-----
      2
```

The following SQL returns the smallest z coordinate of a linestring in a 4D geometry.

```
SELECT ST_ZMin(ST_GeomFromEWKT('LINESTRING ZM (0 1 2 3, 4 5 6 7, 8 9 10 11)'));
```

```
st_zmin
-----
      2
```

SupportsBBox

SupportsBBox returns true if the input geometry supports encoding with a precomputed bounding box. For more information about support for bounding boxes, see [Bounding box](#).

Syntax

```
SupportsBBox(geom)
```

Arguments

geom

A value of data type GEOMETRY or an expression that evaluates to a GEOMETRY type.

Return type

BOOLEAN

If *geom* is null, then null is returned.

Examples

The following SQL returns true because the input point geometry supports being encoded with a bounding box.

```
SELECT SupportsBBox(AddBBox(ST_GeomFromText('POLYGON((0 0,1 0,0 1,0 0))')));
```

```
supportsbbox
-----
t
```

The following SQL returns false because the input point geometry doesn't support being encoded with a bounding box.

```
SELECT SupportsBBox(DropBBox(ST_GeomFromText('POLYGON((0 0,1 0,0 1,0 0))')));
```

```
supportsbbox
-----
f
```

String functions process and manipulate character strings or expressions that evaluate to character strings. When the *string* argument in these functions is a literal value, it must be enclosed in single quotation marks. Supported data types include CHAR and VARCHAR.

The following section provides the function names, syntax, and descriptions for supported functions. All offsets into strings are one-based.

Deprecated leader node-only functions

The following string functions are deprecated because they run only on the leader node. For more information, see [Leader node-only functions](#)

- GET_BYTE
- SET_BIT
- SET_BYTE
- TO_ASCII

|| (Concatenation) operator

Concatenates two expressions on either side of the || symbol and returns the concatenated expression.

Similar to [CONCAT function](#).

Note

If one or both of the expressions is null, the result of the concatenation is NULL.

Syntax

```
expression1 || expression2
```

Arguments

expression1

A CHAR string, a VARCHAR string, a binary expression, or an expression that evaluates to one of these types.

expression2

A CHAR string, a VARCHAR string, a binary expression, or an expression that evaluates to one of these types.

Return type

The return type of the string is the same as the type of the input arguments. For example, concatenating two strings of type VARCHAR returns a string of type VARCHAR.

Examples

The following examples use the USERS and VENUE tables from the TICKIT sample database. For more information, see [Sample database](#).

To concatenate the FIRSTNAME and LASTNAME fields from the USERS table in the sample database, use the following example.

```
SELECT (firstname || ' ' || lastname) as fullname
FROM users
ORDER BY 1
LIMIT 10;
```

```
+-----+
|  fullname  |
+-----+
| Aaron Banks |
| Aaron Booth |
| Aaron Browning |
| Aaron Burnett |
```

```
| Aaron Casey |
| Aaron Cash |
| Aaron Castro |
| Aaron Dickerson |
| Aaron Dixon |
| Aaron Dotson |
+-----+
```

To concatenate columns that might contain nulls, use the [NVL and COALESCE functions](#) expression. The following example uses NVL to return a 0 whenever NULL is encountered.

```
SELECT (venueName || ' seats ' || NVL(venueSeats, 0)) as seating
FROM venue
WHERE venuestate = 'NV' or venuestate = 'NC'
ORDER BY 1
LIMIT 10;
```

```
+-----+
|          seating          |
+-----+
| Ballys Hotel seats 0     |
| Bank of America Stadium seats 73298 |
| Bellagio Hotel seats 0  |
| Caesars Palace seats 0  |
| Harrahs Hotel seats 0   |
| Hilton Hotel seats 0    |
| Luxor Hotel seats 0     |
| Mandalay Bay Hotel seats 0 |
| Mirage Hotel seats 0    |
| New York New York seats 0 |
+-----+
```

ASCII function

The ASCII function returns the ASCII code, or the Unicode code-point, of the first character in the string that you specify. The function returns 0 if the string is empty. It returns NULL if the string is null.

Syntax

```
ASCII('string')
```

Argument

string

A CHAR string or a VARCHAR string.

Return type

INTEGER

Examples

To return NULL, use the following example. The NULLIF function returns NULL if the two arguments are the same, so the input argument for the ASCII function is NULL. For more information, see [NULLIF function](#).

```
SELECT ASCII(NULLIF('', ''));
```

```
+-----+
|  ascii  |
+-----+
|   NULL  |
+-----+
```

To return the ASCII code 0, use the following example.

```
SELECT ASCII('');
```

```
+-----+
|  ascii  |
+-----+
|     0   |
+-----+
```

To return the ASCII code 97 for the first letter of the word amazon, use the following example.

```
SELECT ASCII('amazon');
```

```
+-----+
|  ascii  |
+-----+
```

```
| 97 |  
+-----+
```

To return the ASCII code 65 for the first letter of the word Amazon, use the following example.

```
SELECT ASCII('Amazon');
```

```
+-----+  
| ascii |  
+-----+  
| 65 |  
+-----+
```

BPCHARCMP function

Compares the value of two strings and returns an integer. If the strings are identical, the function returns 0. If the first string is greater alphabetically, the function returns 1. If the second string is greater, the function returns -1.

For multibyte characters, the comparison is based on the byte encoding.

Synonym of [BTTEXT_PATTERN_CMP function](#).

Syntax

```
BPCHARCMP(string1, string2)
```

Arguments

string1

A CHAR string or a VARCHAR string.

string2

A CHAR string or a VARCHAR string.

Return type

INTEGER

Examples

The following examples use the USERS table from the TICKIT sample database. For more information, see [Sample database](#).

To determine whether a user's first name is alphabetically greater than the user's last name for the first ten entries in the USERS table, use the following example. For entries where the string for FIRSTNAME is later alphabetically than the string for LASTNAME, the function returns 1. If the LASTNAME is alphabetically later than FIRSTNAME, the function returns -1.

```
SELECT userid, firstname, lastname, BPCHARCMP(firstname, lastname)
FROM users
ORDER BY 1, 2, 3, 4
LIMIT 10;
```

userid	firstname	lastname	bpcharcmp
1	Rafael	Taylor	-1
2	Vladimir	Humphrey	1
3	Lars	Ratliff	-1
4	Barry	Roy	-1
5	Reagan	Hodge	1
6	Victor	Hernandez	1
7	Tamekah	Juarez	1
8	Colton	Roy	-1
9	Mufutau	Watkins	-1
10	Naida	Calderon	1

To return all entries in the USERS table where the function returns 0, use the following example. The function returns 0 when FIRSTNAME is identical to LASTNAME.

```
SELECT userid, firstname, lastname,
BPCHARCMP(firstname, lastname)
FROM users
WHERE BPCHARCMP(firstname, lastname)=0
ORDER BY 1, 2, 3, 4;
```

userid	firstname	lastname	bpcharcmp
--------	-----------	----------	-----------

```

|      62 | Chase   | Chase   |      0 |
|    4008 | Whitney | Whitney |      0 |
|   12516 | Graham  | Graham  |      0 |
|   13570 | Harper  | Harper  |      0 |
|   16712 | Cooper  | Cooper  |      0 |
|   18359 | Chase   | Chase   |      0 |
|   27530 | Bradley | Bradley |      0 |
|   31204 | Harding | Harding |      0 |
+-----+-----+-----+-----+

```

BTRIM function

The BTRIM function trims a string by removing leading and trailing blanks or by removing leading and trailing characters that match an optional specified string.

Syntax

```
BTRIM(string [, trim_chars ] )
```

Arguments

string

The input VARCHAR string to be trimmed.

trim_chars

The VARCHAR string containing the characters to be matched.

Return type

The BTRIM function returns a VARCHAR string.

Examples

The following example trims leading and trailing blanks from the string ' abc ':

```

select '   abc   ' as untrim, btrim('   abc   ') as trim;

untrim   | trim
-----+-----

```

```
abc | abc
```

The following example removes the leading and trailing 'xyz' strings from the string 'xyzaxyzbxyzcxyz'. The leading and trailing occurrences of 'xyz' are removed, but occurrences that are internal within the string are not removed.

```
select 'xyzaxyzbxyzcxyz' as untrim,
btrim('xyzaxyzbxyzcxyz', 'xyz') as trim;
```

```
untrim | trim
-----+-----
xyzaxyzbxyzcxyz | axyzbxyzc
```

The following example removes the leading and trailing parts from the string 'setuphistorycassettes' that match any of the characters in the *trim_chars* list 'tes'. Any t, e, or s that occur before another character that is not in the *trim_chars* list at the beginning or ending of the input string are removed.

```
SELECT btrim('setuphistorycassettes', 'tes');
```

```
btrim
-----
uphistoryca
```

BTTEXT_PATTERN_CMP function

Synonym for the BPCHARCMP function.

See [BPCHARCMP function](#) for details.

CHAR_LENGTH function

Synonym of the LEN function.

See [LEN function](#).

CHARACTER_LENGTH function

Synonym of the LEN function.

See [LEN function](#).

CHARINDEX function

Returns the location of the specified substring within a string.

See [POSITION function](#) and [STRPOS function](#) for similar functions.

Syntax

```
CHARINDEX( substring, string )
```

Arguments

substring

The substring to search for within the *string*.

string

The string or column to be searched.

Return type

INTEGER

The CHARINDEX function returns an INTEGER corresponding to the position of the substring (one-based, not zero-based). The position is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters. CHARINDEX returns 0 if the substring is not found within the string.

Examples

To return the position of the string `fish` within the word `dog`, use the following example.

```
SELECT CHARINDEX('fish', 'dog');
```

```
+-----+
| charindex |
+-----+
|          0 |
+-----+
```

To return the position of the string `fish` within the word `dogfish`, use the following example.

```
SELECT CHARINDEX('fish', 'dogfish');
```

```
+-----+
| charindex |
+-----+
|          4 |
+-----+
```

The following example uses the SALES table from the TICKIT sample database. For more information, see [Sample database](#).

To return the number of distinct sales transactions with a commission over 999.00 from the SALES table, use the following example. This command counts commissions greater than 999.00 by checking if the decimal is more than 4 places from the beginning of the commission value.

```
SELECT DISTINCT CHARINDEX('.', commission), COUNT (CHARINDEX('.', commission))
FROM sales
WHERE CHARINDEX('.', commission) > 4
GROUP BY CHARINDEX('.', commission)
ORDER BY 1,2;
```

```
+-----+-----+
| charindex | count |
+-----+-----+
|          5 |    629 |
+-----+-----+
```

CHR function

The CHR function returns the character that matches the ASCII code point value specified by the input parameter.

Syntax

```
CHR(number)
```

Argument

number

The input parameter is an INTEGER that represents an ASCII code point value.

Return type

CHAR

The CHR function returns a CHAR string if an ASCII character matches the input value. If the input number has no ASCII match, the function returns NULL.

Examples

To return the character that corresponds with ASCII code point 0, use the following example. Note that the CHR function returns NULL for the input 0.

```
SELECT CHR(0);
```

```
+-----+
| chr |
+-----+
|     |
+-----+
```

To return the character that corresponds with ASCII code point 65, use the following example.

```
SELECT CHR(65);
```

```
+-----+
| chr |
+-----+
| A   |
+-----+
```

To return distinct event names that begin with a capital A (ASCII code point 65), use the following example. The following example uses the EVENT table from the TICKIT sample database. For more information, see [Sample database](#).

```
SELECT DISTINCT eventname FROM event
WHERE SUBSTRING(eventname, 1, 1)=CHR(65) LIMIT 5;
```

```
+-----+
|          eventname          |
+-----+
| A Catered Affair          |
```

```
| As You Like It      |
| A Man For All Seasons |
| Alan Jackson       |
| Armando Manzanero  |
+-----+
```

COLLATE function

The COLLATE function overrides the collation of a string column or expression.

For information on how to create tables using database collation, see [CREATE TABLE](#).

For information on how to create databases using database collation, see [CREATE DATABASE](#).

Syntax

```
COLLATE( string, 'case_sensitive' | 'case_insensitive');
```

Arguments

string

A string column or expression that you want to override.

'case_sensitive' | 'case_insensitive'

A string constant of a collation name. Amazon Redshift only supports *case_sensitive* or *case_insensitive*.

Return type

The COLLATE function returns VARCHAR or CHAR depending on the first input expression type. This function only changes the collation of the first input argument and won't change its output value.

Examples

To create table T and define col1 in table T as case_sensitive, use the following example.

```
CREATE TABLE T ( col1 Varchar(20) COLLATE case_sensitive );

INSERT INTO T VALUES ('john'),('JOHN');
```

When you run the first query, Amazon Redshift only returns john. After the COLLATE function runs on col1, the collation becomes case_insensitive. The second query returns both john and JOHN.

```
SELECT * FROM T WHERE col1 = 'john';

+-----+
| col1 |
+-----+
| john |
+-----+

SELECT * FROM T WHERE COLLATE(col1, 'case_insensitive') = 'john';

+-----+
| col1 |
+-----+
| john |
| JOHN |
+-----+
```

To create table A and define col1 in table A as case_insensitive, use the following example.

```
CREATE TABLE A ( col1 Varchar(20) COLLATE case_insensitive );

INSERT INTO A VALUES ('john'),('JOHN');
```

When you run the first query, Amazon Redshift returns both john and JOHN. After the COLLATE function runs on col1, the collation becomes case_sensitive. The second query returns only john.

```
SELECT * FROM A WHERE col1 = 'john';

+-----+
| col1 |
+-----+
| john |
| JOHN |
+-----+

SELECT * FROM A WHERE COLLATE(col1, 'case_sensitive') = 'john';
```

```
+-----+
| col1 |
+-----+
| john |
+-----+
```

CONCAT function

The CONCAT function concatenates two expressions and returns the resulting expression. To concatenate more than two expressions, use nested CONCAT functions. The concatenation operator (||) between two expressions produces the same results as the CONCAT function.

Syntax

```
CONCAT ( expression1, expression2 )
```

Arguments

expression1, *expression2*

Both arguments can be a fixed-length character string, a variable-length character string, a binary expression, or an expression that evaluates to one of these inputs.

Return type

CONCAT returns an expression. The data type of the expression is the same type as the input arguments.

If the input expressions are of different types, Amazon Redshift tries to implicitly type casts one of the expressions. If values can't be cast, an error is returned.

Usage notes

- For both the CONCAT function and the concatenation operator, if one or both expressions is null, the result of the concatenation is null.

Examples

The following example concatenates two character literals:

```
SELECT CONCAT('December 25, ', '2008');
```

```
concat
-----
December 25, 2008
(1 row)
```

The following query, using the || operator instead of CONCAT, produces the same result:

```
SELECT 'December 25, ' || '2008';

?column?
-----
December 25, 2008
(1 row)
```

The following example uses a nested CONCAT function inside another CONCAT function to concatenate three character strings:

```
SELECT CONCAT('Thursday, ', CONCAT('December 25, ', '2008'));

concat
-----
Thursday, December 25, 2008
(1 row)
```

To concatenate columns that might contain NULLs, use the [NVL and COALESCE functions](#), which returns a given value when it encounters NULL. The following example uses NVL to return a 0 whenever NULL is encountered.

```
SELECT CONCAT(venueName, CONCAT(' seats ', NVL(venueSeats, 0))) AS seating
FROM venue WHERE venueState = 'NV' OR venueState = 'NC'
ORDER BY 1
LIMIT 5;

seating
-----
Ballys Hotel seats 0
Bank of America Stadium seats 73298
Bellagio Hotel seats 0
Caesars Palace seats 0
Harrahs Hotel seats 0
```

```
(5 rows)
```

The following query concatenates CITY and STATE values from the VENUE table:

```
SELECT CONCAT(venuecity, venuestate)
FROM venue
WHERE venueseats > 75000
ORDER BY venueseats;
```

```
concat
-----
DenverCO
Kansas CityMO
East RutherfordNJ
LandoverMD
(4 rows)
```

The following query uses nested CONCAT functions. The query concatenates CITY and STATE values from the VENUE table but delimits the resulting string with a comma and a space:

```
SELECT CONCAT(CONCAT(venuecity, ', '), venuestate)
FROM venue
WHERE venueseats > 75000
ORDER BY venueseats;
```

```
concat
-----
Denver, CO
Kansas City, MO
East Rutherford, NJ
Landover, MD
(4 rows)
```

The following example concatenates two binary expressions. Where abc is a binary value (with a hexadecimal representation of 616263) and def is a binary value (with hexadecimal representation of 646566). The result is automatically shown as the hexadecimal representation of the binary value.

```
SELECT CONCAT('abc'::VARBYTE, 'def'::VARBYTE);
```

```
concat
-----
```

```
616263646566
```

CRC32 function

CRC32 is a function used for error detection. The function uses a CRC32 algorithm to detect changes between source and target data. The CRC32 function converts a variable-length string into an 8-character string that is a text representation of the hexadecimal value of a 32 bit-binary sequence. To detect changes between source and target data, use the CRC32 function on the source data and store the output. Then, use the CRC32 function on the target data and compare that output to the output from the source data. The outputs will be the same if the data was not modified, and the outputs will be different if the data was modified.

Syntax

```
CRC32(string)
```

Arguments

string

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

Return type

The CRC32 function returns an 8-character string that is a text representation of the hexadecimal value of a 32-bit binary sequence. The Amazon Redshift CRC32 function is based on the CRC-32C polynomial.

Examples

To show the 8-bit value for the string Amazon Redshift.

```
SELECT CRC32('Amazon Redshift');
```

```
+-----+
|  crc32  |
+-----+
| f2726906 |
+-----+
```

DIFFERENCE function

The DIFFERENCE function compares the American Soundex codes of two strings. The function returns an INTEGER to indicate the number of matching characters between the Soundex codes.

A Soundex code is a string that is four characters long. A Soundex code represents how a word sounds rather than how it is spelled. For example, Smith and Smyth have the same Soundex code.

Syntax

```
DIFFERENCE(string1, string2)
```

Arguments

string1

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

string2

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

Return type

INTEGER

The DIFFERENCE function returns an INTEGER value from 0–4 that counts the number of matching characters in the American Soundex codes of the two strings. A Soundex code has 4 characters, so the DIFFERENCE function returns 4 when all 4 characters of the strings' American Soundex code values are the same. DIFFERENCE returns 0 if one of the two strings is empty. The function returns 1 if neither string contains valid characters. The DIFFERENCE function converts only English alphabetical lowercase or uppercase ASCII characters, including a–z and A–Z. DIFFERENCE ignores other characters.

Examples

To compare the Soundex values of the strings % and @, use the following example. The function returns 1 because neither string contains valid characters.

```
SELECT DIFFERENCE('%', '@');
```

```
+-----+
| difference |
+-----+
|          1 |
+-----+
```

To compare the Soundex values of Amazon and an empty string, use the following example. The function returns 0 because one of the two strings is empty.

```
SELECT DIFFERENCE('Amazon', '');
```

```
+-----+
| difference |
+-----+
|          0 |
+-----+
```

To compare the Soundex values of the strings Amazon and Ama, use the following example. The function returns 2 because 2 characters of the strings' Soundex values are the same.

```
SELECT DIFFERENCE('Amazon', 'Ama');
```

```
+-----+
| difference |
+-----+
|          2 |
+-----+
```

To compare the Soundex values of the strings Amazon and +-*/%Amazon, use the following example. The function returns 4 because all 4 characters of the strings' Soundex values are the same. Notice that the function ignores the invalid characters +-*/% in the second string.

```
SELECT DIFFERENCE('Amazon', '+-*/%Amazon');
```

```
+-----+
| difference |
+-----+
|          4 |
+-----+
```

```
+-----+
```

To compare the Soundex values of the strings AC/DC and Ay See Dee See, use the following example. The function returns 4 because all 4 characters of the strings' Soundex values are the same.

```
SELECT DIFFERENCE('AC/DC', 'Ay See Dee See');
```

```
+-----+
| difference |
+-----+
|          4 |
+-----+
```

INITCAP function

Capitalizes the first letter of each word in a specified string. INITCAP supports UTF-8 multibyte characters, up to a maximum of four bytes per character.

Syntax

```
INITCAP(string)
```

Argument

string

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

Return type

VARCHAR

Usage notes

The INITCAP function makes the first letter of each word in a string uppercase, and any subsequent letters are made (or left) lowercase. Therefore, it is important to understand which characters (other than space characters) function as word separators. A *word separator* character is any non-

alphanumeric character, including punctuation marks, symbols, and control characters. All of the following characters are word separators:

```
! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [ \ ] ^ _ ` { | } ~
```

Tabs, newline characters, form feeds, line feeds, and carriage returns are also word separators.

Examples

The following examples use data from the CATEGORY and USERS tables in the TICKIT sample database. For more information, see [Sample database](#).

To capitalize the initials of each word in the CATDESC column, use the following example.

```
SELECT catid, catdesc, INITCAP(catdesc)
FROM category
ORDER BY 1, 2, 3;
```

```
+-----+-----+-----+
+-----+-----+-----+
| catid |          catdesc          |          initcap          |
+-----+-----+-----+
|    1  | Major League Baseball    | Major League Baseball    |
|    2  | National Hockey League    | National Hockey League    |
|    3  | National Football League  | National Football League  |
|    4  | National Basketball Association | National Basketball Association |
|    5  | Major League Soccer       | Major League Soccer       |
|    6  | Musical theatre           | Musical Theatre           |
|    7  | All non-musical theatre   | All Non-Musical Theatre   |
|    8  | All opera and light opera  | All Opera And Light Opera  |
|    9  | All rock and pop music concerts | All Rock And Pop Music Concerts |
```

```

|    10 | All jazz singers and bands          | All Jazz Singers And Bands
|
|    11 | All symphony, concerto, and choir concerts | All Symphony, Concerto, And
Choir Concerts |
+-----+-----+
+-----+

```

To show that the INITCAP function does not preserve uppercase characters when they do not begin words, use the following example. For example, the string MLB becomes M**l**b.

```

SELECT INITCAP(catname)
FROM category
ORDER BY catname;

```

```

+-----+
| initcap |
+-----+
| Classical |
| Jazz      |
| Mlb       |
| Mls       |
| Musicals  |
| Nba       |
| Nfl       |
| Nhl       |
| Opera     |
| Plays     |
| Pop       |
+-----+

```

To show that non-alphanumeric characters other than spaces function as word separators, use the following example. Several letters in each string will be capitalized.

```

SELECT email, INITCAP(email)
FROM users
ORDER BY userid DESC LIMIT 5;

```

```

+-----+-----+-----+
|          email          |          initcap          |
+-----+-----+-----+
| urna.Ut@egetdictumplacerat.edu | Urna.Ut@Egetdictumplacerat.Edu |
| nibh.enim@egestas.ca          | Nibh.Enim@Egestas.Ca      |

```

```
| in@Donecat.ca | In@Donecat.Ca |  
| sodales@blanditviverraDonec.ca | Sodales@Blanditviverradonec.Ca |  
| sociis.natoque.penatibus@vitae.org | Sociis.Natoque.Penatibus@Vitae.Org |  
+-----+-----+
```

LEFT and RIGHT functions

These functions return the specified number of leftmost or rightmost characters from a character string.

The number is based on the number of characters, not bytes, so that multibyte characters are counted as single characters.

Syntax

```
LEFT( string, integer )
```

```
RIGHT( string, integer )
```

Arguments

string

A CHAR string, a VARCHAR string, or any expression that evaluates to a CHAR or VARCHAR string.

integer

A positive integer.

Return type

VARCHAR

Examples

The following example uses data from the EVENT table in the TICKIT sample database. For more information, see [Sample database](#).

To return the leftmost 5 and rightmost 5 characters from event names that have event IDs between 1000 and 1005, use the following example.

```

SELECT eventid, eventname,
LEFT(eventname,5) AS left_5,
RIGHT(eventname,5) AS right_5
FROM event
WHERE eventid BETWEEN 1000 AND 1005
ORDER BY 1;

```

eventid	eventname	left_5	right_5
1000	Gypsy	Gypsy	Gypsy
1001	Chicago	Chica	icago
1002	The King and I	The K	and I
1003	Pal Joey	Pal J	Joey
1004	Grease	Greas	rease
1005	Chicago	Chica	icago

LEN function

Returns the length of the specified string as the number of characters.

Syntax

LEN is a synonym of [LENGTH function](#), [CHAR_LENGTH function](#), [CHARACTER_LENGTH function](#), and [TEXTLEN function](#).

```
LEN(expression)
```

Argument

expression

A CHAR string, a VARCHAR string, a VARBYTE expression, or an expression that implicitly evaluates to a CHAR, VARCHAR, or VARBYTE type.

Return type

INTEGER

The LEN function returns an integer indicating the number of characters in the input string.

If the input string is a character string, the `LEN` function returns the actual number of characters in multi-byte strings, not the number of bytes. For example, a `VARCHAR(12)` column is required to store three four-byte Chinese characters. The `LEN` function will return 3 for that same string. To get the length of a string in bytes, use the [OCTET_LENGTH](#) function.

Usage notes

If *expression* is a `CHAR` string, trailing spaces are not counted.

If *expression* is a `VARCHAR` string, trailing spaces are counted.

Examples

To return the number of bytes and the number of characters in the string `français`, use the following example.

```
SELECT OCTET_LENGTH('français'),
LEN('français');
```

```
+-----+-----+
| octet_length | len |
+-----+-----+
|           9 |   8 |
+-----+-----+
```

To return the number of bytes and the number of characters in the string `français` without using the `OCTET_LENGTH` function, use the following example. For more information, see the [CAST function](#).

```
SELECT LEN(CAST('français' AS VARBYTE)) as bytes, LEN('français');
```

```
+-----+-----+
| bytes | len |
+-----+-----+
|     9 |   8 |
+-----+-----+
```

To return the number of characters in the strings `cat` with no trailing spaces, `cat` with three trailing spaces, `cat` with three trailing spaces cast as a `CHAR` of length 6, and `cat` with three trailing spaces cast as a `VARCHAR` of length 6, use the following example. Notice that the function

does not count trailing spaces for CHAR strings, but it does count trailing spaces for VARCHAR strings.

```
SELECT LEN('cat'), LEN('cat  '), LEN(CAST('cat  ' AS CHAR(6))) AS len_char,
       LEN(CAST('cat  ' AS VARCHAR(6))) AS len_varchar;
```

```
+-----+-----+-----+-----+
| len | len | len_char | len_varchar |
+-----+-----+-----+
|  3  |  6  |      3  |      6  |
+-----+-----+-----+-----+
```

The following example uses data from the VENUE table in the TICKIT sample database. For more information, see [Sample database](#).

To return the 10 longest venue names in the VENUE table, use the following example.

```
SELECT venuename, LEN(venuename)
FROM venue
ORDER BY 2 DESC, 1
LIMIT 10;
```

```
+-----+-----+
|          venuename          | len |
+-----+-----+
| Saratoga Springs Performing Arts Center | 39 |
| Lincoln Center for the Performing Arts  | 38 |
| Nassau Veterans Memorial Coliseum      | 33 |
| Jacksonville Municipal Stadium         | 30 |
| Rangers BallPark in Arlington         | 29 |
| University of Phoenix Stadium         | 29 |
| Circle in the Square Theatre          | 28 |
| Hubert H. Humphrey Metrodome          | 28 |
| Oriole Park at Camden Yards           | 27 |
| Dick's Sporting Goods Park            | 26 |
+-----+-----+
```

LENGTH function

Synonym of the LEN function.

See [LEN function](#).

LOWER function

Converts a string to lowercase. LOWER supports UTF-8 multibyte characters, up to a maximum of four bytes per character.

Syntax

```
LOWER(string)
```

Argument

string

A VARCHAR string or any expression that evaluates to the VARCHAR type.

Return type

string

The LOWER function returns a string that is the same data type as the input string. For example, if the input is a CHAR string, the function will return a CHAR string.

Examples

The following example uses data from the CATEGORY table in the TICKIT sample database. For more information, see [Sample database](#).

To convert the VARCHAR strings in the CATNAME column to lowercase, use the following example.

```
SELECT catname, LOWER(catname) FROM category ORDER BY 1,2;
```

```
+-----+-----+
| catname | lower |
+-----+-----+
| Classical | classical |
| Jazz      | jazz     |
| MLB       | mlb      |
| MLS       | mls      |
| Musicals  | musicals |
| NBA       | nba      |
| NFL       | nfl      |
| NHL       | nhl      |
```

```
| Opera      | opera      |
| Plays     | plays     |
| Pop       | pop       |
+-----+-----+
```

LPAD and RPAD functions

These functions prepend or append characters to a string, based on a specified length.

Syntax

```
LPAD(string1, length, [ string2 ])
```

```
RPAD(string1, length, [ string2 ])
```

Arguments

string1

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

length

An integer that defines the length of the result of the function. The length of a string is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters. If *string1* is longer than the specified length, it is truncated (on the right). If *length* is zero or a negative number, the result of the function is an empty string.

string2

(Optional) One or more characters that are prepended or appended to *string1*. If this argument is not specified, spaces are used.

Return type

VARCHAR

Examples

The following examples use data from the EVENT table in the TICKIT sample database. For more information, see [Sample database](#).

To truncate a specified set of event names to 20 characters and prepend the shorter names with spaces, use the following example.

```
SELECT LPAD(eventname, 20) FROM event
WHERE eventid BETWEEN 1 AND 5 ORDER BY 1;
```

```
+-----+
|      lpad      |
+-----+
|      Salome    |
|    Il Trovatore |
|    Boris Godunov |
|  Gotterdammerung |
|La Cenerentola (Cind |
+-----+
```

To truncate the same set of event names to 20 characters but append the shorter names with 0123456789, use the following example.

```
SELECT RPAD(eventname, 20, '0123456789') FROM event
WHERE eventid BETWEEN 1 AND 5 ORDER BY 1;
```

```
+-----+
|      rpad      |
+-----+
| Boris Godunov0123456 |
| Gotterdammerung01234 |
| Il Trovatore01234567 |
| La Cenerentola (Cind |
| Salome01234567890123 |
+-----+
```

LTRIM function

Trims characters from the beginning of a string. Removes the longest string containing only characters in the trim characters list. Trimming is complete when a trim character does not appear in the input string.

Syntax

```
LTRIM( string [, trim_chars] )
```

Arguments

string

A string column, expression, or string literal to be trimmed.

trim_chars

A string column, expression, or string literal that represents the characters to be trimmed from the beginning of *string*. If not specified, a space is used as the trim character.

Return type

The LTRIM function returns a character string that is the same data type as the input *string* (CHAR or VARCHAR).

Examples

The following example trims the year from the `listtime` column. The trim characters in string literal `'2008-'` indicate the characters to be trimmed from the left. If you use the trim characters `'028-'`, you achieve the same result.

```
select listid, listtime, ltrim(listtime, '2008-')
from listing
order by 1, 2, 3
limit 10;
```

listid	listtime	ltrim
1	2008-01-24 06:43:29	1-24 06:43:29
2	2008-03-05 12:25:29	3-05 12:25:29
3	2008-11-01 07:35:33	11-01 07:35:33
4	2008-05-24 01:18:37	5-24 01:18:37
5	2008-05-17 02:29:11	5-17 02:29:11
6	2008-08-15 02:08:13	15 02:08:13
7	2008-11-15 09:38:15	11-15 09:38:15
8	2008-11-09 05:07:30	11-09 05:07:30
9	2008-09-09 08:03:36	9-09 08:03:36
10	2008-06-17 09:44:54	6-17 09:44:54

LTRIM removes any of the characters in *trim_chars* when they appear at the beginning of *string*. The following example trims the characters 'C', 'D', and 'G' when they appear at the beginning of `VENUENAME`, which is a VARCHAR column.

```
select venueid, venuename, ltrim(venueid, 'CDG')
from venue
where venueid like '%Park'
order by 2
limit 7;
```

venueid	venueid	btrim
121	ATT Park	ATT Park
109	Citizens Bank Park	itizens Bank Park
102	Comerica Park	omerica Park
9	Dick's Sporting Goods Park	ick's Sporting Goods Park
97	Fenway Park	Fenway Park
112	Great American Ball Park	reat American Ball Park
114	Miller Park	Miller Park

The following example uses the trim character 2 which is retrieved from the venueid column.

```
select ltrim('2008-01-24 06:43:29', venueid)
from venue where venueid=2;
```

```
ltrim
-----
008-01-24 06:43:29
```

The following example does not trim any characters because a 2 is found before the '0' trim character.

```
select ltrim('2008-01-24 06:43:29', '0');
```

```
ltrim
-----
2008-01-24 06:43:29
```

The following example uses the default space trim character and trims the two spaces from the beginning of the string.

```
select ltrim(' 2008-01-24 06:43:29');
```

```
ltrim
```

2008-01-24 06:43:29

OCTETINDEX function

The OCTETINDEX function returns the location of a substring within a string as a number of bytes.

Syntax

```
OCTETINDEX(substring, string)
```

Arguments

substring

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

string

A CHAR string, a VARCHAR string, or an expression that implicitly evaluates to a CHAR or VARCHAR type.

Return type

INTEGER

The OCTETINDEX function returns an INTEGER value corresponding to the position of the *substring* within the *string* as a number of bytes, where the first character in the *string* is counted as 1. If the *string* doesn't contain multibyte characters, the result is equal to the result of the CHARINDEX function. If the *string* does not contain the *substring*, the function returns 0. If the *substring* is empty, the function returns 1.

Examples

To return the position of the substring `q` in the string `Amazon Redshift`, use the following example. This example returns 0 because the *substring* is not in the *string*.

```
SELECT OCTETINDEX('q', 'Amazon Redshift');
```

```
+-----+
| octetindex |
+-----+
|          0 |
+-----+
```

To return the position of an empty substring in the string `Amazon Redshift`, use the following example. This example returns 1 because the *substring* is empty.

```
SELECT OCTETINDEX('', 'Amazon Redshift');
```

```
+-----+
| octetindex |
+-----+
|          1 |
+-----+
```

To return the position of the substring `Redshift` in the string `Amazon Redshift`, use the following example. This example returns 8 because the *substring* begins on the eighth byte of the *string*.

```
SELECT OCTETINDEX('Redshift', 'Amazon Redshift');
```

```
+-----+
| octetindex |
+-----+
|          8 |
+-----+
```

To return the position of the substring `Redshift` in the string `Amazon Redshift`, use the following example. This example returns 21 because the first six characters of the *string* are double-byte characters.

```
SELECT OCTETINDEX('Redshift', 'Ἀμαζον Amazon Redshift');
```

```
+-----+
| octetindex |
+-----+
|         21 |
+-----+
```

OCTET_LENGTH function

Returns the length of the specified string as the number of bytes.

Syntax

```
OCTET_LENGTH(expression)
```

Argument

expression

A CHAR string, a VARCHAR string, a VARBYTE expression, or an expression that implicitly evaluates to a CHAR, VARCHAR, or VARBYTE type.

Return type

INTEGER

The OCTET_LENGTH function returns an integer indicating the number of bytes in the input string.

If the input string is a character string, the [LEN](#) function returns the actual number of characters in multi-byte strings, not the number of bytes. For example, a VARCHAR(12) column is required to store three four-byte Chinese characters. The OCTET_LENGTH function will return 12 for that string, and the LEN function will return 3 for that same string.

Usage notes

If *expression* is a CHAR string, the function returns the length of the CHAR string. For example, the output of a CHAR(6) input is a CHAR(6).

If *expression* is a VARCHAR string, trailing spaces are counted.

Examples

To return the number of bytes when the string français with three trailing spaces is cast to a CHAR and a VARCHAR type, use the following example. For more information, see the [CAST function](#).

```
SELECT OCTET_LENGTH(CAST('français ' AS CHAR(15))) AS octet_length_char,
       OCTET_LENGTH(CAST('français ' AS VARCHAR(15))) AS octet_length_varchar;
```

```
+-----+-----+
| octet_length_char | octet_length_varchar |
+-----+-----+
|                15 |                11 |
+-----+-----+
```

To return the number of bytes and the number of characters in the string `français`, use the following example.

```
SELECT OCTET_LENGTH('français'), LEN('français');
```

```
+-----+-----+
| octet_length | len |
+-----+-----+
|             9 |   8 |
+-----+-----+
```

To return the number of bytes when the string `français` is cast as a `VARBYTE`, use the following example.

```
SELECT OCTET_LENGTH(CAST('français' AS VARBYTE));
```

```
+-----+
| octet_length |
+-----+
|             9 |
+-----+
```

POSITION function

Returns the location of the specified substring within a string.

See [CHARINDEX function](#) and [STRPOS function](#) for similar functions.

Syntax

```
POSITION(substring IN string )
```

Arguments

substring

The substring to search for within the *string*.

string

The string or column to be searched.

Return type

The POSITION function returns an INTEGER corresponding to the position of the substring (one-based, not zero-based). The position is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters. POSITION returns 0 if the substring is not found within the string.

Examples

To return the position of the string `fish` within the word `dog`, use the following example.

```
SELECT POSITION('fish' IN 'dog');
```

```
+-----+
| position |
+-----+
|         0 |
+-----+
```

To return the position of the string `fish` within the word `dogfish`, use the following example.

```
SELECT POSITION('fish' IN 'dogfish');
```

```
+-----+
| position |
+-----+
|         4 |
+-----+
```

The following example uses the SALES table from the TICKIT sample database. For more information, see [Sample database](#).

To return the number of distinct sales transactions with a commission over 999.00 from the SALES table, use the following example. This command counts commissions greater than 999.00 by checking if the decimal is more than 4 places from the beginning of the commission value.

```
SELECT DISTINCT POSITION('.' IN commission), COUNT (POSITION('.' IN commission))
FROM sales
WHERE POSITION('.' IN commission) > 4
GROUP BY POSITION('.' IN commission)
ORDER BY 1,2;
```

```
+-----+-----+
| position | count |
+-----+-----+
|          5 |    629 |
+-----+-----+
```

QUOTE_IDENT function

The QUOTE_IDENT function returns the specified string as a string with a leading double quotation mark and a trailing double quotation mark. The function output can be used as an identifier in a SQL statement. The function appropriately doubles any embedded double quotation marks.

QUOTE_IDENT adds double quotation marks only where necessary to create a valid identifier, when the string contains non-identifier characters or would otherwise be folded to lowercase. To always return a single-quoted string, use [QUOTE_LITERAL](#).

Syntax

```
QUOTE_IDENT(string)
```

Argument

string

A CHAR or VARCHAR string.

Return type

The QUOTE_IDENT function returns the same type of string as the input *string*.

Examples

To return the string "CAT" with doubled quotation marks, use the following example.

```
SELECT QUOTE_IDENT('"CAT"');
```

```
+-----+
| quote_ident |
+-----+
| ""CAT""    |
+-----+
```

The following example uses data from the CATEGORY table in the TICKIT sample database. For more information, see [Sample database](#).

To return the CATNAME column surrounded by quotation marks, use the following example.

```
SELECT catid, QUOTE_IDENT(catname)
FROM category
ORDER BY 1,2;
```

```
+-----+-----+
| catid | quote_ident |
+-----+-----+
| 1     | "MLB"       |
| 2     | "NHL"       |
| 3     | "NFL"       |
| 4     | "NBA"       |
| 5     | "MLS"       |
| 6     | "Musicals"  |
| 7     | "Plays"     |
| 8     | "Opera"     |
| 9     | "Pop"       |
| 10    | "Jazz"      |
| 11    | "Classical" |
+-----+-----+
```

QUOTE_LITERAL function

The QUOTE_LITERAL function returns the specified string as a single quoted string so that it can be used as a string literal in a SQL statement. If the input parameter is a number, QUOTE_LITERAL treats it as a string. Appropriately doubles any embedded single quotation marks and backslashes.

Syntax

```
QUOTE_LITERAL(string)
```

Argument

string

A CHAR or VARCHAR string.

Return type

The QUOTE_LITERAL function returns a CHAR or VARCHAR string that is the same data type as the input *string*.

Examples

To return the string ' 'CAT' ' with SINGLE quotation marks, use the following example.

```
SELECT QUOTE_LITERAL(''CAT'');
```

```
+-----+
| quote_literal |
+-----+
| ''CAT''      |
+-----+
```

The following examples use data from the CATEGORY table in the TICKIT sample database. For more information, see [Sample database](#).

To return the CATNAME column surrounded by single quotation marks, use the following example.

```
SELECT catid, QUOTE_LITERAL(catname)
FROM category
ORDER BY 1,2;
```

```
+-----+-----+
| catid | quote_literal |
+-----+-----+
| 1     | 'MLB'         |
| 2     | 'NHL'         |
| 3     | 'NFL'         |
```

```

|      4 | 'NBA' |
|      5 | 'MLS' |
|      6 | 'Musicals' |
|      7 | 'Plays' |
|      8 | 'Opera' |
|      9 | 'Pop' |
|     10 | 'Jazz' |
|     11 | 'Classical' |
+-----+-----+

```

To return the CATID column surrounded by single quotation marks, use the following example.

```

SELECT QUOTE_LITERAL(catid), catname
FROM category
ORDER BY 1,2;

```

```

+-----+-----+
| quote_literal | catname |
+-----+-----+
| '1'          | MLB     |
| '10'         | Jazz   |
| '11'         | Classical |
| '2'          | NHL    |
| '3'          | NFL    |
| '4'          | NBA    |
| '5'          | MLS    |
| '6'          | Musicals |
| '7'          | Plays  |
| '8'          | Opera  |
| '9'          | Pop    |
+-----+-----+

```

REGEXP_COUNT function

Searches a string for a regular expression pattern and returns an integer that indicates the number of times the specified pattern occurs in the string. If no match is found, then the function returns 0. For more information about regular expressions, see [POSIX operators](#) and [Regular expression](#) in Wikipedia.

Syntax

```

REGEXP_COUNT( source_string, pattern [, position [, parameters ] ] )

```

Arguments

source_string

A CHAR or VARCHAR string.

pattern

A UTF-8 string literal that represents a regular expression pattern. For more information, see [POSIX operators](#).

position

(Optional) A positive INTEGER that indicates the position within *source_string* to begin searching. The position is based on the number of characters, not bytes, so that multibyte characters are counted as single characters. The default is 1. If *position* is less than 1, the search begins at the first character of *source_string*. If *position* is greater than the number of characters in *source_string*, the result is 0.

parameters

(Optional) One or more string literals that indicate how the function matches the pattern. The possible values are the following:

- *c* – Perform case-sensitive matching. The default is to use case-sensitive matching.
- *i* – Perform case-insensitive matching.
- *p* – Interpret the pattern with Perl Compatible Regular Expression (PCRE) dialect. For more information about PCRE, see [Perl Compatible Regular Expressions](#) in Wikipedia.

Return type

INTEGER

Examples

To count the number of times a three-letter sequence occurs, use the following example.

```
SELECT REGEXP_COUNT('abcdefghijklmnopqrstuvwxyz', '[a-z]{3}');
```

```
+-----+
| regexp_count |
+-----+
|             8 |
```

```
+-----+
```

To count the occurrences of the string FOX using case-insensitive matching, use the following example.

```
SELECT REGEXP_COUNT('the fox', 'FOX', 1, 'i');
```

```
+-----+
```

```
| regexp_count |
```

```
+-----+
```

```
|           1 |
```

```
+-----+
```

To use a pattern written in the PCRE dialect to locate words containing at least one number and one lowercase letter, use the following example. The example uses the `?=` operator, which has a specific look-ahead connotation in PCRE. This example counts the number of occurrences of such words, with case-sensitive matching.

```
SELECT REGEXP_COUNT('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+', 1, 'p');
```

```
+-----+
```

```
| regexp_count |
```

```
+-----+
```

```
|           2 |
```

```
+-----+
```

To use a pattern written in the PCRE dialect to locate words containing at least one number and one lowercase letter, use the following example. It uses the `?=` operator, which has a specific connotation in PCRE. This example counts the number of occurrences of such words, but differs from the previous example in that it uses case-insensitive matching.

```
SELECT REGEXP_COUNT('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+', 1, 'ip');
```

```
+-----+
```

```
| regexp_count |
```

```
+-----+
```

```
|           3 |
```

```
+-----+
```

The following example uses data from the USERS table in the TICKIT sample database. For more information, see [Sample database](#).

To count the number of times the top-level domain name is either org or edu, use the following example.

```
SELECT email, REGEXP_COUNT(email, '@[^\.]*\.(org|edu)') FROM users
ORDER BY userid LIMIT 4;
```

email	regexp_count
Etiam.laoreet.libero@sodalesMaurisblandit.edu	1
Suspendisse.tristique@nonnisiAenean.edu	1
amet.faucibus.ut@condimentumegetvolutpat.ca	0
sed@lacusUt nec.ca	0

REGEXP_INSTR function

Searches a string for a regular expression pattern and returns an integer that indicates the beginning position or ending position of the matched substring. If no match is found, then the function returns 0. REGEXP_INSTR is similar to the [POSITION](#) function, but lets you search a string for a regular expression pattern. For more information about regular expressions, see [POSIX operators](#) and [Regular expression](#) in Wikipedia.

Syntax

```
REGEXP_INSTR( source_string, pattern [, position [, occurrence] [, option [, parameters
] ] ] ] )
```

Arguments

source_string

A string expression, such as a column name, to be searched.

pattern

A UTF-8 string literal that represents a regular expression pattern. For more information, see [POSIX operators](#).

position

(Optional) A positive INTEGER that indicates the position within *source_string* to begin searching. The position is based on the number of characters, not bytes, so that multibyte characters are counted as single characters. The default is 1. If *position* is less than 1, the search begins at the first character of *source_string*. If *position* is greater than the number of characters in *source_string*, the result is \emptyset .

occurrence

(Optional) A positive INTEGER that indicates which occurrence of the pattern to use. REGEXP_INSTR skips the first *occurrence*-1 matches. The default is 1. If *occurrence* is less than 1 or greater than the number of characters in *source_string*, the search is ignored and the result is \emptyset .

option

(Optional) A value that indicates whether to return the position of the first character of the match (\emptyset) or the position of the first character following the end of the match (1). A nonzero value is the same as 1. The default value is \emptyset .

parameters

(Optional) One or more string literals that indicate how the function matches the pattern. The possible values are the following:

- *c* – Perform case-sensitive matching. The default is to use case-sensitive matching.
- *i* – Perform case-insensitive matching.
- *e* – Extract a substring using a subexpression.

If *pattern* includes a subexpression, REGEXP_INSTR matches a substring using the first subexpression in *pattern*. REGEXP_INSTR considers only the first subexpression; additional subexpressions are ignored. If the pattern doesn't have a subexpression, REGEXP_INSTR ignores the 'e' parameter.

- *p* – Interpret the pattern with Perl Compatible Regular Expression (PCRE) dialect. For more information about PCRE, see [Perl Compatible Regular Expressions](#) in Wikipedia.

Return type

Integer

Examples

The following examples use data from the USERS table in the TICKIT sample database. For more information, see [Sample database](#).

To search for the @ character that begins a domain name and returns the starting position of the first match, use the following example.

```
SELECT email, REGEXP_INSTR(email, '@^[^.]*')
FROM users
ORDER BY userid LIMIT 4;
```

email	regexp_instr
Etiam.laoreet.libero@sodalesMaurisblandit.edu	21
Suspendisse.tristique@nonnisiAenean.edu	22
amet.faucibus.ut@condimentumegetvolutpat.ca	17
sed@lacusUt nec.ca	4

To search for variants of the word Center and returns the starting position of the first match, use the following example.

```
SELECT venuename, REGEXP_INSTR(venuename, '[cC]ent(er|re)$')
FROM venue
WHERE REGEXP_INSTR(venuename, '[cC]ent(er|re)$') > 0
ORDER BY venueid LIMIT 4;
```

venuename	regexp_instr
The Home Depot Center	16
Izod Center	6
Wachovia Center	10
Air Canada Centre	12

To find the starting position of the first occurrence of the string FOX, using case-insensitive matching logic, use the following example.

```
SELECT REGEXP_INSTR('the fox', 'FOX', 1, 1, 0, 'i');
```

```
+-----+
| regexp_instr |
+-----+
|           5 |
+-----+
```

To use a pattern written in PCRE dialect to locate words containing at least one number and one lowercase letter, use the following example. It uses the `?=` operator, which has a specific look-ahead connotation in PCRE. This example finds the starting position of the second such word.

```
SELECT REGEXP_INSTR('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+',
1, 2, 0, 'p');
```

```
+-----+
| regexp_instr |
+-----+
|          21 |
+-----+
```

To use a pattern written in PCRE dialect to locate words containing at least one number and one lowercase letter, use the following example. It uses the `?=` operator, which has a specific look-ahead connotation in PCRE. This example finds the starting position of the second such word, but differs from the previous example in that it uses case-insensitive matching.

```
SELECT REGEXP_INSTR('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+',
1, 2, 0, 'ip');
```

```
+-----+
| regexp_instr |
+-----+
|          15 |
+-----+
```

REGEXP_REPLACE function

Searches a string for a regular expression pattern and replaces every occurrence of the pattern with the specified string. `REGEXP_REPLACE` is similar to the [REPLACE function](#), but lets you search a string for a regular expression pattern. For more information about regular expressions, see [POSIX operators](#) and [Regular expression](#) in Wikipedia.

REGEXP_REPLACE is similar to the [TRANSLATE function](#) and the [REPLACE function](#), except that TRANSLATE makes multiple single-character substitutions and REPLACE substitutes one entire string with another string, while REGEXP_REPLACE lets you search a string for a regular expression pattern.

Syntax

```
REGEXP_REPLACE( source_string, pattern [, replace_string [ , position [, parameters ] ] ] )
```

Arguments

source_string

A CHAR or VARCHAR string expression, such as a column name, to be searched.

pattern

A UTF-8 string literal that represents a regular expression pattern. For more information, see [POSIX operators](#).

replace_string

(Optional) A CHAR or VARCHAR string expression, such as a column name, that will replace each occurrence of pattern. The default is an empty string ("").

position

(Optional) A positive integer that indicates the position within *source_string* to begin searching. The position is based on the number of characters, not bytes, so that multibyte characters are counted as single characters. The default is 1. If *position* is less than 1, the search begins at the first character of *source_string*. If *position* is greater than the number of characters in *source_string*, the result is *source_string*.

parameters

(Optional) One or more string literals that indicate how the function matches the pattern. The possible values are the following:

- *c* – Perform case-sensitive matching. The default is to use case-sensitive matching.
- *i* – Perform case-insensitive matching.
- *p* – Interpret the pattern with Perl Compatible Regular Expression (PCRE) dialect. For more information about PCRE, see [Perl Compatible Regular Expressions](#) in Wikipedia.

Return type

VARCHAR

If either *pattern* or *replace_string* is NULL, the function returns NULL.

Examples

To replace all occurrences of the string FOX within the value quick brown fox using case-insensitive matching, use the following example.

```
SELECT REGEXP_REPLACE('the fox', 'FOX', 'quick brown fox', 1, 'i');
```

```
+-----+
|  regexp_replace  |
+-----+
| the quick brown fox |
+-----+
```

The following example uses a pattern written in the PCRE dialect to locate words containing at least one number and one lowercase letter. It uses the `?=` operator, which has a specific look-ahead connotation in PCRE. To replace each occurrence of such a word with the value `[hidden]`, use the following example.

```
SELECT REGEXP_REPLACE('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+', '[hidden]', 1, 'p');
```

```
+-----+
|      regexp_replace      |
+-----+
| [hidden] plain A1234 [hidden] |
+-----+
```

The following example uses a pattern written in the PCRE dialect to locate words containing at least one number and one lowercase letter. It uses the `?=` operator, which has a specific look-ahead connotation in PCRE. To replace each occurrence of such a word with the value `[hidden]`, but differs from the previous example in that it uses case-insensitive matching, use the following example.

```
SELECT REGEXP_REPLACE('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+', '[hidden]', 1, 'ip');
```

```

+-----+
|          regexp_replace          |
+-----+
| [hidden] plain [hidden] [hidden] |
+-----+

```

The following examples use data from the USERS table in the TICKIT sample database. For more information, see [Sample database](#).

To delete the @ and domain name from email addresses, use the following example.

```

SELECT email, REGEXP_REPLACE(email, '@.*\\.(org|gov|com|edu|ca)$')
FROM users
ORDER BY userid LIMIT 4;

```

```

+-----+-----+
|          email          |          regexp_replace          |
+-----+-----+
| Etiam.laoreet.libero@sodalesMaurisblandit.edu | Etiam.laoreet.libero |
| Suspendisse.tristique@nonnisiAenean.edu      | Suspendisse.tristique |
| amet.faucibus.ut@condimentumegetvolutpat.ca  | amet.faucibus.ut      |
| sed@lacusUtnecc.ca                          | sed                    |
+-----+-----+

```

To replace the domain names of email addresses with `internal.company.com`, use the following example.

```

SELECT email, REGEXP_REPLACE(email, '@.*\\.[[:alpha:]]{2,3}', '@internal.company.com')
FROM users
ORDER BY userid LIMIT 4;

```

```

+-----+-----+
|          email          |          regexp_replace          |
+-----+-----+
| Etiam.laoreet.libero@sodalesMaurisblandit.edu | Etiam.laoreet.libero@internal.company.com |
| Suspendisse.tristique@nonnisiAenean.edu      | Suspendisse.tristique@internal.company.com |
+-----+-----+

```

```

| amet.faucibus.ut@condimentumegetvolutpat.ca | amet.faucibus.ut@internal.company.com
|
| sed@lacusUtneq.ca | sed@internal.company.com
|
+-----+
+-----+

```

REGEXP_SUBSTR function

Returns characters from a string by searching it for a regular expression pattern. REGEXP_SUBSTR is similar to the [SUBSTRING function](#) function, but lets you search a string for a regular expression pattern. If the function can't match the regular expression to any characters in the string, it returns an empty string. For more information about regular expressions, see [POSIX operators](#) and [Regular expression](#) in Wikipedia.

Syntax

```
REGEXP_SUBSTR( source_string, pattern [, position [, occurrence [, parameters ] ] ] )
```

Arguments

source_string

A string expression to be searched.

pattern

A UTF-8 string literal that represents a regular expression pattern. For more information, see [POSIX operators](#).

position

A positive integer that indicates the position within *source_string* to begin searching. The position is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters. The default is 1. If *position* is less than 1, the search begins at the first character of *source_string*. If *position* is greater than the number of characters in *source_string*, the result is an empty string ("").

occurrence

A positive integer that indicates which occurrence of the pattern to use. REGEXP_SUBSTR skips the first *occurrence* - 1 matches. The default is 1. If *occurrence* is less than 1 or greater than the number of characters in *source_string*, the search is ignored and the result is NULL.

parameters

One or more string literals that indicate how the function matches the pattern. The possible values are the following:

- `c` – Perform case-sensitive matching. The default is to use case-sensitive matching.
- `i` – Perform case-insensitive matching.
- `e` – Extract a substring using a subexpression.

If *pattern* includes a subexpression, `REGEXP_SUBSTR` matches a substring using the first subexpression in *pattern*. A subexpression is an expression within the pattern that is bracketed with parentheses. For example, for the pattern `'This is a (\\w+)'` matches the first expression with the string `'This is a '` followed by a word. Instead of returning *pattern*, `REGEXP_SUBSTR` with the `e` parameter returns only the string inside the subexpression.

`REGEXP_SUBSTR` considers only the first subexpression; additional subexpressions are ignored. If the pattern doesn't have a subexpression, `REGEXP_SUBSTR` ignores the `'e'` parameter.

- `p` – Interpret the pattern with Perl Compatible Regular Expression (PCRE) dialect. For more information about PCRE, see [Perl Compatible Regular Expressions](#) in Wikipedia.

Return type

VARCHAR

Examples

The following example returns the portion of an email address between the `@` character and the domain extension. The users data queried is from the Amazon Redshift sample data. For more information, see [Sample database](#).

```
SELECT email, regexp_substr(email, '@[^.]*')
FROM users
ORDER BY userid LIMIT 4;
```

email	regexp_substr
Suspendisse.tristique@nonnisiAenean.edu	@nonnisiAenean
amet.faucibus.ut@condimentumegetvolutpat.ca	@condimentumegetvolutpat

```
sed@lacusUtneC.ca | @lacusUtneC
Cum@accumsan.com | @accumsan
```

The following example returns the portion of the input corresponding to the first occurrence of the string FOX using case-insensitive matching.

```
SELECT regexp_substr('the fox', 'FOX', 1, 1, 'i');
```

```
regexp_substr
-----
fox
```

The following example returns the portion of the input corresponding to the second occurrence of the string FOX using case-insensitive matching. The result is NULL (empty) because there is no second occurrence.

```
SELECT regexp_substr('the fox', 'FOX', 1, 2, 'i');
```

```
regexp_substr
-----
```

The following example returns the first portion of the input that begins with lowercase letters. This is functionally identical to the same SELECT statement without the c parameter.

```
SELECT regexp_substr('THE SECRET CODE IS THE LOWERCASE PART OF 1931abc0EZ.', '[a-z]+',
1, 1, 'c');
```

```
regexp_substr
-----
abc
```

The following example uses a pattern written in the PCRE dialect to locate words containing at least one number and one lowercase letter. It uses the ?= operator, which has a specific look-ahead connotation in PCRE. This example returns the portion of the input corresponding to the second such word.

```
SELECT regexp_substr('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+',
1, 2, 'p');
```

```

regexp_substr
-----
a1234

```

The following example uses a pattern written in the PCRE dialect to locate words containing at least one number and one lowercase letter. It uses the `?=` operator, which has a specific look-ahead connotation in PCRE. This example returns the portion of the input corresponding to the second such word, but differs from the previous example in that it uses case-insensitive matching.

```

SELECT regexp_substr('passwd7 plain A1234 a1234', '(?=[^ ]*[a-z])(?=[^ ]*[0-9])[^ ]+',
1, 2, 'ip');

regexp_substr
-----
A1234

```

The following example uses a subexpression to find the second string matching the pattern `'this is a (\w+)'` using case-insensitive matching. It returns the subexpression inside the parentheses.

```

SELECT regexp_substr(
    'This is a cat, this is a dog. This is a mouse.',
    'this is a (\w+)', 1, 2, 'ie');

regexp_substr
-----
dog

```

REPEAT function

Repeats a string the specified number of times. If the input parameter is numeric, REPEAT treats it as a string.

Synonym for [REPLICATE function](#).

Syntax

```
REPEAT(string, integer)
```

Arguments

string

The first input parameter is the string to be repeated.

integer

The second parameter is an INTEGER indicating the number of times to repeat the string.

Return type

VARCHAR

Examples

The following example uses data from the CATEGORY table in the TICKIT sample database. For more information, see [Sample database](#).

To repeat the value of the CATID column in the CATEGORY table three times, use the following example.

```
SELECT catid, REPEAT(catid,3)
FROM category
ORDER BY 1,2;
```

```
+-----+-----+
| catid | repeat |
+-----+-----+
| 1 | 111 |
| 2 | 222 |
| 3 | 333 |
| 4 | 444 |
| 5 | 555 |
| 6 | 666 |
| 7 | 777 |
| 8 | 888 |
| 9 | 999 |
| 10 | 101010 |
| 11 | 111111 |
+-----+-----+
```

REPLACE function

Replaces all occurrences of a set of characters within an existing string with other specified characters.

REPLACE is similar to the [TRANSLATE function](#) and the [REGEXP_REPLACE function](#), except that TRANSLATE makes multiple single-character substitutions and REGEXP_REPLACE lets you search a string for a regular expression pattern, while REPLACE substitutes one entire string with another string.

Syntax

```
REPLACE(string, old_chars, new_chars)
```

Arguments

string

CHAR or VARCHAR string to be searched

old_chars

CHAR or VARCHAR string to replace.

new_chars

New CHAR or VARCHAR string replacing the *old_string*.

Return type

VARCHAR

If either *old_chars* or *new_chars* is NULL, the return is NULL.

Examples

The following example uses data from the CATEGORY table in the TICKIT sample database. For more information, see [Sample database](#).

To convert the string Shows to Theatre in the CATGROUP field, use the following example.

```
SELECT catid, catgroup, REPLACE(catgroup, 'Shows', 'Theatre')
```

```
FROM category
ORDER BY 1,2,3;
```

```
+-----+-----+-----+
| catid | catgroup | replace |
+-----+-----+-----+
|    1  | Sports   | Sports   |
|    2  | Sports   | Sports   |
|    3  | Sports   | Sports   |
|    4  | Sports   | Sports   |
|    5  | Sports   | Sports   |
|    6  | Shows    | Theatre  |
|    7  | Shows    | Theatre  |
|    8  | Shows    | Theatre  |
|    9  | Concerts | Concerts |
|   10  | Concerts | Concerts |
|   11  | Concerts | Concerts |
+-----+-----+-----+
```

REPLICATE function

Synonym for the REPEAT function.

See [REPEAT function](#).

REVERSE function

The REVERSE function operates on a string and returns the characters in reverse order. For example, `reverse(' abcde ')` returns `edcba`. This function works on numeric and date data types as well as character data types; however, in most cases it has practical value for character strings.

Syntax

```
REVERSE( expression )
```

Argument

expression

An expression with a character, date, timestamp, or numeric data type that represents the target of the character reversal. All expressions are implicitly converted to VARCHAR strings. Trailing blanks in CHAR strings are ignored.

Return type

VARCHAR

Examples

The following examples use data from the USERS and SALES tables in the TICKIT sample database. For more information, see [Sample database](#).

To select five distinct city names and their corresponding reversed names from the USERS table, use the following example.

```
SELECT DISTINCT city AS cityname, REVERSE(cityname)
FROM users
ORDER BY city LIMIT 5;
```

```
+-----+-----+
| cityname | reverse |
+-----+-----+
| Aberdeen | needrebA |
| Abilene  | enelibA  |
| Ada      | adA      |
| Agat     | tagA     |
| Agawam   | mawagA   |
+-----+-----+
```

To select five sales IDs and their corresponding reversed IDs cast as character strings, use the following example.

```
SELECT salesid, REVERSE(salesid)
FROM sales
ORDER BY salesid DESC LIMIT 5;
```

```
+-----+-----+
| salesid | reverse |
+-----+-----+
| 172456 | 654271 |
| 172455 | 554271 |
| 172454 | 454271 |
| 172453 | 354271 |
| 172452 | 254271 |
+-----+-----+
```

RTRIM function

The RTRIM function trims a specified set of characters from the end of a string. Removes the longest string containing only characters in the trim characters list. Trimming is complete when a trim character does not appear in the input string.

Syntax

```
RTRIM( string, trim_chars )
```

Arguments

string

A string column, expression, or string literal to be trimmed.

trim_chars

A string column, expression, or string literal that represents the characters to be trimmed from the end of *string*. If not specified, a space is used as the trim character.

Return type

A string that is the same data type as the *string* argument.

Example

The following example trims leading and trailing blanks from the string ' abc ':

```
select '   abc   ' as untrim, rtrim('   abc   ') as trim;
```

untrim		trim
-----+		-----
abc		abc

The following example removes the trailing 'xyz' strings from the string 'xyzaxyzbxyzcxyz'. The trailing occurrences of 'xyz' are removed, but occurrences that are internal within the string are not removed.

```
select 'xyzaxyzbxyzcxyz' as untrim,  
rtrim('xyzaxyzbxyzcxyz', 'xyz') as trim;
```

```

      untrim      |      trim
-----+-----
xyzaxyzbxyzcxyz | xyzaxyzbxyzc

```

The following example removes the trailing parts from the string 'setuphistorycassettes' that match any of the characters in the *trim_chars* list 'tes'. Any t, e, or s that occur before another character that is not in the *trim_chars* list at the ending of the input string are removed.

```
SELECT rtrim('setuphistorycassettes', 'tes');
```

```

      rtrim
-----
setuphistoryca

```

The following example trims the characters 'Park' from the end of VENUENAME where present:

```
select venueid, venuename, rtrim(venueName, 'Park')
from venue
order by 1, 2, 3
limit 10;
```

venueid	venueName	rtrim
1	Toyota Park	Toyota
2	Columbus Crew Stadium	Columbus Crew Stadium
3	RFK Stadium	RFK Stadium
4	CommunityAmerica Ballpark	CommunityAmerica Ballp
5	Gillette Stadium	Gillette Stadium
6	New York Giants Stadium	New York Giants Stadium
7	BMO Field	BMO Field
8	The Home Depot Center	The Home Depot Cente
9	Dick's Sporting Goods Park	Dick's Sporting Goods
10	Pizza Hut Park	Pizza Hut

Note that RTRIM removes any of the characters P, a, r, or k when they appear at the end of a VENUENAME.

SOUNDEX function

The SOUNDEX function returns the American Soundex value consisting of the first letter of the input string followed by a 3–digit encoding of the sounds that represent the English pronunciation of the string that you specify. For example, Smith and Smyth have the same Soundex value.

Syntax

```
SOUNDEX(string)
```

Arguments

string

You specify a CHAR or VARCHAR string that you want to convert to an American Soundex code value.

Return type

VARCHAR(4)

Usage notes

The SOUNDEX function converts only English alphabetical lowercase and uppercase ASCII characters, including a–z and A–Z. SOUNDEX ignores other characters. SOUNDEX returns a single Soundex value for a string of multiple words separated by spaces.

```
SELECT SOUNDEX('AWS Amazon');
```

```
+-----+
| soundex |
+-----+
| A252    |
+-----+
```

SOUNDEX returns an empty string if the input string doesn't contain any English letters.

```
SELECT SOUNDEX('+-*/%');
```

```
+-----+
| soundex |
+-----+
|         |
+-----+
```

Examples

To return the Soundex value for Amazon, use the following example.

```
SELECT SOUNDEX('Amazon');
```

```
+-----+
| soundex |
+-----+
| A525    |
+-----+
```

To return the Soundex value for smith and smyth, use the following example. Note that the Soundex values are the same.

```
SELECT SOUNDEX('smith'), SOUNDEX('smyth');
```

```
+-----+-----+
| smith | smyth |
+-----+-----+
| S530  | S530  |
+-----+-----+
```

SPLIT_PART function

Splits a string on the specified delimiter and returns the part at the specified position.

Syntax

```
SPLIT_PART(string, delimiter, position)
```

Arguments

string

A string column, expression, or string literal to be split. The string can be CHAR or VARCHAR.

delimiter

The delimiter string indicating sections of the input *string*.

If *delimiter* is a literal, enclose it in single quotation marks.

position

Position of the portion of *string* to return (counting from 1). Must be an integer greater than 0.

If *position* is larger than the number of string portions, SPLIT_PART returns an empty string. If

delimiter is not found in *string*, then the returned value contains the contents of the specified part, which might be the entire *string* or an empty value.

Return type

A CHAR or VARCHAR string, the same as the *string* parameter.

Examples

The following example splits a string literal into parts using the \$ delimiter and returns the second part.

```
select split_part('abc$def$ghi','$',2)

split_part
-----
def
```

The following example splits a string literal into parts using the \$ delimiter. It returns an empty string because part 4 is not found.

```
select split_part('abc$def$ghi','$',4)

split_part
-----
```

The following example splits a string literal into parts using the # delimiter. It returns the entire string, which is the first part, because the delimiter is not found.

```
select split_part('abc$def$ghi','#',1)

split_part
-----
abc$def$ghi
```

The following example splits the timestamp field LISTTIME into year, month, and day components.

```
select listtime, split_part(listtime,'-',1) as year,
```

```
split_part(listtime, '-', 2) as month,
split_part(split_part(listtime, '-', 3), ' ', 1) as day
from listing limit 5;
```

listtime	year	month	day
2008-03-05 12:25:29	2008	03	05
2008-09-09 08:03:36	2008	09	09
2008-09-26 05:43:12	2008	09	26
2008-10-04 02:00:30	2008	10	04
2008-01-06 08:33:11	2008	01	06

The following example selects the LISTTIME timestamp field and splits it on the '-' character to get the month (the second part of the LISTTIME string), then counts the number of entries for each month:

```
select split_part(listtime, '-', 2) as month, count(*)
from listing
group by split_part(listtime, '-', 2)
order by 1, 2;
```

month	count
01	18543
02	16620
03	17594
04	16822
05	17618
06	17158
07	17626
08	17881
09	17378
10	17756
11	12912
12	4589

STRPOS function

Returns the position of a substring within a specified string.

See [CHARINDEX function](#) and [POSITION function](#) for similar functions.

Syntax

```
STRPOS(string, substring )
```

Arguments

string

The first input parameter is the CHAR or VARCHAR string to be searched.

substring

The second parameter is the substring to search for within the *string*.

Return type

INTEGER

The STRPOS function returns an INTEGER corresponding to the position of the *substring* (one-based, not zero-based). The position is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters.

Usage notes

STRPOS returns 0 if the *substring* is not found within the *string*.

```
SELECT STRPOS('dogfish', 'fist');
```

```
+-----+
| strpos |
+-----+
|      0 |
+-----+
```

Examples

To show the position of fish within dogfish, use the following example.

```
SELECT STRPOS('dogfish', 'fish');
```

```
+-----+
| strpos |
+-----+
|      4 |
+-----+
```

The following example uses data from the SALES table in the TICKIT sample database. For more information, see [Sample database](#).

To return the number of sales transactions with a COMMISSION over 999.00 from the SALES table, use the following example.

```
SELECT DISTINCT STRPOS(commission, '.'),
COUNT (STRPOS(commission, '.'))
FROM sales
WHERE STRPOS(commission, '.') > 4
GROUP BY STRPOS(commission, '.')
ORDER BY 1, 2;
```

```
+-----+-----+
| strpos | count |
+-----+-----+
|      5 |   629 |
+-----+-----+
```

STRTOL function

Converts a string expression of a number of the specified base to the equivalent integer value. The converted value must be within the signed 64-bit range.

Syntax

```
STRTOL(num_string, base)
```

Arguments

num_string

String expression of a number to be converted. If *num_string* is empty (' ') or begins with the null character ('\0'), the converted value is 0. If *num_string* is a column containing a NULL value, STRTOL returns NULL. The string can begin with any amount of white space, optionally

followed by a single plus '+' or minus '-' sign to indicate positive or negative. The default is '+'. If *base* is 16, the string can optionally begin with '0x'.

base

INTEGER between 2 and 36.

Return type

BIGINT

If *num_string* is null, the function returns NULL.

Examples

To convert string and base value pairs to integers, use the following examples.

```
SELECT STRTOL('0xf',16);
```

```
+-----+
| strtol |
+-----+
|    15 |
+-----+
```

```
SELECT STRTOL('abcd1234',16);
```

```
+-----+
|  strtol  |
+-----+
| 2882343476 |
+-----+
```

```
SELECT STRTOL('1234567', 10);
```

```
+-----+
| strtol |
+-----+
| 1234567 |
+-----+
```

```
SELECT STRTOL('1234567', 8);
```

```
+-----+
| strtol |
+-----+
| 342391 |
+-----+
```

```
SELECT STRTOL('110101', 2);
```

```
+-----+
| strtol |
+-----+
|      53 |
+-----+
```

```
SELECT STRTOL('\0', 2);
```

```
+-----+
| strtol |
+-----+
|       0 |
+-----+
```

SUBSTRING function

Returns the subset of a string based on the specified start position.

If the input is a character string, the start position and number of characters extracted are based on characters, not bytes, so that multi-byte characters are counted as single characters. If the input is a binary expression, the start position and extracted substring are based on bytes. You can't specify a negative length, but you can specify a negative starting position.

Syntax

```
SUBSTRING(character_string FROM start_position [ FOR number_characters ] )
```

```
SUBSTRING(character_string, start_position, number_characters )
```

```
SUBSTRING(binary_expression, start_byte, number_bytes )
```

```
SUBSTRING(binary_expression, start_byte )
```

Arguments

character_string

The string to be searched. Non-character data types are treated like a string.

start_position

The position within the string to begin the extraction, starting at 1. The *start_position* is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters. This number can be negative.

number_characters

The number of characters to extract (the length of the substring). The *number_characters* is based on the number of characters, not bytes, so that multi-byte characters are counted as single characters. This number cannot be negative.

binary_expression

The *binary_expression* of data type VARBYTE to be searched.

start_byte

The position within the binary expression to begin the extraction, starting at 1. This number can be negative.

number_bytes

The number of bytes to extract, that is, the length of the substring. This number can't be negative.

Return type

VARCHAR or VARBYTE depending on the input.

Usage Notes

Following are some examples of how you can use *start_position* and *number_characters* to extract substrings from various positions in a string.

The following example returns a four-character string beginning with the sixth character.

```
select substring('caterpillar',6,4);
substring
-----
```

```
pill
(1 row)
```

If the *start_position* + *number_characters* exceeds the length of the *string*, SUBSTRING returns a substring starting from the *start_position* until the end of the string. For example:

```
select substring('caterpillar',6,8);
substring
-----
pillar
(1 row)
```

If the *start_position* is negative or 0, the SUBSTRING function returns a substring beginning at the first character of string with a length of *start_position* + *number_characters* - 1. For example:

```
select substring('caterpillar',-2,6);
substring
-----
cat
(1 row)
```

If *start_position* + *number_characters* - 1 is less than or equal to zero, SUBSTRING returns an empty string. For example:

```
select substring('caterpillar',-5,4);
substring
-----

(1 row)
```

Examples

The following example returns the month from the LISTTIME string in the LISTING table:

```
select listid, listtime,
substring(listtime, 6, 2) as month
from listing
order by 1, 2, 3
limit 10;
```

listid	listtime	month
1	2008-01-24 06:43:29	01
2	2008-03-05 12:25:29	03
3	2008-11-01 07:35:33	11
4	2008-05-24 01:18:37	05
5	2008-05-17 02:29:11	05
6	2008-08-15 02:08:13	08
7	2008-11-15 09:38:15	11
8	2008-11-09 05:07:30	11
9	2008-09-09 08:03:36	09
10	2008-06-17 09:44:54	06

(10 rows)

The following example is the same as above, but uses the FROM...FOR option:

```
select listid, listtime,
substring(listtime from 6 for 2) as month
from listing
order by 1, 2, 3
limit 10;
```

listid	listtime	month
1	2008-01-24 06:43:29	01
2	2008-03-05 12:25:29	03
3	2008-11-01 07:35:33	11
4	2008-05-24 01:18:37	05
5	2008-05-17 02:29:11	05
6	2008-08-15 02:08:13	08
7	2008-11-15 09:38:15	11
8	2008-11-09 05:07:30	11

(10 rows)

You can't use SUBSTRING to predictably extract the prefix of a string that might contain multi-byte characters because you need to specify the length of a multi-byte string based on the number of bytes, not the number of characters. To extract the beginning segment of a string based on the length in bytes, you can CAST the string as VARCHAR(*byte_length*) to truncate the string, where *byte_length* is the required length. The following example extracts the first 5 bytes from the string 'Fourscore and seven'.

```
select cast('Fourscore and seven' as varchar(5));
```

```
varchar  
-----  
Fours
```

The following example shows a negative start position of a binary value `abc`. Because the start position is `-3`, the substring is extracted from the beginning of the binary value. The result is automatically shown as the hexadecimal representation of the binary substring.

```
select substring('abc'::varbyte, -3);
```

```
substring  
-----  
616263
```

The following example shows a `1` for the start position of a binary value `abc`. Because there is no length specified, the string is extracted from the start position to the end of the string. The result is automatically shown as the hexadecimal representation of the binary substring.

```
select substring('abc'::varbyte, 1);
```

```
substring  
-----  
616263
```

The following example shows a `3` for the start position of a binary value `abc`. Because there is no length specified, the string is extracted from the start position to the end of the string. The result is automatically shown as the hexadecimal representation of the binary substring.

```
select substring('abc'::varbyte, 3);
```

```
substring  
-----  
63
```

The following example shows a `2` for the start position of a binary value `abc`. The string is extracted from the start position to position `10`, but the end of the string is at position `3`. The result is automatically shown as the hexadecimal representation of the binary substring.

```
select substring('abc'::varbyte, 2, 10);

 substring
-----
 6263
```

The following example shows a 2 for the start position of a binary value abc. The string is extracted from the start position for 1 byte. The result is automatically shown as the hexadecimal representation of the binary substring.

```
select substring('abc'::varbyte, 2, 1);

 substring
-----
 62
```

The following example returns the first name Ana which appears after the last space in the input string Silva, Ana.

```
select reverse(substring(reverse('Silva, Ana'), 1, position(' ' IN reverse('Silva,
Ana'))))

 reverse
-----
 Ana
```

TEXTLEN function

Synonym of LEN function.

See [LEN function](#).

TRANSLATE function

For a given expression, replaces all occurrences of specified characters with specified substitutes. Existing characters are mapped to replacement characters by their positions in the *characters_to_replace* and *characters_to_substitute* arguments. If more characters are specified in the *characters_to_replace* argument than in the *characters_to_substitute* argument, the extra characters from the *characters_to_replace* argument are omitted in the return value.

TRANSLATE is similar to the [REPLACE function](#) and the [REGEXP_REPLACE function](#), except that REPLACE substitutes one entire string with another string and REGEXP_REPLACE lets you search a string for a regular expression pattern, while TRANSLATE makes multiple single-character substitutions.

If any argument is null, the return is NULL.

Syntax

```
TRANSLATE( expression, characters_to_replace, characters_to_substitute )
```

Arguments

expression

The expression to be translated.

characters_to_replace

A string containing the characters to be replaced.

characters_to_substitute

A string containing the characters to substitute.

Return type

VARCHAR

Examples

To replace several characters in a string, use the following example.

```
SELECT TRANSLATE('mint tea', 'inea', 'osin');
```

```
+-----+
| translate |
+-----+
| most tin  |
+-----+
```

The following examples use data from the USERS table in the TICKIT sample database. For more information, see [Sample database](#).

To replace the at sign (@) with a period for all values in a column, use the following example.

```
SELECT email, TRANSLATE(email, '@', '.') as obfuscated_email
FROM users LIMIT 10;
```

email	obfuscated_email
Cum@accumsan.com	Cum.accumsan.com
lorem.ipsum@Vestibulumante.com	lorem.ipsum.Vestibulumante.com
non.justo.Proin@ametconsectetuer.edu	non.justo.Proin.ametconsectetuer.edu
non.ante.bibendum@porttitorTellus.org	non.ante.bibendum.porttitorTellus.org
eros@blanditatnisi.org	eros.blanditatnisi.org

at@Duis.com	at.Duis.com
quam@facilisisvitaeorci.ca	quam.facilisisvitaeorci.ca
mi.lorem@nunc.edu	mi.lorem.nunc.edu

To replace spaces with underscores and strips out periods for all values in a column, use the following example.

```
SELECT city, TRANSLATE(city, ' .', '_')
FROM users
WHERE city LIKE 'Sain%' OR city LIKE 'St%'
GROUP BY city
ORDER BY city;
```

city	translate
Saint Albans	Saint_Alban

+-----+	+-----+	+-----+

TRIM function

Trims a string by blanks or specified characters.

Syntax

```
TRIM( [ BOTH | LEADING | TRAILING ] [trim_chars FROM ] string )
```

Arguments

BOTH | LEADING | TRAILING

(Optional) Specifies where to trim characters from. Use **BOTH** to remove leading and trailing characters, use **LEADING** to remove leading characters only, and use **TRAILING** to remove trailing characters only. If this parameter is omitted, both leading and trailing characters are trimmed.

trim_chars

(Optional) The characters to be trimmed from the string. If this parameter is omitted, blanks are trimmed.

string

The string to be trimmed.

Return type

The TRIM function returns a VARCHAR or CHAR string. If you use the TRIM function with a SQL command, Amazon Redshift implicitly converts the results to VARCHAR. If you use the TRIM function in the SELECT list for a SQL function, Amazon Redshift does not implicitly convert the

results, and you might need to perform an explicit conversion to avoid a data type mismatch error. See the [CAST function](#) and [CONVERT function](#) functions for information about explicit conversions.

Examples

To trim both leading and trailing blanks from the string `dog` , use the following example.

```
SELECT TRIM('  dog ');
```

```
+-----+
| btrim |
+-----+
| dog   |
+-----+
```

To trim both leading and trailing blanks from the string `dog` , use the following example.

```
SELECT TRIM(BOTH FROM '  dog ');
```

```
+-----+
| btrim |
+-----+
| dog   |
+-----+
```

To remove the leading double quotation marks from the string `"dog"`, use the following example.

```
SELECT TRIM(LEADING '"' FROM "dog");
```

```
+-----+
| ltrim |
+-----+
| dog"  |
+-----+
```

To remove the trailing double quotation marks from the string `"dog"`, use the following example.

```
SELECT TRIM(TRAILING '"' FROM "dog");
```

```
+-----+
| rtrim |
+-----+
```

```
| "dog |
+-----+
```

TRIM removes any of the characters in *trim_chars* when they appear at the beginning or end of *string*. The following example trims the characters 'C', 'D', and 'G' when they appear at the beginning or end of VENUENAME, which is a VARCHAR column. For more information, see [Sample database](#).

```
SELECT venueid, venuename, TRIM('CDG' FROM venuename)
FROM venue
WHERE venuename LIKE '%Park'
ORDER BY 2
LIMIT 7;
```

venueid	venuename	btrim
121	AT&T Park	AT&T Park
109	Citizens Bank Park	itizens Bank Park
102	Comerica Park	omerica Park
9	Dick's Sporting Goods Park	ick's Sporting Goods Park
97	Fenway Park	Fenway Park
112	Great American Ball Park	reat American Ball Park
114	Miller Park	Miller Park

UPPER function

Converts a string to uppercase. UPPER supports UTF-8 multibyte characters, up to a maximum of four bytes per character.

Syntax

```
UPPER(string)
```

Arguments

string

The input parameter is a VARCHAR string or any other data type, such as CHAR, that can be implicitly converted to VARCHAR.

Return type

The UPPER function returns a character string that is the same data type as the input string. For example, the function will return a VARCHAR string if the input is a VARCHAR string.

Examples

The following example uses data from the CATEGORY table in the TICKIT sample database. For more information, see [Sample database](#).

To convert the CATNAME field to uppercase, use the following.

```
SELECT catname, UPPER(catname)
FROM category
ORDER BY 1,2;
```

catname	upper
Classical	CLASSICAL
Jazz	JAZZ
MLB	MLB
MLS	MLS
Musicals	MUSICALS
NBA	NBA
NFL	NFL
NHL	NHL
Opera	OPERA
Plays	PLAYS
Pop	POP

SUPER type information functions

Following, you can find a description for the type information functions for SQL that Amazon Redshift supports to derive the dynamic information from inputs of the SUPER data type.

Topics

- [DECIMAL_PRECISION function](#)
- [DECIMAL_SCALE function](#)
- [IS_ARRAY function](#)

- [IS_BIGINT function](#)
- [IS_BOOLEAN function](#)
- [IS_CHAR function](#)
- [IS_DECIMAL function](#)
- [IS_FLOAT function](#)
- [IS_INTEGER function](#)
- [IS_OBJECT function](#)
- [IS_SCALAR function](#)
- [IS_SMALLINT function](#)
- [IS_VARCHAR function](#)
- [JSON_SIZE function](#)
- [JSON_TYPEOF function](#)
- [SIZE](#)

DECIMAL_PRECISION function

Checks the precision of the maximum total number of decimal digits to be stored. This number includes both the left and right digits of the decimal point. The range of the precision is from 1 to 38, with a default of 38.

Syntax

```
DECIMAL_PRECISION(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

INTEGER

Examples

To apply the DECIMAL_PRECISION function to the table t, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (3.14159);

SELECT DECIMAL_PRECISION(s) FROM t;
```

```
+-----+
| decimal_precision |
+-----+
|                   6 |
+-----+
```

DECIMAL_SCALE function

Checks the number of decimal digits to be stored to the right of the decimal point. The range of the scale is from 0 to the precision point, with a default of 0.

Syntax

```
DECIMAL_SCALE(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

INTEGER

Examples

To apply the DECIMAL_SCALE function to the table t, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (3.14159);

SELECT DECIMAL_SCALE(s) FROM t;
```

```
+-----+
```

```
| decimal_scale |
+-----+
|           5 |
+-----+
```

IS_ARRAY function

Checks whether a variable is an array. The function returns `true` if the variable is an array. The function also includes empty arrays. Otherwise, the function returns `false` for all other values, including null.

Syntax

```
IS_ARRAY(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if `[1, 2]` is an array using the `IS_ARRAY` function, use the following example.

```
SELECT IS_ARRAY(JSON_PARSE('[1,2]'));
```

```
+-----+
| is_array |
+-----+
| true     |
+-----+
```

IS_BIGINT function

Checks whether a value is a BIGINT. The `IS_BIGINT` function returns `true` for numbers of scale 0 in the 64-bit range. Otherwise, the function returns `false` for all other values, including null and floating point numbers.

The IS_BIGINT function is a superset of IS_INTEGER.

Syntax

```
IS_BIGINT(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if 5 is a BIGINT using the IS_BIGINT function, use the following example.

```
CREATE TABLE t(s SUPER);  
  
INSERT INTO t VALUES (5);  
  
SELECT s, IS_BIGINT(s) FROM t;
```

```
+---+-----+  
| s | is_bigint |  
+---+-----+  
| 5 | true      |  
+---+-----+
```

IS_BOOLEAN function

Checks whether a value is a BOOLEAN. The IS_BOOLEAN function returns `true` for constant JSON Booleans. The function returns `false` for any other values, including null.

Syntax

```
IS_BOOLEAN(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if TRUE is a BOOLEAN using the IS_BOOLEAN function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (TRUE);

SELECT s, IS_BOOLEAN(s) FROM t;
```

```
+-----+-----+
| s    | is_boolean |
+-----+-----+
| true | true      |
+-----+-----+
```

IS_CHAR function

Checks whether a value is a CHAR. The IS_CHAR function returns true for strings that have only ASCII characters, because the CHAR type can store only characters that are in the ASCII format. The function returns false for any other values.

Syntax

```
IS_CHAR(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if `t` is a CHAR using the `IS_CHAR` function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES ('t');

SELECT s, IS_CHAR(s) FROM t;
```

s	is_char
"t"	true

IS_DECIMAL function

Checks whether a value is a DECIMAL. The `IS_DECIMAL` function returns `true` for numbers that are not floating points. The function returns `false` for any other values, including null.

The `IS_DECIMAL` function is a superset of `IS_BIGINT`.

Syntax

```
IS_DECIMAL(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if 1.22 is a DECIMAL using the IS_DECIMAL function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (1.22);

SELECT s, IS_DECIMAL(s) FROM t;
```

```
+-----+-----+
| s     | is_decimal |
+-----+-----+
| 1.22  | true      |
+-----+-----+
```

IS_FLOAT function

Checks whether a value is a floating point number. The IS_FLOAT function returns true for floating point numbers (FLOAT4 and FLOAT8). The function returns false for any other values.

The set of IS_DECIMAL the set of IS_FLOAT are disjoint.

Syntax

```
IS_FLOAT(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if 2.22::FLOAT is a FLOAT using the IS_FLOAT function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES(2.22::FLOAT);

SELECT s, IS_FLOAT(s) FROM t;
```

```
+-----+-----+
|  s    | is_float |
+-----+-----+
| 2.22e+0 | true    |
+-----+-----+
```

IS_INTEGER function

Returns `true` for numbers of scale 0 in the 32-bit range, and `false` for anything else (including null and floating point numbers).

The `IS_INTEGER` function is a superset of the `IS_SMALLINT` function.

Syntax

```
IS_INTEGER(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if 5 is an INTEGER using the `IS_INTEGER` function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (5);
```

```
SELECT s, IS_INTEGER(s) FROM t;
```

```
+---+-----+
| s | is_integer |
+---+-----+
| 5 | true      |
+---+-----+
```

IS_OBJECT function

Checks whether a variable is an object. The `IS_OBJECT` function returns `true` for objects, including empty objects. The function returns `false` for any other values, including `null`.

Syntax

```
IS_OBJECT(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if `{"name": "Joe"}` is an object using the `IS_OBJECT` function, use the following example.

```
CREATE TABLE t(s super);

INSERT INTO t VALUES (JSON_PARSE('{"name": "Joe"}'));

SELECT s, IS_OBJECT(s) FROM t;

+-----+-----+
|      s      | is_object |
+-----+-----+
```

```
| {"name":"Joe"} | true      |
+-----+-----+
```

IS_SCALAR function

Checks whether a variable is a scalar. The `IS_SCALAR` function returns `true` for any value that is not an array or an object. The function returns `false` for any other values, including null.

The set of `IS_ARRAY`, `IS_OBJECT`, and `IS_SCALAR` cover all values except nulls.

Syntax

```
IS_SCALAR(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if `{"name": "Joe"}` is a scalar using the `IS_SCALAR` function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (JSON_PARSE('{"name": "Joe"}'));

SELECT s, IS_SCALAR(s.name) FROM t;
```

```
+-----+-----+
|      s      | is_scalar |
+-----+-----+
| {"name":"Joe"} | true      |
+-----+-----+
```

IS_SMALLINT function

Checks whether a variable is a SMALLINT. The IS_SMALLINT function returns `true` for numbers of scale 0 in the 16-bit range. The function returns `false` for any other values, including null and floating point numbers.

Syntax

```
IS_SMALLINT(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return

BOOLEAN

Examples

To check if 5 is a SMALLINT using the IS_SMALLINT function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES (5);

SELECT s, IS_SMALLINT(s) FROM t;
```

```
+---+-----+
| s | is_smallint |
+---+-----+
| 5 | true       |
+---+-----+
```

IS_VARCHAR function

Checks whether a variable is a VARCHAR. The IS_VARCHAR function returns `true` for all strings. The function returns `false` for any other values.

The IS_VARCHAR function is a superset of the IS_CHAR function.

Syntax

```
IS_VARCHAR(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

BOOLEAN

Examples

To check if abc is a VARCHAR using the IS_VARCHAR function, use the following example.

```
CREATE TABLE t(s SUPER);

INSERT INTO t VALUES ('abc');

SELECT s, IS_VARCHAR(s) FROM t;
```

```
+-----+-----+
|  s   | is_varchar |
+-----+-----+
| "abc" | true       |
+-----+-----+
```

JSON_SIZE function

The JSON_SIZE function returns the number of bytes in the given SUPER expression when serialized into a string.

Syntax

```
JSON_SIZE(super_expression)
```

Arguments

super_expression

A SUPER constant or expression.

Return type

INTEGER

The JSON_SIZE function returns an INTEGER indicating the number of bytes in the input string. This value is different from the number of characters. For example, the UTF-8 character #, a black dot, is 3 bytes in size even though it is 1 character.

Usage notes

JSON_SIZE(x) is functionally identical to OCTET_LENGTH(JSON_SERIALIZE). However, note that JSON_SERIALIZE returns an error when the provided SUPER expression would exceed the VARCHAR limit of the system when serialized. JSON_SIZE does not have this limitation.

Examples

To return the length of a SUPER value serialized to a string, use the following example.

```
SELECT JSON_SIZE(JSON_PARSE('[10001,10002,"#"]'));
```

```
+-----+
| json_size |
+-----+
|          19 |
+-----+
```

Note that the provided SUPER expression is 17 characters long, but # is a 3-byte character, so JSON_SIZE returns 19.

JSON_TYPEOF function

The JSON_TYPEOF scalar function returns a VARCHAR with values boolean, number, string, object, array, or null, depending on the dynamic type of the SUPER value.

Syntax

```
JSON_TYPEOF(super_expression)
```

Arguments

super_expression

A SUPER expression or column.

Return type

VARCHAR

Examples

To check the type of JSON for the array [1, 2] using the JSON_TYPEOF function, use the following example.

```
SELECT JSON_TYPEOF(ARRAY(1,2));
```

```
+-----+
| json_typeof |
+-----+
| array      |
+-----+
```

To check the type of JSON for the object {"name": "Joe"} using the JSON_TYPEOF function, use the following example.

```
SELECT JSON_TYPEOF(JSON_PARSE('{"name": "Joe"}'));
```

```
+-----+
| json_typeof |
+-----+
| object      |
+-----+
```

SIZE

Returns the binary in-memory size of a SUPER type constant or expression as an INTEGER.

Syntax

```
SIZE(super_expression)
```

Arguments

super_expression

A SUPER type constant or expression.

Return type

INTEGER

Examples

To use SIZE to get the in-memory size of several SUPER type expressions, use the following example.

```
CREATE TABLE test_super_size(a SUPER);

INSERT INTO test_super_size
VALUES
  (null),
  (TRUE),
  (JSON_PARSE('[0,1,2,3]')),
  (JSON_PARSE('{ "a":0, "b":1, "c":2, "d":3 }'))
;
```

```
SELECT a, SIZE(a)
FROM test_super_size
ORDER BY 2, 1;
```

a	size
true	4
NULL	4
[0,1,2,3]	23
{ "a":0, "b":1, "c":2, "d":3 }	52

VARBYTE functions and operators

Amazon Redshift functions and operators that support the VARBYTE data type include:

- [VARBYTE operators](#)
- [FROM_HEX](#)
- [FROM_VARBYTE](#)
- [GETBIT](#)
- [TO_HEX](#)
- [TO_VARBYTE](#)
- [CONCAT](#)
- [LEN](#)
- [LENGTH function](#)
- [OCTET_LENGTH](#)
- [SUBSTRING function](#)

VARBYTE operators

The following table lists the VARBYTE operators. The operator works with binary value of data type VARBYTE. If one or both inputs is null, the result is null.

Supported operators

Operator	Description	Return type
<	Less than	BOOLEAN
<=	Less than or equal	BOOLEAN
=	Equal	BOOLEAN
>	Greater than	BOOLEAN

Operator	Description	Return type
>=	Greater than or equal	BOOLEAN
!= or <>	Not equal	BOOLEAN
	Concatenation	VARBYTE
+	Concatenation	VARBYTE
~	Bitwise not	VARBYTE
&	Bitwise and	VARBYTE
	Bitwise or	VARBYTE
#	Bitwise xor	VARBYTE

Examples

In the following examples, the value of 'a'::VARBYTE is 61 and the value of 'b'::VARBYTE is 62. The :: casts the strings into the VARBYTE data type. For more information about casting data types, see [CAST](#).

To compare if 'a' is less than 'b' using the < operator, use the following example.

```
SELECT 'a'::VARBYTE < 'b'::VARBYTE AS less_than;
```

```
+-----+
| less_than |
+-----+
| true      |
+-----+
```

To compare if 'a' equals 'b' using the = operator, use the following example.

```
SELECT 'a'::VARBYTE = 'b'::VARBYTE AS equal;
```

```
+-----+
| equal |
+-----+
| false |
+-----+
```

To concatenate two binary values using the || operator, use the following example.

```
SELECT 'a'::VARBYTE || 'b'::VARBYTE AS concat;
```

```
+-----+
| concat |
+-----+
| 6162 |
+-----+
```

To concatenate two binary values using the + operator, use the following example.

```
SELECT 'a'::VARBYTE + 'b'::VARBYTE AS concat;
```

```
+-----+
| concat |
+-----+
| 6162 |
+-----+
```

To negate each bit of the input binary value using the FROM_VARBYTE function, use the following example. The string 'a' evaluates to 01100001. For more information, see [FROM_VARBYTE](#).

```
SELECT FROM_VARBYTE(~'a'::VARBYTE, 'binary');
```

```
+-----+
| from_varbyte |
+-----+
| 10011110 |
+-----+
```

To apply the & operator on the two input binary values, use the following example. The string 'a' evaluates to 01100001 and 'b' evaluates to 01100010.

```
SELECT FROM_VARBYTE('a'::VARBYTE & 'b'::VARBYTE, 'binary');
```

```
+-----+
| from_varbyte |
+-----+
|      01100000 |
+-----+
```

FROM_HEX function

FROM_HEX converts a hexadecimal to a binary value.

Syntax

```
FROM_HEX(hex_string)
```

Arguments

hex_string

Hexadecimal string of data type VARCHAR or TEXT to be converted. The format must be a literal value.

Return type

VARBYTE

Examples

To convert the hexadecimal representation of '6162' to a binary value, use the following example. The result is automatically shown as the hexadecimal representation of the binary value.

```
SELECT FROM_HEX('6162');
```

```
+-----+
| from_hex |
+-----+
|      6162 |
+-----+
```

FROM_VARBYTE function

FROM_VARBYTE converts a binary value to a character string in the specified format.

Syntax

```
FROM_VARBYTE(binary_value, format)
```

Arguments

binary_value

A binary value of data type VARBYTE.

format

The format of the returned character string. Case insensitive valid values are hex, binary, utf8 (also utf-8 and utf_8), and base64.

Return type

VARCHAR

Examples

To convert the binary value 'ab' to hexadecimal, use the following example.

```
SELECT FROM_VARBYTE('ab', 'hex');
```

```
+-----+
| from_varbyte |
+-----+
|           6162 |
+-----+
```

To return the binary representation of '4d', use the following example. The binary representation of '4d' is the character string 01001101.

```
SELECT FROM_VARBYTE(FROM_HEX('4d'), 'binary');
```

```
+-----+
```

```
| from_varbyte |
+-----+
|    01001101 |
+-----+
```

GETBIT function

GETBIT returns the bit value of a binary value at the specified index.

Syntax

```
GETBIT(binary_value, index)
```

Arguments

binary_value

A binary value of data type VARBYTE.

index

An index number of the bit in the binary value that is returned. The binary value is a 0-based bit array that is indexed from the rightmost bit (least significant bit) to the leftmost bit (most significant bit).

Return type

INTEGER

Examples

To return the bit at index 2 of the binary value `from_hex('4d')`, use the following example. The binary representation of '4d' is 01001101.

```
SELECT GETBIT(FROM_HEX('4d'), 2);
```

```
+-----+
| getbit |
+-----+
|      1 |
+-----+
```

To return the bit at eight index locations of the binary value returned by `from_hex('4d')`, use the following example. The binary representation of '4d' is 01001101.

```
SELECT GETBIT(FROM_HEX('4d'), 7), GETBIT(FROM_HEX('4d'), 6),
       GETBIT(FROM_HEX('4d'), 5), GETBIT(FROM_HEX('4d'), 4),
       GETBIT(FROM_HEX('4d'), 3), GETBIT(FROM_HEX('4d'), 2),
       GETBIT(FROM_HEX('4d'), 1), GETBIT(FROM_HEX('4d'), 0);
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+
| getbit | getbit | getbit | getbit | getbit | getbit | getbit | getbit |
+-----+-----+-----+-----+-----+-----+-----+-----+
|      0 |      1 |      0 |      0 |      1 |      1 |      0 |      1 |
+-----+-----+-----+-----+-----+-----+-----+-----+
```

TO_HEX function

TO_HEX converts a number or binary value to a hexadecimal representation.

Syntax

```
TO_HEX(value)
```

Arguments

value

Either a number or binary value (VARBYTE) to be converted.

Return type

VARCHAR

Examples

To convert a number to its hexadecimal representation, use the following example.

```
SELECT TO_HEX(2147676847);
```

```
+-----+
| to_hex |
```

```
+-----+
| 8002f2af |
+-----+
```

To convert the VARBYTE representation of 'abc' to a hexadecimal number, use the following example.

```
SELECT TO_HEX('abc'::VARBYTE);
```

```
+-----+
| to_hex |
+-----+
| 616263 |
+-----+
```

To create a table, insert the VARBYTE representation of 'abc' to a hexadecimal number, and select the column with the value, use the following example.

```
CREATE TABLE t (vc VARCHAR);
INSERT INTO t SELECT TO_HEX('abc'::VARBYTE);
SELECT vc FROM t;
```

```
+-----+
|   vc   |
+-----+
| 616263 |
+-----+
```

To show that when casting a VARBYTE value to VARCHAR the format is UTF-8, use the following example.

```
CREATE TABLE t (vc VARCHAR);
INSERT INTO t SELECT 'abc'::VARBYTE::VARCHAR;
```

```
SELECT vc FROM t;
```

```
+-----+
| vc   |
+-----+
| abc  |
+-----+
```

TO_VARBYTE function

TO_VARBYTE converts a string in a specified format to a binary value.

Syntax

```
TO_VARBYTE(string, format)
```

Arguments

string

A CHAR or VARCHAR string.

format

The format of the input string. Case insensitive valid values are hex, binary, utf8 (also utf-8 and utf_8), and base64.

Return type

VARBYTE

Examples

To convert the hex 6162 to a binary value, use the following example. The result is automatically shown as the hexadecimal representation of the binary value.

```
SELECT TO_VARBYTE('6162', 'hex');
```

```
+-----+
| to_varbyte |
+-----+
|      6162 |
+-----+
```

To return the binary representation of 4d, use the following example. The binary representation of '4d' is 01001101.

```
SELECT TO_VARBYTE('01001101', 'binary');
```

```
+-----+
```

```
| to_varbyte |
+-----+
|          4d |
+-----+
```

To convert the string 'a' in UTF-8 to a binary value, use the following example. The result is automatically shown as the hexadecimal representation of the binary value.

```
SELECT TO_VARBYTE('a', 'utf8');
```

```
+-----+
| to_varbyte |
+-----+
|          61 |
+-----+
```

To convert the string '4' in hexadecimal to a binary value, use the following example. If the hexadecimal string length is an odd number, then a 0 is prepended to form a valid hexadecimal number.

```
SELECT TO_VARBYTE('4', 'hex');
```

```
+-----+
| to_varbyte |
+-----+
|          04 |
+-----+
```

Window functions

By using window functions, you can create analytic business queries more efficiently. Window functions operate on a partition or "window" of a result set, and return a value for every row in that window. In contrast, non-windowed functions perform their calculations with respect to every row in the result set. Unlike group functions that aggregate result rows, window functions retain all rows in the table expression.

The values returned are calculated by using values from the sets of rows in that window. For each row in the table, the window defines a set of rows that is used to compute additional attributes. A window is defined using a window specification (the `OVER` clause), and is based on three main concepts:

- *Window partitioning*, which forms groups of rows (PARTITION clause)
- *Window ordering*, which defines an order or sequence of rows within each partition (ORDER BY clause)
- *Window frames*, which are defined relative to each row to further restrict the set of rows (ROWS specification)

Window functions are the last set of operations performed in a query except for the final ORDER BY clause. All joins and all WHERE, GROUP BY, and HAVING clauses are completed before the window functions are processed. Therefore, window functions can appear only in the select list or ORDER BY clause. You can use multiple window functions within a single query with different frame clauses. You can also use window functions in other scalar expressions, such as CASE.

Window function syntax summary

Window functions follow a standard syntax, which is as follows.

```
function (expression) OVER (  
  [ PARTITION BY expr_list ]  
  [ ORDER BY order_list [ frame_clause ] ] )
```

Here, *function* is one of the functions described in this section.

The *expr_list* is as follows.

```
expression | column_name [, expr_list ]
```

The *order_list* is as follows.

```
expression | column_name [ ASC | DESC ]  
[ NULLS FIRST | NULLS LAST ]  
[, order_list ]
```

The *frame_clause* is as follows.

```
ROWS  
{ UNBOUNDED PRECEDING | unsigned_value PRECEDING | CURRENT ROW } |  
  
{ BETWEEN  
{ UNBOUNDED PRECEDING | unsigned_value { PRECEDING | FOLLOWING } | CURRENT ROW }
```

```
AND  
{ UNBOUNDED FOLLOWING | unsigned_value { PRECEDING | FOLLOWING } | CURRENT ROW }
```

Arguments

function

The window function. For details, see the individual function descriptions.

OVER

The clause that defines the window specification. The OVER clause is mandatory for window functions, and differentiates window functions from other SQL functions.

PARTITION BY *expr_list*

(Optional) The PARTITION BY clause subdivides the result set into partitions, much like the GROUP BY clause. If a partition clause is present, the function is calculated for the rows in each partition. If no partition clause is specified, a single partition contains the entire table, and the function is computed for that complete table.

The ranking functions DENSE_RANK, NTILE, RANK, and ROW_NUMBER require a global comparison of all the rows in the result set. When a PARTITION BY clause is used, the query optimizer can run each aggregation in parallel by spreading the workload across multiple slices according to the partitions. If the PARTITION BY clause is not present, the aggregation step must be run serially on a single slice, which can have a significant negative impact on performance, especially for large clusters.

Amazon Redshift doesn't support string literals in PARTITION BY clauses.

ORDER BY *order_list*

(Optional) The window function is applied to the rows within each partition sorted according to the order specification in ORDER BY. This ORDER BY clause is distinct from and completely unrelated to ORDER BY clauses in the *frame_clause*. The ORDER BY clause can be used without the PARTITION BY clause.

For ranking functions, the ORDER BY clause identifies the measures for the ranking values. For aggregation functions, the partitioned rows must be ordered before the aggregate function is computed for each frame. For more about window function types, see [Window functions](#).

Column identifiers or expressions that evaluate to column identifiers are required in the order list. Neither constants nor constant expressions can be used as substitutes for column names.

NULLS values are treated as their own group, sorted and ranked according to the NULLS FIRST or NULLS LAST option. By default, NULL values are sorted and ranked last in ASC ordering, and sorted and ranked first in DESC ordering.

Amazon Redshift doesn't support string literals in ORDER BY clauses.

If the ORDER BY clause is omitted, the order of the rows is nondeterministic.

Note

In any parallel system such as Amazon Redshift, when an ORDER BY clause doesn't produce a unique and total ordering of the data, the order of the rows is nondeterministic. That is, if the ORDER BY expression produces duplicate values (a partial ordering), the return order of those rows might vary from one run of Amazon Redshift to the next. In turn, window functions might return unexpected or inconsistent results. For more information, see [Unique ordering of data for window functions](#).

column_name

Name of a column to be partitioned by or ordered by.

ASC | DESC

Option that defines the sort order for the expression, as follows:

- ASC: ascending (for example, low to high for numeric values and 'A' to 'Z' for character strings). If no option is specified, data is sorted in ascending order by default.
- DESC: descending (high to low for numeric values; 'Z' to 'A' for strings).

NULLS FIRST | NULLS LAST

Option that specifies whether NULLS should be ordered first, before non-null values, or last, after non-null values. By default, NULLS are sorted and ranked last in ASC ordering, and sorted and ranked first in DESC ordering.

frame_clause

For aggregate functions, the frame clause further refines the set of rows in a function's window when using ORDER BY. It enables you to include or exclude sets of rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers.

The frame clause doesn't apply to ranking functions. Also, the frame clause isn't required when no ORDER BY clause is used in the OVER clause for an aggregate function. If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required.

When no ORDER BY clause is specified, the implied frame is unbounded, equivalent to ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING.

ROWS

This clause defines the window frame by specifying a physical offset from the current row.

This clause specifies the rows in the current window or partition that the value in the current row is to be combined with. It uses arguments that specify row position, which can be before or after the current row. The reference point for all window frames is the current row. Each row becomes the current row in turn as the window frame slides forward in the partition.

The frame can be a simple set of rows up to and including the current row.

```
{UNBOUNDED PRECEDING | offset PRECEDING | CURRENT ROW}
```

Or it can be a set of rows between two boundaries.

```
BETWEEN  
{ UNBOUNDED PRECEDING | offset { PRECEDING | FOLLOWING } | CURRENT ROW }  
AND  
{ UNBOUNDED FOLLOWING | offset { PRECEDING | FOLLOWING } | CURRENT ROW }
```

UNBOUNDED PRECEDING indicates that the window starts at the first row of the partition; *offset* PRECEDING indicates that the window starts a number of rows equivalent to the value of *offset* before the current row. UNBOUNDED PRECEDING is the default.

CURRENT ROW indicates the window begins or ends at the current row.

UNBOUNDED FOLLOWING indicates that the window ends at the last row of the partition; *offset* FOLLOWING indicates that the window ends a number of rows equivalent to the value of *offset* after the current row.

offset identifies a physical number of rows before or after the current row. In this case, *offset* must be a constant that evaluates to a positive numeric value. For example, 5 FOLLOWING ends the frame five rows after the current row.

Where `BETWEEN` is not specified, the frame is implicitly bounded by the current row. For example, `ROWS 5 PRECEDING` is equal to `ROWS BETWEEN 5 PRECEDING AND CURRENT ROW`. Also, `ROWS UNBOUNDED FOLLOWING` is equal to `ROWS BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING`.

Note

You can't specify a frame in which the starting boundary is greater than the ending boundary. For example, you can't specify any of the following frames.

```
between 5 following and 5 preceding
between current row and 2 preceding
between 3 following and current row
```

Unique ordering of data for window functions

If an `ORDER BY` clause for a window function doesn't produce a unique and total ordering of the data, the order of the rows is nondeterministic. If the `ORDER BY` expression produces duplicate values (a partial ordering), the return order of those rows can vary in multiple runs. In this case, window functions can also return unexpected or inconsistent results.

For example, the following query returns different results over multiple runs. These different results occur because `order by dateid` doesn't produce a unique ordering of the data for the `SUM` window function.

```
select dateid, pricepaid,
sum(pricepaid) over(order by dateid rows unbounded preceding) as sumpaid
from sales
group by dateid, pricepaid;
```

dateid	pricepaid	sumpaid
1827	1730.00	1730.00
1827	708.00	2438.00
1827	234.00	2672.00
...		

```
select dateid, pricepaid,
sum(pricepaid) over(order by dateid rows unbounded preceding) as sumpaid
```

```
from sales
group by dateid, pricepaid;
```

dateid	pricepaid	sumpaid
1827	234.00	234.00
1827	472.00	706.00
1827	347.00	1053.00
...		

In this case, adding a second ORDER BY column to the window function can solve the problem.

```
select dateid, pricepaid,
sum(pricepaid) over(order by dateid, pricepaid rows unbounded preceding) as sumpaid
from sales
group by dateid, pricepaid;
```

dateid	pricepaid	sumpaid
1827	234.00	234.00
1827	337.00	571.00
1827	347.00	918.00
...		

Supported functions

Amazon Redshift supports two types of window functions: aggregate and ranking.

Following are the supported aggregate functions:

- [AVG window function](#)
- [COUNT window function](#)
- [CUME_DIST window function](#)
- [DENSE_RANK window function](#)
- [FIRST_VALUE window function](#)
- [LAG window function](#)
- [LAST_VALUE window function](#)
- [LEAD window function](#)
- [LISTAGG window function](#)

- [MAX window function](#)
- [MEDIAN window function](#)
- [MIN window function](#)
- [NTH_VALUE window function](#)
- [PERCENTILE_CONT window function](#)
- [PERCENTILE_DISC window function](#)
- [RATIO_TO_REPORT window function](#)
- [STDDEV_SAMP and STDDEV_POP window functions](#) (STDDEV_SAMP and STDDEV are synonyms)
- [SUM window function](#)
- [VAR_SAMP and VAR_POP window functions](#) (VAR_SAMP and VARIANCE are synonyms)

Following are the supported ranking functions:

- [DENSE_RANK window function](#)
- [NTILE window function](#)
- [PERCENT_RANK window function](#)
- [RANK window function](#)
- [ROW_NUMBER window function](#)

Sample table for window function examples

You can find specific window function examples with each function description. Some of the examples use a table named WINSALES, which contains 11 rows, as shown following.

SALESID	DATEID	SELLERID	BUYERID	QTY	QTY_SHIPPED
30001	8/2/2003	3	B	10	10
10001	12/24/2003	1	C	10	10
10005	12/24/2003	1	A	30	
40001	1/9/2004	4	A	40	

SALESID	DATEID	SELLERID	BUYERID	QTY	QTY_SHIPPED
10006	1/18/2004	1	C	10	
20001	2/12/2004	2	B	20	20
40005	2/12/2004	4	A	10	10
20002	2/16/2004	2	C	20	20
30003	4/18/2004	3	B	15	
30004	4/18/2004	3	B	20	
30007	9/7/2004	3	C	30	

The following script creates and populates the sample WINSALES table.

```
CREATE TABLE winsales(  
    salesid int,  
    dateid date,  
    sellerid int,  
    buyerid char(10),  
    qty int,  
    qty_shipped int);  
  
INSERT INTO winsales VALUES  
    (30001, '8/2/2003', 3, 'b', 10, 10),  
    (10001, '12/24/2003', 1, 'c', 10, 10),  
    (10005, '12/24/2003', 1, 'a', 30, null),  
    (40001, '1/9/2004', 4, 'a', 40, null),  
    (10006, '1/18/2004', 1, 'c', 10, null),  
    (20001, '2/12/2004', 2, 'b', 20, 20),  
    (40005, '2/12/2004', 4, 'a', 10, 10),  
    (20002, '2/16/2004', 2, 'c', 20, 20),  
    (30003, '4/18/2004', 3, 'b', 15, null),  
    (30004, '4/18/2004', 3, 'b', 20, null),  
    (30007, '9/7/2004', 3, 'c', 30, null);
```

AVG window function

The AVG window function returns the average (arithmetic mean) of the input expression values. The AVG function works with numeric values and ignores NULL values.

Syntax

```
AVG ( [ALL ] expression ) OVER  
(  
  [ PARTITION BY expr_list ]  
  [ ORDER BY order_list  
                frame_clause ]  
)
```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression for counting. ALL is the default. DISTINCT is not supported.

OVER

Specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the AVG function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of

rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

The argument types supported by the AVG function are SMALLINT, INTEGER, BIGINT, NUMERIC, DECIMAL, REAL, and DOUBLE PRECISION.

The return types supported by the AVG function are:

- BIGINT for SMALLINT or INTEGER arguments
- NUMERIC for BIGINT arguments
- DOUBLE PRECISION for floating point arguments

Examples

The following example computes a rolling average of quantities sold by date; order the results by date ID and sales ID:

```
select salesid, dateid, sellerid, qty,
avg(qty) over
(order by dateid, salesid rows unbounded preceding) as avg
from winsales
order by 2,1;
```

salesid	dateid	sellerid	qty	avg
30001	2003-08-02	3	10	10
10001	2003-12-24	1	10	10
10005	2003-12-24	1	30	16
40001	2004-01-09	4	40	22
10006	2004-01-18	1	10	20
20001	2004-02-12	2	20	20
40005	2004-02-12	4	10	18
20002	2004-02-16	2	20	18
30003	2004-04-18	3	15	18
30004	2004-04-18	3	20	18
30007	2004-09-07	3	30	19

(11 rows)

For a description of the WINSALES table, see [Sample table for window function examples](#).

COUNT window function

The COUNT window function counts the rows defined by the expression.

The COUNT function has two variations. COUNT(*) counts all the rows in the target table whether they include nulls or not. COUNT(expression) computes the number of rows with non-NULL values in a specific column or expression.

Syntax

```
COUNT ( * | [ ALL ] expression) OVER  
(  
[ PARTITION BY expr_list ]  
[ ORDER BY order_list  
                frame_clause ]  
)
```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression for counting. ALL is the default. DISTINCT is not supported.

OVER

Specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the COUNT function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of

rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

The COUNT function supports all argument data types.

The return type supported by the COUNT function is BIGINT.

Examples

The following example shows the sales ID, quantity, and count of all rows from the beginning of the data window:

```
select salesid, qty,
count(*) over (order by salesid rows unbounded preceding) as count
from winsales
order by salesid;
```

```
salesid | qty | count
-----+-----+-----
10001 | 10 | 1
10005 | 30 | 2
10006 | 10 | 3
20001 | 20 | 4
20002 | 20 | 5
30001 | 10 | 6
30003 | 15 | 7
30004 | 20 | 8
30007 | 30 | 9
40001 | 40 | 10
40005 | 10 | 11
(11 rows)
```

For a description of the WINDSALES table, see [Sample table for window function examples](#).

The following example shows how the sales ID, quantity, and count of non-null rows from the beginning of the data window. (In the WINDSALES table, the QTY_SHIPPED column contains some NULLs.)

```
select salesid, qty, qty_shipped,
count(qty_shipped)
```

```
over (order by salesid rows unbounded preceding) as count
from winsales
order by salesid;
```

```
salesid | qty | qty_shipped | count
-----+-----+-----+-----
10001 | 10 |          10 |    1
10005 | 30 |           |    1
10006 | 10 |           |    1
20001 | 20 |          20 |    2
20002 | 20 |          20 |    3
30001 | 10 |          10 |    4
30003 | 15 |           |    4
30004 | 20 |           |    4
30007 | 30 |           |    4
40001 | 40 |           |    4
40005 | 10 |          10 |    5
(11 rows)
```

CUME_DIST window function

Calculates the cumulative distribution of a value within a window or partition. Assuming ascending ordering, the cumulative distribution is determined using this formula:

$$\text{count of rows with values } \leq x \text{ / count of rows in the window or partition}$$

where x equals the value in the current row of the column specified in the ORDER BY clause. The following dataset illustrates use of this formula:

Row#	Value	Calculation	CUME_DIST
1	2500	(1)/(5)	0.2
2	2600	(2)/(5)	0.4
3	2800	(3)/(5)	0.6
4	2900	(4)/(5)	0.8
5	3100	(5)/(5)	1.0

The return value range is >0 to 1, inclusive.

Syntax

```
CUME_DIST (
OVER (
```

```
[ PARTITION BY partition_expression ]  
[ ORDER BY order_list ]  
)
```

Arguments

OVER

A clause that specifies the window partitioning. The OVER clause cannot contain a window frame specification.

PARTITION BY *partition_expression*

Optional. An expression that sets the range of records for each group in the OVER clause.

ORDER BY *order_list*

The expression on which to calculate cumulative distribution. The expression must have either a numeric data type or be implicitly convertible to one. If ORDER BY is omitted, the return value is 1 for all rows.

If ORDER BY doesn't produce a unique ordering, the order of the rows is nondeterministic. For more information, see [Unique ordering of data for window functions](#).

Return type

FLOAT8

Examples

The following example calculates the cumulative distribution of the quantity for each seller:

```
select sellerid, qty, cume_dist()  
over (partition by sellerid order by qty)  
from winsales;
```

sellerid	qty	cume_dist
1	10.00	0.33
1	10.64	0.67
1	30.37	1
3	10.04	0.25
3	15.15	0.5

3	20.75	0.75
3	30.55	1
2	20.09	0.5
2	20.12	1
4	10.12	0.5
4	40.23	1

For a description of the WINDSALES table, see [Sample table for window function examples](#).

DENSE_RANK window function

The DENSE_RANK window function determines the rank of a value in a group of values, based on the ORDER BY expression in the OVER clause. If the optional PARTITION BY clause is present, the rankings are reset for each group of rows. Rows with equal values for the ranking criteria receive the same rank. The DENSE_RANK function differs from RANK in one respect: if two or more rows tie, there is no gap in the sequence of ranked values. For example, if two rows are ranked 1, the next rank is 2.

You can have ranking functions with different PARTITION BY and ORDER BY clauses in the same query.

Syntax

```
DENSE_RANK() OVER  
(  
[ PARTITION BY expr_list ]  
[ ORDER BY order_list ]  
)
```

Arguments

()

The function takes no arguments, but the empty parentheses are required.

OVER

The window clauses for the DENSE_RANK function.

PARTITION BY *expr_list*

(Optional) One or more expressions that define the window.

ORDER BY *order_list*

(Optional) The expression on which the ranking values are based. If no PARTITION BY is specified, ORDER BY uses the entire table. If ORDER BY is omitted, the return value is 1 for all rows.

If ORDER BY doesn't produce a unique ordering, the order of the rows is nondeterministic. For more information, see [Unique ordering of data for window functions](#).

Return type

INTEGER

Examples

The following examples use the sample table for window functions. For more information, see [Sample table for window function examples](#).

The following example orders the table by the quantity sold and assigns both a dense rank and a regular rank to each row. The results are sorted after the window function results are applied.

```
SELECT salesid, qty,
DENSE_RANK() OVER(ORDER BY qty DESC) AS d_rnk,
RANK() OVER(ORDER BY qty DESC) AS rnk
FROM winsales
ORDER BY 2,1;
```

salesid	qty	d_rnk	rnk
10001	10	5	8
10006	10	5	8
30001	10	5	8
40005	10	5	8
30003	15	4	7
20001	20	3	4
20002	20	3	4
30004	20	3	4
10005	30	2	2
30007	30	2	2
40001	40	1	1

Note the difference in rankings assigned to the same set of rows when the `DENSE_RANK` and `RANK` functions are used side by side in the same query.

The following example partitions the table by `sellerid`, orders each partition by the quantity, and assigns a dense rank to each row. The results are sorted after the window function results are applied.

```
SELECT salesid, sellerid, qty,
DENSE_RANK() OVER(PARTITION BY sellerid ORDER BY qty DESC) AS d_rnk
FROM winsales
ORDER BY 2,3,1;
```

salesid	sellerid	qty	d_rnk
10001	1	10	2
10006	1	10	2
10005	1	30	1
20001	2	20	1
20002	2	20	1
30001	3	10	4
30003	3	15	3
30004	3	20	2
30007	3	30	1
40005	4	10	2
40001	4	40	1

To successfully use the last example, use the following command to insert a row into the `WINSALES` table. This row has the same `buyerid`, `sellerid`, and `qtysold` as another row. This will cause two rows to tie in the last example and thus will show the difference between the `DENSE_RANK` and `RANK` functions.

```
INSERT INTO winsales VALUES(30009, '2/2/2003', 3, 'b', 20, NULL);
```

The following example partitions the table by `buyerid` and `sellerid`, orders each partition by the quantity, and assigns both a dense rank and a regular rank to each row. The results are sorted after the window function is applied.

```
SELECT salesid, sellerid, qty, buyerid,
```

```
DENSE_RANK() OVER(PARTITION BY buyerid, sellerid ORDER BY qty DESC) AS d_rnk,
RANK() OVER (PARTITION BY buyerid, sellerid ORDER BY qty DESC) AS rnk
FROM winsales
ORDER BY rnk;
```

salesid	sellerid	qty	buyerid	d_rnk	rnk
20001	2	20	b	1	1
30007	3	30	c	1	1
10006	1	10	c	1	1
10005	1	30	a	1	1
20002	2	20	c	1	1
30009	3	20	b	1	1
40001	4	40	a	1	1
30004	3	20	b	1	1
10001	1	10	c	1	1
40005	4	10	a	2	2
30003	3	15	b	2	3
30001	3	10	b	3	4

FIRST_VALUE window function

Given an ordered set of rows, FIRST_VALUE returns the value of the specified expression with respect to the first row in the window frame.

For information about selecting the last row in the frame, see [LAST_VALUE window function](#).

Syntax

```
FIRST_VALUE( expression ) [ IGNORE NULLS | RESPECT NULLS ]
OVER (
  [ PARTITION BY expr_list ]
  [ ORDER BY order_list frame_clause ]
)
```

Arguments

expression

The target column or expression that the function operates on.

IGNORE NULLS

When this option is used with `FIRST_VALUE`, the function returns the first value in the frame that is not `NULL` (or `NULL` if all values are `NULL`).

RESPECT NULLS

Indicates that Amazon Redshift should include null values in the determination of which row to use. `RESPECT NULLS` is supported by default if you do not specify `IGNORE NULLS`.

OVER

Introduces the window clauses for the function.

`PARTITION BY` *expr_list*

Defines the window for the function in terms of one or more expressions.

`ORDER BY` *order_list*

Sorts the rows within each partition. If no `PARTITION BY` clause is specified, `ORDER BY` sorts the entire table. If you specify an `ORDER BY` clause, you must also specify a *frame_clause*.

The results of the `FIRST_VALUE` function depends on the ordering of the data. The results are nondeterministic in the following cases:

- When no `ORDER BY` clause is specified and a partition contains two different values for an expression
- When the expression evaluates to different values that correspond to the same value in the `ORDER BY` list.

frame_clause

If an `ORDER BY` clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows in the ordered result. The frame clause consists of the `ROWS` keyword and associated specifiers. See [Window function syntax summary](#).

Return type

These functions support expressions that use primitive Amazon Redshift data types. The return type is the same as the data type of the *expression*.

Examples

The following examples use the VENUE table from the sample TICKIT data. For more information, see [Sample database](#).

The following example returns the seating capacity for each venue in the VENUE table, with the results ordered by capacity (high to low). The FIRST_VALUE function is used to select the name of the venue that corresponds to the first row in the frame: in this case, the row with the highest number of seats. The results are partitioned by state, so when the VENUESTATE value changes, a new first value is selected. The window frame is unbounded so the same first value is selected for each row in each partition.

For California, Qualcomm Stadium has the highest number of seats (70561), so this name is the first value for all of the rows in the CA partition.

```
select venuestate, venueseats, venueName,
first_value(venueName)
over(partition by venuestate
order by venueseats desc
rows between unbounded preceding and unbounded following)
from (select * from venue where venueseats >0)
order by venuestate;
```

venuestate	venueseats	venueName	first_value
CA	70561	Qualcomm Stadium	Qualcomm Stadium
CA	69843	Monster Park	Qualcomm Stadium
CA	63026	McAfee Coliseum	Qualcomm Stadium
CA	56000	Dodger Stadium	Qualcomm Stadium
CA	45050	Angel Stadium of Anaheim	Qualcomm Stadium
CA	42445	PETCO Park	Qualcomm Stadium
CA	41503	AT&T Park	Qualcomm Stadium
CA	22000	Shoreline Amphitheatre	Qualcomm Stadium
CO	76125	INVESCO Field	INVESCO Field
CO	50445	Coors Field	INVESCO Field
DC	41888	Nationals Park	Nationals Park
FL	74916	Dolphin Stadium	Dolphin Stadium
FL	73800	Jacksonville Municipal Stadium	Dolphin Stadium
FL	65647	Raymond James Stadium	Dolphin Stadium
FL	36048	Tropicana Field	Dolphin Stadium
...			

The following example shows the use of the IGNORE NULLS option and relies on the addition of a new row to the VENUE table:

```
insert into venue values(2000,null,'Stanford','CA',90000);
```

This new row contains a NULL value for the VENUENAME column. Now repeat the FIRST_VALUE query that was shown earlier in this section:

```
select venuestate, venueseats, venuename,
first_value(venuename)
over(partition by venuestate
order by venueseats desc
rows between unbounded preceding and unbounded following)
from (select * from venue where venueseats >0)
order by venuestate;
```

venuestate	venueseats	venuename	first_value
CA	90000	NULL	NULL
CA	70561	Qualcomm Stadium	NULL
CA	69843	Monster Park	NULL
...			

Because the new row contains the highest VENUSEATS value (90000) and its VENUENAME is NULL, the FIRST_VALUE function returns NULL for the CA partition. To ignore rows like this in the function evaluation, add the IGNORE NULLS option to the function argument:

```
select venuestate, venueseats, venuename,
first_value(venuename) ignore nulls
over(partition by venuestate
order by venueseats desc
rows between unbounded preceding and unbounded following)
from (select * from venue where venuestate='CA')
order by venuestate;
```

venuestate	venueseats	venuename	first_value
CA	90000	NULL	Qualcomm Stadium
CA	70561	Qualcomm Stadium	Qualcomm Stadium
CA	69843	Monster Park	Qualcomm Stadium
...			

LAG window function

The LAG window function returns the values for a row at a given offset above (before) the current row in the partition.

Syntax

```
LAG (value_expr [, offset ])  
[ IGNORE NULLS | RESPECT NULLS ]  
OVER ( [ PARTITION BY window_partition ] ORDER BY window_ordering )
```

Arguments

value_expr

The target column or expression that the function operates on.

offset

An optional parameter that specifies the number of rows before the current row to return values for. The offset can be a constant integer or an expression that evaluates to an integer. If you do not specify an offset, Amazon Redshift uses 1 as the default value. An offset of 0 indicates the current row.

IGNORE NULLS

An optional specification that indicates that Amazon Redshift should skip null values in the determination of which row to use. Null values are included if IGNORE NULLS is not listed.

Note

You can use an NVL or COALESCE expression to replace the null values with another value. For more information, see [NVL and COALESCE functions](#).

RESPECT NULLS

Indicates that Amazon Redshift should include null values in the determination of which row to use. RESPECT NULLS is supported by default if you do not specify IGNORE NULLS.

OVER

Specifies the window partitioning and ordering. The OVER clause cannot contain a window frame specification.

PARTITION BY *window_partition*

An optional argument that sets the range of records for each group in the OVER clause.

ORDER BY *window_ordering*

Sorts the rows within each partition.

The LAG window function supports expressions that use any of the Amazon Redshift data types. The return type is the same as the type of the *value_expr*.

Examples

The following example shows the quantity of tickets sold to the buyer with a buyer ID of 3 and the time that buyer 3 bought the tickets. To compare each sale with the previous sale for buyer 3, the query returns the previous quantity sold for each sale. Since there is no purchase before 1/16/2008, the first previous quantity sold value is null:

```
select buyerid, saletime, qtysold,
lag(qtysold,1) over (order by buyerid, saletime) as prev_qtysold
from sales where buyerid = 3 order by buyerid, saletime;
```

buyerid	saletime	qtysold	prev_qtysold
3	2008-01-16 01:06:09	1	
3	2008-01-28 02:10:01	1	1
3	2008-03-12 10:39:53	1	1
3	2008-03-13 02:56:07	1	1
3	2008-03-29 08:21:39	2	1
3	2008-04-27 02:39:01	1	2
3	2008-08-16 07:04:37	2	1
3	2008-08-22 11:45:26	2	2
3	2008-09-12 09:11:25	1	2
3	2008-10-01 06:22:37	1	1
3	2008-10-20 01:55:51	2	1
3	2008-10-28 01:30:40	1	2

(12 rows)

LAST_VALUE window function

Given an ordered set of rows, The LAST_VALUE function returns the value of the expression with respect to the last row in the frame.

For information about selecting the first row in the frame, see [FIRST_VALUE window function](#) .

Syntax

```
LAST_VALUE( expression ) [ IGNORE NULLS | RESPECT NULLS ]  
OVER (  
  [ PARTITION BY expr_list ]  
  [ ORDER BY order_list frame_clause ]  
)
```

Arguments

expression

The target column or expression that the function operates on.

IGNORE NULLS

The function returns the last value in the frame that is not NULL (or NULL if all values are NULL).

RESPECT NULLS

Indicates that Amazon Redshift should include null values in the determination of which row to use. RESPECT NULLS is supported by default if you do not specify IGNORE NULLS.

OVER

Introduces the window clauses for the function.

PARTITION BY *expr_list*

Defines the window for the function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY clause is specified, ORDER BY sorts the entire table. If you specify an ORDER BY clause, you must also specify a *frame_clause*.

The results depend on the ordering of the data. The results are nondeterministic in the following cases:

- When no ORDER BY clause is specified and a partition contains two different values for an expression
- When the expression evaluates to different values that correspond to the same value in the ORDER BY list.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows in the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Return type

These functions support expressions that use primitive Amazon Redshift data types. The return type is the same as the data type of the *expression*.

Examples

The following examples use the VENUE table from the sample TICKIT data. For more information, see [Sample database](#).

The following example returns the seating capacity for each venue in the VENUE table, with the results ordered by capacity (high to low). The LAST_VALUE function is used to select the name of the venue that corresponds to the last row in the frame: in this case, the row with the least number of seats. The results are partitioned by state, so when the VENUESTATE value changes, a new last value is selected. The window frame is unbounded so the same last value is selected for each row in each partition.

For California, Shoreline Amphitheatre is returned for every row in the partition because it has the lowest number of seats (22000).

```
select venuestate, venueseats, venue_name,  
last_value(venue_name)  
over(partition by venuestate  
order by venueseats desc  
rows between unbounded preceding and unbounded following)  
from (select * from venue where venueseats >0)  
order by venuestate;
```

```

venuestate | venueseats |          venue         |          last_value
-----+-----+-----
+-----+
CA          |      70561 | Qualcomm Stadium     | Shoreline Amphitheatre
CA          |      69843 | Monster Park         | Shoreline Amphitheatre
CA          |      63026 | McAfee Coliseum      | Shoreline Amphitheatre
CA          |      56000 | Dodger Stadium       | Shoreline Amphitheatre
CA          |      45050 | Angel Stadium of Anaheim | Shoreline Amphitheatre
CA          |      42445 | PETCO Park           | Shoreline Amphitheatre
CA          |      41503 | AT&T Park            | Shoreline Amphitheatre
CA          |      22000 | Shoreline Amphitheatre | Shoreline Amphitheatre
CO          |      76125 | INVESCO Field        | Coors Field
CO          |      50445 | Coors Field          | Coors Field
DC          |      41888 | Nationals Park       | Nationals Park
FL          |      74916 | Dolphin Stadium      | Tropicana Field
FL          |      73800 | Jacksonville Municipal Stadium | Tropicana Field
FL          |      65647 | Raymond James Stadium | Tropicana Field
FL          |      36048 | Tropicana Field      | Tropicana Field
...

```

LEAD window function

The LEAD window function returns the values for a row at a given offset below (after) the current row in the partition.

Syntax

```

LEAD (value_expr [, offset ])
[ IGNORE NULLS | RESPECT NULLS ]
OVER ( [ PARTITION BY window_partition ] ORDER BY window_ordering )

```

Arguments

value_expr

The target column or expression that the function operates on.

offset

An optional parameter that specifies the number of rows below the current row to return values for. The offset can be a constant integer or an expression that evaluates to an integer. If you do not specify an offset, Amazon Redshift uses 1 as the default value. An offset of 0 indicates the current row.

IGNORE NULLS

An optional specification that indicates that Amazon Redshift should skip null values in the determination of which row to use. Null values are included if IGNORE NULLS is not listed.

Note

You can use an NVL or COALESCE expression to replace the null values with another value. For more information, see [NVL and COALESCE functions](#).

RESPECT NULLS

Indicates that Amazon Redshift should include null values in the determination of which row to use. RESPECT NULLS is supported by default if you do not specify IGNORE NULLS.

OVER

Specifies the window partitioning and ordering. The OVER clause cannot contain a window frame specification.

PARTITION BY *window_partition*

An optional argument that sets the range of records for each group in the OVER clause.

ORDER BY *window_ordering*

Sorts the rows within each partition.

The LEAD window function supports expressions that use any of the Amazon Redshift data types. The return type is the same as the type of the *value_expr*.

Examples

The following example provides the commission for events in the SALES table for which tickets were sold on January 1, 2008 and January 2, 2008 and the commission paid for ticket sales for the subsequent sale. The following example uses the TICKIT sample database. For more information, see [Sample database](#).

```
SELECT eventid, commission, saletime, LEAD(commission, 1) over ( ORDER BY saletime ) AS  
next_comm
```

```

FROM sales
WHERE saletime BETWEEN '2008-01-09 00:00:00' AND '2008-01-10 12:59:59'
LIMIT 10;

```

eventid	commission	saletime	next_comm
1664	13.2	2008-01-09 01:00:21	69.6
184	69.6	2008-01-09 01:00:36	116.1
6870	116.1	2008-01-09 01:02:37	11.1
3718	11.1	2008-01-09 01:05:19	205.5
6772	205.5	2008-01-09 01:14:04	38.4
3074	38.4	2008-01-09 01:26:50	209.4
5254	209.4	2008-01-09 01:29:16	26.4
3724	26.4	2008-01-09 01:40:09	57.6
5303	57.6	2008-01-09 01:40:21	51.6
3678	51.6	2008-01-09 01:42:54	43.8

The following example provides the maximum difference for the commission for events in the SALES table for and the commission paid for ticket sales for the subsequent sale for the same event. This example shows how to use LEAD with a GROUP BY clause. Since window functions aren't allowed in aggregate clauses, this example uses a subquery. The following example uses the TICKIT sample database. For more information, see [Sample database](#).

```

SELECT eventid, eventname, max(next_comm_diff) as max_commission_difference
FROM
(
  SELECT sales.eventid, eventname, commission - LEAD(commission, 1) over (ORDER BY
sales.eventid, saletime) AS next_comm_diff
  FROM sales JOIN event ON sales.eventid = event.eventid
)
GROUP BY eventid, eventname
ORDER BY eventid

LIMIT 10

```

eventid	eventname	max_commission_difference
1	Gotterdammerung	7.95
2	Boris Godunov	227.85
3	Salome	1350.9
4	La Cenerentola (Cinderella)	790.05

5	Il Trovatore	214.05	
6	L'Elisir d'Amore	510.9	
7	Doctor Atomic	180.6	
9	The Fly	147	
10	Rigoletto	186.6	
+-----+-----+-----+-----+			

LISTAGG window function

For each group in a query, the LISTAGG window function orders the rows for that group according to the ORDER BY expression, then concatenates the values into a single string.

Syntax

```
LISTAGG( [DISTINCT] expression [, 'delimiter' ] )
[ WITHIN GROUP (ORDER BY order_list) ]
OVER ( [PARTITION BY partition_expression] )
```

Arguments

DISTINCT

(Optional) A clause that eliminates duplicate values from the specified expression before concatenating. Trailing spaces are ignored, so the strings 'a' and 'a ' are treated as duplicates. LISTAGG uses the first value encountered. For more information, see [Significance of trailing blanks](#).

aggregate_expression

Any valid expression (such as a column name) that provides the values to aggregate. NULL values and empty strings are ignored.

delimiter

(Optional) The string constant to will separate the concatenated values. The default is NULL.

WITHIN GROUP (ORDER BY *order_list*)

(Optional) A clause that specifies the sort order of the aggregated values. Deterministic only if ORDER BY provides unique ordering. The default is to aggregate all rows and return a single value.

OVER

A clause that specifies the window partitioning. The OVER clause cannot contain a window ordering or window frame specification.

PARTITION BY *partition_expression*

(Optional) Sets the range of records for each group in the OVER clause.

Returns

VARCHAR(MAX). If the result set is larger than the maximum VARCHAR size (64K – 1, or 65535), then LISTAGG returns the following error:

```
Invalid operation: Result size exceeds LISTAGG limit
```

Examples

The following examples uses the WINDSALES table. For a description of the WINDSALES table, see [Sample table for window function examples](#).

The following example returns a list of seller IDs, ordered by seller ID.

```
select listagg(sellerid)
within group (order by sellerid)
over() from winsales;
```

```
listagg
-----
11122333344
...
...
11122333344
11122333344
(11 rows)
```

The following example returns a list of seller IDs for buyer B, ordered by date.

```
select listagg(sellerid)
within group (order by dateid)
over () as seller
from winsales
where buyerid = 'b' ;
```

```

seller
-----
3233
3233
3233
3233

```

The following example returns a comma-separated list of sales dates for buyer B.

```

select listagg(dateid,',')
within group (order by sellerid desc,salesid asc)
over () as dates
from winsales
where buyerid = 'b';

```

```

          dates
-----
2003-08-02,2004-04-18,2004-04-18,2004-02-12
2003-08-02,2004-04-18,2004-04-18,2004-02-12
2003-08-02,2004-04-18,2004-04-18,2004-02-12
2003-08-02,2004-04-18,2004-04-18,2004-02-12

```

The following example uses DISTINCT to return a list of unique sales dates for buyer B.

```

select listagg(distinct dateid,',')
within group (order by sellerid desc,salesid asc)
over () as dates
from winsales
where buyerid = 'b';

```

```

          dates

2003-08-02,2004-04-18,2004-02-12
2003-08-02,2004-04-18,2004-02-12
2003-08-02,2004-04-18,2004-02-12

```

The following example returns a comma-separated list of sales IDs for each buyer ID.

```

select buyerid,
listagg(salesid,',')

```

```

within group (order by salesid)
over (partition by buyerid) as sales_id
from winsales
order by buyerid;

```

```

+-----+-----+
| buyerid |      sales_id      |
+-----+-----+

| c        | 10001,10006,20002,30007 |
| c        | 10001,10006,20002,30007 |
| c        | 10001,10006,20002,30007 |
+-----+-----+

```

MAX window function

The MAX window function returns the maximum of the input expression values. The MAX function works with numeric values and ignores NULL values.

Syntax

```

MAX ( [ ALL ] expression ) OVER
(
  [ PARTITION BY expr_list ]
  [ ORDER BY order_list frame_clause ]
)

```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression. ALL is the default. DISTINCT is not supported.

OVER

A clause that specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the MAX function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

Accepts any data type as input. Returns the same data type as *expression*.

Examples

The following example shows the sales ID, quantity, and maximum quantity from the beginning of the data window:

```
select salesid, qty,
max(qty) over (order by salesid rows unbounded preceding) as max
from winsales
order by salesid;
```

salesid	qty	max
10001	10	10
10005	30	30
10006	10	30
20001	20	30
20002	20	30
30001	10	30

```

30003 | 15 | 30
30004 | 20 | 30
30007 | 30 | 30
40001 | 40 | 40
40005 | 10 | 40
(11 rows)

```

For a description of the WINDSALES table, see [Sample table for window function examples](#).

The following example shows the salesid, quantity, and maximum quantity in a restricted frame:

```

select salesid, qty,
max(qty) over (order by salesid rows between 2 preceding and 1 preceding) as max
from winsales
order by salesid;

```

```

salesid | qty | max
-----+-----+-----
10001 | 10 |
10005 | 30 | 10
10006 | 10 | 30
20001 | 20 | 30
20002 | 20 | 20
30001 | 10 | 20
30003 | 15 | 20
30004 | 20 | 15
30007 | 30 | 20
40001 | 40 | 30
40005 | 10 | 40
(11 rows)

```

MEDIAN window function

Calculates the median value for the range of values in a window or partition. NULL values in the range are ignored.

MEDIAN is an inverse distribution function that assumes a continuous distribution model.

Syntax

```

MEDIAN ( median_expression )
OVER ( [ PARTITION BY partition_expression ] )

```

Arguments

median_expression

An expression, such as a column name, that provides the values for which to determine the median. The expression must have either a numeric or datetime data type or be implicitly convertible to one.

OVER

A clause that specifies the window partitioning. The OVER clause cannot contain a window ordering or window frame specification.

PARTITION BY *partition_expression*

Optional. An expression that sets the range of records for each group in the OVER clause.

Data types

The return type is determined by the data type of *median_expression*. The following table shows the return type for each *median_expression* data type.

Input Type	Return Type
INT2, INT4, INT8, NUMERIC, DECIMAL	DECIMAL
FLOAT, DOUBLE	DOUBLE
DATE	DATE

Usage notes

If the *median_expression* argument is a DECIMAL data type defined with the maximum precision of 38 digits, it is possible that MEDIAN will return either an inaccurate result or an error. If the return value of the MEDIAN function exceeds 38 digits, the result is truncated to fit, which causes a loss of precision. If, during interpolation, an intermediate result exceeds the maximum precision, a numeric overflow occurs and the function returns an error. To avoid these conditions, we recommend either using a data type with lower precision or casting the *median_expression* argument to a lower precision.

For example, a SUM function with a DECIMAL argument returns a default precision of 38 digits. The scale of the result is the same as the scale of the argument. So, for example, a SUM of a DECIMAL(5,2) column returns a DECIMAL(38,2) data type.

The following example uses a SUM function in the *median_expression* argument of a MEDIAN function. The data type of the PRICEPAID column is DECIMAL (8,2), so the SUM function returns DECIMAL(38,2).

```
select salesid, sum(pricepaid), median(sum(pricepaid))
over() from sales where salesid < 10 group by salesid;
```

To avoid a potential loss of precision or an overflow error, cast the result to a DECIMAL data type with lower precision, as the following example shows.

```
select salesid, sum(pricepaid), median(sum(pricepaid)::decimal(30,2))
over() from sales where salesid < 10 group by salesid;
```

Examples

The following example calculates the median sales quantity for each seller:

```
select sellerid, qty, median(qty)
over (partition by sellerid)
from winsales
order by sellerid;
```

```
sellerid qty median
-----
```

```
1  10 10.0
1  10 10.0
1  30 10.0
2  20 20.0
2  20 20.0
3  10 17.5
3  15 17.5
3  20 17.5
3  30 17.5
4  10 25.0
4  40 25.0
```

For a description of the WINDSALES table, see [Sample table for window function examples](#).

MIN window function

The MIN window function returns the minimum of the input expression values. The MIN function works with numeric values and ignores NULL values.

Syntax

```
MIN ( [ ALL ] expression ) OVER  
(  
[ PARTITION BY expr_list ]  
[ ORDER BY order_list frame_clause ]  
)
```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression. ALL is the default. DISTINCT is not supported.

OVER

Specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the MIN function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of

rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

Accepts any data type as input. Returns the same data type as *expression*.

Examples

The following example shows the sales ID, quantity, and minimum quantity from the beginning of the data window:

```
select salesid, qty,
min(qty) over
(order by salesid rows unbounded preceding)
from winsales
order by salesid;
```

salesid	qty	min
10001	10	10
10005	30	10
10006	10	10
20001	20	10
20002	20	10
30001	10	10
30003	15	10
30004	20	10
30007	30	10
40001	40	10
40005	10	10

(11 rows)

For a description of the WINSALES table, see [Sample table for window function examples](#).

The following example shows the sales ID, quantity, and minimum quantity in a restricted frame:

```
select salesid, qty,
min(qty) over
(order by salesid rows between 2 preceding and 1 preceding) as min
from winsales
```

```
order by salesid;

salesid | qty | min
-----+-----+-----
10001 | 10 |
10005 | 30 | 10
10006 | 10 | 10
20001 | 20 | 10
20002 | 20 | 10
30001 | 10 | 20
30003 | 15 | 10
30004 | 20 | 10
30007 | 30 | 15
40001 | 40 | 20
40005 | 10 | 30
(11 rows)
```

NTH_VALUE window function

The NTH_VALUE window function returns the expression value of the specified row of the window frame relative to the first row of the window.

Syntax

```
NTH_VALUE (expr, offset)
[ IGNORE NULLS | RESPECT NULLS ]
OVER
( [ PARTITION BY window_partition ]
  [ ORDER BY window_ordering
             frame_clause ] )
```

Arguments

expr

The target column or expression that the function operates on.

offset

Determines the row number relative to the first row in the window for which to return the expression. The *offset* can be a constant or an expression and must be a positive integer that is greater than 0.

IGNORE NULLS

An optional specification that indicates that Amazon Redshift should skip null values in the determination of which row to use. Null values are included if IGNORE NULLS is not listed.

RESPECT NULLS

Indicates that Amazon Redshift should include null values in the determination of which row to use. RESPECT NULLS is supported by default if you do not specify IGNORE NULLS.

OVER

Specifies the window partitioning, ordering, and window frame.

PARTITION BY *window_partition*

Sets the range of records for each group in the OVER clause.

ORDER BY *window_ordering*

Sorts the rows within each partition. If ORDER BY is omitted, the default frame consists of all rows in the partition.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows in the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

The NTH_VALUE window function supports expressions that use any of the Amazon Redshift data types. The return type is the same as the type of the *expr*.

Examples

The following example shows the number of seats in the third largest venue in California, Florida, and New York compared to the number of seats in the other venues in those states:

```
select venuestate, venue name, venueseats,
nth_value(venueseats, 3)
ignore nulls
over(partition by venuestate order by venueseats desc
rows between unbounded preceding and unbounded following)
as third_most_seats
```

```
from (select * from venue where venueseats > 0 and
venuestate in('CA', 'FL', 'NY'))
order by venuestate;
```

venuestate	venue name	venueseats	third_most_seats
CA	Qualcomm Stadium	70561	63026
CA	Monster Park	69843	63026
CA	McAfee Coliseum	63026	63026
CA	Dodger Stadium	56000	63026
CA	Angel Stadium of Anaheim	45050	63026
CA	PETCO Park	42445	63026
CA	AT&T Park	41503	63026
CA	Shoreline Amphitheatre	22000	63026
FL	Dolphin Stadium	74916	65647
FL	Jacksonville Municipal Stadium	73800	65647
FL	Raymond James Stadium	65647	65647
FL	Tropicana Field	36048	65647
NY	Ralph Wilson Stadium	73967	20000
NY	Yankee Stadium	52325	20000
NY	Madison Square Garden	20000	20000

(15 rows)

NTILE window function

The NTILE window function divides ordered rows in the partition into the specified number of ranked groups of as equal size as possible and returns the group that a given row falls into.

Syntax

```
NTILE (expr)
OVER (
  [ PARTITION BY expression_list ]
  [ ORDER BY order_list ]
)
```

Arguments

expr

The number of ranking groups and must result in a positive integer value (greater than 0) for each partition. The *expr* argument must not be nullable.

OVER

A clause that specifies the window partitioning and ordering. The OVER clause cannot contain a window frame specification.

PARTITION BY *window_partition*

Optional. The range of records for each group in the OVER clause.

ORDER BY *window_ordering*

Optional. An expression that sorts the rows within each partition. If the ORDER BY clause is omitted, the ranking behavior is the same.

If ORDER BY does not produce a unique ordering, the order of the rows is nondeterministic. For more information, see [Unique ordering of data for window functions](#).

Return type

BIGINT

Examples

The following example ranks into four ranking groups the price paid for Hamlet tickets on August 26, 2008. The result set is 17 rows, divided almost evenly among the rankings 1 through 4:

```
select eventname, caldate, pricepaid, ntile(4)
over(order by pricepaid desc) from sales, event, date
where sales.eventid=event.eventid and event.dateid=date.dateid and eventname='Hamlet'
and caldate='2008-08-26'
order by 4;
```

eventname	caldate	pricepaid	ntile
Hamlet	2008-08-26	1883.00	1
Hamlet	2008-08-26	1065.00	1
Hamlet	2008-08-26	589.00	1
Hamlet	2008-08-26	530.00	1
Hamlet	2008-08-26	472.00	1
Hamlet	2008-08-26	460.00	2
Hamlet	2008-08-26	355.00	2
Hamlet	2008-08-26	334.00	2
Hamlet	2008-08-26	296.00	2

Hamlet	2008-08-26	230.00	3
Hamlet	2008-08-26	216.00	3
Hamlet	2008-08-26	212.00	3
Hamlet	2008-08-26	106.00	3
Hamlet	2008-08-26	100.00	4
Hamlet	2008-08-26	94.00	4
Hamlet	2008-08-26	53.00	4
Hamlet	2008-08-26	25.00	4

(17 rows)

PERCENT_RANK window function

Calculates the percent rank of a given row. The percent rank is determined using this formula:

$$(x - 1) / (\text{the number of rows in the window or partition} - 1)$$

where x is the rank of the current row. The following dataset illustrates use of this formula:

Row#	Value	Rank	Calculation	PERCENT_RANK
1	15	1	(1-1)/(7-1)	0.0000
2	20	2	(2-1)/(7-1)	0.1666
3	20	2	(2-1)/(7-1)	0.1666
4	20	2	(2-1)/(7-1)	0.1666
5	30	5	(5-1)/(7-1)	0.6666
6	30	5	(5-1)/(7-1)	0.6666
7	40	7	(7-1)/(7-1)	1.0000

The return value range is 0 to 1, inclusive. The first row in any set has a PERCENT_RANK of 0.

Syntax

```
PERCENT_RANK ( )
OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Arguments

()

The function takes no arguments, but the empty parentheses are required.

OVER

A clause that specifies the window partitioning. The OVER clause cannot contain a window frame specification.

PARTITION BY *partition_expression*

Optional. An expression that sets the range of records for each group in the OVER clause.

ORDER BY *order_list*

Optional. The expression on which to calculate percent rank. The expression must have either a numeric data type or be implicitly convertible to one. If ORDER BY is omitted, the return value is 0 for all rows.

If ORDER BY does not produce a unique ordering, the order of the rows is nondeterministic. For more information, see [Unique ordering of data for window functions](#).

Return type

FLOAT8

Examples

The following example calculates the percent rank of the sales quantities for each seller:

```
select sellerid, qty, percent_rank()  
over (partition by sellerid order by qty)  
from winsales;
```

```
sellerid qty  percent_rank  
-----
```

```
1  10.00  0.0  
1  10.64  0.5  
1  30.37  1.0  
3  10.04  0.0  
3  15.15  0.33  
3  20.75  0.67  
3  30.55  1.0  
2  20.09  0.0  
2  20.12  1.0  
4  10.12  0.0
```

`4 40.23 1.0`

For a description of the WINDSALES table, see [Sample table for window function examples](#).

PERCENTILE_CONT window function

PERCENTILE_CONT is an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification, and returns an interpolated value that would fall into the given percentile value with respect to the sort specification.

PERCENTILE_CONT computes a linear interpolation between values after ordering them. Using the percentile value (P) and the number of not null rows (N) in the aggregation group, the function computes the row number after ordering the rows according to the sort specification. This row number (RN) is computed according to the formula $RN = (1 + (P * (N - 1)))$. The final result of the aggregate function is computed by linear interpolation between the values from rows at row numbers $CRN = \text{CEILING}(RN)$ and $FRN = \text{FLOOR}(RN)$.

The final result will be as follows.

If ($CRN = FRN = RN$) then the result is (value of expression from row at RN)

Otherwise the result is as follows:

$(CRN - RN) * (\text{value of expression for row at } FRN) + (RN - FRN) * (\text{value of expression for row at } CRN)$.

You can specify only the PARTITION clause in the OVER clause. If PARTITION is specified, for each row, PERCENTILE_CONT returns the value that would fall into the specified percentile among a set of values within a given partition.

Syntax

```
PERCENTILE_CONT ( percentile )  
WITHIN GROUP (ORDER BY expr)  
OVER ( [ PARTITION BY expr_list ] )
```

Arguments

percentile

Numeric constant between 0 and 1. Nulls are ignored in the calculation.

WITHIN GROUP (ORDER BY *expr*)

Specifies numeric or date/time values to sort and compute the percentile over.

OVER

Specifies the window partitioning. The OVER clause cannot contain a window ordering or window frame specification.

PARTITION BY *expr*

Optional argument that sets the range of records for each group in the OVER clause.

Returns

The return type is determined by the data type of the ORDER BY expression in the WITHIN GROUP clause. The following table shows the return type for each ORDER BY expression data type.

Input Type	Return Type
INT2, INT4, INT8, NUMERIC, DECIMAL	DECIMAL
FLOAT, DOUBLE	DOUBLE
DATE	DATE
TIMESTAMP	TIMESTAMP

Usage notes

If the ORDER BY expression is a DECIMAL data type defined with the maximum precision of 38 digits, it is possible that PERCENTILE_CONT will return either an inaccurate result or an error. If the return value of the PERCENTILE_CONT function exceeds 38 digits, the result is truncated to fit, which causes a loss of precision. If, during interpolation, an intermediate result exceeds the maximum precision, a numeric overflow occurs and the function returns an error. To avoid these conditions, we recommend either using a data type with lower precision or casting the ORDER BY expression to a lower precision.

For example, a SUM function with a DECIMAL argument returns a default precision of 38 digits. The scale of the result is the same as the scale of the argument. So, for example, a SUM of a DECIMAL(5,2) column returns a DECIMAL(38,2) data type.

The following example uses a SUM function in the ORDER BY clause of a PERCENTILE_CONT function. The data type of the PRICEPAID column is DECIMAL (8,2), so the SUM function returns DECIMAL(38,2).

```
select salesid, sum(pricepaid), percentile_cont(0.6)
within group (order by sum(pricepaid) desc) over()
from sales where salesid < 10 group by salesid;
```

To avoid a potential loss of precision or an overflow error, cast the result to a DECIMAL data type with lower precision, as the following example shows.

```
select salesid, sum(pricepaid), percentile_cont(0.6)
within group (order by sum(pricepaid)::decimal(30,2) desc) over()
from sales where salesid < 10 group by salesid;
```

Examples

The following examples use the WINDSALES table. For a description of the WINDSALES table, see [Sample table for window function examples](#).

```
select sellerid, qty, percentile_cont(0.5)
within group (order by qty)
over() as median from winsales;
```

sellerid	qty	median
1	10	20.0
1	10	20.0
3	10	20.0
4	10	20.0
3	15	20.0
2	20	20.0
3	20	20.0
2	20	20.0
3	30	20.0
1	30	20.0
4	40	20.0

(11 rows)

```
select sellerid, qty, percentile_cont(0.5)
```

```
within group (order by qty)
over(partition by sellerid) as median from winsales;
```

sellerid	qty	median
2	20	20.0
2	20	20.0
4	10	25.0
4	40	25.0
1	10	10.0
1	10	10.0
1	30	10.0
3	10	17.5
3	15	17.5
3	20	17.5
3	30	17.5

(11 rows)

The following example calculates the PERCENTILE_CONT and PERCENTILE_DISC of the ticket sales for sellers in Washington state.

```
SELECT sellerid, state, sum(qtysold*pricepaid) sales,
percentile_cont(0.6) within group (order by sum(qtysold*pricepaid::decimal(14,2) )
desc) over(),
percentile_disc(0.6) within group (order by sum(qtysold*pricepaid::decimal(14,2) )
desc) over()
from sales s, users u
where s.sellerid = u.userid and state = 'WA' and sellerid < 1000
group by sellerid, state;
```

sellerid	state	sales	percentile_cont	percentile_disc
127	WA	6076.00	2044.20	1531.00
787	WA	6035.00	2044.20	1531.00
381	WA	5881.00	2044.20	1531.00
777	WA	2814.00	2044.20	1531.00
33	WA	1531.00	2044.20	1531.00
800	WA	1476.00	2044.20	1531.00
1	WA	1177.00	2044.20	1531.00

(7 rows)

PERCENTILE_DISC window function

PERCENTILE_DISC is an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the given set.

For a given percentile value P, PERCENTILE_DISC sorts the values of the expression in the ORDER BY clause and returns the value with the smallest cumulative distribution value (with respect to the same sort specification) that is greater than or equal to P.

You can specify only the PARTITION clause in the OVER clause.

Syntax

```
PERCENTILE_DISC ( percentile )  
WITHIN GROUP (ORDER BY expr)  
OVER ( [ PARTITION BY expr_list ] )
```

Arguments

percentile

Numeric constant between 0 and 1. Nulls are ignored in the calculation.

WITHIN GROUP (ORDER BY *expr*)

Specifies numeric or date/time values to sort and compute the percentile over.

OVER

Specifies the window partitioning. The OVER clause cannot contain a window ordering or window frame specification.

PARTITION BY *expr*

Optional argument that sets the range of records for each group in the OVER clause.

Returns

The same data type as the ORDER BY expression in the WITHIN GROUP clause.

Examples

The following examples use the WINDSALES table. For a description of the WINDSALES table, see [Sample table for window function examples](#).

```
SELECT sellerid, qty, PERCENTILE_DISC(0.5)
WITHIN GROUP (ORDER BY qty)
OVER() AS MEDIAN FROM winsales;
```

sellerid	qty	median
3	10	20
1	10	20
1	10	20
4	10	20
3	15	20
2	20	20
2	20	20
3	20	20
1	30	20
3	30	20
4	40	20

```
SELECT sellerid, qty, PERCENTILE_DISC(0.5)
WITHIN GROUP (ORDER BY qty)
OVER(PARTITION BY sellerid) AS MEDIAN FROM winsales;
```

sellerid	qty	median
4	10	10
4	40	10
3	10	15
3	15	15
3	20	15
3	30	15
2	20	20
2	20	20
1	10	10
1	10	10
1	30	10

To find PERCENTILE_DISC(0.25) and PERCENTILE_DISC(0.75) for the quantity when partitioned by the seller ID, use the following examples.

```

SELECT sellerid, qty, PERCENTILE_DISC(0.25)
WITHIN GROUP (ORDER BY qty)
OVER(PARTITION BY sellerid) AS quartile1 FROM winsales;

```

sellerid	qty	quartile1
4	10	10
4	40	10
2	20	20
2	20	20
3	10	10
3	15	10
3	20	10
3	30	10
1	10	10
1	10	10
1	30	10

```

SELECT sellerid, qty, PERCENTILE_DISC(0.75)
WITHIN GROUP (ORDER BY qty)
OVER(PARTITION BY sellerid) AS quartile3 FROM winsales;

```

sellerid	qty	quartile3
3	10	20
3	15	20
3	20	20
3	30	20
4	10	40
4	40	40
2	20	20
2	20	20
1	10	30
1	10	30
1	30	30

RANK window function

The RANK window function determines the rank of a value in a group of values, based on the ORDER BY expression in the OVER clause. If the optional PARTITION BY clause is present, the rankings are reset for each group of rows. Rows with equal values for the ranking criteria receive the same rank. Amazon Redshift adds the number of tied rows to the tied rank to calculate the next rank and thus the ranks might not be consecutive numbers. For example, if two rows are ranked 1, the next rank is 3.

RANK differs from the [DENSE_RANK window function](#) in one respect: For DENSE_RANK, if two or more rows tie, there is no gap in the sequence of ranked values. For example, if two rows are ranked 1, the next rank is 2.

You can have ranking functions with different PARTITION BY and ORDER BY clauses in the same query.

Syntax

```
RANK ( ) OVER  
(  
[ PARTITION BY expr_list ]  
[ ORDER BY order_list ]  
)
```

Arguments

()

The function takes no arguments, but the empty parentheses are required.

OVER

The window clauses for the RANK function.

PARTITION BY *expr_list*

Optional. One or more expressions that define the window.

ORDER BY *order_list*

Optional. Defines the columns on which the ranking values are based. If no PARTITION BY is specified, ORDER BY uses the entire table. If ORDER BY is omitted, the return value is 1 for all rows.

If ORDER BY does not produce a unique ordering, the order of the rows is nondeterministic. For more information, see [Unique ordering of data for window functions](#).

Return type

INTEGER

Examples

The following example orders the table by the quantity sold (default ascending), and assign a rank to each row. A rank value of 1 is the highest ranked value. The results are sorted after the window function results are applied:

```
select salesid, qty,
rank() over (order by qty) as rnk
from winsales
order by 2,1;
```

```
salesid | qty | rnk
-----+-----+-----
10001 | 10 | 1
10006 | 10 | 1
30001 | 10 | 1
40005 | 10 | 1
30003 | 15 | 5
20001 | 20 | 6
20002 | 20 | 6
30004 | 20 | 6
10005 | 30 | 9
30007 | 30 | 9
40001 | 40 | 11
(11 rows)
```

Note that the outer ORDER BY clause in this example includes columns 2 and 1 to make sure that Amazon Redshift returns consistently sorted results each time this query is run. For example, rows with sales IDs 10001 and 10006 have identical QTY and RNK values. Ordering the final result set by column 1 ensures that row 10001 always falls before 10006. For a description of the WINSALES table, see [Sample table for window function examples](#).

In the following example, the ordering is reversed for the window function (`order by qty desc`). Now the highest rank value applies to the largest QTY value.

```
select salesid, qty,
rank() over (order by qty desc) as rank
from winsales
order by 2,1;
```

salesid	qty	rank
10001	10	8
10006	10	8
30001	10	8
40005	10	8
30003	15	7
20001	20	4
20002	20	4
30004	20	4
10005	30	2
30007	30	2
40001	40	1

(11 rows)

For a description of the WINDSALES table, see [Sample table for window function examples](#).

The following example partitions the table by SELLERID and order each partition by the quantity (in descending order) and assign a rank to each row. The results are sorted after the window function results are applied.

```
select salesid, sellerid, qty, rank() over
(partition by sellerid
order by qty desc) as rank
from winsales
order by 2,3,1;
```

salesid	sellerid	qty	rank
10001	1	10	2
10006	1	10	2
10005	1	30	1
20001	2	20	1
20002	2	20	1
30001	3	10	4
30003	3	15	3
30004	3	20	2
30007	3	30	1

```

40005 |      4 | 10 | 2
40001 |      4 | 40 | 1
(11 rows)

```

RATIO_TO_REPORT window function

Calculates the ratio of a value to the sum of the values in a window or partition. The ratio to report value is determined using the formula:

$$\text{value of } \mathit{ratio_expression} \text{ argument for the current row} / \text{sum of } \mathit{ratio_expression} \text{ argument for the window or partition}$$

The following dataset illustrates use of this formula:

```

Row# Value Calculation RATIO_TO_REPORT
1 2500 (2500)/(13900) 0.1798
2 2600 (2600)/(13900) 0.1870
3 2800 (2800)/(13900) 0.2014
4 2900 (2900)/(13900) 0.2086
5 3100 (3100)/(13900) 0.2230

```

The return value range is 0 to 1, inclusive. If *ratio_expression* is NULL, then the return value is NULL. If a value in *partition_expression* is unique, then function will return 1 for that value.

Syntax

```

RATIO_TO_REPORT ( ratio_expression )
OVER ( [ PARTITION BY partition_expression ] )

```

Arguments

ratio_expression

An expression, such as a column name, that provides the value for which to determine the ratio. The expression must have either a numeric data type or be implicitly convertible to one.

You cannot use any other analytic function in *ratio_expression*.

OVER

A clause that specifies the window partitioning. The OVER clause cannot contain a window ordering or window frame specification.

PARTITION BY *partition_expression*

Optional. An expression that sets the range of records for each group in the OVER clause.

Return type

FLOAT8

Examples

The following examples use the WINDSALES table. For a information about how to create the WINDSALES table, see [Sample table for window function examples](#).

The following example calculates the ratio-to-report value of each row of a seller's quantity to the total of all seller's quantities.

```
select sellerid, qty, ratio_to_report(qty)
over()
from winsales
order by sellerid;
```

sellerid	qty	ratio_to_report
1	30	0.13953488372093023
1	10	0.046511627906976744
1	10	0.046511627906976744
2	20	0.09302325581395349
2	20	0.09302325581395349
3	30	0.13953488372093023
3	20	0.09302325581395349
3	15	0.06976744186046512
3	10	0.046511627906976744
4	10	0.046511627906976744
4	40	0.18604651162790697

The following example calculates the ratios of the sales quantities for each seller by partition.

```
select sellerid, qty, ratio_to_report(qty)
over(partition by sellerid)
from winsales;
```

sellerid	qty	ratio_to_report

2	20	0.5
2	20	0.5
4	40	0.8
4	10	0.2
1	10	0.2
1	30	0.6
1	10	0.2
3	10	0.13333333333333333
3	15	0.2
3	20	0.26666666666666666
3	30	0.4

ROW_NUMBER window function

Assigns an ordinal number of the current row within a group of rows, counting from 1, based on the ORDER BY expression in the OVER clause. If the optional PARTITION BY clause is present, the ordinal numbers are reset for each group of rows. Rows with equal values for the ORDER BY expressions receive the different row numbers nondeterministically.

Syntax

```
ROW_NUMBER() OVER(  
  [ PARTITION BY expr_list ]  
  [ ORDER BY order_list ]  
)
```

Arguments

()

The function takes no arguments, but the empty parentheses are required.

OVER

The window function clause for the ROW_NUMBER function.

PARTITION BY *expr_list*

Optional. One or more column expressions that divide the results into sets of rows.

ORDER BY *order_list*

Optional. One or more column expressions that defines the order of rows within a set. If no PARTITION BY is specified, ORDER BY uses the entire table.

If ORDER BY does not produce a unique ordering or is omitted, the order of the rows is nondeterministic. For more information, see [Unique ordering of data for window functions](#).

Return type

BIGINT

Examples

The following examples use the WINDSALES table. For a description of the WINDSALES table, see [Sample table for window function examples](#).

The following example orders the table by QTY (in ascending order), then assigns a row number to each row. The results are sorted after the window function results are applied.

```
SELECT salesid, sellerid, qty,
ROW_NUMBER() OVER(
  ORDER BY qty ASC) AS row
FROM winsales
ORDER BY 4,1;
```

salesid	sellerid	qty	row
30001	3	10	1
10001	1	10	2
10006	1	10	3
40005	4	10	4
30003	3	15	5
20001	2	20	6
20002	2	20	7
30004	3	20	8
10005	1	30	9
30007	3	30	10
40001	4	40	11

The following example partitions the table by SELLERID and orders each partition by QTY (in ascending order), then assigns a row number to each row. The results are sorted after the window function results are applied.

```
SELECT salesid, sellerid, qty,
ROW_NUMBER() OVER(
  PARTITION BY sellerid
```

```
ORDER BY qty ASC) AS row_by_seller
FROM winsales
ORDER BY 2,4;
```

salesid	sellerid	qty	row_by_seller
10001	1	10	1
10006	1	10	2
10005	1	30	3
20001	2	20	1
20002	2	20	2
30001	3	10	1
30003	3	15	2
30004	3	20	3
30007	3	30	4
40005	4	10	1
40001	4	40	2

The following example shows the results when not using the optional clauses.

```
SELECT salesid, sellerid, qty, ROW_NUMBER() OVER() AS row
FROM winsales
ORDER BY 4,1;
```

salesid	sellerid	qty	row
30001	3	10	1
10001	1	10	2
10005	1	30	3
40001	4	40	4
10006	1	10	5
20001	2	20	6
40005	4	10	7
20002	2	20	8
30003	3	15	9
30004	3	20	10
30007	3	30	11

STDDEV_SAMP and STDDEV_POP window functions

The STDDEV_SAMP and STDDEV_POP window functions return the sample and population standard deviation of a set of numeric values (integer, decimal, or floating-point). See also [STDDEV_SAMP and STDDEV_POP functions](#).

STDDEV_SAMP and STDDEV are synonyms for the same function.

Syntax

```
STDDEV_SAMP | STDDEV | STDDEV_POP  
( [ ALL ] expression ) OVER  
(  
[ PARTITION BY expr_list ]  
[ ORDER BY order_list  
                frame_clause ]  
)
```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression. ALL is the default. DISTINCT is not supported.

OVER

Specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

The argument types supported by the STDDEV functions are SMALLINT, INTEGER, BIGINT, NUMERIC, DECIMAL, REAL, and DOUBLE PRECISION.

Regardless of the data type of the expression, the return type of a STDDEV function is a double precision number.

Examples

The following example shows how to use STDDEV_POP and VAR_POP functions as window functions. The query computes the population variance and population standard deviation for PRICEPAID values in the SALES table.

```
select salesid, dateid, pricepaid,
round(stddev_pop(pricepaid) over
(order by dateid, salesid rows unbounded preceding)) as stddevpop,
round(var_pop(pricepaid) over
(order by dateid, salesid rows unbounded preceding)) as varpop
from sales
order by 2,1;
```

salesid	dateid	pricepaid	stddevpop	varpop
33095	1827	234.00	0	0
65082	1827	472.00	119	14161
88268	1827	836.00	248	61283
97197	1827	708.00	230	53019
110328	1827	347.00	223	49845
110917	1827	337.00	215	46159
150314	1827	688.00	211	44414
157751	1827	1730.00	447	199679
165890	1827	4192.00	1185	1403323
...				

The sample standard deviation and variance functions can be used in the same way.

SUM window function

The SUM window function returns the sum of the input column or expression values. The SUM function works with numeric values and ignores NULL values.

Syntax

```
SUM ( [ ALL ] expression ) OVER  
(  
  [ PARTITION BY expr_list ]  
  [ ORDER BY order_list  
                                frame_clause ]  
)
```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression. ALL is the default. DISTINCT is not supported.

OVER

Specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the SUM function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

The argument types supported by the SUM function are SMALLINT, INTEGER, BIGINT, NUMERIC, DECIMAL, REAL, and DOUBLE PRECISION.

The return types supported by the SUM function are:

- BIGINT for SMALLINT or INTEGER arguments
- NUMERIC for BIGINT arguments
- DOUBLE PRECISION for floating-point arguments

Examples

The following example creates a cumulative (rolling) sum of sales quantities ordered by date and sales ID:

```
select salesid, dateid, sellerid, qty,
sum(qty) over (order by dateid, salesid rows unbounded preceding) as sum
from winsales
order by 2,1;
```

salesid	dateid	sellerid	qty	sum
30001	2003-08-02	3	10	10
10001	2003-12-24	1	10	20
10005	2003-12-24	1	30	50
40001	2004-01-09	4	40	90
10006	2004-01-18	1	10	100
20001	2004-02-12	2	20	120
40005	2004-02-12	4	10	130
20002	2004-02-16	2	20	150
30003	2004-04-18	3	15	165
30004	2004-04-18	3	20	185
30007	2004-09-07	3	30	215

(11 rows)

For a description of the WINSALES table, see [Sample table for window function examples](#).

The following example creates a cumulative (rolling) sum of sales quantities by date, partition the results by seller ID, and order the results by date and sales ID within the partition:

```
select salesid, dateid, sellerid, qty,
sum(qty) over (partition by sellerid
order by dateid, salesid rows unbounded preceding) as sum
from winsales
order by 2,1;
```

```

salesid | dateid | sellerid | qty | sum
-----+-----+-----+-----+-----
30001 | 2003-08-02 | 3 | 10 | 10
10001 | 2003-12-24 | 1 | 10 | 10
10005 | 2003-12-24 | 1 | 30 | 40
40001 | 2004-01-09 | 4 | 40 | 40
10006 | 2004-01-18 | 1 | 10 | 50
20001 | 2004-02-12 | 2 | 20 | 20
40005 | 2004-02-12 | 4 | 10 | 50
20002 | 2004-02-16 | 2 | 20 | 40
30003 | 2004-04-18 | 3 | 15 | 25
30004 | 2004-04-18 | 3 | 20 | 45
30007 | 2004-09-07 | 3 | 30 | 75
(11 rows)

```

The following example numbers all of the rows sequentially in the result set, ordered by the SELLERID and SALESID columns:

```

select salesid, sellerid, qty,
sum(1) over (order by sellerid, salesid rows unbounded preceding) as rownum
from winsales
order by 2,1;

```

```

salesid | sellerid | qty | rownum
-----+-----+-----+-----
10001 | 1 | 10 | 1
10005 | 1 | 30 | 2
10006 | 1 | 10 | 3
20001 | 2 | 20 | 4
20002 | 2 | 20 | 5
30001 | 3 | 10 | 6
30003 | 3 | 15 | 7
30004 | 3 | 20 | 8
30007 | 3 | 30 | 9
40001 | 4 | 40 | 10
40005 | 4 | 10 | 11
(11 rows)

```

For a description of the WINSALES table, see [Sample table for window function examples](#).

The following example numbers all rows sequentially in the result set, partition the results by SELLERID, and order the results by SELLERID and SALESID within the partition:

```
select salesid, sellerid, qty,
sum(1) over (partition by sellerid
order by sellerid, salesid rows unbounded preceding) as rownum
from winsales
order by 2,1;
```

salesid	sellerid	qty	rownum
10001	1	10	1
10005	1	30	2
10006	1	10	3
20001	2	20	1
20002	2	20	2
30001	3	10	1
30003	3	15	2
30004	3	20	3
30007	3	30	4
40001	4	40	1
40005	4	10	2

(11 rows)

VAR_SAMP and VAR_POP window functions

The VAR_SAMP and VAR_POP window functions return the sample and population variance of a set of numeric values (integer, decimal, or floating-point). See also [VAR_SAMP and VAR_POP functions](#).

VAR_SAMP and VARIANCE are synonyms for the same function.

Syntax

```
VAR_SAMP | VARIANCE | VAR_POP
( [ ALL ] expression ) OVER
(
  [ PARTITION BY expr_list ]
  [ ORDER BY order_list
                frame_clause ]
)
```

Arguments

expression

The target column or expression that the function operates on.

ALL

With the argument ALL, the function retains all duplicate values from the expression. ALL is the default. DISTINCT is not supported.

OVER

Specifies the window clauses for the aggregation functions. The OVER clause distinguishes window aggregation functions from normal set aggregation functions.

PARTITION BY *expr_list*

Defines the window for the function in terms of one or more expressions.

ORDER BY *order_list*

Sorts the rows within each partition. If no PARTITION BY is specified, ORDER BY uses the entire table.

frame_clause

If an ORDER BY clause is used for an aggregate function, an explicit frame clause is required. The frame clause refines the set of rows in a function's window, including or excluding sets of rows within the ordered result. The frame clause consists of the ROWS keyword and associated specifiers. See [Window function syntax summary](#).

Data types

The argument types supported by the VARIANCE functions are SMALLINT, INTEGER, BIGINT, NUMERIC, DECIMAL, REAL, and DOUBLE PRECISION.

Regardless of the data type of the expression, the return type of a VARIANCE function is a double precision number.

System administration functions

Topics

- [CHANGE_QUERY_PRIORITY](#)
- [CHANGE_SESSION_PRIORITY](#)
- [CHANGE_USER_PRIORITY](#)
- [CURRENT_SETTING](#)
- [PG_CANCEL_BACKEND](#)

- [PG_TERMINATE_BACKEND](#)
- [REBOOT_CLUSTER](#)
- [SET_CONFIG](#)

Amazon Redshift supports several system administration functions.

CHANGE_QUERY_PRIORITY

CHANGE_QUERY_PRIORITY enables superusers to modify the priority of a query that is either running or waiting in workload management (WLM).

This function enables superusers to immediately change the priority of any query in the system. Only one query, user, or session can run with the priority CRITICAL.

Syntax

```
CHANGE_QUERY_PRIORITY(query_id, priority)
```

Arguments

query_id

The query identifier of the query whose priority is changed. Requires an INTEGER value.

priority

The new priority to be assigned to the query. This argument must be a string with the value CRITICAL, HIGHEST, HIGH, NORMAL, LOW, or LOWEST.

Return Type

None

Examples

To show the column `query_priority` in the `STV_WLM_QUERY_STATE` system table, use the following example.

```
SELECT query, service_class, query_priority, state  
FROM stv_wlm_query_state WHERE service_class = 101;
```

```

+-----+-----+-----+-----+
| query | service_class | query_priority | state |
+-----+-----+-----+-----+
| 1076 |          101 | Lowest        | Running |
| 1075 |          101 | Lowest        | Running |
+-----+-----+-----+-----+

```

To show the results of a superuser running the function `change_query_priority` to change the priority to `CRITICAL`, use the following example.

```
SELECT CHANGE_QUERY_PRIORITY(1076, 'Critical');
```

```

+-----+
|                               change_query_priority                               |
+-----+
| Succeeded to change query priority. Priority changed from Lowest to Critical. |
+-----+

```

CHANGE_SESSION_PRIORITY

`CHANGE_SESSION_PRIORITY` enables superusers to immediately change the priority of any session in the system. Only one session, user, or query can run with the priority `CRITICAL`.

Syntax

```
CHANGE_SESSION_PRIORITY(pid, priority)
```

Arguments

pid

The process identifier of the session whose priority is changed. The value `-1` refers to the current session. Requires an `INTEGER` value.

priority

The new priority to be assigned to the session. This argument must be a string with the value `CRITICAL`, `HIGHEST`, `HIGH`, `NORMAL`, `LOW`, or `LOWEST`.

Return type

None

Examples

To return the process identifier of the server process handling the current session, use the following example.

```
SELECT pg_backend_pid();
```

```
+-----+
| pg_backend_pid |
+-----+
|           30311 |
+-----+
```

In this example, the priority is changed to LOWEST for the current session.

```
SELECT CHANGE_SESSION_PRIORITY(30311, 'Lowest');
```

```
+-----+
+
|                                     change_session_priority
+-----+
+
| Succeeded to change session priority. Changed session (pid:30311) priority to lowest.
+-----+
+
```

In this example, the priority is changed to HIGH for the current session.

```
SELECT CHANGE_SESSION_PRIORITY(-1, 'High');
```

```
+-----+
+
|                                     change_session_priority
+-----+
+
| Succeeded to change session priority. Changed session (pid:30311) priority from
  lowest to high. |
+-----+
+
```

To create a stored procedure that changes a session priority, use the following example. Permission to run this stored procedure is granted to the database user `test_user`.

```
CREATE OR REPLACE PROCEDURE sp_priority_low(pid IN int, result OUT varchar)
AS $$
BEGIN
    SELECT CHANGE_SESSION_PRIORITY(pid, 'low') into result;
END;
$$ LANGUAGE plpgsql
SECURITY DEFINER;
GRANT EXECUTE ON PROCEDURE sp_priority_low(int) TO test_user;
```

Then the database user named `test_user` calls the procedure.

```
CALL sp_priority_low(pg_backend_pid());

+-----+
|                result                |
+-----+
| Success. Change session (pid:13155) priority to low. |
+-----+
```

CHANGE_USER_PRIORITY

`CHANGE_USER_PRIORITY` enables superusers to modify the priority of all queries issued by a user that are either running or waiting in workload management (WLM). Only one user, session, or query can run with the priority `CRITICAL`.

Syntax

```
CHANGE_USER_PRIORITY(user_name, priority)
```

Arguments

user_name

The database user name whose query priority is changed.

priority

The new priority to be assigned to all queries issued by `user_name`. This argument must be a string with the value `CRITICAL`, `HIGHEST`, `HIGH`, `NORMAL`, `LOW`, `LOWEST`, or `RESET`. Only

superusers can change the priority to CRITICAL. Changing the priority to RESET removes the priority setting for user_name.

Return type

None

Examples

To change the priority for the user analysis_user to LOWEST, use the following example.

```
SELECT CHANGE_USER_PRIORITY('analysis_user', 'lowest');
```

```
+-----+
|               change_user_priority               |
+-----+
| Succeeded to change user priority. Changed user (analysis_user) priority to lowest. |
+-----+
```

To change the priority to LOW, use the following example.

```
SELECT CHANGE_USER_PRIORITY('analysis_user', 'low');
```

```
+-----+
+
|               change_user_priority               |
|
+-----+
+
| Succeeded to change user priority. Changed user (analysis_user) priority from Lowest
to low. |
+-----+
+
```

To reset the priority, use the following example.

```
SELECT CHANGE_USER_PRIORITY('analysis_user', 'reset');
```

```
+-----+
|               change_user_priority               |
+-----+
| Succeeded to reset priority for user (analysis_user). |
```

```
+-----+
```

CURRENT_SETTING

CURRENT_SETTING returns the current value of the specified configuration parameter.

This function is equivalent to the [SHOW](#) command.

Syntax

```
current_setting('parameter')
```

The following statement returns the current value of the specified session context variable.

```
current_setting('variable_name')
current_setting('variable_name'[, error_if_undefined])
```

Arguments

parameter

Parameter value to display. For a list of configuration parameters, see [Configuration reference](#)

variable_name

The name of the variable to display. This must be a string constant for session context variables.

error_if_undefined

(Optional) A boolean value that specifies the behavior if the variable name doesn't exist. When `error_if_undefined` is set to `TRUE`, which is the default, Amazon Redshift throws an error. When `error_if_undefined` is set to `FALSE`, Amazon Redshift returns `NULL`. Amazon Redshift supports the `error_if_undefined` parameter only for session context variables. This can't be used when the input is a configuration parameter.

Return type

Returns a CHAR or VARCHAR string.

Examples

To return the current setting for the `query_group` parameter, use the following example.

```
SELECT CURRENT_SETTING('query_group');
```

```
+-----+
| current_setting |
+-----+
| unset          |
+-----+
```

To return the current setting for the variable `app_context.user_id`, use the following example.

```
SELECT CURRENT_SETTING('app_context.user_id', FALSE);
```

PG_CANCEL_BACKEND

Cancels a query. `PG_CANCEL_BACKEND` is functionally equivalent to the [CANCEL](#) command. You can cancel queries currently being run by your user. Superusers can cancel any query.

Syntax

```
pg_cancel_backend( pid )
```

Arguments

pid

The process ID (PID) of the query to be canceled. You cannot cancel a query by specifying a query ID; you must specify the query's process ID. Requires an INTEGER value.

Return type

None

Usage notes

If queries in multiple sessions hold locks on the same table, you can use the [PG_TERMINATE_BACKEND](#) function to terminate one of the sessions, which forces any currently running transactions in the terminated session to release all locks and roll back the transaction. Query the `PG__LOCKS` catalog table to view currently held locks. If you cannot cancel a query because it is in transaction block (`BEGIN ... END`), you can terminate the session in which the query is running by using the `PG_TERMINATE_BACKEND` function.

Examples

To cancel a currently running query, first retrieve the process ID for the query that you want to cancel. To determine the process IDs for all currently running queries, run the following command.

```
SELECT pid, TRIM(starttime) AS start,
duration, TRIM(user_name) AS user,
SUBSTRING(query,1,40) AS querytxt
FROM stv_recents
WHERE status = 'Running';
```

pid	starttime	duration	user	querytxt
802	2013-10-14 09:19:03.55	132	dwuser	select venue name from venue
834	2013-10-14 08:33:49.47	1250414	dwuser	select * from listing;
964	2013-10-14 08:30:43.29	326179	dwuser	select sellerid from sales

To cancel the query with process ID 802, use the following example.

```
SELECT PG_CANCEL_BACKEND(802);
```

PG_TERMINATE_BACKEND

Terminates a session. You can terminate a session owned by your user. A superuser can terminate any session.

Syntax

```
pg_terminate_backend( pid )
```

Arguments

pid

The process ID of the session to be terminated. Requires an INTEGER value.

Return type

None

Usage notes

If you are close to reaching the limit for concurrent connections, use `PG_TERMINATE_BACKEND` to terminate idle sessions and free up the connections. For more information, see [Limits in Amazon Redshift](#).

If queries in multiple sessions hold locks on the same table, you can use `PG_TERMINATE_BACKEND` to terminate one of the sessions, which forces any currently running transactions in the terminated session to release all locks and roll back the transaction. Query the `PG_LOCKS` catalog table to view currently held locks.

If a query is not in a transaction block (`BEGIN ... END`), you can cancel the query by using the [CANCEL](#) command or the [PG_CANCEL_BACKEND](#) function.

Examples

To query the `SVV_TRANSACTIONS` table to view all locks in effect for current transactions, use the following example.

```
SELECT * FROM svv_transactions;
```

```
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
| txn_owner | txn_db |  xid | pid |      txn_start      |  lock_mode  |
| lockable_object_type | relation | granted |
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
| rsuser   | dev    | 96178 | 8585 | 2017-04-12 20:13:07 | AccessShareLock | relation
|          |        | 51940 |      |                    |                  |
| rsuser   | dev    | 96178 | 8585 | 2017-04-12 20:13:07 | AccessShareLock | relation
|          |        | 52000 |      |                    |                  |
| rsuser   | dev    | 96178 | 8585 | 2017-04-12 20:13:07 | AccessShareLock | relation
|          |        | 108623 |      |                    |                  |
| rsuser   | dev    | 96178 | 8585 | 2017-04-12 20:13:07 | ExclusiveLock   |
| transactionid |      | true |
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
```

To terminate the session holding the locks, use the following example.

```
SELECT PG_TERMINATE_BACKEND(8585);
```

REBOOT_CLUSTER

Reboot the Amazon Redshift cluster without closing the connections to the cluster. You must be a database superuser to run this command.

After this soft reboot has completed, the Amazon Redshift cluster returns an error to the user application and requires the user application to resubmit any transactions or queries interrupted by the soft reboot.

Syntax

```
SELECT REBOOT_CLUSTER();
```

SET_CONFIG

Sets a configuration parameter to a new setting.

This function is equivalent to the SET command in SQL.

Syntax

```
SET_CONFIG('parameter', 'new_value' , is_local)
```

The following statement sets a session context variable to a new setting.

```
set_config('variable_name', 'new_value' , is_local)
```

Arguments

parameter

Parameter to set.

variable_name

The name of the variable to set.

new_value

New value of the parameter.

is_local

If true, parameter value applies only to the current transaction. Valid values are `true` or `1` and `false` or `0`.

Return type

Returns a CHAR or VARCHAR string.

Examples

To set the value of the `query_group` parameter to test for the current transaction only, use the following example.

```
SELECT SET_CONFIG('query_group', 'test', true);
```

```
+-----+
| set_config |
+-----+
| test      |
+-----+
```

To set session context variables, use the following example.

```
SELECT SET_CONFIG('app.username', 'cuddy', FALSE);
```

System information functions

Amazon Redshift supports numerous system information functions.

CURRENT_AWS_ACCOUNT

Returns the AWS account associated with the Amazon Redshift cluster that submitted a query.

Syntax

```
current_aws_account
```

Return type

Returns an integer.

Example

The following query returns the name of the current database.

```
select user, current_aws_account;
current_user | current_account
-----+-----
dwuser      | 987654321
(1 row)
```

CURRENT_DATABASE

Returns the name of the database where you are currently connected.

Syntax

```
current_database()
```

Return type

Returns a CHAR or VARCHAR string.

Example

The following query returns the name of the current database.

```
select current_database();

current_database
-----
tickit
(1 row)
```

CURRENT_NAMESPACE

Returns the cluster namespace of the current Amazon Redshift cluster. Amazon Redshift cluster namespace is the unique ID of the Amazon Redshift cluster.

Syntax

```
current_namespace
```

Return type

Returns a CHAR or VARCHAR string.

Example

The following query returns the name of the current namespace.

```
select user, current_namespace;
current_user | current_namespace
-----+-----
dwuser      | 86b5169f-01dc-4a6f-9fbb-e2e24359e9a8

(1 row)
```

CURRENT_SCHEMA

Returns the name of the schema at the front of the search path. This schema will be used for any tables or other named objects that are created without specifying a target schema.

Syntax

Note

This is a leader-node function. This function returns an error if it references a user-created table, an STL or STV system table, or an SVV or SVL system view.

```
current_schema()
```

Return type

CURRENT_SCHEMA returns a CHAR or VARCHAR string.

Examples

The following query returns the current schema:

```
select current_schema();

current_schema
-----
public
(1 row)
```

CURRENT_SCHEMAS

Returns an array of the names of any schemas in the current search path. The current search path is defined in the `search_path` parameter.

Syntax

Note

This is a leader-node function. This function returns an error if it references a user-created table, an STL or STV system table, or an SVV or SVL system view.

```
current_schemas(include_implicit)
```

Argument

include_implicit

If true, specifies that the search path should include any implicitly included system schemas. Valid values are `true` and `false`. Typically, if `true`, this parameter returns the `pg_catalog` schema in addition to the current schema.

Return type

Returns a CHAR or VARCHAR string.

Examples

The following example returns the names of the schemas in the current search path, not including implicitly included system schemas:

```
select current_schemas(false);

current_schemas
-----
{public}
(1 row)
```

The following example returns the names of the schemas in the current search path, including implicitly included system schemas:

```
select current_schemas(true);

current_schemas
-----
{pg_catalog,public}
(1 row)
```

CURRENT_SESSION_ARN

Returns the ARN of the currently authorized global user. Global users present with the same identity across Redshift accounts, clusters, and Serverless workgroups. Global users log in through IAM Identity Center, or through IAM-based session authentication. Data lake users are global AWS users.

This function is typically used in the context of using multi-dialect AWS Glue views. For more information about identity management with IAM Identity Center and Redshift, see [Connect Redshift with IAM Identity Center to give users a single sign-on experience](#). For more information about multi-dialect Glue views [Creating views in the AWS Glue Data Catalog](#).

Syntax

```
current_session_arn()
```

Return type

Returns a VARCHAR string of the globally authenticated user or a null value.

Usage notes

Local users aren't supported and result in a null response.

Example

The following query returns the name of the current session ARN:

```
SELECT current_session_arn();

current_session_arn
-----
arn:aws:iam::123456789012:user/user
(1 row)
```

CURRENT_USER

Returns the user name of the current "effective" user of the database, as applicable to checking permissions. Usually, this user name will be the same as the session user; however, this can occasionally be changed by superusers.

Note

Do not use trailing parentheses when calling CURRENT_USER.

Syntax

```
current_user
```

Return type

CURRENT_USER returns a NAME data type and can be cast as a CHAR or VARCHAR string.

Usage notes

If a stored procedure was created using the SECURITY DEFINER option of the CREATE_PROCEDURE command, when invoking the CURRENT_USER function from within the stored procedure, Amazon Redshift returns the user name of the owner of the stored procedure.

Example

The following query returns the name of the current database user:

```
select current_user;
```

```
current_user
-----
dwuser
(1 row)
```

CURRENT_USER_ID

Returns the unique identifier for the Amazon Redshift user logged in to the current session.

Syntax

```
CURRENT_USER_ID
```

Return type

The CURRENT_USER_ID function returns an integer.

Examples

The following example returns the user name and current user ID for this session:

```
select user, current_user_id;

current_user | current_user_id
-----+-----
dwuser      |                1
(1 row)
```

DEFAULT_IAM_ROLE

Returns the default IAM role currently associated with the Amazon Redshift cluster. The function returns none if there isn't any default IAM role associated.

Syntax

```
select default_iam_role();
```

Return type

Returns a VARCHAR string.

Example

The following example returns the default IAM role currently associated with the specified Amazon Redshift cluster,

```
select default_iam_role();
           default_iam_role
-----
arn:aws:iam::123456789012:role/myRedshiftRole
(1 row)
```

GET_MOUNTED_ROLE

When invoked as part of a multi-dialect AWS Glue view, it allows returning the IAM role used to mount the Lake Formation schema or database. Multi-dialect means that the SQL is supported across multiple query engines, such as Amazon EMR and Redshift. For more information about multi-dialect Glue views, see [Creating views in the AWS Glue Data Catalog](#).

Syntax

```
get_mounted_role()
```

Return type

Returns a VARCHAR string or a null value.

Usage notes

This function returns null for any use case outside of an external Lake Formation view.

Example

The following query returns the identity to mount the Lake Formation resource.

```
CREATE EXTERNAL PROTECTED VIEW external_schema.remote_view AS
SELECT mycol, get_mounted_role() FROM external_schema.remote_table;

mycol | get_mounted_role
-----
1      arn:aws:iam::123456789012:role/salesrole
(1 row)
```

HAS_ASSUMEROLE_PRIVILEGE

Returns Boolean `true` (t) if the specified user has the specified IAM role with the privilege to run the specified command. The function returns `false` (f) if the user doesn't have the specified IAM role with the privilege to run the specified command. For more information about privileges, see [GRANT](#).

Syntax

```
has_assumerole_privilege( [ user, ] iam_role_arn, cmd_type)
```

Arguments

user

The name of the user to check for IAM role privileges. The default is to check the current user. Superusers and users can use this function. However, users can only view their own privileges.

iam_role_arn

The IAM role that has been granted the command privileges.

cmd_type

The command for which access has been granted. Valid values are the following:

- COPY
- UNLOAD
- EXTERNAL FUNCTION
- CREATE MODEL

Return type

BOOLEAN

Example

The following query confirms that the user `reg_user1` has the privilege for the `Redshift-S3-Read` role to run the `COPY` command.

```
select has_assumerole_privilege('reg_user1', 'arn:aws:iam::123456789012:role/Redshift-S3-Read', 'copy');
```

```
has_assumerole_privilege
-----
true
(1 row)
```

HAS_DATABASE_PRIVILEGE

Returns `true` if the user has the specified privilege for the specified database. For more information about privileges, see [GRANT](#).

Syntax

Note

This is a leader-node function. This function returns an error if it references a user-created table, an STL or STV system table, or an SVV or SVL system view.

```
has_database_privilege( [ user, ] database, privilege )
```

Arguments

user

The name of the user to check for database privileges. The default is to check the current user.

database

The database associated with the privilege.

privilege

The privilege to check. Valid values are the following:

- CREATE
- TEMPORARY
- TEMP

Return type

Returns a CHAR or VARCHAR string.

Example

The following query confirms that the GUEST user has the TEMP privilege on the TICKIT database.

```
select has_database_privilege('guest', 'ticket', 'temp');

has_database_privilege
-----
true
(1 row)
```

HAS_SCHEMA_PRIVILEGE

Returns `true` if the user has the specified privilege for the specified schema. For more information about privileges, see [GRANT](#).

Syntax

Note

This is a leader-node function. This function returns an error if it references a user-created table, an STL or STV system table, or an SVV or SVL system view.

```
has_schema_privilege( [ user, ] schema, privilege)
```

Arguments

user

The name of the user to check for schema privileges. The default is to check the current user.

schema

The schema associated with the privilege.

privilege

The privilege to check. Valid values are the following:

- CREATE
- USAGE

Return type

Returns a CHAR or VARCHAR string.

Example

The following query confirms that the GUEST user has the CREATE privilege on the PUBLIC schema:

```
select has_schema_privilege('guest', 'public', 'create');

has_schema_privilege
-----
true
(1 row)
```

HAS_TABLE_PRIVILEGE

Returns `true` if the user has the specified privilege for the specified table and returns `false` otherwise.

Syntax

Note

This is a leader-node function. This function returns an error if it references a user-created table, an STL or STV system table, or an SVV or SVL system view. For more information about privileges, see [GRANT](#).

```
has_table_privilege( [ user, ] table, privilege )
```

Arguments

user

The name of the user to check for table privileges. The default is to check the current user.

table

Table associated with the privilege.

privilege

Privilege to check. Valid values are the following:

- SELECT
- INSERT
- UPDATE
- DELETE
- DROP
- REFERENCES

Return type

BOOLEAN

Examples

The following query finds that the GUEST user doesn't have SELECT privilege on the LISTING table.

```
select has_table_privilege('guest', 'listing', 'select');

has_table_privilege
-----
false
```

The following query lists table privileges, including select, insert, update, and delete, using output from the pg_tables and pg_user catalog tables. This is a sample only. You might have to specify a schema name and table names from your database. For more information, see [Querying the catalog tables](#).

```
SELECT
  tablename
  ,username
  ,HAS_TABLE_PRIVILEGE(users.username, tablename, 'select') AS sel
  ,HAS_TABLE_PRIVILEGE(users.username, tablename, 'insert') AS ins
  ,HAS_TABLE_PRIVILEGE(users.username, tablename, 'update') AS upd
  ,HAS_TABLE_PRIVILEGE(users.username, tablename, 'delete') AS del
FROM
  (SELECT * from pg_tables
  WHERE schemaname = 'public' and tablename in ('event','listing')) as tables
  ,(SELECT * FROM pg_user) AS users;
```

tablename	username	sel	ins	upd	del
event	john	true	true	true	true
event	sally	false	false	false	false
event	elsa	false	false	false	false
listing	john	true	true	true	true
listing	sally	false	false	false	false
listing	elsa	false	false	false	false

The previous query also contains a cross join. For more information, see [JOIN examples](#). To query tables that are not in the public schema, remove the schemaname condition from the WHERE clause and use the following example prior to your query.

```
SET SEARCH_PATH to 'schema_name';
```

LAST_USER_QUERY_ID

Returns the query ID of the most recently completed user query in the current session. If no queries have been run in the current session, `last_user_query_id` returns -1. The function does not return the query ID for queries that run exclusively on the leader node. For more information, see [Leader node-only functions](#).

Syntax

```
last_user_query_id()
```

Return type

Returns an integer.

Example

The following query returns the ID of the latest query run by a user completed in the current session.

```
select last_user_query_id();
```

Results are the following.

```
last_user_query_id
```

```
-----  
      5437  
(1 row)
```

The following query returns the query ID and text of the most recently completed query run by a user in the current session.

```
select query_id, query_text from sys_query_history where query_id =  
last_user_query_id();
```

Results are the following.

```
query_id, query_text  
-----  
+-----  
5556975 | select last_user_query_id() limit 100 --RequestID=<unique request ID>;  
TraceID=<unique trace ID>
```

PG_BACKEND_PID

Returns the process ID (PID) of the server process handling the current session.

Note

The PID is not globally unique. It can be reused over time.

Syntax

```
pg_backend_pid()
```

Return type

Returns an integer.

Example

You can correlate PG_BACKEND_PID with log tables to retrieve information for the current session. For example, the following query returns the query ID and a portion of the query text for queries completed in the current session.

```
select query, substring(text,1,40)
from stl_querytext
where pid = PG_BACKEND_PID()
order by query desc;
```

```
query | substring
-----+-----
14831 | select query, substring(text,1,40) from
14827 | select query, substring(path,0,80) as pa
14826 | copy category from 's3://dw-tickit/manif
14825 | Count rows in target table
14824 | unload ('select * from category') to 's3
(5 rows)
```

You can correlate PG_BACKEND_PID with the pid column in the following log tables (exceptions are noted in parentheses):

- [STL_CONNECTION_LOG](#)
- [STL_DDLTEXT](#)
- [STL_ERROR](#)
- [STL_QUERY](#)
- [STL_QUERYTEXT](#)
- [STL_SESSIONS](#) (process)
- [STL_TR_CONFLICT](#)
- [STL_UTILITYTEXT](#)
- [STV_ACTIVE_CURSORS](#)
- [STV_INFLIGHT](#)
- [STV_LOCKS](#) (lock_owner_pid)
- [STV_RECENTS](#) (process_id)

PG_GET_COLS

Returns the column metadata for a table or view definition.

Syntax

```
pg_get_cols('name')
```

Arguments

name

The name of an Amazon Redshift table or view. For more information, see [Names and identifiers](#).

Return type

VARCHAR

Usage notes

The PG_GET_COLS function returns one row for each column in the table or view definition. The row contains a comma-separated list with the schema name, relation name, column name, data type, and column number. The formatting of the result of the SQL depends on the SQL client used.

Examples

The following examples return results for a view named SALES_VW in schema public and table named sales in schema myticket1 that are created by the user in the connected database dev.

The following example returns the column metadata for a view named SALES_VW.

```
select pg_get_cols('sales_vw');

pg_get_cols
-----
(public,sales_vw,salesid,integer,1)
(public,sales_vw,listid,integer,2)
(public,sales_vw,sellerid,integer,3)
(public,sales_vw,buyerid,integer,4)
(public,sales_vw,eventid,integer,5)
(public,sales_vw,dateid,smallint,6)
(public,sales_vw,qtysold,smallint,7)
(public,sales_vw,pricepaid,"numeric(8,2)",8)
(public,sales_vw,commission,"numeric(8,2)",9)
(public,sales_vw,saletime,"timestamp without time zone",10)
```

The following example returns the column metadata for the SALES_VW view in table format.

```
select * from pg_get_cols('sales_vw')
cols(view_schema name, view_name name, col_name name, col_type varchar, col_num int);
```

view_schema	view_name	col_name	col_type	col_num
public	sales_vw	salesid	integer	1
public	sales_vw	listid	integer	2
public	sales_vw	sellerid	integer	3
public	sales_vw	buyerid	integer	4
public	sales_vw	eventid	integer	5
public	sales_vw	dateid	smallint	6
public	sales_vw	qtysold	smallint	7
public	sales_vw	pricepaid	numeric(8,2)	8
public	sales_vw	commission	numeric(8,2)	9
public	sales_vw	saletime	timestamp without time zone	10

The following example returns the column metadata for the SALES table in schema myticket1 in table format.

```
select * from pg_get_cols('"myticket1"."sales"')
cols(view_schema name, view_name name, col_name name, col_type varchar, col_num int);
```

view_schema	view_name	col_name	col_type	col_num
myticket1	sales	salesid	integer	1
myticket1	sales	listid	integer	2
myticket1	sales	sellerid	integer	3
myticket1	sales	buyerid	integer	4
myticket1	sales	eventid	integer	5
myticket1	sales	dateid	smallint	6
myticket1	sales	qtysold	smallint	7
myticket1	sales	pricepaid	numeric(8,2)	8
myticket1	sales	commission	numeric(8,2)	9
myticket1	sales	saletime	timestamp without time zone	10

PG_GET_GRANTEE_BY_IAM_ROLE

Returns all users and groups granted a specified IAM role.

Syntax

```
pg_get_grantee_by_iam_role('iam_role_arn')
```

Arguments

iam_role_arn

The IAM role for which to return the users and groups that have been granted this role.

Return type

VARCHAR

Usage notes

The `PG_GET GRANTEE BY IAM_ROLE` function returns one row for each user or group. Each row contains the grantee name, grantee type, and granted privilege. The possible values for the grantee type are `p` for public, `u` for user, and `g` for group.

You must be a superuser to use this function.

Example

The following example indicates that the IAM role `Redshift-S3-Write` is granted to `group1` and `reg_user1`. Users in `group_1` can specify the role only for `COPY` operations, and user `reg_user1` can specify the role only to perform `UNLOAD` operations.

```
select pg_get_grantee_by_iam_role('arn:aws:iam::123456789012:role/Redshift-S3-Write');
```

```
pg_get_grantee_by_iam_role
```

```
-----
(group_1,g,COPY)
(reg_user1,u,UNLOAD)
```

The following example of the `PG_GET GRANTEE BY IAM_ROLE` function formats the result as a table.

```
select grantee, grantee_type, cmd_type FROM
pg_get_grantee_by_iam_role('arn:aws:iam::123456789012:role/Redshift-S3-Write')
res_grantee(grantee text, grantee_type text, cmd_type text) ORDER BY 1,2,3;
```

```
grantee | grantee_type | cmd_type
-----+-----+-----
group_1 | g             | COPY
```

```
reg_user1 | u | UNLOAD
```

PG_GET_IAM_ROLE_BY_USER

Returns all IAM roles and command privileges granted to a user.

Syntax

```
pg_get_iam_role_by_user('name')
```

Arguments

name

The name of the user for which to return IAM roles.

Return type

VARCHAR

Usage notes

The PG_GET_IAM_ROLE_BY_USER function returns one row for each set of roles and command privileges. The row contains a comma-separated list with the user name, IAM role, and command.

A value of `default` in the result indicates that the user can specify any available role to perform the displayed command.

You must be a superuser to use this function.

Example

The following example indicates that user `reg_user1` can specify any available IAM role to perform COPY operations. The user can also specify the `Redshift-S3-Write` role for UNLOAD operations.

```
select pg_get_iam_role_by_user('reg_user1');
```

```
pg_get_iam_role_by_user
```

```
-----  
(reg_user1,default,COPY)
```

```
(reg_user1,arn:aws:iam::123456789012:role/Redshift-S3-Write,COPY|UNLOAD)
```

The following example of the `PG_GET_IAM_ROLE_BY_USER` function formats the result as a table.

```
select username, iam_role, cmd FROM pg_get_iam_role_by_user('reg_user1')
res_iam_role(username text, iam_role text, cmd text);
```

username	iam_role	cmd
reg_user1	default	None
reg_user1	arn:aws:iam::123456789012:role/Redshift-S3-Read	COPY

PG_GET_LATE_BINDING_VIEW_COLS

Returns the column metadata for all late-binding views in the database. For more information, see [Late-binding views](#)

Syntax

```
pg_get_late_binding_view_cols()
```

Return type

VARCHAR

Usage notes

The `PG_GET_LATE_BINDING_VIEW_COLS` function returns one row for each column in late-binding views. The row contains a comma-separated list with the schema name, relation name, column name, data type, and column number.

Example

The following example returns the column metadata for all late-binding views.

```
select pg_get_late_binding_view_cols();

pg_get_late_binding_view_cols
-----
(public,myevent,eventname,"character varying(200)",1)
(public,sales_lbv,salesid,integer,1)
```

```
(public,sales_lbv,listid,integer,2)
(public,sales_lbv,sellerid,integer,3)
(public,sales_lbv,buyerid,integer,4)
(public,sales_lbv,eventid,integer,5)
(public,sales_lbv,dateid,smallint,6)
(public,sales_lbv,qtysold,smallint,7)
(public,sales_lbv,pricepaid,"numeric(8,2)",8)
(public,sales_lbv,commission,"numeric(8,2)",9)
(public,sales_lbv,saletime,"timestamp without time zone",10)
(public,event_lbv,eventid,integer,1)
(public,event_lbv,venueid,smallint,2)
(public,event_lbv,catid,smallint,3)
(public,event_lbv,dateid,smallint,4)
(public,event_lbv,eventname,"character varying(200)",5)
(public,event_lbv,starttime,"timestamp without time zone",6)
```

The following example returns the column metadata for all late-binding views in table format.

```
select * from pg_get_late_binding_view_cols() cols(view_schema name, view_name name,
  col_name name, col_type varchar, col_num int);
view_schema | view_name | col_name      | col_type                | col_num
-----+-----+-----+-----+-----
public      | sales_lbv | salesid       | integer                  |      1
public      | sales_lbv | listid        | integer                  |      2
public      | sales_lbv | sellerid      | integer                  |      3
public      | sales_lbv | buyerid      | integer                  |      4
public      | sales_lbv | eventid       | integer                  |      5
public      | sales_lbv | dateid        | smallint                 |      6
public      | sales_lbv | qtysold       | smallint                 |      7
public      | sales_lbv | pricepaid     | numeric(8,2)            |      8
public      | sales_lbv | commission    | numeric(8,2)            |      9
public      | sales_lbv | saletime      | timestamp without time zone |     10
public      | event_lbv | eventid       | integer                  |      1
public      | event_lbv | venueid       | smallint                 |      2
public      | event_lbv | catid         | smallint                 |      3
public      | event_lbv | dateid        | smallint                 |      4
public      | event_lbv | eventname     | character varying(200)  |      5
public      | event_lbv | starttime     | timestamp without time zone |      6
```

PG_GET_SESSION_ROLES

Returns session roles of the currently logged in user. Session roles of a user are the groups defined by an identity provider (IdP) for the logged in user. For example, an identity provider (IdP) such

as [Microsoft Azure Active Directory \(Azure AD\)](#) verifies the identity of the user and provides any external groups the user is part of during the user login process. These external groups are transformed into Amazon Redshift roles and are available during the current session. These roles are called session roles. An administrator can grant privileges to a session role similar to other Amazon Redshift roles. For information about using roles, see [Role-based access control \(RBAC\)](#). For information about managing identities with an identity provider (IdP), see [Native identity provider \(IdP\) federation for Amazon Redshift](#) in the *Amazon Redshift Management Guide*.

To view the roles defined in the Amazon Redshift catalog, query the system view [SVV_ROLES](#).

Syntax

```
pg_get_session_roles()
```

Return type

A set of rows that consists of two values. The first value has two parts separated by a colon(:) that contains an `idp-namespace:role-name`. The `idp-namespace` is the namespace of the identity provider (IdP). The `role-name` is the name of the external group in the identity provider (IdP). The second value contains a `role-id` which is the role identifier.

Usage notes

The `PG_GET_SESSION_ROLES` function returns one row for each returned session role.

Examples

The following example returns one row for each role from the Azure Active Directory IdP. The returned columns are cast to `sess_roles` with columns `name` and `roleid`. Each name consists of the Azure Active Directory namespace and a group name in Azure Active Directory.

```
SELECT * FROM pg_get_session_roles() AS sess_roles(name name, roleid integer);
```

name	roleid

my_aad:test_group_1	106204
my_aad:test_group_2	106205
my_aad:test_group_3	106206
my_aad:test_group_4	106207
my_aad:test_group_5	106208

The following example returns one row for each IAM group that the currently logged in IAM user is a member of. The returned columns are cast to `sess_roles` with columns `name` and `roleid`. Each name consists of the IAM namespace and IAM group name.

```
SELECT * FROM pg_get_session_roles() AS sess_roles(name name, roleid integer);
```

name	roleid

IAM:myGroup	110332

PG_LAST_COPY_COUNT

Returns the number of rows that were loaded by the last COPY command run in the current session. `PG_LAST_COPY_COUNT` is updated with the last COPY ID, which is the query ID of the last COPY that began the load process, even if the load failed. The query ID and COPY ID are updated when the COPY command begins the load process.

If the COPY fails because of a syntax error or because of insufficient privileges, the COPY ID is not updated and `PG_LAST_COPY_COUNT` returns the count for the previous COPY. If no COPY commands were run in the current session, or if the last COPY failed during loading, `PG_LAST_COPY_COUNT` returns 0. For more information, see [PG_LAST_COPY_ID](#).

Syntax

```
pg_last_copy_count()
```

Return type

Returns BIGINT.

Example

The following query returns the number of rows loaded by the latest COPY command in the current session.

```
select pg_last_copy_count();
```

pg_last_copy_count

192497

(1 row)

PG_LAST_COPY_ID

Returns the query ID of the most recently completed COPY command in the current session. If no COPY commands have been run in the current session, PG_LAST_COPY_ID returns -1.

The value for PG_LAST_COPY_ID is updated when the COPY command begins the load process. If the COPY fails because of invalid load data, the COPY ID is updated, so you can use PG_LAST_COPY_ID when you query STL_LOAD_ERRORS table. If the COPY transaction is rolled back, the COPY ID is not updated.

The COPY ID is not updated if the COPY command fails because of an error that occurs before the load process begins, such as a syntax error, access error, invalid credentials, or insufficient privileges. The COPY ID is not updated if the COPY fails during the analyze compression step, which begins after a successful connection, but before the data load.

Syntax

```
pg_last_copy_id()
```

Return type

Returns an integer.

Example

The following query returns the query ID of the latest COPY command in the current session.

```
select pg_last_copy_id();

pg_last_copy_id
-----
              5437
(1 row)
```

The following query joins STL_LOAD_ERRORS to STL_LOADERROR_DETAIL to view the details errors that occurred during the most recent load in the current session:

```
select d.query, substring(d.filename,14,20),
d.line_number as line,
substring(d.value,1,16) as value,
substring(le.err_reason,1,48) as err_reason
from stl_loadererror_detail d, stl_load_errors le
```

```
where d.query = le.query
and d.query = pg_last_copy_id();
```

query	substring	line	value	err_reason
558	allusers_pipe.txt	251	251	String contains invalid or unsupported UTF8 code
558	allusers_pipe.txt	251	ZRU29FGR	String contains invalid or unsupported UTF8 code
558	allusers_pipe.txt	251	Kaitlin	String contains invalid or unsupported UTF8 code
558	allusers_pipe.txt	251	Walter	String contains invalid or unsupported UTF8 code

PG_LAST_UNLOAD_ID

Returns the query ID of the most recently completed UNLOAD command in the current session. If no UNLOAD commands have been run in the current session, PG_LAST_UNLOAD_ID returns -1.

The value for PG_LAST_UNLOAD_ID is updated when the UNLOAD command begins the load process. If the UNLOAD fails because of invalid load data, the UNLOAD ID is updated, so you can use the UNLOAD ID for further investigation. If the UNLOAD transaction is rolled back, the UNLOAD ID is not updated.

The UNLOAD ID is not updated if the UNLOAD command fails because of an error that occurs before the load process begins, such as a syntax error, access error, invalid credentials, or insufficient privileges.

Syntax

```
PG_LAST_UNLOAD_ID()
```

Return type

Returns an integer.

Example

The following query returns the query ID of the latest UNLOAD command in the current session.

```
select PG_LAST_UNLOAD_ID();
```

```
PG_LAST_UNLOAD_ID
-----
                5437
(1 row)
```

PG_LAST_QUERY_ID

Returns the query ID of the most recently completed query in the current session. If no queries have been run in the current session, PG_LAST_QUERY_ID returns -1. PG_LAST_QUERY_ID does not return the query ID for queries that run exclusively on the leader node. For more information, see [Leader node-only functions](#).

Syntax

```
pg_last_query_id()
```

Return type

Returns an integer.

Example

The following query returns the ID of the latest query completed in the current session.

```
select pg_last_query_id();
```

Results are the following.

```
pg_last_query_id
-----
                5437
(1 row)
```

The following query returns the query ID and text of the most recently completed query in the current session.

```
select query, trim(querytxt) as sqlquery
from stl_query
where query = pg_last_query_id();
```

Results are the following.

```
query | sqlquery
-----+-----
5437 | select name, loadtime from stl_file_scan where loadtime > 1000000;
(1 rows)
```

PG_LAST_UNLOAD_COUNT

Returns the number of rows that were unloaded by the last UNLOAD command completed in the current session. PG_LAST_UNLOAD_COUNT is updated with the query ID of the last UNLOAD, even if the operation failed. The query ID is updated when the UNLOAD is completed. If the UNLOAD fails because of a syntax error or because of insufficient privileges, PG_LAST_UNLOAD_COUNT returns the count for the previous UNLOAD. If no UNLOAD commands were completed in the current session, or if the last UNLOAD failed during the unload operation, PG_LAST_UNLOAD_COUNT returns 0.

Syntax

```
pg_last_unload_count()
```

Return type

Returns BIGINT.

Example

The following query returns the number of rows unloaded by the latest UNLOAD command in the current session.

```
select pg_last_unload_count();

pg_last_unload_count
-----
192497
(1 row)
```

SLICE_NUM Function

Returns an integer corresponding to the slice number in the cluster where the data for a row is located. SLICE_NUM takes no parameters.

Syntax

```
SLICE_NUM()
```

Return type

The SLICE_NUM function returns an integer.

Examples

The following example shows which slices contain data for the first ten EVENT rows in the EVENTS table:

```
select distinct eventid, slice_num() from event order by eventid limit 10;
```

eventid	slice_num
1	1
2	2
3	3
4	0
5	1
6	2
7	3
8	0
9	1
10	2

(10 rows)

The following example returns a code (10000) to show that a query without a FROM statement runs on the leader node:

```
select slice_num();
slice_num
-----
10000
(1 row)
```

USER

Synonym for CURRENT_USER. See [CURRENT_USER](#).

ROLE_IS_MEMBER_OF

Returns true if the role is a member of another role. Superusers can check the membership of all roles. Regular users who have the ACCESS SYSTEM TABLE permission can check all users' membership. Otherwise, regular users can only check roles to which they have access. Amazon Redshift errors out if the provided roles don't exist or the current user doesn't have access to the role.

Syntax

```
role_is_member_of( role_name, granted_role_name)
```

Arguments

role_name

The name of the role.

granted_role_name

The name of the granted role.

Return type

Returns a BOOLEAN.

Example

The following query confirms that the role isn't a member of role1 nor role2.

```
SELECT role_is_member_of('role1', 'role2');
```

```
role_is_member_of
-----
                False
```

USER_IS_MEMBER_OF

Returns true if the user is a member of a role or group. Superusers can check the membership of all users. Regular users who are members of the sys:secadmin or sys:superuser role can check all users' membership. Otherwise, regular users can only check themselves. Amazon Redshift sends an error if the provided identities don't exist or the current user doesn't have access to the role.

Syntax

```
user_is_member_of( user_name, role_name | group_name )
```

Arguments

user_name

The name of the user.

role_name

The name of the role.

group_name

The name of the group.

Return type

Returns a BOOLEAN.

Example

The following query confirms that the user isn't a member of role1.

```
SELECT user_is_member_of('reguser', 'role1');

 user_is_member_of
-----
                False
```

VERSION

The VERSION function returns details about the currently installed release, with specific Amazon Redshift version information at the end.

Note

This is a leader-node function. This function returns an error if it references a user-created table, an STL or STV system table, or an SVV or SVL system view.

Syntax

```
VERSION()
```

Return type

Returns a CHAR or VARCHAR string.

Examples

The following example shows the cluster version information of the current cluster:

```
select version();
```

```
version
```

```
-----  
PostgreSQL 8.0.2 on i686-pc-linux-gnu, compiled by GCC gcc (GCC) 3.4.2 20041017 (Red  
Hat 3.4.2-6.fc3), Redshift 1.0.12103
```

Where 1.0.12103 is the cluster version number.

Note

To force your cluster to update to the latest cluster version, adjust your [maintenance window](#).

Reserved words

The following is a list of Amazon Redshift reserved words. You can use the reserved words with delimited identifiers (double quotation marks).

Note

While START and CONNECT are not reserved words, use delimited identifiers or AS if you're using START and CONNECT as table aliases in your query to avoid failure at runtime.

For more information, see [Names and identifiers](#).

System tables and views

Amazon Redshift has many system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any other database tables. This section shows some sample system table queries and explains:

- How different types of system tables and views are generated
- What types of information you can obtain from these tables
- How to join Amazon Redshift system tables to catalog tables
- How to manage the growth of system table log files

Some system tables can only be used by AWS staff for diagnostic purposes. The following sections discuss the system tables that can be queried for useful information by system administrators or other database users.

Note

System tables are not included in automated or manual cluster backups (snapshots). STL system views retain seven days of log history. Retaining logs doesn't require any customer action, but if you want to store log data for more than 7 days, you have to periodically copy it to other tables or unload it to Amazon S3.

Types of system tables and views

There are several types of system tables and views:

- SVV views contain information about database objects with references to transient STV tables.
- SYS views are used to monitor query and workload usage for provisioned clusters and serverless workgroups.
- STL views are generated from logs that have been persisted to disk to provide a history of the system.
- STV tables are virtual system tables that contain snapshots of the current system data. They are based on transient in-memory data and are not persisted to disk-based logs or regular tables.
- SVCS views provide details about queries on both the main and concurrency scaling clusters.
- SVL views provide details about queries on main clusters.

System tables and views do not use the same consistency model as regular tables. It is important to be aware of this issue when querying them, especially for STV tables and SVV views. For example, given a regular table `t1` with a column `c1`, you would expect that the following query to return no rows:

```
select * from t1
where c1 > (select max(c1) from t1)
```

However, the following query against a system table might well return rows:

```
select * from stv_exec_state
where currenttime > (select max(currenttime) from stv_exec_state)
```

The reason this query might return rows is that `currenttime` is transient and the two references in the query might not return the same value when evaluated.

On the other hand, the following query might well return no rows:

```
select * from stv_exec_state
where currenttime = (select max(currenttime) from stv_exec_state)
```

Visibility of data in system tables and views

There are two classes of visibility for data in system tables and views: visible to users and visible to superusers.

Only users with superuser privileges can see the data in those tables that are in the superuser-visible category. Regular users can see data in the user-visible tables. To give a regular user access to superuser-visible tables, grant `SELECT` privilege on that table to the regular user. For more information, see [GRANT](#).

By default, in most user-visible tables, rows generated by another user are invisible to a regular user. If a regular user is given [SYSLOG ACCESS UNRESTRICTED](#), that user can see all rows in user-visible tables, including rows generated by another user. For more information, see [ALTER USER](#) or [CREATE USER](#). All rows in `SVV_TRANSACTIONS` are visible to all users. For more information about data visibility, see the AWS re:Post knowledge base article [How can I allow Amazon Redshift database regular users permission to view data in system tables from other users for my cluster?](#).

For metadata views, Amazon Redshift doesn't allow visibility to users that are granted `SYSLOG ACCESS UNRESTRICTED`.

Note

Giving a user unrestricted access to system tables gives the user visibility to data generated by other users. For example, `STL_QUERY` and `STL_QUERY_TEXT` contain the full text of `INSERT`, `UPDATE`, and `DELETE` statements, which might contain sensitive user-generated data.

A superuser can see all rows in all tables. To give a regular user access to superuser-visible tables, [GRANT](#) `SELECT` privilege on that table to the regular user.

Filtering system-generated queries

The query-related system tables and views, such as `SVL_QUERY_SUMMARY`, `SVL_QLOG`, and others, usually contain a large number of automatically generated statements that Amazon Redshift uses to monitor the status of the database. These system-generated queries are visible to a superuser, but are seldom useful. To filter them out when selecting from a system table or system view that uses the `userid` column, add the condition `userid > 1` to the `WHERE` clause. For example:

```
select * from svl_query_summary where userid > 1
```

Migrating provisioned-only queries to SYS monitoring view queries

Migrating from provisioned clusters to Amazon Redshift Serverless

If you're migrating a provisioned cluster to Amazon Redshift Serverless, you may have queries using the following system views, which only store data from provisioned clusters.

- All STL views
- All STV views
- All SVCS views
- All SVL views
- Some SVV views
 - For a full list of SVV views unsupported in Amazon Redshift Serverless, see the list at the bottom of [Monitoring queries and workloads with Amazon Redshift Serverless](#) in the *Amazon Redshift Management Guide*.

To keep using your queries, refit them to use columns defined in the SYS monitoring views that correspond to the columns in your provisioned-only views. To see the mapping relation between the provisioned-only views and the SYS monitoring views, go to [System view mapping for migrating to SYS monitoring views](#)

Updating queries while staying on a provisioned cluster

If you're not migrating to Amazon Redshift Serverless, you might still want to update your existing queries. The SYS monitoring views are designed for ease of use and reduced complexity, providing a complete array of metrics for effective monitoring and troubleshooting. Using SYS views such as [SYS_QUERY_HISTORY](#) and [SYS_QUERY_DETAIL](#) that consolidate the information of multiple provisioned-only views, you can streamline your queries.

Improving query identifier tracking using the SYS monitoring views

SYS monitoring views such as [SYS_QUERY_HISTORY](#) and [SYS_QUERY_DETAIL](#) contain the `query_id` column, which holds the identifier for users' queries. Similarly, provisioned-only views such as [STL_QUERY](#) and [SVL_QLOG](#) contain the `query` column, which also holds the query identifiers. However, the query identifiers recorded in the SYS system views are different from those recorded in the provisioned-only views.

The difference between the SYS views' `query_id` column values and the provisioned-only views' `query` column values is as follows:

- In SYS views, the `query_id` column records user-submitted queries in their original form. The Amazon Redshift optimizer might break them down into child queries for improved performance, but a single query you run will still only have a single row in [SYS_QUERY_HISTORY](#). If you want to see the individual child queries, you can find them in [SYS_QUERY_DETAIL](#).
- In provisioned-only views, the `query` column records queries at the child query level. If the Amazon Redshift optimizer rewrites your original query into multiple child queries, there will be multiple rows in [STL_QUERY](#) with differing query identifier values for a single query you run.

When you migrate your monitoring and diagnostic queries from provisioned-only views to SYS views, consider this difference and edit your queries accordingly. For more information on how Amazon Redshift processes queries, see [Query planning and execution workflow](#).

Example

For an example of how Amazon Redshift records queries differently in provisioned-only and SYS monitoring views, see the following sample query. This is the query written as you would run it in Amazon Redshift.

```

SELECT
  s_name
  , COUNT(*) AS numwait
FROM
  supplier,
  lineitem l1,
  orders,
  nation
WHERE   s_suppkey = l1.l_suppkey
        AND o_orderkey = l1.l_orderkey
        AND o_orderstatus = 'F'
        AND l1.l_receiptdate > l1.l_commitdate
        AND EXISTS (SELECT
                      *
                    FROM
                      lineitem l2
                    WHERE  l2.l_orderkey = l1.l_orderkey
                          AND l2.l_suppkey <> l1.l_suppkey )
        AND NOT EXISTS (SELECT
                        *
                      FROM
                        lineitem l3
                      WHERE  l3.l_orderkey = l1.l_orderkey
                            AND l3.l_suppkey <> l1.l_suppkey
                            AND l3.l_receiptdate > l3.l_commitdate )
        AND s_nationkey = n_nationkey
        AND n_name = 'UNITED STATES'
GROUP BY
  s_name
ORDER BY
  numwait DESC
  , s_name LIMIT 100;

```

Under the hood the Amazon Redshift query optimizer rewrites the above user-submitted query into 5 child queries.

The first child query creates a temporary table to materialize a subquery.

```

CREATE TEMP TABLE volt_tt_606590308b512(l_orderkey
                                         , l_suppkey
                                         , s_name ) AS SELECT
                                         l1.l_orderkey
                                         , l1.l_suppkey

```

```

        , public.supplier.s_name
FROM
    public.lineitem AS l1,
    public.nation,
    public.orders,
    public.supplier
WHERE  l1.l_commitdate <

l1.l_receiptdate
        AND l1.l_orderkey =
public.orders.o_orderkey
        AND l1.l_suppkey =
public.supplier.s_suppkey
        AND public.nation.n_name
= 'UNITED STATES'::CHAR(8)
        AND
public.nation.n_nationkey = public.supplier.s_nationkey
        AND
public.orders.o_orderstatus = 'F'::CHAR(1);

```

The second child query collects statistics from the temporary table.

```
padb_fetch_sample: select count(*) from volt_tt_606590308b512;
```

The third child query creates another temporary table to materialize another subquery, referencing the temporary table created above.

```

CREATE TEMP TABLE volt_tt_606590308c2ef(l_orderkey
        , l_suppkey) AS (SELECT

    volt_tt_606590308b512.l_orderkey
        ,
    volt_tt_606590308b512.l_suppkey
        FROM
            public.lineitem AS l2,
            volt_tt_606590308b512
        WHERE  l2.l_suppkey <>

    volt_tt_606590308b512.l_suppkey
        AND l2.l_orderkey =
    volt_tt_606590308b512.l_orderkey)
        EXCEPT distinct (SELECT
    volt_tt_606590308b512.l_orderkey, volt_tt_606590308b512.l_suppkey
        FROM public.lineitem AS
    l3, volt_tt_606590308b512

```

```

13.1_receiptdate                                WHERE 13.1_commitdate <
volt_tt_606590308b512.l_suppkey                  AND 13.1_suppkey <>
volt_tt_606590308b512.l_orderkey);              AND 13.1_orderkey =

```

The fourth child query again collects the temporary table's statistics.

```
padb_fetch_sample: select count(*) from volt_tt_606590308c2ef
```

The last child query uses the temporary tables created above to generate the output.

```

SELECT
  volt_tt_606590308b512.s_name AS s_name
  , COUNT(*) AS numwait
FROM
  volt_tt_606590308b512,
  volt_tt_606590308c2ef
WHERE   volt_tt_606590308b512.l_orderkey = volt_tt_606590308c2ef.l_orderkey
        AND volt_tt_606590308b512.l_suppkey = volt_tt_606590308c2ef.l_suppkey
GROUP BY
  1
ORDER BY
  2 DESC
  , 1 ASC LIMIT 100;

```

In the provisioned-only system view `STL_QUERY`, Amazon Redshift records five rows at the child query level, as follows:

```

SELECT userid, xid, pid, query, querytxt::varchar(100);
FROM stl_query
WHERE xid = 48237350
ORDER BY xid, starttime;

```

```

userid | xid   | pid     | query   |
querytxt
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
      101 | 48237350 | 1073840810 | 12058151 | CREATE TEMP TABLE
      volt_tt_606590308b512(l_orderkey, l_suppkey, s_name) AS SELECT 11.1_orderkey, 11.1

```

```

101 | 48237350 | 1073840810 | 12058152 | padb_fetch_sample: select count(*) from
volt_tt_606590308b512
101 | 48237350 | 1073840810 | 12058156 | CREATE TEMP TABLE
volt_tt_606590308c2ef(l_orderkey, l_suppkkey) AS (SELECT volt_tt_606590308b512.l_or
101 | 48237350 | 1073840810 | 12058168 | padb_fetch_sample: select count(*) from
volt_tt_606590308c2ef
101 | 48237350 | 1073840810 | 12058170 | SELECT s_name , COUNT(*) AS numwait FROM
supplier, lineitem l1, orders, nation WHERE s_suppkkey = l1.
(5 rows)

```

In the SYS monitoring view SYS_QUERY_HISTORY, Amazon Redshift records the query as follows:

```

SELECT user_id, transaction_id, session_id, query_id, query_text::varchar(100)
FROM sys_query_history
WHERE transaction_id = 48237350
ORDER BY start_time;

 user_id | transaction_id | session_id | query_id |
         | query_text
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
      101 |      48237350 | 1073840810 | 12058149 | SELECT s_name , COUNT(*) AS numwait
FROM supplier, lineitem l1, orders, nation WHERE s_suppkkey = l1.

```

In SYS_QUERY_DETAIL, you can find child query-level details using the query_id value from SYS_QUERY_HISTORY. The child_query_sequence column shows the order the child queries are executed in. For more information on the columns in SYS_QUERY_DETAIL, see [SYS_QUERY_DETAIL](#).

```

select user_id,
       query_id,
       child_query_sequence,
       stream_id,
       segment_id,
       step_id,
       start_time,
       end_time,
       duration,
       blocks_read,
       blocks_write,
       local_read_io,
       remote_read_io,
       data_skewness,
       time_skewness,

```

```

    is_active,
    spilled_block_local_disk,
    spilled_block_remote_disk
from sys_query_detail
where query_id = 12058149
    and step_id = -1
order by query_id,
    child_query_sequence,
    stream_id,
    segment_id,
    step_id;

```

```

user_id | query_id | child_query_sequence | stream_id | segment_id | step_id |
start_time      |          end_time      | duration | blocks_read |

System table query, process, and session ids

When analyzing query, process, and session ids that appear in system tables, be aware of the following:

- The query id value (in columns such as `query_id` and `query`) can be reused over time.
- The process id or session id value (in columns such as `process_id`, `pid`, and `session_id`) can be reused over time.
- The transaction id value (in columns such as `transaction_id` and `xid`) is unique.

SVV metadata views

SVV views are system views in Amazon Redshift that contain information about database objects.

Note

Amazon Redshift reports a `WARNING`, not an `ERROR`, if a database response fails for any reason. Amazon Redshift doesn't send `ERROR` messages when you're querying objects in a datashare.

SVV_ACTIVE_CURSORS

SVV_ACTIVE_CURSORS displays details for currently open cursors. For more information, see [DECLARE](#).

SVV_ACTIVE_CURSORS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#). A user can only view cursors opened by that user. A superuser can view all cursors.

Table columns

Column name	Data type	Description
user_id	integer	The ID of the user who created the cursor.
cursor_name	varchar(128)	The name of the cursor.
transaction_id	bigint(128)	The ID of the transaction.
session_id	integer	The ID of the process with the active cursor.
declare_time	timestamp	The time the cursor was declared.
total_bytes	bigint	The size of the cursor result set, in bytes.
total_rows	bigint	The number of rows in the cursor result set.
fetches_rows	bigint	The number of rows currently fetched from the cursor result set.
cursor_storage_limit_used_percent	integer	The percentage of disk space currently used by the cursor.

SVV_ALL_COLUMNS

Use `SVV_ALL_COLUMNS` to view a union of columns from Amazon Redshift tables as shown in `SVV_REDSHIFT_COLUMNS` and the consolidated list of all external columns from all external tables. For information about Amazon Redshift columns, see [SVV_REDSHIFT_COLUMNS](#).

`SVV_ALL_COLUMNS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database.
schema_name	varchar(128)	The name of the schema.
table_name	varchar(128)	The name of the table.
column_name	varchar(128)	The name of the column.
ordinal_position	integer	The position of the column in the table.
column_default	varchar(4000)	The default value of the column.
is_nullable	varchar(3)	A value that indicates whether the column is nullable. Possible values are yes and no.
data_type	varchar(128)	The data type of the column.
character_maximum_length	integer	The maximum number of characters in the column.
numeric_precision	integer	The numeric precision.
numeric_scale	integer	The numeric scale.
remarks	varchar(256)	Remarks.

Sample queries

The following example returns the output of SVV_ALL_COLUMNS.

```
SELECT *  
FROM svv_all_columns
```

```

WHERE database_name = 'tickit_db'
      AND TABLE_NAME = 'tickit_sales_redshift'
ORDER BY COLUMN_NAME,
      SCHEMA_NAME
LIMIT 5;

```

database_name	schema_name	table_name	column_name	ordinal_position	column_default	is_nullable	data_type	character_maximum_length	numeric_precision	numeric_scale	remarks
tickit_db	public	tickit_sales_redshift	buyerid	4		NO	integer				
					0						
tickit_db	public	tickit_sales_redshift	commission	9		YES	numeric				
					2						
tickit_db	public	tickit_sales_redshift	dateid	7		NO	smallint				
					0						
tickit_db	public	tickit_sales_redshift	eventid	5		NO	integer				
					0						
tickit_db	public	tickit_sales_redshift	listid	2		NO	integer				
					0						

SVV_ALL_SCHEMAS

Use `SVV_ALL_SCHEMAS` to view a union of Amazon Redshift schemas as shown in `SVV_REDSHIFT_SCHEMAS` and the consolidated list of all external schemas from all databases. For more information about Amazon Redshift schemas, see [SVV_REDSHIFT_SCHEMAS](#).

`SVV_ALL_SCHEMAS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database where the schema exists.
schema_name	varchar(128)	The name of the schema.
schema_owner	integer	The user ID of the schema owner. For information about user IDs, see PG_USER_INFO .
schema_type	varchar(128)	The type of the schema. Possible values are external, local, and shared schemas.
schema_acl	varchar(128)	The string that defines the permissions for the specified user or user group for the schema.
source_database	varchar(128)	The name of the source database for external schema.
schema_option	varchar(256)	The options of the schema. This is an external schema attribute.

Sample query

The following example returns the output of SVV_ALL_SCHEMAS.

```
SELECT *
FROM svv_all_schemas
WHERE database_name = 'tickit_db'
ORDER BY database_name,
        SCHEMA_NAME;
```

```

database_name |    schema_name    | schema_owner | schema_type | schema_acl |
source_database | schema_option
-----+-----+-----+-----+-----
+-----+-----
   tickit_db   |      public      |      1       |   shared   |           |
   |

```

SVV_ALL_TABLES

Use SVV_ALL_TABLES to view a union of Amazon Redshift tables as shown in SVV_REDSHIFT_TABLES and the consolidated list of all external tables from all external schemas. For information about Amazon Redshift tables, see [SVV_REDSHIFT_TABLES](#).

SVV_ALL_TABLES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database where the table exists.
schema_name	varchar(128)	The schema name for the table.
table_name	varchar(128)	The name of the table.
table_acl	varchar(128)	The string that defines the permission for the specified user or user group for the table.
table_type	varchar(128)	The type of the table. Possible values are views, base tables, external tables, and shared tables.
remarks	varchar(256)	Remarks.

Sample queries

The following example returns the output of `SVV_ALL_TABLES`.

```
SELECT *
FROM svv_all_tables
WHERE database_name = 'tickit_db'
ORDER BY TABLE_NAME,
        SCHEMA_NAME
LIMIT 5;
```

database_name	schema_name	table_name	table_type	table_acl	remarks
tickit_db	public	tickit_category_redshift	TABLE		
tickit_db	public	tickit_date_redshift	TABLE		
tickit_db	public	tickit_event_redshift	TABLE		
tickit_db	public	tickit_listing_redshift	TABLE		
tickit_db	public	tickit_sales_redshift	TABLE		

If the `table_acl` value is null, no access privileges have been explicitly granted to the corresponding table.

SVV_ALTER_TABLE_RECOMMENDATIONS

Records the current Amazon Redshift Advisor recommendations for tables. This view shows recommendations for all tables, whether they are defined for automatic optimization or not. To view if a table is defined for automatic optimization, see [SVV_TABLE_INFO](#). Entries appear only for tables visible in the current session's database. After a recommendation has been applied (either by Amazon Redshift or by you), it no longer appears in the view.

`SVV_ALTER_TABLE_RECOMMENDATIONS` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
type	character (30)	The type of recommendation. Possible values are distkey and sortkey.
database	character (128)	The database name.
table_id	integer	The table identifier.
group_id	integer	The group number of a set of recommendations. All recommendations in a group should be applied to see the maximum benefit. Possible values are -1 for a sort key recommendation, and a number larger than zero for a distribution key recommendation.
ddl	character (1024)	The SQL statement that must run to apply the recommendation.
auto_eligible	character (1)	The value indicates if the recommendation is eligible for Amazon Redshift to run automatically. If this value is t, then the indication is true, if f then false.

Sample queries

In the following example, the rows in the result show recommendations for distribution key and sort key. The rows also show whether the recommendations are eligible for Amazon Redshift to automatically apply them.

```
select type, database, table_id, group_id, ddl, auto_eligible
from svv_alter_table_recommendations;
```

```
type      | database | table_id | group_id | ddl
          | auto_eligible
```

```

diststyle | db0      | 117884 | 2      | ALTER TABLE "sch"."dp21235_tbl_1" ALTER
DISTSTYLE KEY DISTKEY "c0"
          | f
diststyle | db0      | 117892 | 2      | ALTER TABLE "sch"."dp21235_tbl_1" ALTER
DISTSTYLE KEY DISTKEY "c0"
          | f
diststyle | db0      | 117885 | 1      | ALTER TABLE "sch"."catalog_returns"
ALTER DISTSTYLE KEY DISTKEY "cr_sold_date_sk", ALTER COMPOUND SORTKEY
("cr_sold_date_sk","cr_returned_time_sk") | t
sortkey   | db0      | 117890 | -1     | ALTER TABLE "sch"."customer_addresses"
ALTER COMPOUND SORTKEY ("ca_address_sk")
          | t

```

SVV_ATTACHED_MASKING_POLICY

Use `SVV_ATTACHED_MASKING_POLICY` to view all the relations and roles/users with policies attached on the currently connected database.

Only superusers and users with the [sys:secadmin](#) role can view `SVV_ATTACHED_MASKING_POLICY`. Regular users will see 0 rows.

Table columns

Column name	Data type	Description
<code>policy_name</code>	text	The name of the masking policy attached to the table.
<code>schema_name</code>	text	The schema of the table to which the policy is attached.
<code>table_name</code>	text	The name of the table to which the policy is attached.
<code>table_type</code>	text	The type of the table to which the policy is attached.
<code>grantor</code>	text	The name of the user that attached the policy.

Column name	Data type	Description
grantee	text	The name of the user/role to whom the policy is attached.
grantee_type	text	The type of grantee. This can be <i>role</i> , <i>user</i> , or <i>public</i> .
priority	int	The priority of the attached policy.
input_columns	text	The input column attributes of the attached policy.
output_columns	text	The output column attributes of the attached policy.

Internal functions

SVV_ATTACHED_MASKING_POLICY supports the following internal functions:

mask_get_policy_for_role_on_column

Get the highest priority policy that applies to a given column/role pair.

Syntax

```
mask_get_policy_for_role_on_column
    (relschema,
     relname,
     colname,
     rolename);
```

Parameters

relschema

The name of the schema the policy is in.

relname

The name of the table the policy is in.

colname

The name of the column the policy is attached to.

rolename

The name of the role the policy is attached to.

mask_get_policy_for_user_on_column

Get the highest priority policy that applies to a given column/user pair.

Syntax

```
mask_get_policy_for_user_on_column
    (relschem,
     relname,
     colname,
     username);
```

Parameters***relschem***

The name of the schema the policy is in.

relname

The name of the table the policy is in.

colname

The name of the column the policy is attached to.

rolename

The name of the user the policy is attached to.

SVV_COLUMNS

Use SVV_COLUMNS to view catalog information about the columns of local and external tables and views, including [late-binding views](#).

SVV_COLUMNS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

The SVV_COLUMNS view joins table metadata from the [System catalog tables](#) (tables with a PG prefix) and the [SVV_EXTERNAL_COLUMNS](#) system view. The system catalog tables describe Amazon Redshift database tables. SVV_EXTERNAL_COLUMNS describes external tables that are used with Amazon Redshift Spectrum.

All users can see all rows from the system catalog tables. Regular users can see column definitions from the SVV_EXTERNAL_COLUMNS view only for external tables to which they have been granted access. Although regular users can see table metadata in the system catalog tables, they can only select data from user-defined tables if they own the table or have been granted access.

Table columns

Column name	Data type	Description
table_catalog	text	The name of the catalog where the table is.
table_schema	text	The schema name for the table.
table_name	text	The name of the table.
column_name	text	The name of the column.
ordinal_position	int	The position of the column in the table.
column_default	text	The default value of the column.
is_nullable	text	A value that indicates whether the column is nullable.
data_type	text	The data type of the column.

Column name	Data type	Description
character_maximum_length	int	The maximum number of characters in the column.
numeric_precision	int	The numeric precision. If the data_type column is numeric, this column returns the number of significant digits in the entire value.
numeric_precision_radix	int	The numeric precision radix. If the data_type column is numeric, this column returns the base of the columns numeric_precision and numeric_scale.
numeric_scale	int	The numeric scale. If the data_type column is numeric, this column returns the number of significant digits in the decimal value.
datetime_precision	int	The datetime precision.
interval_type	text	The interval type.
interval_precision	text	The interval precision.
character_set_catalog	text	The character set catalog.
character_set_schema	text	The character set schema.
character_set_name	text	The character set name.
collation_catalog	text	The collation catalog.
collation_schema	text	The collation schema.

Column name	Data type	Description
collation_name	text	The collation name.
domain_name	text	The domain name.
remarks	text	Remarks.

SVV_COLUMN_PRIVILEGES

Use `SVV_COLUMN_PRIVILEGES` to view the column permissions that are explicitly granted to users, roles, and groups in the current database.

`SVV_COLUMN_PRIVILEGES` is visible to the following users:

- Superusers
- Users with the `ACCESS SYSTEM TABLE` permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
namespace_name	text	The name of the namespace where a specified relation exists.
relation_name	text	The name of the relation.
column_name	text	The name of the column.
privilege_type	text	The type of the permission. Possible values are <code>SELECT</code> or <code>UPDATE</code> .
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.

Column name	Data type	Description
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group or public.

Sample query

The following example displays the result of the SVV_COLUMN_PRIVILEGES.

```
SELECT
  namespace_name,relation_name,COLUMN_NAME,privilege_type,identity_name,identity_type
FROM svv_column_privileges WHERE relation_name = 'lineitem';
```

```
namespace_name | relation_name | column_name | privilege_type | identity_name |
identity_type
-----+-----+-----+-----+-----+
+-----+
public        | lineitem     | l_orderkey  | SELECT        | reguser      |
user
public        | lineitem     | l_orderkey  | SELECT        | role1        |
role
public        | lineitem     | l_partkey   | SELECT        | reguser      |
user
public        | lineitem     | l_partkey   | SELECT        | role1        |
role
```

SVV_DATABASE_PRIVILEGES

Use SVV_DATABASE_PRIVILEGES to view the database permissions that are explicitly granted to users, roles, and groups in your Amazon Redshift cluster.

SVV_DATABASE_PRIVILEGES is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
database_name	text	The name of the database.
privilege_type	text	The type of the permission. For permissions with a privilege_scope of database, possible values are USAGE, CREATE, TEMPORARY, TEMP, and ALTER. For privilege_scope values other than database, possible values include any permission type available on the permission's scope.
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group, or public.
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.
privilege_scope	text	<p>The scope of the permission specified in privilege_type. Possible values are as follows:</p> <ul style="list-style-type: none"> • DATABASE • SCHEMAS • TABLES • FUNCTIONS • LANGUAGES <p>For information on scoped permissions, go to Scoped permissions.</p>

Sample query

The following example displays the result of the `SVV_DATABASE_PRIVILEGES`.

```
SELECT database_name,privilege_type,identity_name,identity_type,admin_option FROM
svv_database_privileges
WHERE database_name = 'test_db';
```

database_name	privilege_type	identity_name	identity_type	admin_option
test_db	CREATE	reguser	user	False
test_db	CREATE	role1	role	False
test_db	TEMP	public	public	False
test_db	TEMP	role1	role	False

SVV_DATASHARE_PRIVILEGES

Use `SVV_DATASHARE_PRIVILEGES` to view the datashare permissions that are explicitly granted to users, roles, and groups in your Amazon Redshift cluster.

`SVV_DATASHARE_PRIVILEGES` is visible to the following users:

- Superusers
- Users with the `ACCESS SYSTEM TABLE` permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
datashare_name	text	The name of the datashare.
privilege_type	text	The type of the permission. Possible values are ALTER or SHARE.
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.

Column name	Data type	Description
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group, or public.
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.

Sample query

The following example displays the result of the SVV_DATASHARE_PRIVILEGES.

```
SELECT datashare_name, privilege_type, identity_name, identity_type, admin_option FROM
svv_datashare_privileges
WHERE datashare_name = 'demo_share';
```

datashare_name	privilege_type	identity_name	identity_type	admin_option
demo_share	ALTER	superuser	user	False
demo_share	ALTER	reguser	user	False

SVV_DATASHARES

Use SVV_DATASHARES to view a list of datashares created on the cluster, and datashares shared with the cluster.

SVV_DATASHARES is visible to the following users:

- Superusers
- Datashare owners
- Users with ALTER or USAGE permissions on a datashare

Other users can't see any rows. For information on the ALTER and USAGE permissions, see [GRANT](#).

Table columns

Column name	Data type	Description
share_name	varchar(128)	The name of a datashare.
share_id	integer	The ID of the datashare.
share_owner	integer	The owner of the datashare.
source_database	varchar(128)	The source database for this datashare.
consumer_database	varchar(128)	The consumer database that is created from this datashare.
share_type	varchar(8)	The type of the datashare. Possible values are INBOUND and OUTBOUND.
createdate	timestamp without time zone	The date when datashare was created.
is_publicaccessible	boolean	The property that specifies whether a datashare can be shared to a publicly accessible cluster.
share_acl	varchar(256)	The string that defines the permissions for the specified user or user group for the datashare.
producer_account	varchar(16)	The ID for the datashare producer account.
producer_namespace	varchar(64)	The unique cluster identifier for the datashare producer cluster.

Column name	Data type	Description
managed_by	varchar(64)	The property that specifies the AWS service that manages the datashare.

Usage notes

Retrieving additional metadata – Using the integer returned in the `share_owner` column, you can join with `usesysid` in [SVL_USER_INFO](#) to get data about the datashare owner. This includes the name and additional properties.

Sample query

The following example returns the output for `SVV_DATASHARES`.

```
SELECT share_owner, source_database, share_type, is_publicaccessible
FROM svv_datashares
WHERE share_name LIKE 'tickit_datashare%'
AND source_database = 'dev';
```

```
share_owner | source_database | share_type | is_publicaccessible
-----+-----+-----+-----
      100    |      dev       | OUTBOUND  |          True
(1 rows)
```

The following example returns the output for `SVV_DATASHARES` for outbound datashares.

```
SELECT share_name, share_owner, btrim(source_database), btrim(consumer_database),
share_type, is_publicaccessible, share_acl, btrim(producer_account),
btrim(producer_namespace), btrim(managed_by) FROM svv_datashares WHERE share_type =
'OUTBOUND';
```

```
share_name | share_owner | source_database | consumer_database | share_type |
is_publicaccessible | share_acl | producer_account| producer_namespace
| managed_by
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
```

salesshare	1	dev	OUTBOUND
True		123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d
marketingshare	1	dev	OUTBOUND
True		123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d

The following example returns the output for SVV_DATASHARES for inbound datashares.

```
SELECT share_name, share_owner, btrim(source_database), btrim(consumer_database),
share_type, is_publicaccessible, share_acl, btrim(producer_account),
btrim(producer_namespace), btrim(managed_by) FROM svv_datashares WHERE share_type =
'INBOUND';
```

share_name	share_owner	source_database	consumer_database	share_type	is_publicaccessible	share_acl	producer_account	producer_namespace	managed_by
salesshare		123456789012		INBOUND	False		123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d	
marketingshare		123456789012		INBOUND	False		123456789012	13b8833d-17c6-4f16-8fe4-1a018f5ed00d	

ADX

SVV_DATASHARE_CONSUMERS

Use SVV_DATASHARE_CONSUMERS to view a list of consumers for a datashare created on a cluster.

SVV_DATASHARE_CONSUMERS is visible to the following users:

- Superusers
- Datashare owners
- Users with ALTER or USAGE permissions on a datashare

Other users can't see any rows. For information on the ALTER and USAGE permissions, see [GRANT](#).

Table columns

Column name	Data type	Description
share_name	varchar(128)	The name of the datashare.
consumer_account	varchar(16)	The account ID for the datashare consumer.
consumer_namespace	varchar(64)	The unique cluster identifier of the datashare consumer cluster.
share_date	timestamp without time zone	The date that the datashare was shared.

Sample query

The following example returns the output for `SVV_DATASHARE_CONSUMERS`.

```
SELECT count(*)
FROM svv_datashare_consumers
WHERE share_name LIKE 'tickit_datashare%';
```

```
1
```

SVV_DATASHARE_OBJECTS

Use `SVV_DATASHARE_OBJECTS` to view a list of objects in all datashares created on the cluster or shared with the cluster.

`SVV_DATASHARE_OBJECTS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

For information about viewing a list of datashares, see [SVV_DATASHARES](#).

Table columns

Column name	Data type	Description
share_type	varchar(8)	The type of the specified datashare. Possible values are OUTBOUND and INBOUND.
share_name	varchar(128)	The name of the datashare.
object_type	varchar(64)	The type of a specified object. Possible values are schemas, tables, views, late binding views, materialized views, and functions.
object_name	varchar(512)	The name of the object. The object name extends to include the schema name, such as schema1.t1.
producer_account	varchar(16)	The ID for the datashare producer account.
producer_namespace	varchar(64)	The unique cluster identifier for the datashare producer cluster.
include_new	boolean	The property that specifies whether to add any future tables, views, or SQL user-defined functions (UDFs) created in the specified schema to the datashare. This parameter is only relevant for OUTBOUND datashares and only for schema types in the datashare.

Sample query

The following examples return the output for SVV_DATASHARE_OBJECTS.

```
SELECT share_type,
       btrim(share_name)::varchar(16) AS share_name,
       object_type,
       object_name
FROM svv_datashare_objects
WHERE share_name LIKE 'tickit_datashare%'
AND object_name LIKE '%tickit%'

SVV_DEFAULT_PRIVILEGES

Use SVV_DEFAULT_PRIVILEGES to view the default privileges that a user has access to in an Amazon Redshift cluster.

SVV_DEFAULT_PRIVILEGES is visible to the following users:

- Superusers

- Users with the ACCESS SYSTEM TABLE permission

Other users can only see default permissions granted to them.

Table columns

Column name	Data type	Description
schema_name	text	The name of the schema.
object_type	text	The object type. Possible values are RELATION, FUNCTION, or PROCEDURE.
owner_id	integer	The owner ID. Possible value is the user ID.
owner_name	text	The name of the owner.
owner_type	text	The owner type. Possible value is user.
privilege_type	text	The privilege type. Possible values are INSERT, SELECT, UPDATE, DELETE, RULE, REFERENCES TRIGGER, DROP, and EXECUTE.
grantee_id	integer	The grantee ID. Possible values are user ID, role ID, and group ID.
grantee_type	text	The grantee type. Possible values are user, role, and public.
admin_option	boolean	The value that indicates whether the user can grant permissions to other users and roles. It is always false for role and group type.

Sample query

The following example returns the output for SVV_DEFAULT_PRIVILEGES.

```
SELECT * from svv_default_privileges;
```

```

schema_name | object_type | owner_id | owner_name | owner_type | privilege_type
| grantee_id | grantee_name | grantee_type | admin_option
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
public | RELATION | 106 | u1 | user | UPDATE
| 107 | u2 | user | f | |
public | RELATION | 106 | u1 | user | SELECT
| 107 | u2 | user | f | |

```

SVV_DISKUSAGE

Amazon Redshift creates the SVV_DISKUSAGE system view by joining the STV_TBL_PERM and STV_BLOCKLIST tables. The SVV_DISKUSAGE view contains information about data allocation for the tables in a database.

Use aggregate queries with SVV_DISKUSAGE, as the following examples show, to determine the number of disk blocks allocated per database, table, slice, or column. Each data block uses 1 MB. You can also use [STV_PARTITIONS](#) to view summary information about disk utilization.

SVV_DISKUSAGE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Note

This view is only available when querying provisioned clusters.

Table columns

Column name	Data type	Description
db_id	integer	Database ID.
name	character (72)	Table name.
slice	integer	Data slice allocated to the table.

Column name	Data type	Description
col	integer	Zero-based index for the column. Every table you create has three hidden columns appended to it: INSERT_XID, DELETE_XID, and ROW_ID (OID). A table with 3 user-defined columns contains 6 actual columns, and the user-defined columns are internally numbered as 0, 1, and 2. The INSERT_XID, DELETE_XID, and ROW_ID columns are numbered 3, 4, and 5, respectively, in this example.
tbl	integer	Table ID.
blocknum	integer	ID for the data block.
num_values	integer	Number of values contained on the block.
minvalue	bigint	Minimum value contained on the block.
maxvalue	bigint	Maximum value contained on the block.
sb_pos	integer	Internal identifier for the position of the super block on disk.
pinned	integer	Whether or not the block is pinned into memory as part of pre-load. 0 = false; 1 = true. Default is false.
on_disk	integer	Whether or not the block is automatically stored on disk. 0 = false; 1 = true. Default is false.
modified	integer	Whether or not the block has been modified. 0 = false; 1 = true. Default is false.
hdr_modified	integer	Whether or not the block header has been modified. 0 = false; 1 = true. Default is false.
unsorted	integer	Whether or not a block is unsorted. 0 = false; 1 = true. Default is true.
tombstone	integer	For internal use.
preferred_diskno	integer	Disk number that the block should be on, unless the disk has failed. Once the disk has been fixed, the block will move back to this disk.

Column name	Data type	Description
temporary	integer	Whether or not the block contains temporary data, such as from a temporary table or intermediate query results. 0 = false; 1 = true. Default is false.
newblock	integer	Indicates whether or not a block is new (true) or was never committed to disk (false). 0 = false; 1 = true.

Sample queries

SVV_DISKUSAGE contains one row per allocated disk block, so a query that selects all the rows potentially returns a very large number of rows. We recommend using only aggregate queries with SVV_DISKUSAGE.

Return the highest number of blocks ever allocated to column 6 in the USERS table (the EMAIL column):

```
select db_id, trim(name) as tablename, max(blocknum)
from svv_diskusage
where name='users' and col=6
group by db_id, name;
```

```
db_id | tablename | max
-----+-----+-----
175857 | users      | 2
(1 row)
```

The following query returns similar results for all of the columns in a large 10-column table called SALESNEW. (The last three rows, for columns 10 through 12, are for the hidden metadata columns.)

```
select db_id, trim(name) as tablename, col, tbl, max(blocknum)
from svv_diskusage
where name='salesnew'
group by db_id, name, col, tbl
order by db_id, name, col, tbl;
```

```
db_id | tablename | col | tbl | max
```

```

-----+-----+-----+-----+-----
175857 | salesnew | 0 | 187605 | 154
175857 | salesnew | 1 | 187605 | 154
175857 | salesnew | 2 | 187605 | 154
175857 | salesnew | 3 | 187605 | 154
175857 | salesnew | 4 | 187605 | 154
175857 | salesnew | 5 | 187605 | 79
175857 | salesnew | 6 | 187605 | 79
175857 | salesnew | 7 | 187605 | 302
175857 | salesnew | 8 | 187605 | 302
175857 | salesnew | 9 | 187605 | 302
175857 | salesnew | 10 | 187605 | 3
175857 | salesnew | 11 | 187605 | 2
175857 | salesnew | 12 | 187605 | 296
(13 rows)

```

SVV_EXTERNAL_COLUMNS

Use `SVV_EXTERNAL_COLUMNS` to view details for columns in external tables. Use `SVV_EXTERNAL_COLUMNS` also for cross-database queries to view details on all columns from the table on unconnected databases that users have access to.

`SVV_EXTERNAL_COLUMNS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>redshift_database_name</code>	text	The name of the local Amazon Redshift database.
<code>schemaname</code>	text	The name of the Amazon Redshift external schema for the external table.
<code>tablename</code>	text	The name of the external table.
<code>columnname</code>	text	The name of the column.

Column name	Data type	Description
external_type	text	The data type of the column.
columnnum	integer	The external column number, starting from 1.
part_key	integer	If the column is a partition key, the order of the key. If the column isn't a partition, the value is 0 .
is_nullable	text	Defines whether a column is nullable or not. Some values are <code>true</code> , <code>false</code> , or " " empty string that represents no information.

SVV_EXTERNAL_DATABASES

Use `SVV_EXTERNAL_DATABASES` to view details for external databases.

`SVV_EXTERNAL_DATABASES` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
eskind	integer	The type of the external catalog for the database; 1 indicates a data catalog, 2 indicates a Hive metastore.
esoptions	text	Details of the catalog where the database resides.

Column name	Data type	Description
databasename	text	The name of the database in the external catalog.
location	text	The location of the database.
parameters	text	Database parameters.

SVV_EXTERNAL_PARTITIONS

Use SVV_EXTERNAL_PARTITIONS to view details for partitions in external tables.

SVV_EXTERNAL_PARTITIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views..](#)

Table columns

Column name	Data type	Description
schemaname	text	The name of the Amazon Redshift external schema for the external table with the specified partitions.
tablename	text	The name of the external table.
values	text	Values for the partition.
location	text	The location of the partition. The column size is limited to 128 characters. Longer values are truncated.
input_format	text	The input format.
output_format	text	The output format.
serialization_lib	text	The serialization library.
serde_parameters	text	SerDe parameters.

Column name	Data type	Description
compressed	integer	A value that indicates whether the partition is compressed; 1 indicates compressed, 0 indicates not compressed.
parameters	text	Partition properties.

SVV_EXTERNAL_SCHEMAS

Use SVV_EXTERNAL_SCHEMAS to view information about external schemas. For more information, see [CREATE EXTERNAL SCHEMA](#).

SVV_EXTERNAL_SCHEMAS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
esoid	oid	External schema ID.
eskind	smallint	The type of the external catalog for the external schema: 1 indicates a data catalog, 2 indicates a Hive metastore, 3 indicates a federated query to Aurora PostgreSQL or Amazon RDS PostgreSQL, 4 indicates a schema for a local Amazon Redshift database, 5 indicates a schema for a remote Amazon Redshift database, 6 indicates a schema for a system table, 8 indicates a schema for remote MySQL databases, 9 indicates a schema for an Amazon Kinesis data stream, and 10 indicates an Amazon Managed Streaming for Apache Kafka data stream.
schemaname	name	External schema name.
esowner	integer	User ID of the external schema owner.

Column name	Data type	Description
database_name	text	External database name.
esoptions	text	External schema options.

Example

The following example shows details for external schemas.

```
select * from svv_external_schemas;

esoid | eskind | schemaname | esowner | database_name | esoptions
-----+-----+-----+-----+-----+-----
100133 |      1 | spectrum   |      100 | redshift      |
{"IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
```

SVV_EXTERNAL_TABLES

Use `SVV_EXTERNAL_TABLES` to view details for external tables; for more information, see [CREATE EXTERNAL SCHEMA](#). Use `SVV_EXTERNAL_TABLES` also for cross-database queries to view metadata on all tables on unconnected databases that users have access to.

`SVV_EXTERNAL_TABLES` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
redshift_database_name	text	The name of the local Amazon Redshift database.

Column name	Data type	Description
schemaname	text	The name of the Amazon Redshift external schema for the external table.
tablename	text	The name of the external table.
tabletype	text	The type of table. Some values are TABLE, VIEW, MATERIALIZED VIEW, or " " empty string that represents no information.
location	text	The location of the table.
input_format	text	The input format
output_format	text	The output format.
serialization_lib	text	The serialization library.
serde_parameters	text	SerDe parameters.
compressed	integer	A value that indicates whether the table is compressed; 1 indicates compressed, 0 indicates not compressed.
parameters	text	Table properties.

Example

The following example shows details `svv_external_tables` with a predicate on the external schema used by a federated query.

```
select schemaname, tablename from svv_external_tables where schemaname = 'apg_tpch';
```

```

schemaname | tablename
-----+-----
apg_tpch   | customer
apg_tpch   | lineitem
apg_tpch   | nation
apg_tpch   | orders
apg_tpch   | part
apg_tpch   | partsupp
apg_tpch   | region
apg_tpch   | supplier
(8 rows)

```

SVV_FUNCTION_PRIVILEGES

Use `SVV_FUNCTION_PRIVILEGES` to view the function permissions that are explicitly granted to users, roles, and groups in the current database.

`SVV_FUNCTION_PRIVILEGES` is visible to the following users:

- Superusers
- Users with the `ACCESS SYSTEM TABLE` permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
<code>namespace_name</code>	text	The name of the namespace where a specified function exists.
<code>function_name</code>	text	The name of the function.
<code>argument_types</code>	text	The string that represents the type of input argument for a function.
<code>privilege_type</code>	text	The type of the permission. Possible value is <code>EXECUTE</code> .

Column name	Data type	Description
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group, or public.
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.

Sample query

The following example displays the result of the SVV_FUNCTION_PRIVILEGES.

```
SELECT
  namespace_name, function_name, argument_types, privilege_type, identity_name, identity_type, admin_option
FROM svv_function_privileges
WHERE identity_name IN ('role1', 'reguser');
```

```
namespace_name | function_name | argument_types | privilege_type |
identity_name | identity_type | admin_option
-----+-----+-----+-----+
public | test_func1 | integer | EXECUTE |
role1 | role | False
public | test_func2 | integer, character varying | EXECUTE |
reguser | user | False
```

SVV_GEOGRAPHY_COLUMNS

Use SVV_GEOGRAPHY_COLUMNS to view the list of GEOGRAPHY columns in your data warehouse. This list of columns includes columns from datashares.

SVV_GEOGRAPHY_COLUMNS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
f_table_catalog	varchar(128)	The name of the database where the table with the GEOGRAPHY column exists.
f_table_schema	varchar(128)	The name of the schema where the table with the GEOGRAPHY column exists.
f_table_name	varchar(128)	The name of the table where the GEOGRAPHY column exists.
f_geography_column	varchar(128)	The name of the GEOGRAPHY column.
coord_dimension	integer	The number of dimensions of the GEOGRAPHY data.
srid	integer	The spatial reference system identifier (SRID) of the GEOGRAPHY data.
type	varchar(128)	The spatial geography data type name.

Sample query

The following example displays the result of the SVV_GEOGRAPHY_COLUMNS.

```
SELECT * FROM svv_geography_columns;
```

```
f_table_catalog | f_table_schema | f_table_name | f_geography_column |
coord_dimension | srid | type
-----+-----+-----+-----
+-----+-----+-----
```

```
dev          | public          | spatial_test | test_geography | 2
| 0         | GEOGRAPHY
```

SVV_GEOMETRY_COLUMNS

Use `SVV_GEOMETRY_COLUMNS` to view the list of `GEOMETRY` columns in your data warehouse. This list of columns includes columns from datashares.

`SVV_GEOMETRY_COLUMNS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>f_table_catalog</code>	<code>varchar(128)</code>	The name of the database where the table with the <code>GEOMETRY</code> column exists.
<code>f_table_schema</code>	<code>varchar(128)</code>	The name of the schema where the table with the <code>GEOMETRY</code> column exists.
<code>f_table_name</code>	<code>varchar(128)</code>	The name of the table where the <code>GEOMETRY</code> column exists.
<code>f_geometry_column</code>	<code>varchar(128)</code>	The name of the <code>GEOMETRY</code> column.
<code>coord_dimension</code>	<code>integer</code>	The number of dimensions of the <code>GEOMETRY</code> data.
<code>srid</code>	<code>integer</code>	The spatial reference system identifier (SRID) of the <code>GEOMETRY</code> column.
<code>type</code>	<code>varchar(128)</code>	The spatial geometry type name.

Sample query

The following example displays the result of the SVV_GEOMETRY_COLUMNS.

```
SELECT * FROM svv_geometry_columns;

f_table_catalog | f_table_schema | f_table_name | f_geometry_column |
coord_dimension | srid | type
-----+-----+-----+-----
+-----+-----+-----+-----
dev            | public        | accomodations | shape              | 2
| 0           | GEOMETRY
dev            | public        | zipcode        | wkb_geometry       | 2
| 0           | GEOMETRY
```

SVV_IAM_PRIVILEGES

Use SVV_IAM_PRIVILEGES to view explicitly granted IAM privileges on users, roles and groups.

SVV_IAM_PRIVILEGES is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see entries they have access to.

Table columns

Column name	Data type	Description
iam_arn	text	Name of the namespace.
command_type	text	Privilege types. Possible values are COPY, UNLOAD, CREATE MODEL, or EXTERNAL FUNCTION.
identity_id	integer	Identity ID. Possible values are user ID, role ID, or group ID.

Column name	Data type	Description
identity_name	text	Identity name.
identity_type	text	Identity type. Possible values are user, role, group, or public.

Sample queries

The following example shows the results of SVV_IAM_PRIVILEGES.

```
SELECT * from SVV_IAM_PRIVILEGES ORDER BY IDENTITY_ID;
 iam_arn          | command_type | identity_id | identity_name | identity_type
-----+-----+-----+-----+-----
 default-aws-iam-role | COPY        |           0 | public        | public
 default-aws-iam-role | UNLOAD      |           0 | public        | public
 default-aws-iam-role | CREATE MODEL |           0 | public        | public
 default-aws-iam-role | EXFUNC      |           0 | public        | public
 default-aws-iam-role | COPY        |          106 | u1            | user
 default-aws-iam-role | UNLOAD      |          106 | u1            | user
 default-aws-iam-role | CREATE MODEL |          106 | u1            | user
 default-aws-iam-role | EXFUNC      |          106 | u1            | user
 default-aws-iam-role | COPY        |        118413 | r1            | role
 default-aws-iam-role | UNLOAD      |        118413 | r1            | role
 default-aws-iam-role | CREATE MODEL |        118413 | r1            | role
 default-aws-iam-role | EXFUNC      |        118413 | r1            | role
(12 rows)
```

SVV_IDENTITY_PROVIDERS

The SVV_IDENTITY_PROVIDERS view returns the name and additional properties for identity providers. For more information about how to create an identity provider, see [CREATE IDENTITY PROVIDER](#).

SVV_IDENTITY_PROVIDERS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

```

SVV_INTEGRATION

SVV_INTEGRATION displays details about the configuration of integrations.

SVV_INTEGRATION is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

For information about zero-ETL integrations, see [Working with zero-ETL integrations](#).

Table columns

Column name	Data type	Description
integration_id	character (128)	The identifier associated with the integration.
target_database	character (128)	The database in Amazon Redshift that receives the integration data.
source	character (128)	The source data for the integration. Possible types include MySQL and PostgreSQL .
state	character (128)	The state of the integration. Possible values include PendingDbConnectState , SchemaDiscoveryState , CdcRefreshState , and ErrorState .
current_lag	bigint	The current lag time (milliseconds) between the source and destination of the integration.

Column name	Data type	Description
last_replicated_checkpoint	character (128)	The last replicated checkpoint.
total_tables_replicated	integer	The number of total tables currently in the replicated state.
total_tables_failed	integer	The number of total tables currently in the failed state.
creation_time	timestamp	The time (UTC) when the integration is created. It is defined as the time when the target database is created from the integration.

Sample queries

The following SQL command displays the currently defined integrations.

```
select * from svv_integration;
```

```

      integration_id          | target_database | source |      state
    | current_lag |      last_replicated_checkpoint      | total_tables_replicated |
total_tables_failed |      creation_time
-----+-----+-----+-----

0      | 2023-09-19 21:05:27.520299

```

SVV_INTEGRATION_TABLE_STATE

SVV_INTEGRATION_TABLE_STATE displays details about table-level integration information.

SVV_INTEGRATION_TABLE_STATE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

For more information, see [Working with zero-ETL integrations](#).

Table columns

Column name	Data type	Description
integration_id	character(128)	The identifier associated with the integration.
target_database	character(128)	The name of the Amazon Redshift database.
schema_name	character(128)	The name of the Amazon Redshift schema.
table_name	character(128)	The name of the table.
table_state	character(128)	The state of the table. Possible values are Synced, Failed, Deleted, ResyncRequired, and ResyncInitiated.
table_last_replicated_checkpoint	character(128)	The current synced log coordinates.
reason	character(256)	The reason for the last state transition. Common reasons can be unsupported data types in tables, tables don't have primary keys. To learn more about how to troubleshoot common issues, see Troubleshooting zero-ETL integrations in Amazon Redshift .
last_updated_timestamp	timestamp without time zone	The time (UTC) when the table is last updated.

Sample queries

The following SQL command displays the log of integrations.

```
select * from svv_integration_table_state;

      integration_id      | target_database | schema_name |      table_name
| Table_state | table_last_replicated_checkpoint | reason | last_updated_timestamp
```

```

SVV_INTERLEAVED_COLUMNS

Use the SVV_INTERLEAVED_COLUMNS view to help determine whether a table that uses interleaved sort keys should be reindexed using [VACUUM REINDEX](#). For more information about how to determine how often to run VACUUM and when to run a VACUUM REINDEX, see [Minimizing vacuum times](#).

SVV_INTERLEAVED_COLUMNS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
tbl	integer	Table ID.
col	integer	Zero-based index for the column.
interleaved_skew	numeric(9,2)	Ratio that indicates of the amount of skew present in the interleaved sort key columns for a table. A value of 1.00 indicates no skew, and larger values indicate more skew. Tables with a large skew should be reindexed with the VACUUM REINDEX command.
last_reindex	timestamp	Time when the last VACUUM REINDEX was run for the specified table. This value is NULL if a table has never been reindexed or if the underlying system log table, STL_VACUUM, has been rotated since the last reindex.

Sample queries

To identify tables that might need to be reindexed, run the following query.

```
select tbl as tbl_id, stv_tbl_perm.name as table_name,
col, interleaved_skew, last_reindex
from svv_interleaved_columns, stv_tbl_perm
where svv_interleaved_columns.tbl = stv_tbl_perm.id
and interleaved_skew is not null;
```

```
tbl_id | table_name | col | interleaved_skew | last_reindex
-----+-----+-----+-----+-----

SVV_LANGUAGE_PRIVILEGES

Use SVV_LANGUAGE_PRIVILEGES to view the language permissions that are explicitly granted to users, roles, and groups in the current database.

SVV_LANGUAGE_PRIVILEGES is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
language_name	text	The name of the language.
privilege_type	text	The type of the permission. Possible value is USAGE.
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.

Column name	Data type	Description
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group, or public.
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.

Sample query

The following example displays the result of the SVV_LANGUAGE_PRIVILEGES.

```
SELECT language_name,privilege_type,identity_name,identity_type,admin_option FROM
svv_language_privileges
WHERE identity_name IN ('role1', 'reguser');
```

language_name	privilege_type	identity_name	identity_type	admin_option
exfunc	USAGE	reguser	user	False
exfunc	USAGE	role1	role	False
plpythonu	USAGE	reguser	user	False

SVV_MASKING_POLICY

Use SVV_MASKING_POLICY to view all masking policies created on the cluster.

Only superusers and users with the [sys:secadmin](#) role can view SVV_MASKING_POLICY. Regular users will see 0 rows.

Table columns

Column name	Data type	Description
policy_database	text	The name of the database in which the masking policy was created.
policy_name	text	The name of the masking policy.
input_columns	text	The attributes provided in the WITH clause of CREATE POLICY statement.
policy_expression	text	The masking expression used in the policy.
policy_modified_by	text	The name of the user who last modified the policy.
policy_modified_time	timestamp	The timestamp of when the policy was created or last modified.

SVV_ML_MODEL_INFO

State information about the current state of the machine learning model.

SVV_ML_MODEL_INFO is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	char(128)	The database of the model.

Column name	Data type	Description
schema_name	char(128)	The schema of the model.
user_name	char(128)	The owner of the model.
model_name	char(128)	The name of the model.
life_cycle	char(20)	The lifecycle status of the model.
is_refreshable	integer	The state of the model whether it is refreshable if original tables and columns in the training query still exist and the user still has the permissions to them. Possible values are: 1 (refreshable) and 0 (not refreshable).
model_state	char(128)	The current state of the model.

Sample query

The following query displays the current state of machine learning models.

```
SELECT schema_name, model_name, model_state
FROM svv_ml_model_info;
```

```

schema_name |          model_name          |          model_state
-----+-----+-----
public      | customer_churn_auto_model    | Train Model On SageMaker In Progress
public      | customer_churn_xgboost_model | Model is Ready
(2 row)
```

SVV_ML_MODEL_PRIVILEGES

Use SVV_ML_MODEL_PRIVILEGES to view the machine learning model permissions that are explicitly granted to users, roles, and groups in the cluster.

SVV_ML_MODEL_PRIVILEGES is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
namespace_name	text	The name of the namespace where a specified machine learning model exists.
model_name	text	The name of the machine learning model.
model_version	integer	The version number of the model.
privilege_type	text	The type of the permission. Possible value is EXECUTE.
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group, or public.
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.

Sample query

The following example displays the result of the `SVV_ML_MODEL_PRIVILEGES`.

```

SELECT
  namespace_name,model_name,model_version,privilege_type,identity_name,identity_type,admin_option
FROM svv_ml_model_privileges
WHERE model_name = 'test_model';

```

```

namespace_name | model_name | model_version | privilege_type | identity_name |
identity_type | admin_option
-----+-----+-----+-----+-----
+-----+-----+
      public   | test_model |          1    | EXECUTE       | reguser      |
user          | False
      public   | test_model |          1    | EXECUTE       | role1        |
role          | False

```

SVV_MV_DEPENDENCY

The SVV_MV_DEPENDENCY table shows the dependencies of materialized views on other materialized views within Amazon Redshift.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

SVV_MV_DEPENDENCY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	char(128)	The database that contains the specified materialized view.
schema_name	char(128)	The schema of the materialized view.
name	char(128)	The name of the materialized view.
dependent_database_name	char(128)	The materialized view database on which this materialized view depends.
dependent_schema_name	char(128)	The materialized view schema on which this materialized view depends.

Column name	Data type	Description
dependent_name	char(128)	The name of the materialized view on which this materialized view depends.

Sample query

The following query returns an output row that indicates that the materialized view `mv_over_foo` uses the materialized view `mv_foo` in its definition as a dependency.

```
CREATE SCHEMA test_ivm_setup;
CREATE TABLE test_ivm_setup.foo(a INT);
CREATE MATERIALIZED VIEW test_ivm_setup.mv_foo AS SELECT * FROM test_ivm_setup.foo;
CREATE MATERIALIZED VIEW test_ivm_setup.mv_over_foo AS SELECT * FROM
  test_ivm_setup.mv_foo;

SELECT * FROM svv_mv_dependency;
```

```
database_name | schema_name          | name          | dependent_database_name |
dependent_schema_name | dependent_name
-----+-----+-----+-----
+-----+-----
dev           | test_ivm_setup      | mv_over_foo | dev |
test_ivm_setup | mv_foo
```

SVV_MV_INFO

The `SVV_MV_INFO` table contains a row for every materialized view, whether the data is stale, and state information.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

`SVV_MV_INFO` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	char(128)	The database that contains the materialized view.
schema_name	char(128)	The schema of the database.
user_name	char(128)	The user who owns the materialized view.
name	char(128)	The materialized view name.
is_stale	char(1)	A t indicates that the materialized view is stale. A <i>stale</i> materialized view is one where the base tables have been updated but the materialized view hasn't been refreshed. This information might not be accurate if a refresh hasn't been run since the last restart.
state	integer	The state of the materialized view as follows: <ul style="list-style-type: none"> • 0 – The materialized view is fully recomputed when refreshed. • 1 – The materialized view is incremental. • 101 – The materialized view can't be refreshed due to a dropped column. This constraint applies even if the column isn't used in the materialized view. • 102 – The materialized view can't be refreshed due to a changed column type. This constraint applies even if the column isn't used in the materialized view. • 103 – The materialized view can't be refreshed due to a renamed table. • 104 – The materialized view can't be refreshed due to a renamed column. This constraint

Column name	Data type	Description
		<p>applies even if the column isn't used in the materialized view.</p> <ul style="list-style-type: none"> 105 – The materialized view can't be refreshed due to a renamed schema.
autorewrite	char(1)	A t indicates that the materialized view is eligible for automatic rewriting of queries.
autorefresh	char(1)	A t indicates that the materialized view can be automatically refreshed.

Sample query

To view the state of all materialized views, run the following query.

```
select * from svv_mv_info;
```

This query returns the following sample output.

```

database_name |      schema_name      | user_name | name | is_stale | state |
autorefresh  | autorewrite
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
dev          | test_ivm_setup        | catch-22 | mv   | f        | 1    |
      1 |          0
dev          | test_ivm_setup        | lotr     | old_mv | t        | 1    |
      0 |          1

```

SVV_QUERY_INFLIGHT

Use the SVV_QUERY_INFLIGHT view to determine what queries are currently running on the database. This view joins [STV_INFLIGHT](#) to [STL_QUERYTEXT](#). SVV_QUERY_INFLIGHT does not show leader-node only queries. For more information, see [Leader node-only functions](#).

SVV_QUERY_INFLIGHT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

 **Note**

This view is only available when querying provisioned clusters.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
slice	integer	Slice where the query is running.
query	integer	Query ID. Can be used to join various other system tables and views.
pid	integer	Process ID. All of the queries in a session are run in the same process, so this value remains constant if you run a series of queries in the same session. You can use this column to join to the STL_ERROR table.
starttime	timestamp	Time that the query started.
suspended	integer	Whether the query is suspended: 0 = false; 1 = true.
text	character(200)	Query text, in 200-character increments.
sequence	integer	Sequence number for segments of query statements.

Sample queries

The sample output below shows two queries currently running, the SVV_QUERY_INFLIGHT query itself and query 428, which is split into three rows in the table. (The starttime and statement columns are truncated in this sample output.)

```
select slice, query, pid, starttime, suspended, trim(text) as statement, sequence
from svv_query_inflight
order by query, sequence;
```

```
slice|query| pid |      starttime      |suspended| statement | sequence
-----+-----+-----+-----+-----+-----+-----
1012 | 428 | 1658 | 2012-04-10 13:53:... |      0 | select ... |      0
1012 | 428 | 1658 | 2012-04-10 13:53:... |      0 | enueid ... |      1
1012 | 428 | 1658 | 2012-04-10 13:53:... |      0 | atname,... |      2
1012 | 429 | 1608 | 2012-04-10 13:53:... |      0 | select ... |      0
(4 rows)
```

SVV_QUERY_STATE

Use SVV_QUERY_STATE to view information about the runtime of currently running queries.

The SVV_QUERY_STATE view contains a data subset of the STV_EXEC_STATE table.

SVV_QUERY_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Note

This view is only available when querying provisioned clusters.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
query	integer	Query ID. Can be used to join various other system tables and views.

Column name	Data type	Description
seg	integer	Number of the query segment that is running. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process.
step	integer	Number of the query step that is running. A step is the smallest unit of query runtime. Each step represents a discrete unit of work, such as scanning a table, returning results, or sorting data.
maxtime	interval	Maximum amount of time (in microseconds) for this step to run.
avgtime	interval	Average time (in microseconds) for this step to run.
rows	bigint	Number of rows produced by the step that is running.
bytes	bigint	Number of bytes produced by the step that is running.
cpu	bigint	For internal use.
memory	bigint	For internal use.
rate_row	double precision	Rows-per-second rate since the query started, computed by summing the rows and dividing by the number of seconds from when the query started to the current time.
rate_byte	double precision	Bytes-per-second rate since the query started, computed by summing the bytes and dividing by the number of seconds from when the query started to the current time.
label	character(25)	Query label: a name for the step, such as scan or sort.
is_diskbased	character(1)	Whether this step of the query is running as a disk-based operation: true (t) or false (f). Only certain steps, such as hash, sort, and aggregate steps, can go to disk. Many types of steps are always performed in memory.
workmem	bigint	Amount of working memory (in bytes) assigned to the query step.

Column name	Data type	Description
num_part	integer	Number of partitions a hash table is divided into during a hash step. A positive number in this column does not imply that the hash step runs as a disk-based operation. Check the value in the IS_DISKBASED column to see if the hash step was disk-based.
is_rrscan	character(1)	If true (t), indicates that range-restricted scan was used on the step. Default is false (f).
is_delayed_scan	character(1)	If true (t), indicates that delayed scan was used on the step. Default is false (f).

Sample queries

Determining the processing time of a query by step

The following query shows how long each step of the query with query ID 279 took to run and how many data rows Amazon Redshift processed:

```
select query, seg, step, maxtime, avgtime, rows, label
from svv_query_state
where query = 279
order by query, seg, step;
```

This query retrieves the processing information about query 279, as shown in the following sample output:

```
query | seg | step | maxtime | avgtime | rows | label
-----+-----+-----+-----+-----+-----+-----
 279 | 3 | 0 | 1658054 | 1645711 | 1405360 | scan
 279 | 3 | 1 | 1658072 | 1645809 | 0 | project
 279 | 3 | 2 | 1658074 | 1645812 | 1405434 | insert
 279 | 3 | 3 | 1658080 | 1645816 | 1405437 | distribute
 279 | 4 | 0 | 1677443 | 1666189 | 1268431 | scan
 279 | 4 | 1 | 1677446 | 1666192 | 1268434 | insert
 279 | 4 | 2 | 1677451 | 1666195 | 0 | aggr
(7 rows)
```

Determining if any active queries are currently running on disk

The following query shows if any active queries are currently running on disk:

```
select query, label, is_diskbased from svv_query_state
where is_diskbased = 't';
```

This sample output shows any active queries currently running on disk:

```
query | label          | is_diskbased
-----+-----+-----
1025  | hash tbl=142  |          t
(1 row)
```

SVV_REDSHIFT_COLUMNS

Use SVV_REDSHIFT_COLUMNS to view a list of all columns that a user has access to. This set of columns includes the columns on the cluster and the columns from datashares provided by remote clusters.

SVV_REDSHIFT_COLUMNS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database where the table containing the columns exists.
schema_name	varchar(128)	The name of the schema for the table.
table_name	varchar(128)	The name of the table.
column_name	varchar(128)	The name of a column.
ordinal_position	integer	The position of the column in the table.

Column name	Data type	Description
data_type	varchar(32)	The data type of the column.
column_default	varchar(4000)	The default value of the column.
is_nullable	varchar(3)	A value that defines whether a column is nullable. Possible values are yes, no, and " " (an empty string that represents no information).
encoding	varchar(128)	The encoding type of the column.
distkey	boolean	A value that is true if this column is the distribution key for the table, and false otherwise.

Column name	Data type	Description
sortkey	integer	<p>A value that specifies the order of the column in the sort key.</p> <p>If the table uses a compound sort key, then all columns that are part of the sort key have a positive value that indicates the position of the column in the sort key.</p> <p>If the table uses an interleaved sort key, then each column that is part of the sort key has a value that is alternately positive or negative. Here, the absolute value indicates the position of the column in the sort key.</p> <p>If <code>sortkey</code> is 0, the column isn't part of a sort key.</p>
column_acl	varchar(128)	A string that defines the permissions for the specified user or user group for the column.
remarks	varchar(256)	Remarks.

Sample query

The following example returns the output of `SVV_REDSHIFT_COLUMNS`.

```
SELECT *  
FROM svv_redshift_columns
```

```

WHERE database_name = 'tickit_db'
      AND TABLE_NAME = 'tickit_sales_redshift'
ORDER BY COLUMN_NAME,
      TABLE_NAME,
      database_name
LIMIT 5;

```

```

database_name | schema_name |      table_name      | column_name | ordinal_position |
data_type | column_default | is_nullable | encoding | distkey | sortkey | column_acl
| remarks
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
+-----+-----
   tickit_db |   public   | tickit_sales_redshift |  buyerid   |          4       |
integer |           | NO | az64 | False | 0 |           |
   tickit_db |   public   | tickit_sales_redshift |  commission |          9       |
numeric | (8,2) | YES | az64 | False | 0 |           |
   tickit_db |   public   | tickit_sales_redshift |   dateid   |          6       |
smallint |           | NO | none | False | 1 |           |
   tickit_db |   public   | tickit_sales_redshift |   eventid  |          5       |
integer |           | NO | az64 | False | 0 |           |

integer |           | NO | az64 | True  | 0 |           |

```

SVV_REDSHIFT_DATABASES

Use `SVV_REDSHIFT_DATABASES` to view a list of all the databases that a user has access to. This includes the databases on the cluster and the databases created from datashares provided by remote clusters.

`SVV_REDSHIFT_DATABASES` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>database_name</code>	<code>varchar(128)</code>	The name of the database.
<code>database_owner</code>	<code>integer</code>	The database owner user ID.

SVV_REDSHIFT_FUNCTIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database where the cluster that has these functions exists.
schema_name	varchar(128)	The name of the schema that specifies a given function.
function_name	varchar(128)	The name of a specified function.
function_type	varchar(128)	The type of function. Possible values are regular functions , aggregate functions, and stored procedures.
argument_type	varchar(512)	A string that represents the type of a function's input argument.
result_type	varchar(128)	The data type of a function's return value.

Sample query

The following example returns the output of SVV_REDSHIFT_FUNCTIONS.

```
SELECT *
FROM svv_redshift_functions
WHERE database_name = 'tickit_db'
      AND SCHEMA_NAME = 'public'
ORDER BY function_name
LIMIT 5;
```

```

database_name | schema_name |      function_name      | function_type |
argument_type | result_type
-----+-----+-----+-----
+-----+-----
    tickit_db |   public   |  shared_function  | REGULAR FUNCTION | integer,
integer |   integer

```

SVV_REDSHIFT_SCHEMA_QUOTA

Displays the quota and the current disk usage for each schema in a database.

SVV_REDSHIFT_SCHEMA_QUOTA is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

This view is available when querying provisioned clusters or Redshift Serverless workgroups.

Table columns

Column name	Data type	Description
database_name	character(128)	The database that contains the schema.
schema_name	character(128)	The name of the schema.
schema_owner	integer	The internal user ID of the schema owner.
quota	integer	The amount of disk space (in MB) that the schema can use.
disk_usage	integer	The disk space (in MB) that is currently used by the schema.

Sample query

The following example displays the quota and the current disk usage for the schema named `sales_schema`.

```
SELECT TRIM(SCHEMA_NAME) "schema_name", QUOTA, disk_usage FROM
svv_redshift_schema_quota
WHERE SCHEMA_NAME = 'sales_schema';
```

```
schema_name | quota | disk_usage
-----+-----+-----
sales_schema | 2048 | 30
```

SVV_REDSHIFT_SCHEMAS

Use SVV_REDSHIFT_SCHEMAS to view a list of all schemas that a user has access to. This set of schemas includes the schemas on the cluster and the schemas from datashares provided by remote clusters.

SVV_REDSHIFT_SCHEMAS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database where a specified schema exists.
schema_name	varchar(128)	The namespace or schema name.
schema_owner	integer	The internal user ID of the schema owner.
schema_type	varchar(16)	The type of the schema. Possible values are shared and local schemas.
schema_acl	varchar(128)	The string that defines the permissions for the specified

Column name	Data type	Description
		user or user group for the schema.
schema_option	varchar(128)	The options of the schema.

Sample query

The following example returns the output of SVV_REDSHIFT_SCHEMAS.

```
SELECT *
FROM svv_redshift_schemas
WHERE database_name = 'tickit_db'
ORDER BY database_name,
        SCHEMA_NAME;
```

```
database_name |      schema_name      | schema_owner | schema_type | schema_acl |
-----+-----+-----+-----+-----
+-----+
tickit_db    |      public          |      1      |      shared |            |
```

SVV_REDSHIFT_TABLES

Use SVV_REDSHIFT_TABLES to view a list of all tables that a user has access to. This set of tables includes the tables on the cluster and the tables from datashares provided by remote clusters.

SVV_REDSHIFT_TABLES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database_name	varchar(128)	The name of the database where a specified table exists.
schema_name	varchar(128)	The name the schema for the table.

Column name	Data type	Description
table_name	varchar(128)	The name of the table.
table_type	varchar(128)	The type of table. Possible values are views and tables.
table_acl	varchar(128)	The string that defines the permissions for the specified user or user group for the table.
remarks	varchar(128)	Remarks.
table_owner	varchar(128)	The owner of the table.

Sample query

The following example returns the output of SVV_REDSHIFT_TABLES.

```
SELECT *
FROM svv_redshift_tables
WHERE database_name = 'tickit_db' AND TABLE_NAME LIKE 'tickit_%'
ORDER BY database_name,
TABLE_NAME;
```

```
database_name | schema_name |          table_name          | table_type | table_acl |
remarks | table_owner
-----+-----+-----+-----+-----+
+-----+-----+
  tickit_db | public | tickit_category_redshift | TABLE | |
+

```

If the `table_acl` value is null, no access privileges have been explicitly granted to the corresponding table.

SVV_RELATION_PRIVILEGES

Use `SVV_RELATION_PRIVILEGES` to view the relation (tables and views) permissions that are explicitly granted to users, roles, and groups in the current database.

`SVV_RELATION_PRIVILEGES` is visible to the following users:

- Superusers
- Users with the `SYSLOG ACCESS UNRESTRICTED` permission

Other users can only see identities they have access to or own. For more information about data visibility, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>namespace_name</code>	text	The name of the namespace where a specified relation exists.
<code>relation_name</code>	text	The name of the relation.
<code>privilege_type</code>	text	The type of the permission. Possible values are <code>INSERT</code> , <code>SELECT</code> , <code>UPDATE</code> , <code>DELETE</code> , <code>REFERENCES</code> , or <code>DROP</code> .
<code>identity_id</code>	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.
<code>identity_name</code>	text	The name of the identity.
<code>identity_type</code>	text	The type of the identity. Possible values are <code>user</code> , <code>role</code> , <code>group</code> , or <code>public</code> .

Column name	Data type	Description
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.

Sample query

The following example displays the result of the SVV_RELATION_PRIVILEGES.

```
SELECT
  namespace_name,relation_name,privilege_type,identity_name,identity_type,admin_option
FROM svv_relation_privileges
WHERE relation_name = 'orders' AND privilege_type = 'SELECT';
```

namespace_name	relation_name	privilege_type	identity_name	identity_type	admin_option
public	orders	SELECT	reguser	user	False
public	orders	SELECT	role1	role	False

SVV_RLS_APPLIED_POLICY

Use SVV_RLS_APPLIED_POLICY to trace the application of RLS policies on queries that reference RLS-protected relations.

SVV_RLS_APPLIED_POLICY is visible to the following users:

- Superusers
- Users with the sys:operator role
- Users with the ACCESS SYSTEM TABLE permission

Note that sys:secadmin isn't granted this system permission.

Table columns

Column name	Data type	Description
username	text	The name of the user that ran the query.
query	integer	The ID of the query.
xid	long	The context of the transaction.
pid	integer	The leader process running the query.
recordtime	time	The time when the query was recorded.
command	char(1)	The command for which the RLS policy was applied. Possible values are k for unknown, s for select, u for update, i for insert, y for utility, and d for delete.
datname	text	The name of the database of the relation to which the row-level security policy is attached.
relschema	text	The name of the schema of the relation to which the row-level security policy is attached.
relname	text	The name of the relation to which the row-level security policy is attached.
polname	text	The name of the row-level security policy that is attached to the relation.
poldefault	char(1)	The default setting of the row-level security policy that is attached to the relation. Possible values are f for false if the default false policy has been applied and t for true if the default true policy has been applied.

Sample query

The following example displays the result of the `SVV_RLS_APPLIED_POLICY`. To query the `SVV_RLS_APPLIED_POLICY`, you must have the `ACCESS SYSTEM TABLE` permission.

```
-- Check what RLS policies were applied to the run query.
SELECT username, command, datname, relschema, relname, polname, poldefault
FROM svv_qls_applied_policy
WHERE datname = CURRENT_DATABASE() AND query = PG_LAST_QUERY_ID();

username | command | datname | relschema | relname | polname
| poldefault
-----+-----+-----+-----+-----+-----
+-----+-----
  molly  |   s    | tickit_db | public | tickit_category_redshift |
policy_concerts |
```

SVV_RLS_ATTACHED_POLICY

Use `SVV_RLS_ATTACHED_POLICY` to view a list of all relations and users that have one or more row-level security policies attached on the currently connected database.

Only users with the `sys:secadmin` role can query this view.

Table columns

Column name	Data type	Description
<code>relschema</code>	text	The name of the schema of the relation to which the row-level security policy is attached.
<code>relname</code>	text	The name of the relation to which the row-level security policy is attached.
<code>relkind</code>	text	The type of the object, such as table.
<code>polname</code>	text	The name of the row-level security policy that is attached to the relation.
<code>grantor</code>	text	The name of the user that has attached this policy.

Column name	Data type	Description
grantee	text	The name of the user or role that this policy has been attached to.
granteekind	text	The type of grantee. Possible values are user or role.
is_pol_on	boolean	The parameter that indicates whether a row-level security policy is turned on or off on a table. Possible values are true and false.
is_rols_on	boolean	The parameter that indicates whether a row-level security is turned on or off on a table. Possible values are true and false.
rls_conjunction_type	character (3)	The parameter that indicates whether relation combine RLS policies with and or or.

Sample query

The following example displays the result of the SVV_RLS_ATTACHED_POLICY.

```
--Inspect the policy in SVV_RLS_ATTACHED_POLICY
SELECT * FROM svv_rols_attached_policy;
```

```
relschema |      relname      | relkind |   polname   | grantor | grantee
| granteekind | is_pol_on | is_rols_on | rls_conjunction_type
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
public    | tickit_category_redshift | table | policy_concerts | bob     | analyst
| role     | True     | True     | and
public    | tickit_category_redshift | table | policy_concerts | bob     | dbadmin
| role     | True     | True     | and
```

SVV_RLS_POLICY

Use SVV_RLS_POLICY to view a list of all row-level security policies created on the Amazon Redshift cluster.

SVV_RLS_POLICY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
polddb	text	The name of the database in which the row-level security policy is created.
polname	text	The name of the row-level security policy.
polalias	text	The table alias used in the policy definition.
polatts	text	The attributes provided to the policy definition.
polqual	text	The policy condition provided in the USING clause of the CREATE POLICY statement.
polenabled	boolean	Whether the policy is turned on globally.
polmodifiedby	text	The name of the user that created or modified the policy most recently.
polmodifiedtime	timestamp	The timestamp of when the policy is created or last modified.

Sample query

The following example displays the result of the SVV_RLS_POLICY.

```
-- Create some policies.
CREATE RLS POLICY pol1 WITH (a int) AS t USING ( t.a IS NOT NULL );
CREATE RLS POLICY pol2 WITH (c varchar(10)) AS t USING ( c LIKE '%public%');

-- Inspect the policy in SVV_RLS_POLICY
SELECT * FROM svv_rls_policy;
```

```

 polddb | polname | polalias |                polatts                |
        | polqual |          | polenabled | polmodifiedby | polmodifiedtime
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
```

```

my_db | pol1      | t          | [{"colname":"a","type":"integer"}] |
"t"."a" IS NOT NULL | t          | policy_admin | 2022-02-11
14:40:49
my_db | pol2      | t          | [{"colname":"c","type":"character varying(10)"}] |
"t"."c" LIKE CAST('%public%' AS TEXT) | t          | policy_admin | 2022-02-11
14:41:28

```

SVV_RLS_RELATION

Use SVV_RLS_RELATION to view a list of all relations that are RLS-protected.

SVV_RLS_RELATION is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
datname	text	The name of the database containing the relation.
relschema	text	The name of the schema containing the relation.
relname	text	The name of the relation.
relkind	text	The type of the relation, such as tables or views.
is_ri_on	boolean	The parameter that indicates whether the relation is RLS-protected.
is_ri_data_share_on	boolean	The parameter that indicates whether the relation is RLS-protected over datashares.
ri_conjunction_type	character(3)	The parameter that indicates whether relation combine RLS policies with and or or.
ri_data_share_conjunction_type	character(3)	The parameter that indicates whether relation combine RLS policies with and or or over datashares.

Sample query

The following example displays the result of the SVV_RLS_RELATION.

```
ALTER TABLE tickit_category_redshift ROW LEVEL SECURITY ON FOR DATASHARES;

--Inspect RLS state on the relations using SVV_RLS_RELATION.
SELECT datname, relschema, relname, relkind, is_rols_on, is_rols_datashare_on FROM
svv_rols_relation ORDER BY relname;

 datname | relschema | relname | relkind | is_rols_on |
is_rols_datashare_on | rls_conjunction_type | rls_datashare_conjunction_type
-----+-----+-----+-----+-----+-----
tickit_db | public | tickit_category_redshift | table | t |
| and | | and | | |
(1 row)
```

SVV_ROLE_GRANTS

Use SVV_ROLE_GRANTS to view a list of roles that are explicitly granted roles in the cluster.

SVV_ROLE_GRANTS is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
role_id	integer	The ID of the role.
role_name	text	The name of the role.
granted_role_id	integer	The ID for the granted role.

Column name	Data type	Description
granted_role_name	text	The name for the granted role.

Sample query

The following example returns the output of SVV_ROLE_GRANTS.

```
GRANT ROLE role1 TO ROLE role2;
GRANT ROLE role2 TO ROLE role3;

SELECT role_name, granted_role_name FROM svv_role_grants;
```

```
role_name | granted_role_name
-----+-----
role2    | role1
role3    | role2
(2 rows)
```

SVV_ROLES

Use SVV_ROLES to view role information.

This table is visible to all users.

Table columns

Column name	Data type	Description
role_id	integer	The role ID.
role_name	text	The name of the role.
role_owner	text	The name of the role owner.
external_id	text	The unique identifier of the role in the third-party identity provider.

Sample query

The following example returns the output of SVV_ROLES.

```
SELECT role_name,role_owner FROM svv_roles WHERE role_name IN ('role1', 'role2');
```

```
role_name | role_owner
-----+-----
role1    | superuser
role2    | superuser
```

SVV_SCHEMA_PRIVILEGES

Use SVV_SCHEMA_PRIVILEGES to view the schema permissions that are explicitly granted to users, roles, and groups in the current database.

SVV_SCHEMA_PRIVILEGES is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
namespace_name	text	The name of the namespace where a specified schema exists.
privilege_type	text	The type of the permission. For permissions with a privilege_scope of schema, possible values are CREATE, USAGE, and ALTER. For privilege_scope values other than schema, possible values include any permission type available on the permission's scope.

Column name	Data type	Description
identity_id	integer	The ID of the identity. Possible values are user ID, role ID, or group ID.
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user, role, group, or public.
admin_option	boolean	A value that indicates whether the user can grant the permission to other users and roles. It is always false for the role and group identity type.
privilege_scope	text	<p>The scope of the permission specified in privilege_type. Possible values are as follows:</p> <ul style="list-style-type: none">• SCHEMA• TABLES• FUNCTIONS <p>For information on scoped permissions, go to Scoped permissions.</p>

Sample query

The following example displays the result of the SVV_SCHEMA_PRIVILEGES.

```
SELECT namespace_name, privilege_type, identity_name, identity_type, admin_option FROM
svv_schema_privileges
WHERE namespace_name = 'test_schema1';
```

namespace_name	privilege_type	identity_name	identity_type	admin_option
test_schema1	USAGE	reguser	user	False
test_schema1	USAGE	role1	role	False

SVV_SCHEMA_QUOTA_STATE

Displays the quota and the current disk usage for each schema.

Regular users can see information for schemas for which they have USAGE permission. Superusers can see information for all schemas in the current database.

SVV_SCHEMA_QUOTA_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

This view is only available when querying provisioned clusters.

Table columns

Column name	Data type	Description
schema_id	integer	The namespace or schema ID.
schema_name	character (128)	The namespace or schema name.
schema_owner	integer	The internal user ID of the schema owner.
quota	integer	The amount of disk space (in MB) that the schema can use.
disk_usage	integer	The disk space (in MB) that is currently used by the schema.
disk_usage_pct	double precision	The disk space percentage that is currently used by the schema out of the configured quota.

Sample query

The following example displays the quota and the current disk usage for the schema.

```
SELECT TRIM(SCHEMA_NAME) "schema_name", QUOTA, disk_usage, disk_usage_pct FROM
  svv_schema_quota_state
WHERE SCHEMA_NAME = 'sales_schema';
schema_name | quota | disk_usage | disk_usage_pct
-----+-----+-----+-----
sales_schema | 2048 | 30          | 1.46
(1 row)
```

SVV_SYSTEM_PRIVILEGES

SVV_SYSTEM_PRIVILEGES is visible to the following users:

- Superusers
- Users with the ACCESS SYSTEM TABLE permission

Other users can only see identities they have access to or own.

Table columns

Column name	Data type	Description
system_privilege	text	The name of the system permission.
identity_id	integer	The ID of the identity. Possible values are user ID or role ID.
identity_name	text	The name of the identity.
identity_type	text	The type of the identity. Possible values are user or role.

Sample query

The following example displays the result for the specified parameters.

```
SELECT system_privilege,identity_name,identity_type FROM svv_system_privileges
WHERE system_privilege = 'ALTER TABLE' AND identity_name = 'sys:superuser';
```

```
system_privilege | identity_name | identity_type
-----+-----+-----
ALTER TABLE    | sys:superuser |      role
```

SVV_TABLE_INFO

Shows summary information for tables in the database. The view filters system tables and shows only user-defined tables.

You can use the SVV_TABLE_INFO view to diagnose and address table design issues that can influence query performance. This includes issues with compression encoding, distribution keys, sort style, data distribution skew, table size, and statistics. The SVV_TABLE_INFO view doesn't return any information for empty tables.

The SVV_TABLE_INFO view summarizes information from the [STV_BLOCKLIST](#), [STV_NODE_STORAGE_CAPACITY](#), [STV_TBL_PERM](#), and [STV_SLICES](#) system tables and from the [PG_DATABASE](#), [PG_ATTRIBUTE](#), [PG_CLASS](#), [PG_NAMESPACE](#), and [PG_TYPE](#) catalog tables.

SVV_TABLE_INFO is visible only to superusers. For more information, see [Visibility of data in system tables and views](#). To permit a user to query the view, grant SELECT permission on SVV_TABLE_INFO to the user.

Table columns

Column name	Data type	Description
database	text	Database name.
schema	text	Schema name.
table_id	oid	Table ID.
table	text	Table name.

Column name	Data type	Description
encoded	text	Value that indicates whether any column has compression encoding defined.
diststyle	text	Distribution style or distribution key column, if key distribution is defined. Possible values include EVEN, KEY(<i>column</i>), ALL, AUTO(ALL) , AUTO(EVEN) , and AUTO(KEY(<i>column</i>)).
sortkey1	text	First column in the sort key, if a sort key is defined. Possible values include <i>column</i> , AUTO(SORTKEY) , and AUTO(SORTKEY(<i>column</i>)).
max_varchar	integer	Size of the largest column that uses a VARCHAR data type.
sortkey1_enc	character(32)	Compression encoding of the first column in the sort key, if a sort key is defined.
sortkey_num	integer	Number of columns defined as sort keys.
size	bigint	Size of the table, in 1-MB data blocks.
pct_used	numeric(10,4)	Percent of available space that is used by the table.

Column name	Data type	Description
empty	bigint	For internal use. This column is no longer used and will be removed in a future release.
unsorted	numeric(5,2)	Percent of unsorted rows in the table.
stats_off	numeric(5,2)	Number that indicates how stale the table's statistics are; 0 is current, 100 is out of date.
tbl_rows	numeric(38,0)	Total number of rows in the table. This value includes rows marked for deletion, but not yet vacuumed.
skew_sortkey1	numeric(19,2)	Ratio of the size of the largest non-sort key column to the size of the first column of the sort key, if a sort key is defined. Use this value to evaluate the effectiveness of the sort key.
skew_rows	numeric(19,2)	Ratio of the number of rows in the slice with the most rows to the number of rows in the slice with the fewest rows.
estimated_visible_rows	numeric(38,0)	The estimated rows in the table. This value does not include rows marked for deletion.

Column name	Data type	Description
risk_event	text	<p>Risk information about a table. The field is separated into parts:</p> <pre><i>risk_type</i> <i>xid</i> <i>timestamp</i></pre> <ul style="list-style-type: none"> The <code>risk_type</code> , where 1 indicates that a COPY command with the EXPLICIT_IDS option ran. Amazon Redshift no longer checks the uniqueness of IDENTITY columns in the table. For more information, see EXPLICIT_IDS. The transaction ID, <code>xid</code>, that introduced the risk. The <code>timestamp</code> when the COPY command ran. <p>The following example shows the values in the field.</p> <pre>1 1107 2019-06-22 07:16:11.292952</pre>
vacuum_sort_benefit	numeric(12,2)	The estimated maximum percentage improvement of scan query performance when you run vacuum sort.

Column name	Data type	Description
create_time	timestamp without time zone	The timestamp for when the table was created.

Sample queries

The following example shows encoding, distribution style, sorting, and data skew for all user-defined tables in the database. Here, "table" must be enclosed in double quotation marks because it is a reserved word.

```
select "table", encoded, diststyle, sortkey1, skew_sortkey1, skew_rows
from svv_table_info
order by 1;
```

table	encoded	diststyle	sortkey1	skew_sortkey1	skew_rows
category	N	EVEN			
date	N	ALL	dateid	1.00	
event	Y	KEY(eventid)	dateid	1.00	1.02
listing	Y	KEY(listid)	dateid	1.00	1.01
sales	Y	KEY(listid)	dateid	1.00	1.02
users	Y	KEY(userid)	userid	1.00	1.01
venue	N	ALL	venueid	1.00	

(7 rows)

SVV_TABLES

Use SVV_TABLES to view tables in local and external catalogs.

SVV_TABLES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
table_catalog	text	The name of the catalog where the table exists.

Column name	Data type	Description
table_schema	text	The name the schema for the table.
table_name	text	The name of the table.
table_type	text	The type of table. Possible values are views, external tables, and base tables.
remarks	text	Remarks.

SVV_TRANSACTIONS

Records information about transactions that currently hold locks on tables in the database. Use the SVV_TRANSACTIONS view to identify open transactions and lock contention issues. For more information about locks, see [Managing concurrent write operations](#) and [LOCK](#).

SVV_TRANSACTIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
txn_owner	text	Name of the owner of the transaction.
txn_db	text	Name of the database associated with the transaction.
xid	bigint	Transaction ID.
pid	integer	Process ID associated with the lock.
txn_start	timestamp	Start time of the transaction.

Column name	Data type	Description
lock_mode	text	Name of the lock mode held or requested by this process. If lock_mode is Exclusive Lock and granted is true (t), then this transaction ID is an open transaction.
lockable_object_type	text	Type of object requesting or holding the lock, either relation if it is a table or transactionid if it is a transaction.
relation	integer	Table ID for the table (relation) acquiring the lock. This value is NULL if lockable_object_type is transactionid .
granted	boolean	Value that indicates whether that the lock has been granted (t) or is pending (f) .

Sample queries

The following command shows all active transactions and the locks requested by each transaction.

```
select * from svv_transactions;

txn_
lockable_
owner | txn_db | xid  | pid |          txn_start          | lock_mode |

SVV_USER_GRANTS

Use `SVV_USER_GRANTS` to view the list of users that are explicitly granted roles in the cluster.

`SVV_USER_GRANTS` is visible to the following users:

- Superusers
- Users with the `ACCESS SYSTEM TABLE` permission

Other users can only see roles that are explicitly granted to them.

Table columns

Column name	Data type	Description
user_id	integer	The user ID for the user.
user_name	text	The name of the user.
role_id	integer	The role ID for the granted role.
role_name	text	The role name for the granted role.
admin_option	boolean	A value that indicates whether the user can grant the role to other users and roles.

Sample queries

The following queries grant roles to users and show the list of users that are explicitly granted roles.

```
GRANT ROLE role1 TO reguser;
GRANT ROLE role2 TO reguser;
GRANT ROLE role1 TO superuser;
GRANT ROLE role2 TO superuser;

SELECT user_name,role_name,admin_option FROM svv_user_grants;
```

```
user_name | role_name | admin_option
-----+-----+-----
superuser | role1     | False
reguser   | role1     | False
superuser | role2     | False
reguser   | role2     | False
```

SVV_USER_INFO

You can retrieve data about Amazon Redshift database users with the SVV_USER_INFO view.

SVV_USER_INFO is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_name	text	The user name for the role.
user_id	integer	The user ID for the user.
createdb	boolean	A value that indicates whether the user has permissions to create databases.
superuser	boolean	A value that indicates whether the user is a superuser.
catalog_update	boolean	A value that indicates whether the user can update system catalogs.
connection_limit	text	The number of connections that the user can open.
syslog_access	text	A value that indicates whether the user has access to the system logs. The two possible values are RESTRICTED and UNRESTRICTED . RESTRICTED means that users that are not superusers can see their own records. UNRESTRICTED means that user that are not superusers can see all records in the system views and tables to which they have SELECT privileges.
last_ddl_timestamp	timestamp	The timestamp for the last data definition language (DDL) create statement run by the user.
session_timeout	integer	The maximum time in seconds that a session remains inactive or idle before timing out. 0 indicates that no timeout is set. For information about the cluster's idle or inactive timeout setting, see Quotas and limits in Amazon Redshift in the <i>Amazon Redshift Management Guide</i> .

Column name	Data type	Description
external_user_id	text	Unique identifier of the user in the third-party identity provider.

Sample queries

The following command retrieves user information from SVV_USER_INFO.

```
SELECT * FROM SVV_USER_INFO;
```

SVV_VACUUM_PROGRESS

This view returns an estimate of how much time it will take to complete a vacuum operation that is currently in progress.

SVV_VACUUM_PROGRESS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_VACUUM_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

For information about SVV_VACUUM_SUMMARY, see [SVV_VACUUM_SUMMARY](#).

For information about SVL_VACUUM_PERCENTAGE, see [SVL_VACUUM_PERCENTAGE](#).

Note

This view is only available when querying provisioned clusters.

Table columns

Column name	Data type	Description
table_name	text	Name of the table currently being vacuumed, or the table that was last vacuumed if no operation is in progress.
status	text	Description of the current activity being done as part of the vacuum operation: <ul style="list-style-type: none"> • Initialize • Sort • Merge • Delete • Select • Failed • Complete • Skipped • Building INTERLEAVED SORTKEY order
time_remaining_estimate	text	Estimated time left for the current vacuum operation to complete, in minutes and seconds: 5m 10s , for example. An estimated time is not returned until the vacuum completes its first sort operation. If no vacuum is in progress, the last vacuum that was performed is displayed with Completed in the STATUS column and an empty TIME_REMAINING_ESTIMATE column. The estimate typically becomes more accurate as the vacuum progresses.

Sample queries

The following queries, run a few minutes apart, show that a large table named SALESNEW is being vacuumed.

```
select * from svv_vacuum_progress;
```

```

table_name | status | time_remaining_estimate
-----+-----+-----
salesnew | Vacuum: initialize salesnew |
(1 row)
...
select * from svv_vacuum_progress;

table_name | status | time_remaining_estimate
-----+-----+-----
salesnew | Vacuum salesnew sort | 33m 21s
(1 row)

```

The following query shows that no vacuum operation is currently in progress. The last table to be vacuumed was the SALES table.

```

select * from svv_vacuum_progress;

table_name | status | time_remaining_estimate
-----+-----+-----
sales | Complete |
(1 row)

```

SVV_VACUUM_SUMMARY

The SVV_VACUUM_SUMMARY view joins the STL_VACUUM, STL_QUERY, and STV_TBL_PERM tables to summarize information about vacuum operations logged by the system. The view returns one row per table per vacuum transaction. The view records the elapsed time of the operation, the number of sort partitions created, the number of merge increments required, and deltas in row and block counts before and after the operation was performed.

SVV_VACUUM_SUMMARY is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_VACUUM_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

For information about SVV_VACUUM_PROGRESS, see [SVV_VACUUM_PROGRESS](#).

For information about SVL_VACUUM_PERCENTAGE, see [SVL_VACUUM_PERCENTAGE](#).

Note

This view is only available when querying provisioned clusters.

Table columns

Column name	Data type	Description
table_name	text	Name of the vacuumed table.
xid	bigint	Transaction ID of the VACUUM operation.
sort_partitions	bigint	Number of sorted partitions created during the sort phase of the vacuum operation.
merge_increments	bigint	Number of merge increments required to complete the merge phase of the vacuum operation.
elapsed_time	bigint	Elapsed runtime of the vacuum operation (in microseconds).
row_delta	bigint	Difference in the total number of table rows before and after the vacuum.
sortedrow_delta	bigint	Difference in the number of sorted table rows before and after the vacuum.
block_delta	integer	Difference in block count for the table before and after the vacuum.
max_merge_partitions	integer	This column is used for performance analysis and represents the maximum number of partitions that vacuum can process for the table per merge phase iteration. (Vacuum sorts the unsorted region into one or more sorted partitions. Depending on the number of columns in the table and the current Amazon Redshift configuration, the merge phase can process a maximum number of partitions in a single merge iteration. The merge phase will still work if the number of

Column name	Data type	Description
		sorted partitions exceeds the maximum number of merge partitions, but more merge iterations will be required.)

Sample query

The following query returns statistics for vacuum operations on three different tables. The SALES table was vacuumed twice.

```
select table_name, xid, sort_partitions as parts, merge_increments as merges,
elapsed_time, row_delta, sortedrow_delta as sorted_delta, block_delta
from svv_vacuum_summary
order by xid;
```

table_	xid	parts	merges	elapsed_	row_	sorted_	block_
name				time	delta	delta	delta
users	2985	1	1	61919653	0	49990	20
category	3982	1	1	24136484	0	11	0
sales	3992	2	1	71736163	0	1207192	32
sales	4000	1	1	15363010	-851648	-851648	-140

(4 rows)

SYS monitoring views

Monitoring views are system views in Amazon Redshift that are used to monitor query and workload resource usage of provisioned clusters and serverless workgroups. These views are located in the `pg_catalog` schema. To display the information provided by these views, run SQL `SELECT` statements.

Unless noted otherwise, these views are available for Amazon Redshift clusters and Amazon Redshift Serverless workgroups.

`SYS_SERVERLESS_USAGE` gathers usage data for Amazon Redshift Serverless only.

SYS_ANALYZE_COMPRESSION_HISTORY

Records details for compression analysis operations during COPY or ANALYZE COMPRESSION commands.

SYS_ANALYZE_COMPRESSION_HISTORY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The ID of the user who generated the entry.
start_time	timestamp	The time when the compression analysis operation started.
transaction_id	bigint	The transaction ID of the compression analysis operation.
table_id	integer	The table ID of the table that was analyzed.
table_name	character(128)	The name of the table that was analyzed.
column_position	integer	The index of the column in the table that was analyzed to determine the compression encoding.

Column name	Data type	Description
old_encoding	character(15)	The encoding type before compression analysis.
new_encoding	character(15)	The encoding type after compression analysis.
mode	character(14)	The possible values are: PRESET Specifies that the <code>new_encoding</code> is determined by the Amazon Redshift COPY command based on the column data type. No data is sampled. ON Specifies that the <code>new_encoding</code> is determined by the Amazon Redshift COPY command based on an analysis of sample data. ANALYZE ONLY Specifies that the <code>new_encoding</code> is determined by the Amazon Redshift ANALYZE COMPRESSION command based on an analysis of sample data. However, the encoding type of the analyzed column is not changed.

Sample queries

The following example inspects the details of compression analysis on the `lineitem` table by the last COPY command run in the same session.

```
select transaction_id, table_id, btrim(table_name) as table_name, column_position,
       old_encoding, new_encoding, mode
from sys_analyze_compression_history
where transaction_id = (select transaction_id from sys_query_history where query_id =
pg_last_copy_id()) order by column_position;
```

transaction_id	table_id	table_name	column_position	old_encoding	new_encoding	mode
8196	248126	lineitem	0	mostly32	mostly32	ON
8196	248126	lineitem	1	mostly32	mostly32	lzo
8196	248126	lineitem	2	lzo	lzo	ON
8196	248126	lineitem	3	delta	delta	ON
8196	248126	lineitem	4	bytedict	bytedict	ON
8196	248126	lineitem	5	mostly32	mostly32	ON
8196	248126	lineitem	6	delta	delta	ON
8196	248126	lineitem	7	delta	delta	ON
8196	248126	lineitem	8	lzo	lzo	ON
8196	248126	lineitem	9	runlength	runlength	ON
8196	248126	lineitem	10	delta	delta	ON
8196	248126	lineitem	11	delta	delta	ON
8196	248126	lineitem	12	delta	delta	ON
8196	248126	lineitem	13	bytedict	bytedict	ON
8196	248126	lineitem	14	bytedict	bytedict	ON
8196	248126	lineitem	15	text255	text255	ON

(16 rows)

SYS_ANALYZE_HISTORY

Logs details for [ANALYZE](#) operations.

`SYS_ANALYZE_HISTORY` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The ID of the user who generated the entry.
<code>transaction_id</code>	long	The transaction ID.
<code>query_id</code>	long	The query identifier in SYS_QUERY_HISTORY .
<code>database_name</code>	char(30)	The name of the database.
<code>table_name</code>	char(30)	The name of the table.
<code>table_id</code>	integer	The ID of the table.
<code>is_automat ic</code>	char(1)	The value is true (t) if the operation included an Amazon Redshift ANALYZE operation by default. The value is false (f) if the ANALYZE command was run explicitly.
<code>status</code>	char(15)	The result of the analyze command. Possible values are Full, Skipped, and PredicateColumn.
<code>start_time</code>	timestamp	The time in UTC of when the ANALYZE operation started running.
<code>end_time</code>	timestamp	The time in UTC of when the ANALYZE operation finished running.
<code>rows</code>	double	The total number of rows in the table
<code>modified_ rows</code>	double	The total number of rows that were modified since the last ANALYZE operation.

Column name	Data type	Description
analyze_threshold_percent	integer	The value of the analyze_threshold_percent parameter.
last_analyze_time	timestamp	The time in UTC of when the table was previously analyzed.

Sample queries

```

user_id | transaction_id | database_name | schema_name | table_name |
table_id | is_automatic | Status | start_time | end_time
| rows | modified_rows | analyze_threshold_percent | last_analyze_time
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----

```

SYS_APPLIED_MASKING_POLICY_LOG

Use SYS_APPLIED_MASKING_POLICY_LOG to trace the application of dynamic data masking policies on queries that reference DDM-protected relations.

SYS_APPLIED_MASKING_POLICY_LOG is visible to the following users:

- Superusers
- Users with the sys:operator role
- Users with the ACCESS SYSTEM TABLE permission

Regular users will see 0 rows.

Note that `SYS_APPLIED_MASKING_POLICY_LOG` isn't visible to users with the `sys:secadmin` role.

For more information on dynamic data masking, go to [Dynamic data masking](#).

Table columns

Column name	Data type	Description
<code>policy_name</code>	text	The name of the masking policy.
<code>user_id</code>	text	The ID of the user who ran the query.
<code>record_time</code>	timestamp	The time that the system view entry was recorded.
<code>session_id</code>	int	The process ID.
<code>transaction_id</code>	long	The transaction ID.
<code>query_id</code>	int	The query ID.
<code>database_name</code>	text	The name of the database on which the query was run.
<code>relation_name</code>	text	The name of the table that the masking policy is applied to.
<code>schema_name</code>	text	The name of the schema that the table is in.
<code>attachment_id</code>	long	The attached masking policy's ID.
<code>relation_kind</code>	text	The type of the relation that the masking policy is applied to. Possible values are <code>TABLE</code> , <code>VIEW</code> , <code>LATE BINDING VIEW</code> , and <code>MATERIALIZED VIEW</code> .

Sample queries

The following example shows that the `mask_credit_card_full` masking policy is attached to the `credit_db.public.credit_cards` table.

```
select policy_name, database_name, relation_name, schema_name, relation_kind
from sys_applied_masking_policy_log;

policy_name          | database_name | relation_name | schema_name | relation_kind
-----+-----+-----+-----+-----
mask_credit_card_full | credit_db     | credit_cards  | public      | table

(1 row)
```

SYS_AUTO_TABLE_OPTIMIZATION

Records automated actions taken by Amazon Redshift on tables defined for automatic optimization.

`SYS_AUTO_TABLE_OPTIMIZATION` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>transaction_id</code>	long	The transaction identifier.
<code>session_id</code>	int	The session identifier of the process that executed the alter command.
<code>table_id</code>	int	The table identifier.
<code>alter_table_type</code>	character (32)	The type of recommendation. Possible values are <code>distkey</code> , <code>sortkey</code> , and <code>encode</code> .
<code>status</code>	character (128)	The completion status of the recommendation. Possible values are <code>Start</code> , <code>Complete</code> , <code>Skipped</code> , <code>Abort</code> , <code>Checkpoint</code> , and <code>Failed</code> .

Column name	Data type	Description
event_time	timestamp	The timestamp of the status column.
alter_from	character (200)	The previous distribution style and sort keys of the table before applying the recommendation. The value is truncated into 200-character increments.

Sample queries

In the following example, the rows in the result show actions taken by Amazon Redshift.

```
SELECT table_id, alter_table_type, status, event_time, alter_from
FROM SYS_AUTO_TABLE_OPTIMIZATION;
```

```

table_id | alter_table_type | status
| event_time | alter_from
-----+-----+-----

```

SYS_CONNECTION_LOG

Logs authentication attempts and connections and disconnections.

SYS_CONNECTION_LOG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
event	character(50)	Connection or authentication event.
record_time	timestamp	Time the event occurred.
remote_host	character(45)	Name or IP address of remote host.
remote_port	character(32)	Port number for remote host.
session_id	integer	Process ID associated with the statement.
database_name	character(50)	Database name.
user_name	character(50)	Username.

Column name	Data type	Description
auth_method	character(32)	Authentication method.
duration	integer	Duration of connection in microseconds.
ssl_version	character(50)	Secure Sockets Layer (SSL) version.
ssl_cipher	character(128)	SSL cipher.
mtu	integer	Maximum transmission unit (MTU).
ssl_compression	character(64)	SSL compression type.
ssl_expansion	character(64)	SSL expansion type.
iam_auth_guid	character(36)	The IAM authentication ID for the CloudTrail request.
application_name	character(250)	The initial or updated name of the application for a session.
driver_version	character(64)	The version of ODBC or JDBC driver that connects to your Amazon Redshift cluster from your third-party SQL client tools.
os_version	character(64)	The version of the operating system that is on the client machine that connects to your Amazon Redshift cluster.
plugin_name	character(32)	The name of the plugin used to connect to your Amazon Redshift cluster.

Column name	Data type	Description
protocol_version	integer	<p>The internal protocol version that the Amazon Redshift driver uses when establishing its connection with the server. The protocol versions are negotiated between the driver and server. The version describes the features available. Valid values include:</p> <ul style="list-style-type: none"> • 0 (BASE_SERVER_PROTOCOL_VERSION) • 1 (EXTENDED_RESULT_METADATA_SERVER_PROTOCOL_VERSION) – To save a round trip per query, the server sends extra result set metadata information. • 2 (BINARY_PROTOCOL_VERSION) – Depending on the data type of the result set, the server sends data in binary format. • 3 (EXTENDED2_RESULT_METADATA_SERVER_PROTOCOL_VERSION) – The server sends case sensitivity (collation) information of a column.
global_session_id	character(36)	The globally unique identifier for the current session. The session ID persists through node failure restarts.

Sample queries

To view the details for open connections, run the following query.

```
select record_time, user_name, database_name, remote_host, remote_port
from sys_connection_log
where event = 'initiating session'
and session_id not in
(select session_id from sys_connection_log
where event = 'disconnecting session')
order by 1 desc;
```

record_time	user_name	database_name	remote_host	remote_port
-------------	-----------	---------------	-------------	-------------

```

-----+-----+-----+-----
+-----
2014-11-06 20:30:06 | rdsdb      | dev          | [local]      |
2014-11-06 20:29:37 | test001    | test        | 10.49.42.138 | 11111
2014-11-05 20:30:29 | rdsdb      | dev          | 10.49.42.138 | 33333
2014-11-05 20:28:35 | rdsdb      | dev          | [local]      |
(4 rows)

```

The following example reflects a failed authentication attempt and a successful connection and disconnection.

```

select event, record_time, remote_host, user_name
from sys_connection_log order by record_time;

          event          |          record_time          | remote_host | user_name
-----+-----+-----+-----
authentication failure | 2012-10-25 14:41:56.96391    | 10.49.42.138 | john
authenticated          | 2012-10-25 14:42:10.87613    | 10.49.42.138 | john
initiating session     | 2012-10-25 14:42:10.87638    | 10.49.42.138 | john
disconnecting session  | 2012-10-25 14:42:19.95992    | 10.49.42.138 | john
(4 rows)

```

The following example shows the version of the ODBC driver, the operating system on the client machine, and the plugin used to connect to the Amazon Redshift cluster. In this example, the plugin used is for standard ODBC driver authentication using a login name and password.

```

select driver_version, os_version, plugin_name from sys_connection_log;

driver_version          |          os_version          |          plugin_name          |
-----+-----+-----+-----
Amazon Redshift ODBC Driver 1.4.15.0001 | Darwin 18.7.0 x86_64        | none
Amazon Redshift ODBC Driver 1.4.15.0001 | Linux 4.15.0-101-generic x86_64 | none

```

The following example shows the version of the operating system on the client machine, the driver version, and the protocol version.

```
select os_version, driver_version, protocol_version from sys_connection_log;
```

```
os_version          | driver_version          | protocol_version
-----+-----+-----
Linux 4.15.0-101-generic x86_64 | Redshift JDBC Driver 2.0.0.0 | 2
Linux 4.15.0-101-generic x86_64 | Redshift JDBC Driver 2.0.0.0 | 2
Linux 4.15.0-101-generic x86_64 | Redshift JDBC Driver 2.0.0.0 | 2
```

SYS_COPY_JOB (preview)

This is prerelease documentation for autocopy (SQL COPY JOB), which is in preview release. The documentation and the feature are both subject to change. We recommend that you use this feature only in test environments, and not in production environments. Public preview will end on October 31, 2024. Preview clusters will be removed automatically two weeks after the end of the preview. For preview terms and conditions, see [Betas and Previews in AWS Service Terms](#).

Use SYS_COPY_JOB to view details of COPY JOB commands.

This view contains the COPY JOB commands that have been created.

SYS_COPY_JOB is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
job_id	bigint	The copy job identifier.
job_name	character(128)	The name of the copy job.
iam_role	character(128)	The IAM role specified in the COPY statement.

Column name	Data type	Description
job_text	character(256)	The parameters of the COPY statement.
is_auto	integer	Indicates whether the COPY JOB is automatically run by Amazon Redshift. A 1 indicates true, 0 indicates false.
on_error_suspend	integer	This information is for internal use only.

SYS_COPY_REPLACEMENTS

Displays a log that records when invalid UTF-8 characters were replaced by the [COPY](#) command with the ACCEPTINVCHARS option. A log entry is added to SYS_COPY_REPLACEMENTS for each of the first 100 rows on each node slice that required at least one replacement.

You can use this view to see information about serverless workgroups and provisioned clusters.

SYS_COPY_REPLACEMENTS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	ID of the user who generated the query.
query_id	bigint	The query ID. The column used to join other system tables and views.
table_id	integer	The table ID.
file_name	character (256)	The complete path to the input file for the COPY command.

Column name	Data type	Description
column_name	character (127)	The first field that contains an invalid UTF-8 character.
line_number	bigint	The line number in the input data file that contains an invalid UTF-8 character. -1 indicates that the line number is not available, such as when copying from a columnar data file.
raw_line	character (1024)	The raw load data that contains an invalid UTF-8 character.

Sample queries

The following example returns replacements for the most recent COPY operation.

```
select query_idp, table_id, file_name, line_number, colname
from sys_copy_replacements
where query = pg_last_copy_id();
```

```
query_id | table_id | file_name |
line_number | column_name
-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
   96  |    26  | s3://DOC-EXAMPLE-BUCKET/allusers_pipe.txt |

...
```

SYS_DATASHARE_CHANGE_LOG

Records the consolidated view for tracking changes to datashares on both producer and consumer clusters.

SYS_DATASHARE_CHANGE_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The ID of the user taking the action.
user_name	varchar(128)	The name of the user taking the action.
session_id	integer	The ID of the session.
transaction_id	bigint	The ID of the transaction.
share_id	integer	The ID of the datashare affected.
share_name	varchar(128)	The name of the datashare.
source_database_id	integer	The ID of the database to which the datashare belongs.
source_database_name	varchar(128)	The name of the database to which the datashare belongs.
consumer_database_id	integer	The ID of the database imported from the datashare.

Column name	Data type	Description
consumer_database_name	varchar(128)	The name of the database imported from the datashare.
arn	varchar(192)	The ARN of the resource backing the imported database.
record_time	timestamp	The timestamp of the action.
action	varchar(128)	The action being run. Possible values are CREATE DATASHARE, DROP DATASHARE, GRANT ALTER, REVOKE ALTER, GRANT SHARE, REVOKE SHARE, ALTER ADD, ALTER REMOVE, ALTER SET, GRANT USAGE, REVOKE USAGE, CREATE DATABASE, GRANT, or REVOKE USAGE on a shared database, DROP SHARED DATABASE, ALTER SHARED DATABASE.
status	integer	The status of the action. Possible values are SUCCESS and ERROR-ERROR CODE.
share_object_type	varchar(64)	The type of database object that was added to or removed from the datashare. Possible values are schemas, tables, columns, functions, and views. This is a field for the producer cluster.
share_object_id	integer	The ID of database object that was added to or removed from the datashare. This is a field for the producer cluster.
share_object_name	varchar(128)	The name of database object that was added to or removed from the datashare. This is a field for the producer cluster.
target_user_type	varchar(16)	The type of users or groups that a privilege was granted to. This is a field for both the producer and consumer cluster.
target_user_id	integer	The ID of users or groups that a privilege was granted to. This is a field for both the producer and consumer cluster.

Column name	Data type	Description
target_user_name	varchar(128)	The name of users or groups that a privilege was granted to. This is a field for both the producer and consumer cluster.
consumer_account	varchar(16)	The account ID of the data consumer. This is a field for the producer cluster.
consumer_namespace	varchar(64)	The namespace of the data consumer account. This is a field for the producer cluster.
producer_account	varchar(16)	The account ID of the producer account that the datashare belongs to. This is a field for the consumer cluster.
producer_namespace	varchar(64)	The namespace of the product account that the datashare belongs to. This is a field for the consumer cluster.
attribute_name	varchar(64)	The name of an attribute of the datashare or shared database.
attribute_value	varchar(128)	The value of an attribute of the datashare or shared database.
message	varchar(512)	The error message when an action fails.

Sample queries

The following example shows a SYS_DATASHARE_CHANGE_LOG view.

```
SELECT DISTINCT action
FROM sys_datashare_change_log
WHERE share_object_name LIKE 'ticket%';
```

```
      action
-----
"ALTER DATASHARE ADD"
```

SYS_DATASHARE_CROSS_REGION_USAGE

Use the SYS_DATASHARE_CROSS_REGION_USAGE view to get a summary of cross-Region data transferred usage caused by cross-Region datasharing query. SYS_DATASHARE_CROSS_REGION_USAGE aggregates details at the segment level.

SYS_DATASHARE_CROSS_REGION_USAGE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
query_id	integer	The ID of the query. Use this value to join other system tables and views.
child_query_sequence	integer	The sequence of the rewritten user query, starting with 1.
segment_id	bigint	The number of the segment. A query consists of multiple segments, and each segment consists of one or more steps.
start_time	time	The time in UTC that the data transfer began.
end_time	time	The time in UTC that the data transfer ended.
transferred_data	bigint	The number of bytes of data transferred from a producer Region to a consumer Region.
source_region	char(25)	The producer Region that the query transferred data from.

Sample queries

The following example shows a SYS_DATASHARE_CROSS_REGION_USAGE view.

```
SELECT query, segment, transferred_data, source_region
from sys_datashare_cross_region_usage
```

```
where query = pg_last_query_id()
order by query,segment;
```

query	segment	transferred_data	source_region
200048	2	4194304	us-west-1
200048	2	4194304	us-east-2

SYS_DATASHARE_USAGE_CONSUMER

Records the activity and usage of datashares. This view is only relevant on the consumer cluster.

SYS_DATASHARE_USAGE_CONSUMER is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The ID of the user issuing the request.
session_id	integer	The ID of the leader process running the query.
transaction_id	bigint	The context of the current transaction.
request_id	varchar(50)	The unique ID of the requested API call.
request_type	varchar(25)	The type of the request made to the producer cluster.
transaction_uid	varchar(50)	The unique ID of the transaction.
record_time	timestamp	The time when the action is recorded.
status	integer	The status of the requested API call.

Column name	Data type	Description
error_message	varchar(512)	The message for an error.

Sample queries

The following example shows the SYS_DATASHARE_USAGE_CONSUMER view.

```
SELECT request_type, status, trim(error) AS error
FROM sys_datashare_usage_consumer
```

```

request_type | status | error_message
-----+-----+-----
"GET RELATION" | 0      |

```

SYS_DATASHARE_USAGE_PRODUCER

Records the activity and usage of datashares. This view is only relevant on the producer cluster.

SYS_DATASHARE_USAGE_PRODUCER is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
share_id	integer	The object ID (OID) of the datashare.
share_name	varchar(128)	The name of the datashare.
request_id	varchar(50)	The unique ID of the requested API call.

Column name	Data type	Description
request_type	varchar(25)	The type of the request made to the producer cluster.
object_type	varchar(64)	The type of the object being shared from the datashare. Possible values are schemas, tables, columns, functions, and views.
object_oid	integer	The ID of the object being shared from the datashare.
object_name	varchar(128)	The name of the object being shared from the datashare.
consumer_account	varchar(16)	The account of the consumer account that the datashare is shared to.
consumer_namespace	varchar(64)	The namespace of the consumer account that the datashare is shared to.
consumer_transaction_uid	varchar(50)	The unique transaction ID of the statement on the consumer cluster.
record_time	timestamp	The time when the action is recorded.
status	integer	The status of the datashare.
error_message	varchar(512)	The message for an error.
consumer_region	char(64)	The Region that the consumer cluster is in.

Sample queries

The following example shows the `SYS_DATASHARE_USAGE_PRODUCER` view.

```
SELECT DISTINCT
FROM sys_datashare_usage_producer
```

```
WHERE object_name LIKE 'tickit%';

    request_type
-----
"GET RELATION"
```

SYS_EXTERNAL_QUERY_DETAIL

Use `SYS_EXTERNAL_QUERY_DETAIL` to view details for queries at a segment level. Each row represents a segment from a particular WLM query with details like the number of rows processed, number of bytes processed, and partition info of external tables in Amazon S3. Each row in this view will also have a corresponding entry in the `SYS_QUERY_DETAIL` view, except this view has more detail information related to external query processing.

`SYS_EXTERNAL_QUERY_DETAIL` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The identifier of the user who submitted the query.
<code>query_id</code>	bigint	The query identifier of the external query.
<code>transaction_id</code>	bigint	The transaction identifier.
<code>child_query_sequence</code>	integer	The sequence of the rewritten user query. Starts with 0, similar to <code>segment_id</code> .
<code>segment_id</code>	integer	The segment identifier of the query segment.
<code>source_type</code>	character(32)	The data source type of the query, it could be S3 for Redshift Spectrum, PG for federated query.

Column name	Data type	Description
start_time	timestamp	The time when the query began.
end_time	timestamp	The time when the query completed.
duration	bigint	The amount of time (microseconds) spent on the query.
total_partitions	integer	The number of partitions an Amazon S3 query required.
qualified_partitions	integer	The number of partitions an Amazon S3 query scanned.
scanned_files	bigint	The number of Amazon S3 files scanned.
returned_rows	bigint	The number of scanned rows for an Amazon S3 query, or the number of returned rows for a federated query.
returned_bytes	bigint	The number of scanned bytes for an Amazon S3 query, or the number of returned bytes for a federated query.
file_format	text	The file format of Amazon S3 files.
file_location	text	The Amazon S3 location of external table.
external_query_text	text	The segment level query text for a federated query.

Column name	Data type	Description
warning_message	character(4000)	The warning message displayed when the query runs.
table_name	character(136)	The table name of the step that is being operated.
is_recursive	character(1)	Indicates whether there is recursive scan for subfolders.
is_nested	character(1)	Indicates whether the nested column data type is accessed.
s3list_time	bigint	The duration of file listing in milliseconds.
get_partition_time	long	Time spent to list and qualify partitions for a given external object from the AWS Glue Data Catalog and Apache Hive.

Sample queries

The following query shows the external query details.

```
SELECT query_id,
       segment_id,
       start_time,
       end_time,
       total_partitions,
       qualified_partitions,
       scanned_files,
       returned_rows,
       returned_bytes,
       trim(external_query_text) query_text,
       trim(file_location) file_location
FROM sys_external_query_detail
```

```
ORDER BY query_id, start_time DESC
LIMIT 2;
```

Sample output.

```

query_id | segment_id |          start_time          |          end_time          |
| total_partitions | qualified_partitions | scanned_files | returned_rows |
returned_bytes | query_text | file_location

          |

```

SYS_EXTERNAL_QUERY_ERROR

You can query the system view `SYS_EXTERNAL_QUERY_ERROR` to get information about Redshift Spectrum scan errors. `SYS_EXTERNAL_QUERY_ERROR` displays a sample of logged errors. The default is 10 entries per query.

`SYS_EXTERNAL_QUERY_ERROR` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The identifier of the user that generated this row.
<code>query_id</code>	bigint	The query identifier of the query that generated this row.
<code>file_location</code>	char(256)	The location of the data being queried.

Column name	Data type	Description
rowid	char(2100)	<p>The location of the error within the file. The <code>rowid</code> parts are separated with a <code>:</code> (colon) and additional parts might be added in the future.</p> <pre><i>row_offset :row_group :row_id</i></pre> <p>A <code>row_offset</code> is the offset (in bytes) of the row within the file and is set to <code>-1</code> for unsupported file formats. A table is divided into <code>row_groups</code>, and each group has rows with distinct <code>row_ids</code>.</p>
column_name	char(127)	The name of the column returned by the query.
original_value	char(1024)	Original value queried.
modified_value	char(1024)	Modified value returned based on the data handling configuration option specified in the query.
trigger	char(128)	Data handling option specified in the query.
action	char(128)	Action associated with the data handling option specified in the query.
action_value	char(128)	Value of action parameter associated with the data handling option specified in the query.
error_code	integer	Result code of the data handling option specified in the query.

Sample query

The following query returns the list of rows for which data handling operations were performed.

```
SELECT * FROM sys_external_query_error;
```

The query returns results similar to the following.

user_id	query_id	file_location	rowid
column_name	original_value	modified_value	trigger
action	action_value	error_code

SYS_INTEGRATION_ACTIVITY

SYS_INTEGRATION_ACTIVITY displays details about completed integration runs.

SYS_INTEGRATION_ACTIVITY is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

For information about zero-ETL integrations, see [Working with zero-ETL integrations](#) in the Amazon Redshift Management Guide.

Table columns

Column name	Data type	Description
integration_id	character (128)	The identifier associated with the integration.
target_database	character (128)	The database in Amazon Redshift that receives the integration data.
source	character (128)	The source data for the integration. Possible types includes MySQL and PostgreSQL .
checkpoint_name	character (128)	The name of the checkpoint replicating binlog coordinates.
checkpoint_type	character (16)	The type of checkpoint. Possible values include: snapshot, cdc.
checkpoint_bytes	bigint	The number of bytes in this checkpoint.
last_commit_timestamp	timestamp	The timestamp when last committed in this checkpoint.
modified_tables	integer	The number of tables modified in the checkpoint.
integration_start_time	time	The time (UTC) when integration started for this checkpoint.

Column name	Data type	Description
integration_end_time	time	The time (UTC) when integration ended for this checkpoint.

Sample queries

The following SQL command displays the log of integrations.

```
select * from sys_integration_activity;

      integration_id          | target_database | source |
      checkpoint_name        | checkpoint_type | checkpoint_bytes |

SYS_INTEGRATION_TABLE_STATE_CHANGE

SYS_INTEGRATION_TABLE_STATE_CHANGE displays details about table state change logs for integrations.

A superuser can see all rows in this table.

For more information, see [Working with Zero-ETL integrations](#).

Table columns

Column name	Data type	Description
integration_id	character (128)	The identifier associated with the integration.
database_name	character (128)	The name of the Amazon Redshift database.
schema_name	character (128)	The name of the Amazon Redshift schema.
table_name	character (128)	The name of the table.
new_state	character (128)	The state of the table. Possible values are Synced, ResyncRequired , ResyncInitiated , Deleted, Failed, and ResyncDeleted .
table_last_replicated_checkpoint	character (128)	The current synced log coordinates.
state_change_reason	character (256)	The reason for the last state transition.
record_time	timestamp	The time (UTC) when this record was updated.

Sample queries

The following SQL command displays the log of integrations.

```
select * from sys_integration_table_state_change;
```

```

      integration_id          | database_name | schema_name | table_name

SYS_LOAD_DETAIL

Returns information to track or troubleshoot a data load.

This view records the progress of each data file as it is loaded into a database table.

This view is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	ID of the user who generated the entry.
query_id	integer	Query ID.
file_name	character(256)	File name to be loaded.
bytes_scanned	integer	The number of bytes scanned from the file in Amazon S3.
lines_scanned	integer	Number of lines scanned from the load file. This number may not match the number of rows that are actually loaded.

Column name	Data type	Description
		For example, the load may scan but tolerate a number of bad records, based on the MAXERROR option in the COPY command.
record_time	timestamp	Time that this entry was last updated.
splits_scanned	Number of splits of this file.	Number of splits of this file.
start_time	timestamp	Time that this file processing started.
end_time	timestamp	Time that this file processing finished.

Sample queries

The following example returns details for the last COPY operation.

```
select query_id, trim(file_name) as file, record_time
from sys_load_detail
where query_id = pg_last_copy_id();
```

```
query_id |          file          |          record_time
-----+-----+-----
 28554   | s3://dw-tickit/category_pipe.txt | 2013-11-01 17:14:52.648486
(1 row)
```

The following query contains entries for a fresh load of the tables in the TICKIT database:

```
select query_id, trim(file_name), record_time
from sys_load_detail
where file_name like '%tickit%' order by query_id;
```

```
query_id |          btrim          |          record_time
-----+-----+-----
 22475   | tickit/allusers_pipe.txt | 2013-02-08 20:58:23.274186

The fact that a record is written to the log file for this system view does not mean that the load committed successfully as part of its containing transaction. To verify load commits, query the `STL_UTILITYTEXT` view and look for the `COMMIT` record that corresponds with a `COPY` transaction. For example, this query joins `SYS_LOAD_DETAIL` and `STL_QUERY` based on a subquery against `STL_UTILITYTEXT`:

```

select l.query_id,rtrim(l.file_name),q.xid
from sys_load_detail l, stl_query q
where l.query_id=q.query
and exists
(select xid from stl_utilitytext where xid=q.xid and rtrim("text")='COMMIT');

```

query_id	rtrim	xid
22600	tickit/date2008_pipe.txt	68311

SYS_LOAD_ERROR_DETAIL

Use `SYS_LOAD_ERROR_DETAIL` to view details of `COPY` command errors. Each row represents a `COPY` command. It contains both running and finished `COPY` commands.

`SYS_LOAD_ERROR_DETAIL` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The identifier of the user who submitted the copy.
<code>query_id</code>	bigint	The query identifier of the copy.
<code>transaction_id</code>	bigint	The transaction identifier.
<code>session_id</code>	integer	The process identifier of the process running the copy.
<code>database_name</code>	character(64)	The name of the database the user was connected to when the copy was issued.
<code>table_id</code>	integer	The table identifier.
<code>start_time</code>	timestamp	The time (UTC) when the copy began.

Column name	Data type	Description
file_name	character(256)	The complete path to the input file to load.
line_number	bigint	The line number in the load file with the error. When you load a JSON file, the line number of the last line of the JSON object with the error.
column_name	character(127)	The field with the error.
column_type	character(10)	The data type of the field with the error.
column_length	character(10)	The column length, if applicable. This field is populated when the data type has a limit length. For example, for a column with a data type of "character(3)", this column contains the value "3."
position	integer	The position of the error in the field.
error_code	integer	The error code.
error_message	character(512)	The explanation of the error.

Sample queries

The following query shows the load error details of copy command for specific query.

```
SELECT query_id,
       table_id,
       start_time,
```

```

    trim(file_name) AS file_name,
    trim(column_name) AS column_name,
    trim(column_type) AS column_type,
    trim(error_message) AS error_message
FROM sys_load_error_detail
WHERE query_id = 762949
ORDER BY start_time
LIMIT 10;

```

Sample output.

```

query_id | table_id |          start_time          |          file_name
| column_name | column_type |          error_message

Integer

```

SYS_LOAD_HISTORY

Use `SYS_LOAD_HISTORY` to view details of COPY commands. Each row represents a COPY command with accumulated statistics for some of the fields. It contains both running and finished COPY commands.

`SYS_LOAD_HISTORY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The identifier of the user who submitted the copy.
<code>query_id</code>	bigint	The query identifier of the copy.

Column name	Data type	Description
transaction_id	bigint	The transaction identifier.
session_id	integer	The process identifier of the process running the copy.
database_name	text	The name of the database the user was connected to when the operation was issued.
status	text	The status of the copy. Valid values are running, completed , aborted.
table_name	text	The name of the table copying into.
start_time	timestamp	The time when the copy began.
end_time	timestamp	The time when the copy completed.
duration	bigint	The amount of time (microseconds) spent in the COPY command.
data_source	text	The Amazon S3 location of files input to copy.
file_format	text	The source file format. Formats include csv, txt, json, avro, orc, or parquet.
loaded_rows	bigint	The number of rows copied to a table.

Column name	Data type	Description
loaded_bytes	bigint	The number of bytes copied to a table.
source_file_count	integer	The number of files count in source files.
source_file_bytes	bigint	The number of bytes in source files.
file_count_scanned	integer	The number of scanned files from Amazon S3.
file_bytes_scanned	bigint	The number of bytes scanned from the file in Amazon S3.
error_count	bigint	The number of errors count.
copy_job_id	bigint	The copy job identifier. A 0 indicates no job identifier.

Sample queries

The following query shows the loaded rows, bytes, tables, and datasource of specific copy commands.

```
SELECT query_id,
       table_name,
       data_source,
       loaded_rows,
       loaded_bytes
FROM sys_load_history
WHERE query_id IN (6389,490791,441663,74374,72297)
ORDER BY query_id,
         data_source DESC;
```

Sample output.

```

SYS_MV_REFRESH_HISTORY

The results include information about the refresh history of all materialized views. The results include the refresh type, such as manual or auto, and the status of the most recent refresh.

`SYS_MV_REFRESH_HISTORY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The identifier of the user who submitted the refresh.
session_id	integer	The process identifier for the process running the materialized view refresh.
transaction_id	bigint	The transaction identifier.
database_name	char(128)	The database that contains the materialized view.
schema_name	char(128)	The schema of the materialized view.
mv_id	bigint	Object ID of the materialized view.
mv_name	char(128)	The materialized view name.
refresh_type	char(32)	The type of refresh, such as manual or auto.
status	text	The status of the refresh. For detailed information about statuses, see the status column for SVL_MV_REFRESH_STATUS .
start_time	timestamp	The start time of the refresh.
end_time	timestamp	The end time of the refresh.

Column name	Data type	Description
duration	bigint	The amount of time in microseconds it took to refresh the materialized view.

Sample queries

The following query shows the refresh history for materialized views.

```
SELECT user_id,
       session_id,
       transaction_id,
       database_name,
       schema_name,
       mv_id,
       mv_name,
       refresh_type,
       status,
       start_time,
       end_time,
       duration
from sys_mv_refresh_history;
```

The query returns the following sample output:

```
user_id | session_id | transaction_id | database_name | schema_name |
mv_id  | mv_name    | refresh_type  | status      |
       | start_time | end_time     | duration

SYS_MV_STATE

The results include information about the state of all materialized views. It includes base table information, schema properties, and information about recent events, like dropping a column.

SYS_MV_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	bigint	The ID of the user who created the event.
transaction_id	bigint	The transaction ID of the event.
database_name	char(128)	The database that contains the materialized view.
event_desc	char(500)	The event that prompted the state change. Example values include the following: <ul style="list-style-type: none"> Column type was changed Column was dropped

Column name	Data type	Description
		<ul style="list-style-type: none"> Column was renamed Schema name was changed Small-table conversion TRUNCATE Vacuum <p>Note that there are other possible values for this column.</p>
start_time	timestamp	The start time of the event.
base_table_database_name	char(128)	The database name for the base table.
base_table_schema	char(128)	The schema of the base table.
base_table_name	char(128)	The name of the base table.
mv_schema	char(128)	The schema of the materialized view.
mv_name	char(128)	The name of the materialized view.
state	character(32)	<p>The changed state of the materialized view, which are as follows:</p> <ul style="list-style-type: none"> Recompute Unrefreshable

Sample queries

The following query shows the materialized view state.

```
select * from sys_mv_state;
```

The query returns the following sample output:

```

user_id | transaction_id | database_name | event_desc | start_time

SYS_PROCEDURE_CALL

Use the `SYS_PROCEDURE_CALL` view to get information about stored procedure calls, including start time, end time, status of a stored procedure call, and call hierarchy for nested stored procedure calls. Each stored procedure call receives a query ID.

`SYS_PROCEDURE_CALL` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>session_user_id</code>	integer	The identifier of the user who created the session and is the invoker of the top-level stored procedure call.
<code>security_user_id</code>	integer	The identifier of the user whose privileges were used to run the statement within the stored procedure. If the stored procedure is <code>DEFINER</code> , then this will be the owner <code>user_id</code> of the stored procedure.
<code>query_id</code>	integer	The query identifier of the stored procedure call.
<code>query_text</code>	char(4000)	The text of the stored procedure call query.
<code>start_time</code>	timestamp	The time in UTC when the query started running. The

Column name	Data type	Description
		timestamp uses six digits of precision for fractional seconds, for example: 2009-06-12 11:29:19.131358.
end_time	timestamp	The time in UTC when the query finished running. The timestamp uses six digits of precision for fractional seconds, for example: 2009-06-12 11:29:19.131358.
status	char(10)	The status of the stored procedure call. When the stored procedure was stopped by the system or canceled by the user, the value is canceled. If the stored procedure call runs to completion, the value is success.
caller_procedure_query_id	integer	If the stored procedure call was invoked by another stored procedure call, then this column contains the query ID of the outer call. Otherwise, the field is NULL.

Sample queries

The following query returns a nested stored procedure call hierarchy.

```
select query_id, datediff(seconds, start_time, end_time) as elapsed_time, status,
trim(query_text) as call, caller_procedure_query_id from sys_procedure_call;
```

Sample output.

```
query_id | elapsed_time | status | call |
caller_procedure_query_id
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
      3087 |           18 | success | CALL proc_bd906c98c45443ffa165e9552056902d(1) |
          3085
      3085 |           18 | success | CALL proc_bd906c98c45443ffa165e9552056902d_2(1); |
(2 rows)
```

SYS_PROCEDURE_MESSAGES

SYS_PROCEDURE_MESSAGES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
transaction_id	bigint	The transaction identifier.
query_id	integer	The query identifier of the stored procedure call.
record_time	timestamp	The time in UTC when the message was generated.
log_level	char(10)	The log level of the generated message. Possible values are LOG, INFO, NOTICE, WARNING, and EXCEPTION.
message	char(1024)	The text of the generated message.

Column name	Data type	Description
line_number	integer	The line number of the generated message.

Sample queries

The following query shows sample output of SYS_PROCEDURE_MESSAGES.

```
select transaction_id, query_id, record_time, log_level, trim(message), line_number
from sys_procedure_messages;
```

```
transaction_id | query_id |          record_time          | log_level |          btrim
              | line_number

SYS_QUERY_DETAIL

Use SYS_QUERY_DETAIL to view details for queries at a step level. Each row represents a step from a particular WLM query with details. This view contains many types of queries such as DDL, DML, and utility commands (for example, copy and unload). Some columns might not be relevant depending on the query type. For example, external_scanned_bytes is not relevant to internal tables.

SYS_QUERY_DETAIL is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The identifier of the user who submitted the query.
query_id	bigint	The query identifier.
child_query_sequence	integer	The sequence of the rewritten user query, starting with 1.
stream_id	integer	The stream identifier of the query stream.
segment_id	integer	The segment identifier of the query running segment.
step_id	integer	The step identifier in a segment.
step_name	text	The step name in a segment. Possible values are aggregate , broadcast , delete, distribute , hash, hashjoin, insert, limit, merge, nestloop, parse, return, save, scan, sort, sortlimit , unique, and window.
table_id	integer	The table identifier for permanent table scans.
table_name	character(136)	The table name of the step that is being operated.
is_rrscan	character	A value that indicates whether a step is a scan

Column name	Data type	Description
		step. True (t) indicates that a range-restricted scan was used.
start_time	timestamp	The time when the query step began.
end_time	timestamp	The time when the query step completed.
duration	bigint	The amount of time (microseconds) spent on the step.
alert	text	The description of the alert event.
input_bytes	bigint	The input bytes for the current step.
input_rows	bigint	The input rows for the current step.
output_bytes	bigint	The output bytes for the current step.
output_rows	bigint	The output rows for the current step.
blocks_read	bigint	The number of block the step read.
blocks_write	bigint	The number of block the step wrote.
local_read_IO	bigint	The number of blocks read from local disk cache.

Column name	Data type	Description
remote_read_IO	bigint	The number of blocks read from remote.
source	text	The type of database object that was scanned. This column only has a value when the row's <i>step_name</i> value is scan.
data_skewness	integer	The skewness of output rows distribution among all steps. It is a number in the range of 0% to 100%. The larger the number, the more unbalanced is the distribution.
time_skewness	integer	The skewness of execution time distribution among all steps. It is a number in the range of 0% to 100%. The larger the number, the more unbalanced is the distribution.
is_active	character	The state of the query at the step level. Possible values are 't' that shows the step is actively running or 'f' that indicates the step completes running.
spilled_block_local_disk	bigint	The number of blocks spilled to local disk.

Column name	Data type	Description
spilled_block_remote_disk	bigint	The number of blocks spilled to Amazon Simple Storage Service.
step_attribute	character(64)	Contains information about the associated step. Possible values for scan steps: <code>multi-dimensional</code> .

Sample queries

The following example returns the output of `SYS_QUERY_DETAIL`.

The following query shows the query metadata detail at step level, including step name, `input_bytes`, `output_bytes`, `input_rows`, `output_rows`.

```
SELECT query_id,
       child_query_sequence,
       stream_id,
       segment_id,
       step_id,
       trim(step_name) AS step_name,
       duration,
       input_bytes,
       output_bytes,
       input_rows,
       output_rows
FROM sys_query_detail
WHERE query_id IN (193929)
ORDER BY query_id,
         stream_id,
         segment_id,
         step_id DESC;
```

Sample output.

```

```

To view the tables in your database in order from most used to least used, use the following example. Replace `sample_data_dev` with your own database. Note that this query will count queries starting when your cluster is created, but your system view data is not saved when your data warehouse is lacking space.

```

SELECT table_name, COUNT (DISTINCT query_id)
FROM SYS_QUERY_DETAIL
WHERE table_name LIKE 'sample_data_dev%'
GROUP BY table_name
ORDER BY COUNT(*) DESC;

```

```

+-----+-----+
|          table_name          | count |
+-----+-----+
| sample_data_dev.tickit.venue |      4 |
| sample_data_dev.myunload1.venue |      3 |
| sample_data_dev.tickit.listing |      1 |
| sample_data_dev.tickit.category |      1 |
| sample_data_dev.tickit.users |      1 |

| sample_data_dev.tickit.sales |      1 |
| sample_data_dev.tickit.event |      1 |
+-----+-----+

```

SYS_QUERY_HISTORY

Use `SYS_QUERY_HISTORY` to view details of user queries. Each row represents a user query with accumulated statistics for some of the fields. This view contains many types of queries, such as data definition language (DDL), data manipulation language (DML), copy, unload, and Amazon Redshift Spectrum. It contains both running and finished queries.

`SYS_QUERY_HISTORY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The identifier of the user who submitted the query.
query_id	bigint	The query identifier.
query_label	character(320)	The short name for the query.
transaction_id	bigint	The transaction identifier.
session_id	integer	The process identifier of the process running the query.
database_name	character(128)	The name of the database the user was connected to when the query was issued.
query_type	character(32)	The type of query, such as, SELECT, INSERT, UPDATE, UNLOAD, COPY, COMMAND, DDL, UTILITY, CTAS, and OTHER.
status	character(10)	The status of the query. Valid values: planning, queued, running, returning, failed, canceled, and success.
result_cache_hit	Boolean	Indicates whether the query matches the result cache.
start_time	timestamp	The time when the query began.
end_time	timestamp	The time when the query completed.

Column name	Data type	Description
elapsed_time	bigint	The total amount of time (microseconds) spent on the query.
queue_time	bigint	The total time (microseconds) spent on the service class query queue.
execution_time	bigint	The total time (microseconds) running in the service class.
error_message	character(512)	The reason a query failed.
returned_rows	bigint	The number of rows returned to the client.
returned_bytes	bigint	The number of bytes returned to the client.
query_text	character(4000)	The query string. This string might be truncated.
redshift_version	character(256)	The Amazon Redshift version when the query ran.
usage_limit	character(150)	List of usage limit IDs reached by the query.

Column name	Data type	Description
compute_type	varchar(32)	Indicates whether the query runs on the main cluster or concurrency scaling cluster. Possible values are <code>primary</code> (query runs on the main cluster), <code>secondary</code> (query runs on the secondary cluster), or <code>primary-scale</code> (query runs on the concurrency cluster). This is only applicable to provisioned cluster.
compile_time	bigint	The total time (microseconds) spent on compilation of the query.
planning_time	bigint	The total time (microseconds) spent on planning of the query.
lock_wait_time	bigint	The total time (microseconds) spent on waiting for relation lock.
service_class_id	integer	The service class's ID. For a list of service class IDs, go to WLM service class IDs . This column is only used for queries run on provisioned clusters. For queries run on Redshift Serverless, this column contains -1.

Column name	Data type	Description
service_class_name	character(64)	<p>The service class name.</p> <p>This column is only used for queries run on provisioned clusters. For queries run on Amazon Redshift Redshift Serverless, this column is empty.</p>
query_priority	character(20)	<p>The priority of the queue in which the query ran. Possible values are as follows:</p> <ul style="list-style-type: none">• NULL• lowest• low• normal• high• highest <p>NULL means that query priority isn't supported for the query.</p> <p>This column is only used for queries run on provisioned clusters. For queries run on Redshift Serverless, this column is empty.</p>

Column name	Data type	Description
short_query_accelerated	character(10)	<p>Whether the query was accelerated using short query acceleration (SQA). Possible values are as follows:</p> <ul style="list-style-type: none">• true• false• NULL <p>This column is only used for queries run on provisioned clusters. For queries run on Redshift Serverless, this column is empty.</p>

Sample queries

The following query returns running and queued queries.

```
SELECT user_id,  
       query_id,  
       transaction_id,  
       session_id,  
       status,  
       trim(database_name) AS database_name,  
       start_time,  
       end_time,  
       result_cache_hit,  
       elapsed_time,  
       queue_time,  
       execution_time  
FROM sys_query_history  
WHERE status IN ('running', 'queued')  
ORDER BY start_time;
```

Sample output.

```

user_id | query_id | transaction_id | session_id | status | database_name |
start_time          |          end_time          | result_cache_hit | elapsed_time |
queue_time | execution_time
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----

2022-02-15 19:03:19.67849 | 2022-02-15 19:03:19.739811 | f              |              |
61321 |           0 |              0

```

The following query returns the query start time, end time, queue time, elapsed time, planning time, and other metadata for a specific query.

```

SELECT user_id,
       query_id,
       transaction_id,
       session_id,
       status,
       trim(database_name) AS database_name,
       start_time,
       end_time,
       result_cache_hit,
       elapsed_time,
       queue_time,
       execution_time,
       planning_time,
       trim(query_text) as query_text
FROM sys_query_history
WHERE query_id = 3093;

```

Sample output.

```

user_id | query_id | transaction_id | session_id | status | database_name |
start_time          |          end_time          | result_cache_hit | elapsed_time |
queue_time | execution_time | planning_time | query_text
-----+-----+-----+-----+-----+-----

```

The following query lists the 10 most recent SELECT queries.

```
SELECT query_id,
       transaction_id,
       session_id,
       start_time,
       elapsed_time,
       queue_time,
       execution_time,
       returned_rows,
       returned_bytes
FROM sys_query_history
WHERE query_type = 'SELECT'
ORDER BY start_time DESC limit 10;
```

Sample output.

COMMAND		92

SYS_QUERY_TEXT

Use `SYS_QUERY_TEXT` to view the query text of all queries. Each row represents the query text of queries up to 4000 characters starting with sequence number 0. When the query statement contains more than 4000 characters, additional rows are logged for the statement by incrementing the sequence number for each row. This view logs all user query text such as DDL, utility, Amazon Redshift queries, and leader-node only queries.

`SYS_QUERY_TEXT` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The identifier of the user who submitted the query.
<code>query_id</code>	bigint	The query identifier.
<code>transaction_id</code>	bigint	The identifier of the transaction associated with the statement.
<code>session_id</code>	integer	The process identifier of the session running the query.
<code>start_time</code>	timestamp	The time when the query starts.
<code>sequence</code>	integer	When a single statement contains more than 4000 characters, additional rows

Column name	Data type	Description
		are logged for the statement . Sequence 0 is the first row, 1 is the second row, and so on.
text	character (4000)	The text of the SQL query that is in 4000-character increments. This field might contain special characters, such as backslash (\) and newline (\n).

Sample queries

The following query returns running and queued queries.

```
SELECT user_id,
       query_id,
       transaction_id,
       session_id, start_time,
       sequence, trim(text) as text from sys_query_text
ORDER BY sequence;
```

Sample output.

```
user_id | query_id | transaction_id | session_id |          start_time          |

SYS_RESTORE_LOG

Use `SYS_RESTORE_LOG` to monitor the migration progress of each table in the cluster during a classic resize to RA3 nodes. It captures the historic throughput of data migration during the resize operation. For more information about classic resize to RA3 nodes, see [Classic resize](#).

`SYS_RESTORE_LOG` is visible only to superusers.

Table columns

Column name	Data type	Description
<code>event_time</code>	timestamp	A timestamp that indicates when the log entry is recorded.
<code>database_name</code>	char(128)	The name of the database.
<code>schema_name</code>	char(128)	The name of the schema.
<code>table_name</code>	char(128)	The name of the table.

Column name	Data type	Description
table_id	integer	The ID of the table.
action	char(128)	The action taken at the time of the entry. Values can include: Migration started, checkpoint, resumed, completed, cancelled, or reset.
table_size	long	The size of the table.
total_data_processed	long	The size of the data in MB processed up to this point for the table.
delta_data_processed	long	Size of data processed since the last event_time update, in MB. This helps you determine how much of the data has been processed since the previous recorded time interval. You can compare this with the table_size to get a sense of how quickly data processing is going.
message	char(512)	A detailed explanation for the value in the action column.
redistribution_type	char(32)	The redistribution type for the table. Either KEY conversion or an EVEN rebalancing task. For more information about distribution styles, see Distribution styles .

Sample queries

The following query calculates the throughput of data processing, using SYS_RESTORE_LOG.

```
SELECT
  ROUND(sum(delta_data_processed) / 1024.0, 2) as data_processed_gb,
  ROUND(datediff(sec, min(event_time), max(event_time)) / 3600.0, 2) as duration_hr,
  ROUND(data_processed_gb/duration_hr, 2) as throughput_gb_per_hr
from sys_restore_log;
```

Sample output.

```
data_processed_gb | duration_hr | throughput_gb_per_hr
-----+-----+-----
                0.91 |          8.37 |                0.11
(1 row)
```

The following query that shows all redistribution types.

```
SELECT * from sys_restore_log ORDER BY event_time;
```

```
database_name |      schema_name      |      table_name      | table_id |

```

SYS_RESTORE_STATE

Use `SYS_RESTORE_STATE` to monitor the migration progress of each table during a classic resize. This is specifically applicable when the target node type is RA3. For more information about classic resize to RA3 nodes, see [Classic resize](#).

`SYS_RESTORE_STATE` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The identifier of the user who submitted the query.
<code>database_name</code>	char(64)	The name of the database of the table.
<code>schema_id</code>	integer	The schema ID of the table.
<code>table_id</code>	integer	The ID of the table.
<code>table_name</code>	char(128)	The name of the table.

Column name	Data type	Description
redistribution_status	char(128)	The status of redistribution progress of the table. Possible values are Completed , In progress, and Pending.
percentage_redistributed	float	The percentage of the redistribution progress of the table. Possible values are from 0 to 100%. For example, a value of 25 indicates that 25% of the data is redistributed.
redistribution_type	char(32)	The redistribution type for the table. Either KEY conversion or an EVEN rebalancing task. For more information about distribution styles, see Distribution styles .

Sample queries

The following query returns records for running and queued queries.

```
SELECT * FROM sys_restore_state;
```

Sample output.

```
userid | database_name | schema_id | table_id | table_name | redistribution_status
| percentage_redistributed | redistribution_type
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
      1 | test1        | 124865   | 124878 | customer_key_4 | Pending
|      0 |              |         |         | Rebalance Disteven Table
```

1		dev		124865		124874		customer_key_3		Pending
				0				Rebalance Disteven Table		
1		dev		124865		124870		customer_key_2		Completed
				100				Rebalance Disteven Table		
1		dev		124865		124866		customer_key_1		In progress
				13.52				Restore Distkey Table		

The following gives you the data-processing status.

```
SELECT
    redistribution_status, ROUND(SUM(block_count) / 1024.0, 2) AS total_size_gb
FROM sys_restore_state sys inner join stv_tbl_perm stv
    on sys.table_id = stv.id
GROUP BY sys.redistribution_status;
```

Sample output.

```
redistribution_status | total_size_gb
-----+-----
Completed            |           0.07
Pending              |           0.71
In progress          |           0.20
(3 rows)
```

SYS_SCHEMA_QUOTA_VIOLATIONS

Records the occurrence, transaction ID, and other useful information when a schema quota is exceeded. This system table is a translation of [STL_SCHEMA_QUOTA_VIOLATIONS](#).

`r_SYS_SCHEMA_QUOTA_VIOLATIONS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>owner_id</code>	integer	The ID of the schema owner.

Column name	Data type	Description
user_id	integer	The ID of the user who generated the entry.
transaction_id	bigint	The transaction ID associated with the statement.
session_id	integer	The process ID associated with the statement.
schema_id	integer	The namespace or schema ID.
schema_name	character (128)	The namespace or schema name.
quota	integer	The amount of disk space (in MB) that the schema can use.
disk_usage	integer	The disk space (in MB) that is currently used by the schema.
record_time	timestamp without time zone	The time when the violation occurred.

Sample queries

The following query shows the result of a quota violation:

```
SELECT user_id, TRIM(schema_name) "schema_name", quota, disk_usage, record_time FROM
sys_schema_quota_violations WHERE SCHEMA_NAME = 'sales_schema' ORDER BY timestamp DESC;
```

This query returns the following sample output for the specified schema:

```
user_id| schema_name | quota | disk_usage | record_time
-----+-----+-----+-----+-----
104    | sales_schema | 2048  | 2798      | 2020-04-20 20:09:25.494723
(1 row)
```

SYS_SERVERLESS_USAGE

Use `SYS_SERVERLESS_USAGE` to view details of Amazon Redshift Serverless usage of resources. This system view doesn't apply to provisioned Amazon Redshift clusters.

This view contains the serverless usage summary including how much compute capacity is used to process queries and the amount of Amazon Redshift managed storage used at a 1-minute granularity. The compute capacity is measured in Redshift processing units (RPUs) and metered for the workloads that you run in RPU-seconds on a per-second basis. RPUs are used to process queries on the data loaded in the data warehouse, queried from an Amazon S3 data lake, or accessed from operational databases using a federated query. Amazon Redshift Serverless retains the information in `SYS_SERVERLESS_USAGE` for 7 days.

For examples on compute cost billing, see [Billing for Amazon Redshift Serverless](#).

`SYS_SERVERLESS_USAGE` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>start_time</code>	timestamp	The time when the interval began.
<code>end_time</code>	timestamp	The time when the interval completed.
<code>compute_seconds</code>	double precision	The accumulated compute unit (RPU) seconds consumed during this time interval. This value accounts for the base RPU capacity allocated for the account.
<code>compute_capacity</code>	double precision	The average number of compute units (Redshift processing units, or RPUs)

Column name	Data type	Description
		allocated during this time interval. The compute_capacity value can be dynamically changed.
data_storage	integer	The average data storage space in MB used during this time interval. Used data storage can change dynamically as data is loaded or deleted from the database.
cross_region_transferred_data	integer	The accumulated data transferred for cross-Region data sharing in bytes during this time interval.
charged_seconds	integer	The accumulated compute unit (RPU) seconds charged during this time interval. This is computed after transactions end, and hence can be 0 while a transaction runs. Use charged_seconds to calculate cost for an Amazon Redshift Serverless workgroup. This value accounts for the RPU capacity allocated for the Amazon Redshift Serverless workgroup.

Usage notes

- There are situations where `compute_seconds` is 0 but `charged_seconds` is greater than 0, or vice versa. This is normal behavior resulting from the way data is recorded in the system view. For a more accurate representation of serverless usage details, we recommend aggregating the data.

Example

To get the total charges for RPU hours used for a time interval by querying `charged_seconds`, run the following query:

```
select trunc(start_time) "Day",
(sum(charged_seconds)/3600::double precision) * <Price for 1 RPU> as cost_incurred
from sys_serverless_usage
group by 1
order by 1
```

Note that there can be idle time during the interval. Idle time doesn't add to RPUs consumed.

SYS_SESSION_HISTORY

Use the `SYS_SESSION_HISTORY` to view information about the current active sessions and session history.

`SYS_SESSION_HISTORY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	<code>char(50)</code>	The identifier of the user who generated the entry.
<code>session_id</code>	<code>integer</code>	The ID of the session associated with the statement.
<code>database_name</code>	<code>char(50)</code>	The name of the database.

Column name	Data type	Description
status	char	The status of the session. Possible values are active, timed out, and closed.
session_timeout	integer	The maximum time in seconds that a session remains inactive or idle before timing out. 0 indicates that no timeout is set.
start_time	timestamp	The timestamp that the connection was established.
end_time	timestamp	The timestamp that the connected stopped.

Example

The following is a sample output of SYS_SESSION_HISTORY.

```
select * from sys_session_history;
 user_id | session_id | database_name | status | session_timeout |
 start_time          |          end_time

SYS_SPATIAL_SIMPLIFY

You can query the system view `SYS_SPATIAL_SIMPLIFY` to get information about simplified spatial geometry objects using the `COPY` command. When you use `COPY` on a shapefile, you can specify `SIMPLIFY tolerance`, `SIMPLIFY AUTO`, and `SIMPLIFY AUTO max_tolerance` ingestion options. The result of the simplification is summarized in `SYS_SPATIAL_SIMPLIFY` system view.

When `SIMPLIFY AUTO max_tolerance` is set, this view contains a row for each geometry that exceeded the maximum size. When `SIMPLIFY tolerance` is set, then one row for the entire `COPY` operation is stored. This row references the `COPY` query ID and the specified simplification tolerance.

For more information about loading a shapefile, see [Loading a shapefile into Amazon Redshift](#).

`SYS_SPATIAL_SIMPLIFY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>query_id</code>	<code>bigint</code>	The ID of the query (<code>COPY</code> command) that generated this row.
<code>line_number</code>	<code>bigint</code>	When <code>COPY SIMPLIFY AUTO</code> option is specified, this value is the record number of the simplified record in the shapefile.
<code>maximum_tolerance</code>	<code>double precision</code>	The distance tolerance value specified in the <code>COPY</code> command. This is either the maximum tolerance value using the <code>SIMPLIFY AUTO</code> option, or the fixed tolerance value using the <code>SIMPLIFY</code> option.
<code>initial_size</code>	<code>bigint</code>	The size in bytes of the <code>GEOMETRY</code> data value before simplification.
<code>simplified</code>	<code>char(1)</code>	When the <code>COPY SIMPLIFY AUTO</code> option is specified, <code>t</code> if the geometry was successfully simplified, or <code>f</code> otherwise.

Column name	Data type	Description
		The geometry might not be simplified successfully if after the simplification with the given maximum tolerance its size is still larger than the maximum geometry size.
final_size	bigint	When the COPY SIMPLIFY AUTO option is specified, this is the size in bytes of the geometry after simplification.
final_tolerance	double precision	Final tolerance chosen for the simplification.

Sample query

The following query returns the list of records that COPY simplified.

```
SELECT * FROM sys_spatial_simplify;
```

```

query_id | line_number | maximum_tolerance | initial_size | simplified | final_size |
final_tolerance

```

SYS_STREAM_SCAN_ERRORS

Records errors for records loaded via streaming ingestion.

SYS_STREAM_SCAN_ERRORS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
external_schema_name	character (128)	The name of the Kinesis stream or Amazon MSK topic's schema. It is case sensitive.
stream_name	character (255)	The name of the stream or topic. It is case sensitive.
mv_name	character (128)	The name of the associated materialized view. Empty if none. It is case sensitive.
transaction_id	bigint	The transaction ID.
query_id	bigint	The query ID.
stream_timestamp_type	character (1)	The type of the stream timestamp. It is case sensitive.
stream_timestamp	timestamp without time zone	The time when the record arrived.
record_time	timestamp without time zone	The time when the error message was logged.
partition_id	character (128)	The partition/shard id. It is case sensitive.
position	character (128)	The position of the record. This corresponds with the sequence number in Kinesis or the offset in Amazon MSK. It is case sensitive.

Column name	Data type	Description
error_code	integer	The error code.
error_reason	character (128)	The error reason. It is case sensitive.

SYS_STREAM_SCAN_STATES

Records scan states for records loaded via streaming ingestion.

SYS_STREAM_SCAN_STATES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
external_schema_name	character (128)	The external schema name. It is case sensitive.
stream_name	character (255)	The stream name. It is case sensitive.
mv_name	character (128)	The name of the associated materialized view. Empty if none. It is case sensitive.
transaction_id	bigint	The transaction ID.
query_id	bigint	The query ID.
record_time	timestamp without	The time when the data was logged.

Column name	Data type	Description
	time zone	
partition_id	character (128)	The partition or shard id. It is case sensitive.
latest_position	character (128)	The position of the last record read in the batch. This corresponds with the sequence number in Kinesis or the offset in Amazon MSK. It is case sensitive.
scanned_rows	bigint	The number of records that were scanned in the batch.
skipped_rows	bigint	The number of records that were skipped in the batch.
scanned_bytes	bigint	The number of bytes that were scanned in the batch.
stream_record_time_min	timestamp without time zone	Kinesis or Amazon MSK arrival time for the earliest record in the batch.
stream_record_time_max	timestamp without time zone	Kinesis or Amazon MSK arrival time for the latest record in the batch.

The following query shows stream and topic data for specific queries.

```
select
  query_id,mv_name::varchar,external_schema_name::varchar,stream_name::varchar,sum(scanned_rows)
  total_records,
sum(scanned_bytes) total_bytes from sys_stream_scan_states where query in
(5401180,8601939) group by 1,2,3,4;
```

```

query_id | mv_name | external_schema_name | stream_name | total_records |
total_bytes
-----+-----+-----+-----+-----
+-----
5401180 | kinesitest | kinesis | kinesistream | 1493255696 |
3209006490704
8601939 | msktest | msk | mskstream | 14677023 |
31056580668
(2 rows)

```

SYS_TRANSACTION_HISTORY

Use SYS_TRANSACTION_HISTORY to see details of a transaction when tracking a query.

SYS_TRANSACTION_HISTORY is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	ID of the user who generated the entry.
transaction_id	bigint	The ID of the transaction.
isolation_level	text	The isolation level of the transaction. Possible values are <code>Serializable</code> and <code>Snapshot Isolation</code> .
status	text	The status of the transaction. Possible statuses are <code>committed</code> and <code>rolledback</code> .
transaction_start_time	timestamp	The start time of the transaction.

Column name	Data type	Description
commit_start_time	timestamp	The start time of the commit.
commit_end_time	timestamp	The end time of the commit.
blocks_committed	bigint	The number of blocks that had to be written as part of this commit.
undo_transaction_id	bigint	The ID of the undo transaction if any transactions have been undone. Otherwise, this value is -1.

Sample queries

```
select * from sys_transaction_history order by transaction_start_time desc;
```

```

user_id | transaction_id | isolation_level | status   | transaction_start_time
| commit_start_time | commit_end_time | blocks_committed |
undo_transaction_id

```

SYS_UDF_LOG

Records system-defined error and warning messages generated during user-defined function (UDF) execution.

SYS_UDF_LOG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
query_id	bigint	The query identifier.
function_name	text	The name of the user-defined function.
record_time	timestamp	The time that the record was created.
sequence	integer	The sequence of a single log message.
message	text	The log message text.

Sample queries

The following example shows how UDFs handle system-defined errors. The first block shows the definition for a UDF function that returns the inverse of an argument. When you run the function and provide a 0 as your argument, the function returns an error. The last statement returns the error message logged in SYS_UDF_LOG.

```
-- Create a function to find the inverse of a number.
CREATE OR REPLACE FUNCTION f_udf_inv(a int)

RETURNS float

IMMUTABLE AS $$return 1/a

$$ LANGUAGE plpythonu;

-- Run the function with 0 to create an error.
Select f_udf_inv(0);

-- Query SYS_UDF_LOG to view the message.
Select query_id, record_time, message::varchar from sys_udf_log;
```

```
query_id | record_time | message
```

```

-----+-----
+-----
2211      | 2023-08-23 15:53:11.360538 | ZeroDivisionError: integer division or
         | modulo by zero line 2, in f_udf_inv\n return 1/a\n

```

The following example adds logging and a warning message to the UDF so that a divide by zero operation results in a warning message instead of stopping with an error message.

```

-- Create a function to find the inverse of a number and log a warning if you input 0.
CREATE OR REPLACE FUNCTION f_udf_inv_log(a int)
  RETURNS float IMMUTABLE
  AS $$
  import logging
  logger = logging.getLogger() #get root logger
  if a==0:
    logger.warning('You attempted to divide by zero.\nReturning zero instead of error.
\n')
    return 0
  else:
    return 1/a
$$ LANGUAGE plpythonu;

-- Run the function with 0 to trigger the warning.
Select f_udf_inv_log(0);

-- Query SYS_UDF_LOG to view the message.
Select query_id, record_time, message::varchar from sys_udf_log;

 query_id |          record_time          | message
-----+-----
          0 | 2023-08-23 16:10:48.833503 | WARNING: You attempted to divide by zero.
\nReturning zero instead of error.\n

```

SYS_UNLOAD_DETAIL

Use `SYS_UNLOAD_DETAIL` to view details of an UNLOAD operation. It records one row for each file created by an UNLOAD statement. For example, if an UNLOAD creates 12 files, `SYS_UNLOAD_DETAIL` will contain 12 corresponding rows.

`SYS_UNLOAD_DETAIL` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The identifier of the user who generated the entry.
query_id	integer	The query identifier of the UNLOAD command.
session_id	integer	The ID of the process associated with the query statement.
transaction_id	bigint	The ID of the transaction associated with the query statement.
file_name	character (1280)	The complete Amazon S3 object path for the file.
start_time	timestamp	The time when the transaction began.
end_time	timestamp	The time when the transaction completed.
line_count	bigint	The number of lines (rows) unloaded to the file.
transfer_size	bigint	The number of bytes transferred.
file_format	character (10)	The file format of the unloaded files.

Sample queries

The following query shows the unloaded query details, including format, rows, and file count of unload command.

```
select query_id, substring(file_name, 0, 50), transfer_size, file_format from
sys_unload_detail;
```

Sample output.

```
query_id | substring | transfer_size
| file_format

395689 | Text
(6 rows)
```

SYS_UNLOAD_HISTORY

Use `SYS_UNLOAD_HISTORY` to view details of `UNLOAD` commands. Each row represents a `UNLOAD` command with accumulated statistics for some of the fields. It contains both running and finished `UNLOAD` commands.

`SYS_UNLOAD_HISTORY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The identifier of the user who submitted the unload.
query_id	bigint	The query identifier of the UNLOAD command.
transaction_id	bigint	The transaction identifier.
session_id	integer	The process identifier of the process running the unload.
database_name	text	The name of the database the user was connected to when the operation was issued.
status	text	The status of the UNLOAD command. Valid values include: running, completed , aborted, and unknown.
start_time	timestamp	The time when the unload began.
end_time	timestamp	The time when the unload completed.
duration	bigint	The amount of time (microseconds) spent in the UNLOAD command.
file_format	text	The file format of the output files.
compression_type	text	The compression type.

Column name	Data type	Description
unloaded_location	text	The Amazon S3 location of unloaded files.
unloaded_rows	bigint	The number of rows.
unloaded_files_count	bigint	The file count of the output file.
unloaded_files_size	bigint	The file size of the output file.
error_message	text	The error message of the UNLOAD command.

Sample queries

The following query shows the unloaded query details, including format, rows, and file count of unload command.

```
SELECT query_id,
       file_format,
       start_time,
       duration,
       unloaded_rows,
       unloaded_files_count
FROM sys_unload_history
ORDER BY query_id,
file_format limit 100;
```

Sample output.

```
query_id | file_format |          start_time          | duration | unloaded_rows |
unloaded_files_count
-----+-----+-----+-----+-----+
527067 | Text       | 2022-02-09 05:18:35.844452 | 5932478 |          10 |
1
```

SYS_USERLOG

Records details for the following changes to a database user:

- Create user
- Drop user
- Alter user (rename)
- Alter user (alter properties)

You can query this view to see information about serverless workgroups and provisioned clusters.

SYS_USERLOG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
user_id	integer	The identifier of the user who submitted the unload.
user_name	character(50)	Username of the user affected by the change.
original_user_name	character(50)	The original username in a rename action. This field is empty for all other actions.
action	character(10)	The action that occurred. Valid values are alter, create, drop, and rename.
has_create_db_privs	integer	If true (a value of 1), the user has create database permissions.
is_superuser	integer	If true (a value of 1), the user can update system catalogs.

Column name	Data type	Description
has_update_catalog_privs	integer	If true (a value of 1), the user can update system catalogs.
password_expiration	timestamp	The password expiration date.
session_id	integer	The process ID.
transaction_id	bigint	The transaction ID.
record_time	timestamp	Time in UTC of when the query started.

Sample queries

The following example performs four user actions, then queries the SYS_USERLOG view.

```
CREATE USER userlog1 password 'Userlog1';
ALTER USER userlog1 createdb createuser;
ALTER USER userlog1 rename to userlog2;
DROP user userlog2;

SELECT user_id, user_name, original_user_name, action, has_create_db_privs,
       is_superuser from SYS_USERLOG order by record_time desc;
```

```
user_id | user_name | original_user_name | action | has_create_db_privs |
is_superuser
-----+-----+-----+-----+-----+-----+
  108 | userlog2 |                  | drop   |                    1 | 1
  108 | userlog2 |      userlog1     | rename |                    1 | 1
  108 | userlog1 |                  | alter  |                    1 | 1
  108 | userlog1 |                  | create |                    0 | 0
(4 rows)
```

SYS_VACUUM_HISTORY

Use `SYS_VACUUM_HISTORY` to view details of vacuum queries. For information on the `VACUUM` command, see [VACUUM](#).

`SYS_VACUUM_HISTORY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>user_id</code>	integer	The ID of the user who initiated the query.
<code>transaction_id</code>	long	The transaction ID for the <code>VACUUM</code> statement.
<code>query_id</code>	long	The query identifier for the <code>VACUUM</code> statement. You can join this table to the <code>SYS_QUERY_DETAIL</code> view to see the individual SQL statements that are run for a given <code>VACUUM</code> transaction. If you vacuum the whole database, each table is vacuumed in a separate transaction. For automated <code>VACUUM</code> operations, this value is null.
<code>database_name</code>	text	The name of the database.
<code>schema_name</code>	text	The name of the schema.
<code>table_name</code>	text	The name of the table.
<code>table_id</code>	integer	The ID of the table.

Column name	Data type	Description
<code>vacuum_type</code>	character	<p>The type of the VACUUM operation. Possible values are as follows:</p> <ul style="list-style-type: none">• Delete• Sort• Reindex• Recluster• Full <p>For more information on vacuum types, see VACUUM.</p>
<code>is_automatic</code>	boolean	<p><code>true</code> if the operation is an automatic vacuum. Otherwise, <code>false</code>.</p>
<code>status</code>	character	<p>Description of the current activity being done as part of the vacuum operation:</p> <ul style="list-style-type: none">• Initialize• Sort• Merge• Delete• Select• Failed• Complete• Skipped• Building INTERLEAVED SORTKEY order

Column name	Data type	Description
start_time	timestamp	The time the vacuum operation started.
end_time	timestamp	The time the vacuum operation ended. If the operation is ongoing, this field is blank.
record_time	timestamp	The time the vacuum operation was recorded in SYS_VACUUM_HISTORY.
duration	integer	The number of microseconds between the start and end of the vacuum operation. If the vacuum operation is ongoing, this field is blank.
rows_before_vacuum	bigint	The actual number of rows in the table plus any deleted rows that are still stored on disk (waiting to be vacuumed).
size_before_vacuum	integer	The size of the table before the vacuum operation began, in MB.
reclaimable_rows	bigint	The number of rows the vacuum operation estimates it will reclaim before starting.
reclaimed_rows	bigint	The number of rows the vacuum operation reclaimed.
reclaimed_blocks	bigint	The number of blocks the vacuum operation reclaimed.

Column name	Data type	Description
sortedrows_before_vacuum	integer	The number of sorted rows in the table before the vacuum operation started.
sortedrows_after_vacuum	integer	The additional number of sorted rows in the table after the vacuum operation finished. This doesn't include the rows counted in sortedrows_before_vacuum .

System view mapping for migrating to SYS monitoring views

When you migrate your Amazon Redshift provisioned cluster to Amazon Redshift Serverless, your monitoring or diagnostic queries might reference system views that are only available on provisioned clusters. You can update your queries to use the SYS monitoring views. This page provides provisioned-only to SYS view mappings for you to reference when updating your queries.

System monitoring (provisioned only)

The following system tables and views can be queried on provisioned clusters. STL and STV tables and views contain a subset of data found in several of the system tables. These provide quicker and easier access to commonly queried data found in those tables.

SVCS views provide details about queries on both the main and concurrency scaling clusters. SVL views provide information only for queries run on the main cluster, with the exception of SVL_STATEMENTTEXT. SVL_STATEMENTTEXT can contain information for queries run on concurrency scaling clusters as well as the main cluster.

STL views for logging

STL system views are generated from Amazon Redshift log files to provide a history of the system.

These files reside on every node in the data warehouse cluster. The STL views take the information from the logs and format them into usable views for system administrators.

Log retention – STL system views retain seven days of log history. Log retention is guaranteed for all cluster sizes and node types, and it isn't affected by changes in cluster workload. Log retention also isn't affected by cluster status, such as when the cluster is paused. You have less than seven days of log history only in the case where the cluster is new. You don't need to take any action to retain logs, but you have to periodically copy log data to other tables or unload it to Amazon S3 to keep log data that's more than 7 days old.

STL_AGGR

Analyzes aggregate execution steps for queries. These steps occur during execution of aggregate functions and GROUP BY clauses.

STL_AGGR is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_AGGR only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
slots	integer	Number of hash buckets.
occupied	integer	Number of slots that contain records.
maxlength	integer	Size of the largest slot.

Column name	Data type	Description
tbl	integer	Table ID.
is_diskbased	character(1)	If true (t), the query was run as a disk-based operation. If false (f), the query was run in memory.
workmem	bigint	Number of bytes of working memory assigned to the step.
type	character(6)	The type of step. Valid values are: <ul style="list-style-type: none"> HASHED. Indicates that the step used grouped, unsorted aggregation. PLAIN. Indicates that the step used ungrouped, scalar aggregation. SORTED. Indicates that the step used grouped, sorted aggregation.
resizes	integer	This information is for internal use only.
flushable	integer	This information is for internal use only.

Sample queries

Returns information about aggregate execution steps for SLICE 1 and TBL 239.

```
select query, segment, bytes, slots, occupied, maxlength, is_diskbased, workmem, type
from stl_aggr where slice=1 and tbl=239
order by rows
limit 10;
```

```
query | segment | bytes | slots | occupied | maxlength | is_diskbased | workmem |
type
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+

```

STL_ALERT_EVENT_LOG

Records an alert when the query optimizer identifies conditions that might indicate performance issues. Use the STL_ALERT_EVENT_LOG view to identify opportunities to improve query performance.

A query consists of multiple segments, and each segment consists of one or more steps. For more information, see [Query processing](#).

STL_ALERT_EVENT_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_ALERT_EVENT_LOG only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
pid	integer	Process ID associated with the statement and slice. The same query might have multiple PIDs if it runs on multiple slices.
xid	bigint	Transaction ID associated with the statement.
event	character (1024)	Description of the alert event.
solution	character (1024)	Recommended solution.
event_time	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .

Usage notes

You can use the `STL_ALERT_EVENT_LOG` to identify potential issues in your queries, then follow the practices in [Query performance tuning](#) to optimize your database design and rewrite your queries. `STL_ALERT_EVENT_LOG` records the following alerts:

- **Missing statistics**

Statistics are missing. Run ANALYZE following data loads or significant updates and use STATUPDATE with COPY operations. For more information, see [Amazon Redshift best practices for designing queries](#).

- **Nested loop**

A nested loop is usually a Cartesian product. Evaluate your query to ensure that all participating tables are joined efficiently.

- **Very selective filter**

The ratio of rows returned to rows scanned is less than 0.05. Rows scanned is the value of `rows_pre_user_filter` and rows returned is the value of rows in the [STL_SCAN](#) system view. Indicates that the query is scanning an unusually large number of rows to determine the result set. This can be caused by missing or incorrect sort keys. For more information, see [Sort keys](#).

- **Excessive ghost rows**

A scan skipped a relatively large number of rows that are marked as deleted but not vacuumed, or rows that have been inserted but not committed. For more information, see [Vacuuming tables](#).

- **Large distribution**

More than 1,000,000 rows were redistributed for hash join or aggregation. For more information, see [Data distribution for query optimization](#).

- **Large broadcast**

More than 1,000,000 rows were broadcast for hash join. For more information, see [Data distribution for query optimization](#).

- **Serial execution**

A `DS_DIST_ALL_INNER` redistribution style was indicated in the query plan, which forces serial execution because the entire inner table was redistributed to a single node. For more information, see [Data distribution for query optimization](#).

Sample queries

The following query shows alert events for four queries.

```
SELECT query, substring(event,0,25) as event,
```

```
substring(solution,0,25) as solution,
trim(event_time) as event_time from stl_alert_event_log order by query;
```

```
query |          event          |          solution          |          event_time
-----+-----+-----+-----
+-----+
 6567 | Missing query planner statist | Run the ANALYZE command      | 2014-01-03
18:20:58
 7450 | Scanned a large number of del | Run the VACUUM command to rec| 2014-01-03
21:19:31
 8406 | Nested Loop Join in the query | Review the join predicates to| 2014-01-04
00:34:22
29512 | Very selective query filter:r | Review the choice of sort key| 2014-01-06
22:00:00

(4 rows)
```

STL_ANALYZE

Records details for [ANALYZE](#) operations.

STL_ANALYZE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_ANALYZE_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who generated the entry.
xid	long	The transaction ID.
database	char(30)	The database name.
table_id	integer	The table ID.

Column name	Data type	Description
status	char(15)	The result of the analyze command. Possible values are Full, Skipped, and PredicateColumn .
rows	double	The total number of rows in the table.
modified_rows	double	The total number of rows that were modified since the last ANALYZE operation.
threshold_percent	integer	The value of the analyze_threshold_percent parameter.
is_auto	char(1)	The value is true (t) if the operation included an Amazon Redshift analyze operation by default. The value is false (f) if the ANALYZE command was run explicitly.
starttime	timestamp	The time in UTC that the analyze operation started running.
endtime	timestamp	The time in UTC that the analyze operation finished running.
prevtime	timestamp	The time in UTC that the table was previously analyzed.
num_predicate_cols	integer	The current number of predicate columns in the table.
num_new_predicate_cols	integer	The number of new predicate columns in the table since the previous analyze operation.
is_background	character(1)	The value is true (t) if the analysis was run by an automatic analyze operation. Otherwise, the value is false (f).
auto_analyze_phase	character(100)	Reserved for internal use.
schema_name	char(128)	The schema name for the table.

Column name	Data type	Description
table_name	char(136)	The name of the table.

Sample queries

The following example joins STV_TBL_PERM to show the table name and execution details.

```
select distinct a.xid, trim(t.name) as name, a.status, a.rows, a.modified_rows,
  a.starttime, a.endtime
from stl_analyze a
join stv_tbl_perm t on t.id=a.table_id
where name = 'users'
order by starttime;
```

xid	name	status	rows	modified_rows	starttime	endtime
1582	users	Full	49990	49990	2016-09-22 22:02:23	2016-09-22 22:02:28
244287	users	Full	24992	74988	2016-10-04 22:50:58	2016-10-04 22:51:01
244712	users	Full	49984	24992	2016-10-04 22:56:07	2016-10-04 22:56:07
245071	users	Skipped	49984	0	2016-10-04 22:58:17	2016-10-04 22:58:17
245439	users	Skipped	49984	1982	2016-10-04 23:00:13	2016-10-04 23:00:13

(5 rows)

STL_ANALYZE_COMPRESSION

Records details for compression analysis operations during COPY or ANALYZE COMPRESSION commands.

STL_ANALYZE_COMPRESSION is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_ANALYZE_COMPRESSION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who generated the entry.
start_time	timestamp	The time when the compression analysis operation started.
xid	bigint	The transaction ID of the compression analysis operation.
tbl	integer	The table ID of the table that was analyzed.
tablename	character(128)	The name of the table that was analyzed.
col	integer	The index of the column in the table that was analyzed to determine the compression encoding.
old_encoding	character(15)	The encoding type before compression analysis.
new_encoding	character(15)	The encoding type after compression analysis.
mode	character(14)	The possible values are: PRESET Specifies that the <code>new_encoding</code> is determined by the Amazon Redshift <code>COPY</code> command based on the column data type. No data is sampled.

Column name	Data type	Description
		<p>ON</p> <p>Specifies that the <code>new_encoding</code> is determined by the Amazon Redshift COPY command based on an analysis of sample data.</p> <p>ANALYZE ONLY</p> <p>Specifies that the <code>new_encoding</code> is determined by the Amazon Redshift ANALYZE COMPRESSION command based on an analysis of sample data. However, the encoding type of the analyzed column is not changed.</p>
<code>best_compression_encoding</code>	<code>character(15)</code>	The encoding type that gives the best compression ratio.
<code>recommended_bytes</code>	<code>character(15)</code>	The bytes used by adopting the new encoding.
<code>best_compression_bytes</code>	<code>character(15)</code>	The bytes used by adopting the best compression encoding.
<code>ndv</code>	<code>bigint</code>	The number of distinct values in the sampled rows.

Sample queries

The following example inspects the details of compression analysis on the `lineitem` table by the last COPY command run in the same session.

```
select xid, tbl, btrim(tablename) as tablename, col, old_encoding, new_encoding,
       best_compression_encoding, mode
from stl_analyze_compression
where xid = (select xid from stl_query where query = pg_last_copy_id()) order by col;
```

```

xid | tbl | tablename | col | old_encoding | new_encoding |
best_compression_encoding | mode

STL_BCAST

Logs information about network activity during execution of query steps that broadcast data. Network traffic is captured by numbers of rows, bytes, and packets that are sent over the network

during a given step on a given slice. The duration of the step is the difference between the logged start and end times.

To identify broadcast steps in a query, look for bcast labels in the SVL_QUERY_SUMMARY view or run the EXPLAIN command and then look for step attributes that include bcast.

STL_BCAST is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_BCAST only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .

Column name	Data type	Description
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
packets	integer	Total number of packets sent over the network.

Sample queries

The following example returns broadcast information for the queries where there are one or more packets, and the difference between the start and end of the query was one second or more.

```
select query, slice, step, rows, bytes, packets, datediff(seconds, starttime, endtime)
from stl_bcast
where packets>0 and datediff(seconds, starttime, endtime)>0;
```

```
query | slice | step | rows | bytes | packets | date_diff
-----+-----+-----+-----+-----+-----+-----
  453 |     2 |     5 |     1 |    264 |         1 |         1
   798 |     2 |     5 |     1 |    264 |         1 |         1
 1408 |     2 |     5 |     1 |    264 |         1 |         1
 2993 |     0 |     5 |     1 |    264 |         1 |         1
 5045 |     3 |     5 |     1 |    264 |         1 |         1
 8073 |     3 |     5 |     1 |    264 |         1 |         1
 8163 |     3 |     5 |     1 |    264 |         1 |         1
 9212 |     1 |     5 |     1 |    264 |         1 |         1
 9873 |     1 |     5 |     1 |    264 |         1 |         1
(9 rows)
```

STL_COMMIT_STATS

Provides metrics related to commit performance, including the timing of the various stages of commit and the number of blocks committed. Query STL_COMMIT_STATS to determine what portion of a transaction was spent on commit and how much queuing is occurring.

STL_COMMIT_STATS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_TRANSACTION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
xid	bigint	Transaction id being committed.
node	integer	Node number. -1 is the leader node.
startqueue	timestamp	Start of queueing for commit.
startwork	timestamp	Start of commit.
endflush	timestamp	End of dirty block flush phase.
endstage	timestamp	End of metadata staging phase.
endlocal	timestamp	End of local commit phase.
startglobal	timestamp	Start of global phase.
endtime	timestamp	End of the commit.
queuelen	bigint	Number of transactions that were ahead of this transaction in the commit queue.
permblocks	bigint	Number of existing permanent blocks at the time of this commit.

Column name	Data type	Description
newblocks	bigint	Number of new permanent blocks at the time of this commit.
dirtyblocks	bigint	Number of blocks that had to be written as part of this commit.
headers	bigint	Number of block headers that had to be written as part of this commit.
numxids	integer	The number of active DML transactions.
oldestxid	bigint	The XID of the oldest active DML transaction.
extwritel atency	bigint	This information is for internal use only.
metadatar ritten	int	This information is for internal use only.
tombstone dblocks	<i>bigint</i>	This information is for internal use only.
tossedblo cks	bigint	This information is for internal use only.
batched_by	bigint	This information is for internal use only.

Sample query

```
select node, datediff(ms,startqueue,startwork) as queue_time,
datediff(ms, startwork, endtime) as commit_time, queuelen
from stl_commit_stats
where xid = 2574
order by node;
```

```
node | queue_time | commit_time | queuelen
-----+-----+-----+-----
```

```

-1 |          0 |          617 |          0
 0 | 444950725641 |          616 |          0
 1 | 444950725636 |          616 |          0

```

STL_CONNECTION_LOG

Logs authentication attempts and connections and disconnections.

STL_CONNECTION_LOG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_CONNECTION_LOG](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
event	character(50)	Connection or authentication event.
recordtime	timestamp	Time the event occurred.
remotehost	character(45)	Name or IP address of remote host.
remoteport	character(32)	Port number for remote host.
pid	integer	Process ID associated with the statement.
dbname	character(50)	Database name.
username	character(50)	User name.
authmethod	character(32)	Authentication method.
duration	integer	Duration of connection in microseconds.
sslversion	character(50)	Secure Sockets Layer (SSL) version.
sslcipher	character(128)	SSL cipher.

Column name	Data type	Description
mtu	integer	Maximum transmission unit (MTU).
sslcompression	character(64)	SSL compression type.
sslexpansion	character(64)	SSL expansion type.
iamauthguid	character(36)	The IAM authentication ID for the CloudTrail request.
application_name	character(250)	The initial or updated name of the application for a session.
os_version	character(64)	The version of the operating system that is on the client machine that connects to your Amazon Redshift cluster.
driver_version	character(64)	The version of ODBC or JDBC driver that connects to your Amazon Redshift cluster from your third-party SQL client tools.
plugin_name	character(32)	The name of the plugin used to connect to your Amazon Redshift cluster.

Column name	Data type	Description
protocol_version	integer	<p>The internal protocol version that the Amazon Redshift driver uses when establishing its connection with the server. The protocol versions is negotiated between the driver and server. The version describes the features available. Valid values include:</p> <ul style="list-style-type: none"> • 0 (BASE_SERVER_PROTOCOL_VERSION) • 1 (EXTENDED_RESULT_METADATA_SERVER_PROTOCOL_VERSION) – To save a round trip per query, the server sends extra result set metadata information. • 2 (BINARY_PROTOCOL_VERSION) – Depending on the data type of the result set, the server sends data in binary format. • 3 (EXTENDED2_RESULT_METADATA_SERVER_PROTOCOL_VERSION) – The server sends case sensitivity (collation) information of a column.
sessionid	character(36)	The globally unique identifier for the current session. The session ID persists through node failure restarts.
compression	character(16)	The compression algorithm in use for the connection.

Sample queries

To view the details for open connections, run the following query.

```
select recordtime, username, dbname, remotehost, remoteport
from stl_connection_log
where event = 'initiating session'
and pid not in
(select pid from stl_connection_log
where event = 'disconnecting session')
order by 1 desc;
```

```

recordtime          | username      | dbname      | remotehost        | remoteport
-----+-----+-----+-----+-----
2014-11-06 20:30:06 | rdsdb        | dev         | [local]           |
2014-11-06 20:29:37 | test001      | test        | 10.49.42.138     | 11111
2014-11-05 20:30:29 | rdsdb        | dev         | 10.49.42.138     | 33333
2014-11-05 20:28:35 | rdsdb        | dev         | [local]           |
(4 rows)

```

The following example reflects a failed authentication attempt and a successful connection and disconnection.

```

select event, recordtime, remotehost, username
from stl_connection_log order by recordtime;

          event          |          recordtime          | remotehost | username
-----+-----+-----+-----
authentication failure | 2012-10-25 14:41:56.96391 | 10.49.42.138 | john
authenticated          | 2012-10-25 14:42:10.87613 | 10.49.42.138 | john
initiating session     | 2012-10-25 14:42:10.87638 | 10.49.42.138 | john
disconnecting session  | 2012-10-25 14:42:19.95992 | 10.49.42.138 | john
(4 rows)

```

The following example shows the version of the ODBC driver, the operating system on the client machine, and the plugin used to connect to the Amazon Redshift cluster. In this example, the plugin used is for standard ODBC driver authentication using a login name and password.

```

select driver_version, os_version, plugin_name from stl_connection_log;

driver_version          | os_version          | plugin_name
-----+-----+-----
Amazon Redshift ODBC Driver 1.4.15.0001 | Darwin 18.7.0 x86_64 | none

```

```
Amazon Redshift ODBC Driver 1.4.15.0001 | Linux 4.15.0-101-generic x86_64 | none
```

The following example shows the version of the operating system on the client machine, the driver version, and the protocol version.

```
select os_version, driver_version, protocol_version from stl_connection_log;
```

os_version	driver_version	protocol_version
Linux 4.15.0-101-generic x86_64	Redshift JDBC Driver 2.0.0.0	2
Linux 4.15.0-101-generic x86_64	Redshift JDBC Driver 2.0.0.0	2
Linux 4.15.0-101-generic x86_64	Redshift JDBC Driver 2.0.0.0	2

STL_DDLTEXT

Captures the following DDL statements that were run on the system.

These DDL statements include the following queries and objects:

- CREATE SCHEMA, TABLE, VIEW
- DROP SCHEMA, TABLE, VIEW
- ALTER SCHEMA, TABLE

See also [STL_QUERYTEXT](#), [STL_UTILITYTEXT](#), and [SVL_STATEMENTTEXT](#). These views provide a timeline of the SQL commands that are run on the system; this history is useful for troubleshooting and for creating an audit trail of all system activities.

Use the `STARTTIME` and `ENDTIME` columns to find out which statements were logged during a given time period. Long blocks of SQL text are broken into lines 200 characters long; the `SEQUENCE` column identifies fragments of text that belong to a single statement.

`STL_DDLTEXT` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
xid	bigint	Transaction ID associated with the statement.
pid	integer	Process ID associated with the statement.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter is not set, this field is blank.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
sequence	integer	When a single statement contains more than 200 characters, additional rows are logged for that statement. Sequence 0 is the first row, 1 is the second, and so on.
text	character(200)	SQL text, in 200-character increments. This field might contain special characters such as backslash (\\) and newline (\n).

Sample queries

The following query returns records that include previously run DDL statements.

```
select xid, starttime, sequence, substring(text,1,40) as text
```

```
from stl_ddltext order by xid desc, sequence;
```

The following is sample output that shows four CREATE TABLE statements. The DDL statements appear in the text column, which is truncated for readability.

```
xid |          starttime          | sequence |          text
-----+-----+-----
+-----+-----+-----
1806 | 2013-10-23 00:11:14.709851 |         0 | CREATE TABLE supplier ( s_supkey int4
N
1806 | 2013-10-23 00:11:14.709851 |         1 | s_comment varchar(101) NOT NULL )
1805 | 2013-10-23 00:11:14.496153 |         0 | CREATE TABLE region ( r_regionkey int4
N
1804 | 2013-10-23 00:11:14.285986 |         0 | CREATE TABLE partsupp ( ps_partkey int8
1803 | 2013-10-23 00:11:14.056901 |         0 | CREATE TABLE part ( p_partkey int8 NOT
N
1803 | 2013-10-23 00:11:14.056901 |         1 | ner char(10) NOT NULL , p_retailprice
nu
(6 rows)
```

Reconstructing Stored SQL

The following SQL lists rows stored in the text column of STL_DDLTEXT. The rows are ordered by xid and sequence. If the original SQL was longer than 200 characters multiple rows, STL_DDLTEXT can contain multiple rows by sequence.

```
SELECT xid, sequence, LISTAGG(CASE WHEN LEN(RTRIM(text)) = 0 THEN text ELSE RTRIM(text)
END, '') WITHIN GROUP (ORDER BY sequence) as query_statement
FROM stl_ddltext GROUP BY xid, sequence ORDER BY xid, sequence;
```

```
xid      | sequence | query_statement
-----+-----+-----
7886671  |         0 | create external schema schema_spectrum_uddh\nfrom data catalog
\ndatabase 'spectrum_db_uddh'\niam_role ''\ncreate external database if not exists;
7886752  |         0 | CREATE EXTERNAL TABLE schema_spectrum_uddh.soccer_league\n(\n
league_rank smallint,\n prev_rank smallint,\n club_name varchar(15),\n
league_name varchar(20),\n league_off decimal(6,2),\n le
7886752  |         1 | ague_def decimal(6,2),\n league_spi decimal(6,2),\n
league_nspi smallint\n)\nROW FORMAT DELIMITED \n  FIELDS TERMINATED BY ',' \n
LINES TERMINATED BY '\\n\\l'\nstored as textfile\nLOCATION 's
```

```
7886752      2          3://mybucket-spectrum-uddh/'\ntable properties
('skip.header.line.count'='1');
...
```

To reconstruct the SQL stored in the text column of STL_DDLTEXT, run the following SQL statement. It puts together DDL statements from one or more segments in the text column. Before running the reconstructed SQL, replace any (\n) special characters with a new line in your SQL client. The results of the following SELECT statement puts together three rows in sequence order to reconstruct the SQL, in the query_statement field.

```
SELECT LISTAGG(CASE WHEN LEN(RTRIM(text)) = 0 THEN text ELSE RTRIM(text) END) WITHIN
GROUP (ORDER BY sequence) as query_statement
FROM stl_ddltext GROUP BY xid, endtime order by xid, endtime;
```

```
query_statement
-----
create external schema schema_spectrum_uddh\nfrom data catalog\ndatabase
'spectrum_db_uddh'\niam_role ''\ncreate external database if not exists;
CREATE EXTERNAL TABLE schema_spectrum_uddh.soccer_league\n(\n league_rank smallint,\n\n prev_rank smallint,\n\n club_name varchar(15),\n\n league_name varchar(20),\n\n league_off decimal(6,2),\n\n league_def decimal(6,2),\n\n league_spi decimal(6,2),\n\n league_nspi smallint\n)\nROW FORMAT DELIMITED \n  FIELDS TERMINATED BY ',' \n
LINES TERMINATED BY '\\n\\l'\nstored as textfile\nLOCATION 's3://mybucket-spectrum-
uddh/'\ntable properties ('skip.header.line.count'='1');
```

STL_DELETE

Analyzes delete execution steps for queries.

STL_DELETE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_DELETE only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
tbl	integer	Table ID.

Sample queries

In order to create a row in STL_DELETE, the following example inserts a row into the EVENT table and then deletes it.

First, insert a row into the EVENT table and verify that it was inserted.

```
insert into event(eventid,venueid,catid,dateid,eventname)
values ((select max(eventid)+1 from event),95,9,1857,'Lollapalooza');
```

```
select * from event
where eventname='Lollapalooza'
order by eventid;
```

eventid	venueid	catid	dateid	eventname	starttime
4274	102	9	1965	Lollapalooza	2008-05-01 19:00:00
4684	114	9	2105	Lollapalooza	2008-10-06 14:00:00
5673	128	9	1973	Lollapalooza	2008-05-01 15:00:00
5740	51	9	1933	Lollapalooza	2008-04-17 15:00:00
5856	119	9	1831	Lollapalooza	2008-01-05 14:00:00
6040	126	9	2145	Lollapalooza	2008-11-15 15:00:00
7972	92	9	2026	Lollapalooza	2008-07-19 19:30:00
8046	65	9	1840	Lollapalooza	2008-01-14 15:00:00
8518	48	9	1904	Lollapalooza	2008-03-19 15:00:00
8799	95	9	1857	Lollapalooza	

(10 rows)

Now, delete the row that you added to the EVENT table and verify that it was deleted.

```
delete from event
where eventname='Lollapalooza' and eventid=(select max(eventid) from event);
```

```
select * from event
where eventname='Lollapalooza'
order by eventid;
```

eventid	venueid	catid	dateid	eventname	starttime
4274	102	9	1965	Lollapalooza	2008-05-01 19:00:00
4684	114	9	2105	Lollapalooza	2008-10-06 14:00:00
5673	128	9	1973	Lollapalooza	2008-05-01 15:00:00
5740	51	9	1933	Lollapalooza	2008-04-17 15:00:00
5856	119	9	1831	Lollapalooza	2008-01-05 14:00:00
6040	126	9	2145	Lollapalooza	2008-11-15 15:00:00

```

7972 |      92 |      9 |   2026 | Lollapalooza | 2008-07-19 19:30:00
8046 |      65 |      9 |   1840 | Lollapalooza | 2008-01-14 15:00:00
8518 |      48 |      9 |   1904 | Lollapalooza | 2008-03-19 15:00:00
(9 rows)

```

Then query `stl_delete` to see the execution steps for the deletion. In this example, the query returned over 300 rows, so the output below is shortened for display purposes.

```
select query, slice, segment, step, tasknum, rows, tbl from stl_delete order by query;
```

```

query | slice | segment | step | tasknum | rows | tbl
-----+-----+-----+-----+-----+-----+-----
  7 |     0 |     0 |    1 |     0 |    0 | 100000
  7 |     1 |     0 |    1 |     0 |    0 | 100000
  8 |     0 |     0 |    1 |     2 |    0 | 100001
  8 |     1 |     0 |    1 |     2 |    0 | 100001
  9 |     0 |     0 |    1 |     4 |    0 | 100002
  9 |     1 |     0 |    1 |     4 |    0 | 100002
 10 |     0 |     0 |    1 |     6 |    0 | 100003
 10 |     1 |     0 |    1 |     6 |    0 | 100003
 11 |     0 |     0 |    1 |     8 |    0 | 100253
 11 |     1 |     0 |    1 |     8 |    0 | 100253
 12 |     0 |     0 |    1 |     0 |    0 | 100255
 12 |     1 |     0 |    1 |     0 |    0 | 100255
 13 |     0 |     0 |    1 |     2 |    0 | 100257
 13 |     1 |     0 |    1 |     2 |    0 | 100257
 14 |     0 |     0 |    1 |     4 |    0 | 100259
 14 |     1 |     0 |    1 |     4 |    0 | 100259
...

```

STL_DISK_FULL_DIAG

Logs information about errors recorded when the disk is full.

`STL_DISK_FULL_DIAG` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description		
currenttime	bigint	The day and time the error was generated in microseconds since January 1, 2000.		
node_num	bigint	The identifier for the node.		
query_id	bigint	The identifier for the query that caused the error.		
temp_blocks	bigint	The number of temporary blocks created by the query.		

Sample queries

The following example returns details about the data stored when there is a disk-full error.

```
select * from stl_disk_full_diag
```

The following example converts the `currenttime` to a timestamp.

```
select '2000-01-01'::timestamp + (currenttime/1000000.0)* interval '1 second' as
currenttime,node_num,query_id,temp_blocks from pg_catalog.stl_disk_full_diag;
```

currenttime	node_num	query_id	temp_blocks
2019-05-18 19:19:18.609338	0	569399	70982
2019-05-18 19:37:44.755548	0	569580	70982
2019-05-20 13:37:20.566916	0	597424	70869

STL_DIST

Logs information about network activity during execution of query steps that distribute data. Network traffic is captured by numbers of rows, bytes, and packets that are sent over the network during a given step on a given slice. The duration of the step is the difference between the logged start and end times.

To identify distribution steps in a query, look for dist labels in the QUERY_SUMMARY view or run the EXPLAIN command and then look for step attributes that include dist.

STL_DIST is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_DIST only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision

Column name	Data type	Description
		for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
packets	integer	Total number of packets sent over the network.

Sample queries

The following example returns distribution information for queries with one or more packets and duration greater than zero.

```
select query, slice, step, rows, bytes, packets,
datediff(seconds, starttime, endtime) as duration
from stl_dist
where packets>0 and datediff(seconds, starttime, endtime)>0
order by query
limit 10;
```

query	slice	step	rows	bytes	packets	duration
567	1	4	49990	6249564	707	1
630	0	5	8798	408404	46	2
645	1	4	8798	408404	46	1
651	1	5	192497	9226320	1039	6
669	1	4	192497	9226320	1039	4

```

 675 | 1 | 5 | 3766 | 194656 | 22 | 1
 696 | 0 | 4 | 3766 | 194656 | 22 | 1
 705 | 0 | 4 | 930 | 44400 | 5 | 1
111525 | 0 | 3 | 68 | 17408 | 2 | 1
(9 rows)

```

STL_ERROR

Records internal processing errors generated by the Amazon Redshift database engine.

STL_ERROR does not record SQL errors or messages. The information in STL_ERROR is useful for troubleshooting certain errors. An AWS support engineer might ask you to provide this information as part of the troubleshooting process.

STL_ERROR is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

For a list of error codes that can be generated while loading data with the Copy command, see [Load error reference](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
process	character(12)	Process that threw the exception.
recordtime	timestamp	Time that the error occurred.
pid	integer	Process ID. The STL_QUERY table contains process IDs and unique query IDs for completed queries.
errcode	integer	Error code corresponding to the error category.
file	character(90)	Name of the source file where the error occurred.

Column name	Data type	Description
linenum	integer	Line number in the source file where the error occurred.
context	character(100)	Cause of the error.
error	character(512)	Error message.

Sample queries

The following example retrieves the error information from STL_ERROR.

```
select process, errcode, linenum as line,
trim(error) as err
from stl_error;
```

```

  process      | errcode | line | err
-----+-----+-----+-----
+-----+-----+-----+-----
padbmaster    |    8001 |  194 | Path prefix: s3://redshift-downloads/testnulls/
venue.txt*
padbmaster    |    8001 |  529 | Listing bucket=redshift-downloads prefix=tests/
category-csv-quotes
padbmaster    |        2 |  190 | database "template0" is not currently accepting
connections
padbmaster    |       32 | 1956 | pq_flush: could not send data to client: Broken pipe
(4 rows)
```

STL_EXPLAIN

Displays the EXPLAIN plan for a query that has been submitted for execution.

STL_EXPLAIN is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_EXPLAIN only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling

clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
nodeid	integer	Plan node identifier, where a node maps to one or more steps in the execution of the query.
parentid	integer	Plan node identifier for a parent node. A parent node has some number of child nodes. For example, a merge join is the parent of the scans on the joined tables.
plannode	character(400)	The node text from the EXPLAIN output. Plan nodes that refer to execution on compute nodes are prefixed with XN in the EXPLAIN output.
info	character(400)	Qualifier and filter information for the plan node. For example, join conditions and WHERE clause restrictions are included in this column.

Sample queries

Consider the following EXPLAIN output for an aggregate join query:

```
explain select avg(datediff(day, listtime, saletime)) as avgwait
from sales, listing where sales.listid = listing.listid;
          QUERY PLAN
```

```
-----
XN Aggregate (cost=6350.30..6350.31 rows=1 width=16)
```

```

-> XN Hash Join DS_DIST_NONE (cost=47.08..6340.89 rows=3766 width=16)
    Hash Cond: ("outer".listid = "inner".listid)
    -> XN Seq Scan on listing (cost=0.00..1924.97 rows=192497 width=12)
    -> XN Hash (cost=37.66..37.66 rows=3766 width=12)
        -> XN Seq Scan on sales (cost=0.00..37.66 rows=3766 width=12)
(6 rows)

```

If you run this query and its query ID is 10, you can use the `STL_EXPLAIN` table to see the same kind of information that the `EXPLAIN` command returns:

```

select query,nodeid,parentid,substring(plannode from 1 for 30),
substring(info from 1 for 20) from stl_explain
where query=10 order by 1,2;

```

query	nodeid	parentid	substring	substring
10	1	0	XN Aggregate (cost=6717.61..6	
10	2	1	-> XN Merge Join DS_DIST_NO	Merge Cond:("outer"
10	3	2	-> XN Seq Scan on lis	
10	4	2	-> XN Seq Scan on sal	

(4 rows)

Consider the following query:

```

select event.eventid, sum(pricepaid)
from event, sales
where event.eventid=sales.eventid
group by event.eventid order by 2 desc;

```

eventid	sum
289	51846.00
7895	51049.00
1602	50301.00
851	49956.00
7315	49823.00
...	

If this query's ID is 15, the following system view query returns the plan nodes that were completed. In this case, the order of the nodes is reversed to show the actual order of execution:

```

select query,nodeid,parentid,substring(plannode from 1 for 56)

```

```
from stl_explain where query=15 order by 1, 2 desc;
```

query	nodeid	parentid	substring
15	8	7	-> XN Seq Scan on eve
15	7	5	-> XN Hash(cost=87.98..87.9
15	6	5	-> XN Seq Scan on sales(cos
15	5	4	-> XN Hash Join DS_DIST_OUTER(cos
15	4	3	-> XN HashAggregate(cost=862286577.07..
15	3	2	-> XN Sort(cost=1000862287175.47..10008622871
15	2	1	-> XN Network(cost=1000862287175.47..1000862287197.
15	1	0	XN Merge(cost=1000862287175.47..1000862287197.46 rows=87

(8 rows)

The following query retrieves the query IDs for any query plans that contain a window function:

```
select query, trim(plannode) from stl_explain
where plannode like '%Window%';
```

query	btrim
26	-> XN Window(cost=1000985348268.57..1000985351256.98 rows=170 width=33)
27	-> XN Window(cost=1000985348268.57..1000985351256.98 rows=170 width=33)

(2 rows)

STL_FILE_SCAN

Returns the files that Amazon Redshift read while loading data by using the COPY command.

Querying this view can help troubleshoot data load errors. STL_FILE_SCAN can be particularly helpful with pinpointing issues in parallel data loads, because parallel data loads typically load many files with a single COPY command.

STL_FILE_SCAN is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_FILE_SCAN only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency

scaling clusters, we recommend that you use the SYS monitoring view [SYS_LOAD_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
name	character(90)	Full path and name of the file that was loaded.
lines	bigint	Number of lines read from the file.
bytes	bigint	Number of bytes read from the file.
loadtime	bigint	Amount of time spent loading the file (in microseconds).
curtime	Timestamp	Timestamp representing the time that Amazon Redshift started processing the file.
is_partial	integer	Value that if true (1) indicates the input file is split into ranges during a COPY operation. If this value is false (0), the input file isn't split.
start_offset	bigint	Value that, if the input file is split during a COPY operation, indicates the offset value of the split (in bytes). If the file isn't split, this value is 0.

Sample queries

The following query retrieves the names and load times of any files that took over 1,000,000 microseconds for Amazon Redshift to read.

```
select trim(name)as name, loadtime from stl_file_scan
where loadtime > 1000000;
```

This query returns the following example output.

name	loadtime
listings_pipe.txt	9458354
allusers_pipe.txt	2963761
allevents_pipe.txt	1409135
tickit/listings_pipe.txt	7071087
tickit/allevents_pipe.txt	1237364
tickit/allusers_pipe.txt	2535138
listings_pipe.txt	6706370
allusers_pipe.txt	3579461
allevents_pipe.txt	1313195
tickit/allusers_pipe.txt	3236060
tickit/listings_pipe.txt	4980108

(11 rows)

STL_HASH

Analyzes hash execution steps for queries.

STL_HASH is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_HASH only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
slots	integer	Total number of hash buckets.
occupied	integer	Total number of slots that contain records.
maxlength	integer	Size of the largest slot.

Column name	Data type	Description
tbl	integer	Table ID.
is_diskbased	character(1)	If true (t), the query was performed as a disk-based operation. If false (f), the query was performed in memory.
workmem	bigint	Total number of bytes of working memory assigned to the step.
num_parts	integer	Total number of partitions that a hash table was divided into during a hash step.
est_rows	bigint	Estimated number of rows to be hashed.
num_blocks_permitted	integer	This information is for internal use only.
resizes	integer	This information is for internal use only.
checksum	bigint	This information is for internal use only.
runtime_filter_size	integer	Size of the runtime filter in bytes.
max_runtime_filter_size	integer	Maximum size of the runtime filter in bytes.

Sample queries

The following example returns information about the number of partitions that were used in a hash for query 720, and indicates that none of the steps ran on disk.

```
select slice, rows, bytes, occupied, workmem, num_parts, est_rows,
       num_blocks_permitted, is_diskbased
from stl_hash
```

```
where query=720 and segment=5
order by slice;
```

```
slice | rows | bytes | occupied | workmem | num_parts | est_rows |
num_blocks_permitted | is_diskbased
-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
      0 |  145 | 585800 |          1 | 88866816 |          16 |          1 |
52      |      | f      |          0 |          0 |          16 |          1 |
      1 |    0 |    0   |          0 |          0 |          16 |          1 |
52      |      | f      |          0 |          0 |          16 |          1 |
(2 rows)
```

STL_HASHJOIN

Analyzes hash join execution steps for queries.

STL_HASHJOIN is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_HASHJOIN only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.

Column name	Data type	Description
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
tbl	integer	Table ID.
num_parts	integer	Total number of partitions that a hash table was divided into during a hash step.

Column name	Data type	Description
join_type	integer	<p>The type of join for the step:</p> <ul style="list-style-type: none"> • 0. The query used an inner join. • 1. The query used a left outer join. • 2. The query used a full outer join. • 3. The query used a right outer join. • 4. The query used a UNION operator. • 5. The query used an IN condition. • 6. This information is for internal use only. • 7. This information is for internal use only. • 8. This information is for internal use only. • 9. This information is for internal use only. • 10. This information is for internal use only. • 11. This information is for internal use only. • 12. This information is for internal use only.
hash_looped	character(1)	This information is for internal use only.
switched_parts	character(1)	Indicates whether the build (or outer) and probe (or inner) sides have switched.
used_prefetching	character(1)	This information is for internal use only.
hash_segment	integer	The segment of the corresponding hash step.
hash_step	integer	The step number of the corresponding hash step.
checksum	bigint	This information is for internal use only.

Column name	Data type	Description
distribution	integer	This information is for internal use only.

Sample queries

The following example returns the number of partitions used in a hash join for query 720.

```
select query, slice, tbl, num_parts
from stl_hashjoin
where query=720 limit 10;
```

```
query | slice | tbl | num_parts
-----+-----+-----+-----
  720 |     0 | 243 |         1
  720 |     1 | 243 |         1
(2 rows)
```

STL_INSERT

Analyzes insert execution steps for queries.

STL_INSERT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_INSERT only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
tbl	integer	Table ID.
inserted_mega_value	character(1)	This information is for internal use only. This information shows whether the given insert step has inserted a large value. A large value will be stored in multiple blocks. Block size is 1 MB by default, a large value is greater than 1 MB in a default setting.

Sample queries

The following example returns insert execution steps for the most recent query.

```
select slice, segment, step, tasknum, rows, tbl
from stl_insert
where query=pg_last_query_id();
```

```
 slice | segment | step | tasknum | rows | tbl
-----+-----+-----+-----+-----+-----
      0 |         2 |     2 |        15 | 24958 | 100548
      1 |         2 |     2 |        15 | 25032 | 100548
(2 rows)
```

STL_LIMIT

Analyzes the execution steps that occur when a LIMIT clause is used in a SELECT query.

STL_LIMIT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_LIMIT only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
checksum	bigint	This information is for internal use only.

Sample queries

In order to generate a row in STL_LIMIT, this example first runs the following query against the VENUE table using the LIMIT clause.

```
select * from venue
order by 1
limit 10;
```

```
venueid |          venuename          |   venuecity   | venuestate | venuesseats
-----+-----+-----+-----+-----
        1 | Toyota Park                 | Bridgeview    | IL         |           0
```

```

 2 | Columbus Crew Stadium      | Columbus      | OH      |      0
 3 | RFK Stadium                | Washington    | DC      |      0
 4 | CommunityAmerica Ballpark | Kansas City   | KS      |      0
 5 | Gillette Stadium           | Foxborough    | MA      | 68756
 6 | New York Giants Stadium    | East Rutherford | NJ      | 80242
 7 | BMO Field                  | Toronto       | ON      |      0
 8 | The Home Depot Center      | Carson        | CA      |      0
 9 | Dick's Sporting Goods Park | Commerce City | CO      |      0
10 | Pizza Hut Park             | Frisco        | TX      |      0

```

(10 rows)

Next, run the following query to find the query ID of the last query you ran against the VENUE table.

```

select max(query)
from stl_query;

```

```

max
-----
127128
(1 row)

```

Optionally, you can run the following query to verify that the query ID corresponds to the LIMIT query you previously ran.

```

select query, trim(querytxt)
from stl_query
where query=127128;

```

```

query |          btrim
-----+-----
127128 | select * from venue order by 1 limit 10;
(1 row)

```

Finally, run the following query to return information about the LIMIT query from the STL_LIMIT table.

```

select slice, segment, step, starttime, endtime, tasknum
from stl_limit
where query=127128

```

Column name	Data type	Description
slice	integer	Slice loaded for this entry.
name	character(256)	System-defined value.
filename	character(256)	Name of file being tracked.
byte_offset	integer	This information is for internal use only.
lines_scanned	integer	Number of lines scanned from the load file. This number may not match the number of rows that are actually loaded. For example, the load may scan but tolerate a number of bad records, based on the MAXERROR option in the COPY command.
errors	integer	This information is for internal use only.
curtime	timestamp	Time that this entry was last updated.
status	integer	This information is for internal use only.
file_format	character(16)	Format of the load file. Possible values are as follows: <ul style="list-style-type: none">• Avro• JSON• ORC• Parquet• Text
is_partial	integer	Value that if true (1) indicates the input file is split into ranges during a COPY operation. If this value is false (0), the input file isn't split.
start_offset	bigint	Value that, if the input file is split during a COPY operation, indicates the offset value of the split (in bytes). Each file split is logged as a separate record with the corresponding start_offset value. If the file isn't split, this value is 0.

Column name	Data type	Description
copy_job_id	bigint	The copy job identifier. A 0 indicates no job identifier.

Sample queries

The following example returns details for the last COPY operation.

```
select query, trim(filename) as file, curtime as updated
from stl_load_commits
where query = pg_last_copy_id();
```

query	file	updated
28554	s3://dw-tickit/category_pipe.txt	2013-11-01 17:14:52.648486

(1 row)

The following query contains entries for a fresh load of the tables in the TICKIT database:

```
select query, trim(filename), curtime
from stl_load_commits
where filename like '%tickit%' order by query;
```

query	btrim	curtime
22475	tickit/allusers_pipe.txt	2013-02-08 20:58:23.274186
22478	tickit/venue_pipe.txt	2013-02-08 20:58:25.070604
22480	tickit/category_pipe.txt	2013-02-08 20:58:27.333472

(12 rows)

The fact that a record is written to the log file for this system view does not mean that the load committed successfully as part of its containing transaction. To verify load commits, query the `STL_UTILITYTEXT` view and look for the `COMMIT` record that corresponds with a `COPY` transaction. For example, this query joins `STL_LOAD_COMMITS` and `STL_QUERY` based on a subquery against `STL_UTILITYTEXT`:

```
select l.query,rtrim(l.filename),q.xid
from stl_load_commits l, stl_query q
where l.query=q.query
and exists
(select xid from stl_utilitytext where xid=q.xid and rtrim("text")='COMMIT');
```

query	rtrim	xid
22600	tickit/date2008_pipe.txt	68311
22480	tickit/category_pipe.txt	68066
7508	allusers_pipe.txt	23365
7552	category_pipe.txt	23415
7576	allevents_pipe.txt	23429
7516	venue_pipe.txt	23390
7604	listings_pipe.txt	23445
22596	tickit/venue_pipe.txt	68309
22605	tickit/listings_pipe.txt	68316
22593	tickit/allusers_pipe.txt	68305
22485	tickit/allevents_pipe.txt	68071
7561	allevents_pipe.txt	23429
7541	category_pipe.txt	23415
7558	date2008_pipe.txt	23428

```

STL_LOAD_ERRORS

Displays the records of all Amazon Redshift load errors.

STL_LOAD_ERRORS contains a history of all Amazon Redshift load errors. See [Load error reference](#) for a comprehensive list of possible load errors and explanations.

Query [STL_LOADERROR_DETAIL](#) for additional details, such as the exact data row and column where a parse error occurred, after you query STL_LOAD_ERRORS to find out general information about the error.

STL_LOAD_ERRORS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_LOAD_ERRORS only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_LOAD_ERROR_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
slice	integer	Slice where the error occurred.
tbl	integer	Table ID.
starttime	timestamp	Start time in UTC for the load.
session	integer	Session ID for the session performing the load.
query	integer	Query ID. The query column can be used to join other system tables and views.
filename	character(256)	Complete path to the input file for the load.
line_number	bigint	Line number in the load file with the error. For COPY from JSON, the line number of the last line of the JSON object with the error.
colname	character(127)	Field with the error.
type	character(10)	Data type of the field.
col_length	character(10)	Column length, if applicable. This field is populated when the data type has a limit length. For example, for a column

Column name	Data type	Description
		with a data type of "character(3)", this column will contain the value "3".
position	integer	Position of the error in the field.
raw_line	character(1024)	Raw load data that contains the error. Multibyte characters in the load data are replaced with a period.
raw_field_value	char(1024)	The pre-parsing value for the field "colname" that lead to the parsing error.
err_code	integer	Error code.
err_reason	character(100)	Explanation for the error.
is_partial	integer	Value that if true (1) indicates the input file is split into ranges during a COPY operation. If this value is false (0), the input file isn't split.
start_off set	bigint	Value that, if the input file is split during a COPY operation , indicates the offset value of the split (in bytes). If the line number in the file is unknown, the line number is -1. If the file isn't split, this value is 0.
copy_job_id	bigint	The copy job identifier. A 0 indicates no job identifier.

Sample queries

The following query joins STL_LOAD_ERRORS to STL_LOADERROR_DETAIL to view the details errors that occurred during the most recent load.

```
select d.query, substring(d.filename,14,20),
d.line_number as line,
substring(d.value,1,16) as value,
substring(le.err_reason,1,48) as err_reason
from stl_loadererror_detail d, stl_load_errors le
```

```
where d.query = le.query
and d.query = pg_last_copy_id();
```

query	substring	line	value	err_reason
558	allusers_pipe.txt	251	251	String contains invalid or unsupported UTF8 code
558	allusers_pipe.txt	251	ZRU29FGR	String contains invalid or unsupported UTF8 code
558	allusers_pipe.txt	251	Kaitlin	String contains invalid or unsupported UTF8 code
558	allusers_pipe.txt	251	Walter	String contains invalid or unsupported UTF8 code

The following example uses `STL_LOAD_ERRORS` with `STV_TBL_PERM` to create a new view, and then uses that view to determine what errors occurred while loading data into the `EVENT` table:

```
create view loadview as
(select distinct tbl, trim(name) as table_name, query, starttime,
trim(filename) as input, line_number, colname, err_code,
trim(err_reason) as reason
from stl_load_errors sl, stv_tbl_perm sp
where sl.tbl = sp.id);
```

Next, the following query actually returns the last error that occurred while loading the `EVENT` table:

```
select table_name, query, line_number, colname, starttime,
trim(reason) as error
from loadview
where table_name = 'event'
order by line_number limit 1;
```

The query returns the last load error that occurred for the `EVENT` table. If no load errors occurred, the query returns zero rows. In this example, the query returns a single error:

table_name	query	line_number	colname	error	starttime
event	309	0	5	Error in Timestamp value or format [%Y-%m-%d %H:%M:%S]	2014-04-22 15:12:44

```
(1 row)
```

In cases where the COPY command automatically splits large, uncompressed, text-delimited file data to facilitate parallelism, the *line_number*, *is_partial*, and *start_offset* columns show information pertaining to splits. (The line number can be unknown in cases where the line number from the original file is unavailable.)

```
--scan ranges information
SELECT line_number, POSITION, btrim(raw_line), btrim(raw_field_value),
btrim(err_reason), is_partial, start_offset FROM stl_load_errors
WHERE query = pg_last_copy_id();

--result
-1,51,"1008771|13463413|463414|2|28.00|38520.72|0.06|0.07|N0|1998-08-30|1998-09-25|
1998-09-04|TAKE BACK RETURN|RAIL|ans cajole sly","N0","Char length exceeds DDL
length",1,67108864
```

STL_LOADERROR_DETAIL

Displays a log of data parse errors that occurred while using a COPY command to load tables. To conserve disk space, a maximum of 20 errors per node slice are logged for each load operation.

A parse error occurs when Amazon Redshift cannot parse a field in a data row while loading it into a table. For example, if a table column is expecting an integer data type and the data file contains a string of letters in that field, it causes a parse error.

Query STL_LOADERROR_DETAIL for additional details, such as the exact data row and column where a parse error occurred, after you query [STL_LOAD_ERRORS](#) to find out general information about the error.

The STL_LOADERROR_DETAIL view contains all data columns including and prior to the column where the parse error occurred. Use the VALUE field to see the data value that was actually parsed in this column, including the columns that parsed correctly up to the error.

This view is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_LOADERROR_DETAIL only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and

concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_LOAD_ERROR_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
slice	integer	Slice where the error occurred.
session	integer	Session ID for the session performing the load.
query	integer	Query ID. The query column can be used to join other system tables and views.
filename	character(256)	Complete path to the input file for the load.
line_number	bigint	Line number in the load file with the error.
field	integer	Field with the error.
colname	character(1024)	Column name.
value	character(1024)	Parsed data value of the field. (May be truncated.) Multibyte characters in the load data are replaced with a period.
is_null	integer	Whether or not the parsed value is null.
type	character(10)	Data type of the field.
col_length	character(10)	Column length, if applicable. This field is populated when the data type has a limit length. For example, for a column with a data type of "character(3)", this column will contain the value "3".

Sample query

The following query joins `STL_LOAD_ERRORS` to `STL_LOADERROR_DETAIL` to view the details of a parse error that occurred while loading the `EVENT` table, which has a table ID of 100133:

```
select d.query, d.line_number, d.value,
       le.raw_line, le.err_reason
from stl_loaderror_detail d, stl_load_errors le
where
d.query = le.query
and tbl = 100133;
```

The following sample output shows the columns that loaded successfully, including the column with the error. In this example, two columns successfully loaded before the parse error occurred in the third column, where a character string was incorrectly parsed for a field expecting an integer. Because the field expected an integer, it parsed the string "aaa", which is uninitialized data, as a null and generated a parse error. The output shows the raw value, parsed value, and error reason:

query	line_number	value	raw_line	err_reason
4	3	1201	1201	Invalid digit
4	3	126	126	Invalid digit
4	3		aaa	Invalid digit

(3 rows)

When a query joins `STL_LOAD_ERRORS` and `STL_LOADERROR_DETAIL`, it displays an error reason for each column in the data row, which simply means that an error occurred in that row. The last row in the results is the actual column where the parse error occurred.

STL_MERGE

Analyzes merge execution steps for queries. These steps occur when the results of parallel operations (such as sorts and joins) are merged for subsequent processing.

`STL_MERGE` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

`STL_MERGE` only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling

clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#) . The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.

Sample queries

The following example returns 10 merge execution results.

```
select query, step, starttime, endtime, tasknum, rows
from stl_merge
limit 10;
```

query	step	starttime	endtime	tasknum	rows
9	0	2013-08-12 20:08:14	2013-08-12 20:08:14	0	0
12	0	2013-08-12 20:09:10	2013-08-12 20:09:10	0	0
15	0	2013-08-12 20:10:24	2013-08-12 20:10:24	0	0
20	0	2013-08-12 20:11:27	2013-08-12 20:11:27	0	0
26	0	2013-08-12 20:12:28	2013-08-12 20:12:28	0	0
32	0	2013-08-12 20:14:33	2013-08-12 20:14:33	0	0
38	0	2013-08-12 20:16:43	2013-08-12 20:16:43	0	0
44	0	2013-08-12 20:17:05	2013-08-12 20:17:05	0	0
50	0	2013-08-12 20:18:48	2013-08-12 20:18:48	0	0
56	0	2013-08-12 20:20:48	2013-08-12 20:20:48	0	0

(10 rows)

STL_MERGEJOIN

Analyzes merge join execution steps for queries.

STL_MERGEJOIN is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_MERGEJOIN only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.

Column name	Data type	Description
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
tbl	integer	Table ID. This is the ID for the inner table that was used in the merge join.
checksum	bigint	This information is for internal use only.

Sample queries

The following example returns merge join results for the most recent query.

```
select sum(s.qtysold), e.eventname
from event e, listing l, sales s
where e.eventid=l.eventid
```

```
and l.listid= s.listid
group by e.eventname;

select * from stl_mergejoin where query=pg_last_query_id();
```

```
userid | query | slice | segment | step | starttime | endtime |
tasknum | rows | tbl
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----

```

STL_MV_STATE

The STL_MV_STATE view contains a row for every state transition of a materialized view.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

STL_MV_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_MV_STATE](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	bigint	The ID of the user who created the event.
starttime	timestamp	The start time of the event.
xid	bigint	The transaction id of the event.

Column name	Data type	Description
event_desc	char(500)	<p>The event that prompted the state change. Some example values include the following:</p> <ul style="list-style-type: none"> • Column type was changed • Column was dropped • Column was renamed • Schema name was changed • Small table conversion • TRUNCATE • Vacuum <p>Note that there are other possible values for this column.</p>
db_name	char(128)	The database that contains the materialized view.
base_table_schema	char(128)	The schema of the base table.
base_table_name	char(128)	The name of the base table.
mv_schema	char(128)	The schema of the materialized view.
mv_name	char(128)	The name of the materialized view.
state	character(32)	<p>The changed state of the materialized view as follows:</p> <ul style="list-style-type: none"> • Recompute • Unrefreshable

The following table shows example combinations of event_desc and state.

event_desc	state
TRUNCATE	Recompute
TRUNCATE	Recompute
Small table conversion	Recompute
Vacuum	Recompute
Column was renamed	Unrefreshable
Column was dropped	Unrefreshable
Table was renamed	Unrefreshable
Column type was changed	Unrefreshable
Schema name was changed	Unrefreshable

Sample query

To view the log of state transitions of materialized views, run the following query.

```
select * from stl_mv_state;
```

This query returns the following sample output:

```
userid |          starttime          | xid |          event_desc          | db_name |

STL_NESTLOOP

Analyzes nested-loop join execution steps for queries.

STL_NESTLOOP is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_NESTLOOP only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
tbl	integer	Table ID.
checksum	bigint	This information is for internal use only.

Sample queries

Because the following query neglects to join the CATEGORY table, it produces a partial Cartesian product, which is not recommended. It is shown here to illustrate a nested loop.

```
select count(event.eventname), event.eventname, category.catname, date.caldate
from event, category, date
where event.dateid = date.dateid
group by event.eventname, category.catname, date.caldate;
```

The following query shows the results from the previous query in the STL_NESTLOOP view.

```
select query, slice, segment as seg, step,
datediff(msec, starttime, endtime) as duration, tasknum, rows, tbl
from stl_nestloop
where query = pg_last_query_id();
```

query	slice	seg	step	duration	tasknum	rows	tbl
6028	0	4	5	41	22	24277	240
6028	1	4	5	26	23	24189	240
6028	3	4	5	25	23	24376	240
6028	2	4	5	54	22	23936	240

STL_PARSE

Analyzes query steps that parse strings into binary values for loading.

STL_PARSE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_PARSE only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.

Sample queries

The following example returns all query step results for slice 1 and segment 0 where strings were parsed into binary values.

```
select query, step, starttime, endtime, tasknum, rows
from stl_parse
where slice=1 and segment=0;
```

query	step	starttime	endtime	tasknum	rows
669	1	2013-08-12 22:35:13	2013-08-12 22:35:17	32	192497
696	1	2013-08-12 22:35:49	2013-08-12 22:35:49	32	0
525	1	2013-08-12 22:32:03	2013-08-12 22:32:03	13	49990

```

585 | 1 | 2013-08-12 22:33:18 | 2013-08-12 22:33:19 | 13 | 202
621 | 1 | 2013-08-12 22:34:03 | 2013-08-12 22:34:03 | 27 | 365
651 | 1 | 2013-08-12 22:34:47 | 2013-08-12 22:34:53 | 35 | 192497
590 | 1 | 2013-08-12 22:33:28 | 2013-08-12 22:33:28 | 19 | 0
599 | 1 | 2013-08-12 22:33:39 | 2013-08-12 22:33:39 | 31 | 11
675 | 1 | 2013-08-12 22:35:26 | 2013-08-12 22:35:27 | 38 | 3766
567 | 1 | 2013-08-12 22:32:47 | 2013-08-12 22:32:48 | 23 | 49990
630 | 1 | 2013-08-12 22:34:17 | 2013-08-12 22:34:17 | 36 | 0
572 | 1 | 2013-08-12 22:33:04 | 2013-08-12 22:33:04 | 29 | 0
645 | 1 | 2013-08-12 22:34:37 | 2013-08-12 22:34:38 | 29 | 8798
604 | 1 | 2013-08-12 22:33:47 | 2013-08-12 22:33:47 | 37 | 0
(14 rows)

```

STL_PLAN_INFO

Use the STL_PLAN_INFO view to look at the EXPLAIN output for a query in terms of a set of rows. This is an alternative way to look at query plans.

STL_PLAN_INFO is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_PLAN_INFO only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
nodeid	integer	Plan node identifier, where a node maps to one or more steps in the execution of the query.
segment	integer	Number that identifies the query segment.
step	integer	Number that identifies the query step.
locus	integer	Location where the step runs. 0 if on a compute node and 1 if on the leader node.
plannode	integer	Enumerated value of the plan node. See the following table for enums for plannode. (The PLANNODE column in STL_EXPLAIN contains the plan node text.)
startupcost	double precision	The estimated relative cost of returning the first row for this step.
totalcost	double precision	The estimated relative cost of executing the step.
rows	bigint	The estimated number of rows that will be produced by the step.
bytes	bigint	The estimated number of bytes that will be produced by the step.

Sample queries

The following examples compare the query plans for a simple SELECT query returned by using the EXPLAIN command and by querying the STL_PLAN_INFO view.

```
explain select * from category;
QUERY PLAN
-----
XN Seq Scan on category (cost=0.00..0.11 rows=11 width=49)
(1 row)

select * from category;
```

```

catid | catgroup | catname | catdesc
-----+-----+-----+-----
1 | Sports | MLB | Major League Baseball
3 | Sports | NFL | National Football League
5 | Sports | MLS | Major League Soccer
...

select * from stl_plan_info where query=256;

query | nodeid | segment | step | locus | plannode | startupcost | totalcost
| rows | bytes
-----+-----+-----+-----+-----+-----+-----+-----
+-----
256 | 1 | 0 | 1 | 0 | 104 | 0 | 0.11 | 11 | 539
256 | 1 | 0 | 0 | 0 | 104 | 0 | 0.11 | 11 | 539
(2 rows)

```

In this example, PLANNODE 104 refers to the sequential scan of the CATEGORY table.

```

select distinct eventname from event order by 1;

eventname
-----
.38 Special
3 Doors Down
70s Soul Jam
A Bronx Tale
...

explain select distinct eventname from event order by 1;

QUERY PLAN
-----
XN Merge (cost=1000000000136.38..1000000000137.82 rows=576 width=17)
Merge Key: eventname
-> XN Network (cost=1000000000136.38..1000000000137.82 rows=576
width=17)
Send to leader
-> XN Sort (cost=1000000000136.38..1000000000137.82 rows=576
width=17)
Sort Key: eventname
-> XN Unique (cost=0.00..109.98 rows=576 width=17)
-> XN Seq Scan on event (cost=0.00..87.98 rows=8798)

```

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
checksum	bigint	This information is for internal use only.

Sample queries

The following example returns all rows for query steps that were used to evaluate expressions for slice 0 and segment 1.

```
select query, step, starttime, endtime, tasknum, rows
from stl_project
where slice=0 and segment=1;
```

query	step	starttime	endtime	tasknum	rows
86399	2	2013-08-29 22:01:21	2013-08-29 22:01:21	25	-1
86399	3	2013-08-29 22:01:21	2013-08-29 22:01:21	25	-1

(26 rows)

STL_QUERY

Returns execution information about a database query.

Note

The STL_QUERY and STL_QUERYTEXT views only contain information about queries, not other utility and DDL commands. For a listing and information on all statements

run by Amazon Redshift, you can also query the `STL_DDLTEXT` and `STL_UTILITYTEXT` views. For a complete listing of all statements run by Amazon Redshift, you can query the `SVL_STATEMENTTEXT` view.

`STL_QUERY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
<code>userid</code>	integer	ID of the user who generated the entry.
<code>query</code>	integer	Query ID. The query column can be used to join other system tables and views.
<code>label</code>	character(320)	Either the name of the file used to run the query or a label defined with a <code>SET QUERY_GROUP</code> command. If the query is not file-based or the <code>QUERY_GROUP</code> parameter is not set, this field value is default.
<code>xid</code>	bigint	Transaction ID.
<code>pid</code>	integer	Process ID. Normally, all of the queries in a session are run in the same process, so this value usually remains constant if you run a series of queries in the same session. Following certain internal events, Amazon Redshift might restart an active session and assign a new PID. For more information, see STL_RESTARTED_SESSIONS .
<code>database</code>	character(32)	The name of the database the user was connected to when the query was issued.

Column name	Data type	Description
querytxt	character(4000)	Actual query text for the query.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
aborted	integer	If a query was stopped by the system or canceled by the user, this column contains 1 . If the query ran to completion (including returning results to the client), this column contains 0 . If a client disconnects before receiving the results, the query will be marked as canceled (1), even if it completed successfully in the backend.
insert_pristine	integer	Whether write queries are/were able to run while the current query is/was running. 1 = no write queries allowed. 0 = write queries allowed. This column is intended for use in debugging.
concurrency_scaling_status	integer	Indicates whether the query ran on the main cluster or on a concurrency scaling cluster. Possible values are as follows: 0 - Ran on the main cluster 1 - Ran on a concurrency scaling cluster Greater than 1 - Ran on the main cluster

Sample queries

The following query lists the five most recent queries.

```
select query, trim(querytxt) as sqlquery
from stl_query
order by query desc limit 5;
```

query	sqlquery
129	select query, trim(querytxt) from stl_query order by query;
128	select node from stv_disk_read_speeds;
127	select system_status from stv_gui_status
126	select * from systable_topology order by slice
125	load global dict registry

(5 rows)

The following query returns the time elapsed in descending order for queries that ran on February 15, 2013.

```
select query, datediff(seconds, starttime, endtime),
trim(querytxt) as sqlquery
from stl_query
where starttime >= '2013-02-15 00:00' and endtime < '2013-02-16 00:00'
order by date_diff desc;
```

query	date_diff	sqlquery
55	119	padb_fetch_sample: select count(*) from category
121	9	select * from svl_query_summary;
181	6	select * from svl_query_summary where query in(179,178);
172	5	select * from svl_query_summary where query=148;
...		

(189 rows)

The following query shows the queue time and execution time for queries. Queries with `concurrency_scaling_status = 1` ran on a concurrency scaling cluster. All other queries ran on the main cluster.

```
SELECT w.service_class AS queue
       , q.concurrency_scaling_status
```

```
    , COUNT( * ) AS queries
    , SUM( q.aborted ) AS aborted
    , SUM( ROUND( total_queue_time::NUMERIC / 1000000,2 ) ) AS queue_secs
    , SUM( ROUND( total_exec_time::NUMERIC / 1000000,2 ) ) AS exec_secs
FROM stl_query q
     JOIN stl_wlm_query w
         USING (userid,query)
WHERE q.userid > 1
      AND service_class > 5
      AND q.starttime > '2019-03-01 16:38:00'
      AND q.endtime < '2019-03-01 17:40:00'
GROUP BY 1,2
ORDER BY 1,2;
```

STL_QUERY_METRICS

Contains metrics information, such as the number of rows processed, CPU usage, input/output, and disk use, for queries that have completed running in user-defined query queues (service classes). To view metrics for active queries that are currently running, see the [STV_QUERY_METRICS](#) system view.

Query metrics are sampled at one second intervals. As a result, different runs of the same query might return slightly different times. Also, query segments that run in less than one second might not be recorded.

STL_QUERY_METRICS tracks and aggregates metrics at the query, segment, and step level. For information about query segments and steps, see [Query planning and execution workflow](#). Many metrics (such as `max_rows`, `cpu_time`, and so on) are summed across node slices. For more information about node slices, see [Data warehouse system architecture](#).

To determine the level at which the row reports metrics, examine the `segment` and `step_type` columns.

- If both `segment` and `step_type` are -1, then the row reports metrics at the query level.
- If `segment` is not -1 and `step_type` is -1, then the row reports metrics at the segment level.
- If both `segment` and `step_type` are not -1, then the row reports metrics at the step level.

The [SVL_QUERY_METRICS](#) view and the [SVL_QUERY_METRICS_SUMMARY](#) view aggregate the data in this view and present the information in a more accessible form.

STL_QUERY_METRICS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user that ran the query that generated the entry.
service_class	integer	ID for the service class. Query queues are defined in the WLM configuration. Metrics are reported only for user-defined queues.
query	integer	Query ID. The query column can be used to join other system tables and views.
segment	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process. If the segment value is -1, metrics segment values are rolled up to the query level.
step_type	integer	Type of step that ran. For a description of step types, see Step types .
starttime	timestamp	Time in UTC that the query started executing, with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
slices	integer	Number of slices for the cluster.
max_rows	bigint	Maximum number of rows output for a step, aggregated across all slices.
rows	bigint	Number of rows processed by a step.

Column name	Data type	Description
max_cpu_time	bigint	Maximum CPU time used, in microseconds. At the segment level, the maximum CPU time used by the segment across all slices. At the query level, the maximum CPU time used by any query segment.
cpu_time	bigint	CPU time used, in microseconds. At the segment level, the total CPU time for the segment across all slices. At the query level, the sum of CPU time for the query across all slices and segments.
max_block_s_read	bigint	Maximum number of 1 MB blocks read by the segment, aggregated across all slices. At the segment level, the maximum number of 1 MB blocks read for the segment across all slices. At the query level, the maximum number of 1 MB blocks read by any query segment.
blocks_read	bigint	Number of 1 MB blocks read by the query or segment.
max_run_time	bigint	The maximum elapsed time for a segment, in microseconds. At the segment level, the maximum run time for the segment across all slices. At the query level, the maximum run time for any query segment.
run_time	bigint	Total run time, summed across slices. Run time doesn't include wait time. At the segment level, the run time for the segment, summed across all slices. At the query level, the run time for the query summed across all slices and segments. Because this value is a sum, run time is not related to query execution time.

Column name	Data type	Description
max_block_s_to_disk	bigint	The maximum amount of disk space used to write intermediate results, in MB blocks. At the segment level, the maximum amount of disk space used by the segment across all slices. At the query level, the maximum amount of disk space used by any query segment.
blocks_to_disk	bigint	The amount of disk space used by a query or segment to write intermediate results, in MB blocks.
step	integer	Query step that ran.
max_query_scan_size	bigint	The maximum size of data scanned by a query, in MB. At the segment level, the maximum size of data scanned by the segment across all slices. At the query level, the maximum size of data scanned by any query segment.
query_scan_size	bigint	The size of data scanned by a query, in MB.
query_priority	integer	The priority of the query. Possible values are -1, 0, 1, 2, 3, and 4, where -1 means that query priority isn't supported.
query_queue_time	bigint	The amount of time in microseconds that the query was queued.
service_class_name	character (64)	The name of the service class.

Sample query

To find queries with high CPU time (more the 1,000 seconds), run the following query.

```
Select query, cpu_time / 1000000 as cpu_seconds
from stl_query_metrics where segment = -1 and cpu_time > 1000000000
order by cpu_time;

query | cpu_seconds
-----+-----
```

25775	9540
-------	------

To find active queries with a nested loop join that returned more than one million rows, run the following query.

```
select query, rows
from stl_query_metrics
where step_type = 15 and rows > 1000000
order by rows;
```

query	rows
-----+-----	
25775	2621562702

To find active queries that have run for more than 60 seconds and have used less than 10 seconds of CPU time, run the following query.

```
select query, run_time/1000000 as run_time_seconds
from stl_query_metrics
where segment = -1 and run_time > 60000000 and cpu_time < 10000000;
```

query	run_time_seconds
-----+-----	
25775	114

STL_QUERYTEXT

Captures the query text for SQL commands.

Query the STL_QUERYTEXT view to capture the SQL that was logged for the following statements:

- SELECT, SELECT INTO
- INSERT, UPDATE, DELETE
- COPY
- UNLOAD
- The queries generated by running VACUUM and ANALYZE
- CREATE TABLE AS (CTAS)

To query activity for these statements over a given time period, join the `STL_QUERYTEXT` and `STL_QUERY` views.

Note

The `STL_QUERY` and `STL_QUERYTEXT` views only contain information about queries, not other utility and DDL commands. For a listing and information on all statements run by Amazon Redshift, you can also query the `STL_DDLTEXT` and `STL_UTILITYTEXT` views. For a complete listing of all statements run by Amazon Redshift, you can query the `SVL_STATEMENTTEXT` view.

See also [STL_DDLTEXT](#), [STL_UTILITYTEXT](#), and [SVL_STATEMENTTEXT](#).

`STL_QUERYTEXT` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_TEXT](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
xid	bigint	Transaction ID.
pid	integer	Process ID. Normally, all of the queries in a session are run in the same process, so this value usually remains constant if you run a series of queries in the same session. Following certain internal events, Amazon Redshift might restart an active session and assign a new PID. For more information, see STL_RESTARTED_SESSIONS . You can use this column to join to the STL_ERROR view.

Column name	Data type	Description
query	integer	Query ID. The query column can be used to join other system tables and views.
sequence	integer	When a single statement contains more than 200 characters, additional rows are logged for that statement. Sequence 0 is the first row, 1 is the second, and so on.
text	character(200)	SQL text, in 200-character increments. This field might contain special characters such as backslash (\\) and newline (\n).

Sample queries

You can use the `PG_BACKEND_PID()` function to retrieve information for the current session. For example, the following query returns the query ID and a portion of the query text for queries completed in the current session.

```
select query, substring(text,1,60)
from stl_querytext
where pid = pg_backend_pid()
order by query desc;
```

```
query | substring
-----+-----
28262 | select query, substring(text,1,80) from stl_querytext where
28252 | select query, substring(path,0,80) as path from stl_unload_l
28248 | copy category from 's3://dw-tickit/manifest/category/1030_ma
28247 | Count rows in target table
28245 | unload ('select * from category') to 's3://dw-tickit/manifes
28240 | select query, substring(text,1,40) from stl_querytext where
(6 rows)
```

Reconstructing stored SQL

To reconstruct the SQL stored in the `text` column of `STL_QUERYTEXT`, run a `SELECT` statement to create SQL from 1 or more parts in the `text` column. Before running the reconstructed SQL,

replace any (`\n`) special characters with a new line. The result of the following `SELECT` statement is rows of reconstructed SQL in the `query_statement` field.

```
SELECT query, LISTAGG(CASE WHEN LEN(RTRIM(text)) = 0 THEN text ELSE RTRIM(text) END)
  WITHIN GROUP (ORDER BY sequence) as query_statement, COUNT(*) as row_count
FROM stl_querytext GROUP BY query ORDER BY query desc;
```

For example, the following query selects 3 columns. The query itself is longer than 200 characters and is stored in parts in `STL_QUERYTEXT`.

```
select
1 AS a0123456789012345678901234567890123456789012345678901234567890,
2 AS b0123456789012345678901234567890123456789012345678901234567890,
3 AS b012345678901234567890123456789012345678901234
FROM stl_querytext;
```

In this example, the query is stored in 2 parts (rows) in the `text` column of `STL_QUERYTEXT`.

```
select query, sequence, text
from stl_querytext where query=pg_last_query_id() order by query desc, sequence limit
10;
```

```
query | sequence |
      |         | text
-----+-----
45 | 0 | select\n1 AS
a0123456789012345678901234567890123456789012345678901234567890,\n2 AS
b0123456789012345678901234567890123456789012345678901234567890,\n3 AS
b012345678901234567890123456789012345678901234
45 | 1 | \nFROM stl_querytext;
```

To reconstruct the SQL stored in `STL_QUERYTEXT`, run the following SQL.

```
select LISTAGG(CASE WHEN LEN(RTRIM(text)) = 0 THEN text ELSE RTRIM(text) END, '')
  within group (order by sequence) AS text
from stl_querytext where query=pg_last_query_id();
```

To use the resulting reconstructed SQL in your client, replace any (`\n`) special characters with a new line.

```
text
```

```
-----
select\n1 AS a0123456789012345678901234567890123456789012345678901234567890,\n2 AS b0123456789012345678901234567890123456789012345678901234567890,\n3 AS b0123456789012345678901234567890123456789012345678901234\nFROM stl_querytext;
```

STL_REPLACEMENTS

Displays a log that records when invalid UTF-8 characters were replaced by the [COPY](#) command with the `ACCEPTINVCHARS` option. A log entry is added to `STL_REPLACEMENTS` for each of the first 100 rows on each node slice that required at least one replacement.

`STL_REPLACEMENTS` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

`STL_NESTLOOP` only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the `SYS` monitoring view [SYS_COPY_REPLACEMENTS](#). The data in the `SYS` monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
<code>userid</code>	integer	ID of the user who generated the entry.
<code>query</code>	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
slice	integer	Node slice number where the replacement occurred.
tbl	integer	Table ID.
starttime	timestamp	Start time in UTC for the COPY command.
session	integer	Session ID for the session performing the COPY command.
filename	character (256)	Complete path to the input file for the COPY command.
line_number	bigint	Line number in the input data file that contained an invalid UTF-8 character. A -1 indicates that the line number is not available, such as, when copying from a columnar data file.
colname	character (127)	First field that contained an invalid UTF-8 character.
raw_line	character (1024)	Raw load data that contained an invalid UTF-8 character.

Sample queries

The following example returns replacements for the most recent COPY operation.

```
select query, session, filename, line_number, colname
from stl_replacements
where query = pg_last_copy_id();
```

```
query | session | filename | line_number | colname
-----+-----+-----+-----+-----
  96 |    6314 | s3://DOC-EXAMPLE-BUCKET/allusers_pipe.txt |      251 | city
  96 |    6314 | s3://DOC-EXAMPLE-BUCKET/allusers_pipe.txt |      317 | city
  96 |    6314 | s3://DOC-EXAMPLE-BUCKET/allusers_pipe.txt |      569 | city
  96 |    6314 | s3://DOC-EXAMPLE-BUCKET/allusers_pipe.txt |      623 | city
  96 |    6314 | s3://DOC-EXAMPLE-BUCKET/allusers_pipe.txt |      694 | city
...
```

STL_RESTARTED_SESSIONS

To maintain continuous availability following certain internal events, Amazon Redshift might restart an active session with a new process ID (PID). When Amazon Redshift restarts a session, STL_RESTARTED_SESSIONS records the new PID and the old PID.

For more information, see the examples following in this section.

STL_RESTARTED_SESSIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_SESSION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
currenttime	timestamp	Time of the event.
dbname	character (50)	Name of the database associated with the session.
newpid	integer	Process ID for the restarted session.
oldpid	integer	Process ID for the original session.
username	character (50)	Name of the user associated with the session.
remotehost	character (45)	Name or IP address of the remote host.
remoteport	character (32)	Port number of the remote host.
parkedtime	timestamp	This information is for internal use only.
session_vars	character (2000)	This information is for internal use only.

Sample queries

The following example joins `STL_RESTARTED_SESSIONS` with `STL_SESSIONS` to show user names for sessions that have been restarted.

```
select process, stl_restarted_sessions.newpid, user_name
from stl_sessions
inner join stl_restarted_sessions on stl_sessions.process =
  stl_restarted_sessions.oldpid
order by process;

...
```

STL_RETURN

Contains details for *return* steps in queries. A return step returns the results of queries completed on the compute nodes to the leader node. The leader node then merges the data and returns the results to the requesting client. For queries completed on the leader node, a return step returns results to the client.

A query consists of multiple segments, and each segment consists of one or more steps. For more information, see [Query processing](#).

`STL_RETURN` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

`STL_RETURN` only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the `SYS` monitoring view [SYS_QUERY_DETAIL](#). The data in the `SYS` monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.

Column name	Data type	Description
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
packets	integer	Total number of packets sent over the network.
checksum	bigint	This information is for internal use only.

Sample queries

The following query shows which steps in the most recent query were performed on each slice.

```
SELECT query, slice, segment, step, endtime, rows, packets
from stl_return where query = pg_last_query_id();
```

```
query | slice | segment | step |          endtime          | rows | packets
-----+-----+-----+-----+-----+-----+-----
```

```

 4 |      2 |      3 |      2 | 2013-12-27 01:43:21.469043 |      3 |      0

(7 rows)

```

STL_S3CLIENT

Records transfer time and other performance metrics.

Use the STL_S3CLIENT table to find the time spent transferring data from Amazon S3.

STL_S3CLIENT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
recordtime	timestamp	Time the record is logged.
pid	integer	Process ID. All of the queries in a session are run in the same process, so this value remains constant if you run a series of queries in the same session.
http_method	character (64)	HTTP method name corresponding to the Amazon S3 request.
bucket	character (64)	S3 bucket name.

Column name	Data type	Description
key	character (256)	Key corresponding to the Amazon S3 object.
transfer_size	bigint	Number of bytes transferred.
data_size	bigint	Number of bytes of data. This value is the same as transfer_size for uncompressed data. If compression was used, this is the size of the uncompressed data.
start_time	bigint	Time when the transfer began (in microseconds since January 1, 2000).
end_time	bigint	Time when the transfer ended (in microseconds since January 1, 2000).
transfer_time	bigint	Time taken by the transfer (in microseconds).
compression_time	bigint	Portion of the transfer time that was spent uncompressing data (in microseconds).
connect_time	bigint	Time from the start until the connect to the remote server was completed (in microseconds).
app_connect_time	bigint	Time from the start until the SSL connect/handshake with the remote host was completed (in microseconds).
retries	bigint	Number of times the transfer was retried.
request_id	char(32)	Request ID from Amazon S3 HTTP response header
extended_request_id	char(128)	Extended request ID from Amazon S3 HTTP header response (x-amz-id-2).
ip_address	char(64)	IP address of the server (ip V4 or V6).
is_partial	integer	Value that if true (1) indicates the input file is split into ranges during a COPY operation. If this value is false (0), the input file isn't split.

Column name	Data type	Description
start_offset	bigint	Value that, if the input file is split during a COPY operation , indicates the offset value of the split (in bytes). If the file isn't split, this value is 0.

Sample query

The following query returns the time taken to load files using a COPY command.

```
select slice, key, transfer_time
from stl_s3client
where query = pg_last_copy_id();
```

Result

```
slice | key | transfer_time
-----+-----+-----
0 | listing10M0003_part_00 | 16626716
1 | listing10M0001_part_00 | 12894494
2 | listing10M0002_part_00 | 14320978
3 | listing10M0000_part_00 | 11293439
3371 | prefix=listing10M;marker= | 99395
```

The following query converts the start_time and end_time to a timestamp.

```
select userid,query,slice,pid,recordtime,start_time,end_time,
'2000-01-01'::timestamp + (start_time/1000000.0)* interval '1 second' as start_ts,
'2000-01-01'::timestamp + (end_time/1000000.0)* interval '1 second' as end_ts
from stl_s3client where query> -1 limit 5;
```

```
userid | query | slice | pid | recordtime | start_time | end_time |
-----+-----+-----+-----+-----+-----+-----+
0 | 0 | 0 | 23449 | 2019-07-14 16:27:17.207839 | 616436837154256 | 616436837207838 |

```

STL_S3CLIENT_ERROR

Records errors encountered by a slice while loading a file from Amazon S3.

Use the STL_S3CLIENT_ERROR to find details for errors encountered while transferring data from Amazon S3 as part of a COPY command.

STL_S3CLIENT_ERROR is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views. The query ID -1 is for internal use.
sliceid	integer	Number that identifies the slice where the query was running.
recordtime	timestamp	Time the record is logged.
pid	integer	Process ID. All of the queries in a session are run in the same process, so this value remains constant if you run a series of queries in the same session.
http_method	character (64)	HTTP method name corresponding to the Amazon S3 request.

Column name	Data type	Description
bucket	character (64)	Amazon S3 bucket name.
key	character (256)	Key corresponding to the Amazon S3 object.
error	character (1024)	Error message.
is_partial	integer	Value that, if true (1), indicates the input file is split into ranges during a COPY operation. If this value is false (0), the input file isn't split.
start_offset	bigint	Value that, if the input file is split during a COPY operation , indicates the offset value of the split (in bytes). If the file isn't split, this value is 0.

Usage notes

If you see multiple errors with "Connection timed out", you might have a networking issue. If you're using Enhanced VPC Routing, verify that you have a valid network path between your cluster's VPC and your data resources. For more information, see [Amazon Redshift Enhanced VPC Routing](#).

Sample query

The following query returns the errors from COPY commands completed during the current session.

```
select query, sliceid, substring(key from 1 for 20) as file,  
substring(error from 1 for 35) as error  
from stl_s3client_error  
where pid = pg_backend_pid()  
order by query desc;
```

Result

```

query | sliceid | file | error
-----+-----+-----+-----
362228 | 12 | part.tbl.25.159.gz | transfer closed with 1947655 bytes
362228 | 24 | part.tbl.15.577.gz | transfer closed with 1881910 bytes
362228 | 7 | part.tbl.22.600.gz | transfer closed with 700143 bytes r
362228 | 22 | part.tbl.3.34.gz | transfer closed with 2334528 bytes
362228 | 11 | part.tbl.30.274.gz | transfer closed with 699031 bytes r
362228 | 30 | part.tbl.5.509.gz | Unknown SSL protocol error in conne
361999 | 10 | part.tbl.23.305.gz | transfer closed with 698959 bytes r
361999 | 19 | part.tbl.26.582.gz | transfer closed with 1881458 bytes
361999 | 4 | part.tbl.15.629.gz | transfer closed with 2275907 bytes
361999 | 20 | part.tbl.6.456.gz | transfer closed with 692162 bytes r
(10 rows)

```

STL_SAVE

Contains details for *save* steps in queries. A save step saves the input stream to a transient table. A transient table is a temporary table that stores intermediate results during query execution.

A query consists of multiple segments, and each segment consists of one or more steps. For more information, see [Query processing](#).

STL_SAVE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_SAVE only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.

Column name	Data type	Description
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
tbl	integer	ID of the materialized transient table.
is_diskbased	character(1)	Whether this step of the query was performed as a disk-based operation: true (t) or false (f).
workmem	bigint	Number of bytes of working memory assigned to the step.

Sample queries

The following query shows which save steps in the most recent query were performed on each slice.

```
select query, slice, segment, step, tasknum, rows, tbl
```

```
from stl_save where query = pg_last_query_id();
```

```

query | slice | segment | step | tasknum | rows | tbl
-----+-----+-----+-----+-----+-----+-----
52236 |    3 |    0 |    2 |    21 |    0 | 239
52236 |    2 |    0 |    2 |    20 |    0 | 239
52236 |    2 |    2 |    2 |    20 |    0 | 239
52236 |    3 |    2 |    2 |    21 |    0 | 239
52236 |    1 |    0 |    2 |    21 |    0 | 239
52236 |    0 |    0 |    2 |    20 |    0 | 239
52236 |    0 |    2 |    2 |    20 |    0 | 239
52236 |    1 |    2 |    2 |    21 |    0 | 239
(8 rows)

```

STL_SCAN

Analyzes table scan steps for queries. The step number for rows in this table is always 0 because a scan is the first step in a segment.

STL_SCAN is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_SCAN only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
fetches	bigint	This information is for internal use only.
type	integer	ID of the scan type. For a list of valid values, see the following table.
tbl	integer	Table ID.
is_rrscan	character(1)	If true (t), indicates that range-restricted scan was used on the step.
is_delayed_scan	character(1)	This information is for internal use only.

Column name	Data type	Description
rows_pre_filter	bigint	For scans of permanent tables, the total number of rows emitted before filtering rows marked for deletion (ghost rows) and before applying user-defined query filters.
rows_pre_user_filter	bigint	For scans of permanent tables, the number of rows processed after filtering rows marked for deletion (ghost rows) but before applying user-defined query filters.
perm_table_name	character(136)	For scans of permanent tables, the name of the table scanned.
is_rlf_scan	character(1)	If true (t), indicates that row-level filtering was used on the step.
is_rlf_scan_reason	integer	This information is for internal use only.
num_em_blocks	integer	This information is for internal use only.
checksum	bigint	This information is for internal use only.
runtime_filtering	character(1)	If true (t), indicates that runtime filters are applied.
scan_region	integer	This information is for internal use only.
num_sortkey_as_predicate	integer	This information is for internal use only.
row_fetcher_state	integer	This information is for internal use only.

Column name	Data type	Description
consumed_scan_ranges	bigint	This information is for internal use only.
work_stealing_reason	bigint	This information is for internal use only.
is_vectorized_scan	character(1)	This information is for internal use only.
is_vectorized_scan_reason	integer	This information is for internal use only.
row_fetcher_reason	bigint	This information is for internal use only.
topology_signature	bigint	This information is for internal use only.
use_tpm_partition	character(1)	This information is for internal use only.
is_rrscan_expr	character(1)	This information is for internal use only.
scanned_mega_value	character(1)	This information is for internal use only. This information shows whether the given scan step has scanned a large value. A large value will be stored in multiple blocks. Block size is 1 MB by default, a large value is greater than 1 MB in a default setting.

Scan types

Type ID	Description
1	Data from the network.
2	Permanent user tables in compressed shared memory.
3	Transient row-wise tables.
21	Load files from Amazon S3.
22	Load tables from Amazon DynamoDB.
23	Load data from a remote SSH connection.
24	Load data from remote cluster (sorted region). This is used for resizing.
25	Load data from remote cluster(unsorted region). This is used for resizing.
28	Read data from a time series view with UNION ALL on multiple tables.
29	Read data from Amazon S3 external tables.
30	Read partition information of an Amazon S3 external table.
33	Read data from a remote Postgres table.
36	Read data from a remote MySQL table.
37	Read data from a remote Kinesis stream.

Usage notes

Ideally rows should be relatively close to `rows_pre_filter`. A large difference between rows and `rows_pre_filter` is an indication that the execution engine is scanning rows that are later discarded, which is inefficient. The difference between `rows_pre_filter` and `rows_pre_user_filter` is the number of ghost rows in the scan. Run a VACUUM to remove rows marked for deletion. The difference between rows and `rows_pre_user_filter` is the number of

rows filtered by the query. If a lot of rows are discarded by the user filter, review your choice of sort column or, if this is due to a large unsorted region, run a vacuum.

Sample queries

The following example shows that `rows_pre_filter` is larger than `rows_pre_user_filter` because the table has deleted rows that have not been vacuumed (ghost rows).

```
SELECT query, slice, segment, step, rows, rows_pre_filter, rows_pre_user_filter
from stl_scan where query = pg_last_query_id();
```

query	slice	segment	step	rows	rows_pre_filter	rows_pre_user_filter
42915	0	0	0	43159	86318	43159
42915	0	1	0	1	0	0
42915	1	0	0	43091	86182	43091
42915	1	1	0	1	0	0
42915	2	0	0	42778	85556	42778
42915	2	1	0	1	0	0
42915	3	0	0	43428	86856	43428
42915	3	1	0	1	0	0
42915	10000	2	0	4	0	0

(9 rows)

STL_SCHEMA_QUOTA_VIOLATIONS

Records the occurrence, timestamp, XID, and other useful information when a schema quota is exceeded.

STL_SCHEMA_QUOTA_VIOLATIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_SCHEMA_QUOTA_VIOLATIONS](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
ownerid	integer	The ID of the schema owner.
xid	bigint	The transaction ID associated with the statement.
pid	integer	The process ID associated with the statement.
userid	integer	The ID of the user who generated the entry.
schema_id	integer	The namespace or schema ID.
schema_name	character (128)	The namespace or schema name.
quota	integer	The amount of disk space (in MB) that the schema can use.
disk_usage	integer	The disk space (in MB) that is currently used by the schema.
disk_usage_pct	double precision	The disk space percentage that is currently used by the schema out of the configured quota.
timestamp	timestamp without time zone	The time when the violation occurred.

Sample queries

The following query shows the result of quota violation:

```
SELECT userid, TRIM(SCHEMA_NAME) "schema_name", quota, disk_usage, disk_usage_pct,
timestamp FROM
stl_schema_quota_violations WHERE SCHEMA_NAME = 'sales_schema' ORDER BY timestamp DESC;
```

This query returns the following sample output for the specified schema:

--

```

userid | schema_name | quota | disk_usage | disk_usage_pct | timestamp
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
104    | sales_schema | 2048 | 2798      | 136.62         | 2020-04-20
      20:09:25.494723
(1 row)

```

STL_SESSIONS

Returns information about user session history.

STL_SESSIONS differs from STV_SESSIONS in that STL_SESSIONS contains session history, where STV_SESSIONS contains the current active sessions.

STL_SESSIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_SESSION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
starttime	timestamp	Time in UTC that the session started.
endtime	timestamp	Time in UTC that the session ended.
process	integer	Process ID for the session.
user_name	character(50)	User name associated with the session.
db_name	character(50)	Name of the database associated with the session.

Column name	Data type	Description
timeout_sec	int	The maximum time in seconds that a session remains inactive or idle before timing out. 0 indicates that no timeout is set.
timed_out	int	A value that indicates why the connection was terminated. It can have the following values: <ul style="list-style-type: none"> • 0: The connection was terminated due to an unknown error. • 1: The connection timed out. • 2: The client side terminated the connection. • 3: An Amazon Redshift backend internal error terminated the connection.

Sample queries

To view session history for the TICKIT database, type the following query:

```
select starttime, process, user_name, timeout_sec, timed_out
from stl_sessions
where db_name='tickit' order by starttime;
```

This query returns the following sample output:

```

      starttime          | process | user_name          | timeout_sec | timed_out
-----+-----+-----+-----+-----
+-----+

```

STL_SORT

Displays sort execution steps for queries, such as steps that use ORDER BY processing.

STL_SORT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_SORT only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.

Column name	Data type	Description
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
bytes	bigint	Size, in bytes, of all the output rows for the step.
tbl	integer	Table ID.
is_diskbased	character(1)	If true (t), the query was performed as a disk-based operation. If false (f), the query was performed in memory.
workmem	bigint	Total number of bytes in working memory that were assigned to the step.
checksum	bigint	This information is for internal use only.

Sample queries

The following example returns sort results for slice 0 and segment 1.

```
select query, bytes, tbl, is_diskbased, workmem
from stl_sort
```

```
where slice=0 and segment=1;
```

```

query | bytes | tbl | is_diskbased | workmem
-----+-----+-----+-----+-----
  567 | 3126968 | 241 | f           | 383385600
  604 |    5292 | 242 | f           | 383385600
  675 | 104776 | 251 | f           | 383385600
  525 | 3126968 | 251 | f           | 383385600
  585 |    5068 | 241 | f           | 383385600
  630 | 204808 | 266 | f           | 383385600
  704 |      0 | 242 | f           |      0
  669 | 4606416 | 241 | f           | 383385600
  696 | 104776 | 241 | f           | 383385600
  651 | 4606416 | 254 | f           | 383385600
  632 |      0 | 256 | f           |      0
  599 |    396 | 241 | f           | 383385600
86397 |      0 | 242 | f           |      0
  621 |    5292 | 241 | f           | 383385600
86325 |      0 | 242 | f           |      0
  572 |    5068 | 242 | f           | 383385600
  645 | 204808 | 241 | f           | 383385600
  590 |    396 | 242 | f           | 383385600
(18 rows)

```

STL_SSHCLIENT_ERROR

Records all errors seen by the SSH client.

STL_SSHCLIENT_ERROR is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.

Column name	Data type	Description
slice	integer	Number that identifies the slice where the query was running.
recordtime	timestamp	Time that the error was logged.
pid	integer	Process that logged the error.
ssh_username	character (1024)	The SSH user name.
endpoint	character (1024)	The SSH endpoint.
command	character (4096)	The complete SSH command.
error	character (1024)	The error message.

STL_STREAM_SEGS

Lists the relationship between streams and concurrent segments.

Streams in this context are Amazon Redshift streams. This system view doesn't pertain to [Streaming ingestion to a materialized view](#).

STL_STREAM_SEGS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_STREAM_SEGS only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
stream	integer	The set of concurrent segments of a query.
segment	integer	Number that identifies the query segment.

Sample queries

To view the relationship between streams and concurrent segments for the most recent query, type the following query:

```
select *
from stl_stream_segs
where query = pg_last_query_id();
```

```
query | stream | segment
-----+-----+-----
    10 |      1 |      2
    10 |      0 |      0
    10 |      2 |      4
    10 |      1 |      3
    10 |      0 |      1
(5 rows)
```

STL_TR_CONFLICT

Displays information to identify and resolve transaction conflicts with database tables.

A transaction conflict occurs when two or more users are querying and modifying data rows from tables such that their transactions cannot be serialized. The transaction that runs a statement that would break serializability is stopped and rolled back. Every time a transaction conflict occurs,

Amazon Redshift writes a data row to the STL_TR_CONFLICT system table containing details about the canceled transaction. For more information, see [Serializable isolation](#).

STL_TR_CONFLICT is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_TRANSACTION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
xact_id	bigint	Transaction ID for the rolled back transaction.
process_id	bigint	Process associated with the transaction that was rolled back.
xact_start_ts	timestamp	Timestamp (UTC) when the transaction started.
abort_time	timestamp	Timestamp (UTC) when the transaction was stopped.
table_id	bigint	Table ID for the table where the conflict occurred.

Sample query

To return information about conflicts that involved a particular table, run a query that specifies the table ID:

```
select * from stl_tr_conflict where table_id=100234
order by xact_start_ts;
```

```
xact_id|process_|      xact_start_ts      |      abort_time      |table_
      |id      |      |      |      |      |
-----+-----+-----+-----+-----
 1876 |  8551 | 2010-03-30 09:19:15.852326| 2010-03-30 09:20:17.582499|100234
 1928 | 15034 | 2010-03-30 13:20:00.636045| 2010-03-30 13:20:47.766817|100234
 1991 | 23753 | 2010-04-01 13:05:01.220059| 2010-04-01 13:06:06.94098  |100234
```

```
2002 | 23679 | 2010-04-01 13:17:05.173473 | 2010-04-01 13:18:27.898655 | 100234
(4 rows)
```

You can get the table ID from the DETAIL section of the error message for serializability violations (error 1023).

STL_UNDONE

Displays information about transactions that have been undone.

STL_UNDONE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_TRANSACTION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
xact_id	bigint	ID for the undo transaction.
xact_id_undone	bigint	ID for the transaction that was undone.
undo_start_ts	timestamp	Start time for the undo transaction.
undo_end_ts	timestamp	End time for the undo transaction.
table_id	bigint	ID for the table that was affected by the undo transaction.

Sample query

To view a concise log of all undone transactions, type the following command:

```
select xact_id, xact_id_undone, table_id from stl_undone;
```

This command returns the following sample output:

```
xact_id | xact_id_undone | table_id
-----+-----+-----
1344 |      1344 | 100192
1326 |      1326 | 100192
1551 |      1551 | 100192
(3 rows)
```

STL_UNIQUE

Analyzes execution steps that occur when a DISTINCT function is used in the SELECT list or when duplicates are removed in a UNION or INTERSECT query.

STL_UNIQUE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_UNIQUE only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.

Column name	Data type	Description
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
type	character(6)	The type of step. Valid values are: <ul style="list-style-type: none"> HASHED. Indicates that the step used grouped, unsorted aggregation. PLAIN. Indicates that the step used ungrouped, scalar aggregation. SORTED. Indicates that the step used grouped, sorted aggregation.
is_diskbased	character(1)	If true (t), the query was performed as a disk-based operation. If false (f), the query was performed in memory.
slots	integer	Total number of hash buckets.
workmem	bigint	Total number of bytes in working memory that were assigned to the step.

Column name	Data type	Description
max_buffers_used	bigint	Maximum number of buffers used in the hash table before going to disk.
resizes	integer	This information is for internal use only.
occupied	integer	This information is for internal use only.
flushable	integer	This information is for internal use only.
used_unique_prefetching	character(1)	This information is for internal use only.
bytes	bigint	The number of bytes of all the output rows for the step.

Sample queries

Suppose you run the following query:

```
select distinct eventname
from event order by 1;
```

Assuming the ID for the previous query is 6313, the following example shows the number of rows produced by the unique step for each slice in segments 0 and 1.

```
select query, slice, segment, step, datediff(msec, starttime, endtime) as msec,
tasknum, rows
from stl_unique where query = 6313
order by query desc, slice, segment, step;
```

query	slice	segment	step	msec	tasknum	rows
6313	0	0	2	0	22	550
6313	0	1	1	256	20	145
6313	1	0	2	1	23	540
6313	1	1	1	42	21	127
6313	2	0	2	1	22	540

```

6313 | 2 | 1 | 1 | 255 | 20 | 158
6313 | 3 | 0 | 2 | 1 | 23 | 542
6313 | 3 | 1 | 1 | 38 | 21 | 146
(8 rows)

```

STL_UNLOAD_LOG

Records the details for an unload operation.

STL_UNLOAD_LOG records one row for each file created by an UNLOAD statement. For example, if an UNLOAD creates 12 files, STL_UNLOAD_LOG will contain 12 corresponding rows.

STL_UNLOAD_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_UNLOAD_LOG only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_UNLOAD_HISTORY](#) and [SYS_UNLOAD_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	The query ID.
slice	integer	Number that identifies the slice where the query was running.
pid	integer	Process ID associated with the query statement.
path	character(1280)	The complete Amazon S3 object path for the file.

Column name	Data type	Description
start_time	timestamp	Start time for the transaction.
end_time	timestamp	End time for the transaction.
line_count	bigint	Number of lines (rows) unloaded to the file.
transfer_size	bigint	Number of bytes transferred.
file_format	character(10)	Format of unloaded file.

Sample query

To get a list of the files that were written to Amazon S3 by an UNLOAD command, you can call an Amazon S3 list operation after the UNLOAD completes. You can also query STL_UNLOAD_LOG.

The following query returns the pathname for files that were created by an UNLOAD for the last query completed:

```
select query, substring(path,0,40) as path
from stl_unload_log
where query = pg_last_query_id()
order by path;
```

This command returns the following sample output:

```
query |          path
-----+-----
 2320 | s3://amzn-s3-demo-bucket/venue0000_part_00
 2320 | s3://amzn-s3-demo-bucket/venue0001_part_00
 2320 | s3://amzn-s3-demo-bucket/venue0002_part_00
 2320 | s3://amzn-s3-demo-bucket/venue0003_part_00
(4 rows)
```

STL_USAGE_CONTROL

The STL_USAGE_CONTROL view contains information that is logged when a usage limit is reached. For more information about usage limits, see [Managing Usage Limits](#) in the *Amazon Redshift Management Guide*.

STL_USAGE_CONTROL is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
eventtime	timestamp	The time (UTC) when the query exceeded a usage limit.
query	integer	The query identifier. You can use this ID to join various other system tables and views.
xid	bigint	The transaction identifier.
pid	integer	The process identifier associated with the query.
usage_limit_id	character(40)	A universally unique identifier (UUID) generated by Amazon Redshift, for example 25d9297e-3e7b-41c8-9f4d-c4b6eb731c09 .
feature_type	character(30)	The feature whose usage limit was exceeded. Possible values include CONCURRENCY_SCALING and SPECTRUM.

Sample query

The following SQL example returns some of the information logged when a usage limit is reached.

```
select query, pid, eventtime, feature_type
from stl_usage_control
order by eventtime desc
limit 5;
```

STL_USERLOG

Records details for the following changes to a database user:

- Create user
- Drop user
- Alter user (rename)
- Alter user (alter properties)

STL_USERLOG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_USERLOG](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user affected by the change.
username	character(50)	User name of the user affected by the change.
oldusername	character(50)	For a rename action, the original user name. For any other action, this field is empty.
action	character(10)	Action that occurred. Valid values: <ul style="list-style-type: none"> • Alter • Create • Drop • Rename
usecreatedb	integer	If true (1), indicates that the user has create database privileges.

Column name	Data type	Description
usesuper	integer	If true (1), indicates that the user is a superuser.
usecatupd	integer	If true (1), indicates that the user can update system catalogs.
valuntil	timestamp	Password expiration date.
pid	integer	Process ID.
xid	bigint	Transaction ID.
recordtime	timestamp	Time in UTC that the query started.

Sample queries

The following example performs four user actions, then queries the STL_USERLOG view.

```
create user userlog1 password 'Userlog1';
alter user userlog1 createdb createuser;
alter user userlog1 rename to userlog2;
drop user userlog2;

select userid, username, oldusername, action, usecreatedb, usesuper from stl_userlog
order by recordtime desc;
```

```
userid | username | oldusername | action | usecreatedb | usesuper
-----+-----+-----+-----+-----+-----
  108 | userlog2 |             | drop   |             | 1
  108 | userlog2 | userlog1    | rename |             | 1
  108 | userlog1 |             | alter  |             | 1
  108 | userlog1 |             | create |             | 0
(4 rows)
```

STL_UTILITYTEXT

Captures the text of non-SELECT SQL commands run on the database.

Query the STL_UTILITYTEXT view to capture the following subset of SQL statements that were run on the system:

- ABORT, BEGIN, COMMIT, END, ROLLBACK
- ANALYZE
- CALL
- CANCEL
- COMMENT
- CREATE, ALTER, DROP DATABASE
- CREATE, ALTER, DROP USER
- EXPLAIN
- GRANT, REVOKE
- LOCK
- RESET
- SET
- SHOW
- TRUNCATE

See also [STL_DDLTEXT](#), [STL_QUERYTEXT](#), and [SVL_STATEMENTTEXT](#).

Use the STARTTIME and ENDTIME columns to find out which statements were logged during a given time period. Long blocks of SQL text are broken into lines 200 characters long; the SEQUENCE column identifies fragments of text that belong to a single statement.

STL_UTILITYTEXT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
xid	bigint	Transaction ID.
pid	integer	Process ID associated with the query statement.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter is not set, this field is blank.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
sequence	integer	When a single statement contains more than 200 characters, additional rows are logged for that statement. Sequence 0 is the first row, 1 is the second, and so on.
text	character(200)	SQL text, in 200-character increments. This field might contain special characters such as backslash (\\) and newline (\n).

Sample queries

The following query returns the text for "utility" commands that were run on January 26th, 2012. In this case, some SET commands and a SHOW ALL command were run:

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_VACUUM_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who generated the entry.
xid	bigint	The transaction ID for the VACUUM statement. You can join this table to the STL_QUERY view to see the individual SQL statements that are run for a given VACUUM transaction. If you vacuum the whole database, each table is vacuumed in a separate transaction.
table_id	integer	The Table ID.
status	character(30)	<p>The status of the VACUUM operation for each table. Possible values are the following:</p> <ul style="list-style-type: none"> • Started • Started Delete Only • Started Delete Only (Sorted >= nn%) <p>Only the delete phase was started for a VACUUM FULL. The sort phase was skipped because the table was already sorted at or above the sort threshold.</p> <ul style="list-style-type: none"> • Started Sort Only • Started Ranged Partition • Started Reindex • Finished <p>Time the operation completed for the table. To find out how long a vacuum operation took on a specific table, subtract the Started time from the Finished time for a particular transaction ID and table ID.</p>

Column name	Data type	Description
		<ul style="list-style-type: none"> <li data-bbox="691 212 857 247">• Skipped <p data-bbox="724 289 1446 373">The table was skipped because the table was fully sorted and no rows were marked for deletion.</p> <li data-bbox="691 396 1125 432">• Skipped (delete only) <p data-bbox="724 474 1446 558">The table was skipped because DELETE ONLY was specified and no rows were marked for deletion.</p> <li data-bbox="691 581 1084 617">• Skipped (sort only) <p data-bbox="724 659 1414 785">The table was skipped because SORT ONLY was specified and the table was already sorted fully sorted.</p> <li data-bbox="691 808 1336 844">• Skipped (sort only, sorted>=xx%) <p data-bbox="724 886 1507 1012">The table was skipped because SORT ONLY was specified and the table was already sorted at or above the sort threshold.</p> <li data-bbox="691 1035 1029 1071">• Skipped (0 rows) <p data-bbox="724 1113 1370 1155">The table was skipped because it was empty.</p> <li data-bbox="691 1178 878 1213">• VacuumBG <p data-bbox="724 1255 1458 1535">An automatic vacuum operation was performed in the background. This status is prepended to other statuses when they're performed automatically. For example, a delete only vacuum performed automatically would have a starting row with the status [VacuumBG] Started Delete Only .</p> <p data-bbox="691 1612 1507 1696">For more information about the VACUUM sort threshold setting, see VACUUM.</p>

Column name	Data type	Description
rows	bigint	The actual number of rows in the table plus any deleted rows that are still stored on disk (waiting to be vacuumed). This column shows the count before the vacuum started for rows with a Started status, and the count after the vacuum for rows with a Finished status.
sortedrows	integer	The number of rows in the table that are sorted. This column shows the count before the vacuum started for rows with Started in the Status column, and the count after the vacuum for rows with Finished in the Status column.
blocks	integer	The total number of data blocks used to store the table data before the vacuum operation (rows with a Started status) and after the vacuum operation (Finished column). Each data block uses 1 MB.
max_merge_partitions	integer	This column is used for performance analysis and represents the maximum number of partitions that vacuum can process for the table per merge phase iteration. (Vacuum sorts the unsorted region into one or more sorted partitions. Depending on the number of columns in the table and the current Amazon Redshift configuration, the merge phase can process a maximum number of partitions in a single merge iteration. The merge phase will still work if the number of sorted partitions exceeds the maximum number of merge partitions, but more merge iterations will be required.)
eventtime	timestamp	When the vacuum operation started or finished.

Column name	Data type	Description
reclaimable_rows	bigint	The number of reclaimable rows for the current cutoff_xid. This column shows Redshift's estimated number of reclaimable rows before the vacuum started for rows with a Started status, and the actual number of reclaimable rows remaining after the vacuum for rows with a Finished status.
reclaimable_space_mb	bigint	Reclaimable space in MB for the current cutoff_xid. This column shows Redshift's estimated amount of reclaimable space before the vacuum started for rows with a Started status, and the actual amount of reclaimable space remaining after the vacuum for rows with a Finished status.
cutoff_xid	bigint	The cutoff transaction ID for the VACUUM operation. Any transactions after the cutoff are not included in the VACUUM operation.
is_recluster	integer	If 1 (true), the VACUUM operation executed the recluster algorithm, If 0 (false), it was not.

Sample queries

The following query reports vacuum statistics for table 108313. The table was vacuumed following a series of inserts and deletes.

```
select xid, table_id, status, rows, sortedrows, blocks, eventtime,
       reclaimable_rows, reclaimable_space_mb
from stl_vacuum where table_id=108313 order by eventtime;
```

```

xid   | table_id | status           | rows | sortedrows | blocks | eventtime
      |          | reclaimable_rows |      |            |        |          |
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
14294 |   108313 | Started         | 1950 |          408 |      28 | 2016-05-19
17:36:01 |          | 984 |          17
```

```

14294 | 108313 | Finished          | 966 | 966 | 11 | 2016-05-19
18:26:13 |          0 |                   |     |     |    |
15126 | 108313 | Skipped(sorted>=95%) | 966 | 966 | 11 | 2016-05-19
18:26:38 |          0 |                   |     |     |    |

```

At the start of the VACUUM, the table contained 1,950 rows stored in 28 1 MB blocks. Amazon Redshift estimated it could reclaim 984, or 17 blocks of disk space, with a vacuum operation.

In the row for the Finished status, the ROWS column shows a value of 966, and the BLOCKS column value is 11, down from 28. The vacuum reclaimed the estimated amount of disk space, with no reclaimable rows or space remaining after the vacuum operation completed.

In the sort phase (transaction 15126), the vacuum was able to skip the table because the rows were inserted in sort key order.

The following example shows the statistics for a SORT ONLY vacuum on the SALES table (table 110116 in this example) after a large INSERT operation:

```

vacuum sort only sales;

select xid, table_id, status, rows, sortedrows, blocks, eventtime
from stl_vacuum order by xid, table_id, eventtime;

xid |table_id|      status      | rows |sortedrows|blocks|      eventtime
-----+-----+-----+-----+-----+-----+-----
...
2925| 110116 |Started Sort Only|1379648| 172456 | 132 | 2011-02-24 16:25:21...
2925| 110116 |Finished          |1379648| 1379648 | 132 | 2011-02-24 16:26:28...

```

STL_WINDOW

Analyzes query steps that perform window functions.

STL_WINDOW is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

STL_WINDOW only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling

clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_DETAIL](#) . The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
slice	integer	Number that identifies the slice where the query was running.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
starttime	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
endtime	timestamp	Time in UTC that the query finished. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .
tasknum	integer	Number of the query task process that was assigned to run the step.
rows	bigint	Total number of rows that were processed.
is_diskbased	character(1)	If true (t), the query was performed as a disk-based operation. If false (f), the query was performed in memory.

Column name	Data type	Description
workmem	bigint	Total number of bytes in working memory that were assigned to the step.

Sample queries

The following example returns window function results for slice 0 and segment 3.

```
select query, tasknum, rows, is_diskbased, workmem
from stl_window
where slice=0 and segment=3;
```

```
query | tasknum | rows | is_diskbased | workmem
-----+-----+-----+-----+-----
86326 |      36 | 1857 | f             | 95256616
   705 |      15 | 1857 | f             | 95256616
86399 |      27 | 1857 | f             | 95256616
   649 |      10 |    0 | f             | 95256616
(4 rows)
```

STL_WLM_ERROR

Records all WLM-related errors as they occur.

STL_WLM_ERROR is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
recordtime	timestamp	Time that the error occurred.
pid	integer	ID for the process that generated the error.

Column name	Data type	Description
error_string	character(256)	Error description.

STL_WLM_RULE_ACTION

Records details about actions resulting from WLM query monitoring rules associated with user-defined queues. For more information, see [WLM query monitoring rules](#).

STL_WLM_RULE_ACTION is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	User that ran the query.
query	integer	Query ID.
service_class	integer	ID for the service class. Query queues are defined in the WLM configuration. Service classes greater than 5 are user-defined queues.
rule	character(256)	Name of a query monitoring rule.
action	character(256)	Resulting action. Possible values are as follows: <ul style="list-style-type: none"> log hop(reassign) hop(restart) abort change_query_priority none

Column name	Data type	Description
		A value of none indicates that the rule's predicates were met but the action was superseded by another rule with a higher severity action.
recordtime	timestamp	Time the action was logged in UTC.
action_value	character(256)	If action is change_query_priority , then possible values are highest, high, normal, low, and lowest. If action is log, hop, or abort then the value is empty.
service_class_name	character(64)	The name of the service class.

Sample queries

The following example finds queries that were stopped by a query monitoring rule.

```
Select query, rule
from stl_wlm_rule_action
where action = 'abort'
order by query;
```

STL_WLM_QUERY

Contains a record of each attempted execution of a query in a service class handled by WLM.

STL_WLM_QUERY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
xid	integer	Transaction ID of the query or subquery.
task	integer	ID used to track a query through the workload manager. Can be associated with multiple query IDs. If a query is restarted, the query is assigned a new query ID but not a new task ID.
query	integer	Query ID. If a query is restarted, the query is assigned a new query ID but not a new task ID.
service_class	integer	ID for the service class. For a list of service class IDs, see WLM service class IDs .
slot_count	integer	Number of WLM query slots that a query uses according to the concurrency level set for the queue. Default is 1. For more information, see wlm_query_slot_count .
service_class_start_time	timestamp	Time that the query was assigned to the service class. This time is in the UTC time zone.
queue_start_time	timestamp	Time that the query entered the queue for the service class. This time is in the UTC time zone.
queue_end_time	timestamp	Time when the query left the queue for the service class. This time is in the UTC time zone.
total_queue_time	bigint	Total number of microseconds that the query spent in the queue
exec_start_time	timestamp	Time that the query began executing in the service class. This time is in the UTC time zone.

Column name	Data type	Description
exec_end_time	timestamp	Time that the query completed execution in the service class. This time is in the UTC time zone.
total_exec_time	bigint	Number of microseconds that the query spent executing.
service_class_end_time	timestamp	Time that the query left the service class. This time is in the UTC time zone.
final_state	character(16)	Reserved for system use.
est_peak_mem	bigint	Reserved for system use.
query_priority	char(20)	The priority of the query. Possible values are n/a, lowest, low, normal, high, and highest, where n/a means that query priority isn't supported.
service_class_name	character(64)	The service class name. For more information about service classes, see WLM system tables and views .

Sample queries

View average query Time in queues and executing

The following queries display the current configuration for service classes greater than 4. For a list of service class IDs, see [WLM service class IDs](#).

The following query returns the average time (in microseconds) that each query spent in query queues and executing for each service class.

```
select service_class as svc_class, count(*),
avg(datediff(microseconds, queue_start_time, queue_end_time)) as avg_queue_time,
avg(datediff(microseconds, exec_start_time, exec_end_time )) as avg_exec_time
from stl_wlm_query
where service_class > 4
group by service_class
order by service_class;
```

This query returns the following sample output:

svc_class	count	avg_queue_time	avg_exec_time
5	20103	0	80415
5	3421	34015	234015
6	42	0	944266
7	196	6439	1364399

(4 rows)

View maximum query time in queues and executing

The following query returns the maximum amount of time (in microseconds) that a query spent in any query queue and executing for each service class.

```
select service_class as svc_class, count(*),
max(datediff(microseconds, queue_start_time, queue_end_time)) as max_queue_time,
max(datediff(microseconds, exec_start_time, exec_end_time )) as max_exec_time
from stl_wlm_query
where svc_class > 5
group by service_class
order by service_class;
```

svc_class	count	max_queue_time	max_exec_time
6	42	0	3775896
7	197	37947	16379473

(4 rows)

STV tables for snapshot data

STV tables are virtual system tables that contain snapshots of the current system data.

STV_ACTIVE_CURSORS

STV_ACTIVE_CURSORS displays details for currently open cursors. For more information, see [DECLARE](#).

STV_ACTIVE_CURSORS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#). A user can only view cursors opened by that user. A superuser can view all cursors.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
name	character (256)	Cursor name.
xid	bigint	Transaction context.
pid	integer	Leader process running the query.
starttime	timestamp	Time when the cursor was declared.
row_count	bigint	Number of rows in the cursor result set.
byte_count	bigint	Number of bytes in the cursor result set.
fetches_ows	bigint	Number of rows currently fetched from the cursor result set.

STV_BLOCKLIST

STV_BLOCKLIST contains the number of 1 MB disk blocks that are used by each slice, table, or column in a database.

Use aggregate queries with STV_BLOCKLIST, as the following examples show, to determine the number of 1 MB disk blocks allocated per database, table, slice, or column. You can also use [STV_PARTITIONS](#) to view summary information about disk utilization.

STV_BLOCKLIST is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Note

STV_BLOCKLIST only records blocks owned by the provisioned cluster or serverless namespace. If the database includes blocks shared from a datashare producer, those blocks

aren't included in STV_BLOCKLIST. For more information about datashares, go to [Data sharing in Amazon Redshift](#).

Table columns

Column name	Data type	Description
slice	integer	Node slice.
col	integer	Zero-based index for the column. Every table you create has three hidden columns appended to it: INSERT_XID, DELETE_XID, and ROW_ID (OID). A table with 3 user-defined columns contains 6 actual columns, and the user-defined columns are internally numbered as 0, 1, and 2. The INSERT_XID, DELETE_XID, and ROW_ID columns are numbered 3, 4, and 5, respectively, in this example.
tbl	integer	Table ID for the database table.
blocknum	integer	ID for the data block.
num_values	integer	Number of values contained on the block.
extended_limits	integer	For internal use.
minvalue	bigint	Minimum data value of the block. Stores first eight characters as 64-bit integer for non-numeric data. Used for disk scanning.
maxvalue	bigint	Maximum data value of the block. Stores first eight characters as 64-bit integer for non-numeric data. Used for disk scanning.
sb_pos	integer	Internal Amazon Redshift identifier for super block position on the disk.
pinned	integer	Whether or not the block is pinned into memory as part of pre-load. 0 = false; 1 = true. Default is false.

Column name	Data type	Description
on_disk	integer	Whether or not the block is automatically stored on disk. 0 = false; 1 = true. Default is false.
modified	integer	Whether or not the block has been modified. 0 = false; 1 = true. Default is false.
hdr_modified	integer	Whether or not the block header has been modified. 0 = false; 1 = true. Default is false.
unsorted	integer	Whether or not a block is unsorted. 0 = false; 1 = true. Default is true.
tombstone	integer	For internal use.
preferred_diskno	integer	Disk number that the block should be on, unless the disk has failed. Once the disk has been fixed, the block will move back to this disk.
temporary	integer	Whether or not the block contains temporary data, such as from a temporary table or intermediate query results. 0 = false; 1 = true. Default is false.
newblock	integer	Indicates whether or not a block is new (true) or was never committed to disk (false). 0 = false; 1 = true.
num_references	integer	Number of references on each block.
flags	integer	Internal Amazon Redshift flags for the block header.

Sample queries

STV_BLOCKLIST contains one row per allocated disk block, so a query that selects all the rows potentially returns a very large number of rows. We recommend using only aggregate queries with STV_BLOCKLIST.

The [SVV_DISKUSAGE](#) view provides similar information in a more user-friendly format; however, the following example demonstrates one use of the STV_BLOCKLIST table.

To determine the number of 1 MB blocks used by each column in the VENUE table, type the following query:

```
select col, count(*)
from stv_blocklist, stv_tbl_perm
where stv_blocklist.tbl = stv_tbl_perm.id
and stv_blocklist.slice = stv_tbl_perm.slice
and stv_tbl_perm.name = 'venue'
group by col
order by col;
```

This query returns the number of 1 MB blocks allocated to each column in the VENUE table, shown by the following sample data:

```
col | count
-----+-----
 0 | 4
 1 | 4
 2 | 4
 3 | 4
 4 | 4
 5 | 4
 7 | 4
 8 | 4
(8 rows)
```

The following query shows whether or not table data is actually distributed over all slices:

```
select trim(name) as table, stv_blocklist.slice, stv_tbl_perm.rows
from stv_blocklist, stv_tbl_perm
where stv_blocklist.tbl=stv_tbl_perm.id
and stv_tbl_perm.slice=stv_blocklist.slice
and stv_blocklist.id > 10000 and name not like '%#m%'
and name not like 'systable%'
group by name, stv_blocklist.slice, stv_tbl_perm.rows
order by 3 desc;
```

This query produces the following sample output, showing the even data distribution for the table with the most rows:

```

table | slice | rows
-----+-----+-----
listing | 13 | 10527
listing | 14 | 10526
listing | 8 | 10526
listing | 9 | 10526
listing | 7 | 10525
listing | 4 | 10525
listing | 17 | 10525
listing | 11 | 10525
listing | 5 | 10525
listing | 18 | 10525
listing | 12 | 10525
listing | 3 | 10525
listing | 10 | 10525
listing | 2 | 10524
listing | 15 | 10524
listing | 16 | 10524
listing | 6 | 10524
listing | 19 | 10524
listing | 1 | 10523
listing | 0 | 10521
...
(180 rows)

```

The following query determines whether any tombstoned blocks were committed to disk:

```

select slice, col, tbl, blocknum, newblock
from stv_blocklist
where tombstone > 0;

slice | col | tbl | blocknum | newblock
-----+-----+-----+-----+-----
4 | 0 | 101285 | 0 | 1
4 | 2 | 101285 | 0 | 1
4 | 4 | 101285 | 1 | 1
5 | 2 | 101285 | 0 | 1
5 | 0 | 101285 | 0 | 1
5 | 1 | 101285 | 0 | 1
5 | 4 | 101285 | 1 | 1
...
(24 rows)

```

STV_CURSOR_CONFIGURATION

STV_CURSOR_CONFIGURATION displays cursor configuration constraints. For more information, see [Cursor constraints](#).

STV_CURSOR_CONFIGURATION is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
current_cursor_count	integer	Number of cursors currently open.
max_disk_space_usable	integer	Amount of disk space available for cursors, in megabytes. This constraint is based on the maximum cursor result set size for the cluster.
current_diskspace_used	integer	Amount of disk space currently used by cursors, in megabytes.

STV_DB_ISOLATION_LEVEL

STV_DB_ISOLATION_LEVEL displays the current isolation level for databases. For more information about isolation levels, see [CREATE DATABASE](#).

STV_DB_ISOLATION_LEVEL is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
db_name	character (128)	The database name.

Column name	Data type	Description
isolation_level	character(20)	The isolation level of the database. Possible values include <code>Serializable</code> and <code>Snapshot Isolation</code> .

STV_EXEC_STATE

Use the `STV_EXEC_STATE` table to find out information about queries and query steps that are actively running on compute nodes.

This information is usually used only to troubleshoot engineering issues. The views `SVV_QUERY_STATE` and `SVL_QUERY_SUMMARY` extract their information from `STV_EXEC_STATE`.

`STV_EXEC_STATE` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the `SYS` monitoring view [SYS_QUERY_DETAIL](#). The data in the `SYS` monitoring view is formatted to be easier to use and understand. We recommend that you use the `SYS` monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
query	integer	Query ID. Can be used to join various other system tables and views.
slice	integer	Node slice where the step completed.
segment	integer	Segment of the query that ran. A query segment is a series of steps.
step	integer	Step of the query segment that completed. A step is the smallest unit that a query performs.

Column name	Data type	Description
starttime	timestamp	Time that the step ran.
currenttime	timestamp	Current time.
tasknum	integer	Query task process that is assigned to complete the step.
rows	bigint	Number of rows processed.
bytes	bigint	Number of bytes processed.
label	char(256)	Step label, which consists of a query step name and, when applicable, table ID and table name (for example, scan tbl=100448 name =user). Three-digit table IDs usually refer to scans of transient tables. When you see tbl=0, it usually refers to a scan of a constant value.
is_diskbased	char(1)	Whether this step of the query was completed as a disk-based operation: true (t) or false (f). Only certain steps, such as hash, sort, and aggregate steps, can go to disk. Many types of steps are always completed in memory.
workmem	bigint	Number of bytes of working memory assigned to the step.
num_parts	integer	Number of partitions a hash table is divided into during a hash step. A positive number in this column does not imply that the hash step ran as a disk-based operation . Check the value in the IS_DISKBASED column to see if the hash step was disk-based.
is_rrscan	char(1)	If true (t), indicates that range-restricted scan was used on the step. Default is false (f).
is_delayed_scan	char(1)	If true (t), indicates that delayed scan was used on the step. Default is false (f).

Sample queries

Rather than querying `STV_EXEC_STATE` directly, Amazon Redshift recommends querying `SVL_QUERY_SUMMARY` or `SVV_QUERY_STATE` to obtain the information in `STV_EXEC_STATE` in a more user-friendly format. See the [SVL_QUERY_SUMMARY](#) or [SVV_QUERY_STATE](#) table documentation for more details.

STV_INFLIGHT

Use the `STV_INFLIGHT` table to determine what queries are currently running on the cluster. If you're troubleshooting, it's helpful for checking the status of long-running queries.

`STV_INFLIGHT` does not show leader-node only queries. For more information, see [Leader node-only functions](#). `STV_INFLIGHT` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Troubleshooting with STV_INFLIGHT

If you use `STV_INFLIGHT` to troubleshoot performance for a query, or a collection of queries, note the following:

- Long-running open transactions generally increase load. These open transactions can result in longer running times for other queries.
- Long-running COPY and ETL jobs can affect other queries running on the cluster, if they're taking a lot of compute resources. In most cases, moving these long-running jobs to times of low use increases performance for reporting or analytics workloads.
- There are views that provide related information to `STV_INFLIGHT`. These include [STL_QUERYTEXT](#), which captures the query text for SQL commands, and [SVV_QUERY_INFLIGHT](#), which joins `STV_INFLIGHT` to `STL_QUERYTEXT`. You can also use [STV_RECENTS](#) with `STV_INFLIGHT` for troubleshooting. For example, `STV_RECENTS` can indicate if specific queries are in a *Running* or *Done* state. Combining this information with results from `STV_INFLIGHT` can give you more information about a query's properties and compute-resource impact.

You can also monitor running queries using the Amazon Redshift console.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
slice	integer	Slice where the query is running.
query	integer	Query ID. Can be used to join various other system tables and views.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter is not set, this field is blank.
xid	bigint	Transaction ID.
pid	integer	Process ID. All of the queries in a session are run in the same process, so this value remains constant if you run a series of queries in the same session. You can use this column to join to the STL_ERROR table.
starttime	timestamp	Time that the query started.
text	character(100)	Query text, truncated to 100 characters if the statement exceeds that limit.
suspended	integer	Whether the query is suspended or not. 0 = false; 1 = true.
insert_pristine	integer	Whether write queries are/were able to run while the current query is/was running. 1 = no write queries allowed. 0 = write queries allowed. This column is intended for use in debugging.
concurrency_scaling_status	integer	Indicates whether the query ran on the main cluster or on a concurrency scaling cluster, Possible values are as follows:

Column name	Data type	Description
		0 - Ran on the main cluster
		1 - Ran on a concurrency scaling cluster

Sample queries

To view all active queries currently running on the database, type the following query:

```
select * from stv_inflight;
```

The sample output below shows two queries currently running, including the STV_INFLIGHT query itself and a query that was run from a script called `avgwait.sql`:

```
select slice, query, trim(label) querylabel, pid,
starttime, substring(text,1,20) querytext
from stv_inflight;
```

slice	query	querylabel	pid	starttime	querytext
1011	21		646	2012-01-26 13:23:15.645503	select slice, query,
1011	20	avgwait.sql	499	2012-01-26 13:23:14.159912	select avg(datediff(

(2 rows)

The following query selects several columns, including `concurrency_scaling_status`. This column indicates whether queries are being sent to the concurrency-scaling cluster. If the value is 1 for some results, it's an indication that concurrency-scaling compute resources are being used. For more information, see [Concurrency scaling](#).

```
select userid,
query,
pid,
starttime,
text,
suspended,
concurrency_scaling_status
from STV_INFLIGHT;
```

Column name	Data type	Description
recordtime	timestamp	Time the record is logged.
bytes_to_load	bigint	Total number of bytes to be loaded by this slice. This is 0 if the data being loaded is compressed
bytes_loaded	bigint	Number of bytes loaded by this slice. If the data being loaded is compressed, this is the number of bytes loaded after the data is uncompressed.
bytes_to_load_compressed	bigint	Total number of bytes of compressed data to be loaded by this slice. This is 0 if the data being loaded is not compressed.
bytes_loaded_compressed	bigint	Number of bytes of compressed data loaded by this slice. This is 0 if the data being loaded is not compressed.
lines	integer	Number of lines loaded by this slice.
num_files	integer	Number of files to be loaded by this slice.
num_files_complete	integer	Number of files loaded by this slice.
current_file	character (256)	Name of the file being loaded by this slice.
pct_complete	integer	Percentage of data load completed by this slice.

Sample query

To view the progress of each slice for a COPY command, type the following query. This example uses the PG_LAST_COPY_ID() function to retrieve information for the last COPY command.

```
select slice , bytes_loaded, bytes_to_load , pct_complete from stv_load_state where
query = pg_last_copy_id();
```

```
slice | bytes_loaded | bytes_to_load | pct_complete
-----+-----+-----+-----
2 | 0 | 0 | 0
```

```

3 | 12840898 | 39104640 | 32
(2 rows)

```

STV_LOCKS

Use the STV_LOCKS table to view any current updates on tables in the database.

Amazon Redshift locks tables to prevent two users from updating the same table at the same time. While the STV_LOCKS table shows all current table updates, query the [STL_TR_CONFLICT](#) table to see a log of lock conflicts. Use the [SVV_TRANSACTIONS](#) view to identify open transactions and lock contention issues.

STV_LOCKS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
table_id	bigint	Table ID for the table acquiring the lock.
last_commit	timestamp	Timestamp for the last commit in the table.
last_update	timestamp	Timestamp for the last update for the table.
lock_owner	bigint	Transaction ID associated with the lock.
lock_owner_pid	bigint	Process ID associated with the lock.
lock_owner_start_ts	timestamp	Timestamp for the transaction start time.
lock_owner_end_ts	timestamp	Timestamp for the transaction end time.
lock_status	character (22)	Status of the process either waiting for or holding a lock.

Sample query

To view all locks taking place in current transactions, type the following command:

```
select table_id, last_update, lock_owner, lock_owner_pid from stv_locks;
```

This query returns the following sample output, which displays three locks currently in effect:

```

table_id |          last_update          | lock_owner | lock_owner_pid
-----+-----+-----+-----
100004   | 2008-12-23 10:08:48.882319 |    1043    |          5656
100003   | 2008-12-23 10:08:48.779543 |    1043    |          5656
100140   | 2008-12-23 10:08:48.021576 |    1043    |          5656
(3 rows)

```

STV_ML_MODEL_INFO

State information about the current state of the machine learning model.

STV_ML_MODEL_INFO is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
schema_name	char(128)	The namespace of the model.
user_name	char(128)	The owner of the model.
model_name	char(128)	The name of the model.
life_cycle	char(20)	The lifecycle status of the model.
is_refreshable	integer	The state of the model whether it is refreshable if original tables and columns in the training query still exist and the user still has the permissions to them. Possible values are: 1 (refreshable) and 0 (not refreshable).
model_state	char(128)	The current state of the model.

Sample query

The following query displays the current state of machine learning models.

```
SELECT schema_name, model_name, model_state
FROM stv_ml_model_info;
```

```

schema_name |          model_name          |          model_state
-----+-----+-----
public      | customer_churn_auto_model    | Train Model On SageMaker In Progress
public      | customer_churn_xgboost_model | Model is Ready
(2 row)
```

STV_MV_DEPS

The STV_MV_DEPS table shows the dependencies of materialized views on other materialized views within Amazon Redshift.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

STV_MV_DEPS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
db_name	char(128)	The database that contains the specified materialized view.
schema	char(128)	The schema of the materialized view.
name	char(128)	The name of the materialized view.
ref_schema	char(128)	The materialized view schema on which this materialized view depends.
ref_name	char(128)	The name of the materialized view on which this materialized view depends.

Column name	Data type	Description
ref_datab ase_name	char(128)	The name of the database on which this materialized view depends.

Sample query

The following query returns an output row that indicates that the materialized view `mv_over_foo` uses the materialized view `mv_foo` in its definition as a dependency.

```
CREATE SCHEMA test_ivm_setup;
CREATE TABLE test_ivm_setup.foo(a INT);
CREATE MATERIALIZED VIEW test_ivm_setup.mv_foo AS SELECT * FROM test_ivm_setup.foo;
CREATE MATERIALIZED VIEW test_ivm_setup.mv_over_foo AS SELECT * FROM
  test_ivm_setup.mv_foo;

SELECT * FROM stv_mv_deps;

 db_name | schema          | name          | ref_schema | ref_name |
 ref_database_name
-----+-----+-----+-----+-----+
+-----+
 dev     | test_ivm_setup  | mv_over_foo  | test_ivm_setup | mv_foo   | dev
```

STV_MV_INFO

The `STV_MV_INFO` table contains a row for every materialized view, whether the data is stale, and state information.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

`STV_MV_INFO` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
db_name	char(128)	The database that contains the materialized view.

Column name	Data type	Description
schema	char(128)	The schema of the database.
name	char(128)	The materialized view name.
updated_u pto_xid	bigint	Reserved for internal use.
is_stale	char(1)	<p>A <code>t</code> indicates that the materialized view is stale. A <i>stale</i> materialized view is one where the base tables have been updated but the materialized view hasn't been refreshed. The information might not be accurate if a refresh hasn't been run since the last restart.</p> <p>The <code>is_stale</code> column is always set to <code>t</code> if the materialized view depends on a mutable function. A mutable function returns a different result when given the same argument or arguments. For instance, most functions that return a date or timestamp are mutable functions.</p>
owner_use r_name	char(128)	The user who owns the materialized view.

Column name	Data type	Description
state	integer	The state of the materialized view as follows: <ul style="list-style-type: none">• 0 – The materialized view is fully recomputed when refreshed.• 1 – The materialized view is incremental.• 101 – The materialized view can't be refreshed due to a dropped column. This constraint applies even if the column isn't used in the materialized view.• 102 – The materialized view can't be refreshed due to a changed column type. This constraint applies even if the column isn't used in the materialized view.• 103 – The materialized view can't be refreshed due to a renamed table.• 104 – The materialized view can't be refreshed due to a renamed column. This constraint applies even if the column isn't used in the materialized view.• 105 – The materialized view can't be refreshed due to a renamed schema.
autorewrite	char(1)	A t indicates that the materialized view is eligible for automatic rewriting of queries.
autorefresh	char(1)	A t indicates that the materialized view can be automatically refreshed.

Sample query

To view the state of all materialized views, run the following query.

```
select * from stv_mv_info;
```

This query returns the following sample output.

```

db_name |      schema      | name | updated_upto_xid | is_stale | owner_user_name
| state | autorefresh | autorewrite
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
dev      | test_ivm_setup   | mv    |          1031 | f        | catch-22
| 1 | 1 | 0
dev      | test_ivm_setup   | old_mv |          988 | t        | lotr
| 1 | 0 | 1

```

STV_NODE_STORAGE_CAPACITY

The STV_NODE_STORAGE_CAPACITY table shows details of total storage capacity and total used capacity for each node in a cluster. It contains a row for each node.

STV_NODE_STORAGE_CAPACITY is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
node	integer	The node number.
used	integer	The number of 1 MB disk blocks currently in use on the node. For RA3 node types, used blocks include both locally cached blocks and blocks persisted in Amazon S3.
capacity	integer	The total storage capacity provisioned for the node in 1 MB blocks. The capacity includes space that is reserved by Amazon Redshift on DC2 node types for internal use. The capacity is larger than the nominal node capacity, which is the amount of node space available for user data. For RA3 node types, this capacity is the same as the total managed storage quota for the cluster. For more information about capacity by

Column name	Data type	Description
		node type, see Node type details in the <i>Amazon Redshift Management Guide</i> .

Sample queries

Note

The results of the following examples vary based on the node specifications of your cluster. Add column `capacity` to your SQL `SELECT` to retrieve the capacity of your cluster.

The following query returns used space and total capacity in 1 MB disk blocks. This example ran on a two-node `dc2.8xlarge` cluster.

```
select node, used from stv_node_storage_capacity order by node;
```

This query returns the following sample output.

```
node | used
-----+-----
  0  | 30597
  1  | 27089
```

The following query returns used space and total capacity in 1 MB disk blocks. This example ran on a two-node `ra3.16xlarge` cluster.

```
select node, used from stv_node_storage_capacity order by node;
```

This query returns the following sample output.

```
node | used
-----+-----
  0  | 30591
```

STV_PARTITIONS

Use the STV_PARTITIONS table to find out the disk speed performance and disk utilization for Amazon Redshift.

STV_PARTITIONS contains one row per node per logical disk volume.

STV_PARTITIONS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
owner	integer	Disk node that owns the partition.
host	integer	Node that is physically attached to the partition.
diskno	integer	Disk containing the partition.
part_begin	bigint	Offset of the partition. Raw devices are logically partitioned to open space for mirror blocks.
part_end	bigint	End of the partition.
used	integer	Number of 1 MB disk blocks currently in use on the partition.
tossed	integer	Number of blocks that are ready to be deleted but are not yet removed because it is not safe to free their disk addresses. If the addresses were freed immediately, a pending transaction could write to the same location on disk. Therefore, these tossed blocks are released as of the next commit. Disk blocks might be marked as tossed, for example, when a table column is dropped, during INSERT operations, or during disk-based query operations.

Column name	Data type	Description
capacity	integer	Total capacity of the partition in 1 MB disk blocks.
reads	bigint	Number of reads that have occurred since the last cluster restart.
writes	bigint	Number of writes that have occurred since the last cluster restart.
seek_forward	integer	Number of times that a request is not for the subsequent address given the previous request address.
seek_back	integer	Number of times that a request is not for the previous address given the subsequent address.
is_san	integer	Whether the partition belongs to a SAN. Valid values are 0 (false) or 1 (true).
failed	integer	This column is deprecated.
mbps	integer	Disk speed in megabytes per second.
mount	character (256)	Directory path to the device.

Sample query

The following query returns the disk space used and capacity, in 1 MB disk blocks, and calculates disk utilization as a percentage of raw disk space. The raw disk space includes space that is reserved by Amazon Redshift for internal use, so it is larger than the nominal disk capacity, which is the amount of disk space available to the user. The **Percentage of Disk Space Used** metric on the **Performance** tab of the Amazon Redshift Management Console reports the percentage of nominal disk capacity used by your cluster. We recommend that you monitor the **Percentage of Disk Space Used** metric to maintain your usage within your cluster's nominal disk capacity.

⚠ Important

We strongly recommend that you do not exceed your cluster's nominal disk capacity. While it might be technically possible under certain circumstances, exceeding your nominal disk capacity decreases your cluster's fault tolerance and increases your risk of losing data.

This example was run on a two-node cluster with six logical disk partitions per node. Space is being used very evenly across the disks, with approximately 25% of each disk in use.

```
select owner, host, diskno, used, capacity,
(used-tossed)/capacity::numeric *100 as pctused
from stv_partitions order by owner;
```

owner	host	diskno	used	capacity	pctused
0	0	0	236480	949954	24.9
0	0	1	236420	949954	24.9
0	0	2	236440	949954	24.9
0	1	2	235150	949954	24.8
0	1	1	237100	949954	25.0
0	1	0	237090	949954	25.0
1	1	0	236310	949954	24.9
1	1	1	236300	949954	24.9
1	1	2	236320	949954	24.9
1	0	2	237910	949954	25.0
1	0	1	235640	949954	24.8
1	0	0	235380	949954	24.8

(12 rows)

STV_QUERY_METRICS

Contains metrics information, such as the number of rows processed, CPU usage, input/output, and disk use, for active queries running in user-defined query queues (service classes). To view metrics for queries that have completed, see the [STL_QUERY_METRICS](#) system table.

Query metrics are sampled at one second intervals. As a result, different runs of the same query might return slightly different times. Also, query segments that run in less than 1 second might not be recorded.

STV_QUERY_METRICS tracks and aggregates metrics at the query, segment, and step level. For information about query segments and steps, see [Query planning and execution workflow](#). Many metrics (such as `max_rows`, `cpu_time`, and so on) are summed across node slices. For more information about node slices, see [Data warehouse system architecture](#).

To determine the level at which the row reports metrics, examine the `segment` and `step_type` columns:

- If both `segment` and `step_type` are `-1`, then the row reports metrics at the query level.
- If `segment` is not `-1` and `step_type` is `-1`, then the row reports metrics at the segment level.
- If both `segment` and `step_type` are not `-1`, then the row reports metrics at the step level.

STV_QUERY_METRICS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
<code>userid</code>	<code>integer</code>	ID of the user that ran the query that generated the entry.
<code>service_class</code>	<code>integer</code>	ID for the WLM query queue (service class). Query queues are defined in the WLM configuration. Metrics are reported only for user-defined queues.
<code>query</code>	<code>integer</code>	Query ID. The query column can be used to join other system tables and views.
<code>starttime</code>	<code>timestamp</code>	Time in UTC that the query started executing, with 6 digits of precision for fractional seconds. For example: <code>2009-06-12 11:29:19.131358</code> .
<code>slices</code>	<code>integer</code>	Number of slices for the cluster.

Column name	Data type	Description
segment	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process. If the segment value is -1, metrics segment values are rolled up to the query level.
step_type	integer	Type of step that ran. For a description of step types, see Step types .
rows	bigint	Number of rows processed by a step.
max_rows	bigint	Maximum number of rows output for a step, aggregated across all slices.
cpu_time	bigint	CPU time used, in microseconds. At the segment level, the total CPU time for the segment across all slices. At the query level, the sum of CPU time for the query across all slices and segments.
max_cpu_time	bigint	Maximum CPU time used, in microseconds. At the segment level, the maximum CPU time used by the segment across all slices. At the query level, the maximum CPU time used by any query segment.
blocks_read	bigint	Number of 1 MB blocks read by the query or segment.
max_block_s_read	bigint	Maximum number of 1 MB blocks read by the segment, aggregated across all slices. At the segment level, the maximum number of 1 MB blocks read for the segment across all slices. At the query level, the maximum number of 1 MB blocks read by any query segment.

Column name	Data type	Description
run_time	bigint	Total run time, summed across slices. Run time doesn't include wait time. At the segment level, the run time for the segment, summed across all slices. At the query level, the run time for the query summed across all slices and segments. Because this value is a sum, run time is not related to query execution time.
max_run_time	bigint	The maximum elapsed time for a segment, in microseconds. At the segment level, the maximum run time for the segment across all slices. At the query level, the maximum run time for any query segment.
max_blocks_to_disk	bigint	The maximum amount of disk space used to write intermediate results, in 1 MB blocks. At the segment level, the maximum amount of disk space used by the segment across all slices. At the query level, the maximum amount of disk space used by any query segment.
blocks_to_disk	bigint	The amount of disk space used by a query or segment to write intermediate results, in 1 MB blocks.
step	integer	Query step that ran.
max_query_scan_size	bigint	The maximum size of data scanned by a query, in MB. At the segment level, the maximum size of data scanned by the segment across all slices. At the query level, the maximum size of data scanned by any query segment.
query_scan_size	bigint	The size of data scanned by a query, in MB.
query_priority	integer	The priority of the query. Possible values are -1, 0, 1, 2, 3, and 4, where -1 means that query priority isn't supported.
query_queue_time	bigint	The amount of time in microseconds that the query was queued.

Step types

The following table lists step types relevant to database users. The table doesn't list step types that are for internal use only. If step type is -1, the metric is not reported at the step level.

Step type	Description
1	Scan table
2	Insert rows
3	Aggregate rows
6	Sort step
7	Merge step
8	Distribution step
9	Broadcast distribution step
10	Hash join
11	Merge join
12	Save step
14	Hash
15	Nested loop join
16	Project fields and expressions
17	Limit the number of rows returned
18	Unique
20	Delete rows
26	Limit the number of sorted rows returned
29	Compute a window function

Step type	Description
32	UDF
33	Unique
37	Return rows from the leader node to the client
38	Return rows from the compute nodes to the leader node
40	Spectrum scan.

Sample query

To find active queries with high CPU time (more the 1,000 seconds), run the following query.

```
select query, cpu_time / 1000000 as cpu_seconds
from stv_query_metrics where segment = -1 and cpu_time > 1000000000
order by cpu_time;
```

```
query | cpu_seconds
-----+-----
25775 |          9540
```

To find active queries with a nested loop join that returned more than one million rows, run the following query.

```
select query, rows
from stv_query_metrics
where step_type = 15 and rows > 1000000
order by rows;
```

```
query | rows
-----+-----
25775 | 1580225854
```

To find active queries that have run for more than 60 seconds and have used less than 10 seconds of CPU time, run the following query.

```
select query, run_time/1000000 as run_time_seconds
```

```

from stv_query_metrics
where segment = -1 and run_time > 60000000 and cpu_time < 10000000;

query | run_time_seconds
-----+-----
25775 |                      114

```

STV_RECENTS

Use the STV_RECENTS table to find out information about the currently active and recently run queries against a database.

STV_RECENTS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Troubleshooting with STV_RECENTS

STV_RECENTS is particularly helpful for determining if a query or collection of queries is currently running or done. It also shows the duration a query has been running. This is helpful for getting a sense for which queries are long running.

You can join STV_RECENTS to other system views, such as [STV_INFLIGHT](#), to gather additional metadata about running queries. (There's an example that shows how to do this in the sample queries section.) You can also use returned records from this view along with the monitoring features in the Amazon Redshift console for troubleshooting in real time.

System views that compliment STV_RECENTS include [STL_QUERYTEXT](#), which retrieves the query text for SQL commands, and [SVV_QUERY_INFLIGHT](#), which joins STV_INFLIGHT to STL_QUERYTEXT.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.

Column name	Data type	Description
status	character(20)	Query status. Valid values are Running , Done .
starttime	timestamp	Time that the query started.
duration	integer	Number of microseconds since the session started.
user_name	character(50)	User name who ran the process.
db_name	character(50)	Name of the database.
query	character(600)	Query text, up to 600 characters. Any additional characters are truncated.
pid	integer	Process ID for the session associated with the query, which is always -1 for queries that have completed.

Sample queries

To determine which queries are currently running against the database, run the following query:

```
select user_name, db_name, pid, query
from stv_recents
where status = 'Running';
```

The sample output below shows a single query running on the TICKIT database:

```
user_name | db_name | pid | query
-----+-----+-----+-----
dwuser    | tickit  | 19996 |select venueName, venueSeats from
venue where venueSeats > 50000 order by venueSeats desc;
```

The following example returns a list of queries (if any) that are running or waiting in a queue to run:

```
select * from stv_recents where status <> 'Done';
```

```

status |      starttime          | duration |user_name|db_name| query      | pid
-----+-----+-----+-----+-----+-----+-----
Running| 2010-04-21 16:11...    | 281566454| dwuser  |ticket | select ...| 23347

```

This query does not return results unless you are running a number of concurrent queries and some of those queries are in a queue.

The following example extends the previous example. In this case, queries that are truly "in flight" (running, not waiting) are excluded from the result:

```

select * from stv_recents where status<>'Done'
and pid not in (select pid from stv_inflight);
...

```

For more tips on troubleshooting query performance, see [Query troubleshooting](#).

STV_SESSIONS

Use the STV_SESSIONS table to view information about the active user sessions for Amazon Redshift.

To view the session history, use the [STL_SESSIONS](#) table, rather than STV_SESSIONS.

STV_SESSIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_SESSION_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
starttime	timestamp	Time that the session started.
process	integer	Process ID for the session.

Column name	Data type	Description
user_name	character(50)	User associated with the session.
db_name	character(50)	Name of the database associated with the session.
timeout_sec	int	The maximum time in seconds that a session remains inactive or idle before timing out. 0 indicates that no timeout is set.

Sample queries

To perform a quick check to see if any other users are currently logged into Amazon Redshift, type the following query:

```
select count(*)
from stv_sessions;
```

If the result is greater than one, then at least one other user is currently logged in to the database.

To view all active sessions for Amazon Redshift, type the following query:

```
select *
from stv_sessions;
```

The following result shows four active sessions running on Amazon Redshift:

```

      starttime          | process | user_name          | db_name
      | timeout_sec
-----+-----+-----
+-----+-----+-----
 2018-08-06 08:44:07.50 |   13779 | IAMA:aws_admin:admin_grp | dev
      | 0
 2008-08-06 08:54:20.50 |   19829 | dwuser              | dev
      | 120
 2008-08-06 08:56:34.50 |   20279 | dwuser              | dev
      | 120
```

```
2008-08-06 08:55:00.50 | 19996 | dwuser | ticket
| 0
(3 rows)
```

The user name prefixed with IAMA indicates that the user signed on using federated single sign-on. For more information, see [Using IAM authentication to generate database user credentials](#).

STV_SLICES

Use the STV_SLICES table to view the current mapping of a slice to a node.

The information in STV_SLICES is used mainly for investigation purposes.

STV_SLICES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
node	integer	Cluster node where the slice is located.
slice	integer	Node slice.
localslice	integer	This information is for internal use only.
type	character (1)	This information is for internal use only.

Sample query

To view which cluster nodes are managing which slices, type the following query:

```
select node, slice from stv_slices;
```

This query returns the following sample output:

```
node | slice
```

```

-----+-----
 0 |      2
 0 |      3
 0 |      1
 0 |      0
(4 rows)

```

STV_STARTUP_RECOVERY_STATE

Records the state of tables that are temporarily locked during cluster restart operations. Amazon Redshift places a temporary lock on tables while they are being processed to resolve stale transactions following a cluster restart.

STV_STARTUP_RECOVERY_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
db_id	integer	Database ID.
table_id	integer	Table ID.
table_name	character(137)	Table name.

Sample queries

To monitor which tables are temporarily locked, run the following query after a cluster restart.

```
select * from STV_STARTUP_RECOVERY_STATE;
```

```

 db_id | tbl_id | table_name
-----+-----+-----
100044 | 100058 | lineorder
100044 | 100068 | part
100044 | 100072 | customer
100044 | 100192 | supplier

```

(4 rows)

STV_TBL_PERM

The STV_TBL_PERM table contains information about the permanent tables in Amazon Redshift, including temporary tables created by a user for the current session. STV_TBL_PERM contains information for all tables in all databases.

This table differs from [STV_TBL_TRANS](#), which contains information about transient database tables that the system creates during query processing.

STV_TBL_PERM is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
slice	integer	Node slice allocated to the table.
id	integer	Table ID.
name	character (72)	Table name.
rows	bigint	Number of data rows in the slice.
sorted_rows	bigint	Number of rows in the slice that are already sorted on disk. If this number does not match the ROWS number, vacuum the table to resort the rows.
temp	integer	Whether or not the table is a temporary table. 0 = false; 1 = true.
db_id	integer	ID of the database where the table was created.
insert_privilege	integer	For internal use.
delete_privilege	integer	For internal use.

Column name	Data type	Description
backup	integer	Value that indicates whether the table is included in cluster snapshots. 0 = no; 1 = yes. For more information, see the BACKUP parameter for the CREATE TABLE command.
dist_style	integer	Distribution style of the table that the slice belongs to. For information on the values, see Viewing distribution styles . For information on distribution styles, see Distribution styles .
block_count	integer	Number of blocks used by the slice. The value is -1 when the block count can't be calculated.

Sample queries

The following query returns a list of distinct table IDs and names:

```
select distinct id, name
from stv_tbl_perm order by name;
```

```

  id  | name
-----+-----
100571 | category
100575 | date
100580 | event
100596 | listing
100003 | padb_config_harvest
100612 | sales
...
```

Other system tables use table IDs, so knowing which table ID corresponds to a certain table can be very useful. In this example, `SELECT DISTINCT` is used to remove the duplicates (tables are distributed across multiple slices).

To determine the number of blocks used by each column in the `VENUE` table, type the following query:

```
select col, count(*)
from stv_blocklist, stv_tbl_perm
```

```

where stv_blocklist.tbl = stv_tbl_perm.id
and stv_blocklist.slice = stv_tbl_perm.slice
and stv_tbl_perm.name = 'venue'
group by col
order by col;

```

```

  col | count
-----+-----
    0 |      8
    1 |      8
    2 |      8
    3 |      8
    4 |      8
    5 |      8
    6 |      8
    7 |      8
(8 rows)

```

Usage notes

The ROWS column includes counts of deleted rows that have not been vacuumed (or have been vacuumed but with the SORT ONLY option). Therefore, the SUM of the ROWS column in the STV_TBL_PERM table might not match the COUNT(*) result when you query a given table directly. For example, if 2 rows are deleted from VENUE, the COUNT(*) result is 200 but the SUM(ROWS) result is still 202:

```

delete from venue
where venueid in (1,2);

select count(*) from venue;
count
-----
200
(1 row)

select trim(name) tablename, sum(rows)
from stv_tbl_perm where name='venue' group by name;

tablename | sum
-----+-----
venue     | 202
(1 row)

```

To synchronize the data in STV_TBL_PERM, run a full vacuum the VENUE table.

```
vacuum venue;

select trim(name) tablename, sum(rows)
from stv_tbl_perm
where name='venue'
group by name;

tablename | sum
-----+-----
venue     | 200
(1 row)
```

STV_TBL_TRANS

Use the STV_TBL_TRANS table to find out information about the transient database tables that are currently in memory.

Transient tables are typically temporary row sets that are used as intermediate results while a query runs. STV_TBL_TRANS differs from [STV_TBL_PERM](#) in that STV_TBL_PERM contains information about permanent database tables.

STV_TBL_TRANS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
slice	integer	Node slice allocated to the table.
id	integer	Table ID.
rows	bigint	Number of data rows in the table.
size	bigint	Number of bytes allocated to the table.
query_id	bigint	Query ID.
ref_cnt	integer	Number of references.

Column name	Data type	Description
from_suspended	integer	Whether or not this table was created during a query that is now suspended.
prep_swap	integer	Whether or not this transient table is prepared to swap to disk if needed. (The swap will only occur in situations where memory is low.)

Sample queries

To view transient table information for a query with a query ID of 90, type the following command:

```
select slice, id, rows, size, query_id, ref_cnt
from stv_tbl_trans
where query_id = 90;
```

This query returns the transient table information for query 90, as shown in the following sample output:

slice	id	rows	size	query_	ref_	from_	prep_
				id	cnt	suspended	swap
1013	95	0	0	90	4	0	0
7	96	0	0	90	4	0	0
10	96	0	0	90	4	0	0
17	96	0	0	90	4	0	0
14	96	0	0	90	4	0	0
3	96	0	0	90	4	0	0
1013	99	0	0	90	4	0	0
9	96	0	0	90	4	0	0
5	96	0	0	90	4	0	0
19	96	0	0	90	4	0	0
2	96	0	0	90	4	0	0
1013	98	0	0	90	4	0	0
13	96	0	0	90	4	0	0
1	96	0	0	90	4	0	0
1013	96	0	0	90	4	0	0
6	96	0	0	90	4	0	0
11	96	0	0	90	4	0	0

```

15 | 96 | 0 | 0 | 90 | 4 | 0 | 0
18 | 96 | 0 | 0 | 90 | 4 | 0 | 0

```

In this example, you can see that the query data involves tables 95, 96, and 98. Because zero bytes are allocated to this table, this query can run in memory.

STV_WLM_CLASSIFICATION_CONFIG

Contains the current classification rules for WLM.

STV_WLM_CLASSIFICATION_CONFIG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
id	integer	Service class ID. For a list of service class IDs, see WLM service class IDs .
condition	character(128)	Query conditions.
action_seq	integer	Reserved for system use.
action	character(64)	Reserved for system use.
action_service_class	integer	The service class where the action takes place.

Sample query

```

select * from STV_WLM_CLASSIFICATION_CONFIG;

id | condition | action_seq | action |
-----+-----+-----+-----
1 | (system user) and (query group: health) | 0 | assign |
2 | (system user) and (query group: metrics) | 0 | assign |

```

```

3 | (system user) and (query group: cmstats) | 0 | assign |
3
4 | (system user) | 0 | assign |
4
5 | (super user) and (query group: superuser) | 0 | assign |
5
6 | (query group: querygroup1) | 0 | assign |
6
7 | (user group: usergroup1) | 0 | assign |
6
8 | (user group: usergroup2) | 0 | assign |
7
9 | (query group: querygroup3) | 0 | assign |
8
10 | (query group: querygroup4) | 0 | assign |
9
11 | (user group: usergroup4) | 0 | assign |
9
12 | (query group: querygroup*) | 0 | assign |
10
13 | (user group: usergroup*) | 0 | assign |
10
14 | (querytype: any) | 0 | assign |
11
(4 rows)

```

STV_WLM_QMR_CONFIG

Records the configuration for WLM query monitoring rules (QMR). For more information, see [WLM query monitoring rules](#).

STV_WLM_QMR_CONFIG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
service_class	integer	ID for the WLM query queue (service class). Query queues are defined in the WLM configuration. Rules can be defined only for user-defined queues. For a list of service class IDs, see WLM service class IDs .

Column name	Data type	Description
rule_name	character(256)	Name of the query monitoring rule.
action	character(256)	Rule action. Possible values are log, hop, abort, and change_query_priority .
metric_name	character(256)	Name of the metric.
metric_operator	character(256)	The metric operator. Possible values are >, =, <.
metric_value	double	The threshold value for the specified metric that triggers an action.
action_value	character(256)	If action is change_query_priority , then possible values are highest, high, normal, low, and lowest. If action is log, hop, or abort then the value is empty.

Sample query

To view the QMR rule definitions for all service classes greater than 5 (which includes user-defined queues), run the following query. For a list of service class IDs, see [WLM service class IDs](#).

```
Select *
from stv_wlm_qmr_config
where service_class > 5
order by service_class;
```

STV_WLM_QUERY_QUEUE_STATE

Records the current state of the query queues for the service classes.

STV_WLM_QUERY_QUEUE_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
service_class	integer	ID for the service class. For a list of service class IDs, see WLM service class IDs .
position	integer	Position of the query in the queue. The query with the smallest position value runs next.
task	integer	ID used to track a query through the workload manager. Can be associated with multiple query IDs. If a query is restarted, the query is assigned a new query ID but not a new task ID.
query	integer	Query ID. If a query is restarted, the query is assigned a new query ID but not a new task ID.
slot_count	integer	Number of WLM query slots.
start_time	timestamp	Time that the query entered the queue.
queue_time	bigint	Number of microseconds that the query has been in the queue.

Sample query

The following query shows the queries in the queue for service classes greater than 4.

```
select * from stv_wlm_query_queue_state
where service_class > 4
order by service_class;
```

This query returns the following sample output.

```
service_class | position | task | query | slot_count | start_time |
queue_time
```

```

-----+-----+-----+-----+-----+-----+-----
+-----
          5 |          0 | 455 | 476 |          5 | 2010-10-06 13:18:24.065838 |
20937257
          6 |          1 | 456 | 478 |          5 | 2010-10-06 13:18:26.652906 |
18350191
(2 rows)

```

STV_WLM_QUERY_STATE

Records the current state of queries being tracked by WLM.

STV_WLM_QUERY_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
xid	integer	Transaction ID of the query or subquery.
task	integer	ID used to track a query through the workload manager. Can be associated with multiple query IDs. If a query is restarted, the query is assigned a new query ID but not a new task ID.
query	integer	Query ID. If a query is restarted, the query is assigned a new query ID but not a new task ID.
service_class	integer	ID for the service class. For a list of service class IDs, see WLM service class IDs .
slot_count	integer	Number of WLM query slots.
wlm_start_time	timestamp	Time that the query entered the system table queue or short query queue.

Column name	Data type	Description
state	character(16)	<p>Current state of the query or subquery.</p> <p>Possible values are the following:</p> <ul style="list-style-type: none"> • Classified – Query has been assigned to a service class. • Completed – Query is finished running. The query either ran successfully or was canceled. For the final state, check the results of STL_QUERY. • Dequeued – Internal use only. • Evicted – Query has been evicted from the service class for restart. • Evicting – Query is being evicted from the service class for restart. • Initialized – Internal use only. • Invalid – Internal use only. • Queued – Query was sent to the query queue because no slots were available to run it. • QueuedWaiting – Query is waiting in the query queue. • Rejected – Internal use only. • Returning – Query is returning results to the client. • Running – Query is running. • TaskAssigned – Internal use only.
queue_time	bigint	Number of microseconds that the query has spent in the queue.
exec_time	bigint	Number of microseconds that the query has been running.

Column name	Data type	Description
query_priority	char(20)	The priority of the query. Possible values are n/a, lowest, low, normal, high, and highest, where n/a means that query priority isn't supported.

Sample query

The following query displays all currently executing queries in service classes greater than 4. For a list of service class IDs, see [WLM service class IDs](#).

```
select xid, query, trim(state) as state, queue_time, exec_time
from stv_wlm_query_state
where service_class > 4;
```

This query returns the following sample output:

```
xid      | query | state   | queue_time | exec_time
-----+-----+-----+-----+-----
100813  | 25942 | Running |           0 | 1369029
100074  | 25775 | Running |           0 | 2221589242
```

STV_WLM_QUERY_TASK_STATE

Contains the current state of service class query tasks.

STV_WLM_QUERY_TASK_STATE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
service_class	integer	ID for the service class. For a list of service class IDs, see WLM service class IDs .

Column name	Data type	Description
task	integer	ID used to track a query through the workload manager. Can be associated with multiple query IDs. If a query is restarted, the query is assigned a new query ID but not a new task ID.
query	integer	Query ID. If a query is restarted, the query is assigned a new query ID but not a new task ID.
slot_count	integer	Number of WLM query slots.
start_time	timestamp	Time that the query began executing.
exec_time	bigint	Number of microseconds that the query has been executing.

Sample query

The following query displays the current state of queries in service classes greater than 4. For a list of service class IDs, see [WLM service class IDs](#).

```
select * from stv_wlm_query_task_state
where service_class > 4;
```

This query returns the following sample output:

```
service_class | task | query | start_time | exec_time
-----+-----+-----+-----+-----
          5 | 466 | 491 | 2010-10-06 13:29:23.063787 | 357618748
(1 row)
```

STV_WLM_SERVICE_CLASS_CONFIG

Records the service class configurations for WLM.

STV_WLM_SERVICE_CLASS_CONFIG is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
service_class	integer	ID for the service class. For a list of service class IDs, see WLM service class IDs .
queueing_strategy	character(32)	Reserved for system use.
num_query_tasks	integer	Current actual concurrency level of the service class. If <code>num_query_tasks</code> and <code>target_num_query_tasks</code> are different, a dynamic WLM transition is in process. A value of -1 indicates that Auto WLM is configured.
target_num_query_tasks	integer	Concurrency level set by the most recent WLM configuration change.
evictable	character(8)	Reserved for system use.
eviction_threshold	bigint	Reserved for system use.
query_working_mem	integer	Current actual amount of working memory, in MB per slot, per node, assigned to the service class. If <code>query_working_mem</code> and <code>target_query_working_mem</code> are different, a dynamic WLM transition is in process. A value of -1 indicates that Auto WLM is configured.
target_query_working_mem	integer	The amount of working memory, in MB per slot, per node, set by the most recent WLM configuration change.
min_step_mem	integer	Reserved for system use.
name	character(64)	The name of the service class.
max_execution_time	bigint	Number of milliseconds that the query can run before being terminated.

Column name	Data type	Description
user_group_wild_card	Boolean	If TRUE, the WLM queue treats an asterisk (*) as a wildcard character in user group strings in the WLM configuration.
query_group_wild_card	Boolean	If TRUE, the WLM queue treats an asterisk (*) as a wildcard character in query group strings in the WLM configuration.
concurrency_scaling	character(20)	Describes if the concurrency scaling is on or off.
query_priority	character(20)	The value of the query priority.
user_role_wild_card	Boolean	If TRUE, the WLM queue treats an asterisk (*) as a wildcard character in user strings in the WLM configuration.

Sample query

The first user-defined service class is service class 6, which is named Service class #1. The following query displays the current configuration for service classes greater than 4. For a list of service class IDs, see [WLM service class IDs](#).

```
select rtrim(name) as name,
num_query_tasks as slots,
query_working_mem as mem,
max_execution_time as max_time,
user_group_wild_card as user_wildcard,
query_group_wild_card as query_wildcard
from stv_wlm_service_class_config
where service_class > 4;
```

name	slots	mem	max_time	user_wildcard	query_wildcard
Service class for super user	1	535	0	false	false
Queue 1	5	125	0	false	false
Queue 2	5	125	0	false	false
Queue 3	5	125	0	false	false
Queue 4	5	627	0	false	false
Queue 5	5	125	0	true	true

```
Default queue | 5 | 125 | 0 | false | false
```

The following query shows the status of a dynamic WLM transition. While the transition is in process, `num_query_tasks` and `target_query_working_mem` are updated until they equal the target values. For more information, see [WLM dynamic and static configuration properties](#).

```
select rtrim(name) as name,
num_query_tasks as slots,
target_num_query_tasks as target_slots,
query_working_mem as memory,
target_query_working_mem as target_memory
from stv_wlm_service_class_config
where num_query_tasks > target_num_query_tasks
or query_working_mem > target_query_working_mem
and service_class > 5;
```

```
name | slots | target_slots | memory | target_mem
-----+-----+-----+-----+-----
Queue 3 | 5 | 15 | 125 | 375
Queue 5 | 10 | 5 | 250 | 125
(2 rows)
```

STV_WLM_SERVICE_CLASS_STATE

Contains the current state of the service classes.

`STV_WLM_SERVICE_CLASS_STATE` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
<code>service_class</code>	integer	ID for the service class. For a list of service class IDs, see WLM service class IDs .
<code>num_queued_queries</code>	integer	Number of queries currently in the queue.
<code>num_executing_queries</code>	integer	Number of queries currently executing.

Column name	Data type	Description
num_serviced_queries	integer	Number of queries that have ever been in the service class.
num_executed_queries	integer	Number of queries that have run since Amazon Redshift was restarted.
num_evicted_queries	integer	Number of queries that have been evicted since Amazon Redshift was restarted. Some of the reasons for an evicted query include a WLM timeout, a QMR hop action, and a query failing on a concurrency scaling cluster.
num_concurrency_scaling_queries	integer	Number of queries run on a concurrency scaling cluster since Amazon Redshift was restarted.

Sample query

The following query displays the state for service classes greater than 5. For a list of service class IDs, see [WLM service class IDs](#).

```
select service_class, num_executing_queries,
num_executed_queries
from stv_wlm_service_class_state
where service_class > 5
order by service_class;
```

```
service_class | num_executing_queries | num_executed_queries
-----+-----+-----
          6 |          1 |          222
          7 |          0 |          135
          8 |          1 |           39
(3 rows)
```

STV_XRESTORE_ALTER_QUEUE_STATE

Use STV_XRESTORE_ALTER_QUEUE_STATE to monitor the migration progress of each table during a classic resize. This is specifically applicable when the target node type is RA3. For more information about classic resize to RA3 nodes, go to [Classic resize](#).

STV_XRESTORE_ALTER_QUEUE_STATE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_RESTORE_STATE](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who initiated the resize.
db_id	integer	The ID of the database.
schema	char(128)	The name of the schema.
table_name	char(128)	The name of the table.
tbl	integer	The ID of the table.
status	char(64)	The status of the migration progress of the table. Possible values are as follows. <ul style="list-style-type: none"> • Waiting: Waiting for redistribution to start • Applying: Currently redistributing • Finished: Finished redistributing
task_type	integer	The redistribution type for the table. Possible values are as follows. <ul style="list-style-type: none"> • 1: KEY • 2: EVEN <p>For more information about distribution styles, see Distribution styles.</p>

Sample query

The following query shows the number of tables in a database that are waiting to be resized, are currently being resized, and are finished resizing.

```
select db_id, status, count(*)
from stv_xrestore_alter_queue_state
group by 1,2 order by 3 desc
```

db_id	status	count
694325	Waiting	323
694325	Finished	60
694325	Applying	1

SVCS views for main and concurrency scaling clusters

SVCS system views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the tables with the prefix STL except that the STL tables provide information only for queries run on the main cluster.

Topics

- [SVCS_ALERT_EVENT_LOG](#)
- [SVCS_COMPILE](#)
- [SVCS_CONCURRENCY_SCALING_USAGE](#)
- [SVCS_EXPLAIN](#)
- [SVCS_PLAN_INFO](#)
- [SVCS_QUERY_SUMMARY](#)
- [SVCS_S3LIST](#)
- [SVCS_S3LOG](#)
- [SVCS_S3PARTITION_SUMMARY](#)
- [SVCS_S3QUERY_SUMMARY](#)
- [SVCS_STREAM_SEGS](#)
- [SVCS_UNLOAD_LOG](#)

SVCS_ALERT_EVENT_LOG

Records an alert when the query optimizer identifies conditions that might indicate performance issues. This view is derived from the STL_ALERT_EVENT_LOG system table but doesn't show slice-level for queries run on a concurrency scaling cluster. Use the SVCS_ALERT_EVENT_LOG table to identify opportunities to improve query performance.

A query consists of multiple segments, and each segment consists of one or more steps. For more information, see [Query processing](#).

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the tables with the prefix STL except that the STL tables provide information only for queries run on the main cluster.

SVCS_ALERT_EVENT_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
segment	integer	Number that identifies the query segment.
step	integer	Query step that ran.
pid	integer	Process ID associated with the statement and slice. The same query might have multiple PIDs if it runs on multiple slices.
xid	bigint	Transaction ID associated with the statement.

Column name	Data type	Description
event	character (1024)	Description of the alert event.
solution	character (1024)	Recommended solution.
event_time	timestamp	Time in UTC that the query started. Total time includes queuing and execution. with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358 .

Usage notes

You can use the SVCS_ALERT_EVENT_LOG to identify potential issues in your queries, then follow the practices in [Query performance tuning](#) to optimize your database design and rewrite your queries. SVCS_ALERT_EVENT_LOG records the following alerts:

- **Missing statistics**

Statistics are missing. Run ANALYZE following data loads or significant updates and use STATUPDATE with COPY operations. For more information, see [Amazon Redshift best practices for designing queries](#).

- **Nested loop**

A nested loop is usually a Cartesian product. Evaluate your query to ensure that all participating tables are joined efficiently.

- **Very selective filter**

The ratio of rows returned to rows scanned is less than 0.05. Rows scanned is the value of `rows_pre_user_filter` and rows returned is the value of rows in the [STL_SCAN](#) system table. Indicates that the query is scanning an unusually large number of rows to determine the result set. This can be caused by missing or incorrect sort keys. For more information, see [Sort keys](#).

- **Excessive ghost rows**

A scan skipped a relatively large number of rows that are marked as deleted but not vacuumed, or rows that have been inserted but not committed. For more information, see [Vacuuming tables](#).

- **Large distribution**

More than 1,000,000 rows were redistributed for hash join or aggregation. For more information, see [Data distribution for query optimization](#).

- **Large broadcast**

More than 1,000,000 rows were broadcast for hash join. For more information, see [Data distribution for query optimization](#).

- **Serial execution**

A DS_DIST_ALL_INNER redistribution style was indicated in the query plan, which forces serial execution because the entire inner table was redistributed to a single node. For more information, see [Data distribution for query optimization](#).

Sample queries

The following query shows alert events for four queries.

```
SELECT query, substring(event,0,25) as event,
substring(solution,0,25) as solution,
trim(event_time) as event_time from svcs_alert_event_log order by query;
```

query	event	solution	event_time
6567	Missing query planner statist	Run the ANALYZE command	2014-01-03 18:20:58
7450	Scanned a large number of del	Run the VACUUM command to rec	2014-01-03 21:19:31
8406	Nested Loop Join in the query	Review the join predicates to	2014-01-04 00:34:22
29512	Very selective query filter:r	Review the choice of sort key	2014-01-06 22:00:00

(4 rows)

SVCS_COMPILE

Records compile time and location for each query segment of queries, including queries run on a scaling cluster as well as queries run on the main cluster.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the views with the prefix SVL except that the SVL views provide information only for queries run on the main cluster.

SVCS_COMPILE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

For information about SCL_COMPILE, see [SVL_COMPILE](#).

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who generated the entry.
xid	bigint	The transaction ID associated with the statement.
pid	integer	The process ID associated with the statement.
query	integer	The query ID. You can use this ID to join various other system tables and views.
segment	integer	The query segment to be compiled.
locus	integer	The location where the segment runs, 1 if on a compute node and 2 if on the leader node.
starttime	timestamp	The time in Universal Coordinated Time (UTC) that the compile started.
endtime	timestamp	The time in UTC that the compile ended.

Column name	Data type	Description
compile	integer	A value that is 0 if the compile was reused and 1 if the segment was compiled.

Sample queries

In this example, queries 35878 and 35879 ran the same SQL statement. The compile column for query 35878 shows 1 for four query segments, which indicates that the segments were compiled. Query 35879 shows 0 in the compile column for every segment, indicating that the segments did not need to be compiled again.

```
select userid, xid, pid, query, segment, locus,
datediff(ms, starttime, endtime) as duration, compile
from svcs_compile
where query = 35878 or query = 35879
order by query, segment;
```

userid	xid	pid	query	segment	locus	duration	compile
100	112780	23028	35878	0	1	0	0
100	112780	23028	35878	1	1	0	0
100	112780	23028	35878	2	1	0	0
100	112780	23028	35878	3	1	0	0
100	112780	23028	35878	4	1	0	0
100	112780	23028	35878	5	1	0	0
100	112780	23028	35878	6	1	1380	1
100	112780	23028	35878	7	1	1085	1
100	112780	23028	35878	8	1	1197	1
100	112780	23028	35878	9	2	905	1
100	112782	23028	35879	0	1	0	0
100	112782	23028	35879	1	1	0	0
100	112782	23028	35879	2	1	0	0
100	112782	23028	35879	3	1	0	0
100	112782	23028	35879	4	1	0	0
100	112782	23028	35879	5	1	0	0
100	112782	23028	35879	6	1	0	0
100	112782	23028	35879	7	1	0	0
100	112782	23028	35879	8	1	0	0
100	112782	23028	35879	9	2	0	0

(20 rows)

SVCS_CONCURRENCY_SCALING_USAGE

Records the usage periods for concurrency scaling. Each usage period is a consecutive duration where an individual concurrency scaling cluster is actively processing queries.

SVCS_CONCURRENCY_SCALING_USAGE This table is visible to superusers. The database's superuser can choose to open it up to all users.

Table columns

Column name	Data type	Description
start_time	timestamp without time zone	When the usage period starts.
end_time	timestamp without time zone	When the usage period ends.
queries	bigint	Number of queries run during this usage period.
usage_in_seconds	numeric(27,0)	Total seconds in this usage period.

Sample queries

To view the usage duration in seconds for a specific period, enter the following query:

```
select * from svcs_concurrency_scaling_usage order by start_time;
```

```
start_time | end_time | queries | usage_in_seconds
```

```
-----+-----+-----+-----
2019-02-14 18:43:53.01063 | 2019-02-14 19:16:49.781649 | 48 | 1977
```

SVCS_EXPLAIN

Displays the EXPLAIN plan for a query that has been submitted for execution.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the tables with the prefix STL except that the STL tables provide information only for queries run on the main cluster.

SVCS_EXPLAIN is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
nodeid	integer	Plan node identifier, where a node maps to one or more steps in the execution of the query.
parentid	integer	Plan node identifier for a parent node. A parent node has some number of child nodes. For example, a merge join is the parent of the scans on the joined tables.
plannode	character(400)	The node text from the EXPLAIN output. Plan nodes that refer to execution on compute nodes are prefixed with XN in the EXPLAIN output.
info	character(400)	Qualifier and filter information for the plan node. For example, join conditions and WHERE clause restrictions are included in this column.

Sample queries

Consider the following EXPLAIN output for an aggregate join query:

```
explain select avg(datediff(day, listtime, saletime)) as avgwait
from sales, listing where sales.listid = listing.listid;
          QUERY PLAN
-----
XN Aggregate  (cost=6350.30..6350.31 rows=1 width=16)
-> XN Hash Join DS_DIST_NONE  (cost=47.08..6340.89 rows=3766 width=16)
    Hash Cond: ("outer".listid = "inner".listid)
-> XN Seq Scan on listing  (cost=0.00..1924.97 rows=192497 width=12)
-> XN Hash  (cost=37.66..37.66 rows=3766 width=12)
    -> XN Seq Scan on sales  (cost=0.00..37.66 rows=3766 width=12)

(6 rows)
```

If you run this query and its query ID is 10, you can use the SVCS_EXPLAIN table to see the same kind of information that the EXPLAIN command returns:

```
select query,nodeid,parentid,substring(plannode from 1 for 30),
substring(info from 1 for 20) from svcs_explain
where query=10 order by 1,2;
```

query	nodeid	parentid	substring	substring
10	1	0	XN Aggregate (cost=6717.61..6	
10	2	1	-> XN Merge Join DS_DIST_NO	Merge Cond:("outer"
10	3	2	-> XN Seq Scan on lis	
10	4	2	-> XN Seq Scan on sal	

(4 rows)

Consider the following query:

```
select event.eventid, sum(pricepaid)
from event, sales
where event.eventid=sales.eventid
group by event.eventid order by 2 desc;
```

eventid	sum
289	51846.00

```

7895 | 51049.00
1602 | 50301.00
 851 | 49956.00
7315 | 49823.00
...

```

If this query's ID is 15, the following system table query returns the plan nodes that were performed. In this case, the order of the nodes is reversed to show the actual order of execution:

```

select query,nodeid,parentid,substring(plannode from 1 for 56)
from svcs_explain where query=15 order by 1, 2 desc;

```

query	nodeid	parentid	substring
15	8	7	-> XN Seq Scan on eve
15	7	5	-> XN Hash(cost=87.98..87.9
15	6	5	-> XN Seq Scan on sales(cos
15	5	4	-> XN Hash Join DS_DIST_OUTER(cos
15	4	3	-> XN HashAggregate(cost=862286577.07..
15	3	2	-> XN Sort(cost=1000862287175.47..10008622871
15	2	1	-> XN Network(cost=1000862287175.47..1000862287197.
15	1	0	XN Merge(cost=1000862287175.47..1000862287197.46 rows=87

(8 rows)

The following query retrieves the query IDs for any query plans that contain a window function:

```

select query, trim(plannode) from svcs_explain
where plannode like '%Window%';

```

query	btrim
26	-> XN Window(cost=1000985348268.57..1000985351256.98 rows=170 width=33)
27	-> XN Window(cost=1000985348268.57..1000985351256.98 rows=170 width=33)

(2 rows)

SVCS_PLAN_INFO

Use the SVCS_PLAN_INFO table to look at the EXPLAIN output for a query in terms of a set of rows. This is an alternative way to look at query plans.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the tables with the prefix STL except that the STL tables provide information only for queries run on the main cluster.

SVCS_PLAN_INFO is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
nodeid	integer	Plan node identifier, where a node maps to one or more steps in the execution of the query.
segment	integer	Number that identifies the query segment.
step	integer	Number that identifies the query step.
locus	integer	Location where the step runs. 0 if on a compute node and 1 if on the leader node.
plannode	integer	Enumerated value of the plan node. See the following table for enums for plannode. (The PLANNODE column in SVCS_EXPLAIN contains the plan node text.)
startupcost	double precision	The estimated relative cost of returning the first row for this step.
totalcost	double precision	The estimated relative cost of executing the step.

Column name	Data type	Description
rows	bigint	The estimated number of rows that will be produced by the step.
bytes	bigint	The estimated number of bytes that will be produced by the step.

Sample queries

The following examples compare the query plans for a simple SELECT query returned by using the EXPLAIN command and by querying the SVCS_PLAN_INFO table.

```

explain select * from category;
QUERY PLAN
-----
XN Seq Scan on category (cost=0.00..0.11 rows=11 width=49)
(1 row)

select * from category;
catid | catgroup | catname | catdesc
-----+-----+-----+-----
 1 | Sports | MLB | Major League Baseball
 3 | Sports | NFL | National Football League

SVCS_QUERY_SUMMARY

Use the SVCS_QUERY_SUMMARY view to find general information about the execution of a query.

Note that the information in SVCS_QUERY_SUMMARY is aggregated from all nodes.

Note

The SVCS_QUERY_SUMMARY view only contains information about queries completed by Amazon Redshift, not other utility and DDL commands. For a complete listing and information on all statements completed by Amazon Redshift, including DDL and utility commands, you can query the SVL_STATEMENTTEXT view.

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the views with the prefix SVL except that the SVL views provide information only for queries run on the main cluster.

SVCS_QUERY_SUMMARY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

For information about SVL_QUERY_SUMMARY, see [SVL_QUERY_SUMMARY](#).

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
query	integer	Query ID. Can be used to join various other system tables and views.
stm	integer	Stream: A set of concurrent segments in a query. A query has one or more streams.

Column name	Data type	Description
seg	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process.
step	integer	Query step that ran.
maxtime	bigint	Maximum amount of time for the step to run (in microseconds).
avgtime	bigint	Average time for the step to run (in microseconds).
rows	bigint	Number of data rows involved in the query step.
bytes	bigint	Number of data bytes involved in the query step.
rate_row	double precision	Query execution rate per row.
rate_byte	double precision	Query execution rate per byte.
label	text	Step label, which consists of a query step name and, when applicable, table ID and table name (for example, scan tbl=10044 8 name =user). Three-digit table IDs usually refer to scans of transient tables. When you see <code>tbl=0</code> , it usually refers to a scan of a constant value.
is_diskbased	character(1)	Whether this step of the query was performed as a disk-based operation on any node in the cluster: true (t) or false (f). Only certain steps, such as hash, sort, and aggregate steps, can go to disk. Many types of steps are always run in memory.
workmem	bigint	Amount of working memory (in bytes) assigned to the query step.
is_rrscan	character(1)	If true (t), indicates that range-restricted scan was used on the step. Default is false (f).

Column name	Data type	Description
is_delayed_scan	character(1)	If true (t), indicates that delayed scan was used on the step. Default is false (f).
rows_pre_filter	bigint	For scans of permanent tables, the total number of rows emitted before filtering rows marked for deletion (ghost rows).

Sample queries

Viewing processing information for a query step

The following query shows basic processing information for each step of query 87:

```
select query, stm, seg, step, rows, bytes
from svcs_query_summary
where query = 87
order by query, seg, step;
```

This query retrieves the processing information about query 87, as shown in the following sample output:

```
query | stm | seg | step | rows | bytes
-----+-----+-----+-----+-----+-----
87    | 0  | 0  | 0  | 90  | 1890
87    | 0  | 0  | 2  | 90  | 360
87    | 0  | 1  | 0  | 90  | 360
87    | 0  | 1  | 2  | 90  | 1440
87    | 1  | 2  | 0  | 210494 | 4209880
87    | 1  | 2  | 3  | 89500 | 0
87    | 1  | 2  | 6  | 4  | 96
87    | 2  | 3  | 0  | 4  | 96
87    | 2  | 3  | 1  | 4  | 96
87    | 2  | 4  | 0  | 4  | 96
87    | 2  | 4  | 1  | 1  | 24
87    | 3  | 5  | 0  | 1  | 24
87    | 3  | 5  | 4  | 0  | 0
(13 rows)
```

Determining whether query steps spilled to disk

The following query shows whether or not any of the steps for the query with query ID 1025 (see the [SVL_QLOG](#) view to learn how to obtain the query ID for a query) spilled to disk or if the query ran entirely in-memory:

```
select query, step, rows, workmem, label, is_diskbased
from svcs_query_summary
where query = 1025
order by workmem desc;
```

This query returns the following sample output:

```
query| step|  rows  |  workmem  |  label          |  is_diskbased
-----+-----+-----+-----+-----+-----
1025 |  0  |16000000| 141557760 |scan tbl=9      | f
1025 |  2  |16000000| 135266304 |hash tbl=142    | t
1025 |  0  |16000000| 128974848 |scan tbl=116536| f
1025 |  2  |16000000| 122683392 |dist            | f
(4 rows)
```

By scanning the values for IS_DISKBASED, you can see which query steps went to disk. For query 1025, the hash step ran on disk. Steps might run on disk include hash, aggr, and sort steps. To view only disk-based query steps, add **and is_diskbased = 't'** clause to the SQL statement in the above example.

SVCS_S3LIST

Use the SVCS_S3LIST view to get details about Amazon Redshift Spectrum queries at the segment level. One segment can perform one external table scan. This view is derived from the SVL_S3LIST system view but doesn't show slice-level for queries run on a concurrency scaling cluster.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the views with the prefix SVL except that the SVL views provide information only for queries run on the main cluster.

SVCS_S3LIST is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

For information about SVL_S3LIST, see [SVL_S3LIST](#).

Table columns

Column name	Data type	Description
query	integer	The query ID.
segment	integer	The segment number. A query consists of multiple segments.
node	integer	The node number.
eventtime	timestamp	The time in UTC that the event is recorded.
bucket	char(256)	The Amazon S3 bucket name.
prefix	char(256)	The prefix of the Amazon S3 bucket location.
recursive	char(1)	Whether there is recursive scan for subfolders.
retrieved_files	integer	The number of listed files.
max_file_size	bigint	The maximum file size among listed files.
avg_file_size	double precision	The average file size among listed files.
generated_splits	integer	The number of file splits.
avg_split_length	double precision	The average length of file splits in bytes.
duration	bigint	The duration of file listing, in microseconds.

Sample query

The following example queries SVCS_S3LIST for the last query performed.

```
select *
from svcs_s3list
where query = pg_last_query_id()
order by query, segment;
```

SVCS_S3LOG

Use the SVCS_S3LOG view to get troubleshooting details about Redshift Spectrum queries at the segment level. One segment can perform one external table scan. This view is derived from the SVL_S3LOG system view but doesn't show slice-level for queries run on a concurrency scaling cluster.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the views with the prefix SVL except that the SVL views provide information only for queries run on the main cluster.

SVCS_S3LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

For information about SVL_S3LOG, see [SVL_S3LOG](#).

Table columns

Column name	Data type	Description
pid	integer	The process ID.
query	integer	The query ID.
segment	integer	The segment number. A query consists of multiple segments, and each segment consists of one or more steps.

Column name	Data type	Description
step	integer	The query step that ran.
node	integer	The node number.
eventtime	timestamp	The time in UTC that the event is recorded.
message	char(512)	The message for the log entry.

Sample query

The following example queries `SVCS_S3LOG` for the last query that ran.

```
select *
from svcs_s3log
where query = pg_last_query_id()
order by query, segment;
```

SVCS_S3PARTITION_SUMMARY

Use the `SVCS_S3PARTITION_SUMMARY` view to get a summary of Redshift Spectrum queries partition processing at the segment level. One segment can perform one external table scan.

Note

System views with the prefix `SVCS` provide details about queries on both the main and concurrency scaling clusters. The views are similar to the views with the prefix `SVL` except that the `SVL` views provide information only for queries run on the main cluster.

`SVCS_S3PARTITION_SUMMARY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

For information about `SVL_S3PARTITION`, see [SVL_S3PARTITION](#).

Table columns

Column name	Data type	Description
query	integer	The query ID. You can use this value to join various other system tables and views.
segment	integer	The segment number. A query consists of multiple segments.
assignment	char(1)	The type of partition assignment across nodes.
min_start_time	timestamp	The time in UTC that the partition processing started.
max_endtime	timestamp	The time in UTC that the partition processing completed.
min_duration	bigint	The minimum partition processing time used by a node for this query (in microseconds).
max_duration	bigint	The maximum partition processing time used by a node for this query (in microseconds).
avg_duration	bigint	The average partition processing time used by a node for this query (in microseconds).
total_partitions	integer	The total number of partitions in an external table.
qualified_partitions	integer	The total number of qualified partitions.
min_assigned_partitions	integer	The minimum number of partitions assigned on one node.

Column name	Data type	Description
max_assigned_partitions	integer	The maximum number of partitions assigned on one node.
avg_assigned_partitions	bigint	The average number of partitions assigned on one node.

Sample query

The following example gets the partition scan details for the last query performed.

```
select query, segment, assignment, min_starttime, max_endtime, min_duration,
       avg_duration
from svcs_s3partition_summary
where query = pg_last_query_id()
order by query, segment;
```

SVCS_S3QUERY_SUMMARY

Use the SVCS_S3QUERY_SUMMARY view to get a summary of all Redshift Spectrum queries (S3 queries) that have been run on the system. One segment can perform one external table scan.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the views with the prefix SVL except that the SVL views provide information only for queries run on the main cluster.

SVCS_S3QUERY_SUMMARY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

For information about SVL_S3QUERY, see [SVL_S3QUERY](#).

Table columns

Column name	Data type	Description
userid	integer	The ID of the user that generated the given entry.
query	integer	The query ID. You can use this value to join various other system tables and views.
xid	bigint	The transaction ID.
pid	integer	The process ID.
segment	integer	The segment number. A query consists of multiple segments, and each segment consists of one or more steps.
step	integer	The query step that ran.
starttime	timestamp	The time in UTC that the Redshift Spectrum query in this segment started running. One segment can have one external table scan.
endtime	timestamp	The time in UTC that the Redshift Spectrum query in this segment completed. One segment can have one external table scan.
elapsed	integer	The length of time that it took the Redshift Spectrum query in this segment to run (in microseconds).
aborted	integer	If a query was stopped by the system or canceled by the user, this column contains 1 . If the query ran to completion, this column contains 0 .
external_table_name	char(136)	The internal format of name of the external name of the table for the external table scan.
file_format	character(16)	The file format of the external table data.

Column name	Data type	Description
is_partitioned	char(1)	If true (t), this column value indicates that the external table is partitioned.
is_rrscan	char(1)	If true (t), this column value indicates that a range-restricted scan was applied.
is_nested	varchar(1)	If true (t), this column value indicates that the nested column data type is accessed.
s3_scanned_rows	bigint	The number of rows scanned from Amazon S3 and sent to the Redshift Spectrum layer.
s3_scanned_bytes	bigint	The number of bytes scanned from Amazon S3 and sent to the Redshift Spectrum layer, based on compressed data.
s3query_returned_rows	bigint	The number of rows returned from the Redshift Spectrum layer to the cluster.
s3query_returned_bytes	bigint	The number of bytes returned from the Redshift Spectrum layer to the cluster. A large amount of data returned to Amazon Redshift might affect system performance.
files	integer	The number of files that were processed for this Redshift Spectrum query. A small number of files limits the benefits of parallel processing.
files_max	integer	The maximum number of file processed on one slice.
files_avg	integer	The average number of file processed on one slice.

Column name	Data type	Description
splits	bigint	The number of splits processed for this segment. The number of splits processed on this slice. With large splittable data files, for example, data files larger than about 512 MB, Redshift Spectrum tries to split the files into multiple S3 requests for parallel processing.
splits_max	integer	The maximum number of splits processed on this slice.
splits_avg	bigint	The average number of splits processed on this slice.
total_split_size	bigint	The total size of all splits processed.
max_split_size	bigint	The maximum split size processed, in bytes.
avg_split_size	bigint	The average split size processed, in bytes.
total_retries	bigint	The total number of retries for the Redshift Spectrum query in this segment.
max_retries	integer	The maximum number of retries for one individual processed file.
max_request_duration	bigint	The maximum duration of an individual file request (in microseconds). Long running queries might indicate a bottleneck.
avg_request_duration	bigint	The average duration of the file requests (in microseconds).
max_request_parallelism	integer	The maximum number of parallel requests at one slice for this Redshift Spectrum query.

Column name	Data type	Description
avg_request_parallelism	double precision	The average number of parallel requests at one slice for this Redshift Spectrum query.
total_slowdown_count	bigint	The total number of Amazon S3 requests with a slow down error that occurred during the external table scan.
max_slowdown_count	integer	The maximum number of Amazon S3 requests with a slow down error that occurred during the external table scan on one slice.

Sample query

The following example gets the scan step details for the last query run.

```
select query, segment, elapsed, s3_scanned_rows, s3_scanned_bytes,
       s3query_returned_rows, s3query_returned_bytes, files
from svcs_s3query_summary
where query = pg_last_query_id()
order by query, segment;
```

```
query | segment | elapsed | s3_scanned_rows | s3_scanned_bytes | s3query_returned_rows
| s3query_returned_bytes | files
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
4587 |      2 |  67811 |           0 |           0 |           0
|           0 |     0
4587 |      2 |  591568 |      172462 |    11260097 |          8513
|           170260 |     1
4587 |      2 |  216849 |           0 |           0 |           0
|           0 |     0
4587 |      2 |  216671 |           0 |           0 |           0
|           0 |     0
```

SVCS_STREAM_SEGS

Lists the relationship between streams and concurrent segments.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the tables with the prefix STL except that the STL tables provide information only for queries run on the main cluster.

SVCS_STREAM_SEGS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
stream	integer	The set of concurrent segments of a query.
segment	integer	Number that identifies the query segment.

Sample queries

To view the relationship between streams and concurrent segments for the most recent query, type the following query:

```
select *
from svcs_stream_segs
where query = pg_last_query_id();

query | stream | segment
-----+-----+-----
```

```

10 |      1 |      2
10 |      0 |      0
10 |      2 |      4
10 |      1 |      3
10 |      0 |      1
(5 rows)

```

SVCS_UNLOAD_LOG

Use the SVCS_UNLOAD_LOG to get details of UNLOAD operations.

SVCS_UNLOAD_LOG records one row for each file created by an UNLOAD statement. For example, if an UNLOAD creates 12 files, SVCS_UNLOAD_LOG contains 12 corresponding rows. This view is derived from the STL_UNLOAD_LOG system table but doesn't show slice-level for queries run on a concurrency scaling cluster.

Note

System views with the prefix SVCS provide details about queries on both the main and concurrency scaling clusters. The views are similar to the tables with the prefix STL except that the STL tables provide information only for queries run on the main cluster.

SVCS_UNLOAD_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who generated the entry.
query	integer	The query ID.
pid	integer	The process ID associated with the query statement.
path	character(1280)	The complete Amazon S3 object path for the file.
start_time	timestamp	The start time for the UNLOAD operation.

Column name	Data type	Description
end_time	timestamp	The end time for the UNLOAD operation.
line_count	bigint	The number of lines (rows) unloaded to the file.
transfer_size	bigint	The number of bytes transferred.
file_format	character(10)	The format of unloaded file.

Sample query

To get a list of the files that were written to Amazon S3 by an UNLOAD command, you can call an Amazon S3 list operation after the UNLOAD completes; however, depending on how quickly you issue the call, the list might be incomplete because an Amazon S3 list operation is eventually consistent. To get a complete, authoritative list immediately, query SVCS_UNLOAD_LOG.

The following query returns the path name for files that were created by an UNLOAD for the last query completed:

```
select query, substring(path,0,40) as path
from svcs_unload_log
where query = pg_last_query_id()
order by path;
```

This command returns the following sample output:

```
query |          path
-----+-----
 2320 | s3://amzn-s3-demo-bucket/venue0000_part_00
 2320 | s3://amzn-s3-demo-bucket/venue0001_part_00
 2320 | s3://amzn-s3-demo-bucket/venue0002_part_00
 2320 | s3://amzn-s3-demo-bucket/venue0003_part_00
(4 rows)
```

SVL views for main cluster

SVL views are system views in Amazon Redshift that contain references to STL tables and logs for more detailed information.

These views provide quicker and easier access to commonly queried data found in those tables.

Note

The SVL_QUERY_SUMMARY view only contains information about queries run by Amazon Redshift, not other utility and DDL commands. For a complete listing and information on all statements run by Amazon Redshift, including DDL and utility commands, you can query the SVL_STATEMENTTEXT view.

SVL_AUTO_WORKER_ACTION

Records automated actions taken by Amazon Redshift on tables defined for automatic optimization.

SVL_AUTO_WORKER_ACTION is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
table_id	integer	The table identifier.
type	character (32)	The type of recommendation. Possible values are distkey and sortkey.

Column name	Data type	Description
status	character (128)	The completion status of the recommendation. Possible values are Start, Complete, Skipped, Abort, Checkpoint, and Failed.
eventtime	timestamp	The timestamp of the status column.
sequence	integer	The sequence number of a truncated <code>previous_state</code> value. When a single <code>previous_state</code> contains more than 200 characters, additional rows are logged for that value. Sequence is 0 is the first row, 1 is the second, and so on.
previous_state	character (200)	The previous distribution style and sort keys of the table before applying the recommendation. The value is truncated into 200-character increments.

Some examples of values of the `status` column are as follows:

- Skipped:Table not found.
- Skipped:Recommendation is empty.
- Skipped:Apply sortkey recommendation is disabled.
- Skipped:Retry exceeds the maximum limit for a table.
- Skipped:Table column has changed.
- Abort:This table is not AUTO.
- Abort:This table has been recently converted.
- Abort:This table exceeds table size threshold.

Sample queries

In the following example, the rows in the result show actions taken by Amazon Redshift.

```
select table_id, type, status, eventtime, sequence, previous_state
```

```
from SVL_AUTO_WORKER_ACTION;
```

```

table_id | type | status |
eventtime | sequence | previous_state |

```

SVL_COMPILE

Records compile time and location for each query segment of queries.

SVL_COMPILE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

 **Note**

SVL_COMPILE only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

For information about SVCS_COMPILE, see [SVCS_COMPILE](#).

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
xid	bigint	Transaction ID associated with the statement.
pid	integer	Process ID associated with the statement.
query	integer	Query ID. Can be used to join various other system tables and views.
segment	integer	The query segment to be compiled.
locus	integer	Location where the segment runs. 1 if on a compute node and 2 if on the leader node.
starttime	timestamp	Time in UTC that the compile started.
endtime	timestamp	Time in UTC that the compile ended.
compile	integer	0 if the compile was reused, 1 if the segment was compiled.

Sample queries

In this example, queries 35878 and 35879 ran the same SQL statement. The compile column for query 35878 shows 1 for four query segments, which indicates that the segments were compiled. Query 35879 shows 0 in the compile column for every segment, indicating that the segments did not need to be compiled again.

```
select userid, xid, pid, query, segment, locus,
datediff(ms, starttime, endtime) as duration, compile
from svl_compile
where query = 35878 or query = 35879
order by query, segment;
```

userid	xid	pid	query	segment	locus	duration	compile
100	112780	23028	35878	0	1	0	0
100	112780	23028	35878	1	1	0	0
100	112780	23028	35878	2	1	0	0
100	112780	23028	35878	3	1	0	0
100	112780	23028	35878	4	1	0	0
100	112780	23028	35878	5	1	0	0
100	112780	23028	35878	6	1	1380	1
100	112780	23028	35878	7	1	1085	1
100	112780	23028	35878	8	1	1197	1
100	112780	23028	35878	9	2	905	1
100	112782	23028	35879	0	1	0	0
100	112782	23028	35879	1	1	0	0
100	112782	23028	35879	2	1	0	0
100	112782	23028	35879	3	1	0	0
100	112782	23028	35879	4	1	0	0
100	112782	23028	35879	5	1	0	0

100	112782	23028	35879	7	1	0	0
100	112782	23028	35879	8	1	0	0
100	112782	23028	35879	9	2	0	0

(20 rows)

SVL_DATASHARE_CHANGE_LOG

Records the consolidated view for tracking changes to datashares on both producer and consumer clusters.

SVL_DATASHARE_CHANGE_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_DATASHARE_CHANGE_LOG](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user taking the action.
username	varchar(128)	The name of the user taking the action.
pid	integer	The ID of the process.
xid	bigint	The ID of the transaction.
share_id	integer	The ID of the datashare affected.
share_name	varchar(128)	The name of the datashare.
source_database_id	integer	The ID of the database to which the datashare belongs.
source_database_name	varchar(128)	The name of the database to which the datashare belongs.
consumer_database_id	integer	The ID of the database imported from the datashare.
consumer_database_name	varchar(128)	The name of the database imported from the datashare.

Column name	Data type	Description
arn	varchar(192)	The ARN of the resource backing the imported database.
recordtime	timestamp	The timestamp of the action.
action	varchar(128)	The action being run. Possible values are CREATE DATASHARE, DROP DATASHARE, GRANT ALTER, REVOKE ALTER, GRANT SHARE, REVOKE SHARE, ALTER ADD, ALTER REMOVE, ALTER SET, GRANT USAGE, REVOKE USAGE, CREATE DATABASE, GRANT or REVOKE USAGE on a shared database, DROP SHARED DATABASE, ALTER SHARED DATABASE.
status	integer	The status of the action. Possible values are SUCCESS and ERROR-ERROR CODE.
share_object_type	varchar(64)	The type of database object that was added to or removed from the datashare. Possible values are schemas, tables, columns, functions, and views. This is a field for the producer cluster.
share_object_id	integer	The ID of database object that was added to or removed from the datashare. This is a field for the producer cluster.
share_object_name	varchar(128)	The name of database object that was added to or removed from the datashare. This is a field for the producer cluster.
target_user_type	varchar(16)	The type of users or groups that a privilege was granted to. This is a field for both the producer and consumer cluster.
target_userid	integer	The ID of users or groups that a privilege was granted to. This is a field for both the producer and consumer cluster.
target_username	varchar(128)	The name of users or groups that a privilege was granted to. This is a field for both the producer and consumer cluster.
consumer_account	varchar(16)	The account ID of the data consumer. This is a field for the producer cluster.

Column name	Data type	Description
consumer_namespace	varchar(64)	The namespace of the data consumer account. This is a field for the producer cluster.
producer_account	varchar(16)	The account ID of the producer account that the datashare belongs to. This is a field for the consumer cluster.
producer_namespace	varchar(64)	The namespace of the product account that the datashare belongs to. This is a field for the consumer cluster.
attribute_name	varchar(64)	The name of an attribute of the datashare or shared database.
attribute_value	varchar(128)	The value of an attribute of the datashare or shared database.
message	varchar(512)	The error message when an action fails.

Sample queries

The following example shows a SVL_DATASHARE_CHANGE_LOG view.

```
SELECT DISTINCT action
FROM svl_datashare_change_log
WHERE share_object_name LIKE 'ticket%';
```

```
action
```

```
-----
"ALTER DATASHARE ADD"
```

SVL_DATASHARE_CROSS_REGION_USAGE

Use the SVL_DATASHARE_CROSS_REGION_USAGE view to get a summary of cross-Region data transferred usage caused by cross-Region datasharing query. SVL_DATASHARE_CROSS_REGION_USAGE aggregates details at the segment level.

SVL_DATASHARE_CROSS_REGION_USAGE is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_DATASHARE_CROSS_REGION_USAGE](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
query	integer	The ID of the query. Use this value to join other system tables and views.
segment	bigint	The number of the segment. A query consists of multiple segments, and each segment consists of one or more steps.
start_time	time	The time in UTC that the data transfer began.
end_time	time	The time in UTC that the data transfer ended.
transferred_data	bigint	The number of bytes of data transferred from a producer Region to a consumer Region.
source_region	char(25)	The producer Region that the query transferred data from.
recordtime	timestamp	The time when the action is recorded.

Sample queries

The following example shows a SVL_DATASHARE_CROSS_REGION_USAGE view.

```
SELECT query, segment, transferred_data, source_region
from svl_datashare_cross_region_usage
where query = pg_last_query_id()
order by query, segment;
```

```

query | segment | transferred_data | source_region
-----+-----+-----+-----
200048 | 2 | 4194304 | us-west-1
200048 | 2 | 4194304 | us-east-2

```

SVL_DATASHARE_USAGE_CONSUMER

Records the activity and usage of datashares. This view is only relevant on the consumer cluster.

SVL_DATASHARE_USAGE_CONSUMER is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_DATASHARE_USAGE_CONSUMER](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user issuing the request.
pid	integer	The ID of the leader process running the query.
xid	bigint	The context of the current transaction.
request_id	varchar(50)	The unique ID of the requested API call.
request_type	varchar(25)	The type of the request made to the producer cluster.
transaction_uid	varchar(50)	The unique ID of the transaction.
recordtime	timestamp	The time when the action is recorded.

Column name	Data type	Description
status	integer	The status of the requested API call.
error	varchar(512)	The message for an error.

Sample queries

The following example shows a SVL_DATASHARE_USAGE_CONSUMER view.

```
SELECT request_type, status, trim(error) AS error
FROM svl_datashare_usage_consumer
```

```
 request_type | status | error
-----+-----+-----
"GET RELATION" |    0   |
```

SVL_DATASHARE_USAGE_PRODUCER

Records the activity and usage of datashares. This view is only relevant on the producer cluster.

SVL_DATASHARE_USAGE_PRODUCER is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_DATASHARE_USAGE_PRODUCER](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
share_id	integer	The object ID (OID) of the datashare.

Column name	Data type	Description
share_name	varchar(128)	The name of the datashare.
request_id	varchar(50)	The unique ID of the requested API call.
request_type	varchar(25)	The type of the request made to the producer cluster.
object_type	varchar(64)	The type of the object being shared from the datashare. Possible values are schemas, tables, columns, functions, and views.
object_oid	integer	The ID of the object being shared from the datashare.
object_name	varchar(128)	The name of the object being shared from the datashare.
consumer_account	varchar(16)	The account of the consumer account that the datashare is shared to.
consumer_namespace	varchar(64)	The namespace of the consumer account that the datashare is shared to.
consumer_transaction_uid	varchar(50)	The unique transaction ID of the statement on the consumer cluster.
recordtime	timestamp	The time when the action is recorded.
status	integer	The status of the datashare.
error	varchar(512)	The message for an error.
consumer_region	char(64)	The Region that the consumer cluster is in.

Sample queries

The following example shows a SVL_DATASHARE_USAGE_PRODUCER view.

```
SELECT DISTINCT request_type
FROM svl_datashare_usage_producer
WHERE object_name LIKE 'tickit%';

    request_type
-----
"GET RELATION"
```

SVL_FEDERATED_QUERY

Use the SVL_FEDERATED_QUERY view to view information about a federated query call.

SVL_FEDERATED_QUERY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_EXTERNAL_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user running the query.
xid	bigint	The transaction ID.
pid	integer	The ID of the leader process running the query.
query	integer	The query ID of a federated call.
sourcetype	character (32)	The federated call source type, for example "PG".

Column name	Data type	Description
recordtime	timestamp	The time when a query is sent for federation. UTC is used.
querytext	character (4000)	The query string sent to the remote PostgreSQL engine for execution.
num_rows	bigint	The number of rows returned by the federated query.
num_bytes	bigint	The number of bytes returned by the federated query.
duration	bigint	The time (microseconds) spent fetching rows from cursor calls. It is the time spent running the federated query, as well as, getting results back.

Sample queries

To show information about federated query calls, run the following query.

```
select query, trim(sourcetype) as type, recordtime, trim(querytext) as "PG Subquery"
from svl_federated_query where query = 4292;
```

```

query | type |          recordtime          |                               pg subquery
-----+-----+-----+-----
4292 | PG   | 2020-03-27 04:29:58.485126 | SELECT "level" FROM functional.employees
WHERE ("level" >= 6)
(1 row)
```

SVL_MULTI_STATEMENT_VIOLATIONS

Use the SVL_MULTI_STATEMENT_VIOLATIONS view to get a complete record of all of the SQL commands run on the system that violates transaction block restrictions.

Violations occur when you run any of the following SQL commands that Amazon Redshift restricts inside a transaction block or multi-statement requests:

- [CREATE DATABASE](#)
- [DROP DATABASE](#)
- [ALTER TABLE APPEND](#)
- [CREATE EXTERNAL TABLE](#)
- DROP EXTERNAL TABLE
- RENAME EXTERNAL TABLE
- ALTER EXTERNAL TABLE
- CREATE TABLESPACE
- DROP TABLESPACE
- [CREATE LIBRARY](#)
- [DROP LIBRARY](#)
- REBUILD CAT
- INDEX CAT
- REINDEX DATABASE
- [VACUUM](#)
- [GRANT](#)
- [COPY](#)

Note

If there are any entries in this view, then change your corresponding applications and SQL scripts. We recommend changing your application code to move the use of these restricted SQL commands outside of the transaction block. If you need further assistance, contact AWS Support.

SVL_MULTI_STATEMENT_VIOLATIONS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user who caused the violation.
database	character(32)	The name of the database that the user was connected to.
cmdname	character(20)	The name of the command that cannot run inside a transaction block or multi-statement request. For example, CREATE DATABASE, DROP DATABASE, ALTER TABLE APPEND, CREATE EXTERNAL TABLE, DROP EXTERNAL TABLE, RENAME EXTERNAL TABLE, ALTER EXTERNAL TABLE, CREATE LIBRARY, DROP LIBRARY, REBUILD CAT, INDEXCAT, REINDEX DATABASE, VACUUM, GRANT on external resources, CLUSTER, COPY, CREATE TABLESPACE, and DROP TABLESPACE.
xid	bigint	The transaction ID associated with the statement.
pid	integer	The process ID for the statement.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter is not set, this field is blank.

Column name	Data type	Description
starttime	timestamp	The exact time when the statement started executing , with 6 digits of precision for fractional seconds, for example: 2009-06-12 11:29:19.131358
endtime	timestamp	The exact time when the statement finished executing , with 6 digits of precision for fractional seconds, for example: 2009-06-12 11:29:19.193640
sequence	integer	When a single statement contains more than 200 characters, additional rows are logged for that statement. Sequence 0 is the first row, 1 is the second, and so on.
type	varchar(10)	The type of SQL statement: QUERY , DDL , or UTILITY .
text	character(200)	The SQL text, in 200-character increments. This field might contain special characters such as backslash (\) and newline (\n).

Sample query

The following query returns multiple statements that have violations.

```
select * from svl_multi_statement_violations order by starttime asc;

userid | database | cmdname | xid | pid | label | starttime | endtime | sequence | type
| text
=====
1 | dev | CREATE DATABASE | 1034 | 5729 |label1 | ***** | ***** | 0 | DDL |
create table c(b int);
1 | dev | CREATE DATABASE | 1034 | 5729 |label1 | ***** | ***** | 0 | UTILITY |
create database b;
1 | dev | CREATE DATABASE | 1034 | 5729 |label1 | ***** | ***** | 0 | UTILITY |
COMMIT
...
```

SVL_MV_REFRESH_STATUS

The SVL_MV_REFRESH_STATUS view contains a row for the refresh activity of materialized views.

For more information about materialized views, see [Materialized views in Amazon Redshift](#).

SVL_MV_REFRESH_STATUS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_MV_REFRESH_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
db_name	char(128)	The database that contains the materialized view.
userid	bigint	The ID of the user who performed the refresh.
schema_name	char(128)	The schema of the materialized view.
mv_name	char(128)	The materialized view name.
xid	bigint	The transaction ID of the refresh.
starttime	timestamp	The start time of the refresh.
endtime	timestamp	The end time of the refresh.
status	text	<p>The status of the refresh. Example values include the following:</p> <ul style="list-style-type: none"> <i>Refresh successfully updated MV incrementally</i> <p>If it's a materialized view for streaming, the message might have additional qualifiers regarding the number of records. These include the following:</p>

Column name	Data type	Description
		<ul style="list-style-type: none"> • <i>Stream returned no new data</i> – There were no records retrieved. • <i>All records received from the stream were skipped</i> – Records were retrieved, but due to errors all were skipped. • <i>Some stream records were skipped</i> – Records were retrieved, but due to errors some were skipped. <p>If there are no qualifiers, then at least one record was retrieved and all records are available in the materialized view. There is one remaining possible qualifier:</p> <ul style="list-style-type: none"> • <i>The stream may contain more data</i> – The refresh ended before Amazon Redshift determined that there were no further records to consume. The stream can be up to date, but it hasn't been confirmed by Amazon Redshift. • <i>Refresh successfully recomputed MV from scratch</i> • <i>Refresh partially updated MV incrementally up to an active transaction</i> • <i>MV was already updated</i> • <i>Refresh failed. A base table column was renamed</i> • <i>Refresh failed. A base table column type was changed</i> • <i>Refresh failed. A base table was renamed</i> • <i>Refresh failed due to an internal error</i> • <i>Refresh failed. A base table column was dropped</i>

Column name	Data type	Description
		<ul style="list-style-type: none"> Refresh failed. Schema of MV was renamed Refresh failed. MV was not found Auto refresh aborted due to excessive user workload Refresh failed. Serializable isolation violation
refresh_type	char(32)	The definition of the refresh type. Example values include <i>Manual</i> and <i>Auto</i> .

Sample query

To view the refresh status of materialized views, run the following query.

```
select * from svl_mv_refresh_status;
```

This query returns the following sample output:

```
db_name | userid | schema | name | xid | starttime | endtime | status | refresh_type

```

SVL_QERROR

The SVL_QERROR view is deprecated.

SVL_QLOG

The SVL_QLOG view contains a log of all queries run against the database.

Amazon Redshift creates the SVL_QLOG view as a readable subset of information from the [SVL_QUERY](#) table. Use this table to find the query ID for a recently run query or to see how long it took a query to complete.

SVL_QLOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user who generated the entry.
query	integer	Query ID. You can use this ID to join various other system tables and views.
xid	bigint	Transaction ID.
pid	integer	Process ID associated with the query.
starttime	timestamp	Exact time when the statement started executing, with six digits of precision for fractional seconds—for example: 2009-06-12 11:29:19.131358
endtime	timestamp	Exact time when the statement finished executing, with six digits of precision for fractional seconds—for example: 2009-06-12 11:29:19.193640
elapsed	bigint	Length of time that it took the query to run (in microseconds).
aborted	integer	If a query was stopped by the system or canceled by the user, this column contains 1 . If the query ran to completion, this column contains 0 . Queries that are canceled for workload management purposes and subsequently restarted also have a value of 1 in this column.
label	character(320)	Either the name of the file used to run the query, or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter is not set, this field value is default.
substring	character(60)	Truncated query text.

Column name	Data type	Description
source_query	integer	If the query used result caching, the query ID of the query that was the source of the cached results. If result caching was not used, this field value is NULL.
concurrency_scaling_status_text	text	A description of whether the query ran on the main cluster or concurrency scaling cluster.
from_sp_call	integer	If the query was called from a stored procedure, the query ID of the procedure call. If the query wasn't run as part of a stored procedure, this field is NULL.

Sample queries

The following example returns the query ID, execution time, and truncated query text for the five most recent database queries run by the user with `userid = 100`.

```
select query, pid, elapsed, substring from svl_qlog
where userid = 100
order by starttime desc
limit 5;
```

```
query | pid | elapsed | substring
-----+-----+-----+-----
187752 | 18921 | 18465685 | select query, elapsed, substring from svl_...
204168 | 5117 | 59603 | insert into testtable values (100);
187561 | 17046 | 1003052 | select * from pg_table_def where tablename...
187549 | 17046 | 1108584 | select * from STV_WLM_SERVICE_CLASS_CONFIG
187468 | 17046 | 5670661 | select * from pg_table_def where schemaname...
(5 rows)
```

The following example returns the SQL script name (LABEL column) and elapsed time for a query that was cancelled (**aborted=1**):

```
select query, elapsed, trim(label) querylabel
```

```

from svl_qlog where aborted=1;

 query | elapsed |      querylabel
-----+-----+-----
      16 | 6935292 | alltickittablesjoin.sql
(1 row)

```

SVL_QUERY_METRICS

The SVL_QUERY_METRICS view shows the metrics for completed queries. This view is derived from the [STL_QUERY_METRICS](#) system table. Use the values in this view as an aid to determine threshold values for defining query monitoring rules. For more information, see [WLM query monitoring rules](#).

SVL_QUERY_METRICS is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user that ran the query that generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
service_class	integer	ID for the WLM query queue (service class). Query queues are defined in the WLM configuration. Metrics are reported only for user-defined queues. For a list of service class IDs, see WLM service class IDs .
dimension	varchar(24)	Dimension on which the metric is reported. Possible values are query, segment, and step.
segment	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query

Column name	Data type	Description
		segments can run in parallel. Each segment runs in a single process. If the segment value is 0, metrics segment values are rolled up to the query level.
step	integer	ID for the type of step performed. The description for the step type is shown in the <code>step_label</code> column. .
step_label	varchar(30)	Type of step performed.
query_cpu_time	bigint	CPU time used by the query, in seconds. CPU time is distinct from query run time.
query_blocks_read	bigint	Number of 1 MB blocks read by the query.
query_execution_time	bigint	Elapsed execution time for a query, in seconds. Execution time doesn't include time spent waiting in a queue. See <code>query_queue_time</code> for the time queued.
query_cpu_usage_percent	bigint	Percent of CPU capacity used by the query.
query_temp_blocks_to_disk	bigint	The amount of disk space used by a query to write intermediate results, in MB.
segment_execution_time	bigint	Elapsed execution time for a single segment, in seconds.
cpu_skew	numeric(38,2)	The ratio of maximum CPU usage for any slice to average CPU usage for all slices. This metric is defined at the segment level.
io_skew	numeric(38,2)	The ratio of maximum blocks read (I/O) for any slice to average blocks read for all slices.

Column name	Data type	Description
scan_row_count	bigint	The number of rows in a scan step. The row count is the total number of rows emitted before filtering rows marked for deletion (ghost rows) and before applying user-defined query filters.
join_row_count	bigint	The number of rows processed in a join step.
nested_loop_join_row_count	bigint	The number of rows in a nested loop join.
return_row_count	bigint	The number of rows returned by the query.
spectrum_scan_row_count	bigint	The number of rows scanned by Amazon Redshift Spectrum in Amazon S3.
spectrum_scan_size_mb	bigint	The amount of data, in MB, scanned by Amazon Redshift Spectrum in Amazon S3.
query_queue_time	bigint	The amount of time in seconds that the query was queued.

SVL_QUERY_METRICS_SUMMARY

The SVL_QUERY_METRICS_SUMMARY view shows the maximum values of metrics for completed queries. This view is derived from the [STL_QUERY_METRICS](#) system table. Use the values in this view as an aid to determine threshold values for defining query monitoring rules. For more information about rules and metrics for query monitoring for Amazon Redshift, see [WLM query monitoring rules](#).

SVL_QUERY_METRICS_SUMMARY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of the user that ran the query that generated the entry.
query	integer	Query ID. The query column can be used to join other system tables and views.
service_class	integer	ID for the WLM query queue (service class). Query queues are defined in the WLM configuration. Metrics are reported only for user-defined queues. For a list of service class IDs, see WLM service class IDs .
query_cpu_time	bigint	CPU time used by the query, in seconds. CPU time is distinct from query run time.
query_blocks_read	bigint	Number of 1 MB blocks read by the query.
query_execution_time	bigint	Elapsed execution time for a query, in seconds. Execution time doesn't include time spent waiting in a queue.
query_cpu_usage_percent	numeric(3,2)	Percent of CPU capacity used by the query.
query_temp_blocks_to_disk	bigint	The amount of disk space used by a query to write intermediate results, in MB.
segment_execution_time	bigint	Elapsed execution time for a single segment, in seconds.
cpu_skew	numeric(3,2)	The ratio of maximum CPU usage for any slice to average CPU usage for all slices. This metric is defined at the segment level.
io_skew	numeric(3,2)	The ratio of maximum blocks read (I/O) for any slice to average blocks read for all slices.

Column name	Data type	Description
scan_row_count	bigint	The number of rows in a scan step. The row count is the total number of rows emitted before filtering rows marked for deletion (ghost rows) and before applying user-defined query filters.
join_row_count	bigint	The number of rows processed in a join step.
nested_loop_join_row_count	bigint	The number of rows in a nested loop join.
return_row_count	bigint	The number of rows returned by the query.
spectrum_scan_row_count	bigint	The number of rows scanned by Amazon Redshift Spectrum in Amazon S3.
spectrum_scan_size_mb	bigint	The amount of data, in MB, scanned by Amazon Redshift Spectrum in Amazon S3.
query_queue_time	bigint	The amount of time in seconds that the query was queued.

SVL_QUERY_QUEUE_INFO

Summarizes details for queries that spent time in a workload management (WLM) query queue or a commit queue.

The SVL_QUERY_QUEUE_INFO view filters queries performed by the system and shows only queries performed by a user.

The SVL_QUERY_QUEUE_INFO view summarizes information from the [STL_QUERY](#), [STL_WLM_QUERY](#), and [STL_COMMIT_STATS](#) system tables.

SVL_QUERY_QUEUE_INFO is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
database	text	The name of the database the user was connected to when the query was issued.
query	integer	Query ID.
xid	bigint	Transaction ID.
userid	integer	ID of the user that generated the query.
querytxt	text	First 100 characters of the query text.
queue_start_time	timestamp	Time in UTC when the query entered the WLM queue.
exec_start_time	timestamp	Time in UTC when query execution started.
service_class	integer	ID for the service class. Service classes are defined in the WLM configuration file.
slots	integer	Number of WLM query slots.
queue_elapsed	bigint	Time that the query spent waiting in a WLM queue (in seconds).
exec_elapsed	bigint	Time spent executing the query (in seconds).
wlm_total_elapsed	bigint	Time that the query spent in a WLM queue (queue_elapsed), plus time spent executing the query (exec_elapsed).
commit_queue_elapsed	bigint	Time that the query spent waiting in the commit queue (in seconds).

Column name	Data type	Description
commit_exec_time	bigint	Time that the query spent in the commit operation (in seconds).
service_class_name	character(64)	The name of the service class.

Sample queries

The following example shows the time that queries spent in WLM queues.

```
select query, service_class, queue_elapsed, exec_elapsed, wlm_total_elapsed
from svl_query_queue_info
where wlm_total_elapsed > 0;
```

```

  query | service_class | queue_elapsed | exec_elapsed | wlm_total_elapsed
-----+-----+-----+-----+-----
 2742669 |          6 |          2 |          916 |          918
 2742668 |          6 |          4 |          197 |          201
(2 rows)
```

SVL_QUERY_REPORT

Amazon Redshift creates the SVL_QUERY_REPORT view from a UNION of a number of Amazon Redshift STL system tables to provide information about completed query steps.

This view breaks down the information about completed queries by slice and by step, which can help with troubleshooting node and slice issues in the Amazon Redshift cluster.

SVL_QUERY_REPORT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
query	integer	Query ID. Can be used to join various other system tables and views.
slice	integer	Data slice where the step ran.
segment	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process.
step	integer	Query step that completed.
start_time	timestamp	Exact time in UTC when the segment started executing, with 6 digits of precision for fractional seconds. For example: 2012-12-12 11:29:19.131358
end_time	timestamp	Exact time in UTC when the segment finished executing, with 6 digits of precision for fractional seconds. For example: 2012-12-12 11:29:19.131467
elapsed_time	bigint	Time (in microseconds) that it took the segment to run.
rows	bigint	Number of rows produced by the step (per slice). This number represents the number of rows for the slice that result from the execution of the step, not the number of rows received or processed by the step. In other words, this is the number of rows that survive the step and are passed on to the next step.
bytes	bigint	Number of bytes produced by the step (per slice).
label	char(256)	Step label, which consists of a query step name and, when applicable, table ID and table name (for example, scan tbl=100448 name

Column name	Data type	Description
		=user). Three-digit table IDs usually refer to scans of transient tables. When you see <code>tbl=0</code> , it usually refers to a scan of a constant value.
is_diskbased	character (1)	Whether this step of the query was performed as a disk-based operation: true (t) or false (f). Only certain steps, such as hash, sort, and aggregate steps, can go to disk. Many types of steps are always performed in memory.
workmem	bigint	Amount of working memory (in bytes) assigned to the query step. This value is the <code>query_working_mem</code> threshold allocated for use during execution, not the amount of memory that was actually used
is_rrscan	character (1)	If true (t), indicates that range-restricted scan was used on the step.
is_delayed_scan	character (1)	If true (t), indicates that delayed scan was used on the step.
rows_pre_filter	bigint	For scans of permanent tables, the total number of rows emitted before filtering rows marked for deletion (ghost rows) and before applying user-defined query filters.

Sample queries

The following query demonstrates the data skew of the returned rows for the query with query ID 279. Use this query to determine if database data is evenly distributed over the slices in the data warehouse cluster:

```
select query, segment, step, max(rows), min(rows),
case when sum(rows) > 0
then ((cast(max(rows) -min(rows) as float)*count(rows))/sum(rows))
else 0 end
from svl_query_report
where query = 279
group by query, segment, step
order by segment, step;
```

This query should return data similar to the following sample output:

```

query | segment | step | max | min | case
-----+-----+-----+-----+-----+-----
279 | 0 | 0 | 19721687 | 19721687 | 0
279 | 0 | 1 | 19721687 | 19721687 | 0
279 | 1 | 0 | 986085 | 986084 | 1.01411202804304e-06
279 | 1 | 1 | 986085 | 986084 | 1.01411202804304e-06
279 | 1 | 4 | 986085 | 986084 | 1.01411202804304e-06
279 | 2 | 0 | 1775517 | 788460 | 1.00098637606408
279 | 2 | 2 | 1775517 | 788460 | 1.00098637606408
279 | 3 | 0 | 1775517 | 788460 | 1.00098637606408
279 | 3 | 2 | 1775517 | 788460 | 1.00098637606408
279 | 3 | 3 | 1775517 | 788460 | 1.00098637606408
279 | 4 | 0 | 1775517 | 788460 | 1.00098637606408
279 | 4 | 1 | 1775517 | 788460 | 1.00098637606408
279 | 4 | 2 | 1 | 1 | 0
279 | 5 | 0 | 1 | 1 | 0
279 | 5 | 1 | 1 | 1 | 0
279 | 6 | 0 | 20 | 20 | 0
279 | 6 | 1 | 1 | 1 | 0
279 | 7 | 0 | 1 | 1 | 0
279 | 7 | 1 | 0 | 0 | 0
(19 rows)

```

SVL_QUERY_SUMMARY

Use the SVL_QUERY_SUMMARY view to find general information about the execution of a query.

The SVL_QUERY_SUMMARY view contains a subset of data from the SVL_QUERY_REPORT view.

Note that the information in SVL_QUERY_SUMMARY is aggregated from all nodes.

Note

The SVL_QUERY_SUMMARY view only contains information about queries performed by Amazon Redshift, not other utility and DDL commands. For a complete listing and information on all statements performed by Amazon Redshift, including DDL and utility commands, you can query the SVL_STATEMENTTEXT view.

SVL_QUERY_SUMMARY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

For information about SVCS_QUERY_SUMMARY, see [SVCS_QUERY_SUMMARY](#).

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
query	integer	Query ID. Can be used to join various other system tables and views.
stm	integer	Stream: A set of concurrent segments in a query. A query has one or more streams.
seg	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process.
step	integer	Query step that ran.
maxtime	bigint	Maximum amount of time for the step to run (in microseconds).
avgtime	bigint	Average time for the step to run (in microseconds).
rows	bigint	Number of data rows involved in the query step.
bytes	bigint	Number of data bytes involved in the query step.
rate_row	double precision	Query execution rate per row.
rate_byte	double precision	Query execution rate per byte.
label	text	Step label, which consists of a query step name and, when applicable, table ID and table name (for example, scan tbl=10044

Column name	Data type	Description
		8 name =user). Three-digit table IDs usually refer to scans of transient tables. When you see <code>tbl=0</code> , it usually refers to a scan of a constant value.
<code>is_diskbased</code>	<code>character(1)</code>	Whether this step of the query was performed as a disk-based operation on any node in the cluster: true (t) or false (f). Only certain steps, such as hash, sort, and aggregate steps, can go to disk. Many types of steps are always performed in memory.
<code>workmem</code>	<code>bigint</code>	Amount of working memory (in bytes) assigned to the query step.
<code>is_rrscan</code>	<code>character(1)</code>	If true (t), indicates that range-restricted scan was used on the step. Default is false (f).
<code>is_delayed_scan</code>	<code>character(1)</code>	If true (t), indicates that delayed scan was used on the step. Default is false (f).
<code>rows_pre_filter</code>	<code>bigint</code>	For scans of permanent tables, the total number of rows emitted before filtering rows marked for deletion (ghost rows).

Sample queries

Viewing processing information for a query step

The following query shows basic processing information for each step of query 87:

```
select query, stm, seg, step, rows, bytes
from svl_query_summary
where query = 87
order by query, seg, step;
```

This query retrieves the processing information about query 87, as shown in the following sample output:

```
query | stm | seg | step | rows | bytes
-----+-----+-----+-----+-----+-----
```

```

87      | 0 | 0 | 0 | 90 | 1890
87      | 0 | 0 | 2 | 90 | 360
87      | 0 | 1 | 0 | 90 | 360
87      | 0 | 1 | 2 | 90 | 1440
87      | 1 | 2 | 0 | 210494 | 4209880
87      | 1 | 2 | 3 | 89500 | 0
87      | 1 | 2 | 6 | 4 | 96
87      | 2 | 3 | 0 | 4 | 96
87      | 2 | 3 | 1 | 4 | 96
87      | 2 | 4 | 0 | 4 | 96
87      | 2 | 4 | 1 | 1 | 24
87      | 3 | 5 | 0 | 1 | 24
87      | 3 | 5 | 4 | 0 | 0
(13 rows)

```

Determining whether query steps spilled to disk

The following query shows whether or not any of the steps for the query with query ID 1025 (see the [SVL_QLOG](#) view to learn how to obtain the query ID for a query) spilled to disk or if the query ran entirely in-memory:

```

select query, step, rows, workmem, label, is_diskbased
from svl_query_summary
where query = 1025
order by workmem desc;

```

This query returns the following sample output:

```

query| step|  rows  |  workmem  |  label          |  is_diskbased
-----+-----+-----+-----+-----+-----
1025 |  0  |16000000| 141557760 |scan tbl=9      | f
1025 |  2  |16000000| 135266304 |hash tbl=142    | t
1025 |  0  |16000000| 128974848 |scan tbl=116536| f
1025 |  2  |16000000| 122683392 |dist            | f
(4 rows)

```

By scanning the values for `IS_DISKBASED`, you can see which query steps went to disk. For query 1025, the hash step ran on disk. Steps might run on disk include hash, aggr, and sort steps. To view only disk-based query steps, add **and is_diskbased = 't'** clause to the SQL statement in the above example.

SVL_RESTORE_ALTER_TABLE_PROGRESS

Use SVL_RESTORE_ALTER_TABLE_PROGRESS to monitor the migration progress of each table in the cluster during a classic resize to RA3 nodes. It captures the historic throughput of data migration during the resize operation. For more information about classic resize to RA3 nodes, go to [Classic resize](#).

SVL_RESTORE_ALTER_TABLE_PROGRESS is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_RESTORE_LOG](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Note

Rows with a progress of 100.00% or ABORTED are deleted after 7 days. Rows for tables dropped during or after a classic resize can still appear in SVL_RESTORE_ALTER_TABLE_PROGRESS.

Table columns

Column name	Data type	Description
tbl	integer	The ID of the table.
progress	char(32)	The status of redistribution progress of the table. Possible values are percentages from 0.00% to 100.00% and the message ABORTED. ABORTED means that the redistribution was stopped without finishing, with the reason explained in the message column.
message	char(256)	The message associated with the redistribution progress of the table.

Sample query

The following query returns running and queued queries.

```
select * from svl_restore_alter_table_progress;
```

tbl	progress	message
105614	ABORTED	Abort:Table no longer contains the prior dist key column.
105610	ABORTED	Abort:Table no longer contains the prior dist key column.
105594	0.00%	Table waiting for alter diststyle conversion.
105602	ABORTED	Abort:Table no longer contains the prior dist key column.
105606	ABORTED	Abort:Table no longer contains the prior dist key column.
105598	100.00%	Restored to distkey successfully.

SVL_S3LIST

Use the SVL_S3LIST view to get details about Amazon Redshift Spectrum queries at the segment level.

SVL_S3LIST is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

SVL_S3LIST only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_EXTERNAL_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
query	integer	The query ID.

Column name	Data type	Description
segment	integer	The segment number. A query consists of multiple segments.
node	integer	The node number.
slice	integer	The data slice that a particular segment ran against.
eventtime	timestamp	The time in UTC that the event is recorded.
bucket	text	The Amazon S3 bucket name.
prefix	text	The prefix of the Amazon S3 bucket location.
recursive	char(1)	Whether there is recursive scan for subfolders.
retrieved_files	integer	The number of listed files.
max_file_size	bigint	The maximum file size among listed files.
avg_file_size	double precision	The average file size among listed files.
generated_splits	integer	The number of file splits.
avg_split_length	double precision	The average length of file splits in bytes.
duration	bigint	The duration of file listing, in microseconds.

Sample query

The following example queries SVL_S3LIST for the last query to run.

```
select *
```

```

from svl_s3list
where query = pg_last_query_id()
order by query, segment;

```

SVL_S3LOG

Use the SVL_S3LOG view to get details about Amazon Redshift Spectrum queries at the segment and node slice level.

SVL_S3LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

SVL_S3LOG only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_EXTERNAL_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
pid	integer	The process ID.
query	integer	The query ID.
segment	integer	The segment number. A query consists of multiple segments, and each segment consists of one or more steps.
step	integer	The query step that ran.
node	integer	The node number.
slice	integer	The data slice that a particular segment ran against.

Column name	Data type	Description
eventtime	timestamp	Time in UTC that the step started executing.
message	text	Message for the log entry.

Sample query

The following example queries SVL_S3LOG for the last query that ran.

```
select *
from svl_s3log
where query = pg_last_query_id()
order by query,segment,slice;
```

SVL_S3PARTITION

Use the SVL_S3PARTITION view to get details about Amazon Redshift Spectrum partitions at the segment and node slice level.

SVL_S3PARTITION is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

SVL_S3PARTITION only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_EXTERNAL_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
query	integer	The query ID.
segment	integer	A segment number. A query consists of multiple segments, and each segment consists of one or more steps.
node	integer	The node number.
slice	integer	The data slice that a particular segment ran against.
starttime	timestamp without time zone	Time in UTC that the partition pruning started executing.
endtime	timestamp without time zone	Time in UTC that the partition pruning completed.
duration	bigint	Elapsed time (in microseconds).
total_partitions	integer	Number of total partitions.
qualified_partitions	integer	Number of qualified partitions.
assigned_partitions	integer	Number of assigned partitions on the slice.
assignment	character	Type of assignment.

Sample query

The following example gets the partition details for the last query completed.

```
SELECT query, segment,
```

Column name	Data type	Description
min_start_time	timestamp	The time in UTC that the partition processing started.
max_endtime	timestamp	The time in UTC that the partition processing completed.
min_duration	bigint	The minimum partition processing time used by a node for this query (in microseconds).
max_duration	bigint	The maximum partition processing time used by a node for this query (in microseconds).
avg_duration	bigint	The average partition processing time used by a node for this query (in microseconds).
total_partitions	integer	The total number of partitions in an external table.
qualified_partitions	integer	The total number of qualified partitions.
min_assigned_partitions	integer	The minimum number of partitions assigned on one node.
max_assigned_partitions	integer	The maximum number of partitions assigned on one node.
avg_assigned_partitions	bigint	The average number of partitions assigned on one node.

Sample query

The following example gets the partition scan details for the last query completed.

```
select query, segment, assignment, min_starttime, max_endtime, min_duration,
       avg_duration
from svl_s3partition_summary
where query = pg_last_query_id()
order by query,segment;
```

SVL_S3QUERY

Use the SVL_S3QUERY view to get details about Amazon Redshift Spectrum queries at the segment and node slice level.

SVL_S3QUERY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Note

SVL_S3QUERY only contains queries run on main clusters. It doesn't contain queries run on concurrency scaling clusters. To access queries run on both main and concurrency scaling clusters, we recommend that you use the SYS monitoring view [SYS_EXTERNAL_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand.

Table columns

Column name	Data type	Description
userid	integer	The ID of user who generated a given entry.
query	integer	The query ID.
segment	integer	A segment number. A query consists of multiple segments, and each segment consists of one or more steps.
step	integer	The query step that ran.
node	integer	The node number.

Column name	Data type	Description
slice	integer	The data slice that a particular segment ran against.
starttime	timestamp	Time in UTC that the query started executing.
endtime	timestamp	Time in UTC that the query execution completed
elapsed	integer	Elapsed time (in microseconds).
external_table_name	char(136)	Internal format of external table name for the s3 scan step.
is_partitioned	char(1)	If true (t), this column value indicates that the external table is partitioned.
is_rrscan	char(1)	If true (t), this column value indicates that a range-restricted scan was applied.
s3_scanned_rows	bigint	The number of rows scanned from Amazon S3 and sent to the Redshift Spectrum layer.
s3_scanned_bytes	bigint	The number of bytes scanned from Amazon S3 and sent to the Redshift Spectrum layer.
s3query_returned_rows	bigint	The number of rows returned from the Redshift Spectrum layer to the cluster.
s3query_returned_bytes	bigint	The number of bytes returned from the Redshift Spectrum layer to the cluster.
files	integer	The number of files that were processed for this S3 scan step on this slice.

Column name	Data type	Description
splits	int	The number of splits processed on this slice. With large splittable data files, for example, data files larger than about 512 MB, Redshift Spectrum tries to split the files into multiple S3 requests for parallel processing.
total_split_size	bigint	The total size of all splits processed on this slice, in bytes.
max_split_size	bigint	The maximum split size processed for this slice, in bytes.
total_retries	integer	The total number of retries for the processed files.
max_retries	integer	The maximum number of retries for an individual processed file.
max_request_duration	integer	The maximum duration of an individual Redshift Spectrum request (in microseconds).
avg_request_duration	double precision	The average duration of the Redshift Spectrum requests (in microseconds).
max_request_parallelism	integer	The maximum number of outstanding Redshift Spectrum on this slice for this S3 scan step.
avg_request_parallelism	double precision	The average number of parallel Redshift Spectrum requests on this slice for this S3 scan step.

Sample query

The following example gets the scan step details for the last query completed.

```
select query, segment, slice, elapsed, s3_scanned_rows, s3_scanned_bytes,
       s3query_returned_rows, s3query_returned_bytes, files
from svl_s3query
where query = pg_last_query_id()
order by query,segment,slice;
```

```
query | segment | slice | elapsed | s3_scanned_rows | s3_scanned_bytes |
s3query_returned_rows | s3query_returned_bytes | files
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
4587 |      2 |     0 |   67811 |           0 |           0 |
    0 |      |      |         0 |           0 |           0 |
4587 |      2 |     1 |   591568 |       172462 |       11260097 |
   8513 |      |      |   170260 |           1 |           0 |
4587 |      2 |     2 |   216849 |           0 |           0 |
    0 |      |      |         0 |           0 |           0 |
4587 |      2 |     3 |   216671 |           0 |           0 |
    0 |      |      |         0 |           0 |           0 |
```

SVL_S3QUERY_SUMMARY

Use the SVL_S3QUERY_SUMMARY view to get a summary of all Amazon Redshift Spectrum queries (S3 queries) that have been run on the system. SVL_S3QUERY_SUMMARY aggregates detail from SVL_S3QUERY at the segment level.

SVL_S3QUERY_SUMMARY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_EXTERNAL_QUERY_DETAIL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

For SVCS_S3QUERY_SUMMARY, see [SVCS_S3QUERY_SUMMARY](#).

Table columns

Column name	Data type	Description
userid	integer	The ID of the user that generated the given entry.

Column name	Data type	Description
query	integer	The query ID. You can use this value to join various other system tables and views.
xid	bigint	The transaction ID.
pid	integer	The process ID.
segment	integer	The segment number. A query consists of multiple segments, and each segment consists of one or more steps.
step	integer	The query step that ran.
starttime	timestamp	Time in UTC that the query started executing.
endtime	timestamp	Time in UTC that the query completed.
elapsed	integer	The length of time that it took the query to run (in microseconds).
aborted	integer	If a query was stopped by the system or canceled by the user, this column contains 1 . If the query ran to completion, this column contains 0 .
external_table_name	char(136)	The internal format of name of the external name of the table for the external table scan.
file_format	character(16)	The file format of the external table data.
is_partitioned	char(1)	If true (t), this column value indicates that the external table is partitioned.
is_rrscan	char(1)	If true (t), this column value indicates that a range-restricted scan was applied.

Column name	Data type	Description
is_nested	char(1)	If true (t), this column value indicates that the nested column data type is accessed.
s3_scanned_rows	bigint	The number of rows scanned from Amazon S3 and sent to the Redshift Spectrum layer.
s3_scanned_bytes	bigint	The number of bytes scanned from Amazon S3 and sent to the Redshift Spectrum layer, based on compressed data.
s3query_returned_rows	bigint	The number of rows returned from the Redshift Spectrum layer to the cluster.
s3query_returned_bytes	bigint	The number of bytes returned from the Redshift Spectrum layer to the cluster. A large amount of data returned to Amazon Redshift might affect system performance.
files	integer	The number of files that were processed for this Redshift Spectrum query. A small number of files limits the benefits of parallel processing.
files_max	integer	The maximum number of files processed on one slice.
files_avg	integer	The average number of files processed on one slice.
splits	int	The number of splits processed for this segment. The number of splits processed on this slice. With large splittable data files, for example, data files larger than about 512 MB, Redshift Spectrum tries to split the files into multiple S3 requests for parallel processing.
splits_max	int	The maximum number of splits processed on this slice.
splits_avg	int	The average number of splits processed on this slice.

Column name	Data type	Description
total_split_size	bigint	The total size of all splits processed.
max_split_size	bigint	The maximum split size processed, in bytes.
avg_split_size	bigint	The average split size processed, in bytes.
total_retries	integer	The total number of retries for one individual processed file.
max_retries	integer	The maximum number of retries for any of processed files.
max_request_duration	integer	The maximum duration of an individual file request (in microseconds). Long running queries might indicate a bottleneck.
avg_request_duration	double precision	The average duration of the file requests (in microseconds).
max_request_parallelism	integer	The maximum number of parallel requests at one slice for this Redshift Spectrum query.
avg_request_parallelism	double precision	The average number of parallel requests at one slice for this Redshift Spectrum query.
total_slowdown_count	bigint	The total number of Amazon S3 requests with a slow down error that occurred during the external table scan.

Column name	Data type	Description
max_slowdown_count	integer	The maximum number of Amazon S3 requests with a slow down error that occurred during the external table scan on one slice.

Sample query

The following example gets the scan step details for the last query completed.

```
select query, segment, elapsed, s3_scanned_rows, s3_scanned_bytes,
       s3query_returned_rows, s3query_returned_bytes, files
from svl_s3query_summary
where query = pg_last_query_id()
order by query, segment;
```

query	segment	elapsed	s3_scanned_rows	s3_scanned_bytes	s3query_returned_rows
4587	2	67811	0	0	0
		0	0		
4587	2	591568	172462	11260097	8513
		170260	1		
4587	2	216849	0	0	0
		0	0		
4587	2	216671	0	0	0
		0	0		

SVL_S3RETRIES

Use the SVL_S3RETRIES view to get information about why an Amazon Redshift Spectrum query based on Amazon S3 has failed.

SVL_S3RETRIES is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description		
query	integer	The query ID.		
segment	integer	Segment number. A query consists of multiple segments, and each segment consists of one or more steps. Query segments can run in parallel. Each segment runs in a single process.		
node	integer	The node number.		
slice	integer	The data slice that a particular segment ran against.		
eventtime	timestamp without time zone	Time in UTC that the step started executing.		
retries	integer	The number of retries for the query.		
successful_fetches	integer	The number of times data was returned.		
file_size	bigint	This size of the file in bytes.		
location	text	The location of the table.		

Column name	Data type	Description		
message	text	The error message.		

Sample query

The following example retrieves data about failed S3 queries.

```
SELECT svl_s3retries.query, svl_s3retries.segment, svl_s3retries.node,
       svl_s3retries.slice, svl_s3retries.eventtime, svl_s3retries.retries,
       svl_s3retries.successful_fetches, svl_s3retries.file_size,
       btrim((svl_s3retries."location")::text) AS "location",
       btrim((svl_s3retries.message)::text)
AS message FROM svl_s3retries;
```

SVL_SPATIAL_SIMPLIFY

You can query the system view `SVL_SPATIAL_SIMPLIFY` to get information about simplified spatial geometry objects using the `COPY` command. When you use `COPY` on a shapefile, you can specify `SIMPLIFY tolerance`, `SIMPLIFY AUTO`, and `SIMPLIFY AUTO max_tolerance` ingestion options. The result of the simplification is summarized in `SVL_SPATIAL_SIMPLIFY` system view.

When `SIMPLIFY AUTO max_tolerance` is set, this view contains a row for each geometry that exceeded the maximum size. When `SIMPLIFY tolerance` is set, then one row for the entire `COPY` operation is stored. This row references the `COPY` query ID and the specified simplification tolerance.

`SVL_SPATIAL_SIMPLIFY` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the `SYS` monitoring view [SYS_SPATIAL_SIMPLIFY](#). The data in the `SYS` monitoring view is formatted to be easier to use and understand. We recommend that you use the `SYS` monitoring view for your queries.

Table columns

Column name	Data type	Description
query	integer	The ID of the query (COPY command) that generated this row.
line_number	integer	When COPY SIMPLIFY AUTO option is specified, this value is the record number of the simplified record in the shapefile.
maximum_tolerance	double	The distance tolerance value specified in the COPY command. This is either the maximum tolerance value using the SIMPLIFY AUTO option, or the fixed tolerance value using the SIMPLIFY option.
initial_size	integer	The size in bytes of the GEOMETRY data value before simplification.
simplified	char(1)	When the COPY SIMPLIFY AUTO option is specified, t if the geometry was successfully simplified, or f otherwise. The geometry might not be simplified successfully if after the simplification with the given maximum tolerance its size is still larger than the maximum geometry size.
final_size	integer	When the COPY SIMPLIFY AUTO option is specified, this is the size in bytes of the geometry after simplification.
final_tolerance	double	

Sample query

The following query returns the list of records that COPY simplified.

```
SELECT * FROM svl_spatial_simplify WHERE query = pg_last_copy_id();
query | line_number | maximum_tolerance | initial_size | simplified | final_size |
final_tolerance
```

```

-----+-----+-----+-----+-----+-----
+-----
      20 |    1184704 |           -1 |    1513736 | t           |    1008808 |
1.276386653895e-05
      20 |    1664115 |           -1 |    1233456 | t           |    1023584 |
6.11707814796635e-06

```

SVL_SPECTRUM_SCAN_ERROR

You can query the system view SVL_SPECTRUM_SCAN_ERROR to get information about Redshift Spectrum scan errors.

SVL_SPECTRUM_SCAN_ERROR is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_EXTERNAL_QUERY_ERROR](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Displays a sample of logged errors. The default is 10 entries per query.

Column name	Data type	Description
userid	integer	The ID of the user that generated this row.
query	integer	The ID of the query that generated this row.
location	character(128)	The location of the data being queried.
rowid	character(128)	The location of the error within the file. The rowid parts are separated with a : (colon) and additional parts might be added in the future. <div style="border: 1px solid #ccc; border-radius: 10px; padding: 5px; margin: 10px 0;"> <code>row_offset :row_group :row_id</code> </div> A row_offset is the offset (in bytes) of the row within the file and is set to -1 for unsupported file formats. A table

Column name	Data type	Description
		is divided into row_groups, and each group has rows with distinct row_ids.
colname	character(128)	The name of the column returned by the query.
original_value	character(128)	Original value queried.
modified_value	character(128)	Modified value returned based on the data handling configuration option specified in the query.
trigger	character(128)	Data handling option specified in the query.
action	character(128)	Action associated with the data handling option specified in the query.
action_value	character(128)	Value of action parameter associated with the data handling option specified in the query.
error_code	integer	Result code of the data handling option specified in the query.

Sample query

The following query returns the list of rows for which data handling operations were performed.

```
SELECT * FROM svl_spectrum_scan_error;
```

The query returns results similar to the following.

```
userid  query      location
        original_value      modified_value      trigger      colname
        action_valueerror_code
```

SVL_STATEMENTTEXT

Use the SVL_STATEMENTTEXT view to get a complete record of all of the SQL commands that have been run on the system.

The SVL_STATEMENTTEXT view contains the union of all of the rows in the [STL_DDLTEXT](#), [STL_QUERYTEXT](#), and [STL_UTILITYTEXT](#) tables. This view also includes a join to the STL_QUERY table.

SVL_STATEMENTTEXT is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	ID of user who generated entry.
xid	bigint	Transaction ID associated with the statement.
pid	integer	Process ID for the statement.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter is not set, this field is blank.
starttime	timestamp	Exact time when the statement started executing, with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.131358
endtime	timestamp	Exact time when the statement finished executing, with 6 digits of precision for fractional seconds. For example: 2009-06-12 11:29:19.193640
sequence	integer	When a single statement contains more than 200 characters, additional rows are logged for that statement. Sequence 0 is the first row, 1 is the second, and so on.
type	varchar(10)	Type of SQL statement: QUERY , DDL , or UTILITY .
text	character(200)	SQL text, in 200-character increments. This field might contain special characters such as backslash (\\) and newline (\n).

Sample query

The following query returns DDL statements that were run on June 16th, 2009:

```
select starttime, type, rtrim(text) from svl_statementtext
where starttime like '2009-06-16%' and type='DDL' order by starttime asc;
```

starttime	type	rtrim
2009-06-16 10:36:50.625097	DDL	create table ddltest(c1 int);
2009-06-16 15:02:16.006341	DDL	drop view allticketjoin;
2009-06-16 15:02:23.65285	DDL	drop table sales;
2009-06-16 15:02:24.548928	DDL	drop table listing;
2009-06-16 15:02:25.536655	DDL	drop table event;
...		

Reconstructing stored SQL

To reconstruct the SQL stored in the text column of SVL_STATEMENTTEXT, run a SELECT statement to create SQL from 1 or more parts in the text column. Before running the reconstructed SQL, replace any (\n) special characters with a new line. The result of the following SELECT statement is rows of reconstructed SQL in the query_statement field.

```
select LISTAGG(CASE WHEN LEN(RTRIM(text)) = 0 THEN text ELSE RTRIM(text) END, '')
within group (order by sequence) AS query_statement
from SVL_STATEMENTTEXT where pid=pg_backend_pid();
```

For example, the following query selects 3 columns. The query itself is longer than 200 characters and is stored in parts in SVL_STATEMENTTEXT.

```
select
1 AS a0123456789012345678901234567890123456789012345678901234567890,
2 AS b0123456789012345678901234567890123456789012345678901234567890,
3 AS b012345678901234567890123456789012345678901234
FROM stl_querytext;
```

In this example, the query is stored in 2 parts (rows) in the text column of SVL_STATEMENTTEXT.

```
select sequence, text from SVL_STATEMENTTEXT where pid = pg_backend_pid() order by
starttime, sequence;
```

```

sequence |
          text
-----+-----
0 | select\n1 AS
a0123456789012345678901234567890123456789012345678901234567890,\n2 AS
b0123456789012345678901234567890123456789012345678901234567890,\n3 AS
b0123456789012345678901234567890123456789012345678901234
1 | \nFROM stl_querytext;

```

To reconstruct the SQL stored in `STL_STATEMENTTEXT`, run the following SQL.

```

select LISTAGG(CASE WHEN LEN(RTRIM(text)) = 0 THEN text ELSE RTRIM(text) END, '')
within group (order by sequence) AS text
from SVL_STATEMENTTEXT where pid=pg_backend_pid();

```

To use the resulting reconstructed SQL in your client, replace any (`\n`) special characters with a new line.

```

          text
-----+-----
select\n1 AS a0123456789012345678901234567890123456789012345678901234567890,\n2 AS
\n2 AS b0123456789012345678901234567890123456789012345678901234567890,\n3 AS

```

SVL_STORED_PROC_CALL

You can query the system view `SVL_STORED_PROC_CALL` to get information about stored procedure calls, including start time, end time, and whether a call is canceled. Each stored procedure call receives a query ID.

`SVL_STORED_PROC_CALL` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_PROCEDURE_CALL](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
userid	integer	The ID of the user whose privileges were used to run the statement. If this call was nested within a SECURITY DEFINER stored procedure, then this is the userid of the owner of that stored procedure.
session_userid	integer	The ID of the user that created the session and is the invoker of the top-level stored procedure call.
query	integer	The query ID of the procedure call.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter isn't set, this field value is default.
xid	bigint	The transaction ID.
pid	integer	The process ID. Usually, all of the queries in a session are run in the same process, so this value usually remains constant if you run a series of queries in the same session. Following certain internal events, Amazon Redshift might restart an active session and assign a new pid value. For more information, see STL_RESTARTED_SESSIONS .
database	character(32)	The name of the database that the user was connected to when the query was issued.
querytxt	character(4000)	The actual text of the procedure call query.

Column name	Data type	Description
starttime	timestamp	The time in UTC that the query started running, with six digits of precision for fractional seconds, for example: 2009-06-12 11:29:19.131358.
endtime	timestamp	The time in UTC that the query finished running, with six digits of precision for fractional seconds, for example: 2009-06-12 11:29:19.131358.
aborted	integer	If a stored procedure was stopped by the system or canceled by the user, this column contains 1. If the call runs to completion, this column contains 0.
from_sp_call	integer	If the procedure call was invoked by another procedure call, this column contains the query ID of the outer call. Otherwise, the field is NULL.

Sample query

The following query returns the elapsed time in descending order and the completion status for stored procedure calls in the past day.

```
select query, datediff(seconds, starttime, endtime) as elapsed_time, aborted,
trim(querytxt) as call from svl_stored_proc_call where starttime >= getdate() -
interval '1 day' order by 2 desc;
```

```

query | elapsed_time | aborted |
-----+-----+-----
+-----+-----+-----
4166 |          7 |      0 | call search_batch_status(35, 'succeeded');
2433 |          3 |      0 | call test_batch (123456)
1810 |          1 |      0 | call prod_benchmark (123456)
1836 |          1 |      0 | call prod_testing (123456)
1808 |          1 |      0 | call prod_portfolio ('N', 123456)
1816 |          1 |      1 | call prod_portfolio ('Y', 123456)

```

SVL_STORED_PROC_MESSAGES

You can query the system view `SVL_STORED_PROC_MESSAGES` to get information about stored procedure messages. Raised messages are logged even if the stored procedure call is canceled. Each stored procedure call receives a query ID. For more information about how to set the minimum level for logged messages, see `stored_proc_log_min_messages`.

`SVL_STORED_PROC_MESSAGES` is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_PROCEDURE_MESSAGES](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
<code>userid</code>	integer	The ID of the user whose privileges were used to run the statement. If this call was nested within a SECURITY DEFINER stored procedure, then this is the <code>userid</code> of the owner of that stored procedure.
<code>session_userid</code>	integer	The ID of the user that created the session and is the invoker of the top-level stored procedure call.
<code>pid</code>	integer	The process ID.
<code>xid</code>	bigint	The transaction ID of the procedure call query.
<code>query</code>	integer	The query ID of the procedure call.
<code>recordtime</code>	timestamp	The time in UTC that the message was raised.
<code>loglevel</code>	integer	The numeric value of the log level of the raised message. Possible values: 20 – for LOG 30 – for INFO 40 – for NOTICE 50 – for WARNING 60 – for EXCEPTION

Column name	Data type	Description
loglevel_text	character(10)	The log level that corresponds to the numeric value in loglevel. Possible values: LOG, INFO, NOTICE, WARNING, and EXCEPTION.
message	character(1024)	The text of the raised message.
linenum	integer	The line number of the raised statement.
querytext	character(500)	The actual text of the procedure call query.
label	character(320)	Either the name of the file used to run the query or a label defined with a SET QUERY_GROUP command. If the query is not file-based or the QUERY_GROUP parameter isn't set, this field value is default.
aborted	integer	If a stored procedure was stopped by the system or canceled by the user, this column contains 1. If the call runs to completion, this column contains 0.
message_xid	bigint	The transaction ID of the raised message.

Sample query

The following SQL statements show how to use SVL_STORED_PROC_MESSAGES to review raised messages.

```
-- Create and run a stored procedure
CREATE OR REPLACE PROCEDURE test_proc1(f1 int) AS
$$
BEGIN
    RAISE INFO 'Log Level: Input f1 is %',f1;
    RAISE NOTICE 'Notice Level: Input f1 is %',f1;
    EXECUTE 'select invalid';
    RAISE NOTICE 'Should not print this';

EXCEPTION WHEN OTHERS THEN
```

```

    raise exception 'EXCEPTION level: Exception Handling';
END;
$$ LANGUAGE plpgsql;

-- Call this stored procedure
CALL test_proc1(2);

-- Show raised messages with level higher than INFO
SELECT query, recordtime, loglevel, loglevel_text, trim(message) as message, aborted
FROM svl_stored_proc_messages
WHERE loglevel > 30 AND query = 193 ORDER BY recordtime;

query |          recordtime          | loglevel | loglevel_text |          message
      |          | aborted
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
    193 | 2020-03-17 23:57:18.277196 |      40 | NOTICE       | Notice Level: Input f1
is 2   |          |      1
    193 | 2020-03-17 23:57:18.277987 |      60 | EXCEPTION     | EXCEPTION level:
Exception Handling |          |      1
(2 rows)

-- Show raised messages at EXCEPTION level
SELECT query, recordtime, loglevel, loglevel_text, trim(message) as message, aborted
FROM svl_stored_proc_messages
WHERE loglevel_text = 'EXCEPTION' AND query = 193 ORDER BY recordtime;

query |          recordtime          | loglevel | loglevel_text |          message
      |          | aborted
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
    193 | 2020-03-17 23:57:18.277987 |      60 | EXCEPTION     | EXCEPTION level:
Exception Handling |          |      1

```

The following SQL statements show how to use SVL_STORED_PROC_MESSAGES to review raised messages with the SET option when creating a stored procedure. Because test_proc() has a minimum log level of NOTICE, only NOTICE, WARNING, and EXCEPTION level messages are logged in SVL_STORED_PROC_MESSAGES.

```

-- Create a stored procedure with minimum log level of NOTICE
CREATE OR REPLACE PROCEDURE test_proc() AS
$$
BEGIN

```

```

RAISE LOG 'Raise LOG messages';
RAISE INFO 'Raise INFO messages';
RAISE NOTICE 'Raise NOTICE messages';
RAISE WARNING 'Raise WARNING messages';
RAISE EXCEPTION 'Raise EXCEPTION messages';
RAISE WARNING 'Raise WARNING messages again'; -- not reachable
END;
$$ LANGUAGE plpgsql SET stored_proc_log_min_messages = NOTICE;

-- Call this stored procedure
CALL test_proc();

-- Show the raised messages
SELECT query, recordtime, loglevel_text, trim(message) as message, aborted FROM
svl_stored_proc_messages
WHERE query = 149 ORDER BY recordtime;

```

query	recordtime	loglevel_text	message	aborted
149	2020-03-16 21:51:54.847627	NOTICE	Raise NOTICE messages	1
149	2020-03-16 21:51:54.84766	WARNING	Raise WARNING messages	1
149	2020-03-16 21:51:54.847668	EXCEPTION	Raise EXCEPTION messages	1

(3 rows)

SVL_TERMINATE

Records the time when a user cancels or terminates a process.

`SELECT PG_TERMINATE_BACKEND(pid)`, `SELECT PG_CANCEL_BACKEND(pid)`, and `CANCEL pid` creates a log entry in SVL_TERMINATE.

SVL_TERMINATE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_QUERY_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
pid	integer	The process ID of the canceled or terminated process.
eventtime	timestamp	The time when the process is canceled or terminated.
userid	integer	The user ID of the user running the command.
type	string	The type of termination. It can be CANCEL or TERMINATE.

The following command shows the latest cancelled query.

```
select * from svl_terminate order by eventtime desc limit 1;
 pid |          eventtime          | userid | type
-----+-----+-----+-----
 8324 | 2020-03-24 09:42:07.298937 |      1 | CANCEL
(1 row)
```

SVL_UDF_LOG

Records system-defined error and warning messages generating during user-defined function (UDF) execution.

SVL_UDF_LOG is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_UDF_LOG](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
query	bigint	The query ID. You can use this ID to join various other system tables and views.
message	char(4096)	The message generated by the function.
created	timestamp	The time that the log was created.
traceback	char(4096)	If available, this value provides a stack traceback for the UDF. For more information, see traceback in the Python Standard Library.
funcname	character(256)	The name of the UDF that is executing.
node	integer	The node where the message was generated.
slice	integer	The slice where the message was generated.
seq	integer	The sequence of the message on the slice.

Sample queries

The following example shows how UDFs handle system-defined errors. The first block shows the definition for a UDF function that returns the inverse of an argument. When you run the function and provide a 0 argument, as the second block shows, the function returns an error. The third statement reads the error message that is logged in SVL_UDF_LOG

```
-- Create a function to find the inverse of a number

CREATE OR REPLACE FUNCTION f_udf_inv(a int)
  RETURNS float IMMUTABLE
AS $$
  return 1/a
$$ LANGUAGE plpythonu;

-- Run the function with a 0 argument to create an error
Select f_udf_inv(0) from sales;

-- Query SVL_UDF_LOG to view the message

Select query, created, message::varchar
from svl_udf_log;

query |          created          | message
-----+-----
+-----+-----
  2211 | 2015-08-22 00:11:12.04819 | ZeroDivisionError: long division or modulo by
zero\nNone
```

The following example adds logging and a warning message to the UDF so that a divide by zero operation results in a warning message instead of stopping with an error message.

```
-- Create a function to find the inverse of a number and log a warning

CREATE OR REPLACE FUNCTION f_udf_inv_log(a int)
  RETURNS float IMMUTABLE
AS $$
  import logging
  logger = logging.getLogger() #get root logger
  if a==0:
    logger.warning('You attempted to divide by zero.\nReturning zero instead of error.
\n')
    return 0
  else:
    return 1/a
$$ LANGUAGE plpythonu;
```

The following example runs the function, then queries SVL_UDF_LOG to view the message.

```
-- Run the function with a 0 argument to trigger the warning
Select f_udf_inv_log(0) from sales;

-- Query SVL_UDF_LOG to view the message

Select query, created, message::varchar
from svl_udf_log;

query |          created          | message
-----+-----+-----
      0 | 2015-08-22 00:11:12.04819 | You attempted to divide by zero.
                                           Returning zero instead of error.
```

SVL_USER_INFO

You can retrieve data about Amazon Redshift database users with the SVL_USER_INFO view.

SVL_USER_INFO is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
username	text	The user name for the role.
usesysid	integer	The user ID for the user.
usecreate db	boolean	A value that indicates whether the user has permissions to create databases.
usesuper	boolean	A value that indicates whether the user is a superuser.
usecatupd	boolean	A value that indicates whether the user can update system catalogs.
useconnlimit	text	The number of connections that the user can open.

Column name	Data type	Description
syslogaccess	text	A value that indicates whether the user has access to the system logs. The two possible values are RESTRICTED and UNRESTRICTED . RESTRICTED means that users that are not superusers can see their own records. UNRESTRICTED means that user that are not superusers can see all records in the system views and tables to which they have SELECT privileges.
last_ddl_ts	timestamp	The timestamp for the last data definition language (DDL) create statement run by the user.
sessiontimeout	integer	The maximum time in seconds that a session remains inactive or idle before timing out. 0 indicates that no timeout is set. For information about the cluster's idle or inactive timeout setting, see Quotas and limits in Amazon Redshift in the <i>Amazon Redshift Management Guide</i> .
external_id	text	Unique identifier of the user in the third-party identity provider.

Sample queries

The following command retrieves user information from SVL_USER_INFO.

```
SELECT * FROM SVL_USER_INFO;
```

SVL_VACUUM_PERCENTAGE

The SVL_VACUUM_PERCENTAGE view reports the percentage of data blocks allocated to a table after performing a vacuum. This percentage number shows how much disk space was reclaimed. See the [VACUUM](#) command for more information about the vacuum utility.

SVL_VACUUM_PERCENTAGE is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Some or all of the data in this table can also be found in the SYS monitoring view [SYS_VACUUM_HISTORY](#). The data in the SYS monitoring view is formatted to be easier to use and understand. We recommend that you use the SYS monitoring view for your queries.

Table columns

Column name	Data type	Description
xid	bigint	Transaction ID for the vacuum statement.
table_id	integer	Table ID for the vacuumed table.
percentage	bigint	Percentage of data blocks after a vacuum (relative to the number of blocks in the table before the vacuum was run).

Sample query

The following query displays the percentage for a specific operation on table 100238:

```
select * from svl_vacuum_percentage
where table_id=100238 and xid=2200;
```

```
xid | table_id | percentage
-----+-----+-----
1337 | 100238 | 60
(1 row)
```

After this vacuum operation, the table contained 60 percent of the original blocks.

System catalog tables

Topics

- [PG_ATTRIBUTE_INFO](#)
- [PG_CLASS_INFO](#)
- [PG_DATABASE_INFO](#)
- [PG_DEFAULT_ACL](#)
- [PG_EXTERNAL_SCHEMA](#)
- [PG_LIBRARY](#)
- [PG_PROC_INFO](#)

- [PG_STATISTIC_INDICATOR](#)
- [PG_TABLE_DEF](#)
- [PG_USER_INFO](#)
- [Querying the catalog tables](#)

The system catalogs store schema metadata, such as information about tables and columns. System catalog tables have a PG prefix.

The standard PostgreSQL catalog tables are accessible to Amazon Redshift users. For more information about PostgreSQL system catalogs, see [PostgreSQL system tables](#)

PG_ATTRIBUTE_INFO

PG_ATTRIBUTE_INFO is an Amazon Redshift system view built on the PostgreSQL catalog table PG_ATTRIBUTE and the internal catalog table PG_ATTRIBUTE_ACL. PG_ATTRIBUTE_INFO includes details about columns of a table or view, including column access control lists, if any.

Table columns

PG_ATTRIBUTE_INFO shows the following column in addition to the columns in PG_ATTRIBUTE.

Column name	Data type	Description
attacl	aclitem[]	The column-level access privileges, if any, that have been granted specifically on this column.

PG_CLASS_INFO

PG_CLASS_INFO is an Amazon Redshift system view built on the PostgreSQL catalog tables PG_CLASS and PG_CLASS_EXTENDED. PG_CLASS_INFO includes details about table creation time and the current distribution style. For more information, see [Data distribution for query optimization](#).

PG_CLASS_INFO is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

PG_CLASS_INFO shows the following columns in addition to the columns in PG_CLASS. The oid column in PG_CLASS is called relid in the PG_CLASS_INFO table.

Column name	Data type	Description
relcreation_time	timestamp	Time in UTC that the table was created.
releffectivediststyle	integer	The distribution style of a table or, if the table uses automatic distribution, the current distribution style assigned by Amazon Redshift.

The RELEFFECTIVEDISTSTYLE column in PG_CLASS_INFO indicates the current distribution style for the table. If the table uses automatic distribution, RELEFFECTIVEDISTSTYLE is 10, 11, or 12, which indicates whether the effective distribution style is AUTO (ALL), AUTO (EVEN), or AUTO (KEY). If the table uses automatic distribution, the distribution style might initially show AUTO (ALL), then change to AUTO (EVEN) when the table grows or AUTO (KEY) if a column is found to be useful as a distribution key.

The following table gives the distribution style for each value in RELEFFECTIVEDISTSTYLE column:

RELEFFECTIVEDISTSTYLE	Current distribution style
0	EVEN
1	KEY
8	ALL
10	AUTO (ALL)
11	AUTO (EVEN)
12	AUTO (KEY)

Example

The following query returns the current distribution style of tables in the catalog.

```
select relid as tableid,trim(nspname) as schemaname,trim(relname) as
  tablename,reldiststyle,relaffectivediststyle,
CASE WHEN "reldiststyle" = 0 THEN 'EVEN'::text
  WHEN "reldiststyle" = 1 THEN 'KEY'::text
  WHEN "reldiststyle" = 8 THEN 'ALL'::text
  WHEN "relaffectivediststyle" = 10 THEN 'AUTO(ALL)'::text
  WHEN "relaffectivediststyle" = 11 THEN 'AUTO(EVEN)'::text
  WHEN "relaffectivediststyle" = 12 THEN 'AUTO(KEY)'::text ELSE '<<UNKNOWN>>'::text
END as diststyle,relcreationtime
from pg_class_info a left join pg_namespace b on a.relnamespace=b.oid;
```

```
tableid | schemaname | tablename | reldiststyle | relaffectivediststyle | diststyle |
relcreationtime
-----+-----+-----+-----+-----+-----+
+-----+
3638033 | public    | customer |      0 |          0 | EVEN      |
2019-06-13 15:02:50.666718
3638037 | public    | sales    |      1 |          1 | KEY       |

(6 rows)
```

PG_DATABASE_INFO

PG_DATABASE_INFO is an Amazon Redshift system view that extends the PostgreSQL catalog table PG_DATABASE.

PG_DATABASE_INFO is visible to all users.

Table columns

PG_DATABASE_INFO contains the following columns in addition to columns in PG_DATABASE. The oid column in PG_DATABASE is called datid in the PG_DATABASE_INFO table. For more information, see the [PostgreSQL documentation](#).

Column name	Data type	Description
datid	oid	The object identifier (OID) used internally by system tables.
datconnlimit	text	The maximum number of concurrent connections that can be made to this database. A value of -1 means no limit.

PG_DEFAULT_ACL

Stores information about default access privileges. For more information on default access privileges, see [ALTER DEFAULT PRIVILEGES](#).

PG_DEFAULT_ACL is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
defacluser	integer	ID of the user to which the listed privileges are applied.
defaclnamespace	oid	The object ID of the schema where default privileges are applied. The default value is 0 if no schema is specified.
defaclobjtype	character	The type of object to which default privileges are applied. Valid values are as follows: <ul style="list-style-type: none"> r–relation (table or view)

Column name	Data type	Description
		<ul style="list-style-type: none">• f–function• p–stored procedure

Column name	Data type	Description
defaclacl	aclitem[]	<p>A string that defines the default privileges for the specified user or user group and object type.</p> <p>If the privileges are granted to a user, the string is in the following form:</p> <pre>{ username=privilegestring/grantor }</pre> <p><i>username</i></p> <p>The name of the user to which privileges are granted. If <i>username</i> is omitted, the privileges are granted to PUBLIC.</p> <p>If the privileges are granted to a user group, the string is in the following form:</p> <pre>{ "group groupname=privilegestring/grantor" }</pre> <p><i>privilegestring</i></p> <p>A string that specifies which privileges are granted.</p> <p>Valid values are:</p> <ul style="list-style-type: none"> • r–SELECT (read) • a–INSERT (append) • w–UPDATE (write) • d–DELETE • x–Grants the privilege to create a foreign key constraint (REFERENCES). • X–EXECUTE • *–Indicates that the user receiving the preceding privilege can in turn grant the same privilege to others (WITH GRANT OPTION).

Column name	Data type	Description
		<p><i>grantor</i></p> <p>The name of the user that granted the privileges.</p> <p>The following example indicates that the user <code>admin</code> granted all privileges, including <code>WITH GRANT OPTION</code>, to the user <code>dbuser</code>.</p> <pre>dbuser=r*a*w*d*x*x*/admin</pre>

Example

The following query returns all default privileges defined for the database.

```
select pg_get_userbyid(d.defacluser) as user,
n.nspname as schema,
case d.defaclobjtype when 'r' then 'tables' when 'f' then 'functions' end
as object_type,
array_to_string(d.defaclacl, ' + ') as default_privileges
from pg_catalog.pg_default_acl d
left join pg_catalog.pg_namespace n on n.oid = d.defaclnamespace;
```

user	schema	object_type	default_privileges
admin	tickit	tables	user1=r/admin + "group group1=a/admin" + user2=w/admin

The result in the preceding example shows that for all new tables created by user `admin` in the `tickit` schema, `admin` grants `SELECT` privileges to `user1`, `INSERT` privileges to `group1`, and `UPDATE` privileges to `user2`.

PG_EXTERNAL_SCHEMA

Stores information about external schemas.

`PG_EXTERNAL_SCHEMA` is visible to all users. Superusers can see all rows; regular users can see only metadata to which they have access. For more information, see [CREATE EXTERNAL SCHEMA](#).

Table columns

Column name	Data type	Description
esoid	oid	External schema ID.
eskind	integer	Kind of external schema.
esdbname	text	External database name.
esoptions	text	External schema options.

Example

The following example shows details for external schemas.

```
select esoid, nspname as schemaname, nspowner, esdbname as external_db, esoptions
from pg_namespace a,pg_external_schema b where a.oid=b.esoid;
```

```
esoid | schemaname          | nspowner | external_db | esoptions
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
100134 | spectrum_schema    |      100 | spectrum_db | {"IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
100135 | spectrum           |      100 | spectrumdb  | {"IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
100149 | external           |      100 | external_db | {"IAM_ROLE":"arn:aws:iam::123456789012:role/mySpectrumRole"}
```

PG_LIBRARY

Stores information about user-defined libraries.

PG_LIBRARY is visible to all users. Superusers can see all rows; regular users can see only their own data. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
name	name	Library name.
language_oid	oid	Reserved for system use.
file_store_id	integer	Reserved for system use.
owner	integer	User ID of the library owner.

Example

The following example returns information for user-installed libraries.

```
select * from pg_library;
```

```
name          | language_oid | file_store_id | owner
-----+-----+-----+-----
f_urlparse   |          108254 |           2000 |    100
```

PG_PROC_INFO

PG_PROC_INFO is an Amazon Redshift system view built on the PostgreSQL catalog table PG_PROC and the internal catalog table PG_PROC_EXTENDED. PG_PROC_INFO includes details about stored procedures and functions, including information related to output arguments, if any.

Table columns

PG_PROC_INFO shows the following columns in addition to the columns in PG_PROC. The oid column in PG_PROC is called prooid in the PG_PROC_INFO table.

Column name	Data type	Description
prooid	oid	The object ID of the function or stored procedure.
prokind	"char"	A value that indicates the type of functions or stored procedures. This value is 'f' for regular functions, 'p' for stored procedures, and 'a' for aggregate functions.
proargmodes	"char"[]	An array with the modes of the procedure arguments, encoded as 'i' for IN arguments, 'o' for OUT arguments, and 'b' for INOUT arguments. If all the arguments are IN arguments, this field is NULL. Subscripts correspond to positions in the proallargtypes array.
proallargtypes	oid[]	An array with the data types of the procedure arguments. This array includes all types of arguments (including OUT and INOUT arguments). However, if all the arguments are IN arguments, this field is NULL. Subscripting is one-based. In contrast, proargtypes is subscripted from zero.

The field `proargnames` in `PG_PROC_INFO` contains the names of all types of arguments (including OUT and INOUT), if any.

PG_STATISTIC_INDICATOR

Stores information about the number of rows inserted or deleted since the last ANALYZE. The `PG_STATISTIC_INDICATOR` table is updated frequently following DML operations, so statistics are approximate.

`PG_STATISTIC_INDICATOR` is visible only to superusers. For more information, see [Visibility of data in system tables and views](#).

Table columns

Column name	Data type	Description
stairelid	oid	Table ID
stairows	float	Total number of rows in the table.
staiins	float	Number of rows inserted since the last ANALYZE.
staidels	float	Number of rows deleted or updated since the last ANALYZE.

Example

The following example returns information for table changes since the last ANALYZE.

```
select * from pg_statistic_indicator;
```

stairelid	stairows	staiins	staidels
108271	11	0	0
108275	365	0	0
108278	8798	0	0
108280	91865	0	100632
108267	89981	49990	9999
108269	808	606	374
108282	152220	76110	248566

PG_TABLE_DEF

Stores information about table columns.

PG_TABLE_DEF only returns information about tables that are visible to the user. If PG_TABLE_DEF does not return the expected results, verify that the [search_path](#) parameter is set correctly to include the relevant schemas.

You can use [SVV_TABLE_INFO](#) to view more comprehensive information about a table, including data distribution skew, key distribution skew, table size, and statistics.

Table columns

Column name	Data type	Description
schemaname	name	Schema name.
tablename	name	Table name.
column	name	Column name.
type	text	Datatype of column.
encoding	character(32)	Encoding of column.
distkey	boolean	True if this column is the distribution key for the table.
sortkey	integer	Order of the column in the sort key. If the table uses a compound sort key, then all columns that are part of the sort key have a positive value that indicates the position of the column in the sort key. If the table uses an interleaved sort key, then each column that is part of the sort key has a value that is alternately positive or negative, where the absolute value indicates the position of the column in the sort key. If 0, the column is not part of a sort key.
notnull	boolean	True if the column has a NOT NULL constraint.

Example

The following example shows the compound sort key columns for the `LINEORDER_COMPOUND` table.

```
select "column", type, encoding, distkey, sortkey, "notnull"
```

```

from pg_table_def
where tablename = 'lineorder_compound'
and sortkey <> 0;

```

column	type	encoding	distkey	sortkey	notnull
lo_orderkey	integer	delta32k	false	1	true
lo_custkey	integer	none	false	2	true
lo_partkey	integer	none	true	3	true
lo_suppkey	integer	delta32k	false	4	true
lo_orderdate	integer	delta	false	5	true

(5 rows)

The following example shows the interleaved sort key columns for the `LINEORDER_INTERLEAVED` table.

```

select "column", type, encoding, distkey, sortkey, "notnull"
from pg_table_def
where tablename = 'lineorder_interleaved'
and sortkey <> 0;

```

column	type	encoding	distkey	sortkey	notnull
lo_orderkey	integer	delta32k	false	-1	true
lo_custkey	integer	none	false	2	true
lo_partkey	integer	none	true	-3	true
lo_suppkey	integer	delta32k	false	4	true
lo_orderdate	integer	delta	false	-5	true

(5 rows)

`PG_TABLE_DEF` will only return information for tables in schemas that are included in the search path. For more information, see [search_path](#).

For example, suppose you create a new schema and a new table, then query `PG_TABLE_DEF`.

```

create schema demo;
create table demo.demotable (one int);
select * from pg_table_def where tablename = 'demotable';

```

schemaname	tablename	column	type	encoding	distkey	sortkey	notnull
------------	-----------	--------	------	----------	---------	---------	---------

The query returns no rows for the new table. Examine the setting for `search_path`.

```
show search_path;

 search_path
-----
 $user, public
(1 row)
```

Add the demo schema to the search path and run the query again.

```
set search_path to '$user', 'public', 'demo';

select * from pg_table_def where tablename = 'demotable';

schemaname| tablename | column | type   | encoding | distkey | sortkey | notnull
-----+-----+-----+-----+-----+-----+-----+-----
demo      | demotable | one    | integer | none     | f       |         | f
(1 row)
```

PG_USER_INFO

PG_USER_INFO is an Amazon Redshift system view that shows user information, such as user ID and password expiration time.

Only superusers can see PG_USER_INFO.

Table columns

PG_USER_INFO contains the following columns. For more information, see the [PostgreSQL documentation](#).

Column name	Data type	Description
username	name	The username.
usesysid	integer	The user ID.
usecreate db	boolean	True if the user can create databases.

Column name	Data type	Description
usesuper	boolean	True if the user is a superuser.
usecatupd	boolean	True if the user can update system catalogs.
passwd	text	The password.
valuntil	abstime	The password's expiration date and time.
useconfig	text[]	The session defaults for run-time variables.
useconlimit	text	The number of connections that the user can open.

Querying the catalog tables

Topics

- [Examples of catalog queries](#)

In general, you can join catalog tables and views (relations whose names begin with **PG_**) to Amazon Redshift tables and views.

The catalog tables use a number of data types that Amazon Redshift does not support. The following data types are supported when queries join catalog tables to Amazon Redshift tables:

- bool
- "char"
- float4
- int2
- int4
- int8
- name
- oid
- text

- `varchar`

If you write a join query that explicitly or implicitly references a column that has an unsupported data type, the query returns an error. The SQL functions that are used in some of the catalog tables are also unsupported, except for those used by the `PG_SETTINGS` and `PG_LOCKS` tables.

For example, the `PG_STATS` table cannot be queried in a join with an Amazon Redshift table because of unsupported functions.

The following catalog tables and views provide useful information that can be joined to information in Amazon Redshift tables. Some of these tables allow only partial access because of data type and function restrictions. When you query the partially accessible tables, select or reference their columns carefully.

The following tables are completely accessible and contain no unsupported types or functions:

- [pg_attribute](#)
- [pg_cast](#)
- [pg_depend](#)
- [pg_description](#)
- [pg_locks](#)
- [pg_opclass](#)

The following tables are partially accessible and contain some unsupported types, functions, and truncated text columns. Values in text columns are truncated to `varchar(256)` values.

- [pg_class](#)
- [pg_constraint](#)
- [pg_database](#)
- [pg_group](#)
- [pg_language](#)
- [pg_namespace](#)
- [pg_operator](#)
- [pg_proc](#)
- [pg_settings](#)

- [pg_statistic](#)
- [pg_tables](#)
- [pg_type](#)
- [pg_user](#)
- [pg_views](#)

The catalog tables that are not listed here are either inaccessible or unlikely to be useful to Amazon Redshift administrators. However, you can query any catalog table or view openly if your query does not involve a join to an Amazon Redshift table.

You can use the OID columns in the Postgres catalog tables as joining columns. For example, the join condition `pg_database.oid = stv_tbl_perm.db_id` matches the internal database object ID for each `PG_DATABASE` row with the visible `DB_ID` column in the `STV_TBL_PERM` table. The OID columns are internal primary keys that are not visible when you select from the table. The catalog views do not have OID columns.

Some Amazon Redshift functions must run only on the compute nodes. If a query references a user-created table, the SQL runs on the compute nodes.

A query that references only catalog tables (tables with a PG prefix, such as `PG_TABLE_DEF`) or that does not reference any tables, runs exclusively on the leader node.

If a query that uses a compute-node function doesn't reference a user-defined table or Amazon Redshift system table returns the following error.

```
[Amazon](500310) Invalid operation: One or more of the used functions must be applied on at least one user created table.
```

Examples of catalog queries

The following queries show a few of the ways in which you can query the catalog tables to get useful information about an Amazon Redshift database.

View table ID, database, schema, and table name

The following view definition joins the `STV_TBL_PERM` system table with the `PG_CLASS`, `PG_NAMESPACE`, and `PG_DATABASE` system catalog tables to return the table ID, database name, schema name, and table name.

```
create view tables_vw as
select distinct(stv_tbl_perm.id) table_id
,trim(pg_database.datname) db_name
,trim(pg_namespace.nspname) schema_name
,trim(pg_class.relname) table_name
from stv_tbl_perm
join pg_class on pg_class.oid = stv_tbl_perm.id
join pg_namespace on pg_namespace.oid = pg_class.relnamespace
join pg_database on pg_database.oid = stv_tbl_perm.db_id;
```

The following example returns the information for table ID 117855.

```
select * from tables_vw where table_id = 117855;
```

table_id	db_name	schema_name	table_name
117855	dev	public	customer

List the number of columns per Amazon Redshift table

The following query joins some catalog tables to find out how many columns each Amazon Redshift table contains. Amazon Redshift table names are stored in both PG_TABLES and STV_TBL_PERM; where possible, use PG_TABLES to return Amazon Redshift table names.

This query does not involve any Amazon Redshift tables.

```
select nspname, relname, max(attnum) as num_cols
from pg_attribute a, pg_namespace n, pg_class c
where n.oid = c.relnamespace and a.attrelid = c.oid
and c.relname not like '%pkey'
and n.nspname not like 'pg%'
and n.nspname not like 'information%'
group by 1, 2
order by 1, 2;
```

nspname	relname	num_cols
public	category	4
public	date	8
public	event	6
public	listing	8

```
public | sales      |      10
public | users       |      18
public | venue       |       5
(7 rows)
```

List the schemas and tables in a database

The following query joins STV_TBL_PERM to some PG tables to return a list of tables in the TICKIT database and their schema names (NSPNAME column). The query also returns the total number of rows in each table. (This query is helpful when multiple schemas in your system have the same table names.)

```
select datname, nspname, relname, sum(rows) as rows
from pg_class, pg_namespace, pg_database, stv_tbl_perm
where pg_namespace.oid = relnamespace
and pg_class.oid = stv_tbl_perm.id
and pg_database.oid = stv_tbl_perm.db_id
and datname = 'tickit'
group by datname, nspname, relname
order by datname, nspname, relname;
```

```
datname | nspname | relname | rows
-----+-----+-----+-----
tickit  | public  | category |    11
tickit  | public  | date     |   365
tickit  | public  | event    |  8798
tickit  | public  | listing  | 192497
tickit  | public  | sales    | 172456
tickit  | public  | users    | 49990
tickit  | public  | venue    |   202
(7 rows)
```

List table IDs, data types, column names, and table names

The following query lists some information about each user table and its columns: the table ID, the table name, its column names, and the data type of each column:

```
select distinct attrelid, rtrim(name), attname, typtype
from pg_attribute a, pg_type t, stv_tbl_perm p
where t.oid=a.atttypid and a.attrelid=p.id
and a.attrelid between 100100 and 110000
```

```
and typename not in('oid','xid','tid','cid')
order by a.attrelid asc, typename, attname;
```

```
attrelid | rtrim | attname | typename
-----+-----+-----+-----
  100133 | users | likebroadway | bool
  100133 | users | likeclassical | bool
  100133 | users | likeconcerts | bool
...
  100137 | venue | venuestate | bpchar
  100137 | venue | venueid | int2
  100137 | venue | venueseats | int4
  100137 | venue | venuecity | varchar
...
```

Count the number of data blocks for each column in a table

The following query joins the STV_BLOCKLIST table to PG_CLASS to return storage information for the columns in the SALES table.

```
select col, count(*)
from stv_blocklist s, pg_class p
where s.tbl=p.oid and relname='sales'
group by col
order by col;
```

```
col | count
----+-----
  0 |      4
  1 |      4
  2 |      4
  3 |      4
  4 |      4
  5 |      4
  6 |      4
  7 |      4
  8 |      4
  9 |      8
 10 |      4
 12 |      4
 13 |      8
(13 rows)
```

Modifying the server configuration

You can change the server configuration in the following ways:

- By using a [SET](#) command to override a setting for the duration of the current session only.

For example:

```
set extra_float_digits to 2;
```

- By modifying the parameter group settings for the cluster. The parameter group settings include additional parameters that you can configure. For more information, see [Amazon Redshift Parameter Groups](#) in the *Amazon Redshift Management Guide*.
- By using the [ALTER USER](#) command to set a configuration parameter to a new value for all sessions run by the specified user.

```
ALTER USER username SET parameter { TO | = } { value | DEFAULT }
```

Use the `SHOW` command to view the current parameter settings. Use `SHOW ALL` to view all the settings that you can configure by using the [SET](#) command.

```
SHOW ALL;
```

```
name                | setting
-----+-----
analyze_threshold_percent | 10
datestyle            | ISO, MDY
```

<code>extra_float_digits</code>		2
<code>query_group</code>		default
<code>search_path</code>		<code>\$user, public</code>
<code>statement_timeout</code>		0
<code>timezone</code>		UTC
<code>wlm_query_slot_count</code>		1

Note

Note that configuration parameters are applied to the database you are connected to in your data warehouse.

`analyze_threshold_percent`

Values (default in bold)

10, 0 to 100.0

Description

Sets the threshold for percentage of rows changed for analyzing a table. To reduce processing time and improve overall system performance, Amazon Redshift skips ANALYZE for any table that has a lower percentage of changed rows than specified by `analyze_threshold_percent`. For example, if a table contains 100,000,000 rows and 9,000,000 rows have changed since the last ANALYZE, then by default the table is skipped because fewer than 10 percent of the rows have changed. To analyze tables when only a small number of rows have changed, set `analyze_threshold_percent` to an arbitrarily small number. For example, if you set `analyze_threshold_percent` to 0.01, then a table with 100,000,000 rows will not be skipped if at least 10,000 rows have changed. To analyze all tables even if no rows have changed, set `analyze_threshold_percent` to 0.

You can modify the `analyze_threshold_percent` parameter for the current session only by using a SET command. The parameter can't be modified in a parameter group.

Example

```
set analyze_threshold_percent to 15;
```

```
set analyze_threshold_percent to 0.01;  
set analyze_threshold_percent to 0;
```

cast_super_null_on_error

Values (default in bold)

on, off

Description

Specifies that when you try to access a nonexistent member of an object or element of an array, Amazon Redshift returns a NULL value if your query is run in the default lax mode.

datashare_break_glass_session_var

Values (default in bold)

There is no default. The value can be any character string generated by Amazon Redshift when an operation occurs that isn't recommended, as described following.

Description

Applies a permission that allows certain operations that generally aren't recommended for an AWS Data Exchange datashare.

In general, we recommend that you don't drop or alter an AWS Data Exchange datashare using the DROP DATASHARE or ALTER DATASHARE SET PUBLICACCESSIBLE statement. To allow dropping or altering an AWS Data Exchange datashare to turn off the publicly accessible setting, set the datashare_break_glass_session_var variable to a one-time value. This one-time value is generated by Amazon Redshift and provided in an error message after the initial attempt at the operation in question.

After setting the variable to the one-time generated value, run the DROP DATASHARE or ALTER DATASHARE statement again.

For more information, see [ALTER DATASHARE usage notes](#) or [DROP DATASHARE usage notes](#).

Example

```
set datashare_break_glass_session_var to '620c871f890c49';
```

datestyle

Values (default in bold)

Format specification (**ISO**, Postgres, SQL, or German), and year/month/day ordering (**DMY**, **MDY**, **YMD**).

- ISO – uses the datestyle of YYYY-MM-DD HH:MM:SS.
- Postgres – uses the datestyle of MM-DD HH:MM:SS YYYY.
- SQL – uses the datestyle of MM-DD-YYYY HH:MM:SS.
- German – uses the datestyle of DD-MM-YYYY HH:MM:SS.

Description

Sets the display format for date and time values and also the rules for interpreting ambiguous date input values. The string contains two parameters that you can change separately or together.

Example

```
show datestyle;
DateStyle
-----
ISO, MDY
(1 row)

set datestyle to 'SQL,DMY';
```

default_geometry_encoding

Values (default in bold)

1, 2

Description

A session configuration that specifies if spatial geometries created during this session are encoded with a bounding box. If `default_geometry_encoding` is 1, then geometries are not encoded with a bounding box. If `default_geometry_encoding` is 2, then geometries are encoded with a bounding box. For more information about support for bounding boxes, see [Bounding box](#).

`describe_field_name_in_uppercase`

Values (default in bold)

off (false), on (true)

Description

Specifies whether column names returned by SELECT statements are uppercase or lowercase. If this parameter is on, column names are returned in uppercase. If this parameter is off, column names are returned in lowercase. Amazon Redshift stores column names in lowercase regardless of the setting for `describe_field_name_in_uppercase`.

Example

```
set describe_field_name_in_uppercase to on;

show describe_field_name_in_uppercase;

DESCRIBE_FIELD_NAME_IN_UPPERCASE
-----
on
```

`downcase_delimited_identifier`

Values (default in bold)

on, off

Description

This configuration is being retired. Instead use `enable_case_sensitive_identifier`.

Enables the super parser to read JSON fields that are in uppercase or mixed case. Also enables federated query support to supported PostgreSQL databases with mixed-case names of database, schema, table, and column. To use case-sensitive identifiers, set this parameter to off.

Usage Notes

- If you're using row-level security or dynamic data masking features, we recommend setting the `downcase_delimited_identifier` value in your cluster or workgroup's parameter group. This ensures that `downcase_delimited_identifier` stays constant throughout creating and attaching a policy, and then querying a relation that has a policy applied. For information on row-level security, see [Row-level security](#). For information on dynamic data masking, see [Dynamic data masking](#).
- When you set `downcase_delimited_identifier` to off and create a table, you can set case sensitive column names. When you set `downcase_delimited_identifier` to on and query the table, the column names are downcased. This can produce query results different from when `downcase_delimited_identifier` is set to off. Consider the following example:

```
SET downcase_delimited_identifier TO off;
--Amazon Redshift preserves case for column names and other identifiers.

--Create a table with two columns that are identical except for the case.
CREATE TABLE t ("c" int, "C" int);

INSERT INTO t VALUES (1, 2);

SELECT * FROM t;

 c | C
---+---
 1 | 2
(1 row)

SET enable_downcase_delimited_identifier TO on;
--Amazon Redshift no longer preserves case for column names and other identifiers.

SELECT * FROM t;

 c | c
---+---
 1 | 1
```

(1 row)

- We recommend that regular users querying tables with dynamic data masking or row-level security policies attached have the default `lowercase_delimited_identifier` setting. For more information, see [For information on row-level security](#), see [Row-level security](#). For information on dynamic data masking, see [Dynamic data masking](#).

enable_case_sensitive_identifier

Values (default in bold)

true, **false**

Description

A configuration value that determines whether name identifiers of databases, tables, and columns are case sensitive. The case of name identifiers is preserved when enclosed within double quotation marks. When you set `enable_case_sensitive_identifier` to true, the case of name identifiers is preserved. When you set `enable_case_sensitive_identifier` to false, the case of name identifiers is not preserved.

The case of a *username* enclosed in double quotation marks is always preserved regardless of the setting of the `enable_case_sensitive_identifier` configuration option.

Examples

The following example shows how to create and use case sensitive identifiers for a table and column name.

```
-- To create and use case sensitive identifiers
SET enable_case_sensitive_identifier TO true;

-- Create tables and columns with case sensitive identifiers
CREATE TABLE "MixedCasedTable" ("MixedCasedColumn" int);

CREATE TABLE MixedCasedTable (MixedCasedColumn int);

-- Now query with case sensitive identifiers
SELECT "MixedCasedColumn" FROM "MixedCasedTable";
```

```

MixedCasedColumn
-----
(0 rows)

SELECT MixedCasedColumn FROM MixedCasedTable;

mixedcasedcolumn
-----
(0 rows)

```

The following example shows when the case of identifiers is not preserved.

```

-- To not use case sensitive identifiers
RESET enable_case_sensitive_identifier;

-- Mixed case identifiers are lowercased
CREATE TABLE "MixedCasedTable2" ("MixedCasedColumn" int);

CREATE TABLE MixedCasedTable2 (MixedCasedColumn int);

ERROR: Relation "mixedcasedtable2" already exists

SELECT "MixedCasedColumn" FROM "MixedCasedTable2";

mixedcasedcolumn
-----
(0 rows)

SELECT MixedCasedColumn FROM MixedCasedTable2;

mixedcasedcolumn
-----
(0 rows)

```

Usage Notes

- If you're using autorefresh for materialized views, we recommend setting the `enable_case_sensitive_identifier` value in your cluster or workgroup's parameter group. This ensures that `enable_case_sensitive_identifier` stays constant when your

materialized views are refreshed. For information on autorefresh for materialized views, see [Refreshing a materialized view](#). For information on setting configuration values in parameter groups, see [Amazon Redshift parameter groups](#) in the *Amazon Redshift Management Guide*.

- If you're using row-level security or dynamic data masking features, we recommend setting the `enable_case_sensitive_identifier` value in your cluster or workgroup's parameter group. This ensures that `enable_case_sensitive_identifier` stays constant throughout creating and attaching a policy, and then querying a relation that has a policy applied. For information on row-level security, see [Row-level security](#). For information on dynamic data masking, see [Dynamic data masking](#).
- When you set `enable_case_sensitive_identifier` to on and create a table, you can set case sensitive column names. When you set `enable_case_sensitive_identifier` to off and query the table, the column names are downcased. This can produce query results different from when `enable_case_sensitive_identifier` is set to on. Consider the following example:

```
SET enable_case_sensitive_identifier TO on;
--Amazon Redshift preserves case for column names and other identifiers.

--Create a table with two columns that are identical except for the case.
CREATE TABLE t ("c" int, "C" int);

INSERT INTO t VALUES (1, 2);

SELECT * FROM t;

 c | C
---+---
 1 | 2
(1 row)

SET enable_case_sensitive_identifier TO off;
--Amazon Redshift no longer preserves case for column names and other identifiers.

SELECT * FROM t;

 c | c
---+---
 1 | 1
(1 row)
```

- We recommend that regular users querying tables with dynamic data masking or row-level security policies attached have the default `enable_case_sensitive_identifier` setting. For information on row-level security, see [Row-level security](#). For information on dynamic data masking, see [Dynamic data masking](#).

`enable_case_sensitive_super_attribute`

Values (default in bold)

true, **false**

Description

A configuration value that determines whether navigating SUPER data type structures with non-delimited attribute names is case sensitive. When you set `enable_case_sensitive_super_attribute` to true, navigating SUPER type structures with non-delimited attribute names is case sensitive. When you set the value to false, navigating SUPER type structures with non-delimited attribute names is not case sensitive.

When you enclose an attribute name in double quotation marks and set `enable_case_sensitive_identifier` to true, case is always preserved, regardless of the setting of the `enable_case_sensitive_super_attribute` configuration option.

`enable_case_sensitive_super_attribute` only applies to columns with the SUPER data type. For all other columns, consider using `enable_case_sensitive_identifier` instead.

For more information on the SUPER data type, see [SUPER type](#) and [Semistructured data in Amazon Redshift](#).

Examples

The following example shows the results of selecting SUPER values with `enable_case_sensitive_super_attribute` enabled and with it disabled.

```
--Create a table with a SUPER column.  
CREATE TABLE tbl (col SUPER);  
  
--Insert values.  
INSERT INTO tbl VALUES (json_parse('{
```

```
"A": "A", "a": "a"
}')));

SET enable_case_sensitive_super_attribute TO ON;

SELECT col.A FROM tbl;
  a
-----
 "A"
(1 row)

SELECT col.a FROM tbl;
  a
-----
 "a"
(1 row)

SET enable_case_sensitive_super_attribute TO OFF;

SELECT col.A FROM tbl;
  a
-----
 "a"
(1 row)

SELECT col.a FROM tbl;
  a
-----
 "a"
(1 row)
```

Usage Notes

- Views and materialized views follow the value of `enable_case_sensitive_super_attribute` at the time of their creation. Late-binding views, stored procedures, and user-defined functions follow the value of `enable_case_sensitive_super_attribute` at the time of querying.
- If you're using autorefresh for materialized views, we recommend setting the `enable_case_sensitive_identifier` value in your cluster or workgroup's parameter group. This ensures that `enable_case_sensitive_identifier` stays constant when your materialized views are refreshed. For information on autorefresh for materialized views, see

[Refreshing a materialized view](#). For information on setting configuration values in parameter groups, see [Amazon Redshift parameter groups](#) in the *Amazon Redshift Management Guide*.

- The column name in statement results is always downcased, regardless of the value of `enable_case_sensitive_super_attribute`. To make the column name case sensitive as well, enable `enable_case_sensitive_identifier`.
- We recommend that regular users querying tables with row-level security policies attached have the default `enable_case_sensitive_identifier` setting. For more information, see For information on row-level security, see [Row-level security](#).

enable_numeric_rounding

Values (default in bold)

on (true), **off (false)**

Description

Specifies whether to use numeric rounding. If `enable_numeric_rounding` is on, Amazon Redshift rounds NUMERIC values when casting them to other numeric types, such as INTEGER or DECIMAL. If `enable_numeric_rounding` is off, Amazon Redshift truncates NUMERIC values when casting them to other numeric types. For more information on numeric types, see [Numeric types](#).

Example

```
--Create a table and insert the numeric value 1.5 into it.
CREATE TABLE t (a numeric(10, 2));

INSERT INTO t VALUES (1.5);

SET enable_numeric_rounding to ON;
--Amazon Redshift now rounds NUMERIC values when casting to other numeric types.

SELECT a::int FROM t;

 a
---
 2
(1 row)
```

```
SELECT a::decimal(10, 0) FROM t;
```

```
 a
---
 2
(1 row)
```

```
SELECT a::decimal(10, 5) FROM t;
```

```
  a
-----
1.50000
(1 row)
```

```
SET enable_numeric_rounding to OFF;
```

```
--Amazon Redshift now truncates NUMERIC values when casting to other numeric types.
```

```
SELECT a::int FROM t;
```

```
 a
---
 1
(1 row)
```

```
SELECT a::decimal(10, 0) FROM t;
```

```
 a
---
 1
(1 row)
```

```
SELECT a::decimal(10, 5) FROM t;
```

```
  a
-----
1.50000
(1 row)
```

enable_result_cache_for_session

Values (default in bold)

on (true), off (false)

Description

Specifies whether to use query results caching. If `enable_result_cache_for_session` is on, Amazon Redshift checks for a valid, cached copy of the query results when a query is submitted. If a match is found in the result cache, Amazon Redshift uses the cached results and doesn't run the query. If `enable_result_cache_for_session` is off, Amazon Redshift ignores the results cache and runs all queries when they are submitted.

Example

```
SET enable_result_cache_for_session TO off;  
--Amazon Redshift now ignores the results cache
```

enable_vacuum_boost

Values (default in bold)

false, true

Description

Specifies whether to enable the vacuum boost option for all VACUUM commands run in a session. If `enable_vacuum_boost` is true, Amazon Redshift runs all VACUUM commands in the session with the BOOST option. If `enable_vacuum_boost` is false, Amazon Redshift doesn't run with the BOOST option by default. For more information about the BOOST option, see [VACUUM](#).

error_on_nondeterministic_update

Values (default in bold)

false, true

Description

Specifies whether UPDATE queries with multiple matches per row return an error.

Example

```
SET error_on_nondeterministic_update TO true;

CREATE TABLE t1(x1 int, y1 int);

CREATE TABLE t2(x2 int, y2 int);

INSERT INTO t1 VALUES (1,10), (2,20), (3,30);

INSERT INTO t2 VALUES (2,40), (2,50);

UPDATE t1 SET y1=y2 FROM t2 WHERE x1=x2;

ERROR: Found multiple matches to update the same tuple.
```

extra_float_digits

Values (default in bold)

0, -15 to 2

Description

Sets the number of digits displayed for floating-point values, including float4 and float8. The value is added to the standard number of digits (FLT_DIG or DBL_DIG as appropriate). The value can be set as high as 2, to include partially significant digits. This is especially useful for outputting float data that must be restored exactly. Or it can be set negative to suppress unwanted digits.

Example

The following example sets `extra_float_digits` to -2. First, show the current parameter setting.

```
show all;
  name                | setting
-----+-----
```

```
analyze_threshold_percent | 10
datestyle                 | ISO, MDY
extra_float_digits       | 2
query_group              | default
search_path               | $user, public
statement_timeout        | 0
timezone                 | UTC
wlm_query_slot_count     | 1
```

Then, set the new value to -2.

```
set extra_float_digits to -2;
```

Finally show the updated parameter setting.

```
show all;
  name                | setting
-----+-----
analyze_threshold_percent | 10
datestyle             | ISO, MDY
extra_float_digits    | -2
query_group           | default
search_path           | $user, public
statement_timeout     | 0
timezone              | UTC
wlm_query_slot_count  | 1
```

interval_forbid_composite_literals

Values (default in bold)

false, **true**

Description

A session configuration that modifies the value of an interval that contain both YEAR TO MONTH and DAY TO SECOND parts.

If `interval_forbid_composite_literals` is `true`, an error is returned if an interval with both YEAR TO MONTH and DAY TO SECOND parts is encountered. For example, the following SQL contains an INTERVAL DAY TO SECOND with both YEAR TO MONTH and DAY TO SECOND parts.

```
SELECT INTERVAL '1 year 1 day' DAY TO SECOND;
ERROR: Interval Day To Second literal cannot contain year-month parts. Disable the GUC
interval_forbid_composite_literals to suppress this error and silently discard the
year-month part.
```

If `interval_forbid_composite_literals` is false, Amazon Redshift suppresses an error and truncates the YEAR TO MONTH part from an INTERVAL DAY TO SECOND value. For example, the following SQL contains an INTERVAL DAY TO SECOND with both YEAR TO MONTH and DAY TO SECOND parts.

```
SET interval_forbid_composite_literals to "false";
SELECT INTERVAL '1 year 1 day' DAY TO SECOND;
```

```
intervald2s
-----
1 days 0 hours 0 mins 0.0 secs
```

json_serialization_enable

Values (default in bold)

false, true

Description

A session configuration that modifies the JSON serialization behavior of ORC, JSON, Ion, and Parquet formatted data. If `json_serialization_enable` is true, all top-level collections are automatically serialized to JSON and returned as VARCHAR(65535). Noncomplex columns are not affected or serialized. Because collection columns are serialized as VARCHAR(65535), their nested subfields can no longer be accessed directly as part of the query syntax (that is, in the filter clause). If `json_serialization_enable` is false, top-level collections are not serialized to JSON. For more information about nested JSON serialization, see [Serializing complex nested JSON](#).

json_serialization_parse_nested_strings

Values (default in bold)

false, true

Description

A session configuration that modifies the JSON serialization behavior of ORC, JSON, Ion, and Parquet formatted data. When both `json_serialization_parse_nested_strings` and `json_serialization_enable` are true, string values that are stored in complex types (such as, maps, structures, or arrays) are parsed and written inline directly into the result if they are valid JSON. If `json_serialization_parse_nested_strings` is false, strings within nested complex types are serialized as escaped JSON strings. For more information, see [Serializing complex types containing JSON strings](#).

max_concurrency_scaling_clusters

Values (default in bold)

1, 0 to 10

Description

Sets the maximum number of concurrency scaling clusters allowed when concurrency scaling is enabled. Increase this value if more concurrency scaling is required. Decrease this value to reduce the usage of concurrency scaling clusters and the resulting billing charges.

The maximum number of concurrency scaling clusters is an adjustable quota. For more information, see [Amazon Redshift quotas](#) in the *Amazon Redshift Management Guide*.

max_cursor_result_set_size

Values (default in bold)

0 (defaults to maximum) - 14400000 MB

Description

The `max_cursor_result_set_size` parameter is no longer used. For more information about cursor result set size, see [Cursor constraints](#).

mv_enable_aqmv_for_session

Values (default in bold)

true, false

Description

Specifies whether Amazon Redshift can perform automatic query rewriting of materialized views at the session level.

navigate_super_null_on_error

Values (default in bold)

on, off

Description

Specifies that when you try to navigate a nonexistent member of an object or element of an array, Amazon Redshift returns a NULL value if your query is run in the default lax mode.

parse_super_null_on_error

Values (default in bold)

off, on

Description

Specifies that when Amazon Redshift tries to parse a nonexistent member of an object or element of an array, Amazon Redshift returns a NULL value if your query is run in the strict mode.

pg_federation_repeatable_read

Values (default in bold)

true, *false*

Description

Specifies the federated query transaction isolation level for the results from the PostgreSQL database.

- When `pg_federation_repeatable_read` is true, federated transactions are processed with REPEATABLE READ isolation level semantics. This is the default.
- When `pg_federation_repeatable_read` is false, federated transactions are processed with READ COMMITTED isolation level semantics.

For more information, see the following:

- [Considerations when accessing federated data with Amazon Redshift.](#)
- [Managing concurrent write operations.](#)

Examples

The following command sets `pg_federation_repeatable_read` to on for a session. The show command shows the value of the set value.

```
set pg_federation_repeatable_read to on;
```

```
show pg_federation_repeatable_read;
```

```
pg_federation_repeatable_read  
-----  
on
```

query_group

Values (default in bold)

No default; the value can be any character string.

Description

Applies a user-defined label to a group of queries that are run during the same session. This label is captured in the query logs. You can use it to constrain results from the `STL_QUERY` and `STV_INFLIGHT` tables and the `SVL_QLOG` view. For example, you can apply a separate label to every query that you run to uniquely identify queries without having to look up their IDs.

This parameter doesn't exist in the server configuration file and must be set at runtime with a `SET` command. Although you can use a long character string as a label, the label is truncated to 30 characters in the `LABEL` column of the `STL_QUERY` table and the `SVL_QLOG` view (and to 15 characters in `STV_INFLIGHT`).

In the following example, `query_group` is set to **Monday**, then several queries are run with that label.

```
set query_group to 'Monday';
SET
select * from category limit 1;
...
...
select query, pid, substring, elapsed, label
from svl_qlog where label = 'Monday'
order by query;
```

query	pid	substring	elapsed	label
789	6084	select * from category limit 1;	65468	Monday
790	6084	select query, trim(label) from ...	1260327	Monday
791	6084	select * from svl_qlog where ..	2293547	Monday
792	6084	select count(*) from bigsales;	108235617	Monday
...				

search_path

Values (default in bold)

'\$user', **public**, *schema_names*

A comma-separated list of existing schema names. If **'\$user'** is present, then the schema having the same name as `SESSION_USER` is substituted, otherwise it is ignored.

Description

Specifies the order in which schemas are searched when an object (such as a table or a function) is referenced by a simple name with no schema component:

- Search paths aren't supported with external schemas and external tables. External tables must be explicitly qualified by an external schema.
- When objects are created without a specific target schema, they are placed in the first schema listed in the search path. If the search path is empty, the system returns an error.
- When objects with identical names exist in different schemas, the one found first in the search path is used.
- An object that isn't in any of the schemas in the search path can only be referenced by specifying its containing schema with a qualified (dotted) name.
- The system catalog schema, `pg_catalog`, is always searched. If it is mentioned in the path, it is searched in the specified order. If not, it is searched before any of the path items.
- The current session's temporary-table schema, `pg_temp_nnn`, is always searched if it exists. It can be explicitly listed in the path by using the alias `pg_temp`. If it is not listed in the path, it is searched first (even before `pg_catalog`). However, the temporary schema is only searched for relation names (tables, views). It is not searched for function names.

Example

The following example creates the schema `ENTERPRISE` and sets the `search_path` to the new schema.

```
create schema enterprise;
set search_path to enterprise;
show search_path;

 search_path
-----
 enterprise
(1 row)
```

The following example adds the schema `ENTERPRISE` to the default `search_path`.

```
set search_path to '$user', public, enterprise;
```

```
show search_path;

          search_path
-----
"$user", public, enterprise
(1 row)
```

The following example adds the table FRONTIER to the schema ENTERPRISE.

```
create table enterprise.frontier (c1 int);
```

When the table PUBLIC.FRONTIER is created in the same database, and the user does not specify the schema name in a query, PUBLIC.FRONTIER takes precedence over ENTERPRISE.FRONTIER.

```
create table public.frontier(c1 int);
insert into enterprise.frontier values(1);
select * from frontier;

frontier
----
(0 rows)

select * from enterprise.frontier;

c1
----
1
(1 row)
```

spectrum_enable_pseudo_columns

Values (default in bold)

true, false

Description

You can disable the creation of pseudocolumns for a session by setting the `spectrum_enable_pseudo_columns` configuration parameter to false.

Example

The following command disables the creation of pseudocolumns for a session.

```
set spectrum_enable_pseudo_columns to false;
```

enable_spectrum_oid

Values (default in bold)

true, false

Description

You can also disable only the `$spectrum_oid` pseudocolumn by setting the `enable_spectrum_oid` configuration parameter to false.

Example

The following command disables the `$spectrum_oid` pseudocolumn by setting the `enable_spectrum_oid` configuration parameter to false.

```
set enable_spectrum_oid to false;
```

spectrum_query_maxerror

Values (default in bold)

-1, integer

Description

You can specify an integer to indicate the maximum number of errors to accept before canceling the query. A negative value turns off maximum error data handling. The results are logged in [SVL_SPECTRUM_SCAN_ERROR](#).

Example

The following example assumes ORC data that contains surplus characters and characters that are not valid. The column definition for `my_string` specifies a length of 3 characters. Following is the sample data for this example:

```
my_string
-----
abcdef
gh✦
ab
```

The following commands set the maximum number of errors to 1 and perform the query.

```
set spectrum_query_maxerror to 1;
SELECT my_string FROM orc_data;
```

The query stops and the results are logged in [SVL_SPECTRUM_SCAN_ERROR](#).

statement_timeout

Values (default in bold)

0 (turns off limitation), x milliseconds

Description

Stops any statement that takes over the specified number of milliseconds.

The `statement_timeout` value is the maximum amount of time a query can run before Amazon Redshift terminates it. This time includes planning, queueing in workload management (WLM), and execution time. Compare this time to WLM timeout (`max_execution_time`) and a QMR (`query_execution_time`), which include only execution time.

If WLM timeout (`max_execution_time`) is also specified as part of a WLM configuration, the lower of `statement_timeout` and `max_execution_time` is used. For more information, see [WLM timeout](#).

Example

Because the following query takes longer than 1 millisecond, it times out and is canceled.

```
set statement_timeout = 1;

select * from listing where listid>5000;
ERROR: Query (150) canceled on user's request
```

stored_proc_log_min_messages

Values (default in bold)

LOG, INFO, NOTICE, WARNING, EXCEPTION

Description

Specifies the minimum logging level of raised stored procedure messages. Messages at or above the specified level are logged. The default is **LOG** (all messages are logged). The order of log levels from highest to lowest is as follows:

1. EXCEPTION
2. WARNING
3. NOTICE
4. INFO
5. LOG

For example if you specify a value of NOTICE, then messages are only logged for NOTICE, WARNING, and EXCEPTION.

timezone

Values (default in bold)

UTC, time zone

Syntax

```
SET timezone { TO | = } [ time_zone | DEFAULT ]
```

```
SET time zone [ time_zone | DEFAULT ]
```

Description

Sets the time zone for the current session. The time zone can be the offset from Universal Coordinated Time (UTC) or a time zone name.

Note

You can't set the `timezone` configuration parameter by using a cluster parameter group. The time zone can be set only for the current session by using a SET command. To set the time zone for all sessions run by a specific database user, use the [ALTER USER](#) command. `ALTER USER ... SET TIMEZONE` changes the time zone for subsequent sessions, not for the current session.

When you set the time zone using the `SET timezone (one word)` command with either `T0` or `=`, you can specify *time_zone* as a time zone name, a POSIX-style format offset, or an ISO-8601 format offset, as shown following.

```
SET timezone { T0 | = } time_zone
```

When you set the time zone using the `SET time zone` command *without* `T0` or `=`, you can specify *time_zone* using an INTERVAL and also a time zone name, a POSIX-style format offset, or an ISO-8601 format offset, as shown following.

```
SET time zone time_zone
```

Time zone formats

Amazon Redshift supports the following time zone formats:

- Time zone name
- INTERVAL
- POSIX-style time zone specification
- ISO-8601 offset

Because time zone abbreviations, such as PST or PDT, are defined as a fixed offset from UTC and don't include daylight savings time rules, the SET command doesn't support time zone abbreviations.

For more details on time zone formats, see the following.

Time zone name – The full time zone name, such as America/New_York. Full time zone names can include daylight savings rules.

The following are examples of time zone names:

- Etc/Greenwich
- America/New_York
- CST6CDT
- GB

 **Note**

Many time zone names, such as EST, MST, NZ, and UCT, are also abbreviations.

To view a list of valid time zone names, run the following command.

```
select pg_timezone_names();
```

INTERVAL – An offset from UTC. For example, PST is –8:00 or –8 hours.

The following are examples of INTERVAL time zone offsets:

- –8:00
- –8 hours
- 30 minutes

POSIX-style format – A time zone specification in the form *STDOffset* or *STDOffsetDST*, where *STD* is a time zone abbreviation, *offset* is the numeric offset in hours west from UTC, and *DST* is an optional daylight-savings zone abbreviation. Daylight savings time is assumed to be one hour ahead of the given offset.

POSIX-style time zone formats use positive offsets west of Greenwich, in contrast to the ISO-8601 convention, which uses positive offsets east of Greenwich.

The following are examples of POSIX-style time zones:

- PST8
- PST8PDT
- EST5
- EST5EDT

Note

Amazon Redshift doesn't validate POSIX-style time zone specifications, so it is possible to set the time zone to an invalid value. For example, the following command doesn't return an error, even though it sets the time zone to an invalid value.

```
set timezone to 'xxx36';
```

ISO-8601 Offset – The offset from UTC in the form \pm [hh] : [mm].

The following are examples of ISO-8601 offsets:

- -8:00
- +7:30

Examples

The following example sets the time zone for the current session to New York.

```
set timezone = 'America/New_York';
```

The following example sets the time zone for the current session to UTC–8 (PST).

```
set timezone to '-8:00';
```

The following example uses INTERVAL to set the time zone to PST.

```
set timezone interval '-8 hours'
```

The following example resets the time zone for the current session to the system default time zone (UTC).

```
set timezone to default;
```

To set the time zone for database user, use an ALTER USER ... SET statement. The following example sets the time zone for dbuser to New York. The new value persists for the user for all subsequent sessions.

```
ALTER USER dbuser SET timezone to 'America/New_York';
```

use_fips_ssl

Values (default in bold)

true, **false**

Description

A parameter group value that specifies if FIPS-compliant SSL mode is used. If `use_fips_ssl` is `true`, then FIPS-compliant SSL mode is used. If `use_fips_ssl` is `false`, then FIPS-compliant SSL mode is not used. For more information, see [Configuring security options for connections](#) in the *Amazon Redshift Management Guide*.

To configure parameters for an Amazon Redshift provisioned cluster, see [About parameter groups](#) in the *Amazon Redshift Management Guide*. To configure parameters for Redshift Serverless, see [Configuring a FIPS-compliant SSL connection to Amazon Redshift Serverless](#) in the *Amazon Redshift Management Guide*, and [CreateWorkgroup](#) or [UpdateWorkgroup](#) in the *Redshift Serverless API Reference*.

wlm_query_slot_count

Values (default in bold)

1, 1 to 50 (cannot exceed number of available slots (concurrency level) for the service class)

Description

Sets the number of query slots that a query uses.

Workload management (WLM) reserves slots in a service class according to the concurrency level set for the queue. For example, if concurrency level is set to 5, then the service class has 5 slots. WLM allocates the available memory for a service class equally to each slot. For more information, see [Workload management](#).

Note

If the value of `wlm_query_slot_count` is larger than the number of available slots (concurrency level) for the service class, the query fails. If you encounter an error, decrease `wlm_query_slot_count` to an allowable value.

For operations where performance is heavily affected by the amount of memory allocated, such as vacuuming, increasing the value of `wlm_query_slot_count` can improve performance. In particular, for slow vacuum commands, inspect the corresponding record in the `SVV_VACUUM_SUMMARY` view. If you see high values (close to or higher than 100) for `sort_partitions` and `merge_increments` in the `SVV_VACUUM_SUMMARY` view, consider increasing the value for `wlm_query_slot_count` the next time you run Vacuum against that table.

Increasing the value of `wlm_query_slot_count` limits the number of concurrent queries that can be run. For example, suppose that the service class has a concurrency level of 5 and `wlm_query_slot_count` is set to 3. While a query is running within the session with `wlm_query_slot_count` set to 3, a maximum of 2 more concurrent queries can be run within the same service class. Subsequent queries wait in the queue until currently running queries complete and slots are freed.

Examples

Use the SET command to set the value of `wlm_query_slot_count` for the duration of the current session.

```
set wlm_query_slot_count to 3;
```

Document history

Note

For a description of new features in Amazon Redshift, see [What's new](#).

The following table describes the important documentation changes to the *Amazon Redshift Database Developer Guide* after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

API version: 2012-12-01

For a list of the changes to the *Amazon Redshift Management Guide*, see [Amazon Redshift Management Guide Document History](#).

For more information about new features, including a list of fixes and the associated cluster version numbers for each release, see [Cluster Version History](#).

Change	Description	Date
Support for spatial 3D and 4D geometries and new spatial functions	You can now use additional spatial functions and 3D and 4D geometry support is added to some functions.	August 19, 2021
Support for column compression encoding for automatic table optimization	You can specify the ENCODE AUTO option for a table to automatically manage compression encoding for all columns in the table.	August 3, 2021
Support for multiple SQL statements or an SQL statement with parameters using the Amazon Redshift Data API	You can now run multiple SQL statements or a statement with parameters with the Amazon Redshift Data API.	July 28, 2021

Support for case-insensitive collation with column level overrides	You can now use the COLLATE clause within a CREATE DATABASE statement to specify the default collation.	June 24, 2021
Support for data sharing across accounts	You can now share data across AWS accounts.	April 30, 2021
Support for hierarchical data queries with recursive CTE	You can now use a recursive common table expression (CTE) in your SQL.	April 29, 2021
Support for cross-database queries	You can now query data across databases in a cluster.	March 10, 2021
Support for fine-grained access control on COPY and UNLOAD commands	You can now grant the privilege to run COPY and UNLOAD commands to specific users and groups in your Amazon Redshift cluster to create more fine-grained access control policy.	January 12, 2021
Support for native JSON and semi-structured data	You can now define the SUPER data type.	December 9, 2020
Support for federated query to MySQL	You can now write a federated query to a supported MySQL engine.	December 9, 2020
Support for data sharing	You can now share data across Amazon Redshift clusters.	December 9, 2020
Support for automatic table optimization	You can now define automatic distribution and sort keys.	December 9, 2020

Support for Amazon Redshift ML	You can now create, train, and deploy machine learning (ML) models.	December 8, 2020
Support for automatic refresh and query rewrite of materialized views	You can now keep materialized views up-to-date with automatic refresh and query performance can be improved with automatic rewrite.	November 11, 2020
Support for TIME and TIMETZ data types	You can now create tables with TIME and TIMETZ data types. TIME data type stores the time of day without timezone information, and TIMETZ stores the time of day including timezone information	November 11, 2020
Support for Lambda UDFs and tokenization	You can now can write Lambda UDFs to enable external tokenization of data.	October 26, 2020
Support for altering a table column encoding	You can now alter a table column encoding.	October 20, 2020
Support for querying across databases	Amazon Redshift can now query across databases in a cluster.	October 15, 2020
Support for HyperLogLog Sketches	Amazon Redshift can now store and process HyperLogLogSketches.	October 2, 2020
Support for Apache Hudi and Delta Lake	Enhancements to creating external tables for Redshift Spectrum.	September 24, 2020

Support for enhancements to querying spatial data	Enhancements include loading a shapefile and several new spatial SQL functions.	September 15, 2020
Materialized view support external tables	You can create materialized views in Amazon Redshift that reference external data sources.	June 19, 2020
Support to write to external table	You can write to external tables by running CREATE EXTERNAL TABLE AS SELECT to write to a new external table or INSERT INTO to insert data into an existing external table.	June 8, 2020
Support for storage controls for schemas	Updates to commands and views that manage storage controls for schemas.	June 2, 2020
Support for federated query general availability	Updated information about querying data with federated queries.	April 16, 2020
Support for additional spatial functions	Added descriptions of additional spatial functions.	April 2, 2020
Support for materialized views general availability	Materialized views are generally available starting with cluster version 1.0.13059 .	February 19, 2020
Support for column-level privileges	Column-level privileges are available starting with cluster version 1.0.13059.	February 19, 2020

ALTER TABLE	You can use an ALTER TABLE command with the ALTER DISTSTYLE ALL clause to change the distribution style of a table.	February 11, 2020
Support for federated query	Updated the guide to describe federated query with an updated CREATE EXTERNAL SCHEMA.	December 3, 2019
Support for data lake export	Updated the guide to describe new parameters of the UNLOAD command.	December 3, 2019
Support for spatial data	Updated the guide to describe support for spatial data.	November 21, 2019
Support for the new console	Updated the guide to describe the new Amazon Redshift console.	November 11, 2019
Support for automatic table sort	Amazon Redshift can automatically sort table data.	November 7, 2019
Support for VACUUM BOOST option	You can use the BOOST option when vacuuming tables.	November 7, 2019
Support for default IDENTITY columns	You can create tables with default IDENTITY columns.	September 19, 2019
Support for AZ64 compression encoding	You can encode some columns with AZ64 compression encoding.	September 19, 2019
Support for query priority	You can set the query priority of an automatic WLM queue.	August 22, 2019

Support for AWS Lake Formation	You can use a Lake Formation Data Catalog with Amazon Redshift Spectrum.	August 8, 2019
COMPUPDATE PRESET	You can use a COPY command with COMPUPDATE PRESET to enable Amazon Redshift to choose the compression encoding.	June 13, 2019
ALTER COLUMN	You can use an ALTER TABLE command with ALTER COLUMN to increase the size of a VARCHAR column.	May 22, 2019
Support for stored procedures	You can define PL/pgSQL stored procedures in Amazon Redshift.	April 24, 2019
Support for an automatic workload management (WLM) configuration	You can enable Amazon Redshift to run with automatic WLM.	April 24, 2019
UNLOAD to Zstandard	You can use the UNLOAD command to apply Zstandard compression to text and comma-separated value (CSV) files unloaded to Amazon S3.	April 3, 2019
Concurrency scaling	When concurrency scaling is enabled, Amazon Redshift automatically adds additional cluster capacity when you need it to process an increase in concurrent read queries.	March 21, 2019

UNLOAD to CSV	You can use the UNLOAD command to unload to a file formatted as CSV text.	March 13, 2019
AUTO distribution style	To enable automatic distribution, you can specify the AUTO distribution style with a CREATE TABLE statement. When you enable automatic distribution, Amazon Redshift assigns an optimal distribution style based on the table data. The change in distribution occurs in the background, in a few seconds.	January 23, 2019
COPY from Parquet supports SMALLINT	COPY now supports loading from Parquet formatted files into columns that use the SMALLINT data type. For more information, see COPY from Columnar Data Formats	January 2, 2019
DROP EXTERNAL DATABASE	You can drop an external database by including the DROP EXTERNAL DATABASE clause with a DROP SCHEMA command.	December 3, 2018
Cross-region UNLOAD	You can UNLOAD to an Amazon S3 bucket in another AWS Region by specifying the REGION parameter.	October 31, 2018

Automatic vacuum delete	Amazon Redshift automatically runs a VACUUM DELETE operation in the background, so you rarely, if ever, need to run a DELETE ONLY vacuum. Amazon Redshift schedules the VACUUM DELETE to run during periods of reduced load and pauses the operation during periods of high load.	October 31, 2018
Automatic distribution	When you don't specify a distribution style with a CREATE TABLE statement, Amazon Redshift assigns an optimal distribution style based on the table data. The change in distribution occurs in the background, in a few seconds.	October 31, 2018
Fine grained access control for the AWS Glue Data Catalog	You can now specify levels of access to data stored in the AWS Glue Data Catalog.	October 15, 2018
UNLOAD with data types	You can specify the MANIFEST VERBOSE option with an UNLOAD command to add metadata to the manifest file, including the names and data types of columns, file sizes, and row counts.	October 10, 2018

Add multiple partitions using a single ALTER TABLE statement	For Redshift Spectrum external tables, you can combine multiple PARTITION clauses in a single ALTER TABLE ADD statement. For more information, see Alter External Table Examples .	October 10, 2018
UNLOAD with header	You can specify the HEADER option with an UNLOAD command to add a header line containing column names at the top of each output file.	September 19, 2018
New system table and views	SVL_S3Retries , SVL_USER_INFO , and STL_DISK_FULL_DIAG documentation added.	August 31, 2018
Support for nested data in Amazon Redshift Spectrum	You can now query nested data stored in Amazon Redshift Spectrum tables. For more information, see Tutorial: Querying Nested Data with Amazon Redshift Spectrum .	August 8, 2018
SQA on by default	Short query acceleration (SQA) is now enabled by default for all new clusters. SQA uses machine learning to provide higher performance, faster results, and better predictability of query execution times. For more information, see Short Query Acceleration .	August 8, 2018

Amazon Redshift Advisor	You can now get tailored recommendations on how to improve cluster performance and reduce operating costs from the Amazon Redshift Advisor. For more information, see Amazon Redshift Advisor .	July 26, 2018
Immediate alias reference	You can now refer to an aliased expression immediately after you define it. For more information, see SELECT List .	July 18, 2018
Specify compression type when creating an external table	You can now specify compression type when creating an external table with Amazon Redshift Spectrum. For more information, see Create External Tables .	June 27, 2018
PG_LAST_UNLOAD_ID	Documentation added for a new System Information function: PG_LAST_UNLOAD_ID. For more information, see PG_LAST_UNLOAD_ID .	June 27, 2018
ALTER TABLE RENAME COLUMN	ALTER TABLE now supports renaming columns for external tables. For more information, see Alter External Table Examples .	June 7, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon Redshift Database Developer Guide* before June 2018.

Change	Description	Date changed
COPY from Parquet includes SMALLINT	COPY now supports loading from Parquet formatted files into columns that use the SMALLINT data type. For more information, see COPY from columnar data formats	January 2, 2019
COPY from columnar formats	COPY now supports loading from files on Amazon S3 that use Parquet and ORC columnar data formats. For more information, see COPY from columnar data formats	May 17, 2018
Dynamic maximum run time for SQA	By default, workload management (WLM) now dynamically assigns a value for the short query acceleration (SQA) maximum run time based on analysis of your cluster's workload. For more information, see Maximum runtime for short queries .	May 17, 2018
New column in STL_LOAD_COMMITS	The STL_LOAD_COMMITS system table has a new column, <code>file_format</code> .	May 10, 2018
New columns in STL_HASHJOIN and other system log tables	The STL_HASHJOIN system table has three new columns, <code>hash_segment</code> , <code>hash_step</code> , and <code>checksum</code> . Also, a <code>checksum</code> was added to <code>STL_MERGEJOIN</code> , <code>STL_NESTLOOP</code> , <code>STL_HASH</code> , <code>STL_SCAN</code> , <code>STL_SORT</code> , <code>STL_LIMIT</code> , and <code>STL_PROJECT</code> .	May 17, 2018
New columns in STL_AGGR	The STL_AGGR system table has two new columns, <code>resizes</code> and <code>flushable</code> .	April 19, 2018
New options for REGEX functions	For the REGEXP_INSTR and REGEXP_SUBSTR functions, you can now specify which occurrence of	March 22, 2018

Change	Description	Date changed
	<p>a match to use and whether to perform a case-sensitive match. REGEXP_INSTR also allows you specify whether to return the position of the first character of the match or the position of the first character following the end of the match.</p>	
New columns in system tables	<p>The tombstonedblocks, tossedblocks, and batched_by columns were added to the STL_COMMIT_STATS system table. The localslice column was added to the STV_SLICES system view.</p>	March 22, 2018
Add and drop columns in external tables	<p>ALTER TABLE now supports ADD COLUMN and DROP COLUMN for Amazon Redshift Spectrum external tables.</p>	March 22, 2018
Redshift Spectrum new AWS Regions	<p>Redshift Spectrum is now available in the Mumbai and São Paulo Regions. For a list of supported Regions, see Amazon Redshift Spectrum Regions.</p>	March 22, 2018
Table limit increased to 20,000	<p>The maximum number of tables is now 20,000 for 8xlarge cluster node types. The limit for large and xlarge node types is 9,900. For more information, see Limits and quotas.</p>	March 13, 2018
Redshift Spectrum support for JSON and Ion	<p>Using Redshift Spectrum, you can reference files with scalar data in JSON or Ion data formats. For more information, see CREATE EXTERNAL TABLE.</p>	February 26, 2018
IAM role chaining for Redshift Spectrum	<p>You can chain AWS Identity and Access Management (IAM) roles so that your cluster can assume other roles not attached to the cluster, including roles belonging to another AWS account. For more information, see Chaining IAM roles in Amazon Redshift Spectrum.</p>	February 1, 2018
ADD PARTITION supports IF NOT EXISTS	<p>The ADD PARTITION clause for ALTER TABLE now supports an IF NOT EXISTS option. For more information, see ALTER TABLE.</p>	January 11, 2018

Change	Description	Date changed
DATE data for external tables	Redshift Spectrum external tables now support the DATE data type. For more information, see CREATE EXTERNAL TABLE .	January 11, 2018
Redshift Spectrum new AWS Regions	Redshift Spectrum is now available in the Singapore, Sydney, Seoul, and Frankfurt Regions. For a list of supported AWS Regions, see Amazon Redshift Spectrum Regions .	November 16, 2017
Short query acceleration in Amazon Redshift workload management (WLM)	Short query acceleration (SQA) prioritizes selected short-running queries ahead of longer-running queries. SQA executes short-running queries in a dedicated space, so that SQA queries aren't forced to wait in queues behind longer queries. With SQA, short-running queries begin executing more quickly and users see results sooner. For more information, see Short query acceleration .	November 16, 2017
WLM reassigns hopped queries	Instead of canceling and restarting a hopped query, Amazon Redshift workload management (WLM) now reassigns eligible queries to a new queue. When WLM reassigns a query, it moves the query to the new queue and continues execution, which saves time and system resources. Hopped queries that are not eligible to be reassigned are restarted or canceled. For more information, see WLM query queue hopping .	November 16, 2017
System log access for users	In most system log tables that are visible to users, rows generated by another user are invisible to a regular user by default. To permit a regular user to see all rows in user-visible tables, including rows generated by another user, run ALTER USER or CREATE USER and set the SYSLOG ACCESS parameter to UNRESTRICTED.	November 16, 2017

Change	Description	Date changed
Result caching	With Result caching , when you run a query Amazon Redshift caches the result. When you run the query again, Amazon Redshift checks for a valid, cached copy of the query result. If a match is found in the result cache, Amazon Redshift uses the cached result and doesn't run the query. Result caching is turned on by default. To turn off result caching, set the enable_result_cache_for_session configuration parameter to off.	November 16, 2017
Column metadata functions	PG_GET_COLS and PG_GET_LATE_BINDING_VIEW_COLS return column metadata for Amazon Redshift tables, views, and late-binding views.	November 16, 2017
WLM queue hopping for CTAS	Amazon Redshift workload management (WLM) now supports query queue hopping for CREATE TABLE AS (CTAS) statements as well as read-only queries, such as SELECT statements. For more information, see WLM query queue hopping .	October 19, 2017
Amazon Redshift Spectrum manifest files	When you create a Redshift Spectrum external table, you can specify a manifest file that lists the locations of data files on Amazon S3. For more information, see CREATE EXTERNAL TABLE .	October 19, 2017
Amazon Redshift Spectrum new AWS Regions	Redshift Spectrum is now available in the EU (Ireland) and Asia Pacific (Tokyo) Regions. For a list of supported AWS Regions, see Amazon Redshift Spectrum limitations .	October 19, 2017
Amazon Redshift Spectrum added file formats	You can now create Redshift Spectrum external tables based on Regex, OpenCSV, and Avro data file formats. For more information, see CREATE EXTERNAL TABLE .	October 5, 2017

Change	Description	Date changed
Pseudocolumns for Amazon Redshift Spectrum external tables	You can select the <code>\$path</code> and <code>\$size</code> pseudocolumns in a Redshift Spectrum external table to view the location and size of the referenced data files in Amazon S3. For more information, see Pseudocolumns .	October 5, 2017
Functions to validate JSON	You can use the IS_VALID_JSON and IS_VALID_JSON_ARRAY functions to check for valid JSON formatting. The other JSON functions now have an optional <code>null_if_invalid</code> argument.	October 5, 2017
LISTAGG DISTINCT	You can use the DISTINCT clause with the LISTAGG aggregate function and the LISTAGG window function to eliminate duplicate values from the specified expression before concatenating.	October 5, 2017
View column names in uppercase	To view column names in SELECT results in uppercase, you can set the describe_field_name_in_uppercase configuration parameter to <code>true</code> .	October 5, 2017
Skip header lines in external tables	You can set the <code>skip.header.line.count</code> property in the CREATE EXTERNAL TABLE command to skip header lines at the beginning of Redshift Spectrum data files.	October 5, 2017
Scan row count	WLM query monitor rules uses the <code>scan_row_count</code> metric to return the number of rows in a scan step. The row count is the total number of rows emitted before filtering rows marked for deletion (ghost rows) and before applying user-defined query filters. For more information, see Query monitoring metrics for Amazon Redshift provisioned .	September 21, 2017

Change	Description	Date changed
SQL user-defined functions	A scalar SQL user-defined function (UDF) incorporates a SQL <code>SELECT</code> clause that executes when the function is called and returns a single value. For more information, see Scalar SQL UDFs .	August 31, 2017
Late-binding views	A late-binding view is not bound to the underlying database objects, such as tables and user-defined functions. As a result, there is no dependency between the view and the objects it references. You can create a view even if the referenced objects don't exist. Because there is no dependency, you can drop or alter a referenced object without affecting the view. Amazon Redshift doesn't check for dependencies until the view is queried. To create a late-binding view, specify the <code>WITH NO SCHEMA BINDING</code> clause with your <code>CREATE VIEW</code> statement. For more information, see CREATE VIEW .	August 31, 2017
OCTET_LENGTH function	OCTET_LENGTH returns the length of the specified string as the number of bytes.	August 18, 2017
ORC and Grok files types supported	Amazon Redshift Spectrum now supports the ORC and Grok data formats for Redshift Spectrum data files. For more information, see Data files for queries in Amazon Redshift Spectrum .	August 18, 2017
RegexSerDe now supported	Amazon Redshift Spectrum now supports the RegexSerDe data format. For more information, see Data files for queries in Amazon Redshift Spectrum .	July 19, 2017
New columns added to <code>SVV_TABLES</code> and <code>SVV_COLUMNS</code>	The columns <code>domain_name</code> and <code>remarks</code> were added to SVV_COLUMNS . A <code>remarks</code> column was added to SVV_TABLES .	July 19, 2017

Change	Description	Date changed
SVV_TABLES and SVV_COLUMNS system views	The SVV_TABLES and SVV_COLUMNS system views provide information about columns and other details for local and external tables and views.	July 7, 2017
VPC no longer required for Amazon Redshift Spectrum with Amazon EMR Hive metastore	Redshift Spectrum removed the requirement that the Amazon Redshift cluster and the Amazon EMR cluster must be in the same VPC and the same subnet when using an Amazon EMR Hive metastore. For more information, see Working with external catalogs in Amazon Redshift Spectrum .	July 7, 2017
UNLOAD to smaller file sizes	By default, UNLOAD creates multiple files on Amazon S3 with a maximum size of 6.2 GB. To create smaller files, specify the MAXFILESIZE with the UNLOAD command. You can specify a maximum file size between 5 MB and 6.2 GB. For more information, see UNLOAD .	July 7, 2017
TABLE PROPERTIES	You can now set the TABLE PROPERTIES numRows parameter for CREATE EXTERNAL TABLE or ALTER TABLE to update table statistics to reflect the number of rows in the table.	June 6, 2017
ANALYZE PREDICATE COLUMNS	To save time and cluster resources, you can choose to analyze only the columns that are likely to be used as predicates. When you run ANALYZE with the PREDICATE COLUMNS clause, the analyze operation includes only columns that have been used in a join, filter condition, or group by clause, or are used as a sort key or distribution key. For more information, see Analyzing tables .	May 25, 2017

Change	Description	Date changed
IAM policies for Amazon Redshift Spectrum	To grant access to an Amazon S3 bucket only using Redshift Spectrum, you can include a condition that allows access for the user agent <code>AWS Redshift/Spectrum</code> . For more information, see IAM policies for Amazon Redshift Spectrum .	May 25, 2017
Amazon Redshift Spectrum Recursive Scan	Redshift Spectrum now scans files in subfolders as well as the specified folder in Amazon S3. For more information, see External tables for Redshift Spectrum .	May 25, 2017
Query monitoring rules	Using WLM query monitoring rules, you can define metrics-based performance boundaries for WLM queues and specify what action to take when a query goes beyond those boundaries—log, hop, or abort. You define query monitoring rules as part of your workload management (WLM) configuration. For more information, see WLM query monitoring rules .	April 21, 2017
Amazon Redshift Spectrum	Using Redshift Spectrum, you can efficiently query and retrieve data from files in Amazon S3 without having to load the data into tables. Redshift Spectrum queries execute very fast against large datasets because Redshift Spectrum scans the data files directly in Amazon S3. Much of the processing occurs in the Amazon Redshift Spectrum layer, and most of the data remains in Amazon S3. Multiple clusters can concurrently query the same dataset on Amazon S3 without the need to make copies of the data for each cluster. For more information, see Amazon Redshift Spectrum	April 19, 2017

Change	Description	Date changed
New system tables to support Redshift Spectrum	<p>The following new system views have been added to support Redshift Spectrum:</p> <ul style="list-style-type: none"> • SVL_S3QUERY • SVL_S3QUERY_SUMMARY • SVV_EXTERNAL_COLUMNS • SVV_EXTERNAL_DATABASES • SVV_EXTERNAL_PARTITIONS • SVV_EXTERNAL_TABLES • PG_EXTERNAL_SCHEMA 	April 19, 2017
APPROXIMATE PERCENTILE_DISC aggregate function	The APPROXIMATE PERCENTILE_DISC aggregate function is now available.	April 4, 2017
Server-side encryption with KMS	You can now unload data to Amazon S3 using server-side encryption with an AWS Key Management Service key (SSE-KMS). In addition, COPY now transparently loads KMS-encrypted data files from Amazon S3. For more information, see UNLOAD .	February 9, 2017

Change	Description	Date changed
New authorization syntax	You can now use the IAM_ROLE, MASTER_SYMMETRIC_KEY, ACCESS_KEY_ID, SECRET_ACCESS_KEY, and SESSION_TOKEN parameters to provide authorization and access information for COPY, UNLOAD, and CREATE LIBRARY commands. The new authorization syntax provides a more flexible alternative to providing a single string argument to the CREDENTIALS parameter. For more information, see Authorization parameters .	February 9, 2017
Schema limit increase	You can now create up to 9,900 schemas per cluster. For more information, see CREATE SCHEMA .	February 9, 2017
Default table encoding	CREATE TABLE and ALTER TABLE now assign LZO compression encoding to most new columns. Columns defined as sort keys, columns that are defined as BOOLEAN, REAL, or DOUBLE PRECISION data types, and temporary tables are assigned RAW encoding by default. For more information, see ENCODE .	February 6, 2017
ZSTD compression encoding	Amazon Redshift now supports ZSTD column compression encoding.	January 19, 2017
PERCENTILE_CONT and MEDIAN aggregate functions	PERCENTILE_CONT and MEDIAN are now available as aggregate functions as well as window functions.	January 19, 2017

Change	Description	Date changed
User-defined function (UDF) User Logging	You can use the Python logging module to create user-defined error and warning messages in your UDFs. Following query execution, you can query the SVL_UDF_LOG system view to retrieve logged messages. For more information about user-defined messages, see Logging errors and warnings in Python UDFs	December 8, 2016
ANALYZE COMPRESSION estimated reduction	The ANALYZE COMPRESSION command now reports an estimate for percentage reduction in disk space for each column. For more information, see ANALYZE COMPRESSION .	November 10, 2016
Connection limits	You can now set a limit on the number of database connections a user is permitted to have open concurrently. You can also limit the number of concurrent connections for a database. For more information, see CREATE USER and CREATE DATABASE .	November 10, 2016
COPY sort order enhancement	COPY now automatically adds new rows to the table's sorted region when you load your data in sort key order. For specific requirements to enable this enhancement, see Load your data in sort key order	November 10, 2016
CTAS with compression	CREATE TABLE AS (CTAS) now automatically assigns compression encodings to new tables based on the column's data type. For more information, see Inheritance of column and table attributes .	October 28, 2016
Time stamp with time zone data type	Amazon Redshift now supports a timestamp with time zone (TIMESTAMPTZ) data type. Also, several new functions have been added to support the new data type. For more information, see Date and time functions .	September 29, 2016

Change	Description	Date changed
Analyze threshold	To reduce processing time and improve overall system performance for ANALYZE operations, Amazon Redshift skips analyzing a table if the percentage of rows that have changed since the last ANALYZE command run is lower than the analyze threshold specified by the analyze_threshold_percent parameter. By default, <code>analyze_threshold_percent</code> is 10.	August 9, 2016
New <code>STL_RESTARTED_SESSIONS</code> system table	When Amazon Redshift restarts a session, STL_RESTARTED_SESSIONS records the new process ID (PID) and the old PID.	August 9, 2016
Updated the Date and Time Functions documentation	Added a summary of functions with links to the Date and time functions , and updated the function references for consistency.	June 24, 2016
New columns in <code>STL_CONNECTION_LOG</code>	The STL_CONNECTION_LOG system table has two new columns to track SSL connections. If you routinely load audit logs to an Amazon Redshift table, you will need to add the following new columns to the target table: <code>sslcompression</code> and <code>sslexpansion</code> .	May 5, 2016
MD5-hash password	You can specify the password for a CREATE USER or ALTER USER command by supplying the MD5-hash string of the password and user name.	April 21, 2016
New column in <code>STV_TBL_PERM</code>	The backup column in the STV_TBL_PERM system view indicates whether the table is included in cluster snapshots. For more information, see BACKUP .	April 21, 2016

Change	Description	Date changed
No-backup tables	For tables, such as staging tables, that won't contain critical data, you can specify <code>BACKUP NO</code> in your CREATE TABLE or CREATE TABLE AS statement to prevent Amazon Redshift from including the table in automated or manual snapshots. Using no-backup tables saves processing time when creating snapshots and restoring from snapshots and reduces storage space on Amazon S3.	April 7, 2016
VACUUM delete threshold	By default, the VACUUM command now reclaims space such that at least 95 percent of the remaining rows are not marked for deletion. As a result, VACUUM usually needs much less time for the delete phase compared to reclaiming 100 percent of deleted rows. You can change the default threshold for a single table by including the <code>TO <i>threshold</i> PERCENT</code> parameter when you run the VACUUM command.	April 7, 2016
SVV_TRANS ACTIONS system table	The SVV_TRANSACTIONS system view records information about transactions that currently hold locks on tables in the database.	April 7, 2016
Using IAM roles to access other AWS resources	To move data between your cluster and another AWS resource, such as Amazon S3, DynamoDB, Amazon EMR, or Amazon EC2, your cluster must have permission to access the resource and perform the necessary actions. As a more secure alternative to providing an access key pair with <code>COPY</code> , <code>UNLOAD</code> , or <code>CREATE LIBRARY</code> commands, you can now specify an IAM role that your cluster uses for authentication and authorization. For more information, see Role-based access control .	March 29, 2016

Change	Description	Date changed
VACUUM sort threshold	The VACUUM command now skips the sort phase for any table where more than 95 percent of the table's rows are already sorted. You can change the default sort threshold for a single table by including the <i>TO threshold</i> PERCENT parameter when you run the VACUUM command.	March 17, 2016
New columns in STL_CONNECTION_LOG	The STL_CONNECTION_LOG system table has three new columns. If you routinely load audit logs to an Amazon Redshift table, you will need to add the following new columns to the target table: <code>sslversion</code> , <code>sslcipher</code> , and <code>mtu</code> .	March 17, 2016
UNLOAD with bzip2 compression	You now have the option to UNLOAD using bzip2 compression.	February 8, 2016
ALTER TABLE APPEND	ALTER TABLE APPEND appends rows to a target table by moving data from an existing source table. ALTER TABLE APPEND is usually much faster than a similar CREATE TABLE AS or INSERT INTO operation because data is moved, not duplicated.	February 8, 2016
WLM query queue hopping	If workload management (WLM) cancels a read-only query, such as a SELECT statement, due to a WLM timeout, WLM attempts to route the query to the next matching queue. For more information, see WLM query queue hopping	January 7, 2016
ALTER DEFAULT PRIVILEGES	You can use the ALTER DEFAULT PRIVILEGES command to define the default set of access privileges to be applied to objects that are created in the future by the specified user.	December 10, 2015
bzip2 file compression	The COPY command supports loading data from files that were compressed using bzip2.	December 10, 2015

Change	Description	Date changed
NULLS FIRST and NULLS LAST	You can specify whether an ORDER BY clause should rank NULLS first or last in the result set. For more information, see ORDER BY clause and Window function syntax summary .	November 19, 2015
REGION keyword for CREATE LIBRARY	If the Amazon S3 bucket that contains the UDF library files does not reside in the same AWS Region as your Amazon Redshift cluster, you can use the REGION option to specify the region in which the data is located. For more information, see CREATE LIBRARY .	November 19, 2015
User-defined scalar functions (UDFs)	You can now create custom user-defined scalar functions to implement non-SQL processing functionality provided either by Amazon Redshift-supported modules in the Python 2.7 Standard Library or your own custom UDFs based on the Python programming language. For more information, see User-defined functions .	September 11, 2015
Dynamic properties in WLM configuration	The WLM configuration parameter now supports applying some properties dynamically. Other properties remain static changes and require that associated clusters be rebooted so that the configuration changes can be applied. For more information, see WLM dynamic and static configuration properties and Workload management .	August 3, 2015
LISTAGG function	The LISTAGG function and LISTAGG window function return a string created by concatenating a set of column values.	July 30, 2015

Change	Description	Date changed
Deprecated parameter	The <i>max_cursor_result_set_size</i> configuration parameter is deprecated. The size of cursor result sets are constrained based on the cluster's node type. For more information, see Cursor constraints .	July 24, 2015
Revised COPY command documentation	The COPY command reference has been extensively revised to make the material friendlier and more accessible.	July 15, 2015
COPY from Avro format	The COPY command supports loading data in Avro format from data files on Amazon S3, Amazon EMR, and from remote hosts using SSH. For more information, see AVRO and Copy from Avro examples .	July 8, 2015
STV_STARTUP_RECOVERY_STATE	The STV_STARTUP_RECOVERY_STATE system table records the state of tables that are temporarily locked during cluster restart operations. Amazon Redshift places a temporary lock on tables while they are being processed to resolve stale transactions following a cluster restart.	May 25, 2015
ORDER BY optional for ranking functions	The ORDER BY clause is now optional for certain window ranking functions. For more information, see CUME_DIST window function , DENSE_RANK window function , RANK window function , NTILE window function , PERCENT_RANK window function , and ROW_NUMBER window function .	May 25, 2015

Change	Description	Date changed
Interleaved sort keys	Interleaved sort keys give equal weight to each column in the sort key. Using interleaved sort keys instead of the default compound keys significantly improves performance for queries that use restrictive predicates on secondary sort columns, especially for large tables. Interleaved sorting also improves overall performance when multiple queries filter on different columns in the same table. For more information, see Sort keys and CREATE TABLE .	May 11, 2015
Revised tuning query performance topic	Query performance tuning has been expanded to include new queries for analyzing query performance and more examples. Also, the topic has been revised to be clearer and more complete. Amazon Redshift best practices for designing queries has more information about how to write queries to improve performance.	March 23, 2015
SVL_QUERY_QUEUE_INFO	The SVL_QUERY_QUEUE_INFO view summarizes details for queries that spent time in a WLM query queue or commit queue.	February 19, 2015
SVV_TABLE_INFO	You can use the SVV_TABLE_INFO view to diagnose and address table design issues that can influence query performance, including issues with compression encoding, distribution keys, sort style, data distribution skew, table size, and statistics.	February 19, 2015
UNLOAD uses server-side file encryption	The UNLOAD command now automatically uses Amazon S3 server-side encryption (SSE) to encrypt all unload data files. Server-side encryption adds another layer of data security with little or no change in performance.	October 31, 2014

Change	Description	Date changed
CUME_DIST window function	The CUME_DIST window function calculates the cumulative distribution of a value within a window or partition.	October 31, 2014
MONTHS_BETWEEN function	The MONTHS_BETWEEN function determines the number of months between two dates.	October 31, 2014
NEXT_DAY function	The NEXT_DAY function returns the date of the first instance of a specified day that is later than the given date.	October 31, 2014
PERCENT_RANK window function	The PERCENT_RANK window function calculates the percent rank of a given row.	October 31, 2014
RATIO_TO_REPORT window function	The RATIO_TO_REPORT window function calculates the ratio of a value to the sum of the values in a window or partition.	October 31, 2014
TRANSLATE function	The TRANSLATE function replaces all occurrences of specified characters within a given expression with specified substitutes.	October 31, 2014
NVL2 function	The NVL2 function returns one of two values based on whether a specified expression evaluates to NULL or NOT NULL.	October 16, 2014
MEDIAN window function	The MEDIAN window function calculates the median value for the range of values in a window or partition.	October 16, 2014
ON ALL TABLES IN SCHEMA <i>schema_name</i> clause for GRANT and REVOKE commands	The GRANT and REVOKE commands have been updated with an ON ALL TABLES IN SCHEMA <i>schema_name</i> clause. This clause allows you to use a single command to change privileges for all tables in a schema.	October 16, 2014

Change	Description	Date changed
IF EXISTS clause for DROP SCHEMA, DROP TABLE, DROP USER, and DROP VIEW commands	The DROP SCHEMA , DROP TABLE , DROP USER , and DROP VIEW commands have been updated with an IF EXISTS clause. This clause causes the command to make no changes and return a message rather than terminating with an error if the specified object doesn't exist.	October 16, 2014
IF NOT EXISTS clause for CREATE SCHEMA and CREATE TABLE commands	The CREATE SCHEMA and CREATE TABLE commands have been updated with an IF NOT EXISTS clause. This clause causes the command to make no changes and return a message rather than terminating with an error if the specified object already exists.	October 16, 2014
COPY support for UTF-16 encoding	The COPY command now supports loading from data files that use UTF-16 encoding as well as UTF-8 encoding. For more information, see ENCODING .	September 29, 2014
New workload management tutorial	Tutorial: Configuring manual workload management (WLM) queues walks you through the process of configuring Workload Management (WLM) queues to improve query processing and resource allocation.	September 25, 2014
AES 128-bit encryption	The COPY command now supports AES 128-bit encryption as well as AES 256-bit encryption when loading from data files encrypted using Amazon S3 client-side encryption. For more information, see Loading encrypted data files from Amazon S3 .	September 29, 2014
PG_LAST_UNLOAD_COUNT function	The PG_LAST_UNLOAD_COUNT function returns the number of rows that were processed in the most recent UNLOAD operation. For more information, see PG_LAST_UNLOAD_COUNT .	September 15, 2014

Change	Description	Date changed
New troubleshooting queries section	Query troubleshooting provides a quick reference for identifying and addressing some of the most common and most serious issues you are likely to encounter with Amazon Redshift queries.	July 7, 2014
New loading data tutorial	Tutorial: Loading data from Amazon S3 walks you through the process of loading data into your Amazon Redshift database tables from data files in an Amazon S3 bucket, from beginning to end.	July 1, 2014
PERCENTILE_CONT window function	PERCENTILE_CONT window function is an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification, and returns an interpolated value that would fall into the given percentile value with respect to the sort specification.	June 30, 2014
PERCENTILE_DISC window function	PERCENTILE_DISC window function is an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the set.	June 30, 2014
GREATEST and LEAST functions	The GREATEST and LEAST functions return the largest or smallest value from a list of expressions.	June 30, 2014
Cross-region COPY	The COPY command supports loading data from an Amazon S3 bucket or Amazon DynamoDB table that is located in a different region than the Amazon Redshift cluster. For more information, see REGION in the COPY command reference.	June 30, 2014
Best Practices expanded	Amazon Redshift best practices has been expanded, reorganized, and moved to the top of the navigation hierarchy to make it more discoverable.	May 28, 2014

Change	Description	Date changed
UNLOAD to a single file	The UNLOAD command can optionally unload table data serially to a single file on Amazon S3 by adding the PARALLEL OFF option. If the size of the data is greater than the maximum file size of 6.2 GB, UNLOAD creates additional files.	May 6, 2014
REGEXP functions	The REGEXP_COUNT , REGEXP_INSTR , and REGEXP_REPLACE functions manipulate strings based on regular expression pattern matching.	May 6, 2014
COPY from Amazon EMR	The COPY command supports loading data directly from Amazon EMR clusters. For more information, see Loading data from Amazon EMR .	April 18, 2014
WLM concurrency limit increase	You can now configure workload management (WLM) to run up to 50 queries concurrently in user-defined query queues. This increase gives users more flexibility for managing system performance by modifying WLM configurations. For more information, see Implementing manual WLM	April 18, 2014
New configuration parameter to manage cursor size	The <code>max_cursor_result_set_size</code> configuration parameter defines the maximum size of data, in megabytes, that can be returned per cursor result set of a larger query. This parameter value also affects the number of concurrent cursors for the cluster, enabling you to configure a value that increases or decreases the number of cursors for your cluster. For more information, see DECLARE in this guide and Configure Maximum Size of a Cursor Result Set in the <i>Amazon Redshift Management Guide</i> .	March 28, 2014

Change	Description	Date changed
COPY from JSON format	The COPY command supports loading data in JSON format from data files on Amazon S3 and from remote hosts using SSH. For more information, see COPY from JSON format usage notes .	March 25, 2014
New system table STL_PLAN_INFO	The STL_PLAN_INFO table supplements the EXPLAIN command as another way to look at query plans.	March 25, 2014
New function REGEXP_SUBSTR	The REGEXP_SUBSTR function returns the characters extracted from a string by searching for a regular expression pattern.	March 25, 2014
New columns for STL_COMMIT_STATS	The STL_COMMIT_STATS table has two new columns: numxids and oldestxid .	March 6, 2014
COPY from SSH support for gzip and lzop	The COPY command supports gzip and lzop compression when loading data through an SSH connection.	February 13, 2014
New functions	The ROW_NUMBER window function returns the number of the current row. The STRTOL function converts a string expression of a number of the specified base to the equivalent integer value. PG_CANCEL_BACKEND and PG_TERMINATE_BACKEND enable users to cancel queries and session connections. The LAST_DAY function has been added for Oracle compatibility.	February 13, 2014
New system table	The STL_COMMIT_STATS system table provides metrics related to commit performance, including the timing of the various stages of commit and the number of blocks committed.	February 13, 2014

Change	Description	Date changed
FETCH with single-node clusters	When using a cursor on a single-node cluster, the maximum number of rows that can be fetched using the FETCH command is 1000. FETCH FORWARD ALL is not supported for single-node clusters.	February 13, 2014
DS_DIST_ALL_INNER redistribution strategy	DS_DIST_ALL_INNER in the Explain plan output indicates that the entire inner table was redistributed to a single slice because the outer table uses DISTSTYLE ALL. For more information, see Join type examples and Evaluating the query plan .	January 13, 2014
New system tables for queries	Amazon Redshift has added new system tables that customers can use to evaluate query execution for tuning and troubleshooting. For more information, see SVL_COMPILE , STL_SCAN , STL_RETURN , STL_SAVE STL_ALERT_EVENT_LOG .	January 13, 2014
Single-node cursors	Cursors are now supported for single-node clusters. A single-node cluster can have two cursors open at a time, with a maximum result set of 32 GB. On a single-node cluster, we recommend setting the ODBC Cache Size parameter to 1,000. For more information, see DECLARE .	December 13, 2013
ALL distribution style	ALL distribution can dramatically shorten execution times for certain types of queries. When a table uses ALL distribution style, a copy of the table is distributed to every node. Because the table is effectively collocated with every other table, no redistribution is needed during query execution. ALL distribution is not appropriate for all tables because it increases storage requirements and load time. For more information, see Data distribution for query optimization .	November 11, 2013

Change	Description	Date changed
COPY from remote hosts	In addition to loading tables from data files on Amazon S3 and from Amazon DynamoDB tables, the COPY command can load text data from Amazon EMR clusters, Amazon EC2 instances, and other remote hosts by using SSH connections. Amazon Redshift uses multiple simultaneous SSH connections to read and load data in parallel. For more information, see Loading data from remote hosts .	November 11, 2013
WLM memory percent used	You can balance workload by designating a specific percentage of memory for each queue in your workload management (WLM) configuration. For more information, see Implementing manual WLM .	November 11, 2013
APPROXIMATE COUNT(DISTINCT)	Queries that use APPROXIMATE COUNT(DISTINCT) execute much faster, with a relative error of about 2%. The APPROXIMATE COUNT(DISTINCT) function uses a HyperLogLog algorithm. For more information, see the COUNT function .	November 11, 2013
New SQL functions to retrieve recent query details	Four new SQL functions retrieve details about recent queries and COPY commands. The new functions make it easier to query the system log tables, and in many cases provide necessary details without needing to access the system tables. For more information, see PG_BACKEND_PID , PG_LAST_COPY_ID , PG_LAST_COPY_COUNT , PG_LAST_QUERY_ID .	November 1, 2013

Change	Description	Date changed
MANIFEST option for UNLOAD	The MANIFEST option for the UNLOAD command complements the MANIFEST option for the COPY command. Using the MANIFEST option with UNLOAD automatically creates a manifest file that explicitly lists the data files that were created on Amazon S3 by the unload operation. You can then use the same manifest file with a COPY command to load the data. For more information, see Unloading data to Amazon S3 and UNLOAD examples .	November 1, 2013
MANIFEST option for COPY	You can use the MANIFEST option with the COPY command to explicitly list the data files that will be loaded from Amazon S3.	October 18, 2013
System tables for troubleshooting queries	Added documentation for system tables that are used to troubleshoot queries. The STL views for logging section now contains documentation for the following system tables: STL_AGGR, STL_BCAST, STL_DIST, STL_DELETE, STL_HASH, STL_HASHJOIN, STL_INSERT, STL_LIMIT, STL_MERGE, STL_MERGE JOIN, STL_NESTLOOP, STL_PARSE, STL_PROJECT, STL_SCAN, STL_SORT, STL_UNIQUE, STL_WINDOW.	October 3, 2013
CONVERT_TIMEZONE function	The CONVERT_TIMEZONE function converts a timestamp from one time zone to another, with the option to automatically adjust for daylight savings time.	October 3, 2013
SPLIT_PART function	The SPLIT_PART function splits a string on the specified delimiter and returns the part at the specified position.	October 3, 2013
STL_USERLOG system table	STL_USERLOG records details for changes that occur when a database user is created, altered, or deleted.	October 3, 2013

Change	Description	Date changed
LZO column encoding and LZOP file compression.	LZO column compression encoding combines a very high compression ratio with good performance. COPY from Amazon S3 supports loading from files compressed using LZOP compression.	September 19, 2013
JSON, regular expressions, and cursors	Added support for parsing JSON strings, pattern matching using regular expressions, and using cursors to retrieve large data sets over an ODBC connection. For more information, see JSON functions , Pattern-matching conditions , and DECLARE .	September 10, 2013
ACCEPTINVCHAR option for COPY	You can successfully load data that contains invalid UTF-8 characters by specifying the ACCEPTINVCHAR option with the COPY command.	August 29, 2013
CSV option for COPY	The COPY command now supports loading from CSV formatted input files.	August 9, 2013
CRC32	The CRC32 function performs cyclic redundancy checks.	August 9, 2013
WLM wildcards	Workload management (WLM) supports wildcards for adding user groups and query groups to queues. For more information, see Wildcards .	August 1, 2013
WLM timeout	To limit the amount of time that queries in a given WLM queue are permitted to use, you can set the WLM timeout value for each queue. For more information, see WLM timeout .	August 1, 2013
New COPY options 'auto' and 'epochsecs'	The COPY command performs automatic recognition of date and time formats. New time formats, 'epochsecs' and 'epochmillisecs' enable COPY to load data in epoch format.	July 25, 2013

Change	Description	Date changed
CONVERT_TIMEZONE function	The CONVERT_TIMEZONE function converts a timestamp from one timezone to another.	July 25, 2013
FUNC_SHA1 function	The FUNC_SHA1 function converts a string using the SHA1 algorithm.	July 15, 2013
max_execution_time	To limit the amount of time queries are permitted to use, you can set the max_execution_time parameter as part of the WLM configuration. For more information, see Modifying the WLM configuration .	July 22, 2013
Four-byte UTF-8 characters	The VARCHAR data type now supports four-byte UTF-8 characters. Five-byte or longer UTF-8 characters are not supported. For more information, see Storage and ranges .	July 18, 2013
SVL_QERROR	The SVL_QERROR system view has been deprecated.	July 12, 2013
Revised Document History	The Document History page now shows the date the documentation was updated.	July 12, 2013
STL_UNLOAD_LOG	STL_UNLOAD_LOG records the details for an unload operation.	July 5, 2013
JDBC fetch size parameter	To avoid client-side out of memory errors when retrieving large data sets using JDBC, you can enable your client to fetch data in batches by setting the JDBC fetch size parameter. For more information, see Setting the JDBC fetch size parameter .	June 27, 2013
UNLOAD encrypted files	UNLOAD now supports unloading table data to encrypted files on Amazon S3.	May 22, 2013
Temporary credentials	COPY and UNLOAD now support the use of temporary credentials.	April 11, 2013

Change	Description	Date changed
Added clarifications	Clarified and expanded discussions of Designing Tables and Loading Data.	February 14, 2013
Added best practices	Added Amazon Redshift best practices for designing tables and Amazon Redshift best practices for loading data .	February 14, 2013
Clarified password constraints	Clarified password constraints for CREATE USER and ALTER USER, various minor revisions.	February 14, 2013
New guide	This is the first release of the <i>Amazon Redshift Developer Guide</i> .	February 14, 2013
